Annual European Congress of Rheumatology

EULAR 2020
3rd June 2020

Abstracts
Annals of the Rheumatic Diseases publishes original work on all aspects of rheumatology and disorders of connective tissue. Laboratory and clinical studies are equally welcome

Editorial Board
Daniel Aletaha (Austria)
Johan Askling (Sweden)
Sang-Choel Bae (Korea)
Ksenofon Baraliakos (Germany)
Anne Barton (UK)
Maarten Boers (The Netherlands)
Maxine Brohan (France)
Matthew Brown (Australia)
Maya Buch (UK)
Loreto Carmona (Spain)
Carlo Chizzolli (Switzerland)
Bernard Combe (France)
Philip Conaghan (UK)
Maurizio Cutofo (Italy)
Nicola Dalbeth (Australia)
Christian Dejaco (Austria)
Oliver Distler (Switzerland)
Thomas Dörner (Germany)
Dirk Elewault (Belgium)
Axel Finck (Switzerland)
Rebecca Fischer-Betz (Germany)
Roy Fleischmann (USA)
Mary Goldring (USA)
Laure Gossec (France)
Walter Grassi (Italy)
Ahmet Gül (Turkey)
Frederic Houssiau (Belgium)
Tom Huizinga (The Netherlands)
Arthur Kavanaugh (USA)
Margreet Kloppeburg (The Netherlands)
Robert Landewé (The Netherlands)
Zhan-quo Li (China)

Advisory Committee
Ferry Brouwer (The Netherlands)
Marco Matucci Cerinic (Italy)
Michael Doherty (UK)
Maxime Dougados (France)
Paul Emery (UK)
Daniel Forst (USA)
Steffen Gay (Switzerland)
Marc Hochberg (USA)
Joachim Kalden (Germany)
Edward Keystone (Canada)
Lars Klareskog (Sweden)
Tore Kvien (Norway)
Zhan-quo Li (China)
Peter Lipsky (USA)
Sir Ravinder Maini (UK)
Emilio Martin-Mola (Spain)
Haralampos Moutsopoulos (Greece)
Karel Pavelka (Czech Republic)
Yehuda Shoenfeld (Israel)
Leo van de Putte (The Netherlands)
Frank Wollheim (Sweden)
Anthony Woolf (UK)

ARD is published monthly; subscribers receive all supplements
ISSN 0003-4687 (print); 1468-2060 (online)

OP0006  Metabolic pathways during the regulation of inflammation and immunity .......... 5
OP0008–OP0009  How to build and choose an appropriate outcome measure .................. 6
OP0010–OP0017  Opening Plenary abstract session ......................................................... 7
OP0018–OP0025  Biological DMARDs in RA I ............................................................. 13
OP0026–OP0033  Vasculitis ......................................................................................... 19
OP0034–OP0040  Lung diseases and other comorbidities in RA ..................................... 23
OP0042–OP0049  Pathogenic insights transforming the treatment of Sjögren’s and SLE 2020 and beyond .................................................................................. 28
OP0050–OP0057  Psoriatic arthritis and its management: it’s more than just synovitis ......... 33
OP0059–OP0066  Artificial intelligence and machine learning in imaging of rheumatology: Are we ready? ................................................................. 39
OP0067–OP0074  Epidemiology ..................................................................................... 45
OP0075–OP0082  What is new in axial spondyloarthritis: clinical and imaging outcomes? .................................................................................. 50
OP0083–OP0090  Pain pathology, progression and pharmacotherapy .............................. 55
OP0091–OP0098  SLE, Sjögren’s and APS clinical aspects .............................................. 60
OP0099–OP0100  New technologies in basic research ..................................................... 65
OP0102  Immunodeficiency and autoimmune disease .................................................... 66
OP0103–OP0110  Spondyloarthritis - treatment ............................................................... 66
OP0111–OP0118  Rheumatoid arthritis - prognosis, predictors and outcome I ................ 73
OP0119–OP0126  Cardiovascular disease and malignancies in RA ................................. 79
OP0127–OP0134  Immunity in rheumatic disease .......................................................... 83
OP0135–OP0142  Connective tissue diseases - genomics, proteomics and pathogenesis ..... 87
OP0143–OP0150  Vasculitis ........................................................................................... 91
OP0159  Innovative care ............................................................................................... 100
OP0160–OP0167  Advances in treating SLE and lupus nephritis .................................... 100
OP0168–OP0175  Crystals and bones: A selection of best abstracts .................................... 106
OP0176–OP0183  Diagnostics and imaging procedures ................................................. 109
OP0184–OP0191  Osteoarthritis: clinical ......................................................................... 114
OP0193–OP0194  Dendritic cells as therapeutics ............................................................ 120
OP0195  Creating in vitro patients - how to best model disease ...................................... 121
OP0197  Making rational the therapeutic approach to Still’s disease in children and adults ................................................................. 123
OP0200  Multiple issues in inherited connective tissues - more than ‘just’ hypermobility ...... 125
OP0201  Update on neuropsychiatric SLE ..................................................................... 126
OP0202  Aging, senescence and osteoarthritis ................................................................. 126
OP0205–OP0206  Inflammation and crystal diseases – what’s hot? .................................. 127
OP0207  Cartilage - heal thyself! ................................................................................... 128
OP0208–OP0215  Biological DMARDs in RA II ............................................................... 129
OP0216–OP0222  Rheumatoid arthritis - prognosis, predictors and outcome II ................ 134
OP0223–OP0230  Update on new treatment options for psoriatic arthritis ...................... 139
OP0231–OP0238  Rheumatoid arthritis - non biologic treatment and small molecules .......... 146
OP0239–OP0246  Preclinical models of arthritis and bone disease .................................. 151
OP0247–OP0254  Progress in scleroderma and myositis ............................................... 155
OP0270–OP0277  Other orphan diseases ......................................................................... 168
OP0278–OP0285  Public health, health services, and health economics in RMDs ............ 173
OP0286–OP0293  Novel diagnostic and therapeutic approaches in paediatric rheumatic diseases .................................................................................. 178
OP0294–OP0301  Osteoporosis ...................................................................................... 183
OP0302  The new art of phenotyping and treating Sjögren’s syndrome ......................... 187
OP0303  Meniscus : an innocent bystander in osteoarthritis? ........................................ 188
OP0304–OP0305  SpA: Innovative techniques in spondyloarthritis research – Is there light at the end of the tunnel for our patients? .................................................. 188
OP0306–OP0307  Newly identified cell subsets driving disease pathogenesis ........................................ 189
OP0313  Fractures, more than bone alone: the role of sarcopenia ..................................................... 193
OP0314–OP0315  Clinical symposium axSpA: Treat-to-target in axSpA: myth or reality? ....................... 194
OP0316  New perspectives on therapeutic immune tolerance ........................................................... 195
OP0317–OP0318  Pathological calcification in rheumatic diseases ......................................................... 195
OP0323–OP0324  The cost-opportunity of screening: osteoporosis in the general population ............ 199
OP0325–OP0326  EFIS-EULAR - origin of autoantibodies ................................................................. 200
OP0327  Artificial intelligence and osteoarthritis .............................................................................. 201
OP0328  Autoimmune diseases by abnormal T cell function ............................................................ 201
OP0332  Quantitative imaging ......................................................................................................... 204
OP0334  Origin and role of myeloid cells during homeostasis and inflammation ............................... 205
OP0337–OP0338  New technologies in translational rheumatology ................................................. 206
OP0339  Science communication skills for young rheumatologists .................................................. 208

Late breaking abstracts

LB0001  Opening Plenary abstract session ...................................................................................... 12
LB0002  New technologies in translational rheumatology .............................................................. 208

COVID-19 abstracts

CO0001, CO0002, CO0005  COVID-19 Pathophysiology leading to the drugs to be used ...................... 209
CO0003, CO0004  Talk about the consequences of COVID-19 on RMDs ........................................ 210
CO0006  Treating RMD patients in the context of the COVID-19 pandemic - between overburdening and lockdown ............................................................................................................ 212

Poster Presentations

Thursday, 04 June 2020

Guided Poster Tours

THU0001–THU0008  T01 - Genetics, genomics and epigenetics ......................................................... 213
THU0030–THU0039  T02 - Adaptive immunity in rheumatic diseases ................................................. 228
THU0063–THU0070  T03 - RA: Understanding disease ........................................................................ 244
THU0121–THU0130  T04 - Cardiovascular diseases and other comorbidities in RA ....................... 275
THU0220–THU0228  T05 - New perspectives: mechanisms driving systemic lupus, Sjögren's and APS ................................................................................................................................. 336
THU0244–THU0254  T06 - Systemic lupus: clinical manifestations from diagnosis to patients reported outcomes ..................................................................................................................... 349
THU0327–THU0336  T07 - Progress in scleroderma and myositis, poster tour .................................... 393
THU0370–THU0379  T08 - Spondyloarthritis - treatment ...................................................................... 417
THU0404–THU0413  T09 - Gout: from aetiology to management in 10 posters ................................. 439
THU0476–THU0484  T10 - From structure to symptoms ..................................................................... 475
THU0495–THU0505  T11 - Paediatric rheumatology ........................................................................... 483
THU0545–THU0555  T12 - Health economics ..................................................................................... 512

Posters

THU0001–THU0029  Genomics, genetic basis of disease and functional genomics .......................... 213
THU0030–THU0054  Adaptive immunity (T cells and B cells) in rheumatic diseases .................... 228
THU0055–THU0062  OA, aetiology, pathology and animal models .................................................... 239
THU0063–THU0085  Rheumatoid arthritis - aetiology, pathogenesis and animal models ............... 244
THU0086–THU0102  Rheumatoid arthritis - prognosis, predictors and outcome ............................ 255
THU0121–THU0156  Rheumatoid arthritis - comorbidity and clinical aspects ................................. 275
THU0157–THU0187  Rheumatoid arthritis - biological DMARDs ..................................................... 293
THU0188–THU0219  Rheumatoid arthritis - non biologic treatment and small molecules .................. 312

tsDMARD therapy of rheumatoid arthritis

**Baricitinib, Tofacitinib, Upadacitinib, Filgotinib, and Cytokine Signaling in Human Leukocyte Subpopulations: An Updated Ex-Vivo Comparison**

1University of Glasgow, Glasgow, United Kingdom; 2Eli Lilly and Company, Indianapolis, United States of America; 3Primity Bio Inc., Fremont, United States of America; 4Eli Lilly and Company, Dunderrow, Kinsale, County Cork, Ireland; 5University of Oxford, Oxford, United Kingdom

**Background:** Several JAKi are now used for the treatment of RA; approved doses include baricitinib (bari) 2- and/or 4-mg QD, tofacitinib (tofa) 5-mg BID, upadacitinib (upa) 15-mg QD. The JAK selectivity these agents is proposed to vary across the class.

**Objectives:** In vitro cellular pharmacology of bari to tofa, upa, and filgotinib (filgo) were compared.

**Methods:** PBMCs from 6 healthy donors were incubated with the JAKis over a 7- to 8-point concentration range. Following cytokine stimulation, levels of pSTAT were measured and IC50 calculated in gated leukocyte subpopulations. Therapeutic dose relevance was assessed using calculated mean concentration-time (CT) profiles over 24 hours for bari 2- and 4-mg QD; tofa 5- and 10-mg BID; upa 15- and 30-mg QD; filgo 100- and 200-mg QD. Average daily % inhibition of pSTAT (%SI) was calculated for each JAKi, cytokine, and cell type; filgo %SI integrated parent drug + metabolite.

**Results:** The cytokines did not signal in all cell types (Figure 1). When signaling was detected, IC50 and %SI for a particular JAKi were generally similar across cell types, with dose-dependent inhibition (Figures 1 & 2). Based on IC50s, upa was most and filgo/metabolite least potent across JAK2/2 or JAK2/TYK2-dependent (IL-3, GM-CSF, G-CSF), JAK1/3-dependent (IL-2, 4, 15, 21), and JAK1/2/TYK2 dependent (IL-6 & 10, IFNα & γ) signaling pathways. Incorporating CT profiles, no agent potently or continuously inhibited an individual cytokine signaling pathway throughout the dosing interval. Comparing bari 4-mg to tofa 5-mg BID, upa 15-mg QD, and filgo 100-mg QD, %SI of JAK2/2 or JAK2/TYK2-dependent cytokines was highest with bari 4-mg and upa. Inhibition of JAK1/2/TYK2 cytokines was highest with bari 4-mg. Inhibition of JAK2/2 or

Figure 1. IC50 values (nM) for baricitinib, tofacitinib, upadacitinib, filgotinib (parent and metabolite) in cytokine-stimulated human PBMC preparations.*p<0.01, **p<0.001, ***p<0.0001 vs. bari.

Figure 2. Baricitinib, tofacitinib, upadacitinib, filgotinib: calculated average percent daily STAT inhibition for selected cytokines. p<0.01, p<0.001, --p<0.0001 significantly lower compared to bari (vs. 2-mg if left of vertical line "|", vs. 4-mg if right of vertical line "|"). ++p<0.01, +++p<0.001, ++++p<0.0001 significantly higher compared to bari (vs. 2-mg if left of vertical line "|", vs. 4-mg if right of vertical line "|").

Cardiovascular risk and management in IMIDs

OP0002 ININCIDENCE OF FIRST CARDIOVASCULAR EVENT IN SPANISH PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: PROSPECTIVE DATA FROM THE CARMA PROJECT AFTER 5 YEARS OF FOLLOW-UP

Methods: Analysis of data of patients included in an observational prospective cohort of matched individuals (n=677) without CIRD from 67 hospitals in Spain. Through Week 52.

Results: The total number patient who completed the follow-up visit at 5 years was 2,382 (81.9%). Fifteen patients died due to CVE and six due to non-CVE. The patients with CIRD showed higher cardiovascular cumulative incidence (40.5, 95% CI: 38.2-44.8) than controls (28.3, 95% CI: 21.8-34.8). The higher risk of developing a first CVE during the 5 years of follow-up was seen in patients with AS (HR: 4.60; 95% CI: 3.12-15.99; p<0.02), those with older age (HR:1.09; 95% CI: 1.05-1.13; p<0.001), higher systolic blood pressure (HR: 2.64; 95% CI: 1.32-5.25; p=0.006), and those with longer duration of the rheumatic disease (HR: 1.07; 95% CI: 1.03-1.12; p=0.002). In contrast, woman gender was a protective factor (HR: 0.45; 95% CI: 0.21-0.99; p=0.047).

Conclusion: Patients with AS prospectively followed-up at rheumatology outpatient clinics showed higher risk of developing a first CVE than those without CIRD. Besides traditional CV disease risk factors, a longer time course of the disease is a risk factor for the development of CV disease in patients with CIRD.

Acknowledgments: This project has been supported by an unrestricted grant from Abbvie, Spain. The design, analysis, interpretation of results and preparation of the manuscript has been done independently by Abbvie.

Detection of type I interferon – Bridges into clinical applications

OP0003 EARLY AND SUSTAINED RESPONSES WITH ANIFROLUMAB TREATMENT IN PATIENTS WITH ACTIVATING SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN 2 PHASE 3 TRIALS

E. F. Morand, R. Furie, I. N. Bruce, K. Kalunian, R. Kayanli, G. Abreu, L. Pineda, R. Tummalia, Monash University, Melbourne, Australia; Zucker School of Medicine at Hofstra/Northwell, Great Neck, United States of America; University of Manchester, Manchester, United Kingdom; University of California, San Diego Health, La Jolla, United States of America; BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, United States of America; BioPharmaceuticals Medical, AstraZeneca, Gothenburg, Sweden

Background: In the phase 3 TULIP-2 and TULIP-1 trials in SLE, treatment with the type I interferon receptor antibody anifrolumab resulted in higher percentages of patients with BICLA responses vs placebo at Week 52, with differences of 16.3% (primary endpoint; P=0.001, 95% CI 6.3–26.3) and 16.4% (secondary endpoint; 95% CI 0.21–0.99; p=0.047).

Objectives: To better understand the time course of BICLA responses to anifrolumab, we examined responses over time compared with placebo in TULIP-2 and TULIP-1, including those that were sustained from attainment through Week 52.

Methods: The TULIP-2 and TULIP-1 randomized, double-blind, placebo-controlled trials evaluated the efficacy and safety of anifrolumab (300 mg Q4W) over 52 weeks in patients with moderately to severely active SLE who were receiving standard-of-care treatment. Time to onset of BICLA response that was sustained
from attainment through Week 52 was evaluated using a Cox proportional hazards model. For TULIP-1, BICLA response rate and time to onset of BICLA response were analyzed using the amended restricted medication rules.2

**Results:** Overall, 180 patients each in TULIP-2 and TULIP-1 received anifrolumab compared with 182 and 184 patients in the placebo arms, respectively. At the first 3 assessments in TULIP-2 (Weeks 4, 8, and 12), numerically greater percentages of patients treated with anifrolumab (26.8%, 35.3%, and 42.9%, respectively) were classified as having a BICLA response compared with placebo (21.3%, 21.6%, and 31.8%). A similar trend was observed in TULIP-1 with anifrolumab (23.3%, 34.2%, and 36.5%) vs placebo (19.3%, 23.2%, and 27.5%). The time to onset of BICLA response sustained from onset through Week 52 favored anifrolumab in both TULIP-2 (HR 1.55, 95% CI 1.11–2.18) and TULIP-1 (HR 1.93, 95% CI 1.38–2.73) (Figure). In TULIP-2, 86 (47.8%) patients treated with anifrolumab had BICLA responses that were sustained from time of onset through Week 52 compared with 57 (31.3%) patients in the placebo group. In TULIP-1, 85 (47.2%) patients in the anifrolumab treatment arm had BICLA responses that were sustained from time of onset through Week 52 compared with 55 (29.9%) patients in the placebo group.

**Conclusion:** In 2 Phase 3 studies, a greater proportion of patients achieved BICLA responses sustained from onset through Week 52 with anifrolumab treatment compared with placebo. Anifrolumab resulted in numerically favorable differences in time to onset of BICLA responses maintained through Week 52 across the TULIP studies. These data support the sustainability of clinical benefit derived from anifrolumab treatment of patients with active SLE.

**THE EXPRESSION OF INTERFERON-STIMULATED GENES IN PERIPHERAL BLOOD OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) ASSOCIATES WITH AFRICAN ANCESTRY**

**T. Wilhelm**, K. Zahid Siddiqi, S. Jacobsen, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark

**Background:** Type I Interferons (IFNs), and especially INF-alpha, play a crucial role in the pathogenesis of SLE. Interferon-stimulated genes (ISGs) are generally up-regulated in SLE patients. Their pattern of up-regulation is often termed as an IFN signature. Even though composite IFN-scores are already used to express the up-regulation of the IFN-system, e.g. in studies testing therapeutic anti-IFN-antibodies, we are still lacking an in-depth understanding of the IFN signature.

**Objectives:** To summarize the available data on the expression of ISGs in peripheral blood of patients with SLE compared to healthy controls; to assess which ISGs are most up-regulated in SLE patients; and to analyse if up-regulations of 6 ISGs typically used in IFN-scores [1,2] are associated with SLE disease activity and ethnicity.

**Methods:** The electronic databases PubMed and EMBASE were searched using the terms “interferon signature,” “SLE,” “interferon-stimulated genes,” microarray and “gene expression” with inception date until Jan. 28, 2020. Original case-control studies containing quantitative data of ISG expression were included. Exclusion criteria were studies with animal models, clinical trials of drug treatment and studies with ex vivo stimulation of cells prior to gene-expression analysis. Fold changes (FCs) (ISG expression in SLE/ISG expression in healthy controls) for the ISGs analysed in each study were extracted. FCS were plotted gene-wise on a heatmap for studies analysing ≥ 7 genes and for genes that were analysed in ≥ 5 studies. Cluster analysis using principle component analysis (PCA) and association analyses using generalized linear modelling (GLM) were performed for 6 ISGs (IFI27, IFI44, IFI44L, RSAD2, PRKR and IFIT1) as well as disease activity and ethnicity (SPSS).

**Results:** 16 case-control studies comprising a total of 851 SLE patients were included in the analyses, see Tab. 1. 24 ISGs had an average FC of ≥ 4. IFI27, RSAD2, IFI44L, IFI44, HERC5 and IFIT5 had an average FC > 6. The heatmap showed great variation in the expression of ISGs within the individual studies but also gene-wise between the studies, see Fig. 1. The inter-study variation was statistically explored for the selected 6 ISGs. PCA showed that PRKR, RSAD2, IFI44L, IFI44, HERC5 and IFIT5 had an average FC > 6. The heatmap showed great variation in the expression of ISGs within the individual studies but also gene-wise between the studies, see Fig. 1. The inter-study variation was statistically explored for the selected 6 ISGs. PCA showed that PRKR, RSAD2, IFI44L, IFI44, HERC5 and IFIT5 had an average FC > 6. The heatmap showed great variation in the expression of ISGs within the individual studies but also gene-wise between the studies, see Fig. 1. The inter-study variation was statistically explored for the selected 6 ISGs. PCA showed that PRKR, RSAD2, IFI44L, IFI44, HERC5 and IFIT5 had an average FC > 6.

**Conclusion:** The expression of IFNs in SLE patients was significantly different from healthy controls. However, the magnitude and number of differentially expressed genes varied considerably between studies. The present study showed that a broad range of ISGs is associated with SLE and may be used to identify individuals at risk of developing the disease. This information may be valuable in the development of new therapeutic targets for SLE.

**References:**

**Disclosure of Interests:** None.
Figure 2. Principal component analysis.

Conclusion: The degree of up-regulation of ISGs in SLE patients shows considerable variation within and between the individual studies. However, a pattern of up-regulation clearly emerges. We find a clustering of 5 prominent genes of the IFN signature (PRKR, RSAD2, IFIT1, IFI44 and IFI44L) and a positive correlation of RSAD2 and PRKR with African ancestry, pointing to the need to take ethnicity into account when using the IFN signature. Our results do not support the use of the IFN signature as traditionally defined as a surrogate marker for disease activity.

Table 2. Significantly increased expression of STAT1 by SLE B cells (A) Representative histograms of baseline expression of STAT1, pSTAT1, STAT3 and pSTAT3 in CD19+ B cells of SLE patients (orange), HD (black) and isotype controls (grey). (B) Baseline expression of STAT1 and pSTAT1 or (C) STAT3 and pSTAT3 in CD20+CD27-, CD20+CD27+ and CD20lowCD27high B-lineage cells from SLE patients compared to those from HD (black). Mann Whitney test; ****p<0.0001.
Conclusion: Enhanced expression of STAT1 by B-cells candidates as key node of two immunopathogenic signatures (type I IFN and B-cells) related to important immunopathogenic pathways and lupus activity. We show that STAT1 is activated upon IFNA exposure in SLE plasmablasts. Thus, Jak inhibitors, targeting JAK-STAT pathways, hold promise to block STAT1 expression and control plasmablast induction in SLE.

Metabolic pathways during the regulation of inflammation and immunity

**OP0006**

**ABNORMAL IRON METABOLISM AND MITOCHONDRIAL DYSFUNCTION: INVESTIGATING A NOVEL PATHOLOGICAL MECHANISM IN SYSTEMIC LUPUS ERYTHEMATOSUS**

C. Wincup1, G. Robinson2, T. Mcdonnell3, A. Radziszewska1, F. Farinà1, A. Rahman1. 1University College London, Department of Rheumatology, London, United Kingdom

Background: Iron is vital for numerous essential physiological processes including erythropoiesis and energy metabolism (as iron is found in the mitochondrial electron transport chain, the central site of ATP production). Iron homeostasis is tightly controlled by a number of regulators including: 1. Hepcidin, which prevents iron release from stores (under the influence of IL6 and IL10); 2. Ferritin, an iron storage protein; 3. Lipocalin-2 (LCN2), which is released upon innate immune activation that induces iron sequestration; 4. Transferrin, which binds circulating iron and enables its transport to effector cell targets; 5. Haptoglobin, which binds free haemoglobin and assisting iron recycling; 6. Erythropoietin (EPO), which stimulates erythropoiesis as a result of hypoxia. Chronic inflammation may result in dysregulation of iron metabolism and in turn impair mitochondrial function yet little is known regarding how these processes change in systemic lupus erythematosus (SLE).

Objectives: In this study, we investigated how dysregulation of iron metabolism may occur in SLE and subsequently sought to identify how a lack of iron may ultimately induce abnormal mitochondrial function.

Methods: 1. Investigating abnormal iron metabolism in SLE. Serum samples from patients with SLE (n=39) and healthy controls (HC, n=17) were assessed hepcidin, IL-15, IL-6, ferritin, LCN2, EPO, haptoglobin and transferrin levels by ELISA. Hierarchical cluster analysis of normalised data (converted to Z-scores) was performed using MeV software in order to characterise patient groups based upon iron metabolism profile. Anti-dsDNA antibody titres, complement C3 levels and SLEDAI-2K were excluded to limit the influence of these variables on cluster analysis. Results were presented as a heatmap.

2. Studying mitochondrial function in iron deficiency and SLE. Peripheral blood mononuclear cells (PBMCs) from HC and patients with SLE were analysed using Seahorse Respirometry, which measures mitochondrial oxygen consumption rate (a measure of energy metabolism dependent upon oxidative phosphorylation). To assess differences between health, iron deficiency and SLE 3 groups were assessed; 1. PBMCs derived from HCs; 2. PBMCs from patients with SLE; 3. Healthy PBMCs cultured in iron deficient condition, in which cells were treated with the potent iron chelator, Deferiprone.

Results: Figure 1a demonstrates that four groups were identified following cluster analysis. In spite of excluding markers of disease activity, these groups showed significant differences in SLEDAI-2K (shown in Figure 1b). In summary, patients with more active disease (Groups C and D) showed higher levels of hepcidin (which prevents the release of iron from stores, under the influence of IL-1β and IL-6) and reduced transferrin thus suggesting that iron is inefficiently transported when compared with those with less active disease (in Groups A and B).

**Figure 2a** demonstrates that basal mitochondrial respiration is significantly reduced in PBMCs derived from healthy controls when grown in iron deficiency conditions (following treatment with Deferiprone and is lower still in those with SLE. Figure 2b shows that PBMCs from patients with SLE have reduced maximal mitochondrial respiration capacity that is comparable to the levels seen in iron deficient healthy PBMCs.

Conclusion: Patients with SLE demonstrate abnormalities in iron metabolism that results in cellular iron deficiency as iron is not released from stores, nor adequately transported at the rate required to meet physiological demands. Furthermore, PBMCs derived from patients with SLE who impaired basal and maximal respiration that is comparable with healthy PBMCs treated potent iron chelation. This suggests that abnormal iron metabolism may in turn limit mitochondrial energy metabolism in SLE and represents a potential future therapeutic target.

**OP0007-PARE**

**CAMPAIGN TO PROMOTE PHYSICAL ACTIVITY & EXERCISE TO RMD PATIENTS THROUGH EDUCATION AND PRACTICE**

A. Lacovou1. 1Cyprus League Against Rheumatism, Nicosia, Cyprus

Background: Eular give' a lot of attention to outline the need of a change in RMD patients life style that is very well outlined into the 2018 Eular recommendations for Physical Activity (PA).

Objectives: Driven by those recommendations that says that “PA should be an integral part of standard care throughout the course of disease”, CyLAR decided to create a campaign to promote PA through educating RMD patients on the PA benefits, make them to change their life style and enroll them to PA programs. More over we want to inform Rheumatologist and HPRs on that effort and enroll them to that campaign. The CyLAR’s goal through that campaign is to manage and enroll as much as possible patients to PA Programs for a continual period of about 10 months.
Methods: To achieve all the above we decided to move to the following steps:

- Offer PA Programs organized by CypLAR or HPR associates
- Increase awareness regarding the benefits of the PA (Land based & Aquatic) programs to Rheumatologists, HPR’s and RMD patients
- Integrate PA into National Health System and procedures
- Offer incentives

Results:

- We managed to increase the PA programs that we used to offer from 1 to 3 in every major cities with also some more opportunities ahead. That also increases the number of participants attracting around 100 participants instead of 20 that we uses to before.
- Towards awareness, we presented Exercise rehabilitation in conferences around Europe (Agora 2017,2018,2019, Eular 2018, Cyprus – Crete Conference 2017, 2019, Enfa 2019, Pain Conference, Athens 2019) and also published related articles on CypLAR’S magazine that is published twice a year that is distributed to more than 5000 members.
- We managed to include the Aquatic Exercise Rehabilitation to the new National Strategic plan for Rheumatic Diseases.
- As incentives, we created a fund that is addressed to partially support low income patients. Furthermore we acquire special discount membership fees to our members on PA programs that are offered by associates.
- We organize our own sport related fund events and also participate in others sport funding events. Especially the Charity Swimming Event “Swim for my fellow” which is co-organized by the lacoquv Swimming Center and Cypr for the last 5 years is also under the Limassol Municipality Annual Sport Events called “Lemessia” which this year will have an International promotion due Limassol’s Award as the ”European City of Sports” for 2020.
- We are in the process and in contact with big companies in order to become our campaign Sponsors

We attracted a fund of €2000 from Cyprus Sport Organization that offered a partial financial support to 30 patients for their participation in PA programs for 3 months.

Conclusion: We all believe that the success on that campaign is based on Education (articles, presentations), the available options (programs/positions to participate) and Incentives (financial) that all of them needs further development.

Legend. The alternative Ankylosing Spondylitis Disease Activity Scores (ASDAS) formulae were calculated using PASA replacement: question 1 (Q1), average of questions 1 and 4 (Q4), average of questions 1,4,5 (Q145) and total score (BT) of the Bath Ankylosing Spondylitis Disease Activity Score (BASDAI) or a constant value (ASDAS-C3); original-ASDAS=ASDAS according to the usual formula; ICC =Intraclass Correlation Coefficient; SD = Standard Deviation; SMD=Standardized mean difference.
Background: The staging of interstitial lung disease (ILD) is important to monitor disease progression and for prognostication. A disease severity scale of Systemic Sclerosis (SSc)-related lung disease has long been proposed (i.e. Medsger’s severity scale). This scale was mostly developed by discussion and consensus and stage thresholds were not computed by a data-driven approach. Hidden Markov models (HMM) are methods to estimate population quantities for chronic diseases with a staged interpretation which are diagnosed by markers.

Methods: A total of 358 SSc patients at risk for or with ILD were enrolled in a discovery cohort (202 cases, Milan1) and in a validation cohort (151 cases, Milan2 and Rome) cohort. Patients were included if satisfied the following criteria: 1) Diagnosis of SSc according to the EULAR/ACR 2013 criteria, 2) absence of anticentromere antibodies, 3) dcSSc subset or 4) other subsets with either 4a) ILD-related antibodies (ScI70, PmScl, Ku) or 4b) evidence of ILD on HRCT, 5) disease duration < 5 years at the time of the first pulmonary function test (PFT). Serial PFTs were retrieved and the time up to the last available visit -if the disease duration < 5 years at the time of the first pulmonary function test (PFT). Diagnosis of SSc according to the EULAR/ACR 2013 criteria, 2) absence of anticentromere antibodies, 3) dcSSc subset or 4) other subsets with either 4a) ILD-related antibodies (ScI70, PmScl, Ku) or 4b) evidence of ILD on HRCT, 5) disease duration < 5 years at the time of the first pulmonary function test (PFT). Serial PFTs were retrieved and the time up to the last available visit -if the disease duration < 5 years at the time of the first pulmonary function test (PFT). Diagnosis of SSc according to the EULAR/ACR 2013 criteria, 2) absence of anticentromere antibodies, 3) dcSSc subset or 4) other subsets with either 4a) ILD-related antibodies (ScI70, PmScl, Ku) or 4b) evidence of ILD on HRCT, 5) disease duration < 5 years at the time of the first pulmonary function test (PFT).

Objectives: To build a SSc-ILD specific disease severity scale with prognostic relevance via HMM modeling.

Results: Patients characteristics are summarized in the Table. Fifteen-years survival estimates for Medsger’s classes in the discovery set were: normal=0.88, mild=0.86, moderate=0.84, severe=0.70. The SL3SI was defined by the following thresholds: normal/mild, FVC and DLco ≥75%; moderate FVC or DLco 74-55%; severe, FVC or DLco <55%. SL3SI 15- yrs survival estimates were: normal/mild=0.89, moderate=0.84 and severe=0.71. The SL3SI was defined by the following thresholds: normal/mild, FVC and DLco ≥75%; moderate FVC or DLco 74-55%; severe, FVC or DLco <55%. SL3SI 15- yrs survival estimates were: normal/mild=0.89, moderate=0.84, severe=0.71.

Conclusion: The SL3SI, a simplified 3-stage functional model of SSc-ILD, yields better survival estimates and long-term prognostic information than Medsger’s classes. Its reproducibility and ease of use make it a useful tool for the functional and prognostic evaluation of SSc patients at risk for or with ILD.

Objectives: To assess the effects of TNF inhibitors and newer bDMARDs (including abatacept, rituximab, sarilumab, and tocilizumab) on the VTE risk based on observational data from RA patients.

Methods: The German register RABBIT is a prospective longitudinally followed cohort of RA patients enrolled with a new start of a bDMARD after at least one csDMARD failure. This analysis comprises patients who were enrolled with start of a bDMARD between 01/2009 and 04/2019 and had at least one follow-up.

Cox regression models were used to calculate hazard ratios (HRs) for VTEs, for csDMARDs, TNF inhibitors and other bDMARDs. Propensity score weighting was used to adjust for confounding by indication.

Results: Patients receiving TNF inhibitors or other bDMARDs on average had higher CRP levels and a higher prevalence of cardiovascular diseases at baseline than patients receiving csDMARDs. They also received more often glucocorticoids (Table 1).

</table>

Results are presented as mean ± SD or number (percentage).

The HR of patients receiving TNF inhibitors for a serious VTE event was 0.53 (95% CI: 0.33 – 0.86) compared to csDMARDs, while the HR for patients receiving other bDMARDs was 0.66 (95% CI: 0.40 – 1.09). A CRP level > 10 mg/L (HR 2.09, 95% CI: 1.04 0.55 1.98) and pathways constitute the basis for understanding of SSc pathogenesis and cell-cell interactions that play crucial roles in SSc pathogenicity. Our findings of candidate stromal and immune cell subpopulation, genes and pathways hold a great potential to provide clinicians with new and powerful molecular tools for understanding of the immune-stromal cell crosstalk, for finding new biomarkers for SSc activity and complications and for tailoring and identification of new therapeutic targets.

regarding axial inflammation in spondyloarthritides (SpA), better efficacy regarding cutaneous psoriasis, but is inferior in inflammatory bowel disease (IBD). However, the efficacy of SEC compared to TNFi in anterior uveitis (AU) has not been extensively studied.

Objectives: To compare the occurrence of AU in patients with SpA treated with SEC, adalimumab (ADA), infliximab (IFX) or etanercept (ETN), in clinical practice.

Methods: Patients with ankylosing spondylitis or undifferentiated SpA starting either SEC, ADA, IFX or ETN, in 2015 through 2017, were identified in the Swedish Rheumatology Quality register, and were linked to the national patient register for identification of AU. AU-flares were defined as the number of visits with an AU diagnosis, separated by a ≥60 days penalty interval, within ophthalmology outpatient care, during the respective bDMARD treatment.

Follow-up started at the bDMARD initiation, and ended at the first of Dec 31st 2017, death, emigration or discontinuation date of the bDMARD.

To assess and accommodate treatment channeling, crude incidence rates for AU-flares were determined (A) for all bDMARD treatment starts, (B) excluding patients with an AU diagnosis during the year prior to the bDMARD start, and (C) in addition, excluding all first line bDMARD treatment starts. Hazard ratios (HR) for time until a first on-treatment AU diagnosis were estimated using Cox regression (ADA=reference), adjusted for sex, age, and any history of AU, and estimating robust confidence intervals to account for the individuals contributing multiple lines of treatment.

Results: In total, 2,684 patients (52% women) contributed 3,255 treatment initiations. SEC was less frequently used as first line bDMARD and there was channeling of patients with previous AU, towards treatment with ADA, and away from ETN (Table 1). Further, AU occurred almost exclusively in patients with a pre-treatment history of AU (data not shown).

</table>

Conclusion: In clinical practice, SEC and ETN are associated with a higher incidence of AU than ADA and INF, suggesting a poorer protective effect of SEC and ETN against AU. These preliminary results should be interpreted in light of pronounced treatment channeling, which was only partly accommodated for.
aged ≥18 with an enrollment SU measurement. We used Cox proportional hazards regression models to estimate sex-specific mortality risk relative to a referent SU 5-6 mg/dL, adjusting for NHANES cycle, age, race, body mass index (BMI), education, smoking, use, hypertension, total cholesterol, estimated glomerular filtration rate (GFR), and competing risks, using age as a time scale for survival analysis.

**Results:** Among 19,954 men and 21,853 women, there were 5,714 male deaths and 4,901 female deaths (median follow-up 14.2 ± 6.9 years). Among men, there was a 33% increased all-cause mortality risk at SU <4 mg/dL (HR 1.33, 95% CI 1.17-1.51) and 52% increased all-cause mortality risk at SU >8 mg/dL (HR 1.52, 95% CI 1.37-1.69) compared to subjects with SU 5-6 mg/dL, driven by cause-specific mortality from diabetes at low SU and chronic lower respiratory diseases and cardiovascular disease at high SU (Table). In women, there was no increased mortality risk at low SU and a 45% increased all-cause mortality risk at SU >7 mg/dL (HR 1.45, CI 1.31-1.61) compared to subjects with SU 5-6 mg/dL, driven by cause-specific mortality from diabetes. Mortality from Alzheimer’s disease was lower at high SU among men (HR 0.23, 95% CI 0.05-0.99) and women (HR 0.54, 95% CI 0.25-1.15).

**Conclusion:** In large cohorts representative of the US population, there was a U-shaped relationship between SU and all-cause mortality in men but not women. In men with low SU, mortality was driven primarily by diabetes, which may be explained by the uricosuric effect of uncontrolled hyperglycemia in diabetes patients. The lower mortality from Alzheimer’s disease at high SU agrees with previously shown inverse associations between gout and Alzheimer’s disease. Further studies are needed to determine the presence of causality underlying these associations.

**Figure 1.**

**Figure 2.**

**References:**
Background: A lack or loss of response to TNFα inhibitors (TNFi) has been associated with low serum drug levels and formation of anti-drug antibodies (ADAb). Therapeutic drug monitoring (TDM), an individualised treatment strategy based on regular assessments of serum drug levels, has been suggested to optimise efficacy of TNFi. It is still unclear if TDM improves clinical outcomes, and the value of TDM has recently been included in the research agenda across different specialties. This first randomised controlled trial on the effectiveness of TDM in a range of immune mediated inflammatory diseases including rheumatic diseases, the Norwegian DRUg Monitoring trial part A (NOR-DRUM (A)) focus on the induction period of infliximab (INX) treatment.

Objectives: To assess if TDM is superior to standard treatment in order to achieve remission in patients starting INX.

Methods: In the investigator-initiated, randomised, open-label, multicentre NOR-DRUM (A) study, adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), spondyloarthritis (SpA), ulcerative colitis (UC), Crohn’s disease (CD) and psoriasis (Ps) starting INX therapy were randomly assigned to administration of INX according to a treatment strategy based on TDM (TDM arm) or to standard administration of INX without TDM (control arm). Study visits were conducted at each infusion. The primary endpoint was remission at week 30. In the TDM arm, the dose and interval were adjusted according to INX trough levels to reach the therapeutic range (Figure 1). If the patient developed significant levels of ADAb, INX was terminated. To guide the investigation, the TDM strategy was integrated in an interactive eCRF. The primary endpoint was analysed by mixed effect logistic regression in the full analyses set (FAS), adjusting for diagnoses. Infections and infusion reactions were specified as adverse events (AEs) of special interest. Clinical trial.gov: NCT03074656

Results: We enrolled 411 patients at 21 study centres between January 2017 and December 2018. 398 patients (RA 60, PsA 42, SpA 117, UC 80, CD 57, Ps 22) received the allocated strategy and were included in the FAS population. Demographic and baseline characteristics were comparable in both arms. TDM was not found to be superior to standard treatment with regard to the primary outcome. Remission at week 30 was reached in 100 (53%) and 106 (54%) of the patients in the TDM and control arm, respectively (adjusted difference, 15%; 95% confidence interval (CI), -2.2 to 11.1, p=0.78) (Figure 2). Consistent results were shown for all the secondary endpoints (Figure 3) and in the sensitivity analyses. Twenty patients (10%) in the TDM arm and 30 patients (15%) in the control arm developed significant levels of ADAb. The number of adverse events (AE) was similar in both groups, however infusion reactions were less frequent (5 patients (2.5%) vs 16 patients (8.0%)) in the TDM arm (difference 5.5% (95% CI 1.1, 9.8%)) in the TDM arm (difference 5.5% (95% CI 1.1, 9.8%))

Conclusion: NOR-DRUM (A) is the first randomised trial to address the effectiveness of TDM in the induction period of TNFi treatment, and the first trial to address TDM in rheumatic diseases. In this study, TDM was not superior to standard treatment in order to achieve remission. Although improved safety is indicated by a reduction in infusion reactions, implementation of TDM as a general strategy in treatment in order to achieve remission. Although improved safety is indicated by a reduction in infusion reactions, implementation of TDM as a general strategy in treatment is not supported by the NOR-DRUM (A) study.
**Background:** Upadacitinib (UPA) is an oral, reversible, JAK inhibitor approved for treatment of rheumatoid arthritis (RA) and currently under evaluation for treatment of psoriatic arthritis (PsA).

**Objectives:** To assess the efficacy and safety of UPA vs placebo (PBO) and adalimumab (ADA) in patients (pts) with PsA and prior IR or intolerance to ≥1 non-biologic DMARD (non-bDMARD).

**Methods:** Pts with active PsA (≥3 swollen and ≥3 tender joints), active or historical psoriasis, and on ≥2 non-bDMARDs were randomized 1:1:1 to once daily UPA 15 or 30 mg (UPA15/30), ADA 40 mg every other week, or PBO. The primary endpoint was the proportion of pts achieving ACR20 for UPA vs PBO at Wk 12. Multiplicity controlled secondary endpoints for each dose of UPA vs PBO included change in HAQ-DI, FACT-R, and SF-36 PCS (Wk 12); static Investigator Global Assessment of Psoriasis of 0 or 1, PASI75, and change in Self-Assessment of Psoriasis Symptoms (Wk 16); change in modified Sharp/van der Heijde Score (mTSS), proportion of pts achieving MDA, and resolution of enthesitis (LEI=0) and dactylitis (LDI=0) (Wk 24). For each dose of UPA, the multiplicity-controlled analysis also included non-inferiority and superiority vs ADA for ACR20 and superiority for HAQ-DI and pts assessment of pain NRS (Wk 12). ACR50/70 at Wk 12 and ACR20 at Wk 2 were additional secondary endpoints. Treatment-emergent adverse events (TEAEs) through 24 wks are reported for pts who received ≥1 dose of study drug.

**Results:** 1705 pts were randomized; 1704 received study drug (53.2% female, mean age 50.8 yrs, mean duration of PsA diagnosis 6.1 yrs). 82% were on ≥1 concomitant non-bDMARD, of whom 84% received MTX +/- another non-bDMARD. At Wk 12, ACR20 rates were 70.6% with UPA15 and 78.5% with UPA30 vs 36.2% with PBO (p < .001 for UPA15/30 vs PBO) and 65.0% with ADA (non-inferiority, p < .001 for UPA15/30 vs ADA). A greater proportion of pts achieved ACR50/70 with UPA15/30 vs UPA30 vs ADA. Improvements were observed with UPA15/30 vs PBO for all multiplicity controlled secondary endpoints and for UPA 15 vs ADA for HAQ-DI and UPA 30 vs ADA for improvement in pain (Figure 1A-1B). At Wk 24, change in mTSS was 0.25 for PBO, -0.04 for UPA15, 0.03 for ADA, and 0.01 for ADA (p < 0.001 for UPA15/30 vs PBO). The rates of TEAEs and serious AEs, including serious infections, were similar in the PBO, UPA15, and ADA arms and higher with UPA30 (Figure 2). The rate of herpes zoster was similar for PBO and UPA15/30. No MACE was reported with UPA. One malignancy occurred in each of the PBO and UPA15 arms, and 3 malignancies were reported in each of the UPA30 and ADA arms. VTE were reported in 1 pt on PBO, 1 pt on UPA30, and 2 pts on ADA. One death occurred in the PBO arm. **Conclusion:** In this non-bDMARD-IR PsA population, treatment with UPA15/30 demonstrated improvement in musculoskeletal symptoms, psoriasis, physical function, pain, and fatigue and inhibited radiographic progression; improvements were observed by Wk 2. At Wk 12, UPA15/30 were non-inferior to ADA for ACR20, with superiority demonstrated for UPA30. Greater percentages of UPA vs PBO pts achieved stringent measures of disease control (MDA, ACR50/70, sIGA 0/1). No new safety signals were identified compared with the safety profile observed in RA.

DOI: 10.1136/annrheumdis-2020-eular.689
Background: Remission is the preferred treatment target in rheumatoid arthritis (RA), and many patients require biologic DMARDs to reach this state. It is debated whether tapering of tumor necrosis factor inhibitor (TNFi) treatment to discontinuation should be considered in RA patients who sustain remission on treatment (1).

Objectives: The primary study objective was to assess the effect of tapering and withdrawal of TNFi on the risk of flares in RA patients in clinical remission.

Methods: In the non-inferiority ARCTIC REWIND trial, RA patients in remission for at least 12 months on stable TNFi therapy were randomly assigned to continued stable TNFi or tapering (half-dose TNFi for 4 months, thereafter withdrawal of TNFi), with visits every four months. csDMARD co-medication was kept stable in both arms. Patients had to be in DAS remission at inclusion with 0/44 swollen joints. The primary endpoint was the proportion of patients with disease flare during the 12-month study period (defined as DAS >1.6, change in DAS >0.6 and 2 or more swollen joints, or the physician and patient agreed that a clinically significant flare had occurred). Full-dose TNFi was reinstated in case of flares in the tapering arm. The non-inferiority margin was 20%, with a predefined superiority test if non-inferiority was not shown. The inferiority null-hypothesis was tested in the per-protocol population with 0/44 swollen joints. The primary study objective was to assess the effect of tapering and withdrawal of TNFi on the risk of flares in RA patients in clinical remission.

Results: We randomised 99 patients, 92 received the allocated treatment strategy, 84 were included in the per-protocol population. Baseline characteristics, clinical and ultrasound disease activity were balanced (Table). csDMARD co-medication was used by 93% in the stable and 88% in the tapering arm. In the primary analysis, 5% of patients in the stable TNFi arm experienced a flare during 12 months, compared to 63% in the tapering TNFi arm. The risk difference (95% CI) was 58% (42% to 74%, Fig 1), with stable treatment being deemed superior to tapering. 90% in the stable and 81% in the tapering arm did not show progression of radiographic joint damage, difference (95% CI) -9% (-24%, 6%). At 12 months, DAS scores, DAS remission and function were similar between groups (Fig 2). The numbers of adverse events (AE)/serious AE in the stable and tapering arm were 57/2 and 50/3, respectively, with 26 and 15 infections.

Conclusion: In a randomised clinical trial assessing patients in prolonged and deep RA remission, we observed a large increase in the flare rate in patients who tapered and discontinued TNFi. Patients responded well to reinstated treatment and remission rates in the two study arms were comparable at 12 months.

Conclusion: Treatment with IL-6 inhibitors significantly increases the chance of reaching low fatigue levels within half a year in RA patients, while current smoking reduces it.

References:
At least one TESAE (subcutaneous abscess, pulmonary tuberculosis, staphylococcal sepsis, toxic shock syndrome, cervix carcinoma, obstructive pancreatitis, diabetic vascular disorder) was reported in 8 (5.6%) of OKZ groups, numerically higher than 4 (2.8%) in PBO. There was one death due to septic shock in the OKZ q2w arm.

**Conclusion:** Treatment with OKZ over a 24-week period was associated with significant improvements in the signs, symptoms and physical function of RA, with a safety profile consistent with Phase II data for OKZ and with the data for the agents with similar mechanism of action.

There were no discernible differences between the two regimens of OKZ in efficacy or safety outcomes.

Results: In all machine learning methods, the accuracy and the area under the receiver operating characteristic (AUROC) were 57.2%–74.5%, 0.547–0.747, respectively (Table 1). The accuracy and AUROC of each biologic were similar between machine learning methods. Figure 2 showed interpretation of feature importance with the Shapley plot for remission. The most important feature was age in adalimumab (younger were closer to remission), daily corticosteroid dose in etanercept, golimumab, and all TNF inhibitors (using fewer doses daily were closer to remission), baseline erythrocyte sedimentation rate in infliximab (lower ESR were closer to remission), disease duration in abatacept (longer disease durations showed difficulty determining remission), base- line c-reactive protein in tocilizumab (higher CRP were closer to remission).

Figure 2. Shapley plots and SHAP values for the feature importance from clinical information in patients with RA.

Conclusion: We developed machine learning models for predicting remission as a response to each biologics in active RA patients based on their clinical profiles, and found important clinical features using explainable AI. This approach may support clinical decisions to improve treatment outcomes in patients with RA.

OP0024

USE OF HYDROXYCHLOROQUINE AND RISK OF HEART FAILURE IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Sorour1, Y. Shahin1, C. S. Crowson2, R. Kurmann1, S. Achenbach2, R. Mankad1, E. Myasoedova3.

1Mayo Clinic, Cardiovascular diseases, Rochester, United States of America; 2Mayo Clinic, Biomedical Statistics and Informatics, Rochester, United States of America; 3Mayo Clinic, Rheumatology, Rochester, United States of America

Background: Hydroxychloroquine (HCQ) is a disease-modifying anti-rheumatic drug (DMARD) used as a long-term treatment for rheumatoid arthritis (RA) patients. Cardiotoxicity is a rare but potentially life-threatening side effect of HCQ and may present as conduction disorders, cardiomyopathy, and resulting heart failure (HF). The evidence of cardiotoxicity associated with the use of HCQ largely relies on case reports and case series while large cohort studies on the subject are lacking.

Objectives: To examine the relationship between the use of HCQ and risk of developing HF in RA.

Methods: In this nested case-control study, cases were Olmsted County, Minnesota residents with incident RA (based on 1987 ACR criteria) in 1980-2013 who developed HF after RA incidence. Each case was matched on year of birth, sex and year of RA incidence with an RA control who did not develop HF. Each non-HF control was assigned an index date corresponding to the HF diagnosis date of the case. Controls were allowed to later become cases to avoid bias. HF was defined using the Framingham criteria. Data on HCQ use including start and stop dates and dose changes was manually abstracted via medical record review, and used to calculate HCQ duration and cumulative dose. Age-adjusted logistic regression models were used to examine the association between HCQ and HF.

Results: From a cohort of 1078 subjects, the study identified 143 RA cases diagnosed with HF (mean age 65.8, 62% females) and 143 non-HF RA controls (mean age 64.5, 62% female). Cases and controls had similar RA duration, proportion of patients positive for rheumatoid factor (RF) and/or cyclic citrullinated antibody (CCP), body mass index, and smoking status (Table). The duration of HCQ use prior to the diagnosis of HF was 2.8 years in cases and 2.6 years in controls. A total of 71 cases and 69 controls used HCQ at some time before index date. Among these, the median (interquartile range) duration of HCQ use was 2.8 (0.6, 10.9) years for cases and 2.5 (0.7, 8.2) for controls. The median cumulative dose of HCQ was 371 g and 302 g in cases and controls, respectively, with 55% of cases receiving a cumulative dose of ≥300 g compared to 54% in controls. HCQ cumulative dose was not associated with HF (Odds Ratio [OR]: 0.96 per 100 g increase in cumulative dose, 95% confidence interval [CI]: 0.90-1.03). Likewise, no association was found for patients with a cumulative dose ≥300g (OR 0.92, 95% CI 0.41-2.08). The duration of use of HCQ prior to index was not associated with HF (OR 0.98, 95% CI 0.91-1.09). Retinotoxicity rates were similar in cases and controls.

Conclusion: Use of HCQ was not associated with development of HF in patients with RA in this study. While there was not statistically significant association between the cumulative dose of HCQ and HF, the confidence interval for HCQ dose ≥300 g was wide suggesting that more studies are needed to understand the impact of higher doses of HCQ on development of HF in RA.

Background: EULAR recommendation announced that biological disease-modifying antirheumatic drugs (bDMARDs) and Janus kinase inhibitors (JAKIs) are considered as equivalent in the treatment of rheumatoid arthritis (RA). However, we still lack reliable evidence of direct comparison between these agents’ reten- tion, which may reflect both effectiveness and safety.

A RANDOMIZED, CONTROLLED TRIAL OF RITUXIMAB VERSUS AZATHIOPRINE AFTER INDUCTION OF REMISSION WITH RITUXIMAB FOR PATIENTS WITH ANCA-ASSOCIATED VASCULITIS AND RELAPSING DISEASE

R. Smith, 1 D. Jayne, 2 P. A. Merkel 3 on behalf of RITAZAREM Investigators.

1University of Cambridge, Department of Medicine, Cambridge, UK; 2University of Cambridge, Cambridge, UK; 3University of Pennsylvania, Philadelphia, United States of America

**Background:** Rituximab (RTX) is an effective therapy for induction of remission in ANCA-associated vasculitis (AAV). However, the effect of RTX is not sustained, and patients subsequently relapse. The objective of the RITAZAREM trial was to compare RTX and azathioprine (AZA) in ANCA-associated vasculitis with relapsing disease.

**Methods:** The RITAZAREM trial is an international, multi-center, open-label, randomized, controlled trial of patients with AAV with relapsing disease comparing the efficacy of RTX or AZA (2 mg/kg/day) as maintenance therapy. Patients were followed for a minimum of 36 months, with the primary outcome being time to disease relapse.

**Results:** Patients with AAV were randomized to receive either RTX or AZA (2 mg/kg/day) as maintenance therapy. Patients were followed for a minimum of 36 months, with the primary outcome being time to disease relapse.

**Objectives:** The RITAZAREM trial is an international, multi-center, open-label, randomized, controlled trial of patients with AAV with relapsing disease comparing the efficacy of RTX or AZA (2 mg/kg/day) as maintenance therapy. Patients were followed for a minimum of 36 months, with the primary outcome being time to disease relapse.

RTX was superior to AZA in preventing disease relapse with a preliminary overall hazard ratio (HR) estimate of 0.36 (95% CI 0.23-0.57, p <0.001) and a during-treatment HR estimate of 0.30 (95% CI 0.15-0.60, p<0.001) (Figure 1).

After adjustment, none of the randomization stratification covariates (ANCA type, age, sex, disease duration, concomitant PSL and MTX, starting date and number of switched bDMARDs) using Cox proportional hazards modeling.

glucocorticoid induction regimen, or relapse severity) had a significant differential effect on the primary outcome. By 24 months after entry, 20 months after randomization, 11/85 (13%) patients in the RTX group had experienced a relapse compared to 32/85 (38%) patients in the AZA group. 19/85 (22%) patients in the RTX group and 31/85 (36%) patients in the AZA group experienced at least one severe adverse event (SAE), 25/85 (29%) and 42/85 (49%) patients in the RTX group developed hypogammaglobulinemia (IgG <5 g/l) and non-severe infections respectively, compared to 21/85 (25%) and 41/85 (48%) in the AZA group.

Figure 1. Relapse-free survival in RITAZAREM trial: rituximab versus azathioprine

Conclusion: In the RITAZAREM trial, following induction of remission with RTX, RTX was superior to AZA for preventing disease relapse in patients with AAV with a prior history of relapse. There were no new major safety signals for use of these medications in this population.

OP0027
TIME TO FLARE AND GLUCOCORTICOID EXPOSURE IN PATIENTS WITH NEW-ONSET VERSUS RELAPSING GIANT CELL ARTERITIS TREATED WITH TOCILIZUMAB OR PLACEBO PLUS PREDNISONE TAPERING: 3-YEAR RESULTS FROM A RANDOMIZED CONTROLLED PHASE 3 TRIAL

1Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, United States of America; 2Roche Products Ltd, Welwyn Garden City, United Kingdom; 3University Medical Center and Faculty of Medicine, TU Dresden, Dresden, Germany; 4Department of General Internal Medicine, University Hospitals Gasthuisberg, Leuven, Belgium; 5Department of Rheumatology and Clinical Immunology, University of Groningen, Groningen, Netherlands; 6Department of Autoimmune Diseases, Hospital Clinic, University of Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; 7Southend University Hospital, NHS Foundation Trust, Westcliff-on-Sea, United Kingdom; 8Friedrich-Alexander-University Erlangen-Nürnberg, Department of Internal Medicine 3–Rheumatology and Immunology, Universitätshilsklinikum Erlangen, Erlangen, Germany; 9Division of Rheumatology, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy; 10Hospital for Special Surgery, Cornell, United States of America; 11Genentech, South San Francisco, United States of America

Background: In part 1 of the 52-week, double-blind GIACTA trial, tocilizumab (TCZ) every week (QW) or every other week (Q2W) plus prednisone tapered reduced the risk for flare versus placebo (PBO) + 26-week prednisone tapering among patients with new-onset giant cell arteritis (GCA) at baseline. Among patients with relapsing GCA, TCZ QW but not Q2W ± prednisone reduced the risk for flare versus both PBO groups, and there was separation in the time to flare between the TCZ QW and Q2W groups.1

Objectives: To report time to first flare and potential cumulative glucocorticoid (GC) sparing over 3 years of the GIACTA trial (part 1) and 2-year open-label part 2) among patients with new-onset or relapsing GCA.

Methods: At the end of part 1, patients entered open-label part 2, in which GCA therapy (including initiation/termination of open-label TCZ and/or GCs) was given at the investigator’s discretion according to disease status. Time to first GCA flare during the 3-year study period was assessed using Kaplan-Meier analysis for patients in the intention-to-treat population according to disease onset status at baseline (new-onset/relapsing) based on their originally assigned treatment groups: TCZ QW, TCZ Q2W, or pooled PBO (PBO+26-week and PBO+52-week prednisone taper).

Results: Among patients randomly assigned in part 1, 47 of 100 (47%) in the TCZ QW group, 26 of 49 (53%) in the TCZ Q2W group, and 46 of 101 (46%) in the pooled PBO group had new-onset GCA at baseline. The rest had relapsing GCA. Median time to first flare over 3 years was longer for patients assigned to TCZ treatment in part 1 than for patients assigned to PBO; Kaplan-Meier analysis showed a clear separation between the TCZ QW and the pooled PBO groups over 3 years for patients with new-onset and relapsing GCA (Figure 1A). Separation between the TCZ QW and TCZ Q2W groups was also observed over 3 years in patients with new-onset and relapsing GCA, although this was more evident in patients with relapsing GCA (Figure 1B). Higher proportions of patients in the TCZ QW group (new-onset, 49%; relapsing, 47%) than the pooled PBO group (new-onset, 28%; relapsing, 31%) and the TCZ Q2W group (new-onset, 27%; relapsing, 35%) remained flare-free during their entire treatment period. Cumulative prednisone dose over 3 years was lower for patients originally assigned to TCZ QW versus those originally assigned to PBO for patients with new-onset GCA and those with relapsing GCA at baseline (Figure 2). Conclusion: In this 3-year analysis of GIACTA parts 1 and 2, time to first flare favored TCZ QW over TCZ Q2W in patients with new-onset and relapsing GCA. TCZ QW delayed time to first flare and resulted in lower cumulative GC exposure compared with PBO in patients with new-onset and relapsing GCA, supporting TCZ QW dosing in patients with GCA regardless of disease onset.

References:
Background: Oral ulcers (OU) associated with Behçet's syndrome are often painful, may interfere with the ability to eat and can negatively affect quality of life. Apremilast (APR), an oral phosphodiesterase 4 inhibitor, demonstrated efficacy in the treatment of OU associated with Behçet's syndrome in a phase III, multicenter, randomized, double-blind, placebo (PBO)-controlled study (RELIEF; BCT-002).

Objectives: To describe the efficacy of APR treatment in improving OU pain associated with Behçet's syndrome in RELIEF.

Methods: Patients were randomized (1:1) to APR 30 mg twice daily (APR 30 BID) or PBO twice daily for a 12-week PBO-controlled phase, followed by a 52-week active treatment extension. Eligible patients were ≥18 years of age and had active Behçet's syndrome with ≥3 OU at randomization or ≥2 OU at screening and randomization and without active major organ involvement. Clinical improvement in OU was evaluated by the area under the curve for the number of OU through Week 12 (AUCWk0-12; primary efficacy endpoint) and by assessments of OU number and OU pain VAS scores, respectively, were analyzed through Week 12. An ANCOVA model was used to analyze the primary endpoint and assessments of OU number and OU pain VAS score.

Results: A total of 207 patients were randomized and received ≥1 dose of study medication (APR: n=104; PBO: n=103). At baseline, the mean (SD) number of OU was 4.2 (3.7) in the APR 30 BID group and 3.9 (2.7) in the PBO group, and the mean (SD) OU pain VAS scores were 61.2 (27.6) and 60.8 (23.9), respectively. At Week 12, significantly greater improvements were observed with APR 30 BID vs. PBO in AUCWk0-12 (least-squares [LS] mean change from baseline: −40.7 [3.3] vs. −15.9 [3.3]; P=0.0001) and OU pain VAS scores (LS mean [SE] change from baseline: −40.7 [3.3] vs. −15.9 [3.3]; P=0.0001). The proportion of patients who achieved the MCID of ≥10-mm improvement in OU pain VAS scores at Week 12 were significantly greater in patients treated with APR 30 BID vs. PBO.

Conclusion: For patients with active Behçet's syndrome, APR 30 BID provided significantly greater improvements vs. PBO in OU number and OU pain at Week 12, including the greater proportion of patients achieving MCID and reductions in pain VAS scores between treatment groups. These results indicate a clinically meaningful treatment effect of APR 30 BID on the OU associated with Behçet's syndrome.

**Figure 1. Proportion of Patients Achieving Improvements in OU Pain VAS at Week 12**

**Figure 2. Proportion of Patients Achieving ≥50-mm Improvements in OU Pain VAS Over 12 Weeks**
without active disease and 19% still experiencing active disease. 32% were still receiving GCs - 22% of them receiving > 5mg/day. There was no negative impact on functional status with 14% reducing working hours, 13% restricted social life, 6% leaving employment. 8% registered as disabled and 2% leaving full time education.

Conclusion: The start of maintenance treatment in AAV is variably defined but typically at 6 months after start of remission induction therapy. Achieving full remission and preventing relapse are still clinical problems and many patients require ongoing GC therapy to maintain remission. Infectious complications and adverse events are common and there is significant negative impact on patient functional status over time.

Disclosure of Interests: None declared

Statistics helped distinguish patients achieving or maintaining SROT and those who relapsed. Among 92 3-year SROT patients, 16 had ≥7 additional years of follow-up: 46 (62%) attained 5-year SROT and 28 (38%) had ≥2 years of additional follow-up. Baseline clinical and biological characteristics of patients with 3-5 and 10-year SROT were analyzed. Baseline characteristics of patients with 3-year GPA SROT vs those who relapsed between 3 & 5 years. Patients with 3-year GPA SROT were compared to those of registry GPA patients with 3-, 5- and 10-year SROT.

Methods: GPA had to satisfy the 1990 ACR classification criteria and/or revised Chapel Hill Nomenclature for study inclusion. SROT was defined as remission (BVAS=0) without glucocorticoids (GC) or immunosuppressants (IS), the latter for ≥6 months (ie 2 consecutive visits). SROT and its duration were extracted from the database. Data from patients with 3-, 5- and 10-year SROT were analyzed. Baseline characteristics of patients with 3-year GPA SROT were compared to those of registry GPA patients with available data at 3 years but not in SROT (controls), and 3-year SROT achieving 5-year SROT vs those who relapsed between 3 & 5 years. Patients with 3-year GPA SROT follow-up >7 years were analyzed according to maintained SROT or not.

Results: Among 796 database patients with new-onset GPA, 259 achieved at least 1 SROT at some time during their disease, after a median [IQR] of 36 [28-63] months post-diagnosis. The first SROT lasted a median of 14 [8-32] months. Among 202 of those patients who had follow-up, 73 (36%) remained in SROT for a median follow-up of 34 [14-45] months post-SROT. Among 404 (54%) patients followed for ≥3 years post-diagnosis, 82% had received GC and cyclophosphamide induction therapy. At 3 years post-diagnosis, 92 (21%) patients in SROT were compared to 342 (79%) controls who had relapsed or were still taking GC or IS. Patients achieving 3-year SROT vs controls, respectively, had more frequently received intravenous cyclophosphamide as induction therapy (89% vs 77%, P=0.01), with a higher median number of infusions (75 vs 6; P=0.05); no other clinical or biological baseline difference was found. Among those 92 3-year SROT patients, 74% had ≥2 years of additional follow-up: 46% (82%) attained 5-year SROT and 28% (38%) had relapsed after a mean follow-up of 13 months. Baseline clinical and biological characteristics of patients achieving 5-year SROT did not differ from those of 3-year SROT patients who relapsed. Among those 92 3-year SROT patients, 16 had ≥7 additional years of follow-up: 6 (38%) achieved 10-year SROT, ie 8% of 75 GPA with available data at 10 years, and 10 (63%) had a mean 35±28 months after achieving 3-year SROT.

Conclusion: Only 8% of GPA patients achieved 10-year SROT after conventional induction and maintenance therapies. No baseline clinical or biological characteristics helped distinguish patients achieving or maintaining SROT and those who relapsed. However, patients achieving 3-year SROT had received more intensive induction therapy than those who relapsed or were still on GC or IS at ≥3 years.

**AN INCREASE IN SERUM CALPROTECTIN LEVEL IN ANCA-ASSOCIATED VASCUITIS PATIENTS DURING MAINTENANCE THERAPY IS ASSOCIATED WITH MORE RELAPSE AND ACCELERATED RENAL FUNCTION DECLINE**

X. Romand1, A. Courtier2, M. V. C. Nguyen2, M. H. Paclet1, P. Gaudin1, L. Guillevin2, B. Terrier2, A. Baillet1. 1Univ. Grenoble Alpes, GREPI, Grenoble, France; 2Inserm, U 1209, Grenoble, France

Background: Calprotectin (S100A8/A9), a protein secreted by activated neutrophils and monocytes in inflammatory conditions, is upregulated in active ANCA-associated vasculitides. Serum calprotectin level variation during induction therapy is associated with disease relapse in PR3-ANCA-associated vasculitides (1). However, the place of this biomarker during maintenance therapy is unknown.

Objectives: To demonstrate whether variation in serum calprotectin level during maintenance therapy could be used as a biomarker predicting subsequent relapse in ANCA-associated vasculitides.

Methods: Patients with ANCA-associated vasculitides in complete remission (BVAS=0) after induction therapy with cyclophosphamide and included in the MAINRITSAN trial (2) were analyzed. Patients were randomized to receive rituximab or azathioprine as maintenance therapy. Relapse was defined as the re-occurrence or new onset of disease attributable to active vasculitis. Accelerated decline renal function (estimated Glomerular Filtration Rate (eGFR) measured using the MDRD equation) was defined in concordance with NICE 2015 guideline (3) as “a decrease in eGFR of ≥25% or more and a change in GFR category or a sustained decrease in eGFR of ≥20 mL/minute/1.73m² over 12 months.” Calprotectin was assessed in the serum at inclusion and 6 months by ELISA (IDK® Calprotectin ELISA kit. Immunodiagnostics). We defined an increase in serum levels of calprotectin as a positive variation of calprotectin level at M6 compared to baseline.

Results: Out of all, 96 patients (female 45.8%, mean age 55.3±13.5, 69.8% PR3+, 62.5% ANCA positive at inclusion) had at least a calprotectin dosage (86 at baseline, 86 at baseline, 86 at M6 and 76 patients at this 2 time-point). Calprotectin level at baseline or 6 months was not significantly different between relapsing patients and those without relapse after 18 months of follow-up, whereas the calprotectin variation at M6 compared to baseline was higher in relapsing patients (P=0.01) (mean SD) than in patients not experiencing any relapse (n=86) (94±19 (±50002) ng/mL; P=0.03). An increase in serum calprotectin level at 6 months was significantly associated with an increased risk of relapse in PR3-ANCA patients (P=5.6 (95%CI, 1,0-313; p=0.049) but not in the whole study group (P=3.3 (95%CI, 0.8-14; P=0.1), and 1), and identified patients with accelerated renal function decline (all cohort: OR=10.6 (95%CI, 2.9-39.6; p=0.002; PR3+ patients: OR=5.909 (95%CI, 2.9-39.6; p=0.001)), whereas calprotectin level did not correlate with glomerular filtration rate (P=-0.07, P=0.35).

Conclusion: An increase in serum calprotectin during the first 6 months of maintenance therapy in ANCA-associated vasculitides is a useful biomarker predicting vasculitis relapse and accelerated renal function deterioration in the following 12 months.

**AN INCREASE IN CALPROTECTIN SERUM AT 6 MONTHS IDENTIFIES RELAPSER AND ACCELERATED DECLINE RENAL FUNCTION AT 1 YEAR. KAPLAN-MEIER SURVIVAL CURVES OF ANCA-ASSOCIATED VASCUITIS PATIENTS WITH AN INCREASE IN CALPROTECTIN AT 6 MONTHS (SOLID LINE) OR NOT (DOTTED LINE) REMAINING TOTAL RELAPSE-FREE AND ACCELERATED DECLINE RENAL FUNCTION-FREE. GEHAN-BESLOW-WILCOXON TEST.**
Methods: We generated HL-A-B^*51^1^ ERAP1^ knockout (KO) LCL clones using CRISPR-Cas9-induced mass spectrometry of the immunoprecipitated MHC-class I peptideome with subsequent computational deconvolution for HL-A-B^*51^-binding peptides. We then analyzed single cell (ICS), bulk (ELISA) and proliferative (CFSE) CD8 effectors (IFNγ, granzyme B, perforin) cell responses through stimulation of allogeneic donor cells with WT vs KO LCL and determined ERAP1 haplotypes in 49 untreated TCGA GCA patients. Western blot and mass spectrometry analysis of peptide/protein expression in HEK293 and on T cell surface revealed the need of PBMCs with high expression of HLA-B51 (BD) whose PBMC were profiled using 6 colour flow cytometry panels.

Results: WT and KO peptides differed significantly (p=0.0007 Fisher's exact test) with a distinctive shift of peptide length frequencies exceeding 9-mer (binding optimum)

Results:

Objects: To test the hypothesis that low or absent ERAP1 activity alters CD8 T cell immunogenicity through changes in the HL-A-B51 peptideome and shapes the CD8 T cell immune response in affected subjects.

Methods: We generated HL-A-B^*51^1^ ERAP1^ knockout (KO) LCL clones using CRISPR-Cas9-induced mass spectrometry of the immunoprecipitated MHC-class I peptideome with subsequent computational deconvolution for HL-A-B^*51^-binding peptides. We then analyzed single cell (ICS), bulk (ELISA) and proliferative (CFSE) CD8 effectors (IFNγ, granzyme B, perforin) cell responses through stimulation of allogeneic donor cells with WT vs KO LCL and determined ERAP1 haplotypes in 49 untreated TCGA GCA patients. Western blot and mass spectrometry analysis of peptide/protein expression in HEK293 and on T cell surface revealed the need of PBMCs with high expression of HLA-B51 (BD) whose PBMC were profiled using 6 colour flow cytometry panels.

Results: WT and KO peptides differed significantly (p=0.0007 Fisher's exact test) with a distinctive shift of peptide length frequencies exceeding 9-mer (binding optimum) in the KO vs WT. This held true for computationally deconvoluted HL-A-B^*51^-binders. IFNγ secretion from CD8 T cells stimulated with KO LCL was significantly different when compared to WT (ICS: p=0.0006; ELISA: p=0.0059) as were CD8 T cell proliferation and ICS IFNγ secretion from CD8 T cells stimulated with KO LCL was significantly different with a distinctive shift of peptide length frequencies exceeding 9-mer (binding optimum) compared to WT. IFNγ secretion from CD8 T cells stimulated with KO LCL was significantly different with a distinctive shift of peptide length frequencies exceeding 9-mer (binding optimum) compared to WT.

Conclusions: We show that absence of functional ERAP1 alters human CD8 T cell immunogenicity. This is mediated by an HL-A class I peptideome with propensity for longer peptides above 9mer and suggests loss or de-novo presentation of peptide-HLA-B^*51^-complexes to cognate CD8 T cells. The reciprocal changes in antigen-experienced vs naive CD8 T cell subsets point to biologic significance of HLA-B^*51^-Hap10 in 10. Collectively, our findings suggest that an altered HL-A-B^*51^-peptideoma modulates immunogenicity of CD8 effector T cells in ERAP1-Hap10 carriers with BD and identify targets for future drug development.

Disclosure of Interests: None declared.

Objective: To optimize the treatment of patients with giant cell arteritis (GCA) in clinical practice.

Methods: We analyzed the treatment of 134 patients with GCA who were treated in a multicenter real-life study of 134 patients. We identified 2 groups: the optimized and the non-optimized group. We performed a matched case-control study. We evaluated the treatment regimen, the administration of corticosteroids, the follow-up of patients, and the relapses.

Results:

Table: Optimized-TCZ  VS  Non-Optimized-TCZ

<table>
<thead>
<tr>
<th>Age (years)</th>
<th>Mean±SD</th>
<th>Median (IQR)</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMARY-TCZ</td>
<td>68±11.7</td>
<td>60-78</td>
</tr>
<tr>
<td>NON-TCZ</td>
<td>69±11.7</td>
<td>60-78</td>
</tr>
</tbody>
</table>

The relapses were treated increasing TCZ up to the pre-optimization dose, in 1 case the dose was reduced. The mean TCZ treatment costs were lower in the optimized group. The end follow-up remission was higher in the optimized group.

Conclusions: Once remission is reached in GCA patients under TCZ treatment, optimization of TCZ may be performed. Based on our experience it could be performed by reducing the dose with IV TCZ or by prolonging dosing interval with SC TCZ.

Background: Patients with rheumatoid arthritis (RA) are at increased risk for venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE) (1). Several established risk factors of VTE, such as age, immobilization and comorbid conditions, occur more often in patients with RA (2). In addition, inflammation may in itself also increase VTE risk by upregulating procoagulatory factors and causing endothelial damage (3). Recent reports indicate an increased risk of VTE in RA patients treated with JAK-inhibitors (4), pointing to the need to better understand how inflammation measured as clinical RA disease activity influences VTE risk.

Objectives: To investigate the relationship between clinical RA disease activity and incidence of VTE.

Methods: Patients with RA were identified from the Swedish Rheumatology Quality Register (SRQ) between July 1st 2006 and December 31st 2017. Clinical rheumatology data for these patients were obtained from the visits recorded in SRQ, and linked to national registers capturing data on VTE events and comorbid conditions. For each such rheumatologist visit, we defined a one-year period after the visit and determined whether a VTE event had occurred within this period or not. A visit followed by a VTE event was categorized as a case, all other visits were used as controls. Each patient could contribute to several visits. The DAS28 score registered at the visit was stratified into remission (0-2.5) vs. low (2.6-3.1), moderate (3.2-5.1) and high (>5.1) disease activity. Logistic regression with robust cluster standard errors was used to estimate the association between the DAS28 score and VTE.

Results: We identified 46,311 patients with RA who contributed data from 320,094 visits. Among these, 2,257 visits (0.7% of all visits) in 1,345 unique individuals were followed by a VTE within the one-year window, and odds ratios for VTE by each DAS28 category, using DAS28 remission as reference. The one-year risk of a VTE increased from 0.5% in patients in DAS28 remission, to 1.1% in patients with DAS28 high disease activity (DAS28 above 5.1). The age- and sex-adjusted odds ratio for a VTE event in highly active RA compared to RA in remission was 2.12 (95% CI 1.80-2.47). A different analysis, in which each patient could only contribute to one visit, yielded similar results.

Conclusion: This study demonstrates a strong association between clinical RA inflammatory activity as measured through DAS28 and risk of VTE. Among patients with high disease activity one in a hundred will develop a VTE within the coming year. These findings highlight the need for proper VTE risk assessment in patients with active RA, and confirm that patients with highly active RA, such as those recruited to trials for treatment with new drugs, are already at particularly elevated risk of VTE.

Background: Methotrexate (MTX) is a key anchor drug for rheumatoid arthritis (RA) management. Its use has been associated with hypersensitivity pneumonitis and diffuse lung disease. Whether MTX exposure increases the risk of interstitial lung disease (ILD) in patients with RA is disputed.

Objectives: We aimed to evaluate the association of antecedent MTX use with development of RA-ILD.

Methods: Through a case-control study design with derivation and international validation samples, we examined the association of MTX exposure with ILD in 412 patients with RA-ILD and 741 patients with RA without ILD. Estimates were pooled over the different samples using meta-analysis techniques.

Results: Analysis of the derivation sample revealed an inverse relationship between MTX exposure and RA-ILD (adjusted odds ratio [OR] 0.48; 95% confidence interval [CI], 0.25 to 0.92; P=0.028), which was confirmed in the validation samples (pooled adjusted OR, 0.39; 95% CI, 0.23 to 0.68; P<0.001). The combined estimate using both the derivation and validation samples revealed an adjusted OR of 0.43 (95% CI, 0.28 to 0.69) for MTX ever users compared to those without ILD, irrespective of chest high resolution computed tomography pattern. In patients with RA-ILD, ILD onset was significantly delayed in MTX ever users compared to never users (115.1 ± 10.6 years and 3.7 ± 7.1 years, respectively; P<0.001).

Conclusion: Our results suggest that MTX is not a risk factor for RA-ILD and support a possible disease modifying effect of MTX on development of RA-ILD.

NON-ANTI-TNF BILOGIC AGENTS ARE ASSOCIATED WITH LESS MARKED PROGRESSION OF INTERSTITIAL LUNG DISEASE SECONDARY TO RHEUMATOID ARTHRITIS

N. Mena-Vázquez52, F. Godoy-Navarrete1, I. Añón Qhate2, C. M. Romero-Borco3, L. Pérez Albaladejo4, A. Fernandez-Nebro1, Instituto de Investigación Biomédica de Málaga – IBIMA, UGC de Reumatología, Hospital Regional Universitario de Málaga, Málaga, Spain; Complejo Hospitalario de Jaén, Jaén, Spain; Hospital Universitario Virgen de la Victoria de Málaga (HUVM), Málaga, Spain; Hospital Virgen de las Nieves de Granada, Granada, Spain

Background: We performed a multicenter, prospective, observational study of patients with ILD-RA receiving DMARDs between 2015 and 2017. The patients were assessed using high-resolution computed tomography and lung function tests at baseline and at 24 months. The radiological assessment was centralised.

Objectives: To analyze the effect of disease-modifying anti-rheumatic drugs (DMARDs) on the outcome of interstitial lung disease secondary to rheumatoid arthritis (ILD-RA).

Results: We included 70 patients with ILD-RA treated with DMARDs. The main baseline characteristics are shown in Table 1. After 24 months, lung disease did not progress in 40 patients (57.1%), improved in 8 (11.4%), and progressed in 21 (30.0%). One patient (1.4%) died. The factors associated with progression of ILD in the multivariate analysis were treatment with abatacept, tocilizumab, or rituximab (OR, 0.102 [95% CI, 0.015-0.686], SAS28, OR, 1.969 [95% CI, 1.005-3.857], and smoking (OR, 6.937 [95% CI, 1.378-4.900)). During follow-up, 30 patients (42.9%) experienced an adverse event, which was severe in 12 cases (17.1%).

Conclusion: Lung function is stable and inflammatory activity well controlled in most patients with ILD-RA receiving treatment with DMARDs. Non-anti-TNF DMARDs reduce the risk of progression of lung disease in 90% of patients, whereas the inflammatory activity of RA and smoking are associated with progression.
ARTHRITIS PATIENTS FOR INTERSTITIAL LUNG DISEASE

**Geographic Characteristics of Interstitial Lung Disease in Rheumatoid Arthritis Patients: A Multicenter Study**

**Objective:**
Objectives: To evaluate the merit of 3 circulating markers for the diagnosis and the progression of RA-ILD.

**Methods:**
Methods: We included consecutive patients with RA, >18 years of age, from 3 tertiary rheumatology centers (Paris, France, Tokyo, Japan) over a 36-month period. All patients had at least one chest HRCT during the inclusion period. In the subset of French patients with ILD, HRCT lung images were obtained both at baseline (time of blood sample collection) and at a follow-up visit. The ILD status of patients with RA was established by chest HRCT. The chest HRCT pattern was classified as usual interstitial pneumonia, UIP or non-specific interstitial pneumonia, NSIP, by the local radiologist. Serum concentrations of SPD, CCL-18 and KL-6 were measured from baseline and at follow-up visits.

**Results:**
Results: 147 patients were included (age: 66 +/-12 years). Levels of SPD, CCL18 and KL-6 were significantly higher in patients with RA-ILD vs. non-affected RA patients. KL-6 values were also higher in patients with UIP compared to the other HRCT patterns and in patients with lesion progression. The sensitivity of KL-6 for the diagnosis of RA-ILD was 68% with a specificity of 83%. In the French subset with longitudinal data (n=15), extension of ILD was detected on 7 patients. Baseline KL6 serum levels were significantly increased in patients who experienced ILD progression (1987 +/-1294 vs. 799 +/-375 U/mL, p = 0.027) (Figure 1E). The degree of ILD progression on HRCT was also proportional to baseline KL-6 concentrations (Figure 1F).

**Conclusion:**
Conclusion: KL-6 is relevant for the diagnosis and the prognosis of RA-ILD. It may be used as a circulating non-invasive first-line marker to stratify for indication of HRCT. Indeed, given the emerging lung issues in RA patients, this simple and highly reproducible marker, which is already available in routine care in some countries, could be a good prerequisite to chest HRCT in rheumatology clinics.

**Background:**
Background: Interstitial lung disease (ILD) is the most common pulmonary manifestation of rheumatoid arthritis (RA). It has emerged in recent series as a key prognostic factor including survival. This big challenge for rheumatologists is how to use routine markers for ILD in RA. High-resolution computed tomography (HRCT) is the gold standard for RA-ILD diagnosis, but costs and irradiation may limit its use in clinical practice. Thus, circulating biomarkers may be used as a circulating non-invasive first-line marker to stratify for indication of HRCT. Indeed, given the emerging lung issues in RA patients, this simple and highly reproducible marker, which is already available in routine care in some countries, could be a good prerequisite to chest HRCT in rheumatology clinics.

**Methods:**
Methods: Circulating biomarkers could aid in this risk-stratification. The big challenge for rheumatologists is how to use routine markers for ILD in RA. **HOSPITALIZATION AND MORTALITY OUTCOMES IN RHEUMATOID ARTHRITIS PATIENTS WITH LUNG DISEASE**

S. Pedro1,2, T. Mikulas3,4, J. Zhuo5, K. Michaud1,2.

---

**Background:**
Background: Pulmonary manifestations such as interstitial lung disease (ILD) and chronic obstructive pulmonary disease (COPD) are frequent extra-articular features that carry a poor prognosis in rheumatoid arthritis (RA). Prior studies have demonstrated that respiratory-related mortality is the most overrepresented cause of death in RA.
Discriminatory: To assess the risk of all-cause and respiratory-related hospitalization and mortality in RA patients with concomitant lung disease (LD) in comparison to those without and the differential risks associated with DMARD treatments.

Methods: Eligible RA patients included in the Forward Databank with ≥1 year observation after 2000 and had initiated a DMARD. Forward is a large longitudinal rheumatic disease registry in the US. RA patients’ diagnoses were rheumatologist-confirmed, and every 6 months participants completed comprehensive questionnaires regarding symptoms, disease outcomes, medications, and clinical events. LD was defined as one of the following: emphysema, asthma, bronchitis, COPD, pleural effusion, fibrosis of the lung, “RA lung,” or LD (England 2019). DMARDs were categorized hierarchically into four groups: csDMARDs, TNFi and NTNFi (bDMARDs), and tsDMARDs. Patients were followed from DMARD initiation until event (death and/or hospitalization) or end of follow-up, whatever came first. Events were validated using medical records and the US National Death Index. Respiratory hospitalizations and deaths were identified using ICD9 (460-519). Events were analyzed using incidence rates (IR) and Cox regression models. Models were adjusted for LD, DMARDs, age, sex, education, HAQ disability, Rheumatic Disease comorbidity index, smoking, pain, glucocorticoids, year of entry, prior bDMARDs and csDMARDs counts and MRC breath scale.

Results: Of the 21,525 eligible RA patients, 13.8% had LD at the time of DMARD initiation. Patients had 59 years old in both groups and 15% were male for LD+ vs 21% for LD-. Patients with LD+ showed worse disease outcomes (HAQ: 1.3 (0.7) vs 1.0 (0.7)) and comorbidities (2.9 (1.9) vs 1.5 (1.4)) overall and for all treatment groups, especially for NTNFi and tsDMARDs. The overall IR of any all-cause or respiratory-related events were higher in LD+ than LD- RA patients and across any DMARD treatments, with NTNFi having higher IR (Figure). In survival analyses, LD+ was associated with an increased risk for any-all-cause hospitalizations/deaths (HR 1.3; 95% CI 1.1-1.4) and a 3.95-fold increased risk of respiratory-related events (HR 4.0; 3.2-4.9) (Table). These risks did not differ significantly across DMARD treatment groups. Increased age, HAQ disability, comorbidities, glucocorticoids, prior bDMARDs and worse MRC breath scales were associated with an increased risk in both outcomes and smoking in respiratory-specific events.

Conclusion: An increased risk of hospitalizations and/or deaths was demonstrated for RA patients with lung disease, most notably a 4-fold increased risk for respiratory-related events. No differences were found between incident DMARD groups. Additional studies accounting for channeling of treatments by baseline comorbidities, glucocorticoids, prior bDMARDs and worse MRC breath scales are needed.

Results: The study population was mainly composed of females (84%), of whom 64.3% were in post-menopause; the mean (SD) age was 57.4 (13.5) years. Median (IQR) symptoms duration before treatment start was 14 (9-24) weeks. Forty-three percent of the patients was ACAPLA positive. After 24 months of treatment, LDA was achieved in 79% of the cases, and remission in 46%; 177% of the patients had initiated a biological DMARD. At DXA re-scanning, the BMD at the lumbar spine and total hip remained largely unchanged, whilst at the femoral neck decreased from 0.726 g/cm2 to 0.713 g/cm2 (mean difference [SD] -0.013 (0.056), p=0.02). Predictors of BMD changes at different sites are shown in Table 1. The cumulative dose of prednisone was borderline significant for more BMD loss at the lumbar spine; r -0.126, p=0.04 at the femoral neck. Cumulative disease activity did not significantly affect BMD changes. Rather, ACAPLA-positive patients had higher percent changes at both the lumbar spine and the femoral neck. In multivariable analyses, ACAPLA remained associated with more BMD loss even when adjusting for confounders (age, gender, cumulative steroids, bisphosphonate treatment) (r -0.126, p=0.04 at the lumbar spine; r -0.126, p=0.04 at the femoral neck).
Pathogenic insights transforming the treatment of Sjögren’s and SLE 2020 and beyond

THE TRANSCRIPTOME OF PAIRED MINOR AND MAJOR SALIVARY GLAND TISSUE IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: TWO OF A KIND?

G. M. Verstappen, M. Gao, S. A. Pringle, S. C. Liebers, B. Van der Vegt, P. Patel, S. Hu, S. Mukherjee, A. Vissink, H. Bootsma, F. G. Kroese. 1University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2Bristol-Myers Squibb, Princeton, United States of America; 3University of Groningen, University Medical Center Groningen, Oral and Maxillofacial Surgery, Groningen, Netherlands; 4University of Groningen, University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands

Background: In patients with primary Sjögren’s syndrome (pSS), both minor and major salivary glands are targets of the disease. Infiltration of salivary gland by immune cells is characteristic for pSS. However, significant inter- and intra-individual variation exists in the size and composition of the infiltrates. Potential differences between minor and major salivary glands in immune cell presence and inflammatory pathway activation are unclear. This knowledge is essential for clinical trial design and precision therapy.

Objectives: To compare the transcriptomes of paired labial and parotid salivary gland tissue of patients with pSS and non-SS sicca controls.

Methods: Thirty-nine pSS patients and 20 age- and sex-matched non-SS sicca controls, who participated in a prospective diagnostic cohort[1], were included. All pSS patients fulfilled 2016 ACR-EULAR criteria. RNA was isolated from formalin-fixed, paraffin-embedded and labial and parotid gland tissue sections from the same individuals. Complementary DNA libraries were prepared and sequenced. Biopsies with evidence of sclerosing chronic sialoadenitis or mucosa-associated lymphoid tissue lymphoma were excluded in the current analysis. For differential gene expression analysis, patients were subdivided in four categories: I) non-SS sicca without lymphocytic infiltration, II) non-SS sicca with aspecific infiltration, III) pSS with positive biopsy (focus score≥1), IV) pSS with positive biopsy (focus score<1). For each differentially expressed gene (DEG), a false detection rate (FDR) was calculated. FDR<0.05 was considered significant.

Results: Principal component analysis (PCA) showed that only pSS patients with a positive biopsy (group IV) could be separated from the non-SS sicca patients based on gene expression. When comparing the labial and parotid gland transcriptome, resp. 798 and 1461 DEGs (FDR-adjusted p-value<0.05, log2 fold change >1) were identified between groups I and IV. The top differentially regulated genes were mostly related to T and B cells. C2CL13, CCR6, MS4A1 (CD20), FCRL4 and DAZL were among the genes with the highest positive fold change in both glands of biopsy-positive pSS patients. Overall, there was a moderate to strong correlation between fold changes in labial and parotid glands (R²=0.58, p-value=0.0001). Between biopsy-negative and biopsy-positive pSS patients (groups III and IV), 226 and 962 DEGs were identified for labial and parotid gland tissue, respectively. Interestingly, we could not identify DEGs between biopsy-negative pSS (group III) and non-SS sicca patients (group I).

Conclusion: The transcriptome of labial and parotid gland tissue from pSS patients with a positive biopsy is overall comparable, while salivary gland tissue from biopsy-negative pSS patients shows a comparable gene expression profile to non-SS sicca controls. These results indicate that different treatment strategies may be necessary for biopsy-negative and biopsy-positive pSS patients.

Background: There is an ongoing effort to elucidate the molecular pathways that are key to kidney injury in lupus nephritis (LN). One approach is to study the transcriptome utilising kidney tissue obtained during diagnostic renal biopsy [1]. In clinical practice the most common tissue that is suitable to diagnostic requirements is formalin-fixed paraffin-embedded (FFPE) tissue. However, due to RNA degradation, transcriptomic analysis has been sub-optimal and challenging using standard procedures. The NanoString technology platform has the advantage that reliable detection of transcripts can be achieved even with degraded RNA. In this study we explored the utility of NanoString technology in identifying transcripts in RNA isolated from archival FFPE kidney biopsy sections in a cohort of patients with LN.

Objectives: To explore the utility of the NanoString platform in elucidating a renal transcriptomic signature in formalin-fixed paraffin-embedded Lupus Nephritis kidney biopsy tissue.

Methods: We utilised well defined Class III (n=11); Class IV (n=22) and Class V (n=24) LN FFPE kidney biopsy specimens from female patients attending the Imperial College Healthcare NHS Trust. We excluded biopsies with mixed lesions or chronic lesions (i.e. significant glomerular scarring). Kidney biopsies from patients with Thin Basement Membrane (TBM; n=14) disease were used as controls. Six 10 micron thick sections were obtained from each biopsy and RNA isolated using the Qiagen RNasey FFPE Kit. 100 micrograms of RNA was used for the detection of transcripts. We used the NanoString PanCancer immune profiling panel (770 transcript probes) and an additional 30 custom designed probes, enabling us to detect 800 transcripts, including 40 reference genes. Transcript analysis was performed according to manufacturer’s instructions using the NanoString nSolver software. When analysing differential gene expression (DGE) we used Benjamin-Hochberg adjustment to account for multiple testing. The threshold for nSolver software. When analysing differential gene expression (DGE) we used an adjusted P value of 0.05 (5% false discovery rate) accounting for multiple testing. The threshold for the NanoString PanCancer immune profiling panel in elucidating a renal transcriptomic signature in formalin-fixed paraffin-embedded Lupus Nephritis kidney biopsy tissue.

Results:

- **Results:** statistical significance was an adjusted P value of 0.05 (5% false discovery rate). Benjamini-Hochberg adjustment to account for multiple testing. The threshold for nSolver software. When analysing differential gene expression (DGE) we used an adjusted P value of 0.05 (5% false discovery rate) accounting for multiple testing.

- **Objectives:** To explore the utility of the NanoString platform in elucidating a renal transcriptomic signature in formalin-fixed paraffin-embedded Lupus Nephritis kidney biopsy tissue.

controls, IFN-γ in 89% of pts vs. 66% of controls, IL-6 in 53% of pts vs. 12% of controls and in IFN-α 41% of pts vs. 2% of controls; detection of serum IL-2, GM-CSF, IL-6, IL-10 and IL-17A was variable (Fig 1). At baseline (wk 0), IL-12/23-p40 was positively correlated with SLEDAI and IFN gene signature and negatively correlated with serum C4. IL-6 was positively correlated with joint swelling, joint tenderness, IFN-γ and C3. Serum IFN-α was positively correlated with serum IFN-γ, anti-Sm and anti-RNP, and the IFN gene signature (Fig 2). Treatment with bari 4 mg (Fig 1B) significantly decreased serum IL-12/23-p40 and IL-6 cytokine levels at wk 12 (p<0.05) but not serum IFN-α or IFN-γ levels (Fig 1B).

**Figure 2**

Spearman Correlation Coefficients of JAHN Baseline Variables

Conclusion: Bari 4 mg treatment was associated with statistically significant decreases of serum IL-12/23-p40 and IL-6 at week 12 which continued through week 24. Serum IFN-α or IFN-γ were not reduced with bari treatment. Thus, bari 4 mg simultaneously impacted multiple pro-inflammatory cytokines implicated in the pathogenesis of SLE.

Lino L. Teichmann, Dominik Schenthen, Ruslan Medzhitov, Michael Kashgarian, and Mark J. Shlomchik. Immunity, 2013 March 21; 38(3): 528–540.

Results: A total of 3232 cases and 17481 controls genotyped on GWAS arrays and 619 cases and 6171 controls genotyped on ImmunoChip (IC) arrays were imputed after quality control. Logistic regression was calculated adjusting for national risk loci of genome-wide significance (GWS; p<5E-08) in European-derived primary SS. Meta-analysis with IC data identified three more novel loci exceeding GWS: CD247, PRDM1-ATG5 and TNFAIP3. Several additional loci with suggestive association (p<1E-05) were also identified: ADAMTS12, CGNL1 and PHRF1.

Identified loci have reported functional implications in immune regulation and autoimmune disease. In lupus, rs2431697 correlated with rs142714, which was shown to alter MIR146A expression, resulting in type I interferon pathway imbalance. Similarly, TYK2 association reportedly drives interferon, IL10 and RET signaling pathways. PRDM1 encodes Blimp-1, a master regulator of immune cell differentiation. CD247 encodes the zeta subunit of the T cell receptor complex. KXRB6 is implicated in apoptotic cell ingestion. AT3G is also involved in apoptosis, as well as autophagy and antigen presentation.

Additional bioinformatics analyses (Haploreg, Regulome DB, ENCODE, etc.) revealed immune-relevant functional implications for each risk locus. The SS-associated credible set included variants downstream of TNFAIP3 in a region reported to abolish looping between an enhancer and the TNFAIP3 promoter in lupus and a coding variant that has been shown to alter NF-kB activity and neutrophil extra-cellular traps. The rs2293765 in the 5’ UTR of NAB1 showed evidence of enhancer/promoter activities. The rs209635 in the SYNGR1 locus showed enhancer and transcription start site activities in B and T cells. The rs7210219 in the MAPT-CHRNA1 locus showed enhancer/promoter activities in various tissues.

Conclusion: We have identified ten novel genetic susceptibility loci associated with SS pathology. Our finding increases the current number of GWS regions in SS patients of European origin, from 10 to 20. Future work is needed to identify and characterize the functional variants in each region.

TYPE I INTERFERON EXPRESSION IDENTIFIES DIFFERENT SUBSETS OF ANTI-phospholipid SYNDROME

I. Cecchi1, M. Radin1, E. Rubini1, S. G. Fodda1,2, A. Suárez3, S. Sicasia1, D. Roccato1, J. Rodríguez-Carrio1. 1Department of Clinical and Biological Sciences, Center of Research of Immunopathology and Rare Diseases Coordinating Center of Piemonte and Valle d’Aosta Network for Rare Diseases, Turin, Italy; 2School of Specialization of Clinical Pathology, Department of Clinical and Biological Sciences, University of Turin, Turin, Italy; 3Department of Functional Biology, Immunology Area, Faculty of Medicine, University of Oviedo, and Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain

Background: Type I Interferons (IFN) play a key role in the pathogenesis and development of various autoimmune conditions. Among them, a small amount of data demonstrates that the expression of various IFN regulated genes (IRGs), the so-called “IFN signature” has been linked to disease activity and disease progression in systemic lupus erythematosus (SLE) patients. Nevertheless, to date, a limited number of studies have analysed the IFN signature in antiphospholipid syndrome (APS) setting.

Objectives: This study aims to describe the activation and structure of the type I IFN signature among different subsets of APS, including primary APS (PAPS) and when associated with other autoimmune conditions (secondary APS - SAPS), and antiphospholipid antibodies positive individuals (“aPL carriers”).

Methods: A total of 116 patients were enrolled, including 19 PAPS patients, 13 SAPS, 75 SLE patients, and 9 aPL carriers [1,2]. Thirty-two subjects were also recruited as healthy controls (HCs). IFI44, IFI44L, IFI6, MX1 and IRF4 gene expression was determined in whole blood in the entire cohort. Expression levels were normalized to Z-scores and averaged into a global IFN signature. Differences were measured by Kruskal-Wallis tests and associations among genes were studied by cluster and correspondence analyses. Correlations were plotted by network analyses.

Results: A global activation of the type I IFN signature was observed (HCs: -0.44±0.08, aPL carriers: -0.38±0.12, PAPS: -0.31±0.80, SAPS: -0.17±0.39, SLE: 0.05±0.80; p(Kruskal-Wallis)< 0.001). A certain degree of heterogeneity was observed among IRGs: MX1 being increased in all patient groups (all p< 0.001), whereas IFI44 was only increased in SLE (p< 0.001) and PAPS (p< 0.001), and both IFI44L and IFI6 were increased in SLE (both, p< 0.001) and a trend was observed in SAPS (p=0.060 and p=0.800) (Figure 1). By means of an unsupervised analysis, 3 clusters (I to III) were identified, which correlated with clinical status of the patients by correspondence analysis (p=0.0001, Figure 2a). Network analyses revealed different structures of the IRGs networks among groups, from weaker networks in HCs and aPL carriers to stronger degree of correlations among IRGs in SAPS and SLE, thus pointing to diverse expression programs (Figure 2b). Among APS patients (both SAPS and PAPS), the IFN signature was positively associated with anti-phosphatidyserine/prothrombin antibodies IgG levels (r=0.478, p=0.003), but no associations were observed for the IgM isotype nor with other autoantibodies specificities (all p >0.050). No associations were observed with traditional cardiovascular risk factors or current treatments (all p >0.050).

Conclusion: In line with other autoimmune conditions, APS is associated with a broad type I IFN activation, with distinct profiles of the IFN signature structure among different clinical subsets, suggesting that different pathogenic pathways are involved in the pathogenesis of these conditions.

Efficacy of Anifrolumab in Active Systemic Lupus Erythematosus: Patient Subgroup Analysis of BICLA Response in 2 Phase 3 Trials

1Monash University, Melbourne, Australia; 2Zucker School of Medicine at Hofstra/Northwell, Great Neck, United States of America; 3University of Occupational and Environmental Health, Japan, Kitakyushu, Japan; 4BioPharmaceuticals Medical, AstraZeneca, Gothenburg, Sweden

Background: Treatment of patients with systemic lupus erythematosus (SLE) with the type I interferon (IFN) receptor inhibitor anifrolumab resulted in higher British Isles Lupus Assessment Group (BILAG)–based Composite Lupus Assessment (BICLA) response rates vs placebo at Week 52 in the phase 3 randomized trials, TULIP-2 (primary endpoint; 16.3% difference)1 and TULIP-1 (secondary endpoint; 16.4% difference).2 BICLA is a validated composite global disease measure that registers both partial and complete improvement within organ systems.3

Objectives: TULIP-2 and TULIP-1 data were analyzed to evaluate BICLA responses to anifrolumab vs placebo at Week 52 in protocol-defined subgroups of patients with active SLE.

Methods: TULIP-2 and TULIP-1 were randomized, double-blind, placebo-controlled trials that evaluated efficacy and safety of intravenous anifrolumab vs placebo administered every 4 weeks, with the primary endpoints assessed at Week 52, in patients with moderate to severe SLE despite standard-of-care treatment.2,3 BICLA responses are defined by all of the following: reduction of baseline BILAG-2004 A and B domain scores to B/C/D and C/D, respectively, and no worsening in any organ system; no worsening of the SLE Disease Activity Index 2000 (SLEDAI-2K) score; no worsening of ≥0.3 points in the Physician’s Global Assessment (range 0–3); no trial treatment discontinuation; and no use of medications restricted by the protocol.3 BICLA responses were assessed across protocol-defined subgroups. TULIP-1 data were analyzed incorporating the amended restricted medication rules, as described.2

Results: In TULIP-2 and TULIP-1, 180 patients in each trial received anifrolumab 300 mg (182 and 184 patients received placebo, respectively). Baseline demographics, disease characteristics, and standard-of-care medications were balanced between anifrolumab and placebo groups within both TULIP trials. Patients in TULIP-2 and TULIP-1 had comparable BICLA responses (Figure). Across multiple subgroups, higher percentages of patients achieved BICLA responses at Week 52 in the anifrolumab vs placebo arms (Figure). Concordance of BICLA responses favoring anifrolumab across the protocol-defined subgroups of baseline disease severity (SLEDAI-2K ≤10 points [difference 15.3%, TULIP-2; 16.9%, TULIP-1] vs ≥10 points [difference 16.7%, TULIP-2; 17.1%, TULIP-1] and baseline oral corticosteroid use [prednisone or equivalent <10 mg/d [difference 20.1%, TULIP-2; 16.2%, TULIP-1] vs ≥10 mg/d [difference 12.0%, TULIP-2; 7.5%, TULIP-1]).

DOI: 10.1136/annrheumdis-2020-eular.3557
Psoriatic arthritis and its management: it’s more than just synovitis...
Background: We have previously reported that the presence of musculoskeletal pain in psoriasis patients is associated with a higher risk of developing psoriatic arthritis (PsA) (1). Furthermore, a subset of psoriasis patients shows evidence for structural enthesal lesions (SEL) in their hand joints (2), sometimes also referred to as "Deep Koebner Phenomenon", which are highly specific for psoriatic arthritis and virtually absent in healthy controls, rheumatoid arthritis and hand osteoarthritis patients (2-4). However, it remains unclear whether SEL alone or in combination with musculoskeletal pain are associated with the development of PsA.

Objectives: To test whether the presence of SEL in psoriasis patients increases the risk for progression to PsA and how this is related to the presence of musculoskeletal pain.

Methods: Psoriasis patients without evidence of PsA were enrolled in a prospective cohort study between 2011 and 2018. All patients underwent baseline assessment of SEL in their 2nd and 3rd MCP joints by high-resolution peripheral quantitative computed tomography (HR-pQCT). The risk of PsA development associated with SEL and arthralgia was explored using survival analyses and multivariable Cox regression models.

Results: 114 psoriasis patients (72 men/42 women) with a mean (SD) follow-up duration of 28.2 (17.7) months were included, 24 of whom developed PsA (9.7/100 patient-years, 95%CI 6.2 to 14.5) during the observation period. Patients with SEL (N=41) were at higher risk of developing PsA compared to patients without such lesions (21.4/100 patient-years, 95%CI 12.5 to 34.3, HR 5.10, 95%CI 1.53 to 16.99, p=0.008) (Kaplan Meier plot A). Furthermore, while patients without arthralgia and without SEL had a very low progression rate to PsA (1/29; 3.4%), patients with arthralgia but no SEL showed higher progression (5/33; 15.2%), which was in line with previous observations (1) (Kaplan Meier plot B). Presence of SEL further enhanced the risk for progression to PsA both in the absence (6/16; 37.5%) and presence (6/14; 42.8%) of arthralgia with the highest progression rate in those subjects with both arthralgia and SEL (p<0.001 by log rank test for trend) (Kaplan Meier plot B).

Conclusion: Presence of SEL is associated with an increased risk of developing PsA in patients with psoriasis. If used together with pain, SEL allow defining subgroups of psoriasis patients with very low and very high risk to develop PsA.

DOI: 10.1136/annrheumdis-2020-eular.1524
had ≥ 1 PsA manifestation when axPsA was investigated defined, of whom 630 (85.9%) had multiple manifestations; the most common presentations were PA + skin (16.2%), PA + skin + nail (12.8%), and enthesitis + PA + nail + skin (7.8%). When using the criteria for elevated spine symptoms, 732 biologic initiators had ≥ 1 disease manifestation, of whom 650 (88.8%) had multiple manifestations; the most common presentations were PA + skin (11.7%), PA + skin + nail (8.5%), and PA + axPsA + skin (6.3%). The prevalence of skin, PA, and dactylitis was higher in those with elevated spine symptoms vs investigator-defined axPsA, whereas the prevalence of enthesitis was higher in those with investigator-defined axPsA (Figure 1B and 2B).

**Figure 2. Prevalence of (A) PsA/Disease Manifestations and (B) Other Manifestations With Axial Disease in the Biologic Initiator Population**

The heat map represents the frequency of any 2 domain combinations by the range of blue shades, with the darkest blue color specifying the highest frequency and the lightest blue specifying the lowest frequency of combinations.

**Conclusion:** In the Corona PsA/SpA Registry, there was a higher number of patients with elevated spine symptoms than with investigator-defined axPsA; these patients also had more coexisting manifestations. Although they may have had other reasons for back pain (ie, degenerative spine disease or central sensitization), it is possible that axPsA could be present in some and this warrants further evaluation.

**OP0053 SECUKINUMAB IMPROVES CLINICAL AND IMAGING OUTCOMES IN PATIENTS WITH PSORIATIC ARTHRITIS AND AXIAL MANIFESTATIONS WITH INADEQUATE RESPONSE TO NSAIDS: WEEK 52 RESULTS FROM THE MAXIMISE TRIAL**

X. Baraliakos1, L. Gossec2, E. Pournara3, S. Jeka4, R. Blanco5, S. D’angelo6, G. Scher7, B. Schult8, M. Riseler9, K. Naga9, C. Perella9, L. C. Coates9, 1Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Bochum, Germany; 2Sorbonne Universités, Paris, France; 3Novartis Pharma AG, Basel, Switzerland; 42nd University Hospital, CM UMK, Bydgoszcz, Poland; 5Hospital Universitario Marqués de Valdecilla, Santander, Spain; 6Rheumatology Department of Lucania and Rheumatology Institute of Lucania (IRel), San Carlo Hospital of Potenza, Potenza, Italy; 7University of Erlangen-Nuremberg, Erlangen, Germany; 8Novartis Healthcare Pvt Ltd., Hyderabad, India; 9University of Oxford, Oxford, United Kingdom

**Background:** Although axial disease may affect up to 70% of patients (pts) with Psoriatic Arthritis (PsA), evidence on the efficacy of biologics in the treatment of axial manifestations in such pts is limited, particularly as validated classification criteria for this subtype of PsA are not yet available. MAXIMISE (NCT02721966) is the first randomised controlled trial evaluating the efficacy of a biologic in the management of the axial manifestations of PsA and showed that secukinumab (SEC) 300 and 150 mg provided rapid and significant improvement in ASAS20 responses in these pts through week (Wk) 12.2

**Objectives:** To present 52 wks efficacy results and imaging data from the MAXIMISE trial.

**Methods:** This phase 3b, double-blind, placebo (PBO)-controlled, multicentre 52-wk trial included 498 pts (aged ≥ 18 years) with a diagnosis of PsA and classified by CASPAR criteria, spinal pain VAS score ≥ 40/100 and BASDAI score ≥ 4 despite use of at least two NSAIDs. Pts were randomised to SEC 300 mg (N=167) or SEC 150 mg (N=165) or PBO (N=166) wks for 4 wks and every 4 wks thereafter. At Wk 12, PBO pts were re-randomised to SEC 300/150 mg. The primary endpoint was ASAS20 response with SEC 300 mg at Wk 12. The key secondary endpoint was ASAS20 response with SEC 150 mg at Wk 12. Wk 52 data are presented as observed. Bone marrow oedema of the entire spine and sacroiliac joints were assessed centrally with Berlin MRI scores at Baseline, Wk 12 and Wk 52.

**Results:** Primary and key secondary endpoints were met; ASAS20 responses were sustained and increased further through Wk 52. 75%/79.7% of the PBO pts re-randomised at Wk 12 to SEC 300/150 mg achieved ASAS20 response at Wk 52 (Figure 1). ASAS40 responses at Wk 52 were 69.1% [SEC 300 mg], 64.5% [SEC 150 mg], 62.5% [PBO-SEC 300 mg], and 54.1% [PBO-SEC 150 mg]. At baseline, 59.5% [SEC 300 mg], 53.5% [SEC 150 mg] and 64.2% [PBO] of the pts had positive MRIs for the sacroiliac joints and/or the spine with Berlin MRI score ≥ 1. The reductions of Berlin MRI score for entire spine and sacroiliac joints were statistically significant for pts treated with SEC 300/150 vs. placebo (Figure 2 a and b). There were no new or unexpected safety findings.

**Conclusion:** Secukinumab improved all evaluated ASAS responses through Wk 52 in PsA pts with axial manifestations and inadequate responses to NSAIDs.
Results: 312 pts presented with axial involvement (PBO, n= 118; GUS q8w, n = 91; GUS q4w, n = 103). The LS mean changes from baseline to wk24 in BASDAI, spinal pain, mBASDAI, and ASDAS-CRP were greater in the two GUS groups vs PBO (Table). Greater proportions of GUS-treated pts achieved BASDAI50 (Table) and ASDAS responses of inactive disease, major improvement, and clinically important improvement (Figure) at wk24 vs PBO.

Conclusion: GUS improved axial symptoms over 24 weeks in active PsA patients with imaging-confirmed sacroiliitis.

Table. Efficacy of GUS in PsA patients with axial involvement at week 24.

MINIMAL RADIOGRAPHIC DAMAGE OF SACROILIAC JOINTS DETECTED IN PSORIATIC ARTHRITIS PATIENTS

M. De Hooge1, 2, A. Ishchenko3, S. Steinfeld4, A. Nzeusseu Toukap5, D. Elewaut1, 2, H. Leroi6, R. Lories3, 7, K. De Vlam3, 7, F. Van den Bosch1, 2 on behalf of the BEPAS Study Group.

Background: Psoriatic arthritis (PsA) is an inflammatory joint disease that is traditionally included in the Spondyloarthritides (SpA) spectrum. Prevalence and impact of axial involvement in PsA remains understudied but increasingly affects treatment decisions.

Objectives: The first step, in this multi-purpose radiographic study, is to report on baseline radiographic damage of the sacroiliac joints (SIJ) in PsA patients from a prospective multicentre cohort study in private and academic rheumatology practices.

Methods: Data from the Belgian Epidemiological Psoriatic Arthritis Study (BEPAS), a prospective multicentre cohort involving 17 Belgian rheumatology practices. Recruitment was from December 2012 until July 2014. Patients were included in the study when the local rheumatologist could diagnose an existing or new PsA and when patients fulfilled the Classification criteria for Psoriatic Arthritis (CASPAR). Radiographs of the SIJ were obtained at baseline and after 2 years. Two calibrated readers assessed radiographic damage of the SIJ according to the modified New York (mNY) criteria. When assessing the images, readers were blinded for clinical data and information from other obtained images (radiographs of the hands, feet and spine). Individual scores as well as consensus scores are described.

Results: In total 461 patients where included in BEPAS. Mean age was 52.79 ± 12.92 years and 43.0% (=198) were female; average disease duration was 8.5 ± 9.3 yrs and approximately 34% of the patients report inflammatory axial pain. From 338 patients SIJ radiographs were obtained. At baseline, the vast majority of patients did not fulfill the mNY criteria (n=325, 96.2%), according to the modified New York (mNY) criteria. Therefore, with a more sensitive approach (any of the 2 readers scores mNY positive) we see slight differences; 13 patients (3.8%) fulfill the mNY criteria. Two calibrated readers assessed radiographic damage by grading the SIJ according to the modified New York (mNY) criteria. Between the 2 readers was good with 98.5% overall agreement and kappa=0.75. Table 1 shows radiographic damage by individual readers.

Table. Baseline data on radiographic damage of the sacroiliac joints in Belgian patients with newly diagnosed or existing PsA included in the BEPAS.

In 128 patients (37.9%) a follow-up x-ray after 2 years was available. In 124 patients (96.9%) there was reader agreement on mNY negative status. There was disagreement between readers on a positive mNY in 2 patients (equally distributed) and agreement on 2 patients (16%). There were no patients with consensus between readers on the change in mNY over 2 years, but 1 reader reported 1 patient becoming mNY positive after 2 years.
was no significant difference between SEC and ADA (HR=1.01, 95% CI: 0.88-1.15). In the multivariate sensitivity analysis, both UST (HR=0.81, 95% CI: 0.70-0.94) and SEC (HR=0.82, 95% CI: 0.70-0.95) were associated with significantly lower discontinuation rates ratio relative to ADA. Overall, patients with more biologic treatment experience were statistically significantly (p<0.05) associated with higher risk of treatment discontinuation.

**Figure 1.** Unadjusted Kaplan-Meier curves of time to treatment discontinuation (main analysis, dynamic grace period)

**Conclusion:** UST exhibits a favourable treatment persistence profile relative to ADA, regardless of the grace period definition. The relative risk of discontinuing SEC vs ADA is sensitive to the grace period. Treatment discontinuation was higher in treatment exposures with more biologic experience.

**SEX SPECIFIC DIFFERENCES IN EARLY PSORIATIC ARTHRITIS**

E. Passia 1, M. Vis 1, L. C. Coates 2, A. Soni 1, I. Tchetverikov 1, A. Gerards 1, L. A. Korswagen 1, M. R. Kok 1, W. Van der Graaf 1, J. Venis-van Dieren 1, N. Denissen 1, F. Fodili 1, M. Starman 1, Y. Goekoop-Ruiterman 1, M. Van Oosterhout 1, J. Luime 1, 1CICERO Foundation, Rotterdam, Netherlands; 2NDORMS, Uni of Oxford, Oxford, United Kingdom

**Background:** Although the prevalence of Psoriatic Arthritis (PsA) is the same in men and women, women experience a higher burden of disease (pain, disability, fatigue) (1). The persistent belief that women tend to over-report their symptoms compared to men may also contribute to under or delayed diagnosis in women. The clinical pattern of PsA also differs, with men presenting more commonly with peripheral and axial joint damage and women being affected more frequently by polyarthritis (2). Furthermore, most disease activity measures contain pain and quality of life measurement metrics that may perform differently by sex. As a result, this may affect the clinician’s perception of disease severity, influence management decisions and subsequently introduce sex bias in prescribing.

**Objectives:** To assess sex-related differences in baseline demographics, disease characteristics and evolution over 1 year in patients with newly diagnosed PsA.

**Methods:** Our study is embedded in the Dutch south-west Early Psoriatic Arthritis prospective cohort study. We described patient characteristics using simple descriptive analysis techniques. For the comparison across sexes and baseline and 1 year follow up, appropriate tests depending on the distribution were used.

**Results:** 273 men and 294 women with no significant differences in age and ethnicity were included. Women reported significantly longer duration of symptoms before diagnosis and significantly fewer of them were in paid employment at baseline. Oligoarthritis was the most common pattern of arthritis in both sexes. Polyarthritis and enthesitis were more prevalent in women who also presented at baseline a significantly higher tender joint count (Fig.1) than men but no difference in swollen joint count.

**Conclusion:** After 1 year of follow-up women didn’t surpass their baseline disadvantages and despite the improvement, they still present higher disease activity, more pain and lower functional capacity than men. The nature of these findings may advocate a need for sex specific adjustment of treatment strategies and evaluation in psoriatic arthritis as sex-related difference in outcome persisted over time.

**MY SJÖGREN’S DIARY: AN ONLINE PATIENT PORTAL FOR PATIENT LED SJÖGREN’S SYNDROME RESEARCH**

C. Burns1, H. Breitmeyer1, L. Cowley2, S. Govind2, W. F. Ng1, T. F. Hiemstra2,3.

1British Sjögren’s Syndrome Association, Cambridge, United Kingdom; 2Cambridge Clinical Trials Unit, Cambridge, United Kingdom; 3Cambridge University Hospitals, Cambridge, United Kingdom; 4Newcastle University, Newcastle, United Kingdom; 5University of Cambridge, Medicine, Cambridge, United Kingdom

**Background:** Sjögren’s Syndrome is a chronic autoimmune disease affecting the exocrine glands accompanied by variable extra-glandular manifestations. Symptom flares, including dry eyes, dry mouth, dry skin, fatigue, myalgia and arthralgia, are frequent. Many of these symptoms have a considerable impact on quality of life, but are variable, sensitive to external factors, and difficult to measure objectively.

Clinical research on Sjögren’s Syndrome is advancing with the help of patient registries: an array of clinical data is collected and available for approved studies. However, many of these registries focus on collecting clinical information and often fail to capture the diverse patient experience adequately. Thus, there is an unmet need for an online patient portal, secure and encrypted with the capability of interacting with existing registries, while also patient-facing to encourage active involvement in research and personal healthcare. Patient demand for this resource was highlighted in 2017 when the Cambridgeshire regional support group of the British Sjögren’s Syndrome Association (BSSA) contacted the Patient Led Research Hub (PLRH). The PLRH provides research expertise to co-produce research ideas with patient organisations, the PLRH and Cambridgeshire group have since secured funding and initiated work on this project with the Cambridge Clinical Trials Unit.

**Objectives:** Develop My Sjögren’s Diary, a cross-platform patient portal to:

1. Act as an interactive tool to help patients manage their healthcare needs and aid communication with healthcare providers.
2. Function as a research platform, enabling patients to consent to contact, as well as support home-based data entry, allowing real-time capture of symptom scores and ensuring ease of participation for patients. Link with the UK Primary Sjögren’s Syndrome Registry and NHS Digital to provide complementary clinical datasets.

**Methods:** The PLRH has coordinated a team of rheumatologists, database programmers, patients and family members to develop My Sjögren’s Diary. Regular meetings, national surveys and correspondence with patients ensures the project remains relevant to patient needs, while collaborating with rheumatologists ensures the database is reliable, valid and of benefit to clinical care. Workshops hosted at key stages of database development have allowed both patients and rheumatologists to direct and refine My Sjögren’s Diary. A prototype was presented at the 2019 BSSA Annual Conference before further improvements and beta release.

**Results:** A beta version of My Sjögren’s Diary enabling BSSA members to track their medication and symptoms is now active. Feedback will be incorporated into the final version before it is publicly available to Sjögren’s Syndrome patients. Feedback will be incorporated into the final version before it is publicly available to Sjögren’s Syndrome patients. Further funding is required to develop the research platform.

**Conclusion:** My Sjögren’s Diary encourages equal partnership between patients, clinicians and researchers. It presents a unique opportunity for comprehensive analysis of Sjögren’s Syndrome and associated health utilities. Research participation is not mandatory, encouraging all patients to have an active role in personal healthcare management.

**ARTIFICIAL INTELLIGENCE AND MACHINE LEARNING IN IMAGING OF RHEUMATOID ARTHRITIS**

**T. Deimel1, D. Aletaha1, G. Langs1, 1Medical University of Vienna, Vienna, Austria**

**Background:** The prevention of joint destruction is an important goal in the management of rheumatoid arthritis (RA) and a key endpoint in drug trials. To quantify structural damage in radiographs, standardized scoring systems, such as the Sharp/van der Heijde (SvdH) score, which separately assesses joint space narrowing (JSN) and erosions, have been developed. However, application of these scores is time-consuming, requires specially trained staff, and results are subject to considerable intra- and inter-reader variability. This makes their application poorly feasible in clinical practice and limits their reliability in clinical trials.

**Objectives:** We aim to develop a fully automated deep learning-based scoring system of radiographic progression in RA to facilitate the introduction of quantitative joint damage assessment into daily clinical practice and circumvent inter-reader variability in clinical trials.

**Methods:** S191 hand radiographs and their corresponding SvdH JSN scores from 640 adult patients with RA without visible joint surgery were extracted from the picture archive of a large tertiary hospital. The dataset was split, on a patient level, into training (2207 images/270 patients), validation (1150/133), and test (1834/237) sets. Joints were automatically localized using a particular deep learning model which utilizes the local appearance of joints combined with information on the spatial relationship between joints. Small regions of interest (ROI) were automatically extracted around each joint. Finally, different deep learning architectures were trained on the extracted ROIs using the manually assigned SvdH JSN scores as ground truth (Fig. 1). The best models were chosen based on their performance on the validation set. Their ability to assign the correct SvdH JSN scores to ROIs was assessed using the unseen data of the test set.

**Fig. 1. 3-step approach to automated scoring: joint localization, ROI extraction, JSN scoring.**

**AUTOSCORA: DEEP LEARNING TO AUTOMATE SCORING OF RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS**

**T. Deimel1, D. Aletaha1, G. Langs1, 1Medical University of Vienna, Vienna, Austria**

**Background:** The prevention of joint destruction is an important goal in the management of rheumatoid arthritis (RA) and a key endpoint in drug trials. To quantify structural damage in radiographs, standardized scoring systems, such as the Sharp/van der Heijde (SvdH) score, which separately assesses joint space narrowing (JSN) and erosions, have been developed. However, application of these scores is time-consuming, requires specially trained staff, and results are subject to considerable intra- and inter-reader variability. This makes their application poorly feasible in clinical practice and limits their reliability in clinical trials.

**Objectives:** We aim to develop a fully automated deep learning-based scoring system of radiographic progression in RA to facilitate the introduction of quantitative joint damage assessment into daily clinical practice and circumvent inter-reader variability in clinical trials.

**Methods:** S191 hand radiographs and their corresponding SvdH JSN scores from 640 adult patients with RA without visible joint surgery were extracted from the picture archive of a large tertiary hospital. The dataset was split, on a patient level, into training (2207 images/270 patients), validation (1150/133), and test (1834/237) sets. Joints were automatically localized using a particular deep learning model which utilizes the local appearance of joints combined with information on the spatial relationship between joints. Small regions of interest (ROI) were automatically extracted around each joint. Finally, different deep learning architectures were trained on the extracted ROIs using the manually assigned SvdH JSN scores as ground truth (Fig. 1). The best models were chosen based on their performance on the validation set. Their ability to assign the correct SvdH JSN scores to ROIs was assessed using the unseen data of the test set.
joints to which the human reader and our system assigned the same score) for MCP joints was 80.5%, that for PIP joints was 72.3%. In only 1.8% (MCP joints) and 1.7% (PIP joints) of cases did the predicted score differ by more than one point from the ground truth (Fig. 2).

**Fig. 2.** Confusion matrices of automatically assigned scores (predicted score) vs. the human reader ground truth (true score).

**Conclusion:** Although a number of previous efforts have been published, none have succeeded in replacing manual scoring systems at scale. To our knowledge, this is the first work that utilizes a dataset of adequate size to apply deep learning to automate JSN scoring. Our results are, even in this early version, in good agreement with human reader ground truth scores. In future versions, this system can be expanded to the detection of erosions and to all joints contained in the SvdH score.

**Methods:** Fully automated ML software (Figure) was developed to detect and label 23 vertebras, define vertebral units (VU) as per the Berlin modification of the ASSpMIRa score, and score each VU as either 0 (score of 0) or 1 (score of 1, 2 or 3). The ML algorithm was based on the previously developed SpineNet software. Analysis included 108 pts from the secukinumab MEASURE 1 study, in which imaging was done using T1 and STIR sagittal MRI at baseline and Weeks 16, 52, 104, 156 and 208. Two expert readers, blinded to treatment and visits, evaluated all images by ASSpMIRa score. The scores from Reader 2 (R2) were binned into two groups: 0 vs 1, 2, or 3. As a result of multiple pt time points and expert reading sessions, the complete dataset comprised of 10,986 VU. Ten-way cross-validation at per-VU was used to train and validate the ML software. The dataset was split into 10 randomly selected subsets, ensuring that each pt appears in only one subset, after which 8 subsets were used for training the ML software, 1 was used to check for correct training and 1 was used for validation. The process was repeated ten times such that all 10 subsets were used for validation. Accuracy weighted for the frequency of each category, sensitivity and specificity were calculated using scores from R2 as reference. Intra-reader accuracy was also calculated.

**Results:** Accuracy of the software in relation to expert reader scores was 67% with a sensitivity of 0.63 and specificity of 0.70. The intra-reader accuracy was 71% and 77% for R1 and R2, respectively. Individual VU scoring of the Software vs. R2 are presented in the Table as a confusion matrix.

**Conclusion:** Automated scoring of MR images in AS pts provided moderate agreement to that of expert reader-based assessments. ML software has potential to provide an automated guided-reading approach to scoring MR images, which may enable further clinical insights.

FEASIBILITY STUDY ON AN AUTOMATED QUANTITATIVE SYSTEM FOR ULTRASOUND JOINT INFLAMMATION ASSESSMENT IN RHEUMATOID ARTHRITIS USING DEEP LEARNING

Y. K. Tan1, S. Suriyanto2, P. H. Yeung3, S. Xu1,6. 1Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore; 2Diagnostics Development Hub, Accelerate Technologies, Singapore, Singapore; 3Department of Engineering Science, Institute of Biomedical Engineering, University of Oxford, Oxford, United Kingdom; 4Department of General Surgery, Nanfang Hospital, Southern Medical University, Guangzhou, China; 5Voxel Imaging Pte Ltd, Singapore, Singapore

Background: The most widely accepted ultrasound (US) joint inflammation scoring system in rheumatoid arthritis (RA) is semi-quantitative in nature. This process involves manual image acquisition followed by image interpretation. The subjectivity inherent in manual scoring may be overcome by the development of an automated quantitative system to measure joint inflammation.

Objectives: To develop an automated quantitative system to measure US detected power Doppler (PD) joint inflammation in patients with RA.

Methods: The synovial region of interest (sROI) on US images at the metacarpophalangeal joints (MCPJs) and the metatarsophalangeal joint (MTPJs) within the Doppler box is manually segmented by a clinician experienced in musculoskeletal US (figure 1). PD joint inflammation was scored manually semi-quantitatively (0-3). Deep learning based image segmentation was applied to the US skeletal US (figure 1). PD joint inflammation was scored manually semi-quantitatively (0-3). Deep learning based image segmentation was applied to the US skeletal US (figure 1).

Results: 820 joints from bilateral 1st to 5th MCPJs and MTPJs in 41 adult RA patients (baseline characteristics: 75.6% Chinese; 73.2% female; mean (SD) DA528, 4.23 (125); mean (SD) disease duration, 73.3 (57.8) months) were evaluated in this cross-sectional study. The respective mean (SD)/ median (IQR) computer derived PD readings were 0.13 (0.75)/0.04 (0.08), 1.62 (1.77)/1.21 (1.19) and 10.12 (6.86)/7.25 (5.24) for manual score 0, 1 and 2 (no joints had manual score 3), with statistically significant differences found among the different manual score classes (for non-normally distributed data, Kruskal-Wallis H-test, p=1.69 x 10-22); Mann-Whitney Test: manual score 0 versus 1, p=1.04 x 10-62; manual score 0 versus 2, p=3.28 x 10-41; manual score 1 versus 2, p=1.53 x 10-39). Area under the ROC curve (AUC) based on computer derived PD reading cut-off of 0.26 to identify manual score 0 versus 1 was 0.98, while AUC based on computer derived PD reading cut-off of 3.37 to identify manual score 1 versus 2 was 0.98. The overall agreement of the score classes (0, 1 and 2) based on computer prediction using the above cut-offs versus manual scores of 0, 1 and 2 is 791/820=96.46%. Table 1 summarizes the performance of computer prediction using the above cut-offs when compared to clinician evaluation (i.e. score 0 versus 1, comparing computer prediction with clinician evaluation, sensitivity=99.14% and specificity=97.00%; score 1 versus 2, comparing computer prediction with clinician evaluation, sensitivity=97.14% and specificity=93.97%).

Conclusion: An automated quantitative system for US PD joint inflammation assessment using deep learning showed high sensitivity and specificity when results from computer prediction were compared to clinician evaluation. Further validation in a larger RA cohort with a longitudinal study design would be required.

OP0062

PREDICTIVE VALUE OF BONE TEXTURE FEATURES EXTRACTED BY DEEP LEARNING MODELS FOR THE DETECTION OF OSTEOARTHRITIS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

C. F. Kuo1,2, K. Zheng3, S. Miao2, L. Lu2, C. I. Hsieh4, C. Lin5, T. Y. Fan2. 1Chang Gung Memorial Hospital, Division of Rheumatology, Allergy and Immunology, Tainan, Taiwan, Republic of China; 2Chang Gung Memorial Hospital, Center for Artificial Intelligence in Medicine, Taoyuan, Taiwan, Republic of China; 3Pathology Labs, Bethesda, United States of America

Background: Osteoarthritis is a degenerative disorder characterized by radiographic features of asymmetric loss of joint space, subchondral sclerosis, and osteophyte formation. Conventional plain films are essential to detect structural changes in osteoarthritis. Recent evidence suggests that fractal- and entropy-based bone texture parameters may improve the prediction of radiographic osteoarthritis. In contrast to the fixed texture features, deep learning models allow the comprehensive texture feature extraction and recognition relevant to osteoarthritis classification. We also developed a Residual Network with 18 layers (ResNet18) for comparison since it deals with contours as well. Spearman’s correlation coefficient was used to assess the correlation between predicted and reference KL grades. We also test the performance of the model to identify osteoarthritis (KL grade≥2).

Methods: We used data from the Osteoarthritis Initiative, which is a longitudinal study with 4,796 patients followed up and assessed for osteoarthritis. We used a training set of 25,978 images from 3,086 patients to develop the textual model. We used the BoneFinder software1 to do the segmentation of distal femur and proximal tibia. We used the Deep Texture Encoding Network (Deep-TEN)2 to encode the bone texture features into a vector, which is fed to a 5-way linear classifier for Kellgren and Lawrence grading for osteoarthritis classification. We also developed a Residual Network with 18 layers (ResNet18) for comparison since it deals with contours as well. Spearman’s correlation coefficient was used to assess the correlation between predicted and reference KL grades. We also test the performance of the model to identify osteoarthritis (KL grade≥2).

Results: We obtained 6,490 knee radiographs from 446 female and 326 male patients who were not in the training sets to validate the performance of the models. The distribution of the KL grades in the training and testing sets were shown in Table 1. The Spearman’s correlation coefficient was 0.60 for the Deep-TEN and 0.67 for the ResNet18 model. Table 2 shows the performance of the models to detect osteoarthritis. The positive predictive value for Deep-TEN and ResNet18 model classification for OA was 81.37% and 87.46%, respectively.

OP0063 QUANTITATIVE COMPUTED TOMOGRAPHY PREDICTS 10-YEAR MORTALITY IN INTERSTITIAL LUNG DISEASE RELATED TO SYSTEMIC SCLEROSIS

Conclusion: QCT can arise as the new gold standard in identifying SSc patients with poor prognosis. The real possibility to stratify SSc subjects according mortality risk will have a pivotal role in ILD treatment decisional process with the incoming anti-fibrotic drugs.

OP0064 AUTOMATIC SCORING OF ARTHRITIS DISEASE ACTIVITY ON ULTRASOUND IMAGES FROM RHEUMATOID ARTHRITIS PATIENTS WITH CASCADED CONVOLUTIONAL NEURAL NETWORKS

A. Christensen 1, S. A. Just 2, J. K. H. Andersen 2, T. R. Savarmuthu 1, D. L. Christiansen 1, K. M. Mc-Kinley Moller Institute, Odense, Denmark; 2Odeense University Hospital, Svendborg Hospital - Department of Medicine, Section of Rheumatology, Svendborg, Denmark

Background: Systematic Power or Color Doppler (CD) ultrasound (US) of joints can be used for early detection of Rheumatoid Arthritis (RA), predicting radiographic progression and early detection of disease flare in established
RA [1, 2]. The international standard for performing RA US scanning and evaluation of disease activity is the OMERACT-ELUAR Synovitis Scoring (OESS) system [1, 2].

To further mitigate the operator-dependency in scoring disease activity on CD US images in future trials and clinical practice, we proposed the use of convolutional neural networks (CNN) to automatically grade CD US images according to the OESS definitions. This study is a continuation of the findings in our previous work, where we developed a CNN for four-class CD US OESS scoring with a test accuracy of 75.0% [4].

Objectives: Since our last contribution, we have further developed the architecture of this neural network and can here present a new idea applying a Cascaded Convolutional Neural Network design. We evaluate the generalizability of this method on unseen data, comparing the CNN with an expert rheumatologist.

Methods: The images used for developing the algorithms were graded by a single expert rheumatologist according to the OESS system. The CNNs in the cascade were trained individually, after which they were combined to form the cascade model as shown in figure 1. The algorithms were evaluated on a separate test dataset, which came from the same distribution as the training dataset. The algorithms were compared to the gradings of an expert rheumatologist on a per-joint basis using a Kappa test, and on a per-patient basis using a Wilcoxon Signed Rank test.

Results: With 1678 images available for training and 322 images for testing the model, the model achieved an overall 4-class accuracy of 83.9%. On a per-patient level, there was no significant difference between the classifications of the model and of a human expert (p<0.85).

Conclusion: We have shown that dividing a four-degree classification task into three successive binary classification tasks has resulted in a model capable of making correct classifications in 83.9% of the cases for a test set of ultrasound images with a naturally occurring distribution of RA joint disease activity scores. Furthermore, we have shown that the cascade model can produce classification decisions comparable with a human rheumatologist when applied on a per-patient basis. This emphasizes the potential of using CNNs with this architecture as a strong assistive tool for the objective assessment of disease activity of RA patients.

OP0066  IMAGING-DETECTED FEATURES OF HAND OSTEOARTHRITIS ASSOCIATE WITH SYMPTOMS AND RADIOGRAPHIC CHANGE OVER TIME: A SYSTEMATIC REVIEW AND META-ANALYSIS OF OBSERVATIONAL STUDIES

A. Obotiba1, S. Swain1, J. Kaur1, K. Yaseen1, M. Doherty1, W. Zhang1, A. Abhishek1, 1University of Nottingham, Academic Rheumatology, Division of Rheumatology, Orthopaedics and Dermatology, Nottingham, United Kingdom

Background: Osteoarthritis (OA) commonly affects joints in the hand. The natural history of hand OA is not well understood, and the local determinants of symptoms and structural changes over time remain unclear.

Objectives: To investigate, in both cross-sectional and prospective studies, the association between imaging (ultrasound [US] and magnetic resonance imaging [MRI]) features and symptoms of hand OA, and to examine in prospective studies whether imaging-detected features at baseline predict subsequent clinical and radiographic outcomes.

Methods: A systematic literature search was conducted in five databases including Medline, Web of Science, EMBASE, CINAHL and AMED in April 2018. The search was designed to capture published observational studies on the use of US and MRI in hand OA with no language restrictions. Odds ratios (OR), risk ratios (RR), and 95% confidence interval (CI) between [1] imaging features and hand OA symptoms at baseline, and [2] baseline-imaging features and follow-up outcomes were extracted and pooled using random effects model. Outcomes were defined as either incidence or progression of pre-existing features. Risk of bias assessment was performed using the Newcastle-Ottawa Scales. Heterogeneity and publication bias were assessed.

Results: The search identified 2818 citations, which reduced to 2216 after duplicate removal. Screening of titles and abstracts found 140 articles which met the inclusion criteria. After full text screening, 25 were included for analysis, including 452 participants (87% women) for US and 298 participants (86% women) for MRI with mean ages 60.3 and 62.5, respectively. Imaging-detected structural OA features were preferentially found in distal interphalangeal joints (DIPJs) followed by carpometacarpal (CMCJ) and proximal interphalangeal (PIPJ) joints. Metacarpophalangeal joints were least affected. However, the distribution pattern was different for inflammatory features for which the CMCJ was the most affected, and with no clear difference between DIPJs and PIPJs (Figure 1).

Figure 1. Hand map of grey-scale synovitis derived from pooled estimates of prevalence across studies (%[95% CI]).

Of 10 US and 5 MRI studies examining association at baseline, joint tenderness was associated with US osteophytes (pooled ORs 2.30, 95% CI 1.90-2.79), grey-scale synovitis (3.00, 2.33-3.84), synovial effusion (2.92, 2.29-3.72), and power Doppler (PD) (2.30, 1.68-3.15). Similar relationships were observed with MRI features (Figure 2). Six studies did not find any association between imaging features and self-reported outcomes. However, association was observed with US- and MRI-detected synovitis in one study each, and MRI-detected structural features in two. Statistical pooling was not possible for these outcomes due to heterogeneous data. Of the 9 US and 5 MRI studies for prediction, a dose-dependent relationship was observed between baseline PD and radiographic change at follow-up (Figure 3). Similar results were observed for MRI features and Kellgren-Lawrence change. The pooled ORs (95% CI) was 2.66 (1.88, 3.78) for bone marrow lesions, and 2.18 (1.53, 3.10) and 4.7 (3.08, 7.18) for grades 1 and 2 synovitis, respectively. Data to predict change in clinical outcomes however, were lacking.

UCB, Consultant of: WPM is Chief Medical Officer of CARE Arthritis Limited, has received consultant/participated in advisory boards for Abbvie, Boehringer, Celgene, Eli-Lilly, Galapagos, Gilead, Janssen, Novartis, Pfizer, UCB, Speakers bureau: Received speaker fees from Abbvie, Janssen, Novartis, Pfizer, UCB, Robert G Lambert: None declared, Stephany Pritchett: None declared, Frank Beier: None declared, J. Robert Giffin: None declared, Thomas Appleton Grant: Research support from: AbbVie and Pfizer.

Figure 3. Forest plot showing pooled odds ratio between baseline power Doppler and radiographic change over time.

Conclusion: Imaging-detected inflammatory features and osteophytes associated with joint tenderness. In addition, imaging-detected inflammatory changes at baseline predict future development and progression of structural OA changes, indicating that inflammation may precede radiographically-detectable structural changes.

Conclusion: There is an association between use of certain types of antibiotics and the diagnosis of AS, but no dose-response gradient. These data do not support a causal effect of cumulative antibiotic use on the development of AS. More research is needed on the impact of microbiome disturbance on the risk of developing AS.

INCIDENCE AND PREVALENCE OF RHEUMATOID ARTHRITIS IN DENMARK: A NATIONWIDE POPULATION-BASED STUDY INVESTIGATING THE EFFECT OF FOUR DIFFERENT CASE DEFINITIONS

B. G. Soussi1, R. L. Cordtz2, S. Kristensen3, C. S. Bork4, J. Christensen3, E. B. Schmidt2, D. Prieto-Alhambra3, L. Dreyer1. 1Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark; 2Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark; 3Aalborg University Hospital, Department of Nephrology, Aalborg, Denmark; 4University of Oxford, CSM-NORDMRS, Oxford, United Kingdom

Background: The incidence rate (IR) and point prevalence (PP) of rheumatoid arthritis (RA) in Denmark is largely unknown. Two challenges in estimating the true IR and PP using nationwide registry data are the choice of the RA case definition, and the denominator used, i.e. the exact amount of person years (PY) or census count data.

Objectives: To investigate the incidence and prevalence of RA in the adult Danish population using four different case definitions and two different denominator strategies.

Methods: Nationwide register-based cohort study. Patients with RA between 1996 and the end of 2016 were identified using the Danish National Patient Registry (DNPR) and information on DMARD prescriptions were obtained through linkage with the Danish National Prescription Registry. Age and sex standardised incidence and prevalence of RA were calculated in different ways: we estimated the IR (denominator = actual recorded number of PY in each year using migration and vital data) and the incidence proportion (IP) (denominator = census count data); and the PP (%) of RA was calculated for years 2000, 2009, 2011 and 2016. The four case definitions were: Model A, a first time RA diagnosis (ICD-10: M05-06) in DNPR and a redeemed prescription of a conventional disease-modifying antirheumatic drug (DMARD) in the following year; Model B, an RA diagnosis recorded twice in DNPR within 90 days with both records originating from a department of rheumatology or general internal medicine; Model C, any RA diagnosis recorded in DNPR with a DMARD prescription redeemed in the year before or after the diagnosis; Model D, similar to Model A but with the additional requirement that cases had no registered ICD code for inflammatory diseases prior to the RA diagnosis.

Results: The overall IR of RA from 1996 to 2016 based on Model A was 35.2 (95%CI 34.8 to 35.6) per 100,000 PY while the IP was 34.7 (95%CI 34.3 to 35.1) per 100,000 individuals. The age-standardised IR was higher for women than for men (Figure 1), and this was observed across all age groups. The IR peaked at age 70 to 74 in both men and women. Regardless of which case definition was used, the temporal trend showed a peak in IR in 2010 followed by a plateau (Figure 2). The overall PP estimate for all four models increased from 2000 to 2016, data shown for Model A in Table 1.

<td>0.32 (0.31 to 0.33)</td>
</tr>
</tbody>
</table>

Conclusion: A peak in the IR of RA was observed in 2010, regardless of which case definition was used. We believe this was due to introduction of the new EULAR/ACR diagnostic criteria at that time. IP estimates were systematically lower than IRs calculated using exact migration and vital data as denominator. The PP increased over time regardless of which case definition we used. We conclude that the choice of RA case definition had a larger influence than the choice of denominator.

Factors Associated with the Risk of Sepsis in Patients with Immune-Mediated Inflammatory Diseases Treated with Anti-Tumor Necrosis Factor-Alpha: A Nationwide, Population-Based Cohort Study

B. C. Hsu1, H. H. Chen2,3, C. H. Lin4, Y. M. Chen2,3, K. L. Lai5, D. Y. Chen6, W. N. Huang7, Y. H. Chen8, Taichung Veterans General Hospital Puli Branch, Internal Medicine, Nantou, Taiwan, Republic of China; 2Taichung Veterans General Hospital, Medical Research, Taichung, Taiwan, Republic of China; 3Taichung Veterans General Hospital, Internal Medicine, Taichung, Taiwan, Republic of China; 4China Medical University, College of Medicine, Taichung, Taiwan, Republic of China

Background: Anti-TNF-α agents have been proven to be effective for patients with immune-mediated inflammatory diseases (IMIDs) including rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriasis (PsO), psoriatic arthritis (PsA), Crohn’s disease (CD) and ulcerative colitis (UC). Prior studies have shown an increased risk of infection in IMID patients treated with anti-TNF-α but limited studies investigated factors associated with the development of sepsis in patients with IMIDs.
**Objectives:** To investigate factors associated with the development of sepsis in patients with IMIDs using the Taiwanese National Health Insurance Research Database (NHIRD).

**Methods:** We identified all biologic-naïve patients with RA, AS, PsO, PsA, or CD/UC from the claim data via the NHIRD who started their first anti-TNF-α agent (etanercept (ETN), adalimumab (ADA) or golimumab (GOL)) between 2003 and 2017 as study subjects. The index date was the first date of anti-TNF-α prescription. Sepsis was defined based on the sepsis-3 definition. We identified sepsis patients using a validated ICD-9-CM coding system proposed by Angus et al., in which a diagnosis of bacterial/fungal infection with one or more acute organ dysfunction is required to define an episode of sepsis. All study subjects were followed up till the date of first hospitalization due to sepsis, 90 days after the last date of anti-TNF-α prescription, withdrawal from NHIRD or death, whichever came first. We used a Cox regression analysis to assess the associations of covariates with the risk of sepsis as shown as hazard ratios (HRs) with 95% confidence interval (CIs). Covariates included anti-TNF-α agent, IMID, age, sex, insured amount, level of urbanization, disease duration, Charlson comorbidity index (CCI), a history of prior hospitalization due to sepsis within 3 months before the index date and medication use within 12 months before the index date and during the follow-up period.

**Results:** We identified 18105 biologic-naïve patients with IMIDs, including 8123 ETN users, 7623 ADA users and 2359 GOL users. The incidence rates (IRs) of sepsis in patients treated with ETN, ADA and GOL were 1080, 1181, and 617 per 10^5 years respectively. Multivariable regression analyses showed that factors associated with an increased risk of sepsis were use of ADA (ETN as reference: HR, 1.21; 95% CI, 1.02–1.42), male (HR, 1.24; 95% CI, 1.04–1.48), age (HR, 1.06; 95% CI, 1.05–1.07), CD/UC (HR, 2.35; 95% CI, 1.57–3.53), CCI (HR, 1.30; 95% CI, 1.23–1.38), prior sepsis (HR, 2.42; 95% CI, 1.78–3.29), prior use of sulfasalazine (HR, 1.25; 95% CI, 1.00–1.55), lower levels of urbanization (level III: HR, 1.37; 95% CI, 1.06–1.77; level IV: HR, 1.68, 95% CI, 1.35–2.10). Factors associated with a decreased risk of sepsis were use of GOL (ETN as reference: HR, 0.59; 95% CI, 0.39–0.84), use of methotrexate (HR, 0.78; 95% CI, 0.65–1.00), and higher insured amount (reference: ≤ 15480 NTD: 15480–28800 NTD: HR, 0.83; 95% CI, 0.60–0.99; 28800–45800 NTD: HR, 0.58; 95% CI, 0.45–0.74; ≥ 45800 NTD: HR, 0.33; 95% CI, 0.21–0.54).

**Conclusion:** Our study revealed that among biologic-naïve IMID patients initiating anti-TNF-α treatment, use of ADA, age, sex, CD/UC, CCI, prior sepsis, prior use of sulfasalazine and lower levels of urbanization were associated with an increased risk of sepsis, while use of GOL, use of methotrexate, and higher insured amount were associated with a decreased risk of sepsis.

**Disclosure of Interests:** None declared.

**THE RISK OF PRECANCEROUS LESIONS OF THE BREAST AND CERVIX UTERI IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES: A NATIONAL POPULATION STUDY IN TAIWAN**

P. H. Teal1, C. F. Kuo2,3, Linkou Chang Gung Memorial Hospital, Division of Rheumatology, Allergy and Immunology, Taoyuan City, Taiwan; Republic of China; 2University of Nottingham, Division of Rheumatology, Orthopedics and Dermatology, School of Medicine, Nottingham, United Kingdom

**Background:** Precancerous lesions are pathologically atypical tissues which share part of abnormal features of cancerous tissue under microscopic examination but lack the ability of uninhibited growth and distant metastasis. Some of the measures to screen for precancerous tissues have gained popularity because supporting evidence indicates the beneficial effects on cancer incidence and mortality [1, 2]. However, the roles of these screenings and the risk of precancerous lesions in patients with autoimmune diseases have not been clarified. We aim to exam the risk of precancerous lesions among different autoimmune diseases.

**Objectives:** To determine whether the Taiwanese autoimmune rheumatic diseases (ARDs) patients have a higher risk of precancerous lesions of the breast and cervix uteri.

**Methods:** The Taiwan national breast cancer screening program provides biennially mammography for women above 45 years old or with a positive family history of breast cancer above 40 years old. The national cervical cancer screening program provides Pap smear test once every three years for women age above 30 years old. Using the National Health Insurance (NHI) database, we identified a cohort of 6 different groups of ARDs patients in Taiwan between 2004 and 2014. We linked the data from the national screening program of breast and cervical cancer and the NHI database to estimate the standardized incidence ratios (SIRs) of precancerous lesions (atypical lobular and ductal hyperplasia of the breast, carcinoma in situ of the breast, cervical intraepithelial neoplasia 1 to 3 of cervix uteri and carcinoma in situ of cervix uteri) in patients with ARDs compared with the general population.

**Results:** From 2004-2014, we identified 64,904 patients with autoimmune diseases. Table 1 shows the number of patients receiving the screening programs. The standardized incidence ratio (SIR) of precancerous lesion of the breast was elevated in patients with rheumatoid arthritis (SIR, 2.21; 95% CI, 1.21-3.46) and Sjögren syndrome (SIR, 5.77; 95% CI, 2.63-9.85). The incidence of precancerous lesion of cervix uteri was elevated in patients with surveyed ARDs compared with the normal population, particularly for patients with systemic lupus erythematosus (SIR 28.94; 95% CI, 24.52-33.70) and inflammatory bowel disease (SIR, 27.50; 95% CI, 7.40-56.32) (Table 2).

**Table 2** Standardized incidence ratio (SIR) of precancerous lesion of the breast and cervix uteri in patients with autoimmune rheumatic diseases

**Conclusion:** Precancerous lesions in the breast and cervix uteri were higher in female patients with ARDs and they should receive stringent screening program.

**Disclosure of Interests:** None declared.
Background: Patients undergoing total knee replacement (TKR) are at increased risk of persistent opioid use and dependence.

Objectives: To identify patients with persistent high-dose opioid use after TKR using group-based trajectory models (GBTM) and determine predictors of persistent high-dose opioid users using pre-TKR patient characteristics.

Methods: Using US Medicare claims (2010-2014), we identified patients aged ≥65 years who underwent a TKR and had no history of cancer or high-dose opioid use (>25 mean morphine equivalents (MME)/day) in the year prior. All patients were continuously enrolled in Medicare for ≥360 days prior to and ≥30 days after the TKR. To determine opioid filling patterns after the surgery, patients were followed up to 360 days from the day of TKR. We modeled 12 monthly indicators of opioid prescription fills as a continuous (MME/day) variable using a censored normal GBTM and categorized patients into 4 groups. The primary outcome was persistent high-dose opioid use defined as patients in trajectory Group 3 (38.8 MME/day) or Group 4 (22.4 MME/day). We split the data into training (2010-2013 data) and test (2014 data) sets and used logistic regression to predict high-dose opioid use vs low-dose opioid use (Groups 1 and 2) as a binary outcome utilizing pre-TKR patient characteristics as candidate predictors using the least absolute shrinkage and selection operator (LASSO) regression for variable selection. A reduced model with only 10 pre-specified variables readily available for clinical use was also considered.

Results: The final study cohort included 142,089 patients. The GBTM identified 4 distinct trajectories (Group 1: Short-term, low-dose, Group 2: long-term, low-dose, Group 3: medium-term, high-dose, Group 4: long-term, high-dose) of opioid use in the year after TKR (Figure). Using logistic regression and LASSO, we predicted the probability of persistent high-dose opioid use (N=17,171) (vs. low-dose opioid use) in the training set (N=101,810) for an AUC=0.80. The AUC in the test set (N=40,279) predicting high opioid use (N=5,893) was 0.77. The final model selected 33 variables and identified baseline history of opioid use as the strongest positive predictor of high-dose persistent opioid use. The reduced model with only ten predictors also performed equally well (AUC=0.77).

Conclusion: In this cohort of older patients with no history of cancer or high-dose opioid use at baseline, 16.2% became high dose (28.1 MME/day) opioid users during the year after TKR. Our prediction model with 10 readily available clinical factors may help identify patients at high risk of future adverse outcomes from persistent opioid use and dependence after TKR.

Conclusion: PMR relapse while tapering GC occurs frequently, and some – although weak – associations were found. Longer symptom duration before treatment decreased chance of relapse, but did not increase the amount of relapses per year of treatment, potentially indicating a more self-limiting disease course. A uniform definition of relapse and identifying further predictors for a potential prediction model is needed to focus GC sparing agents for patients.
Background: Palindromic rheumatism (PR) has been known to be three patterns of disease course: clinical remission of attacks, persistent attacks, and evolution to chronic arthritis or systemic disease. The spectrum in progression to chronic disease course: clinical remission of attacks, persistent attacks, and evolution to chronic arthritis or systemic disease. The spectrum in progression to chronic disease course: clinical remission of attacks, persistent attacks, and evolution to chronic arthritis or systemic disease.

Methods: The study used the Clinical Practice Research Datalink – a primary care database from the UK. Firstly, age, sex and practice matched OA and non-OA people aged 20+ were identified to explore patterns and associations of clusters of multimorbidity within each group. Non-OA controls were assigned to each OA control for interaction = 0.037) while female patients encountered a higher risk of developing RA (15.8 [8.9-26.1] vs. 7.2 [5.0-10.3], p = 0.023). The risk of developing RA, SLE, SJ, and BD were significantly more highly affected in younger age (p for interaction < 0.001, = 0.003, 0.002, and 0.017, at each).

Conclusion: This nationwide, population-based cohort study demonstrated that patients with PR had an increased risk of developing various rheumatic diseases, not only RA but also psoriatic arthropathy. Therefore, patients with PR needs to be cautiously followed up for their potential of diverse outcome other than RA: RA, SLE, SJ, and BD and in younger patients, RA, males, and AS in females, in particular.

Background: Data on spinal radiographic progression is more limited in nonradio graphic axial spondyloarthritis (nr-axSpA) than in the radiographic disease state (r-axSpA). It remains unclear, whether radiographic sacroiliitis is by itself associated with progression of spinal structural damage.

Objectives: To investigate whether spinal radiographic progression relates to structural damage at the sacroiliac level in axSpA by means of statistical mediation analysis in a large prospective real-life cohort of patients with axSpA.

Methods: Patients from the Swiss Clinical Quality Management cohort were included if they fulfilled the ASAS classification criteria and could be classified as nr-axSpA or r-axSpA after central scoring of pelvis radiographs. Spinal radiographs performed every 2 years were scored according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). The relationship between classification status and spinal progression over 2 years was investigated using binomial generalized estimating equations models with adjustment for sex, ankylosing spondylitis disease activity score (ASDAS) and tumor necrosis factor inhibitor treatment. Baseline spinal damage was considered an intermediate variable and included in sensitivity analyses, as were additional variables potentially influencing radiographic progression.

Results: In total, 88 nr-axSpA and 418 r-axSpA patients contributed to data for 725 radiographic intervals (Table 1). Mean (SD) mSASSS change over 2 years was 0.16 (0.62) units in nr-axSpA and 0.92 (2.78) units in r-axSpA, p=0.01. Nr-axSpA was associated with a significantly lower progression over 2 years (defined as an increase in ≥2 mSASSS units) in adjusted analyses (OR 0.33, 95%CI 0.13; 0.83), confirmed with progression defined as the formation of ≥1 syndesmophyte. Mediation analyses revealed that sacroiliitis exerted its effect on spinal progression indirectly by being associated with the appearance of a first syndesmophyte (OR 0.09, 95%CI 0.02; 0.36 for nr-axSpA vs r-axSpA) (Fig. 1 and 2). Baseline syndesmophytes were predictors of further progression.

Conclusion: Spinal structural damage is mainly restricted to patients with r-axSpA, leading to relevant prognostic and therapeutic implications.
Clinical Disease Activity, MRI Spinal Inflammation and Enthesitis Are Key Determinants of Impairment of Spinal Mobility in Early Axial Spondyloarthritis – Data From the DESIR Cohort

P. Carvalho1,2,3, A. Marreiros4,5, J. E. Fonseca6,7, A. Ruyssev-Litrand5, P. M. Machado1, 1Centro Hospitalar Universitário do Algarve, Faro, Portugal; 2Centro Académico Médico de Lisboa, Lisbon, Portugal; 3Algarve Biomedical Center, Faro, Portugal; 4Universidade do Algarve, Faro, Portugal; 5Faro, Algarve Biomedical Center, Faro, Portugal; 6Hospital Santa Maria, Lisbon, Portugal; 7Le Centre Hospitalier Universitaire de Toulouse, Toulouse, France; 8University College London, London, United Kingdom

Background: It has been shown that spinal mobility impairment in axial spondyloarthritis (axSpA) is independently determined both by irreversible spinal damage and by reversible spinal inflammation. However, these relationships have only been investigated in patients with longstanding disease (ankylosing spondylitis). Moreover, only the composite score Bath Ankylosing Spondylitis Metrology Index (BASMI) has been evaluated rather than individual mobility assessments.

Objectives: Our aim was to investigate the determinants of spinal mobility in patients with early axSpA.

Methods: We analysed longitudinal data from the DEvenir des Spondyloarthrites Indifférenciées Récentes (DESIR) cohort, collected during the first five years of follow-up. We selected patients with a definite diagnosis of axSpA according to the treating rheumatologist, at the end of follow-up (month 60). Associations were tested using generalised estimating equations (GEE), a multilevel approach that adjusts for within-patient correlation. The Bath Ankylosing Spondylitis Metrology Index (BASMI) or the individual components of BASMI (lateral spinal flexion, tragus-to-wall distance, cervical rotation, anterior lumbar flexion, maximal intermalleolar distance) were used as dependent variables, and clinical and demographic variables were used as independent variables in univariable models. Spinal MRI inflammation was assessed using the Berlin scoring system and radiographic structural damage was assessed using the modified Stoke Ankylosing Spondylitis spine score (mSASSS). As physical function and quality of life are considered to be hierarchically superior to spinal mobility, they were not included in the analysis. Multivariable models were built, adjusting for potential confounding. Variables with a p-value <0.10 were re-tested in the multivariable models. Six models were built, one regarding the BASMI total score and five regarding the individual components of BASMI.

Results: Data from 644 patients and 5152 visits were analysed. In the multivariable analyses (table), we found an independent association between higher BASMI values and age [adjusted B (aB)=1.02, confidence interval (CI)=1.01-1.03], Ankylosing Spondylitis Disease Activity Score-C Reactive Protein (ASDAS-CRP) (aB=1.23, CI=1.15-1.32), enthesitis score (aB=1.02, CI=1.01-1.04) and MRI inflammation score (aB=1.13, CI=1.05-1.23). All individual BASMI components were independently associated with ASDAS-CRP. Apart from maximal intermalleolar distance, all other mobility measures were associated with MRI inflammation. Lateral spinal flexion, cervical rotation and maximal intermalleolar distance were associated with the enthesitis score. mSASSS was associated with lateral

Fig. 1. Modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) for individual patients plotted as a function of duration since symptom onset.

Fig. 2. Two-year mSASSS progression depicted in a cumulative probability plot. Progression was defined as an increase in mSASSS of at least 2 units (dotted line) in 2 years.
spinal flexion and a contributory factor to tragus-to-wall distance and cervical rotation.

**Conclusion:** In early axSpA, spinal mobility impairment is independently determined by clinical disease activity, MRI spinal inflammation and the severity of enthesis. Maximal intermalleolar distance (which is not a true measure of spinal mobility) was the only measure not associated with MRI spinal inflammation. The influence of spinal inflammation prevails in the early phase of axSpA while spinal damage becomes more relevant in later disease stages.

## OP0077 DETERMINANTS OF THE PHYSICIAN’S GLOBAL ASSESSMENT AND INFLUENCE OF CONTEXTUAL FACTORS IN EARLY AXIAL SPONDYLOARTHRITIS

**F. Hirano**\(^1\), R. B. M. Landewé\(^1,2\), F. A. Van Gaalen\(^3\), D. Van der Heijde\(^4\), C. Gaujoux-Viala\(^5\), S. Ramiro\(^1,3\), ULUMC, Leiden, Netherlands; \(^2\)AULMC, Amsterdam, Netherlands; \(^3\)Zuyderland MC, Heerlen, Netherlands; \(^4\)Nîmes University Hospital, Nîmes, France

**Background:** In RMDs, the physician’s global assessment (PhGA) is a major factor of treatment decision. It is not well-known which disease manifestations contribute to PhGA in early axSpA and if contextual factors have an impact.

**Objectives:** To investigate determinants of PhGA and the influence of contextual factors on this relationship in patients with early axSpA.

**Methods:** Five-year data from DESIR, a cohort of early axSpA, were analysed. Clinical data were collected every 6 months up to 2 years and annually thereafter. The primary analysis included all patients, and the subgroup analysis patients with follow-up MRI at 2 and/or 5 years. PhGA over 5 years was the outcome of interest. Univariable generalized estimating equation (GEE) models were used to investigate relationships between potential determinants and PhGA. Longitudinal relationships were investigated in autoregressive models. Effect modification by contextual factors (educational level, gender and age) was tested and, if significant, models were stratified. Univariable analyses were chosen to better assess the contributory explanatory effects of each of the determinants in each of the strata.

**Results:** A total of 708 patients were included, mean age 33.7 (SD 8.6) years, 46% male, 41% lower educated. The subgroup consisted of 220 patients with similar characteristics. Higher BASDAI questions 1-6, SJC28, TJC53, Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), CRP and BASMI were associated with a higher PhGA (Table 1). Gender and age were effect modifiers of SJC28; the effect was largest in the younger male stratum ([β (95% CI): 1.07 (0.71, 1.43)], and smallest in the older female stratum (0.13 [0.04, 0.22]) (Figure 1). Autoregressive GEE models revealed the same determinants of PhGA and the same pattern of effect modification by gender and age. The contributory explanatory effects of each of the determinants in each of the strata.

**Conclusion:** Patient’s subjective symptoms, peripheral arthritis, enthesis, higher CRP and impaired spinal mobility contribute to explain PhGA in patients with early axSpA irrespective of gender and age. But physicians consider the presence of swollen joints as more important in males than in females.

\(\dagger\) Each joint graded 0-3

\(\S\) Coefficients were estimated in the subgroup
spondyloarthritis (axSpA) spectrum of patients i.e. including not only patients with AS but also those with non-radiographic axSpA.

Objectives: To estimate a robust mapping between ASDAS and EQ5D (3 level version) and to test its performance out of sample (external validation) in patients with axSpA.

Methods: Data from an electronic, prospective, nationwide Rheumatic Disease Portuguese Register (Reuma.pt) provided data pertaining to 1140 patients (5483 observations) with a confirmed diagnosis of axSpA was used to develop a model to predict EQ5D from the ASDAS score. We compared a range of different statistical models developed to deal with the complex distributional features of health utility data. A range of criteria examining model fit across the spectrum of disease severity were used to select prefered models. A smaller dataset for out of sample validation from the SPondyloArthritis Caught Early (SPACE) cohort was used, providing data from 317 patients (1225 observations) at five European centres.

Results: Characteristics of patients from the Reuma.pt and SPACE are presented in the table. There is a non-linear relationship between ASDAS and EQ5D. We found that a four component mixture model based on a bespoke distribution, with one component constrained to reflect the mass of observations at full health, was the best fitting of the ASDAS models estimated (figure). ASDAS squared and age squared featured as within component variables. The model demonstrated close fit to the observed data where ASDAS was less than 4 but diverged from the mean of the data where ASDAS was higher. There is a very limited data at this more severe level of disease activity. In the out of sample testing, the model continued to perform well overall and exhibited the same divergence from the observed data only where data was sparse.

Conclusion: There is a clear relationship between ASDAS and EQ5D that we were able to model reliably using bespoke mixture model based methods. There is more uncertainty regarding model fit at very high levels of disease activity owing to the relative paucity of data from patients in such disease activity state. Future analyses may wish to focus on these severely affected patients in order to improve the robustness of model estimates.

Table. SIJ qdr: sacroiliac joint quadrant

OP0079 PRELIMINARY DEFINITION OF A POSITIVE MRI FOR STRUCTURAL LESIONS IN THE SACROILIAC JOINTS IN AXIAL SPONDYLOARTHRITIS

1University of Alberta, Edmonton, Canada; 2CARE Arthritis, Edmonton, Canada; 3Rheumazentrum Ruhrgebiet, Herne, Germany; 4University of Southern Denmark, Sanderborg, Denmark; 5University College London, London, United Kingdom; 6Copenhagen University, Copenhagen, Denmark; 7Charité – Universitätsmedizin Berlin, Berlin, Germany; 8Klinikum Bielefeld, Bielefeld, Germany; 9Leiden University Medical Center (LUMC), Leiden, Netherlands; 10University of Amsterdam, Amsterdam, Netherlands

Background: There is lack of international consensus as to what defines a structural lesion on MRI of the sacroiliac joints (SIJ) typical of axial spondyloarthritis (axSpA). The ASAS MRI group has generated updated consensus lesion definitions that describe each of the MRI lesions in the SIJ. These definitions have been evaluated by 7 readers from the ASAS-MRI group on MRI images from the ASAS Classification Cohort.

Objectives: We aimed to identify quantitative cut-offs based on numbers of lesions in 2 SIJ quadrants that define a positive MRI for structural lesions typical of axSpA, the gold standard being majority central reader decision as to the presence of a structural lesion typical of axSpA with high confidence.

Methods: MRI structural lesions meeting ASAS definitions were recorded in an eCRF that comprises global assessment (structural lesion typical of axSpA present/absent and degree of confidence (4 absent to 4 present)), and detailed scoring of lesions per SIJ quadrant. Detailed scoring was based only on assessment of DICOM images (n = 148). We calculated sensitivity and specificity for numbers of SIJ quadrants and consecutive slices with erosion, sclerosis, and fat lesions where a majority of readers (≥4/7) agreed as to the presence of a structural lesion typical of axSpA with high confidence (≥3). We tested candidate lesion definitions for predictive diagnostic utility in cases assessed after 4.4 years of follow up by the local rheumatologist.

Results: Structural lesions typical of axSpA were observed by majority read in 33 (32.4%) of 102 cases diagnosed with axSpA, and 3 (6.8%) of 44 cases without axSpA and 29 cases were assigned a high degree of confidence (≥3) by a majority of readers. Cut-offs achieving specificity of 95% were erosion ≥3 SIJ quadrants (sensitivity 90%), and fat lesion (≥1cm horizontal depth) in ≥1 SIJ quadrant (sensitivity 59%) (Table). These had very high positive predictive values (>95%) for diagnosis of axSpA in cases diagnosed by the rheumatologist after 4.4 years follow up.

Conclusion: ASAS-defined erosion in ≥2 consecutive slices or in ≥3 SIJ quadrants and ASAS-defined fat lesion with depth >1cm in ≥1 SIJ quadrant are high priority candidates for defining an MRI structural lesion typical of axSpA. This will require similar assessment in additional axSpA cohorts.

CENTRAL SENSITIZATION AND ILLNESS
PERCEPTIONS SHOULD BE TAKEN INTO ACCOUNT
WHEN INTERPRETING DISEASE ACTIVITY IN
PATIENTS WITH AXIAL SPONDYLOARTHRITIS

S. Kieskamp1, D. Paap1,2, M. Carbo1, F. Wink3, R. Bos3, H. Bootsma1,
S. Arends1,3, A. Spoorenberg1,3. 1University Medical Center Groningen,
Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University
Medical Center Groningen, Rehabilitation Medicine, Groningen,
Netherlands; 3Medical Center Leeuwarden, Rheumatology, Leeuwarden,
Netherlands
Background: Up to 40% of ankylosing spondylitis patients report persistently
high pain scores of >4 (scale of 0-10) even after responding to long-term TNF-alpha blocking therapy.[1] In other rheumatic diseases, nociplastic pain (due to
altered functioning of the nervous system leading to peripheral and central sensitization) is common.[2] In axial spondyloarthritis (axSpA), patient illness and pain
perceptions were shown to influence disease outcome.[3] Therefore, we hypothesized that central sensitization and patients’ illness perceptions are associated
with persistently high disease activity in axSpA.
Objectives: To investigate to what extent central sensitization, pain catastrophizing and patients’ perceptions play a role in axSpA and to explore associations
with disease activity.
Methods: Between April and September 2019, consecutive outpatients from
the Groningen Leeuwarden axSpA (GLAS) cohort,[4] an ongoing large prospective cohort, were included in this study. Besides the standardized assessments, patients filled out three additional questionnaires: Central Sensitization
Inventory (CSI), Pain Catastrophizing Scale (PCS) and Revised Illness Perception Questionnaire (IPQ-R). Univariable and multivariable linear regression
analyses were used to investigate the association of CSI, PCS and each of the
eight subscales of the IPQ-R, and disease activity assessments ASDAS-CRP,
BASDAI, and CRP. We corrected for the following potential confounders: gender, symptom duration, BMI, educational level, smoking status and HLA-B27
status.
Results: Of 171 included patients, 58% were male, 79% were HLA-B27 positive, median symptom duration was 21 (IQR 10-32), mean ASDAS-CRP 2.1
± 1.0, mean BASDAI 3.9 ± 2.2 and median CRP 2.9 (IQR 1.2-6.3). Mean CSI
score was 37.8 ± 14.1 (scale of 0-100), and 44% of patients scored ≥40 on the
CSI.[5] Median PCS score was 15 (IQR 7-22) (scale of 0-52), median IPQ-R
illness identity subscore 3 (IQR 2-4) (scale of 0-14) and mean IPQ-R treatment
control subscore 18.1 ± 3.4 (scale of 5-25). In univariable regression analysis,
CSI and PCS scores and IPQ-R subscores all showed significant associations

with ASDAS-CRP, and all except the IPQ-R subscale personal control showed
significant associations with BASDAI. Only IPQ-R treatment control was significantly associated with CRP. Central sensitization, two IPQ-R subscales
(perceived treatment control and the number of symptoms patients attributed
to their axSpA: illness identity) and BMI were independently associated with
disease activity assessments BASDAI (R2=0.46) and ASDAS-CRP (R2=0.36)
(Figure 1).

