Methods: Data were pooled from 2 Phase 3 studies (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]) for pts receiving tofacitinib 5 or 10 mg twice daily (BID) or placebo (PBO). DAPSA was determined by summing swollen joint count (SJ66); tender/painful joint count (TJC68); Patient’s Global Assessment of Arthritis (PtGA; visual analogue scale [VAS]); pain (VAS); and CRP. Pts were classified as achieving MDA or VLDA when meeting ≥5 (MDA) or ≥7 (VLDA) of the following criteria: TJC68; Patient’s Global Assessment of Arthritis (PG; visual analogue scale [VAS]); pain (VAS); and CRP. Pts were classified as achieving MDA or VLDA when meeting ≥5 (MDA) or ≥7 (VLDA) of the following criteria: TJC68; Patient’s Global Assessment of Arthritis (PG; visual analogue scale [VAS]); pain (VAS); and CRP. Pts were classified as achieving MDA or VLDA when meeting ≥5 (MDA) or ≥7 (VLDA). Disease activity in pts with PsA treated with tofacitinib was assessed using categorical scores at Month (M)3. DAPSA LDA (≤14), MDA, remission (DAPSA and DAS28-3[CRP]) and VLDA generally increased over time in pts with PsA receiving tofacitinib. DAPSA LDA showed moderate agreement with MDA, and DAPSA remission showed at least moderate agreement with VLDA, confirming that DAPSA and MDA are useful measurement tools to assess disease activity in pts with PsA treated with tofacitinib.

Smolen Grant/research support from: AbbVie, AstraZeneca, Celgene, Celltrion, Chugai, Eli Lilly, Gilead, ILTOO, Janssen, Novartis-Sandoz, Pfizer Inc, Samsung, Sanofi, Consultant of: AbbVie, AstraZeneca, Celgene, Celltrion, Chugai, Eli Lilly, Gilead, ILTOO, Janssen, Novartis-Sandoz, Pfizer Inc, Sanofi, Philip J Mease Grant/ research support from: AbbVie, Amgen, Biogen Idec, BMS, Eli Lilly, Genentech, Janssen, Pfizer, UCB – speakers bureau, Enrique Soriano Grant/research support from: AbbVie, Eli Lilly, GlaicoSmithKline, Novartis, Pfizer Inc, Sandoz, Consultant of: AbbVie, Eli Lilly, least moderate agreement (defined by kappa values 0.41–0.60) was observed between DAPSA LDA and MDA, and between DAPSA remission and VLDA, with both doses of tofacitinib at M6 (Figure c).

Conclusion: Remission and LDA rates generally increased over time in pts with PsA receiving tofacitinib. DAPSA LDA showed moderate agreement with MDA, and DAPSA remission showed at least moderate agreement with VLDA, confirming that DAPSA and MDA are useful measurement tools to assess disease activity in pts with PsA treated with tofacitinib.

Significant correlation was observed between the SF levels of both forms of PsoP27 Ab and the swollen joints count (Native: r=0.408). In contrast, in RA patients there was no correlation between other inflammatory processes, this antigen has not been investigated in relation to PsA.

**Conclusion:** We determined for the first time the presence of antibodies to psoriatic-related autoantigen PsoP27 in SF of PsA, RA and OA patients. Low SF level of PsoP27 Ab in OA compared to a high Ab level in RA and PsA may suggest a potential new biomarker discriminating between inflammatory arthritis versus OA. Furthermore, we showed a positive correlation between the SF levels of antibodies to PsoP27 in SF and disease activity in PsA, but not in RA. Also, we demonstrated the presence of citrullination and antibodies against citrullinated peptides in PsA, a process thought to be specific to RA. Our results suggest that antibodies to PsoP27 in SF may be a potential biomarker in PsA, both for diagnosis and disease assessment.

**CLINICAL CHARACTERISTICS OF PSORIATIC ARTHRITIS IN CHINESE PATIENTS: A CROSS-SECTIONAL OBSERVATIONAL STUDY**

Z. Song1, B. Li1, Z. Zhang1. 1Peking University First Hospital, Beijing, China

**Background:** The clinical features of psoriatic arthritis(PsA) greatly varied in reports from different countries. There was no exact data in China.

**Objectives:** To disclose the characteristics of PsA in China, we initiated an investigation in our cohort of PsA patients.

**Methods:** A cross-sectional observational study was conducted in our PsA cohort of Peking University First Hospital. All the clinical and imaging data at the patient’s first visit were collected, including the age, gender, disease course,
skin lesion, arthritis, dactylitis, enthesitis, laboratory tests, concomitant diseases and so on.

Results: Two hundred and seventy-nine patients with PsA were enrolled in this study. Their mean age was 41 year-old with 132 (47.3%) female. Median disease duration was 3 years. Among these patients, 196(73.4%)patients had the skin lesion first, 47 (17.6%)patients had the arthritis first, and the other 24(9.0%) patients had the psoriasis and the arthritis at the same time. Arthri-
tis was the most common manifestation. Polyarthritis was the most common arthritis manifestation with proximal interphalangeal (PIP) joint as the most frequently involved joint. Dactylitis was observed in 89 (31.9%) patients, mostly at the second, third and fourth toe. Enthesis was found in 18 (6.5%) patients by physical examination, however, in 158 (56.5%) patients with the aid of ultra-
sonography and MRI.

Conclusion: Polyarthritis was the most common arthritis type in Chinese PsA patients, and PIP joint was the most involved joint, and the second, the middle and the fourth toe were the most frequently digits. The imaging techniques, especially ultrasound dramatically increased the identification of enthesis.

AB0835
THE IMPACT OF ADALIMUMAB VS PLACEBO ON PATIENT-REPORTED OUTCOMES AND UTILITY MEASURES AMONG PATIENTS WITH MODERATELY TO SEVERELY ACTIVE PSORIATIC ARTHRITIS

V. Strand1, P. Patel2, N. Chen3, E. Lesser4. 1Stanford University School of Medicine, Palo Alto, United States of America; 2AbbVie Inc, North Chicago, United States of America

Background: Physical function and health-related quality of life (HRQoL) are negatively impacted in patients(pts) with PsA. Treatment with conventional and biological (b) DMARDs improved patient-reported outcomes (PROs).

Objectives: To assess impact of adalimumab(ADA) vs placebo(PBO) on PROs following 12-week (wk) treatment.

Methods: Pts(n=315) with moderately to severely active PsA and bDMARD naïve were randomized to ADA 40mg or PBO every other wk. We assessed PROs at baseline(BL) and wk 12 using the 36-item Short-Form(SF-36) Health Survey physical(PCS) and mental component summary(MCS) scores, 8 domain scores ranging from 0(worst) to 100(best), and SF-6D utility measure derived from all 8 SF-36 domains with scores ranging from 0.296(worst) to 1.00(full health) and minimally important difference(MID) of 0.041. Patient Global Assessment of disease activity(PtGA) and pain(both utilizing 100 mm visual analog scale[VAS]) and HAQ disability index(DI) were assessed. Mean changes from BL, percentages of pts with improvements ≥minimum clinically important differences(MCID), and scores ≥US age-and gender-matched normative values(A/G norms) were analyzed, based on as observed data. P values were assessed by analysis of variance model for continuous variables and Cochran–Mantel–Haenszel test for binary outcomes, adjusting by baseline MTX use and extent of psoriasis. Numbers needed to treat(NNTs) are reported using proportions of pts reporting improvements ≥MCID in SF-36, PtGA, pain, and HAQ-DI.

Results: BL PRO scores were similar between ADA(n=151) and PBO(n=162; Table 1). Improvements from BL at wk 12 with ADA vs PBO were significant in PtGA, pain, HAQ-DI, and SF-36 PCS(change: 9.3 vs 1.4; P<0.001) but not in SF-36 MCS(1.6 vs 1.2; Table 1). Six of 8 SF-36 domains significantly improved from BL to wk 12 with ADA vs PBO(all P<0.05; Table 1 and Figure 1). SF-6D improvements exceeded MID with ADA(change: 0.071) vs PBO(0.018). Proportions of pts reporting improvements ≥MCID at wk 12 were significantly greater with ADA vs PBO in all PROs, except SF-36 role emotional and mental health domains, with corresponding NNTs ≤6(Fig-
ure 2). Proportions of pts who reported scores ≥A/G norms in HAQ-DI, SF-36 PCS, and 6 of 8 SF-36 domains were significantly greater with ADA vs PBO(Figure 2).

PREVALENCE AND DETERMINANTS OF FATIGUE IN PSORIATIC ARTHRITIS IN AN ASIAN POPULATION
J. S. Q. Tan1,2, W. Fong1,3, Y. H. Kwan3, Y. Y. Leung1,3. 1Singapore General Hospital, Rheumatology and Immunology, Singapore, Singapore; 2Yong Loo Lin School of Medicine, Singapore, Singapore; 3Duke-NUS Medical School, Singapore, Singapore

Background: Fatigue is one of the core domains to be measured in all clinical trials for psoriatic arthritis (PsA). Studies of fatigue in PsA in Asia are scarce.

Objectives: To describe the prevalence and evaluate the factors associated with fatigue in PsA patients within a multi-ethnic Asian population.

Methods: We used data from the PRESPOND registry for PsA patients attending an outpatient clinic of a tertiary institution in Singapore. Demographics data and disease characteristics were evaluated. Fatigue was assessed by question 1 of BASDAI (BASDAI-F) and the vitality domain of SF-36 (SF-36 VT).

Results: 131 patients (50.4% men, 63.4% Chinese, median PsA duration 1.78 years) with completed data for fatigue were included. The median (IQR) tender and swollen joint count was 2 (5) and 1 (3) respectively. 45 patients (34%) experienced high fatigue (defined by BASDAI-F ≥ 6). 5 clusters of factors were identified using principal component analysis that explained 66.2% of the variance of all factors, which mapped to disease activity, disease chronicity, demographics (ethnicity and gender), and BMI (Figure 1). Of these, disease activity and chronicity were significantly associated with BASDAI-F and SF-36 VT. In a multivariate analysis, back pain, peripheral joint pain, and patient global assessment were associated with BASDAI-F, whereas peripheral joint pain, HAQ-DI, and BMI were associated with SF-36 VT (Table 1).

Conclusion: PsA-associated fatigue is prevalent in this Asian PsA cohort and is associated with disease activity and chronicity.

ITCH AS THE MAJOR MEDIATOR OF THE EFFECT OF TOFACITINIB ON HEALTH-RELATED QUALITY OF LIFE IN PSA: A MEDIATION ANALYSIS
P. C. Taylor1, A. G. Bushmakina2, J. C. Cappelleri3, P. Young4, R. Germino5, J. F. Merola6, G. Yosipovitch2. 1University of Oxford, Oxford, United Kingdom; 2Pfizer Inc, Groton, United States of America; 3Pfizer Inc, Collegeville, United States of America; 4Pfizer Inc, New York, United States of America; 5Harvard Medical School, Boston, United States of America; 6University of Miami, Miami, United States of America

Background: PsA is a chronic, systemic inflammatory disease with signs and symptoms across multiple domains, including cutaneous manifestations, which can impact health-related quality of life (HRQoL). Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. In two Phase 3 randomised studies, patients (pts) with active PsA treated with tofacitinib experienced greater improvements in various dermatologic endpoints, compared with placebo. As pruritus is a bothersome symptom of skin disease in pts with PsA, we sought to determine how tofacitinib affects HRQoL via clinical improvements in skin symptoms including itch.

Objectives: To determine the relationships between tofacitinib treatment, dermatologic symptoms and pt-reported HQoL related to skin disease in PsA.

Methods: Analyses used data (mean scores from Months 1 and 3) from two Phase 3 studies (OPAL Broaden [NCT01877668]; OPAL Beyond [NCT01882439]) of pts with active PsA treated with tofacitinib 5mg twice daily or placebo; pts

BASDAI-F, BASDAI Fatigue; SF-36 VT, SF-36 Vitality; PGA, Patient Global Assessment; HAQ-DI, Health Assessment Questionnaire Disability Index; BMI, body mass index; SD, standard deviation.
were tumour necrosis factor inhibitor (TNFi)-naive or had previous inadequate response (IR) to ≥1 TNFi. All pts were treated continuously with a single conventional synthetic DMARD. Mediation modelling, a statistical method used to assess mechanisms underlying observed relationships between different variables via other explanatory variables (mediators), was applied. The mediation model included: treatment, as the independent (explanatory) binary variable (tofacitinib 5mg BID vs placebo); HQLoQ, measured by Dermatology Life Quality Index (DLQI), as the dependent (outcome) variable; and two mediators, pt-reported Itch Severity Index (ISI) and Physician’s Global Assessment of Psoriasis (PGA-PsO) (a latent variable represented by erythema, induration and scaling). The initial model designated the treatment effect on DLQI mediated via ISI and PGA-PsO as an indirect effect, and treatment effects not attributable to ISI or PGA-PsO as a direct effect (Figure 1).

Results: Data were collected from 468 pts, pooled from both studies. In the initial model (pooled data), the effect of tofacitinib treatment on DLQI was largely mediated by itch (measured by ISI) and PGA-PsO (indirect effect) (p=0.0001); the effect of treatment attributable to factors other than ISI and PGA-PsO (direct effect) was not statistically significant (p>0.05). Results were consistent for pooled and individual study data. Because the direct effect was small and not statistically significant, the model was re-specified to exclude the direct effect of tofacitinib treatment on DLQI. In the revised model (pooled data), 17.7% of the indirect effect was attributable to PGA-PsO (p<0.0001) and 82.3% was attributable to itch (assessed by ISI) (p<0.0001) (Figure 2). Analyses of individual studies using the revised model gave results generally consistent with pooled data.

Conclusion: Dermatology-focused mediation modelling showed that a majority of the effect (~80%) of tofacitinib treatment on DLQI is mediated by improvement in itch, with ~20% mediated via improvements in PGA-PsO.

Figure 1. Initial mediation model

![Image](https://example.com/image1)

Figure 2. Revised mediation model

![Image](https://example.com/image2)

Treatment is represented by a binary variable (tofacitinib 5mg BID vs placebo). DLQI, Dermatology Quality of Life Index; ISI, Itch Severity Index; PGA-PsO, Physician’s Global Assessment of Psoriasis.

AB0836-IDENTIFYING MEDIATORS OF PAIN REDUCTION IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH TOFACITINIB: ROLE OF INFLAMMATION ASSOCIATED WITH PERIPHERAL ARTHRITIS, ENTHESITIS AND SKIN DISEASE

P. C. Taylor1, K. De Vlam2, A. G. Bushmakin3, L. Fallon4, J. F. Merola5, J. C. Cappelleri3, M. A. Hsu3, P. J. Mease6, 1University of Oxford, Oxford, United Kingdom; 2ZU Leuven, Leuven, Belgium; 3Pfizer Inc, Groton, United States of America; 4Pfizer Inc, Montreal, Canada; 5Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America; 6University of Washington, Seattle, United States of America

Background: Treatment effect on pain is a priority for patients (pts) with psoriatic arthritis (PsA) and physicians. As pain is multidimensional, there is growing interest to understand the mechanisms of pain relief during treatment. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. Previous analyses showed that the effect of tofacitinib on pain in pts with PsA was partially mediated through improvement of inflammation as assessed by C-reactive protein (CRP) and Swollen Joint Count (SJC). Additional potential inflammation-associated mediators that might contribute to tofacitinib’s effect on pain include enthesitis and skin disease.

Objectives: To describe the interrelationship between pain, tofacitinib treatment and potential inflammatory-associated outcomes, using mediation modelling.

Methods: Data from two Phase 3 studies (OPAL Broaden [NCT01877668]; OPAL Beyond [NCT01882439]) of pts with active PsA treated with tofacitinib 5mg twice daily (BID) or placebo were used; pts were tumour necrosis factor inhibitor (TNFi)-naive or had previous inadequate response to ≥1 TNFi. All pts were treated continuously with a single conventional synthetic DMARD. Analyses were completed using pooled and individual study data at Months 1 and 3 (using mean scores across visits). Mediation modelling seeks to explain mechanisms underlying observed relationships between independent and dependent variables via other variables (mediators). This initial model included: treatment as the independent (explanatory) binary variable (tofacitinib 5mg BID vs placebo); pain, measured by Patient’s Assessment of Arthritis Pain (VAS, 0–100 mm), as the dependent (outcome) variable; mediators were: pt-reported Itch Severity Index (ISI); CRP; SJC; Psoriasis Area and Severity Index (PASI); and enthesitis, measured by Leeds Enthesitis Index (LEI) or Spondyloarthritis Research Consortium of Canada Enthesitis Index (SPARC). The final model was revised based on results of the initial model.

Results: The initial model (N=329; pooled data) showed that tofacitinib treatment affects pain mainly indirectly via ISI, CRP, SJC, PASI and enthesitis (LEI), with 16.0% (p=0.53) attributable to the direct effect. The indirect effect via SJC (<1%) was not significant (p=0.99); the indirect effect via PASI was contradic-tory (-14.4%, p=0.10). The final model (Figure 1) excluded SJC and PASI. Analysis of the final model (N=468; pooled data) revealed that 29.5% (p=0.00579) of tofacitinib treatment effect on pain was attributable to the direct effect, and 70.5% (p<0.0001) was attributable to the indirect effect. ISI, LEI and CRP mediated 37.4% (p=0.0002), 17.8% (p=0.0157) and 15.3% (p=0.0107) of the tofacitinib treatment effect on pain, respectively. Results for individual studies were consistent with pooled data, as were those when enthesitis was represented by SPARC in the model.

Conclusion: The majority of tofacitinib treatment effect on pain in pts with PsA is collectively mediated by itch, enthesitis and CRP, with itch being the main mediator of treatment effect (~37%), using mediation modelling analyses.
AB0830 RELIABILITY OF COMPOSITE MEASURES FOR THE ASSESSMENT OF PSORIATIC ARTHRITIS

W. Tillett1, P. Helliwell2, O. Fitzgerald3, R. Waxman2, A. Antony4, L. C. Coates5, D. Jaden6, P. Creamer7, S. Lane8, M. Massarotti9, C. Cavill10, M. Brooke10, Deepak Jadon11, E. Korendowych10, A. Lissina12, N. McHugh12 on behalf of on behalf of the PROMPT study group.

Background: Composite measures of disease activity have been developed for use in Psoriatic Arthritis (PsA) to capture the wide spectrum of disease but there is a lack of consensus regarding which to adopt for routine practice. It is recognised that more data is required to understand the measurement properties of existing instruments and consider the impact of modifications that may improve face validity, responsiveness or feasibility. It is important to have an estimate of a measurement instrument’s reliability in the setting of stable disease in order to understand measurement error and responsiveness. To our knowledge no data exists on the stability of composite measures in PsA.

Objectives: To measure test re-test reliability of composite measures of disease activity in PsA.

Methods: Clinical and patient reported outcomes to enable the calculation of composite measures were administered to 141 patients with PsA at five time points in a UK multicentre observational study. All patients fulfilled the CASPAR criteria. Twenty-nine patients with clinically stable disease and receiving no treatment intervention underwent repeat assessment by the same examiner within 2 weeks. Patients in high and low disease were included. Reliability was evaluated by intra-class correlation coefficient (ICC) and Bland Altman plots.

Results: Of the 29 patients included 15 were male, the mean age was 52.4 years (SD 13.39), mean disease duration at T0 was 9.2yrs (SD 8.11). The mean swollen joint count was 3.4 (SD 5.1), tender joint count 11.3 (SD 16.03) and PASI 1.0 (SD1.04). The ICC (95% CI) for tender and swollen joint counts were 0.94 (0.87-0.97) and 0.91 (0.80-0.96) respectively. The ICC for PASI was 0.95 (0.90-0.98). All composite measures demonstrated high levels of test-retest reliability with ICC >0.85, table. The most reliable measure was the PASDAS ICC 0.98 (95% CI 0.954-0.991). The individual ICC for each composite measures are reported in the table and Bland Altman plots, figure.

Conclusion: All composite measures show high levels of test-retest reliability in this cohort. The PASDAS was the most stable measure. Modifications to these instruments can now be tested and the impact compared to the original versions.

Background: Osteoporosis is one of the major comorbidities in patients with psoriasis and psoriatic arthritis (PsA). It has been reported that PsA induces fragility bone structure and high risk of osteoporosis. However, there is no report about relationship between psoriatic arthritis and osteoporosis in Japanese patients and its mechanism has not been elucidated. 

Objectives: The object of this study is to investigate influence of PsA on bone mineral density (BMD) and its mechanism including analysis between axial and peripheral PsA in Japanese patients.

Methods: This study was retrospective study. We examined 58 cases of PsA and 29 cases of RA that underwent DXA tests at our facility from January 2017 to July 2019 (Table 1). The axial PsA was classified as axial SpA using the ASAS classification criteria. First, we investigated influence of PsA containing both axial (n=30, 19 males, 11 females, mean age: 56.0 years) and peripheral (n=28, 19 males, 9 females, mean age: 58.0 years) subtypes on BMD measured by dual-energy X-ray absorptiometry. Second, we measured serum bone metabolism markers (P1NP: type I procollagen-N-propeptide, TRACP-5b: tartrate-resistant acid phosphatase 5b) and bone remodeling effector molecules (Dkk1: Dickkopf1, sclerostin, 25(OH)D: 25-hydroxyvitamin D) to elucidate differences in BMD between axial and peripheral PsA. Furthermore, rheumatoid arthritis (RA) (n=29, 2 males, 27 females, mean age: 66.2 years) subtypes on BMD measured by dual-energy X-ray absorptiometry. Second, we measured serum bone metabolism markers and bone remodeling effector molecules between axial and peripheral PsA, but the relationship between BMD and these parameters were not confirmed. Further studies are needed to elucidate bone loss mechanism in these PsA.

Results: 58 patients with PsA indicated low T-score, Z-score and %YAM in both lumbar spine and proximal femur (Table 1). Axial PsA and peripheral PsA showed osteoporosis in 16.7% and 35.7%, and osteopenia in 20.0% and 32.1%, respectively, despite the fact that there were many middle-aged men. Comparison between axial and peripheral PsA, axial PsA showed higher BMDthan peripheral PsA. In bone remodeling markers, P1NP in both PsA was almost same, but TRACP-5b, bone resorption marker, in axial PsA was lower than that in peripheral PsA(Table 2). In bone remodeling influencer molecules, Dkk1, and sclerostin in axial PsA was slightly higher than those in peripheral PsA, whereas 25(OH)D is almost same as the both PsA. On the other hand, RA also indicated low T-score and %YAM in both lumbar spine. P1NP in RA showed slightly lower, but TRACP-5b and Homocysteine in RA higher than peripheral PsA, whereas sclerostin in axial PsA was slightly higher than those in peripheral PsA, whereas 25(OH)D is almost same as the both PsA.

Conclusion: Peripheral PsA indicated more severe bone loss than axial PsA in our study. There were some differences in bone remodeling markers and bone remodeling effector molecules between axial and peripheral PsA, but the relationships between BMD and these parameters were not confirmed. Further studies are needed to elucidate bone loss mechanism in these PsA.

References:
Conclusion: Reflecting the complexity of PsA, different degrees of improvement were observed across all treat-to-target outcomes with greater improvements in patients that met ACR50 response regardless of skin resolution. These findings at week 24 need to be confirmed with a longer duration of treatment.

AB0842 DISCOVERY OF ARTHRITIS IN PSORIASIS FOR EARLY RHEUMATOLOGICAL REFERRAL (DAPPER): A CROSS-SECTIONAL STUDY

T Van Hall1, M Mulder1, M Wenink1, M Pasch1, J Van den Reek1, E De Jong1, Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands; 2Radboudumc, Dermatology, Nijmegen, Netherlands

Background: In three patients with psoriasis (PsO) will develop psoriatic arthritis (PsA) (1). When untreated, this can lead to disability and irreversible joint damage (2). Current screening methods are mostly based on questionnaires. These lack specificity and sensitivity (3,4). Thus, a significant portion of PsA patients remains undetected.

Objectives: Our main objective is to ascertain the prevalence of PsA in a cohort of PsO patient, treated at a dermatology outpatient clinic. Secondary, we wish to make a referral tool for dermatologist to detect patients suspected of PsA.

Methods: A sample of 300 patients, stratified for current skin therapy (topical, systemic non-biologic, biologic), will be screened by a rheumatologist resident for PsA signs and symptoms. When PsA is suspected, patients are referred to a rheumatologist for confirmation. We gather information about demography, treatment (past and current) and comorbidity. On top of that, we gather data on disease specifics (age of onset, disease duration, severity). We store biomaterials and DNA. Eventually, all these data will be used to form a more specific prediction model which can be used at the dermatology department for more efficient referral.

Results: We will present preliminary data of the first 100 patients. In this cohort, we found 14 patients with known PsA. 10 patients were suspected of (previously undiagnosed) PsA, and were referred to a rheumatology clinic. Three cases were confirmed, and 4 are still under analysis. This makes the prevalence of PsA in PsO 17%. Of these three new cases, one was treated with topical therapy only, one was treated with a biologic, and one received targeted therapy. In the patients with PsA, we found a higher amount of men. On top of that, we found a trend towards more intensive therapy. This may be due to indication bias, were the presence of arthritis may lead to a more aggressive treatment. Interestingly, 2 of the 3 previously undiagnosed PsA patients were treated with a biological for their skin symptoms.

Conclusion: Preliminary data of the DAPPER study reveal that the prevalence of confirmed PsA in PsO patients is 17%. If all suspected PsA are confirmed, this rises to 21%. Even under systemic biologic treatment, arthritis can still be active.

Background: Patients with psoriatic arthritis (PsA) experience substantial functional impairment, which impacts on health-related quality of life. Evidence from randomized clinical trials (RCTs) suggests better patient-reported functional outcomes when lower disease activity is achieved.2-4

Objectives: To evaluate the impact of achieving DAPSA remission (REM) or low disease activity (LDA) on long term function measured by HAQ-DI. To verify predictors of achieving a minimum clinically important difference (MCID) in HAQ-DI (≤ -0.35).

Methods: This is a longitudinal analysis of a real-life retrospective cohort. Inclusion criteria were adult patients fulfilling CASPAR criteria for PsA with at least 4 years of follow-up in the PsA Clinic. Demographic and clinical data were extracted from electronic medical records. Comparison of HAQ-DI variation between patients with DAPSA REM/LDA and those with moderate/high disease activity was performed using generalized estimating equation (GEE), adjusted by Bonferroni test. Correlation between HAQ-DI and DAPSA was analyzed by Spearman correlation method. A multivariate hierarchical regression model was applied in order to evaluate predictors of achieving a MCID in HAQ-DI scores.

Results: Seventy-three patients were included in the analysis, of which 58.9% were female, with a median (25/75th) of 8 (3-15) years since PsA diagnosis and a mean follow up time of 6.2±1.2 years. In total, 37% of patients (N=27) presented a MCID in HAQ-DI during the follow-up. Function measured by HAQ-DI was determined by PsA disease activity measured by DAPSA (interaction test: p < 0.0001) (Figure 1). A moderate and statistically significant correlation between ΔDAPSA and ΔHAQ-DI was observed (r = 0.60; p<0.001) (Figure 2), demonstrating that a decrease in PsA disease activity was associated to improvement in function. Only patients in DAPSA REM demonstrated a constant declining in HAQ-DI scores during the 6 years of follow-up (Figure 1). While ethnicity and older age at baseline were predictors for not achieving MCID in HAQ-DI (RR 0.33 95% CI 0.16-0.67, p=0.002 and RR 0.96 95% CI 0.93-0.98, p<0.0001, respectively), while higher scores of HAQ-DI at baseline were predictors of achieving a MCID (RR 1.71 95% CI 1.12-2.60, p=0.013).

References:
Figure 1. Variation in HAQ-DI according to PsA disease activity measured by DAPSA.

Figure 2. Correlation between changes in PsA disease activity (ΔDAPSA) and changes in functional indices (ΔHAQ-DI) over three years of follow-up.

Conclusion: In PsA, patients who maintained DAPSA REM/LDA over time had better long term functional outcomes. Higher HAQ-DI scores at baseline, non-white ethnicity and younger age were predictors for achieving a clinical significant improvement in HAQ-DI.

AB0844 SERUM SCD40L LEVEL CAN PREDICT SHORT-TERM CLINICAL OUTCOMES IN PATIENTS WITH PSORIATIC ARTHRITIS ON TREATMENT WITH APREMILAST.

V. Venerito1, D. Natuzzi1, F. Bizzocca1, N. Lacarpia1, M. Fornaro1, M. Giannotta1, G. Righetti1, G. Lopalco1, F. Iannone1, 1Rheumatology Unit, Department of Emergency and Organ Transplantations, University of Bari “Aldo Moro”; Bari, Italy

Background: The pathogenesis of Psoriatic Arthritis (PsA) involves several pathways simultaneously, including the CD40/CD40L interaction. In vitro evidence suggests that the cleavage of soluble CD40L (sCD40L) may happen as a Phosphodiesterase 4- (PDE4) dependent reaction [1-3].

Objectives: Here we investigate whether apremilast, a PDE4 inhibitor, could modify circulating level of soluble CD40L (sCD40L) in PsA patients, and the possible associations of these changes with clinical response.

Methods: Consecutive patients with PsA starting apremilast in routine clinical practice between October 2018 and September 2019 in a single center were longitudinally observed. Sera were collected at baseline and at the 6-month follow up visit. Demographics and clinical characteristics at different observation times were recorded. Samples were ran in a Bio-Plex ProTM plate for sCD40L level. To investigate the association of sCD40L level with DAPSA minor response and DAPSA Low Disease Activity (LDA) and/or Remission (ie DAPSA ≤14) at 6 months of treatment, multivariate logistic regression models with backward selection (p <0.05) were built.

Results: We studied n.27 patients (16/27 women, 59.6%) with PsA with mean age (± SD) of 58.4 ± 10.4 years. A significant reduction of the mean values of DAPSA, LEI and PASI was evidenced at 6 months. Mean serum level of sCD40L decreased from 5364.02 ± 2025.70 to 4412.14 ± 2629.81 pg/ml after 6 months of apremilast treatment (p=0.01, Figure 1). Baseline sCD40L was an independent predictor of DAPSA minor response (OR 1.0006, 95% CI 1.0001-1.0012; AUC 0.76 (95% CI 0.55-0.97)). Moreover baseline DAPSA (OR 0.80, 95% CI 0.65-0.98) and baseline sCD40L (OR 1.001, 95%CI 1.0001-1.0028; AUC 0.85 95% CI 0.69-0.98, Figure 2) were independently associated with DAPSA LDA/Remission.

Conclusion: Apremilast may decrease sCD40L level in PsA patients. Higher baseline serum sCD40L level may predict short-term clinical response to apremilast.

Background: PsA is a disease with multiple manifestations; it has significant impact on physical and emotional aspects of patient’s life. PRos as well as disease activity are an important instrument for assessing treatment response. Tofacitinib (TF) is an oral Janus kinase inhibitor; in RCT TF demonstrated efficacy in active PsA pts concerning PRos [1] but there is currently no evidence from real clinical practice.

Objectives: To study the influence of TF on disease activity and PRos in 3/6 mo of therapy in pts with active PsA in clinical practice.

Methods: 41 (M/F=24/58.5%)/17 (41.5%) PsA pts fulfilling the CASPAR criteria were included. Mean age 42.4±10.3 years (yrs), median (Me) PsA duration 72 [35;120] mo, pts had inadequate response to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs, mostly Methotrexate)/biological (b) DMARDs (29% of pts). Pts were treated with TF 5 mg twice daily after signing consent participation forms. At baseline (BL) and in 3/6 mo of therapy PsA activity was evaluated by Tender Joint Count (TJC68), Swollen Joint Count (SJc66); PGA, physician global assessment by Visual Analog Scale (VAS), DAPSA. PRos were measured by PIGA VAS, PtPain VAS, BAS-DAI, HAQ, DLOI, RAPID, FACIT, PsAID12, Patient-Acceptable Symptom State (PASS) of PsAID12≥4. PsAID12 was analyzed as a change above the minimal clinical important difference (MCID) -1.25 points [2]. Higher PsAID12 scores are considered to be worse and correspond to poorer PsA-specific health-related quality of life. M±SD, Me [Q25; Q75], %, t-test, Pierson-χ², Mann-Whitney tests were performed. All p<0.05 were considered to indicate statistical significance.

Results: At BL 87.8% of pts had high PsA activity by DAPSA. By 3/6 mo of therapy significant improvement in all PsA activity indexes and PRos were observed (table 1) (for all p<0.0001). By 6 mo of therapy DAPSA remission was seen in 11 out of 41 pts (26.8%). After 3/6 mo of therapy all PsAID12 domains and significant improvement (p<0.0001) (Figure 1). The PsAID12 improvement above MCID in -1.25 points reached 90.2% of pts by 6 mo. In 3/6 mo of therapy PsAID12 PASS was achieved in 66.7%/71.8% pts accordingly.

regarding fulfillment of the 4 PsA criteria (Figure 2A). Moreover, 86% fulfilled the ASAS peripheral or axial SpA criteria, while the 1987 ACR definition of RA was met by 27% – in both cases with the great majority also classifiable as PsA (Figure 2B). Most patients not fulfilling any PsA criteria had either no verified arthritis or polyarticular disease (Table). Overall, only 6.5% of the clinical PsA diagnoses were judged as clearly wrong by the rheumatologists performing the medical record assessments.

Conclusion: The validity of clinical ICD-10 diagnoses for PsA in the Swedish National Patient Register is good, with a PPV of 86% for the fulfillment of established PsA classification criteria.

AB0847

HIGH TOLERABILITY OF USTEKINUMAB IN THE TREATMENT OF PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS – RESULTS OF THE NON-INTERVENTIONAL STUDY SUSTAIN

J. Wendler1, M. Sieburg2, E. Movshovich3, N. Damann4, F. Behrens5, 1Rheumatologische Schwerpunktklinik, Erlangen, Germany; 2Rheumatologische Facharztpraxis, Magdeburg, Germany; 3Janssen-Cilag GmbH, Neuss, Germany; 4Rheumatologie und Fraunhofer Institut IME-TMP, Frankfurt, Germany

Background: Several biologics available for the treatment of psoriatic arthritis (PsA) have demonstrated effectiveness. A major aim of the treating physician is to find the safest treatment for his patients.

Objectives: In this work we analyzed the safety of ustekinumab in the treatment of PsA in a real-world setting.

Methods: The SUSTAIN study is a prospective, multi-center non-interventional study in Germany designed to evaluate long term effectiveness and safety, quality of life, and other patient reported outcomes in patients with active PsA under treatment with ustekinumab in routine clinical care over the course of 160 weeks. Treatment with ustekinumab is according to the label recommendations. In the third interim analysis we evaluated the data of 336 included patients till week 112.

Safety was evaluated based on the following parameters: numbers of adverse events (AEs), serious AEs (SAEs), and physicians’/patients’ assessment of tolerability of treatment with ustekinumab. AEs are either reported by the subject voluntarily or are obtained by means of subject interviews at study visits. AE definitions, attribution rules, and severity criteria were pre-specified in the study protocol. All AEs/SAEs were recorded and described including information on date of onset, seriousness, severity, outcome, action taken, and relationship to treatment as evaluated by the physician. All AEs were followed to satisfactory resolution or a clinically stable endpoint.

Results: For this analysis 336 patients (57% women) at 75 centers were included. Data for key study visits were obtained for the following numbers of patients: 310 patients at week 4, 237 patients at week 40, 160 patients at week 76, and 108 patients at week 112. A total of 88 SAEs (9.0% of all reported AEs) have been documented through the data cut-off date including SAEs of...
the categories musculoskeletal and connective tissue disorders (n=21, 6.3% of all reported AEs), nervous system disorders (n=8, 2.4%), infections and infestations (n=9, 2.7%), neoplasms (n=4, 1.2%), cardiac disorders (n=7, 2.1%). Overall, 14 (1.4%) of all reported AEs of the 88 SAEs were assessed as related to ustekinumab (Table 1). AEs and SAEs lead to permanent discontinuation of treatment with ustekinumab in 119 and 11 patients, respectively. The vast majority of AEs leading to treatment discontinuation amount to ineffective drug or drug effect decrease (n=84) and psoriatic arthropathy (n=16). The most frequent SAE leading to discontinuation was psoriatic arthropathy (n=4). Tolerability of therapy with ustekinumab was assessed as “very good” or “good” by 98.7% of patients at week 76 and by 100% at week 112 (Figure 1 A). Tolerability was assessed as “very good” or “good” by 98.7% of patients at week 76 and by 100% at week 112 (Figure 1 B). Overall, the safety profile of ustekinumab in this population of psoriatic arthritis patients through week 112 was generally consistent with that demonstrated in earlier studies.

Conclusion: In this interim analysis of safety data from the non-interventional SUSTAIN study, ustekinumab was highly tolerated in the treatment of patients with active PsA in routine clinical practice through up to 112 weeks.

AB0848 IS THERE A WINDOW OF OPPORTUNITY IN EARLY PSORIATIC ARTHRITIS? RETROSPECTIVE DATA FROM A REAL LIFE SETTING

S. G. Werner1, M. Vlachou2, H. E. Langer2, R. Chatelain2. 1RHIO (Rheumatology, Immunology, Osteology) and RHIO Research Institute Düsseldorf, Düsseldorf, Germany; 2Evangelical Hospital Düsseldorf, Department of Dermatology, Faculty of Health, University of Witten-Herdecke, Düsseldorf, Germany

Background: In early rheumatoid arthritis (ERA) a window of opportunity (WoO) is well established since its first proposal in 2002 (1). ERA patients achieved a better clinical outcome when DMARD therapy was initiated within the first 12-16 weeks after start of symptoms (disease duration (Xd) (2). To the best of our knowledge, comparable data are missing for early psoriatic arthritis (EPsA), even though the benefit of tight control is known in EPsA (3,4). In contrast to ERA early PsA is usually defined as Xd<24months (3,4).

Objectives: To study in a setting of routine rheumatologic care if a WoO like in ERA also can be observed in EPsA comparable to ERA.

Methods: n=90 consecutive outpatients with definite PsA were recruited in this retrospective longitudinal cohort study with the following inclusion criteria: DMARD- and steroid-naive at the first time of visit in our outpatient clinic (t0), minimum follow-up of 3 years, classification as very early psoriatic arthritis (VEPsA, Xd≤3 months, n=30), late early psoriatic arthritis (LEPsA, > 3 Xd ≤ 12 months, n=30) and late psoriatic arthritis (LAPsA, Xd > 36 months, n=30). Standardized assessments had been performed at regular intervals of 3 months within the framework of routine rheumatologic care. Outcome at 3 years (t36) was analyzed within groups and between groups (DAS28, Physician Global Assessment (PhG), HAQ, fatigue, morning stiffness).

Results: Cohorts did not differ between gender and age (mean age 54 years). There was no significant difference in DAS28, HAQ, PhG and morning stiffness at t0. Fatigue at t0 differed between cohort 1 and 3 significantly (p<0.03). In all cohorts DAS28 and PhG have been decreased at t36 significantly (minimal p<0.006). In comparison to VEPsA LEPsA showed a significant difference in DAS28 (p<0.04) and PhG (p<0.05), but not in morning stiffness and fatigue. Highly significant differences between VEPsA and LAPsA were observed for DAS28 (p<0.007), morning stiffness (p<0.001), PhG (p<0.05) and fatigue (p<0.006) at t36.

Conclusion: Significant and relevant differences between the outcomes at 3 years of patients with VEPsA, LEPsA and LAPsA could be identified in this retrospective pilot study. Particularly the highly significant difference between VEPsA and LAPsA (<3 months vs. >36months) is remarkable. The data suggest a window of opportunity also in patients with EPsA. With a time interval of Xd<12 this window seems to be longer than in ERA. Further studies with higher number of patients were needed to confirm our findings from this real life setting.

FATIGUE IN PSORIATIC ARTHRITIS – PREVALENCE AND IMPACT IN DAILY RHEUMATOLOGIC OUTPATIENT CARE

C. B. Vigener-Buxel1, H. E. Langer2, S. G. Werner3, R. Chatelain1, 1Fakultät für Gesundheit der Universität Witten/Herdecke, Evangelisches Krankenhaus Düsseldorf, Department of Dermatology, Düsseldorf, Germany; 2RHIQ (Rheumatology, Immunology, Osteology) and RHIQ Research Institute, Düsseldorf, Düsseldorf, Germany.

Background: Fatigue is a major problem in various rheumatic diseases. Only a few studies so far have focused on the occurrence of fatigue in psoriatic arthritis (PsA) (1).

Objectives: The aim of this study was to explore the prevalence and impact of fatigue in patients with PsA and its potentially association with disease activity in daily routine rheumatologic care.

Methods: 105 consecutive outpatients with definitive PsA (mean age 62 years, mean disease duration 8 years) were included in this prospective study. Patients received a clinical examination and laboratory tests. Furthermore, following assessments were used: assessment of disease activity (patient (PG) and physician global (PhG)), NRS, 0-10, DAS28, CDAI, pain (NRS, 0-10), HAQ, SF-36, fatigue (NRS (0-10) and Chalder Fatigue Scale (CFS); bimodal: 0-3 no fatigue, 4-11 fatigue; Likert scale: 0-3 no fatigue, 4-33 fatigue, 19-33 severe fatigue/surgeon global (PhG), NRS, 0-10), DAS28, CDAI, pain (NRS, 0-10), HAQ, SF-36, fatigue strongly correlated with the PG (r=0.72) as well as with DAS28 

Results: In the CFS questionnaire 56/105 patients (53%) were classified as fatigue cases (bimodal score >4). 22/105 (21%) suffered from severe fatigue/ chronic fatigue syndrome (score >19, Likert scale). Mean fatigue was 14.9 (CFS, Likert Scale) and 4.5 (NRS). In n=47 (45%) patients fatigue was pre-

Conclusion: Our results show that fatigue is a major problem in PsA with rele-

Conclusion: Patients with psoriatic arthritis have a higher cardiovascular risk, as proven by the increased cIMT found on carotid ultrasound results. Therefore, it is advisable to perform a carotid ultrasound in patients with PsA to achieve an optimal management of the disease. The rheumatologist must be aware of the importance of performing a complete cardiovascular evaluation to provide a correct treatment in order to lower possible cardiac events.

Garza Acosta1, Hospital Universitario “Dr. José Eleuterio González” UANL, Rheumatology, Monterrey, Mexico; 2Hospital Universitario “Dr. José Eleuterio González” UANL, Cardiology, Monterrey, Mexico; 3Hospital Universitario “Dr. José Eleuterio González” UANL, Radiology, Monterrey, Mexico

Background: Patients with psoriatic arthritis (PsA) have an increased risk of cardiovascular disease (CVD). The carotid ultrasound, which measures both carotid intima-media thickness (cIMT) and carotid plaque (CP), is a non-invasive tool useful in the detection of subclinical atherosclerosis. However, carotid ultrasound differences between PsA patients and general population have not yet been well described.

Objectives: This study aimed to compare the carotid ultrasound characteristics in PsA patients with controls.

Methods: This cross-sectional study included 70 PsA patients that fulfilled the CASPAR (Classification Criteria for Psoriatic Arthritis) criteria and 70 controls subjects matched by age and comorbidities. Patients with a history of previous atherosclerotic CVD (ischemic heart disease, cerebrovascular accident or peripheral arterial disease) and pregnancy were excluded. A clinical history and blood tests were performed. Carotid B-mode ultrasonography was used for measurements of cIMT and the presence of plaques. Increased cIMT was defined as ≥0.9mm to 1.1mm. CP was defined as a focal narrowing ≥0.5mm of the surrounding lumen or a ≥1.2mm. Descriptive analysis was done with frequencies (%), mean (±SD) and median (q25-q75), and comparisons with Chi square, Student’s t and Mann-Whitney U tests.

Results: A total of 138 subjects were included. Clinical and demographic characteristics are shown in Table 1. Increased cIMT and right carotid plaque were significantly more prevalent in PsA patients compared to controls (p=0.017 and p=0.001, respectively). No significant differences were found in the prevalence of carotid plaque and in the intima-media thickness between the PsA patients and the control group.

A. K. Aggarwal1, N. Aggarwal1, D. Jain1, Institute of Rheumatology and Pain, Brij Medical Centre, Rheumatology & Pain, Ghaziabad, India

Background: Knee osteoarthritis (OA) is a progressive degenerative condition resulting in functional loss besides pain and discomfort.[1] The aim of treatment as of today should be joint preservation in order to prevent surgery, alleviation of symptoms and improvement of functions.

Viscosupplementation (VES) with Intra-articular hyaluronic acid (IAHA) injections has been shown to have protective physiochemical functions and may confer disease-modifying, long term effects on the articular cartilage.[2][3] However, ever conflicting guidelines, availability of multiple varieties, and absence of good studies or any treatment protocol has resulted in lack of confidence of the results of IAHA.

Objectives: To determine the long term effectiveness of VES with various types of IAHA in OA in maintaining functional improvement of the knees and the duration of effect of first and repeat injections of VES.

Methods: From the 15 year retrospective longitudinal study of data of VES with different types of IAHA in our Centre, we evaluated the following outcomes:

1. The WOMAC scores were regularly done on each visit of the study group. Those with maintained improvement in the WOMAC total score were followed and reinjected when the scores started decreasing.
2. All patients who were given Non Animal Source Hyaluronic Acid (NASHA) were included in the study. Patients with repeat IAHA were further evaluated for Type of NASHA used and were categorized into 2 groups accordingly:
   a. Those with High Molecular weight Hyaluronic Acid (HMW-HA) 6-8mg/ml – 6ml single injections
   b. Those with Very High Molecular weight, Cross linked Hyaluronic acid (VHMW-HA) 20-40mg/ml – 3ml injections

Results: The total number of patients treated over the last 15 years was 1206 with 689 having Kelgren and Lawrence (KL) Grade III OA, and 517 KL Grade IV OA. The data showing distribution of type of IAHA used in the group, the average Gap between the injections with the Range in years for the least gap and the longest gap between the injections, along with the follow up to giving the 3rd injection was given in summarized in Chart 1: Time gap between repeat IAHL injections in OA knees.

IMPACT OF ULTRASONOGRAPHY-DETECTED PES ANSERINE BURSITIS ON PAIN AND FUNCTION IN PATIENTS WITH PRIMARY KNEE OSTEOARTHRITIS

M. A. Mortada1, Y. A. Amer1, R. Zaghlol1. Zagazig University - Faculty of Medicine, Rheumatology, Zagazig, Egypt

Background: Pes anserine bursitis (PAB) is one of the most common causes of knee pain. Hence, this study aimed to compare the pain and function among all primary knee osteoarthritis (KOA) patients with or without ultrasonic-detected PAB and the associated clinical and radiological findings.

Objectives: To compare pain, function, and clinical and radiological findings among primary KOA patients with or without ultrasonic-detected PAB.

Methods: A single-center cross-sectional study was conducted on 245 patients with primary KOA. Patients with more symptomatic knee examined by musculoskeletal ultrasound (MSUS), then according to the presence or absence of PAB, the patients were categorized into two groups. To differentiate between grades of inflammation of PAB on ultrasonography, the authors developed a semi-quantitative scale (0–2) as follows: Grade 0, normal hyper-echic picture of pes anserine tendons without tendonitis or bursitis; Grade 1, mild hypoechogenicity and/or mild swelling or mild loss of fibrillar pattern of the pes anserine tendons and/or mild anechoic effusion related to the tendons; and Grade 2, marked hypoechogenicity and/or large swelling or marked loss of fibrillar pattern of the pes anserine tendons without tendonitis or bursitis.

Results: Of 110 (44.9%) patients were diagnosed with PAB where 91 (82.7%) of them had Grade 1 and only 19 (17.3%) had Grade 2. The presence of PAB was statistically significant related (P < 0.05) with age, BMI, VAS-II, WOMAC subscales, synovitis, and radiographic Grades 3 and 4. However, there was no statistically significant difference (P ≥ 0.05) between KOA patients without PAB and KOA patients with PAB, regarding sex, body mass index, baker cyst, and effusion.

Conclusion: The presence of PAB on USG is associated with increased pain and disability in KOA. MSUS should be more widely used to establish the association between PAB and symptom severity and disability among KOA patients.

METABOLIC FACTORS ASSOCIATED TO CLINICAL HAND OSTEOARTHRITIS IN INDIVIDUALS WITH KNEE PAIN

M. Andersson1,2, E. Haglund3,4, K. All4,5, A. Bremander3,5,7, S. Bergman3,8

1Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden; 2Halmstad University, School of Business, Engineering and Science, Halmstad, Sweden; 3Svenskt hushålls- och forskningscentrum, Halmstad, Sweden; 4School of Health and Welfare, Halmstad, Sweden; 5University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 6The Sahlgrenska Academy, University of Gothenburg, Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden

Background: There is some evidence supporting associations between metabolic factors, clinical hand osteoarthritis (OA) and radiographic knee OA. However, more studies are needed regarding early knee OA.

Objectives: The aim was to study associations between metabolic factors and clinical hand OA at baseline in a cohort of individuals with knee pain, with and without radiographic knee OA.

Methods: In an ongoing five-year longitudinal study of knee pain, hand OA was assessed by clinical examinations in 296 of the included individuals at baseline [1]. BMI, waist circumference (WC) and blood pressure was measured. Body composition was assessed with Inbody 770. Fasting plasma glucose, triglycerides, cholesterol, LDL-cholesterol and HbA1c was analysed. Metabolic syndrome (MetS) was present if central obesity (WC ≥ 84 cm in men and ≥ 80 cm in women) plus any two of the following factors: raised blood pressure (systolic blood pressure ≥ 130 or diastolic blood pressure ≥ 85 mm Hg or treatment of hypertension), raised triglycerides (≥ 1.7 mmol/L or specific treatment), reduced HDL-cholesterol (men ≤ 1.30 mmol/L and women ≤ 1.29 mmol/L or specific treatment), raised glucose (glucose ≥ 5.6 mmol/L, or type 2 diabetes). Hand strength and self-reported disability of the arm, shoulder and hand (QuickDASH) was assessed.

The individuals were divided according to having clinical hand OA or not, according to Altman [1]. The associations between background factors and clinical hand OA were calculated by crude logistic regression analyses, adjusting for age and sex.

Results: Fifty-five percent of the individuals in the study was overweight or obese, 40% had MetS and 23% had radiographic knee OA. In total 34% of the individuals had clinical hand OA. The group with hand OA were older, had higher proportion of body fat, fasting plasma glucose, HbA1c, worse QuickDASH score and lower hand strength. Table 1. Clinical hand OA was significantly associated to higher age (OR 1.04, 95%CI 1.01-1.07), higher fasting plasma glucose (1.56, 1.05-2.30), worse QuickDASH (1.04, 1.02-1.06) and lower hand strength (0.99, 0.99 –0.998), but not to proportion of body fat and HbA1c.

AB0555  THE “HORSE SADDLE” SIGN: A NEW ULTRASOUND SIGN FOR OSTEOARTHRITIS

G. Añez1, E. Trallero1, A. Erra1, M. Barceló-Bru1, M. Lopez Lasanta1, J. J. De Agustín1, 1Vall d’Hebron University Hospital, Rheumatology, Barcelona, Spain

Background: Hand Osteoarthritis is one of the most prevalent rheumatic diseases that can give early visible findings by ultrasound where synovial hypertrophy, effusion, osteophytes and articular cartilage decrease stand out. However, these findings, although sensitive, may not be very specific since they are also observed in inflammatory arthritis. Throughout our clinical practice in osteoarthritis, we have seen, over repeated examinations, an specific morphological change of bone not previously described in the literature. It is a bone extension in the head of the phalanx of the finger joints that causes a deformity that we have called “horse saddle” and that is typically located in the proximal and distal interphalangeal joints of the fingers. This sign can be seen in the longitudinal exploration of the palm of the hand by grayscale ultrasound. This sign that we have not found specifically described in the literature reviewed to date is considered to be useful for the diagnosis of osteoarthritis.

Objectives: To Assess the sensitivity and specificity of the “horse saddle” sign in the diagnosis of osteoarthritis.

Methods: An exploratory clinical comparative cross-sectional study where an ultrasound of the hands and comparative radiographs in PA view were performed on patients with osteoarthritis, inflammatory arthritis and healthy people. The ultrasound was done in the Rheumatology clinic of the Vall de Hebron Hospital. Age, sex and time of evolution of the disease were collected as clinical variables. The MCP, PIP and DIP joints from the second to the fifth finger of both hands were viewed with grayscale in longitudinal and transverse plane of both the dorsal and palmar face, assessing for osteophytes, synovitis and the horse saddle sign. A General Electric Logiq S8 machine was used with an 8-13 MHz linear probe. All patients signed an informed consent and approval was obtained from the hospital ethics committee. The statistical analysis was carried out with Stata 15.1.

Results: A total of 38 patients with osteoarthritis, 20 patients with inflammatory arthritis (8 psoriatic, 9 RA, 1 LES, 1 PMR and 1 Sjögren) and 2 healthy patients were assessed. It was found that the horse saddle sign had a sensitivity of 66.7% and specificity of 86.4% in osteoarthritis showing a p-value of 0.052 by means of the chi-square test. 87% of patients with the horse saddle sign had osteoarthritis and only in 2 patients with RA and in the patient with LES. In contrast for osteoarthritics a sensitivity of 100% was observed with a specificity of 45.45% (p of 0.001) for synovitis a sensitivity of 53.3% and specificity of 77.27% was observed with p of 0.039.

Conclusion: The horse saddle sign is an ultrasound sign with good sensitivity and specificity for the diagnosis of hand osteoarthritis comparable to other classic ultrasound signs such as osteophytes and synovitis.

AB0566  A PLACEBO-CONTROLLED, DOUBLE-BLIND, RANDOMIZED, TRIAL OF AMZ001 – A NOVEL DICOLOFENAC SODIUM 3.06% GEL – FOR THE TREATMENT OF KNEE OSTEOARTHRITIS SYMPTOMS

A. Bjilah1, I. Byrlaßen1, H. B. Nielsen2, J. Andersen1, L. Delpy3, C. Deme4, D. Carrara5, 1Nordic Bioscience Clinical Development, Herlev, Denmark; 2Sanos Clinic, Herlev, Denmark; 3Amzell BV, Hoofddorp, Netherlands

Background: Development of improved topical treatments of painful joints is warranted. A novel diclofenac sodium gel formulation, AMZ001, has been developed with the purpose of improving 1) The onset and duration of pain relief, and 2) The ease of use by reducing the required daily frequency of gel application. Previous trials in human subjects have confirmed improved permeability of a reduced volume of AMZ001 gel as compared to approved diclofenac topical products with a comparable safety and tolerability profile, supporting trials to evaluate the efficacy and safety of AMZ001 in painful joint conditions.

Objectives: The current abstract reports the main results of a randomized trial of AMZ001 once or twice daily application versus placebo in symptomatic knee osteoarthritits.

Methods: The trial was a placebo-controlled, parallel group, double-blind, randomized trial to evaluate the efficacy and safety of AMZ001 or placebo in subjects with knee osteoarthritis. The main inclusion criteria were Kellgren-Lawrence radiographic severity of 1-3, and pain ≥40 and ≤90 out of 100 using the WOMAC pain subscale (5 questions) at the time of screening. The subjects were randomized to apply AMZ001 gel once (QD) or twice (BID) daily or placebo twice daily per OA knee for a period of 28 days, or to apply Voltaren® Gel 1 % four times daily (QID) in a single-blind fashion for exploratory comparison. The primary endpoint was change from baseline at week 4 in WOMAC pain (5 questions). The main secondary endpoints included WOMAC subscales, Patient Global Assessment (PGA) and quality of life using the EQ-5D. In addition to the main analysis, a post-hoc subgroup analysis of subjects meeting the pain criterion at both screening and baseline was performed.

Results: A total of 444 subjects were randomized. The main baseline characteristics were well balanced between treatment groups. AMZ001 QD and BID led to statistically significant reductions in pain compared to baseline with an estimated difference (95% CI) normalized to 0-100 at week 4 of -27.33 (-30.50, -24.17), and -26.49 (-29.60, -23.38), respectively. Reduction in pain at week 4 was statistically significantly superior to placebo for AMZ001 QD (p=0.04), and borderline significant for AMZ001 BID (p<0.10) as shown in Figure 1.

Both AMZ001 QD and BID led to statistically significant improvements in PGA at week 4 compared to placebo (p<0.05 for both), and AMZ001 BID led to significantly improved quality of life (p<0.05) compared to placebo. There were no statistically significant differences between AMZ001 QD or BID in any of the end-points. In the post-hoc analysis of subjects meeting the pain criterion at both screening and baseline the differentiation to placebo was strengthened for all efficacy end-points, as shown in Figure 2.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.1735
While the study design and differences in sample sizes does not allow formal comparisons between the double- and single blinded groups, the exploratory comparator, Voltaren OID, did not reach statistically significant differences to placebo or AMZ001 in any of the endpoints, in neither the ITT nor the subgroup analyses. The safety and tolerability of AMZ001 was favorable, as the frequency of AEs leading to discontinuation of treatment was similarly low (ranging between 2.8 % to 6.6 %) between AMZ001 once or twice daily and placebo or Voltaren Gel 1%. The most common treatment-emergent AEs were application site dryness, and application site erythema. No serious adverse events were reported during the trial.

Conclusion: AMZ001, a novel topical diclofenac formulation, either once or twice daily was efficacious in the treatment of knee OA pain with a good tolerability and safety profile, suggesting AMZ001 may be a promising alternative to existing pain-relieving treatments in knee OA.

**A NEW BIOPSYCHOSOCIAL QUESTIONNAIRE FOR PATIENTS WITH KNEE OSTEOARTHRITIS**

Z. I. Bulut1, E. Uenal2, A. Dogru3, Y. Yakut4, 1Hasan Kalyoncu University, Gaziantep, Turkey; 1Hacettepe University, Ankara, Turkey; 2Suleyman Demirel University, Isparta, Turkey

**Background:** OA is a problem that cartilage damage occurs, which leads to stiffness in the joint, pain and functional limitations (1). This problem can also cause psychosocial impact like other chronic diseases (2). As with other rheumatic diseases, this complex picture of inflammation required biopsychosocial approaches and measurement methods for knee OA.

**Objectives:** This study was planned to investigate the validity and reliability of a new biopsychosocial questionnaire which is named Cognitive Exercise Therapy Approach Biopsychosocial Questionnaire (BETY-BQ) in individuals with knee osteoarthritis (OA).

**Methods:** The study included 150 individuals who diagnosed knee osteoarthritis at stage 1 or 2 according to the Kellgren-Lawrence scale. For determining daily living activities; Health Assessment Questionnaire (HAQ), for quality of life Short Form-36 (SF-36) Quality of Life Scale, for anxiety and depression levels; Hospital Anxiety and Depression Scale (HADS), for severity of disease Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and for biopsychosocial evaluation BETY-BQ were used.

**Results:** The correlation between BETY-BQ and other scales was examined by Spearman correlation analysis (r=0.252, 0.633, p<0.05), Cronbach’s alpha coefficient and item-total correlation were used as reliability methods. Cronbach's alpha coefficient was examined for the internal consistency of the scale and was found to be 0.887 for the first evaluation, 0.917 for measurements after 1 week and 0.843 for measurements after 3 months. Item total correlation, which was another indicator of reliability, ranged from 0.632 to 0.854 (p<0.05).

**Table 1. Correlation coefficients among all questionnaires and Cognitive Exercise Therapy Approach Biopsychosocial Questionnaire (BETY-BQ).**

| Cognitive Exercise Therapy Approach Biopsychosocial Questionnaire (BETY-BQ) |
|---------------------------|-----------------|----------------|----------------|
|                           | WOMAC-Pain      | WOMAC-Physical Function | WOMAC-Total Score |
|                           | 0.473 <0.001    | 0.514 <0.001           | 0.550 <0.001     |
|                          | hospital anxiety | depression           | scale anxiety    |
|                           | 0.615 <0.001    | 0.252 0.022          | -0.252 <0.001   |
|                           | hospital anxiety | depression           | -0.252 <0.001   |
|                           | -0.440 <0.001   | -0.357 <0.001        | -0.357 <0.001   |

**Conclusion:** As a result of our study, it was concluded that BETY-BQ is a valid and reliable biopsychosocial questionnaire in individuals with knee OA diagnosis. This result showed that BETY-BQ can be used in clinics to evaluate biopsychosocial involvement in patients with knee OA.

**AB0855 TREATMENT ALGORITHM FOR ANKLE OSTEOCHONDRAL LESIONS AND DEFECTS**

O. Burianov1, L. Khimion2, T. Omelchenko1, E. Levitkys3, V. Lyanskonysky3, 1Bogomolets National Medical University, Traumatology and Orthopedics, Kyiv, Ukraine; 2Shupyk National Medical Academy of Postgraduate Education, Family Medicine, Kyiv, Ukraine

**Background:** Traumatic ankle joint osteochondral lesions and defects (OHLD) is frequent cause of OA, chronic pain and loss of joint function; results of traditional treatment strategy are often unsatisfying.

**Objectives:** To develop treatment algorithm for OHLD based on evaluation of previously determined main prognostic factors.

**Methods:** The analysis of long-term (36 ± 4.5 months) treatment results of 239 patients after traumatic ankle joint OHLD revealed the following factors with the greatest predictive value (defined by PC – prognostic coefficient) for good result of treatment (defined as AOFAS function score 75-100 points): age < 40 years (PC = 8.5); size of OHLD ≤ 10.0 cm²; volume ≤ 1.5 cm³ (PC = 8.0); osteoarthritic stage ≤ II (PC = 7.2). Based on these factors, a step-by-step, discrete and alternative algorithm for the choice of treatment tactics was created. The algorithm includes use of arthroscopic or open debridement, abrasive chondroplasty, bone marrow regeneration stimulation (microfracturing or tunneling), mosaic osteochondroplasty, arthroplasty or arthrodesis, the use of cellular regenerative technologies (bone marrow cells, platelet riched plasma), and others. Patients of older age with advanced OA need complex, step up approach, surgical treatment combined with regenerative cell technologies. The effectiveness of the differentiated approach to treatment was studied in 72 patients with OHLD (main group) in comparing to 72 patients in whom traditional treatment approaches were used, based on the stage of injury according to the Berndt & Hardy classification (comparison group).

**Results:** Compared to the traditional approach, the developed algorithm and treatment system allowed to half terms of hospitalization, to reduce the intensity of pain syndrome (by NRS) and increase the functional activity (by AOFAS) by 25%. In 3 years after trauma good/excellent results of treatment demonstrated 86% patients of main group and 32.2% of patients from comparing group.

**Conclusion:** Implementation of the developed treatment algorithm increases the number of good and excellent long-term results by 2.6 times and reduces the number of complications and unsatisfactory results by 4.9 times.

**IMPROVEMENTS IN PHYSICAL FUNCTION IN PATIENTS WITH OSTEOARTHRITIS RECEIVING SUBCUTANEOUS TANEZUMAB IN 3 RANDOMIZED CONTROLLED TRIALS**

S. P. Stanos1, W. J. Chang1, C. Hultman2, M. Sadrahari3, T. Yamabe1, P. Park3, 1Swedish Pain Services, Swedish Health System, Seattle, United States of America; 2Eli Lilly and Co., Indianapolis, United States of America; 3Pfizer Inc., New York, United States of America; 4Pfizer Inc., Groton, United States of America

**Background:** Tanezumab, a monoclonal antibody against nerve growth factor, is in development for the treatment of the signs and symptoms of osteoarthritis (OA).

**Objectives:** To assess the improvement in physical function following treatment with subcutaneous (SC) tanezumab in three Phase 3 OA studies.

**Methods:** All three randomized, double-blind, controlled studies enrolled patients (pts) with radiographically-confirmed OA of the hip or knee, who had inadequate response or could not tolerate standard of care analgesics. Study 1 was a dose-titration study (NCT02697773), where pts received two SC doses of: placebo at baseline/week (wk) 8; tanezumab 2.5 mg at baseline/wk 8; or...
tanezumab 2.5 mg at baseline/5 mg at wk 8. In Study 2 (NCT02709486), pts received three SC doses of placebo, tanezumab 2.5 mg, or 5 mg (at baseline/wk 8/wk 16). In Study 3 (NCT02528188), pts received a stable dose of nonsteroidal anti-inflammatory drugs (NSAIDs) before randomization to double-blind tanezumab 2.5 mg or 5 mg (at baseline and every 8 wk during a 56 wk treatment period) or twice daily oral NSAIDs. Pts completed Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Physical Function subscale questionnaires in clinic. The least squares (LS) mean (standard error (SE)) change from baseline was calculated for each timepoint up to wk 16 and significance was calculated versus placebo (Studies 1 and 2) or NSAID (Study 3).

Results: A total of 4541 pts were evaluated (n=696 in Study 1, n=849 in Study 2 and n=2996 in Study 3). In Studies 1 and 2, there were statistically significant improvements from baseline for all tanezumab treated groups versus placebo at wks 2, 4, 8, 12 and 16 (Table 1). In Study 3, the tanezumab 2.5 mg group showed a significant improvement from baseline at wk 2, compared with the NSAID group (Table 2). At wk 4, both tanezumab treatment groups showed a significant improvement from baseline compared with the NSAID group (Table 2). The tanezumab 5 mg group showed a significant improvement from baseline compared with the NSAID group at wks 8 and 16 (Table 2).

Conclusion: Consistent improvements in WOMAC Physical Function were seen across the first 16 wks for all dose groups of tanezumab-treated pts versus placebo in Study 1 and 2. The tanezumab 5 mg group in Study 3 showed a significant improvement at wks 4, 8 and 16 compared with the NSAID group. Improving physical function could help OA pts attain treatment goals beyond pain relief, improving their ability to perform important daily activities.

CURRENT PHARMACOTHERAPY FOR KNEE OSTEOARTHRITIS: SPECIFIC FEATURES OF SYMPTOMATIC AND DISEASE MODIFYING EFFECTS

L. Denisov1, E. Tsvetkova, N. Ionuchenok, A. Lilia, IVA. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Objectives: to study the specific features of the symptomatic effect and tolerability of paracetamol (P), glucosamine sulfate (GS), chondroitin sulfate (CS), and meloxicam (M) in patients with knee osteoarthritis (OA).

Methods: An 18-month open-label randomized prospective parallel-group trial enrolled 80 patients with knee OA who fulfilled the American College of Rheumatology criteria and signed the informed consent. They had Kellgren and Lawrence grades I-III OA with visual analogue scale pain intensity of >40mm in the target knee, a body mass index of <35kg/m², and no clinical dysfunctions of vital organs and systems. The patients were randomized into 4 groups: 1) P 2g daily; 2) a standard GS regimen; 3) a standard CS regimen; 4) M 15mg daily. The patients were followed up for 18 months. The effectiveness was evaluated by the WOMAC questionnaire, Lequesne index, and OMERACT-OARSI (D scenario) during 8 visits. Laboratory and clinical examination as well as electrocardiography were performed. Adverse events were recorded during each visit.

Results: After 4 weeks of treatment, symptomatic improvement was noted in all groups; however, the best effect was achieved by the use of M and continued to the end of the study. The percentage of patients reacting to the therapy by the OMERACT-OARSI criteria was highest in M group (100%), reached 90% in GS, 85% in CS groups and 75% in P group. In the groups of P, GS and CS failed to respond to treatment 25, 10, and 15% correspondingly. However, medium narrowing of articular space (NAS) was measured at the end of the study and was significantly lower in GS group (-0.07; p=0.0002), CS (-0.1; p=0.004) and M (-0.06; p=0.006). Besides, the quota of patients without heavy NAS (>0.5mm in medial KJ) was the lowest in GS group compared with three other groups.

Conclusion: The results of this trial suggest that it is expedient to use GS, CS and M long, support the recent guidelines of the European Society for Clinical and Economic aspects of Osteoporosis and OA (ESCEO), and can give proofs of the efficiency and safety of GS, CS, and M used in the treatment of knee OA.

AB0862 CONSENSUS STATEMENT ON INTRA-ARTICULAR INJECTIONS OF PLATELET-RICH PLASMA FOR THE MANAGEMENT OF KNEE OSTEOARTHRITIS

F. Eymard1, P. Ornetti1, J. Maillet3, E. Noel4, P. Adam5, V. Grémeaux Bader9, J. F. Kaux10, K. Louati11

Background: Osteoarthritis (OA) is a leading cause of disability worldwide and pain is its cardinal symptom. Ranging from structural injuries to central sensitization, multifactorial mechanisms play an important role in pain perception in patients with knee OA (KO) defining a discrepancy between pain and structural damage. Imaging modalities such as radiography and musculoskeletal ultrasound may assess those structural findings and both are well embedded in routine clinical practice. However, their association with pain severity is poorly studied.

Objectives: To evaluate the place of X-ray- and ultrasound-derived parameters of structural damage for pain perception in knee osteoarthritis patients.

Methods: Sixty-four knees from 38 patients with KOA fulfilling the ACR criteria were assessed. The pain severity was evaluated in all knees by 100-millimeters (mm) visual analogue scale (VAS). Anteroposterior radiographs of the fully extended knees in an upright weight-bearing position were obtained and images were evaluated according to the Kellgren-Lawrence (KL) and OARSI atlas. All patients were investigated with a portable MyLab 25 Gold system equipped with an LA435 transducer (Esaote SpA, Genoa, Italy) by two experienced ultrasonographers. The presence or absence of synovial thickening, effusion in the suprapatellar bursa, and popliteal cyst were assessed. Medial meniscal extrusion and medial and lateral femoral cartilage thickness (medial and lateral) were measured in mm in full extension and flexion position, respectively. Femoral osteophytes were semi-quantitatively scored using a scale consisted of four grades (0-3).

Results: The levels of pain differed significantly in the KL groups (p = .001) and in the groups classified according to the medial/biblomeral compartment narrowing defined in line with the OARSI atlas (p = .005). The other knee osteoarthritis radiographic characteristics derived from the OARSI atlas did not correlate with the pain. From the assessed ultrasound parameters, medial
meniscal extrusion and medial femoral cartilage showed a weak correlation with pain levels (r = .254, p = .043; r = -.265, p = 0.034, respectively). Nevertheless, in the multivariate analysis after adjusting for age and BMI, both variables did not reach significance for explaining the differences in VAS levels. No association between the presence of synovial effusion and popliteal cyst and pain severity was found.

Conclusion: Plain radiography and ultrasonography reflect different structural changes in osteoarthritis that may play an important role in pain perception. Both imaging modalities can complement each other in order to improve the evaluation of the patient with KOA.

DO CORTICOSTEROIDS AND HYALURONIC ACID INJECTIONS CAUSE INFECTIONS? A SYSTEMATIC REVIEW OF LITERATURE ON ADVERSE EFFECTS AND INFECTION RATES OF INTRA-ARTICULAR CORTICOSTEROID AND HYALURONIC ACID INJECTIONS IN PATIENTS WITH KNEE OSTEOARTHRITIS

C. Hatzeantoni1, 1Luton and Dunstable Hospital, Trauma and Orthopaedics, Luton, United Kingdom

Background: Knee osteoarthritis has been a leading cause of chronic pain and disability in our increasingly aging population. Conservative management options of physiotherapy and oral analgesics offer some relief, but delivery of intra-articular injections such as corticosteroids or hyaluronic acid has increasingly become the mainstay of pain management of knee osteoarthritis. In a clinical setting, intra-articular injections offer a means to delay a total knee replacement. Despite the abundance of literature on corticosteroids and hyaluronic acid, there is no known percentage of infection rates or adverse effects that clinicians may use to inform patients prior to obtaining consent for the injection.

Objectives: To determine a rate of adverse events and infection rates in patients undergoing intra-articular injections of corticosteroids or hyaluronic acid.

Methods: A systematic review of current literature including studies involving patients ranging from 45 patients (Carmona L, 2018) to Cochrane reviews of 1767 patients (Campbell Kirk, 2015). From these studies, the number of patients, adverse reactions (i.e. pain, erythema) and serious adverse reactions (infections) were calculated.

Results: Within our study, there was a large variation of numbers of adverse effects of hyaluronic acid and corticosteroids amongst studies, with percentages as variable as 0-9.3%. Corticosteroids demonstrated 11-26% reduction of adverse events compared to hyaluronic acid. However, confidence intervals were found to not be statistically significant.

Conclusion: Intra-articular injections of corticosteroids and hyaluronic acid, although deemed clinically effective, continue to demonstrate variable rates of adverse effects and infection amongst patients with progressive knee osteoarthritis.

EPIDURITIS IN INFECTIOUS SPONDYLODISCITIS

J. Mahboub1, 1O. Jomaas2, 1S. Zrou3, 1I. Beija4, 1M. Touzi5, 1N. Bergaoui6on behalf of Rheumatology Department. 1Hospital Fattouma Bourguiba, Rheumatology Department, Monastir Tunisia

Background: The main problem with infectious spondylodiscitis (ISD) is the diagnosis difficulty. Tuberculosis, with deceptive clinical rheumatology, remains to date the most common cause in underdeveloped and developing countries.

Objectives: To report the frequency and characteristics of epiduritis in ISD and to specify its short and medium-term impact through a series of 70 cases.

Methods: A descriptive retrospective study was conducted including patients with ISD, hospitalized in the rheumatology department at Fattouma Bourguiba Hospital, Monastir Tunisia between January 2009 and August 2019. Socio-demographic, clinico biological and radiological data were collected.

Results: 34 male and 36 female were included. The average age was 53.91 ±15.3 years. The mean time to visit was 80.3±89 days [4,520]. Co-morbidity was noted in 66.7% of patients: diabetes (22%), hypertension (18%), hemodialysis (8), heart disease (4), and long term corticosteroid therapy (4). Tuberculosis contagion was present in 72% of patients. The most frequent reason for consultation was low back pain (63.8%) with a root syndrome in most patients (>50%). Neurological abnormalities were noted in 8.7% of patients. Skin swelling was noted in 4.3% of patients. Biological inflammatory syndrome and hyperleukocytosis were the most biological abnormalities reported respectively in 81.2% and 30.4% of patients. Among 70 ISD: 29 were with common germ, 18 with tuberculosis, 8 with brucellosis, and 14 with an undetermined germ. 91.3% of patients underwent a spinal magnetic resonance imaging (MRI): epiduritis was documented in 72% of cases, frequently anterior (53%). The epidural abscesses association was noted in 33 patients. It was pronounced mostly at the lumbar (19) and dorsal (14) levels. Epiduritis was frequently associated with para-vertebral soft tissues infiltration: pre-vertebral thickening (32), pre-vertebral collection (17), pus intra muscle abscesses, (13). Spinal cord compression was noted in 2 patients. On 3-month visit, the ISD associated with epiduritis evolution was characterized by persistence of pain, hence radiological control was justifled in 6 patients. A persistent biological inflammatory syndrome was noted in 27% of cases. Furthermore, 2 deaths were observed in this group of patients.

Conclusion: Epiduritis rate in ISD requires a well-coded diagnostic and therapeutic strategy that will consider carefully the neurological prognosis involved.

THE PREVALENCE AND CLINICAL FEATURES OF FRAILTY SYNDROME IN PATIENTS WITH SYMPTOMATIC RADIOGRAPHIC KNEE OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS: A STUDY OF THE KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (KNHANES)

S. H. Joo1, 2, J. Lee2, 2Y. W. Song1, 1College of Medicine, Pusan National University, Department of Microbiology and Immunology, Yangsan, Korea, Rep. of (South Korea); 2Baeckseodaehospital, Department of Internal Medicine, Yangsan, Korea, Rep. of (South Korea); 3Inha University Hospital, Prevention and Management Center, Incheon, Korea, Rep. of (South Korea); 4Seoul National University Hospital, Seoul, Korea, Rep. of (South Korea); 5Graduate School of Convergence Science and Technology, and College of Medicine, Medical Research Center, Seoul National University, Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul, Korea, Rep. of (South Korea)

Background: Frailty is defined as syndrome of physical decline in late life, characterized by marked vulnerability to adverse health outcomes. Knee osteoarthritis (OA) could be one of the major diseases related to frailty conditions. The prevalence and clinical features of frailty syndrome in knee OA and rheumatoid arthritis (RA) were not reported previously.

Objectives: We studied the clinical features and nutritional status of knee OA and RA patients with frailty syndrome in nationwide survey data.

Methods: Symptomatic knee osteoarthritis patients were defined who had knee joint pain accompanied with grade 2 or more Kellgren-Lawrence score in plain radiographic studies from the data of KNHANES (N=17,873, from 2010 to 2013). RA was defined who diagnosed by physician. We calculated the frailty index (score 0-1) using 46 items from the frailty related co-morbidities and laboratory abnormalities according to Rockwood clinical frailty scale. We analyzed the clinical features of three frailty groups [robust (≤0.10), pre-frail (0.1 < ≤0.21), and frail (>0.21)] in symptomatic radiographic knee OA patients and RA patients.

Results: The prevalence of Knee OA patients was 8.59% [95% CI: 8.19-9.01]. Relative risk ratio is significantly increased in pre-frail (OA: 2.66 [2.26-3.14], RA:4.02 [3.07-5.27]) and frail group (OA: 6.27 [5.20-7.57], RA:7.00[5.03-9.74]) in polytomous logistic regression. Body mass index (BMI), white blood cell, platelet, and serum creatinine were significantly increased in knee OA and RA patients with frailty syndrome. But, hemoglobin, estimated GFR (ISCD-EPI equation) and EQ-5D were significantly decreased in knee OA and RA patients with frailty syndrome (Table). The daily nutritional intakes of total calories, carbohydrate, protein, fat, sodium and potassium were significantly decreased in knee OA patients with the frailty syndrome. In RA patients, the significant decreased nutritional intakes of total calories, carbohydrate, protein, and fat were observed.

Conclusion: We showed increased BMI, decreased renal function and lower nutritional status in symptomatic radiographic knee OA and RA patients with frailty syndrome.

INCREASED ADIPONECTIN LEVELS ARE ASSOCIATED WITH HIGHER RADIOGRAPHIC SCORES IN THE KNEE JOINT, BUT NOT IN THE HAND JOINT: THE DONG-GU STUDY

J. H. Kang¹, S. E. Choi², H. Xu³, D. J. Park¹, S. S. Lee¹. Chonnam National University Medical School & Hospital, Gwangju, Korea, Rep. of (South Korea)

Background: Several studies have evaluated the association between serum adiponectin levels and knee and hand osteoarthritis (OA), with mixed results.

Objectives: The aim of this study was to investigate the relationship between OA and serum adiponectin levels according to the radiographic features of knee and hand OA.

Methods: A total of 2,402 subjects were recruited from the Dong-gu Study. Base-line characteristics were collected via a questionnaire, and X-rays of knee and hand joints were scored by a semi-quantitative grading system. The relationship between serum adiponectin levels and radiographic severity was evaluated by linear regression analysis.

Results: Subjects with higher tertiles of serum adiponectin were older and had a lower body mass index than those with lower tertiles. In the knee joint scores, serum adiponectin levels were positively associated with the total score (P<0.001), osteophyte score (P=0.003), and joint space narrowing (JSN) score (P<0.001) among the three tertiles after adjustment for age, sex, body mass index, smoking, alcohol consumption, education, and physical activity. In the hand joint scores, no association was found between serum adiponectin levels and the total score, osteophyte score, JSN score, subchondral cyst score, sclerosis score, erosion score, and malalignment score among the three tertiles after adjustment.

Conclusion: In this study, we found that increased adiponectin levels were associated with higher radiographic scores in the knee joint, but not in the hand joint, suggesting different pathophysiologic mechanisms in the development of OA.

EFFICACY AND SAFETY OF PULSED ELECTROMAGNETIC FIELDS IN THE TREATMENT OF OSTEOARTHRITIS: RESULTS OF A MULTICENTER BLIND PLACEBO-CONTROLLED STUDY.

A. Karantee¹, E. Pogozheva¹, M. Sukhareva², A. Lila². Nasonov Research Institute of Rheumatology, Moscow, Russian Federation; ²Nasonov Research Institute of Rheumatology, Moscow, Russian Federation

Background: Pulsed electromagnetic fields (PEMF) is a well-known method of non-pharmacological treatment that is widely used in knee osteoarthritis (KOAJ).

Objectives: To evaluate the effectiveness and safety of PEMF in KOAJ.

Methods: The study group consisted of 231 KOA patients, 77.9% of women, age 61.9±12.2 years, BMI 30.6±5.8 kg/m², average disease duration 5.0 [2.0;10] years. Patients were randomly assigned to two groups. Group 1 patients received PEMF for 14 days using a device that creates a low-frequency pulsed magnetic field, group 2-a false PEMF (a device that completely simulates a working device, but does not create a magnetic field). We evaluated the dynamics of the WOMAC index, the severity of pain at rest and when moving on a 100-mm visual analog scale (VAS), the need for non-steroidal anti-inflammatory drugs (NSAIDs), and the evaluation of the patient’s treatment result (on a 5-point scale).

Results: Statistically significant reduction in pain, stiffness, and improved function was observed in both true PEMF and false PEMF. Thus, the WOMAC pain in Group 1 decreased from 231 [180; 290] to 110 [60; 186.3], p<0.001; in Group 2 from 212.4 [145; 260] to 143 [78.5; 200], p<0.001, the severity of pain in rest (VAS) decreased in Group 1 from 47 [27.8; 60] to 20 [10; 30], p<0.001; in Group 2 from 40 [20; 57.5] to 20 [75; 40], p<0.001. After therapy, the need for NSAIDs also decreased: in Group 1 NSAIDs were canceled or reduced in 33.1% of patients, in Group 2 - in 16.8% (p=0.006). For all indicators, the dynamics were statistically more significant in Group 1 than in Group 2. The result of treatment as “good” and “excellent” was evaluated by 58.5% of patients in Group 1 and 39.8% of patients in Group 2, p=0.001. No serious adverse reactions were observed when using true and false PEMF. Two patients who received false PEMF therapy were interrupted due to increased joint pain.

Conclusion: PEMF with short-term use provides a significant improvement in the condition of KOA patients. PEMF is well tolerated and does not cause serious complications.

