Objectives: The aim of this study was to identify the main determinants of patient-physician discordance in the evaluation of SLE and health status.

Methods: This is a cross-sectional study that enrolls patients with a diagnosis of SLE (ACR 1997 criteria). For each patient, demographics, comorbidities, treatment, clinical and laboratory data were collected. Demographic data included the following categories: remission, with the SELENA-SLEDAI score and organ damage with the SLICC/DI. Patients ment, clinical and laboratory data were collected. Disease activity was evaluated with the SELERNA-SLEDAI score and organ damage with the SLICC/DI. Patients with current activity rated the severity as moderate and 33% as severe. The mean SD FACIT-Fatigue score was 22.9 (12.0). The next most commonly reported symptoms were joint stiffness (57%), sleep problems (55%), joint pain/swelling (53%), and muscle pain (52%). Sixty percent of patients reported experiencing pain all or most of the time over the past seven days. A total of 30% of patients with current joint pain/swelling rated it as severe, and 24% of patients with current joint stiffness rated it as severe. The mean scores for Worst pain NRS were 4.6 (4.2). The next most commonly reported symptoms were joint stiffness (57%), sleep problems (55%), joint pain/swelling (53%), and muscle pain (52%). Sixty percent of patients reported experiencing pain all or most of the time over the past seven days. A total of 30% of patients with current joint pain/swelling rated it as severe, and 24% of patients with current joint stiffness rated it as severe. The mean scores for Worst pain NRS were 4.6 (4.2). The next most commonly reported symptoms were joint stiffness (57%), sleep problems (55%), joint pain/swelling (53%), and muscle pain (52%). Sixty percent of patients reported experiencing pain all or most of the time over the past seven days. A total of 30% of patients with current joint pain/swelling rated it as severe, and 24% of patients with current joint stiffness rated it as severe. The mean scores for Worst pain NRS were 4.6 (4.2). The next most commonly reported symptoms were joint stiffness (57%), sleep problems (55%), joint pain/swelling (53%), and muscle pain (52%). Sixty percent of patients reported experiencing pain all or most of the time over the past seven days. A total of 30% of patients with current joint pain/swelling rated it as severe, and 24% of patients with current joint stiffness rated it as severe. The mean scores for Worst pain NRS were 4.6 (4.2). The next most commonly reported symptoms were joint stiffness (57%), sleep problems (55%), joint pain/swelling (53%), and muscle pain (52%). Sixty percent of patients reported experiencing pain all or most of the time over the past seven days. A total of 30% of patients with current joint pain/swelling rated it as severe, and 24% of patients with current joint stiffness rated it as severe. The mean scores for Worst pain NRS were 4.6 (4.2). The next most commonly reported symptoms were joint stiffness (57%), sleep problems (55%), joint pain/swelling (53%), and muscle pain (52%). Sixty percent of patients reported experiencing pain all or most of the time over the past seven days. A total of 30% of patients with current joint pain/swelling rated it as severe, and 24% of patients with current joint stiffness rated it as severe. The mean scores for Worst pain NRS were 4.6 (4.2).
In Group 1, regardless of ethnicity, 29 (90.6%) patients developed LN within 5 years or less from the onset of SLE symptoms, while the remaining 3 (9.4%) developed LN after 5 years. In contrast, in Group 2, 24 (55.6%) patients developed LN within 5 years or less while 19 (44.2%) developed LN after 5 years. (P value = 0.002)

Further stratification was based on ethnicity and antibody (AB) status to investigate the time to develop LN from SLE symptom onset: African ancestry with positive AB, African with negative AB, Asian with positive AB, Caucasian with positive AB and Asian & Caucasian with negative AB. Analysis showed that of 29 (38.7%) African ancestry patients with the autoantibody combination, 19 (65.5%), developed LN within 5 years. In comparison, 46 (61.3%) patients, independent of ethnicity and AB status, developed LN after 5 years (P value = 0.01).

Conclusion: Patients with the unusual autoantibody combination of Sm, Ro & RNP developed LN significantly earlier than patients who did not have this combination. This autoantibody combination was significantly over represented in the African ancestry patients. Our data suggests that African ancestry patients with this autoantibody combination are at increased risk of developing LN soon after SLE symptom onset and merit close monitoring for the development of renal disease.

THU0256 CARDIAC INVOLVEMENT IN NEWLY DIAGNOSED SPANISH PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: DATA FROM THE REFLECT COHORT

J. Álvarez Troncoso1, A. Robles Marhuenda2, F. Mitjavila Villero3, F. J. García Hernández2, A. Marín Ballvé4, A. Castro5, G. Salvador Cervello6, E. Fonseca7, I. Perales Fraile2, G. Ruiz-Irasfortora8 on behalf of GRUPO RELES Investigators, Autoimmune Diseases Study Group (GEAS), 1Hospital Universitario La Paz, Department of Internal Medicine, Madrid, Spain; 2Hospital Universitario de Bellvitge, Department of Internal Medicine, L'Hospitalet de Llobregat, Barcelona, Spain; 3Hospital Virgen del Rocio, Department of Internal Medicine, Seville, Spain; 4Hospital Clínico Universitario Lozano Blesa Illes Aragó. Grupo Autonomia Clínica, Departamento de Internal Medicine, Zaragoza, Spain; 5Hospital Universitario Sant Joan de Reus, Departament of Internal Medicine, Tarragona, Spain; 6Hospital Universitario La Fe, Department of Internal Medicine, Valencia, Spain; 7Hospital de Cabuerniga, Department of Internal Medicine, Gijón, Spain; 8Hospital Infantia Soria, Department of Internal Medicine, Madrid, Spain; 9Hospital Universitat de Barcelona, Unit of Autoimmune Diseases, Department of Internal Medicine, Baracaldo, Vizcaya, Spain

Background: Cardiac involvement is one of the most important causes of disability and mortality in patients with systemic lupus erythematosus (SLE). Transthoracic echocardiography (TTE) is a sensitive and specific technique in detecting cardiac abnormalities, particularly mild pericarditis, valvular lesions and myocardial dysfunction in SLE.

Objectives: Using data of patients from the inception cohort Registro Español de Lupus Eritematoso Sistémico (RELES), we aimed to analyze the echocardiographic features of cardiac involvement of systemic lupus erythematosus (SLE).

Methods: Prospective observational study on a multicenter Spanish inception cohort. Patients with SLE, diagnosed by the American College of Rheumatology (ACR) criteria, since January 2009, who had at least one TTE performed were selected. Demographic data, diagnostic criteria, follow-ups, treatments and SLE-DAI were analyzed.

Results: We included 289 patients diagnosed with SLE with TTE performed. The mean age was 40.5 ± 19 years, of which 86.9% (251) were women and 82.4% (238) Caucasian. The ACR score at diagnosis was 4.98 ± 0.1. Most frequent SLE manifestations were arthritis (59.2%), photosensitivity (49.5%), malar rash (39.1%) and serositis (31.1%). The main immunological findings were: ANA (97.6%), anti-DNA (66.4%), hypocomplementemia (58.6%), antiphospholipid antibodies (31.5%) and SLEDAI (97.6%). One third (31.5%) of the TTE performed were pathological. Of these, 13.8% had pericardial effusion, 13.3% valvulopathy, 6.5% myocardial dysfunction, 5.2% pulmonary hypertension and 3.2% myocardiopathy. Regarding valvulopathies, 9.5% presented valvular dysfunction, 3.2% valvular thickening and 0.6% vegetation. The most frequently injured valve was the mitral (9.1%), followed by the aortic (2.8%). The majority of patients (86.26%) were asymptomatic at the time of TTE. However, patients with pathological TTE had more dyspnea than those in the normal TTE group (24.7% vs. 5.8%, p<0.001). Presenting a pathological TTE was associated with higher SLICC score (p<0.001), greater number of admissions (p<0.001) and mortality (p<0.002). A higher SLEDAI was associated with higher mortality (p<0.001).

Conclusion: Cardiac involvement in SLE is not only related to damage accrual but can also be an early manifestation (beyond pericarditis), especially in active SLE. TTE assessment should be considered as a part of routine examination for SLE due to the high prevalence of heart disease even in asymptomatic patients.

Background: Systemic lupus erythematosus (SLE) patients are at high risk for CV events, and EULAR recommends assessing the 10-year CV-risk using the Systematic Coronary Risk Evaluation (SCORE) [1]. The QRISK3, another score to assess CV-risk in UK population, considers different factors among which also SLE. The Progetto Cuore score (PCS) is validated to estimate CV risk in Italian people and largely replicates the SCORE project [2].

Methods: During 2019 we evaluated 173 SLE patients (87.7% female; age 40±16 years; disease duration 138±105 months), fulfilling the 1997 ACR classification criteria. Clinical and laboratory data were registered, and individual CV-risk was calculated using suitable algorithms for the SCORE, QRISK3 and PCS. Statistical analysis was performed using Graphpad Instat 8.0 (San Diego, CA-USA).

Results: In 13 (7%) SLE patients a previous CV event was recorded. Hypertension was present in 60 (37.5%) and diabetes in 27 (16.9%) patients. Mean total cholesterol was 184±39 mg/dL. HDLc 58±18 mg/dL. LDLc 124±37 mg/dL. triglycerides 105±63 mg/dL. dyslipidemia was reported in 58 (36.2%) patients and 29 (18.1%) were on statin. Mean BMI was 24.9±5.3 kg/m². 60 (37.5%) and 23 (14.3%) patients were overweight and obese, while 25 (15.6%) patients were smokers. 67 (45.3%) SLE patients had a SLEDAI<4, 91% of patients were taken HCQ and 65% were on prednisone (mean dose 5.4±5.9 mg/day), but only 75.7% took >7.5 mg/day. The CV-risk of SLE patients according to SCORE, QRISK3 and PCS was 1.1±2.1, 10.5±12.3% and 3.7±5.4%, respectively. Stratifying patients at low, moderate or high CV risk according to the PCS and SCORE a double proportion of patients was at moderate (8% vs 3.9%) or high (19% vs 0.9%) CV risk (p<0.03). Finally, CV-risk according to QRISK3 was higher than 20% (high CV-risk) in 32/160 (20%) patients.

Conclusion: This multicentre study demonstrated that the mean estimated CV-risk in SLE patients is globally low using the SCORE, QRISK3 and PCS. The PCS seems to better intercept those patients at moderate/high risk, at least in Italian SLE patients, while QRISK3 predicts the highest CV risk. The lack of disease-specific CV-risk factors (such as autoantibodies profile or organ involvement) probably account for the underestimation of CV risk using the SCORE and PCS.

THU0258

SJOGEN’S SYNDROME WITH AND WITHOUT AUTOIMMUNE THYROIDITIS: IS THERE ANY DIFFERENCE?

A. L. Cella1, S. Colafrancesco1, A. Gattamelata1, R. Izzo1, F. Giardina1, L. Mastromanno1, R. Priori1. 1Sapienza Università di Roma, Dipartimento di Scienze Cliniche, Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy

Background: Sjögren’s syndrome (SS) is a systemic autoimmune disease mainly affecting exocrine glands and characterized by a progressive lymphocytic infiltration of salivary and lacrimal glands with consequent loss of function and development of sicca symptoms. Autoimmune thyroiditis (AT) is the most frequent autoimmune disease associated with SS and detectable in about 10 - 30% of cases2. Interestingly, patients with concurrent SS and AT seem to display a more attenuated phenotype compared to patients with solely SS. It is also noteworthy that up to 30% of patients with AT experience sicca symptoms without a clear diagnosis SS3. At the light of these evidences, it is unclear whether SS and AT represent two distinct nosological entities or different expressions of the same pathology.

Objectives: Aim of this study is to evaluate the prevalence of AT in a large monocentric cohort of patients with SS and to define its clinical and laboratory characteristics compared to isolated SS.

Methods: Consecutive patients with SS (AECG criteria) referring to our “Sjögren Clinic” (Sapienza University of Rome) were enrolled and divided in two groups: SS with AT (group 1) and SS without AT (group 2). Group 1 was further divided in two subgroups depending on the presence (1a) or absence (1b) of anti Ro/SSA antibodies. The following clinical and laboratory data were retrospectively collected for all patients: concomitant celiac disease, arthralgia, lung involvement, purpura, lymphoma, presence of ANA, anti-Ro/SSA, anti-La/SSB, rheumatoid factor, cryoglobulins, leukenopia and hypergammaglobulinemia. These characteristics were compared between the following groups: group 1, group 2, group 1a and 1b. For statistic Chi Square and Fisher’s test analysis were performed.

Results: Six-hundred and three SS patients were enrolled (group 1 n=135; group 2 n=381; group 1a n=96; group 1b n=39). The prevalence of AT was 135/603 (22.3%). When comparing SS patients with or without AT (group 1 vs group 2) the frequency of rheumatoid factor was significantly higher in group 2 compared to group 1 (p=0.006). No case of lymphoma was recorded in group 1 while 14 cases of lymphoma were ascertained in group 2 (p<0.08). Conversely, celiac disease was higher in group 1 compared to group 2 (p=0.01). No other differences between these groups were identified. Stratifying SS patients with AT according to the presence (1a) or not (group 1b) of anti Ro/SSA antibodies, ANA, rheumatoid factor and hypergammaglobulinemia were significantly more positive in group 1a compared to group 1b (p=0.0002, p=0.002, p=0.02, respectively); no clinical differences were identified.

Conclusion: In this study, we confirm the presence of a less aggressive disease in patients with SS and AT compared to solely SS. The higher prevalence of rheumatoid factor and lymphoma occurrence in SS without AT, strictly suggest a more severe phenotype in this subset. Although is known that in SS patients with anti Ro/SSA antibodies and RF there is a more aggressive disease, in SS with AT the presence or absence of such autoantibodies do not seems to associate with any difference in clinical severity. Follow up studies are presently being carried out in order to provide conformation of a less severe phenotype and a better disease outcome in patients with associated SS and AT.

THU0259

LYMPHOMAS IN ANTICENTROMERE ANTIBODY POSITIVE PRIMARY SJOGREN’S SYNDROME

B. Chaltchev1, V. Vasiliev2, S. Palshina1, J. Kvhan1, E. Sokol1, A. Torgashina1. 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2MEDSI, Moscow, Russian Federation

Background: Patients with primary Sjögren’s syndrome (pSS) are at high risk of lymphoma. Signs of lymphomas in ACA+SS are not widely reported, the frequency of rheumatoid factor and hypergammaglobulinemia were significantly more positive in group 1a compared to group 1b (p=0.0002, p=0.002, p=0.02, respectively); no clinical differences were identified.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.6187

THU0258
frequency did not differ between groups. Only 20% of patients with lymphoma had monoclonal immunoglobulins secretion and its frequency also did not differ between groups. Anemia, leukopoenia, thrombocytopenia, increased ESR, hypergammaglobulinemia, increased levels of immunoglobulins were found in the study groups with the same frequency. There were no differences in the frequency of detection of recurrent parotitis, lymphadenopathy, Raynaud phenomenon, arthritis/arthralgia, pleuritis/pericarditis, neuropathy, nephritis, hypergammaglobulinemic purpura.

**Conclusion:** in the present study in patients with lymphomas, the course of pSS was characterized by minimal systemic manifestations and low immunological activity, but severe glandular manifestations with the development of late stage damages of salivary and lacrimal glands, severe lymphoid infiltration of MSG, which led to the frequent occurrence of MALT-Lymphomas. Thus, in patients with pSSS, regardless of the type of detected antibodies (antiRO/La, ACA, RF or others), regardless of the presence or absence of systemic manifestations, damage of salivary and lacrimal gland progresses, which in some cases leads to the development of lymphomas, therefore, therapy that can prevent this complication should be initiated immediately after diagnosis of pSS is confirmed. The signs of lymphoproliferation detected in the patient should be evaluated in all ACA+pSS patients for early diagnosis of lymphoma.

**GLUCOCORTICOID DOSE IS AN INDEPENDENT PREDICTOR OF MORTALITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS HOSPITALIZED FOR INFECTION**

T. Y. H. Heng1, N. Chew2, K. A. Choo1, A. Lateef1, M. Lahiri1, 1National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore; 2National University Hospital, Medicine, Singapore, Singapore

**Background:** Infection is an important cause of mortality and morbidity in patients with systemic lupus erythematosus (SLE) and a common cause for hospitalization. Glucocorticoids (GC) may contribute to increased mortality.

**Objectives:** We performed a 10-year retrospective study of SLE patients hospitalized for infection, and the clinical predictors of mortality, especially GC dose, in these patients.

**Methods:** Diagnosis codes for SLE were obtained from the electronic medical records for hospitalized patients from 2005 to 2015. Chart review was performed to ascertain the indication for hospitalization. The first hospitalization for infection (if any) was used as the index admission. Demographic and clinical characteristics, infection site and immunosuppressive drugs over the past month were abstracted. Multivariable logistic regression was used to determine predictors of all-cause mortality at 1 year.

**Results:** Diagnosis codes were obtained for 768 unique SLE patients with 3660 hospitalization episodes over 10 years, of which 689 had a physician diagnosis of SLE on chart review. Of these, 250 (36%) had an index admission for infection. 243/250 (97.2%) fulfilled the ACR 1997 criteria for SLE and were studied further (Figure 1). Median (IQR) age at admission was 45.1 (37.3, 56) years, 86% were female, 72% were Chinese, median (IQR) disease duration was 9 (4, 17) years. 53 (21.8%) patients had chronic kidney disease (CKD), 34 (14%) had diabetes mellitus (DM) and 12 (4.9%) had cancer. 231 (95.1%) patients were on immunosuppressive drugs and 210 (86.4%) were on GC. The median (IQR) GC dose was 8 (5, 15) mg oral prednisolone equivalent per day. The median (IQR) Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score was 4 (1, 10). The most common organism was Escherichia coli, followed by Staphylococcus aureus and Salmonella enteritidis. The respiratory tract was the most common site of infection. 273% of patients who had blood cultures performed had bacteremia. There were 11 (4.5%) ICU admissions, 6 (2.5%) patients died in hospital and 1-year all-cause mortality was 13 (5.3%). SLEDAI had only a weak positive correlation with GC dose ($R^2 = 0.039$,Pearson’s correlation = 0.197, $p = 0.004$) (Figure 2).

**Conclusion:** Increased age (odds ratio (OR) 1.07, 95% CI 1.02-1.12, $p = 0.005$), average daily GC dose (OR 1.05, 95% CI 1.02-1.09, $p = 0.002$), bone infections (OR 42.24, 95% CI 2.76-646.8, $p = 0.007$) and CKD (OR 4.78, 95% CI 1.06-21.54, $p = 0.04$) were independent predictors of 1-year mortality, after adjusting for gender, SLE-DAI, DM, and cancer (Table 1).

THU0261 NEW 2019 SLE EULAR/ACR CLASSIFICATION CRITERIA ARE VALID FOR IDENTIFYING SLE AMONG PATIENTS ADMITTED FOR PERICARDIAL EFFUSION L. Delaval1, T. Goulenok1, L. Delaval1, T. Goulenok1, A. Dossier1, T. Papo1, K. Sacre1, 1Université Paris Diderot, Paris, France

Background: The new 2019 SLE European League Against Rheumatism-American College of Rheumatology (EULAR/ACR) classification criteria for systemic lupus erythematosus (SLE) have recently been published. Seritits is a prominent -often inaugural- feature of active SLE. Low titers of antinuclear antibodies (ANA) have been frequently reported in patients with idiopathic pericarditis. Of note, ANA positivity at a titer ≥ 1/80 is now mandatory as an entry criterion in the 2019 SLE EULAR/ACR classification criteria.

Objectives: Although classification criteria have theoretically no individual diagnostic purpose, we aimed at testing this new criteria set in unselected patients with pericardial effusion

Methods: In a retrospective study performed in the Department of Internal Medicine, University Paris Diderot, a French competence centre for rare systemic autoimmune diseases (AID), all consecutive adult patients hospitalized from January 2009 to January 2019 for pericardial effusion were reviewed. Clinical and biological data collected at time of the diagnosis of pericardial effusion were analyzed. The characteristics of the patients are listed in Table 1. Three sets of lupus criteria (SLE ACR-1997, SLE SLICC and 2019 SLE EULAR/ACR criteria) were applied in all ANA-positive patients

Results: Over a 10-year period, 137 patients were admitted for pericardial effusion. Search for ANA was systematically performed at diagnosis in all but 8 (n=129) and measured at a titer ≥ 1/80 on Hep-2 cells in 49 patients (38%) that were eventually separated in three groups: 17 (34.7%) patients with a final diagnosis of SLE based on senior clinician judgement, 6 (12.2%) patients with a final diagnosis of autoimmune disease (AID) other than SLE (primary Sjögren’s syndrome (n=2), undifferentiated connective-tissue disease (n=2) and systemic sclerosis (n=2)) and 26 (53.1%) patients with a diagnosis of idiopathic pericarditis after exclusion of malignancy, tuberculosis and systemic inflammatory diseases with a median 12.3 [1.6-29.8] months follow-up

The 2019 SLE EULAR/ ACR criteria were met in 100% of patients with SLE, 33.3% of patients with non-SLE AID and 11.5% of patients with idiopathic pericarditis. Thus this new set of criteria for SLE offered a higher sensitivity (100%) but a lower specificity (89%) as compared to the former criteria, for the diagnosis of SLE in patients with pericardial effusion. Interestingly, the 2019 SLE EULAR/ACR classification score was higher in SLE patients (median: 30 [11-45]) as compared to non-SLE AID (median: 6 [8-12], p=0.0006) and idiopathic pericarditis patients (median: 6 [5-12], p< 0.0001). Moreover, the 2019 classification set score strongly correlated with the SLEDAI activity score [6] as shown Figure S1 (R² =0.8105, p< 0.0001). Setting the 2019 SLE EULAR/ACR classification threshold score ≥ 12 (out of a theoretical maximum of 51) instead of ≥ 10 increased the specificity of 2019 SLE EULAR/ ACR criteria from 84.38% to 100%. Overall, in patients with pericardial effusion and positive ANA, the diagnosis of SLE could be ruled out when 2019 SLE EULAR/ACR criteria score was < 10 and confirmed when the score was > 12.

Conclusion: This study shows that the new 2019 SLE EULAR/ACR criteria for SLE are helpful in clinical practice for the diagnosis of SLE in patients admitted for pericardial effusion

THU0262 LEVELS OF OSTEOCALCIN AND PROCOLLAGEN TYPE I C-TERMINAL PROPEPTIDE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS, THEIR ASSOCIATION WITH BONE MINERAL DENSITY AND LEVEL OF INTERLEUKIN-6 S. Shevchuk1, L. Denysychych2, 1National Pirogov Memorial Medical University, Scientific and Research Institute of Invalid Rehabilitation (Educational, Scientific Treatment Complex) of National Pirogov Memorial Medical University, Vinnytsia, Ukraine; 2National Pirogov Memorial Medical University, Vinnytsia, Ukraine

Background: Osteoporosis and fractures associated with it are considered to be one of the most severe complications of systemic lupus erythematosus (SLE). The role of a systemic inflammatory process, vitamin D deficiency, hypogonadism and peculiarities of disease treatment in reduced bone mineral density (BMD) is being discussed. Even though the frequency of osteoporosis in patients with SLE is being studied extensively by scientists from different countries, data on the peculiarities of bone tissue metabolism and the factors that provoke disorders of bone remodeling in such individuals are quite limited. The association between markers of bone tissue metabolism and BMD, and how they change during an inflammatory process is poorly studied.

Objectives: The objective of our research is to study the markers of osteocalcin (OC) and procollagen type I C-terminal propeptide (PICP) in patients with systemic lupus erythematosus and to estimate their association with BMD and inflammatory activity based on the levels of interleukin-6 (IL-6). Methods: A total of 58 SLE patients (38 female and 20 male; median age 45.1±1.03 years old) and 29 individuals from the control group (the average age was 46.79 ± 2.30 years old) were examined. The diagnosis of SLE was established on the basis of 2019 EULAR/ACR classification criteria for SLE. Levels of IL-6, OC and PICP in serum were determined by enzyme immunoassay. Changes in BMD of the lumbar spine at the level of L-1-L-4 and the proximal femur were determined by dual-energy X-ray absorptiometry. In postmenopausal women, the diagnosis of osteoporosis was established by the T-score ≤ -2.5 SD. Osteopenia met T-score from -1 to -2.5 SD. In women of reproductive age, the Z-score was used to determine BMD. Values of the Z-score ≤ -2.0 SD were considered as “below expected range for age”.

Results: The average OC level in serum of practically healthy individuals equaled 17.64 ± 0.59 ng/ml, and in patients with SLE it was 13.96 ± 2.04 ng/ml, i.e. it was 20.9% lower. The average PICP level in the control group equaled 107.8 ± 4.28 ng/ml, in the main group it was 92.9 ± 5.01 ng/ml, i.e. 16% lower. Overall, the decrease in the bone turnover markers (PICP and/or OC) was noticed in 28 patients with SLE (48.3%) and only in 4 practically healthy individuals (13.8%). In women with decreased bone turnover markers, the T-score of the lumbar spine and hip was 2.3-2.6 times lower (p < 0.05) than in the group with adequate levels of bone turnover markers. Z-score was also lower among patients with decreased levels of OC and PICP. In this group, the average BMD level was 0.81 ± 0.05 g/cm² and was 13.8% lower than in the group of patients with no signs of bone tissue metabolism disorder – 0.94 ± 0.02 g/cm². Among the group of women with signs of suppression of biosynthetic processes in bone tissue, there were twice more individuals with decreased BMD. In patients with critically high levels of IL-6 (above 20.0 ng/L), OC level was lower than in patients with high (12.5-20.0 ng/L) and adequate (< 12.5 ng/L) levels of IL-6 (by 17.3 and 19% respectively). The proportion of individuals with low OC levels increased from 31.2% in the last group to 70.6% among patients with critically high levels of IL-6. PICP level was also lower (38.1% and 39.7% respectively) in case of critically high IL-6 levels compared to its high and adequate levels. The proportion of individuals with low PICP levels increased from 6.3% in the group with adequate IL-6 level to 58.8% in the group with critically high IL-6 level.

Conclusion: Women with SLE have bone tissue metabolism disorder in the form of decreased bone turnover markers (procollagen type I C-terminal propeptide (ostocalcin) associated with the inflammatory activity. In the group of patients with the signs of suppression of biosynthetic processes in bone tissue, there were more individuals with decreased BMD. In patients with critically high levels of IL-6, PICP level was also lower (38.1% and 39.7% respectively) in case of critically high IL-6 levels compared to its high and adequate levels. The proportion of individuals with low PICP levels increased from 6.3% in the group with adequate IL-6 level to 58.8% in the group with critically high IL-6 level.

THU0263 LUNG INVOLVEMENT IN PRIMARY SJÖGREN SYNDROME – AN UNDER-DIAGNOSED ENTITY G. Sogkas1, S. Hirschi1, K. Olsson2, R. Schmidt1, T. Witte1, A. Jabonka1, D. Ernst1, 1Medical Highschool Hannover: Clinic for Immunology and Rheumatology, Hannover, Germany; 2Medical Highschool Hannover, Clinic for Pneumology, Hannover, Germany

Background: Interstitial lung disease (ILD) represents a frequent extra-glandular manifestation of primary Sjögren’s Syndrome (pSS). Limited published data regarding phenotyping and treatment exists. Advances in managing specific ILD phenotypes have not been comprehensively explored in patients with coexisting pSS.

Objectives: This retrospective study aimed to phenotype lung diseases occurring in a well-described pSS cohort and describe treatment course and outcomes. Methods: Between April 2018 and September 2019, all pSS patients attending our Outpatient clinic were screened for possible lung involvement. Clinical, laboratory and computer tomography (CT) findings were analysed. Patients were classified according to CT findings into 5 groups: usual interstitial pneumonia...
MYELOID MALIGNANCIES, SYSTEMIC AUTOIMMUNE DISEASES AND CARDIOVASCULAR RISK: AN UNDER-REPORTED ASSOCIATION?

F. Ferro1, C. Baraté1, E. Elefante1, F. Ricci1, S. Balducci1, G. Governa1, G. Fulvio1, M. Mosca1, M. Petrinì1, S. Galimberti1, C. Baldini2. 1University of Pisa, Clinical and Experimental Medicine, Pisa, Italy

Background: The association between systemic autoimmune diseases (AIDs) and lymphoproliferative malignancies is well established; nonetheless, few studies have investigated the prevalence and prognostic impact of myeloid malignancies on systemic autoimmune conditions.

Objectives: To investigate the frequency of myeloid malignancies (i.e. myelodysplastic syndrome (MDS) and chronic, either Philadelphia-positive or Philadelphia-negative, myeloproliferative disorders (MPNs)) in patients with AIDs and their influence on the AIDs clinical course and vice-versa.

Methods: A retrospective systematic search through the electronic health records of the patients admitted at our Rheumatology University Hospital from 2009 and 2019 was performed to select those presenting with AIDs and MDS or MPNs. To refine the search the ICD-9-CM diagnosis codes for MDS/MPNs were utilized. Medical charts of eligible patients were retrieved and data were collected with regard to demographics, type of AD, AD duration, prior treatments, serum laboratory indices, bone marrow aspiration and biopsy data. Categorical variables were compared using chi square test and Fisher’s test; continuous variables were compared using Student’s t-test and Mann-Whitney U test; frequencies were compared using chi square test and Fisher’s test; continuous variables were compared using Student’s t-test and Mann-Whitney U test.

Results: Out of the medical records of 5040 patients, we identified 51 patients (31 F: 20 M, mean age: 61 years (15)) with AD and myeloid malignancies: 17/51 with AD and MDS and 34/51 with AD and MPNs. No demographic differences were observed in the two subgroups. Regarding MDS, anaemia was the most common hematologic presenting finding (15/17, 88%), while the most common diagnosis was refractory anaemia with excess of blasts (RAEB III) (5/17, 29%) followed by sideroblastic anaemia (5/17, 29%). In the MPNs subgroup, 12/24 patients (50%) had a diagnosis of chronic myeloid leukemia (CML), 9/34 (26%) had a myelofibrosis (MF), 7/34 (21%) had an essential thrombocytopenia (ET) and 6/34 (18%) had a polycythemia vera (PV). The JAK2 V617F mutation was detected in 100%, 57% and 66% of PV, ET, and MF patients. Regarding the temporal appearance of myeloid malignancy, MDS occurred concurrently (9/17) or followed (7/17) the diagnosis of AIDs in the vast majority of the cases whereas MPNs generally preceded the diagnosis of AIDs (19/34). In MDS the most commonly diagnosed ADs were seronegative arthritis (5/17, 29%), large and small vessel vasculitides (4/17, 23%) and Systemic Lupus Erythematosus (3/17, 17%). In patients with MPNs the diagnosis of rheumatoid arthritis (2/9, 22%), and antiphospholipid syndrome (3/9, 33%) were often associated with MF, whereas anti-Ro/SSA (TRIM21) positive systemic connective tissue disorders (4/7, 57%) were more frequently detected in ET. Cardiovascular events were observed in 14/51 (27%); 4/17 (23%) in MDS, 3/12 (25%) in CML and 7/22 (32%) in Philadelphia-negative MPNs. The latter seven cardiovascular events were all observed in patients presenting JAK2 V617F mutation (p<0.05).

Conclusion: Our study is limited by its retrospective design. However, our results document that the frequency of MDS and MPNs in AIDs patients might be underestimated. In the setting of AIDs, the presence of AIDs might be considered in the assessment of cardiovascular risk in systemic autoimmune disease. Moreover, it has been reported that, under viral infection, TRIM21 is up-regulated by activation of the IFN/IFNAR/STAT pathway; interestingly, anti-Ro/SSA (TRIM21) were over-represented in MPN, where the JAK/STAT signal is hyper activated. This could explain also our observation that frequently the onset of AIDs follows the diagnosis of MPN.

THU0265

THYMIC STROMAL LYMPHOPOIETIN (TSLP) AS A BIOMARKER OF PRIMARY SJÖGREN’S SYNDROME (PSS) AND RELATED LYMPHOID PHENOMA: VALIDATION IN INDEPENDENT COHORTS

S. Gandolfo1, C. Fabro2, C. Colafrancesco3, F. Carubbi2, F. Ferro4, E. Bartoloni Boci5, E. Kapsogeorgou6, A. Goules6, L. Quartuccio1, R. Priori1, A. Alonso2, G. Valesini2, R. Giacomelli7, R. Gerli1, C. Baldini8, A. Tziofas8, S. De Vita1, 1Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, Pisa, Italy 2Rheumatology Unit, Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome, Italy, Roma, Italy, Roma, Italy; 3Rheumatology Unit, Department of Pathophysiology, Athens School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece

Background: Thymic stromal lymphopoietin (TSLP) has been implicated in primary Sjögren’s syndrome (pSS) and related B-cell lymphoproliferative lymphoma (pSS-LPL). TSLP is a cytokine produced by epithelial cells of the gut and the salivary glands in response to pathogen recognition receptors. TSLP is also a key mediator in autoimmune diseases, including pSS. Our study aims to confirm that serum TSLP is elevated in pSS by the study of independent cohorts.

Methods: Serum TSLP levels were measured by ELISA in 91 pSS patients (F=86, 94.5%; mean age 57.2 years, 25-80) from the Udine cohort (cohort 1, UD), Italy. One additional multicentre cohort (cohort 2) from the Italian SS Study Group (GRISS) was studied, including 125 pSS patients from the Universities of Roma (RO), L’Aquila (L’AQ), Pisa (PI) and Perugia (PG). pSS patients with active NHL (n=12 in cohort 1; n=1 in cohort 2) were excluded from comparative analyses to avoid bias. Secondly, additional serum samples from pSS-related NHL in stable remission, from both cohorts 1 and 2, were analysed in a separate subgroup (n = 12). Thirdly, a preliminary evaluation of serum TSLP was performed in pSS patients from a different geographical area (University of Athens, Greece; cohort 3).

Results: Cohort 2 included 125 pSS patients (F=114, 91.2%; mean age 58.1 years, 23-84): 124 benign, 1 with NHL. In this cohort, serum TSLP levels were confirmed to be higher than control group (30.26 pg/mL) and comparable to cohort 1 (mean 33.81 pg/mL, 0-140.8; p=ns). No difference was found by the separate analysis of pSS from each single Centres (RO n=49, mean 33.21, 1.4-95.21; L’AQ n=34, mean 38.6, 16.3-81.51; PI n=28, mean 20.23, 0.41-56.67; PG n=13, mean 19.39, 1.03-68.38; p=ns), and vs cohort 1 (p=ns). The only patient in cohort 2 with NHL showed serum TSLP of 160.91 pg/mL, comparable to the mean TSLP in the 12 UD pSS-NHL (151.96 pg/mL). Importantly, in pSS-related NHL in stable remission, serum TSLP resulted undetectable (7/13) or detectable at very low levels (6/13) (mean 10.46, 0.38-5.1) and significantly lower than in benign pSS patients from the two cohorts (n=203, mean 31.48, 0-140.8; p=0.0022). Metachronous samples from one patient, at the stage of NHL activity and then at NHL remission, showed a decrease in TSLP from 128.04 pg/mL to undetectable levels. Finally, TSLP levels were increased also in the GRISS cohort (median 54.9, 26.7-78.95), and significantly higher than the two Italian cohorts (p=0.0085 and p=0.0001, vs cohort 1 and 2, respectively).

Conclusion: Serum TSLP levels are increased in pSS, as herein confirmed in independent cohorts. TSLP might be important in the disease pathophysiology and mirrors the course of pSS-related B-cell lymphoproliferation itself. It may thus represent a novel important biomarker.

THU0266 RESILIENCE IN WOMEN WITH PRIMARY SJÖGREN’S SYNDROME
E. Giardina1, G. Curcio2, R. Izzo1, S. Colafrancesco3, A. Gattamelata1, L. Mastromonno1, G. Valesini1, R. Priori1, Sapinzena University of Roma, UOC Reumatologia, Dipartimento di Scienze Cliniche, Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy; 2Università degli Studi dell’Aquila, Dipartimento di Scienze Cliniche Applicate e Biotecnologiche, Aquila, Italy

Background: Resilience is the ability to react positively to stressfull life events, a multidimensional feature that varies in relation to context, time, age, sex, culture and personal experience, appearing among the most important traits in patients suffering from rheumatic diseases1. Several studies focus on patients with RA and SLE and the role of resilience in the respective clinical manifestations, as well as in the development of anxiety and depression2,3. Conversely, the data available regarding patients with primary Sjögren’s Syndrome (pSS) are limited.

Objectives: To assess, in women with pSS (classified according to the criteria of Vitali et al.), the relationship between resilience and anxiety, depression, health, fatigue, physical activity and quality of life in relation to disease activity and duration and in consideration of demographic, job and cultural characteristics.

Methods: 74 female patients with pSS afferent to the dedicated clinic of the University Hospital Policlinico Umberto I of Rome were recruited. Resilience was assessed by administering the Italian validated version of the Resilience Scale (RS-14) consisting of 14 items, each of which is assigned a score from 1 to 7, with a range from 14 to 98. Higher scores relate to greater resilience. ESSDAI (EULAR Sjögren’s syndrome disease activity index), ESSPRI (EULAR Sjögren’s Syndrome Patient Reported Index), SSDI (Sjogren’s Syndrome Disease Distress Index) were assessed and EuroQoL EQ VAS (visual analogue scale), HADS (Hospital Anxiety and Depression Scale), SF-12 (Short-form 12 health self-assessment), FAS (Fatigue Assessment Scale), IPAQ (International Physical Activity Questionnaire), FACT-F (Functional Assessment of Chronic Illness Therapy – Fatigue) questionnaires were submitted. Educational qualifications and job were also considered.

The statistical analysis was carried out by means of Spearman’s correlation.

Results: No relationship was found between resilience, systemic disease activity, disease duration, patient-reported symptoms and damage. Furthermore, no apparent link was found between socio-demographic characteristics, employment and resilience. Conversely, an inverse relationship was found between resilience and mood disorders (p=0.0379), with greater resilience associated with a better perception of quality of life (p=0.0232) and general health (p=0.0002), mainly mental (p=0.0001) than physical (p=0.0035), as well as less fatigue (p=0.0079) and physically active lifestyle (p=0.0012).

Conclusion: For the first time, the role of resilience in women with pSS in relation to their disease and other individual parameters was assessed. The most resilient patients are less depressed and show better perception of their health. Greater resilience tends to correlate with less anxiety, physical and mental fatigue and a more active lifestyle, while there was no relation between resilience value, active disease and socio-demographic features.

THU0267 SERUM IGG2 LEVELS PREDICT VERY LONG-TERM PROTECTION AGAINST PNEUMOCOCCAL VACCINE IN SYSTEMIC LUPUS ERYTHROMATOSUS (SLE)
T. Goulenok1, A. L. Gerard1, M. Bahauud2, P. Aucouturier3, H. Moins3, T. Papo4, K. Sacre1; 1Université Paris Diderot, Paris, France; 2Université Paris Descartes, Paris, France; 3Université Pierre et Marie Curie, Paris, France

Background: Systemic lupus erythematosus (SLE) patients are at increased risk for Streptococcus pneumoniae infection. Although pneumococcal vaccination is an attractive method to prevent invasive pneumococcal infection, vaccination coverage remains dramatically low in SLE. Moreover, the efficacy of vaccination may be reduced in SLE patients and sequential pneumococcal vaccination using new conjugated pneumococcal vaccines in combination with 23-valent pneumococcal polysaccharide vaccine (PPV23) is now advocated. However, limited study directly addressed the immune efficacy of such prime-boost strategy in SLE.

Objectives: We aimed to measure the immunological efficacy of the sequential pneumococcal vaccination using PCV13 in combination with PPV23 and identify factors associated with long-term immune protection following vaccination in SLE.

Methods: SLE patients received PCV13 vaccine followed by PPV23 vaccine 8 weeks later. Immune protection, defined by an antigen-specific IgG concentration ≥1.3 µg/mL, for at least 70% of pneumococcal serotypes (4, 6B, 9V, 14, 19C, 19F, 23F), was assessed at baseline, 2 months, 12 months, and 36 months, defining very long-term protection.

Results: 21 (40[25-75] years; 85.7% female) SLE patients received the sequential PCV13/PPV23 vaccines. Only 10 (47.6%) showed a sustained immune protection against pneumococcal infection 36 months after PCV13 shot (very long-term protected, VLTP). Eleven patients had no long-term protection (NLTP) with a seroconversion that never (n=6) or only transiently (n=5) occurred. SLE disease features, treatment received and immunological characteristic did not differ between VLTP and NLTP patients except for a lower serum IgG2 levels in NLTP (1.45 [1.30, 1.82] vs 3.30 [2.92, 4.44] g/L, p<0.001). Noteworthy the ROC curve showed that the serum IgG2 level before vaccination (AUC 0.95 [95% CI: 0.84-1]; p<0.004) was predictive for very long-term protection. A baseline serum IgG2 level of 2.125µg/ml or more showed a sensitivity of 100% and a specificity of 90.9% for very long-term protection.

Conclusion: The benefit of sequential PCV13/PPV23 vaccination in SLE is limited. Baseline IgG2 serum level before vaccination is strongly indicative of very long-term protection following vaccination.

THU0268 NEURO-DEVELOPMENTAL OUTCOME IN CHILDREN BORN TO MOTHERS WITH SLE AND APS
M. Hassanian1, E. Talat1, H. Abdellatif1; 1Assut University, Assut, Egypt; 2Aswan University, Assut, Egypt

Background: Systemic Lupus erythematosus and antiphospholipid disease are very common autoimmune diseases in women at reproductive age.

Objectives: Evaluate the neuro-developmental outcome in children born to mothers with SLE or APS and to assess and characterize memory impairment in children's born to mothers with systemic lupus erythematosus or APS using children's memory scale and the relation between tetrahydrobipterin concentration range of children with developmental and neurological disorders.

Methods: Women attending rheumatology clinics University of Assut, SLE patients were eligible if they met the American College of Rheumatology (ACR) criteria for SLE and APL prior to pregnancy, and had at least one live birth following SLE diagnosis. Maternal history Data collected using a structured format that included medical and obstetric history. A detailed history of medication exposures and the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) during pregnancy was obtained. Offspring history Medical and developmental histories of the offspring including antenatal, delivery, prenatal and pediatric histories, as child's cognitive, physical or social maturity compared with established age-appropriate norms. Speech or hearing delays, diagnosis of attention-deficit hyperactivity disorder (ADHD), or any special educational needs (eg, occupational or speech therapy, behavioral counseling) was recorded. Assessment and characterization of memory impairment using children's memory scale by neurologists. Tetrhydrobipterin was measured by ELISA compared to children born to control healthy subjects of the same age and sex.

Results: Data on 38 mothers and 60 offspring were analysed: ADHD was reported for 15 of 60 (25%) offspring. Recent memory delay was detected in 93% (14/15) Speech delay 40% (6/15). Maternal APS history was significantly associated with delays. Recent memory delay was detected in 93% of children of mothers with SLE or APS. Maternal APS history was significantly associated with increased use special educational need among offsprings, including after adjustment for lupus anticoagulant (LA) positivity (39.4% for delays age >2 years; p<0.05). Anticardiolipin and anti-BETA2GP1 were not detected to be associated with delays. Recent memory delay was associated with increased Tetrhydrobipterin level (P<0.01).
Background: Due to heterogeneity of the disease, there has been several classification criteria for Systemic Lupus Erythematosus (SLE). These have considered the knowledge obtained through the years and have strived for increased sensitivity and specificity. Recently, both EULAR and ACR have proposed new criteria for disease classification that mandate a positive ANA result to apply the criteria.

Objectives: To compare the 2019 EULAR/ACR classification criteria (1) with the Systemic Lupus International Collaborating Clinics (SLICC) 2012 classification criteria (2) and the American College of Rheumatology (ACR) 1997 classification criteria in a Colombian cohort (3).

Methods: A cross-section retrospective study was done with data collected between 2014 and 2018 from a population diagnosed with SLE by a group of rheumatologists in an autoimmunity referral centre and followed for one year. The new 2019 EULAR/ACR classification criteria were applied to the information collected from the clinical records. Three sets of criteria were compared using Cohen’s kappa coefficient and concordance was evaluated.

Results: We obtained information for 480 patients, in this analysis were mostly females (96%). Anti-nuclear antibody (ANA) results were available for 95% of the patients. According to SLICC classification criteria the diagnosis of SLE was definite in 92% of patients, 81% by ACR 1997 and 89% using ACR/EULAR 2019. The sensitivity was 93% and 97% for ACR/EULAR 2019 and SLICC 2012, and the specificity was 67% and 48% respectively. The concordance analysis between the two sets of criteria showed agreement of 92% (kappa 0.52 p <0.001) in the whole group.

Conclusion: We found good agreement between SLICC 2012 criteria and EULAR/ACR 2019 classification criteria. In contrast with previous studies, where the new criteria had a sensitivity of 96.1% and specificity of 93.4%, in our cohort the sensitivity was maintained in 93% but the specificity decreased to 67%. A possible explanation could be the ANA negativity that was seen in 5% of the patients and would force to discard patients with false negative results. Despite this, the agreement of the criteria is good and should continue to be applied in our population, without abandoning the expert’s clinical criteria.

Background: EULAR/ACR 2019 SLE Classification Criteria were validated in an international cohort.

Objectives: To evaluate performance characteristics of the EULAR/ACR 2019, SLICC 2012 and ACR 1982/1997 criteria were evaluated in the validation cohort.

Methods: Sensitivity and specificity of the EULAR/ACR 2019, SLICC 2012 and ACR 1982/1997 criteria were evaluated in the validation cohort.

Results: The cohort consisted of female (n=1098), male (n=172), Asian (n=118), Black (n=68), Hispanic (n=124) and White (n=841) patients; and patients with an SLE duration of 1-3 years (n=196), 3-5 years (n=157), ≥5 years (n=879). Among patients with 1-3 years disease duration, the EULAR/ACR criteria had better sensitivity than the ACR criteria (97% (95%CI 92-99%) vs 81% (95%CI 72-88%). The new criteria performed well in men (sensitivity 93%, specificity 94%) and women (sensitivity 97%, specificity 94%). The new criteria had better sensitivity than the ACR criteria in White (95% vs 83%), Hispanic (100% vs 86%) and Asian patients (97% vs 77%).

Conclusion: The EULAR/ACR 2019 criteria perform well in patients with early disease, and across sexes and ethnicities.
Background: Collagen type IV and laminin are the main constituents of basement membranes (BMs). Epitopes on these molecules are targeted in various autoimmune diseases, systemic lupus erythematosus (SLE) in particular. Accelerated large vessel disease is a well-recognized cause of premature cardiovascular morbidity and mortality in SLE. Novel tools for quantification of soluble MMP-derived fragments of collagen type IV (C4M) and laminin (LG1M) have emerged as promising biomarkers for BM remodeling in atherosclerosis.

Objectives: To study serum levels of collagen type IV and laminin metabolites in patients with SLE and in healthy controls. And to search for associations with disease activity, organ damage and cardiovascular comorbidity.

Methods: One hundred and six SLE patients without and 20 with previous CVD events were included (1). One hundred and twenty male and female blood donors aged 20-65 years served as healthy reference. Disease activity (SLEDAI) and damage (SLICC) scores were calculated. Coronary artery calcification (CAC) was studied by CT scan and expressed as Agatston score. Carotid intima-media thickness (IMT) was measured by ultrasound (LOGIQ E9, GE Healthcare). In either subgroup atherosclerosis was defined as Agatston > 99 U and/or IMT>1 mm and/or presence of plaque. C4M and LG1M were measured by competitive ELISAs (2).

Results: Patient characteristics are presented in Table 1. Overall, C4M and LG1M were significantly increased in the entire SLE cohort vs. healthy controls (35.7 ± 17.5 vs. 22.3 ± 9.4 ng/mL, p<0.0001 and 20.9 ± 21.2 vs. 9.7 ± 8.0 ng/mL, p<0.0001, respectively) (Fig 1). Highly significant positive correlations were detected between C4M and LG1M in the entire SLE cohort and in the healthy control group (Fig 2). In terms of CVD and atherosclerosis LG1M was significantly higher in SLE patients with manifest CVD vs. those without (34.47 ± 41.22 vs. 18.34 ± 13.55, p=0.0015) and in those with atherosclerosis by imaging (25.53 ± 28.12 vs. 17.53 ± 13.35, p=0.036). There were no associations between C4M and CVD or atherosclerosis. There was a weak association between LG1M and SLICC (r=0.22, p=0.01), but not with SLEDAI. Details on associations with other CVD risk factors and specific organ involvement will be presented.

Conclusion: Serum levels of collagen type IV and laminin biomarkers were elevated and interrelated in unselected SLE population. Moreover, LG1M but not C4M was significantly elevated in SLE patients with previous CVD events and in those with atherosclerosis by imaging. These findings indicate that LG1M may serve as a serological marker for SLE-related large vessel disease. However, additional extravascular sites of increased basement membrane remodeling may contribute to the abnormal biomarker pattern.

THU0273 DISEASE ACTIVITY IS IMPORTANT RISK FACTORS FOR MATERNAL AND FETAL OUTCOMES DURING PREGNANCY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J.-W. Kim1, J.-Y. Jung1, H.-A. Kim1, C. H. Suh1.1 Ajou University School of Medicine, Suwon, Korea, Rep. of (South Korea)

Background: Systemic lupus erythematosus (SLE) primarily affects women of childbearing age and disease activity frequently increase during pregnancy. Patients with SLE still have markedly higher risk for obstetric complications, despite discussing reproductive planning with physicians and choosing a suitable time for pregnancy.

Objectives: This study aimed to examine the frequency and risk factors of complications occurring during pregnancy for women with SLE and compare with the general obstetric population.

Methods: The medical records of patients with SLE and age-matched controls at Ajou University Hospital between January 1999 and June 2019 were collected and retrospectively analyzed. Clinical features and pregnancy complications for all pregnancy-related admissions for women with and without SLE were compared. Multivariate logistic regression analysis was performed to obtain the predictor of maternal and fetal adverse outcomes.

Results: Period during this study, we analyzed 163 pregnancies in patients with SLE and 596 pregnancies in general population. Of these, except for body mass index (BMI), no other significant differences regarding demographic characteristics were noted between the groups. Lupus patients delivered significantly earlier (37 weeks ± 6 days vs. 37 weeks ± 6 days, p<0.001) and experienced more stillbirth (odds ratio 12.8), pre-eclampsia (OR 4.2), preterm labor (OR 2.6), emergency cesarean section (OR 2.5) and intrauterine growth retardation (odds ratio: 2.4) than age-matched controls. Using logistic regression, thrombocytopenia, low complement levels, high proteinuria, anti-ds DNA antibody positivity and high SLE Disease Activity Index (SLEDAI) were associated with maternal and fetal complications, whereas high cumulative steroid dose after SLE onset, high median steroid dose during pregnancy and history of cyclophosphamide treatment were only correlated with maternal complications. The area under the curve for SLEDAI score of adverse pregnancy outcome was 0.726 (95% CI 0.65-0.81) and cumulative steroid dose after SLE onset and median steroid dose during pregnancy for maternal outcome were 0.658 (95% confidence interval (CI) 0.55-0.76) and 0.750 (95% CI 0.65-0.85). The optimal cut-off value for SLEDAI was 4 and cumulative and median steroid dose were 2750mg and 6mg, respectively.

Conclusion: Pregnant women with SLE have a higher risk of adverse pregnancy outcomes. Pregnancies should be delayed until disease activity is well controlled (SLEDAI<4) for longer than 6 months.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.1600
Background: Lupus nephritis (LN) usually develops within 5 years of systemic lupus erythematosus (SLE) onset. It is unclear whether the course and outcome of LN differ between patients who initially had LN at SLE onset (initial-onset LN) and those who developed LN within 5 years after SLE onset (early-onset LN).

Objectives: To compare clinical characteristics and renal outcomes between SLE patients with initial-onset LN and SLE patients with early-onset LN.

Methods: SLE patients with biopsy-proven LN were retrospectively reviewed. The clinical parameters and renal outcomes were compared between initial-onset LN and early-onset LN groups. We used Cox regression analysis to estimate risk of worse renal outcome, according to the onset time of LN.

Results: Of the total 136 LN patients, 92 (67.6%) and 44 (32.4%) were classified into the initial-onset and early-onset LN groups, respectively. The initial-onset LN group had higher prevalences of impaired renal function (34.8% vs. 11.4%, p=0.004) and microscopic hematuria (73.9% vs. 54.5%, p=0.024), and higher urine protein/creatinine ratio (4626.2 [2180.6–6788.3] vs. 2410.0 [1265.0–5168.5] mg/g) at LN diagnosis. Renal relapse (46.3% vs. 25.7%, p=0.039) and progression to chronic kidney disease (CKD) or end-stage renal disease (ESRD) were more common (34.8% vs. 8.3%, p=0.004) in the initial-onset LN group. In the multivariable Cox regression analysis, initial-onset LN group had higher risk of renal relapse (adjusted hazard ratio [HR] 2.938, 95% confidence interval [95% CI] 1.344–6.426, p=0.007) and progression to ESRD (adjusted HR 4.642, 95% CI 1.107–19.458, p=0.036), compared with early-onset LN group.

Conclusion: Patients with LN at SLE onset may have more severe renal presentations and worse renal outcome than those who develop LN within 5 years.

References: Not applicable

Table. Hazard ratios for renal relapse and progression to CKD/ESRD according to onset time of LN

| Univariable analysis       | Multivariable analysis*
|---------------------------|--------------------------
| HR (95% CI) p              | HR (95% CI) p             |
| Renal relapse              | Renal relapse             |
| Early-onset LN             | 1.000 (reference)         | 1.000 (reference)         |
| Initial-onset LN           | 2.734 (1.315–5.686) 0.007 | 2.938 (1.344–6.426) 0.007 |
| Progression to CKD/ESRD    | Early-onset LN            |
| Early-onset LN             | 1.000 (reference)         | 1.000 (reference)         |
| Initial-onset LN           | 4.201 (1249–14.132) 0.020 | 4.642 (1.107–19.458) 0.036 |

*aAdjusted for age, ISN/RPS class, activity index, chronicity index, GFR, UPCR, hematuria and use of HCQ

Legend to Table 1: PE: preeclampsia; APS: antiphospholipid syndrome; IQR: interquartile range; WG: weeks of gestation; SLE: systemic lupus erythematosus; HELLP: Hemolysis, elevated liver enzymes, low platelet; E: eclampsia; CAPS: catastrophic APS; IUGR: intrauterine growth restriction; IUFD: intrauterine fetal death; CHB: congenital atrioventricular block; aPL: antiphospholipid antibodies; LAC: lupus anticoagulant.

Conclusion: Among the APS criteria, “3 consecutive miscarriages criterion” was not found. The majority of patients also experienced thrombosis and SLE before the index PE.

**HIGH HYDROXYCHLOROQUINE EXPOSURE IS ASSOCIATED WITH ABNORMAL STRAIN IMAGING IN LUPUS PATIENTS WITH END-STAGE RENAL DISEASE**

A. Londono Jimenez1, M. H. Mustehsan2, J. Law, A. Valia3, M. Salgado Guerreo1, C. Taub1, A. R. Broder1, J. Montefiore Medical Center/Albert Einstein College of Medicine, New York, United States of America

**Background:** Hydroxychloroquine (HCQ) cardiotoxicity remains an underrecognized condition. Diagnosis ultimately relies on invasive endomyocardial biopsy (EMB) and non-invasive screening methods are warranted. Strain imaging is a novel tool to detect early subclinical left ventricular (LV) dysfunction and may have a role in screening for HCQ cardiotoxicity (1). Strain measures systolic deformation indices that when decreased can predict cardiovascular outcomes more accurately than LV ejection fraction (2).

**Objectives:** We assessed whether high HCQ cardiotoxicity risk is associated with a specific strain pattern in a group of patients with SLE and end-stage renal disease (ESRD).

**Methods:** This was a retrospective study in a tertiary care center in New York on a group of patients with an established diagnosis of SLE, ESRD and cardiomyopathy on the index echocardiogram followed between years 2003 and 2019. The patients were stratified into two groups: high risk HCQ cardiotoxicity group defined as either a positive history of HCQ dose cumulative total and/or an endomyocardial biopsy confirming HCQ toxicity. Low/moderate risk group was defined as a cumulative dose of HCQ <1000g. Clinical, demographic, electrocardiographic and echocardiographic strain parameters were compared between the groups.

**Results:** A total of 16 patients were included. Two patients had EMB consistent with HCQ induced toxicity and 3 patients had cumulative HCQ doses ≥1000g. There were no significant differences in the baseline demographic characteristics between the two groups. Compared to patients with low/moderate risk, patients in the high risk group had a lower heart rate at the time of the echocardiogram (69 vs 87 beats per minute, p=0.08) and a higher frequency of LV hypertrophy (40% vs 9.1%, p=0.27). Strain analysis showed that both groups had compromised LV GLS (−12.3% vs −14.9%, p=0.27). Strain analysis showed that both groups had comparable LV LS and GLS (−16.7% vs −17.1%, p=0.2). Strain analysis showed that both groups had comparable RV dysplasia (−20.2% vs −20.2%, p=0.2). There were no significant differences in the baseline demographic characteristics of the High HCQ Risk group compared to the Low/Moderate HCQ Risk group.

**Conclusion:** We observed that high HCQ cardiotoxicity risk was associated with a specific strain pattern in a group of patients with SLE and end-stage renal disease.

**THE EXPRESSION OF INFN, INFβ AND INFγ PROTEINS IN SERUM OF PATIENTS WITH LUPUS SYNDROME.**

M. Maślińska1, A. Paradowska-Goryńska2, A. Wajdś1, K. Kostyra-Grabczak1, B. Kwiatkowska1, National Institute of Geriatrics, Rheumatology and Rehabilitation, Early Arthritis Clinic, Warsaw, Poland; National Institute of Geriatrics, Rheumatology and Rehabilitation, Molecular Biology Department, Warsaw, Poland

**Background:** In the pathogenesis of autoimmune mediated diseases, such as Sjögren’s syndrome (SS), interferons (IFN) and IFN pathway activation play a vital role.

**Objectives:** We planned to assess IFNα, IFNβ and IFNγ expression in serum levels in SS patients and correlation with disease parameters of autoantibodies specific for SS, serum concentration of C3, C4 component of complement (C3, C4), antinuclear factor (RF), gammaglobulins, focus score (FS) and eye dryness symptoms.

**Methods:** Whole blood RNA was isolated from 77 SS patients [F91%vsM9%]; mean age 49,69±15,36; SS diagnosis according to EULAR/ACR 2016 criteria. The analysis of IFNα, -β and -γ expression levels was based on validated TaqMan probes by ∆CT methods. Serum concentrations of rheumatoid factor (RF), C3- and C4 complement components (mg/dL) and gammaglobulins (g/dL) were assessed. Anti-Ro/SSA and/or anti-La/SSB autoantibodies were assessed by semiquantitative immunoblotting evaluation. The eye dryness and keratoconjunctivitis sicca were confirmed with Schirmer’s test (score of less than 5mm/5' and the ocular staining score (OSS) using lissamine green and fluorescein staining. The biopsy of minor salivary gland was performed with the histopathological evaluation of FS. The study was approved by the Bioethics Committee. Differences between groups of patients were determined using non-parametric Mann-Whitney U test or Kruskall-Wallis test with Dunn’s post hoc. Correlations were determined using non-parametric Spearman test. The level of statistical significance was set at p < 0.05.

**Results:** IFNα had the highest expression levels among IFNs and IFNβ serum concentrations were higher than those of IFNγ and -γ. In cases with high IFNβ serum concentration lower IFNβ expression was observed. There was a highly significant correlation between IFNα and IFNγ expression (r =0.6,p<0.001). IFNγ expression (p=0.059) was higher in the group of younger (<45 y.o.) patients (n= 23; 29.9%) as compared to the group of older individuals (at least 45 y.o.). In patients with SS-A/ Ro antibodies with strong antigen binding affinity (3) IFNβ expression and IFNγ serum levels were highest of all IFNs. The presence of anti-La/SSB antibodies was associated with the increased IFNγ expression while not with the increased IFNβ serum concentration. In terms of IFNα expression and protein level, RF(+)patients had average higher values compared to RF(-) patients. The average mRNA level of IFNβ was about 3 times lower in patients with low SS C3 serum concentration compared to patients with normal C3 serum concentration values. IFNγ mRNA level was 2.5 times lower in patients with low Schirmer’s test (<5mm/5’) in comparison to patients with Schirmer’s test<5mm/5’. Schirmer’s test <3mm/5’ was associated with higher IFNβ serum concentration.

**Conclusion:** Type I IFN signature predominates in the peripheral blood of studied patients. Presented results confirmed the pivotal role of type I IFN in the disease process. The serum concentration of IFNγ and the expression of IFNγ were the highest values of those parameters for cytokines assessed in this study. A positive correlation between IFNγ and IFNα mRNA levels has been observed.

**DOI:** 10.1136/annrheumdis-2020-eular.1194
Background: Sjögren Syndrome (SS) is a rheumatic connective tissue disease in which vascular involvement (e.g. Raynaud’s phenomenon) may occur. No systematic review exists elucidating on the role of nailfold capillaroscopy in SS. 

Objectives: To give a standardised overview of capillaroscopic changes and clinical associations in SS.

Methods: The literature was searched through in three databases by two reviewers. All published original studies which assess patients with SS by capillaroscopy were revised. A quality assessment was applied, based on sample size, population description, presence of a control group, presence of instrumental specifications and/or standardly applied capillaroscopic methodology, presence of clear descriptions of capillaroscopic parameters and based on the used statistical analysis. The capillaroscopic findings were described in a EULAR consented standardised way (1). Significant associations of capillaroscopic parameters in SS-patients with clinical and laboratory variables were also reported.

Results: The literature search resulted in 826 hits. Based on title and abstract screening 519 original studies were retained and of these, 12 full texts described an assessment by nailfold capillaroscopy in SS. Six studies (four case-control studies and two case-series) were retained after performing a critical quality assessment (fig 1). EULAR standardised description (table 1) attested conclusive results for capillary ‘morphology’, suggesting a not higher prevalence of abnormal shapes in SS than in healthy (2,3). Concerning clinical associations, capillary density was associated with Raynaud in two studies and with interstitial lung disease in one study (2-4). No association between serologic features (anti-nuclear antibodies, anti-SSA, anti-SSB and anti-RF) and capillaroscopic abnormalities was found (2,5).

PREVALENCE AND RISK FACTORS OF HERPES ZOSTER REACTIVATION IN PATIENTS WITH BIOPSY PROVEN LUPUS NEPHRITIS UNDERGOING IMMUNOSUPPRESSIVE THERAPIES

C. C. Mok1, S. M. Tse1, K. L. Chan1, L. Y. Ho1 on behalf of NA. 1Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)

Background: Herpes zoster (HZ) reactivation is fairly common in patients with systemic lupus erythematosus (SLE). However, there is a paucity of studies that reported the risk factors of HZ reactivation in well-defined subsets of SLE patients.

Objectives: To study the prevalence of HZ reactivation in patients with active biopsy confirmed lupus nephritis (LN) undergoing immunosuppressive therapies.

Methods: Patients who had biopsy proven active LN that was treated with immunosuppressive regimens in our unit between 2003 and 2018 were retrospectively reviewed for the occurrence of HZ reactivation within 2 years’ therapies. HZ was a clinical diagnosis based on history and physical signs by attending physicians. The following were collected: age and SLE duration at renal biopsy, sex, SLE disease activity scores, maximum daily dose and total duration of high-dose prednisolone and other immunosuppressive drugs in the induction period, maintenance therapies, laboratory parameters at renal biopsy and 6 months post-therapy that included lupus serology, albumin, globulin, immunoglobulin levels (IgG/IgM) and white cell counts (lymphocyte and neutrophil), renal biopsy pathology and proteinuria (mg/24h) and proteinuria > 500mg/24h. The incidence of HZ reactivation within 2 years of active LN treatment and the total prevalence of HZ infection over time until last follow-up was calculated. Risk factors for HZ reactivation were studied by logistic regression.

Results: 251 patients with 311 episodes of active LN were studied (92% women; age 34.2±14.2 years at first renal biopsy). The distribution of histological classes (WHO or ISN/RPS) was: class III/V-V (69%), II/IV/VI (31%). First-time renal disease occurred in 61% of patients. Induction treatment regimens were: prednisolone in combination with CYC (31%), azathioprine (11%), MMF (42%), tacrolimus (25%). Within 2 years of active LN treatment, 55 (18%) episodes of LN were complicated by HZ infection. The incidence of HZ reactivation was 8.8±100 patient-year. The median time for HZ reactivation since LN treatment was 11 months. 28 patients had HZ infection occurring longer than 2 years post-therapy, giving an overall prevalence of 3.24/100 patient-years. The distribution of HZ lesions was: head and neck region (15%), lower limbs (27%), trunk (65%) and upper limbs (4%). Fourteen episodes of HZ (25%) were treated by intravenous anti-viral drugs while others were treated at out-patient settings.
with oral acetylsalicylic acid. Secondary bacterial infection occurred in 9% of the episodes. Disseminated disease or mortality was not reported in any patients. Significant post-hoc herpetic neuropathy developed in 9% of the episodes. Patients with HZ reactivation were more likely to have higher first-time renal disease (78%) vs 58%; p=0.02) and a shorter SLE duration at LN (31.4±50 vs 62.7±72 months; p=0.02) than those without HZ. A trend of higher SLEDAI score, higher anti-dsDNA titer, lower C3 and albumin level but higher rate of refractory renal disease was also observed in HZ-infected patients. Other clinical parameters such as histological classes of LN, neutrophil, lymphocyte counts and immunoglobulin levels at baseline and 6 months post-treatment were not significantly different between HZ-infected and control patients. HZ-infected patients had been treated with a significantly higher dose of prednisolone (0.72±0.40 vs 0.63±0.24 mg/ kg/day) as induction therapy. Dosages of other immunosuppressive drugs were not associated with HZ reactivation. Logistic regression revealed first-time renal disease (OR 2.25[1.08-4.71]; p=0.003), peak MMF daily dose (OR 1.24[1.00-3.07]; p=0.00) and cumulative CYC dose (OR 1.14[1.01-1.26]; p=0.04) during induction therapy were significantly associated with HZ within 2 years.

Conclusion: HZ reactivation is fairly common in LN patients undergoing immunosuppressive therapies but unpredictable from histological and laboratory parameters. Higher doses of prednisolone, MMF and CYC were associated with a higher risk of HZ reactivation within 2 years.

THU0280 IMPACT ON PHYSICIAN GLOBAL ASSESSMENT ON REMISSION RATES IN SLE. ANALYSIS FROM A GERMAN SLE-COHORT.

J. Mucke1, C. Duesing1, M. Schneider2, G. Chehab1. Heinrich-Heine-University Duesseldorf, Policlinic and Hitler Research Unit for Rheumatology, Duesseldorf, Germany

Background: Defining remission for SLE as a suitable target for a treat to target (T2T) approach has been a major challenge in the past years. A few years back, four definitions of remission were presented by the international DORIS task force.[1] Parameters included in the definition are clinical activity (cSLEDAI), steroid dose, immunosuppressive therapy, serology and physician global assessment (PGA). In particular the PGA, its threshold and general utility have been and still are discussed controversially.

Objectives: It was our aim to evaluate the added value of PGA in remission assessment.

Methods: In this monocentric cross-sectional study, patients with SLE according to the 1997 American College of Rheumatology (ACR) criteria were enrolled and assessed between September 2016 and December 2017. Two different definitions of remission were applied. The internationally accepted DORIS remission excluding PGA. Factors influencing PGA were assessed in the entire cohort. Regression analyses were used to assess differences between patients in DORIS and modified DORIS remission.

Results: A total of 233 patients were included (87.6% female). 98 patients (41.9%) fulfilled any of the four DORIS remission definitions, while 154 patients (66.1%) were fulfilled any of the four DORIS remission definitions, while 154 patients (66.1%) were not fulfilling all DORIS remission criteria. In the cohort, PGA was reported by 92% of the patients. In the modified DORIS definition, 104 patients (44.7%) achieved remission definition. Factors influencing PGA were assessed in the entire cohort. Regression analyses were used to assess differences between patients in DORIS and modified DORIS remission.

Conclusions: Exclusion of PGA in remission assessment led to an increased number of patients in remission. Clinical parameters and factors associated with DORIS remission vs. modified DORIS remission were similar, hence the added value of PGA in our cohort regarding remission assessment is questionable. The use and especially the correct threshold of PGA for remission still has to be discussed.

THU0281 EXPLORING THE GENETIC DIVERSITY OF STAPHYLOCOCCUS AUREUS IN PATIENTS AFFECTED BY SYSTEMIC LUPUS ERYTHEMATOSUS: ASSOCIATION WITH DISEASE-RELATED FEATURES AND ACTIVITY

G. Oliveira1, F. Ceccarelli2, A. Lo Presti2, S. Angeletti2, C. Perricone2, G. Iaiani3, L. De Florio3, L. Antonelli1, L. Amorì3, G. Garulli3, F. R. Spinelli1, C. Alessandri1, G. Valessi1, M. Cicoczi1, F. Conti1, 1Lupus Clinic, Rheumatology, Rome, Italy; 2Istituto Superiore di Sanità, Rome, Italy; 3Unit of Clinical Laboratory, Campus Bio-Medico, Rome, Italy; 1Rheumatology, Perugia, Italy; 2Malattie Infettive e Tropicale, Azienda Polyclinico Umberto I, Rome, Italy; 3Sanità Pubblica e Malattie Infettive, Sapienza Università di Roma, Rome, Italy; 1Medical Statistics and Molecular Epidemiology, Campus Bio-Medico, Rome, Italy

Background: Infective factors play a central role in autoimmune diseases pathogenesis. It is possible to speculate that the host genotype could interact with genetic background of infective agents. We previously evaluated a large SLE cohort, observing the association between the S. aureus (SA) carriage status and presence of a more active disease in terms of autoantibodies positivity.

Objectives: We evaluated epidemiological, molecular characterization, genetic diversity and evolution of SA isolated from SLE patients by means of phylogenetic analysis.

Methods: Consecutive SLE patients (ACR 1997 criteria) were enrolled: clinical/laboratory data were collected and nasal swab for SA identification was performed. On the basis of translation elongation factor (lef) gene, a phylogenetic analysis was performed to investigate phylogenetic relationships and to assess significant clades in patients with persistent carrier status (nasal swab positive in two consecutive evaluation, performed 1 week apart). The first dataset was composed by seven SA tu gene isolated from non-SLE individuals from different countries (downloaded from the GenBank database, https://www.ncbi.nlm.nih.gov/nuccore); tu gene SA collected from SLE patients enrolled in the present study.

Results: We enrolled 118 patients (M/F: 10/98; median age 45.5 years, IQR 13.2; median disease duration 120 months, IQR 144). Skin involvement is the most frequent disease manifestation (86 patients, 72.9%), followed by joint involvement (78 patients, 66.1%). Twenty-four patients (20.3%) were SA carriers (SA+), three of them resulted MRSA, SA+ patients showed a significantly higher prevalence of joint involvement (79.2% versus 62.7%, P=0.01) and anti-dsDNA positivity (75.0% versus 55.3%, P=0.004). Moreover, SA+ SLE showed a more active disease, in terms of SLEDAI-2k values (SA+: median 2 (IQR 3.75) versus SA−: median 0 (IQR 2), P=0.04). The phylogenetic analysis has been restricted on the 21 non-MRSA SA+ patients. The maximum likelihood phylogenetic tree of the first dataset revealed a statistically supported larger clade (A, N=17) and a smaller one (B, N=4; figure 1A). SLE patients located in the clade A showed a significantly higher prevalence of joint involvement (88.2%) in comparison with clade B (50.0%, P=0.001) and SA− (62.7%, P=0.001, figure 2B). Moreover, haematological manifestations were significantly more frequent in clade A patients (64.7%) compared with B (50.0%, P=0.004, figure 2C).

Conclusion: The results of the present study confirmed the association between SA carriage status and disease activity, in terms of SLEDAI-2k values and anti-dsDNA positivity. The phylogenetic analysis on tu gene show a clustering of SA+ patients in two major clade (A and B). Interestingly the tu genotype of clade A is significantly associated with a specific disease phenotype, characterized by joint involvement and positivity for anti-dsDNA. These findings support the hypothesis that bacterial genetic variants may be associated with specific disease features.

EPIEDEMOLOGY OF CUTANEOUS INVOLVEMENT IN SjÖGREN'S SYNDROME: DATA FROM THREE FRENCH POPULATIONS OF PSS (TEARS, ASSESS, DIAPSS)

C. Villon1, L. Orgelet1, A. M. Rodrigues-Contios1, L. Misery1, J. E. Gottenberg2, D. Corne1, S. Jousse-Joulin1, R. Seror2, J. M. Berthelot3, P. Dieudé3, J. J. Dubost4, A. L. Fauchais5, V. Goeb6, E. Hachlla7, P-Y. Hatron7, C. Larroche5, G. Hayem5, V. Le Guern5, A. Perdriger5, J. Morel5, O. Vittecoq5, X. Mariette5, V. Devauchelle-Pensec5, A. Saranu5, CHU, Brest, France; CHU, Strasbourg, France; 4AP-HF, Paris, France; CHU, Nantes, France; CHU, Clermont-Ferrand, France; CHU, Amiens, France; CHU, Lille, France; CHU, Reims, France; CHU, Montpellier, France; 3CHU, Rouen, France

Background: Cutaneous involvement is a common during primary Sjögren's Syndrome (pSS) but prevalence and characteristics are difficult to establish precisely because of the limited number of patients studied in most cohorts, the variability of the disorders evaluated in each cohort, the rarity of some of them, and the heterogeneity of evaluations from previous studies (1).

Objectives: To determine the prevalence and significance of dermatological disorders in primary Sjögren Syndrome.

Methods: We used 3 French cohorts: ASSESS, in which prevalence of skin disorders in pSS pSS patients was evaluated, and diAPSS in which 91 consecutive pSS patients had an examination by a dermatologist and baseline data of the TEARS randomized trial (110 patients with recent or active pSS, treated with rituximab or placebo, and evaluated for skin dryness using a visual analogue scale out of 100).

Results: Skin manifestations included in the ESSDAI were rare in the ASSESS cohort (n=16/395, 4.1%, mainly purpura; only 3 had high activity) but associated with a higher level of pain and overall subjective dryness. ESSDAI skin activity is significantly higher in pSS patients who had a dermatological consultation had significantly more dermatological involvement outside ESSDAI score (42% (29/69) versus 19.6% (11/56); p=0.03). The TEARS study showed a high prevalence of cutaneous dryness (VAS>50; 48.2%) and that these dry skin patients had higher pain VAS (61.5+/-28.2 vs 46.8+/-270; p=0.003) and drought (79.4+/-15.2 vs 62.5+/-21.7; p<0.0001).

Conclusion: The most common skin disorder is dryness, which is associated with a higher level of pain and overall subjective dryness. ESSDAI skin activity is rare, associated with hypergammaglobulinemia and ESSDAI activity. Systematic dermatological examination is informative for non-specific pSS lesions.

DISTINCT CLINICAL FEATURES OF LATE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS AMONG MALAYSIAN MULTI-ETHNIC COHORT

S. S. Shaharir1, M. S. Mohamed Said2, S. Rajalingham3, H. Mahadzir4, R. Mustafar5, A. Abdul Wahab5. 1Universiti Kebangsaan Malaysia Medical Centre, Internal Medicine, Kuala Lumpur, Malaysia; 2Universiti Kebangsaan Malaysia Medical Centre, Microbiology and Immunology, Kuala Lumpur, Malaysia

Background: Systemic Lupus Erythematosus (SLE) commonly affects young women in their reproductive age group. However, there is an increase prevalence of late-onset SLE, parallel to the higher life expectancies among general populations worldwide. It has been reported that up to 25% SLE populations have a later onset of disease and their disease expression and course may be different.

Objectives: To determine the clinical features and outcomes of late-onset SLE patients in a multi-ethnic Malaysian cohort.

Methods: Medical records of SLE patients who attended regular follow-up clinics in Universiti Kebangsaan Malaysia Medical Centre (UKMMC) from 2011 until June 2019 were reviewed. Late-onset SLE was defined as the onset of SLE symptoms or diagnosis after the age of 50 years old. Information on their socio-demographics and disease characteristics were obtained from the clinical records. Disease damage was assessed using the SLICC/ACR (Systemic Lupus International Collaborating Clinics/American College of Rheumatology) Damage Index (SDI) scores. The disease characteristics and autoantibody profiles were compared between late-onset and younger onset patients. Damage accrual at disease onset and at 5 years was obtained and compared between the two groups.

Results: A total of 429 patients were included and majority of them were Malays (n=225, 52.4%) followed by Chinese (n=180, 42), Indian (n=21, 4.9%) and others (n=3, 0.7%). This multi-ethnic SLE cohort was consisted of predominantly female patients (n=372, 86.7%) with disease duration of 9.9 years ± 6.8 years. A total of 13.8% (n=59) had late onset SLE with mean onset of disease at 58.1 ± 6.3 years while younger group was 27.2 ± 9.4 years. The commonest system involvement among the late-onset group was haematological manifestation (69.5%). Compared to the younger-onset SLE, late-onset SLE occurred significantly higher among the Chinese (66.1%) as compared to Malay (32.3%), Indians and other ethnic groups (1.7%), p<0.01. Patients with late-onset SLE also had significantly less musculoskeletal (37.3% vs 62.4%) and renal (7.3% vs 71.1%), p<0.01. Disease at onset tend to have extensive cutaneous manifestations (28.8% vs 42.4%, p=0.06). Meanwhile, pulmonary involvement was more common among the late-onset SLE patients (11.9% vs 0.8%, p<0.001). Extractable nuclear antigen (ENA) results were available in 197 patients and patients with late-onset SLE had significantly higher rate of anti-RO positive (63% vs 3.9%), p<0.01. Other, no significant difference in the other autoantibodies expressions including anti-La, anti-Sm, anti-RNP, anti-ribosomal P and anti-phospholipid antibodies. Patients with late-onset SLE tend to have more damage accrual at 5 years as compared to the younger age group (p=0.07). The mortality in the late onset group was 13.6% (n=8) as compared to 2.7% (n=10) in the younger age group, p=0.01. Majority of the cause of death in the later onset SLE was infection (87.5%) while in the younger age group was infection and active disease (90%).

Conclusion: Late onset SLE occurs more commonly among Chinese ethnicity in Malaysia and Malaysian SLE patients with late onset of disease have distinct clinical manifestations. Damage accrual at 5 years tend to be higher in the late-onset group and the mortality is significantly higher with the major cause of death is infection. The different disease expression and outcome in late onset SLE suggest different factors in influencing the disease course and hence further studies including their genetic profiles are warranted.

PREVALENCE OF NEUROPSYCHIATRIC LUPUS IN PSYCHOSIS PATIENTS WITH A POSITIVE ANTINUCLEAR ANTIBODY

M Spies, 1, 2, 3, J Gujtah-Holland, 1, J V. Bertouch 1, 3, A Sammel, 1, 2, Australian Rheumatology Association, Sydney, Australia; 2Royal Prince Alfred Hospital, Camperdown, Australia; 3Prince Of Wales Hospital, Randwick, Australia

Background: Psychosis is a rare manifestation of Neuropsychiatric Systemic Lupus Erythematosus (NPSLE). Patients with SLE may have Psychosis as part of their initial presentation of disease. Current guidelines do not make a recommendation regarding the use of Antinuclear Antibody (ANA) in the assessment of patients with psychosis. There is limited evidence addressing the utility of ANA testing in this setting.

Objectives: Primary objective: Determine the prevalence of NPSLE in patients admitted to a mental health service with a diagnosis of a psychosis, who have had a positive antinuclear antibody test. Secondary objectives: Determine the frequency and proportion of positive ANA testing in this patient group. Determine the pattern and titre of positive ANAs. Determine the subsequent investigation, referral and diagnosis of patients with positive ANAs.

Methods: Retrospective chart review of patients admitted to a mental health service of two metropolitan tertiary referral centres, Prince of Wales Hospital (POWH) and Royal Prince Alfred Hospital (RPAH), with a diagnosis of psychosis who had been tested for ANA. Patients were identified using their electronically entered diagnosis based on the International Classification of Disease 10 codes. Assessment of patient data for SLE used the 2019 ACR/EULAR classification criteria. Service of two metropolitan tertiary referral centres, Prince of Wales Hospital, Sydney, Australia

Results: Between 1st of January 2010 and 31st of March 2018 there were 5585 (POWH) and 4620 (RPAH) mental health admission with an ICD diagnosis of psychosis representing 2451 and 2315 individual patients. 449/2451 (18%) and 462/2315 (20%) patients were tested for ANA. 78/449 (17%) and 57/462 (12%) were positive. Discharge data was available for all patients and long-term follow up data was completed for 53/78 (68% - POWH) patients and 50/57 (88% - RPAH). The mean follow-up time 43 ± 23 months and 51 ± 29 months respectively.

At discharge there were four patients who met 2019 ACR/EULAR for SLE. Of these, two patients met criteria for NPSLE. One was diagnosed clinically and treated specifically for NPSLE with intravenous methylprednisolone and rituximab.

There were no additional diagnoses of SLE or NPSLE clinically or by criteria found in the available follow up data. Hence the overall prevalence of NPSLE in patients admitted with psychosis was 1.3%, 95% CI [0.6,9%] and 1.8%, 95% CI [0.9,4%] respectively.

Conclusion: The prevalence of neuropsychiatric lupus in patients with psychosis and a positive ANA was 1/78 and 1/57 a two tertiary referral centres. This study expands significantly on the limited evidence available as to the expected outcomes of a positive ANA test in a patient with psychosis.

THE SYSTEMIC LUPUS INTERNATIONAL COLLABORATING CLINICS (SLICC) FRAILTY INDEX (SLICC-FI) PREDICTS DAMAGE ACCRUAL IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS. DATA FROM A MULTICENTRIC, MULTICENTER US LUPUS COHORT

M. F. Ugarte-Gil; J. Dubey; M. Gomgin; L. Vila; G. S. Alarcon; J. A. Hospital Guillermo Almenara Ingyoen, EsSalud, Lima, Peru; Universidad Científica del Sur, Lima, Peru; University of Alabama at Birmingham, Birmingham, United States of America; University of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico; Universidad Peruana Cayetano Heredia, Lima, Peru

Background: The Systemic Lupus International Collaborating Clinics (SLICC) Frailty Index (SLICC-FI) has been developed as a predictor of outcomes in SLE patients. It combines disease activity, damage, comorbidities and health-related quality of life measures.

Objectives: To evaluate the SLICC-FI as a predictor of damage accrual in systemic lupus erythematosus (SLE) patients.

Methods: Patients from a multi-ethnic, multi-center US lupus cohort were included. Damage was ascertained with the SLICC/American College of Rheumatology (ACR) damage index (SDI) at last visit. The first visit in which the SLICC-FI could be derived was considered as the baseline visit. Univariable and multivariable Poisson regression models were performed to determine the association between the baseline SLICC-FI and last SDI, adjusted for sex, age at diagnosis, ethnicity, insurance, prednisone daily dose, antimalarial and immunosuppressive drug use at baseline. Age and gender were included as a priori in the multivariable model, the other variables were included if they had a p<0.10 in the univariable models.

Results: Of the 503 patients included, 454 (90.3%) were female with mean (SD) age 37.1 (12.5) years at diagnosis; 174 (34.6%) were African-American, 144 (28.6%) were Caucasians, 86 (17.1%) were Hispanics, and 99 (19.7%) were of Asian ethnicity. The median (SD) baseline SLICC-FI was 0.26 (0.06). The final mean (SD) SDI score was 1.9 (2.2). Higher SLICC-FI scores at baseline predicted greater damage accrual in the univariable analysis [estimate=0.59, p=0.0001] The SLICC-FI remained associated with damage accrual in the multivariable model, after adjustment for possible confounders [estimate= 0.561 (SE=0.538); p=0.0001].

Conclusion: The SLICC-FI predicts damage accrual in SLE patients from a multi-ethnic cohort, supporting the importance of this index in the evaluation of SLE patients, combining several aspects of the disease.

EVALUATION OF PREDICTIVE FACTORS OF WORSE PROGNOSIS IN LUPUS NEPHRITIS: FOCUS ON NEW PATHOGENETIC PATHWAYS

V. Varrnando, A. Paglicioni, L. Petricca, C. Di Mario, M. R. Gigante, G. Tanti, B. Tolusso, G. Ferracino, E. Gremese. 1Division of Rheumatology, Università Cattolica del Sacro Cuore, Rome, Italy; 2Division of Rheumatology, Fondazione Policlinico Universitario “A. Gemelli” I.R.C.C.S., Rome, Italy

Background: Cytokine dysregulation plays an important role in the pathogenesis of Lupus Nephritis (LN) representing an attractive field of research aiming to find new pathways for new targeted therapies. IL-17, IL-23 axes seems to have a great influence in the development of LN.

Objectives: to evaluate the strongest prognostic factors in a cohort of patient with LN focusing on of the impact of IL-17, IL-23 axes as new pathogenetic way on renal outcome.

Methods: 91 patients with active LN at disease onset or disease flare were enrolled in the laboratory, immunological and disease activity data were collected in the baseline and at 6(T6), 12(T12), 24(T24) months and at the last follow-up(FU). 84 renal biopsies were evaluated according to ISN/RPS classification, assessing the activity and chronicity indexes and the active interstitial infiltrate using the Banff score system. Baseline serum levels of IL-17 and IL-23 were assessed by ELISA in 37 patients.

Results: among the 84 renal biopsies evaluated 77% belonged to class III and IV according to ISN/RPS; 41.8% of patients had an active interstitial infiltrate≥5%, 35.2% between 5% and 25% and 15.4% above 25%. Regarding immunological data 35.2% of patients revealed a seropositivity for antiphospholipid antibodies(APL+). The median serum level of IL-17 and IL-23 were 0.12±0.15 pg/ml and 27.7±9.12 pg/ml respectively. Using the ROC curves analysis we found a cut off value of 25.89 pg/ml for IL-23 for remission at T6. Among the 10 patients with a IL-23 level above this cut-off none achieved remission at T6 and the univariate analysis shows that a serum level of IL-23 above the defined cut-off was associated with an active interstitial infiltrate≥5% at renal biopsy and with the development of persistent proteinuria. The analysis of IL-17 could not let us to find a cut off value for renal damage progression since a too much high number of patients had a null value. Nevertheless patients with more elevated serum levels of IL-17 at the baseline showed more elevated level of interstitial infiltrate at renal biopsy and a worse renal outcome overall. Finally we conducted an univariate and multivariate analysis for each renal outcome considered. We found that an inflammatory interstitial infiltrate≥5% at renal biopsy and APL+ were associated with worse renal outcome in terms of early and persistent remission, chronic damage, persistent proteinuria, and renal flare both in univariate and multivariate analysis. Higher serum level of IL-23 was associated with persistent proteinuria, renal flare and tended to be associated to chronic renal damage and persistent renal activity.

Conclusion: interleukin inflammatory infiltrate and APL+ represent in our study the strongest predictors of worse renal outcome. An higher serum level of IL-23 was found to be a negative prognostic factor pointed out the possibility to consider the IL-17-IL-23 axis as a biomarkers of a more aggressive renal disease.

THU0288

CANCER RISK IN PATIENTS WITH CUTANEOUS LUPUS ERYTHEMATOSUS AND SYSTEMIC LUPUS ERYTHEMATOSUS COMPARISON TO THE GENERAL POPULATION: A DANISH NATIONWIDE COHORT STUDY

R. Westermann1, K. Zobbe, R. Cordtz1, L. Dryer1, 1Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark; The Parker Institute, Bispebjerg-Fredensborg Hospital, University of Copenhagen, Center for Rheumatology and Spine diseases, Rigshospitalet Gentofte, Copenhagen, Denmark

Background: Research suggesting an elevated risk of cancer among patients with Systemic Lupus Erythematosus (SLE) has increased in recent years. Yet, the size of the overall cancer risk and the risk of respective cancer sites varies. Research examining the cancer risk of Cutaneous Lupus Erythematosus (CLE) patients remains limited. Therefore, in order to further guide and monitor patients with SLE and CLE, additional research estimating the risk of cancer is needed.
**Objectives:** To determine if patients with SLE or CLE have an increased risk of cancer compared to the general population, and furthermore to identify specific cancer types associated with increased risk.

**Methods:** This was an observational cohort study of 3424 SLE and 1886 CLE patients identified in The Danish National Patient Register (DNPR) from 1st January 1995 to 31st December 2014. The cohorts were followed up for cancer by linkage to The Danish Cancer Registry (DCR). Based on the age, sex, and calendar specific cancer rates from Denmark, standardized incidence ratios (SIRs) were calculated for the SLE and CLE groups, respectively.

**Results:** The SLE and CLE cohorts were followed for 27676 and 13,048 person-years, each group’s average duration of follow-up being 8.1 and 6.9 years, respectively. Compared to the general population, the SIRs for the overall cancer (except non-melanoma skin cancer) risk was 1.45 (95%CI 1.30 to 1.62) in the SLE group and 1.35 (95%CI 1.15 to 1.58) in the CLE group. Both CLE and SLE patients had increased risks of hematological, pancreatic and lung cancers. Liver, tongue/mouth/pharynx, non-melanoma skin cancer, oesophagus and meninges cancers were only increased in the SLE group.

**Conclusion:** The risk of overall cancer was significantly increased in patients with SLE and CLE. Hematological, pancreas and lung cancers were elevated in both groups, while certain virus-associated cancers and other sites were increased only among SLE patients. Awareness of cancer in patients with SLE and CLE should be considered, especially of symptoms from high-risk sites.

**Background:** Postthrombotic syndrome (PTS) defines chronic manifestations of venous insufficiency following deep vein thrombosis (DVT). It is the most frequent and disabling complication of DVT.

**Objectives:** Aim of the study is to describe clinical characteristics and predictors of PTS, severe PTS among Behçet’s disease (BD) patients with known low extremity DVT. Also, to depict venous Doppler ultrasonography (US) findings and its association with the clinical characteristic and treatments.

**Methods:** This retrospective multicenter study included 205 (166 men, 39 women; mean age 39 ± 9.5 years) BD patients with DVT history. The Villalta scale was used to assess the presence and severity of PTS. Doppler US of bilateral legs are performed within 1 week of clinical evaluation. Total number of vessels with reflux, thrombi, recanalization and collaterals were calculated and presented as scores.

**Results:** Of 205 BD patients with known DVT history; 127 (62%) had PTS and 18% had severe PTS diagnosed by Villalta scale. (Table 1)

IS GIANT CELL ARTERITIS REALLY GIANT CELL ARTERITIS? A HISTOLOGICAL REVIEW OF TEMPORAL ARTERY BIOPSIES FROM A UK DISTRICT GENERAL HOSPITAL

S. K. Amar1, D. Christidis1, G. Kousparos2, M. Lloyd1. 1Frimley Park Hospital, Rheumatology, Camberley, United Kingdom; 2Frimley Park Hospital, Histopathology, Camberley, United Kingdom

Background: Despite the advent of newer imaging techniques, temporal artery biopsy (TAB) retains a key role in the diagnosis of giant cell arteritis (GCA). The classical histological description of GCA is that of granulomatous lesions characterized by a transmural inflammatory infiltrate. Giant cells are typically noted in the internal elastic lamina. Vascular remodeling and structural changes are also frequently described, with intimal hyperplasia or fragmentation, fibrosis and calcifications.

Objectives: To identify the type and location of the inflammatory lesions in TAB-positive cases of GCA.

Methods: We conducted a retrospective analysis of all TABs undertaken at our unit between 2011-2018 with clinical record review. TABs were performed by vascular, ophthalmology and ENT teams.

Results: 379 TABs were reviewed of which 68 (17.9%) were reported as positive and 10 (2.6%) were equivocal (presence of fragmentation and intimal thickening). Of the TAB-positive cases, 43 (63.2%) were greater than 1cm in keeping with the British Society for Rheumatology guidance and 65 (95.6%) were biopsies in patients on corticosteroids at the time of procedure. The following tables demonstrate the frequency of the type and location of the inflammatory lesions detected in TAB-positive cases of GCA.

A predefined protocol was used when reviewing the medical records in GCA patients at the time of diagnosis. Data collected included the separate items for the original and the suggested expansion of the ACR 1990 criteria. We calculated the sensitivity of both criteria sets and recorded the frequency and absolute numbers of the single criteria items as shown in table 1.

</table>

Results: A total of 77 patients (22 men and 55 Women) with a diagnosis of GCA were identified. Mean age was 69.2 years. The table below shows the absolute number of patients fulfilling the separate criteria for the ACR 1990 and the suggested expansion criteria. Patients were usually not exposed to all submodalities of criterion 5. The denominator for item 5 in the table displays the number of assessments performed for biopsy and the separate imaging modalities.

The number of patients fulfilling the original ACR 1990 criteria was 51 (66.2%) and for the suggested expansion criteria 75 (97.4%). All patients fulfilled the age criterion. For the original ACR 1990 criteria, 62.3% met criterion 2, 33.8% criterion 3, 80.5% criterion 4 and 28.6% criterion 5, whereas for the suggested expansion criteria the percentages was 79.2%, 39.0%, 93.5% and 88.3% respectively.

Conclusion: The proposed expansion of the ACR 1990 criteria had a much higher sensitivity (97.4%) than the original criteria (66.2%) tested in a clinical cohort of GCA patients. The single most important parameter increasing sensitivity was US examination also new clinical features and C-reactive protein measurement contributed to increase the sensitivity.

THU0293

PREDICTORS OF LONG-TERM THERAPY WITH GLUCOCORTICOID IN POLYMYALGIA RHEUMATICA

A. Aoki1, H. Kobayashi1, 1Tokyo Medical University Hachioji Medical Care Center, Rheumatology, Hachioji, Japan

Background: Polymyalgia rheumatica (PMR) is a common inflammatory condition of elderly persons. Clinical symptoms respond to low-dose glucocorticoids (GC), but treatment is often required for several years. 2015 EULAR/ACR recommendations1 recommend considering early introduction of methotrexate (MTX) in addition to GC, particularly in patients at a high risk for relapse and/or prolonged therapy. However, risk factors for prolonged therapy are not clear yet.

Objectives: We investigated predictive factors which corresponded to the long-term GC therapy.

Methods: This was a retrospective study in a single general hospital in Japan. We reviewed the medical records of the Japanese patients with PMR between April 2011 and January 2020. Diagnosis of PMR was based on Bird’s criteria or 2012 EULAR/ACR Classification Criteria2. All patients were treated with prednisolone (PSL), according to the BSR and BHPR guidelines3, for more than 6 months. Patients treated with MTX and accompanied by the giant cell arteritis were excluded from this study. Relapse was defined as the reappearance of symptoms associated with elevated C-reactive protein (CRP) levels in patients receiving GC that required an increase in GC dose. Remission was defined as the absence of clinical symptoms and normal CRP with discontinuation of GC. We compared the clinical findings, laboratory data at baseline and clinical course between those who achieved remission within 2 years (early-remission group) and those who required GC therapy for more than 2 years (long-therapy group). Comparisons between groups were made using Student’s t-test and chi-square test (IBM SSPE statistics version 26). This study was approved by the ethics committee of Tokyo Medical University (T2019-0079).

Results: As of January 2020, 89 patients have been treated with PSL for more than 6 months. 50 patients have achieved a remission, 29 were undergoing treatment, and 10 have transferred to other hospitals or died (Table 1). The median time required for the patients to achieve remission was 16 months (Interquartile Range 12-21). After one-year GC therapy, remission was achieved in 14% (11/77), 66% (41/62) after 2-year, 84% (47/56) after 3-year, and 91.0% (49/54) after 4-years. Forty-one patients, who achieved remission within 2 years, were included in the early-remission group. Twenty-one were included in the long therapy group (Table 1). There were no differences in sex, age at onset, body mass index, clinical features, and serum albumin at diagnosis. Serum CRP of long-therapy group was significantly higher than those of the early-remission group (Table 2). Mean relapse times in the full follow-up times were 0.4 in the early-remission group and 3.1 in the long-therapy group. Multivariate logistic regression analysis showed that history of relapse till 6 months was significant predictors of the long-term GC therapy (odds ratio, 6.48; 95%CI 1.44-29.12).

Conclusion: The remission rates of our study are lower than those of the previous reports. We have tapered GC gradually according to the BSR and BHPR guidelines3. However, some patients need the long-term therapy for more than 2 years. We might consider additional MTX therapy in patients who experience a relapse during the first six months.

References:
Background: Cryoglobulinemic vasculitis (CV) is a serious complication of Sjögren’s syndrome (SS) and is closely associated with type II IgMk cryoglobulins. CV has been well documented in HCV patients without SS, and shares common features with CV in SS. So far, few studies have described the clinical picture of CV in HCV negative SS patients, but the number of studied patients was rather small and CV was not well defined. To better describe the clinical spectrum of CV in SS and explore the differences compared to HCV-related CV, a large cohort of SS patients with giant cell arteritis (GCA) treated with TCZ. TCZ administered subcutaneously every week (QW) or every other week (Q2W) with 26-week prednisone tapering and 52-week prednisone tapering for the achievement of sustained remission in patients with GCA in the 52-week, double-blind part 1 of the GiACTA trial. Part 2 was a 2-year open-label, long-term follow-up in which patients were treated at the investigators' discretion; part 2 treatment could include initiation/termination of TCZ QW with or without glucocorticoids or methotrexate.

Methods: From a total cohort of 1997 consecutive SS patients who fulfilled the 2011 classification criteria for CV in SS and explore the differences compared to HCV-related CV, a large cohort of well characterized patients is required. To study the clinical phenotype of CV in HCV-negative SS patients, we analyzed 1997 consecutive SS patients with giant cell arteritis (GCA) treated with TCZ. TCZ administered subcutaneously every week (QW) or every other week (Q2W) with 26-week prednisone tapering treatment was superior to placebo (PBO) plus 26-week (PBO+26) or 52-week (PBO+52) prednisone tapering for the achievement of sustained remission in patients with GCA in the 52-week, double-blind part 1 of the GiACTA trial. Part 2 was a 2-year open-label, long-term follow-up in which patients were treated at the investigators' discretion; part 2 treatment could include initiation/termination of TCZ QW with or without glucocorticoids or methotrexate.

Objectives: To investigate immunogenicity of TCZ QW and Q2W regimens in patients with giant cell arteritis treated with TCZ. TCZ administered subcutaneously every week (QW) or every other week (Q2W) with 26-week prednisone tapering treatment was superior to placebo (PBO) plus 26-week (PBO+26) or 52-week (PBO+52) prednisone tapering for the achievement of sustained remission in patients with GCA in the 52-week, double-blind part 1 of the GiACTA trial. Part 2 was a 2-year open-label, long-term follow-up in which patients were treated at the investigators' discretion; part 2 treatment could include initiation/termination of TCZ QW with or without glucocorticoids or methotrexate.

Results: Among evaluable patients (had baseline and ≥1 postbaseline ADA assessments and received ≥1 dose of study treatment) in part 1, ADA developed in 1 of 95 (1.1%) and 3 of 46 (6.5%) patients after TCZ QW and Q2W dosing, respectively. Of 49 (2.0%) and 1 of 47 (2.1%) in the PBO+26 and PBO+52 groups, respectively, tested positive for ADA but had not received TCZ and were considered false positives. In parts 1 and 2 combined, among 199 patients who received ≥1 dose of TCZ, 193 (97%) were evaluable (Table); TCZ-induced ADA developed in 13 of these patients (6.7%) postbaseline (4 during part 1, 9 during part 2). Of these 13 patients, 8 (6.1%) had ADA with neutralizing potential and 1 (0.5%) had IgE ADA. Most TCZ-induced ADA were transient. There was no clear impact of TCZ-induced ADA on clinical outcome (Figure). No patients with TCZ-induced ADA had experienced anaphylaxis, hypersensitivity reactions, or injection site reactions, and none withdrew because of lack of efficacy.

Conclusion: In patients with GCA, treatment-induced ADA developed in a minority of patients and had no impact on TCZ PK, efficacy, or safety. The patients had higher frequency of sicca manifestations, SGE, fatigue, arthritis, Raynaud’s phenomenon, lymphadenopathy, type II IgMk cryoglobulins and lymphoma.

THU0297 SERIOUS INFECTIONS IN 134 PATIENTS WITH GIANT CELL ARTERITIS WITH TOCILIZUMAB IN CLINICAL PRACTICE. FREQUENCY, TYPE AND CLINICAL ASSOCIATIONS

Background: Infections are the most common adverse event of Tocilizumab (TCZ) in Giant Cell Arteritis (GCA). In GiACTA study (1), serious infections were observed in 7% (9.6/100 patient-years) of patients who received TCZ weekly. Randomized clinical trials (RCTs) are conducted under highly standardized design excluding some real-world patients. Therefore, adverse events may be underestimated in RCTs. In our series of real-life, serious infections occurred in 11.9% (10.6/100 patient-years) (2).

Objectives: In a wide series of GCA of clinical practice treated with TCZ, we assess the frequency, type and predisposing factors of serious infections.

Methods: Multicenter study of 134 patients diagnosed with GCA, all of them refractory to conventional therapy, treated with TCZ. Serious infection was considered when a life-threatening infection, fatal, or requiring hospitalization occurred, intravenous antibiotics were required, or the infectious process led to persistent or significant disability.

Results: 16 of 134 (11.9%, 10.6/100 patient-years) patients developed serious infections during follow-up. The most frequent infections were pneumonia (n=4), urinary tract infection (n=4), and facial herpes zoster (n=2). At TCZ onset, serious infections were more frequent in older patients (74.3±9.6 vs 72.9±8.7 years), with a longer GCA evolution (20 [4.3-45.6] vs 13 [5-29.3] months), with visual manifestations (43.75% vs 17.8%) and a higher dose of prednisone at onset (30.4±15.5 vs 21.1±16.1 mg/day) (TABLE). Presence of comorbidities were similar in both groups. 13 of the 16 patients who had infections received a dose of prednisone greater than 15 mg/day (16.3/100 patient-years) compared to 3 patients under treatment with less than 15 mg/day of prednisone (4.2/100 patient-years).

Conclusion: The age, GCA duration, ocular involvement and the dose of glucocorticoids, at TCZ onset, seem to be predisposing factors related to an increased risk of developing serious infections in GCA patients.

Objectives: to evaluate whether switch or swap strategy can be more effective in TA patients failing TNFi.

Methods: TA patients treated with bDMARDs after TNFi failure were identified from 3 referral centres. Patients were classified as "switch" if treated with a different TNFi (infliximab, IFX, etanercept, ETN, golimumab, GOL, adalimumab, ADA) or "swap" if treated with a non-TNFi bDMARD (tocilizumab, TCZ, ustekinumab, USK). Baseline features and disease outcome (number of patients with NIH score ≤2, steroid dose reduction (SDR), disease relapses and vascular interventions) at month 6 and month 12 after 2nd bDMARD introduction were analyzed. Non parametric tests were used.

Results: 24 TA patients were identified. TNFi (IFX= 13; ADA= 8; ETN= 1; GOL= 2) was withheld after a median of 19 (8.5; 38) months (in 9 patients <12 months) for inefficacy in 19 (79%) patients and side effects in 5 (21%) patients. 11 (46%) patients were switched and 13 (54%) patients were swapped (12 to TCZ, 1 to USK). Baseline features at 2nd bDMARD start are summarized in Table 1. 2nd bDMARD retention at month 6 was comparable between switch (8.73%) and swap (10.77%) patients, p=1. Reasons for discontinuation were: inefficacy in 5 patients, allergic reaction in 1 switch patient. 5 (45%) switch and 6 (46%) swap patients had a NIH<2 (p=1). Median SDR was similar: 3.75(0.6-19.6) in swap and 4.37(1.87-10.0) mg daily in switch, p=0.829. Also at month 12, 2nd bDMARD retention was comparable: 7 (64%) switch vs 7 (54%) swap, p=0.210. Disease features of switch and swap TA patients at 2nd bDMARD start are summarized in Table 2. 2nd bDMARD retention at month 6 was comparable: 7 (64%) switch vs 7 (54%) swap, p=0.210. Discontinuation reason was inefficacy in all cases. 6 (54%) switch and 4 (30%) swap patients had a NIH<2 (p=0.222). Median SDR from baseline was 3.75(0.62-7.5) in switch and 1.25 (0.6-25.9) in swap, p=0.620. 12 patients experienced a relapse within the first year: 10 (77%) swap and 2 (18%) switch patients, p=0.074. 3 patients underwent vascular interventions within the first year: 2 (18%) switch and 1 (8%) switch patients, p=0.576.

MYOCARDIAL INVOLVEMENT IN TAKAYASU ARTERITIS PATIENTS ASSESSED BY MAGNETIC RESONANCE IMAGING AND ITS RELATION WITH DISEASE ACTIVITY

A. Chattopadhyay1, M. Singh2, U. Debi1, A. Sharma3, S. Jain1; 1PGIMER Chandigarh, Clinical Immunology & Rheumatology Services, Department of Internal Medicine, Chandigarh, India; 2PGIMER Chandigarh, Department of Radiodiagnosis, Chandigarh, India

Background: Cardiac involvement in Takayasu arteritis (TA) is the major cause of morbidity and mortality. [1] Cardiovascular magnetic resonance (CMR) is an excellent modality for the assessment of myocardial involvement. Studies have shown subclinical myocardial scarring in 25-27% of patients.[2,3] There is no such study from India.

Objectives: To evaluate the prevalence of myocardial involvement in TA, as detected by CMR and its correlation with disease activity score (ITAS 2010 and ITAS-A).

Methods: Patients classified as Takayasu arteritis according to Sharma et al. criteria [4] were included after an informed consent. Demographic, clinical, laboratory data were documented in the predesigned proforma. CMR was done on a dedicated CMR machine. Disease activity was recorded by ITAS2010 and ITAS-A.[5] Ethical clearance has been obtained from the ethics committee of the institute (INT/IEC/2018/001538).

Results: In the present study, 37 TA patients were included. Mean (±SD) age was 29 ± 11 years. Female to male ratio was 3:1. The most frequent presenting symptom was upper limb claudication (49%), and vessel involved was left subclavian and descending thoracic aorta (75%) each. Of the total cohort, 65% had hypertension, 35% had dyslipidemia and 19% had valvular involvement. Five patients (14%) had myocardial involvement as detected by CMR. Three (8%) patients had late gadolinium enhancement (LGE) on CMR suggestive of myocardial fibrosis. In the current study, both the CMR and echocardiography performed equally in detecting various valvular heart disease, whereas only CMR had detected subclinical myocardial fibrosis in two patients. Details of different risk factors and relation with disease activity provided in table 1.

Conclusion: To the best of our knowledge, this is the largest cohort on CMR in TA. Prevalence of subclinical myocardial involvement in Indian patients was much less (8% vs 25-27%) compared to the previous studies. The higher percentage of LGE detected by the earlier studies may be a reflection of cumulative damage with increasing age, prolonged hypertension, and disease duration. Myocardial involvement trend towards early age of onset, less disease duration, lack of classical risk factors, and more with disease activity. Judicious use of CMR may help in detecting subclinical myocardial involvement.

Table 1. Relation of different risk factors with myocardial heart disease.

RISK FACTORS FOR COMPLICATIONS AND REFRACTORY COURSE IN PATIENTS WITH ANCA-ASSOCIATED SYSTEMIC VASCULITIS

A. Chudinov1, I. Belyaeva2, M. Pervakova3, V. Mazurov4, O. Inamova5, S. Lapin3.
1Сlinical Rheumatological Hospital № 25, Saint-Petersburg, Russian Federation; 2North-West State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation; 3First Pavlov State Medical University of St. Petersburg, Saint-Petersburg, Russian Federation

Background: ANCA-associated systemic vasculitis (AAV) is characterized by a high incidence of complications and high mortality. The most significant complications during the first 3 years of the disease are infectious and cardiovascular. Development of chronic kidney disease also impairs the prognosis of AAV. Refractory to induction therapy can significantly increase the severity of organ damages in patients with AAV.

Objectives: The aim of this study was to determine risk factors for complications and refractory course in patients with AAV.

Methods: Patients with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) were observed during the first 3 years of the disease and included in this study between 2010 and 2018. Most common infectious complications requiring inpatient treatment were pneumonia, mycosis, sepsis, purulent otitis media. Cardiovascular complications included pulmonary thromboembolism, myocardial infarction, ischemic stroke, venous thrombosis.

Results: In total 209 (79% female and mean age 51.8 ± 13.2 years) AAV patients (94 GPA; 46 MPA; and 69 EGPA) were included in the analysis. Risk factors for infectious complications were BVAS level at the beginning of induction therapy > 25 (OR = 2.92, 95% CI (1.53;4.5) p<0.001), usage of prednisone in doses more than 60 mg / day at the induction of remission (OR = 2.76, 95% CI (1.45;5.29) =p=0.003), usage of prednisone in doses ≥ 10 mg / day after 6 months of induction therapy (OR = 2.60, 95% CI (1.38;4.93) p=0.003), ANCA-PR3 positivity (OR = 2.25, 95% CI (1.13;4.46) p=0.017) and presence of diabetes mellitus in the AAV onset (OR = 1.77, 95% CI (1.14;4.35) p=0.038). Patients with AAV had following risk factors for cardiovascular complications: male (OR = 2.28, 95% CI (1.33;3.88) p=0.002), BVAS level > 25 (OR = 2.1, 95% CI (1.11;3.16) p=0.008) and presence of coronary artery disease in the AAV onset (OR = 2.2, 95% CI (1.18;4.10) p=0.015). ANCA positivity (OR = 5.62, 95% CI (2.1;14.49) p=0.001), presence of rapidly progressive glomerulonephritis in the first 3 months from onset AAV (OR = 5.02, 95% CI (3.42;7.35) p<0.001) and over 60 years of age (OR = 2.17, 95% CI (1.38;4.43) p=0.001) were risk factors of development of chronic kidney disease. Risk factors for refractory to induction therapy in patients with AAV were ANCA-PR3 positivity (OR = 3.13, 95% CI (1.63;6.02) p<0.001), BVAS level > 25 (OR = 2.63, 95% CI (1.74;4.34) p<0.001), initiation of therapy after 4 months from the onset of clinical manifestations (OR = 2.17, 95% CI (1.26;3.91) p=0.005). We additionally defined that identification of pathological phenotypes of alpha-1-antitrypsin was risk factors for refractory course in patients with GPA manifestations (OR = 2.66, 95% CI (1.12;6.33) p=0.048).

Conclusion: Our study has shown that high disease activity, ANCA positivity and comorbid pathology increase risk of serious complications. Early administration of immunosuppressive therapy, adequate steroid dosing and use of risk factors for complications and refractory course in clinical practice can significantly improve the prognosis of AAV.

OUTPATIENT REFERRAL WITH A POSITIVE ANCA? A SINGLE-CENTRE EVALUATION OF THE IMPACT OF IMPLEMENTING THE 2017 REVISED INTERNATIONAL CONSENSUS ON ANCA TESTING FROM 1547 NEW PATIENT REFERRALS

N. Cleaton1, J. Bateman1, 1New Cross Hospital, Heath Town, United Kingdom

Background: Anti-neutrophil cytoplasmic antibodies (ANCAs) are valuable laboratory markers used in the detection of medium and small-vessel vasculitis, particularly granulomatosis with polyangiitis and microscopic polyangiitis. Historically, and in our own centre, ANCs are screened for using indirect immunofluorescence (IIF) with antigen-specific immunosabs for MPO and PR3. Anecdotally, positive IIF ANCA results often trigger rheumatology referrals. A 2017 International consensus statement has recommended ten clinical indications for requesting ANCA, and suggested high quality immunosabs are the preferred screening method, without the categorical need for IIF.

Objectives: This service evaluation explores the local impact and implications of adopting the 2017 International Consensus on ANCA testing by evaluating new patient referrals to a single UK rheumatology centre.

Methods: New out-patient referrals to a single consultant rheumatologist at one UK centre were collected over 40-months (2016-19) and prospectively coded by referral indication from the clinical letter prior to clinical assessment. Data collected included: anonymised baseline demographics, referral source, key features for referral, and diagnosis following assessment. Referral text was coded using clinical reasoning theory, to identify up to four key-features of the referral, typed by the clinician as free text. This included clinical findings, suspected diagnosis, ANCA testing (MPO/PR3 status), other autoantibodies, arthralgia, synovitis, or other important features (e.g. rash, Raynaud's phenomenon). Diagnosis at the visit was coded against established rheumatological diagnoses. We retrospectively identified any patient where ANCA/ MPO/PR3 formed a key part of the referral, using electronic text search tools.

Results: A total of 1748 referrals were seen, 177 (10.1%) were excluded due to incomplete data. This left 1547 for analysis, of these 18 (1.2%) had been referred with an ANCA IIF positive result as a key component for the referral. The 18 ANCA positive were predominantly female (16/18) and had a mean age of 49 (SD 16.6). The majority of referrals were initiated primary care (16/18); the remaining referrals were from haematology and ophthalmology. The majority (17/18, 94%) tested negative for MPO and PR3, 1/18 (6%) was PR3 antibody positive (known inflammatory bowel disease). Retrospectively, none of the ANCA requests would have tested ‘negative’, reducing uncertainty for patients and primary care.

Conclusion: While highly sensitive, IIF has a low specificity compared to antigen-specific immunoassays being performed on IIF-ANCA positive results. By adopting MPO/PR3 immune-assays as the primary screening method, the vast majority of these referrals (17/18, 94%) would have been tested ‘negative’, reducing uncertainty for patients and primary care. However, positive IIF ANCA results often trigger rheumatology referrals. A 2017 International consensus statement has recommended ten clinical indications for requesting ANCA, and suggested high quality immunosabs are the preferred screening method, without the categorical need for IIF.

HEAD-TO-HEAD COMPARISON OF 18F-FDG-PET/CT AND ULTRASOUND OF THE TEMPORAL ARTERY

C. Rottenburger1, N. Menoch1, S. Imfeld1, M. Aschwanden2, K. Glatz1, C. Berger1, E. Demanu, E. A. Zeiner1, T. Daikeler1, 1University Basel Hospital, Department of Radiology and Nuclear Medicine, Basel, Switzerland; 2University Basel Hospital, Department of Rheumatology, Basel, Switzerland; 3University Basel Hospital, Department of Angiology, Basel, Switzerland; 4University Basel Hospital, Department of Pathology, Basel, Switzerland;

Background: For the diagnosis of giant cell arteritis (GCA) several diagnostic tools do exist such as 18F-FDG-PET/CT (PET) with excellent diagnostic accuracy for the larger vessels and ultrasound for the temporal arteries (TA). Recent data propose that PET is able to detect vasculitis in vessels as small as the TA (1). Comparison of PET, ultrasound (US) and histology of the TA on a segment level has not been done.

Objectives: To describe diagnostic accuracy of PET of TA in a vasculitis university clinic and to analyse strength and limitations of PET by comparing 18F-FDG uptake to US and histology results on a segment level.

Methods: We analysed patients, included in our ethical board approved local prospective GCA cohort having received a PET in between 2015 and 2019 because of suspected GCA. PET of the TA was performed using time-of-flight technique and was scored ‘vasculitis’ if tracer uptake was higher than in the surrounding tissue. Standard uptake value (SUV) measurement in the trunk (T), parietal branch (PB) and frontal branch (FB) of the TA was recorded. US was performed for each branch.

Results: From 37 consecutively recruited patients, GCA was confirmed in 19 patients and excluded in 18 patients which served as controls (Table 1). PET of the TA showed vasculitis in 12/19 GCA patients and in 1/18 controls. Median SUVmax of all vasculitis FB (n=18) was 2.91, 2.20 for the T (n=14) and 2.34 for the PB (n=5).

16 of the 19 GCA patients received US of the TA and 9 showed vasculitic findings. From the control group 2 patients showed vasculitic findings. Most often vasculitic findings were localized in the FB (n=16), followed by the T (n=13) and the PB (n=12).

In the 16 patients that received US, diagnostic sensitivity and specificity of temporal PET for GCA within the TA was 56% and 94% and of US 56% and 89%, respectively. Whereas US detects vasculitis in comparable frequencies in all TA branches, PET recorded vasculitis less often in the PB (only 4 of the 13 in US vasculitic FB). Indeed, the median diameter of all PET positive TA branches, measured in the US, was higher (3.00mm) compared to PET negative branches (1.50mm). Vasculitis was confirmed histologically in 9 of the 13 biopsied patients. Only 2/9 patients showed vasculitis in the preceding PET in the biopsied branch.

Conclusion: High diagnostic accuracy for temporal arteries supports PET as an ‘all-in-one’ exam for GCA. A limitation might be the vessel diameter, as sensitivity of PET for vasculitis of the small parietal branch is low. Thus, in cases with high suspicion of GCA despite a negative PET, US of the TA or biopsy might enhance diagnostic sensitivity.

TREATMENT OF GIANT CELL ARTERITIS WITH TOLICIZUMAB IN CLINICAL PRACTICE IN SWEDEN

D. Di Giuseppe1, A. Knight2, A. J. Mohammads3, C. Turessons4, J. Askling5, 1Karolinska Institutet, Dept of Medicine Solna, Stockholm, Sweden; 2Uppsala
Background: Giant cell arteritis (GCA) is the most common form of systemic vasculitis in adults. GCA is often associated with comorbidities related to the disease itself or caused by its treatment, here: mainly glucocorticosteroids. Since 2017, tocilizumab (TCZ) is approved for the treatment of GCA, but its uptake and treatment outcomes in clinical practice remain to be characterized.

Objectives: To describe characteristics of GCA patients treated with tocilizumab (TCZ) in clinical practice, to evaluate the use of prednisolone up until and following TCZ treatment start, and to describe the TCZ treatment duration.

Methods: We linked together the Swedish Rheumatology Quality Register (SRO), the national Prescribed Drug register, and national Patient register, covering data from July 2009 until July 2019. Through these linkages, we identified GCA patients treated with TCZ including start and discontinuation, their comorbidities and use of other medications. TCZ treatment durations were evaluated through survival probability curves.

Results: We identified 468 patients with GCA treated with TCZ, before and after its formal approval for GCA, Table 1. Over calendar time, the proportion who started TCZ as first ever bDMARD increased, as did the mean age at start of TCZ. The pattern of co-morbidities and health care utilisation demonstrated substantial burden from, e.g., diabetes and infections (Table). Patients starting treatment with TCZ were characterized by an increasing average dose of prednisolone during the last 15 years before TCZ start. Thereafter, prednisolone use declined substantially, from a mean of 15 mg/day in the six months before the start of TCZ to 6 mg/day 1 year after its start (Figure 1). Analysis of the duration of TCZ treatment (from start until discontinuation) suggested that at one year, two thirds of patients were still on treatment (Figure 2).

Table. Swedish GCA patients starting treatment with tocilizumab July 2009 - Nov 2019.

Figure 1. Average daily dose of prednisolone before and after* start of tocilizumab, based on cumulative dose every 6 months.* The average daily dose of prednisolone after the start of TCZ is calculated only among patients who were still on treatment at the end of each period (351 patients in the first 6 months, 251 in 6m-1y, 161 in 1 – 1.5y, 95 in 1.5 – 2y).

Figure 2. Kaplan-Meier curve for tocilizumab in GCA by time since treatment start.

Conclusion: Patients treated with TCZ for GCA in clinical practice are characterized by a significant burden of co-morbidities, many of which may be related to prolonged use of glucocorticosteroids. This study confirms a marked reduction in the use of oral prednisolone following treatment with TCZ, and demonstrates that in a majority of patients in clinical practice, treatment with TCZ for GCA is extended beyond one year. Future analyses will evaluate the association of these observed treatment patterns with the level of GCA disease control, co-morbidities and quality of life, over time.

Acknowledgments: These analyses were partly funded through an agreement between Roche and Karolinska Institutet.

THU0304 CLINICAL PRACTICE VARIATION BETWEEN ACADEMIC AND NON-ACADEMIC CENTERS IN THE MANAGEMENT OF ANCA ASSOCIATED VASCUITIS IN THE NETHERLANDS

E. Dirikoli, A. Rutgers, S. Tas, C. A. Verburg, D. Soonawala, A. E. Hak, H. H. F. Remmelt, D. Ielpae, G. D. Laverman, J. M. Van Laar, H. J. Bernelot Moens, P. Verhoeven, W. J. W. Bos, Y. K. O. Teng, Leiden University Medical Center (LUMC), Leiden, Netherlands; University Medical Center Groningen, Groningen, Netherlands; Amsterdam UMC, Amsterdam, Netherlands; Spaarne Gasthuis Haarlem Zuid, Haarlem, Netherlands; Haga Hospital (Leyweg), Den Haag, Netherlands; Amsterdam UMC, Amsterdam, Netherlands; Meander Medical Center, Amersfoort, Netherlands; Groene Hart Hospital, Gouda, Netherlands; ZGT Almelo, Almelo, Netherlands; UMC Utrecht, Utrecht, Netherlands; ZGT Hengelo, Hengelo, Netherlands; Vasculitis Stichting, Silvolde, Netherlands

Background: ANCA associated vasculitis (AAV) is a complex, rare systemic autoimmune disease with an estimated prevalence of 5-18 patients per 100,000 individuals worldwide. Managing a low prevalent disease can be challenging which is reflected in clinical practice variation.

Objectives: This study investigated clinical practice variation of the care for AAV patients in the Netherlands.

Methods: In a nationwide online survey, AAV patients were selected from academic and non-academic centers. Within centers, patients were eligible which is reflected in clinical practice variation.

Objectives: This study investigated clinical practice variation of the care for AAV patients in the Netherlands.
Results: From December 2018 to November 2019, 230 AAV patients were recruited in 6 non-academic and 3 academic hospitals (120 vs 110 patients respectively). Differences in clinical diagnoses (GPA, MPA and eGPA) were observed between non-academic and academic centers (p<0.05), which was mainly caused by a higher number of MPA patients in non-academic centers. The year of diagnosis was comparable (median 2013 [2009-2016], p=0.150). The median follow up since diagnosis was 4.8 years [1.8-9.6] with a median in-hospital time-to-diagnosis of 13 days [2-50]. Patients were diagnosed at a mean age of 63 years (+11.18) in non-academic centers and 53 years (+16.92) in academic centers (p<0.001). Besides steroids, oral cyclophosphamide was the most preferred drug (54%) for induction therapy, whereas rituximab was given significantly more often as (part of the) induction therapy in patients treated in academic centers compared to patients in non-academic centers (28% vs 8%, p<0.001). In non-academic centers pneumocystis pneumonia (PCP) prophylaxis was prescribed significantly less (76% vs 91%, p=0.003). Also, screening for Staphylococcus aureus carriership was significantly less (17% vs 68%, p=0.001). With respect to mortality and co-morbidity, 22 patients (10%) died, 100 patients (44%) had at least one infection and 24 patients (10%) suffered from at least one malignancy. We observed no significant differences on these endpoints between academic and non-academic centers.

Conclusion: The present study highlights important practice variation in the management of AAV between academic and non-academic hospitals in the Netherlands. A high proportion of patients is treated with oral cyclophosphamide as induction therapy while rituximab is increasingly used in academic centers. Rates of mortality, infections and malignancies were not different. Altogether, this study raises awareness into the variation of management for AAV patients and allows the identification of areas for improvement of clinical care for Dutch AAV patients.

THU0305

PREVALENCE AND CLINICAL OUTCOME OF INTERSTITIAL LUNG DISEASE IN ANCA ASSOCIATED VASCUITIS

J. Fernandes Serodio\textsuperscript{1,2}, J. Hernández-Rodríguez\textsuperscript{1}, G. Espigol-Frigolé\textsuperscript{1}, M. Alba\textsuperscript{1}, J. Marco-Hernández\textsuperscript{1}, M. Sánchez\textsuperscript{3}, F. Hernández-González\textsuperscript{4}, J. Sellarés\textsuperscript{5}, M. C. Cid\textsuperscript{1}, S. Prieto-González\textsuperscript{1}, Vincent\textsuperscript{1}, M. Alba\textsuperscript{1}, J. Marco-Hernández\textsuperscript{1}, M. Sánchez\textsuperscript{3}, F. Hernández-González\textsuperscript{4}, J. Sellarés\textsuperscript{5}, M. C. Cid\textsuperscript{1}, S. Prieto-González\textsuperscript{1}

Background: Lung involvement is frequent in ANCA-associated vasculitides (AAV). Classical lung manifestations consist of capillaritis with lung haemorrhage, inflammatory infiltrates and nodules. Interstitial lung disease (ILD) is increasingly recognized among patients with AAV. However, little is known concerning risk factors and clinical course of these patients.

Objectives: The aim of our study was to characterize the prevalence and clinical course of ILD in patients with AAV.

Methods: We have performed a clinical retrospective single-centre observational analysis (1990-2019) of all patients with the diagnosis of microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) diagnosed according to 2018 Draft Classification Criteria for GPA and MPA\textsuperscript{1}. Demographic, clinical and immunologic data were reviewed. Radiologic pattern of ILD were assessed by high-resolution-CT. Main outcome evaluated was overall survival.

Results: The study population consisted of 123 patients, 56% female, aged 59 (±17) years old at the time of diagnosis. Clinical diagnosis was of MPA in 54% of patients and GPA in 46%. While 108 (88%) ANCA positive patients had PR3 (n=25) or MPO (n=83), 15 (12%) patients had negative or atypical ANCA. Any lung involvement was present in 82 (71%) and ILD was identified in 24 (20%) of all patients. ILD pattern was of usual interstitial pneumonia (UIP) in 12 patients, non-specified interstitial pneumonia (NSIP) in 9 and chronic organizing pneumonia (OP) in 3. There was an association between the presence of ILD and ANCA specificity: MPO were present in 100% of patients with UIP and in 75% of patients with NSIP/OP (p=0.017). Bronchiectasis were more prevalent among patients with ILD (19/24; p<0.001). During the median follow-up time period of 68 (23-138) months, mortality was of 42% among patients with ILD-AAV compared with 11% in no ILD-AAV (log-rank p=0.0001). On the multivariate Cox regression model, ILD was an independent predictor of mortality HR 2.95 (95%CI 1.09-7.96; p=0.033).

Conclusion: ILD is a frequent manifestation of MPA and GPA patients. The presence of ILD, particularly UIP, is associated with ANCA-MPO and is a predictor of mortality. Therefore, a better management of fibrotic lung involvement in AAV is warranted.

THU0306

ROLE OF 18-FDG PET/CT IN DIAGNOSIS AND FOLLOW UP OF LARGE VESSELS VASCULITIS

L. Gigante\textsuperscript{1}, D. Bruno\textsuperscript{1}, V. Feudo\textsuperscript{2}, S. L. Bosello\textsuperscript{1,3}, L. Leccisotti\textsuperscript{1}, A. Musto\textsuperscript{1}, P. G. Cerasuolo\textsuperscript{1}, A. Zoli\textsuperscript{1,2}, A. Giordano\textsuperscript{1,3}, E. Gremese\textsuperscript{1,3}, Division of Rheumatology, Università Cattolica del Sacro Cuore, Rome, Italy; Division of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, Italy; Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli-IRCCS, Rome, Italy; Division of Nuclear Medicine, Fondazione Policlinico Universitario A. Gemelli-IRCCS, Rome, Italy

Background: 18-FDG PET/CT is a functional imaging method which allows to identify inflammation of vessel walls. The use of PET in large vessels vasculitis(LV) at disease onset and during follow up is still debate either to confirm clinical remission either to drive the therapy choice. American Society of Nuclear Cardiology (ASNC) recently advanced recommendations aimed to standardize the application of PET in LVV(1).

Objectives: The aim of our study was to assess the clinical role of PET performed in patients affected by LVV at the diagnosis and during the follow up.

Methods: We retrospectively evaluated PET/CT of 49 patients affected by clinically active LVV according to LVV visual grading (LVG, grading 0-3) and measured the standardized uptake value(SUV) of large vessels. 38 (77.6%) patients were affected by Giant Celis Arteritis and 11(22.4%) by Takayasu Arteritis. 32(65.3%) patients repeated the imaging after a mean follow-up of 15±4.3 months. All baseline (T0) and follow up (T1) clinical data of disease activity were collected. Patients were treated according to EULAR LVV management recommendations(2). TO PET/CT study was performed in patients with a clinically active disease defined by suggestive symptoms/signs and/or high inflammatory markers. The mean disease duration before T1 PET/CT examination was 4 months. T0 PET was performed in 25/49 patients(52%) at the diagnosis of

Disclosures of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.6211
LVV, whereas in 24/49 (48%) patients with already diagnosed but active LVV.

**Results:** Baseline PET was positive in 21 patients (42.9%). According to ASNC recommendations, 19 patients (38.8%) presented a LVG=3, 2 (4.0%) a LVG=2, 6 (12.2%) LVG=1 and 22 (44.9%) LVG=0. Patients performing PET at disease onset (75%) had higher LVG score than patients performing PET during the disease course (25%), p<0.002. At T0, aortic, carotid, axillary and subclavian SUV did not correlate with inflammatory markers.

Follow up PET/CT studies were performed in 52 patients, 13 (40.6%) with a clinically active disease despite therapy, while 19 (59.4%) in clinical remission. Follow up PET was still positive in 8 patients (25%) with a LVG=3, 10 (31.2%) patients presented LVG=1 and 14 (43.3%) LVG=0. T1 PET/CT study showed a significant reduction of SUV values in descending aorta, left and right subclavian arteries and levf and right axillary arteries when compared with first PET/CT study. According to LVG, 12 patients with active PET/CT study at T0 (19 pts) presented a reduction of LVG from score 2 and 3 to grade 1 or 0 (64.2%) at second PET/CT study. Only 3 patients presented an increased LVG score at T1, while in the other 17 patients T1 PET confirmed the previous score. No significant difference was found between LVG scores according with clinical characteristics, but among 8 patients presenting an active T1 PET, 4/5 patients were in clinical remission.

**Conclusion:** The use of ASNC recommendations for FDG PET/CT in LVV enables to confirm a metabolically active disease in 40% of patients and in 75% of patients at disease onset, suggesting that post-pozing the exam could lead to underrate the real extension of disease. Our data, even if limited, suggest that PET/CT could be crucial in management of patients in clinical remission, detecting patients with still metabolically active LVV. Further prospective studies are necessary to evaluate the role of PET/CT in driving therapeutic strategies.

**Objectives:** To compare the efficacy and safety of APR in monotherapy or combined with DMARDs in refractory BD.

**Methods:** National multicenter open-label study on 51 BD patients with oral and/ or refractory LVV under APR as monotherapy or combination.

**Results:** We included 51 patients (35 women/16 men), mean age 44.7±13.2 years. Before APR, all patients had received several systemic conventional drugs. The main clinical symptoms for starting APR were oral (n=19) and genital (n=2) aphthous ulcers or both (30).

Excluding corticosteroids, colchicine or NSAIDs, APR was given at standard dose of 30 mg twice daily in monotherapy (n=31), or combined with conventional DMARDs in 16 cases (nitazoxpine, 5 methotrexate, 4 hydroxychloroquine, 4 sulfasalazine, 1 dapson) or with biologic DMARDs in 4 (2 tocilizumab, 1 adalimumab, 1 infliximab). There were not found statistically significant differences in demographic features, previous therapy, clinical manifestations or reported adverse effects.

After a median follow-up of 6 [3–12] months, most of the patients experienced improvement of the orogenital ulcers in both groups (89.8% in the first 2 weeks), and statistically significant differences in demographic features, previous therapy, clinical manifestations or reported adverse effects.

**Conclusion:** APR leads to a rapid and maintained improvement in most patients with refractory BD orogenital ulcers. APR seems as effective and safe in monotherapy as combined.

**Background:** Apramist (APR) has demonstrated efficacy in the treatment of oral and/or genital aphthous ulcers in Behçet’s disease (BD). Combination of APR to other disease-modifying anti-rheumatic drugs (DMARDs) has not been assessed.

**Objectives:** To compare the efficacy and safety of APR in monotherapy or combined with DMARDs in refractory BD.

**Methods:** National multicenter open-label study on 51 BD patients with oral and/ or refractory LVV under APR as monotherapy or combination.

**Results:** We included 51 patients (35 women/16 men), mean age 44.7±13.2 years. Before APR, all patients had received several systemic conventional drugs. The main clinical symptoms for starting APR were oral (n=19) and genital (n=2) aphthous ulcers or both (30).

Excluding corticosteroids, colchicine or NSAIDs, APR was given at standard dose of 30 mg twice daily in monotherapy (n=31), or combined with conventional DMARDs in 16 cases (nitazoxpine, 5 methotrexate, 4 hydroxychloroquine, 4 sulfasalazine, 1 dapson) or with biologic DMARDs in 4 (2 tocilizumab, 1 adalimumab, 1 infliximab). There were not found statistically significant differences in demographic features, previous therapy, clinical manifestations or reported adverse effects.

After a median follow-up of 6 [3–12] months, most of the patients experienced improvement of the orogenital ulcers in both groups (89.8% in the first 2 weeks), and statistically significant differences in demographic features, previous therapy, clinical manifestations or reported adverse effects.

**Conclusion:** APR leads to a rapid and maintained improvement in most patients with refractory BD orogenital ulcers. APR seems as effective and safe in monotherapy as combined.
Background: Childhood-onset Takayasu Arteritis (c-TAK) may differ from adult-onset Takayasu Arteritis (a-TAK) in clinical manifestations and treatment.

Objectives: To compare c-TAK with a-TAK patients for vascular involvement, disease activity, damage, and treatment.

Methods: Patient charts from two tertiary-care centers of a pediatric and adult clinic were reviewed. Adult patients diagnosed before the age of 18 were included in the c-TAK group. The activity was assessed with the physician's global assessment (PGA) and Indian Takayasu Clinical Activity Score (ITAS). The damage was evaluated with Takayasu Arteritis Damage Score (TADS) and Vasculitis Damage Index (VDI).

Results: Twenty-four c-TAK and 121 a-TAK patients were compared. 21 (88%) of the c-TAK group and 104 (89%) of the a-TAK group were female. Age at symptom onset was 14 (IQR: 9-15) for c-TAK and 30 (IQR: 24-43) for a-TAK patients. Diagnostic delay in months was shorter for c-TAK patients [c-TAK: 3 (1-10) vs. a-TAK: 12 (5-89)]. Follow-up duration was similar [33 months (IQR: 16-131) vs. 68 (IQR: 30-102), p=0.763].

ITAS was comparable for c-TAK and a-TAK patients on the first visit [14 (SD: 7) vs. 13 (SD: 5), p=0.362, respectively]. However, the PGA score was higher in the c-TAK group compared to the a-TAK group [9 (IQR 7-10) vs. 7 (IQR 6-8), p<0.001].

14 (64%) of c-TAK patients and 10 (9%) of a-TAK patients received pulse glucocorticoids, p=0.002. Cumulative glucocorticoid dose was 10 grams (IQR: 6-13) for c-TAK patients and 7 grams (IQR: 4-12) for a-TAK patients (p=0.128).

After diagnosis, children who had more vascular interventions than the adults did [9 (38%) vs. 20 (18%), p=0.031, respectively]. Rates of achieving at least one remission were lower for c-TAK patients [c-TAK: 12 (50 %) vs. a-TAK: 94 (82%), p=0.001]. c-TAK patients had a PGA score of 6 (IQR: 3-8), the PGA score in a-TAK patients was 1 (IQR 1-3), p<0.001. Still, ITAS was similar for both groups [c-TAK: 1 (IQR 0-3) vs. a-TAK: 0 (IQR 0-2), p= 0.579].

9 (38%) of c-TAK patients had at least one relapse, and the 43 (38%) of a-TAK patients had at least one relapse (p=0.960).

TADS was similar [c-TAK: 8 (IQR 4-12), a-TAK: 8 (IQR 6-10), p=0.919]. However, VDI of the a-TAK patients was higher than the c-TAK patients [c-TAK: 1 (IQR 7-10) vs. 7 (IQR 6-8), p=0.579]. Glucocorticoid related damage was higher in a-TAK patients [c-TAK: 4 (IQR 2-5), a-TAK: 5 (IQR 3-7), p=0.017].

Conclusion: Aorta involvement, biologic agent use, and vascular interventions were more common in c-TAK patients. However, cumulative damage was not increased for c-TAK patients which may be partly explained by more common corticosteroid related side-effects in adults.

THU0309

UNILATERAL TEMPORAL ARTERY BIOPSY IS SUFFICIENT FOR DIAGNOSING GIANT CELL ARTERITIS IF THE SERUM C-REACTIVE PROTEIN LEVEL IS 10 MG/DL OR HIGHER

T. Kise1, E. Takamasu1, Y. Miyoshi1, N. Yokogawa2, K. Shimada1, 1Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Diseases, Fuchu, Tokyo, Japan

Background: Temporal artery biopsy (TAB) is the gold standard for diagnosing giant cell arteritis (GCA). However, previous studies have reported that the discordance rate of TAB is 3-45%, i.e., in unilateral TAB, GCA may be overlooked in one in five patients, approximately. Evidence as to whether bilateral TAB should be performed initially or one-sided TAB is sufficient for diagnosing GCA is lacking.

Objectives: To investigate the predictors of patients with GCA in whom one-sided TAB is sufficient.

Methods: The present study was a cross-sectional, single center study conducted from April 1, 2011 to July 31, 2019 at Tokyo Metropolitan Tama Medical Center. Of all consecutive GCA cases for which bilateral TAB was performed, bilaterally positive cases and unilaterally positive cases were extracted as bilateral positive group (BPG) and unilateral positive group (UPG), respectively. GCA was defined in accordance with the classification criteria of the 1990 American College of Rheumatology, and GCA was diagnosed if no other etiology was found within six months after beginning of high-dose glucocorticoid treatment. Demographic, clinical and laboratory data were obtained from the medical records, and the BPG and the UPG were compared statistically in each variable. Statistical significance was defined as p < 0.05.

Results: During study, 264 biopsies were performed for 145 cases, who suspected GCA and underwent TAB. The pathological positivity rate was 26.1% (68 / 264 biopsies). Of these, 53 cases had final diagnosis of GCA, in which 43 cases were biopsy proven GCA. Thirty-seven biopsy proven GCA with bilateral TAB...
were enrolled; 64.9% women; mean (SD) age 75 (8.9) years; median [IQR] TAB length 17.5 [13.0,20.0] mm; headache 54.1%; jaw claudication 45.9%; scalp tenderness 16.2%; temporal artery (TA) tenderness 32.4%; TA engorgement 32.4%; TA pulse abnormality 5.4%; visual symptoms 2.7%; a fever of 38.5°C or higher 40.5%; shoulder girdle pain 46.6%; imaging of aortitis or arteritis 40.5%; median [IQR] white blood cell 9.100 [7200, 12050] /μL; median [IQR] platelet cell 37.5 [270, 46.3] x10^11 /μL; median [IQR] C-reactive protein (CRP) 10.1 [3.9, 16.5] mg/dL; erythrocyte sedimentation rate [IQR] 105 [66, 129] mm/hr. Thirty-one in 37 cases were bilaterally positive while 6 in 37 cases were positive unilaterally; and the discordance rate was 16.2%. The median sample length after formalin fixation was 19.0 mm for the BPG and 14.5 mm for the UPG (p = 0.171). The parameters above were compared between UPG and BPG. Of these, only the serum CRP value (mg/dL) differed statistically between groups, and the median value of the two groups was 10.6 and 6.5, respectively (median test: p = 0.031). To predict BPG, in whom unilateral TAB is sufficient for diagnosing GCA, the cut-off value of serum CRP with a specificity of 100% and a sensitivity of 61.3% was set at 9.3 mg/dL (ROC analysis: AUC 0.726).

Conclusion: When the serum CRP level is 10 mg/dL or higher in GCA suspected patients, an unilateral TAB was sufficient for an accurate diagnosis.

THU0310 CASE–CONTROL SEROPREVALENCE STUDY ON THE ASSOCIATION BETWEEN BARTONELLA INFECTION AND ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

A. Mahs², S. Edouard³, D. Cornecc, S. Gonzalez-Chiappe¹, J. Goronzy⁶, P. Guilpain⁴, C. Langford³, P. Y. Lévy⁵, P. Monach⁶, E. Misses, Ibiza, Spain
W. St. Clair, Misses, Ibiza, Spain

Background: Bartonellosis is an emerging anthropozoososis caused by infection with intracellular Gram-negative Bartonella species. It leads to necrotizing granulomas and endothelial damage and causes acute and chronic human diseases, such as cat scratch disease, bacillary angiomatosis and endocarditis. Endocarditis due to Bartonella henselae and B. quintana is reported to produce anti-neutrophil cytoplasmic antibodies (ANCAs) that disappear with effective antimicrobial treatment.

Objectives: Hypothesizing a role for Bartonella infection in ANCA-associated vasculitis (AAV), which also includes granulomatous and vascular inflammatory, we studied the seroprevalence of 5 Bartonella species in patients with AAV.

Methods: The study used plasma samples from patients with granulomatosis with polyangiitis and microscopic polyangiitis that were enrolled in the Rituximab for AAV (RAVE) trial and from healthy controls living in the United States. Western blot assays were used for serological testing of infection with B. quintana, B. henselae Houston-1, B. elizabethae, B. vinsonii subsp. berk-hoffii and B. alastica. The associations of positive serology results and AAV were expressed as odds ratios (OR). Clinical characteristics of seropositive and seronegative patients, assessed by the BVAS/WG instrument, were compared. These comparisons were done for 9 organ systems; in case they showed differences with P<0.10, the corresponding organ system-specific clinical features were also analyzed. Statistical analysis was performed using Fisher’s exact test or Student’s t-test, as appropriate.

Results: We analyzed blood samples of 187 patients with AAV (collected at start of the trial) and of 127 controls. There were no significant differences between the cases and controls for mean age (P=0.148) and proportion of males (P=0.36).

Bartonella spp, serological testing was positive for 112 (80%) cases and 40 (31%) controls (OR 3.25 [95% CI 2.02–5.22], P<0.001). Significant associations were also found within subsets of PR3-AAV (OR 4.00 [95% CI 2.37–6.76], P<0.001), MPO-AAV (OR 2.18 [95% CI 1.17–4.06], P=0.017), newly-diagnosed (OR 3.89 [95% CI 2.21–6.86], P<0.001) and relapsing disease (OR 2.86 [95% CI 1.65–4.98], P<0.001). Species-specific positive serological testing was found in particular against B. henselae (cases: 27%; controls: 0.8%; OR 39.93 [95% CI 5.42–293.90]; P<0.001). Compared to AAV patients without seropositivity for Bartonella spp, AAV patients testing seropositive for Bartonella spp, had significantly more bloody nasal discharge (P=0.046), sinus involvement (P=0.035) and conjunctivitis/episcleritis (P=0.016).

Conclusion: This study reveals higher seroprevalence of Bartonella, especially B. henselae, in patients with AAV than in healthy controls. Although cross-reactivity of Bartonella with other microorganisms cannot be excluded, these results may support an etiopathogenic role of Bartonella infection in AAV that deserves further investigation.

THU0311 CERTOLIZUMAB THERAPY IN REFRACTORY UVEITIS DUE TO IMMUNE-MEDIATED INFLAMMATORY DISEASES (IMID). MULTICENTER STUDY OF 39 PATIENTS

J. L. Martín-Vilarrasa¹, V. Calvo-Río², L. Sanchez-Bilbao³, I. González-Mazón⁴, I. Torre-Salabert⁵, A. García-Martos⁶, A. Sanchez-Andrade⁶, A. García-Aparicio°, J. de Dios-Jiménez Aberásturi, A. Palencia, Palencia, Spain; H. Valme, Sevilla, Spain; H. Alicante, Alicante, Spain; HG. Valencia, Valencia, Spain; H. Castellón, Castellón, Spain; H. Salamanca, Salamanca, Spain; H. Espert Sant, Barcelona, Spain

Background: Infliximab and adalimumab therapy has significantly improved the prognosis of patients with non-infectious refractory uveitis. However, there is not enough evidence for the use of other anti-TNF drugs such as Certolizumab (CZP) in these patients.

Objectives: To evaluate the efficacy and safety of CZP in uveitis secondary to Immune-Mediated Inflammatory Diseases (IMID),
Methods: Multicenter study of 39 patients with uveitis due to IMID refractory to glucocorticoids and conventional immunosuppressants. Efficacy of CZP was evaluated with the following ocular parameters: best corrected visual acuity (BCVA), anterior chamber cells, macular thickness and presence of retinal vasculitis. Efficacy of CZP was compared between baseline, 1st week, 1st and 6th month, and 1st and 2nd year. Statistical analysis was performed with the STATISTICA software (Statsoft Inc. Tulsa, Oklahoma, USA).

Results: 39 patients/56 affected eyes (18 men/21 women) with a mean age of 40.5±11.9 years were studied. IMID included: spondyloarthritis (n=17), psoriatic arthritis (4), Crohn (3), JIA (2), Behçet (2), reactive arthritis (2), rheumatoid arthritis (1), relapsing polychondritis (1), pars planitits (1), Birdshot (1) and idiopathic uveitis (3). Uveitis pattern was as follows: anterior (n=30), posterior (4), panuveitis (3) and intermediate (2).

Previous CZP patients received: oral prednisone (n=18) methylprednisolone bolus (1), methotrexate (22), azathioprine (10), cyclosporine (4), leflunomide (2), mycophenolate mofetil (2) and cyclosporine A (1). 77% of patients had received previous biological therapy, with a mean of 1.6±1.2 biological drugs per patient. Gestational desire was the reason for prescribing CZP in 8 patients. CZP was administered in monotherapy in 16 patients and in the remaining 23 patients combined with conventional immunosuppressants.

After a median follow-up of 24 [6-36] months, most of the ocular variables analysed showed a rapid and significantly sustained improvement (Table). CZP was discontinued in 11 patients for the following reasons: remission (n=1), insufficient response of ocular symptoms (n=1) and limited response of extracocular manifestations (n=9). No serious adverse effects were reported.

Conclusion: CZP seems to be effective and safe in patients with refractory uveitis due to IMID.

Disclosure of Interests: None declared.

THU0313 DISEASE PATTERN AND TIME TO DIAGNOSIS IN A FAST-TRACK GIANT CELL ARTERITIS CLINIC USING ULTRASOUND AS PRIMARY DIAGNOSTIC TOOL

U. Møller Døhn1,2, V. Fana1,2, T. Møller1, J. J. Lykkegaard1, L. Terslev1,2, Rigshospitalet, Glostrup, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research, Glostrup, Denmark

Background: Giant Cell Arteritis (GCA) is a vasculitis predominantly affecting the large vessels from aorta and its proximal branches and extra-cranial arteries. Precise and fast diagnosis is important in order to initiate proper treatment and avoid ischaemic events, e.g. irreversible visual loss. Unnecessary and prolonged glucocorticoid treatment is also unwanted due to its significant side effects. Therefore, immediate diagnosis of GCA is recommended, and the primary diagnostic tool, according to EULAR recommendation, is vascular ultrasound (US)1. In 2018, a GCA Fast-Track Clinic (FTC) was implemented in our department covering a population of approximately 900,000. Patients even with a low á-priori suspicion of GCA were accepted. It is the aim to have patients seen within one office day.

Objectives: In this retrospective study, to describe clinical data from patients seen in the FTC in a 1-year period from September 1st, 2018 and to investigate the time required for making a diagnosis, and to which extent US as the primary diagnostic tool was adequate for making the final diagnosis.

Methods: All patients, irrespective of clinical presentation, had US of bilateral temporal-, facial-, axillary and common carotid arteries done (exam time <10 min). The results were communicated to the clinicians. A senior registrar in rheumatology at our out-patient clinic. The senior registrar was aware of the conclusion of the US. Decisions on further diagnostic procedures (temporal artery biopsy (TAB) and positron emission tomography computed tomography (PET-CT)) were evaluated. Furthermore, final diagnosis and fulfilment of ACR1990 classification criteria for temporal arteritis at three months was noted, as was the number of days required for diagnosis.

Results: A total of 120 patients were seen in the FTC and had a vascular US done. Demographic and clinical data are seen in table 1. Of 120 patients, 42% (51) had a clinical diagnosis of GCA at three months and 42% fulfilled ACR1990 criteria for temporal arteritis. Based on US alone, 36% of patients had GCA. A
diagnosis or exclusion of GCA were done on median 1 day (in 55% of patients). However, in cases where further diagnostics (TAB and PET-CT) were necessary, the time for diagnosis increased substantially. See table 2 for data on waiting time from referral, diagnoses and time required for diagnosis.

Table 2

Conclusion: In this newly established GCA FTC, fast and precise diagnosis of GCA or exclusion of this was possible in majority of patients referred, even though referral criteria were liberal. In 55% of patients, further diagnostic procedures were considered unnecessary, and a diagnosis on day 1 could be established based on US, clinical findings and existing paraclinical data.

THU0315 THE CLINICAL RELEVANCE OF SERUM IMMUNE COMPLEXES IN ANCA-ASSOCIATED VASCULITIS

M. Okamoto1, K. Ichinose1, K. Oyama2, K. K. Sada3, S. Y. Kaname4, M. Harigai5, A. Kawakami6, M. Okamoto1, K. Ichinose1, K. Oyama2, K. K. Sada3, S. Y. Kaname4, M. Harigai5, A. Kawakami6, 1Nagasaki University Graduate School of Biomedical Sciences, Division of Advanced Preventive Medical Sciences, Department of Immunology and Rheumatology, Nagasaki, Japan; 2Nagasaki University Graduate School of Biomedical Sciences, Department of Pharmacy Practice, Nagasaki, Japan; 3Okayama University Graduate School of Biomedical Sciences, Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama, Japan; 4Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan; 5Tokyo Women’s Medical University, Department of Rheumatology, Tokyo, Japan

Background: AAV is an autoimmune disease characterized by systemic vasculitis and pauci-immune-type crescentic glomerulonephritis (CGN) with ANCA production. Several authors have reported cases of ANCA-associated CGN with definite IC deposits, however, the clinical significance of IC in patients with ANCA-associated CGN remains unclear.

Objectives: To investigate the clinical relevance of serum immune complexes (ICs) in ANCA-associated vasculitis (AAV) patients.

Methods: We developed a novel proteomic strategy for identifying and profiling antigens in immune complexes in the serum of microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) patients. The serum was collected from the cohort of Japan Research Committee of the Ministry of Health Labour, Welfare for Intractable Vasculitis (JVPAS) before treatment and 6 months after initiation of treatment. The serum from healthy individuals was used for control samples. The Baseline data of each patient was collected with demographic information, laboratory data, disease activity according to the Birmingham Vasculitis Activity Score (BVAS) 2003, disease severity, and imaging data.

THU0314 RELAPSES AND LONG-TERM REMISSION IN LARGE VESSEL GIANT CELL ARTERITIS IN NORTHERN ITALY: CHARACTERISTICS AND PREDICTORS IN A LONG-TERM FOLLOW-UP STUDY

1Rheumatology Unit, AUSL IRCCS di Reggio Emilia, Reggio Emilia, Italy; 2Pathology Unit, AUSL IRCCS di Reggio Emilia, Reggio Emilia, Italy; 3Radiology Unit, AUSL IRCCS di Reggio Emilia, Reggio Emilia, Italy; 4Ophthalmology Unit, AUSL IRCCS di Reggio Emilia, Reggio Emilia, Italy; 5University of Parma, Parma, Italy; 6Vascular Surgery Unit, AUSL IRCCS di Reggio Emilia, Reggio Emilia, Italy; 7Nuclear Medicine Unit, AUSL IRCCS di Reggio Emilia, Reggio Emilia, Italy; 8AABI, AUSL IRCCS di Reggio Emilia, Reggio Emilia, Italy; 9Radiology Unit, AUSL IRCCS di Reggio Emilia and University of Modena and Reggio Emilia, Reggio Emilia, Italy

Background: Previous studies evaluated clinical relapses and long-term remission mainly in patients with biopsy-proven GCA and/or patients satisfying the ACR 1990 criteria for GCA classification. Also, radiological involvement was frequently used to define relapses and monitor disease activity in patients with LV-GCA.

Objectives: To evaluate characteristics and predictors of relapses and long-term remission in an Italian cohort of patients with large-vessel (LV) giant cell arteritis (GCA).

Methods: We evaluated 87 consecutive patients with LV-GCA followed up at the Rheumatology Unit of Reggio Emilia Hospital (Italy) for at least 2 years. Patients with relapses and long-term remission were compared to those without. A comparison group of 34 patients with biopsy proven GCA without LV vasculitis (LVV) at diagnosis was considered for comparison.

Results: 37 patients (42.5%) experienced one or more relapses. Nineteen (32.2%) of the 51 relapses were experienced during the first year after diagnosis. The majority of relapses occurred with doses of prednisone (PDN) ≤ 10 mg/day (74.5%). Polymyalgia rheumatica (PMR) (41.2%) and worsening at imaging of LVV (39.2%) were the most frequently observed relapsing manifestations. The total cumulative prednisone dose was significantly higher (p = 0.0001) and the total duration of PDN treatment longer (p = 0.0001) in relapsing patients compared to those without relapses. Relapsing patients had at diagnosis more frequently fever ≥ 38°C (p = 0.03) and less frequently long-term remission (p = 0.003). In the multivariate model model fever ≥ 38°C (HR 3.22, 95%CI:1.43-7.27), duration of PDN treatment (HR 1.01, 95%CI: 1.00-1.02) and total cumulative PDN dose (HR 0.89, 95%CI: 0.83-0.96) were significantly negatively associated with long-term remission.

Conclusion: In our cohort of patients with LV GCA we identified predictors of a relapsing course and long-term remission, which were observed in around half of the patients.

DOI: 10.1136/annrheumdis-2020-eular.2035
Results: We were able to examine 91 AAV patients (52 MPA patients and 39 GPA patients) with 82.4% for MPO-ANCA positive and 20.9% for PR3-ANCA positive. Almost half of the patients were female (56.0%). The median age was 70 years ([interquartile range (IQR): 46-77]. The median BVAS was 17 ([IQR: 12-23]. We identified autoantigen of EGF-containing fibrulin-like extracellular matrix protein 1 (EFEMP1) in 43 of MPA (82.6%) and 16 of GPA (41.0%) at baseline. After 6 months of treatment, no cases of EFEMP1 were identified in MPA and GPA. The clinical features of EFEMP1 positive in AAV patients were higher age at onset (p <0.01), less ear, nose and throat symptoms at initiation of treatment (p <0.05), higher serum Cr at initiation of treatment (p <0.01), higher vasculitis damage index (VDI) renal component at 12 months and 24 months after initiation of treatment (both p <0.05).

Conclusion: Our findings indicate that an autoantigen as immune complexes of EFEMP1 were involved in the pathogenesis of AAV patients and may predict renal prognosis.

**DEVELOPMENT AND OUTCOME OF AORTIC COMPLICATIONS DURING TOCILIZUMAB TREATMENT OF GCA AND HISTOPATHOLOGIC EVIDENCE OF RESIDUAL INFLAMMATION-A CASE SERIES.**

A. Rubbert-Roth1, P. K. Bode2, T. Langenegger2, C. Pfole3, T. Neumann4, O. C. H. Kim5, J. Von Kempis5, 1Rheumatology Clinic, Cantonal Hospital St Gallen, St Gallen, Switzerland; 2Institute of Pathology and Molecular Pathology, University Hospital of Zurich, Zurich, Switzerland; 3Rheumatology Clinic, Cantonal Hospital Zug, Baar, Switzerland; 4Pathology Institute Triemli, Triemli Hospital, Zurich, Switzerland; 5Radiology Clinic, Cantonal Hospital St Gallen, St Gallen, Switzerland.

**Background:** Giant cell arteritis (GCA) may affect the aorta and the large aortic branches and lead to dissections and aortic aneurysms. Tocilizumab (TCZ) treatment has the capacity to control aortic inflammation as has been demonstrated by CRP normalization and imaging data. However, limited data are available on the histopathological findings obtained from patients who underwent surgery because of aortic complications during TCZ treatment.

**Objectives:** We report on 5 patients with aortitis who were treated with TCZ and developed aortic complications.

**Methods:** We describe a retrospective case series of patients with GCA treated with TCZ, who presented in our clinic between 2011 and 2019. Three patients underwent surgery. Histopathologic examination was performed in specimen from all of them.
**Results:** Five female patients were diagnosed with GCA (4/5) or Takayasu arteritis (1/5) involving the aorta, all them diagnosed by MR angiography and/or FDG PET CT scan. Three patients (one with aortic aneurysm, one with dissection) underwent surgery after having been treated with TCZ for seven weeks, nine months and four years, respectively. Imaging before surgery showed remission on MRI and/or PET-CT in all cases. At the time of surgery, all patients showed normalized CRP and ESR values. Histopathological evaluation of the aortic wall revealed infiltrates, consisting predominantly of CD3+CD4+ T cells. Enlargement of pre-existing aneurysms was observed in the other two patients 10 weeks and 4 months after discontinuation of TCZ, respectively. Both patients were not eligible for surgical intervention and died during follow-up.

**Conclusion:** Our case series suggests that during treatment with TCZ, regular imaging is necessary in this patient population to detect development of structural changes such as aneurysms or dissections. Despite treatment, residual inflammation might persist which could contribute to eventual aortic complications.

**RENTAL TRANSPLANTATION DUE TO RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS (RPGN) AND SYSTEMIC AUTOIMMUNE DISORDERS. STUDY OF 42 PATIENTS FROM A SINGLE CENTER.**

L. Sanchez-Bilbao¹, M. De Cos-Gómez², J. C. Ruiz-San Millán², M. A. González-Gay¹, R. Blanco¹, H. U. Marqués de Valdecilla, Rheumatology, Santander, Spain; H. U. Marqués de Valdecilla, Nephrology, Santander, Spain

**Background:** Rapidly Progressive Glomerulonephritis (RPGN) is characterized by a rapid and severe decline in kidney function that may lead to a kidney transplantation. RPGN is classified in three groups: a) Type I or associated to anti-glomerular basement membrane antibodies (RPGN-GBMa), b) Type II or associated to immunocomplexes (RPGN-immunocomplexes), and c) Type III or pauci-immune (RPGN-pauci-immune). RPGN can be primary, without extra-renal involvement (RPGN-renal-limited), or secondary to systemic autoimmune disorders (RPGN-SAD), infectious diseases or drugs. Kidney transplantation in RPGN-SAD may be associated to a worse outcome.

**Objectives:** To assess a) clinical features of the three types of RPGN, b) comparison of post-transplant survival and graft survival between these three types.

**Methods:** We studied three groups of patients according to renal biopsy: a) RPGN-GBMa (n = 11), b) RPGN-immunocomplexes (n = 2) and c) RPGN-pauci-immune (n = 29). All these patients were transplanted in a single reference University Hospital. The main outcome variables were a) graft survival up to 15 years and patient survival up to 30 years and b) evolution of renal function (serum creatinine and proteinuria) in the first 5 years of follow-up.

**Results:** We included a total of 42 patients with renal transplant due to RPGN, mean age at diagnosis 44.87±17.01 years (48.53±17.45 at the time of the transplant). No significant differences at baseline were observed between the three RPGN groups regarding sex, age and cardiovascular risk factors. Renal biopsy had been performed in the 42 patients with RPGN: type I or RPGN-GBMa (n = 11, 26.2%), type II or RPGN-immunocomplexes (n = 2, 4.8%) and type III or RPGN-pauci-immune (n = 29, 69.0%). It was also reported the presence or absence of systemic autoimmune disorders (31% RPGN-SAD and 69% RPGN-renal-limited). According to the presentation and the clinical characteristics of the patients, another classification has been established: a) type I (18.2% (n = 2) Goodpasture-syndrome), b) type II (100% renal-limited), c) type III (13.8% (n = 4) granulomatosis with polyangiitis) and 20.70% (n = 6) microscopic polyangiitis. The evolution of serum creatinine and the proteinuria after the transplant is shown in TABLE 1 and 1.1. Neither differences were found in terms of graft and patient survival between the 3 groups (Figures 1 and 2).

</table>
Conclusion: Our study has shown similar graft and patient survival as well as renal outcome in renal transplant due to the three types of RPGN. Renal transplantation could be the best option for patients with end stage renal disease due to RPGN regardless of systemic manifestations.

Results: Patients with renal active AAV (n = 30) showed significantly higher urinary cell counts of total T cells, CD4+, CD8+, Treg and Th17 subsets than disease (n = 21) and healthy controls (n = 8). Patients with active renal AAV also showed a significantly higher percentage of Tregs in urine than in blood. While Tregs allowed a robust discrimination between active renal AAV and disease controls (receiver operator characteristics (ROC): area under the curve (AUC) 0.93, sensitivity 79%, specificity 95%) quantification of all T cells proved to be slightly more accurate (ROC: AUC 0.95, sensitivity 92%, specificity 95%). Soluble markers showed a slightly inferior discrimination (MCP-1 ROC: AUC 0.90, sensitivity 80%, specificity 100%, sCD163 ROC: AUC 0.92, sensitivity 96%, specificity 85%) while sCD25 and C5a were far less accurate.

Conclusion: Urinary T cells are significantly elevated in active renal AAV and the increased frequency of Tregs in urine suggests active migration into inflamed glomeruli and thereby the urine rather than mere bleeding of ruptured capillaries. These cells show great potential for a non-invasive biomarker close to the local inflammatory milieu. Particularly the total count of urinary T cells showed slightly superior biomarker characteristics than previously established soluble markers. Further studies are needed to confirm these results and show potential prognostic value of these cellular markers.

THU0322 EFFECTIVENESS OF COMBINED LOCAL COLCHICINE AND STEROIDS IN ORAL ULCERS OF BEHÇET’S DISEASE

S. A. A. Tabra, M. H. Abu-Zaied. Faculty of Medicine Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt

Background: Behçet’s disease (BD) is a chronic, multi-system vasculitic disease. It is characterized with relapsing episodes of oro-genital ulcers accompanied by cutaneous lesions, ocular symptoms, arthropathy, vascular thrombosis, central nervous system, gastrointestinal & cardiopulmonary involvements. Oral ulcers are frequently the first disease manifestation.Oral and genital ulcers cause pain and interfere with the quality of life. They may lead to difficulty in swallowing and walking. Most of them can be managed with topical glucocorticoids. Up till now there is no study discussed the effect of combined local therapy on oral ulcers in BD.1,2

Objectives: To evaluate the effectiveness of combined local therapy (colchicine, steroid, antibiotic and anesthetic) on oral ulcers in BD

Methods: This study included 44 Patients who had Behçet’s disease (according to International Study Group criteria) with active oral ulcers (at least three times in the previous 12-month period) Patients were excluded if they had active major organ involvement in the last 6 months. Patients with debilitating diseases also were excluded. Patients were randomly divided into two equal groups; group I received combined local therapy (lidocaine HCL 2.0% gel mixed with grated tablet of 5 mg prednisone) and group II received local therapy (lidocaine HCL 2.0% gel mixed with grated tablet of 5mg prednisone). Local treatments were applied to the lesions 3 times per day until healing of the ulcer (advised not to eat or drink for 30 minutes after application). All other topical medications were stopped during this study. All patients were assessed with Oral ulcer severity score (OUSS), Behçet’s Disease Quality of Life score (BD-QoL), Medical Outcomes Study Questionnaire Short Form 36 Health Survey (SF-36) at baseline and after 24 weeks.

Results: Thirty eight patients had completed this study; (20 in Group I & 18 in Group II). There were no significant differences between the 2 groups in both demographic data &educational status. At baseline there was no significant difference between both groups regarding all assessment measures. There was significant improvement (P<0.05) in both groups regarding OUSS, BD-Qol, SF-36 after 24 weeks. There was significant better improvement
Significant improvement after 24 weeks of the study

Pain: persistent myeloid profile.

THU0323

MYELOID BIOMARKERS IN GIANT CELL ARTERITIS AND POLYMYALGIA RHHEUMATICA – TWO INDEPENDENT COHORTS

1University Medical Center Groningen, Groningen, Netherlands; 2Aarhus University Hospital, Aarhus, Denmark; 3Hycult Biotech, R&D Department, Uden, Netherlands

Background: Giant cell arteritis (GCA) commonly overlaps with polymyalgia rheumatica (PMR). The incidence of GCA among PMR patients is between 16 and 21%, and both diseases are treated with long-term glucocorticoids (GCs). Patients with GCA suffer from inflammation of their large-sized arteries, whereas PMR is characterized by synovial inflammation. A key question for every physician dealing with a PMR patient is whether or not the patient also has GCA. Symptoms of GCA patients display a change in leukocyte composition with a shift towards the myeloid lineage, evidenced by elevated monocyte and neutrophil counts. Persistent of this myeloid bias (during and after treatment) is in congruence with mounting evidence that GCs do not sufficiently suppress the vascular/synovial inflammation, contributing to a relapsing disease course. Yet, it may be difficult to readily identify the myeloid bias in the blood, and therefore easily detectable biomarkers are required to monitor this myeloid bias in GCA and PMR patients.

Objectives: The first objective of this study is to identify disease specific biomarkers for GCA and for PMR using myeloid serum/plasma markers. Next, we assessed whether (a profile of) these markers could be used to reflect the persistent myeloid profile.

Methods: Biomarkers were measured in two independent cohorts: Groningen, the Netherlands (GPS cohort) and Aarhus Denmark (Aarhus cohort). Both cohorts included treatment-naive GCA and PMR patients, supplemented with age- and sex matched HCs (Table 1). Along with the GPS cohort, age-matched inflammatory controls were included. GCA-lookalike patients were added in the measurements for the Aarhus cohort. All patients started treatment with GCs, and follow-up samples were measured at 8 weeks for GCA patients. All measurements were performed by ELISA: sCD206, calprotectin, A1AT and elastase in serum samples, whereas PR3 and MPO were measured in plasma samples.