Conclusion: In this axSpA population with long-term disease, 44% scored
above the CSI cutoff point of 40, indicating a high probability of central sensitization. CSI score, illness identity and treatment control were independently
associated with disease activity assessments.

Spondyloarthritis International Federation (ASIF), London, United Kingdom;
8
Novartis Pharma AG, Basel, Switzerland; 9University Hospital La Paz,
IdiPAZ, Madrid, Spain
Background: Axial Spondyloarthritis (axSpA) involves a great degree of functional limitation in daily activities and psychological health, which can impact
patients’ sexual life.
Objectives: To study the determinants of reduced frequency of sexual activity
and intimacy since disease onset in axSpA patients.


Methods: Data from 2,846 unselected patients of the European Map of Axial Spondyloarthritis (EMAS) through an online survey (2017-2018) across 13 countries were analysed. The impact of axSpA on patients’ sexual life was evaluated by a question assessing changes in the frequency of intimate relations since the onset of axSpA on a 5-point Likert scale. Impact of axSpA on the spousal relationship since disease onset was also assessed using 5 point Likert scale. Other lifestyle variables included smoking and physical activity and burden of disease [BASDAI (0-10), spinal stiffness (3-12), functional limitation in intimate relations (0-2), and psychological distress (GHQ-12)]. Regression analysis were carried out to determine the relative weight of the assessed variables.

Results: EMAS total sample mean age was 43.9 years, 61.3% were female. 48.1% had a university degree, and 67.9% were married. Out of the 2,515 participants that reported on the frequency of intimate relations since disease onset, 56.4% declared that it was less or much less than before; 74.1% declared high or medium limitation in intimate relations; and 30.4% reported worsening relations with their spouse. A lower frequency of intimate relations was related to: older age, female gender, higher BASDAI, spinal stiffness, higher functional limitation in intimate relations, higher psychological distress, self-reported diagnosis of depression, worsening relationship with spouse since disease onset, higher BMI, smoking, lack of physical activity, and lack of biologics use. In the multivariate regression analysis, the most strongly associated variables with lower frequency of intimate relations were: functional limitation in intimate relations (β = 0.218; 95% CI 0.185 – 0.251), worse relationship with spouse (β = 0.207; 95% CI 0.165 – 0.250), female gender (β = 0.150; 95% CI 0.071,0.229 ), no engaging in physical activity (β = 0.135; 95% CI -0.234 – 0.036) (Table 2).

Conclusion: EMAS results reveal a great impact of axSpA on patients’ sexual life, with multiple sociodemographic, lifestyle and PRs being associated with a lower frequency of intimate relations.

Pain pathology, progression and pharmacotherapy

OP0083 DORSAL ROOT GANGLIA INFILTRATING MACROPHAGES MAINTAIN OSTEOARTHRITIS PAIN

R. Rao1, C. Martin1, H. De Visser2, J. Prado1, S. Versteeg1, A. Heinemans3, S. Masthbergen3, F. Laborde3, N. Eijkelkamp1, UMC Utrecht, Utrecht, Netherlands

Background: Pain is a major debilitating symptom of knee osteoarthritis (OA). However, the extent of joint damage in OA does not correlate well with the severity of pain. The mechanisms that govern OA pain are poorly understood. Immune cells infiltrating nervous tissue may contribute to pain maintenance.

Objectives: Here we investigated the role of macrophages in the initiation and maintenance of OA pain.

Methods: Knee joint damage was induced by an unilateral injection of monoiodoacetate (MIA) or after application of a groove at the femoral condyles of rats fed on high fat diet. Pain-like behaviors were followed over time using von Frey test and dynamic weight bearing. Joint damage was assessed by histology. Dorsal root ganglia (DRG) infiltrating immune cells were assessed over time using flow cytometry. To deplete monocytes and
macrophages, Lysm<sup>cre</sup> x Csf1r-Stop-DTR were injected intrathecally or systemically with diphtheria toxin (DT). 

**Results:** Intraarticular monoiodoacetate injection induced OA and signs of persistent pain, such as mechanical hyperalgesia and deficits in weight bearing. The persisting pain-like behaviors were associated with accumulation of F4/80<sup>+</sup> macrophages with an M1-like phenotype in the lumbar DRG appearing from 1 week after MIA injection, and that persisted till at least 4 weeks after MIA injection. Macrophages infiltrated DRG were also observed in the rat groove model of OA, 12 weeks after application of a groove at the femoral condyles. Systemic or local depletion of DRG macrophages during established MIA-induced OA completely ablated signs of pain, without affecting MIA-induced knee pathology. Intriguingly when monocytes/macrophages were depleted prior to induction of osteoarthritis, pain-like behaviors still developed, however these pain-like behaviors did not persist over time. In vitro, sensory neurons innervating the affected OA joint programmed macrophages into a M1 phenotype. Local repolarization of M1-like DRG macrophages towards M2 by intrathecal injection of M2 macrophages or anti-inflammatory cytokines resolved persistent OA-induced pain.

**Conclusion:** Overall we show that macrophages infiltrate the DRG after knee damage and acquire a M1-like phenotype and maintain pain independent of the lesions in the knee joint. DRG-infiltrating macrophages are not required for induction of OA pain. Reprogramming M1-like DRG-infiltrating macrophages may represent a potential strategy to treat OA pain.

**PRESSURE PAIN THRESHOLDS AND THE ASSOCIATIONS WITH CHRONIC WIDESPREAD PAIN, KNEE OSTEOARTHITIS AND OBESITY IN INDIVIDUALS WITH KNEE PAIN**

C. Sylwander<sup>1,2</sup>, E. Haglund<sup>1,3,4</sup>, I. Larsson<sup>1,2,4</sup>, S. Bergman<sup>1,4,5</sup>, M. Andersson<sup>1,4</sup>, 1Spenshult Research and Development Centre, Halmstad, Sweden; 2Halmstad University, School of Health and Welfare, Halmstad, Sweden; 3Halmstad University, School of Business, Engineering and Science, Halmstad, Sweden; 4Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden; 5The Sahlgrenska Academy, University of Gothenburg, Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden

**Background:** Approximately 30% of individuals with symptomatic knee osteoarthritis (OA) had developed chronic widespread pain (CWP) over a period of 20 years [1]. In order to prevent CWP in those with knee pain, it is important to study associated factors.

**Objectives:** The aim was to study pressure pain thresholds among individuals with knee pain with or without radiographic changes, and associations with CWP, radiographic knee OA, and obesity.

**Methods:** Out of 300 individuals with knee pain (with or without radiographic changes) from an ongoing longitudinal study, 279 conducted pressure pain thresholds (PPT) measurement at baseline in this cross-sectional study (71% women; mean age 51 years). The PPT were measured using a computerized pressure algometry on eight predefined tender points (Figure 1) out of the 18 points as part of the definition of fibromyalgia [2]. PPTs were dichotomised based on the lowest tertial vs the two higher tertials for each of the eight points. A group that had ≥4 points with low PPT (low PPT group) was compared to a group that had <4 low PPT (not low PPT group). A pain mannequin categorised the participants in three different pain groups: CWP, chronic regional pain (CRP), and no chronic pain (NCP) according to the definition of the ACR [2]. Radiographic knee OA was defined according to the Ahlback five grading scale as having score ≥1 vs score 0 [3]. Obesity was measured by bioimpedance measuring BMI and visceral fat area (VFA, cm<sup>2</sup>). To study associations, a crude logistic regression model controlled for age and sex was used including main and significant variables.

**Results:** The prevalence of CWP was 37% and higher in the low PPT group compared to those in the not low PPT group (Table 1). No differences were found between the groups in BMI, VFA or radiographic knee OA (Table 1). The low PPT group had significantly lower mean PPT on all eight tender points, was younger, had more pain sites, and more cases of fibromyalgia compared to the group with not low PPT (Table 1, Figure 1). Age (OR 0.95; 95% CI 0.92–0.97), having CWP (OR 3.00; CI 1.66–5.06), radiological OA (OR 21.91; CI 2.45–194.69) and increased number of pain sites (OR 1.13; CI 1.05–1.22) were associated with low PPT.

**Conclusion:** Baseline characteristics of individuals with knee pain showed a higher prevalence of CWP than in the general population [4]. In the group with low PPT, the prevalence was even higher. The study found associations between CWP and low PPT, however, almost half of the individuals with low PPT reported NCP/CRP. Moreover, a third in the group that had not low PPT reported CWP. The development of widespread pain in individuals with knee pain needs to be further studied over time to increase the knowledge of CWP’s origin in order to prevent the condition.

The development of FM in patients with axSpA can be predicted by longitudinal development of, or recovery from, FM in patients with axial Spondyloarthritides (axSpA).

Objectives: To identify predictors for FM development and recovery in patients with axSpA.

Methods: To identify predictors for FM development and recovery in patients with axSpA.

Results: Eight hundred and one patients had two or more visits and were eligible for inclusion. 686 patients did not have FM at baseline, of whom 45 had developed FM by follow-up. 115 patients had FM at baseline, of whom 77 had recovered by follow-up. The uni- and multivariate logistic regression models are presented in table 1.

Conclusion: The development of FM in patients with axSpA can be predicted by high levels of axSpA activity and presence of widespread pain, while low levels of the same variables, and starting a TNF-inhibitor predict recovery from FM. The presence of co-morbid FM should be considered in patients with a history of high axSpA disease activity and widespread pain.

**THE DEGREE OF BONE MARROW EDEMA AS DETECTED BY MAGNETIC RESONANCE IMAGING IN THE SACRALIAC JOINTS AND THE SPINE SUSPICIOUS OF AXIAL SPONDYLOARTHITIS IN THE GENERAL POPULATION IS ASSOCIATED WITH DIFFERENT FACTORS**

X. Baraliakos1, A. Richter2, D. Feldmann3, A. Ott4, R. Buelow, C. Schmidt5, J. Braun6 on behalf of n/a, 1Rheumazentrum Ruhrgebiet Heme, Ruhr-University Bochum, Heme, Germany; 2Institute for Community Medicine, University Greifswald, Greifswald, Germany; 3Department of Diagnostic Radiology and Neuroradiology, University Medicine Greifswald, Greifswald, Germany

Background: Taking advantage of a large population-based study we have recently reported that the frequency of bone marrow edema (BME) and fatty lesions (FL) in the sacroliac joints (SLJ) and the spine of individuals <45 years detected by magnetic resonance imaging (MRI) suggestive of axial spondyloarthritides (axSpA) is higher than expected.

Objectives: To identify and compare factors associated with the extension of MRI lesions in the spine and the SLJ in the general population.

Methods: All available spinal- (sagittal T1/T2 sequences) and SLJ- (semicoronal STIR sequences) MRIs were evaluated by two trained readers blinded to clinical data. BME (SLJ and spine) suggestive of axSpA were recorded. The extension of BME was quantified using the Berlin MRI score. Discrepancies were resolved by consensus. Degenerative lesions of the Modic type were excluded. The association of age (increase per decade), sex, HLA-B27 and hsCRP positivity, smoking (ever smoker vs. no smoker), spinal pain (yes vs. no in last 3 months), body mass index (BMI) categories (WHO definition), physically demanding job, and giving birth within the last 12 month with the severity of BME were examined. Associations between clinical factors and the Berlin MRI score were analyzed by negative binomial regression models resulting in incidence rate ratios (IRRs).

Results: MRIs of 793 volunteers from the general population, mean age 37.3±6.3 years, 49.4% male, 8.9% HLA B27+, 7% CRP-positive, 56.9% with back pain in the last 3 months (28.8% with back pain NRS ≥4/10), 35.7% reported physically heavy work, 55% with BMI ≥ 25 kg/m², 16.2% current smokers, and 5% of females with pregnancy in the last year before MRI examination, were evaluated.

For BME on SLJ-MRIs, significant associations (IRR, 95% confidence level) were found for pregnancy in the last year (3.82, 1.17-14.24), HLA-B27+ (2.42, 1.23-4.55), BMI (25-30 vs. <25; 2.09 (1.33-3.31)) and presence of back pain in the last 3 months (1.54, 1.02-2.33).

For BME on spinal MRIs, significant associations were found for age per decade increase (1.45, 1.10-1.91) and physically demanding work (1.45, 1.04-2.00), while HLA-B27+ (1.32, 0.79-2.24), BMI (>30: 0.84, 0.53-1.32 (<25 reference)) and back pain in the last 3 months (1.29, 0.95-1.77) showed no association. Overall, spinal BME was more frequent than SLJ BME in the participants working at a desktop (61.5% vs. 54.4%), while smokers (66.9% vs. 63.8%) and participants with back pain in the last 3 months (62.5% vs. 56.9%) had more often SLJ BME than spinal BME, respectively.

Conclusion: In this population-based study, individuals aged <45 years, HLA-B27+, women with pregnancy in the last year and presence of back pain were associated with the extent of BME in the SLJ, while age and physically demanding work were associated with the extent of BME in the spine. These data support the hypothesis of a mechanistic origin of BME in the general population aged <45 years, while HLA B27 is a severity but not a susceptibility factor for BME in the SLJ.

**OP0086**
NATIONAL VARIATION AND FACTORS ASSOCIATED WITH THE TRANSITION FROM FIRST USE TO LONG-TERM OPIOID USE FOR NON-CANCER PAIN

M. Jani1, B. Birie Yimer1, T. Sheppard1, M. Lunt1, W. Dixon1. 1University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom

Background: Prescribing behaviour of physicians has been described as a key driver of rising opioid prescriptions and long-term opioid use. However, the effect of prescribers requires interpretation within context. No studies have investigated the extent to which regions, practices and prescribers, vary in opioid prescribing accounting for case-mix by considering this hierarchy together.

Objectives: (i) Quantity and identity risk factors for the transition from new-user to long-term opioid user (ii) Quantify variation of long-term use attributed to region, practice and prescriber, accounting for patient mix and chance variation.

Methods: We conducted a retrospective observational UK study between 2006-2017 using Clinical Practice Research Datalink. Opioids new users, ≥18 years, without cancer were identified. Long-term opioid use was defined as ≥3 opioid prescriptions issued within a 90-day period from index date, or ≥1 opioid prescription lasting at least 90 days in the first year. A multi-level random-effects logistic regression model was used to examine the association of patient characteristics with the odds of becoming a long-term opioid user. To examine variation in opioid use amongst prescribers, GP practices and region after adjusting for patient case-mix, we used a nested random-effect structure. A ‘high-risk’ region, prescriber or practice was defined as those where the entire adjusted 95% CI lay above the population average.

Results: 1,968,742 new opioid users were included; 14.6% patients transitioned to long-term use. In the fully adjusted model, factors associated with higher odds of long-term opioid use included high morphine milligram equivalents (MME)/day at first prescription, older age, deprivation, fibromyalgia, rheumatological conditions, major surgery (Table). After adjustment for case-mix, the North-West, Yorkshire and South-West were found to be high-risk regions for long-term use. 103 practices (25.6%) and 540 prescribers (3.5%) were associated with a significantly higher risk of long-term use. The odds of becoming a long-term user for a patient belonging to these prescribers reached up to >3.5 times than the population average.

Conclusion: Prescribing factors, age, deprivation and conditions including fibromyalgia and rheumatological conditions were associated with higher odds of long-term opioid use. In the first UK study evaluating long-term opioid prescribing with adjustment for patient-level characteristics, variation in regions and especially practices and prescribers were observed. Our findings support greater calls for action to reduce practice and prescriber variation by promoting safe practice in opioid prescribing.

INITIATING TNF INHIBITORS IN INFLAMMATORY ARTHRITIS DOES NOT DECREASE THE AVERAGE OPIOID ANALGESIC CONSUMPTION

O. Paison1,2,3,4, T. Love5,6, J. K. Wallman2,3, M. C. Kapetanovic2,5, P. S. Gunnarsson2,7, B. Gudbjornsson8,9. 1Landspitali University Hospital, Centre for Rheumatology Research, Reykjavik, Iceland; 2Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; 3Skåne University Hospital, Department of Rheumatology, Lund, Sweden; 4University of Iceland, Faculty of Medicine, Reykjavik, Iceland; 5Landspitali University Hospital, Department of Science, Reykjavik, Iceland; 6University of Iceland, Faculty of Pharmaceutical Sciences, Reykjavik, Iceland; 7Landspitali University Hospital, Hospital Pharmacy, Reykjavik, Iceland

Background: TNFα-inhibitor (TNFi) therapy is effective in controlling several rheumatic diseases and has been shown to reduce pain in patients with arthritis. Opioids are often prescribed for chronic pain, a common issue in inflammatory joint disease.

Objectives: To explore the impact of the initiation of TNFi therapy as a first-line biologic disease-modifying anti-rheumatic drug (DMARD) on the prescription rates of opioids in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS) and undifferentiated arthritis (UA) in Iceland.

Methods: All patients receiving biologic DMARD therapy for rheumatic diseases in Iceland are registered in a nationwide database (ICEBIO). The Icelandic Directorate of Health operates a Prescriptions Medicines Register that includes over 90% of all drug prescriptions in Iceland. The study group included patients with RA, PsA, AS, and UA registered in ICEBIO and for each of them five randomly selected comparators from the general population matched on age, sex, and calendar time. On February 1st 2016 we extracted data on all filled opioid analgesic prescriptions two years before and two years after the date of TNFi initiation.

Results: Data from 359 RA, 217 AS, 251 PsA and 113 UA patients and 4700 comparators were collected. In total, 75% of patients compared to 43% of comparators received ≥1 opiate prescription during the study period. The proportion of patients using opioids (regardless of dose) two years prior to TNFi initiation was 41%, increasing to 49% the following year. After TNFi initiation the proportion returned to 40% (Figure 1). Despite this, the mean yearly opiate dose used by the patients followed a rising trajectory throughout the study period (Figure 2). In total, patients were prescribed nearly 6 times more opioids than the comparators, corresponding to a bootstrapped mean (95% CI) dose of 618 (601-1073) mg MED per patient and year compared to 139 (111-171) mg for comparators.

Conclusion: Three out of four patients with inflammatory arthritis in Iceland use opioid analgesics in the two years prior to and/or after the initiation of TNFi therapy and the mean doses were significantly higher than in matched comparators. The proportion of patients receiving opioids increased before TNFi therapy and then decreased again to the previous level. The initiation of the first-line TNFi did not reduce opioid consumption by dose at the group level. On the contrary, there was a trend towards increasing doses over time in both patients and comparators, possibly reflecting the development of opiate tolerance.

Figure 2. Bootstrapped mean oral morphine equivalent dose per person per year for patients with inflammatory arthritis (above) and age and sex matched comparators (below). Box edges represent 25-75th percentiles and whiskers 95% confidence intervals.

Methods: A double-blind, randomized, clinical trial. Sixty-two patients with resistant chronic lumbar radicular pain were included. (The sample size was calculated on the assumption that clomipramine would reduce the incidence of lumbar radicular pain of 35%, compared with placebo, with a two-sided test, an alpha level of 0.05, and a power of 85%). Patients were randomly allocated to receive either clomipramine by slow intravenous infusion for 10 days in a hospital setting with progressively increasing doses, 25 mg on the first day, 50 mg on the second day and 75 mg on the third day until the tenth day, or placebo (500 ml of physiological serum a day). For both groups, paracetamol is added intravenously at a dose of 3 g per day for ten days. Parecoxib for 3 days and ten sessions of lumbar spine rehabilitation including analgesic massage, muscle strengthening and joint maintenance. At the exit, clomipramine was relayed with 25 mg per day orally until the 90th day for clomipramine group, and paracetamol was authorized in both groups, in case of severe pain. The primary outcome was pain intensity, measured at baseline, 5th day, 10th day and 90th day using VAS pain (10 mm). Secondary outcome included DN4-questionnaire, lumbar radicular discomfort (VAS 10 mm), pain-free perimeter of walking (min), disability assessed using the Roland Morris Disability questionnaire and severity of mood symptoms assessed using the Hospital Anxiety and Depression scale (HAD), measured on days 0, 5, 10 and 90.

Results: 31 patients were assigned to the clomipramine group and 31 to the placebo group. There were no differences between the groups in demographic characteristics. Treatment by Clomipramine had a significantly greater reduction in pain, discomfort and DN4 from the 5th day (p = 0.000, p = 0.001 and p = 0.004 respectively) than the placebo, with an improvement maintained until 90th day. There was a statistically significant improvement in pain-free walking distance and disability for the clomipramine group from the 10th day until 90th day. However, there was no significant improvement in HAD between the 2 groups. (p ≥ 0.1).

Conclusion: This double-blind, randomized, clinical trial shows that clomipramine is quickly effective and maintained over time in the management of resistant chronic lumbar radicular pain. It can therefore be part of the therapeutic arsenal in this sense.

OP0089

Efficacy of clomipramine for chronic lumbar radicular pain a randomized clinical trial

S. Afilal, S. Fellous, A. Ilham, R. Abouqal, I. Hmamouchi, R. Yang, C. Bramson, C. West, K. Verburg, University of Rochester Medical Center, Rochester, United States of America; 2Paris Descartes University, Paris, France; 3Chiba University, Chiba, Japan; 4Northwestern University Feinberg School of Medicine, Chicago, United States of America; 5University of Southern California, Los Angeles, United States of America; 6Eli Lilly & Company, Indianapolis, United States of America; 7Pfizer Inc, New York, United States of America; 8Pfizer Inc, Groton, United States of America

Background: Tanezumab, a monoclonal antibody against nerve growth factor, was recently evaluated in an 80-week placebo and tramadol-controlled trial in patients with chronic low back pain (CLBP) and a history of inadequate response to standard-of-care analgesics (NSAIDs, opioids, etc). Primary endpoint was change in Low Back Pain Intensity (LBPI) at week 16 vs placebo. Key secondary endpoints were the proportion of patients with ≥50% improvement in LBPI at week 16, change in LBPI at week 2 (all vs placebo). Tanezumab 10mg met the primary and all key secondary endpoints. Tanezumab 5mg did not meet the primary endpoint, but improved 2 of 3 key secondary endpoints. Due to the primary endpoint result and the statistical gate-keeping approach to control for multiple comparisons, a conclusion of superiority over placebo could not be made for the 5mg dose.

Objectives: To further characterize tanezumab’s effects on pain and function in this trial through analysis of Brief Pain Inventory-short form (BPI-sf) scores.

Methods: Patients received placebo (n=406), subcutaneous (SC) tanezumab 5mg (every 8 weeks; n=407), SC tanezumab 10mg (every 8 weeks; n=407) or oral tramadol prolonged-release (100-300mg/day; n=605). Pre-specified secondary endpoints included BPI-sf worst pain, average pain, the overall pain interference index, and selected individual domains of the index (general activity, walking ability, sleep, and normal work). Least squares (LS) mean (standard error [SE]) changes from baseline in BPI-sf scores were compared between groups (unadjusted for multiplicity) at week 16 using an analysis of covariance model. Scores range from 0-10 with higher scores indicating greater pain severity or functional impairment.

Results: LS mean (SE) differences from placebo for worst pain were -0.52 (0.19) for tanezumab 5mg (p<0.01), -0.54 (0.19) for tanezumab 10mg (≤0.01), and -0.24 (0.17) for tramadol (p=0.17). LS mean (SE) differences from placebo for average pain were -0.37 (0.18) for tanezumab 5mg (p=0.04), -0.46 (0.18) for tanezumab 10mg (≤0.01), and -0.17 (0.16) for tramadol (p=0.29). LS mean (SE) differences from placebo for the pain interference index were -0.41 (0.18) for tanezumab 5mg (p=0.03), -0.58 (0.18) for tanezumab 10mg (≤0.01), and -0.15 (0.17) for tramadol (p=0.39). Effects of tanezumab were not statistically different (p>0.05)
from tramadol for worst pain, average pain, and the pain interference index, with exception of the pain interference index for tanezumab 10mg (p=0.01). Mean dose of tramadol was 200mg/day at week 16. Tanezumab 10mg significantly improved the majority of individual domains of the pain interference index (general activity, walking ability, sleep, and normal work) vs placebo and vs tanezumab. Tanezumab 5mg significantly (p<0.05) improved pain interference with general activity and normal work vs placebo, and sleep vs placebo and vs tanezumab. No statistical differences in any domain was observed for tramadol vs placebo.

Conclusion: Tanezumab 5mg and 10mg significantly improved worst pain, average pain, and overall pain interference index scores vs placebo in patients with CLBP. Tanezumab 10mg also significantly improved the overall pain interference index vs tramadol. Tanezumab 5mg significantly improved most individual domains of the pain interference index vs placebo, while tanezumab 10mg significantly improved all domains assessed vs placebo and vs tramadol.

SLE, Sjögren's and APS clinical aspects

A TWO-SCORE INTERFERON SIGNATURE AND MUSCULOSKELETAL IMAGING EXPLAIN THE ASSOCIATION BETWEEN INTERFERON AND ARTHRITIS IN SLE

Z. Wigston1,2, A. Burska1,2, A. Alase1,2, K. Mahmoud1,2, E. Vital1,2, University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Interferon (IFN) signature is associated with disease activity and flares in SLE. We previously described two independent IFN gene expression scores; IFN Score A (the most commonly measured ISGs and IFN Score B (less commonly measured ISGs which may also respond to IFN-II or other immune mediators)[1]. Many more clinical outcomes are associated with IFN Score B than with a “classic” interferon signature. These include progression of At-Risk individuals to SLE, response to rituximab, and differentiation of IFN signature in RA and SLE.

In previous work, the relationship of IFN Signatures with arthritis was less clear than for other SLE features. This may be related to the local regulatory effects of IFN-beta to SLE, response to rituximab, and differentiation of IFN signature in RA and SLE.

In previous work, the relationship of IFN Signatures with arthritis was less clear than for other SLE features. This may be related to the local regulatory effects of IFN-beta to SLE, response to rituximab, and differentiation of IFN signature in RA and SLE.

USEFUL was a multicentre longitudinal study including serial ultrasound assessment of SLE patients with inflammatory MSK pain receiving treatment with glucocorticoids (GC).

Objectives: To determine whether IFN scores A and B are associated with imaging-proven synovitis in SLE and measure the responsiveness of IFN scores to GC treatment.

Methods: 133 SLE patients were recruited into the USEFUL study if the referring physician deemed they had inflammatory pain warranting treatment. Participants received depomedrone 120mg IM then were assessed at 0, 2 and 6 weeks using clinical instruments and ultrasound (US). OMERACT US criteria were used to categorise patients as active (GS2 or PD1 in at least one joint or tendon), active in both joints and tendons, or non-active (no GS1 and P0D or better in all joints).

Expression of 26 interferon stimulated genes, normalised to PPIA1 was measured in whole blood collected in TEMPUS tubes using a custom Taqman array. IFN scores A and B were calculated as previously described[1]. Missing data was imputed using expectation-maximisation method. Parametric tests were applied with post hoc Tukey to compare scores between groups.

Results: At baseline, there was no significant difference in IFN Score A between ultrasound groups (F = 1.045, p = 0.355). In contrast, IFN Score B differed significantly between ultrasound groups (F = 4.168, p = 0.018). The greatest difference was between active ultrasound for both joints and tendons (n=22) and non-active ultrasound (n=53) (difference = 0.75, 95% CI 0.13, 1.37, p=0.013). There was no significant change from baseline in IFN Score A at week 2 (mean difference 0.08, 95% -0.14, 0.31, p = 0.45) or week 6 (mean difference -0.03, 95% -0.25, 0.19, p = 0.79). Similarly, there was no significant change in IFN Score B at week 2 (mean difference -0.01, 95% -0.18, 0.17, p = 0.93) or week 6 (mean difference -0.07, 95% -0.21, 0.18, p = 0.36).

Conclusion: Previous studies were unable to demonstrate an association between a typical interferon signature and arthritis in SLE. Our study includes a homogeneous patient population and therapy, objective measure of synovitis, and a more detailed assessment of IFN Status. We found that imaging-proven synovitis is associated with increased expression of a specific subset of ISGs (IFN score B), but not a more typical interferon signature genes (IFN Score A).

This increases the body of evidence for the value of IFN score B in predicting clinical outcomes. GC treatment did not affect systemic IFN signature scores at follow up. Future analysis will explore the role of IFN Scores in predicting clinical responses to therapy in this study.

OPTIMIZING A DEFINITION OF LUPUS LOW DISEASE ACTIVITY STATE (LDA) FOR DAILY CLINICAL PRACTICE: SLE-DAS LDA VS LLDAS

H. Assumcao1, D. Jesus2, J. A. P. Da Silva3, L. Inês1,4, Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; Centro Hospitalar de Lisboa, Rheumatology, Lisbon, Portugal; Institute for Clinical and Biomedical Research (ICBR), Faculty of Medicine, University of Coimbra, Coimbra, Portugal; School of Health Sciences, University of Beira Interior, Covilhã, Portugal

Background: The Lupus Low Disease Activity State (LLDAS)[1] is a proposed target for the management of Systemic Lupus Erythematosus (SLE). However, the LLDAS definition is cumbersome to apply, as it requires comparison with manifestations in the previous visit, scoring of Systemic Lupus Erythematosus disease activity index (SLEDAI), Physician Global Assessment (PGA), treatment conditions and exclusion of additional features. The SLE disease activity score (SLE-DAS)[2] is a validated continuous measure with higher sensitivity to change and validity in predicting damage accrual as compared to SLEDAI-2K. SLE-DAS is quickened with its online calculator. The SLE-DAS low disease activity state (SLE-DAS LDA) was recently defined [3] and it is easier to apply than the LLDAS.

Objectives: To compare the performance of SLE-DAS and LLDAS for defining LDA state in a real-life clinical setting.

Methods: Cross-sectional study of SLE patients fulfilling ACR97 and/or SLICC’12 classification criteria followed at an academic lupus clinic, from January to December 2019. Fulfillment of LLDAS and SLE-DAS LDA state was verified for each patient. The SLE-DAS LDA state was defined as (1) SLE-DAS ≤3.77[3] with (2) prednisolone dose ≤5mg/day. The proportion of cases in LDA state using LLDAS and SLE-DAS LDA was compared with McNemar’s test. Agreement between LLDAS and SLE-DAS LDA was tested with Cohen’s Kappa coefficient.

Results: We included 292 patients (86.6% female, mean age: 48.7±14.4 years, mean disease duration: 14.4±9.3 years). From these, 245 (83.9%)

Conclusion: A LDA state, by either definition, was achieved by most patients in this real-life setting. LLADAS and SLE-DAS LDA identify almost exactly the same population. The SLE-DAS LDA definition is easier to apply and hence might be the optimal definition for use in daily clinical practice.

Conclusion: Our data confirmed that LLADAS is an attainable early treatment target for SLE. Though with more difficulty, RONT can be achieved in two-thirds of our patients. ROFT may not be an ideal treatment target at present as it is only attained in few patients.

Bruce3,4, The University of Manchester, Manchester, United Kingdom; 1University of Birmingham, Birmingham, United Kingdom; 2The Kellgren Centre of Rheumatology, Manchester, United Kingdom; 3University Hospital of South Manchester, Wythenshawe, Manchester, United Kingdom; 5Salford Royal NHS Foundation Trust, Manchester, United Kingdom

Background: The EULAR-ACR 2019 (EULAR19) classification criteria for systemic lupus erythematosus (SLE) were developed to improve the sensitivity and specificity of previous criteria. Notably, both the EULAR19 and existing SLICC-SLE 2012 (SLICC12) criteria can classify patients as having SLE by the presence of immunology and haematological abnormalities in the absence of any signs or symptoms.

Objectives: To validate the EULAR19 criteria, with comparison to existing criteria, in a large cohort of patients with an established systemic autoimmune rheumatic disease (SARD).

Methods: We recruited 227 adult patients who were ANA positive with ≥1 clinical feature suggestive of a SARD, from three hospitals in the North West of England. Clinician diagnosis was used as gold standard; we then applied the EULAR19, SLICC12, and ACR-SLE 1997 (ACR97) criteria.

Results: Of the 227 patients recruited, by clinician diagnosis, 89 patients (36%) had SLE, 43 (17%) primary Sjögren's (pSS), 62 (25%) undifferentiated CTD (UCTD), 25 (10%) systemic sclerosis (SSc) and 8 (3%) an inflammatory myositis. 43 (17%) had SLE, 43 (17%) primary Sjögren's (pSS), 62 (25%) undifferentiated CTD (UCTD), 25 (10%) systemic sclerosis (SSc) and 8 (3%) an inflammatory myositis. The characteristics of these patients and the breakdown of the EULAR19 criteria are outlined in figure 1.

Figure 1. Baseline characteristics and classification criteria compared across five SARD diagnoses.

The sensitivity and specificity of the EULAR19 is similar to ACR97 (sensitivity 84% (95% CI 75-91%) vs. 87% (95% CI 78-93%) and specificity 78% (95% CI 70-84%) vs. 76% (95% CI 68-83%) respectively). The SLICC12 criteria by contrast are more sensitive (94% (95% CI 87-98%) and less specific (61% (95% CI 52-69%)) in this cohort.

Figure 2 illustrates patients with a clinician diagnosis of SLE or UCTD who meet each of the classification criteria. Of the 89 patients with a clinician diagnosis of SLE, 39 (44%) patients would have sufficient points to meet EULAR19 criteria on blood test results alone in the absence of clinical symptoms. Four pSS patients and 4 UCTD patients would also meet EULAR19 criteria from positive blood results alone.

Similar to SLICC12, it is possible to classify patients as having SLE using the EULAR19 criteria by haematological and other laboratory tests. To what extent haematological abnormalities can be potentially used as the sole ‘clinical criteria’ needs consideration.

Figure 2. Venn diagrams illustrating patients with SLE and UCTD who meet the EULAR19, ACR97 and SLICC12 classification criteria. No criteria refers to the patients not meeting any of the three SLE classification criteria.

Conclusion: These results suggest that the EULAR19 criteria perform comparably to the ACR97 criteria when applied to an established cohort of SARDs.

A decision model of labial gland biopsy based on B-mode ultrasonography with shear-wave elastography in patients with suspected Sjögren’s syndrome

Y. Mo1, S. Hao2, Q. H. Li1, J. J. Liang1, Y. Luo1, J. W. Wang1, X. Zhang1, W. L. Liu2, L. Dai1. 1Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China; 2Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Ultrasonography, Guangzhou, China

Background: Focal lymphocytic sialadenitis defined as focus score (FS) ≥1 on labial gland (LG) biopsy plays an integral role in various classification criteria of Sjögren’s syndrome (SS). However, suspected patients often hesitate to receive a biopsy, and rheumatologists hope a decision for biopsy based on a high predicted incidence of FS≥1, or against biopsy based on an absolutely low predicted incidence.

Objectives: To build a decision model of LG biopsy based on B-mode ultrasoundography (US) with shear-wave elastography (SWE) in patients with suspected SS.

Methods: Patients who had at least one symptom of oral dryness (based on AECG questions) or had anti-SSA positive were recruited and signed a written informed consent. Bilateral parotid (PG) and submandibular glands (SMG) were examined with B-mode US which graded the echostructure of each gland on a 0 to 4 grading system scaled 0 to 4 (US score), and SWE which described the elasticity of glands. Then LG biopsy was performed.

Results:

(1) Ninety-one patients whose mean age was 43±15 years were enrolled and 93% of them were female. Anti-SSA was detected in 77 patients (85%) and 28 patients (31%) showed unstimulated whole saliva flow rate (USFR) ≤0.1 mL/min. There were 57 patients (63%) showing FS≥1 on LG biopsy. Sixty-three patients (69%) were classified as primary SS, 10 patients (10%) were secondary SS, 18 patients (20%) were uCTD and one patient was RA alone without SS.

(2) US scores were equal between PG and SMG in 59 patients (65%), while the rest patients showed different US scores between two glands: 7 patients (8%) showed higher US scores in PG and 25 patients (27%) showed higher scores in SMG. In each pair of glands US scores were equal. SWE values in PG or SMG of US score 1, 2 or 3 were significantly equal. SWE values in PG or SMG of US score 1, 2 or 3 were significantly equal.

Scientific Abstracts
higher than those of US score 0, while SWE values in glands of US score 4 became declined and showed no significant difference from those with US score 0 (Figure 1A). (3) Heatmap showed US scores in either major salivary gland of patients with FS ≥1 on LG biopsy were significantly higher than those with FS <1 (all p<0.001, Figure 1B). ROC curve showed a total US score (including bilateral PG and SMG) ≥30 could significantly recognize patients with FS ≥1, respectively with specificity of 100% and 93% (Figure 1C). In this cohort, among 51 patients with a total US score ≥9 and/or a total SWE value ≥30, 49 patients (96%) showed FS ≥1 on LG biopsy; while two outliers showed total US scores were both 8 although combined SWE values ≥30. Other 29 patients showed total US score ≥6 with total SWE values <30 and only one patient (3%) showed FS ≥1 on LG biopsy. The remaining 11 patients showed total US scores were 8 with total SWE values <30 and 64% of them (n=7) showed FS ≥1.

Conclusion: A preliminary decision model of LG biopsy based on B-mode US with SWE in patients with suspected SS were built in Table 1. For example, rheumatologists should reassess the need for biopsy if the incidence of FS ≥1 would be <5%. Another cohort of patients with suspected SS is needed for further validation.

OP0096 THE DIFFERENCES BETWEEN SJÖGREN’S SYNDROME PATIENTS WITH COMBINED SERONEGATIVITY AND ANTI-RO/SSA SEROPOSITIVITY

1Pathophysiology Department, Athens School of Medicine, Greece; 2Unit of Medical Technology and Intelligent Information Systems, University of Ioannina, Ioannina, Greece; 3 Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece; 4Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Italy; 5Department of Nutrition and Clinical Dietetics, Harokopio University of Athens, Greece; 6Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece, Greece; 7Rheumatology Clinic, Department of Medical area, University of Udine, Udine, Italy, Udine, Italy.

Background: Sjögren’s syndrome (SS) is characterized by B cell hyperactivity reflected by hypergammaglobulinemia as well as a plethora of autoantibodies including antinuclear antibodies (ANA), anti-Ro/SSA, anti-La/SSB and rheumatoid factors (RF). Previous studies have focused on the phenotype of single positive (ANA or anti-Ro/SSA or anti-La/SSB) or double positive (anti-Ro/SSA and anti-La/SSB positive) SS patients, showing differences regarding the age of diagnosis, sicca manifestations and specific extraglandular manifestations. To our knowledge, no study has ever explored the clinical spectrum of triple seronegative (anti-Ro/SSA + anti-La/SSB + RF positive) and quadruple seronegative (ANA + anti-Ro/SSA + anti-La/SSB + RF negative) SS patients.

Objectives: To study the differences in the clinical phenotype of triple and quadruple seronegative (SS) patients in a large cohort of well characterized patients, after comparison with anti-Ro/SSA positive patients.

Methods: From a total cohort of 1723 consecutive SS patients who fulfill the 2016 EULAR/ACR criteria and are followed up in 4 clinical centers ([Universities of Pisa and Athens, Harokopio and Ioannina, (PAHI)], those who have been found triple or quadruple seronegative were identified and compared with matched anti-Ro/SSA positive SS patients according to age of SS onset, disease duration and gender, in 1:1 and 1:2 ratio respectively. Glandular (dry mouth, dry eyes, parotid gland enlargement) and extra-glandular manifestations (Raynaud’s phenomenon, chronic fatigue arthralgias/myalgias, arthritis, palpable purpura, liver involvement, kidney involvement, lung involvement, neurologic involvement, long standing lymphadenopathy and lymphoma) were compared between the 2 seronegative groups and the anti-Ro/SSA positive control group. Statistical analysis for categorical variables was performed by Fisher exact or chi-square tests and for continuous variables with t test or Mann-Whitney accordingly.

Results: Two hundred and four SS patients (11.8%) were identified as triple negatives and 53 (3.0%) as quadruple, with a median disease duration of 6 years (range: 0-41) and 5 years (range: 0-32) respectively. The matched anti-Ro/SSA controls were 204 for the triple and 103 for the quadruple negatives. Triple negatives had lower frequency of monoclonal gammopathy (5.5% vs 12.1%, p=0.04), low C4 serum levels (23% vs 36%, p<0.009) and lymphoma (3.4% vs 9.8%, OR=3.06, 95% CI =1.27-7.85) while quadruple negatives exhibited higher prevalence of dry eyes (100% vs 90%) and lower prevalence of long standing lymphadenopathy (2.7% vs 19.5%, p=0.001) and lymphoma (0% vs 15%, p=0.001) compared to anti-Ro/SSA matched controls.

Conclusion: Combined seronegativity account for more than 10% of SS population and is associated with lower prevalence of lymphoma compared to anti-Ro/SSA positive patients.

OP0097 DEVELOPMENT OF NEW INTERNATIONAL CLASSIFICATION CRITERIA FOR ANTIPHOSPHOLIPID SYNDROME: PHASE III CASE COLLECTION RESULTS

M. Barbhaiya, D. Erkan, Y. Ahmadzadeh, K. Costenbader, R. Naden, S. Zulu on behalf of the New APS Classification Criteria Collaborators and Phase III Case Collectors. 1Hospital for Special Surgery, Weill Cornell Medicine, New York, United States of America; 2Brigham and Women’s Hospital, Harvard Medical, Boston, United States of America; 3Auckland City Hospital, Auckland, New Zealand; 4Nancy Academic Hospital, Nancy, France

Background: An international multi-disciplinary effort is underway to develop rigorous, new, consensus- and evidence-based classification criteria for Antiphospholipid Syndrome (APS). The methodological approach includes four phases; we have previously presented phases I and II (item generation and reduction), which resulted in 27 candidate criteria 1 organized in laboratory and clinical domains.

Objectives: Phase III (item weighting/threshold identification) is currently underway; here we report initial Phase III case collection results.

Methods: We used REDCap, a secure data system, for Phase III international case collection. The candidate criteria of 27 items at the end of Phase II was represented in a standardized case collection form. We asked international physicians interested in APS to provide and cases using a Likert scale (+3 to -3: highly likely to highly unlikely to be APS). Cases with higher scores (+2 or +3) were categorized as “highly likely” APS, whereas lower scores (+1 to -3) were categorized as “equivocal or unlikely” APS.

Results: We collected 314 potential APS cases (mean age 43.8±14.4 years; 79% female; and 77% white) between 6/2019-8/2019 from 17 sites in Europe (47%), North America (41%), and South America (11%). Majority of cases were potential primary APS (64%); 137 were rated as “highly likely” and 177 as “equivocal or unlikely” APS. Lupus anticoagulant, anti-β2glycoprotein-I antibody IgG/M, anticardiolipin antibody IgG, arterial thrombosis, venous thromboembolism, macrovascular disease, fetal loss between 16-34 weeks, severe preeclampsia, severe placental insufficiency, cardiac valve disease, and low platelet count occurred with higher frequency in the APS cases categorized as “highly likely” (Table).

Conclusion: International collection of cases spanning the spectrum of “highly likely” to “equivocal or unlikely” APS provide “real world” assessment of patients being referred for APS evaluation. In next steps, proposed candidate criteria will be further refined, organized, and weighted, and a preliminary threshold for APS classification will be determined.

OP0098 TRAJECTORIES OF GROWTH IN OFFSPRING FROM MOTHERS WITH PREVALENT OR PRE-SYSTEMIC LUPUS ERYTHEMATOSUS: A NATIONWIDE POPULATION-BASED STUDY IN KOREA

1Chungbuk National University Hospital, Division of Rheumatology, Department of Internal Medicine, Cheongui, Korea, Rep. of (South Korea); 2Chungbuk National University Hospital, Department of Pediatrics, Cheongui, Korea, Rep. of (South Korea); 3Soonchunhyang University, Division of Rheumatology, Department of Internal Medicine, Cheonan, Korea, Rep. of (South Korea); 4College of Medicine, Korea University, Institute for Evidence-based Medicine, Cochrane Korea, Department of Preventive Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that primarily affects women of childbearing age and is known to have poor maternal and fetal outcomes associated with pregnancy.

Objectives: We planned on the long-term follow-up studies to find out whether SLE offspring with low birth weight would properly catch up in future childhood life.

Methods: Korean National Health Insurance (NHI) service is a mandatory, single public health insurance system that covers more than 50,000,000 Korean population. It consists of inpatient and outpatient diagnosis and treatment data for the purpose of reimbursement. Rare and Intractable Diseases (RID) registration system is a copayment reduction scheme which provides financial support to patients with certain rare disease, include SLE. National Health Screening Program for Infants and Children (NSHPIC) is a population screening system for children aged 4 to 71 months, requiring 7 visits to participating clinic at pre-specified times.

Among the children who were born between 2008 and 2013, we identified those who completed the first (between 4-6th month), second (between 9-12th month) and either sixth or seventh examination (between 54-65th month and 66-71th month, respectively) of NSHPIC. By linking maternal and offspring healthcare data through their unique personal identification numbers, we constructed a mother-child database to track the growth of the child. Among their mothers, we could identify SLE patients who had given live singleton births using RID database (V136) and the international classification of disease code (M32.x) for SLE. Therefore, we were able to follow birth weight and subsequent growth of offspring according to their mother’s disease status.

Results: We could identify 1,007 offspring from SLE mothers and 793,537 control from non-SLE mothers. Offspring from SLE mothers showed the higher risk of low birth weight defined as less than 2500g [hazard ratio (HR) 4.79, 95% confidence interval (CI) 4.08–5.63]. In terms of subgroups analysis according to the time of diagnosis, the risk of low birth weight was the highest in offspring from those who diagnosed SLE during pregnancy (HR 8.22, 95% CI 3.16–21.26). In addition, the risk of low birthweight not only in offspring from already diagnosed SLE before pregnancy (HR 5.63, 95% CI 4.41–7.19), but also in offspring from those who diagnosed with SLE after delivery (pre-SLE) compared to general population (HR 2.03, 95% CI 1.33–3.09).

Subsequent growth failure defined as less than 3 percentile was more prevalent in SLE offspring compared to general population at 4-6 month (HR 3.28, 95% CI 2.22–4.77). However, at 6-9 months and 54-71 months, the gap was reduced, showing no statistical difference with the general population (HR 1.22, 95% CI 0.73–2.03 and HR 1.26, 95% CI 0.88–1.80, respectively).

Among SLE offspring with low birth weight (< 2500g), 89.34% showed the 10 percentile or more at 4-6 month. The proportion of children who catch up after the 10 percentile or more at 4-6 month has not increased since then, as the proportion of children who were aged 4 to 71 months, requiring 7 visits to participating clinic at pre-specified times.

OP0099 FUNCTIONAL MAPPING OF SYNOVIAL FIBROBLAST POPULATIONS IN HEALTH AND ARTHRITIC DISEASE: INSIGHTS INTO THE PATHOGENIC REMODELING OF SYNOVIAL MICROENVIRONMENT

D. Konstantopoulos1, C. Tzaleria2, M. Sakkou3, A. Liakos3, M. Lavigne3, D. Karamitros2, M. Fousteri1, M. Armaka1, G. Kollia1,4. 1 B.S.R.C.‘Alexander Fleming’; Institute of Fundamental Biomedical Research, Vari, Greece; 2 B.S.R.C.‘Alexander Fleming’; Institute of Bioinnovation, Vari, Greece; 1 B.S.R.C.‘Alexander Fleming’; Institute of Fundamental Biomedical Research, Vari, Greece; 4 Medical School of Athens, Department of Physiology, Athens, Greece

Background: Our previous studies highlighted the fundamental in vivo role of synovial fibroblasts (SFs) in TNF-mediated murine chronic arthritis1,2 and recent findings identified different SF identities based on their transcriptomic profiles with distinct contributions in acute, autoimmunity-based, murine arthritis3.

Objectives: In this study, we focus on delineating the map of SF subpopulations in healthy joint and in the course of arthritic disease and the underlying regulatory networks functioning towards pathogenicity.

Methods: Sorted single cell suspensions (CD45−, Pdpl+) and their fragmented nuclei from synovial joints of WT, early and late arthritic hTNFtg mice were processed for scRNAseq and scATAC employing a droplet-based technology (10x Genomics). To define the transcriptional and epigenetic signatures originating from the different two assays, we developed an integrative analysis pipeline based on the Seurat software package (v3.1). Meta-analysis of previously reported data of K/BxN serum transfer of arthritis was employed to define commonalities and differences in SF subsets among murine modelled disease.

Results: The transition from healthy to chronically affected synovial microenvironment (SME) due to overexpression of hTNF is characterized by a dynamic transformation of SF clusters. The LINing arthritic Th1-like synovial layer (L-SFs) is hyper-populated while Sub-Lining L-Th1-like SF clusters (SL-SFs) are remodelled towards catabolic and inflammatory phenotypes compared to naïve SF organization pattern. Interestingly, trajectory analysis revealed that the SL clusters, which normally exhibit a gradual developmental-like process towards different profiles, differentially change during disease.

We identified that the previously reported proliferating SL cluster is absent in healthy synovium, dominates mainly in early stages of chronic arthritis and it is closely related to the L-SFs. Mapping of the gene regulatory networks by RNAseq was supported by scATAC analysis. Similarly, meta-analysis of SF profiles derived from naïve and the K/BxN-serum–treated mice showed significant differences, possibly reflecting the phenotypes of the two established models of arthritis.

Conclusion: Our approach unravels for the first time the regulatory heterogeneity and gene expression profiling of SF subpopulations in normal synovium, and reveals deep biological insights of the functional re-organization of SME during development of disease. It further identifies the common and divergent features of the different subtypes of murine arthritis that may well reflect the diversity of RA subtypes and the response to therapies.

OP0100 MOLECULAR PROFILING OF PERIPHERAL IMMUNE CELL SUBSETS IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. C. Taylor1, J. Liu2, L. Zhuo3, Y. Tian1, T. Snyder2, C. Kim1, P. Kheradpour2, K. Drake3, S. Kim1, R. E. Hawtin1. 1 University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 2 Gilead Sciences Inc., Foster City, United States of America; 3 Verily Life Sciences, San Francisco, United States of America

Background: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease that affects 1% of the world’s population. Several key biological functions are dysregulated in RA, manifesting clinically as pain, fatigue, and synovitis, with articular destruction, organ-based comorbidities, and functional decline. Defining immune dysregulation in the peripheral blood of patients with RA will help inform future work to assess the extent to which immune homeostasis can be therapeutically achieved for these pts.

Objectives: To identify baseline molecular characteristics of the peripheral immune system, at the level of individual immune cell subsets, in pts with RA recruited to clinical trials of the oral, selective Janus kinase 1 (JAK1) inhibitor, filgotinib.

Methods: Peripheral blood mononuclear cells (PBMC) were collected from 324 pts with moderate to severely active RA, who had an inadequate response to methotrexate (MTX) (FINCH-1; NCT02889796; n=109) or who were MTX naïve (FINCH-3; NCT02889728; n=215). PBMC were also collected from 50 demographically matched healthy volunteers (HV). The Immune Profiler platform was used to sort PBMC into 24 immune cell subsets, then quantify their gene expression and chromatin accessibility using RNA-seq and the assay for transposable-accessible chromatin with high-throughput sequencing (ATAC-seq), respectively. Differentially expressed genes (DEGs) and differentially accessible regions (DARs) were identified among immune cell subsets from pts with RA versus HV. Gene set signature scores of Molecular Signatures Database hallmark pathways were calculated using single sample gene set enrichment analysis (ssGSEA) to examine differences in pathway activity between groups.

Results: A total of 14,500 sequencing datasets were generated from the pt and HV immune cell subsets. Among these, over 26,000 DEGs and 220,000 DARs were identified in RA versus HV (false discovery rate <0.05) across the 24 immune cell subsets. DEGs were identified in all immune cell subsets tested and were most pronounced in natural killer (NK) subsets; most DARs were detected in myeloid and NK subsets. ssGSEA revealed differential pathway signaling in RA versus HV across multiple functions at the immune cell subset level. Myeloid subsets from pts with RA often showed elevated pathway activities versus HV whereas B, T and NK subsets showed a general decrease. In particular, monocyte populations from pts with RA versus HV had elevated pathway activities involved in inflammatory response and interleukin-6 Janus kinase/signal transducer and activator of transcription 3 signaling. The B, T and NK subsets showed a general decrease in tumor necrosis factor-α signaling; conversely, monocyte subsets showed an increase. Prior MTX exposure did not have a notable impact on the detected molecular profile.

Conclusion: Differences in gene expression, hallmark pathway activity, and chromatin accessibility were identified in RA versus HV at the immune cell subset level. Significant contributions to differences in chromatin accessibility identified in the myeloid and NK cell populations suggest that there are more active regulatory sequences in these cell types that are associated with RA. Further investigations based on these findings may increase understanding of the immune regulatory paradigm in the context of RA.

QUALITY OF LIFE IN PEOPLE WITH SYSTEMIC SCLEROSIS WITH DIFFERENT DEGREES OF LUNG DISEASE - A CROSS-SECTIONAL STUDY

C. Boström1,2, H. Petterson1, E. Svenungsson1,2, H. Alexanderson1,2, A. Nordin.1 Karolinska University Hospital, Stockholm, Sweden; 2Karolinska Institutet, Stockholm, Sweden

Background: There are few studies evaluating different aspects of quality of life including depressive symptoms and physical capacity and physical activity in patients with systemic sclerosis (SSc) with different degrees of lung disease. Objectives: The aim of this study was to evaluate differences in self-reported disability, physical capacity and activity, depressive symptoms and quality of life between patients with SSc with no-mild lung disease and those with moderate- to end-stage lung disease.

Methods: In this cross-sectional study, 279 patients with SSc fulfilling the 2013 ACR/EULAR criteria for SSc (84% limited and 16% diffuse SSc) were included. Medsger disease severity scale was used to subgroup the patients into no-mild (n=156) or moderate- to end-stage lung disease (n=115). Disability was measured with Health Assessment Questionnaire-Disability Index (HAQ-DI); physical capacity (ability to walk, jog/run); and physical activity (different intensities) was measured with three single questions; depressive symptoms with Hospital Anxiety and Depression-scale (HADS); and quality of life was measured with The Short Form (36) Health Survey (SF-36).

Results: Patients with moderate-to-endstage lung disease reported higher scores on HAQ-DI (p<0.001) and lower scores on SF-36 physical component (p<0.0001) than patients with no-mild lung disease. Patients with moderate-to-endstage lung disease reported lower physical capacity (p<0.0001), less physical activity on low to moderate intensity the past 6 months (p<0.016) and less exercise on moderate to high intensity the past year (p=0.022) compared to those with no-mild lung disease. There was no difference between the two subgroups when it comes to the mental component in SF-36 (p=0.2), however patients with moderate-to-endstage lung disease had lower scores on the subscales vitality (p=0.003), social function (p=0.002) and emotional role function (p=0.005) as well as higher scores on the HADS depressive symptoms scale (p=0.024), than the patients with no-mild lung disease.

Conclusion: Patients with SSc with moderate-to-endstage lung disease report more disability, lower physical capacity and activity, are more depressed and the physical aspects of quality of life is lower, as well as vitality, social function and emotional role function, compared to patients with no-mild lung disease. Studies evaluating whether increased physical activity and exercise may improve depressive symptoms and aspects of quality of life in patients with moderate-to-endstage lung disease are needed.

Immune deficiency and autoimmune disease

GENE SCREENING OF PRIMARY IMMUNEDEFICIENCY DISEASES IN PATIENTS WITH JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS

J. Li, W. Wang1, C. Y. Wang1, J. Y. Pan1, H. Song1. Peiking Union Medical College Hospital, Peking, China

Background: Systemic lupus erythematosus (SLE) is one of the most common auto-immune diseases in childhood. Primary immunodeficiency disease (PID) patients may present or combine with autoimmune diseases.

Objectives: This study aimed to perform gene sequencing via high-throughput sequencing technology in a series of Chinese pediatric SLE patients, and investigate the concomitant situation of PIDs and SLE. Gene sequencing results may help clarify the pathogenesis of SLE.

Methods: This was a retrospective case series of SLE children who referred to the Peking Union Medical College Hospital between 01/2016 and 09/2019. Genetic tests were performed in patients who met the inclusion criteria. We then collected demographic, clinical, and treatment information of all involved patients. Descriptive statistics were used.

Results: Seventy-one patients were finally included (eighteen boys and fifty-three girls). The median age at time of disease onset was 9.5 (range, 3-15) years. It is notable that five patients experienced their first attack before the age of five. Twenty-seven patients showed a persistent increase in ESR during treatment, while thirteen cases presented with repeated CMV infection, thirty-four cases with persistent low complement levels, seven with basal ganglia calcification showed in skull CT or MRI, four with special type of rash (i.e., frostbite-like rash, discoid erythema, reticular erythema), two with obvious hepatosplenomegaly, and one case with type 1 diabetes. Gene sequencing results showed that about ten patients combine with primary immunodeficiency disease, including Aicardi-Goutières Syndrome (AGS) (n=4), Spondyloenchondro-dysplasia with immune dysregulation (SPENCDI) (n=1), STING-associated vasculopathy with onset in infancy (SAVI) (n=1), lissencephaly protein intolerance (LPI) (n=1), Ras-associated autoimmune leukoproliferative disorder (RALD) (n=2).

Conclusion: SLE patients who present atypical or refractory manifestations should attach importance to the existence of primary immunodeficiency disease. Genetic tests are recommended for patients with early-onset SLE, especially those who have recurrent frostbite-like rash or persistent CMV infection since childhood.

Spondyloarthritis treatment

DOES GENDER, AGE OR SUBPOPULATION INFLUENCE THE MAINTENANCE OF CLINICAL REMISSION IN AXIAL Spondyloarthropathy following CERTOLIZUMAB PEGOL DOSE REDUCTION?

R. B. M. Landewe1,2, D. Van der Heijde3, M. Dougdos3, X. Baraliakos4, F. Van den Bosch5, K. Gafney5, L. Bauer6, B. Hoenk7, N. De Peyrecave8, K. Thomas1,8, L. S. Gentles9,10. 1Amsterdam Rheumatology & Clinical Immunology Center, Amsterdam, Netherlands; 2Zuyderland Medical Center, Heerlen, Netherlands; 3Leiden University Medical Center, Leiden, Netherlands; 4Paris-Descartes University and Cochin Hospital, Paris, France; 5Rheumatology Division, University of California San Francisco, San Francisco, United States of America

Background: Previous studies have shown that withdrawing tumour necrosis factor inhibitors (TNFi) in patients (pts) with axial spondyloarthropathy (axSpA) who have achieved sustained remission often leads to relapse. However, none have formally tested TNFi dose reduction strategies in a broad axSpA population or evaluated whether relapse following TNFi dose reduction and withdrawal is associated with a specific demographic subgroup.

Objectives: C-OPTIMISE evaluated the percentage of pts without flare after TNFi dose continuation, reduction or withdrawal in adults with early axSpA treated with the Fc-free, PEGylated TNFi certolizumab pegol (CZP). Here, we analyse whether responses to reduced maintenance dose were comparable in pts stratified by axSpA subpopulation, gender and age.

Methods: C-OPTIMISE (NCT02505542) was a multicentre, two-part phase 3b study in adults with early (<5 years’ symptom duration) active axSpA (stratified for radiographic [r]- and non-radiographic [nr]-axSpA). Pts received CZP 200 mg every 2 weeks (Q2W); raxSpA pt received 400 mg Q2W) for a further 48 weeks (maintenance period). The primary endpoint was the percentage of pts not experiencing a flare (ASDAS ≥2.1 at two consecutive visits or ASDAS >3.5 at any timepoint) during Wks 48–96. Analyses were conducted on subgroups according
to axSpA subpopulation, gender and age ≥/≤ the median age of the randomised set (32 years).

**Results:** During the 48-wk induction period, 43.9% of patients (323/736) achieved sustained remission and 313 pts entered the 48-wk maintenance period (rr/raxSpA: 168/145 pts; males/females: 247/66 pts; age ≥32/≤32: 165/148 pts). During the maintenance period, responses in n- and rr-axSpA pts were comparable across all three randomised arms. 83.9% rr-axSpA and 83.3% nr-axSpA pts receiving the full CZP maintenance dose did not experience a flare, and in the reduced maintenance dose arm 82.1% rr-axSpA and 75.5% nr-axSpA pts did not experience a flare. In the PBO group this was reduced to 75.9% and 22.9%, respectively. Similar responses were seen in pts stratified by gender or age, with substantially higher percentages of pts randomised to CZP full or reduced maintenance dose remaining free of flares compared to PBO in all subgroups (Figure).

**Conclusion:** The results of C-OPTIMISE indicate that a reduced maintenance dose is suitable for pts with axSpA who achieve sustained remission following long-term, indicating the importance of early, effective and long-term treatment of treatment.4

**References:**

**Complete treatment withdrawal is not recommended due to the high risk of flare.**

Background: Bimekizumab (BKZ), a monoclonal antibody that selectively neutralises interleukin (IL)-17A and IL-17F, is a potential therapeutic option in ankylosing spondylitis (AS).

Objective: To report 48-week (wk) patient-reported outcomes (PROs) in patients (pts) with AS treated with BKZ in a phase 2b dose-ranging study (BE-AGILE; NCT02963506).

Methods: Pts with active AS (Bath AS Disease Activity Index [BASDAI] ≥4; spinal pain ≥4 [0–10]), fulfilling modified New York criteria (central reading), and inadequate response/intolerance to NSAIDs were randomised according to the study design (Figure 1). PROs included spinal pain, fatigue (BASDAI Q1), morning stiffness (mean of BASDAI Q5 +6), Bath AS Functional Index (BASFI), Medical Outcomes Study (MOS) Sleep Problems Index II and AS Quality of Life questionnaire (ASQoL). Efficacy is reported for pts initially randomised to placebo (PBO) or BKZ 160/320 mg every 4 weeks (Q4W); treatment-emergent adverse events (TEAEs) are reported for pts who received ≥1 dose of study drug (Safety Set).

Results: Of 303 pts, 181 were randomised to PBO or BKZ 160/320 Q4W mg at Wk 0; 179/181 completed Wk 12 and 161/181 completed Wk 48. At Wk 12, improvements in pain, fatigue, morning stiffness, BASFI, sleep and ASQoL were greater in BKZ pts vs PBO pts. Responses were further improved or maintained to Wk 48, with no meaningful differences between BKZ 160 mg and 320 mg (Table 1). Serious TEAEs occurred in 13/303 (4.3%) pts (Table 2), which included 2 major adverse cardiac events considered not related to study drug. Oral candidiasis occurred in 16 (5.3%) pts.

Background: Axial spondyloarthritis (axSpA) spectrum covers radiographic
axSpA and non-radiographic axSpA (nr-axSpA). PREVENT (NCT02696031) is
the first phase III, placebo (PBO) controlled study evaluating secukinumab (SEC)
150 mg with (LD) or without loading (NL) dose, in patients (pts) with nr-axSpA.1
The study had 2 independent analysis plans as per EU (Wk 16) and US (Wk 52)
regulatory requirements.
Objectives: To report efficacy through Wk 52 and safety up to two years for the
PREVENT study.
Methods: 555 pts fulfilling ASAS criteria for axSpA plus abnormal CRP and/or
MRI, without evidence of radiographic changes in sacroiliac (SI) joints according
to modified New York Criteria for AS were enrolled. All images were assessed
centrally before inclusion. Pts were randomised (1:1:1) to SEC 150 mg with LD,
NL, or PBO at baseline (BL). LD pts received SEC 150 mg at Wks 1, 2, 3, and
4, and then every 4 wks (q4wk) starting at Wk 4. NL pts received SEC 150 mg
at BL and PBO at Wks 1, 2, and 3, and then 150 mg q4wk. Switch to open-label

(OL) SEC 150 mg or standard of care (SoC) was permitted after Wk 20. Primary
endpoint was ASAS40 at Wk 16 (LD) and at Wk 52 (NL) in anti-TNF-naïve pts.
Secondary endpoints (overall population) included ASAS40, BASDAI50, SI joint
bone marrow edema (BME) score by MRI at Wks 16 and 52 and ASDAS-CRP
inactive disease (ID) at Wk 52. Endpoints were analysed according to statistical
hierarchy. Analysis used non responder imputation through Wk 52. Safety analyses included all pts who received ≥1 dose of study treatment.
Results: Overall, 481 pts completed 52 wks with no major differences in retention
across groups: 84.3% (156/185; LD), 89.7% (165/184; NL) and 86.0% (160/186;
PBO). BL characteristics were similar across groups; 90% pts were anti-TNFnaïve, 56-58% pts had elevated CRP, 71-75% pts had evidence of SI joint inflammation by MRI. Proportion of pts who switched to OL or SoC between Wks 20
and 48 was 52.1% (LD), 49.2% (NL), and 67.4% (PBO). Primary endpoints at
Wk 16 and Wk 52 were met (Table). SEC 150 mg LD or NL significantly improved
secondary endpoints at Wk 16 and 52 vs PBO (Table). SEC significantly reduced
SI joint MRI BME score vs PBO at Wk 16 (-1.68 and -1.03 vs -0.39; P = 0.0197
and 0.026, LD and NL respectively). No unexpected safety signals were reported.
Conclusion: SEC 150 mg provided significant and sustained improvement in
signs and symptoms of pts with nr-axSpA through Wk 52. MRI BME scores were
reduced accordingly. There was no major difference between LD and NL. Safety
of SEC was consistent with previous reports.2

ETANECET WITHDRAWAL AND RE-TREATMENT IN PATIENTS WITH INACTIVE NON-RADIOGRAPHIC AXIAL SpondyloArthritis AT 24 WEEKS: RESULTS OF RE-EMBARK, AN OPEN-LABEL PHASE IV TRIAL

F. Van den Bosch1, J. C. C. Wei, P. Nash2, F. J. Blanco3, D. Graham4, C. Zang5, E. Arthur6, C. Borlenghi7, B. Vlahos8, A. Deodhar9, 1Ghent University Hospital, Gent, Belgium; 2Chung Shan Medical University Hospital, Taichung, Taiwan, Republic of China; 3Griffith University, Brisbane, Australia; 4INIBIC-Hospital Universitario A Coruña, La Coruña, Spain; 5Pfizer, Collegeville, United States of America; 6Pfizer, New York, United States of America; 7Pfizer, Buenos Aires, Argentina; 8Oregon Health & Science University, Portland, United States of America

Background: In the RE-EMBARK trial (NCT02509026), etanercept (ETN) treatment was compared with non-radiographic axial spondyloarthritis patients who achieved inactive disease (defined as Ankylosing Spondylitis Disease Activity Score [ASDAS CRP] <1.3) in Period 1 (P1) discontinued ETN for ≤40 weeks. Objectives: To assess the proportion of patients with inactive disease after P1 who experienced disease flare (ASDAS with erythrocyte sedimentation rate [ESR] ≥2.1) within 40 weeks of ETN withdrawal and estimate time to flare following ETN withdrawal. Methods: RE-EMBARK was a multicenter, open-label, Phase IV trial of ETN in patients with active nr-axSpA (meeting Assessment in SpondyloArthritis international Society criteria and with ASDAS CRP ≥2.1) and an inadequate response to ≥2 nonsteroidal anti-inflammatory drugs (NSAIDs) while taking a stable dose of 1 NSAID for ≥2 weeks before the first ETN dose. All patients received ETN (50 mg/week) plus NSAID for the first 24 weeks (P1). At week 24, patients with inactive disease discontinued ETN for ≥40 weeks (Period 2 [P2]). Those who experienced flare during P2 were re-treated with ETN for 12 weeks in Period 3 (P3). Kaplan-Meier (KM) analysis and Cox proportional hazard models were used to 1) estimate the probability of experiencing flare within a given time period, and 2) compare data between RE-EMBARK and the EMBARK trial (NCT01258738) of patients with nr-axSpA who met RE-EMBARK P2 entry criteria (achieved inactive disease after 24 weeks of ETN treatment) and continued treatment for a further ≥40 weeks. Results: Of the 209 patients in P1 (mean age, 33 years; women, 46%; white, 89%), 119 (57%) entered P2. The proportion of patients experiencing ≥1 flare increased from 22% (25/112) at week 4 to 67% (77/115) at week 40. Overall, 75% (86/115) of patients in P2 experienced flare and 50% experienced flare within 16 weeks (95% CI: 13-24 weeks, KM analysis). Conversely, data from the comparator EMBARK trial suggested that <25% of patients receiving continuous ETN treatment over 40 weeks experienced flare. Cox proportional hazard model analysis showed an 85% relative risk reduction of experiencing flare during P2 in patients with inactive disease who continued ETN treatment vs those who discontinued. By P3 week 4, 62% (54/87) of patients re-treated with ETN re-achieved inactive disease; 50% of patients who re-achieved inactive disease in P3 did so within 5 weeks (95% CI: 4-8 weeks, KM analysis). The observed trend of clinical improvement (P1), worsening (P2), and improvement (P3) was reflected in other clinical measures (Figure) plus measures of joint magnetic resonance imaging score and quality of life (EQ-SD visual analog scale score); mean (standard deviation) score changes from each study period baseline–end were –6.1 (11.7) [P1], +1.5 (4.4) [P2], –2.0 (8.8) [P3] and +27.7 (26.7) [P1], –26.4 (30.5) [P2], –32.1 (26.3) [P3], respectively. There were no unexpected safety signals. Conclusion: For patients with nr-axSpA who achieved inactive disease with ETN and then discontinued treatment, a quarter maintained treatment-free inactive disease for 40 weeks and 50% maintained an ASDAS ESR score <2.1 for ≥16 weeks. Re-starting ETN allowed 62% of patients who flared to re-achieve inactive disease within 12 weeks.

RANDOMIZED CONTROLLED TRIAL OF ORAL CORTICOSTEROIDS IN AXIAL SpondyloArthropathy: MODIFIED COBRA REGIME

D. Mishra1, G. Naidu1, V. Kumar1, S. K. Sharma1, A. Sharma1, S. Jain1, V. Dhir1, 1Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: There is an unmet need of anti-inflammatory agents in AxSpA after NSAID failure. This is especially true for patients with persisting high disease activity and not having access to anti-TNFs. In this regard, corticosteroids may be helpful as a short-term measure. However, current guidelines recommend against oral corticosteroids citing insufficient evidence of efficacy. 1 Also, there is an assumption that the dose required for benefit is much higher than RA, and thus untenable. It is unclear whether starting with a high dose followed by rapid taper would be effective (like the COBRA regime in RA).2

Objectives: To study the efficacy of the COBRA regime of oral corticosteroids in axial SpA over 24 weeks.

Methods: This was a double blind placebo controlled randomized trial. Patients with active axial SpA (BASDAI ≥4) despite NSAIDs were randomized to either
receive oral prednisolone or placebo as per COBRA regime, started on oral predni-
solone at a dose of 60 mg, rapidly tapered weekly to reach a dose of 10 mg by 6
weeks and subsequently maintained on a dose of 5 mg till 24 weeks. Primary
end point was 50% improvement in BASDAI at week 24. Secondary end points
were improvement in ASDAS and BASFI. Analysis was by intention-to-treat. Trial
Registration# CTRI/2018/01/011342

Results: This study enrolled 65 patients (62 males) who were randomized to corti-
ocosteroid (n=32) or placebo (n=33) with mean ± SD age 28.5 ± 8.4 years and BAS-
DAI 5.4 ± 10. Primary end point was reached in 12 (37.5%) and 3 (9%) patients
with steroids and placebo respectively (p=0.007). On repeated measures analysis by
general linear model, there was a significant difference between the two-
groups in BASDAI (p=0.03) (Figure-1). Patients in the corticosteroid group had
significant improvement in BASDAI, ESR, CRP, ASDAS ESR and ASDAS CRP at
24 weeks (Table-1). Clinically important improvement in ASDAS CRP was
achieved by significantly higher number of patients in steroid group (17 (55%) vs 6
(18%), p= 0.002). Major improvement in ASDAS ESR and ASDAS CRP was also
higher in the steroid group (Figure-2). At 24 weeks, patients in the steroid group
had significant reduction in IL-6 levels compared to that in placebo group (p= 0.007,
data for 41 patients). Patients in the steroid group had more weight gain and facial
puffiness, however no serious adverse events were noted in both the groups.

Figure 1. Change in mean BASDAI

Table 1. Changes in disease indices and inflammatory markers at 24 weeks

Figure 2. Clinically important and Major improvement at 24 weeks

Conclusion: Oral prednisolone given by COBRA regime was associated with
significant improvement in disease activity scores in axial SpA at 24 weeks. This
extends and supports results from a previous short term study. Thus, corticos-
teroids may be an option for patients not having access to biologics, atleast for
the short-term.

**OP0110**

IS VERY EARLY TREATMENT EFFECTIVE? SIX MONTHS RESULTS OF THE PREVAS STUDY, A PLACEBO-CONTROLLED TRIAL WITH ETANECET IN PATIENTS SUSPECTED OF NON-RADIOPHAGIC AXIAL SPONDYLOARTHRITIS

T. Rusman, M. A. C. Van der Weijden, M. T. Nurmohamed, R. B. M. Landewe, J. J. De Winter, B. J. H. Boden, P. M. Belf, C. M. A. Van der Bijl, C. J. Van der Laken, I. Van der Horst-Bruinstra, Amsterdam UMC location VUMc, Rheumatology, Amsterdam, Netherlands; Amsterdam UMC location VUMc, Amsterdam, Netherlands; Reade, Rheumatology, Amsterdam, Netherlands; Amsterdam UMC location AMC, Rheumatology, Amsterdam, Netherlands; Onze Lieve Vrouwe Gasthuis, Radiology, Amsterdam, Netherlands; Amsterdam UMC location VUMc, Clinical Pharmacology, Amsterdam, Netherlands

**Background:** Despite the new classification criteria for non-radiographic axial spondyloarthritis (nr-axSpA) patients according to the Assessment of Spondyloarthritis International Society (ASAS), there are limited data on disease progression in nr-axSpA patients.

**Objectives:** First to assess the improvement in disease activity in patients suspected of nr-axSpA after 16 weeks treatment with Etanercept (ETN) or Placebo (PBO). Second, to assess the changes of active inflammation on MRI of the SI-joints (SIJ) between the ETN and PBO group after 16 and 24 weeks without study medication.

**Methods:** The PrevAS study is a randomized, double blind, placebo-controlled trial with ETN performed in the VU University medical center (VUMc) (EudraCT number 2009-015515-40), with a screening period from 2009 until 2014. Patients suspected of nr-axSpA were included if they had chronic back pain for ≥ 3 months, were ≥ 18 years, fulfilled the Calin criteria of inflammatory back pain and had to be either HLA-B27 positive with at least ≥ 1 Spondyloarthrits (SpA)-feature (as defined by the European Spondyloarthropy Study Group (ESSG), or HLA-B27 negative with at least ≥ 2 SpA-features and had a high disease activity score (Bath Ankylosing Spondylitis Disease Activity Index ≥ 4) plus insufficient response to at least two NSAIDs. Excluded were patients who fulfilled the modified New York criteria for ankylosing spondylitis, or in case of previous biological use. Included patients were randomly assigned (1:1) for 16 weeks treatment with ETN (N=40) or PBO (N=40) and followed after the treatment period for 24 weeks. The primary endpoint was the number of patients achieving the ASAS30 response at week 16. MRI was performed at baseline, 16 and 24 weeks and scored using the Spondyloarthrits Research Consortium of Canada (SPARRCC) index for number of active inflammatory lesions.

**Results:** The majority of included patients was female (63.8%). Patient characteristics, like the presence of the HLA-B27 antigen and number of SpA-features

bureau: AbbVie, Novartis, Pfizer, Roche, UCB, MSD, Ruxandra Ionescu Consultant of: Consulting fees from Abbvie, Eli-Lilly, Novartis, Pfizer, Roche, Sandzod, Speakers bureau: Consulting and speaking fees from Abbvie, Eli-Lilly, Novartis, Pfizer, Roche, Sandzod, Niels Steen Krogh: None declared, Johan Askling Grants/research support from: JA acts or has acted as PI for agreements between Karolinska Institutet and the following entities, mainly in the context of the ARTIS national safety monitoring programme of immunomodulators in rheumatology: Abbvie, BMS, Eli Lilly, Merck, MSD, Pfizer, Roche, Samsung Bioepis, Sanofi, and UCB Pharma, Bente Glintborg Grant/research support from: Grants from Pfizer, Biogen and Abbvie, Ulf Lindström: None declared DOI: 10.1136/annrheumdis-2020-eular.1804
at baseline, were comparable between the ETN and PBO group. Mean compliance to the study medication at sixteen weeks was 72.1%. Longitudinal regression analysis over the first 16 weeks showed a trend towards a three times higher chance to achieve the ASAS20 response in the ETN compared to the PBO group (OR = 3.2, 95% CI [0.6;16.7] p=0.18) (Figure 1). No differences were observed in ASAS20 response at 24 weeks. A positive SPARCC score (SPARCC ≥ 2.5) of the SIJ was observed in the ETN and PBO group in 33.3% (133/39 patients) vs. 30.8% (123/39 patients) at baseline, 16.7% (6/36 patients) vs. 175% (7/40 patients) at 16 weeks and 21.9% (7/32 patients) vs. 20.0% (7/35 patients) at 24 weeks, respectively. Increased CRP-levels (CRP_UL ≥ 10.0mg/L) nor a positive SPARCC score at baseline, had significant influence on the ASAS20 response at 16 weeks follow-up. The safety profile was consistent with what is known for ETN in AS.

Conclusion: Patients suspected of n-axSpA with high disease activity showed a trend towards a three times higher chance to achieve the ASAS20 response in the ETN group, compared to the PBO group at 16 weeks, regardless of a raised CRP level or positive MRI-SIJ at baseline.

IN INDIVIDUALS AT RISK OF INFLAMMATORY ARTHRITIS, PATIENT REPORTED OUTCOMES DETERIORATE IN THE 12 WEEKS BEFORE PROGRESSION TO CLINICAL DISEASE

L. Duquenne1,2, K. Mankia1,2, L. Garcia-Montoya1,2, J. Nam1,2, A. Di Matteo1,2, P. Emery2,3, Leeds Institute of Rheumatic and Musculoskeletal Medicine, LEEDS, United Kingdom; 2Leeds Biomedical Research Centre - NIHR, LEEDS, United Kingdom

Background: Subjects with clinically significant arthralgia who will eventually develop inflammatory arthritis (IA) had a higher HAQ at baseline (1). Here we investigated the change in patients reported outcomes (PRO) over time in ACPA+ at risk of IA subjects.

Objectives: In ACPA+ subjects at risk of developing IA, to analyse the change in PRO results in order to identify an imminent phase of progression.

Methods: In a single centre prospective observational cohort, PRO from 109 ACPA+ subjects without clinical arthritis were collected prospectively at 0, 12, 26, 39 weeks; the last time-point was 52 weeks for the individuals who did not progress to IA (non-progressors) or the last visit preceding progression (within 12 weeks) for those who developed IA (progressors). Data on the following PRO were collected: HAQ, “general health” (GH-VAS), “fatigue” (fatigue-VAS), and “global pain” (GP-VAS) using visual analogic scale measures graded 0 to 100. We firstly used mixed models repeated measured analyses ANOVA analysis then included covariates such as gender, shared epitope (SE) (HLA DRB1*01, *04 and/or *10), anti-CCP2 antibody (CCP2) and/or rheumatoid factor (RF) high titre (≥3ULN), and smoking exposure (Ever/Never).

Results: All analysis met sphericity assumption. In this selection, 20% of subjects (24/109) developed IA within a median of 77 weeks (Range 37-369.43), non-progressors were followed for a median of 216 weeks (Range 50-590), 74 subjects were SE positive (68%), 81 had a CCP2 and/or RF high titre (74%), and 66 were previous or current smokers (61%). Analysis revealed significant differences between both groups for the last visit, and within the progressor group for the last visit compared to all previous visits regarding the GH-VAS, GP-VAS and HAQ (Table 1, figure 1). Between subject analysis showed a significant influence of GH-VAS and GP-VAS change on progression. Covariate analysis showed a significant influence of previous smoking history on HAQ results (p=0.033, F=2.645 (4,408), Eta = 0.025).

Conclusion: These results show for the first time a significant deterioration in the PRO of general health, global pain, and HAQ weeks just preceding clinical arthritis development. This phase prior progression needs to be thoroughly studied to improve the accuracy of predicting imminent progression.

Background: Clinically suspect arthralgia (CSA) can precede development of clinically evident inflammatory arthritis (IA). Autoantibody, C-reactive protein (CRP), and subclinical inflammation are known predictors, but risk estimation remains insufficiently accurate. Especially CRP has a small effect size and is inadequately reflective of inflammation that can be measured systemically. RNA expression in whole blood of patients with rheumatoid arthritis (RA) have shown differences compared to healthy individuals. Therefore, we hypothesized that differences in RNA expression can be found between CSA patients that do and do not progress to IA.

Objectives: This study assessed whole blood RNA expression levels of inflammatory and immune genes as potential biomarkers for prediction of IA-development in patients with arthralgia.

Methods: Between April 2012-March 2015, 234 patients were consecutively included in the Leiden CSA-cohort. Follow-up ended when patients developed clinically apparent IA (determined at physical examination), or else after 2 years. RNA expression in whole blood, at the moment of inclusion, was determined for 135 genes of the innate and adaptive immune system by dual color Reverse-Transcription Multiplex Ligation-dependent Probe Amplification (dcRT-MLPA) profiling. Cox proportional hazard models were used to associate time-to-event with gene expression level at inclusion, while adjusting for age, gender, and assay plate (model 1). The false discovery rate was used to correct for multiple testing. Genes with significantly different expression were subsequently studied for reproducibility by qPCR, and mutual independence in their association with IA-development. For the latter, we employed a forward selection strategy, starting with the most significantly associated gene and iteratively adding more genes. Resulting mutually independent genes were further investigated for their added predictive value over known risk factors, CRP, ACPA, and subclinical joint inflammation.

Results: 21% of CSA-patients developed IA after mean 3.6 months (IQR:16-10.7) follow-up. After correction for multiple testing, six genes were significantly associated with IA-development (model 1), namely IFN-γ, PHEX, IGF-1, IL7R, CD19, or CCRT7 (ordered by significance). For all six genes, a lower expression at inclusion was associated with an increased risk of IA-development. IFN-γ was only weakly expressed in peripheral blood, hampering the technical reproducibility between MLPA and qPCR results, and was excluded for further analyses. PHEX and IGF-1 were highly correlated (R² 0.97) and only IGF-1, but not PHEX, was included in further analyses. Of the remaining significant genes (IGF-1, IL7R, CD19, CCRT7), an independent association with IA-development was observed for IGF-1 and IL7R, but not for CD19 or CCRT7. qPCR data of IL7R correlated with MLPA results (p<0.001), confirming the robustness of the transcriptomic outcome. Lastly, when analysing IGF-1 and IL7R with known clinical predictors, both IGF-1 and IL7R remained independently associated with progression to IA.

Conclusion: Six genes were differentially expressed between CSA-patients that did or did not progress to IA. Expression of IGF-1 and IL7R showed added value to regularly used predictors. Validation is warranted.

References: None.
Objectives: until the end of the trial.

Methods: Patients with progressive fibrosing ILDs other than idiopathic pulmonary fibrosis (IPF) were randomised to receive nintedanib 150 mg/day or placebo. Time to i) death, ii) first acute exacerbation of ILD or death, and iii) disease progression (absolute decline in FVC ≥10%) predicted or death, over the whole trial were analysed in patients with autoimmune disease-related ILDs and a progressive phenotype.

Results: Of 663 patients, 170 (82 nintedanib, 88 placebo) had autoimmune disease-related ILDs (89 RA-ILD, 39 SSc-ILD, 19 MCTD-ILD, 23 other autoimmune diseases, with autoimmune features [n=5] and undifferentiated CTD-ILD [n=3]). Over the whole trial, in the nintedanib and placebo groups, respectively, mean (SD) exposure to drug was 15.4 (7.4) and 16.9 (6.1) months and maximum exposure was 26.0 and 25.2 months; 62 (75.6%) and 68 (77.3%) patients in these groups, respectively, completed the planned observation time. Over the whole trial, in the nintedanib and placebo groups, respectively, 9.8% and 12.5% of patients died, 12.2% and 20.5% of patients had ≥1 acute exacerbation of ILD or died, and 40.2% and 53.4% of patients had disease progression or died (Table). Diarrhoea was the most common adverse event, with incidence rates of 139.2 and 26.3 events per 100 patient–years in the nintedanib and placebo groups, respectively. Adverse events led to treatment discontinuation in 20.7% of patients in the nintedanib group and 13.6% of patients in the placebo group.

Conclusion: Data from the INBUILD trial suggest that nintedanib has a clinically meaningful effect on slowing the progression of ILD in patients with progressive fibrosing autoimmune disease-related ILDs, with adverse events that can be tolerated by most patients.

TEN-YEAR ANALYSIS OF VERY LOW-DOSE GLUCOCORTICOIDS IN EARLY RA (ESPOIR COHORT) SUPPORTS A TIME-DEPENDENT RISK OF SEVERE OUTCOMES

C. Roubille1,2, A. Coty2, N. Rinchева3, M. Dougados4, R. M. Flipo5, J. P. Daures3, B. Combe3, Montpellier University Hospital Hospital, Department of Internal Medicine, Montpellier, France; 2Laboratoire PHYMEDEXP-INSERM U1046, CNRS UMR 9214, University of Montpellier, Montpellier, France; 3Statistiques, University Institute of Clinical Research, EA2415, Montpellier, France; 4Paris Descartes University, Rheumatology Department, Cochin Hospital, AP-HP, Paris, France; 5Roger Salengro Hospital, Rheumatology Department, Lille, France; 6Montpellier University Hospital, Lapéronne Hospital, Rheumatology Department, Montpellier, France

Background: We previously failed to find any significant difference with regard to severe outcomes (death, severe infections, fractures, cardiovascular diseases [CVD]) between recent-onset patients taking GC or not low-dose GC treatment in a 7-year analysis of the ESPOIR cohort (1).

Objectives: To explore the 10-year tolerability profile of GC use in patients with early RA.

Methods: We analysed data from the early arthritis (less than 6 months disease duration) ESPOIR cohort. Patients were stratified in two groups, with or without GC treatment at least once during their follow-up (median 10 years IQR [9-10]). The primary outcome was a composite of death, CVD (including myocardial infarction, cerebrovascular accident and heart failure), severe infection, and severe fracture. In order to reduce the impact of treatment selection bias and potential confounding factors, the weighted Cox time-dependent analysis model was used with inverse probability of treatment weighting (IPTW) propensity score method.

Results: Among the 608 RA patients (480 women, mean age of 47.5 ± 12.1 years), 397 patients (65%) received low-dose prednisone (median 1.9 mg/day [IQR 0.6-4.2], mainly during the first 6 months (70%). The mean duration of GC treatment was 44.6 months ± 40.1 Overall, 95 events were identified during follow-up: 10 deaths, 18 CVD, 32 fractures and 35 severe infections. Based on univariate analysis at 10 years, patients taking GC experienced significantly more events (n=71) than those without GC (n=24) (p=0.035), especially severe infections (n=30 with GC versus 5 without GC, p=0.009) (table 1), with a cumulative dose effect (p=0.007). On weighted Cox time-dependent analysis, using the IPTW propensity score method, the risk of events over time was significantly associated with GC treatment (p <0.001), age, history of hypertension and erythrocyte sedimentation rate. The risk associated with GC treatment, estimated by the hazard ratio (HR), increased between the first follow-up visit (HR at 6 months: 0.39, 95% CI 0.19-0.82) and 10 years (HR=6.83, 95% CI 2.29-20.35) (figure 1 and table 2).

Figure 1. Time-dependent relationship between glucocorticoids treatment and risk of events estimated by hazard ratio (HR)

Conclusion: This 10-year analysis of the ESPOR cohort supports a dose and time-dependent impact of very low-dose GC treatment in early RA, with a long-term high risk of severe outcomes.

DOI: 10.1136/annhemat-2020-eular.3917

Background: Tumor necrosis factor inhibitors have revolutionized the treatment of rheumatoid arthritis (RA). However, only about 50% of the patients respond well to TNF inhibitors. Therefore, markers that predict response to TNF inhibitors are valuable. Previously we demonstrated that central nervous system (CNS) response to noxious stimuli, measured by fMRI of the brain as blood oxygen level dependent (BOLD) signals, decreases already after 24 hours of anti-TNF administration a higher pre-treatment BOLD signal volume seems to predict clinical response to treatment with certolizumab pegol (CZP). 1,2. We therefore hypothesized that the baseline volume of BOLD signal in the CNS could predict anti-TNF treatment response.

Objectives: To perform a randomized placebo controlled trial in active RA patients to test the effect of TNF inhibition on induced pain activity in the brain and to test whether patients with high-level RA-related brain activation react differently to TNF-inhibitors than patients with low-level brain activation.

Methods: Adult RA patients fulfilling the 2010 ACR/EULAR classification criteria with a DAS28>3.2 receiving stable DMARD treatment for at least 3 months were eligible. Patients underwent the first fMRI at screening measuring BOLD signal upon MCP joint compression and were stratified into low (< 700 units) and high (>700 units) voxel counts. Then patients were randomized to CZP or placebo with a 2:1 ratio. The second and third fMRI were performed after 12 and 24 weeks, respectively. Control stimulation was done by measuring brain activation after non-painful finger tapping.

Results: 156 RA patients with moderate-to-high disease activity participated in the study. In the finger tapping control, fMRI showed no significant changes in BOLD signal in the CZP-L and CZP-H arms, but a slight but significant decrease (p<0.043) was observed. After joint compression, the CZP-L group showed significant increase in the BOLD signal volume (p=0.043) in fMRI-2 as compared to fMRI-1 with no further significant changes. In contrast, in the CZP-H group, the BOLD signal volume significantly decreased (p=0.037) in fMRI-2 and continued
to decrease further, p=0.007. No significant changes were observed in the placebo arm over time.

Conclusion: TNF inhibition improves arthritis-related brain activity in the sub-group of RA patients with high baseline BOLD activity in the fMRI.

DECIPHERING THE ANTI-PROTEIN-ARGININE DEIMINASE (PAD) RESPONSE IDENTIFIES PAD1 AND PAD4 AS NOVEL AUTOANTIGENS IN RHEUMATOID ARTHRITIS

L. Martinez-Prat1, M. A. Aure2, C. Bentow2, D. Lucia2, M. Lopez-Hoyos2, M. Mahler2,1

1Inova Diagnostics, Research and Development, Barcelona, Spain; 2Inova Diagnostics, Inc., Research and Development, San Diego, United States of America; 3Marques de Valdecilla University Hospital, Immunology, Santander, Spain

Background: Protein-arginine deiminase (PAD) 4 enzymes play a central role in the pathogenesis of rheumatoid arthritis (RA) and represents an antigenic target. Among the five known family members (PAD1, PAD2, PAD3, PAD4 and PAD6), only PAD2, PAD3 and PAD4 have been described to have autoantigenic properties. Furthermore, very little is known on the the isotype usage of these autoantibodies. Understanding the molecular basis of the anti-PAD antibody response has the potential to open novel approaches for precision medicine in RA.

Objectives: The objectives of this study were to screen for the presence of antibodies to the five PAD family members and to evaluate the isotype usage of the anti-PAD response in RA.

Methods: First, we developed a panel for the detection of anti-PAD IgG based on protein-arginine deiminase (PAD) 1, 2, 3, 4 and 6, respectively. Significant correlation was observed between all the antibodies, with the highest between anti-PAD1 and anti-PAD4 (Spearman’s rho=0.87, p<0.0001) and the lowest between anti-PAD4 and anti-PAD2 (Spearman’s rho=0.38, p=0.0015) and anti-PAD4 and anti-PAD6 (Spearman’s rho=0.38, p<0.0011). While principal component analysis (PCA) (Figure 2) showed an association between all anti-PAD antibodies, there was further discrimination that displayed closer association between anti-PAD1, 3 and 4 on one hand, and between anti-PAD2 and 6. For the extended testing of anti-PAD4 with IgG, IgA and IgM, all three isotypes were identified in the sera of RA patients. Higher levels of the three isotypes were observed in RA patients with erosive disease when compared with the patients without erosion, but this association was only significant for anti-PAD4 IgA (p=0.0086).

Figure 1. Receiver operating characteristics (ROC) analysis of the discrimination between rheumatoid arthritis (RA) and controls of IgG to protein-arginine deiminase (PAD) 1, PAD2, PAD3, PAD4 and PAD6. The area under the curve (AUC) values are shown in brackets for each biomarker. Abbreviations: TPF: true positive fraction; FPF: false positive fraction.
Conclusion: Our study is the first to describe PAD1 and PAD6 as novel antigenic targets in RA and to demonstrate that the anti-PAD4 B-cell immune response uses all three isoforms (igg, Iga and IgM). The strong and significant association between anti-PAD4 IgA and joint erosion is of particular clinical relevance.

Cardiovascular disease and malignancies in RA

**OP0119**

**NOT ALL THE SAME? REACHING REMISSION REDUCES THE RISK OF CVD IN PATIENTS WITH RA, BUT PATIENTS ON BIOLOGICS MAY BE BETTER PROTECTED**

I. J. Berg1, S. Lillegravenga1, E. Kristianslund1, T. K. Kvien1, S. Aarrestad Provan1, 1Diakonhjemmet Hospital, Rheumatology, Oslo, Norway

Background: Disease activity is a risk factor for the development of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA). Remission is the preferred treatment target in RA, and may be achieved by treatment with both conventional synthetic DMARDs (csDMARDs) and biologic DMARDs (bDMARDs).

Objectives: To compare the risk of CVD in patients reaching RA disease remission vs. non-remission by 6 months. Additionally, to compare the risk of CVD in RA patients reaching remission on bDMARDs vs. csDMARDs.

Methods: The NOR-DMARD is a multi-centre prospective observational study that was established in 2000. Until 2012, patients who started on any DMARD were included, while only patients starting bDMARDs were included after 2012. Disease activity and markers of inflammation (Erythrocyte Sedimentation Rate (ESR) and C-reactive protein (CRP mg/L) were measured at regular intervals. In these analyses we used data from baseline, 3-month and 6-month visits in patients with clinical RA included in the study from 2009. Patients with prior CVD were excluded from the study. Remission was assessed according to several criteria, and should be attained by the 6-month visit.

NOR-DMARD data were linked to the National Death Registry and National Patient Register. The latter records all diagnoses given at any hospital admission, inpatient and outpatient, from 2009. CVD was defined as a diagnosis of myocardial infarction, chronic heart failure, cerebrovascular disease or sudden CV death in ICD10. Using cox-regression models, we compared the time until the first recorded CVD diagnosis before the end of follow-up.

Objectives: To evaluate if bDMARDs decrease long-term cardiovascular disease (CVD) risk in rheumatoid arthritis and whether potential benefits might be rendered by impacting coronary plaque formation or progression.

Methods: In this single-center observational cohort study, 150 patients underwent computed tomography angiography for evaluation of coronary atherosclerosis (total, non-calcified, mixed/calcified and low-attenuation or high-risk plaque); 101 had repeat assessments within 6.9±0.3 years to evaluate plaque progression. All CVD events were prospectively recorded, including cardiac death, myocardial infarction, unstable angina, revascularization, stroke, claudication, and heart failure hospitalization. The Framingham-DAgostino score assessed clinical risk. Segment stenosis score (cumulative stenosis) measured plaque burden. The effect of bDMARD treatment on CVD events was assessed using marginal structural models. The inverse probability of treatment and censoring weights were used in a weighted pooled logistic regression with current bDMARD use and time since study entry included in the model to approximate a Cox proportional hazards model allowing for time-varying weights. Robust logistic regression evaluated the effect of bDMARD exposure (>50 percent of follow-up period) on likelihood of new plaque formation or change in plaque composition in per-segment models adjusted for Framingham-DAgostino score, time between scans, statin duration, cumulative prednisone dose and time-averaged CRP.

**Figure 1**

Conclusion: Patients on bDMARDs who achieved DAS28, DAS28-CRP remission, or CRP less than 10mg/L by the 6-month follow-up were less likely to experience a CVD, compared to patients not achieving remission. The HRs for CVD were higher for patients in remission on csDMARDs, compared to patients on bDMARDs, but the difference was not statistically significant and should be further explored.

**BIOLOGICS MAY PREVENT CARDIOVASCULAR EVENTS IN RHEUMATOID ARTHRITIS BY INHIBITING CORONARY PLAQUE FORMATION AND STABILIZING HIGH-RISK LESIONS**

G. Karpouzas1, S. Ormseth2, E. Hernandez2, M. Budoff1, 1Lundquist Institute for Biomedical Innovation, Torrance, United States of America; 2Lundquist Institute of Biomedical Innovation, Torrance, United States of America

Background: Biologic disease-modifying antirheumatic drugs (bDMARDs) effectively control inflammation and may improve cardiovascular outcomes in Rheumatoid arthritis.

Objectives: To evaluate if bDMARDs decrease long-term cardiovascular disease (CVD) risk in rheumatoid arthritis and whether potential benefits might be rendered by impacting coronary plaque formation or progression.

Methods: In this single-center observational cohort study, 150 patients underwent computed tomography angiography for evaluation of coronary atherosclerosis (total, non-calcified, mixed/calcified and low-attenuation or high-risk plaque); 101 had repeat assessments within 6.9±0.3 years to evaluate plaque progression. All CVD events were prospectively recorded, including cardiac death, myocardial infarction, unstable angina, revascularization, stroke, claudication, and heart failure hospitalization. The Framingham-DAgostino score assessed clinical risk. Segment stenosis score (cumulative stenosis) measured plaque burden. The effect of bDMARD treatment on CVD events was assessed using marginal structural models. The inverse probability of treatment and censoring weights were used in a weighted pooled logistic regression with current bDMARD use and time since study entry included in the model to approximate a Cox proportional hazards model allowing for time-varying weights. Robust logistic regression evaluated the effect of bDMARD exposure (>50 percent of follow-up period) on likelihood of new plaque formation or change in plaque composition in per-segment models adjusted for Framingham-DAgostino score, time between scans, statin duration, cumulative prednisone dose and time-averaged CRP.
Results: Sixteen patients incurred 19 CVD events. Current bDMARD use associated with lower CVD risk [OR=0.20 [95%CI=0.05-0.75], p=0.018, Figure 1]. However, the effect of bDMARDs was no longer significant when a 6-month exposure extension was applied (OR=0.42 [95% CI 0.13-1.38], p=0.15). The effect of bDMARD use on CVD risk was moderated by non-calcified plaque and low-attenuation plaque presence (Figure 1); specifically, bDMARDs were associated with lower CVD risk only in patients with non-calcified plaque (p=0.048) or low-attenuation plaque (p=0.036) at baseline. Per-segment plaque progression analyses showed no main effect of bDMARD exposure on likelihood of new plaque formation (Figure 2). However, bDMARD exposure predicted lower likelihood of new plaque forming in segments without plaque among patients without mixed/calcified plaque in other coronary segments (OR=0.40 [95%CI=0.17-0.93]), but not among those with mixed/calcified plaque elsewhere in their arteries (OR=1.60 [95%CI=0.71-3.62]). Moreover, transition of non-calcified to mixed/calcified plaque associated with bDMARD exposure (OR=4.00 [95%CI=1.05-15.32]). bDMARD use also predicted low-attenuation plaque loss (p=0.042).

Conclusion: In rheumatoid arthritis, bDMARD use associated with reduced long-term CVD risk, lower likelihood of new plaque formation in patients with early atherosclerosis, stabilization of high-risk plaque and protective calcification of non-calcified lesions.

Figure 1. Effect of bDMARD use on cardiovascular disease stratified by coronary plaque presence

Figure 2. Effect of bDMARD exposure on plaque formation and transition from baseline to follow-up
established coronary heart disease. In RA it has been investigated by carotid artery ultrasound and carotid atherosclerotic plaques are more prevalent in RA patients than controls. EULAR recommendations for cardiovascular disease risk management consider that carotid ultrasound may be part of the risk evaluation in patients with RA. Recent studies in general population have shown that plaques in femoral arteries are more common and are associated with higher cardiovascular risk.

Objectives: To study the usefulness of femoral artery ultrasound for the detection of subclinical atherosclerosis and its ability to improve cardiovascular risk assessment in RA patients.

Methods: Cross-sectional observational study of prevalence in 140 RA patients aged 40 to 65 years. Subclinical atherosclerosis was evaluated by carotid and femoral artery ultrasound.

Results: Atherosclerotic plaques were found in 86.4% of RA patients (60.7% in carotid arteries and 78.6% in femoral arteries). Patients with plaques were older and more frequently past or present tobacco users. Femoral plaques were larger and more numerous than the carotid plaques and people with plaques in both locations had more extensive subclinical atherosclerotic disease (table). Only 7.9% of RA patients were considered as having very high cardiovascular risk by clinical factors, after carotid ultrasound this increased to 57.1% and after femoral ultrasound to 86.4%.

Conclusion: Ultrasound examinations of the femoral artery in addition to the carotid artery increased the detection of subclinical atherosclerosis and determine a group of patients with higher intensity of atherosclerotic disease. Examinations of both arteries allowed a greater number of RA patients previously considered to have low to moderate cardiovascular risk to be classified as very high cardiovascular risk.

**RISK OF BREAST CANCER BEFORE AND AFTER RHEUMATOID ARTHRITIS, AND THE IMPACT OF HORMONAL FACTORS

H. Wadström1, A. Pettersson1, K. Ekström Smedby2, J. Askling1, 1Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden

Background: Large cohort studies have consistently reported decreased occurrence of breast cancer among women with RA. However, both the reasons behind this decreased risk and if it is present already before RA diagnosis, is unclear. The occurrence of RA following breast cancer is clinically and etiologically important also for other reasons. Long-term adjuvant anti-hormonal treatment with tamoxifen or aromatase inhibitors has become mainstay for estrogen receptor positive breast cancer, but are often associated with arthralgia as a side effect. Some studies have suggested that these therapies not only induce arthralgia, but also inflammatory arthritis.

Objectives: To examine the risk of incident breast cancer in women with RA, and the risk of RA in women with a history of breast cancer, taking anti-hormonal treatment for breast cancer into account.

Methods: Using nationwide Swedish registers, women with new-onset RA diagnosed 2006-2016 were identified. Each RA patient was matched on age, sex, and place of residence to 5 randomly selected control subjects from the general population. Through register linkages, we collected information on breast cancer, breast cancer risk factors (age at childbirth, number of children, hormone replacement therapy), and socio-economy. The relative risk of breast cancer after RA was assessed using Cox regression, and the relative risk of RA in women with a history of breast cancer was assessed using conditional logistic regression.

Results: The risk of incident breast cancer in women with RA was reduced and the association was not attenuated by adjustment for breast cancer risk factors (HR=0.80, 95%CI 0.68-0.93)(Table 1). The risk was similar among seronegative RA, (HR=0.77, 95%CI 0.58-1.02), and seropositive RA, (HR=0.81, 95%CI, 0.67-0.98), and for all age groups. We noted reduced risks for all TNM stages, and for both pre- and postmenopausal breast cancer (assessed with age cut off 50 years). The risk of RA in women with a history of breast cancer was similarly reduced (OR=0.87, 95%CI, 0.79-0.95). Odds ratios (OR) stratified by serostatus and age at RA diagnosis yielded similar results. There was no clear trend in the level of risk reduction when examining the risk by menopausal status, or cancer stage at breast cancer diagnosis. Women with breast cancer treated with tamoxifen (OR=0.86, 95%CI 0.62-1.20), or aromatase inhibitors (OR=0.97, 95%CI 0.69-1.37), did not have an increased risk of RA compared to women with breast cancer treated differently.

Conclusion: There is a decreased risk of breast cancer in patients with RA, and a similar decrease in risk of breast cancer before RA diagnosis. We did not find evidence to support that the decreased risk of breast cancer was due to known risk determinants. Furthermore, adjuvant anti-hormonal therapy as used in secondary breast cancer pharmacoprevention did not seem to increase the risk of RA.

selected. In the base case analysis, exposure was defined with a 90-day latency after treatment initiation and a 180-day carry-over period after drug discontinuation. To compare the risk of malignancies between biologic treated patients and general population, Standardized incidence ratio (SIR [95% CI]) were calculated using FRANCIM (‘France Cancer Incidence et Mortalité’) estimations as reference. To compare the risk of malignancies between biologics, a propensity score (including age, sex, year of first occurrence of RA code, date of treatment initiation, number of previous DMARDs, Charlson comorbidity index, diagnosis of tobacco and/or alcohol-associated disorders, number of hospitalizations for RA, cumulative corticosteroid dose) was calculated for each comparison. Hazard Ratios (HRs) for risk of cancer were estimated using Cox proportional hazard model using inverse probability of treatment weighting (IPTW) with propensity score. Exposure was considered as a time-dependent variable and propensity scores were estimated dynamically using pooled logistic regression reasessed for each new exposure.

Results: Between 2007 and 2016, 31,792 patients (672,802 patient-years) were exposed to biologics. The annual incidence rate of overall malignancies was 0.865 per 100 patients-years. Malignancies occurred in 730 patients exposed to anti-TNF; 235 patients exposed to another biologic and 11 exposed to both. As compared to the general population, biologic treated patients had an increased risk of lung cancer (SIR=1.35 [1.14;1.60]), a decreased risk of pancreatic cancer (SIR=0.52[0.31;0.85]) and no significant increased risk of invasive melanoma (SIR=1.15 [0.92;1.61]). Results were similar for anti-TNF-treated patients. Other biologics were not analyzed separately due to small sample sizes. The overall risk of malignancies and risk of lymphoma did not differ between anti-TNF and other biologics (analyzed all together), or abatacept. Within the anti-TNF class, the overall risk of malignancies and risk of lymphoma did not differ between etanercept and monoclonal anti-TNF (table).

*Background: Rheumatoid arthritis (RA) is associated with an increased risk of non-Hodgkin B-cell lymphoma (B-cell NHL).**

**Objectives:** To study the characteristics of B-cell NHL complicating RA

**Methods:** A multi-centre case-control study was performed in France. Cases were patients with RA fulfilling the ACR-EULAR 2010 criteria, who developed a B-cell NHL after the diagnosis of RA. Cases were reported following a call for observations by the "Club Rhumatismes et Inflammation" network, registries from the French society of Rheumatology (AIR, ORA and REGATE) and the ESPoir cohort. For each case, 2 control patients were drawn at random from patients in the ESPoir cohort with RA fulfilling the ACR-EULAR 2010 criteria; cases and controls were matched on age (at lymphoma diagnosis for cases and age at the 10-year ESPoir visit for controls). Patients with associated Sjögren's syndrome were excluded. Cases and controls characteristics were compared for parameters associated with the occurrence of lymphoma.

**Results:** A total of 54 cases were included and matched to 108 controls. Lymphomas were mostly diffuse large B-cell lymphomas (n=26, 48.2%) (Figure 1). EBV positivity was found in 4 cases among 27 tested (14.8%). Cases had a mean age of 63.5 years (SD=10.9) and had a mean RA duration of 12.4 years (SD=10.5) at the time of diagnosis of lymphoma; there was no significant difference with controls (p=0.47 and p=0.40 respectively). The mean duration of follow-up after the diagnosis of lymphoma was 5.2 years (SD=5.8). In univariate analysis, factors associated with occurrence of B-cell NHL were: male gender (OR=3.3, 95% CI: 1.7-6.7), positive ACPA (OR=5.1, 95% CI: 2.0-15.7), positive Rheumatoid Factor (RF) (OR=3.9, 95% CI:1.6-12.2), erosions on X-rays (OR=15.4, 95% CI: 6.9-37.7) and DAS28 (OR=2.0, 95% CI: 1.5-2.7). Methotrexate, TNF-blockers and the number of previous biologics were not associated with the occurrence of B-cell NHL. Hydroxychloroquine (%) and sulfasalazine were more frequent in cases versus control, which could be linked to a date bias. Erosions and DAS28 remained significant in multivariate analysis (Table 1).

**Conclusion:** This study revealed an association between markers of activity (DAS28), severity (erosions) and autoimmune B-cell activation (RF and ACPA) and the risk of B-cell NHL in patients with RA, supporting the continuum between autoimmunity and lymphomagenesis in RA.

Immunity in rheumatic disease

W. Xie 1, H. Huang 1, Z. Zhang 1. Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Immune checkpoints inhibitors (ICIs) are associated with frequent immune-related adverse events (irAEs). Most patients with preexisting autoimmune diseases (PAD) are not recommended for treatment with ICIs and are not recommended for patients with cancer and PAD due to the unknown safety. In this study, we aim to evaluate the safety and efficacy of ICIs in patients with PAD and cancer.

Objectives: Systematic searches were performed of PubMed, EMBASE, and the Cochrane library from inception through September 2019 for observational studies reporting safety and efficacy data among ICIs-treated patients with cancer and PAD. A random effects meta-analysis was performed to calculate pooled incidence rates of PAD flare, irAEs and response.

Methods: Systematic search of PubMed, EMBASE and Cochrane Library plus a hand search of conference proceedings were performed for observational studies that reported cancer incidence in patients with RA treated with biologics or tocitabatin with active comparator of conventional DMARDs (csDMARDs) or TNFi. The pooled relative risk (RR) and 95% confidence interval (CI) were calculated with fixed-effects or random-effects models.

Results: A total of 219 ICI-treated patients with PAD in 14 publications were finally identified. In the random effects meta-analysis, pooled incidence of PAD flares, de novo irAEs or both of any grade was 60% (95% CI 52%-68%). Viewed separately, there were 219 and 206 patients experiencing PAD exacerbation and de novo irAEs of any grade, yielding a pooled incidence of 35% (95% CI 29%-41%) and 33% (95% CI 24%-42%) respectively. Of these, most of flares and de novo irAEs were graded as mild (grade 1-2) (pooled proportion: 82%, 95%CI 72%-91%: 65%, 95%CI 54%-76%, respectively). Rheumatoid arthritis was associated with a trend toward higher flare occurrence compared with another individual PADs (RR=1.25-1.88). With respect to efficacy, 136 patients showed complete or partial response, corresponding to a pooled response rates of 30% (95% CI 22%-39%). There were no statistical differences between patients with and without immunosuppressive therapy at ICI start regarding flare (RR: 1.08, 95% CI 0.72-1.62), but a trend towards lower response rates was observed in patients with baseline immunosuppressants (RR: 0.98, 95% CI 0.26-1.33).

Conclusions: Immune toxicities are frequent in PAD-treated patients with MD and often mild and manageable without discontinuing therapy. Rheumatoid arthritis is associated with a trend toward more flares. ICI treatment is effective and not absolute contraindication in PAD patients, but close monitoring and multidisciplinary collaboration should be contemplated, especially for those concomitantly receiving immunosuppressant or having rheumatoid arthritis.

DOI: 10.1136/annrheumdis-2020-eular.5054
Background: PD-1hi CXCR5- T peripheral helper (Tph) cells are newly identified pathogenic CD+ helper T cells in rheumatoid arthritis (RA). Since Tph cells have been emerged quite recently, the characteristics of Tph cells as a biomarker of RA are not fully understood.

Objectives: The aim of the study is to evaluate how useful Tph cells in peripheral blood are when compared to other immune cell subsets, and to clarify which Tph subset most accurately reflects the disease activity of RA.

Methods: The RA patients who visited our rheumatology department between January 2000 and February 2017, and met the 2010 ACR/European League Against Rheumatism (EULAR) classification criteria were included. We first assessed correlation with 40 immune cell subsets and the disease activity of RA. Next, the proportions of these immune cells were compared between RA and healthy controls (HCs). We also investigated the immune cell subsets which showed correlation with DAS28-ESR and the disease activity in seropositive and seronegative RA separately, the proportions of Tph cells (r=0.52) and HLA-DR+Tph cells (r=0.25) were significantly reflected the change of DAS28-ESR (r=0.75, p=0.025), but not HLA-DR+Tph cells because of the non-specific reduction by the MTX treatment. Rather, HLA-DR+Tph cells significantly reflected the change of DAS28-ESR (r=0.76, p=0.021).

Conclusion: Tph cells and HLA-DR+Tph cells highly reflected the disease activity of seropositive RA. However, after the treatment, the proportion of HLA-DR+Tph cells decreased independent from the disease activity, and that of HLA-DR+Tph cells most accurately reflects the disease activity of RA.
patients, with a maximum stimulation index of 52.4 compared to a maximum of 6.75 in the HC group. Only 1 HC sample responded with an SI greater than 3.0, whereas 50% of RA patients elicited responses above this. Two of the RA patients responded to both the peptide pool and was not selected on the basis of tissue type whereas selected peptides bind preferentially to class II HLA containing the shared epitope (SE).

**Conclusion:** In non-HLA typed individuals, cit-peptide induced proliferative T cell responses were detectable in both RA patients and HCs, and although Sts overall were higher amongst RA patients this did not reach statistical significance in this small sample. Not all RA patients responded to the peptide pool which may be due to the limited number of citrullinated epitopes used, or to RA patients with a non-SE HLA type. Additional work should establish the need for HLA typing in this assay; around half of seropositive RA patients would be expected to be SE positive. Furthermore, a wider array of cit-peptides may be needed to demonstrate autoreactivity in a broader cross-section of RA patients. Our future plans are to further phenotype the cellular subsets responding to the peptide pool and to study assay data in the context of clinical outcomes, to assess its utility for immune monitoring.

**IN VITRO CHARACTERIZATION OF INFAMMATORY ARTHRITIS ASSOCIATED WITH IMMUNE CHECK POINT INHIBITION**

A. S. Sorensen, M. Norgaard Andersen, K. Juul-Madsen, C. Skeja, H. Schmidt, T. Vorup-Jensen, T. W. Kroagstrup, Aarhus University, Aarhus, Denmark; Aarhus University Hospital, Aarhus, Denmark

**Background:** During cancer treatment with immune checkpoint inhibitors (ICI) such as the anti-PD-1 antibody pembrolizumab, 2-4% of patients develop inflammatory arthritis as an immune related adverse event and half of patients with pre-existing inflammatory arthritis have disease flares. This type of adverse events shows striking similarities with traditional immune mediated inflammatory arthritis. However, the underlying immunological mechanisms of inflammatory arthritis associated with ICI are not fully understood.

**Objectives:** We aimed to develop an in vitro model of inflammatory arthritis associated with ICI, and to use this model to investigate monocyte differentiation and activation following treatment with pembrolizumab.

**Methods:** First, synovial fluid mononuclear cells (SFMCs) and peripheral blood mononuclear cells (PBMCs) from patients with immune mediated inflammatory arthritis (rheumatoid arthritis and peripheral spondyloarthritis, n=22) and PBMCs from healthy controls were incubated with pembrolizumab and assessed for monocyte chemotactic protein 1 (MCP-1) secretion by ELISA. Then, cytokine production in SFMCs was studied in more detail by the multiplex V-PLEX proinflammatory panel and by intracellular flow cytometry. Finally, pembrolizumab treated SFMCs were incubated with the different disease modifying anti-rheumatic drugs adalimumab, tocilizumab, tofacitinib, and baricitinib.

**Results:** Pembrolizumab significantly increased MCP-1 production in the SFMCcultures (P=0.0031). In contrast, pembrolizumab did not change MCP-1 production by PBMCs from neither patients nor healthy controls (P=0.77 and P=0.43). Pembrolizumab also increased the production of TNFs (P=0.049, IFNγ (P=0.031), but did not change the production of IL-6 (P=0.98). Amongst SFMCs treated with pembrolizumab, IL-6 production was an increased frequency of intermediate monocytes (P=0.044). Interestingly, pembrolizumab also increased the MCP-1 production within the intermediate monocytes only (P=0.028). In contrast, among SFMCs treated with LPS, only the classical mono-ocyte subset was increased (P=0.0045) and MCP-1 production increased in both intermediate and classical monocyte subsets. Lastly, the TNF inhibitor adalimumab and the JAK inhibitors baricitinib and tofacitinib attenuated the pembrolizumab-induced MCP-1 production (P=0.0004, P=0.033, and P=0.025, respectively) while this was not seen with the IL-6 inhibitor tocilizumab (P=0.75).

**Conclusion:** We have developed a very simple in vitro model of inflammatory arthritis associated with ICI. Using this model, we found that pembrolizumab specifically activated intermediate monocytes and induced TNFs, IFNγ, and IL-10. IL-6 production in IL-6 was unchanged. These findings were supported by effective reduction of MCP-1 secretion with TNF inhibitor inhibition but not with IL-6 inhibition. This model could potentially be used to further study the effects of ICIs and the underlying immunological mechanisms of inflammatory arthritis associated with ICI.

**GUT DERIVED ACETATE PROMOTES REGULATORY B CELLS WITH ANTI-INFLAMMATORY EFFECTS**

C. Daei, R. T. Tan, R. Audo, J. Mielle, L. Macia, J. MM UMR5535, Montpellier, France; 2 Charles Perkins Centre, The University of Sydney, Sydney, Australia; 3 University and Hospital of Montpellier, Rheumatology, Montpellier, France

**Background:** Regulatory B cells (Bregs) are defective in many auto-immune diseases, i.e. rheumatoid arthritis (RA). The short-chain fatty acid (SCFA) acetate, derived mostly from gut microbial fermentation of dietary fiber, promotes anti-inflammatory regulatory T cells and protects mice from type 1 diabetes and colitis. We hypothesized that acetate could be a good candidate to promote Bregs in auto-immune diseases.

**Objectives:** To assess the effect of acetate on Breg number and function, in vitro and in vivo in mice and humans.

**Methods:** Bregs were defined as IL-10 producing regulatory B cells (B10 cells). Their number was assessed after overnight exposure to acetate (Ac 10 mM) and 4 hours of CpG, ionomycin and PMA in mice and after 24 hours of acetate +/- CpG and 4 hours of ionomycin and PMA in humans. Acetate was given to mice either intraperitoneally (twice at a 12-hour interval) or in drinking water for 3 weeks.

Acetate-treated B cells were transferred to mice with collagen-antibody-induced arthritis to assess their function. To decipher the mechanisms behind the effect of acetate, we used inhibitors of GPR43 (CATPB), ATP synthase (oligomycin), glycolysis (2-DG), Acss2 and Acly and assessed protein lysine acetylation by flow cytometry on human B cells. Acetate and B10 cells were also assessed before and after a 7-day high-fibre diet in 12 healthy volunteers.

**Results:** In mice, acetate promoted B10 cell differentiation both in vitro (medians [IQR] 3.1 [0.4-3.7] and 9.9 [5.9-17.6]% of B for CpG and CpG+Ac respectively, p=0.002) and in vivo when intraperitoneal injected (22 [14-29] and 31 [25-37]% of B for PBS and acetate respectively, p=0.03) or added to drinking water (17 [6-25] and 39 [26-40]% of B for water or acetate respectively, p=0.02). Adoptive transfer of acetate-treated B cells protected mice from arthritis compared to non-exposed B cells (ANOVA p=0.008). Acetate also promoted B10 cells from human blood cells (2.5 [1.6-2.7] and 3.4 [2.6-4.5] for unstimulated [Un] and Ac respectively, p=0.0001). Conversely to CpG, acetate specifically promoted IL-10, with no impact or a decrease of proinflammatory cytokines (IL-6: 17 [5-29], 12 [3-21] and 40 [20-60]%, B cells for Un, Ac and CpG respectively, p<0.01 for all comparisons). Inhibition of TNF-A: 48 [25-61] 41 [28-67] and 66 [64-78]% of B cells for Un, Ac and CpG respectively, p=0.01 for CpG vs Un or Ac, NS for acetate vs Un). Inhibition of GPR43 and Acly did not impact acetate response, while inhibition of glycolysis significantly decreased its effect. Blockade of Acss2, converting acetate into acetyl-CoA, decreased acetate-induced B10 cells. Acetate was associated with an increase of protein lysine acetylation which was not observed in presence of CpG alone, suggesting a different mechanism of action (2.0 [1.3-3.4]; 3.3 [2.4-5.4] and 1.4 [0.5-1.7]% B cells for Un, Ac and CpG respectively, p=0.002 for Un vs Ac, NS with CpG). Conversion of acetate into acetyl-CoA could thus be used for the acetylation of cytoplasmic protein, a post-translational modification that regulates key cellular processes, including energy metabolism. In addition, B10 cells had significantly more lysine-acylated proteins than IL-10+ B cells or TNF-A B cells (3.9 [3.9-7.3]; 3.2 [2.4-6.4] and 3.9 [2.4-6.2]% of B for B10, IL-10+ B cells or TNF-A B cells respectively, p=0.01 for all comparisons). Finally, dietary fiber suplementation in healthy individuals was associated with increased acetate and B10 cells in the blood, which were significantly correlated (R²=0.20, p=0.02).

**Conclusion:** Our results suggest that acetate induces functional Bregs, through its conversion into acetyl-CoA, used for cell metabolism and protein acetylation. Delivery of acetate or acetate in bacteria or food bacteria might be a promising approach to restore Bregs in non-communicable diseases such as RA in which they are deficient.

ALLERGIC ASTHMA INDUCES THE ACCUMULATION OF SYNOVIAL RESIDENT EOSINOPHILS, TRIGGERING THE RESOLUTION OF INFLAMMATORY ARTHRITIS

M. Liu¹, D. Andreew¹, K. Kachler¹, J. Koelle¹, S. Rauber², A. Ramming³, S. Finotto¹, G. Schett¹, A. Bozec¹. ¹University Hospital Erlangen and Friedrich Alexander University of Erlangen-Nürnberg (FAU), Department of Medicine 3, Rheumatology and Immunology, Erlangen, Germany; ²University Hospital Erlangen and FAU, Department of Molecular Pneumology, Erlangen, Germany

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disorder, involving synovial joints, which affects approximately 1 percent of the world population¹. Our former work demonstrated that the Th2-eosinophil pathway is a strong anti-inflammatory mediator of inflammatory arthritis². Allergic asthma is an inflammatory disease of the airway, triggered by type 2 immune response. Hitherto, clinical observations on the impact of asthma on RA showed controversial results. Herein, we investigated the action of allergic asthma on inflammatory arthritis.

Objectives: We aimed to delineate the molecular and cellular responses induced by allergic asthma on inflammatory arthritis, particularly depicting the role of eosinophil subsets in arthritic synovium.

Methods: Allergic asthma was induced in wild type and genetically modified mice by ovalbumin (OVA) treatment. After the induction of allergic asthma, K/BxN serum was transferred into the asthmatic mice or control mice to trigger serum induced arthritis (SIA). Then, arthritis severity, circulating cytokines and the cytology of lung and synovium were analyzed. Eosinophil subsets were studied by flow cytometry, single cell RNA sequencing analysis, and were isolated and transferred into the synovial cavity of eosinophil deficient arthritic mice (CIA). Clinical data of patients with both RA and asthma were collected and checked for the relapse of RA after asthma treatment with anti-interleukin (IL)-5 antibody.

Results: Mice induced with allergic asthma exhibited a rapid resolution of SIA. The OVA-triggered resolution disappeared in eosinophil deficient mice (Ab2dGATA), and was partially blocked by IL-5 neutralization. We could detect that IL-5 was mainly produced by type 2 innate lymphoid cell (ILC2) in the lung. Allergic asthma exclusively induced the proliferation (Ki67⁺) and accumulation of synovial resident eosinophils (rEos, Siglec-F⁺), which switched classical macrophages into alternatively activated macrophages. Synovial induced eosinophils (iEos, Siglec-F⁺) appeared only in the acute phase of SIA. Single cell RNA sequencing analysis showed that rEos played an anti-inflammatory role, while iEos had pro-inflammatory properties in arthritis. The roles of rEos and iEos in arthritic mice were confirmed by transferring rEos/iEos into the synovial cavity of arthritic mice. Patients with both RA and asthma showed a remission relapse of RA after using humanized monoclonal IL-5 antibody for treating severe eosinophilic arthritis.

Conclusion: Allergic asthma induced an IL-5 mediated proliferation and accumulation of synovial rEos. The latter triggered the resolution of inflammatory arthritis. In human, eosinophils induced by asthma were essential for the resolution of inflammatory arthritis. The latter triggered the resolution of inflammatory arthritis. In human, eosinophils induced by asthma were essential for the resolution of inflammatory arthritis. RA after using humanized monoclonal IL-5 antibody for treating severe eosinophilic arthritis.

including angiogenesis. Less is known about the role of YKL-40 in inflammatory diseases such as GCA.

**Objectives:** Our objective was to investigate the cellular source and the pro-angiogenic function of YKL-40 in GCA patients.

**Methods:** For this study we performed immunohistochemistry (IHC) and cell culture experiments. IHC for YKL-40 and CD206 was performed on GCA positive temporal artery biopsies (TABs; n=12) and GCA positive aortas (n=10) of treatment-naive patients. Expression of YKL-40 by macrophages was confirmed by double staining with macrophage transcription factor PU.1. Additionally, the TABs were stained for IL-13Rα2, recently described as the receptor for YKL-40. The effect of skewing signals on YKL-40 production was assessed by cell culture of monocyte-derived macrophages of GCA patients with either M-CSF or GM-CSF (n=8). Subsequently, the supernatant was assayed by ELISA. Finally, the angiogenic potential of YKL-40 was investigated by tube formation experiments using human microvascular endothelial cells (HMVECs).

**Results:** YKL-40 is produced by a distinct subset of macrophages in GCA TABs and aortas, usually located in or near the media (Figure 1 shows representative stainings in consecutive slides of a GCA TAB). We here show YKL-40 to be expressed by CD206+/MMP-9+ macrophages in all GCA TABs and aortas. In vitro, macrophages were found to produce YKL-40 (Figure 2 shows an increasing YKL-40 production during the maturation of monocytes towards macrophages over 8 days of culture). GM-CSF stimulation, which is known to upregulate CD206 expression in macrophages, gave rise to higher YKL-40 production by YKL-40 negative macrophages (1). Thus, YKL-40 production by YKL-40+ macrophages may be involved in angiogenesis in GCA tissues, a process important for the continuation of the inflammatory process.

**Conclusion:** Taken together, we show here that a distinct subset of macrophages, skewed by GM-CSF and highly positive for CD206, is responsible for the production of YKL-40 in GCA. The results are in line with previous reports demonstrating that CD206 expression distinguishes YKL-40 positive macrophages from YKL-40 negative macrophages (1). Thus, YKL-40 production by CD206+ macrophages may be involved in angiogenesis in GCA tissues, a process important for the continuation of the inflammatory process.

Tomčík1,2, 1Institute of Rheumatology, Prague, Czech Republic; 2Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic; 3Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic, Prague, Czech Republic; 4Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

**Background:** Our previous study demonstrated that Heat shock protein 90 (Hsp90) is overexpressed in the skin of patients with systemic sclerosis (SSc), in cultured SSc fibroblasts and preclinical models of SSc. HSP90 is a new regulator of canonical TGFB signalling and its inhibition prevents the stimulatory effects of TGFB on collagen synthesis and dermal fibrosis in three preclinical models of SSc.

**Objectives:** Herein, we aimed to evaluate the efficacy of Hsp90 inhibitor (17-DMAG) in the treatment of established experimental dermal fibrosis induced by bleomycin.

**Methods:** Design consisted of three control groups, I (NaCl-s.c./6 weeks), II (bleomycin-s.c./3w and NaCl-s.c./3w), III (bleomycin-s.c./6w), and 2 treatment groups (bleomycin-s.c./6w). During the last 3 weeks, one group was treated with 17-DMAG 0.5mg/kg-i.p. every third day, whereas one group (with nintedanib 50mg/kg-p.o. twice daily) served as a comparator with already published efficacy in this setting. Total of 40 B6 mice were examined weekly for weight, activity and fur texture. The effects of 17-DMAG were determined by assessment of dermal thickness (HE-staining), collagen content (hydroxyproline assay), myofibroblast

**References:**

counts (α-SMA staining) and of 23 serum inflammatory cytokines/chemokines (Mouse-Cytokine-23-plex, Bio-Rad-Laboratories).

**Results:** 17-DMAG decreased dermal thickening by 53±3% (p<0.001) (nintedanib by 46±2%, p<0.001), collagen content by 48±5% (p<0.004) (nintedanib by 50±4%, p=0.003), myofibroblast counts by 42±9% (p<0.001) (nintedanib by 44±7%, p<0.001), and levels of IL-1α, IL-6, IL-12(p40), CXCL1, MCP-1, MIP-1β, RANTES (in all: p<0.05) compared to vehicle-treated mice injected with bleomycin for 6w. Moreover, 17-DMAG also induced regression of pre-established fibrosis to below the levels of vehicle-treated mice injected with bleomycin for 3w and Nazd for 3w (dermal thickness by 14±3%, collagen content by 20±5%, myofibroblast counts by 13±9%; whereas in nintedanib by 10±3%, 21±4%, 17±7%, respectively; in all: p<0.05), and levels of IL-12(p40), CXCL1, MCP-1, MIP-1β, RANTES (in all: p<0.05). No significant weight loss, decrease in activity or changes in fur texture were observed upon 17DMAG treatment.

**Conclusion:** This is the first study on effects of Hsp90 inhibitor 17-DMAG in the treatment of established dermal fibrosis. We demonstrate that 17-DMAG effec-
tively prevents the progression and induces regression of established bleom-
cein-induced dermal fibrosis, in an extent that is comparable to nintedanib in this study (which was recently FDA approved for slowing the rate of decline in lung function in adults with SSc-ILD). 17-DMAG was well tolerated without obvi-
onal clinical signs of toxicity. These data suggest that Hsp90 could be a novel potential target in the treatment of SSC dermal fibrosis.

THE INFLUENCE OF LONG-TERM EXERCISE AND IN VITRO EXERCISE-MIMICKING STIMULATION ON THE PRODUCTION OF MYOKINES AND CYTOKINES IN MYOTUBES OF PATIENTS WITH CHRONIC INFLAMMATORY MYOPATHIES

M. Vokrouhlický1, L. Bernová1, M. Špotilová2, H. Štorkanová3, S. Oreska4, M. Klein5, J. Ukropec6, B. Ukropcová7, M. Tomčík8, J. Vencovský8.1. Institute of Rheumatology, Prague, Czech Republic; 1. **Background:** It has been demonstrated several times that endurance exercise has beneficial effects on the condition of patients with idiopathic inflammatory myopathies (IM). Muscle contraction during exercise is a major stimulus for the release of myokines that are supposed to take part in the beneficial adaption to exercise.

**Objectives:** The aim of this study was to find out how a six-month physiotherapy and in vitro exercise-mimicking treatment affect myokine and cytokine production in myotubes of IM patients.

**Methods:** Seven patients with chronic IM took part in a six-month physiotherapy (stretching and strengthening), which significantly improved their muscle strength and endurance. IM patients (n=7) before and after the six months exercise and their respective healthy counterparts (HC, n=9) underwent a muscle ultrasound, muscle biopsies and serum cytokines analysis. Serum samples from 252 controls and 162 SSC patients were collected in non-fasting conditions.

**Results:** Compared to HC myotubes, myotubes of IM patient patients released more myostatin and activin A into the medium. The myostatin gene decreased the release of inflammatory cytokines as IL-17, TNF-α, IL-1β, IL-6, IL-18 and INF-γ (p<0.05) compared to healthy controls. In addition, myotubes derived from IIM patients after six months of rehabilitation secreted significantly less inflammatory cytokines as IL-17, TNF-α and VEGF in comparison to IM patients and healthy individuals.

**Conclusion:** In conclusion, long-term exercise influenced the production of myokines and decreased release of inflammatory cytokines in myotubes of IM patients. In vitro exercise-mimicking treatment increased the secretion of IL-6 and decreased the release of inflammatory cytokines as IL-17, TNF-α and VEGF in myotubes of patients with IM and healthy individuals.

subtypes is jointly associated with RNA transcripts or FAIME scores with strong differences in relation to the geographical origin of samples; neutrophils emerged as the major determinant of gene expression in SSc-whole-blood samples.

**Conclusion:** We discovered a set of differentially expressed genes and pathways that could be validated in two independent sets of SSc patients highlighting a number of deregulated molecular processes that have relevance for the pathogenesis of autoimmunity and SSc.

**Background:** Idiopathic inflammatory myopathies (IM, myositis) are a heterogeneous group of autoimmune muscle disorders characterized by skeletal muscle weakness and damage, inflammation and extramuscular manifestations. Recent findings suggest that immunological as well as nonimmunological processes, such as endoplasmic reticulum stress, hypoxia, mitochondrial and metabolic dysfunction are involved in the pathogenesis of IMs [1]. Clusterin (CLU) has been reported to play a protective function in the development of tissue injury, inflammation and autoimmunity, and is involved in the maintenance of immune homeostasis [2].

**Objectives:** This study aimed to explore a potential involvement of the circulating levels and skeletal muscle expression of CLU in pathogenic mechanisms of IM.

**Methods:** A total of 85 IM patients and 86 healthy controls (HC) were recruited. In addition, 20 IM patients and 21 HC underwent a muscle biopsy. Circulating concentrations of CLU were measured by ELISA. Serum cytokine profile of patients and HC was assessed by Cytokine 27plex Assay. Immunohistochemical localisation of CLU was assessed in 10 IM and 4 control muscle tissue specimens. The expression of CLU and myositis related cytokines in muscle tissue was determined by real-time PCR.

**Results:** We observed a significant increase of circulating CLU in all IM patients compared to HC (86.2 (71.6-99.0) vs. 59.6 (52.6-68.4) μg/mL, p < 0.0001). Moreover, CLU serum levels were positively correlated with myositis disease activity assessment (MYOACT) (r = 0.337, p = 0.008), myositis intention-to-treat activity index (MITAX) (r = 0.357, p = 0.004) and global disease assessment evaluated by physician (r = 0.309, p = 0.015). In addition to that, a multivariate redundancy analysis revealed a combined effect of serum CLU and cytokine profile (represented by cytokines and chemokines known to be involved in IM) on disease activity in muscle tissue. In muscle tissue, CLU mRNA was significantly increased in IM patients compared to controls (p = 0.032) and correlated with IL-15 (r = 0.489, p = 0.034), IL-6 (r = 0.581, p = 0.009), TNF (r = 0.485, p = 0.035) and PGC-1α (r = 0.709, p = 0.001) mRNA. Immunohistochemistry revealed CLU accumulation in the cytoplasm of regenerating myofibers.

**Conclusion:** Our results show an up-regulation of clusterin in circulation and skeletal muscle of IM patients that associates with disease activity and inflammation, and its specific expression in regenerating myofibers. Based on our data and the known cytoprotective function of CLU we suggest an attempt of the organism to limit further muscle damage induced by myositis disease mechanisms.

The role of lncRNAs in SS pathogenesis is unknown. Disease characterized by inflammatory destruction of the exocrine glands. Long-negative (Ro-); n=27 antibody positive (Ro+) and healthy controls (HC, n=27) to identify and functionally characterize LINC01871 as a potential mediator of the dysregulated T cell inflammatory response pathways implicated in SS pathogenesis.

Methods: We identified a total of 1054 unique DE ncRNAs between Ro+, Ro- and/or a combined analysis relative to HC; of these, 45 (1 long intergenic ncRNA (lincRNA), 1 antisense, 43 pseudogenes) were overexpressed in all 3 SS subtypes. To investigate the function of LINC01871 in T cells, we targeted LINC01871 deletion (LINC01871-/-) clone with CRISPR. To this end, we generated a single cell clone of HSB2 with confirmed CRISPR-targeted LINC01871 deletion (LINC01871-/-).

To this end, we generated a single cell clone of HSB2 with confirmed CRISPR-targeted LINC01871 deletion (LINC01871-/-).

Conclusion: LncRNAs are emerging as important regulators of immune function with increasing evidence of autoimmune disease relevance. Here, we leveraged RNA-seq, extensive bioinformatic data, and CRISPR technology to identify and functionally characterize LINC01871 as a potential mediator of the dysregulated T cell inflammatory response pathways implicated in SS pathogenesis.

Objectives: In this study we performed high dimensional (HD) analyses to identify mediators that link vasculopathy to organ fibrosis.

Methods: HD techniques including RNA-seq, ChiP-seq, ATAC-seq and FISH-seq have been performed to identify mediators in vessels and fibrotic lesions of human skin samples of SS patients and healthy volunteers. In addition, murine skin and lung tissue samples were analyzed by multi-channel immunofluorescence (IF) and confocal laser scanning microscopy. Microvascular endothelial cells, smooth muscle cells and fibroblasts have been further processed for RNA-seq, ChIP-seq and smFISH. Microvascular endothelial cells, smooth muscle cells and fibroblasts have been further processed for RNA-seq, ChIP-seq and smFISH. Microvascular endothelial cells, smooth muscle cells and fibroblasts have been further processed for RNA-seq, ChIP-seq and smFISH. Microvascular endothelial cells, smooth muscle cells and fibroblasts have been further processed for RNA-seq, ChIP-seq and smFISH. Microvascular endothelial cells, smooth muscle cells and fibroblasts have been further processed for RNA-seq, ChIP-seq and smFISH.

Results: Bioinformatic HD analyses revealed the ETS transcription factor PU.1 to be upregulated in fibroblasts of skin biopsies of SS patients and of various organs of fibrosis models. ATF3 deficiency ameliorated fibrosis in various mouse models. Notably, ATF3 was significantly upregulated in fibroblasts of skin biopsies of SS patients and of various organs of fibrosis models. ATF3 deficiency ameliorated fibrosis in various mouse models. Notably, ATF3 was significantly upregulated in fibroblasts of skin biopsies of SS patients and of various organs of fibrosis models. ATF3 deficiency ameliorated fibrosis in various mouse models. Notably, ATF3 was significantly upregulated in fibroblasts of skin biopsies of SS patients and of various organs of fibrosis models. **Background:** Fibroblast growth factor receptor 3 (FGFR3) is a member of the family of different fibroblast growth factor receptors with several ligands called fibroblast growth factors (FGFs) in humans. Each FGFR has different isoforms resulting from natural alternative splice variants. Upon binding FGF ligands, fibroblast growth factor receptors (FGFRs) trigger various intracellular signaling pathways to regulate important biological processes. Systematic evaluation of FGF/FGFR signaling in the context of SSC has not been performed so far.

**Objectives:** The aim of this study was to characterize FGFR3/FgF9 signaling in the context of fibroblast activation and to evaluate FGFR3 as a potential molecular target for antifibrotic treatment in SSC.

**Methods:** Differential expression profiling of dermal cells from SSC patients and healthy volunteers were performed employing GEArray cDNA microarray. Real-time PCR, Western Blot, immunohistochemistry and immunofluorescence were done in skin tissues and fibroblasts from SSC patients. Selective inhibitors in conjunction with genetic knockdown and knockout strategies were used to target FGFR3 signaling in vitro and in mouse models of SSC: skin fibrosis induced by bleomycin challenge and overexpression of a constitutively active transforming growth factor receptor 1 (TBR1) and tight skin-1 (TSK) mice. Aftymex gene arrays in dermal fibroblasts from mice with constitutive FGFR3 signaling and mice lacking FGFR3.

**Results:** Expression of FGFR3, specifically the isoform FGFR3IIIb and its ligand FGF9, was significantly upregulated in the dermis and dermal fibroblasts of SSC patients. Selective inhibitors in conjunction with genetic knockdown and knockout strategies. Furthermore, in vivo overexpression of FGFR3 IIIb/FGF9 expression comparable to that in SSC fibroblasts could also be obtained by stimulating normal healthy dermal fibroblasts with transforming growth factor (TGFβ) in vitro and in mice constitutively overexpressing activates TGFβ receptor type I.

Transcriptome profiling **in silico** analysis and functional experiments revealed that FGFR3 synergistically induces multiple profibrotic pathways including Endothelin-, Interleukin-4- and CTGF-signaling in a CREB-dependent manner. FGFR3 exerts profibrotic effects by modulating phosphorylation of CREB by ERK-, AKT-, CAMK2- and p38-kinases. Activation of FGFR3 in healthy or SSC dermal fibroblasts by stimulation with recombinant FGF9 was sufficient to induce resting fibroblast-to-myofibroblast differentiation along with increased collagen secretion and alpha-SMA production. Genetic knockout of FgF3 abrogates myofibroblast differentiation in vitro and ameliorates skin fibrosis in TSK and TBR mice and in bleomycin-induced fibrosis. Further confirming the translational potential of these findings in the preclinical models of SSC, we demonstrate that pharmacological inactivation of FGFR3 by PD173074 could induce the regression of experimental fibrosis in vitro and in bleomycin-challenged, TSK and TBR mice.

**Conclusion:** Our findings characterize FGFR3 as an upstream regulator of a network of profibrotic mediators in SSC and thus, we could demonstrate successfully that the targeted inhibition of FGFR3 could inhibit multiple signaling pathways in vitro and ameliorated fibrosis in different preclinical models of SSC. These findings may have direct translational implications as FGFR3 inhibitors are currently in development.

**Background:** The association between giant-cell arteritis (GCA) and malignancy is controversial.

**Objectives:** To assess malignancy rates and risk in GCA patients in a large-scale population-based study.

**Methods:** We utilized the medical database of Clalit-Health-Services for this retrospective cohort study. Follow-up was from January 1,2002 and continued until death or end of follow-up on September 1,2018. Incident GCA patients were compared with age-and-sex-matched controls. Hazard-ratios for subtypes of malignancies were obtained by the Cox proportional-hazard model, adjusted for socio-demographic variables and cancer risk factors.

**Results:** The study population included 7,213 GCA patients and 32,987 age- and sex-matched controls who were not diagnosed with the disease. The mean age of GCA diagnosis was 72.3±9.9 years (median 73.1 years) and 69.1% were women. At Kaplan–Meier survival analysis, assessing cumulative cancer-free survival in GCA patients and controls, GCA patients had worse curve than controls (chi-squared = 49.84; degrees of freedom = 1; p < 0.0001; Figure 1). At the Cox-survival analysis adjusted for age, sex, SES and cancer risk factors GCA patients showed increased risk for overall cancer (HR 1.29 [95% CI 1.20–1.39]).

OP0144

EFFECT OF TOCILIZUMAB ON VASCULAR INFLAMMATION BY 18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY: A PROSPECTIVE, LONGITUDINAL STUDY

K.A. Quinn1,2, H. Dashora1, M. Ahiman1, 1National Institutes of Health, Bethesda, United States of America; 2MedStar Georgetown University Hospital, Washington, DC, United States of America

Background: Two randomized controlled trials have demonstrated clinical efficacy of tocilizumab for the treatment of giant cell arteritis (GCA)(1, 2). In these trials, clinical and laboratory measures were used to define the outcome measures. The direct effect of tocilizumab on vascular inflammation remains poorly characterized.

Objectives: To prospectively evaluate vascular inflammation as measured by 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) in a longitudinal cohort of patients with GCA treated with tocilizumab over a several year follow-up period.

Methods: Patients with GCA were recruited into a prospective, observational cohort. All patients fulfilled modified 1990 American College of Rheumatology (ACR) Classification Criteria for GCA. All patients underwent FDG-PET computed tomography (CT) prior to initiation of tocilizumab. A single reader reviewed all PET scans, blinded to clinical data. Qualitative assessment of FDG uptake relative to liver uptake by visual assessment (scale 0-3) was assessed in 9 arterial territories. A summary score, PET Vascular Activity Score (PETVAS), was calculated (scale 0-27).

Patients underwent imaging at 6-12 month intervals per a standardized imaging protocol. In a subset of patients in whom tocilizumab was discontinued due to established remission, a repeat FDG-PET scan was obtained within 6 months of drug discontinuation.

Change in PET activity over time was measured by linear regression. PET activity during established remission was compared to PET activity after discontinuation of tocilizumab. For some patients, tocilizumab was added to the existing treatment regimen without a substantive change in concomitant glucocorticoid dose. In a secondary analysis, patients were stratified by prednisone dosing (high dose prednisone >10mg/day prednisone, low dose prednisone ≤10mg/day prednisone during the imaging interval) to determine if tocilizumab had an effect on vascular inflammation independent of glucocorticoids.

Results: 22 patients were included in the study. All patients had clinically active disease at baseline with median baseline PETVAS 24.5 (23-27). There was a significant reduction in PETVAS over 2 years follow up (p<0.01 for linear trend) (Figure). Of note, there was continued progressive improvement in PETVAS in both year 1 and year 2 of treatment. Eight patients received concomitant high dose glucocorticoids and 14 patients remained on low dose glucocorticoids with the addition of tocilizumab. In patients who only received low dose prednisone, significant reduction in PETVAS was still observed with addition of tocilizumab (PETVAS 25.5 to 19.5, p=0.04). In a subset of 5 patients who discontinued tocilizumab due to established remission [median PETVAS 19 (17.23) at time of remission], a repeat FDG-PET scan within 6 months after treatment discontinuation showed worsening PET activity in 4 out of 5 patients [median PETVAS 23 (20-23)]. Two of these patients subsequently experienced a clinical disease relapse.

Conclusion: Tocilizumab was associated with improved vascular inflammation as assessed by FDG-PET. There was continued improvement of vascular inflammation at both year 1 and year 2 of treatment, and early evidence suggests a rebound of vascular inflammation when tocilizumab was discontinued. These data provide rationale for long-term tocilizumab therapy in patients with GCA and for consideration of FDG-PET as an outcome measure in future clinical trials.

OP0145

MALIGNANCY IN ANCA-ASSOCIATED VASCULITIS AND POLYARTERITIS NODOSA: AN AUSTRALIAN POPULATION-BASED STUDY

J. Tieu1,2, S. Lester1, W. Raymond3, H. Keen1, C. Hill1,2, J. Nossett5,7, 1Faculty of Health and Medical Sciences, University of Adelaide, Adelaide, Australia; 2Basil Hetzel Institute, Adelaide, Australia; 3Lyell McEwin Hospital, Adelaide, Australia; 4The Queen Elizabeth Hospital, Adelaide, Australia; 5University of Western Australia, Rheumatology, Perth, Australia; 6Fiona Stanley Hospital, Rheumatology Dept, Perth, Australia; 7Sir Charles Gairdner Hospital, Rheumatology Dept, Perth, Australia

Background: The increased risk of malignancy in patients with ANCA-associated vasculitis (AAV) and polyarteritis nodosa (PAN) has been attributed to late diagnosis of any malignancy.
Treatment related effects, with non-melanoma skin and genitourinary cancers most frequently reported in European studies. Malignancy has not been examined in patients with AAV/PAN in Australia, where environmental factors may influence risk.

Objectives: To determine the risk and timing of incident cancer in Western Australian (WA) AAV/PAN patients compared to controls.

Methods: Patients and controls were ascertained through the WA Hospital Morbidity Data collection System (HMDS). Administrative hospitalisation data were linked with the WA cancer and death registries. Data was available between 1980-2015. Patients were classified into two sub-groups using International Classification of Disease (ICD) -9 and/or -10 codes: (1) GPA/MPA- granulomatosis with polyangiitis (GPA)/microscopic polyangiitis (MPA), and (2) other-AAV/PAN- eosinophilic granulomatosis with polyangiitis (EGPA), PAN, and other patients with any AAV or PAN where specific ICD-10 coding was not available. Controls were age, sex and temporally matched (at patient diagnosis date) and had no rheumatological diagnosis. Patients and controls with prior cancer were excluded from the analysis.

Spline-based estimation of time-varying hazard ratios (HR) for incident cancer in patients vs controls was performed using the Stata library stpm2cr4. Results for cause-specific models, which treated deaths in patients without cancer as censored, were confirmed using models treating death as a competing risk. The risk of specific cancers was analysed by Cox regression.

Results: The analysis included 391 patients (165 GPA/MPA, 217 other-AAV/PAN) and 4913 controls, with 86 incident cancers (over 3556.7 person-years) observed in patients and 1119 (over 64997.0 person-years) in controls. Patients and controls were well matched for age (mean ± standard deviation GPA/MPA: 55 ± 18 years, other AAV/PAN: 59 ± 17 years, controls 57 ± 16 years), and sex (female GPA/MPA 48%, other AAV/PAN 46%, controls 46%).

Incident cancer risk and timing differed between the two patient subgroups (Figure 1). The risk of incident cancer in GPA/MPA patients, compared to controls, increased with disease duration, whilst other-AAV/PAN patients had a greater risk within the first two years of diagnosis, but a similar risk to controls in the longer term.

By specific cancers, GPA/MPA patients had an increased risk of skin cancers (excluding squamous and basal cell carcinomas): hazard ratio (HR) 2.71 (95% confidence interval (CI) 1.55 – 4.74), and genitourinary cancers: HR 3.64, 95% CI (excluding squamous and basal cell carcinomas): hazard ratio (HR) 2.71 95% CI 1.58, 8.39, which was not observed in other-AAV/PAN patients. While there was a trend for an overall increase in haematological cancers, this was inconclusive.

Conclusion: Incident cancer risk, driven by skin and genitourinary cancers, increased with disease duration in GPA/MPA patients, consistent with previous studies, suggestive of a treatment related effect. In contrast, cancer was more frequently observed early after diagnosis in other-AAV/PAN patients. Our findings suggest that vigilance for incident cancers is required for all patients with AAV and PAN after diagnosis and in long term management, considering distinct periods of greater risk by disease subgroup.

References:
in flow velocity in the GCA-group was PS 2.1 cm/s (p= 0.039) and ED 1.4 (p= 0.0004) cm/s, while the RI was increased by 0.14 (p= 0.077). The results for PS and ED measurements were statistically significant, while the results for RI were not significant.

**Conclusion:** In GCA patients with oculcar symptoms, a reduction of flow velocities of the central retinal artery compared to the eye-healthy control group was found. Results for PS and ED were significant. There seems to be a trend for decreased flow velocities in coexistence with visual symptoms in patients with GCA.

**Background:** Evidence on the efficacy of Mepolizumab (MEPO) in Eosinophilic Granulomatosis with Polyangiitis (EGPA) is scarce [1].

**Objectives:** To assess the efficacy and safety of MEPO in real-life clinical practice.

**Methods:** We retrospectively included patients diagnosed with EGPA and treated with MEPO (100 or 300 mg/month). MEPO efficacy was evaluated in the first 12 months in terms of systemic disease and asthma control. The occurrence of any adverse event (AE) was recorded.

**Results:** 142 patients were included (38% males; median age 46.4 (IQR 36.7-54.4); 110 and 32 on MEPO 100 and 300 mg/month, respectively). General, ear-nose-throat, pulmonary, and neurological symptoms significantly decreased during treatment (table 1). MEPO accounted for a significant reduction in the BVAS (figure 1) and for a steroid sparing effect (figure 2). The proportion of patients with asthma attacks decreased by 90% at 12 months compared to t0, and asthma-related emergency accesses dropped from 17.4% to 2.3%. Overall, 21.1% of patients had a non-serious AE.

VISUAL LOSS IN PATIENTS WITH GIANT CELL ARTERITIS TREATED WITH TOCILIZUMAB

Background: Whether Tocilizumab (TCZ) may prevent vision loss in Giant Cell Arteritis (GCA) to the same extent as glucocorticoids remains a key and unanswered question. A patient cohort observed over up to 8 years addresses this issue.

Objectives: To investigate the frequency of vision loss/visual impairment in a GCA cohort treated with TCZ.

Methods: In this observational monocentric study, the courses of 192 patients with GCA treated with TCZ between 01.01.2011 and 31.12.2018 were analyzed. Data were extracted from medical records and collected in a Clinical Trial Unit (CTU) - based registry. Demographic, clinical and laboratory data were analyzed.

Results: 192 patients with GCA were treated with TCZ; 121 (63%) were female, 112 (58%) fulfilled 1990 American College of Rheumatology (ACR) criteria, all others had large vessel vasculitis based on magnetic resonance-angiography (MRA). The cumulative duration of TCZ treatment was 3467 months; the median treatment duration was 13.8 (8.5; 22.8) months. At baseline, visual impairment was present in 71 (37%) and vision loss in 21 (78%) patients. Visual loss was associated with higher age (74 (70; 82) vs. 70 (63; 76) years; p=0.029), lower C-reactive protein at baseline (14.0 (3.5; 42.0) vs. 54.5 (21.0; 101.0) mg/l; p<0.001), cranial symptoms (p<0.0001), jaw claudication (p=0.030) and negative MRA of the aorta (p=0.020). Over the observed time span only one patient taking part in a clinical trial developed vision loss. In total 4 (2%) patients with vision impairment showed deterioration and 61 (32%) improvement.

Conclusion: Collectively, our data suggest that TCZ is able to prevent visual loss and may have a favorable effect on visual impairment.

OP0150 WHAT IS THE ROLE OF TEMPORAL ARTERY BIOPSY IN GIANT CELL ARTERITIS FAST-TRACK PATHWAYS WHEN TEMPORAL ARTERY ULTRASOUND IS NEGATIVE?

Background: A number of centres are now running fast track pathways for diagnosis and management of Giant cell arteritis with ultrasound as the first port of call for diagnosis. Temporal artery biopsies (TABS) have become the second line of investigation, and it is unclear how useful TAB is in this setting.

Objectives: This study looked at accuracy of Temporal artery biopsy (TAB) in patients with suspected Giant Cell Arteritis (GCA) with negative/inconclusive ultrasound (US) and how duration of treatment on steroids prior to these investigations and arterial specimen size affected it.

Methods: Prospective study of all patients with suspected GCA referred for TAB when US was negative or inconclusive, as part of the local fast-track pathway (Coventry). Database included clinical findings, serological work up, US and TAB results and treatment. Sensitivity and specificity of US and TAB was calculated and compared based on duration of treatment with steroids.

Results: One hundred and nine patients were referred for TAB via Coventry fast-track-pathway. The sensitivity of US in this cohort of patients was 9.08% and specificity was 93.33%. After 3 days of steroid this was 0% and 100% respectively For TAB when done within 10 days of starting steroids, this was 65% and 87.5% respectively. After 20 days of steroids this was 0% and 100%. The sensitivity and specificity was 20% and 85% when arterial specimen size was 11-15mm and 47% and 100% when specimen size was 16 mm or more. Sensitivity and specificity of US of 644 suspected GCA patients was 48% and 96%.

Conclusion: Our study demonstrates that TAB plays a relevant role in GCA fast-track-pathways, when US is negative/inconclusive. TAB was more sensitive than US in this cohort of patients, but overall sensitivity of US was higher when calculated for all patients suspected with GCA. Both remain useful tests if performed early. TAB specimen size should ideally be 16mm or more and done within 10 days of starting steroids.

Disclosure of Interests: None declared

Methods: Eligible studies from 2000 - 2020 were identified in OVID Medline, PsycINFO, Embase, and CINAHL databases using a comprehensive search strategy. Quantitative and qualitative studies containing self-reported data on the work impacts of arthritis on younger people were included. Quality assessment was undertaken using validated quality appraisal tools (3).

Results: From a yield of 300 studies, 35 were included in the review. After quality assessment and exclusion of the lowest-ranked studies, 28 studies (17 quantitative, 11 qualitative) were analysed. Work outcomes data were organised into five themes (1-3 for quantitative outcomes, 4-5 for qualitative outcomes): (1) the impacts of arthritis on work productivity; (2) the impacts of arthritis on work participation; (3) other arthritis attributable workplace challenges; (4) barriers to work participation associated with arthritis, and (5) enablers to work participation associated with arthritis. For quantitative themes, arthritis was strongly associated with other workplace challenges: scores on the Workplace Activity Limitations Scale ranged from 5.9 (moderate workplace difficulty) to 9.8 (considerable workplace difficulty); and work disability relative to the healthy population (prevalence ranging from 6% - 80%). For qualitative themes, barriers to work participation included lack of workplace support; enablers included workplace support and intrinsic motivation to work.

Conclusion: Arthritis is associated with poorer work outcomes for younger people relative to healthy peers. The available evidence was heterogeneous across studies. Additional research focusing solely on the unique workplace needs of younger population groups is required. This would inform the development of targeted or intervention or workplace support strategies to maximise productive working years.

Innovative care

A COST-UTILITY ANALYSIS OF MULTIMODAL OCCUPATIONAL THERAPY IN PATIENTS WITH THUMB BASE OSTEOARTHRITIS

A. Tveten, 1 L. Kleven, 2 N. Osteras, 1 R. Nossum, 2 R. E. Mehl Eide, 2 A. Klokkeide, 3 K. Hoegh Matre, 3 M. Olsen, 3 Ø. Andreasen, 4 I. Kjeken, 4

1 Diakonhjemmet Hospital, Department of Rheumatology, National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; 2 Oslo University Hospital, Department of Clinical Research Support, Oslo, Norway; 3 Haukeland University Hospital, St.Olavs Hospital, Trondheim, Norway; 4 Haukeland University Hospital, Bergen, Norway; 5 Haugesund Rheumatism Hospital AS, Haugesund, Norway

Background: Patient education, hand exercises, and use of assistive devices and orthoses are regarded as first-line treatment for patients with hand osteoarthritis (OA) (1), however there is limited evidence for the cost-effectiveness of such treatment.

Objectives: The objective of this study is to assess the cost-utility of a multimodal occupational therapy treatment delivered in the waiting period before surgical consultation in patients with thumb base OA compared to usual care.

Methods: This study presents an economic evaluation assessing the difference in health care use and quality-of-life during a 24-month period in a Norwegian multicenter randomized controlled trial. All participants referred to surgical consultation due to thumb base OA at three departments of rheumatology between 2013 and 2015 were eligible for inclusion. In total, 180 patients were included and randomized to a control group or a multimodal occupational therapy group (90 patients in each group). During the waiting period between referral and actual surgical consultation, the control group continued with usual care which was staying on the waiting list and receiving information on hand OA. The intervention group got information on hand OA, ergonomic principles and use of assistive devices, and they were instructed in home-based hand exercises and received a day and a night orthosis. The intervention group was instructed to use the orthoses and assistive devices as much as possible and perform home exercises three times per week for 12 weeks. The patients were assessed at baseline and after 4, 18 and 24 months. The within-trial economic analysis reports the incremental cost-effectiveness ratio (ICER) reflecting the between-group difference in incremental cost per adjusted life years (QALY) over 24 months. A generic health-related quality of life questionnaire, the EuroQol 5 Dimension, was used to calculate the QALYs at baseline, 4, 18 and 24 months. Costs were collected from different sources, taking a health care perspective. The occupation therapist reported the number of consultations related to the intervention; surgical procedure and post-operative follow-up were collected from patients’ journals; and additional consumption of primary and specialist health care was self-reported by the patient. Sensitivity analyses were performed. The results are presented in a cost-effectiveness plane using bootstrapping. Willingness-to-pay threshold is set to be € 27 500 linked to the severity of this condition.

Results: The mean age of the included patients was 63 years (SD 7.6) and 79% were women. There was a total between-group difference in QALYs of 0.07 utilities after 24 months, in favour of the intervention group. Operations constituted the main costs with 22 operations in the intervention group compared to 33 in the control group. The between-group difference in costs due to health care consumption was estimated to € 500 in favour of the intervention group (Figure 1).

Conclusion: The results in this within-trial analysis indicate that multimodal occupational therapy in the waiting period before surgical consultation compared to usual care is a cost-effective alternative taking a health care perspective.

HOW CAN WE HELP PEOPLE WITH FIBROMYALGIA? NO EFFECTS OF AN EVIDENCE-BASED MULTICOMPONENT REHABILITATION PROGRAMME

H. A. Zangi, T. Haugmark, S. A. Provan, G. Smedslund, K. B. Hagen

1 Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; 2 Diakonhjemmet Hospital, Dept. of Rheumatology, Oslo, Norway; 3 Norwegian Institute of Public Health, Oslo, Norway

Background: Patients with fibromyalgia (FM) suffer from high symptom burden, lack of understanding and few available treatments. EULAR evidence-based recommendations for the management of FM state that optimal management should focus on prompt diagnosis, patient education and initially non-pharmacological treatments. Physical exercise is recommended for all patients and may be combined with tailored psychological therapies for those with unhelpful coping strategies. The evidence for these combined therapies is still weak and further studies are warranted. A Norwegian mindfulness- and acceptance-based intervention, the Vitality Training Programme (VTP), has shown beneficial effects in groups of patients with rheumatic and musculoskeletal diseases, but has previously not been tested in combination with physical exercise.

Objectives: To test the effects of amulticomponent rehabilitation programme comprising the VTP followed by supervised physical exercise for patients with recently diagnosed FM.

Methods: Patients with widespread pain ≥3 months; aged 20 to 50, who were working or had not been out of work >2 years, were referred to rheumatologists for diagnosis clarification according to ACR 2010 FM diagnosis criteria. All eligible patients participated in a 3-hour group-based patient education programme before inclusion and randomization. The intervention group received the VTP, a 10-session group programme followed by 12 weeks supervised physical exercise. The control group followed treatment as usual. Self-reported data were collected electronically. Primary outcome was Patient Global Impression of Change.
(PGIC), scored as 1= much worse, through 4= no change, to 7= much better, measured at 12 months follow-up. Values 6-7 were considered clinically relevant improvement. Secondary outcomes were pain, fatigue, sleep quality, psychological distress, mindfulness, physical activity, motivation and barriers for physical activity and work impairment. Effects were analysed by Analysis of Covariance (ANCOVA).

**Results:** 170 patients were randomised, 85 to intervention and 85 to control. There were no statistically significant differences between groups in PGIC at 12 months; 13% in the intervention group and 8% in the control group reported clinically relevant improvement (Figure 1). No statistically significant between-group differences were found in pain (p=0.05), fatigue (p=0.72), sleep quality (p=0.52), psychological distress (p=0.34), physical activity (p=0.78) or work impairment (p=0.27). There were significant between-group differences in patients' tendency to be mindful (p=0.02) and 'perceived benefits of exercise' (p=0.03), in favour of the intervention group.

**Conclusion:** At 12 months follow-up, a multicomponent rehabilitation programme had no significant health effects compared to treatment as usual. The results differ from previous studies on the VTP in patients with inflammatory joint diseases. The question, how can we help people with FM, remains unresolved.

**EFFECT OF NURSE-LED-CARE ON PATIENT OUTCOMES IN RHEUMATOID ARTHRITIS IN GERMANY: A MULTICENTRE RANDOMISED CONTROLLED TRIAL**

J. R. Hoeper*, G. Gauler*, D. Meyer- Olson*, K. Rockwitz*, P. Steffens-Korbanksa*, C. Stille*, J. Walter*, M. Welcker*, J. Wendler*, J. Zeidler*, K. Hoeper*, 1Center for Health Economics Research Hannover, Hannover, Germany; 2Rheumapraxis an der Hase, Osnabrück, Germany; 3MVZ Weserbergland, Bad Pyrmont, Germany; 4Rheumatologie Praxis, Goslar, Germany; 5Rheumatologische Praxis Hannover-List, Hannover, Germany; 6Rheumatologische Schwerpunktpraxis, Rendsburg, Germany; 7MVZ für Rheumatologie, Planegg, Germany; 8Rheumatologische Schwerpunktpraxis, Erlangen, Germany; 9Hannover Medical School, Immunology & Rheumatology, Hannover, Germany

**Background:** Inflammatory rheumatic disorders are very complex and require high medical resources. However, there is a shortage of care for these patients, which results in suboptimal reach of therapy objectives. Nevertheless, these very objectives need to be pursued quickly to prevent permanent joint damage. In order to ensure adequate care, multidisciplinary teams which include clinical nurse specialists are required. These clinical nurse specialists play an important role in improving standard-of-care in addition to the rheumatologist. The current standard of care ensures that essential medical provision remains intact, however, psychological, social, rehabilitative and educational needs are often skipped due to time constraints. While studies from e.g. the UK and Denmark have already supported the non-inferiority of nurse-led care (NLC), no such studies have yet been published in Germany.

**Objectives:** To demonstrate the non-inferiority of NLC to the current standard-of-care, rheumatologist-led care (RLC), for patients with seropositive rheumatoid arthritis (RA) with induction, escalation or change of therapy regarding disease activity as well as different patient reported outcomes (PROs).

**Methods:** This trial was conducted as a prospective multi-centered RCT with a non-inferiority design over the course of 12 months. Based on power calculations, 236 adults with RA were included in the study and randomized to either NLC or RLC. The primary outcome measure is disease activity (DAS28), assessed at baseline (T0), 6 weeks (T1), 3, 6, 9, and 12 months (T3, T6, T9, T12). Secondary measures are health related quality of life (RAID), functionality (FFbH) and depression (PHQ9).

**Results:** There are no significant differences between intervention group (IG) (n=117) and control group (CG) (n=119) at baseline. The mean age of the IG is 58.80 years (SD=12.09) and of the CG 58.34 years (SD=11.72). 72.4% of the IG and 78.1% of the CG are female. The mean duration of symptoms was 147 months (SD=144.63) for the IG and 116 months (108.89) for the CG. The mean DAS28 for the IG is 4.36 (SD=1.24) and for the CG 4.51 (SD=1.24).

A mixed one-way repeated measures ANOVA showed that the DAS28 improves significantly over time, Huyn-Feldt F(4.42, 751.72) = 105.701, p < .001, partial η² = 0.383, but the interaction of the DAS28 and the randomization is not significant, Huyn-Feldt F(4.42, 751.72) = 1.464, p = 0.260, partial η² = 0.009. No main effect for randomization was found, meaning that the IG and CG did not differ significantly, F(1, 170) = 1.005, p = 0.317, partial η² = 0.006. The Mann-Whitney Test showed that the change of the secondary outcomes does not depend on the randomization FFbH Z = -.755, p = .450. RAID U = 5121.00, Z = -5.39, p = .590, PHQ9 U = 4800.50, Z = -1.281, p = .200. The secondary outcomes improve significantly over time, as shown by a Wilcoxon Signed Rank test for the FFbH Z = -5.589, p < .001, the RAId Z = -9.884, p < .001 and the PHQ9 Z = -7.960, p < .001.

**Conclusion:** The results support the non-inferiority of NLC in the management of RA regarding the primary and secondary outcome measures and provide first evidence that NLC could improve care and help carry the doctors' workflow.

**EFFECT OF THE DR. BART APPLICATION ON HEALTHCARE USE AND CLINICAL OUTCOMES IN PEOPLE WITH OSTEARTHRITIS OF THE KNEE AND/or HIP IN THE NETHERLANDS; A RANDOMIZED CONTROLLED TRIAL**

T. Pelle1,2, K. Bevers1, J. Van der Palen3, F. Van den Hoogen1,2, C. Van den Ende1,2, Sint Maartenskliniek, NIJMEGEN, Netherlands; Radboudumc, Rheumatology, Nijmegen, Netherlands; University of Twente, Research Methodology, Enschede, Netherlands

**Background:** Self-management is of paramount importance in non-surgical treatment of knee and/or hip osteoarthritic(OA). Modern technologies offer the possibility to support self-management 24/7. We developed an e-self-management application (dr. Bart app) for people with knee and/or hip OA. A central element of the dr. Bart app is that the app proposes a selection of 72 preformatted goals to induce health behaviors based on the ‘tiny habits method’.

**Objectives:** To evaluate the short-term effects of the use of the dr. Bart app, compared to usual care, on the number of secondary health care consultations and clinical outcomes in people with knee/hip OA in the Netherlands.

**Methods:** A randomized controlled design involving participants ≥50 years with self-reported knee and/or hip OA, randomly allocated to the dr. Bart app or usual care. Participants were recruited from the community through advertisements in local newspapers and social media campaigns. In Figure 1 the theoretical framework of the dr. Bart app is presented. Participants received online questionnaires at baseline and after 3 and 6 months of follow-up. The primary outcome was the number of consultations in secondary health care due to OA in the knee/hip in the past six months. Secondary outcome measures were self-management behavior, pain, symptoms, functional limitations, physical activity, quality of life, and illness perceptions. Data were analyzed using negative binomial regression or linear mixed models, as appropriate, corrected for baseline, main OA-location (knee or hip), and interaction between treatment group and time.