AB0869
CLINICAL FEATURES OF WOMEN WITH KNEE OSTEOARTHRITIS AT DIAGNOSIS IN CAMEROON, SUB-SAHARAN AFRICA

P. Kemta Lekpa¹, ², A. Tidjong Kamkui³, H. Namme Luma³, S. P. Choukem¹, ². ¹Douala General Hospital, Internal Medicine, Douala, Cameroon; ²University of Dschang, Faculty of Medicine, Dschang, Cameroon; ³Douala General Hospital, Douala, Cameroon

Background: To the best of our knowledge, no study has been done in sub-Saharan Africa among those who suggest that knee osteoarthritis is more severe in women.

Objectives: To assess differences in features of knee osteoarthritis between female and male patients in a sub-Saharan Cameroonian population.

Methods: A cross-sectional study from December 2018 to April 2019 conducted in the Rheumatology Unit of the General Hospital, Douala, Cameroon. We included patients with a recent diagnosis of knee osteoarthritis according to 1986 ACR criteria and Kellgren-Lawrence radiographic grading ≥2. Sociodemographic, clinical, radiographic and therapeutic data at diagnosis were collected. Assessment of the functional disability was done using the Lequesne algofunctional index, more adapted to Africans than WOMAC index. We compared these data between women and men. A p <0.05 was considered to be statistically significant.

Results: We screened 168 patients with the diagnosis of knee osteoarthritis. Seventeen patients with Kellgren-Lawrence radiographic grading at 1 were excluded. Then, we included 151 patients (120 women and 31 men) in the final analysis. The main characteristics of patients at diagnosis are summarized in Table 1. Knee osteoarthritis in women was characterized by a low level of education, a low financial income, and a high frequency of obesity. There was no difference between women and men for age at diagnosis, place of residence, intensity of pain, functional disability, number of compartments of the affected knee, Kellgren-Lawrence radiographic grading, and treatment previously received.
Table 1. Main characteristics of patients with knee osteoarthritis at diagnosis

Analysis: Female were 60% and 67% in control and PBSCs group respectively. The mean age was 56.3±6.7 and 55.8±7.3 year in control and PBSCs. After 12 weeks of stem cell therapy, pain reduction and functional significant improvement was observed in both groups. However, after 24 weeks further significant pain reduction, functional improvement was observed in PBSCs group. Moreover, the cartilage thickness measured by high frequency ultrasound and the mean cartilage thickness was increased by 0.14 mm from the baseline among PBSCs group.

Conclusion: PBSCs is promising in patients with primary OA knee. Further large scale research is solicited.

PAIN AND FUNCTIONAL OUTCOME OF PERIPHERAL BLOOD DERIVED STEM CELLS IN PRIMARY OSTEOARTHRITIS OF KNEE AT LOW RESOURCES SETTING: A PHASE II PILOT RCT

M. R. Khasru1 1Bangabandhu Sheikh Mujib Medical University, Physical Medicine and Rehabilitation, Dhaka, Bangladesh

Background: Osteoarthritis (OA) of the knee is one of the main causes of musculoskeletal disablement. Osteoarthritis is now often considered as organ failure. Because of limitations in the effectiveness of conventional management options, alternative possibilities such as cell based therapies are approaching into vogue.

Objectives: To assess the effectiveness of peripheral blood derived stem cells (PBSCs) therapy for primary OA knee.

Methods: This phase-II pilot RCT was conducted after the IRB ethical clearance. Patients attending PM&R department of BSMMU having KL grade III osteoarthritis knee those fulfilled the selection criteria were considered as the sample. All respondents were divided into two groups by using randomization technique. In control group, 15 respondents received standard care for Knee Osteoarthritis. In PBSCs group, 15 cases received with single dose autologous peripheral blood derived stem cells (PBSCs). Stem cells were harvested using GC-CSF 30MU and CD34 stem cells were collected through apheresis. Quality was ensured measuring cell viability and surface antigen. All respondents were assessed before treatment and at week 4, week 12 and week 24 for pain reduction and for functional improvement using Visual Analogue Scale (VAS 0-10 cm) and validated Bengali WOMAC questionnaire. Joint sonography was done before treatment, at 12 week and 24 week after treatment commencement.

Results: The duration of OA was 8.75 [2.58; 26] years. The distribution of patients according to the X-ray stage of OA: I - 9.6%, II - 57.6%, III - 26.9%, IV - 5.9% of the patients. The BMI range was from 21 to 43 kg/m2. A BMI to 30 kg/m2 was found in 22 patients: 17.3% - normal weight, 25% - excess body weight. Thirty patients has BMI more than 30 kg/m2: I degree - 38.4%, II degree - 15.3%, III degree - 4%. Obese patients rated pain according to the VAS scale of 1.3 the score is more intensively than patients with a BMI <30 kg/m2 (p <0.01). A detailed examination of each subsequent degree of obesity revealed a tendency to reduce the pain syndrome from 7.52 points at 1 degree of obesity to 5 points at 3 degrees of obesity (p <0.001). With increasing body weight, there was an increase in difficulties in daily activities according to the WOMAC (p <0.05). Reactive knee synovitis was detected in 25 (48%) patients. The incidence of synovitis in patients with a BMI <30 kg/m2 is 27%, with a BMI >30 kg/m2 is 68%. Patients with obesity of 1° degree had synovitis in 65%, 2° degree - 75%, 3° degree - 84% of cases (p <0.05). A high correlation between the x-ray stage of OA and BMI (r = 0.74; p <0.001) was revealed. According to the EQ-SD questionnaire, patients with the 1° degree of obesity (2.31 ± 1.3) were very anxious, but the level of anxiety decreases in patients with 3rd degree of obesity (1.44 ± 0.9) and it's equal to that of patients with 1° degree of obesity (1.44 ± 0.9). With increasing body weight, there was also an increase in limitations in daily activities and emotional distress (p <0.05). The level of anxiety for one's condition decreases.

Conclusion: The existence of obesity in patients with OA is associated with increased biomechanical stress. However, the association of OA with metabolic syndrome is more multifaceted, since overweight and obese people have a similar increased risk of OA of the hand joints that do not carry weight, due to systemic factors.

AB0072 EFFICACY AND SAFETY OF THE COMBINATION OF APOCYNIN AND PAEONOL (APPA) IN PATIENTS WITH OSTEOARTHRITIS: AN UNCONTROLLED PATIENT CASE SERIES

N. Larkins1,2; 1AKL Research and Development Ltd, Stevenage, United Kingdom

Background: Apocynin and paenol are secondary metabolites of plants used in traditional Asian medicine for centuries. The combination of synthetic versions of these two molecules (APPA) was developed initially for the treatment of osteoarthritis (OA) in animals where it has been found at least as effective as meloxicam. Human clinical trials are currently ongoing.

Objectives: To report the outcomes from a case series of patients treated with APPA.

Methods: Subjects with a diagnosis of OA, who had tried unsuccessfully a number of standard therapies, requested treatment with APPA from the author (NL), often following successful treatment of their animals with the combination or via networking. The usual daily dose was 1240 mg paenol and 352 mg of apocynin taken as two 400mg capsules twice daily.

Results: Twenty-three subjects with a diagnosis of OA of whom 7 were scheduled for surgery have been treated with APPA. There were 10 female and 13 males with an age range from 40 to 81 years. Nine patients had OA of the knees, 5 of whom had bilateral involvement, 7 had hip OA, 5 bilaterally and 2 with end stage bone on bone disease. Four patients had hand OA, one of whom also had hip disease of the lower back and feet. In 3 patients the joints involved was not recorded. In 19 patients treatment was reported as effective. In 4 patients the treatment was ineffective, all of whom were scheduled or had been recommended for surgery. In 2 of these cases cases this was bone on bone. The duration of treatment for OA at the last recorded follow-up was reported for 16 patients in whom treatment was deemed effective and ranged from 9 to 120 months (median 24 months). In a further 3 patients the treatment duration was not reported. In the 4 patients where no benefit was reported APPA was discontinued within a few weeks. In no case was there a report of APPA being discontinued due to adverse events. In 13 patients it was specifically stated that there had been no adverse events whereas for the remaining 10 patients it was not documented whether adverse events had occurred or not.

Conclusion: Treatment with APPA was reported as effective by 82.6% of patients. In all patients in which the combination was ineffective the disease was severe with joint replacement recommended or scheduled; in two patients this was bone on bone. This would suggest that APPA is not a simple analgesic, a conclusion supported by effects seen in the rat meniscal tear model where possible disease modifying effects have been reported (1).

AB0087 ULTRASOUND GUIDED INTRA-ARTICULAR INJECTION WITH HYALURONIC ACID AGENTS IN MODERATE HIP OSTEOARTHRITIS

M. Micu1, A. Micu2, S. Boboacă3,4; 1Rehabilitation Clinical Hospital Cluj-Napoca, Rheumatology Division, Cluj-Napoca, Romania; 2“Iuliu Hatieganu” University of Medicine and Pharmacy Cluj-Napoca, Cluj-Napoca, Romania; 3“Iuliu Hatieganu” University of Medicine and Pharmacy Cluj-Napoca, Department of Medical Informatics and Biostatistics, Cluj-Napoca, Romania

Background: Current guidelines usually only include hyaluronic acid (HA) intra-articular injection as an alternative therapy option for knee osteoarthritis (OA). When compared to the blind approach, ultrasound guided intra-articular injections (USGIA) have shown a higher efficacy and reduced number of adverse events due to injection techniques [1]. This has allowed targeting deep joints like the hip. The objective of the study is to evaluate the short and long term efficacy and safety of HA-USGIA in moderate hip OA.

Methods: Patients with Kellgren-Lawrence II and III hip OA (refractory to NDA), pain killers and chondroprotective agents were prospectively recruited to receive 3 consecutive weekly doses of HA-USGIA using free hand technique [2]. Informed written consent was signed. VAS pain scale and WOMAC score was performed at baseline and at 3 and 6 months after the end of treatment. The first injection was performed after a 1-month wash out. X ray assessment was made at baseline and after 6 months. Ultrasound evaluation was made at baseline and at each visit.

Results: Fifteen patients (median age 67 years, 13/15 women) with hip OA were enrolled and 28 hip joints were injected (Fig 1a,b). None of the hips presented ultrasound detected capsular distension (suggesting inflammation) during the study. Table 1 presents the results on medication efficacy at 3 and 6 months. The pain evaluated by VAS score showed a significant and progressive decrease from baseline to 3 and 6 months respectively (Table 1). Indeed, a significant and sustained decrease of total WOMAC scores and its separate domains- pain, stiffness and function was recorded from baseline to 3 and 6 months (Fig 2a,b). No significant changes were observed regarding the WOMAC score stiffness and function domains when comparing results at 3 and 6ms. Moreover, WOMAC-pain score was significantly lower at 6ms as compared to 3ms (Table 1), highlighting the dramatic and sustained medication impact on the most relevant parameter for clinical practice, in patients with hip OA. Neither drug-related nor injection technique related adverse effects were recorded. No patient developed signs of hip osteonecrosis or inflammatory lesions during follow-up.

Conclusion: The results suggest that HA – USGIA may be an effective and safe treatment for moderate hip OA, due to its short and long term benefits. This treatment should not be delayed until advanced OA is diagnosed. Longitudinal controlled studies on larger cohorts are warranted to confirm these preliminary results.

FUNCTIONALITY IN OSTEOARTHRITIC GAIT IS RELATED TO TREATMENT DECISION. A MULTIFACTORIAL ANALYSIS

S. Tassani1, L. Tío2, F. Castro3, J. Monfort3, J. C. Monllau2, M. Á. González-Ballestera4, J. Noaillay1. 1Universitat Pompeu Fabra, BCN MedTech, DTIC, Barcelona, Spain; 2Hospital del Mar, Rheumatology Department, Barcelona, Spain; 3Hospital del Mar, Traumatology Department, Barcelona, Spain, 4Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

Background: Osteoarthritis (OA) is a degenerative disease with complex underlying mechanisms1-3. The interactions among several factors make the study of the disease very complex and often lead to different treatment, i.e. surgical or conservative, decisions for subjects clinically and radiologically similar. Recent explorations performed at the body level pointed out that macro-factors, like overweight or gait, can influence the development of the disease4. The number of related factors is high, and they are very likely to interact with each other. However, the literature lacks randomized and balanced studies to verify such effects of multiple factors5.

Objectives: The aim of this work was to develop a multifactorial analysis to explore whether and how gait functionality and dynamics can be related to treatment decision. Methods: A multifactorial analysis of gait dynamics in OA subjects was developed. 81 OA subjects, graded 2–3 in KL, were selected based on 4 clinical factors: Gender (male – female), Age (60–67 – 68–75), BMI (25–29.9 – 30+) and therapy. Gait analyzers: Gender (male – female), Age (60-67 – 68-75), BMI (25–29.9 – 30+) and age – p<0.02 – Figure 1).

Dynamics: Forces at the joints seemed to be affected by the gender and an interaction between age and BMI (p<0.005, p<0.02) but not by the kind of therapy. Differently, torques were statistically related to the clinical treatment (p<0.007). Age was also significant as was the interaction between age and BMI (both p<0.007).

Conclusion: Reduced functionality seems to be related to the selection of therapy. In contrast to current paradigm, forces at the joints may have no role in the definition of the best therapy for OA subjects. Subjects requiring TKR do not present higher loads at the joints. However, torques seems to be related to the therapy selected. Instead of forces, kinematics and posture assessments might support rational definitions of the therapy and future multifactorial analysis should take them into consideration.

THE BENEFIT AND SAFETY OF DIACEREIN IN AGED AND OBESE PATIENTS WITH SYMPTOMATIC KNEE OSTEOARTHRITIS: DATA FROM THE DISSCO CLINICAL STUDY

1University of Montreal Hospital Research Centre (CRCHUM), Osteoarthritis Research Unit, Montreal, Canada; 2Institut de Rhumatologie de Montréal, Montreal, Canada; 3StatSciences Inc., Notre-Dame-de-l’Île-Perrot, Canada; 4Arthrolab Inc., Montreal, Canada.

BACKGROUND: The DISSCO trial (6-month international, multicentre, double-blind, randomised study on the effect of diacerein vs celecoxib in symptomatic knee osteoarthritis [OA] patients) showed that diacerein had comparable efficacy to celecoxib at reducing the level of pain (WOMAC pain).

OBJECTIVES: To assess the effect of age, body mass index (BMI), and gender on the efficacy/safety profile of diacerein following 6 months of treatment.

METHODS: Of the patients (n=380) that were randomised, 186 received treatment with 50mg diacerein once daily for the first month and twice daily thereafter. This study was done on the intent-to-treat population (n=183). Efficacy outcome assessments which included absolute change in WOMAC pain (score 0-50) and function (score 0-170), and VAS (score 0-10) were analysed following stratification based on age (< 65 vs ≥ 65 years old) and BMI (< 30 vs ≥ 30 kg/m²) at time of randomisation. Treatment effects on continuous efficacy outcomes were performed using covariance analysis (ANCOVA). For gastrointestinal (GI) safety outcomes, the adverse events (AEs), including diarrhoea, soft faeces, abdominal pain and dyspepsia, and the time-to-onset from baseline were stratified according to age of patients at randomisation. Treatment-related GI AEs were also assessed according to the gender. The independent variables were treatment, stratification variable, interaction between both, and the outcome measure at baseline. Comparisons between groups were carried out using Chi-square.

RESULTS: No significant differences were found between the two age groups (<65 years old [n=106], ≥65 years old [n=78]) in the level of reduction in WOMAC pain (-10.3 ± 1.1, -8.6 ± 1.3, respectively; p=0.30), VAS (2.3 ± 0.2, -2.2 ± 0.3, p=0.73) or improved physical function (-29.7 ± 3.7, -22.1 ± 4.2, p=0.18). The reported incidences of treatment-related GI AEs were also similar between the two age groups; more specifically for diarrhoea, incidence for patients <65 years old [n=12] 11.3% and for those ≥65 years old [n=7] 8.8% (p=0.63) with a mean time-to-onset (day 61 ±51, respectively; p=0.11). Moreover, gender had no influence on treatment-related GI AEs (p=0.42).

In regard to treatment response of obese (n=101) vs. non-obese (n=82) patients in terms of pain reduction (WOMAC: -10.1 ± 1.2, -9.1 ± 1.1, respectively; p=0.58; VAS: -2.6 ± 0.3, -2.0 ± 0.3; p=0.15), or improved WOMAC physical function (-29.8 ± 4.2, -23.5 ± 3.8; p=0.26), there were also no significant differences.

CONCLUSION: In symptomatic knee OA patients, the level of effectiveness and safety profile of treatment with diacerein were found not to be influenced by age, BMI or gender.

CLINICAL EFFICACY AND SAFETY PROFILE OF TOPICAL ETOFENAMATE IN THE TREATMENT OF PATIENTS WITH MUSCULOSKELETAL DISORDERS: RESULTS OF A SYSTEMATIC REVIEW

A. Pereira1,2,3, A. Marinho4, CINTESTIS - Health Technology and Services Research Center (Ageing-C), Porto, Portugal; 2University of Aveiro, Department of Education and Psychology, Aveiro, Portugal; 3Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal; 4CMV - Viseu Medical Center - Coimbra Rehabilitation Institute, Coimbra, Portugal; 5BIAL, Medical Affairs Department, Porto, Portugal.

BACKGROUND: Musculoskeletal disorders affect millions of people of all ages around the world [1]. Nonsteroidal anti-inflammatory drugs (NSAIDs) are, in general, the cornerstone of musculoskeletal pain management; however, systemic adverse events with oral formulations of NSAIDs are common. To address this, topical formulations of some NSAIDs have been developed. [2] Although there are many nonsteroidal anti-inflammatories, only a few are used as local therapeutics. This is because the physicochemical properties of these substances, which were originally developed for oral administration, frequently do not guarantee a satisfactory pharmaceutical formulation with satisfactory topical absorption. [3]

OBJECTIVES: The aim of this systematic review was to assess the available evidence on the efficacy and safety of the topical formulations of the NSAID etofenamate in patients with musculoskeletal disorders.

METHODS: A systematic search of PubMed and Web of Science was conducted, using the key words (topical etofenamate efficacy) OR (topical etofenamate safety) OR (topical etofenamate effectiveness) to identify studies of etofenamate published from inception to November 2018. Some published manuscripts of interest known by the authors but not identified in the PubMed search were also included to ensure the review article was as comprehensive as possible.

RESULTS: Overall, 12 studies were identified. [3-14] These studies demonstrated the ability of topical etofenamate (administered either in gel [5% or 10%), cream [10%] or lotion [10%] formulations) to improve pain and reduce inflammation in patients with musculoskeletal disorders, including blunt injuries and rheumatic diseases. Etofenamate was shown to have an overall efficacy that was superior to other topical NSAIDs, such as 1% ibuprofen and 1% diclofenac, and to be as effective as topical formulations of 2.5% ketoprofen gel and 2% ketocarol gel (although ketocar- ol suggested a better elimination at some time points). Overall, when compared to placebo, etofenamate gel 5% demonstrated significant better results in the reduction of pain symptoms (with or without combination with ultraphonophoresis). Furthermore, clinical evidence indicates that etofenamate is generally well tolerated in these indications.

CONCLUSION: The available clinical evidence suggests that etofenamate could be an effective therapeutic option for the management of musculoskeletal disorders, such as blunt traumas, lumbago or osteoarthritis. However, larger and well-controlled clinical trials comparing the efficacy and safety of etofenamate with other newer topical NSAIDs are warranted.

existing options, there is still no general consensus on the choice and priority of the best intra-articular injection in knee osteoarthritis.

**Objectives:** Our study compare the short and long-term efficacy of the intra-articular injections of HA (3 doses weekly), PRP, platelet-rich plasma (PRGF), and ozone in patients with knee osteoarthritis (OA).

**Methods:** In this single-blinded randomized clinical trial, 238 patients with mild to moderate knee OA were randomized into 4 groups of IAs: HA (3 doses weekly), PRP (2 doses with 3 weeks interval), PRGF (2 doses with 3 weeks interval), and Ozone (3 doses weekly). Our outcome measures were the mean changes from baseline until 2, 6, and 12 months post intervention in scores of visual analog scale, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), and Lequesne index.

**Results:** A total of 200 patients enrolled final analysis. The mean age of patients was 56.9 ± 6.3 years, and 69.5% were women. In 2 months follow up, significant improvement of pain, stiffness, and function were seen in all groups compared to the baseline, but the ozone group had the best results (P < 0.05). In 6 months follow up HA, PRP, and PRGF groups demonstrated better therapeutic effects in all scores in comparison with ozone (P < 0.05). At the end of the 12th month, only PRGF and PRP groups had better results versus HA and ozone groups in all scores (P < 0.05). Despite the fact that ozone showed better early results, its effects begin to wear off earlier than other products and ultimately disappear in 12 months.

**Conclusion:** Ozone injection had rapid effects and better short-term results after 2 months, but its therapeutic effects did not persist after 6 months and at the 6-month follow up, PRP/PRGF and HA were superior to ozone. Only patients in PRP and PRGF groups improved symptoms persisted for 12 months. Therefore, these products could be the preferable choices for long-term management.

**NEUROPATHIC PAIN IN PATIENTS WITH KNEE OSTEOARTHRITIS: PREVALENCE AND RELATED FACTORS**

A. Ben Tekaya1, L. Rouached1, A. Slimi2, O. Saidane3, S. Boudien3, R. Tekaya1, I. Mahmoud1, L. Abdelmoula1, 1Hospital Charles Nicolle, Rheumatology, Tunis, Tunisia; 2Community Health Center, Kef, Tunisia, Kef, Tunisia

**Background:** Discordance between radiographic and pain severity in osteoarthritis (OA) has led researchers to investigate other pain mechanisms, including neuropathic pain (NP). Recent meta-analysis concluded that NP prevalence in people with knee or hip OA was 23% [1].

**Objectives:** The primary objective of this study was to determine the prevalence of NP in patients with painful knee OA. Secondly, we evaluated the relationship between NP and pain intensity, function, and radiographic severity of knee OA.

**Methods:** This cross-sectional study enrolled patients with knee OA (ACR criteria) from a rheumatology outpatient Hospital over a four-month period. Exclusion criteria were: knee surgery, chronic conditions of the nervous system, cognitive or psychiatric disorders. The patient’s characteristics and pain severity using the Visual Analogue Scale (VAS) were evaluated. The NP was assessed according to the Douleur Neuropathique 4 questionnaire (DN4) (arabic valid version). Functional impairment was estimated using the short form of the Knee and Osteoarthritis Outcome Score (KOOS) (KOOS-PS scores to 0 representing no difficulty and 100 representing extreme difficulty). Radiographs were rated using the Kellgren Lawrence (KL) grade classification (I-IV). Statistical analysis was performed to find the factors closely related with NP.

**Results:** Ninety three patients with knee OA were included in the study. The mean age was 65.03 ± 10.7 years with a sex ratio of 0.08. Mean duration of symptoms was 3.5 years [3months-20 years]. Concerning the marital status: 53.8% were married, 34.4% were widow and 10.8% were divorced. The majority of patients were illiterate (65.6%) and only 2.2% went to university. Patients were overweight (25 to <30), obese (up to 30). Pain level was evaluated using the Visual Analogue Scale (VAS). Function was assessed by the short form of the Knee injury and Osteoarthritis Outcome Score (KOOS-PS) (KOOS-PS scores to 0 representing no difficulty and 100 representing extreme difficulty). The patients’ knee radiographies were graded according to Kellgren Lawrence criteria (KL). The patients were allocated in two groups; as grade I-II KL (Group 1) and grade III-IV KL (Group 2).

**Results:** We included 143 patients with a mean age of 65.17 ± 10.7 years and 58.1% of women. Patients were from low socio-economic class in 30.8% of cases. Mean disease duration of the KOA was 5.4 years [3months-20 years] and mean BMI was 31.8 ± 5.6 kg/m². Patients were with normal weight in 52.4% overweight in 19.6% and obese in 24.3%.

**Conclusion:** Knee OA was bilateral in 85.3% and other OA sites were associated in 37.8% of patients. Mean VAS pain of knee OA was 6.6 ± 1.5 and KOOS-PS was 48.8 ± 16.5/100. Concerning the radiographic damage; we found grade I-II KL in 22.6% and grade III-IV KL in 77.4%.

**High BMI (BMI≥25 kg/m²) was not significantly associated with worse KOOS score (p=0.09), more pain (p=0.5) or an increasing severity of radiological knee osteoarthritis (p=0.14). Moreover, the level BMI was not associated with the presence of other OA sites (p=0.9) or a bilateral KOA (p=0.07).

**Conclusion:** These data, from a subset of participants with symptomatic radiographic knee OA, demonstrate no correlation between obesity and pain, functional impairment and radiographic severity.

**DOES BODY WEIGHT INFLUENCE THE KNEE INJURY AND OSTEOARTHRITIS OUTCOME SCORE IN PERSONS WITH SYMPTOMATIC KNEE OSTEOARTHRITIS?**

A. Ben Tekaya1, L. Rouached1, A. Slimi2, O. Saidane3, S. Boudien3, R. Tekaya1, I. Mahmoud1, L. Abdelmoula1, 1Hospital Charles Nicolle, Rheumatology, Tunis, Tunisia; 2Community Health Center, Kef, Tunisia, Kef, Tunisia; 1Department of Rehabilitation Medicine Department, Djebel Oust, Tunisia

**Background:** Overweight is a major risk factor for the development and progression of knee osteoarthritis (OA). Weight loss for patients with knee OA has been assessed by the short form of the Knee injury and Osteoarthritis Outcome Score (KOOS). Pain level was evaluated using the Visual Analogue Scale (VAS). Function was estimated using the short form of the Knee injury and Osteoarthritis Index (WOMAC), and Lequesne index. These data, from a subset of participants with symptomatic knee OA, demonstrate no correlation between obesity and pain, functional impairment and radiographic severity.

**Methods:** This cross-sectional study enrolled patients with knee OA (ACR criteria) from a rheumatology outpatient Hospital over a four-month period. Exclusion criteria were: knee surgery, chronic conditions of the nervous system, cognitive or psychiatric disorders. The patient’s characteristics and pain severity using the Visual Analogue Scale (VAS) were evaluated. The NP was assessed according to the Douleur Neuropathique 4 questionnaire (DN4) (arabic valid version).

**Conclusion:** The primary objective of this study was to determine the prevalence of NP in patients with painful knee OA. Secondly, we evaluated the relationship between NP and pain intensity, function, and radiographic severity of knee OA.

AB0881 COMPARISON OF FUNCTIONAL OUTCOMES BETWEEN PRIMARY AND REVISION TOTAL KNEE ARTHROPLASTY

K. Sevíc1, T. Unver1, B. Unver1. 1 Dokuz Eylul University, Izmir, Turkey

Background: Total knee arthroplasty (TKA) is the gold-standard treatment for end-stage knee osteoarthritis (OA). An increase in the prevalence of primary and revision TKA is projected due to aging of the population, increase in the obesity and OA prevalence, patients' quality of life perceptions and primary TKA procedures. Although TKA reliably improves pain and function; gait ability and function are still low compared to normal levels [1]. It is important to understand the prognosis to decide to undergo a rTKA (revision total knee arthroplasty) or enhance treatment protocols [2].

Objectives: The aim of the study is to compare the functional results of primary and revision TKA.

Methods: Hospital Of Special Surgery knee score (HSS), The Figure-Of-S-2 Walk Test (F8WT), The Modified Four Step Square Test (mFSST) and the 3-Meter Backwards Walk Test (3MBWT) were used for function assessment.

Conclusion: Functional status, fall risk, balance and walking skills of the rTKA patients were lower than the TKA patients. rTKA patients experience longer operation time, hospital stay and make fewer functional gains. Improvement after rTKA is also reported to be lower than TKA and balance could be worsened or does not improve after TKA [2]. Walking skills of the rTKA patients were worse than the TKA patients which may cause rTKA patients to be more cautious and tentative due to fear of falling and failure of the implant leading a more impaired function [2]. rTKA patients' balance was lower and had more fall risk than the patients with TKA. These may be due to the recurrent incision of soft tissues causing a loss of more mechanoreceptors and a greater impairment of proprioception. These findings can help clinicians to make a more informed decision for both primary and revision procedures [3].

AB0882 RELIABILITY OF THE MODIFIED FOUR SQUARE STEP TEST IN PATIENTS WITH REVISION TOTAL KNEE ARTHROPLASTY

B. Unver1, K. Sevíc1, V. Karatosun2. 1 Dokuz Eylul University, Izmir, Turkey; 2 Dokuz Eylul University Hospital, Izmir, Turkey

Background: Patients with total knee arthroplasty (TKA) often experience pain and reduced balance control, which may predispose them to greater fall risk. The patients with revision total knee arthroplasty (rTKA), have more pain, stiffness and physical dysfunction and less postoperative improvement compared to the patients with TKA [1]. Falls in people with gait or balance disorders have significant consequences. Fear of falling can also predispose people to inactivity, which can lead to problems of debilitation, increased handicap, and disability by itself. Most of the falls take place in the course of movement, and the trips and slips were determined as the most common cause of elderly falls. Trips are responsible of falls between 40% to 60% and slips between 10% to 15%, showing that the capability to take a quick step would prevent many falls [2]. Literature has found stepping speed to the different directions declines with aging and are lesser for fallers than for nonfallers [3]. Modified four square step test (mFSST) was developed to assess fall risk and dynamic balance by scoring time while participants stepping for 3MBWT twice on the same day. Between the trials, patients waited for an hour on sitting position to prevent fatigue.

Results: The 3MBWT showed a excellent test-retest reliability. Intraclass correlation coefficient ICC for 3MBWT was 0.97. The standard error of measurement and MCID at the 95% confidence level for 3MBWT were 1.08 and 2.99 respectively.

Conclusion: The 3MBWT has an excellent test-retest reliability in patients with rTKA. It is an effective and reliable tool for measuring fall risk, dynamic balance and walking skills. As a clinical test, the 3MBWT is easy to score, has no cost, needs no special equipment and can be applied in a short time as part of the routine medical examination.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.4336
Methods: mFSST administered on 22 patients undergoing rTKA. mFSST is performed by using tapes to make one horizontal and one vertical line like a cross to create 4 quadrants. Patients’ performances were timed as patients were success- fully stepping clockwise and counter-clockwise while avoiding touching on tapes, turn- ing their body or losing balance. Two trials performed and patients rested between trials and were encouraged to rest as often as they required to prevent fatigue.

Results: ICC_{xy} for mFSST was 0.83. The standard error of measurement and MCID were 0.67 and 185 respectively (95% confidence level).

Conclusion: The mFSST has a good test-retest reliability in patients with rTKA. It is a reliable and responsive tool for measuring fall risk, dynamic balance, and mobility. The mFSST is an excellent measure of gait variability, stepping in multiple directions and dynamic balance, also can easily identify real clinically important changes in patients with rTKA in simple environments and minimal equipment.

24. Osteoporosis

**AB0886 INCIDENCE OF FRACTURES IN A BARIATRIC SURGERY COHORT**

M. D. P. Abadijo Guzman1, R. M. Veiga Caballero1, M. Cantealejo Moreira2, J. Ruiz Ruiz3, A. Zapatero Gaviria1. 1Hospital Universitario de Fuenlabrada, Rheumatology Unit, Madrid, Spain; 2Htal Central de la Defensa Gómez Ulla, Rheumatology Service, Madrid, Spain; 3Hospital Universitario de Fuenlabrada, Rheumatology Unit, Fuenlabrada, Spain; 4Hospital Universitario de Fuenlabrada, Internal Medicine Service, Madrid, Spain

**Background:** Bariatric surgery is the set of surgical techniques whose objective is weight reduction, and it could have complications. One of them may be the increase in the incidence of fractures (1), secondary to nutritional defects (2), among others, that could modify bone metabolism with an increase in remodeling (3).

**Objectives:** To carry out a retrospective observational pilot analysis of a cohort of 140 morbidly obese patients after bariatric surgery, of a total of 304, descriptive of axial and peripheral fractures, among other variables.

**Methods:** Data were collected from the University Hospital of Fuenlabrada of a cohort of morbidly obese people who underwent bariatric surgery from 2009 to the present. Were included as variables in age, sex, body mass index (BMI) before surgery, evolution time since surgery in years, incidence of sleep apnea syndrome (OSAS), incidence and type of fracture, osteoporotic or not, and axial or peripheral. A descriptive and frequency analysis, and a chi-square contingency table between incidence of fracture, and gender, OSAS, or childhood obesity, were performed.

**Results:** A 48.76 years old cohort was observed, 25.7% men/74.3% women, 30.8% childhood obesity. BMI of 45.65 kg/m2, and 45% with a diagnosis of OSAS. A 15% of fractures were noted: 66.66% considered as osteoporotics (40.76% axial, 50.31% peripheral, and 8.93% of both) in a time of evolution of 5.81 years, and without relationship with gender, OSAS or childhood obesity (p = 0.7, p = 0.15, p = 0.16).

**Conclusion:** It is a study that highlights that bariatric surgery in Fuenlabrada area is mainly performed on morbidly obese women in adulthood. There is a high rate of OSAS, and an increase in the incidence of fractures unrelated to gender, OSAS or childhood obesity, despite the fact that in the bariatric surgery protocol densitometric osteoporosis is an exclusion criterion.

**AB0887 PATIENTS DEMOGRAPHIC CHARACTERISTICS WITH ESTABLISHED OSTEOPOROSIS TREATED WITH DENOSUMAB IN A THIRD LEVEL HOSPITAL**

E. Andreu Trashko1, D. Fernandez2, R. Dos Santos Sobrin1, I. González Fernández3, A. Souto Vilas3, E. Perez-Pampín1, A. Mera Varela1. 1San Esteban de Compostela, 2Rheumatology, Santiago de Compostela, Spain

**Background:** Osteoporosis (OP) is the most common cause of fragility fractures. It is characterized by a loss of bone mass that modifies the bone microstructure, increases fragility and predisposes to fractures. There are numerous risk factors for fragility fracture that must be evaluated for diagnosis and treatment. The treatment consists of non-pharmacological measures (balanced diet and exercise), adequate intake of calcium and vitamin D and specific pharmacological treatment (bisphosphonates, teriparatide, denosumab or selective estrogen receptor modulator) 1-3.

**Objectives:** To perform a descriptive evaluation of the demographic and clinical characteristics of patients with osteoporosis treated with Denosumab, their degree of compliance with the therapy as well as the evaluation of the possible causes of treatment cessation.

**Methods:** All patients diagnosed with OP from January 2015 to January 2020 have been reviewed in the Rheumatology Service of the University Hospital of Santiago de Compostela and patients treated with denosumab have been selected. The demographic, clinical, and treatment data have been collected from data collected in their electronic medical record.

**Results:** Of the 507 patients diagnosed with Osteoporosis from January 2015 to January 2020, a total of 133 patients (26.2%) have received treatment with Denosumab. The majority are women (92.5% n = 122) with a mean age of 76 years (age range: 49-105 years). Previously, 38% (n = 51) had vertebral fractures, with 8% (n = 11) standing out who had presented 3 or more vertebral fractures prior to Denosumab treatment.

The mean time to start Denosumab therapy since the diagnosis of Osteoporosis (by Densitometry or established by fractures) has been 35 months (0 to 84 months from diagnosis).

Through the electronic Medical Record the dispensations were accessed in the Denosumab pharmacy office and its administration in Primary Care was verified.

Complete adherence to treatment (without skipping any dose) was observed in 73% of patients (n = 97). In 5.2% (n = 7) an omission was avoided. In 21.8% (n = 29) 2 or more dose omissions were corroborated 9 patients (6.8%) completed treatment with Denosumab in the follow-up period (55% due to the need for dental interventions, 33% for loss of follow-up and 12% for fear of secondary effects).

In 66 patients (49.6%) risk factors were identified to present Osteoporosis; being corticosteroid therapy at doses greater than 5 mg / day of Prednisone or equiva-

lent (26%) was the most frequently identified risk factor.

No vertebral fractures were registered at the end of treatment with Denosumab, with an average time since the end of treatment of 2.77 years (6 months - 8 years).

**Conclusion:** The rate of patients diagnosed with Osteoporosis who receive Denosumab therapy at some time reaches 26%, being the most frequent drug used after bisphosphonates.

Complete adherence to treatment has been observed in 73% of patients.

We have not observed vertebral fractures after suspension of Denosumab in our series of patients, although the total exposure time (from the end of treatment to the end of follow-up) is short: 2.77 years

**AB0888 REASONS FOR LETHALITY IN ELDERLY AND SENIOR AGE PATIENTS WITH OSTEOPOROTIC FRAC TURES OF FEMUR**

J. Averkieva1, T. Raskina1, M. Letaeva1, O. Malyshenko1, I. Grigoreva1. 1Federal State Educational Institution of Higher Education "Kemerovo State Medical University"; Kemerovo, Russian Federation

**Objectives:** To identify the causes of mortality in middle-aged and elderly patients during the first year after they had a low-energy hip fracture.

**Methods:** the causes of lethality were examined of the patients with a non-traumatic femur fracture. 432 patients with osteoporotic hip fractures were under observation: 328 women and 104 men. The mean age of women was 75, 4 (70; 82) years, the mean age of men was 71,5 (65; 80) years.

**Results:** after 12 months, mortality rate was 137 cases (total mortality - 31.8%). Most of the deaths were due to cardiovascular system diseases. The total number of fatal cases was 93 (67.8%): for men - 22 (66.0%) cases, for women - 71 (68.3%) (p = 0.65). Diseases of the respiratory system caused death in 23 (16.8%) patients: in men - 5 (15.1%) cases and in women - 18 (17.3%) (p = 0.31). Mortality from oncological diseases was 15 (10.9%) cases: in men - 3 (9.0%) cases and in women - 12 (11.5%) (p = 0.45). Diseases of the digestive system, as the cause of death, were detected in 5 (3.6%) men and women (2.6%) and 3 (2.9%) cases, respectively (p = 0.1).

**Conclusion:** the most of the deceased men and women had cardiovascular and respiratory diseases. The gender differences in mortality rates were not found.

Background: Sarcopenia is a loss of skeletal muscle mass, muscle strength, and function, with an impact on the quality of life, increased risk of bone loss and fracture, which is associated with normal aging.

Objectives: To determine the effect of sarcopenia on the recovery of patients after hip fracture, their functionality, and quality of life

Methods: A prospective study had 60 patients with hip fractures of both sexes, > 65 years of age (70.8), in the experimental group of patients with sarcopenia and the control group without sarcopenia. All anthropometric measurements were performed: BMI (kg/m²), waist circumference, the volume of the upper arm and lower leg muscle mass, handgrip force (kg) - dynamometry. The following questionnaires were used to assess functionality, mobility, and quality of life: Health assessment questionnaire (HAQ), Harrison hip score (HHS), Sarcopenia and Quality of life (SarQoL)

Results: Muscle mass (BMI) was significantly lower in the experimental group patients (p <0.05) compared to the control group. The clamp strength measured by the dynamometer was significantly lower in patients with hip fractures (p <0.005) compared to the control group. The BPs has been poorly investigated.

Disclosure of Interests:

Objective 2: To compare management of our CKD patients to 2018 KDIGO guidelines.

Methods: We randomly selected 70 patients in whom data was available from renal clinics between May and September 2019.

Results: Mean age was 67.3 yrs. 41 male, 29 female. 33 patients had CKD 3a-b; 31 had CKD 4; 6 had CKD 5. Mean duration of CKD was 10.6 yrs. 10 patients were taking activated vitamin D analogues; 13 were taking 25-(OH)D analogues. 25-(OH)D levels ranged from 24-158 nmol/L (mean 65nmol/L). PTH levels were taking calcium and phosphate (Ca/PO4) within 12 mths in CKD 3a-b, within 6 mths in CKD 5. Alkaline phosphatase (ALP) should be checked at baseline in CKD 3a-b within 12 mths in CKD 4 and within 6 mths in CKD 5.

Conclusion: Optimum PTH levels in CKD patients are not known, and therapeutic options in CKD-MBD often limited. Nevertheless, our results suggest that bone biochemistry could be checked more consistently in CKD patients. Although detection of vascular calcification may not alter renal management, abdominal imaging provides an opportunity to screen for vertebral fracture, present in a

AB0890 VITAMIN D PROMOTES BONE MINERAL DENSITY ACCURR AFTER DISCONTINUATION OF ALENDRONATE.

A. Catalianno1, F. Bellone1, A. Gaudio2, M. C. Sottile1, S. A. Stoian1, F. Lo Piano1, S. Maisano1, F. Corica1, N. Morabito1, 1University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy; 2University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy

Background: Vitamin D repletion is known to maximize the response to bisphosphonates (BPs) in terms of both bone mineral density (BMD) changes and anti-fracture efficacy. The contribute of vitamin D to BMD after discontinuation of BPs has been poorly investigated.

Objectives: To explore whether change of vitamin D status may contribute to the tail effect of alendronate (ALE) on BMD.

Methods: Participants in this retrospective study were postmenopausal osteoporotic women exposed to ALE. Either cholecalciferol or calcidiol have been administered, as vitamin D supplementation in accordance to good clinical practice, during ALE treatment and after ALE discontinuation. BMD was evaluated by Dual-energy X-ray absorptiometry (DXA) at lumbar spine and femoral site. Vitamin D status has been checked by measuring 25(OH)D serum levels through HPLC. Surrogate bone formation and resorption markers (i.e. C-terminal telopeptide of type I collagen (CTX) and alkaline phosphatase (ALP), respectively) were also evaluated. The Fracture Risk Assessment Tool (FRAX) served to estimate the participants' 10-year fracture risk for major osteoporotic and hip fracture.

Results: 88 postmenopausal osteoporotic women (age 61.14 ± 6.96 yr.) were included in the final analysis. The 10-year probability of major and hip fractures was 18.31±11.51 and 8.60 ± 10.55 %, respectively. Participants were exposed to ALE treatment for 31.27 ± 20.69 months; then they stopped treatment for 33.33 ± 18.97 months. Change of BMD was inversely related to drug holiday (r=-0.27, p=0.005). Modification of 25(OH)D was inversely associated with change of ALP (r=-0.22, p=0.018) and CTX levels (r=-0.3, p=0.06). By distributing participants in tertiles according to variation of 25(OH)D levels over time, women allocated in the tertile with the higher increase of 25(OH)D showed a 5.7% BMD gain that was two times larger in comparison with participants with lower increase of 25(OH)D.

AB0891 BARE TO THE BONE - AN AUDIT OF RENAL BONE DISEASE AGAINST KDIGO GUIDELINES

N. Cernovcic3, S. Zeb4, T. Salter1, M. Lloyd2, 1Frimley Park Hospital, Frimley, United Kingdom

Background: Chronic kidney disease-mineral and bone disorder (CKD-MBD) is complex and management is difficult. We aimed to compare management of our CKD patients to 2018 KDIGO guidelines. The guidelines suggest checking calcium and phosphate (Ca/Po4) within 12 mths in CKD 3a and 3b, within 6 mths for CKD 4, and within 3 mths for CKD 5. Parathyroid hormone (PTH) should be checked at baseline in CKD 3a-b, within 12 mths in CKD 4 and within 6 mths in CKD 5. Alkaline phosphatase (ALP) should be measured within 12 mths in CKD 4 and 5. 25-(OH)D levels might be measured at baseline in CKD 3a to 5D. BMD scanning is suggested if the result will impact treatment decisions. Lateral abdominal X ray is recommended as an alternative to CT for detection of vascular calcification. Calcium and vitamin D analogues are no longer routinely advised in CKD 3a-5; 25-(OH)D insufficiency should be corrected as in the normal population.

Objectives: To compare management of our CKD patients to 2018 KDIGO guidelines

Methods: We randomly selected 70 patients in whom data was available from renal clinics between May and September 2019.

Results: Mean age was 67.3 yrs. 41 male, 29 female, 33 patients had CKD 3a-b; 31 had CKD 4; 6 had CKD 5. Mean duration of CKD was 10.6 yrs. 10 patients were taking activated vitamin D analogues; 13 were taking 25-(OH)D analogues. Change of BMD was inversely related to drug holiday (r=-0.27, p=0.005). Modification of 25(OH)D was inversely associated with change of ALP (r=-0.22, p=0.018) and CTX levels (r=-0.3, p=0.06). By distributing participants in tertiles according to variation of 25(OH)D levels over time, women allocated in the tertile with the higher increase of 25(OH)D showed a 5.7% BMD gain that was two times larger in comparison with participants with lower increase of 25(OH)D.

AB0892
PREGNANCY AND LACTATION ASSOCIATED OSTEOPOROSIS: FIRST CASE SERIES IN IRAN

M. Aghaei1, S. Sedighi1, M. Hassan1, M. R. Damirchi2. 1Golestan University of Medical Sciences, Golestan Rheumatology Research Center, Gorgan, Iran (Islamic Republic of)

Background: Osteoporosis is a common rheumatologic disorder in postmenopausal women which could lead to morbidities later in life. However, this condition has not been properly studied in premenopausal women.

During pregnancy, the fetus needs a total of 30 grams of calcium for its skeleton and during lactation, 200mg of calcium is secreted in the breast milk per day which the mother acquires by doubling its intestinal absorption rate. If the calcium intake of the mother is not sufficient to satisfy the fetus’ needs, it will be provided by bone resorption, which will decrease the maternal calcium reserves [1]. Pregnancy and Lactation Associated Osteoporosis (PLAO) is a rare condition associated with pregnancy that should be considered in premenopausal women. The most commonly affected sites are the vertebral and, more rarely, the hips, pubic rami and ribs [2].

An important complication of osteoporosis is fracture and a preemptive diagnosis and treatment thereof, can have drastic effects on the quality of life.

Objectives: Our objective is to document the relevant risk factors, present signs and symptoms, course of illness, and response to treatment in three cases of PLAO. It is quite possible that osteoporosis in pregnancy and lactation is more frequent than recognized, simply because it is only recognized when an unexpected fracture occurs[3]. Thus, in this article we are presenting three cases that showcase the need for more rigorous research on PLAO risk factors, the need for screening in high risk patients, and the advantages of early detection in patients’ outcome.

Methods: The clinical cases of the patients whose PLAO diagnoses had been confirmed by both a radiologist and a rheumatologist in the past year was extracted. Information related to demographic indices, clinical manifestations, and the treatment methods was evaluated and compared.

Results: In the past year, three patients with a chief complaint of low-back pain have visited our clinic. The first, a 22-year-old woman with a nursing history of 3 months, and the last, a 22-year-old woman with a nursing history of 4 months. All three patients had low back pain and tenderness. Two out of three patients had deficient vitamin D levels and the other had a normal one. All three patients had low BMD in lumbar vertebra and MRI images indicative of osteoporotic fracture.

Conclusion: Since the symptoms of PLAO are often confused with pain in other low-back pain conditions associated with pregnancy, PLAO is a mostly overlooked diagnosis[4]. It is only recognized when an unexpected fracture occurs [3]. Therefore, high risk patients with less severe symptoms are usually not diagnosed and thusly, should undergo a proper screening test, so that they are recognized early and the morbid sequelae are averted.

AB0893
THE EFFECTS OF THREE DIFFERENT VITAMIN D3 SUPPLEMENTATION REGIMENS IN DEFICIENT SUBJECTS - A RANDOMIZED OPEN-LABEL PARALLEL GROUP STUDY.

A. Fassio1, G. Adami1, O. Viapiana1, G. Orsolini1, A. Giolli1, M. Rossini1, D. Gatti.1 Rheumatology Unit, University of Verona, Verona, Italy

Background: Currently, most experts agree that levels of serum 25OHD-Vitamin D (25OHD) lower than 20ng/mL represent an acceptable threshold for deficiency (1). However, recommendations for vitamin D supplementation vary between scientific societies, and the best regimen to treat deficient patients is still not clear (1).

Objectives: The aim of our study was to compare the pharmacokinetic profile of three different regimes of cholecalciferol supplementation in terms of 25OHD exposure and their safety profiles.

Methods: We evaluated, in healthy subjects affected by vitamin D deficiency (defined as 25OHD<20 ng/mL), 18 to 60 years of age, the efficacy of three different oral supplementation regimens: daily 10,000iu administered for 8 weeks, weekly 50,000iu for 12 weeks and biweekly 100,000iu for 12 weeks. Serum 25OHD was dosed at baseline, at week 2, 4, 8 in all three groups and also at week 12 in the 50,000 and 100,000iu groups (the blood sample was taken before the drug administration if scheduled on the same day). Baseline characteristics and 25OHD changes from baseline to the various observation points were tested with ANOVA and t-test. 25OHD was measured by the IDS-ISYSMulti-Discipline automated analyser (Immunodiagnostic System, Boldon, UK) based on chemiluminescence technology. The CV intra-assay measured in our laboratory was 6% (inter-assay CV 9%). The study was approved by the local ethical committee (protocol DIBA/11. Supported by Abiogen Pharma, Italy).

Results: A total of 75 subjects were randomized to receive one supplementation regimen. The descriptive of the sample at baseline and relative 25OHD levels at the various observation points are reported in table 1. 25OHD increased significantly already at week 2 (p<0.000 vs both groups). In addition, the 25OH levels of the daily regimen group at week 8 were higher than both the ones of the weekly and the biweekly regimen groups both at week 12 and week 12 (p=0.000 vs both groups).

AB0894 OBSERVANCE OF ZOLEDRONIC ACID INFUSION. A RETROSPECTIVE 3 YEARS STUDY
J. Zalc, G. Camille, B. Lisa, B. Frédéric, HIA Bègin, Saint Mandé, France

Background: Osteoporosis is a public health issue. Lack of therapeutic compliance is often a problem in the treatment of osteoporosis, with potentially dramatic consequences. No studies have evaluated the observance of zoledronic acid infusion after 3 years, the time of the therapeutic reassessment.

Objectives: The main objective of assessing the level of compliance was to evaluate the level of zoledronic acid infusion adherence at 1, 2 and 3 year periods, in a cohort of osteoporotic patients on discharge from Bègin hospital, following treatment for fracture caused by low-energy trauma. The first infusion was prescribed by rheumatologists, with the following infusions to be prescribed by general practitioners.

Methods: We performed a retrospective observational study initially conducted by written and telephone questionnaires on a population of patients hospitalized in the rheumatology department of HIA Bègin for an osteoporotic fracture. Data was collected between July 2015 and December 2018. A first letter, containing a stamped addressed envelope to the Bègin hospital for ease of reply, was sent to the patients selected for the study. The protocol had to be modified following a very low response rate, unable to address quality addresses. We then tried to contact the patients by phone 3 times and, if unable to reach them, we called their general practitioners on 3 occasions.

Results: 94 patients were initially selected. Every year, we retained within the study patients who had followed their annual zoledronic acid infusion protocol. Taking into account all 94 patients, adherence level for the first infusion was 41.4%, down to 29.7% for the second infusion and down to 12.8% for the third infusion. For those who had the first infusion performed, adherence level for the second infusion was 71.8%, down to 30.8% for the third infusion.

Conclusion: The observance and follow-up of zoledronic acid infusion in France by general practitioners is not adequate. Follow-up measures on an annual basis by the rheumatologist could significantly improve adherence.

AB0895 RELATIONSHIP BETWEEN BONE MINERAL DENSITY, INFLAMMATORY ACTIVITY AND AUTOIMMUNITY IN A COHORT OF EARLY RHEUMATOID ARTHRITIS PATIENTS
S. Garcia Carazo, D. Peiteado, A. Villalba, L. Nuño, M. Díaz, A. Balsa, P. Aguado, Hospital La Paz, Rheumatology, Madrid, Spain; Hospital La Paz, Rheumatology, Madrid, Spain; Hospital La Paz, Rheumatology, Madrid, Spain; Hospital La Paz, Biostatistics, Madrid, Spain

Background: The etiology of bone loss in Rheumatoid Arthritis (RA) is multifactorial and systemic inflammation plays a relevant role. Recently, a relationship between autoimmunity and bone mineral density (BMD) has been described in patients with RA.

Objectives: To study BMD and biochemical parameters of bone metabolism in a cohort of patients with early rheumatoid arthritis, and assess the relationship between them and autoimmunity and other markers of inflammation.

Methods: A prospective longitudinal study was performed. 128 patients from an early Rheumatoid Arthritis Unit (ERAU) were included. All of them fulfilled ACR 2010 classification criteria for RA. Demographic, clinical, biochemical, immunological, radiological and densitometric data, and also inflammatory activity index DAS 28, HAQ functional index, were collected. Any value >20 IU/mL for RF and >30 IU/mL for ACPA was defined as positive.

Results: Between January 2009 and June 2017, 801 patients were evaluated in our ERAU. After two years of follow-up, the most frequent definitive diagnoses were: Early RA 221 (27.6%), Undifferentiated Arthritis 97 (12.1%), Psoriatic Arthritis 62 (7.7%), Spondyloarthritis 54 (6.7%) and autoimmune Diseases 28 (3.4%).

From the 128 patients with early rheumatoid arthritis evaluated, 104 (81.9%) were ACPA positive and 98 (77.2%) RF positive. The mean BMD in the total column was 0.96 ±0.14 g/cm2 and in the femoral neck was 0.76 ±0.12 g/cm2. No correlation of BMD with autoimmunity markers was found in either of the two locations studied, while a negative relationship between BMD and the PCR inflammation marker (BMD femoral neck: r=0.203, p = 0.027 and BMD lumbar spine r=-0.27; p = 0.003) was found. The BMD did not correlate with DAS28 nor the HAQ index.

The mean baseline serum calcium value was 20.7±8.9mg/ml and a negative correlation of basal serum calcium with the functional HAQ index was observed (r=0.23, p = 0.008). No correlation between other autoimmunity (FR and ACPA) and inflammation (VSG, PCR and DAS 28) markers and vitamin D was found.

Conclusion: The BMD in patients with early rheumatoid arthritis of our cohort correlates with the PCR inflammation marker. Unlike other studies shows, in our cohort, serological autoimmunity factors do not have to show an independent effect on BMD.

AB0896 EFFECTIVENESS OF SACROPLASTY IN THE MANAGEMENT OF OSTEOPOROTIC SACRAL FRACTURE IN ELDERLY PATIENTS
S. Hecquet, F. Verhoeven, S. Aubry, C. Prat, D. Wendling, CHRU Jean Minjoz, Rheumatology, Besançon, France; CHRU Jean Minjoz, Radiology, Besançon, France

Background: Sacral fractures are a source of pain leading to loss of autonomy in elderly patients. Sacroplasty may be an effective alternative of conservative medical treatment.

Objectives: To evaluate the short-term analgesic effect of sacroplasty compared to conservative treatment in patients with osteoporotic sacral fractures.

Methods: This is a retrospective study of cases of osteoporotic sacral fractures treated with sacroplasty, compared with cases treated with conservative medical procedure over the same period. Outcome was evaluated by pain (Visual analogic scale) short-term (one month) evolution and side effects occurrence.

Results: From January 2009 to June 2019, eleven patients were treated with sacroplasty for osteoporotic fractures at the Besançon University Hospital Centre. These were compared to 12 patients with osteoporotic sacral fracture with exclusive medical management, as a control group. The two groups were similar in age, gender and pain level at baseline. The median WAS was 7/10 in both groups at baseline. In the sacroplasty group, a significant decrease of pain was observed over the first two weeks, with a tendency remaining at day 30. There were no significant differences in the conservative treatment group at one week (p=0.2), fourteen days (p=0.6) and thirty days (p=0.7) compared to basal assessment.

When comparing the sacroplasty group and the conservative treatment group, no differences were noted at baseline between the two groups, there was a significant difference between the two groups the following day (p=0.001), one
Background: Frailty-fractures (FF) are a health problem and among them, the VFF. They have worse vital prognosis, are at greater risk of new FF, had higher comorbidity, with clinical manifestations in only 30%-40% of cases. One in 6 women and one in 12 adult males will have a VFF.

Objectives: To analyze the clinical characteristics of FF patients attended in the FLS at Virgen Macarena University Hospital. Compare the sociodemographic and clinical characteristics of VFF patients with those with OFF.

Methods: Design: Prospective cohort. Patients attended in the FLS from May 2018 to November 2019 in a protocolized manner (OpenClinica®). Inclusion criteria: a clinical FF in the previous two years. Descriptive statistics: percentages and means with 25th and 75th percentile. Inferential statistic by parametric and nonparametric tests. The project was approved by the Ethics Committee and patients signed consent to participate.

Results: Data from 414 patients with a first FF are analyzed, 101 (25%) with VFF and 313 (75%) with OFF. 188 (45%) hip, 66 (16%) distal radius, 32 (8%) humerus and 27 (6%) miscellaneous (pelvis, ribs, tibia). All VFFs analyzed had clinical symptoms and the number of fractured vertebrae was 2 (1-3). In 28 (37%) were FF of dorsal vertebrae, at 25 (33%) lumbar and 23 (30%) dorsal and lumbar. Comparative analysis showed differences in age VFF 71 (62-77) vs OFF 76 (68 – 83) years, p=0.005. It highlighted a bimodal distribution according to age, with a peak incidence of 55 to 68 years and another between 75-80 years (Graph). Referral unit to FLS: VFF Rheumatology (42%) and/or Traumatology Emergency Room (44%) vs OFF Internal Medicine (45%) and General Traumatology Unit (38%), p=0.001. There were also differences in the treatment with teriparatide (VFF 20% vs OFF 4%); zoledronate (VFF 6% vs OFF 3%) and alendronate (VFF 44% vs OFF 63%, p=0.001); days of immobilization (VFF 30 (0-60) vs OFF 10 (0 - 30), p=0.01); they have greater independence to carry out activities of daily life (Barthel Scale) VFF 95(81 – 100) vs OFF 80 (60 – 95), p=0.001 and lower risk of falls (J D Downton Scale) (VFF 43% vs OFF 60%, p=0.01).

Regarding analgesic treatments, 30% of patients in the sacroplasty group could reduce their analgesic treatment for OP in patients with RA.

Conclusion: VFF have a bimodal age-based distribution, usually occurring in younger patients, with a higher degree of independence and muscle strength and lower risk of falls, although they are associated with longer duration of immobilization, compared to OFF. In our cohort, VFFs affect 2 or more vertebrae and they are commonly treated with parenteral osteoporotic drugs. The use of glucocorticoids doubled the risk of developing a VFF, these findings are similar to those of others published cohorts. This project received a grant of the Ministry Health of the Junta de Andalucía Ref.PIN-0092-2016.

AB0898

IMPACT OF BIOLOGICAL AGENTS, ORAL GLUCOCORTICOIDS, OR BOTH ON THE EFFICACY OF DAILY TERIPARATIDE TREATMENT FOR OSTEOPOOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y Hiraga1, H. Kosugiya2, K. Hattori2, D. Kihira2, 1Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan; 2Nagoya University Graduate School of Medicine, Orthopaedic Surgery and Rheumatology, Nagoya, Japan

Background: Daily teriparatide (dTP) strongly affects bone metabolism in patients with rheumatoid arthritis (RA), resulting in increased bone mineral density (BMD). We reported the 2-year results of dTP treatment for osteoporosis (OP) in patients with RA in EULAR2014 [1]. Drugs affecting bone metabolism, such as biological agents (BIos) and glucocorticoids (GCs), are frequently administered to patients with RA in addition to dTP in daily clinical practice. Although dTP increases bone turnover, BIos reduce osteoclast activity and GCs decrease bone turnover. We reported the effects of GCs or BIos on the efficacy of dTP in EULAR2015 [2]. The present retrospective study investigated the effects of GCs or BIos on the efficacy of dTP in patients with RA using a larger patient cohort.

Objectives: To evaluate the effects of BIos, GCs, or both on the efficacy of dTP treatment for OP in patients with RA.

Methods: The study included 56 female patients who had completed 2 years of dTP treatment. We separated these patients into four groups according to their treatment regimen at dTP initiation: B(-)G(-), included patients who did not receive BIos or GCs (n = 14); B(+)+G(+), included patients treated only with BIos (n = 8); B(-)+G(+), included patients treated only with GCs (n = 24); B(+)+G(+), included

Bibliography:
patients treated with both BIOs and GCs (n = 10). We determined baseline (BL) characteristics, % changes in BMD in the lumbar spine (LS) and total hip (TH) from BL to 24 months, and % changes in serum bone turnover markers (BTMs), such as BAP, P1NP, NTX, and TRACP-5b, from BL to 6 months after dTP initiation. Dunnett’s test was used for comparisons between B(−)G(−) and other groups.

**Results:** The mean ages of the B(−)G(−), B(+)G(−), B(−)G(+), and B(+)% G(+) groups at BL were 70.0, 65.5, 69.6, and 71.5 years, whereas the mean duration of RA in these groups were 15.4, 20.8, 69.9, and 71.5 years, respectively. Furthermore, the mean baseline DAS28-CRP levels in these groups were 2.8, 2.2, 2.8, and 2.3. The mean LS-BMD (g/cm²) at BL were 0.795, 0.619, 0.826, and 0.853, whereas the mean TH-BMD at BL were 0.619, 0.570, 0.601, and 0.629, respectively. The mean % changes in LS-BMD at 24 months were 15.5%, 12.7%, 11.9%, and 8.1%, respectively (Fig 1A). There were no significant differences between B(−)G(−) and other groups. The mean % changes in TH-BMD at 24 months in the B(−)G(−), B(+)% G(−), B(−)G(+), and B(+)% G(+) groups were 6.4%, 5.3%, 4.4%, and 13.5%, respectively (Fig 1B). A significant difference was observed between the B(−)G(−) and B(+)% G(+) groups (p = 0.03). The % changes in BTMs in the B(−)G(−), B(+)% G(−), B(−)G(+), and B(+)% G(+) groups were as follows: BAP, 90.5%, 44.0%, 29.5%, and 87.7%; P1NP, 374.1%, 338.2%, 225.9%, and 640.0%; NTX, 54.5%, 42.5%, and 80.5%; and TRACP-5b, 75.8%, 43.8%, 20.4%, and 87.7%, respectively. No significant differences were observed in the changes in BTMs among the groups.

**Conclusion:** This study suggested that concomitant use of BIOs and GCs inhibited the increase in BMD induced by dTP treatment in patients with RA, particularly TH-BMD. Although BTM analysis revealed no statistical significance, GCs tended to decrease the % change in BTMs.

**TREATMENT STATUS OF PATIENTS WITH GLUCOCORTICOID-INDUCED OSTEOPOROSIS IN THE AKITA ORTHOPEDIC GROUP ON RHEUMATOID ARTHRITIS REGISTRY**

T. Kawano1, T. Kashiwagura2, M. Kobayashi3, Y. Sugimura4, H. Sato5, N. Miyakoshi1, Y. Shimada1. 1Akita University Graduate School of medicine, Orthopedic, Akita, Japan; 2Akita City Hospital, Orthopedic, Akita, Japan; 3Hiraka General Hospital, Orthopedic, Yotokuta, Japan; 4Nakadori General Hospital, Orthopedic, Akita, Japan; 5Kita Akita Municipal Hospital, Orthopedic, Kita Akita, Japan

**Background:** Glucocorticoids (GC) have potent anti-inflammatory and immunosuppressive effects and are used to treat a variety of diseases. However, GC are associated with several adverse effects. Glucocorticoid-induced osteoporosis (GIO), a bone metabolism disorder, accounts for 25% of the side effects associated with GC, and long-term use of these agents leads to fragility fractures in 30 to 50% of patients [1]. GC are frequently used to treat rheumatoid arthritis (RA). No report on the current treatment status for glucocorticoid-induced osteoporosis (GIO) has been published following the publication of the new guidelines for the management and treatment of GIO issued by the Japanese Society for Bone Mineral Research provided in 2014 (Figure 1) [1].

**Objectives:** The present study aimed to investigate the current treatment status of GIO patients in the Akita Orthopedic Group on Rheumatoid Arthritis (AORA) registry.

**Methods:** This retrospective, multicenter study included 683 patients (138 men, 545 women) with fracture risk factor scores ≥3 based on the new guidelines who were in the AORA registry. We examined patient characteristics, differences in patient backgrounds between treated and non-treated groups.

**Results:** There were no significant differences in mean GC dose between men and women (4.0 ± 2.3 mg/day vs 3.6 ± 1.8 mg/day, p = 0.08). The mean disease duration of RA in women was significantly longer than in men (180.2 ± 140.2 months vs 143.8 ± 129.6 months). Untreated GIO patients were significantly more likely to be men and younger. The univariate analysis showed that clinic visits, male sex, younger age, and longer disease duration were significant risk factors for lack of therapeutic intervention for GIO. Multivariate analysis showed that being treated in a clinic, male sex, and younger age were significant risk factors for lack of therapeutic intervention for GIO.

**Conclusion:** Our results emphasize the importance of considering the prevention and treatment of GIO in all patients with RA, including younger and male patients, who have lower intervention rates.

**FREQUENCY OF LOCAL COMPLICATIONS AFTER TOTAL HIP ARTHROPLASTY IN PATIENTS WITH RHEUMATIC DISEASES.**

A. Khramov1, M. Makarov1, S. Makarov1, E. Naryshkin1, S. Maglevaniy1. 1V.A. Nasonova Research Institute of Rheumatology, Orthopaedic, Moscow, Russian Federation

**Background:** Surgical treatment of patients with rheumatic diseases (RD) is associated with an increased risk of complications. It is caused by presence of an inflammatory process, osteoporosis, reduced physical activity, severity of functional impairment, long-term glucocorticoid therapy, biological and disease-modifying antirheumatic drugs. All this provides elongated wound healing period, the development of infectious complications and increased risk of periprosthetic fractures.

**Objectives:** To study a frequency of local complications of total hip arthroplasty (THA) in patients with inflammatory RD and osteoarthritis (OA).

**Methods:** We analyzed 1591 THA, which were performed to RD patients between 2000 and 2019 years.

**Results:** We performed 882 arthroplasties in patients with inflammatory RD, which consisted of patients with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), juvenile rheumatoid arthritis (JRA), ankylosing spondylitis (AS), systemic scleroderma (SSD), and also 709 operations in OA patients. Local complications after THA were 120 (7.5%), of these 83 (9.41%) in patients with inflammatory RD and 37 (5.22%) in OA patients. We revealed a significantly greater number of complications in patients with inflammatory RD (p<0.005).

**Conclusion:** Inflammatory RD (RA, SLE, JRA, AS, SSD) patients have local complications after THA (9.41%) 1.8 times more often than OA patients (5.22%). It shows that the operative treatment of patients with RD requires a special approach, management and careful treatment of the bone and surrounding tissues during surgery.

AB9001 PREVALENCE OF OSTEOPOROSIS IN ITALIAN POSTMENOPAUSAL WOMEN ACCORDING TO DEFRA ALGORITHM

A. M. Lurati1, A. Laria2, L. Castelanova3, R. Faggioni4, A. Tamburello5, A. Massone6, 1Rheumatology Unit Fornaroli Hospital Magenta Italy; Magenta, Italy; 2Internal Medicine Unit, Ospedale Civile, Legnano, Italy

Background: Osteoporosis is a recognized health problem and the burden of the disease is mostly associated with the occurrence of hip and vertebral fracture.

Objectives: This study was aimed at evaluating the prevalence of osteoporosis in Italian postmenopausal women, defined as DEFRA calculation as a 10 years fracture risk equal or higher than 20%.

Methods: This is a monocenter cohort study evaluating 1850 post-menopausal women aged 50 years and older. All the participants were evaluated as far as anthropometrics. Defra questionnaire was administered and calculated with bone mineral density (DXA) measured at lumbar spine and femoral neck.

Results: The prevalence of osteoporosis as assessed by DEFRA was 29.8% in the whole population, according to literature. The frequency of a risk fracture equal or higher than 20% varied from 7.9% in the group aged 50-59 years to 35% in subjects aged >80. Among clinical risk factors for fracture, the presence of a previous fracture (spine primarily) was the most commonly observed.

Conclusion: Our data showed that about one third of post-menopausal women aged 50 and older in Italy has osteoporosis on the basis of DEFRA algorithm, with a high 10 years fracture risk. A previous fracture is the most common risk factor. The data should be considered in relation to the need to increase prevention strategies and therapeutic intervention.

AB9002 BONE HEALTH IN PATIENTS WITH JUVENILE ONSET DERMATOMYOSITIS ASSESSED AFTER LONG-TERM FOLLOW-UP: A CASE CONTROL STUDY

H. Marstein1,2,3, K. Godang4, B. Flato2,5, I. Sjaastad1,3,6, J. Bollerslev2,7, H. Sanner1,8, 1Institute for Experimental Medical Research and KG Jebsen Center for Cardiovascular Research, Oslo University Hospital, Ullevål, Oslo, Norway; 2Bjørknes University College, Oslo, Norway; 3Faculty of Medicine; University of Oslo, Oslo, Oslo, Norway; 4Dept of Endocrinology; Oslo University Hospital, Rikshospitalet, Oslo, Norway; 5Dept of Rheumatology, Oslo University Hospital, Rikshospitalet, Oslo, Norway; 6Dept of Cardiology, Oslo University Hospital, Ullevål, Oslo, Norway

Background: Patients with juvenile dermatomyositis (JDM) are at risk of developing low bone mineral density (BMD) and not reach peak bone mass, mainly due to prednisolone (pred) treatment [1], making them prone to osteoporotic fractures later in life.

Objectives: To compare BMD in longterm JDM patients (Pts) with that of controls (Ctr) and in Pts explore how disease variables affect BMD.

Methods: Pts (n=59) were clinically examined median 16.8y (range 6.6 - 27.0 y) after disease onset and compared 1:1 with age/sex matched Ctr. Dual-energy X-ray absorptiometry (DXA) was used to measure BMD and Z-scores in whole body, lumbar spine at L2-L4 (spine). In those ≥20y; also proximal (PR) and distal 1/3 radius (DR), and total hip were examined. Pred at follow up was reported, and cumulative dose calculated. Bone remodeling factors: C-terminal telopeptide (CTX), aminoterminal propeptide (P1NP) and 25(OH) vitamin D (25(OH)D) were measured in serum.

Results: BMD was lower in Pts than Ctr, and both WB and spine BMD and Z scores were lower in Pts than Ctr < 20y (Tb1). DBM and Z score were both lower in Pts ≥20y. Serum analysis showed lower 25(OH)D was lower in Pts than Ctr. In Pts ≥20y VitD was lower and eSR was higher compared to Ctr.

In Pts ≥20y: moderate negative associations were found between both BMD WB and spine, and pred use at follow up (R = -0.43), and between BMD PR and VitD (R=-0.34). There was a positive moderate association between Z-score PR and CTX (-0.45) not found in Ctr, and between Z-score total hip and cumulative pred use (R = 0.38; p<0.05).

In Pts <20y moderate negative associations were found between Z-score for spine and months of pred use and cumulative pred doses (R’s = -0.40 and -0.48, p<0.05). Other associations found in Pts <20y were also found in respective Ctr.

Conclusion: We found that Pts bone health was affected differently in young and adult JDM-Pts. Association analysis between BMD, Z-scores and mediators for bone remodeling factors were not conclusive. We will perform linear regression analysis to determine if and how BMDs and Z-scores are dependent on pred use, time and doses, and factors important for bone remodeling.

AB9003 VITAMIN D LEVELS IN PRIMARY CARE AND RHEUMATOLOGY PATIENTS

H. D. Marta1, A. Garcia Dorita1, C. Luis Zárate1, S. Bustabad2, F. Diaz-Gonzalez2, 1Hospital Universitario de Canarias, San Cristóbal de La Laguna, Spain

Background: Although many studies are calling into question the benefits commonly attributed to vitamin D out of the bone sphere, in the recent years its determination and supplementation has been generalized in the population. Causes of this trend are not clear, but generalist media pressure or even specialized over patients and doctors, along with overrated normality levels could be contributing to this fact. Actual literature23 indicates that 25-OH vitamin D levels of 30ng/ml or higher are not necessary, and most of the authors agree that 20ng/ml levels are enough for the general population, and only levels below 12.5ng/ml must be considered deficient and subsidiaries of supplementation.

Objectives: To obtain the vitamin D levels distribution from a sample of individuals with no bone pathology, or supplementation prescription in Tenerife’s North Area.

Methods: Retrospective descriptive study of the 25-OH vitamin D levels requests from the Tenerife’s North Area, made for any reason by the Primary Care Doctor or the rheumatologist, both in the Primary Care Centers and the Hospital University of Canarias (HUC). 25-OH vitamin D values were gathered from 2662 blood samples from a total of 2635 patients, from September to November of 2018 (2241 from Primary Care and 421 from rheumatology). In order to determine the use of calcium and vitamin D supplements, and the presence of bone pathology, either renal or from a malabsorptive process, 400 individuals were randomized (250 from primary care and 150 from rheumatology). Demographic data (age and gender), calcium serum, phosphorus and 25-OH vitamin D were gathered for the individual records. With regards to the treatment, data about vitamin D supplements, calcium with vitamin D, or the sum of both, that the patient may have in electrical prescriptions at that time; as well as osteoporosis treatment (bisphosphonates, denosumab or teriparatide) were gathered.

Results: Using the age, gender, male/female relation, the levels of vitamin D, calcium and phosphor, as comparison factors; the characteristics of the random population were statistically indistinguishable from the global population. Regarding the random sample characteristics, from the 150 rheumatology patients, 11 were men (73%) and 139 women (27%). While from the 250 primary care patients, 66 were men (26.4%) and 184 were women (73.6%). The average age of the primary care sample was 55.76±19.72 years and 65.16±13.84 years in the rheumatology sample.

In the total random healthy population: without bone pathology, renal or malabsorptive and without calcium, vitamin D or antiresorptive drug (n=181) treatment, the levels of vitamin D were 31±14ng/ml with a normal distribution and without clear differences between the primary care and rheumatology patients. When the healthy population distribution was studied by vitamin D levels, the 55% presented values below 30ng/ml, 12% below 20ng/ml and 4% showed levels below 12.5ng/ml levels agreed as deficient (see graph).

Conclusion: The 55% of the patients studied in primary care and rheumatology, without renal, digestive or bone disease and without vitamin D supplement,
presented vitamin levels below the actual limits of 30ng/mL. These limits, used by most of the laboratories, tend to overestimate the vitamin D deficiency.

AB0905
THE PREVALENCE AND RISK FACTORS OF OSTEOPOROSIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES: A TUNISIAN STUDY

J. Mnif1, H. Gdoura1, L. Chtourou1, A. Amouri1, M. Boudabous1, N. Tahni1.
1University Hospital Hedi Chaker, Gastroenterology, Sfax, Tunisia

Background: Osteoporosis is as known a chronic complication of inflammatory bowel diseases (IBD). Its etiopathogenesis is often multifactorial.

Objectives: The aim of our study was to describe the prevalence of reduced bone mineral density and to identify risk factors of osteoporosis in patients with inflammatory bowel diseases.

Methods: This is a retrospective study over three years, collecting patients suffering from IBD and having benefited from a bone densitometry. We have specified for each patient the clinical data and the IBD characteristics. Bone mineral density (BMD, g/cm²) was assessed by dual x-ray absorptiometry. Osteoporosis was diagnosed when BMD was 2.5 standard deviations below the mean peak value in young adults (T score, 2.25 SD). Patients with other pathology that may change the bone metabolism were excluded.

Results: sixty-one patients were included with an average age of 38 ± 13 years [16-73]. The sex ratio M / F was 1.25, 69% of patients had ulcerative colitis. The bone density profile was normal in 49.2% of the cases. Osteoporosis and osteopenia were noted in 13.1% and 37.7% of patients, respectively. Osteoporosis was associated with advanced age (50.5 ± 16.5 years vs 36.26 ± 12.93 years; p = 0.007) and longer course disease (6.75 ± 7, 4 years vs 2.5 ± 4 years; p = 0.015). The cumulative dose of prednisone equivalent used in patients with osteoporosis was significantly higher than the other patients (2775 ± 3338 mg vs 706 ± 1449 mg; p = 0.003). Osteopenia was more frequently associated with crohn's disease (58% vs 28.6% p = 0.0029). There was no significant difference between the group with osteoporosis or osteopenia and the group with normal bone densitometry for sex and body mass index.

Conclusion: Osteoporosis during IBD is associated with advanced age, longer duration of illness and administration of high doses of corticosteroids. The high proportion of osteoporosis and osteopenia in our study underlines the importance of systematic BMD measurement in all IBD patients as a base for initiating the appropriate treatment.

AB0906
PREVALENCE OF HYPOVITAMINOSIS D IN DIAGNOSTIC PATIENTS OF BREAST NEOPLASIA IS GREATER THAN EXPECTED FOR THE GENERAL POPULATION? SERIES OF 200 DIAGNOSTIC PATIENTS OF BREAST NEOPLASIA IN A TERTIARY HOSPITAL INITIATING TREATMENT WITH AROMATASE INHIBITORS

D. Montero1, O. Ibarguengoitia1, L. Vega1, C. Garcia1, J. M. Blanco1, M. E. Ruiz1, A. R. Inchaurre1, O. Fernandez1, I. Calvo1, C. E. Perez1, M. L. Garcia Vivar1, E. Cuande1, E. Galindez1, A. Bilbao1, I. Torre1, 1Basurto University
Background: In our population the prevalence of hypovitaminosis D is high. A recent cross-sectional observational study conducted in Spain shows that 63% of postmenopausal women who receive osteoporosis (OP) therapy and 76% who do not receive treatment had 25 (OH) D levels below 30 ng/mL. The latest studies show a relationship between hypovitaminosis D and the development of systemic inflammatory and tumor diseases, determined by the presence of receptors in various tissues, including breast.

Objectives: To determine which levels of serum 25 (OH) D, and secondarily calcium, phosphorus, PTH and CTX, present 200 patients diagnosed with breast cancer and taking hormonal treatment, referred to a monographic OP consultation of a tertiary hospital for the assessment of their bone metabolism, and if these values differ from what is expected for the general population.

Methods: Retrospective cross-sectional study of 200 women diagnosed with breast cancer receiving treatment with aromatase inhibitors (AI), performed in a tertiary hospital. Blood levels of vitamin D, calcium, phosphorus, PTH and CTX have been collected, as well as other variables and risk factors.

Results: 200 patients with a mean age of 64.8 years and an ED of 9.5 were collected. The median is 64.5 (Q1 58 and Q3 72). The vitamin D levels presented by the study patients were <10 ng/mL in 13 patients (6.67%), 11-20 ng/mL in 50 (25.64%), 21-30 ng/mL in 68 (34.87%), 31-70 ng/mL in 62 (31.79%), and > 70 ng/mL in 2 (1.03%). This implies that in 67.18% of the patients they had values below the optimal range. 92.51% of patients (180) presented PTH values within the normal range and only 76.9% presented values above normal. The serum calcium and phosphorus levels of the patients selected for the study had ranges within normal (99.49%) except 1 case that presented high values (0.51%) for both. The values of CTX (carboxyterminal telopeptide used as a marker of bone resorption) were in the normal range in 81.86% of patients (195), low values in 0.52% (1) and values above the normal range by 17.53% (34).

Conclusion: The prevalence of insufficient levels of vitamin D in our study (Breast cancer + AI) is not greater than that estimated for the general population according to various studies. Our study found that 67.18% of patients (2/3 of the selected population) had values below those considered optimal (<30 ng/mL) and 32% had values <20. Only 76.9% of the patients presented PTH values above the normal range. In 82% of patients, CTX used as a marker of bone resorption had normal values.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.5595
Background: Glucocorticosteroids (GCS) are widely used in the treatment of rheumatoid arthritis (RA) as bridge-therapy. Though, according to last recommenda-
tions for the treatment of RA GCS should be considered in short-term and different doses in the context of administration and should be tapered as rapidly as clinically feasible. But in some cases, patients received GCS for a long period in low doses (<75 mg/day prednisone equivalent). It is well known, that long-term GCS use is associated with osteoporosis and increased risk of fracture, even at low daily doses. On the other hand, RA itself leads to the changes in the biomechanical properties of bones through the increased production of pro-in-
fammatory cytokines. Furthermore, immobilization due to pain from inflamed joints and impairment of physical activity are in response for osteoporosis formation. In addi-
tion, patients with RA are often co-prescribed a proton pump inhibitor, which have a reported effect on occurrence of osteoporosis. Taking into consideration all mentioned above patients with RA, receiving GCS therapy reveal high risk for osteoporosis and fracture formation and require corresponding treatment.

Objectives: The aim of this study is to evaluate the effect of 12 months treat-
ment with denosumab (bone-modifying agent) in patients with RA, contin-
uing to receive GCS.

Methods: 50 female patients with RA (mean age 54 ± 6.3 years) were enrolled in this study. Duration of RA was 10.5 ± 3.2 years. All patients received pred-
nisone 15.3 ± 10.25 mg/day with gradually escalation of dose for ≥ 12 months. As DMARD therapy patients received methotrexate dose in average 15-20 mg/week (75%), leflunomide 20 mg/day (25%). Bone mineral density (BMD) is measured in all patients by Dual-energy X-ray absorptiometry (DEXA) at baseline and 12 months after treatment with denosumab. All patients received denosumab 60 mg subcutaneously once every 6 months.

Results: The measurement of BMD at baseline revealed the following results: T-score in lumbar spine was -1.95 ± 1.36 and in total hip -1.64 ± 0.94 with high major osteoporotic fracture risk. All patients completed the study. The BMD after 12 months significantly increased both in lumbar spine +4.2 ± (p < 0.001) and in total hip +2.1% (p < 0.001).

Conclusion: Denosumab should be considered as a drug of choice in RA patients, continuing to receive GCS. Further large investigations are needed to assess the BMD after discontinuation of denosumab and evaluate fracture risk in this population of patient.

AB0911 PREVALENCE AND RISK FACTORS OF HIP FRACTURE ASSOCIATED WITH OSTEOPOROSIS IN A GERIATRIC POPULATION FROM COLOMBIAN NORTH EAST.