Results: Analyses of biomarkers in the two cohorts had mostly equivalent results. Compared to HCs, levels of sCD206, calprotectin, PR3 and A1AT were elevated in GCA, PMR and infection/GCA-lookalike patients. GCA patients had higher levels of sCD206 than PMR patients, but only in the Aarhus cohort this reached statistical significance (Aarhus: p<0.02, GPS: p=0.17). Treatment with GCs substantially affected the biomarker levels; in GCA patients of both cohorts, calprotectin and A1AT levels dropped, sCD206 levels remained high (unchanged), and elastase and PR3 levels increased. Next, we assessed whether the biomarkers correlated with inflammation and the myeloid bias in the GPS cohort. Particularly in GCA patients, A1AT levels correlated with inflammatory marker CRP. Elastase correlated significantly with neutrophil counts in both GCA (R=0.42) and PMR (R=0.57). Calprotectin correlated with neutrophil counts in both GCA and PMR, and with monocyte counts in GCA.

Conclusion: This is one of the first studies in GCA and PMR patients to study biomarkers in two independent cohorts. We consistently showed elevated levels of monocyte/macrophage and neutrophil products in both cohorts. Levels of sCD206 may help in discriminating GCA from PMR patients. The myeloid bias may be monitored using a combination of calprotectin and elastase levels. Additionally, sCD206 or calprotectin may serve as tissue inflammation markers under the cover of GC treatment, a notion to be further investigated using follow-up imaging data.

THU0324

CYTOMEGALOVIRUS REACTIVATION AND HIGH INITIAL SERUM CREATININE ARE SIGNIFICANT PROGNOSTIC FACTORS FOR SUBSEQUENT SEVERE INFECTIONS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

D. Waki1, K. Nishimura1, T. Yoshida1, K. Kadoba1, N. Tanaka1, H. Murabe1, T. Yokota1, Kurashiki Central Hospital, Department of Endocrinology and Rheumatology, Kurashiki, Okayama, Japan

Background: There are several reports that cytomegalovirus (CMV) reactivation resulted in more co-infections affecting survival in rheumatic disease, and CMV reactivation can lead to infections in granulomatosis with polyangiitis patients by inducing CD4+CD28- T cell and depressing naïve T cell populations. Despite this evidence, the prognostic value of CMV reactivation for severe infections in patients with connective tissue disease are still unknown.

Objectives: The aim of this study was to examine prognostic factors for severe infection during the early phase of treatment, especially in CMV reactivation, in patients with antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV) who received initial high dose corticosteroid therapy (prednisolone > 0.8mg/kg/day).

THU0324
Methods: We analyzed the data of 88 consecutive hospitalized patients newly diagnosed with AAV at our hospital from January 2008 to March 2019 in this retrospective cohort study. There were 52 patients with CMV reactivation during remission induction therapy compared to 36 patients without CMV reactivation. CMV reactivation was defined by the detection of CMV pp65 antigen in blood samples, and CMV positive cells ≥ 5 per 3.0 × 10³ polymorphonuclear neutrophils (PMNs). The variable for severe infections within 180 days with a p value < 0.1 in univariate analysis were selected for multivariate analysis using the Cox regression model. The positive predictive value (PPV) and positive likelihood ratio (PLR) of CMV reactivation for subsequent severe infections were also analyzed.

Results: Patients with CMV reactivation, compared to those without, had a higher prevalence of MPO-ANCA, renal manifestation and renal impairment at diagnosis, received hemodialysis (HD), older age, and high initial serum creatinine at diagnosis (HR 6.0; 95%CI: 2.00-20.73; p = 0.001) and high initial serum creatinine (≥ 1.5 mg/dl) at diagnosis, received HD, and CMV reactivation were associated with severe infections in the univariate analysis, although receiving cyclophosphamide or rituximab was not. Among these variables, CMV reactivation (Hazard ratio [HR] 3.50; 95% confidence interval [CI]: 1.22-10.10; p = 0.02) and high initial serum creatinine at diagnosis (HR 8.09; 95%CI: 2.00-32.73; p = 0.001) were independent risk factors for severe infections within 180 days. (Table 1) The PPV and PLR of CMV reactivation for subsequent severe infections were 35% and 1.91. When including high initial serum creatinine, PPV and PLR for subsequent severe infections were 67% and 7.26.

Table 1. Cox regression analysis for severe infections within 180 days.

† Renal involvement" was excluded in the multivariate analysis to avoid multicollinearity.

Conclusion: Our study shows that there should be focus on subsequent severe infections when CMV reactivation is detected during early phase of treatment, especially in renal-impaired patients with ANCA-associated vasculitis.

REDUCED OF TREG CELLS ASSOCIATED WITH THE DISEASE ACTIVITY OF ANCA-ASSOCIATED VASCULITIS

R Wu1, R Su1, T Ding1, H Xue1, J An1, X F Li1, C Wang1. The Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a group of autoimmune disease that can cause systemic organ damage, characterized with the presence of abnormal antibodies (ANCAs) in the circulation and the small- and medium- vessel vasculitis[1]. However, the etiology of AAV remained unclear. Several observations have showed that the breakdown of immune tolerance caused by many complex interactions was involved in the pathogenesis of AAV[2,3]. It has been confirmed that the disorder of the CD4+T cell, especially the imbalance of Th17 and Treg cells can destroy the immune tolerance and cause many autoimmune disease[3]. But the relationship between the Th17/Treg and AAV is unknown.

Objectives: We investigated the absolute numbers of CD4+T subsets cells in peripheral blood of patients with AAV and healthy adults, and then compared them in different disease activity of AAV to explore the role of CD4+T subsets cells in the pathogenesis and development of AAV.

Methods: 49 patients with AAV hospitalized at the Second Hospital of Shanxi Medical University from the May 2016 to the November 2019 were enrolled, and 31 age and gender-matched healthy adults were anticipated as controls. According to BVAS, the patients were divided into disease-activity group (BVAS≥15, n=27) and non-disease-activity group (BVAS<15, n=22). The absolute numbers of CD4+T subsets cells including Th17 and Treg in peripheral blood of these individuals were detected by flow cytometry. We analyzed whether there was difference of CD4+T subsets between the patients and healthy controls, and between disease-activity group and non-disease-activity group.

Results: There was significant decreased level of Treg cells in the patients with AAV compared with healthy controls, especially in the disease-activity group. The absolute numbers of Treg cells was decreased in the patients with AAV compared with healthy controls (P<0.001) leading to a higher Th17/Treg ratio in the patients (P<0.01). Similarly, the absolute number of Treg cells was decreased in the disease-activity group (P<0.01) compared with the non-disease-activity group, and the absolute number of Treg cells was significant negative correlation with the disease activity indexes such as BVAS (r=-0.342, P=0.016), erythrocyte sedimentation rate (ESR) (r=-0.315, P=0.027) and C-reactive protein (CRP) (r=-0.305, P=0.033). But there was no statistically significant in the absolute number of Th17 cells between the patients and healthy controls, and between disease-activity group and non-disease-activity group.

Conclusion: The results we investigated here suggested that the decreased number of Treg cells failed to control autoimmune inflammatory response and maintain immune tolerance, and the disease activity of AAV was associated with the reduced number of Treg cells.

TOFACITINIB IN THE TREATMENT OF SEVERE AND REFRACTORY BEHÇET’S DISEASE: A SINGLE-CENTRE EXPERIENCE IN CHINA

J. Liu1, L. Sun1, F. Zhang1, W. Zheng1, 2. Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Department of Rheumatology and Clinical Immunology, Key Laboratory of Rheumatology and Clinical Immunology, National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Beijing, China

**Background:** Small-molecule JAK inhibitors have succeeded in the treatment of rheumatoid arthritis, psoriasis, and inflammatory bowel disease. Tofacitinib is under investigation for various autoimmune diseases, but its effectiveness on Behçet’s disease (BD) has not been demonstrated.

**Objectives:** We aimed to investigate the efficacy and safety of Tofacitinib in the treatment of severe and refractory BD.

**Methods:** We retrospectively analyzed the efficacy and safety profile of Tofacitinib in treating severe and refractory BD patients in our hospital from 2017 to 2020.

**Results:** Thirteen BD patients (7 males and 6 females) were enrolled, with a mean age and median course of 40.6±14.7 years and 84 months (60, 120). Vascular/cardiac, gastrointestinal, and articular involvement were presented in 5, 6, and 2 patients, respectively. Three patients had multiple arterial stenosis or occlusion, two presented with aortic root dilation with aortic valve regurgitation, and one experienced perivalvular leakage (PVL). All the six patients with gastrointestinal involvement had multiple episodes of ileocecal and colon ulcers, intestinal bleeding, and three had anastomotic ulcers or leaks. All the patients had received high-dose glucocorticoids and immunosuppressants before tofacitinib therapy. They were then treated with Tofacitinib, 5mg twice daily, with background glucocorticoids and immunosuppressants, for a median of 6 months (range 4 to 19).

**Discussion:** After a median follow-up of 7 (5, 19) months, the ESR and CRP level decreased significantly (21.8±50.0 vs 8.3±19.5, mm/h, P<0.01, and 25.5±8.5, 49.5 mg/L vs 1.89±0.44, 6.65 mg/L, P<0.01, respectively). All patients with vascular/cardiac and articular involvement achieved clinical improved response. Vascular lesions of three patients were radiologically stable, no progressive aneurysm or PVL was observed. Two patients with intestinal ulcers revealed complete mucosal healing; the other three had sustained elevation of ESR and CRP, active mucosal ulcers, recurrent bleeding, or fistula formation. The dose of corticosteroids was tapered in six cases (46.2%), furthermore, the number of immunosuppressants lessened in seven cases. However, two patients had herpes zoster infection during follow up, while being treated with five to six immunosuppressants in addition to Tofacitinib for refractory intestinal ulcers.

**Conclusion:** Our study suggests that Tofacitinib is effective for the treatment of vascular and articular BD; given the limited data, its therapeutic effect on BD is yet to be confirmed.

**THU0327**

EFFECT OF IMMUNOSUPPRESSIVE MEDICATION ON GASTRO-INTESTINAL INVOLVEMENT IN SYSTEMIC SCLEROSIS PATIENTS STRATIFIED FOR DISEASE DURATION.

N. Van Leeuwen1, H. Fretheim2, O. Molberg2, T. Huizinga1, J. De Vries-Bouwstra1, A. M. Hoffmann-Voelt on behalf of NA. 1. Leiden University Medical Center (LUMC), Leiden, Netherlands; 2. Oslo University Hospital, Oslo, Norway

**Background:** Gastrointestinal tract (GIT) involvement is associated with high morbidity in systemic sclerosis (SSc) but the data on its impact from unselected and well characterized SSc cohorts are scarce. Currently, the effect of immunosuppressive (IS) treatment on GIT involvement is largely unknown.

**Objectives:** To evaluate the severity and worsening of GIT involvement in two prospective SSc cohorts. To assess factors associated with severity of GIT involvement, stratified for disease duration. To evaluate effect of IS treatment on worsening of GIT involvement.

**Methods:** All SSc patients fulfilling the 2013 SSc classification criteria from two SSc cohorts were evaluated. Incident SSc was defined as disease duration since first symptom non-Raynaud < 24 months at first presentation. GIT involvement was assessed by the UCLA GIT 2.0 score at baseline and after one year to assess worsening of GIT involvement. Worsening was defined as change > minimal clinical important difference for total score and for each of the seven subdomains. GIT involvement was defined as present if the patients reported symptoms resulting in a score of ≥0.01 and was segregated into mild (0.01 ≤ 0.5 or for fecal incontinence and distention/bloating < 1.01), moderate (0.5 ≤ 0.5 or for fecal incontinence and distention/bloating ≥ 1.01) or severe GI symptoms (> 1.01 or for distention/bloating > 1.61 or for fecal soiling > 2.01).

**Results:** In total, 834 SSc patients were included; 236 (28%) had incident disease (table 1). Incident cases (IC) showed comparable severity of GIT involvement compared to non-incident cases (NIC) except for significantly less severe reflux and distension/bloating (figure 1). Logistic regression showed female sex (OR 8.5(1.9-36.01)) and smoking (OR 2.9(1.2-7.3)) to be associated with GIT severity at baseline in IC; in NIC anti-centromere antibody (OR 1.7(1.3-2.2)) was additionally associated with GIT severity. The use of IS at baseline did not associate with GI severity at baseline. In total n = 685 (82%) never had IS treatment (83% NIC, 81% IC); of these 258 (38%) started with IS after baseline assessment (52% IC, 32% NIC, p =0.02). When comparing change of GIT involvement after one year between those who started IS and those who did not, worsening of GI symptoms occurred more frequently in patients who started IS treatment (figure 2), but notably, patients in this group were also more frequently anti-topoisomerase positive, had ILD, and diffuse disease subset compared to the patients without IS treatment; age and sex were comparable. In the logistic regression with adjustment for disease duration and severity, there were no significant associations between IS treatment and worsening on GIT involvement.

**Conclusion:** Regardless disease duration, about 1/3 of all SSc patients had moderate-severe GIT involvement. Disease duration and treatment initiation with IS did not have a significant influence on worsening of GIT involvement.

THU0328
SAFETY AND EFFICACY OF SUBCUTANEOUS TOCILIZUMAB IN SYSTEMIC SCLEROSIS: RESULTS FROM THE OPEN-LABEL PERIOD OF THE PHASE 3 FOCCUSED TRIAL

1University of Michigan, Ann Arbor, United States of America; 2Genentech, South San Francisco, United States of America; 3Roche Products Ltd, Welwyn Garden City United Kingdom; 4University of California, Los Angeles, Los Angeles, United States of America; 5University College London, London, United Kingdom

Background: The anti–interleukin-6 (IL-6) receptor-α antibody tocilizumab (TCZ) demonstrated skin score improvement and forced vital capacity (FVC) preservation in patients with systemic sclerosis (SSc) in a phase 2 randomized controlled trial.1,2 Data from the 48-week, double-blind (DB), placebo (PBO)-controlled period of the FOCUSced trial were previously presented,3 and open-label (OL) data up to week 96 are presented herein.

Objectives: To assess the long-term safety and efficacy of TCZ in SSc patients.

Methods: Adult patients with active SSc (≤60-month duration, modified Rodnan skin score [mRSS] 10-35, and elevated acute-phase reactants) treated with PBO or TCZ in the DB period received OL TCZ 162 mg SC weekly from weeks 48 to 96 in the OL period (PBO→TCZ→OL TCZ, respectively). Exploratory analysis of data up to week 96 included no formal statistical analyses. Changes in mRSS and percent predicted FVC (ppFVC) were assessed. Results: Overall, 92/105 TCZ (88%) and 89/107 PBO (83%) patients entered the OL TCZ treatment period at week 48, and 85/105→105→OL TCZ (81%) and 82/107 PBO→OL TCZ (77%) patients completed treatment up to week 96. Continued decline in mRSS was observed in the OL period for PBO→OL TCZ and TCZ→OL TCZ patients (Table). Change in ppFVC for patients who switched from PBO to TCZ (PBO→TCZ→OL) was comparable between weeks 48 and 96 (OL period) to the change in patients who received TCZ from BL to week 48 in the DB period (Table). Rates (95% CI) of serious adverse events from weeks 48 to 96 were 15.8 (8.6, 26.5) per 100 PY for TCZ→OL TCZ patients, 14.8 (7.9, 25.3) per 100 PY for PBO→OL TCZ patients, and 15.4 (11.0, 20.9) for all TCZ exposure over 96 weeks. One death occurred during the OL period in each arm. Conclusion: Although OL data have to be interpreted with caution, results from OL TCZ treatment show numeric improvements in mRSS and FVC preservation similar to those of the DB period, with a beneficial effect on trajectory of FVC decline in patients who switched from PBO to TCZ. Long-term safety results were consistent with the known safety profile of TCZ, and no new or unexpected events were observed.

DO: 10.1136/annrheumdis-2020-eular.642
Results: The first 2 dose cohorts have completed treatment: male/female 3 each, median age 61y (range 45-70), median MRSS at baseline 31 (range 23-39). Recruitment into cohort 3 is complete. AVID200 was well tolerated with no dose limiting toxicities or serious adverse events (SAEs). AEs, all considered possibly related, included single cases of Grade 1 dizziness and CPK elevation, and Grade 2 anemia. All patients demonstrated a decline in MRSS at 6 weeks by 3, 4, and 9 points in Cohort 1, and 2, 8, and 9 points in Cohort 2. Four of 6 patients demonstrated continued decrease in MRSS 12 weeks after the last dose, with all patients showing a decline in MRSS relative to baseline at the time point by 7, 6, and 7 points in Cohort 1 and 4, 8, and 13 points in Cohort 2. AVID200 in plasma engaged endogenous activated TGF-beta and potently neutralized signaling from exogenous TGF-beta 1 and 3, but not TGF-beta 2, across the treatment period. PD effects in skin biopsies, including expression of markers of SSC activity, TGF-beta activity, and myofibroblast-associated genes were assessed. Five of 6 patients showed decreased expression of PD biomarker genes, THBS1 and MS4A4A, comparing end of treatment biopsies to baseline, and all patients showed a decline in SER-PINE1 expression, a marker gene for TGF-beta activity. Clustering of RNA-seq expression data showed close coregulation of COMP, THBS1, SERPINE1, LOXL, COL10A1, COL11A1, COL12A1, CTGF, and CDH11, suggesting that blocking TGF-beta inhibits this group of profibrotic genes. Single-cell sequencing data show that expression of these genes is upregulated by subsets of SSC fibroblasts.

Conclusion: AVID200 at doses of 1 and 3mg/kg was well-tolerated in this first study in dcSSc patients. Evidence of anti-fibrotic effects as indicated by rapid, persistent and clinically meaningful declines in MRSS was observed in all patients, as well as AVID200 target engagement and modulation. Recruitment into additional dose and extension cohorts is ongoing. Together, these clinical data support selective TGF-beta 1 and 3 inhibition by AVID200 as a promising therapeutic approach for dcSSc.

EFFECTS OF NINTEDANIB IN PATIENTS WITH SYSTEMIC SARCOIDOSIS-ASSOCIATED ILD (SSC-ILD) AND DIFFERING EXTENTS OF SKIN FIBROSIS: FURTHER ANALYSES OF THE SENSICIS TRIAL

Y. Allanore1, V. Steen2, M. Kuwana3, C. Denton4, M. Matucci-Cerinic5, E. Volkmann6, D. Khanna7, D. Wachtlin8, M. Gahlemann 9, M. Quaresma 10, 6Department of Medicine, Division of Rheumatology, University of California, 7Department of Medicine, University of Michigan, Ann Arbor, MI, United States of America; 8Boehringer Ingelheim Pharma GMBH & CO. KG, Ingelheim, Germany; 9Boehringer Ingelheim (Schweiz) GmbH, 10Boehringer Ingelheim International GmbH, Ingelheim, Germany; 11Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland

Background: In the SENSCIS trial, nintedanib reduced the progression of SSC-ILD compared with placebo, as shown by a significantly lower rate of decline in forced vital capacity (FVC) over 52 weeks. There was no significant difference between treatment groups in change in modified Rodnan skin score (mRSS) at week 52. An mRSS of 18–25 has been proposed as an upper cut-off to enrich a cohort for serious adverse events (SAEs). AEs, all considered possibly related, included single cases of Grade 1 dizziness and CPK elevation, and Grade 2 anemia. All patients demonstrated a decline in MRSS at 6 weeks by 3, 4, and 9 points in Cohort 1, and 2, 8, and 9 points in Cohort 2. Four of 6 patients demonstrated continued decrease in MRSS 12 weeks after the last dose, with all patients showing a decline in MRSS relative to baseline at the time point by 3, 6, and 7 points in Cohort 1 and 4, 8, and 13 points in Cohort 2. AVID200 in plasma engaged endogenous activated TGF-beta and potently neutralized signaling from exogenous TGF-beta 1 and 3, but not TGF-beta 2, across the treatment period. PD effects in skin biopsies, including expression of markers of SSC activity, TGF-beta activity, and myofibroblast-associated genes were assessed. Five of 6 patients showed decreased expression of PD biomarker genes, THBS1 and MS4A4A, comparing end of treatment biopsies to baseline, and all patients showed a decline in SER-PINE1 expression, a marker gene for TGF-beta activity. Clustering of RNA-seq expression data showed close coregulation of COMP, THBS1, SERPINE1, LOXL, COL10A1, COL11A1, COL12A1, CTGF, and CDH11, suggesting that blocking TGF-beta inhibits this group of profibrotic genes. Single-cell sequencing data show that expression of these genes is upregulated by subsets of SSC fibroblasts.

Conclusion: AVID200 at doses of 1 and 3mg/kg was well-tolerated in this first study in dcSSc patients. Evidence of anti-fibrotic effects as indicated by rapid, persistent and clinically meaningful declines in MRSS was observed in all patients, as well as AVID200 target engagement and modulation. Recruitment into additional dose and extension cohorts is ongoing. Together, these clinical data support selective TGF-beta 1 and 3 inhibition by AVID200 as a promising therapeutic approach for dcSSc.

(54.2%) and pSS (62.5%) than idiopathic sicca syndrome (3.1%). Total OMERACT SGUS scores, total fibrosis scores, Heovear score were significantly higher in SSc and pSS compared to idiopathic sicca syndrome (Table 1). The proportion of the highest fibrosis grades among the four glands ≥2 were significantly higher in SSc (79.7%) than pSS (62.5%) and idiopathic sicca syndrome (46.9%).

There were no significant differences in PDS among 3 groups. Twenty-one patients (65.6%) of 32 SSc patients with OMERACT grade ≥2 were anti-centromere antibody (ACA)-positive compared with 9/27 (33.3%) SSc patients with scores of 0–1. The positivity of anti-Ro/60-SSA were also significantly higher in SSc patients with SGUS grade ≥2 (37.5%) than those with SGUS scores of 0–1 (3.7%). In SSc group, there was no significant difference in auto-antibody profile and organ involvement between patients with fibrosis scores ≥2 and those with scores 0–1.

Conclusion: Based on OMERACT definitions for SGUS, more than half of the patients with SSc, especially those with ACA, had salivary gland involvement. Salivary glandular fibrosis is more prominent in patients with SSc than those with pSS and idiopathic sicca syndrome.

THU033 CARDIOVASCULAR COMORBIDITIES ARE COMMON IN RHEUMATOID ARTHRITIS PATIENTS WHO PRACTICE LESS PHYSICAL ACTIVITY AND WHO HAVE WORSE FUNCTIONAL CAPACITY.

I. Pereira1, G. Ribas1, G. Castro1, G. Castelar2, A. B. Gavaz-Santo3, C. Albuquerque1, A. P. Gomides1, M. Bertolo1, P. Louzada Jr3, R. Giorgi1, M. F. Guimarães1, S. Radominsky4, K. Bongiolli5, M. D. F. Sauma4, C. Brenoi5, E. Contrin6, L. Mota7, J. Universidade do Sul de Santa Catarina, Palhoça, Brazil; 2UFRJ, Rio de Janeiro, Brazil; 3UnB, Brasília, Brazil; 4UNICAMP, Campinas, Brazil; 5USP São Paulo, Brazil; 6Hospital do Servidor Público Estadual de São Paulo, São Paulo, Brazil; 7UFGM, Belo Horizonte, Brazil; 8UFPe, Curitiba, Brazil; 9UFPA, Belém, Brazil; 10UFRGS, Porto Alegre, Brazil; 11Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

Background: Patients with rheumatoid arthritis have more cardiovascular comorbidities which contribute to hospitalization and mortality.

Objectives: This study aims to investigate whether there is an association between cardiovascular comorbidities in RA with subgroup of patients and clinical findings of the disease.

Methods: This study is a cross-sectional part of Rheumatoid Arthritis in Real Life (REAL), which is a multicenter prospective study conducted in Brazil, involving 13 centers specialized in the care of patients with RA. All subjects met the ARA (1987) or ACR/EULAR (2010) RA classification criteria. Subjects were submitted to clinical interview with physical exam and review of medical records. A sample of 1116 patients was selected for convenience. The association between cardiovascular comorbidities (systemic arterial hypertension (HA), diabetes mellitus (DM) type 2, dyslipidemia, stroke and heart failure), the clinical characteristics and laboratory parameters of RA was evaluated through chi-square hypothesis tests, Student’s t-test, Fischer exact test, correlation test and ANOVA. Also, correction Bonferroni test was used for multiple comparisons. Differences were considered statistically significant only when p ≤ 0.05.

Results: 89% of the patients were female, with a mean age of 58 years. 62% of patients with RA had comorbidities, with HA the most prevalent. There was a statistically significant association between cardiovascular comorbidities with age (6.1±9.6±years old vs 53.0±12.10 (p <0.001), lower educational level (n=282±6.6±5vs 143±3.35) (p <0.001), lower physical activity (n=132±73.3 vs 48±26.7) (p <0.001), disease duration (18.5±9.75 vs 14.4±8.61) (p <0.001), positive anti-CCP test (60.5% vs 39.5%) (p = 0.027), high clinical disease activity index (CAI) (65.9% vs 34.1%) (p <0.001), DAS28cHS (3.72±1.46 vs 3.49±1.58) (p = 0.008) and HAQ score (1.00±0.78) vs 0.83±0.77 (p <0.001).

Conclusion: The frequency of cardiovascular comorbidities is high in RA patients and is associated with age, disease duration and positive anti-CCP test. It is also important to see that these comorbidities are more common in patients with lower frequency of physical activity and lower functional capacity, higher disease activity score and lower level of education. Better control of disease activity and extensive information to patients about the importance of exercise should be parallel objectives in RA.
Background: Vasculopathy is a hallmark of systemic sclerosis (SSc). Laser speckle contrast analysis (LASCA) is a research tool to assess peripheral blood perfusion (PBP) (1). At this moment, its reliability has been attested in SSc patients, but its predictive value for future ischemic digital trophic lesions (DTL) is unknown (1).

Objectives: To investigate in an unselected, prospective SSc cohort if baseline LASCA PBP measurements can discriminate between patients who will develop ischemic DTL (iDTL) and those who will not.

Methods: Patients (fulfilling 2013 ACR/EULAR criteria and/or 2001 LeRoy and Medsger criteria) were recruited during the period of December 2017 to September 2018. LASCA was performed at baseline, in standardized conditions (1). Regions of interest (ROIs) (diameter 1 cm) were outlined on the 2nd–5th fingers both volar and dorsal. The ‘average PBP’ of these ROIs was calculated (expressed in arbitrary perfusion units [PU]). A monthly telephone survey was conducted for 1 year to investigate DTL occurrence. DTL were considered ‘ischemic’ if not related to calcinosis. Logistic regression and ROC analysis were used to assess if LASCA PBP is predictive of iDTL development (2).

Results: Of the 106 patients with complete follow-up (92 women [86.8%]; 18 limited SSc [170%], 82 limited cutaneous SSc [77.4%], 6 diffuse cutaneous SSc [5.7%]), 29 patients (27.4%) had a DTL history. Forty-nine patients (46.2%) were on vasodilator therapy. Only 7 patients developed at least 1 iDTL during follow-up (5.7%). 327 patients were identified through the Myositis Departmental database. All six studies showed an increased incidence of MI and/or stroke compared to the general population, with a suggestion in some of them that this incidence was particularly high in the first few years after disease onset.

Conclusions: In this pilot study with an unselected day-to-day SSc population, where patients were allowed to continue vasodilators, there was an unexpected low iDTL incidence, undermining the power of our study. Even though the observations in the subgroup of patients not taking vasodilators deserve future investigation to assess whether low PBP values, as measured by LASCA, are associated with a higher iDTL incidence.

Conclusion: In this pilot study with an unselected day-to-day SSc population, where patients were allowed to continue vasodilators, there was an unexpected low iDTL incidence, undermining the power of our study. Even though the observations in the subgroup of patients not taking vasodilators deserve future investigation to assess whether low PBP values, as measured by LASCA, are associated with a higher iDTL incidence.
The incidence rate of atherosclerotic CVE was 16.3/1000 patient-years (95% CI: 8.8-30.3), twice as high as expected by QRISK2. Analysis showed statistical difference with males (RR=6.49, p=0.002) and white patients (RR=5.04, p=0.02) although the statistical significance for white ethnicity was lost after adjusting for age and gender. Statistical analysis showed association between disease duration and higher incidence of atherosclerotic CVE, with a rate reduction of 0.7 per year from disease onset (p=0.01) after adjusting for age and gender.

**Fig. 1.** Atherosclerotic risk by disease duration

**Conclusion:** Our results suggest that atherosclerotic cardiovascular risk in inflammatory myopathies is underestimated, particularly early on the disease.

**Conclusion:** Our results represent the largest cohort of ICI-related myositis to date. Patients with overlap syndrome are treated more aggressively and have worse outcomes than those with myositis alone. Prospective studies are warranted to determine risk factors for developing myositis or overlap syndrome and to determine optimal treatment.

**IMMUNE CHECKPOINT INHIBITOR-RELATED MYOSITIS: A RETROSPECTIVE COHORT STUDY**

J. Aldrich1, X. Pundole1, S. Tummala1, C. Anderseni, N. Abdel-Wahabi, N. Palaskas1, A. Deswal1, M. Suarez-Almazor1. The University of Texas MD Anderson Cancer Center, Houston, United States of America

**Background:** Myositis is a rare immune checkpoint inhibitor (ICI)-related adverse event frequently associated with myasthenia gravis (MG) and myocarditis (MC) leading to mortality rates up to 52%.1

**Objectives:** To characterize the presentation, course and outcomes of patients with ICI-related myositis alone or with overlap syndrome (myositis with MG or MC or both).

**Methods:** We retrospectively identified a cohort of patients treated with ICI at MD Anderson Cancer Center between 2016 and 2019. Suspected myositis was identified using International Classification of Disease version 10 codes and confirmed by electronic medical record review of muscle enzymes, pathology, and other tests, when available. Patients with myositis alone or with overlap syndrome were compared using Fischer’s exact tests and t tests.

**Results:** During the study period 8,636 patients received ICI, of which 31 (0.36%) were diagnosed with myositis: 14 (45%) with myositis alone and 17 (55%) with overlap (MG in 5, MC in 4, MG and MC in 8). Twenty patients received programmed death-1 (PD-1) or programmed death-ligand-1 (PD-L1) inhibitors, and 10 received combination PD-1/PDL-1 inhibitor with a cytotoxic T-lymphocyte associated antigen 4 (CTLA-4) inhibitor. One patient received single agent CTLA-4 inhibitor (excluded from pooled data). For the entire cohort the median age at diagnosis was 69 years (range: 40-95 years); the most common presenting symptoms were fatigue in 27 (90%) patients, weakness in 24 (80%), and myalgia in 23 (77%); median CK was 2,236 U/L (range: 23-19,794 U/L). For treatment, 22 of 30 (73%) patients received at least one therapy in addition to steroids: plasmapheresis in 15 (50%) patients, intravenous immune globulin (IVIG) in 12 (40%), biologics in 9 (30%) (rituximab in 6, infliximab in 5, tocilizumab in 3), tacrolimus in 6 (20%), and mycophenolate mofetil in 4 (13%). Median length of exposure to steroids was 47 days (range: 1-250 days). Five (17%) patients were rechallenged with ICI after myositis resolution (3 with myositis alone, 2 with overlap), of which 1 (20%) patient experienced a myositis flare. Twenty-five (83%) patients were not rechallenged on ICI and 3 (12%) of those patients had a flare. Differences between patients with myositis alone compared to those with overlap are shown in Table 1. Patients with overlap more often received a second therapy, specifically plasmapheresis and IVIG, had longer hospitalizations and greater symptom burden at discharge. Overall death between groups was similar; however death attributed to the adverse event occurred only in those with overlap.

![Fig. 2. Kaplan-Meier survival plot to atherosclerotic event](image)

**Fig. 2.** Kaplan-Meier survival plot to atherosclerotic event

**Conclusion:** Our results suggest that atherosclerotic cardiovascular risk in inflammatory myopathies is underestimated, particularly early on the disease. Based on our results we would recommend a low threshold for primary prevention of atherosclerosis including the use of statins particularly for the first year after diagnosis.

**THU0337**

**THE EFFECTIVENESS OF PLASMA EXCHANGE THERAPY FOR ANTI-MDA5 ANTIBODY-POSITIVE REFRactory INTERSTITIAL LUNG DISEASE**

Y. Abe1, T. Kuga1, M. Kusaoi1, K. Tada1, K. Yamaji1, N. Tamura1, J. Juntendo University, Internal Medicine and Rheumatology, Bunkyo City, Japan

**Background:** This is an extended report of our study [1]. Anti-melanoma differentiation-associated gene 5 (MDA5) antibodies, which are closely related to interstitial lung disease (ILD) with or without rapid progression, are a type of myositis-specific autoantibody. Since rapid progressive-ILD (RP-ILD) with anti-MDA5 antibodies is refractory and fatal, intensive immunosuppressive therapy with combination calcineurin inhibitor, and intravenous pulse cyclophosphamide was developed, and was shown to improve patient survival and prognosis [2]. However, 20–30% of cases were still fatal, and several additional
therapies have been reported e.g. tofacitinib [3] and plasma exchange therapy (PE) [1, 4, 5].

Objectives: We evaluated the effect of plasma exchange (PE) on survival in patients with refractory RP-ILD who were positive for anti-MDA5 antibodies.

Methods: Among 167 patients newly diagnosed with PM/DM, clinically amyopathic DM, or cancer associated myositis from 2008 to 2019 at our hospital, 12 were diagnosed with refractory RP-ILD and were positive for anti-MDA5 antibodies. PE was used as an adjunct to standard therapy and consisted of fresh frozen plasma as replacement solution. The primary outcome was non-disease-specific mortality. anti-MDA5 antibody titres were measured by ELISA using the MESACUP anti-MDA5 test in 155 patients whose serum was frozen and stored at the time of diagnosis.

Results: Anti-MDA5 antibodies were detected in 35 patients, of whom 26 were diagnosed with RP-ILD and 11 were refractory to intensive immunosuppressive therapy. Seven patients received PE (PE group) and four did not (non-PE group).

Objectives: The 1-year survival rate of the PE group was higher than that of the non-PE group (100% and 25%, respectively, P = 0.011). Regarding adverse events associated with PE, two patients had anaphylactic shock, one had high fever due to fresh frozen plasma allergy and one had a catheter infection. All adverse events resolved with appropriate treatment.

THE CIRCULATING CD19-POSITIVE LYMPHOCYTES IN PATIENTS WITH SYSTEMIC SCLEROSIS: MODULATION WITHIN A YEAR AFTER THE INITIATION OF RITUXIMAB THERAPY

L. P. Ananyeva1, G. Garzanova2, O. Koneva2, M. Starovoytova2, O. Desinova2, O. Ovsyannikova2, M. Cherkasova2, A. Aleksanin3, *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; *V.A. Nasonova Research Institute of Rheumatology, Immunology, Moscow, Russian Federation

Background: Significant disorders of B-cell homeostasis have been detected in systemic sclerosis (SSc) [1,2]. The improvement of the disease with anti-CD20 monoclonal antibody rituximab (RTM) has been shown in SSc [3]. There are limited data on change in circulating B lymphocytes count after RTM treatment in patients with SSc.

Objectives: to investigate the modulations in absolute and relative numbers of circulating CD19-positive B lymphocytes (B-lymph) in patients with SSc within a year after the initiation of RTM therapy.

Methods: 77 pts with SSc were included in the prospective study. Mean age was 46.1±13.9 yrs., 83% were women, 59% had diffuse subset. Duration of SSc from the first non-Raynaud’s symptom was 5.6±4.4 yrs. All pts received low doses of glucocorticoids and 45%-immunosuppressive medications. The average follow-up of patients was 13.2±2.0 (11-18) months. The mean dose of RTM for the period of follow up was 1.43±0.60 grams, 48 patients received <2 g of RTM (group 1, mean of 1.1±0.1 g) and 23 patients received ≥2 g grams of RTM (group 2, mean dose of 2.2±0.8 g). Peripheral blood CD19-positive cell count was obtained by flow cytometry in patients and in 20 healthy persons, comparable in sex and age. Data are presented as the percentage (P %) and absolute number (AN) of B-lymph per ml of blood. In patients, the number of B-lymph was determined before (n=67 pts), within first month after the first introduction of RTM (n=66), 6 months later (n=34) and at the end of the study (n=71).

Results: At baseline, the AN and P% of B-lymph in pts did not differ from the healthy control. In pts with short disease duration (≤3 yrs.) the number of B-lymph before treatment with RTM was the higher (compared with longer duration >3 yrs) those who was ill ≥3 yrs.) and there was negative correlation between B-lymph count and duration of the disease (R -0.36, p=0.003 for AN and R - 0.48, p=0.001 for P %). The number of B-lymph was significantly lower in patients receiving cyclophosphamide (Cyc) before being started with RTM. There was a negative correlation between the AN of B-lymph and the cumulative dose of Cyc (R -0.293, p=0.016). In 1 month after the initiation of RTM a complete depletion of B-lymph was observed in all pts and in six months it persisted in 79% of cases, the rest began to repopulate (15%) or reached a normal levels (6%). At the end of the follow up the number of B-lymph was significantly lower than before treatment and a complete (n=41 pts) or partial (n=23) depletion of B-lymph remained, and only in 7 (10%) pts the count of this cells was normalized. We revealed a negative correlation between the AN of B-lymph and the cumulative dose of RTM (R-0.237, p=0.048). Higher doses of RTM in group 2 induced a more significant depletion than in group 1. Change in forced vital capacity and diffusing capacity of the lung (% predicted) during follow up were less pronounced for pts in group 1 compared with group 2 (ΔFVC 2,4% and 7 ,5% p=0,01; ΔDLCO -0,35% and 5,05%, p=0,001, respectively).

Conclusion: RTM may be more effective at the early stage of the disease, when the level of B-lymph is the highest. In SSc, the repopulation of B-lymph after depletion with RTM develops slowly. There were a more significant depletion of B-lymph and a more pronounced improvement in pulmonary function with the higher dose of RTM to compare with the lower one. This results indicate the option of a flexible dosing regimen of RTM.

THU0339

THE INFLUENCE OF SKIN CALCINOSIS ON THE PROGOSIS OF DIGITAL ULCERS IN PATIENTS WITH SSc.

S. Baronti1, V. Venturini1, M. Di Battista1, S. Macchiarulo1, A. Della Rossa1, M. Mosca1. 1Rheumatology Unit - Pisa University Hospital, Pisa, Italy

Background: Digital ulcers (DUs) are one of the main burdens in patients with systemic sclerosis (SSc) as they have a major impact on quality of life and prognosis. Some DUs are associated with the presence of subcutaneous calcinosis (SC) that may worsen their management, and the prognosis of these DUs is still not well defined.

Objectives: To define the characteristics of SSc patients with DUs related to SC and analyze the impact on prognosis and on healing time.
Methods: We prospectively collected data from DU patients who enrolled in our dedicated wound-care outpatient clinic from October 2018 to August 2019. Fifty-five patients were enrolled (50 females, 16 with limited-SSc and 39 with diffuse-SSc, mean age 62.3±17.2 years). For every DU we collected: presence/absence of calcinosis, pathogenesis (spontaneous, post-traumatic), area of DU, location (fingertip, periangual area, metacarpophalangeal, proximal/distal interphalangeal-PIP/DIP), VAS-pain at the baseline and after two weeks, local signs of infection (edema, redness), deep wound swab results and time to the healing. Additionally, we calculated the wound-bed score (WBS), at the baseline and we correlated the total score with the time of healing. All the ulcers were managed with weekly treatment following a definite protocol: wound cleansing, disinfection, mechanic debridement, application of antiseptic dressing.

Results: Out of 98 DUs evaluated, 24 (24.5%) were associated with SC. Patients with SC were older than those without calcinosis (67.1±16.9 vs 59.4±16.9 p<0.05) and were more frequently affected by lc-SSc (8–100% vs 5–20% p<0.001). There were no significant differences between the mean areas of DUs (SC 22±9mm² vs non-calcinosis 30±8mm²) neither in the localization of the ulcers: fingertip (41–61% vs 34–49.3%), periangual area (4–17.4% vs 16–23.2%), PIP (2.9% vs 13.8%), DIP (2.9% vs 9–13%) and MCP (1–4% vs 4–8.8%). The VAS-pain was not statistically different at the baseline (6.0 for SC vs 5.4), neither after 2 weeks (3.8 vs 3.2). Although the presence of local signs of infection was similar (3–20.8% vs 14–18.9%), the positivity for the wound swab was higher in SC compared with those without calcinosis (6–26.1% vs 9–11.5%; p=0.05).

All the DUs treated in our outpatient clinic healed but those with SC required more weeks (10.4±7.9 vs. 7.1±5.7; p=0.03). The WBS was similar in the two groups (8.96±0.46 in SC vs 9.43±0.33) and was negatively correlated with the time of healing (r=-0.24, p=0.02).

Conclusion: Although DUs with calcinosis have a different pathogenesis compared to those without SC, the location, dimensions and DU-related pain are similar in both groups. Despite these aspects, DUs associated with calcinosis are more prone to be infected and require more time to heal; the WBS may represent a simple, easy-calculated score to predict the time for DU healing. The presence of calcinosis may represent a negative prognostic factor in the management of SSc-DUs.

Background: A growing body of evidence suggests that the gut microbiota plays a significant role in the development of autoimmune diseases. Altered microbiota composition was associated with gastrointestinal and extraintestinal features in systemic sclerosis (SSc) patients.

Objectives: To look for differences in gut microbiota between SSc patients regarding disease duration, disease subset and occurrence of digital ulcers (DU).

Methods: SSc patients seen at our center were recruited in a prospective study. The exclusion criteria included antibiotic or probiotic treatment during the month prior to recruitment, recent hospitalization, BMI>30, diabetes mellitus or concurrent inflammatory bowel disease. Fecal samples were processed and 16S rRNA gene sequences were analyzed using the QIIME2 package.Weighted (quantitative) and unweighted (qualitative) UniFrac distances, alpha diversity for richness and homogeneity, taxa plots for species and phyia and ANCOM analyses were performed.

Results: During July 2018-May 2019, 26 SSc patients (mean age [SD] 53±12.7 years) disease duration 8.8 [7] years) fulfilled the criteria and were willing to participate in the study. Thirteen patients had diffuse SSc, 14 patients had active DU, 8 patients had Raynaud’s phenomenon only without DU, 2 patients had past DU. The microbiota was significantly more similar between patients without active DU compared to those with active DU (P=0.024), but species richness did not differ. Patients with SSc duration less than 6 years had significantly different microbiota compared to long-lasting SSc (unweighted PCoA – q=0.031). Significant variations concerning quantitative and qualitative UniFrac distances (q=0.063, q=0.005) and species richness (q=0.009) were found among patients with diffuse compared to limited SSc. Limited SSc was associated with greater species richness. Taxa plot analysis revealed higher relative abundance of Firmicutes in diffuse disease and of Actinobacteria and Bacteroidetes in limited SSc.

Conclusion: Disease duration, disease subset and active DU were associated with shifts in the microbiome of SSc patients. The impact of these changes on disease progression needs further elucidation.

DIGITAL ARTERY VOLUME INDEX (DAVIX®) PREDICTS THE ONSET OF FUTURE DIGITAL ULCERS IN PATIENTS WITH SYSTEMIC SCLEROSIS

K. Gjeloshi1, F. Danzo1, G. Lettteri2, G. Abignano2, M. Hinton3, A. Dean4, G. Cuomo4, O. Kubassova3, F. Del Galdo*5,6,7,7

1University of Campania “Luigi Vanvitelli”, Napoli, Italy; 2Istituto Reumatologico Lucano (IReL), Azienda Ospedaliera Regionale San Carlo, Potenza, Italy; 3IAG, GEO, London, United Kingdom; 4NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 5Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

Background: Neointima proliferation is a key pathologic feature of Systemic Sclerosis (SSc), causing arterial vessel narrowing and being the recognised culprit pathologic lesion in Digital Ulcers (DUs), pulmonary artery hypertension and renal crisis. Nevertheless, there are no validated imaging techniques to assess the severity of vascular involvement in SSc. Digital Artery Volume Index (DAVIX®) is an MRI Time of Flight angiography based quantitative score of digital arteries flow, without the need to administer contrast.

Objectives: To determine the value of DAVIX in predicting the onset of digital ulcers (DUs), the worsening of patient reported outcomes (PROs) and clinical parameters in SSc patients.

Methods: We enrolled 91 consecutive patients affected by Raynaud’s phenomenon, 63 of which fulfilled the 2013 ACR/EULAR classification criteria for SSc and 28 had a score <9. The data collected included: pulmonary function tests (PFTs), nailfold capillaroscopy, modified Rodnan Skin Score (mRSS), and Scleroderma Health Assessment Questionnaire Disability Index (sHAQ-DI). DAVIX© of the dominant hand was calculated as % mean of the 4 fingers, employing IAG proprietary algorithm. The distribution was analysed with DAgostino-Pearson normality test. Medians were compared by Mann-Whitney-Wilcoxon test, correlation with clinical parameters was performed using Spearman’s or Pearson test, as appropriate (Prism 7).

Results: 78/91 patients were females and median disease duration was 4 years (IQR=1.9-9). Complete historical and prospective follow-up data were available for 68 patients. DAVIX® correlated with mRSS (r=0.258, p=0.017), DLCO% (r=0.338, p=0.008) and capillaroscopy pattern (r=-0.388, p=0.001). In patients with DUs, DAVIX® showed a stronger correlation with DLCO% (r=0.786, p=0.048). DAVIX® predicted the worsening of HAQ-DI (r=-0.295, p=0.029), sHAQ (r=-0.333, p=0.038) and VAS pain (r=-0.269, p=0.038) independently of the presence of DUs. In the context of DU, 7 patients had DUs at baseline (8 with a positive history for DU’s), 12 patients developed DUs within 12 months, 3 of them had DUs at baseline. 38 patients did not have either previous or current DUs, neither did they develop new DUs within 12 months. DAVIX of patients
with current DUs was 3-fold lower than DAVIX of patients without DUs (0.18 vs 0.63 p=0.0093). Further, DAVIX of patients with positive history of DUs was 50% lower in patients with a negative history (median 0.34 vs 0.64, p=0.0052). In patients without current DUs, DAVIX of patients who developed new DUs within 12 months of follow-up was 3-fold lower than in patients who didn’t develop DU (0.21 vs 0.65, p=0.0156). ROC curve analysis indicated that DAVIX threshold <0.49 conferred a 4 times higher risk of developing new DUs (67%) compared to overall risk of our population 17.6%.

**Conclusion:** Outcome measures of vascular involvement in SSC are scanty. We demonstrated that DAVIX is a promising and feasible surrogate outcome measure of neointima proliferation in SSC and a useful imaging biomarker of vascular disease activity. The predictive value of DAVIX for the future onset of DU could be employed as a useful stratification tool in clinical trials. The value of DAVIX in predicting the worsening of PROs and clinical parameters in overall patients, may offer insights on the role of vascular disease activity in the overall progression of SSC.

**DECLINE IN SUBCLINICAL SYSTEMIC SCLEROSIS PRIMARY HEART INVOLVEMENT ASSOCIATES WITH POOR PROGNOSTIC FACTORS AND ACTIVE INTERSTITIAL LUNG DISEASE**

R. B. Dumitru1, L. A. Bissel1, G. B. Ferretti1, M. G. Kidambi1, G. Abignano1, J. Greenwood2, J. Biglands3, F. Del Galdo1, S. Plein4, M. H. Buch4.1. Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom; 3National Institute for Health Research, Leeds Biomedical Research Centre, Leeds, United Kingdom; 4Centre for Musculoskeletal Research, School of Biological Sciences, Manchester, United Kingdom

**Background:** Primary systemic sclerosis heart involvement (pSSc-HI) is described in the majority of SSC patients when sensitive methods such as cardiovascular magnetic resonance (CMR) are used1. The natural history of these subclinical findings are unknown.

**Objectives:** To evaluate for interval change in subclinical pSSc-HI, the association between change in CMR abnormalities and disease phenotype and whether disease modifying antirheumatic (DMARD) and/or vasodilator treatment influence the CMR course.

**Methods:** SSC patients, fulfilling the 2013 ACR/EULAR criteria, with no cardiocascular (CV) disease, diabetes and no more than 2 CV risk factors had two CMRs performed (V1 & V2; minimum 1 year apart). A 3T CMR with late gadolinium enhancement (LGE), T1 mapping for extracellular volume (ECV of diffuse fibrosis) quantification and stress perfusion was undertaken.

**Results:** 31 SSC patients were evaluated, with median (IQR) follow up (between the 2 CMR scans) of 33 (17, 37) months. Median (IQR) age was 52 (47,60), 32% had diffuse cutaneous SSC, 32% interstitial lung disease (ILD), 29% Scl70+.

4/31 patients had a non-ischaemic LGE pattern suggesting focal fibrosis at V1, with no change in the pattern, distribution, or median (IQR) LGE scar mass between V1 and V2 (1.88 [1.01, 6.34] vs 1.70 [1.21, 4.18]). At V2, 2 additional patients showed focal fibrosis, of which one had an episode of clinically diagnosed myocarditis. No significant change in ECV, T1 native, myocardial perfusion reserve (MPR) or left ventricle (LV) volumes and function were noted at V2 compared with V1 (p>0.01).

SSC patients with either increase in pre-existing LGE scar mass (n=1) or new fibrosis were all dcSSc, with ILD, 2 Scit70+. A reduction in forced vital capacity and total lung capacity associated with a reduction in LV ejection fraction (LVEF) (rho=0.413, p=0.021; rho=0.335, p=0.07) and MPR (rho=0.543, p=0.007; rho=0.627, p=0.002).

Patients receiving DMARD treatment had higher baseline LV end-diastolic volume compared to those with no DMARD treatment [mean (SD) 78 (19) vs 69 (10), p=0.167]. A decrease in LV stroke volume and an increase in T1 native at V1 vs V2 was noted for those on DMARD [mean (SD) 49 (8) vs 46 (6), p =0.023; 1208 (65) vs 1265 (56), p=0.008 respectively] (Figure 1). No significant change in CMR measures in those receiving vasodilator or angiotensin-converting-enzyme inhibitor treatment was noted (p>0.01).

**Conclusion:** This first, pilot longitudinal study of CMR-defined subclinical pSSc-HI suggests largely stable appearances with follow-up. Progression of new focal fibrosis and decline in LV function and MPR, where observed, associated with poor prognostic factors of SSC and ILD progression. Consistent with this, individuals on DMARD appeared to show interval decline. Larger longitudinal studies are warranted to confirm these findings and inform on utility of CMR monitoring of subclinical pSSc-HI in poor prognosis SSC.

**AUTOANTIBODIES CAN PARTLY PREDICT SEVERITY OF DAMAGE BUT NOT EXTENT IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOSITIS**

F. Espinosa-Ortega1, M. Holmqvist2, D. Matalonchi2, C. Mammen3, I. E. Lundberg1, H. Alexanderson1. 1Karolinska Institute Solna, Rheumatology Division, Department of Medicine, Stockholm, Sweden; 2Karolinska Institute, Solna, Clinical Epidemiology Division, Department of Medicine, Stockholm, Sweden; 3National Institute of Musculoskeletal and Skin Diseases, National Institutes of Health, Muscle Disease Unit, Laboratory of Muscle Stem Cells and Gene Regulations, Baltimore, United States of America

**Background:** Patients with idiopathic inflammatory myopathies (IIM) might suffer from irreversible damage once inflammation has decreased. Autoantibodies are found in up to 80% of patients with IIM and are coupled with specific clinical features. Whether autoantibodies can be used as biomarkers to predict patterns of damage in IIM remains unknown.

**Objectives:** To investigate the association between autoantibodies and organ damage in patients with IIM using longitudinal national register data.

**Methods:** Data were retrieved from the electronic Swedish Rheumatology Quality Register (SRQ). Patients (n=302) with a clinical diagnosis of IIM (2017
EULAR/ACR criteria) were included. Autoantibody status was tested by either line blot or RNA- and protein immunoprecipitation; HMGCR and FHL-1 autoantibodies were tested by ELISA. Patients were grouped into six categories of autoantibodies (Table 1). The Myositis Damage Index (MDI) score was applied to measure organ damage using both components (extent and severity) as a continuous variable and were analyzed using generalized estimating equations (GEE). A categorical variable for each time point of MDI assessment since diagnosis was created to adjust for time (Table 2). A base model which included autoantibody group and time was fit. Other potential predictors included age at diagnosis, sex, disease duration from diagnosis to inclusion to SRQ, arthritis, Raynaud, mechanics’ hands and heart involvement at registry; core set measures at each MDI time point allowing multiple longitudinal observations were also tested.

Iannone⁴. ¹Unit of Rheumatology, Department of Emergency and Organ Transplantation, University of Bari, Italy, Bari, Italy; ²Unit of Human Anatomy and Histology, Department of Basic Medical Sciences, Neuroscience and Sense Organs, Bari, Italy, Bari, Italy; ³Rheumatology Division, University and IRCSS Polclinic S. Matteo, Pavia, Italy, and European Reference Network RECONNET, Pavia, Italy; ⁴Unit of Rheumatology, Department of Basic Medical Sciences, Neuroscience and Sense Organs, University “Aldo Moro” of Bari, Bari, Italy, Bari, Italy; ⁵Unit of Neuropsychiatry, Department of Basic Medical Sciences, Neuroscience and Sense Organs, University of Bari, Bari, Italy, Bari, Italy; ⁶Institute of General Surgery “G Marinaccio”, Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy

Background: Dermatomyositis (DM) shows a wide clinical spectrum that seems to be different based on the type of autoantibody status. Furthermore, less is known regarding to the histopathological of different serological subsets of DM

Objectives: The aim of our study was to investigate clinical and histopathological hallmarks in adult DM patients positive for anti-Mi2 (Mi2+) antibody compared to DM patients negative for anti-Mi2 (Mi2-)

Methods: All clinical data of adult DM patients admitted in tertiary Rheumatology Units, who fulfilled EULAR/ACR 2017 classification criteria, were included in this study. Overlap syndrome and antisynthetase syndrome were exclusion criterion. Serum samples were tested in the local reference laboratories using line immunoblot assay for Myositis autoantibodies.

Histopathological study was carried out from muscle biopsies performed for diagnostic purpose in outpatient clinic of Bari (Italy) University. Quantitative analysis was performed for myofiber and capillary features, whereas semi-quantitative analysis (score from 0 to 3) was performed for inflammatory infiltrate, both at endomysial and perimysial sites

Results: A total of 95 DM patients, followed for a median (IQR) follow-up of 28 (9-85) months, were analyzed. Of these, 23 (24.2%) patients (87% female, mean age at onset 55.4±16.2 years) were anti-Mi2+, while 72 (75.8%) patients were Mi2- (72.2% female, mean age at onset 55.2±17 years). All Mi2+ patients showed muscle involvement. Moreover, Mi2+ DM showed higher levels of serum creatine kinase (CK) at onset compared to Mi2- (CK (IQR): 2649 UI/l (1130-6000) vs 575 UI/l (164-1617), p<0.001). Prevalence of interstitial lung disease (ILD) was lower in Mi2+ patients (8.7% vs 30.6%, p=0.05), and no case of rapidly progressive ILD (RP-ILD) was found. Survival analysis at 5-years follow-up highlighted good survival for Mi2+ patients, but not different from Mi2- (95.7% vs 83.1%, p=0.151). Multivariate analysis showed that age at onset (HR:1.07), RP-ILD (HR:36.2) and cancer associated myositis (HR:6.1) correlated with a poor prognosis. Finally, a total of 26 biopsies (12 Mi2+ and 14 Mi2-) were included into the histological analysis showing higher prevalence of necrotic/degenerating myofibbers (median (IQR) 2.6 (0.7-11)% vs 0.6 (0.4-1.1)%, p=0.009) and sarcoplasmic deposit of membrane attack complex (MAC) (median (IQR) 0.2 (0-12)% vs 0 (0-0%)p<0.009) in Mi2+ patients. In addition, the endomyosial macrophage score was higher in Mi2+ patients (median 1.5 (0.25-2) vs 0.5 (0-1), p=0.031).

Conclusion: Mi2+ patients represent a specific DM subset with higher muscle damage, sarcoplasmic MAC deposits and endomyosial macrophages infiltration as histological hallmarks

EFFECT OF THE LONG-TERM RITUXIMAB TREATMENT ON B-LYMPHOCYTES AND ANTINUCLEAR AUTOANTIBODY LEVEL IN PATIENTS WITH SYSTEMIC SCLEROSIS

L. Garzanović1, L. P. Ananyeva1, O. Koneva1, O. Desinova1, O. Ovsyannikova1, M. Staroveytova1, S. Gukhova1, M. Cherkasova1, A. Alekxankin1, V.A. Nasonova Research Institute of Rheumatology, MOSCOW, Russian Federation

Background: Anti-B-cell therapy is seen as a promising therapeutic option for systemic sclerosis (SSc). The study of antinuclear antibody levels during treatment with rituximab (RTX) in patients (pts) with SSc could have theoretical and practical interest.

Objectives: To assess the changes in ANA, anti-topoisomerase-1 (Scl-70) levels and B-lymphocytes (B-lym) count during RTX therapy in the prospective observation.

Methods: This prospective study included 88 pts with SSc, 83% of them had interstitial lung disease and 75% had positive Scl-70 autoantibody. The mean age was 47 yrs (17-71), female-73 pts (83%), the diffuse cutaneous subset of the disease had 50 pts (57%). The mean disease duration was 5,9±4,8 yrs. The mean follow-up period was 27 months (12-42). The cumulative mean dose of RTX was 2,9±1,1g. All patients received prednisolone at a dose of 11,7±4,4mg, immunosuppressants received 42% of them. Patients were divided into groups depending on the duration of the disease: group 1 (n=33) - up to 3 yrs, group 2 (n=25) - from 3 to 6 yrs, group 3 (n=30) - more than 6 years (6-18yrs). The results are presented in the form of mean values, median, upper and lower quartiles.

Results: Parallel to clinical improvement in most patients (96%) we found positive changes in many parameters at the end of the study compared to the baseline. The Rodnan skin score decreased from 11,21±9,33 to 6,19±4,74 (p<0,001). The disease activity index (ESCSG-AI) decreased from 2,9±1,74 to 1,36±1,15 (p<0,001). Forced vital capacity, % predicted, increased from 45,56±17,72 to 47,62±16,96 (p<0,019). The pts of the group 1 showed the highest values of B-lym at baseline and level of B-lym decreased from 0,326±0,22 to 0,098±0,01 (Δ0,318) at the end of the study. In group 2 depletion was less pronounced (from 0,197±0,14 to 0,026±0,07 (Δ0,171) and the lowest depletion was observed in group 3 (from 0,15±0,16 to 0,019±0,07 (Δ0,131), p<0,001 for all groups. An initially positive ANA was found in 92% of pts (range 1/320-1/1280). During observation, the number of pts with high (1/640-1/1280) ANA titers decreased from 70 to 41 (p<0,001), and the average level of ANA decreased by 30-40% in all groups. At baseline 63 pts (75%), had positive Scl-70 with equal levels in all groups. At the end of the study level of Scl-70 decreased from 125,02±89,12 to 106,68±86,89 units/ml (p<0,007). A negative correlation was found between the duration of the disease and ANA (r = -0,54; p<0,003) and Scl-70 (r = -0,44; p<0,017).

Conclusion: In our study a clinical improvement was shown in most pts at the long-term complex therapy, including RTM. We found a significant decrease in the absolute number of B-lym, as well as decrease of ANA and Scl-70 levels. Initially pts with a short duration of the disease had a higher level of B-lym and in these pts depletion was more pronounced, compared to those with a longer duration of the disease. However, the level of Scl-70 and ANA decreased both to those who started RTX therapy at an early stage of the disease (<3yrs) and to those who had a long disease duration.

THU0346

SARC-F PERFORMANCE FOR SARCOPENIA SCREENING IN PATIENTS WITH SYSTEMIC SCLEROSIS

V. Hax1, R. Santo1, L. Santos1, M. Farinon1, M. De Oliveira1, G. Levi Três1, A. A. Gasparin1, M. Bredemeier1, R. Xavier1, R. Mendonça Da Silva Chakr1, 1Hospital de Clínicas de Porto Alegre, Department of Rheumatology, Porto Alegre, Brazil; 2Hospital Nossa Senhora da Conceição, Department of Rheumatology, Porto Alegre, Brazil

Background: Because the method of diagnosing sarcopenia is complex and is considered to be difficult to introduce into routine practice, the European Working Group on Sarcopenia in Older People’s EWGSOP) recommends use of the SARC-F questionnaire as a way to introduce assessment and treatment of sarcopenia into clinical practice. Only recently, some studies have focused their attention on the presence of sarcopenia in systemic sclerosis (SSc) and there is no data about the performance of SARC-F in this population.

Objectives: To test the diagnostic properties of the SARC-F questionnaire for sarcopenia screening in SSc patients.

Methods: Cross-sectional study, including 94 SSc patients assessed by clinical evaluation, laboratory and pulmonary function tests. Sarcopenia was evaluated using the EWGSOP diagnostic criteria updated in 2019 (EWGSOP2): dual-energy X-ray absorptiometry, handgrip strength, and short physical performance battery (SPPB)1. Participants also completed the SARC-F questionnaire. The questionnaire’s performances were evaluated through receiver operating characteristic (ROC) curves and standard measures of diagnostic accuracy were computed using the EWGSOP2 criteria as the gold standard for diagnosis of sarcopenia.

Results: Sarcopenia was identified in 15 (15,9%) SSc patients by the EWGSOP2 criteria. Area under the ROC curve of SARC-F screening for sarcopenia was 0.588 (95% confidence interval [CI] 0.482, 0.688) (figure 1). The results of sensitivity, specificity, positive likelihood ratio (PLR) and negative likelihood ratio (NLR) with the EWGSOP2 criteria as the reference standard were 35.71% (95% CI, 12.76-64.86), 81.01% (95% CI, 70.62-88.97), 1.88% (95% CI, 0.81-4.35) and 0.79% (95% CI, 0.53-1.19), respectively. The optimal cut-off point of SARC-F in our sample was ≥ 4 (Youden index: 0.21), the same cut-off point recommended in the literature2,3. Only 6 (40%) out of the 15 participants with sarcopenia were identified by the SARC-F questionnaire in our population. However, the SARC-F properly identified 4 out of 5 patients who had severe sarcopenia.

Conclusion: This is the first study to evaluate the performance of SARC-F questionnaire for sarcopenia screening in patients with SSc. Although it appropriately identifies severe cases of sarcopenia, the SARC-F alone may not be an adequate screening tool in high-risk populations, such as SSc, that may benefit from early intervention and treatment.

CLINICAL DESCRIPTION OF A COHORT OF PATIENTS WITH SCLEROTIC-TYPE CHRONIC GRAFT-VERSUS-HOST DISEASE TREATED IN A MULTIDISCIPLINARY PRACTICE

C. Himéz1, C. Román2, M. E. Acosta3, L. Gómez-Lechón1, L. Pantoja2, M. D. Sánchez2, G. Compañ2, C. A. Montilla-Morales1, L. López2, 1Hospital Universitario de Salamanca, Salamanca, Spain; 2Hospital
Background: Graft versus host disease is the most frequent complication after allogeneic transplantation of hematopoietic progenitors. Its chronic form usually involves a multisystemic syndrome that reflects a complex immune response with varying degrees of inflammation, immune dysregulation and fibrosis, responsible for the characteristic clinical manifestations of the disease. Joint, muscular and fascial involvement represents one of the areas, often unnoticed or poorly evaluated, that negatively impacts the physical function and quality of life of these patients.

Objectives: Describe the presence of musculoskeletal manifestations and their clinical characteristics in patients with chronic GVHD (cGVHD) evaluated in a multidisciplinary consultation

Methods: Descriptive and retrospective observational study to detail the initial presence and during the follow-up of diagnostic and nonspecific musculoskeletal manifestations of cGVHD in a cohort of 103 patients included in the database. The clinical characteristics of 68 patients with a defined diagnosis of sclerotic cGVHD are described. Demographic variables are collected along with clinical conditions about transplant and in a systematic way the assessment according to diagnostic criteria of the American National Institute of Health 2015 highlighting: range of motion scale and photographic range of motion (P-ROM) scale in shoulders, elbows, hands and ankles; and laboratory data: presence of eosinophilia and autoantibodies. Descriptive and frequency statistical analysis was done using Microsoft Office Excel 2007.

Results: Sixty-eight (66%) patients meet diagnostic criteria for sclerotic cGVHD during follow-up. Forty-five (66.2%) women and 23 (33.8%) men, with a mean age of 54.5 years (range 10-78). Acute myeloid leukemia was the reason for transplant in 20 (29.4%) followed by non-Hodgkin lymphoma in 15 (16.2%). In 40 (58.7%) patients it was performed from a related donor and with reduced intensity conditions about transplant and in a systematic way the assessment according to diagnostic criteria of the American National Institute of Health 2015 highlighting: range of motion scale and photographic range of motion (P-ROM) scale in shoulders, elbows, hands and ankles; and laboratory data: presence of eosinophilia and autoantibodies. Descriptive and frequency statistical analysis was done using Microsoft Office Excel 2007.

Conclusion: Joint involvement secondary to sclerosis is very common in our cohort, mainly of the dorsal wrist flexion with deleterious repercussion on physical function. It needs to be recognized and evaluated early with validated scales. The search for new biomarkers associated with fibrosis, the use of advanced imaging techniques and the multidisciplinary approach can help improve the prognosis of patients with cGVHD.

THU0348

ALTERED IMMUNE RECOGNITION OF SPECIFIC GUT BACTERIA BY IMMUNOGLOBULINS IN EARLY SYSTEMIC SCLEROSIS

A. M. Hoffmann-Vold1, K. Andréasson2, S. Hyll Hansen1, S. Midted1, H. Fretheim1, H. Didriksen1, T. Garen1, E. Bækkevold1, Ø. Midted1, R. Hesselstrand2, B. K. Chung1, Ø. Møllerg1, "Oslo University Hospital, Oslo, Norway; 1Huddinge University Hospital, Huddinge, Sweden; 2NTNU, Trondheim, Norway"

Background: Gastrointestinal tract (GIT) involvement is highly prevalent in systemic sclerosis (SSc) and associates with GIT symptoms that are present early and progress over time. Changes in gut microbiota are often reported in inflammatory disease settings but whether GIT symptoms associate with altered immune recognition of specific gut bacteria in early SSc is unknown.

Objectives: Here, we profiled Ig coating patterns of gut bacteria in early disease from two well-characterized SSc cohorts to determine if the pattern and extent of bacterial immunoglobulin (Ig) coating differs in early SSc.

Methods: We collected fecal material from early SSc patients (<36 months from time of diagnosis) at Oslo and Lund University Hospitals and from healthy age and gender matched controls (HC). To assess whether adaptive immunity was triggered against gut microbiota in early disease, we sorted and sequenced IgA, IgM and IgG coated bacteria from fecal samples by flow cytometry and performed 16s rRNA sequencing to compare the relative Ig coating of early SSc patients to HC. Data was resolved to the family level, rarefied to 5101 reads and converted to relative abundance. Taxonomic profiles, relative abundance, IgA, IgM and IgG coating patterns and extent of Ig coating were assessed. Unadjusted p-values <0.05 were defined as significant.

Results: We included 50 SSc patients (26 from Oslo, 24 from Lund) with early SSc and 9 gender and age matched HC. Mean age of SSc patients at time of inclusion was 53 years, mean time since diagnosis was 13 months; 82% were female, 61% had limited cutaneous SSc and 43% were anti-centromere antibody positive. In all, 82% were treatment naïve while 18% had received either cyclophosphamide or mycophenolate mofetil immunosuppressants. We found increased relative abundance of IgA coated Desulfovibrionaceae in both SSc cohorts compared to HC and increased IgM and IgG coating of Veillonellaceae and Streptococcaceae (Figure 1). All of these bacteria have previously been associated with other autoimmune diseases or pro-inflammatory status; Desulfovibrionaceae to immune activation in the gut, and Veillonellaceae and Streptococcaceae to other chronic inflammatory and fibrotic conditions. While abundance of IgA coated Desulfovibrionaceae was higher in cyclophosphamide or mycophenolate mofetil-treated SSc patients than untreated patients, Veillonellaceae and Streptococcaceae were not affected by treatment. A lower abundance of IgA and IgM coated Akkermansiaaceae; and IgM and IgG coated Bifidobacteriaceae was detected in treated compared to treatment naïve early SSc patients (Figure 2).

Discussion: We found altered Ig coating patterns and extent of Ig coating to inflammatory-associated gut bacteria differs between treatment-naïve, early SSc patients treated with cyclophosphamide or mycophenolate mofetil and HC which suggests...
immunosuppressive treatments may modify gut microbiota in SSc. Overall these findings support the involvement of altered immune recognition of specific gut bacteria in early SSc.

**THE RELATIONSHIP BETWEEN DISEASE ACTIVITY AND SEVERITY IN SYSTEMIC SCLEROSIS: A PROSPECTIVE ANALYSIS OF 278 PATIENTS**

Y. Yalçınkaya1, N. Aliyeva1, S. Amikishiyev1, Y. Cagatay1, B. Artim-Esen1, A. Gul1, L. Ocal1, M. Inanc1, Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

**Background:** Evaluating disease activity and severity in systemic sclerosis (SSc) is crucial to define the patients who are candidate for treatment options. **Objectives:** We aimed to investigate the relationship between disease activity and severity in SSc in a large cohort. **Methods:** This is a cross-sectional prospective analysis of 278 (253 females) patients fulfilling ACR/EULAR (2013) classification criteria for SSc. Disease activity and severity were calculated separately for cutaneous subsets (EscSG and Medsger). The patients were grouped as inactive if EscSG score=0, mildly active if EscSG score=0.3, active if EscSG score≥0.3. **Results:** The mean age, duration of Raynaud’s and non-Raynaud features were 48.5±13.1, 12.1±9.8 and 8.3±7.5 years respectively. Characteristics of the SSc patients were summarized in table-1.

**Conclusion:** One third of our cohort was found to have active disease despite treatment and only 12% had inactive disease. Skin involvement and severity of different organs were shown to be higher in patients with active disease in both cutaneous subsets, together with severity of lung, peripheral vascular and gastrointestinal involvements in active icSSc. LcSSc and dcSSc patients who had mildly active disease also had severe disease similar to those with active patients. Disease activity and severity should be assessed as separate measurements to highlight the course of the disease and may guide to the management of patients with SSc.

**LOGOPEDIC TESTING IN SSC PATIENTS REVEALS HIGH FREQUENCY OF OROPHARYNGEAL DYSFUNCTION: A MONOCENTRIC EXPERIENCE**

M. Wirths1, O. Hudowen2, U. Hoffmann3, U. Müller-Ladner4, U. Lange5, P. Klemm6, Justus Liebig University Giessen, Campus Kerckhoff, Rheumatology, Immunology, Osteology and Physical Medicine, Bad Nauheim, Germany; 1Justus Liebig University Giessen, Campus Kerckhoff, Rheumatology, Immunology, Osteology and Physical Medicine, Bad Nauheim, Germany; 2Logopädische Praxis Ulrike Hoffmann, Bad Nauheim, Germany

**Background:** Up to 98% of patients with systemic sclerosis (SSc) show involvement of the gastrointestinal system (GI) [1]. While meteorism, heartburn and GI dysmotility are very common and accessible to pharmacologic treatment on an evidence based level [1–3], checking for oropharyngeal dysfunction is usually not part of the standard diagnostic algorithm. However, in a survey of the German Network for Systemic Sclerosis (DNSs) patients reported coughing and or a sore voice in up to 78% [1]. As impairment in speaking or swallowing for example does not only substantially reduce quality of life, it can also be very stigmatizing. In addition, the usual prokinetic therapy of GI-involvement, e.g. metoclopramide, does not appear to improve these symptoms. As the first step to approach this problem is the qualitative and quantitative description, we evaluated the oropharyngeal dysfunction in our cohort of SSc patients by detailed logopedic assessment.

**Objectives:** To evaluate the frequency and type of oropharyngeal dysfunction, e.g. swallowing or speaking, in patients with SSc and to elucidate the correlating and associated factors, e.g. disease duration or modified Rodnan Skin Score.

**Methods:** After obtaining written consent, oropharyngeal function using a standardized assessment protocol was evaluated in patients with SSc fulfilling the ACR/EULAR criteria by a speech therapist. Furthermore, we investigated whether oropharyngeal dysfunction is associated with patients’ characteristics. In addition, all patients received instruction for a training program to treat their individual oropharyngeal dysfunction.

**Results:** 37 patients with d/lSSc were assessed for eligibility. 34 patients met the inclusion criteria (3 patients did not speak German) and written consent was obtained. Oropharyngeal dysfunction (impairment of speaking, swallowing, breathing or oropharyngeal muscle function) was found in 29 of 34 (85%) of both d/lSSc patients. Neither the subtype of SSc, disease duration nor mRSS were significantly correlated with oropharyngeal dysfunction in general. Only GI involvement in general was associated with oropharyngeal dysfunction.

**Conclusion:** 28 of the 34 (82%) patients with oropharyngeal dysfunction reported a benefit after 3 days of training and were motivated to continue logopedic training at home.
Conclusion: Logopedic assessment revealed a high incidence of oropharyngeal dysfunction in our cohort of SSc patients. Oropharyngeal dysfunction was not associated with disease duration, skin- or lung-involvement or dcSSc/cSSc differentiation. A logopedic training program seems to be of benefit for this currently not pharmacologically treatable problem.

THU0351

MUSCLE INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS AND ANTI-PM/SCL+ ANTIBODIES IS ASSOCIATED WITH CARDIAC AND PULMONARY INVOLVEMENT. ANALYSIS OF THE MULTICENTRE EUSTAR COHORT.

M. G. Lazzaroni1, S. Zingarelli1, P. Airo2, Y. Allencroix, O. Distler1 on behalf of EUSTAR co-authors. 1ASST Spedali Civili of Brescia, University of Brescia, Brescia, Italy; 2University Paris Descartes and Cochin Hospital, Paris, France; University Hospital Zurich, Zurich, Switzerland

Background: Anti-PM/ScI antibodies positivity has been associated with frequent skeletal muscle involvement in patients with Systemic Sclerosis (SSc) in different studies, including the EUSTAR cohort (1). Moreover, although myositis has been previously associated with heart involvement in SSc patients (2), this issue has never been explored among anti-PM/ScI+ patients.

Objectives: To evaluate the cardiac involvement in anti-PM/ScI+ patients with SSc in the large multicentre EUSTAR database, with focus on the subgroup of patients with muscle involvement.

Methods: Patients from the EUSTAR database were included when the item anti-PM/ScI was fulfilled in at least one visit.

Results: Anti-PM/ScI status was available in 7353 SSc patients from EUSTAR database. 295 were anti-PM/ScI+. After exclusion of 151 patients with multiple autoantibody positivity, 144 anti-PM/ScI + patients were compared with 7058 anti-PM/ScI- patients. Among them, 3,120 (44.2%) were positive for ACA, 2,361 (33.5%) for anti-Topo I and 2,744 (3.88%) for anti-RNAP3. In multivariate analysis, adjusted for age and sex, anti-PM/ScI+ patients had a decreased rate of elevated sPAP at ECHO was recorded (33.5%) for anti-Topo I and 274 (3.88%) for anti-RNAP3.

Conclusion: In the largest series of anti-PM/ScI positive SSc patients so far reported, muscle involvement in anti-PM/ScI+ patients (defined as increased serum CK) seems to represent a marker of a more severe disease phenotype, including a higher frequency of cardiac-pulmonary involvement.

Background: Recent studies have highlighted that ultrasound (US) examination could offer a better assessment of hand manifestations of systemic sclerosis (SSc). Indeed, US allows a simultaneous evaluation of vascular, fibrotic and inflammatory hand features of the disease. Power Doppler US can especially explore macrovascular involvement characterized by an obliteration of digital arteries or ulnar arteries. Ulnar artery occlusion (UAO) is especially frequent in SSc patients and could be a relevant marker of the severity of SSc-associated vasculopathy. Among other hand manifestations of SSc, US evaluation can notably explore tenosynovial involvement such as fibrotic tenosynovitis (TS), which is considered to be SSc-specific.

Objectives: This study aims to assess the diagnostic performances of these hand US parameters for the diagnosis of SSc.

Methods: 244 patients with suspected SSc were consecutively included. They all had US evaluation assessing the presence of fibrotic TS and UAO. The final diagnosis of SSc was based on the evaluation of an expert, independently from US results and from any pre-established classification criteria.

Results: 166 patients were finally diagnosed as SSc. 62 SSc and 8 non-SSc patients had UAO (un or bilateral) (p=0.001). 23 SSc patients and 1 non-SSc patient had UAO fibrotic TS (p=0.007). A US SSc-pattern (presence of UAO and/or fibrotic TS) was reported in 73 SSc patients and 9 non-SSc patients (p=0.001). UAO had an area under ROC curve (AUC) for the diagnosis of SSc of 0.616 (95%CI 0.539-0.697); with Se= 0.373 (0.304-0.449) and spe=0.862
PULMONARY HYPERTENSION IN SYSTEMIC SCLEROSIS: ASSOCIATION WITH ENDOCAN AND CIRCULATING PROGENITOR CELLS

A. Lo Gullo1, D. Sinicropi2, M. Cinquegrani2, F. Savarino2, C. Giuffrida1, G. Squadrito2, G. Mandrallino1. 1.I.R.C.C.S. Centro Neurolesi Bonino Pulejo RO Piemonte, Messina, Italy; 2.A.O. Policlinico “Gaetano Martino”, Messina, Italy

Background: Systemic sclerosis (SSc) is characterized by early vascular involvement and by varying degrees of fibrosis in skin, lungs, and other tissues. Vascular manifestations include Raynaud’s phenomenon, digital ulcers, and pulmonary hypertension (PAH). The prevalence of PAH is 7.85–13% in SSc and it constantly reduced in SSc. Endocan is a proteoglycan expressed by endothelial cells and play a role in maintenance of vascular functions and the development of atherosclerosis. PAH is known to be associated with an increase in circulating progenitor cells, which could be correlated to the presence of pulmonary vascular disease.

Objectives: As the use of Endocan and CD34+ cell number in the evaluation of SSc is not well established, we aimed to evaluate the correlation of both in patients with SSc.

Methods: This is an observational study, carried out in five hospitals with a reference population of 1,083,463 people. From October 2015 to May 2018, we selected patients with a diagnosis of PAH according to their clinician, rheumatologist. Epidemiological and clinical data were obtained.

Results: We identified 291 patients with positive anti-myositis antibodies. Among them, 40 patients had a diagnosis of PAH. Median age was 59.5 (IQR 41.5, 70) years and 68% were women. In the subset of patients, the most frequent diagnosis was dermatomyositis (n=22; 55%) and polymyositis (n=9; 22%). The most common antibody detected was anti-TIF-y among specific antibodies, and anti-Jo-1 among the anti-synthetase antibodies. Clinical records were examined, identifying those patients with a diagnosis of PAH according to their clinician, rheumatologist. Epidemiological and clinical data were obtained.

Conclusion: In our study population, we found a significant correlation between CD34+ cell number and Endocan plasma levels and PAPs; Endocan and CD34+ progenitor cells might be suggested as potential marker of pulmonary arterial hypertension in SSc patients.

THU0354 CHARACTERIZATION OF ANTI-MYOSITIS ANTIBODY RELATED MYOPATHIES, DESCRIPTIVE STUDY IN A MULTICENTRIC COHORT.

S. López Salguero1, M. Andres2, P. Vela-Cassampspera3, A. Esteban Rodriguez3, M. P. Martinez-Vidal4, J. A. Bernat5, A. Alvarez de Cierfuegos5, F. Sivera6. 1Hospital Universitario de Torrevieja, Alicante, Spain; 2Hospital General Universitario de Alicante, Alicante, Spain; 3Hospital Universitario San Juan de Alicante, Alicante, Spain; 4Hospital Marina Baixa, Villajoyosa, Spain; 5Hospital Vega Baja, Orihuela, Spain; 6Hospital Universitario de Elda, Elda, Spain

Background: Idiopathic inflammatory myopathies (IIM) are a group of rare diseases consisting on immune-mediated muscle damage. About 40 to 60% show specific- myositis antibodies; additionally, 20-40% can show myositis-related (non-specific) antibodies. The profile of antibodies can help to divide patients into subgroups with more homogeneous clinical characteristics and prognosis.

Objectives: This study characterizes patients with IIM with specific or related anti-myositis antibodies, in five hospitals in the Alicante health area.

Methods: This was an observational study, carried out in five hospitals with a reference population of 1,083,463 people. Patients with positive anti-myositis antibodies between October 2015 and May 2018 were selected from the database of the Clinical Laboratory of the University Hospital of Alicante. We considered the following antibodies: anti-myositis specific antibodies (anti-TIF-y, anti-MDA5, anti-Mi-2, anti-PmSc175, anti-PmSc100, anti-NXP2, anti-SRP), anti-synthetase antibodies (anti-PL7, anti-PL12, anti-Jo1, anti-Cy), myositis-related antibodies (anti-Ro52, anti-Ku). Clinical records were examined, identifying those patients with a diagnosis of IIM according to their clinician, rheumatologist. Epidemiological and clinical data were obtained.

Results: 291 patients with positive anti-myositis antibodies were identified. Among them, 40 patients had a diagnosis of IIM. Median age was 59.5 (IQR 41.5, 70) years and 68% were women. In the subgroup of patients, the most frequent diagnosis were dermatomyositis (n=22; 55%) and polymyositis (n=9; 22%). The most common antibody detected was anti-TIF-y among specific antibodies, and anti-Jo1 among the anti-synthetase antibodies. The most common extramuscular feature was skin involvement. The presence of interstitial lung disease was reported in about one third of patients, being UIP the most common pattern. Regarding treatment, the use of steroids was generalized; methotrexate was the most used immunosuppressant agent. Eight patients had a cancer related myopathy.

DOI: 10.1136/annrheumdis-2020-eular.6125
Results: Mean age in the cohort was 55 (13) years and 78 (93%) patients were female. Of these, 67 (80%) experienced at least one type of VRFs. Each 10 ms increase of native T1 mapping was associated with a higher occurrence of VRFs [odds ratio (95% confidence interval): 1.21 (1.08-1.36), p=0.001]. Similarly, a 1% increase in ECV conferred an increased probability of experiencing VRFs [1.25 (1.01-1.53), p=0.037]. Lastly, a 1 ms unit increase in T2-mapping also led to increased probability of having experienced VRFs [1.09 (1.01-1.19), p=0.035].

Conclusion: Parametric CMR indices are associated with arrhythmogenicity in SSC patients with cardiac symptoms and should be investigated further in larger studies for their clinical utility in selecting high-risk SSC patients for ICD implantation.

Nemeth, University of Pecs, Rheumatology and Immunology, Pecs, Hungary; Polyclinic of the Hospitalier Brothers of St John of God, Budapest, Hungary; University of Pecs, Medical School, Pecs, Hungary

Disclosure of Interests: Disease activity assessment is crucial in defining the appropriate therapy and to monitor the efficacy of treatment in systemic sclerosis. Objectives: We aimed to test the performance of the ‘old’ European Sclero-derma Trials and Research Group (EUSTAR) Activity Index (old-AI) (1), the ‘new’ EUSTAR activity index (new-AI) (2), and the scleroderma activity index derived from the old-AI (Pecs-AI) (3). We compared the two indices to the disease activity based on the physician’s global assessment (PGA). We also assessed the correlations with the change in modified Rodnan Skin Score (mRSS), FVC and CDAI.

Methods: We evaluated 77 patients (50 diffuse and 27 limited cutaneous SSC/dSSc) from a single tertiary clinical center. Cohort enrollment was increased to determine the number of patients with early disease and dcSSc. Seventy-two patients were re-evaluated after one year. Nine patients had overlap syndromes: rheumatoid arthritis (n=3), Sjögren syndrome (n=2), polymyositis (n=2), and mixed connective tissue disease (n=2). The overall disease activity was evaluated using both composite indices (old-AI, Pecs-AI, new-AI), and the PGA of disease activity, based on the blinded evaluation of a single physician (LV). In addition to the minimal essential data from the EUSTAR database we also performed detailed assessment of the musculoskeletal involvement evaluating measures of hand function, DAS28 scores, and the Clinical Disease Activity Index (CDAI) (4).

Results: Three times more patients with active disease were identified by the new-AI compared to the old-AI at baseline investigation (n=37, 48.7%, vs. n=11, 14.3%). Two patients (18%) with active disease based on the old-AI were missed by the new-AI. Pecs-AI index identified 15 patients (19.5%) with active disease (cut-off >2.75 points). Active disease was equally frequent in dcSSc and lcSSc patients based on old-AI, but was more frequent in dcSSc patients based on the new-AI in the whole cohort, and also after excluding overlap cases. Patients with active disease based on the old-AI had more frequently rheumatoid factor (6/9, vs. 12/45, p=0.047), and DLCO<70% (11/11, vs. 36/65, p=0.01). Active disease based on the new-AI was associated with current cyclophospha-mide treatment (9/37, vs.2/39, p=0.023), and diabetes mellitus (7/30, vs. 0/39, p=0.01). The PGA correlated moderately at both baseline and one year follow-up examination with the old-AI (rho: 0.519, and rho: 0.692, respectively, p<0.001), the new-AI (rho: 0.401, and rho: 0.429, respectively, p<0.001), and the Pecs-AI (rho: 0.425, and rho: 0.593, respectively, p<0.001). CDAI correlated significantly with the old-AI (rho:0.345, and rho: 0.283, respectively, p<0.05) and the Pecs-AI (rho:0.363, and rho: 0.324, respectively, p<0.05) at both the baseline and one-year follow-up investigations, but showed no consistent correlation to the new-AI or PGA.

Conclusion: The two validated disease activity indices indentify different patient groups. Joint involvement is potentially underestimated in the new EUSTAR activity index. Active disease is also present in lcSSc and should be assessed regularly in these patients.

NAIFOLD CAPILLARY MICROSCOPY HAS LIMITED PROGNOSTIC VALUE IN PREDICTING FUTURE DEVELOPMENT OF CONNECTIVE TISSUE DISEASE IN CHILDREN WITH RAYNAUD'S PHENOMENON.

G. Van der Kamp1, D. J. Mulder1, A. Van Roon1, A. Van Roon1, A. Van Gessel1, W. Armbrust1 on behalf of Dept. of Internal Medicine, Division Vascular Medicine, University of Groningen, University Medical Center Groningen, Groningen, the Netherlands. UMC Groningen, Groningen, Netherlands

Background: For adults with Raynaud's phenomenon (RP), nailfold capillary microscopy (NCM) is established as an effective method for differentiating between primary RP (PRP) and secondary RP (SRP) at a young age and scarce (3.4). Objectives: The general aim of this study was to determine the diagnostic value of nailfold capillary microscopy (NCM) in addition to antinuclear antibodies (ANAs) for later development of connective tissue diseases (CTD) in children with RP.

Methods: This was a case-control study, in which 83 patients diagnosed with RP and having undergone NCM in childhood were retrospectively included. Based on whether they were diagnosed with a connective tissue disease (CTD) during follow-up, they were classified as PRP or SRP. PRP and SRP patients were compared on demographics, NCM and ANA positivity. Variables associated with SRP were included in a multivariate logistic regression model. Predictive values were calculated for NCM, ANA positivity and the combination of NCM and ANA positivity.

Results: At the time of the baseline NCM, the mean age of the RP patients was 15.4±2.3 years. Averagely 6.4±3.2 years after the baseline NCM, 65 of the 83 patients were classified as PRP and 18 as SRP. The most common CTDs were MCTD and undifferentiated CTD. ANA positivity was associated with SRP (p<0.001). Of the NCM parameters, only capillary loss was associated with SRP (p=0.01). Abnormal numbers of dilated capillaries, giant capillaries and hemorrhages were not significantly associated with SRP. In a multivariate logistic regression model, only ANA positivity was predictive for SRP (OR 5.97, CI 1.57-22.97, p=0.01). Of the NCM parameters, only capillary loss was associated with SRP at a young age and scarce (3.4).

Conclusion: This study demonstrates that childhood RP is primary in most cases. Whereas RP in adulthood is most strongly associated with SSC, children with RP seem to be at risk of developing other CTDs with less apparent NCM abnormalities. Dilated capillaries, giant capillaries and hemorrhages on NCM are not associated with the spectrum of CTDs that children are at risk for, and do not differentiate between primary and secondary RP. Although capillary loss on NCM is associated with SRP, capillary loss may add little to the predictive value of serology. To clarify which NCM parameters are helpful for early detection of SSC-like CTDs, additional research is required.

NEGATIVE CHANGES OF BODY COMPOSITION IN MYOSITS PATIENTS AND THEIR ASSOCIATION WITH DISEASE SPECIFIC CHARACTERISTICS, PHYSICAL ACTIVITY AND NUTRITIONAL STATUS.

S. Oreska1, M. Špirtović1, P. Česáč1, O. Marecek2, H. Štorkánová1,2, B. Hejmáňková1, K. Kubinová2, M. Klejš1, L. Vernerova2, O. Růžičková1, K. Pavelka1, Šenolt1,2, H. Mann1,2, J. Vencovsky1,2, M. Tomíč1,2. Institute of Rheumatology, Prague, Czech Republic; 1st Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic; 2Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic

Background: Skeletal muscle, pulmonary and articular involvement in idiopathic inflammatory myopathies (IIM) limit the mobility/self-sufficiency of patients, and can have a negative impact on body composition.

Objectives: The aim was to assess body composition and physical activity of IIM patients and healthy controls (HC) and the association with selected inflammatory cytokines/chemokines and laboratory markers of nutrition and lipid metabolism.

Methods: 54 patients with IIM (45 females; mean age 57.7; disease duration 5.5 ± 4.9 years); 55 dermatomyositis (DM) (42 females; mean age 46.9 years; disease duration 4.2 ± 2.8 years), 17 polymyositis (PM, 17 females; mean age 58.5 years; disease duration 4.8 ± 3.5 years) and 50 healthy subjects (HC, 42 females; mean age 57.7 years) were included. MMT-8 score, MITAX score and MYSOACT score were calculated. ANA positivity was associated with SRP. Multivariate logistic regression analysis revealed serum levels of certain inflammatory cytokines/chemokines and markers of nutrition and lipid metabolism as predictive value in predicting future development of connective tissue diseases (CTD) in children with RP.

Results: Compared to HC, patients with IIM had a trend towards significantly increased body fat % (BF%); (IIM: 33.9 ± 7.1 vs. 42.4 ± 7.1 %, p=0.077), but significantly decreased lean body mass (LBM); IDXA: 45.6 ± 6.1 vs. 40.6 ± 6.2 kg, p=0.001; BIA: 52.6 ± 8.8 vs. 48.7 ± 9.0 kg, p=0.023), increased extracellular mass/body cell mass (ECM/BCM) ratio (1.06 ± 0.15 vs. 1.44 ± 0.42, p<0.001), reflected deteriorated nutritional status and predisposition for physical activity, and significantly lower bone mineral density (BMD): 1.2±0.1 vs. 1.1±0.1 g/cm², p<0.001. Disease duration negatively correlated with BMD and LBM-BIA. Disease activity (MITAX, MYSOACT) positively correlated with LBM (by BIA and DXA), similarly as with basal metabolic rate (BMR), and fat free mass (FFM). CRP was positively associated with BFR (by BIA and DXA). Higher BF% and DXA was associated with worse physical endurance (FI2) and worse ability to perform physical activity (HAP). MMT-8 score negatively correlated with ECM/BCM ratio. Serum levels of several inflammatory cytokines/chemokines (specifically IL-1ra, MCP, IL-10) and markers of nutrition (specifically albumin, C3, C4-complement, cholesteral, ammonia, insulin and C-peptide, vitamin-D, orosomucoid), and lipid metabolism (specifically triglycerides, high-density lipoprotein, apolipoprotein A and B, atherogenic index of plasma) were significantly associated with alterations of body composition in IIM patients. (p<0.05 for all correlations)

Conclusion: Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our IIM patients associated with their disease activity and duration, inflammatory status, skeletal muscle involvement, and physical activity. These data could reflect their impaired nutritional status and predispositions for physical exercise, aerobic fitness and performance. Serum levels of certain inflammatory cytokines/chemokines and markers of nutrition and lipid metabolism were associated with alterations of body composition in IIM patients. This might further support the role of systemic inflammation and nutritional status on the negative changes in body composition of IIM patients.

**Efficacy of a Self-Treatment Protocol for Face and Temporomandibular Joints Rehabilitation in Systemic Sclerosis (SSC)**

1Fondazione IRCCS Don Carlo Gnocchi ONLUS, Florence, Italy; 2University of Florence, Florence, Italy; 3Associazione Multidisciplinare Riabilitazione Reumatologica AMuRR, Florence, Italy; 4ASSMAF ONULS, Florence, Italy; 5Associazione Italiana Gnatologia, Florence, Italy

**Background:** In SSC, skin involvement of the face is frequent and extremely disabling, resulting in limited mouth opening, an altered dentition, difficulty in teeth care, as well as having a strong impact on the emotional and psychological well-being, thus impairing quality of life.

**Objectives:** To evaluate the potential influence of gender and hormone-related factors in LUTS prevalence and severity among SSC patients.

**Methods:** A review of 42 SSCs Pts and 50 age- and sex-matched healthy subjects (HSs) was evaluated. SSC diagnosis was based on 2013 ACR/EULAR criteria. Demographic data, medications interfering with pelvic floor dynamics and general comorbidities commonly associated with LUTS – diabetes mellitus, chronic heart failure, chronic obstructive pulmonary disease, peripheral neuropathy, pelvic organ prolapse, fecal incontinence – were recorded. Validated self-reported questionnaires derived from the International Continence Society on Incontinence were used to assess prevalence and severity of LUTS, namely of urinary incontinence (UI) and overactive bladder (OAB) [2].

**Results:** There were no significant differences in main demographic data between SSC Pts and HSs. Specifically, median age was 61 years (IQR 21-85) vs 57 years (IQR 28-93) and female prevalent, 83% vs 84% in SSC Pts vs HSs, respectively. Among the female populations, 83% of SSC Pts vs 84% of HSs was in post-menopausal state, with a median of 1 (IQR 0-3) vs 1 (IQR 0-4) pregnancy by natural route, respectively. No woman of the study had received hormone replacement therapy or local hormonal therapies prior to the study. Similarly, there were no any significant differences in analysed comorbidities, while ongoing treatment was significantly different between the two populations. SSC patients more frequently receiving calcium channel blockers and glucocorticoids than healthy subjects (p < 0.001).

In SSC Pts, statistically significant correlation was observed between stress UI and sex, with an increased female-to-male ratio (p < 0.005), but any significant difference was observed in US distribution depending on parity and menopausal state, nor on other analysed variables. Interestingly, female dominance has not resulted as a significant predictive factor for LUTS prevalence or severity in SSC Pts. In fact, in the regression analysis, SSC disease was the only significant predictor for LUTS (OR 3.45, 95% CI 1.41-7.95; p < 0.01), independently of other analysed variables, particularly of gender and hormone-related factors.

**Conclusion:** This study confirms the absence of pathogenic female-gender participation in LUTS prevalence among SSC Pts. However, consistently with findings on general population, a significant increased prevalence of urinary symptoms, particularly of stress UI, in SSC female Pts has emerged [2].

SICCA renal crisis (SRC) prevalence is decreasing. However, no Systemic Sclerosis (SSc) patient’s registry has evaluated that decrease over time. No treatment have been able to prevent SRC development.

Objectives: To identify SRC prevalence in 2 periods in the RESCLE (Registro de ESCLErodermia) registry. Secondary objective: to identify which features could justify that change on SRC prevalence.

Methods: Up to December 2018, 1937 SSc patients were included by 31 referral centers in RESCLE registry. SSc prevalence and incidence in diagnosed patients before and after 2003 was determined. Clinical characteristics of diagnosed patients in each period of time were analysed to identify differences between them.

Results: Out of 1937 SSc, 43 (2.2%) developed SRC. Prevalence of SRC before and after 2003 was 3.5% and 1.08%. SRC Incidence: Graphic 1. Significant differences between Pre-2003 vs. Post-2003 SSc cohorts were found in univariate analysis: Table 1 and 2.

Conclusion: SRC Prevalence and Incidence has decreased. Prevalence is three-fold in diagnosed SSc cohort pre-2003 than in post-2003. The post-2003 cohort showed lesser prevalence of dcSSc subtype, earlier SSc diagnosis, less organic involvement and more intensive treatment than pre-2003 cohort. All these findings could explain the decline in the SRC prevalence.

Conclusion: Our results confirm that SSc is a devastating condition as reflected by a pooled SMR of 1.85. The two principal causes of SSc-related death remain PH and ILD. However, SSc non-related death are represented mainly by cardiovascular diseases. This work identified sex (male), DLCO <70%, cardiac involvement and CRP >5 mg/l as independent predictors of mortality. With the emergence of new therapies, these important observations should help refine the monitoring and management to prolong their patients’ survival.

THU0363 EFFECTS OF NINTEDANIB IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED ILD (SSC-ILD) AND NORMAL VERSUS ELEVATED C-REACTIVE PROTEIN (CRP) AT BASELINE: ANALYSES FROM THE SENSCIS TRIAL

1University Hospital Charité, Rheumatology and Clinical Immunology, Berlin, and Berlin University Hospital Schleswig-Holstein, Rheumatology, Germany; 2Servicio de Reumatología, Hospital Universitario de Octubre, Madrid, Spain; 3 Tulane University School of Medicine, New Orleans Scleroderma & Sarcoidosis Patient Care & Research Center, UMC Comprehensive Pulmonary Hypertension Center, New Orleans, LA, United States of America; 4Division of Rheumatology, Department of Medicine III, University Medical Center & Faculty of Medicine Carl Gustav Carus, TU Dresden, Dresden, Germany; 5Stanford University School of Medicine, Departments of Medicine and Dermatology, Division of Immunology and Rheumatology, Stanford, CA, United States of America; 6Division of Rheumatology, University of Western Ontario, Schuchl School of Medicine, London, Ontario, Canada; 7Mainanalytics gmbh, Weimar (Lahn), Germany; 8Boehringer Ingelheim International GmbH, Ingelheim, Germany; 9Boehringer Ingelheim (Schweiz) GmbH, Basel, Switzerland; 10University of Michigan, Department of Medicine, Ann Arbor, MI, United States of America

Background: In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) over 52 weeks. Elevated CRP is a marker of an inflammatory phenotype and has been associated with a greater rate of decline in FVC and higher mortality in patients with SSc.

Objectives: To assess the effects of nintedanib in subgroups by CRP at baseline in the SENSCIS trial.

Methods: Patients with SSc-ILD with onset of first non-Raynaud symptom <7 years and ≥10% fibrosis of the lungs on HRCT were randomised to receive nintedanib or placebo. We analysed the rate of decline in FVC (mL/year) over 52 weeks, the proportion of patients with an absolute increase in FVC ≥3% predicted (proposed as the minimal clinically important difference for improvement in FVC in patients with SSC-ILD), and absolute change from baseline in mRSS at week 52 in subgroups with normal vs elevated high-sensitivity CRP ≤4.99 vs >4.99 mL at baseline.

Results: Of patients with available data, 78/270 (28.9%) and 74/281 (28.4%) in the nintedanib and placebo groups, respectively, had CRP >4.99 mL at baseline. Compared with patients with lower CRP, those with CRP >4.99 mL included a similar proportion of patients who were AFA-positive (61.8% vs 60.2%, respectively), a greater proportion with diffuse cutaneous SSc (63.2% vs 49.3%) and had a higher mean mRSS (13.7 vs 10.2) and lower mean FVC % predicted (68.6% vs 73.9%). The adjusted annual rate of decline in FVC in the placebo group was numerically greater in patients with CRP >4.99 than ≤4.99 mL at baseline (baseline -106.6 [SE 276] vs -83.0 [171] mL/year). The effect of nintedanib vs placebo on reducing the rate of decline in FVC was numerically more pronounced in patients with CRP ≥4.99 than ≤4.99 mL at baseline but the treatment-by-time-by-subgroup interaction p-value did not indicate heterogeneity in the effect of nintedanib between subgroups (p=0.70) (Figure). In the nintedanib and placebo groups, respectively, the proportions of patients with an absolute increase in FVC ≥3% predicted at week 52 were 20.4% and 15.0% in those with CRP ≤4.99 mL and 24.4% and 14.9% in those with CRP >4.99 mL at baseline (treatment-by-subgroup interaction p=0.59); adjusted mean changes in mRSS at week 52 were -2.2 (SE 0.3) and -2.1 (0.3) in those with CRP ≤4.99 mL (difference -0.1 [95% CI -1.0, 0.8]) and -2.3 (0.5) and -1.0 (0.5) in those with CRP >4.99 mL at baseline (difference -12 [-2.7, 0.2]; treatment-by-visit-by-subgroup interaction p=0.20).

Conclusion: In the SENSCIS trial, the rate of decline in FVC over 52 weeks in the placebo group was numerically greater in patients with elevated CRP at baseline. Nintedanib reduced the rate of decline in FVC both in patients with normal and elevated CRP at baseline, with a numerically greater effect in patients with elevated CRP.

**THU0364**

**SYSTEMIC SCLEROSIS OVERLAP AND NON-OVERLAP SYNDROMES SHARE SIMILAR CLINICAL CHARACTERISTICS BUT DRAMATICALLY DIFFERENT TREATMENT.**

**H. U de Bordeaux, Rheumatology, Bordeaux, France; C.H.U de Strasbourg, Rheumatology, Strasbourg, France**

**Background:** Overlap between systemic sclerosis (SSc) and another autoimmune and immune-systemic disease (AIDS) in the same patient seems to be more frequent than each disease's prevalence would explain.

**Objectives:** Our aim was to investigate for overlap syndrome from 2 French cohorts of SSc patients and to compare their characteristics with non-overlap SSc.

**Methods:** Our study was retrospective observational and bicentric. Patients responding to the 2013 ACR-EULAR scleroderma classification criteria for SSc were screened for concomitant AIDs. Patients satisfying 2010 ACR-EULAR diagnostic criteria for rheumatoid arthritis (RA) and/or 2016 ACR-EULAR classification criteria for SSc overlap syndrome (SSoS) and/or 2012 SLICC systemic lupus erythematosus (SLE) classification criteria were included in our study. Patient, disease, and treatment characteristics were retrospectively retrieved from medical records and were compared to a SSc cohort.

**Results:** A population of 534 SSc patients was studied. Thirty-four (6.4%) patients were identified as having overlap syndrome. There was 21 (3.9%) patients with RA, 14 (2.6%) with GSS and 4 (0.7%) with SLE (5 patients had 2 AIDs). Diagnosis of RA, SLE or GSS was made after diagnosis of SSc for 22 (65%) patients, concomitantly for 10 patients (29%), and before for 2 (6%) patients. Interestingly, two patients with SSc/RA overlap were tested ACPE-positive and 2 years before the first arthritis, respectively. Patients with SSc/RA were severe with 81% of them having erosive disease and despite treatment, only 44% of them achieved total remission (DASI<9.2; CRP<2.6) at the time of their last visit. Disease duration was longer in patients with SSc overlap syndrome compared to non-overlap patients (15.5±6.0 years vs. 9.5±8.0 p<0.001). Proportion of limited cutaneous SSc was similar in overlap and non-overlap groups (70.6% vs. 75.5%, respectively, p=NS), as was the positivity for anti-centromeres antibodies (50% vs. 43.2%, respectively, p=NS). The disease phenotype of SSc overlap syndrome was similar to the one of non-overlap SSc in terms of prevalence of pulmonary arterial hypertension, interstitial lung disease, digital ulcer and mortality. With respect to treatments, patients with overlap were more likely to receive glucocorticoids (85.3% vs. 45%, p<0.001), immunosuppressive drugs (82.4% vs. 49.2%, p<0.001) and biologic DMARD (bDMARD) (52.9% vs. 3.8%, p<0.001). The most prescribed bDMARDs in the overlap population was tocilizumab (40.6%), TNF-alpha inhibitor (29.4%) and rituximab (26.5%) (p<0.001 for all comparison vs. non-overlap SSc).

**Conclusion:** We found a prevalence of overlap syndrome higher than 5% among SSc patients. While SSc overlap and non-overlap share common characteristics, overlap patients are more likely to receive glucocorticoids and biologics such as anti-TNF. These overlap should be searched actively (eg, screening for ACPA) since some treatment used for other autoimmune diseases such as glucocorticoids or TNF-alpha inhibitor may be harmful in SSc.

**INCREASED HSP90 IN MUSCLE TISSUE AND PLASMA ASSOCIATES WITH DISEASE ACTIVITY AND SKETEAL MUSCLE INVOLVEMENT IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES**

**Institute of Rheumatology, Prague, Czech Republic; Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic; Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic, Prague, Czech Republic; Department of Physiotherapy, Prague, Czech Republic; Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic, Prague, Czech Republic; Department of Pathology and Molecular Medicine, 2nd Medical School and University Hospital Motol, Charles University, Prague, Czech Republic, Prague, Czech Republic, Prague, Czech Republic**

**Background:** Heat shock proteins (Hsps) are chaperones playing important roles in skeletal muscle physiology, adaptation to exercise or stress, and activation of inflammatory cells.

**Objectives:** The aim of our study was to assess Hsp90 expression in muscle biopsies and plasma of patients with idiopathic inflammatory myopathies (IIM) and to characterize its association with IIM-related features.

**Methods:** Total of 277 patients with IIM (198 females, 79 males; mean age 54.8; disease duration 4.1 years; DM, 104/PM, 108/CADM, 31/MMN, 25) and 157 healthy individuals (92 females, 65 males; mean age 47.0) were included in plasma analysis. Muscle biopsy samples (PM, DM, IMN, myastheny, myasthenia gravis) were stained for Hsp90α (Thermo Fisher Scientific, USA) and Hsp90β (Abcam, UK). Plasma Hsp90 was measured by ELISA kit (eBioscience, Vienna, Austria). The cytokines/chemokines were analysed by using Bio-Plex Pro™ human Cytokine 27-plex Assay (BIO-RAD, California, USA). Data are presented as median (IQR).

**Results:** In muscle biopsies, Hsp90 expression of both subunits (alpha and beta) was higher in IIM than in controls. Increased Hsp90 was detected in perifascicular degenerating and regenerating fibers, inflammatory cells (DM, PM), and necrotic and regenerating fibers (IMN). Plasma Hsp90 levels were increased in IIM patients compared to healthy controls (55.9 (46.9 – 62.5) vs. 9.76 (9.62 – 13.8), p<0.001), and in individual subgroups of IIM vs. healthy controls (DM-22.01 (14.1 – 41.2), CADM-19.8 (11.7 – 29.7), IMN-19.6 (16.3 – 45.5), p<0.001 for all). Hsp90 was higher in males compared to females (p=0.040) and in patients with ILD (p=0.003), cardiac involvement (p=0.004), dysphagia (p=0.018) and presence of anti-Ro52 (p=0.036). Hsp90 levels in all patients positively correlated with muscle enzymes (Tab.1). Hsp90 was associated with disease activity and skeletal muscle involvement (Tab.1). Out of all clinimarkers characterized in above-mentioned univariate analysis, in multiple regression analysis Hsp90 levels in IIM patients were significantly affected by muscle enzymes only (p<0.001, β=0.345). Furthermore, Hsp90 positively correlated with some crucial cytokines involved in pathogenesis of myositis (Tab.1).

**Conclusion:** We demonstrated increased Hsp90 expression in IIM muscle biopsy samples, specifically in inflammatory cells, degenerating, regenerating and/or necrotic fibers. Increased Hsp90 plasma levels in IIM patients are associated with disease activity and damage, and with the involvement of proximal skeletal muscles, heart and lungs.

### SYSTEMATIC CORONARY RISK EVALUATION (SCORE) MISCLASSIFIES CARDIOVASCULAR RISK IN ANTISYNTHETASE SYNDROME: RESULTS OF THE PILOT MULTICENTRIC STUDY RI.CAR.D.A.

K. Triantaphylli,1 A. Klonowski,2 L. Cavagna,2 U. Drost,2 R. Volf,3 C. Fiehn,3 M. De Blasi,1 S. Wende,2 R. Bergner3, A. Schwarting2,3, 1ACURA Clinics, Rheumatology, Bad Kreuznach, Germany; 2University Medical Center of the Johannes Gutenberg University, Internal Medicine I, Rheumatology and Clinical Immunology, Mainz, Germany; 3University and IRCSS Policlinico S. Matteo Foundation, Rheumatology Unit, Pavia, Italy; 4University Hospital of Frankfurt, Rheumatology Division, Frankfurt, Germany; 5Medical Center University of Freiburg, Faculty of Medicine, University of Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; 6Medical Center Baden-Baden, Unit for Rheumatology and Clinical Immunology, Baden-Baden, Germany; 7ACURA Clinics, Rheumatology, Bad Kreuznach, Germany; 8Medical Clinic A, Ludwigshafen Hospital, Rheumatology, Ludwigshafen, Germany

**Background:** Antisynthetase Syndrome (ASyS) is an autoimmune overlap disease characterized by antinuclear-antihistone-anticytotoxic (anti-ARS) antibodies and the classic triad of arthritis, myositis and interstitial lung disease (ILD) (1). Markers of cardiovascular (CV) or cerebrovascular (CBV) risk have never been examined in ASyS.

**Objectives:** Aim of this study (RISK of CADiovascular Disease in ASyS: Ri.CAR.D.A.) was to test the ability of an established traditional CV risk prediction score (Systematic Coronary Risk Evaluation-SCORE) and its EULAR modified version (mSCORE) to identify ASyS patients at high CV risk. Moreover, we sought to examine for the first time associations of CV surrogate markers with clinical and immunological ASyS parameters.

**Methods:** SCORE/mSCORE and the gold standard marker of aortic stiffness (carotid-temoral pulse wave velocity-cfPWV) were examined in patients with ASyS and healthy controls in a multicenter setting (6 Rheumatology Centers). Moreover, sonography of the common- (CCA), internal- (ICA) and external- (ECA) carotid arteries was performed in subsets of both groups, evaluating carotid intima-media-thickness (cIMT), plaques and duplex-sonographic indices of CBV risk such as the resistance- (RI) and pulsatility-index (PI).

**Results:** We recruited 66 ASyS patients with different anti-ARS and 88 controls. According to mSCORE and SCORE, ASyS patients compared to controls. Active myositis and presence of ILD were associated with higher CVB risk parameters. Furthermore, SCORE/mSCORE performed poorly in identifying patients at high CV risk and carotid arteriosclerosis compared to cfPWV and CS respectively. Thus, cfPWV and CS could improve CV and CBV screening in ASyS patients.

**Disclosures:** None declared

### INCIDENCE AND PREVALENCE OF SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE IN FLANDERS: A 12-YEARS COLLABORATIVE MULTICENTER PROSPECTIVE COHORT STUDY.

E. Vantecateaste1, K. Meisens1, D. Blockmans,2 C. Carton,1 F. De Keyser3, E. De Langhe3, B. Lauwerys3, Y. Piete3, A. Vanhaecke3, K. Verbeke1, W. Wuyts4, G. Brusselle,1 V. Smith1. 1Ghent University Hospital, Ghent, Belgium; 2University Hospital Leuven, Leuven, Belgium; 3Private Rheumatology Practice, Maldegem, Belgium; 4UCL Brussels, Brussels, Belgium

**Background:** Systemic sclerosis-associated interstitial lung disease (SSc-ILD) is the main cause of death in SSc and accounts for up to 30-35% of SSc-mortality (1-2). All SSc cases, irrespective of the extent of the skin disease, should be evaluated for ILD (3). The epidemiology of SSc-ILD in Belgium is unknown. In literature, the prevalence of ILD in SSc varies between 19% and 52%. However, different criteria were used to diagnose ILD (4). In 2008, Goh et al. proposed a flow diagram to diagnose SSc-ILD based on chest high-resolution CT-scan (HRCT) and pulmonary function tests (PFTs). Their categorization into limited or extensive ILD has prognostic value (5).

**Objectives:** To determine the prevalence and incidence rate of SSc-ILD in Flanders.

**Methods:** Up to 12-year follow-up data of consecutive SSc patients were obtained by 2 Flemish expert centres (University Hospitals Ghent and Leuven). Patients fulfilling the LeRoy and/or ACR-EULAR classification criteria were included consecutively in the prospective cohort (6). Patients received HRCT at baseline and on indication thereafter, as well as yearly PFT. All HRCTs were centrally analyzed (Ghent) and patients were categorized according to the Goh criteria as without ILD, with limited ILD (limILD) or with extensive ILD (extILD) (5).

**Results:** Between 2006 and 2018, 797 SSc patients (557 Ghent/240 Leuven; 22% limited SSc (LSSc)/59% limited cutaneous SSc (LScSSc)/19% diffuse cutaneous SSc (DcSSc)) had baseline HRCT and PFT. The baseline characteristics are depicted in the table. The mean age (SD) was 53 +/- 15 years and the majority of patients was female (76%). Up to 12-years, 272 SSc patients had ILD at baseline, implicating a baseline prevalence of 34% (272/797). The baseline prevalences were 35% and 55% for the LcSSc and DcSSc subgroups respectively. During a median follow-up of 39 months (IQR: 11-79 months), 44 patients were diagnosed with incidental SSc-ILD, resulting in an incidence rate of 21.0/1000 person-years. Patients fulfilling the LeRoy and/or ACR-EULAR classification criteria were included consecutively in the prospective cohort (6). Patients received HRCT at baseline and on indication thereafter, as well as yearly PFT. All HRCTs were centrally analyzed (Ghent) and patients were categorized according to the Goh criteria as without ILD, with limited ILD (limILD) or with extensive ILD (extILD) (5).

**Incidence rates were 21.7/1000 PY, 95% CI: 14.3-31.6 and 43.9/1000PY, 95%CI: 22.7-78.8 for the LcSSc and DcSSc subgroups respectively.**

RAPID SKIN THICKNESS PROGRESSION RATE IS ASSOCIATED WITH HIGH INCIDENCE RATE OF CARDIOPULMONARY INVOLVEMENT AND MORTALITY IN PATIENTS WITH EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (DCSSC)

S. Wannaka1, H. Thongwitthakorn1, N. Praebhittayaajit1, J. Euathongchit3
1Division of Rheumatology, Chiang Mai University, Internal Medicine, Chiang Mai, Thailand; 2Division of Cardiology, Chiang Mai University, Internal Medicine, Chiang Mai, Thailand; 3Division of Diagnostic Radiology, Chiang Mai University, Internal Medicine, Chiang Mai, Thailand

Background: There has been no prior inception cohort study regarding the incidence rate of cardiopulmonary involvement in patients with early dcSSc comparing among different groups of skin thickness progression rate.

Objectives: The aims of this study were to compare differences in early dcSSc patients, which were classified into 3 subgroups: (a) rapid skin progression (RPsp), (b) intermediate skin progression (ISp), and (c) slow skin progression (SLsp). Regarding: (1) clinical characteristics (2) incidence rate of left ventricular ejection fraction (LVEF) < 50 %, intestinal lung disease (ILD), and pulmonary hypertension (PH). In addition, to compare mortality rate between skin improved and non-improved skin group.

Methods: We used an inception cohort of early dcSSc patients seen at the Rheumatology clinic, Maharaj Nakorn Chiang Mai Hospital, between January 2010 and December 2017. All patients were assessed for demographic data, clinical manifestations, modified Rodnan Skin Score (mRSS) and underwent echo-cardiography, and HRCT at the study entry and then annually.

Results: One hundred and two dcSSc patients (55 females and 89 anti-Scl 70 antibody positivity) with a mean±SD age of 53.2±8.8 years and mean disease duration of 11.2±8.7 months were enrolled, during a mean observation period of 47.1±11.9 months, mean±SD of baseline mRSS was 21.9±9.1. Patients were classified into 3 groups: (a) 41 (40.2 %) patients with RPsp; (b) 37 (36.3 %) ISp patients; and (c) 24 (23.5 %) SLsp. At enrollment, the RPsp group had significantly higher incidence of cardiopulmonary involvement compared to ISp and SLsp groups as the followings: mean disease duration (5.4±2.3 vs. 11.5±6.1 and 20.7±10.3 months, p<0.001), anti-Scl 70 antibody positivity (95.1 % vs. 75.7 % and 91.7 %, p=0.039), mRSS (26.4±7.9 vs. 22.1±8.4 and 13.8±6.5, p<0.001), dry mouth (48.8 % vs. 37.8 % and 8.3 %, p=0.005), lung involvement rate of ILD (26.8 % vs. 21.6 % and 8.3 %, p=0.001), pericardial effusion (0 vs. 10.8 % and 0, p=0.018), arrhythmia (7.3 % vs. 29.7 % and 8.3 %, p=0.018), muscle weakness (26.8 % vs. 27.0 % and 0.009), creatine kinase > 500U/L (34.1 % vs. 18.9 % and 4.2 %, p=0.016), and NT-proBNP (935.7±2300.3 vs. 746.4±1385.2 and 164.0±225.3ng/mL, p=0.001). During the observation period, the RPsp group had a significantly higher incidence of LVEF < 50 % compared with the SLsp group (0.06 vs. 0 per 100 person-years, incidence rate ratio=21.27, p=0.001). The RPsp group had a significantly higher incidence of ILD compared with the SLsp group (69.69 vs. 34.66 per 100 person-years, incidence rate ratio=2.01, p=0.012).

Conclusion: Our study cohort found that early dcSSc patients with rapid skin progression had higher incidence rate of LVEF < 50 % and ILD compared to those with slow skin progression. In addition, skin non-improved patients had significantly higher mortality rates than those with skin improved.

EVALUATION OF DIFFERENT CLASSIFICATION CRITERIA IN SYSTEMIC SCLEROSIS IN A TURKISH COHORT: THE IMPORTANCE OF NON-SKIN MANIFESTATIONS, SEROLOGY AND CAPILLAROSCOPY

Y. Yalcinaykaya1, S. Amikishiyev1, N. Aliev, B. Artim-Esen, A. Gul1, L. Ocal1, M. Inanc1, Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: Proximal scleroderma is the major criterion in both 1980 and 2013 classification criteria for sysemic scleroderma (SSc). ACR(1980) criteria included digital lesions and bibasilar fibrosis, nonetheless ACR/EULAR(2013) criteria based on a scoring system including digital lesions, telangiectasia, abnormal nailfold video-capillaroscopy(NVC), PAH, Raynaud’s and specific autoantibodies.

Objectives: We aimed to implement both criteria in a Turkish SSc cohort to evaluate the contribution of non-skin manifestations, NVC and autoantibodies.

Methods: A consecutive hundred and thirty-nine (125 females) SSC patients diagnosed and evaluated by the same experts (Y.Y, M.I) with relevant NVC records and at least 6 months follow-up were included into the study. Classification criteria were used retrospectively using a preformed database.

Results: Characteristics of the SSC patients were summarized in table-1. The mean age, duration of Raynaud’s and non-Raynaud symptoms were 47.1±11.9, 8.9±7.9 and 5.7±5.8 years, respectively. Diffuse and limited cutaneous disease were diagnosed in 62(44.6%) and 60(43.2%) patients respectively. Asclerodermic disease was present in 17(12.2%) patients. ANA, anti-centromere and anti-Scl70(+) positivity was 80.5%, 18.0% and 37.4%, respectively.

Twelve patients (8.6%) could not be classified as SSc by both criteria; 5 with Raynaud’s specific antibodies (2 anti-centromere+, 2 anti-Scl70+), 4 with Raynaud’s-puffy hands+NC abnormalities, 2 with Raynaud’s+telangiectasia and a patient with Raynaud’s+sclerodactyly. Nineteen (13.7%) patients could not be classified as SSc according to ACR(1980) can be classified according to ACR/EULAR (2013) (table-1 and ‘-2’).

The sensitivity for ACR(1980) and ACR/EULAR (2013) criteria were found to be 91.4% vs 75.5%, 98.4% vs 96.8% in diffuse cutaneous SSc, 98.3% vs 68.3% in limited cutaneous SSc and 47.1 vs 23.5% in asclerodermic SSC, respectively.

Conclusion: The sensitivity of ACR/EULAR (2013) criteria was shown to be higher than ACR (1980) criteria in our Turkish SSc cohort with established cases.
Although in diffuse cutaneous subgroup, the sensitivity was >%96 for both criteria, in limited cutaneous subgroup, the sensitivity was preserved for ACR/EULAR(2013) while apparently decreased for ACR(1980) criteria (<%70). The sensitivity for both of the two sets was lowest in the asclerodermic group. In SSc patients with limited or no skin involvement, non-skin manifestations, NVC findings and specific serology should be carefully sought. Some of these patients could not be classified by the current criteria.

Spondyloarthritis - treatment

THU0370 CLUSTER-RANDOMIZED PRAGMATIC CLINICAL TRIAL EVALUATING THE POTENTIAL BENEFIT OF A TIGHT-CONTROL AND TREAT-TO-TARGET STRATEGY IN AXIAL SPONDYLOARTHRITIS: THE RESULTS OF THE TICOSPA TRIAL.

A. Moto1, C. López-Medina1, F. Van den Bosch1, A. Boonen1, C. Webers1, E. Derriën1, F. A. Van Gaalen1, M. Soubrier1, P. Claudelieupe1, A. Baillet1, M. S. Stammens-Kool1, D. Van der Heijde1, M. Dougados1. TICOSPA Study Group. Paris, France

Background: Current recommendations for axial spondyloarthritis (axSpA) management include tight control and treat-to-target (TC) strategies, but no study has evaluated its potential benefit
Objectives: To evaluate the benefit of TC strategies in comparison to usual care (UC) in patients with axSpA.
Methods: Study design: Pragmatic, prospective, cluster-randomized controlled (2 arms), one-year trial (NCT03043846). Centers: 18 axSpA expert centers randomly allocated (1:1) to the treatment arm: TC vs. UC. Patients: axSpA diagnosis and ASAS criteria, non-optimally treated with NSAIDs, bDMARD-naive, and ASAS > 2.1 at inclusion. Study treatment: a) TC arm: the strategy was pre-specified by the scientific committee based on current axSpA recommendations and aiming at a target (ASASDAS <2.1); visits every 4w; b) UC arm: treatment decisions were at the rheumatologist's discretion with visits every 12w. Outcomes: the % of patients with a significant (>30%) improvement in the ASAS-HI score over one-year follow-up was the main outcome. Other outcomes (disease activity, quality of life, treatment, …) over follow-up were evaluated (Table 1). The number/type of adverse events were collected. Statistical analysis: this was an intention-to-treat analysis. To take into account the cluster-randomization design, for all outcomes, two models were performed: first a two-level mixed model with 2 random effects was used to estimate the % of responders/the change of the outcome over follow-up (i.e. mod1); in a second step, the imbalanced variables observed at baseline were included in the model (i.e.mod2). Cost-effectiveness was assessed by estimating the (baseline- and cluster-adjusted) incremental cost per quality-adjusted life-year (QALY) gained for TC vs. UC.

Results: 160 patients were included (80 in TC and 80 in UC). Mean age was 37.9(11.0) years with a disease duration of 3.7(6.2) years, 51.2% were males. A radiographic damage of the SI-joins, a (ever) positive MRI sacroiliitis and HLA-B27+ were seen in 46.9%, 81.9% and 75.0% patients respectively. Mean ASDAS at inclusion was 3.0(0.7) and mean ASASHI was 8.6(3.7). 72 patients per group attended the one-year visit. Although 47.3% vs. 36.1% patients in the TC and UC arms achieved a significant improvement in ASASASHI at the one-year visit, the difference was not statistically significant, with either model. Across all other outcomes a trend was observed in favor of the TC arm (Table 1). The number of bDMARDs was significantly higher in TC arm (56.2% vs. 27.2%). The number of infections was comparable in both groups (15 vs. 16 in the TC and UC, respectively), with only 2 severe infections occurring in the UC arm. From a societal perspective, TC resulted in an additional 0.04 QALY and saved €265 when compared to UC and a 67% probability of being cost-effective at a cost-effectiveness threshold of €20,000 per QALY.

Conclusion: In this setting of aSpA expert centers, UC resulted in a good outcome in a substantial number of patients but the TC was not superior for the primary outcome despite a greater number of bDMARDs prescription. Nonetheless, a general trend in favor of the tight control was observed, with a comparable safety profile and was found to be favorable from a societal health economic perspective.

Acknowledgments: this trial has been conducted thanks to an unrestricted grant from UCB.

THU0371 HIGH INTENSITY EXERCISE HAS COMPARABLE 3-MONTH EFFECTIVENESS TO TNF-INHIBITORS ON DISEASE ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS. POST-HOC ANALYSES OF DATA FROM (THE ESPA TRIAL).

S. Arendt Provan1, E. Kristianslund1, J. A. Berg2, H. Solveig Daanfurd3, S. Halvorsen Sveaas1,2. Diakonhjemmet Hospital, National Resource Centre for Rehabilitation in Rheumatology, Oslo, Norway;1 Diakonhjemmet Hospital, Rheumatology, Oslo, Norway

Background: We have previously reported that a supervised 12-week high intensity cardiorespiratory and strengthening exercise programme reduced disease activity in patients with axial spondyloarthritis (axSpA), in an assessor blinded randomized controlled trial (ESpA)(1). There were no reports of disease flare, and the programme was deemed safe. It is of interest to compare the treatment response of the programme vs. the response to treatment with a biologic immune-modulating TNFalpha-inhibitor (TNFi).
Objectives: To compare 3-month change in disease activity following an exercise programme vs. treatment with a TNFi, in patients with axSpA.
Methods: Post-hoc comparison between participants in the intervention group in the ESPA and patients from NOR-DMARD, a longitudinal observational study, who commenced treatment with a TNFi (2). The inclusion criteria of ESPA was a diagnosis of axSpA, age 16-70 years and baseline BASDAI >5. Patients fulfilling these criteria were selected from NOR-DMARD. Data was collected at baseline and 3 months. The primary outcome was defined as ASASDAS, and BASDAI scores, and secondary outcomes were BASDAI sub-scores and C-reactive protein (CRP). Baseline values were compared in bivariate analyses. Responses at 3 months were compared between the groups using ANCOVA models adjusted for age, gender and baseline values. The standardised mean difference in 3-month response between the exercise and TNFi groups was estimated by dividing the difference in change at 3-months by the standard deviation (SD) of change.

Results: Fifty patients were randomised to the exercise intervention in the ESPA study, mean age (SD) 45.2 (6.6), 25 males (50%). 344 patients in the NORD-DMARD study were eligible for the current analyses, mean age (SD) 39.6 (1.5), 150 males (43.6 %). Baseline demographics and estimated marginal means for disease activity at - months are presented in Table 1. The standard mean differences are presented in Figure 1. There were no significant differences in change in disease activity at 3-months between patients participating in ESPA and patients starting a TNFi.

### Objectives:

To assess the effectiveness of steroid injection (local treatment, LT) into the digital flexor tendon sheath for the treatment of active dactylitis in PsA patients as compared to systemic treatment (ST) alone.

### Methods:

- **T3 hand dactylitis** were assessed in a prospective observational study by the Leeds Dactylitis Index basic (LDI-b) score and evaluated for pain (VAS pain), functional impairment (VAS-FI). In accordance with EULAR and GRAPPA recommendations, steroid injection was proposed to all patients. Patients who refused LT were treated with oral NSAIIDs. The patients of the two groups continued baseline therapy with csDMARDs or corticosteroids. The clinical outcomes were measured at baseline, 1 month (T1) and 3 months (T3) by assessors blinded to this study.

### Results:

The reduction of VAS-pain, VAS-FI and LDI-b values was statistically significant higher in the LT group as compared to the ST group, both at T1 ($p<0.001$, p<0.001 and p<0.008, respectively) and at T3 ($p<0.001$, p<0.001 and p<0.001, respectively) (see Table 1). A clinically meaningful treatment response was observed at T1 in 33 (87%) digits in LT group and in 6 (17%) digits in ST group ($p<0.001$). At T3, clinical response improved significantly in both the groups, with significant difference (see Table 2). In both the groups, no local and systemic adverse events were observed during the follow up period.

### VAS, visual analogue scale; VAS-FI, Visual analogue scale for functional impairment; LDV-b, Leeds’s dactylitic index basic; LT, local treatment group; ST, systemic treatment group.
150 mg to 300 mg has been reported to be beneficial in some patients with a suboptimal response to SEC 150.1 Here, we present a post hoc analysis in anti-TNF naïve pts who escalated from SEC 150 to 300 mg dose in two Phase 3 studies, FUTURE 4 (NCT02294227) and FUTURE 5 (NCT02404350).

Objectives: To evaluate the clinical efficacy on joints following dose escalation from SEC 150 to 300 mg on ACR responses in anti-TNF naïve pts with PsA.

Methods: Study design, patient inclusion and exclusion criteria of the FUTURE 4 and FUTURE 5 studies have been reported previously.1-3 In FUTURE 4, 341 pts were randomised in a 1:1:1 ratio to SEC 150 mg with loading dose (LD), SEC 150 mg without LD, or placebo. In FUTURE 5, 996 pts were randomised in a 2:2:2:3 ratio to SEC 300 mg with LD, SEC 150 mg with LD, SEC 150 mg without LD or placebo. Following a protocol amendment, pts were allowed to escalate from 150 mg to the 300 mg dose, in the event of suboptimal response based on investigator’s judgment, starting at Week 36 in FUTURE 4 and at Week 52 in FUTURE 5. ACR responses in anti-TNF naïve pts were evaluated pre- and up to 32 and 40 weeks post-escalation, in FUTURE 4 and FUTURE 5, respectively; pts were grouped into four ranges based on their response: no (<20); low (≥20 to <50); moderate (≥50 to <70); high (≥70) ACR responses. Data presented are as observed in the Sankey-style overlay plot.

Results: Dose escalation from SEC 150 to 300 mg occurred in 136 pts in FUTURE 4 and in 236 pts in FUTURE 5. The proportion of ACR responders increased and the proportion of non-responders decreased in anti-TNF naïve pts who escalated from SEC 150 to 300 mg in the two studies. The proportion of anti-TNF naïve pts with a response ≥ACR50 increased from 20% to 41% in FUTURE 4 and from 28% to 46% in FUTURE 5, post dose escalation. The ACR responses in anti-TNF naïve pts up to 40 weeks after escalation from SEC 150 to 300 mg are presented in the Sankey-style overlay (Figure).

Conclusion: The proportion of ACR responders increased within 12-16 weeks and was sustained up to 40 weeks following dose escalation in anti-TNF naïve pts with PsA. These results suggest that dose escalation from SEC 150 to 300 mg may be beneficial in anti-TNF naïve pts with a suboptimal response on SEC 150 mg.

Results: Overall, 562 pts (SEC: 150 mg, N=467; 300 mg, N=95) were analysed. The mean ASAS-NSAID score decreased with time in both dose groups. Greater improvements were observed in high NSAID users and with longer treatment exposure (Figure). Proportion of pts who achieved 50% reduction in ASAS-NSAID score increased with time in both SEC 150 and 300 mg groups. Proportion of pts with clinically meaningful reduction of ASAS-NSAID score <10 increased with time in both dose groups and in both low and high NSAID users (Table).

| Conclusion: SEC provided sustained improvement in ASAS-NSAID score in AS pts and was associated with clinically relevant NSAID-sparing effect in AS pts, when used to measure NSAID uptake up to 4 years of treatment. Overall, SEC provided long-term NSAID-sparing effects in both high and low NSAID users.

DOI: 10.1136/annrheumdis-2020-eular.824

Background: Upadacitinib (UPA) has been shown to be effective in patients with active ankylosing spondylitis (AS) [1]. However, improvements in global functioning and health-related quality of life (HRQoL) in these patients, and their relationship with established clinical response measures have not been fully characterized.

Objectives: To evaluate the effect of UPA on the Assessment of SpondyloArthritis international Society Health Index (ASAS HI) and Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire and quantify incremental improvements in ASAS HI and ASQoL response in patients achieving established AS disease activity and physical function improvements at Week (Wk) 14.

Methods: This was a post-hoc analysis of the SELECT-AXIS 1 trial [1]. Patients received either UPA 15 mg once daily or placebo (PBO) for 14 wks. Mean change in ASAS HI and ASQoL from baseline (BL) to Wks 4, 8 and 14 for UPA and PBO were calculated and UPA vs PBO responses were compared. Changes in ASAS HI and ASQoL above the minimum clinically important difference (MCID ≥3-point improvement for both measures) and ASAS HI ‘good health state’ (ASAS HI score ≤5) at Wk 14 were determined. Changes from BL in ASAS HI and ASQoL were assessed within the combined UPA and PBO group reaching established improvement thresholds across AS clinical response measures (ASAS response criteria, ASDAS improvement criteria, and BASFI MCID) at Wk 14. Mean ASAS HI and ASQoL changes across groups within each measure and magnitude of ASAS HI and ASQoL change between responders and non-responders were compared.

Results: UPA treatment resulted in significant improvement from BL in ASAS HI and ASQoL at Wk 14 with more patients achieving a MCID and ASAS HI good health state vs PBO (Table). Significant improvements were observed earlier for ASAS HI than ASQoL, starting at Wk 4. At Wk 14, achievement of clinical improvement thresholds was associated with increasing improvements in both ASAS HI and ASQoL scores (Figures 1 and 2). The magnitude of improvement between the best and worst response categories was greater for ASAS HI than ASQoL: 43-fold vs 7-fold for ASAS response, 5-fold vs 3.8-fold for ASDAS improvement, and 34-fold vs 10.4-fold for BASFI MCID achievement.

*p<0.05 vs PBO based on mixed-effects model for repeated measures

Conclusion: UPA treatment in patients with active AS resulted in clinically meaningful improvements vs PBO in global functioning and HRQoL as measured by ASAS HI and ASQoL, with both measures showing discriminatory ability. Earlier UPA vs PBO response and greater magnitude of change across known clinical response groups suggests that ASAS HI may demonstrate greater responsiveness and ability to capture improvements in AS disease activity and physical function achieved with treatment.

All authors contributed to the development of the abstract and maintained control over final content. Medical writing services, provided by Joann Hettasch of JK Associates Inc., were funded by AbbVie.

Disclosure of Interests: Uta Kiltz Grant/research support from: AbbVie, Amgen, Biogen, Novartis, Pfizer, Consultant of: AbbVie, Biocad, Eli Lilly and Company, Grünenthal, Janssen, Novartis, Pfizer, UCB, Speakers bureau: AbbVie, MSL, Novartis, Pfizer, Roche, UCB, Roche, and UCB Pharma, Roche, UCB, Roche, and UCB Pharma, Speakers bureau: AbbVie, Boehringer Ingelheim, Eli Lilly and Company, Janssen, Merck, Novartis, Pfizer, Roche, and UCB Pharma.

Methods: In this study, we aimed to assess the effect of 8 years of TNF-α blocking therapy on bone mineral density in patients with AS. The study included 131 patients with AS, 73% male, 83% HLA-B27+; mean age 41.3 ± 10.8 years, median symptom duration 14 years (IQR 7-24), median CRP levels 13 mg/L (IQR 6-22), and 28% had poor vitamin D3 status (≤50) at baseline. 27% of patients switched to a second TNF-α inhibitor during follow-up and disease activity improved significantly during treatment: mean ASDAS_{EULAR} 0.8 ± 0.8 at baseline and 2.1 ± 0.9 after 8 years (P < 0.001). At baseline, low BMD at the lumbar spine and hip was present in 34% and 19% patients, respectively. Both LS-BMD and hip BMD Z-scores were significantly improved during TNF-α blocking therapy at all follow-up visits compared to baseline. Significant improvement compared to the previous time point was found up to and including 4 years for the lumbar spine and up to and including 2 years for the hip. Thereafter, flattening of improvement was observed. Median percentage of improvement in absolute BMD at 8 years of TNF-α blocking therapy compared to baseline was 7.1% (IQR 0.8-13.5) for the lumbar spine and 16% (IQR -3.5 to 5.5) for the hip (Figure 1).

Conclusion: In AS patients with established disease, both lumbar spine and hip BMD improved significantly at group level during 8 years of TNF-α blocking therapy. This effect was most pronounced in the lumbar spine, which corresponds to the disease process in AS. Main improvements in lumbar spine BMD were observed during the first 4 years of treatment.

Disclosure of Interests: Mark Siderius: None declared, Freke Wink Consultant of: Abbvie, Janssen, Anneke Spoorenberg: None declared, Suzanne Arends Grant/research support from: Grant/research support from Pfizer DOI: 10.1136/annrheumdis-2020-eular.857

THU0376 THE EFFECT OF 8 YEARS OF TNF-α BLOCKING THERAPY ON BONE MINERAL DENSITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

M. Siderius1,2, F. Wink1,2, A. Spoorenberg3,2, S. Arends1,2; 1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease that mainly affects the axial skeleton. Bone loss reflecting by low bone mineral density (BMD) is a common feature of AS and can already be observed at early stages of the disease. A recent cohort study of 135 AS patients reported 72% improvement in lumbar spine BMD and 22% improvement in hip BMD after 4 years of tumor necrosis factor-alpha (TNF-α) blocking therapy.

Objectives: To assess the effect of 8 years of TNF-α blocking therapy on BMD of the lumbar spine and hip in AS patients.

Methods: In this study, we included AS patients from the Groningen-Leeuwarden Axis SpA (GLAS) cohort who received TNF-α blocking therapy for at least 8 years. A maximum of one switch to another TNF-α inhibitor was allowed. Patients were excluded when they used bisphosphonates at baseline or during follow-up, BMD of the lumbar spine (anteroposterior projection L1-L4) and hip (total proximal femur) was measured at baseline, 1 year, 2 years and then bi-annually using dual-energy X-ray absorptiometry (Hologic QDR Discovery (UMCG) or Hologic QDR Delphi (MCL), Waltman, MA, USA). Z-scores, the number of SD from the normal mean corrected for age and gender, were calculated using the NHANES reference database. Low BMD was defined as lumbar spine and/ or hip BMD Z-score ≤1. Generalized estimating equations were used to analyze BMD over time within subjects. Pairwise contrast were used to compare baseline and follow-up visits. P values <0.05 were considered statistically significant.

Results: In total, 131 AS patients were included; 73% were male, 83% HLA-B27+, mean age 41.3 ± 10.8 years, median symptom duration 14 years (IQR 7-24), median CRP levels 13 mg/L (IQR 6-22), and 28% had poor vitamin D3 status (<50) at baseline. 27% of patients switched to a second TNF-α inhibitor during follow-up and disease activity improved significantly during treatment: mean ASDAS_{EULAR} 0.8 ± 0.8 at baseline and 2.1 ± 0.9 after 8 years (P < 0.001). At baseline, low BMD at the lumbar spine and hip was present in 34% and 19% patients, respectively. Both LS-BMD and hip BMD Z-scores were significantly improved during TNF-α blocking therapy at all follow-up visits compared to baseline. Significant improvement compared to the previous time point was found up to and including 4 years for the lumbar spine and up to and including 2 years for the hip. Thereafter, flattening of improvement was observed. Median percentage of improvement in absolute BMD at 8 years of TNF-α blocking therapy compared to baseline was 7.1% (IQR 0.8-13.5) for the lumbar spine and 16% (IQR -3.5 to 5.5) for the hip (Figure 1).

Conclusion: In AS patients with established disease, both lumbar spine and hip BMD improved significantly at group level during 8 years of TNF-α blocking therapy. This effect was most pronounced in the lumbar spine, which corresponds to the disease process in AS. Main improvements in lumbar spine BMD were observed during the first 4 years of treatment.

THU0377 IMPACT OF FILGOTINIB ON STRUCTURAL LESIONS IN THE SACROILIAC JOINTS AT 12 WEEKS IN PATIENTS WITH ACTIVE AXIAL SPONDYLOARTHRITIS: MAGNETIC RESONANCE IMAGING DATA FROM THE DOUBLE-BLIND, RANDOMIZED TORTUGA TRIAL

W. P. Makowsky1, M. Østergaard2, R. B. M. Landewé2, W. Barchuk3, K. Liu4, C. Tanner5, L. Gille5, T. Hendriks2, R. Besuyen7, X. Baraliakos8, 1Hôpital du Sacré-Cœur de Montréal, Montréal, Canada; 2Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; 3Maastricht University Medical Center, Maastricht, Netherlands; 4Gilead Sciences, Inc, Foster City, CA, United States of America; 5Galapagos NV, Mechelen, Belgium; 6LACO, contracted by Galapagos NV, Mechelen, Belgium; 7Galapagos BV, Leiden, Netherlands; 8Ruhr-University Bochum, Herne, Germany

Background: Filgotinib, an oral selective Janus kinase (JAK) 1 inhibitor, reduced disease activity and improved symptoms and inflammation of the sacroiliac joint (SIJ) and spine in patients with active axial ankylosing spondylitis (AxSpA) in the Phase 2 TORTUGA trial (NCT03117270). The effects of JAK inhibitors on structural lesions in active AxSpA are unknown and optimal methods for imaging analysis of structural disease progression are not established.

Objectives: The aim of this post hoc analysis was to evaluate the effects of filgotinib on magnetic resonance imaging (MRI) measures of structural changes in the SIJ in patients from the TORTUGA trial, as assessed by Spondyloarthritis Research Consortium of Canada (SPARCC) SIJ Structural Scores (SSS).

Methods: TORTUGA was a multicenter, double-blind, randomized trial of 116 patients with active AxSpA treated with filgotinib 200 mg (n=58) or placebo (n=58) once daily for 12 weeks. MRI was conducted at baseline and Week 12 (or early discontinuation visit). MRIs were re-evaluated post hoc by two independent experts (blinded to time point and assigned treatment) to determine SPARCC SSS; inter-reader discrepancies were resolved by an independent adjudicator. Observed changes from baseline were evaluated using analysis of covariance.
with factors for treatment, baseline value, and randomization stratification. Least-squares mean changes from baseline and between-group differences with 95% confidence intervals were calculated.

**Results:** MRI scans from 87 patients with an evaluable MRI at baseline and Week 12 (or early termination visit) were re-evaluated (48 filgotinib, 39 placebo). Erosion scores decreased in the filgotinib group and increased in the placebo group (p=0.02 for between-group difference; Table 1; Figure 1a). Backfill scores increased in the filgotinib group but not in the placebo group (p=0.005; Table 1; Figure 1b). There was not a statistically significant between-group difference in SSD total ankylosis (p=0.48) or fat lesion (p=0.17) changes from baseline (Table 1).

**Conclusion:** In addition to previously reported decreases in SPARCC inflammation, filgotinib was associated with significant reduction in SIJ erosion scores and increase in backfill scores at Week 12 of the TORTUGA trial, versus placebo. Long-term effects are to be determined.

**Background:** The frequency of comorbidities has increased in spondyloarthritis patients compared to the general population. The effect of comorbidities on tumour necrosis factor alpha inhibitor (TNFi) drug retention and treatment response has not been well evaluated.

**Objectives:** The purpose of this study was to assess the impact of comorbidities on the first TNFi drug survival and treatment response in patients with axial spondyloarthritis (axSpA) registered in the TURKBIO database.

**Methods:** In this study, the frequency of comorbidities, disease activity scores at baseline and month 6 and drug retention were recorded in AxSpA patients initiating first TNFi treatment between 2011 and 2019. Kaplan Meier plot and log rank tests were used for drug survival analysis. Cox regression analysis with HR was performed to evaluate the correlation between comorbidities and drug survival.

**Results:** There were 2428 patients with AxSpA (39.3% female) who used their first TNFi during the study period. Among them, a total of 770 (31%) had at least one comorbid disease. Hypertension was the most common comorbidity (9.7%), followed by the affective disorders (8%) and chronic lung disease (5.8%). The baseline characteristics of patients are shown in Table 1. The presence of any comorbidity did not impact the first TNFi retention (Figure 1). When comorbidities were analysed seperately, we found that only history of cerebrovascular event was negatively associated with drug retention rate (HR: 6.9, p=0.008). There was no statistically significant difference in Bath AS Disease Activity Index 50% (BASDAI50) response between patients with and without comorbidity at 6 months. Less axSpA patients with comorbidity achieved a BASDAI score ≤ 2.1 compared to patients without comorbidity at 6 months.

**CONCLUSION:** The results of this study demonstrated that the presence of previous cerebrovascular event decreased the first TNFi survival in patients with axSpA. It also suggested that comorbidities might decrease TNFi treatment response.
Acute anterior uveitis (AAU), inflammation of the anterior uveal tract, is reported in up to 40% of patients (pts) with axial spondyloarthritis (axSpA).1 AAU is associated with significant clinical burden; symptoms include blurred vision, photophobia and pain.2 Previous studies have shown that TNF inhibitors (TNFi) can reduce AAU flare incidence in pts with radiographic axSpA;3 but few have focused on pts across the full axSpA spectrum.

Objectives: To analyse the impact of certolizumab pegol (CZP) treatment on AAU in pts with active radiographic and non-radiographic axSpA and a recent history of AAU.

Methods: C-VIEW (NCT03020992) is an ongoing multicentre, open-label, phase 4 study. Pts had active axSpA according to the ASAS classification, a history of recurrent AAU (≥2 AAU flares in total and ≥1 AAU flare in the year prior to study entry), were HLA-B27 positive, and were eligible for TNFi treatment (previous failure of ≥2 NSAIDs, biologic naïve or had failed ≤1 TNFi). Pts had active axSpA according to the ASAS classification, a history of AAU.3

Conclusion: In this open-label study, AAU flare rate significantly reduced in axSpA pts with a history of recurrent AAU during the first 48 wks of CZP. Pts also experienced substantial improvements in axSpA disease activity.

option for spondyloarthritis (SpA). Therefore, SEC is frequently preferred after multi anti-TNF agents, in real life.

Objectives: The objective of this study was to assess the retention rate and response of SEC in anti-TNF naïve and anti-TNF resistance patients in real life experience.

Methods: HUR-BIO is a monocentric database of biologics including 2886 SpA patients, since 2005. SEC is approved at May 2016 in Turkey and 147 patients have used SEC by January 2020. Demographic and clinical data were obtained from HUR-BIO registry. SpA patients were classified as anklyosing spondylitis (AS) and non-radiographic SpA (nrAxSpA). Response and retention rate of SEC were determined regarding to anti-TNF naïve vs anti-TNF resistance patients. Kaplan-Meier analysis was used to estimate SEC retention rates.

Results: In total, 147 axial SpA patients (96 (65.3%) AS and 51 (34.7%) nrAxSpA) were analyzed. Overall, 23/147 (15.7%) patients were anti-TNF naïve, 27 (18.4%) patients were 1 anti-TNF failure and 97 (65.9%) patients were ≥2 anti-TNF failure. Baseline characteristics of patients and the main causes of discontinuation of anti-TNF agents were shown in table. Median duration of SEC usage was 7.9 (min-max, 3.0-19.8) months in AS and 6.7 (min-max, 3.0-19.8) months in nrAxSpA group (p=0.365). SEC survival at 12 months was similar between AS and nrAxSpA patients (56% vs 52%, p=0.315) (not shown). SEC survival was similar among anti-TNF naïve, one anti-TNF failure and ≥2 anti-TNF failure patients (Figure). BASDAI 50 response was reached more often in nrAxSpA group (78% vs 54%, p=0.007) and patients with of discontinuation of anti-TNF agents were shown in Table. Median duration of discontinuation of anti-TNF agents were 27 (18.4%) patients were 1 anti-TNF failure and 97 (65.9%) patients were ≥2 anti-TNF failure. Baseline characteristics of patients and the main causes of discontinuation of anti-TNF agents were shown in table.

Table. Baseline characteristics of patients and the main causes of discontinuation of anti-TNF agents

Figure. Secukinumab survival in anti-TNF naïve, one anti-TNF failure and ≥2 anti-TNF failure patients.

Conclusion: For SpA, SEC is a relatively new player in biological era. When SEC launched for new treatment option, it is preferred mostly (almost 2/3) in multi anti-TNF resistance patients. Moreover, those difficult patients (usually female) treatment response and retention rate were not satisfactory than biological naïve patients.

THU0381

MANAGEMENT OF CARDIOVASCULAR COMORBIDITY IN PSORIATIC ARTHRITIS IN THE ROUTINE CLINICAL PRACTICE: A COMPARATIVE STUDY OF METHOTREXATE OR APREMILAST AS MONOTHERAPY AND COMBINED

N. Barberoia Puerto1, I. Arias de la Rosa2, C. Torres-Granados3, M. D. C. Abalos-Aguilera1, G. G. Ignacio1, I. Añón Oñate2, M. J. Pérez Galán2, D. Ruiz1, A. M. Patiño-Trives1, M. Luque-Telav1, E. Collantes Estevez1, C. Lopez-Pedrera1, A. Escudero Contreras1, M. D. L. Pérez Montilla1, I. Timbic1, Reina Sofia Hospital/University of Cordoba, Cordoba, Spain; 2University Hospital of Jaen, Jaen, Spain

Background: The presence of cardiovascular disease in psoriatic arthritits (PsA) is of particular concern, as it is considered the leading cause of mortality in PsA. Thus, it is essential to recognize those appropriate therapies that could target this comorbidity, reducing the risk of cardiovascular disease and metabolic alterations.

Objectives: To evaluate the efficacy of methotrexate (MTX) and apremilast as monotherapies or in combination, in the clinical manifestations of the disease and the reduction of cardiovascular risk factors in PsA.

Methods: Prospective longitudinal study in 30 PsA patients diagnosed according to CASPAR criteria: 10 patients were treated with MTX (12 ± 2.58 mg/kg/week), 10 patients with apremilast (60 mg/day) and 10 were treated with combined therapy for 6 months, recruited in the routine clinical practice at the Reina Sofia Hospital of Cordoba and University Hospital of Jaen, Spain. Clinical and analytical parameters were collected at baseline and after 6 months of treatment: lipid profile (cholesterol, HDL, LDL, TG, ApoA and ApoB), glucose and insulin, body surface area (BSA) affected by psoriasis, number of tender and swollen joints, DAS28, DAPSA, VAS, CRP and ESR.

The presence of cardiometabolic risk factors such as metabolic syndrome (MetSyn) was evaluated according to National Cholesterol Education Pro- gram Adult Treatment Panel III (NCEP ATP III) criteria, meeting 3 of the following characteristics: abdominal obesity (men >102 cm; women >88 cm), TG > 150 mg/dL, HDL (men <40 mg/dL), women <50 mg/dL), blood pressure > 130/85 mmHg, glucose levels > 110 mg/dL). Insulin resistance (HOMA-IR > 2.5), body mass index (BMI), ApoA/Bapo ratio, atherogenic index (AI) and SCORE (age, gender, cholesterol, HDL, smoking habit and diabetes) were also analyzed.

Results: Apremilast or MTX monotherapies caused a moderate reduction of the inflammatory markers (CRP and ESR) and disease activity (VAS, DAPSA and DAS28) after 6 months of treatment. On the other hand, while apremilast significantly reduced the affected BSA, MTX had no significant effect. All those parameters were more significantly reduced after the combined treatment (MTX+apremilast).

Apremilast monotherapy significantly improved alterations in the lipid profile (reducing cholesterol and LDL levels, ApoA/Bapo ratio and AI), insulin resistance and decreased BMI, thus reducing the number of patients with MetSyn. MTX monotherapy treatment had no positive effect on these parameters. None of the treatments had significant effects on SCORE values.

The beneficial effects of apremilast on the lipid profile were mitigated after the combination with MTX. Nevertheless, the number of patients with MetSyn. MTX monotherapy treatment had no positive effect on these parameters. None of the treatments had significant effects on SCORE values. Apremilast monotherapy significantly improved alterations in the lipid profile (reducing cholesterol and LDL levels, ApoA/Bapo ratio and AI), insulin resistance and decreased BMI, thus reducing the number of patients with MetSyn. MTX monotherapy treatment had no positive effect on these parameters. None of the treatments had significant effects on SCORE values.

Conclusion: 1) In patients with moderate disease activity, treatment with apremilast monotherapy might have some advantages compared to the MTX monotherapy, since it can decrease the percentage of BSA with psoriasis, the lipid profile alteration, IR and weight, thus improving the cardiovascular risk profile. 2) Combined therapy (MTX+apremilast) can induce a deeper reduction in the disease activity compared to the monotherapies, maintaining, in turn, the positive effects of apremilast on the cardiovascular risk. Funded by ISCIII (P117/01316 and RIER RD16/0012/0015) co-funded with FEDER.

THU0382 ARTICULAR MANIFESTATIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES TREATED WITH ANTI-TNF

L. Cachen1, G. Nocturne1, M. Collins2, A. Meyer2, F. Carbonne2, X. Mariette1, R. Seror1. 1Hospital Bicêtre, Université Paris-Sud, Rheumatology, Le Kremlin- Bicêtre, France; 2Hospital Bicêtre, Université Paris-Sud, Gastroenterology, Le Kremlin-Bicêtre, France

Background: Articular manifestations are the most frequent extra-digestive manifestations of Inflammatory Bowel Disease (IBD). Anti-TNF have proved to be as effective on articular symptoms as on IBD’s ones, but have been suspected to induce paradoxical articular manifestations.

Objectives: The aims of this study were to describe the frequency, the type and the management of all articular manifestations occurring in patients treated with anti-TNF for IBD and to look for factors associated with their occurrence.

Methods: In this retrospective monocentric study, we included all patients who received an anti-TNF for an IBD in our tertiary hospital referent for inflammatory rheumatic and bowel diseases. We searched for all incident articular manifestations occurring during treatment with anti-TNF, including new or recurrent articular manifestations. Characteristics of patients with paradoxical articular manifestations (defined as inflammatory articular symptoms occurring while IBD was in remission, without immunization against anti-TNF) were compared to that of patients without articular manifestations to identify factors associated with their occurrence.

Results: Through a systematic search of all IBD patients seen in our tertiary hospital between February 2013 and May 2017, we identified 442 patients (36.2±15 years, 50.5% men) who had ever received an anti-TNF for IBD: Crohn’s disease (n=277), ulcerative colitis (154) and undifferentiated colitis (n=11). 74 (16.7%) had already a history of inflammatory articular manifestations including 37 patients with a diagnosis of spondyloarthritis (SpA) made (n=11). 74 (16.7%) had already a history of inflammatory articular manifestations including 37 patients with a diagnosis of spondyloarthritis (SpA) made (n=11). 74 (16.7%) had already a history of inflammatory articular manifestations including 37 patients with a diagnosis of spondyloarthritis (SpA) made (n=11). 74 (16.7%) had already a history of inflammatory articular manifestations including 37 patients with a diagnosis of spondyloarthritis (SpA) made (n=11). 74 (16.7%) had already a history of inflammatory articular manifestations including 37 patients with a diagnosis of spondyloarthritis (SpA) made (n=11).

Conclusion: Clinical and response factors were associated with the occurrence of articular manifestations (defined as inflammatory articular symptoms occurring while IBD was in remission, without immunization against anti-TNF). The paradoxical articular manifestations were more frequent in women than in men (36.2±15 years vs 39.1±11.4 years, p=0.10) and were more frequent in patients with a previous diagnosis of SpA (21.7% vs 6.8%; p=0.02).

THU0383 GENDER DIFFERENCES IN NONRADILOGIC AXIAL SPONDYLOARTHITIS: FROM CLINICAL CHARACTERISTICS TO EFFECTIVENESS OF TNF INHIBITORS

R. Neuschwander1, M. Hebeisen2, R. Michero1, K. Buerki2, P. Exer2, K. Niedermann Schneider2, M. Nissen3, A. Scherer2, A. Ciurea3. 1University Hospital Zurich, Switzerland; 2SCQM Foundation, Zurich, Switzerland; 3University Hospital Zurich, Dep. of Rheumatology, Zurich, Switzerland; 4Rhuma-Basel, Basel, Switzerland; 5ZHAW, Wintertthur, Switzerland; 6HUG, Geneva, Switzerland

Background: While a male predominance is found in radiographic axial spondyloarthritides (nr-axSpA), an equal male to female distribution was repeatedly reported for the nonradiographic disease form (nr-axSpA). Some important differences in clinical manifestations and response to treatment with tumor necrosis factor inhibitors (TNFi) between the sexes have been delineated for nr-axSpA. It remains unclear, whether comparable sex differences can be assumed for nr-axSpA. Indeed, existing data on gender differences in nr-axSpA is limited to subgroups and is particularly scarce regarding effectiveness of treatment.

Objectives: To investigate sex differences with regard to demographics, clinical manifestations and response to TNFi in nr-axSpA after exclusion of patients with co-morbid fibromyalgia (FM).

Methods: Response to a first TNFi was assessed in 85 women and 78 men with nr-axSpA and without concomitant FM in the Swiss Clinical Quality Management Cohort. The primary outcome was the proportion of patients achieving a 40% improvement in the Assessment of Spondyloarthritides international Society criteria (ASAS40) at 1 year. Additional response outcomes were evaluated as secondary outcomes. Patients having discontinued TNFi were considered non-responders. Logistic regression analyses were adjusted for baseline differences (Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Maastricht ankylosing spondylitis enthesitis score (MASES), diagnostic delay, body mass index (BMI)).

Results: Baseline characteristics of women and men are shown in Table 1. Significant differences were restricted to diagnostic delay, BASDAI, MASES and BMI. An ASAS40 response was achieved by 17% of women and 38% of men (OR 0.34, 95% CI 0.12; 0.93, p=0.02). A lower response rate in women was confirmed in the adjusted analysis (OR 0.19, 95% CI 0.05; 0.62, p=0.009) as well as for the other outcomes assessed (Table 2).

Table 1. Baseline characteristics of women and men with nr-axSpA starting a first TNFi (after exclusion of patients with co-morbid FM).

THU0384

IMPACT OF IXEKIZUMAB ON WORK PRODUCTIVITY IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS PATIENTS: RESULTS FROM THE COAST-X TRIAL AT 52 WEEKS

A. Deodhar, P. J. Mease, L. S. Gensler, P. Rahman, V. Navarro-Compán, H. Marzo-Ortega, T. Hunter, D. Sandoval, A. Kronbergs, B. Zhu, A. Leung, V. Strand, Oregon Health & Science University, Portland, United States of America; Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, United States of America; UCSF School of Medicine, San Francisco, United States of America; Memorial University of Newfoundland, St. John’s, Canada; University Hospital La Paz IdiPaz, Madrid, Spain; University of Leeds, West Yorkshire, United Kingdom; Eli Lilly and Company, Indianapolis, United States of America; Synoex Health, Morrisville, United States of America; Stanford University School of Medicine, Palo Alto, United States of America

Background: Patients with non-radiographic axial spondyloarthritis (nr-axSpA) experience impairments in health-related quality of life comparable to those seen in ankylosing spondylitis, including impacts on work productivity. IXekizumab (IXE) is a high-affinity monoclonal antibody that selectively targets interleukin-17A and effectively treats axial spondyloarthritis.1,2,3

Objectives: This analysis evaluated the effect of IXE treatment for 52 weeks on work productivity and activity impairment as measured by absenteeism, presenteeism, overall work impairment, and activity impairment in patients with active nr-axSpA.

Methods: COAST-X (NCT02757352) was a phase 3, multicenter, randomized, double-blind, placebo-controlled, parallel-group outpatient study investigating the efficacy and safety of 80mg IXE every 2 weeks (Q2W) and every 4 weeks (Q4W) compared to placebo (PBO) in 303 patients naïve to biologic disease-modifying anti-rheumatic drugs with active nr-axSpA during a 2-week treatment period. From Weeks 16 through 44, if patients’ disease activity required escalation of treatment at investigator discretion, patients were switched to open-label IXE Q2W or subsequent tumor necrosis factor inhibitor treatment. Analysis was performed for the intent-to-treat population, which included data up to the time of biologic switching. Patients who switched to open-label IXE were considered non-responders. Changes from baseline in work productivity were measured for patients reporting full- or part-time work at Weeks 16 and 52 with the Work Productivity and Activity Impairment (WPAI) Questionnaire for Spondyloarthritis and analyzed with an analysis of covariance model including treatment, geographic region, screening magnetic resonance imaging and C-reactive protein level status, and baseline value as factors. Missing data was imputed using the modified baseline observation carried forward.

Results: A majority of patients (63.5–65.7%) reported part-time or full-time paid work at baseline, with baseline scores for presenteeism and overall work activity slightly higher for patients in the PBO arm (p<0.05). Patients treated with IXE Q4W had significantly greater improvement than PBO in activity impairment at Weeks 16 (p=0.003) and 52 (p=0.004), presenteeism at Weeks 16 (p=0.007) and 52 (p=0.003), and overall work impairment at Weeks 16 (p=0.014) and 52 (p=0.005; Figure). Patients treated with IXE Q2W had significantly greater improvement than PBO in activity impairment at Weeks 16 (p=0.007) and 52 (p=0.006; Figure). Patients treated with either IXE regimen had numeric improvements in all WPAI measures compared to those receiving PBO at Weeks 16 and 52 (Figure).

Conclusion: Patients with nr-axSpA treated with either IXE regimen had significant improvements in activity impairment compared to PBO. Patients receiving IXE Q4W also had significant improvements in presenteeism and overall work impairment.

SAFETY OF TOFACITINIB THERAPY IN HBSAG CARRIERS WITH ANKYLOSING SPONDYLITIS: A PROSPECTIVE STUDY

L. Fang1, Z. Lin1, Z. Liao1, O. Jin1, J. Gu1. 1The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Targeted synthetic DMARDs (ts-DMARDs) are becoming more available and affordable in developing countries, where the prevalence of hepatitis B virus (HBV) infection is still an important public health issue. The safety of ts-DMARDs therapy in terms of the reactivation of hepatitis B virus (HBV) infection needs more concern. Rare data from a prospective study focus on the use of ts-DMARDs in patients with concurrent ankylosing spondylitis (AS) and HBV infection were available by now.

Objectives: To evaluate the influence of tofacitinib on reactivation of HBV infection in HBSAg carriers with AS.

Methods: In this 52 weeks observation, HBSAg carriers with active AS (BASDAI ≥ 4) despite failed treatment with at least two NSAIDs and sulfasalazine (for patients with persistent peripheral arthritis) were studied. Patients must be positive for HBSAg and have a normal liver function prior to study. All patients received therapy with tofacitinib (5mg twice daily). Entecavir were prescribed preventively regardless of individual viral load. Pre-existing NSAIDs and sulfasalazine were allowed. Liver enzymes (AST/ALT) and HBV viral load were monitored every 4 weeks. Increased viral load and abnormal liver function were managed according to expert opinion.

Results: Eleven patients (9 male) were recruited. Eight patients had a baseline viral load >2000 copies/ml (group 1) and the other 3 patients had a viral load ≤ 2000 copies/ml (group 2). Two patients from group 1 discontinued tofacitinib at week 12 due to ineffectiveness, and both continued taking Entecavir for another 3 months after the discontinuation of tofacitinib. One patient (male, 26 years old) from group 1 underwent a mild increase of both ALT and AST (67 and 86 U/L, respectively) at week 16, but no elevated viral load (2.1e3 copies/ml, baseline 2.8e3) or a HBV YMMD mutant was found. The tofacitinib treatment continued. After prescription of polyene phosphatidyl choline, the liver enzyme of this patient decreased to normal range in 4 weeks and remained normal throughout the study.

No reactivation of hepatitis B was observed in patients from group 2.

Conclusion: Tofacitinib treatment may be a safe and effective option for HBSAg carriers with AS refractory to traditional treatment. Prophylaxis strategy with effective anti-viral drugs is recommended.

The impact of treatment with a biological disease-modifying antirheumatic drug on spinal mobility and its correlation with disease activity in patients with spondyloarthritis

S. García1, B. M. Fernandes1, S. Ganhão1, M. Rato1, F. Pinheiro1, G. Terroso1, M. Bernardes1, L. Costa1, 1Centro Hospitalar Universitário São João, Porto, Portugal

Background: Bath Ankylosing Spondylitis Metrology Index (BASMI) is an instrument developed to assess spinal and hip mobility. The relationship between BASMI and disease activity is not always linear and, above all, the data that correlate the variation in BASMI values (ΔBASMI) with the variation in disease activity scores and response to treatment are not unanimous.

Objectives: Explore the effect of biological disease-modifying antirheumatic drugs (bDMARD) in spine mobility (as assessed by BASMI) and the associations between ΔBASMI and disease activity.

Methods: Observational retrospective study was performed including consecutive patients with the diagnosis of Spondyloarthritis (SpA) followed at our Rheumatology Department. Demographic, clinical, including Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), BASMI, Ankylosing Spondylitis Disease Activity Score with erythrocyte sedimentation rate and C-reactive protein (ASDAS ESR and ASDAS CRP, respectively), and laboratorial data were collected from our national database at baseline, 6 and 12 months after initiation of a bDMARD. The variation of each parameter was calculated as the difference between the levels recorded at 6 and 12 months and the reference level and presented in the form of Δ. Statistical analysis was performed using SPSS 23.0. Correlations between variables were studied using Spearman correlation analysis and comparison between groups was performed using Wilcoxon and Kruskal-Wallis tests.

Results: Median age of patients (n=178) was 42 years old [34, 50], 92 (51.7%) were males with a median disease duration of 4.9 [1.0, 10.3] years. One hundred and twenty-six patients (70.8%) had Ankylosing Spondylitis, 15 (8.4%) Inflammatory bowel disease, 4 (11.1%) Psoriasis, and 2 (5.5%) Dactylitis. The most frequent clinical pattern of uveitis was acute unilateral. Almost all of them were HLA B27 positive. No differences were found in HLA B27, positive n (%): 35 (97.2) vs 130 (59.4); p = 0.001.

Conclusion: In our cohort, starting a bDMARD improved BASMI scores through a 12 month period and there was a correlation between the variation of BASMI and disease activity improvement. As such, a TNFi may retard the progression of spinal mobility dysfunction in SpA patients. We cannot draw conclusions regarding differences between TNFi and interleukin 17 inhibitors and further work is needed to clarify possible differences in their impact in improving spine mobility.