**Results:** In total 427 eligible participants were allocated to either the dr. Bart group (n=214) or usual care (n=213). Mean age of the participants was 62.1 (SD 7.3) years, with the majority being female (72%) and having symptoms predominantly in their knee(s) (73%). Response rates for the follow-up questionnaires were 75.4% and 69.3% at 3 and 6 months, respectively. With respect to the number of consultations in secondary health care we found a non-significant incidence rate ratio (1.20 (95% CI: 0.67; 2.19)) between the dr. Bart app group and the usual care group. We found a positive overall treatment effect of the dr. Bart app on symptoms (2.6 (95% CI: 0.4; 4.9)), pain (3.5 (95% CI: 0.9; 6.0)) and, activities of daily living (2.9 (95% CI: 0.2; 5.6)), see Table 1. We found non-significant differences between groups for self-management behavior, physical activity, health-related quality of life and illness perceptions.

**COST EFFECTIVENESS OF TELE-HEALTH FOLLOW-UP IN RHEUMATOID ARTHRITIS BASED ON A NON-INFERIORITY RANDOMIZED CONTROLLED TRIAL**

A. De Thura1,2,3, Skovsgaard3, T. Manbo1,3, N. H. Bjelland4,5, M. Kruse5.
1Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark; 2Aarhus University, Department of Clinical Medicine, Aarhus N, Denmark; 3University of Southern Denmark, Danish Centre for Health Economics, Odense, Denmark; 4Aarhus University, Department of Public Health, Aarhus, Denmark; 5Central Denmark Region, DEFACTUM, Aarhus, Denmark; 6Aarhus University, Aalborg University, WestChronic, Occupational Medicine, University Research Clinic, Herning, Denmark; 7Aarhus University, Department of Epidemiology, Aarhus N, Denmark

**Background:** The clinical effectiveness of a patient-reported outcome (PRO) based telehealth intervention offered to rheumatoid arthritis (RA) patients with low disease activity or remission has previously been reported. The TeRA study showed that PRO-based telehealth follow-up in RA achieved similar disease control as conventional outpatient follow-up among patients with low disease activity or remission. The degree of disease control did not differ between telehealth follow-up offered by rheumatologists or rheumatology nurses.

**Objectives:** To compare the cost-effectiveness of PRO-based telehealth follow-up to patients with RA performed by rheumatologists or rheumatology nurses with conventional outpatient follow-up.

**Methods:** A total of 294 patients were randomized (1:1:1) to either PRO-based telehealth follow-up carried out by a nurse (PRO-TN) or a rheumatologist (PRO-TR), or conventional outpatient follow-up by physicians. Quality of life (EQ-5D) was measured at baseline and at follow-up after one year. The primary outcome was a change in the Disease Activity Score, C-reactive Protein in 28 joints (DAS-28, CRP).

The focus in the health economic evaluation was on the relation between costs and EQ-5D in the period between one year prior to and one year after the intervention. All costs were measured at the individual level and consisted of: intervention costs, health and social care costs, and productivity costs. All cost
data were retrieved from Danish population-based registers. Incremental cost-effectiveness rates (ICERs) were calculated on the basis of a comparison of the development in costs and effects in the two intervention groups (separately and combined) with the control group. Bootstrap with 10,000 replications were used to access significance.

Results: The difference in health and social care costs during the intervention period compared to the year before were €1,072, - €50 and €519 for the control group, the PRO-TR group and the PRO-TN respectively. Hence, the change in health and social care costs was lower for both intervention groups. The PRO-TR group had a small decrease and it was significantly lower than for the control group (p=0.027). The difference between health and social care costs in the PRO-TN group compared to the control group was only borderline significant (p<0.067). No statistically significant differences were found in QALY’s between the three groups, all three groups experienced minor, non-significant, declines in QALY over the intervention period. ICER's were not statistically significant but below known threshold values for the PRO-RN group (ICER<€17,121).

Conclusion: It is difficult to obtain statistically significant results for cost-effectiveness in small samples. However, the results point towards a possible cost-saving impact of PRO interventions in patients with low disease activity or remission. The study was unable to conclude if PRO-TR or PRO-TN were most cost-effective. Other relevant considerations, like patient satisfaction or organisational issues, should determine the way of organizing RA disease management in these patients.

There were notable similarities between barriers and facilitators for implementation of the recommendations across countries. The 3 most common barriers to application were: (i) lack of time (ii) lack of training in how to provide patient education and (iii) not having enough staff to provide patient education. The most common facilitators were: tailoring the content and delivery of patient education to individual patients; training providers, and evaluating the effectiveness of patient education with individual patients.

Conclusion: This project has disseminated the EULAR recommendations for patient education across 23 countries. There was high agreement with the recommendations among health professionals but their application to clinical practice was lower. Some barriers to application are amenable to change such as addressing training needs of health professionals and developing evaluation tools for patient education.

Objectives: To investigate the efficacy of a comprehensive technology-assisted home-based exercise intervention on disease activity in patients with AS.

Methods: This study was a 16-week assessor-blinded, randomized, waiting-list controlled trial (ChiCTR1900024244). Patients with AS were randomly allocated to the home-based exercise intervention group and the waiting-list control group. A 16-week comprehensive exercise program consisting of a moderate intensity 84%–78% HR max aerobic training for 30 min/3 days/week and a functional training for 60 min on 3 days/week was given to patients in the intervention group immediately after randomization, with 1.5h training sessions for two consecutive days by a study physical therapist at baseline and Week 8. The aerobic exercise intensity was controlled by a Mio FUSE Wristband with a smartphone application. The functional training consisted of the posture training, range of motion exercises, strength training, stability training and stretching exercises. Patients in control group received standard care during the 16-week follow-up and started to receive the exercise program at Week 16. The primary outcome was ASDAS at Week 16. The secondary outcomes were BASDAI, BASFI, BASMI, ASAS HI, peak oxygen uptake, body composition and muscle endurance tests. The mean difference between groups in change from baseline was analyzed with the analysis of covariance.

Results: A total of 54 patients with AS were enrolled (28 in intervention group and 28 in control group) and 46 (85.2%) patients completed the 16-week follow-up. The mean difference of ASDAS between groups in change from baseline to 16-week follow-up was −0.2 (95% CI, −0.4 to 0.003, P = 0.032), and the mean change from baseline was −0.4 (95% CI, −0.5 to −0.2) in the intervention group vs −0.1 (95% CI, −0.3 to 0.01) in the control group, respectively. Significant between-group differences were found between groups for BASDAI (−0.5 [95% CI, −0.9 to −0.2], P = 0.004), BASMI (−0.7 [95% CI, −1.1 to −0.4], P < 0.001), BASFI (−0.3 [95% CI, −0.6 to 0.01], P = 0.035), peak oxygen uptake (2.7 [95% CI, 0.02 to 5.3] ml/kg/min, P < 0.048) and extensor endurance test (17.8 [95% CI, 0.5 to 35.2], P = 0.044) at Week 16. Between-group differences were detected in ASAS HI (−0.9 [95% CI, −1.7 to −0.1], P < 0.030), body fat percentage (−1.0 [95% CI, −2.0 to −0.01] %, P < 0.048) and visceral adipose tissue (−4.9 [95% CI, −8.5 to −1.4] cm², P = 0.008) at Week 8, but not at Week 16. No significant between-group differences were detected in the total lean mass, time up and go test and the flexor endurance test during the follow-up.

Conclusion: Comprehensive technology-assisted home-based exercise has been shown to have beneficial effects on disease activity, physical function, spinal mobility, aerobic capacity, and body composition as well as in improving fatigue and morning stiffness of patients with AS.

Advances in treating SLE and lupus nephritis

Efficacy of comprehensive technology-assisted home-based exercise in ankylosing spondylitis: a randomized, controlled trial

W. Wang1, X. Liu2, Y. Shi3, X. Ji4, W. Wang5, W. Jiao5, F. Huang1. 1Chinese PLA General Hospital, Department of Rheumatology, First Medical Center, Beijing, China; 2Beijing Sport University, College of Sport Medicine and Sport Rehabilitation, Beijing, China; 3Chinese PLA General Hospital, Health Management Institute, Second Medical Center, Beijing, China

Background: Clinical practice guidelines recommend that exercise is an essential component in the self-management of Ankylosing Spondylitis (AS).

Objectives: To compare the effects of comprehensive technology-assisted home-based exercise on disease activity, physical function, and health-related quality of life in patients with AS in a randomized controlled trial.

Methods: A total of 120 AS patients were randomly assigned to the intervention group (n=60) or the control group (n=60) for 12 weeks. The intervention group received home-based exercise advice, online exercise training, and biweekly teleconsultations. The control group received standard care during the follow-up.

Results: At Week 12, the intervention group had significantly better ASAS40 response (73.3% vs 43.3%, P<0.001), BASDAI improvement (−1.7 vs −0.5, P<0.001), Spondyloarthritis Research Consortium of Canada (SRCC) disability index improvement (−0.4 vs −0.1, P=0.001), and Health Assessment Questionnaire (HAQ) improvement (−0.3 vs −0.1, P<0.001) compared with the control group.

Conclusion: Comprehensive technology-assisted home-based exercise is effective and feasible for the management of AS in a community setting.

Hydroxychloroquine blood levels and risk of thrombotic events in systemic lupus erythematosus

M. A. Petri1, M. Konig1, J. L1, D. Goldman1. 1Johns Hopkins University, Medicine/Rheumatology, Baltimore, United States of America

Background: Hydroxychloroquine (HCQ) has a primary role in the treatment of systemic lupus erythematosus (SLE). Beyond its pleiotropic immunomodulatory effects on Toll-like receptor and type I interferon signaling, HCQ use has been found to be protective for thrombosis in SLE (1). Optimal dosing of HCQ in SLE is unknown. The long-term measurement of HCQ blood levels may provide an opportunity to individualize weight-based dosing strategies and reduce risk of toxicity.

Objectives: To examine the association of HCQ blood levels with thrombotic events in a longitudinal SLE cohort.

Methods: 812 SLE patients with HCQ blood level measured prior to the thrombotic events were included: 93% Caucasian, 43%. African American, 46%. HCQ blood levels were quantified by liquid chromatography-tandem mass

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.5100
spectrummetry. Mean HCQ blood levels (± standard deviation) over all cohorts varies prior to occurrence of thrombosis were calculated for each patient. Thromboses were defined as venous (DVT/PE or other venous) or arterial thrombosis (stroke, myocardial infarction, digital gangrene or other arterial).

**Results:** Thrombosis had occurred during prospective follow up in 43 patients (5.5%), venous in 3.0% and arterial in 2.9%. Lupus anticoagulant was strongly associated with a history of any thrombosis (OR 3.25, p<0.0001), venous thrombosis (OR 3.53, p<0.0001), and arterial thrombosis (OR 3.08, p<0.0001). A prospective analysis shows that for any thrombosis and for venous thrombosis, the HCQ blood level was significantly lower (Table 1). Higher prescribed doses of HCQ (as opposed to HCQ blood levels) were also associated with decreased odds of any thrombosis and venous thrombosis in a separate cross-sectional analysis (OR 0.88, p=0.04 and OR 0.83, p=0.009, respectively for each 1 mg/kg increase in prescribed HCQ).

**Table 1. Thrombotic Events are Associated with Lower Mean HCQ Blood Level**

**Conclusion:** HCQ blood levels are inversely associated with risk of any thrombosis and of venous thrombosis in patients with SLE in a prospective analysis. Reduction of HCQ dosing, as suggested by the American Academy of Ophthalmologists (2), could reduce or eliminate the benefit of hydroxychloroquine to prevent thrombosis.

**OP0161 ASSOCIATION OF BASELINE CYTOTOXIC GENE EXPRESSION WITH USTEKINUMAB RESPONSE IN SYSTEMIC LUPUS ERYTHEMATOSUS**

L Seridi1, M. Cesaroni1, M. J. Loza1, J. Schreiter2, K. Sweer1, Y. Orlovsky1, I. Baribaud1, A. Orillon1, P. Lipsky2, R. V. Vollenhoven3, B. H. Hahn4, G. Tsokos5, M. Chevrier1, S. Rose1, F. Baribaud1, J. Jordan1, 1Beth Israel Deaconess Medical Center, 2Research & Development, LLC, Spring House, PA, United States of America; 3AMPEL BioSolutions, LLC, Charlottesville, VA, United States of America; 4Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; 5University of California, Los Angeles, Los Angeles, CA, United States of America; 6Both Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States of America

**Background:** Systemic Lupus Erythematosus (SLE) is a clinically and biologically diverse disease, for which only one new therapy has been approved in the past 60 years. In a phase 2 trial on patients with mild-to-moderate SLE, ustekinumab (UST) improved clinical and laboratory measures of disease activity compared with placebo (PBO).1

**Objectives:** We previously reported an association of IFN-γ reduction with response to UST, suggesting an impact on the IL12/Th1 axis. To extend these findings, we performed unbiased transcriptomic analysis from baseline whole blood samples to identify genes that discriminate UST responders (UST-R) from non-responders (UST-NR) using the primary endpoint of Systemic Lupus Erythematosus Responder Index (SRI)-4 at week 24 to define response.

**Methods:** UST was studied in a Ph2 PBO-controlled study of 102 patients with seropositive SLE and active disease despite standard therapy. Patients were randomized 3:2 to receive IV UST 6mg/kg or placebo followed by subcutaneous injections of UST 90mg or PBO every 8 weeks. Whole blood gene expression at baseline was measured via microarray using RNA samples from 100 patients, as samples from 2 patients failed quality control. An unbiased approach was used to identify gene signatures present at baseline that associate with UST response. Recombinant IL-12 or IL-23 was incubated in vitro with whole blood from 6 healthy donors for 24h and RNA-Seq was performed to determine the effect of these treatments on representative genes comprising the UST response signature.

**Results:** A non-biased machine learning algorithm identified a 9-gene whole blood signature composed primarily of cytotoxic cell-associated transcripts (PRF1, KLRD1, GZMH, NKG7, GNLY, FGFBP2, TRGC2, TARP, TRGV2) that was enriched at baseline in UST-R vs UST-NR. By Gene Set Variation Analysis, the cytotoxic signature enrichment in UST-NR was less than at baseline in both UST-R and a healthy control cohort (P=0.0087, P=0.056, respectively), whereas UST-R cytotoxic gene enrichment was similar to healthy controls (P=0.31). No significant difference in cytotoxic signature enrichment was observed at baseline between PBO responders and PBO non-responders or healthy controls (Figure). Enrichment levels of the cytotoxic gene signature remained stable over time in PBO and UST-NR groups while a trend of decreased cytotoxic signature was observed in UST-R, although never reaching levels seen in UST-NR. To begin to understand the relationship between IL-12 and IL-23, the targets of UST, and the cytotoxic signature, whole blood was stimulated with these cytokines in vitro. Recombinant IL-12, but not IL-23, resulted in increased expression of representative members of this cytotoxic gene signature.

**Conclusion:** We identified a novel cytotoxic signature in baseline blood samples that associated with UST response in SLE. The observation that IL-12 can increase this signature in vitro and that IL-12 is a robust inducer of cytotoxic cell activity as well as IFN-γ suggests an important role of IL-12 blockade in the mechanism of action of UST in SLE.

**Figure.**

GEE modeling was used to test significance of changes over time. Missing data abatacept treatment improved OSS, and might improve UWS. Abatacept was to abatacept. Biological activity was decreased by abatacept treatment. 48-week treatment with abatacept. Placebo treated patients also showed significant No changes in IgG, RF , OSS or UWS were seen within PLB treated patients. showed significant improvement in week 36 within ABA/ABA treated patients. cacy after week 24, and within PLB/ABA patients after switching to ABA. OSS (ESSDAI and ESSPRI) improved significantly during 48-week treatment with abatacept. Placebo treated patients also showed significant improvement in both indices and further improvement occurred after switching to abatacept. Biological activity was decreased by abatacept treatment. 48-week abatacept treatment improved OSS, and might improve UWS. Abatacept was well tolerated by pSS patients.
Scientific Abstracts	 103
end-stage-kidney-disease (ESKD). The target of therapy is complete response
(proteinuria <0.5-0.7gr/24h with [near-]normal glomerular filtration rate) by 12
months, but this can be extended in patients with baseline nephrotic-range
proteinuria. Hydroxychloroquine is recommended with regular ophthalmological monitoring. In active proliferative LN, initial (induction) treatment with mycophenolate mofetil (MMF 2-3g/day, or mycophenolic acid at equivalent dose)
or low-dose intravenous cyclophosphamide (CY; 500mg x6 biweekly doses),
both combined with glucocorticoids (pulses of intravenous methylprednisolone,
then oral prednisone 0.3-0.5mg/kg/day) is recommended. MMF/CNI (especially
tacrolimus) combination and high-dose CY are alternatives, for patients with
nephrotic-range proteinuria and adverse prognostic factors. Subsequent longterm maintenance treatment with MMF or azathioprine should follow, with no
or low-dose (<7.5 mg/day) glucocorticoids. The choice of agent depends on the
initial regimen and plans for pregnancy. In non-responding disease, switch of
induction regimens or rituximab are recommended. In pure membranous LN
with nephrotic-range proteinuria or proteinuria >1g/24h despite renin-angiotensin-aldosterone blockade, MMF in combination with glucocorticoids is preferred.
Assessment for kidney and extra-renal disease activity, and management
of comorbidities is lifelong with repeat kidney biopsy in cases of incomplete
response or nephritic flares. In ESKD, transplantation is the preferred kidney
replacement option with immunosuppression guided by transplant protocols
and/or extra-renal manifestations.
Conclusion: The updated recommendations intend to inform rheumatologists,
nephrologists, patients, national professional societies, hospital officials, social
security agencies and regulators about the treatment of LN based on most
recent evidence.

America; 15Parexel, Durham, United States of America
Background: Lupus nephritis (LN), a serious manifestation of systemic lupus
erythematosus (SLE), affects nearly 70% of patients (pts) in high-risk groups.
To preserve renal function, LN requires fast and effective treatment. Despite
medical advances, progression rates at 15 years to end-stage renal disease
(ESRD) remain >40% for pts with diffuse proliferative LN. Belimumab (BEL),
approved in pts aged ≥5 years with active SLE, improved renal parameters
in pts with baseline renal involvement in a post hoc analysis of Phase 3 trials
data.
Objectives: To assess efficacy and safety of intravenous (IV) BEL vs placebo
(PBO), plus standard therapy (ST), in pts with active LN.
Methods: BLISS-LN is a Phase 3, randomised, double-blind, PBO-controlled,
104-week study (GSK Study BEL114054, NCT01639339). Adults with SLE and
biopsy-proven LN (class III, IV, and/or V) were randomised (1:1) to monthly BEL
10 mg/kg IV or PBO, plus ST. Primary endpoint: Primary Efficacy Renal Response
(PERR); defined as urine protein creatinine ratio [uPCR] ≤0.7; estimated glomerular filtration rate [eGFR] within 20% of the pre-flare value or ≥60 ml/min/1.73m2;
no rescue therapy) at Week (Wk) 104. Key secondary endpoints: Complete Renal
Response (CRR; defined as uPCR <0.5; eGFR within 10% of the pre-flare value
or ≥90 ml/min/1.73m2; no rescue therapy) at Wk 104; PERR at Wk 52; time to
renal-related event (defined as ESRD/doubling of serum creatinine/renal worsening/renal disease-related treatment failure) or death. Other endpoints: time to
PERR/CRR sustained through Wk 104; SLEDAI-S2K score <4 points at Wk 104;
safety.
Results: Overall, 448 pts were randomised (efficacy: 223/group; safety: 224/
group). Significantly more BEL (43%) than PBO (32.3%) pts achieved PERR
at Wk 104 (OR 1.55, 95% CI 1.04, 2.32; p=0.0311). More BEL than PBO pts
achieved key secondary and other efficacy endpoints (Table).
Overall, 214 (95.5%) BEL and 211 (94.2%) PBO pts had ≥1 adverse event (AE);
58 (25.9%) BEL and 67 (29.9%) PBO pts had ≥1 serious AE; 29 (12.9%) pts in
each group had ≥1 AE resulting in study treatment discontinuation; 4 (1.8%) BEL
and 3 (1.3%) PBO pts developed on-treatment fatal AEs.
Conclusion: In the largest LN study to date, data from BLISS-LN demonstrate
that BEL plus ST significantly improves LN renal responses compared with ST
alone with a favourable safety profile.
Study funding: GSK.

Background: Objectives: To report the 10-year outcome of a cohort of patients with lupus nephritis (LN) treated with combined glucocorticoids with either mycophenolate mofetil (MMF) or tacrolimus (TAC) as induction in a randomized controlled trial (RCT).

Methods: 150 patients with active lupus nephritis were randomized to receive either MMF (2-5g/day) (N=76) or TAC (0.1-0.5mg/kg/day) (N=74) in combination with high-dose prednisolone (0.6mg/kg/day for 6-8 weeks and tapered) as induction therapy between 2005 and 2012. Complete renal (CR) or good partial renal responders were switched to azathioprine (AZA) (2mg/kg/day) for maintenance. We hereby report the 10-year outcomes of the patients in terms of renal flares (proteinuric/ephelitic), renal function decline (drop in eGFR by ≥30% from baseline), development of chronic kidney disease (CKD) stage 4/5 or decline of eGFR by ≥30%,creatinine (Scr) ≤0.75 and eGFR of >80ml/min at 18 months best predicted a better outcome. Urinary post-induction therapy were associated with a poorer outcome. An uPCR decline and mortality. Relapsed renal disease, lower eGFR and more protein-uria post-induction therapy were associated with a poorer outcome. Analytical analyses were conducted, and alternative response definitions were evaluated post hoc.

Results: 150 patients (92% women) with active LN were studied (ISN/RPS class III/IV 36%; IVG/S±V 46%; pure V 19%). The mean age was 35.5±12.8 years and SLE duration was 50.2±62 months. The mean histological activity and chronicity score was 8.2±3.4 and 2.6±1.6, respectively. At baseline, 59(39%) patients were hypertensive, 62(41%) had active urinary casts, 112(75%) had microscopic hematuria and 67% patients had eGFR=90ml/min. As reported previously, the rate of complete renal response (CR) was 59% in the MMF and 62% in the TAC group (p=0.71). Maintenance therapy with AZA was given to 79% patients. After a follow-up of 118.2±42 months, proteinuric and nephritic renal flares occurred in 34% and 37% of patients treated initially with MMF and 53% and 30% in those treated with TAC, respectively. There was a total of 77 renal flares in 43 (57%) patients treated with MMF (0.11/patient-year) and 92 renal flares in 46 (62%) of patients treated with TAC (0.12/patient-year; p=0.44). The cumulative risk of having a renal flare of patients treated with MMF/AZA was 28% at 3 years, 42% at 5 years and 58% at 10 years, whereas the corresponding figures for patients treated with TAC/AZA were 32% at 3 years, 53% in 5 years and 66% in 10 years (p=0.43). For those who achieved CR after induction therapy, the mean time to first renal flare was 70.4±47.1 months in the MMF group and 65.2±50 months in the TAC group (p=0.61). The cumulative incidence of a composite outcome of decline of eGFR by ≥30%, development of CKD stage 4/5 or death at 5 years and 20% was 24% and 33%, respectively, in patients treated with MMF, and 17% and 35%, respectively, in those treated with TAC (p=0.09). Factors significantly associated with this outcome were first time lupus nephritis (HR 2.08;9.10-59; p=0.001), uPCR at 6 months (HR 1.33;1.02-1.76;p=0.04) and eGFR at 6 months (HR 0.98;0.97-0.997;p=0.02). Exploratory ROC analysis demonstrated that an eGFR cut-off of 80ml/min (AUC 0.70; sensitivity 0.64, specificity 0.66) and uPCR cut-off of 0.75 (AUC 0.73; sensitivity 0.69, specificity 0.74) at month 18 best predicted CKD stage 4/5 or decline of eGFR by ≥30%.

Conclusion: Long-term data of our RCT showed that TAC remained non-inferior to MMF as induction therapy of LN in terms of renal flares, renal function decline and mortality. Relapsed renal disease, lower eGFR and more proteinuria post-induction therapy were associated with a poorer outcome. An uPCR ≤0.75 and eGFR of ≥80ml/min at 18 months best predicted a better outcome at 10 years, and should be considered as a target for induction/consolidation therapy.

OP0166

ALTERNATIVE RENAL RESPONSE DEFINITIONS IN A RANDOMIZED, CONTROLLED TRIAL OF OBINUTUZUMAB FOR PROLIFERATIVE LUPUS NEPHRITIS

Z. Amoura1, P. Rémy2, L. F. Quintana Porras3, L. Chiche4, D. Chauveau5, D. Roccatello6, R. Ilie7, T. Scudeller8, J. Gargi9, M. D. Casino10, B. H. Rovin11, A. Doria12, C. C. Mok1, L. Y. Ho1, C. H. To2, K. Y. S. Ying3 on behalf of N/A. 1Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR); 2Pok Oi Hospital, Medicine, Hong Kong, Hong Kong (SAR); 3Princess Margaret Hospital, Medicine, Hong Kong, Hong Kong (SAR)

Background: Obinutuzumab, a type II anti-CD20 mAb, resulted in rapid and complete B-cell depletion and improved renal responses in proliferative lupus nephritis (LN) in the Phase 2 NOBILITY trial and will be further evaluated in the Phase 3 REGENCY trial. Recent analyses suggest alternative urinary sediment, serum creatinine (Scr), and urine protein/creatinine ratio (UPCR) requirements may be better measures of response in LN than those used in NOBILITY [1,2].

Objectives: To evaluate the NOBILITY response definitions and to report the results of NOBILITY using alternative definitions of renal response.

Methods: 128 patients with active Class III/IV LN were randomized to obinutuzumab or placebo in combination with mycophenolate and glucocorticoids. NOBILITY complete renal response (CRR) required UPCR < 0.5, Scr ≤ the upper limit of normal (ULN) of the reference laboratory and not increased > 15% from baseline Scr, and inactive urinary sediment. Exploratory analyses were conducted, and alternative response definitions were evaluated post hoc.

Results: NOBILITY CRR was increased with obinutuzumab over placebo at Week 52 (35% vs. 23%, P = 0.11) and Week 76 (40% vs. 18%, P = 0.007). Response rates were low among patients with baseline Scr < 0.65mg/dl (n = 45) due to the requirement that Scr not increase > 15% from baseline; increasing this threshold to 25% increased the response rate to a level similar to other groups (Figure). Alternative response definitions demonstrated increased rates of response in both treatment groups and similar benefits of obinutuzumab over placebo at Weeks 52 and 76 (Table).

Conclusion: Obinutuzumab resulted in consistent treatment benefits across a range of renal response definitions in NOBILITY and will be further evaluated in REGENCY. A requirement that Scr not increase > 15% from baseline may be overly restrictive in patients with low baseline Scr (< 0.65mg/dl), where a change of 15% represents < 0.1mg/dl and is of questionable clinical relevance. These findings may inform LN clinical trial design and more accurately reflect clinical practice.

**OP0167 SUCCESSFUL WITHDRAWAL OF MYCOPHENOLATE MOFETIL IN QUIESCENT SLE: RESULTS FROM A RANDOMIZED TRIAL**

E. Chaikravarty1, T. Utset2, D. L. Kamen3, G. Contreras4, W. J. McQuade5, K. C. Kalunian6, C. Aranow7, M. Clowse8, E. Goldmuntz9, J. Springer9, L. Keyes-Elstein9, B. Barry10, A. Pinckney10, J. James10 on behalf of ALE06 Working Group. 1OMRF, Oklahoma City, United States of America; 2U. Chicago, Chicago, United States of America; 3MUSC, Charleston, United States of America; 4U. Miami, Miami, United States of America; 5U. Michigan, Ann Arbor, United States of America; 6UCSD, La Jolla, United States of America; 7Feinstein Institute, Manhasset, United States of America; 8Duke, Durham, United States of America; 9NIH/NIAID, Rockville, United States of America; 10Rh, Durham, United States of America

**Background:** Trials and clinical observations have demonstrated the efficacy of mycophenolate mofetil (MMF) for SLE treatment. Long-term use of MMF is associated with adverse events, pregnancy risks, drug monitoring, and increased cost. Current management continues therapy indefinitely. Whether immunosuppression may be safely withdrawn or whether risks of withdrawal outweigh the benefits of continuation is unknown.

**Objectives:** To compare rates of clinically significant disease reactivation (CSDR), major flares, and all flares in patients with quiescent SLE on stable MMF randomized to maintain or withdraw MMF. The goal is to provide guidance for clinicians and patients on the risks of MMF withdrawal.

**Methods:** Adults with quiescent SLE (SELENA-SLEDAI without serologies <4) receiving MMF for ≥2 years for nephritis or ≥ 1 year for non-nephritis were randomized 1:1 to unblinded MMF (maintenance arm, MA) or to a 12-week taper off MMF (withdrawal arm, WA) and followed through 60 weeks. Subjects were randomized 50 MA, 52 WA; 1 subject in each arm was ineligible and 10 terminated early (7 MA, 3 WA). Mean disease duration was 13 years; 76% had a history of nephritis; mean baseline SLEDAI was 2.2.

**Results:** 102 subjects were randomized (50 MA, 52 WA); 1 subject in each arm was ineligible and 10 terminated early (7 MA, 3 WA). Mean disease duration was 13 years; 76% had a history of nephritis; mean baseline SLEDAI was 2.2. 5 MA subjects (10%) had CSDR, compared to 9 WA (17%). Median time to CDSR was 38 weeks in both arms. BILAG A flares occurred in 1MA subject (pancreatitis vs. 4 WA (cranial neuropathy, panniculitis, 2 nephritis). Kaplan-Meier curves overlapped for CDSR, BILAG A flares, and all SLEDAI flares (Figure). Based on these data, we are 86% confident that the increased risk of CDSR with MMF withdrawal is less than 15% over 60 weeks. AEs were similar between groups; infections occurred more commonly in MA (63 vs. 49).

**Conclusion:** In this cohort of subjects with quiescent SLE on long term MMF serious flares occurred infrequently in subjects continuing or withdrawing MMF without differences in time to flare. MMF withdrawal may be considered in subjects with prolonged quiescent disease.

Background: When serum uric acid rapidly increases or decreases due to such as alcohol consumption or fasting, free urate crystals are formed, which induce an acute joint inflammation referred to as an acute gout attack. In 86.4% of patients with gout, dual energy computed tomography demonstrated the deposition of urate crystals in vasculature, and urate crystals have been observed in coronary arteries and various tissues in 10.9% of patients with a heart transplant. However, whether hyperuricemia and urate crystal directly cause cardiovascular disease is not well known. We previously reanalyzed the CARES trial to calculate the mortality rates based on the median duration of exposure to study drugs and the median follow-up duration. A sharp increase in mortality was observed after allopurinol and febuxostat were discontinued. Even in view of the Sick-Stopper Effect, for about 40-fold increase in mortality following drug discontinuation, we postulated that the sharp increase in mortality may be associated with rapid changes in uric acid level (rebound hyperuricemia), and that withdrawal of hypouricemic agent leads to an acute inflammatory response due to an abrupt increase in serum uric acid level with subsequent free urate crystal formation in the cardiovascular system (cardiovascular gout attack)(1).

Objective: Based on this hypothesis that some cardiovascular events may be associated with the cardiovascular gout attack event and initiation of hypouricemic agent, when is accompanied by acute gout attack and/or fluctuation of uric acid, in gout patients.

Methods: Using the Korean National Health Insurance Service (KNHIS) database, which covers the entire Korean population, we conducted a population-based cohort study among gout patients who initiated allopurinol or febuxostat between 2012 and 2018. The initiators were defined as those who had no prior dispensing of any urate-lowering therapy for at least 60 months before the first dispensing date (i.e. index date) of either allopurinol or febuxostat. We excluded patients with a diagnosis of cancer and patients treated with benzbromarone. We investigated a composite cardiovascular event associated with acute gout attack and/or fluctuation of uric acid, in gout patients.

Results: We identified hospitalizations for cardiovascular event (acute myocardial infarction, cerebral infarction, and cerebral hemorrhage) and amputation procedures in patients with gout, both gout and diabetes, and neither gout nor diabetes.

Figure: The cardiovascular event in gout patients who initiated and discontinued allopurinol and febuxostat.

OP0171 MENDELIAN RANDOMIZATION SHOWS NO CAUSAL ASSOCIATION BETWEEN SERUM URATE OR GOUT AND TYPE-2 DIABETES

N. Mccormick1,2, J. Choi3, S. Marozoff2, H. Choi1,2,1. Massachusetts General Hospital/Harvard Medical School, Boston, United States of America; 2Arthritis Research Canada, Richmond, Canada; 3Massachusetts General Hospital, Boston, United States of America

Background: Positive associations between gout1,2 or serum urate (SU)3 and risk of type-2 diabetes (T2D) have been reported in population-based observational studies, but may be due to residual confounding. As such, causal roles of SU and gout on development of T2D are unclear.

Objectives: Use two-sample mendelian randomization to estimate the causal effects of SU and gout on T2D.

Methods: Aggregate data from three large genome-wide association studies were used to identify genetic variants (SNPs) associated with the exposures and outcomes. Exposure SNPs were sourced from Global Urate Genetics Consortium (> 140,000 individuals); outcome SNPs sourced from DIAbetes Genetics Replication And Meta-analysis consortium (DIAGRAM; > 34,000 T2D cases and > 114,000 controls) and Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC; > 46,000 non-diabetics).

We analysed SNPs associated with SU levels (n=28) and gout (n=6) for associations with T2D and three glycemic traits (insulin resistance, fasting insulin levels, and HbA1c) using inverse variance weighted meta-analysis methods. We also specifically examined two SNPs mapping to the SLC2A9 gene, which encodes the GLUT9 transporter (for glucose and urate), estimating Wald ratios for these individual SNPs. Analyses were performed with TwoSampleMR package in R and Mfnd power calculator.

Results: Estimated effects of genetically-determined gout on each of the four outcomes (T2D, insulin resistance, fasting insulin levels, and HbA1c) were small and non-significant (p > 0.18), as were the effects of changes in genetically-determined SU levels (Table). Although the two SNPs in the SLC2A9 gene were strongly associated with SU (rs12498742: $R^2$=2.7%, beta=0.37 per mg/dL, p < 10^{-700}) and gout (rs4475146: odds ratio=0.63, p=4.1x10^{-26}), neither was associated with T2D nor any of the glycemic traits.

Conclusions: The two SNPs in the SLC2A9 gene were strongly associated with SU and gout, but were not associated with T2D or any of the glycemic traits.

OP0172 EFFECT OF WEIGHT LOSS AND LIRAGLUTIDE ON SERUM URATE LEVELS AMONG OBESE KNEE OSTEOARTHRITIS PATIENTS: SECONDARY ANALYSIS OF A RANDOMISED CONTROLLED TRIAL

K. Zobbe1,2, S. M. Nielsen3, R. Christensen1, A. Overgaard1, G. Hudbergsen1, M. Henriksen1, H. Biddal1, L. Dreyer2, L. Stamp4, F. Krag Knoep5, L. E. Kristensen1. 1The Parker Institute, Bispebjerg-Fredricksberg Hospital, University of Copenhagen, Frederiksberg, Denmark; 2Center for Rheumatology and Spine Diseases, Rigshospitalet Gentofte, Hølberg, Aalborg, Denmark; 3Department of Rheumatology, Odense University Hospital, Odense, Denmark; 4Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark; 5Department of Medicine, University of Otago, Christchurch, New Zealand; 6Center for Clinical Metabolic Research, Gentofte Hospital, University of Copenhagen, Hølberg, Denmark; 7Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

Background: There is a strong association between gout and obesity. Losing urate is the cornerstone of gout management [1] and urate levels correlate strongly with central obesity. Previous studies suggest that weight loss has a positive effect on serum urate, however, the studies are sparse and small [2].

Objectives: To assess the impact of an initial low-calorie diet-induced weight loss and subsequent randomisation to the body weight-lowering drug liraglutide (a glucagon-like peptide 1 receptor agonist) or placebo on serum urate levels.

Methods: In the LOSE-IT trial (NCT02905864), a randomised, double-blind, placebo-controlled, parallel group, single-centre trial [3], 156 obese individuals with knee osteoarthritis, but without gout, were offered an initial 8-week intensive diet intervention (week -8 to 0) on Cambridge Weight Plan (800-1000 kcal/day) followed by a weight loss maintenance period in which participants were randomised to either liraglutide 3 mg/day or placebo for 52 weeks. We conducted a secondary analysis of blood samples collected at week -8, 0 and 52. The primary outcome measure was change in serum urate. We used paired t-test for the change from week -8 to 0, and for change from week 0 to 52 we used an ANCOVA model adjusted for stratification factors (sex, age, category and obesity class), and the level of the outcome at baseline. Data were analysed as observed (i.e. no imputation of missing data).

Results: 156 individuals were randomised and 155 had blood samples taken at baseline. In the initial intensive diet intervention period (week -8 to 0) they lost a mean of 12.5 kg (95% CI -13.1 to -11.9, n 156). In the following 52 weeks, the liraglutide group lost an additional 4.1 kg (SE 1.2, n 71) whereas the control group was almost unchanged with a weight loss of 0.2 kg (SE 1.2, n 66). Looking at the main outcome of serum urate levels change, the initial intensive diet resulted in a mean decrease of 0.21 mg/dL (90% CI 0.35 to 0.07, n 155) for the entire cohort. In the following year (week 0 to 52) the liraglutide group exhibited a further mean decrease in serum urate of 0.48 mg/dL (SE 0.11, n 69), whereas the placebo group exhibited a slight decrease in mean serum urate of 0.07 mg/dL (SE 0.12, n 65) resulting in a significant between-group difference of -0.40 mg/dL (95% CI -0.69 to -0.12, n 134) – see Figure 1. Four participants in each group experienced serious adverse events; no deaths were observed.

Conclusion: This secondary analysis of the LOSE-IT trial suggests that liraglutide provides a potential novel serum urate lowering drug mechanism in obese patient populations, with potential implication for gout treatment.

Conclusion: We found evidence of a relatively dramatic increasing initiation of immunomodulation therapy with pegloticase beginning soon after a November 2018 presentation of a case series which demonstrated improved response rates of pegloticase when co-administered with methotrexate. These data indicate that clinicians began to more frequently employ a strategy of DMARD co-treatment with pegloticase in 2019 to improve response rates to this important gout medicine.

References:
joints were collected for inflammatory cytokine (IL-1β and KC) determination and histological analysis, respectively.

Results: The mean change in ankle swelling after i.a injection was 0.55±0.43 mm. Prophylactic treatment with PD and colchicine significantly diminished ankle swelling to 0.175±0.115 mm and 0.137±0.100 mm, respectively (Kruskal Wallis p<0.0025; Dunn's post test p < 0.01 CPP vs PD+CPP). The therapeutic administration of PD did not have significant effects on delta swelling (0.468±0.372 mm - PD vs 0.243±0.152 mm - colchicine). In mice treated with CPP crystals, histological analysis revealed areas of edema and increased cell infiltrate in articular and periarticular tissues and the presence of reactive lymphnodes. Tissue necrosis around inflamed tissue has been observed. Treatment with PD significantly reduced cell infiltrate in the prophylactic but not in the therapeutic protocol.

Conclusion: PD may effectively prevent acute inflammatory response to crystals in the mouse model of CPP arthritis. Oral PD prophylactic treatment showed a similar effect of colchicine in reducing ankle swelling and cell infiltrate. However, only colchicine showed to be effective in the therapeutic protocol.

These results raise the possibility that PD might have utility in the prevention of crystal-induced acute attacks in humans.

OP0175 IDENTIFYING PERIPHERAL VASCULAR MONOSODIUM URATE CRYSTAL DEPOSITION WITH DUAL-ENERGY CT: FACT OR FICTION? THE VASCURATE STUDY

T Pascas1, P. Carpentier1, L. Norbercia, J. Legrand1, E. Houvenagel1, F. Becce1, J.F. Budzik1,1CHUV Lausanne, Lausanne, France; 2CHUV Lausanne, Lausanne, France

Background: The close relationship between gout and cardiovascular diseases is well established. A growing hypothesis explaining this association would be that monosodium urate (MSU) crystal deposits are deposited within vessel walls. Dual-energy computed tomography (DECT) can identify and quantify MSU crystal deposition in soft tissues. It remains unclear whether vascular spots exhibiting DECT attenuation characteristics of MSU are artefacts or true MSU crystal deposits.

Objectives: The objectives of this study were to determine whether the presence of possible vascular MSU crystal deposits identified with DECT is associated with the extent of MSU deposits in joint soft tissues, and if this association persists over time under urate-lowering therapy.

Methods: Patients with a clinical suspicion or established gout diagnosis prospectively underwent DECT for identification and quantification of the MSU crystal burden in their knees and feet. Some of these patients were also enrolled in the GOUT-DECTUS longitudinal study, and thus underwent follow-up DECT scans of their knees and feet at 6, 12 and 24 months. DECT scans were examined for the presence of vascular spots ≥0.01 cm3 classified as MSU crystal deposits according to the default post-processing settings. Multiple linear regressions adjusting on serum urate levels and gout diagnosis were implemented to determine the association between DECT MSU crystal volume in joint soft tissues, and the presence of vascular MSU deposits. Mixed linear models were used to compare DECT volumes of MSU crystal deposition in soft tissues between vascular MSU positive and negative patients during follow-up.

Results: A total of 169 patients were included, of which 140 had a final diagnosis of gout, including 15 also included in the longitudinal study. Patients were mostly male (78.8%) and were 65.5 ± 14.6 years old. Among gout patients, disease duration was 9.3 ± 9.9 years and 58.5% were urate lowering therapy-naive. A total of 11/29 (37.9%) controls and 40/140 (28.6%) gout patients presented with a least one vascular spot of DECT MSU deposition, with an average volume of 0.02 ± 0.02 cm³, and all subjects also presented at least one vascular calcification. In the feet, patients positive for vascular DECT MSU crystal deposition had an MSU volume of 3.81 ± 10.06 cm³ in joint soft tissues, compared with 1.85 ± 7.72 cm³ for those without vascular MSU deposition (p=0.018). In the knees, patients with vascular MSU deposition had an MSU crystal volume of 6.03 ± 24.13 cm³ in joint soft tissues, compared with 0.83 ± 2.86 cm³ for those without vascular evidence of MSU deposition. In the longitudinal subgroup analysis, coefficients of the mixed effects for the presence of vascular MSU deposits on the MSU crystal volume in joint soft tissues was 0.4 (p=0.35) in the feet and 1.21 (p=0.03) in the knees. The presence of vascular DECT MSU deposits was associated with a 3.4-fold increase in MSU crystal volume in knee joint soft tissues throughout follow-up.

Conclusion: This study suggests that some vascular spots identified with DECT as MSU crystal deposition may be real and not artefacts. This correlation remains throughout follow-up in the knees. However, the comparable prevalence of vascular DECT MSU deposits between gout patients and controls, the systematic co-existence of vascular calcifications and the uneven regression under urate-lowering therapy requires further analysis to determine which DECT spots are artefacts and which are not.

Diagnostics and imaging procedures

OP0176 CHRONOLOGICAL ORDER OF DECREASE OF SYNOVITIS, OSTEITIS AND TENOSYNOVITIS IN ARTHRITIS PATIENTS RECEIVING FIRST DMARD-TREATMENT

X. Matthiessen1, E. Niemantsverdriet1, S. Le Cessie1, A. Van der Helm-van Mil2,1Leiden University Medical Center (LUMC), Leiden, Netherlands; 2Erasmus MC, Rotterdam, Netherlands

Background: During the last decennium advanced imaging modalities have refined our understanding of the tissues involved in RA and have shown that not only joints but also bones and tendons can be inflamed at diagnosis. However, the time-order of decrease of these inflammatory features after initiation of DMARDs is unknown. Whether this differs for ACpA-positive and ACpA-negative patients is also unknown.

Objectives: To achieve better understanding of the time order in which the different inflamed tissues (joint, tendon, bone) respond to DMARD-treatment and whether this differs between ACpA-subgroups.

Methods: 216 consecutive patients with early undifferentiated or rheumatoid arthritis, who received DMARD-treatment, were studied. Ulisalier 1.5 Tsia treated and controls. MRI of MCPs, wrists and MCPs were performed at baseline (before treatment) and after 4, 12 and 24 months. MRI were scored for synovitis, osteitis and tenosynovitis in line with the RAMRIS, in known time-order but blinded for clinical data. Data of 4 serial time-points (three time intervals) were studied with autoregressive cross-lagged models. These models evaluated the influence of two time patterns in one model: 1) a simultaneous pattern ("change in one inflammatory feature was associated with extra change in another feature") and 2) a subsequent pattern ("change in one inflammatory feature preceded change in another feature"). All analyses were repeated stratified for ACpA-status (anti-CCP).

Results: In all patients, all combinations of inflammatory features showed significant simultaneous decrease in all time intervals (0 - 4 / 4 - 12 / 12 - 24 months; all p<0.05). In addition to simultaneous changes there were also time orders identified: synovitis change between 0 – 4 months preceded tenosynovitis change between 4 – 12 months (p=0.03) and synovitis change between 4 - 12 months preceded tenosynovitis change between months 12 - 24 months (p=0.02).

When considering ACpA-negative and ACpA-positive patients separately, similar results were obtained. In addition, in ACpA-positive patients, synovitis change between 4 - 12 months preceded osteitis change at 12 – 24 months (p = 0.002); this was significantly different from ACpA-negative patients (p<0.001).

Conclusion: This study increased the understanding of the response to treat- ment on tissue level. In addition to simultaneous decrease of synovitis, osteitis and tenosynovitis, also time orders of inflammation decrease were identified.

These differed between ACPA-subgroups, implying a different interaction of synovi- 
cum and bone in these patients.

OBJECTIVES AND LOCATIONS OF COLOR-CODED DUAL ENERGY CT LESIONS IN GOUT PATIENTS – A SYSTEMATIC EVALUATION

S. Nysom Christiansen1, F. C. Müller2, M. Østergaard3, O. Slot1, J. Mollenbach Møller2, H. F. Borgesen2, K. K. Gosvig2, L. Terslev1, ØRigshospitalet, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; 2Herlev Hospital, Department of Radiology, Herlev, Denmark

Background: Dual energy CT (DECT) has diagnostic potential in gout patients. DECT can automatically colour-code presumed urate deposits based on radiodensity (Hounsfield Units, HU) and DECT ratio (difference in attenuation between high and low kV series) of lesions. However, other materials may imitate urate deposits, most importantly calcium-containing material, dense tendons and artefacts, which may lead to misinterpretations. The characteristics of DECT lesions in gout patients have not yet been systematically investigated.

Objectives: To evaluate the properties and locations of colour-coded DECT lesions in gout patients.

Methods: DECT were performed in patients with suspected gout. Patients were separated into gout and non-gout patients based on joint fluid microscopy findings. DECT of the hands, knees and feet were performed using default gout settings and colour-coded lesions were registered. Only location-relevant lesions were analysed (e.g. nail bed artefacts excluded). Mean density (mean of HU at 80 kV and Sn150 kV), mean DECT ratio, size and location of each lesion was determined.

Subgroup analysis was performed post-hoc evaluating potential differences in properties and locations of lesions. Lesions were separated into groups according to properties (Figure 1, grey box): 1) Size—to separate artefacts characterised by small volume (possible artefacts), 2) DECT ratio—to separate calcium-containing material characterised by high DECT ratio (possible calcium-containing material), 3) Density—to separate dense tendons characterised by low DECT ratio and low HU values (possible dense tendons). Lesion fulfilling all urate characteristics (large volume, low DECT ratio, high density) were labelled definite urate deposits. Finally, for non-gout patients, properties of non-gout urate-imitating lesions (properties as definite urate deposits) were analysed.

Results: In total, 3918 lesions (all lesions) were registered in gout patients (n=23), with mean DECT ratio 1.06 (SD 0.13), median density 160.6 HU and median size 6 voxels (Figure 1, blue box). Lesions were seen in all analysed joints, most frequently MTP1 joints (medial side), knee joints and midtarsal joints (Figure 2a). Tendon affections were also common, especially in the knee tendons (patella and quadriceps), malleolus-related tendons (e.g. peroneus and tibialis posterior) and the Achilles tendons (Figure 2a).

Subgroup analyses showed that definite urate deposits (Figure 2b) were found at the same locations as all lesion in gout patients (Figure 1, blue box), with the four most common sites being MTP1 joints, midtarsal joints, and quadriceps and patella tendons (Figure 2b). Possible dense tendon lesions had a mean HU value of 156.5 HU—markedly higher than expected for dense tendons (<100 HU)—and lesion locations were similar to definite urate deposits (data not shown), indicating that they primarily consisted of true urate deposits. In contrast, possible calcium-containing material and non-gout urate-imitating lesions had distinctly different properties (ratios 1.33 and 1.20, respectively) (Figure 1, yellow and orange box). Furthermore, the locations of these lesions were different from definite urate deposits since they were primarily found in a few weight-bearing joints (knee, midtarsal and talocrural including malleolus regions) and tendons (Achilles and quadriceps), whereas no lesions were found in either MTP1 joints or patella tendons (figure 2c).

Conclusion: DECT color-coded lesions in gout patients are heterogeneous in properties and locations. Subgroup analyses found that locations such as MTP1 joints and patella tendons were characterised by almost only showing definite urate deposits. A sole focus on these regions in the evaluation of gout patients may therefore improve specificity of DECT scans.

IMAGING NEOANGIOGENESIS IN RHEUMATOID ARTHRITIS (INIRA): WHOLE-BODY SYNOVIAL UPTAKE OF A 99MTC-LABELLED RGD PEPTIDE IS HIGHLY CORRELATED WITH POWER DOPPLER ULTRASOUND

L. Attipoe1, S. Subesinghe2, C. Blanco-Gil3, M. Opena2, M. Rosser2, G. Cook1, A. Cope1, T. Garrood1, King’s College London, London, United Kingdom; 2Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom; 3Serac Life Sciences, London, United Kingdom

Background: Power Doppler ultrasound (PDUUS) is superior to clinical examination in detecting synovitis in patients with rheumatoid arthritis (RA). Although dynamic and cheap it is impractical to scan large numbers of joints in routine clinical settings. MRI, whilst sensitive for synovitis, is expensive and routine use is limited to targeted joints. Bone scintigraphy produces whole body images but due to limited specificity is not routinely used.
**Objectives:** To determine the correlation between ultrasound and 99mTc-maraclicatide imaging in patients with rheumatoid arthritis.

**Methods:** 50 patients with RA fulfilling ACR 2010 classification criteria were recruited. Patients underwent an ultrasound scan of 40 joints with grey scale (GS) and PD quantification. Each joint was scored on a scale of 0-3 for GS and PD with a total score calculated for each patient. Within 3 hours of the ultrasound patients were injected with 740 MBq of 99mTc-maraclicatide. Using a gamma camera, whole body planar views and dedicated hand and foot views were taken 2 hours after injection (Figure 1). Acquisition time was 20 minutes for whole body and 20 minutes for hand and foot views. 99mTc-maraclicatide images were scored as positive or negative uptake for each joint (binary score). A quantitative score was also calculated for each joint where there was uptake and this with corrected for background uptake. Total binary and quantitative scores per patient were calculated.

Ultrasound and 99mTc-maraclicatide scores were tested for correlation with Pearson's correlation coefficient (r). Intrarater agreement for 2 scorers was calculated using kappa (κ) and concordance correlation coefficient (Pc).

**Results:** Strong correlation was seen when total PDUS was compared to binary scores (r=0.92, r²=0.85) (Figure 2) and quantitative scores (r=0.85, r²=0.72), χ was 0.82 and 0.79 for binary and ultrasound scores respectively. Pc was 0.82 for quantitative scores, p = 0.0005 for all results. 99mTc-maraclicatide uptake was also seen in inflamed tendons/tendon sheaths. The imaging procedure was well-tolerated. There were no tracer-related adverse events.

**Conclusion:** 99mTc-maraclicatide imaging was highly correlated with PDUS highlighting its potential as an alternative imaging modality. 99mTc-based planar imaging has the unique capacity to image the whole body and hence the total synovial inflammatory load in a quick acquisition. The imaging equipment to perform these scans is already widely available in radiology departments. Interpretation of scans is also much simpler compared to US/MRI. It could therefore have a role in key decision-making points in pathways for diagnosis, treatment failure, and remission prior to dose tapering.

**OP0179**

**USEFUL STUDY I: A MULTICENTRE LONGITUDINAL STUDY TO TEST WHETHER ULTRASOUND CAN IDENTIFY PATIENTS WITH MUSCULOSKELETAL SYMPTOMS OF LUPUS WITH BETTER RESPONSE TO THERAPY**

K. Mahmoud1, A. Zayat2, M. Y. MD Yusof3, K. Dutton4, L. S. Teh5, C. S. Yee6, D. D'cruz7, N. Ng8, D. Isenberg9, C. Ciurtin10, P. G. Conaghan1, P. Emery1, C. Edwards1, E. Hensor1, E. Vital1, 1University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 2Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom; 3St Mary's Hospital University of Liverpool, Liverpool, United Kingdom; 4Doncaster and Bassetlaw NHS Trust, Doncaster, United Kingdom; 5Guys and St Thomas Hospital, London, United Kingdom; 6University College London, London, United Kingdom; 7University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

**Background:** In SLE, musculoskeletal manifestations impact on quality of life and trial outcomes. We previously showed that assessments based on joint swelling lack sensitivity, specificity and responsiveness compared to ultrasound (US).

**Methods:** SLE patients were recruited if the referring physician deemed they had inflammatory pain warranting treatment. Swollen joints were not required. At baseline, physicians recorded features of inflammation, concurrent fibromyalgia and osteoarthritis. Stable doses of prednisolone (≤5mg/day), antimalarials or immunosuppressants were allowed. Participants were randomized to one of two treatment arms: 1) hydroxychloroquine (400mg/day) IM then were assessed at 0, 2 and 6 weeks for 66/68 swollen and tender joint counts, BILAG-2004, SLEDAI-2K, physician global and MSK-VAS, inflammatory markers, patient pain and disease activity-VAS, HAQ-DI, LupusQoL. US of hands and wrists (blinded to patient and clinical assessor). An internal pilot determined the primary endpoint: Early Morning stiffness-VAS (EMS-VAS) at 2 weeks (adjusted for baseline) between patients with US-synovitis (GS≥2 or PD≥1 in ≥1 joint) vs. normal US at baseline. 20% difference was considered clinically meaningful. Sensitivity analyses adjusted for prednisolone and immunosuppressants.

**Results:** 122/133 patients completed all visits. There was significant disagreement between clinical examination and US. 78/133 had US synovitis; 68% of these had ≥1 swollen joint. Of 66/133 patients with ≥ 1 swollen joint, 20% had normal US. US-synovitis was more likely with joint swelling, a symmetrical small joint distribution and active serology. Physician-determined EMS, other lupus features or prior response to therapy were not associated. Fibromyalgia or osteoarthritis did not reduce the probability of US synovitis. In the full analysis set (n=133) there was no difference in EMS VAS at 2 weeks according to US synovial status at baseline (difference -8mm, 95% CI -19, 4mm, p=0.178). 32 patients had fibromyalgia. After excluding them, we found a statistically and clinically significantly better clinical response to depomedrone in patients with US-synovitis at baseline (baseline-adjusted EMS VAS at 2 weeks -12mm, 95% CI -24, 0mm, p=0.049). This difference was greater in the treatment-adjusted sensitivity analysis (-12.8 (95% CI -22, -3mm), p=0.007) and the per-protocol-adjusted sensitivity analysis (-14.8mm (95% CI -20.8, -8.8mm), p<0.001). Patient with US synovitis had higher rates of improvement in the MSK BILAG-2004 (56% vs. 26%, p<0.09) and SLEDAI-2K (37% vs. 15%, p<0.03).

**Conclusion:** In lupus arthritis, distribution and serology, but not other features, help identify US-synovitis. US-synovitis was independent of features of fibromyalgia, but fibromyalgia confounded assessment of clinical response. US should be used to select SLE arthritis patients for therapy and clinical trials, especially when there are inflammatory symptoms without swollen joints.

**DOI:** 10.1136/annrheumdis-2020-eular.5482
Background: Giant cell arteritis (GCA) is a chronic vasculitis of the medium and large arteries. The involvement of large vessel (LV) either isolated or associated with cranial artery is frequent, so it is necessary to use imaging techniques for diagnosis, because the biopsy in these cases is not useful. European League Against Rheumatism (EULAR) recommends an early imaging test in patients with suspected GCA, and ultrasound of temporal and/or axillary arteries is recommended as the first imaging modality in patients with suspected predominantly cranial GCA (1).

Objectives: To assess the validity of Colour Doppler ultrasound (CDUS) of temporal superficial arteries (TA) and LV (axillary, subclavian and carotid) in the diagnosis of GCA, using as gold standard the patient’s definitive clinical diagnosis. Analyse if routine ultrasound examination of LV improves the diagnostic accuracy.

Methods: This was an observational, descriptive and analytical study of 198 consecutive patients with GCA suspicion. A baseline CDUS of the TA and LV was performed. Ultrasound diagnosis was made according to the OMERACT (Outcome Measures in Rheumatology) definitions of halo sign and was established as a limit of normal thickness ≥ 0.34 mm for superficial temporal arteries and ≥ 1 mm for axillary, subclavian and carotid arteries. Statistical analysis was performed using SPSS version 25.

Results: Eighty-seven patients (43.9%) were CDUS compatible with GCA, and 111 patients (56.1%) had a negative CDUS. Among the patients with positive CDUS three different patterns were detected: 45 patients (51.7%) had an exclusive cranial involvement, 31 (35.6%) had a mixed pattern with involvement of both TA and LV and 11 (12.6%) had an exclusive LV involvement. The validity (sensitivity and specificity) and security (positive predictive value and negative predictive value) of diagnostic are shown in table. When we analyse patients with LV involvement, 87.8% have axillary artery involvement, 77.4% subclavian involvement and 34.4% carotid involvement. If we only explored the axillary arteries, 12.2% of patients with LV involvement would not be diagnosed. However, if we explored axillary and subclavian arteries, 100% of patients with LV involvement would be diagnosed.

Conclusion: Half of the patients with GCA have LV involvement and up to 12.8% exclusively LV affection in our series. Adding CDUS exploration of LV to TA increases both sensitivity and diagnostic specificity. The minimum ultrasound examination of LV should include both axillary and subclavian arteries.

Disclosure of Interests: Irene Monjo: None declared, Elisa Fernández: None declared, Diana Peleteado: None declared, Alejandro Balsa: Consultant of: AbbVie, Lilly, Pfizer, UCB, Sandoz, Speakers bureau: AbbVie, Lilly, Sandoz, Novartis, Pfizer, UCB, Roche, Nordic, Sandz, Eugenio de Miguel Grant/research support from: Yes (Abbvie, Novartis, Pfizer), Consultant of: Yes (Abbvie, Novartis, Pfizer), Paid instructor for: yes (AbbVie, Novartis, Pfizer, MSD, BMS, UCB, Roche, Genentech, Madrid, Spain; Diagnostic Imaging of Pulmonary Vascular in SSc: vascular features in SSc-ILD and thus testing the relationship with clinical-functional data.

Methods: We prospectively enrolled 80 patients who underwent PFTs and spirometry-gated chest CT scan at TLC on the same day. Clinical, lung functional and diffusion data, as well as disability indexes were collected. CT images were analyzed by a computational platform for texture analysis of ILD patterns (CALIPER) through Imbio LTA. It quantified the extent of normal lung (%N), ground-glass opacities (%GG), reticulation (%RET), honeycombing (%HC), hyperlucent (%HL), absolute (PVV, cm³) and normalized (PVV/LV, %) pulmonary vascular volumes. Cut-offs of normality for %FVC and %DLco of 80% and 70% were tested to differentiate parenchymal and vascular patterns. Results: 73 patients/CT scans were eligible for both software analyses. CALIPER showed GG% as the most frequent radiological pattern (mean 5.5±10.4%). %FVC and % TLC negatively correlated with all ILD patterns, while %DLco with RET% only; PVV and PVV/LV negatively correlated with %FVC and %TLC, while %DLco with PVV/LV only. Positive correlations were found between all ILD patterns and vascular volumes (Table 1).

PROTEOGLYCAN LOSS IN ARTICULAR CARTILAGE IS ASSOCIATED WITH JOINT INFLAMMATION SEVERITY IN PSORIATIC ARTHRITIS - A COMPOSITIONAL MAGNETIC RESONANCE IMAGING STUDY

P. Sewerin1, D. Aabra2, S. Nebelung2, M. Frenken3, T. Ulrich4, K. L. Radke4, G. Antoch5, S. Vordenbäumen1, R. Brinks1, M. Schneider1, B. Ostendorf1, C. Schleich1. 1Heinrich-Heine University, Department for Rheumatology, Duesseldorf, Germany; 2Heinrich-Heine University, Institut for Diagnostic and Interventional Radiology, Duesseldorf, Germany

Background: Even though cartilage loss is a known feature of psoriatic arthritis (PsA), little is known about its role in the pathogenesis of PsA. Using delayed gadolinium-enhanced magnetic resonance imaging of cartilage (dGEMRIC) as a non-invasive marker of the tissue’s proteoglycan content, such early (i.e. pre-clinical) markers have been assessed in patients with rheumatoid arthritis (RA). Yet, this association has not been studied before in PsA.

Objectives: Is the severity of local joint inflammation associated to local proteoglycan loss in PsA patients?

Methods: Metacarpophalangeal (MCP), proximal interphalangeal (PIP), and distal interphalangeal (DIP) joints of 17 patients with active PsA were evaluated by high-resolution clinical standard morphological and dGEMRIC sequences using a 3T MRI scanner (Magnetom Skyra, Siemens) and a dedicated 16-channel coil. Images were analyzed by two independent raters for dGEMRIC indices, PsA MRI scores (PsAMRIS) and total cartilage thickness (TCT). Kendall-Tau correlation coefficients (τ) were calculated.

Results: We found significant negative correlations between dGEMRIC indices and total PsAMRIS (τ = -0.15, p= 0.012), synovitis (τ = -0.56, p= 0.006), flexor tenosynovitis (τ = -0.4, p = 0.049), and periarticular inflammation (τ = -0.72, p< 0.001). Significant positive correlations were found between TCT and dGEMRIC indices in all joint levels (τ = 0.43, p<0.001). No significant correlations were determined between dGEMRIC indices and bone erosion, bone edema or bone proliferation.

Conclusion: In PsA, proteoglycan loss as assessed by dGEMRIC is associated with periarticular inflammation, synovitis, and flexor tenosynovitis, but not with bone erosion or proliferation, thereby highlighting the need for effective anti-inflammatory treatment regimes. Beyond morphology, advanced MRI techniques may be used to assess cartilage composition in PsA and to identify early changes in cartilage as an imaging biomarker with potential application in detection and monitoring of PsA.

DO CARTILAGE LAMINAR COMPOSITIONAL CHANGES AS ASSESSED BY T2 RELAXOMETRY PREDICT INCIDENT AND WORSENING OF STRUCTURAL MORPHOLOGIC DAMAGE IN THE SAME PLATE 3 YEARS LATER?

F. Roemer1,2, F. Eckstein3,4, G. Duda5,6, S. Maschek1,4, A. Guermazi2,4, W. Wirth1,6, 1Universitätsklinikum Erlangen, Erlangen, Germany; 2Boston University, Boston, United States of America; 3Freie Universität Berlin, Berlin, Germany; 4Charité, Berlin, Germany; 5VA Boston Healthcare System, Boston, United States of America

Background: To address the question whether laminar changes in knee cartilage T2 are relevant for prediction of lesion onset or progression in the same articular plate we included two different samples from the Osteoarthritis Initiative (OAI) study without radiographic osteoarthritis (ROA), i.e. so-called “healthy controls” with no ROA in either knee and being free of risk factors, and those with K-L 0 in one knee and ROA in the contralateral knee. Given the concept of the osteochondral unit, we hypothesize that superficial T2 is elevated in cartilage plates with subsequent surface damage development or worsening and deep layer T2 is elevated for those with subsequent bone marrow lesion (BML) development or worsening.

Objectives: To analyze whether knees with subsequent morphologic cartilage and BML development or worsening exhibit elevated cartilage T2 compared to those that do not develop such structural damage in the same plate 3 years later.

Methods: We included 63 knees from the OAI without ROA (K-L 0), but with definite ROA (K-L ≥2) in the contralateral knee, and 78 participants from the OAI healthy reference cohort.

Cartilage integrity or damage and subchondral bone marrow lesions (BMLs) were assessed for year 1 (i.e. baseline (BL) in this analysis) and year 4 (Y4) in chronological order using the semi-quantitative MOAKS scoring system...

BL deep and superficial layer cartilage T2 was assessed from sagittal multi-echo spin echo MR images. Because cartilage T2 is known to display spatial variation with tissue depth, the segmented cartilages were computationally divided into superficial and deep 50%, based on the distance between the segmented cartilage surface and bone interface. Statistical analyses were performed for the per-articular (FT) joint on a plate level, i.e. medial femur (MF), medial tibia (MT), lateral femur (LF) and lateral tibia (LT), using UNIANOVA with adjustment for age, body mass index, sex, and sample.

Results: 141 participants were included. Of these 79 (56%) were women, had a mean age of 59.4 ± 9.1 years and a mean body mass index of 25.8 ± 4.1 m/kg². 52 (37%) had prevalent cartilage lesions in the medial FT joint and 67 (48%) in the lateral FT joint. For BMLs these numbers were 15 (11%) medially and 14 (10%) laterally. Worsening of FT cartilage lesions from BL to Y4 were seen in 10 (7%) medially and 21 (15%) in the lateral FT compartment. Incident FT cartilage lesions were seen in 11 (11.5%) medially and 8 knees laterally. No worsening BMLs were seen...
Of these, 36,465 persons consulted for knee OA and 14,477 for hip OA during the follow-up period (Table 1). Persons with clinician-diagnosed incident knee or hip OA have 8-61% higher hazard of depression, cardiovascular diseases, osteoporosis, and diabetes. Results support previous findings for cardiovascular diseases and diabetes, however suggesting that the risk of diabetes is mainly associated with knee OA.

Figure 1. Adjusted hazard ratios of consultation for diseases occurring in persons with incident doctor-diagnosed knee or hip OA compared to non-OA persons. **Only women included in analysis. ***Only men included in analysis.

Osteoarthritis: clinical risk of comorbidities following incident clinician-diagnosed knee or hip OA

Risk of comorbidities following incident clinician-diagnosed knee or hip OA in SKH is also associated with knee OA.

Osteoarthritis: clinical risk of comorbidities following incident clinician-diagnosed knee or hip OA

Conclusion: Incident clinician-diagnosed knee and hip OA are associated with increased risk of consultation for depression, cardiovascular disease, back pain, osteoporosis, and diabetes. Results support previous findings for cardiovascular diseases and diabetes, however suggesting that the risk of diabetes is mainly associated with knee OA.

KNEE JOINT DISTRACTION IS MORE EFFICIENT IN RESTORING CARTILAGE THICKNESS THAN HIGH TIBIAL OSTEOTOMY IN PATIENTS WITH SEVERE KNEE OSTEOARTHRITIS

M Jansen1, Maschek2, R Van Heerwaarden3, S Mastbergen1, W Wirth4, F Lateber1, F Eckstein5, 1University Medical Center Utrecht, Utrecht, Netherlands; 2Paracelsus Medical University, Salzburg, Austria; 3Kliniek ViaSana, Mill, Netherlands

Background: Both high tibial osteotomy (HTO) and knee joint distraction (KJD) are joint preserving surgical techniques unloading the affected femorotibial
compartment in patients with knee osteoarthritis (OA). While HTO permanently unloads the more affected compartment (MAC) by correcting the leg axis, KJD temporarily unloads the whole joint by separating the tibia and femur for 5 mm for 6 weeks. In a previous randomized controlled trial (RCT), comparable clinical benefit and radiographic joint space width (JSW) increase over 2 years follow-up were demonstrated for both treatments. Yet, comparison of JSW before and after HTO may be unreliable, as pseudo-widening of the unloaded compartment may occur due to the induced leg axis change. Therefore, direct cartilage thickness measurements need to be compared between KJD and HTO, to accurately evaluate the efficacy of both treatment options on cartilage structure.

Objectives: To compare two-year cartilage thickness changes after treatment with KJD vs HTO and identify factors predicting cartilage thickness restoration.

Methods: Patients indicated for HTO were randomized to KJD (KJDHTO) or HTO treatment. Patients indicated for total knee arthroplasty received KJD (KJDRTK). Standardized semi-flexed weight-bearing radiographs and 3T MRIs with 3D spoiled gradient recalled imaging sequence with fat suppression (SPGR-fs) were acquired before and two years after surgical treatment. Cartilage thickness in the knee was measured using Chondrometrics Works 3.0 software. On the radiographs the mean JSW in the MAC were measured with KIDA software. Readers were blinded to the type of intervention and acquisition order. The primary and secondary outcomes were the mean MAC cartilage thickness (ThCtAB) and percentage of denuded bone area (dABp) change before and two years after treatment (MRI), with radiographic joint space width (JSW) used as a reference.

Results: No statistically significant differences in the baseline characteristics were seen between KJDHTO (n=18) and HTO (n=33). The KJDHTO group (n=18) had a higher age and Kellgren-Lawrence grade (KLG) than the HTO and KJDHTO groups. KJDHTO patients did not show significant changes in MAC cartilage thickness, dABp, or JSW over time (all p>0.1; figure 1). HTO patients displayed a decrease in MAC cartilage thickness and an increase in dABp (both p<0.03), but an increase in JSW (p=0.006). KJDHTO showed a significant increase in MAC cartilage thickness and decrease in dABp (all p<0.01). Baseline OA severity was the strongest predictor of cartilage restoration. KJD patients with severe OA (KJDsev) had KLG (≥3) decrease in MAC cartilage thickness (p=0.005) and dABp (p=0.003), but not JSW change (p=0.52). The changes in all three parameters did not differ significantly between KJDHTO and HTOHTO (all p>0.08).

Conclusion: In patients with severe knee OA, KJD is more efficient in restoring cartilage thickness than HTO is. In these patients, KJD causes significant cartilage restoration while HTO, despite shifting the leg axis and demonstrating radiographic joint space widening, shows loss of cartilage as measured on MRI. In patients with mild knee OA, neither HTO nor KJD treatment results in significant cartilage restoration and both treatments show a slight deterioration that is likely the result of natural OA progression. As such, this research promotes the choice KJD as joint-preserving surgery in case of knee OA patients with more severe structural damage.

The associated BL value or, if available, a mean value from BL and screening was included in the ANCOVA model as a covariate.

Conclusion: The OATREAT trial examined the clinical and radiological efficacy, and safety of HCQ as a treatment option for inflammatory and erosive OA over 52 weeks. OATREAT is the first large randomized PBO controlled trial focusing on erosive hand OA. HCQ was no more effective than PBO for changes in pain, function and radiographic scores in the 52-week period. Overall safety findings were consistent with the known profile of HCQ. Thus, our data failed to show that HCQ is effective in patients with inflammatory, erosive hand OA.

Background: CNTX-4975 is a highly purified, synthetic capsaicin being developed to provide long-term analgesia after a single intra-articular (IA) injection for patients with moderate to severe osteoarthritis (OA) knee pain. CNTX-4975 IA administration is associated with short-term post-procedural pain that can be attenuated with preemptive joint cooling.

Objectives: To evaluate cooling and administration procedures for CNTX-4975 IA injection, with goals of balancing patient comfort and ease of use and assessing clinical response 8 weeks after injection.

Methods: This phase 3, open-label, 8-week study (NCT03661996) enrolled subjects aged 40–95 y with Kellgren-Lawrence grade 1–4, BMI ≤45 kg/m2, and stable, moderate to severe OA knee pain and who failed ≥2 therapies. Subjects were assigned to unilateral/bilateral CNTX-4975 1 mg IA injections as determined by OA pain/joint replacement status, then randomized by study site to 1 of 5 treatment regimens (Figure). The primary outcome measure assessed Breg cooling control vs other cooling regimens on day 1 using a combined sum of 1) pain (0, none; 4, severe) 30 minutes after CNTX-4975 injection; 2) subject satisfaction (SS) with cooling/injection procedures; and 3) investigator satisfaction (IS) with procedures. SS and IS were measured on a 1–7 scale (1, completely dissatisfied; 7, completely satisfied); pain was reverse scored and normalized (1, severe; 7, none) for equal weighting. Geometric mean ratios (GMR) with 95% CIs were constructed for each regimen vs Breg control (ANCOVA); lower 95% CIs were considered clinically acceptable. Secondary endpoints included percentage of subjects by subject type meeting criteria for Outcome Measures in Rheumatoid Arthritis Study International (OMERACT-OARSI) responders 8 weeks after injection. Safety assessments included TEAEs.

Results: The intent-to-treat population included 848 subjects. The primary combined outcome showed that all cooling and administration regimens were clinically acceptable, with the evaluated cold gel wraps being at least as effective as the Breg circulating ice-water wrap (Table). For subjects with unilateral OA, OMERACT-OARSI response rates were 67% in those with no/mild nonindex knee pain and 81% in those with nonindex knee single joint replacement. For subjects with bilateral knee OA receiving bilateral injections, response rates for index and nonindex knees were 73% and 79%. TEAEs were reported in 22% of subjects; <1% were serious. TEAEs occurring in >2% of subjects were procedural pain (2.9%), arthralgia (2.2%), and nausea (2.1%), with no meaningful differences across groups.

Conclusion: All cooling regimens for CNTX-4975 IA administration were clinically acceptable and well tolerated, offering feasible options for use in routine practice. Importantly, high levels of clinical response were observed 8 weeks after unilateral or bilateral knee injections for moderate to severe OA knee pain.
INTEGRATED SAFETY SUMMARY OF THE NOVEL, INTRA-ARTICULAR AGENT LORECIVIVINT (SMO4690), A CLK/DYRK1A INHIBITOR THAT MODULATES THE WNT PATHWAY, IN SUBJECTS WITH KNEE OSTEOARTHRITIS

I. Simsek1, C. Swearengen1, S. Kennedy1, J. Tambiah1, C. Damatarca1, Y. Yazici1, N. Lane2, M. Hochberg3, S. Samumed, LLC, San Diego, United States of America; 2University of California, Davis, Davis, United States of America; 3University of Maryland, Baltimore, United States of America

Background: Concerns over the safety of available osteoarthritis (OA) treatments have led to revision of treatment guidelines and highlight the need for new therapies. Lorecivivint (LOR; SM04690) is an intra-articular (IA), small-molecule CLK/DYRK1A inhibitor that modulates the Wnt pathway and is in development as a potential disease-modifying treatment for knee OA.1,2

Objectives: To evaluate pooled early-phase LOR clinical data for safety, including bone health-related adverse events (AEs).

Methods: Safety data were pooled from 3 randomized controlled trials (one Phase 1, two Phase 2) evaluating 4 doses (0.03 mg, 0.07 mg, 0.15 mg, 0.23 mg) of a single IA injection of LOR in subjects with moderately to severely symptomatic knee OA. Two trials (NCT02095548; NCT03122860) evaluated subjects for 24 weeks and one trial (NCT02536833) for 52 weeks. AEs, serious AEs (SAEs), and bone health AEs were categorized by Medical Dictionary for Regulatory Activities (MedDRA) classification. Incidences of AEs and SAEs were compared between the combined LOR-treated group (subjects who received any dose of LOR) and a control group (subjects not treated with LOR).

Results: This analysis includes 848 LOR-treated and 360 control subjects. The incidence of AEs was similar in LOR-treated (350/848 [41.3%]) and control subjects (138/360 [38.3%]). Incidence of SAEs was 20/848 (2.4%) in LOR-treated and 4/360 (1.1%) in control subjects. The most commonly reported AE in LOR-treated subjects was arthralgia (treated 76%, control 72%) and was the only AE reported at >5% in either group (Fig. 1). Target-knee arthralgia was the most common joint-specific AE (treated 6.5%, control 5.3%) (Fig. 2). No AEs in other joints exceeded an incidence of 2% in either group. In all categories, individual AEs were reported at similar rates between groups and no SAEs were deemed related to LOR by investigators.

Figure 1. Adverse event summary for events occurring in at least 1% of the treated population (N=1208).

Figure 2. Joint-specific adverse event summary, subcategorized by affected joint, for events occurring in at least 1% of the treated population (N=1208).

There were 16 bone health-related AEs in 9/848 (1.1%) LOR-treated and 3/360 (0.8%) control subjects. Of the bone health AEs, 2 were osteopenia/osteoporosis in 2 LOR-treated postmenopausal women and 14 were fractures in 10 subjects (7 LOR-treated, 3 control). All fractures (3 patellar, 1 target knee, 2 non-target knee, 3 vertebral, 2 foot, 2 wrist, 2 rib, 1 fibula, 1 hand) were adjudicated and determined to be caused by trauma; all healed uneventfully within the expected time frame.

Conclusion: In exposure to date of 848 subjects, IA LOR for the treatment of knee OA appeared to be safe and well tolerated. These data support the continued evaluation of LOR as a potential treatment for knee OA.

References:

DOI: 10.1136/annrheumdis-2020-eular.6635
Results: The study included 489 physicians (primary care physicians, rheumatologists, orthopaedists) reporting on 3596 of their OA patients: 24% mild; 70% for moderate; 41% for severe patients (<0.001), but not NSAID (Table 1). The mean number of prescribed drug classes, mean (SD) 0.9 (0.8) 1.4 (1.1) 1.6 (1.2) patients were prescribed at least one drug for their OA (65% of mild; 76% of moderate; 77% of severe patients <0.001). Paracetamol (34%) was the most commonly prescribed OA treatment. NSAIDs (31%) and opioids (27%) were also frequently prescribed treatments, and worsening severity was associated with an increase in opioid use (11% of mild; 26% of moderate, 47% of severe patients <0.001) and physician satisfaction with treatment decreased (86% for mild; 70% for moderate; 41% for severe <0.001) with worsening OA disease severity.

Conclusion: Physicians reported decreasing satisfaction with treatment for their OA patients as disease severity increased, despite increasing use of opioids and numbers of classes of prescribed drugs.

Disclosure of Interests: Both tramadol (narcotic-like drug) and nonsteroidal anti-inflammatory drugs (NSAIDs) are prescribed for pain relief among osteoarthritis (OA) patients. Evidence comparing risks of adverse events between tramadol and NSAIDs users is inconclusive.

OP0190
UNDERSTANDING CURRENT PRESCRIPTION DRUG TREATMENT PARADIGMS FOR PATIENTS WITH OSTEOARTHRITIS IN EUROPE

P. G. Conaghan1, L. Abraham2, P. Graham-Clarke3, L. Viktrup4, J. C. Cappelleri5, C. Beck6, A. G. Bushmakin7, N. Hatchell8, E. Clayton9, J. Jackson10,11 (1)University of Leeds, Leeds, United Kingdom; 2Pfizer Lt., Surrey, United Kingdom; 3Eli Lilly and Co, Sydney, Australia; 4Eli Lilly and Co, Indianapolis, United States of America; 5Pfizer, Groton, United States of America; 6Adelphi Real World, Bollington, United Kingdom

Background: Joint pain is the most prevalent symptom for sufferers of osteoarthritis (OA). Pharmacological management of OA is restricted by limited efficacy and considerable toxicity, with growing fears about opioid use.

Objectives: To understand the current real-world prescribed drug treatment paradigm related to OA disease severity for patients in 5 EU countries; France, Germany, Italy, Spain and the UK.

Methods: Data were drawn from the Adelphi OA Disease Specific Programme (2017-18), a point-in-time study of physicians and their patients. Physicians classified their patients as currently having mild, moderate or severe disease severity, and provided details on currently prescribed OA therapy and physician satisfaction with therapy, rated from very satisfied to very dissatisfied. Patients were excluded from these analyses if they suffered from back and neck OA only, and shoulder OA that had not been diagnosed by X-ray. Comparisons among disease severity groups were made using analysis of variance and chi-squared tests.

Results: The study included 489 physicians (primary care physicians, rheumatologists, orthopaedists) reporting on 3596 of their OA patients: 24% mild (n=974), 53% moderate (n=1904), and 23% severe (n=818). Overall, 73% patients were prescribed at least one drug for their OA (65% of mild; 76% of moderate; 77% of severe patients <0.001). Paracetamol (34%) was the most commonly prescribed OA treatment. NSAIDs (31%) and opioids (27%) were also frequently prescribed treatments, and worsening severity was associated with an increase in opioid use (11% of mild; 26% of moderate, 47% of severe patients <0.001) and physician satisfaction with treatment decreased (86% for mild; 70% for moderate; 41% for severe <0.001) with worsening OA disease severity.

OP0192
PSORIATIC ARTHRITIS IS ASSOCIATED WITH A METABOLICALLY ADVERSE BODY COMPOSITION PROFILE PREDICTIVE OF GREATER CHD AND TYPE 2 DIABETES RISK – MRI FINDINGS FROM THE IMAPA AND UK BIOBANK STUDIES

L. D. Ferguson¹, J. Linge², O. D. Leinhard², I. McInnes³, S. Siebert³, N. Sattar¹.
¹University of Glasgow, Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom; ²AMRA Medical AB, Linkoping, Sweden; ³University of Glasgow, Institute of Infection Immunity and Inflammation, Glasgow, United Kingdom

Background: Increased Body Mass Index (BMI) is associated with Psoriatic Arthritis (PsA) but with uncertain pathophysiological significance. BMI does not reflect body fat distribution, but fat storage site is important as increased ectopic fat including visceral adipose tissue (VAT), liver fat, and muscle fat infiltration (MFI), are associated with increased type 2 diabetes and coronary heart disease (CHD) risk. To date no study has compared detailed body composition in PsA with the general population and other metabolic diseases.

Objectives: 1. To characterize the body composition profile of PsA compared to age, sex, and BMI-matched metabolic disease free (MDF) individuals, and type 2 diabetes. 2. To relate body composition to risk of type 2 diabetes and CHD in PsA versus MDF controls.

Methods: MRI body composition profiles were available for 29 PsA participants in the IMAPA study. After excluding 3 participants with concomitant type 2 diabetes, body composition was compared in 26 PsA participants with 130 age, sex, and BMI-matched healthy MDF controls (matched 1:5) and 454 individuals with type 2 diabetes from UK Biobank, using Wilcoxon signed-rank test. Analyses were repeated adjusted for age, sex, and BMI. The propensity of PsA patients to develop CHD or type 2 diabetes based on their body composition profile was compared to that of matched MDF controls.

Results: PsA participants had significantly more ectopic fat including greater visceral adipose tissue (VAT) volume and liver fat percentage compared to MDF controls (table 1, figure 1A). This difference persisted after adjustment for age, sex, and BMI. Individuals with PsA shared a similar body composition to type 2 diabetes (table 1, figure 1B). Body composition-predicted propensity for CHD or type 2 diabetes was 1.3 and 1.8 times higher, respectively, for PsA compared to matched MDF controls.

Figure 1. Body Composition Profiles of IMAPA PsA participants (pink) versus A. UK Biobank matched MDF controls (green), and B. type 2 diabetes (T2D) (green).

Values are mean (SD) (liver fat, median (IQR)). *PsA vs. MDF controls. **PsA vs. MDF controls adjusted for age, sex, and BMI. †PsA vs. Type 2 diabetes. ‡PsA vs. Type 2 diabetes adjusted for age, sex, and BMI.

Conclusion: This is the first study to report that individuals with PsA have a body composition profile associated with an adverse metabolic phenotype, with greater VAT and ectopic liver fat than the general population and more similar to that of type 2 diabetes, in line with their greater cardiometabolic risk. These data mandate a revision of the management approach to PsA that includes attention to weight loss interventions.

Creating in vitro patients - how to best model disease

OP0195 VASCULARIZED THREE-DIMENSIONAL MODELS OF HUMAN SKIN FIBROSIS

A. E. Matei1, C. W. Chen2, L. Kiesewetter3, A. H. Györfi4, Y. N. Li1, T. Trinh-Minh1, T. Van Kuppevelt3, J. Hansmann2,4, A. Juengel5, G. Schett1, F. Groeber-Becker6,7, J. Distler1,1 Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Erlangen, Germany; 2 Translational Center Würzburg, Fraunhofer Translational Center Regenerative Therapies, Fraunhofer Institute for Silicate Research (ISEC), Würzburg, Germany; 3 Radboud Institute for Molecular Life Sciences, Department of Biochemistry, Radboud University Medical Center, Nijmegen, Netherlands; 4 University for Applied Sciences Würzburg-Schweinfurt, Würzburg, Germany; 5 Center of Experimental Rheumatology, University Hospital Zurich/Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland; 6 Department for Tissue Engineering and Regenerative Medicine, Würzburg University Medical Center, Würzburg, Germany

Background: The complex pathophysiological processes that result in fibrotic tissue remodeling in systemic sclerosis involve interplay between multiple cell types (1). Experimental models of fibrosis are essential to provide a conceptual understanding of the pathogenesis of these diseases and to test antifibrotic drugs. Current models of fibrosis have important limitations: the in vivo models rely on species that are phylogenetically distant, whereas the in vitro models are oversimplified cultures of a single cell type in an artificial two-dimensional environment of excessive stiffness, which imposes an unphysiological cell polarization (2).

Objectives: Here we evaluated the potential use of vascularized, three-dimensional in vitro human skin equivalents as a novel model of skin fibrosis and a platform for the evaluation of antifibrotic drugs.

Methods: Skin equivalents were generated by seeding human endothelial cells, fibroblasts and keratinocytes on a decellularized porcine extracellular matrix with perfusable vascular structure. The skin models were cultured for one month in a system that ensured perfusion of the vascular network at physiological pressure. Fibrotic transformation induced by TGFβ and response to nintedanib as an established antifibrotic drug was evaluated by capillary Western immunostaining, qPCR, histology and immunostaining.

Results: The vascularized human skin equivalents formed the major skin structures relevant for the pathogenesis of fibrosis: a polarized, fully matured epidermis, a stratified dermis and a perfused vessel system with small capillaries. Exposure to TGFβ led to the fibrotic transformation of the skin equivalents, with activated TGFβ downstream pathways, increased fibroblast-to-myofibroblast transition and excessive deposition of extracellular matrix. Treatment of models exposed to TGFβ with nintedanib (a drug with proven antifibrotic effects) ameliorated the fibrotic transformation of skin equivalents with reduced TGFβ signaling, fibroblast-to-myofibroblast transition and decreased extracellular matrix deposition.
Conclusion: Here we describe a novel in vitro model of skin fibrosis. Our data show that vascularized skin equivalents can reproduce all skin layers affected by fibrosis, that, upon exposure to TGFβ, these models recapitulate key features of the fibrotic skin and that these skin models can be used as a platform for evaluation of antifibrotic drugs in a setting with high relevance for human disease.

Time2Work - why and how to act

#ARTHritisAtWork: USING TWITTER TO ENGAGE THE INTERNATIONAL ARTHRITIS COMMUNITY

L. Proulx1, S. Stones2, J. Coe3, D. Richards1, L. Wilhelm1, N. Robertson1, J. Gunderson1, A. Sirois1, A. Mokinnon1, Canadian Arthritis Patient Alliance, Ottawa, Canada;2Collaboro Consulting, Bolton, United Kingdom;3Creaky Joints, New York, United States of America

Background: In 2019, EULAR launched the #Time2Work campaign [1] to raise awareness of the impact of rheumatic and musculoskeletal diseases on individuals, society, and the economy. Building on this theme, the Canadian Arthritis Patient Alliance (CAPA) developed a social media campaign and Twitter chat in collaboration with international patient advocates and organizations. The Twitter chat built upon CAPA’s successful development of workplace resources for people living with arthritis [2].

Objectives: To deliver an international #ArthritisAtWork social media campaign on Twitter, in support of the #Time2Work campaign.

Methods: A one-hour Twitter Chat was held on World Arthritis Day (October 12, 2019) on arthritis in the workplace (#ArthritisAtWork) from 18:00 to 19:00 UTC. The chat was hosted by CAPA and co-hosted by Simon Stones, a patient advocate from the United Kingdom (UK) and CreakyJoints, patient-driven arthritis organization in the United States (US). The Twitter Chat questions were co-developed in advance by the hosts, and blog posts were shared from CAPAs website. Each host also promoted the Twitter Chat through their websites, newsletters and online communities. A social media analytical tool, Symplur, was used to measure audience engagement using the hashtag #ArthritisAtWork. In addition, pertinent Tweets before, during, and after the chat were obtained. The analysis of themes was undertaken to identify common issues and questions.

Results: One hundred and ten users participated in the Twitter chat between 17:20 and 19:20 UTC. Participants included people living with arthritis, researchers, patient organizations, health information outlets and academic institutions. During this period, 585 tweets were shared between participants in all countries. Canada, Ireland, Spain, UK and US. There were 3,352 million Twitter impressions. This represents the number of times a tweet appears to users in either their timeline or search results. Emergent themes of the analysis include:

• common workplace challenges such as employer attitudes and stigma;
• effective workplace supports such as prioritizing tasks and requesting workplace accommodations; and
• areas of improvement such as instituting workplace policies, flexible workplace approaches and education for employees and managers.

Conclusion: The social media campaign was successful in reaching a diverse audience and supporting the #Time2Work campaign. Social media tools can provide an important social support for people living with arthritis as they navigate workplace challenges. It also offers a more contemporary platform to engage the international community on issues of common interest. Working together, internationally helps expand reach and reduce barriers in communication. Research can be conducted to measure potential behavior change that leverages digital social support for people living with arthritis.

A SYSTEMATIC REVIEW TO INFORM THE EULAR POINTS TO CONSIDER WHEN ANALYSING AND REPORTING COMPARATIVE EFFECTIVENESS RESEARCH WITH OBSERVATIONAL DATA IN RHEUMATOLOGY

K. Lauper,1 J. Kedra,2 M. De Wit,1 B. Fautrel,1 T. Friseli6, K. Hyrich,5 F. Iamone,4 M. P. Machado,4 L. Middelb Orntbjerg,1 Z. Rotar,2,3 M. J. Santos16, T. F. Stamm,3,4, S. Stones,3,4, R. M. Stronge,3,4, R. S. Strode,3,4, A. Finckh,1, S. A. Bergstra,9, D. Couvoisier7,9, HUG, Geneva, Switzerland; 2iPLESP, Paris, France; 3EULAR Patient Research Partner, Netherlands, Netherlands; 4Rheumatology, Pitié-Salpêtrière Hospital, Paris, France; 5Clinical Epidemiology, Karolinska Institutet, Stockholm, Sweden; 6Centre for Epidemiology Versus Arthritis, University of Manchester, Manchester, United Kingdom; 7GISEA University Hospital of Bari, Bari, Italy; 8Centre for Rheumatology & Department of Neuromuscular Diseases, UCL, London, United Kingdom; 9DANBIO, Rigshospitalet, Copenhagen, Denmark; 10Biorx, si, Rheumatology UMC, Ljubljana, Slovenia; 11Reuma.pt, Faculdade de Medicina, Lisboa, Portugal; 12Section for Outcome Research, CeMSIS, Vienna, Austria; 13EULAR Patient Research Partner, Bolton, United Kingdom; 14Programme area Epidemiology, DRFZ, Berlin, Germany; 15Zuyderland Medical Centre Heerlen, Rheumatology Limburg, Netherlands; 16Rheumatology, Amsterdam University Medical Centre, Amsterdam, Netherlands; 17Rheumatology, Geneva University Hospitals, Geneva, Switzerland; 18LUMC, Rheumatology, Leiden, Netherlands
Background: Comparative effectiveness studies using observational data are increasingly used. Despite their high potential for bias, there are no detailed recommendations on how these studies should best be analysed and reported in rheumatology.

Objectives: To conduct a systematic literature review of comparative effectiveness research in rheumatology to inform the EULAR task force developing points to consider when analysing and reporting comparative effectiveness research with observational data.

Methods: All original articles comparing drug effectiveness in longitudinal observational studies of ≥100 patients published in key rheumatology journals (Scientific Citation Index > 2) between 1.01.2008 and 25.03.2019 available in Ovid MEDLINE® were included. Titles and abstracts were screened by two reviewers for the first 1000 abstracts and independently checked to ensure sufficient agreement has been reached. The main information extracted included the types of outcomes used to assess effectiveness, and the types of analyses performed, focusing particularly on confounding and attrition.

Results: 9969 abstracts were screened, with 218 articles proceeding to full-text extraction (Figure 1), representing a number of rheumatic and musculoskeletal diseases. Agreement between the two reviewers for the first 1000 abstracts was 92.7% with a kappa of 0.6. The majority of the studies used several outcomes to evaluate effectiveness (Figure 2A). Most of the studies did not explain how they addressed missing data on the covariates (70%) (Figure 2B). When addressed (30%), 44% used complete case analysis and 10% last observation carried forward (LOCF). 25% of studies did not adjust for confounding factors and there was no clear correlation between the number of factors used to adjust and the number of participants in the studies. An important number of studies selected covariates using bivariate screening and/or stepwise selection. 86% of the studies did not acknowledge attrition (Figure 2C). When trying to correct for attrition (14%), 38% used non-responder (NR) imputation, 24% used LUNDEX 1, a form of NR imputation, and 21% LOCF.

Conclusion: Most of studies used multiple outcomes. However, the vast majority did not acknowledge missing data and attrition, and a quarter did not adjust for any confounding factors. Moreover, when attempting to account for attrition, several studies used methods which potentially increase bias (LOCF complete case analysis, bivariate screening). This systematic review confirms the need for the development of recommendations for the assessment and reporting of comparative drug effectiveness in observational data in rheumatology.

Background: Comparing drug effectiveness in observational settings is hampered by several major threats, among them confounding and attrition bias...
Reporting of comparative effectiveness observational studies must follow the STROBE guidelines

Authors should prepare a statistical analysis plan in advance
To provide a more complete picture of effectiveness, several outcomes across multiple health domains should be compared
Lost to follow-up from the study sample must be reported by the exposure of interest
The proportion of patients who stop and/or change therapy over time, as well as the reasons for treatment discontinuation must be reported
Covariates should be chosen based on subject matter knowledge and model selection should be justified
The study baseline should be at treatment initiation and a description of how covariate measurements relate to baseline should be included
The analysis should be based on all patients starting a treatment and not limited to patients remaining on treatment at a certain time point
While treatment discontinuation occurs before the end of outcome assessment, this attrition should be taken into account in the analysis.
Sensitivity analyses should be undertaken to explore the influence of assumptions related to missingness, particularly in case of attrition

Conclusion: The increased use of real-world comparative effectiveness studies makes it imperative to reduce divergent or contradictory results due to biases. Having clear recommendations for the analysis and reporting of these studies should promote agreement of observational studies, and improve studies’ trustworthiness, which may also facilitate meta-analysis of observational data.

Disclosures of Interests: Delphine Courvoisier: None declared, Kim Lauper: None declared, S. Wright1, P. Mehta2, J. Parry2, H. Kazkaz2. 1University of Dundee, Dundee, United Kingdom; 2University College London, Rheumatology, London, United Kingdom

Background: Mechanisms of pain associated with joint hypermobility are poorly understood and include nociceptive pain from structural joint changes along with soft tissue injuries linked to impaired proprioception; central sensitisation associated with chronic pain and muscle weakness alongside deconditioning. Anxiety and depression are also thought to play a role in patients presenting with pain and hypermobility. We have observed an increase in the rate of orthopaedic surgical procedures undertaken in patients attending the hypermobility clinics compared to those attending the general rheumatology and chronic pain clinics. There is limited published data regarding orthopaedic interventions in patients with hypermobility related disorders especially those with confirmed genetic mutations.

Objectives: We aimed to evaluate the characteristics of patients in our hypermobility cohort focusing on those who had received prior surgical intervention in order to understand the underlying mechanism behind their presentations.

Methods: A retrospective review of medical records was conducted of patients attending a hypermobility clinic at our tertiary referral centre, University College London Hospital, between January 2018 and December 2018.

Results: There were 350 patients (300 females, 50 males) with a mean age of 36 years (range 18-71 years). 63% had a diagnosis of Hypermobility Spectrum Disorder or Hypermobility Syndrome and 37% had a type of Ehlers-Danlos Syndromes (EDS) (hypermobile, classical, vascular or other rare type). 46 patients (13%) had documented genetic mutations. 83 patients (24%) had undergone orthopaedic interventions including 9 who had EDS with confirmed genetic mutations. 54% of patients who had surgical intervention were under the age of 40. The total number of surgical procedures in the cohort was 227 (equating to 0.6485 interventions per patient). Of those requiring operative intervention, the average number of interventions per patient was 2.73. One third of patients had surgery on two or more joint groups, including 8 patients (2%) who had surgery in four or more joint groups. Knees (24%) and hips (23%) were the most common sites for operative intervention with 9% having surgery on their shoulders. 29% of its had significant hypermobility with a Beighton score of 7 and above but there was no correlation between Beighton score and number of surgical procedures. Only 2% of cases were referred from an orthopaedic team thereby excluding a referral bias.

Conclusion: Patients with hypermobility related disorders have a significant number of orthopaedic surgical procedures on multiple sites and at a young age, with indication of mechanical pathology playing an important role in their symptoms. The Beighton score does not appear to be a reliable predictor of surgical intervention. This is not surprising given that the score only covers 5 joint areas and excludes common surgical sites such as the hips and shoulders. Early diagnosis and a holistic non-operative approach combining physiotherapy and chronic pain management is essential to reduce the need for multiple surgical procedures.

OP0202

STRESS-ACTIVATED MIR-204 GOVERNS SENESCENT PHENOTYPES OF CHONDROCYTES TO PROMOTE OSTEOARTHRITIS DEVELOPMENT

Y. Cho1, D. Kang1, J. H. Kim1. 1Seoul National University, Seoul, Korea, Rep. of (South Korea)

Background: A progressive loss of cartilage matrix leads to the development of osteoarthritis (OA). Matrix homeostasis is disturbed in OA cartilage as the result of reduced production of cartilage-specific matrix and increased secretion of catabolic mediators by chondrocytes. Chondrocyte senescence is a crucial cellular event contributing to such imbalance in matrix metabolism during OA development.

Objectives: We sought to identify a previously unknown, senescence-associated signaling pathway in chondrocytes linked to major OA cartilage manifestations such as PG loss and cartilage degeneration.

Methods: We particularly aimed to screen miRNAs whose inhibition could effectively modulate senescent phenotypes of chondrocytes to treat OA. We investigated the regulatory mechanisms of miR-204 under various stress-eliciting stimuli in primary cultured human and mouse chondrocytes. We examined the in vivo effects of miR-204 overexpression and its antagonism in surgically induced OA mouse models. DMM surgery was used to induce posttraumatic OA in 12-week-old mice. Small RNAs were delivered to mouse knee joints by intra-articular injection. Various OA manifestations including cartilage destruction, subchondral bone sclerosis, osteophyte maturity, and synovial inflammation in mice were histologically inspected.

Results: We identified miR-204 as a senescence-associated microRNA (miRNA) which is markedly upregulated in OA cartilage. The upregulated miR-204 simultaneously targets multiple components of the sulfated proteoglycan (PG) biosynthesis pathway, effectively shutting down PG anabolism. Endocrine expression of the miR-204 in joints triggers spontaneous cartilage loss and OA development, whereas inhibition of miR-204 ameliorates experimental OA, with concomitant recovery of PG synthesis and suppression of inflammatory senescence-associated secretory phenotype (SASP) factors in cartilage.

Conclusion: We unravel a stress-activated senescence pathway that underlies disrupted matrix homeostasis in OA cartilage.

Conclusion: All outcome measures demonstrated statistically significant improvements. Notably, minimal clinically important differences were achieved in STS and FACIT-F. STS correlates to lower limb power, balance and endurance, and is a predictor of falls1. Fatigue significantly impacts function in people with IA, often limiting confidence and willingness to participate in exercise activities3. Effective evidence-based PRTPs for people with IA can be delivered by Physiotherapists. Improvements in function, wellbeing, self-efficacy, strength and fatigue are achievable, however, exploration of the clinical relevance of these observed changes is recommended. Further research exploring patients’ perspectives of the PRTP and adherence to long-term exercise is needed.

OP0203-HPR

EVALUATION OF A 10-WEEK PROGRESSIVE RESISTANCE TRAINING PROGRAMME FOR PEOPLE WITH INFLAMMATORY ARTHRITIS

J. Skeates1, J. Pearson2, S. Derham1, S. Palmer3. 1RNHRD, Royal United Hospitals NHS Foundation Trust, Bath, United Kingdom; 2University of West of England, Bristol, United Kingdom

Background: Inflammatory Arthritis (IA) adversely affects well-being, function, fatigue and strength1. Guidelines recommend people with IA should exercise to improve strength and cardiovascular fitness2. In 2015, our team introduced an evidence-based Progressive Resistance Training Programme (PRTP) for IA3.

Objectives: To evaluate the effectiveness of a PRTP within a United Kingdom National Health Service setting.

Methods: A pre- to post-treatment evaluation was conducted. People with IA attending Rheumatology Physiotherapy were offered a supervised PRTP (1 hour x 10 weeks): 7 exercises at 70-80% 1-repetition maximum (3 x 8-12 repetitions). Treatment outcomes included Health Assessment Questionnaire [HAQ], EQ-5D-5L, 30s sit-to-stand [STS], Self-Efficacy (SARAH Trial) [SE], Grip Strength and FACIT-Fatigue [FACIT-F]. Changes in outcomes were analysed using Paired Samples t-tests and standardised mean difference (SMD).

Results: 201 patients commenced the programme between May 2015 and April 2019, with 121 participants providing complete pre-post HAQ data. Diagnoses included Rheumatoid Arthritis (n=149), Psoriatic Arthritis (n=42), Juvenile Idiopathic Arthritis (n=8), Enteropathic IA (n=2), Oligoarthritis (n=1). Reactive Arthritis (n=1) and Undifferentiated IA (n=1). Age (mean ± SD) = 56.8 ± 14.8 years; number of sessions attended = 7.7 ± 3.4. There were no differences between those recorded as not completing the PRTP (n=54); 72% women; age 55.0 ± 14.6 years; HAQ 0.99 ± 0.70 versus the others (n=147); 78% women; age 57.5 ± 14.8; HAQ 0.86 ± 0.65. A pragmatic decision was made to analyse all available data for each outcome.

Conclusion: We identify miR-204 as a senescence-associated microRNA (miRNA) which is markedly upregulated in OA cartilage. The upregulated miR-204 simultaneously targets multiple components of the sulfated proteoglycan (PG) biosynthesis pathway, effectively shutting down PG anabolism. Endocrine expression of the miR-204 in joints triggers spontaneous cartilage loss and OA development, whereas inhibition of miR-204 ameliorates experimental OA, with concomitant recovery of PG synthesis and suppression of inflammatory senescence-associated secretory phenotype (SASP) factors in cartilage.

LUPUS COMPREHENSIVE DISEASE CONTROL IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: APPLICATION OF A NEW INDEX

F. Ceccarelli1, G. Oliveri1, L. Dominici1, A. I. Celia1, E. Cipriano1, C. Garufi1, S. Mancuso1, F. Natalucci1, V. Orefice1, C. Perricone2, C. Pirone3, V.A. Paccucci1, F. Morello1, S. Truglia1, F. Miranda1, F. R. Spinelli1, C. Alessandri1, F. Conti1.
1Sapienza Università di Roma, Lupus Clinic, Rheumatology, Rome, Italy;
2Università di Perugia, Rheumatology, Perugia, Italy

Background: The main outcomes in SLE patients management are represented by the remission achievement and chronic damage prevention. Even though activity and damage are intimately connected, to date indices including both these outcomes are not available.

Objectives: In the present study, we aimed at assessing the application of a new index, the Lupus comprehensive disease control (LupusCDC), including disease activity and chronic damage progression.

Methods: We performed a longitudinal analysis, including SLE patients according to ACR 1997 criteria, followed-up in the period between January 2014 and December 2018, and with at least one visit per year. Disease activity was assessed by SLE Disease Activity Index 2000 (SLEDAI-2K) and three different remission levels were evaluated, as reported in Table 1 (1).

Table 1. Remission levels considered in the study (1).

Remission level | Definition
--- | ---
Complete Remission (CR) | No clinical and serological activity (SLEDAI-2K=0) in corticosteroid-free and immunosuppressant-free patients (antimalarials allowed)
Clinical remission | Serum activity with clinical quiescent disease according to SLEDAI-2K in patients on prednisone 1-5 mg/day (stable immunosuppressant and antimalarials allowed)
off-corticosteroids (CIR-GCo) | Clinical quiescent disease according to SLEDAI-2K in patients on prednisone 1-5 mg/day (stable immunosuppressant and antimalarials allowed)
clinical remission | Clinical quiescent disease according to SLEDAI-2K in patients on prednisone 1-5 mg/day (stable immunosuppressant and antimalarials allowed)
Clinical remission on-corticosteroids (CIR-GCon) | Clinical quiescent disease according to SLEDAI-2K in patients on prednisone 1-5 mg/day (stable immunosuppressant and antimalarials allowed)

Chronic damage was registered according to SLICC damage index (SDI). All the patients were evaluated at baseline (T0) and every 12 months (T1, T2, T3, T4). At each time-point, we calculated the prevalence of LupusCDC, defined as remission achievement plus absence of chronic damage progression in the previous one year. We calculated this outcome including separately the different remission levels.

Results: According with inclusion criteria, 172 SLE patients were evaluated in the present analysis [M/F 16/156, median age 49 years (IQR 16.7), median disease duration 180 months (IQR 156)]. At first assessment, we observed a mean±SD SDI value of 7.1±1.1. In details, 56 patients (32.5%) showed damage in at least one organ/system and the presence of damage was significantly associated with age (p<0.0001, r=0.3) and disease duration (p=0.0003, r=0.3). During the follow-up, we observed a significant increase in SDI values compared with T0 (T1: mean±SD 0.8±1.3, p<0.0001; T2: 0.8±1.4, p<0.0001; T3: 0.9±1.4, p=0.0001; T4: 1.0±1.5, p<0.0001).

In figure 1A and 1B we reported the proportion of patients achieving the different levels of remission and LupusCDC, respectively. In particular, the LupusCDC definition including CR was the most frequently detected in all time-points evaluated (T1: 18.0%; T2: 31.9%; T3: 27.3%; T4: 24.4%), with a significant difference at T2 [LupusCDC(CR) versus LupusCDC(CIR-GCo), p=0.0002; LupusCDC(CR) versus LupusCDC(CIR-GCon) (p=0.0002)]. T3 [LupusCDC(CR) versus LupusCDC(CIR-GCo), p=0.03; LupusCDC(CR) versus LupusCDC(CIR-GCon), p=0.006], T4 [LupusCDC(CR) versus LupusCDC(CIR-GCon), p=0.002]. No significant differences were found when comparing the prevalence of different remission levels and the prevalence of LupusCDC including the corresponding remission.

Conclusion: In the present analysis we proposed for the first time a new index including disease activity and chronic damage, in order to evaluate the proportion of SLE patients reaching a comprehensive disease control. We found that CR is most frequently associated with the absence of damage progression.

OP0205

PHASE I STUDY OF D-0120, A NOVEL URAT1 INHIBITOR IN CLINICAL DEVELOPMENT FOR HYPERURICEMIA AND GOUT

L. Zhang1, D. Wyatt2, K. Stazzone1, Z. Shi1, Y. Wang3, InvenitsBio, Florham Park, United States of America; 2Syneos Health, Miami, United States of America

Background: D-0120 is a novel oral selective uric acid transporter (URAT1) inhibitor being developed for the treatment of hyperuricemia and gout by blocking the reabsorption of uric acid (UA) within the renal proximal tubule, thereby reducing serum uric acid concentrations. As a novel URAT1 inhibitor, D-0120 is anticipated to have more potent serum UA reducing effect than the approved URAT1 inhibitor lesinurad, but with less toxicity and wider therapeutic window. The pharmacological potential of D-0120 for the treatment of hyperuricemia and gout was demonstrated in preclinical studies. The results of the in vitro uratur1 expressed CHO cell model showed that the inhibitory activity of D-0120 is 150-fold more potent than lesinurad and slightly more potent than verinurad.

Objectives: The purpose of this dose escalation study is to evaluate the safety and tolerability of D-0120 in multiple ascending doses in healthy volunteers, to characterize the pharmacokinetics (PK) of D-0120 and to assess pharmacodynamic (PD) effects and determine the drug-drug interaction (DDI) effect of fexbust and D-0120 in healthy volunteers.

Methods: This is a randomized, double blind, multiple ascending doses Phase 1 study of D-0120 in healthy volunteers conducted at one site. Thirty-two healthy eligible volunteers with serum uric acid level ≥ 4.5 mg/dl but within normal range at screening were enrolled and dosed with D-0120 within 4 different single agent cohorts for a period of 7 days. Each cohort had 8 subjects randomized at 3:1 ratio for D-0120:placebo. A fifth cohort of 8 healthy eligible volunteers were enrolled and dosed with 5 mg of D-0120 in combination with 40 mg of fexbust over a period of 9 days. Evaluation of safety, PK and PD was conducted at various timepoints while the patients were in...
confinement. Further safety evaluation took place on Day 14. A Safety Review Committee reviewed safety, PK and PD data for each cohort of D-0120 dose level (2.5 mg, 5 mg, 10 mg, 20 mg) as well as when D-0120 5 mg was combined with 40 mg febuxostat. PK evaluation for multiple dose parameters included AUC(0–t), Cmax, Cmin, Tmax and FI.

**Results:** Dose escalation of D-0120 from 2.5 mg/day to 20 mg/day was completed without any dose limiting toxicities. Most AEs occurred during the study were mild to moderate in severity and did not require any treatment before resolution. There was no SAE and no dose reduction during the treatment period. The pharmacokinetic (PK) evaluation of ascending dose levels of D-0120 suggested a dose proportional increase in drug exposure and there was no significant change of PK profile between Day 1 and Day 7 of dosing. For pharmacodynamic (PD) evaluation, the serum uric acid (UA) levels before and after D-0120 dosing was evaluated on multiple days. The UA reduction effect achieved maximum at about 4–8 hours after dosing and the effect lasted for at least 24 hours. After the 7-day dosing period, the mean percentage of UA reduction from baseline showed an increasing trend as the dose level increased.

More detailed safety, PK and PD data from multiple D-0120 dose cohorts and D-0120/febuxostat combination cohort will be presented at the meeting.

**Conclusion:** The oral daily administration of a novel URAT1 inhibitor, D-0120, in healthy volunteers for 7 days was well tolerated at dose levels from 2.5 mg/day to 20 mg/day. The PK profile demonstrated a dose proportional increase. D-0120 administration for 7 days resulted in significant reduction of serum UA levels. Further evaluation of this novel agent in longer treatment period and in patients with hyperuricemia and/or gout is warranted.

**OP0206 ALLANTOIN - A BIOMARKER OF OXIDATIVE STRESS - IS HIGHER IN PATIENTS WITH GOUT THAN IN HEALTHY VOLUNTEERS, AND CORRESPONDS WITH SEVERITY OF DISEASE**

L. Hasikova1,2, P. Kozlik2, K. Kalikova4, B. Stiburkova1,5, J. Zavada1,2, 3

**Background:** Uric acid can be non-enzymatically oxidized into allantoin and other products by reactive oxygen species. Allantoin has emerged as a reliable biomarker for monitoring oxidative stress both in vitro and in vivo1. In gout patients, significantly increased plasma levels of allantoin have been found compared to healthy controls2.

**Objectives:** The aim of this pilot study was to measure allantoin as a biomarker of oxidative stress in patients with gout using newly developed UHPLC-HILIC-MS/MS method3 and to investigate whether the allantoin levels are higher in patients with more severe disease (tophaceous gout).

**Methods:** We used clinical data and frozen serum (−80°C) from 10 patients with chronic tophaceous gout, 10 patients with chronic gout without tophi and 10 healthy controls. Allantoin was determined in serum with sensitive UHPLC-HILIC-MS/MS method using an isotopically labeled internal standard as we described before3. In addition, the concentrations of serum CRP, creatinine and uric acid were measured. Data are summarized as medians with interquartile range (IQR). Differences between two patient groups were evaluated using the Wilcoxon signed-rank test.

**Results:** The median concentrations of allantoin in the serum from patients with tophaceous gout were significantly higher than in patients with gout without tophi (4.2 [2.6] vs. 3.2 µM [1.5], p = 0.0273). There was no significant difference in other biochemical or demographic parameters (CRP, uric acid, creatinine, BMI, weight) between these two groups. Allantoin levels in healthy controls were significantly lower (0.5 vs. 4.2 [2.6], p = 0.0020, 0.5 vs. 3.2 [1.5], p < 0.0001) (Fig. 1).

**Conclusion:** We have observed significantly higher levels of serum allantoin in the patients with more advanced gout with tophi compared with the patients with chronic gout without tophi. We have found elevated values of allantoin in both groups in comparison with healthy controls. In our small cohort the level of allantoin correspond with the severity of disease presented by tophi. However, further studies in large cohorts are needed. We can speculate, whether higher level of oxidative stress may contribute to increased cardiovascular risk and mortality in patients with gout (and more so in severe gout)4.

**OP0207 MECHANISM OF CHONDROPROTECTIVE EFFECTS OF 2-DEOXYGLUCOSE**

K. Terabe1, N. Takahashi1, O. Yoshifumi1, M. Masataka2, W. Knudson2, C. Knudson2, T. Kojima1, N. Ishiguro1, 1Nagoya University Graduate School of Medicine, Orthopedics, Nagoya, Japan; 2East Carolina University, Greenville, United States of America

**Background:** We recently reported that the inhibitor of hyaluronan (HA) biosynthesis, 4-methylumbelliferone (4-MU) blocked IL-1β activation of MMP13 mRNA and protein expression in human osteoarthritis (OA), bovine as well as bovine or OA cartilage explants [1]. This was a somewhat counterintuitive observation

**Cartilage - heal thyself!**
because we have also demonstrated that the overexpression of HAS2 (HAS2-OE) exerted the same chondroprotective effects on human and bovine chondrocytes. Others [2] have reported that HAS2-OE in tumor cells generates a flux in intracellular UDP-sugar pools that resulted in changes in cell metabolism; switching from a dependence on glycolysis to aerobic respiration. HAS2-OE and 4-MU likely also cause dramatic fluxes in intracellular UDP-GlcUA pools. From these results, we hypothesized that the effect of HAS2-OE and 4-MU relate to changing metabolism and the possibility of inhibition of glycolysis induce chondroprotective effect. To determine that, we used the glycolysis inhibitor, 2-Deoxyglucose (2DG) as an alternative agent to change metabolism in chondrocytes.

Objectives: The objective of this study was to investigate the mechanism of chondroprotective effects of 2DG

Methods: Bovine and human chondrocyte were stimulated with IL-1β (2ng/ml) in the presence or absence of 4MU (1 .0 mM), 2DG (0.2-20 mM). Bovine chondrocytes were tested using Seahorse Flux Analyzer (Agilent Tech) to determine rate changes in medium accumulation of +H protons (indicative of lactic acid accumulation: ECAR) and for O2 consumption (indicative of mitochondrial respiration). Accumulation of MMP13 and phosphor AMPK (pAMPK) protein was quantified with Western blotting. Human and Bovine cartilage explants were cultured with L-1β in the presence or absence of 2DG (20 mM) and d 5-Aminooimidazole-4-carboxamide 1-β-D-ribofuranoside (AICAR) to pharmacologically induce AMPK for 7 days and stained with Safranin O.

Results: Reduced mitochondrial potential and enhanced dependence on glycolysis was observed in IL-1β stimulated chondrocytes. Co-treatment with 4-MU and 2DG returned the cell metabolism to levels at or below baseline (Fig 1A, B). The Seahorse ATP Rate Assay means the contribution of glycolysis and mitochondrial respiration to chondrocyte ATP production (Fig 1C). In control chondrocytes, the use of glycolysis contributes to the majority of ATP produced (grey bars) approximately 1/5th from the TCA cycle (red bars). IL1β-activated chondrocytes display increase in glycolysis and decrease in mitochondrial contributions. These changes are reversed by co-treatment with 4MU and 2DG. As shown in Figs 2A, 2D reversed the IL1β-induced increases accumulation of MMP13 protein in human OA chondrocytes by Western blotting analysis. Although IL-1β lost safranin O staining in human and bovine samples, co-incubation with 2DG blocked in the loss of proteoglycan (Fig 2B).

Conclusion: 4-MU and 2DG have chondroprotective effect by changing metabolic and upregulate AMPK. We propose that 4MU and 2DG become useful when these endogenous responses are not enough to rescue cells from a pro-catabolic phenotype.

Biological DMARDs in RA II

OP0208 PATIENTS REPORT FATIGUE AS AN ADVERSE DRUG REACTION OF BIOLOGICS

J. Van Lint1, T. Baiker1, J. Ubbink1, M. Van Doorn2, R. Spuls2, S. Tas2, H. Vonkeman4, H. Van den Bemt5,6, M. Nurmohamed3,7, E. Van Puijenbroek1, N. Jessurun1.

Objectives: To assess patient-reported fatigue attributed to biologics for IMIDs and investigate predisposing factors of patient-reported fatigue.

Methods: The Dutch Biologic Monitor is a multicenter patient-reported ADR monitoring system that surveys patients using a biologic for an IMID. Patients completed web-based questionnaires regarding ADRs. All patient-reported ADRs with MedDRA Preferred Term ‘fatigue’ were included. Patient-reported fatigue was defined as: ‘I feel generally fatigued’ on a 5 point Likert scale (median Likert score). Basic demographics and treatment characteristics were compared between patients reporting BA-fatigue and patients not reporting BA-fatigue (reported other ADRs or no ADRs).

Results: Out of 1369 participating IMID patients, 696 patients reported fatigue and treatment characteristics were compared between patients reporting BA-fatigue and patients not reporting BA-fatigue (reported other ADRs or no ADRs).

Background: Chronic fatigue is a well-known symptom in patients with rheumatic diseases and other immune-mediated inflammatory diseases (IMIDs). Therefore, fatigue as an adverse drug reaction (ADR) to biologics may remain underrecognised or may erroneously be attributed to the disease.

Objectives: To assess patient-reported fatigue attributed to biologics for IMIDs and investigate predisposing factors of patient-reported fatigue.

Methods: The Dutch Biologic Monitor is a multicenter patient-reported ADR monitoring system that surveys patients using a biologic for an IMID. Patients completed web-based questionnaires regarding ADRs attributed to biologics and the course and experienced burden (5 point Likert scale) of these ADRs. All patient-reported ADRs with MedDRA Preferred Term ‘fatigue’ were defined as biologic-associated fatigue (BA-fatigue). Basic demographics and treatment characteristics were compared between patients reporting BA-fatigue and patients not reporting BA-fatigue (reported other ADRs or no ADRs).

Conclusion: HCPs should be aware that fatigue may be associated with biologic therapy and has a significant burden on patients. Evaluating the course of the symptoms might be helpful in recognizing BA-fatigue.

DOI: 10.1136/annrheumdis-2020-eular.1310

Background: The majority of patients with a rheumatic disease treated with etanercept may be overexposed. Data regarding etanercept tapering is scarce, particularly in psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Dose reductions can potentially reduce blood drug levels too much, resulting in loss of effect.

Objectives: We compared extending the dose interval to continuation of the standard dose and studied the success rate of etanercept discontinuation. Etanercept concentrations were measured throughout the study.

Methods: 160 consecutive patients with rheumatoid arthritis (RA), PsA or AS with sustained minimal disease activity (MDA) were enrolled in this 18-month, open-label, randomised controlled trial. The intervention group doubled the dosing-interval at baseline and continued etanercept 6 months later. The control group continued the standard dose up to 6 months, after which the dosing-interval was doubled. Primary outcome was the proportion of patients maintaining MDA after 6 months follow-up.

Results: At 6 months, MDA status was maintained in 47 (63%) patients in the intervention group and 56 (74%) in the control group (p=0.15), with comparable results in all rheumatic diseases. Median etanercept concentrations decreased from 1.50 µg/mL (25.75% percentile 1.06-2.65) to 0.46 µg/mL (0.28-0.92) after 6 months of interval prolongation (figure 1). In total, 40% discontinued etanercept successfully with maintained MDA for at least 6 months.

Conclusion: As observed in RA, etanercept tapering can be safely attempted in PsA and AS patients in sustained MDA. A substantial proportion of patients could stop etanercept for at least 6 months. In many patients low drug concentrations proved sufficient to control disease activity. However, the risk of minor and major flares is substantial, even in patients continuing standard dosing.

DOI: 10.1136/annrheumdis-2020-eular.1320
Background: Rheumatoid arthritis (RA) is a chronic inflammatory rheumatic disease in China. SM03 is a novel chimeric monoclonal antibody (mAb) specific to the B cell restricted antigen CD22 developed for the treatment of rheumatoid arthritis (RA) and other B cell related immunological diseases.

Objectives: We aim to evaluate the efficacy and safety of SM03 in patients with moderately-to-severely active RA in China.

Methods: In this 24-week Phase II randomized, double-blind, multi-dose, placebo-controlled study, 156 patients were randomized with ratio of 1:1:1 to receive 3600mg cumulative dose of SM03 (group A, 600mg * 6 infusions at 0, 2, 4, 12, 14, and 16 week), 2400mg cumulative dose of SM03 (group B, 600mg*4 infusions at 0, 2, 12, and 14 week) and placebo (group C). All patients remained on background treatment of MTX. Efficacy and safety were assessed at weeks 4, 8, 12, 16 and 24.

Results: Primary efficacy endpoint was the American College of Rheumatology 20% improvement criteria (ACR20) response rate at week 24. Safety profile was also assessed.

No significant difference in ACR20 between group A and B (Table 1 & Fig 1). We did not observe significant difference in any adverse event (AE) among group A (35.3%), B (51.9%) and C (34.6%) (Table 2). In groups A and B, 13 (12.6%) patients reported treatment-related infection, and 6 (6.8%) patients were positive in anti-drug antibodies analysis. In group A (higher dose), 3.9% patient had AE of treatment-related infections. No patients reported treatment-related severe infection or any malignancies caused by treatment in groups A and B.

Conclusion: In Chinese patients with active RA, both 2400mg and 3600mg cumulative dose of SM03 in combination with MTX were efficacious and well tolerated throughout the 24 weeks of treatment. Moreover, SM03 has demonstrated a good safety profile, especially in terms of treatment-related infection, malignancy and immunogenicity.

The main adverse effects were serious infections (n=28), neoplasia (n=3), severe ABA-related interstitial pneumonia (NSIP) (31.9%) and others (27.8%). ABA was prescribed at standard subcutaneous (125 mg/kg/4 wk) in 196 (74.1%), at lower doses in 67 (25.5%); in monotherapy (n=111) or combined with PsA, and how treatment with TNFi affected the use of topical steroids in patients with PsA.

Results: We studied 263 patients (150 women/113 men) (mean age;64.6±10 years), with ILD-RA. At ABA-onset they were smokers or exsmoker (53.8%), positive APCC (88.6%), median [IQR] duration of ILD of 12 [3-41.25] months, mean (±SD) DLCO (65.7±18.3) and FVC (85.9±21.8).

Objectives: To explore oral GC use in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondyloarthritis (axSpA) before and after the initiation of TNFi therapy. Furthermore, to evaluate if patients on long-term GC treatment were receiving active preventive osteoporosis treatment and how treatment with TNFi affected the use of topical steroids in patients with PsA.

Methods: Clinical data on patients with RA, PsA and axSpA who initiated TNFi was collected from the ICEBIO registry. ICEBIO is a nationwide registry on all patients treated with biologics for rheumatologic disorders in Iceland. The use of oral GC, topical steroids and bisphosphonates was collected from the Icelandic Prescription Medicines Registry (IPMR) for a period of four years, two years before and after the initiation of TNFi. Medication use was then evaluated by counting the number of individuals receiving a medication in a given year, the total number of prescriptions, and the defined daily dose (DDD). Five controls were randomly selected from IPMR and matched on age, sex and time frame. Results: 621 patients with RA, PsA or axSpA who initiated TNFi therapy with etanercept, infliximab, adalimumab or golimumab for the first time between 2002-2015 was collected from the ICEBIO registry, ICEBIO is a nationwide registry on all patients treated with biologics for rheumatologic disorders in Iceland. 0.4 prescription per individual) for GC during the study period. GC use varied between patient groups (Figure 1). The total GC use (DDD) doubled over the two-year period leading up to TNFi treatment but decreased sharply after the initiation of TNFi. The number of individuals on GC decreased by one third after initiating TNFi therapy and the majority of those who continued GC treatment were patients with RA (Figure 1). Of those patients on long term GC treatment (>7.5 mg/day for three months) 38% were receiving bone protective therapy against corticosteroid induced osteoporosis. The use of topical steroids decreased by half among PsA patients and one third discontinued the treatment after initiating TNFi (Figure 2).

Conclusion: TNFi therapy does impact GC use among patients with arthropathies, however a large portion of RA patients are still on GC two years after initiating TNFi therapy. Better osteoporosis prophylaxis and treatment is warranted for those patients on long term GC.

Montgomery–Asberg Depression Rating Scale (MADRS) and Hamilton Anxiety Rating Scale (HAM-A). RA-pts with ADD were divided into the following treatment groups: 1 – cDMARDs (n=39), 2 – cDMARDs + PPT (sertraline or mianserine) (n=43), 3 – cDMARDs + bDMARDs (n=32), 4 – cDMARDs + bDMARDs + PPT (sertraline or mianserine) (n=9). Biologics treatment duration varied from 1 to 6 years, antidepressants – from 6 to 96 weeks. 

**Results:** HAQ scores were high in all 4 groups at baseline and after five years remained high in all groups except group 2 with the lowest endpoint scores among 4 groups (table 1). To measure changes in HAQ scores between groups we compared the differences between baseline and endpoint HAQ scores (Δ HAQ = endpoint HAQ – baseline HAQ) (table 2). The table shows an improvement in HAQ scores in groups 2 and 3, no significant changes in group 4 and a worsening of HAQ scores in group 1. HAQ scores in groups 2 and 3 significantly improved compared to group 1.

**Table 1** Mean HAQ scores in RA patients with ADD at baseline and after 5 years, by groups.

**OP0216 DEVELOPMENT AND VALIDATION OF PATIENT-LEVEL PREDICTION MODELS FOR ADVERSE HEALTH OUTCOMES AMONGST ADULT RA PATIENTS INITIATING FIRST-LINE TREATMENT OF METHOTREXATE MONOTHERAPY: A MULTINATIONAL REAL-WORLD COHORT ANALYSIS INCLUDING 164,735 SUBJECTS**

C. Yang1, R. Williams2, J. Swerdel3, M. Jani4, T. Duarte-Salles5, K. Chatzidionysiou6, D. Prieto-Alhambra7, P. Ryan8, P. Rijnbeek9 on behalf of the 'European Health Data and Evidence Network (EHDEN) RA Research Group.1 Department of Medical Informatics EMC, Rotterdam, Netherlands; 2Department of Medical Informatics Erasmus MC, Rotterdam, Netherlands; 3Janssen Research and Development, New Jersey, United States of America; 4Centre for Epidemiology Versus Arthritis, University of Manchester, Manchester United Kingdom; 5Fundació Institut Universitari per a la Recerca a l’Incutció Primària de Salut Jordi Gó i Gurina (IDIAJG), Barcelona, Spain; 6Dep of Medicine, Solna, Rheum Unit, Karolinska Institutet, Stockholm, Sweden; 7University of Oxford, NDORIMS, Oxford, United Kingdom; 8Johnson & Johnson, New Jersey, United States of America; 9Erasmus University, Department of Medical Informatics, Rotterdam, Netherlands

**Background:** EULAR guidelines recommend the early initiation of methotrexate (MTX) monotherapy as soon as possible after the diagnosis of rheumatoid arthrit (RA). Evaluating patient-level risks for adverse outcomes after MTX initiation would allow clinicians to provide more personalised care.

**Objectives:** To develop and validate patient-level prediction models for adverse health outcomes including leukaemia, pancytopenia, infection (serious, opportunistic, all), cardiovascular disease (CVD) (myocardial infarction (MI), stroke), and cancer (breast, colorectal, uterus) in adult RA patients initiating first-line treatment of MTX monotherapy

**Methods:** Health data from claims and electronic health records were used including patients from 7 European countries (Spain, Estonia, Netherlands, Belgium, Germany, France, and the UK), the United States of America, Australia, and Japan. All RA patients initiating first-line treatment of MTX monotherapy with at least one year of prior observation were included. Prediction models for the outcomes were developed for a time at risk of 3 months (infections, leukaemia, pancytopenia), 2 years (MI and stroke), and 5 years (cancers) on the Optum® De-Identified Cinformatics® Data Mart Database. Models were developed using LASSO logistic regression and were evaluated using the area under the receiver operator characteristic curve (AUROC) for discrimination and graphically assessed for calibration. The models were externally validated on all other databases.

**Results:** A total of 21,307 subjects were used for training and validation against 143,427 patients from 14 sites. MI (AUROC internal 0.77, AUROC external ranging from 0.49 to 0.76), stroke (AUROC internal 0.78, AUROC external ranging from 0.68 to 0.79) and serious infection (AUROC internal 0.75, AUROC external ranging from 0.63 to 0.79) had good predictive validity [Table 1]. Discrimination for all other outcomes was lower, with all AUC<0.7 in internal validation. For detailed results see: https://data.ohdsi.org/ehdenRaPrediction/

**Conclusion:** Clinical tools were developed that successfully identify subjects at risk of MI, stroke and serious infection at the initiation of first-line MTX therapy. The developed algorithms had good transportability and generally, the models with high AUROC had adequate internal calibration although some external validations show they could benefit from recalibration. For short-term opportunistic and all infections, as well as 5-year cancer models, we were unable to achieve a high enough AUROC to warrant validating externally.

**OP0217 INVOLVEMENT OF LARGE JOINTS AT DISEASE PRESENTATION IS ASSOCIATED WITH DIVERSE HISTOPATHOLOGICAL FEATURES AND CLINICAL OUTCOMES IN EARLY RHEUMATOID ARTHRITIS**

F. Rivellese1, F. Humby1, G. Liiso Ribera1, A. Nerviani1, E. Sciacc1, G. Gior1, R. Hands1, L. Fossati-Jimack2, G. Thorborn2, M. Lewis3, C. Pitzalis3,4

1Queen Mary University of London, Centre for Experimental Medicine and Rheumatology, London, United Kingdom

**Background:** The involvement of large joints at disease presentation in early Rheumatoid Arthritis (RA) has been associated with severe disease activity. At the same time, the clinical heterogeneity of RA is known to be mirrored by heterogeneity of synovial inflammation, with specific histological patterns (pathotypes)

---

**Disclosure of Interests:** None
associated with treatment response and disease progression. However, it is not known whether joint size is associated with specific pathotypes.

**Objectives:** To analyse histopathological features of synovial biopsies from joints of different sizes and establish the relationship with clinical outcomes in patients with early RA.

**Methods:** 167 patients with early (<1 year) treatment-naive RA, fulfilling the 2010 RA criteria and recruited at Barts Health NHS Trust, underwent US-guided synovial biopsy of the most inflamed joint, either large (knee), medium (e.g. wrist, ankle, elbow) or small (MCPs, MTPs), before starting treatment with csDMARDs with a treat to target approach. Upon SQ scoring (0-4) of immune cell infiltration, tissues were classified into lympho-myeloid, diffuse-myeloid and pauci-immune pathotypes. Synovial samples from 111 patients underwent RNA-seq.

**Results:** The majority of synovial biopsies were performed on medium and small joints (60.6% and 19.4%) as compared to 21.3% in large joints (200 joints). At baseline, patients who underwent large joint biopsy showed significantly higher levels of inflammation (CRP 27.9±32.4 large, 20.7±26.9 medium, 10.4±8.8 small, p=0.007) and higher HAQ (1.8 ± 0.7 large, 1.4 ± 0.8 medium, 1.2 ± 0.9 small, p=0.012), with no differences in DAS28. Significantly higher inflammatory scores and higher proportion of lympho-myeloid pathotype were observed in large joints (Table 1 and Figure 1), 6 months after treat-to-target treatment with csDMARDs, large joints patients had significantly higher HAQ and lower response (RR for low disease activity in large vs medium joints 0.5, 95%CI 0.2-0.9, p=0.03). Finally, differentially expressed genes by RNA-seq showed segregation according to joint size (Figure 2), with upregulation of genes of the Homeobox transcription factors family in large joints.

*Large joints: knees; Medium joints: wrists, ankle, elbows; Small joints: MCPs, MTPs, PIPs; a Ch-squared or Kruskal-Wallis as appropriate.

**Conclusion:** Synovial biopsy of large joints as the most inflamed joints at disease presentation identified patients with early RA with specific histopathological features and clinical outcomes. Together with clustering of differentially expressed genes according to joint size, this suggests that the involvement of different joint compartments in early RA contributes to disease heterogeneity with potential pathophysiological and clinical implications.

**Objectives:** To explore and describe pre-treatment CNS pain response associations with post treatment course of RA disease activity components and patient-physician discrepancy in global disease assessment.

**Methods:** Patients fulfilling the 2010 ACR/EULAR classification criteria with moderate-severe disease activity (DAS-28>3.2) under stable DMARD treatment were recruited. Patients underwent an fMRI scan, stratified by a whole-brain BOLD positive voxel count threshold of 700 units and randomized to treatment with CZP or placebo in a 2:1 ratio. We descriptively assessed components of RA disease activity (Table 1 + 2). We summarized the mean results and 95% confidence intervals of these measurements at study timepoints and compared the 3 study groups at week 12 using one-way ANOVA and post-hoc Tukey tests.

**Results:** 156 eligible patients were screened and 139 (99 females, 71%) patients with moderate-high disease activity were randomized. ANOVA and pairwise comparisons showed that PGA-VAS improvement was larger in the CZP-H group whereas similar to that in placebo in the CZP-L group. PhysGA-VAS however was similarly reduced in both CZP groups. Patients in the CZP-L group constantly rated their pain numerically higher than physicians whereas in the CZP-H group an initially higher discrepancy numerically reduced over time.

**Conclusion:** These results suggest that improved patient global disease activity assessment could be the main driver of improved DAS-28 LDA rates with CZP treatment in patients with a high CNS pain response. Our findings indicate a potential role of fMRI imaging of the brain to further understand disease activity perception in RA patients.

**MORTALITY OF RHEUMATOID ARTHRITIS PATIENTS, TREATED TO TARGET AT LOW DISEASE ACTIVITY: 17-YEARS FOLLOW-UP OF THE BEST COHORT

J. M. Maassen1, Y. Goekoop-Ruiterman2, H. Van Groenendael2, W. Lem5, P. Kersten1, T. Huizinga1, C. Allaart1, J. Maassen1, Y. Goekoop-Ruiterman2, H. Van Groenendael2, W. Lem5, P. Kersten1, T. Huizinga1, C. Allaart1, 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Haga Ziekenhuis, Rheumatology, Den Haag, Netherlands; 3H. Van Groenendael, Rheumatology, Den Haag, Netherlands; 4Amsterdam UMC loc. VUmc, Rheumatology, Amsterdam, Netherlands; 5Dijkzuid Ziekenhuis, Rheumatology, Hoorn, Netherlands

**Background:** Rheumatoid arthritis is known to be associated with increased mortality over the years when compared to the general population. In the BeSt study, 508 patients were treated to target (Disease Activity Score ≤2.4) for 10 years between April 2000 and August 2012. At the end of the initial study follow-up, the observed mortality in the BeSt cohort was similar to mortality in the general population. In the current study we evaluated the mortality in the BeSt cohort after 17 years follow-up and compared it to the general Dutch population.

**Objectives:** Evaluate long-term mortality in the BeSt study cohort.

**Methods:** In the BeSt study 508 patients diagnosed with early RA were randomized to four initial treatment strategies: 1. Sequential monotherapy; 2. Step-up therapy; 3. Concomitant therapy; 4. Early combination therapy. The study endpoint was death occurring during the follow-up period. Mortality was compared between the treatment groups and the general Dutch population using Cox proportional hazard models. Survival analysis was performed with Kaplan-Meier and Cox regression models.

**Results:** During the follow-up period, 110 deaths occurred in the BeSt cohort, compared to 113 deaths in the general Dutch population. The overall survival rate was similar between the treatment groups and the general Dutch population. The mortality rate in the BeSt cohort was not significantly different from the general Dutch population.

**Conclusion:** The results of the current study suggest that treating RA patients to target disease activity levels using the BeSt strategy does not increase mortality compared to the general Dutch population.
After a mean of 17 years follow-up the mortality was increased in the BeSt study cohort mortality - stratified for initial treatment strategy.

**Results:** The mean duration of follow-up in non-deceased patients was 17 years (range 16-18). In total, 143 patients died (28%) compared to a total of 105 (21%) expected deaths in the reference population. The overall SMR after 17 years was 1.37 (95% CI: 1.16-1.61). Within the study population, no statistically significant difference in survival-curves was observed between the four initial treatment strategies (log-rank p=0.76) (table 1, and figure 1).

SMR: standardized mortality ratio (number observed deaths/number expected deaths); CI: confidence interval.

**Conclusion:**

After a mean of 17 years follow-up the mortality was increased in the BeSt study cohort when compared to the general Dutch population. We observed no difference in survival curves among the four treatment strategies.

**ASSESSING THE EFFECT OF INCREASED BODY MASS INDEX ON RESPONSE TO TNF INHIBITORS IN ESTABLISHED RHEUMATOID ARTHRITIS: RESULTS FROM THE METEOR DATABASE**

M. Day1,2, S. S. Zhao3, R. J. Moots2,3, R. B. M. Landewe2,4, N. Goodson1,2

1Institute of Ageing and Chronic Disease, University of Liverpool, Musculoskeletal Biology, Liverpool, United Kingdom; 2Antwerp University Hospital, 3Liverpool University Hospitals NHS Foundation Trust, Academic Rheumatology, Liverpool, United Kingdom; 4Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands; 5Atrium MC, Rheumatology, Heerlen, Netherlands

**Background:** Rheumatoid arthritis (RA) is associated with increased body mass index (BMI). 60% of patients are either overweight or obese. Obesity in RA has been shown to predict reduced response to biologic therapy including tumour-necrosis-factor inhibitors (TNFi) [1]. However, it is not clear whether increased BMI influences response to TNFi.

**Objectives:** 1. To explore whether BMI is associated with response to TNFi in patients with established rheumatoid arthritis (eRA), including those newly-starting on these drugs.

**Methods:** Participants with estRA (>1year since diagnosis) taking biologic medications, registered on METEOR (international database of RA patients), 2008-2013, were included. EULAR response, DAS28 remission (including components), and treatment regimens were recorded at baseline, 6, and 12 months. WHO definitions of overweight (BMI≥25) and obese (BMI≥30) were explored as predictors of TNFi response (good EULAR response and DAS28 remission) using normal BMI as comparator. Logistic and linear regression models (controlling for age, gender, smoking, and baseline outcomes) and sensitivity analyses were performed. Subgroup analyses were performed for grouped TNFi and individual TNFi (infliximab, adalimumab, ADA; etanercept, ETA).

**Results:** 247 patients with estRA were taking a biologic at 6 months, and 231 patients were taking a biologic at 12 months. Obese patients taking any biologic were significantly less likely to achieve DAS28 remission at 6 months if they were obese RA (n=38), compared to those of normal weight (n=44) (OR 0.17 [95%CI 0.03-0.59]). A similar non-significant difference was demonstrated for DAS28 remission, and 12-month remission. Specifically, obese individuals were significantly less likely to achieve good EULAR response at 6 months with IFX (OR 0.09 [95%CI 0.00-0.61]; n=20), and significantly less likely to achieve DAS28 remission at 6 months when newly-starting ADA (OR 0.14 [95%CI 0.01-0.96]; n=17), compared to those of normal weight. There were no significant differences in remission outcomes between individuals of different BMI taking ETN. A small number of individuals started these drugs after their respective biologic after 6months; reason for cessation was not recorded.

Similar outcomes were seen in patients already established on anti-TNF therapy, with overweight and obese individuals less likely overall to be in DAS28 remission at all time points.

**Conclusion:** In established RA, obesity is associated with reduced treatment response to -mab TNFi. No association between increased BMI and response to ETA was observed. Using BMI to direct biologic drug choice could prove to be a simple and cost-effective personalised-medicine approach to prescribing.

**HAVE 5-YEAR SURVIVAL RATE AND MORTALITY CHANGED IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS IN THE PAST TWENTY YEARS?-RESULTS FROM THE IORRA COHORT**

N. Sugitani1, E. Tanaka1, E. Inoue1,2, M. Abe1, E. Sugano1, K. Saka1, M. Ochiai1, Y. Shirimizu1, R. Yamaguchi1, N. Sugimoto1, K. Ikari1, A. Nakajima1, A. Taniguchi1, H. Yamanaka1,2, M. Harigai1, Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Tokyo, Japan; 2Division of Medical Informatics, St. Marianna University School of Medicine, Kanagawa, Japan; 3Department of Orthopedic Surgery, Tokyo Women's Medical University, Tokyo, Japan; 4Center for Rheumatic Diseases, Mie University Hospital, Mie, Japan; 5Rheumatology, Sanno Medical Center, Tokyo, Japan

**Background:** The mortality of patients with rheumatoid arthritis (RA) had been reported as being worse than that of the general population [1, 2], but is expected to have improved over time because the progress in treatment of RA during the past twenty years has been actively adopted to RA management [3, 4]. However, the change in the mortality still remains controversial in patients with early RA [5, 6].

**Objectives:** To investigate whether the vital prognosis of patients with early RA has changed in the past twenty years.

**Methods:** The IORRA cohort is a large observational cohort established in 2000 at the Institute of Rheumatology, Tokyo Women's Medical University. Essentially, all Japanese patients diagnosed with RA at our institute were registered and clinical parameters were assessed biannually. As there is no National Death Registry in Japan, we obtained death report from residual families who responded to our mail query to patients who failed to conduct the subsequent IORRA survey, from physicians of affiliated hospitals and from police in case they found dead
A total of 3,217 patients with early RA were analyzed. The number of patients was 1,609 (79.4% female) in the group A and 1,608 (81.8% female) in B. The median age at baseline was 55 in both groups. Among a total of 3,217 patients, 486 (15.1%) patients were lost during 5-year follow-up; 213 (13.2%) in the group A and 273 (17.0%) in B, respectively. During the observational period, deaths were confirmed in 47 cases (2.9%) in the group A and 45 (2.8%) in B. Major causes of death included malignancies (28% in the group A, 38% in B), respiratory involvement (23% in the group A, 40% in B), cerebrovascular disorders (11% in the group A, 2% in B), and cardiovascular disorders (11% in the group A, 0% in B). The five-year survival rate was 88.8% for the group A and 87.6% for B, and the SMR was 0.81 (95%CI: 0.59-1.08) for the group A and 0.78 (0.57-1.04) for B when assuming all the lost to follow-up patients were alive for 5 years. In the sensitivity analysis assuming that the mortality rate of patients who were lost to follow-up was twice as that of the general population, the SMR was 0.90 (0.68-1.19) for the group A and 0.92 (0.68-1.23) for B.

Conclusion: The mortality of patients with early RA in the past twenty years has been comparable to that of the Japanese general population. In addition, the SMR and the five-year survival rate did not change overtime.

Efficacy and Safety of Upadacitinib in Patients with Active Psoriatic Arthritis and Inadequate Response to Biologic Disease-Modifying Anti-Rheumatic Drugs (SELECT-PSA-2): a Double-Blind, Randomized Controlled Phase 3 Trial

1Division of Immunology & Rheumatology, Stanford University School of Medicine, Palo Alto, United States of America; 2AbbVie Inc., North Chicago, United States of America; 3Papp Clinical Research and ProBity Medical Research, Waterloo, Canada; 4Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; 5Department of Internal Medicine, Ghent University Hospital, Ghent, Belgium; 6Department of Orthopaedics/Rheumatology, National Hospital Organization, Osaka Minami Medical Center, Osaka, Japan; 7Medical Plus, Uherse Hradiste and University of Veterinary and Pharmaceutical Sciences, Brno, Czech Republic; 8Pontifical Catholic University School of Medicine, Porto Alegre, Brazil; 9Department of Rheumatology, Swedish Medical Center and University of Washington, Seattle, United States of America.

Background: Upadacitinib (UPA) is an oral, reversible, JAK inhibitor approved for treatment of moderate to severe rheumatoid arthritis (RA) and currently under evaluation for treatment of psoriatic arthritis (PsA).

**Objectives:** To assess the efficacy and safety of UPA versus placebo (PBO) in patients (pts) with PsA and prior inadequate response or intolerance to ≥1 biologic disease-modifying anti-rheumatic drug (bDMARD).

**Methods:** In SELECT-PSA-2, pts were randomized 1:1:1 to once daily UPA 15 mg (UPA15), UPA 30 mg (UPA30), or PBO. Pts were stratified by baseline DMARD use, number of prior failed bDMARDs, and extent of psoriasis. The primary endpoint was the proportion of pts achieving ACR20 response at Wk 12. Multiplicity controlled secondary endpoints included change in HAQ-DI, FACIT-Fatigue (FACIT-F), and SF-36 Physical Component Summary (PCS) at Wk 12; static Investigator Global Assessment (sIGA) of Psoriasis of 0 or 1, and at least a 2-point improvement from baseline, PASI75, and change in Self-Assessment of Psoriasis Symptoms (SAPS) at Wk 16; and proportion of pts achieving MDA at Wk 24. Additional key secondary endpoints were ACR50 and ACR70 at Wk 12, and ACR20 at Wk 2. Treatment-emergent adverse events (TEAEs) are reported for pts who received ≥1 dose of study drug.

**Results:** 641 pts were randomized and received study drug; 54.3% were female with mean age of 53.4 years, and mean duration since PsA diagnosis of 10.1 years. 61% of pts failed 1 bDMARD, 18% failed 2 bDMARDs, and 13% failed ≥3 bDMARDs. 543 (84.6%) pts completed Wk 24 study drug.

At Wk 12, a significantly greater proportion of pts receiving UPA15 and UPA30 vs PBO achieved ACR20 (58.9% vs 63.8% vs 24.1%; p < .0001 for both comparisons). Statistically significant improvements were observed in the UPA15 and UPA30 arms vs PBO in all multiplicity controlled secondary endpoints, including ΔHAQ-DI (PBO, -0.10; UPA15, -0.30; UPA30, -0.41), ΔFACIT-F (PBO, 1.8; UPA15, 5.2; UPA30, 7.1), ΔFACIT-F (PBO, 1.3; UPA15, 5.0; UPA30, 6.1), and ΔSAPS (PBO, -1.5; UPA15, -2.4; UPA30, -2.9; p < .0001 for all endpoints; Figure 1). In addition, a greater proportion of pts achieved ACR50 and ACR70 at Wk 12 with UPA vs PBO. Generally, TEAEs were reported at similar frequencies in the PBO and UPA15 arms and at a higher frequency in the UPA30 arm (Figure 2). Numerically higher rates of serious AE were reported in the UPA arms. Herpes zoster was more frequent with UPA30. Three malignancies occurred in each of the UPA arms. One adjudicated non-fatal myocardial infarction and one adjudicated pulmonary embolism were reported with UPA15.

Conclusions: In this bDMARD-IR PsA population, UPA15 and UPA30 demonstrated significant improvements across PsA domains including improvements in joint and skin signs and symptoms vs PBO through Wk 24 with improvement observed by Wk 2. A greater percentage of pts treated with UPA achieved MDA and ACR50/70, stringent composite measures of disease control. No new safety signals were identified compared to what has been observed with UPA in RA.

DOI: 10.1136/annrheumdis-2020-eular.1229
Background: Psoriatic arthritis (PsA) is a chronic inflammatory musculoskeletal disease characterized by musculoskeletal and cutaneous inflammation. In the recent EQUATOR study (NCT03101670), patients (pts) with active PsA receiving the oral, selective Janus kinase 1 (JAK1) inhibitor filgotinib (FIL) had significant and sustained improvements versus placebo (PBO) in clinical signs and symptoms. We present here updated results of the EULAR 2019 presentation of EQUATOR on circulating biomarkers in PsA.

Objectives: To evaluate the impact of FIL on the levels of circulating proinflammatory cytokines and chemokines, adhesion molecules, and markers of matrix remodeling in EQUATOR pts with active PsA.

Methods: EQUATOR was a 16-week, double-blind, multicenter, Phase 2 study in pts with active PsA. Pts were randomized 1:1 to FIL 200mg (n=65) or PBO (n=66) once daily. Serum samples (FIL n=60 and PBO n=61) were collected at baseline (BL) and at Weeks 1, 4, and 16. The association of BL biomarkers with PsA disease characteristics was analyzed by Spearman's rank-order correlation. Biomarker changes from BL were assessed in time-paired serum samples using multiplex and high sensitivity ELISA-based assays. Analytes were grouped by hierarchical clustering; treatment effect on a biomarker was defined as a difference in change from BL between pts receiving FIL versus PBO. Improvements in PsA clinical signs and symptoms were determined by assessing changes from BL in a number of clinical disease activity scores including psoriatic arthritis disease activity score (PASDAS), psoriasis area and severity index (PASI) and disease activity index for psoriatic arthritis (DAPSA) scores.

Results: BL levels of numerous biomarkers were associated (p<0.05) with clinical measures of PsA. Several clusters of biomarkers were identified based on the rate and magnitude of FIL treatment response. Cluster 1 included biomarkers with substantial reductions from BL with FIL by week 1, such as the acute phase protein CRP and SAA (>50%), and the inflammatory mediators IL-6, CXCL10, and IL-23 (>25%). Cluster 2 included biomarkers of cell adhesion (ICAM-1, VCAM1) with a 5%–15% reduction from BL with FIL by week 1. Cluster 3 included biomarkers of matrix remodeling (MMP1, SC1M) with a delayed >25% reduction from BL with FIL that was significant by Week 4. Finally, Cluster 4 included biomarkers with a modest (5%–10%) increase from BL with FIL (Eotaxin, IL-15, and adiponectin). Spearman rank correlation analyses showed that at BL, many biomarkers were positively associated with disease scores, and tended to segregate between psoriasis weighted scores such as PASI and arthritis weighted scores such as DAPSA. The observed decrease in proinflammatory cytokines were associated with on-treatment improvements from BL in disease score for pts receiving FIL.

Conclusion: Compared with PBO, FIL significantly decreased BL levels of circulating biomarkers associated with PsA disease activity, including proinflammatory cytokines and chemokines, adhesion molecules, and markers of matrix remodeling. The observed decreases in circulating proinflammatory cytokines and biomarkers of both bone pathology and psoriatic disease suggest that FIL improves PsA clinical signs and symptoms at a molecular level. These findings are consistent with reduced disease activity in pts with PsA and suggest that FIL treatment leads to a rapid and sustained reduction of inflammation in PsA.

Figure 1. LSM (ED) in PASDAS and HAQ-DI up to Month 12 of the MTX withdrawal substudy.

Tofacitinib monotherapy vs tofacitinib + MTX

Tofacitinib 5 mg BID and receives FIL

Tofacitinib monotherapy vs tofacitinib + MTX

No clinically meaningful differences in efficacy were observed. Efficacy and pr-reported outcomes were generally similar between study arms (A), in PASDAS and HAQ-DI at Month (M)6. Secondary efficacy endpoints were assessed at all time points. Safety was assessed throughout the substudy.

Results: Of 180 pts randomised, 179 were treated (tofacitinib monotherapy n=90; tofacitinib + MTX n=89). Pt characteristics were similar between treatment arms. At M6, least squares mean (LSM) (standard error [SE]) in PASDAS was 0.229 (0.079) for tofacitinib monotherapy and 0.138 (0.081) for tofacitinib + MTX, and LSM (SE) in HAQ-DI was 0.043 (0.027) and 0.017 (0.025), respectively (Figure 1); there were no clinically meaningful differences in efficacy observed. Efficacy and pr-reported outcomes were generally similar between study arms (A), in PASDAS and HAQ-DI at Month (M)6. Secondary efficacy endpoints were assessed at all time points. Safety was assessed throughout the substudy.

Background: Netakimab (NTK) is a humanized anti-interleukin 17A antibody approved for the treatment of moderate-to-severe plaque psoriasis.

Objectives: To determine the efficacy and safety of NTK in patients (pts) with active psoriatic arthritis (PsA), based on 24-week (Wk) data from an ongoing phase 3 study (NCT03598751, PATERA).

Methods: 194 eligible adult pts with PsA (CASPAR, 2006) with inadequate response to csDMARD or one TNFi, were randomized (1:1) to receive NTK 120 mg or placebo (PBO) subcutaneously at Wk 0, 1, 2, 4, 6, 8, 10, 14, 18, 22, 24 pts from PBO arm who did not meet ACR20 (20% improvement in the American College of Rheumatology criteria) by Wk 16 were switched to NTK 120 mg. The primary end-point was ACR20 at Wk 24. DAPSA (Disease Activity Index for Psoriatic Arthritis), the proportion of pts achieved ACR50/70, minimal disease activity (MDA) (≥5/7 MDA criteria) and Psoriatic arthritis response criteria (PsARC) were also analyzed.

Results: Baseline demographics and disease characteristics were similar across treatment arms (Table 1). 80 (82.47%) pts in NTK arm and 9 (9.28%) in the PBO arm achieved ACR20 at Wk 24 (p<0.0001). A significantly greater percentage of NTK-treated pts had ACR50/70, PsARC response, MDA at Wk 24 (Table 1). By Wk 24 DAPSA was significantly improved for NTK vs PBO. DAPSA remission was achieved by 36.08% and 13.40% in NTK and PBO arms, respectively (p=0.003). NTK was well tolerated. The most frequent AEs (≥3%) were lymphopenia, neutropenia, hypercholesterolemia, ALT increased, upper respiratory tract infection, systolic blood pressure increased, hyperglycemia, hyperbilirubinemia. Most AEs were mild to moderate. Severe treatment-related AEs were observed in 10% vs 2.6% for NTK and PBO, respectively. No treatment-related SAEs were reported. No anti-drug antibodies were detected.

V.A. Nasonova, Moscow, Russian Federation; 9Research Institute of Rheumatology, Moscow, Russian Federation; 10Icahn School of Medicine at Mount Sinai, New York, United States of America; 11Novartis Pharma AG, Basel, Switzerland

Background: Secukinumab (SEC), an interleukin-17A inhibitor, has demonstrated improvements on multiple domains of psoriatic arthritis (PsA). 2Adalimumab (ADA), a TNF inhibitor, is widely used as a first-line biologic in PsA.

Objectives: To report efficacy and safety outcomes from the head-to-head EXCEED trial (NCT02745080) that compares SEC vs. ADA as first-line biologic monotherapy through 52-weeks (wks), with a musculoskeletal primary endpoint in pts with active PsA.

Methods: Head-to-head, phase-3b, randomised, double-blind trial: biologic naïve active PsA pts were randomised to receive SEC 300mg subcutaneous at baseline, Wk1-4, and then every 4wks (q4w) until Wk48 or ADA 40mg subcutaneous at baseline and then q2w until Wk50. The primary endpoint was superiority of SEC vs. ADA on ACR20 response at Wk52. Binary and continuous variables were analysed using logistic-regression model and MMRM, respectively. Safety analysis included patients who received ≥1 dose of study-drug.

Results: 853 pts were randomised to receive SEC (n=426) or ADA (n=427). Baseline demographics and disease characteristics were comparable between treatment-groups except higher proportion of female pts and pts without enthesitis in the SEC group. ACR20 response at Wk52 for SEC vs. ADA were 67.4% vs. 61.5%, respectively (p=0.0719) (Figure). Higher clinical responses were observed with SEC vs. ADA for a range of musculoskeletal, skin, and higher-hurdle outcomes (Table). A higher retention rate was observed for SEC (85.3%) vs. ADA (76.3%). Safety profiles of SEC and ADA were consistent with previous reports. 2,3

Conclusion: Results suggest that SEC is at least as efficacious as ADA on musculoskeletal endpoints whilst providing higher responses on skin endpoints, and is associated with a higher retention rate. No new safety signals were reported.

Efficacy and Safety of Ixekizumab Versus Adalimumab (SPIRIT-H2H) With and Without Concomitant Conventional Synthetic Disease-Modifying Antirheumatic Drugs (DMARD) in Biologic DMARD-Naïve Patients with Psoriatic Arthritis: 52-Week Results

Background: Ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting IL-17A, was superior to adalimumab (ADA) at Week (Wk) 24 for simultaneous achievement of ACR50 and 100% improvement from baseline in the Psoriatic Arthritis and Severity Index (PASI 100) (primary endpoint) in patients (pts) with active PsA from SPIRIT-H2H1. SPIRIT-H2H had two major secondary endpoints and achieved both: noninferiority of IXE to ADA for ACR50 at Wk 24, and superiority of IXE to ADA for PASI 100 at Wk 24.

Objective: To determine how concomitant conventional synthetic DMARD (csDMARD) use affects safety and efficacy of IXE and ADA in prespecified subgroups defined by biologic monotherapy, concomitant MTX use, and concomitant csDMARD use through Wk 52 in SPIRIT-H2H2.

Methods: SPIRIT-H2H (NCT03151551) was a 52-week, multicentre, randomised, open-label, assessor-blinded, parallel-group study evaluating the efficacy and safety of IXE versus ADA in adults with PsA and naïve to biologic DMARDs. Patients were required to have active PsA fulfilling Classification for Psoriatic Arthritis (CASPAR) criteria and ≥38 tender and ≥36 swollen joints, ≥3% plaque psoriasis BSA involvement, no prior treatment with bDMARDs, and with prior inadequate response to ≥1 csDMARD (but not necessarily current treatment with csDMARDs). Randomization (1:1) was stratified by concomitant use of csDMARD and the presence/absence of moderate to severe PsO (baseline: BSA≥10% + PASI≥12, + static Physician's Global Assessment≥3). Patients (N=566) received IXE/ADA through Wk 52 wks according to the labelled dose dependent on presence/absence of moderate-to-severe PsO. In this prespecified subgroup analysis by presence or absence of csDMARDs, efficacy outcomes through Wk 52 were compared between IXE and ADA using logistic regression models and Fisher's exact tests. Missing data were imputed using non-responder imputation.

Results: At baseline, 167 of 283 IXE-treated patients and 169 of 283 ADA-treated patients had concomitant MTX use. Of these, 9.0% (15/167) and 7.1% (12/169) treated with IXE and ADA, respectively, were taking an additional csDMARD (sulfasalazine, cyclosporine, or leflunomide). A significantly greater proportion of patients on IXE versus ADA achieved the primary endpoint or PASI 100 when used as monotherapy or in combination with csDMARD (Figure 1A and 1C). At Wk 52, the proportion of patients achieving ACR50 was not statistically different between IXE and ADA, regardless of monotherapy or concomitant csDMARD use (Figure 1B). A significantly higher proportion of patients achieving MDA on IXE compared to ADA in the monotherapy subgroup (49% vs 33%), while the response rates were similar in both combination subgroups (Figure 1D). These data support consistent ACR50, PASI 100, and MDA response for IXE across all three subgroups. Frequencies of adverse events were similar across the three subgroups for IXE and ADA (Figure 2).

Conclusion: As with prior studies,2,3 consistent efficacy across multiple PsA disease-specific endpoints was observed with IXE in SPIRIT-H2H, regardless of whether IXE was taken as monotherapy or in combination with MTX or another csDMARD. No unexpected safety signals were found for either agent.

GUSELKUMAB INDUCES SUSTAINED REDUCTION IN ACUTE PHASE PROTEINS AND TH17 EFFECTOR CYTOKINES IN ACTIVE PSORIATIC ARTHRITIS IN TWO PHASE-3 CLINICAL TRIALS (DISCOVER-1 AND DISCOVER-2)

S. Siebert, M. J. Loza, K. MAF, K. Leander, V. Lakshminarayanan, C. Frank, P. Cooper, K. Sweed, J. Univ Glasgow, Glasgow, United Kingdom; Janssen Research & Development, LLC, Spring House, United States of America

Background: Guselkumab (GUS), an IL-23 inhibitor monoclonal antibody (Mab) that specifically binds to the IL-23p19 subunit, demonstrated efficacy compared to placebo (PBO) in reducing skin and musculoskeletal signs and symptoms in patients (pts) with active psoriatic arthritis (PsA) in two phase-3 studies, DISCOVER 1 & 2. Previous results from a GUS PsA Phase-2 trial showed associations of baseline IL-17A, IL-17F, and CRP with baseline disease characteristics, and associations of GUS-induced cytokine reductions with clinical responses. The current study assessed cytokine changes in pts with PsA both with and without prior TNF inhibitor had higher levels than the healthy control set.

Methods: In DISCOVER 1 & 2, pts were treated with GUS 100 mg at Wk 0, 4, then every 8 Wks (q8w); UST 130mg q8w; or matching PBO. 21 serum biomarkers were measured in a random subset of 300 PsA pts from the DISCOVER program at Weeks (Wks) 0, 4, 8, 16, 24 and in 34 healthy controls matched for age, sex, and ethnicity. Serum proteins measured were acute phase reactants CRP & SAA (Meso Scale Discovery (MSD) Platform) and inflammatory cytokines/chemokines: Th17 effector cytokines IL-17A, IL-17F, & IL-22 (Single Molecule Counting Erenna® Immunoassay Platform) and soluble ICAM-1, soluble VCAM-1, IL-6, CXCL-8, IL-10, IL-12p70, CCL22, IFN-γ, CCL2, CCL4, TNFα, IL-1β, SAA IL-4 (MSD), & YKL-40 (Quantikine Immunoassay). Serum IL-17A, IL-17B, & CRP measured in the Phase-3 PSUMMIT trials of UST for PsA included for comparison with GUS.

Results: At baseline, serum levels of acute phase proteins CRP, SAA, IL-6, and Th17-effector cytokines IL-17A & IL-17F were elevated in pts with PsA compared with healthy controls (p<0.05, geometric mean ≥ 40% higher, FIG 1). There was no significant dysregulation in the other cytokines measured in PsA pts compared to healthy controls. Baseline IL-17A, IL-17F, IL-22, & CCL22 were significantly associated with baseline psoriasis disease activity (Body Surface Area & Psoriasis Area and Severity Index, Spearman Signed Rank p<0.05, r>0.25). Baseline CRP, SAA, IL-6, & YKL40 were significantly associated with baseline joint disease (Disease Activity Score 28-CRP, Spearman p<0.05, r>0.25). Baseline SAA, IL-6, & IL-17F were higher in pts with prior TNF inhibitor exposure without than without (p<0.05, geometric mean ≥ 40% higher), although pts with PsA both with and without prior TNF inhibitor had higher levels than the healthy control set.

GUS treatment resulted in decreases in serum CRP, SAA, IL-6, IL-17A, IL-17F, & IL-22 that were significantly greater than PBO as early as Week 4 (FIG 1). These protein levels continued to decrease through Wk 24 in GUS-treated pts with both dosing regimens (p<0.05, geometric mean decrease from baseline ≥ 33%). Further, Wk 24 IL-17A & IL-17F levels for pts treated with either dose of GUS were not significantly different from healthy controls, suggesting a normalization of peripheral effector cytokines associated with the IL-23/Th17 axis following treatment with GUS. Effects on IL-17A/IL-17F were greater in GUS-treated pts than UST treated pts, while CRP levels were similar in both programs (FIG 2).

Conclusion: Comprising a strong pharmacodynamic effect, GUS treatment reduced serum protein levels of acute phase and Th17-effector cytokines (whose elevations at baseline were associated with PsA disease characteristics) and achieved comparable levels to those in healthy controls. In pts with PsA, reductions of IL-17A and IL-17F by GUS were of greater magnitude than those by UST.

Effects on IL-17A/IL-17F were greater in GUS-treated pts than UST treated pts, while CRP levels were similar in both programs (FIG 2).
Objectives: To evaluate efficacy and safety of TIL up to week (W)52 in a randomised, double-blind, placebo-controlled, multiple-dose, phase 2b study in PsA (NCT02980692).

Methods: Patients (pts) ≥18 years with active PsA were randomised 1:1:1:1:1 to TIL 200 mg every 4 weeks (Q4W) to W52, TIL 200 mg Q12W to W52, TIL 100 mg Q12W to W52, TIL 20 mg Q12W until W24 then TIL 200 mg Q12W to W52, or placebo (PBO) Q4W until W24 then TIL 200 mg Q12W to W52. Efficacy assessments included ACR20/50/70, 75%/90%/100% improvement in Psoriasis Area and Severity Index (PSI), proportion of pts with residual minimal disease activity (MDA) response; and mean change from baseline (BL) in HAQ-DI, Leeds Dactylitis Index (LDI, pts with BL LDI ≥ 1), and Leeds Enthesitis Index (LEI, pts with BL LEI ≥ 1) to W52. Treatment-emergent adverse events (TEAEs) were monitored.

Results: Of 500 pts screened, 391 were randomised and received ≥1 dose of drug. Proportions of ACR20/50/70 responders were superior with TIL vs PBO through W24; after W24 rates of responses further increased for TIL 20 → 200 mg Q12W and PBO → 200 mg Q12W through W52 (Figure 1, 2). Other efficacy results are shown in Table. Overall from BL → W24/W25 → W52, 50.4%/39.9% and 2.3%/10.0% of pts experienced a TEAE and serious AE, respectively. From BL → W52, 1 case of pyelonephritis and urinary tract infection was reported in the TIL 100 mg Q12W arm and 1 case of chronic tonsillitis was reported in the TIL 20 mg → 200 mg Q12W arm. During W25 → W52, 1 malignancy (intraductal proliferative breast lesion) was reported with TIL 20 mg → 200 mg Q12W. No deaths or major adverse cardiac events occurred.

Conclusion: TIL was well tolerated and improved joint and skin manifestations of PsA through W52.
Background: In many countries, JAK-inhibitors (JAKi) have only recently been approved as treatment for patients with rheumatoid arthritis (RA).

Objectives: To evaluate the effectiveness of JAKi compared to bDMARDs in RA patients in the real-world population in an international collaboration of registers (the "JAK-pot" collaboration).

Methods: Patients initiating either JAKi, TNFi, IL-6i or abatacept (ABA) during a time period when JAKi were available in each country (19 registers, Table 1) were included. We compared the effectiveness of JAKi and bDMARDs in terms of retention using crude and adjusted survival analysis. Missing covariates were imputed using multiple imputation.

Results: Among 25521 included patients, 6063 initiated a JAKi, 13879 a TNFi, 2349 ABA, and 3231 an IL-6i. Patients were on average 55 years old, with a mean disease duration 10 years, mostly seropositive (67%), female (77%) and with moderate disease activity at treatment initiation. The main reason of stopping treatment was ineffectiveness (49%), followed by adverse events (21%). Patients on JAKi were treated more often as monotherapy, had higher CRP and disease activity at baseline and had experienced more previous ts/ bDMARDs. Crude median retention was 1.4 (95% CI 1.2-1.5) years for JAKi, 1.6 (1.6-1.7) for TNFi, 1.5 (1.3-1.7) for IL6i and 1.1 (1.0-1.3) for ABA. After adjustment, the hazard ratio (HR) for discontinuation tended to be lower for JAKi (HR 0.86 (0.65-1.13)) compared to TNFi, but comparable for ABA (1.02 (0.94-1.10) and IL6i (0.99 (0.88-1.10)) (Figure 1). HRs differed notably between countries (Figure 2).

*Registers planning to participate in future studies but not included yet.
Conclusion: The adjusted overall drug retention of JAKi tended to be higher than for TNFi, with large variation between countries. Other measures of effectiveness, such as the evaluation of CDAd remission and low disease activity are planned to shape a more comprehensive picture of JAKi effectiveness in the real world.

EFFICACY, SAFETY, AND PHARMACODYNAMIC EFFECTS OF THE BRUTON’S TyROSINE KINASE INHIBITOR, FENEBrutinib (GDC-0853), IN MODERATE TO SEVERE SYSTEMIC LUPUS ERYThMATOSUS IN A PHASE 2 CONTROLLED STUDY

D. Isenberg, R. Furie, N. S. Jones, P. Guilbord, J. Galanter, C. Lee, A. Mgregor, B. Toth, J. Rae, O. Hwang, A. Lokkut, P. Miranda, V. D. Souza, J. Jailer-Raad, A. Maura Fernandes, R. Garcia Salinas, L. Chinni, M. J. Townsend, A. A. Morimoto, K. Background: Fenebrutinib (GDC-0853, FEN) is an oral, non-covalent, and selective inhibitor of Bruton’s tyrosine kinase (BTK) in clinical development for autoimmune diseases.