M. Romero1, M. Cadena1, J. Osma1, Y. Santamaria1,2. 1Universidad Industrial de Santander, Bucaramanga, Colombia; 2Universidad de Antioquia, Medellín, Colombia

Background: Hip fracture is a frequent cause of hospital admission in older adults. The prevalence of hip fracture associated with osteoporosis in the elderly is 18% in women and 6% in men. Likewise, the attention of this event requires an approximate value of 2,943 dollars, which represents an average of 18.95% of the per capita income of most countries. It is also established that appropriate and timely treatment of osteoporosis can prevent the appearance of fractures.

Objectives: The aim of this study was to determine the prevalence of hip frac-
ture associated with osteoporosis, as well as the associated factors to its present-
ation in a geriatric population in Colombia.

Methods: Cross-sectional study that included 130 patients over 65 years old, who consulted the University Hospital of Santander with hip fracture. The main variable of exposition was the medical history of osteoporosis. Descriptive anal-
ysis was performed with absolute and relative frequency measurements for the qualitative variables and central tendency measures and dispersion according to the distribution of the variables. Subsequently, the bivariate logistic regression analysis was performed to identify the associated risk variables. The analysis was performed with the Stata 12.0 Software.

Results: From the 130 patients included in the study, 33.85% corresponded to the male gender. The average age was 82.49 years with a DS of 8.35 years. The median length of hospital stay was 17.5 days with an interquartile range of 11 to 26 days. The most common comorbidity was hypertension in 65.38%, followed by diabetes and COPD in 21.54%, heart failure in 19.23% and chronic kidney disease in 17.69%. The median Charlson score was 5 with an interquartile range between 4 and 6 points. 13.85% of the patients admitted had concomitant osteoporosis, 77.7% of them were women and 8.46% of them had severe osteo-
porosis, with history of prior fracture, without treatment. In the bivariate analysis, an association was found between having COPD (OR: 4.89, 95% CI 1.7-13.95, p = 0.003), dementia (OR: 3.20, 95% CI 1.05-19.56, p = 0.044), malnutrition (OR: 3.42, IC95% 1.10 - 10.60, p = 0.032), and osteoporosis associated with hip fracture at hospital admission. Likewise, a greater probability was found for the development of in-hospital pneumonia (OR: 2.48, 95% CI 1.14 - 7.98, p = 0.04) in patients with osteoporosis compared to those who did not have bone disease. The OR of 13.85% of those who entered due to hip fracture had osteop-
orosis as comorbidity, data comparable to that previously reported. Vari-
ables associated with the presence of osteoporosis at admission in patients with hip fracture were found like history of COPD, dementia, and malnutri-
tion, which makes it likely that those patients with pathologies that decrease physical activity or food intake can impact in an important way the appear-
ance of osteoporosis. One of the most important contributions of this study
is the identification of in-hospital complication (pneumonia), which should be actively monitored in these patients.

CLINICAL UTILITY OF THE WARD TRIANGLE OF HIP BONE DENSITOMETRY: DATA FROM AN FLS UNIT

J. Rosas1, A. Pons1, C. Cano1, E. Ivans2, M. Lorente Betoret2, J. M. Senabre Gallego1, G. Santos Soler3, J. A. Bernal3, J. A. García-Gómez3, X. Barber3 on behalf of AIRE-MB Group. 1Hospital Marina Baixa, Rheumatology, Villajoyosa (Alicante), Spain; 2Hospital Marina Baixa, Rheumatology, Villajoyosa (Alicante), Spain; 3Hospital General Universitario de Elche, Infectious Disease, Elche, Spain; University Miguel Hernández de Elche, CIIO, Elche (Alicante), Spain

Objectives: To evaluate the clinical utility of Ward's triangle (W) of bone densitometry (BMD) of the hip in a population of postmenopausal women referred to BMD from a FLS Unit coordinated by Rheumatology (FLS-REU).

Methods: Retrospective study, which includes, after informed consent, postmenopausal women referred by any department of specialized medicine or primary care medicine, of the health department, to the FLS-REU Unit of our center, during the period of February 2010 to October 2019. General patient data were collected (age, gender), and risk factors for OP. BMD of the lumbar spine (CL) and hip (femoral neck, total hip and W) was performed, except if there was lumbar surgery, severe scoliosis, or a bilateral hip prosthesis.

The BMD outcome was distributed in normal (T index [Ts] to -1 SD), osteopenia (-1 SD < Ts < -2.5 SD), or severe OP (Ts: <-3 DE).

Results: 5,740 postmenopausal women referred for BMD are included, with the W result available (Table 1). The result of the mean Ts (SD) was: in CL: -1.49 (1.48) SD, femoral neck: -1.33 (1.11) SD and in W: -2.05 (1.12) SD. In 947 (16%) women, the W was normal, with a mean Ts: -0.28 (1.12) SD; osteopenia in 2,606 (45%): -1.83 (1.12) SD and OP in 2,197 (39%) SD, of which 1,010 (61%) had mild-moderate OP and 967 (49%), severe OP.

The table shows the BMD results of W and CL, the correlation coefficient (r) being 0.70, with AUC: 0.757 [0.744-0.770].

In the analysis by ROC curve, the cut-off point of Ts in W is 0.26 (0.24-0.28, P = 0). The probability that a result in W of normal BMD is normal is 0.702 [0.687 -0.716] and for OP in CL -2.35 DE (sensitivity: 0.69, specificity: 0.70, with AUC: 0.757 [0.744-0.770]).

Conclusion: For clinical practice, the usefulness of the W result is low, although if the BMD result is normal, there is a 73% probability that in CL it will also be 2. The correlation between the result of W and CL, although significant, is slight. 3. The cut-off points of Ts, with better sensitivity and specificity, that correlate a W osteopenia or osteoporosis with the result in CL is -1.85 and -2.35 SD, respectively.

Disclosure of Interests: The study was supported by a research grant from the Association for Research in Rheumatology of the Marina Baixa (AIRE-MB).

AB0913

PREDICTING PATIENTS AT RISK OF FRAILITY FRACTURE WITH NORMAL BONE MINERAL DENSITY: AN OBSERVATIONAL STUDY

C. Saleh1, M. Bukhari1, S. M. Bilgrami1. 1Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom

Background: There is an increased risk of low-trauma fracture as bone mineral density (BMD) decreases, however a large proportion of these fragility fractures occur in those without osteoporosis or osteopenia. The widely used FRAX tool uses femoral neck (FN) BMD, amongst other parameters, to predict fracture risk. In those with normal BMD, data is lacking on the weight these other parameters hold in predicting future risk. Indeed, FN BMD can be facultative in the estimation of risk when using FRAX.

Objectives: To establish predictors of fragility fracture in a patient cohort referred for BMD estimation, subsequently found to have bilateral FN BMD of greater than 1.

Methods: A cohort of patients in the North West of England referred between 2004 and 2014 for BMD estimation, with both left and right FN BMD of greater than 1 were identified, and then parameters identified and analysed included age at scan, gender, FN BMD at left hip, body mass index (BMI), fat mass, family history of fracture, alcohol history of 3 or more units per day, smoking status, rheumatoid arthritis (RA), and steroid exposure. Patients with fragility fracture were compared with those without fracture. Chi-square test and T-test were applied to categorical and continuous data respectively. Further univariate and multivariate logistic regression models were fitted to determine parameters associated with future fracture risk.

Results: 619 patients with bilateral FN BMD of greater than 1 were identified and included in analysis. Mean age at scan was 54 years (SD 11.82) and 542 (87.56%) were female. 92 (14.86%) patients had a fragility fracture. Mean left FN BMD was 1.91 (SD 0.71), and mean right FN BMD was 1.92 (SD 0.68). Results of the univariate analysis are described in Table 1 below.

Table 1. Logistic regression analysis of patient parameters with unadjusted and adjusted odds ratios for fragility fracture

AB0914

BONE LOSS AND NEW FRACTURES WITH DENOSUMAB TREATMENT

C. Sanguesa1, I. Casafont-Solé1, A. Nack1, S. Holgado Pérez2, M. Martinez-Morillo3, M. Aparicio Rovira1, A. Prior-Espinol1, M. Aparicio Espinar1, A. Riveros1, L. Mateo1, A. Olive1, L. Gilfe1, 1Germanos Tiss & Pujol University Hospital, Rheumatology, Badalona, Spain
Background: The incidence and factors related to an inadequate response to denosumab (Dmb) treatment remain unclear.

Objectives: To describe clinical, analytical and densitometric characteristics of patients with inadequate response (IR) to Dmb in clinical practice. IR was defined as the presence of a new fracture [fxs-IR] or a significant decrease in BMD (≥5% lumbar or ≥4% femoral) [BMD-IR].

Methods: retrospective study of patients with IR to Dmb treatment. Data of demographic variables, risk factors for osteoporosis, history of fractures, previous anti-osteoporotic treatment, densitometric and analytical parameters were collected before and after IR.

Results: 22 patients were included (19W:3M) with mean age of 75±10years. The causes of osteoporosis were: postmenopausal (50%), induced by glucocorticoids (22.7%), alcoholic (9.09%) and multifactorial (18.8%). Most patients were previously treated with bisphosphonates (59.09%, duration 5.2±2.6y) and had previous vertebral fractures (54.54%, median 3).

During Dmb treatment, 10 patients presented a BMD-IR (with a mean bone loss up to -3.5% at femur and -5.8% at lumbar spine) and 12 had fxs-IR (vertebral [n=8], humerus [n=3], pelvis [n=1], iba [n=1]). No significant differences were observed in duration of Dmb between both IR groups [Fxs-IR: 3.2±1.9 vs BMD-IR:2.4±1.2y]. In the BMD-IR group, the BMD loss was higher at lumbar spine than at total hip (-6.6%±3.7 vs -1.9%±4.8).

Only 1 patient of the fxs-IR had a secondary cause of IR (mieloma multiple).

In the fxs-IR group, most patients started combined treatment with teriparatide (n=4), 1 changed to teriparatide and 7 remained with Dmb. In the BMD-IR group, most maintained Dmb treatment (n=8) and 2 switched to zoledronate.

Conclusion: Most patients who developed IR to Dmb had been previously treated with bisphosphonates and had previous fragility fractures and appears within the first 3 years of treatment. BMD loss seems to be more marked at spine than total hip. Only one patient had a secondary cause of IR.

BONE MINERAL DENSITY AND FRACTURE FREQUENCY IN PREMENOPAUSAL WOMEN WITH RHEUMATIC DISEASES

N. Toropovska1, O. Dobrovolskaya2, O. Nikitinskaya3, N. Demin4, A. Smirnov1, L. Shornikova5, V.A. Nosonova Scientific and Research Institute of Rheumatology, Moscow, Russian Federation

Background: The onset of the disease in young and middle age is typical for rheumatic diseases (RDS), but most studies on osteoporosis were conducted in patients (pts) older than 50 years, which included postmenopausal women.

Objectives: To assess bone mineral density (BMD), fracture frequency and the factors associated with low BMD in premenopausal women with RDS.

Methods: 160 women (median age, 36 [29; 43] years): 120 pts with RDS (43 rheumatoid arthritis [RA], 53 systemic sclerosis [SSc] and 24 parietic arthritis [PsA]) and 40 age-matched healthy controls were enrolled in the study. We performed a dual-energy X-ray absorptiometry (DXA, Hologic Discovery A, USA) to measure BMD in lumbar spine, femoral neck and total hip. BMD decreasing grade was evaluated by the Z-score <-2SD. All pts were interviewed using a unified questionnaire including assessment of daily dietary calcium intake. Serum vitamin D, C-reactive protein and erythrocyte sedimentation rate (ESR) measurements were done.

Results: 25% pts with RDS and only 8% healthy controls have low BMD (p=0.02). RA, SSc and PsA pts had low BMD in 37%, 21% and 13%, respectively, that was more often than in healthy women (p=0.004, p=0.046 and p= 0.081, respectively). 9.3% RA pts and 75% SSc pts had low energy fractures. BMD of RDS pts in all areas of measurement demonstrated a direct correlation with height, weight, body mass index, and serum vitamin D concentration and an inverse correlation with age, weight and bone density at baseline. Also, proximal femur BMD inversely correlated with RDs duration. BMD of femoral neck and total hip inversely correlated with C-reactive protein level in SSc pts. In RA women we found a direct correlation between lumbar spine and femur BMD and ESR.

Conclusion: 25% of premenopausal women with RDS had reduced BMD and needed monitoring and osteoporosis prevention, while 9.3% pts with RA and 75% women with SSc needed anti-osteoporotic treatment.

response to synovial crystals are more pronounced in elderly patients or not is unknown.

**Objective:** To test the hypothesis whether aging associates with a more pronounced synovial inflammation in response to urate and CPP crystals.

**Methods:** Gout or CPPD patients with a synovial fluid (SF) aspiration were included. Clinical, blood and synovial parameters were recorded. In the Cytokine study, SF was analyzed for interleukin (IL)-1 beta, IL-6, IL-8, IL-10, IL-12p70, interferon-gamma (IFN-gamma), tumor necrosis factor-alpha (TNF-alpha), IL-17, and transforming growth factor-beta (TGF-beta) by multiplexed cytokine analysis.

In the Cell study, SF samples were immunophenotyped by flow cytometry, including surface markers CD4+ (CD4+), CD8+ (CD8+), and following stimulation for intracellular IFN-gamma and IL-17. The patients were divided into two groups by age median-split.

**Statistical analysis**

Categorical variables were reported as frequencies. Continuous variables were compared using Student’s t-test or in case of non-normal distribution Mann-Whitney U test.

**AB0918 FACTORS ASSOCIATED WITH ACHIEVEMENT OF TARGET SERUM URIC ACID IN PATIENTS WITH NON-TOPHACEOUS GOUT ATTENDING PRIMARY CARE CLINICS.**

**H. Baharuddin1, S. P. Gan2, S. S. Ch’ng2, M. Mohd Zain2. 1Universiti Teknologi MARA, Faculty of Medicine, Selangor, Malaysia; 2Hospital Selayang, Rheumatology Unit, Selangor, Malaysia**

**Background:** Gout is characterised by deposition of monosodium urate crystal in the synovial fluid of joint and other tissues, in the presence of elevated serum uric acid (SUA). Dose-escalation strategy with allopurinol as first-line urate lowering therapy (ULT) was shown to be cost effective and a target SUA of less than 360µmol/L was recommended in non-tophaceous gout. Some of the barriers to treatment effectiveness were related to physician and patient-related factors. To investigate the factors associated with achievement of target SUA in patients with non-tophaceous gout attending primary care clinics.

**Methods:** A cross-sectional study was conducted over four months on patients with gout attending 21 primary care clinics in Selangor, an urbanised state in Malaysia. The demographic and clinical data, including the most recent SUA within six months of study participation, were obtained from patients’ interview and medical records. Obesity was defined as body mass index (BMI) of >27.5kg/m². Data was analysed for patients with non-tophaceous gout. Comparison between patients who achieved and did not achieve target SUA, defined as <360µmol/L, was performed using chi-square and student t-test for categorical and continuous data, respectively.

**Results:** Four hundred and twenty-six patients with gout participated in this study and 343 (80.5%) patients had non-tophaceous gout. Their mean age was 57.7 (+12.9) years. Majority were men (280 patients), Malay (280 patients) and had at least a secondary education (223 patients). There were high prevalence of cardiovascular co-morbidities; hypertension in 279 (82.3%), dyslipidaemia in 235 (68.5%), diabetes mellitus in 154 (49.4%) and obesity in 167 of 265 (63%). There were 280 patients diagnosed with gout for more than six months and 201 (71.6%) had recent SUA; 44 (21.9%) achieved target SUA and 157 (78.1%) did not achieve target SUA. The factors found to be significantly different between the two groups were age, ethnicity, education level, BMI and SUA level before ULT initiation. (Table 1) The mean allopurinol dose were similar between patients who achieved and did not achieved target SUA (191.3±80.8mg vs 197.1±72.5mg, p=0.56) despite significant difference in the mean SUA (301.5±70.3µmol/L vs 488.3±93.1µmol/L, p<0.01).

**Conclusion:** There was a low percentage of patients who achieved target SUA in primary care clinics. Older age, ethnicity other than Malay, lower BMI and lower SUA level before ULT initiation were significantly associated with achievement of target SUA. Higher education was significantly associated with failure to achieve target SUA and in these patients, allopurinol was not titrated according to SUA level.

Background: Articular involvement in acute gout attack is extremely common and mainly characterized by arthritis, which are usually transient, severe, reversible and well responsive to treatment. The involvement of tendons and entheses in lower extremity is a consequence of monosodium urate related disease through US (ultrasound) assessment have been described. US findings in gout raising the hypothesis that enthesal involvement could be a missing target in the clinical evaluation of gout patients.

Objectives: To evaluate by ultrasound (US) the frequency and characteristics of lower extremity enthesal involvement in acute gout attack patients.

Methods: US assessment were performed by independent rheumatologist on 31 patients with acute gout attack. Presence of lower extremity enthesal involvement were evaluated by grey-scale (GS) and power Doppler (PD). US assessment contain quadriceps, patellar and Achilles tendons, and plantar fascia entheses according to the OMERACT definitions.

Results: US revealed one or more abnormalities in at least one enthesis in 22 out of 31 gout patients (71.0%) and 47 out of 51 entheses (92.2%). Among the affected entheses, the patellar insertion of quadriceps tendon was most commonly involved (57.4%) during acute gout attack, followed by the calcaneal insertion of the Achilles tendon (17.0%) and distal insertion of the patellar tendon (14.9%). The proximal insertion of the patellar tendon and calcaneal insertion of the plantar fascia were involved in 8.5% and 2.1%, respectively. Bone erosions and osteophytes were found in affected entheses (10.6% and 25.5%, respectively).

Conclusion: Our study identifies that lower extremity enthesal involvement is a missing target in the evaluation of patients with acute gout attack. US plays a key role in the assessment of both clinical and subclinical enthesis in gout patients.

AB00921 COMPARISON OF EFFICACY AND SAFETY OF DIFFERENT ANTI-INFLAMMATORY DRUGS AT INITIATION OF URATE-LOWERING THERAPY IN PATIENTS WITH GOUT (PRELIMINARY DATA)

M. Chikina1, M. Eliseev1. 1V.A. Nasonova Research Institute of Rheumatology, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: NSAIDs, colchicine and glucocorticoids are used for prevention of acute gouty arthritis in gout patients, yet there is little data on their comparative efficacy. Objectives: Comparison of efficacy and safety of different anti-inflammatory drugs used for prevention of acute arthritis at initiation of urate-lowering therapy in gout patients.

Methods: This monocentric prospective study included 79 gout patients (75 (94.9%) male and 4 (5.1%) female patients) with the mean age of 51.3±10.9 years old. The inclusion criteria were the following: established gout (ACR/EULAR 2015 criteria), aged 18-80, serum uric acid level <360µmol/L, absence of urate-lowering therapy at baseline and at least one gout flare within past three months. The exclusion criteria were: absolute contraindications to all of the study drugs, GFR <30ml/min/1.73m2. All of the patients were prescribed urate-lowering therapy (allopurinol or febuxostat), the dose was titrated until the target uric acid level (<360µmol/L) was achieved. Simultaneously, preventive anti-inflammatory therapy was initiated and the drug for each patient was chosen individually: colchicine 0.5mg/day or any NSAID in minimal anti-inflammatory dose or prednisolone 7.5mg/day. The analysis of the data included 3-month comparative evaluation of the efficacy of the preventive therapy against the following parameters: frequency of gout flare in the respective treatment period, VAS pain intensity of gouty arthritis. The laboratory tests included serum creatinine level, uric acid level, AST, ALT, creatine phosphokinase, glucose; clinical blood test before, two weeks and three months after the initiation of the therapy.

Results: NSAIDs were received by 14 (17.7%) patients, colchicine by 56 (70.9%) and glucocorticoids by 9 (11.4%) patients. There were no differences initially in age, GFR or lab test values. Three months later, the gout flares frequency median lowered to 1 [0;2] flare per 0.01. The frequency of gout flares did not depend on the chosen drug and was 1 [0;1] for NSAIDs, 1 [0.5;2] for colchicine and 1 [1;2] for glucocorticoids. 40 (50.6%) patients out of 79 did not have a single flare. The patients who received NSAIDs (57.1%) and colchicine (42,9%) experienced no gout flares more often than those who received glucocorticoids (37.5%), but the differences were not significant. However, the VAS pain intensity of gout flares in the patients who received NSAIDs (30.7±12.9mm) was lower than in those who received colchicine (42.1±12.3mm) and glucocorticoids (42.2±8.4mm) (p<0.05 for both). The duration of gout flares on different drugs was not significantly different and was on average 3 [1.5;4] days for the patients on NSAIDs, 5 [3;7] days for those on colchicine and 5 [4;6] days for the patients on glucocorticoids. The NSAID therapy was discontinued in two cases, in which the serum transaminase levels (AST, ALT) more than doubled; the colchicine therapy - because of development of diarrhea in two patients and of myopathy in one.

Conclusion: Efficacy of and tolerance to a three-month course of preventive therapy with NSAIDs and glucocorticoids in gout patients is comparable to that with colchicine. In case of development of gouty arthritis, preventive use of
of NSAIDs is characterized by lower pain intensity than as against colchicine or

Background: Calcific tendinitis of the rotator cuff is a frequent cause of chronic

shoulder pain. It is due to apatite deposits within the tendons. Little data are cur-

rently available about proteins associated to crystals within deposits.

Objectives: The aim of the study was to quantify 6 proteins in calcific powders

obtained from patients who have undergone an ultrasound-guided percutaneous

lavage (UGPL) of their calcification and to look for correlations between their

calcification and to look for correlations between their concentration and patient characteristics.

Methods: Calcific powders were obtained from patients included in the

CALCECHO trial whose main objective was to compare post-procedure pain

between two groups: methylprednisolone or placebo injected at the end of the lav-

age. Based on preliminary in vitro biochemical and literature data, the following pro-

teins have been selected for their link to the mineralization. Correlations between the level of each protein and radiographic and ultrasound appearance of the calcific deposits were sought. We also looked for correlations between level of each protein and duration of pain or response to UGPL (Mann-Whitney test).

Abstracts
Results: Sixty-six samples were studied: mean age was 48.9 (+/- 9.7) and 68% were female. Mean duration of shoulder pain was 30 months with a mean VAS pain of 68/100 (+/-14). Mean calcification size was 1.6 cm. Results of ELISA were as follows: mean level of PEDF at 1097 pg/µg, mean level of OPG at 135 pg/µg, mean level of POSTN at 6.9 pg/µg, mean level of ACT A at 19.6 pg/µg and mean level of OPN at 4.9 pg/µg although BMP-2 was undetectable. There was no correlation between level of proteins and the size of the calcification or the duration of pain. There was no difference in protein levels between type A and type B calcifications on radiography (classification of the French Society for Arthrosc). In contrast, levels of POSTN and OPN were significantly higher in nodular calcifications compared to the homogenous (p=0.003 and p=0.01 respectively) or fragmented types (p=0.03 and p=0.04 respectively). Furthermore, calcifications without acoustic shadowing were enriched in POSTN compared to those with (p=0.04). Finally, the peristin level was significantly higher in calcifications that have responded well to UGPL (p=0.02).

Conclusion: In this cohort of patients treated by UGPL, we observed higher levels of POSTN and OPN in the less dense dense calcifications and POSTN enrichment appeared to be associated with a better response to UGPL. Considering these data, further studies will be necessary to better understand the role of this protein in calcific tendinosis.

**Notes:**
- * = self-reported, intermittent symptoms; ** = all patients classified with gout at baseline also had a clinical gout diagnosis after one year; *** = using a somewhat limited set, see methods
- MRT = magnetic resonance tomography; SUA = serum uric acid; DECT = dual-energy CT; MSU = monosodium urate.

Sensitivity, specificity, positive and negative predictive value, and accuracy values (95% CI) of the classification criteria set we used were 0.91 (0.80-0.96); 1 (0.63-1); 1: 0.57 (0.38-0.74) and 0.92 (0.83-0.97), respectively. The area under the receiver operating characteristics curve (95% CI) was 0.95 (0.91-0.99).

ULT was started in 49/63 (78%) of gout patients; 45/49 (92%) of them had serum uric acid levels ≥ 360 μmol/l and no recent gout attack during one-year follow-up.

**Conclusion:** The 2015 ACR-EULAR gout classification criteria performed well for the diagnosis gout in clinical practice. Most gout patients had been treated successfully, according to current guidelines.

**HIGHER ULTRASOUND BURDEN WITH MONOSODIUM URATE CRYSTALS IN THE JOINTS IS CONNECTED TO MORE PRONOUNCED ARTERIOSCLEROTIC VASCULAR ALTERATIONS**

R. Gancheva1, T. Kondurzhiev2, Z. Kolova1, A. Koundurzhiev1, 1University Hospital St. Ivan Rilski, Medical University, Clinic of Rheumatology, Sofia, Bulgaria; 2Medical University, Faculty of Public Health, Sofia, Bulgaria; 3University Hospital St. Ivan Rilski, Medical University, Clinic of Nephrology, Sofia, Bulgaria

**Background:** The severity of gout and the presence of subcutaneous tophi increase the risk of cardiovascular death. In patients (pts) in the spectrum of gout and in subjects who have inflammatory arthritis with accompanying asymptomatic hyperuricemia, data whether ultrasound (US) burden with monosodium urate (MSU) crystals in the joints is associated with higher cardiovascular risk are contradictory.

**Objectives:** To establish the relationship between US MSU crystal deposits in the joints with diastolic heart function and carotid altered in patients with gout, pts, individuals with asymptomatic hyperuricemia and no sign of inflammatory arthritis and psoriatic arthritis pts with asymptomatic hyperuricemia.

**Methods:** The study is cross-sectional. A total of 121 consecutive pts were included, divided into 85 pts with gout - 63 males and 22 females aged 57.7±14.1 years, 27 subjects with asymptomatic hyperuricemia and no sign of inflammatory arthritis and psoriatic arthritis pts with asymptomatic hyperuricemia.

**Diagnosis:**

|                  | gout (n=43)  | no gout (n=8) |
|------------------|--------------|
|                  | 167 c.u.     | 229 c.u.      |

In all groups DBI is lower than the norm but to a different extent. DBI is slightly impaired just slightly. DB = 167 c.u. in group 2 which indicates a significant disorder of lipid metabolism (p=0.05). Thus the ozonation method is informative and allows with pulse Doppler frequency of 5 MHz were measured: intima-media thickness (IMT), common carotid artery, elastic index (CCE) and the presence of atheromatous plaques was recorded. US of the joints was performed with a high-frequency, linear transducer, one-second contour. The existence of double contour sign, intra-tendinous MSU aggregates, snow storm, tophi, with erosions, or a combination of these US features was assessed. Data were analyzed by Chi-Square, Mann-Whitney, Kruskal Wallis, t-test and ANOVA.

**Results:** In the three groups there was no difference in the mean values of E/A ratio (p=0.591), DT (p=0.498), E/e’ (p=0.662), E/e’ ratio (p=0.754), IMT (p=0.260), CCE (p=0.089) and in the frequency of heterogeneous or homogenous carotid artery plaques (p=0.595). Among pts with and without evidence of MSU crystals in the joints the means of E/A ratio (p=0.452), DT (p=0.367), E/e’ ratio (p=0.218), E/e’ ratio (p=0.230), IMT (p=0.165), CCE (p=0.097) and the frequency of heterogeneous or homogenous plaques (p=0.830) were comparable. The distribution of MSU crystal deposits in two or more joints was the highest in gout pts (56.5%) compared to pts with asymptomatic hyperuricemia (11.1%), and individuals with psoriatic arthritis (22.2%), (p=0.001). Pts with MSU crystal deposits in two or more joints compared to those with crystal deposits in one joint and pts without MSU crystals had the highest CCE (mean±SD; 7.2±0.05 vs 0.69±0.07 vs 0.68±0.07, p=0.019), the longest DT (mean±SD; 236±50±99 msec vs 208.09±34.30 msec vs 216±5.43 msec, p=0.026) and had a tendency of lowest e’ (mean±SD; 10.33±3.96 cm/s vs 12.05±3.83 cm/s vs 11.99±3.98 cm/s, p=0.077), but the values of E/A ratio (p=0.119), E/e’ ratio (p=0.107), IMT (p=0.151) and the distribution of atheromatous plaques (p=0.920) were equal.

**Conclusion:** Pts with higher US MSU burden have more pronounced left ventricular dysfunction and greater vascular stiffness. The changes in their vessels are mainly of the arteriosclerotic type.

**Disclosure of Interests:** None declared.

**AB0928**

**DISORDERS OF FATTY ACID METABOLISM IN THE FORMATION OF ARTERIAL HYPERTENSION IN PATIENTS WITH GOUT**

M. Gromova1, V. Tursko2, O. Kislak3, E. Kiseleva3, 1Pirogov Russian National Research Medical University, Moscow, Russian Federation; 2I.M. Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russian Federation; 3N.N. Semenov Federal Research Center for Chemical Physics, Russian Academy of Science, Moscow, Russian Federation

**Background:** One of the possible mechanisms of the formation of cardiovascular disorders in patients with gout may be a violation of the metabolism of fatty acids. Decrease of the total content of unsaturated fatty acids (UFAs) has a multifaceted adverse effect on a number of metabolic processes which lead to the development of arterial hypertension (AH) and atherosclerosis as a result. There are no studies on the level of UFAs in the blood of patients with gout depending on the presence of hypertension.

**Objectives:** To study the level of UFAs in the blood of patients with gout depending on the presence of AH.

**Methods:** We examined 87 patients with gout and AH. 83% were men (mean age 55.4 ± 12.3 years). All patients had chronic gouty arthritis, 30% of patients had tofus. The duration of gout was 8 [4; 11] years. AH was detected in 49 (56.2%) people. The duration of AH was 7 [2; 10] years. All patients went through standard general clinical, laboratory and instrumental examination. Ozone method was developed and put into practice in N.N. Semenov Federal Research Center for Chemical Physics, Russian Academy of Science (FRCCP RAS), to assess disorders of the lipid metabolism for diagnostic purposes. The essence of the method is to determine the level of unsaturation of serum or blood plasma lipids which depends on the total amount of double bonds (DB) in UFAs both in a free state and within lipid combination. This parameter is called the Double Bond Index (DBI). DBI is measured by a domestic device ADS-M (´Double bond analyzer´) developed at FRCCP RAS. The control group consisted of 20 healthy men, comparable in age. Statistical analysis of the data was carried out using the STATISTICA 10.0 program.

**Results:** Patients were divided into 2 groups: patients with gout with normal blood pressure (group 1; n = 38) and with AH (group 2; n = 49). Patients from group 2 differed by a longer course of gout and had a higher level of uric acid in comparison with patients from group 1. The number of joints involved in the inflammatory process in patients from group 2 exceeded the number of those in patients from group 1. Patients from group 2 had more often attacks of gouty arthritis and the severity of pain during the last year compared with group 1. The normative value of the blood serum lipids DBI was determined for the control group of healthy people (260 ± 20 conventional units (c.u.) by the ozonation method. A significant deviation of the DBI from the norm both increased and decreased is a sign of pathology. In all groups DBI is lower in gout but to a different extent. DBI is slightly reduced relative to the norm (DB = 229 c.u.) in group 1 therefore lipid metabolism is impaired just slightly. DB = 167 c.u. in group 2 which indicates a significant disorder of lipid metabolism (p=0.05). Thus the ozonation method is informative and allows
to quantify the severity of patient general condition and DBI is an integral indicator of changes in the number of fatty acids and body general condition.

**Conclusion:** The presence of AH in patients with gout makes the clinical course of the disease more severe and exacerbates lipid disorders that can make significant changes in the formation of cardiovascular complications in this category of patients. DBI can be used as an additional criteria in laboratory diagnostics and monitoring to develop adequate treatment tactics.

<tr>
<th>AB0929</th>
<th>CALCIUM PYROPHOSPHATE DIHYDRATE CRYSTAL-DEPOSITS: REMEMBER THE SPINE!</th>
</tr>
</thead>
</table>

D. Khadka1, K. Bacouche1, N. El Amri1, H. Zeglaoui1, E. Boujim1. 1. Farhat Hached Hospital, Rheumatology Department, Susah, Tunisia

**Background:** Calcium pyrophosphate dihydrate crystal-deposits (CPPD) is a common crystal disease affecting men and women equally. It is normally seen in peripheral joints. Spine involvement is rare and may mislead the diagnosis.

**Objectives:** To describe clinical, radiological and therapeutic findings of CPPD of the spine.

**Methods:** A retrospective descriptive study was conducted in the rheumatology department of Farhat Hached Hospital, including patients diagnosed with CPPD of the spine over a period of 20 years (1998-2018). Data concerning clinical, radiological and therapeutic aspects of CPPD of the spine were collected from their medical files.

**Results:** Twelve patients had a spinal localisation of CPPD. The mean age was 59.9±16.21 years. Patients were mainly women with a sex ratio men/women of 1:3. Mean duration of symptoms before the diagnosis was 2708±25.69 months.

Spinal presentation was the revealing symptom of CPPD in 45.5% of the cases. It affected the cervical spine in 66.7% and the lumbar spine in 33.3% of the cases. Spinal localisation of CPPD was associated with a peripheral arthropathy in 75% of the cases (the knees in 41.7%, wrists and hands in 66.67%, shoulders in 25% and the hips in 16.7%). 50% of spinal CPPD was found to be incidental on plain radiographs in 16.7% of the cases. When symptomatic, the disease manifested itself as inflammatory pain in 72.7%, mechanical pain in 9.1% and both diurnal and nocturnal pain in 18.2% of the cases. Physical examination revealed stiffness of the spine in 58.3% of the patients. Fever was noted in 8.3% and deterioration of general condition with anorexia was reported in 25% of the patients. Neurological complications were represented by cervical myelopathy in 25%, sciatica in 8.3% and a case of unilateral urological neuropathy was reported. Laboratory tests revealed inflammation in 50% of the cases. However, crystals were present in synovial fluid in only 25% of the patients.

Peripheral calcifications were present in the wrists in 33.3% and the knees in 58.3% of the cases. Crow dens syndrome was reported in 16.7% of the patients. CT-scan helped the diagnosis of calcifications and crown dens syndrome when performed.

MRI was prescribed in 58.3% of the patients and characterized the cervical myelopathy. Treatment relied on analgesics in all patients, NSAIDS were prescribed in 83.3%, colchicine in 66.7% and general corticosteroids in 25% of the cases. Spinal immobilization was recommended in 25% of the cases for a short period. Spinal CPPD was idiopathic in 75%, secondary to hyperparathyroidism in 8.3% of the cases and familial cases were detected in 16.7% of the patients.

**Conclusion:** Axial CPPD is rare and is an under-recognized entity that should be considered in elderly patients with neck or back pain. It can involve the discs or ligaments. The crown dens syndrome is quite suggestive of the diagnosis. The spinal CPPD is suspected, colchicine therapy could be a good therapeutic test and would avoid unnecessary further tests.

<th>AB0931</th>
<th>THE QUALITY OF LIFE IN GOUT PATIENTS WITH ULCERATION OVER TOPHI</th>
</tr>
</thead>
</table>

X. Liu1, Z. Huang2, O. Huang3, Z. Zhong1, W. Zhao1, T. Li1, 2. Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology; Guangzhou; 2. Southern Medical University; The Second School of Clinical Medicine, Guangzhou, China; 3.University of South China, Hengyang, China

**Background:** The prevalence of gouty patients with ulcerations over tophi are increasing over time and it has been reported that gouty patients have significantly poor quality of life (Qol) compared to those healthy controls. [1, 2] there is no study on comparison of the QoL in patients with or without ulceration over tophi.

**Objectives:** To compare the QoL in gout patients with or without ulcerations over tophi.

**Methods:** A total of 79 inpatients with gout who were admitted to Guangdong Second Provincial General Hospital from January 2019 to January 2020 were included. Among them, ulcerations were identified in 28 patients. Short Form-36 Scales (SF-36) were chosen to assess patients. Differences between the groups were tested with Student’s t-test or Mann-Whitney U test for continuous variables, and Chi-square tests for categorical variables.

**Results:** Of 79 subjects, 74 were male, mean age was 54.2±14.3 years, disease duration was 10.9±4.7 years. Gouty patients had moderate- to high-quality levels in general health, vitality, social functioning, role emotional, and.

AB0934 DUAL-ENERGY COMPUTED TOMOGRAPHY IN GOUT PATIENTS: IS IT USEFUL IN GENERAL PRACTICE?

Y. Sherman1, P. Lipsky2, M. Bramwit2, N. Schlesinger1, 1Rutgers Robert Wood Johnson Medical School, New Brunswick, United States of America; 2RUTLITE Research Institute, Charlottesville, VA, United States of America

Background: Dual-Energy CT (DECT) has high sensitivity and specificity for detecting monosodium urate (MSU) crystal deposition. Although widely used in research, few studies have evaluated the usefulness of DECT in clinical practice.

Objectives: To evaluate the use of DECT in a clinical setting and determine its utility.

Methods: We retrospectively evaluated the records of all patients referred for DECT scans over a 6.5-year period. Patient charts were reviewed for clinical features.

Results: 113 patients (173 yr) received DECT evaluation at a university hospital over the study period (234 scans). All were referred by rheumatologists. Medical records were available for 69 patients (134 scans), including 44 males and 25 females (mean age 62 (SD, 12.9, range: 34-85 yrs). Mean duration of gout was 6.7 (SD, 8.1) yrs. DECT was ordered to evaluate known gout (36/69, 52.1%), suspected gout (32/69, 46.4%), and suspected calcium pyrophosphate (CPP) disease (1/69, 1.4%). 32/69 (46.4%) of patients were on urate-lowering therapy. 61% (42/69) had MSU crystal and none had CPP deposition. Mean MSU volume was 1.6cc (SD, 5.2cc; range: 0.01-35 cc.) The joints imaged were feet/ankles (29.6%).

Of patients with positive DECT scans, 24/42 (57%) had symmetric distribution (29.6%). In two cases of three, PPi was almost completely hydrolyzed within 20 hours. The maximum activity (2.4 U·mg⁻¹) was shown by Mt-PPase immobilized on ND-L. Hydrolytic activity for all studied enzymes is only 1-2% of such values under optimal in vitro conditions, most probably due to the inhibiting effect of calcium in synovial fluid. Nevertheless, the activity of Mt-PPase-based samples was comparable with the values typical for some classes of hydrolases. It allows us to consider the suggested PPase-based materials as promising agents for the hydrolysis of PPi in the joint tissues in vivo.

Conclusion: In this work, we applied the 31P NMR spectroscopy to estimate the quantity of Pi and PPi in synovial fluids of patients with CPPD disease. The conjugates of bacterial PPases with denaton nanodiamond were demonstrated to retain enzymatic activity in the hydrolysis of exogenous PPi, in human synovial fluid. These results provide the basis for the further tests of PPase-based conjugates on animal models in vivo.

AB0936 CLINICAL STUDY ON PERIPHERAL BLOOD IMMUNE FUNCTION IN PATIENTS WITH GOUTY ARTHRITIS

H. Wang1, H. Gao1. 1The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China

Background: Gout is an inflammatory disease characterized by hyperuricemia and recurrent arthritis. In severe cases, joint disability and renal insufficiency may occur [1]. In recent years, many studies have found that immune dysfunction plays an important role in the occurrence and development of gout [2]. Therefore,
in-depth study of its internal mechanism is of great significance for the prevention and treatment of gout.

Objectives: This paper mainly discussed the expression of peripheral blood immune function in patients with gouty arthritis and the changes and significance of peripheral blood immune function in gout with different uric acid levels.

Methods: A retrospective analysis was performed on 258 outpatients and inpatients with gout in shanxi medical university from 2016 to 2019, all of which met the diagnostic criteria of the American college of rheumatology (ACR) in 1997, and 41 healthy controls. Complete clinical data and general laboratory data were collected, and peripheral blood lymphocyte and CD4+ T cell counts were completed for all subjects.

Results: (1) Total peripheral blood B cells of gout patients [238.00 (171.50,323.07) and 191.04 (149.65,253.14), Z=2.759, P=0.006] Th cells [814.11 (617.50,1052.89) and 625.84 (562.52,750.15), Z=3.905, P<0.001], TH1/TH2 [1.4 (1.04,2.00) and 1.11 (0.89,1.52), Z=2.862, TH17/Treg [0.36 (0.20,0.60) and 0.24 (0.14,0.34), Z=3.949, P<0.000] and the absolute counts of TH17 cells [9.08 (5.07,15.57) and 7.48 (4.31,10.18), Z=2.520, P=0.012] were higher than those of the healthy control group, and the differences were statistically significant. The absolute count of Treg cells [28.82 (17.48,38.04) and 30.22 (22.74,39.46), Z=2.249, P=0.025] was lower than that of the healthy control group, and the difference was statistically significant. (2) The TH17% [1.05 (0.71,1.42) and 1.27 (0.73,2.00), Z=-1.995, P=0.046] and the TH17/Treg [0.25 (0.14,0.44) and 0.39 (0.23,0.63), Z=-3.147, P<0.000] in peripheral blood of patients with high uric acid in the gout group were higher than those in the normal uric acid group, the difference was statistically significant. The Treg % [3.84 (2.65,5.02) and 3.12 (2.36,4.37), Z=-2.239, P=0.025], and the Treg cells [30.75 (21.97,43.27) and 24.07 (16.84,36.29), Z=-2.522, P=0.012] were lower than those in the uric acid control group, with statistically significant differences.

Conclusion: The level of TH17 cells in peripheral blood of patients with gout increased significantly while the level of regulatory T cells decreased significantly. TH17 cell level in peripheral blood of the high uric acid gout group was significantly increased compared with the normal uric acid group, while the regulatory T cell level was also significantly decreased, and the TH17/Treg ratio was also increased. This suggests that regulatory T cells may play an important role in the pathogenesis of gout and are closely related to uric acid metabolism, so the study of internal mechanism can provide a new target for the treatment of gout.

Infection-related rheumatic diseases

AB0098 COMPARATIVE STUDY OF PYOGENIC SPONDYLODICTIS VERSUS TUBERCULOUS SPONDYLODICTIS
A. Ben Tekaya1, L. Ben Ammar2, M. Ben Hammama3, O. Saidane1, S. Bouden1, R. Tekaya1, I. Mahmoud1, L. Abdelmoula1, 1Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; 2Kassab Institute, Rheumatology, Tunis, Tunisia; 3La Rabta Hospital, Cardiovascular Surgery, Tunis, Tunisia

Background: Infectious spondylodiscitis is a life-threatening infection of the intervertebral disc and adjacent vertebrae that can be caused by a variety of microorganisms. Our country is at intermediate endemity for Tuberculosis in spondylodiscitis.

Objectives: To compare the clinical, biological, radiological characteristics, management and prognosis of pyogenic versus tuberculous spondylodiscitis.

Methods: Retrospective study of 89 patients admitted to our department over a period of 20 years [1998-2018]. The diagnosis of spondylodiscitis was made based on clinical, biological, radiological and bacteriological data.

Results: The average age of the patients was 56.1 years. There were 46 men (51.6%) and 43 women (48.4%) with a female predominance during tuberculous spondylodiscitis (57.1%) versus 26.9% during pyogenic spondylodiscitis (p = 0.009).

Diabetes was more frequent during pyogenic spondylodiscitis but with no statistically significant difference (p = 0.4). The evolution time was statistically greater during tuberculous spondylodiscitis (p < 0.001). Patients with tuberculous spondylodiscitis had more frequently an impaired general condition (p = 0.02). Hyperleukocytosis was noted more frequently in the pyogenic group than in the tuberculosis group (p = 0.03), while the increase in sedimentation rate was not statistically different between the two groups (90 mm/h and 76 mm/h, respectively, p = 0.1). We found no statistically significant difference regarding the site of spondylodiscitis.

Radiologically, the frequency of para-vertebral and psosas abscesses, epiduritis and the presence of spinal cord compression were similar in the two groups (p = 0.2; p = 0.1 and p = 0.1, respectively), whereas isodense geodes were more frequent during tuberculosis (p = 0.04).

Surgical and interventional treatments (percutaneous sampling, abscess drainage) were more frequently noted during pyogenic spondylodiscitis, but without significant difference (p = 0.2). The occurrence of immediate complications was more frequent during tuberculosis but without a statistically significant difference.

Conclusion: In our series, patients with tuberculous spondylodiscitis tend to have a chronic pattern of progression and more often an impaired general condition. However, there was no significant difference in the presence of abscesses, epiduritis and the occurrence of complications between tuberculous spondylodiscitis and pyogenic spondylodiscitis.

DOI: 10.1136/annrheumdis-2020-eular.4834
Therefore, the following were recorded for each year 1946-2018: total number of arthritis, and diagnostic markers derived from synovial fluid/aspirate. The database, Scopus use and diagnostic accuracy of biomarkers to exclude infection in the acute joint presentations. The database of 58 consecutive PMR patients recruited from a single rheumatology secondary care setting was retrospectively analyzed to investigate the frequency of environmental triggers and correlations with clinical characteristics. Patients underwent multidistrict ultrasound examination of both proximal and distal sites. Laboratory tests were repeated after one month from first visit, when steroids were started, and about every three months during follow-up (for at least 24 months).

**Results:** Fifteen PMR patients (26%) described a connection with environmental agents: six PMR patients reported a vaccination, 3 an upper respiratory tract infection and 1 pneumonia before the onset of disease. Five patients reported seasonal influenza as trigger of PMR. The model of multivariate linear regression which better predicted a shorter time to normalize inflammatory reactants (R squared 27.46%, p=0.0042) comprised the presence of an environmental trigger and a higher CRP. A linear regression analysis confirmed an inverse correlation between CRP at onset ant time to normalize inflammatory reactant (r=-0.3031, p=0.0208). A significant correlation was demonstrated between presence of environmental trigger and shorter time to normalize inflammation (r=0.5215, p=0.0001), lesser frequency of gleno-humeral synovitis on US (r=0.3774, p=0.0038).

**Conclusion:** Our work describes a correlation between environmental triggers in PMR and higher CRP at diagnosis and faster response to therapy. We may suppose that these patients belong to a more specific subtype of PMR, in whom external stimuli, such as vaccinations or infections, may lead to a deregulated response within the context of an impaired immune and endocrine system. We recommend a systematic research of previous infections or vaccination in recent onset PMR.

**AB0940** BIOMARKERS IN THE DIAGNOSIS OF ACUTE HOT JOINTS: AN EVALUATION OF RESEARCH INTEREST 1960-2018

M. Day1, M. Al-Attar2, L. Perotto3, I. Wilson1, S. S. Zhao2, S. Duffield1, N. Goodson1, 2. Institute of Ageing and Chronic Disease, University of Liverpool, Musculoskeletal Biology I, Liverpool, United Kingdom; 3. Aintree University Hospital, Liverpool University Hospitals NHS Foundation Trust, Academic Rheumatology, Liverpool, United Kingdom; 4. Manchester Royal Infirmary, Manchester University NHS Foundation Trust, Manchester, United Kingdom; 5. Federal University of Parana, Curitiba, Brazil

**Background:** The acute hot joint presentation is a common clinical emergency, often the result of crystal arthritis or trauma. However, all diagnoses can mimic septic arthritis, which should be excluded promptly due to the potential for rapid joint destruction and significant morbidity. The gold-standard test for septic arthritis is synovial fluid culture, which can take several days to perform. Meanwhile, patients are often admitted and given antimicrobials. Other specialties have made use of rapid tests as trigger of PMR. The model of multivariate linear regression which better predicted a shorter time to normalize inflammatory reactants (R squared 27.46%, p=0.0042) comprised the presence of an environmental trigger and a higher CRP. A linear regression analysis confirmed an inverse correlation between CRP at onset ant time to normalize inflammatory reactant (r=-0.3031, p=0.0208). A significant correlation was demonstrated between presence of environmental trigger and shorter time to normalize inflammation (r=0.5215, p=0.0001), lesser frequency of gleno-humeral synovitis on US (r=0.3774, p=0.0038).

**Conclusion:** Our work describes a correlation between environmental triggers in PMR and higher CRP at diagnosis and faster response to therapy. We may suppose that these patients belong to a more specific subtype of PMR, in whom external stimuli, such as vaccinations or infections, may lead to a deregulated response within the context of an impaired immune and endocrine system. We recommend a systematic research of previous infections or vaccination in recent onset PMR.

**AB0941** NEURALGIC AMYOTROPHY AND HEPATITIS E INFECTION: REPORT OF 6 CASES AND REVIEW OF THE LITERATURE

**Background:** Neuromyotrophic (NA) or Parsonage and Turner syndrome is triggered at least in 25% by a viral infection: parvovirus B19, CMV, HSV, etc... Recently, few cases of Hepatitis E Virus (HEV) related NA were reported. This particular association remains little known and is overlooked by most physicians. Besides, clinical, electrodiagnostic (EDX) and MRI characteristics, as well as evolution of HEV-related NA have not been fully described yet.

**Objectives:** To describe 6 cases of HEV-related NA and to perform a review of the literature.

**Methods:** We describe longitudinally clinical examination, electrodiagnostic (EDX), biological and MRI results of 6 cases of HEV-associated NA, diagnosed in our center.

**Results:** The 6 cases were aged between 33 and 57 years old (mean 44.5), sex ratio was 5M/1F. All patients had positive IgM anti-HEV (serology) and a cervical MRI that could not explain clinical presentation. Overall, the 6 patients totalize 28 mononeuropathies (range 1 to 8 per patient). 5/6 patients had a severe presentation of NA, with bilateral and asymmetric symptoms (3 cases). HEV-related NA involved classical nerves such as supra-scapular (6 cases, twice bilaterally) and long thoracic nerves (5 cases), some less classical nerves like anterior...
interosseous nerve (3 cases, twice bilaterally), and some very unusual ones such as the lateral antebrachial cutaneous nerve (1 case) and the sensory fibers of median nerve (1 case). NA also involved accessory spinal (2 cases, once bilateral and phrenic nerves (1 case bilaterally), one originating from cervical plexus. The EDX pattern of these nerve lesions consisted of unique or multiple extensive asymmetric inflammatory mononeuropathies with severe axonal loss and numerous denervation signs damage involving mostly the supra-scalpul.

On scapular MRI (available for 5/6 patients), amyotrophy in at least one muscle was observed in all patients. Out of 26 nerves involved, after 12 months all had well recovered (above 3/5 MRC scale).

Conclusion: HEV should be systematically screened when NA is suspected, whatever the severity, if the onset is less than 3 or 4 months (before IgM anti-HEV disappear), HEV-related NA appears to be frequently associated with a severe pattern, without modifying the recovery usually observed.

AB0942 INFECTIOUS SPONDYLODICITIS: TUBERCULOSIS VERSUS BRUCELLOSIS

R. Grassa1, J. Anoun2, M. Thabet1, D. E. H. Abid1,2, F. Ben Fredj1,2, A. Rezgui1,2, C. Kechrid3, 1Sahloul Hospital Tunisia, Internal Medicine, Sousse, Tunisia; 2Sahloul Hospital Tunisia, Sousse, Tunisia

Background: Infectious spondylodiscitis is a serious impairment that can compromise the functional and vital prognosis. The determination of the germ responsible is the key of the treatment.

Objectives: The objective of our work is to describe the epidemiological, clinical and evolutionary profile according to the germ responsible by comparing tuberculous and brucellar spondylodiscitis.

Methods: This is a retrospective study including 32 cases of spondylodiscitis with specific germs (Mycobacterium tuberculosis and Brucella) collected in an internal medicine department over a period of 18 years (2000-2018).

Results: These were 20 men and 12 women with an M / F ratio of 1.66. The average age of our patients was 50.63 [16-84]. The germ implicated was Koch's Bacillus in 11 patients (34.38%) and Brucella in 21 patients (65.63%). The mean age for tuberculosis (TB) was 45.18 years versus 53.48 years for brucellosis. Spinal pain was the major symptom in the 02 groups. The deterioration in general condition was present in 80.95% for the brucellosis group versus 81.82% for the tuberculosis group.

Biological inflammatory syndrome was observed in 94.24% of the brucellosis group and 63.63% of the TB group. The lumbar location was the most frequent in the 02 groups (71.88%). It was a multifocal localization in 27.27% (TB) and 61.90% (Brucellosis) respectively. The imaging allowed the detection of paravertebral abscesses in 54.55% for the TB group versus 23.81% for the brucellar group. An epiduritis was objectified in 36.36% of the TB group against 33.33% for that of brucellar. CT-guided biopsy was performed in 54.55% of tuberculosis patients compared to 47.34% in patients with brucellosis. The frequency of vertebral involvement was 91.7% in the TB group and 83.33% in the other group. It was only positive in one case of brucellosis, whereas it allowed diagnosis in 36.36% of cases of TB.

The evolution after initiation of adequate antibiotic treatment was interspersed with neurological complications in the tuberculosis group in 18.18% of cases against 14.29% in the brucellosis group. Draining abscess was necessary in the tuberculosis group in 18.18% and in 9.52% of the brucellosis cases.

Conclusion: Our results show a higher frequency of neurological complications in tuberculosis forms. Vertebral biopsy is of no interest in Brucellar spondylodiscitis unlike tuberculosis forms where it allows the diagnosis.

AB0943 INFECTIOUS SPONDYLODICITIS OF THE ELDERLY: CHARACTERISTICS AND OUTCOMES

J. Mahbouba1, O. Joumaa2, S. Zouari1, I. Beija1, M. Touzi1, N. Bergaoui1 on behalf of Rheumatology department, 1University Hospital of Monastir, TUNISIA, Rheumatology Department, Monastir, Tunisia

Background: Spondylodiscitis still frequent. It affects both old and young patients. It makes diagnostic and therapeutic difficulties.

Objectives: to identify the characteristics and outcomes of infectious spondylopticis (ISD) in patients over 65 years old.

Methods: A monocentric retrospective study including patients hospitalized for ISD in the rheumatology department of university hospital of Monastir, TUNISIA between January 2009 and August 2019.

Results: Among 70 patients with ISD, 21 (11 male, 10 female) or 30% are over 65 years old. The average age was 70.6 years (65-82 years). History of diabetes (n = 9), hypertension (n = 9), hemodialysis (n = 5), heart disease (n = 5) were the most risk factors reported, while in younger patients, spinal surgery, epideral infiltrations and long-term general corticosteroid therapy were the main risk factors. The mean time for consultation was 142.3± 73 days longer than for younger patients. Fever was present in 0.14% of cases. Assessment time found that already 5 patients had paraplegia or spinal cord compression, 19/21 patients had epiduritis on spinal cord MRI. Soft tissue abscesses were present in close rate in both younger and old patients. Biological assessment showed an inflammatory syndrome and hypercorticoysis in 92% and 38% of patients respectively (compared to 73% and 27% in younger patients). Germs were identified in 14 patients (47.3%), Common germ were the most involved (12 patients), while in younger patients, specific-germs were the most reported. Follow up has shown that neurological sequelae are more prevalent in elderly.

Conclusion: ISD in patients over 65 years old require a careful attension in therapeutic management given that age according to this study seems to influence the prognosis. In fact, these patients are more susceptible to disability due to neurological complications.

AB0944 TUBERCULOSIS SEPTIC ARTHRITIS: CLINICAL FEATURES OF TWELVE CASES

O. Khalfa1, K. Bacoocche1, N. El Amri1, H. Zeglaoui1, E. Bouajina1, 1Farhat Hached Hospital, Rheumatology Department, Susah, Tunisia

Background: Extrapulmonary forms of tuberculosis septic arthritis account only for 1% of tuberculous infections. Although TB infection is rare in western countries, arthopathy is still a major problem in developing countries.

Objectives: Describe clinical features of tuberculosis septic arthritis seen by the rheumatologist.

Methods: Retrospective descriptive study, lead in the rheumatology department of Farhat Hached Hospital, including medical files between 1999 and 2020. Data of patients diagnosed with tuberculous arthropathy were analysed.

Results: Twelve patients were diagnosed with tuberculous septic arthritis. Six men and women were enrolled with a sex ratio of 1:1. The mean age of diangnosis was 47±16.16 years. Mean delay of diagnosis was 12.83±16.12 months. A triggering factor like a trauma was described in 8.3% and comorbidities were associated in 16.7% of the cases, mainly diabetes and chronic renal dysfunction. Type of pain was inflammatory in 91.7% of the time. The disease presented as a monoarthropathy in 91.7% and an oligoarthritis in 8.3% of the cases. Chronic forms were observed in 91.7% and acute forms in 8.3% of the cases. Transmission was hematological in 60%, directly inoculated in 20% and secondarily disseminated from another site in 20% of the cases. Arthritis affected the knees in 50%, followed by the hips in 33.3% and then the ankles and wrist in 8.3% of the cases each. Fever was noted in 41.7% and general condition was altered in 50% of the patients. Chest radiographs showed the presence of infiltrates or micronodules in 33.3% of the patients. Bone erosions were detected in 66.7% of plain radiographs, while narrowing of the joint was seen in 83.3% and joint structure osteoporosis in 50% of the cases. MRI showed the presence of absces in 33% of the cases. The Mantoux test was positive in 2 cases, of which, one didn’t receive the recommended neonatal vaccine. Culture was positive in the synovial fluid in 25%, in sputum in 16.7%, and in urine in 83.3% of the cases. Synovial biopsy was performed for all patients. It showed a non specific synovial inflammation in 50%, granulomatous inflammation in 33.3% and caseous necrosis in 16.7% of the cases. Common quadri therapy was prescribed for all patients with a mean treatment duration of 11.41±1.37 months. Surgery was performed in only two
cases with an uncontrolled infection under antibiotics. Disseminated tuberculosis accured in 33.3%, recurrence of the infection in the same site in 16.7% and extension to another articular localisation in 25% of the cases. One patient had a tuberculous meningoencephalitis leading to his death.

Conclusion: Tuberculous septic arthritis is difficult to diagnose and should be recalled especially in endemic countries when dealing with chronic monarthritis. Synovial biopsy is needed most of the time to confirm the diagnosis. Treatment is long and the disease may be complicated with fatal disseminated forms.

CONTRIBUTION OF MICROBIOLOGICAL AND ANATOMOPATHOLOGICAL EXAMINATIONS IN THE DIAGNOSIS OF SPONTANEOUS PYOGENIC SPONDYLODISCITIS IN ADULTS

I. Mahmoud1, M. Moalla1, A. Ben Tekaya1, S. Bouden1, R. Tekaya1, O. Saidane1, L. Abdelmoula1. 1Hospital Charles Nicolle, Rheumatology, TUNIS, Tunisia

Background: Pyogenic spondylodiscitis (SPD) is a serious infection of an intervertebral disc and/or adjacent vertebrae, that remains a topical problem in rheumatological practice. Early diagnosis and treatment are the only guarantees of a favorable outcome. Clinicians must strive to isolate the responsible bacteria in order to tailor the treatment, and thus reduce the risk of resistance and complications due to SPD itself, but also to the multiplication of probabilistic treatments.

Objectives: Our aim was to study the contribution of the different microbiological and anatomopathological examinations in the diagnosis of pyogenic SPD.

Methods: It was a descriptive study in a single rheumatology department. Data were collected retrospectively from observations of patients hospitalized in the last 20 years who had been diagnosed with pyogenic SPD. We excluded cases of tuberculous and brucellar SPD from our study because of their completely different histological and microbiological profiles.

Results: Twenty-two cases of pyogenic SPD were collected (14M/ 8F). The mean age of the population was 55.9 years [29,80]. A bacteriological survey including at least one ctyobacteriological examination of the urine (CBUE), chest X-rays and blood cultures allowed the identification of the bacteria in 16 cases (73%). The most common site were bacteria was identified was blood culture in 16 cases (67%). For patients whose etiological investigation was performed, 84.6% were diagnostic, 15.4% were non-diagnostic.

Infecting bacteria was identified in 14 patients (64%). Gram-negative bacilli (GNB) and staphylococcus aureus were the most frequent germs (7 cases each) including 2 cases of co-infection. GNBs were represented by: Escherichia Coli and Enterobacter Closaceae in 2 cases each, Proteus Mirabilis, Serratia Marcescens and Klebsiella oxytoca in 1 case each. Clostridium clostridiforme and Lactococcus cremoris were isolated in 1 case each. For patients whose etiological investigation remained negative, SPD diagnosis was retained based on imaging (MRI) guided by anamnestic, clinico-biological and histopathological arguments.

Conclusion: SPD is a rare condition that needs to be treated rapidly. Once the diagnosis is suspected, bacteria must be isolated before starting any antibiotic therapy. Simple and non-invasive exams as blood cultures, CBUE and chest roentgen, should be undertaken first. In fact, these simple exams allowed a germ identification in 73% cases in our study. If doubt persist, DVBP could be contributive to the diagnosis.

RECIPROCAL IMPACT OF FIBROMYALGIA ON DISEASE CHARACTERISTICS AND PHYSICAL AND PSYCHOLOGICAL DOMAINS IN SJÖGREN SYNDROME: CROSS SECTIONAL OBSERVATIONAL STUDY.

A. Capacci1, P. Rubortone1, V. Varriano1, A. Paglionico1, S. Perniola1, M. R. Gigante1, B. Tolusso1, S. Alverinni2, E. Gremese2. 1Fondazione Pollicino Universitario A. Gemelli IRCCS, Rome, Italy; 2Fondazione Pollicino Universitario A. Gemelli IRCCS - Università Cattolica del Sacro Cuore, Rome, Italy

Background: Sjogren Syndrome (SS) is an autoimmune exocrinopathy, resulting mainly in ocular and oral dryness, with approximately half of patients displaying symptoms from different organ systems, further adding to the heterogeneous clinical phenotype of the disease. Fatigue and pain are common systemic symptoms in patients with primary SS and fibromyalgia is a frequent condition associated with chronic diseases.

Objectives: The aim of the study was to evaluate the impact of concomitant fibromyalgia in patients with Sjogren Syndrome in terms of clinical features and disease activity.

Methods: 50 patients with Sjogren Syndrome were enrolled in the study (100% female; age: 53.7 ± 13.2 years and disease duration: 8.7 ± 5.3 years), 25(50.0%) with concomitant fibromyalgia (SS/Fibro-group) and 25(50.0%) without (SS-group). 36 patients with primary fibromyalgia (Fibro-group) were included as control group. At study entry, demographic, educational, lifestyle and clinical parameters were recorded for each patient. SS was diagnosed according to the American College of Rheumatology (ACR) classification criteria (1) and fibromyalgia was diagnosed according to criteria for fibromyalgia defined by ACR (2). Moreover, each patient with fibromyalgia, with and without concomitant SS, was asked to fill a self-reported questionnaire to assess the impact of Fibromyalgia on multiple physical and psychological domains (Italian-FIQR).

Results: Stratifying the study cohorts based on the demographic and life-style characteristics, no significant differences were found comparing SS-group, Fibro-group and SS/Fibro-group. However, considering the different organ involvement,
**References:**

**Disclosure of Interests:** Annunziata Capacci: None declared, Pietro Rubortone: [2]

**Conclusion:** SS is affected by concomitant fibromyalgia in terms of subject-dependent parameters (i.e. joint complaints) however the concomitant SS does not affect the impact of fibromyalgia on physical and psychological domains, even if disease activity is higher in SS patients without fibromyalgia.

**AB0948** TIME TO CONSIDER HYPERMOBILITY AS A CAUSE OF SYMPTOMS IN PATIENTS PRESENTING TO EARLY ARTHRITIS CLINICS: A RETROSPECTIVE ANALYSIS OF 279 PATIENTS

S. Dar¹, D. Ludwig², M. Greenwood³, H. Kazakz½, V. Morris³, UCL Medical School, London, United Kingdom; ²University College Hospital, London, United Kingdom

**Background:** Joint hypermobility is a common, although largely ignored physical sign. It is often asymptomatic but can be associated with significant musculoskeletal symptoms. Joint hypermobility may also be a feature of an underlying genetic disorder and patients may present with arthralgia, recurrent soft tissue injuries and intermittent joint swelling due to mechanical instability and poor proprioception. At University College London Hospital, we run a national service for the diagnosis and management of patients with hypermobility related disorders including hypermobility spectrum disorders, Ehlers-Danlos syndromes and Marfan syndrome. Over the years we observed that a significant number of our patients had been referred to the early arthritis clinics years prior to the recognition of their hypermobility. For example, one patient with a vascular type of Ehlers-Danlos syndrome EDS (confirmed COL3A mutation) presented to 3 different hospitals over a 5-year period, with persistent inflammatory arthritis prior to the EDS diagnosis. Several studies have shown that a significant proportion of patients attending early arthritis clinics do not have inflammatory rheumatic diseases. In our experience, heritable disorders of connective tissue and hypermobility spectrum disorders are often overlooked and should be included in the differential diagnosis in patients seen in the early arthritis clinics.

**Objectives:** We aimed to audit the outcome of patients who were seen in the early arthritis clinics focusing on those who were not found to have inflammatory rheumatic diseases and to explore if joint hypermobility was considered as a possible cause of patient’s symptoms.

**Methods:** A retrospective analysis of medical records was conducted of patients attending the early arthritis clinics at University College London Hospital between May 2018 and December 2019.

**Results:** 279 patients (96 males, 189 females) were seen in the early arthritis clinics with a mean age of 48 (range 19-91). 131 patients (47%) did not have inflammatory rheumatic diseases. Sixty-three of these patients (48%) were not given any diagnosis and joint hypermobility was not assessed during the appointment. Eleven patients (8%) had features of hypermobility, 11 patients (8%) were diagnosed with fibromyalgia, 20 patients (15%) received a diagnosis of osteoarthritis, and 27 patients (21%) were given other diagnoses including tendonitis and soft tissue pathology.

**Conclusion:** Almost 50% of patients who were seen in the early arthritis clinics did not have inflammatory rheumatic diseases and 21% of patients were discharged without a clear diagnosis. In these patients, hypermobility was not assessed and this is consistent with our observation. In our experience recognizing joint hypermobility as a cause of arthralgia and intermittent joint swelling usually reassures patients and motivates them to follow appropriate treatment protocols including physiotherapy and occupational therapy thus allowing a more efficient utilization of early arthritis clinic resources towards those with true inflammatory rheumatic diseases. Going forward, we have planned to embed a cognisant attitude towards hypermobility within the relevant clinics to ensure that patients who do not have inflammatory arthritis are assessed for hypermobility and directed towards appropriate management.

**AB0949** AUTONOMIC AND INFLAMMATORY MECHANISMS OF PAIN AND FATIGUE IN FIBROMYALGIA AND ME/CFS: AN INTERVENTIONAL STUDY

J. Eccles¹,², M. Amato¹, C. Thompson¹,², K. Themelis¹,², H. Critchley¹, N. Harrison¹,⁴, K. Davies¹,², Brighton and Sussex Medical School, Falmer, United Kingdom; ³Clinical Investigation and Research Unit, Royal Sussex County Hospital, Brighton, United Kingdom; ⁴University of Warwick, Warwick, United Kingdom; ²CUBRIC, University of Cardiff, Cardiff, United Kingdom

**Background:** Fibromyalgia and ME/CFS are complex disorders with overlapping symptoms; the pathoetiology and clinical distinction are debated, however inflammatory and autonomic abnormalities are observed.

**Objectives:** To investigate the role of inflammatory and autonomic nervous system responses in mechanisms of pain and fatigue in fibromyalgia and ME/CFS

**Methods:** 63 patient participants with clinical diagnoses of fibromyalgia and/or ME/CFS were recruited into a multi-stage interventional study (ISRCTN78820481) alongside 24 healthy controls. All underwent research diagnostic criteria evaluation. The majority underwent autonomic challenge (60 degree head up tilt) and/or inflammatory challenge (placebo-controlled typhoid vaccination) with baseline characterisation of symptoms, inflammatory markers and pre-post measures of pain and fatigue.

**Results:** Of the 63 patients, 32% of patients had received a clinical diagnosis of Fibromyalgia; 38% ME/CFS and 30% dual diagnoses. Following research evaluation 89% met ACR diagnostic criteria for fibromyalgia; 94% Canadian Criteria for ME/CFS; 97% Fukada Criteria for ME/CFS There was a significantly higher ESR in patients compared to controls (p=0.036). There was a trend towards higher CRP in patients compared to controls (p=0.076). ESR correlated with baseline pain score (r=0.309, p=0.011), fatigue severity (r=0.262, p=0.032), fatigue impact (r=0.382, p=0.014) change in fatigue score induced by tilt (r=0.319, p=0.011) and change in pain score induced by placebo-controlled inflammation (r=0.279, p=0.043). Similarly CRP level correlated with baseline pain score (r=0.340, p=0.005), fatigue impact (r=0.439, p=0.004), change in fatigue (r=0.277, p=0.045) and pain score (r=0.394, p=0.014) induced by placebo-controlled inflammation and change in pressure pain threshold induced by tilt (r=0.286, p=0.027).

Baseline IL6 was higher in patients than controls (p=0.002), correlating with baseline pain score (r=0.345, p=0.002) and change in pain score induced by tilt (r=0.281, p=0.021). Change in IL6 induced by inflammatory challenge correlated with inflammation induced fatigue score (r=0.378, p=0.01).

**Conclusion:** Inflammatory and autonomic mechanisms contribute to pain and fatigue in this frequently overlooked patient group, highlighting possibilities for targeted treatments. Such data will be enriched going forward by neuroimaging and transcriptomic insights.

**AB0950** EFFECT OF SELECTIVE SEROTONIN REUPTAKE INHIBITORS AND SEROTONIN NOREPINEPHRINE REUPTAKE INHIBITORS ON BONE MINERAL DENSITY IN EGYPTION PATIENTS WITH PRIMARY FIBROMYALGIA

Y. Gazar-on behalf of prof dr. Hesham salah HamoudDr. Mohammed Magdy GhaithDr. Mohammed Harb. ¹Rheumatology Department, Faculty of Medicine, AL-Azhar University, Cairo, Egypt
Background: Fibromyalgia is characterized by chronic widespread musculoskeletal pain that often co-exists with sleep disturbances, fatigue, cognitive dysfunction, stiffness and tenderness to palpation at specific tender points. Selective serotonin reuptake inhibitors represent a class of commonly used antidepressants. They act by preventing the reuptake of 5-hydroxytryptamine (5-HT) (Serotonin) through the inhibition of the 5-HT transporter (5-HTT) which is located on the presynaptic neuron, thereby increasing levels of 5-HT within the synaptic cleft and modulating neurochemical signaling. Usage of SSRIs was significantly associated with lumbar spine BMD reduction, particularly for old people. DXA and TBS revealed that usage of SSRIs and SNRI was significantly associated with low BMD (Osteopenia and osteoporosis) specially spine BMD reduction with low TBS (Partially degraded and degraded) particularly for old people and despite low BMD was found in the SRI users; it also found in 1ry fibromyalgia not on SRIs so 1ry fibromyalgia should also be considered as a contributing factor for low BM.

Objectives: This work aim to determine the correlation between selective serotonin reuptake inhibitors (SSRIs) and serotonin norepinephrine reuptake inhibitors (SNRIs) usage and bone mineral density (BMD) and trabecular bone score (TBS) changes in primary Fibromyalgia patient

Methods: The present cross sectional study was conducted on a Hundred (100) Egyptian patients diagnosed as primary fibromyalgia divided according to drug medication into two groups, 50 patients on SSRIs and 50 patients on SNRIs, recruited from Rheumatology, Physical Medicine and Rehabilitation departments at Al-Hussein and Sayed Galal, Al-Azhar University Hospitals. In addition to a new group of 25 healthy people as the control group subdivided into: group C-1: 25, 1ry fibromyalgia patients not on those drugs and 25 healthy individuals selected by nurses and medical staff, after an informed consent from all subjects from June 2018 to December 2018..An approval was obtained from the medical ethics committee of Al-Azhar University before starting this study. All the patients were informed about the study procedures and a written consent was obtained from all of them. The patients were categorized into three groups. Group A: 50 1ry fibromyalgia patients on SSRIs. Group B: 50 1ry fibromyalgia patients on SNRIs. Group C: 50 individuals as a the control group subdivided into: group C-1: 25, 1ry fibromyalgia patients non SRIs-users and group C-2: 25 healthy individuals.

Results: DXA and TBS revealed that usage of SSRIs and SNRI was significantly associated with low BMD (Osteopenia and osteoporosis) specifically spine BMD reduction with low TBS (Partially degraded and degraded) particularly for old people and despite low BMD was found in the SRI users; it also found in 1ry fibromyalgia not on SRIs so 1ry fibromyalgia should also be considered as a contributing factor for low BMD.

Conclusion: The present study provided evidence that usage of SSRIs or SNRI was significantly associated with low BMD (Osteopenia and osteoporosis) specially spine BMD reduction with low TBS (Partially degraded and degraded) particularly for old people and despite low BMD was found in the SRI users; it also found in 1ry fibromyalgia not on SRIs so 1ry fibromyalgia should also be considered as a contributing factor for low BMD.

F/M: female/male

Conclusion: The results of this study constitute the first investigation of the effect of a nutritional supplement containing CoQ10, magnesium and tryptophan on FMS. Although the results should be confirmed in larger studies, they suggest that the NSC treatment for 3 months, in addition to pharmaceutical therapy, may be of interest in the management of FMS. This treatment appeared to primarily improve physical symptoms, such as fatigue and pain, with low risk of adverse events.

AB0954 IS CONNECTIVE TISSUE MASSAGE EFFECTIVE IN INDIVIDUALS WITH FIBROMYALGIA?

N. Jain1, N. Reddy2, A. Moorthy1, 1Leicester Royal Infirmary, Leicester, United Kingdom

Background: Cannabinoids has recently gained popularity for use for chronic pain. There is a lot of inquisitiveness among our patients wherein care health professionals are asked about its efficacy, side effects and sometimes even ask for a prescription! As there is paucity of data and research about its use in rheumatology, patient reported outcome(PROM) can guide ahead in expanding our knowledge and experience.

Objectives: To study usage of cannabinoids by rheumatology patients

Methods: Cross sectional survey with two arms. Arm 1 Information from patients attending tertiary rheumatology clinic; including perception regarding the use of Cannabinoids.

Arm 2 consisted of collecting data via web-based survey with 20-question from 100 GPs of Leicestershire. Questions on demographics, perspectives on and knowledge of cannabinoid use. Statistical analysis SPSS software.

Results: Arm1 Total 102 rheumatology patients with 60%were females and 45% secondary education. 48% were unemployed, 75% Caucasians, 18% Asians. RA most common diagnosis followed by OA and FMS, 40% depression and anxiety in addition to Rheumatic disease. 94% reported ongoing pain with 6-8 on a VAS scale. 79% were satisfied with their current therapy 65% had heard about complementary medicine and 15% reported using cannabinoids.

Common most form Cannabinoids oil 60% followed by smoking 20%, 56% reported using >3 months and majority 72% use daily. Median age 55 years. 88% users Caucasians. Mean disease duration 6.25 years among users indicates chronicity of disease has a direct proportion in usage. All users had ongoing pain of 7 on VAS. 87% believed it helps them managing pain effectively with a pain free state. On an average spends between 50-100 pounds per week. More than half believe cannabinoids should be available as a prescription drug in NHS and 30% interested to know more about it.

In Arm 2 consisting of Primary care physicians, response rate 50%. Average clinical experience 5 years. Only 20% heard about usage of complementary medicine by rheumatology patient. Most replied that 10% of their patients use cannabinoids for pain management. Most did not believe use of cannabinoids benefitted the patients. Only 4% recommend its usage. 25% think it should be available as prescription. 40% experienced patients asking about cannabinoids during appointment. 88% of respondents did not know much about cannabinoid usage in rheumatology and have never prescribed it in their practice.

Conclusion: Cannabinoids widely used by the rheumatology patients with PROM favours its efficacy for controlling of chronic pain. Preclinical data suggest that cannabinoids might have a therapeutic potential RA1, OA, FMS2. Clinical data regarding cannabinoid treatment for rheumatic diseases are scarce, therefore, recommendations concerning cannabinoid treatment cannot be made. All patients who reported using it suffered from moderate to severe chronic pain. Thus main indication of usage was pain rather than recreational purpose. Although a small survey clearly highlights lack of knowledge among primary physicians. These results emphasise the need for further research regarding the benefits and risks of cannabinoids in rheumatology.

AB0953 CANNABINOIDS: FRIEND OR FOE OR A BYSTANDER?

A. Keskin1, B. Basaik Calik2, E. Gur Kabul3, V. Cobankara3, 1Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey; 2Medical Faculty of Pamukkale University, Department of Rheumatology, Denizli, Turkey

Background: Fibromyalgia (FM) is a systemic rheumatic disease characterized by diffuse pain in the body, tenderness, fatigue and many more symptoms. Exercise is effective and safe method in individuals with FM. Connective tissue massage, another treatment method, is a reflex therapy where shear force is applied in a certain order at the connective tissue interfaces of the skin. In the literature, there is limited study related compared with clinical pilates exercises and connective tissue massage in individuals with FM.

Objectives: The aim of the study was to examine the effectiveness of clinical pilates exercises and connective tissue massage in Individuals with Fibromyalgia on disease activity, number of painful regions, anxiety, biopsychosocial status and quality of life.

Methods: 32 women (age mean=52.43±s.3.2) diagnosed with FM according to American College of Rheumatology (ACR) criteria were included in this study. Patients were divided into two groups as interventional group (n=15, mean age=48.8±6.7) and control group (n=17, mean age=55.6±4.7). While the connective tissue massage and clinical pilates exercises were applied to the treatment group, only clinical pilates exercises were applied to the control group. After the demographic characteristics and disease related data of the individuals were recorded; number of painful regions were assessed with Pain Location Inventory (PLI), disease impact with Fibromyalgia Impact Questionnaire (FIQ), functional status with Health Assessment Questionnaire (HAQ), anxiety with Beck Anxiety Inventory (BAI), quality of life with Short Form-36 (SF-36) and biopsychosocial status with Cognitive Exercise Therapy Approach (BETY) Scale were evaluated. All evaluations were made before and after treatment. All interventions were applied 3 days per week for 6 weeks by the same experienced physical therapist. One session for clinical pilates exercises consisted of 60 minutes, 10 minutes warm up, 40 minutes clinical pilates exercises, 10 minutes cool down. Connective tissue massage was started from lumbosacral region and continued lower thoracic, scapular, interscapular, and cervical regions, respectively. The Kolmogorov-Smirnov Test was used to determine whether the continuous variables were normal distributions.

Results: When the pre-treatment and post-treatment results are analyzed; the results were significant in the intervention group of PLI (p = 0.007), SF 36 physical component (p = 0.025) and mental component (p = 0.017) and FIQ (p = 0.004), while in the control group the difference in SF 36 physical component (p = 0.008) and mental component (p = 0.024), FIQ (p = 0.001) and BAI (p = 0.043) was significant. Delta values were calculated by subtracting post-treatment results from pre-treatment results. When the delta values of the groups are compared, it was determined that the difference only in the PLI (p = 0.023) were significant in favor of the treatment group.

Conclusion: According to our results, connective tissue massage has been shown to be effective in reducing the number of painful areas in addition to the...
positive effects of clinical pilates exercises in individuals with FM. In order to increase the effectiveness of treatment in individuals with FM, we recommend the use of connective tissue massage as an additional treatment method.

**BIBLIOGRAPHY**

**FEATURES OF THE PAIN SYNDROME IN RHEUMATOID ARTHRITIS (RA)**

S. Lezheneda, N. Shuvalova, A. Lammert, E. Guryanova, Chuvash State University, Cheboksary, Russian Federation; Ya. Yakovlev Chuvash Pedagogical State University, Cheboksary, Russian Federation

**Background:** The neuropathic component is present in the mechanism of pain in RA in 36% of cases. The presence of anxiety-depressive disorders and a deterioration in the quality of life in patients with RA are shown.

**Objectives:** The study of the clinical features of pain in RA in men and women.

**Methods:** The group consisted of 134 patients with RA (94 women and 40 men), aged 36 to 60 years (average age 48.6 ± 7.1 years) and disease duration from 1 year to 10 years (4.03 ± 1.6 years) hospitalized in the rheumatology department of the Republican Clinical Hospital (Cheboksary). At the time of inclusion in the study, all patients were in the active stage of the disease.

An assessment of rheumatological and neurological status was carried out. Pain assessment was performed using: Visual Analog Scale (VAS); Ritchie arthritic index (RAI). The severity of neuropathic pain was determined using the diagnostic neuropathic pain questionnaire DN4 and PainDetect (sensitivity - 82.9%; specificity - 89.9%). To determine the psycho-emotional deviations used: general health questionnaire (anxiety and depression) - General Health Questionnaire (form GHQ - 28); HADS; Spilberg-Hanin situational and personal anxiety scale. Patient mobility limitations were assessed using the Rivermead mobility index score scale, and quality of life was quantified using the EQ-5D visual analogue scale. To assess the activity of the disease, the level of C-reactive protein (CRP), the erythrocyte sedimentation rate (ESR), and the DAS index - 28-CRP were used. To assess mental and physical functioning, a standardized questionnaire The Short Form-36 was used.

To visualize the stage, survey radiographs were used in the direct projection of the metacarpophalangeal and metatarsophalangeal joints, wrist joints, proximal interphalangeal joints of the hands; distal parts of the feet.

**Results:** An analysis of chronic pain syndrome in 36% of patients revealed a neuropathic component of pain (DN4: 5.7 ± 1.1 points, PainDetect: 16.3 ± 4.2). In the group of patients with neuropathic pain (n = 78) aged 55.1 ± 7.9 years, the duration of the disease was 3.4 ± 0.9 years, the more advanced and late clinical stages of the disease, Ill – IV radiological stages of RA were more common, were present neurological disorders and complaints characteristic of peripheral polyneuropathy. Rivermead mobility index in patients with neuropathic disorders, (n = 78) was 9.1 ± 0.8 points, in the absence of neuropathic disorders (n = 56), 11.2 ± 1.1 points. There were no significant differences in process activity (DAS index - 28 - CRP) and quality of life. According to the questionnaire of situational and personal anxiety, Spilberg-Hanin revealed moderate anxiety and mild - depressive disorders. Quality of life was reduced in all patients with RA.