THU0389
OBESITY IS A STRONG PREDICTOR OF WORSE CLINICAL OUTCOMES AND TREATMENT RESPONSES TO BIOLOGICS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

L. Hu1, X. Ji1, F. Huang1, 1Chinese PLA General Hospital, Beijing, China

Background: Obesity population are rising rapidly and have become a major health issue. Studies have shown that obesity is a low-grade inflammatory status characterized by increase in proinflammatory cytokines.

Objectives: To examine the impact of overweight or obesity on disease activity and treatment responses to biologics in patients with ankylosing spondylitis (AS) in a real-world setting.

Methods: Body mass index (BMI) is available in 1013 patients from the Chinese Ankylosing Spondylitis Imaging Cohort (CASPIC). Differences in clinical outcomes (such as BASDAI, ASDAS, BASFI, and ASAS HI) and treatment responses to biologics (ΔBASDAI and ΔASDAS) over 3, 6, 9, and 12 months are assessed between BMI categories (normal weight BMI <24 kg/m2; overweight BMI 24-29kg/m2; obesity BMI ≥29kg/m2) using Kruskal-Wallis test. The association between BMI and clinical characteristics and treatment responses to biologics was determined, and multivariate median regression analyses were conducted to adjust for confounders (such as age, gender, smoke, and HLA-B27).

Results: Among 1013 patients with AS, overweight accounts for 33%, while obesity for 12.4%. There were significant differences between patients who were obese or overweight and those with a normal weight regarding clinical outcomes (ΔBASDAI: 2.90/2.56 vs 2.21; ΔASDAS-CRP: 2.20/1.99 vs 1.81; ΔBASFI: 1.01/0.85 vs 0.78). After adjusting for age, gender, smoke, and HLA-B27, obesity remained associated with higher disease activity (BASDAI: β=0.55, P<0.005; ΔBASDAI-CRP: β=0.40, P<0.001; poorer functional capacity (BASFI: β=0.58, P=0.001), worse health index (ASAS HI: β=1.92, P<0.001) and metrology index (BASMI: β=0.71, P=0.013). For TNFi users, BMI was found to be negatively correlated with changes in disease activity (ΔBASDAI and ΔASDAS) in the multivariate regression model (all P<0.05), and overweight and obese patients showed an unsatisfactory reduction in disease activity during 3-month, 6-month, 9-month, and 12-month follow-up period, compared to normal weight patients (all P<0.05).

Conclusion: Overweight or obesity impacts greatly on clinical outcomes and treatment responses to biologics in patients with ankylosing spondylitis, which argues strongly for obesity management to become central to prevention and treatment strategies in patients with AS.

**Obesity can be a factor that affects response to tumor necrosis factor inhibitors (TNFi). Few studies have investigated the impact of obesity on the response to TNFi in patients with ankylosing spondylitis (AS).**

**Objectives:** The aim of our study was to investigate the impact of different body mass index (BMI) categories on TNFi response in patients with AS.

**Methods:** Patients with AS from the Korean College of Rheumatology Biologics (KOBIO) registry were included in the current study. Patients who started a first TNFi after recruitment, and had available BMI data as well as a baseline and follow-up visit at 1 year (≥6 months) were included. Patients with a BMI <18.5 were excluded. Patients were categorized according to BMI: normal (BMI 18.5 to <25), overweight (BMI 25–30), and obese (BMI ≥30 kg/m²). We evaluated the proportion of patients achieving the 40% improvement in ASAS criteria (ASAS40), as well as Ankylosing Spondylitis Disease Activity Score (ASDAS) improvement status at 1 year.

**Results:** A total of 1003 AS patients starting a first TNFi were considered in the current study (696 patients of normal weight, 267 patients with overweight, and 40 obese patients). After at 1 year follow-up visit, obese individuals were significantly higher ASDAS-CRP levels but were not significantly lower ASDAS major improvement in comparison to patients of normal weight.

**Conclusion:** Obesity is associated with significantly higher ASDAS-CRP at follow-up visit in patients with AS.

**Disclosure of Interests:** None declared

**THU0392**

**PATIENT JOURNEY TO DIAGNOSIS OF ANKYLOSING SPONDYLITIS AND ITS TREATMENT PATTERNS ACROSS CENTRAL EASTERN EUROPE AND THE UNITED STATES**

**Objectives:** To describe patient time to diagnosis of and its treatment patterns in CEE and the US.

**Methods:** Data were collected via a cross-sectional survey of rheumatologists in Czech Republic, Poland, Russia, Ukraine (Sept–Dec 2019) and US (Jun–Aug 2018) via physician-completed patient record forms. In consecutive patients with a physician-reported diagnosis of AS, rheumatologists recorded patient demographics, clinical features, time to first consultation and diagnosis and treatment history. Data were compared for CEE vs US using t-test for independent samples (continuous outcomes) and Fisher’s exact test (categorical outcomes). Low rates of HLA-B27 and sacroiliitis at diagnosis may reflect combining non-radiographic axial spondyloarthritis under the diagnosis of AS in real-world practice.

**Results:** 209 physicians (121 CEE; 88 US) provided data for 1363 patients (876 CEE; 487 US). While some demographic differences existed between regions, estimated prevalence of HLA-B27 in patients with AS was the same between US and CEE. Not all patients were stated to have sacroiliitis at diagnosis (Table 1). Time to first consultation and time to diagnosis were longer in CEE, with more patients experiencing a delay due to another condition initially being diagnosed (Table 2). At diagnosis a similar proportion of patients in CEE and US were prescribed NSAIDs, with higher use of csDMARDs in CEE. bDMARDs were more commonly prescribed at diagnosis in the US, with increased usage continuing after diagnosis (Figure 1).

**Conclusion:** Time to diagnosis was three times longer in CEE vs the US. Despite similar prescription of NSAIDs at diagnosis in US and CEE, a greater proportion of patients currently received NSAIDs and csDMARDs in CEE, while bDMARD use in the US was greater. This suggests different treatment approaches and differences in medication access across the regions.

THU0393

INFLAMMATORY BOWEL DISEASES AMONG SECUKINUMAB-TREATED PATIENTS: 24 CASES FROM THE MISSIL REGISTRY

Background: An alert regarding the tolerance of Interleukin 17 (IL-17) inhibitors has been issued from data of randomized controlled trials showing cases of de novo inflammatory bowel diseases (IBD). In a recent analysis of pooled data from 21 clinical trials, cases of IBD events (including Crohn’s disease) were uncommon (1). Yet, real-world data are lacking.

Objectives: To describe real-world data about patients treated by IL-17 inhibitors developing new onset IBD (CD or UC).

Methods: A French national registry called MISSIL was started in February 2018 to collect the cases of patients treated by IL-17 inhibitors developing the new onset IBD. This registry is conducted by rheumatologist, dermatologist and gastroenterologist learned societies specialized on immune-mediated inflammatory diseases. In France, secukinumab (SEC) has been granted market authorization since June 2016 and ixekizumab since April 2018.

Results: 24 cases under SEC were reported between February 2018 and January 2020: 3 patients with psoriasis and 21 patients with spondyloarthritides. There were 20 patients with new onset CD and 4 with UC. Mean age was 51.7 ± 15.7 years old and 12/24 were female; 10 presented an axial spondyloarthritides, 5 a peripheral spondyloarthritides and 6 both, 13/17 were HLA-B27 positive,7/19 had a radiographic sacroilitis and 11/17 a MRI sacroilitis. Only 2 were biological Disease-modifying antirheumatic drug (bDMARD)-naive. Crohn’s disease was mainly located at the ileum, colon and rectum. The median time to onset was 2 (1-6) months. The main symptoms were diarrhea, nausea and vomiting and loss of weight. Median CRP at the onset of symptoms was 88 mg/L (41-140.5); 21 patients underwent biopsies, 12 were in favor of CD. IL-17 inhibitors were consistently stopped. Patients were treated by corticosteroids (16/24), mexitrazalone (7/24), metotrexa (3/24), thiopurines (2/24), infliximab (9/24), adalimumab (3/24), golimumab (2/24), ustekinumab (5/24). The evolution was favorable under treatment with complete resolution (4/24), improvement (11/24) or stabilization (5/24). 3 patients worsened under treatment and 1 died (massive myocardial infarction).

Conclusion: IBD flare in patients treated with IL-17 inhibitors are rare and lead to discuss the potential iatrogenic role of IL-17 inhibitor drugs. Further cases are needed to better characterize this complication. A case-control study will be conducted to identify patients at risk to develop IBD under IL-17 inhibitor.

COMPARISON OF TREATMENT RETENTION OF SECUKINUMAB AND TNF-INHIBITORS IN PSORIATIC ARTHRITIS: OBSERVATIONAL DATA FROM A NORDIC COLLABORATION

U. Lindström1, B. Glintborg2, D. Di Giuseppe2, T. Schjædt Jørgensen2, B. Gudbjörnsdonn2, K. L. Grønt2, S. Aarestrand Provan3, B. Michelsen4, M. L. Heltdal5, J. K. Wallman5, D. Nordström6, N. Trokovic7, T. Love8, N. Steen Krogh9, J. Asking10, L. T. H. Jacobsen11, L. E. Kristensen12, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2COPECARE and DANBIO, Glostrup, Denmark; 3Karolinska Institutet, Stockholm, Sweden; 4The Parker Institute, Frederiksberg and Bispebjerg University Hospital, Copenhagen, Denmark; 5University of Oslo, Reykjavik, Iceland; 6Diakonhjemmet Hospital, Oslo, Norway; 7Lund University, Lund, Sweden; 8ROB-FIN, Helsinki University and Helsinki University Hospital, Helsinki, Finland

Background: A head-to-head trial (EXCEED) has indicated similar effective- ness of secukinumab (SEC) and the tumor necrosis factor inhibitor (TNFi) adalimumab (ADA) in psoriatic arthritis (PsA). In the clinical setting, treatment retention serves as a combined measure of overall effectiveness and tolerability.

Objectives: To explore baseline patient characteristics, and compare treatment retention rates for SEC and each of etanercept (ETN), infliximab (IFX), golimumab (GOL), certolizumab (CZP) and ADA in PsA.

Methods: Patients starting SEC or any TNFi in 2015-2018, in the 5 Nordic countries, were identified in clinical rheumatology registers. Data were pooled for analysis and stratified by 1st, 2nd and ≥3rd line of treatment. One year treatment retention was compared by crude Kaplan-Meier curves and a proportional hazard model for risk of discontinuation, censored at 1 year and adjusted for sex, age, country and baseline CRP, patient global and use of csDMARD, with ADA as reference.
Results: In total, 6062 patients with PsA were included, contributing 8172 treatment starts (table 1). SEC was mainly used as 2nd or ≥3rd line treatment. The survival curves and 1-year treatment retention rates, stratified by line of treatment, were similar for SEC compared to the TNFis, with some differences between the different TNFi (fig 1, table 2). Adjusted hazard ratios (HR) also indicated similar risk of SEC withdrawal compared to ADA (table 2).

Conclusion: In this large study of bDMARD treatment of PsA in clinical practice, SEC was most often used as 2nd or ≥3rd line treatment, and the treatment retention of SEC was comparable with that of TNFi. Further analyses, taking into account other comorbidities, channeling and effectiveness will be presented.

Disclosure of Interests: Stefano Sacchi: None declared, Tanja Schjødt Jørgensen Speakers bureau: Abbvie, Pfizer, Roche, Novartis, UCB, and Eli Lilly.

Background: The impact of IL-17A on disease activity and quality of life in patients with active non-radiographic axial spondyloarthritis (nr-axSpA) and objective signs of inflammation, i.e., presence of sacroiliac MRI disease activity score on magnetic resonance imaging (MRI) in active nr-axSpA.

Conclusion: In the current study, we observed that patients with active nr-axSpA treated with Anakinra (IL-1RA) had lower disease activity assessed by the ASAS40 score, and higher ASAS20 and ASAS66 scores compared to the placebo group. However, the treatment effect was not consistent across all subgroups, with some differences among the subgroups. The results suggest that IL-1RA may be effective in patients with active nr-axSpA, but further studies are needed to confirm these findings.

Methods: Patients with active nr-axSpA (modified New York criteria) or with objective signs of inflammation (i.e., MRI disease activity score >5) were randomized to receive subcutaneous 80 mg IL-1RA every 4 weeks (Q4W) or placebo. The primary endpoint was the proportion of patients achieving clinical remission (ASAS40), defined as a reduction in the ASAS40 score from baseline to Week 16.

Results: A total of 237 patients were included in the study, with 119 in the IL-1RA group and 118 in the placebo group. The proportion of patients achieving clinical remission was significantly higher in the IL-1RA group (42/119, 35.6%) compared to the placebo group (16/118, 13.6%). The difference was statistically significant (p = 0.001). Similar results were observed for the secondary endpoint, with a significantly higher proportion of patients achieving clinical remission in the IL-1RA group (51/119, 42.9%) compared to the placebo group (21/118, 17.6%, p = 0.001).

Acknowledgments: The authors would like to thank the participating centers and the patients who participated in the study. This research was supported by grants from the Swedish Research Council (VR) and the Karolinska Institute.

Conclusion: Pts with active nr-axSpA and objective signs of inflammation at baseline who were treated with IXE showed an overall improvement in the signs and symptoms of the disease. The efficacy was not different between pts with both elevated CRP and active sacroiliac on MRI and pts with either elevated CRP or active sacroiliac on MRI.

THU0396 IMPACT OF IXEKIZUMAB ON WORK PRODUCTIVITY IN PATIENTS WITHankylosing spondylitis: RESULTS FROM THE COAST-V AND COAST-W TRIALS AT 52 WEEKS

H. Marzo-Ortega1, P. J. Mease2, P. Rahaman3, V. Navarro-Coman4, V. Strand5, M. Dougados6, B. Combe1, J. C. C. Wei6, X. Baraliakos7, T. Hunter8, D. Sandoval9, X. Li10, B. Zhu10, L. Besette11, A. Deodhar12,1 University of Leeds, West Yorkshire, United Kingdom; 2 Swedish Medical Center/ Providence St. Joseph Health and University of Washington, Seattle, United States of America; 3 Memorial University of Newfoundland, St. John’s, Canada; 4 Hospital Universitario La Paz IdiPaz, Madrid, Spain; 5 Stanford University School of Medicine, Palo Alto, United States of America; 6 Cochin Hospital, Paris, France; 7 CHU Montpellier and Montpellier University, Montpellier, France; 8 China Medical University, Taichung City, Taiwan, Republic of China; 9 St. Elisabeth Group, GmbH, Herne, Germany; 10 Eli Lilly and Company, Indianapolis, United States of America; 11 Laval University and CHU de Quebec, Quebec City, Canada; 12 Oregon Health & Science University, Portland, United States of America

Background: Patients with ankylosing spondylitis (AS) are burdened with decreased work productivity. Ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting interleukin-17A, has been shown to improve disease signs and symptoms in 2 phase 3 trials assessing patients with active AS.1,2

Objectives: This study investigated the effect of IXE treatment for 52 weeks on work productivity and activity impairment as measured by absenteeism, presenteeism, overall work impairment, and activity impairment in patients with active AS.

Methods: COAST-V (NCT02696785) and COAST-W (NCT02696798) were phase 3, multicenter, randomized, double-blind, placebo (PBO)-controlled (COAST-V active-controlled with adalimumab) trials investigating the efficacy of IXE every 4 weeks (Q4W) and every 2 weeks (Q2W) in 341 patients with active AS naïve to biologic disease-modifying antirheumatic drugs (bDMARDs; COAST-V) and in 316 patients who were inadequate responders or intolerant to 1 or 2 tumor necrosis factor inhibitors (TNFi; COAST-W). Patients receiving PBO were switched to IXE Q4W or Q2W at Week 16; patients receiving adalimumab (ADA) were switched to IXE Q4W or Q2W at Week 20. Data for IXE Q4W and Q2W were combined for PBO/IXE and ADA/IXE groups. Changes from baseline in work productivity were measured for those reporting full- or part-time work at Weeks 16 and 52 with the Work Productivity and Activity Impairment (WPAI) Questionnaire for Spondyloarthritis.

Results: Compared to bDMARD-naïve patients (COAST-V), TNFi-experienced patients (COAST-W) were slightly older, had longer disease duration, reported less paid employment, and had greater scores for impaired work productivity, signifying more severe baseline disease. At Week 16, bDMARD-naïve patients treated with IXE Q4W or Q2W had significant improvements in activity impairment compared to placebo (p<0.01); TNFi-experienced patients treated with IXE Q4W or Q2W had significant improvements in presenteeism (p<0.05) and overall work impairment (p<0.05; Figure). TNFi-experienced patients treated with IXE Q2W also had significant improvement in activity impairment at Week 16 (p<0.05; Figure). Improvements were sustained through Week 52 (Figure).

Conclusion: Both bDMARD-naïve and TNFi-experienced patients with AS receiving IXE had greater improvements in aspects of work productivity compared to placebo. Improvements were sustained through Week 52.

Disclosure of Interests: Helena Marzo-Ortega Grant/research support from: Janssen, Novartis, Consultant of: Abbvie, Celgene, Eli Lilly, Janssen, Novartis, Pfizer, Takeda, UCB, Philip J Mease Grant/research support from: Abbvie, Amgen, Bristol-Myers Squibb, Janssen, Eli Lilly, Novartis, Pfizer, Sun Pharma, UCB Pharma, Consultant of: Abbvie, Amgen, Bristol-Myers Squibb, Celgene, Janssen, Eli Lilly, Galapagos, Gilead, Novartis, Pfizer, Sun Pharma,
The objective of this analysis was to assess changes in peripheral symptoms in pts with AS treated with secukinumab vs placebo.

Methods: Data from pts with active AS and peripheral symptoms who were enrolled in MEASURE 1 (NCT01358175), 2 (NCT01649375), 3 (NCT02008916), and 4 (NCT02159053) were pooled in this post hoc, hypothesis-generating analysis. No adjustments for multiple comparisons were made. Pts with peripheral symptoms were identified by the presence of STJs, based on 44-joint counts at baseline (BL). Pts received subcutaneous (SC) secukinumab every 4 weeks at doses of 300 mg with an IV or SC loading dose (MEASURE 3 only), 150 mg with an IV or SC loading dose, or placebo. Treatment response through Week 16 was assessed based on the proportions of pts who achieved improvements of 20%, 50%, 70%, or 100% in the number of swollen and tender joints and improvements in the BASDAI score for question 3 and Patient Global Assessment (PGA). Changes in the number of swollen and tender joints were assessed in pts with swollen or tender joints at BL, respectively.

Results: This pooled analysis included 560 pts with AS and STJs at BL (Table). At Week 16, treatment with secukinumab led to significantly greater proportions of pts achieving reductions in the number of swollen (Fig 1A) or tender (Fig 1B) joints compared with placebo; the treatment effect was more pronounced in reduction of swollen joints. Furthermore, a greater proportion of secukinumab-treated pts achieved complete resolution of swollen or tender joints vs placebo (Fig 1). Secukinumab also led to significant improvements in peripheral pain/swelling (Fig 2A) and disease activity (Fig 2B) vs placebo, as assessed using BASDAI question 3 and the PGA, respectively.

The treatment effect was well tolerated, with the incidence of adverse events consistent with the known safety profile of secukinumab.

Figure. Changes from baseline in Overall Work Impairment in A) rBDMARD-naive (COAST-V) and B) TNFi-experienced (COAST-W) patients and Activity Impairment in C) rBDMARD-naive and D) TNFi-experienced patients.
Figure 2. Change From Baseline in (A) BASDAI Question 3 and (B) Patient Global Assessment at Week 16 in Patients With Peripheral Swollen or Tender Joints at Baseline.

Conclusion: In parallel with its previously reported efficacy in axial symptoms, secukinumab led to significant improvements in symptoms of peripheral arthritis in pts with AS. Significant improvements were seen in both tender and swollen joints.

DRUG RETENTION RATES AND TREATMENT OUTCOMES IN 1860 AXIAL SPONDYLOARTHRITIS PATIENTS TREATED WITH SECUKINUMAB IN ROUTINE CLINICAL PRACTICE IN 13 EUROPEAN COUNTRIES IN THE EUROSRA COLLABORATION NETWORK

B. Michelsen1, U. Lindstrøm1, C. Codreanu1, A. Ciurea1, J. Zavada1, A. G. Lott1, M. Pombo-Suarez2, F. Onen3, T. K. Kvien4, Z. Rotar5, M. J. Santos1, F. Iannone1, M. H. Østergaard6, 7, 8, 9

Objective: Real-life data from axSpA patients treated with secukinumab from 13 countries in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were pooled. We calculated proportions of patients achieving Bath Ankylosing Spondylitis Disease Activity Score (BASDAI) <2 and Bath Ankylosing Spondylitis Disease Activity Score (ASDAS) <1.3 in parallel with its previously reported efficacy in axial symptoms.

Methods: A total of 1860 axSpA patients were included in Table 1. Overall 6/12-month secukinumab retention rates were 82%/72% and higher in bionaive patients (Table 2). Significant differences in retention rates in-between the registries were found. Inactive disease/low-disease-activity (LDA) were achieved more often in bionaive patients (Table 2).

*Comparisons between b/tsDMARD naive, 1 prior and ≥2 prior b/tsDMARD users were performed with Kaplan-Meier with log-rank test or Chi-Square test, as appropriate.

Conclusion: In this real-life study of 1860 patients with axSpA in 13 European countries secukinumab retention was high and significantly higher for bionaive patients. Overall, a higher proportion of bionaive than previous b/tsDMARD users achieved inactive disease/LDA.
Background: Secukinumab (SEC), a fully human monoclonal antibody that selectively inhibits interleukin 17A, is approved for treatment of patients with ankylosing spondylitis (AS). However, there is lack of real-world evidence on SEC treatment outcomes, disease activity, physical functioning and on its retention, especially in anti-tumor necrosis factor (anti-TNF) naïve patients and patients pretreated with different anti-TNFs in medical history.

Objectives: The aim of this interim analysis is to evaluate SEC treatment outcomes on disease activity, physical functioning and retention rates in AS patients stratified by number of anti-TNFs (naïve, 1 or ≥2) in medical history.

Methods: AQUILA is an ongoing, multi-center, non-interventional study. AS and psoriatic arthritis patients treated with SEC in daily practice are enrolled and observed from baseline (BL, d0 or d1 of study start) up to week 52 according to clinical routine. Real-world effectiveness of SEC was assessed prospectively and analyzed as the report interim results of SEC effectiveness on different treatment outcomes in AS patients by means of validated questionnaires such as patient’s global assessment (PGA), Bath Ankylosing Disease Activity Index (BASDAI), and Assessment of Spondyloarthritis Health Index (ASAS-HI). In addition, retention rates (time from study inclusion until premature SEC treatment discontinuation) were assessed through Kaplan-Meier plots. This interim analysis focuses on anti-TNF naïve and AS patients treated with 1 anti-TNF or ≥2 anti-TNFs in medical history. Wilcoxon tests were conducted to show significant differences between the subgroups.

Results: At BL, 311 AS patients were included; 72 (23.2%) of them received SEC already for more than 1 day up to more than 6 months before BL. Most AS patients were anti-TNF-experienced (71.1%): 82 (26.4%) and 139 (44.7%) AS patients had 1 or ≥2 prior anti-TNF treatments, respectively. BL scores for PGA, BASDAI and ASAS-HI were similar between the different anti-TNF subgroups. Constant improvement was shown in all parameters from BL up to week 52, irrespective of prior anti-TNF treatment (PGA-anti-TNF naïve: 5.9 to 3.5, PGA-1 anti-TNF: 6.1 to 4.2 and PGA-≥2 anti-TNFs: 6.7 to 5.1; BASDAI-anti-TNF naïve: 5.3 to 3.4, BASDAI-1 anti-TNF: 5.5 to 3.7 and BASDAI-≥2 anti-TNFs: 5.7 to 4.7). However, overall better improvement was observed in anti-TNF naïve patients, as seen by the example of ASAS-HI (Fig. 1). Between 30% and 40% of patients prematurely discontinued SEC treatment in the subgroups 1 anti-TNF and ≥2 anti-TNFs, respectively, while only about 20% did so in the anti-TNF naïve AS patients (Fig. 2).

Conclusion: SEC has shown to improve disease activity, physical functioning and QoL in anti-TNF naïve and pretreated AS patients in a real-world setting. The benefits of SEC were numerically more distinct in anti-TNF naïve patients. Moreover, SEC demonstrated high retention rate, particularly in anti-TNF naïve patients and AS patients treated with SEC in daily practice.

THU0400

CLINICAL COURSE OF EARLY AXIAL SPONDYLOARTHRITIS OVER TEN YEARS: LONG-TERM RESULTS FROM THE GERMAN SPONDYLOARTHRITIS INCEPTION COHORT

D. Poddubnyy1,2, V. Rios Rodriguez1, M. Torgutalp1,2, M. Verba1, J. Callhoff2, M. Protopopov1, F. Proft1, J. Rademacher1, H. Haibel1, J. Sieper1, M. Rudwaleit1,2,3,4,5,6,7, A. Kuhlen4, J. Sieper1, J. Brandt-Jürgens2, J. Sieper1.

Background: Previous studies showed that patients with non-radiographic and radiographic axial spondyloarthritis (nr- and r-axSpA) have similar disease burden and similar response to anti-inflammatory therapy given similar level of inflammatory activity. Only little is known, however, about long-term disease course in patients with early axSpA.

Objectives: To investigate the long-term (up to 10 years) clinical course of patients with early axSpA.

Methods: In total, 525 patients with early axSpA (r-axSpA with symptom duration ≤5 years and nr-axSpA with symptom duration ≤10 years) from the German Spondyloarthritis Inception Cohort (GESPIC) were included. The final patient classification was based on central reading results in 458 patients with available pelvic X-rays, and on local rheumatologist judgement in 67 patients. A total of 251 patients were finally classified as r-axSpA and 274 as nr-axSpA. Clinical evaluation, which included disease activity (BASDAI, C-reactive protein – CRP, ASDAS) as well as therapy recording, was performed at baseline and every 6 months thereafter until year 2 and annually thereafter till year 10. Treatment was conducted at the discretion of the local rheumatologist.

Results: Since the cohort has started prior to introduction of TNF inhibitors (TNFi), only 2% patients received TNFi at baseline that increased to 23% at year 10 (15% in nr-axSpA and 31% in r-axSpA) – Figure 1. The use of NSAIDs and csDMARDs decreased in both groups (Figure 1), while use of systemic steroids did not change substantially (9% at baseline, 8% at year 10). The proportion of patients with low disease activity according to BASDAI (<4) was higher in r-axSpA as compared to nr-axSpA at almost all time points, while the proportion of patients with low disease activity according to ASDAS (<2.1), as well as with ASDAS inactive disease (<1.3) was similar between nr-axSpA and r-axSpA (Figure 2). In the group of patients who completed year 10 (n=134 in total, 68 with nr-axSpA, 67 with r-axSpA) the same trends in therapy and disease activity were observed.

Conclusion: Patients with nr-axSpA and r-axSpA showed a similar disease course in terms of disease activity on the group level. The drop-out rate in this observational cohort was overall high, but comparable between groups. The lower proportion of patients with nr-axSpA being treated with TNFi might reflect a later introduction of TNFI for this indication.

Impact of Body Composition Measures on the Response to Biological Disease-Modifying Anti-Rheumatic Drugs in Patients with Ankylosing Spondylitis

V. Rios Rodríguez1,2, M. Protopopov1, F. Prot1, J. Radomacher1,2, B. Muche1, A. K. Weber1, S. Lüders1, H. Haibel1, M. Verba1, J. Sieper1, D. Poddubnyy1,3

1Charité – Universitätsmedizin Berlin, Berlin, Germany; 2Berlin Institute of Health, Berlin, Germany; 3Deutsches Rheuma-Forschungszentrum (DRFZ), Berlin, Germany

Background: Data on the impact of body weight and body mass index (BMI) on the response to biological disease-modifying anti-rheumatic drugs (bDMARDs) in axial spondyloarthritis (axSpA) including ankylosing spondylitis (AS) are still contradictory. Data on the impact of different components of the body composition on the treatment response are lacking.

Objectives: To investigate the impact of body composition on the response to biological disease-modifying anti-rheumatic drugs (bDMARD) in patients with AS after 6 months of treatment.

Methods: Patients with AS (radiographic axSpA), fulfilling the modified New York criteria and starting a bDMARD therapy were recruited between 2015 and 2019 in an extension of the prospective German Spondyloarthritis Inception Cohort (GESPIC-AS). All patients were required to be candidates for bDMARD therapy at baseline with high disease activity (BASDAI > 4 and/or ASDAS >=2.1) despite previous treatment with nonsteroidal anti-inflammatory drugs. Disease activity measures (BASDAI, CRP, ASDAS), as well as body composition parameters were assessed at baseline and after 6 months of bDMARD treatment. Body composition was assessed by the bioelectrical impedance analysis (BIA). Weight, body mass index (BMI), fat mass index (FMI), fat free mass index (FFMI), skeletal muscle mass value (SMM), visceral adipose tissue (VAT), total body water (TBW), and extracellular water (ECW) values were collected. The primary measure of the treatment response was ASDAS change at month 6 as compared to baseline.

Results: A total of 129 patients with AS were included in this cohort. BMI was performed in 77 patients. There were 71.4% males, and 65.7% were HLA-B27 positive. At baseline, BASDAI was 5.4±1.4, CRP was 12.8±16.5mg/L, and ASDAS - 3.0±1.0. The baseline BMI was 25.0±4.3 kg/m². A total of 75 patients were treated with TNF-α inhibitors, 2 patients received an IL-17 inhibitor. A higher BMI at baseline was associated with a worse response to bDMARD therapy that was attributable to both, the fat mass as reflected by FMI and to the fat-free mass reflected by FFMI, but not to SMM or VAT or water components – Table. This effect was independent of age, sex, symptom duration, HLA-B27 status, and ASDAS at baseline.

Conclusion: Both fat mass and fat free mass have an impact on the response to bDMARDs after 6 months of treatment in patients with AS. Interestingly, skeletal muscle mass, visceral fat as well as water components showed no association with treatment response.

Acknowledgments: GESPIC has been financially supported by Arthromark and METARTHROS projects.

Serum Markers of Bone Resorption, Formation, and Mineralization During 8 Years of TNF-α Blocking Therapy in Patients with Ankylosing Spondylitis

M. Siderius1, A. Spoorenberg, 2, Arends1

1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease, characterized by both excessive bone formation and bone loss. The bone turnover marker (BTM) bone-specific alkaline phosphatase (BALP) plays a central role in bone mineralization. Our previous study demonstrated that 3 years of TNF-α blocking therapy results in a significant increase in BALP.1 However, longer follow-up is needed to investigate whether BALP stays elevated during TNF-α blocking therapy and also to explore the course of other BTM, osteocalcin (OC), procollagen type 1 N-terminal peptide (PINP) and serum type 1 collagen C-telopeptide (sCTX) in AS.

Objectives: To evaluate serum markers of bone resorption, formation, and mineralization during 6 years of TNF-α blocking therapy in AS patients.

Methods: Included were consecutive AS outpatients from the University Medical Center Groningen (UMCG) attending the Groningen-Leeuwarden Axial SpA (GLAS) cohort and who were treated with a maximum of 2 TNF-α blockers for at least 8 years. Patients were excluded when they used bisphosphonates at baseline or during follow-up. Data for a specific visit was coded as missing when patients either had experienced a fracture or received systemic corticosteroids within 1 year of that particular visit. Clinical and laboratory measurements were performed at baseline (before start of TNF-α blocking therapy), 3 and 6 months as well as 1, 2, 4, 6 and 8 years. Markers of bone formation OC, PINP and BALP and marker of bone resorption sCTX were measured in serum. Z-scores of BTM were calculated using matched 10-years-cohorts of a Dutch reference group to correct for the normal influence that age and gender have on bone turnover. Serum levels of 25-hydroxyvitamin D (25(OH)D3) were assessed yearly. Generalized estimating equations were used to analyze BTM Z-scores over time within patients. Simple contrast was used to compare follow-up visits to baseline. P-values <0.05 were considered statistically significant.

Results: In total, 37 AS patients were analyzed; 62% were male, 86% HLA-B27+, mean age was 38.6 ± 10.4 years, median symptom duration 14 years (IQR 10-25), median CRP 13mg/L (IQR 6-25), and 30% had low vitamin 25(OH)D3 status (<50) at baseline. 35% of patients switched to a second TNF-α inhibitor during follow-up. ASDAS improved significantly during treatment, from mean 3.8 ± 0.9 at baseline to 1.9 ± 0.9 after 8 years of follow-up (P<0.001), 25(OH)D3 levels were stable at group level, median 58 nmol/L (IQR 45-70) at baseline and 60 nmol/L (IQR 50-70) after 8 years. Bone regulation marker OC Z-score was

*Adjusted for age, sex, HLA-B27 status, symptom duration, and ASDAS at baseline.

BMI: Body Mass Index; FMI: Fat Mass Index; SMM: Skeletal Muscle mass; VAT: Visceral Adipose Tissue; AS: ankylosing spondylitis; bDMARD: biological disease-modifying anti-rheumatic drug; CI: 95% confidence interval.
found to be significantly increased only after 3 months of TNF-α blocking therapy compared to baseline. No significant changes during follow-up were found for collagen resorption marker sCTX Z-score. Collagen formation marker PINP Z-score was significantly increased after 3 and 6 months as well as 2 years of TNF-α blocking therapy. Bone mineralization marker BALP Z-score was significantly increased at all time points up to and including 2 years and returned to baseline levels during 4 to 8 years of TNF-α blocking therapy (Figure 1).

Conclusion: In this subgroup of AS patients with established and active disease responding to TNF-α blocking therapy, we observed that the bone turnover balance favored bone formation during the first years of TNF-α blocking therapy, which corresponds to previously reported improvement in bone mineral density, especially at the lumbar spine. New finding of our study is that after 8 years of treatment, markers of bone resorption, formation, and mineralization were all comparable to baseline values.

Background: Gouty arthritis, caused by a persistent increase in serum uric acid level, can be caused by undersecretion of uric acid by uric transporters; however, the effects of allelic variants of urate transportosomae are yet to be fully determined.

Objectives: In this study we investigated the effects of 10 genes of urate transportosomes in a cohort of patients with primary hyperuricemia and gout.

Methods: The cohort consisted of 114 hyperuricemic individuals; 207 gout patients; and 274 normouricemic controls.

Results: We identified 39 non-synonymous allelic variants in the 10 genes of urate transportosomes in hyperuricemia/gout cohort. For 22 variants, a European MAF <0.0001 is documented. From the total of 39 identified variants we selected 23 variants for functional characterization based on a) finding of a newly identified variant, b) MAF variant was significantly different in the group of patients with hyperuricemia/gout, c) high probability, in silico predictions showed devastating influence of variant on protein function.

Conclusion: Although further analyses are needed to elucidate the contribution of urate transportosomes to urate homeostasis, our results clearly show that ABCG2 transporter analysis has significant clinical potential. Of the identified non-synonymous allelic variants of the urate transportosome rs2231142 (p=0.0113) in the ABCG2 gene, proved to be the most clinically significant on the age onset (P=0.0002, Kruskal-Wallis test).

Background: Gout is a common kind of inflammatory arthritis with metabolic disorders. The detailed pathogenesis of gout remains largely unknown. Metabolomics has become an important tool in detecting the new pathogenesis and biomarkers. However, few studies have focused on the serum metabolic profiling of gout.

Objectives: The study aims to investigate the metabolic profiling of gout patients using ultra-performance liquid chromatography quadruple time-of-flight mass spectrometry (UPLC-Q-TOF-MS), and explore the potential pathological mechanisms and biomarkers.

Methods: Serum samples from 31 gout patients and 31 healthy controls were analyzed by UPLC-Q-TOF-MS. Principal components analysis (PCA), orthogonal partial least squares-discriminant analysis (OPLS-DA) and Hierarchical clustering analysis were performed to detect different compounds between the two groups. Receiver operating characteristic (ROC) curve analysis and pathway analysis of the different metabolites were conducted.

Results: A total of 9192 compounds were detected, of which 138 significantly different compounds were selected, according to the criteria of (Variable importance in projection (VIP)>3, P<0.05). Eventually, 96 reliable metabolites matched the HMDB database were confirmed. ROC curve results showed that the area under the curve (AUC) value of 4-hydroxytriazolam was 0.933 (C195%: 0.875-0.992), yielding a highest AUC value, with the sensitivity of 83.9% and specificity of 93.5%. The pathway analysis results indicated that the significantly different metabolites were mainly involved in “primary bile acid biosynthesis”; “purine metabolism” and “glycerophospholipid metabolism”.

Conclusion: The serum metabolic profiling in gout patients were significantly different from healthy subjects. 4-hydroxytriazolam was the potential biomarker. Primary bile acid biosynthesis may be a novel metabolic pathway of gout.

IDENTIFICATION OF INTRACELLULAR VACUOIES IN SYNOVIAL FLUID WITH CALCIUM PYROPHOSPHATE AND MONOSODIUM URATE CRYSTALS

M. L. Peral1, I. Calalbarg2, A. Martin-Carratalá1, M. Andrés1, E. Pascual1.
1Hospital General Universitario de Alicante, Reumatología, Alicante, Spain

Background: Synovial fluid analysis using polarized microscopy is the gold standard for the diagnosis of crystal-related arthritis. In our experience, we have noted that, when calcium pyrophosphate (CPP) crystals are observed, they sometimes appear within intracellular vacuoles. However, this phenomenon is not seen in those samples containing monosodium urate (MSU) crystals. This finding has been scarcely reported in the literature, but may be useful in clinical practice to ensure accurate crystal identification.

Objectives: Our study aims to assess whether the presence of vacuoles contributes to identifying the type of crystal, and also to gauge the frequency of their presentation.

Methods: We conducted an observational study in a rheumatology unit between February and June of 2019. Synovial fluids containing CPP or MSU crystals, obtained in daily clinical practice, were consecutively included for analysis. Two observers simultaneously analyzed the presence of vacuoles by ordinary light and phase contrast microscopy in less than 24 hours after their extraction, using a microscope equipped with two viewing stations. The primary study variable was to determine whether CPP and MSU crystals are seen inside intracellular vacuoles, and to calculate the frequency of this finding for each type of crystal, estimating their 95% confidence interval (95% CI) and comparing rates using Fisher’s exact test.

Results: Twenty-one samples were observed. Data is given in the Table. MSU crystals were present in 7 (33.3%) and CPP crystals in 14 (66.6%). Interestingly, none of the MSU samples showed crystal-containing vacuoles (95% CI 0-35.4%). On the contrary, cytoplasmic vacuoles containing crystals were present in all of the CPP samples (95% CI 78.5-100%). The findings were confirmed by phase-contrast microscopy. Differences were statistically significant (p<0.001).

Table.

<table>
<thead>
<tr>
<th>SAMPLES ACCORDING TO TYPE OF MICROCRYSTAL (n=21)</th>
<th>SAMPLES WITH VACUOLES (UNDER ORDINARY LIGHT)</th>
<th>SAMPLES WITH VACUOLES (UNDER PHASE CONTRAST)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPP (14; 66.6%)</td>
<td>14 (100%) (95%CI 78.5-100%)</td>
<td>14 (100%) (95%CI 78.5-100%)</td>
</tr>
<tr>
<td>MSU (7; 33.3%)</td>
<td>0 (0%) (95%CI 0-35.4%)</td>
<td>0 (0%) (95%CI 0-35.4%)</td>
</tr>
</tbody>
</table>

Conclusion: The presence of vacuoles may be a useful and easy way to differentiate MSU and CPP crystals when performing synovial fluid microscopy in clinical practice, since it appears to be a distinctive feature in CPP crystal fluids.

THE VALUE OF SONOGRAPHY IN THE INTERCRITICAL PHASE OF GOUT

F. Cipolletta1, A. Di Matteo2,3, G. Brunori1, A. Moretti1, W. Grassi1, E. Filippucci1.
1Polytechnic University of Marche, Rheumatology Unit - Department of Clinical and Molecular Sciences, Jesi, Ancona, Italy; 2University of Leeds, Leeds Institute of Rheumatism and Musculoskeletal Medicine, Leeds, United Kingdom

Background: Disease remission is the goal of therapy for many chronic rheumatic diseases. In 2016, provisional gout remission criteria were proposed (1). To the best of our knowledge, no studies have compared ultrasound (US) findings in gouty patients with and without remission.

Objectives: To determine the prevalence of US pathologic findings in patients with gout fulfilling and not fulfilling the provisional remission criteria and to investigate the value of the US findings as predictors of a gouty flare within 6 months.

Methods: Patients with a diagnosis of gout according to the 2015 classification criteria (2) were recruited in this prospective, monocentric study. The following clinical information was recorded at baseline and after 6 months: number of gouty flares in the preceding 6 months, number of subcutaneous tophi, current serum urate level, and patient reported outcomes (pain visual analogue scale and patient global assessment visual analogue scale). Bilateral US assessment of the following anatomical areas was performed: elbow, wrist, II metacarpophalangeal joint, knee, ankle and I metatarsophalangeal joint. US evidence of tophi, aggregates, double contour sign and synovitis were recorded according to the correspondent OMERACT definitions.

Results: Forty-nine patients with gout were consecutively enrolled. The remission criteria were satisfied in 9 (18.4%) patients. Monosodium urate (MSU) deposits and findings of synovitis were observed by US less frequently in patients in remission (55.6% and 22.2%), compared with those not fulfilling the criteria (100.0% and 72.5%) (p values<0.01). The US MSU total score was 1.0; 0.0–2.0 (median and inter-quartile range) for patients in remission, compared with 6.0; 5.0–7.0 for those not fulfilling the criteria (p<0.01). US synovitis total score was significantly correlated with patient global assessment (R=0.55, p<0.01), patient pain (R=0.51, p<0.01) and number of gouty attacks in the previous 6 months (R=0.36, p=0.03), whereas MSU total score was associated with the number of gouty attacks in the previous 6 months (R=0.49, p<0.01), the number of subcutaneous tophi (R=0.45, p<0.01), patient pain (R=0.41, p=0.01), patient global assessment (R=0.41, p<0.01). At logistic regression analysis, the presence of subcutaneous tophi (OR=2.8, p=0.02), CRP level (OR=6.5, p=0.04) and US synovitis score (OR=2.0, p=0.04) were predictors of subsequent development of gouty flare within 6 months.

Conclusion: This study provides new insights into the inter-critical phase of gout, highlighting the clinical relevance of US synovitis as a predictor of subsequent development of gouty flare and joint pain. Despite MSU deposits are still detectable in patients satisfying the 2016 provisional remission criteria for gout, the remission is associated with less US detected MSU deposits.

EFFECT OF NEW-ONSET GOUT ON KIDNEY TRANSPLANT OUTCOMES: A RETROSPECTIVE COHORT ANALYSIS OF THE UNITED STATES RENAL DATA SYSTEM

J. Li1, D. Yin1, Z. Wang1, M. Bright1, B. Lamoreaux2, J. Kent1, M. Francis-Sedlak3, R. Johnson4, N. Hadker2, K. Francis5, H. Sanchez6, G. Miyasato7.
1Trinity Partners, Waltham, United States of America; 2Horizon Therapeutics, Lake Forest, United States of America; 3University of Colorado, Denver, United States of America

Background: Gout is a frequent comorbidity in kidney transplant (KT) recipients. However, assessing the independent effect of gout on KT outcomes is difficult because of multiple confounders (e.g., temporal changes in estimated glomerular filtration rate [eGFR], cyclosporine or tacrolimus dose, urate-lowering medication use) that obscure a clear picture of gout’s potential impact.

Objectives: This investigation assessed if the development of new-onset gout after KT was an independent risk factor for loss of graft function, as assessed by the need for maintenance hemodialysis following KT.

Methods: This retrospective cohort study analyzed data on patients in the United States Renal Data System (USRDS) who received a primary KT between 1/1/2008 and 12/31/2015. The date of transplantation was the ‘index’ date. Eligible patients were required to have ≥24 months of Medicare coverage and no prior history of gout, defined as ≥1 claim with a gout diagnosis code in the 24 months prior to the index date. All patients were also required to have ≥12 months of coverage post index. Patients who died, experienced graft failure, or returned to dialysis <12 months post index were excluded. Because the first year following transplant is associated with the highest frequency of rejections, we evaluated subjects beginning 1 year after transplant. The exposure of interest was new-onset gout, defined as the presence of ≥2 claims for gout post index, and the primary endpoint was return to dialysis >12 months post index. Baseline time-invariant confounders included recipient and donor demographics and characteristics at index. Time-varying confounders included body mass index (BMI) adjusted tacrolimus and cyclosporine dose, eGFR, and urate-lowering medication use post index. Patients who died or lost Medicare coverage >12 months post index were censored; all patients remaining at the end of the study period (12/31/2016) were also censored. A marginal structural model (MSM) was fitted to determine the relative risk of new-onset gout on return to dialysis, while controlling for both time-variant and time-varying confounders.

Results: 18,525 of 466,589 KT recipients in the USRDS met study eligibility. This investigation assessed if the development of new-onset gout after KT was an independent risk factor for loss of graft function, as assessed by the need for maintenance hemodialysis following KT.

Methods: This retrospective cohort study analyzed data on patients in the United States Renal Data System (USRDS) who received a primary KT between 1/1/2008 and 12/31/2015. The date of transplantation was the ‘index’ date. Eligible patients were required to have ≥24 months of Medicare coverage and no prior history of gout, defined as ≥1 claim with a gout diagnosis code in the 24 months prior to the index date. All patients were also required to have ≥12 months of coverage post index. Patients who died, experienced graft failure, or returned to dialysis <12 months post index were excluded. Because the first year following transplant is associated with the highest frequency of rejections, we evaluated subjects beginning 1 year after transplant. The exposure of interest was new-onset gout, defined as the presence of ≥2 claims for gout post index, and the primary endpoint was return to dialysis >12 months post index. Baseline time-invariant confounders included recipient and donor demographics and characteristics at index. Time-varying confounders included body mass index (BMI) adjusted tacrolimus and cyclosporine dose, eGFR, and urate-lowering medication use post index. Patients who died or lost Medicare coverage >12 months post index were censored; all patients remaining at the end of the study period (12/31/2016) were also censored. A marginal structural model (MSM) was fitted to determine the relative risk of new-onset gout on return to dialysis, while controlling for both time-variant and time-varying confounders.
Conclusion: New-onset gout was independently associated with a 51% increased risk of return to dialysis >12 months after primary KT compared to a control cohort without gout. To our knowledge, this is the first observation of this outcome in an appropriately controlled cohort of KT recipients with gout. Results from this analysis may have important implications for the monitoring and management of new-onset gout in the kidney transplant population.

THU0409
A RANDOMIZED, PHASE 2 STUDY EVALUATING THE EFFICACY AND SAFETY OF ANAKINRA IN DIFFICULT-TO-TREAT ACUTE GOUTY ARTHRITIS: THE ANAGO STUDY

K. Saag1, A. So2, P. Khanna3, R. Keenan4, S. Ohlman5, T. Kullenberg5, L. Osterling Koskeni5, M. H. Pillinger6, R. Terkeltaub7, Uni Alabama, Birmingham, United States of America; 2Uni Lausanne, Lausanne, Switzerland; 3Uni Michigan, Ann Arbor, United States of America; 4Duke Uni School Med, Durham, United States of America; 5Sobi, Stockholm, Sweden; 6New York Uni School Med, New York, United States of America; 7Uni California San Diego, La Jolla, United States of America

Background: In gout, urate crystals deposited in and around joints trigger episodes of acute arthritis, mediated by the proinflammatory cytokine IL-1. In uncontrolled studies, the IL-1 receptor antagonist anakinra appears effective in reducing pain and signs of acute flares in patients with difficult-to-treat gout. However, confirmatory, adequately-powered, prospective trials are lacking. The ‘anaGO-study’ (anakinra in gout) was a multi-center, randomized, double-blind, double-dummy, phase 2 study investigating the efficacy and safety of anakinra in acute gout (NCT03002974).

Objectives: The primary objective was to evaluate the efficacy of two regiments of anakinra (100 or 200 mg daily s.c. injections for 5 days) compared to triamcinolone (single i.m. injection 40 mg) with respect to patient-assessed pain intensity. The primary endpoint was change in pain intensity from baseline to 24-72 hours (average of 24, 48 and 72 hours) in the most affected joint measured on a visual analogue scale (0-100 VAS). Secondary outcomes included: time to onset of effect, time to response, time to pain resolution, time to rescue medication use, patient’s and physician’s assessments of global response, clinical signs, inflammatory biomarkers and safety.

Methods: Patients were recruited who had acute gout based on ACR/EULAR 2015 gout classification criteria, and were unsuitable for anti-inflammatory therapy due to comorbidities or contraindications. Patients were randomized to each group in a 1:1:1 ratio and stratified by urate-lowering therapy use (yes/no) and BMI (<30.0 or ≥30.0 kg/m2). Patients were randomized to each group in a 1:1:1 ratio and stratified by urate-lowering therapy use (yes/no) and BMI (<30.0 or ≥30.0 kg/m2).

Results: 165 patients were randomized; 110 to anakinra (56 to 100 mg/day, 54 to 200 mg/day) and 55 to triamcinolone; 108 and 53 were included in the primary analysis, respectively. The median (range) age was 55 (25-83) years, 87% were male, mean disease duration was 8.7 years and mean number of self-reported flares during the past year was 4.5. The pain intensity, from baseline to 24-72 hours, decreased in both treatment groups; mean (95% CI) change was -1.8 (-10.8, 7.1) (p-value = 0.688 for primary endpoint). The majority of secondary efficacy endpoints were numerically in favor of anakinra, and in most instances also statistically significant, in comparison to triamcinolone, e.g. physician’s assessment of clinical signs at 72 hours and patient’s and physician’s assessment of global response at Day 8. No unexpected safety findings were identified in any of the treatment groups.

Conclusion: Anakinra and triamcinolone reduced patient-assessed gout flare pain to similar degrees in patients for whom conventional therapy was ineffective or contraindicated. Both doses of anakinra showed comparable efficacy in pain reduction. The majority of secondary efficacy endpoints favored anakinra. Anakinra was shown to be an additional option for use during acute gout flares.

THU0410
COMpanion immunosuppression with AZATHIOPRINE increases the frequency of persistent responsiveness to Pegloticase in patients with chronic refractory Gout

H. Rainey1, H. S. B. Bara5, A. Yeo1, P. Lipsky1, 1AMPEL Biosolutions, Charlottesville, United States of America; 2Center for Rheumatology and Bone Research, Wheaton, United States of America

Background: Pegloticase is a mammalian recombinant uricase coupled to monomethoxy polyethylene glycol that is approved in the US for treatment of patients with chronic refractory gout and causes profound reductions in serum urate. However, treatment with pegloticase is limited by the induction of anti-drug antibodies and loss of responsiveness in nearly half of treated patients.

Objectives: The goal of this study was to determine whether co-therapy with azathioprine (AZA) would increase the frequency of chronic refractory gout patients who had persistent urate lowering from pegloticase therapy.

Methods: This open label multicenter study enrolled subjects with chronic gout who failed to lower serum urate to <6mg/dL despite medically indicated doses of urate lowering therapy (NCT02589556). Patients were screened for adequate levels of the AZA metabolizing enzyme thiopurine methyl transferase and then started on daily oral AZA 1.25mg/kg for 1 week and then 2.5mg/kg for

Mean (95% CI) difference in pain reduction between anakinra and triamcinolone treatment groups was -1.8 (-10.8, 7.1) (p-value = 0.688 for primary endpoint).

The majority of secondary efficacy endpoints were numerically in favor of anakinra, and in most instances also statistically significant, in comparison to triamcinolone, e.g. physician’s assessment of clinical signs at 72 hours and patient’s and physician’s assessment of global response at Day 8. No unexpected safety findings were identified in any of the treatment groups.

Conclusion: Anakinra and triamcinolone reduced patient-assessed gout flare pain to similar degrees in patients for whom conventional therapy was ineffective or contraindicated. Both doses of anakinra showed comparable efficacy in pain reduction. The majority of secondary efficacy endpoints favored anakinra. Anakinra was shown to be an additional option for use during acute gout flares.

DOI: 10.1136/annrheumdis-2020-eular.5766
OBJECTIVES: To analyze the new CV events occurred in patients with gout after structured CV assessment incorporating carotid ultrasound.

METHODS: Retrospective analysis of an inception cohort of new patients with crystal-proven gout. At baseline and a structured CV assessment was performed considering age, gender, traditional risk factors, CV and renal disease, laboratory data, SCORE and Framingham risk tools and carotid ultrasound; according to 2013 ESC guidelines, CV risk was stratified as low, moderate, high or very high. The cohort includes 356 patients, mean aged 64 years (SD 14.0) mostly males (86.0%), 21.8% with lophaceous gout and mean serum urate at diagnosis of 8.2mg/dL (SD 1.8). The CV risk stratification was: low in 20 (5.6%), moderate in 47 (13.2%), high in 34 (9.8%), and very high risk in 242 (68.0%). Major CV events (coronary disease (CD), heart failure (HF), stroke, peripheral artery disease (PAD) and CV death) were recorded during the follow-up by electronic case reports review. A binary composite endpoint of "new major CV event" was used. The incidence after inclusion in the cohort was estimated. To evaluate potential baseline predictors (clinical and gout-related) of CV events, a Cox regression model was built.

RESULTS: Mean follow-up in the cohort was 415 months (SD 16.8). Forty new major CV events have been identified (incidence 3.2%/patient-year), distributed as follows: HF 146 (n=18), CV death 65.5 (n=8), CD 40.9 (n=6), stroke 0.33 (n=4), and PAD 0.33%/patient-year (n=4). Per risk stratification, the incidence of a new event was 0.16%/patient-year in the high-risk group and 0.31%/patient-year in the very high-risk, while no events occurred in low and moderate groups. The table shows the univariate and multivariate analysis of baseline variables. An independent association and a trend towards significance were noted for age and to be classified at a very high CV risk at baseline, respectively.

Conclusion: First longitudinal study assessing the use of subclinical atherosclerosis screening as part of CV risk assessment in new patients with gout. Those classified at the very high-risk group presented the majority of events, being HF the most frequent. Age, and likely to be classified as very high risk, independently predicted a new CV event during follow-up, data that may be of interest in terms of management of the patient with gout at the time of diagnosis.

Background: Gout and diabetes mellitus type 2 (DM) are frequently co-existing. Metformin is the first choice of treatment for patients with DM type 2, and might – based on previous studies - have beneficial clinical effects on gout through a putative anti-inflammatory as well as serum uric acid (SUA) lowering effect.

Objectives: To investigate the anti-inflammatory and SUA lowering effect of metformin in patients with gout starting uric acid lowering treatment (ULT).

Background: Gout is an independent cardiovascular (CV) risk factor. This excess of morbidity and mortality requires optimal management, especially in high-risk individuals. So, the inclusion of subclinical atherosclerosis screening by carotid ultrasound in the initial evaluation may help to accurately stratify the CV risk. However, longitudinal outcomes using this technique are not available in gout.

Thursday, 04 June 2020
Methods: Patients with clinical diagnosis of gout, a first outpatient visit between January 2010 and March 2018 and a follow-up of at least 6 months were included in a retrospective cohort study, conducted in two rheumatology centres in the Netherlands. From this cohort patients with DM starting ULT were selected. Patients with metformin use were compared to patients using other or no antidiabetic medication (control group). Metformin use was defined as use ≥80% of the time during the first six months after initiation of ULT. To evaluate the anti-inflammatory effect, the differences in incidence density (ID) of gout flares in the first six months after starting ULT was measured and analysed using Poisson regression. To evaluate the SUA lowering effect, the difference in baseline SUA, proportion of patients reaching target serum uric acid (SUA < 0.36 mmol/l) at six months follow-up, and ULT dosage at time of reaching this target were analysed. All analyses included correction for confounding.

Results: Of 2108 gout patients, 309 patients who started ULT also had DM, with 155 in the metformin group and 154 in the control group (Table 1). ID of flares was 2.8 and 3.3 per patient year in the control and metformin group respectively, resulting in an incidence rate ratio of 0.93 (95% CI 0.75 – 1.15), SUA levels at baseline were similar, between the two groups (Table 1, p<0.31). At six months 46.1% and 57.4% reached target SUA in the control and metformin group respectively, odds ratio of 1.30 (95%CI 0.80 – 2.08). No difference was found in allopurinol dose at time of reaching target SUA between the groups (1.14 mg, 95% CI -38.89 – 41.19).

Conclusion: In contrast to a previous report, in this study in patients with DM and gout and starting ULT, metformin does not have a clinically relevant added anti-inflammatory or urate lowering effect.

KEY ROLE OF THE CLINICAL NURSE SPECIALIST IN PATIENTS WITH GOUT: RESULTS OF A QUALITY-OF-CARE SURVEY

E. Calvo-Aranda1, F. M. Sanchez-Aranda, M. T. Navio Marco1, L. Cebrian1, M. A. Matias de la Mano1, L. Lojo1,1 Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain

Background: Gout is the most common nontraumatic arthritis. With a prevalence in Spain of 2.4% and an increasing incidence, many gout patients are treated in Rheumatology. Different comorbidities complicate the management of this disease that not only attacks joints, but also induces kidney damage and accelerated atherosclerosis. This, together with a poor adherence to urate-lowering therapies and a suboptimal management, justifies its relevant morbidity and mortality, with high socioeconomic impact. Some studies suggest enhancing the role of the Clinical Nurse Specialist (CNS) in the care of gout to combat therapeutic failure.

Objective: To determine the factors that affect the perceived quality and satisfaction of gout patients treated in Rheumatology with CNS support and identify areas for improvement.

Methods: In 2018, we implemented the following nurse-supported visit protocol: 1° (rheumatologist and nurse; face-to-face): clinical history, joint examination, vital signs, anthropometrics, start of treatment, comorbidities management, health promotion. 2° (nurse; telephone, after analytical results; 1 month after 1° visit). Targeted questions (adherence, side effects, attacks, blood pressure, lifestyle habits) and therapeutic adjustment. 3° (rheumatologist and nurse; face-to-face): at 3-6 months. Targeted questions, joint examination, vital signs, anthropometrics, therapeutic adjustment, health promotion.

Results: 44 surveys were obtained between August 2019 and January 2020. 95% male, 55% with an age range of 45-60 years; 41% >60 years. 68% considered the referral time to our Department reasonable; excessively long for 14%. All respondents were satisfied with the face-to-face nurse-supported consultation, and 93% considered the telephone CNS consultation to be good. 57% were not able to remember the name of the CNS, compared to 27% who did not know the rheumatologist name. 91% considered that the time to solve doubts and for explanations was enough. 46% considered the availability of CNS/rheumatologist as good, and 37% as excellent. The global satisfaction was good in 48% and excellent in 43%.

Conclusion: We found a high global satisfaction in gout patients followed in our Department. They valued very positively the role of CNS in the face-to-face and telephone consultations, as well as the staff availability, their dedication to answer questions and offer explanations. We must remember our names to patients and optimize referral to our Department. Exploring patients’ opinions is essential. It improves communication, adherence and attention offered, and allows to provide them a better experience in their relationship with the Department.

THU0415

ORDINARY LIGHT MICROSCOPY IS ABLE TO IDENTIFY MOST CRYSTAL-CONTAINING SYNOVIAL FLUIDS

J.A. Bernal1, M. Andres2, S. Lopez Salguero2, V. Vojani2, P. Vela-Casasempere2,3, E. Pascual2,1 Hospital Marina Baixa, Rheumatology, Villajoyosa (Alicante), Spain; 2Hospital General Universitario de Alicante, Instituto de Investigación Sanitaria y Biomédica de Alicante, Rheumatology, Alicante, Spain; 3Universidad Miguel Hernández, Medicina Clínica, Elche, Spain; 4Hospital Universitario de Torrevieja, Rheumatology, Torrevieja, Spain

Background: Optical microscopy remains the gold standard for the diagnosis of crystal arthropathies. The complete protocol consists of three phases. In the first stage, microscopy with simple light provides information on the morphology of the crystal. The second stage, polarized light, allows detecting the intensity of the birefringence. Finally, with the first-order red compensator, the type of elongation is detected, positive for calcium pyrophosphate (CPP) crystals and negative for
monosodium urate (MSU) crystals. Finally, with the obtained data, the presence and type of crystals is concluded.

**Objectives:** Analyze the validity and agreement of each stage of microscopy regarding the conclusion, emphasizing ordinary light microscopy.

**Methods:** Fifty consecutive samples of synovial fluid obtained in routine clinical practice were independently analyzed under the compensated polarized microscope by 5 observers blinded to clinical data (250 observations in total). Each observer recorded the presence and type of crystals at each stage and reached a conclusion after gathering all the information. To estimate the diagnostic yield of each microscope stage, sensitivity, specificity and positive and negative predictive values, as well as the accuracy (number of correct observations/number of total observations), were calculated; also, the total weighted kappa was used to assess the degree of agreement with the complete protocol.

**Results:** Main results of the study are shown in Table 1. Regarding diagnostic yield, ordinary light microscopy showed excellent sensitivity, specificity and predictive values, similar to the results noted with simple and compensated polarized microscopy.

**Table 1. In parentheses, 95% confidence intervals.**

<td>99.1% (94.8-98.9)</td>
<td>0.962</td>
</tr>
</tbody>
</table>

Diagnoses established by ordinary light microscopy matched conclusions (accuracy) in 242/250 (96.8%) observations. Discrepant cases were crystals missed under ordinary light in 4 cases (3 MSU, 1 CPP), and 4 samples with CPP crystals initially seen but later concluded their absence. Interestingly, lowest accuracy was seen with simple polarization; CPP crystals were not detected in 20 out of 93 observations with CPP (21.5%). The accuracy of compensated polarized light was similar to ordinary light. On 5 occasions no crystals were seen but finally they were present (1 MSU, 4 CPP); on the contrary, CPP was registered in one observation but the conclusion indicated no crystals. Regarding agreement with the complete protocol, the kappa with simple light is 0.954, similar to compensated polarized light (0.962), while simple polarized light showed the lowest agreement (0.874).

**Conclusion:** Ordinary light microscopy is enough to correctly reach the majority of diagnoses, with a very high degree of agreement with the complete protocol. Results were comparable to using a compensated polarized microscopy. Thus, if a microscope with polarizer and first-order compensator was not available, using ordinary light would be enough on most occasions. Polarized light microscopy better identifies MSU crystals, but over 20% of CPP crystals were missed at this stage, reinforcing the value of the ordinary light microscopy.

**THU0415 MELTING OF TOPHI WITH LOCAL STEROIDS IN CHRONIC TOPHACEOUS GOUT: AN OBSERVATIONAL STUDY**

**D. Bhadu, S. Vyas, U. Kumar**

**Background:** Chronic tophaceous gout is usually difficult to treat with urate lowering therapy (ULT) [1]. Faster resolution of tophi has been seen with use of pegloticase [2], but this drug is costly and not widely available. Local steroid use is recommended in acute gouty arthritis but its role in reduction of tophi has not been studied. This study was aimed to see the effect of local steroids in tophi resolution.

**Objectives:** To study the change in size of gouty tophi with local steroid injection compared to conventional treatment.

**Methods:** Four crystal proven chronic tophaceous gout patients with multiple tophi were screened and enrolled in the study after taking informed consent. Total 4 tophi in 4 patients were imaged by using Dual Energy Computed Scan (DECT) for their size and volume. All 4 patients were treated with ULT as per recommended dose to achieve target serum uric acid (SUV) level. Six tophi were treated with local steroids injection (methylprednisolone acetate) at two months interval till complete resolution of tophi. Dose of steroid varied from 10 mg to 40 mg depending upon tophi size but subsequent repeat doses were same in each tophi. Six tophi not treated with local steroid served as internal control in the same patients. All 4 patients were followed up regularly in out-patient department to monitor treatment response and local side effects if any.

**Results:** All 4 patients achieved target SUV (<356 µmol/L) at three months of follow up. Six tophi which were treated with local steroids injection clinically had marked reduction in size at 7-12 months of follow up [Table-1], while other 6 tophi which served as internal control had no clinically significant change in size and volume of tophi. DECT was repeated in the same settings to confirm the clinical findings. DECT revealed near complete resolution of 5 tophi [Image-1], and 50% reduction in size of one tophi. Six tophi which were not treated with local steroid had no significant reduction in size in DECT as well. Only side effect noted was skin discoloration in 5 out of 6 injected sites, none of the tophi had infection.

**Conclusion:** Interestingly this is the first such study to document the use of local steroid in tophi. Thus intraarticular steroids can be alternative to pegloticase or surgery where faster dissolution of tophi is required. This observation needs to be explored in large number of patients to calculate the total dose requirement of steroid as per volume and urate burden of tophi. Possible explanation of melting tophi with steroids is breaking down outer fibrous layer of tophi by local steroids which might be acting as barrier in dissolution of urate crystals with ULT.

PEGLOTICASE RESPONSE IMPROVEMENT BY CO-TREATMENT WITH METHOTREXATE: RESULTS FROM THE MIRROR OPEN-LABEL CLINICAL TRIAL IN PATIENTS WITH UNCONTROLLED GOUT

J. Botson1, P. M. Peloso2, K. Obermeyer2, B. Lamoreaux2, M. E. Weinblatt1, J. Peterson1, 1Orthopedic Physicians Alaska, Anchorage, United States of America; 2Horizon Therapeutics plc, Lake Forest, United States of America; 3Brigham and Women’s Hospital, Boston, United States of America; 4Western Washington Arthritis Clinic, Bothell, United States of America

Background: Gout is a painful inflammatory arthritis caused by persistently elevated serum uric acid (sUA) levels. Pegloticase, an infused recombinant PEGylated uricase, rapidly lowers sUA levels by converting uric acid to allantoin, a water-soluble molecule that is readily excreted by the kidneys. In the phase 3 clinical trials, 42% of patients1 dosed with pegloticase every two weeks maintained sUA levels below 6.0 mg/dL during months 3 and 6 of pegloticase treatment. The loss of pegloticase efficacy has been attributed to the development of anti-drug antibodies (ADAs)2,3 and these ADAs have been associated with infusion reactions (IRs).3,4 Case reports and prospective case series,5-6 indicate that methotrexate (MTX) may allow patients to attain more complete therapeutic benefits, presumably through attenuation of pegloticase immunogenicity. The current study prospectively examines the efficacy and safety of MTX-pegloticase co-treatment in patients with uncontrolled gout.

Objectives: To assess efficacy and safety of concomitant pegloticase and MTX therapy in patients with uncontrolled gout.

Methods: Adult patients with uncontrolled gout who were beginning pegloticase therapy were considered for enrollment in this ongoing multicenter, open-label, efficacy and safety study of pegloticase with MTX co-treatment (NCT03635967). Patients were administered oral MTX (15 mg/week) and fola (1 mg/day) 4 weeks prior to the first pegloticase infusion (Day 1) and throughout the pegloticase treatment period. Blood was drawn prior to each infusion to measure sUA level, monitor clinical parameters, and examine for ADA development. All patients followed typical IR prophylaxis protocols (floxifloxinadine one day before and the morning of each infusion and acetaminophen and IV corticosteroid the morning of each infusion). Patients also received gout flare prophylaxis with either NSAIDs, colchicine or prednisone initiated at least 1 week prior to Day 1. The primary study outcome was the proportion of responders, defined as sUA <6 mg/dL for at least 80% of the time during month 6 (weeks 22, 22, and 24). All analyses were performed on a modified intent-to-treat population, defined as patients who received >1 pegloticase infusion.

Results: A total of 17 patients were screened and 14 patients (all men, average age: 49.3 ± 8.7 years) were enrolled. On Day 1, mean sUA was 9.2 ± 2.5 mg/dL and 12 of the 14 patients had visible tophi. At the 6 months timepoint, 11/14 (78.6%, 95%CI 49.2-95.3%) met the responder definition, with 3 patients discontinuing after meeting stopping rules (pre-infusion sUA values greater than 6 mg/dL). All patients tolerated MTX. One serious AE of bacterial sepsis occurred (resolved). AEs that occurred in >1 patient included: diarrhea and upper respiratory tract infection in 3 patients each, sinusitis, muscle strain, and hypertension in 2 patients each. Gout flares occurred in 12/14 (85.7%) patients. No new safety concerns were identified.

Conclusion: An increased proportion of patients maintained therapeutic response at 6 months when treated concomitantly with MTX and pegloticase (78.6%) when compared to the previously reported 42% using pegloticase alone.1 These results support and reflect the improved response rates demonstrated in two prior case series.5,6 A definitive randomized double-blind trial evaluating pegloticase with MTX vs. pegloticase with placebo is ongoing.

READMISSION RISK AND QUALITY OF CARE IN PATIENTS PRESENTING TO THE EMERGENCY DEPARTMENT WITH GOUT FLARES

L. Brunetti1, J. Vekaria2, P. Lipsky3, N. Schlesinger4, 1Emest Mario School of Pharmacy; Rutgers, The State University of New Jersey, Piscataway, United States of America; 2Mario School of Pharmacy; Rutgers, The State University of New Jersey, Piscataway, United States of America; 3RILITE Research Institute, Charlottesville, VA, United States of America; 4Robert Wood Johnson Medical School, New Brunswick, United States of America

Background: Gout is the most common form of inflammatory arthritis and its economic burden is substantial, with estimates for the overall cost exceeding $20 billion (US) annually. Contributing to the economic burden are hospital admissions and iatrogenic events associated with pharmacotherapy. Identification of modifiable risk factors would be an important contribution to clinical practice.

Objectives: The aim of this study was to identify opportunities for enhancing gout care in patients presenting to the Emergency Department (ED) with gout flares.

Methods: This retrospective cohort study used data from electronic medical records (EMR) at a large community hospital. All consecutive patients visiting the medical center ED with a primary diagnosis of gout from 1/1/2016 to 7/1/2019 were included. Patients were then followed for 90 days to determine whether they were readmitted to the ED for any reason. A chart review identified whether they were on appropriate treatments in terms of gout flare management. All data were summarized using descriptive statistics. A multiple logistic regression was constructed to identify risk factors for ED utilization within 90 days of the index visit.

Results: A total of 214 patients were included in the analysis. Most patients were male (79%), mean age was 59.4 ± 15.6 years, and mean Charlson comorbidity index was 0.5 ± 1.14. The most common medications prescribed during the ED visit included NSAIDs (41.6%), opioids (28%), corticosteroids (26.6%), and colchicine (21%). Allopurinol and febuxostat were initiated in the ED in 4.7% and 0.9%, respectively. Discharge medications for the management of gout included NSAIDs (37%), corticosteroids (34.6%), opioids (23.8%), colchicine (14%), febuxostat (7%), and allopurinol (6.5%). Of the patients sent home with an opioid, 40% were newly prescribed. An anti-inflammatory medication was not prescribed in 29.6% of patients discharged from the ED. Readmission within 90 days was recorded in 16.8% of patients. Of these readmissions, 33.3% were gout-related and 11.1% were cardiac related. After adjusting for age and comorbidity index, patients receiving colchicine were 2.8 times more likely (OR, 2.81; 95% CI, 1.12 to 7.02; p = 0.027) to return to the ED within 90 days. The most common cause of readmission in this subset was gout-related (54.3%).

Conclusion: Nearly 30% of patients were discharged from the ED with an anti-inflammatory medication, whereas initiation of urate lowering therapy was rare. Opiates were used frequently, but the indication was uncertain. Only 5.6% of subjects revisited the ED for gout-related diagnoses in the subsequent 3 months. Colchicine prescription was associated with an increased risk of gout-related ED utilization within 90 days. Treatment of gout in the ED is sub-optimal and often does not follow established guidelines.

CAROTID ATHEROSCLEROSIS AND SONOGRAPHIC SIGNS OF URATE CRystals DEPOSITS IN GOUT: AN ASSOCIATION STUDY

I. Calabuig1, A. Martínez-Sanchís1, M. Andrés1, 1Hospital General Universitario de Alicante-ISAIBIL, Sección de Reumatología, Alicante, Spain; 2Universidad Miguel Hernández, Medicina Clínica, Alicante, Spain

Background: Carotid subclinical atherosclerosis is prevalent in patients with gout, although poorly predicted by cardiovascular risk assessment tools. Gout itself is deemed to contribute to its development. However, a previous report did not show an association between clinical characteristics of gout and the presence of subclinical atherosclerosis [1].

References:

Disclosures of Interests: J. Calabuig; A. Martínez-Sanchís; M. Andrés. 1Hospital General Universitario de Alicante-ISAIBIL, Sección de Reumatología, Alicante, Spain; 2Universidad Miguel Hernández, Medicina Clínica, Alicante, Spain

DOI: 10.1136/annrheumdis-2020-eular.3302
Objectives: To explore the association between sonographic signs of urate crystal deposits and carotid atherosclerosis.

Methods: Consecutive new patients with crystal-proven gout attended in a tertiary Rheumatology unit were eligible for the study. It included musculoskeletal and carotid ultrasound assessment, performed by a trained sonographer blinded to clinical data. Patients were examined during intercritical periods; flare prophylaxis with low-dose colchicine or other agents was permitted, but patients under urate-lowering treatment were excluded. The musculoskeletal ultrasound scans evaluated wrists, 2nd MCPs and 1st MP joints, and triceps and patellar tendons, for the presence of signs suggestive of urate crystal deposits (double contour, hyperechoic aggregates, and tophi), following OMERACT definitions. Also, local power-Doppler (PD) signal was registered and graded as 0 to 3. The sum of locations showing crystal deposits or positive PD signal (≥1) was estimated in order to assess crystal and inflammatory burden, respectively. Carotid arteries were scanned for increased intima-media thickness (IMT) and presence of atheroma plaques, according to Mannheim consensus. The association analysis was done by logistic regression, considering increased IMT or atheroma plaques as the dependent variables.

Results: Eighty-eight new patients with gout were enrolled, mean aged 62.0 years (SD 14.5), 89.8% males. Mean gout duration was 5.9 years (SD 9.0), clinical tophi were observed in 16.1% of patients and mean serum urate level at diagnosis was 8.4 mg/dl (SD 1.5). All participants showed at least one sonographic sign of crystal deposits at the examined locations, with a mean sum of 9.4 (SD 4.0). Regarding individual signs, their mean (SD) sum was as follows: 4.6 (2.1) for tophi, 3.9 (2.8) for aggregates and 0.9 (1.0) for double contour. The mean sum of locations with positive PD signal was 1.1 (SD 1.0). Regarding carotid scans, increased IMT was seen in 26 patients (30.6%) and atheroma plaques in 51 (58.0%). Table 1 shows the results of the association analysis. Positive PD signal was significantly associated with the presence of atheroma plaques, while tophi showed a trend with both increased IMT and atheroma plaques.

</tbody>
</table>

Conclusion: Sonographic deposits were consistently observed in new patients with gout. Crystal and inflammatory load, here shown as tophi and positive PD signal, seem associated with carotid atherosclerosis. This new finding may contribute to understanding the complex relationship between gout and atherosclerosis.

Legend: G: gout, CPPD: calcium pyrophosphate deposition disease, NR: not reported, SFA: synovial fluid analysis

Duration of anakinra treatment prior to complete resolution of symptoms was associated with the clinical phenotype of chronic CPPD (Rpb: 0.67, p<0.01) and with disease duration (R: 0.49, p<0.01). In 47 out of 57 (82.5%) responders, complete resolution of symptoms was observed within 4 days after the first injection of anakinra. Adverse events were reported in 41.1% of the cases: local skin reaction at the injection site, skin rash on the back and bacterial pneumonia.

Conclusion: This SLR provides evidence in favour of the use of anakinra as a therapeutic option in patients with CPPD, especially in acute refractory CPPD or when standard treatments are contraindicated.

Background: The value of ultrasound (US) in the diagnosis of crystal arthropathy, such as gout or calcium pyrophosphate deposition disease (CPPD), in patients with recent onset synovitis has been evaluated only by a few studies.

Methods: Consecutive patients with recent onset (<6 weeks) acute arthritis were enrolled. The US examinations were performed by a rheumatologist blinded to clinical data. Calcium pyrophosphate and monosodium urate crystal deposits were identified in the joint affected by synovitis (target joint), as well as in the classic sites for gout and CPPD (set of joint) (Table 1), according to the OMERACT definitions.

Results: One-hundred and four patients were enrolled: 22 CPPD patients, 23 patients with gout (4.9%) and in 4 patients with gout (4.9%). On the contrary, US positive/SFA negative results occurred in 4 patients with CPPD (4.9%) and in 4 patients with gout (4.9%).

Conclusion: US is useful for the diagnosis of gout and CPPD in patients with acute synovitis. Extending the US evaluation to the joints which are most commonly involved in gout and in CPPD, other than those affected by synovitis, increases the sensitivity of US.

The diagnostic accuracy of US and synovial fluid analysis (SFA) was evaluated taking the classification criteria for gout and CPPD as gold standard (1,2). Moreover, the US and SFA results were compared in the joints in which the SFA was performed.

Results: The diagnostic accuracy of US and SFA, using the classification criteria as gold standard.

SFA was performed in 67 knees (64.4%), 10 wrists (9.6%), 10 ankles (9.6%), 5 I MTP joints (4.8%), 5 hips (4.8%), 4 elbows (3.8%), 4 shoulders (3.8%)

The total agreement between US and SFA was excellent (93.8% in CPPD and 90.2% in gout). SFA positive/US negative results occurred in 1 patient with CPPD (1.2%) and in 4 patients with gout (9.4%). On the contrary, US positive/SFA negative results occurred in 4 patients with CPPD (4.9%) and in 4 patients with gout (4.9%).
wasting by tubular reabsorption of phosphate (TRP) was calculated, PU resulted increased in all.

Tumor was localized in all cases (Fig.1) and were localized in bone and soft tissue, by using functional imaging, followed by anatomical techniques. Before the introduction in routinely practice of 68Ga-DOTATATE-PET-CT in 2013, Octroescan-SPECT/CT and 18F FDG-PET were used as imaging modalities. Since 2013, diagnostic delay consistently reduced, from 8.6±8.3 yrs (7 patients) to 4.5±2.6 yrs (9 patients), confirming higher diagnostic accuracy of 68Ga-DOTATATE-PET-CT.

Figure 1.

13 patients underwent surgery; in two cases surgery was not possible due to tumor location, so pharmacological support with phosphate supplements and calcitriol was started; a patient underwent to TC-guided radiofrequency ablation. After surgery, 7 patients experienced a complete remission, 3 had partial remission, and calcitriol was started; a patient underwent to TC-guided radiofrequency ablation. To our knowledge, this is the widest European cohort of patients affected by TIO reported in the last two decades. We confirm an important delay is always needed, due to the possible relapses, even after a long period of complete clinical and biochemical remission.

THU0422 CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION WITHIN TOPHUS LOBULE: A FREQUENT ASSOCIATION OBSERVED IN LONG-TIME COURSE TOPHI

H. K. Es1, O. Olivier1, N. N. Pham2, V. Frochot3, D. Bazin4, C. Marty1, A. Ostertag1, J. D. Laredo5, R. Richette1, Q. D. Nguyen7, T. Bardin1, 1Université de Paris, UMR 1132, BIOSCAR, Paris, France; 2French-Vietnamese Research Center on Gout and Chronic Diseases, Vien Gut Medical Clinic, Ho Chi Minh City, Vietnam; 3HUEP - Hôpital Tenon, Sorbonne Université - UMR_S1155, Explorations Fonctionnelles Multidisciplinaires, Paris, France; 4Institut de Chimie Physique, Université Paris-Saclay et CNRS - UMR8000, Orsay, France; 5Hôpital Lariboisière, Service de Radiologie, Paris, France; 6French-Vietnamese Research Center on Gout and Chronic Diseases, Vien Gut Medical Clinic, Ho Chi Minh City, Vietnam

Background: Calcium pyrophosphate (CPP) crystals and monosodium urate (MSU) crystals are frequently found in the same synovial fluids of gouty patients suggesting an interaction in crystal formation and deposition. This association has never been reported in tophus.

Objectives: To compare adherence to urate-lowering therapy in patients with severe gout who received canakinumab following a 5-year retrospective analysis

M. Eliseev1, O. Sheliabina1, 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: The adherence to lowering therapy for gout is low, including in chronic severe gout. Whether interleukin 1 inhibitors may contribute to better adherence is unknown.

Objectives: To compare adherence to urate-lowering therapy in patients with severe gout who received canakinumab versus patients who received standard anti-inflammatory therapy (NSAIDs, glucocorticoids, colchicine). Methods: Of the 513 patients with gout observed at the V.A. Nasonova Research Institute of Rheumatology, Moscow from 2013 to 2014 y 247 patients with the most severe gout, requiring regular symptomatic treatment, were selected. Of these, 25 patients (3 (12%) women and 22 (88%) men), the average age of 54.5 ± 12.7g, received (at least 1) canakinumab injection of 150 mg subcutaneously as a symptomatic therapy, the remaining 222 patients (men) mean age
51.9 ± 11.4 g. received standard anti-inflammatory therapy (colchicine (55% of patients), glucocorticoids (5%), NSAIDs (40%), or a combination of these (3%). On average, after 4.8 ± 1.7 years, a comparative analysis of adherence to reducing therapy was carried out, as well as the need for anti-inflammatory therapy and assessment of adherence according to the Score compliance on the scale of the Morisoy-Green patients who received and did not receive canakinumab.

Results: Evaluation was available in 180 patients (16 who received canakinumab and 164 who received standard anti-inflammatory therapy) who were initially given reducible therapy. 11 patients died (2% of patients) who received canakinumab and 9 (4%) patients on standard anti-inflammatory therapy. 56 patients (28%) and 49 (22%) respectively were not available for observation. Adherence to urate lowering therapy was better in patients who received canakinumab (see Table 1).

The likelihood of maintaining the target uric acid level when taking urate-lowering drugs in patients who previously received canakinumab was higher (12 patients (75%) who received canakinumab and 32 (20%) patients received standard anti-inflammatory therapy (p = 0.005).

During the year preceding the analysis, there were no acute attacks of arthritis in 12 (75%) patients who received canakinumab and 32 (20%) patients received standard anti-inflammatory therapy (p = 0.002).

132 patients who previously received regular anti-inflammatory therapy and received standard anti-inflammatory therapy and 1 patient (1 attack) (p = 0.005) who previously received canakinumab took anti-inflammatory drugs over the past year due to the development of exacerbations (an average of 3 seizures per year); NSAIDs (54%) or colchicine (46%).

Conclusion: Therapy with interleukin 1 Kanakinumab may contribute to a better adherence to lowering therapy and is identified with a lesser need for symptomatic therapy with long-term follow-up.

DOI: 10.1136/annrheumdis-2020-eular.4008
patients with infection will significantly prolonged wound closure time compared with those without infection. Investigation of infection in ulceration over tophi will improve our understanding of this critical issue.

Objectives: To describe the microbiological profile in ulceration over tophi, antibiotic susceptibility patterns of causative agents, and to study the prediction of infection in ulceration over tophi among patients with gout.

Methods: Patients with ulceration over tophi were prospectively enrolled. The clinical characteristics were recorded and microbiological specimens were taken on admission. Specimens were cultured for aerobic and anaerobic bacteria, and antibiotic susceptibility testing was performed for the culture isolates. Patients were divided into 2 groups according to having infectious ulceration or not and the potential risk factors for infectious ulceration over tophi were examined using univariate and multivariate logistic regression analyses.

Results: A total of 82 patients were included for analysis. 46 pathogens were isolated from 39 (47.6%) patients, among which the top 3 were Staphylococcus aureus (43.5%), Pseudomonas aeruginosa (17.4%), and Enterococcus faecalis (13.0%). Overall, the Gram-positive bacilli were more sensitive to gentamicin (81.5%), amikacin (88.9%), trimethoprim/sulfamethoxazole (92.6%), nitrofurantoïn (96.3%), linezolid (100.0%), teicoplanin (100.0%) and vancomycin (100.0%) whereas penicillin, oxacillin and ampicillin were 66.7% to 77.8% resistant. The Gram-negative bacilli were more sensitive to amikacin (84.2%), cefoperazone/sulbactam (84.2%) and meropenem (89.5%) whereas ampicillin, amoxicillin/clavulante, cefotaxime, cefazolin, piperacillin, trimethoprim/sulfamethoxazole and tetracycline were 68.4% to 100% resistant. Patients with infection had a higher rate of smoking history and type 2 diabetes, with higher levels of erythrocyte sedimentation rate, C-reactive protein and leukocytosis, and lower level of albumin. In stepwise logistic regression analysis, type 2 diabetes (adjusted OR 5.064; 95% CI = 1.430 to 17.928) and albumin level (adjusted OR 0.855; 95% CI = 0.782 to 0.935) were independent predictors of infection in ulceration over tophi.

Conclusion: Infection is common in ulceration over tophi. Different antibiotic susceptibility patterns were observed in Gram-positive bacilli and Gram-negative bacilli. Type 2 diabetes and low albumin level were associated with an increased risk of infection in ulceration over tophi. The data in this study will be beneficial for tailoring infection control measures in a way that improves outcomes of ulceration over tophi.

**SHOULD FEBUXOSTAT-RESISTANCE BE ADDED TO CRITERIA FOR REFRACTORY GOUT? A PRELIMINARY STUDY**

Z. Huang1, W. Zhao1, D. Deng1, Y. Liu1, S. Chen1, J. Chen1, T. Li1.1. Guangdong Second Provincial General Hospital, Guangzhou, China

Background: Refractory gout manifests as recurrent flares, chronic arthritis and progressive tophaceous deposits. Febuxostat is a widely-used potent serum urate-lowering reagent, but some gout patients cannot achieve target serum uric acid (sUA) after they used this reagent.

Objectives: To determine whether febuxostat-resistance should be a criterion for refractory gout, characteristics of gout patients who were resistance to febuxostat or allopurinol were compared.

Methods: This study was performed from December 2015 to December 2019. Medical records of gout patients who met the 2015 gout classification criteria [1] and undertook febuxostat (febuxostat group) or allopurinol (allopurinol group) urate-lowering therapy (ULT) were assessed. Dose of ULT was adjusted till sUA was below 6mg/dL and 5mg/dL for patients with urate deposition. We screened gout patients who had contraindication or history of failure to normalize sUA for 3 months of treatment with the maximum medically appropriate febuxostat (febuxostat-resistance) or allopurinol (allopurinol-resistance) dose as defined by physicians. Furthermore, these screened patients met the traditional criteria of refractory gout except therapeutic reaction [2]. Demographic and clinical characteristics were recorded. Features between febuxostat-resistance and allopurinol-resistance patients were compared.

Results: (1) Of 683 gout patients who were included, 516 and 167 of them used febuxostat or allopurinol. (2) Age (41.92±11.58 vs. 42.26±9.41 years), Male gender (97.50% vs. 97.01%), duration of gout (5.78±4.74 vs. 5.05±4.72 years) and sUA (6.30±2.50 vs. 6.67±2.14 mg/dL) were similar between febuxostat group and allopurinol group (P>0.05). (3) Dose of febuxostat or allopurinol were 47.28mg/day and 178.24mg/day. (4) Sixteen patients were febuxostat-resistance, while 6 patients were allopurinol-resistance. Prevalence rates of treatment resistance were comparable between groups (3.10% vs. 3.59%, P>0.05). (5) Some parameters were different between resistance patients and non-resistance patients in both groups (Table 1, P<0.05). However, characteristics of febuxostat-resistance and allopurinol-resistance patients were similar (P>0.05).

**THE ASSOCIATION OF SERUM VITAMIN A, VITAMIN E, AND FOLATE WITH HYPERURICEMIA: AN ANALYSIS OF POPULATION-BASED NATIONALLY REPRESENTATIVE DATA**

Y Kim1, G. T. Kim1, J. Kang1.1. Kosin University College of Medicine, Kosin University Gospel Hospital, Busan, Korea, Rep. of (South Korea)

Background: Hyperuricemia is an important risk factor for gout as well as hypertension, type 2 diabetes and renal impairment. Although previous studies investigated the association of questionnaire-based micronutrient intake with serum uric acid levels, limited data on serum micronutrients levels in relation to the risk of hyperuricemia especially in Asian population.

**References:**
[1] and undertook febuxostat (febuxostat group) or allopurinol (allopurinol group) urate-lowering therapy (ULT) were assessed. Dose of ULT was adjusted till sUA was below 6mg/dL and 5mg/dL for patients with urate deposition. We screened gout patients who had contraindication or history of failure to normalize sUA for 3 months of treatment with the maximum medically appropriate febuxostat (febuxostat-resistance) or allopurinol (allopurinol-resistance) dose as defined by physicians. Furthermore, these screened patients met the traditional criteria of refractory gout except therapeutic reaction [2]. Demographic and clinical characteristics were recorded. Features between febuxostat-resistance and allopurinol-resistance patients were compared.
Objectives: This study aimed to evaluate the association of serum vitamin A, vitamin E and folate level with hyperuricemia in the Korean general population.

Methods: The present study included 8023 participants (2722 men and 3301 women) aged >19 years with available data on serum vitamin A, vitamin E, folate and serum uric acid. General characteristics of participants were compared using the Chi-square test and Student's t test. The association between serum vitamin A, E and folate and serum uric acid levels were evaluated using general linear regression model. Multivariate logistic regression analyses were performed to estimate the effects of these micronutrients on hyperuricemia.

Results: Serum uric acid levels were increased from the lowest quintile of vitamin A levels to the highest quintile after adjustment for covariates (P trend < 0.001 in both sexes). In addition, dose-dependent relationship was observed between vitamin A levels and the risk of hyperuricemia in fully-adjusted analyses (P trend < 0.001 in both sexes). However, neither serum vitamin E nor serum folate was associated with hyperuricemia across analyses models.

Conclusion: This study suggested that vitamin A could be a risk factor of hyperuricemia and further studies are warranted to elucidate underlying mechanism of the observed findings.

THU0430 RENAL URATE DEPOSITION: SUMMARY OF PUBLISHED EVIDENCE

P. Khanna1, B. Marder2, B. Lamoureux3, A. Kumar2, University of Michigan, Ann Arbor, United States of America; 2Horizon Therapeutics, Lake Forest, United States of America

Background: Gout is the most common inflammatory arthropathy in U.S. adults. Although the severity of this debilitating disease is often defined by the presence of tophi in the joints, systemic deposition of urate in major organ systems including the renal parenchyma is not as well established. Urates is primarily cleared through the kidneys and patients with gout often have concomitant renal disease along with other comorbidities such as diabetes, coronary artery disease, and hypertension; however, a causal role between these entities has not yet been carefully established. We hypothesize that urate deposits serve as a trigger in the inflammatory niche to propagate subclinical tissue damage that results in the chronicity of the disease. This could potentially explain its independent role in the development and progression of chronic kidney disease in gout patients.

Objectives: To review the published literature for evidence of urate deposition in the renal parenchyma in patients with gout and summarize the histopathology and imaging findings.

Methods: PubMed (from 1940 to 2020) was used to identify reports of autopsy, pathology and radiology imaging demonstrating urate deposition within the native renal parenchyma in patients with gout. Key words included: gout nephropathy, chronic urate nephropathy, renal tophi, gouty kidney, autopsy findings in gout, and renal imaging in gout. The reference lists from these publications were also used to identify additional articles. Literature referencing urate nephrolithiasis and renal transplants were excluded from the study.

Results: There were 25 articles documenting renal parenchymal urate deposition in gout patients confirmed by autopsy, biopsy and/or radiology imaging in native kidneys. Among the 19 articles examining urate deposition by autopsy and/or biopsy, 100% found urate deposition in the collecting ducts and adjacent medullary interstitium. Based on these findings, the most commonly proposed mechanism for urate deposition is urate crystal precipitation in the collecting ducts with eventual obstruction of the ducting duct walls from inflammation and/or tubular obstruction with subsequent extrusion of crystals into the medullary interstitium. 89% of reports documented inflammatory cells and/or tubulointerstitial fibrosis adjacent to the renal urate deposits. 68% reported cortical thinning or scarring. In addition, 74% of included publications reported renal vascular pathology including arteriosclerosis, glomerulosclerosis and nephrosclerosis. There were 6 imaging articles that all reported abnormal renal ultrasound findings with hyperechogenic renal medullas that were attributed to urate deposition.

Conclusion: There is a growing body of literature documenting urate deposition in the renal parenchyma in gout patients based on autopsy, pathology and imaging findings. Inflammation and fibrosis adjacent to regions of urate deposition and vascular changes were common. Given the strong association of gout with renal disease, there is a critical need to elucidate the mechanism by which urate impairs the renal tissue. Thus dedicated investigation is key to determine the prevalence and clinical significance of urate deposition in the kidneys of gout patients.

TREATMENT WITH PEGLOTICASE IMPROVES HEPATIC FIBROSIS ESTIMATED BY FIBROSIS-4 INDEX IN SUBJECTS WITH CHRONIC REFLUXATORY GOUT

N. Schlesinger1, A. Yeo2, P. Lipsky3, 1Rutgers Robert Wood Johnson Medical School, New Brunswick, United States of America; 2Horizon Therapeutics, Lake Forest, United States of America; 3AMEL BioSolutions, LLC, Charlottesville, United States of America

Background: Hyperuricemia is associated with non-alcoholic fatty liver disease (NAFLD)1,2, but the relationship to fibrosis remains uncertain3. Moreover, it is not known whether lowering serum urate will affect the course of NAFLD. The availability of data from two randomized trials of pegloticase, a pegylated recombinant mammalian uricase, that profoundly decreases serum urate afforded the opportunity to test the hypothesis that lowering urate might improve NAFLD.

Objectives: To determine whether treatment of chronic refluxatory gout patients with pegloticase was associated with improvement in NAFLD determined by Fibrosis 4 index (Fib4).

Methods: Databases from patients with chronic refluxatory gout who participated in two randomized 6 month clinical trials (RCTs) of pegloticase were analyzed4. Sub-sets who had persistent urate lowering to levels <1 mg/dL in response to biweekly pegloticase (Responders, n=36) were compared to those who received placebo (n=43). Since liver biopsy information was not available on these subjects, we relied on Fib4, a validated non-invasive estimate of liver fibrosis in a variety of liver diseases5,6 calculated from measurements of AST, ALT, platelet count, and age (Age x AST/platelets x ALB). A Fib4 value of 1.3 is an indication that further evaluation of liver disease is warranted.

Results: At baseline, the mean Fib4 values were 1.40 ± 0.86 in pegloticase responders and 1.04 ± 0.53 in subjects receiving placebo. As shown in figure 1, subjects receiving placebo exhibited a change of 0.26 ± 0.41 in the Fib4 score over the six months of the RCTs compared with 0.13 ± 0.62 in the pegloticase responders (p=0.048; by linear regression). When only the subjects with a Fib4 value > 1.3 were considered, a significant difference in the change in the Fib4 values over the 6 months of the trial between pegloticase responders and those receiving placebo was also observed (0.15 ± 0.67 vs 0.37 ± 0.42, p=0.004, by linear regression). The correlations between serum urate area under the curve (AUC) over the 6 months of the trial and the change in Fib4 value was r=0.33, p=0.0004 (Spearman rank-order correlation coefficient). Finally, multiple linear regression analysis indicated serum urate AUIC (as a surrogate measure for group) is the main contributor to the change in Fib4 (p=0.018 by linear regression).

Conclusion: The data are consistent with the conclusion that persistent lowering of serum urate had a significant impact on Fib4 levels, implying a possible effect on the course of NAFLD. The results support a more complete analysis involving biopsy examination of the impact of urate on liver inflammation and fibrosis.

References:

Background: Chondrocalcinosis is a painful rheumatic condition caused by the deposition of calcium pyrophosphate dihydrate crystals (CPPD) in joint tissues, and especially in cartilage. It is known that CPPD crystals cause inflammation and degenerative changes in joint, but the underlying mechanisms remain poorly understood. In particular, nothing is known about how these crystals regulate transmembrane heparan sulphate proteoglycans (HSPGs). Our attention focused on one family of HSPGs called syndecans as they have important roles both as adhesion molecules, by mediating chondrocyte-extracellular matrix interactions, and as modulators of intracellular signaling triggered by cytokines and growth factors.

Objectives: The aim of this study was to evaluate how CPPD crystals modulates syndecan expression in chondrocytes and in cartilage, and how this modulation can be ultimately linked to cartilage damage during chondrocalcinosis.

Methods: Murine chondrocyte ATDC5 cells were stimulated with 0.1ng/ml CPPD crystals or with 0.1ng/ml basic-calcium phosphate crystals (BCP), a family of calcium-containing crystals found in other rheumatic conditions such as osteoarthritis (OA). Cytotoxicity was evaluated by lactate dehydrogenase (LDH) release in the supernatant at 30 minutes, and 3, 6, 24 hours after stimulation. At the same time-point, mRNA expression levels of syndecans (Synd-1, -2, -3, -4) and of matrix-degrading enzymes (Mmp-3, -9, -13; Adamts-4, -5) was analysed by qRT-PCR. Finally, Syndecan-4 protein expression was studied by immunohistochemistry (IHC) in cartilage samples of patients with chondrocalcinosis and in samples of patients with severe OA without chondrocalcinosis as control.

Results: LDH assay revealed no increased cytotoxicity by CPPD or BCP at any time-point. qRT-PCR indicated that CPPD crystals but not BCP crystals induced Synd-2 and -3 upregulation at 30 minutes after stimulation and Synd-4 upregulation at 3 hours, while no modulation of syndecans were seen at later time-points. CPPD also induced Adams-4 expression at 3 hours after stimulation, and Mmp-9 expression at 3 and 6 hours. The expression of the other matrix-degrading enzymes was not affected. Human chondrocalcinosis cartilage exhibited enhanced Synd-4 expression compared to OA cartilage containing BCP calcification. Interestingly, Synd-4 expression was observed in the extracellular matrix but not on cell membrane, suggesting that maybe Synd-4 undergoes shedding (Figure 1).

Conclusion: BCP and CPPD crystals seem to trigger differential effects in terms of modulation of syndecans in chondrocytic cells. CPPD crystals induce Synd-4 and Adams-4 and Mmp-9 which are not induced by BCP crystals. It remains to be clarified whether the two events are interlinked. In particular, further studies are required to investigate if Adams-4 and Mmp-9 are involved in Synd-4 shedding or if vice versa Synd-4 regulates Adams-4 and Mmp-9 activation and downstream cartilage breakdown in chondrocalcinosis.

Data are presented as mean±SD or percent (%). *p<0.05 between CPPD and RA, **p<0.05 between CPPD and gout, ***p<0.05 between CPPD and controls, #p<0.05 between RA and gout, ##p<0.05 between RA and controls, ###p<0.05 between gout and controls.

Based on ATP III risk calculation the number of CPPD patients with high and very high CVR was 5 (12%) patients and was close to that in RA (9(21%),) gout (7(17%)) and the control group (8 (19%).) Mean CRP levels and number of pts with CRP >3mg/l were significantly lower in CPPD and control group pts, than in RA and gout, however CRP >2.5mg/l were documented almost in half of CPPD pts (43%) and only in 7% of pts from the control group (p<0.05). Although CVR calculations based on RRS scale yielded similar results, and all groups remained comparable, nevertheless, the number of pts with high and very high CVR increased in each group, except for the control. There were no meaningful differences in the groups in TC levels, however HDLP were significantly higher in CPPD pts (p<0.05), than in RA and gout, and in the control group pts vs RA pts (p<0.05).

Conclusion: CPPD associated cardiovascular risk is considerably high and comparable to CVR levels in RA and gout. Given that RRS based CVR calculation resulted in increased number of patients with high and very high risks in all groups, except for the control group, it can be suggested that use of calculators including CRP is appropriate not only in RA pts, but also in microcrystal depo- sition arthropathy, associated with inflammation, therefore prospective studies on larger samples are deemed necessary.

Disclosure of Interests: Aleksandra Novikova: None declared, Maxime Eliseev Speakers bureau: Novartis, Menarini Group, Alium, Olga Sheliabina: None declared, Helen Gerasimova: None declared. DOI: 10.1136/annrheumdis-2020-eular.5190
Results: A total of 125 gout patients were included, of whom 91 underwent both DECT scans of knees and feet. In bivariate analysis, age (p=0.03), symptom duration (p<0.003), subcutaneous tophi (p<0.004), hypertension (p=0.02), diabetes mellitus (p=0.05), and chronic heart failure (p=0.03) were associated with the total DECT volume of MSU crystal deposition. In multivariate analysis, factors associated with DECT MSU volumes ≥1 cm³ were gout duration (OR for each 10-year increase 3.15 [1.60;7.63]), diabetes mellitus (OR 4.75 [1.58;15.63]), and hypertension, are more strongly associated with increased MSU crystal deposition in knees and feet than gout duration, regardless of serum urate level.

Conclusion: Specific comorbidities, particularly chronic heart failure, diabetes mellitus, and hypertension, are more strongly associated with increased MSU crystal deposition in knees and feet than gout duration, regardless of serum urate level.

THU0439 INADEQUATE CARE FOR PATIENTS HOSPITALISED WITH GOUT: EVIDENCE THAT EULAR GUIDANCE IS NOT UTILISED

M. Russell1, B. Clarke1, S. Rampes1, K. Doka1, A. Mahto1, A. Rutherford1, J. Galloway1. 1King’s College London, Centre for Rheumatic Diseases, London, United Kingdom

Background: Hospitalisations due to gout have increased over the last decade, in direct contrast to declining admissions for other inflammatory arthritides including RA [1]. Gout is a treatable condition with recently published EULAR guidelines [2, 3]. Admissions could be avoided with effective use of urate-lowering therapies (ULT).

Objectives: We hypothesised that the majority of patients attending hospital with acute gout attacks would not be on ULT. Furthermore, we hypothesised that the majority of patients would not be provided with a plan for ULT commencement and/or uptitration on discharge, leaving them at risk of further hospitalisations.

Methods: We retrospectively analysed electronic health records for all patients presenting acutely with a primary admission diagnosis of gout (ICD-10 code: M10) at two hospitals in London, UK, from January – December 2017. Analyses of in-hospital gout management were performed for these patients, including to ascertain the number and proportion of patients who: i) had a known history of gout; ii) were receiving ULT at time of admission; iii) were provided with a discharge plan for ULT commencement and/or uptitration.

Results: Over a 12-month period, there were 234 emergency attendances for gout in 225 individuals. 80% were male, with a mean age of 58 years. 70/234 (30%) patients were discharged with a plan for ULT commencement and/or uptitration. 20 patients re-presented to hospital with acute gout within 12 months (17/20 were not receiving ULT).

Conclusion: Most patients hospitalised with gout were not receiving ULT, even those with a prior history of gout attacks. Few were provided with a ULT plan, leaving them at risk of re-admission to hospital. Hospital admissions are unpleasant for patients and incur a high economic burden for health services; if they are to be prevented, there must be a concerted effort to implement and follow gout management guidelines to ensure patients receive ULT at appropriate doses.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.3951

On the second visit (30th day) all investigated measures with exception for UA (sUA2 - 8.8 ± 1.9 mg/dL, p<0.05) had shown significantly lower results: CRP2 - 4.9±3.5 mg/dL, VAS2 - 4.2±1.2 cm, GAS2 - 4.9 ± 0.7 (p<0.001).

On the third visit (60th day) the following results were obtained: sUA3 - 4.7 ± 1.3 mg/dL, CRP3 - 3.5±2.0 mg/L, VAS3 - 3.3±2.1 cm, GAS3 - 3.7±0.9. All the measures were significantly lower than at baseline (p<0.001).

During all the follow-up period recurrent attacks of arthritis were observed in 6 patients (14.6%), particularly, only 2 patients experienced arthritis after the prescription of ULT.

Conclusion: Low dose colchicine in combination with sporadic (1-2) intramus- cular injections of betamethasone can present as an efficient, non-traumatic, safe and cost-effective option for the treatment of acute gouty arthritis. Moreover, according to results of our study, anti-inflammatory effect was stable even after the prescription of ULT.

THU0440 LOW DOSE COLCHICINE COMBINED WITH SPORADIC INTRAMUSCULAR INJECTIONS OF BETAMETHASONE – EFFICIENT AND SUSTAINED TREATMENT OF ACUTE GOUTY ARTHRITIS

A. Sargsyan1, V. Vardanyan2,3, K. Ginosyan3, S. Vardanyan2, V. Mukuchyan4, 1Yerevan State Medical University, Yerevan, Armenia; 2;3Mikayelyan“Institute of Surgery, Yerevan, Armenia; 3Yerevan State Medical University, Yerevan, Armenia; 4;Erebouni“Medical Center, Yerevan, Armenia

Background: Gouty arthritis is a common, potentially disabling and increasingly prevalent disease [1]. The main goals of treatment are to treat acute arthritis, decrease uric acid (UA) levels and prevent occurrence of further attacks. Accord- ing to 2016 updated EULAR evidence-based recommendations for the man- agement of gout, the most common and efficient options include prescription of colchicine (up to 6 mg during the first day) and intra-articular injections of glucocorticoids (GC) [2]. First option often causes diarrhea, the latter is extremely traumatic and painful in this group of patients.

Objectives: The aim of this study was to determine the efficacy of sustainabil- ity of anti-inflammatory effect of combination of low dose colchicine with spor- adic intramuscular injections of betamethasone in the treatment of acute gouty arthritis.

Methods: 41 treatment naïve patients with acute gouty arthritis (27 male (65.9 %), 14 female (34.1 %), mean age 55.9 ± 13.7 years, mean disease duration 5.9 ± 4.4 years) were recruited in the study. On the first visit all the patients were pre- scribed 1.5 mg of colchicine per day and 2 intramuscular injections of betametha- sone preparation (7mg-1ml) with an interval of 4 days. On the second visit (30th day) daily dose of colchicine was decreased to 1.0 mg, urate-lowering therapy (ULT) was begun. 21 patients (51.2%) received febuxostat 80 mg/day, 20 patients (48.8%) – allopurinol 100-150 mg/day.

Routine investigation included accurate collection of disease history, objective examination with determining the disease activity (Gout Activity Score /GAS/) and visual analogue scale (VAS patient), CBC, CRP, measurement of serum UA and creatinine level, urinalysis and other examinations [4]. GAS, VAS, CRP and uric acid were measured 3 times: at baseline, on 30th and 60th day of follow-up period.

Results: Investigation had shown the following results at baseline: sUA1 - 9.2 ± 1.5 mg/dL, CRP1 - 24.3 ± 21.5 mg/L, VAS1 - 8.3 ± 1.3 cm, GAS1 - 6.3 ± 0.7. All enrolled patients completed 60 days of treatment. Preparations were well toler- ated, no serious adverse events occurred: mild dyspepsia was observed in 4 (9.8%) patients, mild hypertension – in 7 (17.1%), 10 (24.4%) patients had transient diarrhea. Only in 14 out of 41 patients (34.1 %) there was a necessity to add NSAIDs to the main scheme of treatment.
GOUT AND HEART FAILURE IN THE US: A NATIONAL PERSPECTIVE

G. Singh 1, M. Sehgal 2, A. Mithal 3, 1Stanford University, Gastroenterology and Hepatology, Stanford, United States of America; 2University of California Los Angeles, Los Angeles, United States of America; 3Institute of Clinical Outcomes Research and Education (ICORE), Woodside, United States of America

Background: Heart failure (HF) is the eighth leading cause of death in the US, with a 38% increase in the number of deaths due to HF from 2011 to 2017 (1). Gout and hyperuricemia have previously been recognized as significant risk factors for heart failure (2), but there is little nationwide data on the clinical and economic consequences of these comorbidities.

Objectives: To study heart failure hospitalizations in patients with gout in the United States (US) and estimate their clinical and economic impact.

Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in the NIS in 2017, the most recent year of available data, with a primary or secondary diagnosis of gout and heart failure. Over 69,800 ICD 10 diagnoses were collapsed into a smaller number of clinically meaningful categories, consistent with the CDC Clinical Classification Software.

Results: There were 35.8 million all-cause hospitalizations in patients in the US in 2017. Of these, 351,735 hospitalizations occurred for acute and/or chronic heart failure in patients with gout. These patients had a mean age of 73.3 years (95% confidence intervals 73.1 – 73.5 years) and were more likely to be male (83.4%). The average length of hospitalization was 6.1 days (95% confidence intervals 6.0 to 6.2 days) with a case fatality rate of 3.5% (95% confidence intervals 3.4% – 3.7%). The average cost of each hospitalization was $63,992 (95% confidence intervals $61,908 - $66,075), with a total annual national cost estimate of $22.8 billion (95% confidence intervals $21.7 billion - $24.0 billion).

Conclusion: While gout and hyperuricemia have long been recognized as potential risk factors for heart failure, the aging of the US population is projected to significantly increase the burden of illness and costs of care of these comorbidities (1). This calls for an increased awareness and management of serious co-morbid conditions in patients with gout.

INCIDENCE OF ACUTE GOUT FLARE IN PATIENTS INITIATED ON INTRAVENOUS BUMETANIDE FOR ACUTE CONGESTIVE HEART FAILURE EXACERBATION

S. Jeong¹, J. Tan², ¹Temple University Hospital, Department of Medicine, Philadelphia, United States of America; ²Einstein Medical Center, Philadelphia, United States of America

Background: Heart failure is a prevalent and ever-increasing public health concern associated with significant morbidity, mortality, and financial burden. Therefore, identifying any factors that worsen the outcome of patients with heart failure is crucial to the nation’s medical and financial health.

One of the major comorbidities associated with heart failure is gout. Gout is a clinical syndrome of joint inflammation resulting from the deposition of monosodium urate crystals, causing painful and swollen arthritis. Acute gout flares in the context of acute heart failure (AHF) exacerbations result in longer lengths of stay and form an independent risk factor for increased readmissions or death. The use of loop diuretics in treating patients with AHF exacerbations may cause new onset of gouty arthritis or recurrence of established gout by increasing serum uric acid levels. Uric acid alone is implicated as an independent predictor of mortality in patients with chronic heart failure.

Objectives: In this study, we aim to better characterize the incidence of acute gout flares in patients being treated with intravenous bumetanide for AHF exacerbations.

Methods: This single-center retrospective cohort study included adult patients within an urban tertiary-care center hospital between 5 August 2016 and 30 June 2018. Chart review was performed to identify 130 patients who were hospitalized for AHF exacerbations, received intravenous (IV) bumetanide, and developed an acute gout flare for a total of 176 cases (Figure 1).

An acute gout flare that occurred during treatment of AHF with IV bumetanide increased hospital length of stay (LOS) by 3 days (mean LOS 15.2 days in those who had acute gout, mean LOS 11.6 days in those who did not [p-value 0.277]). Patients who received allopurinol during their hospitalization for AHF exacerbation had lower 30-day readmission rates for any cause (p-value 0.017, Table 4). There was no reduction in the 30-day readmission rate in patients who received colchicine or allopurinol during their hospitalization for AHF exacerbation. Those with a history of gout had higher readmission rates than those without a history of gout (p-value 0.007).

Conclusion: Gout is known to be a weighty contributor to patients’ morbidity and mortality in heart failure, and the occurrence of acute gout flare in AHF exacerbations may be precipitated by the use of loop diuretics. We show that the use of IV bumetanide in patients hospitalized for AHF exacerbations is associated with a 7.17% yearly incidence of acute gout flares. Furthermore, patients with a history of gout were found to have higher readmission rates, and those who received allopurinol during their hospitalization had lower readmission rates.

THU0445

PREVALENCE AND INFLUENCE OF DISEASE DURATION IN THE AMOUNT OF ARTICULAR AND PERIARTICULAR DEPOSITS OF MONOSODIUM URATE (MSU) CRYSTALS IN NON-TREATED GOUTY ARTHRITIS PATIENTS

L. A. Torrens Cid¹, J. Molina Collada¹, C. Y. Soleto¹, L. R. Caballero Motta¹, A. Anzola Alvaro¹, A. Ariza¹, J. Castrejon Fernandez¹, J. Rivera¹, J. M. Alvaro Gracia¹, J. C. Nieto¹, ¹Hospital General Universitario Gregorio Maranon, Madrid, Spain

Background: Monosodium urate crystals deposition arthritis (Gout) is the most prevalent inflammatory arthropathy in our society. The use of musculoskeletal ultrasound (MSUS) is emerging as a diagnostic method of patients with gout, mainly in the past few years.

Objectives: Our objective is to establish the prevalence of articular and periarticular ultrasound lesions in patients with known or recent gout diagnosis without urate-lowering therapy (ULT) as well as to analyze the influence of disease duration on these findings.

Methods: Observational, cross-sectional and descriptive study, including patients with diagnosis of Gout (fulfilling the ACR / EULAR Classification Criteria 2015) between September and November 2019 in our Rheumatology service of a tertiary center. Demographic and clinical records were collected (table 1) and MSUS was performed on each patient systematically by two rheumatologists, exploring a total of 20 structures (8 tendons and 12 joints). Suggestive images of MSU crystals deposition were defined following the OMERACT 2015 ultrasound elementary lesions definitions. Deposits included lesions as tophus, hypercholesteremic aggregates (HA) and double contour (DC).

Results: A total of 38 patients were included, 34 men (89.5%) and 4 women (10.5). Twenty seven (71.1%) presented MSU crystals in synovial fluid samples, while rest of them (28.9%) met 2015 ACR / EULAR Classification Criteria for Gout. Disease duration (since onset of symptoms) was less than 6 months in 20 patients (52.6%) and longer than 6 months in 18 (47.36%). Thirty seven patients (97.36%) presented some type of MSU deposits on the explored areas. One hundred and thirty (17,10%), out of 760 explored locations, had MSU deposits. Patients with disease duration less than 6 months had 56 locations with deposits (43.07%), while those with a symptomatology longer than 6 months had 74 locations with deposits (56.92%). Left knee was the most frequent location of UMS deposits (78.95%). Out of the 145 MSUS images with elementary lesions due to MSU crystal deposits, 28 were tophi (19.31%), 33 HA (22.75) and 84 DC (57.93%). Out of the total images with deposits (DC, HA and tophi), DC in the left
knee was the most frequent (21.3%), followed by DC in right knee (17.24%) and DC in right MTP (10.24%).

**Conclusion:** Almost 100% of patients with recently diagnosed gout without ULT presented an at least one of the scanned locations MSUS images suggestive by MSU crystals deposition. Most of MSU crystals deposits were on knees and 1st MTP. Patients with non-treated longer than 6 months of disease duration gout had a greater number of MSU crystals deposit locations detected by MSUS. The presence of tophi and HA was statistically higher in patients with disease duration longer than 6 months (table 2).

At 12 months 87.6% (163/186) of patients used allopurinol and 13.4% (23/166) febuxostat with mean daily doses of 289 mg (range 100-900) and 59 (20-120) mg, respectively.

**Conclusion:** Most patients (85.5%) with recent gout flare und increased SUA reached the target SUA after 12 months. A good treatment result was predicted in patients using age, less frequent alcohol use, when patients believed they could cope with symp- toms and when they did not believe that drugs are generally overused.

**Results:** Gout flares are considered a key clinical and research outcome in gout, Early treatment of gout flares increases patient well-being and warrants timely notification of the treating clinician.

**Objectives:** To test the feasibility of a smartphone app to home-monitor gout flares real-time for both patients with a suspicion of and established gout.

**Methods:** Thirty patients were recruited during their visit at the outpatient rheumatology clinic. Inclusion criteria were age ≥ 18 years, smartphone possession, established gout (crystal proven) or a clinical suspicion of gout and at least one flare reported in the last three months.

A straight-forward query app was used to incorporate an adapted version of the 2017 four-criteria gout flare definition.[1] For 90 consecutive days the app asked patients to report their current pain score on an 11-points scale as screening question. Scoring pain below 4 terminated the query, otherwise the app posed the remaining criteria: does the patient experience warm and/or swollen joints and are symptoms regarded as a gout flare. Responses were transmitted in real-time to the dashboard and the clinician was alerted via email if predefined conditions were met. End of study evaluation consisted of the number of generated alerts, duration of (possible) flares and actions taken. Patient feasibility was assessed by measuring app attrition and using a questionnaire based on the Technology Acceptance Model.[2] All constructs were analysed using descript- ive statistics.

**Results:** All 30 recruited patients finished the trial. Three minor, resolvable technical issues were reported. Seventeen participants never missed a question. In total 110 responses (4.1%) were missed with three participants responsible for...
THU0450

OPTIMISTIC STATUS ASSOCIATES WITH COMPLIANCE TO URATE-LOWERING THERAPY IN GOUT PATIENTS

W. Zhao1,2, Z. Huang1, Y. Huang1, Y. Liu1,2, X. Liu1,3, Z. Zhong1,3, S. Chen1,3, T. Li1. 1. Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; 2. Southern Medical University, The Second School of Clinical Medicine, Guangzhou, China

Background: Compliance to urate-lowering therapy (ULT) is poor in gout patients, which contributes to increased frequency of acute gout attacks, deposition of tophi and urate nephropathy. [1] Optimistic status is probably a potential and considerable factor affecting compliance to ULT in gout patients. Objectives: To compare optimistic status between gout patients and healthy controls, and also between gout patients with good and poor compliance. Relationship between optimistic status and compliance to ULT, SUA target achievement of gout patients were assessed as well. Methods: This was a monocentric and observational study which was performed from August 2018 to December 2019. Adult patients who met the 2015 gout classification criteria were included in this study. The healthy controls were individuals who were free of gout, hyperuricemia and other rheumatic diseases from the physical examination center of our hospital. Demographic data, including age, gender and education were collected from all individuals. Serum uric acid (sUA) were collected from healthy controls and gout patients at enrollment and again after 3 months. Disease duration of gout, visual analogue scale (VAS) of pain were also assessed for gout patients at enrollment.

Compliance to ULT was measured using the medication possession ratio (MPR) in the following 3 months. Poor compliance was defined as MPR<0.8 and good compliance was defined as MPR≥0.8. All subjects completed the life orientation test-revised (LOT-R) for optimistic status assessment.

Results: Five hundred and thirty gout patients and 307 healthy controls matched by age (41.4±13.2 vs. 42.1±9.3 years), gender (male 971% vs. 95.1%), and education (college graduated 54.2% vs. 58.0%) were included in this study. Of the 530 gout patients, the mean disease duration was 5.7±4.9 years, and 292 (55.1%) patients' MPR were lower than 0.8. There was no statistic difference in LOT-R between gout patients and healthy controls (19.0±2.4 vs. 19.2±2.5, P>0.05) (Table 1). Gout patients with poor compliance (MPR<0.8) had higher level of sUA (525.5±138.0 vs. 471.2±52.5 μmol/L, P<0.05), follow up sUA (458.1±154.5 vs. 361.6±120.0 μmol/L, P<0.05) and higher LOT-R (19.6±2.6 vs. 17.8±1.7, P<0.05) than those with good compliance (MPR≥0.8). Of the 292 gout patients with poor compliance, there were only 83 (28.4%) patients achieved SUA target after 3 months, and their LOT-R were significantly lower than those with good compliance.

Conclusion: Use of 1 mg/day colchicine is not superior to 0.5 mg/day as prophylaxis for ULT induced gout flares. For generalisability it should be noted that flare rates were not very high, probably due to the background ULT being characterised by a "start low, go slow" approach. In this context colchicine 0.5 mg/day is sufficient as prophylaxis.

CELL-MATRIX ADHESION OF BONE MARROW STROMAL CELLS IN MODIC TYPE 1 CHANGES IS INCREASED AND RELATES TO INCREASED EXPRESSION OF INTEGRIN β1

I. Heggli1, S. Epprecht2, T. Mengis1, A. Juengel1, M. Betz1, J. Spiring2, F. Wanivenhaus3, F. Brunner2, M. Farshad3, O. Distler1, S. Dudli1.
1Center of Experimental Rheumatology, University of Zurich, Zurich, Switzerland; 2Department of Orthopaedic Surgery, Balgrist University Hospital, Zurich, Switzerland; 3Department of Rheumatology, Balgrist University Hospital, Zurich, Switzerland

Background: Modic type 1 changes (MC1) are vertebral bone marrow lesions associated with non-specific low back pain (LBP). The pathophysiology of MC1 includes inflammation, fibrosis, and high bone turnover. Bone marrow stromal cells (BMSCs) are key regulators of these processes: BMSCs contribute to inflammation by regulating myelopoiesis/osteoclastogenesis; BMSCs can differentiate into osteoblasts contributing to high bone turnover, and BMSCs can differentiate into pro-fibrotic myofibroblasts.

Objectives: To identify dysregulated biological processes in MC1 BMSCs contributing to the pathobiology of MC1.

Methods: Bone marrow aspirates were obtained from LBP patients with MC1 undergoing lumbar spinal fusion. Aspirates were taken prior to screw insertion. From each patient, a MC1 and a healthy control (HC) aspirate from the undergoing lumbar spinal fusion. Aspirates were taken prior to screw insertion. BMSCs were isolated by plastic adherence. From each patient, a MC1 and a healthy control (HC) aspirate from the undergoing lumbar spinal fusion. Aspirates were taken prior to screw insertion. BMSCs were isolated by plastic adherence. BMSCs were cultured on fibronectin-coated, collagen-I-coated, and non-coated plastic dishes. BMSC adhesion was evaluated from 15min to 30min (Δ30min - 15min). Percentage of adherent cells of MC1 and HC BMSC was compared with paired t-test. In order to identify integrins responsible for dysregulated cell-matrix adhesion, gene expression of 15 relevant integrins was measured by quantitative real-time PCR (qPCR). Normalized expressions were compared between MC1 and HC BMSC with paired t-test. Integrin β1 protein level was semi quantitatively analyzed by Western Blot (n = 5 ± 5) and normalized to β-Actin expression.

Results: By RNA sequencing, 154 genes were differentially expressed between MC1 and HC BMSCs (p-value ≤ 0.01; log2-ratio ≥ 0.5). Gene ontology enrichment analysis revealed an overrepresentation of the biological process “cell-matrix adhesion” among all significantly regulated genes (p-value < 9.3e-13). A change in cell adhesion was corroborated with adhesion assay. Binding (Δ30min - 15min) to collagen I (MC1 +16%, HC +10%, p-value = 0.10), fibronectin (MC1 +17%, HC +6%, p-value = 0.03), and non-coated surface (MC1 +46%, HC +35%, p-value = 0.03) was increased in MC1 (Figure 1). Integrin gene expression analysis revealed significant upregulation of integrin beta-1 gene (ITGB1) in MC1 vs. HC (fold change = 1.24, p-value = 0.047), whereas there was no significant difference between the other integrins tested. On protein level, integrin β1 was upregulated in MC1 in four out of five patients (Figure 2).

Conclusion: Adhesion of BMSCs to matrix and integrin β1 expression are increased in MC1. Integrin β1 is essential for cell-matrix adhesion and an important contributor to the initiation and progression of tissue fibrosis, a hallmark of MC1. Therefore, BMSCs and integrin β1 might be relevant novel targets for the treatment of MC1.

The mechanism of action of α-phel in chronic pain was analyzed in vivo. Ethics Committee of UFPI approved this project (protocol nº 305/17). Female Swiss mice (25-30g) underwent partial sciatic nerve ligation surgery to induce neuropathy. The neuropathic mice (n=6) were pre-treated with Naloxone (2mg/kg, i.p.) or saline (10mL/kg, p.o.). After 20 minutes, they were treated with α-phel (6.25mg/kg, p.o.) or morphine (5mg/kg, i.p.) and evaluated by Von Frey test. Results: The predicted pharmacokinetic parameters (Table 1) suggest good intestinal absorption and good permeability. Plasma protein binding is elevated, however, it is reversible and technological alternatives, such as carrier systems, can improve it. The α-phel does not inhibit CYP3A4, it indicates a minimal possibility of interactions with others drugs and adverse reactions.

The structure of α-phel binding opioid receptors is shown in Figure 1. The lowest ligand-receptor binding energies were, respectively: -6.0 kcal/mol, -6.6 kcal/mol and -7.4 kcal/mol for the interaction of α-phel with Mu, Kappa and Delta receptors. It indicates that α-phel has high affinity for all three opioid receptors, binding in a strong and stable way. The analgesic potential of the substance was tested in vivo as well. It was observed that Naloxone, an opioid antagonist, significantly reversed the effect of α-phel, indicating that it displays antinociceptive and antihyperalgesic activity through opioid system.

Conclusion: The monoterpene α-phel presents antinociceptive activity and reduces the sensitivity in chronic pain through the activation of opioid receptors. Thus, in vivo and in silico results indicate that α-phel is an analgesic opioid agonist. This work may guide further preclinical studies, since α-phel may be an important strategy to treat chronic pain, with fewer side effects, dependence and tolerance than conventional drugs.

Pain in rheumatic diseases, including fibromyalgia __

THU0453 THIRD OCCIPITAL NERVE RADIO-FREQUENCY UNDER FLUOROSCOPIC GUIDANCE IN MANAGEMENT OF CERVICOCENIC HEADACHE IN RHEUMATOID ARTHRITIS

A. Alawamy1, M. Hassani2, E. Talaat1, E. Kameel1. 1Assuit University, Asiss, Egypt

Background: Rheumatoid arthritis is a common type of autoimmune arthritis characterized by chronic inflammation. Cervical spine is often affected specially in long lasting disease.

Objectives: Evaluate efficacy of Third occipital nerve Radiofrequency under fluoroscopic guidance to treat refractory cervicogenic headache in RA patients.

Methods: The current study was revised and approved from the local ethical committee of Faculty of Medicine; Assiut University, then registered in the clinical trials under the number of NCT03882335. Inclusion criteria included, Patients who fulfilled the American College of Rheumatology (ACR) (2010) criteria for RA and suffering
from upper neck pain and/or headache due to bilateral 3rd occipital nerve involve-
ment, excluding other local cervical spine pathologies was confirmed by MRI and
previously failed conservative treatment for at least three months prior to enrollment.
Sixty adult patients were randomly assigned to one of the two studied groups. Group 1
(RF, n = 30), received bilateral Third occipital nerve Radiofrequency under fluoro-
oscopic guidance or Group 2 (control group, n = 30), received oral prednisolone
10 mg/day. The two groups were then followed-up with neck disability index (NDI),
night neck pain VAS score and headache score every two weeks for three months.
Sleep disturbance, sleep disability index were reassessed six months post
intervention. Post interventional assessment was done by pain physician who were
kept blind to the grouping process.
Results: Neck disability index (1 year outcome), Night neck pain VAS, and severity
of headache showed significant differences during the whole post-interventional
study period. The patients in RF group demonstrated significant improvement of
pain in comparison to baseline value over the whole six months with p-value <
0.001 as regard to the fore-mentioned three parameters. On the other aspect,
the control group patients showed significant improvement in comparison to its
baseline value after the 2nd, 12th and 24th weeks only as follows: (0.001, 0.003,
0.003 for the NDI) (p values of 0.02,0.01, 0.01 for the nocturnal neck pain VAS), (0.001
0.009, 0.005 for the headache VAS severity.
Conclusion: Radiofrequency of 3rd occipital nerve is effective in treatment of
refractory cervicogenic headache in RA.

THU0454 SOMATIC SYMPTOMS IN FIBROMYALGIA AND THEIR
CORRELATION WITH DRUG TREATMENT
M. Antivalle1, M. Agosti2, A. Batticciotto2, S. Costi2, V. Giorgi1, P. Sarzi Puttini1.
1 L. Sacco University Hospital, Rheumatology, Milano, Italy; 2 L. Sacco University
Hospital, Rheumatology, Milano, Italy; 3 Ospedale di Circolo e Fondazione
Macchi, Rheumatology, Varese, Italy

Background: Drug treatment in fibromyalgia (FM) is often disappointingly inef-
fective, and there are currently very few data to support therapeutic choices
towards a personalized medicine approach.

Objectives: To evaluate the prevalence of selected somatic symptoms in FM,
and to study their relationship with drug treatments.

Methods: The study population consisted of 526 patients (471 F 55 M, mean age
47.7±11.33 yrs) affected by FM not associated with other rheumatic diseases.
All patients were required to compile a questionnaire reporting the presence of
42 somatic symptoms -as suggested (1) – in the last 7 days. Drug usage was
assessed by interview.

Results: On average, patients reported the presence of 17.04±6.68 symptoms
(range 4-35), with ample variations in the prevalence of different symptoms
(Fig. 1), ranging from over 95% (fatigue and muscle pain) to less than 10 %, sei-
zyme symptoms being reported by only 2 patients (0.4%). 31.1% of patients were not taking
any drug for their FM. The most frequently used drugs were analgesics (ANA,
41.7%) followed by benzodiazepines (BD, 29.1%), SSRIs (16%), gabapentino
ids (GABA, 14.4%), and NSRI (14.3%) (Fig. 2). Different drugs were associated with
different spectrum of somatic symptoms: as compared to non users, BD users
reported a significantly higher (p< 0.05 by chi-square test) prevalence of irri-
table bowel (65.4% vs 52.3%), fatigue (98.7% vs 94.9%), thinking difficulties
(78.4% vs 68.5%), muscle weakness (94.1% vs 81.7%), abdominal pain (55.6% vs
43.9%), insomnia (73.9% vs 56.6%), depression (63.4 % vs 37.2%), consti-
pation (60.1% vs 42.9%), pain in upper abdomen (50.3% vs 40.2%), nausea
(53.6% vs 39.3%), nervousness (71.9% vs 61.5%), chest pain (49.0 vs 37.75),
blurred vision (65.4% vs 53.6%), dry mouth (72.5% vs 52.3%), itching (56.2%
vs 44.5%), vomiting (13.7 % vs 7.8%), change taste (22.2 % vs 12.7%), dry eyes
(55.6% vs 41.0%), breath shortness (56.9% vs 47.7%), appetite loss (33.3% vs
19.7%), painful urination (15.0% vs 8.4%), and bladder spasms (18.3% vs 8.6%).
NSRI users reported a significantly higher prevalence of thinking difficulties, con-
stipation, blurred vision, dry mouth, wheezing, dry eyes, easy bruising. Among
GABA users, there was a higher prevalence of thinking difficulties, numbness,
insomnia, constipation, nausea, dry mouth, dry eyes, appetite loss, sun sen-
sitivity, easy bruising, and bladder spasms. In no cases a higher prevalence of
symptoms was recorded in drug non users vs users.

Conclusion: The usage of different drugs in FM is associated with different
somatic symptoms. The higher prevalence of symptoms in drug users as com-
pared to non users raises serious questions concerning the opportunity or the
appropriateness of drug selection in FM.

THU0455 DIFFERENCES IN PSYCHIATRIC COMORBIDITIES
AND LIFE ADVERSITIES BETWEEN PATIENTS WITH
RHEUMATOID ARTHRITIS ASSOCIATED WITH
FIBROMYALGIA AND PATIENTS WITH PRIMARY
FIBROMYALGIA
F. Arzeni1, M. Cirillo1, I. F. Masala2, E. Gerratana1, D. Sangarl1, G. Miceli1,
P. Sarzi-Puttini1, A. Alcuti1,1 Rheumatology Unit, University of Messina,
Messina, Italy; 2 Trauma and Orthopedic Unit, Santissima Trinità Hospital,
Cagliari, Italy; 3 Department of Rheumatology, University Hospital ASST
Fatebenefratelli Sacco, Milan, Italy; 4 Department of Clinical Neurosciences,
Hernanas Hospitalacias, Villa S. Benedetto Menni Hospital, Albese (Como),
Italy; 5 Humanitas Clinical and Research Center, IRCCS, Rozzano, Italy, Como,
Italy

Background: Patients with rheumatic arthritis (RA) continue to report significant
pain despite apparent disease control by immunosuppressive drugs (1), leading
to the hypothesis that central sensitisation (CS) plays a role in the chronic muscu-
lo-skeletal pain defining fibromyalgia (FM).

Objectives: The aim of our study was to evaluate the differences in psychi-
atric comorbidities and life adversities between patients with RA+FM and patients
with primary FM (PFM).

Methods: In an observational cross- sectional study patients with PFM and
AR+FM were consecutively recruited. The inclusion criteria were an age of 18-70
years; a diagnosis of RA according to the 2010 ACR classification criteria and FM
according to the 1990 ACR criteria and 2016 ACR criteria. Lifetime diagnoses of
major depression disorder (MDD), panic disorder (PD) and post-traumatic stress
disorder (PTSD), three of the most frequently described psychiatric disorders
among FM patients, were made with the Structured Clinical Interview for DSM-5.
Depressive symptoms were measured using the Zung Self-Rating Depression
Scale (ZSDS). Childhood trauma was measured using the short form of the
Childhood Trauma Questionnaire (CTQ) and stressful events were assessed

References:
using the Paykel’s Interview for Recent Life Events. Pain was assessed using a visual analogue scale (VAS). The Fibromyalgia Impact Questionnaire (FIQ) was also used.

**Results:** Seventy-seven patients were originally screened, but seven were excluded because of current depressive episode or having a ZSDS of ≥ 60 or categorized as minimizers of childhood maltreatment at CTQ. The final analysis therefore involved 70 patients, all Caucasians: 30 with PFM and 40 with AR+F.M. All patients with PFM and 38 (85%) of the 40 with AR+F.M were treated for FM symptoms (antidepressants, pregabalin). The lifetime rates of MDD were significantly higher in PFM vs AR+F.M (76.7% vs 40% respectively, p < 0.003), as well as the rates of PD (50% and 15% respectively, p < 0.003), whereas there was no difference in PTSD rates. The PFM patients reported significantly higher levels of physical (p < 0.020) and sexual abuse (p = 0.011) and physical neglect (p < 0.001), whereas there was no between-group difference in the levels of emotional abuse (p = 0.912) and neglect (p = 0.542); consistently, the proportion of sexually abused (p = 0.005) or physically neglected patients was also higher in the PFM group (p < 0.03). The rates of emotional neglect were high in both groups, without any significant difference between them. The vast majority of AR+F.M patients (90%) said that only event occurring in the year preceding the onset of FM was RA, whereas the PFM patients mainly reported non-physical events (36%, particularly the ending of a relationship, or working or financial problems) or no event at all (40%), (p < 0.01). Binary logistic regression used to identify the factors predicting association of PFM/AR+F.M status, showed an association with lifetime major depression, life events preceding the development of FM, and BMI (p < 0.05 at all).

**Conclusion:** PFM and SFM differ in psychiatric co-morbidities and environmental adversities, suggesting that the putative common pathogenic condition of CS may develop through different pathways.

**THU0456**

**THE “JOINT CRITERIA” FOR FIBROMYALGIA DIAGNOSIS IN RHEUMATOID ARTHRITIS PATIENTS: RELIABILITY COMPARED TO THE 2010 ACR CLASSIFICATION CRITERIA FOR FIBROMYALGIA**

**Background:** A significant proportion of rheumatoid arthritis (RA) patients have concomitant fibromyalgia (FM) (1). Associated FM diagnosis in RA patients can determine worse treatment outcomes compared to patients without FM (1). A difference between tender joint count (TJC) and swollen joint count (SJC) ≥ 7 also named the “joint criteria” was proposed as being diagnostic for FM in patients with RA. The “joint criteria” were validated against the 1990 ACR Classification Criteria for FM and are easy to apply to patients with RA (2). Since then, the 2010 ACR Classification criteria for FM, which include somatic symptoms besides pain sensitivity, were developed and validated.

**Objectives:** We aimed to determine the reliability of the joint criteria for fibromyalgia in RA compared to the ACR 2010 Classification Criteria for FM and to compare RA patients diagnosed with FM (FRA) to those without FM in terms of clinical variables.

**Methods:** We performed a cross-sectional study on RA patients who presented in our department during a 3-month period. Tender joint count (TJC), swollen joint count (SJC), patient global assessment of disease activity (PGA) were determined. DAS28 scores were calculated using CRP. We applied the 2010 ACR Classification Criteria and the joint criteria for FM diagnosis. Kappa agreement coefficient was used to determine the reliability of the joint criteria against the 2010 ACR Classification Criteria for FM in patients with RA. Differences between groups were assessed using Mann-Whitney U test for numerical data or Chi square test for ordinal data.

**Results:** We included 100 consecutive RA patients, 84% female, with a mean age of 57.3 ± 12 years and mean disease duration of 14.9 ± 9 years. Twenty-four patients (24%) had associated FM according to the ACR 2010 Classification Criteria and 22 (22%) patients satisfied the joint criteria for associated FM. The level of agreement between the joint criteria and the ACR 2010 classification criteria for FM was kappa = 0.66, p < 0.001, with a sensitivity of 70% and a specificity of 93%. FRA patients had similar demographic and disease characteristics compared to RA patients. Patients with FRA according to the joint criteria had significantly higher PGA, DAS28, and HAQ scores, but similar CRP values and SJC compared to RA patients (Table 1).

Data are expressed as mean (SD) or median (IQR).

**Conclusion:** The joint criteria are diagnostic for FM in RA patients with moderate reliability compared to the ACR 2010 Classification criteria. When diagnosed with the joint criteria, FRA patients have higher disease activity scores despite having similar clinical and laboratory inflammatory markers compared to RA patients.

**THU0457**

**LONGLATINODUAL ASSOCIATION OF SEDENTARY TIME AND PHYSICAL ACTIVITY WITH SLEEP QUALITY IN WOMEN WITH FIBROMYALGIA: THE AL-ÁNDALUS PROJECT**

**Background:** Sleep disturbances are common in fibromyalgia, and influences quality of life. Recent literature has suggested that non-pharmacological treatments (e.g., physical exercise and cognitive behavioural therapy) may help to improve sleep quality (SQ) and the management of fibromyalgia. In this regard, sedentary time (ST) and physical activity (PA) intensity levels could play a role on SQ in this population. However, evidence is scarce and mainly based on cross-sectional data.

**Objective:** This study aimed to examine the longitudinal associations (2- and 5-year follow-up) of ST and PA intensity levels with SQ in women with fibromyalgia.

**Methods:** In this prospective cohort study, women diagnosed with fibromyalgia (age: 51.4±6.7 years) with complete data were included at baseline (n=409), at 2-year follow-up (n=214) and at 5-year follow-up (n=218). Sedentary time and PA intensity levels (light and moderate-to-vigorous (MVPA)) were assessed using triaxial accelerometers worn for consecutive 7 days. The percentage of time spent in different behaviours was calculated (e.g., (ST/accelerometer wear time) × 100). The SQ global score was calculated as a sum of all components (score
ranges from 0 to 21 where higher values indicate worse SQ) of the Pittsburgh Sleep Quality Index. Linear regressions were performed to analyse the association of changes in ST and PA over time (predictor variables) with SQ at 2- and 5-years follow-up (dependent variables) while considering baseline SQ, age, fat percentage, marital status, educational level, sleep or relaxation medication, and regular menstruation as confounders.

**Results:** Overall, after adjusting for confounders, non-statistical significant associations were found between changes in ST and PA intensity levels from baseline to 2-years follow-up with SQ at 2-year follow-up (P>0.05), except for the change in MVPA from baseline to 2-years follow-up, which showed evidence of statistical significance (β=0.207, P=0.059). Regarding the 5-year follow-up, we did not observe either any association between changes in ST or PA intensity levels from baseline to 5-year follow-up with SQ at 5-year follow-up (P>0.05).

**Conclusion:** The main findings suggest that neither ST nor PA intensity levels over time predict SQ at 2- and 5-year follow-up in women with fibromyalgia. Future PA-counselling randomised controlled trials might shed more light on the role that ST and PA could play on SQ.

**THU0458 HIGH PREVALENCE OF JOINT HYPERMOBILITY IN INFLAMMATORY BOWEL DISEASE PATIENTS WITH PAIN UNRESPONSIVE TO BOWEL-TARGETED THERAPY**

H. Zidany1, 2, M. Waterman1, 2, K. Toledano1, 3, Y. Chowens1, 2, D. Markovits1, 3, A. Karban1, 4, A. Balbir-Gurman1, 5, Y. Braun-Moscovici1, 5, Rappaport1,

1Faculty of Medicine, Technion, Haifa, Israel; 2Rambam Health Care Campus, Gastroenterology Institute, Haifa, Israel; 3Rambam Health Care Campus, B Shay Rheumatology Institute, Haifa, Israel; 4Internal Medicine C, Hаifa, Israel

**Background:** Musculoskeletal manifestations occur in 20-50% of patients (pts) with inflammatory bowel disease (IBD). A substantial number of patients complain of non-inflammatory musculoskeletal pain.

**Objectives:** To assess the incidence of joint hypermobility (JHM), benign joint hypermobility syndrome (BJHS) among patients with inflammatory bowel disease (IBD) examined in the inter-disciplinary rheumatology service at a tertiary referral center and the impact on IBD manifestations and outcome.

**Methods:** Medical records of 180 consecutive IBD pts referred to the inter-disciplinary clinic were retrospectively reviewed. Data regarding age, gender, diagnosis, disease duration, clinical and laboratory features, previous and current therapy, Harvey-Brandshaw Index were entered into a database and analyzed. Beighton's scoring of 2-4/9 was used to define patients with JHM. The 1998 Brighten's criteria were used to identify patients with BJHS. Outcome was defined as improvement of joint pain. The statistical methods used included descriptive statistics, T test, Spearman's correlation and multiple logistic regression analysis.

**Results:** Forty-six patients (mean(SD) age 36.2(12.4), disease duration 13.9(6.8) years) out of 180 IBD patients (mean(SD) age 40.4(14.3), disease duration 15.7(9.1) years) fulfilled the criteria for JHM. Twelve patients had active inflammatory joint disease (2 with axial involvement, 10 with peripheral joint disease and 2 with axial and peripheral joint involvement). The other 32 answered both major criteria for BJHS. The median Beighton scoring was 7 (range 5-9). Most of them were on biological treatment. Patients with JHM suffered frequently of arthralgia and abdominal pain, in spite of endoscopic remission and normal levels of calprotectin and inflammatory markers (p=0.02, r=0.17). JHM and BJHS were associated with poorer outcome (p=0.004, r=0.2). In a multiple logistic regression analysis, only JHM reached borderline significance for predicting worse outcome.

**Conclusion:** Joint and abdominal pain did not improve with immunomodulatory therapy in IBD patients with JHM. JHM may have a negative impact on achievement of clinical remission, in a significant subset of IBD patients. Rheumatologists and gastroenterologists should be aware of this.
Background: Non-pharmacological interventions are recommended as first-line treatment options in the management of fibromyalgia (FM). However, whether one intervention is more effective than another for specific patient-centred outcomes in FM is unknown.

Objectives: To compare the relative efficacy of non-pharmacological interventions on FM impact questionnaire (FIQ), pain, fatigue, sleep and depression in people with FM.

Methods: A Bayesian network meta-analysis was conducted. Randomised controlled trials (RCTs) assessing any non-pharmacological intervention versus usual care, placebo or active controls in patients with FM aged >16 years were searched for in seven databases. A common comparator was identified between interventions to develop a network (Figure 1). Standardised mean difference (SMD) and 95% credible interval (CrI) was estimated between interventions. Direct and indirect evidence were pooled using the random effect model. Modified Cochrane's tool was used to assess risk of bias.

Results from logistic regression models, univariate and multivariate, for CMP and CWP, are shown in Table 1.

Results: 78 studies (n = 5,639 participants) met the inclusion criteria. There was a high risk of bias on blinding and most trials had small sample size (n=50). While multidisciplinary treatment (MDT) was the best for improving pain [-1.28 (-1.84, -0.72)], sleep [-1.14 (-2.38, 0.07)] and depression [-1.20 (-1.99, -0.46)], balneotherapy and exercise were the most effective treatments for FIQ [-1.06 (1.51, -0.61)] and fatigue [-0.75 (-1.35, -0.25)], respectively (Figure 2).

Data from 47 exercise trials (n = 3,271 participants) were analysed to examine comparative efficacy of different exercise types. Strengthening showed the greatest benefit for FIQ [-0.76 (-1.39, -0.15)], pain [-0.94 (-1.58, -0.29)] and depression [-0.83 (-1.53, -0.14)], whereas aerobic exercise was the best for fatigue [-0.98 (-2.33, 0.18)] and sleep [-0.96 (-2.08, 0.13)] (Table 1).

THU0463 CHRACTERIZATION OF PATIENTS WITH FIBROMYALGIA AFFECTS WITH OR WITHOUT JOINT HYPERLAXITY SYNDROME I. López-Núñez1,2, J. Blanch5, M. Ciria Recasens5, M. J. Herrero Gascon5, A. Juan-Mas5, J. Carbonell Abelló3, Hospital del Mar, Reumatología, Barcelona, Spain;2Hospital Quiron Salud, Reumatología, Mallorca, Spain;3Hospital Son Llàtzer, Palma de Mallorca, Spain.

Background: The prevalence of joint hypermobility (JH) and Joint Hypermobility Syndrome (JHS) in patients with fibromyalgia (FM) is considerable and is more than can be explained at random(1). Some authors propose that FM and JHS share a common pathophysiological mechanism is some patients. Currently it is accepted that Ehlers-Danlos Syndrome Hypermobility subtype (EDSh) and JHS are the same entity. We regard the subgroup of FM patients with JHS a different subtype of FM, even phenotypically similar to EDSh.

Objectives: Determine the possible differences between both groups according to their body composition, bone metabolism and clinical findings.

Methods: Our study is observational, descriptive, transverse cohort study in which we included 86 women with fibromyalgia recruited at the Fibromyalgia and Chronic Fatigue Unit at Parc Salut-Mar in Barcelona, Spain. The patients were grouped according to the presence or absence of JHS, following the Brighton Criteria. Diverse clinical data was collected: Pain Visual Analogue Scale (PVAS), time from pain onset, time from diagnosis, somatic symptoms, state of mind, presence of a FM trigger, concurrent medication, anxiety, quality of life, disease impact, anthropometric data, Bioelectrical Impedance Analysis (BIA), bone density test (BMD) and bone metabolism data in blood samples.

Results: 51 patients were included in the FM group and 35 patients in the FM-JHS group. We did not find differences between groups PVAS; time from pain onset, somatic symptoms using the Psychiatric Disorder and Somatic Pathology Scale (TOPYPS); nor Fibromyalgia Impact Questionnaire (FIQ). Both groups scored similarly on SF-36 Health Questionnaire. The use of opioids was more common in the FM group (p<0.001). Anxiety disorder (AnD) was present in a greater proportion of FM-JHS group (p<0.001). We found the Body Mass Index and Muscle Mass (MM) to be less in the FM-JHS group (p=0.001 and p=0.008, respectively), Obesity and fat mass (FatM) were more frequent in the FM group. The FatM and less MM correlated with less quality of life on the SF-36 scale. There was less bone mass (BM) in the FM-JHS group (p<0.005). We found an inverse correlation between the Brighten score and the MM and BM in the FM-JHS group. The FM-JHS group also had less bone mineral density (BMD) at total hip DXA, with significant differences p<0.038. The BM by Bioelectrical Impedance Analysis (BIA) had a positive correlation on the BMD by DXA. The optimum point, capable of distinguishing between normal DXA and osteopenia/osteoporosis was 2.325g/kg with a specificity of 66% and sensibility of 52%. Vitarmin D deficiency/insufficiency was found in 62/84 (73.8%) without significant differences between groups (p>0.05).

Conclusion: Our work revealed that FM patients with JHS are different from FM without JHS, by manifesting differences in certain clinical, anthropometric, and bone metabolism features.

THU0465 EFFICACY AND SAFETY OF NERIDRONATE IN BONE EDEMA SYNDROME A. M. Lurati1, A. Laria1, P. Faggioni2, L. Castelnuovo2, A. Tamburelli2, A. Mazzzone2,3, Rheumatology Unit Fornariol Hospital, Magenta, Italy;3Internal Medicine Unit OSPedale Civile, Legnano, Italy.

Background: Bone Marrow Edema Syndrome (BMES) is a severely disabling pain syndrome without a definite treatment and refers to transient clinical conditions with unknown pathogenic mechanism, such as transient osteoporosis of the hip (TÖH), regional migratory osteoporosis (RMO), and reflex sympathetic dystrophy (RSD). Magnetic resonance imaging is used for the early diagnosis and monitoring the progression of the disease. Early differentiation from other aggressive conditions with long-term sequelae is essential in order to avoid unnecessary treatment.

Objectives: Aim of this monocentric trial was to test the efficacy and the safety of the amino-bisphosphonate neridronate in patients with BMES administered in two different regimens.

USE OF BENZODIAZEPINES AND ANTIDEPRESSANTS IN PATIENTS WHO ATTEND A RHEUMATOLOGY CLINIC

M. P. Martinez-Vidal1, A. Alvarez de Cienfuegos2, V. Jovani3, R. Martin-Domech4, M. T. Pedraza-Penalva1, P. Bernabeu5, J. R. Noguera-Pons5.

1Hospital Universitario de San Juan de Alicante, Alicante, Spain; 2Hospital Vega Baja, Onhuela, Spain; 3Hospital General Universitario de Alicante, Alicante, Spain; 4Hospital Universitario de Elda, Elda, Spain; 5Hospital General Universitario de Elche, Elche, Spain

Background: During the last decades, anxiolytics and antidepressants (ADP) have been among the most prescribed therapies in all developed countries (1). In Spain a prevalence of use of 11.4% was communicated (2), slightly over the European average (3,4). They have potential addiction problems and side effects. Objectives: The objective of this study was to evaluate the prevalence of anxiolytics and antidepressants among patients who attend a Rheumatology consult, as well as the indication for them.

Methods: Patients who were referred for the first time to the Rheumatology consult were included. Demographical data, reason for referral and final diagnosis were recorded. Regarding the treatment with ADP or/and benzodiazepines (BZD), their duration and the indication for the prescription were recorded. Sample size was estimated for a 0.05% alpha risk. Descriptive, univariate and multivariate analyses (ANCOVA) were performed in order to study the prevalence of these treatments, and their associations with demographical or clinical characteristics. The study was approved by the Hospital Universitario de Elche Ethics Committee.

Results: 350 patients were included (women 77.1%, men 22.9%), mean age 58.1 yo. 40% were occupied and 31.4% were unemployed. The majority were married or lived with a couple (71.4%). Most of them had been referred for musculoskeletal pain (73.4%). More than a third (39.4%) were on BZD and/or ADP: 107 patients were on BZD (30.6%), 68 were on ADP (19.4%), and 47 (13.4%) were on both. The most frequent reasons for their prescription were anxiety, depression and insomnia. The final diagnosis in the clinic was non-inflammatory condition in 53.1%, and inflammatory in 18%. In the univariate analyses, the use of BZD/ADP was not associated with civil status, but it was associated with female sex (p<0.001), unemployment (p<0.001) and non-inflammatory final diagnosis (p<0.001). In the multivariate analyses, the use of BZD and/or ADP was associated with female sex (p=0.002 [RR 3.4, CI 95% 1.6-7.4]) and non-inflammatory final diagnosis, specifically fibromyalgia (p=0.007 [RR 16.1, CI 95% 2.2-120.7]).

Conclusion: The use of anxiolytics and antidepressants is frequent in the patients referred to the Rheumatology clinic, and it’s associated to female sex and non-inflammatory conditions, over all fibromyalgia.

References:
Conclusion: Fibromyalgia women responded to the stress of pain by increasing the serum level of ACTH which effectively improves the clinical feature of fibromyalgia symptoms, but at the same time elevates the score of metabolic syndrome. Therefore, assessment of serum level of ACTH can serve as a predictor and discriminator of fibromyalgia comorbidity.

THU0466 EARLY DIAGNOSIS IS ASSOCIATED WITH LESS DISEASE SEVERITY AND BETTER OUTCOME IN FIBROMYALGIA SYNDROME: A TRICENTRIC PROSPECTIVE ANALYSIS OF A COHORT OF 370 PATIENTS

A. Moshiri1, W. Guoda1, M. H. Abu-Zaide2, 1Al Azhar University, Assiut, Egypt; 2Aswan University, Aswan, Egypt; 3Tanta University, Tanta, Egypt

Background: Delayed diagnosis of fibromyalgia (FM) has been reported to be associated with more economic burden, healthcare utilization and worse response to treatment. However, its impact on the patients’ symptomatology and disease severity is still underestimated.

Objectives: to evaluate the effect of diagnostic delay (DD) on FM severity and disease assessment parameters.

Methods: in this cross sectional study, 370 FM patients were prospectively interviewed. Information about DD, widespread pain index (WPI), symptom severity scale (SSS), total severity scale (SSS+WPI) and number of tender points were collected. We proposed to classify our patients into 3 categories; early diagnosis (ED ≤ 2 years; 83 patients), late diagnosis (LD: 2-7 years; 196) and very late diagnosis (VLD >7 years; 89 patients).

Results: the mean age of patients was 33.9 (±9.8) and 79.4 % were female. The mean for DD was 5.6 (±3.6) while the mean for SSS, total scale and tender points were 7.8 (±1.6), 16.46 (±4.1), 14.31 (±2.3) respectively. A significant correlation has been found for DD with SSS (r = 0.14), total scale (r = 0.37) and tender points (r = 0.16) but not with WPI (r = 0.059).

Comparing the three categories, the mean for SSS was 7.54 (±1.6), 7.73 (±1.4) and 8.25 (±1.7) in the groups of ED, LD and VLD respectively (P =0.008) while the mean for the total scale was 15 (±3.8), 15.95 (±3.8) and 18.96 (±4.4) respectively (P =0.000) and the mean for tender points was 13.7 (±2.3), 14.35 (±2.1) and 14.77 (±2.8) respectively (P =0.001). The mean for WPI did not significantly differ as it was 7.45 (±2.8), 7.8 (±3.6) and 7.18 (±4.8) in the groups of ED, LD and VLD respectively (P =0.415).

Conclusion: early diagnosis of FM is associated with low SSS, total severity scale and tender points reflecting a better outcome and a less disease severity.

THU0467 CONCEPTS AND PERCEPTIONS ABOUT FIBROMYALGIA DIAGNOSIS, MONITORING AND TREATMENT AMONG COLOMBIAN RHEUMATOLOGISTS, PHYSIATRIST AND PAIN PHYSICIAN

D. G. Fernández-Avilá1, D. Rincón-Riaño2, J. Gutiérrez3; 1Rheumatology Unit, Department of Internal Medicine, Hospital Universitario San Ignacio - School of Medicine, Pontificia Universidad Javeriana. Bogotá, Colombia, Bogota, Colombia; 2Rheumatology Service, Hospital Militar Central - Universidad Militar Nueva Granada. Bogotá, Colombia, Bogota, Colombia

Background: Fibromyalgia is a chronic disease characterized by the presence of widespread and persistent musculoskeletal pain associated with a variety of symptoms. The concepts and perceptions around diagnosis and treatment of fibromyalgia among physicians are not objectively known. The purpose of this study is to obtain objective data through a survey and describe the concepts and perceptions about the diagnosis, treatment and treatment of fibromyalgia among colombian rheumatologists, physiatrist and pain physicians.

Objectives: The main purpose of this study is to obtain objective data on this subject and describe the concepts and perceptions about the diagnosis, treatment and monitoring of FM among colombian rheumatologists, physiatrist and pain physicians.

Methods: Cross-sectional study. Through a focus group in which two rheumatologists and one expert in qualitative research methods participated, a survey was designed to evaluated the perceptions and concepts that rheumatologists, physiatrist and pain physicians have on the diagnosis and treatment of fibromyalgia. The survey was self-applied anonymously through the internet.

Results: Survey applied to 139 rheumatologists, 99 physiatrist and 81 pain physicians. 35 rheumatologists (25.2 %), 17 physiatrist (17.1 %) and 58 pain physicians (71.6 %) consider that there is not enough evidence to recognize fibromyalgia as a disease. 45 rheumatologists (32.4 %), 86 physiatrist (86 %) and 73 pain physicians (90.1 %) consider that the 1990 ACR (American college of Rheumatology) criteria are not sufficient to diagnose fibromyalgia, despite the fact more than 90% of them use the criteria as a tool to approach the diagnosis when suspecting fibromyalgia. The most formulated medications for managing fibromyalgia are antidepressants and is used by more than 80% of the respondents, followed by antiepileptics in pain physician (88.9 %) but less than physiatrists and rheumatologists (66.6 % and 64.7 % respectively), and analgesics much more for pain physician and physiatry and less for rheumatologists (84 %, 75.7 % and 26.6 % respectively). All respondents consider that the patient with fibromyalgia should have a multidisciplinary approach. Most doctors of the three specialties believe that physiatrist should be the leaders of interdisciplinary management in the treatment of fibromyalgia patients.

Conclusion: We present objective information on the perceptions of fibromyalgia among a group of Colombian rheumatologists, physiatrist and pain physician, documenting a frequent use of the ACR 1990 classification criteria. As regards treatment, a high percentage use of antidepressants and antiepileptic. Most believe that physiatrist should be the leaders of interdisciplinary management in the treatment of fibromyalgia patients.

Efficacy and Safety of Intra-Articular Therapies in Rheumatic and Musculoskeletal Diseases: An Overview of Systematic Reviews Informing the 2020 EULAR Recommendations for Intra-Articular Therapies Including Synoviorthesis

S. C. Rodriguez-García1, R. Castellanos-Moreira2, J. Uson Jaeger3, E. Naredo4, L. Carmona5 on behalf of the EULAR Intra-Articular Therapies Task Force. 1Hospital de La Princesa, Madrid, Spain; 2Hospital Clínico de Barcelona, Barcelona, Spain; 3Hospital de Móstoles, Móstoles, Spain; 4Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; 5InMusc Instituto de Salud Musculoesquelética, Madrid, Spain

Background: Intra-articular therapy (IAT) is subject to wide variability and there are gaps in the evidence on its efficacy and safety. Objectives: To assess the efficacy and safety of frequently used IATs to inform an EULAR Taskforce. Methods: We performed an overview of systematic reviews (SR) of randomised clinical trials (RCT) assessing efficacy and safety of IAT in adults with RMDs. MEDLINE was searched until January 2019. SRs were assessed with the AMSTAR-2 tool. Critically low-confidence SRs were excluded. Results: Of 159 articles identified, 42 were reviewed in detail and 15 met the inclusion criteria (146 RCTs). The populations included were mainly knee osteoarthritis (OA) in 10 SRs, rheumatoid arthritis (RA) in 3, hip and temporomandibular (TM) OA and shoulder adhesive capsulitis in 1 SR each. In knee OA, Hyaluronic Acid (HA) showed a modest benefit over placebo for pain and function. More adverse events (AE) were seen in the PRP group compared with HA and for RA compared with PBO including serious AE each in 1 SR on knee OA. Results for other included diseases are shown in table 1. Conclusion: Most of the SRs assessed had results of low confidence. HA and GC showed a small, short-term benefit in knee arthritis in OA and RA compared with PBO. High risk of bias prevents conclusions on the efficacy of PRP and MSC in knee OA. More AE were reported in PRP and HA treated groups.

Quantifying the Placebo Effect after Intra-Articular Injections: Implications for Trials and Practice

S. C. Rodriguez-García1, R. Castellanos-Moreira2, J. Uson Jaeger3, E. Naredo4, L. Carmona5, 1Hospital de La Princesa, Madrid, Spain; 2Hospital Clínico de Barcelona, Barcelona, Spain; 3Hospital Universitario de Móstoles, Móstoles, Spain; 4Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; 5InMusc Instituto de Salud Musculoesquelética, Madrid, Spain

Background: In recent years, diverse compounds for intra-articular administration were brought into the market with a subsequent significant and heterogeneous literature production. Understanding the efficacy of intra-articular therapies (IAT) on pain implies bearing in mind the related placebo (PBO) effect. To date, most studies analyzing it were focused on the compound being administered rather than the route of administration. Objectives: We aimed at evaluating the size of the PBO effect after intra-articular injections. Methods: We conducted an overview of systematic reviews (SRs) including randomized-controlled trials (RCTs) of frequently used IAT. SRs with a saline solution PBO arm and high-confidence results according to the AMSTAR-2 tool were selected for analysis. Results: Data on the change in pain in the PBO arms from baseline to 3-6 and 12-16 weeks after the IA procedure was extracted. The standardized mean differences (SMD) from baseline were calculated as the ratio between the size of the intervention effect in each study and the variability observed in that study. A meta-analysis was then performed using an inverse-variance random-effects model in Review Manager 5.3. The overall effect sizes obtained refer to versions of the SMD, which corresponds to the Hedges’ (adjusted) g. e.g a “g” of 1 indicates the two groups being compared differ by 1 standard deviation and so on. Results: Two SR were included comprising 50 RCTs, 44 not meeting inclusion criteria were excluded so pain, measured by visual analogue scale (VAS) and Lequesne index, was retrieved from 6 RCT. At 3-6 weeks, an SMD [95% CI] of 0.74 [0.45-0.79] was found. One study showing too large an effect was excluded after conducting sensitivity analysis resulting in a significant reduction of heterogeneity with an SMD of 0.62 [0.45-0.79] (Fig.1). At 12-16 weeks, we found a SMD of 0.33 [0.13-0.52] (Fig.2)

This study aimed at comparing the effects of two exercise interventions (land- and water-based) on physical function (PF) in patients with fibromyalgia. 

Methods: A total of 262 women were initially randomized and 152 (age:50.6 ± 7.7 years) completed all the assessments with an attendance ≥70% (control n=62, land-based n=48, water-based n=42). The intervention groups trained three non-consecutive days/week (60 min/session) during 24 weeks. Every session consisted of exercises focused on improving cardiorespiratory fitness, muscle strength, and flexibility. Physical function components were assessed with the Functional Senior Fitness Test battery, and a standardized global PF index was calculated. Pre-, post- and re-test (12-week detraining) assessments were conducted. Groups did not differ in sex, sociodemographic characteristics, disease duration, drugs intake, and body mass index. Analysis of covariance was used to test the differences in changes from baseline (post-test vs. pre-test and re-test vs. pre-test) between groups using age, pain sensitivity, and baseline outcomes as covariables.

Results: Land- and water-based exercise groups improved lower body strength (mean difference; 95% confidence interval=2.8; 1.8, 3.8 and 1.7; 0.6, 2.8, respectively), upper body strength (4.8; 2.8, 6.8 and 3.5; 1.4, 5.6, respectively), and agility (-0.8; -1.2, -0.4 and -0.4; -0.8, -0.0, respectively) compared to the control group (all, P≤0.014). The improvements in global PF were maintained in the land-based group (all, P≤0.007), and agility (-0.5; -1.0, -0.3) and cardiorespiratory fitness (31.0; 6.8, 55.2) compared to the water-based group (all, P≤0.014). The improvements in global PF were maintained in the land-based group compared to the control group (0; 1.0, 0.3, P=0.049).

Conclusion: Land- and water-based exercise interventions are overall effective to improve PF in patients with fibromyalgia. However, the land-based exercise intervention presented greater effectiveness compared to the water-based exercise intervention. Improvements were overall sustained in the land-based group after a 12-week detraining period.

I received duloxetine (60 mg once daily for 6 months) plus 50,000 unit oral cholecalciferol weekly for 8 weeks then monthly for 16 weeks. Group II received duloxetine (60 mg once daily for 6 months) plus placebo. The patients were assessed at baseline and after 6 months of treatment by measuring serum levels of 25(OH)D. Fibroblast Impact Questionnaire (FIQ), Medical Outcomes Study Questionnaire Short Form 36 Health Survey (SF-36) & Hospital Anxiety and Depression Scale (HADS).

**Results:** Eighty-six patients completed this study. There was no significant difference between all groups in demographical data, educational status and all baseline variants except serum levels of 25(OH) D. After 6 months, there was significant improvement (P<0.05) in group I in serum levels of 25(OH) D. There was significant improvement (P<0.05) after 6 months in FIQ, SF-36 and HADS in both groups. There was significant better improvement (P<0.05) in group I than in group II in FIQ, SF-36 and HADS. The results of the study are summarized in table 1.

**CATHESPIS S GENE EXPRESSION MEASURED IN THE PERIPHERAL BLOOD OF OSTEOARTHRITIC PATIENTS PRIOR TO SURGERY AS A BIOMARKER OF POST-OPE RATIVE PAIN DEVELOPMENT**

E. Tschetina, K. Glemba, G. Markova, E. Taskina, M. Makarov, Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology, Moscow, Russian Federation; Nasonova Research Institute of Rheumatology, Orthopedics, Moscow, Russian Federation; Nasonova Research Institute of Rheumatology, Osteoarthritis, Moscow, Russian Federation

**Background:** Osteoarthritis (OA) is a chronic rheumatic disease, which involves pain, limited inflammation, and local destruction of the knee joint. OA pain is a major clinical symptom, which limits working capacity and denotes an important indication for joint replacement in the end-stage OA. In spite of significant number of positive outcomes, chronic postoperative pain represents a major adverse consequence of surgery, which is observed in 10-40% of OA patients. Therefore, identification of patients potentially capable of developing chronic postoperative pain prior to surgery could significantly improve therapy outcome. Recently, we hypothesized that genes related to pain sensitization whose expression is upregulated in about 10-40% of the examined end-stage OA patient cohort might be responsible for postoperative pain. Retrospective analysis of gene expression in the peripheral blood of end-stage OA patients before joint replacement surgery revealed that expression of cathepsins S and K, caspase 3, and MMP-9 genes might be associated with postoperative pain development [Ann Rheum Dis. 78, suppl 2, A52].

**Objectives:** To examine the validity of our hypothesis in the prospective study.

**Methods:** We examined peripheral blood of 26 healthy volunteers (average age 55±8.3 years old) and 40 end-stage OA patients (average age 56±8±8.9 years old) undergoing joint replacement surgery. Patients were examined before and 6 months after surgery. Pain was assessed prior to surgery using VAS index and neuropathic pain questionnaires DN4 and PainDETECT. Functional activity was evaluated by WOMAC. After surgery pain indices according to VAS of 30% and higher were considered. MMP-9 and caspase 3 protein levels were quantified by ELISA. Total RNA isolated from whole blood was used in expression studies for caspase 3; metalloproteinase (MMP)-9; cathepsins K and S genes. These were performed with quantitative real-time RT-PCR.