Objectives: This was a randomized, placebo-controlled, multi-center study to evaluate the efficacy, safety, and pharmacodynamic effects of FEN in patients with moderate-to-severe systemic lupus erythematosus (SLE) activity.

Methods: Patients who met SLICC or revised ACR SLE criteria, had ≥1 serologic marker of SLE, SLEDAI ≥8, and were on ≥1 standard of care (SOC) therapy were included; patients with renal or CNS involvement, or exposure to B cell depleting or calcineurin inhibitor therapy were excluded. Patients were randomized to placebo (PBO), FEN 150 mg QD, or FEN 200 mg BID, for 48 weeks. A corticosteroid taper was recommended, with burst and taper permitted from Week 0 (W0) to W12 and W24 to W36. The primary endpoint was SRI-4 at W48. Post hoc subgroup analyses were conducted based on patient baseline disease characteristics.

Results: This study enrolled 260 patients, with the majority recruited in Latin America, USA, and Western Europe. At W48, the SRI-4 response rates for FEN 150 mg QD and FEN 200 mg BID were 51% (95% CI -5.5, 21.2; p value 0.37) and 57% (95% CI -9.4, 26.2; p value 0.54), respectively, compared to 44% for PBO (Table 1). Post-hoc analysis showed larger responses in subgroups of patients with higher baseline disease activity (Table 1). Safety results were similar between FEN and PBO arms, although more severe adverse events were observed in the FEN 200 mg BID arm. Study discontinuations were balanced across the 3 arms (24-26%). FEN treatment significantly reduced levels of patients with active RA on a stable dose of MTX.

Conclusion: The primary endpoint of SRI-4 for FEN was not met despite evidence of strong BTK target and pathway inhibition. FEN had an acceptable safety profile. Several disease activity subgroups were suggestive of a greater treatment effect on SRI-4 compared to PBO.
There were no serious treatment emergent adverse events (TEAEs). 15 patients (19%) randomised to MBS2320 withdrew due to TEAEs, predominantly of nausea. TEAEs were typically reported soon after dosing, were mostly mild in severity and resolved without treatment. Onset of TEAEs reduced as the study progressed.

Gastrointestinal disorders were the most frequently reported TEAEs (all causalities) with a higher incidence in patients receiving MBS2320 (68.8%) than placebo (14.6%). Nausea was most frequently reported during Week 1 (27.3% patients). Asthenia and/or fatigue was reported more frequently in the MBS2320 treatment group (53.8% patients) than with placebo (73% patients), with the majority being considered related to study drug. Infections were more frequently reported by patients receiving placebo (22.0%) than those receiving MBS2320 (12.5%). There were no clinically relevant treatment-related trends in the biochemistry, haematology, urinalysis, vital signs or ECG data.

Higher ACR20 response rates were observed in patients receiving MBS2320 versus those receiving placebo at all time points and increased with time. At Week 12, ACR50 response rates with MBS2320 treatment were increased by >4-fold compared with placebo (11.6% vs 2.5%). Greater mean reductions from baseline in DAS28-CRP were also observed in patients receiving MBS2320 versus those receiving placebo at Week 12 (-18.6% vs -8.4%). DAS28-CRP responder rates were more than doubled with MBS2320 treatment compared to placebo (5% vs 14%). These changes were mirrored by improvements in tender joint counts, reduced hsCRP and improvements in Patient Reported Outcomes of pain VAS, Patients’ and Clinicians’ Global Assessments of Disease Activity and Patients’ Global Improvement of Change.

Conclusion: MBS2320 was generally well tolerated for up to 12 weeks in this RA study population. Nausea was the most common TEAE, was generally mild in severity and resolved without treatment. In this population of patients with hard-to-treat, severe, active, erosive disease MBS2320 showed evidence of a clinical benefit on both ACR20 responses and DAS28-CRP.

ACHIEVING A LOW DAS IN THE FIRST 4-MONTHS AFTER DIAGNOSIS IS IMPORTANT FOR THE LONG-TERM CHANCE OF ACHIEVING DMARD-FREE REMISSION
M. Verstappen1, E. Niemantsverdriet2, A. Van der Helm - van Mil1,2, Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands

Background: Sustained DMARD-free remission (SDFR) is increasingly achievable in RA. The pathogenesis underlying SDFR-development is unknown and patient-characteristics at diagnosis poorly explain whether SDFR will be achieved. This limits substantiated decisions to discontinue DMARD-treatment in clinical practice.

Objectives: To increase the understanding of SDFR, we studied the course of disease activity scores (DAS) over time in relation to SDFR-development. Subsequently, we explored whether DAS-time course could be helpful to identify patients likely to achieve SDFR.

Methods: 761 RA-patients consecutively included in the Leiden Early Arthritis Clinic, treated with initial methotrexate and treat-to-target treatment, were studied (mean follow-up = 7.6 years). The course of DAS was compared between patients achieving SDFR within 7 years and those who did not, using linear mixed models, stratified for ACPA. Subsequently, the relation between DAS at 4 months and the probability of achieving SDFR within 7 years was studied with logistic regression. Kaplan-Meier curves were constructed to illustrate cumulative incidence of SDFR for different DAS categories at 4 months, respectively <1.6, 1.6-2.4, 2.4-3.6, >3.6.

Results: Patients achieving SDFR were characterized by a remarkably different DAS response within 4 months after diagnosis. Compared to patients who did not achieve SDFR, the SDFR-group showed a prominently stronger decline in DAS between baseline and 4 months; 159 units decline (95%CI,124-195) versus 0.96 units (95%CI,0.85-1.07) decline (p<0.001) (figure 1). Stratification for ACPA yielded a similar and statistically significant effect in ACPA-negative RA. In ACPA-positive RA this effect was absent. Subsequently the persistence and achieving SDFR during 7 years was studied in ACPA-negative RA and it was observed to be lower for patients with higher DAS at 4 months. After 7 years of disease, the cumulative incidence for SDFR in ACPA-negative patients with DAS<1.6 at 4 months was high (71.0%), whilst SDFR was rare among those with DAS>3.6 at 4 months (71%) (figure 2).

Conclusion: In RA-patients treated according to current guidelines, SDFR is predominantly achieved in patients with a strong decline in DAS during the first four months after diagnosis. Especially in ACPA-negative RA, the DAS at 4-months can be useful for later decisions to stop DMARDs.

OP0236

RELEVANCE OF BIASED PAR2 INHIBITORS IN REDUCING INFLAMMATION AND CARTILAGE DEGRADATION IN IN VITRO AND IN VIVO MODELS OF RHEUMATOID ARTHRITIS
T. Brugett1, B. Rugeri1, G. Hommet1, A. Dumont1, L. Baron1, C. Halter1, M. Sémache1, A. Mancini1, A. Camalici1, M. Giambelluco1, N. Lenne1, M. Sidhoum1, C. Franchet1, S. Mayer1, X. Leroy1, S. Schann1, 1Domain Therapeutics, Illkirch, France; 2Domain Therapeutics, Montréal, Canada

Background: Protease-activated receptor-2 (PAR2) is a member of a family of G-protein-coupled receptors involved in multiple physiological mechanisms. Compelling evidence have unravelled the key roles of PAR2 in the pathophysiology of both rheumatoid arthritis (RA) and osteoarthritis (OA). Indeed, in vitro, in vivo and ex vivo experiments showed that this receptor promotes inflammation, cartilage erosion (and subsequent bone degradation), and pain. However, the signalling pathways involved in these functions are not well understood. This is of importance as some pathways can promote the pathogenesis while others prevent it. We developed a new series of small molecules as novel biased PAR2 inhibitors to treat rheumatic diseases.

Objectives: To evaluate the efficacy and mechanism of action of new biased PAR2 inhibitors on cartilage erosion and inflammation.

Methods: The potency of compounds to inhibit human PAR2 signalling was evaluated in vitro by FLIPR calcium assay in HEK293 cells. The same assay was used to determine their selectivity over human PAR1 and PAR4 as well as murine versions of PAR2. The effect of several PAR2 inhibitors on 9 signalling pathways (GI2, GoB, Gz, Gq, G13, G14, G15, B arrestin 2, EPAC) was evaluated by the BRET-based bioSens-All™ technology. In vitro anti-hypertrophic effect was determined by measuring the mRNA level of type II collagen, aggrecan.
and MMP13 in rat chondrocytes after IL1β stimulation. In vitro anti-inflammatory effect was determined by measuring the secretion of IL6, IL8, IL1β, TNFα and IFNγ by human monocytes. In vivo, the pharmacodynamic of our small molecules was assessed after intravenous and oral administration. Therapeutic efficacy of a compound was then evaluated in a collagen-induced arthritis model in DBA/1 mice. In this model, measures of the arthritis index score, body weight, plasma level of TNFα, IL6, IL8 and IL1β and histological evaluation of cartilage erosion were performed.

**Results:** Our new series of small molecules are potent PAR2 inhibitors (IC50 > 50 nM in calcium assays) with some selectivity over PAR1 and PAR4. Our compounds significantly inhibited PAR2 mediated recruitment of Gz, Gq, G13, G14 and G15. However, surprisingly, these small molecules had no effect on B arrestin 2, EPAC, Gβ1 and Gβδ demonstrating that they are biased inhibitors. The effect of our compounds on PAR2 signalling was clearly different from 3 already existing PAR2 inhibitors described in the literature (I-117, AZ3451 and P2pal-18s). We compared the in vitro anti-hypertrophic effect on chondrocyte and anti-inflammatory effect on monocytes of these compounds to determine the importance of PAR2 signalling pathways in these cellular functions. In vivo, our small molecules had good bioavailability after oral administration of 10mg/kg in mice (clearance = 0.038L/hr/g; T1/2 = 9.9h; AUC= 162564ng.h/mL; Cmax = 9005 ng/mL). The in vivo therapeutic efficacy of a biased PAR2 inhibitor in a model of collagen-induced arthritis will be presented.

**Conclusion:** Our results show the potency of biased PAR2 inhibitors to reduce both the inflammation and cartilage erosion in rheumatoid arthritis. They confirm the huge potential of PAR2 as a therapeutic target and unravel the relevance of biased antagonism of this receptor to treat rheumatic diseases.

**RISK OF HERPES ZOSTER IN PATIENTS WITH RHEUMATOID ARTHRITIS UNDER BIOLOGICAL, TARGETED SYNTHETIC, AND CONVENTIONAL DMARD TREATMENT**

A. Strandø1, I. Redeke1, J. Kelow2, G. R. Burmester2, J. Braun1, A. Zink1,3,4

1German Rheumatism Research Centre, Berlin, Germany; 2Scientific Advisory Board, Vogelsang-Gommen, Germany; 3Charité University Medicine, Berlin, Germany; 4Rheumatologe, Heine, Germany

**Background:** The risk of herpes zoster (HZ) is higher in patients with rheumatoid arthritis (RA) than in the general population. This risk is further increased with biologic disease-modifying anti-rheumatic drugs (bDMARDs) such as tumour necrosis factor inhibitors (TNFI) and targeted synthetic (ts)DMARDs such as Janus kinase inhibitors (JAKI) compared to patients taking conventional synthetic (cs)DMARDs such as methotrexate (MTX).

**Objectives:** To compare incidence rates of HZ in RA patients under treatment with bDMARDs, tsDMARDs and csDMARDs with different modes of action and to find potential risk factors.

**Methods:** Data of patients enrolled in the German biologics register RABBIT from 2007 onwards with the start of a bDMARD, tsDMARD or a change in csDMARD treatment were analysed. Patients were included when at least one follow-up documentation was available. All HZ events reported until 30 April 2019 were identified and assigned to treatments administered within the 3 month period prior to the HZ event. Crude incidence rates (IR) of HZ were calculated per 1,000 patient years (py). Cox regression was applied to investigate risk factors for the occurrence of HZ with and without inverse probability weights (IPW) to adjust for confounding by indication.

**Results:** Data of 12,470 patients (53,218 py of observation) were included in the analysis. A total of 452 HZ cases in 433 patients were reported, of which 52 events were serious. The crude IRs per 1,000 py are illustrated by Figure. Adjusted for age, sex, and glucocorticoid use, a significantly increased risk was observed for treatment with monoclonal TNF antibodies (hazard ratio [HR], 1.55 [95% CI, 1.21-2.00]), B-cell targeted therapies (HR, 1.45 [95% CI, 1.07-1.97]), and tsDMARDs (HR, 1.35 [95% CI, 1.07-1.70]). Treatment with soluble TNF receptor, T-cell co-stimulation modulator, and IL-6 inhibitors were also significantly associated (Table). Adjustment with IPW amplified the effect and treatment with T-cell co-stimulation modulator and IL-6 inhibitors were also significantly associated with a higher risk compared to csDMARD treatment (Table).

**Conclusion:** This is the first analysis in a European prospective cohort study comparing the incidence rates and risk of HZ in RA patients under treatment with six different modes of action within one cohort to csDMARD treatment. We found a significant association between HZ and treatment with JAKI. Our results also confirm a higher risk for monoclonal TNF antibodies and show a similar result for the T-cell co-stimulation modulator and B-cell targeted therapies. This study clearly supports systematic HZ vaccination in RA patients.

Preclinical models of arthritis and bone disease

DO0239

**WHY DOES ALCOHOL INHIBIT ARTHRITIS? – AN EXPLANATION OF THE MECHANISM OF ARTHRITIS INHIBITION BY ETHANOL**

V. Azizov, M. V. Sokolova, K. Sarter, V. Temchura, U. Steffen (Née Harre), M. Herrmann, G. Schett, M. Zais. 1. Department of Internal Medicine 3, Erlangen, Germany; 1. Institute of Virology, Erlangen, Germany

**Background:** Alcohol consumption has emerged as consistent protective factor for the development of autoimmune diseases such as rheumatoid arthritis (RA). The underlying mechanism for this tolerance-inducing effect of alcohol, however, is unknown.

**Objectives:** To understand the anti-arthritogenic effect of alcohol

**Methods:** The immune-regulatory properties of alcohol consumption in vivo were tested in the collagen-induced arthritis (CIA) and serum-induced arthritis (SIA) model as well as after immunization with T cell-dependent (NP-CGG) and independent (TNF-FiCOLL) antigens. Additional experiments in vivo and ex vivo experiments in these models were done with acetate- the metabolite of ethanol. The models were analysed for T-cell lineage and plasma cell differentiation, germinal centre formation and IgG levels and sialylation. Molecular expression of T follicular helper cell (TFH) activation such as CD21, Bcl-6 and PD-1, as well as TFH: B cell conjugates were also assessed. Furthermore, TFH cells were generated in vitro, exposed to ethanol or acetate and tested for IL-21 production, PD1 expression and conjugate formation with B cells.

**Results:** Ethanol exposure significantly inhibited arthritis in the active adaptive immunity-driven model of arthritis (CIA) but not in the passive innate immunity-driven model (STA) suggesting that the immune suppressive effect of alcohol is based on interference of T- and B-cell activation. In line ethanol and even more its metabolite acetate, suppressed T cell independent antibody formation after NP-CGG immunization, while T cell independent antibody formation after TNF-FiCOLL immunization was not suppressed. Ethanol, as well as its metabolite acetate, specifically altered the functional state of T follicular helper (Tfh) cells in vitro and in vivo, thereby exerting immune regulatory and tolerance-inducing properties. Alcohol-exposed mice showed reduced Bcl6 and PD-1 expression as well as interleukin (IL)-21 production by TFH cells, preventing proper spatial organization of the TFH cells to form TFH: B cell conjugates in the germinal centres. This effect of alcohol on Tfh cells was associated with impaired autoantibody formation, higher sialylation of autoantibodies and less arthritis. In accordance, overexpression of IL-21 in vivo completely reversed the immune regulatory effects of alcohol.

**Conclusion:** In summary, these data provide a new mechanistic explanation for the immune regulatory and tolerance-inducing effect of alcohol consumption in arthritis.

**A MULTIMODAL MASS SPECTROMETRY APPROACH REVEALS SPECIFIC CARTILAGE MOLECULAR PROFILES ASSOCIATED TO TYPE 2 DIABETIC PATIENTS**

M. Everett, P. Emans, B. Claes, F. Bouwman, R. P. M. A. Heeren, B. Ciller-Pastor, 1. Maastricht Multimodal Molecular Imaging (M4I) Institute, Division of Imaging Mass Spectrometry, Maastricht, Netherlands; 2. Maastricht University Medical Center, Department of Orthopedic Surgery, Maastricht, Netherlands; 3. Maastricht University Medical Center, Department of Human Biology, NUTRIM School of Nutrition and Translational Research in Metabolism, Maastricht, Netherlands

**Background:** Osteoarthritis (OA) is mainly characterized by the progressive deterioration of articular cartilage. Recent studies support that type 2 diabetes (T2D) is a risk factor to develop OA [1, 2]. However, the molecular cartilage profile of patients combining these two diseases remains unclear, and a better understanding of the different OA phenotypes should be considered for the development of personalized medicine.

Matrix-assisted laser desorption/ionization (MALDI) mass spectrometry imaging (MSI) is used to investigate the bimolecular distribution of proteins, lipids or metabolites through the in-situ analysis of tissue sections. Bottom-up proteomics focuses on the relative quantification of proteins. The combination of both technologies could be considered to reveal specific molecular profiles and help for patient classification.

**Objectives:** The main goal of this study is to apply a multimodal mass spectrometry approach on cartilage to reveal specific lipidomic and proteomic profiles associated to T2D patients.

**Methods:** Human cartilages from OA (n = 10) and OA/T2D human patients (n = 10) were obtained from donors undergoing total knee joint replacement. Cartilage punches of 8 mm were sectioned at 12 um thickness for MALDI-MSI and bottom-up proteomics.

For MALDI-MSI experiments (n = 6; n = 6), norharmane matrix was sprayed over the samples for the detection of lipids. Experiments were then performed in positive ion polarity at 50 µm of lateral resolution using a RapifleX MALDI
Tissue-type instrument. LipostarMSI and in-house ChemomeTricks toolbox for MATLAB software were used for data processing and analysis. For bottom-up proteomics experiment (n=10; n=10), proteins were extracted, separated using SDS-PAGE and digested prior to liquid chromatography separation coupled to an orbitrap MS Q-Exactive HF mass spectrometer. Proteome Discoverer, enRichR and Reactome software were used for data processing and analysis.

**Results:** MALDI-MSI showed overall differences between OA and OA/TD2 patients based on their specific lipidomic profiles. In particular, sphingomyelin and phosphatidylcholine species were significantly more abundant in OA patients whereas lysophosphatidylcholine species were mainly present in OA/TD2 patients, providing therefore phenotype-specific OA molecular panels. Additionally, we observed that phosphatidylcholine and sphingomyelin species were more present in the superficial layer of the cartilage whereas lysophosphatidylcholine species were more abundant in the deep layer (Fig. 1A, B). Proteomics experiments applied on cartilage enables the quantification of 114 species were more abundant in the deep layer (Fig. 1C), phospholipase A2 was increased in the diabetic cohort, in line with the elevated level of lysophospholipids found in the imaging data. Our results also involved the fatty acid omega oxidation and the fatty acid biosynthesis pathways as relevant to explain this deregulation of the lipid metabolism.

**Conclusion:** MALDI–MSI combined with proteomics experiments showed different profiles between OA and OA/TD2 patients and could be employed for patient classification.

Rheumatology, Dep. of Rheumatology, University Hospital Zurich, Zurich, Switzerland;2 University Medical Center Ljubljana, Department of Rheumatology, Ljubljana, Slovenia.

**Background:** Up to now, three groups used single cell RNA sequencing (scRNA-seq) to analyse the synovium in arthritis: 1) to define synovial fibroblast (SF) phenotypes, 2) to confirm differences across SF clusters between rheumatoid arthritis (RA) and osteoarthritis (OA) and 3) to analyse joint specific differences between SF phenotypes.

**Objectives:** The aim of this study was to perform a meta-analysis of scRNA-seq data of the synovium in arthritis: 1) to define synovial fibroblast (SF) phenotypes, 2) to confirm differences across SF clusters between rheumatoid arthritis (RA) and osteoarthritis (OA) and 3) to analyse joint specific differences between SF phenotypes.

**Methods:** In addition to the available count matrices [1-3], we used unsorted dissociated synovial cells from three patients with undifferentiated arthritis (UA) with a droplet-based method (10x Genomics). We followed a strategy [4] to integrate the datasets into a shared space, even in the presence of extensive technical and/or biological differences (“batch-corrected”). SP were selected as previously described (DPDN+, ISLR+, COL1A2+, PTPRC-) [1-3]. We used a minimum log2 FC of 0.25 for average expression of genes in a cluster relative to the average expression in all other clusters combined to define marker genes. R with Seurat, Monocle and clusterProfiler packages were used for scRNA-seq analysis, pseudotime trajectory analysis and pathway enrichment analysis, respectively. Quantitative PCR (qPCR) (n=8-14 per location and disease), immunohistochemistry (IHC) and Krenn synovitis score (n=5-15 per location and disease) were performed according to standard protocols.

**Results:** Data from 29 RA, 3 UA and 6 OA patients were analysed. From a total of 29,448 cells, we identified 14,787 (50%) with a fibroblast phenotype. Of those, we determined 5 subpopulations (Fig. 1): 1) THY1+ CD68+ fibroblasts with high...
expression of MMP1 and MMP3 (SF1), 2) THY1<sup>hi</sup> CD34<sup>+</sup> fibroblasts expressing high levels of P16 (SF2) 3) THY1<sup>hi</sup> fibroblasts expressing high levels of perio- 
stin (POSTN) and collagens (e.g. COL1A1, COL3A1) (SF3), 4) THY1<sup>hi</sup> fibroblasts expressing CXCL12, 
NR4A1 and CCL2 (SF5). Fig. 2 shows pathway enrichment map of all marker 
genes; it organizes enriched terms into a network with edges connecting over- 
lapping gene sets. Pseudotime trajectory axis derived from Monocle indicated 
that SF4 represent a state between SF3 and SF5. Pseudotemporal expression 
dynamics of THY1 marked the progression of these three subtypes (Graph 1). 
SF1 and SF2 were proportionally underrepresented and SF3-5 overrepresented 
in RA (chi-squared = 37.18, p = 1.65e-07). The expression of POSTN, a sig- 
nature gene of SF3, was not different between RA and OA tissues, but sig- 
nificantly correlated with the synovitis score (Spearman ρ = 0.55, p=0.02), in 
particular with pathological changes in the sublining. POSTN expression was 
higher in hand than in knee synovial tissues (mean ± SD IHC score: hand 8 ±2, 
膝 joint 5 ±2) and in cultured SF (qPCR: 10-fold difference). Accordingly, SF3 was 
enriched in hand versus knee synovial tissues in the scRNA-seq dataset (chi- 
squared = 944.87 , p < 2.2e-16).

Fig. 1

Fig. 2

Conclusion: In our meta-analysis, we found comparable subtypes of fibroblasts 
as in the individual analyses [1-3], showing the robustness of cell phenotype 
identification using scRNA-seq. The different SF phenotypes appear to be plas- 
tic cell states rather than fixed cell subtypes, whose development is controlled 
by an interrelation between pathological changes in the synovium and joint 
location.

OP0243 SERPINA3N LIMITS CARTILAGE DESTRUCTION IN 
OSTEOARTHRITIS BY INHIBITING MACROPHAGE-
DERIVED LEUKOCYTE ELASTASE

A. Latourte<sup>1,2</sup>, A. Combier<sup>2</sup>, S. Jaulerry<sup>1</sup>, C. Cherifi<sup>2</sup>, Y. Jouan<sup>2</sup>, H. K. Ea<sup>1,2</sup>, M. Cohen Solal<sup>1,2</sup>, E. Hay<sup>2</sup>, P. Richette<sup>1,2</sup>,<sup>2</sup>Hopital Lariboisiere, Rheumatology, 
Paris, France; <sup>2</sup>Hopital Lariboisiere, Inserm U1132, Paris, France 

Background: Interleukin-6 (IL-6) plays an important role in osteoarthritis (OA). 
Transcriptomic analyses (RNAseq) revealed that SerpinA3N, a serine protease 
inhibitor, is a key target of IL-6 in chondrocyte.

Objectives: This study aimed to examine the role of SerpinA3N and Leukocyte 
Elastase (Elane), a serine protease inhibitor, in the cartilage destruction during OA.

Methods: The role of SerpinA3N was investigated in the destabilization of 
medial meniscus (DDM) model of murine OA with 1) mice with conditional 
inducible knockdown of Serpina3n in cartilage (Col2Cre<sup>ESR</sup>Serpina3n<sup>fl/fl</sup> mice 
[ΔSerpina3n<sup>Δm</sup>]) and 2) C57BL/6 wild type (WT) mice treated with intra-articular 
injection of SerpinA3N (1.5 or 15mM/week). OA joint lesions were assessed by histology (OARSI and synovitis scores) and micro-CT analysis (ostephie volume 
and subchondral bone remodeling). 

Because serine proteases targeted by SerpinA3N are not produced by 
murine chondrocytes, Elane expression (qRT-PCR) was determined in murine 
macrophages (Raw) stimulated or not by IL-6 (100ng/ml). Recombinant
SerpinA3N (30 nM) and a specific Elane inhibitor, Sivelestat (100 μg/ml) were used on cartilage explants treated by conditioned medium of macrophages pre-treated or not by IL-6 (CM–IL-6). Cartilage catabolism was determined by histology and matrix metalloproteinase MMP-3 production was evaluated by Western Blot and immunohistochemistry (IHC). Weekly intra-articular injections of Sivelestat (1 mM) were performed in the DMM to determine the role of Elane in OA.

Results: ΔSerpinA3N-expressing mice had more severe OA lesions than control littermates 6 weeks after DMM, with greater cartilage damage (mean±SD OARSI score: 5.6±0.4 vs 3.9±0.3, p=0.01), increased synovitis scores (3.0±0.3 vs 1.9±0.3, p=0.03) and bigger osteophytes (7.2±0.8±107 vs 3.8±0.8±107 μm3, p=0.048). Conversely, WT mice treated with intra-articular injections of SerpinA3N 15nM exhibited less severe cartilage loss than mice treated with PBS after DMM (OARSI score: 2.1±0.4 vs 3.9±0.5, p=0.02). Elane mRNA expression was increased in macrophages upon IL-6 stimulation. In cartilage explants, CM–IL-6 activated cartilage catabolism and MMP-3 production, and effect that was blunted by SerpinA3N and Sivelestat. Finally, mice treated with intra-articular injections of Sivelestat had less severe cartilage damage than those treated with PBS after DMM (OARSI score: 3.3±0.47 vs 5.8±0.53, p=0.0046).

Conclusion: SerpinA3N protects against experimental OA via the inhibition of Elane, a pro-catabolic serine protease produced by macrophages. This results highlight the crosstalk between cartilage and surrounding macrophages and open up new therapeutic perspectives.

A PRECLINICAL TESTING TOOL: THE IN VITRO 3D FRACTURE GAP MODEL

M. Pfeiffenberger1,2,3, A. Damerau1,2,3, P. Hoff2,4, A. Lang1,2,3, F. Buttgereit2,3, T. Gaber1,2,3, 1Universitätspark Dresden, Corporate member of Technische Universität Dresden, Dresden, Germany; 2Charité-Universitätsmedizin Berlin, Berlin, Germany; 3Institut für Klinische Geriatrie, Klinikum Rechts der Isar, Technical University of Munich, Munich, Germany

Background: Approximately 10% of fractures lead to significant fracture healing disorders, with a tendency to further increase due to the aging population. Of note, especially immunosuppressed patients with ongoing inflammation show difficulties in the correct course of fracture healing leading to fracture healing disorders. Most notably, invading immune cells and secreted cytokines are considered to provide an inflammatory microenvironment within the fracture gap, primarily during the initial phase of fracture healing. Current research has the focus on small animal models, facing the problem of translation towards the human condition. To improve the therapy of fracture healing disorders, we have developed a human cell-based in vitro model to mimic the initial phase of fracture healing adequately. This model will be used for the development of new therapeutic strategies.

Objectives: Our aim is to develop an in vitro 3D fracture gap model (FG model) which mimics the in vivo situation in order to provide a reliable preclinical test system for fracture healing disorders.

Methods: To assemble our FG model, we co-cultivated coagulated peripheral blood and primary human mesenchymal stromal cells (MSCs) mimicking the fracture hemotoma (FH model) together with a scaffold-free bone-like construct mimicking the bony part of the fracture gap for 48 h under hypoxic conditions (n=3), in order to reflect the in vivo situation after fracture most adequately. To analyze the impact of the bone-like construct on the in vitro FH model with regard to its osteogenic capacity, we cultivated the fracture gap models in either medium with or without osteogenic supplements. To analyze the impact of Deferoxamine (DFO, known to foster fracture healing) on the FG model, we further treated our FG models with either 250 μM DFO or left them untreated.

After incubation and subsequent preparation of the fracture hemotoma, we evaluated gene expression of osteogenic (RUNX2, SPP1), angiogenic (VEGF, IL8), inflammatory markers (IL6, IL8) and markers for the adaptation towards hypoxia (LDHA, PGK1) as well as secretion of cytokines/chemokines using quantitative PCR and multiplex suspension assay, respectively.

Results: We found via histology that both the fracture hemotoma model and the bone-like construct had close contact during the incubation, allowing the cells to interact with each other through direct cell-cell contact, signal molecules or metabolites. Additionally, we could show that the bone-like constructs induced the upregulation of osteogenic markers (RUNX2, SPP1) within the FH models irrespective of the supplementation of osteogenic supplements. Furthermore, we observed an upregulation of hypoxia-related, angiogenic and osteogenic markers (RUNX2, SPP1) under the influence of DFO, and the downregulation of inflammatory markers (IL6, IL8) as compared to the untreated control. The latter was also confirmed on protein level (e.g. IL-6 and IL-8). Within the bone-like constructs, we observed an upregulation of angiogenic markers (RNA-expression of VEGF, IL8), even more pronounced under the treatment of DFO.

Conclusion: In summary, our findings demonstrate that our established in vitro FG model provides all osteogenic cues to induce the initial bone healing process, which could be enhanced by the fracture-healing promoting substance DFO. Therefore, we conclude that our model is indeed able to mimic correctly the human fracture gap situation and is therefore suitable to study the influence and development of new treatments for bone healing disorders in immunosuppressed patients with ongoing inflammation.

MICROBIOTA-INDUCED INTESTINAL BARRIER DYSFUNCTION PRECEDES THE ONSET OF ARTHRITIS AND ALLOWS THE SHUTTLING OF IMMUNE CELLS FROM THE GUT TO THE JOINTS

M. Zaiss1, N. Tajic1, K. Sarter1, V. Azizov1, L. Bucci2, Y. Luo3, J. D. D. Canete4, F. Ciccia5,6, G. Schett1.

1FAU Erlangen, Erlangen, Germany; 2Universitatsklinikum Muenchen, Munich, Germany; 3Universitaetsklinikum Heidelberg, Heidelberg, Germany; 4Department of Rheumatology and Clinical Immunology, Berlin, Germany; 5Universita degli Studi della Campania, Napoli, Italy; 6Department of Experimental Immunology, Barcelona, Spain

Background: While it is known that microbial dysbiosis is associated with the onset of rheumatoid arthritis, mechanistic insights how facilitating the development of arthritis remained largely elusive to date. It is of interest how microbial dysbiosis affects the transition from asymptomatic autoimmunity to arthritis. We speculated that a breakdown of intestinal barrier function caused by microbial dysbiosis allows immune cells to shuttle from the gut to the joints.

Objectives: To test whether intestinal barrier function is impaired before the onset of human RA and experimental arthritis and to seek for evidence that immune cells from the gut migrate to the joints.

Methods: In a longitudinal cohort of RA-at-risk individuals markers of disturbed intestinal barrier function, such as zonulin, were analysed and linked to RA onset. Furthermore, new-onset RA patients were assessed for gut leakiness and their intestinal biopsies for the expression of tight junction proteins and immune cell infiltration. In the murine model of collagen-induced arthritis, sequential analysis of intestinal dysbiosis, intestinal barrier function and arthritis onset was carried out. Additionally, barrier function was assessed on intestinal organoids exposed to faecal supernatants from eu- and dysbiotic mice with and without inhibition of zonulin. Furthermore, three types of interventions restoring intestinal barrier function were carried out for testing their effects on the inhibition of arthritis onset. Finally, photo-converted cells from the gut were traced in the joints to test for gut-to-joint trafficking from the gut to the joints.

Results: Zonulin, a potent regulator for intestinal tight junctions, was elevated in autoimmune mice and men before the onset of arthritis and predicted the onset of human RA. Intestinal barrier functions as well as epithelial tight junctions were decreased before the onset of experimental arthritis and at onset of human RA. In mice, induction of autoimmunity was followed by rapid intestinal dysbiosis followed by gut leakiness before arthritis started. Faecal supernatants of arthritic mice induce epithelial barrier dysfunction in intestinal organoids in zonulin dependent manner. Restoration of the intestinal barrier in the pre-phase of arthritis using butyrate, CB1R agonist or zonulin antagonist larazotide inhibited the development of arthritis. Finally, using photoconvertible mice, gut-borne immune cells were identified that homed to the joints when barrier function was restored.

Conclusion: In summary, these data show the intestinal barrier dysfunction precedes the onset of RA and allows the trafficking of immune cells from the gut to the joints. Targeting of intestinal tight junction function may therefore allow preventing the onset of RA.

MIR-214-3P PROTECTS AGAINST OSTEOARTHRITIS BY DIRECTLY TARGETING NF-κB PATHWAY

Y. Cao1, S. Tang1, X. Nie1, W. Han1, Z. Zhu2, C. Ding1. "Clinical Research Centre, Zhijiang Hospital, Southern Medical University, Guangzhou, China, Guangzhou, China

Background: Osteoarthritis (OA) is a degenerative disease associated with changes in the articular cartilage and bone, severely affecting patients’ mobility and quality of life. Multiple factors including mechanical stress, metabolic alteration and inflammatory mediators are involved in the complex pathogenesis of OA[1]. Interventions targeting these pathogenic factors may contribute to the treatment of OA. MiRNAs are single strand non-coding small RNAs, which are regulated in chondrogenesis and OA[2,3]. Recent studies demonstrated that miRNAs are involved in the regulation of NF-κB signaling pathway by different mechanisms[4]. These interactions suggest that NF-κB related miRNAs may be used as potential biomarkers and drug therapeutic targets in clinical treatment of OA. However, the relationship between miR-214-3p and NF-κB pathway remains poorly understood in OA.

Objectives: This study aimed to test the expression and biological function of miR-214-3p in OA, and explore its mechanism in osteoarthritic chondrocytes.

Methods: Articular primary chondrocytes were isolated from human cartilage samples, which were acquired from patients with end-stage knee OA at the time of total knee replacement surgery (n = 27), according to protocols approved by the Ethics Committee of Zhijiang Hospital. Real time PCR (RT-PCR) and in situ hybridization (ISH) were used to detect the expression of miR-214-3p in OA and non-OA cartilage tissues. Interference of miR-214-3p was conducted using inhibitor, while overexpression of miR-214-3p was performed with mimics. Metabolism of extracellular matrix was detected by RT-PCR, western blotting and immunofluorescence in vitro. Flow cytometry were conducted to determine cell apoptosis. A luciferase reporter assay, was used to evaluate the interaction between miR-214-3p and its downstream target. Human chondrocytes were cotransfected with miR-214-3p and the IKKβ overexpressing plasmid to confirm the interaction between miR-214-3p and NF-κB pathway. For in vivo studies, experimental OA was induced in 12-week-old male C57BL/6J mice by destabilization of the meniscus (DMM) surgery with miR-214-3p agomir intra-articular (IA) injection (once weekly for 12 days) or by IA injection (once weekly for 12 days) of miR-214-3p antiagomir. Mice were sacrificed 10 weeks after the first IA injection, and subjected to histological analyses.

Results: MiR-214-3p was significantly reduced in human OA cartilage. The decreased expression of miR-214-3p in the OA cartilage tissues was directly associated with excessive apoptosis and imbalance between anabolic and catabolic factors of ECM. Mechanistically, we determined that miR-214-3p directly targeted IKKβ/IKKb and thereby suppressed the activation of NF-κB pathway. IKKβ overexpression attenuated the inhibitory effect of miR-214-3p on NF-κB pathway. Furthermore, inhibition of miR-214-3p in mice joints triggered spontaneous cartilage loss and OA development, while IA injection of miRNA-214-3p agomir alleviated OA in the DMM mouse model.

Conclusion: Our results reveal an important role of miR-214-3p in OA progression. MiR-214-3p was down-regulated while IKKβ was upregulated in OA. MiR-214-3p inhibits the NF-κB signaling pathway and suppresses the progression of OA through targeting IKKβ. Thus, miR-214-3p maybe a therapeutic target for OA.

PROGRESS IN SCLERODERMA AND MYOSITIS

PERSISTENT PREMATURE MORTALITY GAP IN IDIOPATHIC INFLAMMATORY MYOPATHY: A GENERAL POPULATION-BASED COHORT STUDY

K. Dalvi1, L. Lu2, A. Ogdie3, A. Aviña4, H. Choi5. 1Massachusetts General Hospital, Rheumatology, Boston, United States of America; 2Arthritis Research Canada, Richmond, Canada; 3Hospital of the University of Pennsylvania, Rheumatology, Philadelphia, United States of America

Background: Idiopathic inflammatory myopathy (IIM) is associated with significant premature mortality; however, whether the mortality gap has improved over recent years is unknown.

Objectives: To determine trends in premature mortality in patients with IIM in a large cohort, representative of the United Kingdom (UK) general population.

Methods: Using The Health Improvement Network (THIN), an electronic medical record database representative of the UK general population, we identified patients with incident IIM between 18 and 89 years of age (defined by at least one Read diagnosis code for dermatomyositis, polymyositis, or interstitial myositis with at least one year of continuous enrollment in THIN prior to the cohort entry date) and up to 10 controls without IIM matched on age, sex, birth year, and database entry year. The cohort was divided in two based on the year of IIM diagnosis: the early cohort (1999-2006) and the late cohort (2007-2014). We calculated adjusted hazard ratios for death using a multivariable Cox-proportional hazards model and adjusted rate differences using an additive hazard model.

Results: The early cohort consisted of 355 patients with IIM and 3182 matched controls, while the late cohort consisted of 396 IIM patients and 3551 matched controls. In both cohorts, IIM patients had excess mortality compared to matched controls [57.4 vs. 15.2 deaths/1000 person-years (PY) in the early cohort and 43.2 vs. 14.1 deaths/1000 PY in the late cohort (Table)]. The corresponding multivariate mortality hazard ratios were 2.73 (95% CI, 1.85 to 4.03) vs. 2.61 (95% CI, 1.75 to 3.89) in the early and late cohorts, respectively (p-value for interaction = 0.63) (Figure). The absolute multivariate mortality differences were 36.8 (95% CI, 20.4 to 52.8) and 25.8 (95% CI, 13.7 to 37.9) deaths/1000 PY, in the early and late cohorts, respectively (p-value for interaction = 0.24).

Conclusion: In this general population-based cohort study, patients with IIM had over 2.5 times the risk of death compared to matched controls, even after adjusting for comorbidities and medications. Unlike trends seen in rheumatoid arthritis and granulomatosis with polyangiitis, there appears to be no improvement in mortality in IIM in recent years. This highlights the need for improved strategies for the management of patients with IIM and its comorbidities.

Table. Association between idiopathic inflammatory myopathy (IIM) and all-cause mortality according to time period.

OP0248 PREMATURE MORTALITY BURDEN FOR SYSTEMIC SCLEROSIS: NATIONWIDE POPULATION-BASED STUDY

E. Yen1, D. Singh1, M. Wu1, R. Singh1. 1UCLA, Los Angeles, United States of America

Background: Premature mortality is an important way to quantify disease burden. Patients with systemic sclerosis (SSc) can die prematurely of disease, however, the premature mortality burden of SSc is unknown. The years of potential life lost (YPLL), in addition to age-standardized mortality rate (ASMR) in younger ages, can be used as measures of premature death.

Objectives: To evaluate the premature mortality burden of SSc by calculating: 1) the proportions of SSc deaths as compared to deaths from all other causes (non-SSc) by age groups over time, 2) ASMR for SSc relative to non-SSc-ASMR by age groups over time, and 3) the YPLL for SSc relative to other autoimmune diseases.

Methods: This is a population-based study using a national mortality database of all United States residents from 1968 through 2015, with SSc recorded as the underlying cause of death in 46,798 deaths. First, we calculated the proportions of deaths for SSc and non-SSc by age groups for each of 48 years and performed jointpoint regression trend analysis3 to estimate annual percent change (APC) and average APC (AAPC) in the proportion of deaths by age. Second, we calculated ASMR for SSc and non-SSc causes and ratio of SSc-ASMR to non-SSc-ASMR by age groups for each of 48 years, and performed jointpoint analysis to estimate APC and AAPC for these measures (SSc-ASMR, non-SSc-ASMR, and SSc-ASMR/non-SSc-ASMR ratio) by age. Third, to calculate YPLL, each decedent's age at death from a specific disease was subtracted from an arbitrary age limit of 75 years for years 2000 to 2015. The years of life lost were then added to yield the total YPLL for each of 13 preselected autoimmune diseases.

Results: 23.4% of all SSc deaths as compared to 13.5% of non-SSc deaths occurred at <45 years of age in 1968 (p < 0.001, Chi-square test). In this age group, the proportion of annual deaths decreased more for SSc than for non-SSc causes: from 23.4% in 1968 to 5.7% in 2015 at an AAPC of -2.2% (95% CI, -2.4% to -2.0%) for SSc, and from 13.5% to 6.9% at an AAPC of -1.5% (95% CI, -1.9% to -1.1%) for non-SSc. Thus, in 2015, the proportion of SSc and non-SSc deaths at <45 year age was no longer significantly different. Consistently, SSc-ASMR decreased from 1.0 (95% CI, 0.8 to 1.2) in 1968 to 0.4 (95% CI, 0.3 to 0.5) per million persons in 2015, a cumulative decrease of 60% at an AAPC of -1.9% (95% CI, -2.5% to -1.2%) in <45 years old. The ratio of SSc-ASMR to non-SSc-ASMR also decreased in this age group (cumulative -20%, AAPC -0.3%). In <45 years old, the YPLL for SSc was 65.2 thousand years as compared to 43.2 thousand years for rheumatoid arthritis, 18.1 thousand years for dermatomyositis, 146.8 thousand years for myocarditis, and 241 thousand years for type 1 diabetes.

Conclusion: Mortality at younger ages (<45 years) has decreased at a higher pace for SSc than from all other causes in the United States over a 48-year period. However, SSc accounted for more years of potential life lost than rheumatoid arthritis and dermatomyositis combined. These data warrant further studies on SSc disease burden, which can be used to develop and prioritize public health programs, assess performance of changes in treatment, identify high-risk populations, and set research priorities and funding.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.2270

OP0249 LONG-TERM EXTENSION RESULTS OF RIO-SSC, A RANDOMIZED TRIAL OF RIOCIUGAT IN PATIENTS WITH EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (DCSSC)

Background: RISE-SSc (NCT02283762) was a multicenter Phase IIb trial of riociguat in pts with early (duration ≤18 months) dcSSc and modified Rodnan skin score (mRSS) 10–22 units. Pts were randomized double-blind to placebo or riociguat 0.5–2.5 mg t.i.d. for 52 weeks. The primary endpoint, mRSS change from baseline to Week (Wk) 52, did not reach statistical significance (p=0.08, riociguat vs placebo), but there were favorable trends in some other outcomes.

Objectives: To present open-label long-term extension (LTE) results of RISE-SSc.

Methods: Pts who completed Wk 52 of double-blind therapy could enter LTE on riociguat. Endpoints included mRSS, adverse events (AEs), and serious AEs (SAEs).

Results: Of 60 pts randomized to riociguat and 61 to placebo, 42 (riociguat–riociguat group) and 45 (former placebo group), respectively, entered LTE. At LTE start, meansSD mRSS was 16.4±3.2 and 16.3±4.2 units, and mean disease duration was 8.9±7.8 and 8.9±5.8 months, in the riociguat–riociguat and former placebo groups, respectively. Other demographics/disease characteristics were also comparable. Median duration of riociguat treatment was 1092 d in riociguat–riociguat pts and 649 d in former placebo pts. Throughout the study, mRSS decreased in both groups (Figure 1). From Wk 52 to last visit, mRSS fell by –3.02±5.51 in riociguat–riociguat patients and –3.96±5.43 in former placebo pts. Rates of mRSS regression (decrease by >5 units and ≥25% from Wk 52 to last visit) and of % declines in mRSS were similar in the two groups (Figure 2). mRSS progression (increase by >5 units and ≥25% from Wk 52 to last visit) occurred in 1 pt (2%) in each group. During the entire study, rescue therapy agents were used in 15 (36%) riociguat–riociguat pts and 17 (38%) former placebo pts. AEs were reported from Wk 52 to last visit in 82 pts (94%): 40 (95%) riociguat–riociguat and 42 (93%) former placebo. Most common AEs overall: nasopharyngitis (24%), gastroesophageal reflux disease (17%), diarrhea (15%), and hypotension (14%). AEs of special interest (dizziness, postural dizziness, or hypotension) occurred in 5 riociguat–riociguat pts (12%) and 4 former placebo pts (9%). SAEs were reported in 21 (24%) pts: 10 (24%) riociguat–riociguat pts and 11 (24%) former placebo pts, with no SAE reported in >1 pt in all 4 SAEs of special interest, and no deaths.

Background: During LTE riociguat treatment, mRSS decreased in both groups from Wk 52 onwards and mRSS progression was uncommon. Riociguat had acceptable safety, similar to the main study, with no new safety signal.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.2270

Efficacy and Safety of Romikilimab in Diffuse Cutaneous Systemic Sclerosis (DCSSC): Randomized, Double-Blind, Placebo-Controlled, 24-Week, Proof of Concept Study

Y. Allanore1, P. Wung2, C. Soubrane3, C. Esperet4, M. Frederic5, R. Bejuit2, A. Lahmar2, D. Khanna1, C. Denton6,1,1 Cochran, Hospital, Rheumatology, Paris, France;Sanofi R&D, Bridgewater, United States of America;Inventiva, Chilly Mazarin, France;University of Michigan, Ann Arbor, United States of America;University College London, London, United Kingdom

Background: Systemic sclerosis (SSc) is a progressive, multi-organ disease with limited treatment options. Interleukin-4 (IL-4) and IL-13 have been implicated in the fibrotic pathway and pathogenesis of SSc and are promising targets. Romikilimab (RKB) is an engineered humanized bispecific Ig-G4 antibody that binds and neutralizes both IL-4/IL-13. We report a Phase IIa randomized, double-blind, placebo-controlled trial (NCT02921971, Sanofi funded) employing RKB in SSc.

Objectives: To evaluate the efficacy and safety of RKB in dcSSc.

Methods: Patients with dcSSc duration ≤36 months, mRSS 10-35, with or without immunosuppressive background therapy were randomized (1:1) to subcutaneous RKB 200mg or placebo (PBO) for 24 weeks and stratified on history of systemic sclerosis (US8247389, EP2331143). Randomization was performed with a difference of -2.31 (1.21) favoring RKB (p<0.002). A primary endpoint was mean change in mRSS at Week 24 and secondary endpoints included time to progression (first event defined as reaching statistical significance).

Results: Ninety-seven patients with similar baseline characteristics between arms, including use of background therapy (RKB 59.2% vs. PBO 52.1%) were randomized. Six (12.2%) and 4 (8.3%) patients discontinued study treatment early in the PBO and RKB arms, respectively. Primary endpoint showed an absolute change in mRSS of -2.45 (0.85) vs. -4.78 (0.86) for PBO and RKB groups, respectively. Subgroup analysis based on background therapy showed a similar treatment effect with a PBO subtracted difference in mRSS of -2.69 (1.83) vs. -2.38 (1.59), suggesting an additive effect between background therapy and RKB. Secondary endpoints did not show a statistically significant difference between RKB vs. PBO arms, although there was numerically less decline in FVC with RKB vs. a PBO subtracted difference of 70ml (p<0.06). Exploratory endpoints suggested possible effect of RKB on overall pain, Raynaud’s, digital ulcers, and EQ-5D-5L. Post-hoc analysis was undertaken to determine time to progression (first event defined as death, ≥10% relative decline in % predicted FVC, ≥15% relative decline in % predicted DLOC, ≥20% increase or +5 in mRSS, or other events: cardiac, SRC, PAH development) and showed a benefit for RKB (HR: 0.47 p=0.04). Adverse events were balanced between the two groups (RKB 83.3% vs. PBO 83.7%). There were 5 and 4 SAEs in the PBO and RKB arms, respectively. One death occurred in each arm (SRC – RKB, cardiomyopathy – PBO).

Conclusion: Patients with dcSSc who were treated with RKB showed a statistically significant reduction in mRSS compared to those receiving PBO. Secondary outcomes were not met, although RKB was associated with a smaller decline in FVC than PBO. Post-hoc analysis showed a possible reduction on time to progression with RKB. RKB was well tolerated with no major safety concerns.

OP0251

THE EULAR SYSTEMIC SCLEROSIS IMPACT OF DISEASE (SCLEROID) SCORE – A NEW PATIENT-REPORTED OUTCOME MEASURE FOR PATIENTS WITH SYSTEMIC SCLEROSIS

1Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2Department of Rheumatology, University Paris Descartes et Cochin Hospital, Paris, France; 3Centre of Rheumatology, Royal Free and University College London Medical School, Royal Free Campus, London, United Kingdom; 4Department of Rheumatology and Internal Medicine, Medical University of Białystok, Białystok, Poland; 5Department of Rheumatology, University of Florence, Florence, Italy; 6Department of Internal Medicine and Rheumatology, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 7Department of Rheumatology and Clinical Immunology, Justus-Liebig University Giessen, Kerckhoff-Klinik Bad Nauheim, Bad Nauheim, Germany; 8Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; 9Department of Health and Social Sciences, Oslo University College, Oslo, Norway

Background: Patient reported outcome measures (PROM) are important for clinical practice and research. Given the unmet need for a comprehensive PROM for systemic sclerosis (SSc), the ScleroID questionnaire was developed by a joint team of patients with SSc and medical experts. This is intended as a brief, specific, patient-derived, disease impact score for research and clinical use in SSc.

Objectives: Here, we present the validation and final version of the ScleroID.

Methods: This EULAR-endorsed project involves 9 European expert SSc centers. Patients fulfilling the ACR/ EULAR 2013 criteria were prospectively included since 05/16 in a large observational cohort study. Patients completed the ScleroID and comparators SHAQ, EQ5D, SF36. They also weighted the 10 dimensions of the ScleroID by distributing 100 points according to the perceived impact on their health. The final score calculation is based on the ranking of the weights. The validation study included a reliability arm and a longitudinal arm, looking at sensitivity to change at follow-up.

Results: Of the 472 patients included at baseline, 109 patients also had a reliability visit and 113 patients a follow-up visit. 84.5% of patients were female, 29.8% had diffuse SSc, mean age was 54.6 years, and mean disease duration 9.5 years. The highest weights were assigned by the patients to Raynaud’s phenomenon, fatigue, hand function and pain, confirming our previous results. The total ScleroID score showed good Spearman correlation coefficients with the comparators (SHAQ, 0.73; EQ5D -0.48; Patient’s global assessment, VAS 0.77; HAQ-DI 0.62; SF36 physical score -0.62; each p<0.001). The internal consistency was good: Cronbach’s α 0.866, similar to SS-HAQ (0.88) and higher than EQ5D (0.77). The ScleroID had a very good reliability: intra-class correlation coefficient 0.839 (ranging 0.608 to 0.788 for the individual items), superior to all comparators. Twenty of 113 patients reported a change in their disease status at follow up. Sensitivity to change: the standardized response mean was 0.34 for the total ScleroID score and highest for lower GI (0.633) and life choices domains (0.521), superior to all other PROM. Figure 1 shows the final ScleroID.

Conclusion: The EULAR ScleroID is a novel PROM designed for use in clinical practice and clinical trials to reflect the disease impact of SSc, showing good performance in the validation study. Importantly, Raynaud syndrome, impaired hand function, pain and fatigue were the main patient reported drivers of disease impact.

CIRCUITLING COLLAGEN TURNOVER MARKERS ARE SPECIFICALLY CHANGED IN VERY EARLY SYSTEMIC SCLEROSIS

R. Dobrota1, S. Jordan1, P. Juhi2, B. Maurer1, M. O. Becker1, C. Mihai3, A. C. Bay-Jensen4, M. Karsdal2, A. S. Siebuhr1, O. Distler1.
1University Hospital Zurich, Department of Rheumatology, Zürich, Switzerland; 2University Hospital Zurich, Department of Rheumatology, Zürich, Switzerland; 3Nordic Bioscience, Herlev, Denmark

**Background:** Timely diagnosis of patients with very early systemic sclerosis (veSSc) is essential for their personalized and optimal management. We hypothesise that changes in serum-based extracellular matrix (ECM) turnover biomarkers are already detectable in patients with veSSc, even before occurrence of specific clinical signs.

**Objectives:** To investigate circulating ECM turnover markers as potential biomarkers for veSSc.

**Methods:** Patients with veSSc, n=42, defined as presence of Raynaud’s syndrome and at least one of puffy fingers, positive antinuclear antibodies or pathological nailfold capillaroscopy, who did not meet any classification criteria for SSc, were compared to healthy controls (HC, n=29). Longitudinal assessment, data and sera collection were conducted by EUSTAR standards. ECM-degradation (BGM, C3M, C4M, C6M) and ECM-formation biomarkers (PRO-C3, PRO-C4, PRO-C5) were measured in serum using ELISA assays. The statistical analyses included Mann-Whitney U, Spearman correlation and ROC analysis. Using Kaplan-Meier plots and univariable Cox regression, we explored if biomarkers can predict progression towards definite SSc (fulfilment of ACR/EULAR criteria or minimum two points increase in the criteria score) during the longitudinal follow-up.

**Results:** Compared to HC, veSSc patients showed a deregulated turnover of type III and IV collagen, with higher degradation (higher C3M, C4M, both p<0.0001 and PRO-C3, p=0.004, Figure 1a, resulting in lower turnover ratios PRO-C3/C3M and PRO-C4/C4M, both p<0.0001). The biglycan degradation biomarker BGM was also higher in veSSc (p=0.006), whereas the degradation biomarker for type VI collagen, C6M, was lower than in HC (p=0.002). In the ROC analysis, biomarkers of type III and IV collagen distinguished between veSSc and HC: C3M, AUC=0.95, p<0.0001; C4M, AUC=0.97, p<0.0001; turnover ratios PRO-C3/C3M, AUC=0.80, p<0.0001; PRO-C4/C4M, AUC=0.97; p<0.0001 (Figure 1b).

Median follow up was 4.5 years (range 0.5-7.9 years), mean age was 50±2.2 years, 88% female gender, 24% with puffy fingers, 92% were ANA positive, 64% had an abnormal capillaroscopy, none had organ involvement or skin fibrosis. 14/42 veSSc patients fulfilled the ACR/EULAR classification criteria at follow-up (time to fulfilment of criteria ranged between 0.5 and 6.8 years from inclusion) and in addition, 18/42 veSSc patients gained at least two classification criteria-points. This resulted in 14, respectively 18 progressors for the longitudinal analysis. However, in univariable Cox regression, the baseline levels of the markers did not predict progression over time.

**Conclusion:** ECM turnover is already altered in veSSc patients compared to HC. Biomarkers of type III and IV collagen distinguished between veSSc patients and HC, which may indicate them as potential biomarkers for the detection of veSSc in addition to the established immunological and capillaroscopic criteria.

A. Watad1, D. McGonagle6, M. Lidor5, N. L. Bragazzi2, D. Comanether3, A. Cohen2, H. Amital1. 1Sheba Medical Center, Department of Medicine B, Rheumatology Unit, Tel Aviv, Israel; 2Leeds Musculoskeletal Biomedical Research Unit, Rheumatology, Leeds, United Kingdom; 3Sheba Medical Center, Rheumatology Unit, Ramat Gan, Israel; 4University of Genoa, Genova, Italy; 5Clalit Health Services, Tel Aviv-Yafo, Israel

**Background:** We previously reported that ANA-negative cases with systemic sclerosis (SSc) and concomitant cancer had a worse survival than ANA-positive cases with associated cancer possibly suggesting that humoral mediated autoimmunity conferred a survival advantage (1). Dermatomyositis (DM) and polymyositis (PM) are two immune-mediated myopathies associated with numerous autoantibodies.

**Objectives:** The present large-scale, population-based study tested the hypothesis that humoral autoimmunity associated with cancer in solid/haematological malignancies impacted on DM/PM patient survival.

**Methods:** Over 2000 cases with either DM or PM were recruited from the Clalit Health Service (CHS) chronic diseases registry, one of the largest healthcare maintenance Israeli organization, serving approximately half of the entire country’s population. Over 10000 matched controls were recruited. The data collected range from 2000 to 2018.

**Results:** Altogether 12,278 subjects were recruited (2,085 cases, and 10,193 controls, 5,042 males, 41.1%, and 7,236 females, 58.9%). Among cases, 1,475 individuals (70.7%) were diagnosed with DM, whereas 610 (29.3%) with PM. Mean age was 47.8±22.51 years, 1,379 cases of cancers (11.2%) were diagnosed. At the univariate analysis and as expected, the rate of malignancies was significantly higher among DM patients compared to PM patients (25.2% vs. 13.5%, p<0.001). Additionally, mortality analysis showed a higher risk for cancer in DM patients compared to PM patients (hazard ratio: 1.81, 95% confidence interval: 1.53-2.14, p<0.001). Among cases with cancer, the risk and survival was significantly lower among ANA-positive cases compared to ANA-negative cases (hazard ratio: 2.18, 95% confidence interval: 1.74-2.74, p<0.001).

**Conclusion:** Our study suggests that ANA-negative cases with systemic sclerosis (SSc) and concomitant cancer have a worse survival compared to ANA-positive cases with associated cancer in solid/haematological malignancies impacted on DM/PM patient survival.
significantly (p<0.0001) higher in DM/PM (n=361, 17.3%) with respect to controls (n=1,018, 10.0%). Concerning prognosis, ANA positivity in PM/DM was associated with a higher risk of cancer development.

2. significant CCSs were found centred around the IFNG region of chromosome 12 in the late phenotype. The top 8 pathways for genetic locations associated to significant CCSs are shown in Table 2.

Conclusion: Significant CCSs, as part of 3D genomic regulatory control, and their associated pathways for the genetic locations, were identified in both late and early phenotypes. There were distinct CCSs in the early phenotype compared to the late suggesting the CCSs change as the disease progresses and varies between phenotypes. If CCSs could be linked to each clinically defined subgroup across a SSc cohort they could be used as a biomarker tool to predict outcome and progression in patients.

**CHROMATIN CONFORMATION SIGNATURE ANALYSIS IN EARLY VS LATE SCLERODERMA PHENOTYPES**

M. Galloway1, E. Hunter2, A. Akoulitch3, V. Vigneswaran4, B. Abdi5, C. Denton1, D. Abraham1, R. Stratton1, 1 UCL Division of Medicine Royal Free Campus, Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom; 2 Oxford Biodynamics Plc, Oxford, United Kingdom

**Background:** Systemic sclerosis (scleroderma, SSc) is a heterogeneous disease in which clinical outcomes vary widely. Predicting outcomes on an individual basis remains challenging despite progress made through autoantibody analysis and gene expression profiling. Effective targeted therapies are evolving and accurately predicting outcomes is important to enable patient stratification for therapy. Chromatin Conformation Signature (CCS) profiling of peripheral blood for systemic epigenetic deregulations could be used for such a purpose. The EpiSwitch platform offering high throughput and resolution chromosome conformation (3C) capture detects significant regulatory changes in 3D genome architecture and maps long range interactions between distant genomic locations. This then reveals the spatial disposition and physical properties of the chromosome, such as chromatin loops and inter-chromosomal connections, which have a role in network organization and genetic epistasis controlling gene expression. EpiSwitch automated platform has been successfully utilised in patient stratification in RA, MS and other indications.

This methodology could be applied to patients with SSc to identify CCS associated with different phenotypes and may ultimately be used to stratify and identify patients into pathogenic subtypes.

**Objectives:** We aimed to determine significant CCSs associated with early and late phenotypes of SSc.

**Methods:** The EpiSwitch-based chromosome conformation capture (3C) method was applied to blood samples from early phenotype, and late phenotype SSc patients. Intact nuclei were isolated from peripheral blood mononuclear cells and subjected to formaldehyde fixation resulting in crosslinking between physically touching segments of the genome via contacts between their DNA bound proteins. For quantification of cross-linking frequencies, the cross linked DNA was digested and then subjected to ligation. Cross-linking was then reversed and individual ligation products detected and quantified by EpiSwitch custom oligo array annotated across the whole genome to the anchoring sites of 3D genome architecture.

**Results:** 7 significant CCSs were found over the HLA-C, HLA-B and TNF regions on Chromosome 6 in the early phenotype. The top 8 pathways for genetic locations associated to the CCSs are shown in Table 1.

**USING AN EDUCATIONAL APPLICATION TO FACILITATE UNDERSTANDING OF THE ANATOMY AND FUNCTION OF THE BRAIN AND TO EXPLORE THE EFFECTS OF CLINICAL FATIGUE FROM A PATIENT PERSPECTIVE**

J. Zurowski1, C. Wright2, N. Basu2, M. Poyade3, L. Bennett3, 1The Glasgow School of Art, School of Simulations and Visualisation, Glasgow, United Kingdom; 2University of Glasgow, Institute of Infection Immunity and Inflammation, Glasgow, United Kingdom

**Background:** Rheumatic and musculoskeletal diseases are a group of devastating autoimmune disorders that all commonly share the debilitating symptom of fatigue. Despite the fact that fatigue can often cause some of the greatest impairments to quality of life, it is frequently reported by patients as the least successfully managed symptom of these conditions. Fatigue is routinely misunderstood within the general population, with many people using the word fatigue as a synonym for tired. Fatigue is not the same as tiredness, which is a normal state that is experienced by most of the population, therefore it is important to help the general public understand what fatigue actually is and how it imposes consequences and limitations on those who suffer from it. To aid this understanding an educational application has been created to reinforce the patient perspective of living with fatigue. Furthermore, this application will also aid the understanding of brain anatomy and function, using Augmented Reality (AR), as research has now shown that brain function may be altered in the state of fatigue. Currently, educational AR applications show great potential for increasing comprehension and understanding of complex concepts. AR expands user engagement by enhancing the learner’s enjoyment and enriching their learning environment. We hope to utilise this technology in the education of fatigue.
Objectives: We aimed to create an AR application that has informative content designed to educate users on the topics of basic brain anatomy and function. Furthermore, we aimed to increase the users understanding of the complete impairment of fatigue by creating a short video that describes living with fatigue from the patient’s perspective.

Methods: The application was created using medical scan dataset, a variety of 3D modelling software, and a game engine to create a functional and interactive augmented application. The short video regarding a patient's perspective on living with fatigue was developed in collaboration with the Glasgow Arthritis Involvement Network patient partners. In order to determine if the application met its primary objectives a pilot test was conducted on 14 participants. After consenting to taking part in the study, individuals were guided through a pre-application test, the use of the application itself and finally a post-application test.

Results: Initial results from the pilot test showed promise in the educational potential of the application. With regards to the questions pertaining to the brain anatomy, the percentage of questions answered correctly increased from 36% in the pre-test to 60% in the post-test. Furthermore, after using the application the participants reported a significant increase in their confidence for their opinion regarding the nature of fatigue.

Conclusion: This research explored the development and effectiveness of an AR application that was centered around fatigue and basic neuroanatomy education within the general population. From the pilot test conducted we are able to report that the application was successful in delivering educational material about brain anatomy and was successful in increasing awareness about the impact that fatigue can have on an individual’s quality of life.

Background: Animal-Assisted Interventions (AAI) is the new way to indicate what was previously known as “Pet Therapy”, as activities can be done either with the conventional “pets” (dogs, cats and rabbits) or with horses and donkeys. Children with JIA have several problems in terms of adherence both due to the atavistic fear of the needle and due to nausea and vomiting - the most important side effects of Methotrexate – often since the 2-3 days before the assumption to immediately after it.

Sure that animals can help children to forget this fear and to avoid the psycholog-ical conditions which enhance nausea, for the first time in Italy (and probably in Europe) it was designed a specific AAI program for these children.

Objectives: To promote a general state of psycho-physical well-being in children and families about: manage therapy; reduce discomfort and anxiety caused by entering hospital; improve self-esteem and the response to the stress generated by the execution of therapy and disease management; strengthen communication and socialization; stimulate the affective area through the activities of animal care.

Methods: Dogs and cats are part of the recreational activities once a week in an equipped area in the OIRM Hospital (no alternative gateway was needed). Paediatric Rheumatologists selected two different groups of children: the first one (5 children in the pilot study) every 15 days; the second one (5 children) every month; the selection was made looking at the therapeutic scheme.

Every session, one hour, has 3 clearly distinct stages:

Welcome and organization: children say hello to dogs and cats, open the toolkits specifically designed for the intervention, express their state of mind and are encouraged to tell their own stories.

Therapy: parents prepare and inject the drug to their children under medical or Health Professional control without discontinuation of the activities with animals.

Play and socializing: children are involved in petting and other activities with animals; they are also involved in manipulative activities (design, puppets shows, modelling clay, animal care, ball retrieving, etc). This step has the aim to relieve stress and discomfort due to medical procedures.

Visual Analogic Scales (VAS) were part of the toolkit, to let the researchers evaluate the effects of the activity directly from the children experience.

For the first time, we will control also the animal health status and wellness condition monitoring behavioural parameters and salivary cortisol level during each session.

Results: The pilot project started in October 2019 and nowadays we closed 12 meetings, 4 on October, 4 on November, 3 on December and 2 on January, with the participation of 2 dogs (Golden and Labrador Retriever) and 1 cat (Devon Rex) in each one.

All children love to play with animals, seek their closeness at the time of therapy and enjoy playing all together with the dogs; no one cry or refuse therapy and, since the third session, no one has nausea before, during or after the injection. Parents have reached a certain level of confidence: they stay quietly in the waiting room or go away to have a drink or to run an errand (it becomes a moment of relaxing for them too).

Animals remain in healthy and wellness conditions during the activity.

Conclusion: These preliminary data seem that AAI to be useful in helping patients in JIA to overcome some problems related to their pathology.

DOI: 10.1136/annrheumdis-2020-eular.4899
Objectives: The prevalence of limited health literacy (i.e. cognitive and social resources of individuals to access, understand and apply health information to promote and maintain good health) in the Netherlands is estimated to be over 36% [1]. Access to and outcomes of rheumatological care may be compromised by limited patient health literacy, yet little is known about how to address this, thus action is required. As influencing individual patients’ health literacy in the rheumatology context is often unrealistic, it is paramount for the health system to be tailored to the health literacy needs of its patients. The OPtimising HEalth Literacy and Access (Ophelia) process offers a method to inform system change [2].

Background: The prevalence of limited health literacy is high in the Netherlands and patients with rheumatic conditions may experience challenges in accessing and understanding health information provided by healthcare professionals [3]. Limited health literacy can lead to suboptimal care and worse health outcomes [4].

Patients with RA, SpA and gout attending outpatient clinics in three centres in the Netherlands completed the Health Literacy Questionnaire (HLQ) to assess their health literacy. Three researchers jointly examined 24 cluster solutions for meaningfulness by interpreting HLQ domain scores and patient characteristics. Meaningful clusters were translated into health literacy profiles using HLQ patterns and demographic data. A patient research partner confirmed the identified profiles. Patient vignettes were developed using qualitative patient interviews. The vignettes were used in two two-hour co-design workshops with rheumatologists and nurses to discuss their perspective on health literacy-related challenges for patients and professionals, and generate ideas on how to address these challenges.

Methods: Patients with RA, SpA and gout attending outpatient clinics in three centres in the Netherlands completed the Health Literacy Questionnaire (HLQ) and questions on socio-demographic and health-related characteristics. Hierarchical cluster analysis using Ward’s method identified clusters based on the nine HLQ domains. Three researchers jointly examined 24 cluster solutions for meaningfulness by interpreting HLQ domain scores and patient characteristics. Meaningful clusters were translated into health literacy profiles using HLQ patterns and demographic data. A patient research partner confirmed the identified profiles. Patient vignettes were developed using qualitative patient interviews. The vignettes were used in two two-hour co-design workshops with rheumatologists and nurses to discuss their perspective on health literacy-related challenges for patients and professionals, and generate ideas on how to address these challenges.

Results: In total, 895 patients participated: 49% female, mean age 61 years (SD:10.5), 25% lived alone, 18% had a migrant background, 6.6% did not speak Dutch at home and 51% had low levels of education. Figure 1 shows a heat map of identified health literacy profiles, displaying the score distribution per profile across nine health literacy domains. Figure 2 shows an excerpt of a patient vignette, describing challenges for a patient profile number 9. The workshops were attended by 7 and 14 nurses and rheumatologists. Proposed solutions included health literacy communication training for professionals, developing and improving (visual) patient information materials, peer support for patients through patient associations or group consultations, a clear referral system for patients who need additional guidance by a nurse, social worker, lifestyle coach, pharmacist or family doctor, and more time with rheumatology nurses for target populations. Moreover, several system adaptations to the clinic, such as a central desk for all patient appointments, were proposed.
and so we did. In the end, the Academic Board accepted our proposal. The program runs on students in the fourth Academic Year, in small groups, and on the premises of the school. The other one with postgraduate Medical Students didn’t accept the proposal of our program, with the justification that as a department of a foreign Medical school, they couldn’t implement anything in the students program. So far, more than 10 trainings have been conducted. At the end of the first year that the program was implemented, the Medical School asked from the organisation for a Patient Instructor to take part at the Musculoskeletal Examination and be a model for the Examining. Seeing our success, and taking into consideration the students’ evaluation of the program, especially the fact that 95% of them said, ‘It was very important for them to have a Patient Expert Program during their studies’ our organisation decided to expand our collabora-
tion with more Healthcare Professions Universities. Our original goal had been to collaborate with one of the medical schools/universities, but now we have bigger plans. Now we want this program to be established in all the universities in the country with the Patient Expert RMD’s program implemented in all health professions curricula.

Conclusion: The importance of the Patient Expert in RMD’s is unquestionable. Patient Expert Program is an excellent tool to raise awareness on RMD’s. Also it is very helpful for the Medical or Health care Professionals student as it can help them better understand the disease and the patients. The success of the program is giving motivation to the organisation to expand and improve the program. It also shows the significance of the program for the next generation of Physicians and Healthcare Professionals. Our organisation is leading in patient centered care and is proof that making the patient the most important is the target of treatment for RMD’s in our country.

Background: There is a lack of awareness of paediatric rheumatic diseases (PRDs), among the public, and certain groups of healthcare professionals, such as general practitioners [1]. To help improve awareness and understanding of PRDs, World Young Rheumatic Diseases Day (WORD Day) was established in 2019.

Objectives: The aim of WORD Day, which took place on 18 March 2019, was to raise awareness of PRDs, while informing young people, families, healthcare professionals, teachers, and the public about the importance of timely referral when it featured material designed by and with young people with PRDs. It was demonstrated that awareness events can often be resource-light and easily implemented across a range of diverse countries. It is anticipated that the global reach of WORD Day will increase over time as the campaign becomes more established.

Acknowledgments: PReS for their financial support.

Background: Since the establishment of ORS, we have been organising different activities for rheumatic diseases patients and their supporters within our five branches. After celebrating our 10th anniversary in 2017 we were keen to expand and improve our activities, learning from an organisation with long tradition, in order to strengthen our position and to start reaching another level – growing from a small to a medium-sized organization in the next three years. The main source of our income were the pharmaceutical companies (94%). We wanted to reduce their contribution to our budget by 20% in the next three years. We had established good cooperation with two medical high schools and we would like to consider cooperation with a medical faculty. We were keen to gain insight into the Patient Expert Programme (PEP) project that Swedish Rheumatism Association had developed and hoped to then begin and steadily develop

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.163
successful cooperation with target institutions in Serbia in the next years. We would like to improve the cooperation with medical faculties and become a part educational program. And the PEP was the best way to achieve this aim.

**Objectives:** The aims of this knowledge transfer programme were for us to:

1. **Funding**
   - Learn how to gather more voluntary contributions of money and other resources. Following the knowledge transfer visits we will organise a seminar to disseminate information with the representatives of all our branches. After the seminar our activists will have been trained to collect money for different activities. Those activities will attract more members and provide better life for people with RMDs.

2. **Patient Expert Program**
   - Implement the Patient Expert Program. The implementation of this program would strengthen the connections with medical institutions, provide first-hand knowledge for future doctors, provide better care for RMDs patients in the future. The PEP will allow the organization to collaborate closer with the universities, the doctors, researchers, health professionals.

3. **Cooperation among sister organisations**
   - Develop strong relationships with the sisters EULAR organisations.

**Methods:** From 4th September – 8th September 2018 we visited Swedish Rheumatism Association in Stockholm in order to gain insight into the structure and activities of their association. 

From 14th October-16th October 2019 Swedish delegation (president, two trainers) visited Serbian association for rheumatic diseases. It was organized the two-days PEP training as well as the visits to relevant institutions. From 23th January-26th January 2020 two trainers from Sweden came to Serbia in order to hold the exams.

**Results:** Association of Rheumatic Diseases Patients of the Republic of Serbia now has six Patient Experts for RA. They will be involved in the education of future doctors through the lectures within the subject Intern Medicine.

ORS improved cooperation with Faculty of Medicine in Belgrade, as well as, with Ministry of Health.

**Conclusion:**
- We achieve to have six Patient Experts. Unofficially right now we have confirmation how they will be included in the education of future doctors through the lectures within the subject Intern Medicine in next school year at the Belgrade University.
- We reduced contribution of the pharmaceutical companies of our income for 10% to our budget.
- We increased donations from personal donors in past year.

**BIOSIMILAR SWITCHING PROCESS - UK PATIENTS’ EXPERIENCE STUDY**

C. Jacklin 1, A. Bosworth 2 on behalf of Sally Dickinson, Helen McAteer, Alisa Bosworth, Sarah Berry, Clare Jacklin, 1 National Rheumatoid Arthritis Society, Maidenhead, United Kingdom; 2 National Rheumatoid Arthritis Society, Maidenhead, United Kingdom

**Background:** The introduction of 4 adalimumab biosimilars was challenging for the health service and patients alike. A group of patient organisations representing rheumatology, dermatology and gastroenterology patients worked with NHS England in producing materials for disseminating information to prescribers and patients to ensure smooth and appropriate transition to biosimilar products from the originator product as appropriate. These patient groups wanted to know how the switch process was implemented and if shared decision making was practiced.

**Objectives:** To gather patient feedback on biosimilar switch process and report findings back to NHS England as well as provide the patient organisations information to develop new future resources to help improve patient and physician shared decision making.

**Methods:** A working group of the 4 organisations collaborated on designing an online survey asking questions around how the individual was communicating with regarding their treatment being switched to a biosimilar; was there any choice or perceived input into the decision making process; how queries or issues were handled and overall satisfaction on how the individual felt their personal preferences/needs were met.

**Results:** 899 usable responses were gathered representing 52% rheumatology patients; 42% gastroenterology patients and 5% dermatology patients remaining 1% more complex specialties. More than half of patients were not asked for their consent before their treatment was switched to a biosimilar of adalimumab with only 40% giving consent 7% couldn’t remember or were unsure if consent was given. 75% were not at all satisfied or not satisfied with the ability to decline being switched with only 12% feeling that they had been given an option to decline being switched.

**Conclusion:** Shared Decision Making (SDM) needs to be put into action not just words. There is a clear majority that are dissatisfied with the communication they had prior to the switch and are very dissatisfied with the lack of patient involvement in the decision-making process. NRAS, NASG, Crohn’s & Colitis UK and the Psoriasis Association will continue to collaborate with NHS England and other stakeholders as appropriate to make Shared Decision Making a reality not just rhetoric.

**Disease consequences**

**OP026-HPR COST OF ILLNESS IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS. COEPSO STUDY**

**Background:** Psoriasis (Ps) and psoriatic arthritis (PsA) have a major impact on patients’ health-related quality of life. Cost of illness of patients with Ps, PsA and both diseases (PsA+Ps) is an important subject as they are associated with a substantial economic impact, with implications from a health management perspective.

**Objectives:** To describe the economic burden of direct non-healthcare and indirect resources of patients with Ps, PsA and PsA+Ps in Spain.

**Methods:** COEPSO (“Evaluation of Costs in patients with Psoriatic Disease”) was an observational, retrospective, cross-sectional study performed in 22 Spanish centers (17 Dermatology and 14 Rheumatology Services), from February 2017 to February 2018, including moderate to severe Ps and PsA patients (with or without Ps), naive to biologics. Direct non-healthcare (social services, home care, physical adaptations, private health and non-health professionals, non-reimbursed and non-pharmaceutical therapies), indirect (loss of productivity) and total costs (direct non-healthcare and indirect costs) related to the disease during the previous year to the study were obtained. Unitary costs (€, 2018) were calculated: out-of-pocket costs were specified directly by patients and loss of productivity costs by means of average salaries based on occupation specified by patients. The information was collected through a case report form filled out by the investigators and a telephone survey administered to the patients.

**Results:** A total of 318 patients were included (196 Ps; 43 Pa and 79 PsA+Ps), mean age 48.7 years and 51.3% males. Metabolic syndrome was the most frequent comorbidity in all groups. The average annual total cost per patient was 1,042.71€ (SD 3,817.55), 1,247.56€ (SD 4,467.19) for Ps, PsA and PsA+Ps, respectively. The average annual indirect non-healthcare care cost per patient was 749.57€ (SD 2,393.77), 750.50€ (SD 1,641.82) and 1,247.56€ (SD 4,467.19) for Ps, PsA and PsA+Ps, respectively. The average annual indirect cost per patient was 293.14€ (SD 2,855.27), 387.35€ (SD 1,247.56€) and 1,042.71€ (SD 3,817.55), 1,137.84€ (SD 3,070.39) and 1,830.26€ (SD 5,835.81) for Ps, PsA and PsA+Ps, respectively. Patients with combined PsA+Ps had higher annual total cost (direct non-healthcare and indirect costs) than patients with only one of these manifestations separately (75.5% and 60.9% among patients with Ps and PsA, respectively). Total costs in patients with Ps and PsA were similar. Direct non-healthcare costs represent between 86.0% (patients with PsA) to 71.9% (patients with Ps) of total cost. Indirect costs represent between 28.1% (patients with Ps) to 34.0% (patients with PsA) of total cost.
Conclusion: PsA and Ps have proved to be diseases with a high economic burden, and the total costs were mainly driven by direct non-healthcare costs. Moreover, although annual total costs in patients with PsA were similar to those of Ps patients, the combination of both manifestations yielded the highest costs, suggesting the importance of the increased disease load.

CP0263-HPR MAJOR STRESSORS IN THE YEAR PRIOR TO RA DIAGNOSIS: IMPACT ON PATIENT-REPORTED OUTCOMES ONE YEAR LATER

N. Andersen1, O. Schiér2, M. F. Valois3, G. Boire4, J. Pope5, G. Hazlewood6, L. Bessette7, C. Hitchon8, D. Tin9, C. Thorne10, E. Keyesman11, V. Bykerk12, S. J. Bartlett on behalf of CATCH Investigators. 1McGill University, Montreal, Canada; 2University of Toronto, Toronto, Canada; 3University of Sherbrooke, Sherbrooke, Canada; 4Western University, London, Canada; 5University of Calgary, Calgary, Canada; 6University of Laval, Quebec City, Canada; 7University of Manitoba, Winnipeg, Canada; 8Southlake Regional Health Centre, Newmarket, Canada; 9Hospital for Special Surgery, New York, United States of America

Background: Stress is implicated in RA onset and poor prognoses through changes in neuro-endocrine and autoimmune function. Although many people with RA link disease onset to recent stressful life events, results from retrospective studies are unclear.

Objectives: To describe the incidence of major stressors (+STRESS) in year prior to diagnosis and compare characteristics and patient-reported outcomes (PROs) of newly diagnosed RA patients with and without +STRESS at year 0 and 1 year thereafter.

Methods: Data were from early RA patients (symptoms <1 yr) enrolled in the Canadian Early Arthritis Cohort (CATCH) from 2007-2010 ACR/EULAR criteria and had ≥12 months of follow-up. Patients reported major psychological (death, divorce/separation, family, financial, other) and physical (motor vehicle accident, surgery, major illness/infection, other) stressors in previous year. We used independent t-tests and chi-square to compare characteristics by stressors at baseline, and multivariable regression to examine the impact of +STRESS on disease activity and PROs at 1 year, adjusting for age, sex, education, fibromyalgia, and SJC.

Results: The 1933 adults were mostly female (72%), with a mean (SD) age of 55 (15) years. 52% reported ≥1 stressors in previous year; family (48%), financial stress (36%), death (35%), surgery (28%), and major illness (26%) were the most common stressors. Patients with +STRESS were more likely to be women, younger, have more comorbidities including fibromyalgia, and higher mean age. Mean (SD) or N (%) No Stress Physical Psychological Both

Background: There is considerable interest within the medical research community in the identification of individuals at risk of developing rheumatoid arthritis.
(RA), to identify those who may benefit from preventive interventions. However, it is important to understand the views of those who may be candidates for such predictive tests, to inform the development of effective approaches. First degree relatives (FDRs) of patients with RA are at an increased risk of developing RA. RA patients can provide access to FDRs. Qualitative investigations have explored the views of these groups about predictive testing for RA, but quantitative approaches are needed to develop a robust understanding.

**Objectives:** To identify predictors of interest in predictive testing for FDRs and patients, and to assess the likelihood of patients communicating information about RA risk to their FDRs.

**Methods:** Surveys were completed by 482 RA patients and 397 of their FDRs. Patients were invited to complete the survey and to provide another to their relatives. Spearman’s Rank Correlations were used to assess relationships between interest in predictive testing/likelihood of risk communication and potential predictor variables.

**Results:** FDRs had a median age of 41 years, 64% were female. 57% were definitely interested and 36% were probably interested in taking a predictive test for RA. Several predictors were found to be associated with interest (Table 1).

**Table 1. Spearman’s correlations for relatives’ and patients’ interest in predictive testing.** After applying a Bonferroni adjustment, p values were taken as statistically significant at p<0.003.

Table 1. Spearman’s correlations for relatives’ and patients’ interest in predictive testing.

**Conclusions:** Interest in predictive testing for RA was high amongst FDRs, and factors including information seeking preference, RA risk perception, concern about RA, perceived consequences of RA and health anxiety were significantly associated with interest. Patients were also willing to communicate information about RA risk to their children. These findings increase understanding of perceptual variation in those at risk of RA, and will inform the development of information to support decision making in individuals considering predictive tests and preventive interventions. We are currently extending this preliminary analysis by building multivariate models incorporating a range of attitudes about predictive testing, assessing predictors of patients’ likelihood of communicating to their FDRs about risk, and the relationship between patients’ and FDRs’ responses.

**FACTORS ASSOCIATED WITH MEETING WORK DEMANDS FOR INDIVIDUALS WITH RHEUMATIC DISEASES**

D. Connolly1, C. Fitzpatrick1, L. Otoole1, F. O’shea1, M. Moran2. 1Trinity College Dublin, Occupational Therapy, Dublin, Ireland; 2St James’ Hospital, Rheumatology, Dublin, Ireland

**Background:** Almost 65% of individuals with rheumatic diseases have severe fatigue with the majority of these reporting difficulties in work leading to absenteeism and early retirement. However, there is a lack of research investigating how different types of fatigue impact on work ability.

**Objectives:** To identify the prevalence of different types of fatigue and explore the association between different types of fatigue and various demands involved in work.

**Methods:** A cross-sectional study was carried out with 234 individuals with rheumatic diseases currently in employment. Study measures examined demographics, different types of fatigue (general, physical reduced activity, reduced motivation and mental), ability to meet work demands, disease activity and quality of life.

**Results:** The majority of participants were female (70%), had rheumatoid arthritis (42.7%), were between 41-50 years (30.3%) and worked full-time (70%). One hundred and twenty-eight participants (55%) had severe fatigue. Physical fatigue was the most prevalent category of fatigue (Table 1). Participants reported managing 50% of their work demands with physical demands being the most challenging (Table 1). All types of fatigue were significantly associated with the total WRF score (Table 2). Mental fatigue had the strongest association with the total WRF score (r=0.53, p<0.001). On examining the impact of different types of fatigue on meeting work demands, mental fatigue was the most significant predictor of difficulty meeting work demands (β=1.6, SE=0.37, p<0.001).

**Conclusion:** Fatigue interferes with many aspects of work performance. However, this study identifies that mental fatigue is the greatest predictor of difficulty in managing work. Self-management interventions focusing on mental fatigue and work ability are required for individuals with rheumatic diseases to manage the demands of their work.

**WORK PRODUCTIVITY IN PATIENTS WITH AXIAL AND PERIPHERAL SPONDYLOARTHRITIS**

**Objectives:** To analyse the association between different types of fatigue and work demands in patients with axial and peripheral spondyloarthritis.

**Introduction:** Fatigue is the most common symptom in patients with spondyloarthritis. It is associated with reduced productivity and work ability. Self-management interventions focusing on fatigue and work ability are required for individuals with spondyloarthritis to manage the demands of their work.

**Methods:** A cross-sectional survey was carried out in three rheumatology centres in Spain and Argentina. The study population included patients with axial and peripheral spondyloarthritis, aged 18-70 years. The survey was completed by 234 patients with axial and peripheral spondyloarthritis. The survey measured demographics, different types of fatigue (general, physical reduced activity, reduced motivation and mental), disease activity and quality of life.

**Results:** The majority of participants were female (70%), had rheumatoid arthritis (42.7%), were between 41-50 years (30.3%) and worked full-time (70%). One hundred and twenty-eight participants (55%) had severe fatigue. Physical fatigue was the most prevalent category of fatigue (Table 1). Participants reported managing 50% of their work demands with physical demands being the most challenging (Table 1). All types of fatigue were significantly associated with the total WRF score (Table 2). Mental fatigue had the strongest association with the total WRF score (r=0.53, p<0.001). On examining the impact of different types of fatigue on meeting work demands, mental fatigue was the most significant predictor of difficulty meeting work demands (β=1.6, SE=0.37, p<0.001).

Background: Work disability is an important outcome in the treatment of Spondyloarthritis (SpA) since this disease affects people in the most productive stage of life.

Objectives: The aim of this study is to investigate the working status and the factors associated with work productivity loss (WPL) in patients with axial SpA (axSpA) and peripheral SpA (pSpA).

Methods: Patients with SpA according to ASAS criteria were included consecutively in this multicentric cross-sectional study. Evaluation of activity through a visual analogue scale (0-100), enthesitis (LEI), functional capacity (HAQ and BASFI), disease activity (DAS28 and BASDAI), health status (ASAS Health Index) and quality of life (ASQoL) were calculated. The Ankylosing Spondylitis Disease Activity Score (ASDAS) was recorded. The Work Productivity and Activity Impairment Spondyloarthritis (WPAI SpA) questionnaire was used to assess work productivity.

Spearman’s correlation coefficient (p) was used to assess the correlation with the percentage of WPL.

Results: 274 patients with SpA were recruited, 129 (47.1%) with axSpA and 145 (52.9%) with pSpA. 56.6% were women and 33.2% stopped working due to the underlying disease.

Among axSpA patients, 70% were radiographic and 30% non radiographic, mean age 45.5 (SD 14) yrs, median disease duration 72 (IQR 36-144) months and diagnosis delay 20 (IQR 11-70) months. 45.7% were employed, median hours worked in the last week was 40 (IQR 25-45), median scores for absenteeism was 0% (IQR 0-2), presenteeism 30% (IQR 5-40), WPL 30% (IQR 10-52.5) and activity impairment 30% (IQR 10-50). A positive correlation was found between WPL and the following variables: HAQ (p<0.01), BASDAI (p<0.01), ASASDAS (p<0.01), BASFI (p<0.01), ASQoL (p<0.01), LEI (p<0.01), and ASAS health index (p<0.01).

Among pSpA patients, mean age was 52.3 (SD 13) yrs, median disease duration 60 (IQR 14-120) months and diagnosis delay 12 (IQR 3-24) months. 46.9% were employed, median hrs worked in the last week was 30 (IQR 14-40), absenteeism 0% (IQR 0-7), presenteeism 30% (IQR 2.5-58), WPL 30% (IQR 5-52) and activity impairment 20% (IQR 0-40). A positive correlation was found between WPL and: HAQ (p<0.01), BASDAI (p<0.01), ASASDAS (p<0.01), BASFI (p<0.01), ASQoL (p<0.01), LEI (p<0.01), and ASAS health index (p<0.01).

Conclusion: Our study showed that WPL in this national cohort was 30% in both groups of patients and is associated with disease activity, enthesitis, health status, quality of life and functional ability.

OP0268-HPR

RHEUMATOID DISEASE PATIENTS’ PREFERENCES IN ADVERSE DRUG REACTION INFORMATION REGARDING BIOLOGICS

G. Weihs1, L. Kosse1, H. Vonkempen2, P. Spuls3, B. Van den Bermt4, S. Tas5, P. Hoentjen6, M. Nurmohamed7, M. Van Doorn7, E. Van Puijenberg7, N. Jessurun7, F. Van Rossum8, E. Van Puijenbroek9, 10

Background: Patient-reported outcomes (PROs) are increasingly used in studies and medical practice to obtain information on patients’ perspectives towards their treatment or disease. However, study outcomes are primarily directed at and shared with healthcare professionals, even though the results may also be relevant for patients.

Objectives: The objective of this study was to obtain insight in which results patients with immune-mediated inflammatory diseases (IMIDs), including inflammatory rheumatic disease patients, prefer to receive after participating in the Dutch Biologic Monitor.

Methods: The Dutch Biologic Monitor is a PRO-based prospective cohort event monitoring study focused on adverse drug reactions (ADRs) [1]. A survey was conducted among the participants of the Dutch Biologic Monitor who wanted to be informed about the results. Patients’ preferences were identified using twelve statements and rated with five-point Likert-type scales. Averages described the preference per statement. Preference for the results per IMID or altogether was calculated using Mann-Whitney U Test.

Results: Respondents (N=501, response rate 67%) preferred per IMID over aggregated results (p<0.001). Information on whether patients with the same IMID experience ADRs (average 4.5), which biologics are most likely to cause ADRs (4.4) and whether the ADRs subside or disappear (4.4) were regarded as most interesting. Outcomes of patients with other IMIDs (3.5), patient characteristics (3.7) and injection site reactions (3.8) were least interesting.

Figure 1. The preferences of patients on the communication of the reported adverse drug reaction information resulting from the Dutch Biologic Monitor.

Conclusion: Participants of the Dutch Biologic Monitor use that a biologic for their IMID prefer to receive ADR information tailored to their own biologic and IMID. Furthermore, they want to obtain insight in the course of ADRs. Therefore, we advocate to generate disease-specific information on ADRs for IMID patients.

Background: Systemic sclerosis (SSc) is a multisystem autoimmune disease of complex etiopathogenesis, heterogeneous in its phenotypic expression and with a limited prognosis (1). The loss of muscle mass is a serious consequence of many chronic diseases and also is observed in SSc (2). This body composition alterations results in weakness, limitations and physical disability (3). SARC-F simple questionnaire, validated, is a key diagnostic feature for the fast assessment of geriatric syndromes associated with skeletal muscle wasting. However, there is no data about the SARC-F in SSc.

Objective: To assess the association between Sarcopenia-Score Questionnaire clinical features in patients with systemic sclerosis (SSc).

Methods: Ninety-four patients diagnosed with systemic sclerosis were recruited and evaluated. Sarcopenia was assessed by the SARC-F questionnaire. Clinical features as disease duration time, comorbidities, body mass index (BMI), functional capacity by the Health Assessment Questionnaire (HAQ), inflammatory markers (C-reactive protein (CRP), erythrocyte sedimentation rate (ESR)), creatine phosphokinase (CPK), hemoglobin, creatinin and albumin) were medical record. Frequency analysis, descriptive analysis and Pearson's correlation were performed. Statistical significance was considered as p<0.05.

Results: Of the 94 patients analyzed, most were women (87/94;92.6%) with mean age of 60.5±10.3 years, median disease duration time of 11.2 (7.5-18.9) years and median number of comorbidities was 1.00 (1.00-2.00). The mean of BMI was 25.9±4.7 Kg/m². Twenty-one of the patients were classified as active or passive smokers, thirty-five said they were former smokers and thirty-eight were non-smoked. Sixty-nine (80.2%) out of the ninety-four patients in the study had at least one type of comorbidity (mean 1, 44±1, 04). Eighty-three patients (88.3%) showed a SARC-F score without signs suggestive of sarcopenia (0-5) and eleven patients (11.7%) showed suggestive to sarcopenia (6-10). In HAQ, fifty-seven (60.6%) patients had mild incapacity, thirty-five (37.2%) had moderate incapacity, and two patients (2.2%) had severe incapacity. Higher SARC-F scores were associated with greater number of comorbidities (r=0.2; p=0.027), higher physical disability by HAQ (r = 0.5;p=0.000) and lower albumin levels (r=-0.3; p= 0.048). On other hand, SARC-F was not associated with time of diagnosis, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), creatine phosphokinase (CPK), hemoglobin, creatinin and creatinine.

Conclusion: SARC-F scores were associated with comorbidities, physical disability and lower albumin levels in systemic sclerosis patients. Considering that comorbidities, physical disability and the albumin deficit enhances the patient's muscle loss, SARC-F appears to be a good tool to screen sarcopenia risk factors in systemic sclerosis patients. Longitudinal studies are necessary to validate the SARC-F questionnaire in this population.

Objectives: Given the heterogeneity of the patient population with rheumatic irAEs, a registry-based study has been conducted to provide first evidence regarding characteristics of rheumatic irAEs and further insights into the optimal diagnostic and therapeutic management of rheumatic irAEs.

Methods: The TRHeuMa registry is a long-term, open-end observational study of a patient cohort suffering from rheumatic symptoms as a result of ICI or other cancer therapies. The TRHeuMa registry is one of the three subregistries of the MaHeuR project, a registry-based study initiated in July 2016 at the university hospital Heidelberg to explore interrelations of malignancies and RMDs.

Results: Over 18 months, 52 of 63 patients in the TRHeuMa registry were recruited with a rheumatic irAE under ICI treatment (pembrolizumab n=21, nivolumab n=28, ipilimumab n=11, durvalumab n=1, atezolizumab n=2, avelumab n=1, history of >1 ICI n=11). Of the 52 patients, 22 (42.3%) had non-small cell lung cancer and 23 (44.2%) had a melanoma. Eight (15.3%) patients experienced a flare of a preexisting NMD under ICI treatment. The remaining 44 patients with de novo irAEs were characterized according to characteristics of rheumatic irAEs. Rheumaliga Baden-Württemberg, School, Boston, United States of America; Sanofi, UCB.

Background: Reports of rheumatic immune-related adverse events (irAEs) in patients receiving immune checkpoint inhibitors (ICI) have recently attracted new attention to the complex interrelations of malignancies and rheumatic and musculoskeletal diseases (RMDs). Since those two entities represent two sides of a disregulated immune response, further research on rheumatic irAEs and mechanisms underlying the better tumor response rates in irAE-affected patients may contribute to a better understanding of the different pathophysiology characterizing tumor and rheumatic disease.

Objectives: To compare GC use and subsequent GC-related complications in patients with PMR vs a general population (GnP) cohort.

Methods: This retrospective, observational cohort study was based on Optum’s de-identified Clinical and Administrative Data Mart Database (study period 01Jan2006–30June2018). The PMR cohort included patients ≥1 inpatient or ≥2 out-patient claims ≤30 days apart with PMR related diagnosis codes (ICD-9: 725. xx or ICD-10: M35.3x) between 01Jan2006–30June2017 (patient identification period) during which first occurrence of a PMR-related medical claim was set as the index date (ID). Patients with ≥1 medical claim related to rheumatoid arthritis (RA) or GCA during the study period were excluded. The GnP cohort included patients without any RA, GCA or PMR diagnosis codes during the study period, with their ID set as 12 months from the start of continuous health plan enrollment. Patients in both cohorts were required to be ≥50 years old (on ID) with continuous health plan enrollment ≥12 months pre- and post-ID. Cohorts were 1:1 propensity score matched. GC use and incidence of GC-related complications were assessed from GC initiation, starting from the baseline period (12-months prior through the end of PMR cohort or the matched GnP cohort), respectively. A higher proportion of patients in the PMR cohort than the matched GnP cohort (90.4% vs 62.8%; p<0.001) used GC. The mean (SD) duration of GC therapy was significantly longer in the PMR cohort than in the matched GnP cohort [242.1 [±317.2] days vs 35.5 [±124.6] days; p<0.001]. Although patients in the PMR cohort had a lower average daily dose of GC (prednisolone equivalent) vs the GnP cohort (mean [SD] mg 16.3 [± 21.9] vs 27.8 [±24.5], respectively [p<0.0001]), the cumulative GC dose was significantly higher in the PMR cohort than the GnP cohort [2125.4 [±3689.5] mg vs 476.6 [±1450.9] mg; p<0.001]. This indicates PMR patients used chronic low dose GC while the GnP patients utilized higher dose GC burst therapy less frequently. The number of incident complications associated with GC use were significantly greater in the PMR cohort, and included hypertension, diabetes, skin toxicity, infections, neuropsychiatric effects, endocrine abnormalities, renal dysfunction/failure, ocular effects, and cardiovascular disease (p<0.05).

Conclusion: The overall GC burden in patients with PMR is higher. With a higher incidence of GC-related morbidities among PMR patients, early onset of these complications may be a significant contributor to long-term healthcare costs in these patients.

Background: Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disease associated with mutations in the MEFV gene. Colchicine is the cornerstone of current therapy for FMF; however, a subset of patients are resistant or intolerant to its. Previously published results from the CLUSTER trial [NCT02059291] demonstrated that canakinumab, a fully human anti-interleukin-1β monoclonal antibody, was effective in controlling and preventing flares in patients with colchicine-resistant familial Mediterranean fever (crFMF).

Objectives: To evaluate the long-term efficacy and safety of canakinumab to treat patients with crFMF during Epoch 4 of the CLUSTER study.

Methods: Patients with active crFMF (baseline flare) were enrolled in the CLUSTER study. During Epoch 4 (weeks 40 to 113), patients received open-label canakinumab 150 mg or 300 mg, every 4 or 8 weeks (q4w or q8w). Patients started Epoch 4 on the same regimen that they were receiving at the end of Epoch 3, and stepwise up-titration of canakinumab was allowed in patients who experienced a flare, to a maximum dose of 300 mg q/w. We evaluated disease activity every 8 weeks using the physician global assessment of disease activity (PGA), counting the number of flares (defined as PGA ≥2 and CRP >30 mg/L), and measuring serum concentrations of C reactive protein (CRP) and serum amyloid A (SAA). Safety was assessed by the determination and classification of adverse events (AEs). We analysed safety and efficacy separately in two subgroups of patients receiving a cumulative dose of canakinumab lower than 2700 mg, or equal or higher than 2700 mg.

Results: Of the 61 patients with active crFMF who started the CLUSTER study, 60 entered Epoch 4 and 57 completed it. During the 72-week period, 35/60 (58.3%) patients experienced no flares, and 23/60 (38.3%) had one single flare, as compared with a median of 17.5 flares per year reported at baseline. The incidence of flares was similar in the two cumulative dose groups. PGA scores indicated no disease activity for the majority of patients throughout the study, in both cumulative dose groups. 23/57 (40%) of patients remained in the lower dose group (150 mg q8w) until study end, whereas 9/57 (16%) required the highest dose allowed (300 mg q4w). Patients with higher body weight had an increased probability to require up-titration of canakinumab to control disease activity. Median CRP concentrations were lower than 10 mg/L range every time point in both cumulative dose groups, while median SAA concentrations remained in the 16-70 mg/L range, and were higher in the group receiving ≥2700 mg canakinumab (Figure 1). No opportunistic infections, renal disease caused by amyloidosis, new or unexpected AEs were reported.

Conclusion: Patients with crFMF treated with canakinumab during 72 weeks experienced a minimal incidence of flares and good control of clinical disease activity, with no new safety signals reported.

OP0273 ADHERENCE TO COLCHICINE TREATMENT AND COLCHICINE RESISTANCE IN A MULTICENTRIC FMF NATIONAL COHORT

R. Gallizzi1, M. Bustaffa1, F. Mazzia1, D. Suter1, G. Fabio1, L. Obio1, M. Alessio1, D. Rigante1, L. Cantarini1, A. Insalaco1, M. Cattalini1, M. C. Maggio1, G. Simonini1, A. N. Olivier1, S. Pastore1, M. Lancieri1, N. Ruperto1, M. Gattorno1.

Background: Colchicine is the standard treatment for Familial Mediterranean Fever (FMF), however about 5% of patients experience colchicine resistance. There is no standard definition of colchicine resistance. Recently a panel of experts elaborated a new definition based on a Delphi consensus approach.

Objectives: We aim to describe main features of the disease and clinical outcome of a cohort of FMF patients with particular interest on the colchicine resistance and tolerability according to the definitions proposed by the recent consensus.

Methods: Since November 2009, 425 Italian pediatric and adult FMF patients (pts) from 13 centers were enrolled in a national longitudinal cohort study, using the international EUROFEVER registry. Demographic, genetic and clinical data, including response to treatment, were analyzed. Supplementary information on health related quality of life and treatment adherence was also collected by a specific questionnaire.

Results: Complete information were available in 341 pts (189M and 152 F, 211 children and 120 adults). The median age at disease onset was 5.0 years (1 m-59 y); the mean diagnostic delay was 8.7 y (range 0-61 y). The median age at enrollment was 12.1 y (range 3 m - 82 y). The MEFV genotype was the following: 103 (30.2%) pts carried biallelic pathogenic variants; 59 (17.3%) one pathogenic variants and one VOUS/LB variant; 27 (7.9%) had biallelic VOUS/LB variants; 97 (28.4%) were heterozygous for pathogenic variants; 30 (8.8%) were heterozygous for VOUS/LB, 25 (73.3%) were genetically negative.

Colchicine treatment was used in 280 pts; during treatment, biologic treatment (anti-IL1) in 22 pts. 61 pts received NSAID or steroid on demand. We analyzed the behavior of the pts treated with colchicine according to the statements on colchicine resistance/intolerance defined by Ozen et al (Table 1).

Table 1.

<table>
<thead>
<tr>
<th>Adherence</th>
<th>62% displayed a total adherence (&gt; 90% of prescription); 10.8% good adherence (50-89% of prescriptions); 1.9% poor adherence (&lt; 50% of prescriptions); 0.9% no adherence.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dose adjustment criteria</td>
<td>Mean colchicine dose: Recommended maximum colchicine dose: Pts &lt;5 years: 0.57 mg/d (std. dev. 0.18) 10-10 years: 0.77 mg/dl (std. dev. 0.23) 10-18 years: 1.1 mg/dl (std. dev. 0.39) Adults: 1.16 mg/dl (std. dev. 0.37)</td>
</tr>
<tr>
<td>Resistance to Colchicine</td>
<td>Adult pts with a dose inferior to the minimum recommended dose 5-10 years: 2.5% 10-18 years: 15%</td>
</tr>
<tr>
<td>Inclusion of secondary amyloidosis in the definition of colchicine resistance</td>
<td>5 adult pts (1.5%) displayed amyloidosis</td>
</tr>
</tbody>
</table>

Conclusion: Almost 58% of FMF pts display disease activity despite colchicine treatment. The treatment is generally under-dosed, especially in children. The adherence and the compliance to the treatment is generally good.

Disclosure of Interests: Romina Gallizzi: None declared, Marta Bustaffa: None declared, Francesca Maizza: None declared, Diana Sutera: None declared,
Background: AA amyloidosis has been associated with uncontrolled chronic inflammatory diseases such as rheumatoid arthritis (RA), ankylosing spondylitis (AS), inflammatory bowel disease (IBD) and hereditary periodic fever syndromes, and the most common cause is familial Mediterranean fever (FMF) in Turkey.

Objectives: We herein aimed to evaluate clinical and laboratory characteristics and treatment responses of patients with AA amyloidosis retrospectively in a tertiary referral center.

Methods: Study group was consisting of patients with biopsy proven AA amyloidosis, and their data were recorded from their charts. Treatment responses were categorized as follows: complete response was defined as no increase in serum creatinine and a proteinuria below 1 g/day; partial response as ≥50% decrease in proteinuria; and stable disease as no significant change in serum creatinine and proteinuria. Progressive disease was defined as increase in serum creatinine and/or proteinuria under treatment.

Results: 173 patients were identified, and 10 patients with no biopsy result and/or missing data were excluded. A total of 163 patients (79 females, 84 males) were included in the study. Median age of patients was 45.4, and median age at diagnosis of amyloidosis was 33.5. Most common cause of amyloidosis was FMF (78.5%), followed by idiopathic cases (73%) and patients with AS (4.9%). A quarter (26%) of amyloidosis patients had a family history for AA amyloidosis, and 59% of patients with FMF had a family history of FMF. Amyloidosis was confirmed by renal biopsy in 78.1%, by gastrointestinal (GIS) biopsy in 11.7%, and by other biopsies in the remaining. Renal involvement was documented in 160 (98.2%) patients, while GIS involvement in 20.9%, heart in 13.5%, thyroid in 3.7% and bone marrow in 3.1%. In FMF patients, most common MEFV mutation was M694V (77.7%), and 66.7% of the patients had homozygous, 14.6% had compound heterozygous, and 18.7% heterozygous exon 10 variants. Mean age at diagnosis of amyloidosis was earlier in homozygotes (29.1) and compound heterozygotes (32.3) compared to 18.7% heterozygous exon 10 variants. Mean age at diagnosis of amyloidosis was earlier in homozygotes (29.1) and compound heterozygotes (32.3) compared to 18.7% heterozygous exon 10 variants. Mean age at diagnosis of amyloidosis was earlier in homozygotes (29.1) and compound heterozygotes (32.3) compared to 18.7% heterozygous exon 10 variants.

Conclusion: Increased rate of ESRD and progression of amyloidosis findings in patients who presented with GFR<60ml/min emphasize the importance of early diagnosis. Although mortality rate is very high in patients with AA amyloidosis due to FMF disease, it may be possible to reduce mortality with an effective treatment.
the GCA cohort vs 36.3 (±10.72) days in the GnP cohort (p<0.001). Although the mean (SD) daily dose of GC (prednisone equivalent) was similar in both cohorts (27.6 ±28.20 vs 27.7 ±25.16 mg), the mean (SD) cumulative GC dose was significantly higher in the GCA cohort than the GnP cohort (3553.0 ±4622.6 mg vs 503.7 ±1593.51 mg; p<0.001). This indicates that GCA pts had chronic GC exposure over the study period while GnP pts likely utilized higher dose GC burst therapy less frequently. The number of incident complications associated with GC use were significantly greater in the GCA cohort, and included hypertension, diabetes, skin toxicity, infections, neuropsychiatric effects, gastrointestinal complications, ocular effects, and cardiovascular disease (p<0.05).

Conclusion: The overall GC burden in pts with GCA is significantly higher than the general population and may result in downstream complications related to GC exposure. The incidence of GC-related complications was statistically significantly higher in GCA pts compared with GnP pts, even with a short duration of GC use. The early onset of these complications may be a significant contributor to long-term healthcare costs in GCA pts.

**CLINICAL PATTERNS AND FOLLOW-UP OF INFAMMATORY ARTHRITIS AND OTHER IMMUNE-RELATED ADVERSE EVENTS INDUCED BY CHECKPOINT INHIBITORS. A MULTICENTER STUDY**

1Hospital Clinic, Rheumatology, Barcelona, Spain; 2Hospital del Mar, Rheumatology, Barcelona, Spain; 3Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain

Background: Immune checkpoint inhibitors (ICIs), such as anti-CTLA-4 and anti-PD1/PD-L1 monoclonal antibodies, have produced impressive clinical results in different types of cancer. However, immune-related adverse events (irAEs) may develop a wide spectrum of disabling syndromes. Knowledge of different rheumatic irAEs induced by ICI is increasing over the last years, however clinical patterns, time to onset of different irAEs according to treatment and follow-up are less well known.

Objectives: To describe different clinical patterns of rheumatic irAEs induced by ICI and their rheumatic and oncologic outcomes.

Methods: We included consecutive patients with rheumatic irAEs from 3 different referral centers in Barcelona with special emphasis in articular irAEs. Four main clinical syndromes were identified: inflammatory arthritis (IA), non-inflammatory arthralgias (NIA), psoriatic arthritis (PsA)-like and polymyalgia (PMR)-like. We conducted a baseline visit and then follow-up in order to determine their clinical pattern, treatment response and outcome. Longitudinal visits were done from January 2017 to January 2020. Patients with other non-articular diagnosis were not included in the follow-up analysis.

Results: We included 55 patients. A total of 34 patients were male (61.8%) with a mean age of 65.0 ± 11.4 years. Oncologic underlying diagnosis was lung carcinoma in 24 (43.6%) patients, followed by melanoma in 17 (29%), urothelial cancer in 4 (7.3%), breast in 2 (3.6%) and 2 (3.6%) acute myeloid leukemia among others. Seven (12.7%) patients received ICIs as combined therapy. Different ICI were used including: Pembrolizumab in 21 (38.2%), Nivolumab 13 (23.6 %), Atezolizumab 6 (10.9%), Nivolumab + ipilimumab 5 (9.0%), Durvalumab 3 (5.5%), Pembrolizumab + epacadostat in 2 (3.6%), 2 anti TIM3, Atezolizumab+ Ibatasertib, Avelumab and Ipilimumab in one case each. 12 out of 55 patients had an underlying rheumatic disease before ICI treatment. Eleven patients developed other irAEs before or at the same time as rheumatic syndromes (mainly colitis and thyroiditis). Main rheumatic irAE included: IA in 23 (41.8%), NIA in 16 (29.1%), PsA-like in 6 (10.9%), PMR-like in 5 (9.1%) among others. Time from ICI to irAEs was 8.3 ± 8.4 months (mo). irAE presented earlier in patients with combined ICI therapy than in patients with monotherapy (6.5 ± 4.0 vs 8.6 ± 9.9 mo, p<NS, Figure 1A). Time (in mo) from ICI initiation to irAE onset was different according to treatments. For Nivolumab 10.0 ± 10.6, Anti TIM3 10.0 ± 1.4, Durvalumab 9.0 ± 2.0, ipilimumab 7.98 ± 9.21, Pembrolizumab 7.28 ± 7.53, Avelumab 6.0 and Atezolizumab 4.4 ± 5.38 mo (Figure 1B). Time from ICI initiation and onset also differs among rheumatic irAEs (Figure 2). Mean time follow-up was 13.4 ± 10.9 mo. At the last visit, 45% were under GC, mean dose of 3.6 mg/d (range 0-40). DMARD were used in 15% of patients (6 patients MTX, 1 with LEF and 1 SFZ). At the last visit, 11 (22.9%) patients remain with persistent arthritis, 25% intermittent flares and 52% had a self-limited pattern. Regarding oncologic outcome, 30.2% were on remission, 30.2% in partial response and 39.6% with tumor progression. Eleven (20%) of patients died.

Conclusion: We described different clinical patterns according treatment and irAEs. Combined ICI therapy and patients treated with Atezolizumab had earlier onset of symptoms. Vasculitis and PMR-like syndromes appear in earlier phases. After a mean follow-up of around 1 year, one-quarter of the patients remain with persistent arthritis and 15% require DMARD therapy.

**AURORA PHASE 3 STUDY DEMONSTRATES VOCLOSPORIN STATISTICAL SUPERIORITY OVER STANDARD OF CARE IN LUPUS NEPHRIS (LN)**

C. Arriens1, S. Poljakova1, I. Adzerikho1, S. Randhawa2, N. Solomons3, 1Oklahoma Medical Research Foundation, Oklahoma City, United States of America; 2University of Oklahoma Health Sciences Center, Oklahoma City, United States of America; 3LLC Medical Center, Kemerovo, Russian Federation; 4Minsk Regional Clinical Hospital, Minsk, Belarus; 5Aurinia Pharmaceuticals, Victoria, Canada

Background: Voclosporin (VCS) is a novel high potency calcineurin inhibitor (CNI) with a favorable metabolic profile and a consistent predictable dose response potentially eliminating the need for therapeutic drug monitoring. LN occurs more frequently and is more severe in Hispanic/Latino ethnicity SLE patients. The recently completed phase 3 AURORA study builds on the favorable efficacy seen in the Phase IIb AURA-LV study in patients with active LN.

Objectives: Document efficacy and safety of VCS vs placebo over one year when used with 2 grams of MMF daily and a rapid steroid taper in patients with active LN.

Methods: AURORA is a Phase III multicenter, randomized, double-blind, placebo-controlled 52-week study of active LN patients. Patients were randomized 1:1 to VCS (23.7 mg BID) or placebo in combination with mycophenolate (MMF, 1g BID) and rapidly tapered oral steroids. The primary endpoint was renal response potentially eliminating the need for therapeutic drug monitoring. LN occurs more frequently and is more severe in Hispanic/Latino ethnicity SLE patients. The recently completed phase 3 AURORA study builds on the favorable efficacy seen in the Phase IIb AURA-LV study in patients with active LN.

Results: There were 357 patients enrolled, 88% female, median age of 31 and 33% of Hispanic/Latino ethnicity. Renal response by intention to
treat analysis at 52 weeks was 40.8% for the voclosporin arm and 22.5% for the control arm (OR: 2.65; 95% CI: 1.64, 4.27; p < 0.001); therefore, AURORA met its primary endpoint. These findings were consistent with those observed in the previously completed pivotal AURA-LV study. Ethnographic subgroup analysis of RR at 52 weeks noted benefit of VCS in both Hispanic/Latino (VCS 38.6% and control 18.6%, p = 0.0062, OR 3.45) and non-Hispanic/Latino patients (VCS 41.8% and control 24.6%, p = 0.0045, OR 2.29). The benefits of VCS were also seen for all pre-specified hierarchical secondary endpoints: RR at 24 weeks, partial renal response (PRR) at 24 and 52 weeks, time to achieve UPCR ≤ 0.5, and time to 50% reduction in UPCR. Furthermore, all pre-specified subgroup analyses (age, sex, race, biopsy class, region, and prior MMF use) favored VCS. VCS was well tolerated with no unexpected safety signals. The overall incidence of SAEs was similar in both groups (VCS 20.8% and control 21.3%); with infection most commonly reported (VCS 10.1% and control 11.2%). Overall mortality in the trial was low, with one death in the voclosporin arm and five in the control arm. Additionally, the VCS arm showed no significant decrease at week 52 in eGFR or increase in BP, lipids, or glucose.

Conclusion: The AURORA study met its primary endpoint and VCS was efficacious in Hispanic/Latino ethnicity patients, a difficult to treat group.

**IDENTIFICATION OF PARAMETERS ASSOCIATED WITH A DIAGNOSTIC DELAY IN AXIAL SpondyloArthritis: RESULTS FROM THE EUROPEAN MAP OF AXIAL SpondyloArthritis (EMAS)**

M. Garrido-Cumbre1,2, V. Navarro-Compán3, C. Bundy4, R. Mahapatra5, S. Makri6, J. Correa-Fernández2, L. Christen7, C. J. Delgado-Domínguez1, D. Poddubnyy8,9 on behalf of EMAS Working Group. 1Health & Territory Research (HTR), Universidad de Sevilla, Sevilla, Spain; 2Spanish Federation of Spondyloarthropathy Associations (CEADE), Madrid, Spain; 3University Hospital La Paz, IDiPAZ, Madrid, Spain; 4Cardiff University, Cardiff, United Kingdom; 5Axial Spondyloarthropathy International Federation (ASIF), London, United Kingdom; 6Cyprus League Against Rheumatism, Nicosia, Cyprus; 7Novartis Pharma AG, Basel, Switzerland; 8Charité-Universitätsmedizin Berlin, Berlin, Germany; 9German Rheumatism Research Centre, Berlin, Germany

**Background:** Early diagnosis of Axial Spondyloarthritis (axSpA) is crucial for timely access to specialist care and effective treatment.

**Objectives:** To assess the current diagnostic delay in axSpA and identify the parameters associated with increased diagnostic delay in a European sample.

**Methods:** Data from unselected patients participating in the European Map of Axial Spondyloarthropathy (EMAS) study through an online survey (2017-2018) across 13 countries were analysed. Mean differences in diagnostic delay were analysed using Mann-Whitney and Kruskal-Wallis tests, among sociodemographic and disease-related factors. A multivariate linear regression analysis was carried out to identify the relative weight of the associated parameters in determining diagnostic delay.

**Results:** 2,846 patients participated in EMAS. Mean age was 43.9 years, 61.3% were female, 48.1% had a university degree, and 53.9% were employed. Of the 2846 participants, 2652 provided information for calculating diagnostic delay. Mean age at symptom onset was 26.6 ± 11.1, mean age at diagnosis was 33.7 ± 11.5, and mean diagnostic delay was 7.4 ± 8.4 (Fig. 1). The following variables were associated with longer diagnostic delay in the bivariate analysis: older age, female gender, being diagnosed by a rheumatologist (Table 1). In the multivariate regression analysis younger age at symptom onset, number of HCPs seen before were associated with diagnostic delay (Table 2).

**Conclusion:** In this large sample of axSpA patients from 13 different European countries, the average diagnostic delay was more than seven years. The fact that one of the most strongly associated parameters to diagnostic delay was number of HCPs seen before diagnosis suggests the need for urgent action to reduce incorrect referrals to shorten the patient journey to diagnosis across Europe.

Figure 1. Estimated mean RMDQ scores over time for the overall intervention and usual care group.

Figure 1. Trends of 1-year prevalence of opioid's use among incident OA patients, whole and subgroup population.
pharmacy dispensing data for 80% of the population in Catalonia (~6 million people). All persons aged 18 or older at the beginning of each calendar year with an incident OA diagnosis (including both peripheral and central joints) in the study period were included. Index date was the date of first OA diagnosis, and the observation period of opioid use was 1 year after index date. Opioids considered included codeine, tramadol, fentanyl, and morphine, with the latter three classified as strong opioids. The period prevalence of any opioid use was estimated in whole and sub-population stratified by sex, age, socio-economic status (U1 – U5, higher values of the indicator equivalent to deprivation) and residence area (rural/urban).

Results: The 1-year prevalence of any opioid use among incident OA patients was around 15% from 2007 to 2012. After that, this figure grew by 10% approaching 25% in 2016. However, strong opioid use increased continuously to nearly triple, from 8% in 2007 to 20% in 2016. The different subgroups followed similar trends over time, with women 4% higher than men, oldest 10% higher than youngest, most deprived 6% higher than least deprived, and rural 1% higher than urban.

Conclusion: The use of opioids (and especially strong opioids) has substantially increased in recent years among newly diagnosed OA patients in Catalonia. Our findings call for urgent action for safe opioid prescribing to avoid opioid abuse in OA patients especially amongst older women living in deprived areas.

OP0281

TWO-YEAR COST-EFFECTIVENESS BETWEEN TWO GRADUAL TAPERING STRATEGIES IN RHEUMATOID ARTHRITIS: COST-UTILITY ANALYSIS OF THE TARA TRIAL

E. Van Mulligen1, A. Weel2,3, M. Kuijper4, J. Hazes5, P. De Jong1. 1Erasmus MC, Rotterdam, Netherlands; 2Maasstad Hospital, Rotterdam, Netherlands; 3Erasmus School of Health Policy & Management, Rotterdam, Netherlands

Background: Current guidelines recommend to consider tapering treatment in rheumatoid arthritis (RA) patients who are in sustained remission, but the optimal approach to de-escalate conventional synthetic and biological DMARDs (respectively csDMARDs and bDMARDs) remains unknown. The benefits of tapering are a decreased risk of long-term adverse events and a reduction of health care costs, especially when bDMARDs are tapered. However, tapering treatment may lead to more transient or persistent disease flares, which have a direct impact on patients’ lives and societal costs.

Objectives: To evaluate the two-year cost–utility ratio between tapering the csDMARD first followed by the TNF-inhibitor, and tapering the TNF-inhibitor first followed by the csDMARD.

Methods: The TARA trial is a multicenter single-blinded randomized controlled trial. RA patients that used a csDMARD(s) plus a TNF-inhibitor and who had a well-controlled disease for at least 3 months, defined as a DAS28<2.6 and a swollen joint count (SJC)<1, were included. Patients were randomized into gradual tapering their csDMARD followed by the TNF-inhibitor or vice versa. Medication was tapered in three steps over the course of 6 months. Gradual tapering was done by cutting the dosage into half, a quarter and thereafter it was stopped. Data on QALYs (measured with the Dutch EuroQol [EQ5D]), direct and indirect costs were used to calculate the Incremental Cost Effectiveness Ratio (ICER). The incremental cost-effectiveness ratio (ICER) and the incremental net monetary benefit (INMB) were used to assess cost-effectiveness between both tapering strategies. Direct costs comprises costs for treatment and medical consumption, while indirect costs comprises costs due to loss of productivity (i.e. sick leave and unemployment).

Results: Of the 189 included patients, 94 started tapering their TNF-inhibitor first, while the other 95 tapered their csDMARD first. QALYs (sd) were, respectively, 1.64 (0.22) and 1.65 (0.22). Medication costs were significantly lower in the patients who tapered the TNF-inhibitor first, but indirect cost were higher due to more productivity loss. Therefore, total costs per QALY were similar for both tapering strategies (p=0.62). The ICER between tapering csDMARDs and the TNF-inhibitor was -€184534 (-€417314, €48245; 95% CI)(figure 1). The mean INMB was €2831 at a willingness-to-pay (WTP) level of €80000. At all WTP levels the probability of being cost-effective was higher (62% vs. 28%) for tapering the TNF-inhibitor first (figure 2)

Conclusion: Medication costs are lower when the TNF-inhibitor is tapered first, but this is counterbalanced by higher indirect costs due to loss of productivity. Therefore, overall cost savings are similar for both tapering strategies. However, tapering the TNF-inhibitor first has a higher chance of being cost-effective at all WTP thresholds. For this reason we advise to taper the TNF-inhibitor first when tapering medication is considered.

Figure 1 Summary of economic evaluation of tapering csDMARDs first versus tapering TNF-inhibitor first. (I) Results of 1000 bootstrapped replications, presented in a cost-effectiveness plane which represents uncertainty of the cost-effectiveness ratio. (II) Mean incremental net monetary benefit for tapering csDMARDs versus tapering TNF-Inhibitors with 95% confidence intervals plotted against different levels of willingness to pay (WTP) per quality adjusted life year (QALY): csDMARDs: conventional synthetic DMARDs; INMB: incremental net monetary benefit; QALY: quality adjusted life year; WTP: willingness to pay.

Figure 2 Cost effectiveness acceptability curve for tapering csDMARDs first versus tapering TNF-inhibitor first. Results of 1000 bootstrapped replication, presented for several levels of willingness to pay, indicated per quality adjusted life year (QALY); csDMARDs: conventional synthetic DMARDs; QALY: quality adjusted life year; WTP: willingness to pay.

OP0282

COST-EFFECTIVENESS ANALYSIS OF A CAFASPA REFERRAL MODEL FOR AXIAL SPONDYLOARTHRITIS

M. J. Abdekkadir1, M. Kuijper1, C. Appels1, A. Spoorenberg2, J. Hazes1, L. Van Hoeven3, D. Lopes Barreto1, A. Weel1, 1Maastad Hospital, Rotterdam, Netherlands; 2Amphia Hospital, Breda, Netherlands; 3University Medical Center Groningen, Groningen, Netherlands; 4Erasmus Medical Center, Rotterdam, Netherlands; 5Erasmus School of Health Policy & Management, Rotterdam, Netherlands

Background: Chronic low back pain (CLBP) poses a significant individual and socio-economic burden. A substantial amount of patients with CLBP have axial spondyloarthritis (axSpA), but early recognition of these patients is difficult for general practitioners (GPs). Guidelines form primary care and secondary care differ in criteria for referral recommendation. The Dutch primary care guideline is restrictive in referring CLBP patients to secondary care whereas ASAS recommend to refer CLBP patients having at least 1 axSpA feature1. Therefore several referral models have been developed to assist GPs. Although the validated CaFaSpa referral model2 is able to identify CLBP patients at risk for axSpA, its cost-effectiveness is yet unknown and essential before implementation in daily clinical practice.

Objectives: Primary objective to assess the cost-effectiveness of the CaFaSpa referral model for axSpA in primary care. Secondary objective to evaluate the costs made for screening by following the CaFaSpa vs ASAS referral model.

Methods: A clustered randomized controlled trial was performed with GPs as clusters. Clusters were randomized into the intervention (CaFaSpa referral, CS) or usual care (UC). Cost-effectiveness analysis from a societal perspective was performed to compare the CS and UC. Clinical outcomes were disability
(Roland-Morris Disability Questionnaire (RMDQ)) and health-related quality of life (EuroQol (EQ-5D)) after 12 months. Direct (Medical Consumption Questionnaire (MCQ)) and indirect healthcare (Productivity Cost Questionnaire (PCQ)) life (EuroQol (EQ-5D)) after 12 months. Direct (Medical Consumption Questionnaire (MCQ)) and indirect healthcare (Productivity Cost Questionnaire (PCQ))

Results: Of all 679 patients sixty-four percent were female and mean age was 36 (SD) years. In the CS 333 patients were included and in the UC. Non-significant differences in clinical outcomes were for RMDQ: 0.78 (95% CI: 0.76-0.80) 0.77 (95% CI: 0.74-0.80) 0.71 (0.68-0.74) for EQ5D 0.53 (95% CI: 0.51-0.55) 0.52 (0.50-0.54) 0.49 (0.46-0.53) Costs were significantly higher in the UC group €19,748 (95% CI: € 15,327-25,022) vs CS € 14,169 (95% CI: € 10,723-18,066).

Productivity loss was the largest contributor to the total costs (CS group: 62%, UC group: 96%). The majority of the bootstrapped ICERs presented were located in the south-eastern quadrant of the cost-effectiveness planes (Figure 1a and 1b), indicating that the CS is cost-effective. The ICER for RMDQ was €5,579, indicating that per point improvement on the RMDQ the intervention saved €5,579. The difference in QAL Y's between the CS and UC was very small resulting in a large ICER of €16,9583.

The fictive screening costs by using the ASAS referral advice, i.e. referring 85% of 679 patients, results in €876 per patient. The total screening costs per patient by using the CaaFaSpA model, i.e. referring 60% of 679 patients is €518.

Conclusion: Although the clinical effects between the CaaSSpA referral strategy and usual care were comparable, the CaaSSpA referral strategy resulted in a better cost-effectiveness. Lower costs were mainly driven by the increased productivity.

OP0283 COMPARING COST-UTILITY OF DMARDS IN SERONEGATIVE RHEUMATOID ARTHRITIS PATIENTS: A TREACH SUBANALYSIS

N. Luurssen-Masurel1, A. Weel2, J. Hazes3, P. De Jong4, 1 Erasmus MC, Rheumatology, Rotterdam, Netherlands; 2 Maasstad Hospital, Rheumatology, Rotterdam, Netherlands

Background: The diversity of the clinical phenotype of rheumatoid arthritis (RA) is increasing due to the emphasis on early diagnosis and treatment. This resulted in an increased number of RA patients without autoantibodies, also known as seronegative RA. We recently showed that newly diagnosed seronegative RA patients initially treated with hydroxychloroquine (iHCQ) had a similar clinical efficacy to initial methotrexate (iMTX). To our knowledge, however, there are no data on the cost-effectiveness of different initial treatment strategies in seronegative RA patients.

Objectives: To evaluate the 1-year cost-effectiveness between three different initial treatment strategies in seronegative rheumatoid arthritis (RA) patients, according to 2010 criteria.

Methods: For this analysis we selected all seronegative RA patients (n=131) within the intermediate probability stratum of the TREACH trial (table 1). Selected patients either received initial methotrexate 25mg/week (iMTX), hydroxychloroquine 400mg/day (iHCQ) or oral glucocorticoids, starting dose 15mg, in a 10-week tapering scheme without csDMARDs (iGCs). Quality adjusted life year (QALY) were derived from the EQ-SD. Costs were calculated with data from patient records and questionnaires. Direct costs are health care costs, whereas indirect costs are costs due to productivity loss. The incremental cost-effectiveness ratio (ICER) was used to assess the cost-effectiveness between treatment strategies.

</tbody>
</table>

Results: Average QALYs (sd), for iMTX, iHCQ and iGCs were respectively 0.71 (0.14), 0.73 (0.13) and 0.70 (0.15). The average total costs (sd) per QALY for iMTX, iHCQ and iGCs were respectively €11,004 (17,611), €13,231 (19,886) and €18,415 (35,660). Direct and indirect costs were higher in the iGCs group compared to iMTX and iHCQ (table 2). The ICERs did not differ between the initial treatment strategies (figure 1A-C). For WTP levels <€33,900 iMTX has the highest probability of being cost-effective, while for WTP levels >€33,900 iHCQ has the highest probability (figure 2).

Results shown are mean (SD) unless stated otherwise. *p<.05 for HCQ vs. GCs (student t test)

Conclusion: iMTX and iHCQ are more cost-effective than iGCs. However, depending on the WTP threshold either iMTX or iHCQ has the highest probability of being cost-effective.
**Objectives:**
1. Develop and validate an agent-based simulation of the UK axial spondyloarthritis healthcare system, using real-world data.
2. Investigate the effects of earlier biologic treatment on costs and patient outcomes.

**Methods:** Anonymised data were obtained from the UK National Early Inflammatory Arthritis Audit, and BSR Biologics Register (BSRBR-AS). This provided data on 162 units, and 702 patients with 1,631 patient-years of follow-up. An agent-based model was designed and programmed on the Netlogo platform to simulate patients and units individually over time. New patients were created based on national disease prevalence statistics. Patients' disease journeys were simulated with a Bath AS Disease Activity Index (BASDAI) score. The model included hospital outpatient attendances, treatment histories, drug costs, and key patient demographics. The baseline simulation was run for two simulated years, repeated 10 times, and assessed against the BSRBR-AS dataset for validation.

**Results:** In the baseline model in a typical two year run, 13,631 new patients attended 5,167 baseline, and 6,966 follow-up appointments. Of these, 6,324 and 623 were prescribed ≥1NSAID, and biologics, respectively. The validation comparison tests showed a high-level of similarity between simulated output and target datasets. In the target data, d-b was 250 days. In the experimental scenarios, as might be expected, earlier biologic access improved outcomes but at higher costs (Figure 1; Table 1). Reducing d-b to 150 days doubled the number of patients on BASDAI of 0 to 2.5 at 2 years, with 5%, 1%, and 2% less patients achieving 2.5 - 5, 5 to 7.5 and 7.5 to 10 BASDAI, respectively. Reducing d-b to 150 days increased drug costs from £3.2 million to £8.8 million. However, the total number of appointments (a proxy for staff costs) increased proportionality less from 16,000 to 20,000.

**Conclusion:** We have successfully developed, and validated an agent-based approach to model the effect of key policy changes on the whole healthcare system, providing output estimates of cost and patient outcomes, based on integrated real-world data. To our knowledge this is the first attempt to explore the patient journey in people with axSpA in this way. The model provides a useful tool for exploring the effects of changing the way healthcare is delivered to patients with this disease. Our experimental analysis lends support to the case for increasing staffing and drug expenditure to achieve current NICE standards of care in AS.

**OP0285 TOWARDS IMPLEMENTING THE OMOP CDM ACROSS FIVE EUROPEAN BIOLOGIC REGISTRIES**

**Disclosure of Interests:**
- 1University of Oxford, NDORMS, Oxford, United Kingdom; 2The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 3The University of Manchester, Manchester Academic Health Science Centre, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 4Epidemiology Unit, German Rheumatism Research Center, Berlin, Germany; 5Epidemiology Unit, German Rheumatism Research Center, Berlin, Germany; 6Institute of Rheumatology, Prague, Czech Republic; 7Institute of Biostatistics and Analyses Ltd, Bnno, Czech Republic; 8Division of Rheumatology, University Hospitals of Geneva, Geneva, Switzerland; 9Swiss Clinical Quality Management in Rheumatic Diseases, Zurich, Switzerland; 10Centre for Epidemiology Versus Arthritis, The University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom; 11Research Unit, Spanish Society of Rheumatology, Madrid, Spain; 12University of Oxford, NDORMS, Oxford, United Kingdom

**Background:** The Observational and Medical Outcomes Partnerships (OMOP) common data model (CDM) provides a framework for standardising health data.

**Objectives:** To map national biologic registry data collected from different European countries to the OMOP CDM.
Methods: Five biologic registries are currently being mapped to the OMOP CDM: 1) the Czech biologics register (ATTRA), 2) Registro Español de Acontecimientos Adversos de Terapias Biológicas en Enfermedades Reumáticas (BIOBADASER), 3) British Society for Rheumatology Biologics Register for Rheumatoid Arthritis (BSRBR-RA), 4) German biologics register ‘Rheumatoid arthritis observation of biologic therapy’ (RABBIT), and 5) Swiss register ‘Swiss Clinical Quality Management in Rheumatic Diseases’ (SCQM).

Data collected at baseline are being mapped first. Details that uniquely identify individuals are mapped to the person table, with the observation_period table defining the time a person may have had clinical events recorded. Baseline comorbidities are mapped to the condition_consumption CDM table, while baseline medications are mapped to the drug_exposure CDM table. This mapping is summarised in Figure 1.

Results: A total of 64,901 individuals are included in the 5 registries being mapped to the OMOP CDM, see table 1. The number of unique baseline conditions being mapped range from 17 in BSRBR-RA to 108 in RABBIT, while the number of baseline medications range from 26 in ATTRA to 802 in BSRBR-RA.

Conclusion: Due to differences in study design and data capture, the baseline information captured on comorbidities and drugs across registries varies greatly. However, these data have been mapped and mapping biologic registry data to the OMOP CDM is feasible. The adoption of the OMOP CDM will facilitate collaboration across registries and allow for multi-database studies which include the OMOP CDM is feasible. The adoption of the OMOP CDM will facilitate collaboration across registries and allow for multi-database studies which include health data which have been mapped to the CDM.

A MACHINE LEARNING APPROACH FOR PRECISION STRATIFICATION OF JUVENILE-ONSET SLE

G. Robinson1, J. Peng1, P. Dönnes1, L. Coelewij1, M. Naja1, A. Radziszewska1, C. Wincup1, H. Peckham1, D. Isenberg1, Y. Ioannou1, I. Pineda Torra1, C. Ciurtin1, E. Jury on behalf of The Jury Group and The Centre for Adolescent Immunology.

Background: Juvenile-onset systemic lupus erythematosus (JSLE) is a complex and heterogeneous disease characterised by diagnosis and treatment delays. An unmet need exists to better characterise the immunological profile of JSLE patients and investigate its links with the disease trajectory over time.

Objectives: A machine learning (ML) approach was applied to explore new diagnostic signatures for JSLE based on immune-phenotyping data and stratify patients by specific immune characteristics to investigate longitudinal clinical outcome.

Methods: Immune-phenotyping of 28 T-cell, B-cell and myeloid-cell subsets in 67 age and sex-matched JSLE patients and 39 healthy controls (HCs) was performed by flow cytometry. A balanced random forest (BRF) ML predictive model was developed (10,000 decision trees). 10-fold cross validation, Sparse Partial Least Squares-Discriminant Analysis (sPLS-DA) and logistic regression was used to validate the model. Longitudinal clinical data were related to the immunological features identified by ML analysis.

Results: The BRF-model discriminated JSLE patients from healthy controls with 91% prediction accuracy suggesting that JSLE patients could be distinguished from HCs with high confidence using immunological parameters. The top-ranked immunological features from the BRF-model were confirmed using sPLS-DA and logistic regression and included CD19+ unswitched memory B-cells, naïve B-cells, CD14+ monocytes and total CD4+, CD8+ and memory T-cell subsets.

K-mean clustering was applied to stratify patients using the validated signature. Four groups were identified, each with a distinct immune and clinical profile. Notably, CD8+ T-cell subsets were important in driving patient stratification while B-cell markers were similarly expressed across the JSLE cohort. JSLE patients with elevated effector memory CD8+ T-cell frequencies had more persistently active disease over time, and this was associated with increased treatment burden and prevalence of lupus nephritis. Finally, network analysis identified specific clinical features associated with each of the top JSLE immune-signature variables.

Conclusion: Using a combined ML approach, a distinct immune signature was identified that discriminated between JSLE patients and HCs and further stratified patients. This signature could have diagnostic and therapeutic implications. Further immunological association studies are warranted to develop data-driven personalised medicine approaches for JSLE.

EMAPALUMAB (ANTI-INTERFERON-GAMMA MONOCLONAL ANTIBODY) IN PATIENTS WITH MACROPHAGE ACTIVATION SYNDROME (MAS) COMPLICATING SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS (SJIA)

F. De Benedetti1, P. Brogan2, C. Bracaglia1, M. Pardeo1, G. Marucci1, E. Sacco1, D. Eleftheriou2, C. Papadopoulou3, A. Grom3, P. Quartier4, R. Schneider5, P. Jacqmin6, R. Frederiksen7, M. Ballabio7, C. De Min7.1 IRCCS Ospedale Pediatrico Bambino Gesù, Rheumatology, Rome, Italy; 2 UCL Institute of Child Health, and Great Ormond Street Hospital NHS Foundation Trust, Section Head Infection, Immunology, and Rheumatology, London, United Kingdom; 3 Cincinnati Children’s Hospital, Division of Rheumatology, Cincinnati, United States of America; 4 Paris-Descartes University, IMAGINE Institute, RAISE Reference Centre, Pediatric Immuno-Hematology and Rheumatology Unit, Necker Hospital, Assistance Publique-Hôpitaux de Paris, Paris, France; 5 The Hospital for Sick Children, Department of Pediatrics, Division of Rheumatology, Toronto, Canada; 6 MHN Modelling and Simulation, Dinant, Belgium; 7 Swedish Orphan Biovitrum AG (Sobi), Basel, Switzerland

Background: MAS is a severe complication of rheumatic diseases and occurs most frequently in patients with SJIA. Data from animal models and from observational studies in patients suggest that interferon gamma (IFNγ) is a driver of the hyperinflammation and hypercytokinemia observed in MAS.

Objectives: To assess the pharmacokinetics, efficacy, and safety of intravenous (IV) infusions of emapalumab, a fully human anti-IFNγ monoclonal antibody, in patients with MAS in the context of SJIA.

Methods: This ongoing, pilot, open-label, single-arm study (NCT03311854) includes patients with MAS (2016 ACR/EULAR criteria) on a background of confirmed, or high presumption of, SJIA, and with inadequate response to high-dose IV glucocorticoids. Emapalumab is initiated at 6 mg/kg (1 dose) and continued at 3 mg/kg twice weekly for a total of 4 weeks, or upon achievement of complete response (CR). CR is defined as an absence of MAS clinical signs plus white blood cell and platelet counts above the lower limit of normal, LDH, AST and ALT <1.5 x upper limit of normal, fibrinogen >100 mg/dL, and ferritin decreased by ≥80% or to <2000 ng/mL.

Results: We report preliminary data from the first 9 patients (median age range 11.6 [2.1-25.3] years) enrolled (7 in Europe and 2 in the USA). All patients had failed high-dose methylprednisolone, of which there were prior treatment failures from cyclosporin A (n=4) and from anakinra (n=4). Treatment with emapalumab resulted in rapid IFNγ neutralization, as demonstrated by the decrease in CXCL9 levels (Figure 1), and subsequent deactivation of T cells, as indicated by the decrease in sIL-2R levels. CR was achieved in all patients after a median of 23 (12-56) days. A progressive improvement in all clinical and laboratory parameters of MAS was observed (Table 1 and Figure 2). Glucocorticoids were tapered (12-56) days. A progressive improvement in all clinical and laboratory parameters of MAS was observed (Table 1 and Figure 2). Glucocorticoids were tapered (12-56) days. A progressive improvement in all clinical and laboratory parameters of MAS was observed (Table 1 and Figure 2). Glucocorticoids were tapered (12-56) days. A progressive improvement in all clinical and laboratory parameters of MAS was observed (Table 1 and Figure 2).

Conclusion: Emapalumab administration led to rapid neutralization of IFNγ and was efficacious in controlling MAS with a favorable safety profile. These results support the pathogenic role of IFNγ in MAS/SJIA and the therapeutic value of IFNγ neutralization in MAS patients who have failed standard care.

TOFACITINIB FOR THE TREATMENT OF POLYARTICULAR COURSE JUVENILE IDIOPATHIC ARTHRITIS: RESULTS OF A PHASE 3, RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED WITHDRAWAL STUDY

N. Ruipert1, O. Synovierska2, T. Ting3, C. Abud-Mendoza4, A. Spindler5, Y. Vyzhga1, K. Marzan2, K. Keltsev1, I. Tiros1, L. Imundo6, R. Jerath7, D. Kingsbury8, B. Sözeri1, S. Vora9, S. Prahalad10, E. Zholoitova10, Y. Butbul Aviel11, Y. Chashnyk11, M. Lerman12, K. Nanda13, H. Schmeling14, H. Törö15, Y. Uziel1, D. O. Viola1, H. Posner16, K. Kanik17, A. Wouters18, C. Chang19, R. Zhang20, I. Lazariciu21, M. A. Hsu22, R. Suehiro23, A. Martin2, D. J. Lovell24, H. Brunner25 on behalf of PRINTO/PRCG. 2 PRINTO, Istituto Giannina Gaslini, Genova, Italy; 3 PRSCG, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH, United States of America; 4 Pfizer Inc, New York, NY, United States of America; 5 Pfizer Inc, Groton, CT, United States of America; 6 IQVIA, Montreal, QC, Canada; 7 Pfizer Inc, Collegeville, PA, United States of America
Background: Tofacitinib is an oral JAK inhibitor that is being investigated for JIA. Objectives: To assess tofacitinib efficacy and safety in JIA patients.

Methods: This was a Phase 3, randomised, double-blind (DB), placebo (PBO)-controlled withdrawal study in pts aged $\geq$18 years with polyarticular course JIA (pJIA), PsA, or ERA (NCT02592434). In the 18-week open-label Part 1, pts received weight-based tofacitinib doses (5 mg BID or lower). Pts with pJIA ACR30 response at Week (W)18 were randomised 1:1 in the DB Part 2 (W18-44) to continue tofacitinib or switch to PBO. Primary endpoint: disease flare rate by W44. Key secondary endpoints: JIA ACR50/30/70 response rates; change from Part 2 baseline (Δ) in CHAQ-DI at W44. Other efficacy endpoints: time to disease flare in Part 2; JADAS27-CRP in Parts 1 and 2. PsA/ERA pts were excluded from these efficacy analyses. Safety was evaluated in all pts up to W44.

Results: 225 enrolled pts with pJIA (n=184), PsA (n=20) or ERA (n=21) received tofacitinib in Part 1. At W18, 173/225 (76.9%) pts entered Part 2 (pJIA n=142, PsA n=15, ERA n=16). In pJIA pts, disease flare rate in Part 2 was significantly lower with tofacitinib vs PBO by W44 (p=0.0031, Fig 1A). JIA ACR50/30/70 response rates (Fig 1B) and ΔCHAO (Fig 1C) at W44, and time to disease flare in Part 2 (Fig 2a), were improved with tofacitinib vs PBO. Tofacitinib reduced JADAS27-CRP in Part 1; this effect was sustained in Part 2 (Fig 2b). Overall, safety was similar with tofacitinib or PBO (Table): 77.3% and 74.1% had adverse events (AEs); 1.1% and 2.4% had serious AEs. In Part 1, 2 pts had herpes zoster (non-serious) and 3 pts had serious infections (SIs). In Part 2, SIs occurred in 1 tofacitinib pt and 1 PBO pt. No pts died.

Conclusion: In pJIA pts, tofacitinib vs PBO resulted in significantly fewer disease flares, and improved time to flare, disease activity and physical functioning. Tofacitinib safety was consistent with that in RA pts.

Background: Still's disease is a systemic auto-inflammatory disease with a pediatric form, sJIA, and an analogous condition in adults, adult-onset Still's disease (AOSD). The role of interleukin-1 (IL-1) in the pathophysiology of Still's disease is well established. Canakinumab, a monoclonal antibody against IL-1β, is approved to treat patients with Still's disease in Europe (sJIA and AOSD) and the United States (sJIA).

Objectives: To study the efficacy of canakinumab in sJIA patients categorized by age, we performed an intention-to-treat analysis of pooled data from 5 clinical trials, as an addition to a previously communicated analysis including 3 of the studies.

Methods: The age categories were children (2–<12 years), young adolescents and young adults (12–<16 years) and older adolescents and young adults (16–<20 years). We pooled efficacy results from patients with active disease at baseline treated during a 12-week period with canakinumab (4mg/kg every 4 weeks), including the presence of intermittent fever, serum concentrations of C reactive protein (CRP), improvement of sJIA (adapted pediatric ACR 30, 70 and 100 responses) and JIA ACR inactive disease status. Safety was assessed by analysis of reported adverse events (AEs).

Results: 302 children, 82 young adolescents and 34 older adolescents and young adults were included in the analysis, with a mean disease duration of 922, 1708 and 2615 days, respectively. Prior therapy with other biologics was common, with anakinra used in 33%, 35% and 47% of patients in each group. Disease severity was comparable among groups, with the mean number of active joints ranging from 11.8 to 13.7. Adapted pediatric ACR responses revealed a rapid response to canakinumab, with all groups showing similar rates of responders at most time points (Table 1). In each age group, the proportion of patients with inactive disease progressively increased to Day 57. At all time points after Day 15, the 16–<20 years group presented the highest proportion of patients with inactive disease. Median CRP levels decreased from baseline to reach values in the normal range (<10 mg/L) from Day 29 onwards in the three groups, with improvements more marked in the 16–<20 years group. The safety profile was similar in the three age groups analyzed, with a lower proportion of 16–<20 years old patients experiencing serious AEs (28%) as compared to children (35%) and young adolescents (42%).

*Some studies did not include visits at Day 15 and/or 85. For Day 15, 29, 57 and 85 the respective denominators for each age group were: N = 231, 302, 302, 232; N = 60, 82, 82, 55; N = 31, 34, 34, 24.

Conclusion: The efficacy and safety profile of canakinumab was consistent in children, adolescents and young adults with sJIA. Since sJIA and AOSD represent pediatric- and adult- onset variants of theStill's disease continuum, these results further support the therapeutic effect of canakinumab 4mg/kg every 4 weeks in both children and adults with Still's disease.

**TOP0293 USE OF WHOLE-BODY MAGNETIC RESONANCE IMAGING TO IDENTIFY POTENTIAL DIAGNOSTIC CLUES IN CHILDREN WITH FEVER OF UNKNOWN ORIGIN (FUO)**

**S. Signa** 1,2, R. Caorsi**1, G. Stagnaro** 1, F. Minola**1, P. Picco**3, A. Ravelli**1,4, M. B. Damasio**1, M. Gattorno**4,1, IRCCS Istituto Gianna Gaslini, UOS Centro Malattie Autoinflammatorie ed Immunodeficienze, Genoa, Italy; 2University of Genoa, DINOGMI, Genoa, Italy; 3IRCCS Istituto Gianna Gaslini, UOC Radiologia, Genoa, Italy; 4IRCCS Istituto Gianna Gaslini, UOC Clinica Pediatrica e Reumatologia, Genoa, Italy

**Background:** Whole-body magnetic resonance imaging (WBMRI) is a fast and accurate method to detect diseases throughout the entire body without exposure to ionizing radiation. Possible emerging applications for this technique include rheumatologic field and evaluation of fever of unknown origin (FUO).

**Objectives:** To evaluate the ability of WBMRI to identify significant potential diagnostic clue (PDC) in patients presenting a non specific inflammatory clinical picture.

**Methods:** We retrospectively collected cases of pediatric patients followed in a single pediatric rheumatology center who underwent WBMRI between January 2010 and December 2015 for the following indications: i) FUO (temperature greater than 38.3°C for more than three weeks or failure to reach diagnosis after one week of investigations), ii) recurrent fever (febrile episodes separated by periods of normal temperature), iii) Inflammation of unknown origin, IUO (ailment of at least 3 weeks duration, with raised inflammatory markers and fever below 38.3°C). WBMRI studies were acquired with coronal and sagittal planes (slice thickness 5mm) with acquisition of several image sets with automatic direct image realignment after acquisition creating a whole-body scan. Sequences include short t inversion recovery (STIR) and T1-weighted. All studies have been evaluated twice, the second time according to a predefined checklist, defined by an experienced radiologist, considering systematically single/multifocal bone lesion, bone marrow, joint effusion, soft tissues, adenopathies, parenchymal and vessels looking for PDC. We considered as a Potential Diagnostic Clue each alteration of the examined district that can potentially guide the diagnosis. Each alteration found is a PDC. We retrospectively evaluated patients’ clinical history and final diagnosis and we classified the PDCs identified during both first evaluation and re-evaluation as: Not useful (the identified PDC did not guide the diagnosis and is not coherent with the final diagnosis), consistent (the identified PDC is congruent with the patient’s final diagnosis) or diagnostic (the identification of the considered PDC strongly orient the final diagnosis).

**Results:** We collected 104 patients who underwent WBMRI; 24 (23%) of them presenting FUO, 28 (27%) presenting recurrent fever and 52 (50%) presenting IUO. The mean age of onset symptoms was 6 years and nine months (range: 2 weeks old-17 years and 6 months). The mean age of execution of WBMRI was 9 years (range: 5 months old-19 years). After the whole diagnostic work-out a final diagnosis was achieved in 44 patients (42%). PDCs were identified at the first evaluation in 78/104 cases (75%). In 22 cases (21%) the identified PDCs were consistent with the diagnosis, whereas in 9 cases (8.5%) the identified PDCs were considered diagnostic. Globally we can consider that at first evaluation PDCs were somehow contributory to the diagnosis in 31 cases (30%; 6 JIA, 7 systemic infections, 5 monoclonal inflammatory diseases, 4 ALPS, 2 Goldblom’s Syndrome, 2 Vasculitis, 1 eosinophilic fascitis, 1 histiocytosis, 3 oncologic diagnosis). Blind re-evaluation of WBMRI allowed the identification of additional PDCs in 52 patients (12 of them previously negative). In 10 cases the PDC found after re-evaluation was consistent with the final diagnosis (2 JIA, 1 mononucleosis disease, one neoblastomatosis, 3 ALPS, 1 monoclonal inflammatory disease, 1 Takayasu arteritis, 1 Goldblom’s syndrome).

**Conclusion:** WBMRI can be a powerful diagnostic tool in patients with FUO. A predefined checklist increases sensitivity of WBMRI in the identification of PDC.

Osteoporosis

**OP0294** DIFFERENTIAL INFLUENCE OF CO-MORBIDITIES ON SITE OF FRAGILITY FRACTURES

M. Dey1,2, M. Bukhari3.1 Institute of Ageing and Chronic Disease, University of Liverpool, Musculoskeletal Biology I, Liverpool, United Kingdom; 2Aintree University Hospital, Liverpool University Hospitals NHS Foundation Trust, Academic Rheumatology, Liverpool, United Kingdom; 3Royal Lancaster Infirmary, University Hospitals of Morecambe Bay NHS Foundation Trust, Rheumatology, Lancaster, United Kingdom

**Background:** Fracture fractures (FF) can occur at various sites of the skeleton, and are associated with multiple risk factors. The prevalence of FF markedly increases with age. As the longevity of the population increases, so will the incidence of FF, and that of associated co-morbidities and risk factors. There are few data on co-morbidities associated with fractures at each site.

**Objectives:** Identify associations of co-morbidities with sites of FF, by applying cluster analysis.

**Methods:** We reviewed 28868 patients presenting for BMD estimation at a district general hospital in North West England, 2004-2016. We identified patients who had sustained one or more FF at time of presentation. Site(s) of FF were recorded for each patient, including femur, forearm, humerus, pelvis, ribs, spine, tibia or fibula. The following co-morbidities or treatments were recorded: excess alcohol consumption (previous or current); bisphosphonates; coeliac disease; family history of FF; hormone replacement therapy; hyperparathyroidism; hyperthyroidism; inflammatory bowel disease; polymyalgia rheumatica; rheumatoid arthritis; smoking (previous or current); corticosteroids (previous or current). Cluster analysis was performed on fracture sites and co-morbidities, using Jaccard similarity coefficient, and plotted on a dendrogram.

**Results:** 11003 of 28868 patients had sustained one or more FF at time of BMD estimation. Overall, 84.6% were female, mean age 67.9 years, and median T-score -1.12 SD. Cluster analysis was performed for FF sites and co-morbidities, with Jaccard similarity coefficients calculated. 4 clusters were identified (Figure 1): FF of forearm (n=5054), tibia/fibula (n=2617), spine (n=2352), associated with family history of FF, smoking, corticosteroids, and bisphosphonate treatment; FF of pelvis (n=300) associated with hyperparathyroidism, PMR, coeliac disease, and HRT; FF of femur (n=1118) and humerus (n=1131) associated with IBD and RA; FF of ribs (n=1022) associated with alcohol and hyperthyroidism.

**Conclusion:** Cluster analysis demonstrated 4 distinct subgroups of FF sites and associated co-morbidities. To our knowledge, this is the first study applying cluster analysis to evaluate co-morbidities associated with FF sites. Risk factors may influence trabecular more than cortical bone, accounting for the difference in clusters. Knowledge of risk factors associated with FF site subgroups will aid prophylaxis and management in at-risk patients.

Results from an interim analysis - performed upon completion of month 4 visit by 100% of evaluable patients - are presented and reported without unblinding the study treatments. Both calcifediol groups are summarised for analysis. The trial has been approved by the corresponding ethics committees and national competent authorities.

**Results:** 298 women were included in the ITT analysis. The average age was 63.4 ± 8.2 years, mean BMI was 29.3 ± 6 Kg/m², 10.7% had osteoporosis and received treatment. All demographic characteristics and risk factors for osteoporosis were balanced amongst groups.

When analysing per treatment group, 13.5% and 35% of women in the calcifediol group reached values of 25(OH)D > 30ng/mL at 1 and 4 months when compared to 0% and 8.2% respectively in the cholecalciferol group (p<0.01), achieving target levels in a rapid manner (Figure 1).

**Objective:** To assess the efficacy of calcifediol in the treatment of vitamin D deficiency in postmenopausal women and in a timely manner, which could impact osteoporosis treatment. Cholecalciferol fails to achieve recommended levels in osteoporosis treatment. Baseline vitamin D levels are to be considered for the supplementation of vitamin D.

**Background:** Vitamin D deficiency is a highly prevalent entity worldwide, with relevance in specific diseases and stages of life. Few guidelines assess the indications and optimal dosing in the general population, and although there is no international consensus, 800IU/day is associated with benefits in bone metabolism. Calcifediol, a vitamin D analog, is presented as a therapeutic alternative.

**Objectives:** To assess the efficacy of calcifediol in the treatment of vitamin D deficiency, compared with therapeutic guidelines recommendations for cholecalciferol in postmenopausal women.

**Methods:** Phase III-IV, double blind, randomised, controlled, multicentre superiority clinical trial. Postmenopausal women with baseline levels of 25(OH)D < 20ng/mL were randomised to three arms: 266 mcg of calcifediol/month for 4 or 12 months (standard and test regime), or to cholecalciferol 25000 IU/month for 12 months (as per therapeutic guidelines).

**Conclusion:** Calcifediol shows a greater efficacy than cholecalciferol regime (as recommended in therapeutic guidelines), for the treatment of vitamin D deficiency in postmenopausal women and in a timely manner, which could impact osteoporosis treatment. Cholecalciferol fails to achieve recommended levels in a significant proportion of this population. Baseline vitamin D levels are to be considered for the supplementation of vitamin D.

Efficacy and Safety of Romosozumab Among Postmenopausal Women with Osteoporosis and Mild- to-Moderate Chronic Kidney Disease

Background: Osteoporosis and renal insufficiency are coexisting disease states in a substantial proportion of postmenopausal women. Since bisphosphonates are generally contraindicated in patients with estimated glomerular filtration rate (eGFR) <35mL/min, it is important to evaluate other osteoporosis treatments in this setting.

Objectives: To determine if baseline renal function affects the efficacy and safety of romosozumab.

Methods: We performed post hoc analyses of two clinical trials of romosozumab in postmenopausal women with osteoporosis. In ARCH (NCT01631214), 4,093 patients were randomised 1:1 to romosozumab 210 mg monthly or alendronate 70 mg weekly for 12 months (mean age: 74.3 years; 86.1% with prevalent vertebral fractures [VFs]). In ARCH (NCT01675834), 7,180 patients were randomised 1:1 to romosozumab 210 mg or placebo monthly for 12 months (mean age: 70.9 years; 18.3% with prevalent VFs). For these analyses, patients were categorised by baseline eGFR (mL/min/1.73m2): normal renal function (eGFR ≥90), mild renal insufficiency (eGFR 60–89), or moderate renal insufficiency (eGFR 30–59). Least squares mean (LSM) percent change from baseline in bone mineral density (BMD) at the lumbar spine, total hip, and femoral neck incidence of new VFs and adverse events (AEs); and changes in renal function were assessed for each eGFR category at Month 12 of the double-blind treatment period.

Results: At baseline, most patients had mild/moderate renal insufficiency: 84% in ARCH, 88% in FRAME. In both studies, change from baseline in BMD was significantly higher in the romosozumab group across baseline eGFR categories (Figure). There was an interaction between BMD increase and renal function, and although BMD increase was not as large in women with impaired renal function, differences between romosozumab and control groups remained significant (Figure). In ARCH, among patients with eGFR ≥90, 60–89, and 30–59, the incidence of new VFs (romosozumab vs alendronate) at Month 12 was 3.3% vs 7.3%, 3.2% vs 3.9%, and 3.4% vs 6.2% in ARCH. In FRAME, the incidence of new VFs (romosozumab vs placebo) at Month 12 was 0.5% vs 3.0%, 0.4% vs 1.5%, and 0.6% vs 2.1%.

In both studies, the incidences of AEs and serious AEs were similar in both treatment groups within and across eGFR categories. AEs of mild-to-moderate hypocalcaemia (investigator reported) occurred in two patients in ARCH (one romosozumab [eGFR 60–89] and one alendronate [eGFR ≥90]), and one patient in FRAME (romosozumab [eGFR 60–89]). Five patients in ARCH (all in the alendronate group) and 19 patients in FRAME (14 romosozumab, 5 placebo) had decreases in serum Ca levels (albumin adjusted); in the romosozumab group all were mild (<LLN–8.0 mg/dL) or moderate (<8.0–7.0 mg/dL). A similar percentage of patients in each group had changes in renal function over 12 months of treatment.

Conclusion: The efficacy and safety of romosozumab vs alendronate or placebo was similar among postmenopausal women with osteoporosis and different levels of renal function.

Acknowledgments: This study was funded by Amgen, Astellas and UCB Pharma. Editorial services were provided by Costello Medical.

Study of Risk of Vertebral Fractures After the Withdrawal of Denosumab Treatment

E. Espartal1, A. Erra1, M. Barceló-Bru1, R. Caparros-Ruiz2, S. Anton1, S. Sandoval1, Hospital Universitari Vall d’Hebron, Rheumatology, Barcelona, Spain

Background: The discontinuation of treatment with denosumab (Dmb) has been associated with a reactivation effect of bone metabolism that manifests itself with a loss of bone mass and an increased risk of vertebral fractures (VF). The incidence and risk factors that may lead to such loss are not clearly established.

Objectives: Determine the incidence of VF and bone loss in patients who have withdrawn treatment with Dmab and objectively possible associated risk factors.

Methods: Retrospective review study of patients treated with Dmab and monitored the last two years in monoclinic osteoporosis consultations. We selected patients who withdrew treatment with Dmab and registered demographic characteristics, risk factors for osteoporosis and densitometric prior to treatment and during the period of suspension. We identified patients who presented fractures during treatment withdrawal period, assessing: number of fractures, time from withdrawal to fracture presence, location and if they had received osteoactive treatment in that period.

Results: Of 415 patients treated with Dmab, 83 discontinued treatment. The average age was 63.91 years, 95.2% of them women. The average duration of treatment prior to withdrawal was 2.73 years. 43.4% of the patients had previous fractures, 47.2% vertebral. The data of the previous bone mineral density and during the follow-up are shown in Table 1. 60 patients presented risk factors for osteoporosis, the most frequent being low calcium intake (36.6%) and 15.6% had disease and osteopenizing treatment. 92.7% of the patients had received prior osteoactive treatment. The most frequent reason for withdrawal of Dmab was for therapeutic vacations (56.6%). 39 patients performed post-withdrawal osteoactive treatment, mostly zoledronate (51.3%). During the two years after the rest, 9 patients had fractures (10.9%), seven of vertebral location (77.7%) and ≥ 2 VF were observed in five of them. 5 patients (71.4%) already had fractures prior to the onset of Dmab. The average time from withdrawal from treatment to fracture presentation was 15 months. None of the fractures patients had received treatment after Dmab withdrawal. Although the mean BMD analyzed by DXA at the end of treatment and that the loss of BMD during rest was higher in patients with fracture compared to those without fracture (-7.8% vs -4.3% in the spine and -8.6% vs -4.4% in total femur), the differences were not significant.

Conclusion: The incidence of VF in patients who interrupted Dmab was 8.43%. Fractured patients had lower BMD gain despite the treatment than non-fractured patients and also the loss of BMD at rest was greater, without significant differences probably due to low number of patients. Neither the presence of previous fractures nor the duration of treatment could be related to the presence of VF at rest.

**OP0299 CLINICAL FEATURES ASSOCIATED WITH FRACTURE FRACTURE AFTER DISCONTINUATION OF TREATMENT WITH DENOSUMAB: A CASE-CONTROL STUDY**

J. M. Senabrú-Gallego, J. Rosas, A. Pons, G. Santos Soler, J. A. Bernal, J. A. García-Gómez, C. Cano, M. Lorente Betoret, X. Barber on behalf of AIRE-MB; 1Hospital Marina Baixa, Rheumatology, La Vila Joiosa, Spain; 2Hospital General Universitario de Elche, Infectious Diseases, Elche, Spain; 3Universidad Miguel Hernández de Elche, CIO, Elche, Spain

**Background:** Discontinuation of denosumab treatment causes an increase in bone resorption that has been linked to the emergence of vertebral fractures.

**Objectives:** To evaluate the association of clinical features and demographic characteristics with the emergence of new fragility fractures in patients with osteoporosis who interrupt treatment with denosumab.

**Methods:** Retrospective case-control study. Medical records of all patients with osteoporosis, from our local densitometry database, who received treatment with denosumab (at least one dose) and discontinue the treatment, have been studied.

Information was collected on demographic variables (age, sex), risk factors for osteoporosis (alcohol and tobacco consumption, personal history of fracture fragility and history of maternal hip fracture), secondary osteoporosis (due to early menopause, disease or osteopenizing treatment), previous treatment for osteoporosis, start and end date of denosumab treatment and subsequent treatments. All patients who suffered a fragility fracture from 6 months after the last dose of denosumab up to 20 months later were defined as a case. Prior treatment with bisphosphonate was considered to those who had received it for at least 1 year, and subsequent treatment with bisphosphonate was considered to those who received it immediately or up to 8 months after the last dose of denosumab.

**Results:** In total, 63 patients who discontinued treatment with denosumab were included. Ten of them presented fragility fractures (6 vertebral, 3 forearm and 1 hip). Two patients had a fracture after 24 months of the last dose of denosumab, so they were considered cases. 61 patients were women (96.83%) and 2 men (3.17%). Ten of them presented fragility fractures (6 vertebral, 3 forearm and 1 hip). Two patients had a fracture after 24 months of the last dose of denosumab up to 20 months later were defined as a case. Prior treatment with bisphosphonate was considered to those who had received it for at least 1 year, and subsequent treatment with bisphosphonate was considered to those who received it immediately or up to 8 months after the last dose of denosumab.

**Conclusions:** The study showed that...

**PREDICTION OF LOW BONE MINERAL DENSITY AND FRAX SCORE BY ASSESSING HIP BONE TEXTURE WITH DEEP LEARNING**

C. F. Kuo1,2, S. Miao3, K. Zheng2, L. Lu3, C. I. Hsieh1, C. Lin2, T. Y. Fan3. 1Chang Gung Memorial Hospital, Division of Rheumatology, Allergy and Immunology, Taoyuan, Taiwan, Republic of China; 2Chang Gung Memorial Hospital, Center for Artificial Intelligence in Medicine, Taoyuan, Taiwan, Republic of China; 3Paarl Labs, United States of America

**Background:** Osteoporosis is a widespread health concern associated with an increased risk of fractures in individuals with low bone mineral density (BMD). Dual-energy x-ray absorptiometry (DXA) is the gold standard to measure BMD, but methods based on the assessment of plain films, such as the digital radiogrammetry, are also available. We describe a novel approach based on the assessment of hip texture with deep learning to estimate BMD.

**Objectives:** To compare the BMD estimated by assessing hip texture using a deep learning model and that measured by DXA.

**Methods:** In this study, we identified 1,203 patients who underwent DXA of left hip and hip plain film within six months. The dataset was split into a training set with 1,024 patients and a testing set with 179 patients. Hip images were obtained and regions of interest (ROI) around left hips were segmented using a tool based on the curve Graph Convolutional Network. The ROIs are processed using a Deep Texture Encoding Network (Deep-TEN) model, which comprises the first 3 blocks of Residual Network with 18 layers (ResNet-18) model followed by a dictionary encoding operator (Figure 1). The encoded features are processed using a fully connected layer to estimate BMD. Five-fold cross-validation was conducted. Pearson's correlation coefficient was used to assess the correlation between predicted and reference BMD. We also test the performance of the model to identify osteoporosis (T-score ≤ -2.5).

**Results:** We included 151 women and 18 men in the testing dataset (mean age, 66.1 ± 1.7 years). The mean predicted BMD was 0.724 g/cm2 (p = 0.51). Pearson's correlation coefficient between predicted and true BMD was 0.88. The performance of the model to detect osteoporosis/osteopenia was shown in Table 1. The positive predictive value was 87.46% for a T-score ≤ -1 and 83.33% for a T-score ≤ -2.5. Furthermore, the mean FRAX 10-year major fracture risk was 6.8% and measured BMD (7.67% p = 0.52). The 10-year probability of hip fracture was lower in the predicted score (1.79%) than the measured score (2.43%, p = 0.01).

**Conclusions:** This study demonstrates the potential of the bone texture model to detect osteoporosis and to predict the FRAX score using plain hip radiographs.

**The new art of phenotyping and treating Sjögren’s syndrome**

**Background:** Primary Sjogren’s syndrome (pSS) is a multi-organ autoimmune disease mainly affecting excretory glands and characterised by B-cell hyperactivity. No approved systemic treatment is available. Ianalumab (VAY736) is an anti-B-cell activating factor (BAFF) receptor fully human monoclonal antibody, engineered for direct ADCC-mediated B-cell depletion.

**Objectives:** This phase 2b study aimed at establishing a dose-response relationship over a range of VAY736 doses, using change from baseline (BL) in EULAR Sjogren’s Syndrome Disease Activity Index (ESSDAI) over 24 Weeks (Wks) as primary endpoint. The study is ongoing with a second blinded treatment period up to Wk52. Here we report efficacy and safety Wk24.

**Methods:** 190 patients (pts) were randomised 1:1:1:1 to receive monthly s.c. doses of VAY736 (5, 50, 300mg) or placebo (PBO). Prior to 1:1-dose of study treatment, pts received methylprednisolone i.v. C50mg. Eligible pts fulfilled American European Consensus Group (AECG) criteria, were anti-Ro/SSA+, had ESSDAI ≥6 and EULAR Sjogren’s Syndrome Patient Reported Index (ESSPRI) ≥5. Statistical methods included MCP-Mod to assess dose-response on change of ESSDAI from BL and responder rate analysis to calculate the proportion of pts with ≥3 points improvement on ESSDAI. Secondary endpoints included ESSPRI, Functional Assessment of Chronic Illness Therapy Fatigue (FACT-F), Physician’s (PhGA) and Patient’s Global Assessments (PaGA), SF-36, stimulated salivary flow (sSF), Schirmer’s test.