Pain syndrome in patients with neuropathic pain with symptomatic (NSAIDs, GC) and basic cyotstatic therapy (methotrexate) showed that, despite the decrease in the severity of the inflammatory process, the positive dynamics was partial (VAS before therapy 6.4 ± 0.7; VAS in the presence of therapy 4.3 ± 0.5 (p> 0.05); PainDetect = 14.9 ± 4.4; DN4 = 4.3 ± 1.5).

In men, statistically significant factors associated with pain were clinical parameters that accounted for 37% and 18% of pain variation (Ritchie arthritic index (CIR); Fsmc = 4.107, p <0.001; SF-36: Fsmc = 2.107, p <0.001). In women, the main significant factors associated with pain were the subjective feeling of pain and psychological characteristics that accounted for 12% of the pain variation (SF-36: Fsmc = 11.118, p <0.001).

**Conclusion:** A dynamic study of patients with RA in accordance with gender and age will further develop additional criteria for evaluating the effectiveness of complex therapy used to treat chronic pain, and will also increase the overall effectiveness of treatment.

DOI: 10.1136/annrheumdis-2020-eular.6704

**AB0056** VERTICAL NAIL RIDGING IN PATIENTS WITH FIBROMYALGIA: FREQUENCY, PROPOSED GRADING AND CORRELATION WITH OTHER DISEASE FEATURES

A. Mostafi1, M. Abdelkareem1, M. Monier1, A. Mosalami1, A. Ismail1, M. Elwan1, A. Saad2, T. Abdelaziz1. 1A’Azhar university, Rheumatology, Assiut, Egypt

**Background:** The vertical nail ridging (VNR) has long been reported to be related to stressful conditions.

**Objectives:** To evaluate the frequency of VNS in FM patients and its relation to other disease parameters depending on a proposed grading.

**Methods:** VNR has been searched for in 212 FM patients (2016 criteria). The number of fingers, the degree of VNR according to this proposed grading (0: no ridging, 1: ridging only detected by a magnifying lens, 2: ridging seen by naked eye and 3: ridging that can be seen and felt) and other FM features according to the new and old ACR criteria have been recorded. 80 subjects of those consulting for knee osteoarthritis have been examined for VNR and those found positive were asked about the FM features and examined for tender points. Patients aged >50 years and those with psoriasis and fungal infections were excluded.

**Results:** The mean age of patients was 32.4±9.9 (73.6% were female). The mean disease duration was 5.8±3.7, while the means of WPS, SSS and tender points were 9.4±2.9, 7.3±1.2 and 14.7±2.3 respectively. VNR was found in 209 patients (98.6%). Of 80 controls, VNR has been found in 61 subjects, of whom FM has been diagnosed in 32 patients (52.3%) by 2016 FM criteria and in 46 (75.4%) by 1990 criteria. The number of fingers with VNR has been found only correlated with the disease duration (r= 0.276, P = 0.000). The severity of VNR was significantly correlating with fatigue (P= 0.002), sleep disturbance (P=0.001), awaking unrefreshed (P= 0.000), WPI (P = 0.01) and mean tender points (P=0.02). Considering the 2016 criteria as a gold standard, the sensitivity of VNR was 98.37%; the specificity was 9.68% and the diagnostic accuracy was 82.8%.

**Conclusion:** Vertical nail ridging is a frequent finding and can be considered helpful for diagnosis of patients with FM. Further studies are needed to validate this sign for diagnosis and follow up of FM patients.

DOI: 10.1136/annrheumdis-2020-eular.5317

**AB0057** IS AQUATIC THERAPY MORE EFFECTIVE THAN LAND-BASED THERAPY IN REDUCING PAIN OF WOMEN WITH FIBROMYALGIA?

S. Rivas Neira1, A. Pasqual Marques2, J. Vivas Costa3, 1Universidad de Coruña, A Coruña, Spain; 2Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

**Background:** Fibromyalgia is a rheumatic disorder characterized by chronic widespread pain often associated with fatigue, unrefreshed sleep and cognitive problems with an increasing prevalence. Aquatic therapy has already been used for managing the symptoms of this syndrome. However, it is not clear whether there is a superiority of aquatic therapy over land-based therapy in improving the symptoms of fibromyalgia patients.

**Objectives:** Determine the effectiveness of two physiotherapy protocols: aquatic therapy versus land-based therapy, for decreasing pain in women with fibromyalgia.

**Methods:** The study protocol was a single-blind randomized controlled trial. Forty women diagnosed with fibromyalgia were randomly assigned into two groups: Aquatic Therapy (n=20) and Land-based Therapy (n=20). Both interventions included 60-min therapy sessions, structured into four sections: Warm-up, Proprioceptive Exercises, Stretching and Relaxation. These sessions were carried out three times a week for three months. The variables analyzed were: pain intensity (Visual Analogue Scale (VAS)), pain threshold (algiometer), quality of life (Revised Fibromyalgia Impact Questionnaire (FIQ/R)), sleep quality (Pittsburgh Sleep Quality Index (PSQI)), fatigue (Multidimensional Fatigue Inventory (MFI)) and physical ability (6-minute Walk Test [6MWT]). Outcome measures were evaluated at baseline, at the end of the 3-month intervention period, and 6-weeks post-treatment. Statistical analysis will be carried out using the SPSS 21.0 program for Windows and a significance level of p ≤0.05 was used for all tests.

**Results:** At the end of intervention period, both therapies were effective in improving pain intensity (p<0.05), pain threshold (p<0.05), quality of life (p<0.05), fatigue (p<0.05) and physical ability (p<0.05). For sleep quality, only the aquatic therapy group experienced a significant improvement (p=0.033). No differences were
observed between the groups in post-treatment, but they were found at the follow-up, in favor of aquatic therapy for pain intensity (p=0.023) and sleep quality (p=0.030).

**Conclusion:** Both physiotherapy interventions showed to be effective in reducing pain in patients with fibromyalgia. However, aquatic therapy was more effective in improving quality of sleep and decreasing pain intensity at six weeks of follow-up than land-based therapy. It seems that the therapeutic effects achieved in post-treatment were maintained for a longer time in the aquatic therapy group.

Even so, in order to maintain the benefits obtained with the interventions, continuous physiotherapy treatment seems to be necessary.

**AB0958**

LOW-ENERGY PULSED ELECTROMAGNETIC FIELD THERAPY REDUCES PAIN IN FIBROMYALGIA: A RANDOMIZED SINGLE-BLIND CONTROLLED PILOT STUDY.

M. Giovale1, L. Novelli1, S. Rampoldi2, R. Galli1, P. Monteforte1, M. Doveri1, G. Bianchi1, L. C. Bottaro4, C. Selmi1. 1Asl3 Genovese, SC Rheumatology Department of Medical Specialties Dial Locomotor System, Genova, Italy; 2Humanitas Research Hospital, Humanitas University, Rheumatology and Clinical Immunology, Rozzano, Italy; 3Therapeutic Solutions, Milan, Italy; 4Asl3 Genovese, Genova, Italy

**Background:** Fibromyalgia is a clinical condition characterized by diffuse chronic muscle-skeletal pain, fatigue, sleep/mood disorders and muscular stiffness. The pathogenesis of fibromyalgia remains poorly understood but numerous lines of evidence suggest a role for alterations of both the central and peripheral nervous systems leading to heightened pain sensitivity along with a corollary of other symptoms1. Low-energy pulsed electromagnetic field (PEMF) has promising data in the prevention of falls in senior individuals and is believed to promote osteogenesis and angiogenesis thus proving promising to treat bone diseases with chronic pain2. No data is available in fibromyalgia.

**Objectives:** To investigate the efficacy and safety of PEMF on fibromyalgia symptoms in a randomized single-blind pilot study.

**Methods:** We enrolled 21 women (median age 59 years, IQR 16.5) affected by fibromyalgia according to the 2016 ACR classification criteria3 not receiving chronic medical treatment for pain; patients were randomly allocated to receive PEMF TEPT (triple energy pain treatment) / New Sunrise 280 (THS - Therapeutic Solutions, Milan, Italy) on the selected points (10 acupuncture points) or scrambled points for 20 minutes at baseline (T0) and after 4 (T4) and 8 (T8) weeks. Outcome measures were recorded at T0, T4 and T8 and included FIQ (fibromyalgia impact questionnaire), WIP (widespread pain index), VAS pain, SS (symptom severity scale), and SF-36 (short form health survey questionnaire).

**Results:** Patients receiving the active treatment had a deep reduction of WIP from T0 to T8 (-76% vs -13% in placebo) with a statistically significant difference compared to the placebo group (p=0.0025) (Figure 1). In all endpoints, we observed a general reduction at T4 and T8 compared to T0 also for FIQ, VAS pain, SS, SF-36, regardless of the treatment arm and the decrease was higher in the active treatment arm compared to the placebo group, albeit not reaching statistical significance (Figure 2).

**Conclusion:** The results of our pilot study show that PEMF is more effective than placebo in reducing widespread pain in fibromyalgia while confirming that a placebo effect is clear in this complex disease.

**AB0959**

FREQUENCY OF SEXUAL DYSFUNCTION IN WOMEN WITH FIBROMYALGIA

O. Teplyakova1, A. Popov1. 1Ural State Medical University, Yekaterinburg, Russian Federation

**Background:** The impact of rheumatic diseases on patients’sexual life has been gathering the attention of the scientific community over the last decade. The existing studies, especially related to fibromyalgia, are scarce.

**Objectives:** To assess the prevalence of sexual dysfunction in women with fibromyalgia followed up at the Outpatient Clinic of the Medical Hospital in Russia.

**Methods:** The main group consisted of 54 women aged from 18 to 55 who sequentially applied for rheumatologist consultation. All subjects fulfilled ACR 2016 Fibromyalgia criteria. The comparison group included 100 healthy women adjusted by age who came for a scheduled health check up and signed the informed consent form. The Female Sexual Function Index (FSFI), obtained by applying a 19-item questionnaire that assesses six domains (sexual desire, arousal, vaginal lubrication, orgasm, sexual satisfaction and pain) and Hospital Anxiety and Depression questionnaire (HADS) were used. The data are presented as means and standard deviations.

**Results:** 26 (48.1%) of the patients interviewed reported no sexual activity over the past 4 weeks. Fibromyalgia patients reported no sexual activity during the previous 4 weeks. Fibromyalgia group had significantly lower values of all FSFI
AB0960

RELATIONSHIP BETWEEN THE CAREGIVER BURDEN AND UPPER LIMB-NECK DISABILITY AND PAIN IN BABY CAREGIVERS

G. Aydin1, A. Demiref, N. Buluf, A. A. Karaduman, S. Serel Arslan1, O. Yilmaz1, I. Gurbuz1, 2Hacettepe Universitesi Saglik Bilimleri Fakultesi Fizyoterapi Ve Rehabilitasyon Bolumu, Ankara, Turkey; 1Hacettepe Universitesi Saglik Bilimleri Fakultesi Fizyoterapi Ve Rehabilitasyon Bolumu, Ankara, Turkey

Background: Although caregiving is a normal part of being a parent of a young child, it is still unclear whether caregiving causes upper limb or neck disability in the caregiver.

Objectives: The aim of this study was to investigate the relationship between caregiver burden and upper limb-neck disabilities and pain in baby caregivers.

Methods: Sixty caregivers who are responsible for the caregiving of a 0-2 year old baby were included in this study. Physical characteristics and the gender of the caregivers were recorded. Caregiver burden was assessed by the Zarit Burden Interview; upper limb problems by DASH and neck problems by the Neck Disability Index and Neck Bournmouth Questionnaire. In addition, pain severity related to neck and upper limb was evaluated by using Visual Analog Scale over a 10 level scale.

Results: The mean age of the caregivers was 30.96 ± 6.43 year. The mean body mass index of the caregivers was 23.34 ± 3.29 indicating normal body mass deficiency and overweight. In general, total FSFI score was 12.86±10.97 on fibromyalgia group versus 23.5±5.84 in the healthy group (maximum possible being 36 points, p<0.0001).

Conclusion: Thus, a significant sexual function decrease was detected in female with fibromyalgia. The most severe dysfunction being associated with the abnormal anxiety, borderline and abnormal depression, divorced status, body mass deficiency and overweight.

AB0961

MYOFASCIAL TRIGGER POINTS ARE THE UNDETECTED HYPOXIC NICHES ALTERING POSTURE AND PHENOTYPE

R. Bubnov1, 2, O. Golubnitschaja3, 4, 5Zabolotny Institute of Microbiology and Virology, NAS of Ukraine, Interferon, Kyiv, Ukraine; 3Clinical Hospital ‘Pneumonia’, Ultrasound, Kyiv, Ukraine; 4Excellence University of Bonn, Bonn, Germany; Breast Cancer Research Centre, Bonn, Germany; 5Excellence University of Bonn, Bonn, Germany, Centre for Integrated Oncology, Bonn, Germany

Objectives: Myofascial trigger point (mTrP) is a pillar pathological unit in development of myofascial pain [1] and postural imbalance [2]. Dry needling (DN) of mTrP under ultrasound (US) guidance is prioritized method for treatment myofascial pain. Hypoxia-related signaling pathways play important role in development of rheumatic diseases and cancer [3,4].

Hypothesis: mTrP are spastic hypervascularized hypoxic low energy areas that can produce organismic signaling, associated with niches in Flammer syndrome [3,4].

Objectives: The aim was to evaluate structure of mTrP in regard to stiffness and “ischemic pattern” before and after DN.

Methods: We included 40 patients (26 females, aged 18–68 y.o.) with low back pain. Healthy 20 individuals (aged 18–52 y.o.) were controls. All patients underwent general exam, MRT, precise physical tests, extensive functional multiparameter neuromuscular US including M-mode, elastography (SWE), B-Flow (LOGIC E9 GE) of multifidus muscles. Then patients received DN of detected mTrP under US guidance.

Results: We successfully detected mTrP as hypoechoic, stiff and hypovascular small areas with different patterns of decreasing motility, contractility (muscle contracted/rested thickness) in all patient and did precise DN. After DN muscle structure improved, motility, contractility restored, VAS scores changed from 7.4 to 2.3 (p<0.05). SWE was 11.6±kPa in mTrP (27 kPa in active, 5-8 kPa in latent MTrP) vs 3.8±0.3 kPa in controls and decreased to 4±0.4 kPa after treatment. Hypoxiasis (“ischemic pattern”) size decreased from 3-4 mm to 0-1.5 mm, correlated with muscle function. Preliminary we found mTrP with more expressed hypovascular pattern, higher sensitivity and retaining levels of in individuals lower BMI and patient with Flammer phenotype [3,4] (13-15/15 positive responses to questionnaire).

Conclusion: mTrP are stiff and most likely hypoxic areas, parameters improved after precise DN. US hunting for “ischemic pattern” markers can be important for patient stratification and targeted treatment and prevention. Metabolic profiling including HIF signaling, proteomic data collecting needed for further investigation for effective patient stratification. For the follow-up studies a correlation of the Flammer syndrome phenotype with individualised profiles of patients and diagnosed ischemic patterns is recommended.

LOW BACK PAIN AMONG MEDICAL STUDENTS: PREVALENCE AND RISK FACTORS

C. Daleite1, S. Boussaid2, S. Jemmal1, S. Rekk1, H. Sahli1, E. Cheeurb, M. Elleuch1, 2La Rabta Hospital, Rheumatology, Tunisia, Tunisia

Background: Low back pain (LBP) is a common health problem among all age groups. Medical students do not seem to be spared. In fact LBP is one of the most common musculoskeletal disorder and its prevalence is variable ranging from 41% to 72%.

Objectives: The aim of our study was to determine the prevalence of LBP among Tunisian medical students and to assess its associated factors.

Methods: We conducted a cross-sectional study over 2 months carried out on medical students in a Tunisian medical college. A digital questionnaire entered by Google forms was sent by e-mail and was completed by the students. Our study included students from the first year of the first cycle of medical studies up to the third year of medical education. Students were considered eligible if they were in their first cycle of medical studies and were aged between 18 and 29 years old. The questionnaire included questions about the sociodemographic characteristics of the students and their medical education, the habits and their abdominal pain, and their posture. The questionnaire also included the ODI (Oswestry Disability Index) validated by the Arab Society of Physical Therapy.

Results: The study included 352 students with a mean age of 23±3 years, 193 females (54.9%). The prevalence of LBP was 47.9% (95%CI 42.7-53.1). The statistical analysis showed that the following factors were significant for the LBP: pain with physical activity (p<0.01), pain with sitting (p<0.01), pain with standing (p<0.01), pain at night (p<0.01), pain with movement (p<0.01), pain on the right side (p=0.02), and pain on the left side (p=0.02). The analysis also showed that the following factors were significant for the LBP: a history of LBP before entry (p<0.01), a history of trauma (p<0.01), and a history of accident (p<0.01). The analysis also showed that the following factors were significant for the LBP: a history of LBP before entry (p<0.01), a history of trauma (p<0.01), and a history of accident (p<0.01).

Conclusion: LBP is a common health problem among Tunisian medical students. The prevalence of LBP is high and varies according to the different factors. Future studies are needed to understand the mechanisms underlying the high prevalence of LBP among Tunisian medical students.

DOI: 10.1136/annrheumdis-2020-eular.2776
the second cycle. Socio-demographic, personal characteristics and life habits were collected. LBP was assessed using the Nordic musculoskeletal health questionnaire. The impact of low back pain was assessed using the Oswestry disability index (ODI).

Results: One hundred and seventy-nine students were included. The mean age was 22.9 ± 2.3 years [19.64-38.21]. The sex ratio was 0.29. The average body mass index was 23.55 ± 4.22 kg/m² [17.67-43.07]. 82% of the students were in the second cycle of medical studies. 26.4% of the students had a regular sports activity, 91.2% spent more than 4 hours a day in a sitting position. The point, annual, and lifetime prevalence of LBP among medical students was 41.2%, 80.4% and 90.6%, respectively. Low back pain was acute in more than 58.8%, subacute in 14.9% and chronic in 26.3%. The mean ODI score was 10.32 ± 8.48% [0-32%]. Students with LBP were significantly younger than students without LBP (p = 0.015). LBP was more common in students who spent more than 4 hours in a sitting position with a difference at the limit of significance (p = 0.059). Being in the 2nd cycle was significantly associated with the occurrence of LBP (p = 0.006). Poor screen projection in the amphitheater was significantly associated with the occurrence of LBP (p < 0.05). We found a statistically very significant relationship between the occurrence of LBP and the poor layout of the amphiteaters (p = 0.000). The feeling of depression was significantly higher among LBP students (p = 0.018). Feelings of fatigue, being overwhelmed, irritability and worry were more frequently found in LBP students, but this difference was not statistically significant. In a multivariate analysis, the only factors that remained statistically significant were feeling of depression (p = 0.046, OR = 0.88, CI = [1.36-11.55]) and the poor layout of the amphiteaters (p = 0.046, OR = 8.96, CI = [2.55-31.69]).

Conclusion: The annual prevalence of LBP was 80.4%. These results testify to the magnitude of this health problem. The factors associated to LBP seemed to be essentially modifiable factors. This encourages special attention from medical schools to increase students' awareness of low back pain and to provide appropriate measures at reduce this musculoskeletal disorder.

AB0963 HOW OFTEN DO DOCTORS TREAT PATIENTS WITH LOCAL DAMAGE TO THE PERIARTICULAR SOFT TISSUES IN REAL CLINICAL PRACTICE?

A. Karateev1, A. Lila1, N. Zagorodny1, E. Pogozheva1, 1Nasonova Research Institute of Rheumatology Moscow, Moscow, Russian Federation; 2Pirogov National Medical Research Center of Traumatology and Orthopedics, Moscow, Russian Federation

Background: Damage of the periarticular soft tissues (DPST) - tendinitis, entesitis, bursitis, etc. are one of the most common reasons for patients to contact rheumatologists and orthopedic surgeons.

Objectives: To evaluate the frequency and localization of DPST in real clinical practice, as well as the effectiveness of therapy for this pathology in the acute period.

Methods: 68 outpatient orthopaedic surgeons evaluated the frequency of initial patient recourse due to DPST within one month. The study did not include patients with systemic rheumatic diseases such as spondyloarthritis. The localization of DPST and the dynamics of clinical manifestations were evaluated in 1227 patients (women 42.5%, cf. age 51.5±13.5 years). Non-steroidal anti-inflammatory drugs (NSAIDs), mainly meloxicam, were used as a first-line treatment for DPST. The results of treatment were evaluated after 10-14 days with repeated visits of patients.

Results: 7766 cases of primary outpatient treatment by orthopedic surgeons were evaluated. DPST was the cause of treatment in 1227 (15.8%) patients. This was the third highest incidence after acute injuries (37.2%) and knee osteoarthritis (20.6%). In patients with DPST, the most common lesions were in the knee area (knee entesopathy, prepatellar bursitis, pes anserinus area tendinitis/bursitis) – 21.2%, the foot (plantar fasciitis) – 16.9%, the shoulder (tendinitis of the rotator cuff) – 16.4%, and the elbow (lateral and medial epicondylitis) – 15.3%. After treatment, there was a significant decrease in the severity of pain during movement – from 6.58±1.61 to 2.48±1.60 points on the numerical rating scale (p<0.001), a decrease in the intensity of pain at rest, at night and during palpation, as well as the severity of functional disorders. The need for local injection of glucocorticoids occurred in 22.1% of patients. Significant improvement was observed in all DPST localities, with 68.1% of patients rating the treatment result as “good” and “excellent”. Adverse reactions were observed in 15.0% of patients, and no serious complications were reported.

Conclusion: DPST is the third most frequent reason of recourse to a doctor after acute injuries and osteoarthritis of large joints in the practice of outpatient orthopedic surgeons. The use of NSAIDs in the maximum therapeutic dose for 10-14 days allows for significant improvement in DPST of different localization.

AB0964 THE ASSOCIATION BETWEEN RESIDUAL SYMPTOMS AND CERVICAL SPINE LESIONS IN RHEUMATOID ARTHRITIS

T. Kashiwagura1, M. Kobayashi2, Y. Sugimura3, T. Kawano4, H. Sato5, N. Miyakoshi6, Y. Shimada7 on behalf of AORA Akita orthopedic group on Rheumatoid Arthritis. 1Akiya City Hospital, Akita, Japan; 2Hiraka General Hospital, Yotsuke, Japan; 3Akiya University Hospital, Akita, Japan; 4Akiya University Graduate School of Medicine, Akita, Japan; 5Kita Akita Municipal Hospital, Kita Akita, Japan

Background: Treatment outcomes in rheumatoid arthritis (RA) have been improved with advances in drug therapy. In daily clinical practice, the outcomes are assessed based on the presence of swollen or tender joints, global assessment using a visual analog scale by a patient (GVAS) and a physician (DrVAS), etc., in addition to inflammatory findings. Although inflammation and joint symptoms are suppressed, many patients show no improvement in GVAS scores. The reported residual RA symptoms include morning stiffness (MS), pain (P), and dullness (D), but their causes are not completely known. Latent cervical spine lesions sometimes exist in RA, but their association with residual RA symptoms is unknown.

Objectives: We examined cervical spine lesions and residual symptoms in patients with RA who achieved the therapeutic goal.

Methods: Of 124 patients with RA, 82 (25 men and 57 women) who achieved a low disease activity (LDA) state on the Disease Activity Score for 28 joints with erythrocyte sedimentation rate (DAS28-ESR) were included. The mean age was 65.7 (28-83) years, and the disease stage was Stage I in 28 patients, Stage II in 14, Stage III in 13, and Stage IV in 27. Dysfunction was graded as Class 1 in 63 patients, Class 2 in 18, and Class 3 in one (Steinbrocker classification). Bio- pharmaceuticals had been administered in 27 patients. As for disease activity, the DAS28-ESR scores indicated complete remission in 54 patients and LDA in 28. The survey form was used to investigate the presence or absence/duration of MS, the presence or absence/severity of P (Pain VAS), and the presence or absence/severity of D (Dullness VAS). On lateral functional radiographs of the cervical spine, patients with spinal lesions were selected and divided into the asymptotic stability (ASS; atlantoaxial dislocation ≤3 mm) + vertical setting (VS; Ranawat value <13 mm) group, the cervical spondylolisthesis group (≥3 mm of slippage on dynamic radiographs), and the spondyloolisthesis group (≥3 mm of slippage on dynamic radiographs). They were examined for association with residual symptoms.

Results: According to cervical spine lesions, the patients who achieved the therapeutic goal were divided into the ASS+VS group comprising 15 patients (18.3%), the spondylolisthesis group comprising 11 (13.4%), and the stenosis group comprising 18 (22.0%). Among them, only the spondylolisthesis group showed significant differences in residual RA symptoms. In the spondylolisthesis group, the disease duration was longer, but there was no difference in age. MS, P, and D were significantly severer. The duration of MS was longer, and both Pain and Dullness VAS scores were higher. The score on each component of the DAS28 showed no difference in inflammatory findings. GVAS and DrVAS scores were higher. No common perceptions of spinal symptoms were shared between any patients with cervical spine lesions and physicians.

Conclusion: Improved patient-reported outcomes (PROs) are considered to be important to achieve more complete remission. There are various reports on the causes of residual RA symptoms, but many aspects remain unknown. Based on the results of this study, because asymptomatic subaxial subluxation is one of concerns in patients with spondylolisthesis with dynamic instability of the cervical spine, cervical spine lesions should also be considered in patients with severe residual symptoms. Not only radiography but also magnetic resonance imaging needs to be performed.

Acknowledgments: The authors wish to acknowledge Miss Sasaki

AB0965 EVALUATION OF THE IMPACT OF THE JOB STRESS ON THE ONSET OF MUSCULOSKELETAL DISORDERS IN THE HEALTHCARE WORKERS OF THE GENERAL HOSPITALS OF DOUALA, CAMEROON

P. Kenta Leksilua1, M. N. Hugo Bertrand2, 1University of Dschang, Dschang, Cameroon; 2Douala General Hospital, Douala, Cameroon

Background: Job stress (workload) and its repercussions on health have already been described. However, very few publications has been performed in sub-Saharan Africa.

Objectives: To assess the link between job stress and musculoskeletal disorders (MSD) among healthcare workers of the Douala General Hospital.

Methods: In this cross-sectional study, the job stress, evaluated according to the Karasek model, made it possible to measure job-strain (high psychological...
demand and low decision-making latitude), iso-strain (job-strain and lack of social support), and low-strain (relaxed or low-load work).

Results: Among the 261 participants in the study, 67.43% were women. The average age was 39.80 ± 9.4 years. The average length of professional service was 8.91 ± 7.30 years [1 - 35 years].

Regarding the job stress, 65.14% of the healthcare workers followed at least 11 hours of weekly work and 46.36% carried heavy loads during work. Job-strain was found in 58.62% of the participants, iso-strain in 7.66% and low-strain in 5.36%. MSDs were described by 225 participants (98.90%). They were mainly low back pain (68.44%), neck pain (52%) and shoulder pain (37.78%).

In multivariate analysis, only weekly work > 40 hours (OR = 2.59; 95% CI 1.33–7.39, p = 0.009)

225 participants (86.21%). They were mainly low back pain (68.44%), neck pain (52%) and shoulder pain (37.78%).

1.11–6.02, p = 0.026) and job-strain (OR = 3.14; 95% CI 1.33–7.39, p = 0.009)

and 99 patients), no

References: This is the first report on the prevalence of IBP in a very low-income population. Over one-third had less than 8$Y, revealing very low literacy. Smoking prevalence was also low compared to 28% smoking prevalence WHO estimates across Europe. These IBP prevalence data are similar to those reported in wealthier populations, living in higher latitude. Data suggest that ASAS IBP definition may be used to discriminate patients with IBP from those with CBP regardless of income and literacy. References: The first report on the prevalence of IBP in a very low-income population. Over one-third had less than 8$Y, revealing very low literacy. Smoking prevalence was also low compared to 28% smoking prevalence WHO estimates across Europe. These IBP prevalence data are similar to those reported in wealthier populations, living in higher latitude. Data suggest that ASAS IBP definition may be used to discriminate patients with IBP from those with CBP regardless of income and literacy.

Conclusion: Using Patient Reported Outcome instruments, these long-term data show that Obesity negatively impacts the outcome of surgical repair of RCT in low-income patients. Smoking status was apparently irrelevant but the number of cigarettes smoked daily was not considered. Emphasis on weight reduction is a practical, affordable though hard to implement measure that could improve surgical results when repairing RCT.

AB0969 GAINED WEIGHT DURING PREGNANCY AND LOW BACK PAIN: IS IT REALLY ASSOCIATED?

M. Yasmin1, S. Miladi1, A. Faza1, L. Souebni1, S. Mariem1, K. Guenniche1, S. Kassab2, S. Chekili2, K. Ben Abdelghani1, A. Latafi3.

1Mongi Slim Hospital, Tunis, Tunisia

Background: Back pain is known to be a common complaint during pregnancy explained by gained weight in this period. Besides, the incidence of low back pain (LBP) in postpartum has also been quoted to be non-negligible even after delivery.

Objectives: The aim of our study was to assess if the development of LBP during the post-partum period was correlated to gained weight after delivery.

Results: Thirty-nine individuals, 60.9±7.1 years-old, 30 female (68.3%) with 5.1 ± 1.9 years follow-up were evaluated; 21 (44.7%) were Smokers and 12 (25.3%) Obese (BMI >30). Other comorbidities included 16 arterial hypertension, 18 dyslipidemia, 17 osteoarthritis, 4 rheumatoid arthritis, 1 gout. Pain VAS values were 5.1 ± 2.8 vs 3.1 ± 2.8 in Obese vs Non-Obese (p =0.03) and 4 ± 2.8 vs 3.37 ± 2.99 in Smokers vs Non-Smokers (p=0.26), respectively. UCLA was 22.4 ± 8.2 vs 28.79 ± 5.6 in Obese vs Non-Obese (p=0.004) and 26.2 ± 6.5 vs 27.75 ± 7.18 (p=0.25) in Smokers vs Non-smokers, respectively. ASES was 47.89 ± 28.3 vs 68.1 ± 25.78 (p=0.021) in Obese vs Non-obese and 58.98 ± 26.69 vs 65.3 ± 28.1 (p=0.243) in Smokers vs Non-Smokers, respectively.

DOI: 10.1136/annrheumdis-2020-eular.1328
Methods: In this prospective study, we assessed a survey of 60 women under the age of 35 for back pain symptoms during the postpartum period from day 1 to 18 months. A structured questionnaire using Google form was used. Data from this survey were then correlated with gained weight and pregnancy outcome, as well as women’s history of LBP.

Results: We interviewed 60 women during their post-partum period. The mean age was 27.9 years old [24, 35] years. Women were on average at 9 months of post-partum [1, 18 months]. The median height was 1.6 meters [1.54-1.74m]. The median weight at the moment of the study was 63.2 kilograms [48-80kg]. Before pregnancy, body mass index was 23.5 Kg/m² [17.54 Kg/m²]. The total gained weight at the end of pregnancy was 14 kg [12-29 kg]. Only 20% gained more than 15kg. LBP was experienced in 35% of cases with a mean delay of 3.2 months post-partum [1-8 months]. The prevalence of persistent LBP was noted in 26% of cases. However, no correlation was found between LBP and gained weight (p=0.07). Sixty five percent reported one or more significant episodes of back pain during their pregnancy. Significantly, more patients suffering from pain in pregnancy had history of previous back pain episodes when not pregnant (p<0.001), as well as during previous pregnancies (p<0.001).

Conclusion: No correlation was found between gained weight and occurrence of LBP. The main factors associated with the development of back pain were previous episodes of back pain while non-pregnant or pregnant.

THE RELATION BETWEEN CONGENITAL STRUCTURAL MALFORMATIONS, DISC-VERTEBRA DEGENERATION AND DISC HERNIATION IN THE PEDIATRIC AGE GROUP

O. G. Illezz1, F. E. Bahadir Ugler2, L. Aktas1, 1Fath Sultan Mehmet Training and Research Hospital, Physical Medicine and Rehabilitation, Istanbul, Turkey; 2Fath Sultan Mehmet Training and Research Hospital, Radiology, Istanbul, Turkey

Background: Disc/vertebral degeneration and disc herniation are rare causes of low back pain in childhood. Their relationship with congenital anomalies were reviewed in few studies in literature (1-3).

Objectives: To examine the relation between congenital structural malformations in the lumbar spine, early degenerative and lumbar disc herniation in pediatric age group patients with low back pain, and to determine the incidence of congenital structural malformations, disc/vertebral degeneration, and disc herniation.

Methods: Four hundred patients with LBP persisting for at least six weeks were included in the study. Demographic characteristics, physical examination findings, and laboratory and imaging results were recorded for all patients. Severity of pain was determined using a visual analog scale (VAS). Lumbosacral X-rays were examined for the presence of lumbosacral transitional vertebral (LSTV) and spina bifida occulta (SBO). The incidence of disc/vertebral degeneration and disc herniation was investigated at the L4-5 and L5-S1 level in lumbosacral magnetic resonance imaging of patients with and without congenital malformations (LSTV-SBO).

Results: The study population consisted of 219 girls and 181 boys aged 10-17 years (mean age 14.9±1.9). Presentation symptoms were low back pain in 90.5% (n=362), and low back-leg pain in 9.5% (n=38). The mean VAS score was 5.3±1.0. LSTV was determined in 67 (16.8%) patients and SBO in 62 (15.5%). Disc herniation was determined in 68 patients, at the L4-5 level in 26.5% (n=18), at the L5-S1 level in 48.5% (n=33), and at both levels in 25% (n=17). Vertebral degeneration was present at the L4-5 level in 14 (8.6%) patients and at the L5-S1 level in 39 (23.9%), while disc degeneration was present at the L4-5 level in 21 (12.8%) patients and at the L5-S1 level in 31 (19.0%). No significant difference was observed in the incidence of disc/vertebral degeneration and disc herniation in patients with congenital malformation. Disc herniation was significantly more common in patients with disc degeneration (p<0.001). Congenital malformations were not observed in approximately 80% of patients without disc herniation and disc/vertebral degeneration.

Conclusion: The presence of congenital malformations does not appear to represent a risk factor for early degeneration and disc herniation in pediatric age group. Congenital malformations, early degeneration, and disc herniation may constitute an underlying pathology in pediatric patients with persistent low back pain.

LONG-TERM EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS: RESULTS FROM A SINGLE-CENTER STUDY

E. Alexeleva1, 2, E. Krekhova3, T. Dvoryakovskaya1, 2, K. Isaveva3, A. Chomakhidze3, E. Chistyakova2, O. Lomakina3, R. Denisova1, A. Mamutova1, A. Fetsova1, M. Gautier2, D. Vankova1, M. Shingarova2, I. Krulinn1, A. Alshevskaya3, A. Moskalev2, 1National Medical Research Center of Children’s Health, Moscow, Russian Federation; 2Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russian Federation; 3Biostatistics and Clinical Trials Center, Novosibirsk, Russian Federation

Background: Results from various phase 3 clinical studies have demonstrated the efficacy of canakinumab to treat patients with systemic juvenile idiopathic arthritis (sJIA). However, limited information is available on the long-term efficacy and safety of this drug to treat children with sJIA.

Objectives: To evaluate the long-term efficacy and safety of canakinumab in patients with sJIA treated at the National Medical Research Center of Children’s health, Moscow, Russia.

Methods: This was a prospective, single-center study that included canakinumab (CAN)-naïve patients diagnosed with sJIA following the International League of Associations for Rheumatology (ILAR) criteria and start receiving CAN treatment from 10/2012 to 03/2016. Patients included in this study also participated, for defined periods of time, in the clinical trial NCT02296424. Patients with active disease started treatment with canakinumab 4 mg/kg. A treat-to-target approach was used, canakinumab was discontinued in patients on clinical remission, either following the NCT02296424 protocol or by investigator’s decision, and re-introduced in those patients who experienced a relapse afterwards. Disease characteristics and demographics were recorded at the time of study entry (study entry).

Disease activity was evaluated periodically using the adapted JIA ACR core set measures, and percentages of patients with inactive disease and on clinical remission were calculated using the sJIA ACR criteria. Response to treatment was also evaluated by calculating modified ACR responses and JADAS-71 scores. Safety was assessed by collecting and classifying adverse events (AEs) at each visit.

Results: Nineteen patients presenting with sJIA were included in this study, with a median age at treatment initiation of 9.6 (interquartile range, IQR 6.4-11.1) years and a median disease duration of 4.4 (IQR 1.2-7.0) years. Most patients (17/19) had been treated previously with one or more biologic agents for sJIA. As of 23 December of 2019, the median time of follow up was 46.5 (47-77) months, with all patients being followed for at least 3.5 years and 5 patients followed for more than 7 years. As it is shown in figure 1, most patients (16/19) were on clinical remission one year after starting therapy, and this effect was sustained at year 3.5 (17/19). ACR 90 responses were observed in 84.2% (16/19) patients at one year and 94.7% (18/19) patients at 3.5 years, whereas JADAS-71 scores decreased from 15 (14: 28.5) at baseline to 0 (0: 0) at one year with 4/19 patients maintained with JADAS-71 >0; at 3.5 years, only one patient had JADAS-71>0 (0.47, due to slight ESR increasing). Concerning the 5 patients with >7 years of follow up, three of them were in clinical remission for more than 3 years, including one who had discontinued therapy more than 2 years. Another patient had a relapse after attempting drug discontinuation, but recovered clinical remission after reinstituting canakinumab, and remained in this state for the last two years. The remaining patient has persistent low levels of disease activity during the last four years of follow up. AE’s required hospitalization were reported in 36.8% (7/19) patients.

DEVELOPMENT OF THE PARENT VERSION OF THE JUVENILE ARTHRITIS DISEASE ACTIVITY SCORE CUT-OFFS FOR MODERATE AND HIGH DISEASE ACTIVITY STATES IN JUVENILE IDIOPATHIC ARTHRITIS IN A LARGE MULTINATIONAL PATIENT SAMPLE

I. Avrusin1,2, R. Naddel3, F. Ridella4, G. Januskeviciute5, M. Kostik6, B. Whitehead7, R. Galizzz8, E. Smolewska9, S. Pastore10, P. Hashiszes11, J. F. Swart12, N. Ruperto13, A. Ravelli14,15, A. Consolaro16,11,12,13,14,15,16,17,18 On behalf of Pediatric Rheumatology International Trials Organization. 1Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation; 2Istituto Giannina Gaslini, Genoa, Italy; 3Policlinico Federico II di Napoli, Naples, Italy; 4Klaipeda Children Hospital, Klaipeda, Lithuania; 5Queensland Children's Hospital, South Brisbane, Australia, Australia; 6University of Messina, Messina, Italy; 7Medical University of Lodz, Lodz, Poland; 8IFIC Burlo Garofolo, Institute for Maternal and Child Health, Trieste, Italy; 9Shaare Zedek Medical Center, Jerusalem, Israel; 10Wilhelmina Kinderziekenhuis, Utrecht, Netherlands; 11University of Genoa, Genoa, Italy

Background: Measurement of disease activity level is of pivotal importance in the care of patients with juvenile idiopathic arthritis (JIA). According to the most recent requirements, both, parent’s and children’s perception should be taken into account while evaluating the disease course and assessing effectiveness of therapy. Therefore, a new disease activity evaluation tool, based only on parent assessment of the outcome, is under development and named Parent Juvenile Arthritis Disease Activity Score (parJADAS) [1].

Objectives: The aim of this study is to develop the parJADAS cut-off values of moderate disease activity (MDA) and high disease activity (HDA) in JIA patients.

Methods: The parJADAS (score range 0-10) is the sum of 4 values: 1) parent’s assessment of disease activity on a 21-numbered circle 0-10 VAS; 2) assessment of pain intensity on a 21-numbered circle 0-10 VAS; 3) proxy assessment of disease activity on a 21-numbered circle 0-10 VAS; 4) assessment of morning stiffness of pain intensity on a 21-numbered circle 0-10 VAS. The parJADAS values as hypothetical test criteria; to obtain the second rating, the categorical ratings of each attending physician were dichotomized and were coded as 0 or 1.

To identify the cut-offs the following methods were implemented: 1) Mapping: the one visit per disease state was retained. At each visit, subjects were subjectively rated as being in inactive disease, low MDA and high disease activity (HDA) in JIA patients. 2) Assessment of the outcome, is under development and named Parent Juvenile Arthritis Disease Activity Score (parJADAS) [1].

Results: Tentative cut-off values for classifying the states of MDA and HAD using parJADAS were calculated. The obtained values will be tested in the validation analysis. Once validated the cut-offs are ideally suited to identify subjects at risk of disease flare when remotely monitored with the parJADAS.

AB0973

THE IMPACT OF YOGA, ANTI-INFLAMMATORY DIET & SELF MONITORING IN CHILDREN WITH RHEUMATIC DISEASES

D. B. Pandya1, 2. 1Dev Children’s Hospital, Pediatric Department, Rajkot, India

Background: There is growing evidence of positive effects of yoga, special diet and an internet-based model of self-monitoring in adults with rheumatic diseases in various small scale independent studies. These studies have shown improvement in disease activity, symptom relief, quality of life, mental health issues and social life and thereby optimizing the disease management in a holistic way.

Objectives: The present study was designed to investigate the combined effects of yoga, anti-inflammatory diet and self monitoring in children with chronic rheumatic diseases.

Methods: In the clinical study, a total of 22 children aged more than 8 years with newly diagnosed rheumatic disease were enrolled. Depending on their consent, they were divided into two groups; 1) experimental group and 2) control group. Experimental and Control Group (n=22)

All 22 participants were advised every month follow up for the next 4 months. Baseline disease activity and damage scores were calculated for all.

Experimental Group (n=14) Three different printed materials were given.

1. Pictures of “Yoga Ashnas” with explanation in their understandable language
2. Pictures of foods under two headings: 1) beneficial and 2) harmful
3. Self monitoring kit: Disease and medicines information leaflets and simplified pictorial version of disease specific monitoring and damage scores.

All 14 participants were enrolled to a single time yoga training session under a guidance of an experienced yoga teacher.

All are advised 45 minutes yoga every day at home.

All are put on strict diet chart.

All should read the material and calculate their disease score/s every time before their next visit.

AB0074 ANALYSIS OF DYSLIPIDEMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. S. H. Chen1, J. H. Lee2, H. Y. Chiao3, H. Y. Wu3, L. C. Wang4, Y. T. Lin5, Y. H. Yang2, B. L. Chiang6, 1Shin Kong Wu Ho-Su Memorial Hospital, Pediatrics, Taipei City, Taiwan, Republic of China; 2National Taiwan University Children’s Hospital, Pediatric Allergy, Immunology and Rheumatology, Taipei City, Taiwan, Republic of China

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease and is characterized by multiple autoantibodies associated with a multisystem illness. However, studies of dyslipidemia in pediatric SLE patients are limited.

Objectives: The aim of our study is to describe the lipid profiles associated with disease activity and organ damage and their correlation with laboratory parameters in pediatric SLE patients.

Methods: We retrospectively reviewed medical records from a single tertiary hospital in Taipei, Taiwan from 2002 to 2018. One hundred and twenty-four patients diagnosed with SLE were included. Dyslipidemia is defined as elevations in total cholesterol (TC), low-density lipoprotein (LDL), and triglyceride (TG) levels, and a reduction in high-density lipoprotein (HDL) levels. We gathered all of the lipid profiles, clinical characteristics, and laboratory parameters from each patient. Pediatric SLE patients participated in this study, based on their lipid profile, were classified as dyslipidemic or not. The mean values of each evaluated parameter were calculated and analyzed with generalized estimating equation (GEE) method.

Results: Total thirty-one SLE patients were enrolled; twenty-four (77%) patients had dyslipidemia. The levels of total cholesterol, TC, and LDL in the dyslipidemic group are significantly higher than those of non-dyslipidemia (214.0±98.8 mg/dL vs. 145.0±62.9 mg/dL, p<0.01). The mean values of total cholesterol were significantly higher than those of non-dyslipidemia group (214.0±98.8 mg/dL vs. 145.0±62.9 mg/dL, p<0.01). The mean values of total cholesterol were significantly higher than those of non-dyslipidemia group (214.0±98.8 mg/dL vs. 145.0±62.9 mg/dL, p<0.01).

Conclusion: It has been well known that CRP could suppress HDL and increase the level of lipid peroxidation products in the blood serum of children with JIA compared with healthy children. The content of dienketoines in the blood serum of children with JIA is 9.14±1.84 μmol/L, in healthy children - 7.13±1.35 μmol/L. A significant (P<0.01) decrease in the serum ACW and ACL in the blood serum of children with JIA was established when compared with the control group: the ACW content in children with JIA was 10.61±5.8 μmol/L, in healthy children - 13.72±5.24 μmol/L, ACL content in children with JIA was 7.21±2.65 μmol/L, in healthy children - 8.81±3.5 μmol/L.

AB0076 CAPTURING THE ENTHESITIS RELATED ARTHRITIS CONTEMPORARY PROFILE OF NORTHERN GREEK PATIENTS IN THE ERA OF BIOLOGICS

D. Deligeorgakis1, M. Trachana2, P. Pratsidou-Gertsi2, D. Dimopoulou1, A. B. Hadich1, A. Garyfallos1.1School of Medicine, Aristotle University of Thessaloniki, Rheumatology Unit, 4th Department of Internal Medicine, Hippokration Hospital, Thessaloniki, Greece; 2School of Medicine, Aristotle University of Thessaloniki, 1st Department of Pediatrics, Pediatric Immunology and Rheumatology Referral Centre, Hippokration Hospital, Thessaloniki, Greece; 3School of Medicine, Aristotle University of Thessaloniki, Department of Hygiene, Social-Preventive Medicine and Medical Statistics, Thessaloniki, Greece

Background: Enthesitis-Related Arthritis (ERA) is a subtype of Juvenile Idiopathic Arthritis (JIA) subtype with an estimated prevalence ranging from 8% to 37.4%. The improvement of the disease course and outcome has been...
related with the introduction of biologic Disease-Modifying Antirheumatic Drugs (bDMARDs) and the uninterrupted monitoring following the transition of young patients to adult rheumatology settings.

Objectives: To compare the contemporary ERA profile in Northern Greek patients by analyzing the characteristics and treatment outcome in the era of bDMARDs.

Methods: This retrospective cohort study included patients who had been monitored on a 3-month schedule for ≥12 months, from 2000 to 2017. The periodic metric assessment included the disease status and burden by applying contemporary tools in respect to activity, clinical remission (CR) and damage (cJADAS, JSpADA, Wallace criteria for CR and JADI, respectively).

Results: Forty-three patients, mainly male (60%) with a mean age at disease onset of 10.75 (SD:2.75) years were enrolled. The predominant joints were the hip, ankle and sacroiliac (56%, 49% and 46%, respectively). Median lag time from diagnosis to bDMARDs initiation was 8.5 months.Patients with sacroiliac joints were more likely to receive bDMARDs (hazard ratio [HR]:3.26, 95% confidence interval [CI]:1.35, 7.88). Thirty-six patients (84%) achieved clinical remission (CR) on medication (CRONM), within a median time of 11 months and correlated with compliance (HR:3.62, 95% CI: 1.34, 9.76). Twenty patients (47%) experienced a flare following CR, mainly as a single episode (75%). The median flare-free survival following remission on and off medication (CROFFM) was 42 and 34 months, respectively. At the last evaluation, both median baseline cJADAS (6), and JSpADA (2) dropped to 0, while 13 patients (30%) were in CRONM, 17 (40%) in CRONM, and 13 (30%) had persistent disease activity. The median percentage of CR per patient was 54% and no patient had JADI >0.

Conclusion: Early administration of bDMARDs and compliance to monitoring and treating improved the long-term outcome in ERA. Axial involvement emerged as a negative prognostic factor with an increased need for bDMARDs and diminished rates of CR.

AB0977 DISEASE COURSE AND TREATMENT RESPONSES IN JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS: A SINGLE CENTER EXPERIENCE

B. Sözeri1, F. Demir1, D. Kilit2, C. Pehlivanoğlu3, 1University of Health Sciences, Umranli Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; 2Umraniye Training and Research Hospital, Pediatrics, Istanbul, Turkey; 3University of Health Sciences, Umranli Training and Research Hospital, Pediatric Nephrology, Istanbul, Turkey

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune inflammatory disease that may cause morbidity and mortality by affecting multiple systems. The 10-20% of patients have juvenile onset and this cluster have may more severe kidney, neuropsychiatric or hematological involvement.

Objectives: The aim of this study was to assess the clinical and laboratory characteristics, disease activity, and treatment response of patients with juvenile SLE (SLE).

Methods: This is a retrospective study involving patients between 1 July 2016 and 1 January 2020. The data of patients diagnosed with SLE and followed up for a minimum of 6 months, were collected. The SLEDAI-2K scores at initiation and at the follow-up (1st, 3rd, 6th, and 12th months of treatment) were examined. The SLEDAI-2K score was considered to be <4, for disease remission status.

Results: A total of 49 children were included in the study. The female/male ratio was 4.4/1 and the median age of the patients at the diagnosis was 13 (IQR: 11.1–15.2) years. The median follow-up of patients was 19 (IQR: 12–25) month. Four of the patients were diagnosed with monogenic SLE. Two siblings were diagnosed with c3 deficiency and two were diagnosed with familial chilblain lupus. The most common clinical findings were for musculoskeletal complaints (69.4%), malaise (51%), oral ulcers (38.8%), and fever (30.6%), respectively in all the group. The frequency of involvement of the system and organs was as follows: mucocutaneous 77.6%, musculoskeletal 69.4%, renal 44.9%, hematological 34.7%, serous membranes 16.3%, neuropsychiatric 12.2%, respectively. All patients had anti-nuclear antibody positivity, while 46.9% had anti-ds DNA, 14.3% had anti-Sm and 8.1% anti-U1RNP. Anti-nuclear antibody positivity was reported in 42% in chloroquine treatment, 22.4% of the patients were received mycophenolate mofetil, 22.4% were azathioprine, 14.3% cyclophosphamide, 12.2% methotrexate and 10.2% were rituximab. The median SLEDAI-2K score was 14 (IQR: 10–18.5) at admission, besides it was found to be 6 (IQR: 4–12), 4 (IQR: 2–6), 2 (IQR: 0–4) in the 1st, 6th and 12th months of treatment, respectively. While 98% of the patients had active disease at admission, 73% at 1 months, 32.7% at 6 months and 22.4% at 12 months still had active disease (SLEDAI-2K >4). Patients with initially high SLE-DAI-2K scores had significantly lower remission rates in the first month (<p=0.003).

It was observed that patients with high SLEDAI-2K scores in admission were more resistant to conventional immunosuppressive treatments and the use of rituximab was more frequent in these patients. At least one major organ (renal, hematological, neurological) were affected in 57% of patients. The remission rate of these patients at 6 months was found significantly decreased compared to the others (<p<0.005). Renal biopsy was performed in 21 patients (42.9%). 12 of them had type 4 lupus nephritis (LN), 5 had type 2, 2 had type 3, and 1 had type 5. It was observed that patients with renal involvement were the group that reached remission latest.

Conclusion: The presence of high initial SLEDAI-2K scores and the major organ involvement have poor predictive value to achieve inactive disease.

AB0978 EFFICACY OF ANAKINRA TREATMENT IN PEDIATRIC RHEUMATIC DISEASES: A SINGLE-CENTER EXPERIENCE

F. Demir1, E. Güler1, B. Çolak2, B. Sözeri1, 1University of Health Sciences, Umranli Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; 2Umraniye Training and Research Hospital, Pediatrics, Istanbul, Turkey

Background: Anakinra, a recombinant IL-1 receptorantagonist, is a treatment option that acts by blocking the biological activity of IL-1 in autoinflammatory conditions. The diseases that the IL-1 was over expressed are the potential conditions for this treatment. Such as familial Mediterranean fever (FMF), cryopyrin-associated periodic syndrome (CAPS), and hyperimmunglobulin D syndrome (HIDS) with monogenic inheritance, and systemic juvenile idiopathic arthritis (SJIA) or idiopathic recurrent pericarditis as non-Mendelian polygenic diseases, can be listed as examples of these diseases.

Objectives: The aim of this study was to review the efficacy of anakinra treatment in children with rheumatic disease followed in our center.

Methods: The study group consisted of children with pediatric rheumatic diseases followed up in the Pediatric Rheumatology Department of University of Health Sciences and treated with anakinra (anti-IL 1) for at least one month, between 1 July 2016 and 1 January 2020. The data of these patients were collected retrospectively. The disease activity of the patients at 3rd month and 12th month after the treatment were assessed. We aim to report our experiences of pediatric rheumatic diseases treated with anakinra.

Results: There were 28 patients treated with anakinra for the different pediatric rheumatic diseases. The diagnoses of these patients were as follows: eight were macrophage activation syndrome (MAS) complicating SoJIA, six were HIDS, four were CAPS, four were FMF, four were idiopathic recurrent pericarditis, one was deficiency of interleukin-36 receptor antagonist (DITTRA), and one was undefined systemic autoinflammatory disease. 46.4% of the patients were male and 53.6% were female. The median age of diagnosis of the patients was 6.5 ((interquartile range (IQR): 4–12)7) years. The median follow-up duration of the patients was 14 (IQR: 3.7–28) months. The patients median anakinra treatment duration was 3 (IQR: 1–4) months. Fewer reduced and C-reactive protein normalized within median 2 (IQR: 1–3) and 5 (IQR: 5–7) days, respectively. In the 3rd month after treatment; It was observed that 53.6% of patients achieved a complete remission (no attack was seen or MAS was improved). The frequency of attacks (frequency of attacks were decreased more than 50%) in 35.7% of patients and less than 50% in 71.1%, 3.6% of patients were unre- sponsive to treatment. In the 12th month assessment after the initiation of treatment, it was observed that 28.6% of patients were still under anakinra treatment and in remission, 10.7% of them were in remission without anakinra treatment in 60.7% of patients, anakinra was switch to other biological treatments for different reasons (35.7% partial response or unresponsiveness, 17.6% injection site reactions and 7.1% daily-injection difficulty). Biologic drug switch to canakinumab and tocilizumab was observed in 88.2% and 11.8% of patients, respectively. One patient developed recurrent MAS episodes when the anakinra dose was tapered, and one another patient was unresponsive to the anakinra and died due to secondary to MAS.

Conclusion: Anakinra seems to be a successful treatment to achieve inactive disease in a significant portion of patients in the early period. The recurrence of disease attacks while drug tapering and injection site reactions were appears the main causes of treatment switch or discontinuation.

AB0079

MEVALONATE KINASE DEFICIENCY AT TREATMENT WITH CANAKINUMAB: RARE BELATED CUTANEOUS FEATURE

R. Dos Santos Sobrin1, B. Lopez-Montesinos1, M. Martí Masanet1, L. Lacruz Pérez1, I. Calvo1. Hospital Universitario y Politécnico La Fe de Valencia, Reumatología Pediatrícia, València, Spain

Background: Mevalonate Kinase Deficiency (MKD) is an autosomal recessive autoinflammatory syndrome. Diagnostic criteria are based in clinical and genetic features (mutations in MVK gene) and its main treatment consists of blocking IL-1β. Likewise, age of diagnosis has been earlier than other case-series (this would be more frequent in other autoinflammatory syndromes, as literature relates).

Objectives: To describe a case-series of a rare belated cutaneous feature.

Methods: From January 2004 to September 2019, all cases diagnosed of MKD have been reviewed.

Results: 15 patients had MKD diagnosis (11 pathogenic mutations, homozygosis or double heterozygosis). Most common symptoms were oral and genital aphthous, abdominal pain, ileitis, and recurrent fever. Mean age of diagnosis was 10.67 years old (8.67 years later from the beginning of symptoms). Mean time of follow-up was 10 years. 3 patients developed this rare belated cutaneous feature: suppurative hydrosadenitis. When the first injury appeared, all were at treatment with Canakinumab (mean time of treatment 4 years) and had 7.67 years of MKD course. This comorbidity began as repeating abscesses in folds with apocrine glands and hair follicles (armpits, inguinal, anal and genital folds). 2 patients continued Canakinumab and 1 switched to Adalimumab because of severity of cutaneous involvement.

Conclusion: This is the first case-series showing suppurative hydrosadenitis associated to MKD that has not been described in literature. Both theories have been found: as immune-mediated disease partnering this autoinflammatory syndrome (MKD) or as adverse event of treatment (anti-IL-1, less presumable).

AB0080

CASE-REVIEW ON FAMILIAL MEDITERRANEAN FEVER IN A SPECIALIZED CENTRE

R. Dos Santos Sobrin1, M. Martí Masanet1, B. Lopez-Montesinos1, L. Lacruz Pérez1, I. Calvo1. Hospital Universitario y Politécnico La Fe de Valencia, Reumatología Pediatrícia, València, Spain

Background: Familial Mediterranean Fever (FMF) is a genetic autoinflammatory disorder caused mostly by mutations in MEFV gene. Its inheritance is autosomal recessive and is the most frequent periodic fever syndrome. First-line treatment is based in colchicine use, so biologics (anti-IL-1) are reserved for refractory cases.

Objectives: To account for clinic and treatment features of patients with FMF in a specialized center as opposed to non-referent centers.

Methods: This study was developed in the Pediatric Rheumatology Service in Hospital Universitario y Politécnico La Fe de Valencia. Descriptive, clinic and treatment data were collected from patients diagnosed of FMF since January 2004 to September 2019.

Results: 196 patients met last FMF criteria5, 55% had a pathogenic mutation in genetic analysis. 52% were female. Before 10 years old, 71% of patients had the diagnosis (51% before 4 years old). Arthralgia/myalgia (73%), periodic fever (62%) and abdominal pain (54%) were the most common symptoms.

Juvenile Idiopathic Arthritis (JIA, 6), other forms of JIA (9) and vasculitis (10) were the most prevalent comorbidities. When talking about treatment, 73.4% received Colchicine (60.5% with good response), 22.6% needed a classical disease modifying antirheumatic drug (mostly Methotrexate) and 22 patients got biologic treatment (73% anti-IL-1).

Conclusion: When analyzing this case-review, JIA has a strong association with our patients, so it could explain severe disease activity and more articular involvement. This could be an illustration to the higher use of Methotrexate. Also, the most relevant symptom was arthralgia while fever is the most frequent in literature. Likewise, age of diagnosis has been earlier than other case-series (this would be more frequent in other autoinflammatory syndromes, as literature relates).

AB0982 SERUM ALBUMIN LEVELS AND DEPRESSION IN JSLE
1Centro Hospitalar e Universitário de São João, Porto, Portugal; 2Faculty of Medicine of Oporto’s University, Oporto, Portugal; 3Centro Hospitalar e Universitário de São João, Young Adult and Pediatric Rheumatology Unit, Oporto, Portugal; 4Centro Hospitalar e Universitário de São João, Department of Clinical Neurosciences and Mental Health, Oporto, Portugal

Background: Albumin is a negative acute phase response protein synthesized in the liver, being an important marker of inflammation. Under inflammatory conditions, the transcapillary escape rate of albumin may increase, leading to hypoalbuminemia. Systemic lupus erythematosus (SLE) is a chronic condition involving multiple organ systems, inducing functional disability and psychological burden responsible for noteworthy depressive symptoms.

Depression may be related with psychosocial, environmental and biological factors, disease activity and treatment. Several studies have reported that immune activation and increased concentrations of positive and decreased concentrations of negative acute phase proteins are involved in the pathogenesis of depression. As albumin has the capacity to bind homocysteine, lowered serum albumin levels leads to hyperhomocysteinemia, a well-known risk factor for depression. Moreover, hypoalbuminemia decrease the availability of tryptophan, an essential amino acid from which the neurotransmitter serotonin is derived, and induce oxidative stress, which further decreases antioxidant levels in people with depression.

Objectives: To assess the association between serum albumin levels and depressive symptoms in juvenile-onset SLE (jSLE) patients.

Methods: A cross-sectional sample of jSLE patients, currently aged ≥ 16 years, completed a psychosocial assessment including quality of life (SF-36) score, anxiety and depressive symptoms (HADS) and cognitive assessment (MMSE), between October 2018- May 2019. Local Ethics Committee approved the study. All patients fulfilled both 2012 and 2019 EULAR/ACR classification criteria for SLE. Juvenile-onset was defined as age at diagnosis <18 years. Demographics and clinical characteristics were collected. Statistical analysis was performed with SPSS®. Spearman’s rank non-parametric test or Pearson’s parametric test were used to assess the bivariate correlation for inflammatory and metabolic variables. P value <0.05 was considered significant for all the statistical tests.

Results: 35 patients were included, with current median (min-max) age of 22 (16-32) years, median (IQR) SLE Disease Activity Index (SLEDAI) as 13 (5-28), mean (SD) SD of 15.8 (2.4) years, 91.4% female. Median ESR was 19 (2-75) mm/h, CRP 1.65 (0.9-6.9) mg/L, albumin 41.6 (17.4-7.3) g/L, proteinuria 0.2 (0-3) g/dL, leukocytosis 0 (0-1362.7)/μL, anemia 0 (0-501.9)/μL, LDL 102.1 (21.6), C4 17.1 (7.4) mg/dL and creatinine 0.63 (0.1) mg/dL. Median SLEDAI was 2 (0-12), All were ANA positive, 40 % positive for antinucleosome antibodies, 25.7% anti-ribosomal P protein antibody, 11.4% anti-Sm, 8.6% anti-cardiolipin, 14.3% lupus anticoagulant, 37.1% anti-SSA and 8.6% anti-SSB. Articular manifestations were present in 48.6%, mucocutaneous in 77.1%, haematological in 45.7%, lupus nephritis in 42.9%, serositis in 8.6% and pulmonary interstitial disease in 2.9%. Mean (SD) total cholesterol values (TC) was 165.3 (44.7) mg/dL and LDL 94.5 (29.9) mg/dL. Median high-density lipoprotein was 52 (16-35) mg/dL and LDL 94.5 (29.9) mg/dL. Median daily prednisolone dose was 5 (0-60) mg. 88.6% were treated with hydroxychloroquine, 31.4% with mycophenolate mophelit and 43.1% with azathioprine. TC was negatively correlated with serum albumin (rho=0.043, p=0.378) and positively with SLEDAI (p=0.032; rho= 0.392), proteinuria (p=0.099; rho= 0.469) and leucocytosis (p=0.031; rho= 0.394). A positive correlation was found between LDL and proteinuria (p=0.043; rho= 0.385) and between TG and CRP (p=0.011; rap=0.575). TG were also positively correlated with prednisolone daily dose (p=0.035; rho= 0.394). Mean LDL was higher in anti-Sm positive patients (p=0.022). No differences were found regarding anti-phospholipids antibodies. Nephritic lupus patients had worse lipid metabolism, but this did not reach statistical significance.

Conclusion: In our cohort, increased expression of TC, LDL and TGs is associated with disease activity in SLE. As expected, higher doses of prednisolone also correlated with lipid metabolism.

AB0984 BIOLOGICAL THERAPIES IN JUVENILE IDIOPATHIC ARTHRITIS: ARE THERE ANY DIFFERENCES BETWEEN CATEGORIES?
A. García Fernández, A. Briones-Figueroa, L. Calvo Sanz, A. Andreu-Suárez, J. Bachiller-Corra1, A. Boteanu, Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

Background: Systemic lupus erythematosus (SLE) is an autoimmune systemic disease associated with premature atherosclerosis. Risk factors include dyslipoproteinemia, inflammation, oxidized low-density lipoprotein (LDL), hyperhomocysteinaemia and anti-phospholipid antibodies. Hyperlipidemic condition is being reported to promote the production of proinflammatory cytokines such as IL-1β, IL-6, and IL-27 and lowering blood lipid levels improves the disease. Oxidative stress is elevated, mainly due to mitochondrial dysfunction, further disrupting lipid metabolism. Some drugs also have an impact on lipid profile, such as chronic steroid use, which worsens LDL, HDL, and TG levels.

Objectives: To assess the relationship between lipid profile and disease activity in juvenile SLE (jSLE) patients.

Methods: Retrospective study of jSLE patients, fulfilling both 2012 and 2019 EULAR/ACR classification criteria for SLE. Juvenile-onset was defined as age at diagnosis <18 years. Demographics and clinical characteristics were collected. To evaluate the activity of SLE, the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) was used. Statistical analysis was performed with SPSS®. Spearman’s rank non-parametric test or Pearson’s parametric test were used to assess the bivariate correlation for inflammatory and metabolic variables. P value <0.05 was considered significant for all the statistical tests.

Results: 52 patients were included, with current median (min-max) age of 22 (16-32) years, median (IQR) SLE Disease Activity Index (SLEDAI) as 15.8 (4.9-28.9), mean (SD) duration of diagnosis of 15.8 (2.4) years, 91.4% female. Median ESR was 19 (2-75) mm/h, CRP 1.65 (0.9-6.9) mg/L, albumin 41.6 (17.4-7.3) g/L, proteinuria 0.2 (0-3) g/dL, leukocytosis 0 (0-1362.7)/μL, anemia 0 (0-501.9)/μL, LDL 94.5 (29.9) mg/dL. Median high-density lipoprotein was 52 (16-35) mg/dL and LDL 94.5 (29.9) mg/dL. Median daily prednisolone dose was 5 (0-60) mg. 88.6% were treated with hydroxychloroquine, 31.4% with mycophenolate mophelit and 43.1% with azathioprine. TC was negatively correlated with serum albumin (rho=0.043, p=0.378) and positively with SLEDAI (p=0.032; rho= 0.392), proteinuria (p=0.099; rho= 0.469) and leucocytosis (p=0.031; rho= 0.394). A positive correlation was found between LDL and proteinuria (p=0.043; rho= 0.385) and between TG and CRP (p=0.011; rap=0.575). TG were also positively correlated with prednisolone daily dose (p=0.035; rho= 0.394). Mean LDL was higher in anti-Sm positive patients (p=0.022). No differences were found regarding anti-phospholipids antibodies. Nephritic lupus patients had worse lipid metabolism, but this did not reach statistical significance.

Conclusion: In our cohort, increased expression of TC, LDL and TGs is associated with disease activity in SLE. As expected, higher doses of prednisolone also correlated with lipid metabolism.

DOI: 10.1136/annrheumdis-2020-eular.4584
Background: Juvenile Idiopathic Arthritis (JIA) is a heterogeneous group of pediatric diseases. Different response to biological treatment (BT) has been reported according to disease subtype.

Objectives: To analyze the prescription and withdrawal of BT in JIA patients with focus on JIA category.

Methods: A retrospective observational study was conducted on JIA patients followed in a referral hospital and who had received at least one BT between 1999 and 2019. Results: 130 JIA patients were analyzed: 29 (22.4%) were Oligoarticular Persistent (OligP), 22 (16.9%) Enthesitis related arthritis (ERA), 20 (15.4%) Systemic (sJIA), 19 (14.6%) Polyarticular RF- (PolyRF-), 14 (10.6%) Polyarticular RF+ (PolyRF+), 10 (7.7%) Oligoarticular-Extended (OligE), 11 (8.4%) Psoiatric Arthritis (PsAOs) and 2 (1.5%) Undifferentiated (Und).

The main characteristics are summarized in table 1. The first line BT most frequently indicated was Etanercept up to 40% in all the categories except for ERA, where the most frequent BT was Adalimumab and sJIA, where the most frequent BT was Anakinra. The time between diagnosis and start of BT was different among the categories (p=0.007). In the Und category, the time until BT was the shortest (median: 1 month), since both patients had coxitis, followed by AptaP [median: 9 months IQR(1-57)] and sJIA [median: 175 months IQR(0,3-146,8)]. The survival of the first BT was different among the categories (p=0.006); 94.7% of the ERA continue receiving the first BT, followed by 76.2% of OligP and 50% of PolyRF+ and AptaP. Only 42% of sJIA continue the first BT prescribed [up to 53.3% were TNF inhibitors (TNFI)]. The categories with less retention of the first BT were: OligE (25%), PolyRF- (27.3%) and Und (0%). The most frequent cause of discontinuation, among these categories, was secondary failure. In the survival analysis between categories, there were differences on OligP (p=0.004), OligE (p=0.042) and PolyRF- (p=0.017). Tocilizumab and Adalimumab were the BT with the highest survival with regards to Etanercept, Infliximab, Abatacept (OligE, PolyRF-) and Certolizumab (OligP). The survival rate of IL1 inhibitors and IL6 inhibitors was higher regarding to TNFi in sJIA patients (p=0.013).

Conclusion: Taking into account JIA category is mandatory to choose BT and to understand the response and discontinuation of BT, OligE and PolyRF- showed a high rate of change of the first BT related to secondary failure of Etanercept and Infliximab when compared to Adalimumab and Tocilizumab, as described in the survival analysis. The category with the highest retention of the first BT was ERA. UND patients started sooner BT due to the presence of coxitis. In sJIA, IL1 inhibitors and IL6 inhibitors were superior to TNFI in the survival analysis, as reported in existing literature.

Table: 1. Demographic characteristics

Variables | Girls (n=26) | Boys (n=22) | p*
--- | --- | --- | ---
Age (years) | 12.96±3.91 | 11.86±3.24 | 0.075

AB0985

THE EFFECT OF GENDER ON CHILDREN AND ADOLESCENTS WITH FAMILIAL MEDITERRANEAN FEVER

E. Gur Kabul1, B. Basakci Calik1, M. Balcı1, G. Otar Yener2, Z. Ekici Tekin2, S. Yüksel2, 1Pras et al severity score 6.35±2.68 5.31±2.60

Background: In the literature, it was reported that children with with Familial Mediterranean fever (FMF) have lower functional capacity and muscle strength than healthy children. With reduced functional capacity, daily activities are negatively affected. The individual starts to adopt an inactive lifestyle and decreases in muscle strength are observed. A vicious circle occurs and results in exacerbation of symptoms and worsen quality of life.

Objectives: The aim of this study is to investigate the effect of gender on dynamic muscular endurance, physical activity and quality of life with FMF.

Methods: Forty-eight children and adolescents (26 girls, 22 boys, mean age=12.43±3.04 years, age range=7-18 years) were included. Exclusion criteria: The presence of another disease. Intraarticular steroid injection or surgery in any joint in the last 3 months. Evaluations were made by the same pediatric rheumatologist and physiotherapist by face to face interview method. Dynamic muscle endurance was evaluated by use of curl up test (30 sec), push up test (30 sec) and one-legged stationary hop test (15 sec); physical activity level by Physical Activity Questionnaire and quality of life by Pediatric Quality of Life Inventory (PedsQL) 3.0 Arthritis Module. Physical Activity Questionnaire contains nine items and evaluates physical activities in last seven days and frequency of these activities. As score increases, level of physical activity increases. In this study, child and parent forms of PedsQL were used to evaluate the quality of life. High scores mean high quality of life.

Results: Difference was significant in Physical Activity Questionnaire (p=0.028) in favor of girl gender whereas in child form (p=0.017) and parent form (p=0.040) of PedsQL (p=0.003) in favor of boy gender.

Conclusion: We see that the physical activity are lower in children and adolescents with FMF who have a gender of girls and, accordingly, lower quality of life. Therefore, we believe that these individuals should increase their physical activities.

NT-PROBNP LEVEL IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

T. Holovko1, L. Bohmat2,3, N. Shchekovenko2,3, A. U. Aflatii1, V.N. Karazin Kharkiv National University, Department of Pediatrics № 2, Kharkiv, Ukraine; 2SI Institute for Children and Adolescents Health Care of NAMS of Ukraine;

Background: In the literature, it was reported that children with with FMF have lower functional capacity and muscle strength than healthy children. With reduced functional capacity, daily activities are negatively affected. The individual starts to adopt an inactive lifestyle and decreases in muscle strength are observed. A vicious circle occurs and results in exacerbation of symptoms and worsen quality of life.
ADULT HEIGHT IN JUVENILE IDIOPATHIC ARTHRITIS
STUDY ON THE FACTORS AFFECTING THE FINAL
C. Hain-Yu1, H. Ya-Chiao1, B. L. Chiang2. 1National Taiwan University Hospital, Taipei, Taiwan; Republic of China

Background: Juvenile idiopathic arthritis (JIA), a chronic inflammatory disease involving limited joints and/or constitutional symptoms in childhood or adolescent, might affect body height and result in short stature in adulthood. Well-controlled disease activity is beneficial in improving growth impairment in JIA patient.

Objectives: To identify any factors that influence final adult height in the patient with juvenile idiopathic arthritis.

Methods: We retrospectively reviewed the medical records of JIA patients between 2009 to 2019 in National Taiwan University Hospital. The diagnosis of JIA was according to the International League of Associations for Rheumatology (ILAR) criteria. Personal history, laboratory reports, and medication were analyzed. The difference between final adult height and target height was calculated in each patient. We defined whose final adult height higher than target height as positive group and the others as negative group. A cox univariate proportional hazards model was applied to compare the variables between these two groups.

Results: Total 120 patients are collected. There are 74 (61.7%) and 46 (38.3%) cases in the positive and the negative group, respectively. The mean onset age of disease is 11.78 ± 3.78 in positive group and 10.83 ± 4.04 in negative group. Male is more than female in both groups, with a ratio of 1.71:1 and 2.71:1 respectively.

Conclusion: In children with JIA there is a decrease of the exercise tolerance that increases with the duration of JIA on the background of preserved myocardial contractility. This is accompanied by a higher basal NT-proBNP level than in healthy children.

Disclosure of Interests: None declared

AB0987

STUDY ON THE FACTORS AFFECTING THE FINAL
ADULT HEIGHT IN JUVENILE IDIOPATHIC ARTHRITIS

C. Hain-Yu1, H. Ya-Chiao1, B. L. Chiang2. 1National Taiwan University Hospital, Taipei, Taiwan; Republic of China

Background: The defeat of the cardiovascular system is considered a proven comorbid state in rheumatic diseases, including rheumatoid arthritis in adults. One of the markers of the cardiovascular failure formation is BNP, namely, its N-terminal inactive fragment (NT-proBNP), which accumulates in specific granules of cardiomyocytes. Its diagnostic value increases with the appearance of minimally expressed symptoms. The long-term course of JIA is also characterized by changes in the state of the cardiovascular system, and there may be no visible clinical manifestations. For their diagnosis a 6-minute walk test is widely used, including in children.

Objectives: To study the content of NT-proBNP in patients with juvenile idiopathic arthritis and control with the level of exercise tolerance.

Methods: Ten patients with JIA (9 girls, 1 boy), average age 12.78 ± 0.95 years, were examined. All children had a particularty RF negative subtype of JIA with a disease duration of more than three years (average disease duration 69.56 ± 17.07 months), received basic methotrexate therapy and did not have dysfunction of the lower extremities joints. The control group included 7 healthy children, comparable by sex, average age 14.25±0.73 years. An ECG, an ultrasound scan of the heart, and a 6-minute walk test (6MTX) were carried out with determining the distance traveled (6MWD) and the increase in heart rate. The level of the N-terminal polypeptide of cerebral natriuretic hormone (B-type) (NT-proBNP) was determined in the morning, after waking up, and studied by competitive immunoassay on an IMMULITE 2000 analyzer ("Siemens").

Results: In children with JIA a decrease in myocardial contractility was not detected. Left ventricular ejection fraction (62.17±0.83%) (60.02 – 64.02) versus 69.84 ± 0.85% (62.3 – 80.3), p <0.05) in children with JIA were within normal limits, but significantly lower than in the control group. According to the results 6MTX indicator 6MWD in JIA-patients was 490.51 ± 11.40 m and in the control group 516.85 ± 8.4 m (p <0.05) and heart rate growth was 27.75 ± 2.30% versus in the control group (37.38 ± 3.86%), p <0.05. A negative correlation between the increase in heart rate and the duration of the disease was found (r = -0.7, p = 0.05). The level of NT-proBNP in patients with JIA was within physiological values and amounted to 47.5 ± 14.09 pg /ml (20 – 128 pg / ml), but this was higher than in children of the control group (20.29 ± 0.29 pg / ml-20-22 pg / ml), p <0.05. A high correlation was found between 6MWD and NT-proBNP (r = -0.4, p = 0.03).

Conclusion: In children with JIA there is a decrease of the exercise tolerance that increases with the duration of JIA on the background of preserved myocardial contractility. This is accompanied by a higher basal NT-proBNP level than in healthy children.

CLINICAL FEATURES AND ANALYSIS OF MEFY GENE
IN 31 PATIENTS WITH FAMILIAL MEDITERRANEAN
FEVER (FMF)

T. Ishizuka1, K. Fujioka1, M. Tanigaki1, S. Inui2, H. Tani1, A. Miwa1, T. Ikeda2, K. Taguchi1, H. Morita1, T. Tomita1, A. Yachie1. 1Gifu Municipal Hospital, Center of General Internal Medicine and Rheumatology, Gifu, Japan; 2Gifu University Graduate School of Medicine, Department of General Internal Medicine, Gifu, Japan; 3Kanazawa University Graduate School of Medicine, Kanazawa, Japan

Background: FMF is recessive systemic autoinflammatory disorder characterized by recurrent fever, peritonitis, pleuritis, pericarditis and arthritis accompanied with headache and abdominal pain. Mutation of MEFV gene encoding pyrin resulted for Paediatric and Adolescent Rheumatology and the uncontrolled presentation of IL-1β. Observations of pathogenesis, clinical features and management in Japanese patients with FMF had been reported. However, the differences of clinical features between mutated and non-mutated of MEFV still remain unclear.

Objectives: We have analyzed 31 Japanese patients with FMF in Gifu district to clarify the association between various clinical features and mutation of MEFV. Methods: Genomic DNA was purified from white blood cells in 31 FMF patients, and mutated MEFV has been explored. We have analyzed MEFV, TNF-related apoptosis-inducing ligand (TRAIL), Malignant melanoma serine/threonine kinase (MST1), autophagy related genes 16 (ATG16), and autocrine motility factor (AMF).

Results: Characteristics of Patients with FMF (22 female/9 male) were as follows: Onset time were 0-56 years-old (21.4 ±11.8), and Frequencies of clinical symptoms such as peritoneal fever, headache, abdominal pain, arthralgia, chest pain, cervical lymph nodes swelling, and myalgia were 31/31, 9/31, 8/31, 6/31, 5/31, 3/31 and 1/31, respectively (double symptoms were observed). Patients with FMF were divided into 3 groups as follows; Patients with typical compound heterozygous mutations of MEFV (E148Q/M694I) which indicated exon 10 mutation, were 5 cases (G1). Patients with atypical mutations, except for exon 10, such as 133G>A in 3UTR, exon one (E84K), 2 (L110P, E148Q), 3 (R202Q, P257L, G304R, P369S, R408Q), 5 (S503C) and 9 (S591M) were 13 cases (G2). Patients with no mutations in MEFV gene were 12 cases (G3). There were no significant differences of age at first visiting hospital (FY) and onset age of fever attack (FA) (FY: 29.0 ± 15.6, 27.1 ± 12.5 years-old (yo) and 34.7 ± 12.7, 27.1 ± 12.5 years-old (yo)), but the differences were significant in duration of fever attack (D) and frequency of fever attack (FF) between G1 and G2 or G3 as observed were significant differences of age at first visiting hospital (FY) and onset age of fever attack (FA) (FY: 29.0 ± 15.6, 27.1 ± 12.5 years-old (yo)); D: 2.2 ± 0.4 days vs 5.5 ± 3.1 days, P<0.05, and 3.8 ± 1.7 days); FF: 0.72 ± 0.3/
TUBERCULOSIS RISK IN CHILDREN WITH RHEUMATIC DISEASES TREATED WITH BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS

C. Kavadrachand1, A. M B1, S. Ajmani2, I. Maccora3, S. Balan4, A. Ramanan5, V. Agarwala6, L. Gupta7. 1Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; 2Arthritis and Rheumatology Clinic, New Delhi, India; 3University of Bristol, Bristol, United Kingdom; 4Aims, Ernakulam, India; 5Bristol Royal Hospital for Children, Bristol, United Kingdom; 6Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Background: Chronic rheumatic diseases entail the use of biologics in children. Immunosuppressive effects of drug therapy put children at risk of various infections. Tuberculosis (TB) is a leading chronic infection in certain parts of the world. Recent estimates suggest the prevalence of TB in India to be 3.2 cases per thousand population1.

Objectives: Thus we reviewed the prevalence of Tuberculosis amongst children with various rheumatic disorders treated with different biologics.

Methods: The search strategy for writing review articles proposed by Gasparyan et al2, was followed. Articles available on MEDLINE and Scopus, published on or after January 1, 2010 to 1 October 2019, were reviewed. (Figure 1) Details on Tuberculosis and disease variables were collected (Table 1).

Results: Data on infections in children with rheumatic disorders on biologics is scant (Table 2, Figure 2A). Tuberculosis was reported on occasion (0-5 cases per country) in the developed world with the highest Tuberculosis reports being from Turkey (Figure 2B). There is particular paucity of data from regions with highest number of incident cases or prevalence of tuberculosis more than 100 per 10 000 population (figure 2C, D).

A: Registry data, B: Cohort, C: Case series, D: Anecdotal reports E. Trials

Retrospective studies of duration 10 m- 10years suggest that TB risk is minimal in pediatric rheumatology patients on biologics in low TB incident areas. However, most prospective studies suffer from short observation period (Table 2). Most registries focus on response to therapy rather than complications.

Conclusion: TB risk is minimal with biologics use in paediatric rheumatology in areas with low TB incidence (<99 cases per 10 000 population). However, most prospective studies are hampered by short observation period. There is...
insufficient data to establish safety in countries with high background prevalence of TB. Long term prospective national registries are needed from TB countries with focus on risk factors for infections.

References:
Background: Subjective sleep problems, including difficulties falling asleep, waking up, un-restorative sleep and daytime sleepiness are highly prevalent in patients with juvenile fibromyalgia (JFM). Sleep disturbances has been considered a consequence of severe pain and depression, but also in healthy individuals sleep deprivation is also a risk factor for the development of chronic widespread pain, tenderness and fatigue, suggesting the important role of sleep in pain control and in the pathophysiology of fibromyalgia.