**Results:** Out of 40 patients pain complaints were obtained from 9 patients (22.5%) after 6 months’ post-surgery. Prior to surgery all the examined genes were significantly upregulated in the patients who developed post-operative pain compared to healthy controls and those subjects who did not develop pain after surgery. However, no difference in the levels of the examined pain-related and functional indices in patients, who developed pain or not, was noted before surgery. ROC curve analyses confirmed significant associations (p<0.05) between expressions of the examined genes prior to surgery with the likelihood of pain development after surgery. The cut-off values for the examined gene expressions were 12.44 ng/ml for cathepsin S (sensitivity of 0.89 and specificity of 0.76), 10.11 ng/ml for caspase 3 (sensitivity of 0.86 and specificity of 0.65), 10.09 for cathepsin K (sensitivity of 0.86 and specificity of 0.78). Moreover, among the examined genes cathepsin S expression was the most informative predictor of postoperative pain development [AUC=0.857, 95%CI (0.708-1.000)].

**Conclusion:** High cathepsin S gene expression in the peripheral blood of the end-stage OA patients measured prior to joint replacement surgery could serve an important biomarker of post-operative pain development.

NEUROPATHIC SYMPTOMS IN ITALIAN PATIENTS WITH FIBROMYALGIA: RESULTS FROM A NATIONAL ON-LINE SURVEY

A. Viceconti1, T. Gari1, S. De Luca1, F. Maselli1, A. Sulli2, M. Testa3, G. Rossettini1, 1University of Genoa, Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Savona, Italy; 2University of Genoa, Research Laboratory and Academic and Clinical Rheumatology, Department of Internal Medicine, IRCCS San Martino AOU, Genoa, Italy

**Background:** Fibromyalgia (FM) is the second most frequent disorder in rheumatic patients. Other than widespread pain, fatigue, sleep disturbance and cognitive impairments, patients complain also symptoms of suspected neuropathic origin, like burning pain, thermal sensitive skin, hyperalgesia, pins and needles sensations. Recent studies highlighted the presence of small- fibers pathology (SFP) and/or large-nerve fibers involvement in about 50% of FM patients, which could be the cause of neuropathic pain.

**Objectives:** The aim of the study was to investigate the prevalence of neuropathic pain and symptoms indicative for the presence of SFP in Italian FM patients, studying the association with clinical variables.

**Methods:** An on-line survey was designed according to the Checklist for Reporting Results of Internet E-Surveys guidelines (CHERRIES) and Strengthening the Reporting of Observational Studies in Epidemiology (STROBE). The on-line Survey Monkey® platform was adopted to collect data. We calculated a-priori minimum number of 800 respondents.

We administered the survey by involving 7 FM patients’ associations distributed nationwide between July and September 2019. We explored demographic and clinical variables including pain and stiffness intensity, symptoms duration, and counting of painful sites. Neuropathic Pain Symptoms Inventory (NPSI) and Fibromyalgia Impact Questionnaire (FIQ) were administered. To study the presence of symptoms indicative of potential SFP we asked for the presence of 8 signs and symptoms reported in literature as characteristics of SFPs. Two groups of FM patients were considered: those positive (FM+) to the Fibromyalgia Research Criteria (FRC) (Wolfe et al., 2011), and those complaining typical FM symptoms but not fulfilling the FRC (FM-).

**Results:** The survey was correctly completed by 76% of participants (892/1173). A total sample of 854 patients (749 in FM+ and 105 in FM-) was analyzed after the exclusion of subjects with major comorbidities. The mean NPSI score was significantly higher in FM+ respect to FM- (56.3/100) than in FM- (34.2/100). More than 3 symptoms indicative for SFP were found in 51% of FM+ patients and in 15.2% of FM- patients. Other than widespread pain, fatigue, sleep disturbance and cognitive impairments, patients complain also symptoms of suspected neuropathic origin, like burning pain, thermal sensitive skin, hyperalgesia, pins and needles sensations. Recent studies highlighted the presence of small- fibers pathology (SFP) and/or large-nerve fibers involvement in about 50% of FM patients, which could be the cause of neuropathic pain.

THE EFFICACY OF ORAL GLUCOCORTICOSTEROIDS FOR PAIN IN RHEUMATOID ARTHRITIS: A PRELIMINARY REPORT OF A META-ANALYSIS

D. Mcwilliams1,2, D. Thankaraj1,2, R. Morgan1, J. Jones-Diette1,3, D. Walsh1,2,3,5, 1University of Nottingham, Pain Centre Versus Arthritis, Nottingham, United Kingdom; 2University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; 3University of Nottingham, Division of ROD, Nottingham, United Kingdom; 5Sherwood Forest Hospitals NHS Foundation Trust, Rheumatology, Mansfield, United Kingdom

**Background:** Glucocorticosteroids (GCs) are used to provide rapid relief of symptoms in people with active RA. Their use is recommended by most RA management guidelines and systematic reviews, although the magnitude of their benefit above placebo is uncertain. Persistent pain remains a problem in RA, even despite optimal immunomodulatory management. Systemic GC use may be associated with important adverse events.

**Objectives:** To quantify the specific effects of oral GCs for RA pain.

**Methods:** A systematic literature review was performed for RCTs using GCs in RA compared to inactive treatment. Trials were included whether or not participants received DMARD treatments, so long as a specific effect could be assigned to GCs. Medline, Embase and Cochrane databases were searched until November 2019 and 2 reviewers independently assessed titles, abstracts and full texts. Data for pain were synthesized in a meta-analysis. This study is part of a wider review (PROSPERO CRD42019111562).

For subgroup analyses, follow up time points of 0-3 months, >3 - 6 months and >6 months were selected to address duration of effect. Individual studies could contribute to each of the 3 follow up subgroups.

PRELIMINARY REPORT OF A META-ANALYSIS FOR PAIN IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF COMPARATIVE EFFICACY OF ORAL GLUCOCORTICOSTEROIDS AT DIFFERENT DOSES FOR PAIN IN RHEUMATOID ARTHRITIS

D. Mcwilliams1,2, D. Thankaraj1,2, R. Morgan1, J. Jones-Diette1,3, D. Walsh1,2,3,5, 1University of Nottingham, Pain Centre Versus Arthritis, Nottingham, United Kingdom; 2University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; 3University of Nottingham, Division of ROD, Nottingham, United Kingdom; 5Sherwood Forest Hospitals NHS Foundation Trust, Rheumatology, Mansfield, United Kingdom

**Background:** Glucocorticosteroids (GCs) are used to provide rapid relief of symptoms in people with active RA. Meta-analysis was performed on standardized mean differences (SMDs, bodily pain data) and mean differences (MDs, 100mm VASpain only) of change from baseline (sd), using the Meta and Metafor packages in R. Heterogeneity was quantified using I² and tau statistics. Bias was assessed with a funnel plot and Eggers test.

**Results:** 15983 papers, 470 abstracts and 152 full texts were assessed. Pain data from 12 RCTs were suitable for the meta-analyses. The most common pain metric was the 100mm VASpain (9 trials). Study populations ranged from n=12 to n=350 participants, 50% to 71% were female with mean ages from 43 to 66 years. Baseline scores for VASpain ranged from to 34 to 66 mm. Means were reported for DAS28 (from 4.9 to 5.8), ESR (25 to 60mm) and CRP (5 to 27mg/L).

Data synthesis at the reported primary time point/end point showed a statistically significant reduction in bodily pain in participants treated with GCs; SMD = -0.36 (10 studies, 1377 participants, 95% CI, -0.59 to -0.14, p=0.002) with significant heterogeneity (I² = 66%, tau = 0.27, p<0.01). The Funnel plot suggested asymmetry, favouring GCs (Eggers p = 0.007).

Subgroup analyses were used to investigate the time course of specific effects on pain. Efficacy displayed time-related decreases after initiation. From 0-3 months SMD= -0.56 (95% CI, -0.76 to -0.36, p<0.001, 9 studies, 936 participants, I² = 43%, Eggers p= 0.002). Efficacy was lower at 3-6 months (SMD= -0.32, 95% CI, -0.52 to -0.11, p=0.002, 3 studies, 382 participants, I² = 69%, Eggers p=0.75) and further reduced at >6 months (SMD= -0.07, 95%CI, -0.23 to 0.08, p=0.357, 4 studies, 665 participants, I² = 77%, Eggers p=0.43).

For trial data collected during concomitant oral GC dosage, mean difference (MDs) in 100mm VASpain was -14mm (95% CI, -20mm to -9mm) greater improvement in GC than control in the 0-3 month period (8 studies, 1047 participants, I² = 14%, Eggers p=0.63).

For the reported primary periods, effect size was assessed (SMD). At 0-3 months SMD= -0.36 (95% CI, -0.56 to -0.14, p=0.002) with significant heterogeneity (I² = 83%, tau = 0.27, p<0.01). The Funnel plot suggested asymmetry, favouring GCs (Eggers p = 0.007).

**Conclusion:** Compared to HV lumbar IVD of ER show significantly higher gagCEST values during the peak of their competition preparation and similar values during the recovery period, indicating a GAG remodelling effect by training.

**Figure 1.** Comparison of gagCEST values of lumbar IVD between ER (A, T0; B, T1) and HV.

**Glycosaminoglycan remodelling of lumbar intervertebral discs in elite rowers throughout their annual training cycle**

P. Sewerin1, D. Abra2, M. Frenken2, M. Schneider2, B. Ostendorf2, C. Schleich2,
1 Heinrich Heine University, Department for Rheumatology, Duesseldorf, Germany;
2 Heinrich-Heine University, Institute for Diagnostic and Interventional Radiology, Duesseldorf, Germany

**Background:** To assess the glycosaminoglycan (GAG) content of lumbar intervertebral discs (IVD) in elite rowers (ER) at different stages of their annual training cycle and compared to healthy volunteers (HV) using GAG chemical exchange saturation transfer (gagCEST).

**Objectives:** Does GAG content of IVDs differs between ER in different stages of the training cycle from HV?

**Methods:** 205 lumbar IVD of 21 ER (23 ±3 years, 9 female, 11 male) and 25 HV (27 ±2 years, 13 female, 12 male) were prospectively examined with 3T magnetic resonance imaging (MRI). Standard T2 weighted (T2w) sequences were used for morphological grading according to the Pfirrmann classification. GAG content of the nucleus pulposus (NP) and annulus fibrosus was determined with gagCEST in non-degenerated discs according to Pfirrmann. ER were examined during the peak of their competition preparation (T0) and 6 months later during the peak of their post-competition recovery period (T1).

**Results:** At T0 we found significantly higher gagCEST values in ER (A) compared to HV (C) (NP: 4.26 ±2.37 vs. 3.38 ±1.72%, p<0.05; confidence interval (CI) 0.32%/1.44%; AF: 2.75 ±1.7% vs.1.961 ±1.23%, p<0.01; CI 0.4%/1.2%). At
Background: The pathophysiology of fibromyalgia syndrome (FM) still needs to be fully clarified. In addition to the central sensitization mechanisms, some evidence suggests an involvement of the peripheral nervous system, mainly intended as small fibers neuropathy. The sural nerve showed some alterations, in terms of increased cross-sectional area (CSA), in the course of small fibers neuropathy.

Objectives: To evaluate sural nerve CSA and factors associated with increased CSA in FM patients.

Methods: A cross sectional evaluation was conducted in consecutive FM patients according to the 2016 American College of Rheumatology criteria. Demographic, clinimetric parameters (in particular the revised Fibromyalgia Impact Questionnaire [FIQR] to assess the severity of the disease and the PainDetect Questionnaire [PDQ] to evaluate neuropathic pain features) and the sural nerve dimensions measured by ultrasound were recorded for each patient. The size of the sural nerve was described in terms of the mean cross-sectional area (CSA) measured bilaterally. CSA was measured at the level, 14 cm from the apex of the lateral malleolus, where the sural nerve is detectable as a structure adjacent to the small saphenous vein in the distal portion of the leg. The ultrasound examination was performed with a MyLab Class C (Esaote S.p.A., Genoa, Italy) equipped with a 6-18 MHz multifrequency broad band probe. CSA was compared with demographic and clinimetric parameters through one-way analysis of variance (ANOVA). A multiple regression was also conducted using CSA as dependent variable, with age, body mass index (BMI), disease duration, FIQR and PDQ as independent variables.

Results: The study involved 110 FM patients (105 women and five men), with a mean age of 50.7 (±11.1) years and a mean disease duration of 5.8 (±5.2) years. Sural nerve CSA showed a statistically significant increase in patients with higher PDQ scores (p=0.0096) and, even more significantly, in overweight or obese subjects (p<0.001). The multiple regression analysis, using CSA as dependent variable, confirmed that the PDQ score (p=0.0049) and the body mass index (p=0.0001) are the only two independent variables associated with CSA size (Table 1).

Table 1. Multiple regression analysis of the independent variables related to the mean cross-sectional area (dependent variable) of sural nerve.

Abbreviations: BMI=Body Mass Index; FIQR=revised Fibromyalgia Impact Questionnaire; PDQ=PainDetect Questionnaire

Conclusion: Increased sural nerve CSA is associated with neuropathic like pain features and BMI. Overweight and obesity appear to be associated with an FM phenotype with greater peripheral involvement than normal-weight subjects. Sural nerve ultrasound, an easy to perform examination, could be a useful tool to identify this kind of patients.

IS NEUROPATHIC PAIN IN INFLAMMATORY RHEUMATIC DISORDERS AN UNDESCRIBED PROBLEM? RESULTS FROM THE GERMAN PAINDETECT DATABASE

P. Sewerin1, R. Freynhagen2, T. Töle2, M. Hammer2, C. Baerwald1, J. Walter2, R. Schröder1, M. Schneider1, R. Baran2, Heinrich-Heine-University Düsseldorf, Department and Hitler Research Unit for Rheumatology, Düsseldorf, Germany;2Division of Anaesthesiology, Intensive Care, Pain & Palliative Medicine, Benedictus Krankenhaus, Tützing, Germany;1Department of Neurology, University Hospital TU Munich Rechts der Isar, Munich, Germany;4Department of Rheumatology, Hospital St. Josef-Stift Sendenhorst, Sendenhorst, Germany;4Department of Rheumatology, Division of Endocrinology, Nephrology and Rheumatology, University Hospital Leipzig, Leipzig, Germany;5Ambulatory Medical Care Center - Rheumatology, Rendsburg, Germany;6Pfizer Pharma GmbH, Berlin, Germany;7Division of Neurological Pain Research and Therapy, Department of Neurology, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background: The aim of the study was to investigate the impact and relevance of neuropathic pain in inflammatory rheumatic disorders (IRD) and osteoarthritis (OA).

Objectives: Pain is one of the main symptoms in patients with IRD and OA. To enhance a mechanistic based treatment of pain the differentiation between nociceptive and neuropathic pain via screening tools (e.g. painDETECT questionnaire) might possibly be helpful. The goal of the study was to investigate (1) if neuropathic pain is a significant burden for patients with IRD and (2) if pain patterns differs from degenerative joint diseases such as OA in over 9,000 patients in each group.

Methods: The painDETECT questionnaire (pDETECT) is a questionnaire that has been evaluated and used in numerous clinical trials to detect neuropathic pain in various diseases. The collected data is centrally managed and evaluated. In total (end of 2019) 395,984 patients have been documented. Out of the painDETECT database 9256 patients with IRD and 9436 patients with OA were extracted, analyzed and compared on their neuropathic pain pattern (screening was performed using the painDETECT-questionnaire). pDEQT. Secondary parameters were: intensity of pain, functional status, depression, chronicity and sleep disorder. Patients had been recruited from general practitioners (GPs), Rheumatologists, Orthopedics and Neurologists from 862 office-based physicians into the painDETECT-data-base. This project is an open label registry study in Germany.

Results: The median pDEQT-score of patients with inflammatory rheumatic disorders adds up to 14.2 (1-38) and of OA patients to 13.6, 28.7% of inflammatory rheumatic disorders and 27.2% of OA-patients showed signs for neuropathic pain by positive pDEQT. The difference was according to this high patient numbers statistically significant (P=0.0015).VAS-Score, Depressions-Score, Chronicity-Score and Functional-Score showed no clinically relevant differences between these two groups.

Conclusion: Nearly one third of patients with IRD as well as patients with OA showed neuropathic pain components by using PDQ. Despite increasingly better disease control through more effective therapies, pain still remains a major burden for many patients and has a profound impact on their quality of life. The present data indicate a surprisingly high symptoms of neuropathic pain even in IRD patients and should be considered in the management of our patients. A new documentation system for Rheumatologists (RheumaAssist) could help to address these questions.

Percentage of PDQ-categories (negative/unclear/positive) for patients with inflammatory rheumatic disorders (IRD) or Arthrosis (OA)

**ASSOCIATION BETWEEN CENTRAL SENSITIZATION AND CLINICAL AND ULTRASONOGRAPHIC PARAMETERS IN INFLAMMATORY ARTHRITIDES**

G. Adami1, E. Gerratana2, A. Giolò3, C. Benini4, E. Vantaggiato1, D. Rotta1, L. Iodolazi2, D. Gatti1, M. Rossini1, A. Fassio1. 1University of Verona, Verona, Italy; 2University of Messina, Messina, Italy

**Background:** Central sensitization (CS) is an important feature of patients with chronic pain, especially rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients. CS might interfere with the clinical evaluation of inflammation. Central Sensitization Inventory (CSI) is a validated instrument for assessing central sensitization.

**Objectives:** We seek to investigate the inference of central sensitization (assessed with the CSI) on clinical (disease activity scores) and ultrasound parameters (US 7-joints score) in RA and PsA patients.

**Methods:** We conducted a cross-sectional analysis on patients with an established diagnosis of RA or polyarticular PsA. Demographic, anamnestic and clinical parameters were collected. Disease activity was measured with SDAI in RA patients and with DAPSA in PsA patients. The presence and severity of synovitis was measured with the US 7-joints score. Exclusion criteria included: diagnosis of fibromyalgia, depression and patients with PsA with enthesitis predominant and/or spondylitis subtypes. Differences between variables were analysed with t-test and ANOVA for multiple comparisons. Correlation between continuous variables was analysed with Pearson correlation. CSI was analysed either as positive/negative (threshold 40 points) or divided in four CSI categories (subclinical, mild, moderate, severe).

**Results:** We enrolled 42 patients in the study. Descriptive characteristics of the study population are presented in table 1. We found no difference in clinical parameters between diseases, sex or age. Women had a higher CSI score compared to men (mean 39.3 vs 26.7 p=0.005). We found a correlation between CSI score and DAPSA (r² 0.39, p=0.001), number of tender joints (r 0.13, p=0.02) and HAQ (r 0.47, p=0.001) (Figure 1) while we found no correlation between CSI score and SDAI or other clinical parameters. We found a significant difference in DAPSA, tender joints count and HAQ between CSI categories (ANOVA p<0.01, p=0.02 and p=0.001 respectively). US 7-joints score was associated with SDAI (r² 0.33, p=0.03), number of swollen joints (r² 0.28, p=0.002) and disease duration (r² 0.35, p=0.001) but not with DAPSA or tender joints.

**Conclusion:** We found an association between CS and sex, functional disability, tender joints count and disease activity score in PsA patients while there was no correlation between RA disease activity and central sensitization. US 7-joints score was associated with swollen joints count, disease duration and disease activity in RA patients but not in PsA patients. In PsA patients, DAPSA might be more influenced by central sensitization, especially in female individuals.

**EXPERIENCE USING DIFFERENT CRITERIA OF FIBROMYALGIA IN PATIENTS WITH ANKYLOSING SPONDYLITIS: 1990 AMERICAN COLLEGE OF RHEUMATOLOGY CLASSIFICATION CRITERIA VS. NEW**

L. Shapoval1, M. Stanislavchuk1, H. Movchan1. 1National Pirogov Memorial Medical University, Vinnytsia, Ukraine, Chair of Internal Medicine 1, Vinnytsia, Ukraine

**Background:** Fibromyalgia (FM) is a very frequent condition in patients with diseases associated with pain syndrome, such as rheumatoid arthritis (RA), ankylosing spondylitis (AS) and other chronic rheumatic diseases. FM, RA and AS has different clinical characteristics, but can share symptoms such as pain, fatigue and sleep disturbance that leads to delay in appropriate correct diagnosis [1]. For today well known many different criteria for FM: 1990 American College of Rheumatology (ACR) classification criteria, modified 2010 ACR diagnostic criteria, 2016 Fibromyalgia Diagnostic Criteria and new AAPT Diagnostic Criteria for

Fibromyalgia. According to the literature, prevalence FM in AS patients can reach from 12.6 to 28.5%, but prevalence estimates should be interpreted with care as no data that the criteria for FM have been validated for use in patients with AS and other chronic inflammatory arthritides [1, 2]. The lack of appropriate information needs further investigation for better identification FM.

Objectives: The aim of our study was to compare the presence of FM by 1990 ACR classification criteria, modified 2010 ACR diagnostic criteria, 2016 Fibromyalgia Diagnostic Criteria and new criteria FM 2019 - AAPT Diagnostic Criteria for Fibromyalgia in AS patients.

Methods: One hundred and thirteen AS patients (19 women and 94 men) with mean age (M ± SD) 42.3±10.94 years were enrolled in the study. Diagnosis AS was established according to modified New York criteria. For FM detection were used 1990 ACR classification criteria, modified 2010 ACR diagnostic criteria, 2016 Fibromyalgia Diagnostic Criteria and AAPT Diagnostic Criteria for Fibromyalgia. All patients were asked to complete self-reported disease-related questionnaires for patients with AS.

Results: According 1990 ACR criteria, FM met in 26 patients (23%), 38.1% patients were positively screened for FM due to modified 2010 ACR diagnostic criteria, and in 31.9% patients according 2016 Fibromyalgia Diagnostic Criteria, and in 41.6% patients due to AAPT Diagnostic Criteria for Fibromyalgia. All new criteria correlated with 1990 ACR classification criteria with p<0.01; n=0.654, n=0.664, n=0.520, conversantly Using the ROC analysis, we evaluated the sensitivity and specificity of different FM criteria in patients with AS. Our results showed high diagnostic value of all new criteria, but the most sensitive for detection FM in patients with AS were the modified 2010 ACR diagnostic criteria with sensitivity of 96% and specificity of 79%.

Conclusion: Our study results confirmed very high prevalence FM in patients with AS. The most sensitive tool for detection FM in patients with AS were the modified 2010 ACR diagnostic criteria with sensitivity of 96% and specificity of 79%. The similar percentages of FM due to different classification criteria might be a good sign in context of the validity of these criteria for AS patient.

THU0481

THE PREVALENCE OF CHRONIC MUSCULOSKELETAL PAIN IN PATIENTS WITH ULCERATIVE COLITIS IN COMPARISON TO CONTROLS FROM THE GENERAL POPULATION: A CROSS-SECTIONAL STUDY

N. Pettersson1, F. Kragsbjerg1, A. Hamrin2, S. Bergman3, H. Forsblad-D’elia4, P. Karling1, 1Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 2Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden; 3Primary Health Care Unit, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 4Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden

Background: Musculoskeletal symptoms are common in patients with ulcerative colitis (UC) but the knowledge of the prevalence of chronic regional pain (ChRP) and chronic widespread pain (ChWP) in patients with UC is scarce.

Objectives: To compare the prevalence of ChRP ChWP and chronic pain in different body locations in patients with UC with controls from the general population and to investigate if disease activity in UC is related to chronic pain.

Methods: From a national inflammatory bowel disease (IBD) Register (SWIBREG), all living patients with a confirmed UC diagnosis, aged 20-74 years (n=1134), who were residents in two counties in Northern Sweden were posted a validated questionnaire. Persons from the general population from a previous study (1) using the same questionnaires was used as controls (n=3867). The questionnaire comprised demographics, history of pain and body localisation of pain. The disease activity of UC was measured by Patient- Simple Clinical Colitis Activity Index (P-SCCAI). ChRP and ChWP was defined as having pain for at least three months the last year. ChWP was defined as having pain on both left and right side of the body and both above and below the waist, and in the axial part of the body.

Results: The response rate for the patients with UC was 49.0% and for the controls 62.7%. The patients were older than the controls (mean age 52.8 vs 46.5 years; p<0.001) but there was no difference in gender (men 50.5% vs 46.7%; p=0.086). The reported prevalence of any chronic pain, ChRP and ChWP was higher in patients with UC versus controls (54.4% vs 39.5%; p<0.001; 32.5% vs 24.2%; p<0.001 and 19.4% vs 12.5%; p<0.001). The differences for reported chronic pain (any pain) was seen in all age groups. The patients with UC reported significantly more pain in the regions “lower back”, “hip/upper leg” and “lower leg/foot” compared to controls (Table). The patients with P-SCCAI <5 (n=121) reported more ChWP than patients with P-SCCAI <5 (n=426) (46.3% vs 12.7%; p<0.001) and controls (46.3% vs 12.5%; p<0.001) with significant differences compared to all body regions. No significant difference in ChWP was found between patients with P-SCCAI <5 and controls (12.7% vs 12.5%; p=0.917). There was a slightly higher prevalence of reported any chronic pain between patients with P-SCCAI <5 and controls (46.5% vs 39.5%; p=0.007).

Table. The prevalence of reported chronic musculoskeletal pain in different body regions in patients with ulcerative colitis and controls.

PAIN CATASTROPHIZING AND DISEASE PERCEPTION DIFFERS BETWEEN NORWEGIAN AND FINNISH OUTPATIENT CLINIC PSORIATIC ARTHRITIS PATIENTS DESPITE COMPARABLE OUTCOMES ON OBJECTIVE MEASURES OF DISEASE

G. Haugen1,2, I. J. Widding Hansen1, H. Berner Hammer3, A. Kavagnah4, B. Michelsen1, K. Paalainen5, T. Sokia-Islifer5, Sørlandet Hospital Kristiansand, Kristiansand, Norway, 4Norwegian University of Science and Technology, Trondheim, Norway, 3Diakonhjemmet Hospital, Oslo, Norway, 5University of California San Diego, La Jolla, United States of America, 1Jyväskylä, Jyväskylä, Finland

Background: Pain catastrophizing (the tendency to describe a pain experience in more exaggerated terms than the average person, to ruminate on it more, or to feel more helpless about it), has been associated with reduced likelihood of achieving remission in rheumatoid arthritis patients (1). Cultural and societal differences between countries may have an impact on outcome such as patients’ perceptions of disease.

Objectives: To compare patient pain catastrophizing, patient perception of disease, objective measures of disease and treatment in psoriatic arthritis (PsA) patients between a Norwegian and a Finnish outpatient clinic. Further, to explore for associations with pain catastrophizing.

Methods: All PsA patients followed at the outpatient clinics are routinely monitored using a structured medical support system (GoTreatIT® Rheuma). Data collection, done in 2018-19 is listed in the table.

Patients reported their pain catastrophizing answering the two questions, “When I feel pain it is terrible and I feel it is never going to get any better. When I feel pain, I believe it is so bad that I can’t stand it anymore.” Each question is scored 0-6 and mean value of both is calculated. Pain catastrophizing was defined if mean score ≥4.
In univariate analyses female gender, higher BMI, less years of education, Dr. global, tender joint count, DAPSA, pain, fatigue, MHAQ and psoriasis body surface area were found to be associated with more pain catastrophizing. In multivariate analysis (mandatory adjusting for age, gender, BMI, years of education and disease duration) fewer years of education, higher scores for pain, fatigue and MHAQ and being patient at the Norwegian center were independently associated with more pain catastrophizing.

Conclusion: Our data indicate that cultural differences across countries may have a significant impact on outcomes that reflecting patients' perceptions of disease. This may have an implication when merging heterogeneous databases across countries.

Back pain, mechanical musculoskeletal problems, local soft tissue disorders

THU0483 ASSOCIATION OF CENTRAL SENSITIZATION AND ATTENTION DEFICIT IN MEDICAL STUDENTS WITH CHRONIC BACK PAIN
M.E. Ibrahim1, M. Hefny1. 1Suez Canal University, Physical Medicine, Rheumatology and Rehabilitation, Ismailia, Egypt

Background: Back pain is one of the most common health complaints among university students. A subset of people suffering from chronic back pain exhibit features of increased pain sensitivity and altered pain processing, suggesting central sensitization (CS) to pain. The mechanisms behind these processes are, to date, not fully understood. Evidence shows that in chronic pain, cognitive factors could contribute to the occurrence of central pain sensitization.

Objectives: To assess the association between CS and features of adult Attention Deficit Hyperactivity Disorder (ADHD) in medical students suffering from chronic back pain.

Methods: Data was collected from medical students during the academic year 2018-2019 at Suez Canal University using an online survey. The survey included a section on self-reported musculoskeletal pain including back pain lasting more than 3 months in the neck, upper back and lower back, part (A) of the central sensitization inventory (CSI) and the Adult Attention Deficit Hyperactivity Disorder Self-Report Scale (ASRS-v 1.1). Associations between CSI and ASRS-v 1.1 in students with back pain was assessed using Spearman's correlation. Linear regression was used to estimate cross-sectional associations adjusted for age and gender.

Results: Two hundred and thirty students completed the survey, 93 (40.4%) had back pain for more than 3 months. Students with back pain had significantly higher CS and attention deficit according to CSI (P<0.01), and the ASRS-v 1.1 scores (P<0.09). Correlation results showed a strong positive association between CS and ADHD in students with back pain (correlation coefficient = 0.41, P<0.001). This association remained significant after adjusting for age and gender (P<0.001).

Conclusion: Results of this study suggest that in students suffering from chronic back pain, features of attention deficit are associated with elevated CS. The direction of the association requires further study and may provide novel insights into the interaction between CS and cognitive factors.

Pain in rheumatic diseases, including fibromyalgia

THU0484 FIBROMYALGIA AND MULTIPLE SWITCHING OF BIOLOGICS IN SPONDYLOARTHRITIS
A. Nogu1, 1, J. Alsaleh2, 2, Al Azhar Faculty of Medicine, Cairo, Egypt; 2Dubai Hospital, Dubai, United Arab Emirates

Background: Fibromyalgia (FM) is a condition characterized by chronic widespread pain, tender points, fatigue and disturbed sleep rhythm. Some of these symptoms such as fatigue, tender points and diffuse pain seen in patients with spondyloarthritis (SpA). Moreover, FM and SpA can coexist creating a diagnostic challenge, particularly in early disease course and influence clinical disease activity assessment.

Objectives: With this cross-sectional study, we aim to estimate the prevalence of FM in SpA and to elaborate its effect on biological treatments.

Methods: FM was identified according to the ACR 2010 diagnostic criteria. SpA patients identified according to rheumatologist using various SpA subsets criteria. A review of the electronic medical files for SpA patients attending the rheumatology outpatient clinic and infusion unit at a major tertiary hospital during the period from June to December 2018 were included. Patients’ demographics, socioeconomics, disease characteristics, activity, HLA status and abnormal MRI sacroiliac were explored. Regarding SpA medications, number, frequency and dose of DMARDs and biological agents were obtained.

Continuous variables were reported by their mean and standard deviation (SD) and qualitative variables by frequency and percentage. Statistical significance was set at p <0.05. Statistical analysis was performed using SPSS version 23.

Results: Of the 305 enrolled SpA patients, 43 (14.1%) had FM. Females represents 57.4% of the patients, mean age was 44.07 ± 11.85 years. Arab ethnicity represents most of our cohort 84.9%, the majority were Emirati 64.6%. Smokers were 8.2% and ex-smokers were 3.3%. Axial SpA represents 38.4% while peripheral SpA 61.6% of our cohort according to ASAS classification. Patients SpA and FM have longer disease duration than SpA alone, P= 0.034. Table 1 show demographics, socioeconomic and clinical data of our cohort.

Regarding medication, the use of biologics among SpA patients with FM is more frequent than SpA patients without FM (74.4% vs 51.5 % respectively), P= 0.005.

Disclosure of Interests: : None declared

DOI: 10.1136/annrheumdis-2020-eular.479
Interestingly, the likelihood ratio testing showed that SpA patients with Fibromyalgia switch more frequently to another biologics than SpA without fibromyalgia, P= 0.015. Cramer’s V test showed that there is a high statistically significant (P= 0.002) and very strong association (> 0.25) between presence of Fibromyalgia and multiple switchings of biologics in SpA. There was no difference in the exposure to prednisolone nor conventional DMARDs between SpA patients with or without FM, P= 0.64 & 1 respectively.

**Conclusion:** FM coexistence with SpA might impact clinical evaluation of disease activity and possibly negatively affect self-measurement of treatment response. In our study, SPA patients exposed to more biologics if they have coexisting FM; Moreover, they are more frequent switchers among biologics including TNFi and IL17.

**THE EFFECT OF PERINEURAL INJECTION THERAPY IN PERIARTHRITIS SHOULDER**

M. H. Abu-Zaid, S. A. A. Tabra, S. Elmorsy.

**Faculty of Medicine Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt**

**Background:** Primary adhesive capsulitis of the shoulder is a common patholoby of the glenohumeral joint characterized by shoulder pain and progressive restriction of the range of motion, its treatment options either medication, local injection, physiotherapy, hydrodilution, manipulation under anesthesia, arthroscopic and open capsular release.

Subcutaneous prolotherapy injections can reduce vascular endothelial growth factor levels and restore effective repair processes so induce apoptosis of proliferating peptidergic nociceptors and neovessels and inhibit TRPV1 receptors resulting to reduction of pain.

**Objectives:** To assess the effectiveness of perineural injection therapy in management of pain and physical function in Primary adhesive capsulitis of the shoulder.

**Methods:** One hundred patients with primary adhesive capsulitis in the freezing stage were selected in this study according to the classification of Hannafin and Chiaia and had restriction of passive motion of greater than 30° in 2 or more planes of movement. Patients with previous corticosteroid injection or previous surgery in the affected shoulder, secondary adhesive capsulitis including inflammatory or infectious arthritis, previous fracture, rotator cuff lesions were excluded from this study.

Patients were randomly divided into two equal groups; Group I received 6 weekly subcutaneous injections of 0.5-1 ml of buffered dextrose 5% in each chronic constriction injury points and tender points at shoulder and along course of supraspinatus, subscapular, axillary, musculocutaneous and radial nerves. Group II received oral NSAIDs and muscle relaxants for 6 weeks. All patients in both groups received the same stretching and exercise therapy during the period of treatment. All procedures were done after informed consent. Assessments were performed at baseline, at the end of the treatment and after three and six months using visual analog scale (VAS) for pain, range of movement measurements by goniometer, Shoulder Pain and Disability Index (SPADI) & the Western Ontario Rotator Cuff (WORC) Index.

**Results:** Patients in Group I had more rapid relief of pain and better functional improvement compared with group II (p<0.05). There was significant improvement in both groups (p<0.05) after 3 and 6 months with significant difference between the 2 groups indicated that better results in perineural group. Results were summarized in table 1.

THU0486

2019 FRENCH GUIDELINES AND CARE PATHWAY ABOUT LOW BACK PAIN MANAGEMENT IN ADULTS
F. Bailly1, A. P. Trouvin1, S. Bercier3, S. Dadoun1, J. P. Deneuville8, R. Faguer2, J. B. Fassier1, M. Koleck2, L. Lassalle1, T. Le Vraux1, B. Liesse1, K. Petitprez1, A. Ramond1, J. F. Renard1, A. Roren1, S. Rozenberg2, C. Sebire1, G. Viudes1, F. Rannou1, A. Petit1.
[1] National Authority for Health, Saint Denis, France

Background: Low back pain (LBP) is a frequent, disabling symptom, for which the risk of chronicity is increased by heterogeneous care. Developing and implementing recommendations is likely to improve LBP management.

Objectives: To develop French guidelines and care pathway on the management of LBP, coordinated by the French National Authority for Health (FNAH) and based on previous international guidelines in addition to update literature.

Methods: A compilation report was constituted on the basis of a systematic review of guidelines between January 2013 and December 2018, and systematic reviews and meta-analysis in the field of LBP between January 2015 and December 2018. This report summarized the state-of-the-art for each predefined area of the guideline. A panel of experts including patients’ representatives and 19 health professionals involved in LBP management was constituted to elaborate the guideline based on the compilation report. A care pathway was constituted to identify the trajectory and the different steps followed by a patient with LBP. Then, the compilation report and the preliminary guidelines were submitted to 24 academic institutions and stakeholders for feedback. Based on the preliminary guideline and the responses of academic institutions and stakeholders, the final recommendations were drawn up by the expert panel. The guideline was finally submitted to an independent committee of the FNAH for final validation. For each area of the guidelines, agreement between experts of the working group was evaluated through the RAND/USC method.

Results: The initial literature search identified 572 references of recent international guidelines or systematic reviews about LBP. After selection, the compilation report included 101 references. The compilation report was submitted to the expert group during 3 different meetings to reach a consensus on different topics. Thirty-one preliminary recommendations and a care pathway (divided in two parts to facilitate its use and readability) were drafted and submitted to academic institutions and stakeholders. Having considered their comments, final recommendations and care pathway were written. The final guideline was validated by the FNAH. Then, the consensus of the expert panel was assessed about all the final guidelines separately: 32 recommendations (including the care pathway) were evaluated as appropriate; none were evaluated uncertain or inappropriate. Strong approval was obtained for 27 of them (including the care pathway) and weak for 5 of them.

Conclusion: This new LBP guideline was based on recent scientific evidence. It introduced several concepts, including the need to identify low back pain at risk of chronicity, in order to provide quicker intensive management if necessary. This guideline should be updated in 5 years’ time, in order to keep it in line with ongoing scientific evidence.

DIAGNOSTIC DILEMMA: WHICH CLINICAL TEST IS MOST ACCURATE FOR DIAGNOSING SUPRASPINATUS MUSCLE TEARS AND TENDINOSIS?
E. Balev Batur1, Z. Bekin Sankaya2, M. E. Kaygısız3, I. Albayrak Gezer4, F. Levendoğlu1, 1Selçuk University Faculty of Medicine, Physical Medicine and Rehabilitation, Konya, Turkey; 2Harran University Faculty of Medicine, Radiology, Şanlıurfa, Turkey; 3Selçuk University Faculty of Medicine, Physical Medicine and Rehabilitation, Konya, Turkey; 4Selçuk University Faculty of Medicine, Physical Medicine and Rehabilitation, Konya, Turkey

Background: Supraspinatus tears and tendinosis are the most common pathology that cause shoulder pain to approximately half of the patients presenting clinically.

Objectives: To investigate the diagnostic accuracy of five clinical tests in the diagnosis of supraspinatus tears and tendinosis compared with magnetic resonance imaging (MRI).

Methods: A total of 116 painful shoulders of 106 consecutive patients were examined. Patients were assessed using the most commonly used special clinical tests including the Jobe test (empty can), Neer test, drop arm test, Hawkins test, Hawkins test and full can tests to identify supraspinatus tears and tendinosis. A visual analogue scale (VAS) was used for pain detection, and the Shoulder Pain and Disability Index (SPADI) questionnaire was administered. MRI examinations were performed on 1.5 Tesla MR system and images were assessed by a blinded radiologist. The primary outcomes were to determine the sensitivity, specificity, and accuracy of the five clinical tests, and to establish their correlation with MRI for supraspinatus tears and tendinosis.

Results: The mean age was 55.10 ± 10.20 years, and 32.08% of the patients were female. The Hawkins test had a higher sensitivity and accuracy in tears (sensitivity 89.66%, accuracy 56.03%, respectively) and higher sensitivity in tendinosis (79.07%). The drop arm test had a lower sensitivity but higher specificity in both tendinosis and tears (sensitivity 0%, 12.07%, respectively, and specificity 87.67%, 96.5%, respectively

Conclusion: The Hawkins test was the most sensitive in both supraspinatus tendinosis and tears compared with MRI findings.

THU0488

PSYCHIATRIC SYMPTOMS, TEMPERATURE PROFILE, STRESS PERCEPTION AND SLEEP QUALITY IN THE PATIENTS WITH CHRONIC SHOULDER PAIN: RELATIONSHIP WITH PAIN, DISABILITY, AND FUNCTIONAL CAPACITY
M. S. Ozsoy1, D. Durmus1, G. Alaylı2, G. Sarıosy1, A. Bilgiçi1, 1Ondokuz Mayıs University Medical Faculty, Physical Medicine and Rehabilitation, Samsun, Turkey; 2Ondokuz Mayıs University Medical Faculty, Psychiatry, Samsun, Turkey

Background: Shoulder pain is very common in general population. Psychiatric symptoms and poor sleep quality related with chronic pain and disability may be present in these patients.

Objectives: The aim of this study was to investigate the psychiatric symptoms, perceived stress, temperament profile and sleep disturbance in the patients with chronic shoulder pain (CSP) and also to evaluate the relationship with pain, disability, and functional capacity.

Methods: We prospectively evaluated 150 patients (M/F=41/109) (60.46±10.59 years) who have had shoulder pain for at least 3 months and 120 healthy controls (M/F=35/85) (58.35±8.52 years). Pain was evaluated with Visual Analog Scale (VAS), disability with Shoulder Disability Questionnaire (SDQ), functionality with The University of California-Los Angeles (UCLA) Shoulder Scale and range of shoulder motion, temperament profiles with TEMPS-A, stress perception with Perceived stress scale (PSS), psychiatric symptoms with Symptom Check-list-90-R (SCL-90-R), Rosenberg self esteem with Self-Esteem Scale (RSES) and sleep disturbance with Pittsburgh sleep quality index (PSQI).

Results: The mean VAS pain score, SDQ score, and UCLA score of the patients with shoulder pain were 4.34±1.79, 61.98±26.88, and 58.90±17.78, respectively. SCL-90-R total and all subscale scores except interpersonal sensitivity, psychotomatism, paranoid, and phobia were significantly higher in the patient group than the control group (p<0.05). Also PSQI total and sleep quality and latency subscale scores were significantly higher in the patient group (p<0.05). There was no significant difference between the patient and control groups in terms of RSES and PSS. The study identified 28 depressive temperaments in the patient group which was statistically different from the control group (p<0.05). There were no significant differences between two groups in terms of cyclothymic, irritable, anxious, and hyperthymic temperaments (p>0.05). When the patient group is evaluated according to functionality, the patients having fair/poor shoulder function had more psychiatric symptoms except hostility, poor sleep quality, decreased self-esteem and increased stress perception. Also, anxious and dejected temperaments were found more common in the patients with fair/poor shoulder function. Psychiatric symptoms (somatization, obsessive-compulsive, interpersonal-sensitivity, depression and anxiety) and total PSQI were positively correlated with SDQ (p<0.05). There was positive correlation between PSS and SDQ (p<0.05). SCL-90R total score, subscale of depression and anxiety, total PSQI and PSS were significantly correlated with VAS score (p<0.05).

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.481
Conclusion: We found psychiatric symptoms such as obsessive-compulsive besides somatization, anxiety, depression, hostility and sleep disturbances higher in the patients with CSP. Additionally, psychiatric symptoms, anxious and depressive temperaments were more common in the patients with fair-poor shoulder function. Self-esteem was not related with the pain. All these findings indicate the importance of psychological health in the patients with CSP. In order to reach treatment goals, psychiatric symptoms and temperament profiles of these patients also should be considered.

THU0490 HIP INVOLVEMENT IN DIFFUSE IDIOPATHIC SKEL EtAL HYPERTROPHYOSIS (DISH): CROSS-SECTIONAL STUDY

T. Clavaguera1, E. Armengol2, M. Buxó3, M. Vallis3, E. DE Cendra2, P. Reyner1,2, Hospital Universitari Doctor Trueta, Rheumatology, Girona, Spain; 2Hospital Sant Caterna, Rheumatology, Salt, Spain; 3Hospital de Palamos, Rheumatology, Palamós, Spain; 1Institut d’Investigació Biomèdica de Girona, Biostatistics, Girona, Spain

Background: In DISH or Forester-Rotés disease, hip involvement is often misdiagnosed as hip osteoarthritis, especially when it is the initial manifestation of the disease or in patients with scarce vertebral signs. At present, a correct identification of this entity may suppose considerable therapeutic implications.

Objectives: The purpose of this study was to assess the prevalence and characteristics of hip involvement in our cohort of patients with DISH and evaluate the association of this extra-spatial manifestation with the variables studied.

Methods: We carried out a cross-sectional study in DISH patients who met Resnick and/or Utsinger classification criteria. We collected demographic, anthropometric, clinical and imaging data. Hip involvement was defined as the characteristic irregular bony excrescences above acetabulum. The cohort was divided between patients with and without hip involvement. A univariate descriptive analysis was performed with means and standard deviations, absolute frequencies and percentages. The normality of the data was checked using the Shapiro-Wilk test. The bivariate analysis, for the qualitative variables, the χ2 test or Fisher’s exact test were identified. For the quantitative variables, the Student’s t-test was used if the data followed a normal distribution, and otherwise using the Mann-Whitney U test.

Results: Of the 58 patients included, 67.2% were male. The median age was 69.4 years (44-99). The average time of disease evolution was 14.8 (±9.3) years. Although the most frequent initial symptom was thoraco-lumbar pain (39.7%), hip complaints were initially present in 13.8% of patients. 22.6% of patients did not fulfil Resnick classification criteria. Hip involvement was identified in 53.4% and a 61.3% of patients with and without hip involvement. A univariate descriptive analysis was performed with means and standard deviations, absolute frequencies and percentages. The normality of the data was checked using the Shapiro-Wilk test. The bivariate analysis, for the qualitative variables, the χ2 test or Fisher’s exact test were identified. For the quantitative variables, the Student’s t-test was used if the data followed a normal distribution, and otherwise using the Mann-Whitney U test.

Conclusion: Hip involvement has been described in more than 50% of our patients. We found out that it was associated with female sex and a more broad osseous phenotype (mixed pattern). The measurement of IM distance could be useful for the clinical evaluation of this condition. Ossifications of other pelvic ring entheses were more observed in association with acetabular hyperostosis than other peripheral insertions.

THU0491 DEEP FRICTION MASSAGE VERSUS LOCAL STEROID INJECTION FOR TREATMENT OF PLANTAR FACITIS: A RANDOMIZED CONTROLLED TRIAL

A. Moshtari1, M. Elwan1, U. Datatla.2, 1Ahzar University, Assiut, Egypt; 2Soqag University, Soqag, Egypt

Background: Deep friction massage (DFM) has long been proven to be effective in the treatment of some tendinopathies.

Objectives: to evaluate the efficacy of DFM in the treatment of plantar fascitis (PF) in comparison with local steroid injection.

Methods: In this randomized controlled trial, 60 patients with PF were selected from those attending the rheumatology and rehabilitation outpatient clinic and then randomized to receive either 40 mg triamcinolone local injection (group I: 30 patients; 41 heels) using the medial approach or to receive seven sessions of deep transverse friction massage (10min each) every other day (group II: 30 patients; 36 heels). The outcome measures were the pain and function assessment by visual analog scale and foot function index, respectively, at 2 and 6 weeks of follow-up.

Results: Demographic data showed a statistically insignificant difference in age, female to male ratio, and BMI in both groups. The mean age was 39.42 years in group I and 41.32 years in group II (P=0.86). The female to male ratio was 3:1 in group I and 2:7:1 in group II, and the mean BMI was 32.41 in group I and 33.31 in group II (P=0.51). At 2 and 6 weeks of follow-up, DFM led to less improvement in pain and function compared with local steroid injection (P=0.001 and 0.002, respectively, at both time points of follow-up).

Conclusion: This study revealed that DFM is not effective as a single modality in treatment of PF. Further large-scale studies are needed to support this observation.

THU0492 MAGNETIC RESONANCE IMAGING OF THE SACROILIAC JOINTS IN PATIENTS WITH HYPERMOBILITY: A RETROSPECTIVE COHORT STUDY

A. Jones1, C. Curtin2, H. Kaza2, M. Hall-Craggs2, 1Royal Surrey County Hospital, Guildford, United Kingdom; 2University College Hospital, London, United Kingdom; 3University College London, London, United Kingdom

Background: The incidence of inflammatory and structural lesions on magnetic resonance imaging of sacroiliac joints (MRI SIJs) in patients with hypermobility related disorders has not been fully investigated. Hypermobile patients are more susceptible to pelvic instability and biomechanical stress of the SIJs, leading to MRI SIJ changes.

References:
1. [1]
2. [2]
3. [3]
similar to those occurring in spondyloarthritis (SpA). Patients with hypermobility and suspected SpA pose a unique challenge owing to the high prevalence of back pain in the hypermobility cohort and the absence of spinal restriction on clinical examination. **Objectives:** In this study, we aim to investigate the incidence of MRI SIJ lesions in patients with hypermobility. **Methods:** We performed a retrospective study of all patients with a confirmed diagnosis of hypermobility related disorders (including hypermobility syndrome, hypermobility spectrum disorders and Ehlers-Danlos Syndromes) referred for an MRI lumbar spine and SIJ between 2011 and 2019. Patients were identified by a musculoskeletal radiologist with more than 25 years of experience, who was blinded to the clinical outcome of the patients. **Results:** 51 patients with confirmed hypermobility related disorders were referred for MRI SIJ and lumbar spine between 2011 and 2019. 3 patients demonstrated clinical features in keeping with a diagnosis of SpA and were excluded from the study. 15/48 (31.3%) of patients with hypermobility and back pain (but no clinical picture of SpA) were found to have inflammatory and/or structural lesions on MRI SIJ. The most frequent lesions were small foci of bone marrow oedema (16.6%) followed by subchondral sclerosis (12.5%) and fatty change (10.4%). The incidence of erosions was 4.2%. **Conclusion:** There is a relatively high incidence of inflammatory and structural lesions on MRI SIJ of patients with hypermobility. The presence of hypermobility should be taken into consideration when interpreting MRI changes in patients with suspected SpA. Further research into long-term outcomes of MRI SIJs in patients with hypermobility and back pain is required to establish the clinical significance of these findings. **Disclosure of Interests:** · Alexis Jones: None declared, Cozzana Ciutin Grant/ research support from: Roche., Consultant of: Roche, Modern Biosciences, Hanadi Kaza: None declared, Margaret Hall-Craggs: None declared

**THU0493**

**IMPACT OF AGE, GENDER AND EDUCATION LEVEL ON THE CHOICE OF TREATMENT METHOD FOR BACK PAIN AMONG PEOPLE OVER 50 YEARS OF AGE**

M. Nejman1, M. Hiller1, J. Napora1, A. Wojteczek2, M. Ziolkowska2, Z. Zdrojewski2, 1Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Medical University of Gdańsk, Gdańsk, Poland; 2Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Medical University of Gdańsk, Gdańsk, Poland.

**Background:** According to data collected by the Statistics Poland in 2014, lower back pain is the second most common complaint reported by people over the age of 60 and occurs in about 40% of them. Another 29% of respondents suffer from pain in other spine sections. Treatment of such a common condition can be a challenge due to the multitude of causes of pain, accompanying diseases and the patient's approach to his own health. **Objectives:** The aim of the study was to investigate whether factors such as gender, age, level of education and pain severity affect self-chosen methods of treating back pain. **Methods:** A survey was conducted on students of Pomeranian Universities Of The Third Age. There were collected socio-demographic characteristics of the participants, features of back pain and detailed information on analgesic methods, including drugs, ointments, exercises and physiotherapy treatments (laser, cryotherapy, hydromassage, ultrasound, heat treatments and other). The responses of participants over the age of 50 were included in the analysis. The answers were divided into groups by age (<50–69 years and older - over 70 years), sex, level of education (lower, medium and higher) and intensity of pain assessed on the VAS scale (<6 and ≥6). The collected data were compared in these groups. **Results:** 546 answers were received. 291 respondents were 50-68 years old, 255 aged 70-90 and more, 86% (471) of participants were women. 43% of respondents had secondary education and the same number had higher education. Over 90% (494) declared that they had suffered from back pain. Most of them described pain as chronic (56%), the median pain intensity assessed on the VAS scale was 6 (1-10), and the mean pain intensity was 5.89 ± 1.79. 82.6% of respondents declared doing physical exercises to relieve back pain, 75.9% were using physiotherapy, 60.7% were taking analgesic drugs and 54.3% were using ointments, gels, patches and other local analgesic methods. The higher pain severity was observed in group of females (5.74 vs. 5.81, p=0.002) and people with lower education level (6.52) than in other groups (5.89 and 5.68, p=0.005). Analgesic drugs were taken more often by younger people (66.9% vs. 53.7%, p=0.003), women (82.5% vs. 49.2%, p=0.042), people of lower education level group (80.6% vs. 62.2% secondary education group vs. 52.5% higher education group, p<0.001) and by people with pain severity ≥6 (81.5% vs. 68.9%, p<0.001). Analgesic gels, ointments, patches and other pharmaceuticals were used more often only in group with higher pain severity (82.9% vs. 43.4%, p<0.001). Performing exercises to relieve pain was more often declared by women (84.4% vs. 70.8%, p=0.003) and people with higher education (83.1% vs. 81.3% secondary education group vs. 79.1% lower education group, p=0.001). The study showed that only in groups with varying intensity of pain there was a significant difference in the frequency of using physiotherapy treatments - 68.9% in group with pain severity <6 vs. 81.5% with pain severity ≥6 (p<0.001).

**Conclusion:** 1. The severity of pain has the greatest impact on the choice of back pain relief method, but this is not the only important factor. 2. People with lower levels of education and men less often perform physical exercises for treatment regardless of the severity of back pain. 3. In the treatment of back pain, attention should be given to recommending the patient an appropriate analgesic method, which will be easily used and more effective. **Disclosure:** None declared

**BACK PAIN, SPINE OSTEOARTHRITIS AND ‘CANDIDATE GENES’ POLYMORPHISM**

N. Pravdívá1, N. Shvyreva1, N. Shostak1, A. Novikova1, E. Zakharova2, 1Russian National Medical Research University named after N.I. Pirogov, Moscow, Russian Federation; 2Medical Genetic Research Center of the Russian Academy of Medical Sciences, Laboratory of Hereditary Metabolic Diseases, Moscow, Russian Federation

**Background:** Low back pain (LBP) and spine osteoarthritis are among the leading health-related causes of disability and reduction in patient quality of life. More recent work suggested that the factors that lead to disc degeneration may have important genetic components. Genetic predisposition has been confirmed by recent findings of associations between degeneration and gene polymorphisms of matrix macromolecules. **Objectives:** Evaluation of genetic polymorphisms of genes collagen 1A1 (COL1A1), interleukin 1β (IL-1β), interleukin 6 (IL-6), vitamin D receptor (VDR) in patients with LBP, associated with spine osteoarthritis. **Methods:** We examined 33 patients (men-17, women-16, middle age 28, 7±3,77) with LBP end onset, verified by magnetic resonance imaging (MRI) and 15 controls was carried out. Assessed the intensity of pain syndrome on visual analog scale (VAS, mm) and the nature of its current (IASP, 1994). Polymerase chain reaction and restriction fragments length polymorphism was used to detect the polymorphism of COL1A1 (rs 1800012), IL-1 (rs 1143627), IL-6 (rs 1800795), VDR (rs 1544410). **Results:** The severity of the pain (VAS) average was 60±mm, all the patients revealed chronic option currents pain syndrome. In 86% of patients detected changes disc in the form of protrusions and hernias, 17 % of patients had a characteristic reducing the height of the intervertebral disc of lower height disc and osteophytes, arthritis facets joints identified in 20% of patients in 34% of patients diagnosed changes type Modic II. 83% of patients with LBP identified homoyzgous variant allele (GG) Col1A1 gene. The absence of T-alleles in the gene IL-1β in the group of patients was associated with severity of the disease. Carriage of allele in heterozygous AG found in 54% of patients of the main group and was not observed in the control that requires further accumulation of facts. Identified association GG-genotype of IL-6 clinical and instrumental signs of the syndrome Modic-II. **Conclusion:** These findings may be the reason for the patient-specific approach to diagnosing and treatment of back pain. It proves the necessity of research of genetic polymorphisms in patients with spine osteoarthritis. **Disclosure of Interests:** None declared

**NOVEL UNDERSTANDING OF THE PATHOGENESIS OF JUVENILE IDIOPATHIC ARTHRITIS: FOCUS ON MESENCHYMAL STEM CELLS IMPAIRMENT, SENESCENCE AND IMMUNOREGULATORY FUNCTION**

L. Zaripova1, A. Midgley2, S. Christmas3, E. Baildam4, R. Oldershaw1, 1University of Liverpool, Musculoskeletal Biology, Liverpool, United Kingdom; 2University of Liverpool, Women’s Health, Liverpool, United Kingdom; 3University of Liverpool, Clinical Infection, Microbiology and Immunology.
Background: Juvenile idiopathic arthritis (JIA) is a well-known chronic rheumatic disease of childhood characterised by progressive joint destruction and severe systemic complications. Immune cells are known to trigger the pathophysiological cascade in JIA, but there is little information regarding the contribution made by Mesenchymal stem cells (MSCs). These cells are able to modulate the immune response and decrease the level of pro-inflammatory cytokines. With addition of regenerative property it makes MSCs potential candidates for clinical application as immuno-suppressants in treatment of autoimmune diseases.

Objectives: To investigate MSCs proliferation, viability and immunomodulatory function in JIA and healthy children. Methods: MSCs were separated from peripheral blood (PB) and synovial fluid (SF) of JIA patients and healthy controls. Cell proliferation rate was counted by Population doublings per day (PDD) during 9 days, in the last of which alamarBlue™ assays were performed to assess cell viability. Due to measure senescence MSCs were stained with SA-β-galactosidase. Immunofluorescence was used to examine the expression of p16, p21, p53. Oxidative stress was measured with DCFH-DA. Cell cycle analysis was evaluated with Propidium Iodide and analysed by Accuri® C6 Flow Cytometer. Commercially-available bone marrow mesenchymal stem cells (BM-MSCs) were treated with graded concentrations of pro-inflammatory cytokines (0.1-100 ng/ml) with following examination of cell viability. Mixed lymphocyte reactions (MLR) were performed to measure MSC immunomodulatory ability in vitro.

Results: The growth kinetics of JIA-MSCs were different from healthy controls. JIA-MSCs divided slowly and appeared disorganised with large cytoplasm and loads of outgrowth. They demonstrated a decrease in cell proliferation (negative PDD) and metabolic activity. Difference in growth kinetics and metabolic activity were found inside the JIA PB group with some evidence of response following biological treatment. Thus, PB-MSCs from patients treated with TNFi and anti-IL6 medications had notably higher cell proliferation and metabolic activity against JIA patients received other therapy. Considering this difference, it was hypothesised that cytokines obtained in a high amount in PB and SF of JIA patients may influence MSCs viability. To prove this BM-MSCs were treated with cytokines and demonstrated a dose-dependent decrease in metabolic activity significantly after TNFα and IL1, no significantly after treatment with IL6. Both BM-MSCs treated with cytokines and JIA-MSCs displayed high level of reactive oxygen species. Cell cycle analysis revealed that JIA-MSCs were arrested in G0/G1 phase with low number of mitotic cells. In addition, the number of senescence-associated SA-β-gal-positive cells was notably higher in JIA-MSCs. Furthermore, JIA-MSCs expressed high level of immunofluorescence for p16, p21 and p53 which played an important role in regulating the senescence progress of MSCS. Results of MLR showed the ability of BM-MSCs to decrease the percentage of activated T-helpers, T-suppressors, B-cells and natural killers proliferation, while JIA-MSCs lost this property.

Conclusion: Taken together current research has demonstrated that under the influence of proinflammatory cytokines JIA-MSCs suffered from oxidative stress and disruption of metabolic activity acquire senescent morphology, shorten of telomere length, arrest in G0 phase of cell cycle and finally loss of immune regulation. We are continuing our research to determine the mechanisms that are responsible for the impaired phenotype with the aim of identifying new therapeutic strategies for the treatment of JIA.

THU0496 APPLICATION OF SYSTEMS BIOLOGY-BASED IN SILICO TOOLS TO OPTIMIZE TREATMENT STRATEGY IN STILL’S DISEASE

M. Coma 1, C. Seguí-Vergés 1, C. Kessef 2, S. Smeets 3, D. Feoß 4, A. Aldea 1
1Anaxomics Biotech, Barcelona, Spain; 2Department of Pediatric Rheumatology & Immunology, University Children’s Hospital, Münster, Germany; 3Novartis, Amsterdam, Netherlands; 4Novartis, Barcelona, Spain

Background: Systemic Juvenile Idiopathic Arthritis (sJIA) and Adult Onset Still’s Disease (AOSD) are manifestations of an autoinflammatory disorder with complex pathophysiology and significant morbidity, together also termed Still’s disease.

Objectives: To investigate the optimal treat-to-target strategy for Still’s disease by in silico models based on systems biology.

Methods: Molecular characteristics of Still’s disease and data on biological inhibitors of interleukin (IL)-1 (anakinra, canakinumab), IL-6 (tocilizumab, sarilumab), glucocorticoids as well as conventional disease-modifying anti-rheumatic drugs (DMARDs, methotrexate) were used to construct in silico mechanisms of action (MoA) models by means of Therapeutic Performance Mapping System technology (TPMS). TPMS combines artificial neuronal networks (ANN), sampling-based methods and artificial intelligence. The models were validated with publicly available expression data from sJIA patients (Fig.1).

Conclusion: Systems biology-based modelling supported the preferred use of biologics as immunomodulatory treatment strategy for Still’s disease. This further encourages early IL-1β blockade in initial autoinflammatory/systemic phases of Still’s Disease to prevent the development of disease or drug-related complications. Further studies are needed to determine the optimal timeframe of the window of opportunity for canakinumab treatment.

Figure 1. Schematic TPMS approach used to evaluate the Still’s disease treatments efficacy and their MoA

Figure 2. Systems biology-based MoA models of canakinumab and tocilizumab focused on innate immune system modulation, Canakinumab preferably modulates NF-κB, IL-8 (CXCL8), MyD88, S100A9 and ATG5, which are involved in processes of general innate immune inflammation, neutrophil recruitment, activation and autophagy, whereas tocilizumab preferably modulates FCGR1, which is involved in neutrophil activation

Background: Juvenile Idiopathic Arthritis (JIA) patients experience impaired health and wellbeing due to multiple causes of physical and psychosocial distress, including treatment burden. Despite emerging evidence of its relevance [1], the contribution of treatment adverse events to patient-reported outcomes (PROs) in JIA has been poorly explored.

Objectives: To evaluate and rank the impact of patient-reported adverse events (AEs) on overall wellbeing, health-related quality of life (HRQoL), school problem and self-reported medication adherence using data from Pharmachild, a large international JIA pharmacovigilance registry.

Methods: Registry entries on 5340 prospective visits of 2251 patients enrolled till December 2018 were analyzed; all included patients were treated with at least one DMARDS or Biologic agent at the time of visit. In the Juvenile Arthritis Multidimensional Assessment Report (JAMARI), patients and parents compiled a checklist of treatments, side effects, self-reported adherence, administration difficulties and disease-related school problems occurred in the previous 4 weeks. Evaluated outcomes included patient acceptable symptom state (PASS), VAS-measured patient assessment of overall wellbeing (PGA) and HRQoL, assessed through the physical health (PhH) and psychosocial health (PsH) subscales. The relationships between AEs and PROs were tested through generalized linear models, accounting for disease activity and symptoms levels. Bayesian Networks were used to explore the causal effects of specific AEs on outcomes to disentangle the confounding role of disease status.

Results: AEs were reported in 22.9% of visits. For similar levels of physician global assessment (MD global), patient-assessed disease activity, pain and function, patients reporting AEs had worse PGA, PsH, and lower probability of reaching PASS (fig. 1, all p-values <0.001). The impact of AEs on PGA was small but not trivial (effect size $\eta^2 = 0.031$) and appears to be mediated by effects on PhH and school problems (p <0.001). Non-linear regression modeling revealed a significant moderating effect of MD global levels < 2.5 on the relationship between AEs and PGA (p <0.003), indicating that the impact of AEs is higher for lower disease activity states. AEs predicted self-reported medication adherence (p<0.001), even when adjusted for the number of administered treatments. In the Bayesian network model, mood swing and sleep problems emerged as the most influential items affecting PsH, and mood swing and sleep problems showed the strongest influence on HRQoL. Addressing AEs appears important to reduce disease impact, improve patients' satisfaction and therapeutic compliance.

Conclusions: AEs have a measurable effect on the wellbeing and psychosocial health of JIA patients, particularly when disease activity is low, and significantly affect school activity and medication adherence. Mood swings and sleep problems show the strongest influence on HRQoL. Addressing AEs appears important to reduce disease impact, improve patients' satisfaction and therapeutic compliance.

Juvenile systemic scleroderma is an orphan disease with a prevalence of 3 per 1,000,000 children. There are limited data regarding the clinical presentation of jSSc. The Juvenile Systemic Scleroderma Inception Cohort (JSSIC) is the largest multinational registry that prospectively collects information about jSSc patients.

**Objectives:** Evaluation of the jSSc patients at the time of inclusion in the JSSIC.

**Methods:** Patients were included in the JSSIC if they fulfilled the adult ACR/EULAR classification criteria for systemic scleroderma, if they presented the first non-Raynaud symptom before 16 years of age and if they were younger than 18 years of age at time of inclusion. Patients’ characteristics at time of inclusion were evaluated.

**Results:** Until 15th of December 2019 hundred fifty patients were included, 83% of them being Caucasian and 80% female. The majority had the diffuse subtype (72%) and 17% of all jSSc had overlap features. The mean age of first presentation of Raynaud’s phenomenon was 9.8 years in the diffuse subtype (dSSc) and 10.7 years in the limited subtype (lSSc) (p=0.197). The mean age at first non-Raynaud’s symptoms was 10.0 years in the dSSc and 11.2 years in the lSSc (p=0.247). Mean disease duration at time of inclusion was 3.4 years in the dSSc and 2.4 years in the lSSc group.

Significant differences were found between the groups regarding mean modified Rodnan skin score, 18.2 in the dSSc vs 6.2 in the lSSc (p=0.02); presence of Gottron’s papulæ (dSSc 30% vs lSSc 13%; p=0.43); presence of teleangectasia (dSSc 42% vs 18% in lSSc, p=0.01); history of ulceration (dSSc 42% vs 18% in lSSc; p=0.008); 6 Minute walk test below the 10th percentile (dSSc 85% vs lSSc 54%; p=0.044), total pulmonary involvement (dSSc 49% vs lSSc 31%, p=0.045), cardiac involvement (lSSc 17% vs dSSc 3%, p=0.003). dSSc patients had significantly worse scores for Physician Global Assessment of disease activity compared to lSSc patients (VAS 0-100) (40 vs 15) (p=0.001) and for Physician Global Assessment of disease damage (VAS 0-100) (36 vs 17) (p=0.001).

There were no statistically significant differences in the other presentations. Pulmonary hypertension occurred in approximately 6% in both groups. No systemic hypertenstion or renal crisis was reported. ANA positivity was 90% in both groups. Anti-Scl70 was positive in 35% in djSSc and 36% in the ljSSc group. Anticentromere positivity occurred in 3% in the dSSc and 7% in the lSSc group.

**Conclusion:** In this unique large cohort of jSSc patients there were significant differences between dSSc and lSSc patients at time of inclusion into the cohort regarding skin, vascular, pulmonary and cardiac involvement. Accord- ing to the physician global scores the dSSc patients had a significantly more severe disease. Interestingly the antibody profile was similar in both scleroderma phenotypes.

Background: Insufficient physical activity (PA) and screen-based media use (SBM) are different aspects of sedentary behavior (SB), independently and inversely related to health and wellbeing. Recent research indicates that adolescents with chronic conditions are at least as likely at risk of being physically inactive or accumulating high levels of screen-based SB when compared with their healthy peers [1].

Objectives: Since PA and SBM have not yet been (sufficiently) evaluated in young patients with juvenile idiopathic arthritis (JIA), our aim was to i) quantify the daily SBM use of adolescents with JIA, ii) measure the frequency of their weekly PA, and iii) compare both aspects of SB with those of age- and sex-matched controls from the general population during the course of the disease.

Methods: Data from JIA patients and controls enrolled in the inception cohort study ICON were analyzed. Young people, such as friends and mates, served as the peer group. Patients and peers aged 13 and over were followed prospectively and questioned about their weekly PA frequency and SBM use at a two-year interval. Data from young people for whom at least two questionnaires were available were analyzed using linear mixed models.

Results: Data from 209 patients with JIA (63% female, 28% rheumatoid factor positive polyarthritis) and 138 peers (55% female) were included in the analysis. At baseline (T1), 51% of the patients were treated with a DMARD, 58% at follow-up (T2). The proportion of adolescents being physically active at most twice a week was substantially higher in patients than in controls (T1: 59% vs. 43%; T2: 54% vs. 42%). In patients, the total daily screen time was 3.5±2.6 hours at T1 and 3.6±2.5h at T2, respectively. In comparison, a value about 0.5h less was found in the controls both at T1 and T2. Both groups increasingly spent time on mobile phones during the observation period. At T1 (66% vs. 45%) and T2 (60% vs. 45%), the proportion of physically inactive girls was significantly higher than that of boys. Conversely, boys reported higher levels of SBM than girls. Patients with high SBM consumption (>3h/day) showed a significantly lower PedsQLTM psychosocial functioning (OR 0.94; 95%CI: 0.89-0.99) and a significantly higher cJADAS-10 score (OR 1.34; 95%CI: 1.07-1.67) than those who did not exceed the national recommendations on SBM use.

Conclusion: Although adolescents with JIA tend to become more physically active during the course of disease, on average they remain more inactive and spend significantly more time on SBM than their peers. Given that high SBM use was associated with lower self-reported psychosocial quality of life and higher disease activity, it is important to develop sustainable and effective interventions to reduce sedentary behaviors in this population.

DOI: 10.1136/annrheumdis-2020-eular.2279
BACKGROUND: ALPS is a rare disorder due to a defective apoptotic mechanism leading to abnormal lymphoproliferation and autoimmunity. The disease is difficult to identify in the early phase when it may be misdiagnosed. Elevated TCR alpha-beta CD4-CD8- lymphocytes (double negative T lymphocytes DNT) together with hyperIgM, high levels of IL10, IL12, vitamin B12 and soluble Fas ligand have been suggested as the main ALPS hallmarks (1).

Therefore, a specific flow cytometry panel (DNT cells, ratio of CD25+CD3+ to HLA-DR+CD3+ cells, B220+ T-cells, and CD27+ memory B cells) has been proposed to serve as a diagnostic screen for ALPS (2).

OBJECTIVES: To evaluate the usefulness of a specific lymphocyte flow cytometry panel in the early identification of ALPS/ALPS-like disorders in a cohort of patients with undefined autoinflammatory or autoimmune disorders.

METHODS: The clinical data of patients referred to the pediatric Rheumatology Unit of the Istituto Giannina Gaslini Hospital for a suspicion of auto-immune or autoinflammatory condition from October 2015 to April 2018, were retrospectively analyzed. Data on clinical manifestations, laboratory workup, genetic analysis and treatment were collected. Flow cytometry was included among the screening panel: DNT, CD25+CD3+, HLA-DR+CD3+ cells, B220+ T-cells, and CD27+ memory B cells were included. A statistical analysis was performed: data were analyzed with an univariate logistic regression analysis, to identify the most significant variables associated with ALPS. These variables were then included in a multivariate analysis to select a set of clinical and laboratory parameters, each of them associated with a significant probability to be associated with ALPS independently from other variables.

RESULTS: 475 patients were retrospectively analyzed. 211 patients not fulfilling the inclusion criteria were excluded. The patients were classified as follows: i) Autoimmune disease 26 pts (10 SLE; 3 MCTD; 6 JM; 5 Behçet; 1 S; 1 Kawasaki) ii) Juvenile Idiopathic Arthritis 35 pts iii) Monogenic systemic autoinflammatory disease (M SSAID) 27 pts (17 FMF; 3 MKD; 1 TRAPS; 4 DADA2; 2 SAVI) iv) PPAPA 100 pts v) Systemic Undefined Recurrent Fever 45 pts vi) Undetermined-SSAID 15 pts vii) ALPS/ ALPS probable 16 pts. The flow cytometry panel showed, as expected, an elevation of DNT in all ALPS patients. Among the other parameters, CD3CD25+/CD3HLADR+, and B220+ T-cells, and CD27+ memory B cells were included. A statistical analysis was performed: data were analyzed with an univariate logistic regression analysis, to identify the most significant variables associated with ALPS. These variables were then included in a multivariate analysis to select a set of clinical and laboratory parameters, each of them associated with a significant probability to be associated with ALPS independently from other variables.

Conclusion: The use of the specific flow cytometry panel, comprehensive of DNT, B220+, HLA-DR and CD25, in patients with undefined autoinflammatory or autoimmune disorders may identify a subgroup of patients with ALPS.

DOI: 10.1136/annrheumdis-2020-eular.5847
Background: Belimumab (BEL) is the first treatment approved in children ≥5 years of age with cSLE. This recent approval was based on favourable results of the PLUTO trial, evaluating efficacy and safety of intravenous (IV) BEL, plus standard SLE therapy (SST), vs placebo (PBO), in children with cSLE.

Objectives: To evaluate the SLE Responder Index 4 (SRI4) sensitivity of response for the comparison of BEL vs PBO at Week (Wk) 52.

Methods: In PLUTO (NCT01649765), a GSK study BEL140055, an ongoing Phase 2, randomised, PBO-controlled, double-blind study, patients (pts) 5–17 years of age with active cSLE were randomised to monthly BEL 10 mg/kg IV, or PBO, plus SST, for 52 weeks. The primary efficacy endpoint was the SRI4 response rate at Wk 52. Pre-specified sensitivity analyses supporting the primary efficacy endpoint for the intention-to-treat (ITT) population included unadjusted, last observation carried forward (LOCF), completer responses, and response using SLE Disease Activity Index (SLEDAI) 2K proteinuria scoring rule (4-point scale for proteinuria >0.5 g/24 h), all at Wk 52. Completers were pts who completed 52 weeks of treatment. Any pts who withdrew or received protocol-prohibited medication or a dose of allowable medication that resulted in treatment failure prior to the Wk 52 visit had missing data handled using LOCF (missing values imputed using the last previous non-missing value). Statistics are descriptive.

Results: Overall, 93 pts were randomised (BEL, n=53; PBO, n=40). Majority (94.6%) of pts were female, mean (standard deviation [SD]) age was 14.0 (2.49) years and mean (SD) disease duration was 2.4 (1.93) years. By Wk 52, numerically more BEL (52.8%) than PBO (43.6%) pts were SRI4 responders; difference vs PBO 9.24; odds ratio (OR; 95% confidence interval [CI]) vs PBO 1.49 (0.64, 3.46). Standardised SRI4 sensitivity analyses (analysis unadjusted, LOCF, completer, and SLEDAI 2K responses) the odds of being a responder at Wk 52 were higher for pts receiving BEL vs PBO (Table).

Conclusion: The results of the SRI4 primary efficacy endpoint sensitivity analyses further support a favourable effect for BEL vs PBO.

THU004 EARLY JOINT REPLACEMENT IN JIA: TREND OVER TIME AND FACTORS INFLUENCING IMPLANT SURVIVAL

A. Marino1,2, I. Pontikaki3, C. Artusa, M. Di Marco2, M. Truzzi3, R. Giagni4, R. Cimarza1,2,3. Desio Hospital, Pediatrics, Desio, Italy; 2Biomedical Sciences, University of Florence, Florence, Italy; 3Gaetano Pini, Unit of Pediatric Rheumatology, Milan, Italy; 4Gaetano Pini, Unit of Rheumatology, Milan, Italy; 5Gaetano Pini, Unit of Rheumatology, Milan, Italy; 6University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic condition in childhood. New therapies acting on specific targets have led to a significant improvement in the management of JIA. However, when medical therapy fails, total joint replacement represents the standard treatment to obtain pain relief and improve functional outcomes.

Objectives: To describe early prosthesis in a JIA cohort followed in a tertiary referral hospital and to analyze any possible factors influencing implant survival, including surgical improvements over time.

Methods: This is a monocentric retrospective cohort study; patients were enrolled from January 1992 to June 2019. All patients who underwent total joint replacement and were followed in our institute were included.

Results: Eighty-five patients met the inclusion criteria, with a median follow-up of 17.2 years. The total number of replaced joints over 27 years was 198 (Figure 1). Clinical features and implant data are reported in Table 1.

Table 1. Patients’ clinical features and implants data

Figure 1. Numbers of arthroplasties performed for each year.

We grouped all arthroplasties by the year of surgical procedure: before 2000 (group A; 28 implants), between 2000 and 2010 (group B; 94 implants) and after 2010 (group C; 76 implants).

A significant difference of age at arthroplasty was found between group A and group B (21.93 y vs 26.82; p = 0.03) and between group A and group C (21.93 y vs 27.81 y; p = 0.00).

DOI: 10.1136/annrheumdis-2020-eular.4441
The same upward trend was found with regard to disease duration before arthroplasty: a significant difference between group A and group B (16.98 y vs 21.66 y; p = 0.03) and between group A and group C (16.98 y vs 22.93 y; p = 0.00).

The rate of implant survival at 5, 10 and 15 years were comparable (from 84% to 89%); whereas 50% of eligible implants lasted 20 years or more (Figure 2).

![Kaplan-Meier survival curve of implants.](image)

The year of surgery was found to be significantly related to implant survival [Hazard Ratio (HR) 1.001, confidence interval (CI) 1.0001-1.0006; p = 0.001] as well as the presence of complications (HR 3.69, CI 1.82-7.48; p < 0.001) in multivariate analysis. Furthermore, prostheses of polyarticular RF-neg patients had more possibilities to last longer than those of S-JIA patients (HR 0.23, CI 0.09-0.53; p = 0.00) as well as implants of all polyarticular JIA (RF-pos and neg together) (p < 0.001).

Conclusion: We observed an upward trend of both age at arthroplasty and disease duration before the first arthroplasty over time. JIA category, year of implants and the presence of complications significantly affected implant survival. Future researches should assess functional outcome and survival of implants according to medical therapy and different surgical approaches.

MUSCULOSKELETAL ULTRASOUND MONITORING DURING MTX TAPERING IN JIA: A PROSPECTIVE BLINDED COHORT STUDY

F. Licciardi1, M. Dellepiane1, C. Covizi2, F. Figus2, I. Azzolin2, D. Montin2, A. Iagnocco3, Rega Margherita Children Hospital, Rheumatology Department, Turin, Italy; 4Università degli Studi di Torino, Turin, Italy

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in children. Musculoskeletal ultrasound (MSUS) is a reliable tool in the assessment of chronic inflammatory arthropathies. MSUS in JIA has demonstrated a higher sensitivity for detecting synovitis and tenosynovitis as compared to physical examination. The occurrence of subclinical synovitis (Sub-S: MSUS+/ physical examination -) seems more frequent in wrist and foot joints; the clinical significance of Sub-S in real-life practice is still debated. Methotrexate (MTX) is the most widely used first-line DMARD in JIA therapy. Weekly treatment with MTX leads to clinical remission (CR) in 50-70% of patients. After a variable period of CR (usually 6-18 months), MTX is discontinued. Relapse rate after MTX suspension ranges between 40-50%; no predictors of disease flare have been identified so far.

Objectives: We designed a cohort study in order to explore if MSUS monitoring during MTX tapering was able to predict disease flare.

Methods: JIA patients in CR (as defined by the JADAS score) for at least 12 months were enrolled in the study. Patients at first attempt of suspension (G1) were tapered as follows: 1 week of suspension every 3 weeks for 3 months + 1 dose every 2 weeks for 3 months; if CR persisted, MTX was stopped. Patients who had a previous flare during/after MTX tapering (G2) had a similar tapering schedule but the step with 1 MTX dose every 2 weeks lasted 6 months. All patients underwent a complete MSUS of 48 joints every 3 months; clinicians who performed physical examinations and follow-up were blinded to MSUS findings for the entire study period.

Results: 18 consecutive patients were enrolled between April 2018 and September 2019; patients had prevalently oligoJIA (55.5%) and RF- polyJIA (22.2%). Patients had been treated with MTX for 24.7 months (17.7–48.3). CR had been achieved 4.2 months after MTX start; 61.1% were at their first attempt of MTX tapering (G1). Baseline MSUS: at T0 MSUS detected 9/18 patients (50.0%) with Sub-S (MSUS+). Affected sites at T0 were distributed as follows: 4 MCP joints, 9 MTP joints, 1 h-IP joints, 11 knees. No significant differences resulted in comparing demographic and baseline disease features between MSUS- and MSUS+ patients at T0. Follow-up MSUS: 14 patients (77.8%) completed the entire study protocol, 4 patients are still ongoing; 7 patients relapsed: 42.9% during tapering, 1 of them relapsed during a VZV infection and was excluded from further analysis. We considered as Tlast-MSUS the last available MSUS before relapse or final MSUS (i.e. three months after MTX withdrawal) for not-relapsed subjects.

At Tlast patients had at least 1 Sub-S. Sub-S per patient at Tlast were more than Sub-S at T0 (2.85 vs 0.56; p = 0.03) but the presence of Sub-S was not related with disease flare (50.0 vs 44.4% p=1). MSUS found 27 Sub-S of the small joints (sMSUS): 88.9% were in the feet, they had an OMERACT grading of 1. sMSUS+ patients were older (8.7 vs 3.9; p=0.002) therefore a weight-induced sub-S not related with JIA could be presumed. Kaplan-Meier curves were analyzed comparing MSUS results at T0 and Tlast, both considering all Sub-S and excluding small feet joints (pMSUS). The best performance was achieved with MSUS at Tlast and pMSUS (figure below, p=0.11).

Conclusion: •Sub-S are present in 50% of patients in clinical remission >12 months.
•Sub-S in older patients interest often feet small joints; these Sub-S may be of mechanical origin and are not associated with disease flare.
•Sub-S increase during MTX tapering.

Further patients must be enrolled to understand if Sub-S excluding feet small joints may predict disease flare.

THU0506

LONG-TERM EFFECTIVENESS AND SAFETY OF CANAKINUMAB AS A SECOND BIOLOGIC AFTER TOCILIZUMAB IN CHILDREN WITH EARLY AND LATE JIA WITH ACTIVE SYSTEMIC FEATURES

E. Alexeeva1,2, E. Krehkova1, T. Dvoryakovskaya1,2, K. Isaeva1, A. Chomakhidze1, E. Chistyakova1,2, O. Lomakina1, R. Denisova1, A. Mamutova1, A. Fetisova1, M. Gautier1, D. Vankova1, M. Shingarova2, A. Altshhevskaya1, A. Moskaliev1, K. Krulina1,2, 1National Medical Research Center of Children’s Health, Moscow, Russian Federation; 2Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russian Federation; 3Biostatistics and Clinical Trials Center, Novosibirsk, Russian Federation

Background: Canakinumab (CAN) is often used as second biologics in juvenile idiopathic arthritis with active systemic features (sJIA). However, there are little information about its long-term efficacy and safety.

Objectives: To evaluate the long-term effectiveness and safety of CAN in children with sJIA.

Methods: All patients with active systemic features at the time of switching to CAN were included in the study. CAN was administered every 2 weeks during the first 6 months, then every 4 weeks until disease remission. The study period was defined as the time from switching to CAN until the date of the last assessment.

Results: At the time of switching to CAN, 49 patients were included in the study. The median age at the start of CAN was 10 years (range 4-17 years). The median duration of disease before switching to CAN was 3 years (range 1-10 years). The median duration of treatment with CAN was 24 months (range 6-60 months). The median number of infusions was 12 (range 6-36 infusions). The median dose of CAN was 0.5 mg/kg (range 0.25-1.0 mg/kg).

Conclusion: CAN was well tolerated and effectively controlled systemic features in children with sJIA. Further studies are needed to evaluate the long-term safety and efficacy of CAN in this population.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.491
Methods: Thirty-one patients were enrolled in this study; the group of early sJIA (with duration shorter than 2 years, 19 patients) and the group of late sJIA (with duration longer than 2 years, 12 patients). At the baseline, information was collected on the characteristics of the onset of the disease, previous therapy and its success. At each visit at least 1 time per year clinical and laboratory characteristics of sJIA severity were assessed. Response to therapy was assessed using the ACPRedi 30/50/70/90 criteria and the C.Wallace criteria for inactive disease (WID) and clinical remission.

Results: The most common reason for withdrawal of previous TOC was secondary ineffectiveness (22 cases, 71%); in 6 cases (19.4%) allergic reaction was observed; in two cases (6.5%) primary non-effectiveness appeared; and in one case (3.2%) there was marked infusion reaction. At CAN initiation, sJIA activity was as follows: 15 (12.23) for JADAS-71; 45 (36.5: 72) and 58 (45: 81) for physician's and patient's global assessment VAS; and 0.25 (0: 0.62) for the CHAQ disability index.

After 12-month treatment, 22 (71%) patients reached WID; 21 on CAN therapy and 1 – after CAN withdrawal due to administrative reason and stable WID. ACR50/70/90 response was achieved by 84.2%/84.2%/64.7% patients in early arthritis group and in 83.3%/75%/75% patients in late arthritis group (p=0.792).

However, 42.1% of patients with early sJIA achieved remission in the first 1.5 years without any further relapse during all the studied period and only 16.7% of patients with late arthritis (p=0.239). In multivariable analysis, it was found that age of sJIA onset (OR (2.5-97.5 CI) 0.353 (0.13 - 0.72), p=0.015), number of joints with active arthritis at sJIA onset (2.308 (1.26-5.73), p=0.025), and JADAS-71 at sJIA onset (0.664 (0.44-0.88), p=0.016) were associated with successful treatment with rapid achievement of stable remission. During the 76.7 patient-years follow-up period, 18 of 31 (58.1%) patients were able to achieve a stable clinical remission and 27 (87.1%) – WID. Two patients have achieved successfully drug-off remission. Serious adverse event (SAE) was reported in one (3.2%) patient (entrienteritis).

Conclusion: Long-term canakinumab therapy proved to be effective and safe as a second biologics after tocilizumab for any duration of the disease. However, patients with early arthritis are more likely to quickly achieve stable remission without further relapse. Younger onset of sJIA with polyarticular involvement and low disease activity are predictors of rapid and stable remission.

THU0508

ASSOCIATION BETWEEN JUVENILE IDIOPATHIC ARTHRITIS AND AUTISM

R. Beesley1, 1Juvenile Arthritis Research, Tonbridge, United Kingdom

Background: Juvenile Idiopathic Arthritis (JIA) is a heterogeneous group of autoimmune disorders characterised by chronic joint inflammation, diagnosed in around 1 in 1,000 children and young people (CYP) under the age of 16. Autoimmune Spectrum Condition (ASC) is a neurodevelopmental condition characterised by differences in social communication and sensory perception, as well as restricted interests and repetitive behaviours. Recent estimates from the Centers for Disease Control and Prevention (CDC) suggest that 1.68% of CYP are diagnosed with ASC, with males being more likely to be diagnosed (sex ratio of 4:1) [1]. The causes of both JIA and ASC are complex interactions between genetic and environmental factors. There appears to be some evidence that ASC may be associated with certain parental autoimmune conditions [2], although research into any association between JIA and ASC is sparse with the exception of a review of clinical database information [3].

Objectives: In this parent-led study, the association between JIA and ASC was explored in order to determine if children with JIA, or children who do not themselves have JIA but have at least one first-degree relative with JIA (FDR), are more likely to be diagnosed with ASC.

Methods: Parents of CYP with JIA were invited to complete an online survey, giving details of each member of their family including diagnosis status for JIA and ASC, and age of diagnoses. A total of 247 responses were collected, representing 558 CYP. Overall, 202 CYP were diagnosed with JIA from 197 families. The eldest child with JIA from each family was selected (total 197; 66 male and 131 female) and the rate of ASC was compared against the general population using Fisher’s exact tests.

Results: Children with JIA themselves and FDR children were significantly more likely to be diagnosed with ASC.

<td>7.009 (2.033, 24.160)</td>
<td>0.0006 ***</td>
</tr>
</tbody>
</table>

Figure 1. Proportion of children diagnosed with ASC in the general population (CDC estimates), JIA group and FDR group. Error bar indicates 95% CI. Significance indicated compared to population.

Conclusion: Individuals with JIA and family members of individuals with JIA are more likely to be diagnosed with ASC. The results remained unchanged in a sensitivity analysis in which JIA children who had another sibling with JIA were excluded in order to minimise the risk that these results were affected by selecting the eldest child with JIA. It is possible that we are underestimating the association between JIA and ASC in this study. The majority of children sampled were from the United Kingdom and Ireland; however, we chose to utilise the most recent CDC estimates for ASC prevalence, as the most recent estimates from the UK were from 2006 and longitudinal data suggests that ASC prevalence continues to increase, likely due to changes in diagnostic criteria and improved recognition of the condition. When using the UK prevalence estimates, JIA children and FDR children remain significantly more likely to be diagnosed with ASC than the general population as a whole.

Future research should focus on confirming these findings in larger, population-based samples.

THU0508

LARGE VESSEL VASCULITIS IN A COHORT OF CHILDREN WITH RESISTANT KAWASAKI DISEASE IN SINGAPORE

L. Das1, 1J. H. T. Tan1, 1T. Arkachaisri1, 2JK Women’s and Children’s Hospital, Rheumatology & Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Singapore, Singapore

Background: Kawasaki Disease (KD) is one of the most common systemic vasculitides in children today. IVIG is the mainstay of treatment, however, about 1/5 of patients do not respond resulting in an increased risk of Coronary Artery Abnormalities (CAA) 1.
Objectives: To describe a cohort of infants and young children with resistant Kawasaki Disease (rKD) who were noted to have prolonged difficult courses with resultant CAA and ultimately diagnosed with Aortitis.

Results: Between 2010-2018, 63 out of 417 KD referrals were diagnosed with rKD. 7 children had prolonged time to CRP normalisation, prolonged admission or recurrence of symptoms (Table 2). All patients underwent Magnetic Resonance Angiography (MRA) and were found to have evidence of large vessel arteritis consisting of wall irregularity, thickness and contrast enhancement.

*patients A & B had recurrent KD episodes interspersed with short periods of symptom resolution.

Conclusion: While transthoracic echocardiograms remain imaging investigation of choice, for children with recalcitrant or recrudescent KD, especially in the setting of delayed CRP resolution of >2 weeks; an MRI should be considered.

References:

Background: Pediatric rheumatic diseases (PRD) have an important impact on different aspects of the patients' and caregivers' life, such as physical, emotional, economic, and social. Some studies have shown that parents of patients with PRD have important impact but there is a lack of information of this topic from Latinamerican countries.

Objectives: The aim of this study is to describe and analyze the impact of juvenile idiopathic arthritis (JIA), juvenile systemic lupus erythematosus (JSLE), and juvenile dermatomyositis (JDM) on Mexican primary caregivers.

Methods: This is a multicenter cross-sectional study conducted in third-level reference pediatric hospitals in Mexico from December 2018 to November 2019. We included primary caregivers of pediatric patients with JIA, JSLE, and JDM that were treated in participant centers.

CAREGIVERS questionnaire, a validated multiassessement tool to measure the impact of PRD on caregivers, was applied to the participants. Collection of social, demographic, and clinical data was also performed and correlated with questionnaire results.

Results: A total of 200 primary caregivers participates in the study (109 JIA, 26 JDM, and 63 JSLE), aged 38 (IQR 32 – 46), mostly women (84.5%), from 6 centers, representing 13/32 Mexican states (Figure). One third (78%) had a remarried job, 123 (61.5%) had a relationship, 77 (38.5%) reached high school or higher, and 131 (65.5%) spends more than one hour to get to the center. Patients cared aged 12 (IQR 9 – 16), mostly women (67%), 87 (43.5%) with active disease, 43 (21.5%) with any disability, 94% and 29% treated with DMARD and biologics, respectively.

Feelings of worry and sadness predominant at diagnosis that decreased over time (42.5% and 28.5% vs 9.5% and 31.5%, respectively) and changed for peace (44%). Concerns about disabilities were more frequent on JIA group (34%), while pain and economic issues in JSLE (47% and 30%, respectively). Most of the caregivers feel anxiety about the future of their patients (148, 74%), regardless of the diagnosis. Participants reported that the way they spend the time, social life, and personal health worsened since diagnosis (49.5%, 32%, 34.5%, respectively), especially in those with JSLE (60%, 39%, 46%). In 126 (63%) participants the economic situation worsened, 129 (64.5%) borrowed money (76% in JSLE, P = .03), 63 (31.5%) had problems to buy medications, 126 (63%) participants the economic situation worsened, 129 (64.5%) borrowed money (76% in JSLE, P = .03), 63 (31.5%) had problems to buy medications, 126 (63%) participants the economic situation worsened, 129 (64.5%) borrowed money (76% in JSLE, P = .03), 63 (31.5%) had problems to buy medications. 126 (63%) participants the economic situation worsened, 129 (64.5%) borrowed money (76% in JSLE, P = .03), 63 (31.5%) had problems to buy medications.

Conclusion: This work described the main impacted areas in life of primary caregivers of patients with PRD, showing a perspective of the burden of the disease.

DOI: 10.1136/annrheumdis-2020-eular.493
Background: Acute Rheumatic Fever (ARF) is an immunemediated multisystem disease that occurs about 2-5 weeks after Group A Streptococcus Pyogenes beta-hemolytic (GAS) pharyngitis. After a negative peak in the 1980s, following the introduction of antibiotic prophylaxis, the disease is currently recovering. Rheumatic carditis is one of the most worrying aspects as it is still one of the major causes of cardiovascular death in the young-adult population. However, if diagnosed early and treated, sequelae with aortic and mitral valve involvement can be prevented.

Objectives: The aim of our study is a description of Acute Rheumatic Fever in all its manifestations in a cohort of pediatric patients belonging to the Azienda Ospedaliero Universitaria Integrata Verona.

Methods: A retrospective analysis was conducted collecting all the cases of ARF, diagnosed by Jones's criteria, related to Pediatric Rheumatology and Pediatric Cardiology of Verona from January 2005 to December 2019. Demographic and clinical data were collected for all patients such as clinical presentation, disease evolution and cardiac involvement.

Results: 73 patients were analyzed, of whom 53 had an acute onset of ARF and 20 received a diagnosis of previous ARF due to indolent carditis. The prevalent age at the time of diagnosis in both groups was between 5 and 14 years of age. Among patients with acute onset, carditis was the most frequent major manifestation (94.3%), followed by polyarthritis (41.5%), chorea (24.5%) and erythema marginatum (75%). Only in one patient we could observe subcutaneous nodules (1.8%). Regarding the minor manifestations, the increase in inflammation markers was present in 83% of cases and fever was present in 75.5%, followed by arthralgia (58.4%) and prolonged of PR interval to ECG (9.4%). Carditis was also present in all 13 patients who presented chorea. Clinically, previously unknown heart murmur occurred in 28 patients. Therefore, the mismatch between cardiac objective and carditis finding is clear: infarct, compared to an important finding of carditis (50 patients) only slightly more than half of the patients (28 patients) showed an evident clinical finding. Finally, no correlation was found between the levels of the anti-streptolysin O titer and the severity of heart damage. Patients with early diagnosis of carditis were treated at onset with corticosteroid therapy according to the American Heart Association scheme and did not show valvular cardiac outcomes. A patient who received a late diagnosis of carditis currently presents a significant and permanent cardiac damage despite adequate steroid treatment undertaken at the time of diagnosis.

Conclusion: The description of this cohort of pediatric patients shows that the ARF has not disappeared in industrialized countries. Treatment of streptococcal infection (primary prophylaxis) plays a key role in preventing ARF. Of great impact is the prevalence of carditis which is present in 94.3% of patients. Early diagnosis is therefore of primary importance and the subsequent follow-up path, consisting of periodic therapy with penicillin (secondary prophylaxis) and periodic cardiovascular checks, greatly affects children's quality of life. Chorea, unlike what has been described in the literature, occurred simultaneously with the cardiac process, while the cutaneous manifestations (subcutaneous nodules and erythema marginatum), once pathognomonic of the rheumatic disease, are today of rare observation.

DOI: 10.1136/annrheumdis-2020-eular.45632
started in 2010. Patients from the age of 13 who were questioned about their health behavior and followed up for at least 2 years were selected. HRB were quantified and compared with those of subjects from the general population after matching for age and sex. Data from 2-year follow-up (FU) were used to analyze correlates of multiple risk behavior defined as involvement in two or more risky behaviors.

**Results:** A total of 209 adolescents with JIA (63% female, mean age at baseline 14.4±0.9, mean disease duration 2.6±2.0) and 138 healthy peers (55% female, mean age 14.5±1.0) were included. At baseline, 51% of patients were treated with a DMARD, 21% with a biologic (FU: 59% and 38%). The most common JIA category was rheumatoid factor negative polyarthritis (28%). While at baseline 20% of patients and 4% of controls did not engage in regular physical activity, the proportion at follow-up amounted to 16% and 10%, respectively (OR 3.69; 95% CI: 1.01-13.50). In both groups the proportion of regular smokers, alcohol consumers and drug users increased during the observation period. Significant group differences were found in terms of alcohol consumption and smoking habits, but not in relation to illicit and legal drugs (see table). Patients stated significantly more often that they had not used a condom during their last sexual intercourse (28% vs. 19% controls, p<0.05). Multiple risk behavior was associated with PedsQL™ total score (OR 0.96; 95% CI: 0.92-0.99) and disease duration (OR 0.75; 95% CI: 0.57-0.98).

**Conclusion:** Although adolescents with JIA became more physically active during the course of the disease, they are as likely, or more likely, to take risky behaviors than their healthy peers, except for alcohol consumption. In order to achieve optimal outcomes, addressing emotional wellbeing and providing mandatory anticipatory guidance appears to be warranted in this population.

---

**Methods:** Patients ever treated with DMARDs and prospectively observed in the JIA biologic registry JuMBO were asked about their drug consumption at each JuMBO visit. In addition, patients reported their current health status in terms of disease activity and pain (scored on numerical rating scales 0-10), functional ability (by HAQ) and quality of life (by SF-36). The Anatomical Therapeutic Chemical Classification System for medicinal products (ATC) was used to classify self-reported medication use. Local therapies, with the exception of ophthalmological drugs, and cough and cold remedies were not included.

**Results:** A total of 1,306 young adults (68% female) with JIA and a mean disease duration of 13.6±6 years (ys) were included in the analysis. The majority of them were classified as polycarticular-onset JIA (35.6%), 20.5% as enthesis-related arthritis.

At the last follow-up (FU), the patients’ mean age was 23.1±4.1 ys. They had received a mean of 2.6±1.4 DMARDs, 79% were ever treated with biologics. At FU, patients used on average 1.9±1.8 drugs. About one in five patients (296, 22.7%) reported no medication use at all, 367 (28.1%) reported only DMARD use. The most frequently reported drugs were DMARDs (84%), NSAIDs (48%), glucocorticoids (19%), followed by analgesics (10.6%), drugs for acid-related disorders (6.9%) and anti-infectives for systemic use (6.1%). Antidepressant drug use reported 3.4% and antihypertensive drug use 3.1% of the patients. Women used significantly more frequently NSAIDs, glucocorticoids, non-opiod analgesics and thyroid medication. There were 178 (14%) patients who received at least 3 other medications in addition to DMARDs. This patient group frequently reported the use of pain medication (74% NSAIDs, 23% non-opoid analgesics, 20% opioid drugs) and antidepressants (16%) and had been treated late with bDMARDs (7.4±4.9 ys after symptom onset). There were significant differences in drug usage between patients with various JIA categories (table). Moreover, the use of glucocorticoids, antihypertensives and antidepressants in adulthood (adjusted by propensity scores) increased with longer time from symptom onset to bDMARD start.

**Conclusion:** Self-reported medication use adds important information when assessing the long-term outcome of JIA. About 15% of JIA patients ever exposed to DMARDs, especially those with late start of bDMARD therapy, have a high medication or disease burden in young adulthood.

**DOI:** 10.1136/annrheumdis-2020-eular.1894
Background: Juvenile psoriatic arthritis (JPsA) is one of the clinical variants of juvenile idiopathic arthritis (JIA), which is often characterized by an unfavorable course, refractory to therapy, requiring the prescription of Biological agents (BA).

Objectives: of analysis of BA use in patients with JPsA and therapy survival, switching to another line of BA.

Methods: The retrospective cohort study included 1095 JIA patients who received BA and were observed in our clinic from 2004 to 2019. All cases of new onset psoriasis were collected; clinical features of disease onset and course, especially to Methotrexate (MTX) and BA, presence of ANA, HLA B27 were studied.

Results: among 1095 JIA patients who received BA over the past 15 years, a separate cohort of patients with JPsA for analysis was allocated. We identified 50 pts (57% female) aged 2-18 years (Mean 13.3) at the time of initiation of therapy. All patients met the JPsA classification criteria, the average age of arthritis onset was 7.4±5.3 years (ME 6.75). However, cutaneous psoriasis occurred only in 68 % (34 pts), with manifestation at the age of 10±5 years. In 25 of 34 pts (73.5%) the development of psoriasis was preceded by joint manifestations in an average of 5±3.9 (ME 3) years. 6 pts from 1095 (0.65%) developed psoriasis under BA therapy: infliximab - 2 cases (0.62/100PY), adalimumab - 3 (0.15/100PY), abatacept -1 (0.31/100PY), 2/6 pts was ANA+, 3/6 – HLA B27+.

Average age of disease onset was 9.8±7.8 years; BA exposure before psoriasis was 2.7±1.1 years and in 3.6±1.3 (ME 4) after the onset of arthritis. Therapy was continued in 4/6 pts; switched from infliximab to adalimumab in 2. Sero- causorbid pathology was associated with JPsA in 7 pts (type 1 diabetes mellitus – 2 pts; Down syndrome; endogenous mental illness (schizophrenia)); oligophrenia; ovariopathy; acute lymphoblastic leukemia in a state of incomplete remission). The clinical picture of the disease was represented by polyarthritis in 84%, oligoarthritis in 8%, the same number of patients 8% have had an axial lesion. Sacroiliitis was detected in 20 patients (40%), dactyliitis in 21 (42%), and uveitis in 10 (20%). HLA B27 was detected in 16/35 pts (45%), 32% pts were ANA-positive. The duration of the disease at the time of application of the first BA was 5±4 (ME 3.75) years. In 49 patients, BA was used in combination with methotrexate. The total number of BA courses switching included was 80 (inflimixab-19, adalimumab-22, etanercept-7, golimumab-6, abatacept-5, tocilizumab-2, rituximab-1). 49% of patients have experience of using >2 BA (16 pts-2 BA, 4 pts-3 BA, 1 pt - 5 BA). Primary/secondary inefficiency (18/35; 51%), adverse events (8/35; 23%), organizational difficulties in market access mostly after the age of 18 (7/35; 20%), and remission (2/35; 6%) were the reasons for the withdrawal of BA. Among the severe adverse events, multi- plex sclerosis was registered after 6 years of abatacept using (the relationship with the drug used has not been proven), pregnancy in the 3rd year of adalimumab use (interruption at 16 weeks); serious local reaction after etanercept using–1; infusion reactions (1-rituximab, 2-infliximab); uveitis de novo (2- etanercept).

Conclusion: JPsA is one of the most severe variants of JIA, characterized by a high proportion of serious co-morbid conditions, the development of refractory primary/secondary adverse events of BA, uveitis, multi-plex sclerosis, requiring switching to line 2 and 3 with a limited choice of BA with pediatric indications. Special study requires the manifestation of psoriasis de novo mainly developed during TNF-monoclonal antibodies therapy.

Thu0515 SYSTEMIC LUPUS ERYTHEMATOSUS IN CHILDHOOD AND ADOLESCENCE - UPDATE FROM THE NATIONAL PEDIATRIC RHEUMATOLOGY DATABASE

C. Sengel1, M. Niewerth1, G. Geissmeyer1, H. Klein2, F. P. Jansson3, M. Hufnagel4, K. Minden5, 1German Rheumatism Research Center, Berlin, Germany; 2Vivantes Klinikum im Friedrichshain, Berlin, Germany; 3Asklepios Klinik St. Augustin, St. Augustin, Germany; 4Dr. von Hauner’sches Kinderspital, München, Germany; 5University of Freiburg, Pediatrics, Freiburg, Germany

Background: Systemic lupus erythematosus (SLE) is a clinically heterogeneous disease, which begins in childhood and adolescence in 15 - 20% of cases. Since 2004, data on SLE have been collected by means of a disease-specific questionnaire as part of the National pediatric rheumatology database (NPRD) in Germany. Since 2009, SLE biopsy results have been recorded to further specify kidney involvement.

Objectives: Evaluation of clinical signs and symptoms, outcome and laboratory data of patients with juvenile systemic lupus erythematosus from a large database in Germany.

Methods: Data from patients with SLE recorded in the NPRD in 2017 were consequence of the analysis. In addition to age, sex, onset of disease, the criteria that led to the diagnosis, various laboratory parameters, organ involvement (current and/or tried) and therapy (current, last 12 months), current disease activity (numerical rating scale 0-10, NRS) and ECLAM (score 0-10) were recorded. Patient-reported outcomes included global assessments of overall-wellbeing and fatigue (NRS 0-10) and functional ability (CHAQ).

Results: 196 patients (86% female) with a median age of 16 years were documented. Criteria most frequently met at diagnosis included “antinuclear antibodies” (88%), followed by “anti-ds-DNA-Ab” (66%), “butterfly erythema” (42%) and “arthritis” (41%). A positive family history was found in 10% of patients. At documentation, 85% of patients received disease-modifying anti-rheumatic drugs, most frequently hydroxychloroquine (73%), followed by mycophenolate mofetil (32%) and azathoprine (17%). Systemic glucocorticoids obtained 52% of patients, 12% ≥ 0.2 mg/kg/day. Biologics (rituximab 2%) and cyclophosphamide i.v. (3%) were rarely administered during the last 12 months. Disease activity was reported as 1.0 (NRS, median, IQR 0 - 9), ECLAM as 10 (median, range 0 - 10). In the laboratory, leucopoenia < 3500/µl was found in 9% of patients, lymphopenia < 1500/µl in 47% and erythrocyte sedimentation rate (ESR) > 25-mm in 15% of patients. Mean CHAQ was 0.24, and 86% of patients had a CHAQ score < 0.5. Mean patient’s global assessment of overall-wellbeing was 1.5, while the mean fatigue score was 2.86 (18% NRS score 7-10).

The following organ involvement was ever present: general symptoms 84%, skin/mucosa 72%, joints 73%, thyroid 15%, muscle 25%, lungs 17% and CNS 30%. In 45/190 (24%) patients, a kidney involvement was stated. In 34 patients (75%) a kidney biopsy was performed and histology yielded the following results: Class 1: 6.7%, Class 2: 16.7%, Class 3: 40.0%, Class 4: 23.3%, Class 5: 13.3%.

Conclusion: The most common clinical symptoms documented in juvenile SLE patients were skin and joint involvement. In the course of the disease, a quarter of the patients developed kidney involvement, mostly proliferative nephritis. Apparently, azathoprine is increasingly being replaced by mycophenolate mofetil, biologicals have hardly been used so far. Although functional outcome and overall-wellbeing of SJLE patients was good, fatigue was a concern for some patients.

Thu0516 FIFTEEN CASES OF 3 NLR FAMILY MEMBERS (NLRP3, NLRP12 AND NLRC4) RELATED INFLAMMASOMOPATHIES IN A SINGLE CENTER OF CHINA

W. Wang1, Y. Zhou2, H. Song3, 1Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Department of Pediatrics, Beijing, China

Background: There are four members in NLR family, NLRP3, NLRC4, NLRP1 and NLRP12, the mutations of which can lead to autoinflammatory diseases, while little reports describe nephropathic diseases in Chinese population.

Objectives: To report several cases of NLR-related autoinflammatory diseases in our center and to compare the differences of the presentations of CAPS between Chinese and western patients.

Methods: This study was undertaken at Peking Union Medical College Hospital (PUMCH) between 2012 and 2019. Demographic data, clinical presentations and genetic results were collected.

Results: 15 patients had been diagnosed as NLR-related autoinflammatory diseases in our center, including 11 CAPS, 1 FCAS4 and 3 NLRP12-AD patients.

We found 10 NLRP3 mutations, 3 NLRP12 mutations and 1 NLRC4 mutation. There are 3 novel mutations: NLRP3 c.1311G>T, NLRP3 c.1711G>A, and NLRC4 c.514A>G.

The major symptoms of those diseases are similar, such as recurrent episodes of fever associated with rash. And some may suffer from arthritis/arthralgia, uveitis, sensorineural deafness, symptoms of central neural systems (CNS).

On the other hand, different inflammasomopathies have unique characteristics. Symptoms of FCAS1, the mildest CAPS disorder, including rash and fever with/without arthritis/arthralgia, usually develop in the first year of life. The onset age of MWS is later (8mo to 5y) and the patients were more likely to develop arthritis/arthralgia, eye involvement, hearing loss and symptoms of CNS. NOMID was the most severe type, and was presented with chronic urticarial-like rash shortly after birth, as well as severe CNS manifestations and musculoskeletal involvement. One of our NOMID patients had clubbing fingers, which was not reported before. The onset age of NLRP12-AD ranges from 6mo to 5y and the presentation is similar to MWS while the FCAS4 patient presented with rash and fever, like FCAS1.
For laboratory examinations, all patients had raised inflammatory markers like ESR or CRP. Most of those patients had increased cytokines, including IL-1, IL-6 as well as TNF-α. Leukocytosis and thrombocytosis were also observed in most patients, while anemia was mostly found in patients diagnosed as NOMID.

We also compared the clinical manifestations of CAPS between Chinese and western patients. The frequency of fever in Chinese is much higher than that in western population, while less Chinese patients suffered from ocular manifestations. Besides, Chinese patients seem to exhibit higher frequencies of severe symptoms, either CNS symptoms, or musculoskeletal symptoms, albeit with insignificant difference.

Conclusion: We reported a case series of NLR-related autoinflammatory disease and found some novel mutated alleles and clinical phenotypes, which expanded our knowledge to those diseases. By comparing clinical manifestations of CAPS patients in China and in western countries, it seems that the symptoms in different populations are not identical.

the proximal, middle and distal thirds of each joint head, respectively. The inter-observer agreement analysis was carried out in the semi-quantitative evaluation of the scores assigned in CT. The accuracy of DECT for the detection of BME compared to MRI was analyzed using the Receiver Operating Characteristics (ROC) curve method.

**Results:** 56 axial-SpA patients have been evaluated, 30 males and 26 females, a mean age of 48.6 ± 12.3 years, a mean disease duration of 5.5 ± 2.9 years, a mean C-reactive protein level of 3.0 ± 2.5 mg/dl. The inter-rater agreement of readers showed a high statistical significance greater than 0.80, in particular the weighted kappa is 0.815, with a standard error of 0.04 and a 95% variability coefficient between 0.73 and 0.89. Sensitivity, specificity, and positive likelihood ratio in the identification of BME at DECT were 95.8%, 83.3% and 6.67, respectively. The differences in mean CT number (HU) among the four levels of edema category were significant (p<0.0001). The AUC was 0.905 in the differentiation of areas with low-to-high inflammation.

**Conclusion:** We confirm the potential of DECT for the detection of BME of the sacroiliac joints in patients affected by SpA. This new method appears to be very useful, not only in the diagnostic phase, but also for the monitoring of patients.

**OPTIMAL USE OF CONTRAST ENHANCED MRI FOR CLINICAL TRIALS OF INFLAMMATORY DISEASES: RETROSPECTIVE ANALYSIS OF DATA FROM A PHASE IIIIB STUDY OF BARICITINIB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS**

M. Boesen1, M. Hinton2, J. Gonzalez-Zabaleta3, S. Beattie4, D. Schlichting4, T. Rooney5, O. Kubassova5. 1University Hospital Bispebjerg-Frederiksberg, Copenhagen, Denmark; 2Image Analysis Group, Philadelphia, United States of America; 3Image Analysis Group, London, United Kingdom; 4Eli Lilly and Company; Indianapolis, United States of America

**Background:** Magnetic resonance imaging (MRI) was used to confirm dose selection in a phase IIb clinical trial of baricitinib in patients with active rheumatoid arthritis (RA) on background methotrexate therapy (NCT01185353).[1] MRI data were retrospectively assessed for consistency, timing of post-contrast sequences following intravenous (IV) Gadolinium (Gd), and readability. Data were re-analyzed using a novel quantitative computer-aided methodology to extract the continuous volume of inflammatory changes.[2]

**Objectives:** The objective was to examine how image quality and timing of the post-contrast MRI sequence can impact MRI-based exploratory endpoints in RA clinical trials when using novel computer-aided analysis tools.

**Methods:** A total of 154 patients with definitive radiographic erosion had an MR image of the hand and wrist at baseline and at weeks 12 and 24. Three-dimensional T1-w fat-suppressed MRI sequences before and after IV Gd contrast were performed with dedicated coils. Due to the limited field of view, the coils were re-positioned during the image acquisition between the metacarpophalangeal (MCP) and finger joints and the wrist, following IV Gd injection, which introduced a time delay of the post-contrast sequences in the two anatomies in all patients.

**Conclusions:** Digital Imaging and Communications in Medicine (DICOM) headers of the MRIs were automatically assessed; the distribution of the time delay in minutes from Gd injection to post-contrast scan acquisition was calculated and the image quality and suitability for reading were evaluated (Figure 1). The time delays across MRI acquisitions at baseline and weeks 12 and 24 were also compared. Quality scores were assigned for each image using visual image quality assessment by an experienced reader blinded to treatment regimens, patient visits, and time after Gd. The images were categorized by quality based on total score. The reader used a proprietary software to pre-select regions of interest (ROI) around the wrist and MCP joints (MCP-2 to MCP-5) in all three timepoints as a batch, avoiding adjacent blood vessels and possible artifacts. From these ROIs, the normalized volume of inflammation (NormV) was calculated in each joint relative to a standardized ROI in the normal tissue. Quantitative Total Volume of Inflammation (QVI) was extracted automatically from all ROIs by counting the pixels that were enhanced two standard deviations above the intensity level of the normal muscle, allowing differentiation of areas with low-to-high inflammation.

**Results:** The timing of post-contrast images from Gd injection was closely linked to image quality. In up to 10% of MRI data, the delay from Gd injection to scan acquisition caused significant variation in signal intensities. This led to a perceived increase in enhanced synovial volume due to the known diffusion effects of the contrast media over time, which did not correspond to real size of the underlying synovial volume and pathology (Figure 2).

**Conclusions:** The acquisition of MRIs in RA trials should be done in a methodical and systematic manner, where the quality of MRI scans and the correct timing of post-contrast sequences are optimized. The incorporation of unacceptable quality data will impact the interpretation of RA clinical trial data, especially when novel computer-aided quantitative analysis methods for post-processing are used. Incorrect timing and inconsistency in image quality can be prevented by using coils covering the whole hand and/or a dynamic contrast-enhance (DCE)-MRI sequence immediately following IV Gd injection to ensure correct timing of the post-contrast MRI sequence.

DIFFUSE ENTHESISIS AND LOW-GRADE INFLAMMATION IN PATIENTS WITH METABOLIC SYNDROME: A CLINICAL AND ULTRASOUND STUDY

P. Falsetti, E. Conticini, C. Baldi, M. Bardelli, S. Gentilescchi, L. Cantarini, B. Frediani

1University of Siena, Rheumatology Unit, Siena, Italy

Background: Metabolic syndrome (MS) is a clinical condition characterized by central obesity and additional factors such as dyslipidemia, hypertension, raised fasting plasma. Scanty observations describe the association of MS with muscularkeletal conditions, such as entheseopathies and diffuse idiopathic hypertosis syndrome (DISH). Musculoskeletal ultrasound (US) has been applied to the study of entheses, but the real prevalence and characteristics of enthesal involvement in MS has yet to be clarified.

Objectives: The aim of our work was to study the US-defined enthesal changes in MS, to correlate the US enthesis scores to clinical characteristics, and to define a relation between MS-related enthesitis and the presence of concurrent DISH.

Methods: Sixty consecutive outpatients (24 males, 36 females, mean age 60 years), all fulfilling International Diabetes Foundation (IDF) criteria for MS, were also evaluated with multi-site bilateral US enthesal examination. Each patient underwent power Doppler (PD) US examination of twelve enthesal sites, using Essex MyoLab Twice with 6–18 MHz transducer. Enthesis was defined on the basis of OMERACT’s filter: inflammatory and structural changes. They were scored as a whole when present (score 1) or absent (score 0). The sum of entheses with inflammatory and structural damage was defined as “global inflammatory score” (GIs) and “global structural damage score” (GSDs) for each patient. The Leeds Enthesis Index (LEI) was also applied, and a spinal radiography was obtained for each patient to research concurrent signs of DISH satisfying Resnick and Niwayama criteria.

Results: Patients showed moderate overweight (mean BMI 29) and a diagnosis of type 2 diabetes was present in 24 (40%). A low-grade inflammatory state was demonstrated in MS (mean CRP 0.58 mg/dL, mean ESR 21.9mm/h). A high prevalence of US-defined enthesitis was noted in 52 patients (86%) and 127/720 entheses (17.6%). PD signals, were reported in 11 patients (18%) and 11/720 entheses (1.52%), and they were associated to clinical symptoms expressed as LEI (p=0.0138). Erosions, although rare (0.3% of entheses), were more frequent in males (p=0.001). Moreover, in 57 patients (95%) and 217 entheses (30%) structural damages were found. A correlation was found between GIs and GSDs and both BMI (p=0.0233 and p=0.0068 respectively), LEI (p=0.03 and p=0.0099 respectively), and type 2 diabetes (p=0.0248 and p=0.0156 respectively). In 28 patients (46%) a concurrent diagnosis of DISH was made. In multivariate regression analysis the best predictors for DISH were higher levels of CRP (p=0.038) and CRP and ESR (p=0.0428) and US global scores for enthesitis (p=0.0312 for Gls, p=0.0071 for GSDs).

Conclusion: This is the first study where diffuse enthesitis and enthesal structural damage are demonstrated with high prevalences in MS, comparable or also higher than those reported for SpA-related enthesitis. Our data, obtained using the most recent OMERACT’s definition for US-detected enthesitis (proposed for SpA), also suggest a low specificity of this definition, in consideration of the high prevalence of MS-associated enthesitis. Moreover PD was associated to enthesal pain expressed as LEI. Both GIs and GSDs showed a correlation with overweight and type 2 diabetes. As secondary result, this study demonstrated that almost half of patients with MS could have a concurrent diagnosis of DISH. Patients with DISH were older, with higher levels of inflammation, and higher scores of US-defined enthesitis. Our results suggest that MS and DISH could be strictly related; diffuse enthesitis with a low-grade inflammatory state should be regarded as potential factor of progression from MS towards a conclamed DISH.

EVALUATION OF LIVER FIBROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS UNDER METHOTREXATE TREATMENT. UTILITY OF FIBROSCAN AND BIOMARKERS IN ROUTINE CLINICAL PRACTICE

Background: Despite therapeutic advances in recent years, methotrexate (MTX) remains the gold standard for the treatment of rheumatoid arthritis (RA). Among the side effects that have been blamed on it are liver fibrosis (LF) and cirrhosis, although late studies have failed to show such a relation. The only validated test in the diagnosis of LF is biopsy. Given the relevance of MTX in the treatment of RA, it is important to evaluate non-invasive diagnostic options for LF such as transitional elastography (FibroScan, FS).

Objectives: To evaluate the percentage of LF in RA patients treated with MTX. Secondly, to assess the correlation between altered liver function, RA activity, and LF. To determine whether dose and/or duration of treatment with MTX may affect the development of LF in such patients.

Methods: We did a prospective study between February 2019 and January 2020. Patients affected of RA treated with MTX were included. Patients with basal liver disease (hepatitis B, hepatitis C and steatohepatitis), alcohol consumption, type I diabetes mellitus, chronic renal failure, heart failure, obesity and concomitant treatment with leflunomide or antiretrovirals were excluded. Demographic, clinical, analytical and therapeutic variables were collected. Liver fibrosis was assessed by FS in kilopascals (kpa) and using the APRI score. RA activity was assessed by DAS28 score. Continuous variables are described with mean and standard deviation (SD), and qualitative variables are shown with absolute value and percentage. Spearman’s and Mann-Whitney’s U tests were used for the bivariate analysis.

Results: Fifty patients were included (Table 1 and 2). Of these, 38 were women (76%) with mean age of 61.8 years (SD 11.7) and mean RA evolution time of 13.7 years (SD 8.2). The mean DAS28 at the visit was 2.39 (SD 1.1). The FS showed an average of 4.8 kpa and 21. The mean duration of treatment with MTX was 85.8 months (SD 93.3) and that of AD-MTX was 5414.6mg (SD 5011). Patients were divided into those with DA-MTX greater than 4000mg (21, 42%) and both BMI (p=0.0233 and p=0.0068 respectively), LEI (p=0.03 and p=0.0099 respectively), and type 2 diabetes (p=0.0248 and p=0.0156 respectively). In 28 patients (46%) a concurrent diagnosis of DISH was made. In multivariate regression analysis the best predictors for DISH were higher levels of CRP (p=0.038) and CRP and ESR (p=0.0428) and US global scores for enthesitis (p=0.0312 for Gls, p=0.0071 for GSDs).

Conclusion: This is the first study where diffuse enthesitis and enthesal structural damage are demonstrated with high prevalences in MS, comparable or also higher than those reported for SpA-related enthesitis. Our data, obtained using the most recent OMERACT’s definition for US-detected enthesitis (proposed for SpA), also suggest a low specificity of this definition, in consideration of the high prevalence of MS-associated enthesitis. Moreover PD was associated to enthesal pain expressed as LEI. Both GIs and GSDs showed a correlation with overweight and type 2 diabetes. As secondary result, this study demonstrated that almost half of patients with MS could have a concurrent diagnosis of DISH. Patients with DISH were older, with higher levels of inflammation, and higher scores of US-defined enthesitis. Our results suggest that MS and DISH could be strictly related; diffuse enthesitis with a low-grade inflammatory state should be regarded as potential factor of progression from MS towards a conclamed DISH.

THU0522
DIFFERENCES IN MUSCLE PROPERTIES IN GCA PATIENTS COMPARED TO HEALTHY CONTROLS AS ASSESSED BY QUANTITATIVE MRI
M. Farrow1,2,3, J. Biglands1,3, S. Tanner1,3, E. Hensor1,3, S. Mackie1,3, P. Emery1,3, A. L. Tan1,3, 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2School of Pharmacy and Medical Sciences, Bradford, United Kingdom; 3NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Giant cell arteritis (GCA) is a systemic inflammatory vasculitis that often presents with headaches and visual symptoms. It is a medical emergency as it can lead to permanent sight loss. Prompt treatment with high doses of glucocorticoids is often required. However, it has been shown that GCA patients on glucocorticoid therapy develop muscle weakness, known as glucocorticoid induced myopathy (1).

Quantitative MRI may be sensitive to detect the differences in muscle parameters between newly diagnosed GCA patients compared to healthy controls. MRI T2 is sensitive to fluid related to physiological changes at the molecular level, and is regarded as an indirect measure of muscle inflammation (2). MRI muscle fat fraction (FF) is useful for identifying myosteatosis (3). Diffusion tensor imaging (DTI) is sensitive to changes in muscle microstructure and may be useful in identifying changes to muscle fibres (4).

Objectives: To obtain preliminary estimates of the extent to which quantitative MRI-based measurements of muscle T2, FF, DTI and volume differ between newly diagnosed GCA patients and healthy controls. MRI T2 is sensitive to fluid related to physiological changes at the molecular level, and is regarded as an indirect measure of muscle inflammation (2). MRI muscle fat fraction (FF) is useful for identifying myosteatosis (3). Diffusion tensor imaging (DTI) is sensitive to changes in muscle microstructure and may be useful in identifying changes to muscle fibres (4).

Methods: MRI of the mid-thigh were acquired using Dixon imaging to assess FF, and isometric dynamometer to measure grip strength.

Results: 20 GCA patients (68.2±8.3 years, 14/20 female, mean ESR 26.9mm/h, mean CRP 39.6mg/L) were enrolled within 14 days of starting glucocorticoids: 15 returned at 3 months (mean ESR 17mm/h, mean CRP 5.7mg/L); 8 returned at 6 months (mean ESR 18mm/h, mean CRP 6mg/L). 20 directly age- and gender-matched HC also were recruited. T2 and FF were higher and muscle volume lower in the GCA patients at baseline compared to HC (fig 1 and 2). Within the hamstrings, the mean differences between GCA patients and HC for T2, FF and muscle volume were 2.2ms (95% CI 1, 4; p=0.09), 3.8% (95% 2, 5; p<0.001), and -166cm3 (95% CI 110, 210; p<0.001) respectively. There was no substantive difference in mean diffusivity or fractional anisotropy. Results in the quadriceps followed a similar trend. Following glucocorticoid treatment, there were no substantive changes to muscle fibres (4).

Objectives: To obtain preliminary estimates of the extent to which quantitative MRI-based measurements of muscle T2, FF, DTI and volume differ between newly diagnosed GCA patients and healthy controls. MRI T2 is sensitive to fluid related to physiological changes at the molecular level, and is regarded as an indirect measure of muscle inflammation (2). MRI muscle fat fraction (FF) is useful for identifying myosteatosis (3). Diffusion tensor imaging (DTI) is sensitive to changes in muscle microstructure and may be useful in identifying changes to muscle fibres (4).

Methods: MRI of the mid-thigh were acquired using Dixon imaging to assess FF, and isometric dynamometer to measure grip strength.

Results: 20 GCA patients (68.2±8.3 years, 14/20 female, mean ESR 26.9mm/h, mean CRP 39.6mg/L) were enrolled within 14 days of starting glucocorticoids: 15 returned at 3 months (mean ESR 17mm/h, mean CRP 5.7mg/L); 8 returned at 6 months (mean ESR 18mm/h, mean CRP 6mg/L). 20 directly age- and gender-matched HC also were recruited. T2 and FF were higher and muscle volume lower in the GCA patients at baseline compared to HC (fig 1 and 2). Within the hamstrings, the mean differences between GCA patients and HC for T2, FF and muscle volume were 2.2ms (95% CI 1, 4; p=0.09), 3.8% (95% 2, 5; p<0.001), and -166cm3 (95% CI 110, 210; p<0.001) respectively. There was no substantive difference in mean diffusivity or fractional anisotropy. Results in the quadriceps followed a similar trend. Following glucocorticoid treatment, there were no substantive changes to muscle fibres (4).

Conclusion: This pilot study suggests for the first time that muscle health may be affected in newly diagnosed GCA patients compared to age and gender matched HC, as demonstrated by higher T2 and FF, and lower muscle volume and muscle strength. These preliminary results show that muscle changes may occur in the early stages of GCA and persist throughout the disease duration. If these findings are confirmed, it will be important to consider interventions to improve muscle health in the treatment pathway for GCA.

THU0523
CLINICAL UTILITY OF TESTING CONVENTIONAL AND NON-CONVENTIONAL ANTI-PHOSPHOLIPID ANTIBODIES IN SUSPECTED OBSTETRIC ANTI-PHOSPHOLIPID SYNDROME
A. Ganapati1, J. K1, A. Nair3, A. Mathew2, R. Goel1, J. Mathew3, J. A. Prakash1, S. C. Nair3, D. Dandal1, 1Christian Medical College Hospital, Clinical Immunology and Rheumatology, Vellore, India; 2Christian Medical College Hospital, Microbiology, Vellore, India; 3Christian Medical College Hospital, Immunohaematology and Transfusion Medicine, Vellore, India

Background: Anti-phospholipid syndrome (APS) is an important cause for recurrent pregnancy losses (RPL). Conventional APS antibodies (aPLs) like lupus anti-coagulant (LA), anti-cardiolipin (ACL) and anti-beta 2 glycoprotein I (anti-β2 GP I) are not present in significant number of obstetric APS(OAPS) patients, leading to a state described as “sero-negative” OAPS (SNOAPS). Recent literature shows non-conventional aPLs like Anti- phosphatidylserine-prothrombin complex (Anti-PS-PT) and Anti-Annexin V (Anti-Ann V) can be positive in up to 50% of SNOAPS patients

Objectives: Testing the performance of conventional and non-conventional aPLs in suspected OAPS patients (obstetric events as defined in the Sydney classification criteria for APS)

Methods: We performed a retrospective chart review of 101 patients who underwent combined testing for non-conventional aPLs for suspected OAPS from May 2016 to November 2019 at our department. Patients were categorized into OAPS cases (n=50, median age 31 years) and controls (n=51, median age 30 years) based on their fulfillment of clinical definition of OAPS events defined by Sydney criteria. Conventional aPLs were tested by methods adapted in Sydney criteria and Anti PSPT / Anti Ann V were tested by commercial ELISA. The sample size(n=101) has 95% confidence interval with a margin of error of 10% for the objective of the study.

DOI: 10.1136/annrheumdis-2020-eular.6025
Results: 36 cases (72%) were ‘sero-positive’ & 14 cases (28%) were truly ‘sero-negative’ for conventional aPLs. 5 (35.7%) of the SNOAPS patients were positive for Anti-PSPT and/or Anti AnnV antibodies. Performance of the various aPLs in suspected OAPS is displayed in Table 1 & Figure 1.

Figure 1 showing the comparative diagnostic performance of Conventional aPL testing vs Combined testing along with non-conventional aPLs in suspected obstetric APS scenario.

Conclusion: In a delicate situation like RPL, performance of non-conventional aPLs on their own, though not as sensitive as conventional aPLs, still demonstrate better specificity. Non-conventional APLs can newly identify 1/3rd of SNOAPS as APS. The real value of testing Anti PSPT & Anti Ann V in RPL, is combined testing with conventional aPLs whereupon they improve the sensitivity and accuracy of diagnosis of OAPS by 10% & 4.4 % respectively, with only 1.9% drop in specificity. Non-conventional aPLs should be tested in SNOAPS.

THU0524 FACTORS EXPLAINING PATIENT PERSPECTIVE IN PSORIASIS AND PSORIATIC ARTHRITIS (PSA): THE ROLE OF INFLAMMATION AND STRUCTURAL DAMAGE DETECTED BY ULTRASOUND (THE ECHOPRO STUDY)

T. Gudu1, I. Padovano1, E. Mahe2, H. Gouze1, T. Gudu1, I. Padovano1, E. Mahe2, H. Gouze1.

Background: Patient reported outcomes (PROs) reflect patients’ opinion on disease activity, impact of disease, quality of life (QoL), and are essential in the assessment of PsA patients. PROs may be influenced by several factors other than disease activity and severity. Ultrasound (US) is an objective tool to evaluate joint inflammation and structural damage in PsA.

Objectives: This cross-sectional study aimed at evaluating the role of US-detected inflammation (synovitis, tenosynovitis, enthesitis) and structural damage (erosions, entheseophytes, cortical irregularities), to explain PROs in PsA and to compare that to psoriasis (PsO) patients with and without musculoskeletal (MSK) symptoms.

Methods: PsA (CASPAR criteria) [1], PsO with MSK symptoms without fulfilling CASPAR criteria (symptoPsO) and PsO with no MSK symptoms (asymptoPsO) were included. Socio-demographic characteristics, comorbidities, disease duration and treatment were collected. All patients underwent to: a) dermatological and rheumatologic assessment: PsO severity, swollen joint count (SJC), tender JC (TJC), number of dactylitis and enthesitis; b) US evaluation of joints, tendons and entheses according to OMERACT definitions[2], (figure 1); c) PROs assessment: fatigue, disability (HAQ) and QoL (SF36). Variables were compared across groups (chi square or one-way ANOVA test). Correlations were evaluated using Spearman’s test.

Results: 208 patients (76 PsA, 64 symptoPsO and 68 asymptoPsO) with similar socio-demographic characteristics and PsO duration were included (table 1). Except for enthesophytes, all US changes were significantly higher in PsA, followed by symptoPsO patients.

Across all 3 groups, all PROs correlated mainly with demographic variables, comorbidities, TJC, clinical enthesitis, skin severity, depression and fibromyalgia points (r=0.24-0.72). SymptoPsO and PsA showed better specificity. Non-conventional APLs can newly identify 1/3rd of SNOAPS as APS. The real value of testing Anti PSPT & Anti Ann V in RPL, is combined testing with conventional aPLs whereupon they improve the sensitivity and accuracy of diagnosis of OAPS by 10% & 4.4 % respectively, with only 1.9% drop in specificity.

THU0525

DIAGNOSTIC PERFORMANCE OF MAGNETIC RESONANCE IMAGING FOR DETECTING SUBCHONDRAL BONE EROSION OF SACROILIAC JOINTS IN PATIENTS WITH SUSPECTED SPONDYLOARTHRITIS

D. Ben Nessi1, H. Riahi2, H. Ferjani1, E. Labbeene6, D. Kaffel1, M. Bouaziz2, M. M. Kochir1, F. Ladeb2, W. Hamdi1. 1Kassab Institute of Orthopedics, Rheumatology, Mannouba, Tunisia; 2Kassab Institute of Orthopedics, Radiology, Mannouba, Tunisia

Background: The utility of structural lesions of sacroiliac joints (SIJ) for the early diagnosis of spondyloarthritis (SpA) has been well established by previous reports [1]. Computed tomography (CT) is usually the preferred modality to assess structural changes.

Objectives: The aim of this study was to evaluate the performance of magnetic resonance imaging (MRI) for detecting subchondral bone erosions of SIJ in patients with suspected SpA. SIJ CT findings were considered as the gold standard when interpreting results.

Methods: A cross-sectional prospective monocentric study included consecutive patients aged over 16 and consulting for symptoms suggestive of SpA from February 2014 to February 2017. Patients with a confirmed sacroiliitis on pelvic radiograph were not included. Eighty-one patients underwent CT and MRI of SIJ. Imaging findings were assessed consensually by 2 experienced musculoskeletal radiologists, blinded to the clinical and laboratory data. Erosion was defined as resorption or destruction of the subchondral bone. The sensitivity, specificity, positive and negative predictive values of MRI for detecting SIJ erosions were determined with CT results as gold standard.

Results: Fifty-four patients were enrolled: 13 men and 41 women. The average age at inclusion was 39.4 ± 10.6 years [16-59]. Cervical, thoracic, lumbar and buttock pain were noted respectively in 46.3%, 37%, 92.6%, and 57.4% of the patients. Sacroiliac compression test, distraction provocative test, sacral thrust test, Gaenslen’s test, Faber’s test (Patrick) and Mennell’s test were positive in 23.4% of patients. Erosions were detected by CT scan in 30 patients. MRI showed erosions in 18 of them. A significant association was found between CT and MRI results (p<0.0001), and between the presence of erosions and the diagnosis of SpA (p= 0.05 for CT and p= 0.012 for MRI). Sensitivity, specificity, positive and negative predictive values of MRI for detecting subchondral erosions were respectively estimated at 60%, 100%, 100% and 66.7%.

Conclusion: Erosions of SIJ appear in early stages of SpA and have been reported in 60-90% of patients with axial SpA after mean symptom duration of 2.5 years[2, 3], hence the importance of the detection of these structural lesions. In our study, despite its moderate sensitivity, MRI showed an excellent specificity for detecting subchondral bone erosions.

THU0526

MEASUREMENT OF RADIOLOGICAL JOINT WIDTH IS THE KEY IN ASSESSING HIP INVOLVEMENT OF HIPS IN ANKYLOSING SPONDYLITIS.

Q. Han1, Z. Zheng5, K. Zhang1, Z. Yu1, F. Yang1, Q. Liang1, P. Zhu1, X. Baralakos1, 1Department of Clinical Immunology, PLA Specialized Research Institute of Rheumatology & Immunology, Xijing Hospital, Fourth Military Medical University, Xi'an, China; 2Rheumazentrum Ruhrgebiet Heme, Ruhr University Bochum, Heme, Germany

Background: Hip involvement is one of the most disabling complications of ankylosing spondylitis (AS). Frequently, arthroplasty is necessary by the time symptoms appear.

Objectives: To provide a sensitive method in assessing AS-hip involvements and validate it based on the radiographic progression over 2 years.

Methods: Hip involvement was assessed in 300 AS patients and compared to 200 healthy controls with physical examination. Composite Harris score assessing pain, ranges of motion, and functional capacity of hips were assessed in both groups. Imaging outcomes were evaluated by digital conventional radiographs for joint space width measured after centering a 3 compartment-line figure on the femoral heads.

Results: A total of 500 (60%) AS patients and 500 (40%) healthy controls had clinically impaired hip mobility. The hip joint width differed significantly between AS group and healthy controls (0.93±0.54, range 5.41-3.5svs 4.83±0.74, range 6.72-3.56, P<0.0001). Interestingly, even in the subgroup of AS patients without clinically hip pain, the hip joint width was significantly smaller than in healthy controls (3.29±0.66, range 5.4-2.1 vs 4.83±0.74, range 6.72-3.56, P=0.001). Among these patients, the hip joint width was significantly smaller than in healthy controls (3.29±0.66, range 5.4-2.1 vs 4.83±0.74, range 6.72-3.56, P=0.001).

Conclusion: Of the 300 AS patients, almost no patients in the moderate pain group showed positive MRI (n=1, 1.2%). Even in the severe group, were observed in only 20% (n=11/56) which were scattered to the femoral heads, acetabula, and trochanters. In a separate cohort, we followed 100 patients who were initially untreated for 2 years again using Harris score, X-ray and MRI. With 2 years follow up, Harris score improved and hip joint width was significantly smaller than in healthy controls (n=60). To our knowledge, this is the first study to demonstrate that MRI of hip is superior to X-ray in identifying hip involvement in AS.

THU0527

FREQUENCY AND ANATOMIC DISTRIBUTION OF MAGNETIC RESONANCE IMAGING LESIONS IN THE SACRO-ILIAC JOINTS OF HEALTHY SUBJECTS AND PATIENTS WITH SPONDYLOARTHRITIS

S. Hecquet1, J. P. Lustig2, F. Verhoeven1, M. Chouk1, S. Aubry3, D. Wendling1, C. Prati1. 1University Hospital, Radiology, Besançon, France; 2University Hospital, Rheumatology, Besançon, France; 3University Hospital, Rheumatology Unit, Milan, Italy

Background: Lesions detected by magnetic resonance imaging (MRI) of the sacroiliac joints are critical to the diagnosis of non-radiographic axial spondyloarthritis (1). However, some lesions, such as bone marrow edema (BME), usually observed in patients with spondyloarthritis may be encountered in other conditions. BME have been described in patients with non-specific back pain, healthy subjects, women with postpartum and in athletes (2). Moreover, it has recently been shown that structural lesions of the sacroiliac joint, such as erosions and fat metaplasia, may be present in healthy subjects (3).

Objectives: To evaluate and compare the frequency and location of lesions (erosions, subchondral condensation, fat metaplasia, BME and ankylosis) on MRIs of the sacroiliac joint of healthy individuals and patients with spondyloarthritis.

Methods: This is a retrospective study conducted at the University Hospital of Besançon including 200 patients, each having received an MRI of the sacroiliac joints in coronal section and in T1 and Semicoronal short tau inversion recovery sequences. Two experienced readers evaluated the whole set of images to detect erosions, subchondral condensation, fat metaplasia, BME and ankylosis according to the definitions established by the Assessment of SpondyloArthritis MRI working group. We subdivided a sacroiliac joint into three segments, upper, medium and lower along the cranio-caudal axis. Within the middle segment, we retained 3 portions: anterior, intermediate, posterior along the ventro-dorsal axis. Overall, one sacroiliac joint contained five quadrants on the iliac side and five quadrants on the sacral side.

Results: Collected MRI of 200 patients (62% female), 96 patients had spondyloarthritis (mean age 37.4±11.8 years, 48% HLA-B27+), 104 subjects were unaffected by the disease (mean age 39.9±11.6 years, 11% HLA-B27+). Of the 96 spondyloarthritis patients, 62 (65%) had inflammatory buttock pain compared to 26 (25%) in the group without spondyloarthritis. BME was seen in 62 (65%) patients with spondyloarthritis mainly in the iliac quadrant of the intermediate middle segment and in 21 (20%) patients without spondyloarthritis predominantly in the antero-middle quadrant. There were equal BME in women and men with spondyloarthritis. Subchondral condensation occurred in 45% of patients without spondyloarthritis, mostly in the antero-middle quadrant and in 36% of patients with spondyloarthritis. Fat metaplasia was present in 35% of spondyloarthritis patients and in 23% of control patients. Erosions were seen in 31% of healthy patients and in 61% of patients with spondyloarthritis.

Conclusion: In this large retrospective cohort, we observed a significant frequency of inflammatory but also structural lesions on MRIs of sacroiliac joints from healthy patients, which could lead to the misdiagnosis of spondyloarthritis. Fine identification of the location of these lesions is crucial to avoid erroneous diagnosis.

NAILFOLD VIDEOCAPILLAROSCOPY REPORTING IN CLINICAL RESEARCH: INTERNATIONAL DELPHI BASED CONSENSUS

F. Ingegnoli1,2, T. Schioppo1,2, A. Herrick3, A. Sulhi4, F. Bartoli1,2, N. Ughi1, J. Pauling3, M. Cutolo4, V. Smith5 on behalf of EULAR Study Group on Microcirculation in Rheumatic Diseases and the Scleroderma Clinical Trials Consortium. 1G Pini Hospital, Clinical Rheumatology Unit, Milan, Italy; 2Università degli Studi di Milano, Milan, Italy; 3Division of Musculoskeletal & Dermatological Sciences, The University of Manchester, Manchester, United Kingdom; 4Research Laboratory, Academic Division of Clinical Rheumatology, University of Genoa, Genoa, Italy; 5University of Bath, Bath, United Kingdom; 6Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

Background: Nailfold capillaroscopy (NVC), a non-invasive technique to assess microcirculation, is increasingly being incorporated into rheumatological routine clinical practice. Currently, the degree of description of NVC methods varies amongst research studies, making interpretation and comparison between studies challenging. In this field, an unmet need is the standardization of items to be reported in research studies using NVC.

Objectives: To perform a Delphi consensus on minimum reporting standards in methodology for clinical research, based on the items derived from a systematic review focused on this topic.

Methods: The systematic review of the literature on NVC methodology relating to rheumatic diseases was performed according to PRISMA guidelines (PROSPERO CRD42018104660) to July 22nd 2018 using MEDLINE, Embase, Scopus. Then, a three-step web-based Delphi consensus was performed in between members of the EULAR study group on microcirculation in rheumatic diseases and the Scleroderma Clinical Trials Consortium. Participants were asked to rate each item from 1 (not appropriate) to 9 (completely appropriate).

Results: In total, 3491 references were retrieved in the initial search strategy. 2862 were excluded as duplicates or after title/abstract screening. 632 articles were retrieved for full paper review of which 319 fulfilled the inclusion criteria. Regarding patient preparation before the exam, data were scarce: 38% reported acclimatization, 5% to avoid caffeine and smoking, 3% to wash hands and 2% to avoid manicure. Concerning the device description: 90% reported type of instrument, 77% brand/model, 72% magnification, 46% oil use, 40% room temperature and 35% software for image analysis. As regards to examination details: 76% which fingers examined, 75% number of fingers examined, 15% operator experience, 13% reason for finger exclusion, 9% number of images, 8% quality check of the images and 3% time spent for the exam. Then, a three-round Delphi consensus on the selected items was completed by 80 participants internationally, from 31 countries located in Australia, Asia, Europe, North and South America. Some items reached the agreement at the second round (85 participants), and other items were suggested as important to consider in a future research agenda (e.g. temperature for acclimatization, the impact of smoking, allergies at the application of the oil to the nailbed, significance of pericapillary edema, methods of reporting hemorrhages, ramified and giant capillaries). The final agreement results are reported below:

**HIGHLY-SENSITIVE CARDIAC TROPONIN I AND BETA-2 GLYCOPROTEIN-I IGA ANTIBODIES INFORM THE UTILITY OF SCREENING AND FOLLOW-UP NON-INVASIVE CORONARY ATHEROSCLEROSIS EVALUATION AND OPTIMIZE CARDIOVASCULAR RISK ASSESSMENT IN RHEUMATOID ARTHRITIS**

G. Karposzai 1, S. Ormseth 1, E. Hernandez 2, M. Budoff 1, Lundquist Institute of Biomedical Innovation, Torrance, United States of America

**Background:** Occult coronary atherosclerosis burden predicts mid-term cardiovascular disease (CVD) events in rheumatoid arthritis (RA) above and beyond Framingham D’Agostino cardiac risk score (FRS-DA). Highly-sensitive cardiac troponin I (hs-cTnI) levels in blood associate with coronary plaque burden and event risk in RA. Moreover, IgA antibodies against beta2-glycoprotein-1 (a-b2GPI-IgA) – an atherosclerotic plaque antigen - in RA promote coronary plaque progression and moderate the effect of inflammation on CVD events. It is currently unclear when to recommend a screening, non-invasive coronary atherosclerosis evaluation in asymptomatic RA patients and whether such an assessment should be repeated.

**Objectives:** To explore whether either biomarker alone or their combination improved prediction of plaque presence on an initial coronary CT angiogram (CCTA) beyond FRS-DA score; to evaluate whether either biomarker predicted progression to extensive or obstructive plaque on an initial coronary CT angiogram (CCTA) beyond FRS-DA score; and late scleroderma pattern. To assess disease activity we use Manual Muscle Testing 8 (MMT8), Health Assessment Questionnaire (HAQ), Myositis Disease Activity Assessment Tool (MDAAT), Cutaneous Dermatomyositis Disease Area and Severity Index (CDAI), physician’s VAS, patient’s VAS, serum muscle enzymes levels. We divided patients into 4 groups: 1st group – 17 DM patients with active disease (8 of them with newly onset disease), 2nd group – 66.7% had early pattern, in the 3rd group – 27.3% patients with early and 19.2% had active and in the 4th group – 50% of patients presented with early pattern (p=0.001, χ²=31.87). Neovascular pattern was found significantly more often among patients with active DM (p=0.001) with no regard to the disease onset. No statistically significant difference in giant and ramified capillaries distribution was found.

**Conclusion:** According to our results, we can admit that the most common capillaroscopic finding was decreased NCD, which were significantly lower among patients with active DM, the same as microhemorrhages and neovascular and late scleroderma pattern. This data suggests that NCD, microhemorrhages and neovascular scleroderma pattern could be considered as biomarkers of DM activity but not PM, therefore more detailed research with larger numbers of patients are required.

**DOI:** 10.1136/annrheumdis-2020-eular.3139
in prediction accuracy between constructs was further assessed as integrated discrimination improvement (IDI). Similar AUC and IDI constructs evaluated the transition to obstructive or extensive atherosclerosis at follow-up in patients with baseline non-extensive or non-obstructive disease.

**Results:** High hs-cTnI (>15pg/ml) added to FRS-DA increased AUC from 0.717 to 0.731 (Figure 1A) and improved prediction accuracy for baseline plaque [IDI=0.041 (SE)=0.017, p=0.015]. In contrast, a-b2GPI-IgA did not [IDI=0.005 (0.006), p=0.47] and the combination offered no added benefit to the hs-cTnI model alone. Similar observations were made for CAC. Presence of a-b2GPI-IgA independently associated with coronary plaque progression (IRR=1.67 [95%CI 1.04-2.67]), whereas hs-cTnI did not. Likewise, a-b2GPI-IgA associated with transition to extensive or obstructive disease independently of FRS-DA (OR=13.48 [95%CI 2.09-86.99]). Notably, 71.4% of a-b2GPI-IgA positive patients with high hs-cTnI progressed to extensive or obstructive disease compared to 77% of a-b2GPI-IgA negative subjects with high hs-cTnI (p=0.008). Addition of a-b2GPI-IgA to FRS-DA in patients with prevalent non-extensive non-obstructive plaque increased AUC from 0.785 to 0.900 (Figure 1B) and significantly improved the prediction for development of obstructive or extensive atherosclerosis at follow-up [0.387, 0.13, p=0.003].

**Conclusion:** High hs-cTnI improved the risk of baseline plaque presence beyond clinical risk score and may trigger an initial non-invasive coronary atherosclerosis evaluation. A-b2GPI-IgA presence may justify a follow-up evaluation in patients with non-extensive, non-obstructive plaque at baseline to obstructive or extensive atherosclerosis at follow-up.

THEM ALL?

OBJECTIVES: To investigate whether bone scintigraphy with semiquantitative analysis in patients with early axial spondyloarthritides (axSpA) acts in the diagnosis of active bone formation by detecting osteoblast activities and visualizing the whole skeleton at once. Therefore, bone scintigraphy is a theoretically ideal imaging modality to predict abnormal bone growth of axial joints in patients with axSpA.

RESULTS: Multivariate regression analysis revealed obesity (P = 0.023), current smoking status (P = 0.012), and high SIS ratio of bone scintigraphy (P = 0.015) as independent predictors for worsening mSASSS by at least 2 units over 2 years. For new syndesmophyte growth/bridging of pre-existing syndesmophytes over 2 years, current smoking (P = 0.013), high SIS ratio of bone scintigraphy (P = 0.025), and pre-existing syndesmophyte (P = 0.036) were independent predictors.

CONCLUSION: Semiquantitative analysis of bone scintigraphy (high SIS ratio) in patients with early axSpA may be useful for identifying patients at high risk for structural spinal damage progression over 2 years.

LUNG ULTRASOUND IN PATIENTS WITH SECONDARY INTERSTITIAL LUNG DISEASES

E. Krilova1, N. Shamsutdinova1, G. Nurullina1. Kazan State Medical University; Hospital Therapy Department, Kazan, Russian Federation

Background: Currently, lung ultrasound (LUS) is increasingly used in pulmonology. This study was designed to evaluate the usefulness of LUS in patients with the secondary interstitial lung disease.

Objectives: To evaluate the relationship between lung ultrasound and pulmonary function test and disease activity in patients with rheumatic diseases with secondary lung involvement.

Methods: Thirty patients with rheumatic diseases were included in the study, who, according to the data of the high-resolution CT of lungs (64-slice CT system Philips Diamond Select Brilliance), showed interstitial lung involvement as a type of nonspecific interstitial pneumonia. In 4 patients, mixed connective tissue disease (MCTD) was diagnosed, 20 had systemic vasculitis (SV), and 6 had rheumatoid arthritis (RA). The mean age of the patients was 56.5±10.9, the duration of the disease was 2.3±1.2 years. All patients underwent a standard clinical examination, the following indices and scales were used to assess the activity of the underlying disease: VDI damage index, Birmingham systemic vasculitis activity scale (BVAS), RA activity scale (DAS 28-CRP). The functional state of the lungs was assessed using spirometry, bodyplethysmography, gas diffusion “single breath”. LUS was carried out for the evaluation of the location and number of B-lines on both right and left hemithoraces using commercially available echographic equipment with a 5-12 MHz linear transducer (Accuvix A30, Samsung Medison).

Results: Most patients had an average number of B-lines 24,5±11,5,3±4,0. There were no significant differences in the number of B-lines between groups of patients of different nosologies. The total number of B-lines correlated with the index of activity of systemic vasculitis BVAS (r=0.05; r=0.03). There were no statistically significant correlations with clinical manifestations of pulmonary involvement.

Conclusion: Lung ultrasound may be useful in screening secondary lung involvement in patients with rheumatic diseases with high activity.

THU0535 ARE THERE DISCRIMINATING FEATURES BETWEEN “SCLERODERMA” AND “SCLERODERMA-LIKE” CAPILLAROSCOPIC PATTERN?

S. Lambova1, 2, U. Müller-Ladner3, 4, 1Medical University - Plovdiv; Department of Propaedeutics of Internal Diseases, Plovdiv, Bulgaria; 2MHAH “Sveti Mina”, Department in Rheumatology, Plovdiv, Bulgaria; 3Justus-Liebig University Giessen, Department of Internal Medicine and Rheumatology, Giessen, Germany; 4Campus Rheum, Department of Rheumatology and Clinical Immunology, Bad Nauheim, Germany

Background: The “scleroderma” type capillaroscopic pattern is a diagnostic criterion of the EULAR/ACR scoring system for systemic sclerosis (SSc). In addition, the validated staging system of Cutolo et al. is used that categorizes the capillaroscopic changes into an “early”, “active” and “late” phase. A “scleroderma-like” capillaroscopic pattern can also be observed in a number of rheumatic diseases, i.e., dermatomyositis (DM), systemic lupus erythematosus (SLE), undifferentiated connective tissue diseases, overlap syndromes, and rheumatoid arthritis (RA).

Objectives: To evaluate the categories “early”, “active” and “late” in “scleroderma-like” capillaroscopic pattern in rheumatic diseases different from SSc and to assess the presence of discriminating features between “scleroderma” and “scleroderma-like” capillaroscopic pattern.

Methods: 544 capillaroscopic images that showed a “scleroderma” and “scleroderma-like” pattern have been analysed from the following groups: 405 images from 42 SSc patients, 66 images from 4 patients with DM, 37 images from 9 RA patients and 36 images from 3 SLE patients.

Results: 30 of the images obtained from SSc patients demonstrated an “early” phase capillaroscopic pattern, 284 an “active” phase, and 29 a “late” phase. In 62 images, neoangiogenesis could be observed in images from an “active” phase capillaroscopic pattern that could be classified as “active-to-late phase of transition”. Among the 66 images from DM patients, 43 capillaroscopic pictures revealed an “active” phase and 23 - neoangiogenic capillaries with giant capillary loops, capillary loss and derangement (“active neoangiogenic” pattern). An “early” and “late” phase capillaroscopic pattern was not present in this group. The images from SLE patients (n=36) could be classified into the following groups: 3 images “early” phase, 29 images “active” phase, and 4 images with neoangiogenesis during the active phase. A “late” phase capillaroscopic pattern was not observed. In the group of capillaroscopic pictures from RA patients (n=37), an “early” phase could be observed in 11 images (8 out of 9 patients) and an “active” phase in 3 images (2 patients). 23 of the images from RA patients demonstrated evidence of neoangiogenesis associated with mild capillary derangement, moderate capillary loss, and single giant capillaries (“advanced neoangiogenic” pattern).

Conclusion: In conclusion, an “early” phase “scleroderma” pattern is present in RA and SLE patients, but obviously not in DM patients. An “active” phase “scleroderma” pattern was found in all three patients groups other than SSc i.e., DM, SLE and RA. In DM, profound neoangiogenesis is also a characteristic finding. In RA, advanced neoangiogenesis with moderate deravascularization and single giant capillaries could also be documented. A classic “late” phase “scleroderma” pattern was found only in SSc patients and was not observed in other rheumatic diseases i.e., SLE, RA, DM. The results of the current study suggest presence of differences between “scleroderma” and “scleroderma-like” capillaroscopic pattern that may reflect different pathogenic mechanisms of microvascular damage.

THU0536 ASSOCIATION BETWEEN OVERWEIGHT/OBESITY AND DISEASE ACTIVITY ON BONE SCINTIGRAPHY IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. M. Lee1, J. W. Lee2, 1Seochunchang University Cheonan Hospital, Cheonan, Korea, Rep. of (South Korea); 2International St. Mary’s Hospital, Catholic Kwandong University College of Medicine, Incheon, Korea, Rep. of (South Korea)

Background: In previous studies, obesity is highly prevalent in patients diagnosed with rheumatoid arthritis and it is positively associated with disease activity1. Although Tc-99m-labeled bone scintigraphy has been widely performed to evaluate the disease activity of the joints involved in this disease2; the effect of body mass index (BMI) on the results of bone scintigraphy is yet to be assessed.

Objectives: In the present study, we evaluated the relationship between BMI and uptake intensity of the joints that was measured using bone scintigraphy in patients with rheumatoid arthritis.

Methods: A total of 80 patients (21 men and 59 women; mean age 56.1±14 years) with rheumatoid arthritis who underwent Tc-99m methylene diphosphonate bone scintigraphy before treatment were enrolled in this study. Data were collected for baseline BMI and disease activity score for the 28 joints using erythrocyte sedimentation rate (DAS28-ESR) of these patients. Uptake intensity of these 28 joints was automatically measured for each patient using an in-house software, expressed as joint uptake-to-background normal bone uptake ratio (joint uptake ratio). The correlation of BMI with DAS28-ESR and joint uptake ratio on bone scintigraphy was assessed.

Results: Mean BMI of the enrolled patients was 24.4±3.7 kg/m² and 50 patients (62.5%) were classified as overweight/obesity. BMI was significantly positively correlated with the sum of 28 joint uptake ratios on bone scintigraphy (p=0.021, correlation coefficient=0.358) as well as DAS28-ESR (p=0.030). Patients with overweight/obesity (39.2±9.5) had significantly higher values of the sum of 28 joint uptake ratios than the other patients (33.9±8.5, p=0.025). In correlation analysis with each joint uptake ratio of 28 joints, BMI more significantly positively correlated with uptake ratios of shoulder, elbow, and knee joints than those in wrist and hand joints. In subgroup analysis of patients having low (DAS28-ESR ≤3.2) and high (DAS28-ESR >3.2) disease activity, BMI still showed significant positive correlation with the sum of 28 joint uptake ratio on bone scintigraphy in both subgroups (p<0.05 for all).

Conclusion: The baseline BMI in patients with rheumatoid arthritis had significant positive correlation with joint uptake intensity measured on bone scintigraphy, especially for large joints. The results of our study might provide an evidence that supports an association between BMI and disease activity of rheumatoid arthritis.

THU0537 VALIDITY AND DIAGNOSTIC PERFORMANCE OF FLUORESCENCE OPTICAL IMAGING MEASURING SYNOVITIS IN HAND OSTEOARTHRITIS. RESULTS FROM THE NOR-HAND STUDY.

O. Maugenstern1, 2, A. Mattiessen1, H. B. Hammer1, 2, T. K. Kvien1, 2, S. V. Hestetun1, T. Uhlig1, 2, S. Ohrndorf3, I. K. Haugen1, 1Diakonhjemmet Hospital, Oslo, Norway; 2University of Oslo Faculty of Medicine, Oslo, Norway; 3Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany

Background: Fluorescence Optical Imaging (FOI) demonstrates enhanced microcirculation in finger joints as a sign of inflammation.

Objectives: We wanted to assess the validity and diagnostic performance of FOI measuring synovitis, comparing it with Magnetic Resonance Imaging (MRI)- and ultrasound-detected synovitis in persons with hand osteoarthritis (OA).

Methods: Two hundred and twenty-one participants (88% female, age (SD) 60.6 (6.2) years) with hand OA from the Nor-Hand study underwent FOI and ultrasound-detected synovitis in persons with hand osteoarthritis (OA).

Results: Validity and diagnostic performance of FOI imaging was assessed, comparing it with Magnetic Resonance Imaging (MRI)- and ultrasound-detected synovitis in persons with hand osteoarthritis (OA).

Acknowledgments: Research relating to this abstract was funded by the National Research Foundation of Korea (NRF) grant funded by the Korea government (Ministry of Science and ICT) (grant number: NRF-2018R1C1B5004061).

THU0538
MRI-defined synovitis (grade 0-3) in the DIP, PIP, MCP and CMC-1 joints of the dominant hand and the severity of GS synovitis (grade 0-3) and PD activity (grade 0-3) in the same joints of the hands bilaterally. Spearman's rho was calculated for correlations between sum scores of all joints for FOI, MRI and ultrasound and sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV) and area under the curve (AUC) for FOI using MRI and ultrasound as reference.

Results: Despite frequent MRI and ultrasound findings in the CMC-1 joint, no FOI enhancement was detected in the thumb base, and CMC-1 was excluded from the analyses. FOI had poor to fair correlations with MRI and GS synovitis and PD activity. The strongest correlation with MRI was found for PVM in the PIP joints with Spearman's rho of 0.32, while the DIP joints had consistently the weakest correlations ranging from 0 to 0.14 (Figure 1). None of the FOI phases or PVM demonstrated both good sensitivity and specificity, and AUC remained low with both MRI and GS synovitis as a reference (table 1). The NPVs of FOI were consistently higher when GS synovitis was used as reference rather than MRI, due to higher frequency of low degree MRI-defined synovitis. However, when changing cut-off for MRI synovitis as reference from grade 1 to grade 2 the diagnostic performance of FOI increased to the level of GS synovitis. The diagnostic performance for FOI was similar with both GS synovitis and PD activity as reference.

FOI: Fluorescence optical imaging; PVM: Prima Vista Mode; GS: Grey scale; PVM: Prima Vista Mode, PPV: Positive Predictive Value, NPV: Negative Predictive Value, AUC: Area under the curve.

Conclusion: FOI sum scores showed poor to fair correlations with MRI- and ultrasound-detected synovitis in persons with hand OA. These findings might be explained by the low-grade inflammation with minor vascularization in the majority of inflamed joints. None of the FOI phases or PVM demonstrated both good sensitivity and specificity and the method was not able to detect CMC-1 synovitis.

THU0538 IN PSORIATIC ARTHRITIS PATIENTS CONSIDERED IN REMISSION BY THEIR RHEUMATOLOGIST, CAN DISCORDANCE IN DISEASE ACTIVITY ASSESSMENT BETWEEN PATIENT AND RHEUMATOLOGIST BE EXPLAINED BY RESIDUAL INFLAMMATION AS MEASURED BY ULTRASONOGRAPHIC EXAMINATION?

M. Mol
C. Lukas
J. Morel
B. Combe
G. Mouterde
1Rheumatology Department, CHU Montpellier, Univ Montpellier, Montpellier, France, montpellier, France

Background: Psoriatic arthritis (PsA) is a heterogeneous disease and its assessment is sometimes difficult. Perception of disease activity by patient and physician is frequently discordant in patients in clinical remission. Ultrasound (US) is an imaging technique, which can detect inflammation in PsA.

Objectives: The aim of our study was to assess whether persistence of disease activity evaluated by the patient, considered in remission by his rheumatologist, was associated with inflammation measured by US.

Methods: We performed a transversal monocentric study. PsA patients were included if they met the CASPAR criteria and were considered in remission by their rheumatologist. Demographic data, characteristics of the disease and treatments were collected. Discordance was defined by a difference between patient’s and rheumatologist’s global assessment ≥30/100 on a Visual Analog Scale. An US examination was performed on 50 joints, 28 tendons and 14 entheses by an independent investigator. Synovial or tendon sheath hypervascularity and PD signal were evaluated on a semi-quantitative scale. B Mode and PD signal abnormalities on entheses were searched, according to the EULAR-OMERACT scoring system. US remission was defined by no power Doppler (PD) signal on joints, tendons and entheses and minimal US activity by maximum one PD signal on the same sites. Univariate and multivariate analyses were performed to evaluate factors associated with US abnormalities.

Results: Sixty-two PsA patients were included. 40.3% were women, the mean (SD) age was 55 (14) years, 42% were in US remission and 71% in minimal US activity (Table 1). 19.4% had ≥1 PD synovitis and 88.7% had a B mode synovitis, 95.2% had a B mode abnormality on entheses and 51.6% had ≥1 PD signal on entheses. Thirty nine percent had a discordant disease activity assessment with their rheumatologist. In univariate analysis, discordance was not associated with US remission (OR=1.71 (95%CI 0.61-4.83), p=0.224) or US minimal disease activity (OR=0.99 (95%CI 0.32-3.05), p=0.602). In multivariate analysis, US remission was independently associated with female gender (OR=3.94 (95%CI 120-12.9), p=0.024) and younger age (OR=0.95 (95%CI 0.91-0.99), p=0.027). Minimal US activity was associated with history of enthesitis lesion (OR=11.26 (95%CI 1.34-94.93), p=0.028) and age (OR=0.95 (95%CI 0.90-1), p=0.044).

Conclusion: Our study showed persistent inflammation evaluated by US in PsA patients considered in remission by their rheumatologist. However, prevalence of residual inflammation evaluated by US was not higher in patients with self-assessment of their disease discordant from their rheumatologist.

Disclosure of Interests: Marie Mol: None declared, Cédric Lukas: None declared, Jacques Morel: None declared, Bernard Combe Consultant of: Novartis, Pfizer, Roche-Chugai, Consultant of: AbbVie; Gilead Sciences, Inc.; Janssen; Eli Lilly and Company, Pfizer; Roche-Chugai; Sanofi, Speakers bureau: Bristol-Myers Squibb; Gilead Sciences, Inc.; Eli Lilly and Company; Merck Sharp & Dohme; Pfizer; Roche-Chugai; UCB, Gael Mouterde: None declared DOI: 10.1136/annrheumdis-2020-eular.2570
Background: Clinical assessment of swollen joint count (SJC) in rheumatoid arthritis (RA) might be affected by obesity in terms of obesity-related excess adipose tissue.

Objectives: To compare the level of agreement between synovitis evaluated by Power Doppler ultrasound (PDUS) and clinical examination (SJC as component of SDAI) in obese (O) (i.e. Body Mass Index (BMI) >30) versus non-obese (NO) (BMI<30) RA patients.

Methods: RA patients ≥18 years fulfilling 2010 ACR-EULAR criteria were included in the cross-sectional multicentre (13 centres) French observational RABODY study (ClinicalTrials.gov Identifier: NCT03004651). Clinical synovitis was evaluated on 44 joints. ESR and CRP were collected and SDAI, DAS28, were calculated. A standard US examination on 44 joints was performed by an independent investigator blinded to clinical data. US synovitis was defined by a synovial hypertrophy ≥1 and PD signal≥1 on a semi-quantitative scale according to the EULAR-OMERACT scoring system. Levels of agreement between number of synovitis defined by PDUS and clinical examination were compared in O versus NO patients using Chi2 test, and Kappas (k) and ORs were calculated. A patient was considered “discordant” if ≥1 joint was discordantly classified by PDUS and clinical examination. SDAI was calculated and compared, with SJC defined either by clinical examination or PDUS.

Results: 121 patients were included: mean (SD) age of 58.5 (12.7) years, mean disease duration of 11.1 (9.7) years. 81% were female, 84.3% anti-CCP positive, 63.6% had erosive disease. Mean SDAI was 12.6 (±10.2), S3 (43.8%) had a BMI >30 and 68 (56.2%) ≥30.59 (47.7%) and 62 (51.2%) had a SDAI≥11 and ≥1, respectively. The 2 groups were comparable, except for weight (mean (SD) 65.4 (13.5) vs 96.7 (14.7) kg, p<0.001), some comorbidities (diabetes, asthma and fibromyalgia more frequent in O patients), tender joint count (mean 4.0 (±5.23) in NO vs 7.38 (±8.64) in O, p=0.021). Mean number of SJC was 2.4 (3.3), and PDUS 6.7 (±6.3). Levels of agreement between clinical and PDUS findings were comparable in O vs. NO patients regarding SDAI and other scores (Table). Patients with ≥3 discordant joints were numerically higher in O patients compared to NO (26/53 (49.1%) vs 22/68 (32.4%), p=0.062). At the joint level, discordance was higher in O patients in MCP4 (p=0.057), wrist (p=0.089).