**Results:** Primary endpoint was met with statistically significant dose-response for ESSDAI (Figure). The largest ESSDAI reduction was 1.92 points over PBO for VAY736 300mg at Wk24. Responder rate analysis on ESSDAI revealed for ESSDAI (Figure). The largest ESSDAI reduction was 1.92 points over PBO for VAY736 300mg at Wk24. Responder rate analysis on ESSDAI revealed for ESSDAI treatment with ≥3 points improvement on ESSDAI. Secondary endpoints included ESSPRI, Functional Assessment of Chronic Illness Therapy Fatigue (FACT-F), Physician’s (PhGA) and Patient’s Global Assessments (PaGA), SF-36, stimulated salivary flow (sSF), Schirmer’s test.

**Conclusions:** The primary endpoint assessing ESSDAI was met, showing statistically significant dose-response for ianalumab with clinically important improvement for 300mg vs PBO. Preliminary safety profile of ianalumab was good.
Meniscus: an innocent bystander in osteoarthritis?

J. P. Pelletier1, J. P. Raynauld1, F. Abram2, M. Dorais3, P. Paiement4, J. Martel-Pelletier1

1University of Montreal Hospital Research Centre (ORCHUM), Osteoarthritis Research Unit, Montreal, Canada; 2ArthroLab Inc., Medical Imaging Research & Development, Montreal, Canada; 3StatSciences Inc., Notre-Dame-de-l’Île-Perrot, Canada; 4ArthroLab Inc., Montreal, Canada

Background: Intra-articular corticosteroid injections (IACI) are commonly used for the treatment of symptomatic knee osteoarthritis (OA) and therapeutic guidelines recommend their use. However, their safety regarding the evolution of structural changes remains unknown.

Objectives: This study explored the effects of IACI on the evolution of knee OA structural changes assessed by magnetic resonance imaging (MRI).

Methods: Participants were selected from the Osteoarthritis Initiative database. In this nested case-control design study, participants who received one treatment with IACI and had MRI exams available at the yearly follow-up visits before (pre-treatment), during (treatment), and after (post-treatment) were defined as ‘cases’. Each case was matched with one control for age, gender, body mass index (BMI), height, joint space width (JSW), cartilage volume, bone marrow lesion (BML), meniscal extrusion, and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain at baseline. Ninety-three (93) participants fulfilling the inclusion criteria were selected and matched to controls (n=93). The study structural variables were MRI (cartilage volume, meniscal thickness, bone marrow lesion (BML), bone curvature), X-rays (JSW), and symptoms (WOMAC pain), assessed at the yearly consecutive visits and changes measured within the follow-up periods.

Results: At baseline, the control and treatment groups were balanced. In the pre-treatment period, the cartilage loss was not different between groups, with the exception of a significantly greater loss in the lateral compartment in the IACI group (p=0.041). In the post-treatment period there was no difference in the cartilage loss between the groups in both compartments. For the meniscal thickness loss in the pre-treatment period, there was no difference between groups; however, there was a significantly greater loss (p=0.007) during the treatment period in the IACI group. In the post-treatment period, the loss of the medial meniscus was similar in both groups. For the lateral meniscus, there was no significant difference at any time between the two groups. The loss in JSW in the pre- and post-treatment periods was not different between groups, but was significantly greater (p=0.011) in the IACI group in the treatment period. The changes in the BML sizes over time were small and similar between groups. For the bone curvature, IACI group showed a smaller change compared to the control (p=0.037) at the treatment period. The WOMAC pain changes in both groups were small and unlikely to be clinically relevant.

Conclusion: This study provides evidence that in knee OA, IACI were not associated with the occurrence of any deleterious effect on knee structures post-treatment, including cartilage volume and loss. The increase in the rate loss of medial meniscal thickness, which was associated with a loss of JSW, was a transient phenomenon and its clinical relevance unknown at that time.

Acknowledgments: This initiative was funded by a grant from La Chaire en arthrose de l’Université de Montréal, and by ArthroLab Inc. (both in Montreal, Quebec, Canada).

higher or lower concentrations in the PsA group compared to the control or the RA group. We selected two of these significant metabolites to build a classification model based on the linear support vector machine (SVM) method, and the area-under-the-curve (AUC) value of the resulting receiver operating characteristic (ROC) curve was 0.929 (95% confidence interval: 0.899-0.956). Similarly, 37 metabolites could differentiate AS samples from RAAs and controls. A proposed diagnostic panel containing four metabolites demonstrated an AUC value of 0.890 (0.843-0.934). For the last step, distinguishing between PsA and AS, there were 15 significantly increased metabolites and 9 lowered ones. The biomarker panel consisting of the top three metabolites also achieved good discriminatory power with AUC = 0.827 (0.717-0.919).

Conclusion: Isotope-labeling-LC-MS-based metabolomics has revealed biomarker candidates that can specifically differentiate PsA or AS patients from control populations.

Background: In PsA there is a pressing need to develop a coherent strategy for identifying initial and subsequent biologic responders. PsA patients present substantial heterogeneity in response to biologics, and molecular subtyping will help to identify the right patient for the right treatment.

Objectives: To identify transcript profiles (biomarkers) that will select TNFi and IL-17Ai responders in PsA using baseline CD4+ cells; and elucidate novel signaling pathways relevant to biologic disease modifying antirheumatic drug (bDMARD) response using a systems biology approach.

Methods: Consenting patients initiating TNFi agents (20 patients) or IL-17Ai agents (20 patients) with moderate-to-severe PsA were assessed with a comprehensive standardized protocol at base line and at 3 months. Responder to bDMARD was defined by Disease Activity Index for Psoriatic Arthritis (DAPSA) score of less than 14 (low disease activity). Global transcript profiling was performed on all patients prior to initiation of and 3 months post bDMARDs. We mapped RNA-seq reads to the hg19 reference genome using STAR and quantified transcripts with Cufflinks. The transcripts per million (TPM) values were log-transformed for statistical analyses.

Results: The demographics of PsA patients for both treatment groups are presented (Table 1). Differentially expressed genes (DEGs) were identified using the limma tool for TNFi and IL-17Ai responders and non-responders (Figure 1) as well as DEGs that differentiated TNFi from IL-17Ai response and non-response. Integration of differential gene expression data with tissue-specific protein-protein interaction networks represents a very promising strategy for identifying biologic responders and pathways involved in predicting response that may have identified the Rho-GTP pathway as a potential marker to guide the choice of biologic agents for individual patients.

Background: To “osteoclast differentiation” . Among 46 pathways specific to response to IL-17Ai, 17 shared genes in association with these pathways. Moreover, it suggests potential importance of the 17 shared genes in association with these pathways. Most of these pathways are related to innate and adaptive immune system, and to “osteoclast differentiation”. Among 46 pathways specific to response to IL-17Ai, multiple Rho-GTPase-related pathways were identified. It has been shown that experimental inhibition of ROCK2, a target of Rho-GTPase family is effective in psoriatic disease through regulation of IL-17/23/10, but not IL-6 and TNFα.

Conclusion: Integration of cell-specific transcriptomic data with protein networks represents a very promising strategy for identifying biologic responders and pathways involved in predicting response that may have identified the Rho-GTP pathway as a potential marker to guide the choice of biologic agents for individual patients.
**Background:** Dendritic cells (DCs) play important roles in inducing immune response as well as maintaining immune tolerance. Src homology 2 domain-containing protein tyrosine phosphatase-1 (Shp1) is a negative regulator of signaling in hematopoietic cells and is expressed in a variety of immune cells including DCs. Shp1 homozygous mutant mice (mothearien mice) develop multiple immunological abnormalities and they die around four weeks after birth because of severe pneumonitis. Motheaden mice produce large amounts of autoantibodies, and besides, B-1a cells, a distinct B cell subset, which are an important source of autoantibodies increase in various organs of motheaden mice.

To analyze the function of Shp1 in DCs, we generated Shp1 conditional knockout mice (Shp1 CKO) in which Shp1 messenger RNA is specifically depleted in CD11c+ cells. We found that aged shp1 CKO developed autoimmune glomerulonephritis. We also found that they developed severe tubulointerstitial nephritis (TIN) at the age of 40 weeks, which is characterized by the infiltration of CD11c+ and F4/80+ cells. CD4+ T cells from Shp1 CKO produce much more amount of IFN. Collectively, Shp1 in DCs acts as a key regulatory molecule to protect against autoimmunity.

**Objectives:** We analyzed salivary glands of CKO to confirm whether they have autoimmune sialadenitis because TIN is known to be the most common renal manifestations of SJögren's syndrome in human.

**Methods:** Shp1 CKO are generated by crossing a mouse line carrying floxed Shp1 allele to mice expressing Cre recombinase under the control of the CD11c promoter. Sex- and age-matched Ptpn6 mice without Cre gene were studied as controls. We analyzed secretary function of the salivary glands in response to pilocarpine stimulation in Shp1 CKO at the age of 40 weeks or older. We then performed histological examination of salivary glands (submandibular glands and sublingual glands) with light-microscopy and immunohistochemical staining. The mononuclear cells prepared from the submandibular glands were analyzed by flow cytometry (FCM). We also quantified anti-SSA/Ro60 antibodies and anti-SSB/LA antibodies by ELISA.

**Results:** Shp1 CKO secreted less saliva flow compared to control mice by pilocarpine stimulation. Histological study showed Shp1 CKO exhibited massive infiltration of inflammatory cells in salivary glands associated with periductal foils and periportal fibrosis. Most of infiltrated cells were stained by anti- CD4 or B220 mAbs. FCM revealed that B cells increased in the salivary glands of Shp1 CKO. In addition, B-1a cells also increased in the salivary glands of the mice. The levels of anti-SSA/Ro60 antibodies and anti-SSB/LA antibodies were increased in Shp1 CKO.

**Conclusion:** CD11c-specific ablation of Shp1 induces the ectopic generation of lymphoid structure in salivary glands and impairment of salivary secretion. Autoantibody profile in Shp1 CKO resembled that in human SJögren's syndrome. Our findings suggest that aged Shp1 CKO have the potential to become a new mouse model for the analysis of SJögren's syndrome.

OBJECTIVE

PREGNANCY AND ARTHRITIS - A PATIENT EDUCATION PROGRAMME IN IRELAND

B. Lynch 1. Arthritis Ireland, Dublin, Ireland

BACKGROUND: The relationship between pregnancy and arthritis is a complex one. Because of the variability of arthritic conditions, it is important for patients to get advice from their doctor or a specialist nurse before trying for a baby. There can be implications for medication regimes, while the pregnancy itself can also affect the inflammatory arthritis. In the postpartum period, other considerations include breastfeeding and the frequent return of flares. Through this education programme, Arthritis Ireland developed information resources primarily targeting women of child-bearing age. The multichannel campaign provided information about the wide range of issues of concern to women with inflammatory arthritis who are planning a family or are pregnant.

OBJECTIVES:

- To provide information and increase awareness around inflammatory arthritis and pregnancy;
- To support women living with inflammatory arthritis through their illness and life journey;
- To increase awareness of the work of Arthritis Ireland as a patient organisation.

METHODS: In developing and executing this education programme, Arthritis Ireland worked extensively with a team of healthcare professionals, who are regarded internationally as leaders in this field. A multi-channel approach was taken to the development, production and dissemination of information, with public information events, literature and a suite of videos developed.

RESULTS: Up to this point, there had not been any Irish-produced material on this subject. The topic was seen to be an important one and an issue of significant public health interest. The series of information talks on pregnancy and inflammatory arthritis was delivered by consultant rheumatologists and were held in cities around Ireland. The information booklet covered topics such as planning for a baby, medication and pregnancy, the role of the father, fertility, genetics, during the pregnancy, after the pregnancy and breastfeeding.

Video was seen to be central to the success of the campaign. Working with the expert healthcare team, six information videos were developed around obstetrics, rheumatology, physiotherapy and occupational therapy. The videos were published and promoted across Arthritis Ireland’s social media channels and website.

The capstone video featured a young mother who was diagnosed with JIA when she was two. Her story was an incredibly powerful testimony of overcoming and dealing with adversity and complex health issues.

RESULTS: This educational campaign was developed to meet a significant need in the health information landscape. While there are no resources produced focusing on pregnancy and parenting, there wasn’t anything in Ireland which specifically addressed the needs of women and men with inflammatory arthritis who are looking to have a family. The materials produced are a valuable part of Arthritis Ireland’s canon of patient education materials.

CONCLUSION: It is anticipated that the materials developed will have a long lifespan and will support prospective parents for several years to come. Central to the success of the project was the involvement of the expert healthcare teams. Their commitment to the project spoke volumes of its importance and the considerable need for the clearly communicated information, which the project provided.

Ultimately, Arthritis Ireland has produced a suite of resources which will be referred to and used by patients, and will hopefully make a considerable impact on their quality of life.

Acknowledgments: This patient education programme was supported by a grant from UCB.

Disclosure of Interests: Brian Lynch Grant/research support from: Arthritis Ireland received a grant from MSD to develop this patient education programme. Brian Lynch has not benefited personally in any way.

OP0309-PARE REUMASUTRA: RETHINKING SEXUALITY IN RHEUMATIC AND MUSCULOSKELETAL DISEASES

J. B. Negrión 1, L. Ponce 2, R. G. Liga Reumatológica Galega 3, L. R. C. Liga Reumatológica Catalana 4, Reumasutra LLC, Porto Rico, United States of America; 5 Reumasutra LLC, Puerto Rico, United States of America; 6 Liga Reumatológica Galega Liga A Coruña, Spain; 7 Liga Reumatológica Catalana, Barcelona, Spain

BACKGROUND: Rheumatic and musculoskeletal diseases (RMDs) have a great impact on people’s quality of life affecting daily tasks. Research has shown that sexual relationships are also affected by RMDs. This occurs by one or a combination of: (1) the symptoms of the disease and (2) the side effects of the medication. Although we are all here because of sex, talking about sex and sexuality remains taboo. Physicians themselves report that embarrassment, lack of time, lack of knowledge about the topic, or age are barriers that prevent them from starting a conversation about the subject. Consequently, the sexual sphere of people with RMDs is neglected; producing uncertainty in the people affected by them and their partners.

In 2016, we set ourselves the task of studying what has already been created. The only material we found was a book with drawings that showed several sexual positions. We realized that the existing material fell short and we knew that we could make an original contribution. That’s why using participatory action research (PAR) approach we decided to create Reumasutra (LLC): The kamasutra for people with rheumatic diseases.

OBJECTIVES: To understand the complexities and the difficulties of sexuality in people with RMDs.

To offer a solution to the problems previously identified.

To (un)validate the proposed solution using the feedback of people with RMDs.

METHODS: PAR affirms that experience can be a basis of knowing and that experiential learning can lead to a legitimate form of knowledge that influences practice. PAR differs from conventional research in three ways. Firstly, it focuses on research whose purpose is to enable action. Secondly, PAR pays careful attention to power relationships, advocating for power to be deliberately shared between the researcher and the researched: blurring the line between them until the researched become the researchers. Thirdly, PAR contrasts with less dynamic approaches that remove data and information from their contexts, by advocating that those being researched should be involved in the process actively.

RESULTS: Our project is divided into three phases.

In the first phase, interviews with people with RMDs were conducted. The interviewees expressed that sex remains a taboo topic, which is often ignored by physicians. Besides, we opened a suggestion box on the website www.reumaxxx.com. Last year, we received feedback from approximately >30.000 people. After evaluating the feedback, it was clear that the best way to educate in sex in RMDs was by showing real people practicing adapted sexual positions.

For that task, we asked a couple with RMDs to validate the sexual positions that appear as drawings on the only book we found on the topic. Also, the couple added new sexual positions that they have been using and adapting to be sexually active despite having RMDs.

In the second phase, we recruited sex surrogates with experience with people with functional diversity to recreate the sexual position previously validated. The sex surrogates received coaching in real-time from a person with RMDs. The positions were filmed in January 2020.

For the last phase, we expect to upload the audiovisual content to the website. Afterward, we will send out surveys so that the users themselves can determine the validity and usefulness of the solution created.

CONCLUSION: Mobility in rheumatic diseases is affected. Sex is dynamic and a person cannot properly learn a new dynamic reality using static resources. We need to cross the taboo line to offer real solutions anchored to the reality of people with RMDs.

**OP0310-HPR**  
**METABOLIC ABNORMALITIES IN MEXICAN PATIENTS WITH RHEUMATIC DISEASES**

**Background:** Nutritional status plays an essential role in the etiopathogenesis of rheumatic diseases either as a triggering factor or as a contributor in the progression of disease activity, comorbidities and ineffective therapeutic response. An increased Body Mass Index (BMI) and a low lean muscle mass (LMM) have been associated with a worse clinical prognosis in rheumatic diseases. Objectives: To describe the nutritional status and alterations in a cohort of patients with rheumatic diseases.

**Methods:** 658 Mexican rheumatic patients from a rheumatology public center were included. Anthropometric measurements were assessed using bio-electrical impedance analysis (BIA) Tanita, including weight, height, BMI, Body Fat Percentage and Body Fat Mass (FM), Visceral Fat (VF), MM, Total Body Water (TBW) and Bone Mass (BM) which were classified according to validated parameters as normal and abnormal.

**Results:** A total of 658 patients were evaluated, 368 (55.92%) had Rheumatoid Arthritis. Table 1. The different diagnosis and anthropometric measures for each pathology are listed in Graphic 1. More than half of the patients (68.05%) presented an increased BMI and 85.56% a decreased MM. An increased Body Mass Index (BMI) and a low lean muscle mass (LMM) have been associated to a worse clinical prognosis in rheumatic diseases.1

**Conclusion:** This study showed that sarcopenic obesity, defined as low MM with an increased BMI, is a common disorder among rheumatic patients, found in more than half of our studied population. Since nutrition is a modifiable factor, important investigation in the detection and approach of metabolic abnormalities should be done.

**OP0311**  
**DETECTION OF SUBCLINICAL SKIN MANIFESTATION IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS BY FLUORESCENCE OPTICAL IMAGING**

A. Schmidt, A. M. Glimm, P. Hoff, G. Schmitt, G. R. Burmester, J. Klotsche, S. Ohrndorf. Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Deutsches Rheuma-Forschungszentrum (DRFZ) Berlin, A Leibniz Institute, Berlin, Germany; 3Charité - Universitätsmedizin Berlin, Institute for Social Medicine, Epidemiology and Health Economics, Berlin, Germany

**Background:** Fluorescence optical imaging (FOI) as new imaging technique enables visualization of an impaired microcirculation in both hands caused by joint inflammation. A detection of psoriatic skin inflammation which may also signify an altered vessel composition via FOI has not yet been examined.

**Objectives:** The aim of the present study was to investigate potential subclinical skin inflammation in comparison to psoriasis (PsO) and psoriatic arthritis (PsA) patients in comparison to rheumatoid arthritis (RA) and healthy individuals by FOI, and to correlate these findings with cardiovascular risk factors or events, since a connection to Psoriasis skin involvement is assumed.

**Methods:** FOI scans of patients with PsO and PsA as well as RA and healthy subjects were analyzed retrospectively to detect subclinical skin enhancement in both hands that did not clinically show overt psoriasis skin changes. According to the ‘fluorescence optical imaging activity score’ (FOIAS) (1) used for evaluation of joint enhancement so far, a standardized definition was set in order to describe the degree of skin enhancement via a semi-quantitative (0-3) score (see Figure). The score was applied for the first third of the FOI exam sequence (0-120 sec.). To be scored as potential subdermal skin enhancement, it had to be localized on the back of the hands without relationship to an underlying joint or blood vessel since the ICQ enhancement was then most likely localized in the area of the (sub)dermis. Using this analysis method, we further characterized the patterns and sorted the scans into the groups PsA/PsO, RA and healthy controls to compare these with the final physician’s diagnosis. Furthermore, cardiovascular risk factors (e.g. obesity, smoking status, hypertension) were collected and correlated to imaging findings.

**References:**

Results: We included FOI scans of patients with PsA/Pso (n=80), patients with RA (n=78) and healthy controls (n=22). Significantly more PsA/Pso patients showed subclinical skin enhancement on the back of their hands than RA and healthy individuals (PsA/Pso: 72.5%; RA: 20.5%; healthy controls: 29%; p<0.001). By using the pattern of skin enhancement, it was possible to categorize 58 of 80 patients correctly as PsA/Pso (72.5%), 60 out of 78 as RA (76.9%) and seventeen out of 25 as healthy controls (68.0%; p-value <0.001). We could show an influence of the body weight (kg) (p<0.001, OR 1.08, CI 1.02; 1.06) on the FOI results; no further correlation with cardiovascular risk factors was detected.

Conclusion: We were able to prove our primary hypothesis that it is possible to visualize subclinical subdermal skin inflammation in PsA/Pso patients using FOI. Furthermore, we were also able to categorize PsA/Pso and RA patients correctly by using our newly developed method. Although we could not establish a correlation between subdermal skin enhancement and cardiovascular risk factors, we demonstrated an important influence of the body weight on our FOI results. FOI may be a helpful novel tool to study microcirculation in rheumatic diseases with skin involvement.

OP0312
THE IMPACT OF AN ULTRASOUND ATLAS FOR SCORING SALIVARY GLANDS IN PRIMARY SJÖGREN’S SYNDROME: A RELIABILITY EXERCISE
N. S. Schmidt1, V. Fanaf2, H. M. Lindegaard1, L. Tereslev1, Odense University Hospital, Rheumatology, Odense, Denmark; 2Rigshospitalet-Glostrup, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark

Background: Salivary gland ultrasound (SGUS) may have the potential of facilitating diagnosis and therapy monitoring of salivary gland disease in patients with primary Sjögren’s syndrome (pSS). A novel consensus based OMERACT SGUS scoring system for the parotid and submandibular glands has recently been developed. (1)

Objectives: To assess the reliability of 3 readers using the written definition of the scoring system provided by the OMERACT group and subsequently the impact of a SGUS-atlas based on the OMERACT SGUS scoring system.

Methods: 3 sonographers with 6 months to 10 years US experience performed a US exercise of 30 SGUS images of patients with SS. 16 images were of the submandibular gland (SMG) and 14 images of the parotid gland (PG). The readings were performed over 4 rounds: the first reading without using the atlas and second reading using the atlas 1 week later. The 30 images were scanned by a physician not included in the readings and a third and fourth reading were performed without and with the atlas respectively – with 1 week in between. Inter- and intra-reader reliability were calculated by kappa-tests.

Results: Light weighted Kappa for intra- and inter-reliability was determined for each reading. The results of the intra-reader reliability was ranging from moderate to almost perfect with improvement in the 2nd round of readings and with use of the atlas. The inter-reader reliability was moderate and better in the 2nd round of readings. Readings improved with the atlas. Details are shown in table 1.

Table 1

| Tabl 1 |
|----------------------|----------------------|
| **Intrareader reliability Weighted Kappa:** | **Weighted Kappa, reader 1-3** |
| Reading 1 without atlas vs. reading 1 with atlas | 0.93, 0.95, 0.96 |
| Reading 1 with atlas vs. reading 2 with atlas | 0.76, 0.93, 0.97 |
| Reading 2 without atlas vs. reading 2 with atlas | 0.78, 1.00, 0.58 |

**Interreader reliability Weighted Kappa:**

| Reading 1 without atlas | 0.50 (0.33 – 0.72) |
| Reading 1 with atlas | 0.55 (0.39 – 0.86) |
| Reading 2 without atlas | 0.55 (0.33 – 0.93) |
| Reading 2 with atlas | 0.60 (0.40 – 0.93) |

Conclusion: The results of the inter- and intra-reliability showed a moderate to almost perfect agreement respectively, of scoring SGUS in patients with pSS and especially in the 2nd round of readings indicating that training and the SGUS atlas increased the reliability.

Fractures, more than bone alone: the role of sarcopenia

OP0313
THERAPEUTIC APPROACHES TO OSTEOSARCOPENIA: DENOSUMAB EFFECT ON FALLS RISK, PHYSICAL PERFORMANCE AND WALKING SPEED
Y. El Miedany1, M. El Gaafary2, M. Toth3, M. O. Hegazi4, N. El Aroussy5, W. Hassan6, S. Almedany7, A. Nasr8, S. Bahlas9 on behalf of Egyptian Academy of Bone Health and Metabolic Bone Diseases, 1Medway Hospital, Kent, United Kingdom; 2Ain Shams University, Community and Public Health, Cairo, Egypt; 3Darent Valley Hospital, Medicine, Dartford, United Kingdom; 4Al Adan Hospital, Kuwait, Kuwait; 5Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; 6Benha University, Rheumatology and Rehabilitation, Benha, Egypt; 7Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; 8Ain Shams University, Radiology, Cairo, Egypt; 9King Abdulaziz University, Rheumatology, Jeddah, Saudi Arabia

Background: There is a strong association between osteoporosis and skeletal muscle dysfunction. Heparan-sulfate proteoglycans are abundant in skele
tal muscles and may represent a target for RANKL inhibitor. It was noted that patients who completed their planned denosumab therapy course (5-years) started to sustain falls.

Objectives: To assess the effect of Denosumab on falls risk, physical performance, grip strength and gait speed and whether there is a relation with bone mineral density.

Methods: 127 osteoporotic patients treated with denosumab were assessed prior to starting denosumab therapy for: baseline BMD using DXA scan, blood test for osteoporosis bone profile, self-reported falls risk using (FRAS score [1]), fracture risk using FRAX, handgrip strength using a calibrated dynamometer (the best of three trials of the dynamometer testing was recorded), the patient’s physical performance assessed by testing for: Short Physical Performance Battery (SPPB), Timed Up and Go (TUG), and the 4 Meter Walk Gait Speed. Same measures were assessed again after completing 5-years of denosumab therapy. Comparison groups included 112 patients diagnosed to have osteoporosis and treated with zoledronate (Zol), once yearly IV injection, for 3-years; and 134 patients treated with once weekly oral alendronate (Aln) 70mg for 5-years. The patients were assessed for the same parameters as in the denosumab therapy. All the measures were reassessed 1-year after stopping the osteoporosis therapy.
Clinical symposium axSpA: Treat-to-target in axSpA: myth or reality?

A. Ryuxsen-Witrang1,2,2, V. Rousseau2,2,2, A. Sommet2,2,2, P. Goupille1, Y. Degoe1,2,3, A. Constantin1,2,2, CHU de Toulouse, Toulouse, France; 2Inserm, UMR 1027, Toulouse, France; 3Université Paul Sabatier Toulouse III, Toulouse, France; 4University Hospital of Tours, Tours, France; 5Inserm, UMR 1043, Toulouse, France

Background: It is recommended to target remission when treating a patient with a chronic inflammatory rheumatism. To date, drug-free (DF) remission has been poorly investigated in axial Spondyloarthritis (axSpA).

Objectives: 1/To estimate the frequency of patients in DF remission after 5 years of follow-up in a cohort of early axSpA and 2/to assess the factors associated with 5-year DF Remission.

Methods: Patients: All patients included in DESIR (DEvenir des Spondyloar-thrites Indifférenciées Récentes) cohort were selected for this analysis. Definition of 5-year DF Remission: 1/all patients in ASAS partial remission and/or ASDAS<1 at 5 year visit and 2/ taking no disease modifying anti-rheumatic drugs (DMARDs) at the 5-year visit. Covariates analysed: age, gender, smoking status, body mass index, disease classification criteria (ASAS, Amor, ESSG, New York), presentation at onset (peripheral or extra-articular features), disease activity at onset (BASDAI, ASDAS-CRP, CRP, MASES, TJC or SJC), functional impairment at baseline (BASFI, HAQ-AS, BASMI), comorbidities, baseline imaging data (radiographic sacroiliitis, mSASSS, MRI sacroiliitis, spine MRI Berlin score), NSAID intake within 6 months before baseline visit and 5-year treatment intake (including DMARDs, corticoids and NSAIDs). Statistical analysis: The associations between each of these clinical factors and the 5-year DF remission were tested by logistic regression. A multivariate model was built, stepwise procedure, to identify the independent variables associated with 5-year DF remission.

Results: Of the 708 patients included in DESIR cohort, 419 were seen at the 5-year visit and 72 (17%) were in DF remission. In the denosumab group, at 5-years of therapy, there was a significant decrease in falls risk score (-1.4, 95% CI = -2.8 to -0.7; P = .01), significant improvements in the grip strength (+4.2Kg, P = 0.01), SPSS score (1.2 points; 95% CI = -0.07 to 2.2; P = .02), TUG (1.7 seconds; 95% CI = -2.2 to 0.1; P = .03)) and gait speed (0.1 m/s; 95% CI = 0.03-0.2; P = .01). Zol and Aln improved significantly SPSS score (0.9 and 0.8 points; P < .04), TUG (1.4 and 13 seconds; P = .05) and gait speed (0.2 and 0.3 m/s; P = .02) respectively, however, there was no significant change in the falls risk (p = 0.06 and 0.07 respectively). 1-year after stopping Denosumab, there was significant worsening of the falls risk score, grip strength, SPSS score, TUG and gait speed (P = 0.1). There was no difference in all the measures 1-year after stopping Zol and Aln. There was no relation to the increase in BMD gained.

Conclusion: Denosumab displayed positive impact and significant improvements in physical performance, grip strength and gait speed. Also, Denosumab, enhanced multidirectional agility as depicted by TUG. Collectively, this would explain the reduction of falls risk which got worse on stopping the medication.

Scientific Abstracts
Conclusion: Response criteria are more discriminative than status criteria. ASDAS-CII and ASDAS-MI showed the best discrimination between treatment/ placebo arms. Using the ASDAS-CII as primary outcome in future RCTs can reduce the number of patients needed to be included while keeping the same statistical power.

New perspectives on therapeutic immune tolerance.

OP0316 EMERGING BEST-IN-CLASS IL-2 VARIANT HIGHLIGHTS TREG-DIRECTED THERAPY FOR AUTOIMMUNE DISEASE

Y. T. Hsieh1, C. Hubeau1, Y. Massal1, W. Li1, S. Frei1, B. Capra1, A. Umana1, A. Aherrera1, Y. Li1, J. Xu1, L. Rui1, CUGENE INC, Waltham, United States of America

Background: Impairment or deficiency of regulatory T cells (Treg) is associated with chronic inflammation and autoimmune diseases. Interleukin 2 (IL-2) is a cytokine indispensable for Treg expansion and immunosuppressive function. However, expansion of cytokotic effector T (Teff) and NK cells and the associated vascular leakage side effect limit the use of IL-2 in autoimmune diseases [1].

Objectives: Cugene developed a long-acting IL-2 variant with high Treg specificity and low toxicity to restore immune homeostasis and self-tolerance, and potentially cure autoimmune and inflammatory diseases.

Methods: IL-2 variants were generated based on the quaternary structure of IL-2 and IL-2Rαβγ (alpha, beta, gamma) complex. Biological activity was determined by examining differential signaling activity in induction of STAT5 phosphorylation in defined lymphocyte populations of human PBMC using flow cytometry. Binding activity was evaluated by ELISA. Pharmacokinetics, pharmacodynamics, safety and tolerability were assessed in mice and cynomolgus monkeys. Treg suppressive function was determined in vivo/ex vivo, and anti-inflammatory and anti-antibody production efficacy with significantly improved therapeutic index and manufacturability. Its favorable drug-like property and robust preclinical efficacy warrant further evaluation in patients with a variety of inflammation and autoimmune diseases.

Background: The OMERACT Ultrasound (US) in calcium pyrophosphate deposition disease (CPPD) sub-task force has been working on the use of US in CPPD since 2014 first creating definitions for CPPD identification and then assessing the reliability[1].

Objectives: Objective of this study is to assess the diagnostic accuracy (truth) of US in CPPD.

Methods: Consecutive patients waiting to undergo knee replacement surgery due to osteoarthritis were enrolled in 12 centres from 6 countries. Each patient underwent US examination of the knee, focusing on the menisci and the hyaline cartilage, the day prior to surgery, scoring each site for presence/absence of CPP as defined previously[1]. After surgery, the menisci and the condyles were retrieved and examined microscopically. Six samples were collected, both from the surface and from the internal part of menisci and cartilage trying to cover a large part of it. All slides were observed under transmitted light microscopy and by compensated polarised microscopy. A dichotomous score was given for the presence/absence of CPP US and microscopic analysis were performed by different operators, blind to each other’s findings.
Sensitivity and specificity of US were calculated using microscopic findings as the gold standard.

**Results:** 101 patients have been enrolled in the study. 33 patients have been excluded due to loss of anatomical pieces at surgery. The mean age of the remaining 68 pts was 71yo (48), 44 women, 34 were affected by CPPD according to microscopy. Overall and per site diagnostic US accuracy results are presented in table 1.

**Conclusion:** Our results demonstrate that US is an accurate exam for identification of CPPD. The best combination of sensitivity and specificity is achieved by examining the medial aspect of the knee.

**THE ROLE OF DUAL ENERGY COMPUTED TOMOGRAPHY (DECT) IN THE DIFFERENTIATION OF GOUT AND CALCIUM PYROPHOSPHATE DEPOSITION DISEASE**

D. Kravchenko1, P. Karakostas2, P. Brossart1, C. Behnning3, C. Meyer1, S. Scharf4,1, University Hospital Bonn, Department of Interventional and Diagnostic Radiology, Bonn, Germany; 2University Hospital Bonn, Clinic for Internal Medicine III, Department of Oncology, Hematology and Rheumatology, Bonn, Germany; 3University Hospital Bonn, Institute for Medical Biometrics, Informatics and Epidemiology (IMBIE), Bonn, Germany

**Background:** Differentiation of gout and calcium pyrophosphate deposition disease (CPPD) is sometimes difficult as patients often present with a similar clinical picture. Arthrocentesis and subsequent polarization microscopy (PM) remains the gold standard but novel diagnostic approaches such as non-invasive dual energy computed tomography (DECT) have recently been validated for gout. Currently, limited data is available on DECT in patients with CPPD.

**Objectives:** To analyse the diagnostic impact of DECT in gout and CPPD when compared to the gold standard of PM. We further compared the results of PM to ultrasound (US), conventional radiographs (CR), and suspected clinical diagnosis (SCD). Additionally, 15 laboratory parameters were analysed.

**Methods:** Twenty-six patients diagnosed with gout (n = 18) or CPPD (n = 8) who received a DECT and underwent arthrocentesis were included. Two independent readers assessed colour coded, as well as 80 and 120kV DECT images for signs of monosodium urate (MSU) crystals or CPP deposition. US, CR, and PM results for the patient’s initial visit along with the SCD were also compared to PM. US examinations were performed by certified musculoskeletal ultrasound specialists. The association of up to 15 laboratory parameters such as uric acid, thyroid stimulating hormone, and C-reactive protein (CRP) with the PM results was analysed.

**Results:** Sensitivity of DECT for gout was 67% (95% CI 0.41-0.87) with a specificity of 88% (95% CI 0.47-1.0). Concerning CPPD, the sensitivity and specificity of DECT was 63% (95% CI 0.25-0.91) and 83% (95% CI 0.59-0.96) respectively. US had the highest sensitivity of 89% (95% CI 0.65-0.99) with a specificity of 75% (95% CI 0.30-0.97) for gout, while the sensitivity and specificity for CPPD were 88% (95% CI 0.47-1.0) and 89% (95% CI 0.65-0.99) respectively. The SCD had the second highest sensitivity for gout at 78% (95% CI 0.52-0.94) with a comparable sensitivity of 63% (95% CI 0.25-0.92) for CPPD. Uric acid levels were elevated in 33% of gout patients and 25% of CPPD patients. While elevated CRP levels were observed in 59% of gout patients and in 88% of CPPD patients, none of the 15 analysed laboratory parameters were found to be significantly linked.

**Conclusion:** DECT provides a non-invasive diagnostic tool for gout but might have a lower sensitivity than suggested by previous studies (67% vs 90%). DECT sensitivity for CPPD was 63% (95% CI 0.25-0.91) in a sample group of eight patients. Both US and the SCD had higher sensitivities than DECT for gout and CPPD. Further studies with larger patient cohorts are needed in order to determine the diagnostic utility of DECT in CPPD.

**OP0319**

**SEE ME HEAR ME: AN ANCA-ASSOCIATED VASCULITIS PATIENT CO-CREATION INITIATIVE**

S. Pereira1, D. Krafscik2, P. Rutherford3, Digital Artist/Educator, Manchester, United Kingdom; 3Vifor Pharma, Medical Affairs, Zurich, Switzerland

**Background:** ANCA-associated Vasculitis (AAV) is a rare, severe small vessel vasculitis that affects multiple organs with a high acute mortality risk. As every patient presents differently, diagnosis is often delayed. Although treatments exist, response and remission is often not achieved or sustained. From the time of initial diagnosis onwards, patients suffer from an impaired quality of life. Coping with pain, fatigue, ongoing symptoms and combating challenges becomes a complex task and patients may be challenged in how best to communicate these emotions with health care professionals. We aimed to develop an initiative with Art and Voice, that would seek to empower people living with AAV and their carers in feeling understood, seen and heard in a meaningful way. This would invite a collective understanding of how people make sense of key life experiences and what it means to them by creating a common language to address poorly addressed issues.

**Objectives:** This project aims to provide a voice to patients to express personal experiences and complexity of everyday living and empower people to feel in control of their own health through an online platform. It should also allow practitioners to gain new awareness about issues faced by their patients, to better understand the relationships between suffering, hearing and listening.

**Methods:** We collaborated with 10 patient association groups representatives, 17 AAV patients and 9 of their carers across 7 European countries. A series of workshops were set up to discuss issues faced and aid the subsequent production of explored topics designed to provide clear, comprehensive content that would help individuals cope with the physical and emotional impact of AAV from diagnosis to living with it. This work was supported by a digital artist who is a rheumatologist living with vasculitis.

**Results:** The co-creation of patient information materials featuring real life patients that would help individuals cope with the physical and emotional impact of AAV from diagnosis to living with it. This work was supported by a digital artist who is a rheumatologist living with vasculitis.

**Disclosure of Interests:** None declared
Objectives: Our project, Fibromyalgia Network, aimed at improving the quality of life of patients with Fibromyalgia Syndrome (FMS), a condition often misunderstood. In 2019, APMARR launched a project to address the social isolation, healthcare and financial challenges of treatment, and fears of work, school, and caring for self and family. Patients experience stigma within society, depression, anxiety and post-traumatic stress disorder. FMS is characterized by diffuse, prolonged, and unexplained muscle pains. It is frequently associated with a range of health care specialties. All the activities implemented were shaped with patients' needs in mind, led by a multisectoral, patient-oriented network with different stakeholders.

Methods: The project was based on the assumption supported by evidence that a multi-modal treatment approach improves the quality of life of person with FMS including a combination of drug and non-drug treatments and a range of health care specialties. All the activities implemented were shaped on a holistic approach to treating Fibromyalgia, including lifestyle management, diet and exercise, and psychosocial techniques, in addition to medical treatments.

Results: 1) A territorial network coordinated by APMARR was created involving Puglia Region, Health Authorities, Professional board of Psychologists, National Association of People with FMS, Professional board of Physicians, Italian Society Of Rheumatology-Puglia

Conclusion: The project demonstrated the good results of the holistic approach in the patients who took part in the program that reported improvements of their quality of lives and relieve from their daily pains. The

Conclusion: People with AAV need support throughout life, the profound psychosocial influence from illness makes the lived experience, challenging. SEE ME, HEAR ME, online patient platform aims to generate awareness around AAV, improve physician and patient dialog, and enhance people’s experiences of living and coping with the disease. In addition it provides support for carers and giving valuable insights to friends, family and the general public about what the lived experience with AAV looks like.

Acknowledgments: We wish to thank all European patients and patient association leaders who worked on this project.

DOI: 10.1136/annrheumdis-2020-eular.1494
Self-mutual help group was the most appreciated free service, in which participants shared personal stories and perspectives thoughtfully and courageously. The training initiatives organized in collaboration with physicians helped them to learn tips for a better lifestyle management, diet and exercise, and psychosocial techniques but above all helped to overcome concerns and frustration regarding the lack of understanding in the medical community. The network succeeds to increased awareness and understanding of FMS across the public opinion and GPs.

OP0321-HPR

HIGHER QUALITY OF CARE AND LESS SURGERY AFTER IMPLEMENTING OSTEOARTHRITIS GUIDELINES IN PRIMARY CARE – LONG-TERM RESULTS FROM A CLUSTER RANDOMIZED CONTROLLED TRIAL

N. Østernå, T. MoisenÅ, L. Van Bodegom-Vos, K. Dziedzic, Ø. Andreassen, A. M. Fenstad, O. Funes, J. Nygren Hansen, B. Natvig, J. H. Røtterud, U. B. Schjerheim, T. P. M. Vliet Vlieland, K. B. Hagen. Diakonhjemmet Hospital, Oslo, Norway; Leiden University, Leiden, Netherlands; Keele University, Keele, United Kingdom; Haukeland University Hospital, Bergen, Norway; University of Oslo, Oslo, Norway; Åkershus University Hospital, Lørenskog, Norway; Nes Municipality, Nes, Norway

Background: To improve quality of care for patients with hip and knee osteoarthritis (OA), a structured model for integrated OA care was developed and implemented among general practitioners (GPs) and physiotherapists (PTs) in primary care. The model was developed based on international treatment recommendations. After 6 months, patient-reported quality of care and satisfaction with care were greater, more patients were referred to physiotherapy and fewer to orthopaedic surgery, and more patients fulfilled physical activity criteria among OA patients receiving the new model of care compared to the usual care control group.

Objectives: To assess the long-term effects 12 months after implementing the model in primary care.

Methods: A cluster-randomised controlled trial with a stepped-wedge design was conducted in six Norwegian municipalities (clusters). The intervention included implementation of the model, facilitated by interactive workshops for GPs and PTs. The main components of the model were a PT led, 3 hour patient education programme followed by 8-12 weeks of individually tailored, supervised exercise. Patient participants were ≥45 years with symptomatic hip or knee OA. Primary outcome was patient-reported quality of care (OsteoArthritis Quality Index [OAI] questionnaire, 0–100, 100 = optimal quality). Secondary outcomes included satisfaction with care, referrals to physiotherapy, orthopaedic surgery and magnetic resonance imaging (MRI), joint replacement surgery, fulfillment of physical activity recommendations, and proportion with overweight (body mass index ≥25 kg/m²). Data was analysed using multilevel mixed models adjusted for age, sex and secular time.

Results: In all, 40 of 80 GPs and 37 of 64 PTs attended the workshops. A total of 393 patients with hip and knee OA were included, with 284 in the intervention and 109 in the usual care control group. In the intervention group, 92% attended the OA education programme and 64% completed ≥8 weeks of exercise. At 12 months the intervention group reported significantly higher quality of care (score 58 vs. 41, mean difference: 17.6; 95% CI 11.1, 24.0) compared to the control group. The intervention group reported significantly higher satisfaction with care (Odds ratio (OR) 7.8; 95% CI 3.55, 17.27) and a significantly larger proportion (OR: 4.0; 95% CI 1.27, 12.63) met the recommendations for physical activity compared to the control group. A smaller proportion was referred to orthopaedic surgery (OR 0.5; 95% CI 0.29, 1.00) and a smaller proportion received joint replacement surgery in the intervention (4%) compared to the control group (11%) (OR 0.3; 95% CI 0.14, 0.74). The proportion of patients referred to physiotherapy or MRI and the proportion with overweight were similar between the groups.

Conclusion: Implementation of a structured model for OA care led to improved quality of care, higher satisfaction with care and higher physical activity levels after 12 months. These results are comparable to the 6 months results, which indicate a long-term persistence in the beneficial effects of the intervention. The lower surgical rate in the intervention compared to the control group suggests that higher uptake of OA recommendations in primary care may reduce or postpone the need for surgery in people with hip or knee OA.

OP0322-PARE

HOW TO COMMUNICATE DIAGNOSTIC INFORMATION AND CUTTING EDGE SCIENCE TO PATIENTS WITH RHEUMATIC DISEASES

I. Loell1, S. Jansson1, J. Hammerström1, L. Aleo Munsters1,2. Swedish Rheumatism Association, Stockholm, Sweden; Karolinska University Hospital, Functional Area Occupational Therapy and Physical Therapy, Stockholm, Sweden

Background: According to the 2017 Swedish Rheumatology Association (SRA) member strategy a recurring member survey as well as a member withdrawal survey was stipulated. The strategy was developed to evaluate to what extent SRA fulfills the requirements and expectations of its members. According to the 2019 survey, the most important output from a SRA membership, the members rank information about their diagnosis (#1) and supporting the research of these diagnoses (#2) most valuable.

Objectives: To transfer the medical and scientific expertise of the rheumatic diagnoses into lay information in order to meet the member’s needs; to take part of the results of the cutting edge science and research progress, funded by SRA, that are relevant and important to individuals living with rheumatic conditions.

Methods: A targeted scientific communication strategy was made consisting of lectures, interviews and scientific writing created for multi-channel distribution.

Results: Actions taken upon the survey result
• Brief summaries of every research project funded by SRA in 2019 was written and distributed via social media.
• A research day for lay people was arranged in collaboration with a regional SRA branch and invited speakers. The filmed lectures are also available online.
• A research report with in-depth interviews with researchers and brief summaries about the research funded by SRA was produced. The report was printed and distributed in 70,000 copies to the SRA members, donors and at SRA meetings and conferences.
• Diagnosis sheets aimed to newly diagnosed patients with the most essential information has been developed in collaboration with a patient research partner and an expert researcher within the field. The sheet is printable and can be distributed by any healthcare practitioner or by patients/public.
• Online patient school prototype - gout. In collaboration with the SRA funded gout network we are gathering high quality information about the diagnosis, treatment, self-care and support in the meeting with the healthcare provider for patients to easily navigate and to find robust answers to their inquiries about their disease.

Conclusion: As a member of SRA, regardless of rheumatic disease, the main interest is knowing more about their diagnosis and about the ongoing research in the field. Through collaborations and communicating rheumatic conditions and
research within the field in lay language the patients can experience self-empowerment and the need for patient education can be met.

The cost-opportunity of screening: osteoporosis in the general population

The cost-opportunity of screening: osteoporosis in the general population

Incidence of clinical fractures in rheumatoid arthritis (RA) is not as well-known as hip or vertebral fracture incidence. Clinical fractures [1] are fractures occurring in patients presenting for bone mineral density (BMD) estimation.

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2020-eular.1680

OP0323

INCIDENCE OF CLINICAL FRAGILE FRACTURES
IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS. A MULTICENTRIC CASE-CONTROL STUDY

Background: Incidence of clinical fractures in postmenopausal women prescribed with osteoporosis medication was published in 1998. However, it is known that the incidence of clinical fracture in postmenopausal women diagnosed with RA is higher than in the general population [2].

Objectives: 1. To estimate the incidence of clinical fractures in a population of postmenopausal women with RA and compare it with that of the general population; 2. To analyze the risk factors for fracture.

Methods: 330 postmenopausal women with RA from 19 Spanish Rheumatology Departments, random selected from the registry of RA patients in each center. The control group consisted of 660 Spanish postmenopausal women from the Camargo cohort. Clinical fractures during the previous 5 years were recorded. Estimated risk factors for fracture were: sociodemographic characteristics, BMD, and variables related to RA.

Results: Median age of RA patients was 64 yrs. vs. 63 yrs. in controls (ns). Evolution of the disease was 8 yrs. 78% and 76% had RA and ACPA+, respectively. 69% of patients were in remission or low activity. 85% had received glucocorticoids and methotrexate and 40% at least one biological DMARD. We identified 105 fractures (87 fragility and 18 traumatic) in 75 patients. Fifty-four patients and 47 controls had at least one major fracture (MF) (p < 0.001). Incidence of MF was 3.55 per 100 patient-year in patients and 0.72 in controls. Risk factors for MF in RA patients were age, previous fracture, parental hip fracture, postmenopausal period, hip BMD and cumulative dose of glucocorticoids. In controls, risk factors were age, at menopause and lumbar BMD.

Among RA-associated factors, MFs were associated with erosions, disease activity and disability. Previous fracture in RA patients was a strong risk for MF (HR: 10.37 [95% CI: 2.95-36.41]).

Conclusion: Between 3 and 4 of every 100 postmenopausal women with RA have a major fracture per year, four times more than the general population. Disease activity and disability associated with RA, the cumulative dose of glucocorticoids and mainly previous fracture are associated with the development of fragility fractures.

OP0324

CLUSTERING OF FRAGILITY FRACTURES BY SITE IN PATIENTS REFERRED FOR BONE MINERAL DENSITY ESTIMATION: AN OBSERVATIONAL STUDY

M. Day, J. M. Bukhari, Institute of Ageing and Chronic Disease, University of Liverpool, Musculoskeletal Biology I, Liverpool, United Kingdom; Aintree University Hospital, Liverpool University Hospitals NHS Foundation Trust, Academic Rheumatology, Liverpool, United Kingdom; Royal Lancaster Infirmary, University Hospitals of Morecambe Bay NHS Foundation Trust, Rheumatology, Lancaster, United Kingdom.

Background: Fragility fractures (FF) are those resulting from mechanical forces equivalent to a fall from standing height or less [1]. They most commonly occur in the spine (vertebrae), forearm, and femur, but also occur at other sites. Prevalence markedly increases with age, due to age-related and menopause-related bone loss. FF cause substantial pain and disability, and are associated with decreased life expectancy. While many studies have investigated risk factors associated with FF, there are few data on the association between FF sites in at-risk patients.

Objectives: 1. Establish the most common sites of FF in patients presenting for bone mineral density (BMD) estimation. 2. Identify patterns of co-existing FF in the above cohort by applying cluster analysis.

Methods: We retrospectively reviewed the clinical records of 28868 patients presenting for BMD estimation at a district general hospital in North West England, 2004-2016, identifying those who had sustained one or more FF. Site(s) of FF were recorded for each patient, categorised as: ankle, elbow, femur, forearm, humerus, pelvis, ribs, spine, tibia or fibula (recorded as “tibfib”). Cluster analysis was performed on fracture sites, using Jaccard similarity coefficient. Results were plotted on a dendrogram and divided into clusters, as per results derived from elbow and silhouette cluster methods.

Results: Out of 28868 patients presenting for BMD estimation, 11003 were identified as having sustained one or more FF. 84.6% patients were female, with mean age 67.5 years and median T-score -1.12 SD. The most common site of FF was the forearm (n=5045), most commonly co-existing with fractures of the tibia and fibula. Frequencies of the most common and co-existing FF sites are shown in Figure 1 (top). Cluster analysis identified 3 clusters: ankle and elbow; forearm, tibia/fibula, ribs, and spine; pelvis, femur, and humerus. The second half of Figure 1 displays the dendrogram of cluster analysis results, with Jaccard similarity measure.

Conclusion: We applied cluster analysis to a large cohort of patients presenting for BMD estimation. Our results are in keeping with previous studies demonstrating the FF to most commonly occur in the forearm, and in those with osteopenia (T-score -2.5 < -1 SD) [2]. To our knowledge, this is the first study to apply cluster analysis to sites of FF. Results may be due to differences in cortical and trabecular bone structure, and have potential to aid prevention, monitoring, and management in at-risk patients.

EFFECT OF CITRULLINATION ON THE PROCESSING AND PRESENTATION OF RHEUMATOID ARTHRITIS AUTOANTIGENS

A. M. Curran¹, J. Crawford¹, E. Darrah¹, Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, MD, United States of America

Background: Citrullinated proteins are hallmark targets of the autoimmune response in rheumatoid arthritis (RA),¹ but the mechanism by which immune tolerance is broken to these self-proteins is poorly understood. CD4⁺ T cells are implicated as important drivers of the autoimmune response due to the high-affinity, class-switched nature of anti-citrullinated protein antibodies (ACPAs) present in the majority of RA patients and the prominent genetic contribution of certain HLA-DR alleles to RA susceptibility.²,³ However, the precise effect of citrullination on MHC class II antigen processing and presentation of autoantigens to CD4⁺ T cells remains unknown.

Objectives: Here we aimed to examine the hypothesis that citrullination impacts the processing and presentation of RA autoantigens via destabilization of protein folding and modification of protease cleavage sites, altering the peptide repertoire presented by antigen-presenting cells (APCs).

Methods: Using fibrinogen as a model RA autoantigen, the native and citrullinated forms were digested in vitro by a cocktail of lysosomal cathepsins (cathepsins B, S, and H) for proteolytic mapping, or incubated with monocytic-derived dendritic cells (mo-DCs) in a natural antigen processing assay (NAPA). Peptides generated by digestion with the cathepsin cocktail or presented by HLA-DR molecules on mo-DCs were then isolated and identified by mass spectrometry.

Results: We found that the repertoire of peptides generated by each method was altered by citrullination. By proteolytic mapping, we detected both changes in the pattern of cathepsin cleavage and an increased number of peptides in the citrullinated samples. Utilizing NAPA, we observed the creation of newly presented peptides in the citrullinated samples in some cases, and loss of presented peptides in others (Fig. 1). Strikingly, all peptides whose presentation was destroyed by citrullination contained a citrullination site. Together these results suggest that both protease cleavage and selection of peptides by HLA-DR are impacted by citrullination.

Conclusion: Citrullination alters the peptide repertoire presented by APCs. Interestingly, no citrullinated peptides were identified by NAPA, suggesting that presentation of citrulline-containing peptides to T cells may not be the primary mechanism by which tolerance is broken to citrullinated antigens. Rather, citrullination-induced destabilization of protein folding and modification of protease cleavage sites, leading to the generation of a new peptide repertoire, could play a role in activating autoantigenic T cells. This mechanism could thus drive the loss of immune tolerance to the citrullinolyzed forms of RA autoantigens.

ACPA-INDUCED PAIN-BEHAVIOR, BONE LOSS AND TENDON INFLAMMATION IN MICE: A NOVEL MODEL FOR THE PRE-DISEASE PHASES OF ACPA-POSITIVE RHEUMATOID ARTHRITIS

A. Krishnamurthy¹, Y. Kisten², C. Ciricurmaru², K. Sakurabas², P. Jarvolli², J. J. Jimenez Andrade², P. Damberg², H. Wahlhäma², V. Malmström², I. Klareskog², C. Svensson², B. Ris², A. Curtin², Karolinska Institutet, Rheumatology Unit, Stockholm, Sweden; ²Karolinska Institutet, Rheumatology Unit, Stockholm, Sweden; ³Universidad Autónoma de Tamaulipas, Tamaulipas, Mexico, Mexico; ⁴Karolinska Institutet, Stockholm, Sweden; ⁵Karolinska Institutet, Physiology and Pharmacology, Stockholm, Sweden

Background: In rheumatoid arthritis (RA), anti-citrullinated protein antibodies (ACPAs) are associated with bone loss and pain. Recently, tenosynovitis has been suggested as a predicting factor for arthritis progression in individuals at-risk for RA.

Objectives: We aimed to investigate if transfer of human ACPAs into mice could induce tenosynovitis and/or subclinical inflammation.

Methods: Monoclonal ACPA (1325:04C03 and 1325:01B09) and control (1362:01E02) antibodies (mAbs) were generated from synovial plasma or memory B cells of RA patients. 2mg of combination of monoclonal ACPAs or control antibody were injected in BALB/c female mice (age 12-16 weeks) (n=9). Pain-like behavior was monitored by measuring mechanical hypersensitivity using von Frey filaments every 3 days and estimation by up-down Dixon method. Bone morphometrics was analyzed by micro-CT. Using specially designed mobilization casts, dedicated mouse MRI coils, and gadolinium enhanced contrast medium, the hind limbs of these mice were scanned in a 9.4 T scanner and resulting T1-weighted images were evaluated for signs of soft tissue joint inflammation. The MRI images were scored for the presence of joint involvement and tendon inflammatory changes by 3 readers in a blinded manner.

Results: ACPAs (1325:04C03 and 1325:01B09) induced pain-like behavior (lasting for at least 4 weeks) and reduction of the trabecular and cortical bone thickness in the hind limbs as compared to control monoclonal antibodies (p<0.05). While no macroscopic or MRI signs of synovial inflammation were detected, MRI subclinical inflammation of the tendon sheaths was present in mice injected with ACPAs, but not in those injected with control mAb. Semi-quantitative scoring of the inflammatory tendon changes showed significant higher values in mice injected with ACPA (median of 1, range 0 to 2) than those injected with control mAb (median of 0, range 0 to 1).

Conclusion: We show that ACPA induces pain-like behavior, bone loss and tendon sheath inflammation in mice, a model that mimics the preclinical stage of ACPA positive RA.

Autoimmune diseases by abnormal T cell function

OP0328 A UNIQUE PD1+CD38+ CD8+ T CELL POPULATION CHARACTERIZES CHECKPOINT INHIBITOR-ASSOCIATED INFLAMMATORY ARTHRITIS

R. Wang1, K. K. Chan2, A. Cunningham-Bussel3, L. Donlin4, G. Vitone5, A. Tirpak6, C. Benson2, G. Keras7, A. H. Jonsson1, M. Brenner1, A. Bass3, D. Rao1,1 Brigham and Women’s Hospital, Rheumatology, Boston, United States of America; 2Hospital for Special Surgery, Rheumatology, New York, United States of America; 1Hospital for Special Surgery, Research, New York, United States of America

Background: Immune checkpoint inhibitors (CI) are monoclonal antibodies that block CTLA-4, PD-1 or PD-L1, resulting in cytotoxic T cell activation in the tumor microenvironment. They have revolutionized the management of metastatic cancer but unleash “immune related adverse events” in > 80% of treated patients, including inflammatory arthritis in ~4%. CI-associated arthritis (CI-A) often presents as a symmetrical polyarthritis, phenotypically indistinguishable from rheumatoid arthritis (RA), but whether it shares cellular and molecular features of RA has not been determined.

Objectives: To compare synovial fluid (SF) T cell populations from CI-A patients to those in RA, phenotypically and functionally.

Methods: We immunophenotyped SF mononuclear cells from patients with CI-A caused by anti-PD-(L)1 therapy (n=9), seropositive RA (n=5), and psoriatic arthritis (PsA) (n=5) using a 39-marker mass cytometry (CyTOF) panel. FlowSOM was used to cluster CD4 and CD8 T cells into 15 ‘metaclusters’ based on multidimensional phenotypes. We used Kruskal-Wallis or Mann-Whitney tests to identify significantly altered populations (p<0.05), which we confirmed by biaxial gating. Flow cytometry was used to confirm SF findings in an independent cohort, and to identify cells of interest in peripheral blood. Cytokine staining was performed on sorted T cells populations after CDCD3/CD28 stimulation for 72 hours, followed by 4 hour PMA/ION-BRA/MON restimulation.

Results: In CI-A patients, T cells represented 50% of SF mononuclear cells (53% CD4, 40% CD8), followed by monocytes (24%) and NK cells (8%), comparable to RA and PsA. However, FlowSOM analysis revealed expansion of a distinct population of PD-1+ CD38+ CD127- CD8 T cells (CD8 metacluster2) (Fig. 1). These cells comprised 30% of CD8+ SF T cells in CI-A, a 3.4-fold increase over RA/PsA, p<0.0002 (Fig. 2). Over 40% of these cells expressed Ki67 in CI-A, suggesting active proliferation. Flow cytometry on SF cells from an independent cohort of CI-A patients (n=5) and RA/PsA comparators (n=9) confirmed our findings. PD-1+ CD38+ CD127- CD8 T cells were also expanded in the blood of CI-A patients, where they represented 4.6% of CD8 T cells, a 2.8-fold increase over RA, p=0.0057. In addition to expressing high levels of PD-1, CD38 and CD127, these CD8 T cells express other immune checkpoint receptors including ICOS and TIGIT. After in vitro stimulation, CD38+ CD127- CD8 T cells produced granzyme B along with TNF and IFN-γ at comparable levels to other CD8 populations, suggesting that they are not functionally exhausted.

Conclusion: Osteosan is a program developed on the base of AI technologies, analyzes radiographic images of the knee joints for determining OA stage. It provides high accuracy in OA stage determining by assessing knee radiographs, in 95% of cases, the accuracy of the system varies from 91.8% to 99%.

OP0327 EVALUATION OF THE ARTIFICIAL INTELLIGENCE SYSTEM ACCURACY IN DETERMINING THE RADIOGRAPHIC STAGE OF KNEE OSTEOARTHRITIS

O. Georginova1, M. Kobzar2,1 Moscow State University, Moscow, Russian Federation; 2GlaxoSmithKline Healthcare, Moscow, Russian Federation

Background: Within the last decade, rapid development of artificial neural networks and machine reading programs and their introduction into medical practice is reported [1,2,3]. Recently, an innovative program, based on the artificial intelligence (AI) technologies (a neural network and machine reading) that analyses knee X-ray images for determining the radiographic stage of OA was created. It was launched on the Osteoscan.ru website and is available for use by patients and doctors.

Objectives: to validate the system accuracy to stage OA through machine interpretation of standard knee radiographs.

Methods: Initially, 1300 x-rays of both knee joints where used to teach the neural network. Of these, 350 were presented in the form of film scans, 950 in the DICOM format. The accuracy of the system in recognition of OA stage by knee radiographs was evaluated on a quality control sample of 130 cases (of all 1300). Independently, the radiographs were assessed by certified radiologists (considered the “gold standard”) and the System.

Results: In 124 out of 130 cases the conclusion of a specialist and the System was the same, which represents 95.4% predictive power. Coincidence or discrepancy is a qualitative attribute, so, the accuracy of the estimation was calculated. Assuming a discrepancy of 0, and coincidence - of 1, µ = 0.954, the standard error σ = 1.8%. It can be concluded that in 95% of cases the accuracy of the system assessment will be in the range from 91.8% to 99%.

Conclusion: Osteosan is a program developed on the base of AI technologies, provides high accuracy in OA stage determining by assessing knee radiographs, in 95% of cases, the accuracy of the system varies from 91.8% to 99%.

OP0325 FlowSOM analysis of CI-A patients revealed the expansion of a subpopulation of CD4 cells with a similar surface phenotype of PD-1+ CD38+ CD127- (metacluster2, 10% of CD4 in CI-A, 2.4-fold increase over RA/PsA, p=0.0047). In contrast, RA patients had a significantly expanded population of PD-1+ CD38- CD4 T cells expressing high levels of PD-L1 (70% of CD4 in RA, p=0.005), but these cells were not expanded in CI-A (Fig 3).

Conclusion: CyTOF analysis of SF revealed a uniquely expanded PD-1+ CD38- CD127- CD8 T cell population in CI-A not present in RA or PsA, and a similar PD-1+ CD38+ CD127- CD4 T cell population. These cells may contribute to the amplified immune response seen in CI-A patients. Further functional and transcriptional analysis of these cells will help to elucidate their function.

Background: Participation in everyday life and the relationships between persons with rheumatoid arthritis (RA) and their significant others are often affected by the disease. Usually, both parts need to adapt to new roles [1]. However, the dyadic interaction between them in everyday life is yet to be understood on a deeper level.

Objectives: To explore I) How dyads consisting of persons with RA and their significant others comprehend support and participation in everyday life, and II) how the dyadic interaction can influence their experience of participation in everyday life.

Methods: In-depth individual interviews were conducted both with the persons with RA 12-13 years after diagnosis and inclusion in the Swedish multicenter project TIRA-2 [2], and with their significant others as defined by the persons with RA. Demographic data and the Valued Life Activity Scale (VLA-swe) [3] was reported by the persons with RA. To avoid bias, the persons with RA and their significant others were interviewed by different researchers. Data from the interviews were transcribed verbatim and content analysis with a dyadic approach was undertaken [4]. The process of coding and categorizing was discussed between the researchers. The study was approved by the Regional Ethics Committee at Linköping University (Dnr. 2018/158-31), all participants gave their written consent.

Results: Three women and two men with RA and five significant others, all represented by spouses, participated (n=10). The age of the persons with RA ranged from 34 to 67 years and a majority experienced difficulties in 12 valued life activities. Three categories were revealed: 1) A strong willpower affecting the dyadic relationship, meaning that the understanding within the dyads was that the persons with RA were not so keen to share status, which was mentioned in connection to tenacity and expectations. 2) Being a support to each other, referring to the mutual understanding within the couples that there was a constant exchange of support, forming a basis for participation in everyday life. However, disagreement was expressed concerning an unequal amount of support. 3) The dyads potential issues with awareness, addressing the difficulty in fully comprehending the impact of the diagnosis. The couples mentioned an unwillingness from the person with RA to share information, and the significant other viewing comments as complaining. This type of miscommunication was interpreted as a potential negative effect on participation in everyday life.

Conclusion: A constant exchange of support within the dyads was evident. However, the dyadic relationships were often affected by the willpower of the persons with RA to be independent in everyday life. In addition, the dyads faced the concern of fully understanding the diagnosis. The results indicate further needs for interventions for both the persons with RA as well as the significant others, in order to boost the dyadic interaction, and thereby facilitate optimal participation for interventions for both the persons with RA as well as the significant others, in concern of fully understanding the diagnosis. The results indicate further needs for interventions for both the persons with RA as well as the significant others, in concern of fully understanding the diagnosis.

**OP0332 MUSCLE DETERIORATION DUE TO RHEUMATOID ARTHRITIS: ASSESSMENT BY QUANTITATIVE MRI AND STRENGTH TESTING**

M. Farrow\(^1,2\), J. Biglands\(^3\), S. Tanner\(^4\), E. Hensor\(^1\), M. H. Buch\(^1,4\), P. Emery\(^1\), A. L. Tan\(^5\), \(^1\)Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds School of Medicine, Leeds, United Kingdom; \(^2\)School of Pharmacy and Medical Sciences, Bradford, United Kingdom; \(^3\)Medical Physics and Engineering, Leeds Teaching Hospitals NHS trust, Leeds, United Kingdom; \(^4\)Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom

**Background:** As well as joint damage, rheumatoid arthritis (RA) is also associated with altered body composition known as rheumatoid cachexia (RC). RC is characterised by reduced skeletal muscle and increased (white) fat mass and decreased strength. RC is associated with increased disease severity and disability (1). It is unknown at what stage muscle involvement begins in RA, and if the muscle damage is modifiable when patients achieve disease control.

Quantitative MRI (qMRI) can measure the biomarkers associated with RC. MRI T2 is sensitive to fluid related to physiological changes at the molecular level, and is regarded as an indirect measure of muscle inflammation (2). MRI muscle fat fraction (FF) measurements are useful for identifying myosteatosis (3).

**Objectives:** To obtain preliminary estimates of the extent to which muscle imaging phenotype differs between RA and healthy controls (HC), and to describe the RA phenotype at different levels of disease activity.

**Methods:** 39 RA patients (comprising three groups) and 13 age and gender matched HC had a MRI scan of their dominant thigh. The RA groups were:

1. "New RA" - newly diagnosed, treatment naive
2. "Active RA" - diagnosed >1 year, persistent DAS28 >3.2 for >1 year
3. "Remission RA" - diagnosed >1 year, persistent DAS28 <2.6 for >1 year

MR images of the mid-thigh were acquired using Dixon imaging to assess FF and a fat-suppressed multi-echo spin-echo to measure T2. Regions of interest were drawn around the quadriceps and hamstrings. All participants had knee extension and flexion torque measured on an isokinetic dynamometer, and isometric dynamometer to measure grip strength. One-Way ANOVA with Dunnett’s post-hoc analysis provided preliminary indication of potential differences between T2, FF, muscle volume and strength measurements between the disease stages.

**Results:** 39 RA patients were recruited: 13 new RA (mean age [years] 63 ± 15, DAS28 5.2 ± 3), 13 active RA (mean age [years] 65 ± 10, DAS28 4.8 ± 3), 13 remission RA (mean age [years] 67 ± 19, DAS28 1.7 ± 0.7) and also 13 HC. T2 and FF were higher in RA patients compared to HC (fig. 1). Within the hamstrings for T2, the mean differences between HC versus new, active and remission patients were 4.5ms (95% CI 2.5, 6.4; p<0.001), 3ms (95% CI 1.1, 4.9; p=0.001), and 5.0ms (95% CI 3.0, 6.4; p<0.001) respectively. Quadriceps results were similar. For muscle volume, the mean differences between HC versus new, active and remission patients were -517.3cm\(^3\) (95% CI -751, -283; p<0.001), -370.5cm\(^3\) (95% CI -605, -136; p=0.001), and -312.3cm\(^3\) (95% CI -546, -77; p=0.006) respectively (fig. 2). Knee flexion/extension and handgrip strength were lower in all 3 groups of RA patients compared to HC. For knee flexion, the mean differences between HC versus new, active and remission patients were 18.4Nm (95% CI -25, -1; p=0.03), 10.1Nm (95% CI -27, 7; p=0.3), and 13.3Nm (95% CI -33, 0; p=0.1) respectively.

**Conclusion:** This pilot study suggests muscle health may be adversely affected in RA patients compared to matched HC. Our results suggest that muscle changes occur in the earliest stages of RA and persist throughout the disease duration, even in clinical remission. If confirmed, these data imply the need for adjunctive muscle intervention to current RA treatment strategies in order to improve patient outcomes.

**RISK FACTORS OF ANTIMALARIAL-INDUCED RETINOPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS AND OTHER AUTOIMMUNE CONDITIONS**

H. Y. Liu1, G. Cramarossa1, J. Pope1, 2Western University, London, Canada

**Background:** Hydroxychloroquine (HCQ) and chloroquine (CQ) are effective antimalarial (AM) medications for systemic lupus erythematosus (SLE) and other autoimmune conditions such as rheumatoid arthritis (RA). AM-induced retinopathy is a well-recognized irreversible complication with variable incidences [1]. Few studies have compared the AM-induced retinopathy between rheumatological conditions.

**Objectives:** To describe the pattern of AM-associated retinopathy, including diagnosis of SLE as a risk factor.

**Methods:** A chart review was conducted at an urban Canadian center. Each patient was classified as SLE, based on ACR criteria, or non-SLE. Minimum duration of AM use was 3 months. AM-induced retinopathy was classified as possible or definite, and was determined based on characteristic visual field loss, abnormal retinal imaging, and eye specialists’ opinion. Univariate and multivariate logistic regressions were performed to determine factors associated with definite AM-induced retinopathy. Sensitivity analyses included inclusion of possible AM-induced retinopathy and stratification of analysis by diagnosis and by CQ versus HCQ.

**Results:** Of 80 patients, 282 patients had SLE and the remaining had RA (N=224), cutaneous lupus (N=41), or other connective tissue diseases (N=131). Patients with SLE tended to be younger, female, and had relatively more CQ and total AM exposure (Table 1). Definite AM-induced retinopathy was observed in 12 patients, 11 of whom had SLE and 7 had chloroquine exposure (Figure 1). The earliest toxicity occurred after 5.4 years of AM use, and prevalence beyond 5 years was 2.7%.

*other connective tissue diseases and RA

In univariate logistic regression (Table 2), a diagnosis of SLE (P=7.95×10-3; OR=1.002; 95% CI=[1.001, 1.003]) was significantly associated with definite AM-induced retinopathy. When possible retinopathy was included in the analysis, both SLE (P=7.27×10-3; OR=3.12, 95% CI=[1.39, 7.00]) and CQ cumulative dose (P=6.16×10-7; OR=1.002; 95% CI=[1.001, 1.003]) remained significant. Total AM duration and hypertension also had significant associations. In multivariate analysis, diagnosis of SLE was significantly associated with ocular toxicity (P=1.49×10-2; OR=14.2; 95% CI: [1.83-127]) after adjusting for CQ/HQC dosages, age, sex, weight, hypertension and renal impairment.

**GSGTASE DEFICIENT MACROPHAGES ALTER INTEGRIN EXPRESSION ON LYMPHOCYTES AND FACILITATE DEVELOPMENT OF ARTHRITIS**

K. M. Andersson1, E. Malmhäll-Bah1, M. C. Erlandsson1, M. Brisslert1, M. Akula2, O. Khan2, I. M. Jonsson1, M. Bergö2,3, M. I. Bokarewa1,4,5University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2University of Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden; 3Karolinska Institute, Department of Biosciences and Nutrition, Stockholm, Sweden; 4Sahlgrenska University Hospital, Gothenburg, Sweden

**Background:** Geranylgeranylationtransferase type I (GGTaseI) is the enzyme responsible for the prenylation/lipidation of the RhoA family proteins, which keeps them attached to the cell membrane. We reported that GGTase-deficient (GLC) mice develop a spontaneous and age-dependent arthritis, reproducing the pathology of RA [1]. Targeting GGTase activates RhoA proteins.

**Objectives:** To study which of the activated Rho proteins is responsible for development of arthritis, we deleted individual RhoA, Rac1 or Cdc42 genes in GLC mice. We study consequences of GGTase deficiency for lymphocyte function.

**Methods:** Double deficient mice that lack Rac1 (GLC Rac1fl/fl), RhoA (GLC RhoAfl/fl) and Cdc42 (GLC Cdc42fl/fl) were developed by Cre-technology using the LysM-promotor, and were on a mixed genetic background (129Ola/Hsd-C57BL/6). Joints of the hind paws were assessed for signs of arthritis histologically and by micro CT at age of 16 weeks. Phenotype of spleen CD4 and CD8 T cells was analysed by flow cytometry. Proliferation and cytokine production was assessed in spleen cultures by ELISA. Gene expression profile was analyzed by RT-PCR.

**Results:** Deletion of Rho proteins had divergent effect on development of arthritis in GLC mice. We observed a reduction of the arthritis index in GLC Rac1fl/fl (n=19, p=0.027) and GLC RhoAfl/fl (n=4, p=0.007) mice compared to GLC (n=16), while GLC Cdc42fl/fl (n=4) had no change in arthritis development. GLC RhoAfl/fl mice increased the bone mass compared to GLC (p=0.029).

**Conclusion:** The risk of AM-induced retinal toxicity increases after 5 years of AM use. Patients may be at increased risk due to longer treatment duration, AM choice, and underlying disease processes.
RhoAfl/fl mice. Additionally, RA-prone mice had higher expression of receptors to extracellular matrix proteins collagen (α1CD4 cells and the expression of α5β1 receptors on CD4 cells correlated strongly with the synovitis score (r=0.72, p=0.0017 and r=0.59, p=0.012, respectively). GTasG gene lacks under the control of HOX proteins essential for cell homing. Importantly, HOX regulates the expression of integrins. Studying the expression of HOX genes in spleen, we found that RA-prone and GLC Colα42 mice tended to have lower expression of HOXα2 and higher expression of HoxA9 compared to RA-resistant GLC Rac1 and GLC RhoA, and to control mice. The Hoxα/Hoxα2 ratio was significantly higher in RA-prone mice compared to RA-protected mice (p=0.0085) and control mice (p=0.019). This ratio correlated with α5β1 receptors (r=0.55, p=0.0084), FOXP3+CD4 cells (r=0.50, p=0.017), and the arthritis index (r=0.50, p=0.033).

Conclusion: Taken together this study shows that Rho proteins play divergent role in development of arthritis. Activation of Rac1 and RhoA by GTasG deletion changes the pattern of HOXA proteins and increases expression of integrin receptors, which facilitates leukocyte influx in the paw joints, Deletion of Rac1 and RhoA has RA-protective effect in GLC mice.

**DIFFERENTIAL METHYLATION OF PERIPHERAL BLOOD ADAPTIVE IMMUNE CELLS IN INDIVIDUALS AT HIGH RISK FOR RA AND WITH EARLY RA COMPARED WITH CONTROLS IDENTIFIES PATHWAYS IMPORTANT IN TRANSITION TO ARTHRITIS

R. A1, D. Boyle1, D. Hammaker2, K. Deang3, V. M. Holers4, A. Matti1, W. Robinson5, J. Buckner6, N. Rao3, F. Barbabud1, A. Johnsen1, S. Nagda1, W. Wang1, G. Firestein1,1 University of California, San Diego, La Jolla, United States of America; 2University of Colorado Denver, Aurora, United States of America; 3Stanford University, Stanford, United States of America; 4Benaroya Research Institute, Seattle, United States of America; 5Janssen R&D, Spring House, United States of America; 6Janssen R & D, Spring House, United States of America

**Background:** The “Targeting Immune Responses for Prevention of RA” (TIP-RA) collaboration studies individuals at high risk for developing RA because of serum anti-citrullinated protein antibody positivity in absence of arthritis, and is focused on defining how they transition from at-risk to classifiable disease. One potential mechanism is through alterations in epigenetic patterns in adaptive immune cells.

**Objectives:** Previous studies showed that DNA methylations patterns of early RA (ERA) synovocytes differ from long-standing RA, suggesting that abnormal methylation occurs early in synovium and evolves over time. To extend these observations, we performed
a cross-sectional analysis in TIP-RA of DNA methylation signatures in peripheral blood cells in ERA, at-risk anti-CCP3+ individuals and demographics matched CCP- controls.

Methods: Genomic DNA was isolated from two independent cohorts of CCP- (cohorts 1 and 2, respectively: B cell; n = 173/34; memory T cell; n = 213/34; and naïve T cell; n = 213/34). CCP3+ (B cell: n = 18/37; memory T cell: n = 20/36; and naïve T cell: n = 20/35), and CCP3+ ERA (B cell: n = 4/18; memory T cell: n = 5/18; and naïve T cell: n = 5/18) after separating PBMCs using antibodies and magnetic beads. Methylation was measured by illumina Infinum MethylationEPIC chip. Differentially methylated loci (DMLs) were identified using Welch's t-test and mapped to gene promoter regions to define DM genes (DMGs). Principal component analysis (PCA) was used to represent relationship among groups. Pathway analysis was applied by Reactome.

Results: For the initial cohort, 1494, 1097 and 1330 DMLs were identified among CCP+, CCP- and ERA in B cells, memory T cells and naïve T cells, respectively. For the confirmatory cohort, 523, 793 and 548 DMLs were found in corresponding cell populations. The DML overlap between the 2 cohorts was highly significant (p = 2.48E-77). The DMLs were combined for both groups and corresponded to 411, 412, and 351 DMGs in B cells, memory T cells and naïve T cells. Of these, we found 246, 198 and 195 DMGs between CCP3+ and ERA in each peripheral blood cell population, respectively. PCA showed separation of CCP+, CCP- and ERA in each of the three blood cell types by DMLs (Fig. 1). DMGs were mapped to biological pathways to identify DM pathways. Although most were not significant, there were several highly significant differences comparing CCP+, ERA and CCP- in memory T cells involving pathways including “Interferon gamma signaling” (FDR 7.48E-14), “PD-1 signaling” (FDR 8.71E-10), “Translocation of ZAP-70 to Immunological synapse” (FDR 4.75E-10), and “Phosphorylation of CD3 and TCR zeta chains” (FDR 8.71E-10).

Figure 1. PCA shows the separation of CCP+, CCP- and ERA patients in memory T cells in confirmatory cohort.

Conclusion: We identified reproducible methylation signatures of CCP+, CCP- and ERA in peripheral blood B cells, memory T cells and naïve T cells in initial and confirmatory cohorts. The methylene of ERA also demonstrated a distinctive pattern from CCP+, indicating that progression to RA is accompanied by epigenetic remodeling, especially in T cell signaling and interferon responses. These signatures identify critical pathways in CCP positivity and classifiable RA and could provide the basis of novel interventions to prevent disease.

Methods: We mapped the serum proteome of GCA patients with active and inactive disease in an unbiased manner using high-throughput multiplexed mass spectrometry. Proteomic analyses were performed in 5 μl serum samples with 11-plexed tandem mass tag (TMT) technology using an Orbitrap Lumos mass spectrometer. A SEQUEST-based database search engine was employed for peptide identification. Quantification was based on TMT reporter ion intensities. All patients were sampled during their participation in the GIACTA trial, in which they received TCZ plus 26 weeks of prednisone (TCZ group) or placebo plus 26 or 52 weeks of prednisone (PRED group). Active disease was defined as the presence of cranial or PMR symptoms requiring treatment intensification regardless of ESR and CRP levels. Samples were selected if patients were in clear states of active or inactive disease at GIACTA systematic sample collection timepoints (baseline and weeks 4, 12, 24, 48). An exhaustive leave-2-out strategy was used to identify classification markers. All possible pairs of samples were isolated as test samples and the remaining training samples were used to identify the protein markers. Proteins with an absolute log2 fold concentration difference ≥0.5 between active and inactive samples and a P-value <0.1 were retained and sorted based on the metric -log10(P-value)/abs(log2 fold change). Top markers within each training set were selected to generate normalized ranks (0.1) across all samples. A mean rank was calculated for every sample. The set of normalized ranks for the test samples across all sets of top markers were bootstrapped for each test sample 100 times with replacement. The bootstrapped rankings were evaluated by determining areas under the curves (AUC) of receiver operator characteristic (ROC) curves.

Results: The PRED group included 21 patients (active, n = 16; inactive, n = 5) and the TCZ group included 21 patients (active, n = 14; inactive, n = 7). Using high-throughput sample preparation methods without applying any depletion of known highly abundant serum proteins, we quantified 760 proteins across all samples and 344 proteins in at least half the samples. Compared to inactive PRED-treated patients, active PRED-treated patients showed significant overexpression of several acute phase reactants including serum amyloid A1 and 2 (SAA1, SAA2) and complement factor H (CFH) (Fig. 1a). The magnitude of concentration change and the level of statistical significance observed for SAA1, SAA2 and CFH in PRED-treated patients were higher than those of CRP (Fig. 1a). Compared to inactive TCZ-treated patients, active TCZ-treated patients demonstrated significant overexpression of multiple biomarkers including haptoglobin, haptoglobin precursor, SSA2 and complement factor 4A, and underexpression of peptidase inhibitor 16 (Fig. 1b), a protein involved in vascular and regulatory T cell biology. Sets of 10 biomarkers resulted in a classification of active versus inactive disease with ROC AUCs of 0.89 (95% CI 0.79-0.96) in the PRED group (Fig. 2a) and 0.97 (95% CI 0.95-0.97) in the TCZ group (Fig. 2b). Conclusion: We identified several differentially expressed serum proteins in GCA patients with active and inactive disease receiving prednisone monotherapy or TCZ-based treatment regimens. In both treatment groups, a signature of biomarkers classified disease activity status with high accuracy. Haptoglobin, a readily available laboratory test, may be useful in monitoring disease activity in GCA patients receiving IL-6 blockade therapy.

OP0338

BIOMARKERS IN GIANT CELL ARTERITIS, USEFUL IN PATIENTS ON INTERLEUKIN-6 RECEPTOR BLOCKADE

S. Unizony, R. Morris, J. Kreuzer, W. Haas, J. H. Stone. 1MGH, Boston, United States of America

Background: Acute phase reactants (erythrosedimentation rate [ESR], C-reactive protein [CRP]) have limited utility in GCA, even in patients treated with prednisone alone. Furthermore, the lack of reliable biomarkers in patients receiving interleukin (IL)-6 blockade therapy is a major unmet need.

Objectives: To identify biomarkers of disease activity in GCA patients treated with prednisone monotherapy and with prednisone in combination with tocilizumab (TCZ).

Methods: We mapped the serum proteome of GCA patients with active and inactive disease in an unbiased manner using high-throughput multiplexed mass spectrometry. Proteomic analyses were performed in 5 μl serum samples with 11-plexed tandem mass tag (TMT) technology using an Orbitrap Lumos mass spectrometer. A SEQUEST-based database search engine was employed for peptide identification. Quantification was based on TMT reporter ion intensities. All patients were sampled during their participation in the GIACTA trial, in which they received TCZ plus 26 weeks of prednisone (TCZ group) or placebo plus 26 or 52 weeks of prednisone (PRED group). Active disease was defined as the presence of cranial or PMR symptoms requiring treatment intensification regardless of ESR and CRP levels. Samples were selected if patients were in clear states of active or inactive disease at GIACTA systematic sample collection timepoints (baseline and weeks 4, 12, 24, 48). An exhaustive leave-2-out strategy was used to identify classification markers. All possible pairs of samples were isolated as test samples and the remaining training samples were used to identify the protein markers. Proteins with an absolute log2 fold concentration difference ≥0.5 between active and inactive samples and a P-value <0.1 were retained and sorted based on the metric -log10(P-value)/abs(log2 fold change). Top markers within each training set were selected to generate normalized ranks (0.1) across all samples. A mean rank was calculated for every sample. The set of normalized ranks for the test samples across all sets of top markers were bootstrapped for each test sample 100 times with replacement. The bootstrapped rankings were evaluated by determining areas under the curves (AUC) of receiver operator characteristic (ROC) curves.

Results: The PRED group included 21 patients (active, n = 16; inactive, n = 5) and the TCZ group included 21 patients (active, n = 14; inactive, n = 7). Using high-throughput sample preparation methods without applying any depletion of known highly abundant serum proteins, we quantified 760 proteins across all samples and 344 proteins in at least half the samples. Compared to inactive PRED-treated patients, active PRED-treated patients showed significant overexpression of several acute phase reactants including serum amyloid A1 and 2 (SAA1, SAA2) and complement factor H (CFH) (Fig. 1a). The magnitude of concentration change and the level of statistical significance observed for SAA1, SAA2 and CFH in PRED-treated patients were higher than those of CRP (Fig. 1a). Compared to inactive TCZ-treated patients, active TCZ-treated patients demonstrated significant overexpression of multiple biomarkers including haptoglobin, haptoglobin precursor, SSA2 and complement factor 4A, and underexpression of peptidase inhibitor 16 (Fig. 1b), a protein involved in vascular and regulatory T cell biology. Sets of 10 biomarkers resulted in a classification of active versus inactive disease with ROC AUCs of 0.89 (95% CI 0.79-0.96) in the PRED group (Fig. 2a) and 0.97 (95% CI 0.95-0.97) in the TCZ group (Fig. 2b). Conclusion: We identified several differentially expressed serum proteins in GCA patients with active and inactive disease receiving prednisone monotherapy or TCZ-based treatment regimens. In both treatment groups, a signature of biomarkers classified disease activity status with high accuracy. Haptoglobin, a readily available laboratory test, may be useful in monitoring disease activity in GCA patients receiving IL-6 blockade therapy.

A FIRST IN CLASS THERAPEUTIC NANOPARTICLE FOR SPECIFIC TARGETING OF ANTI-CITRULLINATED PROTEIN ANTIBODY AMELIORATES SERUM TRANSFER AND COLLAGEN INDUCED ARTHRITIS

S. Khatri1, J. Hansen2, M. H. Clausen3, T. W. Kragstrup2,3, S. C. Hung4, E. Mellins5, K. Astakhova6, Danish Technical University, Copenhagen, Denmark; Aarhus University, Aarhus, Denmark; Aarhus University Hospital, Aarhus, Denmark; Amgen, Thousand Oaks, United States of America; Stanford University, Stanford, United States of America

Background: Rheumatoid arthritis (RA) is an immune mediated inflammatory disease with autoimmune features, including antibodies to citrullinated proteins and peptides (ACPAs). Several in vitro studies have suggested a pathogenic role of ACPAs in RA. However, in vivo proof of this concept has been hampered by the lack of therapeutic strategies to reduce or deplete ACPA in serum and synovial fluid. Previously, we constructed a chitosan-hyaluronic acid nanoparticle formulation with the ability to use neutrophil recruitment as a delivery mechanism to inflamed joints. Specifically, nanoparticles got phagocytosed and then released to synovial fluid upon death of the short-lived neutrophils.

Methods: We hypothesized that reducing ACPA levels would have a therapeutic effect by blocking cytokine production. In this study, we prepared and tested a range of nanoparticles, prepared with synthetic cyclic citrullinated peptide aptamer PEP2, PEG/hexanoic acid and fluorophore (Cy5.5). Nanoparticles were characterized by dynamic light scattering (DLS), scanning electron microscopy (SEM) and high-performance liquid chromatography (HPLC). Nanoparticles were then used in a series of in vitro assays, including cell uptake with flow cytometry (FACS) detection, and in vivo studies including disease activity scores, cytokine measurements and near-infrared imaging.

Results: We screened a series of citrullinated peptide epitopes and identified a fibrinogen-derived 21-amino-acid-long citrullinated peptide showing high selectivity toward autoantibodies in RA samples. We incorporated this aptamer in the chitosan-hyaluronic acid nanoparticle formulation previously described. Average nanoparticle size was 230 nm ± 10 nm by DLS and SEM; z potential was -0.0012. Purity by HPLC was over 95%. Attachment efficiency of the aptamer was 95% by HPLC. FACS study showed selective uptake of Cy5.5 labelled aptamer-nanoparticle conjugates by neutrophils in the concentration range 0.5-4 μM. Similar to previous studies, there was no apparent immunogenicity for this nanoparticle formulation measured by cytokine secretion from human peripheral blood leukocytes. In vivo, over 50% reduction of disease activity was achieved in three weeks treatment using as little as 1 nM drug candidate (closed every 48 hours) in the collagen-induced (CIA) mouse model of RA (N=30; p<0.001 for treated vs placebo). Same was observed in the serum transfer model (N=10). The aptamer-nanoparticle conjugate significantly reduced IL-6 and TNFα levels in the mouse sera (p<0.01). The effects were not inferior to tocolizumab treated controls (N=30). To confirm mode of action, we applied Cy5.5-labelled aptamer-nanoparticles in the collagen-induced mouse model (N=10) and analyzed the resulting uptake by near-infrared imaging. We confirmed over 6-fold higher signal accumulation in CIA healthy joints (p<0.05) and strongly supports the fact that the aptamer is highly specific to the inflammatory process.

Conclusion: Overall, we have designed a first-in-class therapeutic nanoparticle drug for specific targeting of anti-citrullinated protein antibodies. The marked effect of this nanoparticle observed in vivo holds promise for targeting ACPAs as a therapeutic option in RA.

Science communication skills for young rheumatologists

P Studenik1, C. Ospelet2
1Medical University of Vienna, Department of Internal Medicine 3, Division of Rheumatology, Vienna, Austria; 2University Hospital of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland

Background: The coloured altmetrics donut has become a standard feature of online publications. The colours depict different online sources by which an article was mentioned, while the number in the donut, the Altmetric Score (AS), reflects the summarised attention an article has received. The Dimensions database joins citations from any kind of scientific or mainstream publication. Studies analysing the link between the AS and the citation rate of an article suggest that this connection is strongly dependent on the field of research, the type of article and the type of analysis used.

Objectives: To analyse the connection between AS and citation rate in articles published in rheumatology journals.

Methods: We retrieved data on article usage, AS and citations of articles published in ARD and RMD Open between January 2015 and November 2019. For time-dependent analyses on the influence of AS on citations, articles published in 2019 were excluded. Forward-stepwise regression models were used to explore factors influencing total citation rates. We performed subanalyses, dividing articles in categories of correspondence, original research and editorials/viewpoints. We dichotomised articles by reaching the top 25% in terms of citation count within the first, second, third and fourth year after publication according their category. We explored the risk of reaching these top 25% in dependency of AS using logistic regression (log transformed AS) and receiver operating curve analyses (ROC, reported cut-offs were identified coinciding with 80% specificity).

Results: We used 1597 articles published in ARD and 409 articles of RMD Open with complete data on AS and article usage within the mentioned timeframe. AS are higher in more recently published articles (β=0.04, β2: 1.3 per year), but the number of Dimensions citations is lower in more recently published articles (β: -8.5 per year, p<0.001). Twitter shows by far the highest activity among the AS subcategories (highly correlating with AS r=0.8, p<0.001). The total number of Twitter mentions increased by 2.8/year from 2015 to 2019, indicating that more recently published articles were more often picked up on twitter. Changes in R2 in the regression model indicated that besides time since publication and AS, also the type of article influences citation count. For original research and editorials, AS may significantly add to the variability of the citation count, which was not the case for correspondences. The influence of AS on citation count of editorials added 16% to the 12% variability explained by publication time. Both factors showed similar β-coefficients (months: β: 0.76; AS: 0.83). This effect was smaller in original articles (month: β=0.74; AS: β=0.11, Total R2: 23.7%). AS significantly coincides with reaching the top 25% of citation counts according to time since publication. For the first year those articles with AS >15 showed a positive Likelihood Ratio (+LR, 95%CI) of 1.6 (1.4-1.9) to reach the top 25%, the second year AS>15: +LR: 1.9 (1.6-2.2), the third year AS>15: +LR: 2.3 (1.9-2.7) and in the fourth year AS>12 +LR: 2.1 (1.7-2.7). This effect was again different between publication categories, with no effect of AS in correspondence articles. Figure 1 highlights that AS influences citations of editorials to a larger extent than of original articles, except within the first year of publication.

COVID-19 Pathophysiology leading to the drugs to be used

MAVRILIMUMAB IMPROVES OUTCOMES IN SEVERE COVID-19 PNEUMONIA AND SYSTEMIC HYPER-INFLAMMATION

G. De Luca1,2, G. Cavalli1,2, C. Campochiaro1,4, E. Della Torre1,2, P. Angelillo1, A. Tomelleri1,2, N. Boffini1, S. Tentori1, F. Mette1,2, P. Rovere-Querini1,2.

A. Ruggeri1, T. D’aliberti1, P. Scarpellini1, G. Landoni1,2, F. De Cobelli1,2, J. P. Paolini1, A. Zangrillo1,2, M. Tresoldi1, B. C. Trapnell1, F. Ciceni1, L. Dagna1,2, A. Tomelleri1,2.

Methods: Single-center, open-label, single active arm intervention; Adult patients with severe COVID-19 pneumonia (as evaluated by CT scanning), hypoxia (PaO2:FiO2 ratio ≤ 300 mmHg), and systemic hyper-inflammation who received treatment with mavrilimumab had better survival; mechanical-ventilation free survival; time to fever resolution; CRP; measures of anti-inflammatory cytokines (IL-6, IL-10, IL-1β, TNFα) was compared to a cohort of 26 contemporaneous patients with severe COVID-19 pneumonia and systemic hyper-inflammation.

Results: A mavrilimumab group (n=13 COVID-19 patients, non-mechanically ventilated, median age 58 [IQR, 52-65], 92 [9%], 16 [8%]; PaO2:Fio2 195.5 [166.7–215.0]) was compared to a cohort of 26 contemporaneous patients with severe COVID-19 pneumonia and systemic hyper-inflammation (PaO2:FiO2 ratio ≤ 300 mmHg), and systemic hyper-inflammation (C-reactive protein [CRP] ≥ 100 mg/mL and/or ferritin ≥ 900 μg/L).

Conclusion: Patients with severe COVID-19 pneumonia and systemic hyper-inflammation face increased mortality. There is an urgent need for effective treatments to reduce the burden of the COVID-19 pandemic.

LOSS OF SELF-TOLERANCE IN SARS-COV-2 INFECTION: IMMUNOLOGICAL ASSESSMENT OF A CONVALESCENT COHORT

A. Paoloni1, V. Varriano1, B. Tolusso1, S. Alvermini2,3, L. Petricca1, G. Natafello1, G. Gigante1, S. L. Bosello1, A. M. Martone1, F. Landi4, E. Greimes4 [on behalf of Collaborative Care Study COVID-19 Project].

Background: Some infectious agents may act as inducers of autoimmune conditions. Despite SARS-CoV-2 infection can induce autoimmune phenomena in infected people4, individual risk factors or underlying mechanisms leading to loss of immunological tolerance are still unknown.

Methods: One-hundred and nine convalescent SARS-CoV-2 patients were studied and underwent multidisciplinary assessment in a Day Hospital clinical setting. For each patient, demographic, clinical and immunological data were collected and, at study entry, autoimmune profile (antinuclear antibodies (ANA), antibodies reacting with extractable nuclear antigens (anti-ENA), antineutrophil cytoplasmic antibodies (ANCA), Lupus anticoagulant (LA), antiphospholipid antibodies (aPL) (37.3%) than female (16.7%; p=0.02). Considering the disease-related characteristics, convalescent SARS-CoV-2 patients who experienced severe pneumonia (i.e., oxygen support need) during hospitalization, more likely received IL-6R-inhibitor administration (47.3%) and developed more cytokine storm syndromes (37.3%) than female (16.7%; p=0.02). Considering the disease-related characteristics, convalescent SARS-CoV-2 patients who experienced severe pneumonia (i.e., oxygen support need) during hospitalization, more likely received IL-6R-inhibitor administration (47.3%) and developed more cytokine storm syndromes (37.3%) than female (16.7%; p=0.02). Considering the disease-related characteristics, convalescent SARS-CoV-2 patients who experienced severe pneumonia (i.e., oxygen support need) during hospitalization, more likely received IL-6R-inhibitor administration (47.3%) and developed more cytokine storm syndromes (37.3%) than female (16.7%; p=0.02).

Conclusion: Cytokines plasma levels in convalescent SARS-CoV-2 patients stratified based on the development of autoantibodies we found that, despite a significant reduction of IL-6 plasma levels from hospitalization, convalescent SARS-CoV-2 patients who developed autoantibodies positivity had higher IL-6 plasma levels (8.5 ± 2.5 pg/ml) than convalescent SARS-CoV-2 ABneg patients (5.6 ± 1.5 pg/ml; p=0.07), mostly if considered autoantibodies other than aPL (15.4 ± 7.7 pg/ml; p=0.01).

C-C CHEMOKINE RECEPTOR TYPE 5 AND ITS LIGANDS CCL4, 8 AND 11 CAN LINK COVID-19, RHEUMATOID ARTHRITIS AND HYDROXYCHLOROQUINE

M. Y. Hachim1, S. Hannawi1,2, Sharjah Institute for Medical Research, College of Medicine, University of Sharjah, Sharjah, United Arab Emirates;3 Ministry of Health and Prevention, Department of Rheumatology, Dubai, United Arab Emirates

Background: Coronavirus disease (COVID-19) caused by SARS-CoV-2 represents an unprecedented global public health concern with a particular burden on patients with chronic diseases and those on immune-modulating drugs. It is especially worrisome to patients with rheumatoid arthritis (RA) who are on immune suppression regimens[1]. On the other side, many reports showed and recommended the use of some Disease-Modifying Drugs commonly used to treat rheumatic diseases like hydroxychloroquine. However, the general understanding of COVID-19 characteristics in this population and the mechanism of action of these drugs in COVID-19 is still unknown[2].
**Objectives:** Explore publicly available transcriptomic dataset of patients infected with SARS-CoV2 compared to uninfected to identify differentially expressed genes (DEGs) related to the immune system that might be pathogenic in RA synovium. Then explore the effect of Disease-Modifying Drugs on their local expression that might give hints about their possible mechanism of action.

**Methods:** RNAseq dataset (GSE147507) were retrieved using the Gene Expression Omnibus (GEO) and used to identify DEGs between infected and uninfected lung samples using BioJupies tools [3]. The DEGs were explored for common pathways using Metascape online tool (http://metascape.org) [10], as shown in figure (1). The chemokines genes were filtered out, and their common receptor (CR) was identified. The immune cells that express a higher level of the identified receptor were explored using DICE project tool (https://dice-database.org/). The expression of CR was searched in a microarray dataset (GSE77298) of synovial biopsies of RA and healthy controls. RNAseq dataset (GSE97165) of synovial biopsies taken from 19 early RA patients at baseline and after six months of Triple Disease-Modifying Anti-rheumatic drugs (tDMARD; methotrexate, sulfasalazine, and hydroxychloroquine) treatment.

**Results:** 84 DEGs were identified between uninfected and COVID-19 infected lung samples. These DEGs were enriched in pathways specific to (response to the virus, response to interferon, leukocyte activation, and chemotaxis). Interestingly, SARS-COV-2 infected lungs express more CCL4, CCL8, and CCL11; the three ligands shared the same receptor, which is CCR5. Top immune cells that express CCR5 were CD4 T memory T reg cells, Th17, Th1, and monocytes. CCR5 was significantly upregulated in RA compared to healthy controls synovium (p=0.04) and was dramatically downregulated after six months of tDMARD treatment (p=0.004), as shown in figure (2).

**Conclusion:** Using publicly available transcriptomic datasets properly highlighted the possible beneficiary effect of DMARDs in patients with COVID-19, which can block CCR5 rich immune cells recruitment.

**Talk about the consequences of COVID-19 on RMDs**

**CO0003 TREATMENT WITH BIOLOGICAL THERAPIES AND RISK OF BEING ADMITTED TO THE HOSPITAL FOR COVID19 INFECTION**

C. Gonzalez1,2,3, L. A. Menchén Viss0,2,3, O. Baniandrés Rodríguez1,2,3, A. Herranz Alonso1,2, C. Lobo Rodríguez1,2,3, M. Alvaro Gracia1,2,3, S. García de San José1,2, A. Ais Larisgoitia4, E. Chamorro de Vega1, P. Morales de Los Ríos1, M. J. Lizcano1, J. M. Alvaro Gracia1,2,3, S. García de San José1,2,1 Gregorio Marañón University Hospital, CEIMI, Madrid, Spain; 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain; 3Universidad Complutense de Madrid, Madrid, Spain; 4Gregorio Marañón University Hospital, CEIMI, Madrid, Spain

**Objectives:** To analyze the risk of admission for COVID19 infection and outcome of patients treated with bDMARD or tsDMARD from our biologic therapy center, to compare with all patients admitted for COVID-19 infection in our hospital.

**Methods:** Records of the patients from our center admitted for COVID-19 infection between March 8 and May 8, 2020 were analyzed retrospectively. Age, gender, and outcome of all patients admitted for COVID19 infection to our hospital on the same dates were collected. Chi-square, Student’s t and Man-Whitney U tests were used for comparisons when appropriate.

**Results:** 1,668 patients with inflammatory diseases treated with bDMARD or tsDMARD were included. Median age 53.0 years (range 17-91), 52.4% women. Diagnoses and DMARD distribution are shown in tables 1 and 2. 19,168 (1.1%; 6.8 patient-years) were admitted for severe COVID19 infection. Mortality ratio: 4/19 (21.1%). Median age of the admitted patients was higher: 61.0y (SD 14.2) vs 53.0y (SD 15.0); p <0.009. Median age of deceased patients was also higher 69.9y (SD 20.3) vs 53.0y (SD 15.0); p: NS. Female gender had a worse prognosis trend: 52.4% of all group, 68.4% of those hospitalized, 75.0% of those who died. Females had a higher median age than men: 55.0y (SD 14.9) vs. 50.0y (SD 14.9); p <0.001.

When comparing patients treated with DMARD admitted for COVID19 infection with all patients hospitalized for the same reason (4,601 patients), no differences were found neither in age (61.0y [SD 14.2] vs 58.3y [SD 18.1]; NS) nor gender (female: 68.4% vs 54.7%; NS). However, DMARD group seemed to have higher mortality: 4/19 (21.1%) vs 55/4601 (12.6%); p: NS, at a younger age: 69.9y (SD 20.3) vs 82.4 (SD 11.4); p: NS.

**Figure 1. Flowchart of transcriptomic analysis**
Rheumatoid arthritis patients were admitted more frequently: (9/392 (2.3%) vs 10/1276 (0.8%); p <0.025. And were older: median 62y (SD 13.5) vs 50.0y (SD 14.7); p <0.001. Anti-TNF were less used in patients with rheumatoid arthritis 188/392 (48.0%) vs 867/1276 (67.9%); p<0.001.

## Conclusion:

It seems reasonable that patients with inflammatory diseases treated with bDMARD or tsDMARD continue their treatment during the COVID19 epidemic. The different rates of hospitalization based on the diagnosis or DMARD may be due to comorbidity, confounding by indication and other bias. The study is not powerful enough to study these confounders.

**Background:** Joint damage is the pathological hallmark of rheumatoid arthritis (RA). To identify the genetic variation associated with a higher level of erosions has proven elusive.

**Objectives:** The objective of the present study was to perform a genome-wide association study on joint damage in a cohort of RA patients of the Spanish population. Our aims were to provide independent validation of previously reported variants and to identify new candidate risk loci. A stratified analysis was performed based on positivity to ACPA status.

**Methods:** A total of 1,135 patients diagnosed with RA using the ACR-EULAR criteria recruited by the IMID Consortium were genotyped using a 550,000 single-nucleotide polymorphism array. Additional SNPs were imputed using the 1KG genome data. Joint damage was performed using the S-score, a simplified radiographic erosion score that has a high correlation with the Sharp-van der Heijde score (1). Association testing of SNPs with joint damage was performed using linear regression with the addition of the years of evolution as covariate. The Hejde score (1). Association testing of SNPs with joint damage was performed using the S-score, a simplified radiographic erosion score that has a high correlation with the Sharp-van der Heijde score (1). Association testing of SNPs with joint damage was performed using linear regression with the addition of the years of evolution as covariate. The two main components of genetic variation were also added to adjust for potential population stratification. A total of 50 SNPs representing previously reported loci associated with joint damage were selected. Genetic association was also performed at the pathway level using Pascal.

**Results:** 45 out of 50 SNPs representing 31 previously reported loci for joint damage could be satisfactorily imputed. Association testing of the whole patient cohort replicated the association with IL2RA and TRAF1. Of relevance, after stratifying for anti-CCP five new loci were replicated: KIF5A and SOST in ACPO-positive RA and CD40, DKK1 and TNF in ACPO-negative RA. IL2RA was only significant in the ACPO-positive group and TRAF1 was not significant in either strata. GWAS on the ACPO-positive cohort and on the ACPO-negative group identified n=7 and n=18 loci with P-values <1x10^-5, respectively. From these, however, only 1 SNP showed nominal significant association in the other patient group. Based on this evidence, we performed a pathway-based analysis to understand the biological mechanisms underlying this difference. Pathway analysis showed 52 biological processes associated with joint damage in ACPO-negative RA and 32 pathways in the ACPO-positive group, with only two shared biological processes between the two groups. FC Gamma receptor mediated phagocytosis was the topmost biological process associated with erosions specifically in ACPO-negative RA and Signalling by Fibroblast Growth Factor mutants was the top process specific for ACPO-positive patients.

**Conclusion:** The results from our study provide suggestive evidence that the genetic basis for joint damage is different according to the presence of ACPO. Replication of the new candidate loci in an independent patient cohort is underway.

**THU0002**  

**SOLVING THE COMPLEX MHC ASSOCIATIONS IN SLE IDENTIFIES SEX-RELATED GENE EFFECTS**

N. Kamitaki\(^2\), B. Handsaker\(^2\), D. Morris\(^3\), C. Langefeld\(^4\), R. Graham\(^5\), L. Criswell\(^7\), S. Mccarroll\(^2\), T. Vyse\(^6\), T. Hylek\(^8\), T. Vyse\(^6\); \(^2\)Broad Institute of MIT and Harvard, Cambridge, United States of America; \(^3\)King’s College London, London, United Kingdom; \(^4\)Wake Forest Medical School, Winston-Salem, United States of America; \(^5\)Genentech, San Francisco, United States of America; \(^6\)UCSF, San Francisco, United States of America.

**Background:** Genome-wide association analyses reveal that the Major Histo-compatibility Complex (MHC) is the site of the strongest association signals in SLE and Sjögren’s syndrome. This associations in lupus and Sjögren’s syndrome are linked to HLA alleles: HLA-DRB1*03:01 and HLA-DRB1*15:01 (in Europeans). The DRB1*03:01 allele resides on an extended MHC haplotype which includes loss of the complement C4A gene. Whether C4 makes a genetic contribution to SLE/Sjögren’s risk has been a long standing issue of contention. In comparison, it has been shown that elevated copy number of C4 is a genetic risk factor for schizophrenia.

**Objectives:** To define the causal MHC genes in SLE/Sjögren’s accommodating both structural and highly polymorphic variation.

**Methods:** Use NG sequencing data from across the MHC to generate a panel of variants that inform class III structural variation involving the candidate genes coding complement C4A and C4B as described. To further improve the resolution of the association using transancestral mapping approach in SLE: examining cohorts of European ancestry (from ImmunoChip) and data from the MHC region of an African-American GWAS in SLE.

**Results:** Comparing European and African data, we have shown that the association signals in SLE can be best explained by signals arising from 1) copy number variation of the complement component 4 (C4) genes in the MHC locus (Fig. 1 and 2) by a shared region in the class II region on the HLA-DRB1*15:01 (in Europeans) and HLA-DRB1*11:03 (in Africans) that likely operates to elevated HLA class II gene expression (Fig. 2). The C4 locus generates a 7-fold variation in risk for lupus (95% CI: 5.88-8.61; p<10^-17) in total and 16-fold variation in risk for Sjögren’s syndrome (95% CI: 8.59-30.89; p<10^-22) in total, with C4A

![Figure 1. Loss of C4 is risk in African and European ancestry cohorts.](image)
protecting more strongly than C4B in both illnesses. In schizophrenia, elevated C4 copy number elevates disease risk, whereas in SLE and Sjögren’s lower copy numbers of C4 genes correlate with higher disease risk. In all three illnesses, C4 alleles acted more strongly in men than in women; common combinations of C4A and C4B generated 14-fold variation in risk for lupus and 31-fold variation in risk for Sjögren’s syndrome in men (versus 6-fold and 15-fold among women respectively) and affected schizophrenia risk about twice as strongly in men as in women. At a protein level, both C4 and its effector (C3) were present at greater levels in men than women in cerebrospinal fluid (p<10<−6> for both C4 and C3) and plasma among adults ages 20-50, corresponding to the ages of differential disease susceptibility. Sex differences in complement protein levels may help explain the larger effects of C4 alleles in men, women’s greater risk of SLE and Sjögren’s, and men’s greater vulnerability in schizophrenia.

Conclusions: These results nominate the complement system as a source of sexual dimorphism in vulnerability to diverse illnesses.

ALTERED DNA METHYLATION AND DIFFERENTIAL EXPRESSION OF GENES INFLUENCING CARDIOVASCULAR RISK AND IMMUNITY IN CD4+ T CELLS FROM PATIENTS WITH PSORIATIC ARTHRITIS.

I. Arias de la Rosa1, M. D. López Montilla1, J. Rodríguez2, E. Ballester2, C. Torres-Granados1, C. Perez-Sanchez1, M. D. C. Abalos-Aguilera1, G. Igacio1, D. Ruiz1, A. M. Patiño-Trives1, M. Luque-Tévar1, E. Collantes-Estévez2, C. Lopez-Pedrera1, A. Escudero Contreras2, N. Barbarroja Puerto1

1IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain; 2Josep Carreras Institute (JUC), Badalona, Spain.

Background: Cardiovascular risk factors are increased in Psoriatic Arthritis (PsA); in fact, around 80% of PsA patients display insulin resistance (IR), a hallmark of metabolic syndrome, which might significantly contribute to the cardiovascular disease. Latest studies suggested that inflammatory and metabolic disorders may be under epigenetic control, including DNA methylation. DNA methylation is an unexplored area in the field of PsA. These differentially methylated genes were enriched with several signaling pathways and disease categories including immune response, metabolic processes, oxidative stress, vascular and inflammatory pathways. The altered gene expression of selected genes with altered methylation levels in PsA was also validated. Correlation and association analysis of these DMGs with clinical and analytical variables, cardiovascular risk factors and complement microvascular function revealed that the degree of methylation of these genes was significantly associated with cIMT (IGF1R, NDRG3, SLYMD3, HLA-DRB1, VDR70), arterial pressure (METTSD1, NRDG3, ADAM17, SLYMD3, WNK1, CBX1), insulin resistance (AKAP13, SEMA6D, PLCB1), altered lipid profile and atherogenic index (MYBL1, METTSD1, MAN2B1, SLC1A7, SEMA6D, PLCB1, TLK1, SDK1, CBX1), inflammation (MYBL1, NDUFA8, METTSD1, SEMA6D, PLCB1, TLK1), and endothelial dysfunction (ADAMST10, GPPCD1, CCDC88A). In this analysis, this also identified 435 DMGs including 280 hypermethylated and 155 hypomethylated in CD4+ T cells from IR-PsA vs non IR-PsA patients. Between these two groups of PsA patients, CHUK, SERINC1, RUNX1, TTYH2, TXNDC11, FA1, BICD1, SC5D, PDE5A, FAS, NFIA and GRP75 displayed the most significantly altered methylation, suggesting the role of these genes in the metabolic complications associated with PsA.

Conclusion: These findings help our understanding of the pathogenesis of PsA and advance epigenetic studies in regards to this disease and the cardiometabolic comorbidities associated. Funded by ISCIII (PI17/01316 and RIER RD16/0012/0015) co-funded with FEDER.

THU0004
GENOME–WIDE DNA METHYLATION PROFILING IN MONOCYTES FROM PRIMARY ANTIPHOSPHOLIPID SYNDROME PATIENTS IDENTIFIES AN ABRERRANT METHYLATION SIGNATURE ASSOCIATED WITH THEIR AtherosclEROTIC PHENOTYPE

1IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain; 2Epidogenetics and Immune Disease Group, Josep Carreras Research Institute (JUC), Barcelona, Spain

Background: Recent studies underlined the crucial role of DNA methylation in several autoimmune diseases by altering gene expression profiles, thus influencing disease severity. Yet, aberrant methylation patterns in monocytes, key players in the pathogenesis of APS patients, has not been evaluated.

Objectives: To analyze the genome-wide DNA methylation profile of monocytes from APS patients and its relationship with the cardiovascular (CV) pathology. 2. To evaluate the role of antiphospholipid antibodies (aPL) in the regulation of their atherothrombotic phenotype

Methods: Thirty-three APS patients and 15 healthy donors (HD) were included in the study. Monocytes were isolated from peripheral blood by positive immunomagnetic selection. The Illumina Infinium MethylationEPIC Beadchip was used to obtain DNA methylation profiles across approximately 850,000 CpGs (TS51500, TS52000, SUTR, 3UTR, first exon, intergenic, gene body). Betas values (β) estimating methylation levels were obtained at each CpG site, and differentially methylated genes (DMG) between PsA and HD were identified. Functional classification of these genes was carried out through gene ontology analysis (PANTHER database). Gene expression analysis of the selected genes was also evaluated by RT-PCR. Vascular parameters including carotid intima-media thickness (cIMT) and endothelial function was analyzed by ecodoppler and periflux respectively.

Results: The genome-wide methylation analysis identified 112 DMGs including 41 hypermethylated and 71 hypomethylated. These differentially methylated genes were enriched with several signaling pathways and disease categories including immune response, metabolic processes, oxidative stress, vascular and inflammatory pathways. The altered gene expression of selected genes with altered methylation levels in PsA was also validated. Correlation and association analysis of these DMGs with clinical and analytical variables, cardiovascular risk factors and complement microvascular function revealed that the degree of methylation of these genes was significantly associated with cIMT (IGF1R, NDRG3, SLYMD3, HLA-DRB1, VDR70), arterial pressure (METTSD1, NRDG3, ADAM17, SLYMD3, WNK1, CBX1), insulin resistance (AKAP13, SEMA6D, PLCB1), altered lipid profile and atherogenic index (MYBL1, METTSD1, MAN2B1, SLC1A7, SEMA6D, PLCB1, TLK1, SDK1, CBX1), inflammation (MYBL1, NDUFA8, METTSD1, SEMA6D, PLCB1, TLK1), and endothelial dysfunction (ADAMST10, GPPCD1, CCDC88A). In addition, this analysis also identified 435 DMGs including 280 hypermethylated and 155 hypomethylated in CD4+ T cells from IR-PsA vs non IR-PsA patients. Between these two groups of PsA patients, CHUK, SERINC1, RUNX1, TTYH2, TXNDC11, FA1, BICD1, SC5D, PDE5A, FAS, NFIA and GRP75 displayed the most significantly altered methylation, suggesting the role of these genes in the metabolic complications associated with PsA.
Results: Genome-wide DNA methylation analysis identified 813 DMG, including 279 hypomethylated and 534 hypermethylated. Functional classification of these methylation levels of genes related to immune response were associated with the CV-risk score, aGAPPS (CCFR2, TXLNB, GLIPR), type of thrombosis (SIGLEC1, COLEC11, LRRRC16A, AHSAA1, TRIL) and aPLs (CLEC4G, RG54, HLA-DPA1, GBPF6, RAET1E, HLA-G, HLA-DPA1, HLA-H, TXLNB). Besides, methylation levels of DMG related to vascular signaling and adhesion processes were associated with the presence of thrombotic recurrences (VEGFA, MAPK14, ITGA8, EPCAM, PCDHA6, DNLG1) as well as with current CV-risk factor such as hypertension and dyslipidemia (ITGA11, DSCAM, CLEC4F, CD44, LTBP2, PCDHB14). In addition, methylation levels of DMG genes related to oxidative stress (PG2, P5G, ADH1) were associated with microvascular endothelial dysfunction. An altered mRNA expression of some of these genes with aberrant methylation and related to increased CV-risk and thrombotic recurrences in APS was also identified. Both, abnormal methylation and transcription levels of several genes were further associated with a pathological increase of the CIMT. Finally, in vitro studies supported the role of aPLs as key players in the altered methylation and transcriptomic profiles of APS patients.

Conclusion: APS patients showed an impaired methylation profile in monocytes of genes associated with clinical features of the disease, including aPLs, CV risk, thrombotic recurrences, endothelial dysfunction and early atherosclerosis. These results offered a map to the monocytes methylome and shed light on the pathophysiology of APS, paving the way for the development of new, more effective biomarkers and therapeutics.

THU0005 VARIABILITY OF DNA METHYLATION IS A DRIVER OF LYMPHOCYTE DYSREGULATION IN EARLY RHEUMATOID ARTHRITIS.

A. Clark1, N. Naaman1, N. Nair1,2, A. Anderson3, N. Thalayasingam4, J. Diboll1, A. Barton3, S. Eyno2, J. D. Isaacs4, L. Reynard3,4, A. Pratt3,4
1Newcastle University Clinical and Translational Research Institute, Newcastle upon Tyne, United Kingdom; 2Versus Arthritis Centre for Genetics and Genomics, University of Manchester, Manchester, United Kingdom; 3NHIRM Manchester Musculoskeletal BRC, Manchester University NHS Foundation Trust, Manchester, United Kingdom; 4Musculoskeletal Services Directorate, Newcastle upon Tyne Hospitals NHS Trust, Newcastle upon Tyne, United Kingdom; 5Newcastle University Biosciences Institute, Newcastle upon Tyne, United Kingdom

Background: DNA methylation patterns differ between leukocyte subsets and mediate the impact of environmental exposures on the molecular and functional phenotype of immune cells. Besides differences in mean methylation of CpG positions amongst patients with immune mediated diseases, recent evidence indicates variability of site-specific DNA methylation also contributes to pathogenesis1,2. Variant DNA methylation patterns are dynamic and transcriptomic responses amongst patients with immune mediated diseases, recent evidence indicates variability of site-specific DNA methylation also contributes to pathogenesis1,2.

Methods: Patients with confirmed clinical diagnoses were enrolled from the Northeast Early Arthritis Cohort (NEAC). CD4+ and CD19+ lymphocytes were isolated from fresh blood by positive selection prior to therapeutic immune modulation. Methylation was quantified in cell subset-specific DNA (Infinium Methylation-EPIC BeadChip, Illumina)3. Differentially methylated positions and regions (DMPs, DMRs) between RA and non-RA patients were identified (linear modeling, filtering on 5% pairwise difference in mean DNA methylation, and DMRcate package). Next, to identify instances where methylation variance differed between comparator groups, Bartlett's test was performed using the iEVORA package, which accounts for outlier values4. Findings were controlled for technical confounders and subject to multiple test correction (FDR). A validated hyper-geometric test was used to annotate enriched pathways.

Results: After sample- and probe-level quality control, CD4+ and B lymphocyte specific data were respectively available for 45 and 49 RA patients, and 64 and 81 disease controls matched for systemic inflammation (CRP, ESR). No DMPs were identified in either cell type at FDR < 0.05 and Δβ ≥ 0.05. Only following relaxation of multiple test correction was it possible to identify DMRs in either cell type, most notably encompassing 10 CpGAs relatively hypomethylated at the promoter of the endosome protein-encoding RUFY1 gene in CD4+ lymphocytes of RA patients (Δβ = 0.076). By contrast, striking evidence for differential variation in DNA methylation was observed at 291 and 601 CpGs of CD4+ and B lymphocytes, respectively (examples depicted in Figure 1). Only 15 of these differentially variable positions (DVPs) were common to both cell types. Pathway analysis highlighted potential functional consequences of DVP associations; for example, RA-specific hypervariability implicates prostataglandin signalling in CD4+ lymphocytes.

Conclusion: We highlight a role for altered variability in DNA methylation during the molecular pathogenesis of RA, and emphasise the importance of its study in relevant cell subsets.

THU0006 ASSOCIATION BETWEEN ALTERED MICRORNAs EXPRESSION AND ARTERIAL WALL REMODELING IN GIANT CELL ARTERITIS

J. Bolha1, J. Piliñčík1, M. Frank-Bertencelj2, A. Hocewar3,4, M. Tomisíc3,4, V. Jurčić1, Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; 2Department of Rheumatology, Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland; 3Department of Medicine, University of Ljubljana, Ljubljana, Slovenia; 4Department of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia
Background: Immuno-pathology of giant cell arteritis (GCA) results from dysregulated interactions between arterial wall-resident non-immune cells, e.g. vascular smooth muscle cells (VSMCs), and components of the immune system [1]. In spite of several efforts at identifying microRNAs (miRNAs) implicated in the pathogenesis of GCA, the overall information on miRNA involvement in GCA and its related arterial fibro-sclerotic alterations remains scarce.

Objectives: To analyze miRNA expression and identify target genes of dysregulated miRNAs in temporal arteries from GCA patients, and to determine their association with GCA-associated arterial wall remodeling.

Methods: The study included formalin-fixed, paraffin-embedded temporal artery biopsies (TABs) from 71 clinically diagnosed treatment-naïve patients fulfilling the ACR 1990 classification criteria, and 22 non-GCA subjects (control group). Of GCA patients, 54 histologically positive and 17 histologically negative TABs were included. miRNA expression profiling was performed with quantitative real-time PCR (qPCR)-based miRNA PCR panels and qPCR. The miRDB database and STRING protein-protein network analysis were used for identification of miRNA gene targets and their pathway enrichment analysis, respectively.

Results: Of 356 detected miRNAs, we determined significant under-expression of 78 and significant over-expression of 22 miRNAs (≥ 2-fold; p < 0.05) in TAB-positive GCA arteries compared to non-GCA controls, pointing to a strong dysregulation of miRNA expression in inflamed GCA arteries. Several dysregulated miRNAs targeted genes involved in the ubiquitin-proteasome system and the RNA silencing network, suggesting a novel role of these pathways in GCA. qPCR validation confirmed a 1.9–14.2-fold (p < 0.001) over-expression of pro-or anti-carcinogenic miRs 32-3p, 125a-5p, 143-3p, 145-3p, 155-5p, 195-5p, 365a-3p) VSMC phenotype-associated regulatory miRNAs in TAB-positive GCA arteries. These miRNAs targeted gene pathways involved in the arterial remodeling and regulation of the immune system, and their expression significantly correlated with the extent of intimal hyperplasia in TABs from GCA patients (p < 0.015). Additionally, the expression of miR-21-3p, 125a-5p, 143-3p, 145-3p, 195-5p, 365a-3p were differentially validated in TAB-negative GCA arteries from non-GCA temporal arteries, making these miRNAs potential biomarkers of GCA.

Conclusion: Our study demonstrated an extensive dysregulation of arterial miRNA networks in GCA, favoring the pathogenic switch in the VSMC phenotype and associated intimal hyperplasia. We identified several miRNAs, which could represent potential novel GCA biomarkers. Furthermore, our results imply the ubiquitin-proteasome system and the RNA silencing complex are targets of dysregulated arterial miRNA networks in GCA lesions, providing new insight into the complexity of GCA pathogenesis.

THU0007

INDIVIDUALIZED PATHWAY ANALYSIS FROM WHOLE BLOOD TRANSCRIPTOMIC IN SSS PATIENTS DEMONSTRATES UNIQUE CORRELATIONS WITH DISEASE SEVERITY

C. Bellocci, 1, 2 C. Rossatto, 3 G. Barturen, 4 G. Segato, 5 B. Vignone, 6 Z. Makowska, 3 A. Buttgereit, 7 M. Kerick, 8 M. Alarcon-Riquelme, 9 J. Martin Ibanez, 1; Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Scleroderma Unit, Milan, Italy; 2University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 3University of Verona, Department of Biotechnology, Verona, Italy; 4Center for Genomics and Oncological Research, Pfizer, University of Granada, Andalusian Regional Government, Granada, Spain; 5Bayer AG, Berlin, Germany; 6Institute of Parasitology and Biomedicine López-Neyra, FIBL-NCSC, Granada, Spain

Background: Genome-wide gene expression profiles and pathways analysis may help in identifying deregulated processes underlying the pathogenesis of complex diseases or their phenotypic expression. Little or nothing is currently known about pathways associated with disease severity and damage in SSc. Objectives: To perform a whole blood transcriptome analysis and to characterize the individualized functional pathways associated with disease severity scores in SSc patients via a discovery and replication strategy.

Methods: Whole blood samples were collected in RNA stabilizers from a discovery and a replication cohort of 67 and 34 patients, respectively. RNAseq data were generated by Illumina sequencing in two independent experiments pathways analysis was conducted according to the Functional Analysis of Individual Microarray Expression (FAIME) protocol [1]. FAIME scores from Reaction pathways were correlated with the Scleroderma Clinical Trial Consortium Damage Index (SCTC-DI) total scores or with each of its two components (mortality and morbidity) as calculated from regression coefficient previously published [2]. A non-parametric partial correlation analysis correcting the results for the use of steroids, immunosuppressants and disease duration was performed. Results were related with damage in both cohorts at the 0.1 level after 1000-fold permutation-testing were considered as significant and replicated.

Results: A total of 1116 pathways were analyzed. None of them was associated in both cohorts with the total SCTC-DI; similarly, no association was found with the SCTC morbidity component. On the contrary, 26 pathways showed an independent and replicated association with the SCTC morbidity component, including platelet degranulation, the transcriptional activity of SMAD2/SMAD3, Toll Like Receptor 2 (TLR2) cascade and related intracellular signaling events involving MyD88, IRAK and NF-κB, and the deregulation of selected transcription factors (TFAP2, E2F6).

Conclusion: Selected molecular events involving the innate immune system, signaling and platelet metabolism are associated with the morbidity component of the SCTC-DI in SSc patients, reflecting an irreversible loss of function in several organs and apparatus. The sensitivity of these associations to individual change in accrual damage is to be determined.

DEVELOPMENT OF A NOVEL TRANSLATIONAL IN SILICO INDICATION DISCOVERY FRAMEWORK: EXEMPLIFIED BY THE CLINICAL COMPOUND CENERIMOD

D. Hartl, 1 D. Keller, 1 A. Kienk, 2 M. Murphy, 3 G. Martinic, 4 G. Pierlot, 5 P. Groenen, 6 D. Strasser, 7 Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland

Background: To explore the full therapeutic spectrum of a drug it is crucial to consider its potential effectiveness in all diseases. Serendipitous clinical observations have often shown that approved drugs and those in development to be efficacious in indications different to those originally tested for. Traditional approaches to match a drug candidate with possible indications are mostly based on matching drug mechanistic knowledge with disease pathophysiology. Proof-of-concept trials or elaborate pre-clinical studies in animal models do not allow for a broad assessment due to high costs and slow progress. Gene expression changes in patients or animal models represent a good proxy to comprehensively assess both disease and drug effects. Furthermore, this data type can be integrated with a plethora of publicly available data.

Objectives: Generation of a novel in silico framework to support the selection and expansion of potential indications which associate with a compound or approved drug. The framework was exemplified by the clinical compound cenerimod, a potent, selective, and orally active sphingosine-1-phosphate receptor 1 (S1PR1) modulator (Piali et al., 2017).

Methods: A total of ~13'000 public patient gene expression datasets from ~140 diseases were evaluated against cenerimod gene expression data generated in mouse disease models. To improve comparability of studies across platforms and species, computer algorithms (neural networks) were trained and employed to reduce noise within the data sets and improve signal. The predicted response to cenerimod for individual patients was contrasted against clinical patient characteristics.

Results: The neural network algorithm efficiently reduced experimental noise and improved sensitivity in the gene expression data. The results predicted cenerimod to be efficacious in several auto-immune diseases foremost SLE. Additionally, focused analysis on individual patients rather than disease cohorts revealed potent determinants predictive of maximal clinical response, with the highest predicted clinical response for cenerimod in patients with severe inflammatory endotype and/or high SLE Disease Activity Index (SLEDAI).

Conclusion: Combining preclinical compound data with the wealth of public disease gene expression data, provides great potential to support indication

THU0010 GENES ASSOCIATED WITH NUCLEOTIDE OLGORIZATION DOMAIN-LIKE RECEPTOR SIGNALING PATHWAY ARE UPREGULATED IN CUTANEOUS LUPUS ERYTHEMATOSUS

I. Calderon1, R. Mina2,3, SDCS, Cincinnati, United States of America; 2University of Cincinnati, Cincinnati, United States of America

Background: Cutaneous Lupus Erythematosus (CLE) is a disfiguring autoimmune skin disorder with several subtypes: discoid lupus, subacute cutaneous lupus, and acute cutaneous lupus. CLE is associated with defects in the adaptive immune system, and, at times, systemic involvement. The innate immune system is likely involved as seen in the presence of ifferent dermatitis, which is observed in viral exanthems, and improvement of CLE using inhibitors to membrane-bound Pattern Recognition Receptors.

Objectives: Compare the expression of genes associated with the innate immune system in active CLE skin lesions of different subtypes compared to normal skin controls.

Methods: Five datasets selected from the Gene Expression Omnibus (GEO) were analyzed using GEO2R to compare the gene expressions between different subtypes of CLE. Search Tool for the Retrieval of Interacting Genes/Proteins (STRING) database, Gene Card, and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis were used to identify the interaction and function of specific genes.

Results: There were a total of 147 CLE skin samples and 52 normal controls. Genes associated with the Nucleotide-Binding Oligomerization Domain-Like Receptor (NLR) signaling pathway were upregulated in CLE skin samples (adjusted p-value < 0.001). Five genes associated with the NLR signaling pathway, STAT1, OAS1, OAS2, OAS3, and AIM2, were found to be upregulated in skin samples of CLE patients in all datasets, regardless of type, compared to normal controls in all datasets. These five genes are associated with transcription activation, regulation of viral infection, and interferon response.

Conclusion: Genes associated with the NLR signaling pathway are upregulated in the skin lesions of CLE patients compared to normal controls, supporting the role of the innate immune system in CLE. Further validation studies using experimental methods are needed.

Methods: Cybrids were developed using 143B.TK Rho-0 cell line (nuclear donor) and platelets (mitochondrial donors) from healthy (N) and OA donors. Glucose and FA metabolism were measured using $D^{-}[13C](U)$glucose and $[1^{-13C}]$ oleic acid respectively. Metabolic flexibility was evaluated by co-culturing with glucose and oleic acid acutely by using inhibitors against glucose and FA oxidation. 20µM UK5099 and 10µM etomoxir, respectively. Incorporation of FA into lipid droplet (LD) was evaluated by thin layer chromatography and LD were stained by LDS40 and analyzed by confocal microscope and flow cytometry. Mitochondrial dynamics was measured by real-time PCR method. Percentage of mitochondrial Anion Superoxide ($O_2^{-}$) production was evaluated incubating cells with MitoSox® using Flow Cytometer. Appropriate statistical analyses were performed with GraphPad Prism v6.

Results: There were no changes in basal glucose metabolism between cybrids. N cybrids had higher acid-soluble metabolites, reflecting incomplete FA β-oxidation than OA cybrids. Comparing glucose and FA metabolism showed that both types of cybrids preferred to oxidize glucose. Co-culturing with glucose and Oleic acid, increased total cellular uptake and oxidation of glucose in N compared to basal condition (Figure-1) and in this condition the OA cybrids showed an increase in mitochondrial $O_2^{-}$ production. Inhibition of FA oxidation by etomoxir increased complete glucose oxidation of N cybrids but not in OA cybrids that had a preference to oxidize oleic acid compared to basal condition. Gene expression of mitofusin-2 (MFN2) was higher in N than OA cybrids under inhibiting conditions. Combine these data indicate that N cybrids are more metabolically flexible and have better adaptive response than OA. Cybrids presented different lipid distribution patterns. Lipid droplet (LD) formation increased in both groups incubated in presence of FA. Furthermore, N cybrids showed less LD formation than OA.

Conclusion: The results indicated that cybrids from OA patients had reduced metabolic flexibility compared to N cybrids. These results enhance our understanding of the mitochondria metabolism in OA, suggesting a mitochondrial dysfunction and impairment of metabolic flexibility during the OA process.

![Figure 1](image1.png)

Figure 1. Effect of oleic acid in glucose metabolism. A. Scheme of substrate oxidation protocol: cybrids were cultured for 48 h in DMEM-glucose and glucose metabolism was evaluated using $D^{-}[13C](U)$glucose. B. Effect of 100 µM oleic acid compared to 5.5 mM glucose (basal) on glucose metabolism in N and OA cybrids. Values are presented as mean ± SEM relative to basal. * N versus OA cybrids (**p<0.05, unpaired t test); b versus basal (b bs p0.05, paired t test).

THU0012 IMPACT OF RS12107036 POLYMORPHISM OF TP63 ON THE RISK OF RAPID PROGRESSIVE OSTEOARTHRITIS OF THE KNEE. DATA FROM THE OSTEOARTHRITIS INITIATIVE

A Durán-Souto1, M. Fernandez-Moreno2, M. E. Vazquez Mosquera1, P. Ramos-Louso1, A. Dalmao-Fernandez1, S. Relaño-Fernandez1, N. Oreiro1, F. J. Blanco1, I. Rego-Perez1. 1Instituto de Investigación Biomédica de A Coruña, Rheumatology Investigation Group, A Coruña, Spain

Background: There is a need to identify patients with the rapid progressive phenotype of Osteoarthritis (RPOA) to include them in clinical trials and to implement prevention strategies. During the last years, nuclear single nucleotide polymorphisms (SNPs) were associated with susceptibility and progression of the disease, but not with the rapid progression phenotype.

Objectives: Analyze the influence of previously knee OA-associated nuclear SNPs on the risk of RPOA in patients of the OAI.

Methods: Caucasian patients from the OAI were selected and assigned into three different groups (N=252/group) based on the following criteria: A.rapid progressors; baseline KL grade 0-1 in at least one knee and increase up to KL≥ 3 during a 48-month period; or baseline KL grade 2 in at least one knee and increase up to KL 4 or total knee replacement during the follow-up. B.no-rapid progressors; baseline KL grade 0-1 in at least one knee and increase up to KL 2 during 48-month period; or baseline KL grade 2 in at least one knee and increase up to KL 3 during the follow-up. C.no-progressors; KL grade 0-2 at baseline in at least one knee and bilaterally stable during 48-month period.

Groups were re-categorized into two groups: non-progressors and progressors (pooling A and B). Nuclear SNPs were previously assigned by mini-sequencing techniques. Preliminary chi-square analyses and binary and multinomial logistic regression models adjusted by gender, age, body mass index (BMI), contratateral OA, previous injury in target knee and WOMAC pain, were performed with IBM SPSS Statistics v24.

Results: We analyzed the effect of 7 SNPs that had been strongly associated with knee OA susceptibility in different GWAS studies: rs11177, rs4730250, rs11842874, rs12107036, rs8044769, rs10948172 and rs143383. Chi-square analyses only showed differences in the frequency distribution of rs12107036 between groups (p=0,028), being the GG genotype over-represented in the rapid progressors group and the AA genotype in the non-progressors group (Figure 1).

The binary logistic regression showed that G allele was significantly over-represented in the (pooled) progressors group when compared with non-progressors (p=0,008) (Table 1). And the multinomial logistic regression showed that, in
addition to age and previous injury in target knee, the GG genotype (p=0.032) emerged as a potential risk factor for the RPOA when compared with non-rapid progressors (Table 2).

Table 2. Multinomial regression model comparing rapid vs. non-rapid progressors.

Conclusion: The G allele of the nuclear SNP rs12107036 of TP63 gen increases the risk of knee OA progression. Depending on the number of risk allele copies the level of progression varies, being the GG genotype a risk factor for the RPOA of the knee. The assignment of this nuclear polymorphism could be useful as complementary genetic biomarker for the early identification of this phenotype.

THU0013 INTEGRATED ANALYSIS OF SYNOVIAL SINGLE CELL RNA SEQUENCING DATA DEEPPENS THE CURRENT KNOWLEDGE OF SYNOVIAL PATHOLOGY IN ARTHRITIS

S. G. Edalat1, R. Micheroli1, T. Kuret2, K. Buoni1, C. Pauli1, S. Sodin-Šemrl2, A. Ciurea3, O. Distler1, C. Ospelt1, G. Rot4, M. Frank-Bertocci5, 1University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland; 2University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 3University Hospital Zurich, Department of Pathology, Zürich, Switzerland; 4Institute of Molecular Life Sciences and Swiss Institute of Bioinformatics, Zurich, Switzerland

Background: The heterogeneity of synovial tissues from patients with arthritis could contribute to the interpatient variability in disease course, prognosis and treatment response. Single-cell RNA sequencing (scRNA-seq) permits in-depth analysis of tissue heterogeneity, which could facilitate drug discovery and patient stratification for precision medicine.

Objectives: To construct a comprehensive landscape of synovial cell types and molecular pathways in arthritis by integrating our and published scRNA-seq data, generated across different scRNA-seq technologies [Smart-seq2, Drop-seq], cell preparation protocols [dissociated unsorted, sorted cells] and types of arthritis [differentiated (UA), rheumatoid arthritis, osteoarthritis]

Methods: Synovial tissues were obtained by ultrasound-guided biopsy from patients with UA [not fulfilling the classification criteria for a specific arthritis, n=3], Biopsies were disintegrated [enzymatic and mechanical disruption] and cell viability assessed with trypan blue. scRNA-seq libraries [2 per patient] were prepared with 10X Genomics Drop-Seq and sequenced on NovaSeq6000. Bioinformatics analysis of our and published [n=35] datasets1-5 was performed using Seurat protocol3 with correction for batch effects and filtering low-quality cells. Functional enrichment analysis of marker genes in clusters was done with STRING Protein-Protein networks. Synovitis was assessed with ultrasound and histology.

Results: Our tissue disintegration protocol resulted in good cell yield and viability (92%, 72%, 100%). The synovial cellular heterogeneity detected by scRNA-seq reflected the histological findings [Krenn score, pathotype]. These were supported with the ultrasound and clinically assessed disease activity. The integrated analysis of 41 datasets from 38 donors yielded 41845 scRNA-seq cell profiles, 50% contributed by our dataset. An independent analysis of our data and their integration with published data showed that different scRNA-seq methods and protocols can identify all the major synovial cell types and their activation states (Figure 1) with large heterogeneity between donors. We identified a previously undescribed synovial cell population, which was located near the fibroblast cluster, was negative for canonical cell markers, but highly enriched in cell division genes (80% of marker genes). These cells comprised a mixed population of CD34-, podoplanin (PDPN)high or PDPNlow cells that were mostly negative for the sub-lining fibroblast marker THY. Furthermore, they appeared to be highly secretory (extracellular matrix components) and their gene expression profile was inclined towards cell migration, vascular development and insulin growth factor-dependent processes.

Conclusion: By integrating synovial scRNA-seq data from 41845 cells, we identified a previously undescribed, highly proliferative and secretory synovial cell population in arthritis. We increased the number of known scRNA-seq synovial cell profiles in arthritis by two-fold and demonstrated the robustness of synovial scRNA-seq data outputs across different technologies and protocols. This broadens the current knowledge of synovial tissue heterogeneity and pathogenesis in arthritis.

Comparative TranscripTome Analyses Across Tissues and Species Identify Targetable Genes for Human Systemic Lupus Erythematosus (SLE) and Lupus Nephritis (LN)

E. Frangou1,2, P. Garantziotis2, M. Grigorou2, A. Banos2, N. Panoussis3, E. Dermitzakis2, G. Bertsias1, D. Boumpas2,3, A. Filia3, Limassol General Hospital, Limassol, Cyprus; 2Biomedical Research Foundation of the Academy of Athens, Athens, Greece; 3University of Geneva, Geneva, Switzerland; 4University of Crete, Heraklion, Greece; 5University of Athens, Athens, Greece; 6University of Cyprus, Nicosia, Cyprus

Background: Systemic Lupus Erythematosus (SLE) is a complex disease associated with the dysfunction of multiple tissues and cells. The causal tissue for each disease phenotype is not known a priori. Despite improvements in diagnosis and treatment, major organ involvement (such as the kidneys) contributes significantly to morbidity and mortality that still remain increased. There is an unmet need for timely targeted therapy.

Objectives: RNA-sequencing was performed to investigate the patterns of transcription variation across tissues between healthy and lupus-prone mice at different stages of lupus, and how these patterns associate with human Systemic Lupus Erythematosus (SLE).

Methods: NZB/W-F1 lupus prone mice were sacrificed at the pre-puberty, pre-autoimmunity and nephritic stage. Age-matched C57BL/6 were used as controls. An “effector” tissue (spleen) and “end-organs” (kidneys, brain) were collected. Total RNA was isolated, and mRNA-sequencing was performed. A time-series analysis was developed and differentially expressed genes (DEGs) were analyzed with DESeq. Hierarchical clustering and functional enrichment analysis was performed with gprofiler. Human orthologs of mouse tissue DEGs were identified in the whole-blood RNA-sequencing dataset comprised of 55 lupus-nephritis (LN), 65 non-LN SLE patients and 58 healthy individuals (HL). Human orthologs were compared to human DEGs. Using machine learning, human orthologs identified in the mouse dataset were used to predict kidney involvement in the human dataset, which was split in training and validation sets.

Results: Lupus susceptibility and progression signatures at different tissues and different stages of the disease were identified. Tissue-specific signatures and organ-specific cross-tissue signature were also described. Previously detected and novel biological processes and pathways were revealed. The comparative murine-human transcripTome analysis identified human orthologs from the mouse spleen-signature (including CCL5, IFIT and HLA genes) that are involved in systemic autoimmunity. It also identified human orthologs from the kidney- and brain-signature (including FCGR2A, C1Q, JAK1 and APOA2) that are involved in major “end-organ” damage and response mechanisms. Using a neural network model, 193 human orthologs accurately predicted LN patients vs HI (accuracy=0.86, sensitivity=0.82, specificity=0.91 in the validation set). Using a support vector machine model, 30 human orthologs and age and gender were the best predictors of LN vs non-LN SLE patients (accuracy=0.71, sensitivity=0.73, specificity=0.69 in the validation set).

Conclusion: Murine tissue gene signatures identified by RNA-sequencing analysis revealed biological pathways and processes that could be potentially used as biomarkers or therapeutic targets in human SLE. Comparison of the murine dataset with human DEGs. Using machine learning, human orthologs identified in the mouse dataset were used to predict kidney involvement in the human dataset, which was split in training and validation sets.

Type I Interferon Signature Predicts Progression to Inflammatory Arthritis in ACPA+ At-Risk Individuals Without Clinical Synovitis

L. García-Montoya1,2, Z. Wigston1, A. Burska1, K. Mankia1,2, E. Vital1,2, P. Emery1,2, 1LIRMM, University of Leeds, Leeds, United Kingdom; 2Leeds Biomedical Research Centre, NIHR, Leeds, United Kingdom

Background: Interferon (IFN) is known to play a role in the pathogenesis of many autoimmune diseases, among them, rheumatoid arthritis (RA). A study showed that two interferon-stimulated gene expression scores (IFN-Score-A and IFN-Score-B) can be used to predict progression to connective tissue disease (CTD) in at-risk individuals, positive for anti-nuclear antibodies (ANA+) [1]. This validated score could potentially be applied to individuals at-risk of RA.

Objectives: To investigate the role of type I IFN in patients at-risk of RA and assess its potential role as a biomarker to predict progression to inflammatory arthritis (IA).

Methods: PBMC samples were taken from 36 at-risk individuals positive for anti-citrullinated protein antibodies (ACPA+), with a non-specific musculoskeletal complaint but no clinical synovitis and a normal ultrasound scan at baseline (BL). 17 of them developed IA later on, and had a second sample taken at the moment of progression. The other 19 did not progress and had a second sample taken after 1 year. Expression of IFN stimulated genes was assessed using TaqMan. T-test was used to compare the expression of the genes at the two time points of each individual. Binary logistic regression was used to assess BL predictors of progression. Multivariable analysis was adjusted for confounders such as C-reactive protein (CRP) rheumatoid factor (RF) and ACPA titre.

Results: Table 1 shows the list of tested genes. There were no differences in the gene expression of progressors at BL and at the moment of IA diagnosis. Similarly, no differences were found between the non-progressors at BL and after 1 year. Comparing BL samples from progressors and non-progressors, there was a trend to higher expression of IFN-score-B in the progressors (Mann Whitney (p=0.05)), whereas IFN-score-A was similarly expressed in both groups. This is similar to the results found in a cohort of ANA+ individuals at risk of progressing to CTD [1]. Multivariable analysis showed that IFN-score-B and RF titre were predictive for IA progression with an odds ratio (OR) of 2.18 (p=0.048) and OR 1.01 (p=0.035).

Conclusion: These exploratory results suggest that IFN changes in IA progressors precede subclinical inflammation on ultrasound. A preliminary risk model shows that IFN-score-B could be useful to predict progression to IA in at-risk of RA individuals; however, these results require validation in a larger at-risk cohort.

EPIDEMIOLOGIC ANALYSIS OF RA PATIENTS SHOWS DISTINCT BIOLOGICAL PROCESSES ASSOCIATED WITH ANTI-TNF RESPONSE

Background: Blocking Tumor Necrosis Factor (TNF) activity is a successful therapeutic approach for approximately 60% of patients with rheumatoid arthritis (RA). To date, however, the biological basis of the lack of efficacy of anti-TNF agents is unknown.

Objectives: The objective of present study was to characterize the biological basis of anti-TNF lack of efficacy in RA using an epigenomic data approach in two steps: first, to assess the differential methylation changes between respond-ers and non-responders and second, to use this differential methylation profile in a systems biology approach to infer differential methylated biological modules according to anti-TNF response.

Methods: A total of n=68 patients diagnosed with RA according to the ACR-EULAR criteria belonging to 16 Hospitals across Spain were recruited. All patients were >18 years old, with more than 6 months of disease evolution and a baseline disease activity of DAS28 > 3.2. Treatment response was defined according to the EULAR criteria at week 12. Good and moderate responders were aggregated into a single responder group. Genomic DNA was collected at baseline and the methylation profile was assessed using the Illumina Infinium EPIC array, which interrogates 850,000 methylation CpG sites across the genome. Differential Methylation analysis, biological pathway association and the systems Biology approach using Protein-Protein Interaction Networks, were conducted using the R statistical language and the Bio conductor libraries.

Results: From 68 anti-TNF treated patients, n=27 (39.7%) were good responders, n=26 (38.2%) moderate responders and n=15 (22.05%) non-responders at week 12 of treatment. Differential methylation analysis identified two distinctive biological profiles associated with the clinical response: responders were associated to interleukin and cytokine production, and non-responders were associated with biological pathways associated to TGF-β Beta production and T cell regulation. Using these differentially methylated profiles, epigenetic modules with differentially methylated hotspots between responders and non-responders were also found. Two epigenetic modules with significant enrichment in inflammatory and interleukin production and immune regulatory processes were validated in an independent patient cohort.

Conclusion: The epigenetic analysis of whole blood from RA patients using a module-based approach shows reproducible biological mechanisms associated with the response to anti-TNF therapy.

ATTEMPTS TO LINK EXONIC GENE POLYMORPHISMS TO SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)-ASSOCIATED PROTEIN MODIFIED FUNCTIONALITY: A STRUCTURAL BIOLOGY APPROACH

E. Eliopoulos1, G. Goulielmos1, M. Matalliotakis1, D. Vlachakis1, T. Niewold2, M. Zervou3.

Agricultural University of Athens, Department of Biotechnology, Athens, Greece; 2University of Crete, School of Medicine, Heraklion, Greece; 3 Aristotle University of Thessaloniki, Department of Obstetrics and Gynecology, Thessaloniki, Greece; 4NYU School of Medicine, Colton Center for Autoimmunity, New York, United States of America

Background: Gene association studies and genome wide association studies (GWAS) have played a primary role in depicting genetic contributions to systemic lupus erythematosus (SLE) development, while accommodating the exonic polymorphisms on the protein structure level, when available, enhances our understanding of protein function modification or depletion. Linking human genetics with therapeutic targets requires the biological function of the causal gene variant to be known.

Objectives: To investigate recently identified SLE-associated functional gene polymorphisms, such as PARP1, ITGAM, TFNAIP3, NCF1, PON1, IFIH1, SH2B3 and TYK2 [1-4] by correlation to protein structure and function.

Methods: Three-dimensional (3D) homology modeling and molecular mechanics/dynamics studies were applied for the localization of the polymorphisms under study on the respective proteins. The mutants were constructed using molecular modeling with the program Maestro (Schrodinger, LLC), which was also used to analyze the conformational changes caused by the mutation. All figures depicting 3D models were created using the molecular graphics program PyMOL V.2.2 [5].

Results: Modeling revealed that rs1136410 SNP encodes the less common polymorphism Val762Ala on PARP1 that reduces enzymatic activity of PolyADP-ri-bosyltransferase 1 (Figure 1). Furthermore, rs1136410 SNP results in two mutations on integrin alpha M, one of the macrophage-1 antigen complex affects protein surface recognition, TFNAIP3 rs2239026 polymorphism encodes Cys instead of Phe at residue 127 of the ubiquitin editing A20 protein, while rs1802888 polymorphism of the neutrophil cytosolic factor 1 (NCF1) gene modifies the function of the cytosolic subunit of neutrophil NADPH oxidase with the mutation Arg408His. The PON1 is involved in the oxidative stress process that cause tissue damage observed in SLE and anti-phospholipid syndrome (APS). The PON1 Gln192Arg mutation (rs662 SNP) affects shape and recognition of the ligand recognition site as part of the evolutionary process, while IFIH1 (rs35667974) helicase C domain1 mutant i923V is located on an essential RNA beta loop interacting directly with the nucleic acid (Figure 2). Finally, the rs3184504 SNP of SH2B3 gene generates mutant Arg523Trp on SH2 adapter protein 3, acting as a binding pathway involved in autoimmune disorders, while in TYK2 gene one of the Janus kinases, the rs3501880 producing mutant Ala828Val modifies the ADP binding site.

Figure 1. Details of the Val762 interaction where V762A mutation occurs in PARP1 protein.

Figure 2. Nucleic acid interacting IFIH1 helicase beta-loop where I923V mutation occurs (in purple).

Conclusion: Based on several examples, we have tried to define a rational link from SLE-associated gene polymorphisms to structure and to modified function, including metagenomic analysis of SNPs, protein crystallography, protein molecular modeling, molecular mechanics and dynamics. Locating, shaping and understanding the target protein interaction interface plays a decisive role in most cases and provides clues for further pharmacological or medical actions [6].

INTRON REGIONS OF PIK3AP1 (BCAP) AND SPON2 (SPONDIN-2) GENES ARE DIFFERENTIALLY METHYLATED IN PATIENTS WITH PERIODIC FEVER, APHOTHIUS STOMATITIS, PHARYNGITIS AND ADENITIS (PFAPA) SYNDROME

E. Lovšin1, J. Kovac2, T. Tesovnik2, N. Toplak2, D. Perko2, T. Rozman2, M. Debeljak3, T. Avcin1,1 University Medical Centre, Division of Paediatrics, Unit of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia;2University Medical Centre, Division of Paediatrics, Clinical Institute for Specialized Laboratory Diagnostics, Ljubljana, Slovenia;3Medical University of Vienna, Department of Pediatrics and Adolescent Medicine, Wien, Austria

Background: Periodic fever, aphtous stomatitis, pharyngitis and adenitis (PFAPA) syndrome is the most common autoinflammatory disease in children, often grouped together with hereditary periodic fever syndromes, although its cause and hereditary nature remain unexplained.

Objectives: We investigated whether a differential DNA methylation was present in DNA from peripheral blood mononuclear cells (PBMC) in patients with PFAPA versus a group of healthy young individuals.

Methods: A whole epigenome analysis (MeDIP and MBD) was performed using pooled DNA libraries enriched for methylated genomic regions. Of identified candidate genes, two with most significantly different methylation levels were further evaluated with methylation specific restriction enzymes coupled with qPCR.

Results: The analysis showed that PIK3AP1 and SPON2 intronic regions are differentially methylated in patients with PFAPA. MeDIP-qPCR proved as a quick, reliable and cost-effective method to confirm results from MBD and MBD.

Conclusion: Our findings indicate that B cell adapter protein (BCAP) as PI3K binding inhibitor of inflammation and spondin-2 (SPON2) as a pattern recognition molecule and integrin ligand could play a role in etiology of PFAPA. Their role and impact of changed DNA methylation in PFAPA etiology and autoinflammation need further investigation.

THU0020

NO CAUSAL ASSOCIATION OF SERUM URATE OR GOUT WITH ALZHEIMER’S DISEASE: A MENDELIAN RANDOMIZATION ANALYSIS

S. Marzoff1, N. Mccormick2, J. Choi2, H. Choi1,1 Arthritis Research Canada, Richmond, Canada; 2Massachusetts General Hospital, Boston, United States of America

Background: Several epidemiologic studies have found a lower risk of Alzheimer’s disease (AD) among individuals with a history of gout or high serum urate levels, which are the precursor to gout. Serum urate may have neuroprotective benefits for AD, however it is possible that reverse causation and residual confounding could explain the observational evidence.

Objectives: To study the causal associations of serum urate and gout with Alzheimer’s disease using Mendelian Randomization (MR) methods.

Methods: Two-sample MR was performed to examine the causality of: 1) serum urate on Alzheimer’s disease and 2) gout on Alzheimer’s disease. Single nucleotide polymorphisms (SNP) identified from a genome-wide association study of 457,690 adults described 183 SNPs associated with serum urate and gout, which were used as instrumental variables. Additional single-SNP analyses were conducted using SNPs from three genes identified as major determinants of urate levels (SLC2A9, SLC22A12, and ABCG2). SNPs for AD came from the International Genomics of Alzheimer’s Project, comprised of 35,274 AD cases and 59,163 cognitively normal elderly controls. Inverse-variance weighted (IVW) models were the primary method used to examine the associations between each exposure and risk of AD. Additional analyses examined the potential impact of pleiotropy via MR-Egger models. Single-SNP analyses used the Wald ratio. All analyses were performed using R.

Results: There was no evidence of a causal association between genetically-determined serum urate or gout and risk of AD from IVW analyses (both p>0.1) (Table 1). MR-Egger analyses yielded similar estimates (both p>0.1) and the intercepts of the MR-Egger regressions did not suggest the presence of directional pleiotropy (p=0.64 for serum urate exposure and p=0.98 for gout exposure) (Table 1). Additionally, none of the three individual SNPs were significantly associated with risk of AD (all p>0.05) (Table 2).

</tbody>
</table>

Conclusion: Using both serum urate and gout as instrumental variables in MR analysis, these findings suggest that serum urate and gout are not causal determinants for the development of AD. The inverse associations described in observational studies may in part be due to confounding or reverse causality.

Differential DNA Methylation as a Predictor of Tocilizumab Response in Rheumatoid Arthritis Patients

Background: Tocilizumab (TCZ) is a biological disease-modifying antirheumatic drug that blocks IL-6 signalling and is effective in ameliorating disease activity in rheumatoid arthritis (RA). However, approximately 50% of patients do not respond adequately to TCZ and some patients report adverse events. Considering there is growing evidence that DNA methylation is implicated in RA susceptibility and response to some biologics (1, 2), we investigated DNA methylation as a candidate biomarker for response to TCZ in RA.

Objectives: To identify differential DNA methylation signatures in whole blood associated with TCZ response in patients with RA.

Methods: Epigenome-wide DNA methylation patterns were measured using the Illumina EPIC BeadChip (Illumina) in whole blood-derived DNA samples from patients with RA. DNA was extracted from blood samples taken pre-treatment and 3 months after initiation of TCZ therapy, and response was determined at 6 months using the Clinical Disease Activity Index (CDAI). Patients who had good response (n=10) or poor response (n=10) to TCZ by 6 months were selected. Samples from secondary poor responders (n=10) (patients who had an improvement of 30% of CDAI and were in remission at 3 months, followed by a worsening of CDAI at 6 months) were also analysed. Differentially methylated positions and regions (DMPs/DMRs) were identified using linear regression, adjusting for gender, age, cell composition, smoking status, and glucocorticoid use. Gene Set Enrichment Analysis (GSEA) and Functional Enrichment analysis using Gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) annotations were also performed. A number of Differently Expressed Genes were highlighted.

Results: 311 genes were identified as being significantly differentially expressed between patients and controls. In details, 129 downregulated (7 genes have fold change more than 1) and 182 upregulated genes (3 genes have fold change more than 1) are highlighted. These genes are mostly involved in Myogenesis, Innate Immune Signalling and JAK/STAT pathways. Several genes with functions of skeletal muscle development and muscle contraction were identified.

Conclusion: The evidence disclosed that regulation of muscle development and contraction may be also engaged in physiopathology mechanisms of axSpA. These new cues open new perspectives for diagnosis and therapeutic approaches in axSpA.

Acknowledgments: To all patients and healthy people who participate in MySpA study

DOI: 10.1136/annrheumdis-2020-eular.5331
Results: Among the 117 patients with RP, 5 (4.3%) and 6 (5.1%) patients had GD and HT, respectively. Patients with RP were more likely to be complicated with GD (p=1.04×10−10, OR: 7.15, 95%CI 2.68–18.14) but not with HT (p=0.50, 95%CI 0.59–1.27), compared with prevalence in general Japanese population (0.62% and 5.9%, respectively)2. RP patients with GD showed a trend to have nasal involvement (100% vs 45.5%, p=0.023, OR: 2.58, 95%CI 1.09–6.0). We did not observe any differences in clinical manifestation in patients with RP and HT. HLA- DPB1*02:02 demonstrated a trend toward GD complication (20% vs 2.3%, p=0.035, OR: 10.41, 95%CI 1.23–65.38). There were no association of HLA in the complication of HT among patients with RP.

Conclusion: Patients with RP have high co-occurrence ratio of GD. Patients with the two diseases may be characterized by nasal involvement and HLA-DPB1*02:02.

METHYLATION ANALYSIS OF VITAMIN D SIGNALING PATHWAY GENES IN RHEUMATOID ARTHRITIS PATIENTS

E. Puncievicene1,2,3, L. Gaizevska4,5, R. Sabaliauskaite1, L. Venceviciene1,2, D. Vitkus1,3, J. Jarmalaite4,5, I. Butrimiene1,2,3, Centre of Rheumatology, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania; State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania; Clinical of Rheumatology, Traumatology Orthopaedics and Reconstrictory Surgery, Institute of Clinical Medicine of the Faculty of Medicine, Vilnius University, Vilnius, Lithuania; Institute of Biosciences, Life Sciences Center, Vilnius University, Vilnius, Lithuania; Laboratory of Genetic Diagnostics, National Cancer Institute, Vilnius, Lithuania; Clinic of Internal Medicine, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; Centre of Family Medicine, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania; Institute of Biomedical Sciences of the Faculty of Medicine, Vilnius University, Vilnius, Lithuania; Centre of Laboratory Medicine, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania

Background: Vitamin D is known for its immunomodulatory and epigenome interacting effects. Vitamin D deficiency is frequently observed in rheumatoid arthritis (RA) patients compared to healthy controls, is also named as a potential risk factor in RA ethiopatogenesis and may alter DNA methylation of certain genes [1,2]. Still, causality of vitamin D deficiency in RA patients needs to be elucidated.

Objectives: The aim of the study was to evaluate relationship between DNA methylation status of vitamin D related genes (VDR, CYP24A1, CYP2R1), miRNA-155 expression, vitamin D level and its association with RA.

Methods: CdPs islands in promoter region of the VDR, CYP24A1, CYP2R1 genes were chosen for DNA methylation analysis by means of pyrosequencing. DNA from blood mononuclear cells of 31 RA patients and 31 age and sex matched healthy controls was assessed for methylation pattern after informed consent was obtained in Vilnius university Hospital Santaros klinikos Centre of Rheumatology. For miRNA analysis quantitative reverse transcription PCR was used. Chemiluminescent microplate immunoassay was used to assess 25(OH)D serum levels.

Results: 25(OH)D concentrations varied from deficiency (<50 nmol/l), insufficiency (50-75 nmol/l) to normal range (≥75-100 nmol/l) in RA mean 47.49 nmol/l; SD = 27.93) and healthy controls (mean 57.38 nmol/l; SD ± 29.93). CYP24A1 methylation level was significantly higher in comparison to VDR (p<0.0001) and CYP2R1 (p<0.0001) genes in both groups. CYP24A1 hypermethylation was also observed in older subjects (p=0.012). The study demonstrated a significant positive correlation between vitamin D concentration and VDR CYP2R1 genes methylation intensity (r²=0.31, p=0.014; r²=0.25, p=0.042, respectively). However, gene methylation frequency and methylation intensity showed no significant difference between RA patients and healthy controls (VDR – 2.4 vs 2.6 %, CYP24A1 – 16.6 vs 15.3 %, CYP2R1 – 2.6 vs 2.6 %) (p=0.05). To note, miRNA-155 expression negatively correlated with CYP24A1 methylation intensity (r²=-0.43, p=0.009).

Conclusion: Our study identified significant associations between the VDR and CYP2R1 promoter methylation and vitamin D concentration. However, no significant differences in DNA methylation pattern between RA patients and healthy controls were detected. MiR-155 expression was associated with CYP24A1 methylation level, confirming its possible involvement in vitamin D metabolism. The data of our study suggests that epigenetic phenomena are significantly involved in vitamin D metabolism and may have an indirect effect on RA ethiopatogenesis.

Micro-RNAs differentially regulate the alternative PRTN3-mRNA in granulomatosis with polyangiitis

N. Reichard1, A. Kerstein-Staehle1, A. Müller1, G. Riemarken1, P. Lamprecht1, S. Schinke1, University Lübeck, Rheumatology and Clinical Immunology, Lübeck, Germany

Background: Micro-RNAs (miRNAs) are short non-coding RNAs that regulate inflammation mostly by translational repression. Previously, we screened 847 miRNAs in nasal tissue from GPA patients and found a disease associated alteration of miRNA expression compared to healthy controls and chronic rhinosinusitis. MiR-184 was most over expressed in nasal tissue from GPA (13.4x). The dual-luciferase reporter assay confirmed a significant reduction of Proteinase-3 (PRTN3) expression by miR-184 (1).

PRTN3 transcripts with an alternative 3' untranslated region (UTR) have been described in GPA (2). The pathophysiological relevance of this alternative transcript remains unclarified.

Objectives: To identify new miRNA targets of potential pathophysiological relevance in GPA, we validated the effect of the 21 most dysregulated miRNAs on the mRNA of PRTN3. Further, we included the alternative PRTN3 mRNA in our screen to look for new regulatory differences.

Methods: The inhibitory capacity of miRNAs on Proteinase-3 mRNA was estimated by a dual-luciferase reporter system. The sequences of the alternative (132bp longer) and the regular 3'UTR-PRTN3 were cloned and inserted into the pmirGLO vector and co-transfected with 21 miRNA mimics into HeLa cells. Co-transfection with Caenorhabditis elegans miR-67 mimic (cel-miR-67) was used as negative control. Statistical significance was evaluated by students t-test adjusted for multiple comparisons (Holm-Sidak).

Results: For 18 of 21 investigated miRNAs no effects could be observed on the alternative and the regular 3'UTR-PRTN3. But there were remarkable differential effects of let-7i, mir-184 and miR-708. Let-7i (-29.2%) and miR-708 (-23.6%) both showed a suppression of the alternative 3'UTR-PRTN3 but no effect on the regular 3'UTR-PRTN3 while miR-184 only suppressed the regular 3'UTR (-17.5%) and not the alternative variant (fig. 1-2).

Conclusion: Disease specific miRNA signatures together with an increased PRTN3 level and in alternative PRTN3 mRNA in GPA suggest a dysregulation of PRTN3 expression in GPA. To our knowledge this is the first analysis in GPA showing that miRNAs can differentially regulate the expected and the alternative 3'UTR variants of PRTN3-mRNA. As miR-184 is markedly upregulated in GPA, a repression of PRTN3 is to be anticipated, possibly as a reaction to previous neutrophil activation with PRTN3 overexpression. Our findings also strengthen the potential pathophysiological role of the alternative PRTN3 mRNA.

Background: Clonal haematopoiesis of indeterminate potential (CHIP) occurs when somatic mutations arise in myeloid neoplasia driver genes of haematopoietic progenitor cells, in the absence of overt cytopenia or dysplasia. The prevalence of CHIP increases with age. The most common genes affected by CHIP mutations in unselected populations are DNMT3A, ASXL1, and TET2. The presence of CHIP is linked to increased basal level of inflammation and a high risk of cardiovascular disease and all-cause mortality. Rheumatoid arthritis (RA) is one of the most common and debilitating multi-system autoimmune disorders, affecting up to 1% of adults in developed countries. The role of somatic mutations in the pathogenesis of autoimmune diseases is an unexplored area; therefore, we aimed to test the hypothesis that clonal haematopoiesis (CH) is associated with the incidence and severity of RA.

Objectives: To evaluate the association of CH somatic mutation with severity of RA.

Methods: 163 RA patients were recruited from the following cohorts: (i) Early RA treatment naive (n=31), (ii) Refractory RA - non-responders to Disease-Modifying Anti-Rheumatic Drugs (DMARDs) and biologics (n=48), (iii) Flare (n=41) vs Remission patients (n=43) – patients treated with DMARDs and withdrawn from treatment on achieving remission. Six months later, 50% relapse and 50% sustain remission. Single molecule molecular inversion probes (smMIPs) were used to screen for somatic mutations in 40 loci known to carry clonal haematopoiesis driver mutations (CHDMs). Whole exome sequencing was also performed on Flare/Remission patients (n = 84) to screen for CHDMs and other somatic mutations. In-house bioinformatics pipelines were used to call mutations from both the datasets.

Results: We identified CH in RA with an overall prevalence of 14%. Twenty-four unique variants with a variant allele frequency (VAF) of 2-35% were found in ten genes including ASXL1, CBL, DNMT3A, GNAS, GNB1, PTPN11, PTEN, SF3B1, TET2, and TP53. The number of unique patients carrying mutations in these genes are follows: refractory: n=12/48, flare: n=6/41. remission: n=4/43 and early RA: n=2/31. The majority of the mutations occurred in DNMT3A (n=6) followed by TP53 (N=4) and TET2 (n=3). Two variants with VAF of 15% were identified in two patients under the age of 30, both with clinically severe disease. In patients between the ages of 50-59 yrs., 60-69 yrs., and 70-79 yrs., CH was observed at 11% (4/35), 23% (11/46) and 17% (7/41), respectively.

Conclusion: We here report the prevalence of CH in RA, affecting more patients with clinically advanced/refractory disease compared to those with early/less severe disease. Further study will be conducted to confirm the results.

THE ASSOCIATION OF THE RS3567740 DNAE1L3 GENE POLYMORPHISM WITH SLE, RA AND SSC: STRUCTURAL/BIOLOGICAL INSIGHTS

M. Zervou1, A. Andreou2, C. Matalliotaki3, T. Niewold4, G. Goulielmos1, E. Eliopoulos5,1, University of Crete, School of Medicine, Heraklion, Greece; 2Agricultural University of Athens, Department of Biotechnology, Athens, Greece; 3Aristotle University of Thessaloniki, Third Department of Obstetrics and Gynecology, Thessaloniki, Greece; 4NYU School of Medicine, Colton Center for Autoimmunity, New York, Greece

Background: Genome-wide association studies (GWAS) have identified hundreds of autoimmune diseases-associated loci so far but much of the heritability of these diseases remains unknown. In an attempt to identify potential causal variants, various studies revealed that the missense variant rs3567740 at DNAE1L3 is associated with the development of systemic lupus erythematosus...
(SLE), rheumatoid arthritis (RA) and systemic sclerosis (SSc), thus exhibiting a pleiotropic effect. Deoxyribonuclease I-like 3 (DNase1L3) is a member of human DNase I family, representing a nuclease that cleaves double-stranded DNA during apoptosis and is involved in the development of autoimmune diseases [1].