Objectives: To estimate the incidence of polysomnographic alterations in JFM and to explore the relationship between sleep problems and the musculoskeletal pain, fatigue and mood and anxiety disorders.

Methods: 21 patients (M 3: F 18; mean age 16.1) with JFM were included. The objective sleep quality was measured by overnight polysomnography (PSG) (using the EMBLETTA MPR PG device). PSG data were compared to age and sex-matched controls. The subjective sleep disturbances were assessed by the Sleep Condition Indicator (SCI). Musculoskeletal symptoms were evaluated by using the widespread pain index (WPI). Pain intensity was evaluated on a 0-10 visual analogical scale (PVAS). Fatigue was assessed by using the Symptom Severity (SS) questionnaire. Mood and anxiety disorders were evaluated by using the Children Depression Index (CDI) and the Multidimensional Anxiety Scale for Children (MASC). Comparison of categorical data was performed by means of the Fisher’s Exact test. The relationship between sleep quality and clinical symptoms were assessed using Spearman’s rank order correlation coefficient (rs). All statistical test were 2-sided and p values less than 0.05 were considered statistically significant.

Results: Nineteen out of 21 (90.5%) patients complained subjective sleep disturbances and un-restorative sleep. Seven out of 21 (33.3%) patients had mood and anxiety disorders. Eight out of 21 patients (38.1%) showed an electroencephalographic pattern of alpha wave intrusion in slow wave sleep (SWS). SCI was significantly correlated to CDI score rs = -0.775 (p<0.001), MASC 0.61 (p<0.005), WPI rs = -0.731 (p<0.001), SSI 0.492 (p<0.038), PVAS rs = -0.590 (p<0.006).

Conclusion: A substantial percentage of JFM patients experience sleep disturbances, which are, correlated with the severity of the musculoskeletal symptoms and mood and anxiety disorders. One third of JFM patients have alpha intrusion in the SWS. The important role of sleep in pain control suggests that the development of treatments to improve sleep quality may lead to more effective management of fibromyalgia in the future.

AB0094 A CASE SERIES OF KAWASAKI DISEASE FROM KENYA

C. Njeru1, A. Miguna2, 1Aga Khan Hospital, Nairobi, Kenya

Background: Kawasaki disease (KD) has been described across the globe, including the African continent, but none yet from Kenya.

Objectives: To describe the clinical features and management strategies of pediatric patients diagnosed with Kawasaki Disease at a tertiary referral hospital in Kenya.

Methods: A retrospective chart review was undertaken for the period January 2013 to December 2017 for all pediatric patients admitted at Aga Khan University Hospital Nairobi, Kenya. All medical records with a discharge diagnosis of Kawasaki disease were reviewed, de-identified and data extracted using a data collection tool.

Results: Among the 15 cases identified, 8 (53%) had complete KD. The mean age was 1 year 10 months with a slight increase in males (53.3%). The mean duration of symptoms at diagnosis was 7.2 days (range 1-11 days). Fourteen patients (93.3%) received both intravenous immunoglobulin and aspirin but dosing varied from high dose aspirin (80-90 mg/kg/day) to low dose aspirin (3 mg/kg/day). Baseline cardiac evaluations were done among these 14 (93.3%) and one patient was found to have bilateral dilated coronaries. Only 9 patients (33.3%) had repeat echo examinations within 6 weeks after diagnosis all of which were normal.

Conclusion: The challenges faced in the management of KD in Kenya include awareness of the disease, access and expertise to pediatric echocardiography, follow-up, access and cost of IVIG. Increasing awareness and improving health care infrastructure is important in improving outcomes of KD in Kenya.

AB0095 NEW ALTERNATIVE IN THE TREATMENT OF PATIENT WITH MUTATION OF GEN LACC1

R. M. Alcobendas1, C. Quintana2, J. Arostegui3, C. Udaondo1, S. Murias Loza1, A. Remesal1, 1University Hospital La Paz, Madrid, Spain; 2Clinic Hospital, Barcelona, Spain

Background: Few patients have been described in the literature with mutations in the Lacasa Domain containing one (LACC1) gene. Its clinical presentation usually associates sustained systemic inflammation associated with chronic polyarticular erosive arthritis. Until now, there have been multiple treatments described to try to control the disease, however, they are generally unsuccessful in the long term.

Objectives: Describe the clinical course of a patient as well as the different treatments used

Methods: Clinical chart review

Results: Female 18-year-old born from a consanguineous Moroccan couple. Mother, brother and sister with similar conditions. She started at 3 years with fever, anemia, intense elevation of acute phase reactants and symmetric polyarthritides (knees, elbows, carps, shoulders, hands and ankles). Subsequent whole exome sequencing identified c.128_129delGT mutation in the LACC1/FAMIN gene. During the course of her illness, she has received treatment with oral, intravenous and infiltrated corticosteroid, methotrextate and etanercept, without getting adequate control of the disease. In 2016, she started treatment with tocilizumab (8 mg / kg every two weeks), obtaining an acceptable control of the disease (requiring periodic infiltrations every 2-3 months due to persistent arthritis). Nonetheless, in April 2019, she consulted for clinical worsening of the arthritis and laboratory test (C reactive protein 99.7 mg / L, erythrosedimentation rate 53mm / h, leucocytes 13,500/L and neutrophils 10,930/L). At that time, she discontinued therapy with tocilizumab and started tofacitinib 5 mg every 12 hours with good evolution. Since its introduction, it has not required joint infiltration again and the inflammatory parameters (persistently elevated previously) have normalized.

Conclusion: The jak kinasa inhibitors may be a treatment option in those patients with bad response to conventional therapy.

AB0096 JUVENILE ONSET SYSTEMIC LUPUS ERYTHEMATOSUS WITH SJÖGREN’S SYNDROME: CLINICAL AND LABORATORY FEATURES.

M. Kalela1, I. Nikkila2, 1V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation

Background: Systemic lupus erythematosus with juvenile onset (SLE) with Sjögren’s syndrome (SS) in children is a poorly studied and rare combination, the frequency of which, according to the literature, is 7.5-10.0%.

Objectives: To study demographic data, specific features of SLE with SS in single center.

Methods: Retrospective study of all consequently patients (pts) of single-center in pediatric department with combination of SLE and SS.

Results: SS was verified in 14 pts with SLE (14.3% were boys), which amounted to 15.5% of all pts with SLE. The median age of SLE onset was 13.5 y.o. [9.3; 14.9]. The median of disease duration at the time of SS verification was 1.3 y [0.6; 2.9].
Methods:

Results: Case report. Older brother, 15 y.o. developed arthritis of both wrist joints at the age of two. There was erythematous maculo-micropapular scaly rash on the trunk and extremities before the onset of arthritis. By 2009 (5 y.o.), the knees, ankles, and three PLP joints of the left joint were involved. Polyarthritis was characterized by severe effusion and periartricular tissues swelling. He was treated in regional hospital by NSAID, methotrexate, cyclosporine A without significant positive effect. Since 2012 etanercept was added for treatment with variable result. Inactive status of the disease has been achieved since an early childhood with similar clinical picture. We are going to perform genetic analysis of the NOD2/CARD15 gene for the eldest brother.

Conclusion: Our clinical case shows that extremely rare BS may be misdiagnosed as JIA. Lack of efficacy of the etanercept therapy and uveitis de novo developing may be caused by genetic (non-idiopathic) nature of disease. Classic triad of boggy-arthritis, granulomatous uveitis and/or skin lesions without acute phase markers is required to perform genetic assay for the detection of a pathogenetic mutation of the NOD2/CARD15 gene. This case is remarkable by the presence of BS in two (or 3) children of the family.

AB0097

IS HEIGHT ADJUSTMENT NECESSARY IN PEDIATRIC DENSITOMETRY IN ALL CHILDREN?

B. P. Magalhães López1, D. Park2, D. Cerda3, J. Betancourt4, G. Fraga5, S. Boronat6, I. Ghich7, A. M. Marín7, S. Herrera7, J. Malou8, J. Casademont9, A. García-Guillén10, H. Conominas11, Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 2Hospital de Sant Joan Despí Moisès Broggi, Rheumatology, Sant Joan Despí, Spain; 3Hospital de la Santa Creu i Sant Pau, Pediatrics, Barcelona, Spain; 4Hospital de la Santa Creu i Sant Pau, Epidermolysis, Barcelona, Spain; 5Hospital de la Santa Creu i Sant Pau, Internal Medicine, Barcelona, Spain

Background: The current guidelines of the International Society for Clinical Densiometry (1) recommend that in children with linear growth or maturational delay, Z score results should be adjusted. Height for age Z score (HAZ) adjustment is valid and can be calculated using the formula the formula proposed by Zemmel et al(2). It is possible that pediatric populations without linear growth or maturational delay, also benefit from HAZ, to prevent bone size from influencing the final Z score.

Objectives: To evaluate Z score variability adjusted and without adjusting for height for age.

Methods: We analysed data from densitometry performed on patients 2-20 years of age, from 2016 to 2018, assessed in the pediatric rheumatology office of our hospital for presenting risk factors for low bone mass/osteoporosis. The HAZ was calculated according to Zemmel's formula.

Results: Data from 103 patients are presented. Its characteristics are summarized in Table 1

Table 1.

<table>
<thead>
<tr>
<th>Mean age</th>
<th>9.8 years</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>52.4%</td>
</tr>
<tr>
<td>Height Percentil ≤ 3</td>
<td>6.8%</td>
</tr>
<tr>
<td>Height Percentil &gt; 97</td>
<td>4.9%</td>
</tr>
<tr>
<td>LBM (Z score ≤ -2) spine</td>
<td>6.2%</td>
</tr>
<tr>
<td>LBM HAZ spine</td>
<td>6.4%</td>
</tr>
<tr>
<td>LBM whole body</td>
<td>10.5%</td>
</tr>
<tr>
<td>LBM HAZ whole body</td>
<td>7.2%</td>
</tr>
</tbody>
</table>

The table shows that the proportion of patients with BMD decreases in both the spine region and the whole body when adjusting for HAZ. When evaluating the relationship between densitometric measurements we found that spine Z score (ZsS) and whole body Z score (ZWB) had a correlation coefficient of 0.73 (p<0.001). There were no differences between their averages (p=0.170). At the LBM cut-off point (Z score ≤ -2) there were discrepancies in 7%, where 5% presented LBM in ZsWB but not in ZsS. The concussion index at this point was 0.557.

When comparing these measures with their HAZ adjusted equivalents, we observe: HAZ adjusted ZsS vs ZsS without adjusting: There were no differences between their averages (p=0.913) with a correlation coefficient of 0.78 (p<0.001). Concordance index at cut-off point for LBM was 0.498, with a discrepancy of 7%, where 2% had LBM according to HAZ adjusted ZsS but not to ZsS without adjusting.

HAZ adjusted ZsWB vs ZsWB without adjusting: There were no differences between their averages (p=0.367) with a correlation coefficient of 0.82 (p<0.001). Concordance index at cut-off point for LBM was 0.557, with a discrepancy of 7%, where 2% had LBM according to HAZ adjusted ZsWB, but not to ZsWB without adjusting.

Conclusion: There are discrepancies at the LBM cut-off point depending on the HAZ adjustment. The pediatric population without linear growth or maturational delay, can also benefit from HAZ adjustment, especially those with high height percentiles in which their size can hide a diagnosis of LBM.

<td>1,314 ± 0.31</td>
<td></td>
</tr>
</tbody>
</table>

Conclusion: TBS was lower in the patients with LBM by whole body Z score, but not in those with LBM by spine Z score. We observed a decrease in TBS in adolescence, not corresponding with a decrease in BMD, and that should not be interpreted as a pathological finding.

Similar results have been described in other pediatric populations (1, 2), but larger studies are needed to evaluate this phenomenon. We hypothesize that it may be due to a higher rate of growth in adolescence, with a lower rate of calcium apposition into the osteoid material.

Fig. 1. Skin and/or articular syndromes in the onset of the disease in children with definite JPsA.
Among 59 patients with definite JPsA, vulgar psoriasis was observed in 45 (76%) patients, guttate psoriasis in 9 (15%), isolated nail psoriasis in 3 (5%), and palmpoplantar psoriasis in 2 (4%). Fifteen (28%) patients had a combination of cutaneous psoriasis with damage to the nail plates.

Articular syndrome in the onset of the disease was represented by oligoarticular arthritis in 57 (69%) patients, in 15 (18%) children - symmetric rheumatoid-like arthritis, and in 11 (13%) - spondylitis. The most commonly involved joints at both presentation and during the course of the disease were the knee (41%), ankle (31%), and small joints of the hands (29%). During course of the disease, the articular syndrome transformed with symmetric rheumatoid-like arthritis prevalence (Fig. 2).

In 39 (47%) children, the disease at onset was characterized by high level of ESR – 34±12 (32) mm/h.

Conclusion: In most patients with JPsA, the onset of the disease occurred at the age of 6.6±4 years. Articular syndrome in the onset of the disease was presented as oligoarticular arthritis in 69% children. Overall, transformation to symmetric rheumatoid-like arthritis was the most observed. Skin lesions were represented by vulgar psoriasis in 76%, guttate psoriasis in 15%, isolated nail psoriasis in 5%, palmpoplantar psoriasis in 4%, and 28% of patients had a combination of cutaneous psoriasis with damage to the nail plates.

Disclosure of Interests: None declared.
Background: It is proved that rheumatic diseases are accompanied by pronounced changes in calcium-phosphorus metabolism, which underlies the development of osteopenia syndrome. If in previous years glucocorticosteroid therapy (GCS) was considered to be the main reason for this, then the role of pro-inflammatory agents (activity of the pathological process), provision with vitamin D (ViD), and the effect of basic therapy are currently being discussed. It is also known that a decrease blood level of vitamin D leads to a violation of the absorption of calcium and phosphorus, a further increase in the level of parathyroid hormone, which underlies the risk of a decrease in bone mineral density.

Objectives: To study the level of parathyroid hormone in children with juvenile idiopathic arthritis, its relationship with the course of the disease and vitamin D status.

Methods: 91 patients with JIA (61 girls and 30 boys), with polyarticular (n = 41), oligoarticular (n = 29) and undifferentiated (n = 18) variants of JIA were examined. The age of the patients was 10.5 ± 1.7 years. The duration of the disease was 4.1 ± 1.1 years. All children receive basic methotrexate therapy. The control group included 10% of the corresponding gender. JADAS27 was counted, the levels of 25-hydroxycalciferol (25-OH D) and PTH were determined by chemiluminescent method. Correlated to the content of vitamin D in blood serum, the normal level was noted in 14 patients, insufficiency - in 41 patients, deficiency - in 32 patients.

Results: The level of PTH in children with JIA remained within physiological values (30.6 ± 2.1 pg/ml; from 12.7 to 61.8 pg/ml) despite the high frequency of a ViD decrease in blood (80.2%). The level of PTH was not significant in groups of patients with a different level of vitamin D (32.8 ± 2.1 pg/ml at deficiency group; 29.2 ± 2.4 pg/ml at insufficiency group; 29.1 ± 1.8 pg/ml at a normal level of ViD group). PTH was comparable and did not differ in children of different sexes.

The highest level of PTH was in patients with a polyarticular variant of JIA (34.2 ± 4.5 pg/ml; p<0.05), which was accompanied by the lowest level of vitamin D (20.9 ± 2.1 ng/ml; p<0.05) in the same group. There was obtained reliable correlation of activity indicators (JADAS27) taking into account ViD and PTH, as well as with diseases duration and age of patients (p<0.05).

Conclusion: A study of the level of PTH in children with JIA did not show a significant increase depending on the vitamin D status in these patients. However, the age-related state of PTH is associated with the activity of the pathological process, the prevalence of articular syndrome and prolonged illness.
if the number of patients is small. Further studies are needed to identify a reliable predictive marker of uveitis risk in JIA patients. The finding of a significant greater prevalence of anti-DFS70 autoantibodies in healthy ANA + subjects allows to suppose that this autoantibody could represent a possible protective marker for development of AARDs in asymptomatic children with isolated ANA positivity, as for adults. To confirm this hypothesis, it would be useful to carry on the study prospectively, encompassing children with other rheumatological diseases, and prolonging the clinical and laboratory follow up.

AB1004 JUVENILE DERMATOMYOSITIS (JDM) IN SOUTHEAST ASIA: A 20-YEAR SINGAPORE EXPERIENCE

K. L. Tett1, L. Das1, Y. X. Book1, T. Arkachaisri1,2, 1KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Singapore, Singapore

Background: Juvenile dermatomyositis (JDM) is a multisystem inflammatory disease of childhood with variable demographics, clinical features and outcomes. No studies have described the characteristics of JDM patients from Southeast Asia population.

Objectives: To describe the clinical characteristics and outcomes of JDM patients in Singapore over a 20-year period.

Methods: Patients diagnosed with JDM from 1999 to 2019 at KK Women's and Children's Hospital, Singapore, were recruited. Nonparametric descriptive statistics were used to describe data. Kaplan-Meier analyses were used to estimate the probability of remission. Multivariate logistic and Cox regression analyses were used to determine predictors as appropriate. The significant level was set at < 0.05.

Results: 32 JDM were identified. Clinical characteristics and treatment used are shown in Table 1.

*median in months (IQR)

Pulse methylprednisolone (pMP) was used in 53.1% of patients after diagnosis. Median time to inactive disease (ID) was 5.3 months (IQR 2.8 – 12.8). Male, older age and patients on pMP (p = 0.003-0.044) achieved ID sooner. Older patients also developed disease flare sooner after achieving ID (p =0.024). No clinical features nor lab investigations predicted JDM disease course. Malay patients was associated with higher risk of calcinosis (p = 0.017).

Compared to adult dermatomyositis patients in Singapore1, our cohort had more cutaneous manifestations including malar rash, vasculitic rash and nailfold changes. Table 2 shows the time for each muscle enzymes to normalise.

Conclusion: Our cohort of JDM patients had more calcinosis compared to other Asian population2. Malay population is at higher risk of this complication. It is crucial to achieve ID state in the shortest time possible to avoid significant morbidity. Our study suggests that early treatment with pMP is associated with shorter time to ID. There is no predictor identified for disease course, similar to previous studies3.

AB1005 BULLOUS LUPUS (BSLE) AS THE FIRST MANIFESTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS IN THE PEDIATRIC POPULATION (PSLE): A DIAGNOSTIC CHALLENGE IN DAILY PRACTICE

F. Torres1, M. Velasquez1,2, L. Ramirez3, L. Leon4, M. Martinez1, 1Universidad de Antioquia, Medellin, Colombia; 2Hospital San Vicente Fundacion, Medellin, Colombia; 3Hospital Fundacion Valle del Lili, Cali, Colombia; 4Universidad Nacional de Colombia, Bogota, Colombia

Background: Cutaneous manifestations are observed in 59–85% of patients with SLE but less than 5% developed BSLE. In the GLADEL cohort, the prevalence is 0.41%. BSLE literature in children is scarce
Objectives: to describe the clinical characteristics of the patients with BSLE

Methods: series of cases between 2010-2019 of two reference centers. The cases met Camisa and Grimwood criteria for BSLE

Results: 5 cases had bullous lesions that resolved with residual hypopigmentation. One case had focal seizure and other patient had arthritis with leukopenia and thrombocytopenia. 2 patients had proteinuria <500 mg/24 hours. There were no cases of lupus nephritis. The median SLEDAI-2K score was 12 (IR: 8-17). All had ANAs in titers greater than 1:160 and four had anti-DNA (+). 5 patients had anti-RNP and 4 had anti-Sm. One case had anti-Ro/anti-La. All presented low C3 and 80% had low C4. 80% had ESR ≥20 mm/hour and CRP greater than 0.5 mg/dl in 60%. All presented clinical response with glucocorticoids and dapsone; one patient had methemoglobinemia that improved. At 3 months, the blisters did not recur in 4 patients except one case that presented relapse due to inadherence.

Histologically, the most common finding was subepidermal blisters with neutrophils in the papilar dermis. DIF showed linear deposits of Igs and complement in 4 cases and granular deposits in one case; IgG/IgM were in 5 of the samples. IgA was positive in 60% and C3 in 80%

Conclusion: In this series, BSLE was associated with neuropsychiatric, joint and hematological involvement in 40% of patients, without lupus nephritis. Such abnormalities had a parallel course to skin involvement, without recurrences.

BSLE tends to have a single-phase behavior and in children unlike adults, severe renal involvement is uncommon

**AB1006**

**DRUG SURVIVAL OF SYSTEMIC TREATMENTS IN JUVENILE IDIOPATHIC ARTHRITIS**

L. Trives Folguera1, I. Monteagudo1, B. Serrano Benavente1, I. L. Caballero Motta1, A. M. Anzola1, K. López Gloria1, J. C. Nieto1. 1Gregorio Marañón Hospital, Madrid, Spain

**Background:** Juvenile idiopathic arthritis (JIA) comprises a group of inflammatory diseases that frequently requires systemic treatments. There are some studies that evaluate the systemic drug survival in adults with JIA; but there is scarce data about the drug survival in paediatric population.

**Objectives:** Our main objective was to study the drug survival of biologic therapies and synthetic DMARD in a monocentric cohort and the related factors influencing on it.

**Methods:** Patients with JIA visited in the last 12 years were included. We carried out a retrospective, longitudinal study and collected data on treatment (start date, tapering and stop the treatment date; causes of finish and combined treatment or not). We also collected demographic data with date of birth, sex, symptoms onset data and JIA subcategory. We studied time to relapse since the drug suspension. The drug survival for each kind of treatment was analyzed with Kaplan-Meier curves.

**Results:** We included 158 patients with JIA. Demographic data are shown in table 1. One hundred and thirty (82.3%) patients started methotrexate (MTX) with a half-life of 34.8 months; 79 (51.5%) patients started biologic therapy with half-life of 29 months and 14 (17.7%) patients started a second biologic with a half-life of 5 months. Time to first tapering of MTX was 12 months, for the first biologic was 10.5 months and for the second biologic was of 15 months. The main cause of suspension was remission for each group. Treatment according to different JIA subcategories is shown in table 2. In 45 patients (28.5%) systemic treatment was started with half-life of 34.8 months; 79 (51.5%) patients started biologic therapy with half-life of 34.8 months.

**Conclusion:** The drug survival for systemic therapies in children with JIA is more than 2 years, without significant differences between synthetic DMARDs and biologics. Remission is the main cause for ending treatment. Biologic drug survival was significantly shorter between systemic JIA and the other subcategories. Only one fourth of patients had a flared after stopping the systemic treatment.

**Results:** In children with SLE a significant increase in the content of total cholesterol (5.56±0.36 mmol/l) and a decrease in HDL-cholesterol levels (0.94±0.18 mmol/l) were found in comparison with the control group (3.71±0.69 mmol/l and 1.29±0.33 mmol/l, respectively). A significant (p <0.05) decrease in the concentration of ApoA (85.1 [59.8; 94.9] mg/dl), Apoe (2.1 [12; 3] mg/dl) and an increase in ApoB (59.8 [519; 678] mg/dl) in children with SLE were found compared with the control group (1272 [122.1; 132.3] mg/dl, 3.2 [2.3; 5.9] mg/dl and 32.1 [19.9; 50.8] mg/dl, respectively). ApoB / ApoA-1 was established in 7 (28%) children with SLE. The study found a significant (p <0.05) increase in the level of intermediate (DK233, DK278) and final (MDA) LPO products in the blood serum of children with SLE in comparison with the control group, which indicates the activation of LPO processes in these patients. During the correlation analysis, a positive correlation was established between the levels of DK233, DK278 in blood serum and CRP (r = 0.87, p <0.001). When studying the main indicators of the blood lipid spectrum in children with SLE, a significant increase in the serum concentration of total lipids (p <0.01) and triglycerides (p <0.001) was revealed when compared with the control group. When determining indicators of coagulation hemostasis, in children with SLE, a predominance of hypercoagulation was detected, accompanied by a significant increase in serum fibrinogen level (5.08 ± 0.14 g/l) and an increase in platelet level (479.57 ± 8.0110^9/l) in peripheral blood compared with the control group (3.24 ± 0.7 g/l and 294.23 ± 5.3910^9/l, respectively). These indicators correlated with serum CRP concentration (r = 0.62; p <0.01) and ESR level (r = 0.73; p <0.01). A relationship was established between elevated serum levels of fibrinogen and disease activity indicators (r = 0.74; p <0.01).

**Conclusion:** The atherogenic orientation of the blood lipid spectrum, characterized by hyperlipidemia, hypertriglyceridemia, hypercholesterolemia and dyslipoproteinemia in the form of a decrease in HDL-cholesterol and an increase in LDL-cholesterol, as well as an increase in ApoB/ApoA ratio> 1 and a decrease in ApoE, the activation of LPO processes and a significant decrease in ACW and ACl in the serum of children with SLE are cardiovascular event risk factors (pulmonary thromboembolism, myocardial infarction and brain).

**Acknowledgments:** This study would not have been possible without the collaboration of numerous Belarussian pediatric rheumatologists, patients and their parents.

**Disclosure of Interests:** None declared.

**AB1009**

**THE EFFICACY OF TOCILIZUMAB ON THE TREATMENT OF TAKAYASU ARTERITIS IN CHINESE CHILDREN**

C. Wang1, H. Song1, Z. Yu1, M. Guan1.

**Background:** Takayasu arteritis (TA) is the most prevalent large-vessel vasculitis in children. Patients with TA have a high mobility and mortality. It remains a therapeutic challenge because corticosteroids monotherapy can rarely cure TAK and is burdensome to patients. TAK is a rare pediatric vasculitis that affects the aorta and its major branches in young women. The onset of TAK is usually in adolescence, with a peak incidence between the ages of 10 and 20 years.

**Methods:** We retrospectively studied 6 TAK children treated with TCZ in our hospital from July 2017 to October 2018. The demographic and clinical data, laboratory examination results and vascular imaging data were collected.

**Results:** Six pediatric patients with critical or refractory TAK treated with TCZ were analyzed, including 3 males and 3 females. The diagnosis age was ranging in age from 2 to 13 years (median age: 7 years). Three patients were initially treated with TCC and Mycophenolate Mofetil (MMF) as the first-line regimen without corticosteroid or with a quite rapid GC taper duration, two of which had life-threatening coronary arteries involved and heart failure. The other three patients were switched to TCZ from conventional disease modifying anti-rheumatic drugs (DMARDs) or other biologics due to being refractory to them and recurrent relapses. Four patients were given TCZ at 4 weeks regular intervals for 10 to 22 months, while two patients withdrew TCZ because of disease deterioration and unbearable abdominal or chest pain after the second dose. After 6 months follow-up, four patients experienced significant clinical and biological improvement with angiographically progression in one patient. A corticosteroid-sparing effect is obvious. Drug-related side effects occur in 1 patients manifesting as a mild elevated liver function. Neither neutropenia nor infection was observed.

**Conclusion:** Our study shows a clinical, biological, and radiological response in patients with refractory Takayasu arteritis.

**References:**

Background: Anti-nuclear antibodies (ANA) are a group of the antibodies that develop against intracellular components of the cells. It is usually useful for diagnosing some of the connective tissue diseases like systemic lupus erythematosus, mixed connective tissue disease. But it is reported that its positivity rate is about 20% in healthy individuals. Therefore, it can be confusing to check ANA test, if there is not really high suspicion for connective tissue diseases or juvenile idiopathic arthritis.

Objectives: We aimed to evaluate results of long-term follow-up of the patients with ANA positivity who had initially no identifiable rheumatic diseases.

Methods: Six hundred and ninety-four patients with ANA positivity who did not diagnosed as any of the rheumatic diseases at the first examination were found in database. Two hundred and eighty-two patients of them were called so far and questioned about their demographic features and symptoms that are related with rheumatic diseases.

Results: Mean age of the patients at the time of study and at the time of testing were 13.4±4.5 and 9.1±4.0 years. The female: male ratio was 1.05. Mean follow-up duration was 4.3±2.8 years. Most common reasons for the request for ANA test were arthralgia and skin eruptions. ANA testing was most commonly requested by a general pediatrists. Demographic features of the patients were summarized in Table 1.

Most of the diseases were diagnosed in patients with ANA positivity were not related with autoimmune mechanisms that associated with ANA positivity therefore, these diseases are thought to be coincidence. Only in 1 patients, systemic lupus erythematosus that has certain association with ANA positivity was diagnosed. All diseases that are diagnosed were shown in Table 2.

*Idiopathic Thrombocytopenic Purpura. **Periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis syndrome.

Conclusion: We are reporting that in only 0.3% of patients with ANA positivity who don’t have any diseases diagnosed initially, were diagnosed as rheumatologic diseases during to the follow-up period. Since positivity of ANA is also common in the healthy population, requesting this test in only patients with high suspicion for connective tissue disease will reduce confusion in terms of diagnosis.

AB1012 INVESTIGATION OF RELATIONSHIP BETWEEN SEXUAL FUNCTION AND OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY IN PATIENTS WITH BEHÇET’S: PRELIMINARY STUDY

A. Ayan1, M. F. Kucuk2, S. Y. Cetin3, M. K. Erol4, 1Antalya Training and Research Hospital, Rheumatology, Antalya, Turkey; 2Antalya Alaaddin Keykubat University, Ophthalmology, Antalya, Turkey; 3Akdeniz University, Department of Physiotherapy and Rehabilitation, Antalya, Turkey; 4Antalya Training and Research Hospital, Ophthalmology, Antalya, Turkey

Background: Patients with Behçet’s have sexual dysfunction in recently literature. However, depression and anxiety accompanying these studies were not excluded. In addition, increased sexual dysfunction in patients with Behçet’s has been reported in these studies in relation to depression and anxiety. Also it has been stated that endodothelial dysfunction decreases the vasodilator neurotransmitter level. It was emphasized that this may lead to erectile dysfunction in disease of Behçet’s.

Objectives: The aim of this study is to evaluate the relationship between erectile dysfunction (ED) and radial peripapillary capillary (RPC) density determined by Optical Coherence Tomography Angiography (OCTA).

Methods: Patients under 45 years old who had no known additional disease and had no eye and neurological involvement were included in the study. The patients were evaluated with Beck Depression and Anxiety Scale. Accordingly, patients without anxiety and depression were included in the study. An International Index of ErectileFunction (IIEF) questionnaire was applied to a total of 18 patients who met the inclusion criteria. Detailed ophthalmological examination and OCTA imaging were performed by the ophthalmologist. Patients whose eye bottom could not be evaluated clearly (Corneal pathology, cataracts, etc.), image quality was 0.5 and below, and additional eye disease (glaucoma, optic neuropathy, maculopathy) were excluded from the study.

Results: The mean age of the patients was 37 ± 6.5 years, and the duration of the disease was 82.37 ± 47.78 months. There was a strong relationship between RPC Small Vessel Whole Density (RPC-SVWD) and overall satisfaction and sexual satisfaction (p: 0.036 and 0.045). There was a strong positive relationship between RPC Small Vessel Peripapillary Density (RPC-SVPD) and erectile function, sexual desire, sexual satisfaction and general satisfaction (p: 0.036, 0.032, 0.005, 0.004). There was a strong positive relationship between RPC All Vessel Peripapillary Density (RPC-AVPD) and erectile function and sexual satisfaction (p: 0.048, 0.015).

Conclusion: In our study, a significant relationship was found between sexual function and RPC density. In the literature, it has been found that nitric oxide synthesis decreases due to endothelial dysfunction in patients with Behçet’s. Although there are preliminary study data, we found a significant relationship between the vascular layer of both the penis and the eye in our study. The data we obtained in this study, in which all factors that may cause erectile dysfunction are excluded, show that Behçet’s, which is theoretically known to affect all vascular structures, can affect sexual functions by its nature. In our study, although there is a relationship between ED and OCTA data in Behçet’s disease, the large number of cases of our ongoing study will provide clearer information.

**AB1013**

**CYCLOPHOSPHAMIDE VS AZATHIOPRINE FOR THE TREATMENT OF CONNECTIVE TISSUE RELATED INTERSTITIAL LUNG DISEASE**

H. Satsi1, M. Onruit1, R. Bilici Salinan1, H. Babaoglu1, N. Atas1, A. Avanoğlu Güler1, H. Karadeniz1, D. Yapar1, N. Kayahan1, H. Küçük3, S. Haznedaroğlu1, B. Goker1, M. A. Ozturk1, A. Tufan1, H. Türktaşı1, Gazi University Faculty of Medicine, Ankara, Turkey; 2Gulhane Research and Training Hospital, Ankara, Turkey; 3Yenimahalle Research and Training Hospital, Ankara, Turkey

**Background:** Interstitial lung disease (ILD) is a common morbidity and mortality reason for connective tissue disorders (CTD). Data related to treatment options in the literature is limited.

**Objectives:** To describe the role of azathioprine (AZA) in the first line treatment of connective tissue disease related interstitial lung disease CTD-ILD, comparing with cyclophosphamide (CYC)

**Methods:** Between 2009 and 2019 all interstitial lung disease patients admitting rheumatology or pulmonology department were retrospectively evaluated. Among those patients, as an first line regimen treated with either azathioprine or cyclophosphamide were included. Primary end point was FVC percentage change at 6th month.

**Results:** Among 328 CTD-ILD, 57 patients had AZA treat and 79 patients had CYC for the first line treatment. Patients treated with AZA tend to have limited disease and older age. CYC treatment had a mean of 2.41% increase in FVC but in AZA -1.44% decrease in FVC predicted (p:0.041) 5 major CTD groups were defined (systemic sclerosis (SSc), rheumatoid arthritis (RA), primary sjogren syndrome (pSS), dermatomyositis/ polymyositis (PM/DM), autoimmune features of intestinal lung disease (IPAF)). AZA had similar efficacy in, PM/DM and IPAF groups but worse outcome in SSc, RA and pSS compared to CYC.

**Conclusion:** AZA treatment might be an option patients with limited disease extent and the diagnosis of PM/DM or IPAF. CYC was a better treatment in SSc, RA and pSS patients.

**DOI:** 10.1136/annrheumdis-2020-eular.5362
of the last indicator had a direct correlation with stage II of the node (r=0.41, p<0.05) and with the level of LEP (r=0.28, p<0.05), and an inverse correlation with the number of nodes (r=-0.24, p<0.05). The level of LEP increased in 38/100 patients (38.2%), had a direct correlation with Qi (r = 0.46, p<0.05), the affected area (r = 0.31, p<0.05), the concentration of CRP (n=0.36, p<0.05) and an inverse correlation with the number of nodes (r = -0.33, p<0.05).

Conclusion: It is obvious that in case of ILP there is a need to increase knowledge about the markers of inflammatory activity (ESR, CRP, TNF-α and LEP) which correlated with the area of the lesion, VAS pain intensity and temperature increase.

RATE OF PREDEFINING DISEASE ACTIVITY, REMISSION AND RELAPSE OF ADULT-ONSET STILL’S DISEASE: SYSTEMATIC LITERATURE REVIEW

E. Bilgin1, U. Kalayc1, 1Hacettepe Üniversitesi Tip Fakültesi, Internal Medicine, Division of Rheumatology, Ankara, Turkey

Background: Adult-onset Still’s disease (AOSD) is a rare, multisystem and auto-inflammatory disorder. Although several scoring systems are proposed to describe AOSD disease activity, there is no agreement on the definition of disease activity, remission or relapse of AOSD.

Objectives: Aim of this literature review was to determine the rates of defining “disease activity”, “remission” and “relapse” of AOSD.

Methods: We performed a systematic review (May 2019) on Pubmed by using the MeSh word “Adult-onset Still’s disease”; results were restricted to human studies and English language. We excluded case reports, reviews and studies including less than 10 patients; 215 articles were recruited for final assessment. Of this 215 article, we reached the full-texts of the 181 articles. Final assessment was done with 181 articles. In these articles, we searched whether the definitions of disease activity, remission or relapse were made or not.

Results: Total of 181 articles were included to analysis. Mean age was 37±6.6 and 73.6% of patients was female. Articles were devised to 4 main groups according to main focus related to AOSD: Observational studies, laboratory studies, genetic studies and clinical trials. Diagnosis of AOSD was according to Yamaguchi criteria in 159 (87.8%) of articles and Yamaguchi criteria was the most commonly used criteria set. Disease activity was defined in 96 (54.1%) of articles. Remission and relapse were defined in 52 (28.7%) and 18 (10%) of articles, respectively. Most commonly used definition of disease activity was the “systemic score” which was defined by Pouchet et al. Rates of defining “disease activity”, “remission” and “relapse” according to 4 main groups were given in Table 1.

Conclusion: In recent years, new treatment options become available for AOSD. However, data about how to measure the AOSD activity in largely missing. Definitions of disease activity, remission or relapse are missing in the most of the studies, including clinical trials, in current literature. Future studies are needed for this issue.

ANTI RANK LIGAND IN ACUTE CHARCOT NEURO-OSTEARTHROPATHY OF THE FOOT: A PROMISING TREATMENT

S. Carves1, 2, J. Henry1, 2, M. Bourgeon Ghittoni1, 2, R. Belkhir3, 2, G. Nocturne1, 2, F. Besson1, 2, G. Cluzel1, 2, M. Creze1, 2, R. Seror1, 2, X. Mariette1, 2, 1Hôpitaux Universitaires Paris-Sud, Le Kremlin-Bicêtre, France; 2Assistance Publique des Hôpitaux de Paris, Paris, France

Background: Acute Charcot neuroarthropathy (CN) of the foot is a rare and severe complication of peripheral neuropathy leading to joint destruction. Usual treatment rely on standard pressure offloading and no pharmacological treatment is available. Inflammation and increased osteoelastic activity via receptor activator of nuclear factor (RANK) ligand are major features of acute CN.

Objectives: To assess clinical, metabolic and radiographic effect of denosumab, a fully human monoclonal antibody against RANK ligand, in acute CN.

Methods: In this open study, we included all consecutive patients with acute CN treated with denosumab 60mg in our mixed rheumatology/diabetes clinic dedicated to diabetic foot. Diagnosis of acute CN was based on clinical presentation and supported by biology, radiography, magnetic resonance imaging (MRI). Baseline and follow-up assessment included clinical examination and emission tomography–computed tomography (PET-CT).

Results: Seven patients with acute CN were treated with denosumab between 2017 and 2019 (age from 43 to 70 years). Five were diabetic. All patients received denosumab, because of failure of standard pressure offloading, with evolving joint destruction of midfoot. CN evolves since a median of 6 months (2 to 20) at denosumab initiation. All patients clinically improved after denosumab injection (table). After a mean follow-up of 16 months, only 1/7 patients had a new flare. In the 4 patients with available follow-up X-ray, structural damage remained stable. In all 3 patients with available PET-CT evolution, the maximum standardized uptake lean value (SUL max) decreased.

Three patients were retreated, with a mean interval of 6 months: One patients because of persistent clinical and biological inflammation (CRP 17mg/L), one because of relapse due to intensive walking, and one due to an associated osteoporosis.

No adverse event and hypocalcemia was observed.

Conclusion: One to three injection of denosumab 60mg was efficient in preventing flare and further bone destruction in a 16 months medium follow up. These results justify the conduction of a randomized control study to assess the efficacy of denosumab as the first-line pharmacological therapy in acute CN.

L, left; R, right. MOODY, Maturity-Onset Diabetes of the Young;
* Assessment is scheduled on February 2020 (** March 2020)**
Background: Hydronephrosis, a common complication of idiopathic retroperitoneal fibrosis (iRPF), may lead to poor renal outcomes unless it is resolved. Pathological confirmation can help to identify the aetiology of the disease and determine the treatment strategy. But, in most cases, it is difficult to obtain sufficient tissue due to the location of fibrosis. In a recent study, parts of iRPF are correlated with IgG4-related disease characterised by elevated serum IgG4 levels (>135 mg/dL). Normal serum IgG3 level (21-176 mg/dL) has been known to be higher than normal serum IgG4 level (4-86 mg/dL). The reverse IgG4/IgG3 ratio has been suggested to be an IgG4-related disease component that distinguishes it from primary sclerosing cholangitis [1]. However, the ratio of IgG3 and IgG4 may be reversed in iRPF patients with hydronephrosis.

Objective: We aimed to investigate the ratio of IgG subclasses as a predictive factor associated with treatment response of hydronephrosis in patients with iRPF.

Methods: We retrospectively recruited 19 iRPF patients with hydronephrosis who evaluated serum IgG subclasses in a tertiary hospital between 2004 and 2019. Hydronephrosis was evaluated on the basis of imaging findings. Medications and clinical and laboratory findings, including IgG subclasses, were reviewed following the diagnosis of hydronephrosis. Hydronephrosis improvement on subsequent images was evaluated to assess treatment response. Categorised data were compared using chi-square or Fisher’s exact test. Continuous variables were compared using Mann–Whitney U test.

Results: At baseline, median serum IgG3 and IgG4 levels were 64 (IQR 37–82) mg/dL and 71 (IQR 40–171) mg/dL. Five patients had serum IgG4 levels >135 mg/dL and 11 patients had the reverse serum level of IgG4/IgG3. On subsequent images (median follow-up at 3.2 [IQR 1.7–4.0] months), 11 patients showed hydronephrosis improvement. The proportions of positive ratio of serum IgG4/IgG3 (81.8% vs. 25%, p = 0.024), periaortic involvement (81.8% vs. 25%, p = 0.024), and high-dose glucocorticoid treatment (45.5% vs. 0%, p = 0.045) were significantly higher in patients with improvement than in those without improvement (Table 1). Interestingly, even in cases with normal serum IgG4 levels, patients with improvement showed a higher serum IgG4/IgG3 ratio than in those without improvement (median 1.5 vs. 0.7, p = 0.038).

IgG4-RD were approved by ACR and EULAR in 2019. Whether this new criteria improve the diagnosis efficiency needs to be validated in clinical practice.

Objectives: To applicate the 2019 ACR/EULAR classification criteria for the diagnosis of IgG4-RD in previously suspected patients and explore the clinical characteristics of patients with IgG4-RD according to the new classification criteria.

Methods: Patients suspected of having IgG4-RD due to elevated serum IgG4 and swelling or masses in single or multiple organs were recruited in Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University from May 2013 and November 2019. Demographic and clinical data were collected. The diagnosis was reevaluated with the 2011 comprehensive diagnostic criteria (CDC) for IgG4-RD and the 2019 ACR/EULAR classification criteria for IgG4-RD, respectively.

Results:

(1) There were 68 patients recruited and 59(86.8%) of them had elevated serum IgG4 (>135mg/dl) and 53(77.9%) patients showed swelling or masses in single or multiple organs. Most patients first visit general surgery (176%), gastroenterology (16.2%), respiratory medicine (16.2%) and rheumatology (14.7%).

(2) According to the 2011 CDC for IgG4-RD, 4(5.9%) patients were definite IgG4-RD, (1.15%) was probable and 42(61.8%) were possible. According to the 2019 ACR/EULAR criteria, 20(29.4%) patients were diagnosed as IgG4-RD, including the 4 definite patients using the 2011 CDC.

(3) Among the 20 IgG4-RD patients according to the 2019 ACR/EULAR criteria, 19(95.0%) were male and median age of symptom onset was 62(46–69) years. There were 8(39.0%) patients diagnosed at rheumatology, 5(25.0%) at gastroenterology, 3(15.0%) at general surgery, 2(10.0%) at respiratory medicine and 1(5.0%) at stomaatology, endocrinology, orthopedics and urinary surgery, respectively. There were 9(45.0%) patients with bilateral lacrimal or salivary glands involved, 9(45.0%) with pancreas and biliary tree involved, 5(25.0%) with retroperitoneum involved, 2(10.0%) with kidney involved and 1(5.0%) with chest involved.

(4) The median serum IgG4 of the 20 IgG4-RD patients was 15.4(4.14–55.10) g/L. median serum IgG was 279(172–50.2)g/L. There were 20.0%(4/20) patients had elevated serum eosinophil and 93.3%(14/15) had elevated serum IgE. There were 60.0%(9/15) patients had elevated C-reactive protein, 85.7%(12/14) had elevated erythrocyte sedimentation rate and 26.7%(4/15) had hypocomplementemia. There were 35.7%(5/14) patients had positive rheumatoid factor, 37.5%(3/8) had positive antinuclear antibodies. There were 6(30.0%) patients didn't received biopsies, 8(40.0%) patients received surgical removal of salivary glands, lacrimal glands or pancreatic masses and 6(30.0%) patients received needle biopsies of the salivary glands or biopsies by bronchoscopy, gastroscopy or enteroscopy.

(5) Among the patients didn't fulfill the 2011 CDC and the 2019 ACR/EULAR criteria, there were 40 patients had elevated serum IgG4, whose serum IgG4 level were significant lower than those of IgG4-RD patients [3.66(2.39–7.68) g/L vs. 15.4(4.14–55.10)g/L, P<0.001], and percentage of serum IgG4 ≥5× upper limit of normal were also lower than those of IgG4-RD patients [27.5% vs. 73.7%, P=0.002].

Conclusion: The 2019 ACR/EULAR criteria can help diagnosing patients with IgG4-RD even lacking the tissue confirmation. Patients with moderately elevated serum IgG4 need more clinical evidence to diagnose IgG4-RD and exclude mimics.

CHARACTERISTICS AND MANAGEMENT OF RHEUMATIC MANIFESTATION UNDER ESTROGEN RECEPTOR-TARGETING CANCER THERAPIES; DATA FROM A PROSPECTIVE REGISTRY

A. Dr. Patro1, L. Diekmann2, H. M. Lorenz3, B. Kraemer4, K. Benesova2, J. Leipe1
1University Hospital Mannheim, Division of Rheumatology, Department of Medicine V, Mannheim, Germany; 2University Hospital Heidelberg, Heidelberg, Germany, Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg, Germany; 3University Hospital Heidelberg, Heidelberg, Germany, Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg, Germany

Background: The knowledge about interdependencies between rheumatic manifestations and malignancies is limited. Further, reliable data on the occurrence of rheumatic symptoms as side effects of specific cancer therapies beyond checkpointinhibitor-induced immune-related adverse events are sparse. In this regard, although, arthralgia under estrogen receptor-targeting therapies (aromatase inhibitors and the estrogen receptor modulator tamoxifen) has been frequently reported in oncological clinical trials and case reports, prospective data including an assessment of rheumatic manifestations by rheumatologists are lacking.

Objectives: To contribute to a better understanding of interdependencies between rheumatic manifestations and cancer/ estrogen blockade and potentially improve the management of both entities, pilot data were analysed.

Methods: Data on characteristics and treatment of rheumatic manifestations and cancer as well as their timely association were systematically collected and analysed in the MalheuR (‘malignancy and rheumatic disease’) registry, a long-term, observational study designed to study patients suffering from concomitant rheumatic disease and malignancy and/or premalignant lesions.

Results: We identified 11 patients with rheumatic manifestations under estrogen receptor-targeting therapies (3 anastrozol, 4 letrozol, 8 tamoxifen) as part of breast cancer treatment. In addition to breast cancer one patient had a lymphoma 3 years after and another patient had a non-small cell lung cancer 2 years before breast cancer diagnosis. The patients had different cancer stages (5 IA, 3 IIA, 1 IIB, and 1 IVA). Their mean age at cancer diagnosis was 60.4 ±11.6 years and all patients are females. The time interval between diagnosis of cancer and onset of systemic/ rheumatic symptoms was 49.5 ± 34.0 months. Of interest, the time interval between onset of rheumatic symptoms and first assessment by a rheumatologist was 16.9 ± 22.3 months. The following systemic and rheumatic symptoms were reported: arthralgia in 10, arthritis in 8 (small joints in 5, large joints in 3 affected), morning stiffness (>30 min) in 7, in 1, myalgia in 7, sicca symptoms in 2, fever in 1 (new-onset FMF with heterozygous M694U mutation), class IV glomerulonephritis and polyserositis in 1 (with new-onset SLE patient), Disease burden at baseline was rather high with a mean VAS pain of 65 ±12.9/100. Laboratory analyses revealed an increased CRP in 61/77 (55%) with a mean of 10.3 ± 8.2 mg/dl (>5). Autoantibody positivity was observed for ANAs in 5/10 (50%, titers ranging from 1:80 to 1:160), anti-dsDNA in 1, rheumatoid factor in only 1/10 (10%) patients, none was anti-CCP positive. Before cancer diagnosis a rheumatic manifestation was treated with NSAR 3/11 (27%), 1/11 systemic glucocorticoids (91%) with an initial dose of 17.5 ± 19.5 mg and intra-articular glucocorticoids 1/11 (9%). Rheumatological assessment lead to initiation of csDMARDs (3/11 MTX, 1/11 SSZ, 1/11 HQR, 1/11 AZA (later MMF/ rituximab in the SLE patient) 1/11 colchicine) as corticosteroid-sparing agents with good response in the majority of the patients.

Conclusion: Our data demonstrate heterogeneous rheumatic manifestations, partially with severe manifestations beyond arthralgia, so far not reported by oncological studies including follow-up, which might suggest an underreporting. Furthermore, despite close monitoring in tumor aftercare, our data show a considerable delay in referral to a rheumatologist and initiation of suitable treatment. The prospective design of the MalheuR registry enables future validation of our pilot data.

AB1022

PANNICULITIS IN RHEUMATOLOGICAL PRACTICE: THE RESULTS OF LONG-TERM FOLLOW-UP

O. Egorova1, B. Belov1
1VA. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Panniculitis is a group of heterogeneous inflammatory diseases that occur with damage to the subcutaneous fat (SCF), musculoskeletal system, and often internal organs.

Objectives: To evaluate the course and outcome in patients with panniculitis.

Methods: The course of the disease was monitored in 193 patients treated at the VA. Nasonova Research Institute of Rheumatology for 3-5 years (142 women, 51 men) aged 19 to 77 with the referral diagnosis of erythema nodosum (EN) and
undifferentiated panniculitis and with the disease duration of 1 week to 13 years. In addition to general clinical study, serum concentrations of α-1 antitrypsin, amylose, lipase, ferritin, creatinephosphokinase were determined, computed tomography of the chest organs, immunological, ultrasound scanning of the skin and SCF of the node area, tuberculous tests and pathomorphological study of skin biopsies from the node area were performed.

Results: as a result of laboratory and instrumental examination, the following diagnoses were made: EN associated with infection (72 people – group 1), lipo-dermatoscleroses (LDS) (40 –group 2), idiopathic lobular panniculitis (ILP) (32 – group 3), Lo¨fgren’s syndrome (SL) (49 – group 4). During the follow-up period, 6 deaths occurred (3.1%): in a patient with LDS due to acute heart failure and in 5 patients with ILP due to the activity of the disease which led to the development of cardiopulmonary pathology and disseminated intravascular coagulation (DIC) syndrome. In group 1, during the observation period, UE recurred in 18 people (25%), the probable causes were: hypothermia (6), exacerbation of chronic tonsil- litis (6), acute respiratory viral infections (ARVI) (4), stress (1), a rapid decrease in the level of glucocorticoids (GC) (1), the cause is unknown (2). In group 2, recurrence occurred in 19 patients (47.5%) due to the lack of anti-inflammatory therapy (plaquenil) (10), trauma (4), stress (3), and weight lifting (2). There was no recurrence in 7 patients in this group, however, nodes would not disappear completely, which is obviously due to the absence of plaquenil. In group 3, recur- rence was registered in 24 cases (75%) and it was associated with insufficient effect of the ongoing anti-inflammatory therapy (9), a decrease in blood glucose to minimal doses (6), hypothermia (6) and the absence/cancellation of anti-in- flammatory therapy (3). In group 4, recurrence of nodes was registered in 14 cases (28.5%), possible causes: cancellation of GC (9) and cooling/ARVI(5).

Conclusion: in the observed group of patients with panniculitis mortality was 3.1%. The main causes of recurrence in EN were viral-bacterial infections, and in case of ILP, LDS and SL it was insufficient effect/absence of anti-inflammatory therapy.

Disclosure of Interests: None declared.

AB1024 EVALUATION OF CLINICAL FEATURES IN PATIENTS DIAGNOSED WITH JUVENILE AND ADULT-ONSET FAMILIAL MEDITERRANEAN FEVER

D. Erdem Günsör1, H. H. Gezer2, S. Acer Kasman3, N. Özd4, A. Ozer2, M. T. Duruöz1, 2Adyaman Training and Research Hospital, Rheumatology, Adyaman, Turkey; 2Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation, Rheumatology Division, Istanbul, Turkey

Background: Familial Mediterranean Fever (FMF), which is more common in groups in the Mediterranean basin, is a monogenic auto inflammatory disease characterized by recurrent attacks of febrile peritonitis, pleuritis and arthritis.

Objectives: The aim of this study is to investigate the clinical features of patients diagnosed with juvenile and adult-onset Familial Mediterranean Fever (FMF).

Methods: Patients with FMF were included in the study consecutively without sample selection. Data about age, sex, disease duration (month), symptom dura- tion, age at diagnosis, diagnosis delay time, comorbid diseases, and medica- tions were noted. Patients with onset of symptoms <20 years old were classified as juvenile-onset, those >20 years old were classified as adult-onset FMF. The frequency and characteristics of attacks and the presence of amyloidosis will be recorded.

Discourse of interests: None declared.

DOI: 10.1136/annrheumdis-2020-eular.2666
There were no differences between juvenile and adult-onset FMF groups in terms of gender, frequency of attacks, duration of attacks, acute phase values between attacks, colchicine dose, presence of colchicine resistance, and presence of amyloidosis (p>0.05). The last attack diagnosis was significantly higher in patients with adult-onset FMF (p<0.005).

The PRAS disease activity scores were significantly higher in the juvenile-onset FMF group (p=0.001). There were no significant differences between the two groups in terms of SF-36 and HAQ scores (p>0.05).

**Conclusion:** While there were no differences between juvenile and adult-onset FMF patients in terms of quality of life and functional disability, the PRAS disease activity scores were higher in patients with juvenile-onset FMF.

**EVALUATION OF ANXIETY AND DEPRESSION LEVELS IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER**

S. Ergul1,1, Konya Education and Research Hospital, Rheumatology, Konya, Turkey

**Background:** Anxiety and depression are common problems in chronic rheumatological diseases (1). Familial Mediterranean Fever (FMF) is characterized by recurrent fever and serosal inflammation attacks.

**Objectives:** The aim of the study was to evaluate the levels of anxiety and depression in patients diagnosed with FMF, and to examine its relationship with drug compliance and attack frequency.

**Methods:** Sixty female patients aged 18 years or older who were consecutively admitted to the rheumatology outpatient clinic and diagnosed as FMF according to the Tel-Hashomer Classification criteria were included. Patients’ age, gender, body mass index (BMI), educational status, disease duration, drugs used and frequency of attacks were recorded. Beck anxiety scale and Beck depression scale were used to determine the level of anxiety and depression.

**Results:** Sixty female patients with an average age of 32.03 ± 10.3 and an mean disease duration of 9 ± 6.9 years were included in the study. They were divided into minimal, mild, moderate and severe according to their anxiety level. According to the level of anxiety, minimal anxiety was observed in 18 (30%), mild anxiety in 9 (15%), moderate 12 (20%) and severe anxiety in 10 (16.7%) patients. Data related to anxiety are given in table 1. The patients were divided into minimal, mild, moderate and severe depending on the level of depression. Data related to depression are given in table 2.

**Conclusion:** In the case of a chronic disease such as FMF, which has a younger patient population than other rheumatic diseases, anxiety and depression should be evaluated during routine outpatient clinic administration and psychiatric support should be provided if necessary.

**INFLAMMATORY MANIFESTATIONS IN PATIENTS WITH HUMAN LEUKOCYTE ANTIGEN-B*51 POSITIVE AND WITHOUT BEHÇET’S DISEASE**

M. DUarte1, J. Sousa Morais2, R. Faria3, B. Guerra Leal4, A. Marinho1,5, J. Correia1,2, F. Farinha5, P. Pinho Costa1,4, B. Martins Da Silva1,4, C. Vasconcelos1,5,1 Centro Hospitalar e Universitário do Porto, Unidade de Imunologia Clínica, Porto, Portugal; 2Hospital de São Marcos, Braga, Serviço de Medicina, Braga, Portugal; 3Abel Salazar Biomédicas Ciências Institute - University of Porto, UMB, Porto, Portugal; 4ICBAS, Laboratório de Imunogenética, Porto, Portugal; 5INSI, Porto, Portugal

**Background:** Human leucocyte antigen (HLA) B*51 allele is the most important genetic factor in susceptibility to Behçet’s disease (BD), an immune-mediated systemic disorder of unknown etiology, characterized by recurrent episodes of inflammatory manifestations. In fact, there is a considerable clinical overlap of BD with autoinflammatory syndromes. As it’s known, the majority of HLA-B*51 positive individuals do not develop BD. But do these individuals also present inflammatory manifestations?

**Objectives:** Characterize the group of individuals in our hospital with positive HLA-B*51, without BD diagnosis and review whether inflammatory manifestations are present in these individuals.

**Methods:** A retrospective study of HLA-B*51 positive patients between 2000 and 2019. Genomic DNA was obtained from peripheral blood and HLA genotyping was performed using a PCR with Sequence Specific Primers (PCR–SSP) methodology. From the group of 285 B*51 positive patients, BD diagnosis were excluded. Demographic and clinical data were collected by review of clinical files in December 2019.

**Results:** 176 patients, mean age of 48.5 ± 16.5 years (5 to 84 years). Most were female (68%). The HLA study was motivated by multiple diagnostic suspicions: spondyloarthritides (SpA, 25.0%), BD (22.7%) and systemic sclerosis (SSc, 10.8%). The mean time elapsed since the immunogenetic study was 8.3 years, with 12 deaths recorded, 69 (39.2%) subjects had no diagnosis for immune-mediated disease (IMD). Of the other 107 patients, the majority had 1 IMD (64.5%), and the rest were diagnosed with 2 to 4 IMD. The most frequent IMD were SpA (20.8%), psoriasis (10.4%), psoriatic arthritis (9.7%), SSc (9.7%) and rheumatoid arthritis (7.1%). Autoantibodies were detected in 94 individuals (53.4%): antinuclear antibodies (64 patients), rheumatoid factor (26 patients) and CCP antibodies (11 patients). In 55 individuals no inflammatory manifestation was identified but the 68.6% of them presented between 1 to 7 manifestations:

**Conclusion:** Inflammatory manifestations are common in HLA-B*51 positive individuals, even in those without BD diagnosis. Further research is needed, considering other HLA alleles associated with increased risk of BD and including control groups.

**References:**
OBJECTIVES: To analyse the ocular effectiveness of anti-IL6 therapy used subcutaneously (s.c.) in patients with moderate-severe active refractory OG in usual clinical practice.

METHODS: Retrospective descriptive observational study of a series of cases of moderate-severe OG patients treated with anti-IL6 s.c. The patient medical records of those who had received at least 1 cycle of anti-IL6 treatment were reviewed (December 2013-December 2019). The primary effectiveness outcome was the change of the Clinical Activity Score (CAS). Favorable response was considered: reduction of CAS≥2 points together with obtaining inactivity (CAS <3). Demographic data, personal medical history, clinical aspects of GD, previous therapies and data on the use and safety of anti-IL6 were collected. The SPSS11 package was used for statistical analysis, using non-parametric tests for quantitative variables. The study was approved by the local Ethical Committee.

RESULTS: 12 of the 15 patients (80%) were women with a mean of 50.27 years (21-72). 60% (n=9) had smoking history, 40% (n=6) active. 26.7% (n=4) were diabetic, all without retinopathy. 100% of patients received imidazole antifungal treatment. 46.7% (n=7) required beta-blockers and 20% (n=3) diuretics. 66.7% thyroidectomy (n=10) and 20% (n=3) degenerative eye surgery and/or blepharoplasty were performed. Thyroid and ocular radiotherapy were used in 2 patients. 3 patients received botulinum. 80% (n=12) of them had previously received GC. 93.3% (n=14) were naive to biological therapy, only 1 patient previously used Rituximab. All except one patient who was treated with SRL received TCZ as IL6 therapy. A significant favorable response was obtained in 100% of the patients (p=0.008), decreasing CAS average from 4.9 (2-7) to 1.7 (0-2) at the end of the therapy [Figure 1]. The severity of the OG changed from being moderate in 72.7% of the patients to mild in 66.7% of the total. The median time to inactivity was 8 months (2-15). 73.3% (n=11) of the patients finished the treatment reaching inactive OG, the rest (inactive maintained) continued treatment. After 6 months, 100% of those who completed the treatment remained inactive with average CAS of 1.3 (0-2). Smoking did not influence the response, nor any other variable collected. Adverse events appeared in 26.7% (n=4) of the cases, all of them mild and without withdrawal.

CONCLUSION: Treatment with anti-IL6 s.c. steadily decreases the clinical activity measured by CAS in patients with moderate-severe refractory OG, despite poor prognostic factors (such as smoking), with a good safety profile.

REFERENCES:
Background: Familial Mediterranean fever (FMF) is an auto-inflammatory disease commonly affects people from Mediterranean basin. It is characterized by acute self-limiting inflammatory attacks of serous membrane. Some recent studies showed diastolic dysfunction in patients with FMF. However, systolic dysfunction was rarely evaluated before.

Objectives: To assess cardiac functions by using speckle tracking echocardiography (STE) in addition to routine measurements and to evaluate whether there is any difference between colchicine responsive patients and those with colchicine-resistant or severe disease.

Methods: Seventy-four FMF patients (57 responsive [60% female and median age 35 [18-63] years], 17 resistant [53% female and median age 31 [20-49] years]) and 74 healthy controls ([53% female and median age 37 [22-55] years]) were included in the study. Patients with cardiac disease or risk factors affecting LV function were excluded. Patients who had ≥1 attacks in three months despite ≥2 mg/d day of colchicine or who were treated with IL-1 blocking agents were defined as colchicine-resistant or severe disease.

Results: There was no significant difference between groups in terms of age and sex. Disease duration was not different between colchicine responsive and resistant patients (median duration in resistant disease was 11 years [1-27], in responsive patients 6 years [0-33] and, p=0.133). Although ejection fraction was similar among groups, global longitudinal peak systolic strain; a marker of systolic function, was significantly lower in FMF patients in comparison with healthy subjects and this difference was due to colchicine resistant FMF patients (p=0.05). There was no significant difference in echocardiographic parameters between non-resistive and resistive FMF patients (p>0.05) (Table 1).

Conclusion: This study depicts the most common patterns of organ involvement along with the epidemiological, laboratory, radiological data and response to treatment, in IgG4-RD, with a definite ophthalmology referral bias, in a tertiary care centre in North India.

AB1032 CONTRIBUITION OF BONE BIOPSY DURING REVELATORY BONE METASTASES

S. Jiří1, M. Ben Majdouba1, S. Ben Jemaa1, A. Feki1, R. Akrout1, M. Ezzeddine1, M. H. Kalle1, H. Fourati1, S. Baklouti1. 1Hedi Chaker Hospital, Sfax, Tunisia

Background: Bone metastases (BM) are tumor cells that originate in a primary malignant tumor and are localized remotely in bone tissue. They more or less faithfully reproduce the morphological and biological characteristics of the primary tumor. Histological analysis is essential to confirm the diagnosis of BM and to identify the primary tumor if possible and sometimes to help in the selection of treatment.

Objectives: The aim of this work is to study the contribution of bone biopsy during revealing BM in diagnostic strategy and therapeutic decision.

Methods: We retrospectively studied the files of 105 patients hospitalized in a Rheumatology department of for BM revealing from January 2000 until December 2015. For each patient we collected epidemioclinical and anatomopathological data to arrive at the diagnosis of primary neoplasm and histological type.

Results: The patients were divided into 86 men (81.9%) and 19 women (18.1%) with a sex ratio (M / F) of 4.52. The average age of our patients was 64.91 ± 13.29 years. Pain was the most frequent reason for consultation found in 97.1%. This pain was either of bone site (61.9%) or of radicular topography (41.9%). Bone swelling or a pathological fracture revealed BM in 4.8% and 8.6% of the cases, respectively. The onset of neurological damage was noted in 13.3% of the cases.

Histologically, the bone biopsy performed in 64 patients made it possible to specify the histological type (canceroma, adenocarcinoma) in 64% of the cases and to lead to primary cancer in 57.8%. A non-radio-guided percutaneous bone biopsy was performed in 44 patients (68.75%) including 41 osteo-medullary biopsy in iliac crest (BOM) and 3 in the sternum, a bone biopsy directed under scanner in 16 cases (25%) and a surgical bone biopsy in 4 cases.

The BOM was positive in 21 cases (51.2%) showing a poorly or moderately differentiated adenocarcinoma or carcinoma. It allowed referral to a primitive in 20 cases: a prostatic origin in 11 cases, a pulmonary origin in 5 cases, a digestive origin in 2 cases, respectively. The onset of neurological damage was noted in 13.3% of the cases.

Conclusion: Thanks to improved sampling and immunohistochemistry techniques, the precise histological type and location of the primary tumor could be identified, thereby improving the quality of care for patients with increased life expectancy.

AB1034 DEPRESSION AND ANXIETY IN FAMILIAL MEDITERRANEAN FEVER

D. Karatas1, Z. Özünkılı1, D. Çekiç2, Z. Yuensever2, Ü. Erkorkmaz2, E. Gönültil1, 1Sakarya University, Internal Medicine/Rheumatology, Sakarya, Turkey; 2Sakarya University, Internal Medicine, Sakarya, Turkey; 3Sakarya University, Biostatistics Department, Sakarya, Turkey

Background: Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disease characterized by recurrent attacks of fever, peritonitis, pleuritis, arthritis, and skin eruption (1). It is shown by studies that chronic diseases like diabetes mellitus, chronic heart disease, hypertension which other than inflammatory – rheumatologic disease increase depression and anxiety (2). There are a few studies evaluating depression and anxiety in FMF patients, and these results are conflicting (3,4).
Objectives: To assess the frequency of depression and anxiety in patients with Familial Mediterranean Fever (FMF).

Methods: In this study, 77 FMF patients aged 18 and over who were followed up in Sakarya University Education and Research Hospital, Department of Rheumatology, and 78 healthy volunteers aged 18 and over as the control group. Beck depression scale and Beck anxiety scale were used to detect depression and anxiety, respectively. Beck’s depression scale was evaluated as 9 and below normal, 10-16 mild depression, 17-29 moderate depression, 30-63 severe depression. Beck anxiety scale was evaluated as 0-8 normal, 8-15 mild anxiety, 16-25 moderate anxiety, 26 and above severe anxiety. FMF disease severity was determined by Pras scoring.

Results: The study group, comprised 77 diagnosed with FMF with a mean age of 37.18 and a control group comprised of 78 healthy controls (C) with a mean age of 35.32 (p=0.058). In study group (P) %63.6, control group (C) %53.8 as female. %36.4 of the study group, %46.2 of the control group are male (p=0.216). The prevalence of depression was significantly higher in FMF patients compared to the control group (in order P:C normal %24.7, %47.4; mild depression: %40.3; %26.9, moderate depression %19.2, severe depression %11.7; %6.4 p<0.015). Similarly in depression results, the prevalence of anxiety was significantly higher in FMF patients compared to the control group (in order P:C normal %23.4; %57.7, mild anxiety %20.5; %15.4, severe anxiety %24.4; %4.4 p<0.001). Depression status was not correlated with FMF disease severity (p=0.645). A correlation was found between FMF severity and anxiety which it was which is found statistically significant (p<0.005). There was no relationship between erythrocyte sedimentation rate and C-reactive protein.

Conclusion: Both anxiety and depression frequency are increased in FMF patients compared to healthy controls.

INTESTINAL MICROBIOTA COMPOSITION OF ADULT PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER AND HEALTHY CONTROLS (THE RHEUMA-BIOTA STUDY)

N. S. Yasar Bilge1, V. Perez Brocal2, T. Kasıbolu1, U. Bilge3, N. Kasıfoglu4, A. Moya5, E. O. Dineiciy1, Eskeşir Osmangazi University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Eskeşir, Turkey; 2Fundación para el Fomento de la Investigación Sanitaria y Biomédica de la Comunitat Valenciana, Valencia, Spain; 3Eskeşir Osmangazi University Faculty of Medicine, Department of Family Medicine, Eskeşir, Turkey; 4Eskeşir Osmangazi University Faculty of Medicine, Department of Microbiology, Eskeşir, Turkey; 5Integrative Systems Biology Institute (12Sysbio), University of Valencia and Spanish Research Council (CSIC), Valencia, Spain; 6Foundation for the Promotion of Sanitary and Biomedical Research of Valencian Community (FISABIO), Valencia, Spain; 7Eskeşir Osmangazi University Faculty of Medicine, Department of Pediatrics, Eskeşir, Turkey

Background: Although Familial Mediterranean Fever (FMF) is a monogenic disease, microbiota composition may play role in the pathogenesis or phenotypic expression.

Objectives: We aim to evaluate the intestinal microbiota composition in patients with FMF and to compare with healthy controls.

Methods: In this prospective cohort study, a group of 10 adult patients with FMF and 10 age-appropriate healthy controls, for which there was strict inclusion/exclusion, were enrolled. Fecal samples were stored at -80°C until DNA extraction. A region of the 16S rRNA gene (V3-V4) was selected and sequencing was performed on the Illumina MiSeq platform at the Sequencing and Bioinformatics Service of FISABIO foundation.

Results: Alpha and beta diversity tests were similar between FMF and control groups except that Chao1 index. Chao1 index was modestly decreased in FMF group comparing the healthy controls (p<0.05). Our results showed differences in the intestinal microbiota composition of patients with FMF, with a higher abundance of Eggerthella, at genus level. At species level, Eggerthella sinensis and Eggerthella lenta were more abundant in patients with FMF.

Conclusion: Eggerthella lenta was previously shown to be higher in type II diabetes, multiple sclerosis, rheumatoid arthritis and some disseminated infections. In this study we firstly showed abundance of Eggerthella in patients with FMF, especially in E. sinensis and E. lenta; in addition to whether any of observed associations are causal, or the direction of causality is unclear yet and further studies with patients with FMF at the first diagnosis might clarify this issue.

CLINICAL MANIFESTATIONS, CLINICAL COURSE, AND OUTCOMES OF IMMUNOGLOBULIN G4 RELATED DISEASE

W. Katchamart1, K. Phaopraphat2, P. Ngamjanyapol3, P. Narongroeknavin4, N. Kasitanon5, Division of Rheumatology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, Bangkok, Thailand; 2Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, Bangkok, Thailand; 3Division of Rheumatology, Department of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, Bangkok, Thailand; 4Division of Rheumatology, Department of Medicine, Faculty of Medicine Phramongkutklao Hospital, Phramongkutklao College of Medicine, Bangkok, Thailand, Bangkok, Thailand; 5Division of Rheumatology, Department of Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, Chiang Mai, Thailand

Background: Immunoglobulin G4 related disease (IgG4-RD) is an uncommon chronic systemic autoimmune disease, pathologically characterized by lymphoplasma cell, IgG4 plasma cell or storiform fibrosis infiltration with elevated serum IgG4 level. IgG4-RD is a new disease and not widely recognized.

Objectives: The aim of this study was to describe clinical manifestations and outcomes of IgG4-RD in Thai patients.

Methods: This multicenter retrospective cohort study included patients who aged ≥ 18 years and were diagnosed with IgG4-RD according to 2011 comprehensive or consensus diagnostic criteria, between 2000 and 2019 in four academic centers in Thailand. Baseline characteristic, laboratory and pathologic findings, treatments, and outcomes were systematically collected.

Results: Of the 110 patients included, 71% were male with mean age (SD) of 59.6 (13.3) years and median disease duration (IQR) of 28.8 (14.6-53.5) months. Single organ involvement was observed in 60 patients (54.5%). The most common presenting organ involvement was the orbit (29%), followed by the salivary glands (19%), lacrimal glands (18%), bile duct (16%), and pancreas (11%). The most frequently affected organs were the orbits (34%), followed by the salivary glands (26%), lacrimal glands (26%), bile duct (16%), and lymph nodes (19%). Ninety-six percent (96%) had IgG4 level of more than 135 mg/dl at presentation. Most patients (92%) were treated with corticosteroid (CS) alone or in combination immunosuppressive agents. Azathioprine (47%) and methotrexate (11%) were the most commonly used immunosuppressive agents. Additionally, 20% required surgery, and 6.4% underwent stent insertion. One-fourth (26%) were in remission with successfully CS tapering, while 37% and 29% had complete, and partial response. Nevertheless, 22% relapse with median time to relapse (IOR) of 2.22 (12.8-41.1) months. Relapse was common in patients with orbital (p = 0.001) and lung (p = 0.007) involvement, and patients with longer disease duration (median 44.1 and 23.1 months, P=0.001), while serum IgG4 level was insignificantly higher in relapse group (median 1.085 vs. 0.850 mg/dL, p=0.28).

Conclusion: IgG4-RD is a chronic systemic autoimmune disease with diverse manifestations, response to treatment, and outcomes. Most patients responded well to CS and immunosuppressive agents with notable relapse rate, while minority required surgery or mechanical intervention.

CANAKINUMAB FOR TREATMENT OF ADULT ONSET STILL’S DISEASE:RESULTS OF THE 24 WEEKS TREATMENT AND BEYOND: A MULTI-CENTRE, PLACEBO-CONTROLLED STUDY (CONSIDER)

C. Kedir1, J. Listing2, J. Zernicke1, A. Weilb3, F. Behrens4, N. Blank4, J. Hennes5, J. Kekow6, A. Rubbert-Roth6, H. Schulze-Koops7, E. Seipel8, C. Specker9

None declared
Background: Inhibition of interleukin-1 (IL-1) represents a promising treatment option in adult-onset Still's disease (AOSD). Canakinumab is approved for treatment of systemic juvenile idiopathic arthritis and has a marked impact on systemic as well as articular activity of the disease.

Objectives: To investigate the efficacy and safety of canakinumab in patients with AOSD and active joint involvement by means of a multi-centre, double-blinded, randomized, placebo controlled trial over a period of 24 weeks with the option of a long-term extension.

Methods: Patients with AOSD and active joint involvement (tender and swollen joint count ≥4 each) were stratified by pre-treatment status with biologic AOSD and active joint involvement by means of a multi-centre, double-blinded, randomized, placebo controlled trial over a period of 24 weeks with the option of a long-term extension.

Results: At enrollment, patients had high active disease with a mean active disease score (CRP, ESR) of 40 (SD=15, range 10-70) and 34 (SD=14, range 10-65) in the canakinumab group and 50 (SD=15, range 10-70) and 45 (SD=12, range 10-65) in the placebo group (p=0.18). Figure 2 shows the DAS28-ESR disease activity by treatment groups and visits with imputation. In the per-protocol analysis, significantly higher disease activity at week 12 as determined by the change in disease activity score (ΔDAS28 >12).

Conclusion: Although the study was terminated prematurely and the primary endpoint was not achieved, treatment with canakinumab led to an improvement of several outcome measures in AOSD. The overall safety findings were consistent with the known profile of canakinumab. Thus, our data support indication for L1 inhibition with canakinumab in AOSD.

AB1038 INFLAMMATORY ORBITAL DISEASES: THE EXPERIENCE OF A TERTIARY RHEUMATOLOGY CENTRE

M. S. Aksu1, T. K. Sahin1, E. C. Bolek2, L. Kulc3, E. G. Bulur3, K. K. Oğulu3, U. Kalyoncu2, O. Karadag1.1Hacettepe University, Division of Rheumatology, Ankara, Turkey; 2Hacettepe University, Department of Internal Medicine, Ankara, Turkey; 3Hacettepe University, Department of Radiology, Ankara, Turkey

Background: Inflammatory lesions of orbital disease encompass a wide spectrum of clinical entities including rheumatic disorders.

Objectives: To describe our experiences in adult patients who applied to a tertiary rheumatology center due to orbital disease.

Methods: This is a retrospective descriptive study and data were extracted from patient’s charts. We described the clinical, laboratory, radiologic, histopathological presentations and final diagnoses of patients with inflammatory orbital disease who applied to our rheumatology clinic between January 2014 and December 2019.

Results: Thirty-eight patients (Female: 63.2%) were identified; median age at onset of orbital symptoms was 44.5 (min.-max: 5-72) years. Swelling (57.3%) and orbital pain (47.4%) were the most common symptoms, followed by erythema (13.2%), vision loss (13.2%), proptosis (7.9%) and diplopia (%7.9). Table summarizes the demographic and clinical characteristics of the patients. Imaging (MRG) was performed in all patients and 63.2% had an orbital biopsy. Orbital imaging revealed extracocular muscles (71.1%), lacrimal glands (50.0%) and optic nerve (42.1%) involvement. Of patients 34.2% had bilateral and 18.4% had retroorbital involvement. The final diagnoses of patients were: LG4-related disease (34.2%, n = 13), idiopathic orbital inflammatory pseudotumor (36.8%, n = 14), granulomatosis with polyangiitis (18.4%, n = 7), Sjögren’s syndrome (n=1), relapsing polychondritis (n=1), thyroid-associated orbitopathy (n=1) and fungal granulomatous angiitis (n=1).

Conclusion: Inflammatory lesions of the orbit are rare and the diagnosis may be challenging. Differential diagnosis is based on clinical, laboratory, radiologic and histopathologic findings. Although LG4-related disease is a relatively new diagnostic cause for orbital inflammation, it should be considered more in different diagnostic.

AB1039  LL-37, IL-36, GALECTIN-3 AND TLR-3 LEVELS IN IDIOPATHIC GRANULOMATOUS MASTITIS

U. Aydin1, B. Oz2, A. Karataş2, M. Gur2, R. Piskin Sagi3, G. Artsas1, S. Aydin4, S. S. Köca2, 1Firat University, Rheumatology, Elazig, Turkey; 2Firat University, Rheumatology, Elazig, Turkey; 3Firat University, Pathology, Elazig, Turkey; 4Firat University, Biochemistry and Clinical Biochemistry (Firat Hormones Research Group), Elazig, Turkey

Background: Idiopathic granulomatous mastitis (IGM) is a non-infectious inflammatory disorder of the breast characterized by non-caseous granulomas. It is a chronic granulomatous inflammatory disease frequently seen in young fertile women, the cause of which has not been clearly understood. Immunosuppressive agents and surgical interventions are used in the treatment.

LL-37 is a cathelicidin-derived antimicrobial peptide with immunomodulatory properties that are effective in innate immunity. In addition, IL-36, galectin-3, TLR-3 are effective in autoimmunity with proinflammatory properties.

Objectives: With this study, we aimed to investigate the potential alterations of LL-37, IL-36, galectin-3, TLR-3 levels in IGM.

Methods: 35 female patients with biopsy-confirmed IGM and 35 healthy controls were included in the study. The serum samples of the subjects LL-37, IL-36, Galectin-3 and TLR-3 levels were studied using the ELISA method. While studying LL-37 and Galectin 3 levels in the tissue, samples of 10 patients who underwent mammoplasty for cosmetic reasons were used for the control group. Ten patients whose paraffin blocks were eligible for re-study were included in the study for tissue examinations.

Based on the prevalence (0.1: %<25, -0.4: %26-50, 0.6: %51-75, 0.9: %76-100) and severity (0:no, +0.5: very little, +1: little, +2: medium, +3: severe) of immunoreactivity in staining, histoscore was created (histoscores = prevalence x severity). The data were evaluated using appropriate statistical analysis and p <0.05 was considered statistically significant.

Results: When the patient and control groups included in the study were compared, there was no significant difference in age. In serum samples, LL-37, IL-36, Galectin 3 and TLR-3 levels were statistically significantly lower in IGM group compared to the control group (p <0.001 for each) (Table-1). In biopsy samples, LL-37 level was found to be significantly lower in IGM group compared to the control group (p <0.001). However, no significant difference was detected in Galectin 3 levels in tissue studies (Table-2).

Conclusion: In our study, we found that the levels of LL-37, IL-36, Galectin 3 and TLR-3 decreased in serum samples in IGM disease whose etiology was not clearly understood. In addition, we showed that in patients with IGM, LL-37 levels decreased at the tissue level. Studies have shown that in cases of severe sarcoidosis, LL-37 deficiency is reduced both in level and gene expression. So they thought, deficiency of cathelicidin LL 37 may impede resolution of inflammation in the tissue of patients with severe form disease.

F: Female, F1: Family 1, F2: Family 2; DD: Demyelination disease; MS: Multiple sclerosis; MRI: Magnetic resonance imaging; OB: Oligoclonal band; LP: Lumbar punction
Background: In the course of familial Mediterranean fever (FMF), the frequency of other inflammatory diseases increases compared to the general population. Multiple sclerosis (MS) or demyelinating diseases (DD) of central nervous system (CNS) are also more common in FMF patients than in the general population.

Objectives: In this study, we would like to report 5 cases with MS/DD accompanied by FMF or MEFV mutations in two families.

Methods: 4 patients with FMF and 1 patient with MEFV mutation were included in this study. The patients with FMF were diagnosed according to Tell-Hashomer clinical criteria for FMF. The diagnosis of MS was made according to McDonald criteria.

Results: The clinical features of the patients were shown in Table 1. The patients with FMF were diagnosed according to Tell-Hashomer clinical criteria for FMF or MEFV mutations in two families.

AB1041 BIOLOGICS IN ADULT’S ONSET STILL’S DISEASE: TREATMENT STRATEGIES AND SAFETY IN SINGLE CENTER COHORT WITH LONG-TERM FOLLOW-UP

N. Koukias1, N. AvgUSTIDIS1, S. Pitsigavdaki1, K. Pateromichelaki1, A. Repa1, A. Molla Ismail Sali1, A. E. Dolzhenkova3, N. Politova4, E. Zaytseva1, D. Kudinskiy2, L. Blank2, A. Kuzin1, A. Smirnov2, E. Zaytseva1, D. Kudinskiy2, L. Blank2, A. Kuzin1, A. Smirnov2, E. Zaytseva1, D. Kudinskiy2, L. Blank2

Background: Adult-onset Still’s disease (AOSD) is a rare systemic inflammatory disorder. In recent years biological disease modifying antirheumatic drugs (bDMARDs) are becoming increasingly important for its treatment.