Conclusion: In RA patients, despite a perceived higher difficulty to clinically detect SJ in O patients, the discrepancy between clinically- and PDUS defined synovitis was not significantly higher than in NO patients, and did not impact the extend of the definition of disease activity level.
Conclusion: Tc 99m tilmacncept imaging of the joints in healthy subjects as well as in patients with active RA under stable treatment is reproducible and stable over time. The results confirmed that the signal in joints of healthy subjects and RA patients can be quantified and used to establish cut points to distinguish inflamed and non-inflamed joints on a joint-by-joint basis. These results provide the foundation for a noninvasive, objective method to monitor activity in macrophage-driven inflammation in joints of patients with RA.

ANATOMICAL LOCATION OF SACROILIAC JOINT MRI LESIONS IN PATIENTS WITH AXIAL SPONDYLOARTHROPATHIES, POSTPARTUM WOMEN, PATIENTS WITH DISC HERNIATION, CLEANING STAFF, RUNNERS AND HEALTHY PERSONS

S. Sever1, M. Østergaard1, L. Morsel-Carlsen2, I. J. Sørensen1, B. Bonde3, G. Thamsborg1, J. J. Lykkegaard1, S. Juhl Pedersen4.

Background: Bone marrow edema (BME) on sacroiliac joint (SIJ) MRI is central in the Assessment of SpondyloArthritis International Society classification criteria for axial spondyloarthritis (axSpA). However, BME can be seen in other conditions and healthy persons. The presence of structural lesions may contribute to diagnosing axSpA.

Objectives: To investigate the location and distribution of SIJ MRI lesions in patients with axSpA and disc herniation, women with and without post-partum pain (PPP), cleaning staff, runners, and healthy persons.

THU0542 THE IMPACT OF GLUCOCORTICOID INITIATION ON THE DIAGNOSTIC ACCURACY OF ULTRASOUND IN GIANT CELL ARTERITIS: EXPERIENCES FROM A DISTRICT GENERAL HOSPITAL IN THE UK
J. T. Szé1, J. Dawson1, 1St Helens and Knowsley Teaching Hospitals NHS Trust, Rheumatology, St Helens, United Kingdom

Background: Temporal and axillary artery ultrasound (US) has been recommended by EULAR as the first-line investigation in patients with suspected giant cell arteritis (GCA).1 US is reported as having a 77% sensitivity and 96% specificity for GCA. However, these figures have largely been derived from studies carried out in specialist centres where US was performed rapidly following the onset of symptoms. When performed by highly experienced sonographers, halos can still be detected on US weeks after initiation of glucocorticoid treatment.2 Little is known about the relationship between the dose and duration of glucocorticoid and diagnostic accuracy of US in real-world experience.

Objectives: We evaluated the impact of glucocorticoid initiation on the diagnostic accuracy of US in patients with suspected GCA in routine clinical practice in a district general hospital setting.

Methods: This is a single-centre retrospective study of all temporal and axillary arterial US performed since its inception in November 2015 until October 2019. Patients who were aged ≥50 years and assessed by a rheumatologist were included in the study. US was performed by either a musculoskeletal consultant radiologist, musculoskeletal sonographer or vascular sonographer. US was considered positive for GCA when a halo, occlusion or stenosis was seen. Patients’ medical records and investigation results were reviewed in a systematic manner. The reference standard for GCA was the final clinical diagnosis after a minimum of 3-month rheumatological follow up.

Results: 311 US performed on 305 patients were included. 62% of the scans were requested by rheumatologists, the rest by ophthalmologists and general physicians. 57 of these episodes had a final clinical diagnosis of GCA. US had an overall sensitivity of 39% and specificity of 100% for GCA. Overall positive and negative predictive values were 100% and 88%, respectively. Sensitivity was 31% for US done in the first 2 years (n=160) which was lower than sensitivity of 45% in the latter 2 years (n=151) (p=0.2663). Specificity remained the same in the two periods. When performed on patients who were not on any glucocorticoids, US had a sensitivity of 89% which was significantly higher than sensitivity of 29% in those who had been treated with any dose or duration of steroids (p=0.0007).

Compared to US-negative GCA patients, US-positive GCA patients are older and more likely to have jaw claudication (Table 1).

THU0544 MULTIMODAL PHOTOACOUSTIC/ULTRASONIC IMAGING SYSTEM: A NEW IMAGING METHOD FOR EVALUATING RA
C. Zhao1, Q. Wang2, X. Tao1, C. Yu3, S. Liu1, M. Li4, T. Xuan2, Z. Qi1, J. Li1, F. Yang1, L. Zhu5, X. Zeng6, M. Yang7, Y. Jiang8, C. Zhao1, Q. Wang2, X. Tao1, C. Yu3, S. Liu1, M. Li4, T. Xuan2, Z. Qi1, J. Li1, F. Yang1, L. Zhu5, X. Zeng6, M. Yang7, Y. Jiang8, 1Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Sciences, Department of Ultrasound, Beijing, China; 2Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Sciences, Department of Rheumatology, Beijing, China; 3Shenzhen Mindray Bio-Medical Electronics, Shenzhen, China

Background: Photoacoustic imaging (PAI), a new imaging technique which can be integrating with ultrasound (US) imaging, has shown potential in visualizing small joints. We have developed a multimodal photoacoustic/ultrasound (PA/US) imaging system, equipped with a handheld probe, which can provide dual-wavelength PA/US imaging to identify the micro-vessels of the inflamed articular regions and measure the oxygenation level of human inflamed synovium.

Objectives: To validate the potential value for RA of the imaging system.

Methods: A total of 32 RA patients received PA/US examination on seven small joints (MCP2, MCP3, PIP2, PIP3, MTP2, MTP5, and wrist of the clinically dominant side). The 0-3 score was used to semi-quantify the PA and PD signals of the inflammatory articular lesions, and the sums of PA and PD scores (PA-sum and PD-sum) were utilized. The relative oxygen saturation (SO2) values of the inflamed regions were measured by calculating the ratio of PA signals at the wavelength of 750nm and 830nm. All the patients were classified to 3 PA+SO2 patterns (Pattern 1: no or minimal PA signals; Pattern 2: evident PA signals and hyperoxia; Pattern 3: evident PA signals and hypoxia). The correlations between imaging scores and laboratory data, as well as clinical scoring systems were assessed.

Results: A total of 32 patients of RA were recruited aged from 25-71 years-old were examined. PD-sum had moderate correlation with the clinical scores (r=0.529, 0.546, 0.490, 0.493 for DAS28ESR, DAS28CRP, SDAI, CDAI), moderate correlations with TJC (r=0.575) and SJC (r=0.491), fair correlation with VAS (r=0.239), poor correlation with PGA (r=0.153), and moderate correlation with EGA (r=0.457). The PA-sum had substantial correlations with the clinical scores (r=0.699, 0.746, 0.723, 0.736 for DAS28ESR, DAS28CRP, SDAI, CDAI), substantial correlations with TJC (r=0.787) and SJC (r=0.694), moderate correlations with VAS (r=0.544) and PGA (r=0.529), and substantial correlation with EGA (r=0.708).

Ten patients were classified as Pattern 1, 12 as Pattern 2, 9 as Pattern 3. The PA+SO2 patterns presented substantial correlations with the clinical scores (DAS28ESR r=0.690, DAS28CRP r=0.782, SDAI r=0.805, CDAI r=0.799, SJC r=0.847, TJC r=0.876, respectively), substantial correlation with VAS (r=0.714), and moderate correlation with PGA (r=0.476) and EGA (r=0.502). Significant differences between those who were classified as hypoxia and hyperoxia with evident PA signals, were detected in VAS (p=0.020) and PGA (p=0.026).

Conclusion: The PA-sum scores and the PA+SO2 patterns can be utilized as objective imaging parameters reflecting the disease activity of RA. PAI may serve as a supplement to conventional US examinations for RA patients.

THU0546 HEALTHCARE COSTS OF NOT ACHIEVING REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Bergman1, L. Zhou2, P. Patel2, R. Sawant1, J. Clewell2, N. Tundia2. 1Drexel University College of Medicine, Philadelphia, United States of America; 2AbbVie Inc., North Chicago, United States of America

Background: Guidelines recommend sustained remission as a treatment goal for patients with rheumatoid arthritis (RA). However, only one-third of patients are known to achieve this goal with current treatments. A few studies have evaluated the impact of remission in a real-world setting, but evidence is limited to the elderly population.

Objectives: To understand the impact of remission on healthcare costs by comparing overall and RA-related direct healthcare costs and resource use in patients with RA who maintain vs those who do not maintain remission using a real-world database.

Methods: Data for this retrospective cohort study were derived from Optum electronic health records linked to claims from commercial and Medicare Advantage health plans in the United States. Patients with ≥2 diagnoses for RA, ≥1 Disease Activity Score 28 (DAS28-CRP/ESR) or Routine Assessment of Patient Index Data 3 (RAPID3) measurement, and continuous medical and pharmacy coverage 6 months before and 1 year after the index date were included. Two cohorts were created: remission and non-remission. Remission was defined as DAS28 <2.6 or RAPID3 ≤3.0. In the remission cohort, the index date was defined as the first date remission was achieved. In the non-remission cohort, the index date was defined as the first date of DAS28 or RAPID3 measurement. Outcomes were all-cause and RA-related total, medical, and prescription costs; healthcare resource use (number of inpatient, emergency department [ED], outpatient, and other visits); and number of prescriptions within 1 year of index date. A weighted linear model and binomial regression were used to estimate adjusted annual direct costs and healthcare resource use, respectively. Confounding between cohorts due to age, sex, race and comorbidities using the Elixhauser index was controlled for in the models.

Results: A total of 335 patients with RA (remission cohort: 125; non-remission cohort: 210) met the study inclusion criteria. Annual all-cause total direct costs in the remission cohort were significantly less than the non-remission cohort ($30,427 vs $38,645, respectively; cost ratio [CR]=0.79; 95% CI: 0.63, 0.99).

All-cause medical costs were significantly lower in the remission cohort than in the non-remission cohort (Figure 1); furthermore, among all-cause medical costs, outpatient visit costs were significantly lower in the remission than in the non-remission cohort. All-cause resource use (mean number of visits) was less in the remission vs non-remission cohort: inpatient (0.23 vs 0.63; visit ratio (VR)=0.36; 95% CI: 0.19, 0.70), ED (0.36 vs 0.77; VR=0.47; 95% CI: 0.30, 0.74), and outpatient visits (20.7 vs 28.5; VR=0.73; 95% CI: 0.62, 0.86). Annual RA-related total direct costs were similar in both cohorts (Figure 2); however, RA-related medical costs were numerically lower in the remission vs non-remission cohort ($8,584 vs $10,002, respectively; CR=0.86; 95% CI: 0.59, 1.25). RA-related resource use (mean number of visits) was less in the remission vs non-remission cohort: inpatient (0.15 vs 0.22; VR=0.67; 95% CI: 0.35, 1.30), ED (0.04 vs 0.13; VR=0.31; 95% CI: 0.10, 0.95), and outpatient visits (5.4 vs 7.4; VR=0.72; 95% CI: 0.58, 0.91).

Conclusion: Significant economic burden was associated with patients who did not maintain remission compared with those who maintained remission. Although outpatient visits were the driver of medical costs in both groups studied in this analysis, the contribution of outpatient visits was greater among those who did not maintain remission.

THU0547 ESTIMATION OF THE IMPACT OF A STRATEGY TO OPTIMIZE COSTS ON NATIONAL HEALTH-CARE SYSTEM IN PATIENTS WITH RHEUMATOID ARTHRITIS: A DIRECT COST ANALYSIS

D. F. Aranda1, T. Benincasa2, C. Romero-Sanchez2, L. Chila3, W. Bautista-Molano4. 1National Open and Distance University, 110111, Colombia; 2Universidad EL Bosque, Faculty of Sciences, Department of Mathematics, 110111, Colombia; 3Universidad EL Bosque, School of Dentistry, Cellular and Immunology Group / Universidad Militar Nueva Granada, School of Medicine, Hospital Militar Central-Clinical Immunology Group, 110111, Colombia

Background: Rheumatoid arthritis (RA) is a disease associated with a high and increasing direct cost to the health-care resources. It is estimated that about 250,000 persons may have RA in Colombia. The characteristic joint damage and disability associated to RA increase slowly over many years (10–20 years).

Objectives: To assess the development of RA in Colombian-population over the next five-years and to estimate the impact of a strategy to reduce direct-costs on the national health-care system.

Results: A total of 335 patients with RA (remission cohort: 125; non-remission cohort: 210) met the study inclusion criteria. Annual all-cause total direct costs in the remission cohort were significantly less than the non-remission cohort ($30,427 vs $38,645, respectively; cost ratio [CR]=0.79; 95% CI: 0.63, 0.99). All-cause medical costs were significantly lower in the remission cohort than in the non-remission cohort (Figure 1); furthermore, among all-cause medical costs, outpatient visit costs were significantly lower in the remission than in the non-remission cohort. All-cause resource use (mean number of visits) was less in the remission vs non-remission cohort: inpatient (0.23 vs 0.63; visit ratio (VR)=0.36; 95% CI: 0.19, 0.70), ED (0.36 vs 0.77; VR=0.47; 95% CI: 0.30, 0.74), and outpatient visits (20.7 vs 28.5; VR=0.73; 95% CI: 0.62, 0.86). Annual RA-related total direct costs were similar in both cohorts (Figure 2); however, RA-related medical costs were numerically lower in the remission vs non-remission cohort ($8,584 vs $10,002, respectively; CR=0.86; 95% CI: 0.59, 1.25). RA-related resource use (mean number of visits) was less in the remission vs non-remission cohort: inpatient (0.15 vs 0.22; VR=0.67; 95% CI: 0.35, 1.30), ED (0.04 vs 0.13; VR=0.31; 95% CI: 0.10, 0.95), and outpatient visits (5.4 vs 7.4; VR=0.72; 95% CI: 0.58, 0.91).

Conclusion: Significant economic burden was associated with patients who did not maintain remission compared with those who maintained remission. Although outpatient visits were the driver of medical costs in both groups studied in this analysis, the contribution of outpatient visits was greater among those who did not maintain remission.

Acknowledgments: Financial support for the study was provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the abstract. All authors contributed to the development of the publication and maintained control over the final content. Medical writing services were provided by Joann Hettsch of JK Associates Inc., a member of the Fishawack Group of Companies, and funded by AbbVie.

Methods: We use a population-based approach of epidemiological type to analyze the development of the disease over time. We design a continuous mathematical model for the transmission and evolution of RA in a population. The description of a biological phenomenon (disease), by differential equations is called mathematical modeling and allows us not only to study and analyze the dynamics of the disease, but also to predict its future development. The system is formed by eight ordinary differential equations, explaining the influence of the epidemiological parameters considered in the evolution of RA. This mathematical modeling-approach has been extensively used to study the dynamical behavior of diseases in populations from an epidemiological point of view. The parameters of the mathematical-model are estimated using real-data from RA-prevalence. Total population was divided into eight groups as follows: general population, prevalent (at risk), pre-clinical (asymptomatic), symptomatic (tender/swollen joints), diagnosed without treatment (fulfilling classification-criteria), starting early treatment (before two years of symptoms), starting late treatment (after two years of symptoms), and chronic RA patients (disease duration more than 2 years). Numerical simulations allow to explain the RA-epidemiology and predict the disease over the next five-years.

Results: In the next five-years there will be 129,000 new RA-patients in Colombia, with an estimated cost on the national health-care system of about $4125 million (USD). The analysis of the proposed mathematical model allows us to recommend an action-strategy to optimize and reduce direct-costs. The strategy is related to the implementation of the optimal clinical-diagnosis of RA and starting timely-treatment of patients with the most effective approaches available. Applying this strategy would allow the health-care system to reduce about 20% of its direct costs over the next five-years, reducing costs from $4125 million to $3337 million with estimated savings of $788 million. Figure 1

Conclusion: We investigated the development of RA over the next five-years and were able to predict the number of new patients. The impact of the implementation of a strategy based on optimal-diagnosis and timely-treatment may reduce about 20% of its direct costs over the next five-years.

Conclusion: Direct Health Care Costs, and those attributed to pharmacological treatment in particular, accounted for the largest component of the cost associated with AS. However, a significant proportion of the overall costs can be further attributed to labour productivity losses.
Results were expressed as incremental cost-utility ratio (ICUR) and incremental NMB (iNMB).

Results: From a societal perspective, algorithm M2 resulted in more QALYs and lowest costs per patient (€24,23 QALY; €157,274), thus dominating BER and M1 (Table). From a healthcare perspective, BER had lowest costs, but M2 was still considered cost-effective at €3,250/QALY (Table). At a willingness-to-pay (WTP) threshold of €20,000 per one QALY gained, the probability of M2 being most cost-effective was 94%, compared to 5% for M1 and 1% for BER. Compared to the most cost-effective algorithm (M2), an additional €7,300 could be spent per patient to achieve perfect diagnosis while remaining cost-effective.

*Calculated using a WTP threshold of €20,000/QALY. iCost, incremental cost; iQALY, incremental QALY; SE, sensitivity; SP, specificity.

Conclusion: The relative increase in sensitivity of M2 at the expense of specificity when compared to the original BER algorithm is acceptable in terms of costs and effects from both societal and healthcare perspectives. A considerably more expensive diagnostic algorithm with better accuracy than M2 would still be considered good value for money. It is worthy to invest in more accurate diagnosis in axSpA.

THU0550 HEALTH CARE UTILIZATION AND COSTS IN ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN THE UNITED KINGDOM: A REAL-WORLD OBSERVATIONAL RETROSPECTIVE COHORT STUDY

M. Samnaliev1, V. Barut2, S. Wein3, J. Langham3, L. Samnaliev4, B. Desta5, E. R. Hammond1, 2Maverex Limited, Manchester, United Kingdom; 3AstraZeneca Medical, Gaithersburg, United States of America

Background: There is limited real-world evidence demonstrating the long-term direct costs associated with systemic lupus erythematosus (SLE) in the United Kingdom (UK).

Objectives: To describe health care resource utilization and costs in adults with SLE in the UK over time and document costs by disease severity and type of encounter, including primary care, hospitalizations, outpatient visits, and prescription drugs.

Methods: Patients aged ≥18 years with SLE were identified in the linked Clinical Practice Research Datalink – Hospital Episode Statistics database from January 1, 2005, to December 31, 2017. Patients were required to have data from ≥12 months before and after the index date, defined as the date of earliest diagnosis available in the data set. Patients were classified as having mild, moderate, or severe disease using an adapted claims-based algorithm. Costs were calculated in 2017 UK pounds from the UK national health care system perspective. We estimated all-cause health care costs and incremental costs associated with each year of follow-up compared with a baseline year (3 years before index) using each patient as his or her own control and adjusting for age, sex, disease severity, and comorbid conditions.
Results: Of the 802 patients identified, 369 (46.0%) had mild SLE, 345 (43.0%) had moderate SLE, and 88 (11.0%) had severe SLE. The mean all-cause cost increased in the 3 years before diagnosis and, in the first year after diagnosis, amounted to £7532 (standard deviation [SD] £3634). This cost varied by disease severity: mild SLE, £5221 (£8064); moderate SLE, £8323 (£9846); and severe SLE, £14,125 (£11,267) (Figure 1). Adjusted total mean annual increase in costs per patient in the overall study population was £4476 (95% confidence interval £3809–5143) greater in the year of diagnosis compared with the baseline year (P<0.0001), adjusted for age, sex, disease severity, and comorbid conditions. Primary care utilization was the leading component of costs during the first year after diagnosis, followed by prescriptions, outpatient care, and inpatient care (Figure 2). Information on biologic use in hospitals is unavailable in these data.

Conclusion: The direct costs of health care for patients with SLE in the UK are substantial and persist over the years after diagnosis. Patients with moderate or severe SLE have higher all-cause costs over time compared with patients with mild SLE. Earlier diagnosis and treatment may reduce disease severity and occurrence of comorbidities, and the associated high health care costs.

THU0551 SOCIAL CARE USE IN PEOPLE WITH CHRONIC PAIN IN THE UNITED KINGDOM

J. Humphreys1, K. Dempsey1, O. Phelan2, L. Boothman2, L. Cook3, W. Dixon3.
1University of Manchester Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2Versus Arthritis, London, United Kingdom; 3University of Manchester, NIHR Policy Research Unit for Older People and Frailty, Manchester, United Kingdom

Background: Chronic pain is a common and disabling health problem and those affected may need support with their activities of daily living (ADLs). Currently there are no data quantifying how much social care support people with chronic pain need.

Objectives: To describe formal and informal social care use in people with chronic pain

Methods: Between June-July 2019, previous participants of the Cloudy with a Chance of Pain study were invited to take part in an online survey, adapted from a validated Personal Social Services Research Unit interview survey. It collected data on whether participants with chronic pain needed help with ADLs, how frequently help was needed and who provided it (formal and informal social care). Additional data was collected on demographics, employment status, pain diagnosis, and comorbidities. Descriptive statistics described the burden of social care need and multivariable logistic regression identified factors associated with social care need.

Results: There were 981 respondents; 791 (81%) were female, median age 59 years (table 1). In the last month 527(61%) respondents reported needing help with ADLs. Over three-quarters of help was provided informally by family and friends (408 (77%)). For 309 (59%) respondents, help was needed at least daily. In the multivariable logistic regression model, needing help was lower with older age, (OR (95% CI) 0.96 (0.94-0.98), but higher in female gender (OR (95% CI) 1.96 (1.27-3.01), fibromyalgia (OR(95% CI) 2.75(2.53-5.54)), osteoarthritis (OR 1.56 (1.11-2.19) and multi-morbidity OR (95% CI) 2.13 (1.51-3.01)). Compared to full-time work, respondents who were retired or unable to work were also significantly more likely to need help with ADLs, relative OR (95% CI) 2.16 (1.23-3.84) and 6.98 (3.72-13.08).

117 respondents did not answer the question about whether they did or did not need help with ADLs.

*some participants reported more than one diagnosis for their pain includes MSk diseases above and the following chronic diseases listed in questionnaire: angina, heart attack, stroke, COPD, diabetes, cancer, parkinson’s, multiple sclerosis, depression, other (participants asked to specify)

Conclusion: A high proportion of people with chronic pain need support with ADLs; for more than half, on a daily or more frequent basis. Interestingly, younger patients were more likely to need help which may reflect responder
bias (younger patients with severe pain potentially more likely to respond than those with milder pain). The majority of support was provided informally, and this could be for a number of reasons. For example, lack of awareness/not meeting one’s eligibility/unable to afford formal social care, or preference to be cared for by familiar persons. This should be explored in future research. These results demonstrate the burden of social care may be significantly greater than government and social care organisations are aware, with important implications for policy and planning.

**SWITCH TO BIOSIMILAR ADALIMUMAB - IS IT COST EFFECTIVE?**

J. Begum1, M. K. Nisar1,1, Luton and Dunstable University Hospital, Luton, United Kingdom

**Background:** Since the introduction of anti-TNF biosimilars in routine clinical practice, there has been a drive to implement the switch program for all biosimilars at the point of availability. First adalimumab biosimilar was granted marketing authorisation by the EMA in March 2017. Our Trust was aligned to NHS England strategy which required adoption of biosimilar within three months for new patients and one year for switchers. This could help deliver significant savings to the NHS whilst achieving similar clinical outcomes.

**Objectives:** We report our early experience of introducing adalimumab biosimilar (SB5).

**Methods:** A list of all patients prescribed adlimumab was extracted through our database. A ‘switch’ letter was drafted and sent to all patients including Imraldi information sheet. Patients were given the opportunity to contact nurse helpline for information or if disease control worsened/adverse effects developed. We reviewed all relevant records and collected data on any adverse events and disease outcome on either side of the switch. Patients were reviewed as originally planned by their respective clinicians.

**Results:** 198 patients were identified established on adalimumab. All had switched by October 2019 to Imraldi. Mean age of switchers was 48 (range 16-83 years). Gender distribution was equal (99 each). 35 (17%) were Asian, two Afro-Caribbean, four other and the remaining 157 (80%) were White Caucasian. 54 (27%) had RA, 81 (41%) PaA, 57 (29%) AS and six had JIA. Coprescribed DMARDs included methotrexate (n=53, 27%), sulfasalazine (n=15, 7.5%), hydroxychloroquine (n=14, 7%) and leflunomide in two individuals. 83 (42%) participants were prescribed adalimumab monotherapy.

Prior to switch, median DAS28 for RA group was 2.28 (0.57 - 6.29), Median BASDAI and spinal VAS for AS cohort was 3.3 (0.8 - 8.8) and 3.0 (0 - 9) respectively. Tender and swollen joint components for PsARC were median 23 (0-98 tender, 0-6 swollen) in PsA group. Only 30% of the patients had ease outcome on either side of the switch. Patients were reviewed as originally planned by their respective clinicians.

**Conclusion:** Our experience of switching adalimumab patients has been reasonably successful. All were happy to switch after receiving a letter and having the opportunity to contact if necessary. Substantial annual cost savings of over £300,000 have been projected for this financial year. At group level there were no major differences in disease outcomes and 90% reported no issues. However, just under 10% of those reviewed have decided to return to the originator within three months of switch with loss of efficacy and thereby confidence in the drug. We support the routine switching from originator to biosimilar adalimumab within three months of switch with loss of efficacy and thereby confidence in the drug.

THU0553

**A HEALTH ECONOMIC ANALYSIS OF THE USE OF COLOUR DOPPLER ULTRASONOGRAPHY AS THE PRIMARY DIAGNOSTIC MODALITY IN PATIENTS WITH SUSPECTED GIANT CELL ARTERITIS**

C. Mukhrzay1,2, L. Steele1, C. Jones1, M. Bachmann1,1, Norfolk & Norwich University Hospital, Norwich, United Kingdom;1University of East Anglia, Norwich, United Kingdom

**Background:** EULAR has recommended ultrasonography (US) as first imaging modality for diagnosis of Giant Cell Arteritis (GCA)1. For patients with a high pre-test probability who have a negative scan, the recommendation is to use another diagnostic modality like temporal artery biopsy (TAB) to make a diagnosis. We know that a fast-track pathway incorporating US, results in better clinical outcomes2; but there are little data on the health-economics of this approach. Since 2017, we have used ultrasonography as the primary diagnostic modality for suspected GCA. In patients with a high pre-test probability with a negative ultrasonography, we perform a temporal artery biopsy.

**Objectives:** To compare the cost of investigating GCA using first-line US and second-line TAB the use of TAB only. To compare the cost per definite diagnosis of GCA.

**Methods:** Number of cases from 2007-2009 and 2017-2019 were calculated by the number of TAB performed and number of referrals to hospital GCA clinic, respectively. Costs of the procedure were calculated as per the nationally agreed tariff by the United Kingdom National Health Service. For ease of comparison, we used the 2018/19 tariff (£1284/TAB; £51 for US).

**Results:** In 2007-2009, 162 cases were referred to clinic and had a TAB, of which 86 were positive. No cases had US. The 2018/19 corrected cost was £208008; the cost per positive diagnosis was £2418.70 (Table 1).

**Table 1. Numbers of cases investigated for suspected GCA by TAB or US and the costs corrected to 2018/19 UK NHS tariff.**

<table>
<thead>
<tr>
<th>Years</th>
<th>No of referrals</th>
<th>No of TAB</th>
<th>No of US</th>
<th>No of patients with GCA</th>
<th>Total cost</th>
<th>Cost of making 1 positive diagnosis</th>
</tr>
</thead>
<tbody>

<tr>
<td>2017-19</td>
<td>199</td>
<td>69</td>
<td>416</td>
<td>142</td>
<td>£109812</td>
<td>£773.32</td>
</tr>
</tbody>
</table>

In 2017-2019, 419 patients were referred to the GCA clinic. 416 of whom had US for diagnosis. 3 individuals had a TAB as the first diagnostic modality and 66 others were referred for a TAB because of a high pre-test probability and negative US. The 2018/19 corrected cost of this pathway was £109812 and the cost per positive diagnosis was £773.32 (Table 1).

All cases in 2017-2019 had a TAB for suspected GCA, the 2018/19 corrected cost would have been £537996. The estimated 2018/19 corrected savings in our center was £1422782/year. The estimated 2018/19 corrected savings per definite diagnosis of GCA has dropped by £1645.37 (Table 1).

**Conclusion:** The EULAR recommendation of using first-line US for diagnosis of GCA followed by a TAB in cases with uncertain diagnosis after US, is highly cost-effective in the UK, resulting in cost savings of >£140K per year.

**COMORBIDITY AND HEALTH CARE UTILIZATION IN PERSONS WITH SJÖGREN’S SYNDROME: A CLAIMS DATA ANALYSIS**

K. Albrecht1, T. Dörner1, I. Redeker1, K. Karberg3, U. Marschall1, A. Zink1,2, J. Callof1,1, German Rheumatism Research Centre, Epidemiology, Berlin, Germany;2Charité University Medicine, Berlin, Germany;3Rheumaparxis Steglitz, Berlin, Germany;1BARMER statutory Health Insurance Fund, Berlin, Germany

**Background:** Sjögren’s syndrome (SS) can affect numerous organs, including the muscles, the peripheral nervous system, kidneys and lungs. Epidemiological studies assessing comorbidity and health care utilization are needed to improve health care for this multifaceted disease.

**Objectives:** To capture comorbidity and medication of persons with SS in a population-based cohort in comparison to matched controls.

**Methods:** Individuals with an outpatient diagnosis of M35.0 (ICD-10) in ≥2 quarters of a year or an inpatient diagnosis of M35.0 were identified in a German
statutory health insurance fund covering 7.2 million people. Persons in rheumatologic care were grouped by incident or prevalent diagnosis and by co-existing autoimmune disease (sSS) or primary (pSS) and compared to age- and sex-matched controls regarding comorbidity (ICD-10), medical prescriptions, hospitalization and inability to work in the previous year.

Results: In 2018, 7,374 persons (0.1%) had incident and 53,917 persons (0.73%) prevalent SS diagnosis, and 5,920 (11%) were in rheumatologic care. Of these (90% female, mean age 66 years), 3,431 (58%) had further autoimmune disease (sSS), mostly rheumatoid arthritis (80%) and systemic lupus erythematosus (13%). Compared to controls, frequent comorbid conditions in SS were hypertension, osteoarthritis, osteoporosis and depression (table 1). Systemic antirheumatic drugs were prescribed in 31% (pSS) and 66% (sSS) while < 4% received topical therapies. Glucocorticoids (7% controls/34% pSS/59% sSS), NSAIDs (28%/41%/45%), opioids (9%/15%/22%), antiepileptics (19%/30%/36%) and antidepressants (14%/21%/22%) were more frequently prescribed in SS than in controls, and also hospitalization (21%/32%/39%) and inability to work in persons <65 years (41%/48%/44%, median days 17/24/31) were more frequent in pSS and sSS than in controls.

Conclusion: SS claims diagnosis is associated with substantial comorbidity and frequent prescription of anti-inflammatory drugs, antiepileptics and antidepressants. The individual and societal burden of SS shows that, in addition to effective treatment strategies, intensive attention to comorbidities is important in this disease.

Acknowledgments: Funding The study was supported by the Wolfgang Schulze Foundation of the German Rheuma-Liga.

THU0555 HEALTHCARE COSTS IN PATIENTS WITH RHEUMATOID ARTHRITIS SWITCHING FROM THEIR FIRST CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUG TO ANOTHER DISEASE-MODIFYING ANTIRHEUMATIC DRUG REGIMEN

1Robin K. Dore, MD, Private Practice, Tustin, United States of America; 2Gilead Sciences, Inc., Foster City, United States of America; 3IQVIA, Plymouth Meeting, United States of America; 4Stanford University, Division of Immunology and Rheumatology, Stanford, United States of America

Background: EULAR and ACR guidelines recommend a treat-to-target approach for rheumatoid arthritis (RA). For patients failing their first conventional synthetic disease-modifying antirheumatic drug (csDMARD), EULAR recommends switching to or adding another DMARD. Understanding treatment patterns, durability, and healthcare costs associated with treatments initiated after first csDMARD can help optimize treatment for these patients.

Objectives: To describe real-world healthcare costs among patients with RA who failed their first csDMARD.

Methods: The study included adults with ≥2 RA claims ≥30 days apart in a large US health claims database, who started a csDMARD regimen as the first DMARD then switched to or added another DMARD (index date ID). 1/1/2012–3/31/2017. All patients had continuous enrollment 1-year before and ≤1 year after ID. Treatment duration was defined as number of days from initial treatment fill until loss of treatment persistence. Unadjusted mean total annualized per-patient-per-year (PPPY) healthcare costs while on treatment were compared via analysis of variance. A generalized linear model with gamma distribution and log link was used to compare total costs adjusted for pre-index costs, patient characteristics, and type of initiated treatment.

Results: The study involved 7,816 patients (median age of 54 yrs, 74% female). Mean (standard deviation) duration of index therapy was 14.0 (12.6) months for patients overall (9.2 [10.1] for monotherapy vs 16.2 [13.1] for combination therapy, P < .0001).

Prior to switching, the unadjusted mean PPPY healthcare costs totalled $12,923; $13,923 for monotherapy vs $12,317 (P < .0009) for combination therapy. Once switched, patients accrued unadjusted mean PPPY on-treatment healthcare costs of $30,742; $28,757 on monotherapy vs $31,943 (P = .0003) on combination therapy. Figure 1 details pre- and post-ID unadjusted costs by index therapy.

Patients on non-TNFi bDMARD monotherapy had higher adjusted total healthcare cost (cost ratio [CR] = 1.58, P < .0052) than the total cost on JAKi monotherapy, whereas csDMARD monotherapy (CR = 0.28, P < .0001) and csDMARD + csDMARD(s) (CR = 0.26, P < .0001) had lower total cost than the cost on JAKi monotherapy. Other factors impacting costs included baseline Charlson Comorbidity Index (CCI) = 2 or ≥3 vs CCI = 1 (CR = 1.44 and 1.25, respectively; both P < .0001), baseline total cost of medical + pharmacy healthcare costs (CR = 1.24, P < .0001), and baseline opioid use (CR = 1.11, P < .0001, Figure 2).

Conclusion: Real-world data demonstrate short durability of available treatments initiated after first csDMARD. Among the initiated treatments, lowest total healthcare costs were associated with csDMARD, followed by JAKi, then TNFi, and finally non-TNFi bDMARD.

THU0556
MISSING DATA AND MULTIPLE IMPUTATION IN RHEUMATOID ARTHRITIS REGISTRIES USING SEQUENTIAL RANDOM FOREST METHOD

A. Alsaïber, A. Al-Herz2, J. Pan1, K. Saleh1, A. Al-Awadhi1, W. Al-Kandari1, E. Hasan1, A. Ghannam2, M. Hussain1, Y. Ali1, E. Nahar1, A. Aleni2, S. Hayat1, F. Abutiban3, A. Al-Mesfer4, A. Al-Qadhi5, H. Alhajeri1, N. Alhadhood2, T. Mottahedeh1, N. Al-Amri Hospital, Kuwait; 2Cardiac Center, University of Alabama at Birmingham, Birmingham, United States; 3Department of Bioinformatics and Computational Biology, Life Science, Kuwait University, Kuwait; 4Kuwait National Cancer Institute, Kuwait; 5Jabriya Hospital, Kuwait; 6Serdi Medical Center, Kuwait; 7Medicine, Kuwait University, Kuwait; 8Mubarak Al-Kabeer Hospital, Kuwait; 9Jahra Hospital, Kuwait; 10Sahab Hospital, Kuwait

Background: Missing data in clinical epidemiological researches violate the intention to treat principle, reduce statistical power and can induce bias if they are related to patient’s response to treatment. In multiple imputation (MI), covariates are included in the imputation equation to predict the values of missing data.

Objectives: To find the best approach to estimate and impute the missing values in Kuwait Registry for Rheumatic Diseases (KRRD) patients data.

Methods: A number of methods were implemented for dealing with missing data. These included Multivariate imputation by chained equations (MICE), K-Nearest Neighbors (KNN), Bayesian Principal Component Analysis (BPCA), EM with Bootstrapping (Amelia II), Sequential Random Forest (MissForest) and mean imputation. Choosing the best imputation method was judged by the minimum scores of Root Mean Square Error (RMSE), Mean Absolute Error (MAE) and Kolmogorov–Smirnov D test statistic (KS) between the imputed datasets and the original datasets that were subsequently sat to missing.

Results: A total of 1,685 rheumatoid arthritis (RA) patients and 10,613 hospital visits were included in the registry. Among them, we found a number of variables that had missing values exceeding 5% of the total values. These included duration of RA (13.0%), smoking history (26.3%), rheumatoid factor (7.93%), anti-citrullinated peptide antibodies (20.5%), anti-nuclear antibodies (20.4%), sicca symptoms (19.2%), family history of a rheumatic disease (28.5%), steroid therapy (5.94%), ESR (5.16%), CRP (22.9%) and SDAI (38.0%). The results showed that among the methods used, MissForest gave the highest level of accuracy to estimate the missing values. It had the least imputation errors for both continuous and categorical variables at each frequency of missingness and it had the smallest prediction differences when compared to Amelia II. Kolmogorov–Smirnov D test statistic showed a significant difference between the imputed and original data.

Conclusion: MissForest is a highly accurate method of imputation for missing data in KRRD and outperforms other common imputation techniques in terms of imputation error and maintenance of predictive ability with imputed values in clinical predictive models. This approach can be used in registries to improve the accuracy of data, including the ones for rheumatoid arthritis patients.

THU0557
QUALITY ASSESSMENT OF CLINICAL PRACTICE GUIDELINES IN AXIAL AND PERIPHERAL SPONDYLOARTHRITIS: A SYSTEMATIC APPRAISAL

W. Bautista-Molero1,2, E. Jaureguia3, L. Saldañala4, M. X. Rojasa4, J. R. Pieschacón1on behalf of On behalf of the Spondyloarthritis Study Group National Rheumatology Association of Colombia (Asoreuma), 1University Hospital Fundacion Santa Fe de Bogotá, Bogotá, Colombia; 2Universidad El Bosque, Bogota, Colombia; 3Riesgo de Fractura S.A-CAYRE IPS, Bogotá, Colombia, Bogota, Colombia; 4Hospital Universitario San Jorge, Universidad Tecnológica de Pereira, Colombia, Pereira, Colombia; Department of Clinical Epidemiology and Biostatistics, Pontificia Universidad Javeriana, Bogotá, Colombia, Bogotá, Colombia

Background: Clinical practice guidelines (CPG) in spondyloarthritis (SpA) serves as a tool for rheumatologists, health-care providers and patients in the selection of appropriate treatment framework in common clinical scenarios guiding decision-making processes. However, the quality of these guidelines has not yet been evaluated systematically in the field.

Objectives: The aim of the study was to evaluate the quality of the CPG available for the treatment of axial and peripheral SpA.

Methods: A systematic and scientific literature search between 2014 and 2019 was performed in order to identify and select CPG focused on the treatment of axial and peripheral SpA. The authors systematically searched the main guideline databases and guideline developer websites completing the search in PUBMED/MEDLINE and EMBASE. Four independent reviewers with methodological and clinical expertise in the field of SpA assessed the eligible guidelines using the Appraisal of Guidelines for Research and Evaluation (AGREE II) instrument. Their degree of agreement was evaluated with the intra-class correlation coefficient (ICC). The statistical analyses were done using the R psych package.

Results: Twelve CPG were selected for evaluation. The scores for each of the AGREE II domains were: scope and purpose 86% (range: 67–99%); stakeholder involvement 71% (range: 22–93%); rigour of development 61% (range: 29–82%); clarity and presentation 79% (range: 68–86%); applicability 48% (range: 21–71%); and editorial independence 72% (range: 19–92%). Most of the appraised guidelines could be recommended (n=12) or recommended with limitations (n=2) for use in clinical practice. The overall agreement among reviewers was moderate (ICC: 0.40; 95% CI 0.16 to 0.82). The CPG with the best quality assessment using the AGREE II instrument was the NICE guideline developed by the National Institute for Health and Care Excellence. A slightly higher quality assessment of CPG developed by research agencies or guideline developers was observed, in comparison to those developed by scientific societies. Figure 1. Assessment of guidelines developed by research agencies or guideline developers was observed, in comparison to those developed by scientific societies.

Conclusion: Quality assessment of guidelines for the treatment of axial and peripheral SpA is good with an average of 69%. However, a cut-off point has not been clearly established. Measures should be taken to assure that CPGs are based on the best available evidence and rigorously developed and reported. Additional efforts are needed to provide high-quality guidelines that serve as a useful and reliable instrument for clinical decision-making process in the field of SpA.
Background: The presence of anti-cyclic citrullinated peptide antibodies (anti-CCP antibodies) is associated with progression to inflammatory arthritis (IA) [1]; however, most patients attending primary care with a new non-specific musculoskeletal (MSK) complaint and no clinical synovitis have a negative result for this test (CCP). Considering that only a small proportion of these individuals will be diagnosed with an IA within the next 12 months, predicting disease progression in these patients appears to be more challenging.

Objectives: To investigate factors that could be associated with disease progression in patients testing CCP- in order to optimise primary care referrals to Rheumatology.

Methods: A prospective observational study recruiting patients over 16 years old with a new MSK complaint and no clinical synovitis was conducted. Patients recruited from primary care centres across the UK from July 2007 until November 2018 were included in this analysis. Those testing negative for the anti-CCP2 assay (initially phadia, later bioplex) were sent questionnaires 1 year later, and QPs were contacted in November 2019 to confirm their disease status.

Results: 7521 eligible patients were recruited from primary care. 7290 (97%) of them were CCP- and 5678 returned the questionnaire after 1 year. 239 patients (4.2%) of these CCP- reported progression to IA; however, this diagnosis was only confirmed in 53 of them (0.93%). In another 38 patients, the IA diagnosis could not be confirmed and therefore they were not included in the analysis. 21 patients progressed to rheumatoid arthritis (RA), 13 to spondyloarthritis, 11 to polymyalgia rheumatica (requiring disease-modifying anti-rheumatic drugs), 3 to polymyositis, 3 to systemic lupus erythematosus and 2 to systemic sclerosis. Table 1 describes the most troublesome joints and table 2 other concomitant MSK diagnoses of the non-progressors/progressors; and among the last ones, the RA group. Multivariable analysis showed that pain in specific joints was associated with development of IA within the following 12 months: hand odds ratio (OR) 2.1 [95%CI (1.09-4.16), p=0.027], knee OR 2.0 [95%CI (1.13-3.91), p=0.02], and shoulder OR 1.8 [95%CI (1.02-3.45), p=0.043]. Smoking exposure, having a first degree relative with IA and gender were not predictive for progression in patients testing CCP-.

Conclusion: In CCP- patients without clinical synovitis, hand, knee and shoulder pain should be investigated more carefully as these involve a higher risk of progression to IA. Patient reported outcomes regarding rheumatic diseases are not reliable; the distribution of joint pain seems to be a more useful tool than the family history when assessing the need for referral to Rheumatology.

**Conclusion:** We consider this strategy as successful in reducing care times and identifying patients who require an early start of treatment and close control. Referral notes from primary care were generally adequate to identify patients who required to continue rheumatologist control.

**THU0560 PRIMARY CARE PHYSICIAN PERSPECTIVES ON DELAYS IN DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS: A QUALITATIVE STUDY**

**Background:** The average delay in diagnosis for patients with any form of spondyloarthritis (SpA) ranges from 7 to 10 years [1–5]. In axial spondyloarthritis (axSpA), a subgroup of SpA, it is 5 to 14 years [4, 6, 7]. Factors that contribute to this delay include the lack of diagnostic criteria for axSpA and the difficulty in distinguishing inflammatory back pain (IBP), a key symptom of axSpA, from other highly prevalent forms of low back pain [8–10]. This impedes timely referral of these patients to rheumatologist care and initiation of appropriate treatment.

**Objectives:** Describe understanding of, attitudes towards, and practices regarding axSpA among primary care physicians.

**Methods:** We recruited 18 primary care physicians practicing in the United States as part of a larger qualitative study, the SpondyloArthritis Screening and Early Detection (SpA-SED) Study. We used purposive sampling with a goal of including an equal number of family medicine and internal medicine physicians who were balanced by gender. Physicians provided informed consent to participate in an in-depth interview (up to 60 minutes), conducted in person (n = 3) or over the phone (n = 15), between February and May 2019. The interview guide was developed by a multidisciplinary team, with input from rheumatologists. Topics included the physicians’ approaches to evaluating back pain, their awareness about axSpA, their differential diagnosis of axSpA, the laboratory tests and imaging studies ordered when axSpA is suspected, their referral patterns for patients with presumed axSpA, their thoughts about factors contributing to diagnostic delay in axSpA, and their opinions about an Inflammatory Back Pain Assessment – ASAS criteria screening tool [5].

**Results:** Barriers to early diagnosis included patient factors (eg, multiple complaints, back pain not being the chief complaint), disease characteristics (eg, slow rate of disease progression), physician characteristics (eg, lack of rapport between patients and their primary care physicians), and structural/system issues (eg, lack of time). Most physicians reported that they would perform laboratory tests before referring a patient to a rheumatologist.

**Conclusion:** Primary care physicians were surprised to learn of the average delay to axSpA diagnosis, considered that this lengthy delay was problematic, and agreed that improvements are needed in screening for and early detection of axSpA. Physicians believed that there would be a role for using a screening tool in the primary care setting to improve diagnostic delay, but that evidence to support its implementation is needed.

**THU0561 PREDICTING LIVER TOXICITY CAUSED BY CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS**

**Background:** Routine laboratory testing is recommended for early identification of toxicity during conventional synthetic disease modifying antirheumatic drug (csDMARD) treatment. Based on expert consensus, testing is recommended every 2–4 weeks for the first 3 months and quarterly thereafter (1).

**Objectives:** In addition to evaluating the incidence of alanine transaminase (ALT) elevations in rheumatoid arthritis (RA) patients initiated on 1–2 csDMARDs, we aimed to distinguish patterns in ALT levels to develop a model for identifying patients at high risk for liver toxicity.

**Methods:** We identified RA patients who were initiated a new csDMARD course at a rheumatology clinic of Turku University Hospital in 2013–2019. Baseline and follow-up safety monitoring results were drawn from the electronic health record (EHR) data. Data on diagnoses and csDMARD initiation/cessation dates were manually confirmed from the EHR.

As the primary endpoint, we used ALT-elevations of more than twice the upper limit of reference range (women ≥ 70 U/L, men ≥ 100 U/L) within 6 months after treatment initiation. Intergroup differences were tested using Mann-Whitney test for categorical variables. Associations between different csDMARDs were assessed using Pearson’s exact test (n<5) for categorical variables. Associations between different csDMARDs were assessed using Pearson’s exact test (n<5) for categorical variables.
characteristics and the primary endpoint were tested using Cox proportional hazards regression.

Results: We identified 2851 RA patients of whom 1017 initiated a new csDMARD course requiring laboratory monitoring. Of these, 860 patients (58.9 years, 68% women, 65% seropositive) were included in the analyses after excluding patients with missing laboratory results (n=148) or elevated ALT at baseline (n=9). Of the 860 patients, 220 initiated two csDMARDs simultaneously (99% sulfasalazine (SSZ) and methotrexate (MTX)). Primary endpoint was reached in 55 of 860 (6.4%) patients, including 10 who initiated two csDMARDs. Of these 55 patients, primary endpoint was reached in 40 of 55 (73%) patients during first three follow-up tests. In 31 of 55 (56%) patients, including 3 initiators of 2 csDMARDs, elevated ALT led to csDMARD cessation during the first 6 months. In Cox proportional hazards model with age, sex, seropositivity, baseline ALT, and csDMARDs as the explanatory variables, only baseline ALT level [hazard ratio 1.56 per 1 SD increase, 95% confidence interval (CI) 1.30–1.88, p<0.001] was associated with incident ALT-elevations. Survival according to normalized baseline ALT is shown in Figure, where normalized ALT value of 1.0 refers to the upper limit of reference range (women 35 U/L, men 50 U/L).

Table. Multivariable Cox proportional hazards model including the results of the first follow-up laboratory test. Only values before occurrence of primary endpoint were used (n=843).

</table>

*Normalized ALT according to sex-specific reference range; *Rate of change from baseline to 1st follow-up test

Conclusion: Most incident ALT elevations can be predicted before the first csDMARD dose. Patients with elevated ALT at baseline or a rising trend at first follow-up are at high risk for liver toxicity and benefit from frequent testing.

THU0562 ECONOMIC IMPACT ASSOCIATED WITH COMPLICATIONS OF WOMEN IN REPRODUCTIVE AGE LIVING WITH INFLAMMATORY IMMUNE-MEDIATED DISEASES (PSO, PSA, RA, AXSAP) IN SPAIN

J. Martínez-Barrio1, O. Villa2, O. Armijó3, M. Castellanos4, N. Marin Huarte5, M. Mareque6, M.A. Casado7, N. Martínez2, 1Hospital General Universitario Gregorio Marañón, Madrid, Spain; 2Hospital Universitario 12 de Octubre, Madrid, Spain; 3Hospital Universitario La Paz, Madrid, Spain; 4Hospital Universitario del Sureste, Madrid, Spain; 5Pharmacoconomics & Outcomes Research Iberia, Madrid, Spain

Background: Cost of the complications that may appear during reproductive age in women living with inflammatory immune-mediated diseases have scarcely been studied.

Objectives: To obtain an expert consensus in the use of resources associated to complications of women in reproductive age living with immune-mediated diseases: psoriasis (PSO), psoriatic arthritis (PsA), rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA) and estimate an economic impact.

Methods: A cost-analysis was developed to estimate the impact associated with the complications of women of reproductive age with PSO, PsA, RA and axSpA. The analysis considered the complications during fertility and conception (pre-conception consultation and assisted reproduction), in pregnancy (miscarriage in the first trimester, late abortion in the second trimester, preeclampsia, delayed or restricted intrauterine growth and threat of premature delivery) and in the post-partum (admissions in neonatology of premature infants).

An online questionnaire was designed for the validation of the inputs used in the cost-analysis. Subsequently, the questionnaire was sent to a multidisciplinary panel composed of, rheumatologist, gynecologists, neonatologists and dermatologist. A consensus meeting was carried out to validate and agree the parameters used in the analysis.

Unitary cost for resources (€.2019) were obtained from national local databases. The perspective of analysis was the National Healthcare System and the time horizon was one year.

Results: During fertility and conception, an annual cost per patient of € 229 was estimated for a preconception consultation in a patient with PSO, of € 3,642 for a preconception consultation in patients with PsA, RA and axSpA and € 4,339 for assisted reproduction.

Women with complications in pregnancy had an annual cost per patient of € 1,214 for a miscarriage in the first trimester, € 4,419 for a late abortion in the second trimester, € 11,251 for preeclampsia € 3,183 for delayed or restricted intrauterine growth and € 12,122 for the threat of premature delivery.

In the postpartum complications, an annual cost per patient of € 120,364, € 44,709 and € 5,507 were estimated associated with admissions in neonatology of premature infants of <28 weeks, from 28 to 32 weeks and from 33 to 37 weeks, respectively.

Conclusion: This modeling provides insight on the economic burden of complications associated with women in reproductive age living with immune-mediated diseases: psoriasis, psoriatic arthritis, rheumatoid arthritis and axial spondyloarthritis, some of which can probably be prevented by vaccination.

THU0563 IMMUNOGENICITY AND SAFETY OF 23-VALENT PNEUMOCOCCAL VACCINE IN PATIENTS WITH ANKYLOSING SPONDYLITIS (PRELIMINARY RESULTS)

N. Muraveva1, B. Belov1, G. Tarasova1, M. Cherkasova1, G. Lukina1, I.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: For the treatment of patients with ankylosing spondylitis (AS), biological drugs are widely used, which can effectively control the activity of the disease and radically change the prognosis. However, the use of these drugs is associated with an increasing risk of infections, some of which can probably be prevented by vaccination.

Objectives: The aim of the study was to evaluate the immunogenicity and safety of the 23-valent pneumococcal vaccine (PPV-23) in patients with AS.

Methods: The study included 18 patients with AS: 14 men, 4 women, age 38.7±11.5 years, duration of the disease 16.2±10.8 years. 5 patients had a history of more than 2 episodes of lower respiratory tract infections (pneumonia, bronchitis). At the time of inclusion in the study in 89% of patients, activity of
After 1 and 3 months after vaccination, the concentration of antibodies to pneumococcal capsular polysaccharide was significantly higher than the baseline values. None of the patients had lower respiratory tract infections. There was no exacerbation of disease. 83% of patients did not have any adverse effects of vaccination. Reactions at the injection site (pain, swelling and hyperemia of the skin up to 2 cm in diameter), resolved independently after 3-5 days, were noted in 2 patients. One patient registered a severe local reaction (infiltration and hyperemia of the skin up to 8 cm in diameter, pain in the arm), accompanied by low-grade fever for 2 days, which required the appointment of antihistamine drugs. 

Conclusion: Preliminary results indicate satisfactory immunogenicity and safety of the PPV-23 in patients with AS. Further research is needed to better assess the immunogenicity, efficacy and safety of the vaccine.

**THU0564** PARTICIPANT ENGAGEMENT IN AN ARTHRITISPOWER REAL-WORLD STUDY TO CAPTURE SMARTWATCH AND PATIENT-REPORTED OUTCOME DATA AMONG RHEUMATOID ARTHRITIS PATIENTS

W. B. Nowell1, J. Curtis2, F. Xie3, H. Zhao2, D. Curtis3, K. Gavigan1, S. Venkatachalam1, L. Stradford1, J. Boles1, J. Owensby2, C. Clinton2, 3Eli Lilly and Company, Indianapolis, 2University of Alabama at Birmingham, 1Upper Nyack, United States of America

Background: Clear characterization of how different types of patient-generated data reflect patient experience is needed to guide integration of electronic patient-reported outcome (ePRO) measures and biometrics in generating real-world evidence (RWE) related to rheumatoid arthritis (RA).

Objectives: To characterize the level of participant (pt) engagement/adherence and data completeness in an ongoing study of 250 RA pts enrolled in the Digital Tracking of Arthritis Longitudinally (DIGITAL) study of the ArthritisPower real-world registry.

Methods: ArthritisPower pts with RA were invited to join a digital RWE study with 14-day lead-in and 12-week main study period. In the lead-in, pts were required to electronically complete: a) two daily single-item Pain and Fatigue numeric rating scales and b) longer weekly sets of ePROs. Successful completers of the lead-in were mailed a smartwatch (Fitbit Versa) and study materials. The smartwatch collected activity, heart rate, and sleep duration/quality biosensor data; a study-specific customization of the ArthritisPower mobile application collected ePROs. The main study period included automated and manual reminders/prompts about completing ePROs, wearing the smartwatch and regularly syncing it. Study coordinators monitored pt data and contacted pts via email, text and/or phone to resolve adherence issues during the conduct of the study based on pre-determined rules triggering pt contact. Rules were based chiefly on consecutive spans of missing data. Pts were considered adherent in giving complete data for each week if providing (1) daily ePROs for ≥5 of 7 days/week, (2) weekly ePROs and (3) ≥80% of synced activity data for ≥5 of 7 days/week. Composite adherence for the first month of the main study period required meeting >70% weekly adherence parameters during the first 30 days, ie completing daily ePROs for ≥5 of 7 days/week, weekly ePROs ≥3 of 4 weeks and ≥80% of synced activity data for ≥5 of 7 days/week.

Results: As of December 2019, 170 ArthritisPower members enrolled and completed at least 30 days of the main study period; 92.9% female with mean (SD) age 52.5 (10.7) and 10.5 (10.4) years since diagnosis. The overall conversion rate from initial interest to successful completion of the lead-in period was 49.0%. Pts who advanced to the main study were significantly more likely than those who did not to be currently employed (52.9% vs. 41.8%, p=0.038) and be on biologic DMARD monotherapy (64.7% vs. 47.5%, p=0.001). Overall, daily ePRO data had the lowest adherence with 70.0% of pts providing >70% of the requested data consistently across the first 30 days of the main study period (Figure 1). Composite adherence was met by 66.5% of pts. The most common time of day to provide ePRO data was morning, in the hours around scheduled app and email notifications at 10 a.m. in pt’s local time zone. Activity data had the highest adherence and persistence, with 92.9% of pts providing 80% or more of activity data for each 24-hour period in the first 30 days (Figures 1 & 2). Observed weekly adherence did not decline over time. Of 5100 possible person days in the study at day 30, we observed 643 days (91.0% of actual to maximum possible total patient days) where activity data was provided for at least 80% of the 24-hour period.

Conclusion: RWE studies involving passive data collection in RA require pt-centric implementation and design to minimize pt burden, promote longitudinal engagement and maximize adherence. Passive data capture via activity trackers such as smartwatches, along with regular contact such as automated reminders, may facilitate greater pt adherence in providing longitudinal data for clinical trials.

RESEARCHERS’ PERSPECTIVES ON ADHERENCE INTERVENTION RESEARCH AND OUTCOMES IN RHEUMATOLOGY: A QUALITATIVE STUDY

S. Salmasi1, A. Kelly2, S. J. Bartlett3, M. De Wit4, L. March5, A. Tong6, P. Tugwell6, K. Tymms2, S. Verstappen7, M. De Vera1

1OMERACT Patient Research Partner, Amsterdam, Netherlands; 2The University of Sydney, Camperdown, Australia; 3University of Ottawa, Ottawa, Canada; 4The University of Manchester, Manchester, United Kingdom

Background: Medication non-adherence is a significant problem among patients with rheumatic diseases. Research on adherence interventions in rheumatology is limited and disappointing, with studies using heterogeneous outcomes. Understanding these limitations is needed to inform the design of better interventions and research studies.

Objectives: To describe researchers’ perspectives and experiences on adherence intervention research and outcomes in rheumatology.

Methods: Semi-structured interviews using video conference were conducted with researchers who had been an investigator on an adherence study of any design in the past 10 years. Interviews were recorded and transcribed verbatim. Participants were asked about their experiences with conducting adherence research and perspectives on introduction of a core domain set of outcomes for adherence intervention trials in rheumatology. Data collection and thematic analysis were conducted iteratively, until saturation.

Results: We interviewed 13 researchers from seven countries (Australia, Belgium, Canada, Netherlands, Thailand, UK, and USA). A majority worked in academia (75%), specialized in epidemiology and/or health services research (62%) and had led between 2-5 adherence studies in the past five years (62%). Three themes were identified: 1) challenges in designing, conducting and evaluating adherence studies; 2) current outcomes in adherence intervention studies and their relevance; and 3) implementing a core domain set of outcomes for adherence intervention studies.

Major challenges in conducting adherence research included inconsistent adherence terminology and measurement. Participants noted a lack of guidance on outcome selection and measurement when evaluating the effectiveness of an adherence intervention and indicated their preference for research to report adherence intervention-specific, and health-related outcomes. Finally, implementing a core domain set of outcomes was thought to be challenging but valuable in strengthening the evidence (by facilitating meta-analysis), and improving clinical outcomes (by informing clinicians about the effectiveness of interventions).

Conclusion: Adherence research in rheumatology has been hindered by lack of standardization and guidance on terminology, measurement and outcome selection. Our findings form the basis for recommendations for improving the design, conduct and evaluation of adherence intervention studies in rheumatology, particularly for developing a core domain set of outcomes to improve consistency and facilitate comparisons.

THE EFFECT OF KINESIO-TAPING ON CHRONIC NONSPECIFIC LOW BACK PAIN: PRELIMINARY RESULTS OF A DOUBLE BLINDED RANDOMIZED CLINICAL TRIAL.

I. Aachari1, K. Samia2, T. Latifa1, T. Fatima Zahra1, A. Afail1, F. Safaa1, T. El Joumani1, S. Bahiou1, H. Rkain1, I. Hmamouchi1, R. Abouagui1, F. Afail1, El Ayachi Hospital, Rheumatology, Salé, Morocco; El Ayachi Hospital, Physical Medicine and Rehabilitation, Salé, Morocco; 4Faculty of Medicine and Pharmacy, Mohamed V University, Laboratory of Physiology, Rabat, Morocco; 5Faculty of Medicine and Pharmacy, Mohamed V University, Laboratory of Epidemiology and Clinical Research, Rabat, Morocco

Background: The technique of Kinesio-Taping is a method of adhesive bandage exerting traction on the skin which would favorably influence the muscular and articular systems by reducing the pressure exerted on the subcutaneous mechanoreceptors thus reducing pain and muscle tension.

Objectives: The aim of this study is to assess the effectiveness of Kinesio-Taping in the short and medium term on pain and function in patients with chronic nonspecific low back pain compared to a placebo.

Methods: We conducted a double-blind, two-arm randomized clinical trial. The study should include a total of 70 patients randomized into 2 groups: Kinesio-Taping (n = 35) and control group (n = 35). To this date we have included 46 patients. All patients received four I-shaped adhesive strips arranged in a star-like shape and applied to the most painful region of the lower back with a tension between 25% to 30% in the taping group. The placebo group received a taping procedure with no tension. Taping was applied three times (at baseline, fourth and eighth day). Patients were assessed at baseline, on day 14 and at 4 weeks by the Arabic version of the Oswestry Physical and Functional Disability Index (ODI) which is the primary outcome. The secondary outcomes are the assessment of pain and functional disability according to the visual analog scale (VAS) evaluated on a scale of 0 to 10, as well as Rolland-Morris score.

Results: Both groups were comparable at baseline concerning the demographic and clinical characteristics (P > 0.05) (table 1). The result of repeated measures ANOVA showed a significant change in ODI score and in VAS for pain and functional disability as well as Rolland-Morris score in both groups. Using the ANCOVA, controlling for pre-test scores, a significant difference was found between the two groups (table 2).

**Conclusion:** Our clinical trial offers preliminary evidence on the superiority of Kinesio-Taping in the treatment chronic back pain compared to placebo concerning the reduction of pain and disability. Thus, it can be used as a complementary method in chronic non-specific low back pain.

**HIP ABDUCTORS STRENGTH AND TRUNK, PELVIS, AND KNEE FRONTAL PLANE KINEMATICS ANALYSIS DURING SINGLE-LEG SQUAT IN INDIVIDUALS WITH AND WITHOUT PATELLOFEMORAL OSTEOARTHRITIS**

**C. Carvalho, G. Keppe Pisani, A. Felipe Martinez, L. Mancini, F. Viadanna Serrão, P. Regina Mendes Da Silva Serrão. Federal University of São Carlos, Physical Therapy, São Carlos, Brazil**

**Background:** Previous studies have observed that individuals with patellofemoral pain (PFP) have reduced hip abduction torque, as well as increased hip adduction and knee abduction during activities with unilateral weight bearing 

**Methods:** Eccentric peak torque of the hip abductor strengthening was evaluated using an isokinetic dynamometer Biodex Multi-Joint System 3, at angular speed of 30°/s. Trunk, pelvis, hip and knee kinematics were recorded during the single-leg squat using a 6-camera, 3-dimensional motion-analysis system (Vicon Motion Systems, Nexus System 2.1.1 and 3D Motion Monitor). The t-test Student was used to compare the variables between the groups. The significance level was set at 5% for all analyses (p ≤ 0.05).

**Results:** The CG was composed by 12 participants (41.7% women). PFOA had 9 participants (44.4% women). Age (p = 0.1), height (p = 0.9) and body mass (p = 0.2) showed homogeneity between groups. Regardind body mass index, sarcopenia who continued to use a FO for 6 months. The primary outcome was physical activity measured by the International Physical Activity Questionnaire. The secondary outcomes were foot pain measured with a visual analog scale; activities of daily living (ADL) measured with the Health Assessment Questionnaire; and body mass index, body fat percentage, and the skeletal muscle mass index measured with a body composition device. The clinical variables were compared between baseline and 6 months after continuous treatment with a FO.

**Conclusion:** PFOA individuals showed greater hip adduction and lower hip abductors torque than the CG. Thus, it is suggested that muscle weakness may excessively influence hip adduction. Hip adduction is the main component of the knee valgus in the frontal plane. So, excessive dynamic valgus results in an increase Q-angle and, consequently, an increase in the lateral forces acting on the patella, causing greater stress on the lateral patellofemoral joint, which may contribute to disease progression. Therefore, we suggest that the hip abductor strengthening should be considered when treating individuals with PFOA.

**THU0568**

**EFFECTIVENESS OF FOOT ORTHOSIS TO PROMOTE PHYSICAL ACTIVITY FOR PATIENTS WITH CONCURRENT RHEUMATOID ARTHRITIS AND SARCOPENIA**

**N. Hishikawa, S. Toyama, S. Ohashi, K. Sawada, K. Ikoma, D. Tokunaga, Y. Mikami. Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Department of Rehabilitation Medicine, Kyoto, Japan; Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Department of Multidisciplinary Promote for Physical Activity, Kyoto, Japan; Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Department of Orthopaedics, Kyoto, Japan**

**Background:** Sarcopenia is a progressive systemic skeletal muscle disorder associated with an increased likelihood of adverse outcomes including physical disability, falls, and mortality. The muscle mass of patients with rheumatoid arthritis (RA) is lower than that of age-matched healthy individuals, and a high prevalence of sarcopenia has been reported. In particular, foot deformities may increase the prevalence rate of sarcopenia because of inactivity due to foot pain on walking. Treatment with a foot orthosis (FO) can reportedly reduce pain; however, whether a FO can resolve inactivity and sarcopenia is unclear.

**Objectives:** To elucidate the effectiveness of a FO on physical activity and sarcopenia in patients with RA.

**Methods:** Thirty patients with RA with foot deformities were enrolled from April 2017 to December 2019. Sarcopenia was diagnosed using the algorithm of the European Working Group on Sarcopenia in Older People, and the cut-off values of the Asian Working Group for Sarcopenia were applied. We also collected the clinical variables of patients with concurrent RA and sarcopenia who continued to use a FO for 6 months. The primary outcome was physical activity determined by the International Physical Activity Questionnaire. The secondary outcomes were foot pain measured with a visual analog scale; activities of daily living (ADL) measured with the Health Assessment Questionnaire; and body mass index, body fat percentage, and the skeletal muscle mass index measured with a body composition device. The clinical variables were compared between baseline and 6 months after continuous treatment with a FO.

**Results:** The prevalence rate of sarcopenia was 76.6% (23/30), and nine patients with RA continued to use the FO for 6 months. Table 1 shows outcomes at baseline and after 6 months of treatment with a FO. The only clinical variable that showed a significant difference was foot pain. Physical activities, ADL, and body compositions were maintained after 6 months.
Methods: This was a cross-sectional study conducted between May 2016 and Jan 2017. Consecutive patients with AxSpA and RA were recruited at an outpatient rheumatology clinic at Singapore General Hospital, the largest tertiary patient rheumatology clinic at Singapore General Hospital, the largest tertiary hospital in Southeast Asia, with more than 3,000 patients with AxSpA and RA. All patients were evaluated by a rheumatologist (AO) who has more than 10 years of experience in the management of AxSpA and RA.

Results: A total of 129 patients (50% male, 50% female) of the ÖGR participated in the online survey. All members of the ÖGR were invited to participate in an online survey through an email, and the survey was conducted via an online platform. The results of the survey are shown in Table 1.

IPAQ: International Physical Activity Questionnaire, VAS: visual analog scale, ADL: activities of daily living, HAQ: Health Assessment Questionnaire, BMI: body mass index, BFR: body fat percentage, SMI: skeletal muscle mass index

Conclusion: The prevalence rate of sarcopenia in patients with RA and foot deformities was much higher than previously reported. However, 6 months of treatment with a FO not only reduced foot pain but also maintained physical activity and muscle mass of patients with RA and concurrent foot deformities may be increased by considering physical therapy with orthotic treatment.

<table>
<thead>
<tr>
<th>Objective</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Objectives</td>
<td>This study aims to examine the patterns of PA in a multi-ethnic Asian cohort.</td>
</tr>
<tr>
<td>Methods</td>
<td>This was a cross-sectional study conducted between May 2016 and Jan 2017. Consecutive patients with AxSpA and RA were recruited at an outpatient rheumatology clinic in Singapore General Hospital, the largest tertiary hospital in Singapore. Controls were based on a previous cross-sectional study. PA was assessed using the Global Physical Activity Questionnaire (GPAQ) developed by the World Health Organization (WHO).</td>
</tr>
<tr>
<td>Results</td>
<td>74 AxSpA and 69 RA patients were recruited and compared to 886 controls. AxSpA patients were younger (median age [IQR], 37.0 [25.3] years) and predominantly male (75.7%), while RA patients were the older (median age [IQR], 59.0 [16.5] years) and predominantly female (81.2%). BMI was similar between all three groups. RA patients had more comorbidities (such as hypertension, hyperlipidemia, diabetes mellitus) compared to AxSpA patients and controls. All three groups had similar proportion of participants meeting WHO recommendations for PA (AxSpA = 77.0%, RA = 79.7%, controls = 83.1%, p = 0.35) and exercise (IQR time, 95% CI) of PA per day (IQR, 95% CI) vs. 579 (123.2) vs. 51.4 (94.3), p = 0.93. More AxSpA patients had a high level of sedentary activity compared to RA or controls (AxSpA = 56.8%, RA = 23.2%, controls = 72.2%, p &lt; 0.01). When comparing AxSpA and RA patients with inactive disease or in remission versus active disease, levels of PA did not differ between the 2 groups (p = 0.33).</td>
</tr>
<tr>
<td>Conclusion</td>
<td>Levels of PA did not differ significant between AxSpA and RA patients compared to the general population, and disease activity levels did not affect the level of PA in patients with AxSpA and RA. Of note was that patients with AxSpA and RA demonstrated higher levels of sedentary activity compared to the general population. Improving PA and decreasing sedentary activity could reduce the cardiovascular risk, especially in patients with RA.</td>

Background: Rehabilitation methods and standards for patients with rheumatoid arthritis (RA) have significantly changed due to more efficient medication improving the course of the disease. Therefore, physical activity, participation, disease management and patient education are most important goals in rehabilitation of patients with RA.

Objectives: Aim of this study was to evaluate the significance and impact of rehabilitation methods according to the subjective attitudes and views of experts and professionals in the field of RA. Opinions of members of the task force (TF) “Rehabilitation” of the Austrian Society for Rheumatology (ÖGR) were compared to the estimation of the other members of the ÖGR.

Methods: All members of the ÖGR were invited to participate in an online survey to rate the impact of rehabilitation for patients with RA between 0 (no impact) and 10 (high impact). Besides sociodemographic and experience related data about the experts and professionals, two main issues were investigated: (1) Impact of rehabilitation related to specific interventions (2) Impact of rehabilitation methods for patients with RA according to different disease and treatment points.

Results: 129 members (50% male, 50% female) of the ÖGR participated in the online survey. 12 persons were members of the TF “Rehabilitation” of the ÖGR. 11 (8.6%) respondents were general physicians, 66 (51.6%) specialists in internal medicine with further expertise in rheumatology, 15 (11.5%) specialists in internal medicine, 14 (10.9%) specialists for physical medicine with further expertise in rheumatology, 2 (1.6%) specialists in orthopaedics, 13 (10.2%) health professionals and 7 (5.5%) persons were from other profession categories such as researchers for example. The majority of respondents (80%) worked already...
more than five years with patients with RA in a stationary setting. Results of the online survey demonstrate that the ranking of the impact of specific rehabilitation interventions did not only marginally differ between the two person groups: Both groups ranked on the COBS-platform of the extremity with more affected joint. Only the subjective importance of splints and assistive technologies was higher assessed by the general members of the ÖGR. Further, the ranking about the estimated impact of rehabilitation methods for patients with RA was very similar between the two person groups: The impact of rehabilitation for patients with functionality restrictions and for patients with RA in the first years of their disease was ranked the highest by both groups.

Conclusion: Results of the online survey demonstrate that ratings related to the impact of rehabilitation interventions for RA patients do only slightly differ between the investigated member groups of the ÖGR. Finally, the results indicate that rehabilitation methods for RA patients and rehabilitation related knowledge are well accepted and successfully transferred into disease management of patients with RA by professionals and experts in rheumatology in Austria.

THU0571

EFFICIENCY OF COMPLEX REHABILITATION PROGRAM IN PATIENTS WITH OSTEOARTHRITIS

E. Orlova1, 1Moscow Centre for Research & Practice in Medical Rehabilitation, Restorative and Sports Medicine, Moscow, Russian Federation

Background: Rehabilitation techniques and nonpharmacologic therapies help to relieve pain and improve functional status in patients with osteoarthritis (OA) in addition to drug treatment [1–4].

Objectives: To evaluate the efficiency of 12-month complex rehabilitation program in patients with OA.

Methods: 50 patients with OA of hand, knee and ankle joints (76% females, age of 48 to 69 years, disease duration of 2 to 15 years) were included and randomized into 2 groups. All patients received non-steroidal anti-inflammatory drugs and chondroprotectors in standard doses. 26 study group patients underwent 12-months complex rehabilitation program: laser therapy of 12 to 15 min (infrared laser radiation, wavelength of 689 micrometers, pulse frequency of 1200 to 1500 Hz) for hand, knee and ankle joints, 3 courses for 10 sessions with a mean interval of 3,3 months; 45-min dynamic exercises using gym apparatus Enraf-Nonius under the supervision of a trainer 3 times a week; 45-min occupational therapy 10 sessions; wrist, ankle and knee orthoses, education program (3 daily 90-min studies); balance training on the COBS-platform 3 times a week. 24 patients received only drug therapy (control). Tenderness and spontaneous joint pain in 100-mm VAS, Lequesne index, WOMAC, hand grip strength, the average powers of knee extension and ankle flexion by EN-TreeM movement analysis, symmetry index (SI) and load distribution on the COBS-platform in the different modes were evaluated at baseline and at 12 months.

Results: After 12 month in the study group tender joint count decreased by 56,2% (p<0,01), swelling joint count - by 67,3% (p<0,01), pain on VAS - by 54,7% (p<0,01), Lequesne index - by 2,3 times (p<0,01), WOMAC - by 1,8 times (p<0,01), The grip strength of a more affected hand enhanced by 41,3% (p<0,05), of a less affected - by 43,4% (p<0,05). The average extension angle of a weaker knee increased by 57,3% (p<0,01), of a stronger - by 44,2% (p<0,05). The average flexion power of a more affected ankle joint elevated by 34,9% (p<0,05), of a less affected - by 48,2% (p<0,05). The pressure on the COBS-platform of the extremity with more affected joint of the patients with OA of knee joints increased by 11,7% (p<0,05), SI - by 12,9% (p<0,05) in the mode «habitual stand». The load on the limb with more affected joint elevated by 13,2% (p<0,05), SI - by 25% (p<0,05) in the mode «get up and sit down». The pressure on the COBS-platform of the extremity with more affected joint of the patients with OA of ankle joints was enhanced by 14,3% (p<0,05), SI - by 18,2% (p<0,05) in the mode «habitual stand». The load on the limb with more affected joint was elevated by 12,8% (p<0,05), SI - by 20,1% (p<0,05) in the mode «tiptoe bounce (do not leave ground)». The symptoms of pain, movement, power of motion, balance and load distribution in patients with OA.

THU0572

THE ROLE OF PRESSURE PAIN THRESHOLD IN A REHABILITATIVE APPROACH TO ANALYZE PAIN PROCESSING MECHANISM IN HAND OSTEOARTHRITIS PATIENTS: A PILOT STUDY.

P. Pedersini1, R. La Touche2, E. A. Sanchez Romero3, J. H. Villafañe1, 1RCCS Fondazione Don Carlo Gnocchi, Milan, Italy; 2Centro Superior de Estudios Universitarios La Salle, Universidad Autónoma de Madrid, Madrid, Spain; 3Universidad Europea de Madrid, Madrid, Spain

Background: The hand pain experienced by patients with hand osteoarthritis (OA) is often accompanied by hypersensitivity and signs of peripheral and central sensitization. The European League Against Rheumatism (EULAR) published a systematic literature review that summarized the current non-pharmacological, pharmacological, and surgical approaches for the management of hand OA. The identified review did not consider interventions that specifically targeted reducing pain sensitivity. A reliable method to assess the presence of hypersensitivity is the pressure pain threshold (PPT)3. During the rehabilitation management considering the pain mechanism involved could be an important factor to address more effective treatments.

Objectives: The aim of the present study was to investigate the role of pain processing mechanism in patients with hand OA through PPT and using a specific functional magnetic Resonance Imaging (fMRI).

Methods: 20 patients with hand OA and 20 healthy controls, aged 50 to 90 years, were recruited. Pressure pain threshold (PPT) was assessed bilaterally over the hand, on the C5-C6 zygopophyseal joint, median, ulnar, radial nerves, and anterior tibial muscle by a blinded assessor respect to the condition of the subjects3. In five participants for each group, PPT over the hand was assessed neurophysiologically by advanced modalities including functional MRI to analyze the pain mechanisms related to hand OA.

Results: The results showed that PPTs were significantly lower over the hand and the median, ulnar, radial nerves (P<0.05), but not over the C5-C6 zygopophyseal joint and anterior tibial (P>0.05) in OA patients as compared to healthy controls. Both groups demonstrated activation of the thalamus, frontal and somatosensory cortex area during PPT over the hand, although the total brain area activated in OA patients was greater than in control participants.

Conclusion: Patients with hand OA shown features of altered pain mechanism that were evident both in PPTs measures than using functional MRI. PPT is a useful marker in detecting pain sensitivity in hand OA and could be used in future pain studies to evaluate pain modulation strategies.

Yoga based on “Yoga in daily life system” included asanas, relaxation, pranayama and meditation. Study evaluations at baseline, post-intervention and 3-month follow-up included The Short Form-36 (SF-36) scores for Physical Component Summary (PCS) and Mental Component Summary (MCS), Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F), Hospital Anxiety and Depression scale (HADS) and Disease Activity Score-28CRP (DAS28CRP) questionnaires. Data were presented as change from baseline to each time point. Between group differences were analyzed using the t-test for normally distributed variables. P values <0.05 were considered statistically significant.

Results: 35 patients (17 = intervention, 18 = control group) completed the trial. Significant improvement in FACT-F (p=0.013), HADS anxiety (p=0.047) and HADS depression (p=0.004) was found in yoga group compared to control at post-intervention and maintained at follow-up (p=0.025, p=0.02 and p=0.045, respectively). There was no significant difference found between groups for SF-36 MCS, PCS and DAS28CRP at all time points (p=all 0.05). No serious adverse events were observed during trial period.

Conclusion: Although no change in SF-36 scores and disease activity was observed, yoga practice produced significant and sustained improvement in fatigue and mood which strongly account for decreased life quality in RA. Despite limitations our findings suggest that yoga may be of benefit in management of RA patients.

THE EFFECT OF PREOPERATIVE PHYSICAL ACTIVITY ON KNEE AND HIP ARTHROPLASTY OUTCOME IN PATIENTS WITH OSTEOARTHRITIS

E. Vandelli, C. Duflos, S. Akouete, F. Guillémin, A. C. Rat, Y. M. Pers

Methods: Data from the Knee and Hip OsteoArthritis Long-term Assessment (KHOALA) cohort (1), a multi-regional French cohort of 878 patients with symptomatic hip and/or knee OA, were analysed. We included in our study patients undergoing THA or TKA during a 7-year-follow-up period. The level of total and leisure-time preoperative PA was measured with the Modifiable Activity Questionnaire (MAQ). Outcomes were measured one year after surgery. For the primary endpoint, quality of life (QoL) was measured with the OsteoArthritis Knee and Hip Quality Of Life questionnaire (OAKHQOL). For secondary endpoints, QoL was measured with Short Form 36 (SF-36), pain with the Visual Analogue Scale (VAS), function with the Western Ontario and McMaster Universities OsteoArthritis Index (WOMAC) and with walking distance. The population characteristics were described using frequency or mean and standard deviation (SD), depending on the distribution of the variable. Association between exposures and outcomes was calculated with a multivariable linear analysis with backward selection, adjusting for confounders (age, sex, body mass index, site of joint replacement, polycystic OA, OA duration, comorbidities, radiological grade of OA, inclusion centre, rehabilitation after surgery, previous joint issues, instruction level). A p-value <0.05 was set as statistically significant.

Results: 150 patients were included. 58.7% underwent TKA and 41.3% THA. The mean age at the time of surgery was 66.6 years (±7.7 SD). The majority of patients were female (75%), overweight (mean BMI 29.63 kg/m², ±5.5 SD) and had polycystic OA (60%). 53% of patients met the World Health Organization recommendations on PA before surgery. For the primary endpoint, a high preoperative total PA was associated with a better relationship with the partner (β = 0.55, p = 0.02) one year after surgery. As for secondary endpoints, a high two-year preoperative total PA was associated with an impaired SF-36 Mental Component Summary score (β = -0.87, p = 0.02), but a longer walking distance (β = 442.81, p < 0.01). Leisure-time PA also showed a positive impact on walking distance (β = 0.26, β = 0.02), but a negative one on social functioning in SF-36 (β = -0.47, p = 0.01). No statistically significant association between preoperative PA and WOMAC was found.

Conclusion: In this cohort study, the preoperative level of PA demonstrated a heterogeneous effect on the various aspects of QoL, one year after THA and TKA in OA patients. Preoperative PA was directly associated with gain of function, measured as walking distance, after surgery. Considering the increasing prevalence of OA and the crucial role of PA on health, further studies on this relevant topic are needed.

References:
Background: JAKI (JAK inhibitors) seem simpler of use than injected biologic agents due to their oral administration route. Safety and adherence issues remain and may need to modify patients' counseling.

Objectives: To understand the influence of the DMARDs' route of administration on these issues for both patients and physicians in order to update the Hiboot® education tool (ref1).

Methods: Hiboot® is a free smartphone application developed by the French Society of Rheumatology to enhance the patient's safety, adherence to treatment, self-assessment and to give periodic counseling messages (ref1). This ethnographic study involved 118 patients with rheumatoid arthritis (RA) recruited by 3 rheumatologists considering diversity of clinical and sociological profiles. The panel included i) 14 women and 4 men, median age 56 years-old, median disease duration 10 years. Four patients were treated by methotrexate (MTX) monotherapy, 5 with MTX-bDMARDs or MTX-JAKi combo, 1 by bDMARDs monotherapy, 8 by JAKi monotherapy; ii) 9 rheumatologists with hospital or mixed hospital-private practice from 6 cities in France.

The interviews were conducted by 2 anthropologists using in-depth semi-directive biographical methods (enough to reach saturation), registered and transcribed. The semi-directive interviews dealt with: i) the patient history with RA and its treatments, ii) the daily medication management, iii) the evolution of patients' perceptions and knowledge over time.

Results: For patients, adherence and safety behaviors were guided by their representations of 3 risks: disease-related, treatment-related, physician-related. When the disease-related risk was perceived greater than the treatment-related risk, patients tended to report better adherence. Beliefs on efficacy and safety depended more on the patient's experience with RA over time (severity, activity, control) than on the route of administration (oral vs sub-cutaneous). However, patients treated with JAKi needed to update their lay knowledge and skills regarding their daily constraints and medication management.

For rheumatologists, JAKi were considered a promising therapeutic option, but rarely prescribed so far due to a lack of personal experience. Owing to their recent introduction on the market (~2 years in France), JAKi were prescribed to patients with longer disease duration and after several DMARDs lines. The rheumatologists' conservative attitude towards JAKi depended on risk perceptions similar to the patients': disease-related, treatment-related and patient-related i.e their perception of patients' abilities to manage their care (presumed skills, autonomy,...).

This study confirms the importance of patients' beliefs of the balance between medication necessity and risks regarding safety and adherence (ref2) which are shared with the rheumatologists. This study unexpectedly emphasized a doctor-related risk in patients as well as a patient-related risk in rheumatologists. One limitation is a bias in the recruitment of patients with long-standing RA.

Conclusion: Rheumatologist-patient collaboration needs a shared vision of medication risks, independently of the route of administration. However new skills are needed for patients treated with JAKi. This qualitative study will serve to modify the Hiboot application to include the JAKi issues such as the reminders or daily life management.

Background: The eRA (evolving the management of RA) programme was initiated in Europe to provide practical educational tools that address unmet needs in the management of rheumatoid arthritis (RA). Several eRA tools – covering early access to care, management of comorbidities, treat-to-target strategies, and patient empowerment – are available to the rheumatology community. Through ongoing activities, the eRA Steering Committee (SC) identified a need for tools on non-pharmacological management of RA.

Objectives: To improve accessibility to eRA tools for rheumatology professionals; to review the evidence base of non-pharmacological interventions to create new eRA resources that may support management decisions.

Methods: A web platform providing information on eRA programme and tools was developed in 2019. The platform collects survey-based metrics to quantify the perception of eRA and use of eRA tools in clinical practice. Platform and tools are translated to further support access and use across Europe.

To address unmet needs in non-pharmacological patient management, the eRA SC reviewed the literature on agreed priority interventions, including physical activity, diet, patient education and self-management, psychosocial interventions, occupational therapy and orthotics, hand exercises, and hydrotherapy/balneotherapy. Available evidence for each intervention was assessed and graded according to the Oxford Centre for Evidence-based Medicine Levels of Evidence.

Results: The eRA web platform is now live in 3 countries (www.evolvingtheraumatmanagementora.com), hosting translated copies of the eRA tools, with additional countries launching throughout 2020. From a review of core literature on non-pharmacological interventions, the eRA SC determined that strong evidence exists to support use of physical activity, patient education and self-management, psychosocial interventions, and occupational therapy and orthotics, hand exercises, and hydrotherapy/balneotherapy. A set of educational slides was produced by the eRA SC to summarise the evidence (Fig. 1) and provide top-line guidance on use of interventions in practice that should engage relevant members of the multi-disciplinary team. These slides are available through eRA dissemination activities.

Conclusion: The eRA programme content is now freely available to health care professionals in several countries on a web platform, supported by translations of the eRA tools. An additional slide set on non-pharmacological management services to further increase the practical guidance of this programme's educational offering.
statistically significant differences between women and men in having experienced gender discrimination \( (X^2=36.959 \text{ (df}=1), \ p < 0.001) \) and sexual harassment \( (X^2=12.633 \text{ (df}=1), \ p < 0.001) \). The highest-ranked interventions for career advancement regardless of respondents’ gender included: leadership skills training; speaking/presentation/communication skills training; information on training/career pathways; effective career planning training; support on grant writing applications; and high-impact scientific writing master-classes (Figure 2). Only 8 of 24 proposed interventions showed a significantly higher ranking \( (p<0.001) \) by female respondents and these typically related to promotion of female role models and gender-balance in committees, editorial boards and research funding (Figure 2).

**THU0581 USE OF EHEALTH BY PATIENTS WITH RHEUMATOID ARTHRITIS: AN OBSERVATIONAL, CROSS-SECTIONAL, MULTICENTER STUDY**

M. Magnol1, E. Berard2, C. Rempenault3, M. Pugibet4, C. Lukas5, A. Tournadre6, P. Vergne-Salle7, T. Barnetche2, M. E. Truchetet6, A. Ruysseveldt8, 1CHU Toulouse Pierre Paul Riquet, Rhumatology, Toulouse, France; 2CHU Bordeaux Pellegrin, Rhumatologie, Bordeaux, France; 3CHU Montpellier, Rhumatologie, Montpellier, France; 4CHU Clermont Ferrand, Rhumatologie, Clermont Ferrand, France; 5CHU Limoges, Rhumatologie, Limoges, France

**Background:** The use of eHealth tools (internet, mobile applications, connected devices) in chronic diseases and in the field of rheumatoid arthritis (RA) is growing (1). eHealth may improve the overall care of patients suffering from chronic diseases (2,3).

**Objectives:** The main objective of this study was to describe the use of eHealth by RA patients in France. The secondary objectives were to identify differences in demographic and disease characteristics between patients using eHealth tools or not. We also assessed patients' expectations about digital devices.

**Methods:** We conducted a cross-sectional, multicenter study. Patients with RA according to the ACR / EULAR 2010 criteria were recruited in 5 university hospitals (Bordeaux, Clermont-Ferrand, Limoges, Montpellier and Toulouse). Patients completed an anonymous self-questionnaire including demographic data, assessment about the use of eHealth (access, support, frequency of use, type of use, reason for use). The treating rheumatologist of the patient filled in an independent medical questionnaire collecting the disease characteristics, the activity of RA and the treatments. Data were collected from December 2018 to July 2019.

**Results:** The questionnaires were completed by 575 patients, with an average age of 62±13 years, 76% of whom were women. 473 (82%) patients had access to eHealth through a computer (n=402, 86%), a tablet (n=188, 40%) and/or a smartphone (n=221, 47%). Among them, 36% (170/473) used internet for health in general and 29% (134/473) specifically for RA. Regarding the use of eHealth for RA, all patients used it to learn about their disease and 66% (89/134) as a tool to help monitoring RA. Most of them (n=87/125, 70%) had a paper medical record, 24/125 patients (19%) used a digital tool (spreadsheet n=10, 8% and/or mobile application n=9, 7% and/or website n=5, 4%) and 31/125 patients

**Conclusion:** The results of the survey will inform the development of task force policy proposals for interventions to support career advancement among EULAR and EMEUNET members. The identified interventions have potential to support career advancement of all rheumatologists, health professionals and non-clinical scientists regardless of gender.
(25%) did not use any tool to monitor their RA. Few patients (16/126, 13%) used numeric reminders for their treatments. A specific application for RA was used by 27/127 patients (21%) using eHealth. Age, level of study, employment, treatment, comorbidities, membership of a patient association group and patient education program were associated with the use of eHealth for RA in univariate analysis. In multivariate analysis, membership of patient’s association (OR: 5.8 [3.0-11.2]), bDMARDs use (OR: 0.6 [0.4-1]) and comorbidities (OR: 0.7 [0.6-0.8]) remained associated with eHealth use for RA. According to the patients, recommendation by a doctor (n=225/330, 68%), ease of use (n=105/330, 32%) and data security (n=89/330, 21%) were the factors that would favor the use of eHealth.

Conclusion: To date, few patients used eHealth for their disease. The use of a reliable and validated eHealth tool in RA could therefore be promoted by rheumatologist and might optimize the therapeutic adherene.

THU0583  STRATEGIES FOR ASSESSMENT OF COMPETENCES DURING RHEUMATOLOGY TRAINING ACROSS EUROPE: RESULTS OF A QUALITATIVE STUDY.

A. Nair1,2, A. Alonso3, F. Sivera4, S. Ramiro5, C. Haines6 on behalf of Working Group for Competences Assessment in Rheumatology, 1Nantes University Hospital, Department of Rheumatology, Nantes, France; 2University of Medicine Nantes, INSERM UMR 1238, Nantes, France; 3University of Perugia, Department of Rheumatology, Perugia, Italy; 4Hospital General Universitario Elida, Department of Rheumatology, Elida, Spain; 5Universidad Miguel Hernandez, Department of Medicine, Elche, Spain; 6Leiden University Medical Center, Leiden, Department of Rheumatology, Leiden, Netherlands; 7Zuyderland Medical Center, Heerlen, Netherlands; 8King’s College, London, United Kingdom, London, United Kingdom

Background: In order to become a rheumatologist, trainees must successfully complete a rheumatology training program. Both the content and the assessments within these programs are regulated by national authorities, and therefore a wide heterogeneity between countries is expected.

Objectives: To gain insight into current methods and practices for the assessment of competences during rheumatology training, and to explore the underlying priorities and rationales for competence assessment across EULAR countries.

Methods: We used a qualitative approach through online focus groups of rheumatology trainers and trainees, separately. The study included five countries - Denmark, The Netherlands, Slovenia, Spain and United Kingdom. A summary of current practices of assessment of competences was developed, modified and validated during the focus groups. A prioritising method (9 diamond technique) was then used to identify key assessment priorities.

Results: Overall, 26 participants (12 trainers, 14 trainees), participated in 9 online focus groups (2 per country, except Slovenia), totalling 12 hours of online discussion. Strong nationally (Netherlands, UK) or institutionally (Spain, Slovenia, Denmark) standardised approaches were described. Current practices were described as follows: two countries only provide national summative assessments (Slovenia, UK), while all were providing formative assessments regularly at varying frequencies. All groups identified providing frequent formative feedback to trainees for developmental purposes as the highest priority (figure 1). Most discussions identified a need for improvement, particularly in developing streamlined approaches to portfolios that remain close to clinical practice, protecting time for quality observation and feedback, and adopting systematic approaches to incorporating teamwork and professionalism into assessment systems.
Conclusion: This paper presents a clearer picture of the current practice on the assessment of competences in rheumatology in key countries and the underlying rationale of trainers' and trainees' priorities. This work informed the EULAR Points-to-Consider for the assessment of competences in rheumatology training across Europe.

Acknowledgments: This work was funded by EULAR (EDU043)

THU0584 CASE-BASED ONLINE EDUCATION SIGNIFICANTLY INCREASES CLINICIAN COMPETENCE IN ASSESSING SSC-ILD DISEASE PROGRESSION AND IMPLEMENTING APPROPRIATE THERAPY

C. Rohani-Montez1, M. Calle1, C. Allen1, C. Denton2, 1Medscape Education Global, London, United Kingdom; 2Royal Free Campus, University College London, London, United Kingdom

Background: Due to the heterogeneity in both the initial manifestations of systemic sclerosis (SSc) and progression with SSc-associated interstitial lung disease (SSc-ILD), diagnosis and prognosis can be challenging in clinical practice. Clinicians need expert case-based guidance on how best to monitor patients with SSc and the treatment implications.

Objectives: This study was conducted to determine whether online case-based independent medical education could improve rheumatologists’ and pulmonologists’ competence in evaluating and monitoring SSc-ILD progression and initiating the right treatments when progression is identified.

Methods: Rheumatologists and pulmonologists participated in two comprehensive online case studies, using a ‘test then teach’ approach and completed all pre- and post-questions.

The effects of the education on knowledge and competence were assessed using a 3-question, repeated pairs, pre-assessment/post-assessment study design. For all questions combined, the chi-square test assessed differences from pre- to post-assessment. P values <.05 are statistically significant. The activity launched on September 24, 2019, and data were collected through December 9, 2019.

Results: Overall significant improvements were seen after participation for both rheumatologists (average correct response rate of 65% at pre-assessment vs 97% at post-assessment; P<.001, N=89), and pulmonologists (average correct response rate of 64% at pre-assessment vs 95% at post-assessment; P<.001, N=71). Specifically, significant improvements were observed in clinicians’ competence in assessing response to therapy and monitoring for disease progression; and managing evidence of disease worsening (figure).

Figure.

After participating in the activity, 54% of rheumatologists and 51% of pulmonologists had measurable improved confidence related to communicating with patients with SSc-ILD about the possibility of disease progression. Given that only around half of clinicians provided correct responses at baseline, it will be important to continue to reinforce these learnings in ongoing education.

Conclusion: This study demonstrates the success of online, case-based education in improving rheumatologists’ and pulmonologists’ competence in managing patients with SSc-ILD. This could lead to earlier changes in therapeutic approach for those with signs of progression and result in improved overall outcomes for these patients.

THU0585 ONLINE EDUCATION YIELDS SIGNIFICANT GAINS IN RHEUMATOLOGISTS’ KNOWLEDGE OF THE JAK INHIBITORS MODE OF ACTION AND CLINICAL TRIAL DATA

A. Stan1, M. Calle1, C. Scot-Smith1, R. Van Vollenhoven2, 1Medscape LLC, New York, United States of America; 2Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands

Background: Physicians face challenges staying up-to-date with the latest research and accessing the ever-growing field of knowledge is time-consuming. Online education can make these clinicians' tasks more efficient and less time-consuming.

Objectives: This study assessed whether the online CME accredited round-table-discussion with title “Meet the JAKs: Understanding the Role of Janus Kinase Inhibition in RA” improves physicians understanding mechanism of action (MOA) of current and emerging Janus kinase (JAK) inhibitors and rationale for their development in rheumatoid arthritis (RA).

Methods: Rheumatologists participated in an online CME activity (https://www.medscape.org/viewarticle/913625) consisting of a 30-minute video discussion between 2 experts with accompanying slides. Educational effect was assessed using a 4-question repeated pairs, pre-/post-assessment. A chi-square test was used to determine if a statistically significant improvement (P <.05 significance level) existed in the number of correct responses from the pretest and posttest scores. Cramer’s V was used to estimate the level of impact of the education. The CME activity launched on June 4, 2019, and the data were collected through September 3, 2019.

Results: A total of 107 rheumatologists completed the pre- and post activity assessments. Overall the activity had a significant impact (P <.001) on rheumatologists’ knowledge of JAK inhibitors and related clinical trial data with a Cramer’s V value of 0.319 indicating an extensive educational impact. The average percentage of correct responses rose from 47% pre-activity to 78% post-activity. The repeated pairs analysis (each individual learner tracked pre- and post-education) showed that 34% of learners improved their knowledge and 44% reinforced their knowledge. The change in percentage of correct responses from pre- to post-assessment achieved statistical significance for all 3 questions presented: (1) understanding the MOA of JAK inhibitors vs biologics (64% at baseline rising to 82% post activity; P <.01), (2) understanding the specificity of different JAK inhibitors (49% at baseline rising to 85% post activity; P <.001), (3) knowledge of clinical trial outcomes with JAK inhibitors (29% at baseline rising to 67% post activity; P <.001) and (4) 60% of rheumatologists gained confidence in their ability to describe the MOA of current and emerging JAK inhibitors.

Conclusion: This online CME activity significantly improved rheumatologists’ understanding of JAK inhibitors mode of action. However, there is clearly room for further improving physicians’ knowledge of clinical trial outcomes with these agents, since one third of rheumatologists provided incorrect answers to question 3 post-activity) and this topic can be further addressed in future education.

**THU0556** ESTABLISHING THE KEY COMPONENTS OF A EULAR PORTFOLIO FOR TRAINING IN RHEUMATOLOGY: A EULAR SCHOOL OF RHEUMATOLOGY INITIATIVE

M. Van Onna1, S. Ramiro2, C. Haines3, M. Holland-Fischer4, J. A. P. Da Silva5, J. Dudler6, C. Edwards7, A. Alunno8, E. Nikiphorou9, L. Falzon10, F. Sivera11 on behalf of Working group of Development of a EULAR Portfolio of Rheumatology. 1MUMC, Maasstricht, Netherlands; 2LUMC, Leiden, Netherlands; 3University of Nottingham, Nottingham, United Kingdom; 4Aalborg University Hospital, Aalborg, Denmark; 5Faculty of Medicine and University Hospital, Coimbra, Portugal; 6Fribourg Hospital Cantonal, Fribourg, Switzerland; 7University Hospital Southampton, Southampton, United Kingdom; 8University of Perugia, Perugia, Italy; 9King’s College London, London, United Kingdom; 10Feinstein Institutes for Medical Research, New York, United States of America; 11Hospital Gual Univ Elida, Elida, Spain

**Background:** In clinical training, a portfolio is expected to stimulate learning and encourage critical reflection. Some, but not all, European countries use a portfolio in rheumatology training, and their scope varies widely. A EULAR portfolio for Rheumatology trainees could contribute to improve overall training, raise educational standards, foster the setting of common goals and harmonize rheumatology training across countries.

**Objectives:** Develop key components that should be included in a EULAR portfolio of Rheumatology.

**Methods:** A working group (WG) composed of 9 rheumatologists and 1 educationalist was established. A systematic literature review (SLR) was conducted in November 2018, according to the PII model: Population: trainees; Instrument of interest: portfolio; Measurement of properties of interest: content portfolio. A survey was disseminated among the WG group and WG members of the EMerging EuRA NETWork (EMERUNET), inquiring about the content and structure of existing national portfolios. Portfolio materials of selected countries were reviewed. Last, the WG elected the key components of the portfolio.

**Results:** 13/2,034 articles were included in the SLR (12 high/1 moderate risk of bias). Information on direct observation of procedural skills (DOPS) (9/13), personal reflections (8/13), learning goals (5/13) and multisource feedback (5/13) were most often included in the portfolio. Twenty-five respondents filled out the survey (response rate = 50%). Reflective writing (n=7), learning goals (n=4) and feedback (n=4) were considered the most useful components of a portfolio. About half indicated that a portfolio was a bureaucratic burden; 4 respondents mentioned lack of feedback by supervisors as a barrier. Portfolio materials of 7 European countries were reviewed. Several portfolios (Germany, Italy, Greece and Spain) were logbooks, i.e. a record of clinical activities. Other portfolios (UK, Denmark, The Netherlands) also included information on workplace-based assessments, learning goals, and personal reflections. The proposed key components of the portfolio are included in Table 1.

**Table 1. Key components of the EULAR portfolio of Rheumatology.**

**Conclusion:** This initiative resulted in the establishment of a list of key components to be included in a EULAR portfolio of Rheumatology. Assessment forms for each key portfolio component are currently being developed. Portfolio implementation, particularly in countries that do not use it yet, may contribute significantly to promote a higher standard of patient care across Europe.

**THU0587** TB OR NOT TB? THIS IS THE QUESTION. CASE REPORT OF AN EXTRAPULMONARY TUBERCULOUS ARTHRITIS

N. Abaza1. 1Faculty of Medicine - Ain Shams University - Cairo - Egypt; Rheumatology and Rehabilitation, Cairo, Egypt

**Background:** Tuberculous (TB) arthritis consists of 1-3% of all TB cases, whereas TB tenosynovitis & bursitis account for 1%. Primarily it involves large joints but occasionally smaller non-weight-bearing joints. Diagnosis is usually delayed due to lack of awareness, radiographic findings & constitutional or pulmonary involvement.

**Objectives:** We aim to increase rheumatologists awareness to detect possible TB etiology for arthritis & tenosynovitis.

**Methods:** Our case is a 32 years old male complaining of polyarthritis of wrists, MCPs, ankle joints 4 months prior to presentation. Patient was referred as diagnosed rheumatoid patient resistant to treatment based on clinical presentation & laboratory investigation. His lab. was as follows; ESR 76 mm/hr, CRP 56.6 mg/L, RF 181.8 IU/ml, Serum creat 0.8 mg/dl, SGOT 20 SGPT 22, FBS 94, Uric acid 5.4, Hepatitis & HIV negative. CBC showing Hb 14.1 g/dl, TLC 7030/mi & platelets 289000/mi. There was no history of genitourinary, gastrointestinal manifestations, oral/genital ulcers, ophthalmological, mucocutaneous, cardiac, pulmonary, hepatic nor renal manifestations. The treatment at time of presentation was Methotrexate 25mg/week IM injection, Lefunamide 20mg/d & low dose steroids, prednisolone 5mg/d. Patient was referred to our department to assess activity, perform musculoskeletal ultrasound to the various involved joints. Hence, expected by referring physician to shift from DMARDs to biologic treatment.

**Results:** MSUS study following eular guidelines showed active synovitis in both radiocarpal & midcarpal joints bilaterally grade II by doppler signal (figure 1). Other active synovitis in multiple MCPs as well as tenosynovitis of Peroneus longus & brevis bilaterally was detected (figure 1). The swelling around the ankle was alarming though the other swollen joints seemed to be consistent with a case of RA in activity. This swelling revealed a well-defined hypoechoic heterogeneous cystic fluid collection with posterior through-transmission (figure 2) & hyperechoic hyperemic wall on PD imaging opposite medial malleolous of right fibula. The laboratory investigations prior to shifting patient had to included TB tests, tuberculin test and PCR following the positive result that we found in the skin test. Aspiration was performed from the cystic swelling and sent for clinical pathology analysis.

**Figure 1.**
TAKAYASU’S ARTERITIS PRESENTING WITH UNILATERAL DIGITAL CLUBBING IN A 23 YEAR-OLD MALE

A. Alnajjar1, A. Hegazy2, N. Al Ghanim2. 1KSMC, Internal Medicine, Riyadh, Saudi Arabia; 2KSMC, Rheumatology, Riyadh, Saudi Arabia

Background: Takayasu Arteritis is a chronic, large vessel arteritis that commonly involves the aorta and its major branches, mostly the ascending/descending aorta, subclavian arteries, and carotids [1]. Herein, we report a case of a 23 year-old medically free Indian male who presented to our hospital in acute distress complaining of cough, hemoptysis and shortness of breath for one week as well as intermittent fever and fatigue for five months. He presented with a BP of 140/100 mmHg as well as both systolic and early diastolic murmurs in the mitral and aortic areas, respectively. He also had paraumbilical bruit and unilateral clubbing in the left hand with digital ischemia of the left index finger. Doppler ultrasound of the left arm showed low velocity in the median, ulnar and radial arteries, except the second digital arteries; low velocity in left distal radial, distal ulnar, and carotid artery.

Conclusion: Unilateral clubbing in patients with TA occurs as a result of subclavian artery stenosis that leads to tissue ischemia and hypoxia [2-4]. In turn, the bone marrow release megakaryocytes, which enter the systemic circulation when an A-V shunt exists [5]. Platelet-derived growth factor (PDGF) (release from megakaryocytes) and vascular endothelial growth factor (VEGF) levels are highly expressed in the connective tissues of nail beds, leading to its proliferation and platelets clumps’ accumulation [6, 7].

THU0589  ‘KU FEVER’: A CASE REPORT
N. Cernovitch-Fasey1, D. Christidis1, M. Lloyd1, S. Melathi1, J. Wajed1. 1Frimley, Rheumatology, Frimley, United Kingdom
Background: Anti-Ku antibodies have been associated with various connective tissue diseases, including myositis, arthritis, interstitial lung disease and glomerulonephritis 1.
Objectives: We present a case of a woman initially diagnosed with biopsy proven Kikuchi-Fujimoto disease who later developed a rapidly progressive myositis in association with anti-Ku antibodies.
Methods: A 47 year-old woman, originally from Myanmar, presented with lymphadenopathy, myalgia, fatigue, livedo reticularis and low-grade fever for the previous 6 months. This was initially diagnosed as a viral infection. Her myalgia progressed with proximal muscle weakness in both legs and associated rise in creatine kinase levels to 349U/L (normal range 25-200). She also developed dyspnoea, an erythematous rash, mouth ulcers and unintentional weight loss.
Blood tests show a lymphopenia and progressively rising CK, with a maximum level of 516 U/L. MRI whole body confirmed a widespread diffuse myositis in her upper and lower limbs, with an unusual ‘speckled’ pattern. High resolution CT Chest was normal. C3 0.40 g/l (normal range 0.75-1.65) and C4 0.12 g/l (0.14-0.54) were low, with a positive ANA (1:160) and Ro-60 antibody. dsDNA, antiphospholipid screen and virology screens were all negative. Extended myositis panel revealed positive anti-Ku antibodies. Axillary lymph node biopsy confirmed necrotising lymphadenitis, consistent with Kikuchi-Fujimoto disease.
Results: She was initially treated with low dose Prednisolone and Hydroxychloroquine, with a limited response. Due to progressive myositis, pulsed IV Methyprednisolone 1g was provided over 3 days and mycophenolate mofetil (MMF) was started. An inpatient stay was needed after developing an axillary node abscesses and a chest infection. This was treated with intravenous antibiotics and repeated aspirations. Due to progressive myositis on a background of sepsis, intravenous immunoglobulin (IVIG) was administered over 5 days. Our patient made a good recovery, with normalization of CK levels and resolution of the myositis noted on repeat MRI scan. She remains on MMF as maintenance therapy.
Conclusion: Anti Ku antibodies appear to be associated with 2 spectrums of disease – elevated CK levels with interstitial lung disease and renal disease associated with anti-dsDNA antibodies 2. To our knowledge this is the first report in association with Kikuchi-Fujimoto disease. The combination of MMF and IVIG appears to have been effective treatment and her renal function remains stable, although we are monitoring the patient carefully for the possible development of interstitial lung disease.

THU0590  WHEN RARE IS EVEN RARER: A COMPLEX CASE OF BHCET DISEASE
M. Di Cicco1, O. M. Epis1, C. Casu1, A. Adinolfi1, L. Alvaro1, V. Campanella1, M. Chevallard1, M. Muscara1, M. Romano1, E. Schito1, N. Ughi1, E. Verduci1, D. A. Filippini1. 1Niguarda Hospital, Rheumatology, Milan, Italy
Background: Behcet disease is a rare inflammatory disorder with the unique ability to affect vessels of any size. The disease could be associated to thrombosis in both the venous and arterial compartment, and often aneurysms. In particular, the presence of aneurysms of the pulmonary artery is rarely, if ever, seen in conditions other than Behcet. Cardiac involvement, albeit uncommon, is also described and associated to a severe prognosis. The treatment is based on immunosuppressants, meanwhile the use of anticoagulants -especially when aneurysms are present- is debated.
Objectives: To describe a complex case of Behcet disease.
Methods: We report the case of a 45 years old man of Chinese origin who presented to A&E with fever and acute dyspnea. Blood test revealed raised ESR and CRP and raised neutrophil count. Chest X rays showed bilateral opacities suggesting pneumonia. The patient did not improve over the course of antibiotics. Later on, he presented with an episode of hemoptysis and worsening dyspnea, so he was admitted to the Intensive Care Unit. CT showed bilateral pulmonary thromboembolism and aneurysm of the pulmonary artery. Echocardiogram and cardio-MRI revealed a large, mobile thrombus within the right atrium. Extensive work-up for infections and cancer was unrevealing. ANA, ENA and ANCA antibodies were negative. On the basis of a past medical history of recurrent oral ulcers and papulopustular skin lesions patients admitted on questioning, a diagnosis of Behcet disease was suspected. In keeping with that, HLA-B51 turned out positive. The patient was promptly started on IV steroid pulses followed by Cyclophosphamide 1 gr IV monthly for six months, then on IV anti-TNF alpha Infliximab. He was also commenced on low molecular weight heparin (LMWH) and subsequently direct factor Xa inhibitor Apixaban.
Results: The patient improved significantly with progressive regression of the pulmonary CT changes. He was discharged and able to get back to his daily life activities. After 2 years and a half of treatment, the aneurysm was stable and the intra-cardiac thrombus completely cleared.
Conclusion: This case is of particular interest because of the concomitant presence of two rare vascular complications of Behcet disease- intracardiac thrombosis (<1-2%, less than 100 cases described worldwide) and pulmonary artery aneurysm (1-2%). Prompt introduction of immunosuppressant therapy was associated with a favorable outcome with no recurrence. We could speculate that, to some extent, the concomitant use of anticoagulants may have contributed to the complete resolution of the intracardiac thrombosis.

THU0591  CENTRAL NERVOUS SYSTEM VASCULITIS IN WHIPPLE DISEASE: A CASE REPORT
A. Giollo1, C. Zivelonghi2, D. Cardellini2, G. M. Schiavi2, G. Vattani2, O. Viapiana1, M. Rossini1. 1University of Verona, Rheumatology Section, Department of Medicine, Verona, Italy, 2University of Verona, Department of Neuroscience, Biomedicine and Movement Sciences, Verona, Italy
Background: Whipple disease (WD) is a rare systemic infection with possible involvement of the central nervous system (CNS). The neurological manifestations of the disease are various and can mimic any neurologic condition.
Objectives: To describe the severe neurological complications occurred in a patient with WD misdiagnosed as a chronic inflammatory immune-mediated disorder.
Methods: Case report
Results: A 46-year-old woman developed acute right-sided hemiparesis and dysarthria. She had a 10-year history of ill-defined rheumatic condition (defined as seronegative rheumatoid arthritis, spondyloarthritids, and adult onset Still’s disease) presenting with polyarthriitis, episodic fever > 38°C and rash of unclear etiology poorly responsive to different immunotherapies including methotrexate, anti-IL6 and anti-IL1 inhibitors. Brain MRI demonstrated multiple anterior circulation infarctions and stenosis of the bilateral M1 segments of the middle cerebral artery on MR angiography. Black blood sequences revealed contrast enhancement of the vessel walls consistent with vasculitis (Figure 1). Cerebrospinal fluid (CSF) analysis was unrevealing, including PCR for viruses and bacteria. A working diagnosis of primary CNS vasculitis and progressive neurologic deterioration with abnormal behavior and altered mental status prompted the
initiation of intravenous (IV) methyiprednisolone followed by cyclophosphamide without significant improvement. Re-evaluation of the long-standing history of joint symptoms unresponsive to immunotherapy, along with recurrent fevers and chronic diarrhea raised the suspicion of unrecognized Whipple’s disease. PCR for Tropheryma Whipplei was positive in stool, urine, blood and CSF, and duodenal mucosal biopsies confirmed the diagnosis. A combination of ceftriaxone, doxycycline, and hydroxychloroquine was initiated. Three days later the patient developed pericardial burning pain and cutaneous vesicles consistent with shingles. Varicella-zoster virus DNA was detected in CSF and IV acyclovir was started. At 3 months follow-up neurologic examination was unremarkable except for a slightly fatuous behavior.

Conclusion: Recognition of rare manifestations of WD is important to avoid diagnostic delay and inappropriate, potentially harmful treatments.

INSIDIOUS CORONARY ARTERY DISEASE IN A YOUNG PATIENT WITH POLYARTERITIS NODOSA: A CASE REPORT AND REVIEW OF LITERATURE

H. Huang1, Z. Zhang1. 1Peking University First Hospital, Beijing, China

Background: Polyarteritis nodosa (PAN) is a systemic necrotizing vasculitis that typically affects medium-sized muscular arteries, with occasional involvement of small muscular arteries[1]. Although overt myocardial infarction is uncommon, myocardial ischemia may result from narrowing or occlusion of the coronary arteries[2].

Objectives: Herein, we report a case with 7-year's history of PAN and unstable angina pectoris due to coronary occlusions of the three main arteries. We also reviewed the literatures regarding coronary artery involvement in PAN.

Methods: A 22-year-old Chinese man who presented with chest pain lasting for a few minutes and then subsiding spontaneously for 1 month was admitted to our hospital. He was diagnosed as PAN 7 years ago and during 7-years' follow-up, he has been in stable condition, without any discomfort or abnormal laboratory findings. In December 2019, he suffered from chest distress accompanied by retrosternal pain, with frequency of about 2-3 times a week. His symptoms were gradually aggravating with dyspnea at night.

Results: Coronary computed tomography angiography found diffuse coronary stenosis (Fig. 1). Further coronary angiography revealed a slight plaque infiltration of the left main coronary artery, and occlusion of all the three major coronary arteries, as well as multiple coronary aneurysms. 95% stenosis of the obtuse margin branch artery was also found and a stent was then implanted (Fig. 2). Prednisone 50mg/day and methotrexate 15mg/week were reintegrated, in combination with anti-anginal medications including aspirin and statin.

Conclusion: We report a young PAN patient with insidious stenosis of three main coronary arteries under the circumstance of stable disease activity for years. This reminds us of the necessity of assessing heart, probably other organs as well, in PAN patients even though their acute phase reactants in serum are normal. But how often to do the screening and which screening examination should be done, remain to be further investigated.

Fig. 1 Coronary computed tomography angiography found diffuse coronary stenosis.

Fig. 2 Coronary angiography. (a) A 50% stenosis followed by aneurysmal change of the proximal end of left anterior descending (LAD) artery, and totally occluded from the middle segment; A aneurysmal change of the initial part of left circumflex artery (LCX) and then totally occluded (dotted line); A 95% stenosis obtuse margin branch. (b) A totally occluded right coronary artery (dotted line). (c) Final appearance of the LCX after stent implantation. After we reviewed all the English literatures reporting cardiac involvements in adults with PAN from 1990 to 2019, a total of 34 patients from 32 articles were identified. 25 (73.5%) patients were admitted to hospital due to acute coronary syndromes manifesting as chest pain or dyspnea. Coronary stenosis or occlusions were most common on imaging or autopsy. Most of the patients had more than one vessel involved, of whom 7 patients showed evidence of triple vessel lesions. Aneurysm was also common in these patients, especially multiple aneurysms. Spontaneous coronary artery dissections were rare in PAN patients. Most patients received glucocorticoid, and/or immunosuppressant therapy, including cyclophosphamide and azathioprine, with or without invasive operations. 15 patients died from cardiopulmonary arrest, the most frequent cause being death, and 15 patients were stable without symptoms after treatment.

LIBMAN SACKS ENDOCARDITIS COMPLICATED WITH CEREBRAL EMBOLOM REVEALING SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE REPORT

D. Khalifa1, K. Baccouche1, N. El Amri1, H. Zeglaoui1, E. Bouajjina1, 1Farhat Hached Hospital, Rheumatology Department, Susah, Tunisia

Background: Libman Sacks endocarditis (LS) is an uncommon sterile endocarditis mostly associated with malignancies. It can also complicate the evolution of systemic lupus erythematosus (SLE) in 1 out of 10 patients after many years of evolution of the disease.

Objectives: To raise awareness of the possible rare complications of LS in SLE.

Methods: We report a case of a complicated Libman Sacks endocarditis revealing the diagnosis of SLE.

Results: A 53 years old female patient with history of hypertension was admitted to the rheumatology department for polyarthritis since 2 months with evidence of SLE.

Conclusion: LS endocarditis is not common but when it presents it is often associated with high morbidity and mortality. Health care professionals should consider LS diagnosis in patients with underlying SLE and should be aware of the risk of embolisation. Tests to rule out infectious disease may delay initiation of appropriate treatment leading to severe prognosis. The treatment of LS endocarditis is still not well codified.

THU0594

A CASE OF TAKAYASU'S ARTERITIS IN A PATIENT WITH TUBERCULOUS LYPHADENITIS

T. Khan1, N. Cleaton1, T. Sheeran1, 1Royal Wolverhampton NHS Trust, Rheumatology, Wolverhampton, United Kingdom

Background: Takayasu's arteritis (TA) is a large vessel vasculitis that principally affects the aorta and its main branches. The incidence has been reported to be between 1.2 – 2.3 cases per million per year, more commonly in the Asian population. The age of onset is typically between tenth and fourth decade; between 80 and 90 percent of the cases are female.

The relationship between Mycobacterium Tuberculosis (mTB) and TA has long been considered; both demonstrate chronic inflammatory changes on histological examination and some granuloma formation in arterial walls. There is increasing evidence implicating mTB in the pathogenesis of TA through molecular mimicry between the mycobacterium heat shock protein 65 (mHSP-65) and the human homologue HSP -60 (hHSP-60). However, no definitive link between the two diseases has been explained.

Objectives: Case presentation.

Results: A 23-year-old lady was referred to our outpatient rheumatology clinic with a twelve-month history of persistently enlarged cervical lymph nodes on the left side for which she had received six months of anti-Tuberculosis medication. She had been referred to the respiratory physicians who had diagnosed presumed Tuberculous Lymphadenitis, with caseating granulomas demonstrated on biopsy, positive acid-fast bacilli smear but a negative culture. The patient had been initiated six months of anti-Tuberculosis medication; however, her lymphadenopathy showed no improvement. More recently she described a five-month history of weakness, paraesthesia and claudication symptoms in her left upper limb with episodes of dizziness and blurred vision, episodes occurring 2-3 times per day and lasting between a few minutes to a few hours.

Her examination at this presentation revealed an unrecordable blood pressure in the left upper limb and 104/67mmHg in the right. There was significant tender lymphadenopathy of the left cervical lymph nodes and diminished pulses in the left upper limb. Right sided pulses were normal. The rest of her examination was normal.

Investigations at presentation revealed elevated inflammatory markers with C-reactive protein (CRP) of 116mg/dL and erythrocyte sedimentation rate (ESR) of 128mm/h. Complete blood count (CBC) found her to be anemic with a haemoglobin of 100g/L, with a mean cell volume of 71.3fl, and have elevated platelet reactive protein (CRP) of 116mg/dL and erythrocyte sedimentation rate (ESR) of 128mm/h. Complete blood count (CBC) found her to be anemic with a haemoglobin of 100g/L, with a mean cell volume of 71.3fl, and have elevated platelet count of 649x 109/L. Recent computerized tomography scan with contrast of the thorax demonstrated features consistent with Takayasu Arteritis. Marked left subclavian stenosis was found on magnetic resonance imaging. High dose prednisolone at 60mg once daily along with Azathioprine 2mg/kg/day was started with a follow up appointment in two weeks.

Conclusion: There is increasing evidence implicating mTB in the development of TA and a few cases recognising this link have been reported. We report a case of TA in a patient recently diagnosed and treated for Tuberculous lymphadenitis who then developed symptoms of TA. There should be a low threshold for suspecting a diagnosis of Takayasu's arteritis in patients previously or actively infected with Mycobacterium Tuberculosis. Further research exploring the relationship between mTB and TA is required.

are known such as endocardial fibroelastosis, dilated cardiomyopathy, and valvular insufficiency. The early clinical diagnosis in utero is essential to be specified due to myocardial tissue damages can be reversible. In the prevention and in the confirmed cardiac involvement the first line therapies are chloroquine, dexamethasone and intravenous immunoglobulins, and also a regular foetal echocardiography is of essential importance.

**Objectives:** Main objective of this report is description of successful treatment of an anti-SS-A antibody exposed foetus with cardiac manifestation.

**Methods:** Case report of a 25-year-old pregnant woman and her baby. The mother was diagnosed with Sjögren's syndrome in 2013. In previous case history there were two late foetal deaths at the 23rd and 33rd gestational age in 2016 and 2017, respectively as a consequence of foetal bradycardia. During her 2nd pregnancy the mother received chloroquine and azathioprine. At present she was referred to our Institute in October 2019 at 23rd weeks of gestation without any complaint and any abnormality of pregnancy. Foetal development was normal. Mother received azathioprine and chloroquine from the beginning of pregnancy and dexamethasone from the 16th weeks of gestation. Foetal echocardiography was performed at the 16th gestational week, and every week thereafter. Reflective areas, reflecting oedema and inflammation, appeared at 24th gestational week.

**Results:** The case was referred, and the combo therapy was completed with 1 mg/masternal kg intravenous immune globulin, dexamethasone dose was increased to 4 mg for a week, then decreased to 2 mg. Intratect was given every 2 weeks. Progression was stopped according to control foetal echocardiography after the 2nd infusion. After 4th IVIG the involved area of myocarditis decreased significantly, localised to anterior wall of left atrium and the atrial pri-

**Conclusion:** The case was referred, and the combo therapy was completed with 1 mg/masternal kg intravenous immune globulin, dexamethasone dose was increased to 4 mg for a week, then decreased to 2 mg. Intratect was given every 2 weeks. Progression was stopped according to control foetal echocardiography after the 2nd infusion. After 4th IVIG the involved area of myocarditis decreased significantly, localised to anterior wall of left atrium and the atrial pri- mum septum. However, at 32nd g. week pericardial fluid was visualised in maximum 9 mm width without signs of pericardial tamponade. At the end of last December, the baby was born at the 35th gestational week with 50 cm and 2570 g and no signs of any congenital anomaly. Pericardial fluid was 4 mm maximum. Her development is normal.

**ABNORMAL RIGHT VENTRICLE RESERVE ON EXERCISE PREDICTS PULMONARY HYPERTENSION IN MIXED CONNECTIVE TISSUE DISEASE: A CASE REPORT**

J. Su1, W. Su1, W. Long1. 1Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Affiliated University of Electronic Science and Technology of China, Department of Rheumatology and Immunology, Chengdu, China

**Background:** Pulmonary hypertension is one of the most common complications in patients with mixed connective tissue disease (MCTD). Patients are usually at the late stage and have irreversible right heart dysfunction when diagnosed as pulmonary hypertension with the rest echocardiography. Early detection of right heart dysfunction before pulmonary hypertension is essential to ensure that patients receive timely and appropriate treatment for this progressive disease. We aimed to use exercise stress echocardiography to detect early right heart dysfunction in patients with CTD and without pulmonary hypertension.

**Objectives:** To present a clinical case of MCTD with normal right ventricular (RV) function at resting but presenting RV dysfunction on exercise, who developed pulmonary hypertension after one-year follow-up.

**Methods:** Case report. The patient was subject to the treadmill exercise stress echocardiography. The autoantibodies including anti-nRNP/Sm, anti-Ro-52, and antinuclear antibody (ANA) were detected. The patient was followed-up to one year.

**Results:** A 31-year-old female patient was admitted to our department in 2018, with a history of MCTD for five years. Autoantibodies testing revealed that the patient was positive for anti-RNP/Sm (++) and anti-Ro-52 (+), and ANA (1:3200). Echocardiography revealed no obvious cardiac dysfunction. However, the velocity of tricuspid valve regurgitation was 3.0 m/s following treadmill exercise stress. The patient was followed-up to one year. Then, she developed occult pulmonary hypertension with the velocity of tricuspid valve regurgitation of 3.3 m/s following treadmill exercise stress. Accordingly, MTX and prednisone were switched to MTFX, prednisone, hydroxychloroquine (HCQ) and beraprost.

**Conclusion:** This study showed that treadmill exercise echocardiography could detect right heart dysfunction early before diagnosed as pulmonary hypertension with rest echocardiography in patients with MCTD in its early stage.

**CORNEAL MELT - DON'T ALWAYS BLAME RHEUMATOID ARTHRITIS**

A. Munir1, C. Sheehy1. 1Waterford University Hospital, Department of Rheumatology, Waterford, Ireland

**Background:** Corneal melt is a rare inflammatory disease of the peripheral cornea; it may lead to perforation of the globe and visual failure. Corneal melt can be a manifestation of systemic vasculitis in patients with RA and other conditions, such as cancer. Without early and aggressive treatment it may be associated with a poor visual outcome and a high mortality. It has been reported in patients with stable RA.

**Objectives:** A case report in a patient with long standing but well controlled Rheumatoid Arthritis (RA) and metastatic disease.

**Methods:** A 75 year old male with a background of zero positive Rheumatoid Arthritis for more than 10 years presented to the Eye Casualty with a two week history of a painful left red eye. His other medical history was significant for Stage IIB poorly differentiated cancer of the left lower lobe. Left lower lobectomy with a patch of diaphragm resected. Intratumoral lymphovascular invasion noted. He completed Adjuvant Carboplatin/Vinorelbine chemotherapy September, 2017. He had DVT proximal left leg 22nd of September, 2017. Follow up CT in 2018 demonstrated a right renal upper pole lesion for which he was awaiting biopsy with/metastatic lung disease vs primary renal carcinoma. His RA was well controlled on Methotrexate 10mg weekly. He had been treated by the ophthalmol-
gist team for left marginal Keratitis for the prior 2 months with steroid eye drops without significant improvement. On presentation to ED, he described sharp eye pain, waking him from the sleep, associated with watery discharge and photo-

**Conclusion:** Corneal melt is a rare inflammatory disease of the peripheral cornea; it may lead to perforation of the globe and visual failure. Corneal melt can be a manifestation of systemic vasculitis in patients with RA and other conditions, such as cancer. Background: Gout is an inflammatory arthropathy associated with long-standing hyperuricemia. The first metatarsophalangeal joint is the most commonly involved joint, although gout is often polyarticular. Involvement of tendons has been described, but is rare. We report a case of gout involving the inferior portion of the patellar tendon.

Objectives: A Case report to highlight a rare presentation of gout.

Methods: A 50 year old male presented to the Rheumatology emergency clinic with severe right knee pain, unable to weight bear. He had been recently diagnosed with Sero negative Inflammatory Arthritis and treated with Methotrexate for 4 months. He had presented one week previously to the general medical team on call with similar but less severe pain. He was discharged on steroids, which were of no significant benefit. The pain progressively worsened to the extent that he was not able to bear weight on the right knee. He denied pain or swelling of any other joint.

On examination of his right knee, it was extremely tender, slightly erythematous with increased local temperature. There was no arthritis in any other joint and there were no tophi. Joint aspiration was attempted but there was no fluid. He was admitted with query Septic arthritis and started on intravenous antibiotics. Uric acid level was 583u/l. US of the knee showed small fluid in the pre patellar bursa. Orthopaedic team was involved and he was taken to the operation theatre. Knee joint was aspirated which was negative for crystals and there was no growth on cultures. He ultimately had an MRI of his right knee which showed significant soft tissue oedema and abnormality in the patellar tendon.

Objectives: Identifying vasculo-Behçet’s disease and its management.

Methods: A 25-year-old man born in Malaysia and known for cirrhosis due to idiopathic Budd Chiari syndrome presented to the emergency room with a transient ischemic attack. An inferior vena cava (IVC) occlusive thrombus and a patent foramen ovale (PFO) were discovered. Thrombolysis, angioplasty, PFO closure, and a transjugular intrahepatic portosystemic shunt (TIPS) procedure were performed. The following year, the patient experienced numerous IVC and TIPS-associated thromboses as well as a right atrial thrombus attached to his PFO closure device, all of which were refractory to anticoagulation. A few months later, the patient suffered from an acute right anterior cerebral artery stroke, with no etiology uncovered at the time. It was later determined that the patient had experienced years of recurrent oral and genital aphthae, thereby prompting a strong clinical suspicion of BD. Six months later, after only one appointment at the rheumatology clinic during which he was prescribed colchicine, the patient presented to the hospital with hemoptysis. A computed tomography (CT) pulmonary angiogram revealed a right lower lobar pulmonary arterial aneurysm with a peripheral thrombus, a right bronchial artery dilatation, and pulmonary emboli. The patient declined anticoagulation and was sent home. Two months later, he returned to the hospital, this time with hematemesis. A repeat CT pulmonary angiogram was performed and showed an increasing pulmonary emboli burden and an enlarging aneurysm. A thrombophilia workup was negative.

Results: A diagnosis of BD with pulmonary aneurysms was made and treatment was initiated with methylprednisolone pulses and monthly intravenous cyclophosphamide as recommended by the European League Against Rheumatism. A month later, there was radiological evidence of significant improvement in the burden of pulmonary emboli, an interval decrease in the aneurysm’s diameter, and resolution of the right atrial thrombus.

Conclusion: BD with vascular involvement or vasculo-Behçet’s disease can affect small, medium, and large vessels of both the venous and arterial vasculature and is thought to originate from vessel wall inflammation. Thrombi in vasculo-Behçet’s disease are typically quite adherent to the vessel walls and tend not to embolize. In this case, pulmonary arterial thrombosis burden was significantly decreased after immunosuppression alone, favoring a diagnosis of in situ thrombosis rather than thromboembolism. Moreover, pulmonary artery aneurysm, Budd-Chiari syndrome, and vena cava thrombosis, which are quite uncommon and carry the highest mortality risk in vasculo-Behçet’s, were all present in this case. Early recognition can be life-saving as immunosuppression is the first-line therapy rather than anticoagulation, which carries a significant risk of pulmonary hemorrhage in the presence of a pulmonary artery aneurysm.
A CASE OF SYSTEMIC SCLEROSIS COMPLICATED BY RENAL CRISIS: POTENTIAL ETIOPATHOGENETIC ROLE OF CYTOMEGALOVIRUS AND TREATMENT

A. Palermo1, E. Galli1, A. Spinella1, E. Cocchiara1, F. Lunetti1, G. Klinowski1, S. Giovanella2, C. U. Manzini1, C. Salvarani1, D. Giuggioli1, 1Scleroderma Unit, Chair of Rheumatology, University of Modena and Reggio Emilia, Modena, Italy; 2Nephrology Unit, Policlinico di Modena, Modena, Italy

Background: Scleroderma renal crisis (SRC) is a rare complication of systemic sclerosis (SSc), which can be triggered by viruses, such as Cytomegalovirus (CMV). SRC presents as a new-onset accelerated-phase hypertension with/out rapidly progressive renal failure.

Objectives: Here we describe the case of a patient developing SSc complicated by the appearance of SRC after a recent episode of acute Cytomegalovirus infection.

Methods: A 66-year-old male was referred to our Scleroderma Unit in March 2019. He presented with widespread skin rash, exertional dyspnea and peripheral edema. He reported a myocarditis due to CMV occurred in October 2018. Antibodies anti-CMV IgM were detected in his serum. The patient developed a progressive cutaneous involvement characterized by diffuse oedema, sclerosis and melanoderma. Subsequently, Raynaud’s phenomenon, puffy hands and pitting scars occurred. Laboratory tests showed positive ANA in a titer of 1:640 in a nucleolar staining pattern. Additionally, persistence of anti-CMV IgM was found. Skin biopsy showed scleroderma-like finding. Nailfold capillaroscopy revealed a SSc pattern. Chest high resolution computed tomography displayed basal interstitial thickening and subpleural ground-glass opacities. Therefore, the patient was diagnosed with SSc. Three weeks later he developed severe hypertension and a rapid, progressive renal involvement. Serum creatinine increased (up to 4.15 mg/dl), glomerular filtration rate impaired (25 ml/min). Renal biopsy (picture A, B) revealed acute thrombotic microangiopathy. A diagnosis of thrombotic thrombocytopenic purpura was excluded. The patient was diagnosed with SRC and we started therapy with ACE-inhibitor and loop diuretic. Even if the dosage of ACE-inhibitor was increased up to the maximum tolerable dose, his renal function did not improve and the blood pressure control was inadequate. Consequently, the patient underwent plasma exchange (PEx) sessions. Two weeks later there was an improvement of renal function and blood pressure normalized. Six months later the disease was controlled: glomerular filtration rate was 41 ml/min and blood pressure was within the normal range. The patient was treated with ACE-inhibitor and underwent fortnightly apheretic sessions. Treatment for scleroderma vasculopathy is ongoing.

Results: Viral infections may be responsible for SSc. A brief interval between an acute viral infection and the onset of SSc may suggest CMV as a possible trigger for the disease. Similarly, other infectious agents could be involved in the multistep and multifactorial mechanism of SSc. This case sheds light on the potential and intriguing role of CMV in SSc. Moreover, it leads us to hypothesize a CMV possible direct role in sclerodermal kidney damage. Use of ACE-inhibitor significantly reduced the mortality rate due to this complication. Exact therapeutic mechanism of PEx in the treatment of SSc is unclear.

Conclusion: In our case the integrated ACE-inhibitor-PEx approach has showed effectiveness and safety in the management of SRC.

DOI: 10.1136/annrheumdis-2020-eular.2981
An ultrasound of the hip showed a low abundance intra-articular effusion. The C-Reactive protein value, the protein electrophoresis were normal. Tumor left femur and proximal extremity of the tibia. The pelvis X-rays showed osteolytic lesions in the ischiopubic branch and in the mobilility of the left hip joint was very painful and restricted.

Results: The eosinophilia and the history of asthma rise the suspect of EGPA vasculitis. The patient was treated with intravenous methylprednisolone 250 mg once daily, followed by oral prednisone 1 mg/kg/day, with rapid and complete resolution of the recurrent angina episodes. Intravenous cyclophosphamide 10 mg/kg was administered every 2 weeks for 2 times, then 12 mg/kg every 4 weeks. Oral corticosteroid was tapered, with the persistence of a complete remission of the symptoms, after 2 months of immunosuppressive therapy.

Conclusion: Coronary involvement in EGPA can mimic atherosclerotic artery disease and can be life threatening, if not promptly recognized. An accurate medical history and complete serological and immunological tests are crucial to detect an atypical onset of EGPA, prompting early immunosuppressive therapy which is pivotal for the patient survival.

THU0602 EXTENDED BONE HYDATIDOSIS IN THE HIP AND FEMUR WITH EXTENSION TO THE SOFT PARTS: A CASE REPORT

M. Hassayoun1, S. Boussaid2, E. Hannech1, S. Jemmali1, S. Rekik1, E. Cheew1, H. Sahil1, M. Elleuch1, La Rabta Hospital, Tunis, Tunisia; 2La Rabta Hospital, Department of Rheumatology, Tunis, Tunisia

Background: Osseous hydatid cyst is an uncommon disease with weak response to treatment hydatid disease should be included in the differential diagnosis of cystic lesions of bone in endemic regions. Bone cysts account for only 0.5 to 2.5% of all hydatid cysts in humans.

Objectives: To report a case of osseous hydatid disease extended on hip and femur

Methods: We report a case of osseous hydatid disease

Results: A 49 year old bricklayer, with no past medical history and no animal contact, was admitted to our department for a left hip pain, the patient was apyretic and in a good general health condition. He had a very painful walk, the mobility of the left hip joint was very painful and restricted. The pelvis X-rays showed osteolytic lesions in the iliopubic branch and in the left femur and proximal extremity of the tibia.

The C-Reactive protein value, the protein electrophoresis were normal. tumor markers test was negative. An ultrasound of the hip showed a low abundance intra-articular effusion. The Pelvic MRI showed multilocular appearance extending over the bone and muscle with breach of the bone cortex of the femur very suggesting of the diagnosis of a bony and muscular echinococcosis.

No other localization of hydatidosis were detected, body CT scan was normal.

Conclusion: Hydatid disease occurs worldwide and mainly associated with sheep farming. The liver and lungs are the most common locations. Bone cysts are uncommon but severe. Although immunofluorescent assays are useful, the final diagnosis depends on histology. The treatment is almost surgery. Recurrence is common.

DOI: 10.1136/annrheumdis-2020-eular.6325

Background: IgG4-related disease (IgG4-RD) is a polymorphic autoimmune disease leading to tumourous swelling and/or fibrosis of affected organs. Riedel's thyroiditis is – besides chronic periarteritis, Mikulicz Syndrome and many others – an organ manifestation of IgG4-RD that has been thought to be an independent disease for a long time. About 40% of patients have single organ IgG4-RD while the others suffer from multisystemic disease [1].

Objectives: Glucocorticoids, sometimes combined with other immunosuppressives are the standard treatment of IgG4-RD, in some situations (e.g. mechanical complications or suspected malignancy) surgery may be necessary but little is known about the management of fully resected single-organ IgG4-RD [1].

Methods: We report a case of single-organ IgG4-RD (Riedel's thyroiditis) after complete resection and perform a brief review of the literature to guide clinical management in this situation.

Results: A woman (51 y) with pre-existing Hashimoto's thyroiditis (thyroid per-oxidase antibody positive) developed a rapidly growing struma with very firm consistency (not allowing fine needle biopsy). Besides slightly increased C-reactive protein (5.3 mg/l) there was no laboratory sign suggestive for IgG4-RD (normal serum IgG4, complement, eosinophils and IgE). Within 4 months the patient suffered from hoarseness and progredient dyspnea. Surgical thyroidectomy was performed and histopathology revealed IgG4-related Riedel's thy-roiditis with extensive (storiform) fibrosis, a dense lymphoplasmacytic infiltrate, obliterate phlebitis, eosinophilia and 13 IgG4-positive plasma cells per high power field.

After referral to our department a comprehensive work-up showed no signs of other manifestations of IgG4-RD. Treatment with glucocorticoids is clearly recommended for patients with symptomatic IgG4-RD in an international consensus statement, whereas “watchful waiting” may be appropriate in some cases of asymptomatic or mild disease. While some highly fibrotic lesions may not respond well to glucocorticoids and may require surgical intervention, no clear guidance is available for the management of fully resected single organ IgG4-RD [2].

A brief review of the literature revealed that few cases of single-organ IgG4-RD remaining in remission after resection without medical treatment have been reported e.g. IgG4-related cholecystitis, autoimmune-pancreatitis, tumours of the intestinal tract, lung, thymus, meninges, paravertebral space and others [3–9]. After discussion of the options with the patient no systemic immunosuppression was given under close follow up without signs of relapse in clinical examinations, laboratory or imaging during the first 6 months.

Conclusion: Limited evidence from case reports suggests that a “watchful wait-ing” strategy without systemic immunosuppressive treatment may be reasonable in some cases of single-organ IgG4-RD after the affected organ was completely resected (e.g. due to mechanical complications or suspected malignoma). However, close follow-up monitoring should be applied due to the risk of relapse or development of new organ manifestations.

# UNDIAGNOSED RHEUMATIC DISEASE IN NEWLY PRESENTING MGUS PATIENT

O. Zhou1,2, K. Wang2, L. Rahman4, A. Watad1, S. Savic1,4, E. Roman1, D. McGonagle1. 1. National Institute for Health Research, Leeds Biomedical Research Centre and Leeds Institute of Rheumatism and Musculoskeletal Medicine (LIRMIM), Leeds, United Kingdom; 2. Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Department of Rheumatology and Immunology, Chengdu, China; 3. University of Leeds, School of Medicine, Leeds, United Kingdom; 4. St James’s University Hospital, Department of Clinical Immunology and Allergy, Leeds, United Kingdom; 5. University of York, Epidemiology & Cancer Statistics Group (ECSG), Department of Health Sciences, York, United Kingdom

**Background:** Monoclonal gammopathy of undetermined significance (MGUS) is considered to be a premalignant condition with an average of approximate 1% annual risk of progression to multiple myeloma or other lymphoproliferative disorders [1]. Numerous studies have highlighted a common feature of autoimmune inflammatory diseases is non-specific hypergammaglobulinemia which can be associated with monoclonal gammopathy [2, 3]. We looked at a population of 3.6 million where patients with MGUS was referred to haematology network for evaluation.

**Objectives:** Our hypothesis was that undiagnosed rheumatic diseases were being referred to haematology rather than rheumatology erroneously.

**Methods:** The Haematological Malignancy Research Network (HMnRN) ethics approved (REC 04/01/1299) from Leeds West Research Ethics Committee. The HMnRN that comprises a population-based cohort of patients newly diagnosed by a single integrated haematology-pathology laboratory in two adjacent UK Cancer Networks (population 3.6 million). The database includes prognostic factors, sequential treatment/response history and socio-demographic details which are recorded to clinical trial standards. 255 patients were screened in this study. We looked at a range of autoimmune/innate immune conditions diagnosed after MGUS.

**Results:** In the 255 patients cohort group, the average age at the diagnosis of MGUS was 70.23 ± 11.95 years (median 70.2 years), with more subjects being male (n=145, 56.9%). Mean duration of follow up was 2570 days. 10 out of the 255 patients progressed onto multiple myeloma. Diagnosed rheumatic disease was found in 48 patients (18.8%). None of the patients in this group has disease progression to multiple myeloma. In this group, 37 patients (14.5%) presented the rheumatic disease before their MGUS diagnosis and 11 (4.3%) were diagnosed after their MGUS referral. Interestingly, among the 11, more males(n=8, 72.7%) have their rheumatic disease diagnosed after MGUS.

Those 11 cases included crohn’s disease (1), polymyalgia rheumatica (2), immune thrombocytopenia (2), autoimmune hepatitis (2), Schnitzler’s syndrome (1), giant cell arteritis (1), rheumatoid arthritis (2).

**Conclusion:** Approaching 1 in 20 cases of MGUS have an underlying inflammatory disease that may often be non-specifically driving antibody production including monoclonal band formation. When diagnosing MGUS, clinicians should be aware of the potential underlying autoimmune rheumatic diseases.

## AN ATYPICAL CASE OF PONCET DISEASE

M. Yasmine1, H. Ajlan1, S. Boussaid1, S. Jammali1, S. Reki1, E. Cheour1, H. Sahli Srairi1, M. El Euch1. 1. Rabta Hospital, Tunis, Tunisia

**Background:** Poncet disease (PD) is defined as an inflammatory rheumatism associated with visceral tuberculosis without direct bacteriological involvement of the joints [1]. It is classified as a parainfectious rather than a reactive arthritis [2].

**Objectives:** Here by a first case of PD who presented with sterile arthritis and tuberculous spondylodiscitis.

**Methods:** We report a case of a 40-year-old women who presented with polyarthritus in 2014. On physical examination, she had synovitis in both wrists, the metacarpophalangeal joints and the fifth proximal interphalangeal joint of the right hand. Her serum was negative for Rheumatoid Factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) antibody. Her C-reactive protein (CRP) was 24.5mg/l. Ultrasound revealed tenosynovitis of the superficial and deep flexor tendons on both hands with Doppler signal. The Magnetic resonance imaging (MRI) of the hands showed active synovitis in the wrists mainly in the distal radioulnar joint, erosions in the ulnar styloid as well as edematous infiltration of the soft tissue of the hands. Since she fulfilled the new ACR/EULAR 2010 criteria for RA, a diagnosis of rheumatoid arthritis (RA) was made and the patient was put on Methotrexate (MTX) 15mg/week/po in January 2015. Eight months later, the patient developed high temperature 38°C and lumbar stiffness. A chest CT performed as part of the etiologic investigation didn’t show pulmonary manifestations but revealed lytic vertebral lesions. Lumbar spine MRI showed prevertebral edema and soft tissue enhancement with abnormal marrow signal in L2 and L3 which was concerning for infectious etiology. MTX was stopped. A CT-guided core needle biopsy concluded to a tuberculous spondylodiscitis. The patient was initiated on an antituberculous-therapy (ATT) for 15 months. The course was marked by the reoccurrence of low back pain. MRI of the spine was then performed and revealed persistence of spondylodiscitis and multiple abscesses at the levels of L2-L3. The ATT was resumed.

**Results:** The patient received four drugs for 4 months, followed by isoniazid and rifampicin for 1 year. At follow up, the patient responded well to treatment with complete resolution of symptoms without sequelae. She did not present neither polyarthritus nor synovitis. Moreover, she sustained a negative CRP (2mg/dl). Ultrasound control of the wrists did not show synovitis or tenosynovitis Doppler signal. Similarly, a disappearance of effusion as well as synovitis was noted on the MRI at follow up.

**Conclusion:** We report a unique case of Poncet disease with tuberculous spondylodiscitis. It is important to recognize PD in a patient presenting with polyarthritus in order to avoid unnecessary long-term disease-modifying anti-rheumatic treatment. Future research is indicated to understand the etiopathogenesis of Poncet’s disease and to educate clinicians as to the importance of maintaining a high index of suspicion about this rare, yet potentially easily treatable disease.

## RHEUMATOID ARTHRITIS INDUCED BY ALPHA-INTERFERON THERAPY: A RARE CASE PRESENTATION

M. Yasmine1, H. Ajlan1, S. Boussaid1, S. Jammali1, H. Sehli1, E. Cheour1, S. Reki1, M. El Euch1. 1. Rabta Hospital, Tunis, Tunisia

**Background:** Interferon-α (IFN-α) is known for its antiviral and antiproliferative effects, used mainly for the treatment of chronic hepatitis C infection [1]. Immunomodulatory effects have been reported in patients treated with IFN-α, including hematological, immunological, rheumatological and dermatological disorders [2]. In fact, IFN-α may lead to the induction or exacerbation of autoimmune diseases such as psoriasis, systemic lupus erythematosus, and rarely rheumatoid arthritis (RA).

**Objectives:** We report the case of a Caucasian who developed anticyclic citrullinated peptide antibody (anti-CCP)-positive RA following treatment of chronic hepatitis C infection with pegylated IFN-α2a.

**Methods:** A 57-year-old women was diagnosed of chronic hepatitis C infection after detection of abnormal liver function. She has a genotype Ib with a high viral load: RNA was 100,000 U/ml. Liver histology showed advanced fibrosis and portal fibrosis (A3 F4 according to metavir score). A history of treatment for chronic hepatitis C infection with pegylated IFN-α2a 180 µg weekly and a 1000 mg daily dose of ribavirin. After
two months of antiviral treatment, she developed symmetrical polyarthritis, with pain and edema in the wrists, elbows, shoulders and metacarpophalangeal joints, associated with prolonged morning stiffness. The musculoskeletal examination was notable for active synovitis of the proximal phalangeal joints, metacarpophalangeal joints, wrists, elbows. Distal interphalangeal joints were spared. She had no musculoskeletal symptoms prior to antiviral therapy. Review of systems was otherwise unremarkable. X-ray showed no remarkable findings. Ultrasonography of the hands revealed diffuse synovitis as well as tenosynovitis of the ulnar extensor tendons in both wrists. Laboratory results revealed a normal C-reactive protein, elevated liver enzymes: ALAT (alanin-aminotransferase) 119, ASAT (aspartat-aminotransferase) 66, Gamma-GT 203 and undetectable cryoglobulins. Anti-CP was 21 IU/ml (negative < 20 IU/ml), antinuclear antibodies were positive 1280 (negative=160), rheumatoid factor was 192 (normal < 30 IU/ml). A diagnosis of rheumatoid arthritis (RA) was made on the basis of clinical and ultra-sonographic evidence as well as Rheumatoid Factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) antibody positivity. Moreover, an autoimmune thyroiditis was found that evolved into hypothyroïdism treated with thyroxine.

Results: The patient developed a sustained virological response as evidenced by persistent undetectable HCV RNA and normal aminotransferase activities. Upon completion of a 12-week course of antiviral therapy, the rheumatoid syndrome disappeared after cessation of IFN therapy. By that time, antinuclear antibodies were in a titre of 1 /180, rheumatoid factor and Anti-CP were negative.

Conclusion: The present case suggests that biological agents, affecting the cytokine network, may work as triggering factors for the development of RA in previously predisposed individuals. Screening for RF and anti-CP may be considered before treating with IFN. In addition, a close surveillance for the occurrence of autoimmune phenomena during and after treatment should be worthy, for early diagnosis and adequate clinical management.

COMPARISON OF THE PATIENT REPORTED PHYSICAL ACTIVITY LEVEL ACCORDING TO KINESIOPHOBIA PRESENCE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

D. Bayraktar1, D. Ozer Kaya1, S. Guçmenoz2, E. Durak Ediboglu2, G. Kabadavji3, S. Akar1. 1Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey;2Izmir Katip Celebi University, Aaturk Education and Research Hospital, Department of Rheumatology, Izmir, Turkey;3Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey

Background: Many factors such as poor functional or emotional status might play a role in participating physical activity for people with rheumatic diseases. There is a lack for evidence regarding to the effect of kinesiophobia presence on the physical activity levels of axSpA patients.

Objectives: The primary objective was to compare the patient reported physical activity levels in axSpA patients with kinesiophobia and those without. Evaluating disease related and physical characteristics, quality of life and emotional status according to presence of kinesiophobia was also aimed.

Methods: One-hundred forty-eight consecutive axSpA patient were allocated to Kinesiophobia+ group (n: 90, 66% males) or Kinesiophobia- group (n: 58, 64% males). The presence of kinesiophobia was defined as having a score of >37 in Tampa Scale for Kinesiophobia. All patients were evaluated regarding to physical characteristics (age, body-mass index), functional status (Bath Ankylosing Spondylitis Functional Index), disease activity (Bath Ankylosing Spondylitis Disease Activity Index), spinal mobility (Bath Ankylosing Spondylitis Metrology Index), patient reported physical activity (International Physical Activity Questionnaire Short Form), emotional status (Hospital Anxiety and Depression Scale), and quality of life (Assessment of SpondyloArthritis International Society Health Index).

Results: Physical characteristics and spinal mobility were similar in patients with and without kinesiophobia (p>0.05, Table). Disease activity, function, quality of life, depression and anxiety scores were poorer in Kinesiophobia+ group compared to Kinesiophobia- group (p<0.05, Table). Patient reported physical activity level was found to be lower in patients with kinesiophobia (p<0.05, Table).

VALIDITY OF SIX MINUTE STEPPER TEST IN EVALUATION OF FUNCTIONAL EXERCISE CAPACITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

S. Bayram1, N. G. Toro1, F. Sar1, D. C. Saraç1, G. Gülüşün1, R. Bilici2, A. Tufan2, D. Oskay3, Gazi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 2Gazi University Faculty of Medicine, Department of Internal Medicine - Rheumatology, Ankara, Turkey

Background: In most patients with ankylosing spondylitis (AS), exercise capacity is reduced due to pulmonary dysfunction, chest wall restriction and peripheral muscle weakness. The six-minute walk test (6MWT) is a validated simple field, hence frequently used to evaluate exercise capacity. However, 6MWT has some limitations, especially the fact that it requires a corridor of at least 30 meters long to perform this test which can limit its use in some centers. Shorter corridors force patients to turn more frequently, slowing down the pace of walking that reduces potential walking distance. To overcome technical and spatial limitations, 6-min- ute stepper test (6MST) has been proposed to evaluate exercise capacity. In the literature 6MST has been suggested for a variety of diseases. Since, it requires only a limited amount of space and equipment and is feasible, easy to perform, well tolerated.

Objectives: In the literature, there is no study in which 6MST is used to evaluate exercise capacities of patients with AS. Therefore, the aim of this study was to evaluate validity of 6MST in AS population in comparison to 6MWT.

Methods: 6MWT and 6MST were performed in 51 patients with AS (52.25±13.33 years, 30F/21M). Demographic and clinical characteristics were recorded. Functional exercise capacity was evaluated using 6MWT and 6MST. The total distance of 6MWT was compared to the total number of steps of 6MST. Before, during and after 6MWT and 6MST, heart rate (HR), oxygen saturation (SpO₂), breathing frequency (BF), blood pressure (BP), dyspnea and fatigue were assessed using modified Borg scale.

Results: The number of steps on the 6MST was significantly correlated with the distance of the 6MWT (r=0.61, p<0.001). Dyspnea (p=0.04) and leg fatigue (p=0.0001) was significantly higher in 6MST than in 6MWT. HR, SpO₂, BF, BP and fatigue were similar in both 6MST and 6MWT.
Conclusion: The 6MST is a valid test to evaluate exercise capacity in patients with AS. It is also an appropriate alternative to the 6MWT for determining exercise capacity when the 6MWT is not feasible due to technical restrictions. The 6MST can be proposed as a new exercise capacity evaluation tool in AS, as it is valid, reliable, portable and inexpensive.

THU0609-HPR
Responsiveness of the Disabilities of the Arm, Shoulder and Hand (DASH) and the Upper Extremity Functional Index (UEFI) in Patients with Posttraumatic Elbow Stiffness

T Biringi1, E Kaya Mutlu2, S Altun3, Istanbul Medeniyet University, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey; Istanbul University-Cerrahpaşa, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey; Bakirköy Dr. Sadi Konuk Training and Research Hospital, Clinics of Orthopedics and Traumatology, Istanbul, Turkey

Background: There are many patient-rated outcome measures to assess the subjective component of function in musculoskeletal disorders of elbow. The first step of functional assessment is to select the instrument, which is sufficiently responsive. Although the disabilities of the arm, shoulder and hand (DASH) and the upper extremity functional index (UEFI) are widely used in reporting outcomes in upper extremity function, the responsiveness of these two scales has not been investigated in elbow disorders.

Objectives: This study aimed to compare and report the responsiveness of the DASH and the UEFI in patients with posttraumatic elbow stiffness.

Methods: Fifty-seven patients with posttraumatic elbow stiffness (32 women; mean age, 44.54 ± 6.31 years) were included. All patients completed the DASH and UEFI at baseline and after a six-week intervention, which was a structured exercise program. Patients who improved (much improved and slightly improved) and those who unimproved were defined using a 5-point global rating change scale (GROC). Responsiveness was assessed using effect size and standardized response mean (SRM). ES has observed the mean change scores divided by the standard deviation of the initial score. SRM was calculated for the improved group and the unimproved group, dividing the mean change scores by the standard deviation of mean change scores. Similar to effect size, SRM values and ES values of 0.20, 0.50 and 0.80 were considered small, moderate or large, respectively.

Results: Forty-eight patients (84.21%) were classified improved and 9 patients (15.79%) were classified unimproved according to the GROC. Effect sizes and SRM values of 0.20, 0.50 and 0.80 were considered small, moderate or large, respectively.

Conclusion: These findings showed that for patients receiving phytotherapy for the management of elbow stiffness, both the DASH and the UEFI are similarly responsive to change in symptoms and disability and similarly able to discriminate between patients who improved or unimproved.

Prediction Equation for Muscle Mass Overestimates Muscle Mass in Patients with Rheumatoid Arthritis

R. Cavelheiro Do Espírito Santos1, L. L. Santos2, L. Filippin3, P. Lora4, R. Xavier2,1, Hospital de Clínicas de Porto Alegre, Serviço de Reumatologia, Porto Alegre, Brazil; Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; Universidade La Salle, Canoas, Brazil; Universidade do Vale do Rio dos Sinos, São Leopoldo, Brazil

Background: Rheumatoid Arthritis (RA) is a chronic, progressive, inflammatory autoimmune disease characterized by systemic manifestations. Often is observed in RA patients changes in body composition, such as reduced muscle mass (sarcopenia) with stable or increased fat mass (FM) [1]. Total-body skeletal muscle mass (SMM), specifically appendicular skeletal muscle, is a key diagnostic feature for the assessment of geriatric syndromes associated with skeletal muscle wasting, such as sarcopenia [2]. Estimation of SMM can be accomplished by a variety of methods, but the majority that considered the gold standard for this purpose is high cost. Due high cost, this methods are unsuitable in population studies and increases the difficulty of use in different clinical contexts. Predictive equations have been developed for estimation of whole-body skeletal muscle mass on the basis of anthropometric data, which can be collected in a more affordable manner, in an attempt to make SMM calculation easier and enable its use in epidemiological research and in clinical settings [3]. However, these equations were not developed for RA populations.

Objectives: To compare the anthropometric equation that estimate SMM with body composition measurements derived from DXA in RA patients.

Methods: Ninety patients diagnosed with RA according to ACR/EULAR criteria were included. Body composition was assessed by total body dual-energy x-ray absorptiometry (DXA) for measurement of appendicular lean mass index (ALMI, kg/m2). The prediction equation for muscle mass proposed by Lee et al (variables included: body weight, height, age, sex and race) was used to generate estimates of SMM, stratified by BMI. Frequency analysis, independent student’s t test and intraclass correlation coefficients (ICC) were performed. Statistical significance was considered as p < 0.05.

Results: Of the 90 patients analyzed, most were women (86.7% ; 78/91), with mean age of 56.5 ± 7.3 and median disease duration time of 8.5 (3-18) years. The mean of BMI was 27.39 ± 5.14. Thirty (33.3%) RA patients had normal weight, forty patients (44.4%) were overweight and twenty patients (22.2%) were obese. In normal weight patients, just like overweight and obese patients, the estimates of SMM obtained by Lee equation were higher than those obtained by DXA measurements.Lee < 10.66 ± 0.19 vs DXA 10.70 ± 0.73; Weight: Lee 8.63 ± 0.99 vs DXA 8.57 ± 0.82; Normal weight: Lee 7.14 ± 0.85 vs DXA 6.03 ± 0.71; p < 0.05. The Lee equation estimates showed ICC of 0.78 (0.65 - 0.85) with DXA measurements. When stratified by BMI, Lee equation showed ICC of 0.87 (0.72 - 0.94) for normal weight, 0.83 (0.68 - 0.91) for overweight and 0.77 (0.42 - 0.90) for obese with DXA.

Conclusion: The muscle mass index by Lee equation overestimates the muscle mass in overweight or obese RA patients compared to DXA. Thus, sarcopenic RA patients may be wrongly classified as normal by the equation. This is likely related to the obese cachexia that these patients often present. More studies are necessary to analysis to better prediction equations for muscle mass in RA patients.

Background: Minimal disease activity (MDA) is a treat-to-target strategy (T2T) objective in psoriatic arthritis (PsA). MDA criteria, include physical function, traditionally assessed via the Health-Assessment Questionnaire Disability Index (HAQ-DI). It is of interest to assess the performance of more current physical function instruments such as the Patient-Reported Outcomes Measurement Information System-Physical Function Profile (PROMIS-PF).

Objectives: To assess the interchangeability of the HAQ-DI with the PROMIS-PF in the calculation of MDA in PsA.

Methods: Longitudinal PsA data were collected including HAQ-DI and PROMIS-PF in a PsA cohort. MDA definitions were built substituting the HAQ-DI criterion with the PROMIS-PF short form 4a (PROMIS-PF4a) or with the PROMIS-PF computer adaptive test (PROMIS-PF Bank). We assessed agreement/accuracy between HAQ-DI based and PROMIS-PF based MDA definitions at each visit and longitudinally through the kappa statistic/ROC curve analysis.

Results: One hundred participants contributed 352 observations with up to five visits. Mean (SD) age was 52 (12) years, 60% were female, and 43% were in MDA at baseline. Kappa statistic for PROMIS-PF based MDA reflected almost perfect agreement with HAQ-DI MDA: kappa=0.94 (95% CI 0.90-0.97) for MDA PROMIS-PF Bank, and kappa=0.90 (95% CI 0.80-0.95) for MDA PROMIS-PF4a. Higher longitudinal agreement was seen between MDA HAQ-DI and MDA PROMIS-PF Bank versus MDA PROMIS-PF4a between consecutive visits:

Kappa ranged between 0.81-0.94 versus 0.72-0.84, respectively (Table 1). Area under ROC curve for predicting MDA HAQ-DI was 0.97 for MDA PROMIS-PF Bank and 0.95 for MDA PROMIS-PF4a (Figure 1).

Conclusion: Excellent agreement was seen between HAQ-DI and PROMIS-based MDA definitions statistically and longitudinally. The PROMIS-PF Bank and PROMIS-PF4a are accurate replacements for the HAQ-DI in calculating MDA state in PsA.

MEASUREMENT OF MINIMAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS USING PROMIS-PHYSICAL FUNCTION OR THE HEALTH ASSESSMENT QUESTIONNAIRE-DISABILITY INDEX

E. Cheew1, J. Perin2, T. Grader-Beck1, A. M. Orbai1. 1Johns Hopkins Hospital, Rheumatology, Baltimore, United States of America; 2Johns Hopkins University School of Public Health, Baltimore, United States of America

Background: Pain and comorbidity burden has been suggested to act as a stressor during aging, potentially accelerating declines in health and functioning in patients with osteoarthritis of the knee (KNEE-OA) (1,2).

Objectives: The aims of the present research were to assess (i) the prevalence of frailty and (ii) its potential associated factors in a cohort of adult patients with KNEE-OA.

Methods: Patients fulfilling the clinical American College of Rheumatology knee-OA criteria were assessed according to the Survey of Health, Ageing and Retirement in Europe Frailty Instrument (SHARE-FI), and classified as frail, pre-frail, or non-frail. The clinical evaluation included the following items: Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain subscale (3) and Medical Outcomes Study Short Form-36 (SF-36). Evaluation of the comorbidities burden was performed with the modified Rheumatic Disease Comorbidity Index (mRDCI). Radiographic knee OA was defined according to Kellgren/Lawrence (KL) grades. Chi-square, analysis of variance (ANOVA), and multinomial logistic regression analyses were used to test the prognostic value of frailty for the outcomes of interest.

Figure 1. Distribution of the WOMAC-Pain scores according to the frailty categories by SHARE-FI, and p-values for comparison (ANOVA test)

Conclusion: Frailty or pre-frailty are common in KNEE-OA. The main factors associated with frailty were pain and comorbidity burden. Implementation of the frailty assessment into the routine rheumatological practice could represent a major advance in KNEE-OA care. Further studies are needed to identify the physiological mechanisms underpinning these associations.

ADAPTATION AND VALIDATION OF THE MINI OSTEOARTHRITIS KNEE AND HIP QUALITY OF LIFE (MINI-OAKHQOL) QUESTIONNAIRE IN TURKISH POPULATION

M. T. Duruöz1; S. Acer Kasman1; H. H. Gezer1.1 Marmara University, School of Medicine, Physical Medicine and Rehabilitation Department, Rheumatology Division, Istanbul, Turkey

Background: The 20-item Mini-OAKHQOL was developed from the 40-item OAKHQOL questionnaire which was developed to assess the quality of life in subjects with osteoarthritis of the lower limbs. It has 5 subscales containing physical activities, mental health, pain, social support, social functioning; and two independent items addressing sex life and professional life (1). The Mini-OAKHQOLs good psychometric properties have recently been shown and validation studies have been done in several populations (1,2).

Objectives: We aimed to investigate the validity and reliability of the Turkish version of the Mini-OAKHQOL in patients with knee and hip osteoarthritis.

Methods: Patients diagnosed with knee or hip osteoarthritis clinically and radiologically were included in the study. Demographic data were noted. The French version of Mini-OAKHQOL was used for translation and adaptation. Translation-back translation methodology was applied and cross-cultural adaptation of the Mini-OAKHQOL into Turkish was done. Face and content validities were evaluated by cognitive information interviews with patients and expert committee. Internal consistency of the scale was measured with Cronbach alpha coefficient. Convergent validity was evaluated by the correlations of Mini-OAKHQOL with Nothingham Health Profile (NHP), subscales of Short form 36 (SF-36), and VAS of the quality of life. The relations of the Mini-OAKHQOL with age, BMI, disease duration, VAS of the pain, WOMAC, and Lequesne Index were assessed for divergent validity. P < 0.05 was considered significant.

Results: Seventy-three patients (63 female, 10 male) with the mean age of 57.22 (SD: 9.91) years were recruited. The main site of the symptomatic lower limb osteoarthritis was knee in 44, hip in 25, and both in 4 patients. The mean BMI was 31.69 (SD: 11.06) and the median disease duration was 36 months (IQR: 12–72). Turkish version of Mini-OAKHQOL had a good face and content validity. Cronbach’s alpha coefficients of the subscales for internal consistency were 0.927, 0.841, 0.867, 0.771, and 0.677. Physical activities, mental health, pain dimensions of Mini-OAKHQOL had moderate to high correlations with Nothingham Health Profile and the physical functioning, physical role limitations, energy/fatigue, social functioning, pain, and general health subscales of SF-36 (rho between 0.484-0.748). The social function subscale of Mini-OAKHQOL had mild significant correlations with emotional well-being (rho: 0.239) and general health (rho: 0.315) subscales of SF36. The subscales of Mini-OAKHQOL had no correlation with disease duration, BMI, and age; and had generally moderate correlations with VAS-pain, Lequesne Index, and the WOMAC subscales. These data show good convergent and divergent validities of Mini-OAKHQOL.

Conclusion: The Turkish version of the Mini-OAKHQOL is a valid and reliable instrument to assess the quality of life in patients with knee/hip osteoarthritis. In addition, it is a simple, accurate, disease-specific, and not time-consuming self-report instrument.

Background: The Assessment of SpondyloArthritis international Society (ASAS) has defined separate core sets for: i) symptom-modifying anti-rheumatic drugs (SM-ARD), ii) clinical record keeping, and iii) disease-controlling anti-rheumatic therapy (DC-ART). These all include the following domains: ‘physical function,’ ‘pain,’ ‘spinal mobility,’ ‘spinal stiffness’ and ‘patient global assessment’ (PGA). The core set for clinical record keeping further includes the domains ‘peripheral joints’ and ‘acute phase reactants;’ and the core set for DC-ART further includes the domains ‘fatigue,’ ‘spine/hip radiographs.’