**Objectives:** To investigate the role of the rs35677470 polymorphism at DNA-SE1L3 gene leading to the R206C mutation in SLE, RA and SSc [2-3] and the mechanism that may affect the loss of function in the protein structure.

**Methods:** The DNASE1L3 evolution was investigated to define conservation elements in the protein sequence using, BLASTP extended searches [4], TCOFFEE [5] multiple sequence alignments, and MEGAX [6] for phylogenetics analysis. Three-dimensional (3D) homology modeling was used to localize the polymorphism under study. The mutant was constructed by molecular modeling using the structures of homologous DNAses (PDB entries 1atn, 4awn, 3dsw; [7-9]). Molecular mechanics/dynamics studies were applied to validate structural/functional changes caused by the R206C substitution. All figures depicting 3D models were generated using the PyMOL molecular-graphics system V2.2 (Schrodinger, LLC).

**Results:** The evolutionary analysis shows heavily conserved sequence elements among species indicating structural-functional importance. Structural analysis revealed that the rs35677470 SNP codes for a nonconservative amino acid variation, R206C, disrupts the conserved electrostatic network holding protein secondary structure elements to place. Specifically, the R206 to E170 interaction, part of a salt bridge network stabilizing two α-helices, is being interrupted, thereby affecting the molecular architecture (Fig. 1). Indeed, previous studies on the effect of this SNP in Caucasian populations resulting in a lower level of DNase1L3 activity are consistent with this observation [10].

**Conclusion:** This study represents a comprehensive evaluation of the shared autoimmune loci of DNASE1L3 (rs35677470), reported to produce an inactive form of DNASE1L3 [10]. The structural analysis, explains the potential role of the produced mutation by modifying the placement of structural elements and consequently introducing disorder in the protein folding and affecting biological function. Altogether, this study contributes to the delineation of the genetic architecture of SLE, RA and SSc.

**AN EXPLANATION FOR HOW VIRAL INFECTION MAY TRIGGER SPONDYLOARTHROPATHY BASED ON TLR9 DRIVEN TNF RESPONSES FROM ENTHESEAL DERIVED PLASMACYTOID DENDRITIC CELLS**

O. Zhou1,2, J. Vadayekolathu,3 K. Shariat,2 F. Russel2, H. Rowe2, P. Millner1, P. Loughenbury4, A. S. Rao, R. Dunsmiru4, C. Bridgewood,5 Y. El, Sherbiny5, D. Mcconagle6,7,8

**Rheumatology and Immunology, Chengdu, China; 2University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 3Nottingham Trent University, Department of Biosciences, Nottingham, United Kingdom; 4Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 5Leeds Teaching Hospitals, National Institute for Health Research (NIHR) Leeds Biomedical Research Centre, Leeds, United Kingdom**

**Background:** It is well known that viral infections may trigger psoriatic arthritis (PsA), a disease that typically has extensive pre-clinical enthesal abnormalities. Skin resident plasmacytoid dendritic cells (pDCs) produce IFNα that contribute to T cell expansion and the development of experimental psoriasis [1, 2]. IFN pathway SNPs have been reported in both PsA and psoriasis and we previously reported the presence of pDCs at the human entheses [3].

**Objectives:** To investigate whether the TLR9 agonist ODN that replicates viral infection activate a wide array of of enthesal derived pDCs molecular cascades including the TNF pathway that might provide a link between viral infection and PsA. **Methods:** pDCs were sorted from enthesis and blood and stimulated with ODN as previously described (n=16) [3, 4]. IFN protein pre and post stimulation were detected by ELISA. Intracellular flow cytometry (IFC) of enthesal pDCs was used to detect TNF protein. RNA was extracted post-stimulation. The miRNA were hybridised and tagged by probes then measured on the nCounter platform. Data was analysed using nSolver 4.0. Log2 fold change >1 and P-value <0.05 were considered statistically significant. The gene ontology (GO) and Kyoto Encyclopaedia of Genes and Genomes (KEGG) of differentially expressed genes (DEGs) were analyzed using DAVID. Protein-protein interaction (PPI) network was drawn by STRING.

**Results:** Stimulated enthesal pDCs showed a strong DEGs pattern pointing towards increased TNF expression. There were 11 genes significantly upregulated including TNF. RIPK3 is involved in TNF signalling pathway. TNF, RIPK3 and ZBP1 are involved in necroptosis. TNF and ITGB2 are involved in IL-4 and IL-13 signaling pathway. TNF, HLA-DOA, ITGB2/TLR7 are involved in virus infection. Together it highlights extremely activated TNF pathway gene expression. IfN protein was induced in sorted enthesal pDCs following stimulation (n=8). TNF protein was detected by IFC on stimulated enthesal pDCs. (CD45-HLA-DR+CD123+CD303+CD11c-) (n=3). We also compared enthesal and matched peripheral blood pDCs (n=8) following stimulation where no major differences in the TNF pathway were present between groups. The KEGG analysis was mapped in Figure 1. GO analysis showed the most significant change in biological processes was enriched in the positive regulation of DNA binding transcription factor activity. The change in molecular function was mainly enriched in p53 binding.

**Conclusion:** Enthesal pDCs, upon viral molecule stimulation, show several markers of activation. However, TNF pathway genes were highly activated which provides a novel mechanistic link between viral infection and PsA as reported in epidemiological studies.

In our study, 2 mRNA microarray datasets were analyzed to obtain DEGs in T and B cells. After standardization of the microarray results, DEGs in T and B cells were identified respectively (Fig. 1).

Changes in biological processes in T and B cells were both mainly enriched in type I interferon signalling pathway, defense response to virus, and negative regulation of viral genome replication. Changes in cell component in T cells was enriched in the cytosol while in B cells it was in cytoplasm. KEGG pathway analysis revealed that the DEGs of T cells were mainly enriched in influenza A, measles, herpes simplex infection and hepatitis C, while DEGs of B cells were mainly enriched in meiosis. Changes in molecular function were not listed because the p values were ≥0.05. The 4 genes were identified as hub genes (2 each in each population). In T cells, the hub genes are PLSCR1 and GIN52. PLSCR1 may contribute to the prothrombotic tendency of SLE. KE3GG is involved in the initiation of DNA replication and cell cycle progression. In B cells, the hub genes are ISG15 and TOP2A. Increased ISG15 is correlated with lymphocytopenia in SLE patients. TOP2A encodes a DNA topoisomerase and anti-topoisomerase II antibody could be found in SLE.

Conclusion: In our study, 2 mRNA microarray datasets were analyzed to obtain DEGs between SLE T and B cells versus healthy controls. A total of 56 DEGs were identified in T cells and 83 in B cells. Most of the DEGs were upregulated.

Methods: GSE10325 from Gene Expression Omnibus (GEO) database to identify the can-

were identified respectively (Fig. 1).

The hub genes were selected with criteria for selection were: MCODE scores >5, degree cut-off=2, node score considered statistically significant. The PPI networks were drawn using STRING database, and an interaction with a combined score >0.4 was considered statistically significant. The PPI networks of DEGs were constructed.

The PPI analysis revealed that the DEGs of T cells were mainly enriched in influenza A, measles. Changes in molecular function were not listed because the p values were ≥0.05. The 4 genes were identified as hub genes (2 each in each population). In T cells, the hub genes are PLSCR1 and GIN52. PLSCR1 may contribute to the prothrombotic tendency of SLE. KE3GG is involved in the initiation of DNA replication and cell cycle progression. In B cells, the hub genes are ISG15 and TOP2A. Increased ISG15 is correlated with lymphocytopenia in SLE patients. TOP2A encodes a DNA topoisomerase and anti-topoisomerase II antibody could be found in SLE.

Conclusion: In our study, 2 mRNA microarray datasets were analyzed to obtain DEGs between SLE T and B cells versus healthy controls. A total of 56 DEGs were identified in T cells and 83 in B cells. Most of the DEGs were upregulated.

In conclusion, JAK inhibition has a major effect on B cell activation and maturation, with differential outcomes between JAK inhibitors hinting towards distinct and unique effects on B cell homeostasis.

Background: Rheumatoid arthritis (RA) is a highly prevalent and severe systemic autoimmune disease associated with permanent disability and strong socio-economic burdens. Currently, there is no therapeutic treatment and RA patients rely on lifelong, costly treatments. Imcyse develops modified peptides eliciting antigen specific cytolytic CD4 T cells (cCD4+) that induce apoptosis of antigen presenting cells (APC) in a contact dependent manner. cCD4+ also induce apoptosis of autoantigen-specific bystander T-cells, activated by the same APC thus eliminating the risk of general immunosuppression. Peptides consist of MHC class II T cell epitopes of a target autologous modified in their flanking region by the addition of an amino acid sequence containing a thio-disulfide oxidoreductase active motif.

Objectives: The goal of this study was to synthesize modified peptides from a target RA autoantigen and test their potency to generate in vitro specific and cytolytic CD4+ T cells from RA patients.

Methods: We designed modified peptides from a target RA autoantigen after silico and in vitro assessment to identify MHC II core binding region, HLA class II binding properties and physicochemical properties. CD4+ T cells were purified from PBMC of a newly diagnosed seropositive RA patient and co-cultured with autologous APC in the presence of the modified peptide. The CD4+ T cells were restimulated periodically. Peptide's ability to generate specific CD4+ T cells was evaluated by flow cytometric analysis of the expression of surface activation marker CD154 (CD40L). The peptide specific CD4+ T cell lines were sorted based on their surface CD154 expression. The pro-apoptotic activity of CD4+ T cells was assessed after overnight (O/N) co-culture of CD4+ T cells with fluorescent tracer labelled autologous lymphoblastoid cells lines (LCL). Flow cytometry quantification of LCL apoptosis was measured by annexin V staining. MHC II restriction of CD4+ T cells was demonstrated by the addition of blocking antibodies against HLA-DR, DP or DQ molecules.

Results: CD4+ T cells were in vitro expanded after six consecutive stimulations with peptide. We investigated their specificity by flow cytometry and showed that 69% of CD4+ T cells that were stimulated O/N in the presence of the peptide expressed the activation marker CD154 versus 29% of CD4+ T cells that were stimulated in its absence. These cells were sorted based on CD154 expression following specific stimulation. Cell enrichment was then assessed by flow cytometric analysis. Data showed that more than 91% (background 3%) were peptide specific based on CD154 expression. After co-culture of CD4+ T cells with LCL, in independent experiments, Annexin V binding was detected on peptide loaded LCL, ranging from 69% to 89%, while when LCL were kept unloaded these values were between 30% and 55%, respectively, indicating that when specifically activated, these CD4+ T cells had pro-apoptotic activity. When both the peptide and blocking antibodies against HLA-DR, DP or DQ molecules added in the co-culture the pro-apoptotic activity was inhibited by 68%, 20% and 25%, respectively.

Conclusion: The preliminary but very promising data show that our modified peptide generates peptide-specific CD4+ T cells with lytic properties that lyse target APC in an HLA class II specific manner. Our plan is to show that these CD4+ T cells can also induce apoptosis in bystander T cells and to further validate our results in additional RA donors.

ALTERATIONS IN THE PHENOTYPIC LANDSCAPE AND SPECIFICITY OF CD4+ T CELLS IN CCP+ AT RISK SUBJECTS BEFORE THE ONSET OF RHEUMATOID ARTHRITIS (RTR)

C. Rims, V. Muir2, K. Deane2, S. Nagpal1, N. Raos3, F. Baribaud4, G. Vratsanos1, V.M. Holers2, P. Linseby, E. A. James1, J. Buckner1, 1Baron Army Research Institute, Translational Research, Seattle, United States of America; 2Benaroya Research Institute, Bioinformatics, Seattle, United States of America; 3University of Colorado School of Medicine, Division of Rheumatology, Aurora, United States of America; 4Janssen Pharmaceuticals, Spring House, United States of America

Background: The “Targeting Immune Responses for Prevention of RA” (TIP-RA) collaboration studies individuals at high risk for developing rheumatoid arthri-
tis (RA) because of serum anti-citrullinated protein antibody (ACPA) positivity in absence of arthritis at baseline, and is focused on defining how they transform from at-risk to classifiable disease. One potential mechanism is the expansion of antigen specific T cells that recognize self-antigens and acquisition of disease associated T cell phenotypes. ACPA emerge years prior to clinically apparent disease and subsequently increase in their titer and breadth of specificity. However, few studies have characterized T cells during this transition.

Objectives: To identify features associated with progression to RA by examining the specificity and surface phenotype of CD4+ T cells in individuals from the TIP-RA cohort by HLA class II dimmer staining and multi-antigen parameter flow cytometry.

Methods: Tetramer staining and flow cytometry were performed on periph-
ernal blood samples from a baseline visit from CCP3- controls (n=34), CCP3+ at-risk (n=26), CCP3+ positive individuals who transitioned in the near-term to RA (called “RA converters”, n=4), and seropositive early-RA (n=21). Our staining panel allowed us to measure the frequencies of T cells specific for citrullinated alpha-enamealase, aggrecan, cartilage intermediate layer protein (CILP), fibrinogen and vimentin. We then applied both supervised phenotyping and a cluster-based computational approach to compare the phenotypic landscape and specificity of antigen specific and total CD4+ T cells in each cohort.

Results: We observed higher overall frequencies of T cells that recognize citrulli-
nated epitopes in CCP3+ at-risk subjects than CCP- controls (p<0.05). Among the individual specificities, elevated frequencies prior to disease onset were most prom-
inent for CILP specific T cells. Supervised phenotypic analysis revealed an increase in CCR4+ CD4+ T cells in CCP3+ at risk subjects (p<0.001) and a corresponding decrease in CXCR3+ CD4+ T cells that was most pronounced in RA converters and seropositive early-RA (p<0.05). Cluster-based phenotypic analysis defined ten dis-
tinct phenotypic states present within all subjects. Each of these ten immunotypes contained T cells that recognize citrullinated epitopes. However, the predominant immunotype varied for different antigens. During progression, the frequencies of Ag specific T cells diminished when onset was imminently but rebounded shortly after diagnosis. Concomitantly, Ag specific T cells with memory phenotypes were diminished, but subsequently reverted to TSCM, Th1, and Th1-17 like phenotypes.

Conclusion: Our data show that disease associated changes in the antigen specificity of CD4+ T cells are present in CCP3+ at-risk subjects. Furthermore, the number of antigen specific T cells and their phenotype are perturbed before the onset of symptoms and development of fully classified RA. These findings support a continuum of immunologic changes that underlie risk and drive disease, motivating new approaches for early intervention.

Acknowledgments: We gratefully acknowledge the Targeting Immune Responses for Prevention of Rheumatoid Arthritis (TIP-RA) for designing and executing this collaborative study.

OX40L EXPRESSING NEUTROPHILS INDUCE CD4+ T FOLLICULAR AND PERIPHERAL HELPER CELL DIFFERENTIATION IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Pappalardo1, E. Wojciechowski1, J. Odriozola1, I. Douchet1, N. Merillon1, A. Boizard-Moracchini1, P. Duffau1,3, E. Lazaro1,3, M.A. Doucey4, L. Mbou4, C. Riche3,1,2, P. Bianco1,3, 1Bordeaux University, CNRS-UUMR164, ImmunoConCepT, Bordeaux, France; 2Bordeaux University Hospital, Rheumatology Department, Bordeaux, France; 3Bordeaux University Hospital, Internal Medicine Department, Bordeaux, France; 4ICHOS Sciences, Epalinges, Switzerland; 5Bordeaux University Hospital, Immunology and Immunogenetic Department, Bordeaux, France

Background: Neutrophils have been described as potent antigen-presenting cells (APC) that can activate CD4+ T cells through TLR7 or TLR8 agonists and co-stimulatory molecules in tumor immunity. However, little is known about the direct interaction between neutrophils and CD4 T cells with respect to systemic lupus erythematosus (SLE). We have previously showed that OX40L expressing by monocytes from SLE patients promote the differentiation of naive and memory cells into IL21 secreting cells that are able to help B cells.

Objectives: In this study, we investigate OX40L expression on neutrophils from SLE patients and contribution of these OX40L+ neutrophils in SLE pathogenesis to modulation of the B cell helper role of CD4 T cells.

Methods: Surface expression of co-stimulatory molecules (OX40L, ICOSL, GITRL, 4-1BBL) on neutrophils from SLE patients and healthy donors (HD) was measured by flow cytometry (FC). Neutrophils from HD were stimulated with TLR7 or TLR8 agonists and IFN-α after 5 hours of culture, OX40L expression was measured by FC and Western Blotting. CD4 T cells were cultured with the stimulated neutrophils for 3 days. At the end of the co-culture, percentages of

Acknowledgments: with support of vasculitis foundation, CSL Behring, SFR

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.5748
IL21-expressing T follicular (Tfh) and peripheral helper (Tph) cells measured by flow cytometry. These generated Tfh cells were also cultured in the presence of memory B cells. After 5 days of co-culture, plasmablast generation and Ig levels were assessed by FC and ELISA, respectively. Inhibition of OX40-OX40L interaction in vitro was achieved using ISB 830, a novel anti-OX40 mAb currently used in clinical trials.

**Results:** Among the co-stimulatory molecules tested, percentages of OX40L+ neutrophils in SLE (n=54) were increased compared to HD (n=25) (mean ± SD: HD = 1.34 ± 1.62 vs SLE = 4.53 ± 8.1, p=0.02). OX40L expression positively correlated with Tfh disease activity score (SLEDAI) (p = 0.04; r = 0.31) and with anti-DNA antibodies (p=0.04, r = 0.33). Of note, the percentage of OX40L+ neutrophils was higher in anti-sm-RNP+ patients (n=16, mean: 9% ± 8) compared to anti-sm-RNP- patients (n=27, mean = 1.4%±2.5; p = 0.02). The percentage of OX40L+ neutrophils was higher in patients with class III or IV lupus nephritis, and inflammatory infiltrate within the kidney biopsy disclosed OX40L+ neutrophils, in close contact with T cells. Neutrophils from HD express OX40L with TLR8 agonist, or IFNα priming followed by TLR7 agonist. When memory CD4 T cells were cultured in the presence of TLR8-stimulated neutrophils, the proportion of IL21-expressing Tfh (CXCR5+PD1+) and Tph (CXCR5-PD1hi) were increased, compared to culture with unstimulated neutrophils. This process was dependent on OX40-OX40L interactions, as intracellular treatment with the anti-OX40 blocking antibody ISB 830, a novel anti-OX40 mAb currently used in clinical trials.

**Conclusion:** Our results disclose an unprecedented phenomenon where cross-talk between TLR7/8-activated neutrophils and CD4 lymphocytes operates through OX40L-OX40 costimulation, and neutrophils promote the differentiation of pro-inflammatory Tfh and Tph, as well as IL21 production. Therefore, OX40L-OX40 should be considered as a potentially therapeutic axis in SLE patients.

**Background:** Donor-specific anti-HLA antibodies (DSAs) are antibodies in the recipient directed against donor class I/II HLA antigens. The existence of DSAs before allogeneic hematopoietic stem cell transplantation (HSCT) are known to cause primary graft failure. Currently there’s no established method of DSA desensitization due to the long half-life of plasma cells. Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease involving in multiple organ systems mediated by numerous autoantibodies. Recent results have shown that depletion of B cells by CD19 CAR-T cells effectively reversed some manifestations in two SLE mouse models. However, plasma cells could be spared with single CD19 CAR-T cells, and peripheral circulating anti-DNA IgG and IgM autoantibodies remained elevated or increased in treated mice.

**Objectives:** We present the efficacy of BCMA-CD19 compound CAR (cCAR), which target on antibody-producing “root”; both B cells and plasma cells in pre-clinical study and in our first-in-human phase 1 clinical trial.

**Methods:** We constructed a BCMA-CD19 cCAR composed of a complete BCMA-CAR fused to a complete CD19 CAR, separated by a self-cleaving P2A peptide. We assessed the functional activity of CAR in co-culture assay with multiple cell lines. We also verified cCAR efficacy with two mouse models, injected with either BCMA-expressing MM.1S cells or CD19-expressing REH cells. In our phase 1 clinical trial, we enrolled patients with hematologic malignancies with antibody mediated disorders.

**Results:** BCMA-CD19 cCAR exhibited robust cytotoxic activity against the K562 cells engineered to express either CD19 or BCMA in co-culture assays, indicating the ability of each complete CAR domain to specifically lyse target cells. In mouse model study, cCAR-T cells were able to eliminate tumor cells in mice injected with MM.1S cells and REH cells, indicating that both BCMA and CD19 are specifically and equally lysing B cells and plasma cells in vivo, making BCMA-CD19 cCAR a candidate for clinical use.

In our first-in-human clinical trial, the first case is a 48-year-old female patient having resistant B-ALL with high DSA titers. She exhibited complete remission of B-ALL at day 14 post-CAR T treatment. MFI of DSA dropped from 7800 to 1400 in 8 weeks post cCAR treatment, the reduction percentage was approximately 80% (Figure 1). The patient had no CRS, and no neurotoxicity was observed.

The second case is a 41-year-old female patient having a refractory diffuse large B cell lymphoma with bone marrow (BM) involvement. Furthermore, she has a 20 years of SLE, with manifestation of fever dependent of corticosteroids. On day 28 after cCAR treatment, PET/CT scan showed CR, and BM turned negative. In addition, she is independent of steroids, has no fever and other manifestations, CSF/CSF were within normal ranges, and all the ANA dropped significantly, especially the nuclear type ANA, which turned from 1:1000 to be negative at day 64. She had Grade 1 CRS but with no neurotoxicity observed. The absence of B cells and plasma cells persisted more than 5 months post CAR therapy.

**Conclusion:** Our first in human clinical trial on BCMA-CD19 cCAR demonstrated profound efficacy in reducing DSA levels in an ASHCT candidate and ANA titer in a SLE patient. There was strong clinical evidence of depletion of antibody-producing roots, B-cells and plasma cells in both patients. Our results further suggested that BCMA-CD19 cCAR has the potential to benefit patients receiving solid organ transplants or those with other antibody-mediated diseases.

**Figure 1.** A) MFI of DSA and other HLA antibodies before and at different time points after cCAR T infusion. B) the percent reduction post-transfusion of cCAR T cells at different time points.

THU0038 DIFFERENTIAL ROLES OF TNFRI AND TNFRII IN THE MORPHOLOGY OF SECONDARY LYMPHOID ORGANS

K. Jeucken1,2, J. P. Van Hamburg1,2, S. Talis1,2, Amsterdam UMC, Experimental Immunology - Clinical Rheumatology and Immunology, Amsterdam, Netherlands; 2Amsterdam Infection and Immunity Institute, Amsterdam, Netherlands

Background: Tumour necrosis factor (TNF) induced signaling events are important in lymphoid organ development and function, both in health and in immune-mediated inflammatory diseases such as arthritis. Important receptors involved in this process include TNF receptors (R) I and II that exert distinct functions. Mice overexpressing transmembrane (tm)TNF and transgenic cytokine transgenic mice overexpressing recombinant human TNF-α (r-hTNF) were used to investigate the role of TNFR in the development and function of secondary lymphoid tissues.

Methods: Splenocytes and lumbar lymph node (LN) cells from control and r-hTNF mice were fixed and stained for T cell surface markers and FasL using flow cytometry. Tissue sections were stained for immunohistochemistry using antibodies to CCL19, CCL21, and CD45R0.

Results: In comparison to control mice, r-hTNF mice demonstrated a significant increase in the frequency of activated CD4+ T cells expressing CD69 (p = 0.001) and of TNFRII expressing cells (p = 0.002). Furthermore, r-hTNF mice showed a significant increase in the frequency of TNFRII expressing cells in the LN (p = 0.003) and spleen (p = 0.002) compared to control mice. These findings suggest that overexpression of TNF-α leads to an altered morphology of secondary lymphoid tissues, possibly due to the increased expression of TNFRII.

Conclusion: The results presented here indicate that overexpression of TNF-α in secondary lymphoid tissues leads to an altered morphology, which may be important for understanding the role of TNF-α in the development and function of secondary lymphoid tissues.

THU0039 DECIPHERING DISEASE-RELEVANT T CELL SUBSETS IN RHEUMATOID ARTHRITIS IDENTIFIES A NOVEL CELLULAR SUBSET OF PATHOGENETIC IMPORTANCE IN THERAPEUTIC RESISTANCE

M. Nyren1, I. McInnes1, C. Goodyear1, 1Institute of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, Glasgow, United Kingdom

Background: Ablation of an antigen-specific T cell population in a disease-relevant model of rheumatoid arthritis (RA) identifies disease-relevant T cell subsets that may contribute to treatment failure.

Methods: RA synovial fluid, peripheral blood, and synovial biopsies were obtained from RA patients and healthy controls. Flow cytometric analysis and FACS-based immunophenotyping were used to identify disease-relevant T cell subsets.

Results: In RA synovial fluid, a novel T cell subset was identified that is characterized by the co-expression of CD4, CD161, CCR2, and CCR5. This subset was significantly increased in non-responders compared to responders and healthy controls. Moreover, this T cell subset was significantly increased in RA patients with high disease activity, as measured by the Disease Activity Score in 28 joints (DAS28).

Conclusion: The findings presented here identify a novel T cell subset that may play a role in the pathogenesis of RA and contribute to treatment failure.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.5873
Conclusion: Combined, our findings suggest that the CD4+CD161+CCR2+CCR5+ T cell subset represents a substantially abnormal T cell subset in RA, exhibiting exaggerated pro-inflammatory responses, numerical abundance relative to Tregs, and resistant to regulation by Tregs. The CD4+CD161+CCR2+CCR5+ T cell subset appears to be a marker of therapeutic response status in RA, via its contribution to disease pathology and highlights this subset as a potential therapeutic target in RA.

THU0040 PROTEINASE 3-REACTIVE B CELL RECONSTITUTION AFTER TREATMENT WITH RITUXIMAB FOR ANCA-ASSOCIATED VASCULITIS

A. Berti1, S. Hillion2, A. Hummel3, E. Carmona4, T. Peikert5, C. Langford4, A. Merkel6, P. Monach7, P. Reo8, R. Spiera9, E. W. St. Clair10, F. Fervenza11, K. Harris10, J. H. Stone11, J. O. Pers2, U. Specks12, D. Corne12, on behalf of the RAVE group. 1Santa Chiara Hospital, Trento, Italy; 2Université de Bretagne Occidentale, Brest, France; 3Mayo Clinic, Rochester, United States of America; 4Cleveland Clinic, Cleveland, United States of America; 5University of Pennsylvania, Philadelphia, United States of America; 6Brigham and Women’s Hospital, Boston, United States of America; 7Johns Hopkins Medicine, Baltimore, United States of America; 8Hospital for Special Surgery, New York, New York, United States of America; 9Duke University, Durham, United States of America; 10Immune Tolerance Group, Bethesda, United States of America; 11Massachusetts General Hospital, Boston, United States of America

Background: Proteinase 3 (PR3)-reactive B cells are present in PR3-ANCA-associated vasculitides (AAV) at levels higher than healthy controls.

Objectives: To evaluate the dynamics of the PR3-reactive B cell repopulation in patients with PR3-AAV after treatment with rituximab, and to analyze possible associations between these immunological changes and long-lasting remissions.

Methods: We analyzed all available frozen peripheral blood mononuclear cells (n=148) from 23 newly diagnosed AAV patients who participated in the RAVE trial and achieved complete remission (BVAS=0, prednisone=0) after treatment with rituximab.

We measured PR3-reactive B cells and the relative subsets by a multi-color flow cytometry panel including CD19, IgD, CD27, CD38, CD24, and a biotinylated anti-PR3 antibody. Flow cytometry data was analyzed using FlowJo software.

Results: 10/23 (43%) patients relapsed during the follow up. B/10 relapses were severe. At baseline, clinical features, PR3-ANCA levels, % of total PR3-reactive B cells and PR3-reactive B cell subsets were similar between relapsers and non-relapsers. Higher levels of PR3-reactive B cells after rituximab during B cell reconstitution were significantly increased in patients with circulating PR3-PB relative to non-relapsing patients. Higher levels of PR3-PB after rituximab during B cell reconstitution were significantly increased in patients with circulating PR3-PB relative to non-relapsing patients. Higher levels of PR3-PB after rituximab during B cell reconstitution were significantly increased in patients with circulating PR3-PB relative to non-relapsing patients.

Conclusion: In PR3-AAV, during B cell reconstitution after rituximab, the total fraction of PR3-B cells increases, due to the expansion of the transitional and naïve B cell compartments. Circulating PR3-PB within PR3-B cells are enriched in the peripheral blood of relapsing and severely relapsing patients compared to non-relapsing patients. Higher levels of PR3-PB after rituximab during B cell reconstitution significantly increased the risk of subsequent relapse and severe relapse.

THU0041 IFNA AND IL21 PROMOTE DISTINCT POPULATIONS OF EFFECTOR B CELLS

M. Bourgeois1, A. Grasseau1, N. Chriti1, J. O. Pers2, L. Le Potier3, S. Hillion4, 1Univ Brest, Inserm, LAB1, UMR1222 BREST, France

Background: B cells play a crucial role in the pathogenesis of systemic autoimmunity through various effector functions, including auto-antibody production, secretion of pro-inflammatory cytokines and antigen presentation to T cells. Interferon alpha (IFNα), mainly produced by innate cells (Menon et al., 2016), and interleukin (IL)-21 which is secreted by follicular helper T cells (Berglund et al., 2013), promote the generation of auto-reactive IgG-secreting plasma cells. However, it is suggested that IFNa promotes satellite to the generation of regulatory B cells.

Objectives: To further understand the disturbing microenvironmental signals leading to autoimmune diseases, we aim to define a coherent framework integrating the B-cell subsets having different ability to respond to microenvironmental signals, and the signalling pathways driving the differentiation and the functional fate of B cells.

Methods: Naïve and several populations of memory B cells were isolated from peripheral blood of healthy donors and differentiated in vitro in the presence of IL21 or IFNa. The phenotype and the expression of transcription factors were analysed by flow cytometry and molecular identity of these cells was further determined by transcriptomic approaches. Functional analyses were performed to assess the effector functions of B cells and their potential regulatory effects on T cells.

Results: IFNa, in synergy with CpG, promote the generation of CD22hi CD38hi plasmablasts (PB), mainly arising from memory subsets, but not IL21. However, IFNa and IL21 induce the transcriptional program of B-cell differentiation by up-regulating IRF4 and Blimp1 expression. Unlike IFNa, IL21 drive the expansion of CD11c+ Tbet+ cells only from switched memory subsets, suggesting Tbet may be a footprint of long-lived memory B cells. Even though subtle differences were observed in the antibody production between IFNa and IL21-stimulated memory B cells, naïve cells secreted less amount of IgM and IgG1 when stimulated with IL21. Transcriptomic studies are still in progress to further define the molecular profile of those distinct effector B cells.

Conclusion: Taken together, these findings suggest that IFNa promotes a rapid differentiation of B cells into IL10 and IgG-secreting PB whereas IL21 contributes to the generation of Tbet+ atypical pre-PB that may have a role in chronic autoimmune disorders.
DIFFERENTIAL EFFECT OF ABATACEPT VS TNF BLOCKERS, ON THE FREQUENCY OF CIRCULATING FOLLICULAR HELPER (Tfh) AND PERIPHERAL HELPER (Tph) T CELLS IN RHEUMATOID ARTHRITIS

Background: CXCR5+PD-1+ follicular helper (Tfh) and CXCR5+PD-1- peripheral helper (Tph) T cells play an important role in the pathogenesis of Rheumatoid Arthritis (RA) by providing help to autoreactive B cells. Whereas Tfh cells typically dwell in the germinal centers of lymphoid organs, Tph cells accumulate at inflamed tissues. An increased frequency of Tph cells and of circulating counterparts of Tfh cells have been described in the peripheral blood of patients with seropositive RA.

Objectives: To examine the effect of treatment escalation using biological agents (TNF blockers or abatacept), on the frequency of circulating Tfh (cTfh) and Tph (cTph) T cells in RA.

Methods: Peripheral blood was drawn from seropositive RA patients with an incomplete response to csDMARDs (n=29) who initiated biological therapy with TNF blockers (TNFb) (n=17) or abatacept (n=12), prescribed based on routine clinical practice. cTfh and cTph cell frequencies were determined by flow cytometry of freshly isolated PBMCs at the basal visit and 6 months after starting treatment escalation. For each patient, an age and gender-matched healthy control (HC) was also studied at both time points (n=29).

Results: As compared with HC, active RA patients receiving csDMARDs demonstrated a baseline increased frequency of both cTfh and cTph cells. A significant improvement of disease activity as determined by the DAS28 score (ΔDAS28>2.0) was apparent in all of the patients 6 months after initiating biologicals. At that time point, a significant reduction of the previously elevated cTfh cell frequency was observed in both treatment groups. However, cTfh cells remained elevated in patients receiving TNFb notwithstanding a good therapeutic response, whereas subjects receiving abatacept experienced a significant abatement of their cTfh cell frequency. Experimental variation of the cTfh and cTph cell numbers in HC was minimal.

Conclusion: Abatacept but not TNFb, are able to bring down cTfh cell numbers in RA. This indicates that costimulation blockade can help attain an immunological remission, whereas TNF neutralization may allow a persistent pathogenic activity to persist. However, in both treatment groups, frequencies and absolute numbers of both cTfh and cTph cells decreased in patients receiving abatacept at both time points.

SINGLE CELL ANALYSIS OF BONE MARROW AND PERIPHERAL ALTERED B CELL DIFFERENTIATION IN PATIENTS WITH ACTIVE SLE AND THE MECHANISM OF ABNORMAL EARLY B CELL DEVELOPMENT

Background: B cell differentiation and dysfunction play a key role in the pathogenesis of Systemic lupus erythematosus (SLE). Bone marrow (BM) is the developing organ of B cells, and also the home and residence place of plasma cells and memory B cells. However, there is a lack of studies on B cells in BM with lupus.

Objectives: To map the development of BM and peripheral B cells and investigate the mechanism of abnormal early B cell development in SLE.

Methods: A total of 11 SLE patients and 5 age- and sex-matched controls were recruited.BM and peripheral B cell subsets were measured by flow cytometry, sorting-purified B cell subsets were subject to Single-cell RNA sequencing (scRNA-seq) and functional studies. Plasma cytokines and secreted immunoglobulins were detected by Luminex or ELISA. Disease activity of SLE patients was measured using the SLE Disease Activity Index (SLEDAI).

Results: In the present study, we find out that the percentage of monocytes in MNC (p=0.070) and plasma cells(p=0.001)in CD19+ were significantly decreased in BM of SLE, compared to healthy controls. While, SLE patients had increased T%MCNP(p=0.008) and B%CD19+(p=0.002) in BM that controls. In detail, the B cells subsets of bone marrow in patients with active lupus (SLEDAI≥4) were significantly increased, whereas CXCL13 elevated even further.

Conclusion: B cells in BM with lupus exhibit a progressive differentiation error and dysfunction that may contribute to disease activity. Further studies are needed to understand the mechanisms underlying this altered differentiation.

SINGLE CELL RNA SEQUENCING ANALYSIS OF B CELL SUBSETS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Background: Metabolic alterations in patients with systemic lupus erythematosus (SLE) have been associated with immunological dysregulation and disease activity. Single cell RNA sequencing, by enabling the analysis of the transcriptome of individual cells, has the potential to provide detailed insights into the heterogeneity of B cell subsets in SLE.

Objectives: To perform single cell RNA sequencing (scRNA-seq) on B cell subsets from patients with SLE and healthy controls.

Methods: Peripheral blood mononuclear cells (PBMCs) from 11 SLE patients and 11 healthy donors were subjected to scRNA-seq. Clustering analysis was performed to identify distinct B cell subsets, and differential gene expression analysis was conducted to compare these subsets among SLE patients and healthy controls.

Results: The scRNA-seq analysis revealed several distinct B cell subsets, including naive, memory, and plasma cells. Compared to healthy controls, SLE patients showed significant enrichment of memory B cells and plasma cells, while naive B cells were decreased. Moreover, the expression of several metabolic genes was dysregulated in SLE, with increased expression of genes involved in aerobic glycolysis and decreased expression of genes involved in lipid metabolism.

Conclusion: Single cell RNA sequencing provides a comprehensive view of the B cell subsets in SLE and highlights metabolic alterations in these cells that may contribute to the disease pathology.

**Background:** Autoimmunity to citrullinated autoantigens forms a critical com-
ponent of disease pathogenesis in rheumatoid arthritis (RA). Presence of anti-citrullinated protein antibodies (ACPsAs) in patients has high diagnostic value. Recently, several citrullinated antigen specific CD4+T cells have been described. However, detailed studies of their T-cell receptor usage and in-vivo profile suffer from the disadvantage that these cells are present at very low frequencies. In this context, we here present a pipeline for TCR repertoire analy-

**Objectives:** To enable studies of the T cell repertoire of citrullinated antigen-spe-
cific CD4+T cells in rheumatoid arthritis

**Methods:** Peripheral blood mononuclear cells (PBMCs) (n=7) and synovial fluid mononuclear cells (SFMCs) (n=5) from HLA-DR*0401-positive RA patients were cultured in the presence of citrullinated Tenascin C peptide cocktails or influenza peptides (positive control). Citrulline reactive cells were further sup-
plemanted with recombinant human IL-15 and IL-7 on day 2. All cultures were replenished with fresh medium on day 6 and rIL-2 was added every 2 days from then. Assessment of proportion of peptide-HLA-tetramer positive cells was per-
formed using flow cytometry whereby individual antigen-specific CD4+T cells were sorted into 96-well plates containing cell lysis buffer, followed by PCR-

cellular analysis, we map the development of B cells in BM and peripheral and pathogenic characteristics of early B cells, especially proper B.

**Conclusion:** These findings demonstrated that early B cells in BM, especially proper-B are abnormally differentiated with dysregulations, BM is an important organ targeted by SLE. **Background:** Despite advances in understanding how the adaptive T cell landscape is affected in human arthritis, specific T cell subset knowledge has yet to be utilised in clinical settings. We have previously discovered within active arthritic patients, a circulating pathogenic-like lymphocyte (CPLs; CD4+HLA-DR+) within the T-effector compartment, that is phenotypically similar to their synovial counterparts. CPLs are inflammatoty, correlate with disease activity and overlap in synovial TCR repertoire. A similar inflammation-associated T-regulatory (iaTreg; CD4+HLA-DR+) subset, that is activated, poised to migrate to inflamed site and sharing synovial TCR overlap, suggest a common disease ontology that may exist between CPLs and iaTregs.

**Objectives:** Here we seek to determine whether and how the synovial microenvironment plays a role in modulating these two functionally divergent (Teff/Treg compartments) yet pathogenically homologous subsets. This modulation, akin to an immunological rheostat, may be a feature of the disease process.

**Methods:** We examined CD45+ immune cells from synovial and PBMCs (active JIA, inactive JIA, paediatric healthy) through mass cytometry (CyToF). CD4 T cells were sorted into CPLs, iaTregs, Teff and Treg through FACS Aria II, from active JIA PBMCs, paired JIA SFMCs and healthy paediatric PBMCs and examined for their TCR repertoire.

**Results:** Mass cytometric analysis reveal a significant enrichment of synovium signatures in both circulatory CPLs and iaTregs subsets from active arthritic PBMCs, as compared with the conventional pool of Teff/Tregs. This immunological relationship between CPLs/iaTregs is reaffirmed by comparative differential gene expression (DEG) and phylogenetic tree analysis, which indicated transcriptomic convergence between circulating pathogenic CPLs/iaTreg subsets and divergence from their respective conventional Teff/treg pools. Circulatory CPLs/iaTregs exhibit (a) common pathway dysregulation in T cell signalling, (b) restriction in TCR oligoclonality and (c) common transcription factor drivers within the gene regulatory network, suggesting a common pathogenetic mechanism acting on these two disparate compartments.

To understand how the microenvironment plays a role in modulating these two subsets, we compared the transcriptome of CPLs/iaTreg and conventional Teff/Treg subsets from (a) healthy PBMCs, (b) JIA PBMCs and (c) paired JIA SFMCs. The convergence between CPLs/iaTreg increases across the spatial/disease continuum, culminating in 7 key common dysregulated pathways within synovium CPLs/iaTregs. Importantly we detected higher clonotypic sharing of TCRs in CPLs/iaTregs across the spatial and disease continuum, suggesting a common precursor driven by antigenic selection.

**Conclusion:** Our data suggest that CPLs/iaTregs are dichotomous components of a systemic immune rheostat, shape through the synovium environment, modulating autoimmunity in human arthritis. As iaTreg and CPL most likely have the capacity to morph into each other, the molecular crossroads which control this plasticity represent novel therapeutic targets.

**Background:** Previous studies [1] have shown that ATP acts on the receptor P2X7 ligand-gated ion channel (P2X7R) as a second signal to induce gouty arthritis.

**Objectives:** In this study, the functional changes of three SNP genotypes, Ala348 to Thr, Glu496 to Ala and Arg307 to Gin, in P2X7R were analyzed with high uric acid.

**Methods:** After transfection of HEK-293T cells by lentivirus, observing the uptake ability of HEK-293T cells to ethidium bromide. The effect of three different mutants on the P2X7 receptor was thus observed on the P2X7 channel. In addition, THP-1 cells were also transfected, stable expression of a THP-1 cell line that has been transfected with a wild-type or different mutants and thus established. Then three types were set up separately, and each type was randomized into three groups: MSU (labeled M), MSU-ATP (labeled MA), and unstimulated control group (labeled C). Detection of IL-1β protein expression level in serum by ELISA and NLRP3, ASC and Caspase-1 mRNA levels in transfected THP-1 cells by qRT-PCR.

**Results:**
1. These three variants have different effects on the uptake function of ATP-induced ethidium bromide in transfection of HEK-293T cells by lentivirus. Ala348 to Thr increased P2X7-dependent ethidium bromide uptake (145% of wild-type P2X7, response, P<0.001). In contrast, Absent or very reduced P2X7 function was found in Glu496 to Ala and Arg307 to Gin subjects, appeared to abolish P2X7-dependent dye uptake (38% and 32% of wild-type P2X7, responses, P<0.001), who were compared with wild-type.
2. Compared the IL-1β levels of the three variants with the wide-type and empty virus in THP-1 cells, the Ala348 to Thr mutation significantly up-regulated the serum levels of IL-1β compared with the wide-type and empty virus in group MA with high uric acid (P=0.0007; P=0.013, respectively). Moreover, similar results have also been shown in IL-15 mRNA expressions (P=0.0334; P=0.0307, respectively). The Glu496 to Ala and Arg307 to Gin mutations down-regulated the serum levels of IL-1β in group MA (P=0.0189; P=0.0164, respectively).
3. NLRP3 mRNA was significantly increased in the Ala348 to Thr mutation compared with the wide-type and empty virus in group MA (P=0.0003; P=0.001, respectively). However, NLRP3 mRNA was significantly reduced in the Glu496 to Ala and Arg307 to Gin mutations compared with the wide-type in group MA (P=0.0024; P=0.0279, respectively).
4. Wild-type was significantly higher than empty virus in the ASC gene expression in group MA (P=0.0022). Moreover, the Ala348 to Thr mutation was higher than empty virus while Arg307 to Gin mutation was lower than that in group MA (P=0.0138; P=0.0283, respectively).
5. Unlike NLRP3 gene expression, the data showed that the expression of caspase-1 mRNA in group C, M and MA all with no statistical significance, respectively (P>0.05).

**Conclusion:** Our data revealed that Ala348 to Thr up-regulate the functional status of P2X7R and Glu496 to Ala and Arg307 to Gin down-regulate the functional status of P2X7R, which resulted in a significant increase or decrease in IL-1β and NLRP3 expression levels with high uric acid.

**Objectives:** In patients with rheumatoid arthritis (RA) and idiopathic interstitial lung disease (IILD), the expression of coinhibitory molecules on alveolar T cells has not been well studied.

**Methods:** We examined CD45+ immune cells from healthy and RA/IILD patients for the expression of co-inhibitory molecules (PD-1, Tim3, LAG3, TIGIT, TSM) on alveolar T cells.

**Results:** The expression of PD-1 was found to be significantly higher in RA/IILD compared to healthy patients (P<0.05). The expression of Tim3, LAG3, TIGIT, and TSM were found to be lower in RA/IILD compared to healthy patients (P<0.05).

**Conclusion:** Our results suggest that the expression of coinhibitory molecules on alveolar T cells is altered in RA/IILD compared to healthy patients. This may have implications for the pathogenesis of these diseases.

**Disclosure of Interests:** None declared

Previous studies have suggested that alveolar macrophages (AMs) and T cells are associated with the pathogenesis of ILD. Recently, it is reported that coinhibitory molecules are expressed at the site of inflammation such as RA synovium; however, detailed lung immunophenotyping has not been reported.

Objectives: To identify immunologic factors in the lungs of patients with RA-associated ILD (RA-ILD) and IIM-associated ILD (IIM-ILD) and to examine their pathological mechanisms.

Methods: A total of 11 patients with RA-ILD, 16 with IIM-ILD, and 6 with drug-induced ILD (DI-ILD) and 8 healthy controls were enrolled. Peripheral blood and bronchoalveolar lavage fluid (BALF) were immunophenotyped by flow cytometry. AMs were analyzed by RNA-sequence and coculture assay with peripheral naïve CD4+ T cells of healthy individuals.

Results: Several coinhibitory molecules were coexpressed on BALF T cells in the order of CTLA-4, PD-1, Tim-3, and LAG-3 from most to least, whereas only PD-1 was expressed on peripheral T cells among them. In RA-ILD, PD-1+ and Tim-3+ CD4+ T cells in the BALF were increased. PD-1+CD4+ T cells populations correlated differentiated B cells and Tim-3+CD4+ T cell populations correlated with ILD severity and RF titer. In contrast, in IIM-ILD, activated CD8+ T cells were increased and they coexpressed CTLA-4, PD-1 and Tim-3, BALF PD-1+CD4+ T cells rarely expressed CXCXR5, and they positively correlated with plasmablasts and plasma cells, indicating most of them are considered Tph cells. In the coculture experiments, AMs of RA-ILD and IIM-ILD induced more PD-1 and Tim-3 on CD4+ T cells, suggesting that coinhibitory molecule expression on BALF T cells was partly due to AMs. In RNA-sequence, PD-ligand (PD-L1) and PD-L2 genes were significantly downregulated in AMs from RA-ILD compared with DI-ILD.

Conclusion: We identified T cell subsets that play a central role in the pathogenesis of RA-ILD and IIM-ILD. PD-1 on T cells in RA-ILD and Tim-3 on CD4+ T cells in IIM-ILD might be key factors in the disease process. The evaluation of coinhibitory molecules on BALF T cells could be clinically useful.

CONTRIBUTION OF DEFECTIVE NON-APOPTOTIC FAS SIGNALING TO IMMUNE DYSREGULATION IN ADULT-ONSET LYMPHOPROLIFERATIVE SYNDROME (ALPS)

1Medical University Children's Hospital, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; 2Charles University Prague, Department of Paediatric Haematology and Oncology, Prague, Czech Republic; 3University Medical Center Freiburg, Institute of Medical Bioinformatics and System Medicine, Freiburg, Germany; 4Cancer Research Center, Universidad de Salamanca, Salamanca, Spain; 5European Molecular Biology Laboratory, Heidelberg, Germany; 6Institut de Recerca Hospital Sant Joan de Déu Barcelona, Barcelona, Spain; 7University Hospital Neckar-Enfants Malades, Paris, France; 8Instituto de Biomedicina de Sevilla, Sevilla, Spain; 9Hospital Sant Joan de Déu Barcelona, Barcelona, Spain; 10Hospital Universitario 12 de Octubre, Department of Immunology, Barcelona, Spain; 11University Hospital 12 de Octubre, Department of Pediatrics, Barcelona, Spain; 12University Medical Center Freiburg, Institute for Immunodeficiency, Center for Chronic Immunodeficiency, Freiburg, Germany; 13University Medical Center Freiburg, Department of Pathology, Freiburg, Germany; 14Friedrich Alexander University Erlangen-Nürnberg, Erlangen, Germany; 15University of Lausanne, Lausanne, Switzerland; 16Consejo Nacional de Investigaciones Científicas y Técnicas, Medical Physics Department, San Carlos de Bariloche, Argentina

Background: ALPS patients show impaired generation of humoral memory for T independent antigens whereas they generate memory for self-antigens due to impaired FAS-dependent removal of autoantigens by dying B cells. It is known that FAS signaling via caspase activation results in cell apoptosis. However, FAS ligation may also initiate or modulate non-apoptotic signaling as shown for example by its ability to activate NF-κB. Recent data implicate a regulatory role of FAS in the modulation of mTOR signaling in ALPS double-negative T cells. Moreover, C194V FAS mutation disrupts its post-translational modification leading to impaired apoptosis while non-apoptotic signaling is still intact. Consequently, C194V FAS protects from the autoimmune phenotype in the murine ALPS system. This supports the hypothesis that FAS may prevent autoimmune with other mechanisms than inducing apoptosis.

Objectives: We hypothesize that FAS mutations impair this modulatory signaling, leading to hyper-activation of B cells. Therefore we aim to investigate non-apoptotic FAS signaling in B cells derived from healthy individuals and ALPS patients.

Methods: We studied resting and activated B cells in ALPS patients in presence or absence of FAS ligand by flow cytometry analyzing relevant molecules to the FAS signaling pathway.

Results: IFN-γ expression in CD4+ T cells was significantly higher in active AOSD than in HC (p < 0.05). Tregs also significantly induced higher expression of IFN-γ in AOSD than in HC (p < 0.0001) and more IFN-γ producing Treg cells were significantly impaired in their suppression ability (p < 0.05). In both CD4+ T cells and Tregs, expression of IFN-γ was significantly correlated with serum ferritin levels in active AOSD (p < 0.05). IFN-γ expression in CD4+ T cells was significantly higher in patients with splenomegaly than those without that (p < 0.05). The proportion of NK cells was significantly lower in active AOSD than in remission and HC; however, they had no significant correlation with disease activity.

Conclusion: IFN-γ expression in the acute phase of disease was significantly lower in active AOSD than in remission and HC. However, it showed no significant correlation with any analyzed data.

Disclosure of Interests: None declared

NKTR-358, A NOVEL IL-2 CONJUGATE, STIMULATES HIGH LEVELS OF REGULATORY T CELLS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Siddhanti1, C. Fanton1, N. Dixit1, L. Lu2, V. Chindalore2, R. Levin1, I. Diab1, R. Furie1, J. Zalevsky1, B. Kotzin1, Sandoz, David Klatzmann Consultant of: LITOO Pharma

Background: Impaired IL-2 production and dysfunction of regulatory T cells (Tregs) have been identified as key immunological defects leading to the breakdown of immune self-tolerance in SLE. Low-dose IL-2 can expand Tregs, but has a high toxic potential.

Objectives: NKTR-358, a novel IL-2 conjugate, is designed to be highly selective for regulatory T cells (Tregs) and activate pathways not involved in immune dysregulation.
the effect is limited by a narrow therapeutic window for Treg selectivity. Furthermore, the short half-life of IL-2 necessitates frequent administration. NKTR-358 is a polyethylene glycol (PEG) conjugate of recombinant human IL-2 (aldesleukin sequence) and is differentiated from native IL-2 by its altered binding to the IL-2 receptor and prolonged biological activity. NKTR-358 resulted in marked and selective stimulation of Tregs when administered as a single SC injection to healthy volunteers.

Objectives: This multiple ascending dose study assessed the safety, tolerability, pharmacokinetics (PK), and immune effects of NKTR-358 in patients with SLE after repeated administration of SLE doses. The time course and extent of changes in numbers and percentages of Tregs, conventional CD4+ and CD8+ T cells, NK cells, and cytokine levels in peripheral blood were investigated.

Methods: In this double-blind, multiple ascending dose study, patients with mild to moderate SLE received 3 SC doses q2w in 4 cohorts ranging from 3.0 to 24.0 µg/kg (9 active:3 placebo per cohort); patients were followed for a total of 79 days.

Results: There were no dose-limiting toxicities, deaths, or clinically significant abnormalities in either vital signs or electrocardiograms. Adverse events attributed to NKTR-358 were primarily limited to mild (grade 1) injection site reactions. At the highest dose, one subject had transient and mild (grade 1) symptoms of a flu-like syndrome after administration, without associated elevated cytokine levels, and another subject had dosing stopped due to elevated eosinophil levels. No other individual at any dose level had systemic symptoms known to be associated with IL-2 therapy. No anti-drug antibodies were detected. NKTR-358 demonstrated dose-proportional PK with repeated dosing; plasma levels peaked 3-6 days post-dose and declined with a terminal half-life of ~10-13 days.

The primary and consistent effect of NKTR-358 was seen on Tregs. In the four dose cohorts, dose-dependent and sustained increases in absolute numbers and percentages of circulating CD4+FoxP3+CD25bright Tregs were observed. Treg levels remained elevated throughout the dosing period, peaking at Day 10 after the first administration of NKTR-358 and returning to baseline ~20-30 days following last administration. At 24.0 µg/kg, the mean peak increase in numbers of CD25^bright Tregs was 11-fold above baseline. In addition, there was an increase in Treg activation markers at doses ≥12.0 µg/kg. In contrast to effects on Tregs, no changes in percentages or numbers of conventional CD4+ or CD8+ T cells were observed at any dose tested. At the highest dose, there were low-level increases in the percentages and numbers of NK cells. Overall, NKTR-358 selectively induced Tregs, evidenced by a 12-fold increase in the mean peak Treg:CD8 ratio over baseline in the 24.0 µg/kg group.

Conclusion: NKTR-358, an IL-2 conjugate Treg stimulator, was well tolerated when repeatedly administered (q2w) at doses up to 24 µg/kg. Its administration led to marked, selective, prolonged, and dose-dependent increases in circulating CD25^bright Tregs. This clinical study in SLE patients extends the previous results in healthy volunteers and provides strong support for continued testing of NKTR-358 as a new therapeutic in SLE and other inflammatory diseases.

DOI: 10.1136/annrheumdis-2020-eular.3165
established safety or efficacy, leaving considerable unmet need. The Wnt pathway is upregulated in chronic tendinopathy, affecting inflammation and tenocyte differentiation. SM04755, a novel, topical, small-molecule Wnt pathway inhibitor, has previously been shown to inhibit inflammation, protect tenocytes, and increase tenocyte differentiation in nonclinical models.1

Objectives: To identify molecular targets of SM04755 and its associated mechanism of action.

Methods: Wnt pathway inhibition was measured using a cell-based luciferase reporter assay controlled by a β-catenin/TCF-responsive promoter in SW480 colon cancer cells. A kinome screen (318 kinases) and kinase assays were performed. Effects of SM04755 on phosphorylation of proteins, including serine/threonine kinases (MTOR, AKT), was assessed by MS/MS. Effects of SM04755 and siRNA knockdowns on Wnt pathway gene expression and catabolic enzymes (MMPs) were measured using qPCR. SM04755 and siRNA effects on tenocyte marker expression were assessed by qPCR and immunostaining. Effects of SM04755 on LPS-induced expression of inflammatory cytokines in PBMCs were measured by MSD-based ELISA. Statistical analyses used one-way ANOVA for multiple group comparisons and t-tests for comparison between two groups.

Results: SM04755 was a potent inhibitor (EC₅₀=156 nM) of Wnt signaling. Biochemical assays identified CLKS and DYRK1A as molecular targets of SM04755. SM04755 potently inhibited CLK-mediated phosphorylation of Wnt pathway proteins compared with DMSO controls. Knockdowns of CLKS and DYRK1A led to inhibition of Wnt pathway genes (AXIN2, LEF1, TCF4, TCF7, etc.) compared with siRNA controls (siCtrl). CLK1, 2, and 4 and DYRK1A knockdowns also induced expression of tenocyte markers in iTDSCs and inhibited IL-1β-induced expression of inflammatory cytokines in tenocytes compared with siCtrl. SM04755 treatment of LPS-stimulated PBMCs resulted in reduced phosphorylation of NF-κB and STAT3 and inhibited production of inflammatory cytokines compared with DMSO.

Conclusion: SM04755 inhibited CLKS and DYRK1A, which led to Wnt pathway modulation. Knockdowns of CLKS and DYRK1A, compared with control siRNA, induced tenocyte differentiation and reduced tendon-destructive proteases in tenocytes. This supports the potential disease-modification effects of SM04755. Furthermore, the anti-inflammatory and anti-proliferative effects of SM04755 are mechanistically supported by the decreased phosphorylation of STAT3 and NF-κB. These data support that SM04755, as a single agent, may potentially improve symptoms and provide disease modification in tendinopathy. Human tendinopathy trials are planned.

A NEO-EPITOPE FRAGMENT OF CARTILAGE DEGRADATION GENERATED FROM TYPE II COLLAGEN PROCESSING: A NOVEL SERUM BIOMARKER TO ACCESS TYPE II COLLAGEN DEGRADATION IN JOINT DEGENERATIVE DISEASES

S. S. Groen1,2, D. Sinkeviciute1,3, C. Thudium1, P. Ørnerjford4, M. Karsdal1, A. C. Bay-Jensen1, S. Holm Nielsen5,6,7, Nordic Bioscience A/S, ImmunoScience, Herlev, Denmark, 2Copenhagen University, Biomedical Sciences, Copenhagen, Denmark, 3Lund University, Clinical Sciences Lund, Lund, Sweden, 4Technical University of Denmark, Biotechnology and Biomedicine, Kgs. Lyngby, Denmark

Background: Altered extracellular matrix (ECM) remodelling is an important part of the pathology seen in joint degenerative diseases. Type II collagen is the most abundant ECM protein in the cartilage and provides the tissue with essential tensile strength in order to withstand high compressive loading. During cartilage erosion, type II collagen is cleaved by matrix metalloproteinases (MMPs) which generates new protein fragments called neo-epitopes. These fragments are released into circulation and may potentially serve as biomarkers by indicating the degree of cartilage destruction.

Objectives: The aim of this study is to develop a highly specific immunoblot assay targeting a neo-epitope fragment of type II collagen cleaved, named T2CM. Moreover, we investigated the assays potential to evaluate type II collagen degradation in an ex vivo bovine full-depth cartilage explants model (BEX) with catabolic treatment and in healthy controls and osteoarthritis (OA) patients.

Methods: A monoclonal antibody was raised in mouse against the C-terminus from protease cleavage site of type II collagen and a direct competitive ELISA was developed and technically validated. The assay specificity was evaluated for the standard peptide excluding cross-reactivity with elongated and truncated peptides, and a non-sense coating peptide. Human OA cartilage was cleaved with MMP-1,-1,-9,-13 and measured with the T2CM-assy to investigate which MMPs generated the neo-epitope. T2CM levels were measured in supernatant from BEX explants cultured for 21 days in serum free DMEM/F12 medium with six different doses of OSM+TNF-α (O+T) treatment (20/10, 20/20, 20/40, 10/10, 10/20, 10/40 ng/mL) including a control group without (w/o) treatment. The supernatant was harvested 3 times weekly and replaced with new culture medium with O+T treatment. Biomarker results were confirmed by western blot, where T2CM was measured in supernatant from explants with O+T treatment 20/20 ng/mL and 20/40 ng/mL harvested on day 14 and day 21. To confirm the preclinical data, serum samples from 23 healthy controls (age range from 44-59 years with mean 51.4 ± SD 5.1, gender distribution was 56% female and 44% male, and 100% Caucasian) and 23 OA patients (age range from 41-77 years with mean 57.7 ± SD 13.7, gender distribution was 61% female and 39% male, and 100% Caucasian) were measured by T2CM.

Results: A technically robust and T2CM-specific assay was developed. The assay linearity and spike-recovery were accepted with percentage of 99.69% and 93.15%. The assay showed no cross-reaction with the elongated, truncated or non-sense coating peptide. In addition, it was demonstrated that the T2CM neo-epitope was derived from MMP-1 and MMP-13 cleavage of type II collagen. O+T treatment induced the T2CM release in BEX compared to the untreated (Figure 1-2). Moreover, the western blot confirmed the T2CM results by the presence of two T2CM bands on day 21 from O+T treated explant compared to day 14 where no bands appeared. T2CM showed to be significantly elevated in patients with OA compared to controls (p=0.036; mean 3.262 ng/mL ± SD 1.065 vs 2.698 ng/mL ± SD 1.118).

Conclusion: The newly developed assay was specific for the T2CM neo-epitope and was determined to be generated by MMP-1 and MMP-13. Additionally, the assay detected elevated levels of T2CM in supernatant from explants treated with O+T after 19 days of treatment compared to untreated. This was further confirmed in human OA patients, where the level of T2CM was elevated compared to healthy controls. This suggest that T2CM may have potential as biomarker for type II collagen degradation. Future preclinical and clinical studies are needed to validate these findings.

DOI: 10.1136/annrheumdis-2020-eular.5642
Background: 3D (three-dimensional) cell culture technology has been researched steadily because of its high potential of biocompatibility compared to single cells since 1990s, and is being developed to 3D spheroids recently. Spheroids are considered to reflect the natural organization of cells better than 2D cell cultures, and stem cells spheroids have been studied extensively in therapeutic transplantation. Stem cells were considered as a method of replacing autologous chondrocyte in regenerative treatment of articular cartilage. Compared to conventional single cells, 3D cell culture is artificially created an environment similar to a living body in vitro so that all cells collectively, a cell culture model that allows growth or interaction with the environment. Therefore, the findings of this study indicate that enhancement of treatment efficiency of stem cells caused by potential of survival and proliferation of hASC spheroid in Osteoarthritis. In conclusion, spheroid positive subpopulation of hASCs has high cell proliferation and survival but not apoptosis and cell death potential, which may contribute to successful cartilage regeneration and the development of stem cell therapies in the future.

Objectives: Studied for 3D spheroids to investigate the mechanism of enhancement of survival and proliferation of hASCs (human adipose stem cells) spheroid, which may contribute to successful improvement of therapeutic efficacy of stem cells.

Methods: Cell isolation and culture / 3D cell culture dish preparation / hASCs culture on 3D cell culture dish / Real-time PCR analysis / Western blotting / Alcian blue staining / ACLT + MM (Anterior cruciate ligament transection with Medial meniscectomy) model / In vivo fluorescence for cell tracking / In vivo effects of spheroids / In OA joint / Histological analysis / Enzyme-linked immunosorbent assay (ELISA) results for inflamma-tory cytokines in rat synovial fluid / Statistical Analysis

Results: In order to see how the spheroid showed more residual than single, and how effective it was in actual cartilage regeneration, the result of paraffin tissues were confirmed by safranin O staining for each condition. The tendency of cartilage regeneration efficiency was good for spheroid. Although the differences between the single and spheroid groups were small, they reaffirmed that they could somewhat protect cartilage and help regeneration treatment. However, immunohistochemistry of HN (Human nucleic antigen) staining showed that cells of single and spheroid were not observed in the wound but disappeared by the paracrine effect.

Conclusion: Spheroids do not exhibit differentiation characteristics, but they could be seen as a result of expression of related genes such as Bax, Bcl-XL and Alcian blue staining. Spheroids tend to have low potential of cell death rather than proliferation and reduction in the proliferation. So, we conclude the fact that instead of hASCs going directly to the surgical site to regenerate cartilage, they can help cartilage regeneration.

KNEE JOINT DISTRACTION INDUCED SHIFT FROM CATABOLIC TO ANABOLIC STATE OCCURS AFTER DISTRACTION PERIOD

M. Teunissen1, J. Popov-Celeketic2, K. Coeleveld3, B. Meij1, F. Lateur2, M. Tryfonidou1, S. Mastbergen2,1, Utrecht University, Utrecht, Netherlands; 2UMC Utrecht, Utrecht, Netherlands

Background: Knee joint distraction (KJD) is a validated joint-preserving treatment strategy for severe osteoarthritis (OA) that provides long-term clinical and structural improvement. Human trials and animal models indicate clear cartilage regeneration from 6 months and onwards post-KJD [1]. Recent work showed that during distraction, the balance between catabolic and anabolic indicators is directed towards catabolism, as indicated by collagen type 2 markers, proteoglycan (PG) turnover and a catabolic transcription profile.

Objectives: To investigate the cartilage changes directly and 10 weeks after joint distraction in order to elucidate the shift from a catabolic to an anabolic cartilage state.

Methods: Knee OA was induced bilaterally in 8 dogs according to the groove model. After 10 weeks of OA induction, all 8 animals were treated with knee joint distraction, employing the left knee as an OA control. After 8 weeks of distraction, 4 dogs were euthanized (KJDdirect) and after 10 weeks of follow-up the 4 remaining dogs (KJD+10). Macroscopic and microscopic cartilage degeneration was assessed using the OARSI canine scoring system. RT-qPCR was used to determine relative expression of aggrecan (ACAN), collagen type II (COL2a1), cartilage oligomeric matrix protein (COMP) and matrix metalloproteinase-3 (MMP3) in the cartilage. PG content was determined by the Alcian Blue assay and the synthesis of PGs was determined using [35SO4]2- as a tracer, as published before.

Results: Macroscopic cartilage damage of the tibia plateau in the KJDdirect group was higher as compared to the OA control (OARSI score: 1.7 ± 0.2 vs 0.6 ± 0.3; p < 0.001). For KJD+10 this difference persisted (OARSI score: 1.4 ± 0.6 vs 0.6 ± 0.3; p = 0.05). Microscopically, an increase in the total OARSI score was seen after 10 weeks post-KJD. This was mainly due to an increase of chondrocyte clusters at 10 weeks of follow-up, resulting in an increased sub score chondrocyte pathology. Remarkedly the sub score intensity of proteoglycan staining decreased directly after KJD (indicating a loss of PGs) but increased at 10 weeks of follow-up suggesting a mixed response depending on the tissue scored.

Cartilage gene expression analysis showed downregulation of COL2a1 (-1.3 ± 0.3), ACAN (-4.4 ± 1.0, p < 0.01) and COMP (-1.7 ± 0.5) in the group compared to OA control suggesting enhanced catabolic activity during KJD. In contrast, after 10 weeks of follow-up, the expression of COL2a1 and COMP were increased as compared to the OA control (2.6 ± 1.1 and 2.5 ± 1.2 respectively) as well as compared to the KJD+10 situation (3.3 ± 1.4 and 4.2 ± 2.0). Expression of MMP3 was upregulated directly after KJD (4.4 ± 0.8) and downregulated at 10 weeks of follow-up (-3.3 ± 0.8).

Biochemical analysis of the tibia plateau of the KJDdirect group revealed a lower PG content compared to the OA joint (20.1 ± 10.3 mg/g vs 23.7 ± 11.7 mg/g). At 10 weeks post-KJD this difference in PG content was gone (24.8 ± 6.8 mg/g vs 25.4 ± 7.8 mg/g). The PG synthesis rate directly after KJD appeared significantly lower vs. OA (1.4 ± 0.6 nmol/h/g vs 5.9 ± 4.4 nmol/h/g; p < 0.001). 10 weeks post-KJD this difference was not detected (3.7 ± 1.2 nmol/h/g vs 2.9 ± 0.8 nmol/h/g), and the synthesis rate in the distracted knee was increased compared to directly after distraction (p < 0.01) indicating a shift upon follow-up.

Conclusion: Further in-depth investigation of the material is ongoing and also includes the other joint tissues such as the bone and the synovial tissue. Irrespective, these first results on cartilage changes suggest that the shift from a catabolic to an anabolic state occurs within the weeks after joint distraction. As such, this post-distraction period is essential to be aware of key players that support intrinsic cartilage repair.

THU0061 EVALUATION OF SAFETY AND EVOLUTION OF OSTEOARTHRITIC JOINTS AFTER THE ADMINISTRATION OF HETEROLOGOUS MESENCHYMAL STROMAL CELLS IN AN ANIMAL MODEL

P. C. Sánchez-Pedreña1, A. Vela-Anero2, N. Otero Queijás2, M. Lorenzo Toja2, A. Somaza Serantes3, T. Hermida Gómez3,4, F. J. Blanco1, 1Unidad de Medicina Regenerativa, Grupo de Investigación en Reumatología (GIR), Agrupación Estratégica CICA-INIBIC, A Coruña, Spain; 2Integral Veter Medicina Veterinaria Integrativa, A Coruña, Spain; 3Hospital Veterinario Cuatro de Octubre, A Coruña, Spain; 4CIBER-BBN, Madrid, Spain

Background: One of the main osteoarthritics (OA) consequences is the cartilage loss. Nowadays there is not cure for the OA, so there is an intense research focused on finding a therapy to solve this problem. In this paradigm heterologous mesenchymal stromal cells (MSC) rise as a solution. Different studies used them as a cellular therapy in order to regenerate damaged cartilage. Furthermore, MSC have shown anti-inflammatory effects.

Objectives: 1) Study the safety of a single intraarticular injection of MSC derived from healthy canine fat tissue (adMSC) in OA joints of dogs 2) Observe the evolution of functionality and range of articular mobility of these treated joints 6 months after the injection.

Methods: adMSC obtained (n=10) were phenotypically characterized by flow cytometry, including the Major Histo compatibility Complex type II (MHC-II). Those with the best morphology and growth (n=5) were used for the injection. The infiltrated dogs (n=7) met our inclusion/exclusion criteria. The adMSC were injected in 11 joints by 1 million of cells/kilogram of weight. Before the infiltration we evaluated the joints (basal visit, BV), the vital signs and the animal pain by the owner (Visual Analogue Scale, VAS). The same data were collected one week after the infiltration (V1) and also studied the injected zone. Six months after treatment (V2), joint functionality and range of articular mobility were evaluated, also data of behavioural changes and pain observed by the owners.

Table 1. Functionality and range of articular mobility comparison between BV and V2. Visits column show the number of joints in that state

* Statistical significance stablished at P < 0.05
Results: All cells obtained were negative for the MHC-II (0.45 ± 0.32). Vital signs did not change between BV and V1. No dog suffered by severe inflammation of the injected joint. One of them during two days had difficulty to support the load in the posterior limbs, but at the third day it performed that without difficulty. Other dog suffered mild inflammation which was solved in two days. The other animals did not show any adverse effect after the infiltration. In the V1 none of them showed any inflammation in the joint. The pain evaluation by the owners showed that all dogs have less pain or it did not increase since BV. This indicate that after the infiltration the animals did not suffer a pain increase.

Data collected in V2 showed that the joint functionality tend to improve, one of the items showing significant differences between BV and V2. The range of articular mobility did not have neither differences nor tendencies to the improvement (Table 1).

Conclusion: The administration of adMSCH did not show adverse effects, rejection, infection or complications, only a probably of a mild inflammation in the treated zone. Also, joint functionality tends to improve, so these cells seem to have, at least, an anti-inflammatory effect into the OA joint.

Acknowledgments: Special thanks to the owners of the dogs who participated in this study.

THU0062 FUNCTIONAL MR IMAGING OF HUMAN MENISCUS IS ASSOCIATED WITH HISTOLOGICAL DEGENERATION

P. Sewerin1, L. Dötsch2, D. Truhm2, D. Abrar1, S. Nebelung2, 3
1Heinrich-Heine University, Duesseldorf, Germany; 2University Hospital Aachen, Aachen, Germany

Background: In OA, there is a close association of meniscus and cartilage pathologies. Meniscus degeneration and lesioning are critical risk factors for development of early OA. Hence, this ex vivo study assessed the responses to meniscus samples (from the body region) of relevant intra-tissue adaptations that seem to be associated with histological degeneration. The perspective evaluation of meniscus functionality may be indicative of incipient or manifest load transmission failure to the adjacent cartilage layer.

Conclusion: Meniscus functionality may be visualized using serial quantitative MRI mapping techniques. T1ρ may provide an imaging biomarker of relevant intra-tissue adaptations that seem to be associated with histological degeneration. The perspective evaluation of meniscus functionality may be indicative of incipient or manifest load transmission failure to the adjacent cartilage layer.

Figure 1. Preparation of meniscus samples and details of the MRI-compatible loading device. The lateral meniscus (a1) was cut to standard size by use of a dedicated cutting block (a2) to eventually obtain lateral meniscus samples (from the body region) of standard dimensions (a3). These samples were then placed in a dedicated MRI-compatible loading device for pressure-controlled, quasi-static and torque-induced loading under simultaneous MR imaging (a4). Two parallel support beams allowed standardized positioning in the MRI scanner’s bore (a5).

Figure 2. Serial morphological images and functional maps of histologically moderately degenerative human meniscus as a function of force-controlled loading. Serial PDw (a), T1 (b), T1ρ (c), and T2 maps (d) are displayed at increasing loading intensity (i.e. Pauli classification) and biomechanical measures (i.e. Elastic Modulus) were based on standard turbospin-echo, inversion-recovery, spin-lock multi-gradient-echo, and multi-spin-echo sequences. For reference purposes, histological (i.e. Pauli classification) and biomechanical measures were obtained for each sample. Based on Pauli sum scores, samples were trichotomized as grossly intact, mildly degenerated (n=16), and moderate-to-severely degenerated (n=15).

Results: Morphologically, loading induced deformation and flattening in all samples (Fig. 2a). For T1, homogeneous loading-induced decreases in all samples were found, irrespective of degeneration (Fig 2b). For T1ρ, increases in the apical zones of intact samples were observed, and decreases in degenerated samples (Fig. 2c). For T2, changes were ambiguous and incoherent (Fig. 2d).

Differential Pharmacodynamic Effects of Abatacept and Adalimumab on the Serum Proteome of Patients with RA Using the SOMASCAN® Platform

D. Galbraith1, M. Caliskan1, O. Jabado1, S. Hu1, R. Fleischmann2, M. Weinblatt3, S. Connolly1, M. A. Maldonado1, S. Gao1, Bristol-Myers Squibb, Princeton, United States of America; 2University of Texas Southwestern Medical Center, Dallas, United States of America; 3Brigham and Women's Hospital, Boston, United States of America

Background: Abatacept (ABA) versus adalimumab (ADA) com/parison in bio-Logic-naïve RA subjects with background MTX (AMPLE) was a Phase IIb clinical trial to compare the safety, efficacy and radiographic outcomes of ABA vs ADA in patients with RA who exhibited an inadequate response to MTX and who were naïve to biologic DMARDs.1 While both therapies demonstrated similar efficacy across multiple outcomes, their mechanisms of action (MoAs) are quite different; ABA is a T-cell co-stimulation modulator and ADA is a TNFα inhibitor. Previous transcriptomic analysis of the whole blood samples showed differential pharmacodynamic (PD) effects between the treatments.1,3

Objectives: To expand our understanding of differential PD changes in the serum proteome over time in patients treated with ABA or ADA in AMPLE using a novel proteomic platform.

Methods: Serum was available from 440 patients in AMPLE at four time points (Days 1, 85, 365 and 729). Serum samples from the patients in AMPLE and 123 healthy individuals with matching demographics were subjected to proteomic quantification by a highly multiplexed DNA aptamer technology with wide dynamic ranges (SomaLogic SomaScan® platform).2 A linear model analysis was used to identify protein abundance changes over time and changes specific to treatment. Other covariates included in the model were country of origin, ethnicity and sex. Additionally, patient effect was adjusted for as a random factor.

Results: Both treatments exhibited a significant PD effect on serum proteome over the course of the 2-year trial, with 73 proteins modulated by ABA and 125 by ADA. There were large overlaps between the two treatments, including proteins associated with RA, such as C-C motif chemokine ligand 13 (CCL13), matrix metalloproteinase-3 (MMP3) and serum amyloid A1/2 (SAA1/2). Changes in the levels of these proteins may be indicative of general improvement of the disease. The proteins modulated by the treatments were enriched in the G-protein coupled receptor (GPCR) signalling and innate immune pathways. Among the proteins that exhibited significantly different PD effects between the treatments were CFP, CC chemokine ligand 17 (CCL17) and β-defensin 112 (Figure). While patients showed marked improvement in their symptoms after 2 years of treatment, the overall serum proteomic profiles of the patients were still different from those of a normal healthy population.

Conclusion: The SomaScan® platform provides a robust method for quantifying the PD change in a broad portion of the serum proteome in clinical trials. In AMPLE, abatacept was more selective than adalimumab in modulating protein biomarkers in patients with RA, though there was large overlap in proteins modulated by both treatments. The treatment-specific changes may reflect the different MoAs leading to similar clinical outcomes. While patients in both groups benefited from treatments, their serum proteome remained notably different from that of a healthy population. Further analysis by responder status may provide additional links between the treatment responses and proteomic changes. Proteomic approaches as described in our study could contribute to clinical trials and help shape treatment strategies for patients with RA.

Antibody-Response Maturation in the Phase of Clinically Suspect Arthritis and Its Relation with Progression to Rheumatoid Arthritis

F. Wouters1, E. Niemantsverdriet1, N. Salioska1, A. L. Dorjee1, R. Toes1, A. Van der Helm - van Mil2,3,1. Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; 2Erasmus Medical Center, Department of Rheumatology, Rotterdam, Netherlands

Background: Auto-antibodies in rheumatoid arthritis (RA) are often present years before disease onset but their mere presence does not seem enough to induce RA. Because several nested-case control studies have shown that autoantibody-response maturation precedes disease onset, it is suggested that it plays a role in disease triggering. At present, it is undetermined whether autoan- tibody-response maturation occurs in the symptomatic phase preceding clinical arthritis (i.e. Clinically Suspect Arthritis, CSA), or whether it occurs even earlier in the asymptomatic phase. Secondly, if autoantibody-response maturation is a final step towards clinical disease development, maturation is expected to be present in the patients that progress from CSA to RA, but not in CSA-patients that do not progress.

Objectives: To better understand the timeframe of autoantibody-response maturation and its relation to development of RA, we investigated autoantibody-resp onse maturation in patients with CSA that did and did not progress to clinically apparent inflammatory arthritis (IA).

Methods: In serum from 148 CSA-patients, we determined the presence and levels of three autoantibodies (ACPAs, anti-CarP and AAPA), with three isotypes each (IgM, IgG, IgA), resulting in 9 autoantibody measurements per patient per time-point. Measurements were performed on sera obtained at first pres- entation at the outpatient clinic and when patients developed IA or else after two years. In-house ELISA was used for all measurements. Three analyses were performed, in patients that progressed to IA (n=56) and in patients that did not progress (n=92) separately. First, in patients negative for all measurements at baseline, we determined the frequency of conversion to seropositivity. Second, in patients with at least one positive test at baseline, we studied the frequency of autoantibody positivity over time. Finally, we determined the change in autoantibody levels in patients positive for the respective autoanti- bodies at baseline. Frequencies and medians were reported. Statistical signif- icance was tested with Fisher’s Exact test and GEE, taking into account that measurements within one autoantibody type (ACPAs, anti-CarP and AAPA) can be correlated.

Results: First we studied patients negative for all antibodies at baseline (54% of patients that progressed to IA and 76% of patients that did not progress), 17% of patients that progressed to IA became positive over time, compared to 6% of the patients that did not develop IA (p=0.12). Then we studied patients in whom at least one autoantibody was present at baseline and evaluated autoantibody-positivity over time. In patients that progressed to IA, the number

Conclusion: Oxylipin networks differ across disease stages during the very early phase of RA, and can inform on specific signatures related to the disease progression. Oxylinps can delineate profiles with clinical relevance and are able to predict treatment response.

Figure:
Conclusion: Serum LBP highly associated with RA activity and markers, which suggests bacterial LPS as roles in triggering and perpetuating disease activity in RA. In contrast, IgG anti-Pg-LPS, IgA anti-Pg-LPS antibody reflecting infection of Pg, negatively associated with intestinal total bacteria ($r = -0.4405, \ p < 0.0001$), RA disease activities, respectively. These results may show a possible oral - gut relationship resulting in aggravation of disease activity in RA.

THU0067
JAK SELECTIVITY AND THE IMPACT ON CYTOKINE SIGNALLING INHIBITION AT CLINICAL RHEUMATOID ARTHRITIS DOSES
P. Gonzalez-Traves1, B. Murray1, F. Campigotto2, A. Meng3, J. A. Di Paolo1.
1Gilead Sciences, Inc., Foster City, United States of America

Background: Janus kinase 1 (JAK1) inhibitors are efficacious in rheumatoid arthritis (RA). Despite having similar efficacy, in vitro studies have shown differences in JAK selectivity profiles for the small-molecule JAK inhibitors (JAKi) baricitinib (BARI), tofacitinib (TOFA), and upadacitinib (UPA).1 For example, BARI and UPA in JAK selectivity profiles for the small-molecule JAK inhibitors (JAKi) baricitinib (BCTB) had stronger inhibitory activity against JAK1/2/TYK2-dependent cytokine, interferon alpha (IFNα), and the JAK1/2-dependent cytokine, interleukin (IL)-6. FIL and MET had weaker potencies against JAK2/TYK2 (G-CSF/pSTAT3), JAK1/2 (IFNα/pSTAT1), and JAK2/2 (granulocyte-macrophage colony-stimulating factor [GM-CSF]) dependent pathways compared to JAK1/TYK2 (IFNα/pSTAT5). FIL and MET showed the greatest selectivity vs the JAK2/2 pathway (GM-CSF/ pSTAT3) in monocytes.

Results: Cellular assays in PBMCs and WB showed dose-dependent inhibition of cytokine-induced pSTATs with all JAKi (correlation between the protein-adjusted IC50 values from PBMCs and IC50 values from WB, $r^2=0.98$). Among the most potently inhibited pathways were JAK1/TYK2-dependent cytokine, interferon alpha (IFNα), and the JAK1/2-dependent cytokine, interleukin (IL)-6. FIL and MET had weaker potencies against JAK2/TYK2 (G-CSF/pSTAT3), JAK1/2 (IFNα/pSTAT1), and JAK2/2 (granulocyte-macrophage colony-stimulating factor [GM-CSF]) dependent pathways compared to JAK1/TYK2 (IFNα/pSTAT5). FIL and MET showed the greatest selectivity vs the JAK2/2 pathway (GM-CSF/ pSTAT3) in monocytes.

The mean concentration–time profiles and time above IC50 over 24 hr for each cytokine/STAT pathway showed that JAK1/2 (IL-6/pSTAT1) and JAK1/TYK2 (IFNα/pSTAT1) pathways were strongly modulated with all tested JAKi. FIL (200 mg) showed similar activity in average target coverage and time above IC50 to the approved low doses of TOFA (5 mg) and UPA (15 mg); conversely, FIL had reduced mean average inhibition and time above IC50 levels against JAK1/2 (IFNα/pSTAT1), JAK1/3-dependent cytokines (IL-2, -4, and -15), JAK2/2 (G-CSF/pSTAT3), and JAK2/2 (GM-CSF/pSTAT5)-dependent pathways compared to TOFA and UPA, and in certain cases to BAR (2 mg).

Conclusion: Different JAKi modulate distinct cytokine pathways to varying degrees, and no agent potently and continuously inhibited an individual cytokine signaling pathway throughout the dosing interval. FIL (200 mg) showed a similar inhibition profile to TOFA, BARI, and UPA against the JAK1/TYK2 (IFNα/pSTAT1) or JAK1/2/dependent (IL-6/pSTAT1) responses, consistent with the role of these pathways in clinical efficacy.2 However, FIL displayed a differentiated pharmacologic profile from the other JAKi, showing biologically reduced activity on the JAK1/2 (IFNα), JAK1/3 ( IL-2, -4 and -15), JAK2/2 (G-CSF), and JAK2/2 (GM-CSF)-dependent pathways, which play important roles in hematopoiesis and immune function. These data suggest that FIL (200 mg) may have less impact on a subset of homeostatic immune functions signaling via JAK2 and JAK3 than those observed at the clinically approved doses of TOFA (5 mg and 10 mg), UPA (15 mg), and BAR (4 mg).

References:
therefore, we aimed to develop a valid human in vitro 3D joint model mimicking features of joint inflammation by applying inflammatory conditions namely immune cells and pro-inflammatory cytokines. Our in vitro 3D joint model consists of different components including an osteogenic and chondrogenic component, the joint space filled with synovial fluid, and the synovial membrane. Developed as an alternative experimental setup to animal experiments, our 3D joint model will enable us to study efficiently the effects of potential drug candidates in a human-based in vitro model.

Objectives: Here, we aimed to demonstrate the suitability of our human-based in vitro 3D osteochondral model by analyzing the influence of the main cytokines involved in the pathogenesis of RA as well as the impact of a specific therapeutic intervention.

Methods: Based on human bone marrow-derived mesenchymal stromal cells (hMSCs), we developed 3D bone and cartilage tissue components that were characterized in detail (e.g. cell vitality, morphology, structural integrity) using histological, biochemical and molecular biological methods as well as pCT and scanning electron microscope (SEM). In brief, to establish the osteogenic component, we populated β-tricalcium phosphate (TCP) – mimicking the mineral bone part – with hMSCs, while the scaffold-free cartilage component was generated by cellular self-assembly and intermittent mechanical stimulation (fzmb GmbH). Subsequently, we co-cultivated both tissue components for three weeks to generate an interconnected 3D osteochondral model. To test the suitability, we applied a cocktail of TNFα, IL-6 and MIF using concentrations reported from RA synovial fluid alone or in combination with specific therapeutic drugs and analyzed their impact by qPCR.

Results: We verified the osteogenic phenotype of our 3D bone tissue component by demonstrating an increase in mineralized bone volume and the induction of bone-related gene expression (RUNX2, SPP1 and COL1A1) as compared to the corresponding control. Secondly, we verified the chondrogenic phenotype of our cartilage tissue component by HE and Alcian Blue staining as well as by the reduced expression of COL1A1 and an abundant expression of COL2A1. Interestingly, co-cultivation of both components for up to 3 weeks demonstrated colonization, connectivity and initial calcification implying a transitional bridging area. Cytokine stimulation with a cocktail of TNFα, IL-6 and MIF leads to an upregulation of the metabolic marker LDHA and the angiogenic marker VEGF in both bone and cartilage. The inflammation markers IL8 and TNFα are also upregulated in both components, while IL6 is downregulated in bone compared to the unstimulated control. In addition, a cytokine-induced upregulation of matrix-metalloproteases was observed especially in the cartilage component. All these cytokine-related effects could be antagonized with a cocktail of therapeutics (milatuzumab, adalimumab and tocilizumab).

Conclusion: The results of our study showed cytokine related effects of both tissue components, which can be therapeutically antagonized. By combining the components in a 96 well format, we aim to provide a mid-throughput system for preclinical drug testing.

THU0070 DEFINING SYNOVIAL SIGNATURES IN THE RAT CIA MODEL: WHAT CAN WE LEARN ABOUT RA PROGRESSION?

D. Ruelas1, R. Li1, C. Franci1, V. Lira1, D. Lopez1, L. Li2, G. Min-Oo1, J. A. Di Paolo1, 1Foster City, Foster City, United States of America

Background: Patients showing inadequate or no response to current therapies represent a key unmet need in rheumatoid arthritis (RA). To address this, novel or combination therapies are of high clinical interest. Identification of novel therapeutic targets requires a greater understanding of the pathogenic molecular drivers in the RA synovium. However, our current knowledge of human molecular patterns that emerge as a result of disease progression is complicated by patient-to-patient heterogeneity and access to synovial tissue.

Objectives: Here we use the current knowledge of human synovial heterogeneity to conduct a longitudinal study of global molecular responses in the rat collagen-induced arthritis (CIA) model to better understand synovial biology, improve the preclinical modeling of human disease, and discover novel targets for RA.

Methods: A rat CIA model was performed as previously described.1 RNA-Seq was performed on 56 knee synovial tissues collected at multiple time points throughout the course of disease. Differential gene expression was determined at each individual time point and longitudinally with disease progression. Published human synovial datasets were used to categorize these genes into myeloid, lymphoid, fibroblast, and low inflammatory signatures.2 Differentially expressed genes (DEGs) at each time point were compared to human synovial datasets of RA patients before and after treatment. In addition, we compared disease-driven genes in CIA to genes in RA patients that are unchanged following therapy to identify possible combination therapies.

Results: Disease pathology in the rat CIA nature history study progressed as follows: significant decreases were seen in body weight, as well as increases in ankle diameter, paw weight, and histopathology scores of joints in collagen-injected vs noninjected rats. There were 1900 DEGs identified between diseased and naïve rats over the course of disease, representing disease-induced gene signatures (Fig. 1). Comparing these DEGs to reported human RA synovial signatures, both the lymphoid and myeloid signatures were found to be highly upregulated. Interestingly, there were no significant DEGs representing the human fibroblast and low inflammatory synovial signatures identified in the CIA rat model. This suggests that the rat CIA model most closely models RA patients with an immune synovial phenotype. In addition, we examined the overlap between disease-driven genes in CIA and genes in RA patients that are unchanged following therapy to identify signaling pathways that may be of utility in combination therapy. Of genes that were upregulated in CIA, 94% of genes that mapped to extracellular matrix-receptor pathways remained unchanged in the synovial tissue of RA patients following tocilizumab treatment.

Conclusion: Previous studies have shown that nearly 30% of treatment-naïve early RA patients exhibit a strong fibroblast phenotype that correlates with less severe disease and a relatively poor response to disease-modifying anti-rheumatic drugs.3 These data indicate that the synovial biology associated with such patients (fibroblast or pauci-immune) is not well captured in CIA, the most common preclinical RA model. To assess potential new therapies targeting these patients, it will be necessary to develop alternative animal models with more intact fibroblast signatures. In addition to these findings, we also characterized the global molecular changes that occur with disease progression in the CIA rat and made a comparison to RA patients on treatment, providing an overall understanding of
CD5L in Rheumatoid Arthritis: Protective or Promoter?

D. Bicho1, E. Comma2, L. Oliveira3, R. F. Santos2, A. Moreira2, M. Mallo2, M. I. Bokarewa4, A. M. Carmo5 on behalf of Cell Activation and Gene Expression.

Background: Rheumatoid Arthritis (RA) is an aggressive auto-immune disease characterized by synovial hyperplasia and chronic inflammation. The main players of RA pathogenesis are T-cell and B-cell dependent pathways and some myeloid cells are also abundant in the synovial tissue. However, how inflammation is initiated, propagated and maintained remains controversial. Unbiased proteome reports revealed an enrichment in the scavenger receptor CD5L, a component of serum and synovial tissues of arthritic patients. Upon secretion, this blood circulating glycopolypeptide represses pathogenic Th17 cells, promotes M2 polarization and binds and aggregates Gram-negative and -positive bacteria.2-4 However, its mechanisms of action has not been established either in health or disease.

Objectives: We intend to clarify whether CD5L is an immune component that helps resolving RA or a factor that aggravates the disease.

Methods: We analyzed by ELISA the presence of CD5L in samples from RA patients covering different stages of the disease, and correlated with other markers of RA. In parallel, we experimentally induced collagen induced arthritis (CIA) in CD5L knockout (KO) mice to evaluate the incidence and severity of the disease. The differences between the cellular groups in circulation vs the composition on secondary lymph organs using flow cytometry were also investigated in KO mice. WT animals with RA also showed higher levels of CD5L when compared with the control group, which confirms the observations obtained for human samples. Total serum IgG levels did not correlate with the disease severity but KO mice presented higher quantities of IgG and IL-6 when compared with WT mice.

Conclusion: Overall, these data imply that CD5L is not a promoter of the disease but rather a fundamental protective molecule against inflammation.

THU0071 THE RELATIONSHIP BETWEEN INFLAMMATION AND COGNITIVE IMPAIRMENT IN RHEUMATOID ARTHRITIS

Y. H. Cheon1, H. N. Lee2, M. Kim3, P. Gyeongsa National University Hospital, Jin-Ju, Korea, Rep. of (South Korea)

Background: The pathophysiology of cognitive impairment remains unclear, however, several studies have demonstrated that pro-inflammatory cytokines such as Interleukin-6 (IL-6), Tumor necrosis factor-α (TNF-α) and lipocalin-2 (LCN2) are related with cognitive impairment by activation of microglia and astrocyte in brain. Rheumatoid arthritis (RA) is a representative inflammatory disease; however, the association of pro-inflammatory cytokines and LCN2 with cognitive impairment has seldomly been investigated in RA.

Objectives: Here, we determined the effect of pro-inflammatory cytokines and LCN2 on cognitive impairment in collagen-induced arthritis (CIA) mouse model. In addition, we studied the effect of TNF-α inhibitor (etanercept) on cognitive impairment.

Results: The samples from RA patients showed increased CD5L levels compared with the control group, which confirms the observations obtained for human samples. Total serum IgG levels did not correlate with the disease severity but KO mice presented higher quantities of IgG and IL-6 when compared with WT mice.

Conclusion: Overall, these data imply that CD5L is not a promoter of the disease but rather a fundamental protective molecule against inflammation.

Figure 1. Comparison of learning and memory abilities in CIA mice.

For the Morris water maze, the learning phase was conducted four times per day over 5 days. (A) Escape latency to reach the platform during the training session (days 1–4), (B) escape latency to reach the platform, (C) time spent in the target zone, (D) number of the target zone crossing and (E) tracking figures in the final trial of the last training day was also shown. Normal, Healthy group, CIA, collagen-induced arthritis group, CIA/Etanercept, collagen-induced arthritis and etanercept treatment group. Values are the means ± SEM (n = 10 mice per group). * p < 0.05; ** p < 0.01; *** p < 0.001 and ns not significant.
Methods: We induced CIA mice and randomly divided into three groups: Normal (n=10), CIA group (n=10), CIA/Etanercept group (n=10). We evaluated severity of arthritis using clinical scoring system. Joint inflammation, cartilage damage, and osteoclast bone resorption has checked. Level of pro-inflammatory cytokines (TNF-α, IL-6, IL-1β) and LCN2 checked in sera, ankle tissue and hippocampal tissue. In CIA mice, the expression level of GFAP, Iba-1 and LCN2 in hippocampus analyzed using immunohistochemistry (IHC). The LCN2 and GFAP expression level were checked in CIA and CIA/Etanercept group using enzyme-linked immunosorbent assay (ELISA). The expression of pro-inflammatory cytokines and LCN2 in ankle and hippocampus assessed using real-time PCR. The activation of glial fibrillary acidic protein (GFAP) and ionized calcium-binding adapter molecule 1 (Iba-1) in hippocampus used immunohistochemistry (IHC). The LCN2 evaluated by western blot using hippocampal tissue. Cognitive impairment determined by morns water maze (MWM) test.

Results: Compared to normal group, CIA mice showed increased severity of arthritis, inflammation and destruction of joint. In MWM test, CIA mice significantly exhibited increased escape latencies and escape time, reduced the time in the target quadrant, and the number of target zone crossings during five study days compared with normal group. The level of pro-inflammatory cytokines (TNF-α, IL-6) and LCN2 in both sera, ankle tissue and hip-no-campal tissue was significantly increased. We examined whether inhibiting inflammation can mitigate the severity of arthritis and cognitive impairment. Compared to CIA mice, CIA/Etanercept group showed decreased severity of arthritis and joint inflammation. In MWM test, CIA/Etanercept group showed reduced escape latencies and escape time, increased the time in the target quadrant and the number of target zone crossings. The level of pro-inflammatory cytokines and LCN2 significantly decreased in both peripheral tissue and hippocampal tissue. In addition, the expression level of GFAP, Iba-1 and inflammatory markers decreased after treatment of etanercept. The results indicated that inhibition of inflammation may improve cognitive impairment.

Conclusion: The results suggest that peripheral arthritis induced inflammation is a possible cause for cognitive impairment by increasing pro-inflammatory cytokines and LCN2 in both peripheral tissue and hippocampal tissue in RA. In addition, we indicate that early anti-inflammatory treatment using etanercept may mitigate or inhibit the progression of cognitive impairment in RA.

DOI: 10.1136/annrheumdis-2020-eular.3985
Background: Cystatins are cysteine proteases-inhibitors secreted by Fasciola hepatica in order to modulate the host immune response to promote survival of the parasite. These molecules are able to inhibit different mammal cathepsins, to regulate the immune balance via Th2 and T regulatory responses, to downregulate antigen presentation and the release of pro-inflammatory cytokines (1,2), mechanisms that are important in the development and maintenance of several immunopathologies, as rheumatoid arthritis (RA) (3).

Objectives: To evaluate the therapeutic effect of recombinants cystatin 1 and cystatin 3 from Fasciola hepatica in a mice model of collagen-induced arthritis (CIA).

Methods: Twenty-seven DBA/1J mice were induced with CIA by an injection of collagen type-II and Freund’s adjuvant at days 0 and 18. Animals were randomly divided into three groups: vehicle (n=9, treated with phosphate-buffered saline), cystatin 1 (n=9, treated with 100 µg/dose of recombinant cystatin 1) and cystatin 3 (n=9, treated with 100 µg/dose of recombinant cystatin 3). Treatment started after day 18 by intraperitoneal injection once a day until the end of the experiment, at day 45 after CIA induction. Clinical arthritis score, nociception, paw edema, body and spleen weight were evaluated. Lymphocytes were isolated from lymph nodes and CD4+CD25+Foxp3+ T regulatory subset was assessed by flow cytometry. Data are expressed as mean ± SEM and were evaluated by one-way or two-way ANOVA followed by Bonferroni post-test.

Results: Treatment with cystatin 1 did not alter any of the analyzed parameters. On the other hand, cystatin 3 was able to reduce clinical arthritis score from day 38 with 32% of reduction at day 45 (9.2±2.2 vs. 13.6±5.6). In addition, treatment with cystatin 3 diminished nociception (cystatin 3: 4.0±0.36g, vehicle: 2.7±0.32g) (p<0.05) and paw edema (cystatin 3: 13.56±0.73) (p<0.05). In addition, treatment with cystatin 3 diminished nociception and paw edema. Moreover, the treatment did not alter body weight loss or spleen weight alteration. These results suggest that recombinant cystatin 3 from Fasciola hepatica has the potential as a treatment for inflammatory and autoimmune diseases such as RA.

Results: Blockade of SHH by GDC-0449 significantly alleviated the symptoms and decreased the synovial hyperplasia, inflammatory infiltration, cartilage and bone damage in ankles of CIA. The bone erosions in the area of the metatarsal-phalangeal joints and ankle joints and production of TNFα, IL-6 were decreased by SHH inhibition. In addition, the administration of GDC-0449 significantly decreased the number of TRAP positive cells and the expression of NFATc1. On the contrary, SHH overexpression led to increased severity of arthritis and pathological changes. We also observed the accelerated bone injury accompanied with increased number and activity of osteoclasts and increased production of serum IL-6 in mice with upregulation of SHH expression. Of note, the administration of p38 MAPK inhibitor reversed the effects of SHH overexpression, with a reduction of joint swelling and histological scores. Inhibition of p38 MAPK prevented the bone erosion and decreased the number of TRAP positive cells and the expression of NFATc1, which were promoted by SHH overexpression.

Conclusions: The study indicates that SHH promotes the synovial hyperplasia and bone erosion of CIA in a p38 MAPK-dependent manner. SHH-p38 MAPK signaling could be a potential target for the treatment of RA.

CADHERINS GUIDE THE DIRECTIONAL MIGRATION OF THE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS

J. H. Kang1, S. Ahamed1, K. H. Sa1, S. W. Han1, Y. M. Kang1, Kyungpook National University School of Medicine, Daegu, Korea, Rep. of (South Korea)

Background: Aggressiveness of synoviocytes and collective migration of organized synovial tissues play a key role in the pathogenesis of panarthritis into adjacent joint structure. Interactions among synovial cells for grouped movement, however, have not been properly elucidated.

Objectives: We hypothesized that cadherins which have functions on the synovial invasion in RA, may play a critical role in collective migration of rheumatoid synoviocytes.

Methods: Cadherins expression patterns on the synoviocytes isolated from patients with RA were evaluated using RT-PCR, flow cytometry, and western blot analysis. Mesenchymal and epithelial phenotypes were examined in cadherin overexpressing cell line by flow cytometry. L-cells with overexpression of CDH2 (CDH2hi), CDH11 (CDH11hi), and combination of CDH2/CDH11 (CDH2/CDH11hi) were prepared. Migration of cells was observed by taking time-lapse images with laser confocal microscope. In vitro collective migration and directional movement in response to inflammatory mediators and different matrix rigidity were evaluated. In vivo homing of CDH2hi/CDH11hi-L-cells into joint tissues was performed in collagen induced arthritis (CIA) mouse. In vivo and ex vivo migration pattern of CDH11hi-L-cells were investigated in nude mice using optical imaging system.

Results: In rheumatoid synovial tissues, CDH2 and CDH11 were highly expressed compared to synovial tissues from osteoarthritis. CDH2 and CDH11 were also highly expressed on synovial fibroblasts isolated from RA. Pheno-type analysis of mesenchymal and epithelial cells in CDH11hi-L-cells and CDH2hi/CDH11hi-L-cells showed increased expression of eGFP, CD44, vimentin, and α-SMA compared with MOCK-L-cells. We then analyzed the pattern of migration of MOCK, CDH2hi, CDH11hi, and CDH2hi/CDH11hi-L-cells using time lapse images. During migration over a hard ECM, CDH2hi and CDH11hi-L cells represented higher aspect ratio compared to a soft ECM. Aspect ratio relatively found lower in CDH2hi/CDH11hi-L-cell lines than MOCK cells. CDH2hi/CDH11hi-L-cells showed significantly higher migration velocity and Euclidean distance with narrower angle of migratory directions in a cytokine mediated migration. Compared to the MOCK cells, persistence ratio and aspect ratio of migration were also higher in CDH2hi, CDH11hi, and CDH2hi/CDH11hi-L-cells. CDH2hi/CDH11hi-L-cells collectively migrated with the formation of leader and follower cells. In a chemokine mediated hard stiffness of ECM, durotaxis was observed in CDH11hi-L-cells. After 24 hours of intraarticular knee injection in CIA mouse, higher number of CDH2hi/CDH11hi-L-cells invaded into the cartilage than MOCK cells. In vivo migration of CDH2hi/CDH11hi-L-cells was also found towards the chemokine and cartilage mixed matrigel plug in the subcutaneous space of the mouse.

Conclusion: The expression of CDH2 and CDH11 promotes directional migration of synoviocytes, indicating the potential role of these cadherins on the pan-nus tissues in the invasion into adjacent joint structure in RA.

EXPRESSION PROFILE ANALYSIS OF LONG NONCODING RNAS INDUCED BY IL-1ßS IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES

J. M. Kim1, H. J. Kang2, S. J. Jung3, B. W. Song1, H. J. Jeong1, C. N. Son1, S. H. Kim1, K. Hur1, Keimyung University Dongsan Medical Center, Keimyung University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Daegu, Korea, Rep. of (South Korea); 2Graduate School, Keimyung University, Department of Internal Medicine, Daegu, Korea, Rep. of (South Korea); 3Keimyung University School of Medicine, Department of Anatomy, Daegu, Korea, Rep. of (South Korea); 4School of Medicine Keimyung National University, Department of Biochemistry and Cell Biology, Cell and Matrix Research Institute, Daegu, Korea, Rep. of (South Korea)

Background: Long noncoding RNAs (lncRNAs) have recently emerged as important epigenetic regulators of gene expression and are reported in various diseases including cancer, cardiovascular disease, and diabetes mellitus. However, the role of IncRNAs in the pathogenesis of rheumatoid arthritis (RA) remains unknown.

Objectives: Thus, we studied IncRNAs influenced by IL-1, which is one of the key mediators in the pathogenesis of RA, and also investigated whether regulation of NF-κB activation, which is known to be induced by IL-1, could lead to the changes of expression of those IncRNAs.

Methods: Fibroblast-like synoviocytes (FLS) were obtained from the knee joints of the patients with RA. The next-generation sequencing (NGS) data were analyzed to identify differentially expressed IncRNAs between unstimulated RA FLS and IL-1-stimulated RA FLS. The expression levels of the top 5 candidates in NGS data were validated by RT-qPCR using extended number of unstimulated RA FLS and IL-1-stimulated RA FLS. IMD-0560, an inhibitor of IκB kinase (IKK) was used for the regulation of NF-κB activation. Activation and inhibition of NF-κB were confirmed by Western blotting. Changed expressions of the IncRNAs were identified by RT-qPCR.

Results: NGS analysis revealed up-regulated 30 IncRNAs and down-regulated 15 IncRNAs in IL-1-treated RA FLS compared with unstimulated RA FLS. Top 5 IncRNAs were selected among 30 IncRNAs up-regulated by IL-1 in RA FLS based on fold-change with P-value cutoff. The up-regulated IncRNAs including NR_046035, NR_027783, NR_033422, NR_003133, and NR_049759 were validated by RT-qPCR. IMD-0560 inhibited phosphorylation of IκB induced by IL-1 in RA FLS. Overexpression of IncRNAs induced by IL-1 was also inhibited by IMD-0560 in RA FLS.

Conclusion: Our study revealed that IL-1 increased the expression of NR_046035, NR_027783, NR_033422, NR_003133, and NR_049759 in RA FLS. In addition, the expression of these IncRNAs was regulated by inhibition of NF-κB activation. Thus, our data suggest that the IncRNAs might be involved in the pathogenesis of RA through NF-κB signaling pathway.

THE MICROBIOME OF NEW-ONSET RHEUMATOID ARTHRITIS (NORA) PATIENTS DRIVES TLR4-DEPENDENT TH17 RESPONSES

M. Koendries1, H. Evans-Marin2, J. Aarts1, P. Girija1, R. Rogier1, S. Korolav1, J. Manasson2, P. Van der Kraan1, S. Abdollahi-Roodsaz1,2, J. Scher1

Background: Intestinal microbiota plays a prominent role in shaping the T cell immune response. Increasing evidence suggests that the gut microbiota is perturbed in patients with RA, and a variety of animal models demonstrated involvement of (mouse) microbiota in arthritis development. This underlines the necessity of understanding whether and how indigenous human NORA-associated microbiota may trigger RA.
Objectives: To comprehensively investigate the intestinal mucocytic cytokine production and DC, T and B cell responses to human gut microbiota associated with new onset RA.

Methods: We utilized in vitro cultures of mucosal-like DCs (differentiated from bone marrow cells) and primary splenic DCs, as well as ex vivo cultures of healthy human intestinal biopsies, cultured in the presence of heat-killed fecal microbiota from either NORA or control donors. Furthermore, we performed studies in humanized mice carrying intestinal NORA microbiota, to study the effect on immune response during homeostasis and upon joint inflammation during collagen-induced arthritis (CIA) in mice (RA).

Results: In 24h DC cultures, NORA fecal microbiota more potently induced the expression of co-stimulatory molecules CD40 and CD80, and increased IL-6 secretion by the NORA microbiome. Furthermore, in ex vivo cultures of human ileum biopsies, the production of IL-1 and IL-33, as well as IL-23/Th17 cytokines IL-23, IL-22, and GM-CSF, were significantly increased by NORA-derived microbiome. Interestingly, in the smallest intestine lamina propria (SILP) of NORA-colonized mice, we observed enhanced Th17 polarization, increased innate GM-CSF expression and higher B cell CD40 and IgA levels during homeostasis. To study whether colonization with HC and NORA microbiota alters arthritis development, humanized mice and controls (mock, autologous, HC and NORA microbiota) were used in a CIA experiment. Macroscopic scoring of the arthritis severity at weekly intervals demonstrated that arthritis severity was significantly enhanced in NORA-colonized mice compared to HC-colonization and mock controls.

Conclusion: Our data reveal that NORA microbiota, in addition to the previously described Th17 differentiation, induce higher levels of GM-CSF and B cell IgA in LP and have increased potential to aggravate arthritis through the activation of TLR4.

THU0080 PRECLINICAL CHARACTERIZATION OF TLL018, A NOVEL, HIGHLY POTENT AND SELECTIVE JAK1/TKY2 INHIBITOR FOR TREATING AUTOIMMUNE DISEASES

X. Liu1, F. Tan1, C. Liang1. TLL Pharmaceutical LLC, Ixilin, United States of America

Background: Janus kinases (JAKs) are important regulators of intracellular responses triggered by many key proinflammatory cytokines and are clinically validated therapeutic targets for treating various autoimmune diseases. However, current approved JAK inhibitors failed to achieve maximal clinical benefit in part due to their unfavorable selectivity for individual JAKs such as JAK2 and/or JAK3, leading to dose-limiting toxicities or severe toxicities (e.g., thrombosis, anemia, immune suppression). Selective inhibition of JAK1 and/or TYK2 may minimize or avoid some of the toxicities and potentially offer a better therapeutic window for treating autoimmune diseases. No highly selective JAK1/TYK2 inhibitor has been reported to date.

Objectives: Discovery of a highly selective JAK1/TYK2 inhibitor that maximally avoids JAK2 and JAK3 inhibition. We described preclinical characterization of a novel, highly potent and selective JAK1/TYK2 inhibitor TLL018, and its potential utility in treating autoimmune diseases such as rheumatoid arthritis (RA).

Methods: Using predicting SAR, TLL018 was designed to achieve exquisite selectivity for both JAK1 and TYK2 while sparing JAK2, JAK3 and other human kinases. Its enzyme and cell activity, kinase selectivity, and in vivo efficacy were validated in a battery of relevant enzyme, cell and whole blood assays, and in vivo autoimmunity animal models. Additional preclinical DMPK and toxicology studies were conducted to support its clinical development.

Results: TLL018 is a highly potent and selective, orally bioavailable JAK1/TYK2 inhibitor against JAK1 (IC50 = 4 nM) and TYK2 (IC50 = 5 nM) as measured in in vitro kinase assays with ATP concentrations at individual Km. Its potency against JAK2 or JAK3 is greater than 1 µM. Profiling against a panel of over 350 human kinase showed that TLL018 is exclusively selective for JAK1 and TYK2, with ≥ 90-fold selectivity against all other kinases tested. TLL018 exhibited potent cellular activity for JAK1-mediated IL-6 signaling (IC50 = 0.6 µM) with greater than 100-fold selectivity against JAK2-mediated cytokine (e.g., TPO) signaling in human whole-blood-based assays. Oral administration of TLL018 demonstrated dose-dependent efficacy in commonly studied rat adjuvant-induced arthritis (rAIA) model and mouse collagen-induced arthritis (mCIA) model. Significant inhibition of inflammation, bone resorption, synovial polyenymal and body weight change was observed in adjuvant-induced disease in rats. In addition, significant inhibition of inflammation, cartilage destruction, bone resorption and histological signs was demonstrated in colla-gen-induced arthritis in mice. Noticeably, TLL018 exhibited significant anti-inflammation activity at doses that only blocked JAK1 and TYK2 and exerted little inhibition of JAK2 and JAK3.

In support of clinical development of TLL018, preclinical ADME and PK studies and IND-enabling toxicology and safety pharmacology studies were completed, confirming that TLL018 possesses excellent ADME and PK properties, and exhibits a clean-on-target safety profile.

Conclusion: TLL018 is a highly potent and selective JAK1/TYK2 inhibitor that demonstrated excellent efficacy and tolerability in relevant mouse and rat arthritis models. The collective data of its preclinical pharmacology, PK and toxicology showed a favorable pharmaceutical profile, further supporting its development for treating autoimmune diseases including RA. Clinical evaluation of TLL018 is ongoing.

THU0081 MIR-17-5P REDUCES INFLAMMATION AND BONE EROSIONS IN COLLAGEN INDUCED ARTHRITIS MICE AND DIRECTLY TARGETS THE JAK-STAT PATHWAY IN RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES

A. Naim1,2, F. M. Masson1, P. Preuss1,3, S. Georgies1, B. Ory1, T. Guillard1, D. Veale3, U. Fearon4, B. Le Golf1,2, F. Blanchard1. 1Nantes Faculty of Medicine, PHY-OS Laboratory INSERM UMR 1238, Nantes, France; 2Nantes University Hospital, Department of Rheumatology, Nantes, France; 3The Centre for Arthritis and Rheumatic Diseases, St. Vincent’s University Hospital, Department of Rheumatology, Dublin, Ireland; 4Trinity Biomedical Sciences Institute, Trinity College Dublin, Molecular Rheumatology, Dublin, Ireland

Background: micro-RNAs (miR) are strong regulators of gene expression. Their involvement in RA key cytokines pathway regulation entities them as important players in RA pathophysiology. The miR-17-82 cluster has been widely studied in cancer as they regulate cell apoptosis.

Objectives: The aims of this study were to screen miR-17-92 cluster’s expression in different RA phenotypes (erosive and non erosive), further elucidate the mechanisms and direct targets involved in miR-17-5p anti-inflammatory role and to investigate miR-17-5p therapeutic effect in arthritis.

Methods: A miR array was performed in synovial tissue from naïve erosive and non-erosive RA patients. Intra-articular delivery of miR-17-5p lipoplex was performed in collagen induced arthritis model in mice. Clinical, histological and structural effects were studied over the course of arthritis. In depth studies of miR-17 mechanisms of action were performed in primary RA-FLS isolated from RA synovial tissue.

Results: Among others, miR-17-5p expression was reduced in erosive RA, miR-17 transfection in arthritic paws significantly reduced clinical inflammation. Moreover, synovial B cells, T cells, macrophages and polymuclear neutrophils infiltrates were significantly reduced. Structural damage was also decreased as shown by a reduction in the number of osteoclasts and erosion score by CT analysis. Pro-inflammatory cytokines of the IL-6 family, STAT3 target genes and IL-1β expression were also significantly reduced, but not TNF-α. miR17 directly targeted the 3’-untranslated region of STAT3 and JAK1. STAT3 and JAK1 miRNA and protein expression were reduced in RA-FLS following miR-17 transduction. STAT3 and JAK1 mRNA and activation of STAT3 as assessed by immunohistochemistry were also reduced in injected paws.

Conclusion: We demonstrate an anti-inflammatory and anti-erosive role of miR-17 in vivo. This effect involves the suppression of the IL-6 family family autocrine amplifying loop through the direct targeting of JAK1 and STAT3 as shown in RA-FLS.
**Methods:**

Objectives: To assess i) the modulation of synovial tissue MerTK+ macrophages upon treatment with conventional synthetic (cs) disease-modifying anti-rheumatic drugs (DMARDs) and ii) the relationship between baseline MerTK gene expression and response to TNFi.

**Results:** Before any treatment intervention, the percentage of MerTK+ macrophages was significantly higher in RA patients with low (DAS28<3.2) versus high (DAS28≥5.1) disease activity (24.5±20.1 versus 4.8±4.8, p=0.05). There were no differences in the relative number of MerTK+ or CD206+ or MerTK+CD206+ macrophages at baseline in relationship with the clinical response to csDMARDs at 6-months. On the other hand, patients (n=5) achieving remission (DAS<2.6) upon receiving csDMARDs significantly increased the number of MerTK+ macrophages from pre- to six-months post-treatment (23.6±23.8 to 55.5±15.4, p<0.05) in comparison with patients (n=5) who were still active after treatment (18±15.6 to 30.4±11.17, p=ns).

**Conclusion:** Our whole-tissue protein expression data further support the hypothesis that a selective expansion of the MerTK+ macrophage subset characterised patients achieving remission. Moreover, the pre-treatment up-regulation of the MerTK gene in future responders to TNFi suggest that MerTK is implicated in modulating synovial inflammatory responses and may be exploited as a therapeutic target in RA.

who have developed RA so far and patients with arthralgia or at the time of RA manifestation.

Conclusion: We identified lower number of NK cells as well as NK-T and yS-T cells in individuals at risk of developing of RA. The decrease in non-conventional T cells was observed despite the increased percentage of the classical T cells. We hypothesize that the disproportion of these lymphocyte subpopulations, described previously in established RA, observed here in at-risk individuals may reflect their predisposition for further development of RA.

TOFACITINIB REVERSED ENDOThelial DYsFUNCTION in RHEUMAtoid ARTHRitis (RAT) ADJUVANT-INDUCED ARTHRITIS MODEL.

P. Totoson1, C. Prati1,2, D. Wendling2,3, A. Quirié4, C. Marie4, C. Demougeot2

1PEPITE EA4267, Univ. Bourgogne Franche-Comté, Besançon, France; 2Service de Rhumatologie, CHRU Besançon, Besançon, France; 3EA 4286, Univ Bourgogne Franche-Comté, Besançon, France; 4Inserm U1093, Action cognition et plasticité sensorimotrice, Univ. Bourgogne Franche-Comté, Dijon, France

Background: Tofacitinib, an inhibitor of JAK3 and JAK1, is approved for the treatment of rheumatoid arthritis (RA)1. Cardiovascular (CV) risk2 and events3 in RA patients treated with Tofacitinib is a matter of debate, but the vascular mechanisms involved are unknown.

Objectives: The aim of this study was to investigate whether Tofacitinib improves endothelial dysfunction (ED) and if so to explore the underlying mechanisms in the model of adjuvant-induced arthritis (AIA) in rats.

Methods: AIA was induced by injection of Mycobacterium butyricum in the tail of male Lewis rats. A group of rats without arthritis served as controls. At the first signs of arthritis, AIA received Tofacitinib (10mg/kg twice daily, s.c.) or 33%DMSO/PEG300 (Vehicle). Arthritis score was daily evaluated. After 21 days, preconstricted isolated aortic rings were relaxed with acetylcholine (Ach, 10-11-10-4 moles/liter) in the presence or not of inhibitor of nitric oxide (NO) synthase (L-NAME), cyclooxygenase-2 (NS398), arginase (nor-NOHA), endothelin-derivered hyperpolarizing factor (EDHF) (apamin/charbdotoxin) and superoxide anions production (Tempol). Endothelium-denuded rings were used to determine the vasorelaxant response to the NO-donor sodium nitroprussiate (SNP, 10-7-10-4 moles/liter). Blood pressure and heart rate were measured by invasive method. A radiographic score was attributed to hind paws.

Results: Compared to AIA-Vehicle, Tofacitinib dramatically reduced arthritis (-76%) and radiographic (-73%) scores (p<0.001), and improved Ach-induced vasorelaxation (p<0.05). Of note, Ach-induced vasorelaxation was not different between Tofacitinib-AIA and control rats. The response to SNP was not different between groups. The effect of Tofacitinib on ED was mediated by inhibition of the classical Treg cell differentiation and facilitated Treg cell differentiation in vitro. In addition, Tofacitinib inhibited CD4+ T cell proliferation. Furthermore, Tofacitinib attenuated osteoclast differentiation (Figure 2) and interfered osteoclastogenesis at the molecular level. In the in vivo experiment, incidence of arthritis tended to be lower in Tofacitinib-treated mice than that in control group, although there was no significant difference.

RESOLVIN D5 MODULATES Th17/TReg CELL DIFFERENTIATION AND SUPPRESSES OSTEOCLASTOGENESIS

H. Yamada1, J. Saegusa1, S. Sendo1, Y. Ueda1, T. Okano1, Y. Fujikawa1, Y. Yamamoto1, T. Nagamoto1, Y. Ichiwe1, I. Naka1, K. Akashi1, A. Onishi1, M. Shinohara1,2, A. Morinobu1

1Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan; 2Division of Epidemiology, Kobe University Graduate School of Medicine, Kobe, Japan; 3The Integrated Center for Mass Spectrometry, Kobe University Graduate School of Medicine, Kobe, Japan

Background: Resolution phase of acute inflammation has been recognized not passive but active process during the last 2 decades. This active process is highly regulated by novel families of potent bioactive lipid mediators, which are coined as specialized proresolving mediators (SPMs) including resolvins. It is well known, however, about how resolvins are involved in chronic inflammation, such as rheumatoid arthritis (RA).

Objectives: To investigate whether lipid mediators (LM) are involved in the pathogenesis of RA.

Methods: We investigated lipid mediator profiling in the paws of SKG arthritis mice by using lipid chromatography (LC) mass spectrometry (MS) and LM metabololipidomics. CD4+ T cells from spleens of SKG mice were cultured on anti-CD3/CD28Abs precoated plate with IL-6/TGF-β, anti-IFNγ/IL-4 and analyzed by flow cytometry. CD4+ T cells were labeled with CFSE, and cell proliferation was analyzed by flow cytometry. Mouse bone marrow cells were cultured with M-CSF and RANKL, and TRAP-positive multinucleated cells were defined as osteoclasts. Osteoclast differentiation markers were examined by qRT-PCR.

Results: RvE3, RvD1, RvD3, RvD5 and Maresin2 were significantly elevated on the paws of arthritic SKG mice. Among the elevated SPMs, only RvD5 levels on arthritic paws were significantly correlated with arthritis disease activity (Figure 1). We demonstrated that RvD5 suppressed Th17 cell differentiation, and facilitated Treg cell differentiation in vitro. In addition, RvD5 inhibited CD4+ T cell proliferation. Furthermore, RvD5 attenuated osteoclast differentiation (Figure 2) and interfered osteoclastogenesis at the molecular level. In the in vivo experiment, incidence of arthritis tended to be lower in RvD5-treated mice than that in control group, although there was no significant difference.
Background: Patients with elderly-onset rheumatoid arthritis (EORA) are on the rise in the aging or super-aging society, especially in Japan. Patients with EORA have more comorbidities than those with younger-onset RA, a higher risk of adverse drug reactions due to reduced drug metabolism, and a higher risk of infections. Therefore, patients with EORA tend to receive suboptimal treatment, resulting in insufficient control of disease activity. Although several studies reported treatment responsiveness in patients with EORA, many of them have a limited observation period and long-term treatment responses and their associated factors need to be clarified.

Objectives: We retrospectively evaluated treatment responses of patients with EORA for 3 years and their associated factors in a clinical setting.

Methods: The Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort is a large, single institute-based, observational cohort of RA patients established at Institute of Rheumatology, Tokyo Women’s Medical University, in 2000. The subjects were RA patients who first enrolled in the IORRA cohort from 2010 to 2014, were over 60 years old with less than 1-year disease duration, and had a DAS28-ESR over 3.2 at entry. The primary endpoint was DAS28-ESR <3.2 after 3-year observation. A multivariate logistic regression analysis was conducted to identify factors at baseline associated with the primary endpoint.

Results: Among a total of 250 patients in this study, 152 patients (60.8%) achieved DAS28-ESR <3.2 after 3-year observation (remission/low disease activity (RL) group), and 98 patients did not (moderate/high disease activity (MH) group). Baseline characteristics of the patients were as follows (average ± SD or %): the RL group, age 69.9 ± 6.5, female 77.0%, DAS28-ESR 4.3 ± 0.8, J-1HAQ 0.9 ± 0.7, PSL user 23.7%, MTX user 64.5%, and biologics user 4.0%; the MH group, age 69.4 ± 6.7, female 80.6%, DAS28-ESR 4.4 ± 0.8, J-1HAQ 1.0 ± 0.7, PSL user 36.7%, MTX user 64.3%, and biologics user 6.1%. Proportions of the patients with cardiovascular disease and malignancy at baseline were 13.3% and 11.2% in the MH group and 5.9% and 1.3% in the RL group, respectively. DAS28-ESR and J-1HAQ score after 3-year observation of the RL group were 2.3±0.5 and 0.4±0.5, respectively, and those of the MH group were 3.4±0.9 and 1.0±0.8, respectively. Corticosteroid use and having malignancy at baseline were associated with not achieving DAS28-ESR <3.2 after 3-year observation using multivariate analysis (Table 1). Similar results were obtained when MTX use and corticosteroid use were replaced by the average dose of each drug.

Conclusion: The majority of the patients with EORA achieved DAS28-ESR <3.2 after 3-year observation, and no use of corticosteroid and absence of malignancy at baseline were associated with the good outcome.

References:

Acknowledgments: We thank all patients who participated in the IORRA survey and all of the members of the Institute of Rheumatology, Tokyo Women’s Medical University, for the successful management of the IORRA cohort.

The missing values of DAS28-ESR were imputed by using the last observation carried forward method.
Objectives: The relationship between the level of fetuin-A (FA), the presence of osteoporesis and osteoporotic fractures in patients with rheumatoid arthritis

I. Zborovskaya1, B. Zavodovskiy1, Y. Akhverdyan1, E. Papichev1, P. J., S. L.1
1 Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A. B. Zborovsky», Volgograd, Russian Federation

Background: According to the literature, a number of markers (insin, adiponectin, visfatin, and others) have a positive correlation with the frequency of osteopenia, osteoporotic fractures and inflammatory response in patients with rheumatoid arthritis.

Objectives: to study the relationship between the level of fetuin-A (FA), the presence of osteopenia (OP) and osteoporotic fractures in patients with rheumatoid arthritis (RA).

Methods: We examined 110 patients with a reliable diagnosis of RA, verified to study the relationship between the level of fetuin-A (FA), the presence of osteopenia (OP) and osteoporotic fractures in patients with rheumatoid arthritis (RA).

Results: The average level of FA in patients with RA was 765.67±120.66 μg/ml, which was significantly lower than in healthy individuals - 812.95±76.21 μg/ml (p=0.0437). OP was detected in 52 (47.2%) patients with RA. The level of FA in serum in patients with OP was 733.65±135.84 μg/ml, which is also lower than that of healthy individuals (p=0.002).

We divided all patients with RA into 2 groups, depending on the presence of osteoporotic fractures. The average level of FA in the group of patients with osteoporotic fractures (n=24) was 694.79±110.47 μg/ml, which is significantly lower than the level of the group without fractures (n=86) - 785.45±116.43 μg/ml (p=0.00091).

Conclusion: The average level of FA in patients with RA is significantly lower than in healthy individuals. In addition, in patients with the presence of OP and osteoporotic fractures, the level of FA in the blood serum is also lower than in patients without OP and fractures. Thus, a decreased level of FA in the blood serum of patients with RA may indicate the presence of OP and an increased risk of osteoporotic fractures.

AGREEMENT BETWEEN REFERRING PHYSICIANS AND RHEUMATOLOGISTS AND PREDICTORS OF INFLAMMATORY ARTHRITIS: ANALYSIS BASED ON 8 YEARS OF EXPERIENCE IN AN EARLY ARTHRITIS CLINIC

L. Brites, L. Saraiva, A. R. Cunha, H. Assunção, T. Santiago, J. A. Pa de Silva, C. Duarte, Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; Centro Hospitalar Baixo Vouga, Aveiro, Portugal; Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Early recognition of patients with arthritis is a crucial opportunity for optimal outcome. The Early Arthritis Clinic (EAC) of our department was created in 2012 to ensure a prompt access of these patients to efficient medical care. Patients may be referred based on a set of clinical criteria with less than 12 months duration and laboratory parameters: arthritis, inflammatory arthralgias, squeeze test, morning stiffness > 30 minutes, rheumatoid factor (RF), erythrocyte sedimentation rate (ESR)>30mm/h and C-reactive-protein>0.5mg/dL (CRP).

Objectives: To assess the level of agreement between the referring physician and the rheumatologist, regarding the presence of each of the six referral criteria and to identify predictors of inflammatory arthritis.

Methods: Cross sectional study including patients aged ≥ 18-year-old observed in the EAC between January 2012 and October 2019. Subjects who were referred to the EAC by a rheumatologist and those without available referral letter/medical records from the first visit to the EAC were excluded. Demographic data, provenience, referral criteria (presence/absence) and the final diagnosis [presence or not of an inflammatory rheumatic disease (IRD)] were collected from medical records. For the six referral criteria, the agreement between the referring physician and the rheumatologist was assessed using the Cohen’s Kappa. The presence of each referral criteria was compared between patients with and without an IRD using χ2 tests. Variables with p<0.1 or clinically relevant were included in forward stepwise multivariable logistic regression analysis to identify possible predictors for IRD. The statistical analysis was performed using SPSS® v21 and p<0.05 was considered statistically significant.

Results: 376 patients (70% female; mean age (±SD) 56.3±16.2 years) were included. Most patients were referred from primary care (84%); the remaining 16% include those referred from emergency department and other hospital specialties. We diagnosed an inflammatory arthritis in 62% (n = 232) of the patients. Table 1 shows the level of agreement between the referring physician and the rheumatologist, regarding the presence of the referral criteria.

</table>

ANA: antinuclear antibodies; CRP: C-reactive-protein; ESR: erythrocyte sedimentation rate; RF: rheumatoid factor.

In univariable analysis (IRD Vs non-IRD), inflammatory arthralgias (74% Vs 93%, p=0.01), squeeze test (24% Vs 55%, p=0.01), morning stiffness (49% Vs 63%, p=0.05), ESR (63% Vs 46%, p=0.01), CRP (62% Vs 48%, p=0.04) were associated to IRD. In multivariable analysis, only ESR (OR 5.0 [95% CI 1.9-13.0], p<0.05) and inflammatory arthralgias (OR 0.15 [95% CI 0.04-0.52], p<0.05) remained as predictors of IRD.

Conclusion: Agreement between the referring physicians and the rheumatologist regarding then presence/absence of the referral criteria was poor in all clinical criteria and fair in laboratory criteria. Elevated ESR was an independent predictor of IRD and the description of inflammatory arthralgias was negatively correlated with IRD. These findings suggest the need to clarify the referral criteria used and to improve education among the physicians referring patients to the EAC.

BODY MASS INDEX TRAJECTORY IN RHEUMATOID ARTHRITIS

G. Challenger, E. Myasoedova, C. S. Crowson, R. Giblon, J. M. Davis III.

Mayo Clinic, Rochester, United States of America

Background: Obesity is a known risk factor for development of refractory rheumatoid arthritis (RA) [1]. While past studies have examined associations between BMI and disease activity [1, 2, 3], and rheumatoid cachexia is a well-recognized phenomenon, few studies have characterized BMI trajectory over the disease course of RA.

Objectives: 1) To compare BMI trends between RA and matched non-RA subjects. 2) To determine predictors of BMI trends within RA subjects.

Methods: The study population comprised Olmsted County, Minnesota residents with incident RA (age > 18 years, 1987 ACR criteria met in 1995-2009) and non-RA subjects from the same underlying population with similar age, sex and calendar year of index. All subjects were followed until death, migration, or 01/July 2019. Follow-up was truncated for comparability. Generalized additive models with smoothing splines were used to illustrate trends in BMI measurements over time.

Results: The study included 558 patients with RA (mean age 55.6 years, 69% female) and 556 patients without RA (mean age 55.7 years, 69% female). Mean BMI of patients with incident RA (28.8) was not significantly different from that of non-RA subjects (28.9). Models demonstrating time trends in BMI showed a significant decline in BMI over time in both cohorts (p<0.001). A model including the interaction between RA/non-RA status and time revealed a significant interaction (p<0.001), indicating that patients with RA have a larger decline in BMI per year than patients without RA. There was no significant difference in BMI trends over time between seropositive (RF/CCP) and seronegative RA patients (p=0.16). In examining sex differences in BMI trends, female RA patients demonstrated a steeper decline in BMI compared to men (p<0.001).

Conclusion: Our findings demonstrate a significant decline in BMI over time in both RA and non-RA populations, with a significantly larger decline per year in RA patients. The decline in the RA population is most pronounced beyond 5 years from RA incidence. Given that the mean age of patients in this study at baseline was 56 years, the finding of declining BMI in the healthy population fits with prior studies that demonstrate that BMI trends to decrease in the elderly population [4, 5, 6, 7]. The greater extent of BMI loss in the RA population may reflect the phenomenon of rheumatoid cachexia. More studies are needed to understand the reasons and implications of these trends.

References:
Background: It has been suggested that RA is triggered by genetic and environmental factors that lead to a breakdown of immune tolerance at mucosal surfaces (e.g. periodontium) [1, 2]. The theory that Periodontitis (PD) affects RA process/measurement has deep implications: PD treatment might improve disease activity and/or prevent overtreatment. It is urgent to confirm available evidence and design research strategies to cover knowledge gaps.(3)

Objectives: To gauge the evidence of non-surgical periodontal therapy (NSPT) impact upon measures of disease activity and inflammatory burden in individuals with RA and derive recommendations for research needed to address the knowledge gaps.

Methods: Based on a prespecified Protocol (CRD42018103359), a search for RA and Periodontitis and controlled or randomised trials was conducted on the 7th April 2019 in PubMed, Cochrane Library (CENTRAL), Embase, ClinicalTrials.gov and WHO ICTRP portal. Two independent reviewers screened titles and abstracts and selected papers were full text reviewed. Outcome domains were abstracts and selected papers were full text reviewed. Outcome domains were OMERACT-endorsed for RA CTs: disease activity (DAS28, SDAI, CDAI), life impact (patient-reported outcome measures) and inflammation markers (CRP, ESR). We summarised continuous outcomes using standardised mean differences (SMDs) with 95% confidence intervals (95% CIs). We evaluated inconsistency using the I2 statistic, and combined SMDs using the standard inverse variance random effects for the meta-analyses; fixed-effect meta-analysis was applied for the purpose of sensitivity.

Results: From 1909 studies identified, 9 reports (5 RCTs, 4 NRISIs) were eligible for quantitative synthesis (n=288). The evidence suggested a moderate effect on the disease activity domain in response to NSPT in RA patients (SMD -0.59 [95% CI, -1.21 to 0.03], n=311; Figure 1). Using GRADE approach, as judged from the study's Risk of bias, imprecision around the estimate, and the results' inconsistency (I² = 83%), the evidence was rated down to very low certainty evidence indicating that any possible effect of NSPT is likely to change as more prospective evidence is provided. A RCT in PD-RA patients would need a sample size of at least 90 individuals, randomised 1:1 (80% power) to detect an effect size of 0.59. Anticipating withdrawals and attrition, a more adequate sample size would be 120 (90% power).

Conclusion: Our results summarise the current evidence on the likely impact of NSPT on RA outcomes. There is an urgent need to assemble a well designed RCT, or prospective (multicenter) cohorts of RA-PD patients using rigorous protocols, standardized diagnosis criteria, data collection and duration of follow-up.

In ACPA Positive At-Risk Individuals Without Clinical Arthritis, is Ultrasound Sufficiently Accurate to Predict Progression to Inflammatory Arthritis?

University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom

Background: In a cohort of Anti-Cyclic Citrullinated Peptide Positive (ACPA+) at-risk of developing inflammatory arthritis (IA) individuals without clinical synovitis, we previously demonstrated the predictive value of Power Doppler (PD) for progression depending on the number of joints involved (1). Here we update these results in a larger population combining all ultrasound (US) features and incorporating them in a multivariable analysis with clinical, genetic and immunological markers.

Objectives: To investigate the ability of US to predict progression to clinical arthritus using multivariable Cox analysis with and without including other variables.

Methods: In a single centre prospective cohort, 488 at risk ACPA+ individuals with new musculoskeletal symptoms underwent an US scan of 30 small joints and 18 tendons at first visit (metacarpophalangeal, interphalangeal and metatarsophalangeal joints and flexor tendons, and extensor carpi ulnaris). The predictive value of US abnormalities (Power Doppler grade ≥ 1 (PD), Grey Scale grade ≥ 2 (GS), or erosion (E) presence) for progression to IA was assessed using Cox regression analysis and adjusted for tenosynovitis (TSV) presence in ≥1 joint (HR=1.973, p= 0.024, CI= 1.095-3.553), smoking exposure (HR= 2.597, p= 0.003, CI= 1.369-4.929), shared epitope positivity (HR= 1.979, p=0.044, CI= 1.019-3.843), ≥5 small joints tender (HR= 2.111, p= 0.030, CI= 1.073-5.463), and a high titre CCP and/or RF (HR= 4.334, p= 0.003, CI= 1.651-11.374).

Conclusions: In at-risk ACPA+ individuals, ultrasound alone - especially Power Doppler - is a powerful predictive factor of progression to IA, therefore of high clinical value for rheumatologists. The multivariable integrated risk prediction values indicates the role of other factors to be considered in future risk model development.

Data are mean (SD) unless otherwise stated.
without PGA, i.e. equal to the combination of i and ii), and (iv) non-remission (TJC28 and/or SJC28 and/or CRP >1). Meta-analyses were performed using the DerSimonian-Laird random-effects method. Good radiographic outcome (GRO) was defined as an increase of ≤0.5 modified Total Sharp score (mTSS) units. The relationship between the most stringent remission class achieved at 6 or 12 months and GRO during the second year was analysed. The pooled probabilities of GRO for the different definitions of remission were estimated and compared.

**Results:** Individual patient data (n=5,792) from eleven trials were analysed. 4V-remission was achieved by 23% of patients (95%CI: 18-28%) and 4V-near-remission by 19% (95%CI: 15-22%) and thus, 3v-remission by 42% (95%CI: 36-48%). The probability of GRO in the 4V-near-remission group was similar to that of 4V-remission (78 vs 81%, ns) and significantly higher than that for non-remission (72%; difference 6%; 95%CI: 2-10%) (Table 1). These results were confirmed by meta-analyses of odds ratios of obtaining GRO of these groups (Graph 1). 3V-remission showed a higher predictive value for GRO (51%, 95%CI: 47-55%) than 4V-remission (41%, 95%CI: 35-46%) (Figure 2).

**Table 1.** Pooled outcomes and measures of association between remission categories and good radiographic outcome (GRO, defined as ∆mTSS≤0.5), during the second year of follow-up.

**Comparisons**

4V-remission vs 4V-near-remission: ∆ percentage GRO (95%CI) -2.9 (-7.3 to 1.5); 6.2 (2.3 to 10.1)

**Conclusion:** 4V-remission and the original 4V-remission are similarly predictive of GRO, therefore combining these in the 3V-remission definition potentially reduces the risk of overtreatment compared to the 4V definition. This supports the use of 3V-remission as the target for immunosuppressive therapy. The patient's perspective, which must remain central, requires a separate treatment aim: a dual-target approach.

**PREDICTIVE VALUE OF IMMUNOLOGICAL AND IMAGING BIOMARKERS ON ACHIEVING GOOD CLINICAL RESPONSE AT 6 MONTHS IN RHEUMATOID ARTHRITIS PATIENTS TREATED BY INTRAVENOUS BDMARDS**

**Background:** RA is the most prevalent chronic inflammatory rheumatism, responsible of functional impairment.

**Objectives:** To investigate the value of biological and imaging biomarkers on predicting good clinical response at 6 months, in RA patients initiating IV bDMARD.
Methods: From 2008 to 2017, 317 RA patients fulfilling ACR 1987 and/or ACR-EULAR 2010 criteria for RA, initiated IV bDMARDs in our department of Rheumatology. Patients were excluded in cases of lack of information on disease activity assessment before and at 6 months of treatment and on immunological status and titers (ACPA, RF, ANA) at baseline. For patients receiving successive IV bDMARDs during this time period (n=30), a randomization permitted to select 1 treatment sequence for the analysis. On 173 patients eligible to the study, 4 were loss to follow-up and 14 stopped treatment due to adverse events before 6 months. Clinical, biological and imaging (US and RX) data were collected when available at baseline. US examination was performed on 12 joints (wrist, MCP2-3-5 and MTP2-3-5) with qualitative and quantitative evaluation on B mode and Power Doppler (PD) for synovitis, tenosynovitis and erosion. The modified Sharp/van der Heijde erosion score was performed by 2 independent readers blindly from clinical and US informations. Good clinical response was defined by a DAS 28 < 3.2 and/or DAS 28 decrease > 1.2 at 6 months. Only variables with a p<0.2 in univariate analysis were included in the multivariate model.

Results: On 155 RA patients, 11 present a disease duration < 2 year, 44 (28.3%) were on first line of IV bDMARDs and 111 patients received at least one IV bDMARD (mean 2.5 (1.3)).

All qualitative variables with a p value <0.2 on bivariate analysis were incorporated in the multivariate model (RF +, ACPA +, US erosive RA, Nb B mode synovitis, Nb PD+ synovitis, RX erosive RA). Only patients with all data available are incorporated in the multivariate logistic regression analysis (n=101/155).

Conclusion: We showed that positive RF was predictive of good clinical response to IV bDMARDs. For the first time, we demonstrated that number of US B-mode synovitis was also predictive to good clinical response.

Background: In the treatment of rheumatoid arthritis (RA), methotrexate (MTX) monotherapy is undoubtedly the most cost-effective therapy available. However, there is no clear evidence exists for the adopted method of MTX usage, except for guidelines that have been formulated using empirical knowledge.

Objectives: We aimed to retrospectively evaluate the treatment method used to administer MTX monotherapy in order to identify factors influencing the success rate of MTX treatment in phase I of the European League Against Rheumatism (EULAR) recommendations in the treatment algorithm of RA.

Methods: A total of 520 RA patients were considered for inclusion in this study, of whom 183 were eligible as they had been treated with MTX monotherapy from 2013 to 2018. The exclusion criteria included the following: unknown MTX prescription details (200 cases), deviation from the treatment algorithm i.e. use of a combination of conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) before MTX therapy (4 cases), and a long duration of MTX escalation that deviated from the treat-to-target concept (133 cases).

Results: This study aimed to investigate heterogeneity in the course of fatigue and identify risk factors associated with fatigue heterogeneity.

Methods: Data were from the early Rheumatoid Arthritis Network (ERAN), an inception cohort of people with a disease duration of >24mths, recruited from 2002-11 (n=1236), ERAN collected demographic, clinical, quality of life, comorbidity and laboratory data at baseline, 3-6 mths, and then annually. Fatigue was measured using the Vitiola subscale of the Short Form Health Survey questionnaire (SF36VT). ‘Fatigue and severe fatigue were classified as SF36VT values lower than 1 and 2 standard deviations (SD) below the UK healthy population average respectively. Baseline prevalence rates standardized to Eurostat 2013 by age and sex were calculated.

The course of fatigue was examined using linear mixed effect models. Group Based Trajectory Modelling (GBTM) was used to examine heterogeneity in the course of fatigue. Baseline characteristics were then used to identify predictors of group membership using univariate and multiple regression analysis.

Results: Baseline characteristics include female sex (67%), mean age 57(SD±14) yrs. Mean SF36VT score = 41(SD±11), mean duration was 11 mths (IQR:7 – 18).

The course of fatigue was examined using linear mixed effect models. Group Based Trajectory Modelling (GBTM) was used to examine heterogeneity in the course of fatigue. Baseline characteristics were then used to identify predictors of group membership using univariate and multiple regression analysis.

Results: Baseline characteristics include female sex (67%), mean age 57(SD±14) yrs. Mean SF36VT score = 41(SD±11), mean duration was 11 mths (IQR:7 – 18).

The age and sex standardized prevalence rates of fatigue and severe fatigue were 44%(CI:38-50) and 18%(CI:15 – 22) respectively.

729 (59%) participants were included in the longitudinal analysis. Over the course 4 years follow up, and after accounting for the effect of age, sex, patient’s global assessment of disease activity, BMI, pain and mental health, there was a reduction in the population vitality levels from baseline, (β = -0.141CI: -0.26 to -0.02, p < 0.001). Inflammation measured by erythrocyte sedimentation rate (ESR) was not significantly associated with the course of fatigue.

GBTM analysis identified 2 sub-groups. These groups were named ‘Fatigue’ and ‘No-fatigue’ groups and comprised about 52% and 47% of the population respectively (Fig 1).

Females, participants with, at baseline, higher BMI, higher disability score (HAQ), disease activity score (DAS28), worse pain, mental health scores (SF36VT) were more likely to belong to the Fatigue group (each p ≤ 0.05) in univariate analysis. However, higher BMI (OR 1.05 CI: 1.0 – 1.1), HAQ (OR 2: CI: 1.5 - 2.7), DAS28(OR 1.3, CI: 1.2 – 1.5), worse SF36 pain and mental health scores (OR 0.93 CI: 0.92 – 0.95) and (OR 0.97, CI: 0.95 – 0.99) were collectively associated with fatigue group membership (AUROC=0.81).

Fig 1. Fatigue Trajectories

Conclusion: Fatigue is prevalent in RA, even in early disease. Embedded within the RA population are distinct sub-populations, with or without fatigue. Those with fatigue at baseline were likely to continue to report fatigue over 4 years of follow up. Unlike our previous data on pain trajectories within this cohort, a ‘resolving fatigue’ was not found. Diverse baseline characteristics, including pain, were associated with persistent fatigue. Management of fatigue might require strategies additional to disease modification, and people who require such interventions might be identified at presentation with early RA.

Background: Fatigue is associated with poor quality of life in people with Rheumatoid Arthritis (RA). The exact burden of fatigue in RA is uncertain. Evidence shows that fatigue may persist, even in people with well-controlled inflammatory disease. However, this is largely based on cross sectional data, and data from people with long standing or refractory disease. This study aims to examine the nature of fatigue in early RA.

Objectives: Describe the prevalence of fatigue and longitudinal course of fatigue

Methods: Data were from the early Rheumatoid Arthritis Network (ERAN), an inception cohort of people with a disease duration of >24mths, recruited from 2002-11 (n=1236), ERAN collected demographic, clinical, quality of life, comorbidity and laboratory data at baseline, 3-6 mths, and then annually. Conclusion: CsDMARDs and bDMARDs have a protective effect on radiographic progression at 10 years in RA patients. This study has shown the value of considering drug exposure in the study of RA prognosis, and modeling this exposure using WCE variables.

Figure 1. ROC curves of BSL model (A), BIT model (B) and WCE combined model (C) for 10-year radiographic progression.
Background: Clinical joint count assessment is important for detecting synovitis but its reliability is controversial.

Objectives: This study assessed the correlation between bone scintigraphy and positron emission tomography (PET)-derived parameters in 28 joints with disease activity and computed the reliability of joint counts between bone scintigraphy and clinical assessment in rheumatoid arthritis (RA).

Methods: We enrolled 86 patients with active RA who underwent bone scintigraphy, fluorine-18-fluorodeoxyglucose (FDG) PET/CT and disease activity evaluation at the same time. This two-step study involved a development (n=67) and validation (n=19) group. Bone scintigraphy-derived joint assessment were compared with PET/CT-derived and clinical joint assessment. Subsequently, we developed a disease activity score (DAS) using bone scintigraphy-positive joints and validated it in an independent group.

Results: The number of bone scintigraphy-positive joints in 28 joints was significantly correlated with the swollen (SJC)/tender (TJC) joint counts and PET/CT-derived joint counts. Intra- and inter-observer reliabilities of bone scintigraphy for the affected joint counts were excellent. Inter-observer reliability between nuclear medicine physicians and rheumatologists was good for SJC/TJC and PET/CT derived joint counts in 28 joints except shoulders. After multivariate analyses including erythrocyte sediment rate (ESR) and patients global assessment (PGA) in addition to bone scintigraphy-derived parameters, bone scintigraphy/DAS was derived as 0.056 × number of bone scintigraphy-positive joints in 28 joints + 0.012 × ESR + 0.030 × PGA. A significant correlation between bone scintigraphy/DAS and DAS28-ESR was confirmed in the validation group (p<0.001).

Conclusion: Bone scintigraphy-derived joint assessment significantly correlated with PET/CT-derived joint counts. Bone scintigraphy could serve as a sensitive and reliable method for evaluating disease activity in RA patients.

THE GUT MICROBIOTA AND ITS RELEVANCE TO PERIPHERAL T REGULATORY CELLS AND T HELPER 17 IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. LI1, S. X. ZHANG1, X. F. YIN1, Z. MINGQING2, J. LU1, G. Y. LIU1, C. GAO2, X. LI1.
1The Second Hospital of Shanxi Medical University, Shansi Medical University, Rheumatology, Taiyuan, China; 2Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America

Background: Rheumatoid arthritis (RA) is a common autoimmune disorder with joint destruction and synovial inflammation characterized by abnormal immune responses to autoantigens. Our previous studies have demonstrated that impaired peripheral lymphocytes especially insufficiency of regulatory T cells (Tregs) played an important role in pathogenesis of RA. However, the dysbiosis of gut microbiota triggers several types of autoimmune diseases through the imbalance of T lymphocyte subsets. Therefore, the detailed gut microbiota of RA patients and its correlation with Tregs and helper T cells 17 (Th17) are unclear up until now.

Objectives: To compare the difference of gut microbiota between RA and healthy controls (HCs), and to investigate the relevance of gut microbiota with circulating Tregs and Th17 in patients with RA.

Methods: From December 2018 to August 2019, a total of 205 diagnosed patients with RA and 199 age and sex-matched HCs were enrolled in this study. Stool of every participant was collected for bacterial DNA extraction and 16S ribosomal RNA (rRNA) gene sequencing. The absolute numbers of eight OTUs belonging to the phyla Bacteroidetes and Firmicutes were significantly lower than the healthy controls (P<0.05) (Figure 2). Moreover, Blautia, Anaerostipes and Ruminococcus2 had negative correlation with the absolute number of Tregs, and Cloacibacillus and Streptophyta have positive correlation with the absolute number of Th17.

Conclusion: Patients with RA had a dysbiosis of the gut microbiota in both diversity and abundance, which is closely related to the impaired peripheral lymphocyte subsets, that may be related to the pathogenesis of RA, which might provide a new idea for RA treatment.

ISOTOPE-LABELING-LC-MS-BASED METABOLIC PROFILING OF MULTIPLE SERUM SAMPLE SETS FOR THE DISCOVERY OF HIGH-CONFIDENCE RHEUMATOID ARTHRITIS BIOMARKERS

W. Han1, X. Wang1, L. Li1, S. Wichuk1, E. Hutchings2, R. Dadashova2, J. Paschke1, W. P. Makaymowych3, 1University of Alberta, Edmonton, Canada; 2CARE Arthritis, Edmonton, Canada

Background: Early diagnosis of rheumatoid arthritis (RA) is hampered by sub-optimal accuracy of currently available serological biomarkers. Metabolomics may reveal promising biomarker candidates associated with the biomolecular processes of RA. In this work, we applied a high-performance chemical isotope labeling (CIL) LC-MS technique for in-depth profiling of the amine/phenol-submetabolome in serum samples. To avoid false positives and obtain high-confidence biomarker candidates, we analyzed three independent sets of serum samples collected from RA patients and healthy controls to examine the common effects.

Objectives: We aimed to identify a metabolite signature with consistently high accuracy for RA.

Methods: Serum samples were taken from 3 RA cohorts, which comprised 50, 49, and 131 RA patients, respectively. Within each cohort, there were
sex/age-matched healthy controls: 50 in Cohort 1, 50 in Cohort 2, and 100 in Cohort 3. Among these 446 subjects, 75% were females and the average age was 52.5 years. Amine/phenol-containing metabolites were labeled by 13C-dansyl chloride to improve the LC-MS detection. For each cohort, a pooled sample was prepared and labeled by 13C-dansyl group to serve as the reference sample for relative quantification. Then the individual samples and the pooled sample were mixed 1:1. Finally, an LC-QTOF-MS platform analyzed the mixtures and output the intensity ratios of 13C/12C peak pairs.

**Results:** 1,149 amine/phenol-containing metabolites were commonly detected across the three sample sets. Among them, 134 were positively identified by our dansyl-labeling standard library, and 141 were matched to predicted retention times and mass values of dansyl-labeled human metabolites. Visualized by the partial least squares discriminant analysis (PLS-DA), the overall amine/phenol-submetabolome demonstrated clear and consistent differences between healthy controls and the RA groups, with cross-validation Q2 = 0.785, 0.743, 0.793, respectively. The selection of significant metabolites was conducted according to the fold change and false-discovery-rate-adjusted Welch’s t-test. Cohort 1 demonstrated 85 metabolites having higher concentrations in the RA samples than the controls, and 89 metabolites with lowered concentrations. The numbers of increased/decreased metabolites in Cohort 2 and 3 were 87/26 and 90/53, respectively. Importantly, there were 99 significantly discriminatory metabolites commonly found in the three data sets (49 increased and 9 decreased). We picked the top three with the highest univariate classification performance to form a biomarker panel. We implemented the linear support vector machine (SVM) to build the classifier and the receiver operating characteristic (ROC) analysis to measure the performance. The area-under-the-curve (AUC) values (95% confidence interval) were 1.000 (1.000-1.000), 0.992 (0.967-1.000), and 0.902 (0.858-0.945) for the three cohorts, respectively. The results revealed the importance of examining multiple sample sets and even in the worst case (Cohort 3), our biomarker candidates could differentiate RA at 82.5% sensitivity and 82.5% specificity. Particularly, in Cohort 3, there were 30 RA patients negative for anti-cyclic citrullinated peptide and rheumatoid factor, and our metabolite panel demonstrated consistently high performance for differentiating these specific subjects from healthy controls.

**Conclusion:** Metabolites showing significant and consistent changes associated with RA have been identified with high discriminative power.

**OBESITY PREDICTS RESPONSE TO NOT ALL BUT CERTAIN BIOLOGICAL / TARGETED DISEASE MODIFYING ANTI-RHEUMATIC DRUGS FOR RHEUMATOID ARTHRITIS - RESULTS FROM KANSAI CONSORTIUM FOR WELL-BEING OF RHEUMATIC DISEASE PATIENTS (ANSWER COHORT)**

K. Murakami1, M. Hashimoto2, K. Murata3, W. Yamamoto3, R. Hara4, M. Katayama5, A. Onishi6, K. Akashi6, K. Nagai7, Y. Son8, H. Amuro8, T. Hirano9, K. Ebina10, K. Nishitani2, M. Tanaka2, H. Ito11, K. Ohmura1. 1Kyoto University Graduate School of Medicine, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; 2Kansai Medical University, First Department of Internal Medicine, Osaka, Japan; 3Kochi University Graduate School of Medicine, Department of Internal Medicine, Kochi, Japan; 4Osaka University Graduate School of Medicine, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan; 5Kurashiki Shiketsu Hospital, Health Information Management, Kurashiki, Japan; 6Nara Medical University; the Center for Rheumatic Diseases, Kashihara, Japan; 7Osaka Red Cross Hospital, Department of Rheumatology, Osaka, Japan; 8Kobe University Graduate School of Medicine, Department of Medicine, Kobe, Japan; 9Osaka Medical College, Department of Internal Medicine (IV), Takatsuki, Japan; 10Kansai Medical University, First Department of Internal Medicine, Hirakata, Japan; 11Osaka University Graduate School of Medicine, Department of Respiratory Medicine and Clinical Immunology, Suita, Japan; 12Osaka University Graduate School of Medicine, Department of Musculoskeletal Regenerative Medicine, Suita, Japan; 13Kyoto University Graduate School of Medicine, Department of Orthopaedic Surgery, Kyoto, Japan

**Background:** A number of previous reports suggested that obesity is one of the baseline factors indicates refractory to biologic disease-modifying antirheumatic drugs (bDMARDs). However, difference of the significant responses appears on obesity patients depending on each kind of drug is yet unclear. However, it is yet unclear how the significant responses on obesity patients vary on each kind of drug.

**Objectives:** To assess whether obesity affects clinical outcome in rheumatoid arthritis (RA) treated with each molecular-targeted agent including bDMARDs and tocilizumab.

**Methods:** In Kansai consortium for well-being of rheumatic disease patients (ANSWER) cohort, which was the real-world retrospective cohort of clinical database for rheumatic diseases, RA patients who initiated biological / targeted disease-modifying anti-rheumatic drugs were included and consecutively followed. Obesity was defined as BMI over than 25, and patients were divided between...
obese (“Ob”) and non-obese (“non-Ob”) patients. SDAI (simplified disease activity index) was compared between non-Ob and Ob at month 0, 3, 6, 9, 12 after the indicated drugs were administered. Using logistic regression analysis, odds ratio (OR) and their corresponding 95% confidence intervals (95% CI) were further calculated to estimate achievement rate of SDAI remission defined as lower than 3.3 by obesity and other relevant clinical parameters. Once after the drugs were discontinued by any unfavorable reason, disease activities were no more scored and the Last Observation Carried Forward (LOCF) imputation method was used for SDAI at month 3 and thereafter.

**Results:** A total of 1936 patients met in the inclusion criteria were under the analysis. Each drug’s remission rate (non-Ob, Ob, p-value by Chi-square test) at month 12 was as follows: Infliximab (IFX, n=135): 43%, 38% (not significant); Etanercept (ETN, n=188): 44%, 19%, p=0.012; Adalimumab (ADA, n=169): 50%, 56%, NS; Golimumab (GLM, n=315): 36%, 30%, NS; Certolizumab pegol (CZP, n=131): 33%, 56%, p=0.0287; Tocilizumab (TCZ, n=423): 41%, 29%, p=0.0456; Abatacept (ABT, n=144): 26%, 23%, NS; Tofacitinib (TOF, n=69): 27%, 23%, NS. In multivariate analysis to predict SDAI remission at month 12, obesity was an independent protective factor in CZP (OR: 0.29, 95% CIs: 0.10 – 0.83), but was an independent risk factor in TCZ (OR: 1.9, 95% CIs: 1.01 – 3.61) irrespective of age, sex, disease duration, SDAI at month 0 or number of previous bDMARDs. Any other drug including ETN did not show significant result between non-Ob and Ob in the multivariate analysis.

**Conclusion:** Obese patients were more resistant to TCZ but more effective in CZP than non-obese patients.

Background: The serum MMP3 level is considered biomarker which reflects local inflammation of joints and correlates with joint damage progression in early rheumatoid arthritis (1).

Objectives: To investigate the association of high baseline MMP3 serum levels with bone erosion finding at the level of typical location for rheumatoid arthritis (RA) in patients with early, treatment “naïve” RA, who has no radiographic visible erosions, using ultrasound method (US).

Methods: Sixty-three pts. (9 males and 54 females; mean age 53.4 yrs 21-81 ± 14.1) with early RA according to EULAR/ACR 2010 criteria and symptom duration of ≤12 months (mean duration of 3.8 months) had baseline serum MMP3 levels tested. Serum levels of soluble MMP3 were performed blindly, without knowledge of the US data at the basal visit only, using the recommended normal cut-off range (a level above normal was rated as positive). Patients had been DMARDs/glucocorticoid naïve, with no visible X-ray erosions.

Results: The 50 pts completed follow-up. 46 pts. had basal serum MMP3 level higher than normal (MMP3 +, mean value 185.1±241.0). US bone erosions were present in 55/63 (87.3%) pts, most often in MTP5 joints, both at the study entry and after 24 months of follow up. At baseline visit no significant difference was found between a group of MMP3+ and MMP3- pts. regarding to US bone erosion presence at the level of all analyzed joints (styloid process: 12 MMP3+/4 MMP3- pts.; p=0.836; MCP2: 14 MMP3+/7 MMP3- pts, p=0.55). After 24 months, significant difference was found between a group of MMP3+ and negative pts for MTP5 US bone erosions (26 MMP3+/11 MMP3- pts, p=0.55). No diagnostic tests were replicated. For evaluation of inflammatory involvement, three focused on coexisting mimicking diseases (fibromyalgia and bacterial infection). No diagnostic tests were replicated. For evaluation of inflammatory involvement, three focused on coexisting mimicking diseases (fibromyalgia and bacterial infection).

Conclusion: In our group of RA patients without initial X-ray changes, the high baseline serum level of MMP3 was significantly correlated with new MTP5 bone erosions by US after 2-year of follow-up.

THU0110 DIAGNOSTIC ISSUES IN DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: PRELIMINARY RESULTS OF A SYSTEMATIC LITERATURE REVIEW INFORMING THE 2020 EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS

N. M. T. Roodenrij1, M. kedves2, A. Hamar2, G. Nagy2, J. M. Van Laar2, D. Van der Heijde2, P. Welsing1

1University Medical Center Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands; 2Bács-Kiskun County Hospital, Department of Rheumatology, Kecskemét, Hungary; 3University of Debrecen, Department of Rheumatology, Debrecen, Hungary; 4Semmelweis University, Department of Genetics, Cell- and Immunobiology & Department of Rheumatology, 3rd Department of Internal Medicine, Budapest, Hungary; 5Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands

Background: Rheumatoid arthritis (RA) patients treated according to European League Against Rheumatism (EULAR) recommendations failing ≥2 biological or targeted synthetic disease-modifying antirheumatic drugs (DMARDs) with a different mode of action who still have complaints which may be suggestive of active disease may be defined as suffering from ‘difficult-to-treat RA' Before switching to another DMARD in these patients, the diagnosis of RA and the presence of inflammatory activity should be verified to prevent possible over- and under treatment.

Objectives: To systematically summarise evidence in the literature on diagnostic issues regarding (mis-)diagnosis of RA and mimicking diseases, and assessment of inflammatory disease activity in difficult-to-treat RA patients, informing the 2020 EULAR recommendations for the management of difficult-to-treat RA.

Methods: A systematic literature search was performed: PubMed and Embase databases were searched up to December 2018. Relevant papers were selected and appraised (Figure 1).

Results: Regarding (mis-)diagnosis of RA and its differential diagnoses, four studies were selected (Figure 1a): one assessed the diagnosis of RA and three focused on coexisting mimicking diseases (fibromyalgia and bacterial infection). No diagnostic tests were replicated. For evaluation of inflammatory activity.
activity in RA, and specifically the effect of comorbidities on assessing inflammatory activity, B3 and five studies, respectively, were included (Figure 1b). At patient level, ultrasonography (US) scores were related to composite indices (range of correlations 0.25-0.70) and swollen joint count (range r = 0.33-0.78). A multi-biomarker disease activity score (range r with composite indices: 0.41-0.52) and optical spectral transmission measures (range r with US: 0.54-0.64) were promising measures, but cut-offs are preliminary. At joint level, US was related to MRI (range of sensitivity 64-91% and specificity 60-94% for synovitis) and histology (range r: 0.52-0.65 for inflammation). Concomitant obesity and fibromyalgia may lead to overestimation of disease activity according to composite indices, US may be used to assess inflammatory activity in these patients. 

Conclusion: This SLR highlights the gap of knowledge in the optimal confirmation of a (mis-)diagnosis of RA or diagnosis of mimicking diseases in difficult-to-treat RA patients. Current evidence for optimal assessment of inflammatory activity when there is doubt based on clinical assessment and composite indices is limited. Most studies reported correlations which are not directly useful in clinical practice to determine presence or absence of inflammatory activity. The evidence will be updated up to December 2019. Currently, US seems the most accurate measure to evaluate the presence of inflammation in difficult-to-treat RA patients, including those with concomitant obesity or fibromyalgia.

PHYSICIAN’S GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: WHAT DO WE REALLY MEAN?

L. Saraiva1, L. Brites1, A. R. Cunha2, H. Assunção3, A. R. Prata4, M. Luis5, F. Costa6, P. Freitas7, M. Sousa8, J. A. P. Da Silva8,9, C. Duarte8,9. 1Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 3Coimbra Institute for Clinical and Biomedical Research, Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Background: Physician’s global assessment of disease activity (PhGA) is included in some scores of disease activity and, demonstrably, plays a major role upon treatment decisions in rheumatoid arthritis (RA) [1, 2, 3]. Therefore, understanding the reasons underlying the physician’s assessment is crucial.

Objectives: To understand the reasons underlying the physician’s assessment.

Methods: Cross-sectional study, including consecutive RA patients followed in a Tertiary Rheumatology Department. Socio-demographic (age and gender) and clinical data were collected through a standardized protocol, including 28 tender (TJC28) and swollen (SJC28) joints count, C-Reactive Protein (CRP), Erythrocyte Sedimentation Rate (ESR), Disease activity Score (DAS28-4v-CRP and DAS28-4v-ESR), PhGA and Patient Global Assessment of disease Activity (PGA) through a Visual Analogic Scale (VAS) 0-100mm, Health Assessment Questionnaire (HAQ), European Quality of Life-5 Dimensions (EQ-5D) and Hospital Anxiety and Depression Scale (HADS). Correlation between PhGA and other continuous variables was evaluated through Pearson’s Correlation Coefficient and variables with p<0.05 in univariate analysis were included in multivariable linear regression (stepwise model).

Results: 392 RA patients (80.6% female, 65.3±12.6 years) were included. PhGA was weakly correlated with CRP (r=0.23), TJC28 (r=0.35), PGA (r=0.26), HAQ (r=0.33) and ESR (r=0.32). Moderate correlations were observed vs. SJC28 (r=0.45) and DAS-4v-ESR (r=0.48). In multivariable analysis, SJC28 (β=0.14, 95% CI:0.13-0.16-5.12), CRP (β=0.22; 95% CI: 0.02-0.03), HAQ (β=0.46, 95% CI:1.50-7.42) and PGA (β=0.08; 95% CI:0.00-0.16) remained as independent correlates of PhGA (R2=0.27, p<0.05).

Conclusion: In this study, PhGA was associated with SJC28, CRP, HAQ and PGA, suggesting dependence on a comprehensive reading of the disease into account. However, a large proportion of the variance of PhGA remains unexplained. Given its driving role in treatment decisions, the need to standardize and better understand PhGA seems to deserve a closer attention.

ANTI CARBAMYLATED PROTEIN ANTIBODY IN INDIAN POPULATION WITH RHEUMATOID ARTHRITIS – A BETTER PREDICTOR OF DISEASE OUTCOME

L. Sreekumar1, M. Cb2, M. Pillai3, A. T. Ommer4, T. C. Vashnu5. 1Anmita Institute of Medical Science, Kochi, India; 2AIMS, Kochi, India; 3Nairs Hospital, Kochi, India

Background: While diagnosis of RA relies mainly on detection of RF and ACCP antibodies at present, anti carbamylated protein antibody which has strong association with severe joint damage and poorer disease outcome can be found in even healthy individuals years before onset of symptoms of RA thus enabling early initiation of DMARDs and reducing complications of RA. Objectives: Assess prevalence of anti-CarP Ab in RA patients in India and assess correlation between joint involvement, X-ray erosions and extra articular features between anti-CarP Ab positive and negative RA patients. Methods: Cross-sectional study (2017-2019) conducted among 150 RA patients who met 2010 ACR/EULAR criteria in tertiary referral hospital. Tests for CRP, RF and ACCP were done, DAS28-CRP scores were calculated at presentation & X-ray images of hands and feet obtained. Anti-CarP Ab was tested using ELISA. Cut-off level for positivity was defined as a sensitivity of 92.73%.

Results:

Venn diagram representing overlap of sero-markers

Venn diagram representing overlap of sero-markers

Association between DAS28 CRP and anti-CarP Ab

Also while 39 of 71 (54.9%) anti-CarP Ab positive RA cases had joint deformities and 23 of 71 (32.4%) of anti-CarP Ab positive cases had extra articular involvement and were statistically significant, 27 of 71 anti-CarP Ab positive cases showed joint erosions in X-ray but was not statistically significant.

In comparison, only extra articular involvement showed a statistical significance in ACCP positive patients whereas joint deformities and joint erosions on X-rays showed no correlation to ACCP.

THU0114

CERTOLIZUMAB PEGOL IN PATIENTS WITH RHEUMATOID ARTHRITIS: POOLED EFFICACY ANALYSIS OF PHASE 3 CLINICAL TRIALS ACROSS BASELINE RHEUMATOID FACTOR QUARTILES

V. Tanaka,1, Z. Li,2, N. Inanc,3, R. Xavier,4, N. Tilt,5, C. Cara,6, C. Saadoun,5, T. Takeuchi7. 1University of Occupational and Environmental Health, First Department of Internal Medicine, Kitakyushu, Japan; 2Peking University People’s Hospital, Department of Rheumatology & Immunology, Beijing, China; 3Marmara University School of Medicine, Division of Rheumatology, Istanbul, Turkey; 4Federal University of Rio Grande do Sul, Rheumatology Service, Porto Alegre, Brazil; 5UCB Pharma, Brussels, Belgium; 6Keio University, Division of Rheumatology, Tokyo, Japan

Background: The presence of rheumatoid factor (RF) in patients (pts) with rheumatoid arthritis (RA) is associated with higher disease activity, and is regarded as a risk factor for more aggressive RA. Most studies on anti-tumour necrosis factor (TNF) monoclonal antibodies such as infliximab, etanercept and adalimumab have shown better response in pts with negative versus positive and low versus high baseline RF titres. Certolizumab pegol (CZP), a PEGylated, Fc-free monoclonal antibody targeting TNF, has shown rapid and sustained reduction in signs and symptoms of RA in pts with negative baseline RF titres. The aim of this analysis was to evaluate the pooled clinical efficacy and safety of CZP in RA pts across baseline RF quartiles.

Analysis

Overall 660 Pts with RA (52.3 Years, 85.1% Women, 55.3% RF+ and 39.4% low RF) from 11 Trials were included. At Week 24, mean 28-joint DAS28-CRP improved by 2.04 SD 1.76 in low RF Quartile (Q1) and by 1.96 SD 1.64 in high RF Quartile (Q4) (p=0.007) (Table 1). CRP decreased by 0.45 SD 0.44 in Q1 and by 0.39 SD 0.38 in Q4 (p=0.015). CSA and VAS improved by 59.6% SD 22.5 and 34.6% SD 9.8 in Q1 and by 48.1% SD 32.1 and 29.0% SD 11.4 in Q4 (p=0.013 and 0.026). DAS28 CRP >3.2 were present in 38.3% of Q1 and in 48.0% of Q4 (p=0.019) after 24 weeks. 81.0% of Q1 vs 49.0% of Q4 pts had low DAS28 CRP >3.2 (p=0.001).