Objectives: To evaluate disease outcomes, treatment strategies and their long-term safety in a cohort of AOSD patients treated with bDMARDs.

Methods: A single-center retrospective study of patients diagnosed with AOSD until 2019 was conducted. Patients were included if they: a) were 16 years old or older, b) met the Yamaguchi criteria and c) had received a bDMARD.

Results: Sixteen patients with AOSD (Table 1) refractory to cDMARDs were administrated biologics. The median duration of follow-up was 14 years (range 1-24). Consistent with recent literature, two distinct disease patterns were recognized: the systemic form (SF) and the chronic articular form (CAF). In the SF the leading clinical symptoms were fever, pericarditis and pleuritis. In CAF the leading clinical symptom was persistent RA-like arthritis.

References:

Objective: To assess the bone mineral density (BMD) of the skeleton using the Hologic Discovery A DXA, determine the frequency of low-energy skeletal bone fractures among adult patients with alkaptonuria (AKU), and idenditively factors that affect the occurrence of fractures.

Methods: AKU is a rare genetic disease (1 case per 250,000) which occur to severe damage to the spine and large joints. Serious problem in this category of patients is a decrease in BMD. The study included 40 patients with a reliable diagnosis of AKU (23 men and 17 women) aged from 33 to 78 years (mean 60.32±9.1). Density of the lumbar spine was performed in 40 patients; of the forearm bones in 34 patients; of the proximal femur in 32 patients (8 patients were not examined due to bilateral hip joint replacement).

Results: Normal values of spinal BMD were found in 26 patients (65%), osteopenia – in 12 (30%) and osteoporosis – in 2 (5%) patients. In the proximal parts of the femur, osteoporosis was detected in 12 patients (30%), osteopenia in 13 (32.5%), and normal in 7 (17.5%) patients. In the bones of the forearm,
osteoporosis was found in 22 patients (55%), osteopenia – in 8 (20%), and norm – in 4 (10%) patients. The BMD values (g/cm²) in the group were as follows:

<table>
<thead>
<tr>
<th></th>
<th>N</th>
<th>Mean</th>
<th>25th</th>
<th>75th</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMD L1-L4</td>

<td>0.43</td>
<td>0.54</td>
</tr>
</tbody>
</table>

Peripheral bone fractures were diagnosed in 15 (32.6%) patients – 9 men and 6 women; 25 (62.5%) patients had no fractures. For the first time, fractures were reported in patients aged from 33 to 69 years (mean 55.9±9.5). The localization of fractures was as follows: femur – in 8 patients (20%), forearm – in 6 (15%), shin bones – in 1 (2.5%) patients. Despite lower BMD rates in women, there were no significant differences in the frequency of fractures depending on sex. Correlation analysis (for Spearman) showed the relationship of fractures with age (r=−0.31, p<0.05), femur BMD in general (r=−0.53, p<0.01) and forearm BMD (r=−0.44, p<0.01).

Conclusion: There is a high incidence of osteoporosis, mainly in the proximal femur and forearm in patients of the older age group with AKU. In the lumbar spine (due to the development of calcification of the intervertebral discs and ligamentous apparatus), osteoporosis is rarely detected, but the frequency of osteoporosis is quite high. 32.6% of patients had a history of skeletal bone fractures, and the sex of the patients did not affect the risk of fractures. The occurrence of fractures in patients with AKU is associated with low BMD values of the proximal femur.

AB1043 AWARENESS OF THYROID EYE DISEASE, AN AUTOIMMUNE CONDITION, AMONG RHEUMATOLOGISTS

B. Lamoreaux1, M. Francis-Sedlak1, R. Holt1, J. Rosenbaum2. 1Horizon Therapeutics, Lake Forest, United States of America; 2Oregon Health & Science University, Ophthalmology, Portland, United States of America

Background: Autoimmune inflammatory conditions of the eye may be associated with rheumatic diseases such as rheumatoid arthritis, systemic lupus erythematosus, and granulomatosis with polyangiitis. This is also observed with thyroid eye disease (TED). Loss of immune tolerance to the thyroid stimulating hormone receptor has thyroidal consequences and nearly 40% of patients with thyroid eye disease (TED). Loss of immune tolerance to the thyroid stimulating hormone receptor has thyroidal consequences and nearly 40% of patients with thyroid eye disease (TED). Loss of immune tolerance to the thyroid stimulating hormone receptor has thyroidal consequences and nearly 40% of patients with thyroid eye disease (TED). Loss of immune tolerance to the thyroid stimulating hormone receptor has thyroidal consequences and nearly 40% of patients with thyroid eye disease (TED).

Objective: To describe demographic, clinical and immunological features of a series of patients with ruphus syndrome and to compare them with previously reported series in the literature.

Methods: Review of clinical records of patients attended in a Tertiary Care Rheumatology Unit that fulfill classification criteria for RA (either ACR 1987 or ACR/EULAR 2010) and SLE (either ACR 1997 or SLICC 2012). In addition, a manual search of patients with positivity for both anti-CCP (defined as >3 U/mL) and specific SLE antibodies (either anti-DNA DAs by IIF or anti-Sm by multiplex assay) was conducted. We excluded patients with known mixed connective tissue disease, drug-induced SLE as well as RA patients with anti-DNA DAs or anti-Sm without clinical features of SLE.

Results: We identified 8 patients, all of them women (4 of Latin American origin, 3 Caucasians and 1 Arab) with a mean age at diagnosis of 35 years (range: 19-63 years) and a mean duration of disease of 9 years (+10.5 years). RA and SLE were diagnosed simultaneously in 50% of cases (37.5% onset as RA and 12.5% as SLE, being the mean time between both diagnoses of 16.5 months in those cases). Immunological features of patients are summarized in Table 1. An erosive form of arthritis is present in 37.5%. As extra-articular involvement, 75% have skin lesions (photosensitivity, malar rash, oral ulcers and alopecia as major features) and 100% haematological alterations with lymphopenia (37.5% thrombocytopenia). Serositis (37.5%), renal (25% biopsy proven lupus nephritis, 12.5% non-nephrotic proteinuria) and neurological (present only in one patient) involvement were less common findings. Most common therapies in our series were glucocorticoids (100% of cases, with a mean dose of 21.25 ± 13.5 mg/day at onset), antimalarials (87.5%) and methotrexate (87.5%). 50% of patients required biologic therapy (2 etanercept, 1 adalimumab, 1 rituximab) for inadequate disease control with conventional synthetic DMARDs.

Conclusion: Prevalence of erosive arthritis in our patients is lower than previously reported, though as a limitation an imaging technique with a higher sensitivity for erosion detection than simple X-ray (such as US or MRI) was not available. Moreover, our series sample is small considering the low prevalence of this entity. The proportion of patients with simultaneous diagnosis of both RA and SLE is also higher (with a shorter interval between both diagnoses when this is not the case), so it is the proportion of patients receiving biologic therapy.

AB1044 CLINICAL AND IMMUNOLOGICAL FEATURES OF A SERIES OF PATIENTS WITH RHUPHUS

F. Lozano Morillo1, T. Almoran1, P. Ravilla1, M. Retuerto-Guerrero1, B. A. Blanco Cáceres2. 1Hospital Universitario 12 de Octubre, Madrid, Spain; 2Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: Since its first description in 1971 by Schur, many authors have discussed whether ruphus is an overlap syndrome between RA and SLE, a particular form of SLE with prominent and frequently erosive joint involvement, or if it is a distinct clinical and immunological entity. There are several published case series in medical literature describing the features of that uncommon syndrome that constitutes about 0.01-2% of all systemic rheumatic diseases.

Objectives: To describe demographic, clinical and immunological features of a series of patients with ruphus syndrome and to compare them with previously reported series in the literature.

Methods: Review of clinical records of patients attended in a Tertiary Care Rheumatology Unit that fulfill classification criteria for RA (either ACR 1987 or ACR/EULAR 2010) and SLE (either ACR 1997 or SLICC 2012). In addition, a manual search of patients with positivity for both anti-CCP (defined as >3 U/mL) and specific SLE antibodies (either anti-DNA DAs by IIF or anti-Sm by multiplex assay) was conducted. We excluded patients with known mixed connective tissue disease, drug-induced SLE as well as RA patients with anti-DNA DAs or anti-Sm without clinical features of SLE.

Results: We identified 8 patients, all of them women (4 of Latin American origin, 3 Caucasians and 1 Arab) with a mean age at diagnosis of 35 years (range: 19-63 years) and a mean duration of disease of 9 years (+10.5 years). RA and SLE were diagnosed simultaneously in 50% of cases (37.5% onset as RA and 12.5% as SLE, being the mean time between both diagnoses of 16.5 months in those cases). Immunological features of patients are summarized in Table 1. An erosive form of arthritis is present in 37.5%. As extra-articular involvement, 75% have skin lesions (photosensitivity, malar rash, oral ulcers and alopecia as major features) and 100% haematological alterations with lymphopenia (37.5% thrombocytopenia). Conclusion: Prevalence of erosive arthritis in our patients is lower than previously reported, though as a limitation an imaging technique with a higher sensitivity for erosion detection than simple X-ray (such as US or MRI) was not available. Moreover, our series sample is small considering the low prevalence of this entity. The proportion of patients with simultaneous diagnosis of both RA and SLE is also higher (with a shorter interval between both diagnoses when this is not the case), so it is the proportion of patients receiving biologic therapy. The
rest of clinical and immunological features were similar to previously described in other series.

AB1045  CLINICAL, ANALYTICAL AND RADIOLOGICAL CHARACTERISTICS OF A COHORT OF PATIENTS WITH SARCOIDOSIS.

I. Madroñal García1, C. Aguilera Cros1, L. Mendez Diaz1. Hospital Universitario Virgen del Rocio, Reumatología, Sevilla, Spain

Background: Sarcoidosis is a systemic disease whose etiology is unknown. It is characterized by the formation of granulomas in any tissue of the organism. Ganglionic, pulmonary and cutaneous involvement is the most prevalent.

Objectives:
1. Describe clinical characteristics of a cohort of patients with sarcoidosis diagnosed.
2. Define the association between the ACE's number at diagnosis, radiological lung stage, treatment and course of disease.
3. Evaluate if the extrapulmonary involvement is related to the course of the disease.

Methods: Descriptive retrospective study of patients with S diagnosis treated in our Hospital in 2019. Data were obtained by reviewing medical records. Chi-square tests and parametric tests have been used to establish the differences described in the objectives.

Results: 102 patients diagnosed with sarcoidosis have been included, (51% females) with an average age of 56±11 years. Suspected diagnosis at the onset of disease was in 70.6% of patients, followed by suspected lymphoma (20.6%).

The average time for the definitive diagnosis of S was 9.5 months. 70.6% of the patients had elevated ACE titles at the beginning. Regarding the clinical manifestations, 18.6% of the patients presented fever at the beginning and 66.7% extrathoracic clinical manifestations. 72.5% have lymph node adenopathies, and in 91% there is thoracic involvement (the most frequent pulmonary stage is stage II).

A biopsy was performed in 84.3% of the patients, the lung biopsy being the most performed (52.3%). 88.2% of patients received corticosteroid treatment at the onset of the disease (currently under treatment with corticosteroids 37.3%).

61.1% had fever at the onset of the disease.

14 patients (77.8%) had high ACE values at the onset of the disease, without presenting significant differences with respect to all patients diagnosed with S who do not have joint involvement.

All patients received treatment with C and 10 patients (55.5%) needed an IS treatment, finding no differences with respect to patients who do not have joint involvement (p=0.92).

On the course of the disease, the majority of patients with joint involvement have a chronic course (72.2%). Nor were significant differences found when compared with patients who have no joint involvement (p = 0.73).

Conclusions: Patients with joint involvement in our study have been 175% (18%), an approximate result to that described in the literature (over 10%), although our result may be increased by the fact that the patients who are followed in Rheumatology present or have presented joint involvement. No significant differences were found between patients with S who presented joint involvement and those who did not, with respect to the initial ACE values, treatment and disease course.

AB1047  IGGM-RELATED DISEASE PRESENTATION REQUIRES ADMISSION TO THE EMERGENCY DEPARTMENT IN THE MAJORITY OF CASES

G. Mancuso1,2, E. Della Torre1,2, M. Lanzillotta1,2, G. A. Ramirez1,2, D. Dagnal1,2, 1Università Vita-Salute San Raffaele, Milano, Italy; 2San Rafael Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy

Background: IgG4-related disease (IgG4-RD) is generally considered a chronic fibro-inflammatory condition with insidious presentation and subclinical course. Our clinical experience, however, suggests that a sizable proportion of patients experience multiple accesses to the emergency department (ED), either at disease onset or during the disease course.

Objectives: To compare the clinical, analytical and radiological characteristics of patients presenting to the ED at disease onset or during the disease course.

Methods: We revised our database and identified patients admitted to the ED because of symptoms late attributed to IgG4-RD onset (Group 1) and those that were referred to our outpatient clinic without previous urgent manifestations (Group 2). Acute manifestations were clustered based on the anatomical district affected by IgG4-RD. Epidemiological, clinical, and serological features of Group 1 and Group 2 were compared.

Results: The study included 141 patients with IgG4-RD. 76 (54%) presented to the ED at disease onset. The most common clinical manifestations requiring admission to the ED were jaundice (53%), abdominal pain (41%), and fever (10%). Gastrointestinal involvement was the most frequent cause of referral to the ED (71% of cases), followed by involvement of the retroperitoneum (14.5%), and of the nervous system (6.6%). Pancreato-biliary involvement was significantly more frequent in Group 1. Head, neck, salivary and lacrimal gland involvement was more frequent in Group 2. The diagnostic delay was significantly shorter in Group 1 than in Group 2.

Conclusion: Clinical manifestations associated with IgG4-RD onset require referral to the ED in the majority of cases. This finding contrasts with the general view of IgG4-RD as a condition with non-acute presentation.

AB1048 RHUPUS SYNDROME IN A TERTIARY HOSPITAL
I. Martínez Cordellat1, R. González Mazario1, M. de la Rubia Navarro1, C. Pérez Perales1, S. Leal Rodríguez1, J. Ivorra Cortés1, I. Cánovas Olmos1, J. A. Román Ivorra1.

Background: Rhupus syndrome (RhS) is a rare combination of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Different studies describe RhS cases that begin with erosive arthritis and the presence of rheumatoid factor (RF) and/or anti CCP and then the SLE symptoms.

Objectives: Despite the fact that RhS shows a low prevalence, it would be useful to know clinical characteristics of RhS patients since their therapy and outcome differ from those having RA or SLE alone.

Methods: Retrospective study with systematic revision of electronic clinical records of RhS patients was performed. Demographic, clinical and immunological data were collected.

Results: Eight RhS patients were included (all fulfilled SLICC 2012 criteria for SLE and ACR 2010 for RA). Mean age was 67.3 (45-84) years (7 were female). In 3 cases RA was the first diagnosis with a mean evolution of 4.5 years until SLE diagnosis. In contrast, in 5 cases SLE was the first diagnosis with a mean evolution of 72 years until RA diagnosis. Photosensitivity and arthritis were the predominant clinical manifestations. One patient presented pericarditis and other case showed rheumatoid nodules in elbows. Renal, pulmonary or neurological affection was not reported.

4 patients were under biological/UKJ inhibitors therapies (2 abatacept, 1 rituximab and 1 baricitinib) with favorable response of treatment.

Conclusion: In contrast to other series, only the 37.5% of our RhS cases begins with polyarticular seropositive arthritis. The 62.5% started with SLE symptoms as haematological alterations, cutaneous and serological manifestation, and showed longer progression to have polyarticular affection. Thus, RhS diagnosis is earlier in patients that begin with RA symptoms. 4 RhS patients were refractory to DMARDs treatments, where biological/UKJ inhibitors therapies are needed.

AB1050 CLINICAL IMPLICATIONS OF ULTRASONOGRAPHY (US) IN DIAGNOSIS AND MONITORING DISEASE ACTIVITY OF RELAPSING POLYCHONDritis (RP) AND COMPARATIVE INVESTIGATION BY US BETWEEN AURICLE OF RP, REPEATED TRAUMA, CELLULITIS AND HEALTHY SUBJECT
H. Nishikawa1, Y. Taniguchi1, M. Ogawasara2, I. Inotani1, E. Amano1, T. Matsumoto1, K. Hamada-Ode1, Y. Shimamura, T. Horino1, S. Fujimoto1, Y. Terada1.

1Kochi Medical School Hospital, Nankoku, Japan

Objectives: To assess the clinical implications of ultrasonography (US) in monitoring disease activity and diagnosis of relapsing polychondritis (RP).

Methods: Firstly, auricular (n=5) and nasal (n=1) chondritis of six patients with RP were assessed by US before and after treatments. The relationship between US findings and serum markers were evaluated. Moreover, the comparisons of US findings between the auricle of patients with RP (n=5), cellulitis (n=2) and healthy subjects (n=5) were also assessed.

Results: US finding before treatment showed low-echoic swollen auricular and nasal cartilage with increased power Doppler signals (PDS) in all cases of RP. US finding remained in 1 of 6 cases, and this case showed flare due to PDS. In contrast, disturbances of US findings were observed in 1 of 4 cases of cellulitis.

Conclusion: Ultrasound of auricular and nasal cartilage before treatment showed new sparing drugs.

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2020-eular.998
Background: Kikuchi-Fujimoto disease (KFD) is a rare entity characterized by adenopathies and fever. It raises a broad differential diagnosis that includes lymphoproliferative disorders, infections and systemic autoimmune diseases, and diagnostic confirmation is always by histology, which shows histiocytic necrotizing lymphadenitis. Although its course is generally benign and self-limited, it can be associated both at the time of diagnosis and during follow-up with systemic autoimmune diseases, the most frequent of which is systemic lupus erythematosus (SLE).

Objectives: To describe the clinical and analytical characteristics of patients diagnosed with KFD and the development of systemic autoimmune disease.

Methods: Patients diagnosed with KFD during the 1990s and 2020s are collected in a regional hospital (Granollers General Hospital). The clinic is documented at the diagnosis of EKF, the appearance of systemic autoimmune disease during follow-up and its clinical and analytical characteristics.

Results: A total of 7 patients with EKF were diagnosed. All of them women with a mean age at diagnosis of 30 years. Diagnosis was made in all cases with compatible clinical symptoms, fever and lymphadenopathy, and lymph node biopsy confirming histiocytic necrotizing lymphadenitis. At the time of diagnosis, a patient was also diagnosed with SLE. During the follow-up, 4 of the 6 remaining patients developed clinical manifestations compatible with SLE (3 of them with systemic manifestations and a case of subacute cutaneous lupus). The mean time of onset of SLE was 34 months (between 6 months and 5 years). All of them received treatment with hydroxychloroquine, with good response to treatment. The clinical and analytical characteristics are presented in Table 1 below.

Conclusion: In our center, 5 of the 7 patients (71%) diagnosed with EKF developed manifestations compatible with SLE. The importance of the diagnosis of EKF lies precisely in the possible association with systemic autoimmune disease, the most common being SLE, so it is recommended that patients be monitored to identify those who develop associated autoimmune disease.

AB1052  EVALUATION OF SYMPTOMS, DEPRESSION AND ANXIETY LEVELS IN YOUNG WOMEN WITH IDIOPATHIC GRANULOMATOUS MASTITIS

D. Yalcin Kehribar1, T. Izci Duran1, M. Ozgen1. 1Medical School, Internal Medicine, Samsun, Turkey; 2Medical School, Division of Rheumatology, Department of Internal Medicine, Samsun, Turkey

Background: Idiopathic granulomatous mastitis (IGM) is a rare, chronic, inflammatory disease of the breast characterized by lobulocentric granulomas, and diagnostic and therapeutic procedures are challenging for patients [1]. Gc-corticoids, immunosuppressive drugs, surgical and conservative treatment are used for the treatment of the disease [2]. These patients have many risk factors for delayed wound healing after surgical intervention, fistula formation, secondary infection and frequent postoperative recurrence for anxiety and depression [3].

Objectives: The aim of this study was to investigate the anxiety and depression levels and influential effects of clinical and sociodemographic characteristics of patients with IGM.

Methods: 32 female patients enrolled to the study and who diagnosed as histopathologically proven IGM were included in this study. The sociodemographic and clinical characteristics of the patients were recorded and Beck depression inventory as well as health anxiety inventory were applied to the patients. In the same period, a control group consisting of age and sex matched people without any chronic disease was formed from health employees and their relatives. Correlation and logistic regression analyzes were performed between clinical and sociodemographic characteristics and scale scores.

Results: A total of 32 patients and 32 age and sex matched volunteers were included in the study. A significant difference was found between the Beck depression inventory and health anxiety inventory scores between the patient and control groups. There was a strong correlation between breast mass size and Beck depression inventory (r: 0.83, p: 0.01), in addition moderate correlation was found between breast mass size and health anxiety (r: 0.39, p: 0.05). In the logistic regression model (χ2: 12.274, R2: 0.469, p: 0.01) created by the retrospective elimination method, presentation with fistula (OR: 9.24), bilateral lesion (OR: 7.25) and disease duration (for each month OR:1.29) were found to be significant.

Conclusion: Studies show that patients with IGM experience severe anxiety and have a high risk of developing depression [4], similar in breast cancer even though the method and assessment tools are different than breast cancer. In this study, it was determined that IGM increases anxiety and depression levels in young female patients during both diagnosis and treatment. For this reason, it is thought that psychosocial evaluation of patients from the time of diagnosis, referring them to psychiatric treatment if necessary may improve the quality of life of the patients.

AB1053  EFFECTIVENESS OF METHOTREXATE IN IDIOPATHIC GRANULOMATOUS MASTITIS TREATMENT

D. Yalcin Kehribar1, T. Izci Duran1, A. Kamali Polat1, M. Ozgen2. 1Medical School, Internal Medicine, Samsun, Turkey; 2Medical School, Division of Rheumatology, Department of Internal Medicine, Samsun, Turkey

Background: Idiopathic granulomatous mastitis (IGM) is a rare inflammatory disease of the breast [1], for which there is a lack of consensus on the treatment protocol [2, 3]; it requires long-term follow-up and is associated with a high rate of relapse after surgical treatment. In this study, we report on the largest single-center cohort of idiopathic granulomatous mastitis treated with steroids + methotrexate.

Objectives: We present this study believing that our experience with patients with IGM and use of steroid + methotrexate treatment in them will contribute to the literature.

Methods: We retrospectively examined the data of 33 patients histopathologically diagnosed with idiopathic granulomatous mastitis who were evaluated by our Rheumatology or General Surgery Clinics between 2013 and 2016.

Results: Of the 33 female patients (age: 38.64 ± 6.9 years), 24 were admitted with an initial diagnosis of Idiopathic granulomatous mastitis, whereas 9 were admitted after surgical treatment. The breast symptoms and laboratory values of the patients before and after the steroid and methotrexate treatment are shown in Table 1. Remission was achieved in 87.9% patients with steroid + methotrexate treatment, and there were no relapses during the 24-month follow-up.
Regarding laboratory tests, 46.4% (13/28) of patients presented acute phase reactants, 13% (3/23) had positive serum antibodies and 41.6% (5/12) were HLA-B27 positive. Concerning treatment, 76.3% of patients required systemic corticosteroids (29/38) and 75% received at least one immunosuppressive drug (30/40). Out of this group, 30% needed a second immunosuppressive drug. Response to treatment was good in 63.6% of patients (21/33), partial in 18.1% (6/33), poor despite treatment in 6% (2/33) and poor due to lack of adherence in 12.1% (4/33).

Conclusion: In our cohort, there was a predominance of female, middle-aged patients with bilateral involvement. Anterior uveitis was the most frequent diagnosis. In one-third of patients, the first episode of uveitis led to diagnosis of a systemic disease. Most of our patients presented some type of sequel or local complication and required systemic treatment with corticosteroids and immunosuppressants.

CERTOLIZUMAB PEGOL: A SAFE AND EFFICIENT TREATMENT IN PATIENTS WITH UVEITIS DURING PREGNANCY.

1Marques de Valdecilla University Hospital, Santander, Spain; 2Hospital Clinic, Barcelona, Spain; 3Donostia, San Sebastián, Spain; 4Hospit de Sant History, Vitoria-Gasteiz, Spain; 5Héidz, Mérida, Spain; 6Galdakako, Vizcaya, Spain; 7Hò Hortega, Valladolid, Spain; 8Elche, Alicante, Spain; 9Badajoz, Badajoz, Spain; 10Cabueles, Guión, Spain; 11Castellón, Castellón, Spain; 12Río Carrion, Palencia, Spain; 13León, León, Spain; 14Miguel Servet, Zaragoza, Spain; 15La Princesa, Madrid, Spain

Background: Anti-TNFα agents are useful in uveitis (1-5). Certolizumab pegol (CZP) differs from other anti-TNFα agents due to its limited placental transfer.

Objectives: To assess efficacy and safety of CZP in women with uveitis during pregnancy.

Methods: Multicenter study of women with uveitis under CZP during pregnancy and their neonates.

Results: 14 women (23 eyes); mean age 34.3±5.5 yrs (TABLE 1). Pattern of infections: 4 maternal (3 vaginal, 1 urinary); 11 neonatal (9 lower respiratory, 2 meningitis); 1 conjunctival. Infection rates were 41% (5/12) at 6 months (p=0.03), leading to complete discontinuation in 4. All patients obtained or maintained ocular remission throughout pregnancy.

Conclusion: Certolizumab pegol is safe and effective in women with uveitis during pregnancy.

**SYMPTOMATIC SCLEROSING MENINGITIS REVEALING ERDHEIM-CHESTER DISEASE: A RARE CONDITION MEDIATED BY BRAF**

J. Razanamahery¹, S. Humbert², A. Malakhia³, J. F. Emile³, F. Cohen³, J. Haroche⁴

1 Besancon University Hospital, Internal Medicine Department, Besancon, France; 2 Besancon University Hospital, Besancon, France; 3 Besancon University Hospital, Besancon, France; 4 Ambroise Paré Hospital, Paris, France; 5 Internal Medicine Department 2, Paris, France

**Background:** Sclerosing Mesenteritis (SM) refers to an entire spectrum of digestive inflammatory disorders. Diagnosis is based on imaging showing an increase of fat attenuation displacing bowel loops and is in most cases non-inflammatory. Several conditions (abdominal trauma/surgery, neoplasia, infectious and inflammatory diseases) are responsible for SM (1). Among neoplasia, Erdheim-Chester disease (ECD) is a rare clonal histiocytosis characterized by long bone involvement, peri-nephric fat infiltration and cardio-vascular involvement associated with compatible histology (2). Biopsy is mandatory to confirm tissue infiltration by histiocytes and detect somatic mutation. Almost 80% of ECD patients harbor mutation in mitogen activated protein (MAP) kinase pathway especially BRAF

**SCHNITZLER’S SYNDROME IN THE DIFFERENTIAL DIAGNOSIS OF ADULT STILL’S DISEASE**

S. Salugina¹, E. Borzova², V. Gorodetskiy³, E. Fedoroiv⁴, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; ² Department of Clinical Genetics, National Research and Clinical Institute of Pediatrics named after Yuri Veltishevat the Pirogov Russian National Research Medical University, Moscow, Russian Federation; ³ Department of Dermatology and Venereology, I.M. Sachenov First Moscow State Medical University, Moscow, Russian Federation; ⁴ V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Schnitzler’s syndrome (SchS) and adult onset Still disease (AOSD) are currently considered as multifactorial autoinflammatory diseases (MAIDs) and are classified as systemic inflammation with urticarial rash. Clinical similarities between SchS and AOSD (fever, urticarial rash, arthralgias) increased ESR and CRP and the efficacy of IL-1 inhibitors may lead to the diagnostic delay in SchS pts. Testing for monoclonal gammopathy helps establish the diagnosis in SchS pts but is not routinely used in AOSD pts.

**Objectives:** to examine demographic, clinical and laboratory characteristics, and the therapy of SchS in a single rheumatology center.

**Methods:** 5 SchS patients (2 females, 3 males), aged 32 to 68, underwent inpatient and outpatient examinations in the rheumatology center. All pts underwent a standard rheumatology examination, including ESR, CRP and M-gradient. 4 pts underwent genetic testing for mutations in NLRP3, TNFRSF1A genes to exclude MAIDs, such as CAPS and TRAPS.

**Results:** All pts were initially diagnosed with AOSD. The age at onset ranged between 28 and 66 years. Time to diagnosis varied from 2 to 22 years, being within 4 years in 4 of 5 pts. Patients presented with fever (4), urticarial rash (5) and musculoskeletal manifestations (5) (arthralgia in 3, bone pain in 4). Of 2 pts with serositis one presented with pericarditis and another – with pleuritis. Only 1 demonstrated a sore throat and polyneuropathy of the lower extremities. ESR and CRP were increased in all pts, leukocytosis was noted in 4 (Table 1). The
monoclonal IgM secretion was revealed in 5 pts. IgMx and IgMx – in 1 and IgGx and IgGx. - 1. No NLRP3, TNFRSF1A gene mutations were identified. Prior to the diagnosis, all pts were treated with glucocorticoids with a transient clinical response and a disease relapse after reducing the dose or stopping the treat- ment. 2 pts failed to respond to methotrexate and 1 – to hydroxychloroquine. 4 pts were prescribed with 150 mg canakinumab, a monoclonal antibody targeting IL-1, subcutaneously once every 8 weeks. The treatment duration varied from 6 months to 5 years. 2 pts, who initially received daily 100 mg anakinra subcuta- neously for 2 to 3 months with a positive response, were further treated with canakinumab. During the treatment with canakinumab, all pts rapidly responded with a complete resolution of fever, rash, arthralgias and bone pains, an overall health improvement and a normalization in ESR and CRP levels. The therapy was well tolerated. In 1 patient, the intervals between canakinumab injections were prolonged to 5 months without any evidence of relapse. During this period, the male patient became a parent to a healthy child.

Conclusion: In rheumatology practice SchS can be misdiagnosed with AOSD. AOSD patients should be tested for monoclonal gammopathy. IL-1 inhibitors are a highly effective and well-tolerated treatment option for SchS. In SchS patients with a complete response to canakinumab, injection intervals can be individualized.

DOI: 10.1136/annrheumdis-2020-eular.3856

**AB1058**

**JOINT HYPERMOBILITY SYNDROME AND PRIMARY OPEN-ANGLE GLAUCOMA**

A. Satybaldyev1, A. Zhuravleva2.

1VA Nasonova Research Institute of Rheumatology, Department of Early Arthritis, Moscow, Russian Federation;
2Helmholtz National Medical Research Center of Eye Diseases, Department of Glaucoma, Moscow, Russian Federation

**Background:** Eye symptoms: myopia, prolapse of the upper eyelid, epiblepha- ron in the upper eyelid are small diagnostic criteria for joint hypermobility syn- drome (JHS).

There are few publications in the literature on the relationship between JHS and primary open-angle glaucoma (POAG).

It is known that in the development of JHS, the distribution of collagen of types I and III with the predominance of collagen of type III is important, the latter is encoded by the COL3A1 gene. When using POAG in the connective tissue of the middle and deep layers of the sclera by the immunohistochemical method, intense focal accumulation of type I and III collagen was previously revealed, and in the layers of the sclera’s own substance, type III collagen, unusual for it.

**Objectives:** To study articular and extraarticular clinical manifestations, laboratory signs, as well as to conduct molecular genetic studies on the carriage of the Col3A1 gene in patients with a diagnosis of POAG and compare them.

**Methods:** Nine consecutive patients with an established diagnosis of POAG (burdened heredity by glaucoma) with arthralgia were sent for consultation to the V.A. Nasonova Research Institute of Rheumatology from the Moscow Helmholtz National Medical Research Center of Eye Diseases. All patients are women, the average age is 56.7 ± 10.5 years, the average Beighton score - 4.86 ± 1.7, the mean value of the Westergren ESR - 11.8 ± 5.1 mm/h, CRP - 4.9 ± 9.4 mg/l, all of them were seronegative for rheumatoid factor (RE) and ACCP. All patients responded to the JHS diagnosis according to the 1998 Brighton diagnostic criteria. DNA was isolated from the leukocyte fraction of venous blood using the Wizard DNA Puri- fication Kit (Promega) according to the manufacturer’s instructions. The study of gene polymorphisms was performed by the method of minisequencing with sub- sequent time-of-flight mass spectrometry of a sample on a matrix (MALDI-TOF) in the clinical diagnostic laboratory of NPF LITEX LLC using a standard protocol (Wise C.A., 2003).

**Results:** 9 patients had arthralgia, 8 - vertebralgia, 3 - myalgia. 2 had a history of wrist joint dislocation, 7 had flat feet (3 of them had Hallucis valgus), 5 had spondylosis and spondylolisthesis (protrusions and disc herniation according to MRI of the spine), and 4 had excessive skin and / or striate atrophy of skin. Extraarticular manifestations: mitral valve prolapse was detected in 3 patients (in 1 of them + atrial septal defect) with ultrasound of the heart, in 3 - descent of the internal organs (nephropathy, uterine prolapse), in 4 - pronounced varicose veins of the lower extremities. All patients had a carrier state of the A allele identified by marker C.2092G→A and C allele c.2244T→C of the COL3A1 gene, and a family history of glaucoma. Identification of compliance with JHS diagnostic cri- teria and the presence of genetic factors (COL3A1 gene) in patients with POAG is of great scientific importance, since it confirms not only clinical associations, but also the genetic proximity of these two conditions. It is also difficult to overes- timate the practical value, since patients with POAG need the help of a doctor in the treatment of their articular and other non-ophthalmological manifestations of JHS, and establishing a diagnosis of JHS will require a more thorough examina- tion of the eyes in terms of detecting POAG, its treatment or prevention.

**Conclusion:** The association of JHS, POAG and COL3A1 gene necessitates further study of the association of JHS and POAG. POAG as a clinical manifes- tation of JHS, on the one hand, and the role of JHS as a possible risk factor for the development of POAG - on the other hand.

9anaSTILLS, Boston, United States of America;
10Sobi, Stockholm, Sweden;
11Hosp Sick Children, Toronto, Canada;
12Osp Pediatrico Bambino Gesu, Rome, Italy

**Background:** Adult-onset Still’s disease (AOSD) and systemic juvenile idiio- pathic arthritis (SJIA) are rare autoimmune disorders associated with an activated IL-1 pathway, characterized by spiking fever, rash, arthritis, lymphad- enopathy, hepatosplenomegaly and serositis. There is a growing understanding that SJIA and AOSD are one disease with different ages of onset, i.e. Still’s dis- ease. The anaSTILLS study (anakinra in Still’s disease) was designed to further evaluate efficacy and safety of anakinra in patients with Still’s disease across all age groups.

**Objectives:** The primary objective was to demonstrate efficacy of anakinra versus placebo as assessed by ACR30 response with absence of fever at Week 2. Secondary objectives included: early onset of efficacy, sustained efficacy, time to study drug discontinuation, safety, pharmacokinetics, clinical signs and biomarkers.

Methods: ‘anaSTILLS’ was a randomized, double-blind, placebo-controlled, 12-week study including patients with active and newly diagnosed (6 months) Still’s disease according to adapted ILAR criteria if ≤16, or Yamaguchi criteria, if ≥16 years of age at disease onset. Patients were randomized to anakinra 2 mg/ kg (max 100 mg/day), 4 mg/kg (max 200 mg/day) or placebo.

Results: 12 patients were randomized and received study drug: 6 anakinra (2 mg/kg n=2, 4 mg/kg n=4) and 6 placebo, the study was terminated early due to slow enrollment. 1 patient on placebo had lymphoma, not Still’s disease, and was excluded; thus in total 11 patients were analyzed for efficacy. 8 were chil- dren [median (range) age=4.0 (1-11) years] and 3 were adults [median (range) age=32.0 (25-51) years]. 55% were male and the mean symptom duration was 74.2 days. All patients on anakinra but none on placebo achieved ACR30 response with absence of fever at Week 2. All placebo patients discontinued the study within 6 weeks, 2 due to progressive disease, 2 due to lack of efficacy and 1 due to withdrawal by patient. There was a numerically higher proportion with early onset of efficacy (Week 1) in the anakinra group compared to placebo. The
ACR30/50/70/90 responses in the anakinra group were sustained throughout the study period. Patients in the anakinra group had a prompt and persistent decrease in CRP, and ferritin levels at Week 1, which was not observed in the placebo group. There were no unexpected safety findings. All anakinra patients developed anti-drug antibodies (ADAs) at some timepoint during the study. ADAs were persistent throughout the treatment period, except in one patient. Titers were low to moderate. One placebo patient had low ADA titers at one occasion. No neutralizing antibodies were observed and the ADAs did not appear to impact clinical efficacy or safety.

**Conclusion:** Anakinra is superior to placebo in the treatment of Still’s disease. ADAs occur frequently but do not appear to adversely impact efficacy or safety. These results confirm the benefits of anakinra treatment in patients with active, newly diagnosed Still’s disease across ages.

**AB1061** 2019 ACR/EULAR CLASSIFICATION CRITERIA FOR IGG4-RELATED DISEASE IN RUSSIAN COHORT OF PATIENTS.

**E. Sokol**, S. Palshina, A. Torgashina, J. Khvan, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** IgG4-related disease (IgG4-RD) is a systemic immunemediated fibroinflammatory condition that can affect almost any organ in the body. This is the reason for dramatic variety of clinical symptoms and complexity of diagnostics. 2011 Comprehensive diagnostic criteria (CDC) for IgG4-RD are used to establish the diagnosis for all lesions (except autoimmune pancreatitis type 1). In 2019 the new ACR/EULAR classification criteria for IgG4-RD were proposed to facilitate the formation of more homogeneous groups of patients primarily for clinical trials inclusion purpose. They also provide a framework for clinicians considering diagnosis of IgG4-RD.

**Objectives:** To evaluate 2019 ACR/EULAR classification criteria for IgG4-RD in Russian cohort of patients with IgG4-RD.
Methods: 59 patient with IgG4-RD according to CDC with biopsy proven diagnosis were included.

Results: The mean number of affected organs was 2.1; 31 patients (52.5%) were women. Majority of patients had sialoadenitis (25 patients) and/or oral disease (31 patients), 9 had retroperitoneal fibrosis (RPF). Other affected organs were lungs, pancreas, lymph nodes, paranasal sinuses, thyroid and low urinary tract. Twenty five (25) patients (42.4%) had definite, 14 (23.3%) probable and 20 (34.3%) possible diagnosis of IgG4-RD. Twenty three (23) patients (39%) didn’t fulfill the 2019 ACR/EULAR classification criteria for IgG4-RD. Among them were the majority of patients with RPF (7 patients) who were lacking other organ involvement and IgG4 hypersecretion either in the tissue or serum. The majority of excluded cases were due to inadequate pathomorphological evaluation (lacking of the exact number and percentage if >40%) of IgG4+ cells, lacking of multi-organ involvement or different patterns of involvement, e.g. in case of lungs involvement.

Conclusion: The new 2019 ACR/EULAR classification criteria for IgG4-RD are very useful in evaluation of typical organ involvement and systemic course of IgG4-RD. It is essential to adjust Russian pathomorphologists’s approach to cell counting and percentage determination for IgG4-RD cases to get suitable protocols.

AB1062 LIPODERMATOSCLEROSIS AS A TYPE OF LOBULAR PANNICULITIS: THE EFFECTIVENESS OF NON-PHARMACOLOGICAL TREATMENT METHODS

M. Sukhareva1, O. Egorova1, B. Belov1. 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: In medical practice lobular panniculitis-lipodermatosclerosis (LDS) is becoming more and more common. It is manifested by degenerative-dystrophic changes in subcutaneous fat (SCF) and occurs more often in middle-aged women affected by chronic venous insufficiency.

Objectives: to evaluate the effectiveness of mesotherapy (MT) and shockwave ultrasound therapy (UST) for LDS

Methods: among 539 patients referred to the V.A. Nasonova Research Institute of Rheumatology with the referral diagnoses of erythema nodosum or panniculitis 8.5% (46) of patients (44 women, 2 men) aged 18 to 82 with overweight (32) LDS with the disease duration of 11.8±6.4 months was verified. Patients were randomized into two groups of 23 patients each: group I received daily MT (10 sessions) therapy with drugs that have antioxidant, anti-inflammatory, lytic drainage and lipolytic effects, and 3 MHz UST of the node area twice a week (5 sessions). In group II MT was performed daily with 9% Natrii chloridum solution at a dose comparable to group I. The control methods included general clinical examination (characterization of induration on the lower legs with an assessment of the effect of pressure on the skin, appearance of the appearance of intracellular pathogens, such as Salmonella or Mycobacteria. This rare but unique disease was the majority of patients with RPF (7 patients) who were lacking other organ involvement and IgG4 hypersecretion either in the tissue or serum. The majority of excluded cases were due to inadequate pathomorphological evaluation (lacking of the exact number and percentage if >40%) of IgG4+ cells, lacking of multi-organ involvement or different patterns of involvement, e.g. in case of lungs involvement.

Conclusion: The new 2019 ACR/EULAR classification criteria for IgG4-RD are very useful in evaluation of typical organ involvement and systemic course of IgG4-RD. It is essential to adjust Russian pathomorphologists’s approach to cell counting and percentage determination for IgG4-RD cases to get suitable protocols.

AB1064 IMMUNOGLOBULIN G4-RELATED DISEASE (IGG4-RD): CLINICAL AND LABORATORY CHARACTERISTICS, TREATMENT RESPONSES AND PROGNOSIS IN ONE HUNDRED FIVE PATIENTS.

S. Tsuzuki1, K. Setoguchi1. 1Tokyo Metropolitan Cancer and Disease Center Komagome Hospital, Department of Systemic Immunological Disease, Tokyo, Japan

Background: IgG4-RD is a systemic fibro-inflammatory condition with incompletely understood that is capable of affecting multiple organs.

Objectives: We aimed to investigate clinical and laboratory findings in Japanese patients with IgG4-RD.

Methods: Dates on clinical characteristics, laboratory features, and treatment response from patients with IgG4-RD in our hospital were reviewed retrospectively from January 2004 to September 2019.

Results: Among 105 patients were diagnosed and treated in our hospital, 48% were female and 88% were biopsy-proven. The median age of the patients was 66 years, and female were younger at their diagnosed age (p<0.04). Their median duration of follow-up was 46 months. 48% of the patients had allergic history (including sinusitis, asthma, hay fever), younger patients tended to have allergy history. Mean serum IgE was 303 IU/dL (2-4965 IU/dL). Salivary and lacrimal grand involvement (63%) and dacrocyadentis and ocular and orbital inflammatory disease (56%), autoimmune pancreatitis type 1 pancreatitis (18%), retroperitoneal fibrosis (16%), arthitis (15%) predominantly occurred. 84% of the patients had serum IgG4 higher than 135mg/dL, and high IgG and IgG4 concentration was associated with lower complements (CH50, C4) levels. Mean serum IgG was 1860mg/dL (861-8432mg/dL), and IgG4 was 449mg/dL (28-3210mg/ dL). Male patients show higher serum IgG and IgG4 concentrations at baseline (p<0.01). Younger patients and low serum C4 level were associated with necessity of treatment, 60 of them used steroid, and the mean dose of predncsone they used was 30mg. Most of them responded well and tapering steroid. The cold sparing agents were used in 23% of them. Although 23% of patients relapse as tapering steroid, 15% of them could stop treat with steroid. Treatment with glucocorticoids is not associated with any factors. There were 14 malignancies in 13 patients during the follow-up period.

Conclusion: Our study revealed that IgG4-RD occurred in middle age with allergic disease in Japanese patients. The pattern of head and neck was predominance. For the most part of the patient serum IgG and IgG4 concentrations was high. Serum low complement level could be associated with its diagnosis and necessity of treatment with steroid. Younger patients tend to treat with steroid and they responded well.

Background: Follow-up in all rheumatologic patients is critical, particularly Familial Mediterranean Fever (FMF). Current recommendations for all experts by the EULAR state that patients with FMF should be evaluated 6-monthly intervals to monitor the character and frequency of the attacks and the acute phase response. Disease-related complications such as amyloidosis can be asymptomatic and need only a careful follow-up.

Objectives: To quantify this phenomenon and to find predictive factors of visit compliance in patients with FMF.

Methods: The study included 474 adult patients with a diagnosis of FMF who followed at the outpatient rheumatology clinic of tertiary university hospital, from January 2018 to December 2018. Demographic, socioeconomic data, family history, comorbid disease, medication history, characteristics, the International Severity Score for FMF (ISSF), autoinflammatory disease damage index (ADDI) were recorded. Visit compliance was defined as the presence of two visits in the outpatient rheumatology clinic for FMF last one year for the purposes set out in EULAR suggestion. Those who had fewer than two visits in the last one year were considered noncompliant.

Results: 230 (48.5%) were compliant while 244 (51.5%) patients were noncompliant with their rheumatology visit. Both compliant and noncompliant patients had similar median age and disease duration. Female sex and being married was increased the visit compliance. The results of the logistic regression model exploring factors associated with compliance indicated that presence of family history in parents, absence of family history in sibling, treatment with biologic agents, other drug using, presence of more than 2 attacks except fever and adequate medical care were important predictors of visit compliance.

Conclusion: In conclusion, if FMF patients visit compliance increase, their functionality, medication adherence and quality of life will increase and flares and complication of disease can decrease. Thus, we highlight some recommendations for FMF specialist, patients and health care providers to improve outcomes.
Background: Familial cold autoinflammatory syndrome 3 (FCAS3) is an autoinflammatory disease (AID) caused by mutation of the PLCG2 gene, which has not been reported in China. We will report 2 cases of Chinese FCAS3 patients with no claimed family history, but we found the same mutations in a patient during their genetic analysis. After further inquiry of the patient’s medical history, we confirmed that actually, they were two FCAS3 families. Through a literature review, we found that the clinical features of Chinese patients are milder than foreign countries, and their symptoms are concealed and may be ignored, resulting in mistakes in family history collecting.

Objectives: To summarize the genetic and clinical features of Chinese FCAS3 patients and to provide diagnostic recommendations for the disease.

Methods: Two suspected AID children with recurrent fever and urticaria were enrolled in this study. Clinical data and family history were collected, and genetic analysis was performed by next-generation sequencing (PiD panel or WES) and Sanger-based validation. Literature was reviewed from PubMed, CNKI, and Wanfang Database.

Results: The two children were both diagnosed to be FCAS3 with PLCG2 mutation. The clinical manifestations of 2 children were recurrent fever, urticaria, and increased ESR and CRP. Case 1 has a paternal heterozygous mutation in the PLCG2 gene, while both had claimed without a family history. Further inquiry showed the two parents used to have a fever with urticaria. By comparing with foreign literature, we found our patients were milder than abroad patients. Large fragment deletions were relatively more common in foreign patients.

Conclusion: We reported the case of FCAS3 in China for the first time. Their genotype and phenotype were different from foreign patients. Their symptoms are mild, and heterozygous mutations are more common than foreign patients, which are the main differences. The difference in mutation type may be the reason for different clinical manifestations. Besides, both two families showed a trend of more severe clinical features in the next generation. As the symptoms of their siblings were not obvious and may be ignored, it causes trouble for the genetic diagnosis. Therefore, family history should be collected carefully. For rashes and fevers, which are not too severe in overall symptoms, care should be taken about the possibility of AIDs. Genetic testing can help to make a definite diagnosis.

REGULATORY EFFECT OF SHORT-TERM LOW DOSE OF IL-2 RESTORES REGULATORY T CELLS IN IG4G-RELATED DISEASE

Y. Wu1, X. C. Zhao2, J. Luo3. 1Shanxi Medical University,Taiyuan, Shanxi, China; 2Department of Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; 3Taiyuan, China

Background: Little known about the roles of peripheral immune cell subsets in IgG4-related disease (IgG4-RD).

Objectives: The aim of our study was to analyze the role of low-dose interleukin-2 (IL-2) on these cells in IgG4-RD.

Methods: The percentage and absolute counts of lymphocyte subpopulations [CD3+ (T cells), CD4+, CD8+, CD19+ (B cells) and CD16+CD56+ (NK cells)] and CD4+T cell subsets (Th1, Th2, Th17, regulatory T (Treg)) using single platform flow cytometry in 25 IgG4-RD patients who were admitted and treated, as well as 24 healthy controls (HCs). Among IgG4-RD patients, 19 patients given only conventional treatments while 5 patients were not only given conventional treatments but also received IL-2 (0.5 million IU/day) for 5 days.

Results: We found that the absolute counts of T, CD4+ and Th1 cells were increased in the peripheral immune cells of IgG4-RD patients when compared with HCs. Meanwhile, the percentage of B, Th2, Th17 and Treg cells demonstrated significantly decreased. The ratio of Th1/Th2 and Th1/Treg in IgG4-RD patients were higher than that in HCs. After IL-2 administration, the absolute numbers of Treg cells increased dramatically. Furthermore, the proportion of Treg cells had a trend towards higher values compared with those before treatment. Conversely, the ratio of Th2/Treg was downward. There were no any significant differences in the above subsets between before and after conventional treatments.

Conclusion: Our findings support that the reduction of Treg cells in IgG4-RD patients, as well as IL-2 combination with conventional treatments were able to restore the Treg cells.

AB1089 CONSIDERATION OF YAOS SYNDROME AS A DIFFERENTIAL DIAGNOSIS FOR HEREDITARY PERIODIC FEVER SYNDROMES

Q. Yao1, Stony Brook University, Rheumatology, Stony Brook, United States of America

Background: Yao syndrome (YAOS, OMIM 617321), formerly termed nucleotide-binding oligomerization domain 2-associated autoinflammatory disease, is characterized by periodic fever, dermatitis, arthritis, and swelling of the distal extremities, as well as gastrointestinal and sicca-like symptoms. This disorder shares similar clinical phenotypes with hereditary periodic fever syndromes (HPFs) and thus can mimic one another.

Objectives: This study aimed to exemplify by a comparison of YAOS vs familial Mediterranean fever (FMF).

Methods: In this retrospective study, electronic medical records of a series of patients with YAOS were analyzed. All patients underwent genetic testing for periodic fever syndrome 6-gene panel (MEFV, TNFRSF1A, NLRP3, MVK, MEFV, NLRP12 and NOOD2).

Results: All patients were Caucasian and had recurrent fever, patchy erythema, arthralgia, and gastrointestinal symptoms (Table 1). With negative DNA sequencing for MEFV, these patients were treated with colchicine for presumed FMF, with a good response in patient 2 and minimal or transient response in other two patients. Further genetic testing identified the NOOD2 variants. Unlike HPFS, YAOS is generally sporadic and is mostly reported in adults; spongiotic dermatitis is common; YAOS is associated with the NOOD2 variants, IVS8+158C and in nearly all patients, IVS8+158/702FIV in up to 30%, and IVS8+158/1007hs, G80R or other rarer NOOD2 variants in some patients.

Conclusion: YAOS can masquerade HPFS like FMF. Molecular analysis should cover NOOD2 whole gene sequencing to help distinguish these diseases.

**DIVERSITY ANALYSIS OF INTESTINAL FLORA IN PATIENTS WITH BEHÇET’S DISEASE**

X. F. Yin, Z. Mingxiao. The Second Hospital of Shanxi Medical University, Taiyuan, China

**Background:** Behçet’s disease (BD) may be regarded as a polygenic autoinflammatory disease although adaptive immune system has also been implicated in pathogenesis. The specific components of the microbiota with BD that affect the host response leading to disease remain unknown. Regulation of intestinal microbiota would be able to provide new strategy and target for the treatment of BD.

**Objectives:** To study the diversity and intestinal flora of intestinal microbes in patients with BD and further provide new ideas for clinical treatment.

**Methods:** The stool specimens of 13 BD patients were analyzed at the level of the Phylum, family and genus, and compared with that of 50 healthy controls (HC).

**Results:** Compared with controls, the abundance of intestinal microbiota in patients with BD was significantly different. At the level of phylum, the abundance of Firmicutes was significantly reduced in BD patients compared with that of HC (P<0.05)(fig. 1). At the genus level, in the BD group, the abundance of Lachnospiracea incertae sedis, Anaerostipes and Megasphaera were significantly lower than that of healthy controls. (P<0.05)(fig. 2).

Figure 1. the differences between patients with BD and normal healthy adults were compared at the level of the phylum

Figure 2. the differences between patients with BD and normal healthy adults were compared at the level of the genus

**Conclusion:** The diversity and balance of bacterial community in intestinal microecological environment of patients with BD are significantly different from the healthy control. Intestinal microbiota disorder may be related to the pathogenesis of BD, which might provide theoretical foundation for the regulation of intestinal flora for disease intervention.

**AB1071**

COEXISTENCE OF FAMILIAL MEDITERRANEAN FEVER WITH SPONDYLOARTHRITIS: CLINICAL CHARACTERISTIC AND TREATMENT OUTCOMES

T. Yuçe İnel, I. Sari, M. Biliʁk, G. Can, F. Onen. Dokuz Eylül University Faculty of Medicine, İzmir, Turkey

**Background:** Studies indicate that there is an association with spondyloarthritids (SpA) and familial mediterranean fever (FMF) based on the following: 1) increased incidence of spondorilits in FMF, 2) MEFV gene mutations are significantly increased in ankylosing spondylitis (AS) and 3) both SpA and FMF show some common clinical manifestations such as the pattern of arthritis. However, characteristics of SpA associated with FMF such as clinical characteristics and treatment outcomes have been poorly documented and additional data is required on this topic.

**Objectives:** To study the clinical and treatment characteristics of patients associated with FMF and SpA.

**Methods:** Twenty-eight patients with FMF and SpA who were registered in our database were included in the study. Demographic, clinical, and laboratory data were collected. HLA-B27, MEFV gene mutations were recorded. Pelvic radiographs and sacroiliac joint magnetic resonance imaging (MRI) (if present) were scored based on the modified New York criteria (mNYc) and ASAS MRI definitions respectively. Treatment data were also recorded.

**Results:** There were 28 FMF-SpA patients in the study (mean age 45.1±16.4 years, 52.2% male). The mean age of onset of FMF and SpA were 31.9±17.9 and 35.5±16.2 years respectively. SpA patients were predominantly axial (n=21, 75%), and only 7 (25%) were mainly peripheral type. Fifteen (53.5%) patients were satisfying mNYc for AS. Four (14%) patients were fulfilling ASAS non radiographic axial SpA definition. Bone marrow edema was detected in (36%) of the patients who underwent MRI (n=14). Two (7.1%) patients had SpA symptoms but did not classify into any of the ASAS arms. Arthritis observed in 19 (67.8%) patients with mostly in oligoarthritis type (79%). Ankle and knees were the most affected joints. Total hip replacement was present in 7% of the patients. Amyloidosis confirmed by biopsy was detected in 4 (14%)
patients. Enthesitis (11%), uveitis (11%), Chon’s disease (7%), dactylitis (3%), and psoriasis (3%) was also noted. Nearly 30% patients required non-IL-1 biologic therapy (BTx) to control SpA symptoms (axial 70%, peripheral 30%). 40% of the patients needed to switch non-IL-1 BTx to another biologic agent because of lack of efficacy on SpA symptoms (25%) or due to the adverse event (25%) and active FMF not responding to non-IL-1 biological agent (50%).

Conclusion: We showed the following: 1) more female predominance in FMF-SpA patients compared to classic SpA. 2) FMF-SpA patients had lower frequency of HLA B27. 3) up to 30% of the patients required non-IL-1 BTx to control SpA symptoms and 4) in patients on non-IL-1 BTx FMF symptoms responded in 80%.

AB1072 ROLE OF ULTRASOUND IN DETECTION OF SHOULDER JOINT PATHOLOGIES IN ASYMMPTOMATIC RHEUMATOID ARTHRITIS PATIENTS

M. G. Abdelzaher1, S. Tharwat2, A. Abdelkhalek3, A. Abdelsalam2, 1Faculty of Medicine, Mansoura university, Rheumatology and Immunology Unit, Internal Medicine Department, Mansoura, Egypt; 2Faculty of Medicine, Mansoura University, Rheumatology and Immunology Unit, Internal Medicine Department, Mansoura, Egypt; 3Faculty of Medicine, Mansoura University, Radiodiagnosis Department, Mansoura, Egypt

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that results in progressive destruction of structural components of the joints. It commonly affects the shoulder leading to pain, tenderness and decreased range of motion. Increased shoulder pain has been found to correlate strongly with disease severity, however there is little information available in the literature regarding shoulder pathologies in asymptomatic RA patients.

Objectives: To determine the prevalence of pathologies in asymptomatic shoulders in rheumatoid arthritis patients and role of ultrasound to detect it.

Methods: A cross-sectional study including two groups, first group included 36 RA patients, meeting the ACR/EULAR classification criteria for RA with no shoulder complaints. The second group included 36 healthy control subjects of similar age groups and sex, with no shoulder complaints. They were recruited from rheumatology outpatient clinic in Mansoura University Hospital. Only asymptomatic shoulders of both groups were examined clinically by inspection, palpation and special tests, then examined by ultrasound using Toshiba Xario 200 machine with 13 MHz superficial probe including biceps tendon, subscapularis tendon, supraspinatus tendon, subacromial subdeltoid (SASD) bursa, infraspinatus tendon, posterior glenohumeral joint for effusion or synovitis, acromioclavicular joint and humeral head for erosions. Findings of both groups were compared to each other.

Results: Asymptomatic shoulders in RA patients showed significant number of pathologies in 72% of the examined patients in comparison with healthy subjects (17%). According to frequency, humeral erosions were detected in 12 patients (33%), acromioclavicular osteoarthrosis in 8 patients (22%), biceps tenosynovitis, supraspinatus tendinopathy, glenohumeral effusion in 6 patients (17%), subscapularis tendinopathy in 4 patients (11%), SASD bursitis in 2 patients (6%), infraspinatus tendinopathy in 1 patient (3%).

The healthy group showed less number of pathologies including supraspi-

natus tendinopathy 3 (8%), acromioclavicular osteoarthrosis 2 (6%), humeral erosions 1 (3%).

Conclusion: A significant high rate of different pathologies can be present in shoulders of RA patients despite negative history and normal physical examination. Ultrasound can be used for early detection and better management before irreversible joint destruction.

AB1073 DYNAMICS OF X-RAY CHANGES IN THE HIP JOINTS WITH EARLY AXIAL SPONDYLOARTHRITIS PATIENTS.

E. Agafonova1, T. Dubinina1, S. Erdes1, D. Rumiantceva1, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: In almost half of patients with ankylosing spondylitis (AS) in Russia, damage to the hip joints (HJ) is detected, but the rate of its progression has not been studied.

Objectives: to evaluate the radiological progression of coxitis in patients with early axial spondyloarthritis (axSpA) for two years.

Methods: the study involved the patients of the Moscow cohort CORSAIR (Early SpondyloArthritis Cohort), which was formed in V.A. Nasonova Research Institute of Rheumatology. We analyzed 62 patients with a diagnosis of axSpA (ASAS criteria 2009), observed for at least 2 years and having survey images of the pelvic bones during inclusion in the cohort and 2 years after the start of observation. The average age at the time of inclusion in the cohort was 29.2 ± 6.4 years with an average disease duration of 23.8 ± 16.2 months, 32 men and 30 women, 92% of patients positive for HLA-B27. All patients received standard anti-inflammatory therapy.

Results: When including out of 62 patients in the study, only one (2%) patient showed X-ray changes in HJ, Fig. 1 (a; b). After 2 years of follow-up, the number of patients with radiological changes in HJ increased to 13 (21%), Fig. 1 (a; b).

Patients were divided into two groups depending on the presence of radiological progression in HJ.
A comparative analysis of the groups revealed that progression is more common in men and in younger people (p < 0.05). In other parameters presented in Table 1, the groups did not differ from each other.

</tbody>
</table>

Conclusion: It has been shown that in some patients with axSpA already in the first years of the disease, radiological signs of HJ destruction are detected. The progression of coxitis was not dependent on the activity of the disease and was more often detected in men than in women.

FEATURES OF COMBINED USE OF BIOMARKERS AND VISUALIZATION METHODS FOR DIAGNOSIS OF HEART DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Aleksandrova1, V. Aleksandrov1, L. Shilova4, A. Aleksandrova2, I. Zborovskaya1.

1. Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Volgograd, Russian Federation; 2. Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation

Background: In rheumatoid arthritis (RA), the endocardium is involved in the inflammatory process, which is caused by immunopathogenic mechanisms involving CD4 +, T-cells and proinflammatory macrophages. Minor changes in the cardiovascular system can be successfully detected by ultrasonography in patients with RA.

Objectives: to improve the quality of non-invasive diagnostics of heart disease in patients with RA.

Methods: 57 patients with RA were under observation: 7 men and 50 women aged from 26 to 70 years; mean age 50.45 ± 10.12 years; activity (according to DAS28) was low for 3.5%, medium for 86%, and high for 10.5%. Immunological examination included determination of serum IgM-RF, CRP, antibodies to cyclic citrulline peptide (anti-CCP), antibodies to modified vimentin (anti-MCV), antibodies to antigen RA33, levels of angiotensin-like proteins 3 (ANGPTL3) and 4 (ANGPTL4) types (classical ELISA test), as well as the detection of IgG antibodies to 5'-nucleotidase (5'-NT) and xanthine oxidase (XO) (modified ELISA test). Data from ultrasonography, magnetic resonance (MRT) and computer (CT) tomography were used in assessing the state of the heart structures.

Results: The pathology of cardiovascular system was diagnosed in 28 (49.1%) patients with RA. Signs of the heart damage were noted in 33.3% of cases (pericarditis and valvular heart disease were most often detected). In patients with RA with elevated levels of antibodies to 5'-NT and XO (compared with RA patients with normal parameters), there was a significantly more frequent heart damage (for antibodies to 5'-NT: χ² = 3.8, p = 0.047; for antibodies to XO: χ² = 3.92, p = 0.041). It was discovered that in all patients with an increased level of antibodies to XO, one of the lesions of the heart valvular apparatus of varying severity was noted. According to ultrasonography data (usually confirmed by CT and/or MRT), signs of valvular dysfunction were found in 21 (36.8%) patients with RA. The high frequency of mitral prolapse (28.6%) may be associated with the presence of a chronic inflammatory process that is able to accelerate the development of atherosclerosis and heart disease in RA patients. A tendency to an increase in the prevalence of mitral prolapse in patients with a longer duration of the disease (p = 0.062) and with high levels of serum ANGPTL4 (p = 0.058) was found.

Conclusion: To identify subclinical signs of involvement of cardiovascular system in the pathological process in the early asymptomatic stages of RA, it is advisable to use imaging techniques in combination with immunological markers of heart damage, which can be especially useful for screening, diagnostic evaluation and determining cardiovascular risk.

AB1075 PRESENCE POWER DOPPLER ULTRASOUND AS A PREDICTOR OF RADIOGRAPHIC DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Alekseeva1, A. Smirnov1, D. Kudinsky1, S. Glukhova1, A. Volkov1, E. Nasonov1, V.A. Nasonova Research Institute of Rheumatology, Diagnostic department, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Chief researcher, Moscow, Russian Federation

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that leads to destructive changes and dysfunction of the joints. Ultrasound (US) is used in current practice as an early diagnostic method for detecting structural damage to articular surfaces. US changes in early RA are considered as one of the ways of predicting disease outcomes.

Objectives: to detect power doppler (PD) contribution in evaluation of radiographic RA progression in long term.

Methods: 85 RA pts, mean age 53.0 [44.0; 61.0] yrs, mean disease duration 8 [4; 24] months were treated by Treat-To-Target concept. After first year of therapy management was following real clinical practice rules until the termination of the study (4 years FUP). The wrist, MCP2 and MCP3, PIP2, PIP3, MTP2 and MTP5 joints of the clinically dominant side were examined by US (GS and PD). Clinical, laboratory parameters and US examination was performed at baseline, at Mo 12 (mean ± SD) in 80% of pts had PD synovitis at baseline. PD-synovitis dropped from 85% to 36% at Mo 12.

Results: 80% of pts had PD synovitis at baseline. PD-synovitis dropped from 2 [1,0;6,0] to 0 [0;0;2,0] scores at Mo 12. RA progression by 4 years FUP was identified in 13% of pts. The X-ray erosion score at 4 years FUP in these groups – N, R, LR, IP and PP - were dependent by PD from baseline to Mo 12 (mean level 1 [0;2] 2 [0;4] 3 [0;5] 1 [0;2] and 4,5 [1;10] respectively), but statistically significant differences were found between N and PP groups.

COLOR DOPPLER HIGH-FREQUENCY ULTRASOUND OF DIGITAL ARTERIES IN PATIENTS WITH SYSTEMIC SCLEROSIS

O. Alekseenko1, N. Yudkina1, A. Demina1, A. Volkov1, E. Nasonov2, VA Nasonova Research Institute of Rheumatology, Diagnostic department, Moscow, Russian Federation; VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Systemic sclerosis (SSc) can lead to vascular complications such as digital ulcers or pitting scars (DUP/S). These changes develop in most patients with SSc and exacerbate their condition. However, there are no methods for dynamic assessment of the vascular involvement. The dynamics of capillaroscopic changes is very slow.

Objectives: The aim of the study was to compare blood flow parameters of digital arteries in SSc patients and healthy individuals and to compare with nailfold capillaroscopy and also alterations of ischemia (Angina, DUP/S).

Methods: 32 SSc patients, mean age 49.5 [42.0; 59.0] yrs and 26 ‘healthy’, mean age 43.5 [33.0; 57.0], were included. Groups of patients differed by gender and age. The exclusion criterion was the presence of obliterating vascular disease or digital ulcers. An Esaote MyLab Twice US system with 22 MHz linear probe was used. A total of 8 SSc patients and controls underwent Color Doppler ultrasonography (CDUS) of 376 (256 of the upper extremities. An Esaote MyLab Twice US system with 22 MHz linear probe was used. A total of 8 SSc patients and controls underwent Color Doppler ultrasonography (CDUS) of 376 (256 of the upper extremities. An Esaote MyLab Twice US system with 22 MHz linear probe was used. A total of 8 SSc patients and controls underwent Color Doppler ultrasonography (CDUS) of 376 (256 of the upper extremities.

Results: In digital arteries, pulsatility index (PI), peak systolic velocity (PSV) and end-diastolic velocity (EDV) were significantly lower and RI higher in SSc patients compared with controls (PSV: 13.28 [9.88; 16.7] vs 17.45 [12.65; 22.5] cm/s, p=0.008; EDV: 2.88 [1.78, 4.05] vs 6.37 [4.75, 8.5] cm/s, p=0.000; RI: 0.78 [0.69, 0.81] vs 0.68 [0.59, 0.74], p=0.005; PI: 1.73 [1.32; 2.19] vs 1.22 [0.99, 1.55], p=0.002).

Conclusion: Blood flow is significantly decreased in digital arteries in SSc but clinical features of vasculopathy depend on microcirculatory disorders. It is important to continue research to find methods for dynamic evaluation of microcirculatory changes.

VALIDATION OF A SIMPLIFIED SPANISH TOOL FOR SEMI-AUTOMATED QUANTIFICATION OF SACROILIAC INFLAMMATION BY MAGNETIC RESONANCE IN SPONDYLOARTHRITIS (S-SCAISS).

R. Almodovar1, P. Zarco-Montejo2, A. Bueno3, L. M. Molinero4 on behalf of SCAISS Study Group. 1Hospital Universitario Fundación Alcorcón, Madrid; 2Hospital Universitario Fundación Alcorcón, Madrid; 3Hospital Universitario Fundación Alcorcón, Madrid; 4Hospital Universitario Fundación Alcorcón, Madrid.

Background: To improve quantification of sacroiliitis main- taining a practical perspective, our group developed SCAISS, a semi-automated method to measure bone marrow edema (BME) in MR images from sacroiliac (SI) joints, combining semi-axial and semi-coronal slices [1]. The 2009 ASAS definition of active sacroilitis was based on standard semi-coronal slices only, perpendicular semi-axial slices being considered but optional [2]. We hypothe- sized a simplified SCAISS (s-SCAISS) method using only semi-coronal slices.

Objectives: To analyze the validity and feasibility of a simplified Spanish tool for semi-automated quantification of sacroiliac inflammation by magnetic resonance in spondyloarthritis (s-SCAISS) using a semi-coronal scan instead of combining semi-axial and semi-coronal slices.

Methods: The s-SCAISS was designed as an image-processing software. We performed the following analysis: (1) three readers evaluated SI images of 23 patients with axial SpA and various levels of BME severity with the s-SCAISS and SCAISS, and two non-automated methods, SPARCC and Berlin; (2) 20 readers evaluated 12 patients images, also with the three methods. Convergent validity, reliability and feasibility were estimated.

Results: The interobserver reliability (ICC and 95% CI) in the three observers’ study was: s-SCAISS = 0.69 [0.490–0.845]; SCAISS= 0.770 [0.580–0.889]; Berlin = 0.725 [0.537–0.860]; and SPARCC = 0.824 [0.671–0.916]. In the 20 observers’ study, ICC was: s-SCAISS = 0.66 [0.478–0.863]; SCAISS = 0.801 [0.683–0.927]; Berlin = 0.702 [0.518–0.882]; and SPARCC = 0.790 [0.623–0.923]. Spearman correlation coefficient between s-SCAISS_BERLIN was r= 0.712 and s-SCAISS_SPARCC was r= 0.779 and s-SCAISS_SCAISS was r= 0.90. Similar results showed SCAISS BERLIN and SCAISS_SPARCC (r=0.729 and 0.840, respectively).

Conclusion: The simplified SCAISS (s-SCAISS) using only semi-coronal slice permits a valid, reliable, and fast calculation of overall BME lesion at the SI joint.

AB1078
USE OF MYOSITIS SPECIFIC AUTOANTIBODIES TEST ACROSS A LARGE NHS HOSPITAL TRUST

J. Ball1, A. Radunovic2, C. Scott1, M. Stevens1. 1Barts Health NHS Trust, Immunology, London, United Kingdom; 2Barts Health NHS Trust, Neurology, London, United Kingdom

Background: The immunology laboratory at Barts Health supports a large clinical myopathy service, providing blood tests for myositis-specific autoantibodies (MSA) by a commercial line immunoblot panel for Jo1, PLA, PL12, SRP, Mi2, Ku, PM-Scl and Scl-70. As idiopathic Inflammatory Myositis (IM) disease subtype definitions have evolved from the 1975 Bohan & Peter criteria, the discovery of new antibodies has proven useful in the hands of neuromuscular clinicians whose patients have a high pre-test probability of disease. Ready availability of the test has led to increased demand from: 1. Respiratory physicians with patients with severe Intestinal Lung Disease (ILD) which can be a symptom of some IMUs. 2. The connective tissue disease (CTD) screening section of the laboratory in which many patients are screened for antinuclear antibodies (ANA), which occasionally produces a pattern that may be associated with an MSA.

Objectives: 1. Determine the frequency of MSA requests from different departments. 2. To investigate the possibility of rejecting requests for MSAs at the laboratory in the absence of an elevated creatine kinase (CK), a hallmark of muscle damage associated with myositis.

Methods: MSA were measured by a commercial line blot (Bluedrive) which included Jo-1, PLA, PL12, Mi-2, Ku, SRP-54 and PM-Scl-100. Demographics and results for all MSA requested between September 2017 and November 2019 were pulled from laboratory records, together with CK results (if performed). CK was interpreted as low, normal or elevated according to reference ranges of 25-2000 U/L (female) or 40-3200 U/L (male).
Results: 597 tests were performed between 2017 and 2019. In total 59/597 (10%) were positive for the audited antibodies (Table 1). General Practitioner (GP) requests accounted for 41/597 (6.9%) tests, internal 464/597 (78%) and external 82/597 (14%). External requests were the most frequently positive at 10/82 (12%), internal requests 46/464 (10%), and GP requests only 3/41 (7%) of the time. Of all internal requesting sources, Respiratory accounted for the largest number at 108/597 (18%), followed by neurology with 85/597 (14%) (Figure 1).

</table>

Figure 1.

MSAs had an associated CK result in 75% of internal and 12% of GP requests. A cohort of 17 patients had positive MSAs (3 x SRP, 1 x PL-7, 1 x Jo-1, 2 x Mi-2, 1 x Ku, 8 x PM-Scl100 and 1 x Scl-70) with normal CK.

Conclusion: Demand for MSA from the Respiratory department (screening for ILD) currently exceeds demand from Neurology and from Rheumatology. In the GP cohort, 33 requests (80% of GPs, 5% of all requests) were generated by the laboratory.

A cohort of patients with normal CK results had a positive MSA, implying CK alone cannot be used to limit test access. Interestingly, 10 positive results had no CK requested implying they were not being investigated for myositis.

Further work is needed to determine the specificity and sensitivity of these antibodies for patients with clinically defined myositis, and the appropriateness of allowing the test to be applied in the absence of any clinical evidence of IIM.

AB1079

CORRELATION OF OPTICAL SPECTRAL TRANSMISSION IMAGING WITH ULTRASOUND AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS

A. Blanken1, C. J. Van der Laken1, M. Nurmohamed1,2; 1Amsterdam Rheumatology and immunology Center, Location Reade, Amsterdam, Netherlands; 2Amsterdam Rheumatology and immunology Center, Location Amsterdam UMC, Amsterdam, Netherlands

Background: Optical spectral transmission imaging (OST) is a new imaging method that measures inflammation in the hands of rheumatoid arthritis (RA) patients. OST might be used to assess disease activity instead of disease activity score 28 (DAS28) or ultrasonography (US), with the advantage of OST that it is fast and not operator dependent. Detection of joint inflammation with OST and with US as reference, has provided varying outcomes with ROC AUCs ranging from 0.69-0.88 [1-3]. Further evaluation of the currently available OST device (HandScan) is needed in other RA cohorts.

Objectives: To assess the correlation of OST measurement with US and disease activity, and to compare OST measurements of RA patients with healthy controls.

Methods: OST was done in 24 consecutive RA patients with active disease and 37 age and sex matched healthy controls using the HandScan device from Hemics, the Netherlands. The HandScan calculates OST values for each bilateral wrist, MCP and PIP joint, ranging from 0 to 3. OST total score is then composed of the sum of the 22 OST joint scores and therefore ranges from 0 to 66. US was performed in the same joints as OST and semi-quantitatively scored on a scale of 0 to 3 for grey-scale (GS) synovitis and power Doppler (PD) signal individually. A separate total score for GS synovitis and PD was calculated by summation of the individual joint US scores. Joint scores (at joint level) and total scores (at patient level) were used in separate analyses. Additionally, we measured swollen joint count 28 (SJ28), tender joint count 28 (TJ28), DAS28, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). For all statistical analyses, the non-parametric variant was used.

Results: Patient level

Median OST total score of RA patients was 16.88 (IQR 12.68-19.72). This was significantly higher than healthy controls (OST total score 12.06, IQR 10.32-14.93; p=0.0002).

OST total score of RA patients (patient level) did not significantly correlate with both US total scores (GS synovitis 0.37, p=0.08; PD 0.21, p=0.33), nor with disease activity parameters (DAS28 0.22, p=0.31; SJ28 0.32, p=0.12; TJ28 0.28, p=0.19; ESR -0.02, p=0.93; CRP 0.05, p=0.81).

Joint level

At joint level, there was a significant correlation for almost all joints with GS synovitis on US (table 2). For PD too few joints scored above 0 to allow for statistical comparisons, however for all joints median OST values were higher in PD positive joints than PD negative joints (differences in median OST values ranging from 0.2-0.5).

</table>

Conclusion: OST total score was higher for RA than healthy controls. At patient level, OST total score did not correlate with other disease activity measures. At joint level, GS synovitis scores correlated with OST joint values for almost all joints. In addition, higher OST values were found in PD positive joints but frequency of PD positivity was too low to allow statistical comparisons. The results of this small cohort of new RA patients do not yet demonstrate additional value as compared to US and clinical examination to detection of joint inflammation at cross-sectional assessment, although fast and non-operator dependent OST assessment may also be weighed in further evaluation for clinical use.

DOI: 10.1136/annrheumdis-2020-eular.5800
Background: Optical spectral transmission imaging (OST) is a new imaging method that measures inflammation in the hands of rheumatoid arthritis (RA) patients. OST might be used to assess disease activity instead of disease activity score 28 (DAS28) or ultrasonography (US). The advantage of OST is that it is fast and non operator dependent. Up to now OST has only been investigated cross-sectionally and it is unknown if and to what extent OST can detect inflammatory changes due to anti-inflammatory treatment for RA.

Objectives: To compare OST measurements before and after 1 month of biological treatment for RA and to compare these OST changes with changes on US and disease activity.

Methods: The HandScan device from Hemics, the Netherlands, was used to measure OST scores for 13 RA patients before and after 1 month of anti-inflammatory therapy. Treatment included tumor necrosis factor inhibitor (n=10), tocilizumab (n=2) and tofacitinib (n=1). OST scores range from 0-66 (one score for both hands) and are based on bilateral wrist, MCP and PIP joints. US was performed in the same joints as OST and semi-quantitatively scored on a scale of 0-3 for grey-scale (GS) synovitis and power Doppler (PD) signal. Joint scores of GS synovitis or PD were summed, resulting in a total GS synovitis score and a total PD score, both also ranging from 0-66. Furthermore, tender joint count 28 (TJC28), swollen joint count 28 (SJC28), DAS28, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were determined.

Response to therapy was defined as achieving the minimal clinically interesting improvement of DAS28 (DAS28 difference after 1 month > -1) as proposed by Ward et al. [1].

Results: Baseline OST was 17.73 ± 6.10 and this significantly decreased to 16.01 ± 6.68 (difference -1.71, 95%CI 0.05-3.38, p=0.045) after 1 month of therapy. This decrease was only present in patients who responded to therapy (n=8); OST decreased from 17.24 ± 5.98 to 14.26 ± 5.65, p=0.01) and not in non-responders (n=5); OST increased from 18.52 ± 6.90 to 18.83 ± 7.87, p=0.03).

In the total group, also DAS28 (difference -1.59, 95%CI 0.74-2.45, p=0.002), SJC28 (difference 4.82, 95%CI 1.50-7.73, p=0.007), ESR (Wilcoxon Rank p=0.008) and CRP (Wilcoxon Rank p=0.03) significantly decreased after 1 month of therapy, but TJC28 did not (difference 2.62, 95%CI -2.79 to 7.91, p=0.30).

OST change after 1 month of therapy significantly correlated with TJC28 change (table 1). For GS synovitis the correlation coefficient nearly reached statistical significance. Changes in all other disease activity parameters were not correlated with OST change.

Table 1. Correlation of OST measurement with change in disease activity after 1 months of anti-inflammatory therapy

Conclusion: OST scores significantly decreased after 1 month of anti-inflammatory therapy and only in the RA group that responded well to this therapy. This indicates that OST is capable of detecting therapy induced inflammatory changes in the hands of RA patients. Larger studies are needed to further assess the monitoring value of OST for therapy efficacy in RA patients.

INFLUENCE OF THE VARIATION OF THE OPERATOR, PATIENT POSITION AND DEVICE ON THE MEASUREMENT PERFORMANCE OF RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS)

1University of Siena, Department of Medicine, Surgery and Neurosciences, Siena, Italy; 2University of Verona, Rheumatology Unit, Department of Medicine, Verona, Italy; 3Carlo Poma Hospital, ASST-Mantova, Department of Neurosciences and Rehabilitation, Mantova, Italy; 4ASL 3 Genovea, Genoa, Italy; 5University Hospital of Florence, Department of Experimental and Clinical Biomedical Sciences, Metabolic Bone Diseases Unit, Florence, Italy; 6National Research Council, Institute of Clinical Physiology, Lecce, Italy; 7Galeote Hospital, ASL-LE, O.U. of Rheumatology, San Cesario di Lecce, Italy

Background: The monitoring of bone mineral density (BMD) is a key aspect for patients undergoing pharmacological treatments that might cause BMD changes at non-physiological rates. At present, the short-term follow-up of patients under treatment in terms of BMD change with time remains an unmet clinical need, since the current techniques, including the gold standard dual x-ray absorptiometry (DXA), require at least 1 year between two consecutive measurements [1]. Therefore, an effective strategy for the assessment of BMD should guarantee high accuracy, precision and repeatability of the measurements.

Objectives: The aim is to assess the influence of the variation 1) in patient position, 2) operator (both intra- and inter-) and 3) device on the REMS performance at lumbar spine and femoral neck.

Methods: 210 women were enrolled, divided in 7 groups of 30-patient each for the assessment of the parameters of interest, i.e. inter-device, intra- and inter-operator repeatability for lumbar spine scans and inter-patient position, inter-device, intra- and inter-operator repeatability for femoral neck scans. All patients underwent 2 REMS scans at lumbar spine or femoral neck, performed by the same operator or by 2 different operators or by the same operator using 2 different devices or in different patient position (i.e. supine without constraints or with a constrained 25°-rotation of the leg). The percentage coefficient of variation (CV%) with 95% confidence interval and least significant change for a 95% confidence level (LSC) have been calculated.

Results: For lumbar spine, intra-operator repeatability resulted in CV%=0.37% (95%CI: 0.26%-0.48%), with LSC=0.12%, inter-operator repeatability resulted in CV%=0.53% (95% CI: 0.40%-0.66%), with LSC=1.47%. For femoral neck, intra-operator repeatability resulted in CV%=0.33% (95%CI: 0.23%-0.43%), with LSC=0.91%, inter-operator repeatability resulted in CV%=0.47% (95% CI: 0.34%-0.59%), with LSC=1.30%, inter-device repeatability resulted in CV%=0.42% (95% CI: 0.30%-0.51%), with LSC=1.16%, inter-patient position repeatability resulted in CV%=0.24% (95% CI: 0.18%-0.30%), with LSC=0.96%.

Conclusion: REMS densitometry is highly precise for both anatomical sites, showing high performance in repeatability. These results suggest that REMS might be a suitable technology for short-term monitoring. Moreover, thanks to its ionizing radiation-free approach, it might be applied for population mass investigations and prevention programs also in paediatric patients and pregnant women.