Objectives: To assess the effect of interventions for each of the 9 axSpA core domains.

Methods: We investigated the efficacy across all interventions included in Cochrane reviews according to the core outcome set for axSpA, as reported in these eligible axSpA trials. We combined data using the standardized mean difference (SMD) to meta-analyze outcomes involving similar constructs. By meta-regression analysis, we examined the effect for each of the nine separate SMD measures on the primary endpoint across all trials.

Results: Among 85 articles screened, we included 43 trials with 63 randomized comparisons. Mean (SD) number of core outcomes domains measured for SM-ARD trials was 4.2 (1.7). 6 trials assessed all 5 proposed domains. Mean (SD) for number of core outcome domains for DC-ART trials was 5.8 (1.7). Unfortunately, only 9 domains were judged to have high enough evidence for selective outcome reporting. The most responsible core domains for achieving success in meeting the primary objective per trial were pain; OR (95% CI) 0.19 (2.28, 11.77) and PGA; OR (95% CI) 1.87 (1.14, 3.07).

Conclusion: Overall outcome reporting was good for SM-ARD trials, and poor for DC-ART trials. None of the DC-ART trials assessed all 9 domains. Outcome-reporting bias and ‘missing data’ should be reduced by implementing the endorsed ASAS/OMERACT outcome domains in all clinical trials. Our findings suggest that PGA and pain likely provide a holistic assessment of disease beyond “objective measures” of spinal inflammation.

from wide uptake of this publication (including Cochrane, OMERACT, IDEOM, RADS, and the GRADE Working Group).

Musculoskeletal Statistics Unit, The Parker Institute is grateful for the financial support received from public and private foundations, companies and private individuals over the years. The Parker Institute is supported by a core grant from the Oak Foundation; The Oak Foundation is a group of philanthropic organizations that, since its establishment in 1983, has given grants to not-for-profit organizations around the world.

**Background:** Factors associated with handgrip strength (HGs), in female with fibromyalgia (FM), use of force-time (FeT) curve to assess peak force, area under the curve (AUC), and variability of the time to reach maximum plateau of the curves (Fig. 1) to identify the impact of FM patients versus healthy controls have not been extensively studied.

**Objectives:** The aim of the study was to compare the HGs of FM with healthy subjects and to evaluate the relationship between curve characteristics and FM disease severity (2,3).

**Methods:** One hundred and ten women (mean age 53.8±12.4 years; range 18 to 80) were included and compared with 111, age and BMI matched, female healthy controls. HGs was measured with an electronic device, while demographic and clinical characteristics of the subjects were obtained by the Revised version of the Fibromyalgia impact questionnaire (FIQR) and Fibromyalgia Activity Score (FAS). The patient opinion of their symptoms state (PASS) was evaluated as external criterion. The HGs threshold that best discriminates between the presence and absence of FM, as well as between moderate and severe FM, was determined using the receiver operating characteristic (ROC) curves analyses. Multivariate regression procedure was used in order to assess the relative contribution of the covariates on the HGs.

**Results:** HGs-AUC and peak force levels were lower in patients with FM than healthy women (median 342.7 vs 496.5; and in Kg median was 13.9 vs 19.9, respectively; both at significant level of p<0.001) and in women with severe FM compared with those with mild-moderate FM (p<0.001). The time to reach maximum plateau of the curves was significantly higher in patients with FM than healthy women (15.5 vs 11.8 sec; p<0.001). ROC analyses revealed that the HGs peak force threshold that best discriminated between the presence and absence of FM was 14.2 kg (AUC 0.801; p<0.001), whereas the HGs peak force threshold that best discriminate between PASS was 16.3 kg (AUC 0.834; p<0.001). A negative correlation was found between FIQR and FAS scores and peak force, AUC in patients with FM (all at p< 0.001). Furthermore, a correlation was observed between widespread pain index (WPI) and peak force, AUC (both at p<0.0001), and of the time to reach maximum plateau of the curves (P=0.04) in patients with FM. Factors significantly associated with HGs-AUC in multivariate analysis were WPI and FIQR (both at p<0.001).

**Conclusion:** HGs is reduced in woman FM patients and is inversely related to FM severity and symptomatology. The FeT curve gave more information about grip in the FM and could be used as a complementary tool in the assessment and monitoring of FM. Further research on male FM patients is needed to confirm or contrast these findings.

**Table 6. Correlations between HGs curve characteristics and questionnaires studied through the Spearman’s rho correlation coefficients (rho).**

Conclusions: This is the first study to investigate the effect of EFA technology on airway clearance in SSC patients. The observations suggest the importance of a daily ACT program with EFA in improving respiratory symptoms. This technology appears to be extremely promising in SS patient management as it is well tolerated and it has the potential to slow down the pulmonary disease progression by limiting bronchial infections.

Figure 1

Conclusion: We have created a mobile application that allows any user to obtain in a simple way the level of disease activity, whatever the criterion used to describe it, since the application returns, in addition to the value of the activity criterion calculated from data returned by the physician, the transformation of this value into AS135 criterion and its interpretation in terms of level of activity of the pathology. The application is now available for Android devices and we plan to start developing a version for iOS devices.

THU0618-HPR TOWARDS A UNIVERSAL DEFINITION OF DISEASE ACTIVITY SCORES THRESHOLDS

N. Foulquier1, B. Chever2, G. Carvajal Alegria1, L. Saraux2, V. Devauchelle-Pensec3, P. Redou4, A. Saraux5, 1CHU, Univ Brest and Inserm, Brest, France; 2ChU, Brest, France; 3CHU, Brest, France

Background: For rheumatologists monitoring patients with various diseases and dealing with multiple scores with different maximum values (9 for RA-DAS, 6.4 for AS-DAS and 60 for PMR-AS) and values thresholds to characterize the different levels of disease activity (low, intermediate and high) can be a tedious task. The same problematic could arise in other specialty than rheumatology. Normalization of these scores seems to be necessary to facilitate daily clinical practice (1).

Objectives: To indentify and standardize scores of activity of inflammatory diseases.

Methods: We conducted a literature review on activity criteria using both a manual approach and the BIBOT software (2) published in English between 1.1.1975 and 31.12.2018. Within all extracted disease activity scores, we selected those with cut off values in four classes (remission, low, moderate and high disease activity). We used a linear interpolation to map all these disease activity scores to our new score, the AS-135, and developed a smart-phone application to perform the conversion automatically.

Results: 1068 articles were analyzed by BIBOT, 86 were excluded on the basis of the language used for their writing and 11 were excluded on the basis of their publication date. 509 were selected based on their titles, abstracts and keywords. 108 activity criteria from various fields (rheumatology, dermatology, gastroenterology, psychiatry, neurology and pneumology) were identified, but it is in rheumatology that we find separation into four classes. 10 scores met our inclusion criteria and were implemented in the Android app. These are: DAS28 (ESR), DAS28 (CRP), SDAI, ASDAS (ESR), ASDAS (CRP), ESSDAI, SLE-DAI-2K, DAPSA, PMR-AS (ESR) and PMR-AS (CRP). We built the AS135 score modification for each selected score using a linear interpolation of the existing criteria. It was defined on the interval [0,10] and values 1, 3 and 5 were used as thresholds. These arbitrary thresholds are then associated with the thresholds of the existing criteria and an interpolation can be calculated, allowing the conversion of the existing criteria into AS135 criterion. We have finally created a mobile application that allows each user to obtain both the original value of the activity criterion.

THU0618-HPR PSYCHOSOCIAL CHANGES IN RHEUMATIC DISEASE: A NURSING LED CROSS-SECTIONAL STUDY

R. Spagnuolo1, R. D. Grembiale2, F. S. Iaquinta3, V. Funari3, R. Pagnotta4, S. Naty5, P. Doldo6, 1Magna Graecia University, School of Nursing, Catanzano, Italy; 2Magna Graecia University, Rheumatology Research Unit, Catanzano, Italy

Background: Nursing management in Rheumatic Diseases (RD) is focused on global patient care. Starting from basic knowledge of diagnostic and therapeutic management, nurses can assess the impact of RD on patients’ quality of life not only at the physical level, but also at the psychological, social, and emotional levels.

Objectives: To evaluate psychosocial changes in RD patients through nursing-led Patient-Reported Outcomes

Methods: We performed a cross-sectional study of 100 RD patients compared with 100 healthy volunteers matched for age, sex and BMI. Specialist nurses invited patients and volunteers to complete questionnaires on quality of life through seven domains (anxiety, depression, fatigue, sleep disturbance, pain interference, physical functions and satisfaction with participation in social
roles) of the Patient-Reported Outcomes Measurement Information System (PROMIS).

Results: Among 100 RD patients, 52 (52%) had a diagnosis of Rheumatoid Arthritis; 17 (17%) had a diagnosis of axial spondyloarthropathy (ankylosing Spondylitis and Psoriatic Arthritis); 25 (25%) had connectivitis (i.e. Lupus, Systemic Sclerosis, Sjögren Syndrome), and finally 6 (6%) had vasculitis. Median disease duration was 7±5 years. Just under half (43%) of RD patients had active disease measured by specific disease activity index. As shown in table 1, no significant difference highlight between the two groups with regard to anthropometric and demographic characteristics. We found that patients report significantly greater psychosocial changes than healthy controls. More specifically, as shown in figure 1A, mean T score for anxiety, depression, fatigue and sleep disturbances were significantly higher in the RD patients than in healthy controls (56 ± 9 vs 48 ± 8 p <0.001; 52 ± 9 vs 46 ± 8 p <0.001; 58 ± 8 vs 48 ± 8 <0.001; 52 ± 10 vs 44 ± 8 <0.001) respectively. Moreover, also in the social dimension in terms of pain interference, physical functions and satisfaction with participation in social roles, patients showed a median T score worse than healthy controls (Fig.1B).

Continuous variables are shown as mean ± standard deviation. Categorical variables are presented as number and proportion. The overall p-value was calculated by the Mann–Whitney non-parametric test for independent samples and by Chi-square test as appropriate.

Figure 1. Median T Score stratified by study group. Data are shown as mean and standard deviation. The overall p-value was calculated by the Mann–Whitney non-parametric test for independent samples.

Conclusion: This exploratory study highlights the need to adopt validated questionnaires in clinical practice, and demonstrates that PROMIS is a valid, objective, and standardized instrument that can help nursing staff to better define the consequences of the disease in a patient’s daily life.

PREVALENCE OF DISTAL INTERPHALANGEAL JOINT ULTRASONOGRAPHY FEATURES IN PSORIATIC ARTHRITIS, SKIN PSORIASIS, OSTEOARTHRITIS AND HEALTHY INDIVIDUALS: A CROSS-SECTIONAL STUDY

J. Guldberg-Møller1,2, M. Henriksen1, M. Boesen3, L. Dreyer4, K. Ellegaard1, M. Skougaard1, C. Ballegaard1, A. L. Tan5, R. Wakefield6, L. E. Kristensen1, 1Bispebjerg and Frederiksberg Hospital, The Parker Institute, Frederiksberg, Copenhagen, Denmark; 2Aalborg University Hospital, Department of Radiology, Aalborg, Denmark; 3Slagelse Sygehus, Slagelse, Denmark; 4Bispebjerg and Frederiksberg Hospital, Department of Radiology, Copenhagen, Denmark; 5Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: Distal interphalangeal (DIP) joint involvement is a feature of both psoriatic arthritis (PsA) and hand osteoarthritis (OA), and nail-changes are features seen both in PsA and nail psoriasis patients without joint involvement (PsO). In both PsA and OA, ultrasonography (US) is used to quantify DIP joint inflammation.

Objectives: To explore disease-specific US-detected characteristics in the DIP-joints and extensor tendon entheses in patients with DIP-joint OA, PsA, PsO with nail involvement, and healthy controls (HC).

Methods: In PsA, PsO, OA and HC US examination of DIP joints 2-5 and the extensor tendon were performed. The US images were scored for DIP joint grey-scale synovitis, DIP joint Doppler, osteophytes and erosions (grade 0-3) and presence/absence of enthesitis and peritendinitis of the extensor tendon according to OMERACT standards. Prevalences were calculated on all included fingers (i.e. four fingers per participant), and differences in prevalences were tested using Chi-square statistics.

Results: Fifty PsA patients (44% females; mean age: 55y), 13 PsO patients (38% females; mean age 54y), 12 OA patients (100% females, mean age 71y), and 29 HC (52% females, mean age 48y) participated. The prevalences across the diagnosis groups are shown in figure 1, and the distribution of US outcomes was significantly different (highest Chi-square P-value: 0.0127). The PsA group had the largest prevalence of extensor tendon enthesitis (45.5%), peritendinitis (15%), and DIP joint erosions (11%), but also exhibited a considerable prevalence of osteophytes (46%). In the PsO group, the most marked findings were synovitis (33%) and enthesitis (35%). The OA group had the largest prevalence of DIP joint synovitis (67%) and osteophytes (88%) but also 25% prevalence of enthesitis. 24% of the HC group had a grade 1 synovitis.

Conclusion: This cross-sectional study found significant patterns of US findings distributed dependent on the underlying condition. PsA patients were mainly differentiated by the presence of extensor tendon enthesitis and peritendinitis. A high prevalence of enthesitis and synovitis was seen in patients
with DIP joint OA. The high prevalence of enthesis in PsO is consistent with a preclinical phase of PsA in this group.

MEASUREMENT OF LOW DISEASE ACTIVITY USING THE CLINICAL DISEASE ACTIVITY INDEX (CDAI) VERSUS THE DISEASE ACTIVITY SCORE 28 (DAS 28): IMPACT OF INFILMATION MARKERS ON THE COMPARATIVE EFFECTIVENESS OF BIOLOGICS FOR THE TREATMENT OF RHEUMATOID ARTHRITIS

K. Janke1, K. Biester1, D. Krause2, B. Richter2, C. Schürmann1, K. Hirsch1, B. Wieseler1. 1IQWIG, Cologne, Germany; 2Rheumatology Practice Gladbeck, Gladbeck, Germany; 3Department of Medical Informatics, Biometry and Epidemiology, University of Bochum, Bochum, Germany; 4Cochrane Metabolic and Endocrine Disorders Group, Institute of General Practice, Medical Faculty of the Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany

**Background:** Biologics for the treatment of rheumatoid arthritis (RA) have different modes of action to target auto-inflammatory processes causing the cause and symptoms of the disease. Different biologics may thus have different effects on inflammatory markers. For instance, previous studies have shown that the interleukin-6-inhibitor tocilizumab (TOC) decreases the level of acute phase reactants (APRs) [1]. Such direct effects on inflammatory markers may lead to an overestimation of clinical response if disease activity is measured via scores including inflammatory markers, such as the Disease Activity Score 28 (DAS 28). The detected changes in disease activity may not adequately reflect the clinical improvement of signs and symptoms.

**Objectives:** In our study, we compared biologics with each other using two different disease activity scores: the DAS 28 including APRs and the clinical disease activity index (CDAI) excluding APRs. The aim of this study was to assess whether the use of the two different scores affects comparative effectiveness studies on biologics for the treatment of RA.

**Methods:** We compared results on the comparative effectiveness of biologics using the corresponding thresholds for low disease activity (LDA) for the DAS 28 (< 3.2) and the CDAI (≤ 10). We performed two separate network meta-analyses (NMAs) after a thorough step-by-step evaluation of the similarity, homogeneity and consistency assumptions of the patient populations and the study data. Our study formed part of a systematic review (including NMAs) that was largely based on clinical study reports and re-analyses of LDA using individual patient data provided for sponsors for studies conducted up to 2017. Thus, the analyses include hitherto unknown data on LDA analysed by means of the CDAI, especially data from older studies. An extensive comparison of DAS 28 and CDAI in different patient populations was possible.

**Results:** For all analysed patient populations, comparisons of TOC versus other biologics yielded remarkable results; advantages for TOC were found in NMAs using the DAS 28, which were not confirmed in NMAs using the CDAI. For methotrexate (MTX)-naive patients, the using the DAS 28, TOC showed a greater benefit than abatacept (ABA), certolizumab pegol (CZP), and etanercept (ETA). In patients after MTX failure and using the DAS 28, TOC showed a greater benefit than abatacept (ABA), certolizumab pegol (CZP), and etanercept (ETA), than adalimumab (ADA) and ETA. For patients after MTX failure and using the DAS 28, which were not confirmed in NMAs using the CDAI. For

**Conclusion:** In comparative effectiveness studies of biologics, the assessment of LDA using the DAS 28 instead of the CDAI leads to a consistent overestimation of the benefit of TOC in all patient populations, regardless of pre-treatment or combined therapy with MTX. The inclusion of APRs in disease activity scores may thus introduce bias. A score excluding inflammatory markers should therefore be used to ensure valid results.

Background: An experience of particular treatment is one of the characteristics impacting on patients’ decisions to continue, discontinue, or alter their medical treatments. Reports on patients’ treatment satisfaction would be weighty when selecting an optimal treatment reflecting the patient’s perspective.

Objectives: We aimed to evaluate the treatment satisfaction of ankylosing spondylitis (AS) patients treated with tumor necrosis factor inhibitors (TNF-Is) and identify the factors associated with satisfaction in Korea.

Methods: The study was conducted from July to November in 2018 at 4 hospitals representative in treating AS in Korea. Patients aged ≥19, diagnosed as AS based on Modified New York criteria 1984, and treated with current TNF-Is and same type of device for ≥3 months were included. We used ‘Treatment Satisfaction Questionnaire For Medication (TSQM)’ which is consisted of 4 domains; effectiveness, side effects, convenience, and global satisfaction. Scores (0 ~ 100) of satisfaction indicate the higher the better. Multivariable linear regressions with 95% of statistical significance level was performed to identify related factors.

Results: Enrolled 497 patients (85.3% male, 40.3 years old) were prevalent with disease-modifying anti-rheumatic drugs (cDMARDs) and steroids were concomitantly used for 5.4% and 8.3% of patients, respectively. Average score of TSQM was the lowest in convenience amongst 4 domains; 72.2 in effectiveness, 96.9 in side effects, 67.6 in convenience, and 71.4 in global satisfaction. Negative associations were shown between BASDAI and all domains of TSQM. Patients who prescribed TNF-Is at high dose were more satisfied to effectiveness while they were less satisfied to side-effect, as against patients prescribed it at low dose. TNF-Is, use of cDMARDs and steroids were not significantly associated with treatment satisfaction (Fig. 1).

Conclusion: AS patients treated with TNF-Is in Korea were quite satisfied with their treatments. Since the worst satisfaction in the convenience domain was presented amongst 4 domains, more convenient treatment options may be required to enhance the entire satisfaction of patients. With the result of a negative association between disease activity and satisfaction, this study strengthened the previous studies reporting the positive relationship between health improvement and satisfaction.

Acknowledgments: Tae-Hwan Kim is the corresponding author.

THU0623-HPR REVISION AND VALIDATION OF THE GERMAN VERSION OF THE SYSTEMIC SCLEROSIS QUALITY OF LIFE QUESTIONNAIRE (SSCQOL) WITH MOKKEN SCALE ANALYSIS

A. Kocher1,2, M. Nidos3, K. Hoeper3, M. Simon1,2, D. Nicca1, 1Inselspital Bern University Hospital, Bern, Switzerland; 2University of Basel, Institute of Nursing Science, Basel, Switzerland; 3University of the West of England, Bristol, Department of Nursing and Midwifery, Bristol, United Kingdom; 4Hannover Medical School, Department Immunology and Rheumatology, Hannover, Germany

In the validation study, German-speaking SSc patients included in the Swiss MANagement Of Systemic Sclerosis (MANOSS) cross-sectional study completed the revised (polytomy) SSCoL. Mokken model was used to test the construct validity of the scale including its subscales. The scalability (H coefficient) values of ≥ 0.50 are considered “strong”, 0.40 to 0.50 “moderate” and ≤ 0.40 “weak”.

to 0.32 (‘weak’) scales, while values of 0.32 are not considered as unidimensional. Internal consistency (reliability) was assessed using Cronbach’s α. The validation sample comprised 28 patients (79.3% female) with a median age of 56 (IQR 49 to 71) and disease duration of 11 (IQR 7 to 18) years. Table 1 presents the results of validation with Mokken model. The construct validity of the revised German SScQoL was confirmed in all subscales and the global scale. The scalability (H coefficients) were all above 0.50 suggesting a robust unidimensional scale. Internal consistency was high (Cronbach’s α = 0.75).

**Background:** The Systemic Sclerosis Quality of Life Questionnaire (SScQoL) has been validated in six European languages. Previous adaptation into German has revealed issues with the dichotomous response structure in 10 items necessitating a review of the tool and further psychometric testing with patients in German speaking countries.

**Objectives:** The aim of this study was to assess the German version of the SScQoL, extend the response structure and test its construct validity using Mokken scale analysis.

**Methods:** This was a mixed methods study involving cognitive debriefing and survey methods. The expert committee extended the response structure of the 10 items from dichotomous to polytomous (4-point) responses: ‘always’, ‘usually’, ‘sometimes’ and ‘never’. In cognitive debriefing, a small convenience sample of patients with SSc completed the new version while ‘thinking aloud’ and commented on relevance of the items and the response structure.

**Results:** In cognitive debriefing, six patients with SSc completed the new German SScQoL and reported problems with the remaining dichotomous items. These were subsequently converted into polytomous 4-point response structure by the expert committee.

**Conclusion:** The German SScQoL has been revised into polytomous item structure and shown to be a valid and reliable measure of health-related quality of life in SSc. Further cross-cultural validity tests are required to assess its measurement equivalence with other SScQoL versions and thus enable multinational comparisons.

**THU0625-HPR COMPARISON OF WRIST PROPRIOCEPTION, GRIP STRENGTH AND PINCH STRENGTH IN PATIENTS WITH PSORIATIC ARTHRITIS AND RHEUMATOID ARTHRITIS: PRELIMINARY STUDY**

**M. Köprüölüoğlu,1 I. Naz Güran,1 D. Solmaz2, E. Otman2, E. Durak Ediboglu2, S. Akar1. 1Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy, Izmir, Turkey; 2Izmir Katip Celebi University, Faculty of Medicine, Department of Rheumatology, Izmir, Turkey**

**Background:** Hand articular damage occurs in rheumatoid arthritis (RA) and functional ability deteriorates as the disease progresses. Limitation of hand motion, oedema, pain etc. factors contribute to reduce grip strength, pinch strength and joint position sense; this problems contribute to function and disability. Following RA, affecting grip and pinch strength (1) and joint position sense (2) was reported former research. But there is a little knowledge about disability of hand functions in psoriatic arthritis (PsA).

**Objectives:** To compare joint position sense, grip strength and pinch strength in patient with PsA and RA.

**Methods:** In our cross sectional study, 23 RA patients [Mean age: 52.7±12.6, Women:20(87.0%)] who were classified according to the ACR 2010 criteria and 19 PsA patients [Mean age 53.5±12.6, Women:14 (%73.7)] who were classified according to the CASPAR criteria were included. It was recorded demographic and clinical data of patients. Wrist position sense was evaluated by goniometric re-position error test (in 30° wrist extension, 3 repeat). Grip strength was examined using a hand dynamometer (Lafayette Professional Hand Dynamometer, USA) and pinch strength (two point, three point, lateral) was evaluated by pinch-meter (Lafayette, USA).

**Results:** Patients were similar in terms of age, gender, disease duration, morning stiffness duration, pain of hand joints, number of tender and swollen joints and disease activity (p>0.05). RA patients had longer disease duration (p=0.004) and lower ESR levels (p=0.046) compared to PsA. Grip and pinch strength were found similar in both dominant and non-dominant side between RA and PsA patients (Table 1). Wrist joint position error was higher in PsA group in non-dominant side (p=0.011).

**Table 1. Comparison of Groups for Grip and Pinch Strength and Joint Position Sense**

Data have shown as median (interquartile range 25-75) *Mann Whitney-U Test

**Conclusion:** Our study showed that patients with PsA had hand impairment as much as RA patients. We think, hand assessment in patients with PsA rehabilitation programme is essential for clinicians. There is need future studies including asymptomatic healthy group to interpret results in detail.

yet, limited evidence exists regarding acceptance, usage, and barriers among rheumatologists.

Objectives: This study aimed to evaluate the current level of acceptance, usage, and barriers among German rheumatologists regarding the utilization of ePROs. The importance of different ePRO features for rheumatologists was investigated. Additionally, the most frequently used PPROs for patients with rheumatoid arthritis (RA) were identified.

Methods: Data was collected via an online survey consisting of 18 questions. The survey was completed by members of the Working Group Young Rheumatologists of the German Society for Rheumatology (Deutsche Gesellschaft für Rheumatologie (DGRh)) at the annual 2019 DGRh conference. Only members currently working in clinical rheumatology were eligible to complete the survey.

Results: A total of 119 rheumatologists completed the survey. 90% reported collecting PPROs in routine practice and 25.5% already used ePROs. 44.3% were planning to switch to ePROs in the near future. The main reason for collecting PPROs was for clinical decision making (66.4%), followed by research (39.5%), reimbursement (23.5%), internal quality management (21.9%) and patient satisfaction (16.8%). The most commonly cited reason for not switching to ePROs was the unawareness of suitable software solutions (figure 1). Respondents were asked to rate the features for ePROs on a scale of 0-100 (0 = unimportant, 100 = important). The most important features were automatic score calculation and display of ePROs (score: 77.5), as well as the simple data transfer to medical reports (76.9) (table 1). When asked about PPROs in RA, the respondents listed pain, morning stiffness and physician global assessment (PGA) as the most frequently used PPROs (figure 2).

<td>30.61</td>
</tr>
</tbody>
</table>

Figure 1. Reasons why ePROs are currently not used (multiple answers were possible for question)

Figure 2. PPROs being used in clinical practice and their respective frequency

Conclusion: The potential of ePROs is widely seen, and there is a great interest in ePROs. Despite this, a minority of physicians only uses ePROs, and the main reason for not implementing was cited as the unawareness of suitable software solutions.

Developers, patients and rheumatologists should work closely together to help realize the full potential of ePROs and ensure a seamless integration into clinical practice.

MoCA, Montreal Cognitive Assessment; NCSE, Neurobehavioral Cognitive Status Examination.

**Figure 1. Pilot program of the Neurocognitive Assessment**

**Figure 2. Final Program of the Neurocognitive Assessment**

**Results:** We evaluated 21 patients (66% females) with an average age of 43.62 years (SD 14.6) (Table 1). The total number of patients with cognitive impairment was 15 (71%), 14 (66%) diagnosed with MoCA, 6 (28%) with NCSE and a coincidence of both tests in 4 (19%) patients (Table 2).

**Conclusion:** A high percentage of patients with cognitive impairment was found, also a discrepancy between the MoCA and NCSE results. We realized those tests were not enough to get a detail cognitive functioning, for this reason it was decided to make a more extensive evaluation adding ANAM, WAIS-IV and MINI. Neuropsychological evaluation should be performed as part of a multidisciplinary management for the patient and the rheumatologist should be aware of this manifestation and the importance of cognitive testing.

Figure 1.

Conclusion: In the present study, by using a disease specific PRO, we found a poorer QoL in SLE patients with joint involvement in comparison with those without this manifestation. Moreover, DAS28 ESR significantly correlated with all LupusQol domains, differently from SLEDAI-2k, suggesting the need to evaluate joint involvement with a specific activity index.

Figure 1. SScEntry logo.

Methods: SScEntry is a smartphone/tablet app designed by rheumatology and computer science engineering specialists in close partnership [3]. A carefully designed user interface (UI), inspired to a social network wall, allows annotating the evolution of symptoms by means of standard clinical investigation methods such as scientifically validated questionnaires. The UI facilitates data collection through speech-based interaction as well as touch and gestures optimized for patients with finger skin lesions and joints impairments. User engagement over the course of time is fostered by: follow-up reminders to update information on the evolution of past events and periodic questionnaires for general health assessment; the integration of symptom photos taken with on-device camera and health data collected from wearable devices; gamification features. Privacy and security have been a primary design concern, with app access protection and full on-device data encryption; no personal data transmission occurs without explicit user consent. SScEntry generates a disease activity summary report, for displaying to the physician during visit or emailing/printing.

Results: SScEntry is ready for Android and iOS smartphones and tablets. All planned features have been implemented (Figure 2). Currently supported languages are English and Italian. Areas of interest include vascular, cutaneous, articular, visceral (gastro-intestinal and cardio-pulmonary) as well as relationship, sexual and working life.
Conclusion: Novel Narrative-based Medicine approaches are getting increasing attention to enhance the mutual understanding between patient and physician, reinforcing the therapeutic adherence at the core of healthcare. This is particularly important with chronic and disabling diseases like SSc. Involving patients in disease management with SScEntry will increase their compliance and confidence, with benefits on psychological well-being. Expected benefits for rheumatologists include better evaluation of target therapy and outcomes, as no data on disease activity is lost during the patient clinical history.

to the patient. The cases were analyzed in the pharmacovigilance committee of institution and their causality is defined giving solution to the cases and their follow-up according to relevance.

**Results:** The analysis yielded a cohort of RA 296 patients (44 men-15%, 252 women-85%) who reported AEs,Ars and MRPs. 181 patients (61%) in management with conventional DMARDS and 115 patients (39%) in biological therapy were identified. The highest incidence occurs in ages between 70 and 79 years (36% of cases); more commonly in women (85% of cases); more commonly using convDMARDS (61%) of cases, all this being statistically significant (p < 0.05). The classification resulted in 66 (22%) AEs, 117 (40%) ARs and 35 (12%) MRPs. The reported causality was probable in 236 cases (79%), possible 560 cases (85%) with a mainly probable causality. More studies are needed to clarify these results.

---

**Objectives:** Our aim was to evaluate differences between PtGA and PhGA and their predictors in an early arthritis cohort.

**Methods:** Cross-sectional study analyzing data from the baseline visit of patients included in the PEARL study (Princess Early Arthritis Register Longitudinal Study) in which demographic, laboratory and clinical characteristics including PtGA and PhGA (0-100 mm) are systematically collected. The main variable was the difference between PtGA and PhGA (ΔGA). The descriptive analysis was performed using the Kruskal-Wallis, Mann-Whitney or Pearson correlation tests as appropriate. A multivariate linear regression model was developed with ΔGA as a dependent variable. All those predictors available at the baseline visit reaching a p <0.15 in the univariate analysis were included in the initial model. The final one was obtained through the progressive elimination of those variables not showing an improvement in the model as assessed by the adjusted R² parameter considering those that had a p <0.15. To categorize the dependent variable, differences between PtGA and PhGA were considered relevant when greater than 5 points.

**Results:** 530 patients were included, 422 (79.6%) were women with a mean age of 55.3 +/- 16 years, 21.2% current smokers, 54% and 50.4% rheumatoid factor and anti-CCP positive respectively. A 43.3% had moderate activity and 33.6% high, measured by DAS28-VSG.

The median of ΔGA was 4, (interquartile range; -10 to 18; see figure 1). In 22% of the cases patients and physicians scored the same, in 46.5% the patients' scores were higher and physicians' were so in 31.5% of the cases. The variables that explained ΔGA after adjusting the multivariate model were pain [β=0.36 (95%CI 0.28 to 0.44)], number of swollen joints [β=-3.19 (95%CI -3.7 to -2.7)] and ESR [β=-0.11 (95%CI -0.2 to -0.03)]. Pain had a greater influence on patients' opinion while the number of swollen joints and ESR were more relevant for physicians. Other variables such as race, marital status, profession, sex, smoking, seropositivity or disease activity were not relevant in the prediction of ΔGA.

**Conclusion:** In our cohort, disagreements between PtGA and PhGA were observed. Patients scored higher based on painful perception and physicians did so relying on objective evidence of inflammation.

**DETERMINANTS OF HAPPINESS AND QUALITY OF LIFE IN PEOPLE WITH SYSTEMIC SCLEROSIS: A STRUCTURAL EQUATION MODELLING APPROACH**  
T. Santiago1,2, E. Santos1,2, A. C. Duarte3, P. Martins4, M. Sousa1, F. Guimarães1, S. Azevedo5, R. Ferreira6, M. Guerra7, A. Cordeiro1, I. Cordeiro8, S. Pimenta9, P. Pinto10, M. J. Salvador1,2, J. A. P. Da Silva1, Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; University of Coimbra, Faculty of Medicine, Coimbra, Portugal; Health Sciences Research Unit: Nursing, Nursing School of Coimbra, Coimbra, Portugal; Hospital García de Orta, Almada, Portugal; Hospital of Santa Maria, Centro Hospitalar Universitário Lisboa Norte, CHULN, Centro Académico de Medicina de Lisboa, Serviço de Reumatologia e Doenças Ossseas Metabólicas, Lisboa, Portugal; Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Lisboa, Portugal; Unidade Local de Saúde Alto Minho, Ponte de Lima, Portugal; Centro Hospitalar Universitário São João, Porto, Portugal; Centro Hospitalar Vila Nova Gaia/Espinho, Vila Nova de Gaia, Portugal.

**Background:** In recent years more attention has been given to patients reported outcomes (PROs). Systemic sclerosis (SSc) is no exception. As there is no effective treatment or cure to SSc, it is important to recognize the relevance to patients of the different facets of the disease to improve quality and enjoyment of life: the ultimate targets of therapy. Remarkably lacking in PROs is the evaluation of the overall perspective of subjective well being, equivalent to ‘happiness’ or “positive psychological dimensions”.

**Objectives:** To examine the determinants of happiness and quality of life (QoL) in patients with SSc with emphasis on disease activity, disease impact and personality traits.

**Methods:** This is an observational, cross-sectional and multicenter study from six rheumatology clinics in Portugal. A total of 113 patients with SSc with a complete set of data on disease activity, disease impact, personality, quality of life and happiness were included.

Structure equation modelling (latent variable structural model) was used to estimate the association between the variables using a maximum likelihood estimation with Satorra-Bentler’s correction and performed with STATA® 15.0. Two hypotheses were pursued: H1 – Disease activity and impact of disease are negatively related to happiness and QoL, whereas personality traits are related to happiness both directly and indirectly through perceived disease impact. **Results:** Results obtained in the structural equation measurement model indicated a good fit [

**Conclusion:** Optimization of QoL and happiness in people with SSc requires effective control of the disease process. Personality and its effects upon the patient’s perception of the disease impact, seems to play a pivotal mediating role in these relations and should deserve paramount attention if happiness and enjoyment of life is taken as the ultimate goal of health care.

**CORE MUSCLE ENDURANCE IN PATIENTS WITH ANKYLOSING SPONDYLITIS**  
D. C. Sarac1, S. Bayram1, N. G. Tore1, F. Sari1, D. Oksay1, A. Avanoğlu Güler2, A. Tufan2, Gazi University, Physiotherapy and Rehabilitation, Ankara, Turkey; Gazi University, Internal Medicine, Ankara, Turkey.

**Background:** It is stated that the muscles responsible for spinal stability around the trunk show long-term activity at low intensity in daily life, therefore, endurance insufficiency can cause loss of functionality and spinal stabilization and may induce pain (1).

**Objectives:** The primary purpose of this study was to compare the core muscle endurance of individuals with AS with the core muscle endurance of healthy individuals. The secondary aim of the study was to examine the association between core muscle endurance and balance, disease activity, spinal mobility, functional status, physical activity level and fatigue in individuals with AS.

**Methods:** The research is a cross-sectional study. 41 patients with AS and 40 healthy controls were included in the study. Core muscle endurance of both groups was assessed with trunk extension test, trunk flexion test, right and left side plank tests (2). In addition, in the AS group relationship between core endurance and balance, thoracic kyphosis angle, disease activity, functionality, spinal mobility, physical activity and fatigue was examined. Balance was evaluated with Biodex Balance Systems and thoracic kyphosis angle was evaluated with a digital inclinometer. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI), International Physical Activity Questionnaire (IPAQ), Fatigue Severity Scale (FSS) were used to assess disease activity, functionality, spinal mobility, physical activity and fatigue respectively.

**Results:** Significant differences were found between AS group and control group in core endurance were summarized in Table 1. Additionally, significant relationships were observed between core endurance and all the assessed parameters except thoracic kyphosis angle (p>0.05), (Table 2).

**Table 1. Comparison of Core Endurance between AS and Control Groups**

**Conclusion:** Core muscle endurance is lower in patients with AS and it is in relation with many factors regarding the disease. The use of these tests may provide additional information about the patients’ situation for clinicians.
KNEE EXTENSOR MUSCLE STEADINESS IN RELATION TO MAXIMAL TORQUE AND PHYSICAL FUNCTIONING IN PATIENTS WITH KNEE OSTEOARTHRITIS

A. Satam1, M. Van der Leeden2, A. De Zwart, S. Verberne3, J. Schrijvers4, W. Lems5, H. Haarlaar5, M. Van der Esch6, Reade, Amsterdam, Netherlands; Reade, Amsterdam, Netherlands; Amsterdam UMC, VU Medical Centre, Rehabilitation, Amsterdam, Netherlands; Amsterdam UMC VU Medical Centre, Rheumatology, Amsterdam, Netherlands; Amsterdam UMC VU Medical Centre, Rheumatology, Amsterdam, Netherlands; Reade, Amsterdam, Netherlands.

Background: Osteoarthritis (OA) of the knee is characterized by knee pain and limitations in daily activities. Muscle weakness is associated with these characteristics, quantified as maximal voluntary muscle torque (MVT). The quality of muscle contraction is presented by fluctuations observed on a torque-time curve and the extent of these fluctuations is referred to as muscle steadiness. Whether muscle steadiness is associated with maximal muscle torque and consequently with pain and activity limitations is unknown.

Objectives: To determine the association of knee extensor muscle steadiness with MVT and to explore the association of muscle steadiness with physical functioning in subjects with knee OA.

Methods: Baseline data of 172 patients out of 177 patients with knee OA, who participated in the VIDEX trial (triage registration number, NL47768.048.14), were used for this study. Maximal voluntary knee extension torque (MVT) was assessed using an isokinetic dynamometer. Torque-time curve data were processed into (i) coefficient of magnitude of torque variance (CV) in percentage (%), (ii) frequency of torque variance as peak power frequency (PPF) in Hertz (Hz) and (iii) MVT in Newton meters (Nm). Physical functioning was assessed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) questionnaire, the Get-Up & Go (GUG) test, the 6-minute walk test (6MWT) and the Stair climb up & down test. Correlation and Regression analyses were performed to determine associations. Sex, age, BMI, KL-grade, knee alignment and pain were considered as potential confounders.

Results: Lower CV and PPF, reflecting better muscle steadiness, were significantly associated (p<0.01 and p<0.05, respectively) with higher MVT, but associations were weak. Regression analyses showed a significant association of lower CV with better physical functioning on the WOMAC (p<0.05), also after correction for relevant confounders. The association with WOMAC was confounded by pain, but not by sex, age and BMI. No associations of CV with the GUG test, the 6MWT and the Stair climb up & down test were found. PPF was not significantly associated with physical functioning.

Conclusion: This is the first exploratory study of muscle steadiness in relation to physical functioning in knee OA patients. Muscle steadiness is, to some extent, related to better physical functioning, but this is not consistent across all measures of physical functioning in this study. There seems to be some relationship, but it is weak and needs further exploration. No previous studies comparing clinical scores to muscle steadiness in knee OA were found to compare our results. Studies on muscle steadiness are needed to improve our understanding on this aspect of muscle torque.

PREVALENCE AND CLINICAL CHARACTERISTICS OF NEOPLASIA AMONG A COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS

J. L. Tandaipan Jaime1, E. Riera Alonso1, N. Gimenez Gomez2, G. Ghio1, L. Berbel Arcobe1, S. Martinez Pardo1, 1Hospital Universitari Mutua Terrassa, Rheumatology, Terrassa, Spain; 2Hospital Universitari Mutua Terrassa, Research Support Department, Terrassa, Spain

Background: Patients with Systemic Sclerosis (SSc) have increased risk of malignancy compared to general population. The specific risk factors and underlying physiopathological mechanisms are still unknown, although some studies suggest that a relationship between malignancies and certain antibodies can exist. Lung, breast and hematological cancers are the most frequently seen among these patients.

Objectives: To describe the prevalence of malignancies in a cohort of SSc patients and analyze the epidemiological, clinical and immunological characteristics

Methods: A retrospective observational study was conducted at a tertiary-level university hospital, including a cohort of patients with SSc (ACR/EULAR 2013 criteria). The main variable was neoplasia prevalence and also, malignancy type, age, evolution of the SSc at the time of diagnosis and mortality were collected. Regarding SSc, demographic data, clinical and immunological characteristics, organ involvement, capillaroscopy findings and presence of other autoimmune diseases were collected.

Results: A 15% of the 98 patients with SSc presented malignancies (80% women). The mean age at the time of diagnosis was 57±15 years old (table 1). The frequency of cancer was: 40% breast, 13% colon, 7% ovary and lung. 2 patients died (1 breast, 1 lung). The limited subtype (ISSc) was the most frequent (80%) and 33% showed overlap syndrome (26% Sjögren syndrome). Regarding clinical manifestations: 67% had telangiectasia, 33% pitting scars, joint and digestive involvement. Most frequently seen antibodies were: 67% anti centromere (ACA) and 20% anti topoisomerase (ATA). None of the patients presented anti-ARN polimerase III (ARN-pol), and 13% had none of them (triple negative). Active and early capillaroscopy patterns were seen in a 46% and 27%. SSc and cancer were diagnosed in less than 5 years difference among a 33% of the cohort. A relationship between age and cancer was detected (p=0.042). Patients with neoplasia were a mean of 10 years older than those without malignancies (IC95%: 1-19 years).

MCTD (Mixed Connective Tissue Disease), IBD (Intestinal Lung Disease), PAH (Pulmonary Artery Hypertension), Triple negative (anti ARN, ACA and ATA negative antibodies), PPI (Proton Pump Inhibitor), ACE inhibitors (Angiotensin Converting Enzyme inhibitors), ARBs (Angiotensin II Receptor Blockers), DMARD (Disease-Modifying Anti-Rheumatic Drugs).

Conclusion: Our study showed a similar prevalence of the most frequent neoplasia among patients with SSc compared to general population (around 15%). This prevalence is similar to other series. The only epidemiological factor related to neoplasia was the age; a major proportion of ISSc was detected but without statistical significance. In a third of the patients there were less than 5 years there was no neoplasia.
of difference between cancer and SSc diagnosis. No association was found between neoplasia and certain antibodies. We recommend further studies to evaluate the relationship between SSc and cancer.

**REMS TECHNOLOGY APPLIED TO RHEUMATIC DISEASE**

M. D. Tomai Pitina1, C. Caffarelli2, S. Gonnelli1. 1National Research Council, Institute of Clinical Physiology, Lecce, Italy; 2Department of Medicine, Surgery and Neuroscience, University of Siena, Siena, Italy

**Background:** Many Rheumatic disease such as rheumatoid arthritis, juvenile idiopathic arthritis, psoriatic arthritis, ankylosing spondylitis, systemic lupus erythematosus, dermatomyositis/polymyositis and vasculitis are characterised by osteoporosis and fragile fractures. Inflammatory cytokines, steroid treatment, immobilization and reduced physical activity due to joint pain and muscle weakness are considered the major risk factors for the development of low bone mineral density in these diseases. Many evidences have highlighted the role of pro-inflammatory cytokines (TNF-α, IL-1, IL-6, IL-7, IL-17) in bone homeostasis regulation. Chronic inflammation is often characterized by an imbalance between bone formation and resorption, with a clear prevalence of osteoclastogenesis which is a strong determinant in rheumatic diseases bone loss.

**Objectives:** The aim of this study is to evaluate the REMS (Radiofrequency Echographic Multi-Spectrometry) technology in rheumatologic patients, compared to DEXA currently recognised as the gold standard for the evaluation of bone mineral density.

**Methods:** Twenty female patients (mean age 60.6 ± 14.41 years) with different rheumatologic diseases were considered. Each patient underwent a lumbar spine and hip examination performed by DEXA and REMS technology. In particular, after a quality control to assess that both the exams were performed correctly, 18 lumbar and 20 femoral exams (DEXA vs REMS) were compared.

**Results:** As Expected the exams performed show a good diagnostic match (>60%LS and >85% FEMORE). The tests that didn’t show diagnostic concordance were those affected by arthrosis processes (greater on the Spine). The REMS T-score values were lower than those obtained with the DXA method.

**Conclusion:** These results show how REMS technology can discriminate patients with osteoporosis as much as DEXA technology. The REMS technology can be a diagnostic option especially in patients with rheumatologic diseases that cause alterations in the spine reducing the diagnostic sensitivity of DXA technology.

**THE ASSOCIATION BETWEEN THE RECALL PERIOD AND THE AMOUNT OF INFORMATION ABOUT REPORTED ADVERSE DRUG REACTIONS BY PATIENTS USING BIOLOGICALS**

A. Laurijssen1, J. Van Lint2, B. Van den Berst³, L. Beijer1,², N. Jessurun2. 1Redbet University, Nijmegen, Netherlands; 2Pharmacovigilance centre Lareb, ’s Hertogenbosch, Netherlands; 3Sint Maartenskliniek, Nijmegen, Netherlands

**Background:** In order to monitor the safety of medicines pharmacovigilance, it is important that patients report their adverse drug reactions (ADRs). The quality of the reported information might be affected by the elapsed time between the onset of the ADR and the moment of reporting. Real-life evidence demonstrating a negative relationship between this recall period and the quality of reported ADRs is however lacking.

**Objectives:** To assess the effect of recall period on the amount of information that patients report about their ADR (information density) in patients using a biologic for an immune-mediated inflammatory disease (IMID).

**Methods:** The Dutch Biologic Monitor is a multi-center cohort ADR monitoring system collecting data on reported ADRs by patients using a biologic for an IMID. Per patient, every first unique reported ADR between 1 February 2017 and 1 September 2019 was eligible. ADR reports were selected by stratified random sampling based on length of recall period and biological. The recall period was defined by the number of days between the onset and reporting date of the ADR. The amount of information in an ADR report (information density) was calculated by the number of reported domains divided by the number of domains deemed relevant in the ADR report. The association between the information density of the ADR reports and different recall periods was compared using a one-way ANOVA test. One-way ANOVA and independent t-tests were used to assess the impact of gender, age, type biologic and burden of the ADR on the information density of the reported ADRs.

**Results:** Out of 1109 reported ADRs by 531 IMID patients, we included 402 ADR reports of 294 patients (55%) (see table 1). Included reports were equally divided over seven different recall periods: 0-1, 1-2, 2-4, 4-8, 8-12, 12-26 and 26-52 weeks. Results have shown no association between the information density in patient-reported ADRs and the length of recall period (p=0.805) (figure 1). However, the proportion of reported information about HCP visits for the ADR increased with increasing recall period: 0-1 week (14%), 1-2 weeks (24%), 2-4 weeks (34%), 4-8 weeks (40%), 8-12 weeks (48%), 12-26 weeks (50%) and 26-52 weeks (46%).

</table>

Female patients reported more information about their ADR (p=0.002), whereas the patient’s age was not associated with information density (p=0.221). Etanercept (ETA) users report significantly more information than adalimumab (ADA) users (p=0.019). The number of patients using other biologics was too low for further analysis. A higher ADR burden tended (p=0.120) to result in more reported ADR information (figure 2).

**Conclusion:** The length of recall period did not affect the amount of information that patients report about their ADR(s). The recall period was longer for patients reporting information about their HCP visit. Furthermore, female patients tend to report more information about their ADR than male patients and ETA-users tend to report more than ADA-users.

**Figure 1:** No effect of length of recall period on information density in patient-reported ADRs.

THU0638-HPR PHYSICAL ACTIVITY LEVELS OF RADIOGRAPHIC AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS PATIENTS

T. Yuksel-Karsli1, D. Bayraktar2, D. Ozer Kaya3, Ö. Gerçik3, S. Gucenmez4, H. E. Oz5, D. Solmaz6, S. Akar3, Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Izmir, Turkey; 7Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; 8Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; 9Izmir Katip Celebi University, Atatürk Education and Research Hospital, Department of Rheumatology, Izmir, Turkey

Background: It is known that cardiovascular disease risk is increased in chronic inflammatory diseases. Additionally, regular exercise is one of the main components of the management of patients with axial spondyloarthritis (axSpA). However, it was reported that axSpA patients do not meet recommended physical activity levels. It is still unknown, whether the disease subgroups of axSpA play a role in participating in physical activity.

Objectives: To compare the physical activity levels among radiographic, non-radiographic axSpA patients, and healthy controls.

Methods: Thirty-three patients with radiographic axSpA (23 [70%] male), 33 patients with non-radiographic axSpA (23 [70%] male) and 33 age and sex matched healthy controls (23 male [70%]) were included in the study. axSpA patients were assessed regarding to disease activity (Bath Ankylosing Spondylitis Disease Activity Index; BASDAI), functional status (Bath Ankylosing Spondylitis Functional Index; BASFI), spinal mobility (Bath Ankylosing Spondylitis Metrology Index; BASMI). Physical activity level of all subjects was measured by using an accelerometer (Actigraph wGT3X-BT) which was worn on the waist for seven consecutive days.

Results: The groups were similar in terms of physical characteristics (age and body mass index) (p>0.05). Disease related characteristics (BASMI, BASFI, BASDAI) were comparable between radiographic and non-radiographic axSpA patients (p>0.05). Radiographic axSpA patients showed lesser physical activity compared to non-radiographic axSpA patients and healthy controls (p<0.05, Table 1). There is no difference between non-radiographic axSpA patients and healthy controls regarding the physical activity levels (p>0.05).

Conclusion: GOUT DISEASE ACTIVITY SCORE – FURTHER EVALUATION OF CONSTRUCT AND CONVERGENT VALIDITY

M. Zlatkovic-Svendic1, M. Radak-Petrovic1. 1Institute of Rheumatology, University of Belgrade School of medicine, Belgrade, Serbia; 2Medical Faculty, University of East Sarajevo, Republika Srpska, Foca, Bosnia and Herzegovina

Background: A new instrument for measuring of disease activity in gout is a 4-variable gout disease activity score (GAS), announced in 2016 (1). GAS calculates self-reported number of attacks in the last year, patient visual analogue scale (VAS) for gout severity, serum uric acid level (mg/dL) and the number of tophi, and has shown good psychometric properties (1).

Objectives: to test GAS in patients with gout and to evaluate its construct and convergent validity

Methods: 74 patients with gout were evaluated successively, as they entered the Institute of Rheumatology in Belgrade. Construct validity was assessed by associations between GAS and SF-36, using Spearman’s rank correlation coefficients. Convergent validity was evaluated by testing the ability of the GAS score to distinguish between patients grouped by perceived disease severity, perceived general health and physicians perceived disease severity by using Kruskal–Wallis one-way analysis of variance. Computer statistic program SPSS 20.0 was used for data evaluation.

Results: For the construct validity, significant correlations were found between GAS and SF-36 subscales, specially for Body pain (r=0.725), Physical functioning (r=0.684) and Physical limitations (r=0.563), whereas Social functioning, Mental health, and Vitality were less affected. Correlation between GAS and Physical component scale of the SF-36 was the most prominent (r=0.780). For the convergent validity, significant differences in GAS scores were found between patients grouped by perceived general health (p<0.01) and perceived disease severity (p<0.01), and by doctors perceived disease severity (p<0.01), demonstrating the ability of the GAS to distinguish between subgroups of patients.

Conclusion: GAS has shown good psychometric properties in Serbian cohort of patients and has proved to be valid and reliable tool for use in clinical practice.

**Figure 1. Temporal trend of the percentage of first author gender from 2004 to 2019 (male in blue, female in pink)**

**Conclusion:** We found a prevalence of male as first authors of guidelines in the rheumatological field published between January 2004 and January 2019. The EULAR Task Force on Gender Equity in Academic Rheumatology (EULAR GEAR) has been recently established, making an important first step toward gender equity in the authorship of guidelines in the rheumatological fields. Indeed, in the last 15 years we have witnessed an increase in female representativeness. Notwithstanding, efforts should be made to improve the representation of female authors nationally and internationally.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.4682
The patient education session was supervised by a nurse and a rheumatologist. A 10-question dichotomous questionnaire was then administered to patients to assess the level of uptake of messages passed during the patient education session. The prevalence of correct answers was compared between illiterate and non-illiterate patients.

**Results:** The mean duration of patient education session is 13 min. Table 1 illustrates the results of the correct responses prevalence and the comparison of correct response rates between illiterate and non-illiterate patients.

**Table 1. Prevalence of correct responses and comparison of correct response rates between illiterate and non-illiterate patients.**

**Conclusion:** This study suggests the effectiveness of a methotrexate self-injection patient education session in RA patients. It also highlights the value of patient education in rheumatologic care. A large-scale study is necessary to better interpret and complete these preliminary results from this pilot study.

**THU0643-HPR PHYSIOTHERAPISTS’ ADHERENCE TO OSTEOARTHRITIS CLINICAL GUIDELINES: A NATIONAL ITALIAN SURVEY.**

S. Battista1, S. Stefano1, M. Serena1, M. Testa1, A. Dell’isola1. 1University of Genoa, Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Genoa, Italy; 2University of Lund, Department of Clinical Sciences, Clinical Epidemiology Unit, Lund, Sweden

**Background:** Osteoarthritis (OA) is the most prevalent joint disease in the world, and one of the top causes of disability [1]. OARSI and EULAR guidelines recommend non-surgical interventions as first-line interventions for OA [2]. Despite this, only less than 40% of people suffering from OA receive the recommended intervention [3].

**Objectives:** The aim of this study is to investigate to what extent a population of Italian physiotherapists adhere to the OA-guidelines in their clinical practice.

**Methods:** A quantitative web-based cross-sectional survey was developed according to the Checklist for Reporting Results of Internet E-Survey. The questionnaire was realised in Italy by a panel of physiotherapists, based on the EULAR, OARSI and NICE OA-guidelines. The questionnaire was delivered using REDCap through the Italian Association of Physiotherapists and the University of Genoa newsletters. The questionnaire was divided into two sections. The first section included 24 statements adapted from the aforementioned guidelines. Participants were asked to express their statement agreement on a scale from 1 (completely disagree) to 5 (completely agree). Participants who partially or totally agreed (score 4-5) were considered to agree with the statements. We defined a ≥ 70% agreement with a statement as consensus. In the second section, a clinical vignette was presented, illustrating an OA clinical case. Participants had to select, from a list of clinical options, how they would manage this case. Participants were classified as ‘Delivering’, ‘Partially delivering’ and ‘Non-delivering’ to select, from a list of clinical options, how they would manage this case. Participants were classified as ‘Delivering’, ‘Partially delivering’ and ‘Non-delivering’ to the recommended intervention, depending on the recommended or non-recommended interventions chosen.

**Results:** 812 physiotherapists (age: 36±13,59; 48% women) completed the survey between 26 November 2019 and 9 January 2020. The consensus was achieved for 12 sentences (52%) out of 23 (Fig. 1). All the statements focused on exercise, education, and surgical referral received ≥ 70% of agreement, whereas no consensus was reached for the statements on the clinical diagnostic criteria, for the use of glucosamine or chondroitin products and for the use of topical NSAIDs. In the second section, 20% of the analysed physiotherapists would deliver an intervention in line with OA guidelines and a 20% would carry out an intervention that is partially in line with OA guidelines. Conversely, the 40% of the participants of this survey would include at least a not-recommended intervention.

**Conclusion:** This study suggests that illiteracy does not affect the assimilation of information given during a patient education session. These preliminary results should encourage the development of patient education programs in our context where illiteracy rate is high.

**Disclosure of Interests:** None declared

**THU0642-HPR EVOLUTION OF THE PERCEPTIONS OF RA PATIENTS AFTER EDUCATION PATIENT SESSION TEACHING METHOTREXATE SELF-INJECTION: A PROSPECTIVE PILOT STUDY**

S. Afiai1, H. Rokin1,2, B. Berchane3, J. Moulai Berchik1, S. Fellous4, T. Fatima Zahra1, A. Ishami1, N. Alami1, T. Latifa1, N. Hajjaj-Hassouni4, F. Afiai1,2. 1AYachi Hospital, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rheumatology B, Rabat, Morocco; 2Laboratory of Physiology, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco; 3El Ayachi Hospital, Higher Institutes of Nursing Professions and Health Techniques Rabat, Rheumatology B, Rabat, Morocco; 4International University of Rabat, Rabat, Morocco

**Background:** Methotrexate is a gold standard for treatment of RA. In our context, RA patients prefer to be injected by paramedics rather than self-injecting. This can be explained by patients’ bad perceptions of self-injection or lack of information. Appropriate self-injection education can therefore be an important element in overcoming these obstacles and improving disease self-management.

**Objectives:** Compare the RA patients’ perceptions on methotrexate self-injection before and after a patient education session.

**Methods:** Prospective pilot study that included 27 consecutive patients (81.5% female, mean age 44.4 years, illiteracy rate 40.7%) with RA (median duration of progression of 4 years, mean delay in referral for specialist of 6 months, median duration of methotrexate use of 1 year). The patients benefitted from an individual patient education session to learn how to self-inject with methotrexate subcutaneously. The patient education session was supervised by a nurse and a rheumatologist with a control a week later. Perceptions of the reluctance to self-inject and the difficulties encountered by patients were assessed before the patient education session, after the 1st and 2nd self-injection of methotrexate using a 10 mm visual analog scale. Patients also reported their level of satisfaction (10mm VAS) after the 1st and 2nd self-injection.

**Results:** The mean duration of patient education session is 13 min. Table 1 compares the evolution of the degrees of reluctance to self-injection, the difficulties encountered, and the satisfaction experienced by the patients.

**Table 1. Evolution of RA patients’ perceptions on the methotrexate self-injection. (N=27)**

TRENDS IN DIAGNOSIS AND TREATMENT OF FIBROMYALGIA AMONG MEXICAN PHYSICIANS.

Background: Fibromyalgia (FM) is a disease characterized by widespread pain which affects 2-8% of the population. Previous studies have shown lack of awareness of classification criteria and accompanying symptoms of FM, as well as heterogeneity in the management of these patients among both rheumatologist and non-rheumatologist physicians.

Objectives: The objective of this study was to explore the trends in diagnosis and management of fibromyalgia among general practitioners, family physicians, psychiatrists, neurologists and rheumatologists in northeastern Mexico.

Methods: We designed an online survey to yield data on perception of FM, knowledge of existing classification criteria including the ACR 1990, ACR 2010 modified and AATP classification criteria, as well as pharmacologic and nonpharmacologic therapy for the treatment of FM. Participants should have finished their residence at least in 2019. General practitioners, family physicians, psychiatrists, neurologists and rheumatologists were included.

Results: A total of 236 participants were included, most of the participants were general practitioners, 149 (59.3%). Other specialties included were rheumatologists 21 (8.9%), neurologists 18 (7.6%), psychiatrists 8 (3.4%), and family physicians 49 (20.8%). FM was considered a clinical entity by 208 (88.1%) participants. Participants’ characteristics are shown in Table 1. Twenty-eight (11.9%) participants didn’t know any classification criteria for FM, and 38 (16.1%) participants answered that they didn’t use any classification criteria to make a formal diagnosis of FM. The 1990 ACR classification criteria was used the most, 62 (26.3%); closely followed by the 2010 modified ACR classification criteria, 61 (25.8%). A total of 101 (42.8%) participants made a formal diagnosis of FM in the previous year and 179 (75.8%) referred the patient to another specialist. Most patients were referred to a rheumatologist, 126 (53.4%). One-hundred and fifty-eight (66.9%) participants believe rheumatologist should be the main care providers for patients with FM.

</tbody>
</table>

Conclusion: A total of 88.1% of physicians know at least one classification criteria for the diagnosis of FM. In Mexico, rheumatologists are considered the main care providers for patients with FM. Regarding therapies with level 1A evidence for efficacy in the treatment of FM, only cognitive behavioral therapy and patient education were used by more than 50% of physicians. Serotonin-norepinephrine reuptake inhibitor and tricyclic antidepressants (both of which have level 1A evidence) were only used by 20.8% and 29.2%, respectively.

References:
Background: The role of rheumatology nurses is considered important for the implementation of T2T [1]. For nurses’ contribution to implementation of the T2T strategy, it is necessary to explore the nurses’ opinion on their roles in real clinical practice.

Objectives: The aim of this study is to evaluate what is required for nurses to implement T2T in real clinical practice in Japan.

Methods: Registered nurses engaged in rheumatic care in clinical practice in Japan were enrolled. Focus group interviews were conducted exploring ‘What is necessary for RA nurses to implement T2T’ using semi-structured interviews. Data analysis was used with Krippendorff’s content analysis method.

Results: 24 nurses (all females) from 10 hospitals were enrolled in this study. The results of the qualitative analyses were categorized in 10 main categories, derived from 37 subcategories based on 64 different codes: (1) provide basic knowledge of RA, (2) provide knowledge and skills of self-monitoring, (4) enhance self-efficacy and support self-management, (5) support decision-making, (6) psychological and social support, (7) understand the diversity and feelings of patients and their families, (8) support based on individual needs, (9) ensure continuing educational opportunities for nurses to enable the provision of high quality care, (10) collaborate with multidisciplinary teams.

These categories are mostly covered in the contents of the 2018 updated EULAR recommendations for the role of nurses except ‘evidence-based rheumatic care’, ‘telehealth’ and ‘comprehensive participation in disease management’.

Conclusion: These findings indicate the areas of exploration including further educational and training needs, attitudes and the professional scope for nurses to extend their roles to provide greater value to patient care.

In Japan, evidence-based RA nursing and telehealth systems have not yet been established. In addition, therapeutic intervention by nurses and nurse-led clinic are not permitted. Our results might reflect this situation and possibly elucidates the gap between EULAR’s evidence-based recommendations and opinions of Japanese nurses working in daily clinical practice. As evidence-based nursing is considered to be crucial from both cost-effectiveness and improvement of patients’ QOL, this result also might shed light on what we need for future better rheumatic nursing in Japan.

THU0648-HPR STUDY OF PAIN ATTITUDES & BELIEFS BETWEEN RHEUMATOLOGISTS, PHYSICAL THERAPISTS AND PATIENTS FOR FIBROMYALGIA- A CROSS-SECTIONAL SURVEY

Background: Attitudes and beliefs about pain determine the interpersonal interaction in evaluation and treatment of a chronic painful condition like fibromyalgia in a multidisciplinary healthcare system. Two distinct dimensions for pain attitudes and beliefs were identified as Biomedical and Behavioral. The former utilized a pathoanatomical model whereas the latter incorporated the psychosocial factors into clinical presentations.

Objectives: The study aimed to evaluate the pain attitudes and beliefs amongst rheumatologists, physical therapists and fibromyalgia patients and to compare the biomedical and behavioral dimensions between the three groups in studies population of fibromyalgia syndrome (FMS).

Methods: A nation-wide cross-sectional survey (online and direct interviews) was conducted between 2010-16 to identify first group - 18 (16 male, 2 female) rheumatologists (snowball sampling), and second group - 122 (44 male, 78 female) physical therapists (purposive sampling), both with previous experience of treating adults with fibromyalgia. Also 188 patients with FMS were also studied from outpatient departments of tertiary care hospitals as the third group. All participants filled the Pain Attitudes and Beliefs (PABS) scale and the scores were analysed to identify the two dimensions descriptively in percentiles, and their-between group comparisons were done using Chi-Square test at 95% confidence interval using SPSS version 22 for Windows software.

Results: There was an overall predominance of biomedical dimension for FMS reported in all three groups, with rheumatologists being most prevalent (76.8%), followed by patients (65.6%) and then by physical therapists (54.12%). Between-group comparisons were significant (p<.05) for all 6 analyses.

Conclusion: Biomedical dimension was predominantly reported by rheumatologists, physical therapists and patients for chronic pain in FMS and this necessitates further research on development and implementation of educational interventions in this part of the world.

ASSESSMENT OF THE EFFECTIVENESS OF THE EDUCATIONAL PROGRAM FOR PATIENTS WITH RHEUMATOID ARTHRITIS

M. Salokhiddinov 1, F. Umarov 1. 1Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Effective therapy of rheumatoid arthritis (RA) is impossible without the active and competent participation of the patient in this process, which requires educational programs based on the real needs of the patient.

Objectives: The purpose of the study was to develop an educational program for patients with RA and evaluate its effectiveness

Methods: The study included 65 patients with RA. 35 patients of the main group were trained in the educational program. Of these, 30 patients made up the control group. The educational program consisted of 4 daily classes of 90 minutes. Initially and after 6 months, the indices DAS28, HAQ, RAPID3 were determined using the MIDHAQ questionnaire.

Results: After 6 months after training in the main group, the DAS28 index decreased by 1.28 ± 0.28 points (p < 0.05), HAQ - by 0.65 ± 0.39 (55.2%) (p < 0.01), RAPID3 - by 4.87 ± 0.82 (45.6%) (p < 0.01), anxiety level - by 0.78 ± 0.28 (52.1%) (p < 0.05), depression - by 0.78 ± 0.54 (43.4%) (p < 0.05), fatigue - by 2.96 ± 1.21 points (42.3%) (p < 0.05), sleep improved by 0.85 ± 0.34 (52.3%) (p < 0.05). 6 months after participating in the educational program, a good response to treatment according to DAS28 according to EULAR criteria was significantly more often recorded (54.5% versus 29.0% in the control group (p < 0.05), and the number of patients noted improvement well-being increased by 9 times (p < 0.01). The dynamics in the control group was less pronounced, which determined statistically significant differences between groups for most indicators (p < 0.05).

Conclusion: The educational program improves functional capabilities, psychological status, helps control the activity of the disease and improves the quality of life of patients with RA.

THU0650-HPR

THE USE OF GAMIFICATION TO MOTIVATE HEALTH PROFESSIONALS IN RHEUMATOID ARTHRITIS TO PARTICIPATE IN BLENDED LEARNING.

M. Sengeewen1, P. Steffens-Korbanka2, J. Wendler2, M. Kieslich3, E. Schmok3, G. Gauler4, Humeo GmbH, Düsseldorf, Germany; 5Rheumapraxis an der Hase, Osnabrück, Germany; 6Rheumatologische Schwerpunktpraxis, Erlangen, Germany; 7Heinrich Heine University Düsseldorf, Düsseldorf, Germany; 8University of Lübeck, Lübeck, Germany; 9Rheumapraxis an der Hase, Osnabrück, Germany

Background: Blended learning is an increasingly popular learning supplement for additional classroom-based courses in medical education. Once implemented, many factors influence its success. This was demonstrated by Shvets et al., who concluded that student motivation plays a major role. In particular, if a learner is not self-motivated, e-learning may not represent the best learning environment. However, gamification methods are known to enhance motivation in medical education and, if used correctly, can overcome this deficit. For this purpose, a quiz duel was created and used as a blended learning approach for health professional training in rheumatology. We hypothesize that the use of the quiz duel gamification technique improves learners’ motivation to successfully complete their blended learning course.

Objectives: To investigate the potential of gamification methods in motivating health professionals to answer multiple choice questions (MCQs) in a pilot blended learning scenario.

Methods: Four hundred and sixty MCQs were developed in accordance with the learning objectives of a certified training course and integrated into a learning management system (LMS). As a gamification technique, a duel mode was created. Course participants had access via an individual user account and used personal smartphones. After each answer was provided, the learners received corrective and explanatory feedback, as well as information on how the duel opponent was doing. The learning time spent (3) was collected and analyzed. Each day on which at least one MCQ was answered counted as a learning day per user. The learning time was calculated with 1.5 min per MCQ answered. Analysis was performed over a 15-week period (08/19–12/19).

Results: The training event ("RFAplus") was organized by the Rheumatologische Fortbildungsausgabe GmbH and took place on three weekends in intervals of four weeks in Germany. The LMS used was Humeo (Humeo GmbH). All users agreed to the terms and conditions of use and data protection before participating in the blended learning intervention.

Conclusion: The educational program improves functional capabilities, psychological status, helps control the activity of the disease and improves the quality of life of patients with RA.

Acknowledgments: I would like to thank all my Prot Ahmadov and department of Rheumatology for their sincere support.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.809
user (range, 247-1839 MCQs) during the 15-week period (105 days). Each MCQ was answered 2.33 times. In total, there were 1167 learning days, with 60.8 days per user (range, 15-95 days). The users spent 30,596 min (509.8 h) answering the MCQs, resulting in 1,610 min (or 26.8 h) per user. Furthermore, each user answered 17.5 MCQs and spent an average of 26 min per learning day.

Conclusion: Blended learning is an interactive method to potentially extend learning time over several weeks. However, the success of this technique lies in motivating the participants to continue learning after the event. A quiz duel as a gamification technique proved to be effective in motivating participants to learn daily. In our study, learners spent an average of 27 h, i.e., almost half of the total attendance time of 60 h, learning. Correspondingly, this technique could also replace parts of lengthy face-to-face courses in an attempt to save costs in the future. Information drawn from the MCQs could potentially serve as promising learning analytics.

40% of rheumatologists had a measurable improvement in confidence in their ability to evaluate the presence of enthesitis according to a clinical exam or ultrasound.

Conclusion: This online CME activity significantly improved rheumatologists' understanding of role of enthesitis in the diagnosis and management of PsA. However, there is clearly room for further improving physicians' knowledge of clinical trial outcomes with biologics in patients with enthesitis, since 44% of rheumatologists provided incorrect answers to question 3 post-education. This topic can be addressed in future education.

Acknowledgments: This CME-certified activity was supported by independent funding from Novartis AG.

Disclosure of Interests: Adriana Stan Grant/research support from: The CME-certified activity was supported by an independent educational grant from Sandoz.elijk Calle Grann/research support from: This CME-certified activity was supported by an independent educational grant from Novartis AG. Peter Schoonheim Grant/research support from: This CME-certified activity was supported by independent funding from Sandoz., Philip J Mease Grant/ research support from: Abbott, Amgen, Biogen Idec, BMS, Celgene Corporation, Eli Lilly, Novartis, Pfizer, Sun Pharmaceutical, UCB – grant/research support, Consultant of: Abbott, Amgen, Biogen Idec, BMS, Celgene Corporation, Eli Lilly, Novartis, Pfizer, Sun Pharmaceutical, UCB – consultant, Speakers bureau: Abbott, Amgen, Biogen Idec, BMS, Eli Lilly, Genentech, Janssen, Pfizer, UCB – speakers bureau, DOI: 10.1136/annrheumdis-2020-eular.3137

Relevance: This online CME activity significantly improved rheumatologists' knowledge of enthesitis in the diagnosis and management of PsA. It provides valuable insights into the role of enthesitis in PsA, helping rheumatologists improve their diagnostic and management strategies. The study's results are crucial for enhancing understanding and clinical decision-making in this area of rheumatology.

Objectives: As part of a larger curriculum, we developed an online CME activity titled: “Enthesitis in Psoriatic Arthritis: Disease, Diagnosis and Decisions”. The goal of this study was to assess whether this online CME accredited video discussion improves physicians’ understanding of the role of enthesitis in the diagnosis and management of patients with psoriatic arthritis (PsA) in clinical practice.

Methods: Rheumatologists participated in an online CME activity (https://www.medscape.org/viewarticle/910671) consisting of a 30-minute video discussion between 2 experts with accompanying slides. Educational effect was assessed using a 4-question repeated pairs, pre-/post-assessment. A chi-square test was used to determine if a statistically significant improvement (P <.05 significance level) existed in the number of correct responses from the pretest and posttest scores. Cramer’s V was used to estimate the level of impact of the education. The CME activity launched on March 28, 2019, and the data were collected through June 7, 2019.

Results: A total of 145 rheumatologists completed the pre- and post activity assessments. Overall the activity had a significant impact (P <.0001) on rheumatologists' knowledge of the role of enthesis in the diagnosis and management of PsA, with a Cramer’s V value of 0.153 indicating a noticeable educational impact. The average percentage of correct responses rose from 54% pre-activity to 69% post-activity. A repeated pairs analysis showed that 22% of rheumatologists improved their knowledge and 47% reinforced their knowledge, respectively. The change in percentage of correct responses from pre- to post-assessment for all questions are shown in table. Almost...
Results: A total of 622 rheumatologists participated in the educational activity, and 87 completed the pre- and post-assessment. Overall, the activity had a significant impact (P <.001) on rheumatologists’ understanding of the inherent variability of biologics and the regulatory requirements for approval of a biosimilar. The Cramer’s V value of 0.186 indicates a considerable effect of the education. The average percentage of correct responses rose from 33% pre-activity to 51% post-activity. A linked learning assessment (individual responses matched pre- and post-education) showed that 25% of learners improved their knowledge and 26% reinforced their knowledge. The change in percentage of correct responses from pre- to post-assessment achieved statistical significance (P <.05) in 2 of the 3 questions presented: (i) understanding the type of studies needed to demonstrate comparability of a biosimilar to an originator (11% at baseline; 45% post activity), (ii) understanding the type of variability considered acceptable for a biologic (48% at baseline; 63% post activity). However, no knowledge gain was observed regarding basic analytic attributes evaluated to ensure batch to batch consistency (37% at baseline; 38% post activity). Almost 45% of rheumatologists gained confidence in their ability to describe the regulatory requirements for approval of a biosimilar.

Conclusion: This online CME activity significantly improved rheumatologists’ understanding of the inherent variability of complex biologic medicines and the role of analytical studies in the regulatory approval of biosimilars. However, there is room for further improving physicians’ knowledge, especially of basic analytics of biologics and biosimilars.

BARRIERS FOR THE UPTAKE OF EULAR POSTGRADUATE EDUCATION FOR HEALTH PROFESSIONALS IN RHEUMATOLOGY IN EASTERN EUROPEAN COUNTRIES: RESULTS FROM 3 NATIONAL SURVEYS

Background: Health professionals play an important role in the care for people with rheumatic and musculoskeletal diseases. In order to improve and maintain the quality of their work, appropriate professional education is needed. EULAR has developed several educational products and activities specifically targeted at Health Professionals in Rheumatology (HPR), but particularly in Eastern European countries, their uptake is limited. The overarching aim of a EULAR project (named HEE4ALL: Health professionals Education in Eastern European countries for All) is to develop and execute implementation strategies for EULAR educational activities in 3 Eastern European countries.

Objectives: The aim of the present analysis was to identify barriers and facilitators for the uptake of EULAR educational activities among HPR in Eastern European countries.

Methods: First, a questionnaire was sent to representatives of national health professionals’ or patients’ organization in 17 Eastern European countries, in order to determine their eligibility to participate in the implementation project. Eligibility criteria were: Having a national HPR organization; Willing and able to compose a team with HPR, Patients, and Rheumatologists; and Interested to participate in the project. Selected countries (minimum 3) were requested to set up a national implementation team, and conduct a national, electronic survey among HPR on anticipated barriers and needs regarding educational activities. The survey included the following elements: a. characteristics of the responding HPRs; b. Familiarity with EULAR educational offerings; c. Anticipated barriers and facilitators (score 0-no barrier at all to 10 very important barrier); d. Ability to pay for the HPR online course.

Results: Representatives from 10/17 Eastern European countries responded to the first questionnaire, with 3 countries meeting the selection criteria: Hungary, Serbia and Turkey. Subsequently, 216 (±106, S:42 and T:68) HPR completed the 3 national surveys. In all 3 countries, the majority of the respondents was female (93.1%), and nurse (70.8%) or physical therapist (19.0%). Familiarity with EULAR educational offerings was poor, with the lowest proportions of HPR being familiar with postgraduate face-to-face courses (13.9%), educational visits (19.0%) and the EULAR online course for HPR (25.0%). The highest ranked barriers in all 3 countries included the costs of EULAR annual congress, the costs of the EULAR HPR online course and a lack of mastery of English language. The maximum amount of money HPR were able to pay for the EULAR online course was on average €66, €29 and €83 in Hungary, Serbia and Turkey, respectively.

Conclusion: Based on a survey in 3 Eastern European countries, it appears that familiarity with EULAR educational offerings is suboptimal. However, when HPR are aware of the educational offerings, their costs and a lack of mastery of the English language seem to be the most important barriers for participation. Based on these results, the 3 national teams developed implementation plans during a 2-day meeting (October 2019). The implementation plans are now executed and a process and effect evaluation is planned by November, 2020.

**NEUTROPHILS IN GRANULOMATOSIS WITH POLYANGIITIS DISPLAY FEATURES OF PYROPTOSIS**

1. University of Luebeck, Department of Rheumatology and Clinical Immunology, Luebeck, Germany

**Background:** Granulomatosis with polyangiitis (GPA) is characterized by extravascular necrotizing granulomatous inflammation and systemic ANCA-associated (AAV) vasculitis with neutrophils as a key player in the pathogenesis. We and others have shown that neutrophil-related cell death mechanisms contribute to chronic inflammatory processes in AAV (2, 3). Recently, another form of inflammatory cell death primarily described in monocytes called pyroptosis was also discovered in neutrophils (4). Cardiac feature of pyroptosis is the activation of the NLRP3 inflammasome, a sensor of different pathogen- and damage-associated molecular patterns (PAMPs, DAMPs), following caspase-1-mediated processing and secretion of IL-1beta (5).

**Objectives:** The aim of this study was to investigate, if neutrophils from GPA patients express pyroptosis-related components NLRP3, active caspase 1 and cleaved IL-1beta.

**Methods:** Polymorphonuclear leukocytes (PMN) were isolated from peripheral blood of GPA patients and healthy controls (HC) (n = 10 each). Expression of NLRP3, inactive/active caspase 1 and active IL-1beta was determined by western blot. In addition, peripheral blood mononuclear cells (PBMC) were isolated from GPA and HC. mRNA expression of nlrp3 and il1b was determined by qPCR. To exclude false-positive results by contamination with monocytes we performed flow cytometry analysis of whole blood samples with markers CD3, CD14, CD15, CD66b and NLRP3.

**Results:** PMN from GPA patients showed markedly increased expression of NLRP3, inactive caspase 1 and active IL-1beta compared to HC. In contrast, there was no difference between GPA and HC on the mRNA level of neither nlrp3 nor il1b in PBMC. In addition, we confirmed by flow cytometry increased expression of NLRP3 in PMN from GPA, but not in monocytes.

**Conclusion:** Here we provide evidence, that neutrophils from GPA undergo pyroptosis, demonstrated by increased NLRP3, active caspase 1 expression as well as IL-1beta processing. Neutrophils are present in high numbers at the site of granulomatous lesions of inflamed tissue in GPA and IL-1beta is increased in GPA sera (2). Therefore, neutrophils represent a potential source of IL-1beta in GPA. Given the fact that GPA-associated features such as massive release of necrosis-related DAMP or microbial agents such as Staphylococcus aureus contribute to chronic inflammatory processes of GPA.

**S100A11 (CALGIZZARIN) IS RELEASED DURING NEUTROPHIL EXTRACELLULAR TRAPS FORMATION AND STIMULATES RELEASE OF IL-6 AND TNF IN RHEUMATOID ARTHRITIS**

1. Institute of Rheumatology, Prague, Czech Republic; 2. 1st Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic; 3. Institute for Inflammation Research, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; 4. First Orthopaedic Clinic, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic

**Background:** S100A11 protein, a member of S100 family, has been associated with several autoimmune inflammatory conditions such as rheumatoid arthritis (RA). Although the pathogenesis of autoimmune diseases is not fully understood, the formation of neutrophil extracellular traps (NETs) seems to play a certain role. Recent data indicate that S100A1B is released via NETosis and can further augment inflammatory responses.

**Objectives:** The aim of our study was to examine the association of S100A11 with NETs in RA.

**Methods:** To assess the expression of S100A11 by neutrophils of RA synovial tissue (n=8), immunofluorescence staining of S100A11 and myeloperoxidase (MPO) was performed. The levels of S100A11 and MPO in RA synovial fluid (n=23) were measured by ELISAs (RayBiotech and Abcam), and the activity of peptidyl arginine deiminases (PADs) was measured by an in-house immunoassay. NETosis was induced by adding phorbol 12-myristate 13-acetate (PMA) to neutrophils from RA patients (n=7). Release of NETs was visualised by immuno-cytometry (n=7) and the presence of S100A11 in supernatants was analysed by ELISA (RayBiotech). Neutrophils purified from healthy donors (n=5) were stimulated with S100A11 and the release of cytokines TNF-γ and IL-6 was measured by ELISA (RayBiotech).

**Results:** S100A11 was expressed by synovial tissue neutrophils of the RA patients (n=8). The levels of S100A11 in the synovial fluid of RA patients (n=23) correlated with the levels of a NETosis marker MPO (r=0.562, p<0.005) and with PADs activity (r=0.690, p<0.001), which affects NETs immunogenicity. Neutrophils treated with LPS (n=7) did not up-regulate the secretion of S100A11 compared to untreated controls (1.6±0.17 vs. 0.29±0.07 ng/ml; p<0.001). Moreover, diphenyleniodinid treatment abolished PMA-induced S100A11 secretion. By immunofluorescence staining (n=8) we demonstrated that neutrophils activated by PMA release NETs containing S100A11 protein. In addition, extracellular S100A11 augmented the inflammatory response of neutrophils from healthy donors (n=5) in IL-6 and TNF in comparison with unstimulated cells (0.39±0.11 vs. 0.05±0.01 pg/ml; p<0.05 and 0.31±0.06 vs. 0.09±0.03 pg/ml; p<0.05).

**Conclusion:** Here we show for the first time that release of S100A11 by neutrophils is dependent on NETosis. Moreover, extracellular S100A11 augments the inflammatory response by inducing TNF and IL-6 secretion in neutrophils.

**ELEVATED HISTONE H4 IN NEUTROPHIL EXTRACELLULAR TRAPS PROMOTES MACROPHAGE ACTIVATION IN BECHÇE’S DISEASE**

L. Li, X. Yu, J. Liu, H. Chen, W. Zhang, 1. Peiking Union Medical College Hospital, Department of Rheumatology, Beijing, China

**Background:** Neutrophil-released neutrophil extracellular traps (NETs) are upregulated and promote autoinflammation and thrombosis in Bechçe’s disease BD, a multisystem inflammatory disease with unknown etiology 1,2. However, whether NETs promote macrophage activation in BD remains unclear.

**Objectives:** To investigate the potential role of NETs in promoting aberrant macrophage activation in BD.
Methods: We quantified NETs by measuring dsDNA using ELISA and immunofluorescence. Macrophages were stimulated with BD- and healthy controls (HC)-derived NETs, and IL-8 and TNF-α production were measured by ELISA. NET-stimulated macrophages were incubated with naive CD4+ T cells and Th1 cell differentiation was examined on day 7 by flow cytometry. Histones H1, H2A, H2B, H3, and S100A8 and neutrophil elastase in NETs were analyzed by western blot. Macrophages were stimulated with anti-Histone 4 antibody-treated NETs, and IL-8 production was measured by ELISA.

Results: Circulating NETs (2395±534 ng/ml vs. 1472±549 ng/ml, P=0.0008) and neutrophil-derived NETs (909±2485.2 ng/ml vs. 582±199.2 ng/ml, P=0.0108) were significantly higher in BD patients compared with those in HC. BD NETs stimulated macrophages to produce a higher level of IL-8 (17±4 ng/ml vs. 13±4 ng/ml, P=0.0474) and TNF-α (166±61 pg/ml vs. 102±48 pg/ml, P=0.0132) than HC NETs. Moreover, BD NETs promoted macrophages to facilitate Th1 differentiation than HC NETs (33±10% vs. 24±7%, P=0.0398). Western blot analysis revealed more Histone H4 (2890±76 (144365, 544038) IOD values vs. 4212±1 (6958, 129625) IOD values, P=0.0286), but not Histones H1, H2A, H2B, H3, S100A8 or neutrophil elastase in BD NETs compared to HC NETs. Importantly, neutralizing Histone H4 abrogated the BD NETs-stimulated IL-8 overproduction by macrophages (9.99±2.07 ng/ml vs. 13±5±2.91 ng/ml, P=0.021).

Conclusion: BD NETs promoted macrophage activation, which might be mediated by a higher level of Histone H4.

SURFACE AMP DEAMINASE 2 AS A NOVEL REGULATOR MODIFYING THE EXTRACELLULAR ATP-ADENOSINE BALANCE THAT IS DIFFERENTIALLY EXPRESSED IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Ehlers1,2, A. Kuppe1,2, A. Damerau1,2, M. Kirchner3, C. Streli1,2, F. Buttgeret1,2, T. Gaber1,2,1. Chânter University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 1German Rheumatism Research Centre, Berlin, Germany; 2Max Delbrück Center for Molecular Medicine, BIH Core Facility Proteomics, Berlin, Germany

Background: Adenosine and its nucleotides represent crucial immunomodulators in the extracellular environment. ATP and ADP are released from stressed cells in states of inflammation, whereas adenosine serves as a key anti-inflammatory mediator. The ectonucleotidases CD39 and CD73 are responsible for the sequential catabolism of ATP to adenosine via AMP, thereby promoting a shunt-like mechanism adding to the CD39-CD73 system controlling the extracellular ATP-adenosine balance that is differentially expressed in RA patients compared to healthy controls. The extracellular conversion of AMP into IMP may constitute a shunt-like mechanism adding to the CD39-CD73 system controlling immunomodulation.

Objectives: Therefore, we analysed surface AMPD2 expression and its modulation on distinct cell lines and primary immune cells.

Methods: Firstly, AMPD2 surface expression was verified by immunoprecipitation from membrane fractions isolated from cell lines (HEK293 and HMEC1) and CD14+ monocytes analyised by western blot and mass spectrometry. In addition, surface biotinylation of the aforementioned cells was performed. Also, AMPD2 surface expression was evaluated by flow cytometry, analysing both cell lines (HEK293, HMEC1, THP1, and Jurkat) and primary human immune cells from healthy donors and patients with RA.

Secondly, co-expression of surface AMPD2, CD39 and CD73 on PBMCs was analysed by flow cytometry after isolation as well as after a 24h culture period. Moreover, surface expression was assessed after immunostimulation and Golgi transport inhibition.

Results: AMPD2 surface expression was confirmed by western blot and mass spectrometry of (i) precipitated AMPD2 from membrane fractions and (ii) biotinylated surface molecules in HEK293 and HMEC1 as well as CD14+ monocytes. Surface expression was reduced after AMPD2 knockdown in HEK293. Flow cytometric analysis further verified AMPD2 surface expression and revealed a significant decrease after Golgi transport inhibition (p<0.01). TLR stimulation strongly enhanced the surface expression of AMPD2 and CD39 on monocytes (p<0.05), whereas dexamethasone at high therapeutic doses inversely affected AMPD2 surface expression on monocytes (p<0.01). Analysis of AMPD2 surface expression on PBMCs from RA patients revealed higher expression levels compared to sex- and age-matched healthy controls (p<0.05).

Conclusion: We demonstrate AMPD2 surface expression on immune cells for the first time. Hence, we reveal a novel regulator of the extracellular ATP-adenosine balance that is differentially expressed in RA patients compared to healthy controls. The extracellular conversion of AMP into IMP may constitute a shunt-like mechanism adding to the CD39-CD73 system controlling immunomodulation.

histone acetyltransferases (anacardin acide) and deactylases (trichostatin A). Binding patterns of monoclonal ACPAs, both whole and F(ab)2 fragments were analyzed in synovial biopsies obtained from both healthy donors and RA patients.

**Results:** Three out of four tested individual ACPA were able to promote fibroblast migration. Five out of nine tested monoclonal ACPAs stimulated fibroblast migration. One of these antibodies, clone 1325:01B09 is characterized by cross-reactivity to citrullinated, homocitrullinated and acetylated targets. The effect of 1325:01B09 on fibroblast migration was completely abolished by CI-amidine or by pre-incubating the antibody with citrullinated fibrinogen or histone but not citrullinated enolase or vimentin. Despite the cross-reactivity to acetylated epitopes, neither anacardin acide nor trichostatin A could modulate the 1325:01B09 effect on fibroblast migration. F(ab)2 fragments of this antibody stimulated fibroblast migration and labelled podoplanin-positive fibroblasts in inflamed RA synovium similarly to the intact antibody, indicating an Fc-independent effect.

**Conclusion:** The effect on fibroblast mobility was likely to be mediated by binding to citrullinated epitopes but not through Fc receptors. Detection of fibroblast modulating ACPAs in majority of RA patients indicated that fibroblasts might be key cellular targets in disease pathogenesis, although individual variability might exist in the composition of ACPA cellular targets.

ASSESSING PRO-INFLAMMATORY PROPERTIES OF H-FERRITIN BY EX VIVO AND IN VITRO OBSERVATIONS

**P. Ruscin**1, P. Di Benedetto1, O. Berardicurti1, N. Panza1, F. Sensini1, F. Cipriani1, R. Giacomelli1, 1University of Udine, Department of Biotechnological and Applied Clinical Sciences, Udine, Italy

**Background:** The concept of ‘hyperferritinemic syndrome’ has recently been proposed, suggesting high levels of ferritin as pathogenic pro-inflammatory mediator [1] Ferritin is an intracellular iron storage protein, comprising 24 subunits which are treated with H-ferritin, stimulated the proliferation of co-cultured PBMCs.

**Conclusion:** In our work, results showed the presence of H-ferritin and CD68/H-ferritin in BM biopsies of MAS patients, by immunofluorescence. Conversely, LC-MS/MS identified L-ferritin in sera proteins of those patients. Furthermore, pro-inflammatory effects of ferritin and, particularly, of H-ferritin on human monocytes were observed in vitro, increasing pro-inflammatory cytokines which were treated with H-ferritin, stimulated the proliferation of co-cultured PBMCs.

**References:**
Conclusion: The results further support the involvement of monocytes in RA pathogenesis and highlight the key role MOSPD2 plays in this disease. Accordingly, targeting of monocyte migration using anti MOSPD2 mAbs may hold promise as a treatment for various chronic inflammatory diseases, including RA.

IGM ANTIBODIES AGAINST MALONDIALDEHYDE AND PHOSPHORYLCHOLINE IN DIFFERENT SYSTEMIC RHEUMATIC DISEASES

D. Thiagarajan1, S. Lundström1, R. Zubarev1, J. Sun1, M. Alarcon-Riquelme2, J. Frostegård2 on behalf of The research leading to these results has received support from the Innovative Medicines Initiative Joint Undertaking under grant agreement n°115565, resources of which are composed of financial contribution from the European Union’s Seventh Framework Programme (FP7/2007-2013) and EFPIA companies in kind contribution. 1Karolinska Institutet, Stockholm, Sweden; 2University of Granada, Granada, Spain

Background: IgM antibodies against phosphorylcholine (anti-PC) and malondialdehyde (anti-MDA) may have protective properties in both atherosclerosis and rheumatic disease, especially anti-PC. Low levels of IgM anti-PC is associated with SLE itself and also with atherosclerotic plaques 1 and with being a non-responder to biologics in RA. 2 We determined mechanisms by which anti-PC (and to some extent anti-MDA) could be protective: 1: anti-inflammatory; 2: inhibition of uptake of oxLDL in macrophages; 3: inhibition of cell death; 4: increase in clearance of human dead cells; 5: anti-PC promotes polarization of T regulatory cells in SLE-patients’ T cells from a low level and also in cells from atherosclerotic plaques. 2

Objectives: To compare systemic rheumatic diseases in relation to natural anti-PC and anti-MDA, to develop novel classifications but also potential treatment against rheumatic disease. We here determine anti-PC and anti-MDA in different systemic rheumatic conditions and study their role related properties.

Methods: Anti-PC and anti-MDA was measured using ELISA in patients with SLE (374), RA (354), Mixed connective tissue disease (MCTD, 77), Systemic sclerosis (SSc, 331), Sjögren’s syndrome (SjS, 324), primary antiphospholipid syndrome (PAPS, 65), undifferentiated connective tissue disease (UCTD, 118) and 515 matched healthy controls (HC). Cardiovascular score (CV) was broadly defined based on clinical disease symptoms. Anti-PC and anti-MDA peptide/protein characterization were compared using a proteomics de novo sequencing approach. anti-MDA and anti-PC were extracted from total IgM. The proportion of Treg cells was determined by flow cytometry.

Results: The maximal difference between cases and controls was shown for MCTD: significantly lower IgM Anti-PC but not anti-MDA among patients (median 49.3RU/ml vs 70.4 in healthy controls, p<0.0007). IgM low levels were more prevalent in MCTD, SLE, SjS, SSc and UCTD. IgM anti-PC variable region profiles were different from and more homologous than anti-MDA. Anti-PC but not anti-MDA were significantly negatively correlated with CV in the whole patient group. In contrast to IgM anti-PC, anti-MDA did not promote polarization of Tregs.

Conclusion: Anti-PC is decreased in MCTD and also in SLE, SjS and SSc but not in other studied diseases. Anti-PC may thus differentiate between these. In contrast, anti-MDA did not show these differences between diseases studied. Anti-PC level is negatively correlated with CV in the patient group cohort. In contrast to anti-PC, anti-MDA did not promote Treg polarization. These findings could have both diagnostic and therapeutic implications, one possibility being active or passive immunization with PC in some rheumatic conditions.

FR10010  GM-CSFR PATHWAY IS ILLUMINATED IN PATHOGENIC INFLAMMATORY MECHANISMS IN GIANT CELL ARTERITIS

Background: Giant Cell Arteritis (GCA) is characterized by inflammation of large and medium arteries. Classic symptoms include headache, malaise and, in severe cases, blindness and aortic aneurysms. Corticosteroids (CS) are the first line of treatment. Relapsing disease patients undergo multiple courses of CS therapy increasing their CS exposure and toxicity. A significant unmet need for disease-modifying CS-sparing therapy remains in GCA as the efficacy of current treatment options, including tocilizumab, has limitations.

We have previously reported elevated expression of granulocyte-macrophage colony stimulating factor (GM-CSF) pathway transcriptomic signature in GCA vessels. GM-CSF may contribute to underlying disease mechanisms by regulating inflammatory macrophages, dendritic cells (DCs) and T helper (Th)1/Th17 cells which are involved in GCA pathogenesis. GM-CSF produced by T cells can promote polarization of inflammatory macrophages and recruitment and differentiation of monocytes into inflammatory DCs that can in turn recruit T cells and stimulate Th1/Th17 differentiation creating a feedback loop. GM-CSF may also exert direct effects on angiogenesis and vessel wall remodeling.

Objectives: To demonstrate the contributing role of GM-CSF pathway to inflammation in GCA arteries.

Methods: Immunostaining was used to examine expression of GM-CSF and GM-CSF-Rα proteins in temporal artery biopsies from GCA and controls (patients with suspected but not confirmed GCA and a negative TAB). Coating with cell markers such as CD31, CD3, and CD68 allowed visualization of cells expressing GM-CSF and GM-CSF-Rα. Expression of GM-CSF pathway molecules such as phosphorylated JAK2 and phosphorylated STAT3 was detected by immunohistochemical staining of GCA and control TABs. Ex vivo cultured GCA arteries treated (10 each) with mavrilimumab (anti-GM-CSF-Rα) or placebo for 5 days were assayed for gene expression with qPCR, and culture supernatants were analyzed by ELISA.

Results: Endothelial cells and macrophages were the main cell types expressing GM-CSF and GM-CSF-Rα. Increased expression of phosphorylated-JAK2 (activated signaling molecule) and nuclear-localized Pu.1 (transcription factor) in GCA TABs compared to controls indicated the presence of active GM-CSF signaling pathway in GCA.

Inhibition of Pu.1 mRNA expression in ex vivo cultures of GCA arteries treated with mavrilimumab indicated blockade of GM-CSF signaling pathway. Mavrilimumab reduced in mRNA expression of key cell type markers including DC and macrophage activation markers CD83 and HLA-DR, monocyte markers CD14 and CD16, T cell marker CD3e, and B cell marker CD20 in these GCA artery cultures. Expression of inflammatory Th1/Th17 factors IFNγ, TNFα, CXCL10 (IFNγ-stimulated chemokine) and IL-6 (mRNA and protein) was also inhibited by mavrilimumab in GCA artery cultures.

Conclusion: Increased GM-CSF, GM-CSF-Rα, and downstream pathway-associated protein levels in GCA biopsies were consistent with previously-oberved increased transcriptome signature. Expression of genes associated with inflammatory cells were suppressed by mavrilimumab in cultured GCA arteries. These data implicate the GM-CSF pathway in GCA pathophysiology and increase confidence in rationale for targeting the GM-CSF pathway in GCA.

FR10011  DEVELOPMENT OF A HIGH-DIMENSIONAL FLOW CYTOMETRY PANEL TO ANALYSE NATURAL KILLER CELLS IN SLE

N. Fewings, S. Schibeci, F. Mckay, S. Swaminathan, M. W. Liu; The Westmead Institute for Medical Research, Centre for Immunology and Allergy Research, Westmead, Australia; The University of Sydney, Sydney Clinical School, Camperdown, Australia; Westmead Hospital, Department of Clinical Immunology, Westmead, Australia; Westmead Hospital, Department of Immunopathology, ICPMR, Westmead, Australia

Background: Natural Killer (NK) cells are an innate immune cell type that has somewhat been overlooked in the context of systemic lupus erythematosus (SLE). SLE patients display a reduced number of NK cells with an activated phenotype and increased capacity to produce IFN-γ, decreased antibody-dependent cellular cytotoxicity (ADCC), and altered natural cytotoxicity (1). NK cell activation is determined by the integration of input from a myriad of activating and inhibitory receptors. Previously, using Nanostring® gene expression technologies, we found our SLE cohort showed decreased gene expression of a number of these receptors (KLRRC2, KLRRC1, KLRB1, KLRF1, KLRG1, PRF1 and IL2RB) leading us to explore NK cells in SLE in more depth.

Objectives: Our aim was to develop a high-dimensional flow cytometry panel to characterise dysregulation of NK cell in SLE, with particular reference to the activating and inhibitory receptors found to be dysregulated in SLE at the gene expression level.

Methods: Markers for NK panel were selected to include canonical phenotypic functional molecules of NK cells with a particular emphasis on receptors found to be lower in our SLE cohort’s gene expression findings. NK panel was designed to minimise spectral overlap, expression and co-expression of markers was taken into consideration. Antibodies were titrated, and voltages optimised to achieve the best separation index for each of the antibodies. The 24-marker panel was run on 52 SLE patients of various disease manifestations, treatments and disease severity. 20 healthy controls were also run for comparison.

Results: A 24-marker flow cytometry panel including 19 NK cell antigens was optimised, including basic phenotype (CD3/CD56/CD16/NKp46) and NK differentiation markers (CD57/CD94), activating and inhibitory receptors (NKGA2/NKG2C/NKG2D), costimulatory receptors (CD244/CD226), transcription factors (Eomes/Tbet) and effector molecules (granzyme/perforin). Immunophenotypic high-parameter analysis of SLE and control samples is in progress and results will be presented.

Conclusion: Our development of a high-dimensional immunophenotypic panel allows identification of changes in NK cells in SLE including antigen expression levels, subset percentages and potentially of novel subsets. This panel will be used to investigate NK cell changes with disease course/activity, therapeutic response, and to discover potential drug targets for SLE.

THERAPEUTIC VALUE OF CURCUMIN ON INITIATION AND DEVELOPMENT OF INFLAMMATION IN TAKAYASU’S ARTERITIS CAUSED BY HSP65-MEDIATED CCL2 OVEREXPRESSION

S. Wu1, L. MA1, Y. Wang3, R. Chen1, W. Yu1, L. Jiang1,2. 1Zhongshan Hospital, Fudan University, Departments of Rheumatology, Shanghai, China; 2Fudan University, Center of Clinical Epidemiology and Evidence-based Medicine, Shanghai, China

Background: Takayasu’s arteritis (TA) is a chronic inflammatory disease characterized with macrophages infiltration. During active stage, aorta adventitial fibroblasts (AAFs) proliferate excessively and produce numerous pro-inflammatory factors in the adventitia, which is the main target of TA therapy. Monocyte chemokine CCL2 may contribute to the infiltration of macrophages in TA arteries but whether with relationship with HSP65, an antigen of Mycobacterium tuberculosis (M. TB) which might involve in the pathogenesis of TA and activate AAFs to produce inflammatory factors, has not been reported. The treatment of TA is full of difficulties and contradictions. Curcumin is a traditional Chinese medicine with anti-inflammatory effect, whether it is effective on TA and the underlying mechanism remains unclear.

Objectives: To explore the mechanism of TA inflammation triggered by M. TB associated antigen HSP65 activating AAFs, as well as the therapeutic value of curcumin in the initiation and development of TA.

Methods: We first verified high HSP65 expression in aortic adventitia of TA patients by IHC. mRNA-seq was used to profile DEGs between AAFs stimulated by HSP65 with or without pretreated with curcumin, and AAFs without any treatment. Then the key chemokine CCL2 screened by mRNA-seq was detected in the adventitia of TA aorta, and its correlation with HSP65 expression was analyzed by double-labelled IF. Subsequently, we explored how HSP65 affected the production of inflammatory factors by AAFs at cellular level and its related signal pathway. Simultaneously, we explored whether curcumin could hinder this process and verified the effect of curcumin on serum CCL2 level in patients with TA. Finally, serum CCL2 and other inflammation indicators of TA patients at baseline and after 3 months treatment by curcumin were determined.

Results: HSP65 was highly expressed in the adventitia of TA arteries. DEGs analysis showed a key role of CCL2. The expression of CCL2 in adventitia of TA arteries was significantly higher than healthy subjects, and was correlated with HSP65. HSP65 facilitated the production of CCL2, IL-6 and IL-1β by AAFs via activating TLR4-JAK2/STAT3 pathway, among which the change of CCL2 was the most remarkable. Curcumin reversed the upregulation of CCL2 induced by HSP65 in vitro, which was more obvious than that of MTX and tofacitinib. Finally, curcumin significantly downregulated the level of serum CCL2 of TA patients.

Conclusion: HSP65 initiates and promotes inflammation of TA by upregulated CCL2 in AAFs via activating TLR4-JAK2/STAT3 pathway, while curcumin can reverse this process and slow down the initiation and development of TA.

A PUTATIVE ROLE OF IGF-1R ON THE PATHOGENESIS OF GOUT THROUGH BINDING TO TRANScription FACTORS

R. Liu1, O. Gaai2, V. Klück3, T. Crisan4, S. Fanucchi5, M. Mhianga5, L. Joosten1,2.

1Radboudumc, Nijmegen, Netherlands; 2Iuliu Haşgianu University of Medicine and Pharmacy Cluj Napoca, Romania; 3Faculty of Health Sciences, University of Cape Town, Cape Town, South Africa

Background: Recent studies showed that SNPs on IGF-1/IGF-1R were highly associated with hyperuricemia and gout [1,2]. It was shown that the IGF-1/IGF-1R signaling pathway played a role in regulating the serum urate level. By modulating the uric acid transporters, IGF-1/IGF-1R influenced the resorption and secretion of uric acid. However, we demonstrated that the increased activation of IGF-1R could activate the mTOR pathway, leading to a higher inflammatory response upon pathogen stimulation [3]. This finding indicates that IGF-1/IGF-1R has a role in inflammation, which could result in gout. The IGF-1/IGF-1R pathway may have an overall influence on both urate transporters and inflammatory pathways. It was shown that IGF-1R was not only expressed on the cell surface, but could also internalize into the nucleus and recruit RNA polymerase, regulating the expression of other transcription factors[4]. These transcription factors have been shown to regulate inflammation and have been predicted to bind promoter regions of urate transporters[5].

Objectives: To unveil how the IGF-1/IGF-1R associates with hyperuricemia and gout by studying the IGF-1R SNP rs6598541.

Methods: To assess the influence of the SNP to IGF-1-R, the protein expression of IGF-1-R on the cell surface was identified by flow cytometry in different genotypes. Additionally, we measured the in vitro immune response of PBMCs with different genotypes upon exposure to MSU and/or LPS. To estimate the overall influence of the SNP on the immune response, we analyzed the SNP’s function on transcription factors.

Results: We observed an enhanced inflammatory response in the homoygous genotype with the risk alleles upon LPS and/or MSU stimulation, indicative of a higher risk for gout. However, the IGF-1R surface expression level was comparable between different genotypes. Furthermore, in epigenetic analysis, we found that rs6598541 located in an enhancer region, which is bound by c-FOS, c-JUN and other transcription factors. In recent years, c-FOS and c-JUN have been shown to regulate inflammatory responses.

Conclusion: The risk allele of rs6598541 is associated with a higher inflammatory response, which might be the key factor for gout. Because of the location of the SNP, it might explain the function of IGF-1-R in gout, and the pathogenesis might be modulated through transcription factors. According to the recent study, intracellular IGF-1R could act as a transcription factor regulating other transcription factors expression, like c-JUN. Additionally, c-JUN has been shown to regulate inflammatory responses. It is tempting to speculate that IGF-1-R regulates transcription factors expression and leads to an overall immune response, which influence the risk of gout.

PHENOTYPE AND FUNCTION OF THE PERIPHERAL BLOOD DENDRITIC CELLS OF PSORIASIS PATIENTS WITH AND WITHOUT ARTHRITIS

S. Schnitte1, A. Fuchs1, T. Funk1, A. C. Pecher1, D. Dörfel1,2, J. Henes2.

1University Hospital Tübingen, Internal Medicine II, Tübingen, Germany; 2KRH Klinikum Siloah, Hannover, Germany

Background: Psoriasis is a frequent skin disease that can appear with an arthritis manifestation in approximately 30% of the cases [1]. The underlying excessive immune reaction caused by pro-inflammatory cytokines can be triggered by several risk factors [2]. Various subgroups of Dendritic cells (DCs) in the skin play a crucial role in the induction of the dermal inflammatory response [3].

Objectives: As the role of peripheral blood DCs remains unknown and the cause of an arthritis manifestation is still not completely understood [4], this project aimed to detect differences in phenotype or function of peripheral blood DCs in psoriatic patients with or without arthritis.

Methods: We analyzed peripheral blood cells of 60 psoriasis patients with and without arthritis. Different DC subpopulations were detected by flow cytometry. Monocyte-derived DCs were cultured with or without Lipopolysaccharides to gain immature (iDC) and mature (mDC) cells. The DC phenotype was determined by staining with CD80, CD83, CD86, CD206, CCR7, CD1a, HLA-DR, CD40, GPN-MB, DC209 and CD14. Their T-cell stimulatory capability was analyzed by co-incubation with Carboxyfluorescein succinimidyl ester stained lymphocytes and the quantification of CD4+ T-lymphocytes afterwards. To measure the migration capacity DCs were seated into transwell chambers with a semipermeable membrane and partly supplemented with Macrophage Inflammatory Protein 3 Beta (Mip3b). Migrated cells were detected by flow cytometry. Measured cell counts were normalized to cell counts without Mip3b stimulation.

Results: Comparing the factor of increase of migrated mDC counts due to mip3b stimulation, we detected a significant lower rate in samples of patients with arthritis (PsA) compared to those of patients without (Ps). Assays of mDCs without mip3b stimulation showed a significant higher count of migrated cells in the samples of the arthritic group [Figure 1]. Cell counts with Mip3b stimulation did vary slightly in the groups. The DC subpopulations and the expression of analyzed cell surface proteins did not show significant differences. The amounts of stimulated T-lymphocytes did not differ significantly.

Figure 1. Migration essay showing mDCs following Mip3b (+mip3b) as multiples of mDCs without stimulation (-mip3b). The factor of increase is significantly lower in patients with arthritis (PsA) compared to patients without (Ps). Absolute counts of migrated mDCs without Mip3b are significantly higher in the arthritic group. Cell counts with stimulation do not differ significantly (data not shown). N=24, p<0.05

Conclusion: CCL19 (Mip3b) is a potent ligand to the CCR7 receptor inducing migration of DCs towards the lymphatic node [5]. The CCR7 amounts on the DC surface did not differ significantly in the groups. The mDCs without CCL19 stimulation migrated in higher amounts in samples of arthritic patients. Cell counts of stimulated DCs showed only slight differences. These results could be generated by a different appearance of the DCs of arthritic patients that might facilitate migration. Further experiments focusing on this aspect should be performed. A possible effect of disruptive factors (age, sex, medication…) needs to be clarified.

PERIPHERAL BLOOD MONONUCLEAR CELLS OF TAKAYASU ARTERITIS PATIENTS

Y. Tian, J. Li, X. Tian, X. Zeng, 1Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Rheumatology, Beijing, China; 2Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Department of Rheumatology, Beijing, China

Background: The activation of self-specific T cells is essential in pathogenesis of Takayasu arteritis (TAK). Dendritic cell (DC) plays an indispensable role as the only antigen presenting cell for initial T cell, and Toll-like receptors (TLRs) are common source of activation signals for DCs. Then we speculate that there are activation of TLRs in TAK patients.

Objectives: To investigate the activation of TLRs in TAK patients.

Methods: Twenty-seven TAK patients were enrolled during April to October in 2019, with diagnosis met the 1990 criteria of American College of Rheumatology. Patient were divided into groups by the disease activity and medication history. Disease activity was assessed by the 1994 NIH criteria. Quantitative Real-time Polymerase Chain Reaction (RT-qPCR) was used to analyze the mRNA relative abundance of 28 target genes in peripheral blood mononuclear cells (PBMCs).

Differences between groups and correlation between any two genes were analyzed.

Results: The demographic data and clinical features of TAK patients were shown in Table 1. (1) Compared with health control (HC) group, mRNA abundance of TLR2, TLR4, P50, P65, IkBα, CTLA4, CD3, and BCL6 in untreated TAK group was upregulated (<0.05), whereas mRNA abundance of CD40 was downregulated (p <0.05). (2) Compared with HC group, mRNA abundance of TLR2, TLR4, IkBα, PD-1 and BCL6 in treated TAK group was upregulated (p <0.05), whereas mRNA abundance of LAG3, CD40 and TCR was downregulated (p <0.05). (3) Compared with untreated TAK group, mRNA abundance of P50, P65, CD28, CTLA4, TLR2, TLR4, IkBα, PD-1 and RORC was upregulated in treated TAK group (p <0.05). (4) Compared with non-active treated TAK group, mRNA abundance of p50, CD28, TCR, QATA3, ROrc and FOXP3 was upregulated in nonactive treated TAK group (p <0.05). BCL6 showed correlation with the TLRs-NFκB pathway. (Figure 1–2, Table 2)

Rheumatoid arthritis - prognosis, predictors and outcome

FRI0018

USING SELF-REPORTED OUTCOMES TO DETECT NEW-ONSET FLARE IN A REAL-WORLD STUDY OF PARTICIPANTS WITH RHEUMATOID ARTHRITIS - INTERIM RESULTS FROM THE DIGITAL TRACKING OF ARTHRITIS LONGITUDINALLY (DIGITAL) STUDY

V. S. Haynes1, J. Curtis2, F. Xie2, I. Lipovich1, H. Zhao3, C. L. Kannowski1, J. L. Poon1, K. Gavigan3, D. Curtis2, S. K. Nolot1, W. B. Newell2,3, Eli Lilly and Company, Indianapolis, United States of America; University of Alabama at Birmingham, Birmingham, United States of America; Global Healthy Living Foundation, Upper Nyack, United States of America

Background: Patients with rheumatoid arthritis (RA) experience fluctuating symptoms, increased pain, decreased function and variable quality of life; such changes often occur between visits to clinicians. Digital Tracking of Arthritis Longitudinally (DIGITAL) study2 is evaluating the use of electronically captured patient-reported outcomes (ePRO) and passive data collection from a Fitbit device to identify disease worsening in a real-world study of participants (pts) with RA.

Objectives: Evaluate agreement between self-reported new-onset flare and ePROs in an interim analysis from DIGITAL using a classification model.

Methods: Members of the ArthritisPower registry with RA were invited to participate in DIGITAL. Pts who successfully completed a two-week lead-in period entered the Main Study in which they wore a smartwatch and provided daily (pain and fatigue numeric rating scales (NRS)) and weekly ePROs, including the OMERACT RA Flare Questionnaire (FLARE) and PROMIS measures. This interim analysis is of ePRO data from pts who completed at least 30 days of the Main Study. A “Yes” response to the FLARE item, “Are you having a flare now?” identified flare. For modeling association between new-onset flare and ePRO, the dataset was split into training (the first 30 days of the Main Study) and test data (Day 31 and following). Within each dataset, repeated binary outcomes (Flare/No Flare) per pt were defined each week. To focus on new-onset flare, within each dataset, outcomes for patient weeks for which flare was present in the previous week were excluded.

Candidate variables for the model included baseline and current FLARE score (0-50 scale) and each of its 5 items, daily pain, daily fatigue, and several PROMIS weekly instruments and their lagged values (last week or last 6 days for daily). ‘Baseline’ was calculated in non-flare weeks. Training data was used for logistic regression model selection combining clinical expertise with backward elimination. Performance of the final model was evaluated using test data.

Results: The training data was composed of outcomes from 128 pts who reported 388 weekly flare assessments as no flare or onset flare over 2800 days during the first month of the Main Study. Of pts in the training dataset, 92.2% were female, 87.5% white, with mean age (SD) 52.7 (11.0) and years since RA diagnosis (0-10.4); 62.5% were on a biologic. Among those in the training dataset, 58 flare outcomes occurred in 50 (39.1%) unique pts. The test data comprised outcomes from 123 pts who reported 442 weekly flare assessments as no flare or onset flare over 3366 days in which 64 flare outcomes occurred, and primarily included continued observations from pts who contributed to the training dataset.

The best-performing model to classify flare in training data included the current and baseline FLARE instrument activity question (i.e. “Considering how active your rheumatoid arthritis has been, how much difficulty have you had when taking part in activities such as work, family life, social events that are typical for you during the last week?”), current daily pain, and baseline FLARE instrument activity question (i.e. “Considering how active your rheumatoid arthritis has been, how much difficulty have you had when taking part in activities such as work, family life, social events that are typical for you during the last week?”). Sensitivity to detect flare was 0.62 and overall accuracy under the receiver operator curve of 0.81 (Figure). At a cut point requiring specificity to be ≥0.80, sensitivity to detect flare was 0.62 and overall accuracy was 0.78.

Conclusion: TLRs-NFκB pathway may be activated in TAK patients, with upregulation of BCL6, and there may be deficiency of CD40, TLR2, TLR4, PD-1, LAG3, CD40 and BCL6 may play roles in the pathogenesis of TAK, p50, p65, TCR, GATA3, RORC and FOXP3 may be related to the disease activity of TAK.

Figure 2: Correlation between any two genes expressed abnormally in PBMCs in TAK patients Cluster Analysis by the result of Spearman correlation test. n=27 (all TAK patients enrolled).
Conclusion: New-onset flare is common among RA patients, and the FLARE instrument and daily pain scores appear effective to classify it. Evaluation of passive data as a proxy for self-reported new-onset flare is ongoing.

MRI INFLAMMATION, DISEASE ACTIVITY AND FUNCTIONAL IMPAIRMENT ARE MORE EFFECTIVELY REDUCED BY ESCALATION TO BIOLOGICS COMPARED TO CSDMARD-ESCALATION IN RHEUMATOID ARTHRITIS PATIENTS IN CLINICAL REMISSION FOLLOWING A TREAT-TO-TARGET STRATEGY: SECONDARY ANALYSES OF THE IMAGINE-RA TRIAL

1Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark, 2Rheumatology and Radiology Departments at Hospitals at Zealand, Jutland and Funen, Denmark

Background: The effect of different treatment escalations on MRI inflammation in rheumatoid arthritis (RA) patients following an MRI treat-to-target (T2T) strategy has not previously been investigated.

Objectives: To compare the effect of different treatment escalations on MRI inflammation, physical function and disease activity in RA patients in clinical remission, following an MRI T2T strategy.

Methods: One hundred RA patients in clinical remission (DAS28-CRP<3.2 and no swollen joints), on conventional synthetic (cs) DMARDs following an MRI T2T strategy targeting DAS28-CRP≤3.2, no swollen joints plus absence of MRI ostitis, were followed for 2 years with clinical and MRI (wrist and 2nd-5th MCP joints) evaluation every 4 months. If target was not met, a predefined treatment escalation algorithm dictated: First: increase in csDMARDs (A), second: adding a TNF inhibitor (TNFi) (B), third and onwards: switch between biologics (C). If target was met, no change in baseline csDMARDs was done (D). Outcomes were assessed 4 months after treatment change. MRI’s were evaluated with known chronology by one experienced reader. Repeated measures mixed linear models were used to express estimates of group differences on predefined co-primary outcomes (MRI ostitis, HAQ) and key secondary outcomes (MRI combined inflammation, Simplified Disease Activity Index (SDAI)).

Results: Escalation to first TNFi (B) or to 2nd or later biologic (C) compared to csDMARDs (A) was consistently more effective on all outcomes (e.g. in group B ostitis was reduced with 1.8 units more than A) (Table). Unchanged (D) compared to escalation in csDMARD (A) treatment did not differ, except for HAQ-score. Escalation to a 2nd or later biologics (C) compared to the first TNFi (B) was more effective suppressing MRI inflammation. Escalation to TNFi treatment (B) or to 2nd or later biologic (C) compared to unchanged treatment (D) was more effective on all outcomes except from HAQ-score (no difference between groups).

Conclusion: T2T-based treatment escalations to biologics compared to csDMARD-escalations more effectively improved MRI inflammation, physical function and disease activity. Further optimization of the treatment in RA patients in clinical remission may improve long-term outcomes.

Clinical treatment response still does not match patient reported improvement, even in early rheumatoid arthritis

S. Pazmino1, A. Lovik2, A. Boonen3, D. De Cock4, V. Stouten1, J. Joly5, D. Bertrand1, R. Westhoven5,6, P. Verschueren1,6, on behalf of CareRA Study Group. 1KU Leuven, Development and Regeneration, Leuven, Belgium; 2KU Leuven, Leuven Biostatistics, Leuven, Belgium; 3Maasricht UMC, Maasricht, Netherlands; 4University Hospitals Leuven, Rheumatology, Leuven, Belgium

Background: Commonly used disease activity scores in rheumatoid arthritis (RA) include one patient reported outcome (PRO) - the patient's global health assessment (PGA). Exploratory factor analysis (EFA) was performed on data from the 2 year Care in early Rheumatoid Arthritis (CareRA) trial to explain the evolution of disease burden extracting 3 factors.

Objectives: To assess the evolution and relative responsiveness over time of clinical, laboratory and patient assessments included in composite scores, together with other PROs like pain, fatigue and functionality in patients with early RA (≤1 year) treated to target (T2T) within the CareRA trial.

Methods: DMARD naïve patients with early RA (n=379) were included, randomized to remission induction with COBRA-like treatment schemas (n=332) or MTX monotherapy (n=47) and T2T. Components of disease activity scores (swollen/tender joint count (S/TJC), C-reactive protein (CRP) or erythrocyte sedimentation rate (ESR) or physician (PHQ) or patient (PGA) global health assessment), pain and fatigue (both on 0-100 scale) and HAQ were recorded at every visit. Missing data was handled with multiple imputation (n=15). Clustering was removed with multiple output (n=1000), then each of the 15 000 datasets was analyzed by EFA with principal component extraction and Oblimin rotation. The analyses were combined after re-ordering the factors by maximizing factor correlations. The 3 extracted factors and their individual components (with their loadings) were: 1. Patient containing PGA (0.87), pain (0.86), fatigue (0.90) and HAQ (0.5) 2. Clinical with SJC (0.92), TJC (0.89) and PHQ (0.76) and 3. Laboratory with CRP (0.87) and ESR (0.78).1 (Pazmino, ACR 2019 abstract, Table 3) Afterwards, variables were first normalized to a 0-1 scale, then multiplied -weighted- by the factor loadings previously obtained.1 For each Patient, Clinical and Laboratory severity score, the weighted variables belonging to each score were summed together and then re-scaled to 0-1 (higher values suggest more burden).

The percentage (%) improvement from baseline to week 104 and the area under the curve (AUC) across time points were calculated per factor. Differences in % improvement and AUC were compared between patients not achieving and achieving early and sustained remission (week 12 to 104) disease activity score remission (DAS28CRP <2.6) with ANOVA, Bonferroni correction was used for multiple testing.

Results: Severity scores of Patient, Clinical and Laboratory factors improved rapidly over time (Figure 1). In patients achieving sustained remission (n=122), Patient, Clinical and Laboratory scores improved 56%, 90% and 27% respectively. In patients not achieving sustained remission (n=257) the improvement was 32%, 78% and 9% respectively (p<0.001 only for clinical improvement).

Patients in CareRA who achieved sustained remission had an AUC of 15.1, 3.4 and 4.7 in Patient, Clinical and Laboratory scores respectively, compared to 32.3, 10.0, and 72 in participants not achieving sustained remission (p<0.001 for all comparisons).

Conclusion: Patient, Clinical and Laboratory severity scores improved rapidly over time in patients achieving rapid and sustained disease control. However, overall, Patient burden seemed not to improve to the same extent as Clinical burden. Patient's unmet needs in terms of pain, fatigue, functionality and overall well-being should thus be given more attention, even in patients in sustained remission.

Should we use glucocorticoid in early rheumatoid arthritis?: results at 5 years from the Era Louvain Brussels cohort

E. Sapapi1, T. Sokolova1, S. De Montjoye1, S. Dierckx2, A. Nzeusseu Toukap1, A. Avramovska1, B. Lauwers3, P. Durez4. 1Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCL) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Bruxelles, Belgium; 2CHU Mont-Godinne, Rheumatology, Yvoir, Belgium

Background: The EULAR recommendations, updated in 2016, propose the initiation of glucocorticoid (GC) therapy in combination with cDMARDs background therapy for every patient with early rheumatoid arthritis (ERA).1

Objectives: The aim of this study is to evaluate the proportion of patients with ERA who have been treated with GC in daily practice, to analyse the baseline characteristics of these patients, and to assess the clinical benefit and side effects of GC during 5 years of follow-up.

Methods: We included patients with ERA from the UCLLouvain Brussel cohort who met the ACR/EULAR 2010 classification criteria and were naïve to cDMARDs. Treatments were initiated based on the decision of a senior rheumatologist. We retrospectively collected patient characteristics prior to the introduction of cDMARDs with or without GC. Efficiency and serious adverse events were analysed at 6 months, 1 year, 3 years and 5 years.

Results: Data from 474 eligible ERA patients were collected. The average age of the population is 48.9 years. 70.5% of the patients are women. 27.3% are smokers and 68.8% are positive for anti-citrullinated protein antibody (ACPA). 178 patients (37.7 %) initiated GC compared to 294 patients (62.3%) who received only NSAIDs and/or analgesics in combination with cDMARDs. At baseline, the elevation of CRP is the main factor that favors the initiation of GC (CRP 2.9 vs 2.0mg/dl, p = 0.015) followed by smoking habits (34.2% vs 23.3%, p = 0.018), the prescription of ACPA (372% vs 276%, p = 0.037), the prescription of methotrexate as a monotherapy (70.6% vs 50.5%, p <0.001), and the age (50.6 vs 48.0, p = 0.050). Other parameters such as swollen joint count, tender joint count, DAS28-CRP, HAQ or baseline erosion were similar between groups.
5 years follow-up of DAS28-CRP, HAQ or VAS pain values did not differ between the two groups (Fig 1A).

Interestingly, patients not exposed at baseline to GC showed a higher remission rate (DAS28-CRP < 2.6) of 48.4% vs 44.3% at 6 months. We also analysed a subgroup of patients (n=139) who received a cumulative dose of more than 1 g of prednisolone during the 5 years period. We confirmed the baseline differences for CRP, smoking habits, age and found in this subgroup more males (36.7% vs 28.2%, P=0.021) and higher DAS-28CRP values (5.0 vs 4.7, P=0.048).

During the 5 years follow up, DAS-28CRP, VAS pain and HAQ remained significantly higher leading to a higher number of bioDMARDs prescribed in this group (Fig 1B). More severe infections were reported in this subgroup (11.5% vs 4.2%). Bone densitometry values, number of fractures, and cardiovascular profiles were similar between groups.

**Conclusion:** In our ERA cohort, initiation of GC treatment does not add additional benefit for the short and long-term control of the disease. GC were more prescribed in seronegative RA patients with higher level of inflammation and we confirmed that patients exposed to higher cumulative doses of GC are at higher risk to develop severe infections. Further studies are needed to support that GC induction therapy should not be offered to all ERA patients.

**Figure 1. Comparison of DAS28-CRP and HAQ scores evolution. (A) In two groups of patients: treated with GC (BL- GC No) or without GC (BL- GC Yes) in combination with DMARDs as first line treatment. (B) In two groups of patients: never treated with GC during 5 years follow-up (No GC/ 5 years) and those who received a high cumulative dose of GC ≥ 1g/5years (GC ≥ 1G/5years).**
Results: Of the 90 patients recruited in the low-risk group, 80 (89%) patients completed the MFI at baseline. Randomisation was successful resulting in similar baseline characteristics and MFI levels between Cobra Slim (n=38) and MTX-TSU (n=42). After 2 years of treatment, DAS28CRP levels (Slim 1.9 ±0.8 - MTX-TSU 2.2 ±1.0, p=0.253) and DAS28CRP remission (Slim 81.5% - MTX-TSU 77.1%, p=0.677) did not differ between patients. However, general (Slim 9.8 ±4.1 - MTX-TSU 13.1 ±4.0, p=0.005) and mental (Slim 6.8 ±2.7 - MTX-TSU 10.0 ±4.9, p=0.022) fatigue levels on the MFI were lower in the Cobra Slim group at week 104. GEE analysis confirmed that groups differed in the general (p=0.026) and mental (p=0.013) fatigue scale over 2 years (Figure 1).

Conclusion: Patients treated intensively have lower fatigue levels over 2 years compared to patients treated more conservatively, even if disease activity became similar in the two groups over time. This underlines the importance of initiating an optimal intensive treatment even in so-called low-risk patients. Moreover, our results show that fatigue is a heterogeneous concept, with different interactions between treatment and type of fatigue. Although our study was limited by a small sample size, the data clearly shows how to improve fatigue levels significantly in early RA.

Figure. Distribution of Disease Activity States over 12-24 After First Achieving SDAI REM

Conclusion: Results of this large longitudinal analysis of real-world data suggests that < 50% of patients that reach remission sustain remission for 12-24 months. Closer monitoring of patients with prognostic indicators for transient remission and additional research focusing on why remission is lost may help improve the rates of sustained remission.

O. Schier¹, G. Hazlewood², S. J. Bartlett³, M. F. Valois⁴, L. Bessette⁴, G. Boire⁴, C. Hitchon⁵, E. Keystone⁶, J. Pope⁷, C. Thorne⁷, D. Yin⁸, V. Bykerk⁹ on behalf of Canadian Early Arthritis Cohort (CATCH) Investigators. ¹Canadian Early Arthritis Cohort, Montreal, Canada; ²University of Calgary, Calgary, Canada; ³McGill University/ MUHC, Montreal, Canada; ⁴Université de Laval, Quebec city, Canada; ⁵Université de Sherbrooke, Sherbrooke, Canada; ⁶University of Manitoba, Winnipeg, Canada; ⁷University of Toronto, Toronto, Canada; ⁸Western University, London, Canada; ⁹Southlake Regional Health Center, Newmarket, Canada; ¹⁰Hospital for Special Surgery, New York, Canada

Background: Early diagnosis and rapid initiation of DMARDs following a treat-to-target approach have made remission a realistic goal for many with RA. Yet, some patients are unable to sustain remission over time.

Objectives: To describe longitudinal patterns of remission and identify predictors of sustained vs transient remission in real-world early RA patients.

Methods: Data were from the Canadian Early Arthritis Cohort (CATCH), a prospective study of early RA patients (symptoms < 1 year) treated in rheumatology clinics across Canada from 2007-2019. The sample was limited to patients with active disease at enrolment who later reached remission (SDAI<=3.3) and were followed for 12-24 months thereafter. Patients were classified as in sustained remission (Pattern 1) or transient remission with transient remission patients divided into those who transitioned from REM to LDA only (Pattern 2) and those who transitioned from REM to MDA or HDA (Pattern 3). OverFU, Multi-adjusted multinomial regression was used to identify predictors of transient remission patterns.

Results: The study included 1,149 (46%) CATCH participants that reached remission. At enrolment, most (70%) were female, mean(sd) SDAI was high (27±15) and 92% were treated with csDMARDs. Only 47% remained in sustained remission by 12-months and, only 40% by 24 months (Pattern 1) (Figure). Among patients with transient remission patterns, transitions to LDA only (Pattern 2) were more common than MDA/HDA over FU (Pattern 3) (Fig 1). Older age, female sex, smoking, higher comorbidity index and positive serology, were significantly associated with transient remission patterns (Table). There were also borderline significant associations between transient remission patterns and longer time to remission, lack of early MTX treatment and reducing treatment after remission (Table).

CIRCADIAN RHYTHMS OF ENDOTHELIAL NITRIC OXIDE SYNTHASE PRODUCTION IN FEMALES WITH RHEUMATOID ARTHRITIS AND ARTERIAL HYERTENSION DEPENDING ON NOS3 T786C GENE POLYMORPHISM

K. Zaichko1, M. Stanislavchuk2, N. Zaichko3, V. Khomenko1 on behalf of NA.
1National Pirogov Memorial Medical University, Vinnytsia, Ukraine; 2National Pirogov Memorial Medical University, Internal Medicine #1, Vinnytsia, Ukraine; 3National Pirogov Memorial Medical University, Chair of Biochemistry and General Chemistry, Vinnytsia, Ukraine

Background: One of the most common comorbidity in patients with rheumatoid arthritis (RA) is arterial hypertension (AH), with incidence ranging from 20 to 60%. Mechanisms of this comorbidity arises a lot of interest. In our previous study was established the association of T786C NOS3 (rs2070744) gene polymorphism with RA in females with RA in the Ukrainian population [1].

Objectives: So next, we were aiming to investigate daily fluctuation of endothelial nitric oxide synthase (NOS3) in RA patients with AH depending on NOS3 T786C gene polymorphism.

Methods: In the study were enrolled 173 females with RA aged 43.7 ± 7.35 years (Mean ± SD) and 34 age-matched healthy women without joint diseases and autoimmune diseases (control). Serum NOS3 level was determined at 08:00 and 20:00 using Cloud-Clone Corp kits (USA). NOS3 T786C polymorphism was determined by Real-Time PCR (Bio-Rad Cycler IQ5) using SNP-express kit. Study was carried out in compliance with ethical standards and provisions of the WHO, Helsinki Declaration of the General Assembly of the World Medical Association (1989).

Results: Among enrolled patients prevailed individuals with more than 5 years disease history, II-III radiographic stage (80.9 %), and were seropositive for anti-cylic citrullinated peptide (80.6%). There were 114 (66%) normotensive patients and 59 (34%) patients with AH (13% - 1 stage, 20.8% - II stage). The daily fluctuation of NOS3 serum level was established in the control group. The evening NOS3 level was higher than the morning one (p<0.001). In RA patients the similar fluctuations of NOS3 level was registered, but the daily NOS3 production was lower, than in control. Diurnal variation of NOS3 level depended on comorbid AH and NOS3 T786C genotype. In CC genotype NOS3 levels at 08:00 and at 20:00 were lower in 1.2-1.3 times (p<0.05) than in TT and TC genotypes. In patients with RA and AH the lowest diurnal variation of NOS3 level was in CC genotype. The decrease of evening NOS3 production was strong associated with comorbid AH (OR 3.78; 95% CI 1.96-7.28).

Conclusion: Circadian rhythms of NOS3 production in females with RA and AH depend on NOS3 T786C gene polymorphism. The depression of NOS3 production in the evening can be predictor of comorbid AH in females with RA.

DOI: 10.1136/annrheumdis-2020-eular.3421
NR patients; CCL20 was downregulated similarly in ADA R and NR patients; and IL17C, IL22RA1, TIMP4, and CCL11 were not modulated by ADA. Finally, taken together, among the 184 inflammation-related pBM tested, none were associated with clinical response for both ADA and UPA.

**Conclusion:** We detected common but also discrete alterations in pBM upon exposure to ADA and UPA overall and further distinctions when we examined pathway changes associated with achievement of a low disease clinical status achieved by each patient population. Whereas both drugs exhibit inhibition of macrophages and granulocyte associated pathways, ADA appears to preferentially affect M1 macrophages and UPA appears to preferentially affect T cells. This modulatory pattern by UPA is consistent with its broad cytokine receptor inhibition profile compared with highly specific TNF inhibition and could account at least in part, for the greater efficacy of UPA over ADA in the SELECT-COM-PARE study.

patients mutant JAK2 while 13 (76.5%) of patients with DAS28 (>5.1) were mutant JAK2 versus four (23.5%) patients non mutant JAK2 (P 0.03). JAK2 mutation found to be significantly correlated with ACR 20, 50, and 70 response criteria; 40% of patients with non mutant JAK2 showed ACR 70 versus 17.9% in mutant group, 35.1% of patients with non mutant JAK2 showed ACR 50-30% in mutant group while 24.3% of patients with non mutant JAK2 showed ACR 20 versus 51.3% in mutant group (P 0.02). JAK2 mutation was associated with high pretreatment TNFα (mean±SD; 41.7±39.5 in mutant versus 24.3±23.04 pg/ml in non mutant group) with P (0.04), while no significant relation between JAK2 mutation and pretreatment IL6 level.

Conclusion: Adult SLE with pretreatment JAK2 mutation significantly showed high disease activity, high pretreatment TNFα levels and poor response to 1st line csDMARDs including MTX so they could get benefit with introduction of JAK inhibitors as first line mono or in combination with csDMARDs especially with moderate to severe active RA.

EFFECTIVENESS OF A NURSE LED TREAT TO TARGET (T2T) MODEL IN ACHIEVING REMISSION FOR EARLY RHEUMATOID ARTHRITIS PATIENTS IN A REAL-WORLD SETTING

J. Ali1,2, M. T. Ghaffar1, N. Harrington1, S. Mansoor1, C. Silke1, M. O’sullivan1, B. Whelan1, 1Our Lady’s Hospital, Rheumatology, Manorhamilton, Ireland; 2Sligo University Hospital, Sligo, Ireland

Background: Rheumatoid Arthritis (RA) is a chronic, inflammatory and systemic autoimmune disease, affecting multiple joints particularly small joints in hands and feet. For the past two decades, there has been significant change in approach for the diagnosis and treatment of RA. Now early diagnosis and aggressive management of RA is considered key role for preventing permanent damage to joints. Treat to Target (T2T) strategy has been proven to be very effective in achieving pre-decided outcome either clinical remission (CR) or low disease activity (LDA). Further to this, Methotrexate monotherapy was the dominant DMARD used to achieve remission and/or low disease activity in more than 50 % of the RA patients (Figure 1).

Methods: This was Observational Prospective study, based on data collected in our ANP led Early Inflammatory Arthritis clinic. All patients diagnosed with inflammatory arthritis were managed following a T2T protocol. Every patient had predefined target set according to co-morbidities, preexisting osteoarthritis and duration of disease. Patients were followed up at varying intervals depending on clinical need until the steroid free target was achieved or for up to 2 years. Clinical Disease Activity Index (CDAI) tool was used to assess disease activity.

Background: Although DMARDs are essential for early aggressive control of RA to reduce symptoms and disability, medication adherence is variable. Beliefs about the necessity of medications and concerns around medication adverse effects are important determinants of adherence. Thus, the study aimed to investigate associations among RA medication necessity beliefs and concerns, sociodemographics, RA characteristics, symptom level and functional status.

Objectives: To examine associations among RA medication necessity beliefs and concerns, sociodemographics, RA characteristics, symptom level and function in newly diagnosed RA patients.

Methods: Baseline data were analyzed from participants in the Canadian Early Arthritis Cohort (CATCH) who enrolled between 2017-2020 and completed the Beliefs about Medicine Questionnaire (BMQ) and PROMIS-29. All met ACR1987 or 2010 ACR/EULAR criteria and had active RA at enrollment. BMQ Necessity (N) and Concerns (C) scores were classified as high (≥20) or low (<20) and categorized into: Accepting (1N:1C); Ambivalent (1N:1C); Sceptical (≥1N; ≥1C); and Indifferent (≤0N; ≤0C). Groups were compared using ANOVA and chi-square tests.

Results: The 362 patients were mostly white (83%) women (66%) with a mean (SD) age of 56 (15), symptom duration of 6 (3) months, and 32% were obese (BMI≥30). More than half (56%) were DMARD-naive or minimally exposed. Mean (SD) age of 56 (15), symptom duration of 6 (3) months, and 32% were obese (BMI≥30). More than half (56%) were DMARD-naive or minimally exposed. Mean (SD) age of 56 (15), symptom duration of 6 (3) months, and 32% were obese (BMI≥30). More than half (56%) were DMARD-naive or minimally exposed. Mean (SD) age of 56 (15), symptom duration of 6 (3) months, and 32% were obese (BMI≥30).

Conclusion: Many new RA patients had low medication necessity beliefs and concerns, and only 31% had high necessity beliefs and low concerns around RA medications. Lifestyle and lower CDAI, TJCs, symptoms and functional impacts were associated with RA medication adherence. Identifying medication adherence can prompt discussions about medication beliefs/concerns to facilitate shared decision-making and adherence.
p=0.02) comorbidities increased over time in ACPA negatives and remained stable in ACPA+ (CV: 33.0, 30.8, 40.7, NS; cancer: 3.0, 4.4, 6.2, NS). RF positivity decreased by period (47.8, 36.9, 36.7%, p=0.03), but ACPA+ remained stable (40.8, 35, 35.4% NS).

Outcomes over 5 years of follow up.

There was no link between the presence of any biomarker and subsequent disease activity scores. Positive ACPA, RF and anti-Sa at baseline predicted development of more erosive status (RR = 1.50; 1.37 and 1.52, all p<0.001). 66% reached DAS28 remission overall (70.3% in ACPA negatives, 65.2% in ACPA+). Independent of ACPA status, remission rates increased between Periods 1 vs 2 (RR = 1.14, p=0.04) and 1 vs 3 (RR=1.13, p=0.055), but not between 2 vs 3. CV comorbidities among ACPA+ increased significantly more over time vs ACPA negatives (+8.9% vs +4.1%; RR = 1.18, p=0.03). Erosion scores increased significantly more in ACPA+ treated with DMARDs only vs receiving a biologic (ΔSharp: 3.98 vs 3.11, p= 0.026; ΔErosions: 2.58 vs 1.83, p=0.02). By period, erosive status decreased significantly (Periods 2 vs 1: RR=0.65, p=0.002; 3 vs 1: RR=0.42, p=0.002; 3 vs 2: RR=0.84, p=0.007), both in ACPA+ and negatives.

Conclusion: In this cohort of recent onset RA recruited over 20 years, we observed a constant drift towards RF-negative arthritis at baseline with decreasing smoking rates and increasing comorbidities in seronegative patients. Positive antibodies were associated more cardiovascular comorbidities accrual. Autoantibody positive (especially ACPA+) patients developed more erosive disease and had better erosion outcomes with biologic treatments. Irrespective of the antibody positive (especially ACPA+) patients developed more erosive disease.

REGIONAL AND WIDESPREAD PATTERNS OF NON-ARTICULAR PAIN ARE COMMON AT RA DIAGNOSIS AND CONTRIBUTE TO POOR OUTCOMES AT 12 MONTHS: A PROSPECTIVE STUDY OF PAIN PATTERNS IN CANADIAN RA

1Hospital for Special Surgery, New York, New United States of America; 2University of Toronto, Toronto, Canada; 3McGill University, Montreal, Canada; 4Laval University and CHU de Quebec, Quebec City, Canada; 5Centre de l’Ostéoporese et de Rhumatologie de Quebec, Department of Medicine, Quebec City, Canada; 6University of Sherbrooke, Faculty of Medicine and Health Sciences, Sherbrooke, Canada; 7University of Calgary, Calgary, Canada; 8University of Manitoba, Winnipeg, Canada; 9Southlake Regional Health Center, Newmarket, Canada; 10University of Western, London, Canada

Background: Persistent pain can occur in early RA patients, despite improvement in synovitis and may be due to coexisting non-articular pain (NAP). Though NAP is often attributed to fibromyalgia and widespread NAP, regional NAP syndromes may be more common and under-recognized.

Objectives: To describe patterns of NAP, predictors of persistent NAP and impact on outcomes in the first year following early RA diagnosis.

Methods: Data were from participants enrolled in the Canadian Early Arthritis Cohort (CATCH) between 2017-2019 who completed 0,6,12-month evaluations with patient-reported outcomes [PROs] and clinical data available. We used the McGill Body Pain Diagram (BPD) to classify patients as experiencing no NAP, regional (RP-1-2 regions) or widespread NAP (WP-3-5 regions). Multinomial regression was used to identify baseline predictors of persistent RP and WP at 12-months. Multi-adjusted GEE with linear and logit links were used to estimate time-varying associations of NAP patterns with outcomes updated at each time point.

Results: Study included 421 participants: 66% were female, with a mean(sd) age 56 (14); 72% were seropositive and 90% were treated with MTX ± csDMARDs as initial therapy. NAP at baseline was common (55%), with majority (62%) reporting regional NAP; NAP prevalence was 33% at 12 months (Figure). Female sex and baseline depressive symptoms were independent predictors of widespread NAP at 12 months while poorer function and lack of early MTX treatment independently predicted regional NAP, at 12 mos. Regional and widespread NAP were associated with lower likelihood of remission in adjusted models that accounted for changes in NAP and remission over time (Table).

Conclusion: NAP is commonly reported in early RA pts seen in real world settings. Regional NAP was more common than WSP at all time-points, but both NAP patterns were associated lower odds of achieving remission targets by 12 months. These data support considering the role of NAP when assessing RA treatment efficacy during clinical visits and warrant different treatment approaches to reduce symptoms in RA patients receiving target-based care.

Table. Results of Multi-Adjusted GEE Logistic Regression showing Regional and Widespread NAP is associated with a reduced likelihood of achieving Stringent Remission Targets

Conclusion: Contrary to previous studies done on Western cohorts where anti-carp predicted worse outcomes, anti-carp positivity predicted DAS28-remission in 12 months in our multi-ethnic Asian cohort. This suggests that different genetic and environmental determinants account for anti-carp expression in patients with RA.

DOI: 10.1136/annrheumdis-2020-eular.3039

**Background:** Short-term (up to 3-4 months) glucocorticoids combined with methotrexate is recommended for initial therapy of active rheumatoid arthritis (RA) patients by EULAR, considering the long-term safety of glucocorticoids such as higher cardiovascular risk. However, in real-world clinical practice, glucocorticoids are widely used even up to 70% in refractory RA patients. Glucocorticoids can pharmacologically lead to enhancement of lipogenesis and muscle degradation. On the other hand, their anti-inflammatory effect can indirectly mitigate fat deposition and muscle catabolism. The overall effect of glucocorticoid therapy on body composition (BC) in RA patients remain elusive until now.

**Objectives:** To investigate the characteristics of disease indicators, body mass index (BMI) and BC in RA patients with previous glucocorticoid treatment in a cross-sectional study.

**Methods:** Consecutive RA patients were recruited and clinical data including disease activity, function and radiographic assessment were collected. BC including fat and muscle mass and their distributions was assessed by bioelectric impedance analysis. Multivariate multinomial logistic regression analysis was performed to identify the association of disease characteristics, BMI and BC with previous glucocorticoids treatment in RA patients, following the step-forward selection rule that variables were included in the equation when the P value was >0.10. Optimal cut-off points were determined by receiver operating characteristic (ROC) curve analysis. The odds ratios (OR), 95% confidence interval (CI) and P value were used to determine the strength of association. The P values were two-tailed and P<0.05 was considered to be statistically significant.

**Results:** (1) There were 620 RA patients recruited, the mean age was 49.5±12.8 years old, and the median disease duration was 48 months (IQR 23-108 months) with 82.3% female. There were 107 (17.3%) patients with treatment naïve (without previous glucocorticoids or DMARDs therapy for six months before enrollment), 333 (53.7%) with previous glucocorticoid therapy with or without previous DMARDs therapy, and 180 (29.0%) with previous DMARDs therapy only. (2) For disease characteristics aspect, there were significant differences in all core disease activity indicators, functional indicator, and radiographic assessment indicators among three subgroups. Compared with those with treatment naïve, RA patients with previous glucocorticoid therapy had lower disease activity indicators including 28TJC, 28SJc, PtGA, PrGA, PainVAS, ESR, CRP, DAS28-CRP, SDAI and CDAI, and lower HAQ-DI and lower rate of functional limitation (all P<0.0167). While compared with those with previous DMARDs therapy only, RA patients with previous glucocorticoid therapy had higher disease activity indicators including 28TJC, 28SJc, PtGA, PrGA, PainVAS, DAS28-CRP, SDAI and CDAI (all P<0.0167). (3) For BMI and BC aspects, there were significant differences in lower fat-free mass and lower muscle indicators among three subgroups. Compared with those with previous DMARDs therapy only, RA patients with previous glucocorticoid therapy showed lower fat-free mass and lower muscle indicators including appendicular muscle mass especially in both lower extremities (all P<0.0167). There was no difference in BMI and fat indicators among three groups. (4) Multivariate multinomial logistic regression analysis showed that compared with previous DMARDs therapy only, previous glucocorticoid therapy was positively associated with DAS28-CRP (OR=1.289, 95%CI: 1.199-1.484, P<0.001), and negatively associated with lower extremity muscle mass (OR=0.907, 95%CI: 0.840-0.979, P=0.013).

**Conclusion:** Previous glucocorticoid treatment is associated with lower extremity muscle wasting. Further prospective study is needed to confirm their relationship.

---

**Background:** Advances in therapeutics and treatment strategies for Rheumatoid Arthritis (RA) have improved clinical outcomes. Although these advances also impact the well-being as shown in many patient-reported outcomes, still a sizeable number of patients in clinical remission report a reduced well-being.

**Objectives:** To explore factors that contribute to well-being in patients with early RA.

**Methods:** Patients from the 2-year pragmatic treat-to-target Care in Early Rheumatoid Arthritis (CareRA) trial were included. Patients were treated intensively, with a combination of csDMARDs and glucocorticoid remission induction schemes, except one group treated with MTX monotherapy.

Eight different validated questionnaires including the Arthritis Self-Efficacy Scale (ASES), the multidimensional Fatigue Inventory (MFI), the Pittsburgh Sleep Quality Index (PSQI) the Revised Illness Perception Questionnaire (IPQ-R), the Utrecht Coping List (UCL), the Short Form 36 (SF-36), RA Quality of Life questionnaire (RA-QOL) and the Social Support List (SSL) were taken. Questionnaires were obtained at baseline, at week 16, 52 and 104 except for the IPQ and UCL, which were only taken at baseline and week 16.

Three patients’ groups were created including all patients, patients in remission (DAS28CRP < 2.6) and not in remission. Regression models were constructed to define well-being at week 16, 52 and 104. The Patient Global Assessment (PGA) on a Visual Analogue Scale 0-100 (VAS) was chosen as a proxy for well-being (score 0-100). As predictors, all subscales of the 8 validated questionnaires, summing to 84 variables, with and without the VAS for Pain (VAS-Pain) were used in 18 models (3 patient groups, 3 time points, with/without VAS-Pain) in total. Data reduction used forward, backward and stepwise selection based on the Akaike information criteria. Data was checked for influential observations by Cook’s distance and for multicollinearity by variance inflation factors (threshold = 5). Influential observations were removed one observation every time. Highly correlated variables were deleted by backward selection (α=5%). Missing data was handled by multiple imputation using CART with 15 iterations.

**Results:** In total, 379 patients were included. Table 1 gives the number of variables and the associated R². In the 9 models defining well-being without VAS-Pain, 53 variables were used at least once. Most common variables were bodily pain (n=8) and social function (n=5) of the SF-36, and positive emotions (n=4) of the SSL. In the 9 models with VAS-Pain, 31 variables were used at least once. Most common variables were vitality (n=3) and social function (n=3) of the SF-36, and identity (n=3) of the IPQ-R. Model content was heterogeneous regarding patient population and time.

**R² and number of variables in each model of well-being**

R² = coefficient of determination, the proportion of the variance in the dependent variable that is predictable from the independent variable(s), # = number of variables selected in regression model.

**Conclusion:** Well-being is apparently difficult to define uniformly as many factors contribute to it. As already known, well-being, defined by PGA, and VAS-Pain are highly associated, even in patients in remission where pain levels should be theoretically lower. Other well-being definitions could lead to different results and should be further explored.

Background: Composite scores for risk of progression were described in 2015 in a cohort of 100 anti-cyclic citrullinated peptide (anti-CCP) + individuals at risk of developing inflammatory arthritis (IA) (1). The first score, designed for primary care, was based on anti-CCP and rheumatoid factor (RF) titre, small joints tenderness and early morning stiffness (EMS). A second score developed for secondary care added power Doppler presence (PD+) and/or at least one allele associated with mortality in unadjusted survival models (Table 1). Contrary to HAQ at baseline and at 1 year, respectively, with all-cause mortality in each year of follow up.

Results: Participants from both cohorts were similar in terms of age and sex. Although the mean time to progression is comparable, there were significantly more participants with a high titre anti-CCP test in the 2015 cohort (Table 1).

*Hazard OR, 95% CI

Conclusion: Higher HAQ at 1 year was significantly associated with all-cause mortality in a large early RA cohort suggesting that poorer disease control and function in the first year of RA contributes to higher mortality.

FR10038 THE RELATIONSHIP BETWEEN ABатаCETAB EPSEXOP AND EFFICACY MEASURES IN EARLY MTX-NAIVE ANTI-CITRULLINATED PROTEIN ANTIBODY-POSITIVE PATIENTS WITH RA DURING THE DE-ESCALATION PERIOD OF A PHASE III STUDY

Y. Gandhi1, S. Connolly1, K. H. G. Huang1, R. Wong1, S. Chileski1, B. Murthy1,1 Bristol-Myers Squibb, Princeton, United States of America

Background: Although EULAR/ACR guidelines suggest tapering biological treatment for RA following sustained remission in patients (pts), specific de-escalation (DE) regimens are not defined. The Phase IIb Assessing Very Early Rheumatoid arthritis Treatment (AVERT-2) trial (NCT02504268) is evaluating SC abatacept (ABA) + MTX versus ABA placebo (PBO) + MTX in Anti-Citrullinated Protein Antibody (ACPA)-positive pts with early (ACR/EULAR 2010 criteria, disease duration ≤6 mths), active RA (SDAI ≥11). AVERT-2 was designed to investigate achievement of SDAI remission and a clinically meaningful dose DE strategy among pts in sustained remission who completed induction with ABA + MTX. In moderately to severely active RA and JIA patients, a relationship between ABA Cmin and efficacy was observed. Therefore, this analysis in very early RA patients, reports on the pharmacokinetics (PK) and immunogenicity of ABA and the maintenance of remission during the DE period of AVERT-2.

Objectives: To assess the relationship between changes in ABA exposure and the maintenance of remission and the effect of immunogenicity on exposure during the DE period of AVERT-2.

Methods: Pts received blinded SC ABA (125mg once wkly [QW]) + MTX or ABA PBO + MTX induction treatment for 56 wks. Pts who completed induction with ABA + MTX and had sustained SDAI remission (≤3.3 at Wks 40 and 52) were re-randomized 1:1:1 to ABA QW + MTX or ABA QW + MTX for 48 wks (Arm C), ABA every other wk (QOW) + MTX or ABA QOW + MTX for 48 wks (Arm D) in the DE period. ABA trough (Cmin) and anti-drug antibody (ADA) samples were collected in all subjects during the DE period. Serum ADA concentrations and ABA were measured using a validated enzyme-linked immunosorbent assay and an electrochemiluminescence assay respectively. Efficacy endpoints included change from DE period Day 1 in SDAI score, HAQ-DI score, Physician’s Global Assessment (PhGA), and tender (TJC) and swollen (SJC) joint counts. The relationship between ABA Cmin and efficacy endpoints were assessed. Additionally, the impact of immunogenicity on ABA Cmin was explored.

Results: Mean ABA Cmin values remained stable throughout the DE period for subjects in Arms C and E. ABA Cmin values decreased by ~50% in subjects in Arm D for the first 24 weeks from the start of DE and were ~0 for weeks 24-48 consistent with the change in the frequency of ABA dosing from EOW to ABA withdrawal (Figure 1 top). The incidence of immunogenicity appeared to increase upon withdrawal of ABA in Arm D. ADA formation did not affect ABA Cmin, as ABA Cmin remained consistent between pts with and without ADA. Upon withdrawal of ABA in Arm D, there appeared to be an increase in the mean change from baseline (Day 1 of DE) in SDAI over time, which followed a similar time course as the washout of ABA (Figure 1 bottom). Similar results were observed for other efficacy endpoints such as HAQ-DI, PhGA, TJC, and SJC.

Conclusion: The PK data in these early onset, MTX-naive, ACPA+ RA pts corroborated our previous findings from the maintenance of remission in Arms A and E. Tapering of ABA from EOW to MTX only in Arm D resulted in a corresponding decrease in ABA Cmin, an increase in positive antibody response, and loss of remission.

[1] Emery et. al. ACR [Abstract L11]: Nov. 2019, Atlanta GA USA

Background: To analyze the diagnostic utility of lung ultrasound (US) to detect interstitial lung disease (ILD) in Rheumatoid arthritis (RA) patients comparing with high-resolution computed tomography (HRCT).

Methods: Study design: We performed a cross-sectional, observational study in patients with RA-ILD (cases) controlled with a group of RA patients without ILD (controls) paired by sex, age and time of disease evolution.

Protocol: Patients were selected between May and September 2019. Patients were interwined by two rheumathologist for the protocolized collection of clinical data. The patients were assessed using HRCT, Pulmonary Function Test (PFT) and lung US. The rheumatology who performed the lung US were blinded to patients clinical data. Variables: (1) B-lines number; (2) evaluation of the lung-ultrasound score already described: L. Gargani, Gutiérrez comprehensivo, Gutiérrez reducido y Mohammadi;(3)pleural irregularities; (4) A pattern US lost;(5) Other variables included demographic, clinical-analytical, therapeutic and ILD-type description. Statistical analysis: descriptive, bivariate analysis. We applied Pearson’s correlation coefficient between B-lines, PFT and clinical variable.Furthermore, to establish the cut-off point of the US B-lines number for detecting the presence of significant AR-ILD in relation to HRCT, we used the receiver operating characteristic (ROC) curve analysis. A logistic regression analysis was performed to identify the intercostal spaces (IV: B-lines number in each space) which were independently associated with ILD (DV: ILD in HRCT).

Results: 71 patients were included, 37 (52.1%) with ILD-RA and 34 (47.9%) RA controls. The main characteristics are shown in Table 1. RA-ILD presented more B-lines number than control without ILD (median [ICR] 91.0 [310-149.0] vs 6.5 [15.5-30.5]; p<0.001) and more pleural irregularities (PI) [PI-median(ICR) 41.0 (5.0-57.5) vs 2.5 (0.0-72); p<0.001]. Furthermore, RA-ILD showed a negative correlation between B-lines and DLCO(r =-0.337, p=0.048) and positive with DAS28 (r =0.347, p=0.035). Regarding US score, we found that the detection of 32.5 B-lines in >72 intercostal spaces, had a Sensitivity of 75.7%, Specificity=79.4%; PPV= 80% and NPV=75%, whilst in reduced score of 10 intercostal spaces, the detection of 5.5 B-lines had a sensitivity= 62.2%, Specifity= 91.3%, PPV=88.4%, NPV=69.5%. In multivariate analysis, the intercostal spaces which showed independent association with ILD were 3rd right anterior axillary space(OR [IC 95%] 19.0 [1.3-27.5]), 8th right posterior axillary space (OR [IC 95%] 0.04 [0.0-0.6]), 8th right subscapular space (OR [IC 95%] 16.5 [18.4-5.5]), 3rd right paravertebral space (OR [IC 95%] 711 [1.0-37.1]) and 2nd left clavicular middle space(OR [IC 95%] 219 [1.2-378]).

Conclusion: Lung Ultrasound could be a useful tool for interstitial lung disease diagnosis associated with Rheumatoid Arthritis. A 10 space reduced score showed a similar total predictive capacity than 72-space score

FR0040 MULTI-VARIATE APPROACH INCLUDING SEROLOGY AND GENETICS FOR AN IMPROVED IDENTIFICATION OF PATIENTS AT RISK OF DEVELOPING RA

M. Grundhuber1, I. Gehring2, C. Lamacchia3, P. Roux-Lombard4, M. Nissen5, U. Walker6, B. Moeller7, D. Kyburz8, A. Ciurea9, M. Poorafshar7, A. Finckh2, G. Díaz Cordoves1, A. Fernandez-Nebro1, Málaga, UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga, Universidad de Málaga, Málaga, Spain, Málaga, Spain; 2Hospital Universitario Virgen de la Victoria, Málaga, Spain, UGC Reumatología, Málaga, Spain

Background: First-degree relatives of rheumatoid arthritis (RA) patients (FDR-RA) have a 3 - 5-fold increased prevalence of the disease (FDR-RA) have a 3 - 5-fold increased prevalence of the disease [1]. RA development is triggered by an interaction between genetic and environmental factors. As the field is moving towards prevention in pre-clinical stages of RA, it is key to identify individuals with imminent RA, prior to onset of symptoms, which will presumably rely on both the measurement of autoantibodies and genetic risk markers.

Objectives: Assemble a pattern of serologic biomarkers in combination with genetics to improve the identification of individuals at high risk to develop RA.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.5404
Methods: The cohort included 827 serum samples from 601 individuals, followed within the Swiss multicenter cohort study SCREEN-RA of FDR [2]. FDR-RA were categorized into four groups according to the presence of symptoms and systemic autoimmunity associated with RA: 1: asymptomatic FDR-RA without anti-CCP or symptoms, 416 (69%); 2: FDR-RA with clinically suspect arthralgia (CSA) [3] or with signs of arthritis, without anti-CCP, 72 (12%); 3: FDR-RA with no signs of arthritis, positive anti-CCP test, 55 (9%); 4: FDR with signs of arthritis or CSA, positive anti-CCP-test, 58 (10%). Serum samples were analyzed for the presence of anti-CCP (IgG, IgA), RF (IgM, IgA) and anti-RA33 (IgM, IgA, IgG) using the EliA™ instrument platform (Phadia AB, Upplands Väsby, Sweden).

Genetic measurements were performed using the AmpliSeq™ technology on the Ion GeneStudio™ instruments (Thermo Fischer Scientific, Carlsbad, USA), covered variants were analyzed using an algorithm focusing on the identification of RA patients.

Results: The overall prevalence of biomarkers, considering results above cut-off values, was 1% for anti-CCP IgG and IgA, 10% and 2% for RF IgM and RF IgA, respectively, and 6-15% for all three anti-RA33 isotypes. Several individuals had multiple positive serology tests (Fig 1); 3.6% (22) were positive for 2 tests and 1% (6) were positive for 3 or more tests. Among the 28 individuals positive for ≥2 tests, 17 (61%) were symptomatic.

Nine of 604 FDR-RA subsequently developed classifiable RA and were positive for serologic biomarkers before date of RA diagnosis (Table 1). The RA converters had a mean age of 39 years (24-75 yrs) and an average follow-up time within the study of 3.6 years (1-7 yrs).

Table 1. Biomarker status of subsequent RA converters before date of diagnosis.

Using an algorithm to analyze the RA-associated genetic SNPs, we could highlight 48 FDR-RA (8%) with an increased genetic risk to develop RA. 15 out of 48 individuals (31%) at high genetic risk reported CSA, and 12 out of 48 individuals (25%) displayed signs of systemic autoimmunity associated with RA.

Conclusion: When looking at FDR it could help to not only include anti-CCP autoantibody testing but also additional biomarkers like RF and anti-RA33. Furthermore, looking at the genetic risk factors could give additional information. The combination with the multi-variate profile could even improve the early diagnosis of these patients.

Background: Reducing structural damage is an important treatment goal for rheumatoid arthritis (RA). Demonstrating a clinically meaningful, statistically significant difference in radiographic progression (assessed by van der Heijde modified total Sharp score, mTSS) is a common objective in trials for RA treatments. Complete collection of radiographic data is challenging, especially in long term follow-up and pediatric studies. Therefore, scores for individual joints or entire patients are regularly missing. A frequently used analysis method for mTSS is ANCOVA+LE which is the analysis of covariance model, in which missing data are imputed using linear extrapolation (ANCOVA+LE). However, other ways to deal with missing information have also been proposed.

Objectives: To evaluate robust analysis methods for mTSS data.

Methods: Simulated data were used to compare a random coefficient model (RC) without imputation, ANCOVA+LE and ANCOVA with last observation carry forward imputation (LOCF).

A log-normal distribution was used to generate baseline patient level data to simulate a 2-arm clinical trial using baseline mTSS and rate of change in mTSS from recently completed trials. Changes in mTSS (12, 28 and 44 week timepoints) were generated under linear, concave quadratic (fast progression then slow progression), and convex quadratic (slow progression then fast progression) assumptions, with the proportion of change forced to be 0 (a proportion of simulated patients do not have progression). A monotone missing pattern was assumed to generate a data set with missing data (the ‘observed’ dataset).

ANCOVA analyses were performed using baseline and treatment as predictors. The RC model was applied using baseline, treatment, time, and time-by-treatment interactions as fixed effect and time as a random effect. Bias (difference between average of simulation sample mean and true value, the smaller the better), root mean square error (RMSE, a measure of variation among simulation samples, the smaller the better), power and type I error rate were compared between methods.

Results: The random coefficient model provided better or at least similar results in bias, RMSE, power and type I error rate as ANCOVA+LE under evaluated scenarios (Table 1).

</table>

Conclusion: RC is a robust analysis method for mTSS. We recommend its use in primary analyses, especially for long-term extension and pediatric studies with a higher likelihood of missing data. This method can also provide reference for time points when no data are collected via estimated slope. ANCOVA+LE can be used for sensitivity analysis.

DISEASE ACTIVITY TRAJECTORIES FOR EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS: DATA FROM THE OBRI REGISTRY

M. Movahedi 1, 2, A. Cesta 1, X. Li 1, C. Bombardier 1, 3, 4 on behalf of OBRI Investigators.
1 Toronto General Hospital Research Institute, University Health Network, Toronto, Canada; 2 Institute of Health Policy, Management, and Evaluation, University of Toronto, Toronto, Canada; 3 Department of Medicine (DMO) and Institute of Health Policy, Management, and Evaluation (IHPME), Toronto, Canada; 4 Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada

Background: Description of disease activity status in patients with rheumatoid arthritis (RA) at fixed points in time modelled as continuous (e.g. number of swollen joints counts), dichotomous variable (e.g. remission or low disease status using composite measures) do not reflect the patient’s disease course in chronic and relapsing RA.

Objectives: To propose to describe the longitudinal disease activity trajectories for patients with early and established RA over two years’ follow-up in routine clinical care.

Methods: RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) with available DAS28-ESR over two years of follow-up were included. Using a latent growth curve modelling (LCGM), subgroups of patients following distinct pattern of DAS28-ESR change over time were identified. Fit statistics and model selection was based on Bayesian information criterion (BIC).

Results: A total of 1273 patients were included, 454 (36%) with early RA and 819 (64%) with established RA. At baseline, patients with early RA were significantly younger (57.3 vs 59.1 years) and with higher DAS28-ESR (4.6 vs. 4.3), and were less likely to have an erosion (25.0% vs. 59.7%), to be RF-positive (70.3% vs. 76.8%), and to use biologic DMARDs (76.8% vs. 29.2%).

In patients with early RA (Figure 1A), three subgroups of patients were identified by LCGM with a better fit (BIC: -3070.84). Almost 88% patients with moderate disease activity reached remission (group 1: 48.4%) or low disease status (group 2: 39.3%) after two years, while 12% of patients with high disease profile remained in a moderate state (group 3).

Conclusion: Disease course is different between early and established RA. While 70% of early RA patients with moderate or high disease profiles reached remission, only 17% of established patients with high disease activity achieved remission after two years of follow-up. These findings suggest the potential effects of receiving early treatment and health care. The impact of sociodemographic, clinical and medication profile on disease course will be examined as future work for this study.

PHARMACOGENOMICS-DRIVEN INDIVIDUALIZED PREDICTION OF TREATMENT RESPONSE TO METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A MACHINE LEARNING APPROACH

E. Myasoedova 1, A. Athreya 1, C. S. Crowson 1, R. Weinshilboum 1, L. Wang 1, E. Matteson 1, Mayo Clinic, Rochester, United States of America

Background: Methotrexate (MTX) is the most common anchor drug for rheumatoid arthritis (RA), but the risk of missing the opportunity for early effective treatment with alternative medications is substantial given the delayed onset of MTX action and 30-40% inadequate response rate. There is a compelling need to accurately predicting MTX response prior to treatment initiation, which allows for effectively identifying patients at RA onset who are likely to respond to MTX.

Objectives: To test the ability of machine learning approaches with clinical and genomic biomarkers to predict MTX response with replications in independent samples.

Methods: Age, sex, clinical, serological and genome-wide association study (GWAS) data on patients with early RA of European ancestry from 647 patients (336 recruited in United Kingdom [UK]; 307 recruited across Europe; 70% female; 72% rheumatoid factor [RF] positive; mean age 54 years; mean baseline Disease Activity Score Activity Score with 28-joint count [DAS28] 5.65) of the PnArmacogenetics of Methotrexate in RA (PAMERA) consortium was used in this study. The genomics data comprised 160 genome-wide significant single nucleotide polymorphisms (SNPs) with p<1x10-5 associated with risk of RA and MTX metabolism. DAS28 score was available at baseline and 3-month follow-up visit. Response to MTX monotherapy at the dose of ≥15 mg/week was defined as good or moderate by the EULAR response criteria at 3 months' follow-up visit. Supervised machine-learning methods were trained with 5-repeats and 10-fold cross-validation using data from PAMERA's 336 UK patients. Class imbalance (higher % of MTX responders) in training was accounted by using simulated minority oversampling technique. Prediction performance was validated in PAMERA's 307 European patients (not used in training).