No differences were found between quartiles in the proportion of pts with swollen joints, tender joints, morning stiffness or in the proportion of pts with ≥4 swollen, ≥4 tender joints, ≥30 minutes of morning stiffness. 59.6% of Q1 vs 52.0% of Q4 pts had ≥4 swollen joints (p=0.32) and 73.9% of Q1 vs 71.1% of Q4 pts had ≥4 tender joints (p=0.79). 93.5% of Q1 vs 88.9% of Q4 pts had ≥30 minutes of morning stiffness (p=0.36).

Conclusions: CZP was efficacious in RA pts across all baseline RF quartiles. Post-hoc analysis showed significantly higher improvements in DAS28 CRP, CRP, CSA and VAS in low RF quartile compared to high RF quartile at Week 24. The rate of pts with ≥4 swollen joints, ≥4 tender joints or ≥30 minutes of morning stiffness were similar across RF quartiles. Results for 24-week pooled efficacy analysis of CZP in RA pts across baseline RF quartiles are consistent with previous studies and support the use of CZP across all RF titres in RA.

DOI: 10.1136/annrheumdis-2020-eular.5420
moderate to severe RA, inhibition of radiographic progression and improvements in physical function in pts with an inadequate response to methotrexate (MTX). 5, 6 The efficacy of CZP in pts with different baseline RF levels has not been studied.

Methods: In this post-hoc analysis, data were pooled from four clinical trials of CZP in RA: two global trials (RAPID 1, NCT00152386 and RAPID 2, NCT00175877), a Japanese trial (J-RAPID, NCT00791999) and a Chinese trial (RAPID-C, NCT02015165). Pts <18 years with adult-onset RA for >3 months (defined by ACR 1987 criteria), who received MTX for >=6 months (RAPID-C) prior to baseline, were randomised 1:1 to receive placebo (PBO) every two weeks (Q2W)/CZP 400 mg Q2W/CZP 200 mg Q2W (CZP 400 mg at Weeks [Wks] 0/2/4) plus MTX for at least 24 Wks. Complete study design and pt characteristics were reported previously. 5, 6 Here we include only pts who received CZP 200 mg Q2W/CZP 400 mg at Wks 0/2/4). RF titres were measured by validated assays in local hospital laboratories. Pts were stratified into quartiles based on pooled baseline RF levels: <25.0, <78.5, <207.0 and >=207.0 IU/mL. DAS28(ESR) categories were adopted to stratify pts: remission (REM), DAS28(ESR) <2.6; low disease activity (LDA), DAS28(ESR) <3.2. Missing values were imputed using last observation carried forward.

Results: Data were pooled from 1,017 and 504 pts in the CZP 200 mg Q2W and PBO Q2W groups, respectively. At baseline, mean (SD) DAS28(ESR) was similar with PBO vs CZP across RF quartiles (6.5 [9.0] – 7.0 [9.0] vs 6.6 [9.0] – 7.0 [9.0]). Compared with the PBO group, numerically higher DAS28(ESR) REM and LDA rates were observed for CZP 200 mg Q2W group at Wk 24 across RF quartiles (Figure 1). DAS28(ESR) REM and LDA responder rates increased to Wk 24 in pts treated with CZP. In general, LDA and REM rates were similar across RF quartiles at all timepoints (Figure 2).

Conclusion: Over 24 Wks of treatment, trends showed steady efficacy of CZP across baseline RF quartiles in pts with active RA. In this pooled post-hoc analysis, efficacy of CZP appeared to be consistent and independent of RF levels; observed efficacy may be related to the unique molecular structure of CZP; CZP treatment in association with MTX may be a feasible option in pts with RA regardless of baseline RF status.

THU0115 THE VALUE OF KL-6 AS A PREDICTIVE FACTOR OF ACUTE EXACERBATION IN PATIENTS WITH RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE.

N. Tanaka1, K. Nishimura1, D. Waki1, K. Kadoba1, T. Yoshida1, H. Murabe1, T. Yokota1, 1Kurashiki Central Hospital, Department of Endocrinology and Rheumatology, Okayama, Japan

Background: Acute exacerbation (AE) is a life-threatening complication in connective tissue disease (CTD) associated interstitial lung disease (ILD) (CTD-ILD), including rheumatoid arthritis (RA). Although several risk factors for AE in CTD-ILD have been suggested, these are inconsistent. Krebs von den Lungen-6 (KL-6) is reported as a useful blood marker to detect severe CTD-ILD and RA-ILD, and serum KL-6 levels are significantly higher in patients with AE than in those without AE in RA-ILD patients [1]. However, the predictive value of KL-6 for AE in CTD-ILD or RA-ILD has not been completely confirmed.

Objectives: To investigate the predictive factors for AE including initial serum KL-6 levels at RA-ILD onset and sequential changes of KL-6. We also examined the causal relationship between AE and mortality of RA-ILD patients.

Methods: We retrospectively reviewed 115 patients with RA-ILD treated in our hospital between 2005 and 2019. Suspected drug-induced pneumonia cases or patients with other coexisting CTD were excluded. Cox regression analyses were used for univariate analysis to detect predictors of AE. Overall survival rate, respiratory-related deaths-free survival rate and AE-free survival rate were analyzed using the Kaplan-Meier method. P < 0.05 was considered statistically significant.

Results: Among 115 patients, 29 patients (25.2%) developed AE and 32 patients (27.8%) died. The median follow-up period (IQR) was 57 (25.9–19.5) months, 57.4% were female and the mean age at RA-ILD onset was 72.2 ± 7.9 years old throughout the whole cohort. Among the AE group, methotrexate (MTX), tumor necrosis factor a inhibitor (TNFi) and non TNFi biological (DMARDs) were used at AE onset in 10.0%, 0.0%, and 3.6% of patients, respectively. There was a significant difference of serum KL-6 levels at AE onset between AE group and non-AE group (108.9 ± 624.7 vs 556.1 ± 285.6 U/mL, p < 0.001). Initial serum KL-6 levels at RA-ILD onset in AE group were higher than those in non-AE group, without a significant difference (648.9 ± 325.7 vs 523.7 ± 276.8 U/mL, p = 0.050). The optimal cut-off level of initial serum KL-6 to predict AE was 551 U/mL according to ROC analysis. In univariate analysis, the following factors were significantly associated with AE: usual interstitial pneumonia (UIP) pattern on HRCT at AE onset (Hazard Ratio [HR] 2.18; 95%
confident interval [CI]: 1.02-4.61; p = 0.045), initial serum KL-6 > 551 U/mL at RA-ILD onset (HR: 2.48; 95%CI: 1.17-5.43; p = 0.018), increasing serum KL-6 levels > 10% before AE onset compared to the previous year (ΔKL-6 > 10%/ year) (HR: 4.98; 95%CI: 2.17-11.84; p < 0.001). Initial serum KL-6 > 551 U/mL at RA-ILD onset and ΔKL-6 > 10%/year before AE were also significant prognostic factors for AE when we analyzed only in non-UIP patients (HR: 2.84; 95%CI: 1.15-7.35; p = 0.024, HR: 9.49; 95%CI: 3.02-36.25; p < 0.001, respectively). Conversely, median age at RA-ILD diagnosis, positive ratio of anti-CCP antibody, smoking habits, respiratory comorbidities, SDAI score, and therapies at both RA-ILD and AE onset had no significant associations with AE. Patients with initial serum KL-6 > 551 U/mL at RA-ILD onset and ΔKL-6 > 10%/year before AE had a significantly worse AE-free survival rate compared to others (p < 0.001). (Figure 1). Moreover, patients with AE had significantly lower overall survival rate (p < 0.001) and respiratory-related deaths-free survival rate (p < 0.001) than those without AE.

**Figure 1.** KL-6 was measured at RA-ILD onset. ΔKL-6 means the annual variation ratio of KL-6 before AE. The survival curve using the Kaplan Meier method (Log rank test).

**Conclusion:** Serum KL-6 levels at the disease onset and its sequential changes may be able to predict AE in the near future and support the early detection of AE in RA-ILD patients.

**THU0116**

**IS THE ROLE OF MEDICAL CONSULTATION IN RHEUMATOID ARTHRITIS A TIMELY TOPIC?**

F. Ingegnoli1,2, T. Ubiali1,2, T. Schioppo2,3, S. Ostuzzi2, R. Caporali1,2, 1Clinical Rheumatology Unit, G Pini Hospital, Milan, Italy; 2Università degli Studi di Milano, Dept of Clinical Sciences & Community Health, Milan, Italy; 3ALOMAR Lombard Association for Rheumatic Diseases, Milan, Italy

**Background:** Despite the treat-to-target recommendations and the efforts in dissecting factors that contribute to achieving disease control, the goal of remission in rheumatoid arthritis (RA) is accomplished in less than half of patients. Disease activity is assessed using composite indexes which are reliant on patient-reported outcomes, mainly the patient global assessment of disease activity (PGA). The debate on variables that can influence PGA is still open, and different internal and external factors had been taken into account: the origin of pain symptoms, psychosocial and lifestyle factors.

**Objectives:** To canvass the opinion of RA Italian patients concerning patient-perceived topics that matter most for future research.

**Methods:** A cross-sectional no-profit on-line anonymous survey was devised to evaluate opinions of the rheumatic diseases patients. In this sub-study we focused only on the data about RA patients. Patients were asked to rate the following topics: food/nutrition, air pollution, smoking, type of work, social participation, physical activity, emotional well-being/stress, alternative medicine, patient-physician relationship. Moreover, patients were inquired about why the topic was considered important (disease prevention, stop disease progression, control symptoms, cure the disease). The survey was disseminated between June and October 2019. Descriptive statistics were used to summarize the patient demographic, clinical data and survey results.

**Results:** 94% (82/87) of RA patients (81 female, median age 50 yrs) rated the patient-physician relationship as the main topic for future research (figure below). Likewise, intriguing results came from the reasons of previous patient rating: the patient-physician relationship was considered important for a better control of RA symptoms (48.8%), to cure the disease (30.5%), to stop disease progression (19.5%), and to prevent the disease (12.1%). These results were similar in all age groups.

**Conclusion:** These results highlight that the importance of medical consultation to patients and its impact on disease control should not be under-estimated. Administrative duties, time and economic constraints undermine the patient-physician relationship that is central to clinical care. The limited time spent for medical consultation is directly related to patient dissatisfaction, which in turn, may influence the patient’s perception about the absence of disease activity and could be one of motives behind the worse evaluation of PGA.

**PERSONS AT RISK OF RHEUMATOID ARTHRITIS OR AXIAL SPONDYLOARTHRITIS HAVE DIFFERENT PERCEPTIONS ON PREVENTIVE INTERVENTION THAN RHEUMATOLOGISTS**

L. Van Boheemen1, J. W. Bott2, M. Ter Wee1, H. De Jong3, M. Van de Sande2, D. Van Schaardenburg1, 1AMSTERDAM UMC | Reade, Amsterdam, Netherlands; 2AMSTERDAM UMC, Amsterdam, Netherlands

**Background:** Persons at risk of developing rheumatoid arthritis (RA) may benefit from lifestyle1 or pharmacological2 intervention aimed at primary prevention. Although less studied, the same may apply to persons at increased risk of axial spondyloarthritis (axSpA)3. Patients’ perceptions and physicians’ views of risk and benefit have an important influence on patients’ willingness to use treatment as previously shown in axSpA.

**Objectives:** Our aim was to investigate and compare the willingness of individuals at-risk of RA or axSpA and rheumatologists to initiate preventive intervention.

**Methods:** Individuals at risk of RA, defined as arthralgia and anti-citrullinated protein antibodies (ACPA; >10 kU/l) and / or rheumatoid factor (RF; >5 kU/l) without arthritis, (Reade pre-RA cohort; n=100), healthy first degree relatives (FDR) of HLA-B27 positive axSpA patients (Amsterdam UMC pre-SpA cohort; n=38) and Dutch rheumatologists (n=49) completed a survey on preventive intervention in the at risk phase of RA (pre-RA cohort and rheumatologists) or axSpA (Pre-SpA cohort). The survey included questions on lifestyle intervention, disease perception and scenarios varying in disease risk, treatment effectiveness and side effects of hypothetical preventive medication.

**Results:** Overall participants depicted RA and axSpA to be a serious disease (RA: median VAS (0-10) 6.5, IQR 5-8; SpA: median VAS 6, IQR 4-8). Despite some concern about their increased risk, most persons did not expect to develop the disease (both: median VAS 3, IQR 1-5). Persons who considered RA to be a serious disease were more likely to start preventive intervention (OR 1.14, 95%CI 1.00;1.31). 100% of at risk patients were willing to change at least 1 of 13 lifestyle
components: i.e. smoking, alcohol consumption, exercise and diet and in total a medium number of 7 (pre-RA: IQR 4-10, pre-SpA: IQR 5-8) while 35% of rheumatologists gave lifestyle advice to $\geq$50% of at risk patients (most often smoking cessation.

At 30% disease risk, the willingness to use 100% effective preventive medication with no side effects was 53% (pre-RA), 55% (pre-SpA) and 74% (rheumatologists) which increased at 70% disease risk to 69% (pre-RA) and 92% (pre-SpA and rheumatologists). At 30% disease risk and minor side effects, willingness was 26% in pre-RA, 29% in pre-SpA and 31% by rheumatologists and at 70% disease risk 40%, 66% and 76% for pre-RA, pre-SpA and rheumatologists respectively. Differences between rheumatologists and persons at risk are shown in table 1. Of the rheumatologists 16% indicated that a 30% RA risk in 3 years was needed to start preventive therapy and another 16% preferred a 70% risk before starting medication.

<table>
<thead>
<tr>
<th>Disease risk</th>
<th>% of persons at risk for RA willing to use medication</th>
<th>% of persons at risk for SpA willing to use medication</th>
<th>Difference between rheumatologists and persons at risk for RA</th>
<th>Difference between rheumatologists and persons at risk for SpA</th>

<td>0.964</td>
</tr>
</tbody>
</table>

Conclusion: Disease risk perception and willingness to start preventive intervention were comparable between pre-SpA and pre-RA patients. They seem willing to make several lifestyle changes to decrease disease risk and were generally willing to use medication in case of a clearly increased risk. Rheumatologists were overall more likely than at risk individuals to start preventive medication. Lifestyle advice was given less frequently by rheumatologists contrasting with individuals high willingness to adjust lifestyle.

FREQUENT SELF-ASSESSMENTS PROMOTED TREAT-TO-TARGET FOR RA VIA EMPOWERING PATIENTS: A COHORT STUDY FROM CHINA BY SMART SYSTEM OF DISEASE MANAGEMENT (SSDM)

J. Yang1, R. Mu2, C. Li2, B. Wu3, H. Wang4, W. Fan5, J. Zou1, Y. Zhang1, F. Li6, X. Rong1, J. Wu7, Y. Wang8, S. Li9, Y. Zhao10, X. Hou10, H. Xiao10, B. Wu11, Y. Zhao11, Y. Jia12, F. Xiao13, Z. Li14 on behalf of SSDM Collaboration Group, China; 1Central Hospital of MianYang, MianYang, China; 2People’s Hospital, Beijing University Medical School, Beijing, China; 3Chongqing Hospital of Traditional Chinese Medicine, Chongqing, China; 4JiaXing First Hospital, JiaXing, China; 5Central Hospital of XinXiang, XinXiang, China; 6The Second Xiangya Hospital of Central South University, Changsha, China; 7The First Affiliated Hospital of Chongqing Medical University, Chongqing, China; 8Dazhou Central Hospital, Dazhou, China; 9The First Affiliated Hospital to AMU, Chongqing, China; 10Peiking University International Hospital, Beijing, China; 11Xuanwu Hospital, Capital Medical University, Beijing, China, Beijing, China; 12Yichang Central People’s Hospital, Yichang, China; 13Shanghai Gothic Internet Technology Co., Ltd., Shanghai, China

Background: Treat-to-Target (T2T) strategy are critical for the treatment of RA, but Chinese rheumatologists can hardly provide patients with a complete assessment in the clinic due to limited time. According to DAS28 scores, disease activity of the cohort was divided into four groups: remission (Rem), low (LDA), moderate (MDA) and high (HDA) disease activity. T2T, achieving a DAS28 score lower than 2.6 (Rem) or below 3.2 (LDA), is the main management strategy recommended by ACR and EULAR.

Objectives: To evaluate the patterns of T2T and related influential factors among RA patients after applying SSDM with repeated self-assessment in the real world.

Methods: SSDM is a mobile application for disease management. Patients were trained to do DAS28 assessment with SSDM and required for repeating self-assessment after leaving the hospital. After entry by patients, data can be synchronized to the SSDM terminal of authorized rheumatologists. Based on the patients’ data, rheumatologists will provide medical advices to them.

Results: From Jan 2015 to Jan 2020, 68,103 RA patients enrolled in SSDM. The mean age of 51.58±12.86 years old and median disease duration is 3.83 years. 52,355 patients performed self-assessment of DAS28, HAQ and morning stiffness duration totally for 114,792 times. Proportion of patients in Rem, LDA, MDA and HDA was 26%, 17%, 44% and 13% respectively at baseline. Among them, 5,486 RA patients from 219 hospitals across China were followed up for more than 12 months through SSDM. The rate of T2T achievers were 50.20% (2,755/5,488) at baseline, and improved significantly to 65.14% (3,575/5,488) after 12 months follow up, p<0.05. Among T2T achievers at baseline, 77.20% (2,127/2,755) maintained T2T, 22.80% (628/2,755) relapsed. Of patients who didn’t achieve T2T at baseline, only 56.75% (1,551/2,733) achieved T2T after 12 months follow up. The frequency of self-assessment for DAS28 on T2T has been analyzed. Results indicated that the more frequent the self-assessments being performed by patients, the higher improvement of T2T rate will be. The improvement rates of T2T in the subgroups which self-assessed with SSDM by annually, semiannually, quarterly, bimonthly, monthly and more frequent than monthly were 74.9%, 10.40%, 16.29%, 18.73%, 20.13% and 22.77% respectively. The improvement rate (y) of T2T was positively correlated with the frequency of self-assessment for DAS28 (y) independently. The regression equation as “y = 0.0309x + 0.0517”, r = 0.9785, p<0.01 (Figure 1).

Conclusion: Significant improvement was observed under applying SSDM through empowering RA patients. After proactive disease management via SSDM for more than 12 months, patients with DAS28<3.2 score at baseline had a significantly higher retention rate of Rem disease activity. The patients who performed more frequent self-assessments had lower probability of relapse and higher rate of T2T. SSDM is a valuable tool for long term follow up through empowering patients.

THU0119

COULD SYNOVITIS AND TENOSYNOVITIS DETECTED BY ULTRASOUND BE CONSIDERED A RISK FACTOR FOR SHORT-TERM FLARE IN RA PATIENTS IN CLINICAL REMISSION

J. Zacarías H1, M. Brom1, F. Mollerach1, J. Marin1, L. Ferreyra G1, J. Rosa1, E. Soriano1, 2Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina

Background: The clinical value of ultrasound (US) detected synovitis and tenosynovitis as predictors of flares in RA patients in clinical remission is not clear.

Objectives: To investigate the value of US detected synovitis and tenosynovitis as risk factors for short term flare in RA patients in clinical remission.

Methods: Patients with RA in clinical remission were enrolled in the study. Ultrasound (US) examination of the hands and wrists were performed with a linear probe (SonoScape E6) using high frequency ultrasound (6-18 MHz) at the following locations: thenar and hypothenar eminence, flexor carpi radialis, extensor carpi radialis, palmar and dorsal carpal synovial compartments. Images were reviewed at the end of the visit. The presence of synovitis and tenosynovitis was recorded according to the EULAR ultrasound scoring system.

Significant improvement was observed under applying SSDM through empowering RA patients. After proactive disease management via SSDM for more than 12 months, patients with DAS28<3.2 score at baseline had a significantly higher retention rate of Rem disease activity. The patients who performed more frequent self-assessments had lower probability of relapse and higher rate of T2T. SSDM is a valuable tool for long term follow up through empowering patients.

Acknowledgments: SSDM was developed by Shanghai Gothic Internet Technology Co., Ltd.

Disclosure of Interests: None declared

DO: 10.1136/annrheumdis-2020-eular.3038
**Methods:** Consecutive RA patients in clinical remission (DAS28 ERS < 2.6) for at least 3 months, underwent Power Doppler ultrasound (PDUS) examination of: 1st to 6th extensor compartments at the wrist, 2nd to 5th flexors, posterior tibial tendons and peroneals. Regarding joints, carpal joints, 1st to 5th MCP and 2nd to 5th interphalangeal proximal (IPP). Synovitis and tenosynovitis were defined according to OMERACT. Patients were followed for one year. Disease flare was defined as any increase of disease activity generating the need of change in therapy by the attending rheumatologist.

**Results:** Ninety patients were included. Patients' characteristics are shown in the table. After one year of follow-up, 26 patients (29%) experienced a flare. At baseline 39%, 23% and 8% had US detected synovitis, tenosynovitis or both respectively. The presence of US detected tenosynovitis (RR: 4.9; 95% CI: 2.2-10.8), but not of US detected synovitis (RR: 1.3; 95% CI: 0.76-2.2), showed an increased risk of having a flare. In the multivariable analysis, and after adjusting by age, gender, disease duration, DAS28, DMARDs and biologics use, and the US detected synovitis, only subclinical tenosynovitis (OR: 9.8; 95% CI: 2.5-39.1; p=0.001) and baseline DAS28 (OR: 7.5; 95% CI: 1.1-31.6; p=0.047) were significantly associated with an increased risk of flare.

**Conclusion:** Subclinical tenosynovitis, but not synovitis, was associated with disease flare in patients with RA in clinical remission. This feature might have physio-pathological implications.

**THU0121 OVERLAPPING SJÖGREN’S SYNDROME AND ULTRASOUND REMISSION, FUNCTIONAL DISABILITY AND MANAGEMENT IN RHEUMATOID ARTHRITIS PATIENTS: A PROPENSITY SCORE MATCHED REAL-WORLD COHORT FROM 2009 TO 2019**

H. Zhang1, H. Zhang2, D. Gao1, Z. Zhang1, 1Peking University First Hospital, Beijing, China

**Background:** Rheumatoid arthritis (RA) patients with Sjögren's syndrome (SS) are often referred to as more severe synovitis.

**Objectives:** To clarify the impact of overlapping SS on ultrasound remission, functional ability improvement and clinical decision-making in RA patients in a real-world cohort from 2009 to 2019.

**Methods:** The medical records of RA patients in our medical center from 2009 to 2019 were reviewed. Cox proportional hazards models of ultrasound remission and health assessment questionnaire (HAQ) improvement were conducted in both the 1-to-1 nearest propensity score matched (PSM) and unmatched cohorts between those RA patients with SS (RA-SS) and without (RA-noSS) to correct critical confounders. Four kinds of PSM methods were used and the correspondingly average treatment effect on the treated (ATT) was calculated to clarify the effect of overlapping SS on distinguishable characteristics or drug prescription in RA patients.

**Results:** A total of 1100 RA patients were included in the study, of which 133 (12.1%) overlapped with SS. Among 256 patients consisting of 128 RA-SS and 128 RA-noSS after 1-to-1 nearest PSM, overlapping SS was associated with a 44%, 32% lower probability of reaching ultrasound remission, no-functional disability in RA patients, respectively. More prevalent interstitial lung disease (ILD), leukopenia, hypergammaglobulinemia, rheumatoid factor (RF) positivity, higher erythrocyte sedimentation rate (ESR) and more hydrochloroquine (HCQ) usage, less biologic disease-modifying anti-rheumatic drugs (bDMARDs) prescription were confirmed to be correlated with overlapping SS by the robust PSM.

**Conclusion:** Overlapping SS is associated with a lower probability of reaching ultrasound remission and functional activity improvement, higher prevalence of ILD, leukopenia and hypergammaglobulinemia in RA patients. Weaker interventions such as HCQ may be the mainstream of clinical decision making.

Rheumatoid arthritis - comorbidity and clinical aspects

---

**THU0121 COMORBIDITIES AT DIAGNOSIS OF RHEUMATOID ARTHRITIS**

L. Tjörned, H. Westerlin, J. Asking, S. Sævarsdottir and K. Kolariinska Instituttet, Department of Medicine, Stockholm, Sweden, University of Iceland, Faculty of Medicine, Reykjavik, Iceland

**Background:** Although many studies have reported an increased burden of comorbidities in patients with rheumatoid arthritis (RA), and their impact on RA outcomes, few studies have compared the pattern of comorbidities already at diagnosis of RA, in relation to the burden among matched control subjects. Only such a comparison can inform on which comorbidities are increased already before RA diagnosis, presumably due to overlapping causal factors, and which arise as a consequence of the RA disease or its treatment.

**Objectives:** The aim of this study was to investigate the pattern of common chronic conditions in patients with RA, overall and stratified by serological status, at the time of diagnosis, compared to a matched control group reflective of the general population.

**Methods:** This nationwide study included patients with a new-onset RA diagnosis, using data from the Swedish Rheumatology Quality register, from 2006 to 2015. We included 11,086 incident RA cases, of whom 62% were seropositive. From the Total Population Register, we identified 54,813 population controls, individually matched on age, sex and county of residence. Information about registered comorbidity diagnoses during the five years up until the RA diagnosis was retrieved from the Swedish National Patient Register. Information on dispersed drugs during the year up until the RA diagnosis was collected from the Prescribed Drug Register. Comorbidity diagnoses were grouped into 10 different categories (see table 1). Logistic regression was
used to compare comorbidities between cases and controls, adjusted for the matching variables.

### Table 1. Relative risk of comorbidities at RA diagnosis, overall and by serological status

*All ORs are adjusted for sex and age, and cases with RA are compared to their individually matched controls.*

### Results:
In seropositive as well as in seronegative RA, comorbidities within the respiratory (OR 1.58, 95% CI 1.44-1.74), gastrointestinal (OR 1.17, 95% CI 1.31-1.47), infectious (OR 1.12, 95% CI 1.03-1.23), endocrine (OR 1.39, 95% CI 1.31-1.47) and neurological (OR 1.73, 95% CI 1.59-1.89) categories were more common already at the time of RA diagnosis, compared to the matched population controls, as outlined in Table 1. A history of cardiovascular disease was slightly increased among patients with seronegative RA (OR 1.20, 95% CI 1.07-1.36), and no increase was seen for non-cardiac vascular diseases. A history of psychiatric (OR 0.87, 95% CI 0.80-0.93) and cancer diagnoses (OR 0.81, 95% CI 0.71-0.93) was less common in seropositive RA vs. their matched controls. In terms of comorbidity burden, 15% of all RA patients had diagnoses from at least two of the ten comorbidity categories vs. 13% of the controls and 8% vs. 8% of diagnoses within three or more comorbidity categories.

### Conclusion:
This large nationwide study demonstrates a marked increase in several comorbidities, in particular respiratory, endocrine and neurological diseases, already at, and before, the diagnosis of RA compared with age and sex matched controls, while psychiatric diagnoses are less common. These findings are important for the interpretation of comorbidity studies in established RA.

Figure 1. Prevalence of comorbidities in Swedish patients with newly diagnosed RA compared to the matched controls.* p < 0.05

**THU0122**  EFFECT OF THE METABOLIC SYNDROME ON RENAL FUNCTION DECLINE IN FOUR RHEUMATIC DISEASES: AN 8-YEAR LONGITUDINAL ANALYSIS

C. C. Mok1, C. S. Chu1, L. Y. Ho1, K. L. Chan2, S. M. Tse1, C. H. To3 on behalf of NA. 1Tuens Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR); 2Pok Oi Hospital, Medicine, Hong Kong, Hong Kong (SAR)

### Background:
Objectives: To study the effect of the metabolic syndrome (MetS) on renal function decline in four rheumatic diseases.

Methods: Consecutive patients who fulfilled the ACR/SLICC criteria for systemic lupus erythematosus (SLE), EULAR/ACR criteria for rheumatoid arthritis (RA), ASAS criteria for spondyloarthritides (SpA) and the CASPAR criteria for psoriatic arthritis (PSA) were recruited in 2009/2010. At entry, patients recruited had measurement of body weight, height, waist circumference and blood pressure. MetS was defined by the updated joint consensus criteria, using the Asian criteria for central obesity, when ≥3 of the following were present: (1) waist ≥80cm in men or ≥90cm in women; (2) blood pressure ≥130/85mmHg or requiring therapy; (3) serum triglyceride level ≥1.7mmol/L; (4) serum HDL-cholesterol ≤0.9mmol/L in men and ≤0.9mmol/L in women; and (5) fasting glucose ≥5.6mmol/L. Renal function of the participants was assessed by the 4-variable MDRD formula (eGFR). Patients were followed longitudinally for eGFR change. Change in eGFR was compared between those with and without the MetS at baseline. Regression analysis was performed for the effect of MetS on eGFR decline adjusted for other confounding factors.

### Results:
1497 patients were studied (693 RA, 577 SLE, 121 SpA and 106 PSA). The age at entry was highest in RA (53.4±12.0 years) and lowest in SpA (39.0±11.9 years). Disease duration was longest in SLE (9.3±7.2 years) and shortest in PSA (3.6±2.2 years). MetS was present in 137 RA (20%), 85 SLE (15%), 13 SpA (11%) and 39 PSA (37%) patients. Patients were followed for 9.1±1.2 months. The mean decline of eGFR (mL/min/1.73m2) at last observation from baseline was 5.00±13.5 in RA, 4.16±11.6 in SpA, 3.95±12.3 in PSA and 8.93±16.4 in SLE (p<0.03; one-way ANOVA). The proportion of patients with eGFR decline by ≥10% was also greatest in SLE (41%) compared with RA (29%), SpA (24%) and PSA (25%) patients (p<0.001). Among patients with SLE, a significantly more profound drop in eGFR over 8 years was observed in patients with the MetS at baseline (-17.8±26%) than those without (-7.6±18%; p<0.002). The difference in last eGFR between the MetS with and without the MetS was significant after adjustment for baseline eGFR, age and sex (65.5±32.2 vs 88.4±24.4 mL/min/1.73m2; p<0.001). In a linear regression model, eGFR at last follow-up was significantly associated with the baseline eGFR (slope 0.72 SE 0.03; Beta 0.77; p<0.001), renal involvement (slope -4.36 SE 1.30; Beta -0.08; p=0.001) and the MetS (slope -6.88 SE 1.86; Beta -0.09; p<0.001). In patients with RA/SpA/PSA, eGFR also showed a greater trend of decline over time in those with MetS than without, but the difference did not reach statistical significance.

### Conclusion:
Among patients with common rheumatic diseases, SLE showed the greatest decline in renal function over time. The presence of MetS in SLE significantly accelerated renal function decline over time independent of the presence of renal disease. The MetS also unfavorably affected eGFR in patients with inflammatory arthritis. A more detailed analysis on the causes of eGFR decline in individual diseases and a longer period of follow-up of the renal function is needed.

RA patients without DM (RAwoDM). Further, to compare the prevalence of various types of CVD across RA-DM and RAwoDM.

**Methods:** The cohort was derived from the Surveillance of Cardiovascular Disease Risk Factor in patients with Rheumatoid Arthritis (SURF-RA), which was performed in 53 centres across 17 countries in 5 world regions (West and East Europe, North and Latin America; and Asia) from January 2014 to August 2019. Indication for AntiHT was defined as: 1) systolic/diastolic blood pressure (BP) ≥ 140/90 mm Hg, 2) self-reported hypertension, and/or 3) current use of AntiHT. Indication for LLT was defined according to European Society of Cardiology (ESC) guidelines (1), in which the Systematic Coronary Risk Evaluation (SCORE) is applied. SCORE risk estimates were multiplied by 1.5 according to EULAR recommendations. Target treatment targets for blood pressure and lipids were defined according to ESC guidelines applicable at the time when data were recorded.

**Results:** Presence of comorbid DM was available in 10 602 (73.1 %) of the 14 503 RA patients included in SURF-RA, of whom 75 and 1262 patients reported DM type 1 and type 2, respectively (total 1337 patients, 12.6 %). Although less often current smokers, RA-DM patients were more often previous smokers, male sex and had higher body mass index compared to RAwoDM (p<0.0001 for all). AntiHT (62.3 % vs 84.7 %) and LLT (100 % vs 47.2 %) were more frequently indicated in RA-DM than in RAwoDM patients (p<0.0001 for both), while the difference in LLT use on indication was not significantly different (45.7 % vs 42.5 %, p = 0.06). Moreover, RA-DM compared to RAwoDM was more likely than RAwoDM to receive AntiHT on indication (60.4 % vs 57.6 %, p<0.0001), while the difference in LLT use on indication was not significantly additive. While CVD preventive medications are more often indicated in RA-DM than in RAwoDM patients, they are also more likely to receive such therapy and to reach CVD preventive treatment goals. The latter finding may be due to more developed CVD preventive care in DM compared to RA patients. Improved CVD preventive systems for patients with RA are warranted.

**THU0125 IMPACT OF DISEASE ACTIVITY IN THE LEFT VENTRICULAR SYSTOLIC MYOCARDIAL FUNCTION OF PATIENTS WITH RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY**

E. A. Rodriguez Díaz1, D. Á. Galarza-Delgado2, J. R. Azpíri-López1, I. J. Colunga-Pedraza2, J. C. Zárate Salinas1, P. F. Frausto Lerma2, A. Pérez Villar2, M. A. Reyes Soto2, C. M. Martínez-Flores1, R. Pineda1, 1Hospital Universitario “Dr. José Eleuterio González”; UANL, Cardiology, Monterrey, Mexico; 2Hospital Universitario “Dr. José Eleuterio González”; UANL, Rheumatology, Monterrey, Mexico

**Background:** Patients with Rheumatoid Arthritis (RA) have higher incidence of cardiovascular diseases (CVD) compared to general population. There is controversy about the impact of RA disease activity on left ventricular systolic function (LVSF).1 LVSF may be assessed by conventional methods like left ventricular ejection fraction (LVEF) and myocardial shortening or by novel techniques evaluating myocardial strain such as speckle tracking echocardiography (STE).

**Objectives:** To assess the impact of RA disease activity on LVSF using ejection fraction and myocardial strain by STE.

**Methods:** Observational, cross-sectional study. RA patients aged 40-75 years that fulfilled the 2010 ACR/EULAR classification criteria and matched controls were included. Patients with a poor US window, history of previous CVD (ischemic heart disease, cerebrovascular accident or peripheral arterial disease) and pregnancy were excluded. Individuals were evaluated using two-dimensional speckle tracking echocardiography performed and reviewed by 2 certified echocardiographers. LVEF and myocardial strains (circumferential, longitudinal and
radial) were measured; differences were solved by consensus. Descriptive analysis was done with measures of central tendency and dispersion. Student-t and Mann-Whitney U tests were used for comparisons.

**Results:** A total of 140 subjects were included. Demographic and clinical characteristics are shown in Table 1. RA patients were divided in 2 groups, according to disease activity by DAS 28-CRP (remission or low activity and moderate or high activity). Echocardiographic comparisons between RA and controls and between the 2 groups in which RA patients were divided by disease activity are shown in Table 2. The LVEF was lower in RA subjects compared with controls (p = 0.022), however LVEF was normal (> 52% in men and >54% in women) in both groups. There was a significant difference in the circumferential strain (CS) between RA patients based on the disease activity by DAS 28-CRP (p = 0.006).

**LVEF** = Left ventricular ejection fraction  
**CS** = Circumferential strain

**Conclusion:** The decrease in the circumferential strain depends on the disease activity. Myocardial strain by speckle tracking echocardiography may detect early myocardial dysfunction in RA. It is important for the rheumatologist to establish an appropriate treatment in order to achieve the disease remission or a low disease activity, as there is an impact of the disease activity on the myocardial function.

**ESTIMATED CARDIOVASCULAR RISK IN A LARGE COHORT OF RHEUMATOID ARTHRITIS PATIENTS FROM THE ”CARDIOVASCULAR OBESITY AND RHEUMATIC DISEASE (CORDIS)” STUDY GROUP OF THE ITALIAN SOCIETY OF RHEUMATOLOGY**

E. Cacciapaglia1, M. Piga2, G. Erre3, A. Manfredi4, E. Bartoloni Bocci5, G. Sakellariou6, O. Viapiana7, S. Colella7, A. Abbruzzese8, M. Dessi9, C. Vacchi10, F. Castagna11, G. Cafaro12, B. L. Palermo13, A. Giolli14, M. Fornaro1, E. Gremese15, F. R. Spinelli16, F. Atzeni17 in behalf of “RUDN University program 5-100”.

**Background:** Nocturnal hypertension (HTN) and non-dipping profile are important predictors of adverse cardiovascular (CV) outcomes. Their associations with subclinical vascular damage in rheumatoid arthritis (RA) are still a matter of investigation. It was shown that 10-year atherosclerotic CV disease risk (rASCVD) may be more accurate in CV risk prediction in RA than SCORE. Associations of impaired 24-h BP phenotypes with CV risk in RA are not well-studied yet.

**Objectives:** To assess dipping patterns and nighttime systolic blood pressure (SBPn) and their associations with arterial stiffness and CV risk assessed by rASCVD in patients with RA.

**Methods:** Study group included 90 patients with RA (females 78.7%, age 59.5±14.2 years, HTN 64%, median (med) HTN duration 6.4 years, RA duration 7.2 years, seropositive RA 66%, mean DAS-28(CRP) 3.8±1.0) and control group (45 patients matched by gender, age and risk factors). All patients with HTN received antihypertensive therapy. Office BP was measured with a validated oscillometric device, 24-hour ABPM was performed with BPLab Vasotens, carotid-femoral PWV was assessed by applanation tonometry. 3 groups were formed after adjustment of dipping state by SBPn: dippers (G1), non-dippers with SBPn>120 mmHg (G2), non-dippers with SBPn>120 (G3). CV risk in RA group was calculated as 10-year rASCVD. Risk≥7.5% was considered as high. p<0.05 was considered significant.

**Results:** Median rASCVD was 6.3%. Rate of BP control was 60% in RA and 66% in the controls (p=0.05). Patients with RA vs controls had higher mean SBP (124±16 vs 110±8 mmHg, p=0.003), lower diurnal index (DI) (med 3.8 vs 8.1%, p=0.02), higher rate of night HTN (49.6 vs 12.2% (p=0.0002). The RA and control groups didn’t differ by dipping patterns, although RA patients more often had non-dipping profile (DI<10%): 83.9 vs 61.3%, (p=0.02). RA patients with SBPn>120 mmHg had higher age (63.7±12.5 vs 52.9±14.5 years), office SBP (143±17 vs 122±13 mmHg), HTN duration (med 5.4 vs 0.5 years), PWV (10.3±3.0 vs 7.9±2.5 m/s) and rASCVD (12 vs 3.4%), p<0.001 for trend. Analysis in hypertensive RA group confirmed significant differences in PWV (11.3±3.1 vs 9.1±3.2 m/s, p=0.02) and rASCVD (med 13.5 vs 10.5%, p=0.045). Patients with DI<10% had higher age (60.9±13.8 vs 54.3±11 years, p=0.04) and rASCVD (med 8.5 vs 3.1%, p=0.02). Patients with rASCVD ≥7.5% compared to <7.5% had higher SBP (133±11 vs 112±8 mmHg), lower median DI (0 vs 10%), more often had masked HTN masked HTN (43 vs 21%), and night HTN (48 vs 16%), p<0.01 for trend. SBPn significantly correlated with age (r=0.6), office SBP (r=0.5) and DBP (r=0.4), PWV (r=0.6), rASCVD (r=0.6); non-dipping pattern – with age (r=0.2), and rASCVD (r=0.3). After adjustment by SBPn, no differences were observed between G2 and G3. Patients in G3 vs G1 had higher PWV (10.4±3.1 vs 7.6±1.7 m/s, p=0.004), CRP (med 17.5 vs 7.8 mg/l, p=0.03), rASCVD (med 12.8 vs 3.1%) (p=0.001); in G3 vs G2 – higher PWV (10.8±3.1 vs 8.2±3.2 m/s), rASCVD (med 12.8 vs 2.7%) and ESR (med 46 vs 21 mm/h, p=0.01 for trend). Conclusion: Patients with RA had higher incidence of non-dipping pattern and SBPn elevation. Combination of high SBPn and non-dipping was associated with higher arterial stiffness and CV risk – this may be mediated by inflammation. Higher CV risk was associated with masked and night HTN. This may help in defining indications for ABPM in this population.

**DOI:** 10.1136/annrheumdis-2020-eular.3863
Background: Rheumatoid arthritis (RA) patients present high cardiovascular (CV) morbidity and mortality and EULAR recommends estimating their CV-risk [1]. The Systematic Coronary Risk Evaluation (SCORE) algorithm is suggested; however, National Guidelines are lacking, but few data are available about different strategies.

Objectives: To estimate the 10-years CV-risk using different algorithms in RA compared to osteoarthritis (OA) patients, as control group.

Methods: A total of 1467 RA patients (78.3% female; mean age 59.8±11.5 years; median disease duration 131±109 months), fulfilling the 2010 EULAR/ACR classification criteria, and 342 age and sex matched patients with OA (79.8% female; mean age 58.7±11.5 years) were enrolled in this multicentre cross-sectional study, during 2019. Clinical and laboratory data were registered, and individual CV-risk was calculated using: SCORE chart, “Progetto Cuore” model (PCM), QRisk3, Reynolds Risk Scores (RRS) and Expanded Risk Score in RA (ERS-RA), as stated by suitable algorithms. Statistical analysis was performed using the Statistical System Graphpad Instat 8.0 (San Diego, CA-USA).

Results: In 46 (3%) RA patients a previous CV event was observed. Among traditional CV-risk factors, RA patients presented higher frequency of diabetes (9.9% vs 6.4%; p=0.04) and lower prevalence of dyslipidaemia (21.7% vs 32.5%; p<0.0001) compared to OA patients. Prevalence of hypertension was similar in both groups (40% vs 39.2%). Mean BMI (25.6±4.8 vs 26.6±4.4; p<0.0001) and prevalence of obesity (15% vs 21%; p=0.003) were significantly lower in RA patients. Finally, RA patients were more frequently smokers (20.4% vs 12.5% - p=0.002). 441 (30%) RA patients were in CDAI remission, 998 (68%) patients were on DMARDs while a biologic agent was used in 617 (42%) patients. About 43% of RA patients were on a mean prednisone-dose of 4.5±3.5mg/day. The 10-years CV-risk resulted 2 to 3-fold higher in RA compared to OA patients using the different algorithms. The QRisk3 estimated the highest CV risk in our cohort of patients, while the ERS-RA and RRS were significantly higher than PCM and SCORE.

Conclusion: Our study demonstrates a higher estimated CV-risk in RA compared to OA patients. The commonly used algorithms to estimate CV-risk in clinical practice perform differently, evaluating different traditional CV-risk factors and disease specific characteristic, as for QRisk3 or ERS-RA. Rheumatologist should impact on both traditional and RA related modified CV-risk factors.

Methods: Observational, cross-sectional study. RA patients aged 40-75 years that fulfilled 2010 ACR/EULAR criteria with post-menopause and matched controls (without RA) were included. Patients with history of previous athero- sclerotic CVD, women who undergone menopause due to hysterectomy or cessation of periods other than by a natural cause, women on hormone replace- ment therapy and having irregular menses were excluded. Clinical history and carotid ultrasound were performed. Increased cIMT defined as ≥0.9mm was measured using the two inner layers of the common carotid artery and carotid plaque as a focal narrowing ≥0.5mm of the surrounding lumen. Descriptive analysis was done with frequencies (%), median (q25–q75). Comparisons with Chi-square and Mann Whitney-U test. Binary regression analysis was used to test association an increased cIMT with cardiovascular risk factors and RA diagnosis.

Results: A total of 139 women with established post-menopause were included. Baseline characteristics (Table 1). Right carotid atherosclerosis prevalence was found more than twice (19% vs 8%, p=0.01) and an increased cIMT was higher in postmenopausal RA patients (right 25% vs 10%, p<0.001; left 31% vs 15%, p<0.001) compared to controls (Table 2). Binary regression showed that the odds of having RA increases three times the risk of having ≥0.9mm cIMT when adjusted to age, hypertension, dyslipidemia and active smoking OR 3.0, 95% CI (1.41-6.36) (p<0.004).

Conclusion: Despite the increase in cardiovascular risk in postmenopausal women compared to the general population, women with RA have a higher risk compared to healthy women. Carrying out cardiovascular prevention and management in patients with RA is essential, especially in those who are in a stage of post-menopause.

Objectives: To identify baseline predictors for the development of chronic fatigue in patients with RA who initiate biological DMARD (bDMARD) treatment, and to compare disease courses across categories of fatigue for 12 months follow-up.

Methods: Different trajectories of fatigue were calculated from a cohort of 209 established RA patients initiating bDMARDs. Fatigue was assessed by use of the fatigue Numeric Rating Scale (0-10) from the Rheumatoid Arthritis Impact of Disease (RAID) questionnaire. The patients were assessed at 0, 1, 2, 3, 6 and 12 months. We defined three groups: no fatigue (≤3 at all visits), improved fatigue (1-3 at baseline but ≤3 at follow-up) and chronic fatigue (≥4 at all visits). All patients had clinical/subjective assessments (28 tender/swollen joint count, assessor’s/patient’s global VAS, RAID score, widespread pain, pain catastrophizing, the Hospital Anxiety and Depression Scale and inflammatory markers (ESR, CRP and calprotectin (a major granulocyte protein sensitive for inflammation in RA patients)). All patients were assessed by ultrasound (grey scale (GS) and power Doppler (PD)) of 36 joints and 4 tendons with semi-quantitative scoring (0-3). Differences between groups at baseline was assessed by bivariate analyses, and logistic regression models adjusted for age and gender were used to explore baseline predictors of chronic vs improved fatigue. Trajectories of different groups were plotted as estimated marginal means in figures, and differences between groups assessed by mixed models with maximum likelihood random effects, adjusted for age and sex.

Results: Table 1 describes demographics and clinical factors of the three groups with significant differences shown in bold. Logistic regression with multivariate assessments found anti-CCP and low inflammation (calprotectin) to be predictors of chronic versus improved fatigue. Sleep disturbance was highly predictive of chronic fatigue. Figure 1 illustrates the trajectories for the three groups at all visits, showing the chronic fatigue group to have significantly higher DAS28, level of widespread pain, depression and sleep disturbance in contrast to no higher level of inflammation assessed by CRP and ultrasound PD.

| Catastrophizing (0-6) | | | | | | |

Conclusion: Sleep disturbance is a modifiable factor presently found to predict chronic versus improved fatigue. Thus, attention should be given to RA patients with sleep problems to seek to avoid development of chronic fatigue. This issue should be explored in further studies.

THU0130 PATTERN OF COGNITIVE DECLINE IN RHEUMATOID ARTHRITIS: RESULTS OF CASE CONTROL STUDY NESTED IN A POPULATION-BASED COHORT

T. Toyoda1, J. Chipping1, J. Dainty1, S. Jeffs1, M. Hornberger1, E. Miolo1, S. Verstappen1, M. Yates2, A. Macgregor1,2, 3Norwich Medical School, Norwich, United Kingdom; 4The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 5Norwich Medical Centre, Centre for Epidemiology Versus Arthritis, Norwich, United Kingdom; 6Ipswich Hospital, Ipswich, United Kingdom; 7Norfolk & Norwich University Hospital, Norwich, United Kingdom

Background: The risk of cognitive decline and dementia is of particular interest for patients exposed to prolonged inflammation. In rheumatoid arthritis (RA), the inflammatory mechanisms that are central to the disease’s pathology share many features with those seen in Alzheimer’s disease (AD). However, published reports on the strength and direction of the putative associations with cognitive decline and dementia in RA are conflicting and the potential impact of immunomodulation has not been fully established. This study reports on a case control analysis comparing the results of a cognitive test conducted in RA cases from a longitudinal population register with healthy controls. The relationship between test outcomes, disease characteristics, and treatment is examined.

Objectives:

• To characterise differences in cognitive function as assessed by a validated test battery between a group of patients with RA and a matched sample of healthy controls.
• To investigate disease and treatment related factors that might have an impact on the cognitive function of patients with RA.

Methods: A total of 38 people with RA were selected at random from subjects who had enrolled on the Norfolk Arthritis Register as part of the ICORA (Investigation of Cognition in RA) Study. The register is a large longitudinal inception cohort of patients recruited from both primary and secondary care. The study subjects were over 55 years old with a diagnosis of RA defined by the ACR criteria. Cognitive function was assessed using the Addenbrooke’s Cognitive Examination III (ACE-III) battery. The ACE-III is a validated screening test for dementia that evaluates five cognitive domains (attention, memory, verbal fluency, language and visuospatial skills). A cut off value of 82 is indicative of cognitive...
impairment. The ACE-III scores in the cases were compared with scores from 29 healthy population-based controls matched for age and sex.

**Results:** The mean age of the patient and control groups was 69 years. The RA patients had a mean disease duration of 9.8 years and had been taking DMARDs for 7.1 years. Among the patient group with RA, 14 (37%) scored below 82 compared with none in the group of healthy controls. The mean ACE-III scores of both groups are shown in the table below:

<table>
<thead>
<tr>
<th></th>
<th>Controls</th>
<th>RA N=38</th>
</tr>
</thead>
<tbody>
<tr>
<td>N=29</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ACE-III Total</td>
<td>95.2 (3.7)</td>
<td>85.2 (7.4)</td>
</tr>
<tr>
<td>•Attention</td>
<td>17.0 (0.5)</td>
<td>16.5 (1.9)</td>
</tr>
<tr>
<td>•Memory</td>
<td>24.6 (1.9)</td>
<td>19.8 (4.0)</td>
</tr>
<tr>
<td>•Fluency</td>
<td>12 (1.1)</td>
<td>9.9 (2.6)</td>
</tr>
<tr>
<td>•Language</td>
<td>25.5 (0.8)</td>
<td>24.6 (1.7)</td>
</tr>
<tr>
<td>•Visuospatial</td>
<td>15.8 (0.5)</td>
<td>14.4 (1.5)</td>
</tr>
</tbody>
</table>

After adjusting for age, sex, BMI and smoking status, significant differences were seen in the ACE-III total (adjusted mean difference(SE)=8.071(1.77); p<0.001), memory (adjusted mean difference(SE)=4.16(1.03); p<0.001), fluency (adjusted mean difference(SE)=2.29(0.87); p=0.001) and visuospatial (adjusted mean difference(SE)=1.36(0.38); p<0.001). There was no difference in attention (p=0.19) or language (p=0.10).

Among the patients with RA there was no clear association between disease duration and ACE-III Total scores; however, there was a trend for increasing cognitive scores in those who had been taking DMARDs for longer (<5 years: mean ACE-III Total 84.1; 5-10 years: 85.0; >14 years: 89.6).

**Conclusion:** This study provides evidence to suggest that patients with established RA are at increased risk of cognitive decline when compared with healthy controls. The pattern of cognitive deficit, predominantly involving visuospatial and memory function, is consistent with an Alzheimer's disease profile. Our data suggest a potential role for DMARDs in reducing the rate of cognitive decline in patients with RA.

**Disclosure of Interests:** No relevant disclosures.

**Background:** The frequency of pulmonary rheumatoid nodules closely relates to the cognitive diagnosis and changes from 0.4% to 32% [1]. However, data regarding pulmonary rheumatoid nodules in RA-ILD patients and right inferior lobe was the most common localization of dominant nodules. Prospective studies are needed to determine how the presence and localization of pulmonary rheumatoid nodules affect the RA-ILD disease process.

**References:**

**Disclosure of Interests:** None declared.

**Background:** Rheumatoid arthritis (RA) and dementia have a mechanism that systemic inflammation is involved in the onset, and its relationship can be predicted, but still controversy about the relationship between them. According to the prior literature, rheumatoid arthritis has reduced the risk of progression to Alzheimer’s disease (AD).

**Objectives:** To investigate the risk of dementia in RA patients based on Korean National Health Insurance Service (NHIS) claim database

**Methods:** We conducted a nationwide population-based study using a Korean NHIS consisted of 1 million individuals, who submitted medical care claims between 2002 and 2013. RA was identified using as the International Classification of Diseases code (ICD-10) M05 (seropositive RA) and dementia was defined as having a prescription of anti-dementia drugs with satisfying the AD (ICD 10 F00 or G30) or vascular dementia (VD, ICD 10 F1.0-1.3, F1.8 and F1.9) codes.

The control groups were matched to the RA cohort by age and sex.

**Results:** Of the total 6,028 dementia patients, 100 were diagnosed with RA. In patients with RA over 65 years of age compared to age and sex-matched control group, the dementia risk was shown as whole dementia OR 1.011 (95% CI, 0.811-1.260), AD 1.043 (0.826-1.318), Vascular dementia (VD) 1.274 (0.745-2.177). The sub analysis was performed by dividing the Charlson comorbidity index (CCI) into more than three (moderate) and less than (mild) groups. The mild groups were whole dementia OR 0.851 (0.468-1.546), AD 0.776 (0.392-1.536), VD 0.917 (0.126-6.673), and in the moderate group, whole dementia OR 0.961 (0.750-1.231), AD 0.939 (0.717-0.7) 1.230 and VD 1.219 (0.692-2.149).

J. Kim1, J. A. Chol1, D. H. Yim2, H. M. P. Park2, S. Y. Eom3, J. Chungbuk National University Hospital, Internal Medicine, Cheongju-si, Chungcheongbuk, Korea, Republic of (South Korea); 2Chungbuk National University Hospital, Cheongju-si, Korea, Rep. of (South Korea); 3Chungbuk National University Hospital, Psychiatry, Cheongju-si, Chungcheongbuk-do, Korea, Rep. of (South Korea); 4Chungbuk National University, Preventive Medicine, Cheongju-si, Chungcheongbuk-do, Korea, Rep. of (South Korea)

**Background:** Rheumatoid arthritis (RA) and dementia have a mechanism that systemic inflammation is involved in the onset, and its relationship can be predicted, but still controversy about the relationship between them. According to the prior literature, rheumatoid arthritis has reduced the risk of progression to Alzheimer’s disease (AD).

**Objectives:** To investigate the risk of dementia in RA patients based on Korean National Health Insurance Service (NHIS) claim database

**Methods:** We conducted a nationwide population-based study using a Korean NHIS consisted of 1 million individuals, who submitted medical care claims between 2002 and 2013. RA was identified using as the International Classification of Diseases code (ICD-10) M05 (seropositive RA) and dementia was defined as having a prescription of anti-dementia drugs with satisfying the AD (ICD 10 F00 or G30) or vascular dementia (VD, ICD 10 F1.0-1.3, F1.8 and F1.9) codes.

The control groups were matched to the RA cohort by age and sex.

**Results:** Of the total 6,028 dementia patients, 100 were diagnosed with RA. In patients with RA over 65 years of age compared to age and sex-matched control group, the dementia risk was shown as whole dementia OR 1.011 (95% CI, 0.811-1.260), AD 1.043 (0.826-1.318), Vascular dementia (VD) 1.274 (0.745-2.177). The sub analysis was performed by dividing the Charlson comorbidity index (CCI) into more than three (moderate) and less than (mild) groups. The mild groups were whole dementia OR 0.851 (0.468-1.546), AD 0.776 (0.392-1.536), VD 0.917 (0.126-6.673), and in the moderate group, whole dementia OR 0.961 (0.750-1.231), AD 0.939 (0.717-0.7) 1.230 and VD 1.219 (0.692-2.149).
Conclusion: In conclusion, the risk of dementia in RA patients did not increase when compared to control group. Vascular dementia tended to increase in the RA group, but there was no statistical significance.

THU0133
DIAGNOSES AND COMORBIDITIES IN PRE-RHEUMATOID ARTHRITIS: COMPARISON BETWEEN SEROPOSITIVE AND SERONEGATIVE PATIENTS AND MATCHED NON-RA SUBJECTS

J. M. Davis III*,1, E. Myasoedova1, T. Gunderson2, C. S. Crowson2.
1Mayo Clinic, Rheumatology, Rochester, United States of America; 2Mayo Clinic, Health Sciences Research, Rochester, United States of America

Background: Previous studies have suggested that comorbidities accumulate before the clinical diagnosis of RA, i.e., 'pre-RA' (1). Understanding patterns of diagnoses and comorbidities during the pre-RA period may provide new insights into pathogenesis.

Objectives: To elucidate diagnoses and comorbidities before the onset of clinically apparent RA compared to non-RA subjects, and for seropositive (RF and/or CCP positive) compared to seronegative (RF and CCP negative) patients with RA.

Methods: Adult residents of Olmsted County, Minnesota, with incident RA in 1999-2013 fulfilling the 1987 ACR classification criteria were identified by medical record review. Patients were age- and sex-matched 1:1 to non-RA controls from the same underlying population. The index date for each control corresponded to the incidence date of the matched RA patient. ICD9/10 diagnosis codes (≥2 codes ≥30 days apart prior to index date) were categorized using 16 chronic conditions identified by Clinical Classification Software. Logistic regression models adjusted for age and sex were used to estimate odds ratios (OR) and 95% CI

THU0134
COGNITIVE IMPAIRMENT IN RHEUMATOID ARTHRITIS

C. Edwards1, B. Mcdowell2, C. Holroyd3, C. Cardwell4, M. Mchenry5, G. Meenagh6, C. Holmes7, B. Mogunise8, J. M Davis III Grant/research support from: Pfizer, Consultant of: Served on advisory boards for Abbvie and Sanofi-Genzyme, Elena Myasoedova: None declared, Tina Gunderson: None declared, Cynthia S. Crowson Grant/research support from: Pfizer research grant

Results: The study included 597 RA patients (388 seropositive, 209 seronegative) and 594 controls. The median (range) age was 55 (19-91) years and 70% were female. The median (IQR) of total comorbidities at index was higher among RA patients at 3 (1-6) than controls at 2 (1-5) (p<.001). The median (IQR) of total comorbidities at index was higher in seronegative RA at 4 (2-7) compared to seropositive RA at 3 (1-5) (p=.001); the proportion with six or more was 37% vs. 24% respectively (p<.001). The Table shows the ORs (95% CI) for comorbidities with statistically significant associations with RA overall. The magnitude of the association between total comorbidities and RA peaked at ≥5 comorbidities (OR 1.84; 95% CI 1.4-2.43). Spondylosis, intervertebral disc disorders, and back problems (OR 3.78; 95% CI 1.31-3.41) polymyalgia (OR 1.84; 1.71-19.6) and systemic lupus erythematosus or other connective tissue disorders (OR 5.3; 95% CI 1.78-19.4) were more prevalent than among seronegative than seropositive patients.

Conclusion: The findings provide new insights about diagnoses and comorbidities preceding clinically apparent RA. Future studies of retrospective medical records for patients with particular comorbidities may provide new insights into the pathogenesis and clinical features of the transition from pre-RA to clinically overt RA, especially for seronegative disease.

DOI: 10.1136/annrheumdis-2020-eular.5071
Conclusion: The overall prevalence of PGA-near-remission in patients with RA followed in clinical practice was 1/3 more prevalent than Boolean remission, a difference more pronounced in patients with established disease. Overall, over 61% of all RA patients otherwise in remission failed to satisfy the Boolean definition of remission solely due to one criterion >1). The use of PGA in the definition of treatment target exposes a substantial proportion of patients to the risk of overtreatment with immunosuppressive agents, while being deprived of the adjunctive therapy they probably need.

VERY ELDERLY ONSET RHEUMATOID ARTHRITIS (VEORA): CLINICAL AND THERAPEUTIC IMPLICATIONS AFTER 80 YEARS

A. García Dorta1, C. Almeida2, H. D. Marta1, L. Cáceres Martín3, E. Trujillo4, I. Ferraz-Amaro5, J. C. Quevedo-Abeledo2. 1Hospital Universitario de Canarias, Rheumatology, La Laguna, Tenerife, Spain; 2Hospital Universitario de Gran Canaria Dr Negrín, Rheumatology, Las Palmas de GC, Spain

Background: There are differences in the characteristics of patients with Rheumatoid Arthritis (RA) depending on their age at onset with two traditional groups: YORA (young onset RA) and EORA (elderly onset RA). These aspects have not been studied in cases of very late onset (≥ 80 years).

Objectives: To describe the clinical characteristics, treatments and evolution at one year in very elderly onset RA (VEORA). Compare these characteristics with YORA (40-50 years) and EORA (60-70 years).

Methods: Retrospective and longitudinal study of RA patients from 2 Spanish hospitals.

Results: From 41 studies identified, 8 studies concerning 12 subsamples were analysed (n=23,297 patients; of which 22% had ≥2 years mean disease duration). The overall prevalence of Boolean remission was 12% (95%CI: 10-15%), p<0.005 compared to 19% of PGA-near-remission (15-23%; p<0.005) (Figure 1). In patients with shorter disease duration, PGA-near-remission was more prevalent (14% vs 18%), but even more so in longer disease duration (11% vs 19%).
groups of YORA and EORA patients of the same center, matched by sex, diagnosis date ± 2 years, RF and/or ACPA status and presence of erosions in baseline Rx.

**Results:** A total of 2790 records of RA patients were analyzed, identifying 59 cases of onset in 'very elderly' (2% of the total). Table 1 shows its clinical, analytical characteristics and treatments at diagnosis.

</tbody>
</table>

Elderly patients (EORA and VEORA), compared with YORA, presented with higher frequency of hypertension and CV disease, higher elevation in acute phase reactants at the onset and disease activity at diagnosis. VEORA patients, compared to EORA, showed a higher frequency of dyslipidemia (p = 0.04). There were also no significant differences between VEORA and EORA in the distribution and type of joints affected, time to diagnosis, acute phase reactants or disease activity at the onset. A higher frequency of special forms (such as PMR or RS3PE) was close to statistical significance in the VEORA group (p = 0.054).

Regarding initial treatment, both EORA and VEORA received steroidal treatment more frequently and a lower dose of Methotrexate during the first year. Biological treatments were also significantly higher in YORA (p = 0.000). When comparing VEORA and EORA, differences related to the use of NSAIDs were found, lower in VEORA (p = 0.000), as well as in the maximum dose of Methotrexate reached in the next 12 months, higher in the EORA group (p = 0.01). No differences in adverse events with DMARDs were observed. DAS28-ESR and the number of patients in remission or low activity at one year showed no differences between EORA and VEORA, or between these groups and that of younger patients.

**Conclusion:** There have been few differences in the comorbidity profile and clinical characteristics at the onset between VEORA and EORA patients. Despite the differences observed in its management (more conservative in EORA and VEORA vs YORA, and in VEORA vs EORA), we have not observed differences in DAS28-ESR activity after one year.

**STATINS MEDIATE THE EFFECT OF INFLAMMATION ON CORONARY PLAQUE PROGRESSION AND CARDIOVASCULAR DISEASE RISK IN RHEUMATOID ARTHRITIS**

G. Karouzas, S. O. Ornseth, E. Hernandez, M. Budoff. Lundquist Institute at Biomedical Innovation, Torrance, United States of America

**Background:** Cumulative inflammation correlates with coronary plaque increase and cardiovascular disease (CVD) events in rheumatoid arthritis (RA). Coronary plaque progression predicts CVD risk beyond baseline burden in general patients. Statins inhibit plaque progression and are effective for CVD prevention in general patients. Nevertheless, their impact on coronary plaque trajectory and CVD risk in RA are less clear.

**Objectives:** To explore if statin treatment may reduce CVD event risk, inhibit new plaque formation or promote the regression or protective calcification of prevalent atherosclerotic lesions in RA. We also evaluated whether statins moderate the effects of inflammation (CRP) on CVD risk and on coronary plaque progression.

**Methods:** One hundred-fifty patients underwent computed tomography angiography for coronary atherosclerosis evaluation (total, non-calcified, mixed/calcified plaque); 101 had repeat assessments within 6.9±0.3 years to evaluate plaque progression. CVD events were prospectively recorded, including cardiac death, myocardial infarction, unstable angina, revascularization, stroke, claudication, and heart failure hospitalization. Framingham-D'Agostino score assessed clinical risk. Plaque burden was measured as segment stenosis score (cumulative stenosis). Robust Cox proportional hazards regression models evaluated the effects of time-varying statin use, log-transformed time-varying CRP (mg/dL) and their interaction on CVD risk controlling for Framingham-D' Agostino score, plaque burden and time-varying bDMARD use. Per-segment robust logistic regression assessed the effect of statin duration (years), log-transformed time-averaged CRP and their interaction on likelihood of plaque formation in segments without plaque, and plaque regression or calcification in segments with non-calcified lesions. Models accounted for clustering of coronary segments within patients and controlled for Framingham-D’Agostino score, total prednisone dose, bDMARD duration, and time between scans.

**Results:** Sixteen patients incurred 19 CVD events. There was no main effect of current statin use on CVD risk (adjusted HR 1.10, 95% CI 0.33-3.67). However, there was an interaction between current statin use and time-varying CRP (p-interaction=0.030); higher time-varying CRP predicted greater CVD risk in patients not receiving statins (adjusted HR 2.78, 95% CI 1.01-7.65), but not current statin users (Figure 1A). Likewise, current statin use associated with lower CVD risk when patients had higher time-varying CRP (>0.5 mg/dL) but not when CRP was lower (<0.5 mg/dL, Figure 1B). Statin duration had no main effect on new plaque formation in segments without plaque at baseline (adjusted OR 1.13, 95% CI 0.95-1.05); however, statin use moderated the effect of time-averaged CRP on new plaque formation (p-interaction=0.030, Figure 2A). Time-averaged CRP associated with a higher likelihood of new plaque in patients receiving statins less than one year (adjusted OR 1.75, 95% CI 1.38-2.20) but not those treated for longer (adjusted OR 1.26, 95% CI 0.78-2.02). In segments with non-calcified plaque, longer statin duration predicted protective calcification (adjusted OR 1.28, 95% CI 1.07-1.53, Figure 2B).

**Conclusion:** In RA, statins moderated the effect of CRP on CVD event risk and new plaque formation in coronary segments without plaque. Longer statin duration was also associated with an increased likelihood of protective calcification of non-calcified plaque.

**COMORBIDITIES AMONG KOREAN WOMEN WITH RHEUMATOID ARTHRITIS IN CHILDBEARING YEARS: A NATIONWIDE POPULATION-BASED STUDY**

M. K. Chung, H. S. Lim, J. S. Park, C. H. Lee, J. Lee. 1Division of Rheumatology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Rep. of (South Korea); 2Division of Rheumatology, Department of Internal Medicine, National Health Insurance Service Ilsan Hospital, Goyang, Korea, Rep. of (South Korea)

**Background:** Rheumatoid arthritis is a chronic systemic inflammatory disease known to be associated with many comorbidities. Many women with rheumatoid arthritis (RA) are diagnosed with the disease before completing childbearing, but the risk of comorbidities associated with RA among women in childbearing years is not known.

**Objectives:** We aimed to investigate the risk of comorbidities among Korean women with RA in childbearing years.

**Methods:** From National Health Insurance Service data of 2009-2016, containing inpatient and outpatient claim information for approximately 97% of the Korean population, we identified 20-44 year aged-women with RA and controls without rheumatic diseases such as RA, systemic lupus erythematosus, and ankylosing spondylitis. Prevalence of comorbidities including cancer (Ca), hypertension (HTN), hyperlipidemia (HLD), and diabetes mellitus (DM) were analyzed. The rheumatic diseases and comorbidities were defined by International Classification of Disease (ICD)-10 codes for disease classifications. The comorbidities associated with RA were defined by the ICD-10 codes presented after the RA diagnosis.

**Results:** Total 23,756 women with RA and 208,941 controls were identified. Women with RA had significantly higher prevalence of all comorbidities analyzed compared with the controls (49.92% vs 25.58%, p<0.001). In women with RA, Ca (OR 1.14), DM (OR 1.22), HTN (OR 1.56), and HLD (OR 2.44) occurred significantly more often compared with the controls (p<0.001).

**Conclusion:** During childbearing years, women with RA are more susceptible to comorbidities leading to a significant burden in this specific population of Korean women in childbearing years.

**References:**
Rheumatoid arthritis (RA) is a chronic inflammatory disease that primarily affects the joints. It is characterized by pain, swelling, redness, and stiffness in the joints. The prevalence of sarcopenia, a condition associated with muscle loss, is higher in patients with RA compared to the general population. This increased risk of sarcopenia may be due to factors such as the inflammatory state associated with RA, the use of corticosteroids, and other medications. The aim of this meta-analysis was to assess the prevalence and risk factors of sarcopenia in patients with RA.

Methods:
We searched the studies investigating the prevalence and risk factors of sarcopenia in RA published in PubMed, EMBASE, Cochrane Library, and other databases. We included studies that reported the prevalence and risk factors of sarcopenia in patients with RA. We used random-effect models to calculate the pooled prevalence and risk factors. Sensitivity analysis was performed to assess the stability of the results.

Results:
A total of 23 studies were included in the meta-analysis. The pooled prevalence of sarcopenia in patients with RA was 35%. The risk factors associated with sarcopenia in RA included age, sex, smoking, and the use of corticosteroids. The pooled odds ratio for age was 1.168 (95% CI: 1.067-1.28), for female sex was 4.438 (95% CI: 1.857-10.6), and for corticosteroids was 1.647 (95% CI: 1.255-2.196).

Conclusion:
The prevalence of sarcopenia in patients with RA is high, and age, sex, and corticosteroid use are significant risk factors. More research is needed to further clarify the risk factors and develop effective interventions to prevent sarcopenia in patients with RA.
Background: Bronchiectasis (BR) is a significant pulmonary morbidity common in people with rheumatoid arthritis (RA). Patients with RA and bronchiectasis (RA-BR) often have severe arthritis but the use of biologics may be difficult in this group of patient due to concerns over safety. There is no data comparing the use of rituximb (RTX) and tumour necrosis factor inhibitors (TNFi) in RA-BR.

Objectives: To evaluate the effect of RTX in patients with RA-BR and compare 5-year respiratory survival between those treated with RTX and TNFi.

Methods: A retrospective observational cohort study of RA-BR was conducted in RTX or TNFi-treated RA patients from two UK centres over 10 years. BR was assessed using number of infective exacerbations/year. Respiratory survival was defined as time from therapy initiation to discontinuation either due to lung exacerbation or lung-related deaths.

Results: Of 800 RTX-treated RA patients, 68 had RA-BR (prevalence 8.5%). Post-RTX, new BR was diagnosed in 3/735 patients (incidence 0.4%). At 12 months post-Cycle 1 RTX, 21/68 (31%) patients had fewer exacerbations than the year pre-RTX, 36/68 (53%) remained stable and 11/68 (16%) had increased exacerbations. In multivariable analysis, a factor associated with increased risk of this initial exacerbation was pneumonias colonisation [OR 7.23 (95% CI 1.28-40.80)] while older age reduced risk [OR 0.44 (95% CI 0.21-0.90) per 10 years of age]. The rates of exacerbation improved after Cycle 2 RTX and stabilised up to 5 cycles. Of patients who received ≥2 RTX cycles (n=60), increased exacerbations occurred in 7/60 (12%) and were associated with low IgG, aspergillosis and concurrent alpha-1-antitrypsin deficiency. Respiratory survival was compared between RA-BR patients treated with RTX (N=68) or TNFi (N=46). Most characteristics were matched but median (IQR) number of infective exacerbations/year in the previous 12 months pre-bDMARDs was higher in those treated with RTX than TNFi: 3.0 (1-4) and 0 (0-2) respectively. Overall, 8/68 (11.8%) patients discontinued RTX while 15/46 (32.6%) discontinued TNFi due to respiratory causes. The adjusted 5-year respiratory survival was better in RTX-treated compared to TNFi-treated RA-BR patients; HR 0.40 (95% CI 0.17–0.96); p=0.041.

Conclusion: The majority RA-BR patients had stable or improved pulmonary symptoms during RTX therapy over a prolonged follow-up period. In isolated cases, worsening of exacerbation after RTX therapy had definable causes. Despite a higher rate of exacerbations pre-biologic, rates of discontinuation due to adverse lung outcomes were better for RTX than a matched TNFi cohort. RTX appears to be an acceptable therapeutic choice for RA-BR if a biologic is needed.

THU0144 DESCRIPTIVE ANALYSIS OF PREGNANCY, DELIVERY, AND LACTATION IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM THE IORRA COHORT.

M. Ochiai1, E. Tanaka1, E. Inoue1,2, M. Abe1, E. Sugano1, N. Sugitani1, K. Sakai1, H. Yoko1, Y. Yamaguchi1, N. Sugimoto1, I. Katsunori2, A. Nakajima1, A. Taniguchi1, H. Yamana2, M. Harigai1, Department of Rheumatology, Tokyo Women’s Medical University School of Medicine, Tokyo, Japan; 2Division of Medical Informatics, St. Marianna University School of Medicine, Kanagawa, Japan; 3Department of Orthopedic Surgery, Tokyo Women’s Medical University School of Medicine, Tokyo, Japan; 4Center for Rheumatic Diseases, Mie University Hospital, Mie, Japan; 5Rheumatology, Sanno Medical Center, Tokyo, Japan

Background: Rheumatoid Arthritis (RA) is common in women with reproductive age. For this reason, RA treatment during pregnancy and lactation is very important. In recent years, the use of biologic disease-modifying antirheumatic drugs (bDMARDs) has become common in RA treatment (1), treatment during pregnancy and lactation has changed drastically (2,3).

Objectives: To investigate the pregnancy, delivery and lactation status of RA patients and treatment during that period in daily practice.

Methods: The IORRA cohort is a large, single institute-based, observational cohort of RA patients established at Institute of Rheumatology, Tokyo Women’s Medical University, in 2000. We identified female RA patients aged 20-49 years who answered ‘pregnant’ or ‘delivered’ in the IORRA survey in 2010-2016 and whose pregnancies were confirmed in the medical records. We examined the Disease Activity Score with 28 joint count (DAS28)-CRP medication use situation, the outcome of pregnancy, and lactation in those patients.

Results: A total of 101 patients and 143 pregnancies were confirmed, of which 136 outcomes of pregnancy could be confirmed in the medical records. Among 136 confirmed pregnancy cases, there were 106 births and 30 miscarriages. Among 106 births, 4 cases (3.8%) were birth defects that could be confirmed in the medical records. The average age at pregnancy was 34.2±7.3 years and 36.1±3.3 years in delivered and miscarried cases, respectively. Miscarried cases were significantly older pregnancies (p=0.01). Of the 106 births, 65 birth weeks were confirmed, with an average of 37.9±1.8 weeks. The number of preterm delivery was 11 cases (16.9%). The average birth weight of 59 babies whose birth weight could be confirmed was 2699±517 g. There were 21 cases (35.6%) of low birth weight infants. The proportion of patients in DAS28-CRP remission was 73.1% before pregnancy, 61.6% during pregnancy, and 68.0% 1 year after delivery. Drugs used before pregnancy were glucocorticoid (48.8%), non-steroi-dal anti-inflammatory drugs (14.2%), conventional synthetic DMARDs (24.8%), and bDMARDs (48.0%). Etanercept accounted for 90% of bDMARDs. Among taking bDMARDs patients, 73.8% were discontinued after the pregnancy, and 26.2% were continued during pregnancy. Among those patients who continued bDMARDs, lactating patients were 12/26 (46.2%) cases after delivery, 10/30 (33.3%) cases in six months after delivery, and 7/36 (19.4%) cases in 1 year after delivery, respectively.

Conclusion: The actual situation of pregnancy, delivery, and lactation in RA patients was revealed. Especially, bDMARDs were used at relatively high rates in RA patients who wish to have a child.

Scientific Abstracts Thursday, 04 June 2020 287
Objectives: To describe and compare indications and the incidence of treatment with antidepressants in patients with RA and matched controls.

Methods: The study involved an inception cohort of patients with incident RA ascertained from 1995 to 2002 according to the American College of Rheumatology 1987 classification criteria (4) and randomly drawn, population controls with the same age, sex, and area of residence (ratio 1:5). Indications on redeemed prescriptions for antidepressants were assessed. (3)

Results: The current analyses involved 483 RA patients and 2,167 controls. The incidence of depression is about 1.5-2 times higher in patients versus controls. This could be due to prescription bias or reflect pertinent choice of treatment in patients with RA.

Conclusion: The main indication for prescribing antidepressants in patients with RA was depression. Patients with RA were not exposed to antidepressants more often than controls. This could be due to prescription bias or reflect pertinent choice of treatment in patients with RA.

of finger joint space width of the metacarpal-phalangeal articulations (MCP) using the computer-assisted joint space analysis (Version 1.3.6; Sectra; Sweden). The joint space distance is expressed as mean joint space width of the MCP joints I to V (JSD-MCP total). Remission was defined with a Disease Activity Score 28 < 2.6.

Results: The group with DAS28-remission (DAS28 < 2.6) presented a significant joint space increase with 3.3 % for JSD-MCP total from 0.152 ± 0.033 cm (baseline) to 0.157 ± 0.033 cm (week 52) treated with certolizumab pegol 200 mg as well as with 3.9 % for JSD-MCP total from 0.152 ± 0.031 cm (baseline) to 0.158 ± 0.032 cm (week 52). For the patients without DAS28-remission (DAS28 > 2.6) under the treatment with certolizumab pegol 400 mg a non-significant change of JSD-MCP total from 0.145 ± 0.034 cm (baseline) to 0.144 ± 0.036 cm (week 52) was observed. A similar result was evaluated for the certolizumab pegol 200 mg group (JSD-MCP total: 0.146 ± 0.037 cm [baseline] to 0.143 ± 0.037 cm [week 52]).

Conclusion: The study highlights that patients treated with certolizumab pegol plus methotrexat and a DAS-Remission showed an increase of joint space width of the metacarpal-phalangeal articulations which is potentially associated with reparative effects of the cartilage under the anti-TNF treatment with certolizumab pegol.

THU0147

CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS: DO WE ALREADY HAVE A SENSITIVE AND SPECIFIC INSTRUMENT?

D. Ribeiro1, F. Cunha Santos2, C. Vaz1,2, J. F. Ferreira1,2, 1Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal; 2Sousa Martins Hospital, Guarda Local Health Unit, Rheumatology, Guarda, Portugal

Background: Rheumatoid Arthritis (RA) is a chronic systemic inflammatory disorder with high cardiovascular (CV) risk due to both classic and specific disease risk factors. According to EULAR’s recommendations, all patients should carry out an assessment of their CV risk, however, there are no specific evaluation algorithm’s for RA.

Objectives: To assess the efficacy to predict CV risk in RA patients using the Systematic Coronary Risk Evaluation model (SCORE), Modified SCORE (mSCORE), Framingham Risk Score (FRS), Modified Framingham Risk Score (mFRS) and the American College of Cardiology/American Heart Association algorithm (ACC/AHA).

Methods: Cross-sectional observational study including patients fulfilling 2010 ACR/EULAR classification criteria for RA and followed in the Rheumatology Department at Guarda Local Health Unit. Clinical records were reviewed and sociodemographic, classic CV risk factors and disease related factors, previous history of CV events and current treatment were collected. Individual CV risk was calculated using aforementioned models. Patients were divided in two groups: group 1 (without CV event history) and group 2 (with a history of CV event). Discriminative capacity tests, sensitivity and specificity were asserted and the different models were compared.

Results: A total of 107 patients were included in the study and 10 suffered a CV event. Of 107 patients, 78 % are women, the average age is 55.97 ± 6.78 and the average body mass index is 26.44 ± 4.43 kg/m² (Table 1). Models evaluated revealed reasonable discriminative capacity with areas under the curve between 0.73 and 0.88 (Figure 1). Regarding sensitivity and specificity, we found that SCORE calculator fail to identified high risk in all patients with a CV event, however it presented a specificity of 94%. Others CV risk calculators showed to induce a significant improvement of metabolic alteration whereas TNFi did not show any significant improvement on that, after both 3 months and 6 months of therapy (crude difference of 0.93 of glycated haemoglobin, HbA1c % between groups) [2]. Concerning RA, a progressive reduction of disease activity was observed in both groups [2].

Conclusions: The five models tested in this study have a relative discriminative capacity. SCORE did not identify any CV event, which may compromise its ability to assess the CV risk in this patients. The most sensitive and specific model was the ACC/AHA, a very restricted model. When applying the multiplication factor of 1.5 recommended by EULAR, there is an improvement in sensitivity, however the specificity decreases. This study proves the limitations of CV risk calculators designed for the general population when applied to patients with RA. In conclusion, CV risk assessment is extremely important and there is still no ideal calculator, which is both sensitive and specific, and easily applicable in a clinical context.

THU0148

EFFICACY OF IL-1 INHIBITION ON RHEUMATOID ARTHRITIS AND TYPE 2 DIABETES, LONG-TERM FINDINGS FROM TRACK STUDY, A MULTICENTRE, OPEN-LABEL, RANDOMISED CONTROLLED TRIAL

P. Ruscitti1, S. Alvaro2, V. Iakovou1, F. Sensini1, P. Cipriani2, R. Giacomelli2 on behalf of TRACK Study Group. 1University of Udine, Department of Biotechnological and Applied Clinical Sciences, Udine, Italy

Background: The inflammatory contribution to type 2 diabetes (T2D) has suggested new therapeutic targets by using biologic DMARDs designed for rheumatoid arthritis (RA), and IL-1 would be a common pathogenic mediator, suggesting a possible common therapeutic target [1]. In TRACK study, a multicentre open-label, randomised controlled trial, anakinra, a human interleukin-1 receptor antagonist, showed to induce a significant improvement of metabolic alteration whereas TNFi did not show any significant improvement on that, after both 3 months and 6 months of therapy (crude difference of 0.93 of glycated haemoglobin, HbA1c % between groups) [2]. Concerning RA, a progressive reduction of disease activity was observed in both groups [2].

Objectives: Since TRACK study has been prematurely stopped for “early benefit” after 6 months of follow-up, in this work, we aimed at investigating how long last the improvement of HbA1c% and of RA disease activity, considering the original scheduled 24 months follow-up. We also assessed the rate of antidiabetic and anti rheumatic therapies reduction and stoppage.

Methods: This study was designed as a multicentre, open-label, randomised controlled trial, enrolled participants, with RA and T2D, in 12 Italian Rheumatologic Units, between 2013 to 2016. Participants were randomised to anakinra or to a TNFi and the primary endpoint was the change in HbA1c % (EudraCT:
2012-005370-62; ClinicalTrial.gov: NCT02238481). In this further evaluation, we assessed how long lasted the improvement of HbA1c% and of RA disease activity, considering the original scheduled 24 months follow-up, and the rate of anti-diabetic and anti-rheumatic drugs, mainly focusing on steroids, reduction and stoppage.

Results: In TRACK study, 39 participants with RA and T2D (age 62.72 ± 9.97, 74.4% female gender) were randomised to anakinra or to TNFi; the majority of participants had seropositive RA disease (rheumatoid factor and/or ACPA 70.2%) with active disease (DAS28: 5.54 ± 1.03; C-reactive protein 11.84 ± 9.67 mg/L, respectively) and all participants had T2D (HbA1c%: 7.77 ± 0.70, fasting plasma glucose: 139.13 ± 42.17 mg). Considering the last available observation, a maintenance of reduced levels of HbA1c% was observed in anakinra-treated participants (Baseline: 7.73% ± 0.67; 6 months: 6.70% ± 0.67; last follow-up: 6.60% ± 0.52). Paralleling with HbA1c%, a significant reduction of dosages of anti-diabetic therapies was observed in anakinra-treated patients, with a percentage of patients who discontinued any anti-diabetic therapy. Conversely, an intensification of anti-diabetic therapies was reported in TNFi-treated participants. Concerning RA, the clinical response was maintained during the whole follow-up, although a larger percentage of anakinra-treated patients discontinued the concomitant steroids therapy.

Conclusion: In this study, we observed the benefit of IL-1 inhibition in patients with RA and T2D, reaching the therapeutic targets of both diseases, which lasted longer than first 6 months of follow-up. Although the limitations due to open-label design and the necessity of further confirmatory studies, our results could suggest the concept that IL-1 inhibition may be considered a targeted therapeutic strategy for RA and T2D.

INTERSTITIAL LUNG DISEASE RELATED TO RHEUMATOID ARTHRITIS. WHAT DO WE DON'T KNOW? THE LIRA STUDY (LUNG INVOLVEMENT IN RHEUMATOID ARTHRITIS).

M. Sebastiani1, 2, C. Vacchi1, G. Cassone1, F. Atzeni2, M. Biggioggero4, A. Carriero2, G. L. Erre2, A. L. Fedele2, F. Furini5, P. Tomietto6, V. Venerito3, B. Atienza-Mateo11, G. Della Casa1, G. Sandri2, A. Palermo1, E. Galli1, F. Pancaldi1, M. A. González-Gay1, C. Salvarani1, 13, A. Manfredi1 on behalf of LIRA Study Group. 1University of Modena and Reggio Emilia, Modena, Italy; 2Policlinico of Modena University Hospital of Modena, Modena, Italy; 3University of Messina, Messina, Italy; 4San Carlo Hospital, Potenza, Italy; 5Sant’Anna Hospital, Ferrara, Italy; 6Ospedali Riuniti di Firenze, Firenze, Italy; 7University of Bari, Bari, Italy; 8University of Cantabria, Santander, Spain; 9University of Cantabria, Santander, Spain; 10Arcispedale Santa Maria Nuova, Reggio Emilia, Italy

Methods: All RA patients referring to the involved centres will be evaluated every six months with a digital stethoscope and a software able to identify velcro crackles with a diagnostic accuracy of 83.9% (VECTOR). In fact, velcro crackles are virtually identified in all stages of fibrosing alveolitis like RA-ILD, and their search is as a simple and reliable method to screening patients to be undergone to high resolution computed tomography (HRCT).

For each patient, clinical and serological data are recorded at baseline and every six months; when velcro crackles or other conditions suspicious for ILD, such as cough or dyspnoea, are detected, a HRCT is requested to confirm ILD. Patients

Data collected from each study was: Author and year of publication of the study, study design and population included, number of patients treated, treatment administered and percentage of patients treated for HZ in each treatment arm.

Results: In clinical trials of these drugs, a greater number of opportunistic infections due to varicella zoster virus have been identified compared to placebo, which leads to the appearance of HZ.

The role of different JAKs in the immune response may suggest differences in safety profiles between these drugs, which could have clinical implications. Therefore, we analyze the results separately for each JAK.

Tofacitinib Of the 14 selected works, 4 are phase II, 8 phase III and 2 extension studies. We observe that the incidence of HZ ranges between 1% and 11%, the latter being the case of the Wollenhaupt extension study with a data collection period of nine and a half years. It is remarkable that in some of the studies included in this review there was no case of HZ and in others this information was not even collected.

Baricitinib Two phase II studies, 6 phase III studies and one extension study were analyzed, with an incidence of HZ between 1% and 8%, data similar to those obtained with tofacitinib.

Upadacitinib. An incidence of HZ between 1% and 4% was observed according to the 6 clinical trials (two phase II studies and four phase III studies) published as clinical product development.

Filgotinib Data similar to upadacitinib, with frequencies between 1% and 4% of HZ according to the studies (three phase II studies and one phase III study).

Peficitinib The incidence of HZ ranged between 4% and 75% (three phase III studies, two phase III studies, and one extension study).

Decernotinib There are only published three phase II trials, of short duration and with only four cases collected from HZ

Conclusion: Conclusions: Opportunistic HZ infection have been reported between 1% and 11% in JAKi clinical trials. The results of the included studies seem to suggest that selective JAK inhibitors (Upadacitinib and Filgotinib) develop HZ as a treatment complication less frequently than other JAKi, but more studies are needed to support this conclusion.

with ILD periodically perform pulmonary function tests to monitor lung function evolution.

**Results:** At now, 205 RA patients have been enrolled (female/male 161/44, mean age 64.8±12.9 years, mean disease duration 14.2±8.9 years), anti-citrullinated peptides antibodies (ACPA) and rheumatoid factor (RF) were positive in 77.1% and 78.1%, respectively. The prevalence of ILD was 21% (43 patients). In other 13 patients the HRCT is ongoing; therefore, we could suppose up to a prevalence of 27.3%. Patients with ILD were symptomatic in 53.3% of cases (23 patients), they are more frequently males and were older than patients without ILD (mean age 73.2±7.4 vs 62.7±13.2; p<0.0001, female/male ratio 139/23 vs 22/21; p<0.0001) without significant differences regarding disease duration, positivity for ACPA or RF.

**Conclusion:** The prevalence and the incidence of RA-ILD is still not well defined. Preliminary data of our study confirm a prevalence of ILD higher than 20%, patients are asymptomatic in almost the half of cases and more frequently males and elderly. Our study can help to define the clinical history of these patients, the possible association with clinical and serological features and the supposed role of some drugs.

**RISK OF MALIGNANCIES ASSOCIATED WITH CS DMARDS IN RHEUMATOID ARTHRITIS: COMPARISON WITH GENERAL POPULATION AND BIOLOGIC TREATED PATIENTS (ANALYSIS OF A NATIONAL CLAIM DATABASE)**

1Hôpitaux Universitaires Paris-Saclay, Rheumatology, Le Kremlin-Bicêtre, France; 2Pitié-Salpêtrière Hospital, Biostatistics, Public Health and Medical Information, Paris, France; 3Pitié-Salpêtrière Hospital, Rheumatology, Paris, France

**Background:** Objectives: To estimate the incidence rate of malignancies in csDMARD-treated RA patients and to compare it to that of general population and to biologic-treated RA patients.

**Methods:** We conducted an historical cohort study within the national claim database that prospectively records individual health resource use of 86% of the French population (65 million inhabitants). RA adult patients were identified based on ICD-10 code (M05 or M06) between 2007-2016. Patients with previous cancer history were excluded. Treatment exposures were considered as a time-dependent variable.

**Results:** At propensity score matching, the analysis of malignancies between csDMARD and biologics treated patients were conducted on 19727 patients in each group (mean age: 51±14 yrs; female: 74.6%). Malignancies occurred in 435 patients exposed to biologics and 332 patients exposed to csDMARD. The overall risk of malignancies (figure), risk of solid cancer (excluding non-melanoma skin cancer), lymphoma, and other hematologic malignancies did not differ significantly between csDMARD and all biologics (table). Regarding organ specific cancer, no difference was observed. Results were similar for biologic in monotherapy or associated with csDMARD.

**Conclusion:** Using a large nationwide representative healthcare database, the overall risk of malignancies and the risk of organ-specific cancers and hematologic malignancies in biologic treated RA patients did not differ from that of patients treated with csDMARD. Compared to general population, patients treated with csDMARD had an increased risk of lung cancer and melanoma, but a decreased risk of pancreatic cancer.

**Disclosure of Interests:** Raphaëlle Seror Consultant of: BMS, Medimmune, Novartis, Pfizer, GSK, Lilly, Alexandre Lafourcade: None declared, yann de-rycke: None declared, Bruno Fautrel Grant/research support from: Abbvie, Lilly, MSD, Pfizer, Consultant of: AbbVie, Biogen, BMS, Boehringer Ingelheim, Celgene, Lilly, Janssen, Medac MSD France, Nordic Pharma, Novartis, Pfizer, Roche, Sanofi Aventis, SOBi and UCB, Xavier Mariette Consultant of: BMS, Gilead, Medimmune, Novartis, Pfizer, Servier, UCB, Florence Tubach Grant/research support from: Florence TUBACH is head of the Centre de Pharmacoépidémiologie (Cephep) of the Assistance Publique – Hôpitaux de Paris and of the Clinical Research Unit of Pitié-Salpêtrière hospital, both these structures have received research funding, grants and fees for consultant activities from a large number of pharmaceutical companies, that have contributed indiscriminately to the salaries of its employees. **THE ADVANTAGES OF DISTANCE BLOOD PRESSURE MONITORING IN PATIENTS WITH RHEUMATOID ARTHRITIS**

I. Starodubtseva1, J. Sharapova2, 1NN Burdenko Voronezh State Medical University, Internal Diseases, Voronezh, Russian Federation; 2NN Burdenko Voronezh State Medical University, Voronezh, Russian Federation

**Background:** Cardiovascular complications are very common in patients with rheumatoid arthritis (RA). The monitoring of the course of RA and comorbid conditions is the key aspect of the prevention of early mortality.

**Results:** Between 2007 and 2016, 83,706 RA patients exposed to csDMARD (n=83,837) and/or biologics (n=19,727) were identified. As compared to the general population, csDMARDs treated patients had an increased risk of lung cancer (SIR=1.29 [1.14; 1.43]), invasive melanoma (SIR=1.52 [1.24; 1.86]) and a borderline increased risk of breast cancer (SIR=1.11 [1.01; 1.22]). By contrast, they had a decreased risk of pancreatic cancer (SIR=0.68 [0.51-0.9]) and liver cancer (SIR=0.43 [0.27; 0.67]). This later is due to a protopathic bias.

**Table:**

<table>

**Conclusion:** Using a large nationwide representative healthcare database, the overall risk of malignancies and the risk of organ-specific cancers and hematologic malignancies in biologic treated RA patients did not differ from that of patients treated with csDMARD. Compared to general population, patients treated with csDMARD had an increased risk of lung cancer and melanoma, but a decreased risk of pancreatic cancer.

**Disclosure of Interests:** There are no conflicts of interest to declare.
Objective: To identify the risk factors for worsening of ILD in RA patients under biological DMARD (bDMARDs) therapy; particularly to determine whether types of bDMARDs are associated with exacerbation of ILD.

Methods: A retrospective cohort study was conducted. Subjects were consecutive 91 RA-ILD patients who received HR-CT examination at starting and during bDMARDs therapy. Clinical data were collected by reviewing.

Conclusion: Distance BP monitoring in patients with RA with the use of BP monitors with the function of remote data transmission lets to achieve target BP and hereby, reduce the incidence of adverse cardiovascular complications.

Disclosure of Interests: None declared

THU0154 PERCEPTIONS ABOUT INTERVENTIONS TO ENHANCE INFLUENZA VACCINE UPTAKE DIFFER BETWEEN VACCINATED AND UNVACCINATED RA/JIA PATIENTS

V. Valerio1, M. Bazan1, M. Wang2, B. Mazier2, E. M. Hazei2, C. Pineau3, S. Bernatsky2, I. Colmegna3, 1Research Institute of McGill University Health Center, Montreal, Canada; 2Lady Davis Institute, Montreal, Canada; 3McGill University, Montreal, Canada

Background: To optimize the control of vaccine preventable diseases, high immunization coverage rates must be achieved. Influenza vaccination rates among patients with rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA) are suboptimal. Understanding patient preferences for interventions that may increase vaccine uptake is the first step to inform the development of specific strategies to enhance vaccine coverage in RA/JIA.

Objectives: To compare the perceptions of vaccinated and unvaccinated RA/JIA patients on a multi-modal intervention to enhance seasonal influenza vaccine coverage.

Methods: During the 2018-2019 influenza season, a multi-modal intervention was implemented at a large Canadian academic center. This consisted of (i) a letter sent from the Division of Rheumatology to patients addressing common misconceptions about flu vaccines and encouraging patients to plan for immunization; (ii) a nurse providing inactivated influenza vaccine at the rheumatology clinics for the first 7 weeks after the vaccine was released, and (iii) clinics posters specifically designed for rheumatic patients and rheumatologists to prompt a discussion on influenza prevention. Patients that were vaccinated on site completed a survey evaluating the relevance of the individual components of the intervention. After the intervention, during a scheduled rheumatology visit, RA/JIA patients were asked to complete a similar survey. We compared the responses from RA/JIA patients that were vaccinated at our institution, to those of patients that reported not having received the influenza vaccine in 2018-2019.

Results: During the intervention, 116 immunized RA/JIA patients completed the first survey. Forty RA/JIA patients not vaccinated during the 2018-2019 season completed the post-intervention survey. Both vaccinated and unvaccinated groups were mostly female (74.1% versus 87%), but vaccinated patients were older (50.8±19.4 versus 40.5±14.9; 95% CI 3.7%,17%), and had shorter disease duration (10.1±5.3 versus 15.0±9.8; 95% CI -8.9%-1.1%) than those not vaccinated. Unvaccinated patients were less likely than vaccinated patients to approve of the clinic’s provision of influenza vaccine (98.2% versus 75%; 95% CI 12.6%, 43.5%). When asked about elements of the intervention, unvaccinated patients were less likely than vaccinated patients to consider posters (65.2% versus 38.9%; 95% CI 79%, 42.9%), letters (69.4% versus 35.5%; 95% CI 16.2%, 51.2%), or phone calls (58.0% versus 41.7%; 95% CI 7.9%, 42.9%).

Conclusion: Unvaccinated RA/JIA patients’ opinions about interventions to increase vaccine uptake differ from vaccinated patients. Alternative, novel strategies to target vaccine hesitant RA/JIA patients are needed to optimize vaccine coverage.

SERUM MYOSTATIN IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS CORRELATION WITH BODY COMPOSITIONS.

Y. Wada1,2, M. Sudo2, D. Kobayashi3, T. Kuroda2, I. Narita2. 1Niigata Rinko Hospital, Department of Clinical Rheumatology, Niigata, Japan; 2Niigata University Graduate School of Medical and Dental Sciences, Division of Clinical Nephrology and Rheumatology, Niigata, Japan.

Background: Altered body composition is one of common findings in rheumatoid arthritis (RA), and it is estimated that up to two-thirds of patients may be affected loss of muscle mass and strength and concomitant increase in fat mass, so-called “rheumatoid cachexia”. Despite great advances in the treatment of RA such as biologics and small molecule compounds, it appears that rheumatoid cachexia persists even after joint inflammation improves. Myostatin, a member of the transforming growth factor-beta superfamily, is a potent negative regulator of skeletal muscle growth and its inactivation can induce skeletal muscle hypertrophy, while its overexpression or systemic administration causes muscle atrophy. It enhances proteolysis and inhibits protein synthesis in skeletal muscle, and has generated increasing interest as a potential regulator of cachectic status such as patients with cancers, cardiac failure, and HIV infections.

Objectives: In this study, we investigated the possible role of myostatin for altered body compositions in patients with RA.

Methods: This was a cross-sectional study. Ninety-six RA patients who visited Niigata University Hospital between April to June 2017, were recruited in this study. Body composition was measured by bioelectrical impedance analysis with a tetrapolar impedance meter (InBody S-10, InBody Japan Inc, Tokyo, Japan) in each subject. The right femoral neck bone density was measured using the dual energy X-ray absorption method (DEXA). Serum myostatin level was measured by enzyme-linked immunosorbent assay with a commercially available kit (Quantikine ELISA GDF-8/ Myostatin Immunoassay, R&D systems, MN, USA). Patients’ laboratory findings and disease activities were also measured, and the correlations between the titer of serum myostatin and these factors were analyzed by Spearman’s correlation coefficient and stepwise multiple regression analysis. A p-value of <0.05 was taken to denote statistical significance.

Results: In Spearman’s correlation coefficient analysis, serum myostatin level was positively correlated with skeletal muscle mass index and FFMI, and negatively correlated with percent body fat (%BF), fat mass index (FMI), right femoral neck bone density, swollen joint counts, ESR, and DAS28(4)-ESR. In stepwise multiple regression analysis, FFMI was selected as a positive independent variable (rho=-0.2298, p=0.0154) against serum myostatin levels, and DAS28(4)-ESR as a negative independent variable (rho=0.3620, p=0.00019) while corticosteroids increased the risk of developing diabetes in a dose-dependent manner (Any dose: meta-HR 1.46, 95% CI 1.39-1.53; <10mg/day: meta-HR 1.30, 95% CI 1.13-1.51; >10mg/day: meta-HR 2.25, 95% CI 1.88-2.70). Additionally, concomitant corticosteroids treatment with hydroxylorquine appear to eliminate the excess diabetes risk from corticosteroids (meta-HR 0.64, 95% CI 0.51-0.79).

Conclusion: Our meta-analysis provides important evidence for the impact of antirheumatic drugs on diabetes in RA and may aid clinical decision-making by suggesting that hydroxychloroquine, methotrexate and TNFi decrease diabetes risk while corticosteroids increase such risk in RA. Large, prospective, well-designed studies are needed to explore the effects of such drugs on diabetes development in the RA patients with high-risk diabetes.

THU0156

INCIDENT DIABETES ASSOCIATED WITH HYDROXYCHLOROQUINE, METHOTREXATE, BIOLOGICS AND CORTICOSTEROIDS IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

W. Xie1, X. Yang1, Z. Zhang1. 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China.

Background: Rheumatoid arthritis (RA) is associated with greater risk of diabetes, the coexistence of RA and diabetes significantly increased risk of cardiovascular morbidity and mortality. For this reason, it is important to document the role of individual medications associated with RA in the diabetes development.

Objectives: We aim to evaluate the impact of antirheumatic drugs therapy on risk of developing diabetes in RA patients.

Methods: Electronic database searches of PubMed, EMBASE and Cochrane Library plus a hand search of conference proceedings were performed without language restrictions from inception to 14 October 2019. All study designs assessing the association between diabetes and antirheumatic agents in RA relative to a comparator group were included. The primary outcome was the association between treatments and diabetes. The secondary outcomes were their associations, stratified by dosage, exposure duration. Data were pooled using fixed-effects or random-effects meta-analysis according to I² and pooled hazard ratios (HRs) and 95% confidence intervals (CIs) was used as a summary statistic.

Results: Of 3961 identified articles, a total of 15 studies involving 552,019 patients with RA (11 for hydroxychloroquine, 7 for methotrexate, 6 for tumor necrosis factor inhibitors [TNFi], 8 for corticosteroids) were included. In pooled analysis, a reduced risk of diabetes was reported with hydroxychloroquine (meta-HR 0.61, 95%CI 0.56-0.66), methotrexate (meta-HR 0.81, 95%CI 0.75-0.87), TNFi (meta-HR 0.63, 95%CI 0.55-0.71), while corticosteroids increased the risk of developing diabetes in a dose-dependent manner (Any dose: meta-HR 1.46, 95% CI 1.39-1.53; <10mg/day: meta-HR 1.30, 95% CI 1.13-1.51; >10mg/day: meta-HR 2.25, 95% CI 1.88-2.70). Additionally, concomitant corticosteroids treatment with hydroxylorquine appear to eliminate the excess diabetes risk from corticosteroids (meta-HR 0.64, 95% CI 0.51-0.79).

Conclusion: Our meta-analysis provides important evidence for the impact of antirheumatic drugs on diabetes in RA and may aid clinical decision-making by suggesting that hydroxychloroquine, methotrexate and TNFi decrease diabetes risk while corticosteroids increase such risk in RA. Large, prospective, well-designed studies are needed to explore the effects of such drugs on diabetes development in the RA patients with high-risk diabetes.

‘SWITCH ME IF YOU CAN’ – REAL LIFE EXPERIENCE OF SWITCHING TO BIOSIMILAR DRUGS FROM GARTNAVEL GENERAL HOSPITAL, GLASGOW, UK

M. A. Abdullah1, S. Batool1, S. Bawa1. 1Gartnavel General Hospital, Glasgow, United Kingdom.

Background: Rheumatology has entered the era of biosimilar drugs. Compared with the original approved biological drug, a biosimilar has highly similar physicochemical characteristics and biological activity. There is also equivalent efficacy and no clinically meaningful differences in safety and immunogenicity. Substantial cost savings can be made by starting both biological-naive patients and switching patients receiving original biological DMARDs to biosimilar DMARDs (bsDMARDs). We present our experience of switching to biosimilars at Gartnavel General Hospital, Glasgow, UK.

Objectives: To assess the adherence to bsDMARDs in patients switched from original bDMARDs and to identify factors affecting adherence.
Methods: We identified 69 patients on etanercept and 101 patients on adalimumab who were switched to bsDMARDs. We used patient clinical records and DAS28 scores held in our database to assess the response to treatment and identify patients who were switched back to original bDMARD. We also identified the reason for switching back to bDMARD and any safety concerns were also analysed.

Results: Retention rate was 79.71% (55/69) in biosimilar etanercept and 90.10% (91/101) in biosimilar adalimumab group respectively. The overall failure rate was 20.29% (14/69) in biosimilar etanercept and 9.90% (10/101) in biosimilar adalimumab group. 15.94% (11/69) in biosimilar etanercept and 7.92% (8/101) in biosimilar adalimumab group were switched back to original bDMARD due to perceived disease flare. Control was regained in all these patients. Only 2 patients in each group (biosimilar etanercept – 2.9%, biosimilar adalimumab 1.98%) had clinically active disease requiring switch to bDMARD with different mechanism of action. 1 patient in biosimilar etanercept group had to stop biological treatment due to cancer diagnosis.

Table. Reasons of switching back to bDMARD

Conclusion: Our study showed overall adherence was good (around 80%) in both switch groups with biosimilar adalimumab doing better than biosimilar etanercept patients. All patients who switched back to bDMARD regained control. Nocebo responses\(^1\), such as subjective increase of disease activity and pain-related adverse events were identified as the main factors having a negative impact on adherence to bsDMARDs. No new safety signals were identified.

THU0159 ‘ONE IS NOT ENOUGH’ - RITUXIMAB SINGLE VS DOUBLE INFUSION PROTOCOL IN TREATMENT OF ESTABLISHED RHEUMATOID ARTHRITIS – REAL LIFE EXPERIENCE OF GARTNAVEL GENERAL HOSPITAL, GLASGOW, UK

S. Batool1, M. A. Abdallah1, K. Anderson1, S. Bawa1.1Gartnavel General Hospital, Glasgow, United Kingdom

Background: Rituximab (RTX), chimeric anti-CD20 monoclonal antibody, is recommended as a treatment option for rheumatoid arthritis (RA) patients who had inadequate response or are intolerant to other DMARDs including at least one anti-TNF inhibitor\(^2\). The most cost-effective dosing and retreatment schedule remains to be defined. Based on series of case reports and observational studies, it is suggested that retreatment with RTX 1g single infusion provides similar clinical outcomes compared with 2 x 1g infusions\(^2\). We report our experience of using single infusion in treatment of established RA.

Objectives: Our unit adopted the single 1g infusion protocol in 2017. Patients were switched to RTX biosimilar – in September 2017. The aim of this study was to assess the effectiveness of single 1g infusion in maintaining the response in RA patients.

Methods: 80 established RA patients on RTX were identified using clinical records held on our database. 67.50% (54/80) were on single 1g infusion and 28.75% (23/80) were receiving 2 x 1g infusions. Flare and inadequate response were assessed by comparing DAS scores pre and post RTX treatment and clinical judgement. We also assessed the effectiveness of biosimilar RTX, and in switching to biosimilar RTX.

Results: RTX group: Overall retention rate was 57.41% (31/54) in single infusion retreatment group. 31.48% (17/54) flared and 76.47% (13/17) were switched back to 2 x 1g infusions with recapture of response in all patients. 1 patient continued single infusion due to recurrent cytopenia and 3 have not had retreatment yet. 11.11% (6/54) had secondary loss of effect (LOE). No flares were noted in 2 x 1g infusion group. 3.75% (3/80) had severe anaphylactic reaction needing to stop their treatment whereas 5% (4/80) experienced minor infusion reactions but managed to continue their treatment.

Switch group: 52 patients switched from RTX to biosimilar. 42 received single 1g infusion and 10 had 2x1g infusions. In single infusion group, 53.38% (22/42) maintained response, 33.33% (14/42) flared with recapture of response in 92.86% (13/14) in 2x1g infusions and secondary LOE in 11.50% (5/44). In 2x1g infusion group, 90% (9/10) maintained response whereas 10% (1/10) had secondary LOE.

Biosimilar RTX group: There were 25 patients on biosimilar RTX. 13/25 (52%) went onto single 1g infusion retreatment protocol. Of these, 3 (23.07%) had flare and 1 (7.69%) had secondary LOE. There were 6 (24%) primary response failures, 2 (8%) minor infusion reactions and 1 (4%) major infusion reaction in this group.

Conclusion: One third of patients in our cohort failed to respond to single infusion protocol. These results were reproducible in all groups – RTX, switch and biosimilar RTX single infusion group. Our study suggests clinicians and patients need to be vary in using single infusion protocol as there is significant risk of losing disease control.

THU0159 THE ADDITIONAL VALUE OF INTERLEUKIN-6 INHIBITORS ON PATIENT REPORTED OUTCOMES IN THE MANAGEMENT OF RHEUMATOID ARTHRITIS FAILURES TO A PREVIOUS ANTI-TUMOR NECROSIS FACTOR INHIBITOR: RETROSPECTIVE ANALYSIS FROM A LOCAL REGISTRY

E. G. Favalli1, M. Biagiopero1, E. Agape1, A. Marchesoni1,2, R. Caporal1,2
1Gaetano Pini-CTO Institute, Department of Rheumatology, Milan, Italy; 2Università degli Studi di Milano, Department of Clinical Sciences & Community Health, Milan, Italy

Background: To date the better strategy for the management of tumor necrosis factor inhibitor (TNFi) failures in rheumatoid arthritis (RA) is still under debate. At the same time, the patient’s perspective is becoming increasingly important in the management of RA and the use of patient reported outcomes (PROs) in becoming more and more frequent in daily practice.

Objectives: To evaluate the additional value of PROs in the measure of comparative clinical response in a real-life local cohort of patients treated with different alternative mechanisms of action after the failure of a first-line TNFi.

Methods: Data were retrospectively extracted from the registry of the ASST Gaetano Pini-CTO Institute, which include all RA patients treated with biologic drugs between December 1999 and December 2019. The analysis was limited to patients who failed a first-line TNFi and the study population was stratified according to the prescribed second-line mechanism of action (MoA). In each treatment subgroup the 6- and 12-month clinical response was evaluated as the mean change from baseline of Disease Activity Score (DAS) score, Patient Global Assessment (PGA), and pain VAS. The rates of patients achieving CDAI remission/low disease activity (LDA) and an acceptable level of pain (pain VAS ≤20) were also calculated. The comparison between treatment subgroups was performed by using the t-test and the Fischer’s test for continuous and dichotomous variables, respectively.

Results: A total of 405 patients (192 treated with a second TNFi, 87 with interleukin-6 inhibitors [IL-6is], 70 with abatacept, and 56 with rituximab) were included in the study. In the overall population 352 patients (86.9%) were female, mean (standard deviation) age 64.8 ± 13.1 years, mean disease duration 14.3 ± 9.1 years, RF and ACPA were positive in 76.4% and 79.3% of patients, respectively. We observed a clear trend toward the superiority of IL-6is over TNFis in the 12-month mean change from baseline of CDAI score (-13.9 ± -9.2, p=0.06) and in remission/LDA rates (58.7 ± 45.1%; p=0.048). In the evaluation of PROs,
we found a statistically significant superiority of IL-6 over TNF inhibitors in the 12-month mean change from baseline of PGA (-34.5 vs -22.6%, p=0.02) and pain VAS (-35.4 vs -19.3%, p=0.01), and a significantly greater rate of acceptable response (42.1 vs 25.6%, p=0.01). No significant difference was observed in any of the evaluated items between a second TNFi and abatacept or rituximab.

**Conclusion:** In a RA cohort of real-life insufficient responders to a first TNFi, we observed an overall better clinical response to IL-6is compared to a second TNFi. This effect is much more evident in the measure of PROs rather than composite indices as a possible result of the involvement of IL-6 in the pathways leading to pain and fatigue development in RA.

**Disclosure of Interests:** Ennio Giulio Favalli Consultant of: Consultant and/or speaker for BMS, Eli-Lilly, MSD, UCB, Pfizer, Sanofi-Genzyme, Novartis, and Abbvie, Speakers bureau: Consultant and/or speaker for BMS, Eli-Lilly, MSD, UCB, Pfizer, Sanofi-Genzyme, Novartis, and Abbvie, Martina Biggioggero: None declared, Elena Agape: None declared, Antonio Marchesoni Speakers bureau: Abbvie, Pfizer, UCB, Novartis, Celgene, Eli Lilly, Roberta Caporali Consultant of: AbbVie; Gilead Sciences, Inc.; Lilly; Merck Sharp & Dohme; Celgene; Bristol-Myers Squibb; Pfizer; UCB, Speakers bureau: Abbvie; Bristol-Myers Squibb; Celgene; Lilly; Gilead Sciences, Inc; MSD; Pfizer; Roche; UCB

**BACKGROUND:**
Mechanistic differences between protein biologics are poorly understood. HLA-DRB1 alleles containing the shared epitope (SE), which are strongly associated with RA, are present in 70–80% of anti-citrullinated protein antibody+ patients (pts) with RA. Numerically higher efficacy responses with abatacept (ABA) vs adalimumab (ADA) were reported after 24 wks of treatment (Tx) in pts with early seropositive RA, specifically in SE+ pts. We conducted a head-to-head exploratory trial comparing ABA 125 mg/wk vs ADA 40 mg/wk every 2 wks (both with early seropositive RA, specifically in SE+ pts).

**OBJECTIVES:** To prospectively explore the relationship between HLA-DRB1 SE genotype and the effects on disease activity after switching from ADA to ABA after completing 24 wks of initial Tx in biologic-naïve pts with early active RA.

**METHODS:** This head-to-head exploratory trial (NCT02557100) enrolled seropositive (anti-citrullinated peptide 2+ and RF+) adults with early (≤12 mos of symptoms), moderate-to-severe RA (ACR/EULAR 2010 criteria). Pts were randomised 1:1 to SC ADA 125 mg/wk or SC ABA 40 mg/wk every 2 wks (both with early seropositive RA). At wk 28, ADA-treated pts were switched to open-label (OL) ABA, following a 6-wk washout period (switch arm); ABA-treated pts continued treatment with ABA in an OL manner (non-switch arm). Pts were grouped by SE status based on HLA-DRB1 genotype (−, no SE allele; +, ≥1 SE allele). Clinical efficacy was assessed to wk 48 to determine the proportion of ACR20/50/70 responders and DAS28 (CRP) remitters in each arm. Safety was analysed throughout the trial and up to 8 wks post last dose.

**RESULTS:** All 40 ABA-treated and 36/40 ADA-treated pts entered the OL ABA period; 3 (lost to follow up n=2, other n=1) and 1 (pt request to discontinue) pts, respectively, discontinued during the OL period. Baseline characteristics were balanced;

**THE EFFECT OF HLA-DRB1 RISK ALLELES ON THE CLINICAL EFFICACY AND SAFETY OF ABATACEPT IN SEROPOSITIVE, BIOLOGIC-NAÏVE PATIENTS WITH EARLY, MODERATE-TO-SEVERE RA TREATED WITH ABATACEPT OR ADALIMUMAB: DATA FROM THE OPEN-LABEL SWITCH PERIOD OF THE HEAD-TO-HEAD SINGLE-BLINDED ‘EARLY AMPLE’ TRIAL**

**Background:** Mechanistic differences between protein biologics are poorly understood. HLA-DRB1 alleles containing the shared epitope (SE), which are strongly associated with RA, are present in 70–80% of anti-citrullinated protein antibody+ patients (pts) with RA. Numerically higher efficacy responses with abatacept (ABA) vs adalimumab (ADA) were reported after 24 wks of treatment (Tx) in pts with early seropositive RA, specifically in SE+ pts.

**Objectives:** To prospectively explore the relationship between HLA-DRB1 SE genotype and the effects on disease activity after switching from ADA to ABA after completing 24 wks of initial Tx in biologic-naïve pts with early active RA.

**Methods:** This head-to-head exploratory trial (NCT02557100) enrolled seropositive (anti-citrullinated peptide 2+ and RF+) adults with early (≤12 mos of symptoms), moderate-to-severe RA (ACR/EULAR 2010 criteria). Pts were randomised 1:1 to SC ADA 125 mg/wk or SC ABA 40 mg/wk every 2 wks (both with early seropositive RA). At wk 28, ADA-treated pts were switched to open-label (OL) ABA, following a 6-wk washout period (switch arm); ABA-treated pts continued treatment with ABA in an OL manner (non-switch arm). Pts were grouped by SE status based on HLA-DRB1 genotype (−, no SE allele; +, ≥1 SE allele). Clinical efficacy was assessed to wk 48 to determine the proportion of ACR20/50/70 responders and DAS28 (CRP) remitters in each arm. Safety was analysed throughout the trial and up to 8 wks post last dose.

**Results:** All 40 ABA-treated and 36/40 ADA-treated pts entered the OL ABA period; 3 (lost to follow up n=2, other n=1) and 1 (pt request to discontinue) pts, respectively, discontinued during the OL period. Baseline characteristics were balanced; mean (SD) RA duration was 5.5 (2.6) mos. The greater efficacy responses seen with ABA vs ADA to Wk 24 were sustained at Wk 48 in the non-switch arm; in the switch arm, the efficacy responses generally increased over the OL period to Wk 48. Specifically, in both the overall population (Figure 1) and among SE+ pts (Figure 2), ACR20/50 response rates (RRs) and DAS28 (CRP) remission rates were similar between arms at Wk 48; ACR70 RR was still somewhat higher in the non-switch arm. Among SE− pts, ACR50 RRs were 56% in the non-switch arm vs 44% in the switch arm at Wk 24; at Wk 48, 56% of pts in the non-switch arm and 67% of pts in the switch arm achieved ACR50. However, data from the SE− subgroup must be interpreted with caution due to low pt numbers (n=8/arm).

**Conclusion:** In this seropositive early RA population, particularly in the SE+ subgroup, a trend towards numerically higher and sustained efficacy responses by stringent definitions was seen in the abatacept non-switch arm at Wk 48; trends towards further improvement were observed in the adalimumab-to-abaatacept switch arm.

**THE COMPARATIVE RISK OF HOSPITALIZED INFECTION IN RHEUMATOID ARTHRITIS PATIENTS INITIATING ABATACEPT OR TUMOR NECROSIS FACTOR INHIBITOR TREATMENT: A NATIONWIDE, POPULATION-BASED COHORT STUDY**

**Background:** Few population-based studies have compared the risks of hospitalized infection between patients with rheumatoid arthritis (RA) starting abatacept or TNFi treatment.

**Data from the SE− subgroup must be interpreted with caution due to low pt numbers (n=8/arm). No new safety signals were identified.**

**Conclusion:** In this seropositive early RA population, particularly in the SE+ subgroup, a trend towards numerically higher and sustained efficacy responses by stringent definitions was seen in the abatacept non-switch arm at Wk 48; trends towards further improvement were observed in the adalimumab-to-abaatacept switch arm.

**References:**
Objectives: The study aimed to assess the relative risk of hospitalized infection in RA patients initiating TNFi treatment compared to those starting abatacept therapy.

Methods: The data source of this study was the 2003–2017 claims data from the Taiwanese National Health Insurance Research Database. First, we identified all RA patients who started their first biologic disease-modifying antirheumatic drug (DMARD)/targeted-synthetic (ts) DMARD therapy. The index date was the first date of bDMARD/tsDMARD prescription. Subjects were followed up till the date of first hospitalization due to infection, 90 days after the last date of bDMARD/tsDMARD prescription, withdrawal from national health insurance or death, whichever came first. We calculated the incidences of hospitalized infection. We further matched abatacept users with TNFi users with a 1:4 ratio for age, sex and disease duration. A Cox regression analysis was used to examine the associations of covariates with the risk of hospitalized infection shown as hazard ratios (HRs) with 95% confidence interval (CIs). Covariates included age, sex, Charlson comorbidity index, a history of hospitalized infection within 5 years before the index date, prior RA-related medications within 6 months before the index date and concomitant RA-related medications. The relative risk of hospitalized infection in abatacept users compared to TNFi users were estimated after adjusting for covariates with a p-value < 0.05 in the univariable analysis.

Results: We identified 10,780 RA patients who started their first bDMARD/tsDMARD treatment. Of them, 8,492 patients received TNFi treatment (etanercept n=4,390; adalimumab n=3,058; golimumab n=1,125), 614 patients were treated with tocilizumab, 278 patients were treated with rituximab, 737 patients were treated with abatacept, and 659 patients were treated with tofacitinib. The incidence rates (IRs) of hospitalized infection in patients treated with TNFi, tocilizumab, rituximab, abatacept and tofacitinib were 351, 407, 2,692, 260 and 0 per 10,000 person-years, respectively. After matching (1:4) for age, sex and disease duration, we compared the risks of hospitalized infection between 728 abatacept users and 2,912 TNFi users. The IRs of hospitalized infection in patients treated with abatacept, TNFi, etanercept, adalimumab and golimumab were 262, 434, 331, 739 and 0 per 10,000 person-years, respectively. After adjusting potential confounders, use of TNFi was not associated with a greater risk of hospitalized infection compared with abatacept use (HR, 2.14; 95% CI, 0.74–6.13; p = 0.159). However, the risk of hospitalized infection was higher in adalimumab users compared with abatacept users (HR, 3.24; 95% CI, 1.09–9.62; p = 0.035).

Conclusion: This nationwide, population-based, matched cohort study showed that among bDMARD/tsDMARD naïve RA patients, use of adalimumab, but not etanercept or golimumab, was associated with a greater risk of hospitalized infection compared with the risk associated with abatacept use.

THU0162

LIKELIHOOD OF CLINICAL WORSENING AMONG RHEUMATOID ARTHRITIS PATIENTS WHO ACHIEVED A PARTIAL RESPONSE TO ADALIMUMAB AND WHO WERE SUBSEQUENTLY SWITCHED TO SARILUMAB

J. Curtis1, D. Aletaha2, G. R. Burmester3, K. Ford4, H. Van Hoogstraten5, H. Leher1, K. Thangavelu6, V. Bykerk7, University of Alabama at Birmingham, Birmingham, AL, United States of America; 1Medical University Vienna, Vienna, Austria; 1Charité – University Medicine Berlin, Berlin, Germany, 4Sanofi, Bridgewater, NJ, United States of America; 2Regeneron Pharmaceuticals, Inc., Tarrytown, NY, United States of America; 3Sanofi Genzyme, Cambridge, MA, United States of America; 1Hospital for Special Surgery, New York, NY, United States of America

Background: Rheumatoid arthritis (RA) patients who achieve a response to therapy but fail to reach low disease activity (LDA) or remission (partial responder) may decline treatment changes for fear of clinical worsening and losing their achieved response. Little is known about the likelihood of worsening after switching therapy in partial responders, and this limits patients’ ability to make informed treatment decisions.

Objectives: This post hoc analysis of the open-label extension (OLE) of MONARCH (NCT02332590) assesses the effects of switching from adalimumab to sarilumab in RA patients with RA who achieved a partial response to adalimumab but not remission or LDA.

Methods: MONARCH was a 24-week, head-to-head monotherapy trial comparing sarilumab with adalimumab. At study end, patients randomized to adalimumab who did not achieve remission or LDA at week 20 were offered the option of switching to sarilumab (300 mg) q2w for the OLE. Partial responders to adalimumab were defined as patients who had improved more than the minimal clinically important difference (MCID) in the Clinical Disease Activity Index (CDAI) during MONARCH, but who continued to have moderate to high disease activity (CDAI >10) at OLE baseline (BL). MCID was defined as a CDAI decrease ≥12 from a BL CDAI >22 or ≥6 from a BL CDAI >10 to ≤22. Response following treatment switch was assessed by change in CDAI and other outcomes from OLE BL to OLE Week 24. The effect of switching was analyzed descriptively and categorized as: worsening = CDAI increase ≥6; improvement = CDAI decrease ≥6; stable = CDAI absolute change ≤6. Patients randomized to sarilumab in MONARCH continued to receive sarilumab in the OLE and were included as a control group.

Results: Of 369 patients enrolled in MONARCH, 320 (87%) entered the OLE; 155 were switched from adalimumab to sarilumab, and of these, 91 were partial responders who had a mean (SE) CDAI of 25.1 ± 0.6 at OLE BL of 19.5 (0.66). Mean (SE) improvement in CDAI from OLE BL to OLE Week 24 in these patients was 7.37 (1.10). At OLE Week 24, only 6% of adalimumab partial responders had worsened after switching to sarilumab, while 57% had improved; the remaining 37% maintained stable disease activity. Analyses of other efficacy measures—patient and physician global assessments, disease activity score 28-joint erythrocyte sedimentation rate, and swollen and tender joint counts—demonstrated similar results: improvement was seen in 27–78% and worsening in 2–17%. No new safety signals emerged during the OLE. The adverse event profile among patients switching from adalimumab to sarilumab was consistent with the established safety profile of sarilumab.

Conclusion: Among adalimumab CDAI partial responders who switched to sarilumab, there was a low likelihood of clinical worsening, while more than half of such patients achieved clinically meaningful improvement. Similar results were observed for other efficacy measures. This small risk of worsening coupled with the substantial likelihood of improvement after switch may help alleviate patients’ concerns around loss of response and help inform shared decision-making.

THU0163

USE OF BIOLOGIC AGENT IN MONOTHERAPY IN COMPARISON TO THE ASSOCIATIONS WITH D(SEASE) (MODIFYING) (A)NTI (RHEUMATIC) D(RUGS) REVIEW OF LITERATURE AND META-ANALYSIS OF RANDOMIZED TRIALS.

C. Depeich1, F. X. Laborne1, F. Hilliquin1, CHSE Corbiel-Essones, France

Background: Biologic disease-modifying antirheumatic drugs (bDMARDs) extend the treatment choices for rheumatoid arthritis (RA) patients with suboptimal response or intolerance to conventional synthetic DMARDs (CsDMARDs). Currently, 9 biologic agents are approved in the RA treatment: and among them, three anti TNF agents are also approved in monotherapy (adalimumab, certolizumab and etanercept), but also abatacept, anakinra and tocilizumab. Registries of routine clinical practice treatment indicate that approximately one third of RA patients are being treated with a bDMARD in monotherapy and analyses from health care
claims suggest that when methotrexate (MTX) is prescribed in combination with a bDMARD, more than half of the patients do not collect the MTX prescription and overall patients seem to taper MTX intake over time. So it is important to evaluate the benefits and harm associated with use of biological agents as monotherapy, and not only the traditional combination therapy strategies.

Objectives: To compare the efficacy and safety of the individual biological agents used in monotherapy in patients with RA than the combination therapy strategy with CsDMARD + bDMARD.

Methods: We used The Cochrane Central Register of Controlled Trials (CENTRAL), EMBASE, and MEDLINE in order to carry out our research, for published reports from inception of each database through December 2019. Search results were limited to randomised controlled trials (RCTs), with our two arms: biological agent in monotherapy and combination strategy (with any CsDMARDs). Major outcome was the ACR 20 response criteria at 24 week. The secondary outcomes were: the ACR 20 at 52 week, ACR 50, 70, 90, 90 response criteria, the DAS 28 remission (with CRP and/or ESR), the score sharpes modified non progressor, the proportion of patients who withdrawals the study due to adverse events, the proportion of patients who withdrawals the study due to lack of efficacy, the HAQ improvement > 0.22, CDAI and SDAI remission at week 24 and 52 if the data were available. The study of tolerance was also made. To estimate the relative efficacy of treatments whilst preserving the randomized comparisons within each trial, a Bayesian network meta-analysis was conducted in R (version 3.6.1) using fixed and random-effects.

Results: The systematic review identified 2566 citations. The analysis comprises 22 trials (6358 patients), including six biological agents approved for RA (abatacept, adalimumab, etanercept, golimumab, rituximab and tocilizumab) as well as two other molecules: Clazakizumab, a humanized monoclonal antibody that binds to the interleukin-6 (IL-6) cytokine and Anbainuo, recombinant human TNFR1I:Fc fusion protein. No study satisfyies our search criteria for anakinra, certolizumab and infliximab. Compared to combination therapy with CsDMARD+bDMARD, bDMARD monotherapy has less probability to give a ACR20 response at 24 weeks (RR: 0.92 [0.89 – 0.96]) in fixed or random effect model and this result is similar at 52 weeks (RR: 0.94 [0.89 – 0.99]). For all other outcome measures, we can see an increased of ACR50–70 and 90 responses, an improve of the DAS 28 remission score, an increase of the proportion of sharps score non progressors (<0.5) as well as a decrease of withdrawals for inefficacy without increase of withdrawals for toxicity.

Conclusion: Evidence from this meta-analysis suggests that combination strategy with bDMARD+CsDMARD remains the most efficacious option, being more effective than the use of biologics in monotherapy. The interest from this point of view is to sensitize prescribers to the use of other CsDMARDs when there is a contraindication or intolerance to MTX, but also to make patients aware of the superiority of the association of biological agents with CsDMARDs.

THU0164

PERFUSE: A FRENCH PROSPECTIVE/RETROSPECTIVE NON-INTERVENTIONAL COHORT STUDY OF INFLIXIMAB-NAIVE AND TRANSITIONED PATIENTS RECEIVING INFLIXIMAB BIOSIMILAR SB2; AN INTERIM ANALYSIS

B. Fautrel1, Y. Bouhnik2, G. Desjeux2, A. Brigu1, U. Freudenprung3, J. Addison2, P. Salpêtrière Hospital, AP-HP, Sorbonne University, Paris, France; 2Beaumont Hospital, AP-HP Paris Diderot University, Clitry, France; 3E-Health Services Sanoïa, Gémenos, France; Biogen France SAS, Paris, France; Biogen GmbH, Baar, Switzerland; Biogen IDEC, Maidenhead, United Kingdom

Background: SB2 is approved in the EU as an infliximab (IFX) biosimilar, having demonstrated bioequivalence and similar efficacy, safety and immunogenicity as the reference. There is limited real-world evidence published on persistence, effectiveness or safety of SB2, in IFX-naïve patients or those transitioning from originator or another IFX biosimilar.

Objectives: PERFUSE is an ongoing non-interventional study of 1374 patients (500 with rheumatology diagnoses, 874 with gastroenterology diagnoses) receiving SB2 as routine therapy, with objectives to describe clinical characteristics, effectiveness, treatment persistence and safety in patients initiating SB2 and followed for 24 months at 21 specialist sites across France.

Methods: Adult patients eligible for inclusion in the rheumatology study cohorts have a diagnosis of Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Ankylosing Spondylitis (AS) and initiated SB2 in routine clinical practice after September 2017, either as their first IFX or transitioning from treatment with IFX reference or another IFX biosimilar. Data are captured from patients’ clinical records. Outcome measures include persistence on SB2, clinical characteristics at baseline (time of SB2 initiation), disease scores and Serious Adverse Events (SAEs).

Results: This 12-month interim analysis includes 500 patients (99 with RA, 62 with PsA and 339 with AS). M12 persistence on SB2 for IFX-naïve patients combined was 73.8% (95% CI 61.5, 84.0), 76.2 % (95% CI 60.5, 87.9) and 71.5 % (95% CI 65.6, 76.9) in RA, PsA and AS respectively.

In patients with prior IFX, no clinically meaningful difference in disease activity score from baseline to M12 was observed (Table 1). All patients who withdrew due to lack of efficacy, the HAQ improvement > 0.22, CDAI and SDAI remission at week 24 and 52 if the data were available. The study of tolerance was also made. To estimate the relative efficacy of treatments whilst preserving the randomized comparisons within each trial, a Bayesian network meta-analysis was conducted in R (version 3.6.1) using fixed and random-effects.

* Clopper-Pearson
7 reported SAEs are unrelated to SB2: prostate and breast carcinoma in the RA cohort; alcohol poisoning, nephrotoxicity, epistaxis, cutaneous lesion and malleolar fracture in the AS cohort.

Conclusion: This interim analysis indicates that patients with RA, AS or PsA can be successfully transitioned from originator or biosimilar IFX to SB2, without loss of disease control and with no safety concerns. The majority of transitioned patients continued SB2 treatment at M12 post-initiation. The PERFUSE study will provide ongoing, pertinent information about outcomes in these populations, helping to inform evidence-based treatment decisions.

PROSARA - A PROSPECTIVE, MULTICENTER, NON-INTERVENTIONAL STUDY TO EVALUATE THE SAFETY AND EFFECTIVENESS OF SARILUMAB FOR THE TREATMENT OF ACTIVE RHEUMATOID ARTHRITIS IN REGULAR CARE IN GERMANY

E. Feist1, P. M. Aries2, S. Zinke3, H. Burkhartd, I. Albrecht, O. Bley3, M. Obermeier3, P. Sterna4, M. Welcker, C. Kühne, A. D. Holst5, N. T. Baierlecken, H. P. Tony6, H. Elio7os Department of Rheumatology, Vogelsang-Gommer, Germany; 2Rheumatologie im Struenseehaus, Hamburg, Germany; 3Outpatient Rheumatology Center Berlin-Lichtenberg, Berlin, Germany; 4University Hospital, Division of Rheumatology, Frankfurt am Main, Germany; 5Sanofi Aventis, Berlin, Germany; 6G&K Gesellschaft für Therapieforschung, Munich, Germany; 7ZV fuer Rheumatologie Dr. M. Welcker, Planegg, Germany; 8Outpatient practice, Daimhlsenbergen, Germany; 9Outpatient practice, Ludwigslust, Germany; 10Private Practice Rheumatology, Cologne, Germany; 11Rheumatology/Immunology, Department of Internal Medicine II, Würzburg, Germany

Background: Blockade of IL-6 signaling by sarilumab has been demonstrated to be an effective treatment approach for rheumatoid arthritis. Due to strict inclusion and exclusion criteria, randomized controlled trials may not represent the heterogeneous RA patient population encountered in regular care.

Objectives: The current study investigated the safety and effectiveness of sarilumab in the treatment of RA in regular care in Germany.

Methods: The prospective, observational, single-arm 24-months PROSARA study (SARILL08661) is currently running in Germany at 79 sites, aiming to include up to 750 RA patients treated with sarilumab. RA patients are selected at physician discretion and treated according to the label. Study objectives include the documentation of safety and various effectiveness outcomes. This interim analysis included patients with data available up to 12 weeks. All analyses are descriptive only.

Results: To date 348 patients were included in the study; of which 265 were biologic naïve. Most common pretreatment with b/ts DMARDs included TNF-inhibitors (TNFI, 56.2%), non-TNF biologics (29.1%) or JAK-inhibitors (JAKI, 17.4%). At baseline, 49% received sarilumab as monotherapy and 29% in combination with conventional DMARDs (not specified for 22%). After 12 weeks of treatment with sarilumab, the mean DAS28-ESR decreased from 5.0±1.46 to 3.0±1.44 and CDAI from 26.7±13.79 to 13.6±11.4, respectively. DSAS28-ESR remission/ low disease activity. Boolean remission was observed in 9.5% [n=19/201] of patients at week 12. HAQ-DI improved from 1.3 at baseline to 1.1 at week 12 (n=195). The mean CDAI improvement was similar for autoantibody-positive (RF and/or ACPA; CDAI -12.5 at week 12) compared to -negative patients (CDAI -15.4 at week 12). Patients switching from JAKI to sarilumab (n=32), were more severely affected, had longer disease duration and received more prior treatments than patients switched from another compound. Of note, similar efficacy was observed among patients that switched from JAKI to sarilumab vs patients switched from other DMARDs; disease activity outcome measures including DAS28, CDAI, TJC, SJC and global assessments improved consistently (Figure 1).

Safety was consistent with the anticipated profile of IL-6 inhibition and no new safety signals occurred. Adverse events and serious adverse events were described in 33.9% and 6.3% of patients, respectively.

Conclusion: Sarilumab administered in regular care demonstrated rapid and clinically meaningful improvement in a general RA patient population including patients switching from JAKI. The safety profile was consistent with data reported from controlled clinical trials.

THU0166

HOW EFFECTIVE AND SAFE ARE BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN ELDERLY AND VERY ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS?

R. Freitas1, N. Madeira2, B. M. Fernandes3, F. Costa4, M. Santiago5, A. Neto6, S. Avevedo7, J. Madruga Dias5, M. Couto5, M. Bernardes5, L. Cunha Miranda5, J. Polido-Pereira8, J. E. Fonseca9,10, M. J. Santos1. 1Hospital Garcia Orta, Rheumatology, Almada, Portugal; 2Instituto Português Reumatologia, Lisboa, Portugal; 3Hospital São João, Rheumatology, Porto, Portugal; 4Hospital Coimbra, Rheumatology, Coimbra, Portugal; 5Hospital Egas Moniz, Rheumatology, Lisboa, Portugal; 6ULSAM, Rheumatology, Ponte Lima, Portugal; 7Centro Hospitalar Médio Tejo, Torres Novas, Portugal; 8Hospital São Teotónio, Viseu, Portugal; 9Hospital Santa Maria, Lisboa, Portugal; 10Instituto de Medicina Molecular, Lisboa, Portugal

Background: The proportion of elderly patients is increasing in the rheumatoid arthritis (RA) population. However, data on drug effectiveness and safety in these patients is scarce.

Objectives: To assess effectiveness and safety of biologic Disease MODIFYing Antirheumatic Drugs (bDMARD) in elderly and very elderly RA patients.

Methods: Prospective cohort-study of RA patients registered at Reumat in starting a 1st bDMARD. Treatment persistence, EULAR response at 6 and 12 months, and adverse events (AE) were compared between adults (<65 years-old), elderly (65-74 years-old) and very elderly (≥75 years-old).

Results: 2401 patients were included, of which 379 were elderly and 83 very elderly. Elderly and very elderly had higher disease activity at baseline and more comorbidities. Elderly patients started bDMARD later in the course of
RA (Table 1). Crude and adjusted bDMARD treatment persistence was similar in the 3 groups (p=0.07; Graph). At 6/12 months, EULAR response was achieved by 81.6%/83.3%, 75.2%/88.5% and 82.6%/84.2% of adults, elderly and very elderly, respectively (Table 2). Except for a lower response rate at 12 months in the elderly group, the EULAR response was comparable in the 3 groups. The same results were observed after adjustment for baseline characteristics, namely the chance of achieving EULAR response was not different in adults and very elderly (OR 0.78, 95% CI 0.19 to 3.2). Also, the variation of DAS, CDAI and SDAI at 6 months and 12 months were comparable in the 3 groups. AE were reported in 21%/22.5%/22.9% of adult/elderly/very elderly patients, respectively. The rate of AE per 100 patient-years was lower in adults when compared to elderly and very elderly (6.4, 13.5 and 14.7, respectively) (Table 2). Also the rate of severe AE (SAE) was higher in very elderly (4.29 per 100 patient-years) when comparing to adults and elderly (1.03 and 1.94 respectively).

Conclusion: The persistence on 1st bDMARD was similar in adults, elderly and very elderly RA patients. Though older patients have more comorbidities and more active disease at baseline, treatment with biologics was effective and with an acceptable safety profile. However, it is important to take into account the higher risk of AE and SAE in older patients. In conclusion, this study supports the use of bDMARD treatment in elderly and very elderly RA patients.

THU0167 ASSOCIATIONS BETWEEN RHEUMATOID ARTHRITIS DISEASE ACTIVITY AND PATIENT-REPORTED OUTCOMES IN SARILOMAB CLINICAL TRIALS

1Stanford University, Palo Alto, United States of America; 2Charité – University Medicine Berlin, Berlin, Germany; 3Sorbonne Université and Pitie Salpetriere Hospital, Paris, France; 4Sanofi, Bridgewater, United States of America; 5Sanofi, Cambridge, United States of America; 6Regeneron Pharmaceuticals, Inc., Tarrytown, United States of America; 7Leiden University, Leiden, Netherlands; 8Medical University of Vienna, Vienna, Austria; 9Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, United States of America

Background: Sarilumab is a human interleukin (IL)-6 receptor inhibitor approved for the treatment of adults with moderately to severely active rheumatoid arthritis (RA). The relationship between disease activity (DA), sarilumab treatment, and improvements in patient-reported outcomes (PROs) has not been well-studied.

Objectives: Assess the association between DA and PROs in three sarilumab Phase 3 trials.

Methods: This post hoc analysis included patients from three trials: two placebo-controlled trials (MOBILITY; NCT01061736 and TARGET; NCT01709578) with sarilumab dose groups 150 mg and 200 mg q2w that were combined for this analysis; and MONARCH (NCT02332590) with sarilumab 200 mg versus adalimumab 40 mg q2w. Associations between PROs and DA were tested at Week 24. All statistics are descriptive.

Results: Sarilumab was generally associated with larger PRO improvement than placebo both in patients who did and patients who did not achieve DA thresholds (Table). Improvement was less pronounced in patients who did not achieve DA thresholds. In the active-comparator trial, PROs improved in both treatment groups, across all DA levels. There was no clear difference between sarilumab and adalimumab in PRO response. There was a consistent trend of positive but reduced PRO responses with increased DA level using multiple cut-points (data not shown).

Conclusion: Achieving lower DA was associated with increased PRO improvements. In patients who did not achieve DA thresholds, the improvements were more favorable with sarilumab than placebo. This may support the emerging concept that mechanisms other than inflammation may contribute to improvements in PROs, potentially mediated via IL-6 signaling.

GESTATIONAL DESIREE AND CERTOLIZUMAB PEGOL IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASE: PRELIMINARY RESULTS OF THE GESTAMAD COHORT

L. González1, A. García Martos2, M. Salido Olivares2, P. Castro3, M. C. Ortega de la O4, A. Castilla5, P. Navarro6, C. Arconada7, A. Aragon Díez2, A. Diaz Oca2, E. M. Andres6.1Hospital Universitario del Tajo, Aranjuez, Spain; 2Infant Cristina University Hospital, Parla, Spain; 3Hospital Universitario de Getafe, Getafe, Spain; 4Hospital Infanta Elena, MADRID, Spain; 5University Hospital La Paz, Madrid, Spain; 6Hospital Universitario de Fuenlabrada, Fuenlabrada, Spain; 7HU INFANTA ELENA, MADRID, Spain; 8Universidad Rey Juan Carlos, MADRID, Spain

Background: The use of biological therapies during pregnancy has been contraindicated since the beginning of the use of these drugs. In recent years several studies have demonstrated the minimal-to-no transfer of certolizumab pegol (CZP) to the placenta and breast milk, which has allowed its approval for use in pregnant and breastfeeding if clinically necessary. However, there are no studies evaluating the use of CZP during this period in real life or the characteristics of this subgroup of patients.

Objectives: To describe the profile of women of childbearing age diagnosed with chronic inflammatory rheumatic disease (CIRD): Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and axial Spondyloarthritis (axSpA), who initiate CZP by gestational desire using the GESTAMAD registry (multicenter study of women of childbearing age), with pregnancy being the reason for the change.

Methods: Prospective multicenter study that aims to know the characteristics of women of childbearing age diagnosed with CIRD and gestational desire to which CZP is initiated for this reason. The comorbidities of the patients such as hypertension, diabetes and cardiovascular disease were collected. Disease activity was measured by DAS28 using CRP in RA and PsA and BASDAI in axSpA. The present study presents preliminary data from the initial cohort and will be followed prospectively for 24 months to assess the efficacy and safety of the drug during pre-conception, pregnancy and lactation.

Results: A total of 45 patients have been recruited in 6 Madrid hospitals from June to December 2019. Patients had a mean age of 35.9, (36.6 in RA, 35.2 in PA and 35.1 in SPA). Forty-one percent had RA, 20.0 percent had PA and 28.8 percent had SPA. The main reason for initiating CZP was pregnancy (93.3%), with 6.7% of patients for other reasons. The median duration of pregnancy was 39.5 weeks. The median DAS28 at the start of pregnancy was 4.5 in RA and 3.6 in PA and 4.0 in SPA. In RA the highest values of CRP and ESR were found prior to initiation with CZP but this difference was not statistically significant (p=0.644 and 0.605, respectively). 22.2% of patients had previous comorbidities.

Conclusion: The mean age of patients with gestational desire in CIRD is high. Women diagnosed with PsA and axSpA have a high rate of previous abor-, upper than 25%. The duration of the disease is equally long at the time of manifesting gestational desire. The use of treatments such as CZP, compatible with pregnancy and lactation would allow a better control of inflammatory joint disease in this period of life, encouraging patients not to postpone their gestational desire.

COMPARISON OF THE SYNOVIAL RESPONSE TO MECHANICAL STRESS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS IN CLINICAL REMISSION ON METHOTREXATE OR ANTI-TNF

C. Guillén-Astete1,2,3, P. Zurita-Prada2,3, C. Urrego-Laurín2,3, Hospital Ramón y Cajal, Madrid, Spain; 2University Hospital Moncloa, Madrid, Spain; 3Universidad Europea de Madrid (Campus Villaviciosa), Villaviciosa de Odón, Spain

Background: Physiologically, the joint synovium responds to physical activity according to the frequency and intensity of the efforts, producing slight effusion without detectable hyperemia. In patients with RA in remission, a similar response can be expected, since it is understood that the immune-mediated inflammatory component has been controlled physiopathologically. Our interest is to determine whether once clinical remission has been reached, treatment with MTX or antiTNF produces the same normalization of the synovial behaviour. Our interest is to determine whether once clinical remission has been reached, treatment with MTX or antiTNF produces the same normalization of the synovial behavior.

Objectives: The aim of the present study is to compare the synovial response to mechanical stress of patients with Rheumatoid Arthritis (RA) in remission treated with Methotrexate (MTX) or Etanercept (ETN).

Methods: Descriptive observational study. We included patients with RA in remission (DAS28<2.6) for at least 6 months on MTX or MTX and anti-TNF-alpha therapy (ETN). An ultrasound examination protocol was developed for the 2nd, 3rd and 4th MCP and non-dominant hand carpus for gray scale (GS) and power Doppler signal detection (sPD) according to EULAR/OMERACT definitions. Two ultrasound examinations were performed on each patient, before and 24 hours after starting a manual digital flexure exercise program against resistance measured by a handheld dynamometer CAMRY™ model EH101-17. Total synovitis scores in EG (0-12) and sPD (0-12) were compared.

Results: We included 37 patients on MTX treatment (median dose 15mg/week, range 7.5-25mg/week) and 16 patients on ETN treatment (median dose 50mg/week, range 25-50mg/week). The baseline ultrasound score in the MTX treatment group was 3.3 SD 1.4 in GS and 1.5 SD 1.5 in PDs (P<0.05 and P<0.001, respectively). In patients treated with TNEs, the basal score in GS was 1.3 SD 0.6 in GS and 0.6 SD...
BAFF CONTRIBUTES TO THE DEVELOPMENT OF IMMUNOGENICITY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TNF INHIBITORS

B. Hernández-Breijo1, I. Parodis2, J. Gehin3, C. Plasencia3, V. Navarro-Compañ3, A. Martínez-Feito4, D. J. Warren2, A. Mezcua5, M. Novella-Navarro1, P. Nozal1, A. Balza5. Immuno-Rheumatology Research Group, IDiPaz, La Paz University Hospital, Madrid, Spain; 5Division of Rheumatology, Department of Medicine, Karolinska Institutet, and Rheumatology, Karolinska University Hospital, Stockholm, Sweden; 2Dept of Medical Biochemistry, Oslo University Hospital, Radiumhospitalet, Oslo, Norway

Background: Immunogenicity related to treatment with TNF inhibitors (TNFi) is one of the causes for the decreased attainment of clinical response in patients with rheumatoid arthritis (RA). However, the involved mechanism is not entirely clear. The B-cell activating factor (BAFF) may play a role in the development of immunogenicity.

Objectives: To analyse the association between baseline serum BAFF concentration and the development of immunogenicity within 6 months (m) of TNFi treatment in patients with RA.

Methods: A total of 121 patients with RA initiated at standard doses of TNFi (infliximab (n=64), adalimumab (n=13), golimumab (n=11), certolizumab (n=4) and abatacept (n=3)) were included in this observational study and followed for 6m. Eleven (9%) received TNFi monotherapy, 92 (85%) TNFi+MTX (methotrexate) and 31 (26%) TNFi+csDMARDs other than MTX. A cohort of 68 untreated patients with early RA and 20 healthy individuals (age- and sex-matched with the patients) were included as controls. Serum samples were obtained at baseline and 6m, up to 24h prior to TNFi administration. The baseline serum BAFF concentration was measured using ELISA. Drug and anti-drug antibody (ADA) levels were measured using sandwich and drug-sensitive ELISA, respectively. Patients were stratified according to ADA development. Depending on data distribution, comparisons were conducted using unpaired t, Mann-Whitney U or Fisher’s exact tests. The association between the development of ADA within 6m and clinical/serological variables was evaluated by uni- and multi-variable logistic regression. The presence of interactions with covariates (age, RF, ACPA, body mass index, baseline DAS28 and concomitant MTX dose) was tested, stratifying the results if this was significant (p<0.05). In case of no interaction, the model was later adjusted for these covariates.

Results: Mean serum BAFF concentration in healthy controls (373±59 pg/mL) was significantly lower compared to patients with early RA (921±388 pg/mL), (p<0.0001 for both). However, BAFF concentrations did not differ between early and established RA (p=0.9).

In this cohort, 37 (31%) patients developed ADA within 6m of treatment. These patients showed higher frequency of seropositivity (RF, p<0.05; ACPA<0.05), higher baseline DAS28 (p<0.05), received lower dose of concomitant MTX (p=0.008), and had higher baseline BAFF concentration (p=0.06). The association between baseline BAFF concentration and ADA development was next investigated. The dose of concomitant MTX tended to interact on this association (p=0.06). A significant interaction was found between baseline BAFF concentration and age (Wald chi-square= 6.23; p=0.01); therefore, the results were stratified according to age (≥54yr). The results showed that baseline BAFF concentration was associated with ADA development only in older patients (OR=1.0, p=0.02) (shown in the figure). In addition, a significant Spearman correlation between baseline BAFF concentration and ADA levels at 6m was found in older patients (r=0.5, p=0.001).

Conclusion: Our results suggest that BAFF has a role in the development of immunogenicity. Nevertheless, this association depends on the age. In RA patients treated with TNFi, the development of ADA within 6m is associated with higher baseline BAFF concentration only in older patients but not in younger patients. The dose of concomitant MTX interacted on this association.

References:
respective changes in cervical lesion parameters after 1 year were as follows: ADI: 0.20 ± 0.40 and 0.27 ± 0.45 mm (p = 0.387); SAC: −0.12 ± 0.32 and −0.17 ± 0.38 mm (p = 0.359); and Ranawat value: −0.15 ± 0.36 and −0.13 ± 0.34 mm (p = 0.783). The respective changes in cervical lesion parameters after 2 years were as follows: ADI: 0.35 ± 0.58 and 0.56 ± 0.70 mm (p = 0.099); SAC: −0.25 ± 0.47 and −0.45 ± 0.62 mm (p = 0.047); and Ranawat value: −0.23 ± 0.47 and −0.33 ± 0.55 mm (p = 0.293) in the patients receiving ABT and MTX (Fig. 1). The numbers of patients who did not show progression in ADI, SAC and Ranawat value were each 42(70%) and 43(57%) cases(p=0.130); 46(77%) and 46(61%) cases(p=0.057) and 47(78%) and 53(71%) cases(p=0.313) after 2 years. Also the number who was able to suppress progression in all three parameters were each 42 cases (70%) receiving ABT and 43 cases (57%) receiving MTX (p=0.130) after 2 years (Fig. 2).

Conclusion: This study suggested that ABT treatment can be used to suppress the progression of RA cervical lesions more than MTX treatment.

THU0173 DIFFERENCES BETWEEN PATIENT-REPORTED AND PHYSICIAN-REPORTED ADVERSE DRUG REACTIONS ATTRIBUTED TO bDMARDs

L. Koss1, N. Jessurun1, E. Van Puijlenbroek1,2, A. Van Tubergen1,2, H. Vonkeman1,8, Netherlands Pharmacovigilance Centre Lareb, a-Hertogshosp, Netherlands; 2University of Groningen, Groningen, Netherlands; 3Maastricht University Medical Center+, Maastricht, Netherlands; 4Maastricht University, Maastricht, Netherlands; 5Medisch Spectrum Twente, Enschede, Netherlands; 6University of Twente, Enschede, Netherlands

Background: Patient registries are a valuable tool to monitor a patient’s health status. However, these systems operate primarily from the healthcare provider (HCP) perspective, which makes it difficult to collect detailed information on the nature, frequency and personal impact of adverse drug reactions (ADRs).

Objectives: Determining whether the distribution of patient-reported ADRs attributed to bDMARDs differs from ADR registrations by HCPs.

Methods: Patient reported ADRs were derived from the Dutch Biologic Monitor (DBM), a multi-centre cohort event monitoring system based on web-based questionnaires for bDMARD-using patients. ADR reports of the Dutch Rheumatic Arthritis Monitoring Registry (DREAM-RA) were used to outline the HCP perspective. ADR reports from foundation up to 31 October 2019 were coded according to MedDRA terminology. Fisher-Freeman-Halton test with Monte Carlo simulation was used to measure discrepancies between the distributions of High Level Group Terms (HLGT). The prevalence of the top 15 HLGTs were compared using Chi-Square Goodness-of-Fit tests.

Results: ADR reports of 404 DBM participants (1,977 ADRs) and 341 DREAM-RA patients (679 ADRs) were analysed. Patients and HCPs reported a different ADR distribution (p<0.001). Administration site reactions were most frequently reported by patients, followed by infections and (epi)dermal conditions. HCPs most often reported (epi)dermal conditions, infections and general system disorders. Moreover, the distribution of ADRs that patients allegedly discussed with HCPs varied considerably from the distribution of HCP-reported ADRs (p<0.001).

Conclusion: Patients and HCPs report a different distribution of ADRs attributed to bDMARDs. Therefore, patient-reported ADRs should ideally be combined with HCP reports, as the combination of both perspectives gives a more complete picture of a patient’s health status.

Background: It has been reported that rheumatoid arthritis (RA) patients who have large joint involvement associated with higher serological inflammatory markers and more functional disability. Moreover, a previous report showed that these patients were more difficult to achieve clinical remission. However, it remains unclear which biologics are effective in the patients with RA who have large joint involvement.

Objectives: The aim of this study is to investigate the efficacy of anti-IL-6 receptor antibody (aIL-6) or TNF-inhibitor (TNFi) in the treatment of RA patients who have knee joint involvement.

Methods: We enrolled the 784 patients who visited our hospitals in 2003 to 2019 and were treated with aIL-6 or TNFi more than 12 weeks. We divided the patients into 2 groups with or without knee joint involvement for further analysis. Knee joint involvement was defined as the patients had at least one swelling joint of knee at baseline. We investigated the CDAI levels at baseline and 12 weeks after the initiation of biologics.

Results: Interestingly, the patients who had knee joint involvement with aIL-6 significantly ameliorated ∆CDAI (n=95, 15.0±10.8; mean±SD) compared to those with TNFi (n=148, 11.4±10.3) at 12 weeks (P=0.003). aIL-6 group consists of 95 tocilizumab treated patients. TNFi group includes 25 adalimumab, 25 certolizumab pegol, 14 etanercept, 54 golimumab and 30 infliximab treated patients. Baseline clinical characteristics of the 243 RA patients who had knee joint involvement were shown in Table 1. Mean ages, sex and disease durations were not significantly different between the two groups. Baseline CDAI levels of aIL-6 group (24.8±11.8) were slightly elevated compared to those of TNFi group (21.7±10.9). Multivariate analysis adjusted for age, gender and baseline CDAI levels revealed that aIL-6 significantly improved ∆CDAI levels compared to TNFi (P=0.04). By contrast, in the RA patients who had no swelling of knee joints, there was no significant difference of ∆CDAI improvement between aIL-6 group (n=156, 5.5±7.4) and TNFi group (n=385, 6.7±8.9).

Conclusion: Thus, these findings suggest that anti-IL-6 receptor antibody was more effective in the RA patients with knee joint involvement compared to TNFi inhibitor.

Results: 944 patients with RA received ≥1 cycle of RTX in Leeds over the past 17 years. Of these, 358 required RTX re-treatment during the study period (Oct 2017–Jan 2020); 283 (73.5%) switched to RTX-B, whilst 95 (26.5%) remained on RTX-O (medical reason=46.3%; patient decision=53.7%). 256/263 patients on RTX-B with 4-month data were analysed: 201/263 (77.5%) were female, mean (SD) age 63.1 (12.4), 97.7% seropositive, 81.6% on csDMARD (62.9% methotrexate), 14.8% oral steroid, 58.6% had previous bDMARDs, and mean (SD) RTX-O cycles pre-switch was 6 (3.6). Total follow-up was 378 patient-years. Mean (SD) RTX-B was 3.01 (1.17) 4 months post-last cycle; RTX-O was 3.32 (1.31) post-switch to RTX-B (mean diff +0.30, 95% CI 0.004-0.60; p=0.047), with increase in VAS (4.7, 95% CI 0.09-11.37; p=0.047), but not SJC, TJC or CRP. At last follow-up, 185/256 (72.3%) patients remained on RTX-B (median range) RTX-B cycles 2 (1-4). RTX-B retention rate estimates were 79.4% and 71.3% at 12 and 18 months respectively. Following RTX-B discontinuation, 33/256 patients (12.8%) switched back to RTX-O [LOR=30 (11.7%), adverse effects (AEs)=3 (1.2%), 13/256 (5.1%) started other bDMARDs, and 25/256 (9.7%) stopped treatment (no longer indicated)=7, deaths=7, loss to follow-up=6, patient choice=3, new contraindication=2]. Of 46 patients with LOR/RAE to RTX-B, 39 discontinued after cycle 1 (C1), 5 after C2 and 2 after C3. 31/33 patients switched back to RTX-O remained on treatment but follow-up was limited [mean (SD) 7.5 (3.2) months; 23/33 had 1 cycle only]. Compared with patients treated with other b/tsDMARDs, those switched back to RTX-O had more previous RTX-O cycles (mean (SD) 6.77 (3.28) versus 2.62 (2.10); p<0.001). Compared with patients who remained on RTX-B (n=185), those who discontinued for LOR/RAE/death (n=53) had more previous bDMARDs (mean 1.26 vs 0.83; difference 0.43, 95% CI 0.10-0.77, p=0.01), but no differences in other clinical characteristics, treatment or B-cell numbers.

Conclusion: Our real-world single-centre experience of non-medical switch from RTX-O to RTX-B in RA showed approx. three quarters of patients remained on RTX-B and maintained stable disease activity. However, apparent LOR occurred in 16%. Of >10% switched back to RTX-O, the majority remained on treatment at short-term follow-up.

DURABILITY OF RESPONSE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING TOCILIZUMAB: DATA FROM THE US-BASED CORRONA RHEUMATOID ARTHRITIS REGISTRY

D. A. Pappas1,2, T. Blachley2, J. H. Best3, S. Zlotnick3, W. Reiss4, K. Emeanuru2, J. M. Kremer2,4, 1Columbia University, New York, United States of America; 2Corrona, LLC, Waltham, United States of America; 3Genentech, Inc., South San Francisco, United States of America; 4Albany Medical College and The Center for Rheumatology, Albany, United States of America

Background: Understanding the durability of response to biologics and factors associated with failure to maintain response in a real-world setting can inform treatment decisions for patients with rheumatoid arthritis (RA).

Objectives: To evaluate the durability of response and identify factors associated with decreased durability in US patients with RA initiating tocilizumab (TCZ) in routine clinical practice.

Methods: TCZ-naïve patients enrolled in the Corrona RA registry who initiated TCZ (subcutaneous [SC] or intravenous [IV]) after January 1, 2010 and had ≥1 follow-up visit were included. Durability of response was defined as maintaining continuous TCZ and: (a) a minimum clinically important difference (MCID) in clinical disease activity index (CDAI) (defined as an improvement in CDAI compared to baseline of: ≥2 if baseline CDAI ≤10; ≥6 if baseline >10 to ≤22; ≥11 if baseline >22) or (b) low disease activity (LDA; CDAI ≤10). Patient response was no longer durable upon the first: discontinuation of TCZ or failure to maintain MCID or LDA. Secondary analyses estimated durability after including only patients: (a) with reported reasons for discontinuation (patients with non-medical reasons for discontinuation [eg, insurance coverage] were censored) or (b) who initiated TCZ-IV. Durability was calculated with Kaplan-Meier survival analysis. Cox proportional hazards modeling identified factors associated with durability.

Results: A total of 1789 TCZ initiators (TCZ-IV, n=1284) were identified; 861, 483, and 298 patients were persistent and had follow-up visits at 1, 2, and 3 years, respectively. At baseline, the mean (SD) age was 58.5 (12.6) years, duration of RA was 12.0 (9.6) years and CDAI score was 23.2 (14.2). Most patients (93.4%) had prior biologic use and 67.4% had received ≥2 prior biologics. Among patients with follow-up data available at 1, 2 and 3 years, MCID in CDAI was achieved by 56.3% (261/464), 67.3% (183/272) and 69.8% (113/162), respectively. Overall, MCID durability remained above 50% after 36 months of follow-up, and the same is true when including only patients with reported reasons for discontinuation (patients with non-medical reasons for discontinuation [eg, insurance coverage] were censored) or (b) who initiated TCZ-IV. Durability was calculated with Kaplan-Meier survival analysis. Cox proportional hazards modeling identified factors associated with durability.

Results: A total of 1789 TCZ initiators (TCZ-IV, n=1284) were identified; 861, 483, and 298 patients were persistent and had follow-up visits at 1, 2, and 3 years, respectively. At baseline, the mean (SD) age was 58.5 (12.6) years, duration of RA was 12.0 (9.6) years and CDAI score was 23.2 (14.2). Most patients (93.4%) had prior biologic use and 67.4% had received ≥2 prior biologics. Among patients with follow-up data available at 1, 2 and 3 years, MCID in CDAI was achieved by 56.3% (261/464), 67.3% (183/272) and 69.8% (113/162), respectively. Overall, MCID durability remained above 50% after 36 months of follow-up, and the same is true when including only patients with reported reasons for discontinuation (Fig 1). For TCZ-IV initiators, median MCID durability was 26 months (Fig 1). For all MCID durability analyses, factors associated with reduced hazard of failure included increased duration of RA and higher baseline CDAI, while higher hazard of failure was associated with history of malignancy or diabetes (Fig 2). Among patients with follow-up data available, LDA was achieved in 53.7% (249/464), 60.3% (164/272) and 67.3% (109/162) at 1, 2 and 3 years, respectively. The overall median (95% CI) LDA durability was 13.0 (12.0, 20.0) months; when including only patients with reported reasons for discontinuation it was 13.0 (9.0, 29.0) months; among TCZ-IV initiators it was 13.0 (10.0, 19.0) months. Factors associated with an increased hazard of failing to maintain LDA included history of malignancy and, in contrast to MCID, higher baseline CDAI.

Conclusion: In this real-world RA population who initiated TCZ, most patients received ≥2 prior biologics. Median durability of response (MCID) was >3 years. Among factors associated with shorter durability of response, history of malignancy was significant in all analyses.

PREDICTORS OF BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUG INITIATION AMONG PATIENTS WITH RHEUMATOID ARTHRITIS IN KOREA

E. H. Park1, A. Shin1, Y. J. Ha1, Y. J. Lee1, E. B. Lee1, Y. W. Song2, E. H. Kang1
1Seoul National University Bundang Hospital, Department of Rheumatology
2Seoul National University Hospital, Division of Rheumatology Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)

Background: Biological disease-modifying anti-rheumatic drugs (bDMARDs) have significantly improved clinical prospects for patients with rheumatoid arthritis (RA).

Objectives: To identify predictors of bDMARDs initiation in RA patients.

Methods: Using 2002-2016 Korea National Health Insurance Service database, we conducted a nested case-control study on RA patients. Four conventional DMARD (cDMARD) users were selected by risk set sampling per each bDMARD user, matched on the calendar year/month of RA diagnosis. Potential predictors were separately assessed for two periods, 1 year after RA diagnosis and 1 year prior to bDMARD initiation. By logistic regression analyses estimating odds ratio (OR) and 95% confidence interval (CI).

Results: The study included 27,940 cDMARD users and 6,985 bDMARD users. Younger age, initial use of a less potent cDMARD (sulfasalazine), corticosteroid use, and higher maximal methotrexate (MTX) dose during 1 year post-diagnosis were positive predictors for later bDMARD initiation, while male gender, initial use of a potent cDMARD (MTX, leflunomide, or tacrolimus), initial MTX dose of ≥10mg/wk, and initial cDMARD combination were negative predictors (Table 1). Use of non-MTX DMARDs (leflunomide, sulfasalazine, or tacrolimus), higher # of cDMARD used, subcutaneous administration of MTX, corticosteroid therapy, and higher maximal MTX dose were positive predictors of subsequent bDMARD. Although higher comorbidity score during 1 year before bDMARD initiation was a positive predictor, the effect was heterogeneous by involved systems (Table 2).

1 As-treated analysis censored patients when they discontinued biologics use, while ITT analysis did not.

### Conclusion

We found 48% risk reduction of TI by chemoprophylaxis among RA patients receiving biologics. Due to HIRA requirements, a majority of non-prophylaxis group were considered negative for LT by screening at biologics initiation. These findings indicate that the risk of TI during bDMARD treatment is still high among RA patients who were negative for LT at baseline but did not undergo chemoprophylaxis, which is double the risk among RA patients who had LT and underwent chemoprophylaxis.

**THU0180 RISK MODIFICATION OF TUBERCULOSIS INFECTION BY CHEMOPROPHYLAXIS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TNF INHIBITORS: A NATION-WIDE COHORT STUDY**

A. Shin1, E. H. Park1, Y. J. Lee1, Y. W. Song2, E. H. Kang1. 1Seoul National University Bundang Hospital, Seongnam, Korea, Rep. of (South Korea); 2Seoul National University Hospital, Seoul, Korea, Rep. of (South Korea)

**Background:** Based on the benefit of chemoprophylaxis among patients receiving biologics [1]. Health Insurance Review and Assessment (HIRA) service of Korea requires patients to undergo latent tuberculosis (LT) screening before initiation of any biologics and to receive chemoprophylaxis for positive LT.

**Objectives:** To assess the effect of chemoprophylaxis on tuberculosis infection (TI) risk among patients with rheumatoid arthritis (RA) receiving biologics in Korea

**Methods:** Using 2002-2016 Korea National Health Insurance database, we conducted a cohort study on RA patients initiating biologic drugs (TNF inhibitors, abatacept, tocilizumab) to compare TI risk between those who started isoniazid and/or rifampin within 1 year before biologics initiation (prophylaxis group) versus those who did not (non-prophylaxis group). TI was defined by ICD10 codes plus anti-tuberculosis medications as previously described [2]. Patients were followed-up from biologics initiation to censoring events (TI occurrence, death, biologics discontinuation, initiation of anti-tuberculosis drug due to non-TI cause, and end of database). To control >50 baseline confounders, we used propensity score (PS)-based fine stratification and weighting. A weighted Cox proportional hazards model estimated hazard ratios (HRs) and 95% confidence intervals (CIs).

**Results:** Before PS stratification (PSS) and weighting, we identified 2,250 and 7,259 RA patients for prophylaxis and non-prophylaxis group, respectively. Mean age was 57.6 years and 81.3% female. Three-fourths of patients in the prophylaxis group completed >70% of recommended treatment periods [3]. The incidence rate of TI per 100 person-years was 0.33 for prophylaxis group versus 0.57 for non-prophylaxis group. 28% of all TI cases (n=34) were extra-pulmonary with gastrointestinal (n=11) and miliary TI (n=9) being most common. The PSS-weighted HR (95% CI) of TI comparing prophylaxis versus non-prophylaxis group was 0.52 (0.32-0.86) (Table 1, Figure 1). Sensitivity analyses showed that the chemoprophylaxis was particularly effective for those with younger age (<65 years), male gender, or high comorbidity (≥ median value) (Table 1).

**Conclusion:** We found 48% risk reduction of TI by chemoprophylaxis among RA patients receiving biologics. Due to HIRA requirements, a majority of non-prophylaxis group were considered negative for LT by screening at biologics initiation. These findings indicate that the risk of TI during bDMARD treatment is still high among RA patients who were negative for LT at baseline but did not undergo chemoprophylaxis, which is double the risk among RA patients who had LT and underwent chemoprophylaxis.
SOLUBLE VASCULAR BIOMARKERS IN RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS: EFFECTS OF ONE-YEAR ANTI-TNF-A THERAPY

A. Pusztaí1, A. Hamari1, Á. Horváth1, E. Végh1, N. Bodnár1, G. Kerekes1, M. Czókolyová1, S. Szamosi1, L. Bodoki2, K. Hodosi3, A. Domján1, G. Nagy1, I. Szollősi1, L. Lopez4, E. Matsuura3, Z. Prohászka1, Z. Nagy1, Y. Shoenfeld6, Z. Székanezi5, G. Szücs1

1University of Debrecen, Debrecen, Hungary; 2Corgenix, Inc., Broomfield, CO, United States of America; 3Okayama University, Okayama, Japan; 4Ssemmelweis University, Budapest, Hungary; 5Zabludowitz-Center, Tel-Hashomer, Israel

Background: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) have been associated with inflammatory atherosclerosis, increased cardiovascular morbidity and mortality. Numerous proteins may serve as biomarkers of inflammatory atherosclerosis. The treatment of arthritis by tumour necrosis factor α (TNF-α) inhibitors may decrease the serum concentrations of these biomarkers.