CURRENT PRACTICE AND OPINIONS ON IMAGING-GUIDED INTERVENTIONAL PROCEDURES IN RHEUMATIC AND MUSCULOSKELETAL DISEASES: INTERIM RESULTS OF A MULTINATIONAL MULTIDISCIPLINARY SURVEY TO INFORM EULAR POINTS TO CONSIDER

F. Carubbi1, P. Bosch2, P. M. Machado3, C. A. Sciri4, A. Alunno5, X. Baraliakos5, C. Dejaco1, 2Rheumatology Unit, UAGlia, Italy; 3Medical University Graz, Graz, Austria; 4UCL, London, United Kingdom; 5University of Ferrara, Ferrara, Italy; 6Rheumatology Unit, Perugia, Italy; 7Ruhr University Bochum, Bochum, Germany

Background: Imaging is widely used for diagnostic purposes in patients with rheumatic and musculoskeletal diseases (RMDs). In recent years, it is increasingly used also to guide interventional procedures. However, the extent of imaging application for this purpose as well as the different technical standards employed across Europe are not known.

Objectives: To learn how much imaging is used for interventional procedures in RMDs. To explore the technical standards employed in different settings and how important they are rated by users.

Methods: As part of the work of a multidisciplinary EULAR Task Force to develop recommendations for the use of imaging to guide interventional procedures in patients with RMDs, a survey was developed. The survey explored aspects of different interventional procedures (e.g. joint injection/injection) such as the use of imaging guide and the technical standards. Respondents provided also a 0-10 rating of how important they considered the same conditions/items with regard to each procedure. The survey was distributed to: rheumatologists across Europe, USA, Central America, South America, Asia and Pacific Area, HPs across Europe, European and American associations of other specialities (e.g. radiology, anaesthesiology). The survey was launched in December 2019. Interim results after 4 weeks are presented.

Results: 200 responses from 36 countries were collected. The respondents were mainly rheumatologists (90%) (Figure 1). 90% of respondents performed interventional procedures related to RMDs and of these, 76% use imaging guide. Ultrasoundography (US) is the most commonly used technique (96%) followed by X-ray/fluoroscopy (13%). Among respondents using imaging guide, 60% received training on both imaging and imaging-guided procedures, 20% only on imaging and 16% no training. 49% of respondents perform the whole procedure using direct image guidance, 21% use imaging to find the appropriate anatomical landmark and then perform the procedure blindly. Air and contrast agent to control needle placement are rarely used (≤20%).

Discussion: Respondents provided also a rating (0-10) of how important they considered different technical conditions/items for each procedure and an estimate on a Likert scale of how often they used them for each of the procedures (Figure 1 shows an example). In most cases respondents use always/most of the times the conditions/items that they considered important. Discrepancies were mainly due to barriers at their own center.

Conclusion: Imaging, mainly US, is widely used to guide interventional procedures. However, training is not homogeneous and the use of imaging guide as well as technical conditions are based on the operator’s opinion/experience. This survey will inform the EULAR points to consider for the use of imaging to guide interventional procedures in patients with RMDs.

A SYSTEMATIC REVIEW OF THE ABILITY OF WHOLE BODY MRI TO ASSESS DISEASE ACTIVITY AND TREATMENT RESPONSE IN INFLAMMATORY ARTHRITIS

V. Choids 1,2, A. V. Madenidou1,2, D. Sen1,2, M. Hall-Craggs1,4, C. Curtin1,2,3
1University College London, Centre for Adolescent Rheumatology Versus Arthritis, London, United Kingdom; 2University College London Hospitals NHS Foundation Trust, Rheumatology Department, London, United Kingdom; 3University College London Hospitals NHS Foundation Trust, Radiology Department, London, United Kingdom; 4University College London, Centre for Medical Imaging, London, United Kingdom

Background: Whole body MRI (WBMRI) is an imaging technique that allows the assessment of the spine and peripheral joints in patients with inflammatory arthritis (IA) in a single examination. Depending on the protocol, it can potentially identify synovitis, enthesis, spondyloarthritids and chronic structural changes.

Objectives: To evaluate the performance of WBMRI in patients with IA for detecting inflammation compared with clinical assessments and to show changes in response to treatment.

Methods: We conducted a systematic search of the electronic databases MEDLINE, EMBASE and Cochrane Library. Two authors selected independently the eligible studies, extracted the predefined data and assessed the quality using the QUADAS2 tool. Studies that reported radioscopage activity scores, biopsy or physician reported outcomes or c(results from other imaging tests in IA patients who underwent WBMRI were included. Results: Fourteen studies out of 471 met our inclusion criteria. The majority of the studies were performed in Spondyloarthritis [SpA] (n=9), followed by Rheumatoid Arthritis [RA] (n=4) and Psoriatic Arthritis [PsA] patients (n=3). Nine studies provided clinical and MRI outcome measures. There was great heterogeneity in the quality of studies, disease specific outcomes reported and methodology used to compare with MRI findings. One study documented low correlation between 28 swollen/tender joint count and MRI bone marrow oedema (BME)/synovitis in RA patients, whereas another reported that 31% of MRI negative joints (other than hand joints) exhibited tenderness. In PsA, one study demonstrated correlation between 28 swollen joint count and BME (r=0.54, p=0.03). Superiority of WBMRI in the detection of synovitis and enthesitis over clinical examination was documented in two studies with SpA patients. A third study in SpA showed a ranging agreement of 49 to 100% between clinical and WBMRI enthesis.

Response treatment to biologics was assessed by WBMRI in 7 studies (5 in SpA, 2 in RA). In RA, one study showed numerical but not statistically significant reduction of WBMRI joint count at week 16 following Adalimumab treatment, whereas the reduction was statistically significant for the subset of patients achieving good EULAR response at week 16. The other study demonstrated a reduction in WBMRI synovitis and bone oedema scores after 1 year of anti-TNF or Tocilizumab treatment (median DAS28 score decreased from 5.1 to 2.1). A multicentre open label study reported a reduction in the number of MRI enthesitis lesions, spinal and sacroiliac joint scores at week 48, year 2 and 3 of Etanercept treatment in SpA patients. The mean BASDAI score decreased from 5.4 at baseline to 2.5 at year 2 and 2.2 at year 3. Improvement in WBMRI scores in SpA was also documented in one Adalimumab and one further Etanercept study.

Conclusion: There was a variable level of correlation between clinical and WBMRI outcome measures across the included studies. The clinical significance of the inflammation detected by WBMRI in some studies remains unclear. Many of the devised WBMRI scores appear to decrease after biologic treatment. Further studies are needed to determine the accuracy of WBMRI in detecting inflammation and its potential utility for clinical practice.

ASSESSMENT OF DIAGNOSTIC DELAY IN PATIENTS AFFECTED BY ENTEROPATHIC SPONDYLOARTHRITIS: A CROSS-SECTIONAL STUDY

P. Conigliaro1, M. S. Chimenti1, A. D’antonio1, A. Wlderk2, L. Sichi1, P. Triggianese1, F. Sabuzzi1, G. Sena1, N. Alferi1, V. Da Ros2, L. Biancone3
1University of Rome Tor Vergata, Gastroenterology Unit, Department of “Medicina dei Sistemi”, Rome, Italy; 2University of Rome Tor Vergata, Department of Diagnostic Imaging and Interventional Radiology, Rome, Italy; 3University of Rome Tor Vergata, Department of Gastroenterology Unit, Department of “Medicina dei Sistemi”, Rome, Italy

Background: Diagnostic delay of spondyloarthritis (SpA) has been established even in combination with inflammatory bowel disease and may contribute to radiographic progression and disability.

Objectives: We aimed to evaluate diagnostic delay in enteropathic SpA (eSpA) and explore associated demographic, clinical, and radiographic characteristics.

Methods: We analysed consecutive eSpA patients referred to the combined gastro-rheumatologic clinic of the University of Rome Tor Vergata. Diagnostic delay was defined as the time interval from the date of first symptoms to the date of diagnosis. Conventional radiography (CR) and magnetic resonance imaging (MRI) of sacroiliac (SI) joints and spine were performed in axial (ax)SpA patient and examined by two independent radiologists. MRI were assessed for the presence of active/chronic inflammatory lesions, disease activity by ASDAS and inflammatory markers. Statistical analyses were performed using Mann-Whitney, chi square/Fisher tests and covariance analysis (SPSS software).

Results: 190 eSpA patients (124 female, mean age 47±12.8 years, disease duration 72±67.4 months, 73 UC/117 CD; 118 peripheral SpA, 72 axSpA including 44 non radiographic (nr)-axSpA) were evaluated. Axial eSpA patients had a higher prevalence of men sex (p<0.0001), HLA-B27 positivity (p=0.004), uveitis (p=0.01) and pancolitis (p=0.006) compared with peripheral eSpA. AxSpA patients displayed higher ESR, ASDAS, and VAS pain compared with peripher- al ESpA (p<0.0006, p=0.001, p=0.019, respectively). A higher prevalence of csDMARDs was detected in peripheral eSpA compared with axSpA (p=0.002) while treatment with cs and bDMARDs was similar in rad-axSpA and nr-axSpA patients.

Median diagnostic delay in eSpA was 48 months (IQR 6-77) with no difference between axial and peripheral patients. Rad-axSpA patients displayed a higher diagnostic delay compared with nr-axSpA (median/IQR 36/17-129 vs 31/10-57 months, p=0.03). Patients with rad-axSpA were older and with longer disease duration than patients with nr-axSpA (p=0.005 and p=0.019). Low education staus and high rate of employment were found in rad-axSpA compared with nr-axSpA (p=0.003 and p=0.03, respectively).

Rad-axSpA patients with schizophrenia, syndromes and bridge at CR had a higher diagnostic delay than those without lesions (p=0.03, p=0.043, p=0.0001, Fig. 1A-C). Men showed a higher prevalence of spine damage lesions than women as sclerosis (p=0.02), squaring (p=0.0006), synovitis (p=0.0002) and bridges (p=0.007). Longer disease duration was detected in patients with radiographic damage as bridge (p<0.0001) and sacroiliitis grade 3 (p=0.04). On MRI, SI bone oedema was associated with reduced diagnostic delay (p=0.04) while bone erosions was associated with higher diagnostic delay (p=0.002) compared with that in patients without these lesions (Fig. 1D-E). Rad-axSpA women had a higher prevalence of SI damage lesions at MRI than men (p=0.001). Patients with psoriasis displayed a higher diagnostic delay compared to those without skin involvement (p=0.004).

Figure 1.
Conclusion: Demographic and clinical factors differentiate axSpA from nr-axSpA patients. Diagnostic delay was higher in rad-axSpA compared with nr-axSpA despite the same treatment. Some lesions of spine/SI at CR and MRI, and psoriasis, were mostly associated with diagnostic delay and sex.

AB1086 POWER DOPPLER AND SPECTRAL DOPPLER ULTRASOUND IN SUSPECTED ACTIVE SACROILIITIS: A COMPARISON WITH MAGNETIC RESONANCE IMAGING AS GOLD STANDARD

P. Falsetti1, E. Conticini1, C. Baldi1, M. Bardelli1, S. Gentileschi1, R. D’alessandro1, L. Cantarini1, B. Frediani1, 1University of Siena, Rheumatology Unit, Siena, Italy

Background: SIJ involvement is a characteristic feature of Spondyloarthritides (SpA). Magnetic Resonance imaging (MRI) has been included in the new Assessment of SpA International Society (ASAS) criteria for the classification of Axial SpA. Gray scale US, Color Doppler ultrasound (CDUS), contrast-enhanced CDUS, and spectral Doppler (SD) US has been used in few works to evaluate the inflammatory activity of the SIJ with not conclusive results. Power Doppler ultrasound (PDUS) was not yet applied to the study of SIJ with active SI.

Objectives: The aim of this work was to study with PDUS and SD US the SIJ of patients with suspected active SI, to describe inflammatory flows with spectral wave analysis (SWA) in duplex Doppler US, and to correlate US data with clinical characteristics and the presence of bone marrow edema (BME) in MRI.

Methods: 22 patients (18 females and 4 males, mean age 35 years) with new onset of inflammatory back pain (IBP), were included. Every patient underwent an US examination in prone position. The sonographers were blinded to the clinical data of the patient. A Esaote Twice US machine, equipped with a convex multifrequency 1-8 MHz probe, was used, with standardized parameters: 1-5 MHz for gray scale, 1-92-2.3 MHz frequency for Doppler with Pulse Repetition Frequency (PRF) of 1.0 kHz and a color gain just under the artifact limit. SIJ was located as the hypechoic triangle delimited between the sacrum and iliac bone, and the posterior SI ligament as the upper margin. The first sacral foramen was always localized to avoid measurement of the normal pre-sacral arteries. The PDUS was applied, and if any signals were detected in the SIJ, they were scored with a 3-points scale: 0= absence of signals, 1= isolate vessels, 2= more than one vessel. The signals were also classified as intra-articular or peri-articular. The same vessels were also evaluated using quantitative SD calculating the Resistive Index (RI=peak of systolic flow-end diastolic flow/peak systolic flow), ranging between 0 and 1. Every patient underwent MRI of SIJ within the same week, before treatment. A statistical analysis was performed, estimating the sensitivity and specificity against the gold standard (presence of BME in the same SIJ according to ASAS criteria). The Spearman rank not-parametric test was applied to correlate the presence and grading of BME with PDUS grading and RI. A regression analysis was applied between PDUS results and clinical characteristics.

Results: In 14/22 SIJ MRI revealed BME. In 13 of them, PDUS confirmed abnormal hypervascularisation in the intrarticular portion of SIJ, and in 3 in the periarticular site too. Two SIJ showed hypervascularisation at PD with no BME in MRI. A significant correlation was demonstrated between positivity and grading of PD and presence of BME in MRI (p=0.0005). SD analysis demonstrated low Resistance Index (RI) values in 14 SIJ (mean 0.57). An inverse correlation was demonstrated between RI and grading of BME in MRI (r=-0.6229, p= 0.044). The diagnostic accuracy of SD for detection of active SIJ varied on the basis of RI cut-off value. The best values of sensitivity (62,5%) and specificity (61,5%) were obtained with a RI cut-off values of 0.60. A multiple regression model demonstrated a significant relationship between PDUS signals and ASDAS (p=0.0382), but not with inflammatory reactants.

Conclusion: PDUS and SD US of SIJ can be useful as first imaging assessment in suspected active SI, demonstrating a good diagnostic accuracy compared with MRI. Intra-articular low RI values (<0.60) on SD indicate active SI with good accuracy. Moreover, PDUS signals into the SIJ correlate with clinical symptoms but not with inflammation reactants.

AB1087 DETECTING AXIAL AND PERIPHERAL NEW BONE FORMATION IN SPONDYLOARTHRITIS PATIENTS USING [18F]FLUORIDE PET-CT IMAGING

J. De Jongh1, R. Hemkë2, G. C. J. Zwezerijnen3, M. Yaqbö2, J. Van der Horst-Bruinsma4, 1, M. G. H. Van de Sande4, A. Van Kuijk1, I. Butnik1, L. Burgemeister2, N. M. A. Van Dillen2, A. Voskuyl1, C. J. Van der Laken1, 1Amsterdam UMC Location VUmc, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 2Amsterdam UMC Location AMC, Radiology and Nuclear Medicine, Amsterdam, Netherlands; 2Amsterdam UMC Location AMC, Radiology and Nuclear Medicine, Amsterdam, Netherlands; 2Amsterdam UMC Location VUmc, Radiology and Nuclear Medicine, Amsterdam, Netherlands; 2Amsterdam UMC Location AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 5Reade, Rheumatology, Amsterdam, Netherlands

Background: Bone formation in spondylarthropathies (SpA) is presumably related to local enthesitis/peri-articular inflammation and ultimately may lead to functional limitation (1,2). X-rays only allow long-term monitoring of bone formation (≥2 years) (3). Imaging techniques that can visualize bone formation at an early stage would therefore be valuable. Positron Emission Tomography (PET) using [18F]Fluoride can visualize and quantify (early changes in) bone formation at molecular level (4).

Objectives: To investigate the feasibility of [18F]Fluoride to assess new bone formation at axial and peripheral enthesial sites in SpA patients.

Methods: Thus far, 5 of the total of 15 patients with clinically active ankylosing spondylitis (AS) (according to modified New York criteria and BASDAI ≥4) and 8 of the 25 patients with active psoriatic arthritis (PsA) (according to CASPAR criteria and ≥1 clinically active enthesitis) were included. Of each patient, a whole body [18F]Fluoride PET-CT scan was performed. All scans were visually judged and scored dichotomously by one reader (blinded for clinical data) for PET-positive lesions in the spine, peripheral enthesis sites and joints. Low dose CT was used for anatomical reference.

Results: The study is ongoing, with whole body [18F]Fluoride PET-CT scans available in five AS patients and eight PsA patients. In 4/5 AS scans, at least ≥1 PET positive lesions were found in the cervical, thoracic and/or lumbar vertebral. These were mainly found in anterior corners of vertebrae and bridging syndesmophytes (Fig. 1A). In all eight PsA patients, at least 1 PET positive lesion was visualized, projected either at the site of a tendon attachment (fascia plantaris, achilles- and patella tendon (Fig 1B)) or peri-articularly (in the ankle or wrist).
Background: Nail psoriasis is an extreme diagnostic and therapeutic challenge and represents an enormous physical and psychological burden for affected patients. 50% of patients with psoriasis vulgaris develop nail involvement (NailPsO) during the course of their disease. NailPsO is the strongest predictor of psoriatic arthritis (PsA). Through the synovio-enthesis concept we have observed that there is an anatomical-pathophysiological relationship between DIP joint, extensor tendon and nail matrix. We have observed in daily practice that hypervascularization (HV) in ultrasound Power Doppler (US-PD) of the nail matrix may be a pathognomonic element in its own right. There are no data on this in the literature.

Objectives: Is there a difference in the ultrasound PD examination of the DIP joint and nail area and in the capillary microscopy of the corresponding nail fold in patients with psoriasis vulgaris and nail psoriasis versus patients with psoriasis vulgaris without nail psoriasis.

Methods: Monocentric prospective study of all consecutive patients with psoriasis vulgaris who have come to a rheumatic practice to clarify a PsA. In addition to demographic data, assessments (PASI, DLQI, CASPAR, GEPARD, DAS28, SJTJ, FFBH), clinical examination, a standardized ultrasound PD examination and capillary microscopy of the affected fingertips in PsO patients suffering from nail psoriasis was performed as well as corresponding examinations of the 2nd and 3rd finger right in PsO patients without nail involvement.

Results: 79 patients could be included during the study period. Thereof 25 PsO patients without nail involvement and 44 PsO patients with nail involvement. Since the patients were examined consecutively, the difference results. There was no difference in age, BMI and sex in both groups (PsO and NailPsO). The Caspar criteria as classification criteria for a PsA were positive in 65% of the NailPsO patients and positive in 50% of all PsO patients without nail involvement. Hypervascularization in the US-PD examination in the area of the nail matrix could be seen significantly more frequently in NailPsO compared to non-NailPsO patients. Such a difference did not exist in the HV of the extensor tendons. Capillary microscopy showed a significant difference in the number of torsions/twist capillaries in NailPsO compared to PsO patients without NailPsO. Hypervascularization of the nail matrix is seen significantly more frequently in patients with psoriasis of the nail than in patients without psoriasis of the nail. Such a difference does not exist in DIP joint -extensor tendon- enthesis. At the same time, torsions are significantly more frequently seen in capillary microscopy in NailPsO than in patients without NailPsO.

Conclusion: The US-PD examination is a simple and non-invasive procedure which can be performed routinely in daily practice. The hypervascularization of the nail matrix should also make one think of nail psoriasis in the early stage of PsO, in order to be able to start early an appropriate therapy for this very stigmatizing and therapeutically extremely difficult manifestation of PsO. It seems to occur independently of extensor tendon synovitis as an independent manifestation phenomenon.

The occurrence of torsions in capillary microscopy >50 % also seems to be groundbreaking for a NagellPsO, whereby capillary microscopy is a temporal challenge in daily routine.

April 2019. A total of 154 images were randomly selected and their reports were analyzed. The original reports were compared with the addendum made after the MDT and on the rheumatology electronic records. Clinical letters were also looked into to identify changes in follow up and treatment plans after the MDT.

**Results:** The majority of discussed images were X-rays (88). This is followed by 56 MRIs, 8 Ultrasound and 2 others including CT.

After MDT review 38/88 X-rays (43%), 9/56 MRIs (16%) and 6/9 (67%) in amended MRI reports.

There were 17 rheumatology referrals by GP that were based on erroneous X-rays reporting and 3 of them were rejected after the MDT. The others were brought to the MDT after the first clinic visit and were discharged subsequently.

**Conclusion:** Joint rheumatology/radiology MDT discussion makes significant outcome to patient care by minimizing unnecessary investigations and treatment based on erroneous or unclear reporting. Question is raised about efficacy of outsourcing of radiology reporting and need for intensive training for radiology trainees in reviewing musculoskeletal(MSK) images. Since significant numbers of GP referrals were based on erroneous reports, reporting done by MSK radiologists would have reduced unnecessary burden and waste of outpatient rheumatology resources.

The images submitted for MDT were selected largely by consultant rheumatologists based on their review of the images and relevance on the original report. Therefore, clinical impact is underestimated in this survey as there were potentially other images not reviewed in MDT that had ended in unnecessary clinical consultation. This survey emphasizes the need and importance of incorporating formal musculoskeletal radiology training into routine rheumatology training program.

**AB1090 BIOMARKERS TO DIFFERENTIATE EARLY INDISTINGUISHABLE CASES OF OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS.**

A. Elbejil1, H. El Abd2, A. Shahin3, R. Ibrahim3, A. El Azhar Faculty of Medicine, Rheumatology, Cairo, Egypt; 3El Azhar Faculty of Medicine, Clinical Pathology, Cairo, Egypt

**Background:** Osteoarthritis (OA) and rheumatoid arthritis (RA) are the most frequent inflammatory diseases of the musculoskeletal system, which could not be differentiated in their early stages, and characterized by degradation of articular cartilage and impairment of joint function. Sometimes, criteria and radiography are not sufficient to distinguish early stages of RA and OA and predict disease course, and therefore biomarkers that help clinicians to early diagnose disease are essential.

**Objectives:** The aim of this study is to estimate serum level of Matrix metalloproteinase 3 (MMP3) and hydroxyproline (HP) in early RA and OA patients to see if they can be used to differentiate both diseases at their early stages

**Methods:** The aim of this study is to estimate serum level of Matrix metalloproteinase 3 (MMP3) and hydroxyproline (HP) in early RA and OA patients to see if they can be used to differentiate both diseases at their early stages

**Results:** We found a highly significant elevation of serum MMP3 in OA patients group compared to RA patients and control group, (P < 0.001). Meanwhile, we found a highly significant elevation of HP in OA patients than in RA patients and control groups, (P < 0.001), whereas there was no significant difference between HP in RA patients and control groups (P > 0.05).

**Table 1. Demonstration of serum levels of MMP3 and HP in all groups.**

**Conclusion:** Our results suggest that serum levels of Hydroxyproline (HP) rather than MMP3 could be used as a potential biomarker for early differentiation between osteoarthritis (OA) and rheumatoid arthritis (RA) when diagnostic criteria failed to be fulfilled.

**AB1091 FREQUENCY OF ULTRASOUND ENTHESITIS AND SYNOVITIS IN DIFFERENT ANATOMICAL SITES OF UPPER AND LOWER EXTREMITIES IN PATIENTS WITH PSORIATIC ARTHRITIS: CROSS-SECTIONAL STUDY**

I. Fairushina1, D. Abdulganieva2, E. Kirillova2, E. Mukhametshina3. 1Kazan State Medical University, Kazan, Russian Federation; 2Kazan State Medical University, Department of Internal Diseases, Kazan, Russian Federation; 3Kazan (Volga Region) Federal University, Kazan, Russian Federation

**Background:** Psoriatic arthritis (PsA) is characterized by asymptomatic enthesitis and synovitis. The location of pathological lesions is not clear. Furthermore, ultrasound (US) enthesis indices assess limited number of entheses.

**Objectives:** To detect the most frequent sites of US enthesis and synovitis in PsA.

**Methods:** 57 PsA patients were enrolled to the study. US examination included bilateral large 14 joints; entheses of tendons and ligaments in the projection of examined joints (total number - 54), Totally, 798 joints, 3078 enthesis were examined. The study was conducted by US rheumatologist. Data collection: demographical, clinical, US (total synovitis count by grey scale, enthesis counted as the sum of structural and acute components (US entheseal findings assessed by the definition and scoring for enthesitis in PsA (OMERACT US)2. Chi-square test used to calculate difference of articular and enthesal frequency between upper and lower extremities.

**Results:** In all 57 patients: male - 25 (43.9%), mean age 43.4±10.3(SD) years (y), PsA duration was 7 (3;10) y, Disease Activity in PsA score 18.1 (10.2;26.1).

**Table. Frequency of articular and enthesal involvement of different anatomical sites in PsA**
There was a difference between US synovitis detection of upper (70.4%) and lower (42.9%) extremities (p=0.04). Total count of US enthesis of lower extremities (70.4%) was significantly higher than of the upper (29.6%; p<0.01).

Conclusion: US synovitis detection of lower extremities is significantly higher. US imaging can be used to diagnose enthesis and synovitis, especially in patients in whom symptoms may be difficult to discern, and data on location of pathological lesions will be useful.

ULTRASOUND EXAMINATION OF JOINTS AND PERIARTICULAR TISSUES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES.

G. Gaynulić1, E. Kirillova1, A. Odincova2, E. Belousova1, D. Abdulganieva2,
1Kazan State Medical University, Kazan, Russian Federation; 2Kazan Medical University, Internal Medicine

Background: Joints and entheseal involvement is a common extraintestinal manifestation in inflammatory bowel diseases (IBD) [1]. Recent studies have shown the superiority of ultrasound over clinical findings in the evaluation of joints and periarticular tissues.

Objectives: To assess of joint and entheseal involvement in IBD patients using ultrasound with Power Doppler, their correlation with IBD clinical variables and the difference between Crohn's disease (CD) and ulcerative colitis (UC).

Methods: We prospectively included 38 IBD patients into the study. Disease activity was evaluated in CD by Harvey Bradshaw index. Peripheral joints and entheses were imaged by ultrasound, using Samsung Acucuv A30 5-13 MHz linear array transducer. Ultrasound examination of 14 peripheral joints (hip, knee, ankle, shoulder, acromioclavicular, elbow, wrist) and 35 entheses was performed. Vascularization on them was assessed with Power Doppler (PD). Enthesal abnormalities were scored with US according to indices GUESS, MAISEI and BUSES [2]. Statistical analysis was done by Mann-Whitney test and Spearman criteria by “Statistica” software.

Results: In 38 patients UC was in 22 (58%), CD - in 16 (42%). The mean age of UC patients was 28 (23; 35) years, in CD - 33 (27; 36) years. The mean duration of UC was 24 (10; 48) months; CD - 66 (24; 114) months. The majority of patients had highly active disease: in UC - moderate and severe attacks in 16 pts (72%), in CD out of 16 patients, moderate and severe activity was observed in 9 (56%). Synovitis were found in 19 patients (50%), 8 patients with UC (36%), and 10 patients with CD (62%), synovitis with vascularization was detected in 7 patients (18%), five with CD (13%), two with UC (9%).

Entheses (echogenicity reduction and thickening) was detected in 30 patients (79%), 8 (50%) pts with CD and 17 (77%) pts with UC, enthesis, with vascularization (PD) in 13 pts (34 %), 5 (31%) pts with CD and 8 (36%) pts with UC. Tenosynovitis was observed in 11 pts (29%), three (19%) with CD and 8 (36%) pts - UC, tenosynovitis with vascularization in two patients (5%), one with UC and one with CD. Structure damage (erosion, entheseophysis) were found in 23 patients (61%), 12 patients (75%) with CD and 11 (50%) patients with UC.

There were no significant differences in ultrasound signs of joint and entheses damage between patients with UC and CD. We found an association between the clinical characteristics of IBD and the ultrasound signs of entheses damage: duration of the disease has a direct moderate correlation with the number of entheses ($SR = 0.36; p = 0.026$) and GUESS ($SR = 0.37; p = 0.022$).

There was no statistically significant relationship between the severity of the attack and damage to the joints and entheses.

Conclusion: The severity of joint and periarticular tissues damage is significantly correlated with the duration of the index disease and are independent of IBD activity.

INTEROBSERVER AGREEMENT IN MAGNETIC RESONANCE IMAGING OF SACRIOILIAC JOINTS ABOUT ACTIVE SACROILIITIS

A. C. Genç1, F. Türkoglu Genç1, A. B. Kanı2, Z. Oztunk1, D. Karatas3,
1Uludag University, Department of Radiology, Sakarya, Turkey, 2Uludag University, Department of Radiology, Sakarya, Turkey, 3Uludag University, Internal Medicine, Sakarya, Turkey.

Background: Axial spondyloarthropathy has characteristic clinical features such as enthesis, sacroiliitis and spondylitis, and extra-arthritic manifestations(1). Magnetic resonance imaging (MRI) of sacroiliac (SI) joints is used to detect early sacroiliitis(2). Health institutions in our country carry out some of the radiology reporting services by outsourcing for reasons such as high cost and insufficient number of radiologists(3).

Objectives: We decided to evaluate the interobserver agreement in active MRI findings of SI between radiologist of outsourcing放射学 services and local/ expert radiologist in musculoskeletal diseases.

Methods: Between the years of 2015 and 2019, 8100 sacroiliac MRIs were taken at our center. The MRI of 1150 patients who were reported as active or chronic sacroiliitis from these sacroiliac MRIs or whose MRI was considered by the primary physician in favor of sacroiliitis was included in the study. Concordance between Evaluation and Service Procurement was examined using kappa (κ) coefficients. Mc Nemar test was used to compare the evaluation result between two observers. A p-value <0.05 was considered significant. Analyses were performed using commercial software (IBM SPSS Statistics, Version 23.0. Armonk, NY: IBM Corp.)

Results: Of the 1150 patients examined in the study, 526 (45.7%) were male and 624 (54.3%) were female. The general average age was 37.20 ± 11.65 and the average age of men and women was 34.99 ± 11.19 and 39.07 ± 11.71 respectively. A statistically significant difference was found between the expert radiologists and outsourcing radiologist reports. In other words, a high level of compatibility was not found among the evaluators (p <0.001). When the consistency between expert radiologist and outsourcing radiologist reports was examined, it was observed that there was a medium level of concordance (κ = 0.589).

Conclusion: The diagnosis of a spondyloarthropathy may be delayed for some reasons. In addition to the insidious course of the disease, being contented with an outsourced radiologist report may delay diagnosis. If the patient's clinic and MRI report are not consistent, the patient should not be removed from follow-up.

References:
Background: Myocardial fibrosis is a severe complication of immune-mediated diseases, occurring in up to 30% of systemic lupus erythematosus (SLE) patients. Cardiovascular magnetic resonance imaging allows myocardial scar detection in SLE patients, but it is costly, time consuming, and unfit for patients with renal disease. Scarc imaging echocardiography with ultrasound multi-pulse scheme (eSCAR) is a novel and promising technique that proved to be effective in detecting subendocardic myocardial scars in patients with coronary artery disease (CAD).

Objectives: To evaluate if the eSCAR technique is feasible and to better characterize SLE patients with cardiac involvement by eSCAR.

Methods: We recruited consecutive patients with SLE classified according to the 2019 EULAR/ACR recommendations. Patients with diabetes mellitus, obesity, prior cardiovascular (CV) disease or anti-phospholipid (aPL) syndrome were excluded. Eligible participants underwent a thorough clinical assessment and a full echocardiography examination, including the eSCAR technique. Data on clinical variables were collected; disease activity was estimated by the SLE Disease Activity Index (SLEDAI) score. Lupus flare was defined as new/worse clinical signs and symptoms and/or lab measurements and a change/increase in treatment. Patients were compared according to the presence or absence of eSCAR.

In this preliminary report, only descriptive analyses are provided. Continuous data are reported as median (25%; 75% percentile).

Results: We enrolled fifteen patients diagnosed with SLE (age 45 years [36; 47], disease duration 14 years [12; 20], 15 (87%) were females. Median SLEDAI was 5 [2; 8]. The most frequent disease involvement included arthritis (73%), skin and mucous membranes (60%), lupus nephritis (47%) and cytopenias (47%). Patients had received treatment for lupus with 5 drugs [5; 8]. Cumulative prednisone dosage was 25 g [20; 44], whilst the current daily dosage of prednisone was 4 mg [0.0; 5.0]. Hypertension was present in 4 (27%) and hypercholesterolemia in 2 (13%) subjects; 4 patients (27%) were current or past smokers. The eSCAR technique was feasible in all participants with no adverse effects. Myocardial scars were detected in 2 patients (eSCAR-positive 13%; figure and table); eSCAR positive patients were females and had no history of cardiovascular involvement (including pericarditis); they had at least one relapse within the prior 12 months before enrollment; at least one cardiovascular risk factor was found in both patients (one was a smoker and the other one had hypertension); none received prior treatment with cyclophosphamide or methotrexate; they had no renal involvement; arthritis and cytopenias were the prominent features of disease; anti-dsDNA titer was higher than eSCAR-negative patients.

Conclusion: Echocardiography allowed detection of myocardial scars in patients with SLE. Our preliminary data show that eSCAR is feasible and well tolerated in SLE patients with a more active disease.

The association between PROs and US assessment.

Results: SpA
In total, 2977 abstracts were identified, of which 12 articles were retained in the final analysis: 10 cross-sectional studies assessing disease activity state and 2 longitudinal, non-interventional trials assessing treatment response. The most frequently evaluated domains of health are depicted in table 1. The cross-sectional studies evaluating only one joint area (foot and ankle, sacro-iliac joint, shoulder and hip) showed that overall there is no important association between the PROs and the US parameters. In studies evaluating multiple entheses sites there were several correlations between PROs (pain, disease activity, function, quality of life (QoL)) and US variables, i.e., US inflammatory scores and total enthesitis scores, comprising both inflammatory and structural changes (r=0.24-0.53). In the longitudinal studies there was no consistent association between PROs and US variables.

PsA
Out of the 1267 abstracts identified, 12 were finally included in the qualitative analysis: 5 cross-sectional studies on disease activity state and 7 longitudinal studies, of which 2 on disease activity state and 5 on treatment response. The most frequently evaluated domains of health are depicted in table 1. Overall, in the cross-sectional studies, there was no consistent association between PROs and US assessment. In the longitudinal studies on disease activity, pain and patient global assessment (PGA) were associated with US inflammatory variables (r=0.22-0.28), while disability correlated with US damage (r=0.22-0.39). Change in PGA and pain was associated with change in the global US inflammation score (r=0.28-0.35). In longitudinal studies on treatment response results were inconsistent: two studies showed that there was significant parallel trend of some PROs (function, pain and PGA) and some US entheses scores, but the other 3 studies showed no significant association.

Conclusion: The association between PROs and US in SpA and PsA was rather inconsistent. Patient perspective and US examination seem to provide different, but complementary perspectives on disease assessment and both should be taken into account in SpA and PsA management.

Disclosure of Interests: None declared

measures of disease activity, i.e. imaging techniques such as musculoskeletal ultrasound (US) are also of great interest.

Objectives: The objective of this study was to determine if and to which extent the US assessment reflects patient perspective in patients with RA.

Methods: A systematic literature review was conducted on PubMed and Embase, with the research question being formulated according to the PICO framework. The patient reported domains of health were selected from the ones included in the Core Set for RA [1] and from the ones frequently reported in RA clinical trials and observational studies [2], as well as patient self-assessment of pain or functionality at the joint level. We included articles that evaluated any kind of relationship between PROs and US assessment in RA patients.

Results: Out of the 3757 abstracts identified through the systematic literature review, 53 articles were finally included in the qualitative analysis, of which 38 were cross-sectional and 15 were longitudinal studies (figure 1). The most frequently evaluated domains are depicted in table 1.

Figure 1. Flow chart of the systematic literature review.

Cross-sectional studies: Overall, patient joint self-assessment of joint swelling or tenderness had a rather poor agreement with US evaluation but showed a stronger association with the clinical examination at the joint and/or patient level. In studies evaluating RA patients in remission, disability and patient global assessment (PGA) were associated with Power Doppler (PD) synovitis (r=−0.395 to −0.460), while morning stiffness and patient assessment of flare with PD tenosynovitis (r=0.29; odds ratio, OR 1.95 [95% CI, 1.17, 3.28]). In studies on RA disease activity, morning stiffness showed good associations with US inflammatory findings, especially PD tenosynovitis (r=0.280 – 0.561; OR 3.0 [95% CI, 1.2-7.5] or OR 10.9 [95% CI,12.39-39.13]) and disability with PD synovitis/tenosynovitis (r=0.14 -0.55) and US damage/erosions (r=0.16-0.40). Pain, PGA and quality of life (QoL) mainly did not correlate with US assessment.

Longitudinal studies: In total, there was no clear, consistent longitudinal association between PROs and US variables in RA studies on remission or treatment response. However, in studies on RA disease activity, there was a strong longitudinal association between disability and US inflammatory scores (r=-0.32 - 0.40; beta: -0.009 to -0.025), but not US damage scores. Additionally, US ankle synovitis and/or tenosynovitis were shown to predict ankle pain (beta: 16.8 [95% CI: 4.81, 28.8]), and to a lesser extent disability.

Conclusion: Overall, we found contradictory results regarding the relationship between US evaluation and PROs in RA. While there were some consistent associations such as between disability and US inflammatory and structural findings or between MS and US inflammatory lesions, in particular tenosynovitis, there was no global strong correlation between US and PROs. Therefore, both assessments should be taken into consideration in RA evaluation and management.

STRUCTURAL ELEMENTS OF THE KNEE ENTHESES ASSESSED IN HEALTHY SUBJECTS WITH ULTRA HIGH FIELD MRI (150 MICRONS).

D. Roche1, C. Michel2, P. Daude3, A. Le Troter3, C. Chagnaud4, J. P. Mattei5, L. Pini3, M. Guye6, D. Bendahan4, S. Guis1. 1Aix-Marseille Université, AP-HM, Rheumatologie, Marseille, France; 2Aix-Marseille Université, CNRS, CRBBM-CEMEREM, UMR CNRS 7339, Marseille, France; 3Aix-Marseille Université, CRBBM-CEMEREM, UMR CNRS 7339, Marseille, France; 4Aix-Marseille Université, AP-HM, Radiologie, Marseille, France; 5Aix-Marseille Université, AP-HM, Rheumatologie, Marseille, France; 6Aix-Marseille Université, AP-HM, CNRS, CRBBM-CEMEREM, UMR CNRS 7339, Marseille, France; 7Aix-Marseille Université, AP-HM, CRBBM-CEMEREM, UMR CNRS 7339, Marseille, France.

Background: Fibrocartilaginous enthesis is composed of different histological zones which are commonly referred to the tendon distal extremity (a lamellar tissue with a low cell density, collagen and connective tissue), the fibrocartilageous zone (with chondrocytes), a progressively mineralized zone and the bone. The MRI visualization of the water content of entheses is challenging given the very short relation time so that entheses has been very poorly assessed using US (1).

Objectives: The main objective of the study was to assess the structural elements of the knee enthesis based on the quantitative T2* measurements using Ultra High Field (UHF) MRI.

Methods: Twelve healthy subjects without any osteoarticular pathology were included in the study after they provided their informed consent. 3D gradient echo sequence with a 4.3 ms echo time and T2* mapping were performed. Based on T2* measurements performed using UHF MRI, the different structural elements of the knee enthesis were distinguished. This quantitative stratification could be used to assess changes in pathological conditions such as SpA and trauma.

Results: The quadrupical tendon and the bone trabeculation could be visualized on the UHF MR image. The T2* mapping analysis illustrated a large value (16.4 ± 4 ms) for the subchondral bone and much lower values for the trabecular bone (11 ± 4.5 ms) and the different zones of the knee enthesis (7.7 ± 1.9 ms).

Conclusion: Based on T2* measurements performed using UHF MRI, the different structural elements of the knee enthesis were distinguished. This quantitative stratification could be used to assess changes in pathological conditions such as SpA and trauma.

Figure 1. Maximum sum score of FOIAS in PsO and PsA patients (p=0.0075 in two-sided t-test).

Conclusion: SIJ MRI had an excellent specificity for the diagnosis of SpA but a moderate sensitivity. Consequently, some patients in early stages of SpA might be missed by MRI. In addition, we found that diagnostic based solely on BME lacked sensitivity. Detection of erosions in addition to BME enhanced sensitivity (from 34.9% to 44.9%) without changing specificity. Indeed, many recent studies have pointed out the importance of considering structural lesions of SIJ in addition to inflammatory lesions [1, 2].

THE PERFORMANCE OF COMPUTED TOMOGRAPHY FOR ASSESSING SACRITILITIS IN EARLY SPONDYLOARTHRITIS: WHICH STRUCTURAL LESIONS ARE MOST CONTRIBUTIVE TO THE DIAGNOSIS?

D. Ben Nessib1, H. Riah1, D. Kafeli1, E. Labbene1, K. Maatallah1, M. Bouaziz2, M. M. Kchiri1, W. Hamd2, F. Ladeb2, Kassab Institute of Orthopedics, Rheumatology, Mannouba, Tunisia; 2Kassab Institute of Orthopedics, Radiology, Mannouba, Tunisia

Background: Computed tomography (CT) of sacroiliac joints (SIJ) is usually considered as a third-line modality in the diagnosis of spondyloarthritis (SpA), as it shows only structural lesions. According to 2015 EULAR recommendations, CT may be helpful if conventional radiograph is inconclusive and MRI cannot be performed [1]. However, its contribution for the early assessment of sacroiliitis is still little-studied.

Objectives: The purpose of this study was to assess the performance of CT scan for detecting sacroilitis and the contribution of the different structural lesions to the early diagnosis of SpA.

Methods: This cross-sectional prospective monocentric study included consecutive patients, aged over 16, consulting for symptoms suggestive of SpA between February 2014 and 2017. Patients with pelvic radiograph showing a confirmed sacroiliitis (making CT unnecessary to confirm the diagnostic) were not included. Eligible patients underwent CT of SIJ and the images were reviewed by 2 experimented musculoskeletal radiologists blinded to clinical findings. Then, 2 experienced rheumatologists analyzed clinical, biological and radiological data and classified patients into 2 groups: confirmed non-radiographic spondyloarthropathy (nr-SpA) or no SpA. This classification was considered as the gold standard of this study.

Results: A total of 60 patients, 45 women and 15 men, were included in this study. Forty-six patients were assessed as confirmed nr-SpA (76.6%) and 14 patients as no SpA (23.4%). Mean age at the diagnosis was 39.5 ± 10.8 years [17-59], and the disease duration from first symptoms was 48.6 ± 40 months [6.6-180]. Chronic back pain met the Calin criteria in 37 patients (61.7%), the Berlin criteria in 46 patients (76.7%) and the ASAS criteria in 32 patients (53.3%). Among the patients diagnosed as confirmed SpA, 71.7% were determined to have sacroiliitis at CT. As shown by the following table, the most sensitive lesion was subchondral bone sclerosis and the most specific one was new bone formation at entheses:

</tbody>
</table>

Conclusion: The relatively limited place of SIJ CT can be explained by the lack of investigations evaluating its real contribution in detecting sacroilitis. In this study, we found that the main SI structural lesions were significantly associated to the final diagnosis of SpA with a sensitivity up to 78.3% and a specificity up to 92.9%. The main limitation of this technique remains the large radiation dose delivered to the gonads, especially with the commonly used axial position for CT. However, recent studies found that oblique coronal CT imaging seems to be a very promising technique, since it allows visualization of the subtle radiologic signs of sacroilitis while delivering less radiation dose [2].

COLOR DOPPLER ULTRASOUND OF SACRITILIC JOINTS COMPARED WITH MAGNETIC RESONANCE IMAGING IN NON RADIOGRAPHIC SPONDYLOARTHRITIS

M. Bouaziz1, D. Ben Nessib1, H. Riah1, K. Maatallah1, E. Labbene1, H. Ferjani2, M. M. Kchiri1, W. Hamd2, F. Ladeb2, Kassab Institute of Orthopedics, Rheumatology, Mannouba, Tunisia

Background: Magnetic resonance imaging (MRI) of sacroiliac joints (SIJ) can assess early inflammatory changes, thus allowing an early diagnosis of spondyloarthropathy (SpA). However, its use in clinical practice may be limited by its cost, its duration and its limited availability. In this sense, ultrasound (US) has been suggested as a feasible and easy-to-apply alternative.

Objectives: The objective of this study was to evaluate the validity of Color Doppler Ultrasound (CDUS) in early assessment of sacroilitis, compared to MRI findings as the gold standard.

Methods: A cross-sectional prospective monocentric study included patients attending the rheumatology department with suggestive signs of SpA between February 2014 and February 2017. Patients with pelvic radiography showing a confirmed sacroiliitis (grade 3 or 4) were not included. Eligible patients underwent US and MRI of SIJ. US examinations were performed by an experimented musculoskeletal radiologist blinded to MRI results. Vasculature within the SIJs was explored by the presence of a CDUS. When an artery was found, the resistive index (RI) was measured. The values of the RI ranged between 0 and 1. Doppler of each SIJ was considered as positive when RI < 0.75.

Results: Forty-three patients were included: 10 men and 33 women, with an average age at inclusion of 40.2 ± 11.1 years [17-59]. The mean duration of symptoms was 46±37.5 months [6.6-180]. A personal history of uveitis was noted in 3 patients and of chronic diarrhea in 3 patients. Morning stiffness was noted in 72% (n=31) of patients. Good response to nonsteroidal anti-inflammatory drugs (NSAIDs) and to physical activity were respectively reported by 41.8% (n=18) and 58% (n=25) of patients. Sacroilitis compression test, distraction provocative test, sacral thrust test, Gaenslen’s test, Faber’s test (Patrick) and Mennell’s test were respectively positive in 39.5%, 32.5%, 48.8%, 23.2%, 32.5%, and 51.2% of the patients. Twenty-seven per cent of the patients were HLA-B27+. The MRI showed a confirmed sacroilitis in 14 patients. Doppler signal was detected in 44 SIJ of 25 patients, of whom 14 SIJ of 8 patients showed bone marrow edema at MRI (p=0.054). At the joint level, considering MRI-proven sacroilitis as the diagnostic standard, CDUS had a sensitivity of 70%, a specificity of 54.5%, a positive predictive value of 31.8%, and a negative predictive value of 85.7%. The spectral Doppler RI, averagedly estimated at 0.74±0.12 [0.48-0.87], was not associated with the presence of sacroilitis on MRI (p=0.747).

Conclusion: US, an imaging technique increasingly used in the assessment of musculoskeletal diseases, has been suggested to detect active sacroilitis [1, 2]. Our study revealed that in early SpA, CDUS may be useful to assess active inflammatory changes of SIJ since it had a sensitivity of 70%, despite a relatively reduced specificity. However, RI values, which are expected to be low in patients with active inflammation [3], were unrelated to the presence of sacroilitis. Future studies on larger numbers of patients might be conducted to complete previous data.

DOI: 10.1136/annrheumdis-2020-eular.4954
Background: Medical image analysis using deep learning (DL) has been attracting attention. In previous research, we proposed a DL method for detection of joint region and evaluation for bone destruction at a single point in time in hand X-rays of patients with rheumatoid arthritis (RA) [1-2]. However, in the score of van der Heijde-modified total Sharp scores (mTSS) in X-rays, it is difficult to apply the method as it is. In mTSS, score difference between 2-time points is important, and there is a problem that the score at each time varies depending on the doctor who evaluates.

Objectives: We aimed at developing an mTSS scoring method considering 2-time-point difference with a DL method.

Methods: A total of 104 X-ray image sets of both hands at two time points with an interval of ≥1 year were randomly obtained from patients with RA who had visited our clinic in 2015. Well-trained doctors determined the erosion scores of MP and PIP/IP joints of each hand in X-rays according to mTSS. These evaluations of hand joints were performed using our developed annotation software tool. In the learning phase, joint images were randomly divided into five sets for 5-fold cross-validation. We utilized a convolutional neural network model, such as SSD [2], for detecting joint regions and classifying the scores (Fig 1).

The models for classification were designed in consideration of the difference in erosion scores of each patient between the 2-time points of X-rays. The loss function of the DL model was defined below;

$$
\text{SCE: softmax cross entropy} \\
\text{MSE: mean squared error} \\
t: \text{training data} \\
y: \text{output of DL model} \\
0: \text{the former time point} \\
1: \text{the latter time point} \\
T: \text{transpose of matrix} \\
\gamma: \text{coefficient designed to reduce the error for another set of scores with equal differences.}$$

Here, the coefficient $\gamma$ is designed to reduce the error for another set of scores with equal differences. The first term of the loss function works to optimize the score at each time point, and the second term works to optimize the score difference at both time points. Thus, our method can be trained without being affected by characteristic training data.

Results: The number of joints with differences in erosion score between the former and latter time points was 1 (+2 points), 9 (-1), 2015 (0), 32 (+1), 17 (+2), and 6 (+3). There were no joints with score changes of -5, -4, -3, -2, -1, 0, and +5 points. As a performance of predicting the difference in erosion score between the 2-time points of each patient's X-ray, our models presented a mean error of 0.412 per each joint in one set for 5-cross validation as compared with physicians' evaluation (Fig 2).

Conclusion: Our DL-based models to predict hand joint erosion scores in X-rays were developed with relatively small samples. This suggests that the predictive performance may increase by collecting more training dataset. Next, we will apply our method to the prediction of joint space narrowing score.

DOI: 10.1136/annrheumdis-2020-eular.4107
Background: Abnormal liver function can be seen in not only hepatitis B virus infection (HBV), hepatitis C virus infection (HCV), hepatic carcinoma (HCC), but also in primary biliary cirrhosis (PBC), autoimmune hepatitis (AIH), and systemic autoimmune rheumatic diseases (SARD). Antinuclear antibody (ANA) testing is a common and economical method which contributes to detect SARD and autoimmune liver diseases [1].

Objectives: Our objective was to investigate ANA positivity, titers and their patterns in multiple liver diseases, including PBC, AIH, HBV, HCV, and HCC, compared to healthy controls (HC).

Methods: 2537 patients with SARD, 137 PBC cases, 57 AIH cases, 3420 HBV cases, 769 HCV cases, 268 HCC cases, and 1073 HC were retrospectively assessed. The titers and patterns of ANA were detected with the IIFA method.

Results: ANA positivity rate was considerably discernible between these diseases, which is 90.1% in SARD, 93.4% in PBC, 49.1% in AIH, 19.1% in HBV, 13.9% in HCV and 23.5% in HCC. Moreover, only 4.9% of HCC cases, 2.5% of HBV patients and 1.6% of HCV patients had an ANA titer ≥ 1:320. The mixed pattern which composed of at least two patterns majorly lied in PBC and AC-15 and AC-21 was frequently related to liver diseases; the former pattern was more frequently found in AIH (84.2%) and PBC (8.8%), and the latter pattern was easily seen in PBC (62.2%) and HCC (22.6%). The positive rate of ANA in HC was 12.2% and its major pattern was AC-2.

Conclusion: There are differences in ANA positivity among patients with SARD and various liver diseases. Some mixed patterns may provide important evidence for the diagnosis of PBC. Clinicians should pay attention to ANA patterns and titer during the interpretation of this test.

US synovitis sum scores (0-102)

| GS | 29 (21-38) |
| PD | 2 (1-5) |
| US periarticular PD sum score (0-16) (PIP + DIP) | 1 (0-3) |

Prevalence and bias adjusted Kappa (PABAK) US: Ultrasound GS: Greyscale PD: PowerDoppler

Agreement between clinical and US joint evaluation is shown in table 2. There was poor agreement between TJ and US synovial hypertrophy and hyperaemia (PABAK 0.12 and 0.20, respectively) and fair agreement with periarticular PD (PABAK 0.25). Moderate agreement was found for SJ and intraarticular PD activity (PABAK 0.55). Our definition of US synovitis showed similar agreements with TJ and SJ as US hyperaemia.

Table 2. PABAK agreement of clinical examination and US findings.

| Swollen joint | US synovial hyperaemia (GS) | US synovial hyperaemia (GS+1, PD=0) | US synovitis (GS+1, PD=0) | US periarticular PD (PD) |
| No. of joints | 3108 | 1428 | 1428 | 1428 | 672 | 672 |
| Tender joint | 0.53 | 0.12 | 0.20 | 0.20 | 0.25 | 0.20 |
| Swollen joint | 0.35 | 0.55 | 0.56 | 0.45 | 0.55 |

Prevalence and bias adjusted Kappa (PABAK) US: Ultrasound GS: Greyscale PD: PowerDoppler

Conclusion: In this study TJ did not reflect intra- or periarticular US inflammation in PsA patients. SJ had a better agreement with US findings of inflammation, especially PD, which is in line with previous RA studies.

AB1107 DACTYLITIS IN PSORIATIC ARTHRITIS – PREVALENCE AND RELIABILITY OF ULTRASOUND PATHOLOGIES
S. Kamp Felbo, M. Østergaard, I. J. Sørensen, L. Terslev, Rigshospitalet, Center of Rheumatology and Spine Diseases, Glostrup, Denmark

Background: Dactylitis is an important clinical feature in psoriatic arthritis (PsA). Early imaging studies indicated tenosynovitis and adjacent subcutaneous edema (SCE) as the main components in dactylitis, but more recent ultrasound (US) studies have found involvement of many other structures including synovitis and enthesitis (1). To date, there is no consensus on which US elementary lesions constitutes dactylitis.

Objectives: To investigate by US the prevalence of different elementary lesions found in dactylitis in PsA, and the reliability of scoring these lesions in a clinical setting.

Methods: In a cross-sectional study 31 patients with PsA and dactylitis were included from a rheumatology out-patient clinic. The most affected digit in each patient was examined both dorsal and volar, in longitudinal and transversal plane, using greyscale (GS) and color Doppler (CD) US with a 6-15 MHz linear transducer. One examiner scanned all patients and a 2nd examiner scanned 10 patients for inter-reader reliability. 1st examiner re-read images after appr. 3 weeks for intra-reader reliability. Following pathologies were scored: 1. SCE (hypo- or anechoic areas in the subcutaneous tissue, with/without hyperemia) 2. Soft tissue thickening 3. Synovitis of the metacarpalphalangeal (MCP) or metatarsalphalangeal (MTP), proximal interphalangeal (PIP), distal interphalangeal (DIP) or interphalangeal (IP) joints 4. Tendonitis of the flexor or extensor tendon (ET) entheses at the deep flexor tendon (FT) and the extensor tendon (ET) entheses 6. Paratenonitis of the ET (hypoechoic area and CD around the ET). OMERACT US definitions and scoring were used for synovitis, tenosynovitis and enthesitis.

Results: Patients were 55% males, with short disease duration (median (inter-quartile range (IQR)) 1 (0-6) year) and moderate disease activity (median (IQR) DAS28 3.2 (3.2-4.4), 45% of the examined digits were fingers, 55% toes. 74% were tender, 26% non-tender. US findings and intra- and inter-reader agreements are presented in table 1. Intra- and inter-reader agreements were moderate to excellent, except for some entheses due to low prevalence of findings. Therefore, the prevalence and bias adjusted Kappa was used for these. All pathologies were found primarily in combinations, most commonly SCE and synovitis (71%), followed by SCE and flexor tenosynovitis (52%), and all three in combination (52%). No patient had flexor tenosynovitis as a sole component. No significant difference was found in tenderness versus non-tender dactylitis.

S. Y. Kang1, M. Y. Lee1, M. H. Kim1, W. I. Lee2, Kyung Hee University, College of Medicine, Laboratory Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Autoantibodies that produce the homogenous pattern on anti-nuclear antibody-indirect immunofluorescence assay (ANA-IIF) using human epithelial cell (HEp-2) substrate are histones, dsDNA and nucleosome. Homogenous pattern may be seen in patients with many different systemic autoimmune diseases as well as organ-specific autoimmune diseases. Homogenous pattern is difficult to distinguish from dense fine speckled (DFS) pattern and other staining patterns.

Objectives: The purpose of this study was to analyze the profile of autoantibodies in patients with homogenous pattern on IIF-ANA assay and to find out the clinical significance of homogenous pattern.

Methods: A total of 103 sera samples with homogenous pattern on IIF-ANA assay were obtained. The IIF-ANA assay was performed using the Phadia 100 system (Thermo Fisher Scientific, Freiburg, Germany). Laboratories, Hercules, CA, USA) with Kallestad HEp-2 slides (Bio-Rad Laboratories, Hercules, CA, USA). ELISA CTD Screen and EliA dsDNA (Thermo Fisher Scientific, Freiburg, Germany) were performed using the Phada 100 system (Thermo Fisher Scientific, Freiburg, Germany). EliA CTD Screen has following specific antigens: U1RNP (RNP70, A, C) and SS-A/many) were performed using the Phadia 100 system (Thermo Fisher Scientific, Freiburg, Germany).

Results: Of the 103 patients with homogenous pattern on IIF-ANA assay, 21 were diagnosed as systemic autoimmune rheumatic disease (SARD) or organ-specific autoimmune diseases (autoimmune group), whereas 82 were not patients with autoimmune diseases (non-autoimmune group). Among 103 patients, 62 sera samples were reactive to dsDNA, 52 to histone, and 49 to nucleosome. The detection rates of autoantibodies were 10.7% for dsDNA, 15.5% for histone, and 19.4% for nucleosome. Anti-DFS70 antibody was detected in 6 patients (5.8%) and they were positive and the remaining 14 (44%) were negative on dsDNA, histone or nucleosome. This suggests that homogenous pattern may be masked by homogenous pattern.

Conclusion: It is generally accepted that homogenous pattern is caused by anti-DNA antibody against dsDNA, histone and nucleosome. However, the results of this study found that the majority (79.6%) of patients with homogenous pattern had no autoimmune diseases and only 31% had autoantibodies to dsDNA, histone or nucleosome. Especially, 49.5% of patients were all autoantibodies were positive in 42.9% (9/21) of autoimmune group and 23.2% (19/82) of non-autoimmune group.

AB1109 THE TIME-TO-EVENT ANALYSIS OF THE APPLICATION OF ULTRASOUND TO DISTINGUISHING PMR

T. Kawacuchi1, M. Ogasawara1, K. Yamaji1, N. Tamura1, J. Juntendo University, School of Medicine; Internal Medicine and Rheumatology, Tokyo, Japan

Background: Japan is the world's most aged country. The number of patients with polymyalgia rheumatica (PMR) is expected to increase more. Classification criteria including ultrasound findings were published in 2012(1), but the ability to differentiate PMR from other mimicking diseases was unknown.

Objectives: To clarify whether recently reported ultrasound findings (2, 3) could be characteristic in PMR are helpful for distinguishing from other mimicking diseases and treatment outcome in suspected PMR patients.

Methods: Patients who were clinically suspected of PMR were extracted from the medical record database of the hospital. Patients who had been administrated GC at the first visit and whose records were not confirmed were excluded. Patients were clinically diagnosed with PMR without ultrasound(Ci-PMR), patients who were diagnosed with PMR with ultrasound reports(US-Ci-PMR), patients who were diagnosed by the ultrasound expert only based on ultrasound images(US-PMR).

Results: Of the 103 patients with homogenous pattern on IIF-ANA assay, 403 of 545 was excluded because of preexisting GC therapy and record availability. At the 6 months follow-up, 92.8% of the non-US PMR group and 97% of US-PMR group were positive on PMR at the 12 months follow-up 88.8% and 95% respectively. There was no significant difference in the three time-to-event outcomes.

Conclusion: Ultrasound did not improve the improvement of the PMR outcome. Furthermore, this finding is supported by confounding factors for example, assignment to ultrasound and atypical cases and rheumatologists' uncertainty. Despite confounding factors, US-PMR group was not inferior. These findings showed that ultrasound may be useful for the complicated cases.

AB1110 QUANTUM BLUE® RAPID TDM ASSAY STANDARDIZATION HIGHLY CORRELATES WITH WHO INTERNATIONAL STANDARD FOR INFliximAB

E. Kelkel1, F. Spies2, F. Frei3, V. Eckhardt1, T. Schuster1, M. Schneider1

1BÜHLMANN Laboratories AG, Schönenbuch, Switzerland; 2University of Applied Sciences and Arts Northwestern Switzerland, Muttenz, Switzerland

Background: Therapeutic drug monitoring of RA patients under anti-TNF therapy is based on trough level determination of the drug. Rapid assays and multiple ELISAs are available that measure anti-TNF biologics. An international standard is required to improve comparability among different assays. Recently, WHO introduced a series of anti-TNF standards for etanercept, adalimumab and infliximab. This is the first step for achieving common standardisation of assays available on the market.

Objectives: The aim of the study was to evaluate the correlation of the WHO standard with BÜHLMANN Quantum Blue® Infliximab standardization and to compare spiking recovery in three commercially available infliximab ELISAs and one infliximab rapid test.

Methods: Calibration curves were generated with BÜHLMANN calibrators and with calibrators made from WHO international standard for infliximab (NIBSC 16/170). Twenty-six serum samples, covering a concentration range from 0.5 µg/mL to 19 µg/mL, were analyzed with both calibration curves and compared by Bland-Altman and Passing-Bablok analysis. Furthermore, recovery of six serum samples spiked with WHO international standard for infliximab was determined in the following ELISA TRACKER® Adalimumab (a), Griffols/Progenika Promonitor FIV (b), Immundiagnostik IDKmonitor Infliximab drug level (c) and BÜHLMANN Quantum Blue® Infliximab (d). Spiking recovery experiments were performed according to Westgard 2008.
Results: The sample values gained with BÜHLMANN calibrators showed an excellent correlation with values gained with the WHO international standard for infliximab as calibrator. Passing-Bablok regression analysis revealed a slope of 0.978 and an correlation coefficient (R) of 0.99. Bland-Altman analysis revealed a mean difference in the obtained values of less than five percent. Regarding spiking recovery analysis, all tests exhibit an excellent mean recovery of 101% (85-114%); a), 99% (91-105%); b), 101% (95-107%); c) and 94% (88-100%); d).

Conclusion: Current standardization of Quantum Blue® Infliximab rapid test correlates very well with the WHO international standard for infliximab (NIBSC 16/170). Spiking recovery was highly comparable for ELISAs and the Quantum Blue® Infliximab assay. This rapid test represents a unique and modern analyti-

AB1111 PREDICTIVE VALUE OF FLUORESCENCE-OPTICAL IMAGING TECHNIQUE IN DETECTION OF PSORIATIC ARTHRITIS IN PSORIASIS PATIENTS

M. Köhn1,2,3, S. Ohrndorf4, T. Roßmannith3, M. Backhaus5, G. R. Burmester6, S. Wassenberg6, B. Köhler6, H. Burkhardt1,2,3, F. Behrens1,2,3, 1Goethe-University Frankfurt, Rheumatology Department, Frankfurt, Germany; 2Fraunhofer Cluster of Excellence Immun-Mediated Disease CIMENT, Frankfurt, Germany; 3Fraunhofer IME Translational Medicine and Pharmacology, Frankfurt, Germany; 4Universitätsmedizin Charité, Berlin, Germany; 5Park-Klinik Weissensee, Berlin, Germany; 6Rheumazentrum Ratingen, Ratingen, Germany

Background: Psoriasis (PsO) is one of the most common chronic inflammatory skin diseases in Europe. Psoriatic arthritis (PsA) is closely associated to PsO whereas the skin manifestation appears usually years before PsA-related symptoms emerge. Up to 30% of PsO patients develop PsA, but there is no clear correlation between disease duration of PsO and PsA development. Therefore, biomarkers for its early detection are of major importance. In early PsA, changes in synovial vascularisation combined with increased expression of proangiogenic factors appear first. Therefore, imaging biomarkers for detection of changes in vascularisation might be useful for early detection of musculoskeletal disease.

Fluorescence-optical imaging (FOI) is a new method to detect changes in microvascularisation of the hands.

Objectives: To determine the number of positive PsA diagnosis within a 24 month follow-up period in PsO only patients with subclinical MSK-inflammation detected in FOI.

Methods: Sensitivity of FOI for detection of subclinical signs of musculoskeletal inflammation as biomarker for early PsO was observed in a prospective, multicentre study (XCITING) including patients with dermatological confirmed skin psoriasis. 411 patients were included from dermatology care units across Germany without diagnosis of PsA but potential risk factors for its development (nail psoriasis and/or joint pain or swelling within the last 8 months). Clinical examination (CE; swollen (66) and tender (68) joint count, enthesitis, dactylitis assessment) and standardised ultrasound (US) assessment was performed by a qualified rheumatologist to assess musculoskeletal inflammation. FOI was performed additionally. Data was analysed in focus on increased vascularisation of musculoskeletal structures as inflammatory markers. In case of discrepant results (positive FOI and negative CE and US), MRI was performed to prove the findings. In case of MRI negativity, a follow-up period of 24-months was performed including FOI, CE, US and MRI assessment.

Results: 83 of the 411 patients of the cohort were negative in all assessments (PsO only), 136 of the 411 patients were classified as PsA by rheumatologic assessments. 119 patients showed subclinical signs of musculoskeletal inflammation in the central reading of FOI, whereas CE and US were negative. In 37.5% of those patients, subclinical inflammation was confirmed by MRI assessment. 22 patients of the cohort without MRI positivity were willing to be followed up until month 24. 5 (7.5%) patients developed a clinical PsA until month 24 whereas 7 (10.5%) patients converted to be FOI negative. In 5 patients an additional MRI examination was performed in which one patient showed positive signs for inflammation.

Conclusion: FOI is an innovative method for measurement of changes in microvascularisation in the hands. 6/22 patients initial positive only in FOI (no clinical signs for PsA, negative US, negative MRI) developed either clinical evidence PsA (n=5) or new inflammation in MRI (n=1) during follow-up of 24 months. Therefore, FOI positive signals in PsO patients increase the probability for PsA development.

AB1112 THE DIAGNOSTIC OF THE OSTEOARTHRITIS OF THE HANDS BY CONVENTIONAL RADIOGRAPHY

O. Kurinsky1, L. Aleksieva2, A. Smirnov1, A. Volkov1, O. Aleksieva1, E. Taskina1, A. Sukhlinina1, 1Moscow, Diagnostic Department, Moscow, Russian Federation; 2Moscow, Clinical Department, Moscow, Russian Federation

Background: The most severe phenotype of osteoarthritis (OA) is currently considered to be an inflammatory or erosive phenotype (EOA). There is currently no reliable x-ray picture of this disease in the literature, and the question of whether it is an independent form of OA, a natural more pronounced stage of progression, or a separate nosology is debated in the literature.

Objectives: To identify the localization, frequency, and severity of pain and radiological symptoms in patients with EOA and non-erosive (NOA) disease in the interphalangeal (DIP) and PIP and metacarpal (MCP) joints of the hands.

Methods: 64 women with diagnosis of OA of the hand (HOA) joints according to the ACR criteria were included into study after signing the informed consent form.

Mean age was 65.28 ± 6.82 years (48-77), mean BMI 27.7 ± 4.4 kg/m², mean disease duration 12 ± 8.1 years. Individual patient’s medical record included relevant anthropometric data, records from case history and clinical examination, AUS-CAN scores, patient’s articular status. Instrument diagnostic methods included plain radiography of the hand joints in an anterior-posterior projection. The images were described in accordance with the Kellgren-Lawrence (K-L) system. When evaluating radiographs of 64 patients with HOA, the most common was stage II (49%) according to K-L, and the most common symptoms in distal (DIP), proximal (PIP) interphalangeal and MCP were joint space narrowing (JSN) (100%, 100%, and 95%, respectively) and osteophytes (OP) (88%, 70%, and 45%, respectively). Subchondral osteosclerosis (SO) (5%), erosions (8%), and subluxations (3%) in MCP, as well as subluxation in PIP (6%) were less common. Statistica 10.0 was used for statistical analysis.

Results: 23 patients had EOA, 37 had NOA. Depending on the presence of erosions in interphalangeal joints patients were divided into 2 groups comparable in terms of age, age of OA onset and duration of disease (the average age of patients with EOA interphalangeal joints was 68 ± 6.15 years, and mean disease duration 18,34 ± 7.11 years; in the group without erosive changes in the average age amounted to 65,13±5.43 years, mean disease duration of 16,56±8.84 years).

Results: EOA DIP and PIP was detected in 15 (23%) with radiological changes corresponding to stages III-IV of HOA and in 6 people (12%) with stage II on
the K&L scale. Patients with stage I according to standard radiography had no erosive process.

In DMFs OP (100% and 78%, OR=1.28, 95%, CI [1.08-1.5], p=0.02), SO (74% and 11%, OR=6.8, 95%, CI [2.6-17.9], p<0.0001), subchondral cysts (SC) (61% and 24%, OR=2.5, 95%, CI [1.3-4.8], p=0.006) and subluxations (43% and 14%, OR=3.2, 95%, CI [1.8-5.3], p=0.01) were significantly more often found in patients with EOA. In PiPs SO (43% AND 5%, OR=8.04, 95%, CI [1.93-33.5], p=0.0005), SC (52% and 27%, OR=1.93, 95%, CI [0.1-7.3], p=0.045) and subluxations (17% and 0%, p=0.01) were significantly more frequently detected in patients with EOA compared to the non-erosive group. According to the results of the AUSCAN questionnaire, a significantly greater severity of pain was found in patients with EOA (65%) in comparison with the non-erosive (30%) form of HOA (OR=2.19, 95%, CI [1.23-3.9], p=0.008).

Conclusion: DIPs are most often affected in OA of interphalangeal joints, less often PiPs, the most common symptoms are JSN and OP. At EOA in addition to more frequent detection OP, cysts, SO, subluxations in PiPs, SO, cysts and subluxations in PiPs, there is also significantly more pronounced pain according to AUSCAN data, it can be concluded that EOA is more severe in comparison with the non-erosive form of HOA.

**AB1113**

**DIAGNOSTIC VALUE OF ANTI-SA AND ANTI-HN RNP K ANTIBODIES IN SERONEGATIVE RHEUMATOID ARTHRITIS**

M. Volkova1, A. Kunder1, 1BelMAPGE, Minsk, Belarus

**Background:** The diagnostics of seronegative rheumatoid arthritis (RA) remains the important issue in modern rheumatology. Other biomarkers are studied to close the diagnostic gap. The aim of work is to assess anti-Sa and anti-hnRNP K in patients with RA and to evaluate their diagnostic value in seronegative by anti-CCP and RF RA.

**Methods:** In the study were included 270 patients, which fulfill EULAR/ACR 2010 criteria for RA and 50 healthy controls. The mean of patients age was 52.80 (95% CI:51.70-54.80 years).

Levels of antibodies to anti-CCP and anti-Sa were evaluated by ELISA according to the instructions of the manufacturer (Euroimmune, Germany). The levels of rheumatoid factor (RF) were assessed by kinetic nephelometry using an automatic analyzer Beckman Coulter (USA).

**Results:** Anti-CCP in patients were found 209 (77.41%) patients, RF - in 192 (71.11%) patients, anti-Sa – in 163 (60.37%) patients, anti-hnRNP K – in 63 (23.33%) patients. The incidence of Anti-CCP, RF, anti-Sa, anti-hnRNP K in RA was significantly higher (p<0.05) than in healthy individuals (0%, 0%, 1%, 2.00%), respectively.

The diagnostic sensitivity and specificity of anti-Sa to discriminate seronegative by anti-CCP and RF RA patients from healthy controls by ROC – analysis were determined and made up for anti-Sa - 50.00% (95%CI: 26.1 - 73.9) and 96.77% (95%CI: 83.2 - 99.5) respectively (area under ROC-curve 0.734; 95%CI: 0.588-0.850; p=0.0026), for anti-hnRNP K - 55.56% (95%CI:35.3 - 74.5), 100.00% (95%CI: 95.7 - 100.0) respectively (area under ROC-curve 0.778; 95%CI: 0.689-0.851, p<0.0001). There were no significant differences in clinical (DAS28, CRP, SDAI, treatment options) and laboratory characteristics (ESR, CRP, anti-CCP, RF levels) between anti-Sa-positive and anti-Sa-negative patients (p>0.05) as well as between anti-hnRNP K-positive and anti-hnRNP K-negative patients (p>0.05).

**Conclusion:** Anti-Sa and anti-hnRNP K may serve as potential additional laboratory biomarkers for seronegative RA to allow to close the seronegative RA gap and confirm the diagnosis of RA.

Since patients diagnosed with RA do not necessarily meet classification criteria, it is not surprising that the ML cases and GSs do not overlap. The ML cases overlap to a larger degree with the 1987 GS than with the 2010 GS. Clinically, the ML identified cases do not differ from the 2010 and 1987 GS cohorts except for a slightly higher CCP2 positively compared to the 1987 GS (65 vs 51%) and the combined criteria (65 vs 56%) (Table 1 & 2).

**Conclusion:** ML algorithms processing clinician notes enable fast and efficient selection of cases that are clinically similar to cases selected by criteria based chart review. This allows a significant reduction of time and effort required to construct high quality research cohorts.

**Table 2.** Comparison of baseline characteristics between 3 ML defined cohorts and a criteria based gold standard.

AB1115 REAL-WORLD NAILFOLD VIDEOMICROCIRCULARISCOPE IN A REFERRAL CENTER IN NORTHWESTERN COLOMBIA: A RETROSPECTIVE COHORT STUDY

D. C. Varela Tabares1, J. Gutiérrez Bolanos1, L. M. Rodríguez Padilla3, M. A. Mesa Navas3,4, C. J. Velásquez-Franco3,4 on behalf of EULAR Study Group on Microcirculation in Rheumatic Diseases. Universidad Pontificia Bolivariana, Medellin, Colombia; Universidad Pontificia Bolivariana, Internal Medicine, Medellin, Colombia; Universidad Pontificia Bolivariana, Research, Medellin, Colombia; Universidad Pontificia Bolivariana, Clinica Universitaria Bolivariana, Rheumatology, Medellin, Colombia; EULAR Study Group on Microcirculation in Rheumatic Diseases, Medellin, Colombia

Background: Nailfold videomicrocircapillaroscopy is a non-invasive tool for the assessment of peripheral microcirculation, and it is useful for the diagnosis and prognosis of systemic autoimmune diseases. Despite its frequent use in clinical practice, the indications of this procedure are not standardized and there is no clear information in real-life about the reasons for remission, the presence of clinical findings of autoimmune diseases during the procedure, the frequency of patterns of autoantibodies and specific capillaroscopic findings.

Objectives: To describe the sociodemographic, clinical, paraclinical, and capillaroscopic findings of a cohort of subjects referred to a capillaroscopy service in northwestern Colombia.

Methods: We conducted a retrospective cohort study, including subjects from 2015 to 2018. Patients were evaluated by two expert rheumatologists. Variables: Reasons for referral, capillaroscopic patterns at baseline and at 6-month follow-up, presence of clinical findings of systemic autoimmune diseases during the procedure (Raynaud’s phenomenon, puffy fingers, scarring, pitting scars, digital ulcers, scierosis cutis, platsyma sign, Gottron, and microangiopathy), along with the pattern and number of autoantibodies. Categorical variables were expressed in frequency and percentage and quantitative variables in mean and standard deviation or median with interquartile range, depending on the distribution of the data. Statistical package: SPSS 25. This survey was approved by the institutional Ethics Committee.

Results: A total of 392 capillaroscopies were performed, 318 for the first time. The referral reasons for capillaroscopy were: Raynaud’s phenomenon (n=134; 42.1%), connective tissue disease different than systemic sclerosis (SSc) (n=105; 33.1%), and systemic sclerosis (n=79; 24.8%). The baseline capillaroscopic patterns found were: Normal (n=123; 38.7%), non-specific (n=81; 25.5%), SSc (n=90; 28.3%), sclerodermia-like (n=24; 7.5%), Among SSc patterns, typical pattern (21;90; 23.3%), active, (38/90; 42.2%), and late patterns (31/90; 34.4%) were found. Of the 12 capillaroscopies that presented a non-specific pattern at 6-month follow-up, only one (8.3%) progressed to a systemic sclerosis pattern. In the SSc patterns, the frequency of clinical findings were: scierodermia (n=34; 37.8%), Raynaud’s phenomenon (n=26; 28.9%), puffy fingers (n=10; 11.1%), platsyma sign (n=10; 11.1%), pitting scars (n=8; 8.9%), digital ulcers (n=8; 8.9%), telangiectasia (n=7; 7%), microangiopathy (n=4; 4%), and Gottron (n=11; 1.1%). In the SSc patterns, 42/44 subjects (95.4%) had positive antinuclear antibodies in an mean dilution of 1:320; the most frequent (n=4; 4.4%), and Gottron (n=1; 1.1%). In the SSc patterns, 42/44 subjects (95.4%) had positive antinuclear antibodies in an mean dilution of 1:320; the most frequent (n=4; 4.4%), and Gottron (n=1; 1.1%). In the SSc patterns, 42/44 subjects (95.4%) had positive antinuclear antibodies in an mean dilution of 1:320; the most frequent (n=4; 4.4%), and Gottron (n=1; 1.1%). The baseline capillaroscopic patterns found among the two cohorts from each center performed by three readers were high agreement-high disease activity at baseline. Demographic, clinical and MASEI baseline characteristics are shown in Table 1. Mean global MASEI score was 29.4 (±11.4) and 55 patients (86%) scored ≥18 (proposed cut-off point to diagnose SpA). At the patient level, abnormal US findings consistent with at least one enthesitis showing PD signal were observed in 52(81.3%) of patients using MASEI PD and 48(75%) using OMERACT PD definition without significant variation among the different SpA subtypes (p=0.8 and p=0.6, respectively). The inter-reader reliability among the two cohorts from each center performed by three readers were high (ICC cohort 1:0.92; cohort 2:0.85) and inter three readers kappa was good (0.92 and 0.86 for Doppler and Doppler OMERACT respectively).

Conclusion: PD enthesitis is found in the vast majority of patients with active SpA and PsA, independent of SpA subtype. MASEI PD might have advantages versus OMERACT PD definition to detect active enthesitis. These findings support the usefulness of PD US in the assessment of activity in SpA and PsA at patient level.

**AB1117** CLINICAL IMPACT OF MUSCULOSKELETAL ULTRASOUND ON RHEUMATOID ARTHRITIS IN ROUTINE CLINICAL PRACTICE

J. Molina Collada1, M. Pérez2, I. Castrejon1, C. J. Nieto3, T. González4, J. Rivera5, C. González6, I. Montagudo7, J. M. Alvaro-Gracia8,9,10,11,12, and G. Gregorio Marañón University Hospital, Madrid, Spain; 10Complutense University of Madrid, Madrid, Spain

**Background:** Musculoskeletal ultrasound (MSUS) is a useful tool to assess disease activity in rheumatoid arthritis (RA) patients. However, it has not yet been established if its use would change treatment decisions within a treat to target strategy or whether it would lead to better outcomes in RA patients.

**Objectives:** Our aim was to determine the impact of MSUS in the clinical management of RA patients and investigate factors associated with subsequent clinical actions by the referring rheumatologist.

**Methods:** A prospective analysis of RA patients seen at an MSUS clinic over a 6-month period was undertaken. Pre- and post-US follow-up data (±3 months) were analyzed. Baseline assessment included clinical features, physical examination, and laboratory tests. All MSUS examinations were performed according to EULAR guidelines and using an Esaote MyLab 8 (Esaote, Genoa) with a high frequency (8-15 MHz) transducer. Patients were stratified in groups based on the clinical impact of the MSUS visit: 1) No clinical impact and 2) US findings leading to subsequent clinical action by the referring rheumatologist (including changes in dosages of current rheumatical treatments, addition/subtraction of medications or intervention procedures based on the MSUS results). First, differences between groups were tested using chi-squared and Student’s t-tests in the univariate analysis. Second, multivariate logistic regression models were employed to investigate factors associated to a change in clinical management.

**Results:** A total of 61 RA patients were included for analysis. Mean age was 61.9±11.4 years and 51 (83.6%) were female. Disease activity assessment was the most frequent referral reason (43.70.5%). Overall, MSUS led to a subsequent therapeutic action by the referring rheumatologist in 39 (63.9%) patients and to a change in the underlying diagnosis and/or in the clinical impression of the chief complaint that generated the referral in 7 (11.5%) patients. Baseline characteristics of both groups are compared in Table 1. In the univariate analysis, the detection of Power Doppler (PD) synovitis/tenosynovitis and 28 swollen joint count were significantly associated with a subsequent clinical action. In the multivariate analysis only PD synovitis/tenosynovitis (OR=3.28; 95% CI 1.06-10.27) remained significantly associated with a change in clinical management (Table 2).

**Conclusion:** The most common indication of MSUS examination in RA patients was disease activity assessment. MSUS findings led frequent changes in therapeutic management and even to a change in the diagnosis in some cases. The presence of PD synovitis/tenosynovitis was significantly associated to a change in the therapeutic management. These data highlight the impact of MSUS inflammatory findings in RA patients in daily clinical practice.

**AB1118** OPEN MUSIC BIOPY AS A SAFE AND USEFUL MEANS OF DIAGNOSING VASCULITIS: A SINGLE-CENTER EXPERIENCE OF 210 BIOPY CASES

T. Mori1, N. Yokogawa2, K. Shimada3,1, Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Diseases, Tokyo, Japan

**Background:** We previously reported the utility of open muscle biopsies in diagnosing vasculitis [1]. The number of open muscle biopsies performed at our department has increased to over 200. The purpose of the present study was to evaluate the diagnostic utility of vasculitis and the safety of the open muscle biopsy.

**Objectives:** To clarify the diagnostic utility of vasculitis and the safety profile of the open muscle biopsy.

**Methods:** We retrospectively examined all cases of open muscle biopsy performed between May 2012 and June 2018 in our department. The biopsy results, the presence or absence of adverse events, and blood test data at the time of the biopsy were extracted from the patients’ electronic medical records.