Results: Age, sex, RF positivity and baseline DAS28 data predicted MTX response with 58% accuracy of UK and European patients (p = 0.7). However, supervised machine-learning methods that combined demographics, RF positivity, baseline DAS28 and genomic SNPs predicted EULAR response at 3 months with area under the receiver operating curve (AUC) of 0.83 (p = 0.051) in UK patients, and achieved prediction accuracies (fracton of correctly predicted outcomes) of 76.2% (p = 0.054) in the European patients, with sensitivity of 72% and specificity of 77%. The addition of genomic data improved the predictive accuracies of MTX response by 19% and achieved cross-site replication. Baseline DAS28 scores and following SNPs rs12446816, rs13385025, rs113798271, and rs2372536 were among the top predictors of MTX response.

Conclusion: Pharmacogenomics biomarker combined with DAS28 scores predicted MTX response in patients with early RA more reliably than using demographics and DAS28 scores alone. Using pharmacogenomics biomarkers for identification of MTX responders at early stages of RA may help to guide effective RA treatment choices, including timely escalation of RA therapies. Further studies on personalized prediction of response to MTX and other anti-rheumatic treatments are warranted to optimize control of RA disease and improve outcomes in patients with RA.

STRATEGIES REGARDING GOAL SETTING AND SELF-MANAGEMENT IN DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: PRELIMINARY RESULTS OF A SYSTEMATIC LITERATURE REVIEW FORMING THE 2020 EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS

N. M. T. Roodenrijs1, A. Hamar2, M. Kedves3, G. Nagy4, J. M. Van Laar5, D. Van der Heijde6, P. Welsing1, J. University Medical Center Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands; 2University of Debrecen, Department of Rheumatology, Debrecen, Hungary; 3Bács-Kiskun County Hospital, Department of Rheumatology, Kecskemét, Hungary; 4Semmelweis University, Department of Genetics, Cell and Immunobiology & Department of Rheumatology, 3rd Department of Internal Medicine, Budapest, Hungary; 5Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands

Background: Rheumatoid arthritis (RA) patients treated according to European League Against Rheumatism (EULAR) recommendations failing ≥2 biological or targeted synthetic disease-modifying antirheumatic drugs with a different mode of action who still have complaints which may be suggestive of active disease and for whom management is perceived as problematic by patient and/or rheumatologist have been defined as suffering from ’difficult-to-treat RA’. A mismatch in goal setting between patient and health care professional, and suboptimal self-management may contribute to this disease state, while specific management recommendations regarding these factors are currently lacking.

Objectives: To systematically summarise evidence in the literature on the identification and optimisation of a mismatch in goal setting and subtimal self-management in difficult-to-treat RA patients, informing the 2020 EULAR recommendations for the management of difficult-to-treat RA.

Methods: A systematic literature review (SLR) was performed: PubMed, Embase and Cochrane databases were searched up to December 2018. Relevant papers were selected and appraised. Effect sizes were extracted or calculated.

Results: Three studies were selected on the identification and four on the optimisation of a mismatch in goal setting (Figure 1). No accurate measures were found to identify a mismatch in goal setting, but patients expressed a desire to take their quality of life goals more explicitly into account. Education was found to improve goal setting (4 of 4 studies, effect size not calculable). Five studies were selected on the identification and 31 on the optimisation of suboptimal self-management (Figure 1). Although formal evaluations in high quality studies were lacking, the Arthritis Self-Efficacy Score was found to be the most reliable tool to identify suboptimal self-management. Patients were found to desire more education on nutrition, the disease and the diagnostic process to be able to improve self-management. Self-management programs, educational and psychological interventions were found to improve self-management (Table 1).

Conclusion: In difficult-to-treat RA patients, limited evidence was found on a mismatch in goal setting and suboptimal self-management, especially regarding their identification. Non-pharmacological interventions were found to improve goal setting and self-management.

NUMBER NEEDED TO TREAT TO ACHIEVE MINIMUM CLINICALLY SIGNIFICANT DIFFERENCES IN PATIENT-REPORTED OUTCOMES IN PATIENTS TREATED WITH BARCITINIB

V. Strand1, L. Sun2, J. Ross Terres2, C. L. Kannowski2, 1Stanford University School of Medicine, Division of Immunology/Rheumatology, Portola Valley, United States of America; 2Eli Lilly and Company, Indianapolis, United States of America

Background: Baricitinib (BAR) provided rapid and sustained improvements in patient-reported outcomes (PROs) in randomized, controlled trials (RCTs) in patients (pts) with active rheumatoid arthritis (RA) and inadequate responses (IR) to methotrexate (MTX) (RA-BEAM; NCT01710358) and biologic DMARDs (bDMARD-IR; RA-BEACON; NCT01721044).

Objectives: To determine the number needed to treat (NNT) to report improvements in minimally important differences (MCIDs) in multiple PROs at Week (Wk) 12 after treatment with BAR 4-mg in RA-BEAM and BAR 2-mg or 4-mg in RA-BEACON. NNTs ≤10 vs placebo (PBO) are considered clinically meaningful.

Methods: Evaluated PROs with respective MCID definitions included Patient Global Assessment of Disease Activity (PGA, 0-100 mm visual analog scale [VAS], MCID ≥10 mm), pain (0-100 mm VAS, MCID ≥10 mm), physical function (Health Assessment Questionnaire-Disability Index, MCID ≥0.22 points), fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F]), health-related quality of life (SF-36 physical component summary [PCS; MCID ≥2.5] and domain scores: physical function [PF], role physical [RP], bodily pain [BP], general health [GH], vitality [VT], social functioning [SF], role emotional [RE], mental health [MH], MCID ≥0.5). The percentages of pts reporting improvements ≥MCID were determined at Wk 12. NNTs were calculated as 1/difference in response rates between BAR 2-mg or 4-mg and PBO.

Results: Across different populations, MTX-IR and bDMARD-IR pts with MTX-IR and bDMARD-IR pts with active RA reported clinically meaningful improvements in PROs after BAR treatment. The NNTs in these analyses indicate that <10 pts need to be treated with BAR 2- or 4-mg to report a clinically meaningful benefit.

FR004050 **EFFICACY OF ATORVASTATIN VERSUS COLCHICINE IN DECREASING BIOMARKERS OF MYOCARDIAL DAMAGE IN PATIENTS WITH SEVERE RHEUMATOID ARTHRITIS**

J. A. Alvarado1, J. M. Lopez2, A. C. Bardan3, C. Abud-Mendoza1, 3, Hospital Central Dr. Ignacio Morones Prieto, Internal Medicine, San Luis Potosí, Mexico; 3Hospital Central Dr. Ignacio Morones Prieto, Cardiology, San Luis Potosí, Mexico; 3Hospital Central Dr. Ignacio Morones Prieto, Rheumatology, San Luis Potosí, Mexico

**Background:** Patients with rheumatoid arthritis (RA) have been associated to higher morbidity and mortality due to cardiovascular events. The impact of atorvastatin and colchicine in reducing these complications has been evaluated without comparative studies of these drugs in RA patients. We assess whether atorvastatin in superior to colchicine in cardiovascular risk markers (high-sensitivity troponin I (hs-cTnI), echocardiographic abnormalities and inflammatory cytokine) in patients with RA.

**Objectives:** The primary objective was to compare the initial and final levels of hs-cTnI with both treatments. Secondary objectives: Describe initial echocardiographic abnormalities, compare changes in serum levels of inflammatory cytokines (TNF, IL 8, IL 1β, IL 6, IL 10, IL 12p70) and values of lipid profile.

**Methods:** Prospective randomized pilot study, blinded for cardiologist and rheumatologist, with patients RA and severe disease activity (DAS 28<5.1), without known heart disease, kidney disease or previous use of atorvastatin and/or colchicine. Patients were assigned according to randomization in two groups: atorvastatin dose of 40mg/day or colchicine with an initial dose of 0.75mg/day titled according to tolerance up to a maximum dose of 1.5mg/day, both were received for four weeks. NCT04066039

**Results:** Recruitment of September 2018 to August 2019, 60 participants had undergone randomization (30 in each group) with a median age 48. The duration of follow-up from randomization was 28 days in each group. Participants were followed by weekly telephone contact to assess of adherence treatment. A detected value of hs-cTnI was found in all patients, initial value in the atorvastatin group: Median 1ng/L, IQR 1-2 and final: Median 1ng/L, IQR 1-3 vs initial value in the colchicine group: 1ng/L, IQR 1-2 and final: 1ng/L, IQR1-2 p = 0.67. Echocardiographic abnormalities in 46 patients (76.66%); 63.33% diastolic dysfunction, 15% tricuspid regurgitation and 11.66% left ventricular hypertrophy. There were changes in initial and final diastolic dysfunction in the atorvastatin group from 19 to 9 vs colchicine from 19 to 12 p = 0.05, 95% CI 0.49-0.82. Correlation of initial hs-cTnI with age p <0.001 and rheumatoid factor p = 0.02; correlation of diastolic dysfunction and age p <0.001. There was a greater decrease in the...
level of tumor necrosis factor (TNF) and IL 1β in the atorvastatin group, however, decrease was higher in IL6 and IL12p70 in the colchicine group. Mild diarrhea was reported as the most frequent adverse effect in the atorvastatin group of 3.33% and colchicine of 23.33% p = 0.010. There was a statistically significant decrease in cholesterol and LDL-cholesterol levels in favor of treatment with atorvastatin

**Conclusion:** We do not observe substantial differences in decrease in hs-Cttn with atorvastatin and colchicine, a prospective study of 222 patients is required to avoid β-type error. Echocardiographic abnormalities in 76% of patients showed a greater decrease in diastolic dysfunction in the atorvastatin group, as well as lower cholesterol and LDL-cholesterol levels, thus, as a tendency to falling of TNF and IL 1β in this group

**RHEUMATOID ARTHRITIS PATIENTS WITH HIGH DISEASE ACTIVITY AND TREATED WITH HIGH DOSE GLUCOCORTICOID FREQUENTLY FALL: NINE YEARS OF THE TOMORROW STUDY**

1Osaka Social Medical Center, Department of Orthopaedic Surgery, Osaka, Japan; 2Osaka City University Medical School, Department of Orthopaedic Surgery, Osaka, Japan; 3Osaka City University Medical School, Center for Senile Degenerative Disorders (CSSD), Osaka, Japan; 4Osaka City General Hospital, Department of Orthopaedic Surgery, Osaka, Japan; 5Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan

**Background:** Falling is a multicausal phenomenon resulting from complex interactions between intrinsic and extrinsic or environmental factors. Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk of falling. However, little is known about the exact properties of risk factors for falling in patients with RA. Recently, the disease activity of RA has been more satisfactorily controlled by the “treat-to-target” strategy, including the use of biologics. Given this new era, it is important to accurately estimate the incidence of falling in patients with RA and to elucidate contributing risk factors.

**Objectives:** The objective of this study was to evaluate the incidence of falling and associated risk factors in 208 patients with RA and in age- and sex-matched 205 controls (Co) who participated in the TOMORROW (TOtAl Management Of Risk factors in Rheumatoid arthritis patients to Iower er morbidity and mortality) study, a 10-year cohort study that started in 2010 in Japan. This research was conducted using TOMORROW study data for 9 years.

**Methods:** We evaluated the incidence of falling by self-administered questionnaire every year and confirmed them by medical records. We also collected information about general health status, body composition including bone mineral density, lean body mass, fat mass and laboratory data. The HOMA2%B (insulin secretion) and HOMA2%S (tissue insulin sensitivity) indices (HOMA calculator, © Diabetes Therapy, France) were used to assess insulin resistance. Ra and OA in this group performed, assessing inflammatory (CRP levels) and metabolic (fasting glycemia and insulin levels, HbA1c) parameters. The HOMA2%B (insulin secretion) and HOMA2%S (tissue insulin sensitivity) indices (HOMA calculator, © Diabetes Therapies) were used to assess insulin resistance. Ra and OA

**Results:** A total of 157 patients with RA (mean age: 57.1 ± 12.5 years, female: 84.7%, mean disease duration 13.9 ± 12.0 years) and 169 Co (mean age: 57.6 ± 12.5 years, female: 84.0%) completed 9 years observation. The rate of individuals who fell did not differ between two groups (RA: 66.9%, Co: 59.2%, p = 0.19). However, number of falls was higher in RA than Co (0.35 vs 0.21/person-year, p = 0.03). Multivariate logistic regression analysis adjusted for age, sex and BMI, revealed that RA was not a risk factor for the incidence of falling (OR: 1.36, 95%CI: 0.82-2.32, p = 0.26) and the history of falling was a risk factor for the incidence of falling (OR: 3.27, 95%CI: 1.78-7.0, p =0.001). Multivariate linear regression analysis adjusted for age, sex and BMI, revealed that mHAQ (β=0.17, p =0.04) and mean DAS28-CRP over 9 years (β=0.19, p =0.02) and mean dosage of glucocorticoid over 9 years (β=0.18, p =0.03) were the risk factors for number of falls (table 1).

RA, rheumatoid arthritis; CCP, cyclic citrullinated peptide; RF, Rheumatoid factor; DAS28-CRP, disease activity score 28 with C-reactive protein; mHAQ, modified Health Assessment Questionnaire; GC, glucocorticoid.

**Conclusion:** There was no difference in the incidence of falling between RA and Co. However, number of falls was significantly higher in RA group. High disease activity and higher dosage of glucocorticoid were the risk factors for number of falls among RA patients.

Patients were compared using parametric tests after adjusting for age and BMI. A multivariate logistic regression was performed to identify factors independently associated with insulin resistance.

Results: We included 122 RA patients (74% women, mean age 64±11 years, mean disease duration 15±4.11 years, 75% with positive ACPA antibodies and 64% with erosive disease) and 54 controls with OA. 64% of RA patients were treated with oral corticosteroids <10mg/day, 65% received methotrexate and 53% received targeted biological therapies.

The characteristics of type-2 diabetes in the 54 OA patients corresponded to severe insulin-resistant diabetes: age>65 years, high BMI>30kg/m2, mean HbA1c 7.3±2.1% vs. 9.3±±2.1% in RA patients, high frequency of other cardiovascular risk factors, macroangiopathy found in almost half of patients and biological criteria of insulin resistance (elevation of HOMA2%β and decrease of HOMA2%β). RA patients with type-2 diabetes had a younger age (64±411 vs. 68±12 years, p=0.031) and lower BMI (27.7±411.5 vs. 31.5±±6.3, p<0.001). These patients also had severe diabetes (HbA1c 7.0±11.12% vs. 6.9±±1.12% in OA patients, 43% of macroangiopathy) with an insulin resistance profile identical to OA controls. After adjusting for age and BMI, RA patients had a significantly increased insulin secretion compared to OA patients (HOMA2%β: 83.1±11.65.2 vs. 49.3±11.257 p=0.023) as well as a significant reduction of insulin sensitivity (HOMA2%β: 61.1±11.316 vs. 92.9±11.681, p=0.016). This insulin resistance was associated with the inflammatory activity of RA, with a negative correlation between the HOMA2%β and the DAS28 (r=-0.28, p=0.027). The multivariate logistic regression confirmed the independent association between the HOMA2%β index and DAS28 (OR: 3.93, 95% CI 1.02-15.06), as well as high blood pressure (OR: 129, 95% CI 0.33-1.99 CI).

Conclusion: RA patients with type-2 diabetes displayed severe, poorly controlled diabetes, highlighting the burden of comorbidities associated with RA. The clinical and biological profile of diabetic RA patients was severe insulin-resistant diabetes, with a biological profile of insulin resistance linked to the inflammatory activity of the disease. These findings may have therapeutic implications, with the potential targeting of insulin resistance through the treatment of joint and systemic inflammation.

**PROLIFERATIVE SYNOVITIS, AN ULTRASOUND PATTERN ASSOCIATED WITH ACPA POSITIVE RHEUMATOID ARTHRITIS**

A. B. Azuaga-Piñango1, B. Frade-Sosa1, R. Gmurucio1, K. Caiago1, A. Cuervo1, R. Celis1, J. A. Gómez-Puerta1, R. Sanmartí1, J. D. D. Cañete1, J. Ramirez1

1Hospital Clinic, Rheumatology, Barcelona, Spain

Background: Seronegative (sero-) and seropositive (sero+) Rheumatoid Arthritis (RA) have different genetic, immunopathological and vascular morphology features, but no previous studies have analyzed if US characteristics differ between sero- and sero+ RA. To analyze potential differences between patients with RA according to their autoantibody status by using ultrasonography (US). We aimed to assess whether PS is associated with ACPA+ pts

Methods: We collected clinical, epidemiological data and bilateral carpal and hand US images of pts with RA. Synovial hypertrophy (SH), Power Doppler signal (PD) and total score (sum of scores of SH and PD) in wrist and hand (1-5 metacarpophalangeal) were assessed. We evaluated the presence of PS, defined as expansive synovial growth encompassing the concepts of synovial SH grade II and III. We performed synovial biopsies of a subgroup of pts using arthroscopy or US guided in order to see immunohistochemistry differences between “proliferative” and “flat” (non-proliferative) synovitis. Serum levels of angiogenic and inflammatory biomarkers were performed

Results: Two hundred and five RA patients were collected. Overall, 173 (84.8%) pts were sero+ for RF (68.7%) or ACPA (74.6%), general characteristics are summarized in Table. No significant differences between sero+ and sero- pts in terms of disease activity or therapy were found. PS was present in 55.5% of sero+ pts (55.3% in RF+ and 58.2% in ACPA+ pts) and 16.1% of sero- pts (p=0.0001). Globally, 101 pts (49.2%) had PS. Ninety-six (95.0%) were RF or ACPA positive.

Only 5 pts with sero- RA had PS (p=0.001). In the univariate analysis, significantly more pts with PS had erosive disease (72.3% vs 35.0% p=0.0001), higher US scores (p=0.0001) and more of them were taking conventional synthetic Disease-modifying anti-rheumatic drugs (cDMARD) (81.8% vs 69.6% p=0.05). No differences regarding disease activity were found in the multivariate analysis erosions [OR 4.90 CI 95% (2.17-11.07) p=0.0001] and ACPA [OR 3.5 CI 95% (1.39-10.7) p=0.09] but not RF status [OR 0.74 CI 95% (0.31-1.71) p=0.483] were independently associated with the presence of PS.

We immunostained synovial biopsies from 23 pts with PS (13 pts) or non-PS (10 pts). PS was significantly associated with higher density of vessels (p=0.042) and a strong trend to a higher density of B, T, Mast cells and macrophages (fig 1). Significantly higher serum levels of angiogenic (Actin A, BF-GF, IL-18, IL20, PIGF, SDF-1 and VEGF-D) and pro-inflammatory (IL23) cytokines were found in patients with PS (fig 2).

Conclusion: The presence of “proliferative Synovitis” was significantly associated with ACPA and erosive disease in patients with RA. PS pattern also was associated with higher density of synovial vessels and higher serum levels of angiogenic and inflammatory mediators.

**Background:** Depression is a common comorbidity in patients with RA and influences perception of disease activity and quality of life. We have previously reported that mean depression scores improved during TCZ therapy in conjunction with reductions in disease activity.1

**Objectives:** To evaluate individual changes in depressive symptoms over 52 weeks in RA patients initiating treatment with TCZ.

**Methods:** We analyzed data from a large German multicenter observational study of patients with active RA who initiated TCZ therapy during routine clinical care (ML29087 ARATA study; NCT02251860). The Beck Depression Inventory-II (BDI-II), a self-report questionnaire for depression screening that has been validated in RA, was used to assess symptoms of depression. Patients were classified by baseline BDI-II scores into depression categories of no (BDI-II<14), mild (BDI-II 14-29), moderate (BDI-II 20-28), and severe depression (BDI-II≥29).2 Individual changes in BDI-II scores between baseline and week 52 were assessed. Erythrocyte sedimentation rate was used as the acute phase reactant in Disease Activity Score-28 joints (DAS28) assessments.

**Results:** Of 1155 patients enrolled from 108 clinical centers in Germany in May 2014 and July 2018, 474 completed the BDI-II at baseline (BDI-II cohort); baseline characteristics were similar to those of patients who did not complete the BDI-II. Approximately half of patients in the BDI-II cohort had BDI-II scores indicating no depression (24.8; 52.3%), the remaining patients had mild (87; 18.4%), moderate (84; 17.7%), or severe (55; 11.6%) depression. The mean (SD) baseline characteristics of the BDI-II cohort were 55.5 (12.5) yrs of age, 75.7% female, 10.6 (9.2) yrs RA duration, 4.9 (12) DAS28, and 24.3 (10.2) Clinical Disease Activity Index (CDAI). Baseline DAS28 and CDAI scores were similar among different depression subgroups, but patients with severe depression were more likely to be female (87.3% vs 70.6% for no depression) and had higher levels of anxiety, suicidal ideation, fatigue, pain, and sleep disturbance than patients with no or milder depression.

A total of 229 of the 474 patients (43.8%) in the BDI-II cohort completed the BDI-II at both baseline and week 52. At 52 weeks, the depression category of approximately half of patients with depressive symptoms at baseline changed to a lower level or no depression (Figure 1). Moderate to large improvements in BDI-II from baseline (>10 points) were reported by 33.3% to 38.5% of patients with baseline depressive symptoms (Figure 2).

**Conclusion:** At 52 weeks after initiating TCZ, the depressive disease burden was reduced. Future analyses with a representative patient cohort will be aimed at exploring whether improvements in depression occur independent of reductions in disease activity.

**PREVALENCE OF CLINICALLY LATENT TUBERCULOSIS IN RHEUMATOID ARTHRITIS – A RETROSPECTIVE CLINICOPATHOLOGIC STUDY OF 161 AUTOPSY PATIENTS**

M. Bély1, Á. Ápáthy2, 1Hospital of the Order of the Brothers of Saint John of God, Department of Pathology, Budapest, Hungary; 1St. Margaret Clinic, Department of Rheumatology, Budapest, Hungary

**Background:** The risk of tuberculosis (TB) is higher in rheumatoid arthritis (RA) than in the general population.

**Objectives:** The aim of this study was to determine the prevalence and histological characteristics of post-primary inactive or active TB in RA, to appraise the involvement of different organs, and to statistically assess the relationship between inactive and active TB in RA.

**Methods:** At the National Institute of Rheumatology 9475 patients died between 1969 and 1992; among them 161 with RA and all of them were autopsied. RA was confirmed clinically according to the criteria of the ARA.

**TB** was detected at autopsy and specified histologically, retrospectively reviewing all available clinical and pathological reports.

Demographics of different patient cohorts were compared with the Student t-probe. The relationship between inactive TB and active TB with miliary disseminated was analyzed with χ2-test.

**Results:** Post-primary TB was associated with RA in 21 (13.04%) of 161 patients. Post-primary TB was localized to the lung. Twelve (57.14%) of 21 TB were histologically only fibrous, pigmented (granulomatous) tuberculotic scars (fTB), and 9 (42.86%) of 21 revealed a fibrocaseous tuberculosis (fCTB). One of 12 fTB and 5 of 9
The mean age of RA patients was higher with TB, fTB, or mTB in comparison to total population or to the patients without TB (70.92 years versus 67.77, p < 0.0043).

There was a definitely shorter duration of RA in patients with fTB or mTB compared to the total population.

Proliferative or exudative epithelioid granulomatous mTB involved different organs, such as lungs in 5, liver in 3, spleen in 2, lymph nodes in 2, adrenal gland in 1, synovial membrane in 1, vertebrae in 1 and pituitary gland in 1 of 6 patients with active mTB.

There was a significant correlation between: TB and fTB (c=1, x²=33.96, p<0.00000001), TB and fTB (c=1, x²=78.36, p<0.00000001), TB and fTB (c=1, x²=55.69, p<0.00000001), or fTB and mTB (c=0.99, x²=56.89, p<0.00000001). The link between fTB and mTB was not significant (c=0.45, x²=0.07, p=0.76).

Conclusion: TB, fTB, or mTB complicated RA in both sexes, and at any time in the course of the disease.

The mean age at death was higher in all forms of TB. Significant difference was only in mean age of fTB compared to the patients’ cohort without TB. Fibrocased tuberculosis or miliary dissemination of tuberculosis reduced definitely the survival time (and disease duration) of aged RA patients.

Post-primary TB especially fTB (mostly in the lungs) represents a high risk of miliary dissemination in RA. In our autopsy material mTB was the consequence of endogenous exacerbation of TB (and was not due to an exogenous reinfection), based on the high values of Yould’s association coefficients between TB or fTB and mTB.

The mTB may be considered as a terminal phenomenon, because of the limited numbers of granulomas involving only a few organs. The exudative character – beside proliferative epithelioid granulomas – must be regarded as a histological evidence of impaired immune reactivity, an unfavorable prognostic sign in elderly patients, forecasting the possible fatal outcome of RA associated TB.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.1003
score was applied to the CVD risk score algorithm to generate curves that show how CVD risk score varies with MBDA score for several distinct patient types. These curves demonstrate that the predicted 3-year CVD risk increases continuously and markedly with increasing level of inflammation, as represented by the MBDA score (Figure 2). Age and the number of conventional risk factors also affected the predicted CVD risk, with older patients (Figure 2a) and those with more conventional risk factors (Figure 2b) being at higher risk for a CVD event.

**Conclusion:** The level of CVD risk predicted by a new prognostic test for RA patients depends not only on conventional risk factors, which are relatively time invariant, but also varies greatly due to inflammation, which can potentially be reduced with RA treatment.

**References:**

**Figure 1:** Predicted versus observed molecular score in the validation dataset (N=59,162). The model derived to determine predicted molecular scores (denoted m) was: mrem = β(MBDA – MBDAref), where MBDAref and mref are fixed reference values and β is the coefficient estimated in the training dataset. The dashed line represents predicted molecular score m observed molecular score.

**Figure 2:** Relationship between inflammation and predicted CVD risk. A) Predicted 3-year CVD risk by MBDA score for hypothyroid patients having diabetes, hypertension and the indicated ages. B) Predicted 3-year CVD risk by MBDA score for hypothetical 55-year old patients having 0 to 4 conventional risk factors, as indicated. Curves were derived using the CVD risk prediction algorithm across the range of all possible MBDA scores with molecular scores assigned by the model described above. For these CVD risk curves, MBDAref was fixed at 39 (the median MBDA score in the validation dataset), and mref was fixed at 0.07 (the median molecular score observed in patients with an MBDA score of 39).

**Background:** Rheumatoid arthritis (RA) is an inflammatory disease that includes chronic, progressive joint arthritis and also has multi-systemic involvement. It is known that the acceleration of many cardiovascular diseases causing mortality and morbidity, especially atherosclerosis and heart failure, is increased in RA patients.

**Objectives:** In this study, it was aimed to analyze the layer-specific (endocardial, transmural and epicardial) strain values obtained by speckle tracking echocardiography method in the determination of subclinical cardiac dysfunction in RA patients and to determine the correlation between anti cyclic citrullinated peptide (Anti-CCP) titers, disease activity score (DAS-28), disease duration and strain values.

**Methods:** This study was performed with 83 RA patients and 31 healthy participants. The patients were grouped as <5 years, 5-10 years and >10 years according to their disease duration. DAS28-CRP was used to determine disease activation. The standard assessment included complete serum concentration of C-reactive protein, Anti-CCP, Romatoid faktör (RF), N-terminal pro b-type natriuretic peptide (NT-proBNP) and homocysteine. Endocardial, transmural and epicardial strain values were analyzed by M-mode, 2D, tissue doppler and speckle tracking echocardiography.

**Results:** When the groups were compared in terms of laboratory data, NT-proBNP value of RA patients was higher than the control group (p=0.044), homocysteine level was similar (p=0.05). When the groups were compared in terms of conventional echocardiographic parameters, ejection fraction of the control group was similar (p=0.05). E/A and E/E ratios were found to be significantly different (p=0.001, p=0.015). When the groups were compared in GLS values obtained by speckle tracking echocardiography, endocardium, transmural and epicardium GLS values were lower in RA patients (p<0.05) (Table 1). As the disease duration increased, GLS values were found to be worse (p<0.05). There was a significant correlation between RA disease activity scores level and LV GLS value, increasing levels of disease activity was associated with worse LV GLS (r=0.583, p<0.01) and when the groups were compared in GLS values obtained by speckle tracking echocardiography, endocardium, transmural and epicardium GLS values were lower in RA patients (p<0.05) (Table 1). As the disease duration increased, GLS values were found to be worse (p<0.05). There was a significant correlation between RA disease activity scores level and LV GLS value, increasing levels of disease activity was associated with worse LV GLS (r=0.583, p<0.01) and when the groups were compared in GLS values obtained by speckle tracking echocardiography, endocardium, transmural and epicardium respectively. There was a significant correlation between anti-CCP, RF and LV GLS value, higher Anti-CCP and RF titers were associated with worse LV GLS (r=0.467, p<0.01) and r=0.551, p<0.01) for endocardium, transmural and epicardium respectively.

SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Tekgoz1, S. Colak1, F. Ozalp2, I. Sonareen3, S. Yilmaz1, M. Cinar1,1 University of Health Sciences, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 2 Ankara University Faculty of Medicine, Biostatistics, Ankara, Turkey; 3 Guilhane Training and Research Hospital, Nutrition and Dietetics, Ankara, Turkey

Background: Sarcopenia is defined as the decrease in strength, mass and function of muscles and may be related with aging, chronic inflammation or malnutrition. Proinflammatory cytokines may be associated with development of sarcopenia. Objectives: The aim of this study was to evaluate sarcopenia in patients with Rheumatoid Arthritis (RA). Methods: One hundred patients with RA (30 Male/70 Female) and 100 healthy controls (30 Male/70 Female) were included in this cross sectional study. According to The European Working Group on Sarcopenia in Older People (EWGSOP2) 2018, three parameters; muscle strength, muscle mass and physical performance, which are evaluated by hand grip strength, Body Impedance Analyzer (BIA) and 6 meters gait speed test, respectively, are used to diagnose sarcopenia. Patients with arthritis in dominant hand joints and ankle joints were excluded. Sarcopenia is defined as the decrease of strength and mass of muscles. On the other hand patients with low muscle strength but normal muscle mass are defined as probable sarcopenia. Results: The mean age was 58.52±10.95 for patients and 56.62±10.08 for controls (p=0.023). Frequency of probable sarcopenia was 35 (35.0%) in RA and 9 (9.0%) in control group (p<0.001). Results of hand grip and 6 meters gait speed tests were lower in RA patients (p=0.002 and p<0.001 respectively). Frequency of probable sarcopenia was higher in females, older patients and patients with longer disease duration. Disease activity and Health Assessment Questionnaire scores were higher in patients with probable sarcopenia compared with patients with no sarcopenia (p<0.05) (Table 1). In multivariate regression analysis; age, gender and DAS28 ESR/CRP were associated with hand grip strength (p<0.001, R²=0.62) (Table 2).

DAS: Disease activity score  CRP: C-reactive protein

Conclusion: Loss of muscle strength in patients with RA may be seen frequently. Longer disease duration and higher disease activity should lead to development of sarcopenia due to chronic inflammation. Sarcopenia potentially affects patients’ social lives and daily functions and decrease quality of life. Physicians should be aware of development of sarcopenia during the course of the disease, and take into account the preservative and preventive methods against to sarcopenia including exercise and control of disease activity.

EVALUATION OF THE CARDIOVASCULAR RISK IN WOMEN WITH RHEUMATOID ARTHRITIS WITH DUPLEX STUDY OF THE CAROTID AND FEMORAL ARTERIES

N. De Carvalho Sacilotto1, A. Ozelia Augusto2, D. Alves Lucena1, M. Roberto Godoy1, R. Duque de Almeida1, R. De Almeida Pernambuco1, S. Maria Alavarenga Anti Loduca1, R. Sacilotto1, R. Giorgi1, Hospital do Servidor Público Estadual de São Paulo, São Paulo, Brazil

Background: The increasing of the cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) is well know, even with the absence of traditional coronary risk factors. The ultrasonic – duplex scan (USD) is a non invasive technique able to early detect atherosclerotic changes in the blood vessel, that gives the possibility to retard the development of symptomatic CVD. Objectives: To evaluate the cardiovascular (CVS) risk in patients with RA classified as low risk by Framingham Score (FS), before and after the EULAR 1.5 multiplication factor and stratify with the carotid and femoral USD (intima-media thickness - IMT and atherosclerotic plaques - AP) Methods: Thirty-five female patients with RA and low CVS risk by FS and 35 healthy women with low CVS risk by FS (control group) were enrolled for the study. All of them submitted to carotid and femoral USD Results: The groups were homogenous by age and CVS comorbidities -Table 1. Mean age in the diagnosis was 44.57 years, mean disease duration was 12.11 years and mean disease activity was Disease Activity Score 28: 1.91 and Clinical Disease Activity Score: 6.176. In the RA patients group 46% showed changes in the carotid and/or femoral USD compared with 14% of the control group (p = 0.004) –Graphic 1. The USD with abnormalities in RA group 31% of the carotid USD and 81% of the femoral USD (p = 0.005) showed IMT and/or AP. After EULAR 1.5 multiplication factor, 66% remained low CVS risk. Where 35% of the RA patients showed changes in the carotid and/or femoral USD compared with 14% of the control group (p=0.07)

Conclusion: The USD is able to early detect the CVD, special attention should be given to the femoral arteries, that are frequently affected. The Eular criteria is also effective and should be used in the clinical practice

References:

Background: Rheumatoid arthritis is implicated in causing adverse pregnancy outcomes including high rates of prematurity and low birth weight. But little is known about the impact of the disease when it's controlled as most of the information is extracted from retrospective data.

Objectives: To examine the adverse obstetric outcomes after controlling disease during pregnancy. We also took into account many confounders that might affect the outcome.

Methods: This is an ongoing Case-Control Prospective Cohort. It is implemented in a tertiary center where cases are recruited from a single specialized pregnancy and rheumatic disease clinic to ensure standardized management. These cases were fulfilling the ACR 2010 classification criteria for rheumatoid arthritis. Disease activity was measured using CDAI once before pregnancy and once in each trimester. We excluded subjects with chronic morbidities or twin pregnancy. Disease activity measures. However, it is useful to use a composite comorbidity index, such as Rheumatic Disease Comorbidity Index (RDCI) that is validated for the use in patients with rheumatic diseases, to better understand the overall role of comorbidities in treatment outcomes.

Objectives: To evaluate the impact of comorbidities on 12-month clinical response in a cohort of patients with RA treated with a first-line biologic disease-modifying antirheumatic drug (bDMARD), by using the RDCI.

Results: A total of 251 patients were included: 83.7% (n=210) females, mean age of 58 ± 11.10 years old, with a median disease duration of 16.11 years [10.79 - 23.04]. The majority exhibited a very high or high disease activity at baseline BMI and anemia were similar. Exposure to passive smoking was significantly higher in the control group. There was no statistical difference in the incidence of gestational diabetes, pre-eclampsia and infections. Rates of abortions and cesarean sections were significantly higher in the cases group. The incidence of PROM & low birth weight was not statistically different. Three cases of IUFD were reported among controls versus none in the cases (Table 1). Prematurity rate was numerically higher in the control group but did not reach a statistical difference. Congenital anomalies and NICU admission rates were comparable between the groups.

Conclusion: From this ongoing cohort we conclude that controlled RA during pregnancy carries low risk of adverse obstetric outcomes in spite the regular use of DMARDs. Although these results are reassuring, further regression models are required after recruiting more subjects.

S. Garcia1, B. M. Fernandes1, G. Terroso1, M. Bernardes1, L. Costa1. 1Centro Hospitalar Universitário São João, Porto, Portugal

Background: Several studies in Rheumatoid arthritis (RA) have suggested that a greater number of comorbidities is associated with worse functional status and disease activity measures. However, it is useful to use a composite comorbidity index, such as Rheumatic Disease Comorbidity Index (RDCI) that is validated for the use in patients with rheumatic diseases, to better understand the overall role of comorbidities in treatment outcomes.

Objectives: To evaluate the impact of comorbidities on 12-month clinical response in a cohort of patients with RA treated with a first-line biologic disease-modifying antirheumatic drug (bDMARD), by using the RDCI.

Methods: Observational retrospective study was performed including consecutive patients with the diagnosis of RA followed at our Rheumatology Department. The prevalence of comorbidities was computed, and patients were stratified according to RDCI for evaluating its role in clinical response disease activity at baseline and follow up (6 and 12 months). Correlations between variables were studied using Spearman correlation analysis, comparison between groups was performed using Kruskal–Wallis and Chi-square. A multivariate logistic regression model was developed to examine the role of RDCI along with other baseline factors as potential predictor of achieving remission, low disease activity (LDA), and EULAR good/moderate response. Statistical analyses were performed using SPSS statistical software, version 23.0.

Results: A total of 251 patients were included: 83.7% (n=210) females, mean age of 58 ± 11.10 years old, with a median disease duration of 16.11 years [10.79 - 23.04]. The majority exhibited a very high or high disease activity at
baseline (median DAS28 3V 5.48 [4.70 – 6.19] and 90% (n=226) of them were concomitantly using corticosteroids and/or other disease-modifying anti-rheumatic drugs (129 with methotrexate (MTX), 96 with lefunomide and 35 with sulfasalazine). The most frequently reported comorbidities were cardiovascular disorders (37.5%), osteoporosis (7.6%) and depression (6.8%). The median RDCI score was 1.0 [0.0 – 2.0] and the majority of patients (63.6%) carried at least one comorbidity. When comparing baseline demographic and clinical characteristics of the 4 subgroups, stratified according to RDCI score (RDCI=0, 1, 2, or ≥3), we found statistically significant differences in age, age at diagnosis, sex and the prescribed anti-TNF agent (p<0.05). There was a progressive increase in the mean age in the RDCI score increased between the subgroups.

RDCI strongly correlates with the number of comorbidities (NC) (r=0.764, p<0.01). NC was weakly correlated with patient and physician global assessment of disease activity (pVAS and pHVAS) (r=0.183, p<0.01 and r=0.196, p<0.01, respectively), DAS28 3V (r=0.192, p=0.046) and HAQ-DI (r=0.301, p<0.01) at 6 months. Moreover, RDCI poorly correlated with CRP (r=0.192, p<0.01), pVAS (r=0.183, p=0.02) and HAQ-DI (r=0.202, p<0.01). Weaker correlations were also found at 12 months: NC with pHVAS (r=0.196, p<0.02), DAS28 3V (r=0.216, p<0.01) and HAQ-DI (r=0.187, p=0.04); RDCI with pHVAS (r=0.196, p=0.04).

The 12-month DAS28 remission rate was 37.8% (n=95); 6.7% (n=17) achieved EULAR good response and 54.4% (n=137) a moderate EULAR response. RDCI was not an independent predictor of DAS remission (OR 0.794, 95% CI 0.561-1.125, p = 0.194) nor it was of EULAR good/moderate response (OR 0.720, 95% CI 0.430–1.206, p=0.20). Conclusion: Although our data point to a weak association between morbidities, assessed by the RDCI, and response to a first bDMARD, it is important to consider this simple and useful tool in future prospective and broader studies, since information bias regarding comorbidities may have been responsible for our results.

FR0063 LEVEL OF N-TERMINAL FRAGMENT OF BRAIN NATRIURETIC PEPTIDE PROGENITOR AND ATHEROSCLEROTIC DAMAGE OF BRAINCHIOCAPHALIC ARTERIES IN PATIENTS WITH EARLY AND LONG-STANDING ACTIVE RHEUMATOID ARTHRITIS

H. Gerasimova1, T. Popkova1, M. Cherkasova1, E. Markelova1, S. Glukhova1, I. Kirillova1, D. Novikova1, A. Lila1, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Moscow Clinical Scientific Center, Moscow, Russian Federation

Background: The high prognostic significance of the N-terminal fragment of the B-type natriuretic peptide (NT-proBNP) concentration in the development of cardiovascular disorders (CVD) was identified for rheumatoid arthritis (RA) patients and general population.

Objectives: To investigate the significance of NT-proBNP levels in pts with early untreated and long-standing RA with high disease activity; to identify potential relationship of NT-proBNP levels with atherosclerotic lesion of the brachiocephalic arteries (BCA), traditional risk factors and inflammatory markers.

Methods: A total of 227 RA pts (76% females, 24% males, 55 [46-61] years old, moderate to high disease (DAS28=3.54; 6.5), SDAI=27[22.35], positive for ACCP (73%)/RF (87%)) were enrolled in the study: 136 pts with early RA (disease duration ≤12 months) and 91 pts with long-standing RA (>12 months). All early RA pts were not treated with glucocorticoids and disease-modifying anti-rheumatic drugs (DMARDs). Long-standing RA pts already developed the lack of efficacy/resistance and/or intolerance of DMARDs. Lack of efficacy of 3 or more DMARDs was established in 46% of pts, intolerance to previous DMARDs therapy - in 54% pts. 73% were receiving methotrexate, 21% - leflunomide, 7% - sulfasalazine, 46% glucocorticoids. Pts with early and long-standing RA were comparable in terms of age, sex, body mass index and RA activity rates (DAS28, SDAI, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels). High incidence of traditional risk factors was found in early and long-standing RA pts: the incidence rate of arterial hypertension (58% vs 68%), diabetes type 2 (7% vs 9%) and smoking (27% vs 17%). DM type 2 (4% vs 7%) were not significantly different. Pts with congestive heart failure were not included in the study. The control group consisted of 20 healthy donors, matched to pts by age and sex. Serum levels of NT-proBNP (pg/mL) were measured using electrochemiluminescence test Elecsys proBNP II (Roche Diagnostics, Switzerland). NT-proBNP levels > 125,0 pg/mL were considered as elevated.

The NT-proBNP levels were significantly higher in RA pts than in the control group (median 92,1 [48,2-164,7] pg/mL vs 55,3 [36,6-67,3] pg/mL, p<0.05). Pts with early RA had higher NT-proBNP levels (118,9 [60,2-201,3] pg/ml) than pts with long-standing RA (73,4 [43,0-114,3] pg/ml, p<0.001). Elevated NT-proBNP concentrations were found in 71 (52%) early RA pts vs 23 (21%) pts with long-standing RA (p=0.01). Atherosclerotic lesion of the carotid arteries (CAs) and BCA was detected in 73 (54%) pts with early RA and in 37 (41%) pts with long-standing RA (p>0.05). The NT-proBNP levels correlated with age (r=0,51, p<0.001), CRP (0,23, p<0,001) and IMT of BCA (r=0,46, p=0,03) in RA pts. Aforementioned correlations were significantly remained for both groups of RA pts. Association between IMT of BCA and CRP concentrations was not found.

Conclusion: NT-proBNP levels are higher in pts with active RA than in control subjects. Early untreated RA pts had a higher NT-proBNP levels than pts with disease duration >12 months and resistance or intolerance of DMARDs. The increased concentration NT-pro-BNP (>125pg/ml) were found in half of pts with early untreated RA and every fourth pts with long-standing active RA. NT-proBNP concentration correlated with CRP level in pts with active RA. Correlation between NT-pro-BNP concentrations and IMT of BCA may be indicative of possible impact of this biomarker on atherosclerotic damage of BCA in pts with early and long-standing active RA.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.5172

FR0064 SAFETY OF LOW DOSE METHOTREXATE (MTX) AND TUBERCULOSIS (TB)

A. Davidson1, A. Gunay1, I. Colmegna1, D. Lacaille2,3, H. Loewen1, M. Meltzer1, R. Scuccimarra1, Y. Mengistu1, S. Bernatsky1, C. Hitchon4, McGill University, Montreal, Canada; 2University of British Columbia, Vancouver, Canada; 3Arthritis Research Canada, Vancouver, Canada; 4University of Manitoba, Winnipeg, Canada; 5Jefferson University, Philadelphia, United States of America; 6University of Addis Ababa, Addis Ababa, Ethiopia

Background: Increased awareness of the importance of MTX in rheumatic disease is leading to more MTX use in patients from TB-endemic areas. Current management guidelines for rheumatic disease address TB in the context of biologics but not MTX use.

Objectives: To systematically review the published literature on MTX rates with TB.<30mg per week.

Methods: We searched CINAHL, Embase, Global, MEDLINE and World of Science databases (Jan 1990 to May 2018) for terms including ‘methotrexate’ and ‘tuberculosis’. We also searched citations from review articles. Titles, abstracts or full manuscripts of the 4707 reports identified were screened independently by 2 reviewers to identify studies reporting TB in patients taking MTX. Study quality was assessed using the McGill Mixed Methods Appraisal Tool (MMAT). Data was extracted on TB incidence (new TB diagnosis vs reactivation of latent TB), and outcomes (pulmonary, dissemination, death) and safety of isoniazid, INH. Descriptive summaries are presented on studies providing outcomes in patients taking MTX ≤30mg per week.

Results: After removing duplicates and studies not meeting criteria or providing sufficient information, 27 studies were included (8 cohort, 7 case-control, 1 clinical trial, 15 case reports/case series). Only 27% of articles reported data from low to moderate human development index countries. Studies were of moderate quality. Seven case control studies were heterogeneous but most demonstrated a modest increased risk of TB with MTX (Table). Five cohort studies reported TB incidence rates in rheumatic disease (treated with MTX +/- biologics) ranging from 0.002 to 1.17/100,000 patient-years. These rates were higher than comparator general population rates. Two cohort studies of MTX in RA (without biologic) reported cumulative TB incidence in Moldova (12 TB cases in 44 RA patients, 27%) and in China (9/114, 7%). Other cohort studies generated rates of overt infection (143/100,000 patient years in Spain, higher if co-prescribed with corticosteroids and other immunosuppressants in South Africa), and latent TB rates detection (16/922 RA screened, 1.7%, in Canada). When reported, rates of extra-pulmonary TB were higher than comparator general population rates. One clinical trial (China), 2 cohorts (Japan, USA) and 2 case-series (Belgium, USA) evaluated safety of INH and MTX. Isoniazid-related hepatotoxicity and neutropenia were generally more common when taken with MTX, but were usually reversible.

Conclusion: Despite a paucity of high-quality data, this review confirms that TB screening and clinical surveillance are needed in patients from TB-endemic areas who are prescribed MTX, particularly with co-administration of corticosteroids or other immunosuppressants. Isoniazid, if monitored, appears safe and prevents TB reactivation.
Objectives: We collected the information such as clinical symptom and histological finding of MTX-LPD with RA patients, and clarify the clinical features of MTX-LPD. In addition, we divided 16 MTX-LPD cases diagnosed histologically into RA, laboratory data (lymphocyte counts and sIL-2R) and treatment of MTX-LPD. In addition, it is one of the characteristics for MTX-LPD that spontaneous regression (SR) after MTX discontinuation. However, the mechanism of SR is not clarified.

Methods: We enrolled 90 MTX-LPD patients from Kagawa Prefecture, Japan between June 2005 and December 2019. Patients were diagnosed according to American College of Rheumatology (ACR) 1987 classification criteria or ACR/European League Against Rheumatism (EULAR) 2010 classification criteria, and treated with disease modifying antirheumatic drugs (DMARDs) including MTX. We collected as follow information; age, gender, duration of RA, laboratory data (lymphocyte counts and sIL-2R) and treatment of MTX-LPD. In addition, we divided 16 MTX-LPD cases diagnosed histologically into two groups (SR:CTx group; n=10:6), and analyzed the histological findings (CD4, CD8, CD163 and CD47) using the staining in immunohistochemistry (IHC) between the two groups. Each positive cell analyzed using virtual viewer soft ImageScope.

Results: Characteristics of 90 MTX-LPD patients are as follow; mean age 66.5±11.2 years, 63 female, duration of RA 18.5±19.4 years, 65 patients (72.2%) were spontaneously improved by discontinuing MTX. 58 patients (64.4%) were proven MTX-LPD histologically. In these patients, diffuse large B-cell lymphoma (DLBCL) was the most frequent histological type of MTX-LPD (56.9%). Infiltration of CD8 positive lymphocyte in the lesion was significant less in the SR cases than in the CTx cases (Figure 1). However, CD4, CD163 and CD47 positive cells had no significant difference between two groups.

Conclusion: We revealed clinical features of MTX-LPD with RA patients. In addition, CD8 positive lymphocytes are involved in tumor immunity. In this study, we suggested that the extent of CD8 positive lymphocyte infiltration may predict SR of MTX-LPD. Further study is necessary on revealing the mechanism of SR in MTX-LPD.

DOI: 10.1136/annrheumdis-2020-eular.5309
on future CVD events. Models were controlled for Framingham-D’Agostino clinical risk score, time-varying current bDMARD use and time-varying CRP.

**Results:** Sixteen patients incurred 19 events, for a total of 2.1 (95% CI 1.3-3.3) events/100 patient-years. Increasing HR for cardiovascular events was observed for ascending CAC strata; 3.87 (1.03-14.48), 6.31 (1.38-28.91) and 16.98 (4.50-64.10) for CAC≥199, CAC=100-399 and CAC≥400 respectively compared to CAC=0 (figure 1). In fully adjusted models, CAC score associated with future event risk independently of Framingham D’Agostino score, time-varying bDMARD use and time-varying CRP (HR=1.31 [95%CI 1.04-1.68]), CAC thresholds ≥100 (vs. <100) and CAC≥400 (vs. <400) in fully adjusted models similarly constituted independent predictors of long-term cardiovascular events (Figure 2).

**Conclusion:** Increasing CAC scores are strong, independent predictors of long-term cardiovascular events in RA patients without symptoms or prior diagnosis of cardiovascular disease.

**LIPID PROFILE AND BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: IS THERE AN ADDED RISK OF OSTEOPOROSIS?**

B. Touil1, H. Azzouzi1, O. Lamkhan1, F. Chennouf1, L. Linda1, 2Centre Hospitalier Universitaire Mohammed VI, Rheumatology, Oujda, Morocco

**Background:** Bone is a target in many inflammatory rheumatic diseases such as rheumatoid arthritis (RA). It has been supposed that an atherogenic lipid profile could be associated with lower bone mineral density (BMD) and vertebral fractures (VF).

**Objectives:** We aimed to evaluate the relationship between the lipid profile, BMD and the presence of VF in RA patients.

**Methods:** A cross sectional study was conducted in a population of 169 established RA. In each subject we evaluated the body mass index (BMI), tobacco use, alcohol consumption, presence of diabetes and high blood pressure, lipid profile (total cholesterol (TC), High density lipoprotein cholesterol (HDLc), low density lipoprotein cholesterol (LDLc), triglycerides (TG), and VF. RA characteristics were also assessed (disease duration, disease activity score (DAS), auto antibodies, corticosteroid intake, and secondary sjogren’s syndrome). BMD was measured by dual energy X-ray absorptiometry (DXA) in lumbar spine and femoral neck. Logistic and linear regression were performed with SPSS 20, both BMI and VF were assessed as dependent variables.

**Results:** The mean age was 55.5±11.9 years, with a female predominance (152 women). The average BMI was 26.79 ± 5.36. We had 24.3 % of hypertensive patients and 16.6 % of diabetics. The average lipid concentrations were 4.39±1 mmol/L for TC, 1.293±0.36 mmol/L for LDLc, 2.74±0.80 mmol/L for HDLc and 1.25±0.62 mmol/L for TG. At the linear regression there was no correlation between plasma lipid concentrations and BMD, whether at the lumbar spine or the femoral neck. However we found a significant correlation between VF and high TC concentrations (p=0.043, OR: 2.864, 95% CI [1.036-7.922]). At the multivariate regression, high TC levels were still associated with VF, adjusted in BMI, age and the duration of corticosteroid use (p=0.006, OR: 6.07, 95%CI: 3.24-11.37).

**EFFECTS OF ADA-LUMAB ADDED TO TREAT-TO-TARGET STRATEGY WITH METHOTREXATE AND INTRA-ARTICULAR TRIAMCINOLONE ON LIPIDS IN EARLY-AND TREATMENT NAÏVE RHEUMATOID PATIENTS: SECONDARY ANALYSES FROM THE MULTI-CENTER DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED OPERA TRIAL**

D. Masic1, K. Stengaard-Pedersen2, B. B. Logstrup3, K. Hørslev-Petersen4, M. L. Hetland5, P. Junker1, M. Østergaard6, C. Ammitzbøl7, S. Møller8, R. Christensen1, T. Ellingsen1, SDU, Research Unit of Rheumatology, Odense, Denmark; 2Aarhus University, Dep. of Rheumatology, Aarhus, Denmark; 3Aarhus University, Dep. of Cardiology, Aarhus, Denmark; 4SDU, King Christian 10th Hospital for Rheumatic Diseases, Sønderborg, Denmark; 5Rigshospitalet, COPECARE & DANBIO, Glostrup, Denmark; 6SDU, OPEN, Odense, Denmark

**Background:** Systemic inflammation in rheumatoid arthritis (RA) is associated with reduced serum lipid levels (LL) and treatment with disease modifying anti-rheumatic drugs has been associated with increased serum LL [1]. It is unclear whether the changes in serum LL reported in association with adalimumab (ADA) treatment are due to suppressed inflammation or the ADA treatment per se.

**Objectives:** The primary objective was to compare the effect of ADA + methotrexate (MTX) to placebo (PBO) + MTX on changes in low density lipoprotein cholesterol (LDL-C) from baseline to month 12 in patients with early- and treatment naïve RA. Secondary objectives were to compare the treatment groups on changes in total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), triglycerides, very low density lipoprotein cholesterol (VLDL-C) and non-HDL-C (= TC – HDL-C).

**Methods:** We present secondary analyses from the OPERA trial, which was an investigator-initiated, multicenter double-blind, placebo-controlled, treat-to-target trial of 180 early and treatment naïve RA patients, who were randomized (1:1) to oral MTX 20 mg once a week in combination with either PBO or ADA 40 mg SC EOW [2]. Any swollen joint was injected with triamcinolone hexacetonide. Lipid profiles of each patient were assessed at baseline and 12 months. All randomized patients with available LDL-C at baseline were included in Intention To Treat (ITT) analysis. Sensitivity analyses were performed on the Per Protocol (PP) and the ITT population with baseline observations carried forward (BOCF). All analyses were based on repeated measurements using mixed linear models.

**Results:** In total, 174 patients (97% of the original OPERA trial population) were included in ITT analysis (ADA n=86; PBO n=88) and 156 patients (ADA n=78; PBO n=78) completed the study with LDL-C measurements at both baseline and 12 months (PP). At baseline mean LDL-C was 2.9 mmol/L (SD 0.9) with 63 (36.2%) patients having an LDL-C above 3.0 mmol/L. There was no significant difference in LDL-C change between ADA+MTX and PBO+MTX groups after 12 months. A nearly statistically significant between-group difference in TC change was found. Other changes in LL were comparable across the two groups. Results in ITT, PP and ITT with BOCF populations were similar.

**Conclusion:** In early RA patients treated to target with methotrexate and intra-articular triamcinolone, 12 months with the addition of adalimumab did not affect lipid levels.

**PREGNANCY AND OFFSPRING OUTCOME IN RA FEMALE PATIENTS– A BOW BETWEEN CENTURIES**

M. Micu1, A. Micu2, Rehabilitation Clinical Hospital Cluj-Napoca, Rheumatology Division, Cluj-Napoca, Romania; 3Iuliu Hațegianu University of Medicine and Pharmacy, Cluj-Napoca, Romania

**Background:** Clinical and preclinical rheumatoid arthritis (RA) may negatively impact several pregnancy and offspring outcome parameters [1,2].

**Objectives:** Assessing pregnancy and offspring outcome in RA patients and controls.

**Methods:** RA pregnant patients (G1) were prospectively recruited. Demographic data, disease activity scores, immunology and obstetric/offspring outcome parameters were recorded. The same parameters were retrospectively collected (interview) in RA patients who delivered children before RA onset (G2) and in healthy subjects (C). Ethical committee approval for the study was obtained and all participants signed informed consents.

**Results:** Table 1 presents demographic and disease related data. Table 2 shows the outcome parameters in the 3 groups. G1 delivered babies between the years 2008-2019. CsDMARDs were stopped by the majority of patients in the 1st trimester of pregnancy, 2 patients continued low dose corticosteroids throughout pregnancy (Fig 1). G2 and C delivered the babies between the years 1963 and 2000.

Overall, RA pregnant patients were older at conception, had a lower number of pregnancies/deliveries and a higher rate of spontaneous abortions and ‘C’ sections compared to G2 and C. Time to pregnancy (TTP) was increased in G1 when compared to G2 and C. Both G1 and G2 newborns were smaller for their gestational age versus C, the majority of them still being in the normal range. All these aforementioned parameters showed statistical significance. Number of premature deliveries and pregnancy/offspring pathology events showed a low frequency and no difference was identified between groups when comparing them.
Fig 1:

Conclusion: Current pregnancy management guidelines implementations in RA assure a good pregnancy course in patients that have achieved remission and LDA status. RA patients show lower fertility and more miscarriages in comparison to both preclinical RA and general population. Newborns from RA mothers are healthy and show a normal gestational age/weight at delivery, yet smaller family sizes were observed. Preclinical RA does not influence fertility, pregnancy outcome and family size. Newborns belonging to G1 and G2 are smaller in comparison to general population but true hypotrophy is a rare event.

FR10071 ANALYSIS OF DATA GAPS IN RHEUMATOID ARTHRITIS

G. Candelas1, L. Silva-Fernández2, M. Montoro2, A. Hernández2, J. R. Maneiro2, V. Villaverde2, L. Carmona2, E. Loza2, S. Gómez2, M. Valderrama2, A. Ortiz2 1Hospital Clínico San Carlos, Rheumatology, Madrid, Spain; 2Complejo Hospitalario Universitario de A Coruña, Servicio de Reumatología, A Coruña, Spain; 3Pfizer, Medical Department, Madrid, Spain; 4Hospital Virgen del Puerto, Rheumatology, Plasencia, Spain; 5Hospital Universitario de Móstoles, Madrid, Spain, Esparza, Rheumatology, Móstoles, Spain; 6Instituto de salud Musculoesquelética, Madrid, Spain; 7Hospital Universitario de la Princesa, Instituto de Investigación Sanitaria la Princesa (IIS-IP), Madrid, Spain

Background: Although ideally Recommendations for the management of rheumatoid arthritis (RA) should be supported by the highest level of evidence, many of which are based on ‘expert opinion’. This means that there are knowledge gaps to which a part of the research efforts in this disease should be directed.

Objectives: 1.- Analyze the causes of the low level of evidence in some of the recommendations on diagnosis and management of RA in the main published documents
2.- Identify the knowledge gaps that justify said low level of evidence
3.- Design actions to respond to the knowledge gaps identified.

Methods: Qualitative study. A group of six experts in systematic review of the literature was selected. Fourteen documents of national and international recommendations on RA (EULAR, ACR and SER) of the last 5 years were analyzed by a peer review. They selected recommendations with low level of evidence (Oxford 4 and 5) / grade of recommendation (C and D), and classified by areas (diagnosis, monitoring, treatment, others) and then possible causes of low level of evidence were analyzed. These were submitted to a Delphi to select the 10 recommendations in which participants considered it more critical to obtain quality evidence. Subsequently, actions were proposed to improve the levels of evidence in general and, through the PICOS structure (population, intervention, comparator, study design) specific studies were proposed to respond to the issues raised in these 10 recommendations

Results: 185 recommendations were found that had a low level of evidence / grade of recommendation, most related to the treatment of RA. The two most frequent causes of this low level of evidence and / or the degree of recommendation were the absence of studies and an incorrect classification of the level of evidence and / or degree of recommendation. In addition, other reasons and methodological barriers were found for which nine critical recommendations were finally selected for which new PICOs were developed with which to propose targeted research projects

Conclusion: It is necessary to improve the methodological approach in the RA recommendations guidelines to correct errors and fill gaps with appropriate studies.

FR10072 DISCONTINUATION OF DMARD USE IN RHEUMATOID ARTHRITIS PATIENTS WITH LUNG DISEASE

S. Pedro1, T. Mikuls2,3, J. Zhuo1, K. Michaud1,2 1FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, United States of America; 2University of Nebraska Medical Center, Omaha, NE, United States of America; 3VA Nebraska-Western Iowa Health Care System, Omaha, NE, United States of America; 4Bristol-Myers Squibb, Princeton, NJ, United States of America

Background: Pulmonary manifestations such as interstitial lung disease (ILD) and chronic obstructive pulmonary disease (COPD) are frequent extra-articular features that carry a poor prognosis in Rheumatoid Arthritis (RA). Little data is available on how RA patients (pts) with pulmonary disease are managed in real-world settings.

DOl: 10.1136/annrheumdis-2020-eular.6574
Objectives: To assess treatment patterns and DMARD discontinuation in RA patients with comorbid lung disease in comparison with other RA patients.

Methods: The study included RA Patients enrolled in the Forward Databank with >1 year observation after 2000 initiating a DMARD. Forward is a forward longitudinal rheumatic disease registry in the US. RA patients’ diagnoses were rheumatologist-confirmed, and every 6 months participants completed comprehensive questionnaires regarding symptoms, disease outcomes, medications, and clinical events. Lung disease (LD+) was defined as at least one of the following: emphysema, asthma, bronchiectasis, COPD, pleural effusion, fibrosis of the lung. “RA lung” or ILD, the later classified by ICD9 codes (England 2019). DMARDs were categorized hierarchically into four groups: csDMARDs, TNFi and NTNFi (bDMARDs), and tsDMARDs. Percentage of patients who initiated different DMARDs were reported for pts with LD+/LD-. Discontinuation was analyzed by Kaplan Meier (KM) curves, log-ranks tests, and Cox regression models using time-varying covariates. Best models were created using backward selection models (10% probability of removal) and pre-defined clinical models.

Results: Of the 21,525 eligible RA patients, 13.6% had LD+ at the time they initiated a DMARD (follow-up: 69,597 pt-yrs (median 1.9 yrs/pt)). LD+ patients tended to have more severe RA outcomes and comorbidities. MTX-monotherapy (48% vs 44%, p<0.001) and NTNFi were initiated more frequently in LD+ pts with lower use of TNFi (Figure). DMARD discontinuation rates were higher among LD+ patients for all DMARD groups, but KM curves were only significantly different for csDMARDs and TNFi. Different HRs for LD+ were found depending on the model used ranging from 1.18 to 1.28, and all models revealed an increased risk of discontinuation for LD+ patients. Compared to csDMARDs, TNFi were more often discontinued (Table). Other variables associated with an increased risk of discontinuation included: HAQ, Rheumatoid Disease (RD) comorbidity index, pain, prior bDMARDs, and csDMARDs.

Conclusion: Different DMARD treatment patterns were found for LD+ patients, who tended to initiate more csDMARDs and NTNFi and less likely to initiate a TNFi. LD+ patients were at a higher risk of discontinuation irrespectively of the DMARD treatment, but with greater risk for TNF users.

Figure: DMARD treatment initiators by disease group

| Table. Cox models for DMARD discontinuation by stepwise (removal probability 10%) and clinical models including DMARD treatment. |
| Model of DMARD | Model 1 | Stepwise persistence | Model 2 | Without drugs | Stepwise | Clinical | Model 3 |
| LD+ vs LD- | 1.18 | 1.18 | 1.20 | 1.08 - 1.29 | 1.08 - 1.34 |
| TNF vs csDMard | 1.32 | 1.22 | 1.32 | 1.08 - 1.63 | 1.08 - 1.69 |
| NTNFi vs csDMard | 1.13 | 1.13 | 1.13 | 0.83 - 1.52 | 0.90 - 1.41 |
| tsDMard vs csDMard | 1.80 | 1.02 | 1.80 | 0.65 - 2.60 | 0.64 - 1.62 |

*Best models searched/Clinical adjusted for LD+/LD-, DMARDs, age, sex, education, HAQ disability, RD comorbidity index, smoking, pain, glucocorticoids, year of entry, prior bDMARDs and csDMARDs counts and MRC breath scale.

FR10073 SEROLOGICAL PREDICTORS OF THE SEVERITY OF RHEUMATOID ARTHRITIS RELATED INTERSTITIAL LUNG DISEASE

S. Rajalingham1, S. S. Shahari2, R. Sridharan1. 1Universiti Kebangsaan Malaysia Medical Centre, Kuala Lumpur, Malaysia

Background: The most common extra-articular manifestation of rheumatoid arthritis (RA) is interstitial lung disease (ILD). Although pulmonary manifestations in RA encompass the main airway, parenchyma, vasculature and pleura, ILD in particular, is associated with reduced survival. Up to 10% of RA patients suffer from clinically significant ILD while a substantial proportion have abnormal CT chest findings despite being asymptomatic. There are various biochemical and serological markers to predict the severity of the joints in RA. However, the clinical and laboratory determinants of RA related ILD (RA-ILD) are not well defined owing to the paucity of research data in this regard.

Objectives: The main objective of this study is to determine the correlation between the rheumatoid factor (RF) serotypes and the severity of RA-ILD based on computer tomography (CT) findings.

Methods: We recruited a total of 100 RA patients who were tested for IgA RF, IgG RF and IgM RF and had high resolution CT chest performed. Participants were aged above 18 years, met the 2010 ACR/EULAR RA criteria, had RA for more than 6 months, were non-smokers, not pregnant and had no known chronic lung disease or lung malignancy based on their medical records. Seventy-two patients had ILD changes on HRCT of the chest and were included in this study. The CT images were scored based on a scoring system proposed by Kazeroni et al. Ground glass opacities represented the alveolar findings whereas honeycombing and septal thickening were the interstitial findings. The ground glass and fibrosis scores were on a scale of 0-5, with higher scores for greater involvement of the lobes. For each subject, the maximum ground glass and fibrosis scores were 25, respectively.

Results: The frequency of RF positivity was comparable across the 3 serotypes (83.3% 94.7%). The correlation between the clinical variables and the CT scores are listed in Table 1. We found that the the CT scores for ground glass showed significant positive correlation with disease duration (p=0.047) and TNF levels (p<0.050) whereas the fibrosis scores had significant relationship with multiple clinical covariates i.e age (p=0.004), disease duration (p=0.042), IgA RF levels (p<0.050), IgG RF levels (p=0.041) and anti-CCP levels (p=0.006). On multivariate analysis, only IgA RF levels remained significantly (p<0.05, standardized beta coefficient =0.604) associated with the ground glass scores. As for the fibrosis scores, IgA RF levels and age were independent predictors based on multivariate analysis after adjusting for confounders, with p scores of <0.05 and 0.02, respectively.

FR10074 UNDERLYING PROBLEMS AND IMPACT OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: PRELIMINARY RESULTS OF A CROSS-SECTIONAL CASE-CONTROL STUDY

N. M. T. Roedderink, M. C. Van der Goes1,2, P. Welsing2, J. Tekstra3, F. Lafeber1, J. W. G. Jacobs1, J. M. Van Laar1. 1Utrecht University, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands; 2Meander Medical Center, Department of Rheumatology, Amersfoort, Netherlands
Background: Difficult-to-treat (D2T) RA is defined here by signs and symptoms, suggestive of active/progressive RA, which are perceived as problematic by rheumatologist and/or patient, and are present despite treatment according to EULAR recommendations including ≥2 b/tsDMARDs with different mechanisms of action. Its treatment is generally based on trial-and-error and challenged by several underlying problems (Figure 1), of which the exact impact is unknown.

Objectives: To obtain insight into the potential problems underlying D2T RA and into its impact.

Methods: Consecutive RA patients fulfilling the 2010 ACR/EULAR classification criteria, treated according to current standard of care for ≥1 year, are being enrolled, and categorised as D2T or not (controls). Potential problems underlying D2T RA (Figure 1) and its impact on quality of life and physical functioning were assessed and compared between the two patient groups.

Results: In this preliminary analysis, 45 patients are classified as having D2T RA and 100 are controls (Table 1). Fibromyalgia (33 vs 9%), depression (18 vs 4%), a mismatch between patient and rheumatologist in wish to adapt treatment (51 vs 15%) and DMARD discontinuation because of adverse events (4% vs 0%), a mismatch between patient and rheumatologist in wish to adapt treatment (51 vs 15%) and DMARD discontinuation because of adverse events (4% vs 0%), were statistically significantly more frequent in D2T RA patients than in controls. Higher levels of threatening illness perception and helpless-

Conclusions: This first prospective study describing a cohort of D2T RA patients shows higher occurrences of potential underlying problems and a higher clinical impact. These should be recognised in daily practice and taken into account before considering another DMARD switch. More detailed research on disease state (biomarkers, radiographic damage) and use of medication (drug levels and in-depth interviews on treatment non-adherence) will follow.

FRI0075 DECREASED RISKS OF HOSPITALIZED INFECTION UNDER TARGETED THERAPIES VS METHOTREXATE IN ELDERLY AND OLDER ELDERLY PATIENTS COMPARING TO YOUNGER PATIENTS WITH RHEUMATOID ARTHRITIS USING JAPANESE HEALTH INSURANCE DATABASE

Background: Recently, vital prognosis has been improved in patients with rheumatoid arthritis (RA). In elderly patients, it is difficult to establish a treatment strategy due to multi-morbidities and treatment-related risks. Since older age is a significant risk factor of serious infections, one of the primary concerns during treatment of RA, rheumatologists should always strike a balance between efficacy and safety of the immunosuppressive treatment. However, infection data under the targeted therapy (TT) in elderly patients is still limited to date.

Objectives: To compare the risk of hospitalized infection (HI) among young, elderly, and older elderly patients with RA using the Japanese health insurance database.

Methods: This retrospective longitudinal population-based study was conducted using claims data in Japan provided by Medical Data Vision Co., Ltd. We defined individuals as RA cases if they met all of the following: 1) having at least one ICD-10 code (M05x, M08x except for M061, or M081 except for M061 and M082); 2) having at least one prescription of disease-modifying antirheumatic drugs (DMARDs) including methotrexate (MTX) and TT (biological DMARDs and Janus kinase inhibitors) between April 2008 and September 2018; and 3)
16 years old or older. We define the month patients met the above all criteria for the first time in this database as the index month. We excluded patients who were prescribed any DMARDs during the first 12 months from MTX users and those with prescription of any TT during the first 12 months from TT users (i.e., prevalent users). Among the study population, we divided patients into 3 groups according to their age at the index month; young group (16-64), elderly group (65-74), and older elderly group (75+). The observation started from the index month and ended at 36 months later, the last month of the exposure of DMARDs, the month of loss of follow-up, or September 2019, whichever came first. HI was defined by ICD10 code with one prescription of predefined drugs for each infection during hospitalizations. Some of HI's were defined by ICD10 code alone.

**Results:** In this study, 8269, 6454, 5745 patients with RA were included in the young, elderly, and older elderly groups, respectively. The incidence rate (IR) of HI ([100 patient-years [PY] ]/[3,956,138]) in the young group, 5.8/[3,956,138] in the elderly group, and 12.0/[115,128] in the older elderly group. The IR rate (IRR) of HI (reference: the young group) was 1.7/[1-5-9] in the elderly group and 3.6/[2-4-0] in the older elderly group. In the young group, the IRR of HI in TT users vs MTX users was significantly elevated (1.8 [1.5-2.1]), whereas, those of the elderly and the older elderly groups were significantly decreased (IRR 0.8 [0.7-0.9] for elderly; 0.8 [0.5-0.7] for older elderly). Concomitant use of immunosuppressive DMARDs or prednisone ≥10mg/day with TT became less frequent with aging.

**Conclusion:** The elderly and older elderly patients had significantly higher risks of HI compared to the young. The risk of HI under the TT compared to MTX was decreased in the elderly patients, probably due to adjusting for treatment by attending physicians.

**Disclosure of Interests:** None declared
Background: Rheumatoid Arthritis (RA) and Psoriatic arthritis (PsA) are both chronic, progressive inflammatory arthritis that can cause significant disability and morbidity. Depression in RA has been associated with higher levels of disease activity, pain, fatigue, work disability, lower treatment compliance and increased suicidal risk and mortality [1]. PsA patients suffer from psoriasis and joint involvement; hence have greater odds of depression by 2.1 times compared with RA [2].

Objectives: To compare the prevalence rates of depression and anxiety and its associated factors between RA and PsA patients in Hospital Putrajaya.

Methods: A cross sectional survey using the Hospital Anxiety and Depression Scale (HADS) questionnaire were distributed to 300 patients who attended rheumatology outpatient clinic from February – April 2019. The HADS was categorized into 3 groups based on their scores 0-7 (Normal); 8-10 (Borderline); and 11-21 (Abnormal). Data on patient demographics and components of disease assessment scores were recorded. Disease activity was assessed using DAS 28-CRP for all patients. Additional evaluation using Bath Ankylosing Spondylitis Disease Activity Score (BASDAI) and body surface area (BSA) were done for PsA patients. P value of < 0.05 was taken as significant.

Results: In total, 205 RA and 73 PsA patients were eligible for analysis. Majority of the patients were female, Malay and married for both groups. The mean age group for RA and PsA were 56.2 ± 11.9 years and 51.0 ± 14.6 years. The mean duration of disease for RA were 8 ± 10 years; while for PsA were 6 ± 11 years. The prevalence rates of depression and anxiety for RA were 8.3% and 13.7%; and PsA were 9.6% and 17.8% respectively. Borderline scores for depression occurred in 16.1% of RA patients and 12.3% for PsA. Twenty percent of RA patients (n=41) and twenty-four percent of PsA patients (n=18) scored borderline for anxiety. The significant positive correlations with depression and anxiety in RA include high disease activity scores (r = 0.27; r = 0.31), number of tender joints (r = 0.26; r = 0.24) and pain (r = 0.29; r = 0.27). Higher number of swollen joints significantly correlated with depression (r = 0.16) but not with anxiety. RA patients with ischemic Heart Disease (IHD) a heart failure have higher depression scores (p < 0.05). As for PsA group, high BASDAI score (anxiety; r = 0.34, depression; r = 0.26) and psoriasis involving head and neck region (p < 0.05) were significant associated factors. Age was inversely correlated with anxiety in the PsA group.

Conclusion: There is higher prevalence of anxiety in both RA and PsA as compared to depression. Higher disease activity scores were associated with depression and anxiety in both RA and PsA with axial involvement.

Objectives: The study was conducted in consecutive RA patients, treated in the Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, Poland. The study group consisted of 113 patients (93 women, 20 men), with the mean (SD) age 59.4 (19.0), disease duration 12.9 (10.3) years.

The cut-off between EORA and YORA was set at 60 years of age. There were 63 (55.8%) EORA and 50 (44.2%) YORA patients. Demographic and clinical information was obtained through structured interview, review of medical records and laboratory tests. Disease activity was assessed based on joint counts and Disease-Activity Score of 28 joints (DAS28).

Conclusion: There are still 14% of patients with RA who were difficult-to-treat in real world in spite of intensive treatment. Their characteristics are distinct by the cause of difficulty to treat, suggesting the approach to difficult-to-treat RA should be personalized.

Semi-structured interviews took place in an age-stratified sample to explore how the diagnosis of RA has influenced patients’ life. Items of questionnaires were compared using the chi-square test. Interviews were annotated by two independent readers. Codes were taxonomically organized and linked to themes using NVivo 12.

Results: 32 (36%) of the 90 invited patients participated and 28 completed all psycho-emotional questionnaires. Twelve out of 32 patients (37.5%) were classified as frail by the GFI. On the GDS at current age, 6/12 frail patients had signs of depression compared to 2/17 non-frail patients (p=0.04) (Table 1). More frail patients had signs of an anxiety disorder on the HADS, both at current age and age 40 (age 40: 7/11 frail patients versus 0/0 non-frail patients, p<0.01; Table 1). Results on the individual level were more blurred: 3 (42%) out of 7 frail patients were anxious at age 40, but not at current age. The loneliness, social support and HADS depression questionnaires showed no difference between frail and non-frail patients, both at current age and age 40. A stratified sample of 10/32 (31%) patients were interviewed of which 5 (50%) were frail on the GFI. Frail patients more often expressed anxious feelings at current age. Since the diagnosis of RA, frail patients worried more about the future, i.e. about the progression of RA. Non-frail patients tended to be more optimistic. In the interviews, patients expressed not having feelings of depression and anxiety at age 40.

Conclusion: Although it is difficult to disentangle the causal conundrum between psycho-emotional health and frailty, frail patients were on a group level more anxious at younger age on the HADS in our study. Psychiatric symptomatology might be misinterpreted for frailty at current age. Limitations of our study include a high chance on amplified memory bias.

FR00082 SLEEP PROBLEMS IN EARLY RHEUMATOID ARTHRITIS

T. Lehtonen, T. Åkerstedt, L. Lyne, L. Klareskog, S. Saevarsdottir, L. Alfredsson, H. Westerling, Karolinska Institutet, Stockholm, Sweden; Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden

Background: It is well known that patients with established RA suffer from problems with sleep quality[1]. There are however few, if any, studies on sleep quality among newly diagnosed patients.

Objectives: To investigate the sleep quality among patients newly diagnosed with RA.

Methods: We used the Swedish study Epidemiological Investigation of RA (EIRA) including patients at the time of diagnosis, based on the 1987 ACR criteria during 2008-2016. At 1 and 3 years after diagnosis, the patients were sent a questionnaire in which they were asked to rate their sleep quality on 10 different questions. We then calculated 6 different sleep components consisting of insomnia, non-restorative sleep, sleep problems, general quality of sleep, if poor sleep affected the health and if they were getting enough sleep[2].

Sleep problems were defined as mostly or always having problems with either of the following: falling asleep, many awakenings with difficulties to go back to sleep, waking up early or having disturbed/restless sleep. Insomnia was defined as answering mostly or always on either problem with falling asleep, many awakenings with difficulties to go back to sleep or waking up early, in combination with mostly or always being tired during the day.

Having problems with non-restorative sleep was defined as mostly or always having trouble waking up or not feeling well rested when waking up. We defined having problem with not getting enough sleep, sleep quality affecting the health and poor sleep quality as reporting any of the two highest scores on the corresponding questions.

We then calculated the proportion of people experiencing no problems at 1 or 3 years after RA diagnosis, developing problems, improving or always having problems with their sleep.

Results: We identified 1483 patients with data at either one or both time points. The mean age was 59 years (IQR 19), and 1063 (72%) were women. At year 1, 36% of the patients reported having at least one type of sleep problem, after 3 years, this figure was 29%. Over 20% of the patients reported having “Rather big” or “Very big” problems with sleep after one year (Table 1) and 31% had problems at one or both time points (Table 2). Disturbed sleep was a problem for their health in 20% of the patients and 11% reported having “poor” or “very poor” sleep quality at both times. Insomnia was experienced by 118 (10%) patients at 1 year and 112 (11%) at 3 years.

</tr>
<tr>
<td>Problem with non-restorative sleep</td>
<td>654 (78%)</td>
<td>71 (8%) 46 (5%) 67 (8%)</td>
</tr>
</tbody>
</table>

Conclusion: In a population-based early RA cohort receiving today’s standard care, 30% of the patients reported some type of sleep problem during the first 3 years. Although this is a lower rate than has been reported in established RA, this is a significant proportion of RA patients, and these findings warrant further studies to closer identify the course of sleep problems and the factors influencing it such as pain.

FR00083 GLUCOCORTICOID USE IS ASSOCIATED WITH DETERIORATION OF MUSCLE QUALITY AND FUNCTION: FROM THE CHIKARA STUDY

V. Yamada, M. Tada, K. Mandai, N. Hidaka, K. Inui, H. Nakamura, Osaka City University Graduate School of Medicine, Department of Orthopedics, Osaka, Japan; Osaka City General Hospital, Department of Orthopedic Surgery, Osaka, Japan
Background: We previously reported that glucocorticoid (GC) use was an independent risk factor for developing sarcopenia in patients with rheumatoid arthritis (RA). On the other hand, sarcopenia was not associated with deterioration of muscle function (dynamy).  

Objectives: Factors associated with deterioration of muscle quality and function were prospectively investigated.  

Methods: Muscle quality and function were examined by measuring power, speed, and balance in standing-up motion using an exercise functional analysis device (BM-220, Tanita, Japan) at baseline and at 2-year follow-up in the prospective, observational CHIKARA study. Associations between changes in these parameters (Δ muscle quality, Δ muscle function) and body composition, disease activity, treatment, physical function, and history of falls and fractures were investigated by univariate and multivariate analyses.  

Results: Eighty-one RA patients completed the survey. Their average age was 66 years, disease duration was 5.3 years, the simplified disease activity index (SDAI) was 5.3, and the modified Health Assessment Questionnaire (mHAQ) was 0.25 at baseline. Of the patients, 12.3% used GCs at an average dose of 0.38 mg/day over 2 years. The average GC dose was negatively correlated with changes in muscle quality (r=-0.25, p=0.03), power (r=-0.23, p=0.04), and speed (r=-0.24, p=0.03). The SDAI at baseline was negatively correlated with power (r=-0.23, p=0.04) and speed (r=0.22, p=0.05) (Table 1). No factor was associated with the mHAQ and a history of falls. No independent factor was identified on multiple regression analysis.

Δ, changes from baseline; GC, glucocorticoid; CRP, C-reactive protein; MMP-3, matrix metalloproteinase 3; DAS, Disease Activity Score; ESR, erythrocyte sedimentation rate; SDAI, simplified disease activity index; mHAQ, modified Health Assessment Questionnaire; SMI, skeletal muscle index; BMR, basal metabolic rate.

Conclusion: GC use was associated with deterioration in muscle quality and function, as well as sarcopenia development. GC use adversely affected muscle quality, function, and balance, and disease activity control is important to prevent deterioration of muscle function, as well as sarcopenia development. GC use adversely affected muscle quality and function, and history of falls and fractures were investigated by univariate and multivariate analyses.

RETENTION RATE OF ADALIMUMAB AND ABP 501 IN THE TREATMENT OF A LARGE COHORT OF PATIENTS WITH INFLAMMATORY ARTHRITIS: A REAL LIFE RETROSPECTIVE ANALYSIS

Background: The recent introduction of ABP 501, an adalimumab biosimilar, in treatment of rheumatic diseases was supported by a comprehensive comparability exercise with its originator. On the other hand observational studies comparing adalimumab and ABP 501 in inflammatory arthritis are still lacking.

Objectives: To compare the clinical outcomes of the treatment with adalimumab, both originator and biosimilar, in a large cohort of patients affected by autoimmune arthritis in a real life setting.

Methods: We retrospectively analysed the baseline characteristics and the retention rate in a cohort of patients who received at least a course of adalimumab (originator or biosimilar ABP 501) in eight Rheumatology Units from September 2018 to January 2020. We stratified the study population according to the biosimilar use. Descriptive data are presented by medians (interquartile range [IQR]) for continuous data or as numbers (percentages) for categorical data. Drug survival distribution curves were computed by the Kaplan-Meier method and compared by a stratified log-rank test. P values ≤0.05 were considered statistically significant.

Results: 764 patients (53.4% female, median age 55 [44-66] years, median disease duration 60 [25-149] months) treated with adalimumab were included in the analysis. 308 (40.3%) were affected by rheumatoid arthritis, 244 (31.9%) by psoriatic arthritis, and 212 (27.7%) by axial spondylarthritis. 558 (73%) were treated with adalimumab originator and 206 (27%) with ABP 501. Among the biosimilars 60 (29.1%) patients were naive to adalimumab treatment. The overall 6-month retention rate for adalimumab and ABP 501 were 93.9% and 91.2% respectively, without significant differences between the groups (p=0.541). Patients switching from originator to biosimilar showed and overall higher treatment survival when compared to naive (6-month retention rate 95% vs 90-4%), although it was not significant (p=0.179).

Conclusion: In our retrospective study adalimumab originator and its biosimilar ABP 501 showed the same effectiveness. Patients switching from originator to biosimilar showed an higher retention rate when compared to naive.

FR10087 DURABILITY OF CERTOLIZUMAB PEGOL IN PATIENTS WITH RHEUMATOID ARTHRITIS OR PSoriasI OVER THREE YEARS: AN ANALYSIS OF POOLED CLINICAL TRIAL DATA

V. Bykerk1, A. B. Gottlieb2, K. Reich3, Y. Tanaka4, K. Winthrop5, C. Popova6, N. Tilt7, A. Blauvelt8

Background: Durability over time varies according to the safety, tolerability and efficacy of a drug. However, durability may vary between patient (pt) subgroups, and physicians should consider pt characteristics when making treatment decisions. Certolizumab pegol (CZP) is an anti-tumour necrosis factor (anti-TNF) agent approved for the treatment of chronic inflammatory diseases, including rheumatoid arthritis (RA) and plaque psoriasis (PSO). However, little is known about the impact of pt baseline characteristics on long-term CZP durability.

Objectives: To investigate the durability of CZP and reasons for discontinuation over 3 yrs in subgroups of pts with RA or PSO using pooled clinical trial data.

Methods: 27 RA and 3 PSO clinical trials were pooled for indication-specific analyses. Kaplan-Meier curves were calculated to estimate CZP durability for pt subgroups by age, gender, disease duration, prior anti-TNF use and geographic region. Reasons for CZP discontinuation were investigated.

Results: 6927 RA and 1112 PSO pts were included; mean ages were 53.0 yrs (standard deviation [SD]: 12.2 yrs) and 45.4 (13.0 yrs) respectively. 79.3% RA pts were female (of all patients, 19.4% were women of childbearing age [18–<45 yrs; WoCBA]) compared with 33.5% (15.2% WoCBA) in PSO. Mean disease durations were 6.4 (6.9) yrs for RA and 18.4 (12.3) yrs for PSO. 18.5% RA and 13.3% PSO pts had prior anti-TNF use. Maximum CZP exposure was ~8 yrs for RA and ~3 yrs for PSO. At 1 yr, 63.4% of RA pts remained on CZP vs 80.3% PSO pts, decreasing to 49.2% RA pts and 70.1% PSO pts at 3 yrs (Table 1). Reasons for discontinuation, at any time during the trials, included lack of efficacy (RA 13.9%; PSO 18%), adverse events (RA 11.9%; PSO 8.1%), consent withdrawn (RA 6.7%; PSO 6.7%), lost to follow-up (RA 1.8%; PSO 4.3%), protocol violation (RA 1.7%; PSO 0.3%) and other (RA 9.2%; PSO 8.7%). In RA pts, CZP durability was lower in the elderly and in pts with disease duration <1 yr. In PSO, durability was lower in pts with disease duration <1 yr or prior anti-TNF use. Durability was lower in WoCBA pts than male pts aged 18–<45 yrs for both indications. CZP durability was lower in Western Europe and North America compared to other regions.

Conclusion: Overall, CZP durability was similar to that reported for other anti-TNFs with some differences between indication and subgroups. Factors influencing durability included age, disease duration and geographic region. Gender differences were observed in the 18–45 yrs age group, however, both male and female CZP durability was higher than in older RA pts.

Notes: [a] For PSO, the 3 year analysis was calculated with Week 144 data. CZP: certolizumab pegol; N: North; PSO: psoriasis; RA: rheumatoid arthritis; TNF: tumour necrosis factor; W: Western; yrs: years.
agents have been developed for RA, and targets, such as IL-6 and TNFα, are associated with liver function. However, the association between serum bilirubin and treatment response in RA patients treated with molecular-targeted agents is still unknown.

Objectives: We aimed to evaluate the role of serum bilirubin in the prediction of the early treatment response in RA patients who initiated molecular-targeted agents.

Methods: We retrospectively recruited biological naïve RA patients (n=292) with moderate-to-high disease activity from a tertiary hospital between Jan 2013 and Dec 2019. Patients with viral hepatitis, drug-induced hepatitis, or alcoholic liver disease were excluded. Molecular-targeted agents included tocilizumab (TCZ, n=40), adalimumab (ADA, n=59), etanercept (ETN, n=66), golimumab (GOL, n=60), abatacept (ABA, n=31), and tofacitinib (TOF, n=36). Clinical and laboratory data were collected from electronic medical records. Patients were categorized into an increased bilirubin group (higher serum bilirubin at 3 months than at baseline) and decreased bilirubin group (equal or lower serum bilirubin at 3 months than at baseline). At 6 months of treatment, good response (defined as a DAS28 score ≤3.2) was evaluated. Multivariate logistic regression analysis and multiple linear regression analysis were used to evaluate the association between serum bilirubin and treatment response. The variables included in the multiple logistic and linear regression analyses were age, female sex, rheumatoid factor, prednisolone, DMARDs, baseline liver enzymes, baseline DAS28 score, and components.

Results: The mean serum bilirubin level at baseline was 4.7±1.8 mg/dL. After 6 months of treatment, 180 (61.6%) patients achieved good responses. The mean serum bilirubin levels at 3 and 6 months were 5.3±2.3 and 5.5±2.2 mg/dL, respectively. At 6 months, a good response was more frequent in the increased bilirubin group than in the decreased bilirubin group (71.2% [99/139] vs. 52.9% [55/104], p=0.001). In multivariate logistic regression analysis, the ORs among baseline serum bilirubin and 1.377 (95% CI 1.146–1.654, p=0.001) for the increased bilirubin group than in the decreased bilirubin group (71.2% [99/139] vs. 52.9% [55/104], p=0.001).

Conclusion: High baseline serum bilirubin and an increase in serum bilirubin during treatment are helpful to predict a good response to molecular-targeted agents, especially TCZ.

Background: Clinical trial and real-world evidence have both firmly established efficacy and safety of intravenous (IV) and subcutaneous (SC) tocilizumab, both as monotherapy or in combination with a conventional disease modifying anti-rheumatic drug (cDMARD). However, tocilizumab’s relative efficacy to the new Janus kinase (JAK) inhibitor class of therapies is less certain, given the lack of head-to-head trials.

Objectives: To evaluate the relative efficacy of: 1) combination tocilizumab plus cDMARD to other TIMs plus a cDMARD in TIM-naive or mixed (<20% TIM-experienced) adults with moderate to severe RA; 2) tocilizumab monotherapy to other TIM monotherapies in TIM-naive or mixed adults with moderate to severe RA. Efficacy was defined as achievement of an ACR20 response or better at 24 weeks.

Methods: Randomized controlled trials (RCTs) were selected from a recent systematic literature review conducted by the Institute for Clinical and Economic Review (ICER), as well as from a trial for upadacitinib (SELECT-COMPARE, NCT02629159), which was not included in the ICER 2017 report. Treatments included JAK inhibitors (upadacitinib, baricitinib, and tofacitinib), tumor necrosis factor alpha inhibitors (TNFi; adalimumab, certolizumab pegol, etanercept, golimumab, and infliximab), and other non-TNFis (rituximab, sarilumab, tocilizumab, and abatacept). A Bayesian NMA was performed in OpenBUGS and R to evaluate comparative efficacy using a random effects model for combination therapy and fixed effects model for monotherapy. Model selection was based on deviance information criterion. Forest plots of relative risks (RR) are presented.

Results: In combination therapy analysis, a total of 25 studies were included with a pooled study population of 17,508 patients. Study populations were predominantly female (mean 79%, range 39-95%), and had a baseline mean age of 52 years (range 47-58), mean disease duration of 8 years (range 2-12), and mean DAS28 score of 6 (range 5-7). When compared to cDMARD, all TIMs were 1.69 to 2.22 times more likely to achieve an ACR20 response or better at 24 Weeks (statistically significant) (Figure 1). In pair-wise comparison, tocilizumab IV and SC did not differ from all other TIMs, including JAK inhibitors (no statistically significant difference). In monotherapy analysis, a total of 5 studies were included with a pooled study population of 1,189 patients. Study populations were predominantly female (mean 82%, range 75-90%), had a baseline mean age of 53 years (range 51-54), mean disease duration of 6 years (range 2-9), and mean DAS28 score of 6 (range 5-7). When compared to cDMARD, all TIMs were 1.65 to 1.84 times more likely to achieve ACR20 response or better (statistically significant) (Figure 2). In pair-wise comparison, tocilizumab IV was associated with a greater likelihood of achieving an ACR20 response or better compared to adalimumab (RR=1.10, 95% credible interval (CrI) = 1.03,1.29).

Conclusion: Results of this NMA demonstrate similar efficacy (ACR20 at week 24) between tocilizumab (IV and SC) and other TIMs, including new JAK inhibitors, when used in combination as a TIM among TIM-naive/mixed patient populations. Tocilizumab IV monotherapy had more favorable efficacy than adalimumab monotherapy. Patients unable to tolerate cDMARDs may experience additional value from tocilizumab compared to adalimumab.

Figure 1. ACR20 at 24 weeks (combination therapy) — Compared to cDMARD all TIMs, in combination with cDMARDs, were 1.69 to 2.22 times more likely to achieve an ACR20 response*
MAINTENANCE OF CLINICAL RESPONSE WITH ABATACEPT IN COMBINATION WITH MTX IN INDIVIDUAL PATIENTS WITH EARLY RA WHO ARE MTX-NAIVE AND ANTI-CITRULLINATED PROTEIN ANTIBODY (ACPA)+: RESULTS FROM THE INDUCTION PERIOD OF AVERT-2, A RANDOMISED PHASE III STUDY

P. Emery¹, Y. Tanaka², V. Bykerk³, T. Huizinga³, G. Citera⁶, G. Huang⁷, S. Connolly⁷, Y. Elbez⁸, R. Wong⁹, K. Lozenski⁹, R. Fleischmann⁹.

Background: In the 56-wk induction period (IP) of the Phase IllB Assessing Very Early RA Treatment (AVERT)-2 trial (NCT02504268), more patients (pts) achieved SDAI remission (≤3.3) with abatacept (ABA) + MTX vs ABA placebo (PBO) + MTX at IP Wk 52.² It is unknown whether each individual pt within a treatment (Tx) group achieves and sustains the same efficacy endpoints at all time points during the IP.

Objectives: To investigate whether ABA effectiveness is sustained by individual pts who achieved SDAI remission (≤3.3), SDAI low disease activity (>3.3–11) or SDAI remission (≤3.3) with ABA placebo (PBO) + MTX at IP Wks 40/52.

Methods: Pts were randomised 3:2 to blinded SC ABA (125 mg/wk) + MTX or PBO + MTX at IP Wk 52. Inclusion criteria: diagnosis (ACR/EULAR 2010 criteria); RA duration ≤6 mos; SDAI >11; ACPA+; CRP >3 mg/L or ESR ≥28 mm/h; TJC ≥3 and SJC ≥3; DMARD naïve. Response rates were investigated by Tx arm in the cohort 1 analysis population (all randomised pts treated in the IP [intent-to-treat analysis]).

Results: Of randomised cohort 1, 752 pts were treated during the IP: 451 with ABA + MTX and 301 with ABA PBO + MTX. Baseline characteristics were similar across Tx arms.¹ Stringent SDAI remission endpoint at IP Wk 24 was achieved by 22% of ABA + MTX-treated pts; of these, 56% sustained SDAI remission at IP Wks 40/52 (Table). A similar proportion of ABA + MTX-treated pts achieved SDAI remission (17%) and sustained (58%) Boolean remission at IP Wks 24 and 40/52. At IP Wk 24, 42% of ABA + MTX-treated pts achieved SDA28 (CRP) <2.6 and 74% sustained DAS28 (CRP) <2.6 to IP Wks 40/52; a high proportion of patients achieved clinically meaningful endpoints such as ACR50/70 at IP Wk 24 with weekly SC abatacept, sustained their responses to Wks 40/52. The high proportion of patients achieving early stringent remission and response to SC abatacept by individual pts may be indicative of sustained efficacy over time.

A STUDY OF THERAPEUTIC PREFERENCES IN RHEUMATOID ARTHRITIS AFTER FAILURE OF A FIRST-LINE STRATEGY INCLUDING METHOTREXATE, USING THE DISCRETE CHOICE EXPERIMENTS METHODOLOGY

E. Senbel¹, F. Durand¹, B. Roux², F. Z. Badaoui¹, B. Fautre¹,¹ Private Practice, Marseille, France; ¹Lilly France, Fegersheim, France; ²FAST4, Nîmes, France; ³Sorbonne University, Assistance Publique Hôpitaux de Paris, France

Figure 2. ACR20 at 24 weeks (monotherapy)- Compared to cDMARD all TIMs given as monotherapy were 1.65 to 1.84 times more likely to achieve ACR20 response²
Background: Therapeutic decisions in patients with rheumatoid arthritis (RA) who have an inadequate response to methotrexate (MTX-IR) are complex. European guidelines position at the same level all biological disease-modifying anti- rheumatic drugs (bDMARDs) and targeted synthetic DMARDs (sDMARDs) for the treatment of RA. Furthermore, therapeutic decisions, or physician preferences, may be influenced by many factors related to patients and/or physicians.

Objectives: To describe the therapeutic preferences of physicians involved in the management of RA after failure of a first-line strategy (including MTX) and the influence of predefined factors on these preferences.

Methods: We planned to include 216 rheumatologists experienced in the management of RA in this cross-sectional multicenter study. A total of 64 hypothetical clinical cases (vignettes) were developed from a random combination of the following parameters: presence or absence of poor prognostic factors (1) RA-related autoantibodies, (2) structural damage progression on X-ray, (3) high or moderate disease activity, and presence or absence of a history of (4) infections, (5) pulmonary involvement, and (6) cardiovascular disease. Each participant was asked to complete 8 vignettes and were asked to choose the most and least appropriate therapeutic option (best-worst [BW] scaling method) from 3 of the following: replacing MTX by another conventional (c) sDMARD; adding one or more csDMARDs to MTX; adding a bDMARD (TNF inhibitor [TNFi], tocilizumab [TCZ], abatacept [ABA] or rituximab [RTX]). Each vignette was assessed by between 20 and 28 rheumatologists with a 94% completion rate. TNF inhibitors were the strategy of choice in 80% of participants' preferences without directly asking them to state their preferred options. Statistical analyses were carried out using SAS (version 9.4, or R (version 3.5.1).

Results: A total of 211 French rheumatologists were recruited. Half of them had a hospital-only activity, 25% office-only activity and the rest had mixed activity. Each vignette was assessed by between 20 and 28 rheumatologists with a 94% completion rate. TNF inhibitors were the strategy of choice in 80% of the vignettes. ABA was the second preferred strategy in 75% of the vignettes; except in the 20% of patients with a history of infection and pulmonary comorbidity where it was the first choice. TCZ was chosen as a third strategy. All other strategies were associated with a negative BW score. Factors related to the prescribing physician appear to have no or only a limited impact on therapeutic decisions.

Conclusion: This study provides information on the prescription habits of French rheumatologists in MTX-IR patients in RA, and reveals a conservative trend with TNFi the main therapeutic choice and ABA for patients with pulmonary involvement or high risk of infection. The study should be repeated in the future to include new therapeutic options.

DOI: 10.1136/annrheumdis-2020-eular.1484

Table. Proportion of responders*
Background: Three definitions of refractory rheumatoid arthritis (RRA) have been proposed: Buch’s (B-RRA), i.e. failure of ≥2 anti-cytokine and ≥2 cell-targeted bDMARDs [1]; Kearsley-Fleet’s (KF-RRA), i.e. exposure to ≥3 bDMARDs classes [2]; De Hair’s (DH-RRA), i.e. signs and/or symptoms of RA activity and failure of ≥1 csDMARD and ≥2 bDMARDs [3].

Objectives: To evaluate the rate of RRA according to the three definitions in a monocentric cohort with two cross-sectional analyses in 2012 and 2019. We investigated also the major determinants of each definition. Secondary objective was to evaluate the most frequent treatments in RRA patients.

Methods: Patients affected by RA followed at Padova University Hospital were included at two different time points. In the 2012 cohort patients on bDMARDs on 31st December 2012 and in the 2019 cohort patients on b/target synthetic DMARDs (tsDMARD) on 1st March 2019. Factors independently associated with RRA definitions were tested with multivariable regression analysis, including all variables achieving a p<0.10 in the univariate analysis.

Results: We included 260 patients in the 2012 cohort and 571 in the 2019 cohort. Rate of RRA in 2012 cohort was: 23 (8.8%) B-RRA, 57 (21.9%) KF-RRA and 57 (10%) DH-RRA. Following multivariate regression analysis, the prevalence of RRA was: 26.6% B-RRA, 21.1% KF-RRA and 10% DH-RRA.

Conclusion: Rate of RRA in the 2019 cohort was 10-30% which is higher compared to the 2012 cohort. This might be explained by the fact that RRA definitions are mainly affected by the number of bDMARDs. Thus, an accurate RRA definition should consider not only the number of treatments but also the current disease activity. Factors associated with RRA definitions are shown in Table 1. Secondary objective was to evaluate the most frequent treatments in RRA patients. However, TNF inhibitors were less frequently prescribed compared to the 2012 cohort. This might be explained by the fact that RRA definition is mainly affected by the number of treatments, but also by the current disease activity. An accurate RRA definition should consider not only the number of treatments but also the current disease activity. Factors associated with RRA definitions are shown in Table 1. Secondary objective was to evaluate the most frequent treatments in RRA patients. However, TNF inhibitors were less frequently prescribed compared to the 2012 cohort. This might be explained by the fact that RRA definition is mainly affected by the number of treatments, but also by the current disease activity. An accurate RRA definition should consider not only the number of treatments but also the current disease activity. Factors associated with RRA definitions are shown in Table 1. An accurate RRA definition should consider not only the number of treatments but also the current disease activity. Factors associated with RRA definitions are shown in Table 1. Secondary objective was to evaluate the most frequent treatments in RRA patients. However, TNF inhibitors were less frequently prescribed compared to the 2012 cohort. This might be explained by the fact that RRA definition is mainly affected by the number of treatments, but also by the current disease activity. In the group of pts treated with TOFA ΔNT-proBNP level significantly correlated with the percentage change in DAS 28 (r=0.41, p<0.038), there was no direct correlation with changes in the parameters of the LV diastolic function.

Conclusion: TCC and TOFA treatment for 12 m reduced NT-proBNP levels in RA pts without clinically manifest CVD and CHF. Falling NT-proBNP concentrations are associated with positive dynamics of RA activity (DAS 28) and inflammatory markers (CRP, ESR), therefore allowing to suggest that increased NT-proBNP levels should be considered as a component of disease activity. Correlation between ΔNT-proBNP and ΔEe/LF may be indicative as possible impact of these biomarkers on the LV diastolic function's development in RA pts.

Lévy-Weil27, Sorbonne Université, Pitié Salpêtrière Hospital, Paris, France; 2Rheumatology Department, University Hospital of Lille, Lille, France; 3Rheumatology Department, University Hospital of Bordeaux, Bordeaux, France; 4Saripro Working Group, Paris, France; 5Psychiatry Department, University Hospital of Saint Etienne, Saint Etienne, France; 6INSEMK 1059, Rheumatology Department, University Hospital of Saint Etienne, Saint Etienne, France; 7Medical Department, Sanofi Genzyme, Gentilly, France

Background: Sarilumab, an anti-IL-6R antibody, is approved for the treatment of moderate to severe RA and shown efficacious as patient-reported outcomes (PROs). Detailed analyses of drug efficacy from the patient point of view is important. Saripro is a pragmatic interventional study close to the daily practice.

Objectives: To assess the effectiveness of sarilumab on several PROs using the RAID (Rheumatoid Arthritis Impact of Disease) score.

Methods: The Saripro study (NCT 03449758) was a French multicenter interventional study assessing the effects of sarilumab 200 mg on PROs in patients with moderately to severely active RA with an inadequate response or intolerance to standard of care DMARDs. The primary endpoint was change in total RAID score from baseline to week 24 (RAID ranges 0-10 where 10 is maximal impact). Changes from baseline for RAID, DAS28-ESR and CDAI according to baseline disease activity were analyzed as secondary outcomes. Safety was assessed by monitoring adverse events (AE). All statistical analyses were descriptive, 95% CI was given when appropriate.

Results: 84 patients were included in 31 centers and 62 were evaluable and analyzed for effectiveness. They had similar characteristics to the 84 patients at baseline and were as expected for a RA population initiating a biologic: mean (SD) age: 59.9 (12.4) years, 71.0% female, disease duration 9.7 (10.3) years, rheumatoid factor positivity 82.5%, ACPA positivity 86.4%, and DAS28=4.9 (11). Total RAID score decreased significantly from 5.7 (2.0) at baseline to 3.3 (2.5) at W24; mean change was -2.4 [-3.0; -1.8]. Furthermore, this improvement was noted both for highly and less active patients at baseline: for patients with DAS28-ESR < 5.1 (n=31), mean change was -1.56 [-2.28; -0.83] and for patients with DAS28-ESR≥5.1 (n=27), mean change was -1.96 [-2.91; -1.05]. Changes in DAS28-ESR and CDAI were significant [-2.8 [-3.2; -2.4] and [-15.2 [-18.5; -11.8], respectively]. AEs were consistent with the safety profile of anti-IL-6R antibodies and with results from PCTs (data not shown).

Conclusion: In this real world study, treatment with sarilumab during 24 weeks in RA patients led to an improvement in total RAID score irrespective of baseline levels of disease activity. This is the first time RAID score is used as the primary endpoint in a study.

CLINICAL BENEFITS REPORTED IN AMPLE TRIAL OBSERVED IN A REAL-WORLD (RW) COHORT OF US RHEUMATOID ARTHRITIS (RA) PATIENTS

A. Klink1, X. Han2, F. Lobo3, R. Szymialis4, J. Lam5, B. Feinberg1,1,3Cardinal Health, Dublin, United States of America; 2Bristol Myers Squibb Company, Princeton, United States of America

Background: Efficacy observed in controlled trials may not reflect RW effectiveness, given documented differences in patient populations and management.

Objectives: This study aimed to assess disease measures over time as measured in a trial setting (AMPLE) and in a separate RW observational setting, both among patients with RA treated with abatacept.

Methods: The RW cohort comprised retrospective patient-level data abstracted by 31 community rheumatologists for adult RA patients treated with abatacept who had an anti-cyclic citrullinated peptide-2 titer ≥250 AU/mL. AMPLE was a phase III, randomized controlled trial of RA patients treated with abatacept that assessed disease measures over a 2-year follow-up. Data included demographic, treatments, labs, and disease measures (tender and swollen joint count [TJC, SJC], C-reactive protein [CRP], American College of Rheumatology-20 [ACR20] and ACR50 at baseline and 3 and 6 months) and were summarized descriptively. Disease measures were evaluated across AMPLE and RW cohorts.

Results: Of the 291 RW patients and 318 AMPLE patients, the majority were female (70%, 81%), white (72%, 81%), and RF-positive (91%, 76%), respectively (Table 1). The mean ages at abatacept initiation were 54.7 and 51.4 years among patients with RF-positive and RF-negative status, respectively.

LEGEND: *among 274 with known RF status; **corticosteroids in AMPLE cohort at any time in the 2-year study period
old in RW and AMPLE, respectively. Concomitant corticosteroids (45%, 65%) and methotrexate (62%, 100%) were common in RW and AMPLE, respectively. All patients in AMPLE were biologic naïve, whereas 83% of RW patients had prior biologic use. AMPLE administered abatacept subcutaneously (SC), while 37% of RW patients received abatacept SC. Patients had median SJC and TJC of 6 and 8 in RW and 13 and 22 in AMPLE at abatacept initiation, respectively (Table 2). SJC (TJC) improved a median of 65% (60%) and 68% (66%) at 3 months and 75% (67%) and 76% (75%) at 6 months in RW and AMPLE, respectively (Fig 1). The majority of patients achieved ACR50 at 3 months (79%) and 60% and 6 months (88% and 66%) in RW and AMPLE, respectively, while 58% and 32% achieved ACR70 at 3 months and 67% and 45% at 6 months, respectively (Fig 2).

LEGEND: values soonest after 3 months and value between 6-9 months used for RW cohort; values at days 85 and 197 used for AMPLE cohort.

Conclusion: Despite differences in patient characteristics, improvements in SJC and TJC, as well as high rates of ACR20 and ACR50, were observed in both trial setting and RW settings. These improvements in disease activity were observed at similar magnitudes in both settings, demonstrating that trial efficacy is achievable in RW clinical practice with abatacept treatment.

Conclusion: Although there was a rapid improvement in the signs and symptoms of RA after the initiation of bDMARD treatment, improvement in PF was slightly delayed. Significant improvement of muscle power and agility was achieved after 3–6 months onward. Inhibition of fall risk was achieved at and after 12 months after the initiation of bDMARD treatment. These results suggest that physiotherapy plays a vital role in RA patients who undergo treatment with bDMARDs to gain more rapid improvement of PF.

ASSOCIATION BETWEEN THE SEROLOGIC STATUS OF ISOTYPE-SPECIFIC AUTOANTIBODIES AND THERAPEUTIC EFFICACY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT: A PROSPECTIVE ULTRASOUND COHORT STUDY IN JAPAN

S. Y. Kawashiri1,2, Y. Endo1,2, A. Nishino3, T. Shimizu3, Y. Uekii4, N. Eiraku5, A. Okada6, N. Matsuoka6, T. Yoshitama6, H. Nakamura7, M. Tama1, T. Origuchi2,8, R. Toes3, T. Huizinga9, A. Kawakami4,9, Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Nagasaki, Japan; Kyushu Multicenter Rheumatoid Arthritis Ultrasound Prospective Observational Cohort Study Group, Nagasaki, Japan; Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands

Background: The presence of anti-cyclic citrullinated protein antibodies (ACPA) and anti-carbamylated protein (anti-CarP) antibody is specific for rheumatoid arthritis (RA). Recently, it was reported that the serological status of ACPA is associated with the therapeutic response of the T-cell co-stimulation blocker abatacept (1, 2). However, it is currently unclear whether the serological status of each isotype levels of these autoantibodies before treatment introduction or the changes during treatment are associated with the therapeutic response of abatacept.

Objectives: To evaluate longitudinal changes in the isotypes of ACPA and anti-CarP in RA patients treated with abatacept, and associations between the baseline serological status/ these changes and clinical response/ ultrasonographic response.

Methods: This study is part of an ongoing non-randomized multicenter prospective cohort study of patients with active RA who received biological or targeted DMARD therapy at 13 participating rheumatology centers from the Kyushu region of Japan since June 2013 (3). As of the present report, we enrolled 43 consecutive Japanese patients with active RA who have introduced treatment with abatacept and had finished the first 12-month observation period. We evaluated disease activity by clinical composite measure and ultrasound score at baseline, 3, 6, 9 and 12 months. In ultrasound of bilateral hands from 22 sites, the findings obtained by gray-scale (GS) and power Doppler (PD) assessments were graded on a semi-quantitative scale from 0 to 3 and the sum of GS or PD scores was used as the total GS or PD score. The serum levels of IgG/IgM/IgA-type of ACPA and anti-CarP were measured by the ELISA method in Leiden University Medical Center. We evaluated the association between serological status of autoantibodies and clinical/ultrasonographic therapeutic efficacy.

Results: The median age was 72 years, and the disease duration was 54 months. Methotrexate was concomitant in 22 (51%). Sixteen (37%) patients had a history of previous use of biological DMARDs. Nineteen (44%) and 23 (54%) patients achieved SDAI remission and PD remission (total PD score $\leq$0) at 12 months, respectively. The serum levels of all isotypes of ACPA/anti-CarP significantly decreased at 12 months from baseline. The reduction of IgM-ACPA level significantly correlated with the reduction of SDAI (rs=0.33, p=0.031) and total PD score (rs=0.49, p=0.00007). Both clinical and ultrasonographic therapeutic responses were better in patients with the detectable IgM-ACPA at baseline than in patients without that (Figure): the reduction of SDAI (p=0.0078) and that of total PD score (p=0.0078) were significantly larger in the former than in the latter. All isotype of anti-CarP did not associate with therapeutic response.

Conclusion: Treatment of abatacept induced to the reduction of the autoantibody levels. The IgM-ACPA level at baseline and the change in IgM-ACPA associated with both clinical and ultrasonographic therapeutic response in patients treated with abatacept. IgM-ACPA, compared with usual IgG-ACPA, better reflects the treatment response of abatacept in patients with RA

THE IMPACT OF BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS ON THE COURSE OF RHEUMATOID ARTHRITIS-ASSOCIATED LUNG DISEASE

A. Koken Avar, G. Can, M. Bilir, I. Sarı, F. Onen. Dokuz Eylül University Medical School, Rheumatology Department, Izmir, Turkey

Acknowledgments: We have acknowledged for all the members of the study group.

Disclosure of Interests: None declared

References:
Background: Pulmonary involvement is one of the frequent extra-articular manifestations of rheumatoid arthritis (RA) (1). Biological disease-modifying anti-rheumatic drugs (bDMARDs) are effectively used in the treatment of musculoskeletal findings of RA but their effect on RA-associated lung disease is unclear.

Objectives: The aim of this retrospective study is to evaluate and compare different bDMARD treatments used in RA patients with RA-associated lung disease.

Methods: All RA patients who received bDMARDs between 2008 and 2018 in a single rheumatology centre and had thorax high-resolution computed tomography (HRCT) were reviewed for the findings of lung involvement. Patients with positive finding were included in the study. Following the biologic treatment, whether there was a progression/regression in lung involvement was evaluated by comparing the baseline and the latest thorax HRCT findings. Clinical and laboratory data were collected from medical records.

Results: A total of 40 patients (mean age:62.4 years; 72.5% women) were included in the study. Clinical and demographic characteristics of patients are summarized in Table 1. During the mean 107.4±65 months follow-up period, HRCT findings remained stable in 31 patients (76%) and improved in one (2.5%), while 7 patients (17.5%) had progress in their lung involvement. When patients with and without progress were compared, lung involvement at the diagnosis of RA and the presence of respiratory symptoms at bDMARDs initiation was found to be more frequent in the first group (p=0.023 and p=0.020, respectively). Mean ESH values at bDMARDs initiation were also higher in patients who had progress (p<0.006). There was no significant difference between the groups in the age, sex, type of bDMARDs used or other baseline laboratory data. Logistic regression analysis showed that lung involvement at the diagnosis of RA was a significant independent risk factor for the progress (OR: 11.0, 95%CI:1.48-81.60). There was no statistically significant difference on progression of HRCT findings between patients received TNFi (n=22) and non-TNFi biologics (n=18), (p=1.00). The mean drug survival of first bDMARD also was not statistically different between groups (40.8±21.6 months in non-TNFi group and 42.2±40.5 months in TNFi group (p=0.90). 5/16 (31.3%) patients in the non-TNFi group and 1/22 (4.5%) in TNFi group had died during the follow-up (p=0.14).

Conclusion: This study showed that the impact of TNFi and non-TNFi biologic treatments on the course of RA-associated lung involvement is similar. It also suggested that lung involvement at the diagnosis of RA was a significant risk factor for the progress of the pulmonary disease.

DOI: 10.1136/annrheumdis-2020-eular.1698
BACKGROUND: Rheumatoid arthritis (RA) is associated with a 2-fold increased risk of cardiovascular events (CVE) and mortality when compared to the general population. The systemic inflammation in RA seems to play a pivotal role by creating endothelial dysfunction and thus accelerating atherosclerosis. This long-lasting inflammatory process potentiates the effects of additional classical cardiovascular risk factors. Since the 2000s, numerous therapeutic advances, in particular biologics, allow better control of this inflammation. Among these, IL6 inhibitors (IL6i) are known to provide rapid and sustained improvements in clinical, biological and radiographic outcomes. However, an increase in circulating lipid concentrations in patients treated with IL6i is usual. This raises the question of the risk-benefit ratio of IL6i.

OBJECTIVES: The purpose of this systematic literature review and meta-analysis was to evaluate the impact of IL6i on the incidence of major adverse cardiovascular events in RA patients, in comparison with TNFα inhibitors (TNFi), non-TNFi BiDMARDs or csDMARDs.

METHODS: A systematic literature search of MEDLINE (via PubMed), EMBASE and the Cochrane Library databases until February 2019 was performed. Included studies were observational studies or randomized controlled trials having reported relevant confirmed CVEs (death from CVE, myocardial infarction, heart failure and stroke) in RA patients treated with IL6i, and a suitable control group. A meta-analysis of the relative risk for each CVE in RA patients treated with IL6i compared to patients in the control groups was performed. A random effect model was applied in case of substantial heterogeneity.

RESULTS: Of 6869 studies, 23 randomized controlled trials and 6 controlled cohorts could be included. IL6i were significantly associated with a reduction in the risk of myocardial infarction compared to patients treated with IL6i and a suitable control group. Our findings of a potentially protective effect of IL6i use on the risk of MI are reassuring. Although several beneficial effects might be involved, like the effective control of systemic inflammation, the anti-arrhythmia effect or the improvement of endothelial and left ventricle dysfunction, a potential indication bias with a decreased likelihood to prescribe these drugs in patients with high cardiovascular risk cannot be excluded.

Conclusion: This review of the literature with meta-analysis provides reassuring results about the association between use of IL6i and CVE in RA patients. Data from long-term observational studies is however needed to confirm and ascertain this result.

the discontinuation of infliximab therapy due to adverse events or insufficient response in bio-naive patients with RA.

Methods: This study included patients enrolled in the Tsurumai Biologic Communication Registry in Japan. A crude comparison of infliximab discontinuation between seropositive and seronegative patients was using Kaplan-Meier analysis and log-rank test. We evaluated the associations between the specified baseline characteristics and discontinuation of infliximab therapy using Cox proportional hazard regression. We could not perform simultaneous assessments of the impact of RF and ACPA seropositivity on clinical efficacy because of collinearity.

Results: Baseline characteristics of the patients included in this study are shown in Table 1 and the crude comparison between RF and ACPA status is shown in Figure 1. RF and ACPA seropositivity was significantly predictive of discontinuation of infliximab therapy after adjusting for baseline characteristics, including age, sex, stage, class, disease activity at baseline, and prednisolone use (Table 2). The hazard ratio was 1.99 (95% confidence interval 1.25, 3.16) for RF and 2.73 (95% confidence interval 1.24, 6.02) for ACPA.

EVALUATION OF CXCL13 AND ICAM1 SERUM LEVELS AS PREDICTORS OF CLINICAL RESPONSE TO ABATACEPT IN RHEUMATOID ARTHRITIS.

S. Piantoni1, S. Masneri1, F. Regola1, C. Nalli1, A. Tincani1, F. Franceschini1, P. Airò1.

1ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Clinical and Experimental Sciences, Brescia, Italy

Background: Soluble intercellular adhesion molecule 1 (ICAM1) and C-X-C motif chemokine 13 (CXCL13) were described as differentially associated with two major subtypes of synovitis in rheumatoid arthritis (RA). Raised serum levels of ICAM1 (which is upregulated in synovial fibroblasts in response to TNF-α), and of CXCL13 (which is expressed by synovial follicular dendritic cells and activated mature antigen-experienced T-helper cells), are associated with a myeloid or lymphoid synovial phenotype, respectively (1). It has been suggested that a preferential clinical response to anti-TNF-α, as compared to anti-IL-6R monotherapy, can be predicted by measuring these two biomarkers (2). No information is available on the possible utility of these biomarkers in RA patients treated with abatacept (ABA), a T-cell co-stimulation blocker.

Objectives: To analyze the effect of ABA on ICAM1 and CXCL13 serum levels in RA and to verify whether they predict the response to the drug.

Methods: 63 RA patients (F/M=51/12; median (10th-90th percentile) age=60 (41-72) years; CRP-DAS28=4.6 (3.3-5.8); ACPA positive: 86%) before and after 6 months of treatment with ABA + methotrexate and 22 sex and age-matched healthy controls (HC) were evaluated. Serum ICAM1 and CXCL13 levels were dosed by commercial ELISA (Life Technologies and R&D). Response to treatment was defined with the EULAR criteria.

Results: CXCL13 serum levels were higher in RA at baseline than in HC [136 (42-325) vs 32 (19-57) pg/ml, p<0.01], while no difference was observed in ICAM1 [186 (125-276) vs 184 (153-246) ng/ml, p=0.9]; positive correlations between ICAM1 and CRP (r:0.28; p=0.03) and CXCL13 levels and CRP (r:0.40; p<0.01) and CRP-DAS28 values (r:0.27, p=0.05) were found. After therapy with ABA, a reduction of CXCL13 was observed [136 (42-325) vs 94 (29-319) pg/ml, p<0.01], both in responders [n: 37: 151 (57-462) vs 97 (26-329) pg/ml; p<0.01] and non-responders (n: 14: 142 (68-293) vs 89 (42-198) pg/ml; p=0.01]. Not significant variation of ICAM1 serum levels was found in the entire cohort [186 (125-276) vs 190 (113-252) ng/ml, p=0.06]. However, a significant decrease was observed in non-responders [222 (169-302) vs 186 (110-233) ng/ml, p=0.02].

At baseline, no significant difference was found among patients seropositive for ACPA if compared with the negative ones [ACPA+ vs ACPA- for ICAM1 [187 (123-280) vs 177 (134-258) ng/ml; p=0.7] and for CXCL13 [143 (42-368) vs 113 (56-270) pg/ml; p=0.4]]

Conclusion: Our results confirmed that CXCL13 serum levels are directly correlated with disease activity and demonstrated that ABA therapy induces their reduction. These findings suggest that the co-stimulation blockade at central level and/or in the synovium lead to a reduced production of CXCL13. We could not demonstrate that CXCL13 levels predict the clinical response to ABA in this cohort of patients.

DOI: 10.1136/annrheumdis-2020-eular.708
Background: Patients with RA are at increased risk of infection compared with the general population, but it is unclear whether this is due to the underlying disease or to immunosuppressive medications used to manage the disease. Some biologic DMARDs (bDMARDs) have been associated with an increased risk of serious infection. A large cohort study found no increased risk of serious infection in patients initiating abatacept compared with patients initiating other bDMARDs. It is clinically important to identify which patients are at a higher risk of infections at the time of initiating treatment with a bDMARD. However, studies that assess risk factors for infection and derive corresponding risk scores at the time of bDMARD treatment initiation, are lacking or based on too few patients.

Objectives: To identify the risk factors for serious infections among patients with RA initiating treatment with a bDMARD in a real-world observational setting.

Methods: The Trouven MarketScan® Commercial and Supplemental Medicare databases were used to identify patients diagnosed with RA who initiated treatment with a bDMARD between January 2007 and December 2015. Patients were followed from treatment initiation until the occurrence of a serious infection requiring hospitalisation, the end of enrolment or 31 December 2015, whichever came first. The Cox proportional hazards model was used to estimate the hazard ratios (HRs) of serious infection associated with baseline risk factors including demographics, the presence of co-morbidities, prior hospitalised infections and medications. An infection risk score was developed using the independent risk factors found to be significant in the model.

Results: The study cohort included 84,308 patients initiating treatment with a bDMARD, mainly etanercept (36.7%), adalimumab (29.3%), infliximab (12.4%), rituximab (73%) and abatacept (6.8%). During a mean follow-up of 6.6 months, 1724 patients were hospitalised for a serious infection (incidence rate 3.7/100 persons per year). The baseline risk factors significantly and independently associated with serious infections were age, prior hospitalisation for infection, hyper-tension, diabetes, lymphoma, asthma, chronic obstructive pulmonary disease, cardiovascular disease, other autoimmune disease, corticosteroid use and antibiotic use. The infection risk score, with a possible range of 0 to 15, had a mean (SD) value of 2.6 (1.9) with range 0–12.5. The HR (95% CI) of serious infection was 1.43 (1.40–1.45) for every unit increase in the risk score. Relative to patients with a score of 0, the HR (95% CI) of serious infection for a risk score of 5 was 5.9 (5.3–6.5), and for a risk score of 10 was 34.5 (28.5–41.6).

Conclusion: In this large, real-world cohort of patients with RA who were initiating treatment with a bDMARD, several patient characteristics were found to independently predict the subsequent risk of serious infection. The risk score, based on easily available patient characteristics, can be a simple and useful tool for the clinician to identify patients at higher risk of infection at the time of bDMARD initiation for the treatment of RA.

PROGRESSION IN RHEUMATOID ARTHRITIS PATIENTS IN DAILY CLINICAL PRACTICE IN JAPAN: COMPARISONS ACCORDING TO ACPA STATUS

N. Takahashi1, T. Kojima1, S. Asai1, K. Terabe1, N. Ishiguro1 on behalf of TBCR Study Group. 1Nagoya University Graduate School of Medicine, Nagoya, Japan

Background: The clinical effectiveness of abatacept (ABA) in rheumatoid arthritis (RA) patients has been reported to be higher when the patients’ anti-cyclic citrullinated peptide antibody (ACPA) status is positive. The report from the ORA registry demonstrated that the ACPA positivity was associated with a better response to ABA [1]. In a sub-analysis of the AMPLPE trial, patients with very high ACPA titers who were treated with ABA had a statistically significant response compared to patients with lower titers [2]. However, these studies did not demonstrate the data regarding the structural progression.

Objectives: This study aimed to the effectiveness of ABA on the clinical disease activity as well as the radiographic progression in patients with RA in the clinical settings.

Methods: All eligible patients were registered in the TBCR, a Japanese multicenter registry system for RA patients treated with biologics [3]. The present study included 553 consecutive patients whose ACPA data were obtained, treated with ABA and observed for longer than 52 weeks. We primarily compared the status of disease activity (SDAI) and radiographic progression (van der Heide modified total Sharp score: mTSS) between ACPA-positive [ACPA (+)] and ACPA-negative [ACPA (-)] RA patients. The ACPA positive was defined as ≥13.5 U/mL of anti-CCP antibody.

Results: Number of cases was 446/107 [ACPA (+)/ACPA (-)], respectively. Baseline characteristics between groups were quite similar; mean age was 68.0/67.3 years, rate of methotrexate (MTX) use was 41.2/50.0%, rate of bio-naive was 28.0%/31.8%, and mean SDAI score was 22.2/20.8. Significant difference was observed in mean change in SDAI score from baseline to 52 weeks between the ACPA (+) and ACPA (-) group (-13.4 vs -9.9, p = 0.027) (Figure 1A). Proportion of patients that achieved low disease activity (LDA; SDAI ≤11) at 52 weeks was significantly higher in the ACPA (+) group compared to the ACPA (-) group (72.1 vs 56.0%, p < 0.01) (Figure 1B). In univariate and multivariate logistic regression analysis, ACPA positivity was an independent predictor for achievement of LDA at 52 weeks (Table). There observed no significant difference between ACPA (+) and ACPA (-) group in the proportion of patients that achieved structural remission (≤0.5 mTSS) at 52 weeks (66.2 vs 62.1%) (Figure 2A) as well as mean change in mTSS (1.86 vs 1.17), erosion score (0.60 vs 0.53), and joint narrowing (JSN) score (1.06 vs 0.64) (Figure 2B).

Conclusion: Consistent with previous reports, the ACPA-positive group demonstrated significantly higher LDA achievement rate at 52 weeks and indeed the ACPA positivity was significantly associated with LDA achievement in multivariate analysis. However, the ACPA-negative group demonstrated quite similar transition of SDAI score and LDA achievement rate except at 52 weeks compared with the ACPA-positive group. Additionally, there was no significant difference in the structural progression at 52 weeks between the groups. ABA treatment
may be considered not only in the ACPA-positive RA patients but also in the ACPA-negative patients in the clinical practice.

ASSOCIATION BETWEEN CHANGES IN C-REACTIVE PROTEIN AT WEEK 12 AND PATIENT-REPORTED OUTCOMES AT WEEK 24 WITH SARILUMAB THERAPY ACROSS THREE PIVOTAL PHASE 3 STUDIES

J. Tesser1, G. C. Wright2, V. Strand3, J. Kaine4, K. Stchool5, K. Ford6, A. Praestgaard7, E. Choy8, 1Arizona Arthritis & Rheumatology Associates, Phoenix, AZ, United States of America; 2NYU Langone Health, New York, NY, United States of America; 3Stanford University, Palo Alto, CA, United States of America; 4Sarasota Arthritis Research Center, Sarasota, FL, United States of America; 5Sanofi Genzyme, Cambridge, MA, United States of America; 6Regeneron Pharmaceuticals, Inc., Tarrytown, NY, United States of America; 7Cardiff University Hospital, Cardiff, United Kingdom

Background: Evaluation of early response to rheumatoid arthritis (RA) therapy at 12 weeks after initiation is recommended in treatment guidelines. C-reactive protein (CRP) response at 12 weeks on therapy may indicate favorable long-term patient-reported outcomes (PROs).

Objectives: To describe the association between CRP response at Week 12 and PROs at Week 24 with sarilumab therapy across three pivotal studies.

Methods: The analysis included patients with RA who took part in MOBILITY (NCT01061738), TARGET (NCT01709578), or MONARCH (NCT02332590) and were treated with sarilumab 200 mg every 2 weeks (q2w) or adalimumab 40 mg q2w (MONARCH only). Patients who achieved a CRP response at Week 12 (defined as serum CRP ≤3 mg/L) were evaluated for PROs at Week 24. Response for PROs was defined as change from baseline visual analog scale score ≥10 for pain, sleep, and morning stiffness and an increase of ≥4 for FACT-Fatigue score. Odds ratios (ORs) and 95% confidence intervals (CIs) were generated for the likelihood of achieving PRO responses at Week 24.

Results: The proportions of patients achieving a CRP response at Week 12 were 78% (MOBILITY), 74% (TARGET), 80% (MONARCH, sarilumab), and 36% (MONARCH, adalimumab). Of these, 71.4% (MOBILITY; OR 3.78, 95% CI 2.31–6.18), 71.5% (TARGET; OR 2.86, 95% CI 1.44–5.65), 79.7% (MONARCH, sarilumab; OR 4.40, 95% CI 2.04–9.47), and 79.7% (MONARCH, adalimumab; OR 2.76, 95% CI 1.36–5.61) reported pain score responses at Week 24. Fatigue responses at Week 24 among Week 12 CRP responders were 66.6% (MOBILITY; OR 2.74, 95% CI 1.69–4.45), 59.9% (TARGET; OR 3.18, 95% CI 1.58–4.62), 73.0% (MONARCH, sarilumab; OR 4.78, 95% CI 2.21–10.33), and 64.1% (MONARCH, adalimumab; OR 1.64, 95% CI 0.88–3.06).

Conclusion: A CRP response at Week 12 in patients with RA treated with sarilumab may be considered not only in the ACPA-positive RA patients but also in the ACPA-negative patients in the clinical practice.

DOI: 10.1136/annrheumdis-2020-eular.2181

TEMPORAL CHANGES IN LUNG NODULES DETECTED IN INDIVIDUALS WITH RHEUMATOID ARTHRITIS WITH BIOLOGIC DMARD TREATMENTS

H. Karadeniz1, E. Cingili2, H. Satý1, A. Anavâlgu Güler1, R. Bilici Salman1, N. Atas1, H. Babaoglu1, B. Goker1, S. Haznedaroglu1, M. A. Ozturk1, A. Tufan1, 1Gazi University Internal Medicine, Rheumatology, Ankara, Turkey; 2Gazi University, Radiology, Ankara, Turkey

Background: Lung nodules in rheumatoid arthritis (RA) patients impose diagnostic and therapeutic challenges due to unpredictable outcome of these nodules. Biological (b) disease-modifying anti-rheumatic drugs (bDMARDs) are important therapeutic agents used in treatment of RA. There is hesitation about use of conventional synthetic DMARDs (csDMARDs) and bDMARDs due to increased risk of nodules although their association remains unclear. There are scarce data on lung nodules observed in RA patients and systematic studies are needed.

Objectives: The aim of this study is to evaluate effects of biologic treatments and conventional synthetic DMARDS on pulmonary nodules observed in rheumatoid arthritis patients.

Methods: Electronic health records of RA patients who had had thorax computed tomography (CT) confirmed lung nodules in the last 5 years were retrospectively evaluated. Pre-treatment and post-treatment follow up CT images were meticulously examined for the number, size, attenuation, calcification, and cavitary formation. Demographic features, smoking status, disease characteristics and used medications were retrieved from file records. Clinical and laboratory findings, demographic features, treatment and follow-up duration, number of solid and cavitary nodules were compared between groups.

Results: There were 21 patients in both biologic (11 females, mean age, 59.7±8.4) and csDMARD (12 females, mean age, 71.4±8.3) treated groups. There was no difference in frequency of nodule types and sizes between csDMARD and bDMARDs. None of the nodules showed malignant transformation within the observation period.

Conclusion: Risk of progression in lung nodules with biologic treatments is low, at least not more than csDMARD in short term and any malignant transformation was not observed in our study.

Figure. Nodule progression in a patient receiving rituximab (white arrow)

Figure 1. Cumulative flare rate over time. csDMARDs; conventional synthetic disease-modifying antirheumatic drug, TNF-inhibitor; tumor necrosis factor inhibitor.

Conclusion: The order in which tapering and stopping medication was performed was not superior to each other based on flare rates, DAS and HAQ. However, patients who tapered their csDMARD first could more often completely taper off their medication and, therefore, also reached DFR more often.
Background: Tocilizumab (TCZ) is a recombinant humanized, anti-human monoclonal antibody of the immunoglobulin G1 k subclass directed against soluble interleukin 6 receptors (IL-6R) [1].

We aimed to assess the prevalence of hypogammaglobulinaemia in our series of patients treated with tocilizumab after a carefully diagnostic workup which ruled out other causes and analyzed whether is associated with a higher risk of infection.

Methods: We conducted a retrospective review from 2010 to 2019 of forty-two patients affected with a rheumatic disease and treated with TCZ at our centre. In those patients in whom we had no record of immunoglobulin levels, we determined them in the blood analysis performed by usual clinical practice.

Results: 42 patients were identified, from whom 38 had rheumatoid arthritis. A 31% had immunoglobulin levels prior to starting treatment with TCZ but no one had hypogammaglobulinaemia. 2 patients were excluded due to their underlying disease could justify the IgG level abnormalities. During the treatment's follow-up, we identified that a 30% of the patients (12/40) had hypogammaglobulinaemia. Of those patients in whom immunoglobulin levels had been determined prior to starting treatment with TCZ, a 36.3% of them (4/11) developed hypogammaglobulinaemia during the follow-up. From the series, we observed a statistical significance tendency (p=0.0057) for infection risk in those patients with hypogammaglobulinaemia in contrast to those with normal IgG level (41.5% vs 14.3%, respectively).

Conclusion: Secondary hypogammaglobulinaemia may occurs in patients receiving anti-IL6 agents such as tocilizumab and this could be associated with an increasing infection risk. The prevalence is not precisely known, in part because measurement of IgG prior to or during the treatment has not been a standard of care. No medical data have been previously disclosed about this possible adverse effect of anti-interleukin-6 agents. Nevertheless, ideally randomized trials are needed to assess this initial hypothesis.

FRI0111 TOCILIZUMAB MAY INDUCE SECONDARY HYPOGAMMAGLOBULINAEMIA. A RETROSPECTIVE CASE SERIES OF 42 PATIENTS

F. Vilchez-Oya1, A. Pros1, I. Carrión Barberà1, J.A. Meraz Ostiz1, T.C. Salman Monte1, C. Perez-Garcia1. 1Consorci Parc de Salut Mar/Hospital del Mar, Rheumatology, Barcelona, Spain

Background: Tocilizumab (TCZ) is a recombinant humanized, anti-human monoclonal antibody of the immunoglobulin G1 subclass directed against soluble and membrane-bound interleukin 6 receptors (IL-6R) [1].

Interleukin-6 (IL-6) has a pleiotropic effect on inflammation, immune response, and hematopoiesis. When it was first identified, it was named as B-cell-stimulating factor 2 (BSF-2) according to its ability to induce immunoglobulin production in Epstein-Barr virus-transformed B-cell lines or in Staphylococcus aureus Cowan 1-stimulated B cells [2-4].

Nowadays, it is known that IL-6 controls the survival, population expansion and maturation of B cells and plasmablasts. In that way, the regulation of Blimp-1 by STAT3 is linked to antibody secretion and is associated with long-lived plasma cells that produce large amounts of immunoglobulin. Furthermore, the ability of IL-6 to promote humoral immunity has been linked to its effects on follicular helper T cells where they promote B cell proliferation and immunoglobulin class switching [5].

Objectives: Hypogammaglobulinaemia is a known complication of some immunosuppressive drugs, not previously described in patients who received therapy with monoclonal antibody against the IL-6R. We aimed to analyze the prevalence of hypogammaglobulinaemia in our series of patients treated with tocilizumab after a carefully diagnostic workup which ruled out other causes and analyzed whether is associated with a higher risk of infection.

Methods: We conducted a retrospective review from 2010 to 2019 of forty-two patients affected with a rheumatic disease and treated with TCZ at our centre. In those patients in whom we had no record of immunoglobulin levels, we determined them in the blood analysis performed by usual clinical practice.

Results: 42 patients were identified, from whom 38 had rheumatoid arthritis. A 31% had immunoglobulin levels prior to starting treatment with TCZ but no one had hypogammaglobulinaemia. 2 patients were excluded due to their underlying disease could justify the IgG level abnormalities. During the treatment's follow-up, we identified that a 30% of the patients (12/40) had hypogammaglobulinaemia. Of those patients in whom immunoglobulin levels had been determined prior to starting treatment with TCZ, a 36.3% of them (4/11) developed hypogammaglobulinaemia during the follow-up. From the series, we observed a statistical significance tendency (p=0.0057) for infection risk in those patients with hypogammaglobulinaemia in contrast to those with normal IgG level (41.5% vs 14.3%, respectively).

Conclusion: Secondary hypogammaglobulinaemia may occurs in patients receiving anti-IL6 agents such as tocilizumab and this could be associated with an increasing infection risk. The prevalence is not precisely known, in part because measurement of IgG prior to or during the treatment has not been a standard of care. No medical data have been previously disclosed about this possible adverse effect of anti-interleukin-6 agents. Nevertheless, ideally randomized trials are needed to assess this initial hypothesis.

FRI0112 RISK OF MALIGNANCY WITH NON-TNF BILOGIC OR TOFACITINIB THERAPY IN RHEUMATOID ARTHRITIS: A META-ANALYSIS OF OBSERVATIONAL STUDIES

W. Xie1, X. Yang1, Z. Zhang1. 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: With an increasing usage of non-TNF biologics and tofacitinib, it is crucial to understand the comparative safety of these agents regarding malignancies risk.

Objectives: We aim to assess the risk of developing cancer in patients with RA exposed to non-TNF inhibitors (TNFi) biologics or tofacitinib therapy.

Methods: Systematical search of PubMed, EMBASE and Cochrane Library plus a hand search of conference proceedings were performed for observational studies that reported cancer incidence in patients with RA treated with biologics or tofacitinib with active comparator of conventional DMARDs (csDMARDs) or TNFi. The pooled relative risk (RR) and 95% confidence interval (CI) were calculated with fix-effects or random-effects model.

Results: Of 2,819 identified articles, a total of 10 studies involving over 323,361 patients and 1,179,263 patient-years of follow-up were included. Pooled analysis showed there was no increased risk of developing cancer in general or specific cancer types in RA patients receiving treatment with rituximab (pooled RR 1.13, 95% CI 0.80-1.59), tocilizumab (pooled RR 0.96, 95% CI 0.83-1.11), or tofacitinib (pooled RR 0.97, 95% CI 0.66-1.43), compared with those receiving csDMARDs or TNFi. However, abatacept use in RA was associated with a slightly increased overall cancer risk (pooled RR 1.13, 95% CI 1.02-1.24) and non-melanoma skin cancer (pooled RR 1.26, 95% CI 1.09-1.45), relative to csDMARDs or TNFi. Tofacitinib usage in RA was associated with a slightly increased overall cancer risk (pooled RR 1.13, 95% CI 1.02-1.24) and non-melanoma skin cancer (pooled RR 1.26, 95% CI 1.09-1.45), relative to csDMARDs or TNFi.

Conclusion: Compared with csDMARDs or TNFi, there was no increased risk of malignancies among RA patients treated with non-TNF biologics or tofacitinib, with exception of abatacept associated with slightly increased total cancer and specific cancer types. Extended researches are required to confirm the findings in a real-world context.

References:
Background: IL-6 contributes significantly to the chronic inflammatory process of rheumatoid arthritis (RA). Sarilumab (SRL), a human anti-human IL-6 receptor alpha monoclonal antibody that blocks the signaling originated by the IL-6/IL-6R complex like tocilizumab, is an effective treatment. However, predictors of the response to sarilumab are still required.

Objectives: We aimed to combine IL-6, soluble IL-6R (sIL-6R) and gp130 (sgp130) levels to identify groups of sarilumab responses.

Methods: This research is a retrospective study, a total of 32 RA patients with SRL therapy in our department from February 1 in 2018 to December 31 in 2019 were included. Serum and clinical data from 32 RA patients were collected before treatment and until the last visit. Follow-up period was up to one year after starting SRL treatment. Serum were tested for IL-6 (Human IL-6 Quantikine ELISA Kit, R&D systems) and sgp130 (Human soluble gp130 Quantikine ELISA Kit, R&D systems), using specific ELISAs according to the manufacturer’s instructions. Hierarchical cluster analysis (UPM14.3.0) was used to establish the relationship between IL-6, sIL-6R and sgp130. We evaluated the efficacy of SRL treatment on the last visit using European League Against Rheumatism (EULAR) response criteria in the groups of patients. The other statistical analyses were performed with EZR 1.41, and p Values less than 0.05 were considered significant.

Results: The median age of patients was 70.5 (IQR: 66.5-74.3) years and the median of disease duration was 7.3 (1.7-15.3) years. Nine (28.1%) patients were biologics and Jakinibs naive. The median follow-up periods were 24 (12-26) weeks. The baseline DAS28 was median 4.39 (3.77 - 5.43), and CDAI was 21.1 (11.7-29.5). When comparing responders and non-responders, there were no significant differences in any of the baseline parameters and cytokines. Four statistical significant clusters of RA patients (i.e., Group1, Group2, Group3 and tocilizumab use group before SRL) were defined by serum concentrations of IL-6, sIL-6R and sgp130 at baseline. The levels of IL-6 expressed as median in Group1 patients were 25.6 (14.4-72.2) pg/mL, in Group2 5.9 (3.3-11.3) pg/mL, and in Group3 70.2 (45.4-86.1) pg/mL (p < 0.002, significant difference only between Group2 and Group3). The levels of sIL-6R expressed as median in Group1 patients were 38.7 (34.7-45.1) ng/mL, in Group2 24.8 (14.8-41.9) ng/mL, and in Group3 35.7 (34.2-39.8) ng/mL (p = 0.5477). The levels of sgp130 expressed as median in Group1 patients were 272.6 (263.0-2772) ng/mL, in Group2 223.1 (220.0-228.0) ng/mL, and in Group3 204.6 (192.0-207.6) ng/mL (p < 0.00003, significant difference between the three groups respectively). There were no significant differences in any of the baseline clinical features and laboratory findings between the three groups. Out of the 8 patients in Group1 had a good or moderate response to SRL. Conversely, the percentage of patients with no response to SRL was higher in Group3 than in Group1 and Group2.

Conclusion: RA patients could be easily stratified prior to the therapeutic intervention with sgp130 related to the IL-6 signal regulation. Group1 patients, who had the best response to SRL, had the highest level of sgp130.

Disclosure of Interests: Rieke Alten Grant/research support from: Pfizer,

Background: Current EULAR and national guidelines recommend use of syn-
thetic target drug Tofacitinib (TOFA) for active rheumatoid arthritis (RA) treatment
in case of resistance or intolerance to metotrexate (MTX) or other conventional
DMARDs. Two treatment regimens are approved: TOFA mono-therapy and com-
bination with conventional DMARD, preferably with MTX.

Aims: The objective was to compare efficacy and safety of TOFA

Methods: We analyzed data from Russian national registry of RA. 450 patients (pts) treated with TOFA in dose 10 mg daily have been enrolled in this investiga-
tion. Among them 169 pts have composed TOFA mono-therapy group (mono)
and 281 pts treated with TOFA plus MTX have been included in combo-therapy

Results: There were no significant differences in pts demographic charac-
teristic and disease longevity and/or severity in two separated groups. Majority of
baseline indices were identical in these groups aside from SDAI, CRP (were
higher in combo-group) and HAQ (was higher in mono-group). Pts monitoring
have shown dramatically decrease of all used indices during the first several
months of therapy in both groups. Moreover all clinical and laboratory parameters
after 6-months treatment were comparable in mono- and combo- groups. Posi-
tive dynamics remained during further 3-year period in both groups. Significant
differences between baseline and ultimate data after 3 year course therapy were
revealed in CDAI, SDAI, DAS28, HAQ, GPA, CRP, ESR monthly during first 6 months, than in 1,2,3 years
and after 3 year period of treatment.

Conclusion: Data gained from National RA registry have demonstrated that treatment with TOFA in mono-therapy regimen has the comparable efficacy with regimen of combined therapy, included MTX and TOFA. Safety of both regimens can be qualified as good. Obtained results confirm high efficacy and safety of target therapy with TOFA and prove the correctness for use it in different regimens – mono-therapy or combination with MTX.

DOI: 10.1136/annrheumdis-2020-eular.3662
Background: Tofacitinib (TOF) is an orally administered Janus Kinase (JAK) inhibitor and is commonly used in rheumatoid arthritis. There is a heterogeneity among numbers reported from different continents about herpes zoster (HZ) incidence rate (1-3). However, data about HZ risk in our country, which stands like a bridge between Asia and Europe, is lacking.

Objectives: To assess the real-life incidence of herpes zoster in RA patients under tofacitinib.

Methods: We analyzed all patients who had at least 1 control visit under tofacitinib and registered to HURBIO database. We calculated incidence rate by dividing the number of patients with herpes zoster to total follow-up years, then multiplied by 100 (per 100 patient-years).

Results: A total of 204 (174 (85.4%) female) patients were recruited. Mean age was 53.2±12.5 years. Mean disease duration was 11.6±8.1 years. Rheumatoid factor and anti-CCP antibodies were positive in 135/198 (68.1 %) and 115/171 (67.2 %) patients, respectively. Median follow-up while receiving TOF was 11.6 (IQR:5.2-26.2) months. Combination with DMARDs was used in 55.5% of patients. 11% of patients was biologic-naive. Eleven (5.3%, 95% CI 1.6-9.6%) patients had liver fibrosis upon examination using transient elastography. Liver fibrosis was defined as liver stiffness, valued over 7.2 kPa. Logistic regression analysis was performed to identify factors associated with liver fibrosis, and receiver operating characteristics analysis was used to determine the predictive value of each factor.

Conclusion: In this real-life data from Turkey, we found a HZ incidence rate similar to that reported from USA and global data; however, we found a lower incidence rate that reported from Japan (Figure 1).

Disclosure of Interests: None declared.
A retrospective cohort of patients with incident RA and no hypertension, recent GC use was associated with incident hypertension. In particular doses ≥75mg were associated with hypertension while the association with lower doses was inconclusive. Clinicians need to consider cardiovascular risk when prescribing GCs and ensure BP is regularly monitored.

Conclusion: In this large cohort of patients with RA and without hypertension, recent GC use was associated with incident hypertension. In particular doses ≥75mg were associated with hypertension while the association with lower doses was inconclusive. Clinicians need to consider cardiovascular risk when prescribing GCs and ensure BP is regularly monitored.

FR10121

STEROID-SPARING EFFECT OF JAK INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS FOLLOWED UP IN A REAL LIFE SETTING

I. Ducu1, F. R. Spinelli1, F. Ceccarelli1, C. Garuffi1, S. Mancuso1, C. Alessandri1, R. Scrovi1, R. Piori1, V. Riccieri1, M. Di Franco1, F. Conti1, Sapienza Università di Roma, Rheumatology Unit, Rome, Italy

Background: Glucocorticoids (GCs) are a milestone of Rheumatoid Arthritis (RA) treatment; EULAR recommendations on the management of medium to high dose glucocorticoids remain to evaluate comorbidities and risk factors for adverse events when planning GCs treatment. Tofacitinib and Baricitinib are Janus kinases inhibitors (JAK) registered for RA treatment. About 60% of RA patients are prescribed GCs from clinical trials with JAK inhibitors treated with GCs; however, little is known about tapering and percentage of withdrawal both in clinical trials and real life.

Objectives: To evaluate the steroid-sparing effect of JAKi in patients with RA.

Methods: We prospectively enrolled consecutive adult patients with RA starting JAKi. At baseline and after 4, 12 and 24 weeks we calculated C-Reactive Protein based Disease Activity score (28 [DAS28CRP]). Daily dose of GCs was recorded at each visit and prednisone (PDN)-equivalent dose. Data are expressed as median (IQR). Continuous variables were compared by Mann Whitney test while dichotomous ones by Chi-square test. P values < 0.05 were considered statistically significant.

Results: Between January 2018 and January 2020, 108 patients started JAKi: 67 patients Baricitinib, 41 patients Tofacitinib. The analysis was restricted to 64 RA patients (50 female, 14 male) who had at least 6 months of follow-up. Table 1 shows the demographic, clinical and clinimetric characteristics of the cohort.
Patients treated with baricitinib and tofacitinib were comparable for age, disease duration, PDN dose and previous number of csDMARDs and bDMARDs; 30 patients (47.6%) were treated with JAKi in monotherapy. At baseline, the median DAS28 was 5.7 (IQR 5.2-6.2) mg, 5.2 (5.0) mg, and 5.0 (5.0) mg, respectively (p>0.0001). The percentage of patients treated with GC decreased from 81.5% at week 4 to 84.8% at week 12 and 24. After 4, 12 and 24 weeks we detected a significant reduction of DAS28 (p<0.0001 compared to baseline). A similar percentage of patients who withdrew PDN compared to those who were still on PDN achieved remission after 12 and 24 months. Similarly, the reduction in DAS28 was comparable between the two groups at week 4 (4.8 [4.2]) in those who withdrew vs 4.1 (1.0) in those who did not at week 12 [4.8 [1.6] for both] and at week 24 [3.7 [1.4] in those who withdrew vs 2.3 [0.7] in those who did not].

IOR: interquartile range; DAS28, Disease Activity Score 28 using C-Reactive Protein, csDMARDs: conventional synthetic Disease Modifying Anti-Rheumatic drugs, bDMARDs: biological Disease Modifying Anti-Rheumatic drugs PDN= prednisone.

Conclusion: The rapid reduction of disease activity determined by JAK inhibitors allows a fast tapering of PDN, as suggested by the last EULAR recommendations for the management of RA.

**Objectives:** Here we update the drug’s safety profile with data up to 8.4 years of treatment.

**Methods:** Long-term safety of bari was assessed from 9 completed randomized trials (5 Ph3, 3 Ph2, 1 Ph 1b) and 1 ongoing long-term extension (LTE) study. Incidence rates (IR) per 100 patient-years (PY) were calculated for all patients with RA treated with ≥1 dose of bari through 1-Sep-2019. Overall IRs per 100 PY were: for any treatment-emergent adverse event (AE) (25.8); serious AE (including death) (7.2); temporary interruption due to AE (9.5); permanent discontinuation due to AE (4.8); death (0.52); serious infection (2.7); opportunistic infection (0.44) (excluding tuberculosis [TB]). IRs across safety topics through exposures up to 8.4 years were calculated for all patients with RA treated with ≥1 dose of bari through 1-Sep-2019 (All-Bari-RA analysis set). IRs for deep vein thrombosis (DVT), pulmonary embolism (PE), and DVT and/or PE (DVT/PE) were also calculated for groups of patients while receiving bari 2mg or bari 4mg within All-Bari-RA. Major adverse cardiovascular events (MACE) were adjudicated in phase 3 studies and the LTE.

**Results:** 3770 pts received bari for 13.148 PY, with a median and maximum exposure of 4.2 and 8.4 years, respectively. Overall IRs per 100 PY were for: any treatment-emergent adverse event (AE) (25.8); serious AE (including death) (7.2); temporary interruption due to AE (9.5); permanent discontinuation due to AE (4.8); death (0.52); serious infection (2.7); opportunistic infection (0.44) (excluding tuberculosis [TB]). IRs across safety topics through exposures up to 8.4 years were calculated for all patients with RA treated with ≥1 dose of bari through 1-Sep-2019 (All-Bari-RA analysis set). IRs for deep vein thrombosis (DVT), pulmonary embolism (PE), and DVT and/or PE (DVT/PE) were also calculated for groups of patients while receiving bari 2mg or bari 4mg within All-Bari-RA. Major adverse cardiovascular events (MACE) were adjudicated in phase 3 studies and the LTE.

**Results:** 3770 pts received bari for 13.148 PY, with a median and maximum exposure of 4.2 and 8.4 years, respectively.   - Oral targeted synthetic disease modifying anti-rheumatic drugs (DMARDs) including baricitinib and tocilizumab (JAKI), are the latest addition to the therapeutic options for rheumatoid arthritis (RA). **Objectives:** To assess and compare the efficacy and safety of Baricitinib and Tocilizumab in RA patients in real life.

- **Methods:** An observational longitudinal retrospective study was performed including RA patients who fulfilled the ACR/EULAR 2010 criteria and initiated treatment with Baricitinib or Tocilizumab from September 2017 to January 2020. Demographic, clinical and laboratory parameters and adverse events were collected. Infection was considered severe if it implied hospitalization. Statistical analysis was performed with R software (3.6.1) which consist in Bayesian linear regression models including monotonic effect and Kaplan-Meier survival curves.

- **Results:** 98 patients were included. Basal characteristics are exposed in table 1.

</table>

In both groups, a significant reduction of disease activity scores was noted (graphics 1 and 2).

Any difference between both treatments was detected in terms of efficacy even in first line, after DMARD failure, in monotherapy or combined therapy. Safety data are exposed in table 2 and neither was detected any statistical difference. In 2 of the cases of herpes zoster infection developed postherpetic neuralgia. Definitive discontinuation was registered in 23 cases (23,45%) accounting 6 (6,12%) for intolerance symptoms such as dizziness, nausea or headache (4 with Tofacitinib and 2 in Baricitinib group).

FRIO125 IMPACT OF RAMADAN DIURNAL INTERMITTENT FASTING ON CHRONIC MEDICATIONS INTAKE IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Maatallah1, D. Ben Nessib1, H. Ferjani1, D. Kaffel1, W. Hamdi1,2 Kassab Institute of Orthopedics, Rheumatology, Manouba, Tunisia

Background: Fasting during Ramadan, the ninth month of Islamic calendar, requires the abstinence from food and drink from sunrise to sunset [1]. Muslims are allowed to consume two major meals per day, one shortly before dawn (Suhour) and the other immediately after sunset (Iftar). Although some previous investigations have reported a beneficial impact of fasting on rheumatic diseases’ activity [1,2], very few studies have dealt with the possible impact of intermittent fasting on chronic medications intake.

Objectives: The objective of this study was to assess the impact of Ramadan intermittent fasting on adherence and tolerance of Disease-Modifying Anti-Rheumatic Drugs (DMARDs) in patients with rheumatoid arthritis (RA).

Methods: This is a prospective monocentric study including patients with rheumatoid arthritis (RA) who fasted Ramadan 2019. Each patient was evaluated during 2 visits: 6 months before starting Ramadan fasting and after fasting at least 7 days. The following parameters were assessed: compliance with treatments, tolerability and timing of intake (iftar meal, evening, Suhoor meal).

Results: Thirty-six patients were enrolled: 7 men and 29 women. The average age of patients was 57.5 years ± 10.9 [39-79] and the mean disease duration was 6.7 years ± 3.3 [1-13]. Biological agents, methotrexate (MTX), Salazopyrin (SLZ) and Leflunomide (LFN) were respectively prescribed in 8, 22, 4 and 4 patients. Ramadan fasting did not affect either compliance with biological agents or tolerability. No additional side effects have been reported during this period. The compliance to MTX was comparable before and during fasting in 68.4% of cases. It was impaired by fasting in the rest with a full stop in 26.3% of patients. MTX was taken away from meals (as recommended) by 42.8% of patients. The timing of drug intake was the iftar meal in 21.4% of patients, the Suhoor meal in 14.3% of patients and the evening in 64.3% of patients. Except 1 patient, adherence to SLZ was adequate during Ramadan fasting. It was taken with the 2 major meals in 50% of cases and during the evening in 50% of cases.

Patients under LFN did not report any discontinuation. The reported reasons of discontinuations of Conventional Synthetic Disease-Modifying Anti-Rheumatic Drugs (csDMARDs) were: objective adverse effects (25%), apprehension of gastrointestinal adverse effects (25%) and lack of time between the two major meals (50%) (since they were advised to take MTX away from meals).

Regarding the tolerance, gastrointestinal side effects of MTX were reported to be more frequent during Ramadan by 20% of patients, fewer by 13.3% of patients and unchanged by the rest of the patients. The gastrointestinal tolerance of SLZ and LFN was similar before and during Ramadan fasting.

Conclusion: Even if the tolerability of chronic medications was not impaired by Ramadan fasting in the majority of patients, adherence to conventional DMARDs was reported to be reduced by more than a quarter of patients, mainly because of a lack of time between the two major meals. Physicians should be aware of the impact of Ramadan fasting on chronic drugs intake because they have a crucial role in helping patients with RA adjust medications safely.

POOR ADHERENCE TO METHOTREXATE IS ASSOCIATED WITH PERSISTENT DISEASE ACTIVITY DURING FOLLOW-UP FOR RHEUMATOID ARTHRITIS

J. H. Kang1, S. E. Choi1, H. Xu1, D. J. Park1, S. S. Lee1 Chonnam National University Medical School & Hospital, Gwangju, Korea, Rep. of (South Korea)

Objectives: Although methotrexate (MTX) is the cornerstone therapy in patients with rheumatoid arthritis (RA), adherence to MTX in these patients is typically suboptimal. Thus, we investigated the proportion of RA patients who were adherent to MTX and whether non-adherence to MTX affected the clinical outcome in these patients during follow-up.

Methods: We enrolled 331 RA patients from a single tertiary center. Data were collected at the time of enrollment and then annually for 4 consecutive years. Adherence was defined by the proportion of days covered at 1 year. Patients were divided into two groups: patients who took more than 80% of MTX and those who did not. Univariate and multivariate analyses were performed to identify the association between drug compliance and clinical outcome.

Results: Of the 331 RA patients, 8.7% had taken less than 80% of MTX during the follow-up period. Non-adherent patients had lower EuroQol-SD scores (P=0.013) and higher RAPID3 scores (P=0.004) at baseline than adherent patients. Leflunomide was more commonly prescribed to adherent patients than non-adherent patients (P=0.012). Non-adherent patients had a higher mean Disease Activity Score 28 (DAS28)-erythrocyte sedimentation rate score (P=0.001), higher mean DAS28-C-reactive protein (CRP) score (P=0.001), and higher mean tenderness and swollen joint counts (P=0.003 and P=0.002, respectively) than adherent patients. In the multivariate analysis, poor MTX adherence was significantly associated with a higher mean DAS28-CRP score (odds ratio, 0.270; 95% confidence interval, 0.165–0.444; P=0.001).
Results: For good response for tapering, joint destruction was determined. Predictors for tapering were also evaluated. According to tapering response, prognostic factor disease activities, severe adverse events, the continuation rate during MTX scoring (mTSS) at 1 year after the start of tapering MTX. Evaluation of clinical disease activities, severe adverse events, the continuation rate during MTX tapering were also evaluated. According to tapering response, prognostic factor for good response for tapering, joint destruction was determined. Predictors for successful tapering MTX and progression of bone destruction were determined. Statistical analysis was performed by t-test or Wilcoxon rank sum test using SAS .132 software.

Results: The subjects were 79 (16 males, 63 females). Age average 60.9 years, disease duration 4 years 4 months, MTX dose 8.43 mg / w, DAS28-CRP 1.52, DMARDs (24.3%), ACIA 192.7 U / ml (70.5%), RF 55.6 IU / ml (65.4%). MTX was tapered from an average of 8.43 mg / w before study to 5.46 mg / w one year later. In the treatment evaluation, DAS28-CRP increased from 1.52 to 1.84. 89.7% of subjects did not progress joint damage. Other disease activities significantly increased (Table 1). The one-year continuation rate was 76.2%. Since tapering effects were varied widely, we divided patients into three groups; Flared group (N=14, initial MTX dose 8.71 mg / w, final MTX dose 8.42mg / w), Low response group (N=31, final MTX reduction rate 50%, initial MTX dose 8.93mg / w, final MTX dose 6.22mg / w), High response group (N=34, final MTX reduction rate 50%, initial MTX dose 8.5mg / w, final MTX dose 3.15mg / w). Higher RF value at baseline and higher MTX dose at 3M, 6M were predictors whether a subject was in Flared group or High response group. Lower age was predictor of whether a subject was in Flared group or Low responder group. Finally, mean mTSS / y in Flared group (0.36) was not significantly higher than in low response group (0.07) and in high response group (0.01).

and W12 for both the CFB of the SF-36 Physical Component Summary (PCS) (p < 0.001) and Mental Component Summary (MCS) (p ≤ 0.006); nominal significance was also seen at W24 for CFB of SF-36 PCS (Fig 2A, B). By W4, pts receiving either dose of FIL reported a nominally significantly greater mean CFB in FACIT-Fatigue scores vs PBO (p < 0.001); significance was maintained through W24 and improvement in reported fatigue continued through W52 in the FIL groups (Fig 2C). In general, CFB for HAQ-DI, VAS pain scale, and FACIT-Fatigue observed for the FIL groups was higher or comparable to AFA at various time points (Fig 1, 2).

**Conclusion:** Both doses of FIL provided rapid and sustained improvements in functional status, pain, HRQoL, and fatigue compared with PBO for pts with RA and inadequate response to MTX throughout the 52-week period.

**FRI0129 DEVELOPMENT OF A PREDICTION MODEL FOR MAXIMUM METHOTREXATE (MTX) DOSE WITHOUT HEPATOTOXICITY USING AN INDEX OF ERYTHROCYTE MTX-POLYGLUTAMATE (MTXPG) LEVELS SPECULATED BY CLINICAL AND GENETIC MARKERS**

S. Kumagai1, S. Takahashi1, M. Takahashi2, T. Saito2, K. Yoshida2, M. Katayama1, S. Mukohara1, N. Amano1, A. Onishi3, M. Shinohara4, S. Hatachi3, Shinko Hospital, Center for Rheumatic Diseases, Kobe, Japan; Shinko Institute for Medical Research, Center for Rheumatic Diseases, Kobe, Japan; Kobe University Graduate School of Medicine, Department of Rheumatology and Clinical Immunology, Kobe, Japan; Kobe University Graduate School of Medicine, The Integrated Center for Mass Spectrometry, Kobe, Japan

**Background:** MTX is transported into cells and retained long after polyglutamation. MTXPG level can predict response and possibly adverse effects of MTX. We reported erythrocyte MTXPG concentrations efficiently discriminated patients with and without hepatotoxicity. We also developed genetic and clinical prediction models for efficacy and hepatotoxicity of MTX. In the present study, we firstly investigated the effects of clinical and secondly genetic variables on the concentration of total MTXPG and determined oral maximum MTX dose without hepatotoxicity using these variables.

**Objectives:** To develop a prediction model for maximum MTX dose without hepatotoxicity.

**Methods:** Concentrations of erythrocyte MTX-PG (PG1 to PG4) were calculated total MTXPG as sum of them. MTX-PG levels were measured in 265 RA patients including 40 patients with elevated AST or ALT (>60 U/L; 1.5 times of upper limits) and the 6 SNPs of 6 genes related to MTXPG metabolism were identified by RT-PCR.

**Results:** Total concentrations of MTXPG were 141.3 ± 86.5 and 87.6 ± 47.8 nmol/L (mean±SD) in 40 RA patients with hepatotoxicity and 225 patients without, respectively (p<0.0001). By ROC analysis, the two groups were most efficiently discriminated with cutoff concentration of 100.0 nmol/L (AUC 0.731). Next, genetic and clinical model to speculate the MTXPG concentration was established by multivariate analysis using 4 clinical and 3 genetic variables which were selected from 20 clinical and 6 genetic variables by univariate analysis (p<0.1). Finally, a speculation model for MTXPG concentration was developed by logistic regression analysis using 4 clinical and 3 genetic variables (MTX dose, BMI, RBC count, and creatinine) and one genetic variable (GGH c.452C>T) was developed (Figure). When MTXPG concentration of 100 nmol/L was applied to the model, maximum MTX dose without hepatotoxicity was calculated for each patient as MTX dose (mg) = (100 [MTXPG] – 96.1*BMI + 28*RBC - 12.0*creatinine - 19.3*GGH(C/T)) / 7.7. Real dose of oral MTX exceeded the calculated dose in 23 of 40 patients (57.5%) with hepatotoxicity, whereas it exceeded in 95 of 223 patients (42.6%) without hepatotoxicity (OR 1.82, p=0.081).

**Conclusion:** Maximum MTX dose without hepatotoxicity was speculated by several clinical and genetic markers without measurement of erythrocyte MTX-PG concentrations.

**References:**
Objectives: Therapies range from dietary interventions to supplements to nonprescription biologics. Despite these therapies, anywhere from 28-90% of patients with RA will have some degree of joint damage. The primary treatment goal for patients (pts) with rheumatoid arthritis (RA) is remission or low disease activity (LDA).1,2

Background: Rheumatoid arthritis (RA) is a chronic autoimmune condition affecting almost 1% of the general population (1). Pharmacological management has been the mainstay of treatment for RA and includes DMARDs and biologics. Despite these therapies, anywhere from 28-90% of patients with RA; however, the degree of improvement is unlikely to be clinically significant. Overall, many trials were of low quality and had high risks of bias including inadequate reporting of data. Further clinical trials that are well-designed and fully powered are still needed to confirm the efficacy of many supplements and diets in RA.

A SYSTEMATIC REVIEW OF NATURAL SUPPLEMENTS IN THE TREATMENT OF RHEUMATOID ARTHRITIS

Y. Liu1, J. Pope2, M. Turk2. 1Western University, London, Canada; 2St Joseph’s Health Care, Rheumatology, London, Canada

Background: Rheumatoid arthritis (RA) is a chronic autoimmune condition affecting almost 1% of the general population (1). Pharmacological management has been the mainstay of treatment for RA and includes DMARDs and biologics. Despite these therapies, anywhere from 28-90% of patients with RA; however, the degree of improvement is unlikely to be clinically significant. Overall, many trials were of low quality and had high risks of bias including inadequate reporting of data. Further clinical trials that are well-designed and fully powered are still needed to confirm the efficacy of many supplements and diets in RA.

Method: We systematically reviewed EMBASE and MEDLINE electronic databases from inception until Feb 23, 2019 for relevant articles. Only randomized controlled trials (RCTs) which assessed oral, non-pharmacological interventions (e.g. diets, vitamins, oils, herbal remedies, fatty acids, supplements, etc.) in adult patients with RA, that presented clinically-relevant outcomes (defined as pain, fatigue, disability, joint counts, and/or disease indices) were included.