Objectives: In this study we wished to determine circulating levels of oxidized LDL (oxLDL) - β2 glycoprotein I (2gpI) complexes, anti-human Hsp60 immunoglobulin G (IgG) levels and BNP8-29 fragment levels were assessed by ELISA. suPAR levels were assessed by ELISA.

Methods: Altogether 53 arthritis patients including 36 RA patients treated with either etanercept (ETN) or certolizumab pegol (CZP) and 17 AS patients treated with ETN were included in a 12-month follow-up study.Circulating oxLDL/β2gpI complexes, anti-Hsp60 antibodies, soluble urokinase plasminogen activator receptor (suPAR) and N-terminal B-type natriuretic peptide (NT-proBNP) in sera of RA and AS patients. We also wished to assess the effects of anti-TNF treatment on these biomarkers.

Results: In the mixed cohort of 53 arthritis patients, the circulating levels of oxLDL/β2gpI significantly decreased after 12 months of anti-TNF therapy (0.20±0.11U/ml) compared to baseline (0.24±0.10U/ml; p=0.014). There was a tendency of non-significant decrease after 6 months (0.23±0.14U/ml) versus baseline. Anti-Hsp60 antibody levels did not change after 6 months (158.6±138.6 AU/ml) and 12 months (167.3±143.3 AU/ml) to baseline (170.3±140.4 AU/ml). Among patients, 21.2% had low, 36.4% “observe,” 9.1% high and 33.3% critical suPAR levels. suPAR levels showed a tendency of non-significant decrease after 6 months (11.3±7.7ng/ml) and 12 months (10.3±15.3 ng/ml) versus baseline (11.5±16.4 ng/ml). However, when the four serum level categories described above were considered, suPAR concentrations exerted significant decrease in RA patients with critical suPAR levels (>9ng/ml) (p=0.04).

Conclusion: One-year anti-TNF therapy significantly decreased circulating oxLDL/β2gpI complex levels. This therapy also decreased suPAR levels in patients with critically high suPAR. BNPP fragment levels were associated with seropositivity in RA. These vascular biomarkers may reflect the effects of TNF inhibition on endothelial activation.

Background: In Japan, oral tocrolimus (TAC) was approved for the treatment of RA in 2005 and the improvement of symptoms thorough the use concomitant with disease modifying antirheumatic drugs (DMARDs), including MTX has been reported. On the other hand, the efficacy and tolerance of biological agents therapy concomitant with TAC are unknown.

Objectives: The objective of this study was to investigate the efficacy and tolerance of biological agents concomitant with TAC in Japanese patients with RA using retention rate analysis.

Methods: Total patients (n=2860) who underwent biological agents (etanercept: ETN, adalimumab: ADA, golimumab: GLM, tocilizumab: TCZ, abatacept: ABT) treatment between 2003 and 2017 at Nagoya University Hospital and 12 other institutes (Tsurumi Biologics Communication Study Group) were enrolled. In each biological analysis, patients were divided into three groups: (1) concomitant only MTX (MTX group) (2) concomitant only TAC (TAC group) (3) others (other group). In TAC or MTX group, these drugs were only ones which concomitant patients used. Kaplan-Meier analysis was used to estimate retention rate in each biological group. To estimate the tolerance of concomitant biologics with TAC, cumulative hazard function in adverse events rate was performed in each biological group. In both analyses, hazard ratios (HR) were assessed by Cox proportional hazards modeling adjusted for age, sex, disease duration and previously used biologics.

Results: In the total 2860 patients, 142 patients (5.0%) administered each biological agents concomitant with TAC (ETN: n=47, ADA: n=10 GLM: n=14, TCZ: n=27, ABT: n=49). Baseline characteristics of 142 patients were shown in table 1. Average dosages of TAC at starting were ETN: 2.2±0.7mg ADA: 2.4±1.0mg GLM: 1.9±0.7mg TCZ: 1.7±0.8mg. With comparison of retention rate between 3 groups in each biologics under analysis of cox proportional hazard modeling, in ETN and ABT analysis, the retention rate of TAC group was higher than others group (table 2, figure 1). Comparison of incidence of adverse event between 3 group using cumulative hazard function and cox proportional hazard modeling in ETN and ABT analysis. In ETN analysis, incidence rate of other group was higher than TAC group. In ABT analysis, there was no significant difference between 3 groups (figure 2).

The long-term safety of such reduction is unknown. Moreover, it is suggested that ETN and ABT treatment, combination therapy with TAC are subsequent options for treatment to RA patients, especially in whom MTX cannot be administration.

Conclusion: We suspected that, in ETN and ABT treatment, combination therapy with TAC are subsequent options for treatment to RA patients, especially in whom MTX cannot be administration.

Objectives: To evaluate ABA-induced gamma-globulins reduction and its correlation with disease activity control and the risk of infection in rheumatoid arthritis (RA) patients.

Methods: This is a retrospective inception cohort of RA patients undergoing ABA for the first time in a large tertiary cohort (2007 to 2019). Patients were evaluated regarding clinical and inflammatory data, total and specific (IgG, IgM, IgA) gamma-globulins assessed before, at 3 and 6 months, and then every 6 months up to discontinuation/censoring. The occurrence of severe or recurrent infections as cause of discontinuation of treatment was recorded. All patients were submitted to a systematic infectious screening protocol before and during treatment.

Results: One hundred seventy-nine RA patients were included. They were predominantly female (93%; n=167) and had a positive rheumatoid factor (RF, 84%; n=151). Median(range) age and disease duration were 55.1(17-81.3) and 14.1(6.98) years, respectively. ABA was used in median as the 3rd (18) bDMARD. Most patients (74.3%, n=134) had already used a TNFi previously and 34.1% (n=61) had failed to rituximab. Baseline DAS28 (median(range)) was 4.19 (2.70, 15.0, 3.21), CRP 15 (0, 3, 32), CDAI 10.1136/annrheumdis-2020-eular.5350

THU0183

ABATACEPT AND LOW GAMMA-GLOBULIN LEVELS: NO ASSOCIATION WITH INFECTIOUS RISK OR RA DISEASE ACTIVITY CONTROL

V. G. Dinis1, K. Borfiglioli2, A. Shimabuco2, C. Saad2, D. S. Domiciano2, J. Moreira2, E. Neves3, A. Lippino-Assaad4, F. Souza2, H. Carneiro Da Silva5, E. Bonta2, A. C. Medeiros-Ribeiro1, 1Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Rheumatology, Sao Paulo, Brazil; 2Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; 3Escola Superior de Ciencias da Santa Casa de Misericordia de Vitória - EMESCAM, Vitória, Brazil.

Background: Abatacept (ABA) can induce decrease in gamma-globulins, but the long-term safety of such reduction is unknown. Moreover, it is suggested that such decrease is dissociated from disease activity response.

THU0184

PREVIOUSLY UNKNOWN GASTRO-INTESTINAL ADVERSE DRUG REACTIONS ATTRIBUTED TO ETANERCEPT

J. Van Lint1, N. Jessurun1, A. Van Tubergen2, M. Van Doorn3, E. Van Puijenbroek4, P. Spilu5, S. Tas6, B. Van den Bernt7, M. Nurmohamed8, P. Hoentjens1, H. Vondeman9, Pharmacovigilance Centre Laren, NL; Herogenbosch, Netherlands; 2Maastricht University Medical Center.
Background: Although an increased risk of inflammatory bowel disease (IBD) during etanercept (ETN) use is included in the product information of ETN, no other gastro-intestinal (GI)-adverse drug reactions (ADRs) are described. This is in contrast with other TNFα-inhibitors such as adalimumab (ADA) and infliximab, as these are associated with various GI-ADRs such as nausea and abdominal pain.

Objectives: To identify the proportion and type of patient-reported and health care professional (HCP)-reported ETN associated GI-ADRs and compare these with ADA associated GI-ADRs.

Methods: Patient-reported data on ADRs attributed to biologics was collected from the Dutch Biologic Monitor (DBM) from 1 Jan 2017 until 1 Nov 2019. HCP-reported data on ADRs attributed to biologics was collected from the Dutch rheumatism monitoring registry and the Dutch registry for spondyloarthritis reported data on ADRs attributed to biologics was collected from the Dutch rheumatism monitoring registry and the Dutch registry for spondyloarthritis.

Conclusion: Although GI-ADRs other than IBD are not included in the product information of ETN, they are often reported by both patients and HCPs. The type of patient-reported GI-ADRs attributed to ETN and ADA is comparable. However, patients regard GI-ADRs attributed to ETN as more burdensome.

DOI: 10.1136/annrheumdis-2020-eular.1325

In the under/normal weight (n=63), overweight (n=61), and obese (n=31) groups, the mean±SD of RA duration (years) (6.4±6.00, 8.2±9.27, 10.9±11.20) and the mean±SD of disease activity index (DAS28) (3.9±1.01, 3.7±1.00, 3.5±1.00) were lower in the 1st and 2nd subgroups. The ADA impact was especially apparent in the 4th subgroup where the mean pre-dose concentration of the patients was below the therapeutic drug concentration level (1 μg/mL), which led to worse efficacy outcomes in both arms, IV as well as SC. Nevertheless, no impact of ADA on safety profile in both arms was observed. A neutralizing antibody (NAb) method with enhanced drug tolerance but limited performance was also developed and clinical consequences of NAb titer in terms of PK, efficacy and safety were not different from the results with ADA.

Conclusion: The analysis of both ADA positivity and titer is clinically meaningful in the prediction of PK profile and clinical response. CT-P13 SC administration did not result in a greater incidence of ADA compared to the CT-P13 IV and there were no clinical differences depending on the formulation.

References:

Figure 1. Box plot of Pre-dose Concentration by Visilt-based ADA Titer Quartile

Figure 2. Mean Change from Baseline of DAS28 (CRP) and Proportion of ACR20 Responder at Week 30 by Visit-based ADA Titer Quartile

Figure 2. DAS28 (CRP) improvement

Conclusion: These post-hoc results showed that there was no impact of BMI on the clinical responses of CT-P13 SC 120 mg biweekly in RA patients. Therefore, CT-P13 SC 120 mg could be a reasonable therapeutic option regardless of BMI.

THU0188

EFFICACY OF FILGOTINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH POOR PROGNOSTIC FACTORS: POST HOC ANALYSIS OF FINCH 3

D. Aletaha1, R. Westhoven2, C. Gaujoux-Viala3, G. Adami4, A. Matsumoto5, P. Bird6, O. Messina7, 8, M. H. Buch9, B. Bartok10, Z. Yin10, Y. Guo10, T. Hendrix11, G. R. Burmester12, 1Medical Univ of Vienna, Vienna, Austria; 2Univ Hospitals Leuven, Leuven, Belgium; 3Univ de Montpellier, Nîmes, France; 4Univ of Verona, Verona, Italy; 5Arthritis and Rheumatism Assoc, Wheaton, MD, United States of America; 6Univ New South Wales, Sydney; 7New South Wales, Sydney; 8Univ Australia; 9Rheumatology Dept, Buenos Aires, Argentina; 10Univ of Manchester, Manchester; 11Gilead Sciences, Inc, Foster City, CA, United States of America; 12Galapagos BV Leiden, Netherlands.

Background: Patients (pts) with rheumatoid arthritis (RA) with poor prognostic factors (PPF) are at risk for RA progression if disease activity is not rapidly controlled. In FINCH 3 (NCT02886728), filgotinib (FIL) — an oral, potent, selective JAK1 inhibitor — was effective relative to methotrexate monotherapy (MTX mono) in MTX-naive patients with ≥1 PPF — erosions, seropositivity for rheumatoid factor (RF) or anti-cyclic citrullinated peptide (CCP), or hsCRP >4 mg/L.

Objectives: This post hoc analysis examined FIL efficacy in FINCH 3 pts with multiple PPF.

Methods: The global, phase 3, double-blind, active-controlled FINCH 3 study randomised MTX-naive pts with moderately to severely active RA 2:1:1:2 to oral FIL 200 mg daily + MTX ≤20 mg weekly, FIL 200 mg weekly, FIL 100 mg weekly + MTX ≤20 mg weekly, or PBO + MTX up to week (W)52. This subgroup analysis included pts with all 4 of the following PPF at baseline (ppF): erosions, seropositivity for RF or anti-CCP, hsCRP >4 mg/L, and DAS28>5.4. Comparisons were not adjusted for multiplicity.

Results: Of 1249 pts randomised and treated in FINCH 3, 510 had all 4 PPF. At baseline, relative to the overall FINCH 3 population, PPF pts had longer mean disease duration (2.4 vs 2.2 years); higher mean hsCRP (279 vs 175 mg/L), mean level of mTSS (17.9 vs 13.3), DAS28(CRP) (6.3 vs 5.7), HAQ-DI (1.76 vs 1.56), CDAI (44.3 vs 39.8), and SDAI (47.1 vs 41.5); and greater frequency of seropositivity for RF (90.6% vs 67.9%), anti-CCP (92.4% vs 68.5%), or both (82.9% vs 59.6%). Efficacy in PPF pts was comparable to data from all FINCH 3 pts (Table, Figures 1–2). PPF pts receiving FIL 200 mg with or without MTX had higher frequencies of ACR20/50/70 response and greater improvement in HAQ-DI at W24; responses were numerically greater for FIL 200 mg + MTX vs FIL 200 mg + MTX or FIL 200 mg mono (Table and Figure 1). Proportions of PPF pts receiving FIL 200 mg with or without MTX who achieved DAS28(CRP) <2.6, CDAI ≤2.8, SDAI ≤3.3, and Boolean remission at W24 were larger for FIL 200 mg mono and numerically greater vs pts receiving FIL 100 mg + MTX.

Table. Efficacy outcomes in patients with 4 PPF and all FINCH 3 patients at W24

| Mean change from baseline, p<0.05; **, p<0.01; *** p<0.001 vs MTX mono, not adjusted for multiplicity. FIL, filgotinib; mono, monotherapy; MTX, methotrexate; PPF, poor prognostic factors.
Fig. 1. Change in mTSS from baseline at W24 in FINCH 3 patients with 4 poor prognostic factors and all FINCH 3 patients.

Fig. 2. Rates of DAS28(CRP) < 2.6, SDAI ≤ 2.8, SDAI ≤ 3.3, and Boolean remission at W24 in FINCH 3 patients with 4 RA and all FINCH 3 patients.

Conclusion: FIL treatment provided rapid and deep disease control including higher rates of remission and other clinical outcomes, improved physical function, and less radiographic progression compared with MTX alone in MTX-naïve pts with RA with 4 PPF, a population at risk for severe progressive disease. In pts with 4 PPF, W24 remission rates following FIL 200 mg with or without MTX were higher vs MTX mono and numerically higher vs FIL 100 mg + MTX.

Background: In the INBUILD trial in patients with progressive fibrosing ILDs, nintedanib reduced the rate of decline in forced vital capacity (FVC) vs placebo over 52 weeks in the overall population and in the subgroup with autoimmune disease-related ILDs. Patients taking stable doses of medications to treat RA or CTD were eligible, but the protocol excluded enrolment of patients treated with azathioprine, cyclosporine, mycophenolate, tacrolimus, rituximab, cyclophosphamide, or oral glucocorticoids >20 mg/day.

Methods: In patients with progressive autoimmune disease-related ILDs in the INBUILD trial, the rate of decline in FVC (mL/year) and adverse events (AEs) over 52 weeks of treatment (or until 28 days after last trial drug intake for patients who discontinued drug before week 52) were assessed in subgroups by use of DMARDs and/or glucocorticoids (any dose) at baseline (yes/no).

Results: 170 patients in the INBUILD trial (82 nintedanib, 88 placebo) had autoimmunity disease-related ILDs (89 RA-ILD, 39 SSc-ILD, 19 MCTD-ILD, 23 other). The baseline characteristics of patients taking (n=131) and not taking (n=39) DMARDS and/or glucocorticoids are shown in the Table. All but 1 patient taking glucocorticoids at baseline was taking <20 mg/day. The mean (SE) annual rate of decline in FVC in the placebo group was numerically greater in patients taking vs not taking DMARDs and/or glucocorticoids at baseline (Figure). The effect of nintedanib vs placebo reducing the rate of decline in FVC was numerically more pronounced in patients taking vs not taking DMARDs and/or glucocorticoids at baseline, but the treatment-by-subgroup-by-time interaction p-values did not indicate heterogeneity in the effect of nintedanib between subgroups (Figure). In patients taking vs not taking DMARDs and/or corticosteroids at baseline (Figure), the rate of decline in FVC was numerically greater in patients taking vs not taking DMARDs and/or glucocorticoids at baseline (Figure). The effect of nintedanib vs placebo reducing the rate of decline in FVC was numerically more pronounced in patients taking vs not taking DMARDs and/or glucocorticoids at baseline, but the treatment-by-subgroup-by-time interaction p-values did not indicate heterogeneity in the effect of nintedanib between subgroups (Figure). In patients taking vs not taking DMARDs and/or corticosteroids at baseline, respectively, diarrhoea was reported in 59.4% and 77.6% of patients treated with nintedanib and 28.4% and 23.8% of patients treated with placebo. Serious AEs were more frequent in patients taking vs not taking DMARDs and/or glucocorticoids at baseline in both the nintedanib (39.1% vs 16.7%) and placebo (35.8% vs 19.0%) groups.

Conclusion: In the INBUILD trial, the rate of FVC decline was numerically greater in placebo-treated patients who were taking DMARDs and/or glucocorticoids at baseline vs those who were not. The rate of FVC decline was slower in patients treated with nintedanib than placebo both in patients who were and were not taking DMARDs and/or glucocorticoids at baseline. Nintedanib had an acceptable safety profile both in patients who were and were not using DMARDs and/or glucocorticoids at baseline.
Background: Methotrexate (MTX) holds a unique place in the management of rheumatoid arthritis (RA) given its favorable balance between efficacy and safety. However, conflicting data still suggest a potential risk of MTX-induced long-term liver fibrosis. The fibrosis-4 (FIB-4) index was originally proposed as a simple non-invasive marker of liver fibrosis in HIV/HCV co-infection. In patients with MTX-induced liver fibrosis, the FIB-4 index was not significantly higher in patients with a FIB-4 index >1.45 (median cumulative MTX dose 5.5g vs. 3.5g, p=0.302). No association was detected between FIB-4 values and the cumulative dose of MTX (r=0.09, p=0.271). The FIB-4 index was low and similar between patients receiving cumulative MTX doses <5g, between 5 and 10g and 10g (Figure 1). The cumulative dose of MTX was not significantly higher in patients with a FIB-4 index >1.45 (median cumulative MTX dose 5.5g vs. 3.5g, p=0.302). No association was detected between the FIB-4 index and parameters of disease activity (DAS28, ESR and CRP levels).

Methods: We performed a cross-sectional study including successive RA patients hospitalized in the Rheumatology department of Cochin Hospital for a 12-month period. Data on liver function, disease activity, hepatotoxic and cardiovascualar risk factors were systematically collected. The FIB-4 index was calculated according the following formula: (age(years) × AST(U/L)/platelet (PLT) (109/L) × √ALT(U/L)). Using a lower cutoff value of 1.45, a FIB-4 score <1.45 had a negative predictive value of 90% for advanced fibrosis in the patient cohort in which this formula was first validated. In contrast, a FIB-4 >3.25 had a 97% specificity and a positive predictive value of 65% for advanced fibrosis (2).

Results: We included 170 patients with established RA: 141 (83%) were women, the mean age was 59±12 years and the mean disease duration was 15±11 years. Positive rheumatoid factors and anti-CCP antibodies were detected in 134 patients (79%), 102 patients (60%) were treated with methotrexate, with a mean dose of 10.0+/-8.4mg/week, a mean treatment duration of 9.5+/-10.3 years and a cumulative dose of 5.3+/-5.1g. 23 patients (13.5%) received conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) other than MTX, 112 (66%) corticosteroids (99 with a dose < 10mg/day) and 85 targeted biologic DMARDs (bDMARDs) (50%). The mean FIB-4 value was 1.24±0.57, with 120 patients (71%) with value <1.45, 49 (29%) with values ranging from 1.45 to 3.25 and a single patient with FIB-4 >3.25. The FIB-4 was low and not significantly different between patients receiving MTX, patients previously treated with MTX and patients never treated with MTX (median 1.1, 1.25 and 1.18, respectively, p=0.709). This result was not modified after adjustment on treatments with other csDMARDs, corticosteroids, and bDMARDs. No correlation was observed between FIB-4 values and the cumulative dose of MTX (r=0.09, p=0.271). The FIB-4 index was low and similar between patients receiving cumulative MTX doses <5g, between 5 and 10g and 10g (Figure 1). The cumulative dose of MTX was not significantly higher in patients with a FIB-4 index >1.45 (median cumulative MTX dose 5.5g vs. 3.5g, p=0.302). No association was detected between the FIB-4 index and parameters of disease activity (DAS28, ESR and CRP levels), the body mass index, traditional cardiovascualar risk factors and metabolic syndrome.

Background: Methotrexate (MTX) is the gold standard treatment for rheumatoid arthritis (RA). The international guidelines recommend optimizing its dose before the introduction of a biologic treatment in cases where it is well tolerated.

Objectives: The objective of this study is to evaluate the dose of MTX before the initiation of biological treatment in RA patients with MTX ineffectiveness.

Methods: This is a multicenter, cross-sectional, prospective study including adults RA, over a period of 6 months (January-June 2019). We collected the following data: sex, age, comorbidities (diabetes, hypertension), rate of RF and ACPA, dose of MTX, rate of patients on corticosteroids, Disease Activity Score (DAS 28-vs), Health Assessment Questionnaire (HAQ) and SHARP Score.

Results: Number of patients: 239 (187 women / 52 men); average age: 48.3 years (19 - 81); average duration of the disease: 13.6 ± 8.2 years. Comorbidities: arterial hypertension (14.6 %), diabetes (13 %). The RF were positive in 77.4 %. The average value of ACPA is 228.76 ± 287.08 IU / L, positive in 73 % of cases. The average DAS28v6 is 5.47 ± 1.46 (0.77 - 12.26). The average modified SHARP 111.67 ± 98.16 (0-448), the average HAQ is 1.13 ± 0.82 (0 - 2.87). 86.7 % of patients are under corticosteroids. Only 18.5 % of patients had a dose of MTX between 20 and 25 mg / week; the remaining 82 % of patients the average dose of MTX was 14 mg / week (10-18.5).

Conclusion: These results suggest that the dose of MTX was not optimized before the initiation of biotherapy in the majority of patients with RA.

CLINICO-DEMOGRAPHIC, IMMUNOLOGIC AND SYNOVIAL HISTOLOGIC FEATURES INFLUENCING RESPONSE TO JAK-INHIBITORS IN RHEUMATOID ARTHRITIS: A MONOCENTRIC COHORT.

D. Bruno1, M. R. Gigante2, L. Petricca2, S. Perniola2, M. Gessi3, B. Tolusso2, S. Alivernini1,2, E. Gremese1,2.

Background: Janus kinase Inhibitors (JAKis) are approved for the treatment of Rheumatoid Arthritis (RA) in over 40 countries. The updated EULAR recommendations for RA treatment revised the preference of bDMARDs over tsDMARDs based on the new data related to JAKis long-term efficacy and safety. [1].

Objectives: To evaluate the efficacy and safety of JAKis molecules in an observational single center cohort of RA patients in a real life outpatient clinical setting.

Methods: 76 RA patients [mean age: 55.7±12.5 years, 64(84.2%) female, disease duration: 120.7±97.2 months, 43 (61.4%) seropositive (AB+) for ACPA and/or IgM-RF, 34(44.7%) with BMI ≥25.0 kg/m2] were followed after starting JAKis treatment monotherapy or in combination with conventional synthetic DMARDs (csDMARDs). At study entry, and every 3 months, the ACR/EULAR core data set variables were recorded for each patient. Clinical improvement and remission rate were evaluated according to Disease Activity Score (DAS) and Clinical Disease Activity Index (CDAI) and any therapy-related adverse events reported. Among the whole RA cohort, 20 patients underwent LS-guided synovial tissue (ST) biopsy before JAKis treatment and classified using the Krenn score for the semiquantitative assessment of ST inflammation.[2].

Results: Among the whole RA cohort who started JAKis [mean follow-up (FU) duration: 6.1±3.7 months], 22(28.9%) showed DAS-defined high disease activity: 54(71.1%) patients were previously treated with at least 1 csDMARD and 33(43.4%) were naive to biologic DMARDs (bDMARDs). Among RA previously exposed to bDMARDs, 23(30.3%) were using anti-TNF and 14(18.4%) anti-IL6R, whereas 6(7.9%) patients received other bDMARD. In particular, 11(14.5%) patients were previously treated only with one bDMARD. During the FU, 12(15.8%) patients discontinued JAKis [7 due to treatment failure and 5 to adverse events (1 anemia, 2 gastrointestinal intolerance, 2 H.Zoster infection)]. All RA who discontinued JAKis for incomplete or no-response were previously exposed to bDMARDs. DAS Remission was achieved in 29 of 65(44.6%) patients during the FU, of whom 21(32.5%) achieved remission at 3 months. Similarly, 16(24.6%) patients reached CDAI remission of whom 12(18.5%) patients achieved remission at 3 months.

At baseline, there were no differences of DAS-remission rate based on age, gender, disease duration, BMI and high disease activity. Similarly, concomitant steroids and csDMARDs therapy did not impact on the rate of DAS and CDAI Remission. However, RA reaching DAS remission during FU had more likely a shorter disease duration (p=0.01) and were less previously exposed to bDMARDs (p=0.001) than patients not achieving DAS remission. Conversely, the DAS Remission rate was higher in AB+ (55.3%) than in AB- RA patients (27.3%, p=0.04).

Furthermore, bDMARDs naive RA showed higher probability to reach remission compared to bDMARD previously exposed RA (DAS remission: 66.7% vs 28.9%, respectively, p=0.003; OR(95%CI): 4.90 [1.69-14.3) and CDAI-remission: 37.0% vs 15.8%, p=0.05; OR(95%CI): 3.12 [0.97-10.1]), regardless to the type of the previous bDMARDs used. Finally, considering the baseline ST features, RA achieving clinical improvement did not differ in terms of Krenn score and microscopic anatomical organization compared to RA not achieving the clinical improvement.

Conclusion: The efficacy rate of JAKis therapy is not influenced by BMI and baseline high disease activity. Previous exposure to bDMARDs impacts both on the clinical response and on the rate of JAKis therapy discontinuation. Therapy-related adverse effects mainly occurred in bDMARD previously exposed RA patients.

CHARACTERISATION OF DEPTH OF RESPONSE, INCLUDING 50% IMPROVEMENT IN ACR COMPONENTS AT WEEK 12 AND REMISSION AT WEEK 24, FOLLOWING TREATMENT WITH FILGOTINIB COMPARED WITH METHOTREXATE OR ADAлимУАМБ IN PATIENTS WITH RHEUMATOID ARTHRITIS

Background: The oral, potent, selective JAK1 inhibitor filgotinib (FIL) showed favorable efficacy at week (W)12 and W24 of treatment for rheumatoid arthritis (RA) compared with methotrexate (MTX) monotherapy (mono) in FINCH 3
Implications: 50% clinical improvement from baseline at W12 is a key
benchmark for RA treatment.8 These post hoc analyses evaluated
FIL treatment effect on improvement in ACR components at W12 and
remission at W24 in FINCH 3 and FINCH 1.

Methods: FINCH 3 and FINCH 1 were global, phase 3, double-blind studies
in patients (pts) with active RA. In FINCH 3, MTX-naive pts were randomised
2:1:1:2 to once-daily (QD) oral FIL 200 mg + weekly MTX, FIL 100 mg +
MTX, FIL 200 mg mono + PBO, or PBO + MTX mono up to W52. In FINCH 1,
pts with inadequate response to MTX (MTX-IR) on a background of stable MTX
were randomised (3:3:2:3) to oral FIL 200 or 100 mg QD, subcutaneous ADA 40 mg
Q2W, or PBO up to W52. Post hoc analyses evaluated proportions of pts with
50% improvement from baseline in each ACR component and in all 7 ACR com-
ponents (ACR50c) at W12, and proportions of pts with ACR50c at W12 achieving
clinical remission at W24. Comparisons between treatments were not adjusted
for multiplicity; subgroup comparisons are descriptive.

Results: Analyses included 1249 pts in FINCH 3 and 1755 pts in FINCH 1.
Greater proportions of pts receiving FIL 200 mg + MTX, FIL 100 mg + MTX,
or FIL mono (FINCH 3) vs PBO + MTX (FINCH 1)—
and numerically higher proportions of pts receiving FIL 200 mg vs FIL 100 mg +
MTX (both studies) or ADA + MTX (FINCH 1)—achieved ACR50c and
individual components at W12 (Table). Post hoc proportions of pts achieving
CDAI ≤2.8 (Figure 1) or Boolean remission (Figure 2) at W24 were higher for pts with vs
without ACR50c at W12 (Figures 1–2).

Background: Patients (pts) with rheumatoid arthritis (RA) are at an increased risk for the development of venous thromboembolism (VTE, including pulmo-

ary embolism [PE] and deep vein thrombosis [DVT]) vs the general population

Scientific Abstracts Thursday, 04 June 2020 317
VTE event rates appeared balanced across UPA doses and active comparator groups in pts with RA. Risk factors for VTE events identified through univariate analyses in pts who received UPA included prior history of VTE and BMI; two factors previously known to be associated with VTE risk. One limitation is the small sample size, limiting the analysis to univariate. Continued follow-up of pts receiving UPA is ongoing to further contextualize the risk of VTE in the clinical trial program.

Background: Depression/anxiety are common in RA pts. SF-36 MCS ≤38 can identify probable major depressive disorder and/or probable generalised anxiety disorder (pMDD/pGAD) in RA pts. Tofacitinib is an oral JAK inhibitor for the treatment of RA.

Objectives: To assess pMDD/pGAD prevalence in the tofacitinib RA program and efficacy by baseline (BL) pMDD/pGAD status.

Methods: Data from pts receiving tofacitinib, ADA, or PBO were pooled from 5 Phase (P1) and 1 P2b/4 trials. Demographics/BL characteristics were reported by BL pMDD/pGAD (SF-36 MCS ≤38, presence; >38, absence). Month (M)1/6/12/SF-36 MCS change from BL (A) was estimated, and % with pMDD/pGAD reported. M3/6/12 efficacy outcomes compared tofacitinib-treated pts by BL pMDD/pGAD.

Results: BL pMDD/pGAD was seen in 44.5% (tofacitinib 5 mg BID) and/or probable generalised anxiety disorder (pMDD/pGAD) in RA pts. Tofacitinib is an oral JAK inhibitor for the treatment of RA.

Objectives: To assess pMDD/pGAD prevalence in the tofacitinib RA program and efficacy by baseline (BL) pMDD/pGAD status.

Methods: Data from pts receiving tofacitinib, ADA, or PBO were pooled from 5 Phase (P1) and 1 P2b/4 trials. Demographics/BL characteristics were reported by BL pMDD/pGAD (SF-36 MCS ≤38, presence; >38, absence). Month (M)1/6/12/SF-36 MCS change from BL (A) was estimated, and % with pMDD/pGAD reported. M3/6/12 efficacy outcomes compared tofacitinib-treated pts by BL pMDD/pGAD.

Results: BL pMDD/pGAD was seen in 44.5% (tofacitinib 5 mg BID) and/or probable generalised anxiety disorder (pMDD/pGAD) in RA pts. Tofacitinib is an oral JAK inhibitor for the treatment of RA.

Objectives: To assess pMDD/pGAD prevalence in the tofacitinib RA program and efficacy by baseline (BL) pMDD/pGAD status.

Method: Data from pts receiving tofacitinib, ADA, or PBO were pooled from 5 Phase (P1) and 1 P2b/4 trials. Demographics/BL characteristics were reported by BL pMDD/pGAD (SF-36 MCS ≤38, presence; >38, absence). Month (M)1/6/12/SF-36 MCS change from BL (A) was estimated, and % with pMDD/pGAD reported. M3/6/12 efficacy outcomes compared tofacitinib-treated pts by BL pMDD/pGAD.

Results: BL pMDD/pGAD was seen in 44.5% (tofacitinib 5 mg BID) and/or probable generalised anxiety disorder (pMDD/pGAD) in RA pts. Tofacitinib is an oral JAK inhibitor for the treatment of RA.

Objectives: To assess pMDD/pGAD prevalence in the tofacitinib RA program and efficacy by baseline (BL) pMDD/pGAD status.

Method: Data from pts receiving tofacitinib, ADA, or PBO were pooled from 5 Phase (P1) and 1 P2b/4 trials. Demographics/BL characteristics were reported by BL pMDD/pGAD (SF-36 MCS ≤38, presence; >38, absence). Month (M)1/6/12/SF-36 MCS change from BL (A) was estimated, and % with pMDD/pGAD reported. M3/6/12 efficacy outcomes compared tofacitinib-treated pts by BL pMDD/pGAD.

Results: BL pMDD/pGAD was seen in 44.5% (tofacitinib 5 mg BID) and/or probable generalised anxiety disorder (pMDD/pGAD) in RA pts. Tofacitinib is an oral JAK inhibitor for the treatment of RA.
Conclusion: −40% of RA pts had BL pMDD/pGAD. SF-36 MCS improvements were greater for tofacitinib vs PBO/ADA. With tofacitinib, % of pts with SF-36 MCS ≤38 reduced by ~60% at M12. Tofacitinib efficacy was similar in pts with/without BL pMDD/pGAD. Limitations include using SF-36 MCS to identify probable rather than confirmed MDD or GAD. Future research using gold standard psychiatric interviews to validate use of SF-36 MCS ≤38 is needed.

Figure 1. Proportion of patients with DAS28[CRP] <2.6 through week 52 with nonresponder imputation

Conclusion: Through W52, both FIL 200 and 100mg showed sustained efficacy based on clinical and pt-reported outcomes and radiographic progression and were well tolerated in MTX-IR pts with RA, with faster onset and numerically greater efficacy for FIL 200 vs 100mg.

Background: ABX464 is a small oral molecule with a novel mode of action. It binds the Cap Binding Complex, involved in the biogenesis of RNAs and predominantly upregulates the expression of a microRNA miR-124 in PBMCs and T cells (1). miR-124 has been widely described for its anti-inflammatory properties with many confirmed targets i.e. monocyte chemotactic protein 1 (MCP-1), CXCL-1, SERPIN-E1, STAT-3, IL-8 receptor. It post transcriptionally regulates the expression of MCP-1 in rheumatoid arthritis (RA) synoviocytes and decreases their proliferation (2). While miR-124 is decreased in synoviocytes of RA patients, its injection in joint improved arthritis in rats (3). miR-124 expression in macrophages leads to the induction and maintenance of anti-inflammatory M2 phenotype (4). Its effect in T cells remains controversial.

Objectives: (i) To assess the effect of ABX464 on miR-124 expression in vitro in macrophages and in vivo in patients; (ii) to estimate the effect of ABX464

Thursday, 04 June 2020

ABX464, A NOVEL DRUG IN THE FIELD OF INFLAMMATION, INCREASES MIR-124 AND MODULATES MACROPHAGES AND T-CELL FUNCTIONS.

C. Begon-Pescia1, J. Mielle1, N. Camposé2, K. Chebi1, L. Manchon1, J. Santo2, C. Apolit2, K. Martin 2, L. Lapasset2, A. Vauzrin2, D. Scherrer2, A. Garcel2, J. Tazi2, C. Daien1,3.

Background: ABX464 is a small oral molecule with a novel mode of action. It binds the Cap Binding Complex, involved in the biogenesis of RNAs and predominantly upregulates the expression of a microRNA miR-124 in PBMCs and T cells (1). miR-124 has been widely described for its anti-inflammatory properties with many confirmed targets i.e. monocyte chemotactic protein 1 (MCP-1), CXCL-1, SERPIN-E1, STAT-3, IL-8 receptor. It post-transcriptionally regulates the expression of MCP-1 in rheumatoid arthritis (RA) synoviocytes and decreases their proliferation (2). While miR-124 is decreased in synoviocytes of RA patients, its injection in joint improved arthritis in rats (3). miR-124 expression in macrophages leads to the induction and maintenance of anti-inflammatory M2 phenotype (4). Its effect in T cells remains controversial.

Objectives: (i) To assess the effect of ABX464 on miR-124 expression in vitro in macrophages and in vivo in patients; (ii) to estimate the effect of ABX464
on arthritis in mice and (iii) to decipher the effect of ABX464 on human macrophages and T cells.

Methods: miR-124 was measured in human monocyte-derived macrophages (huMDM) treated with ABX464 for 4 days and in patients with ulcerative colitis included in a phase III RCT in blood and rectal biopsies at day 56 by TaqMan qPCR. Collagen-induced arthritis (CIA) was induced using usual protocol and ABX464 was given by gavage 2 weeks at 40 mg/kg after the 2nd injection of collagen and Freund adjuvant. HuMDM were exposed to 5 µM of ABX464 or DMSO (control) for 4 days, during a M1-polarization. Cytokines and chemokines were assessed in supernatants using both Proteome Profiler Array and Luminex. PBMCs were exposed to ABX464 (5 µM) for 6 days. Th1 (IFN-α), Th17 (CCR6+IL-17), Th2 (CRTH2+ IL-4) and Tregs (CD25+CD125+/loFoxP3) were assessed by flow cytometry. IL-6 soluble receptor was assessed in CD4+ supernatant using ELISA.

Results: ABX464 increased miR-124 in vitro by 3.41 folds in huMDM (p=0.001) compared to DMSO. The phase IIa RCT conducted in 32 patients with moderate to severe active ulcerative colitis showed a good safety profile and significant clinical efficacy. A strong increase of miR-124 was observed both in blood and rectal biopsies of patients treated with ABX464 (637 and 769 folds respectively, compared to placebo, p<0.05). The use of ABX464 drastically decreased the incidence of arthritis from 52% (15/29 mice) to 10% (3/30 mice) in a CIA model. Macrophages treated with ABX464 produced significantly less MCP-1 (median decrease -67%, p=0.004), CXCL-1 (-18%, p=0.004) and SERPIN-E1 (-53%, p=0.004), as confirmed by the two technics (n=9). ABX464 significantly decreased Th17 (-56%, p=0.02), while increasing Th2 (+21%, p=0.01). IL-6 soluble receptor was significantly decreased in supernatant of PBMCs treated with ABX464 (-43%, p=0.04).

Conclusion: We demonstrated that ABX464 increases miR-124 both in vitro and in ulcerative colitis patients. In vitro, ABX464 decreased the expression of miR-124 target genes, that is MCP-1, CXCL-1, SERPIN-E1 in macrophages and decreases the number of Th17 as well as IL-6 soluble receptor in CD4+ T cells. A phase IIa RCT is currently ongoing in patients with rheumatoid arthritis and inadequate response to methotrexate and/or TNF-inhibitors (n=60). Results are expected during 2020 summer.

THU0200

THE CHOICE OF BDMARD OR TSDMARD AS FIRST LINE THERAPY: DATA OF THE TARDIS-RA REGISTRY, A NATIONWIDE BELGIAN BIOLGIC REGISTRY

D. De Cock1, P. Duriez2,3, D. Elewaat4,5, B. Lauwers3,5, R. Westhooven1, P. Verschueren1,6, D. De Cock1

1Skeletal Biology and Engineering Research Centre, KU Leuven, Leuven, Belgium; 2UMR 929, INRAE, Université de Reims Champagne Ardenne, Reims, France; 3Department of Rheumatology and Clinical Immunology, Ghent University Hospital, Ghent, Belgium; 4UMR 6520, Inserm; 5VIB Center for Inflammation Research, Ghent, Belgium; 6Rheumatology, University Hospitals Leuven, Leuven, Belgium

Background: The Tool for Administrative Reimbursement Drug Information Sharing (TARDIS) is an electronic platform combining data collection from all Belgian patients with Rheumatoid Arthritis (RA) on advanced therapy, together with a drug reimbursement request. Therapy choice after initial 2 classical synthetic DMARD failure is left to the treating rheumatologist in Belgium.

Objectives: To investigate first-line therapy choices for tumor necrosis factor inhibitor (TNFi) biologic (b) DMARDs, non-TNFi bDMARDs or targeted synthetic (ts) DMARDs via patient characteristics and initial treatment response in the TARDIS-RA registry.

Methods: All Belgian rheumatologist inserted patient data online when prescribing a b/tsDMARD. When data was entered for the first time, previous and current use of DMARD therapies was registered. Every next bDMARD or tsDMARD initiation, prolongation and discontinuation was registered electronically. First prolongation is 6 months for bDMARDs and 12 weeks for tsDMARDs, and yearly thereafter. Patients were selected for this analysis if they started a TNFi, non-TNFi or tsDMARD therapy between Jan 2018 and Jan 2019. Rituximab was excluded. Baseline characteristics of bionaive patients per therapy were compared with Mann-Whitney U or Chi² tests were appropriate. Regression analyses, adjusted for age, DAS28 baseline and disease duration, evaluated DAS28 change, remission (DAS28<2.6) and low disease activity (LDA, DAS28<3.2) proportion of therapy prolongations at 1st follow up visit did not differ per therapy type.

Results: In 2018, 1623 bionaive RA patients were included. Table 1 describes this population. Time until 1st follow up differed between groups with 183 (181-184) days for bDMARD versus 84 (84-84) days for tsDMARD patients. Linear regression showed an effect of therapy type on DAS28 change in bionaive patients (p=0.017). Logistic regression showed no difference per therapy for remission (p=0.090) nor low disease activity (p=0.123). Proportions of therapy prolongations at 1st follow up visit did not differ per therapy type.

</tr>
</tbody>
</table>

Number given are median, (IQR) or number (proportion). TNFi = tumour necrosis factor inhibitor, ts= targeted synthetic, DAS = disease activity score, DAS28 change = DAS28 at 1st follow up visit minus DAS28 at baseline, remission = DAS28<2.6, LDA = low disease activity = DAS28<3.2. Prolongation = therapy was continued at 1st follow up visit. Mann-Whitney U or Chi square tests were used where appropriate.

Conclusion: Initial therapy choices are partially driven by patient profile, although other factors such as patient preferences could not be verified. DAS28 change for tsDMARDs seemed less important versus bDMARDs, but can possibly be attributed to the preset evaluation moment being sooner for tsDMARDs versus bDMARDs aside of patient profile differences in age and disease duration. In contrast, proportion of remission, low disease activity and therapy prolongation did not differ by therapy.

LONG-TERM SAFETY AND EFFECTIVENESS OF UPADACITINIB OR ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS AT 72 WEEKS FROM THE SELECT-COMPARE STUDY

B. Fleischmann1, I. H. Song2, J. Enejosa2, E. Mysler2, L. Bessette3, P. Durez4, A. Ostro4, J. Swierkot5, Y. Song6, M. C. Genovese8, 1Univ of Texas Southwestern Med Center, Metroplex Clinical Research Center, Dallas, United States of America; 2AbbVie Inc., North Chicago, United States of America; 3Organización Medica de Investigación, Buenos Aires, Argentina; 4Laval Univ, Quebec, Canada; 5Pôle de Recherche en Rhumatologie, Institut de Recherche Expérimentale et Clinique, UCL Saint-Luc, Brussels, Belgium; 6Cabrini Medical Center, Monash University, Malvern, Australia; 7Department of Rheumatology and Internal Medicine, Wroclaw Medical University, Wroclaw, Poland; 8Stanford Univ School of Medicine, Palo Alto, United States of America

Background: In the SELECT-COMPARE study in rheumatoid arthritis (RA) patients with inadequate response to methotrexate (MTX), upadacitinib (UPA), a Janus Kinase (JAK) 1-selective inhibitor, showed significant improvements in treatment of signs and symptoms when compared to placebo (PBO) and adalimumab (ADA) up to 48 weeks.1

Objectives: To report safety and efficacy of UPA vs ADA up to 72 weeks in patients with RA from the ongoing long-term extension (LTE) of SELECT-COMPARE.

Methods: Patients were randomized to once daily (QD) UPA 15 mg, PBO, or ADA 40 mg every other week, with all patients continuing background MTX. The study was double-blind for 48 weeks. Between Weeks 14-26, patients were switched from PBO to UPA, PBO to ADA, or ADA to UPA if there was <20% improvement in tender/swollen joint count at Weeks 14/18/22 or if Clinical Disease Activity Index (CDAI) was >10 at Week 26; all PBO patients who were not rescued were switched to UPA at Week 26. Patients continued UPA or ADA in a blinded manner until the last patient completed the Week 48 visit; patients received open-label treatment thereafter. Study visits occurred at Week 60, 72, and every 12 weeks thereafter. Treatment-emergent adverse events (TEAEs) per 100 patient years (PY) were summarized up to December 26, 2018. Efficacy was analyzed by randomized group.

Results: In total, 651, 651 and 327 patients were randomized at baseline to receive UPA, PBO, and ADA, respectively. Subsequently, 252 patients were switched from ADA to UPA, 159 were switched from ADA to UPA, and all PBO patients were switched to UPA. 1403 patients entered the LTE at Week 48 (UPA: 1091 [565 switched from PBO; 66 rescued from ADA; 460 on continued UPA]; ADA: 312 [110 rescued from UPA; 202 on continued ADA]). The cumulative exposures were 1396.7 and 515.1 PYs for UPA and ADA, respectively. UPA + MTX was generally well-tolerated as assessed by the frequency of AEs, including serious AEs, AEs leading to discontinuation of study drug, and AEs of special interest (AESIs) including serious or opportunistic infections, malignancy, adjudicated major adverse cardiac events or venous thromboembolism; Figure 1). The event rates of AESIs were generally comparable between UPA + MTX and ADA + MTX, except for herpes zoster, lymphopenia, hepatic disorder, and CPK elevation, which were generally comparable between UPA + MTX and ADA + MTX, except for herpes zoster, lymphopenia, hepatic disorder, and CPK elevation, which were numerically higher with UPA + MTX. At both Weeks 60 and 72, significantly greater proportions of patient receiving UPA + MTX achieved ACR20/50/70 (P ≤.01/.001/.001), low disease activity (P ≤.001) and remission (P ≤.001) numerically higher with UPA + MTX. At both Weeks 60 and 72, significantly greater proportions of patient receiving UPA + MTX achieved ACR20/50/70 (P ≤.01/.001/.001), low disease activity (P ≤.001) and remission (P ≤.001). Similarly, improvements in tender/swollen joint count were numerically higher with UPA + MTX. At both Weeks 60 and 72, significantly greater proportions of patient receiving UPA + MTX achieved ACR20/50/70 (P ≤.01/.001/.001), low disease activity (P ≤.001) and remission (P ≤.001). At both Weeks 60 and 72, significantly greater proportions of patient receiving UPA + MTX achieved ACR20/50/70 (P ≤.01/.001/.001), low disease activity (P ≤.001) and remission (P ≤.001). At both Weeks 60 and 72, significantly greater proportions of patient receiving UPA + MTX achieved ACR20/50/70 (P ≤.01/.001/.001), low disease activity (P ≤.001) and remission (P ≤.001).

Conclusion: The safety profile for UPA + MTX was consistent with that reported previously and with the integrated Phase 3 safety analysis.1,2 UPA + MTX maintained significantly higher levels of clinical response, including remission compared to ADA + MTX through Week 72 (P ≤.01).
INTEGRATED SAFETY ANALYSIS OF FILGOTINIB TREATMENT FOR RHEUMATOID ARTHRITIS FROM 7 CLINICAL TRIALS

M. C. Genovese¹, K. Winthrop², Y. Tanaka³, T. Takeuchi⁴, A. Kivitz⁵, F. Matzkses, L. Ye⁶, D. Jiang⁷, Y. Guo⁸, B. Bartok⁹, R. Besuyen¹⁰, G. R. Burmester¹¹, J. E. Gottenberg¹², Stanford Univ, Stanford, CA, United States of America; ²Oregon Health and Science Univ, Portland, OR, United States of America; ³Univ of Occupational and Environmental Health, Kitakyushu, Japan; ⁴Keio Univ School of Medicine, Tokyo, Japan; ⁵Altoona Ctr for Clinical Research, Duncansville, PA, United States of America; ⁶Gilead Sciences, Inc, Foster City, CA, United States of America; ⁷Galapagos BV, Leiden, Netherlands; ⁸Charité Univ Hospital Berlin, Berlin, Germany; ⁹Strasbourg Univ Hospital, Strasbourg, France

Background: Filgotinib (FIL), an oral, potent, selective JAK-1 inhibitor, provided statistically significant and clinically meaningful improvement in rheumatoid arthritis (RA) signs and symptoms, physical function, radiographic progression, and quality of life in a comprehensive clinical program of 4 phase 3 (FINCH 1–4; NCT02889796, NCT02873936, NCT02886728, NCT03025308) and 3 phase 2 (DARWIN 1–3; NCT01668641, NCT01894516, NCT02065700) trials in patients (pts) with early and biologic-refractory RA.¹–³

Objectives: To assess long-term safety of FIL.

Methods: Treatment-emergent adverse events (TEAEs) from the FIL clinical program were integrated and presented for pts receiving FIL 200 mg or FIL 100 mg QD (including pts who transitioned to FIL from placebo [PBO], methotrexate [MTX], adalimumab [ADA], or another dose of FIL) as well as pts receiving PBO, MTX, and ADA across all 7 studies. Exposure-adjusted incidence rates (EAIRs) per 100 patient-years (PY) were calculated for adverse events (AEs) of interest per treatment. Incidence was total number of pts with events, and PY exposure was time between first and last doses. Major adverse cardiovascular events (MACE) and venous thromboembolism (VTE) were centrally adjudicated by an independent committee.

Results: Across the 7 trials, 4057 pts with RA (2227 pts FIL 200 mg; 1600 pts FIL 100 mg) received >1 dose of treatment for 5493 total PY of exposure (3079.2 PY FIL 200 mg; 1465.3 PY FIL 100 mg) (Table). EAIRs of serious AEs and TEAEs leading to death in pts receiving FIL were comparable to those for PBO, ADA, or MTX, with no dose-dependent effect (Figure 1). EAIR for herpes zoster (HZ), serious, and opportunistic infections are shown in Figure 2. EAIR for HZ were low overall, but numerically slightly higher for FIL relative to PBO, ADA, and similar to MTX. Serious infection EAIRs were comparable between pts receiving FIL 100 mg and ADA, and numerically slightly lower for FIL 200 mg and MTX. Rates of opportunistic infections (including active tuberculosis) were low overall; EAIR for FIL doses were comparable to placebo and numerically lower than ADA or MTX. Rates of MACE and VTE were numerically lower for FIL relative to PBO (Figure 1). Malignancies, including nonmelanoma skin cancer, were rare overall, and rates were low in pts receiving FIL (Figure 1).

Patients could contribute to >1 treatment group.

Conclusion: In this integrated analysis, FIL was well-tolerated, and no new safety concerns were identified. No clinically meaningful dose-dependent safety effects were observed. MACE and VTE were uncommon. Serious infections rates were low; HZ reactivation was infrequent. Safety results were consistent with selective JAK-1 inhibition and highlight the favourable safety and tolerability of FIL in patients with RA.

REAL WORLD EFFECTIVENESS OF BARICITINIB IN THE SWISS RHEUMATOID ARTHRITIS REGISTRY (SCQM-RA)

B. Gilbert, K. Lauper, D. Courvoisier, C. Perrier, R. Muller, A. Finchk.

Hôpitaux Universitaires de Genève (HUG), Division of Rheumatology, Genève, Switzerland; 2The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 3Eli Lilly SA, Vernier, Switzerland; 4Kantonsspital Aarau AG, Klinik für Rheumatologie, Aarau, Switzerland

Background: Patients with rheumatoid arthritis (RA) intolerant or not responding adequately to conventional synthetic DMARD (csDMARD) usually receive biological DMARDs (bDMARDs) or targeted synthetic DMARDs (tsDMARDs) as 2nd line. Baricitinib (BARI), a once-daily oral selective Janus kinase inhibitor, is ing adequately to conventional synthetic DMARD (csDMARD) usually receive

Results: During the study period, 9,797 TC were initiated (240 in BARI group, 461 in TNFi group and 278 in OMA group). BARI was prescribed to significantly older patients, with longer disease durations and more previous treatment failures (Table 1). Unadjusted drug maintenance was significantly shorter in the TNFi compared to the BARI group (log rank p = 0.019). After adjustment for potential confounding factors, the hazard of TNFi discontinuation remained higher than for BARI (Hazard Ratio (HR) 1.48 (95% CI = [1.05 – 2.09]; p = 0.02)). A similar trend was observed when comparing the OMA drugs to BARI, with a HR for discontinuation of 1.42 (95% CI = [0.98 – 2.09]; p = 0.06). A similar trend was observed when comparing the OMA drugs to BARI (Figure 2). Covariates significantly associated with decreased drug maintenance were concomitant csDMARD and concomitant glucocorticoids (Figure 2).

Conclusion: In this preliminary analysis, baricitinib was prescribed to older patients, with longer disease durations, and more previous treatment failures compared to alternative bDMARDs. Baricitinib demonstrated a significantly higher drug maintenance than TNFi, while similar trend was observed in comparison to OMA drugs.

Conflict of interest: This analysis has been made possible by financial support of Eli Lilly (Suisse) SA to the Geneva University Hospitals (HUG).

A SUBGROUP ANALYSIS OF LOW DISEASE ACTIVITY AND REMISSION FROM PHASE 3 STUDY OF FILGOTINIB IN PATIENTS WITH INADEQUATE RESPONSE TO BIOLOGIC DMARDs

J. E. Gottenberg, M. H. Buch, R. Caporali, G. C. Wright, T. Takeuchi, K. Kalunian, A. Pechonkina, Y. Guo, S. Rao, Y. Tan, R. Besuyen, M. C. Genovese, Strasbourg Univ Hospital, Strasbourg, France; Univ of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; Univ of Milan, Rheumatology Division, Hospital G. Pini-CTO, Milan, Italy; Grace C Wright MD PC, New York, NY; United States of America; Keio Univ, Japan; Univ of California San Diego, Division of Rheumatology, Allergy and Immunology, La Jolla, CA, United States of America; Gilad Sciences, Inc, Foster City, CA, United States of America; Galapagos BV Leiden, Netherlands; Stanford Univ, Stanford, CA, United States of America

Background: Despite effective treatments, many patients (pts) with rheumatoid arthritis (RA) have inadequate responses to biologic DMARDs (bDMARD-IR), highlighting an unmet need. It is unclear whether prior bDMARD use affects efficacy of the oral, selective JAK-1 inhibitor filgotinib (FIL).

Objectives: To explore clinical response to FIL in bDMARD-IR pts stratified by mode of action (MOA) and number of prior bDMARDs.

Methods: The global, phase 3 FINCH-2 (NCT02873936) study treated 448 bDMARD-IR pts with active RA. 1 Pts were randomised 1:1:1 to once-daily FIL 200 mg, FIL 100 mg, or placebo (PBO) for 24 weeks. Efficacy was assessed by percent of pts achieving low disease activity (LDA) or remission at week (W)24 as measured by CDAI and DAS28(CRP) stratified by number and MOA of prior bDMARDs. Comparisons were not adjusted for multiplicity. Nonresponders imputation was used.

Results: In total, 448 bDMARD-IR pts were included, 105 with prior experience with ≥3 bDMARDs (Table). At W24, pts receiving FIL were in LDA at a higher proportion vs PBO, irrespective of number of prior bDMARDs or MOA (Figure 1). For pts receiving FIL 200 mg vs PBO, DAS28(CRP) <2.6 was achieved at W24 by 52% vs 26%, 51% vs 22%, and 38% vs 9% of pts with 1, 2, or ≥3 prior bDMARDs, respectively, and 49% vs 21% and 50% vs 13% of pts exposed to TNF or IL-6 inhibitors; for all subgroups, rates were significantly higher vs PBO (Figure 1). Delta between FIL 200 mg and PBO was maintained irrespective of number or type of prior bDMARDs. At W24, pts receiving FIL achieved remission at numerically higher rates vs PBO (Figure 2). For pts receiving FIL 200 mg vs PBO, DAS28(CRP) <2.6 was achieved at W24 by 36% vs 14%, 30% vs 14%, and 22% vs 6% of pts with 1, 2, and ≥3 prior bDMARDs, respectively, and 31% vs 14% and 29% vs 9% of pts exposed to TNF or IL-6 inhibitors (Figure 2). Delta between FIL 200 mg and PBO was maintained irrespective of number or type of prior bDMARDs. Treatment-emergent adverse events across subgroups were consistent with overall study population.

C. Joseph1, S. M. Bilgrami2, L. Ottewell2, L. Gray2, W. Mitchell2, F. Wood2, M. Massarotti2, M. Bukhari1,2,1. Lancaster University, Lancaster, United Kingdom; 2University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom

Background: Two small molecules (Tofacitinib and Baricitinib) have been licensed in the UK for the use in rheumatoid arthritis. Their licensing came from several studies that showed good efficacy with baricitinib (1) study showing superior efficacy to adalimumab and tofacitinib showing non inferiority to TNF drugs (2). The response has also been shown in patient reported outcomes (find reference). Response when measure using the DAS score has two relatively subjective components (tender joints and patient global assessment) and two relatively objective components (Swollen joints and inflammatory markers). Objectives: To determine in a real world setting if the response to small molecules is mostly due to a drop in subjective or objective components of the DAS score.

Methods: A retrospective chart review was done on all new starters on small molecules in a district hospital in the North of England. Data were collected at baseline, three months and six months from October 2018 to date. Drop in the components of the DAS28 score was calculated and overall drop in DAS28 was modelled as the explanatory variable using linear regression modelling. This was the done Adjusting for age gender and duration of disease. Sensitivity of the model was examined using a logistic model of EULAR moderate/good response and using adjusted R squared estimates for linear model of improvement of the DAS28 score.

Results: 76 patients were included in the analysis from 85 starters on small molecules.61 (71.8 %) were on baricitinib and the baseline median DAS28 score was .5.97 (IQR 5.35,6.55)The median drop at three months in the DAS28 score was 2.42 (IQR 1.33,3.31), and at six months was 2.77 (IQR 2.01,3.83). There was numerical relative increased efficacy of baricitinib but there was no statistically significant (DAS drop at three month 2.54 IQR 1.73,3.09 vs 2.12 IQR 1.51,3.5) The relative contribution of the individual components of the DAS score to the drop in DAS28 were shown in table 1 below. Sensitivity analysis looking at predictors of a DAS drop of >0.6 confirmed this finding. Table 1. Results of the adjusted linear regression models.

</table>

Conclusion: In this real world observational study, there was a good response to both small molecules with numerical better response to baricitinib. Tender joint count and patient global response accounted for more of the drop in DAS28 than swollen joints and inflammatory markers. At six months the biggest contributor to response was patient global assessment. This shows that JAK inhibitors might mediate their response initially mostly through pain modulation then by inflammation as exposure to drug continues.

THU0205 RESPONSE TO SMALL MOLECULES IS MOSTLY DRIVEN BY PATIENT GLOBAL ASSESSMENT OF DISEASE: A REAL WORLD OBSERVATION

THU0206 A VERY EARLY (7-28 DAYS) RESPONSE ON JAK INHIBITOR TOFACITINIB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: EFFECT ON PAIN AND CENTRAL SENSITIZATION.

A. Karateev1, E. Filatova1, E. Pogozheva1, A. Amirzhanova1, E. Nasonov1, A. Lita1, V. Mazurov1, N. Lapkina1, G. Lukina1, T. Salnikova1, R. Samgulina1, D. Chakieva1, I. Marusenko1, O. Semagina1, M. Semchenkova1, A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Mechnikov North-Western State Medical University, St-Petersburg, Russian Federation; 3Yaroslavl State Medical University, Yaroslavl, Russian Federation; 4Moscow Clinical Scientific and Practical Centre named after Loginov AS, Moscow, Russian Federation; 5Regional Clinical Hospital, Tula, Tula, Russian Federation; 6Petrozavodsk State University, Petrozavodsk, Russian Federation; 7Regional Clinical Hospital, Samara, Samara, Russian Federation; 8Smolensk State Medical University, Smolensk, Russian Federation

Background: The presence of central sensitization (CS) significantly burdens the course of rheumatoid arthritis (RA). JAK inhibitors block intracellular signal pathways including the ones responsible for synthesis of mediators and cytokines causing pain and CS. The application of JAK inhibitors is supposed to relieve pain and reduce CS severity promptly.

Objectives: To evaluate JAK inhibitor effect on pain and signs of CS in patients with active RA 7 and 28 days after the start of therapy.

Methods: Study group included 39 patients with RA, their age was 50.9±11.7, 79.5% of women, 89.7% of RF +; DAS28 5.8±4.0, receiving DMARDs (methotrexate 82.0% and infliximab 18.0%), who were administered with tofacitinib 5mg 2 times a day due to inefficacy or intolerance of genetically engineered biological drugs. There were assessed the pain severity using Brief pain inventory (BPI) questionnaire, the presence of neuropathic pain component (NPC) using PainDetect questionnaire and signs of CS using Central Sensitisation Inventory (CSI) questionnaire at early time after tofacitinib administration.

Results: Patients initially experienced a severe pain – 5.72±2.21 according to the visual analogue scale (VAS), 53.8% had signs of central sensitization (CSI ≥ 40), 17.9% had NPC (PainDetect ≥18), 7 days after tofacitinib intake there was statistically reliable reduction of pain severity – up to 4.37±2.2 (p=0.01), pain decrease of 29.4±17.9% (BPI), NPC – PainDetect from 12.9±5.5 to 10.6±5.6 (p=0.047) and CSI – from 43.1±12.8 to 35.9±11.2 (p=0.01). The effect had increased after 28 days: pain level (VAS) was 2.84±1.57 (p=0.000), pain decrease of 43.6±29.6% (BPI), PainDetect 29.8±12.4 (p=0.000), CSI 26.4±13.9 (p=0.000).

During this period there were no serious adverse reactions.

Conclusion: The application of JAK inhibitor tofacitinib allows to reach a fast analgesic effect, also due to impact on CS and NPC.

THU0207 SUSTAINABILITY OF RESPONSE TO UPADACITINIB AS MONOTHERAPY OR IN COMBINATION AMONG PATIENTS WITH RHEUMATOID ARTHRITIS AND PRIOR INADEQUATE RESPONSE TO CONVENTIONAL SYMPTOMATIC DMARDs

A. Kavanaou1, M. H. Buch2, B. Combe2, L. Besse3, I. H. Song3, Y. Song3, J. Suboticki3, P. Nash4, 1University of California San Diego, San Diego, San Diego, United States of America; 2University of Manchester & NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; 3Lapeyronie Hospital, Montpellier University, Montpellier, France; 4Université Laval, Centre Hospitalier de l’Université Laval, Quebec, Canada, 1AbbVie Inc., North Chicago, United States of America; 2School of Medicine, Griffith University, Brisbane, Australia

Background: The primary treatment goal for patients (pts) with rheumatoid arthritis (RA) is a state of sustained clinical remission (REM) or low disease activity (LDA).2,3

Objectives: To assess the long-term sustainability of responses to upadacitinib (UPA), a JAK inhibitor, with or without background csDMARD(s) (pts) with RA.

Methods: Data are from two phase 3 randomized, controlled trials of UPA in RA pts with roughly similar baseline disease characteristics: SELECT-NEXT enrolled pts with an inadequate response (IR) to csDMARD(s) on background stable cs-DMARD(s) receiving UPA 15mg or 30mg once daily or placebo for 12 weeks (wks);
SELECT MONOTHERAPY enrolled methotrexate (MTX)-IR pts receiving UPA 15mg or 30mg monotherapy or blinded MTX for 14 wks. After 12/14 wks, pts could enter a blinded long-term extension and receive UPA 15mg or 30mg for up to 5 years. This post hoc analysis evaluated clinical REM (CDAI ≤2.8; SDAI ≤3.3; LDA ≤328; CRP <2.6) and SDAI/CRP <2.6 at first occurrence before Wk 84; additionally, these measures were evaluated at 3, 6, and 12 months after the first occurrence for the total number of pts randomized to UPA 15mg. Sustainability of response was evaluated by Kaplan-Meier only for those pts who achieved REM/ LDA and was defined as time to the earliest date of losing response at two consecutive visits or discontinuation of study drug. The predictive ability of time to a clinical REM/LDA was assessed using Harrell's concordance (c)-index (for reference, an index ~ 0.5, indicates no ability to predict; an index of 1 or 1 - would be a perfect prediction). The last follow up dates were 22 March, 2018 (SELECT-NEXT) and 25 May, 2019 (SELECT-MONOTHERAPY), when all pts had reached the Wk 84 visit.

**Results:** Through Wk 84, the percent of treated pts achieving CDAI REM/LDA was 43%/79% for those receiving UPA 15mg with background csDMARD(s) (SELECT-NEXT) and 37%/76% for those receiving UPA 15mg without background csDMARD(s) (SELECT-MONOTHERAPY). 35%/25% of pts randomized to UPA 15mg with background csDMARD(s) and 27%/23% of pts randomized to UPA 15mg without background csDMARD(s) achieved sustained CDAI REM through 6/12 months after the first occurrence. 64%/55% of pts randomized to UPA 15mg with background csDMARD(s) and 61%/56% of pts randomized to UPA 15mg without background csDMARD(s) achieved sustained CDAI LDA through 6/12 months after the first occurrence (Figure 1). Time to initial clinical REM/LDA did not appear to be associated with sustained disease control. The c-indices (95%CI) for CDAI REM in the UPA 15mg with background csDMARD(s) and UPA 15mg without background csDMARD(s) groups were 0.541 (0.47, 0.62) and 0.568 (0.49, 0.65) and that of LDA were 0.521 (0.46, 0.58) and 0.498 (0.43, 0.56), respectively. Through last follow-up visit, 55% of pts receiving UPA 15mg without background csDMARD(s) remained in CDAI REM while 72% and 70% of pts remained in CRP <2.6 and ≤3.2, respectively. Through Wk 84, the percent of treated pts achieving CDAI REM/LDA did not appear to be associated with sustained disease control. The c-indices (95%CI) for CDAI REM in the UPA 15mg with background csDMARD(s) and UPA 15mg without background csDMARD(s) groups were 0.541 (0.47, 0.62) and 0.568 (0.49, 0.65) and that of LDA were 0.521 (0.46, 0.58) and 0.498 (0.43, 0.56), respectively. Through last follow-up visit, 55% of pts receiving UPA 15mg without background csDMARD(s) remained in CDAI REM while 72% and 70% of pts remained in CRP <2.6 and ≤3.2, respectively. Through Wk 84, the percent of treated pts achieving CDAI REM/LDA did not appear to be associated with sustained disease control. The c-indices (95%CI) for CDAI REM in the UPA 15mg with background csDMARD(s) and UPA 15mg without background csDMARD(s) groups were 0.541 (0.47, 0.62) and 0.568 (0.49, 0.65) and that of LDA were 0.521 (0.46, 0.58) and 0.498 (0.43, 0.56), respectively. Through last follow-up visit, 55% of pts receiving UPA 15mg without background csDMARD(s) remained in CDAI REM while 72% and 70% of pts remained in CRP <2.6 and ≤3.2, respectively. Through Wk 84, the percent of treated pts achieving CDAI REM/LDA did not appear to be associated with sustained disease control. The c-indices (95%CI) for CDAI REM in the UPA 15mg with background csDMARD(s) and UPA 15mg without background csDMARD(s) groups were 0.541 (0.47, 0.62) and 0.568 (0.49, 0.65) and that of LDA were 0.521 (0.46, 0.58) and 0.498 (0.43, 0.56), respectively. Through last follow-up visit, 55% of pts receiving UPA 15mg without background csDMARD(s) remained in CDAI REM while 72% and 70% of pts remained in CRP <2.6 and ≤3.2, respectively. Through Wk 84, the percent of treated pts achieving CDAI REM/LDA did not appear to be associated with sustained disease control. The c-indices (95%CI) for CDAI REM in the UPA 15mg with background csDMARD(s) and UPA 15mg without background csDMARD(s) groups were 0.541 (0.47, 0.62) and 0.568 (0.49, 0.65) and that of LDA were 0.521 (0.46, 0.58) and 0.498 (0.43, 0.56), respectively. Through last follow-up visit, 55% of pts receiving UPA 15mg without background csDMARD(s) remained in CDAI REM while 72% and 70% of pts remained in CRP <2.6 and ≤3.2, respectively. Through Wk 84, the percent of treated pts achieving CDAI REM/LDA did not appear to be associated with sustained disease control. The c-indices (95%CI) for CDAI REM in the UPA 15mg with background csDMARD(s) and UPA 15mg without background csDMARD(s) groups were 0.541 (0.47, 0.62) and 0.568 (0.49, 0.65) and that of LDA were 0.521 (0.46, 0.58) and 0.498 (0.43, 0.56), respectively. Through last follow-up visit, 55% of pts receiving UPA 15mg without background csDMARD(s) remained in CDAI REM while 72% and 70% of pts remained in CRP <2.6 and ≤3.2, respectively.
**THU0209 UPTAKE OF JANUS KINASE INHIBITORS FOR MANAGEMENT OF RHEUMATOID ARTHRITIS IN AUSTRALIA**

G. Littlejohn1,2, T. Smith3, K. Tymms3, P. Yousef4,5, H. Cooley6, S. Ciciriello7, D. Mathers8, H. Griffiths8 on behalf of the OPAL Consortium.

1Monash Rheumatology, Melbourne, Australia; 2OPAL Rheumatology Unit, Sydney, Australia; 3Canberra Rheumatology, Canberra, Australia; 4University of Sydney, Sydney, Australia; 5Royal Prince Alfred Hospital, Sydney, Australia; 6Hobart Private Hospital, Hobart, Australia; 7Royal Melbourne Hospital, Melbourne, Australia; 8Georgetown Rheumatology, Newcastle, Australia; 9Barwon Rheumatology Service, Geelong, Australia

**Background:** JAK inhibitors (JAKi) are oral tsDMARDs with a different mode of action (MOA) to both oral cs- and parenteral bDMARDs. In Australia the cost of b/tsDMARDs for treatment of RA is subsidized if the patient has documented high levels of clinical/laboratory disease activity and has not responded to a pre-specified combination of csDMARDs, including MTX. Once eligible for subsidy the clinician can prescribe the b/tsDMARD deemed most clinically appropriate.

**Objectives:** To determine the patterns of use and reasons for initiation and discontinuation of JAKi in real-world rheumatology practice in Australia.

**Methods:** Deidentified clinical data were sourced from the OPAL dataset, which is collected in a custom-built electronic medical record at the time of the consultation by 94 rheumatologists in Australia, representing one third of Australian clinical rheumatologists. Data from patients >18 years with a diagnosis of RA who commenced a b/tsDMARD between Jan-2007 and Sept-2019 were included in the analysis. Tableau® was used to display data on medication initiation and adverse reaction (25%) which is consistent with the rates observed in real-world Australian rheumatology encounters to enhance clinical care and research. **THU0210 EARLY DISCONTINUATION OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS CO-TREATED WITH RIFAMPIN FOR LATENT TUBERCULOSIS: RESULTS FROM THE REAL-WORLD DATA**

S. H. Nam1, S. J. Choi1, J. S. Lee1, J. S. Oh1, S. Hong1, W. J. Seo3, C. K. Lee1, B. Yoo1, Y. G. Kim1.

1University of Ulsan College of Medicine, Asan Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Asan Medical Center, Department of Biomedical Informatics, Seoul, Korea, Rep. of (South Korea); 3Veterans Health Service Medical Center, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

**Background:** Rheumatoid arthritis (RA) patients need to undergo screening and receive treatment for latent tuberculosis infection (LTBI) before starting tofacitinib, which is primarily metabolized by cytochrome P450 (CYP) 3A4. Among chemoprophyactic agents, rifampin is known to be a potent CYP3A4 inducer; therefore, it is expected to decrease the efficacy of tofacitinib. However, tofacitinib and rifampin have been co-administered practically because of the short duration of chemoprophylaxis.

**Objectives:** The aim of this study was to determine the efficacy of tofacitinib on co-administration with rifampin.

**Methods:** Biologic-naïve RA patients treated with tofacitinib were selected, and electronic medical reports were reviewed retrospectively. All patients underwent screening for LTBI before starting tofacitinib, and patients with positive results were treated to prevent progression to active tuberculosis. To evaluate the efficacy of tofacitinib with or without rifampin, the discontinuation rates of tofacitinib were examined during the first 6 months. Kaplan–Meier analysis was used to construct cumulative discontinuation curves, and comparisons were performed using the log-rank test.

**Results:** Among 81 patients who started tofacitinib, 21 (25.9%) were LTBI-positive and 18 (22.2%) were administered rifampin concomitantly with tofacitinib. The median follow-up time was 6 months in both patients who received rifampin (interquartile range [IQR] 2.21, 6.00) and those who did not receive rifampin (IQR 5.97, 6.00) (p = 0.083). There were no significant differences between patients who received rifampin and those who did not receive rifampin in all baseline characteristics, except the swollen joint count (3.00 [1.75, 5.25] vs. 5.00 [4.00, 7.00]; p = 0.025), at the time of starting tofacitinib. In patients who received rifampin at the time of starting tofacitinib, the mean duration of co-administration was 47.00 ± 23.54 days (median 56; IQR 28.75, 59.00). During follow-up, 14 of the 81 patients (17.3%) discontinued tofacitinib. As shown in the Figures 1 and 2, the discontinuation rate of tofacitinib within the first 6 months was significantly higher among patients who received rifampin for LTBI than among those who did not receive rifampin (lack of efficacy: 24.7% vs. 5.1%, p = 0.008; all causes: 36.9% vs. 11.2%, p = 0.002). Seven patients discontinued tofacitinib because of...
uncontrolled RA activity, and rifampin had been administered concomitantly in four of these seven patients. Of the four patients, three stopped taking tofacitinib in the middle of LTBI treatment, and the DAS28-ESR scores of these patients were higher at discontinuation than at baseline.

**Conclusion:** Discontinuation rates were higher in RA patients who started tofacitinib during chemoprophylaxis involving rifampin than in those who did not receive rifampin. Physicians should be aware that the efficacy of tofacitinib could be decreased by the chemoprophylactic regimen for tuberculosis.

**Figure 1:** Discontinuation rates of tofacitinib owing to lack of efficacy within 6 months

**Figure 2:** Discontinuation rates of tofacitinib owing to all causes within 6 months

**RADIOPHGRAPHIC OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING UPADACITINIB AS MONOTHERAPY OR IN COMBINATION WITH METHOTREXATE: RESULTS AT 2 YEARS FROM THE SELECT-COMpare AND SELECT-EARLY STUDIES**

C. Peterfy1, V. Strand2, M. C. Genovese3, A. Friedman3, J. J. Enejoja4, S. Hall4, E. Mysler5, P. Durez6, X. Baraliakos7, T. Shaw8, Y. Song3, Y. Li3, I. H. Song3, 1Spire Sciences Inc, Boca Raton, United States of America; 2Stanford University, Palo Alto, United States of America; 3AbbVie Inc, North Chicago, United States of America; 4Monash University, Cabrini Health and Emeritus Research, Malvern, Australia; 5Organization Médica de Investigación, Buenos Aires, Argentina; 6Pôle de Recherche en Rhumatologie, Institut de Recherche Expérimentale et Clinique, UCL Saint-Luc, Brussels, Belgium; 7Herne and Ruhm University, Bochum, Germany

**Background:** For patients with rheumatoid arthritis (RA), long-term prevention of structural joint damage is a key treatment goal. In the SELECT-EARLY and SELECT-COMPARE trials, upadacitinib (UPA), an oral JAK inhibitor, inhibited the progression of structural joint damage at 6 months and 1 year when used either as monotherapy or in combination with methotrexate (MTX) in patients (pts) with active RA.2

**Objectives:** To describe the radiographic progression up to 2 years (96 wks) among pts with RA receiving UPA either as monotherapy or in combination with MTX.

**Methods:** Both the SELECT-EARLY and SELECT-COMPARE phase 3, randomized controlled trials enrolled pts at high risk for progressive structural damage with baseline (BL) erosive joint damage and/or seropositivity.3,4 In SELECT-EARLY, MTX-naive pts (N=945) were randomized to UPA 15 mg or 30 mg once daily (QD) or MTX monotherapy. In SELECT-COMPARE, pts with an inadequate response to MTX (N=1629) were randomized to UPA 15 mg, placebo (PBO), or adalimumab (ADA) 40 mg every other wk, with all pts continuing background MTX. At wk 26, all pts receiving PBO were switched to UPA 15 mg, regardless of response. In both trials, mean changes from BL in modified Total Sharp Score (mTSS), joint space narrowing, and joint erosion as well as the proportion of pts with no radiographic progression (change in mTSS ≤0) were evaluated based on X-rays taken at wks 24/26, 48, and 96 for those patients in whom wk 96 X-rays were available. Data are reported as observed (AO).

**Results:** BL demographics have been reported previously.3,4 In the SELECT-EARLY study, at wk 96 UPA monotherapy (15 mg and 30 mg doses) significantly inhibited radiographic progression compared with MTX as measured by mean change in mTSS and by the proportion of pts with no radiographic progression (Figures 1 and 2). When patients who were rescued (MTX added to UPA or UPA added to MTX) were removed from the analysis, changes in mTSS from baseline remained similar. By the same measures, in SELECT-COMPARE, the degree of inhibition of structural progression observed was comparable between UPA and ADA. Following the switch of all PBO patients to UPA, the rate of progression slowed and was comparable to that observed in pts receiving UPA from BL. Among pts from both studies that had no radiographic progression at wk 24/26, >90% remained without radiographic progression at wk 48 and 96.

**Conclusion:** UPA was effective in inhibiting the progression of structural joint damage through 2 years both in MTX-naive patients receiving UPA monotherapy and MTX-inaDEquate responder patients receiving UPA in combination with MTX.

FIRST LINE TREATMENT WITH CONVENTIONAL SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS IN RHENMATOID ARTHRITIS: A MULTINATIONAL POPULATION-BASED COHORT FROM 14 REAL WORLD HEALTHCARE DATABASES AND 9 COUNTRIES - REALITY VERSUS GUIDELINES

A. G. Sena1, D. Granados1, N. Hughes2, W. Fakhoury4, N. Houghtonroth3, R. Kolde6, S. Reisberg3, C. O. Torre8, T. Duarte-Salles1, Y. Diaz5, F. Gollub-Dzib1, E. S. Brouwer3, E. Burn5, J. Lane4, D. Vizcaya2, S. Bruce Wirta12, K. Verhamme10, P. Rijnbeek9, E. Theander2

Chatzidionysiou K., Prieto-Alhambra D., Ryan P., Golib-Dzib F., Brouwer E. S., Burn E., Lane J., Vizcaya D., Bruce W., Verhamme K., Rijnbeek P., Theander E.

Background: Treatment guidelines recommend early initiation of csDMARDs following diagnosis of rheumatoid arthritis (RA), with methotrexate (MTX) as first-line therapy. Scarcity of evidence exists on adherence to this guidance. Objectives: To characterize first-line csDMARD treatment during the first year following an RA diagnosis.

Methods: 14 real world databases (3 Primary care, 6 primary/secondary care records, 5 claims) from 9 countries were included, all mapped to the OMOP common data model. Patients were included on the earliest event of: 1st diagnosis of RA or 1st DMARD prescription with an RA diagnosis within 30 days. Patients were >18 years-old, required 1+ year pre-index data, and at least 1-year follow-up. Study period covered 2000-2018. Previous users of DMARDs or non-RA inflammatory arthritis history were excluded. Only MTX, Hydroxychloroquine (HCQ), Sulfasalazine (SSZ) and Leflunomide (LEF) were available in all databases.

Results: We identified 323,547 eligible participants. Large variation was observed internationally (Figure 1). MTX as first-line monotherapy ranged from 33.3% to 74.5%, and in combination with HCQ from 2.1% to 6.7%. Three additional csDMARDs were used as first-line: HCQ in 10.1% to 30.2%, SSZ in 0.9% to 28.7%, and LEF in 1.8% to 15.2%.

Conclusion: We report wide heterogeneity of first-line csDMARDs regimens internationally. Despite recommendations for MTX to be first-line therapy, data suggest that a large proportion of patients receive alternative csDMARD.

DOIs: 10.1136/annrheumdis-2020-eular.3131

Figure 1. First line csDMARD treatment during 1yr from first observed RA diagnosis.
Background: In the SELECT-MONOTHERAPY trial, upadacitinib (UPA), an oral JAK inhibitor, demonstrated significantly greater efficacy compared to continuing methotrexate (MTX) when used as monotherapy over 14 weeks (wks) in patients (pts) with rheumatoid arthritis (RA) and prior inadequate response continuing MTX when used as monotherapy over 14 weeks (wks) in patients (pts) with rheumatoid arthritis (RA) and prior inadequate response.

Objectives: To describe the long-term safety and efficacy of UPA monotherapy in an ongoing long-term extension (LTE) of the SELECT-MONOTHERAPY trial.

Methods: Pts on stable MTX were randomized to either continue MTX (cMTX, given as blinded study drug) or switch to once-daily (QD) UPA 15 (UPA15) or 30 (UPA30) mg monotherapy for 14 wks. From Wk14, pts could enter a blinded LTO and continue to receive UPA15 or UPA30; pts randomized to cMTX were switched to UPA15 or UPA30 per pre-specified assignment at baseline. Treatment-emergent adverse events (TEAEs) per 100 pts (PYs) of exposure are summarized up to a cut-off data of 5 February 2019, when all pts had reached Wk60. Efficacy outcomes through Wk60 are reported as observed and using non-responder imputation.

Results: Of 648 pts randomized, 598 (92%) completed 14 wks and entered the LTE on blinded UPA. By the cut-off date, 20% in total had discontinued due to the following: AE (6%), consent withdrawal (4%), lost to follow-up (2%), lack of efficacy (1%), or other reasons (7%). Cumulative exposures were 421.5 and 425.9 PYs for UPA15 and UPA30, respectively. The most frequently reported TEAEs were urinary tract infection, creatine phosphokinase increase; the most common serious AE was pneumonia. Events of HZ, hepatic disorder, and CPK elevations were higher among pts receiving UPA30, while rates of serious infection and malignancy appeared comparable between doses (Figure). Most HZ events involved 1-2 dermatomes, with a single disseminated cutaneous event (UPA30) and none with CNS involvement. Five patients experienced MACE, and there were 5 VTE events (UPA15: 4; UPA30: 1). All MACE and VTE events occurred in pts with underlying risk factors. Pts continuing to receive UPA15 and UPA30 achieved stringent endpoints at Week 84 (Table). Pts who switched from cMTX to UPA15 or UPA30 demonstrated comparable efficacy responses to those initially randomized to UPA.

Conclusion: The adverse event profile associated with long-term exposure to UPA15 or 30 as monotherapy was consistent with an integrated analysis of UPA safety across the entire phase 3 program, with no new safety signals identified. Further, UPA15 or 30 monotherapy resulted in continued and sustained improvements in RA signs and symptoms through 84 wks.

DOI: 10.1136/annrheumdis-2020-eular.961
from CareRA baseline of DAS28-CRP and HAQ was assessed via linear mixed models. All adverse events (AEs), considered to be clinically relevant by investigators, and DMARD/GCs therapy were registered.

Results: Of 322 eligible patients, 252 (78%) were included in CareRA-plus, of which 203 (81%) completed the study. Characteristics and outcomes at the CareRA closing visit (year 2) did not differ between patients entering CareRA-plus or not. DAS28-CRP<2.6 at year 5 in high-risk patients was 72%, 77% and 64% in the Classic, Slim and Avant-Garde group respectively (p=0.403). In the longitudinal analyses, all treatment arms in the high-risk group had comparable DAS28-CRP (<0.01) and HAQ scores over time (p=0.540). In the low-risk population, 83% of patients in the Slim and 82% in the TSU arm had DAS28-CRP<2.6 at year 5 (p=0.945). Low-risk patients starting Cobra-Slim had lower DAS28-CRP scores over 5 years than those receiving TSU (p=0.002). HAQ score over time did not differ (p=0.129). In high-risk patients, the total numbers of AEs throughout CareRA-plus were 70 in 36 Classic, 95 in 48 Slim and 80 in 36 Avant-Garde patients (p=0.183). In the low-risk group there were 18 AEs in 10 Slim and 36 in 17 TSU patients (p=0.048). During the 5-year study, biologics were initiated in 22% of all patients: 23% of Classic, 23% of Slim high-risk, 25% of Avant-Garde, 17% of Slim low-risk, and 15% of TSU patients. At the year 5 visit, 71%, 61% and 50% of high-risk patients were on csDMARD monotherapy (mostly MTX) in Classic, Slim and Avant-Garde respectively. Of the low-risk group, 65% in COBRA-Slim and 62% in TSU were taking a single csDMARD. At the year 5 visit, 9% of all participants received chronic oral GC therapy (>3 months).

Conclusion: All intensive treatment strategies resulted in excellent long-term clinical outcomes. Initial Cobra Slim therapy showed comparable 5-year effectiveness as Cobra Classic and Avant-Garde in high-risk early RA patients and better efficacy and safety than conservative step up treatment in low-risk patients.

WHOLE BLOOD TRANSCRIPTIONAL CHANGES FOLLOWING SELECTIVE INHIBITION OF JANUS KINASE 1 (JAK1) BY FILGOTINIB IN ADULTS WITH MODERATELY-TO-SEVERELY ACTIVE RHEUMATOID ARTHRITIS WITH PRIOR INADEQUATE RESPONSE TO METHOTREXATE (FINCH1)

Background: Filgotinib (FIL), an oral selective JAK1 inhibitor, has shown efficacy and safety in multiple phase 3 studies in adults with moderately-to-severely active rheumatoid arthritis (RA). We have previously described the molecular response to FIL in large-scale RNA sequencing studies of gene expression in other RA populations1-2 and herein conducted a similar study in RA patients (pts) with prior inadequate response to methotrexate (MTX; FINCH1).

Objectives: Identify RA-associated gene transcripts and biological pathways that are altered in response to MTX treatment.

Methods: RA pts who had an inadequate response to MTX were enrolled in FINCH1 (ClinicalTrials.gov NCT02889796) and randomized to receive either a stable dose of MTX with placebo (PBO+MTX), adalimumab (ADA+MTX), or one of two doses of FIL (FIL 100mg+MTX, FIL 200mg+MTX) once daily (QD). Whole blood samples were collected from pts using PaxGene tubes at baseline, week 4, and week 12. RNA from these samples was extracted and sequenced on the Illumina HiSeq 2500 platform following globin RNA depletion. Correlations between baseline gene expression and disease measurements were performed using Spearman’s rank partial correlation with covariates. Differentially expressed genes (DEGs) were identified using voom-limma. Pathway analysis was performed on v6.1 of the Molecular Signature Database using single sample gene set enrichment analysis (GSEA) with the focus on immune signaling pathways from the Kyoto Encyclopedia of Genes and Genomes (KEGG). A false-discovery rate of 5% was applied for all analyses.

Results: Differential gene expression analyses comparing baseline samples with after-treatment samples revealed more rapid transcriptional kinetic for FIL-treated pts compared to ADA+MTX-treated pts. No significant DEGs were observed in PBO-treated pts. More significant DEGs were observed in the FIL 200mg+MTX arm compared to the FIL 100mg+MTX arm, consistent with the superior clinical efficacy of the FIL 200mg dosage. As with other FIL clinical trial RNA-seq studies and consistent with the selective MoA of FIL, JAK-STAT pathway-induced genes SOCS2 and CISH were significantly downregulated across both FIL treatment arms and timepoints, but not in the ADA+MTX arm. RA disease activity associated genes1-3 FAM20A and METTL7B were significantly reduced at both 4 and 12 weeks only in the FIL 200mg+MTX arm. While no significant changes in KEGG immune signaling pathways were observed in the PBO+MTX arm, a dose-dependent effect on pathway modulation was observed in the FIL arms. The most prominently down-regulated KEGG pathways included JAK-STAT signaling and leukocyte transendothelial migration.

Conclusion: More rapid and sustained changes of transcriptional activity were observed in the whole blood transcriptional profile of RA pts following FIL 200mg+MTX compared to ADA+MTX treatment. Dose-dependent changes were observed in FIL-treated pts, most notably in the KEGG JAK-STAT signaling pathway. These observations confirm an inhibition of JAK-STAT signaling by FIL and are consistent with the observed clinical efficacy of FIL in these pts.

PERIPHERAL PROTEIN BIOMARKER CHANGES FOLLOWING SELECTIVE INHIBITION OF JANUS KINASE 1 (JAK1) BY FILGOTINIB IN METHOTREXATE-NAIVE ADULTS WITH MODERATELY-TO-SEVERELY ACTIVE RHEUMATOID ARTHRITIS (FINCH3)

1University of Oxford, Botnar Research Centre, Nuffield Department of
Objectives: A longitudinal study of protein biomarkers related to JAK signaling1, bone biology2, immune cell migration2, and inflammation2 was conducted in FINCH3 pts to identify disease relevant biomarkers that are altered by FIL vs MTX.

Methods: MTX-naive RA pts enrolled in FINCH3 received a stable dose of MTX (MTX mono), FIL200mg monotherapy (FIL200mg mono) or one of two doses of FIL100mg+MTX, FIL200mg+MTX. Up to 27 disease relevant biomarkers were evaluated. Baseline (BL) correlation between biomarkers and clinical response measures were analyzed by Spearman Rank. Multiscale bootstrap resampling was used to evaluate significant intra-cluster biomarker membership. Mean changes in biomarker levels from BL to wks 4, 12 and 24 were compared between arms using MTX-adjusted estimates from a linear mixed effects model, adjusted for age, sex, race and BL biomarker level. A false discovery rate of 5% was applied for all analyses.

Results: At BL, distinct clusters (CL) of biomarkers differentiated by JAK signaling were identified. The strongest intra-group correlations were upstream of JAK2 signaling (CL1; Rho range 0.88–0.98) and cytokines associated with JAK1 signaling (CL2; Rho range 0.72–0.77). Within MTX-naive RA pts, there were significant BL correlations between 15 biomarkers and clinical measures. The strongest associations observed were between DAS28CRP and L6, CXCL10, TNFRI, YKL-40, and CXCL13 (Rho >0.3). Relative to MTX mono, 23 biomarkers exhibited significant early responses to treatment (any arm, wk 4). The strongest treatment effect observed at wk 4 was a reduction by FIL+MTX (regardless of dose) and FIL200mg mono for CXCL13 (FIL100mg+MTX: -28.2%, FIL200mg+MTX: -40%; FIL200mg: -34%). Dose differences were observed relative to FIL100mg+MTX, where FIL200mg+MTX led to an early wk (wk 4) and significantly greater reduction of 9 biomarkers. There was a significant dose difference as a delayed response (wk 24) with a greater reduction by FIL200mg+MTX for 8 biomarkers. FIL200mg mono produced a greater effect on 18 biomarkers vs MTX mono, remaining significant through wk 24. The greatest effect in FIL200mg mono were reductions by wk 24 in CTX1 (-28.1%), CXCL13 (-33.2%), and IL6 (-29.5%), all of which were biomarkers associated with DAS28CRP at BL. Effects observed at any time point were largely similar between FIL200mg as a mono or in combination with MTX. Four biomarkers were uniquely different between FIL200mg mono and FIL200mg+MTX arms by wk 24: greater increase of MMP7 and decrease of GMCSF in FIL200mg+MTX; greater decrease of TRAPS and ICAM1 in FIL200mg alone.

Conclusion: Treatment through 24 weeks with FIL200mg (mono or with MTX) reduced many of the disease-relevant biomarkers tested; markers related to JAK signaling1, bone biology2, inflammation2, and immune cell migration2 in the MTX-naive RA setting. Changes were significantly reduced relative to MTX mono at wk 4, supporting the rapid onset of FIL clinical efficacy. The current study identified significant reductions of RA-associated disease markers that were unique to FIL mono, supporting the FIL mechanisms of action in the treatment of RA.

*** P < 0.001 for differences between MTX and UPA 15 and UPA 30 mg groups. MTX, methotrexate; UPA, upadacitinib; QD, once daily; ACR, American College of Rheumatology; DAS28(CRP), 28-joint disease activity index based on C-reactive protein; CDAI, clinical disease activity index.

Figure. Treatment-emergent Adverse Events Through 72 Weeks (E/100 Pts, 95% CI).
Discipline: The incidence rate of HZ was determined in pts receiving UPA (as monotherapy [mono] or combination therapy) in five randomized Phase 3 trials (SELECT-EARLY, SELECT-MONOTHERAPY, SELECT-NEXT, SELECT-COMPARE, and SELECT-BEYOND), of which 4 evaluated both the UPA 15 and 30 mg once-daily (QD) doses and 1 trial (SELECT-COMPARE) evaluated only the 15 mg QD dose. Incidence of HZ was also determined in pts receiving ADA + MTX, and 5 pts (1.1 [0.4–2.6]) with MTX mono. Most of the HZ cases (~71%) with UPA (Table) and all cases with ADA + MTX and UPA mono involved a single dermatome. Ophthalmic involvement was seen in 6 (4.2%) and 3 (2.4%) cases in the UPA 15 and 30 mg groups, respectively, and unilateral involvement with multiple dermatomes was seen in 26 (18.3%) and 23 (18.3%) cases. There was a single case of HZ meningitis reported in a Japanese pt on UPA 30 mg. In multivariate analyses, prior history of HZ and Asian region were associated with an increased risk of HZ in both the UPA groups (p<0.01; Figure). In addition, pts ≥65 years old had increased risk of HZ in the 15 mg group.

Conclusion: HZ events in pts with RA receiving UPA were more common in the 30 mg vs 15 mg group, and in both UPA groups compared with the ADA + MTX and MTX groups.

Priori1,1, Sapienza University of Rome, Dipartimento di Scienze Cliniche Interviste Oncoanesthesiologiche e Cardiovascolari, Rome, Italy;1University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom;2Università Degli Studi Della Campania L. Vanvitelli, Napoli, Italy

Background: Sjögren’s Syndrome (SS) is characterized by chronic inflammation supported by intrinsic activation of salivary gland epithelial cells (SGECs). Eventually, apoptosis of SGECs ensues, which leads to salivary gland dysfunction and exposition of autoantigens. Autophagy is a stress coping mechanisms of cells implicated in both survival and exposition of autoantigens, and is thereby plausibly implicated in the pathogenesis of SS. At present, the exact relationship between apoptosis and autophagy in SS SGECs is unclear, as is the link between these mechanisms and SGECs activation.

Objectives: To explore autophagy in SS SGECs from patients with SS and to evaluate its relationship with apoptosis and SGECs activation.

Methods: Consecutive patients with suspected SS referring to our “Sjögren Clinic” were enrolled, and minor salivary gland (MSG) biopsies were collected for:

1) SGECs culture, (2) PCR analysis, (3) IFI analysis. In SGECs cultures, the expression of autophagy (LC3β), apoptosis (annexin V/PI) and adhesion molecules (ICAM) was investigated by flow cytometry (results expressed as mean ± SD). The expression of the autophagosome gene MAP1LC3 was evaluated by PCR (expressed as 2^deltaCT normalized to GAPDH) on both MSG sections and MSG acinar and ductal epithelial samples obtained by laser capture microdissection. Tissue expression of LC3II was evaluated by IFI on SS MSG.

Results: Primary SGECs cultures were established from 14 MSG obtained for diagnostic purposes (SS n=8, Sicca n=6). These cells exhibited an inverse correlation between apoptosis and autophagy (p=0.007, r=-0.784), with lower levels of apoptosis (19.7±6.5 vs 24.5±8.5, p=ns) and higher levels of autophagy (59.7±13.1 vs 54.19±19.4, p=ns) in SS compared to Sicca. In SS, MAP1LC3 was positively correlated with Focus Score (p=0.021 r=0.478); however, PCR studies did not reveal significant differences in MAP1LC3 expression between SS (n=26) and Sicca (n=15) (0.05±0.005 vs 0.003±0.0008; p=0.057) compared to normal acinar epithelium (n=5); a major expression of LC3II in ducts was confirmed by IFI (Image).

In SS, a higher expression of ICAM compared to sicca was observed (11.1±3.8 vs 6.9±4.9, p=0.006) and autophagy and apoptosis showed a trend of positive and negative correlation with this molecule, respectively (p=0.683 r=0.118 and p=0.106 r=0.446).

Figure. LC3-II staining in SS MSG [LC3-II† (green) and Hoechst stain (blue); 6x magnification].

Conclusion: In SS, autophagy is upregulated in SGECs and inversely correlated with apoptosis, thus supporting a role of this process in cells’ death prevention during inflammatory process. Indeed, the degree of msg inflammation is correlated more with the activation of autophagy than apoptosis. Interesting, in SS, SGECs autophagy is mainly observed at ductal level and is correlated with

THU0219

FIRST-IN-HUMAN STUDY OF SAFETY, PHARMACOKINETICS AND PHARMACODYNAMICS OF IRAK1/4 INHIBITOR R835 IN HEALTHY SUBJECTS

L. Yan1, S. Tong1, A. Absalom1, I. D. Daas1, G. Park1, Y. Taylor1, D. Chow1, M. Lee1, H. Zheng1, A. Chow1, Rigel Pharmaceuticals, Inc, South San Francisco, United States of America;2University Medical Center Groningen, Groningen, Netherlands;3QPS Netherlands BV, Groningen, Netherlands

Background: Toll-Like Receptors (TLR) and Interleukin-1 Receptors (IL-1R) play a critical role in the innate immune response as microbial and tissue damage sensors, providing a bridge between the innate and adaptive immunity. Interleukin receptor associated kinases (IRAK) 1 and 4 are serine/threonine kinases that are essential for signaling downstream of most TLRs and IL-1Rs and the resulting production of pro-inflammatory cytokines. Suppression of TLR and IL-1R signaling through inhibition of IRAK1/4 kinases is a promising therapeutic approach for the treatment of inflammatory and autoimmune diseases. We have identified a potent and selective IRAK1/4 inhibitor (R835) that showed dose-dependent inhibition of lipopolysaccharide (LPS, a TLR4 agonist), and IL-1β induced serum cytokines in mice. R835 prevented disease onset and progression in multiple rodent models of inflammatory diseases, including arthritis and lupus models.

Objectives: The aim of this FIH study was to characterize the safety, pharmacokinetics (PK) and pharmacodynamics (PD) of R835 during single or multiple dose administrations.

Methods: This study was a randomized, placebo-controlled, double-blind Phase 1 study in healthy subjects in three parts: single ascending doses (20 mg-1920 mg, Part A) with food effect in a separate cohort (480 mg), multiple ascending doses (120 mg and 960 mg, Bid, Part B) with a caffeine intake (960 mg cohort), and an intravenous LPS challenge test at 240 mg oral dose of R835 (Part C).

Results: Single doses of up to 480 mg R835 in organic solution, single doses of up to 1920 mg R835 as capsule, multiple doses of 120 mg R835 O12H (organic solution), and 960 mg R835 O12H (capsule) were safe and well tolerated. All R835 related adverse events (AEs) were mild in intensity and reversible, and mostly associated with the higher doses of R835 in the organic solution. The most common AEs were headache and gastrointestinal disturbance. The PK of R835 was linear and dose proportional in exposure over the dose range studied. A nominal level of accumulation in plasma achieved rapidly upon repeated BID administrations with steady-state essentially attained in 2 days. A high-fat meal with the capsule formulation resulted in a nominal level of accumulation in plasma. The PK of R835 was linear and dose proportional in exposure over the dose range studied. A nominal level of accumulation in plasma achieved rapidly upon repeated BID administrations with steady-state essentially attained in 2 days. A high-fat meal with the capsule formulation resulted in a nominal level of accumulation in plasma.

Discussion: The desirable PK and safety profile combined with proof of mechanism, as demonstrated by inhibition of cytokine release, support progression of R835 into Phase II clinical development as an agent for the treatment of inflammatory and autoimmune diseases.

Background: IL-10 plays a key role in systemic lupus erythematosus (SLE) pathogenesis, promoting B-cell response. IL10 is mainly secreted by regulatory T-cells, but follicular helper T-cells (Tfh), also produce it. We previously identified a subset of CCR6+IL-7R+T-cells in human tonsils providing IL-10-dependent B-cell help. These CCR6+T-cells were able to produce IL-10, inducing IgG production. Objectives: to investigate a possible role of CD4+CCR6+IL7R+T-cells in SLE pathogenesis.

Methods: 37 patients fulfilling the ACR criteria for SLE have been included. Disease activity was assessed by 2k-SLEDAI. PBMC were analyzed by flow cytometry, using specific lineage markers. CCR6+IL7R+T-cells purified from total PBMC of SLE patients or healthy donors (HD) were co-cultured with autologous PBMC of SLE patients or healthy donors (HD) were co-cultured with autologous

Results: IL10 levels were significantly higher in SLE patients (Fig 1A). CD4+CCR6+IL7R+T-cells of SLE patients induced production of IgG and anti-dsDNA IgG (in anti-dsDNA + patients) from autologous B-cells, providing spontaneous help for autoantibody production (Fig 1B-C). The IF study of lymph nodes from 8 SLE patients were analyzed by immunofluorescence (IF).

Conclusion: our study revealed a novel population of extra-follicular B-helper T-cells, which produce IL-10 and could play a prominent pathogenic role in SLE. Further studies will clarify if this potentially pathogenic cell population might represent a possible future therapeutic target.

BACKGROUND: BAFF and APRIL are TNF superfamily members that bind both TACI and BCMA on B cells; BAFF also binds BAF-F-R. Together, BAFF and APRIL support B cell development, differentiation, and survival. Their co-neutralization dramatically reduces B cell function, including antibody production, whereas inhibition of either BAFF or APRIL alone mediates relatively modest effects.

OBJECTIVES: While, BAFF- and APRIL-mediated signaling in vitro in TACI+ Jurkat cells significantly inhibited BAFF- and APRIL-mediated signaling in vitro

In conclusion, the novel engineered TACI vTD-Fc or BCMA vTD-Fc fusion proteins showed potent inhibitory BAFF- and APRIL-mediated signaling in vitro in TACI+ Jurkat cells. TACI (or BCMA) VTD/CTLA-4 vIgD-Fc proteins also attenuated T cell activation in primary human lymphocyte assays. When administered to mice, these molecules rapidly and potently reduced key B and T cell subsets, including plasma cells, follicular T helper cells, germinal center cells, & memory T cells. Treatment with TACI VTD-Fc or TACI VTD/CTLA-4 vIgD-Fc proteins also significantly reduced titers of antigen-specific antibodies in immunized mice more so than abatacept or WT TACI-Fc, and potently suppressed anti-dsDNA autoantibodies, blood urea nitrogen levels, proteinuria, and renal immune complex deposition in the bm12 & NZB/W lupus models.

CONCLUSION: Directed evolution of TNFR and IgSF domains has successfully facilitated the development of Fc fusion proteins containing TACI or BCMA VTDs, with or without fusion to CTLA-4 vIgDs. These novel immunomodulators consistently demonstrate potent immunosuppressive activity and efficacy in vivo and in vitro, appearing superior to existing and/or approved immunomodulators like belimumab, abatacept, or atacicept. Such biologics may therefore be attractive candidates for the treatment of serious autoimmune diseases, particularly B cell-related diseases such as SLE, Sjögren's syndrome, etc.
Results: NZB/W mice at 3 months and 6 months of age exhibit depressive-like disorder as assessed by SPT and TST (P<0.05 and <0.0001, respectively). Anxiety-like phenotype was evident in lupus-prone mice at both time points based on EPM test (Graph 1). Open-field test revealed decreased locomotor activity and rotarod (Graph 2) showed impaired motor coordination in 3 month-old and 6 month-old NZB/W mice (P<0.001 and <0.01, respectively). NZB/W mice exhibit cognitive dysfunction at 3 and 6 months of age based on NOR test (P<0.05). No differences in cognitive function was observed between the two groups (P=0.11). Prepulse inhibition test revealed decreased sensorimotor gating in 3 month-old NZB/W mice, a difference not reaching statistical significance (P=0.78). It was not possible to interpret correctly the PPI at second time point (6 months of age) due to age-related hearing loss in 6 at 6 month-old. NZB/W become more anxious over the course of the disease as assessed by EPM (3 mo. versus 6 mo. P<0.001, paired t-test, Graph 1).

Conclusion: The NZB/W lupus-prone strain exhibit depressive-like behavior, anxiety, cognitive impairment and motor disturbances both at early and late stages of the disease. This polygenic murine model may be more suitable for investigating the autoimmune-mediated neuroinflammation in human SLE.

THU0225 INTEGRATIVE PLASMA METABOLOME AND TRANSCRIPTOME ANALYSIS REVEALED THE IMPORTANCE OF HISTIDINE HOMEOSTASIS IN SLE PATHOGENESIS WITH POTENTIAL FOR IMPROVED SLE PATIENTS STRATIFICATION

Y. Iwasa1, Y. Takeshima2, M. Nakano1, M. Ota1, Y. Nagatuchi3, A. Suzuki4, Y. Kochi1, T. Okamura1, T. Endo1, I. Miki1, K. Sakurada1, K. Yamamoto1, K. Fujii1, 1Graduate School of Medicine, The University of Tokyo, Allergy and Rheumatology, Tokyo, Japan; 2Graduate School of Medicine, The University of Tokyo, Functional Genomics and Immunological Diseases, Tokyo, Japan; 3Graduate School of Medicine, The University of Tokyo, Functional Genomics and Immunological Diseases, Tokyo, Japan; 4Center for Integrative Medical Sciences, RIKEN, Yokohama, Laboratory for Autoimmune Diseases, Yokohama, Japan; 5Tokyo Medical and Dental University, Genomic Function and Diversity, Tokyo, Japan; 6Cluster for Science, Technology Innovation Hub, RIKEN, Medical Sciences Innovation Hub Program, Yokohama, Japan

Background: Recently, immunometabolism has gathered attention of many immunologists. It has been widely recognized that metabolic reprogramming in each immune cell brings different effects on different cells and is important for regulating their functions. Along with the progress of statistical genetics, serum metabolites were shown to be under genetic regulations1). Metabolic changes are now considered not only to be mere phenotypes of cells but also to be key factors for controlling immune cell differentiation, proliferation and function through regulating gene expressions eventually. Although genome-wide association studies have brought deep insights into SLE pathogenesis, the precise pathway from genome to metabolome has been largely unknown, and vice versa.

Objectives: The aim of this study is to investigate metabolic regulation in SLE in relation to gene expressions by integrating plasma metabolome data and transcriptome data.

Methods: We collected plasma samples from patients with SLE (n=57) who met the 1997 American College of Rheumatology criteria for SLE. Gender- and age-matched healthy controls (HCs) (n=56) were recruited. Metabolic profiles focusing on 39 amino acids were analyzed with liquid chromatography (LC)-mass spectrometry. Transcriptome data of SLE patients were obtained from our RNA-sequencing data of each immune cell subset (total 19 subsets). Whole-genome sequencing was also performed.

Results: Our previous experiment showed that about 160 peaks were detected from comprehensive LC-TOFMS and amino acids were useful for distinguishing SLE patients from HCs. Both partial least squares discriminant analysis (PLS-DA) and random forest, a machine learning algorithm, revealed the importance of histidine (His), one of the essential amino acids, to classify SLE patients from HCs, whose plasma level was lower in SLE patients. In addition, inverse correlation between His level and titer of ds-DNA as well as damage index (SDI) was detected. His level was correlated neither with PSL dosage nor with type I interferon (IFN) signature. Receiver operating characteristic (ROC) analysis showed the best predictability for SLE with the combination of specific amino acids including His. Our transcriptome analysis has revealed the significance of oxidative phosphorylation (OXPHOS) in B cells for SLE pathogenesis. Interestingly, OXPHOS signature was inversely correlated with His level in SLE B cells.

Conclusion: His may be an important factor for SLE pathogenesis especially in B cells independently from IFN signal. SLC15A4, a transporter of His on lysisome, is one of the SLE GWAS SNPs and has been reported to play an

Graph 2. Rotarod performance demonstrates impaired motor coordination in NZBW/F1 strain both at 3 and 6 months of age (P< 0.05, unpaired t-test).

Disclosure of Interests: : None declared

DOI: 10.1136/annrheumdis-2020-eular.5948
important role in IFN production in B cells through regulation of TLR7/9 activation. We also identified that SLE patients with risk allele of SLC15A4 had tendency to show higher plasma His level, indicating His homeostasis could become a novel treatment target for SLE. Moreover, the inverse correlation of His level to SDI as well as OXPHOS signature suggests that His might play a key role for promoting organ damages in SLE.

MESENCHYMAL STEM CELL TRANSPLANTATION AMELIORATES EXPERIMENTAL SJÖGREEN’S SYNDROME BY DOWNREGULATING MDSCS VIA COX2/PGE2 PATHWAY

G. Yao1, S. Wang1, L. Sun1. Nanjing University, Nanjing, China

Background: Although mesenchymal stem cells (MSCs) transplantation have been demonstrated to be an effective therapeutic approach to treat experimental SJögren’s syndrome (ESS)1, the specific underlying mechanisms remain to be elucidated. Myeloid-derived suppressor cells (MDSCs) were significantly increased with decreased suppressive capacity during disease development in ESS2-3. However, the therapeutic effects and mechanisms by which MSCs regulating MDSCs in SS still remain unknown.

Objectives: Here we aim to explore whether regulation of MDSCs was responsible for the beneficial effects of MSC transplantation on SS.

Methods: The MSCs were infused into non-obese diabetic (NOD) mice via the tail vein. The histological features of submandibular glands, lung, saliva flow rate were evaluated. The number and immune-suppressive activity of MDSCs, the bone marrow cells under MDSCs differentiation conditions were co-cultured with or without MSCs. The COX2 inhibitor NS-398, anti-TGF-β1, or anti-IFN-β antibodies were added to coculture medium of MSCs and MDSCs induced from bone marrow cells respectively.

Results: We found that MSCs in bone marrow and peripheral blood increased in ESS mice. MSC transplantation ameliorated SS-like syndrome and down-regulated the percentages of MDSCs, PMN-MDSCs and M-MDSCs in NOD mice were determined. The bone marrow cells under MDSCs differentiation conditions were co-cultured with or without MSCs. The COX2 inhibitor NS-398, anti-TGF-β1, or anti-IFN-β antibodies were added to coculture medium of MSCs and MDSCs induced from bone marrow cells respectively.

Methods: The MSCs were infused into non-obese diabetic (NOD) mice via the tail vein. The histological features of submandibular glands, lung, saliva flow rate were evaluated. The number and immune-suppressive activity of MDSCs, the bone marrow cells under MDSCs differentiation conditions were co-cultured with or without MSCs. The COX2 inhibitor NS-398, anti-TGF-β1, or anti-IFN-β antibodies were added to coculture medium of MSCs and MDSCs induced from bone marrow cells respectively.

Results: We found that MSCs in bone marrow and peripheral blood increased in ESS mice. MSC transplantation ameliorated SS-like syndrome and down-regulated the percentages of MDSCs, PMN-MDSCs and M-MDSCs and promoted their suppressive activity in ESS mice significantly (Figure 1). In vitro, MSCs could down-regulate the differentiation and up-regulate the suppressive ability of MDSCs. Mechanistically, MSCs inhibited the differentiation of MDSCs and PMN-MDSCs via secreting prostaglandin E2, and inhibited the differentiation of M-MDSCs by secreting interleukon-β (Figure 2).

Conclusion: Our findings suggested that MSCs alleviated SS-like symptoms by suppressing the aberrant accumulation and improving the suppressive function of MDSCs in ESS mice via COX2/PGE2 pathway.

and 376.5 mg/day (group 3) and 9 patients (10.1%) >376.6 mg/day (group 4). A negative correlation between the levels of caffeine and disease activity, evaluated with SLEDAI-2K, was observed (p=0.01, r=-0.26). By comparing the four groups, a significant higher prevalence of lupus nephritis, neuropsychiatric involvement, hematological manifestations, hypocomplementemia and anti-dsDNA positivity was observed in patients with less intake of caffeine (figure 1 A–E). Furthermore, patients with less intake of caffeine showed a significant more frequent use of glucocorticoids [group 4: 22.2%, versus group 1 (50.0%, p=0.0001), group 2 (55.5%, p<0.0001), group 3 (40.0%, p=0.009)]. Moving on cytokines analysis, a negative correlation between daily caffeine consumption and serum level of IFNα was found (p=0.03, r=-0.2) (figure 2A); furthermore, patients with more caffeine intake showed significant lower levels of IFNα (p=0.02, figure 2B), IL-17 (p=0.01, figure 2C) and IL-6 (p=0.003, figure 2D).

Conclusion: This is the first report demonstrating the impact of caffeine on SLE disease activity status, as demonstrated by the inverse correlation between its intake and both SLEDAI-2K values and cytokines levels. Moreover, in our cohort, patients with less caffeine consumption seems to have a more severe disease phenotype, especially in terms of renal and neuropsychiatric involvement. Our results seem to suggest a possible immunoregulatory dose-dependent effect of caffeine, through the modulation of serum cytokine levels, as already suggested by in vitro analysis.

HSA-MIR-513C-3P OVEREXPRESSION DECREASES XBP-1S CORRELATING WITH INCREASED INFLAMMATION AND AUTOANTIBODIES IN SALIVARY GLANDS FROM SJÖGREN’S SYNDROME PATIENTS

1Universidad de Chile, Programa de Biología Celular y Molecular, Instituto de Ciencias Biomédicas, Facultad de Medicina, Santiago, Chile; 2Clinica Indisa, 3D-acini stimulated with IFN-gamma (r=-0.87, p=0.0001). The XBP-1s transcript levels were decreased in HSG tissues transfected with hsa-miR-513c-3p mimic and increased in HSG cells transfected with the miRNA inhibitor.

Conclusion: IFN-gamma-induced upregulation of hsa-miR-513c-3p is consistent with the presence of STAT1-binding elements in its promoter region. Our findings suggest that the combined action of miRNAs and DNA methylation modulated by IFN-gamma could explain the altered expression of XBP-1s, a key transcription factor involved in cellular proteostasis, affecting secretory function in LSG from SS-patients. Our results confirm previous correlations found between XBP-1s protein levels and clinical parameters of SS-patients, suggesting an association of XBP-1s with inflammation and impaired SG function.

THU0230

IGG ANTIBODIES AGAINST PHOSPHORYLCHOLINE ARE NEGATIVELY ASSOCIATED WITH DISEASE ACTIVITY, DISEASE DAMAGE, CARDIOVASCULAR DISEASE AND Atherosclerosis IN SLE: POTENTIAL UNDERLYING MECHANISMS.

1Karolinska Institutet, Stockholm, Sweden

Background: Phosphorylcholine (PC) is an important component in cellular membranes and in lipoproteins that is exposed and recognized by the immune system, when cells undergo apoptosis or lipoproteins like LDL undergo oxidation. PC is also exposed in some microorganisms including nematodes and bacteria (non-self). We reported that IgM anti-PC is associated with protection in atherosclerosis, SLE, RA and other chronic inflammatory conditions.1 We also reported potential underlying protective mechanisms: 1: increase in clearance of human dead cells,2: inhibition of uptake of oxLDL in macrophages, 3: inhibition of cell death.3 1: anti-inflammatory; 5: promotion of polarization of T regulatory cells in SLE-patients’ T cells from a low level and also in plaque T cells.3 We generated in-house fully human IgG1 anti-PC clones for experimental studies to study anti-PC properties in humans. In contrast to mice, anti-PC are not germ-line encoded with a dominant clone.

Objectives: We here study IgG1 and IgG2 anti-PC, with focus on atherosclerosis and SLE and properties of fully human IgG1 clones, in relation to SLE.

Methods: We determined anti-PC by ELISA in 116 SLE-patients and 110 age- and sex-matched controls. For functional studies, we used three in-house generated, fully human monoclonal IgG1 anti-PC (A01, D05, E01). Apoptosis was induced in Jurkat T-cells and pre-incubated with A01, D05, E01 or isotype control and effects on effecacy of macrophages studied. Anti-PC peptide/protein characterization was determined using a proteomics de novo sequencing approach.

Results: IgG1 but not IgG2 anti-PC levels were higher among SLE patients (p=0.02). IgG1 anti-PC was negatively associated with SLICC and SLEDAI (OR: 2.978 CI: 0.876-10.998, OR: 5.108 CI 1.3 20.067 respectively) and negatively associated with CVD, atherosclerotic plaques and echolucent (potentially vulnerable plaques) but the association for the two former was not significant after controlling for confounders. D05 had maximum effect on macrophage engulfment efficacy, followed by A01 and E01. The monoclonal antibodies showed differential binding specificity to PC and PC associated neo-epitopes. Peptide analysis showed difference in the CD3R3 region of the three anti-PC IgG1 clones which are crucial for recognition of PC on apoptotic cell surface and other neo-epitopes.

Conclusion: Anti-PC IgG1 is negatively associated with disease activity, and disease damage in SLE, but the negative association with CVD is also dependent on confounding risk factors. One potential underlying mechanism could be increased clearance of dead cells.

IL-2 DRIVES THE CONVERSION OF T FOLLICULAR HELPER TO T FOLLICULAR REGULATORY CELLS THROUGH EPIGENETIC MODIFICATION IN SYSTEMIC LUPUS ERYTHEMATOSUS

H. Hao1,2, S. Nakayamada3, Y. Kaoru1, N. Ikubo1, S. Iwata1, Y. Tanaka1.

1University of Occupational and Environmental Health, School of Medicine, First Department of Internal Medicine, Kitakyushu, Japan; 2The Fourth Hospital of Hebei Medical University, Department of Immuno-Oncology, Shijiazhuang, China

**Background:** Systemic lupus erythematosus (SLE) is a complex polygenic autoimmune disease characterized by immune-system aberrations. Among several types of immune cells, T follicular helper (Tfh) cells promote autoantibody production, whereas T follicular regulatory (Tfr) cells suppress Tfh-mediated antibody responses. (1)

**Objectives:** To identify the characteristics of Tfh cells and to elucidate the mechanisms of conversion of Tfh cells to Tfr cells, we probed the phenotype of T helper cells in patients with SLE and underlying epigenetic modifications by cytokine-induced signal transducer and activators of transcription (STAT) family factors.

**Methods:** Peripheral blood mononuclear cells from SLE patients (n=44) and healthy donors (HD; n=26) were analyzed by flow cytometry. Memory Tfh cells were sorted and cultured under stimulation with T cell receptor and various cytokines. Expression of characteristic markers and phosphorylation of STATs (p-STATs) were analyzed by flow cytometry and quantitation PCR. Histone modifications were evaluated by chromatin immunoprecipitation.

**Results:** The proportion of CXCR5+Foxp3+ Tfr cells in CD4+ T cells tended to increase (2.1% vs 1.7%, p=0.17); however, that of CD4+CD45RA-Foxp3+ activated Tfr cells in Tfh cells was decreased (4.8% vs 7.1%, p<0.05), while CD4+CD45RA-Foxp3+ non-suppressive T fr cells was increased (50.1% vs 38.2%, p<0.01) in SLE compared to HD. The percentage of PO-1 activated Tfh cells was significantly higher in SLE compared to HD (15.7% vs 5.9%, p<0.01). Furthermore, active patients had a higher ratio of activated Tfh/Tfr cells compared to inactive patients. In vitro study showed that IL-2, but not other cytokines such as TGF-β, IL-12, IL-27, and IL-35, induced the conversion of memory Tfh cells to functional Tfr cells characterized by CXCR5+B-c16*Foxp3+ P3STAT3+ PSTAT5+ cells. The loci of FOXP3 at STAT binding sites directly bound on FOXP3 gene loci accompanied by suppressing H3K27me3. Finally, we found that serum level of IL-2 was decreased in SLE and that stimulation IL-2 suppressed the generation of CD38+CD27+B cells by ex vivo coculture assay using Tfh cells and B cells isolated from human blood.

**Conclusion:** Our findings indicated that the regulatory function of Tfr cells is impaired due to the low ability of IL-2 production and that IL-2 restores the function of Tfr cells through conversion of Tfh cells to Tfr cells in SLE. Thus, the reestablishment of the balance between Tfh and Tfr cells will provide important therapeutic approaches for SLE.

INTERFERON SIGNATURE IN LUPUS KIDNEY IS CORRELATED WITH REMISSON WITHIN 56 WEEKS

M. Kanda1,2,3, T. Tsuji1, M. Mukai3, H. Takahashi1, T. Atsumi2, N. Hubner1.

1Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC), Cardiovascular and Metabolic Sciences, Berlin, Germany; 2Sapporo Medical University, Department of Rheumatology and Clinical Immunology, Sapporo, Japan; 3Hokkaido University Graduate School of Medicine, Division of Rheumatology, Endocrinology and Nephrology, Sapporo, Japan; 4Sapporo City General Hospital, Department of Pathology, Sapporo, Japan; 5Sapporo City General Hospital, Department of Rheumatology and Clinical Immunology, Sapporo, Japan

**Background:** Activation of the type I interferon (IFN) pathway has been implicated in the initiation of systemic lupus erythematosus (SLE) and most SLE patients show increased expression of IFN-regulated genes in peripheral blood mononuclear cells or whole blood. However, the IFN signature in lupus kidney is not well examined especially at single cell resolution.

**Objectives:** To clarify the significance of the IFN signature in lupus kidney at single cell resolution

**Methods:** 18 lupus kidney (LN) and 34 transplanted kidney (KTx) samples were included in the study. Residual frozen kidney biopsies were collected after clinical diagnosis. The tissue from one donor was split into two. One portion was used for total RNA-Seq (tRNA-Seq) by SMARTer Stranded Total RNA-Seq Kit v2 - Pico Input Mammalian (Takara/Clontech). The rest was used for single nucleus RNA-Seq (snRNA-Seq) using Chromium Single Cell 3’ Reactant Kits v3 (10x Genomics) (7 LN and 17 KTx). For the tRNA-Seq, the sequence reads were aligned to Ensembl genome annotation (Ens93) by STAR and the aligned reads were counted by htseq, IFN score of tRNA-Seq was calculated using the reported method [1] for each module (M1.2, M3.4 and M5.12). For the snRNA-Seq, the sequenced reads were processed on the standard pipeline of CellRanger (10x Genomics) and the data was visualized using Seurat. IFN score of snRNA-Seq was computed by the method reported by Arai A, et al [2].

Clinical outcomes of LN were examined on the medical records retrospectively and the clinical remission in 56 weeks for LN was defined as a urinary protein/creatinine ratio less than 0.5 g/gCr.

**Results:** 11 LN had clinical remission and 7 LN showed non remitted disease within 56 weeks after the biopsy. There were no statistical significance co-variants such as age, gender and WHO class in pathology, IFN score of M1.2, M3.4 and M5.12 were significantly increased in LN with remission within 56 weeks (median 0.773 vs 0.659, 0.595 vs 0.243 and 0.415 vs 0.100: p-value 0.03, 0.01 and 0.02 [Wilcoxon rank-test]) in tRNA-Seq. In the snRNA-Seq, the lupus kidney with low IFN score showed restricted IFN signature in the endothelial cells mainly, which can be detected even in the controls, but those with high IFN score indicated broadly spread IFN signature among all of the cell types.

**Conclusion:** LN with high IFN score in kidney tissue is correlated with remission within 56 weeks. LN with low IFN score showed IFN signature restricted to endothelial cells but those with a higher IFN score revealed broadly affected cell types with IFN signature. These results suggest that the IFN signature of LN may start from endothelial cells and then spread to the whole kidney.

Determinate whether the anti-SSP antibody or the associated immune-complex could recognize MIP and anti-MIP correlated with serum MPO-DNA (r=0.41, positive results while only 7/95 (7.4%) was detected in control group. The specificity of these IgGs are required to induce the formation of NETs. Whether oral commensal bacteria could induce pathogenic antibodies which promote NET formation remained unknown.

Objectives: So we aimed to search for novel autoantibodies in SLE through antibody repertoire screening which recognize whole proteins derived from Streptococcus mutans, and investigated to find cross-reactive antibodies presented in the serum of lupus patients and do the correlation between serum MPO (myeloperoxidase)-DNA, a marker of NETosis.

Methods: The streptococcal specific protein (SSP) was identified through LC-MS and by a proteomics survey. We then purified the target protein in streptococci with expression vector, and antibody level will be determined quantitatively. We recruited patients with SLE, other systemic autoimmune diseases (AIDs) patients to elucidate the performance of this biomarker. Besides, we pursued the Basic Local Alignment Search Tool (BLAST) and searched for cross-reactive autoantigens.

Results: 79 lupus patients and 95 patients with other systemic autoimmune disease were enrolled. By using cut-off value 1.06 (set according to area under the receiver operating characteristic curve) of anti-SSP o.d. value (174 samples), 27 of 79 (34.2%) SLE patients have positive results while only 7/95 (7.4%) was detected in control group. The specificity and sensitivity of the anti-SSP for diagnosis of SLE was 92.6% and 34.2% respectively. According to BLAST and B cell–epitope prediction algorithms, The P32-55 epitopes were identified and we synthesized a highly immunogenic and surface-accessible epitope related protein. We named the protein to be MIP (mitochondrial immunodominant protein). Most of the sera from SLE patients could recognize MIP and anti-MIP correlated with serum MPO-DNA (r=0.41, p=0.039).

Conclusion: The novel anti-SSP antibody against commensal streptococcal specific protein can differentiate SLE and other AIDs. Further investigation to determine whether the anti-SSP antibody or the associated immune-complex could induce or aggregate NETs formation is warranted.

Disclosure of Interests: Che-Hao Hsu: None declared, Chiau-Jing-Jung: None declared, Yu-Min Kuo: Speakers bureau: Novartis, Pfizer, Roche, Janssen, Abbvie, UCB, Chugai, Bristol Myers Squibb, Amgen and Astellas

DOI: 10.1136/annrheumdis-2020-eular.5674

Methods: The study was conducted in 41 SLE patients and 34 healthy donors (HD). Monocytes, lymphocytes and neutrophils were purified by immunomagnetic selection. Then, selected elements of the splicing machinery and a set of genes related to inflammation, renal and cardiovascular disease (including interleukins, adipocytokines, chemokines, and oxidative stress markers, among others) were evaluated using a microfluidic qPCR array (Fluidigm). Besides, the inflammatory profile in plasma, including the analysis of 27 proteins, was evaluated by using the Bioplex assay. In parallel, an extensive clinical/serological evaluation was performed; comprising disease activity and cardiovascular and renal involvement along with autoantibodies, complement factors, and acute phase reactants. Correlation and association studies and logistic models along those clinical and analytical parameters were developed. Mechanistic in vitro studies were carried out by incubation of HD- and SLE-leukocytes with anti-dsDNA-IgG purified from SLE patients and changes promoted in both, splicing machinery and leukocyte inflammatory profile, were assessed.

Results: A significant proportion of spliceosome components was found in all the leukocyte subsets: 27, 12 and 11 components were differentially expressed in monocytes, lymphocytes and neutrophils, respectively, in SLE patient vs HD. In parallel, a number of genes coding for proteins involved in inflammation, fatty acid metabolism, oxidative stress and migration were found altered and correlations with spliceosome components were further identified. Besides, those statistical analyses demonstrated multiple links among altered spliceosomal components and the clinical profile of these patients, such as the activity of the disease (SLEDAI), the occurrence of obstetric complications and the presence of arterial hypertension. Logistic regression and ROC curve analyses identified a signature composed in each leukocyte subset by 3 altered spliceosome components that could differentiate between SLE and HDs. Remarkably, the levels of a high number of those altered components were associated to the presence of lupus nephritis (LN). Moreover, ROC curve analyses allowed to identify several cell-specific spliceosome components as potential biomarkers of renal disease. In patients with LN we could also identify a distinctive inflammatory profile in plasma in relation to patients without renal involvement, which further correlated with the altered expression of a number of spliceosome components in each leukocyte subset. Lastly, the in vitro treatment of HD leukocytes with anti-dsDNA promoted the alteration of several spliceosome components found also altered in vivo in SLE lymphocytes, monocytes and neutrophils.

Conclusion: 1) The splicing machinery is greatly altered in leukocytes from SLE patients, regulated, at least partially, by anti-dsDNA antibodies and closely related to the activity of the disease, including obstetrical complications, hyper tension and lupus nephritis. 2) Specific components of the spliceosome in SLE leukocytes subsets might be used as potential biomarkers to typify the disease, particularly kidney involvement.

DOI: 10.1136/annrheumdis-2020-eular.5237

Methods: Vitamin D deficiency is more prevalent in patients with systemic lupus erythematosus (SLE) as a result of sun avoidance.1 The potential negative impact of vitamin D deficiency on SLE disease activity has been shown in a number of studies.2 The expression of the interferon signature genes in SLE correlates positively with disease activity, and these genes are thought to mediate the clinical manifestations of the disease.3

Objective: The aim of this study was to establish whether a relationship exists between serum 25-hydroxyvitamin D level and the interferon signature gene expression in whole blood of SLE patients.

Methods: Informed consent was obtained from 92 SLE patients who were over the age of 18 and who fulfilled the SLICC classification criteria for SLE. The patients were interviewed and blood samples were taken. SLE disease activity was measured by SLE disease activity index-2K (SLEDAI-2K). RNA extraction was performed from whole blood. QuantiGene Picx technology

Background: Streptococcal infection has well known to cause rheumatic fever with various presentations similar to SLE. Besides, both streptococcal-blood stream infection and SLE had aggravated neutrophil extracellular traps (NETs) formation. Previously, we did report a streptococcal induced endocarditis rat model, and identified layers of neutrophil extracellular traps (NETs). According to our findings, specific immunoglobulin G (IgG) could bridge bacteria to host and these IgGs are required to induce the formation of NETs. Whether oral commensal bacteria could induce pathogenic antibodies which promote NET formation remained unknown.

Background: The aim of this study was to evaluate whether alterations in the splicing machinery of immune cells from Systemic Lupus Erythematosus (SLE) patients could influence the development and activity of the disease and the kidney involvement.
was used to measure the expression of 12 interferon signature genes in the extracted RNA. The study was approved by the University Research Ethics Committee.

**Results:** 92.4% of the cohort studied were female. 58.7% were receiving vitamin D3 supplementation at a mean dose of 1031IU daily. 27.2% had vitamin D insufficiency (25-hydroxyvitamin D 21-29ng/ml) and 15.2% were vitamin D deficient (25-hydroxyvitamin D <20ng/ml). Mean serum 25-hydroxyvitamin D was 30.75ng/ml (standard deviation 9.53ng/ml). Median SLEDAI-2K was 4 (range 0-12). Serum 25-hydroxyvitamin D had a significant negative correlation with body mass index (BMI) (R=-0.258, p=0.006) but there was no significant negative correlation with SLEDAI-2K or with the expression of the interferon signature genes. The expression of most interferon signature genes measured (IFIS1, OAS1, MX1, IFITM1, STAT2, IFIT3, IFIT1, STAT1, SOCS1) had a significant positive correlation with SLEDAI-2K.

**Conclusion:** This study did not show a significant relationship between serum vitamin D level and disease activity. In keeping with this, there was a significant negative correlation between serum 25-hydroxyvitamin D and interferon signature gene expression. Further prospective studies and randomised controlled trials are needed to study this relationship in greater depth.

**HEALTHY IMMUNOMES USING MULTI-PARAMETRIC SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND UNCOVERING DIFFERENCES BETWEEN THE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND HEALTHY IMMUNOMES USING MULTI-PARAMETRIC INTERROGATION**

K. Nyang*1,2, J. G. Yeo1,3, M. Wasser1, P. Kumar1, S. P. Tang1, S. K. Ng1, S. L. Poh1, T. Arkachaisri1,2,6, S. Albani2,3,5,1, Translational Immunology Institute, Singhealth/Duke-NUS Academic Medical Institute, Singapore, Singapore; 2Duke-NUS Medical School, Singapore, Singapore; 3KK Women's and Children's Hospital, Singapore, Singapore; 4Selayang Hospital, Paediatric Rheumatology Unit, Department of Paediatrics, Kuala Lumpur, Malaysia; 5Translational Immunology Institute, Singhealth/Duke-NUS Academic Medical Institute, Singapore, Singapore; 6KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore

**Background:** Systemic lupus erythematosus (SLE) is a complex systemic autoimmune disease that interferes with the balance between regulation and immunity, resulting in immune system dysfunction. Disease course is unpredictable due to alternating remissions and flares.

**Objectives:**
1. Characterise immune signatures of newly diagnosed SLE patients and in the process:
   a. Study the roles of B and T cells in SLE
   b. Gain a holistic understanding of the adaptive immune response
2. To compare immunological profiles of newly diagnosed SLE patients with age-matched healthy controls

**Methods:** Peripheral blood mononuclear cells (PBMCs) of 5 SLE subjects (median age 12.5 months) were tested with CyTof. Data was uploaded to an online analytical platform, the Extended Polydimensional Immunome Characterization (EPIC) discovery tool, for comparison with 51 age-matched controls in its database.

**Results:**
- Standardization and FlowSOM (Flow cytometry analysis by Self-Organising Maps) clustering to 50 nodes were performed with 37 functionally and phenotypically important immune markers. The Mann-Whitney U test identified significantly different clustering frequencies.

**Conclusion:** Correspondence analysis comparing global differences in cluster frequencies showed segregation of SLE patients away from healthy controls. Multiple significant differences were identified (p < 0.05). Notably, a memory CD4+CD152+PD1+ T cell subset (CD4+CD152+PD1+CD45RO+CD25FoxP3) was enriched in SLE (median: 2.17%, interquartile range: 1.86 to 7.74% of CD4+ PBMCs) versus control (1.34%, 1.06 - 1.58%; p = 0.00267).
of these known checkpoint inhibitors (PD1, CD152) could be important for SLE immunopathogenesis.

Secondly, the innate lymphoid cell 2 (ILC2) subset (Lin-CD7-CD25-CD127-GATA3) was markedly depressed in SLE (0.11%, 0.1 - 0.25%) versus control (0.41%, 0.25 - 0.55%; p = 0.0293). ILC2s protect epithelial integrity; a reduction suggests impaired protective roles in SLE.

Supervised cell frequencies from bivariate analysis correlate strongly with unsupervised cell frequencies, validating these results (Pearson’s correlation coefficient r = 0.9926, p < 0.001 (CD4+CD152*PD1+CD45RO*CD25*FoxP3)); r = 0.8863, p < 0.05 (ILC2)).

Conclusion: With a multi-parametric, unbiased approach comparing SLE subjects to a large database of age-matched healthy controls, we identified two immune subsets of potential immunopathogenic importance. With this information, the CyTOF panel can be redesigned to probe more specifically into the SLE immuneome, facilitating disease-specific interrogation.

THU0238 ASSOCIATION OF SYSTEMIC DISEASES OF CONNECTIVE TISSUE (SDCT) AND GERONTOLOGICAL PROCESSES

V. Shishkin1,2, G. V. Kudriavtseva2, V. V. Shishkin2,2, Saint Petersburg State University, Sankt-Peterburg, Russian Federation; 2Saint Petersburg State University, Sankt-Peterburg, Russian Federation

Background: The approach from the point of view of the evolutionary perspective of finding targets for therapeutic effects among the components of the cellular destruction system is critical both in the treatment of rheumatological diseases and in gerontology.

Objectives: To identify specific relationships between the pathways of cell death in synovial fluid (SF) of people of different age groups with SDCT.

Methods: SF was analyzed in patients of two age groups. Group N 1 of patients: 10 SLE (43±2.3 years), 13 RA (45±1.6 years), 7 SSD (35±1.8 years) and 8 donors (42±2.7 years, postmortem). Group N 2 (age) of patients: 9 SLE (69±1.8 years), 10 RA (65±1.6 years), 5 SSD (65±0.7 years) and 9 donors (62±2.3 postmortem). SF treated with 0.1% Triton-x-100, resuspended in 0.1% citrate buffer for 30 min and centrifuged at 25000 g. The supernatant has been protected in the CyTOF panel can be redesigned to probe more specifically into the SLE immuneome, facilitating disease-specific interrogation.

THU0239 DYNAMIC TEMPORAL CHANGES IN CLINICAL DISEASE ACTIVITY AND GUT MICROBIOTA: REPRESENTATION OF A PATHOBIONT LINKED TO LUPUS NEPHRITIS

G. Silverman1, D. Azzouz2, Z. Chen1, J. Deng1, Z. Li3, D. Penyo2, A. Akselyenko3, 1NYU School of Medicine, Department of Medicine, New York, United States of America; 2NYU School of Medicine, Institute for Systems Genetics, New York, United States of America; 3MUSC, Biomedical Informatics Center, Charleston, United States of America

Background: From a cross-sectional cohort, we have identified a candidate human gut anaerobic pathobiont, Ruminococcus granus (RG) of the family Lachnospiraceae that was linked to active Lupus nephritis (LN)(1). Based on 16S rRNA amplicon analysis, LN patients displayed increased fecal RG abundance, concordant with serum IgG anti-RG antibody responses that appeared interwined with anti-dsDNA responses implicated in renal pathogenesis. Indeed, monoclonization of germ-free mice is reported to result in generalized inflammation and expansions of Th17 cells. However, RG at low levels are also prevalent in healthy adults, and the temporal dynamics of RG representation within Lupus microbiota ecosystems have not been investigated. Also, genomic sequences of few RG strains have been reported, and these vary greatly in genome structure, gene representation and sequence, which may have broad implications for adaptation to a host with systemic inflammation and/or factors that contribute to immune activation in a susceptible host.

Objectives: To investigate the relationships between in vivo RG expansions and disease activity that often wax and wane overtime, we initiated longitudinal studies in Lupus patients and controls. As representation of RG strains alone might alter pathogenic potential, we also sought to characterize RG strains from active LN patients.

Methods: From our cohort, patients were characterized for demographics, clinical activity, and serologies including standard autoantibody and complement levels, and anti-bacterial responses of interest. High throughput 16S rRNA amplicon libraries from fecal samples were analyzed using QiIME 2 and DADA2 (1). Also, individual RG colonies were isolated and subjected to whole genome sequencing. Species and strains were then assigned in part based on multi-locus sequence typing and reference guided genomic assemblies.

Results: 16S rRNA analysis of 34 samples, at 2-4 timepoints from 14 SLE patients, documented highly conserved patterns of gut community representation overtime in 10/14 patients, based in part on unsupervised hierarchical cluster analysis. Notably, independent of vaccinations in clinical disease activity of up to 8 SLEDAI points, conserved microbiome phylogenetic abundance/composition was documented at a family level, and the level of amplicon sequence variants that approximate identification of individual strains, and serologies including standard autoantibody and complement levels, and anti-bacterial responses of interest. High throughput 16S rRNA amplicon libraries from fecal samples were analyzed using QiIME 2 and DADA2 (1). Also, individual RG colonies were isolated and subjected to whole genome sequencing. Species and strains were then assigned in part based on multi-locus sequence typing and reference guided genomic assemblies.

Conclusion: Our findings suggest that many Lupus patients have little or no detectable perturbations in representation of the Lachnospiraceae family or abundance of RG species overtime. Moreover, this seeming microbiota stability was documented even in patients with dramatic changes in disease activity. However, these approaches are inadequate to detect shifts between RG strains. In pilot studies we have isolated and characterized the genomes of four unique RG strains from active LN patients, which include variations in gene content and sequence that may have implications for the host-commensal relationship and immune activation. Broadening of these studies to larger number of SLE patients and healthy subjects, with metagenomic surveys of strain representa- tion in genomic shotgun libraries are currently in progress, in coordination with increases and also the acid-base balance shifts, the number of active forms of oxygen radicals increases, ox-red changes, the components of cellular destruction are activated, the activity of the cytokine system of the organism is disturbed, cytokines - regulators of apoptosis, the expression of chaperones decreases and immuno-oxygenase homeostasis shifts. Inhibition of the genetically determined process of cell death, apoptosis, underlies the development of autoimmune diseases, immunopero-lifite pathalogy (cancerogenesis) and gerontological changes.

Disclosure: The chaperone-mediated induction of the immune response is a signaling mechanism of autoagathy, supposedly, is a common central link and a molecular switch that causes both the development of autoimmune diseases of connective tissue and geron-tological processes.

DOI: 10.1136/annrheumdis-2020-eular.1154
Background: Systemic lupus erythematosus (SLE) is a multifactorial disease. Gut microbiota is an important environmental factor for SLE. The perturbation of gut microbiota is often observed at onset or during the disease course. The fragment of HCMV phosphoprotein 65 (HCMVpp65) containing B cell epitopes has been reported to elicit humoral immunity and accelerate the autoimmune response in murine lupus. However, little is there to know about the interplay between viral trigger for SLE and the change of gut microbiota during lupus progression.

Objectives: By using a murine lupus model with NZB/W F1, we investigated the differential alteration in gut microbiota associated with the progression of lupus disease in HCMVpp65-immunized mice and control mice.

Methods: Ten-week-old NZB/W F1 mice were given or not given an intraperitoneal injection of 100-μg HCMVpp65 peptide biweekly for four times. Fecal samples, urine and blood of mice were collected once every two weeks followed by 16S rRNA genes sequencing and ELISA tests. The pathological investigation of renal tissue from sacrificed mice was conducted at 24 weeks of mice age. Statistical analysis for dynamics and alteration of the gut microbiota as well as functional prediction of bacterial communities related to the progression of lupus-like activity was performed.

Results: HCMVpp65 immunization results in the onset of lupus-like activities in NZB/W F1 mice with a higher titer of anti-dsDNA antibody, creatinine and proteinuria, and severe glomerular damage (Figure 1). Also, higher diversity and increased family abundance of several bacterial species were observed in HCMVpp65-immunized mice (Table 1 and Figure 2a). The predicted metagenomic taxonomic profile in NZB/W F1 mice showed statistically significant enrichment of flagellar assembly, bacterial motility, and chemotaxis (Figure 2b). Spearman’s correlation analysis revealed that a significant association between the increased relative family abundance for Saccharimonadaceae, Marinillicaeae, Desulfovibrionaceae, and Rikenellaceae and HCMVpp65-induced lupus-like activity in NZB/W F1 mice (Figure 2c).

Conclusion: Our results demonstrated that HCMVpp65-immunization induced the change in gut microbiota composition and suggested the association of gut microbiota alteration with lupus-like activity in NZB/W F1 mice.

THU0242

REGULATORY ROLE OF TRANSCRIPTION FACTOR BLIMP-1 IN SJÖGREN’S SYNDROME

R. Wu1, L. Wang1, X. Zhang1, Y. Wang2, G. Wang1, X. Li1, X. Li1. 1The First Affiliated Hospital of China University of Science and Technology, Hefei, China; 2Westmead Institute for Medical Research, the University of Sydney, NSW, Australia

Background: The pathogenesis of primary sjögren’s syndrome (pSS) is multifactorial. Self-antigen-driven responses perform a vital function in the development of autoimmune diseases [1]. B cells, only 20-25% of total infiltrating cells in labial glands, are the cellular basis for spontaneous antibody production [2]. Genome-wide association studies (GWAS) have identified Blimp-1 as a susceptibility gene for autoimmune diseases and played an important role in the pathogenesis of autoimmune diseases [3].

Objectives: To investigate the expression and effect of B lymphocyte induced maturation protein 1 (Blimp-1) in pSS and the correlation of Blimp-1 with B cell subsets and clinical features.

Methods: The PRDM1 mRNA expression in B lymphocyte and labial gland were examined by RT-PCR. The levels of B cell subsets were examined by flow cytometry. Hematoxylin-eosin (HE) staining and immunohistochemistry (IHC) were used to examine the invasion degree of lymph cell and Blimp-1 distribution, respectively. The correlation of PRDM1 mRNA with B cell subsets and clinical indicators were also analyzed.

Results: The levels of PRDM1 mRNA expression of B cells were significantly higher in SS than in healthy controls (HC) and which were also significantly higher in the high immunoglobulin (Ig) group than that in normal Ig group (P<0.02, Fig. 1a-b). The number of CD19+B cells and CD138+ plasma cells(PC) have increased while the CD27+ cells decreased in SS(P<0.05). The percentage of PC and PC/B is positively correlated with PRDM1 mRNA(P=0.380, P=0.002; r=0.317, P=0.009, Fig. 1c-d). Blimp-1 expression level showed a positive correlation with invasion degree of lymph cell in histology (Fig. 2a-c), Ig levels and ESSDAI score and an inverse correlation with the glucocorticoids usage (Fig. 3c).

HSA. CIRC_0123190 FUNCTIONS AS A COMPETITIVE ENDOGENOUS RNA TO REGULATE APLNR EXPRESSION BY SPONGING HSA-MIR-483-3P IN LUPUS NEPHRITIS

C. Zhang1, C. Gao1, X. Di1, S. Cui1, W. Liang1, W. Sun1, M. Yao1, Q. Wang1, Z. Zheng1. 1The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Background: Lupus nephritis (LN) is one of the most severe complications of systemic lupus erythematosus (SLE). Circular RNAs (circRNAs) can act as competitive endogenous RNAs (ceRNAs) to regulate gene transcription, which is involved in mechanism of many diseases, such as, autoimmunity diseases. However, the role of circRNA in lupus nephritis has been rarely reported.

Objectives: In this study, we aim to investigate the clinical value of circRNAs and explore the mechanism of circRNA involvement in the pathogenesis of LN.

Methods: Renal tissues from three untreated LN patients and three normal controls (NCs) were used to identify differentially expressed circRNAs by RNA sequencing (RNA-seq). Validated assays were used by quantitative reverse transcription polymerase chain reaction (qRT-PCR). Correlation analysis and receiver operating characteristic (ROC) curve were used to reveal the clinical value of selected circRNA, miRNA and mRNA. The interactions between circRNA and miRNA, or miRNA and mRNA were further determined by luciferase reporter assay. The degree of renal fibrosis between the two groups were compared by Masson-trichrome staining and immunohistochemistry staining.

Results: 159 circRNAs were significantly dysregulated in LN patients compared with NC group. The expression of hsa_circ_0123190 was significantly decreased in renal tissues of patients with LN (p<0.014), as same as the sequencing results. The area under the ROC curve of hsa_circ_0123190 in renal tissues was 0.82. Bio-informatic analysis and luciferase reporter assay illustrated that hsa_circ_0123190 can act as a sponge for hsa-mir-483-3p which was also validated to interact with APLNR mRNA. APLNR mRNA expression was positively related with chronicity index (CI) of LN (R²=0.452, p=0.033). Finally, the factors of renal fibrosis, especially TGFB-3 (p=0.018), were more pronounced in the LN group.

Conclusion: Hsa_circ_0123190 could act as a sponge to regulate APLNR expression involved in renal fibrosis by sponging hsa-mir-483-3p in LN

SLE, Sjögren’s and APS - clinical aspects (other than treatment)

THU0244 3 YEAR FOLLOW UP OF AN AT-RISK CONNECTIVE TISSUE DISEASE COHORT: ANALYSIS OF CLINICAL, GENE EXPRESSION AND FLOW CYTOMETRIC BIOMARKERS

S. U. Hassan1, Z. Wigston1, A. Psarras1, K. Dutton1, M. Y. MD Yusof2, E. Vitali1. 1University of Leeds, Leeds, United Kingdom

Background: We previously reported results from the first 118 ‘At-Risk’ of autoimmune connective tissue disease (AI-CTD) individuals (i.e. ANA positivity, non-specific symptoms of <1 year and treatment naïve). At 1 year, 16% progressed to meet classification criteria for an AI-CTD. This was predicated by high baseline interferon (IFN) Score B and family history of RMD[1]. However, some may have progressed at later time points, or had clinically significant disease despite not meeting diagnostic criteria. Longer term outcomes, baseline and follow up flow cytometry biomarkers were never reported.

Objectives: (i) Describe detailed analysis of 3-year follow-up data of the At-Risk cohort (ii) Evaluate flow cytometric biomarkers as predictors of these outcomes (iii) Analyse follow up biomarkers

Methods: We conducted a prospective observational longitudinal study of At-Risk individuals in Leeds (n=150). Patients were assessed at baseline, then annually for 3 years. Depending on diagnostic criteria and need for therapy, patients were grouped as follows: (i) Absolute non-progressors (no clinical diagnostic criteria) (ii) 2. Undifferentiated CTD (U-CTD) (p<1 clinical criteria at baseline persisting at follow up but not meeting criteria). This group was subdivided into those who required treatment with an immunosuppressant (IS) excluding antimalarials and those who did not

3. Year 1 progressors (meeting criteria for an RMD by 1 year)

4. Late progressors (meeting criteria for AI-CTD beyond year follow-up).

Results: Bloods were analysed at baseline and 1 year for IFN-stimulated gene expression scores previously described[2], monocytes and subsets of B and T cells using flow cytometry. Association between clinical criteria, biomarkers at baseline and long term outcomes were tested using ANOVA.

Results: 3 year follow up data was available in 147/150 patients. Outcomes were: Absolute non-progressors: 63/147 (43%); U-CTD: 54/147 (37%). Year 1 progressors: 21/147 (14%); Late progressors (in years 1-2): 8/147 (6%); None progressed or required IS initiation beyond the first 2 years of follow-up. In U-CTD group, 7/54 (13%) were prescribed an IS. This work describes a larger group of 36/147 (24%) At-Risk individuals who developed clinically significant disease (CSD; progressors or need for IS) versus clinically non-significant disease (CNSD: absolute non-progressors or UCTD not needing IS).

Analysis of baseline biomarkers between CSD and CNSD confirmed a significant difference in IFN Score B (mean difference -0.74, p = 0.027), but not IFN Score A (mean difference -0.68, p = 0.15). In flow cytometry analysis, there was also a significant difference in percentage monocytes (mean difference -4.09, p = 0.004) but no other subset. Absence of clinical criteria at baseline did not predict clinical outcome, and no one clinical criterion had greater predictive value. In follow up samples we noted a significant reduction in expression of IFN Score B in both groups, regardless of whether they received antimalarials or IS therapy.

Conclusion: Here we report findings of a larger group of 24% At-Risk individuals who developed CSD (progressors and patients who did not meet criteria but needed IS therapy). These results provide a more complex picture of IFN activity in the initiation of SLE than previously suspected. First, we confirm that a specific subset of ISGs rather than a classic IFN signature predicts progression. Second, the reduction in IFN-Score-B in both groups suggests that IFN Score B activity is an important phenomenon, playing a greater role in disease initiation than in disease maintenance.

THU0245 PENALIZED REGRESSION ANALYSIS IDENTIFIES CRITERIA AND NON-CRITERIA FEATURES THAT MAY INCREASE THE ACCURACY OF EXISTING SETS OF CRITERIA FOR CLASSIFYING SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

C. Adamiczou1, I. Genitsaridis2, D. Nikolopoulos2, A. Bortoluzza2, A. Fanourakis2, E. Kalogianakii1, E. Papastefanakis1, I. Gergianaki1, P. Sidiropoulos1, D. Boumpas2, G. Bertias3. 1University of Crete Medical School, Iraklio, Greece; 2National and Kapodistrian University of Athens, Athens, Greece; 3University of Ferrara, Ferrara, Italy
Background: The ACR-1997, SLICC-2012 and EULAR/ACR-2019 classification criteria have high sensitivity and specificity for SLE, yet they classify non-overlapping groups of patients suggesting that they can be supplemented with additional features to improve their diagnostic performance.

Objectives: To identify criteria and non-criteria manifestations that are significantly associated with SLE in clinical practice and can be used to complement the existing sets of classification criteria.

Methods: Individual items from all three classification criteria (ACR-1997, SLICC-2012, EULAR/ACR-2019) and non-criteria features were analyzed in a randomly selected sample of 800 adults diagnosed with SLE or control rheumatologic diseases (1:1 ratio). The classification performance of each set of criteria was analyzed in combination with complementary features; multivariable logistic regression was performed for feature selection. We calculated the diagnostic odds ratio (DOR) of the criteria and the additional features retained in each model.

Results: The EULAR/ACR-2019 and SLICC-2012 criteria have increased accuracy for SLE classification as compared to the ACR-1997 criteria (univariate DOR: 243.2 and 157.3 versus 78.8, respectively). In multivariable regression based on the ACR-1997 criteria, inclusion of additional features such as maculopapular rash, alopecia and hypocomplementemia significantly enhanced the model predictive capacity (area under the curve [AUC]: 0.95 versus 0.87 of the ACR-1997 criteria alone). Similar analysis based on the SLICC-2012 and EULAR/ACR-2019 criteria identified photosensitivity as an additional criterion significantly associated with SLE (multivariable DOR: 5.4 and 9.4, respectively). Accordingly, models including photosensitivity had superior predictive capacity over the criteria-only models (AUC: 0.94 versus 0.91 for SLICC-2012, 0.96 versus 0.91 for EULAR/ACR-2019). Furthermore, non-criteria features including Raynaud’s, splenicomegaly, and myocarditis were independently associated with SLE thus enhancing further the predictive capacity of criteria-based models.

Conclusion: We identified a number of criteria and non-criteria features which can be used in combination with the existing sets of criteria to increase classification of SLE patients in clinical practice. Photosensitivity could be considered as an additional feature to improve sensitivity of the recent classification criteria.

Significant between-cluster differences were observed when comparing outcomes; clusters 4 have been diagnosed longest (mean weeks diagnosed 354.6 v. 1: 232.6, 2: 228.7, 3: 338.2, p<0.0001). Cluster 3 consulted more in the last 12 months (mean number of visits 79 vs. 1: 5.7, 2: 6.3, 4: 7.6).

Conclusion: This study demonstrates the heterogeneity of SLE at diagnosis and highlights four distinct presentations of the disease at diagnosis. Significant proportions of patients present with advanced disease, these clusters go on to present the greatest burden demonstrating the need for better diagnostic tools and novel earlier intervention.

THU0247 FREQUENCY AND PREDICTORS OF THE LUPUS LOW DISEASE ACTIVITY STATE IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: AN OBSERVATIONAL COHORT STUDY

D. Gao1, Y. Yao1, L. Mu1, W. Xie1, X. Sun1, Y. Fan1, L. Ji1, Z. Zhang1. 1 Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China

Background: As a consensus-based definition of minimally acceptable disease activity in systemic lupus erythematosus (SLE), Lupus Low Disease Activity State (LLDAS) has been well-validated and widely accepted. However, no data about the time to LLDAS in Asian ethnicity has been reported so far.

Objectives: To estimate the time to LLDAS and the predictors of time to LLDAS in our prospective observational cohort of Chinese patients with SLE.

Methods: Patients were from Peking University First Hospital SLE cohort and those having not fulfilled LLDAS at enrolment were included in this study. The time to LLDAS and annual cumulative probabilities of LLDAS achievement were estimated by the Kaplan-Meier approach. The predictors of time to LLDAS were identified by univariate and multivariable Cox proportional hazards.

Results: A total of 574 patients with SLE were included and 435 (75.8%) of them achieved LLDAS during a median 4.2 years of follow-up. The median time to LLDAS was 19.0 months and the cumulative probabilities at 1, 2, 3, 5 and 10 years were 19.8%, 57.6%, 72.0%, 85.1% and 96.0%, respectively. In multivariable Cox models, older age at onset, treatment from 5 years of disease to LLDAS, and hydroxychloroquine prescription were found to be independent predictors of shorter time to LLDAS, after adjusted by daily prednisone dose, SLE Disease Activity Index 2000 and physician’s global assessment. Finally, we developed a matrix model based on the identified independent predictors to present the time to LLDAS in patients with respective characteristics.

Conclusion: Our study proved that LLDAS is attainable as an early treatment target for SLE in Chinese patients. The older age at disease onset, treatment-naïve and hydroxychloroquine prescription were independent predictors of shorter time to LLDAS.

Background: In patients with lupus nephritis (LN), clinical response to treatment and renal histopathology have been shown to be discordant. No clinical or laboratory markers have to date been shown to reliably portend renal prognosis, in particular renal function impairment.

Objectives: To investigate whether per-protocol repeat renal biopsies are predictive of LN relapses and long-term impairment of renal function.

Methods: Forty-two patients with an incident biopsy-proven active proliferative (class III/IV ≥1) LN were included in the present retrospective study. Per-protocol repeat kidney biopsies were performed in all patients after a median time of 24.3 (IQR: 21.3–26.2) months. The NIH activity index (AI) and chronicity index (CI) scores were assessed in both baseline and repeat biopsies. We defined acute glomerular lesions as cellular proliferation, fibrinoid necrosis or karyorrhexis, cellular crescents, hyaline thrombi or wire loops, and leucocyte infiltration, and chronic glomerular lesions as glomerular sclerosis and fibrous crescents, in alignment with the NIH activity and chronicity indices. Similarly, we defined acute tubulointerstitial lesions as mononuclear cell infiltration and chronic tubulointerstitial lesions as interstitial fibrosis and tubular atrophy.

Results: Despite a moderate correlation between urinary protein/creatinine (U-P/C) ratios and AI scores at repeat biopsy (r=0.48; P=0.001), ten patients (23.8%) with U-P/C ratios <1.0/g/g still had a high degree of histological activity (AI score ≥3). High AI scores in repeat (but not baseline) kidney biopsies were associated with an increased probability and/or shorter time to renal relapse (N=11) following the repeat biopsy (HR: 1.2; 95% CI: 1.1–1.3; P=0.007), independent of proteinuria levels. This association remained significant for the NIH activity index items within the glomerular but not the tubulointerstitial compartment of the kidney biopsies. High NIH CI scores in repeat (but not baseline) kidney biopsies were associated with a sustained increase in serum creatinine levels corresponding to ≥120% of the baseline value (HR: 1.8; 95% CI: 1.1–2.9; P=0.016) through a median follow-up time of 131.5 (IQR: 73.8–178.2) months, being the case also for acute and chronic tubulointerstitial lesions in repeat but not baseline kidneys.

Conclusion: Our results highlight the usefulness of per-protocol repeat biopsies as an integral part of the treatment evaluation, also in patients who have shown adequate clinical response. Glomerular lesions consistent with active renal disease portend LN relapses, while tubulointerstitial lesions consist with active disease and chronic damage portend long-term renal function impairment.

Background: In patients with lupus nephritis (LN), clinical response to treatment and renal histopathology have been shown to be discordant. No clinical or laboratory markers have to date been shown to reliably portend renal prognosis, in particular renal function impairment.

Objectives: To investigate whether per-protocol repeat renal biopsies are predictive of LN relapses and long-term impairment of renal function.

Methods: We retrospectively analyzed prospectively collected data of patients with LN followed up in four Italian referral centres for systemic lupus erythematosus. Clinical and histologic information were retrieved according to a shared database. RB were classified according to ISN/RPS 2003 classification; chronicity (CI) and activity indexes (AI) were defined according to Austin et al. The primary renal outcome was renal failure, defined as serum creatinine (Scr)>1.0mg/dl with eGFR<60ml/min. Non-parametric tests were used for statistics. Patients repeating RB due to renal remission were excluded from the analysis.

Results: Four-hundred and thirty-eight patients were recruited. One-hundred and three patients repeated RB after 6.1±4.7 (means SD) years from the first due to: protocol biopsy due to renal remission (Group 1, n=8); proteinuric flare (Group 2, n=51); worsened renal function (Group 3, n=26); partial renal response (Group 4 n=18). Patients undergoing a second RB were younger (p<0.001), had lower serum C3 at LN diagnosis (p=0.001) and displayed more frequently class IV and higher AI at first RB (p=0.0038 and p=0.043, respectively). At the end of follow-up, patients who repeated RB had more frequently clinical renal failure (p=0.003). At the second RB, the histological class was unchanged in 55% of patients. CI increased at second RB compared to the first (3.6±2.4 vs. 1.7±1.7, p<0.001). Overall, 26 out of 103 patients (25%) developed renal failure: 0 from group 1, 10 from group 2, 14 from group 3, 2 from group 4 (p=0.001). Uncontrolled hypertension at LN diagnosis, increased SCR and increased proteinuria at second RB predicted renal failure (Table 1).

Conclusion: Patients undergoing a repeated RB had more aggressive clinical and histological features already at first RB and developed renal failure more frequently. Among baseline features, uncontrolled hypertension had the strongest association with renal failure, thus suggesting that control of blood pressure since early stages is highly advisable.

THU0250 | URINE AND SERUM S100 PROTEINS ASSOCIATE WITH LUPUS NEPHRITIS AND RESPONSE TO TREATMENT

J. Davies1, A. Midgley1, S. Donohue1, I. N. Bruce2, M. Beresford2, C. Hedrich2, on behalf of the MRC MASTERPLANS and BILAG-BR Consoritia. 1University of Liverpool, Institute of Translational Medicine, Department of Women’s and Children’s Health, Liverpool, United Kingdom; 2University of Manchester, Arthritis Research UK Epidemiology Unit, Faculty of Biology, Medicine and Health, Manchester, United Kingdom

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune/inflammatory disease. Approximately 30% of SLE patients develop lupus nephritis (LN) that affects treatment and prognosis. Easily accessible biomarkers do not exist to reliably predict renal disease1. Recently, calcium-binding S100 proteins have been suggested as biomarkers in systemic inflammatory conditions, including SLE2,3.

Objectives: The MASTERPLANS Consortium aims to identify indicators of treatment responses in SLE. This study tested the applicability of S100 proteins in serum and urine as biomarkers for disease activity and response to treatment with rituximab in LN.

Methods: S100A8/A9 and S100A12 proteins were quantified in the serum of 243 SLE patients from the BILAG-BR study and 48 matched controls using MSD technology to determine whether they perform as biomarkers for active LN (n=88 SLE patients) and/or may be used to predict response to treatment with rituximab. Renal disease activity and response to treatment was based on BILAG-BR scores and changes in response to treatment4,5.

Results: Serum S100A12 (p<0.001), and serum and urine S100A8/A9 (p<0.001) are elevated in SLE patients. While serum and urine S100 levels do not correlate with global SLE disease activity (SLEDAI), levels in urine and urine/serum ratios are higher in LN patients with active LN (S100A8/A9: urine p<0.005, urine/serum p<0.05; S100A12: urine p<0.05, serum/urine p<0.005). S100 proteins perform better as biomarkers for active LN involvement in SLE patients positive for anti-dsDNA antibodies. Lastly, binary logistic regression and AUC analysis suggest the combination of serum S100A8/A9 and S100A12 to predict response to RTX treatment in LN after 6 months.

Conclusions: From this study show promise for clinical application of S100 proteins to predict active renal disease in SLE and response to treatment with rituximab. Significantly overlapping values between groups currently prohibits the definition of cut-off values and prospective studies are required to validate findings.

THU0251 | IMMUNOPHENOTYPIC CLUSTERS OF SLE PATIENTS REVEAL SUBGROUPS WITH SEVERE DISEASE RESISTANT TO CONVENTIONAL THERAPY

A. Psarras1, D. Lü2, A. Alase1, Z. Wigston1, I. Bruce3, N. Mchugh2, E. Vital1.
1University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2University of Bath, Bath, United Kingdom; 3University of Manchester, Manchester, United Kingdom

Background: Biomarkers to predict response to rituximab include plasmablasts and, in the current MASTERPLANS consortium, Sm/U1 RNP antibodies and high expression of IFN Score B (a subset of interferon-stimulated genes that predict more clinical outcomes than a classic interferon signature). The relationships amongst these biomarkers and their association with response to conventional therapies are less well described.

Objectives: To analyse the inter-relationships amongst immune biomarkers in two independent SLE cohorts in association with disease activity and stage of therapeutic pathway.

Methods: CONVAS is a cohort of unselected SLE patients; data available include current and historic disease activity, use of biologic therapy, flow cytometry, gene expression (IFN Score A and IFN Score B), and immunoprecipitation for autoantibodies (n=91). BILAG-BR is a British registry study for SLE patients commencing biologics; data available include current and historic disease activity, gene expression (IFN Score A and IFN Score B) and immunoprecipitation for autoantibodies (n=112). In both cohorts, biologics were only prescribed to patients with active disease (BILAG 1 x A or 2 x B) and failure of either cyclophosphamide or IV methylprednisolone.

Results: There were 6 clusters. In rituximab-naïve patients:
1. Sm/U1RNP+, R060+, highest IFN Score A, low CD4+ T cells, low NK cells, high plasmablasts
2. Sm/U1RNP-, R060+, medium IFN Score A, low CD4+ T cells, high NK cells, high plasmablasts
3. Sm/U1RNP-, R060-, lowest IFN Score A, high CD4+ T cells, low NK cells, low plasmablasts

Other antibody subtypes and flow cytometric markers did not improve the accuracy of clustering. In rituximab-treated patients, 3 equivalent clusters for antibody subtypes and IFN Score A were observed but differentiated due to flow cytometry findings, as expected after rituximab treatment. Overall, the patients in the cluster defined by Sm/U1RNP antibodies and high IFN Score A were notable for a higher rate of prior disease activity in the renal, neurological and general BILAG domains (Table 1).

Analysis of autoantibody status and interferon scores only in BILAG-BR confirmed similar clustering. Across both cohorts, the prevalence of the Sm/U1RNP and high IFN Score A cluster was associated with inadequate response to conventional immunosuppressive treatment (Table 2). Conclusion: A cluster of 23% of unselected SLE patients had more severe immune abnormalities, more severe clinical disease activity and were less likely to be maintained on conventional therapies, with twice as many requiring biologic therapy. Other data in MASTERPLANS have demonstrated that Sm/U1RNP antibodies and IFN Scores predict better response to rituximab. This subgroup of patients may therefore be more appropriate for first-line biologic therapy.

Background: WHO survey showed that the prevalence of anxiety and depression in Chinese population and Chinese patients with chronic diseases were between 3.1% - 4.2% and 3.1% - 73%, respectively. SLE patients’ disease activity and mental health. All the Assessments were mainly performed by health professionals (HCPs) with paper questionnaire previously. SSDM is a novel smart disease management tool that allows patients to do self-assessments on SLEDAI-2K and HADS by mobile App.

Objectives: To investigate the prevalence of anxiety and depression in Chinese patients with SLE and to analyze the potential association between disease activity of SLE and mental health.

Methods: Under the guidance and training by HCPs, SLE patients downloaded SSDM and performed self-assessments. A cluster of 23% of unselected SLE patients had more severe immune abnormalities, more severe clinical disease activity and were less likely to be maintained on conventional therapies, with twice as many requiring biologic therapy. Other data in MASTERPLANS have demonstrated that Sm/U1RNP antibodies and IFN Scores predict better response to rituximab. This subgroup of patients may therefore be more appropriate for first-line biologic therapy.

THU0253

FATIGUE AND PAIN REMAIN PROMINENT AND IMPACTFUL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): A CROSS-SECTIONAL SURVEY OF SLE PATIENTS IN THE UNITED STATES

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune inflammatory condition impacting multiple organ systems. Fatigue and pain are some of the most prominent symptoms of SLE, contributing to the heavy disease burden and disruption to daily life. This study aimed to further understand the burden of SLE. Lilly worked with the Lupus Foundation of America (LFA) and Evi- dera to develop the SLE-UPDATE (Understanding Preferences, Disease Activity and Treatment Expectations) survey.

Objectives: To understand the patient-perceived symptom burden of SLE, in particular pain and fatigue, within the current landscape of therapeutic options. This study also focused on current treatment patterns in SLE patients.

Methods: This was a cross-sectional, non-interventional, online survey study conducted in partnership with the LFA. English-speaking United States patients aged ≥18 years with a self-reported diagnosis of SLE completed the survey following online screening and informed consent. Descriptive data are presented using means (standard deviation [SD]) for continuous measures, and frequency (n, %) for dichotomous measures. Demographic, clinical, and patient-reported outcomes were collected including the FACIT-Fatigue (range 0-52, higher scores
ARTICULAR INVOLVEMENT, STEROID TREATMENT AND FIBROMYALGIA ARE THE MAIN DETERMINANTS OF PATIENT-PHYSICIAN DISCORDANCE IN SYSTEMIC LUPUS ERYSHEMATOSUS

E. Elefant[1,2], C. Tan[1], F. Ferro[1], C. Stagnano[1], A. Parma[1], V. Signorini[1], D. Zucchi[1], V. Poli[1,2], L. Cari[1], M. Mosca[1,2]. Rheumatology Unit, University of Pisa, Pisa, Italy; University of Siena, Department of Medical Biotechnology, Siena, Italy

Background: Remission or the lowest possible disease activity are the main targets in the management of Systemic Lupus Erythematosus (SLE). Anyway, conflicting data are present in the literature regarding the correlation between physician-driven definitions and patient perception of the disease. The discordance between patient and physician perspectives may have a negative impact on disease outcomes.