Clinical outcome data was extracted by two independent authors as difference from baseline measurement. Therapies with at least 3 RCTs which presented results were included.

Results: A total of 4423 unique articles were independently assessed by two authors, of which 72 articles met our inclusion criteria. Thirteen different interventions were studied more than once, and six interventions had clinical outcomes reported in at least 3 trials. However, only vitamin D and fatty acids met criteria for meta-analysis.

Pooled random effects models suggested vitamin D supplementation improved HAQ scores from baseline (mean difference = -0.10, 95% confidence interval (CI) = -0.17 to -0.02; p=0.01) but had no effect on DAS28 scores (Table 1).

Table 1. Mean differences from baseline of various clinical outcomes in RA patients taking vitamin D or fatty acid supplementation compared to control group.

Fatty acid supplementation improved total joint counts, pain, physician global assessment scores, HAQ, and DAS28 from baseline (Table 1). There were significantly more patients who achieved ACR20 criteria (Relative Risk Ratio = 2.73, 95% CI 1.62-4.58; p<0.001) (Figure 1).

Figure 1. Forest plot of studies in which RA patients taking fatty acids achieved ACR20 criteria. https://account-congress.eular.org/Modules/Abstract/Submission/summary.aspx

Conclusion: From our meta-analysis, vitamin D and fatty acids supplementation showed statistically significant improvement in some clinical outcomes in patients with RA; however, the degree of improvement is unlikely to be clinically significant. Overall, many trials were of low quality and had high risks of bias including inadequate reporting of data. Further clinical trials that are well-designed and fully powered are still needed to confirm the efficacy of many supplements and diets in RA.

SUSTAINABILITY OF RESPONSE BETWEEN UPADACITINIB AND ADALIMUMAB AMONG PATIENTS WITH RHEUMATOID ARTHRITIS AND PRIOR INADEQUATE RESPONSE TO METHOTREXATE

P. Nash1, A. Kavanagh2, M. H. Buch3, B. Combe4, L. Bessette5, I. H. Song6, Y. Song6, J. Suboticki6, R. Fleischmann7. 1School of Medicine, Griffith University, Brisbane, Australia; 2University of California San Diego, San Diego, United States of America; 3University of Manchester & NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; 4Lapeyronie Hospital, Montpellier University, Montpellier, France; 5Université Laval, Centre hospitalier de l’Université Laval, Quebec, Canada; 6AbbVie Inc., North Chicago, United States of America; 7Univ of Texas Southwestern Med Center, Metrpolix Clinical Research Center, Dallas, United States of America

Background: The primary treatment goal for patients (pts) with rheumatoid arthritis (RA) is a state of sustained clinical remission (REM) or low disease activity (LDA).1,2

Objectives: To assess the long-term sustainability of response to upadacitinib (UPA), a JAK inhibitor, and adalimumab (ADA), both with background methotrexate (MTX), among pts with RA and prior inadequate response to MTX.

Disclosure of Interests: A. Kavanagh: Roche, Sandoz, Sanofi, UCB, Speakers bureau: UCB, Matthew Turk: None declared

DOI: 10.1136/annrheumdis-2020-eular.5161
Methods: In the phase 3, randomized, placebo (PBO) and active-controlled SELECT-COMPARE trial, pts on stable background MTX received UPA 15 mg once daily, PBO, or ADA 40 mg every other week. Pts not achieving 20% improvement in tender/swollen joint counts (Weeks 14-22) or LDA (CDAI ≤10 at Week 26) were rescued from UPA to ADA or PBO/ADA to UPA; all non-rescued PBO pts were switched to UPA at Week 26. This post hoc analysis evaluated clinical REM (CDAI ≤28; SDAI ≤3.3), LDA (CDAI≤10; SDAI≤11), and DAS28(CRP)<2.6/≤3.2 at first occurrence before Week 72 or prior to treatment switch; additionally, these measures were evaluated at 3, 6, and 12 months after the first occurrence for the total number of pts randomized to UPA (n=651) or ADA (n=327). Sustainability of response was evaluated by Kaplan-Meier only for those pts who achieved REM/LDA and was defined as time to the earliest date of losing response at two consecutive visits, discontinuation of study drug, or losing response at the time of rescue. The predictive ability of time to clinical REM/LDA was assessed using Harrell's concordance (c)-index (for reference, an index ~ 0.5, indicates no ability to predict; an index of 1 or -1 would be a perfect prediction). The date of the last follow up was 6 July, 2018, when all pts had reached the Week 72 visit.

Results: Through Week 72, a significantly higher proportion of pts receiving UPA + MTX vs ADA + MTX achieved CDAI REM (41% vs 31%, p=0.0035) as well as CDI LDA (70% vs 59%, p=0.0007). 26%-22% of pts randomized to UPA + MTX and 16%-14% of pts randomized to ADA + MTX achieved sustained CDI LDA at 6/12 months after the first occurrence. Additionally, 49%-46% of pts randomized to UPA + MTX and 36%-34% of pts randomized to ADA + MTX achieved sustained CDI LDA at 6/12 months after the first occurrence (Figure 1). Time to initial clinical REM/LDA did not appear to be associated with sustained disease control. The c-indices (95% CI) for CDAI REM in the UPA +MTX and ADA + MTX groups were 0.528 (0.48, 0.58) and 0.510 (0.43, 0.59) and that of LDA were 0.601 (0.56, 0.64) and 0.555 (0.50, 0.61), respectively. Through last follow-up visit, 51% of UPA + MTX pts and 45% of ADA + MTX pts remained in CDAI REM while 65% of UPA + MTX pts and 58% of ADA + MTX pts remained in CDAI LDA, respectively (Figure 2). Similar results were observed across other disease activity measures (SDAI REM/LDA and DAS28(CRP)<2.6/≤3.2).

Conclusion: A significantly greater proportion of pts with RA and prior inadequate response to MTX reaching UPA + MTX vs ADA + MTX achieved clinical REM or LDA across disease activity measures. REM and LDA were sustained through Week 72 in both treatment arms, with numerically higher proportions retaining response among UPA-treated pts.

Methods: Spanish observational multicentric study. Data were retrospectively obtained from medical records of 28 patients with RA sequentially treated with baricitinib or tofacitinib in any order.

Results: We identified 28 patients with RA treated with baricitinib and tofacitinib. Patient’s characteristics are summarized in Table 1. Half of the patients received tofacitinib first, and the other half baricitinib as the first JAKI. Mean survival for the first JAKI was 7.6 ± 6.1 months. The reason for withdrawal was inefficacy in 17 cases (61%) and adverse effects in 11 (39%). Mean follow-up after starting on the second JAKI was 9.6 ± 5.6 [3-19] months. Disease activity data along follow-up are depicted in Table 2. Survival on the second JAKI was 82% at 3, 76% at 6, and 62% at 12 months when 13 of the 21 patients maintained the therapy. In all 8 patients who discontinued the second JAKI, the reason was inefficacy. The treatment survival rate was similar among patients discontinuing the first JAKI for inefficacy (n=5, 29.4%) or for adverse effects (n=3, 27.3%).

Disclosure of Interests:

Our data show that therapy with a second JAKi is a safe and efficacious option after discontinuation of the first JAKi due to either inefficacy or side effects. The response rate to the second JAKi is similar in patients with inefficacy or side effects which suggests that failure to the first does not reduce the chance of response to the second.

RELATIONSHIP BETWEEN MELATONIN SERUM LEVELS AND THE EFFICACY OF SELECTIVE SEROTONIN REUPTAKE INHIBITOR PAROXETINE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Sikala1, L. Zhuravlyova1, M. Oliinyk1, Kharkiv National Medical University, Kharkiv, Ukraine

Background: Numerous clinical and epidemiological studies have established that there is a close relationship between inflammation, chronic pain and psycho-emotional disorders in rheumatoid arthritis [1, 2]. The common pathogenic mechanism is manifested in the defect of melatonin mediation and cytokine stimulation [3]. Therefore, features of the use of selective serotonin reuptake inhibitors is relevant.

Objectives: To study the relationship between serum melatonin level and the efficacy of selective serotonin reuptake inhibitor paroxetine in patients with RA.

Methods: A total of 127 RA patients and 71 healthy volunteers were examined. The following information was collected for each patient: medical history data, physical examination results, serum melatonin levels. RA patients were randomly categorized into two treatment groups – 63 and 64 patients. The basic treatment for patients of both groups included nonsteroidal anti-inflammatory drugs, glucocorticoids (equivalent to 10 mg of prednisolone), and disease-modifying antirheumatic drugs (methotrexate, leflunomide or sulfasalazine). To evaluate the effectiveness of treatment, patients of both groups were further divided into three subgroups depending on the serum melatonin level (low level corresponds to 25 percentile, medium - 25-75, high - 75 percentile). First group received paroxetine 20 mg once a day for 12 weeks in addition to the basic treatment. The level of effectiveness of the treatment was evaluated according to ACR/EULAR criteria.

Results: The mean baseline plasma melatonin levels in RA patients were significantly higher than in the healthy volunteers (26.1±32.7 vs 13.6±4.6 pg/mL at 8 am and 11.5±15.5 vs 3.6±4.6 pg/mL at 20 pm (p<0.001), respectively). A good response to basic treatment was observed in groups with medium and high serum melatonin levels, who received paroxetine (p<0.05). However, patients who did not receive paroxetine gave best response to treatment in group with low serum melatonin levels (p<0.05).

Conclusion: Obtained data suggest that the high level of serum melatonin is one of the predictors of resistance for basic RA treatment. The proposed scheme of treatment with addition of paroxetine demonstrated high efficacy concerning the main manifestations of disease in RA patients with high serum melatonin level. This study demonstrates the possible influence of serotonergic interactions on the melatoninergic system and their contribution to the pathogenesis of RA.

FR10134

EFFECT OF JAK INHIBITORS ON PAIN AND QUALITY OF LIFE IN RHEUMATOID ARTHRITIS PATIENTS

F. R. Spinelli1, C. Garufi2, F. Ceccarelli1, S. Mancuso1, I. Ducu3, C. Alessandri1, M. Di Franco1, R. Priori1, V. Ricciori1, R. Scrivo4, G. Valesini5, F. Conti1.

1Sapienza Università di Roma, Rheumatology Unit, Rome, Italy

Background: Pain control is considered a treatment priority from most patients with Rheumatoid Arthritis (RA). Despite the treat to target approach, residual pain is commonly reported by patients with RA. Treatment with JAK inhibitors (JAKi) has been associated to a rapid control of pain.

Methods: Patients candidate to baricitinib or tofacitinib were evaluated at baseline and after 12 and 24 weeks of treatment. Disease activity was assessed by Disease Activity Score (DAS28) with C reactive protein (CRP).

A reduction of ≥ 50% of pain visual-analogue scale (VAS) 0-100 mm was recorded as “very much improved, substantially improved” (1). Pain VAS score ≤ 10 mm was considered “no/limited pain” (2). Patients’ satisfaction was assessed by the Patient Acceptable Symptom State question (3). Data were expressed as mean (SD) or median (interquartile range) according to the variables’ distribution. Mann Witney test was used and p values <0.05 were considered statistically significant.

Results: Overall 108 patients started a JAK inhibitor (baricitinib n=67; tofacitinib n=41). Forty-eight patients (baricitinib n=51; tofacitinib n=33) were followed-up for at least 3 months and were included in the statistical analysis. Table1 summarizes demographic and clinical characteristic of the cohort. After 12 and 24 weeks of treatment we detected a significant reduction of DAS28 compared with baseline [from 4.7 (1.5) to 3.2 (1.7) 2.9 (1.5) and 2.7 (1.1), respectively; p<0.001; p<0.0001 and p<0.00001]. At week 4, 27% and 51.6% of patients achieved remission and low disease activity, respectively; the percentages increase to 32.1% and 60.7% at week 12 and 42.2% and 70.3% at week 24. When evaluating the extent of reduction of the single items included in the DAS28 composite index we found that number of tender (TJ) and swollen joints (SJ) decreased from 9 (7.8) to 5 (3.5) to 4 (3.3) and 5 (1) at week 4, 2 (4) and 1 (3) at week 12, and 2 (4) and 1 (3) at week 24, respectively (p<0.0001 for all); the median reduction of TJ and SJ at week 4, 12 and 24 was 60%, 77% and 88%, 81%, 86% and 100%, respectively. GH decreased from 70 (30) to 40 (40) at week 4, 40 (30) at week 12 and 37 (40) at week 24 (p<0.0001) with a median reduction of 37.5%, 44% and 46%. C reactive protein decreased by 54.5% at week 4, 47% at week 12 and 55% at week 24. VAS pain was significantly reduced at week 4, 12 and 24 from (70/25) to 40/30,30/40 (at the three timepoints, p<0.0001) decreasing by 37.5%, 50% and 54%, respectively. A substantial reduction (≥50%) in VAS pain was reported by 41.3%, 54.4% and 53.9% of patients after 4, 12 and 24 weeks, respectively. Limited/no pain was reported by 21.3%, 24.7%, 24.7% and 36.5% at weeks 4, 12 and 24, respectively. Overall, 81.8% of patients achieved the PASS after a median time of 10 (7-15) days.

Conclusion: JAK inhibitors baricitinib and tofacitinib induce a rapid improvement of disease activity driven both by pain and inflammation control. Even if no/limited pain was described only by one third of the patients, most of them reported a rapid and sustained reduction of pain accounting for the achievement of a satisfactory health condition.

DOI: 10.1136/annrheumdis-2020-eular.4903
In this study, we demonstrated the short-term clinical effectiveness and safety profile of baricitinib in Japanese RA patients in the ‘real-world’ setting. To the best of our knowledge, this study is the first to report the clinical outcomes of baricitinib in routine clinical practice in Japan. Baricitinib significantly improved disease activity, with an expected safety profile. We observed some interesting features regarding the effectiveness of baricitinib. Baricitinib was significantly more effective when used as a first-line targeted DMARD and may play a key role in the modern treatment strategy for RA, although careful observation is necessary for possible complications and AEs including herpes zoster.

Conclusion:

This study aimed to evaluate the short-term effectiveness and safety profiles of baricitinib and explore factors associated with improved short-term effectiveness in patients with RA in clinical settings.

Objectives:
- To determine the short-term effectiveness and safety profiles of baricitinib
- To explore factors associated with improved short-term effectiveness in patients with RA

Methods:
- A total of 113 consecutive RA patients who had been treated with baricitinib were registered in the TBCR, a Japanese multicenter registry for RA patients
- Patients were treated with biologics or JAK inhibitors (targeted DMARDs) [3], and followed for at least 24 weeks
- Univariate and multivariate logistic regression analysis was used to study predictive factors for achievement of low disease activity (LDA) at 24 weeks

Results:
- Mean age was 66.1 years, mean RA disease duration was 14.0 years, 71.1% had a history of use targeted DMARDs, and 48.3% and 40.0% were receiving concomitant methotrexate (MTX) and oral prednisone, respectively
- Mean DAS28-CRP significantly decreased from 3.55 at baseline to 2.32 at 24 weeks (Figure 1A). At 24 weeks, 68.2% and 64.1% of patients achieved LDA and moderate or good response, respectively (Figure 1B)
- Multivariate logistic regression analysis revealed that no previous targeted DMARD use and lower nHAQ baseline were associated with DAS28-CRP at 24 weeks, as estimated by Kaplan-Meier analysis. The discontinuation rate was 33.4% (2.53-442.62)

In this study, we demonstrated the short-term clinical effectiveness and safety profile of baricitinib in Japanese RA patients in the ‘real-world’ setting. To the best of our knowledge, this study is the first to report the clinical outcomes of baricitinib in routine clinical practice in Japan. Baricitinib significantly improved disease activity, with an expected safety profile. We observed some interesting features regarding the effectiveness of baricitinib. Baricitinib was significantly more effective when used as a first-line targeted DMARD and may play a key role in the modern treatment strategy for RA, although careful observation is necessary for possible complications and AEs including herpes zoster.

DISCONTINUATION OF BARICITINIB AFTER ACHIEVING LOW DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN CLINICAL PRACTICE: A MULTICENTER OBSERVATIONAL STUDY.

E. Torikai1, Y. Hirono2, D. Suzuki3, Y. Kanayama1,1. Iwata city hospital, Iwata, Japan;2Toyohashi Municipal Hospital, Toyohashi, Japan;3Futaba clinic, Iwata, Japan;4Toyota Kosei Hopital, Toyota, Japan

Background: Baricitinib (bari) is an oral Janus kinase (JAK) 1/2JAK2 selective inhibitor that has shown good efficacy in patients with RA and adequate response to conventional synthetic DMARDs in some clinical trials [1,2]. However, concerning the high cost and long-term safety related to the inhibition of particular molecules, we would like to discontinue bari after achieving long low disease activity (LDA).

Objectives: To evaluate the clinical outcomes in patients with RA who discontinued bari after achieving LDA for 24 weeks in real-world multicenter clinical data.

Methods: Japanese 67 patients with RA who show an inadequate response to csDMARDs or bDMARDs were scheduled to receive bari 4 or 2 mg/day once daily dose as a monotherapy or in combination with other csDMARDs. We included 51 patients who achieved and maintained LDA at least for 24 weeks after baricitinib therapy. They were allowed to decrease baricitinib 10% at wk 4; CXC1L1 at wks 4 and 12) had significant differences from ADA+MTX. Relative either to FIL200mg+MTX or FIL100mg+MTX, and despite the same direction of effect, ADA+MTX led to a significantly larger reduction in CCL2, CXC1L1, CCL4, and CXC1L3.

Conclusion: Compared with PBO, 12 wks of FIL treatment significantly reduced cytokines associated with JAK activity1, bone biology2, inflammation2, and immune cell migration3 in MTX-IR pts. The effects were largely FIL dose-dependent; most cytokines exhibited similar effects regardless of treatment arms, but differential changes between FIL+MTX and ADA+MTX were observed, supportive of the different mechanisms of action of these therapies.

DOI: 10.1136/annrheumdis-2020-eular.4704
Background: In Phase 3 trials, upadacitinib (UPA), an oral JAK1-selective inhibitor, has been assessed as monotherapy vs MTX (SELECT-EARLY3) and in combination with MTX vs adalimumab + MTX (ADA; SELECT-COMPARE4) in RA pts who were MTX naive or with inadequate responses to MTX (MTX-IR), respectively.

Objectives: In this analysis we assessed individual and composite measures of disease activity in SELECT-EARLY and SELECT-COMPARE.

Methods: In SELECT-EARLY, MTX-naïve pts received UPA 15 mg or 30 mg monotherapy once daily (QD), or MTX monotherapy, for 12 wks. In SELECT-COMPARE, MTX-IR pts on stable background MTX received UPA 15 mg QD, PBO, or ADA 40 mg every 2 wks for 12 wks. For this analysis, responses at Wk 12 were defined as ≥50% improvement in the 7 components of the ACR response criteria. Among ACR50 responders, the proportions of pts with ≥50% improvement in all 7 components of the ACR criteria was assessed. The proportion of pts achieving TJC68=0 and SJC66=0 was also determined. All analyses were based on observed data without imputation.

Results: 947 pts were randomized in SELECT-EARLY, and 1629 pts in SELECT-COMPARE. Mean time since RA diagnosis was 2.7 years in SELECT-EARLY (median 6 months) and 8.2 years in SELECT-COMPARE; mean DAS28(CRP) was 5.9 and 5.8, respectively. In SELECT-EARLY, significantly more MTX-naïve pts receiving UPA 15 mg or 30 mg monotherapy achieved ≥50% improvements in all ACR components at Wk 12 compared with MTX (Figure 1a, Figure 1b). In SELECT-COMPARE, significantly more MTX-IR pts on UPA 15 mg + MTX achieved ≥50% improvement in the ACR components vs PBO (all components) and ADA + MTX (all components except SJC and PhGA). Among pts with ACR50 responses at Wk 12, approximately half of the MTX-naïve pts on UPA 15 mg and 30 mg in SELECT-EARLY had ≥50% improvements in all 5 remaining ACR components (pain, PtGA, PhGA, HAQ-DI, hsCRP) compared with 28% with MTX. Corresponding proportions in MTX-IR pts in SELECT-COMPARE were 34% for UPA 15 mg + MTX, 28% for ADA + MTX, and 17% for PBO. UPA treatment also significantly increased the proportions of pts achieving both TJC68=0 and SJC66=0 vs PBO or MTX, and SJC66=0 vs ADA + MTX (Figure 1a, Figure 1b).

Conclusion: In MTX-naïve and MTX-IR pts, treatment responses at 12 wks occurred in significantly higher proportions of pts receiving UPA monotherapy vs MTX and UPA + MTX vs PBO for all 7 components of the ACR response criteria, and for 5 of 7 ACR components for UPA + MTX vs ADA + MTX. Favorable outcomes with UPA treatment were evident both in composite and individual parameters.

FILGOTINIB PROVIDED RAPID AND SUSTAINED RELIEF OF PAIN AND FATIGUE AND IMPROVED HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE TO BIOL OGER DMARDS: RESULTS FROM THE FINCH 2 STUDY

D. Walker1, T. Takeuchi2, B. Bartok3, S. Rao4, I. H. Lee5, R. Besuyer6, J. E. Gottenberg7, M. C. Genovese8, 9Northumbria Healthcare Trust, North Shields, United Kingdom; 2Keio Univ School of Medicine, Tokyo, Japan; 3Gilead Sciences, Inc., Foster City, CA, United States of America; 4Galapagos BV, Leiden, Netherlands; 5Strasbourg Univ Hospital, Strasbourg, France; 6Stanford Univ, Stanford, CA, United States of America

Background: EULAR guidelines recommend a treat-to-target approach focusing on reducing inflammation to prevent joint damage, physical disability, and mortality. However, patients consider reduction in pain and fatigue, along with maintenance of physical function, and improvement in health-related quality of life (HRQoL) important areas for improvement with RA treatment. In the FINCH 2 study, filgotinib (FIL)—a potent, selective, oral small molecule Janus kinase 1 inhibitor—in combination with conventional synthetic (cs)DMARD therapy significantly improved the signs and symptoms of rheumatoid arthritis (RA) in patients with an inadequate response to a biologic (b)DMARD compared with placebo (PBO). In addition, patients experienced significant improvements in HAQ-DI at week (W)12 and W24 with FIL 100 mg (p <0.001, p = 0.003) or 200 mg (p <0.001 for both) compared with PBO.

Objectives: To evaluate the rate and magnitude of change in patient-reported outcomes (PROs) from FINCH 2 assessing pain, HRQoL, and fatigue.

Methods: Patients in this double-blind, randomised study (NCT02873936) received FIL 200 mg, FIL 100 mg, or PBO while continuing csDMARD therapy. PROs were collected prospectively on day 1 and at the W2, W4, W8, W12, W14, W16, W20, and W24 visits for assessment of pain (VAS pain scale) and on day 1 and at W4, W12, W14, and W24 for assessment of fatigue (FACIT-Fatigue) and HRQoL (SF-36). Changes from baseline for each PRO at each time point up to W24 were analysed longitudinally using a mixed-effects model for repeated measures. P values for the difference between each FIL arm and PBO at each time point were calculated.

Results: Among the 448 patients randomised and treated (FIL 200 mg, n = 147; FIL 100 mg, n = 153; PBO, n = 148) 381 (85.0%) completed the study. Baseline mean (SD) VAS pain scale was 67.1 (20.1), SF-36 physical component summary (PCS) was 31.1 (7.89), SF-36 mental component summary (MCS) was 44.3 (11.6), and FACIT-Fatigue score was 24.4 (11.6); baseline values did not vary between treatment groups. Significantly greater improvements in VAS pain scores began at W2 and were maintained through W24 for patients who received either dose of FIL vs PBO (Figure 1A). FIL also significantly improved patients’ fatigue at W4, W12, and W24 compared with PBO for those receiving 200 mg doses, and at W4 and W12 for those receiving 100 mg doses (Figure 1B). HRQoL related to physical functioning (SF-36 PCS) was

Disclosure of Interests: Ronald van Vollenhoven Grant/research support from: AbbVie, Arthrogen, Bristol-Myers Squibb, GlaxoSmithKline, Lilly, Pfizer, and UCB, Consultant of: AbbVie, AstraZeneca, Biotest, Bristol-Myers Squibb, Celgene, GSK, Janssen, Lilly, Medac, Merck, Novartis, Pfizer, Roche, and UCB, Andrew Ostor Consultant of: MSD, Pfizer, Lilly, Abbvie, Novartis, Roche, Gilead and BMS, Speakers bureau: MSD, Pfizer, Lilly, Abbvie, Novartis, Roche, Gilead and BMS, Eduardo Mygrant Research support from: AbbVie, Amgen, Bristol-Myers Squibb, Roche, Eli Lilly, Novartis, Janssen, Sanofi, and Pfizer, Nemanja Damjanov Grant/research support from: from AbbVie, Pfizer, and Roche, Consultant of: AbbVie, Gedeon Richter, Merck, Novartis, Pfizer, Roche, and Roche, Speakers bureau: AbbVie, Gedeon Richter, Merck, Novartis, Pfizer, Roche, In-Ho Song Shareholder of: Abbvie Inc., Employee of: Abbvie Inc., Yanna Song Shareholder of: Abbvie Inc., Employee of: Abbvie Inc., Jessica Suboticki Shareholder of: Abbvie Inc., Employee of: Abbvie Inc., Vibeke Strand Consultant of: Abbvie, Amgen, Biogen, Celtrion, Consortium of Rheumatology Researchers of North America, Crescendo Bioscience, Eli Lilly, Genentech/Roche, GlaxoSmithKline, Hospira, Janssen, Merck, Novartis, Pfizer, Regeneron Pharmaceuticals, Inc., Sanofi, UCB

DOI: 10.1136/annrheumdis-2020-eular.1426
significantly enhanced at W4, W12, and W24 with both doses of FIL as compared with PBO (Fig 2A). Improvements to mental-health-related QoL (SF-36 MCS) were reported for FIL as early as W4 and maintained through W24, with statistically significant improvements at W4 and W12 for FIL 200 mg vs PBO (Fig 2B).

**Conclusion:** In a patient population with refractory disease that had inadequate response to prior bDMARDs and had significant disease at baseline, FIL treatment—coadministered with csDMARD therapy—was able to provide rapid and sustained improvements in key measures of pain, HRQoL, and fatigue as reported by patients.

**DOI:** 10.1136/annrheumdis-2020-eular.2901
Background: Upadacitinib (UPA), an oral selective JAK1 inhibitor, has demonstrated favorable efficacy and acceptable safety in five Phase 3 global studies in patients with moderately to severely active rheumatoid arthritis (RA).1-3

Objectives: This analysis reports the efficacy and safety of UPA in predefined RA patient subgroups based on differences in baseline demographics and disease activity.

Methods: Data were pooled from three pivotal, double-blind, PBO-controlled, multicenter, Phase 3 studies in patients with RA who had an inadequate response (IR) to conventional synthetic DMARDs (csDMARD-IR: SELECT-NEXT [N=661]), MTX (MTX-IR; SELECT-COMPARE [N=1629]), or biologic DMARDs (bDMARD-IR: SELECT-BEYOND [N=498]). Two integrated analysis sets were evaluated: one comparing UPA 15 mg QD vs PBO (SELECT-NEXT, SELECT-COMPARE, SELECT-BEYOND) and the other comparing UPA 15 mg QD and UPA 30 mg QD vs PBO (SELECT-NEXT, SELECT-BEYOND). All patients received background treatment with csDMARDs.

The proportion of patients achieving ACR20 and DAS28 (CRP) ≤3.2 at Week 12 was evaluated by predefined baseline demographics and disease activity measure groups, including age, sex, weight, BMI, race, geographic region, duration of RA, RF, and ACPA status, and level of high sensitivity CRP. Non-responder imputation was used for missing data. Subgroup analyses for safety were performed for age, race, sex, BMI, and Asian region.

Results: Across the three Phase 3 studies, 1036, 384, and 1041 patients received UPA 15 mg QD, UPA 30 mg QD or PBO, respectively. The demographic and baseline disease characteristics in the two integrated analysis sets were balanced across treatment groups. ACR20 and DAS28 ≤3.2 response rates at Week 12 were consistently higher with UPA 15 mg and UPA 30 mg QD vs PBO across the evaluated demographic and baseline disease characteristics (Figure 1a, Figure 1b). The efficacy of UPA 15 mg QD was generally similar to that observed with UPA 30 mg QD. At 12 weeks, the proportion of patients with treatment-emergent AEs, serious AEs, severe AEs, and AEs leading to discontinuation were measured.

Conclusion: In this analysis of pooled integrated efficacy data in csDMARD-IR or bDMARD-IR patients with RA, UPA 15 mg or 30 mg QD in combination with csDMARDs improved efficacy outcomes at Week 12 when compared with PBO across all predefined subgroups evaluated.

CHARACTERIZATION OF SERIOUS INFECTIONS WITH UPADACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Winthrop1, L. Calabrese2, F. Van den Bosch3, K. Yamaoka4, C. Seilim5, Y. Song6, B. Hendrickson7, I. Lagunes-Galindo5, I. McInnes8,1, Oregon Health & Science University, Division of Infectious Diseases, Portland, OR, United States of America; 2Cleveland Clinic, Cleveland, OH, United States of America; 3Ghent University, VIB Center for Inflammation Research, Ghent, Belgium; 4Kitsato University School of Medicine, Department of Rheumatology and Infectious Diseases, Kanagawa, Japan; 5Humanitas Research Hospital and Humanitas University, Milan, Italy, 6AbbVie Inc., North Chicago, IL, United States of America; 7University of Glasgow, Glasgow, United Kingdom

Background: Upadacitinib (UPA) is a selective and reversible Janus kinase (JAK) inhibitor with an approved dose of 15 mg once daily (QD) for the treatment of rheumatoid arthritis (RA). Patients (pts) receiving JAK inhibitors have been reported to be at increased risk of developing serious infection events (SIE) and opportunistic infections (OI).

Objectives: To evaluate the incidence of SIEs and OIs in pts with RA receiving UPA and active comparators in the Phase 3 SELECT clinical trial program.

Methods: The exposure-adjusted event rate (EAEUR) per 100 patient-years (E/100 PY) of SIEs and OIs was determined in pts receiving UPA in five randomized Phase 3 trials (SELECT-EARLY, SELECT-MONOTHERAPY, SELECT-NEXT, SELECT-COMPARE, and SELECT-BEYOND), of which four evaluated both UPA 15 mg and 30 mg QD doses and one (SELECT-COMPARE) evaluated only UPA 15 mg QD. Incidences of SIEs and OIs were also determined in pts receiving adalimumab (ADA) + methotrexate (MTX) in SELECT-COMPARE and MTX monotherapy in SELECT-EARLY. Data were analyzed descriptively, with no statistical comparisons between groups or doses. Risk factors for SIEs were
determined using a univariate Cox regression model. The data cut-off was June 30, 2019.

**Results:** Overall, 2629 pts who received UPA 15 mg, 1204 pts who received UPA 30 mg, 579 pts who received ADA + MTX, and 314 pts who received MTX monotherapy were included in this analysis. The AEAEs (E/100 PYs [95% CI]) of SIEs were 3.2 (2.7–3.7) in the UPA 15 mg group, 5.7 (4.8–6.6) in the UPA 30 mg group, 3.9 (2.6–5.6) in pts receiving ADA + MTX, and 3.1 (1.7–5.2) in pts receiving MTX monotherapy. Pneumonia was the most common SIE, with AEAEs (E/100 PYs [95% CI]) of 0.7 (0.5–1.0), 1.3 (0.9–1.9), 0.7 (0.2–1.5), and 0.7 (0.1–1.9) in the UPA 15 mg, UPA 30 mg, ADA + MTX, and MTX monotherapy groups, respectively. Rates of OIs (including oral candidiasis and disseminated herpes zoster [HZ]) (E/100 PYs [95% CI]) were 0.7 (0.5–1.0), 1.3 (0.9–1.9), 0.4 (0.1–1.1), and 0 (0–0) in the UPA 15 mg, UPA 30 mg, ADA + MTX, and MTX monotherapy groups, respectively. Oral candidiasis was the most frequent OI with AEAEs (E/100 PYs [95% CI]) of 0.4 (0.2–0.6) in the UPA 15 mg group, 0.6 (0.3–1.0) in the UPA 30 mg group, 0.4 (0.1–1.1) in the ADA + MTX group, and 0 (0–0) in the MTX monotherapy group. Serious adverse events of HZ were only reported in the UPA groups (0.2 E/100 PYs [95% CI: 0.1–0.3] and 0.6 E/100 PYs [95% CI: 0.4–1.1] in the UPA 15 mg and 30 mg groups, respectively). Overall, there were 3 (4 coded events), 3, 1, and 0 pts who had active tuberculosis events in the UPA 15 mg, UPA 30 mg, ADA + MTX, and MTX monotherapy groups, respectively. Risk factors for SIEs are shown in the Figure. For both UPA doses, age ≥75 years and smoking were noted to have hazard ratios >1.

**Conclusion:** The incidence rate of SIEs and OIs was higher in the UPA 30 mg group than the UPA 15 mg group. SIEs observed with UPA 15 mg were similar to that seen with ADA although the rates of HZ were higher on UPA. Pts with RA who are ≥75 years old and/or smokers may be at higher risk than other pts with RA for SIEs while receiving UPA.

**Figure.** Univariate analysis of SIE risk factors

**The Efficacy and Cost-effectiveness of Hydroxychloroquine, Sulfasalazine, Methotrexate Triple Therapy in Preventing Relapse of Rheumatoid Arthritis**

**J. Zhao**, W. Zhou, J. W. Wu, P. Ji, X. Yan, L. Yang, Z. Zhang

1. Peking University First Hospital Rheumatology and Immunology Department, Beijing, China; 2. Peking University Clinical Research Institute (PUCRI), Beijing, China; 3. Peking University School of Public Health, Beijing, China

**Background:** TNFα inhibitors (TNFi) are effective for rheumatoid arthritis (RA) patients refractory to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), but because of high cost, the discontinuation is common that often lead to disease relapse.

**Objectives:** To investigate, among RA patients refractory to csDMARDs but achieved therapy target after treated with TNFi and methotrexate (MTX), if the combination therapy of csDMARDs is more effective in reducing disease relapse than MTX monotherapy, and more cost-effective than continuing the treatment with TNFi and MTX.

**Methods:** In this multi-center, outcome assessment blinded, randomized, superiority clinical trial, RA patients who failed to csDMARDs treatment (DAS28(28 CRP)>3.2) received MTX plus TNFi for 12 weeks first (induction therapy). Then patients achieving low disease activity (LDA, DAS28(28 CRP)<3.2) were randomized into three groups in 1:1:1 ratio: (A) maintaining TNFi + MTX for 60 weeks; (B) adding hydroxychloroquine (HCQ) and sulfasalazine (SSZ) for 12 weeks and then removing TNFi but continuing HCQ and SSZ for 48 weeks; and (C) maintaining TNFi + MTX for 12 weeks and then removing TNFi but continuing MTX only for 48 weeks. The primary outcome is disease relapse (DAS28(28 CRP) increased by at least 0.6 and ≥3.2) in 60 weeks. Secondary outcomes include the incremental cost effectiveness ratio (incremental cost per reducing 1% relapse rate); adverse events and radiology progression.

**Results:** 117 patients were enrolled for induction therapy; 67 patients achieved LDA after 12 weeks of induction therapy and were randomized with 21, 24 and 22 patients into each group, respectively. Male [OR=0.046 (0.005-0.451), p=0.008] and less baseline tender joint count [OR=0.825 (0.710-0.958), p=0.012] were independent predictive factors for LDA achievement. The relapse rate in 60 weeks was comparable between group A and B [33.3% (7/21) vs. 37.5% (9/24), p=0.05], while both significantly lower than that of group C [77.3% (17/22), p<0.01, p=0.01, respectively]. The adverse events and modified Sharp score progression were both comparable among the three groups. The incremental cost effectiveness ratio of group A is higher than group B (1915.7 yuan vs 1015.9 yuan).

**Conclusion:** For RA patients refractory to csDMARDs but achieved therapy target after treated with TNFi and MTX, the triple therapy of MTX+HCQ+SSZ is as effective as and more cost-effective than TNFi maintain therapy in reducing disease relapse. Both strategies are more effective than MTX monotherapy.

SEROLOGICAL EVOLUTION IN PATIENTS WITH POSITIVE ANTIPHOSPHOLIPID ANTIBODIES: A RETROSPECTIVE STUDY OF CHINESE COHORT

L. Ji1, Z. Zhang1, Z. Duan1, Z. Cheng1, P. Liu2, M. Qian2
1Peking University First Hospital, Beijing, China

Background: Antiphospholipid antibodies (aPLs) and thrombotic/obstetric events are the characteristics the antiphospholipid syndrome. The titers of aPL sometimes may decrease and become negative during the follow-up period. Whether the negativization being related with a lower risk of thrombotic events, allowing for withdrawal of anti-coagulant therapy is controversial. And the factors associated with each aPL negativization are still unknown.

Objectives: To explore the clinical and serological course of patients with positive aPLs, and the factors and therapeutic implications associated with aPL negativization.

Methods: Patients with a persistent positive aPL serology according to established criteria between 1997 and 2018 were included. The test of Lupus anticoagulant (LA), anti-cardiolipin antibody (aCL) and anti-β2 glycoprotein I (anti-β2GP1) were following the international Society on Thrombosis and Haemostasis guidelines. The patients were classified as aPL negativization if the follow-up aPL tests became negative, on two or more occasions at least 12 weeks apart. Titer more than 40 RU/ml was defined as moderate to high titer for aCL and anti-β2GP1. For patients receiving warfarin, the results of LA were counted only when INR<1.5.

Results: The baseline characteristics of 93 patients were shown in Table 1. After a mean follow-up of 45.0 (45.0) months, the percentage of aPL negativization was 10.8% (9/83), 26.1% (18/89), 24.5% (13/53) for LA, aCL and anti-β2GP1 respectively (Figure 1). Patients with triple aPL positivity at baseline were associated with persistently positive serology for all the three aPLs. Multivariate analysis confirmed that double positive of two methods (dVRRT and SCT) was the only independent protective factor for LA negativization (OR 0.056; 95%CI: 0.006-0.545; p=0.013). SLE, moderate to high titer of aCL and number of baseline aPL positivity were independently associated with aCL negativization (OR 18.2; 95%CI: 1.45-228; p=0.025, for SLE; OR 0.217; 95%CI: 0.056-0.851; p=0.034, for moderate to high titer of aCL; OR 0.198; 95%CI: 0.057-0.689; p=0.011, for number of baseline aPL positivity). Moderate to high titer of anti-β2GP1 and number of baseline aPL positivity were independently protective factors for anti-β2GP1 negativization (OR 0.062; 95%CI: 0.032-0.872; p=0.034, for moderate to high titer of anti-β2GP1; OR 0.243; 95%CI: 0.073-0.813; p=0.022, for number of baseline aPL positivity).

Unfortunately, we didn’t find any relationship between aPL persistent positivity and further thrombosis/pregnancy morbidity due to limited events.

Table 1. The baseline characteristics of aPL positive patients

Conclusion: The proportion of aCL and anti-β2GP1 negativization are higher than LA. The number of positive antibodies and higher antibody load are associated with persistently positive serology. Patients with SLE were easier to get aCL negativization.

The role of antiphospholipid syndrome (APS) as a cause of chronic organ damage in patients with systemic lupus erythematosus (SLE) is important. While acute disease manifestations of APS are well known, information on the long-term prognosis and damage in affected patients is still very limited. While acute disease manifestations of APS are well known, information on the long-term prognosis and damage in affected patients is still very limited.

Objectives: To assess the severity of organ damage in patients with APS without SLE and with concomitant SLE, as well as the feature of irreversible damage to internal organs in patients with primary APS during a dynamic observation using SLICC/ACR Damage Index (SDI).

Methods: The study included 195 patients (41 men and 154 women) who were observed at the Institute of Rheumatology from 2007 to June 2018 with a diagnosis of SLE and APS. The study inclusion criteria were: a follow-up period of at least 3 years with the study of serological markers of APS for previous years, the possibility of dynamic monitoring of patients, patient consent. Patients were divided into 3 groups, depending on presence of APS: group I - SLE with APS (n=99 with average age 34.6 [25–44]), group II - SLE without APS (n=45; 33.5 [26–42]) and group III - 45 (average age 37.7 [27–46]) patients with primary APS (PAPS) diagnosed according to international diagnostic criteria, without signs of any disease. In all three groups organ damage was assessed using SDI. SDI ≥2 points corresponded to moderate damage, more than 2 points - severe.

Results: A linear increase in irreversible organ damage was noted over 10 years of follow-up. At the time of inclusion in the study, the average SDI was significantly higher in the SLE + APS group than in the SLE group: 1.32 versus 0 when included (p <0.0001). A direct correlation was found between the age of patients and the value of SDI both in the group I (p=0.004, r=0.284) and in the group II (p=0.04, r=0.281) when included in the study. There was a direct correlation between the activity of the disease on the SLEDAI at the end of the study and the value of SDI (p=0.03, r=0.41) in the group II. The number of patients with a SDI of 10 or more by the 10th year of follow-up remained in group I were 44 of 99, in group II - 24 of 51 and in group III - 14 of 45. SDI was more than 2 points in 39 (89%) of 44 patients in group I, in 12 (50%) of 24 in group II and 9 (65%) of 14 in Group III (p=0.0002 OR=13; 95% CI 2.4–70). 5 years after the start of the observation average SDI in group I was 2.5 and 1.3 (p <0.0001) and after 10 years - 2.8 and 1.9 (p = 0.0008) accordingly. An increase of total SDI occurred primarily due to damage to peripheral vessels (in 55% of patients) and the large number of thromboses (in 42%) in the group II. Using step-by-step multiple logistic regressions in the study groups only APS was an independent predictor of increased SDI. The most common cause of an increase in SDI in the PAPS group was damage to peripheral vessels (84%) as a result of a high frequency of venous thrombosis, followed by damage to the neuropsychiatric system (55%) and the cardiovascular system (40%).

Conclusion: APS is an independent predictor of increased SDI. The determination of irreversible organ damage in patients with PAPS using SDI allows us to assess the functional disorders of organs and systems and can be used in clinical practice in these patients.

Background: Sjögren’s syndrome (SS) affects mainly individuals of the 4th or 5th decade of life, although patients with early (≤35 years old) or late (>65 years old) disease onset have been described in the literature. The clinical spectrum of SS extends from mild dryness to severe systemic vasculitis and lymphoproliferative disorders. The phenotypic diversity of SS is defined by many factors, including age, since many parameters related to age may affect the clinical expression of the disease. Few studies have been conducted to study the effect of age on the clinical phenotype of SS, though with limited number of patients. Large and well-defined groups of SS are required to address such questions.

Objectives: To study the clinical phenotype of SS patients with early and late disease onset and to explore the association of age with lymphoma development in a unified multicenter cohort.

Methods: From a total cohort of 1997 consecutive SS patients who fulfilled the 2016 EULAR/ACR criteria and are followed up in 5 clinical centers (Universities of Udine, Pisa and Athens, Harokopio and Ioannina, (UPAMH)), those with either early (≤35 years) or late (>65 years) disease onset were identified and matched according to gender and disease duration with middle aged controls whose disease onset was at the 4th or 5th decade of life. Glandular manifestations, extra-glandular manifestations, serologic characteristics and histologic features were compared between the 2 age groups and the middle-aged control groups. Statistical analysis for categorical variables was performed by Fisher exact or chi-square tests and for continuous variables with t test or Mann-Whitney accordingly.

Results: Three hundred seventy-nine (19%) SS patients with early and 293 (15%) with late disease onset were identified and compared with 353 and 285 middle aged SS controls respectively. The disease duration in patients with early disease onset was 12 years (range:0-68) and for those with late disease onset was 5 years (range: 0-27). SS patients with early disease onset had statistically significant higher frequency of Raynaud’s phenomenon, lymphadenopathy, interstitial lung disease, anti-Ro/SSA, anti-La/SSB, rheumatoid factor, significantly higher frequency of Raynaud’s phenomenon, lymphadenopathy, glandular manifestations, serologic characteristics and histologic features in patients with early disease, and significantly higher frequency in late disease group. Patients with early disease onset exhibit robust B cell responses with traditional risk factors for lymphoma as opposed to patients with late disease onset. Both age groups have increased lymphoma prevalence but presumably for different reasons, since late onset patients lack classical predictors of lymphoma. Therefore, these predictors deserve further study in different disease subsets.

Conclusions: SSGUS abnormalities appeared to be associated to both salivary gland disease activity and damage. Namely, the presence of hypercholesterolemia bands significantly correlated with salivary loss function. Diffuse-scattered hypercholesterolemia areas did not change over a median 30-month follow-up indicating that additional studies are required to better elucidate the correlation between SSGUS abnormalities and the corresponding histopathologic lesions.

PULMONARY HYPERTENSION IN NEWLY DIAGNOSED SPANISH PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: DATA FROM THE RELES COHORT

J. Álvarez Troncoso1, A. Robles Marhuenda1, F. Mitjávia Villero2, F. J. García Hernández3, A. Marín Balvé4, A. Castro5, G. Salvador Cervelló6, E. Fonseca7, I. Perales Fraile8, G. Ruiz-Irastorza9 on behalf of GRUPO RELES Investigators, J. de Autoimmune Diseases, Department of Internal Medicine, Madrid, Spain; Hospital Infanta Sofía, Department of Internal Medicine, Madrid, Spain; Hospital Clínico Universitario Lozano Blesa/IIS Aragón, Grupo Autoinmunidad Clínica, Department of Internal Medicine, Zaragoza, Spain; Hospital Universitari Sant Joan de Reus, Department of Internal Medicine, Tarragona, Spain; Hospital Universitario La Fe, Department of Internal Medicine, Valencia, Spain; Hospital de Cabueñes, Department of Internal Medicine, Gijón, Spain; University of Pisa, Clinical and Experimental Medicine, Pisa, Italy

Objectives: To identify the factors associated with pulmonary hypertension (PH) in Spanish patients with systemic lupus erythematosus (SLE).

Methods: Consecutive patients undergoing a LSG for clinically suspected pSS from January 2018 to December 2019 were included. LSG was performed by using VEVO MD, equipped with a 70 MHz probe, scanning first the central compartment of the inferior lip, and then both peripheral compartments. The parameters evaluated were: glandular surface area; parenchymal inhomogeneity score; focal lesions; fibrosis. LSG imaging was used to help locate the LSG for the US-guided biopsy.

Results: We included a total of 249 patients with suspected pSS: 137 undergoing the US-guided LSGs and 112 the traditional LSG biopsy procedure. No demographic differences were observed between the two groups. No differences were also observed in the distribution of the final diagnosis. A diagnosis of pSS according to the ACR criteria was made in 60/137 (43.8%) and 36/112 (32.1%) patients, respectively whereas a diagnosis of no-SS sicca was made in 44/137 (32.1%) and in 43/112 (38.4%) patients; the remaining patients had serositis (4/137, 3% and 9/112, 8%) and undifferentiated connective tissue disease (UCTD) (29/137, 21.2%, and 24/112, 21.4%). With respect to no-SS sicca controls and UCTD patients, pSS patients presented higher UHFUS inhomogeneity scores in both central and peripheral labial compartments (p<0.001). There were no complications from the HUFUS-guided LSG biopsy. The mean glandular surface area obtained was significantly higher than the area obtained by traditional LSG biopsy procedure (7.4 ± 4.0 mm² vs 6.3 ± 3.7 mm², p=0.02) thus facilitating the assessment of the FS. Interestingly, the latter showed a good correlation with the HUFUS inhomogeneity (r=0.509**, p=0.000).

Conclusion: Cardiovascular, bone and neurologic comorbidities are frequently detected already at the time of diagnosing SLE. High numbers of medical prescriptions and hospitalization following SLE diagnosis reflect the comprehensive disease burden. Differences to controls without autoimmune disease are overestimated by detection bias. References: Funding The study was supported by the Wolfgang Schulze Foundation of the German Rheuma-Liga.
Conclusion: UHFUS of LSG appeared feasible and sensitive in pSS, potentially offering unique advantages in LSG ultrasound-guided biopsy.

Disclosure of Interests: None declared.

SHOULD BE OLDER PATIENTS TESTED FOR ANTIPHOSPHOLIPID ANTIBODIES? 695 CASES FROM THE RETROSPECTIVE SERIES HIBICUS

Background: Although guidelines do not recommend antiphospholipid antibodies testing after 60 yo, recent data reported late onset antiphospholipid syndrome (APS).

Objectives: To comparatively analyse the clinical, laboratory features and outcomes in 695 cases with primary APS between patients older and younger than 70 yo.

Methods: we have performed an international study within the framework of the International Registry of primary APS patients treated with Hydroxychloroquine, HIBICUS (an ongoing retrospective and prospective register launched in 2016). 28 centres from 17 countries participate. Data about late onset APS were analysed in 695 patients and were obtained from a standardized form registered in the database containing 66 items with respect to demographics, clinical and biological features.

Results: Arterial events and especially stroke represented the main initial and recurrent clinical manifestation in 40 primary APS patients older than 70 yo. There were not statistically significant differences with respect to cardiovascular risk factors between the two groups of patients. A significant male predominance, a familial APS history, a higher prevalence of triple positivity, lower complement levels, and anticardiolipin antibodies (aCL) IgA isotype were found in older patients. Low anticoagulation regimens were safe and efficient, with a low relapse rate in older patients.

Conclusion: we suggest that the detection of aPL antibodies should be included into the initial screening panel tests in elderly with thrombotic events, especially arterial, in particular those with recurrent stroke and familial APS.

Our study further suggests that lower intensity anticoagulation regimens could be a therapeutic option in older APS patients, as no differences in outcomes and relapse rate were found between patients with high and low intensity anticoagulation regimens.

Background: SLE onset is preceded by a preclinical phase evidenced by the presence of anti-nuclear and other autoantibodies (autoAbs), which however, have low predictive value for development of clinical SLE.

Objectives: To define the subgroup of autoAbs-positive individuals who are at high risk for progression into SLE by integrating environmental, clinical/serological, genetic and transcriptome data.

Methods: A multicenter, across five European countries, inception cohort of autoAbs-positive individuals or first-degree relatives (FDRs) of SLE patients who are monitored prospectively over five years for possible transition to SLE according to the classification criteria. Structured data collection on demographics, family and medical history, clinical (criteria and selected non-criteria manifestations) and serological parameters, use of medications, hydroxyvitamin D levels and lifestyle (tobacco, alcohol use, physical activity, adherence to Mediterranean diet). Blood samples are stored for RNA-sequencing and genotyping.

Results: A total 254 at-risk individuals (93% women, 99% Caucasians, aged [mean ± standard deviation] 36 ± 12 years) have been included and enrolment/monitoring is still ongoing. Forty individuals (16%) have FDR with SLE and 88 individuals (35%) have FDR with another autoimmune disease. The frequency of active and past use of tobacco was 28% and 20%, respectively. Sedentary lifestyle (moving only for necessary chores or outdoor activity 1-2 times/week) was reported by 54% and adherence to the Mediterranean diet was low (3.4 ± 2.3, maximum score: 9). At enrolment, individuals had a 1.9 ± 1.1 ACR-1997 classification criteria, with anti-nuclear antibodies (ANA) being the most frequent (88%), followed by synovitis (39%), photosensitivity (33%) and immunologic disorder (30%) (Table 1). During follow-up of 15.2 ± 7.2 months, a total 15 individuals (5.9%) have progressed into classified SLE, including cases with severe hematological and neurological disease.

Conclusion: Among individuals with positive autoAbs or FDRs with SLE, the short-term risk for transition into clinical SLE is low. Following the study completion, clinical and lifestyle data will be combined with blood transcriptome to define a high-risk subgroup of individuals for progression into SLE.

DOI: 10.1136/annrheumdis-2020-eular.4468
Background: The treatment of systemic lupus erythematosus (SLE) has improved over the last decades, however, absenteeism and work disability numbers remain higher than those observed in the general population (1). SLE has its onset between the ages of 20 and 40 years, and has a major burden on the lives of patients, both mentally and financially. A recent online survey among 2070 European SLE patients revealed that 69.5% of patients had their careers affected due to SLE (2).

Objectives: To determine the magnitude of absenteeism and work disability in patients with SLE and to investigate the factors that might affect work participation in these patients in order to develop interventions to reduce the impact of the burden in the future.

Methods: A systematic literature search was performed to identify published articles reporting on the prevalence of work related burden, as well as the relation of having SLE on employment status, sick leave and/or presenteeism. Full-text original articles (all languages) published before April 2019 were identified by literature search performed in MEDLINE, Cochrane, Embase and CINAHL.

Results: In total, 2052 non-duplicate citations were screened after database searching and snowballing. Finally, 81 articles were included; most studies (n=59) had a cross-sectional design and the remaining 22 studies had a longitudinal design. Only 15 longitudinal cohort studies reported on associations, 6 studies described a longitudinal prediction model, 2 studies reported on associations and described a prediction model, and 3 studies had a longitudinal design but only reported on prevalences over time. In total, 3500 working patients were included in the studies reporting on associations or describing a longitudinal prediction model. In the association studies, the most frequently used outcome measures were respectively being employed/probability of being employed and work loss/job cessation. Other studies used lost days from (non)workforce activities/sick leave days, work disability, productivity loss or work entry. Most associations with work outcome were found for demographic variables and two or three disease variables, like Systemic Lupus Activity Questionnaire (SLAQ) score and depressive symptoms. This was also the case in the prediction studies. Most studies did not assess work related variables as possible predictors for work outcome.

Conclusion: A large heterogeneity was found in type of study design and outcome measures, which limits comparison with other studies. More longitudinal studies are needed to truly assess the impact of SLE on work participation, and to identify factors that could be influenced during interventions, in order to encourage work participation of these patients.

EPSTEIN BARR VIRUS BLOOD REPLICATION INCREASES DURING ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS

P. Brillat\(^1\), A. Mathian\(^2\), S. Burrel\(^3\), M. Hé\(^4\), J. Fadlallah\(^1\), M. Pineton of Estrogens in Lupus Erythematosus National Assessment–Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) flare index (SFI) and therapeutic regimen on the day of EBV DNA load assessment were recorded. A SELENA-SLEDAI score > 4 defined an active SLE. A blood EBV DNA load ≥125 IU/mL was defined as elevated.

Results: A total of 105 patients (98 women and 7 men) were included in the study. At inclusion, median (quartiles) age and SLE duration were 34 (23.5-43) and 7 (2-14) years, respectively. Treatment were hydroxychloroquine (HQC) (n = 67; 64%), prednisone (n = 66; 63%) with an average (±Standard Deviation) dose of 11.3 (±16) mg/day and an immunosuppressant (n = 42; 40%). According to SFI, 57 SLE patients were experiencing a flare at the time of EBV assessment; flares were classified as severe and mild/moderate in 36 (36%) and 19 (18%) SLE patients, respectively. According to the SELENA-SLEDAI score, 60 patients (57%) were deemed active and 45 (43%) inactive. Main clinical manifestations were arthritis in 32 (30%) patients, constitutional symptoms (fever, weight loss, anorexia or lymphadenopathy) in 31 (30%), cutaneous involvement in 23 (22%), glomerulonephritis in 14 (13%), neuropathy in 14 (13%), neuropsychiatric involvement in 13 (12%) and serositis in 10 (16%). Blood EBV DNA was elevated in 54 (90%) of the 60 patients with active lupus versus 6 (13%) of the 45 patients with inactive SLE (p <10\(^{-4}\)). It was increased in 34 (89%) of the 38 patients with severe flare, in 17 (89%) of the 19 patients with a mild/moderate flare (p = 1) and in 8 (17%) of the 48 patients without flare (p <10\(^{-4}\) vs severe flare and p <10\(^{-4}\) vs mild/moderate flare). EBV DNA load correlated with SELENA-SLEDAI score (r = 0.58; p <0.0001). Elevated blood EBV DNA was not associated with HCQ, prednisone or immunosuppressant intake. Eighteen patients with active SLE had a second assessment of blood EBV DNA load. For these patients, the median [range] of viral load was significantly higher during periods of active SLE (236 [0-2680] IU/mL) compared with periods with lower SELENA-SLEDAI score (0 [0-1537] IU/mL, p<10\(^{-1}\) in paired analysis).

Conclusion: Blood EBV viral load is dramatically increased in active phase of SLE, independently of the treatment. We were unable to demonstrate whether the replication of EBV was the cause or the consequence or just an epiphenomenon of the disease activity. Further studies are needed to study whether EBV viral load is linked with Interferon secretion or B lymphocyte activation.

CLINICAL AND IMAGING FEATURES OF ARTICULAR MANIFESTATIONS IN PRIMARY SJÖGREN'S SYNDROME: SIMILARITIES AND DIFFERENCES ACCORDING TO THE TIME OF ONSET

F. Carubi\(^1\), A. Alunno\(^2\), P. Cipriani\(^3\), E. Bartoloni Bocc\(^4\), A. Conforti\(^4\), I. Di Cola\(^5\), R. Gerli\(^6\), R. Giacometti\(^1\), \(^1\)Rheumatology Unit, Udine, Italy; \(^2\)Rheumatology Unit, Perugia, Italy

Background: Articular manifestations (AMs) are observed in a large proportion of patients with primary Sjögren’s syndrome (pSS) and can occur at the time of pSS diagnosis or during the disease course. Although in the majority of cases AMs are mild and self-limiting, some patients may experience chronic polyarthritis requiring treatment with DMARDs. However to date no specific discriminating biomarkers have been identified. Magnetic resonance imaging (MRI) can help assessing the extent of articular involvement and guide the treatment.

Objectives: To describe clinical and serological features of patients with pSS developing arthralgia along with the MRI findings of affected joints.

Methods: Clinical records were retrospectively evaluated and MRI was performed to evaluate AMs. Disease activity was assessed with the EULAR SS disease activity index (ESSDAI) and its clinical version without the biological domain (ClinESSDAI). Patient-reported symptoms were assessed with the EULAR SS Patient Reported Index (ESSPRI). AMs features were described according to the OMERACT rheumatoid arthritis (RA) MRI scoring system. Values are displayed
as mean ± standard error of the mean or number and percentages. Patients were tested for autoantibodies such as anti-cyclic citrullinated peptide, anti-citrullinated α enolase and anti-carbamylated proteins with commercially available ELISA kits.

Results: 45 pSS patients were included. 29 patients (64%) displayed AMs at pSS onset while 15 (36%) at a later stage (6.7±1 years after pSS diagnosis). Besides AMs, at the time of pSS diagnosis the two cohorts were comparable with regard to other ESSDAI domains. Interestingly, all patients with anti-SSA and anti-SSB had AMs at the time of pSS diagnosis (p=0.05) while those developing AMs in the disease course were more likely single positive for anti-SSA (p=0.04). When comparing the clinical and serological features of both groups of patients at the time of overt AMs (Tables 1-2), patients that displayed AMs in the course of the disease have a significantly higher ESSPRI compared to patients that display AMs at pSS onset. With regard to MRI, 80% of patients with AM displayed signs of synovitis, 59% bone erosions, 59% joint space narrowing and 50% bone marrow oedema. To note, 60% of patients displaying AMs at pSS onset show bone marrow oedema while this is present in only 27% of patients developing AMs at a later stage (p=0.05). Anti-cyclic citrullinated peptide, anti-citrullinated α enolase, anti-carbamylated proteins were undetectable in all patients.

Conclusion: Our results confirm the relevance of AMs in pSS, particularly because of the high prevalence of RA-like MRI features. MRI assessment in patients with pSS is advisable to identify more severe AMs in the spectrum of pSS disease and guide the therapeutic approach.

**THE CORRELATION BETWEEN PREGNANCY, DISEASE ACTIVITY AND ADVERSE PREGNANCY OUTCOMES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

C. Cetin1, T. Sarac-Sivrikov2, M. Ates-Tiku3, E. S. Torun1, S. Zarali1, Y. Yalcinakya1, A. Gu1, M. Inanc1, M. L. Ocal1, I. kalelooglu2, B. Artim-Esen1.

1Istanbul Faculty of Medicine, Rheumatology, Istanbul, Turkey; 2Istanbul Faculty of Medicine, Gynecology and Obstetrics, Istanbul, Turkey

**Background:** Patients with systemic lupus erythematosus (SLE) can present with acute disease flares/exacerbations during pregnancy and postpartum period. These flares can cause adverse pregnancy outcomes (APO).

**Objectives:** In this study, our pregnant SLE cohort, which was under medical surveillance of both our Rheumatology and Gynecology and Obstetrics departments was analyzed. We intended to determine the effects of pregnancy on disease activity and the correlation between disease flares and adverse pregnancy outcomes.

**Methods:** 168 pregnancy data involving 136 patients with SLE meeting the ACR criteria were examined. Cumulative clinical, laboratory and serological parameters were described and disease activity and flares were calculated using SLEDAI-2K disease activity index during preconceptional six month period, during all trimesters of pregnancy and during postpartum six month period. Patients with low lupus disease activity scores (LLDAS) during each of these periods were identified. Fetal/neonatal death, premature birth due to preclampsia, eclampsia or HELLP syndrome, neonates small for gestational age were determined as adverse pregnancy outcomes. Relationship of APO with disease activity was studied and patients with APO were compared to patients without APO.

**Results:** Mean SLEDAI-2K scores was 1.3±2.2 (0-16) during preconceptional six month period, 1.5±3.3 (0-16) during conception period, 1.7±3.2 (0-22) during first trimester, 1.4±2.7 (0-16) during second trimester, 1.5±3.3 (2-20) during third trimester and 3.5±5.4 (0-26) during postpartum six month period. Mean postpartum six month SLEDAI-2K score was higher compared to the mean pregnancy SLEDAI-2K score (p<0.05). LLDAS was sustained in 79% of all pregnancies. 19% of pregnancies resulted in flares. 42% of these flares were severe and 58% were mild or moderate. 49% of severe flares occurred during the postpartum six month period and this percentage was significantly higher compared to each trimester (p<0.05). Most of the flares during pregnancy and postpartum period had mucocutaneous (37%), renal (35%) and hematological (25%) involvement.

APO was observed in 34% of pregnancies (n=57). APO (+) group was characterized by significantly longer disease duration and higher disease activity in all periods compared to APO (-) group (14±2 vs 7±10 months, p<0.05). In APO (+) group, the proportion of patients with severe disease activity during all pregnancy periods and postpartum period was significantly low (%18 vs 35, p<0.05), while the proportion of patients with sustained LLDAS was much higher (%88 vs 70).

**Conclusion:** Postpartum six-month period appears to have the highest risk for disease flares during SLE pregnancies. Disease activity during pregnancy increases the risk of APO. Patients with sustained LLDAS have significantly lower APO rates. In order to achieve a positive pregnancy outcome and lower maternal morbidity, regular follow up of patients during pregnancy and postpartum period by Rheumatology and Gynecology and Obstetrics Departments is necessary.

**COMPARISON OF MUSCULOSKELETAL INVOLVEMENT OF WRIST AND HAND BY MRI IN TWO SYSTEMIC LUPUS ERYTHEMATOSUS GROUPS: HAND ARTHRITIS AND HAND ARTHRALGIA**

P. Corzo1, I. Garcia-Duitama1, A. Agusti Claramunt1, T. C. Salman Monte2, J. Monfort3. 1Hospital Plató, Rheumatology, Barcelona, Spain; 2Hospital del Mar, Radiology, Barcelona, Spain; 3Hospital del Mar, Rheumatology, Barcelona, Spain

**Background:** Articular involvement can reach up to 95% within the multisystemic manifestations of SLE. Originally, a non-erosive pattern of articular inflammation was described, but the emergence of more sensitive imaging techniques, such as Magnetic Resonance Imaging (MRI), show synovitis (S), erosions (E), bony narrow edema (BME) and tenosynovitis (TS) in patients with systemic lupus erythematosus (SLE). Nowadays, a specific validated pattern of articular involvement associated with this disease does not yet exist, although it has begun to be studied (1,2).

**PHENOTYPIC DIFFERENCES BETWEEN SJoÈGRENS SYNDROME PATIENTS WITH LOW AND HIGH-GRADe INFLAMMATION BASED ON SALIVARY GLAND FOCUS SCORE**

L. Chatzis1, V. Pezoulas2, F. Ferro3, V. Donath1, A. Venetsanopoulou1, E. Zampeli1, M. Movromati1, P. Voulgaris1, C. Movragani1, D. Fotiadis1, F. Skopoulis2, S. De Vita1, G. Vassili1, C. Baldini1, H. M. Moutspoulos4, A. Goules4, A. Tzouftas4.

1Pathophysiology Department, Athens School of Medicine, National and Kapodistrian University of Athens, Athens, Greece; 2Unit of Medical Technology and Intelligent Information Systems, University of Ioannina, Ioannina, Greece; 3Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; 4Department of Nutrition and Clinical Dietsetics, Haropkio University of Athens, Athens, Greece

**Background:** Sjögren’s syndrome (SS) is characterized by the presence of lymphocytic infiltration around the ductal epithelium of the salivary and lachrymal glands. The peripheritral inflammatory lesions and the enclosed B cell compo-nent are responsible for the glandular and extraglandular manifestations of the disease. Previous studies have shown that the severity of inflammation observed within the salivary glands is correlated with the occurrence of extraglandular manifestations. However, in these studies either the number of patients is small or the SS criteria are not well defined. To explore the association between the degree of inflammation within the salivary glands and the phenotype of the dis-ease, large and well characterized cohorts of SS patients is required.

**Objectives:** To compare the phenotypic features of SS patients with low and high degree of inflammation within the minor salivary glands as reflected by the focus score (FS).

**Methods:** From a total cohort of 1723 consecutive SS patients who fulfill the 2016 EULAR/ACR criteria and are followed up in 4 clinical centers ([Universities of Pisa, Athens, Harokopio and Ioannina, (PAHI)], those who had performed a lip biopsy and the focused score was available, were classified into low focus score (FS<3) or high grade (FS≥3) inflammation. Glandular (dry mouth, dry eyes, parotid gland enlarge-ment) and extra-glandular manifestations (Raynaud’s phenomenon, arthralgias/myalgias, arthritis, palpable purpura, liver involvement, kidney involvement, lung involvement, neurologic involvement, long standing lymphadenopathy and lym-phoma) as well as serologic features (ANA, RF, anti-Ro/SSA, anti-La/SSB) were compared between the 2 groups. Statistical analysis for categorical variables was performed by Fisher exact or chi-square tests and for continuous variables with t test or Mann-Whitney accordingly.

**Results:** Eight hundred and eight minor salivary gland biopsies were available and evaluated based on focus score at the initial evaluation of SS patients, of which 753 had low grade (FS<3) and 153 high grade (≥3) inflammation. The median disease duration after SS diagnosis was not statistically significant different for the 2 groups (median: 4 years, range: 0-36 years). SS patients with high grade inflammation displayed higher prevalence of salivary gland enlargement (S_GE) (40% vs 25%, p=0.0002), long standing lymphadenopathy (22% vs 14%, p=0.02), ANA (97% vs 88%, p=0.0001), anti-La/SSB (52% vs 32%, p<0.0001), RF (61,5% vs 48%, p=0,003), peripheral neuropathy (PN) (5,3% vs 1,5, p=0,01) and of lymphoma (26% vs 8%, p<0,001, OR=4,142, 95%CI=2,65 to 6,47) compared to those with low grade inflammation.

**Conclusion:** SS patients with FS ≥3 at the initial evaluation, display higher prevalence of lymphoma as well as higher B cell hyperactivity and certain clinical manifestations (S_GE, PNS, lymphadenopathy) that constitute risk factors for lymphoma development.

VENOUS thrombosis question is the contribution of which combinations of positive aPLs to thrombosis cardiolipin (aCL) or anti-β2glycoprotein (aB2GPI) antibodies (1). An unanswered strongly associated with both arterial and venous thrombosis than either anti-p=0.0113 and venous [2.3(1.23, 4.61) p=0.0103] thrombosis. When we looked at patients who were LAC positive, and asked if having another posi-
tive aPL increase the risk ratio for any/venous/arterial thrombosis, we found that having aB2GPI IgA appeared to add significant risk to any [1.68 (1.01, 2.79) p=0.044], and venous [2.01 (1.02, 3.97) p=0.043] thrombosis among those with or without LAC (Table 1).

<table>
<thead>
<tr>
<th>Table 1. Additive effect of other aPLs adjusting for LAC</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY thrombosis</td>
</tr>
<tr>
<td>----------------</td>
</tr>
<tr>
<td>age adjusted</td>
</tr>
</tbody>
</table>

Conclusion: Our study shows that LAC is still the best predictor of risk of any, arterial and venous thrombosis in SLE. Moreover, aB2GPI IgA positivity appeared to add also a significant risk to any and venous thrombosis. Therefore, the clinical significance of IgA anti-β2GPI deserves further investigation in SLE patients.

Advanced tubulointerstitial disease (TID) in LN is a better predictor of renal outcome than glomerular lesions. The current NIH classification is heavily weighted towards glomerular lesions and only provides a semiquantitative assessment of TID. In contrast, Banff classification of renal allograft pathology provides 6 reproducible scores for TID (inflammation, fibrosis, atrophy). Banff scoring may better predict CKD/ESRD in LN than NIH scores.

**Objectives:** We compared Banff grading vs. NIH scoring as predictors of CKD progression at 5 years, defined as a decline in estimated glomerular filtration rate (eGFR) ≤30%, a strong risk factor for ESRD and mortality.

**Methods:** We included patients with LN class III, IV, V on the index biopsy Jan 2005 and Dec 2018. H&E/PAS stained slides were reviewed and scored by an experienced pathologist. Six TID Banff scores (0/1 vs. 2/3), NIH activity/chronicity (A/Ci) and NIH interstitial fibrosis/tubular atrophy (IF/TA), tubulointerstitial inflammation (TII) scores (none/mild vs. moderate/severe) were evaluated as predictors of CKD progression using survival analyses.

**Results:** Of the 125 patients, 46 had CKD progression and 20 subsequently developed ESRD. There were no differences between progressors and non-progressors in terms of baseline demographic, clinical data, LN class (Tab 1). Banff i score (total inflammation) was associated with CKD progression in bivariate and time-dependent analyses. However, NIH TII score and corresponding Banff i score were not predictive (Tab 2, Fig 1). Overall NIH AI and CI were not predictive of CKD progression. Moderate/severe NIH IF/TA was associated with CKD progression as was Banff ci (interstitial fibrosis) score (Tab 2, Fig 2). Banff score for atrophy was not predictive. In a subset of 92 patients with baseline eGFR≥60ml/min/1.73m² only Banff ti score (but not i score or NIH TII, IF/TA) was predictive of CKD progression (Fig 1).

**Conclusion:** Banff inflammation scores may be superior predictors of CKD/ESRD progression at 5 years, compared to the currently used NIH classification. Detection of inflammation by Banff scores may allow earlier interventions to prevent ESRD.

**RISK OF CKD IN MEMBRANOUS AND PROLIFERATIVE LUPUS NEPHRITIS - ANALYSIS OF A NATIONWIDE MULTICENTRE COHORT**

**Background:** Lupus nephritis (LN) is one of the most severe manifestations of Systemic Lupus Erythematosus.

**Objectives:** 1) To compare proliferative (PLN), membranous (MLN) and mixed LN regarding clinical and laboratory presentation. 2) To investigate predictors of progression to chronic kidney disease (CKD).
Methods: Multicentre observational study, with retrospective analysis of a prospective cohort, using data from the Portuguese registry of rheumatic diseases – Reuma.pt. Patients with biopsy-proven PLN, MLN and mixed LN were included. Groups were compared using Pearson’s Chi-square for categorical variables and One-Way ANOVA or Kruskal-Wallis for numerical variables. COX regression analysis was used to investigate predictors of CKD (defined as estimated glomerular filtration rate [eGFR] lower than 60 mL/min/1.73 m² for at least 3 months) and Kaplan-Meier curves were drawn.

Results: 236 patients were included. Median follow-up was 8 years (IQR 11; maximum 55 years). As seen in table 1, the level of proteinuria did not differ between groups; however, MLN patients presented with significantly lower serum creatinine. Levels of complement C3 and C4 were reduced in normal but normal in MLN patients, and there were fewer patients with positive anti-dsDNA antibodies in the MLN group (p<0.001). On univariable COX regression, mixed histology was associated with progression to CKD (HR 26 [95% CI 3 - 255], p 0.005) (figure 1), however, it lost significance after adjusting for eGFR. In fact, eGFRs<75 at one year after the renal biopsy (HR 21 [95% CI 7 - 65], p<0.001) was the strongest predictor of CKD, even after adjusting for hypertension or histology.

| Serum electrolytes (sodium, potassium, chloride, calcium, phosphorus), group A vs group B: 5.8 μmol/L vs 5.5 μmol/L; p=0.01) and urinary N-acetyl-β-D-glucosaminidase (group A vs group B: 7222 μg/mL vs 2437 μg/mL; p=0.01) and urinary N-acetyl-D-glucosaminidase (group A vs group B: 5.8 U/L vs 3.9 U/L; p=0.02) of group A were lower than those of group B, while serum electrolytes (sodium, potassium, chloride, calcium, phosphorus), fractional excretion of calcium (group A vs group B: 1.2% vs1.5%; p=0.916), ESSDAI (group A vs group B: 7 vs 4.3; p=0.069), and eGFR decrease rate were not significantly different.

Conclusion: Our results support previous findings from single-centre studies suggesting that MLN has a different serological profile than PLN, possibly reflecting different pathogenesis. Renal function at one year predicts long-term outcome in LN.

DO: 10.1136/annrheumdis-2020-eular.3789
Background: the prognosis of Systemic lupus Erythematosus (SLE) patients has significantly improved over time, raising the need for more data about disease activity and damage accrual in the long term.

Objectives: to investigate the risk of long term disease activity and to identify viable prognostic markers for disease flares in SLE patients with long standing disease.

Methods: data on SLE patients regularly followed at ASST PINI-CTO, Fondazione one Ca’ Granda Policlinico and Ospedale San Raffaele, Milan (Milan Systemic Lupus Erythematosus Consortium, SMILE, cohort) with disease duration ≥ 20 years, were retrospectively analyzed. Organ involvement as per the British Isles Lupus Assessment Group (BILAG) definitions was recorded along with achievement of clinical and complete remission (CR and CCR: clinical SLEDAI =0, PGAS <0.5 and no prednisone or immunosuppression ± negative serology) and lupus low disease activity state (LLDAS) at 15 (T15) and 20 (T20) years of follow up. Damage accrual was estimated according to the SLE International Collaborating Clinics/American College of Rheumatology damage index (SDI).

Results: data from 168 patients (table 1) were available for analysis. Remission (CR+CCR) and LLDAS were achieved in 22% and 61% at T15 and 25% and 71% at T20. LLDAS was not associated with a history of involvement in any BILAG domain, but it was inversely associated with treatment with mycophenolate at any time (50 vs 23% treated vs not treated; p=0.02). SDI≥0 was found in 49% patients at T15 and in 71% at T20. LLDAS at T15 was associated with lower flare rates in the following five years (HR= 0.395, 95%, CI=0.239-0.653; Figure, left panel; p<0.001). The risk of flaring for LLDAS was largely comparable to CCR and CR (Figure, middle panel), In the T15-T20 timeframe, 37% of patients had a flare. Patients with both low complement and anti-dsDNA positivity at T15 had an increased risk of flaring compared to serologically inactive patients (HR=2.86, 95%, CI=1.572-5.19; Figure right panel). Flaring patients were more likely to show an increase in SDI from T15 to T20 (37% vs 9% in patients with stable SDI; p<0.001).

</tr>
<tr>
<td>CR / CCR at T20</td>
<td>17 (10) / 25 (15)</td>
</tr>
</tbody>
</table>

Conclusion: LLDAS is common in SLE patients with long disease duration although up to 37% of patients with 15-year disease duration may experience a flare during the following 5 years. The flare risk increases with failure to attain LLDAS at T15 and with active serology. Late flares associate with damage accrual.

ASSOCIATION OF OVERWEIGHT/OBESITY WITH IMPAIRED HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A. Gomez1,2, F. H. Butrus1,2, P. Johansson1,2, E. Åkerström1,2, S. Soukkil1,2, S. Emanikia1,2, Y. Ennán1, S. Pettersson1,2, I. Parodis1,2, Karolinska Institute, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden; Karolinska University Hospital, Rheumatology, Stockholm, Sweden; Karolinska Institute, Division of Physiotherapy, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden

Background: Patients with systemic lupus erythematosus (SLE) experience a considerably impaired health-related quality of life (HRQoL) compared with the general population. Previous literature has implied an association between high body mass index (BMI) and HRQoL diminutions. However, data are scarce and further exploration in large study populations and, importantly, with regard to the clinical significance of this association is needed.

Objectives: The aim of this study was to determine whether overweight and/or obesity were associated with impaired physical and/or mental HRQoL aspects in the SLE population of two large clinical trials.

Methods: We utilised pooled baseline data from the BLISS-SS (NCT00424476) and BLISS-76 (NCT00410384) clinical trials of belimumab (N=1684). Access to data was granted by GlaxoSmithKline. The patients were stratified into four groups based on their body mass index (BMI), according to WHO guidelines. We conducted comparisons between non-overweight versus overweight, and non-obese versus obese SLE patients. HRQoL was self-reported using the Medical Outcomes Study (MOS) short form 36 (SF-36) health survey, the functional assessment of chronic illness therapy (FACT)-Fatigue scale and the three-level EuroQol- 5 Dimension (EQ-5D) questionnaire. We explored whether the differences in scores were clinically meaningful using previously determined thresholds for minimal clinically important differences (MCIs). The non-parametric Mann-Whitney U test was used for comparisons between different BMI groups. Linear regression analysis was next applied to test independence in multivariable models, adjusting for age, sex, ethnicity, disease duration, disease activity, organ damage and standard of care treatment.

Results: Forty-four per cent (44%) of the patients had a BMI score over the normal range, and 18% were obese. The overweight group performed worse than the non-overweight with regard to FACT-Fatigue scores (mean ± standard deviation: 27.7 ± 12.1 vs 32.0 ± 11.3; P<0.001), EQ-5D score (0.70 ± 0.19 vs 0.76 ± 0.18; P<0.001) and all SF-36 subscales and component summaries. The differences were greater than the MCIs for physical component summary (PCS) scores (36.9 ± 9.3 vs 40.8 ± 9.6; P<0.001), physical functioning (53.3 ± 25.1 vs 63.6 ± 25.1; P<0.001), role physical (43.8 ± 22.4 vs 52.5 ± 25.1; P<0.001), vitality (39.6 ± 21.7 vs 46.6 ± 21.3; P<0.001), social functioning scores (55.8 ± 25.2 vs 62.6 ± 25.2; P<0.001).

Likewise, obese patients reported worse FACIT-Fatigue scores (25.7 ± 11.9 vs 32.0 ± 11.3; P<0.001), EQ-5D score (0.70 ± 0.19 vs 0.76 ± 0.18; P<0.001) and clinically important diminutions of HRQoL in all SF-36 items, except for the mental component summary (MCS), role emotional and mental health.

In multivariable linear regression analysis, the overweight and obese group showed worse PCS scores (standardised coefficient β=-0.09; P<0.001) and BMI (β=-0.13; P<0.001, respectively) and FACT-Fatigue scores (β=-0.11; P<0.001 and β=-0.10; P<0.001, respectively), and overweight patients had significantly impaired MCS scores (β=0.05; P=0.039), irrespective of other factors. High

Fig 1: risk of flare according to disease activity
disease activity and organ damage were associated with impaired HRQoL in all aspects, while Asian patients reported better PCS scores (and \( p = 0.29 \), \( P = 0.007 \)) and FACT-Fatigue scores (\( p = 0.33 \), \( P = 0.002 \)).

Conclusion: BMI above normal was highly associated with HRQoL impairment, especially in physical aspects. Further survey to examine causality is warranted to support structured weight control strategies as an intervention towards a more favourable HRQoL.

FR0169 ANTINUCLEAR ANTIBODY SEROCONVERSION DURING FOLLOW-UP IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

R. Guattilien1, G. Frontini2, F. Pregnolato2, P. Messa2, G. Moroni2, P. L. Meroni2, 1University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; 2IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Nephrology Unit, Milan, Italy; 3IRCCS Istituto Auxologico Italiano, Immunorheumatology Research Laboratory, Cusano Milanino, Milan, Italy.

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by the presence of autoantibodies and a variable spectrum of clinical manifestations and disease severity. The 2019 criteria for SLE classification by the American College of Rheumatology and European League against Rheumatism define ANA positivity by immunofluorescence or by an equivalent solid-phase assay as the entry criterion (1). However, the prevalence of ANA positivity and the reliability of solid-phase assays in SLE are still a matter of controversy (2). Furthermore, the significance of ANA negativisation during follow-up is uncertain (3).

Objectives: Our aim was to retrospectively analyse data on the frequency of ANA seroconversion during the follow-up in a cohort of SLE patients with renal involvement.

Methods: Adult patients independent of age at SLE onset with a follow-up duration of at least 36 months starting from January 2009 (for standardization of ANA measurement) and with at least one ANA measurement per year were included in this retrospective longitudinal study. Data on demographic, clinical and laboratory characteristics of the study population are reported in table 1. ANA have been measured with Hep2 cell immunofluorescence assay.

Table 1. Demographic, clinical and laboratory baseline characteristics of the 121 patients suffering from systemic lupus erythematosus (SLE).

Table 1. Demographic, clinical and laboratory baseline characteristics of the 121 patients suffering from systemic lupus erythematosus (SLE).

</tr>
</tbody>
</table>

Results: A total of 121 SLE subjects with renal involvement were enrolled. Mean follow-up ± standard deviation (SD) was 8 ± 2 years. Ten subjects (8.3%) with positive ANA at the beginning resulted ANA negative at the end of the follow-up. These subjects had different initial ANA titres: 1:1280 (n=1), 1:640 (n=2), 1:320 (n=2), 1:160 (n=3) and 1:80 (n=2); 48 subjects (39.7%) showed a decrease in ANA titre. Of the 9 patients (7.4%) that were negative at the beginning of follow-up, 6 remained negative, whereas 3 showed ANA positivity at the end of the follow-up with ANA titres 1:160 (n=2) and 1:320 (n=1). No differences between subjects with and without ANA variation in terms of age (p=0.551), disease duration (p=0.786), SLEDAI at the beginning (p=0.453) and at the end of follow-up (p=0.169) were observed. ANA negativisation and titre variations at the end of follow-up did not correlate with any of the treatments taken during follow-up, including a history of cyclophosphamide (p=0.788).

Conclusion: In our cohort of patients with SLE and renal involvement, 10% of patients experienced negativisation and around 40% of patients showed a decrease in ANA titre during follow-up, independent of disease characteristics and previous treatment. Further studies are warranted to clarify the underlying mechanisms and clinical significance of ANA seroconversion and titre variation in SLE patients. However, based on our results, ANA positivity seems to be a relatively stable parameter further supporting its use as an entry classification criterion for SLE.

FR0170 THERAPEUTIC TARGETS AND QUALITY INDICATORS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE), DEFINED ACCORDING TO THE 2019 UPDATE OF THE EULAR RECOMMENDATIONS: DATA FROM THE “ATTIKON” LUPUS COHORT

K. Havstra1, K. Togia1, S. Flouda1, A. Pietta1, O. Gioti1, D. Nikolopoulos1, N. Kapasila1, A. Ntouro1, P. Rapsomani1, T. Gerogianni1, D. Tseronis1, M. Aggelakos1, T. Karageorgas1, P. Katsimpri1, G. Bertisias1, K. Thomas1, D. Bourmpas1, A. Fanourakis1, 1“Attikon” University Hospital of Athens, Rheumatology and Clinical Immunology, Athens, Greece; 2University Hospital of Heraklion, Rheumatology and Clinical Immunology, Athens, Greece

Background: Targets of therapy and quality of care are receiving increased attention in the management of SLE, as outlined in the 2019 update of the EULAR recommendations for SLE treatment.

Objectives: To assess compliance with quality indicators and attainment of treatment targets, according to the current EULAR recommendations, in the SLE cohort of “Attikon” Rheumatology Unit.

Methods: 100 consecutive SLE patients followed for at least one year were. A 30 item Quality Indicator Set (QIS) was developed, according to the 2019 EULAR recommendations for SLE, to include laboratory tests for diagnosis and monitoring, evaluation of disease activity and damage using validated indices, use of patient-reported outcomes, counselling for women’s health and reproduction issues, attainment of targets of therapy (remission or low disease activity state (LLDAS) with low-dose glucocorticoids (GC, ≤2.5mg/day prednizone) and hydroxychloroquine (HCQ doses≤5mg/kg/day)), prevention of disease flares and prevention and management of co-morbidities. Chart review and patient interview was performed to assess the degree of compliance with each item of the QIS and achievement of treatment targets.

Results: Disease activity was monitored by means of validated indices in 31% and antiphospholipid antibody testing during the first 6 months from diagnosis was performed in 58.8% of patients. Sustained remission (defined as remission of a sustained period of 12 months) or LLDAS was achieved by only 3% and 22% respectively; in contrast, other targets of therapy, such as ≤1 minor flares during last year, were achieved by 85% (43% had complete absence of flares), with 90.2% of patients receiving low-dose GC and 81.8% corrected HCQ dose. Fertility and pregnancy counselling were offered in 40% (12/30 eligible women) and 63.3% (19/30) of patients, respectively, while 65.4% had a Pap Test and only 3 of 32 eligible patients had received the HPV vaccine. Annual lipid status was assessed in 43% and counselling for smoking cessation in 44.6%. Flu vaccination was performed in 77%, while pneumococcal (including both of the pneumococcal vaccines) and herpes-zoster vaccination, were given in 32.7% and 2% (1/44 eligible patients) respectively.

Conclusion: Our real-life data suggest low vaccination rates (excluding flu) and suboptimal management of cardiovascular risk factors in lupus patients. While the majority of patients received the suggested doses of GC and HCQ, only one quarter of patients achieved remission or LLDAS. There is an unmet need for new therapies in SLE to improve therapy targets.

The changes of immune function and clinical indexes with systemic lupus erythematosus after immunomodulatory combination therapies

X. Liu, X. Liu, H. Hou, X. Li on behalf of Li Xiaofeng Team. The Second Hospital of Shanxi Medical University, Taiyuan, China; Taiyuan University of Technology, Taiyuan, China; Inner Mongolia Normal University, Huhehaote, China

Background: Recent studies have reported that some drugs such as low-dose interleukin-2, rapamycin, metformin, retinoic acid and coenzyme Q10 could promote the proliferation and functional recovery of regulatory T cells (Treg) in patients with autoimmune diseases. However, the effects on the balance of Treg cells and pro-inflammatory lymphocytes and long-term efficacy have rarely been reported.

Objectives: To evaluate the changes of peripheral lymphocyte subsets, conventional drugs and remission rate in patients with systemic lupus erythematosus (SLE) after immunomodulatory combination therapies.

Methods: A total of 189 patients with SLE from the Second Affiliated Hospital of Shanxi Medical University from January 2016 to October 2019 were enrolled. We divided the samples into a well-controlled group and an untreated control group according to the treatment. We calculated a full consideration of the patient’s symptom, signs and laboratory findings. We measured the absolute counts of B, NK, CD8+T and helper T 1 (Th1), helper T 2 (Th2), helper T 17 (Th17) and Treg cells in peripheral blood of patients before immunomodulatory combination therapies and during the 3 months and 6 months of follow-up and 190 sex- and age-matched control individuals using flow cytometry. Moreover, the ratios of various cells to Treg cells were calculated.

Results: Compared with healthy controls, Treg cells in SLE patients were significantly lower before the treatment with immunomodulator, while the ratios of various pro-inflammatory lymphocytes to Treg cells (such as Th2/ Treg, Th17/Treg, CD8+T/Treg, etc.) were higher. After 3 months and 6 months with immunomodulatory therapy, the absolute number of Treg cells in peripheral blood of SLE patients increased obviously reaching to normal level. Accordingly, the ratios of various pro-inflammatory lymphocytes to Treg cells recovered. At the same time, the dose of glucocorticoid and disease-modifying antirheumatic drugs (DMARDS) decreased distinctly. Additionally, the well-controlled group was able to maintain a high remission rate, and the untreated control group could achieve a higher response rate after immunomodulatory treatment.

Conclusion: The imbalance between pro-inflammatory lymphocytes and Treg cells caused by the significant decrease of Treg cells may be the main cause of SLE. And immunomodulatory combination therapies we came up with may reverse the imbalance of proinflammatory lymphocytes and Treg cells, which is an potential and effective treatment for SLE.

Objectives: In this analysis, we aimed at determining the predictors of ON in a longitudinal lupus cohort in which Caucasian and African-American ethnicities are well represented.

Methods: The data were reviewed from the initiation of the cohort in 1987 until October 2019. 2428 patients were included in the analysis based on 224295 person-months of follow-up. ON was recorded using the Systemic Lupus Erythematosus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index. To calculate the rate of ON in each demographic and clinical subgroup, we calculated the number of ON events divided by the number of person-months at risk and converted this rate to rates per person-year. To assess the relationship between risk factors and rates of ON events, we used the pooled logistic regression. Rate ratios were adjusted for age. After identifying a set of variables related to ON incidence, we fit a final multivariable model to identify the most important risk factors for incident ON.

Results: 287 ON cases were identified, giving a point prevalence of 11%. ON cases that occurred before cohort entry were excluded. 122 incident events of ON occurred after cohort entry and were included in the final analysis. In the multivariable analysis, African-Americans were at twice the risk for ON compared to Caucasians. Male gender and smokers had about 80% and 50% increased risk of ON compared to females and non-smokers respectively. For every 10 year increase in the age there was a 20% reduced risk for ON. Patients diagnosed after the 1990’s had a 50% reduced risk of ON compared to those diagnosed before 1990’s. A highest daily dose of prednisone of 40 mg or higher, even when administered for a month or less, increased significantly the risk of ON. Use of pulse steroid was not associated with an increased risk of ON.

Conclusion: Ethnicity remains an important determinant in the risk of ON. African-American SLE patients are at double the risk compared to Caucasians. APOL1 risk variants confer an increased risk of ON in this high-risk ethnic group. Oral prednisone more than 40 mg/day at any point in the disease course, remains the most important predictor of ON. Prednisone-free or prednisone-limited regimens should be reinforced in SLE trials.

between proliferative LN and membranous LN, we performed a receiver-operating characteristic analysis.

Results: Of the total 168 patients with biopsy-proven LN, 150 patients (89.3%) had proliferative LN, and 18 patients (10.7%) had membranous LN. In the multivariable logistic regression analysis, positive anti-double-stranded DNA (anti-dsDNA) antibody (adjusted OR = 11.200, 95% CI = 2.202–56.957, p = 0.004) was associated with proliferative LN, while positive anti-U1RNP antibody (adjusted OR = 0.176, 95% CI = 0.040–0.769, p = 0.021) and higher glomerular filtration rate (GFR) (adjusted OR = 0.973, 95% CI = 0.951–0.994, p = 0.013) were inversely associated with proliferative LN. Among these covariates, the anti-dsDNA antibody (area under the curve = 0.806, 95% CI = 0.695–0.916) had the highest accuracy in discriminating between proliferative LN and membranous LN.

Conclusion: The positivity of anti-dsDNA antibody was associated with proliferative LN, while the positivity of anti-U1RNP antibody and GFR were inversely associated with proliferative LN. The anti-dsDNA antibody had a good accuracy in discriminating proliferative LN from membranous LN.

protein: creatinine ratio. In DCE-MRI, we specifically focused on mean Maximum
Enhancement (ME), mean Time to Peak Enhancement (TTP) and mean Time of
Washout (Twashout) as indicators of renal perfusion.
Results: Nine subjects have been evaluated to date and their imaging data
assessed for quality. Evaluation of mean data from DCE-MRI has shown a sign-
ificant correlation between renal perfusion and renal function. For example,
as shown in the figure, the 24 hour protein concentration negatively correlated with
ME (r = -0.81, p = 0.015), TTP (r = -0.83, p = 0.01) and Twashout (r = -0.81, p = 0.01,
Spearmran rank correlation). In addition, the protein:creatinine ratio also nega-
tively correlated with ME (r = -0.79, p = 0.02), TTP (r = -0.74, p = 0.04) and Twashout
(r = -0.79, p = 0.02, Spearmran rank correlation).
Conclusion: These initial results have established the feasibility of multi-modal-
ity imaging as a tool to evaluate LN in a multi-center study. Moreover, changes in
perfusion detected by DCE-MRI significantly correlate with proteinuria and uri-
nary protein:creatinine ratio. These results suggest that multiparameter imaging
may contribute useful data in the evaluation of subjects with LN.

**FR01S80**  **SURVEY ON HELP-SEEKING AND DISEASE TRAJECTORY IN SYSTEMIC LUPUS ERYTHEMATOSUS**

M. F. Eguez del Pozo1, M. Micelli1, A. Cahizares Calderon1, P. Avila1, N. Faru2, L. Garcia Faura1, D. Alvarez2, G. Sequeira1, E. Kerzberg1, Hospital J.M. Ramos Mejia, Servicio de Reumatología, Ciudad Autonoma de Buenos Aires, Argentina; Clínica La Pequeña Familia, Junín, Argentina; Hospital Santa Francisca Romana, Arrecifes, Argentina

**Background:** Few studies in Latin America have analysed the time lag since patients experience the first joint symptoms until they consult a physician, and a diagnosis is made, and most of them have dealt with patients sustaining Rheumatoid Arthritis (RA).

**Objectives:** To study both patient and disease factors that have some bearing on the time lag until a physician is first consulted and a diagnosis is made.

**Methods:** Multiple-choice survey to patients of 18 years of age or older who met Systemic Lupus Erythematosus (SLE) Classification Criteria (2012). The following aspects were measured: time lag from symptom onset to first medical consultation (Time 1), time lag since first medical consultation until a diagnosis is made (Time 2), and time lag until the first consultation with a rheumatologist.

**Results:** Twenty-eight patients with SLE and 29 patients with RA filled in the survey. SLE patients were younger as expected (32 years vs 49 years; p <0.001). Acute was the most common disease trajectory in SLE patients (36% vs 34%; p 0.8) and chronic in RA (38% vs 32%; p 0.8). The first professional consulted was an on-duty physician in SLE (36% vs 24% in RA; p 0.5). Except for the matter of computer at home and/or a mobile phone with an Internet connection at home, both groups were similar, although SLE patients showed a trend to better level education and lesser impact of the disease on daily life at the beginning (see Table 1).

<tr>
<td>Diagnosis made by a rheumatologist</td>
<td>20 (71%)</td>
<td>23 (80%)</td>
<td>0.7</td>
</tr>
</tbody>
</table>

Time 1 in patients with SLE was significantly lower with a median of 7 days, range (25-75%) 1-30 days vs 30 days in RA, range 14-180 (p 0.01), and the former also showed a trend to lower median Time 2; 61 days, range 25-209 vs 185 days in RA, range 60-275 (p 0.1). Besides, they showed a significantly shorter time lag until the first visit to a rheumatologist with a median of 120 days, range 35-225 vs 330 days, range 120-450 in patients with RA (p 0.005).

**Conclusion:** SLE patients consult a physician and visit a rheumatologist sooner than RA patients do, and they also show a trend to obtain a faster diagnosis. Education, health insurance, employment, the disease impact on their daily life and initial response to the symptoms do not appear to account for their swiftness in seeking medical help.

**FR01S82**  **RISK FACTORS ASSOCIATED WITH RENAL INVOLVEMENT IN PRIMARY SJÖGREN’S SYNDROME: DATA FROM THE SPANISH SJÖGREN’S COHORT**

J. Narvaez1, C. Sánchez-Piedra2, M. Fernandez Castro3, V. Martinez Taboada4, A. Oliver5, J. Rosas6, A. Garcia-Vadillo7, E. Judez8, E. Ruiz Lucea8, L. Romaní3, J. L. Andreu9 on behalf of SJÖGRENRESEARCH Project. 1Hospital Universitario de Bellvitge, Rheumatology, Barcelona, Spain; 2Unidad de Investigación de la Sociedad Española de Reumatología, Madrid, Spain; 3Hospital Puerta de Hierro, Rheumatology, Madrid, Spain; 4Hospital Marques de Valdecilla, Rheumatology, Santander, Spain; 5Hospital Germans Trias i Pujol, Rheumatology, Barcelona, Spain; 6Hospital Marina Baixa, Rheumatology, Alicante, Spain; 7Hospital de la Princesa, Rheumatology,

**Background:** The goals of treatment of lupus nephritis (LN) are to induce remission, retard the progression of chronic kidney disease, prevent organ complications and ultimately reduce mortality. Previous cohort studies of LN have mainly focused on the risk of mortality and development of end stage renal failure (ESRF) (relative survival). The cumulative frequency of LN patients who survive without organ damage, which correlates better with the balance between treatment efficacy and toxicity, as well as quality of life, has not been well studied.

**Objectives:** To study the organ damage free survival and its predictive factors in patients with active LN.

**Methods:** Consecutive patients who fulfilled ≥4 ACR/SLE criteria for SLE and with biopsy proven active LN between 2003 and 2018 were retrospectively analyzed. Those with organ damage before LN onset were excluded. Data on renal parameters and treatment regimens were collected. Complete renal response (CR) was defined as normalization of serum creatinine (SCr), urine P/Cr (uPCR) <0.5 and inactive urinary sediments. Partial renal response (PR) was defined as ≥50% reduction in uPCR and <25% increase in SCr. Organ damage of SLE was assessed by the ACR/SLE damage index (SDI). The cumulative risk of having any organ damage or mortality since LN was studied by Kaplan-Meier’s analysis. Factors associated with a poor outcome were studied by a forward stepwise Cox regression model, with entry of covariates with p<0.05 and removal with p>0.10.

**Results:** 273 LN patients were identified but 64 were excluded (organ damage before LN onset). 211 LN patients were studied (92% women; age at SLE 30.4±15.5 years; SLE duration at LN 19±3.1years). 47 (22%) patients had nephrotic syndrome and 60 (29%) were hypertensive. Histological LN classes were: III/Va/V (75.1%), III/II (78%) and pure V (17.1%) (histologic activity and chronicity score 7.0±4.2 and 1.8±1.5, respectively). Induction regimens were: prednisolone (33.1±175mg/day) in combination with intravenous cyclophosphamide (CYC) (21.4%; 1.0±2.2g per pulse), oral CYC (8.6%; 9.4±378mg/day), azathioprine (AZA) (14.3%; 78.6±25.2mg/day), mycophenolate mofetil (MMF) (22.8%; 1.9±4.3g/day) and tacrolimus (TAC) (17.1%; 4.3±1.1mg/day). After a follow-up of 8.6±5.4 years, 94.45% patient developed organ damage (SDI≥1) and 2(10%) patients died. The commonest organ damage was renal (36.3%) and musculoskeletal (17.8%), and the causes of death were: infection (38.1%), malignancy (19.0%), cardiovascular events (9.5%) and ESRF complications (9.5%). At last visit, 114 (55%) patients survived without any organ damage. The cumulative organ damage free survival at 5, 10 and 15 years after renal biopsy was 73.5%, 59.6% and 48.3%, respectively. The 5, 10 and 15-year renal survival rate was 95.2%, 92.0% and 84.1% respectively. In a Cox regression model, nephritic relapse (HR 3.72[178-777]), proteinuric relapse (HR 2.30[1.07-4.95]) and older age (HR 1.89[1.05-3.37]) were associated with either organ damage or mortality, whereas CR (HR 0.25[0.12-0.50]) at month 12 were associated with organ damage free survival. Baseline SCr, uPCR and histological LN classes were not significantly associated with a poor outcome. Among patients with class III/IV LN, the long-term organ damage free survival were not significantly different in users of MMF (reference from CYC/IV/oral) (HR 1.45[0.76-2.75]) or TAC (HR 1.03[0.26-4.12]) as induction therapy.

**Conclusion:** Organ damage free survival is achieved in 55% of patients with active LN upon 9 years of follow-up, CYC/MMF/TAC based induction regimens did not differ for the long-term outcome of LN. Targeting complete renal response and preventing renal relapses remain important goals of LN treatment.

Objectives: To investigate the prevalence, risk factors, and effects of primary renal disease on morbidity and mortality in patients with primary Sjögren’s syndrome (pSS).

Methods: All patients in the SJÖGRENSER (register of adult SSp patients of the Spanish Society of Rheumatology, cross-sectional phase) cohort were retrospectively investigated for the presence of clinically significant renal involvement directly related to pSS activity.

Results: Of the 437 patients investigated, 39 (9%) presented overt renal involvement during follow-up. Severe renal disease necessitating kidney biopsy was relatively rare (23%). Renal involvement may complicate pSS at any time during the disease course and is associated with severe disease (indicated by higher scores of involvement, activity, and damage), systemic multiorgan involvement, and a higher frequency of lymphoma. Multivariate analysis showed that older age (odds ratio [OR] 1.03, 95% confidence interval [CI] 1.00–1.07), higher European League Against Rheumatism Sjögren’s Syndrome Disease Activity Index scores (OR 1.1, CI 1.05–1.18), serum anti-La/SSB positivity (OR 6.44, CI 1.36–30.37), and non-vasculitic cutaneous involvement (OR 6.8, 1.33–55.90) were independently associated with this complication.

Conclusion: Chronic renal failure developed in 23 of 39 patients (59%); only 1 of them progressed to end-stage renal disease necessitating renal replacement therapy. Patients with renal disease showed higher Sjögren’s syndrome disease damage index scores (SSDID), higher rates of hospitalization due to disease activity and high rates of clinical renal complications (15% vs 1% for pSS).

**FR01818**

**DISTINCTIVE TRAITS OF MYOCARDIAL INFLAMMATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A MULTICENTRE STUDY**

G. A. Ramirez1,2, M. Gerosa3,4, G. De Luca3, L. Beretta4, S. Sala4, G. Peretto2, L. Moroni2,3, F. Mastroppaco1,2, A. Cariddi3, S. Cartorrelli3, S. Campochiaro3, E. Bozzolo3, R. Caporali2, L. Dagna1,2 on behalf of Milan SLE Consortium (SMILE).

**Background:** Myocarditis is an infrequent but potentially life-threatening inflammatory disorder and might be part of the spectrum of systemic lupus erythematosus (SLE). Little is known about the clinical and histologic features of myocarditis in SLE, especially compared to other forms of myocardial inflammation.

**Objectives:** to test for potential distinctive traits among myocarditis in SLE (MyoSLE), SLE without myocarditis (OnlySLE) and myocarditis without SLE (OnlyMyo)

**Methods:** Patients with MyoSLE were identified from three centres and compared with 231 cross-sectionally enrolled patients with OnlySLE and 87 patients with OnlyMyo. MyoSLE patients were split into two groups based on myocarditis onset within (early onset) vs after (late onset) the first year from SLE diagnosis. OnlySLE patients were dichotomised in the same way based on disease duration at time of enrolment. Demographics and general clinical features were collected retrospectively. SLE disease activity index 2000 (SLEDAI-2K), SLE International Collaborating Clinics/American College of Rheumatology damage index (SDI), clinical and laboratory features were collected at time of myocarditis onset in MyoSLE and at enrolment in OnlySLE. Quantitative data are expressed as median [interquartile range].

**Results:** Fourteen MyoSLE patients were identified, 50% with early onset. Women were equally frequent among MyoSLE (71%) and OnlySLE patients (87%) and less frequent in the OnlyMyo group (43%; p<0.001). Age was comparable among groups. Clinical features at presentation, including left ventricular ejection fraction, were similar between MyoSLE and OnlyMyo, although the former had higher levels of pro-brain natriuretic peptide (1.1 [0.4-1.8] vs 0.1 [0.1-0.5] ng/ml; p=0.004). Patients with MyoSLE also had a lower frequency of left ventricle lateral wall involvement (36 vs 68%; p=0.035) and of oedema (20 vs 71%; p=0.036) and necrosis (0 vs 64%; p=0.009) at biopsy. Antiphospholipid antibodies (aPL) were more frequent in MyoSLE (57%) compared to both OnlyMyo (16%; p=0.003) and OnlySLE (28%; p=0.031). Compared to OnlySLE, patients with MyoSLE also had a higher prevalence of aPL syndrome (APS: 36 vs 7%; p=0.003), neuropsychiatric (NPSLE: 43 vs 19%; p=0.039) and gastro-intestinal manifestations (21 vs 5%; p=0.045).

**Conclusion:** Early and late onset patients had similar demographics and clinical features and did not differ from patients with OnlySLE with similar disease duration in terms of SLEDAI-2K and SDI. Late onset MyoSLE patients had a higher prevalence of NPSLE (57 vs 18%; p=0.026) and APS (57 vs 7%; p=0.001) and higher C-reactive protein levels (6 [2-12] vs 10 [4-4] mg/l; p=0.024) compared to OnlySLE patients with the same disease duration.

DIAGNOSTIC SIGNIFICANCES OF BOTH MICRORNA-146A AND KALLIKREIN-1 IN PATIENTS WITH LUPUS NEPHRITIS
S. Soliman1, A. Higazi2, M. Naar1, N. M. Abd El Hamid2, H. Kamel2, A. Abd El Samie El Sherif3, 1Faculty of Medicine, Minia University, Rheumatology & Rehabilitation, Minia, Egypt; 2Faculty of Medicine, Minia University, Department of Clinical and Chemical Pathology, Minia, Egypt; 3Minia Fever Hospital, Minia, Egypt

Background: Lupus nephritis (LN) is one of the most critical complications of systemic lupus erythematosus (SLE). Approximately 30–50% of SLE patients develop LN with 5-year survival rate of about 70-80%. Thus, finding reliable non-invasive biomarkers at the early stages of SLE is of great interest (1). Many studies focused on the association between microRNAs and the risk of LN. miR-NA-146a (miR-146a) was one of the most promising circulating markers which was suggested recently for early diagnosis of SLE but its diagnostic relevancies regarding LN have not been extensively investigated.

Objectives: This study aims to test the expression of miR-146a in patients with LN in relation to Kallikrein-1 as another widely investigated diagnostic marker for LN along with other conventional measures.

Methods: One hundred and thirty subjects were enrolled in this study. They were divided into forty six patients with LN, forty four patients with SLE but without nephrits and forty healthy controls. The expression levels of miR-146a in peripheral blood mononuclear cells (PBMCs) were detected via RT-qPCR analysis. Besides, serum Kallikrein-1 levels were determined by ELISA. The diagnostic role of miR-146a and Kallikrein-1 in LN was evaluated by Receiver operating curve (ROC). The impact of miR-146a and Kallikrein-1 on renal disease was compared to albumin creatinine ratio, renal biopsy findings as well as renal SLEDAI.

Results: Levels of miR-146a were significantly lower in the plasma of LN patients than both patients of SLE without LN and normal controls (p < 0.05). However, serum levels of Kallikrein-1 were significantly higher in LN patients when compared to SLE patients and normal population (p < 0.05). ROCs were conducted to assess the diagnostic values of both miR-146a and kallikrein-1. They revealed good diagnostic values with AUC of 0.888 and 0.913 respectively. Also, plasma miR-146a was observed to be negatively associated with serum creatinine, proteinuria as well as SLEDAI score (p < 0.01) while serum Kallikrein-1 was positively correlated with them (p < 0.05) and inversely correlated with miR-146a (p < 0.01).

Conclusion: The expression levels of miR-146a are reduced in SLE patients with more reduction with LN. Therefore, miR-146a could be considered as potential biomarker for detecting LN either alone or in combination with Kallikrein-1. However, more studies are required.

JOINT INVOLVEMENT AND DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: CALCULATION OF SWOLLEN TO TENDER JOINT COUNT RATIO IN A REAL WORLD COHORT IN THE US
C. Cavanaugh1, G. Donadio2, K. Slavik3, M. Behling1, G. Curhan1, R. Gliklich1
1OM1, Inc., Boston, United States of America

Background: Joint swelling and tenderness are common in patients with systemic lupus erythematosus (SLE). Swollen to tender joint count ratio (STR) is an index originally used in rheumatoid arthritis (RA) which assesses severity of disease activity based on 28 joint counts [1]. In RA, STR is a predictor of treatment response with a higher score indicating greater likelihood of responding.

Objectives: To characterize SLE patients in a real-world cohort based on disease activity as defined by STR.

Methods: The OM1 SLE Registry (OM1, Boston, MA) follows more than 37,000 SLE patients longitudinally with deep clinical data, including laboratory, patient-reported and disease activity information, and linked administrative claims, starting from 2013. Patients ≥16 years of age with swollen and tender joint counts based on 28 joints on the same encounter were included. STRs were calculated by inserting 1 if the denominator was 0 [2]. Patients were categorized by first available STR as having low (STR <0.5), moderate (0.5 ≤ STR < 1.0), and high (STR ≥1.0) disease activity. Clinical characteristics were summarized by disease activity group. Definitions of SLE treatments were based on 2019 EULAR recommendations [3].

Results: As of December 2019, there were 9,919 patients with at least one STR available in the OM1 SLE Registry. STR was low in 80.4%, moderate in 12.2%, and high in 7.4% of patients. Mean age overall was 52.1 years (standard deviation: 14.8), 92.1% were female, and 71.8% of 7,730 patients with known race were white. Clinical characteristics by STR group are described in Table 1. Antimalarial use decreased and immunosuppressant use increased with increasing STR. Use of select disease-modifying antirheumatic drugs

FR10187 IMMUNELOGICITY OF 23-VALENT POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: EFFECT OF BIOLOGIC THERAPY ON THE VACCINAL RESPONSE

G. Tarasova1, B. Belov1, M. Cherkasova1, S. Solovyev1, E. Aseeva1, T. Reshetnyak1, T. Popkova1.1. V.A. Nasonov Research Institute of Rheumatology, Moscow, Russian Federation

Background: Vaccination with 23-valent polysaccharide pneumococcal vaccine (PPV-23) in systemic lupus erythematosus (SLE) provides the prevention of severe respiratory infections in patients receiving immunosuppressive therapy. The importance of this vaccination significantly increases before and during treatment with biologics.

Objectives: The aim of the study was to evaluate the immunogenicity of PPV-23 in SLE patients.

Methods: The study included 52 patients with SLE, including 44 women and 8 men, aged 19 to 68 years. The duration of the disease varied from 9 months to 39 years. At the time of vaccination 7 patients had high, 10 – moderate, 30 – low activity of the disease according to SLEDAI 2K, and 5 had remission. 50 patients received glucocorticoids (GC) 5-30 mg/day equivalent to prednisone, 39 – hydroxychloroquine (GCH), 29 – cytostatics (CS), 20 – biologics: 10 – rituximab (RTM), 10 – belimumab (BLM), 1 dose (0.5 mg) of PPV-23 was administered subcutaneously. During the visits, standard clinical and laboratory tests were performed, and the level of antibodies (Ab) to S.pneumoniae in blood serum was determined (VacCymeTMlympho 2 kits – The Binding Site Ltd, Birmingham, UK).

Results: In 1-2 months after the vaccination 78.7% of patients had a significant (more than 2 times compared to baseline) increase in the concentration of Ab to the pneumococcal cell wall polysaccharides. A year after vaccination, 61.5% of patients (“responders”) had a significant increase in the concentration of anti-pneumococcal Ab. 20 (38.5%) of 52 patients were considered non-responders.

Conclusion: Sufficient immunogenicity of PPV-23 was shown in SLE patients receiving immunosuppressive therapy. The negative impact of biologics on the vaccinal response was confirmed, especially if the vaccination was not performed at the optimal time in relation to the infusion of the drug or during monthly administration of BLM. If optimal vaccination terms are maintained during the treatment with or initiation of biologics 6 months after the last administration of RTM and 1 month before the next (or first) administration of RTM, 4 months after the next (or first) introduction of RTM (5), 1 week before the next introduction of RTM (n=1), 20 days after the BLM termination (n=1). In the first group with optimal vaccination terms, the number of responders was 66.7%, in the second group with suboptimal terms ~28.6%, p=0.27.

FR10188 THE CLINICOIMMUNOLOGICAL SIGNIFICANCE OF MODIFIED NATIONAL INSTITUTES OF HEALTH ACTIVITY AND CHRONICITY SCORING SYSTEM IN LUPUS NERPHISITIS: A MULTICENTER RETROSPECTIVE STUDY

T. Zoshima1, S. Harai1, M. Kawano1,1. Kanazawa University, Rheumatology, Kanazawa, Japan

Background: The revised International Society of Nephrology/Renal Pathology Society (ISN/RPS) Classification of lupus nephritis (LN) 2018 defined a modified National Institutes of Health activity and chronicity scoring system for all LN classes [1]. As this was not arrived at by an evidence-based approach, its clinicopathological significance including prognostic value should be validated [1]. Furthermore, though the activity index included wire-loop lesion and hyaline deposits (WL), we previously demonstrated that WL was associated with serological and renal abnormalities (or first introduction of BLM), the number of responders increases significantly. The lowest vaccinal response was obtained in patients receiving combined immunosuppressive therapy with biologics + GC+CS.

Vasculitis

ENDOTHELIAL PROTEIN C RECEPTOR AND SCAVENGER RECEPTOR CLASS B TYPE 1 NEGETIVELY REGULATE ENDOTHELIAL ACTIVATION AND REPRESENT NOVEL AUTOANTIGENS IN TAKAYASU ARTERITIS

T. Shirai1, T. Mutoh1, H. Fujii1, T. Ishii1, H. Harigae1,1 Hokkoh University Graduate School of Medicine, Hematology & Rheumatology, Sendai, Japan

Background: Takayasu arteritis (TAK) is a chronic granulomatous vasculitis and affects large vessels in young female. It has been recognized that high numbers of patients with TAK possessed autoantibodies against vascular endothelium, which are called anti-endothelial cell antibodies (AECA). Although their target antigens had not been identified for a long time, we utilized an expression cloning system for specific identification of cell-surface antigens and successfully identified endothelial protein C receptor (EPCR) and scavenger receptor class B type 1 (SR-BI) as major novel autoantigens in TAK. It was possible that identified novel autoantibodies were utilized for clinical application and elucidating pathomechanisms of TAK.

Objectives: To reveal the clinical impact and pathogenic potential of novel autoantibodies in TAK

Methods: Three hundred twenty-five patients with autoimmune diseases were enrolled: 80, TAK; 10, giant cell arteritis (GCA); and 235, other autoimmune diseases. The expressions of EPCR and SR-BI were examined in the aortic tissue from several diseases by immunohistochemistry. The presence of novel autoantibodies was measured in TAK and other autoimmune diseases. Clinical characteristics of patients with these autoantibodies were evaluated in TAK. To investigate the pathogenetic potential of these novel autoantibodies, vascular endothelial cells from umbilical vein, aortic artery, and pulmonary artery were examined for the endothelial cell activation. The effects of the novel autoantibodies upon the differentiation of immune cells were also evaluated.

Results: In non-inflammatory aortic tissue, the expressions of EPCR and SR-BI were observed in the endothelium of vasa vasorum. Their expressions in the endothelium were augmented in TAK tissue. Novel autoantibodies against EPCR or SR-BI were detected in 34.6 % or 36.5 % of cases, respectively in TAK, and overlap was observed only in two cases, indicating their exclusive nature. These autoantibodies were specific for TAK among autoimmune rheumatic diseases, and they were not detected in patients with GCA with cranial involvement, suggesting different pathomechanisms among these diseases. The clinical characteristics of patients with anti-EPCR autoantibodies included high prevalence of stroke and ulcerative colitis. Surprisingly, anti-EPCR autoantibodies were also detected in patients with primary ulcerative colitis, suggesting their common pathomechanisms with TAK. Serial measurement of these novel autoantibodies revealed their correlation with disease activity of TAK. In mechanistic studies, EPCR and SR-BI functioned as negative regulators of endothelial activation and chemokine production. EPCR further functioned in human T cells and ameliorated Th17 differentiation. Autoantibodies against EPCR and SR-BI blocked the functions of their targets, thereby promoting pro-inflammatory phenotype.

Conclusion: EPCR and SR-BI are preferentially expressed in the endothelium of vaso vasorum and upregulated in TAK tissue. Autoantibodies against EPCR or SR-BI are specific for TAK among autoimmune rheumatic conditions and detected in about 70 % of TAK, suggesting their usefulness for the diagnosis, subclassification, and monitoring of TAK. Autoantibodies inhibit the resolution of activated immune responses and thus would lead to the chronic vascular inflammation.
Objectives: To compare presenting and prognostic features of LV-GCA and C-GCA patients after an adequate vascular imaging evaluation at baseline.

Methods: Data from GCA patients followed-up at our institution were retrospectively collected. Only patients who underwent large-vessel imaging (PET, CTA, MRA) at disease onset or within one week after steroid introduction were included. Patients with evidence of LV involvement were classified as LV-GCA. Differences between LV-GCA and C-GCA patients regarding presenting features, treatment, and prognosis were evaluated. Non-parametric tests were used.

Results: In our cohort, we identified 161/280 patients who underwent vascular imaging study at baseline. Of these, 100 (62.1%) had signs of LV involvement. Table 1 compares demographic features, diagnostic delay, pre-existing comorbidities, and complementary treatment at baseline in LV and C-GCA patients. Table 2 compares disease features at onset in LV and C-GCA patients.

Conclusion: LV-GCA patients are younger and suffer of a greater diagnostic delay. Although a greater systemic inflammation seems to be a feature of LV-GCA patients, CVVAS is more frequent in C-GCA patients, who, conversely, have a greater incidence of ocular complications.

FR10192
MORBALITY IN IGA VASCULITIS: A LONGITUDINAL POPULATION-BASED STUDY

J Nossent1,2, M. Oggnjenovic1, W. Raymond3, H. Keen1,3, C. Inderjeeth1,2, D. Preen1.1 The University of Western Australia, Rheumatology Section, School of Medicine, Crawley, Australia; 2 Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia; 3Fiona Stanley Hospital, Rheumatology, Murdoch, Australia; 4The University of Western Australia, School of Population and Global Health, Crawley, Australia

Background: There is sparse population-level data on outcome in patients with Immunoglobulin-A vasculitis (IgAV) and none from Australia.

Objectives: We compared long-term mortality for paediatric and adult IgAV patients with age- and gender-matched controls.

Methods: Linked health data for pediatric (<20 years=473) and adult (20+ years, n=267) IgAV patients were obtained from state-wide hospital and deaths registries in Western Australia for the period 1980-2015. All-cause mortality rates (MR) (deaths/1000 person-years) were compared with controls using mortality rate ratios (MRR) and with the general population of Western Australia by standardised mortality rate ratios (SMRR) with Poisson derived 95% confidence intervals (CI). We used Kaplan-Meier survival estimates and multivariate Cox regression analysis to control for differences in medical treatment.

Results: In pediatric patients (mean age 7.2 years, 60 % male) MRR was 1.27 (CI: 0.34-4.08, p=0.68) and SMRR was 2.31 (CI: 0.72-5.7, p=0.47) (Table 1) with a 20-year survival rate (>99%) similar to controls. Despite higher rates of renal failure (1.5% vs 0.2%, p=0.002) deaths in pediatric IgAV patients were mainly from unrelated causes. In adult IgAV patients (mean age 55.8 years, 48% males) MMR was 2.06 (CI 1.70-2.50, p<0.01) and SMRR 6.16 (3.04-14.3, p<0.01) (Table 1) during a mean of 19.5 years follow-up with significantly reduced survival at five (72.7 vs. 89.7 %) and twenty years (45.2 vs. 85.6 %) (p<0.05). Renal disease (HR: 1.47, CI 1.04 - 2.06), the presence of any comorbidity (HR:1.30, CI 1.23 - 1.37) and male gender (HR:1.23; CI 1.04 - 1.47) were independent predictors of death. While cardiovascular events (34.2%) and malignancy (19.4%) were the most frequent causes of death, only death from infections (5.8 vs 1.8%, p=0.02) and renal disease (3.6 vs 1.8%, p=0.03) were more frequent in adult IgAV patients than controls.

Mortality data for childhood and adult-onset IgAV patients and controls. Figures indicate mean (±SD), numbers (%) or rate/1000 patient months (95% CI)

Conclusion: Compared to controls and general population, mortality risk was not increased in paediatric IgAV patients for at least 20 years following diagnosis despite a higher rate of end stage renal failure. However, in adult IgAV patients, all-cause mortality risk was six times higher than in the general population leading to significantly reduced five-year survival, especially for male patients with comorbidity including renal disease.

Author WDR received a PhD Scholarship in Memory of John Donald Stewart from the Arthritis Foundation of Western Australia.

Background:

Objectives: To evaluate the frequency of cranial and aortic arch involvement in GCA using color Doppler ultrasonography (CDS).

Methods: We performed CDS of cranial and aortic arch arteries in 248 incident, clinically diagnosed, GCA patients (64.9% females, median (IQR) age 75 (67-80) years) between October 2013 and September 2019, using a Philips IU22 with 5–175 MHz linear probe or Philips Epiq 7 with 5–18.5 MHz linear probe. Temporal, facial, occipital, carotid, vertebral, subclavian, and axillary arteries were examined bilaterally. A halo with positive compression sign was considered a positive finding. Additionally, the thickness of intima-media complex (IMT) of individual vessel was measured, and compared to the IMT of 97 consecutive suspected GCA cases (60.8% females median (IQR) age 74 (65-81) years), in whom GCA was excluded, that served as a control group.

Results: The CDS was positive in 244 (98.4%) patients in at least one of the examined arteries. Temporal arteries were most commonly affected, and were involved in 192 (77.4%) patients, followed by facial and occipital arteries, involved in 122 (49.2) and 72 (29.0%) patients, respectively. Extracranial large vessel involvement (LUV) was found in 87 (35.1%) patients (32 patients had isolated LUV, and 55 concomitant cranial and LUV artery involvement). Among the 161 patients without LUV, 12 (4.8%) had involvement of cranial arteries other than temporal arteries (we found facial and occipital artery involvement in 11 and 3 patients, respectively). Table 1 shows the frequency of individual vessel involvement in GCA, and the IMT of CDS inflamed and non-inflamed arteries in GCA, and in controls.

Legend: GCA giant cell arthritis; IMT thickness of intima-media complex; * means SD.

Conclusion: CDS of seven preselected cranial and aortic arch arteries provides a high diagnostic yield in GCA.

Disclosure of Interests: Rok Jese: None declared, Ziga Rotar Consultant of: Speaker and consulting fees from Abbvie, Amgen, Biogen, Eli Lilly, Medis, MSD, Novartis, Pfizer, Roche, Sanofi., Bettiol...
Predictive variables included the presence of a transmural TAB infiltrate, intimal hyperplasia and male sex.

**Results:** The TAB was consistent with GCA in 27 patients. The TAB revealed transmural inflammation in 18 patients and giant cells in 24 patients. Intimal hyperplasia was found in 20 patients with a positive TAB. Patients with a positive TAB showed higher halo counts and Halo Scores than patients with a negative TAB. Overall, patients with a positive TAB and intimal hyperplasia presented with the highest halo counts and Halo Scores (Figure). Among patients with a positive TAB, only intimal hyperplasia and male sex were predictive of higher halo counts and Halo Scores in the multiple linear regression analysis. Ocular ischaemia was present in 14% of patients with a positive TAB without intimal hyperplasia. However, 40% of patients with a positive TAB and intimal hyperplasia suffered from ocular ischaemia.

**Conclusion:** The ultrasonographic Halo Score is strongly influenced by the presence of intimal hyperplasia, a TAB feature that associates with cranial ischaemic complications in patients with GCA [2,3].

**FR0196 IN VOLUMEN OF THE PULMONARY ARTERIES IN PATIENTS WITH TAKAYASU ARTERITIS**

**Xianpeng Kong**
1. Zhongshan Hospital affiliated to Fudan University, Shanghai, China

**Background:** Takayasu arteritis (TA) is a chronic, granulomatous large- vessel vasculitis. It involves the aorta and its main branches predominantly, and leads to vascular thickness, stenosis and occlusion [1]. Besides the aorta and its branches, pulmonary arteries (PAs) are involved in TA. PAs have been reported to be involved in 6.9% to 80% of TA patients from different populations [2-3].

**Objectives:** We investigated the clinical characteristics, pulmonary parenchymal features and cardiac functions in TA patients with PA involvement by combining multiple imaging modalities (MRA, CTA, PET-CT, lung VQ scan, echocardiography and high-resolution computed tomography (HRCT)). Our aim was to elicit better understanding of TA patients with PA involvement to aid rational treatment for these patients and improve their prognosis.

**Methods:** We enrolled 216 patients with TA from a large prospective cohort. PAI was assessed in each patient based on data from magnetic resonance angiography/computed tomography angiography. Pulmonary hypertension, cardiac function, and pulmonary parenchymal abnormalities were evaluated further in patients with PAI based on echocardiography, New York Heart Association Functional Classification and pulmonary computed tomography, respectively. These abnormalities related to PAI were followed up to evaluate treatment effects.

**Results:** PAI was detected in 56/216 (25.93%) patients, which involved the pulmonary trunk, main PAs and small vessels in the lungs. Among patients with PAI, 28 (50%) patients were accompanied by pulmonary hypertension, which was graded as ‘severe’ in 9 (16.07%), ‘moderate’ in 10 (17.86%) and mild in 9 (16.07%). Forty (71.43%) patients had cardiac insufficiency (IV: 6, 10.71%; III: 20, 35.71%; II: 14, 25.00%). Furthermore, 21 (37.50%) patients presented with abnormal parenchymal features in the area corresponding to PAI (e.g., the mosaic sign, infarction, bronchiectasis). During follow-up, two patients died due to abrupt pulmonary thrombosis. In the remaining patients, the abnormalities mentioned above improved partially after routine treatment.

**Conclusion:** PA involvement is very common in TA patients. Physicians should be alerted to PA involvement even if obvious pulmonary symptoms are absent because they can cause PH, cardiac insufficiency as well as pulmonary parenchymal lesions, which will worsen the prognosis.

**References:**

**Figure 1. Imaging of PA lesions in TA patients:**
A: Dilation of the pulmonary trunk; B: thickness of the pulmonary trunk; C: stenosis of the right main PA; D: embolism of lower PAs on both sides; E: inflammation of the pulmonary trunk; F: absence of left PAs; G-I: pulmonary MRA (G), CTA (H) and VQ scan (I) of a patient with TA. MRA shows a fine right main PA and low perfusion in the right lung (G); CTA demonstrates a fine right main PA and few PAs branches in the right lung (H); lung VQ scan shows multiple arterial emboli in the right lung and obvious less blood supply to the right lung.

**Figure 2. Pulmonary lesions on HRCT:**
A: The mosaic sign in the left lung; B: Pulmonary infarction of the right middle lobe; C: Mild pleural effusion on the left side; D: Bronchiectasis in the right lung; E-F: Ground-glass opacity (E) in the right upper lobe of a TA patient with an embolism of the right upper pulmonary branches (F); G-I: Cavitation (G) and mass-like consolidation (H) in the patient with severe stenosis of right main pulmonary artery (I).
Background: Giant Cell Arteritis (GCA) is one of the most common systemic vasculitides. Temporal artery biopsy (TAB) has been the standard test to confirm the diagnosis of GCA. However, TAB has a lower sensitivity than clinical diagnosis and up to 44% of biopsy-negative patients are clinically diagnosed as having GCA. In a recent meta-analysis of the diagnostic performance of ultrasound (US) in GCA the sensitivity was 77% (1). The included studies were performed by expert groups in single centres. In the to date only multicentre study (TABUL) investigating the diagnostic accuracy of US compared to clinical diagnosis after 6 months the sensitivity was lower (54%) (2).

Objectives: To evaluate the diagnostic accuracy of vascular US compared to TAB in a multicentre study.

Methods: In three Danish centres patients suspected for GCA were included during a period of two years. At baseline, clinical and laboratory data were collected and vascular US of temporal, facial, common carotid and axillary artery were performed. The US examinations were performed with high frequency transducers (15-18 MHz) and followed by a TAB. All ultrasonographers had participated in the same standardized US educational program and were blinded to clinical and laboratory data. An external expert blinded to clinical and laboratory data evaluated all images and made the final US diagnosis. A positive sign for vasculitis in cranial arteries was defined as a hypoechoic intima-media-complex (IMC) thickness (halo sign) and a positive compression sign. A homogeneous IMC increased thickness in axillary artery of ≥1mm and in common carotid artery ≥1.5mm was defined as vasculitis. The consultant rheumatologist's diagnosis at 6 months after initial presentation was considered as the reference standard for the diagnosis of GCA.

Results: During the recruitment period, 112 patients were included, 59 females, mean (SD) age 72.4(7.9) years, among which 91(81.3%) fulfilled the ACR 1990 classification criteria for GCA, 92% of the patients reported a newly emerged localized headache, while 49 (43.8%) experienced polymyalgia rheumatic symptoms. TAB was positive in 46(41.1%) and inconclusive in 6 patients, who were excluded from the analysis. Mean (SD) duration of glucocorticoid therapy prior to US and TAB was 0.91(1.55) and 4.02(2.61) days, respectively. In 62 patients, the final diagnosis was GCA. In all patients with a positive TAB, the US of the temporal artery was also positive for GCA. Of 19 cases with positive US and negative TAB, 12 were clinically diagnosed with GCA of whom 6 had isolated large vessel involvement on US. Among 41 patients with both negative US and TAB, 4 were clinically diagnosed with GCA (Box 1). US had a sensitivity of 93% and specificity of 84% for the diagnosis of GCA, while the sensitivity for TAB was lower (74%) with a specificity of 100%. For the diagnosis of GCA, US had a PPV of 89.2% and a NPV of 90.2%, while for TAB the PPV was 100% and the NPV 73.3%.

Conclusion: US evaluation of the temporal, facial and selected supraaortic arteries performed by trained ultrasonographers can replace biopsy in the diagnosis of GCA.

Ocular morbidity in patients with PMR and GCA in the UK - a CPRD study

M. Yates1,2, A. Clark1, R. Watts3, A. Macgregor1, S. Mackie1 on behalf of Dr Max Yates is part of the TARGET (Treatment According to Response in Giant cell Arteritis) consortium, the UK Biobank Eye and Vision Consortium and an active member of two OMERACT (Outcome Measures in Rheumatology) Working Groups: PMR and Patient Outcomes in Longitudinal Observational Studies.

1University of East Anglia, Norwich Medical School, Norwich, United Kingdom; 2Ipswich Hospital, Rheumatology, Ipswich, United Kingdom; 3Chapel Allerton Hospital, Rheumatology, Leeds, United Kingdom

Background: Visual loss is the most serious consequences of a diagnosis of polymyalgia rheumatic (PMR) and giant cell arteritis (GCA). To date, information on the occurrence of eye disease in GCA has been based almost exclusively on small hospital-based patient series. Furthermore the lack of control group for these studies results in a lack of relative risk estimates for visual loss.

There are no accurate data on the prevalence and nature of eye complications among patients in the community. Patients with GCA may be exclusively managed in the primary care setting without referral for either temporal artery biopsy or ophthalmic department examination. Currently the incidence and prevalence of eye complications within this group are unknown.

Objectives: Examine the absolute rate and relative risk of ocular morbidity, in a longitudinal community setting, in patients with PMR and or GCA including visual loss, AOIN including optic atrophy, cataract and glaucoma identified from Read codes in the (Clinical Practice Research Datalink) CPRD dataset.

Methods: Construction of a disease cohort of incident diagnoses of PMR and GCA from patients in the CPRD matched to controls on age, sex (+/- 2 years) and practice location. Diagnosis were identified by CPRD researchers of those individuals between January 1997 to December 2015, with a minimum age at diagnosis of 50 years. Those with both a diagnosis of PMR and GCA were analysed in the GCA group. The outcomes of ocular morbidity included Read codes for severe visual impairment (multiple codes covered: blindness, severe visual impairment, registered partially sighted, issue of certificate of visual impairment, examination findings of 4/60 or worse), anterior ischaemic optic neuropathy (including codes of optic neuropathy and atrophy but not codes of glaucomatous atrophy), cataract, cataract extraction and glaucoma. Statically modelling with Cox proportional hazards was used to generate hazard ratios for ocular morbidity taking account of censorship through death and moving out of area.

Results: We identified 30,714 individuals with PMR (20,270 women; 66%) with a mean age at diagnosis of 72.9 year (sd 9.1) and 6,104 with GCA (4,309 women; 70.6%) with a mean age of 72.1 years (sd 9.4). Of those diagnosed with GCA 1,669 were also diagnosed with PMR. Using Read codes for severe visual impairment and blindness 5.9% of patients with GCA and 2.7% with PMR had this complication compared with 1.6% of the matched controls. The hazard ratio for the various ocular morbidities and by cases of PMR or GCA are shown in the table below:

<table>

</tbody>
</table>

Conclusion: These community-based national data on risk of ocular morbidity in PMR and GCA show for the first time the risk of various ocular morbidities are increased for both groups. In addition this are the first estimates of relative risk compared to an age and sex matched population. These data are crucial
for providing information to patients about their relative risk of ocular morbidity following a diagnosis of PMR or GCA.

**PRESENCE AND DISTRIBUTION OF VASCULITIS IN TEMPORAL, AXILLARY AND SUBCLAVIAN ARTERIES IN GIANT CELL ARTERITIS ASSESSED BY ULTRASONOGRAPHY AT ONSET OF DIAGNOSIS**

P. M. Andel1, S. Brådland2, V. Haraldstad1, H. Bitter1, A. Diamantopoulos2, G. Haugeberg1,3, 1Sørlandet Hospital Kristiansand, Kristiansand, Norway; 2Martina Hansens Hospital, Bærum, Norway; 3Norwegian University of Science and Technology, Trondheim, Norway

**Background:** In the last two decades ultrasound (US) has become a significant and valuable mode of diagnosing giant cell arteritis (GCA) in clinical practice (1). This is also reflected in the suggested expansion of the ACR 1990 criteria where imaging including US is equated with biopsy (2). Favorable sensitivity compared to biopsy has been shown and explained with the widespread uneven distribution of inflammation in cranial and extracranial arteries (3).

**Objectives:** To explore the prevalence and distribution of inflammatory involvement in temporal, axillary and subclavian arteries in patients diagnosed with GCA at an ordinary rheumatology clinic.

**Methods:** In this retrospective study we identified all patients diagnosed with GCA between 2006 and 2019. Since 2006 US has been used at the clinic to diagnose GCA. The vascular US examination was performed by two experienced ultrasonographers (HB, APD). The medical records were reviewed and data were collected using a predefined protocol including data collection for US at the time of diagnosis. Standard US procedure contained an assessment of both temporal arteries (superficial artery, frontal artery and parietal artery) in longitudinal and transversal planes and without color Doppler mode. A positive US test was defined in presence of hypoechoic vessel wall thickening (halo sign). The axillary and subclavian arteries where assessed in B-mode and intima media thickness (IMT) was measured. A positive test was defined if IMT > 1 mm.

**Results:** A total of 69 GCA patients (20 men and 49 women) with US performed at the time of diagnosis were identified. Among them, 67 (97.1%) patients met the suggested expansion ACR 1990 criteria. The mean age was 69.9 years. Detailed results for vasculitis distribution for the temporal artery with its branches and the axillary and subclavian arteries are shown in the table below. Positive US findings were recorded in 61 patients (88.4%). A total of 45 patients (65.2%) had a positive US test in the temporal artery and 41 patients (59.4%) in the extracranial arteries. Solely extracranial arteritis was observed in 18 patients (29.5%), 22 (36.0%) had exclusively temporal involvement. Involvement of both cranial and extracranial arteries was observed in 21 patients (34.4%). Only nine patients had positive findings at just one site. Five patients had isolated unilateral subclavian affection, and two patients had isolated unilateral frontal artery and superficial artery involvement each.

**Table. Positive US finding in 69 GCA patients**

**Conclusion:** Our data highlights the importance and value of a complete US of cranial and extracranial arteries diagnosing GCA in daily clinical care. Our data demonstrate the widespread nature of arterial affection in GCA and the fact that it is often more than one site that is affected. The spreading pattern was comparable to older studies in the respect of large vessel and multisite involvement.

**WHAT IS NOT NERVOUS SYSTEM INVOLVEMENT IN BEHÇET SYNDROME: A SURVEY OF PATIENTS WITH BEHÇET SYNDROME REFERRED TO NEUROLOGY**

E. Dincses1, E. B. Caliskan2, Z. E. Kaya2, U. Uygunoglu3, M. Tutuncu4, S. Saip5, A. Siva6, M. Melikoglu7, V. Hamuryudan7, G. Hatemi8, 1Istanbul University – Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Behçet’s Disease Research Center, Istanbul, Turkey; 2Istanbul University – Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, Turkey; 3Istanbul University – Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, Behçet’s Disease Research Center, Istanbul, Turkey

**Background:** Nervous system involvement of Behçet syndrome (neuroBS) is a serious, but infrequent manifestation of Behçet syndrome (BS). Although many BS patients present with signs and symptoms related to the nervous system, several of these are diagnosed with conditions other than neuroBS. The differential diagnosis may be difficult in such patients.

**Objectives:** To identify conditions mimicking neuroBS among patients with BS and to determine clinical, laboratory and imaging findings that may help the differential diagnosis.

**Methods:** We retrospectively screened the charts of 500 BS patients who were registered to our clinic between February 2012 and April 2015, to identify those who were referred to neurology at any time during their follow-up. We followed our BS patients in a multidisciplinary clinic and all patients with a sign or symptom related to the nervous system are seen by one of the neurologists of the clinic. The final diagnoses, as well as presenting signs and symptoms, laboratory and imaging results and results of any other diagnostic modalities were retrieved from patient charts.

**Results:** Among the 500 BS patients who were screened, 116 (23%) were referred to neurology. Neurological signs included headache (9), visual disturbances (5), cranial pain (4), memory loss (2), and other neurological symptoms (8), respectively. Only 52 patients were found with signs related to the nervous system, 46 (9.2%) had other diagnoses related to the nervous system, 46 (9.2%) were not diagnosed with a nervous system disorder and their symptoms disappeared and 11 (2.2%) were in inconclusive and lost to follow-up. Of the 29 patients with neuroBS, 20 had parenchymal involvement, 7 had cerebral venous sinus thrombosis, 1 had recurrent parenchymal involvement and cerebral venous sinus thrombosis and 1 had atypical neuroBS. Of the 30 BS patients who were diagnosed with another nervous system condition, 14 (2.8%) had primary headache syndromes including tension type headache (n=5) and migraine (n=9), 6 (12%) had psychiatric disorders including psychiatric disorder (n=1), depression (n=4) and somatization disorder (n=1), the remaining patients had other diagnoses which were entrapment neuropathy (n=2), epilepsy, glial tumor, multiple sclerosis, Meniere’s disease, optic neuritis, neuroretinitis, steroid myopathy and polynuropathy in one patient each. Presentation features such as cerebellar symptoms, motor symptoms, visual problems, altered consciousness, seizure, fever and facial palsy were more common among patients with neuroBS, whereas sensory symptoms and isolated headache were more common among BS patients with other nervous system conditions (Table).

**Table. Clinical characteristics of patients with neuroBS versus other diagnoses**

The differential diagnosis may be difficult in such patients.

**Objectives:** To identify conditions mimicking neuroBS among patients with BS and to determine clinical, laboratory and imaging findings that may help the differential diagnosis.

**Methods:** We retrospectively reviewed the medical records of patients with positive biopsy for GCA at our center from January 2000 through December 2018. Relapse was defined as the appearance of clinical symptoms in a previously asymptomatic patient requiring a dose increase or restart of GCS. Patients with no response to GCS were not included. Qualitative variables are shown with absolute value and percentage and quantitative variables with mean and standard deviation (SD). Kruskal Wallis, Fisher test and Mann-Whitney U test were used for bivariate analysis.

**Results:** 52 patients were found: 39 women (73.6%), with an average age at diagnosis of 776 years (SD ±3.4). At diagnosis, 28 presented visual symptoms (53.84%): oculomotor paralysis 5 (9.61%), amaurosis fugax 8 (15.38%), blindness 6 (11.54%), decreased visual acuity 8 (28.57%), and other visual symptoms 1 (1.92%). Eleven had monocular symptoms (38%) and 9 binocular (32%), in 10 patients this data was not collected. The symptoms were permanent in 11 (21.18%) despite GCS type. Type of visual impairment was: Anterior Ischemic Optic Neuropathy (AION) (12, 24.6%), impairment of cranial pairs (5, 78.6%), central retinal artery occlusion 1 (1.92%), cilioretinal artery occlusion (1, 1.92%), and Posterior Ischemic Optic Neuropathy (1, 1.92%).

**Conclusion:** Among the 500 BS patients who were screened, 116 (23%) were referred to neurology. Neurological signs included headache (9), visual disturbances (5), cranial pain (4), memory loss (2), and other neurological symptoms (8), respectively. Only 52 patients were found with signs related to the nervous system, 46 (9.2%) had other diagnoses related to the nervous system, 46 (9.2%) were not diagnosed with a nervous system disorder and their symptoms disappeared and 11 (2.2%) were in inconclusive and lost to follow-up. Of the 29 patients with neuroBS, 20 had parenchymal involvement, 7 had cerebral venous sinus thrombosis, 1 had recurrent parenchymal involvement and cerebral venous sinus thrombosis and 1 had atypical neuroBS. Of the 30 BS patients who were diagnosed with another nervous system condition, 14 (2.8%) had primary headache syndromes including tension type headache (n=5) and migraine (n=9), 6 (12%) had psychiatric disorders including psychiatric disorder (n=1), depression (n=4) and somatization disorder (n=1), the remaining patients had other diagnoses which were entrapment neuropathy (n=2), epilepsy, glial tumor, multiple sclerosis, Meniere’s disease, optic neuritis, neuroretinitis, steroid myopathy and polynuropathy in one patient each. Presentation features such as cerebellar symptoms, motor symptoms, visual problems, altered consciousness, seizure, fever and facial palsy were more common among patients with neuroBS, whereas sensory symptoms and isolated headache were more common among BS patients with other nervous system conditions (Table).

**Conclusion:** Nervous system conditions other than neuroBS are common in patients with BS who present with nervous system findings. Caution is required to avoid misdiagnosis of these patients as neuroBS.

Methods: Eighty consecutive patients with newly diagnosed PMR/GCA were studied. Diagnosis of PMR/GCA was confirmed by a 40-weeks follow up. A unilateral temporal artery biopsy (TAB) was performed at the time of diagnosis. All included patients underwent an 18F-FDG PET/CT before, or in case of GCA, within 3 days of initiation of high dose oral glucocorticoid (40-75mg). All cancer-suspicious 18F-FDG-PET/CT findings were assessed thoroughly and malignant diseases were confirmed by histology. Total PMR and GCA scores were defined as the sum of a 4-point visual grading scale in each articular/periarticular site as well as arterial segment.

Results: Of the 80 patients, 64 (83.1%) were diagnosed with pure PMR, 10 (13.0%) with concomitant GCA with PMR and 3 (3.9%) with pure GCA. Three patients were diagnosed with rheumatoid arthritis during follow up and excluded from the study. Five types of cancer in 4 (5.2%-95% CI:14.12.8%) patients were found. Two patients had breast cancer, one patient had adenocarcinoma of colon and one patient had squamous cell cancer of the lung. Besides, 4 (5.2%-95% CI:14.12.8%) patients had Monocyctic Gammapathy of Unknown Significance (MGUS). Age and C-reactive protein were significantly higher among those with solid cancers (p=0.049 and MGUS (p=0.017), respectfully (Table1).

Conclusion: The prevalence of cancers in this cohort was higher, compared to the 1-year prevalence of all cancer sites of 1.2% among age-, gender- and region-matched background population in 2016. Occult malignancies are important and relatively prevalent findings in newly diagnosed PMR/GCA patients.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.2238
**Methods:** This prospective study included large cohort of histologically proven adult IgAV cases diagnosed between January 2013 and December 2019 at our secondary/tertiary rheumatology centre. All patients underwent a detailed clinical evaluation and laboratory workup. Patients were then stratified based on baseline serum IgA level into two groups (elevated serum IgA vs. normal serum IgA), and clinical features were compared between the two groups. Next we used multivariable logistic regression analysis to determine factors predicting gastrointestinal (GI) or renal involvement in adult IgAV.

**Results:** During the 84-month observation period, we identified 227 incident adult IgAV cases (60.6% males, median (interquartile range) age 64 (47–76) years, 44 (19.4%) current smokers). One hundred and eleven (48.9%) patients had elevated serum IgA level at baseline, the rest had normal IgA level. None of the patients had subnormal serum IgA level. Skin involvement, constitutional symptoms, arthritis, GI tract and renal involvement developed in 227 (100%), 32 (14.1%), 30 (13.2%), 62 (27.3%), and 93 (41.0%) patients, respectively. Patients with elevated serum IgA level less frequently developed constitutional symptoms (p=0.036) and GI tract involvement (p=0.017), but had more common renal involvement (p<0.001), compared to those with normal serum IgA. Results of univariate analysis are shown in Table 1. In the multivariable logistic regression model, elevated serum IgA level persisted as a factor associated with lower risk of GI tract involvement (OR 0.47 (95% CI 0.23–0.95), and a higher risk of renal involvement (OR 2.71 (95% CI 1.48–4.96). The other factors associated with risk of GI and renal involvement are presented in Table 2.

**Conclusion:** Serum IgA level might be a useful biomarker in IgAV vasculitis, identifying patients at risk for visceral (GI and renal) involvement.

Objectives: The primary objective of this study was to determine the incidence of cancer cases among systemic vasculitis cases followed in a university hospital clinic. Secondary objective was to analyze the relationship between the vasculitis and cancer subtypes and their demographic and clinical features.

Methods: In this study, adult vasculitis patients followed at Hacettepe University Cancer Research, Diagnosis and Treatment Center (HUVAM) between October 2014 and May 2019 were reviewed for neoplastic development and cancer features. Standardized cancer incidence rate was calculated using the online International Agency for Research on Cancer GLOBOCAN database and the population data for Turkey published by Turkish Statistical Institute.

Results: Among 684 patients with a mean age of 46.4±16.9 years and a median follow up duration of 29 months, 38 patients (5.6%) developed cancer. Colon (5 cases, 13%) and lung (4 cases, 11%) were the most commonly seen types of cancer. In this study, adult vasculitis patients followed at Hacettepe University Cancer Research, Diagnosis and Treatment Center (HUVAM) between October 2014 and May 2019 were reviewed for neoplastic development and cancer features. Standardized cancer incidence rate was calculated using the online International Agency for Research on Cancer GLOBOCAN database and the population data for Turkey published by Turkish Statistical Institute.

Compared to the general population in Turkey, cancer incidence was four times higher (SIR: 2.9–5.5, CI: 95%: < 0.001). Patients whom both the vasculitis and cancer diagnosis was within the same year, had a higher ratio of male patients (87%, P<0.001) and had a lower rate of survival (median survival: 54 months, 95% CI: <1 month–125.9 months, P=0.005). There was no association between cytophosphamide (CYC) use and cancer development, with a cumulative cyc dose among cancer patients (median: 2g).

Conclusion: The increase in cancer incidence may indeed be due to chronic inflammation; however, VDI and BVAS scores during the last visit (median: <0.1) indicate that non-inflammatory factor may play a role as the inflammatory damage caused by vasculitis in these patients seems to be low. Similar to other recent cohorts in the literature, there was no association between CYC usage and cancer development.

In conclusion, compared to the general population, cancer incidence is significantly higher in patients with vasculitis and the timing of diagnosis between vasculitis and cancer may be associated with different clinical features.

**Correlations between Neutrophil-to-Lymphocyte Ratio and Th17/Treg Immune Balance in Patients with Behcet's Disease**

Y. Liu1, R. Su2, X. Zheng2, X. Li2, C. Wang2. 1The Second Hospital of Shaxi Medical University, Department of Rheumatology, Taiyuan, China; 2The Second Hospital of Shaxi Medical University, Department of Rheumatology, Taiyuan, China

Background: Behcet’s disease (BD) is a systemic vasculitis where mucocutaneous manifestations are well known to show neutrophilic dermatosis denoted by significant neutrophil infiltration. The neutrophil-to-lymphocyte ratio has been proved as an inflammatory biomarkers in BD. At present, the Th17/Treg immune imbalance may be the involved factors in the pathway of BD. However, the correlations between the number of neutrophil, the number of lymphocyte, the neutrophil-to-lymphocyte ratio and Th17/Treg immune imbalance remain unclear.

Objectives: The aim of this study was to examine correlations between the number of neutrophil, the number of lymphocyte, the neutrophil-to-lymphocyte ratio and Th17/Treg immune balance in patients with BD.

Methods: The study included 59 BD patients and 66 healthy controls. The absolute counts of lymphocyte subsets and CD4+ T cell subsets were detected by flow cytometry for all participants. The neutrophil and lymphocyte were measured by routine blood test for all BD patients. To calculate the NLR, the ratio of absolute neutrophil count to absolute lymphocyte count was obtained. The Mann–Whitney U test was used to compare continuous measures. Correlations between the number of neutrophil, the number of lymphocyte, the NLR and Th17/Treg immune balance were assessed by Spearman’s rank correlation tests.

Results: Compared to healthy controls, the absolute counts of NK cells were decreased (P=0.047), the absolute counts of B cells were increased (P=0.021), the absolute counts of CD4+ T cells were also increased (P=0.035), the absolute counts of Th1 and Th17 cells were significantly increased (P<0.005), the absolute counts of Th2 and Treg cells were decreased (P<0.05), the ratio of Th1/Th2 and Th17/Treg were increased (P<0.001) in BD group. The numbers of neutrophil were positively correlated with Th17/Treg (r=0.344, P=0.008); The NLR was positively correlated with Th17/Treg. Further studies are required to evaluate these preliminary findings in different patient populations and also examine the possible molecular mechanisms behind our observations.

EFFECTS OF ADD-ON METHOTREXATE IN POLYMYALGIA RHAMATICA PATIENTS: A RETROSPECTIVE STUDY

D. Marsman1, T. Bolhuis2, N. Den Broeder3, F. Van den Hoogen4, A. Den Broeder5, A. Van der Maas6. 1Sint Maartenskliniek, Nijmegen, Netherlands

Background: Guidelines on polymyalgia rheumatica (PMR) recommend early introduction of methotrexate (MTX), especially in patients with worse prognosis such as flare or glucocorticoid (GC)-related adverse events (AE). 1 GC-AE are unable to discontinue GCs, emphasizing the need for GC-sparing agents. 3

Objectives: To assess the efficacy of add-on MTX in preventing subsequent flares and GC-sparing in PMR patients.

Methods: In a retrospective cohort of newly diagnosed PMR patients visiting our hospital from April 2008 - January 2018, patients starting methotrexate (index event) were compared to first-time flaring PMR patients in whom MTX was not started (control group). Concomitant inflammatory rheumatic diseases were excluded. Data on patient, disease and treatment characteristics were compared.

Main outcomes were difference in number of subsequent flares per year between groups (multivariable Poisson regression) and mean GC-use (total GC-dose/total weeks until index event).

During follow-up

Flares, n (%) 21 (50) 100 (45) 0.616 4.5 (-2.0; 11.9)
Weeks to first flare (IQR) 36 (24-51) 39 (22-66) 0.257
Mean GC-dose, mg (IQR) 6.2 (4.6-9.7) 4.7 (2.9-6.9) 0.004

Objectives: Identification and characterization of patients with orbital pseudotumor among Polish patients based on the national vasculitis registry, POLUVAS.

Methods: Clinical presentation and management of all GPA patients fulfilling ACR criteria or Chapel Hill Consensus Conference definition included to the Polish registry POLUVAS who developed orbital masses in the course of GPA were seen between MTX treated patients and controls, although within MTX treated patients, flare rates were lower after MTX start. Confounding by indication may explain the lack of difference in the outcomes between groups. The optimal timing and dosage of MTX in PMR remains unclear, justifying a clinical trial.

References:
Results: Ocular involvement was found in 114 (27%) of 417 GPA patients registered in POLVAS, 34 (8%) developed orbital masses. Mean patients’ age was 47.8 (range from 19-75 yrs.), 23 (67%) were women. Forty four per cent of the patients developed tumor at the beginning of the disease, 56% during relapse. Patients’ characteristics on diagnosis of orbital mass: 24 CANCA, 2 PANC, and 8 ANCA negative, 9% active smokers and 31% past smokers, 29% had localized disease, 21% early systemic and 50% systemic with organ involvement, 29% had other type of ophthalmological involvement before pseudotumor occurred, 86% had active panarial sinus involvement, 41% lungs, 15% CNS, 15% skin and 48% eye involvement. In our cohort, thirty seven per cent of patients had positive nasal swabs cultures, 50% of which were positive for Staphylococcus aureus. In 65%, tumor occurred during steroid therapy (46% had prednisone more than 5mg/d) and 45% on immunosuppressive treatment (19% with treated with AZA, 16% MTX, 6.5% MMF and 3.5% CYC). Due to orbital mass 86.5% were treated with CYC and 13.5% with RTX. Twenty one per cent had complete remission of the pseudotumor, 76% partial remission and in 3% patients there was no response to the treatment; 43% developed visual impairment, 20% suffered from blindness.

Conclusion: Orbital inflammatory mass was not common manifestation of GPA among our patients. The mass developed at the beginning or in the course of the disease, even during immunosuppressive treatment. Orbital masses have been resistant to therapeutic interventions and were accompanied by high risk of visual impairment.

**Background:** Persistent low-grade vascular inflammation in giant cell arteritis (GCA) with large vessel involvement (LVV) treated patients could represent the expression of persistent subclinical disease activity or post-inflammatory vas-
cular remodelling. Whether these findings have any impact on future vascular com-
mon disease is still an unmet need.

**Objectives:** To evaluate the frequency and evolution of FDG-PET low-grade vas-
cular inflammation in remitted LVV-GCA patients.

**Methods:** We included all consecutive patients classified as GCA with LVV involve-
ment, with a minimum disease duration of 12 months and clinically remitted, who underwent to at least one PET/MR scan between January 2015 and January 2020. For each scan vessel's metabolic activity was assessed using the Meller's grading

Low-grade vascular inflammation was defined as Meller 1 and 2 (inferior or equal to liver), high metabolic activity as Meller 3 (liver or superior to liver).

**Results:** In total 88 PET scans were performed in 54 LVV-GCA patients, pre-
dominantly female (77.8%), aged 68[78] years, with a regular BMI (23.9[2.8]) and a low-grade metabolic activity in 15% of the cases, while complete remission in 15% and high metabolic activity in 25%. Comparing patients with low-grade vascular inflammation to those with complete remission (Meller 0), they had lower disease duration (28[25.9] vs 73[68] months, but without significance) and they were treated with higher daily prednisone dosage (5[3.8] vs 0[2.2], p=0.042). No significant differences were noted in age, acute phase reactants and type of treatment. Moreover, when compared to those with high metabolic activity (Meller 3), the latter had only significantly higher CRP levels (8.3[13.8] vs 4.1[3.9], p=0.03) and lower disease duration (19[20.6] vs 28[25.9] months, but without significance). While no signif-
ificant differences were noted in age and type of treatment (both glucocorti
coids and immunosuppressants). Among all patients with low-grade vascular inflammation, 81% of them under-
gave to steroids or immunosuppressants tapering due to clinical remission. At the subsequent PET examination, a worsening of metabolic activity (Meller 3) was found in 4/20 patients, with 1 clinical flare. While in 14/20 patients the sub-
sequent PET revealed a persistent metabolic activity. Only in 2/20 there was a complete metabolic remission. Change or increase of the treatment regimen led to an improvement (Meller 0 or 1) in all the cases. Low-grade metabolic activity was associated with a significant increased risk of worsening/failure at the subse-
quent PET examination (RR 5.29[1.87-16.11], p=0.002).

**Conclusion:** Low-grade vascular inflammation at PET examination is a common feature in remitted patients. It is associated with older age, lower disease duration and clinical remission. Treatment tapering is associated with an increased risk of worsening/failure. Further research is urgently needed to address this issue.

Background: Tocilizumab (TCZ) has shown efficacy in large vessel vasculitis (LVV) [1-2]. Early therapy is needed to prevent severe complications.

Objectives: To assess the correlation of the extent of baseline FDG vascular uptake in PET/CT scan with clinical response to TCZ in patients with LVV.

Methods: Single center study of patients with LVV treated with TCZ who were divided into 2 groups depending on the extent of vascular uptake in baseline PET/CT scan: a) ≤2 affected areas b) ≥3 affected areas. Vascular uptake was qualitatively assessed by two experienced nuclear medicine physicians in five areas (supraaortic trunks, thoracic aorta, abdominal aorta, iliac and femorotibial arteries).

Results: 30 patients (24 w/ 6 m); mean age 65.3±10.6 yrs. In baseline PET/CT, vascular uptake was observed in 1 or 2 areas (n=13) and in ≥3 areas (n=17). There was a trend to higher ESR/CRP and shorter evolution of clinical symptoms before TCZ onset in patients with ≥3 affected areas (TABLE 1).

Conclusion: TCZ therapy was effective in patients with LVV regardless the extent of FDG vascular uptake in baseline PET/CT scan. However, a trend to a slower clinical response was observed in patients with ≥3 affected areas.

FR01216 STEROID Sparing EFFECT, LOWER INCIDENCE OF DISEASE RELAPSE AND DIABETES IN GIANT CELL ARTERITIS TREATED WITH IMMUNOSUPPRESSORS AB INITIO OR VERY EARLY: A MULTICENTER RETROSPECTIVE CASE-CONTROL STUDY

L. Quattrocchi, M. Isola, D. Bruno, E. Treppo, L. Gigante, F. Angelotti, R. Capecchi, G. Vitiello, E. Cavallaro, A. Taverni, S. L. Bosello, D. Cammelli, S. De Vita, E. Grebensi, D. Department of Medical Area, Rheumatology Clinic, Udine Academic Hospital “Santa Maria della Misericordia”; Udine, Italy, Udine, Italy, Udine, Italy, 2Department of Medicine, Institute of Statistics, University of Udine, Udine, Italy, Udine, Italy, 3Rheumatology Unit, Catholic University of the Sacred Heart, Rome, Italy, Rome, Italy, 4Department of Internal Medicine, Clinic of Immunology, Pisa, Italy, Pisa, Italy, 5University of Florence, Florence, Italy, 6Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli-IRCCS, Rome, Italy, Rome, Italy

Background: Glucocorticoids (GC) are associated with serious side effects in giant cell arteritis (GCA). Immunosuppressive therapies (IT) gave conflicting results in GCA, regarding GC sparing effect. Recently, tocilizumab by blocking IL-6, has been licensed as first biologic treatment for GCA, being clinically effective and saving GC [1].

Objectives: To evaluate the usefulness of IT for GCA in: 1) minimizing the rate of GC-induced adverse events (AEs) and 2) reducing the risk of relapse.

Methods: A multicenter retrospective case-control study included 165 GCA was performed. The first group of patients (GCA-IT) included 114 patients who were treated with at least one IT given ab initio or within 3 months from the start of GC. The control group included 51 GCA who received only GC or an IT later than 3 months (GCA-steroid). The primary endpoints were the rate of GC-related side effects: infections, hospitalized infections, new onset systemic arterial hypertension, GC-induced diabetes and osteoporotic fractures.

Results: Methotrexate up to 20 mg/week (138 patients), followed by cyclophosphamide (48 patients) and tocilizumab (27 patients) were the most frequently used IT. No difference was observed as concerns the follow-up time between the two groups [48.5 (IQR 26-72) vs 40 (IQR 24-69), p=0.3, rank-sum test]. The two groups were similar as concerns sex (p=0.13), while the first group (69±8 yrs) was slightly younger than the second one (72±7 yrs) (p=0.005). Comorbidity was similar between groups. Patients in the GCA-IT group showed a significant lower incidence of GC-induced diabetes (8/114, 7% vs 12/51, 23.5%; p=0.003, chi-square test), while no differences were documented for rate of infections (p=0.64), including hospitalized infections (p=0.44), new onset systemic arterial hypertension (p=0.68), or osteoporotic fractures (p=0.32). Forty-four patients in the GCA-IT group (36.8%), while 34 patients in the GCA-steroid group (66.7%), experienced at least one relapse (p=0.001, chi square test). There was no difference in terms of time to first relapse between the two groups (p=0.53, log-rank test). GCA-IT group was exposed to lower dose of GC at first (p=0.0001,

sensitivity and specificity of 2019 DCVAS DRAFT CLASSIFICATION CRITERIA FOR GIANT CELLS ARTERITIS AND TAKAYASU ARTERITIS IN A MONOCENTRIC COHORT OF PATIENTS WITH CLINICAL DIAGNOSIS OF LARGE VESSEL VASCULITIS

E. Begea1, A. Tincani1, F. Franceschini1, P. Toniati1. 1Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy

background: Recently, a new set of classification criteria for Giant Cells Arteritis (GCA) and Takayasu Arteritis (TA) has been developed by the DCVAS project and presented as draft criteria at the 19th International Vasculitis and ANCA Workshop held in Philadelphia in 2019. The purpose of the present study is to analyze the performance of the 2019 DCVAS Draft Classification Criteria in differentiating GCA and TA in a cohort of patients with Large Vessel Vasculitis (LVV), comparing their sensitivity and specificity to 1990 ACR Classification Criteria.

methods: 2019 DCVAS Draft Criteria and 1990 ACR Criteria were retrospectively applied to a cohort of 130 consecutive patients with Large Vessel Vasculitis. In all patients the diagnosis of vasculitis was histologically and/or radiologically confirmed.

results: One-hundred patients had a clinical diagnosis of GCA, 25 patients of TA and 5 patients of other form of LVV, different from GCA and TA (idiopathic isolated aortitis n:2, aortitis with retroperitoneal fibrosis n:2, isolated pulmonary artery n:1). Among the 100 patients clinically diagnosed as GCA (F:M: 68/32, age: 74 (60-83)) only 82 fulfilled the 1990 ACR Criteria for GCA, while all of them fulfilled the 2019 DCVAS Draft Criteria for GCA.

prevalence, burden of disease and healthcare utilization among patients with eosinophilic granulomatosis with polyangiitis (egpa) in japan 2005-2017

K. E. Sada1, Y. Kojo2, J. Fairburn-Beech3, K. Sato2, E. Hayashi1, S. Akiyama2, M. Van-Dyke4. 1Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Okayama, Japan; 2GSK, Tokyo, Japan; 3GSK, London, United Kingdom; 4GSK, Collegeville, PA, United States of America

background: EGPA is a rare vasculitis condition with very limited data available in the current literature and may not be known to healthcare providers. EGPA is a polymorphonuclear granulomatous disease with involvement of the skin, lungs, and/or other organs. The disease can be classified as limited (M0) or systemic (M1) disease. The burden of disease includes cost of care, treatment, and complications. EGPA is a uncommon disease with no specific treatment. The median age at diagnosis is 45 years old. EGPA may affect patients of both sexes. The prevalence of EGPA is not well known due to lack of reporting in the literature. EGPA is considered a rare disease with no specific prevalence estimated. In this study, we aim to estimate the prevalence of EGPA in Japan using a large administrative claims database, and to estimate the burden of disease and healthcare utilization among EGPA patients.

objectives: The objectives of this study are to estimate the prevalence of EGPA in Japan using a large administrative claims database, and to estimate the burden of disease and healthcare utilization among EGPA patients.

methods: We performed a retrospective descriptive cohort study using a large administrative claims database to estimate the prevalence, burden of disease and healthcare utilization among EGPA patients. The database included all patients with a diagnosis of EGPA between 2000 and 2017. The prevalence of EGPA was estimated using two methods: a) patients with at least one ICD-10 code for EGPA (M30.1), b) patients with at least two ICD-10 codes for EGPA (M30.1) during the year in which the diagnosis was first recorded. The prevalence was estimated using the number of patients per 1,000,000 population. The burden of disease was estimated using the number of healthcare visits and hospitalizations per patient per year. The healthcare utilization was estimated using the number of healthcare visits and hospitalizations per patient per year. The prevalence of EGPA in Japan was estimated to be 0.02 per 1,000,000 population. The burden of disease and healthcare utilization among EGPA patients was estimated to be low. The study showed that the prevalence and burden of disease and healthcare utilization among EGPA patients were low in Japan. The study showed that the prevalence and burden of disease and healthcare utilization among EGPA patients were low in Japan. The study showed that the prevalence and burden of disease and healthcare utilization among EGPA patients were low in Japan.

results: The total number of newly identified patients in 2006-2016 was 45 persons and the mean (SD) age at diagnosis was 42.3 years (SD 14.7 years). The prevalence (per 1,000,000 patients) of EGPA with case definition a) in Japan in 2017 was estimated to be 38.0. The stratified prevalence (per 1,000,000 patients) age was: 2.3 in the group aged <18 years, 34.0 in those aged 18-50 years, and 91.1 in those aged ≥60 years, respectively. The prevalence in females (50.0) was approximately 1.7-fold higher than that in males (28.7). The prevalence, including stratified results, with definition b) was similar to that with definition a). In the newly identified patients, 60% of patients had at least one hospitalization and 55.6% had inpatient care in the year after the first observed EGPA code during the study period. Following index date, new patients were treated: 77.8% with OCS, 11.1% with prednisone, 8.9% with intravenous immunoglobulin, 6.7% with Cyclophosphamide, 4.4% with Methotrexate, and 2.2% with Rituximab (non mutually exclusive). The mean (SD) maximum recorded daily dose of OCS in the 12 months follow up period was 53.5 (39.9) mg in new patients. The average dose of OCS in new patients was 39.1 (29.0) and 9.8 mg (4.8), respectively. Among those with at least a 14-day supply of OCS, 73.1% could be classified as adherent (≥80%) based on their 1-year proportion of days covered. 6.7% of EGPA patients experienced a potentially worsening with an increase of ≥10 mg daily OCS dose prescription following a previous prescription of <10 mg.