**Results:** Between May 2012 and June 2018, 210 open muscle biopsies were performed, 120 of which were done for vasculitis diagnosis. Diagnostic histopathological findings were obtained in 42 of the 120 cases (35%). The definitive diagnosis in these cases was microscopic polyangiitis (30 cases), eosinophilic granulomatosis with polyangiitis (seven cases), granulomatosis with polyangiitis (one case), polyarteritis nodosa (three cases), and other vasculitis (one case). In 57 cases with myeloperoxidase-anti-neutrophil cytoplasmic antibody (MPO-ANCA) ≥10 U/mL, histopathology of vasculitis was found in one case (16.7%). In all 210 open muscle biopsy cases, complications included minor wound dehiscence (11 cases) and small subcutaneous hematoma (six cases), which were able to be managed by local treatment. Albumin was significantly lower in the patients with wound dehiscence (mean 3.2 vs 2.7, p = 0.049).

Serious complications included anaphylaxis due to local anesthesia (one case), compartment syndrome due to hematoma (one case), hematoma requiring surgical removal (one case), and arterial hemorrhage requiring surgical intervention (one case). The patients in the latter three hemorrhagic cases were receiving antplatelet drugs.

**Conclusion:** An open muscle biopsy is useful for diagnosing vasculitis, especially for MPO-ANCA-positive anca-associated vasculitis. Its safety profile is acceptable. Serious adverse events are rare, but the procedure should be performed carefully when patients are receiving antplatelet drugs.

**AB1119** U9: A NOVEL CLINICALLY ORIENTED ULTRASONOGRAPHIC SCALE AS A USEFUL MARKER FOR MONITORING THERAPEUTIC RESPONSE IN RHEUMATOID ARTHRITIS (MULTI CENTERS STUDY)

M. A. Mortada1, H. Eitta2, R. Elmallah3, A. Radwan4, A. Elsaman5, 1Sohag University, Rheumatology, Sohag, Egypt; 2AL Azhar University, Rheumatology, Cairo, Egypt; 3`Ali Shams University, Rheumatology, Cairo, Egypt; 4Sohag University, Rheumatology, Sohag, Egypt; 5Sohag University, Rheumatology, Sohag, Egypt
Background: Musculoskeletal Ultrasoundography (MSUS) is now a widely used tool for monitoring of rheumatoid arthritis (RA). Although there are many proposed sets of composite scores, a fixed set of joints may not be an ideal tool that assesses a disease like RA, which affects many joints and tendons in different presentations. In previous study (1) U9 score was proven to be correlated with disease activity parameters.

Objectives: To determine whether US assessment using U9 score is useful for monitoring response to treatment for RA or not?

Methods: A prospective, multicenter study were conducted in period from July 2019 to December 2019. All recruited RA patients were subjected to: disease activity assessment by clinical disease activity indices (CDAI and DAS28 ESR). Functional status assessment by (HAQ) and ultrasonographic assessment using U9 score which include 8 joints (bilateral wrists, 2nd MCP, 3rd MCP and knees) plus most clinically affected joint or tendon (one joint or one tendon). Most clinically affected joints from 48 joints. Any affected tendons could be choosing. All targeted joints were evaluated according to EULAR guidelines and by EULAR/OMERACT combined score (0-3). Targeted tendons were scored (0-3). All patients received their treatment (biologic and non biologic DMARDs) according to the decision of the treating physicians.

No specific therapy is needed. CDAI and DAS28 ESR, HAQ and U9 score were repeated after 3 months to detect the response to change after receiving the therapy.

Results: One hundred and forty patients (23.6% were male) with mean age 39.26±11.30 were recruited from 4 tertiary referral university hospitals. There was a significant difference (<0.001) between the first and second visits as regards clinical, laboratory and ultrasonographic parameters. DAS 28 decreased form (5.29±1.21) to (3.95±0.99), ESR decreased from (42.12±15.24) to (26.84±13.32), CDAI improved from (0.652±0.350) to (0.510±0.237) and U9 total US score decreased from (13.56±5.16) to (8.02±4.28).

There was significant correlation between U9 ultrasonographic score and clinical parameters at both visits (table 1).

<table>
<thead>
<tr>
<th>Parameters</th>
<th>U9 at 1st visit</th>
<th>U9 at 2nd visit</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAS-28 Pearson Correlation</td>
<td>0.806</td>
<td>0.790</td>
</tr>
<tr>
<td>CDAI Pearson Correlation</td>
<td>0.787</td>
<td>0.773</td>
</tr>
<tr>
<td>HAQ Pearson Correlation</td>
<td>0.431</td>
<td>0.317</td>
</tr>
</tbody>
</table>

We found that the most suitable cut-off value of U9 score to predict high disease activity was 11.5 (sensitivity 85.7% and specificity 80.6%), cut off value for moderate disease activity was 5.5 (sensitivity 83.2% and specificity 88%) and cut off value for low disease activity was 3.5 (sensitivity of 83.3% and specificity 57.1%). These results are summarized in the following table:

Conclusion: U9 ultrasonographic score is very useful method for evaluating the monitoring the response of treatment.

A TRIAD OF ULTRASOUND DETECTED HIGH-GRADE SYNOVITIS (MID TARSAL & ANKLE JOINTS), HIGH-GRADE TENOSYNOVITIS IN (TIBIALIS POSTERIOR & PERONEAL TENDONS) AND EROSIONS OF FIBULAR DISTAL END IS HIGHLY SUGGESTIVE OF CHARCOT ARTHROPATHY

M.A. Mortada1, N. Ezz El_din1, M. Hammad1, Zagazig University - Faculty of Medicine, Rheumatology, Zagazig, Egypt

Background: Charcot arthropathy poses many clinical challenges in its diagnosis and management. Ultrasoundography (US) may be able to identify pathological changes in cases of Charcot arthropathy.

Objectives: to characterize the ultrasonographic features of patients in early pre-radiographic stages of neuropathic (Charcot) arthropathy.

Methods: This is an extension of our previous study of ultrasonographic features Charcot ankle and foot (1) to an observational study where 42 patients with neuropathic (Charcot) arthropathy of the foot between January 2013 and October 2019 were enrolled. Inclusion criteria included: 1- Foot pain and swelling. 2- Typical MRI findings of Charcot arthropathy in the form of subcondral bone marrow edema with or without sub-chondral microfractures, joint effusion or soft-tissue inflammation.

3- Grade 0 Modified Eichenholtz classification system which means normal radiography of the affected foot. Patients with other forms of arthropathy that may mimic Charcot arthropathy e.g. gouty arthritis and rheumatoid arthritis were excluded from the study. Ultrasoundographic (grey scale and Doppler US) examination of mid-tarsal and ankle joints was performed according to the EULAR guidelines.

Results: Synovitis and effusion/natmid tarsal joints were found in all patients and to a lesser extent in the ankle joints. High degree Doppler activity at both ankle and mid tarsal joints could be observed in most patients. Bony erosions were also common as well as tendinitis. A triad of active synovitis (in mid tarsal joints and ankle joints), active tendinitis (of tibialis posterior and peroneal tendons) and erosions in the distal end of fibula was present in 40 (95.2%) cases.

Conclusion: our study confirms the ability of ultrasoundography to detect inflammatory lesions in early stages of Charcot arthropathy.

IMPLEMENTING HIGH VALUE CARE IN INPATIENT ANTI NUCLEAR ANTIBODY TESTING

S. Murta2, Z.Y. Li1, J. Yoon1, C. Yuvienco1. University of California, San Francisco Fresno Medical Education Program, Internal Medicine, Fresno, United States of America; 1University of California, San Francisco Fresno Medical Education Program, Rheumatology, Fresno, United States of America

Background: Antinuclear Antibody (ANA) testing forms the basis on which many rheumatological diseases are subsequently diagnosed. ANA testing queries the dilution of plasma to produce the titer and staining pattern and this can be a part of an ANA order set that reflexively cascades to sub-se rology if positive. Studies have shown that a low titer ANA may potentially translate into an erroneous diagnosis: if one estimates a 1 percent prevalence of ANA associated disease in the general population then 30% of those individuals would have a false positive result of ANA detected at 1:40 titer [1]. We theorized that there is no need for several methods to coexist within a single inpatient hospital setting especially since diagnostic value of staining patterns alone is limited.

Objectives: To compare the utility and yield of 'ANA screening reflex to profile' (ARP) and 'ANA reflex to titer' (ART) order sets in the inpatient setting of a community tertiary care hospital. We aim to identify the appropriateness of the ANA testing ordered including cost-effectiveness of ordering ARP over ART in order to implement the identified quality measures towards improving utilization of ANA testing.

Methods: We identified all inpatient ANA reflex testing orders performed at Community Regional Medical Center, Fresno, California completed between 11/2018 till 07/2019. This included ART and ARP orders with 6 sub-serologies: SSA, SSB, dsDNA, Smith, Scl-70 and U1RNP. A Health Information Management report was generated which included patients’ age, gender, length of hospital stay, dates of testing ordered, principal diagnosis and type of ANA testing ordered. Descriptive statistics were computed and analyzed.

Results: We reviewed a total of 1,012 ANA lab orders performed between 11/01/2018 until 07/30/2019 performed on 700 patients. According to the laboratory standard using Immunofluorescence Assay, an ANA titer starting from 1:40 is reported as positive. Out of the 1,012 tests, 334 tests were positive i.e. 33%. The ART order by itself contributed to 29.9% of the positive testing while ARP formed 70% of the positive testing. 56 of the 910 ARP (6%) performed had one or more sub-serology antibody positive while in 178 ARP orders (20%) only the ANA titer was positive with negative serology. The most common sub-serology antibody noted positive was dsDNA forming 54% of the positive serology results. Multiple testing was noted with 218 orders of ARP and ART being ordered on the same patient within the same week, which shows 21.5% of ANA lab orders were repetitive. Length of stay was noted to be more than 3 days for 89% of the patients who had repetitive testing, majority of those tests (99%) on the same day by the same medical provider. It cost $5.0 for an ART order that resulted negative and $5.0 for an ARP panel that resulted negative. It cost $10.0 for those patients who had both ART and ARP ordered with negative results. A positive ART result added $12.0 additional to the cost of each positive ANA profile ($67.36) when both tests were ordered together.

Conclusion: Our study findings reflect the need for using higher yield ANA testing that has been standardized. It demonstrated that physicians ordering the testing were not familiar with the ART vs. ARP, and the laboratory orders...
needed to be re-structured. We removed the ART from the inpatient Electronic Medical Record i.e. Epic system so that only the ARP order remained. This would prevent repetitive testing and reduce healthcare costs through reduction in medical management.

Background: It is important to use vascular imaging modalities such as CT, MRI and PET-CT to evaluate disease activity of Takayasu arteritis (TAK). In particular, under treatment with tocilizumab (TCZ), residual vasculitic disease activity may remain even if serum CRP becomes negative. Contrast-enhanced CT, MRI and PET-CT can evaluate the morphology of blood vessel walls and the distribution of lesions and vasculitic activity, but it is invasive (radiation or contrast media exposure), and costly. Ultrasound is superior in terms of morphological evaluation, cost, convenience, and low invasiveness. In particular, Superb Micro-vascular Imaging (SMI) is one of the micro blood flow display methods that can be installed in the ultrasound diagnostic device Aplio series.

There are some case reports in which micro blood flow signals of the carotid artery walls were detected using SMI in Takayasu arteritis [1] [2]. Both reports indicate that SMI blood flow is a comparable indicator of disease activity as serum CRP.

Objectives: To report the usefulness of SMI in 2 TAK patients who had negative serum CRP but had residual disease activity, leading to appropriate adjustment of treatment.

Methods: Two TAK patients who had been newly diagnosed in our department from May 2015 to October 2018 and had received SMI to detect carotid artery wall blood flow signal were retrospectively analyzed.

Results: Case 1
A 32-year-old woman developed neck pain, headaches, fever and she had high serum levels of CRP (8.1 mg/dl) and elevated ESR (98 mm/h). Contrast-enhanced CT showed thickening of the carotid artery, left subclavian artery and thoracic aorta and SMI detected blood flow signal in carotid artery wall. Diagnosis of TAK was made. After 2-week treatment with 1 mg/kg/day of PSL, CRP became negative but the micro blood flow in carotid artery walls was detected by SMI. Therefore, subcutaneous TCZ (162 mg/week) was added in combination with PSL. One year later, micro blood flow disappeared and we could judge there was no vasculitis activity (Figure A).

Case 2
A 47-year-old woman developed left arm pain and fever with high serum CRP levels (71 mg/dl) and elevated ESR (>110 mm/h), and contrast-enhanced CT showed thickening of the carotid arteries and aortic arch. Two weeks after the start of PSL (1 mg/kg/day), CRP became negative at 0.3 mg/dl, but intramural blood flow detected by SMI remained. Then subcutaneous TCZ was added. Two weeks later, CRP became negative, and the SMI blood flow also disappeared (Figure B).

On US, 63 patients (88.7%) were classified as eroded. On US, erosions prevailed at baseline in MTP5 joints, then MCP2 and MCP5 joints on their lateral facets. During follow-up, 28 patients (39.4%) were classified as US progressors, 30 (42.3%) were stable and 13 (18.3%) considered as regressors (figure 1). In early RA disease, three of the four non eroded patients became eroded, USSe progressed in 11 patients (50%) while regression was observed in only one patient. In late RA disease, 17 patients (34.7%) progressed and 12 patients (24.5%) decreased significantly their USSe. Erosion progression prevailed on MTP 5 joints followed by MCP2 and finally MCP5 joints (figure 2).

**Conclusion:** US structural examination is a highly reproducible method to assess erosion in RA disease. The USSe is able to detect structural changes (progression, stabilization and regression) in RA patients during a follow-up of two years especially in RA patients with short disease duration.

**DOI:** 10.1136/annrheumdis-2020-eular.2444
Background: Multiple studies have demonstrated that shoulder complaints are frequent in Rheumatoid arthritis (RA). Recently, it has been shown that shoulder involvement is predictive for RA development in patients with undifferentiated arthritis (UA) and its value is comparable to that of small joint involvement. The phase of clinically suspect arthralgia (CSA) precedes the phase of clinically apparent arthritis; in this phase subclinical tenosynovitis of the hands, is associated with the development of RA. Given the similarities in predictive values between the shoulder and small joints in UA, and the predictive value of tenosynovitis in CSA, we hypothesized that subclinical tenosynovitis of the bicep tendon is also associated with RA development. We examined the biceps tendon, since this is the only tendon of the shoulder that is enclosed by a synovial sheath as it passes through the bicipital groove. 

Objectives: Therefore, the aim of this study is to examine the predictive value of tenosynovitis of the bicep tendon by ultrasound (US) on developing inflammatory arthritis (IA) in CSA-patients.

Methods: The SONAR (Sonographic evaluation of hands, shoulders and feet in patients presenting with inflammatory arthralgia to identify subclinical arthritis) is a multi-center observational cohort study in which patients were followed for the development of clinically apparent inflammatory arthritis (IA). Visits were done at baseline and 6 months thereafter. At baseline a US of both shoulders was made, 1-year follow-up data were used. IA was defined as having an arthritis verified by the treating physician. US abnormalities of (1) the biceps tendon, (2) the glenohumeral joint and (3) the subdeltoid bursa, were assessed for tenosynovitis, arthritis and bursitis.. Reference values for tendon thickness and effusion of the bursa were determined according to Schmidt et al.(1) 

Results: A total of 170 patients were included and underwent bilateral ultrasound (US) of the shoulder joint. Shoulder symptoms were infrequent (Table 1). After one year 37 patients developed IA (22%). ACRA positivity was associated with the development of IA (Table 1). As presented in Table 1, US abnormalities of the shoulder were found but none were associated with IA-development. In particular biceps tenosynovitis was not increased in the patients that developed IA.

Results: 1.092 patients with a total of 1.695 hospitalizations were analysed.
Mean age was 55.1 years (range: 17-90 years, SD: 15.8), mean disease duration
was 6.4 years (range: 0.0-52.8 years, SD: 9.1). 87.5 % were female.
Table 1 shows the frequency of findings per CTD entity. 48 out of all 1.695 examinations were discussed in the hospital discharge letter. In 30 cases, the physician
described the ultrasound results as pivotal for therapeutic decision-making.
Conclusion: Routinely performed abdominal ultrasound rarely yields disease
specific findings which subsequently impact the therapeutic decision-making
process.

LOCALIZATION OF MRI INFLAMMATORY LESIONS
OF THE HAND IN SCLERODERMA AND RHEUMATOID
ARTHRITIS - COMPARATIVE STUDY

B. Stamenković1, A. Stankovic2, S. Stojanović3, V. Živković2, D. Djordjevic2,
J. Nedovic2. 1Institute Niska Banja; Medical Faculty, University of Nis,
Rheumatology, Nis, Serbia; 2Institute Niska Banja; Medical Faculty, University
of Nis, Nis, Serbia; 1Institute Niska Banja; Medical Faculty, University of Nis,
Rheumatology, Nis, Serbia
Background: Inflammatory lesions of hand are frquent clinical feature in rheumatoid artritis (RA), with lower frequency in pts with systemic sclerosis (SSc),
also. MR is useful method for detecting and quantification of inflammatory lesion
of the hand (bone oedema, erosions, synovitis) in RA and SSc.

Objectives: The aim of the study was to compare MR hand feature in SSc
(experimental) and RA (control group) and to detect the localisation of the
highest OMERACT RAMRISinflammatory score on the hand in pts with SSc
and RA
Methods: 110 pts with SSc and 60 with RA were investigated (mean age 53y).
All the pts underwenr clinical examination, X ray and MR on the dominant
hand and wrist. Contrast enhanced low field MRI of the wrist and MCP2-5
joints was performend to all the pts. MRI inflammatory changes (bone
oedema,erosions, synovitis)were assessed and scored by OMERACT RAMRIS scoring system.
Results: Clinical examination confirmed synovitis in 17.1%, and 78% of patients
with SSc using MR I (p <0.001). In the SSc group, erosions (by MR method)
was confirmed in 52 (63.4%), by radiography in 22 pts (27.5%), which is a significantly lower percentage (p <0.001). In the control RA group, erosion was
confirmed in 34 (97.1%) by MR method, and by radiography in 6 (17.1%), which
is a statistically significant difference (p <0.001). Mean values of total MR score
of synovitis (2.69 ± 2.29: 4.37 ± 1.31), oedema (6.58 ± 10.89: 20.57 ± 10.23)
and erosion (6.84 ± 7, 43: 18.60 ± 5.01) on the wrist of the dominant hand were
significantly higher in subjects with control RA than in those in the experimental
SSc (p < 0.001). Mean values of total MR score of synovitis (3.15 ± 2.95: 5.26
± 2.09), oedema (3.99 ± 9.82: 10, 51 ± 7.90) and erosion (4, 04 ± 4.76: 9.69 ±
4.27) on the MCP joints of the dominant hand were significantly higher in the
control RA subjects (p <0.001).The highest OMERACR RAMRIS synovitis score
was on distal radioulnar (DRU joint) of hand in SSc and also In RA pts. The
highest erosion score was found on capitate bone in SSc, but in lunate bone
in RA pts. The highest bone oedema score was also found on capitate bone


Finding 2: Samples are handed off between 3 different lab benches, each of which may be staffed by a different staff member on a different day, and results processing involves handoff to a further 2 different staff members.

Finding 3: ANA demand is close to capacity, ENA demand exceeds current capacity (table 1).

Table 1. Demand for ANA, ENA and DNA tests, compared to capacity

<table>

<td>Plenty</td>
</tr>
</tbody>
</table>

Finding 3: “Less capacity than demand!!”

Figure 1. Current testing strategy (left) and suggested improvement (right)

Figure 2. Control chart of average TAT of dsDNA antibodies by request date

Conclusion: Stopping screening DNA requests on ANA result increased the number of DNA tests performed by about 10 samples per day (30%), but decreased turnaround time by a similar proportion (3.3 to 2.3 days, figure 2). It also reduced turnaround times of ANA and ENA tests.

AB1132

EFFECTIVENESS AND SAFETY OF ULTRASOUND-GUIDED FASCIA HYDRORELEASE ON METATARSALGIA WITHOUT SONOGRAPHIC EVIDENCE OF INFLAMMATION IN PATIENTS WITH RHEUMATOID ARTHRITIS.

M. Suda1,2, K. Muranaka3, S. Ohde4, M. Minoda1,2. 1Suwa Central Hospital, Rheumatology, Chino, Japan; 2St. Luke's International Hospital, Immunology-Rheumatology Center, Chuo City, Japan; 3Suwa Central Hospital, Rheumatology, Chino, Japan; 4St. Luke's International University, Graduate School of Public Health, Tokyo, Japan

Background: Patients with rheumatoid arthritis (RA) who have metatarsal involvement (MTP) joint involvement sometimes complain metatarsalgia without active sonographic inflammation1. Treatment of non-inflammatory metatarsalgia in RA is challenging and the pain sometimes lasts for years even though systemic inflammation completely resolves. On the other hand, intervention to fascia has increasingly attracted attention as a management of fascial pain.2

Objectives: This study is aiming for prospective evaluation of effectiveness and safety of UGFHR on metatarsalgia in patients with RA.

Methods: We enrolled consecutive 11 patients with RA who came to rheumatology service in Suwa Central Hospital and satisfied the following inclusion and exclusion criteria: Inclusion criteria were having at least one MTP joint pain on which the patient has tenderness on the extensor side.

STATISTICAL PROCESS CONTROL AND PROCESS MAPPING QUANTIFY THE EFFECTS OF HISTORICAL CHANGES TO THE CONNECTIVE TISSUE DISEASE TESTING ALGORITHM AND IDENTIFY AREAS FOR FUTURE IMPROVEMENT IN A LARGE DIAGNOSTIC IMMUNOLOGY SERVICE

M. Stevens1, N. Proudlove2, J. Ball1, C. Scott1. 1Barts Health NHS Trust, Immunology Laboratory, London, United Kingdom; 2Alliance Manchester Business School, Manchester, United Kingdom

Background: Pathology test turnaround times (TATs) are a limiting factor in patient flow through rheumatology services. Quality improvement (QI) methodologies such as Lean use tools including statistical process control (SPC) and process mapping to study the performance of the whole of a clinical pipeline, expose unnecessary complexity (non-value-adding activity) and streamline processes and staff roles.

Objectives: Understand effects of changes made to CTD testing algorithm over last 12 years by measuring some of the effects on TATs. Model current processes and suggest changes to workflow to improve TAT.

Methods: High-level flow diagrams of the current testing algorithm, and low-level process maps of analyser and staff processes were drawn. Activity and TATs (working days between report and booking date) for ANA, ENA, DNA and CCP tests were plotted as XmR control charts.

Results: Finding 1: Largest referral laboratory does not currently operate a separate DNA monitoring workstream, resulting in unnecessary ANA and ENA testing (figure 1).

Finding 2: Liaising with main referral lab to develop a DNA monitoring workstream to reduce unnecessary ANA and ENA testing

Finding 3: Reduce handoffs, sample journey around lab analysers, and staff hands-on time by:

• changing ANA test methodology to same as DNA
• creating new staff roles (analyst operators to perform validation/ authorisation steps) and roles
• Create more capacity for ENA testing by increasing the frequency of this test on the weekly rota
• Create more capacity for service expansion by running analysers at weekends (staff consultation required)

• Reduce demand on service by engaging and educating requestors and suppliers
• Improve TAT for DNA by:

• processing samples the day they are booked in, instead of 1 day later
• auto-validating runs
• …using control charts to measure improvement
Exclusion criteria were positive inflammation with ultrasound evaluation (defined as gray scale (GS) ≥2) and/or power doppler scale (PDS) ≥1 or having other cause of pain such as intermetacarpal bursitis, Morton’s neuroma. The patients received UGFHR on the fascia between the MTP joint capsule and the extensor tendon of the toe. We first searched for the stacking fascia between the two structures using ultrasound with longitudinal view of the extensor side of the MTP joint, and injected 2ml of normal saline into the stacking fascia, making it unglued (Fig. 1). If there was no stacking fascia, we injected on the fascia where the joint capsule and the extensor tendon became closest.

Figure 1. The procedure of ultrasound-guided fascia hydrorelease (UGFHR)

Numeric rating scale (NRS) of pain on walking and tenderness on the target MTP joint was measured on 3 occasions: before, immediately after, and one week after the UGFHR. Adverse events were also recorded.

The data were analyzed longitudinally, using Friedman test.

Results: The characteristics of the patients are shown in table 1. Female gender was dominant. Most of them were established RA. Simplified disease activity index (SDAI) were variable.

Table 1. The characteristics of the 11 patients.

</tbody>
</table>

The changes in NRS from before to immediately after and one week after the UGFHR are described in figure 2.

Figure 2. The changes in NRS.

Pain on walking and tenderness on the target joint both significantly decreased immediately after the procedure (∆NRS from before to immediately after the UGFHR: -3.45 (95% confidence interval (CI) -3.22 to -3.69, p<0.01) and -2.45 (95% CI -1.32 to -3.59, p<0.01), respectively), and the change was maintained until one week after the UGFHR (∆NRS from before to one week after the UGFHR: -3.09 (95% CI -1.77 to -4.42, p<0.01) and -3.27 (95% CI -1.80 to -4.75, p<0.01), respectively.

In terms of safety, 7 out of 11 patients complained injection pain, all of which did not last for a week. Otherwise, there was no adverse event such as infection, nerve injury, bleeding, or tendon rupture.

Conclusion: Ultrasound-guided fascia hydrorelease on MTP joint can be an effective and safe treatment option in patients with RA who have metatarsalgia but no sonographic evidence of MTP inflammation.

1Corresponding Threshold=95.2, Specificity=53.8%, Sensitivity=63.3%, Accuracy=63.2%.

Conclusion: The prognostic significance of anti-CCP and RF appears to differ in RA. Specifically, among patients with at least moderate disease activity (DAS28 ≥3.2), anti-CCP - but not RF - is associated with joint damage, being moderately correlated with US detected erosions.

AB1134 ULTRASOUND FINDINGS IN HAND JOINTS INVOLVEMENT: A COMPARATIVE STUDY BETWEEN PSORIATIC AND RHEUMATOID ARTHRITIS

A. R. Ahmed1, S. Tharwat1, A. M. Abd el-Khalek2, E. E. Eltoraby3 on behalf of No. 1Faculty of Medicine, Mansoura University, Rheumatology and Immunology Unit, Internal Medicine department, Mansoura, Egypt; 2Faculty of Medicine, Mansoura University, Diagnostic Radiology, Mansoura, Egypt

Background: Psoriasis is a common skin disease that is associated with multiple conditions. The most prevalent coexisting condition is psoriatic arthritis (PsA) which develops in up to 30% of patients with psoriasis and characterized by diverse clinical features often resulting in delayed diagnosis and treatment. [1] Objectives: The aim of this study was to investigate the potential of ultrasound (US) in the differential diagnosis between rheumatoid arthritis (RA) and PsA at the level of small joints of the hand and wrist.

Methods: Fifteen patients with PsA of the hands and wrists and 20 age and sex-matched RA patients were examined with musculoskeletal US. Radiocarpal, midcarpal, distal radial, metacarpophalangeal (MCP), proximal interphalangeal (PIP) and distal interphalangeal (DIP) joints and flexor and extensor tendons (in wrist and hand) were examined bilaterally. Synovitis, erosions and tenosynovitis were the anterior joint space, cartilage and anterior proximal tibiofibular ligament. The coronal approach led us to the visualization of the joint space, the collateral lateral ligament, the interolateral genicular and posterior tibial recurrent artery, the meniscus and more posteriorly the ligaments of the posterolateral corner (popliteofibular, arcuate and fabellofibular). Finally, the posterior transverse oblique allowed us to study the posterior ligaments and joint recess under the

Results: Among 510 and 680 joints examined in PsA and RA respectively, certain US features such as synovitis and erosions at the DIP were exclusively detected in PsA (p<0.001). Synovitis was frequently present at the radioluar joints in RA in comparison to PsA patients (52.5% vs 26.7% respectively, p=0.029). Joint effusion was frequently detected at radiocarpal and midcarpal joints in RA in comparison to PsA (p=0.047, 0.039 respectively). Effusion at the 3rd PIP joints was more significantly present in PsA than RA (p=0.037), while erosions were significantly detected at radiocarpal joints in RA in comparison to PsA patients (45% vs 20% respectively, p=0.029). Tenosynovitis was significantly detected at the extensor tendons in RA and at the flexor tendons in PsA patients (p=0.021, 0.022 respectively).

Conclusion: There are significant differences in the US findings of the hand and wrist that can help to distinguish between RA and PsA

AB1135 ECHO-ANATOMY OF THE PROXIMAL TIBIOFIBULAR JOINT

M. C. Todoani1, B. Le Goiff2, 1Hospital Pasteur Nice, France; 2Nantes University Hospital Hotel-Dieu, Nantes, France

Background: The proximal tibiofibular joint (PTFJ) should be considered in the differential diagnosis of a patient presenting with complaints in the lateral aspect of the knee. However, this joint is often forgotten, yet involved in many degenerative and inflammatory pathological processes. MRI remains the imaging of choice to study the PTFJ. Ultrasound could also be useful in clinical practice to study the joint and its environment. To our knowledge, there is no systematic descriptive echo-anatomical study of PTFJ that would allow to standardize the ultrasound scanning of this joint.

Objectives: The objective of our study was to describe standardized ultrasonographic scans of the PTF joint and its environment starting from an anatomical study of the joint and then confirming the visibility of the different structures on a series of healthy volunteers.

Methods: We first conducted an anatomical study of the PTFJ on 3 cadavers. The different part of the joint (capsule, cartilage, ligaments) and the environment (nerves, muscles, vessels) were studied allowing an exact correlation between US images and the structures. This step led us to choose 3 scans useful for the study of the different part of the joint in clinical practice (figure 1): an anterior transverse oblique, a strict coronal, and a posterior transverse oblique. Subsequently, a TPFJ ultrasound was performed on 20 healthy volunteer patients to evaluate the feasibility and the visibility of the different structures seen on the dissection part.

Results: The different structures seen on the anterior transverse oblique scan were the anterior joint space, cartilage and anterior proximal tibiofibular ligament. The coronal approach led us to the visualization of the joint space, the collateral lateral ligament, the interolateral genicular and posterior tibial recurrent artery, the meniscus and more posteriorly the ligaments of the posterolateral corner (popliteofibular, arcuate and fabellofibular). Finally, the posterior transverse oblique allowed us to study the posterior ligaments and joint recess under the
Methods: (KL-6) for CTD-ILD in the Uygur population of China.

Results: 2015 and December, 2019 were included. Serum KL-6 levels were measured by People’s Hospital of Xinjiang Uygur Autonomous Region between January, CTD (CTD group) who visited the department of rheumatology and immunology of People’s Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China.

Objectives: may exist.

ILD, but differences in KL-6 expression related to ethnic and/or genetic variants diagnosed interstitial lung disease. Although serum KL-6 level has been studied morbidity and mortality. Currentlly, scientists are still looking for serum markers to diagnose interstitial lung disease. Although serum KL-6 level has been studied in ILD of various aetiologies and revealed to be an important serum marker for ILD, but differences in KL-6 expression related to ethnic and/or genetic variants may exist.

Objectives: To evaluate the diagnosis of the serum Krebs von den Lungen-6 (KL-6) for CTD-ILD in the Uygur population of China.

Methods: 117 Patients with CTD-ILD (CTD-ILD group) and 182 patients with CTD (CTD group) who visited the department of rheumatology and immunology of People’s Hospital of Xinjiang Uygur Autonomous Region between January, 2015 and December, 2019 were included. Serum KL-6 levels were measured by chemiluminescent enzyme immunoassay kit.

Results: The significantly higher levels of KL-6 were determined in the RA-ILD group than RA group [569(287.5, 984) U/ml vs 194(152, 266.5) U/ml](P<0.001) (figure 1). The optimal cutoff value of serum KL-6 for diagnosis of RA-ILD was 345.5 U/ml, and the sensitivity and specificity were 71.8% and 90.1 %, respectively. Area Under the Curve (AUC) was 0.875. (figure 2)

Conclusion: The serum KL-6 is an important biomarker for the diagnosis of CTD-ILD and Serum KL-6 could be a clinically useful biomarker in screening CTD-ILD in the Uygur population of China.

AB1136
THE DIAGNOSTIC VALUE OF SERUM KL-6 IN CONNECTIVE TISSUE DISEASE ASSOCIATED INTERSTITIAL LUNG DISEASE IN THE UYGUR POPULATION OF CHINA.
X. Wu1, L. Wu1, C. N. Luo1, Y. M. Shi1. People’s Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China.

Background: Connective tissue diseases are a group of inflammatory, immune mediated disorders. Interstitial lung disease (ILD) is associated with significant morbidity and mortality. Currentlly, scientists are still looking for serum markers to diagnose interstitial lung disease. Although serum KL-6 level has been studied in ILD of various aetiologies and revealed to be an important serum marker for ILD, but differences in KL-6 expression related to ethnic and/or genetic variants may exist.

Objectives: To evaluate the diagnosis of the serum Krebs von den Lungen-6 (KL-6) for CTD-ILD in the Uygur population of China.

Methods: 117 Patients with CTD-ILD (CTD-ILD group) and 182 patients with CTD (CTD group) who visited the department of rheumatology and immunology of People’s Hospital of Xinjiang Uygur Autonomous Region between January, 2015 and December, 2019 were included. Serum KL-6 levels were measured by chemiluminescent enzyme immunoassay kit.

Results: The significantly higher levels of KL-6 were determined in the RA-ILD group than RA group [569(287.5, 984) U/ml vs 194(152, 266.5) U/ml](P<0.001) (figure 1). The optimal cutoff value of serum KL-6 for diagnosis of RA-ILD was 345.5 U/ml, and the sensitivity and specificity were 71.8% and 90.1 %, respectively. Area Under the Curve (AUC) was 0.875. (figure 2)

Conclusion: The serum KL-6 is an important biomarker for the diagnosis of CTD-ILD and Serum KL-6 could be a clinically useful biomarker in screening CTD-ILD in the Uygur population of China.

AB1137
CLASSIFICATION OF THE EARLY STAGE OF RAPIDLY DESTRUCTIVE COXOPATHY ACCORDING TO THE FEMORAL HEAD DESTRUCTION
T. Yasuda1, K. Matsunaga1, T. Hashimura1, T. Tsukamoto1, T. Sueyoshi1, S. Ota1, S. Fujita1, E. Onishi1, 1Kobe City Medical Center General Hospital, Department of Orthopaedic Surgery, Kobe, Japan.

Background: Rapidly destructive coxopathy (RDC) is an unusual subset of osteoarthritis of the hip characterized by rapid chondrolysis with progressive loss of the joint space as the first manifestation of the disease. Because rapid progression of RDC makes it difficult to obtain sequential radiographs in its early stage, the process of disease progression in the early stage remains unclear. Although the pathogenesis of RDC is still unclarified, the potential causes of RDC include subchondral insufficiency fracture of the femoral head resulting from osteoporosis, pelvic posterior inclination in RDC as a mechanical factor, and increased serum levels of matrix metalloproteinase (MMP)-3 as a biological factor.

Objectives: This study aimed to differentiate the process of disease progression in the early stage of RDC and provide its new classification system.

Methods: This monocentric retrospective study included 42 female patients who met the criteria of RPOH, chondrolysis >2 mm during 12 months from the onset of hip pain based on a series of radiographs and computed tomography (CT). This study also included 9 female patients with osteoarthritis secondary to developmental dysplasia of the hip (DDH), who demonstrated chondrolysis >2 mm during 12 months from the onset of hip pain. Cortical thickness index (CTI) correlated with bone mineral density of the hip, pelvic tilt, and serum concentrations of matrix metalloproteinase (MMP)-3 were analyzed.

Results: RDC were classified into two types based on the absence (type 1, n=17) and presence (type 2, n=25) of subsequent femoral head destruction shown by CT within 12 months after the onset of hip pain. MMP-3 significantly
increased in RDC type 2 compared with type 1 and DDH. Increased posterior pelvic tilt was found in RDC type 2 compared with DDH. Logistic regression and receiver operating characteristic curve analyses indicated that MMP-3 may be associated with differentiation between RDC types 1 and 2. No difference was found in CTI between RDC types and DDH.

RDC type 2 hips developed partial (type 2A) and massive (type 2B) femoral head destruction within the first 12 months. Whereas partial destruction showed <20% collapse ratio, massive destruction demonstrated >40% collapse ratio. Increased posterior pelvic tilt was found in massive destruction. Femoral head destruction started earlier within the first 6 months in massive destruction compared with that in partial destruction. From receiver operating characteristic curve analysis, pelvic tilt differentiated the femoral head destruction types using the initial radiograph at the onset: before first demonstration of femoral head destruction. No difference was found in CTI or MMP-3 between the two subtypes.

**Conclusion:** Disease progression of RDC during 12 months after the onset of hip pain could be classified into two distinct types based on the absence (type 1) and presence (type 2) of femoral head destruction in association with MMP-3 and pelvic tilt as biological and mechanical factors, respectively. MMP-3 may be helpful to differentiate those two types in the early stage of RPOH. The extent of femoral head destruction could further differentiate RDC type 2 into two subtypes based on pelvic tilt.

**ASSESSMENT OF FLUORESCENCE-OPTICAL IMAGING TECHNIQUE OF THE HANDS IN PSORIASIS AND PSORIATIC PATIENTS USING AN INNOVATIVE OBJECTIVE METHOD**

L. Zerneck1,2, U. Henkemeier3,4, P. H. Nguyen2, T. Rossmanith1,2, A. Pippow3,4,5, H. Burkhardt3,4, F. Behrens3,4,5, M. Köhn1,3,5, M. A. Fraunhofer Institute for Applied Information Technology, Sankt Augustin, Germany; 2Fraunhofer Cluster of Excellence Immune-Mediated Diseases, Frankfurt, Germany; 3Fraunhofer IME Translational Medicine and Pharmacology, Frankfurt, Germany; 4Centre of Innovative Diagnostics and Therapeutics Immunology Rheumatology CIRI, Frankfurt, Germany; 5Goethe-University Frankfurt, Frankfurt, Germany

**Background:** Psoriasis (PsO) is one of the most common chronic inflammatory skin diseases in Europe. Psoriatic arthritis (PsA) is closely associated to PsO whereas the skin manifestation appears usually years before PsA-related symptoms emerge. Up to 30% of PsO patients develop PsA, biomarkers for its early detection are of major importance. In early PsA, changes in synovial vascularity appear first. Imaging biomarkers for detection of changes in vascularityisation might be useful for early detection of musculoskeletal disease. Fluorescence-optical imaging (FOI) is a new method to detect changes in microvascularisation of the hands. Each collected data set of the FOI system contains 360 images representing a time progression of the indocyanine green (ICG) distribution.

**Objectives:** To evaluate a reader-independent assessment method for evaluation of FOI in patients with PsO and PsA.

**Methods:** A prospective study including patients with dermatological confirmed skin PsO was performed. 411 patients were included from German dermatology units without PsA diagnosis but potential risk for its development. Clinical examination (CE) was performed by a qualified rheumatologist. For a reader independent evaluation of the FOI images an objective joint-based scoring method was developed. For this method, the joint areas are defined by image segmentation and scored based on generated heatmaps. To calculate a heatmap indicating conspicuous joints from a data set containing 360 images, each pixel is converted to a time series containing 360 values. From this time series, three independent values (features) are extracted: amplitude, average value and maximal slope. Thus, each pixel is reduced to three different feature values. After the three features are determined for each pixel, k-means clustering is performed on each feature. The numbers of centroids (k) are set to 3, 5, 7 and 9. 12 heatmaps (3 features â 4 ks) are calculated, which results in 12 scores for each joint as well. The clusters are then sorted dependent on their centroid value and colored accordingly to a predefined heatmap colour palette. To finally score each joint, the pixels in the segmented joint area and their assigned cluster are summed and normalized by the area’s amount of pixels and k.

**Results:** 271 of the patients were investigated by the newly developed method and compared with the CE scoring. 6426 joints were labeled as healthy whereas 1162 joints were either labeled as swollen, tender or both. The result over all investigated patients for k = 9 is summed in table 1. It is observable that every average and median healthy value is lower than the corresponding affected value.

**Conclusion:** FOI is an innovative method that detects early changes in vascularityisation of the hands. So, this method can be useful in early detection of arthritis especially in risk populations such as PsO patients. The results of the objective scoring method show that there is a clear distinction between healthy and affected joints. A comparison of FOI and CE scoring method show that a clear distinction between healthy and affected joints especially in risk populations such as PsO patients. The results of the objective scoring method show that there is a clear distinction between healthy and affected joints. The expected outcome and motivates further development on the heatmap approach.

**DIAGNOSTICS AND PROGNOSTICS SIGNIFICANCE OF CHEST CT EVALUATION OF SMALL PULMONARY VESSELS IN CONNECTIVE TISSUE DISEASES WITH PULMONARY ARTERIAL HYPERTENSION.**

Y. Zhang1, N. Zhang1, Y. Zhu2, Q. Wang2, L. Zhou2. 1Nanjing Medical University, Nanjing, China; 2The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

**Background:** Pulmonary arterial hypertension (PAH) is a fatal complication of connective tissue diseases (CTDs), Chest CT has been increasingly used in the evaluation of patients with suspected PH noninvasively but there is a paucity of studies.

**Objectives:** Our study was aimed to investigate the cross-sectional area (CSA) of small pulmonary vessels on chest CT for the diagnosis and prognosis of CTD-PAH.

**Methods:** This retrospective study analyzed the data of thirty-four patients with CTD-PAH who were diagnosed by right heart catheterization (RHC) and underwent chest CT between March 2011 and October 2019. We measured the percentage of total CSA of vessels<5 and 5-10 mm2 as a percentage of total lung area (%CSA <5 and %CSA 5-10) on Chest CT. Furthermore, the association of %CSA with mean pulmonary artery pressure (mPAP) was also investigated. Besides, these patients were followed up until October 2019, and Kaplan-Meier survival curves were generated for the evaluation of prognosis.

**Results:** Patients with CTD-PAH had significantly higher %CSA <5-10<0.38 (p=0.049). Patients with %CSA 5-10≥0.38 had a lower survival rate than those with %CSA <5-10<0.38 (p=0.049).

**Conclusion:** Quantitative parameter, %CSA <5-10<0.38 on Chest CT might serve as a crucial differential diagnostic tool for different types of PH. %CSA 5-10≥0.38 is a prognostic indicator for evaluation of CTD-PAH.

ABNORMAL RIGHT VENTRICLE RESERVE FOLLOWING EXERCISE IN PATIENTS WITH CONNECTIVE TISSUE DISEASES

J. Zhang1, T. Wu1, R. Wu1, J. Zhu1. 1Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Affiliated Hospital of University of Electronic Science and Technology of China, Department of Rheumatology and Immunology, Chengdu, China

Background: Recent studies have indicated that cardiac autonomic dysfunction is an early sign of cardiovascular impairment in patients with connective tissue disease (CTD). Previous studies have mainly focused on autonomic regulation during rest in this population. The cardiac autonomic responses to an acute physio-

tological stress might provide additional information on the autonomic dysfunction, serving as a powerful predictor of cardiovascular disease and mortality in patients with CTD.

Objectives: We aimed to use exercise stress echocardiography to detect early right heart dysfunction in patients with CTD and healthy controls.

Methods: Treadmill exercise stress echocardiography was performed in 19 CTD patients (8 systemic sclerosis, 6 mixed CTD and 5 SLE) and 20 healthy volunteers. Parameters of right ventricular (RV) systolic function (RV fractional area change, Doppler tissue s’velocity, and systolic strain and strain rate) and diastolic function (peak E and A velocity, Doppler tissue e’, a’ and early and late diastolic strain rate) were evaluated at baseline and after exercise, with the dif-

f erence (Δ) being systolic and diastolic reserve. The immunoblotting assay was performed to detect the levels of rheumatoid factor (RF) and C-reactive protein (CRP) as well as autoantibodies such as, antinuclear antibody (ANA), anti-U1-ribonucleoproteins (U1RNP), anti-dsDNA, anti-Sm, anti-SSA, anti-SSB, anti-SCL-70 and RO-52.

The correlation between these proteins and RV function was analyzed.

Results: Both the patients with CTD and healthy controls had a normal range of BMI, total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), and triglyceride (TG). The average age of patients with CTD was 48.0 ± 10.4 years. At baseline, these patients presented no cardiovascular disease or pulmo-

nary hypertension. No significant difference in the body weight, height, age, sex, blood pressure, RV and left ventricular (LV) function at rest between the two groups (all P>0.05). The parameters of RV systolic reserve decreased significantly in CTD group compared to those of the healthy controls (Δs’: 5.8±2.1 vs 8.3±2.5 cm/s, P<0.01; Δsr: 2.5±0.8 vs 8.4±7.5 cm/s, P<0.01). Consistently, RV diastolic reserve was significantly decreased in CTD patients compared to controls (Δa’: 2.8±1.5 vs 3.9±2.3 cm/s, P<0.05; Δa: 5.8±2.5 vs 10.9±6.3 cm/s, P<0.05; ΔqS: 0.8±0.2 vs 1.2±0.5 cm/s, P<0.05; ΔqS: 0.9±0.3 vs 1.3±0.6 cm/s, P<0.05). To identify independent predictors of RV function in CTD patients, linear regression was conducted. This suggested that ANA, anti-U1RNP, anti-dsDNA, anti-Sm, anti-SSA, anti-SSB, anti-SCL-70 and RO-52 were not correlated with RV reserve (all P>0.05). A logistic regression analysis revealed that RF (P<0.05) and CRP (P<0.01) were independently associated with RV reserve in CTD patients in response to an acute physio-

logical stress.

Conclusion: Treadmill exercise echocardiography could detect right heart dys-

function early before diagnosed as cardiovascular diseases in patients with CTD. RV reserve after exercise might be a promising parameter to detect cardiovascu-

lar disease early in CTD patients.

EVALUATION OF INFLUENZA AND PNEUMOCOCCAL VACCINATION RATES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS, AND THE AWARENESS OF RHEUMATOLOGISTS ABOUT VACCINATION

I. Kurut Ayis1, M. Aysin2, D. Solmaz2, N. Baş Toma3, F. Koçu4, E. Durak Ediboglu2, G. Kabadayı3, Ö. Gerkiç6, S. Gucmennez6, S. Akar1. 1İzmir Katip Celebi University, Faculty of Medicine, Division of Rheumatology, İzmir, Turkey; 2İzmir Katip Celebi University, Faculty of Medicine, Division of Public Health, İzmir, Turkey; 3İzmir Katip Celebi University, Faculty of Medicine, Division of Rheumatology, İzmir, Turkey

Background: Patients with inflammatory arthritis have increased risk of infec-

tions which may lead to morbidity and mortality. Some of those infections could be prevented by vaccination.

Objectives: The main objectives of the present study were to investigate (a) the uptake rate of influenza and pneumococcal vaccination among patients with rheumatoid arthritis (RA) and spondyloarthrits (SpA) attending a rheumatology outpatient clinic, (b) the factors associated with their vaccination rate and, (c) the attitudes of Turkish rheumatologists about vaccination.

Methods: Patients, followed-up in a tertiary rheumatology outpatient clinic with the diagnosis of RA and SpA, volunteered for participating to study, were included in this cross-sectional study. Data regarding the socio-demographic and disease-related characteristics (including disease duration, medications used, and comorbid conditions) of the patients, vaccination history, the knowl-

edge about the vaccination, and the factors potentially associated with the uptake of vaccination were collected by face-to-face interview using a stand-

ardized questionnaire. 102 out of 345 rheumatologists have participated in a web-based survey.

Results: In total, we collected data from 387 patients (260 with SpA and 114 

with RA; 204 [52.8%] female and mean age 46.6 ± 12.7 years). Only 123 (32.3%) of our patients were responded that their disease or treatment might be related to the increased risk for infectious diseases. Influenza and pneu-

mococcal vaccines were administered to 71 (21.4%) and 21 (6.1%) patients, respectively. Vaccination for influenza was recommended by family physicians in 26 patients and by rheumatologists in 12 patients. Rate of influenza vac-

cination was significantly higher in patients ≥65 years (p=0.021) and with any co-morbid conditions (p=0.002). The main reasons reported by patients regarding not to be vaccination were (a) the belief that they did not need the vaccine (49.4% for influenza and 26.2% for pneumococcal vaccine), (b) the absence of recommendation from their physicians (24.1% for influenza and 22.9% for pneumococcal vaccine), (c) fear of adverse event of vaccination (28.8% for influenza and 3.2% for pneumococcal vaccine), and (d) lack of knowledge about vaccination (6.1% for influenza and 12.5% for pneumococcal vaccine). Even though 50% of rheumatologists who responded to the survey were aware of the presence of national vaccination recommendations, all of them stated that patients with inflammatory arthritis need to be vaccinated for both influenza and pneumococcal infections. Influenza and pneumococ-

cal vaccines were administered to 23 (22.5%) and 4 (3.9%) rheumatologists, respectively.

Conclusion: Although the knowledge and awareness about influenza and pneu-

mococcal vaccinations were seemed to be high among rheumatologists, vac-

cination rates for both were insufficient in RA and SpA patients. There remains significant effort to improve vaccination rates and to prevent morbidity and mor-

tality due to vaccine-preventable infections in inflammatory rheumatic diseases.

AB1142
TREATMENT COSTS OF SELECTED RHEUMATIC DISEASES IN SUB-SAHARAN AFRICA: A CASE FOR IMPROVED INSURANCE COVERAGE FOR AFRICAN PATIENTS

A. Akpabio1, C. Nga2, I. Umoh1, O. Ita1. 1University of Uyo Teaching Hospital, Internal Medicine, Uyo, Nigeria; 2University of Uyo Teaching Hospital, Uyo, Nigeria

Background: Rheumatic diseases lead to substantial economic costs 1 especially in resource-poor settings like sub-Saharan Africa (SSA).2 Annual direct cost of lupus treatment ranges from $13,735-20,926 (patient in the US to £3231($4232)/patient in the UK).1,3

Data is rare for SSA and Nigeria in particular where the minimum wage is N30,000 ($83/mth) with only 5% of citizens covered by health insurance.4,5 The scheme excludes some medications and certain procedures are grossly under-funded. Cost-of-illness studies are invaluable in planning and policy development. They typically include: direct, indirect and intangible costs.6

Objectives: To compare total costs of some rheumatic diseases, highlight underfunded therapies and push for wider insurance coverage of rheumatic diseases.

Methods: A cross-sectional study from the University of Uyo Teaching Hospital - Nigeria using data from 252 clinic patients (20 lupus, 27 rheumatoid arthritis, 25 gout and 180 osteoarthritis). Direct costs were estimated using the hospital pricelist while indirect costs were estimated using the human capital method. Statistical analysis was done with p<0.05.

Results: Females were the majority except for gout patients (44%). Most lupus patients were unemployed (75%) and had the highest annual total cost ($1313-6228) for mild to severe disease. This contrasts with a mean annual national income of $1,000 given that 75% of lupus patients are unemployed. Expanded insurance coverage for rheumatic drugs will further reduce the enormous treatment burden and improve outcomes.

AB1143
BURDEN OF GLUCOCORTICOIDS AMONG RHEUMATOID ARTHRITIS PATIENTS AT DIFFERENT STAGES OF DISEASE-MODIFYING ANTIRHEUMATIC DRUG MANAGEMENT

R. K. Dore1, J. Antonovas2, M. Goritz3, L. Chang2, H. Xi2, M. C. Genovese4. 1Robin K. Dore, MD, private practice, Tustin, United States of America; 2Gilead Sciences, Inc., Foster City, United States of America; 3QVIA, Plymouth Meeting, United States of America; 4Stanford University, Division of Immunology and Rheumatology, Stanford, United States of America

Background: EULAR and ACR guidelines recommend a treat-to-target approach for patients with RA including regular assessments of disease activity. Glucocorticoids are commonly used to control inflammation associated with uncontrolled disease. However, patients using glucocorticoids may develop short- and long-term side effects.

Objectives: To examine the real-world use of glucocorticoids among patients with RA who are disease-modifying antirheumatic drug (DMARD)-naïve or failing their first conventional synthetic DMARD (csDMARD) or biologic DMARD (bDMARD).

Methods: From a large US health claims database, this study included adults with ≥2 RA claims ≥30 days apart who started (index date [ID], 1/1/2012–3/31/2017) a first DMARD (DMARD-naïve) or patients who newly initiated a csDMARD and then switched to or added another DMARD (csDMARD switchers), and patients who initiated a first bDMARD and then switched to another bDMARD or Janus kinase inhibitor (JAKi; bDMARD switchers). All patients had continuous enrollment 1-year before and ≥1 year after ID and were evaluated for pre- and post-ID use of glucocorticoids (oral or injectable), prednisone equivalent dose (PED), and duration of exposure ≥30 days.

Results: The study included 28,201 patients in the DMARD-naïve cohort, 7,816 csDMARD switchers, and 4,656 bDMARD switchers (median age 54 years for all; 73%,78% female).

Among DMARD-naïve patients, 66.5% used glucocorticoids during the pre-ID period (Figure 1) and 61.2% had >7.5 mg/day PED, 21.2% had >30 mg/day PED, and 21.2% had ≥30 days of exposure to glucocorticoids (Figure 2). Post-ID, 69.4% of patients used glucocorticoids, while 54.7% had >7.5 mg/day PED, 13.5% had >30 mg/day PED, and 44.9% had ≥30 days of exposure to glucocorticoids.

Among csDMARD switchers, 84.5% of patients used glucocorticoids during the pre-ID period (Figure 1), and 73.4% had >7.5 mg/day PED, 16.0% had >30 mg/day PED, and 56.4% had ≥30 days of exposure to glucocorticoids (Figure 2). During the post-ID treatment, 74.1% of patients used glucocorticoids, 56.2% had >7.5 mg/day PED, 14.4% had >30 mg/day PED, and 45.8% had ≥30 days of exposure to glucocorticoids.

Among bDMARD switchers, 85.1% of patients used glucocorticoids in the pre-ID period (Figure 1), and 70.2% had >7.5 mg/day PED, 17.4% had >30 mg/day PED, and 55.2% had ≥30 days of exposure to glucocorticoids (Figure 2). During the post-ID treatment, 75.4% of patients used glucocorticoids and 59.7% of patients had >7.5 mg/day PED, 16.7% had >30 mg/day PED, and 45.6% had ≥30 days of exposure to glucocorticoids.

Scientific Abstracts
Background: Early diagnosis and treatment are important for the management of inflammatory rheumatic diseases (RMD). However, the availability of rheumatologists is limited in most European countries and selection strategies lack sensitivity and/or specificity.

Objectives: To evaluate a triage strategy that offers the possibility to see patients within 4 weeks for short term appointments in order to check the probability of an inflammatory RMD and the necessity to further evaluate the patients in due time.

Methods: Physician’s and patient’s information who called our tertiary rheumatology department’s outpatient clinic for a date in the triage system were included in this analysis. The time to first appointment as assessed by a nurse (Step 1), the short evaluation by a rheumatologist in the triage (Step 2) and the patient’s complaints and the diagnoses after an extensive diagnostic evaluation (Step 3) were documented.

Results: In a period of 9 months in 2018, a total of 982 patients presented. A total of 62 patients (6.3%) were considered urgent (appointment within 3 days), while 240 (24.4%) were appointed within 4 weeks at Step 2. Of the former 46 (19.2%), and of the latter 151 patients (62.9%) were diagnosed with inflammatory RMD at Step 3. In total, 334 patients (34.0%) were diagnosed with inflammatory RMD at Step 3, including 126 with RA (37.7%), 71 with axSpA/PsA (21.3%), 95 with connective tissue disease/vasculitis (28.4%) and 20 with gout (6.0%). The diagnosis suspected in Step 2 was confirmed in Step 3 in 773 cases. In 217 patients, the diagnosis suspected in Step 2 was not confirmed in Step 3. Of them, 34 (15.7%) had unclear findings at Step 2 but an inflammatory RMD was found at Step 3, while 148 (68.2%) had a suspected inflammatory RMD at Step 2 but this was not confirmed at Step 3. The most frequent musculoskeletal complaint at the time point of referral was pain in small peripheral joints (hands and/or feet) in 858 patients (87.4%), in large peripheral joints (knees, shoulders and/or hips) in 780 patients (79.4%) and back pain in 682 patients (69.5%). Fever, night sweats and unclear weight loss was reported by 50 patients (5.1%), while 210 patients (24.5%) presented with findings suspicious of inflammatory RMD such as elevated CRP of unclear origin, and 43 patients (4.8%) became aware of a threat of organ damage such as unclear elevation of creatinine, as reported by the referring physician. In addition, 167 patients (17.0%) had received glucocorticoids prior to referral, 87 (52.1%) of which finally did not receive the diagnosis of inflammatory RMD at Step 3, while 737 patients (75.1%) were receiving NSAIDs prior to referral.

Conclusion: In this prospective evaluation of a triage system where all patients were pre-screened by a nurse and were seen within 4 weeks by a rheumatologist, clinical differentiation could be performed timely due to a successfully structured triage system. The initially suspected diagnosis was finally confirmed in ≥75% of cases, while ≥1/3 of patients had a definite inflammatory RMD. This work was supported by an unrestricted Grant from Abbvie.

AB1145 PRESCRIPTION PATTERNS AND DISEASE ACTIVITY IN PORTUGUESE WOMEN OF CHILDBEARING AGE WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, ANKYLOSING SPONDYLITIS AND JUVENILE IDIOPATHIC ARTHRITIS

S. C. Barreira1,2, A. R. Cruz-Machado1,2, A. L. Fernandes1, I. Genrinh0, G. Sequeira1, M. Monteiro2, J. E. Fonseca2,3,1Hospital da Santa Maria, Centro Hospitalar e Universitário de Lisboa Norte, Serviço de Reumatologia e Doenças Osteo Metabólicas, Lisboa, Portugal; 2Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Portugal, Unidade de Investigação em Reumatologia, Lisboa, Portugal; 3Centro Hospitalar Universitário do Algârve, Serviço de Reumatologia, Faro, Portugal; 4Centro Hospitalar Tondela-Viseu, Unidade de Reumatologia, Viseu, Portugal

Background: Disease activity (DA) at conception is one of the main predictors of pregnancy outcomes in women of childbearing age (WoCBA) with rheumatic diseases. Disease activity at conception is one of the main predictors of pregnancy outcomes in women of childbearing age (WoCBA) with rheumatic diseases. Disease activity at conception is one of the main predictors of pregnancy outcomes in women of childbearing age (WoCBA) with rheumatic diseases. Disease activity at conception is one of the main predictors of pregnancy outcomes in women of childbearing age (WoCBA) with rheumatic diseases.
postmenopausal women (PMW) and age-matched men. Evaluate DA in WoCBA comparing to the aforementioned groups.

Methods: Observational transversal study, using data from the Portuguese registry of rheumatic diseases (Reuma.pt) from 3 Portuguese centers. Adult patients (pts) with the diagnosis of RA, PsA, AS or JIA were allocated to the following groups: WoCBA (aged 18–44y), young men (YM) (18–44y), PMW (≥45y) and matched men (≥45y). Demographic and clinical variables are described as means or frequencies. Differences between groups regarding therapy and DA were assessed with Chi-square and ANOVA tests. Linear and logistic regression models were used to find predictors of DA and prescription patterns.

Results: 2133 pts were included, 69.9% female with a mean age of 55.9±15.85 y. 1437 pts are diagnosed with RA, 305 with PsA, 254 with AS and 137 with JIA. Patterns of prescription are detailed in table 1. WoCBA were less likely to be treated with glucocorticoids than PMW (OR 0.66 95%CI 0.44-0.99). WoCBA were 1.76 times more likely to be treated with MTX than YM (95%CI 1.04-2.97). Certolizumab was specially prescribed in WoCBA (OR 13.8, 95%CI 1.4-141.6). WoCBA had significantly higher DA scores than YM (DAS28 3.23±1.18 and BASDAI 3.55±2.0 vs 2.32±1.18 and BASDAI 3.55±2.0 vs 2.43±1.66).

Conclusion: Certolizumab was prescribed preferentially in WoCBA, who also received more MTX than YM. Nevertheless, DA in this group was not well controlled, which may influence future pregnancy outcomes. Ensuring tight DA control in WoCBA through proper and ideally no teratogenic medication remains an unmet clinical need.

REAL-LIFE PRACTICES IN MANAGEMENT OF REPRODUCTIVE HEALTH IN SLE AND APS BY OBSTETRICIANS AND RHEUMATOLOGISTS IN EGYPT. (AN ONLINE-BASED QUESTIONNAIRE)

1 Alexandra University, Faculty of Medicine, Internal Medicine, Rheumatology Department, Alexandria, Egypt; 2Texas Tech University Health Sciences Center, Internal medicine, Lubbock, United States of America; 3Alexandria University, Faculty of Medicine, Internal Medicine, Rheumatology Department, Alexandria, Egypt; 4Alexandria University, Alexandria Students Hospital, Internal Medicine, Rheumatology, Alexandria, Egypt; 5Alexandria University, Alexandria, Egypt; 6Alexandria University, Obstetric and Gynecology, Alexandria, Egypt; 7Alexandria University, Internal Medicine, Rheumatology, Alexandria, Egypt

Background: Systemic lupus erythematosus (SLE) is an auto-immune disease that affect women in their reproductive age. Antiphospholipid syndrome (APS) is a hypercoagulable immune disease that occur as a primary condition or in association with SLE. The reproductive aspects as contraception, fertility, pregnancy are crucial to consider for proper management of SLE/APS.

Addressing these issues require collaboration between rheumatologists and obstetricians, improving their knowledge and ensuring that both are acquainted with the updated guidelines.

Objectives: To assess the knowledge and practice of Egyptian obstetricians and rheumatologists in management of reproductive health issues in SLE and APS, and to detect common misconceptions.

Methods: This research was conducted via google form online survey based on points discussed in EULAR recommendations for women’s health and the management of family planning, assisted reproduction, pregnancy and menopause in patients with SLE and/or APS. It was sent to target obstetricians and rheumatologists by internet clouds like (Facebook, twitter, LinkedIn) from August to November 2019. It included five domains; demographic data, general knowledge and attitudes about pregnancy in SLE and APS, contraception, drugs, and assisted reproductive techniques (ART)

After submitting answers, respondents were shown a link directing them to the 2016 EULAR recommendations.

Results: This study was conducted on 254 physicians, 62% obstetricians and 38% rheumatologists. 64.6% were between the ages of 30-35 years. For general knowledge, 52% of Obstetricians considered pregnancy in inactive SLE to be risky (79.4% vs 54.1%) of (rheumatologists and obstetricians) respectively test for aPgL in SLE patients. More than 70% in both groups were well informed on the increased rate of fetal and maternal complications in both SLE and APS. For fetal surveillance, 87% and 90% of obstetricians preformed first and second trimester U/S, and 79% preformed second trimester Doppler.

For contraception, (57.7% vs 77%) of rheumatologists and obstetricians, (89.7% vs 64.1%) and Cyclophosphamide (89.7% vs 66.2%). However, regarding Hydroxychloroquine and Azathioprine use in pregnancy there was a significant discrepancy between rheumatologists and obstetricians, (89.7 % vs 42%) and (78.4 % vs 36.9%) believed them safe to use in pregnancy. For Mycophenolate Mofetil, (80.4% vs 46.5%) said that it should be avoided in pregnancy. Regarding ART (45.4% vs 71%) considered it safe to use in stable SLE/APS.

Conclusion: The gaps in knowledge identified include the use of hormonal contraception in APS patients and the proper utilization of important medications to prevent and treat lupus flares. Initiation of shared Rheumatology/ obstetric clinics and focusing on the identified educational topics, would lessen the gap in knowledge and discrepancies in practice improve overall patient management.

SCREENED – HIGH REMISSION RATES UNDERLINE THE BENEFIT OF SCREENING CONSULTATION MODELS FOR EARLY RECOGNITION AND TREATMENT OF RHEUMATIC AND MUSCULOSKELETAL DISEASES

K. Benesova1, V. Lion1, O. Hansen2, H. M. Lorenz1. 1University Hospital Heidelberg, Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg, Germany

Background: Early recognition and treatment of rheumatic and musculoskeletal diseases (RMDs) is of critical importance for the individual outcome. However, national healthcare care structures in Germany do not facilitate early access to initial rheumatologic evaluation. Furthermore, waiting times of several months due to substantial capacity constrains in regional rheumatology care services compromise the prognostically relevant “window of opportunity” for subsequent sustained remission. To promote early detection of RMDs, the Division of Rheumatology at the University hospital Heidelberg, Germany has launched a unique screening consultation model that offers early access to rheumatologic evaluation on a regional level.

Objectives: The registry-based study SCREENED (“Screen for early diagnosis”) has been initiated to monitor the outcome of patients that were diagnosed with an RMD at the screening clinic and to assess the costs and benefits of this consultation model for the regional quality of care.
Methods: The screening consultation model has been launched in two phases: in the first phase (02/2016 - 01/2018), a screening clinic open to all patients without previous rheumatologic evaluation with appointments available to the registration order has been established through rearrangement of available capacities. In contrast to regular appointments, the screening clinic took place in shorter consultation time frames and without additional diagnostic procedures. In the second phase (02/2018 - 01/2020), in order to manage and prioritize access to rheumatologic care at our division more efficiently, prior to appointment allocation (not only) to the screening clinic all new patient registrations became subject to a preselection procedure based on the evaluation of an anamnesis questionnaire, medical reports and laboratory findings by an experienced rheumatologist. Furthermore, SCREENED project has been launched for scientific evaluation of both phases of the consultation model.

Results: The screening consultation model achieved a significant reduction in waiting times to few weeks compared to six months for a regular appointment. In the first phase, the screening clinic had a high sensitivity of 94.3% and an improbable specificity of 31.1%. In the retrospective cohort, high remission rates have been observed over all RMD entities (120/206 = 58.3% patients based on physicians’ assessment in the follow-up after screening clinic) and in rheumatoid arthritis (RA) in particular (38/61 = 62.3% and 33/55 = 60% patients with DAS28 score < 2.6 after 12 and 24 months respectively). Remission was usually reached within a year after the first appointment (9.5 ± 6.7 months), however, a trend to higher remission rates in patients with shorter illness duration was obvious. In RA patients, csDMARDs have been initiated in a third of patients immediately at diagnosis in the screening clinic and in another third within six months after the first appointment. After 12 months, > 80% have received csDMARDs, while only 14.2% needed b/tsDMARDs in the follow-up over 24 months.

Conclusion: High sensitivity and significant reduction in waiting times for initial rheumatologic evaluation in the screening clinic pave the way for early recognition and treatment of RMDs. Subsequently, high remission rates in the follow-up were reached. In RA, a high proportion of patients only required csDMARDs to achieve sustained remission. A correspondingly small proportion of patients necessitating b/tsDMARDs in the follow-up points towards a significant health economic benefit of the early rheumatologic intervention in the screening consultation model.

ECONOMIC BENEFIT FROM IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE WITH UPADACITINIB AND COMPARISONS WITH TOFACITINIB AND METHOTREXATE IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE RHEUMATOID ARTHRITIS

A. Bensimon¹, M. Yang², E. Orvis³, J. Cliewei², N. Tundia². ¹Analysis Group, Inc., Boston, United States of America; ²AbbVie Inc., North Chicago, United States of America

Background: Rheumatoid arthritis (RA) is a chronic, debilitating autoimmune disease and is associated with high direct medical costs. Treatment of RA with disease-modifying anti-rheumatic drugs (DMARDs) can improve patients’ health-related quality of life (HRQOL) and has the potential to reduce direct medical costs associated with RA. Treatment with janus kinase inhibitors, such as upadacitinib (UPA), has shown improvements in HRQOL in patients with RA [1].

Objectives: To estimate the economic benefit from improvements in HRQOL and to compare estimated direct medical costs between: (1) UPA and tofacitinib (TOFA) and (2) UPA monotherapy and methotrexate (MTX) monotherapy in patients with RA.

Methods: This economic analysis used individual patient-level data from 2 randomized clinical trials (RCTs) of UPA (SELECT-NEXT and SELECT-MONO) and published aggregate data from 1 RCT of TOFA (ORAL-Standart) in patients with moderate to severe RA that collected repeated measurements of HRQOL based on the Short Form 36 Health Survey (SF-36). Estimated direct medical costs per patient per month (PPPM) for UPA 15mg once daily (QD) and MTX were estimated based on observed SF-36 Physical (PCS) and Mental Component Summary (MCS) scores in the SELECT RCTs using a published regression algorithm [2]. Direct medical costs PPPM for TOFA 5mg twice daily (BID) were estimated from Rendas-Baum, et al [3], which applied the same regression algorithm to SF-36 PCS and MCS scores observed in the ORAL-Standart RCT. Resulting estimates of direct medical costs PPPM in the short-term (12–14 weeks) and long-term (48 weeks) were compared between UPA and TOFA and between UPA and MTX. Costs were inflation-adjusted to 2018 US dollars. Bootstrapping was used to generate 95% confidence intervals (CI).

Results: Over 12 weeks, estimated direct medical costs PPPM were $186 lower (95% CI: $21, $364) in patients treated with UPA compared with those treated with TOFA. Estimated long-term medical costs PPPM at Weeks 24 and 48 (Figure 1) and cumulative costs over the entire 48-week period (difference: $2,120; 95% CI: $1,398, $2,861; Table) were significantly lower for UPA than for TOFA. Over 14 weeks, estimated direct medical costs PPPM were $370 lower (95% CI: $147, $575) in patients treated with UPA monotherapy compared with those treated with MTX alone. Estimated long-term direct medical costs at Week 48 (Figure 2) and cumulative costs over the entire 48-week period (difference: $2,120; 95% CI: $1,398, $2,861; Table) were significantly lower for UPA monotherapy compared with MTX alone.

Conclusion: Based on improvements in HRQOL in the short-term and long-term, UPA 15mg QD was associated with significantly lower direct medical costs than TOFA 5mg BID in patients with active RA. UPA 15mg QD monotherapy was associated with significantly lower direct medical costs than MTX monotherapy in patients with active RA. These results provide evidence of the economic benefits of UPA as a novel treatment for moderate to severe RA.

Conclusion: In this study, HBV vaccination response was poor and lower in rheu-

matic patients treated with biologic therapy than in healthy adults. Vaccination was overall safe but there were 4 severe flares and 3 SAE that lead to treatment switch/ interruption, although causal association is difficult to establish. Our data reinforce the recommendation for HBV vaccination prior to starting biologic therapy, pos-
sibly even as soon as the diagnosis is established. Alternative HBV vaccination strategies should be investigated in patients already treated with biologics.

AB1149 POOR RESPONSE TO HEPATITIS B VACCINATION IN RHEUMATIC PATIENTS TREATED WITH BIOLOGIC THERAPY – IMPLICATIONS FOR CLINICAL PRACTICE

V. C. Romão1,2, P. Ávila-Ribeiro1,2, M. J. Gonçalves1,2, A. R. Cruz-Machado1,2, A. Guerreiro2, V. Teixeira1,2, A. Valido2, J. Silva-Dinis1,2, E. Vieira-Sousa1,2, M. J. Saavedra2, E. Leite3, R. Tato Marinho4, J. E. Fonseca1,2.

Background: Hepatitis B virus (HBV) vaccination is recommended for rheumatic patients starting biologic therapy. There is some evidence that HBV vaccination is effective in patients under conventional disease modifying anti-rheumatic drugs (DMARDs), but it is currently unclear whether this also applies to biologics.

Objectives: To assess the efficacy and safety of HBV vaccination in patients with rheumatic diseases treated with biologics.

Methods: We included patients with any inflammatory rheumatic diseases treated with any biologic, who were negative for anti-HBs and anti-HBc and had never been vaccinated for HBV. Engerix B® was administered at 0, 1 and 6 months and anti-HBs was re-assessed ≥1 month after last dose. Response was defined as anti-HBs>10IU/L and compared against healthy controls (HC) undergoing Occupational Health immunization. Disease flare was evaluated before and until at least 1 month post-vaccination. We recorded serious adverse events (SAE) and immune-related disorders not previously present.

Results: We included 67 patients, most treated with TNF inhibitors (TNFi), and 70 HC (Table 1). Most patients were taking concomitant DMARDs (69%) and were in remission/low disease activity (59%). Only 20 patients (30%) had a positive response to vaccination, in comparison to 68 HC (97%, p<0.001). Mean post-vaccination anti-HBs titre was significantly lower in responding patients than HC (569 ± 772 vs 1316 ± 811U/L, p<0.001). Responders diagnoses were RA (n=8 [25%]), PsA (n=7 [39%]), AS (n=4 [33%]) and IBD-associated SpA (n=1[100%]). Response was seen in 19/53 patients treated with TNFi (36%), but only 1/14 (7%) of patients treated with non-TNFi (p=0.037). Importantly, some responders had to temporarily inter-

rupt biologic therapy due to other intercurrents for at least one administra-

tion. No clinical or demographic variables were associated with response, including age and disease activity. Fourteen patients (21%) experienced disease flares, of which 7 were mild and did not require therapy adjustment; 3 patients required minor treatment/dose adjustments; 4 patients had secondary failures that led to switched. There were 3 SAE (acute diverticulitis; abdominal infection; atrial fibrillation and urinary infection) 1-4 months after 1st/2nd dose, deemed not to be related to vaccination. One RA patient on infliximab had bilateral uveitis 2 months after the 1st vaccine dose, which resolved with topical therapy.

Acknowledgments: Financial support for the study was provided by AbbVie. AbbVie participated in the study design, research, data collection, analysis and interpretation of data, writing, reviewing, and approving the publication. Medical writing services, provided by Joann Hettasch of JK Associates Inc., were funded by AbbVie.

AB1150 ECONOMIC IMPACT ASSOCIATED TO BIOLOGICAL THERAPY / SYNTHETIC FAME OPTIMIZATION IN A COHORT OF PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES TREATED BY OBJECTIVES.

P. Castro1, A. Onteniente2,1, Glorívia Francisco de las Cabezas, Rheumatology, Madrid, Spain; 2Calle del General Aranaz, Pharmacy, Madrid, Spain

Background: Therapeutic decision-making for biologic-therapies/ synthetic FAME (BT/SD) dose optimization, should be based on optimal disease activity results according to a treatment strategy by objectives. The goal of BT optimi-

zation is to guarantee long-term effectiveness and safety, maximising economic savings.

Objectives: To evaluate BT optimization patterns in patients with rheumatic dis-

eases (RD) and associated economic savings.

Methods: An observational and prospective study, which included a cohort of patients with rheumatoid arthritis (RA), spondyloarthropathies (SA) and psoriatic arthritis (PsA) treated with BT from January 2014 to December 2019. BT optimization, achieved by reducing or prolonging the interval at least one dose, was indicated when patients have more than 6 months of treatment and are in clinical remission (DAS28 <2.6 for RA and PsA, and BASDAI<4 for SA).

Variables were described as frequencies and means. Diagnosis, BT (abatacept, adal-

inumab, apremilast, baricitinib, certolizumab, etanercept, golimumab, ixekizumab, secukinumab, tocolizumab, tocilizumab, and ustekinumab), dose regimens, total treatment duration, time on BT optimization (TO) and treatment costs were collected.

Cost savings were calculated per patient by comparing optimization treatment costs to conventional treatment and globally by comparing real cost to theoretical conventional doses cost.

Results: A total of 260 patients were included in the study. Switching was observed in 32.7%. From all patients, 53% were candidates for BT optimization (according to diagnosis: 60.9% with RA, followed by 52.2% with SA and 43.4% with PsA).

A total of 260 patients were included in the study. Switching were

observed in 32.7%. From all patients, 53% were candidates for BT optimization (according to diagnosis: 60.9% with RA, followed by 52.2% with SA and 43.4% with PsA).

A 40% of patients with BT optimization were treated with adalimumab and etan-

cept being also the most common BT used in RD treatment BT optimization allowed a pharmaceutical saving of € 177,539.40 per year against the use of conventional therapy, resulting in a reduction of the total cost of € 1,065,236.40 in the last 6 years. The saving per patient / year was € 707.63 for RA; € 850.40 for SA and of €493.21 for the PsA.
Conclusion: Therapeutic decision-making based on validated disease activity scales has allowed the BT optimization in approximately 53% of patients with RD. BT optimization allowed a pharmaceutical saving of €17,539.40 per year being higher in the RD ($5.805.40) followed by the RA ($707,539) and finally the PsA ($493,21).

The BT optimization allows to reduce costs maintaining the effectiveness and safety.

AB1151

COMPLIANCE/CONCORDANCE WITH MYCOPHENOLET MOFETIL IN PATIENTS WITH CONNECTIVE TISSUE DISORDERS IN COVENTRY.

A. Chauhan1, N. Lovell1, S. Dubey1, 1Coventry and Warwickshire, Rheumatology, Coventry, United Kingdom

Background: Connective tissue disorders like Systemic lupus erythematosus (SLE) are multi-organ systemic conditions characterised by disordered immune function. Mycophenolate Mofetil (MMF) is commonly used for treatment of SLE1 and other connective tissue disorders like Sjogren’s syndrome, myositis and Scleroderma. Compliance with drugs remains a significant issue in management of these conditions and varying reports from across the world2,3 continue to have issues relating to compliance/concordance with MMF treatment and also on age. SLE patients were 34% less compliant with MMF in comparison to other connective tissue disorders. Demographics suggested the significance that lack of concordance resulting in increased disease activity, damage and risk of flares (p = 0.25, p<0.002).

Objectives: The aim of this study was to investigate the compliance/concordance specifically with MMF treatment among patients attending clinics at University Hospitals Coventry and Warwickshire NHS Trust (UHCW) with SLE and other connective tissue disorders.

Methods: Ethical approval was obtained through research and development department within the Trust. This is a retrospective study collating non-identifiable hospital pharmacy data in patients who requested the prescription for MMF drug between January 2015 and December 2018. Since MMF was required to be prescribed from the hospital (i.e. General practitioners within the region were unable to prescribe it), we have records for all prescriptions for these patients. We extracted information on sample size, frequency of prescription requested and length of follow up. Clinical data were obtained from paper and electronic notes of the patients. Data were analysed using the data analysis tool pack for linear regression, on Microsoft Excel package version 16.29.1.

Results: We recruited 144 patients into this study, (74%) of these are females. Age range for this group was 2-89 years, median age was 45 (±11.2) years with a mean ±(SD) age of 35.6 ±(11.2) years and a disease duration of 8.8 (±6.2) years. 73.1% were White British, the remaining included 8.3% Indian, 5.5% Pakistani, 2.7% Black British, 2% Caucasian, 2.1% Chinese, and 6.3% other. Overall, we had 54 patients with SLE and 90 Patients with other connective tissue disorders. Good compliance (81-100%) with MMF was found in 13 patients, (9%). We found a significant correlation between lack of compliance and risk of flares (r = 0.25, p < 0.002), displayed in Figure 1. We also found a significant difference in compliance patters depending on diagnosis and also on age. SLE patients were 34% less compliant with MMF in comparison to other connective tissue disorders. Demographics suggested the degree of compliance increased with age. Patients between 40-69 years of age were 65% more compliant in comparison to the age 20-39 years (p < 0.002).

Conclusion: SLE and connective tissue disorder patients within Coventry continue to have issues relating to compliance/concordance with MMF treatment and this appears to be worse in patients with SLE and in the 20-39 years of age. These patients also appear to be getting flares hence, this remains a major problem in the management of these conditions.

AB1152

INCREASED VACCINATION RATE AMONG PATIENTS UNDER BIOLOGICAL DMARDS AFTER INFECTIOUS RISK ASSESSMENT CLINIC

F. Cunha Santos1, A. S. Pinto1, S. P. Dinis1, C. Quinauz2,3, C. Vaz2,3, 1ULS - Unidade de Saúde Local da Guarda, Rheumatology, Guarda, Portugal; 2ULS - Unidade de Saúde Local da Guarda, Infectious Diseases, Guarda, Portugal; 3Faculdade de Ciências da Saúde, Covilhã, Portugal

Background: Infectious complications are a major concern among immunosuppressed patients. In an attempt to ameliorate these, EUROLAR released an updated version of their recommendations for vaccinations in patients with rheumatic diseases. These should resonate even further, since our patients are deliberately immunosuppressed in order to achieve remission. In 2018, an Infectious Risk Assessment Clinic (IRAC) was created in our centre to address these issues and prepare patients for biological therapy. This work summarizes our experience.

Objectives: Compare vaccination rate among patients with rheumatic diseases before and after the clinic creation.

Methods: A retrospective observational study was conducted in our Rheumatology Department and IRAC, at Local Health Unit of Guarda. All patients under biological therapy followed in our department from 2010 to 2020 were chart reviewed. Sociodemographic and clinical features were collected: sex, age, rheumatic disease diagnosis, current biological treatment and their vaccination history. Studied vaccines were Pneumococcal 13-valent conjugate, Pneumococcal vaccine polyvalent, Influenza virus, Hepatitis A and B, Herpes Zoster and Tetanus/Diphtheria. Patient was considered vaccinated when the correct schedule was followed by the attending physician. If prescription was outside the stipulated timing, it was considered not vaccinated. Chi-square and Fisher's exact test were used to assess associations and p<0.05 was considered statistically significant different.

Results: 65 patients were included, 41 (63.10%) were females, with a mean age of 52.38±11.11 years. Diagnosis distribution is the following: rheumatoid arthritis (52.30%), axial spondylarthropathy (26.20%), psoriatic arthritis (12.30%), peripheral spondylarthropathy (6.20%), 1 (1.50%) patient with Sjogren Syndrome and 1 (1.50%) with systemic sclerosis. Most common drugs were anti-TNFα (64.60%), anti-JAK (15.40%), anti-IL17A (10.80%), anti-CD20 (7.70%) and anti-IL12/IL23 (15.00%). Of all patients, 24 (36.90%) attended IRAC before starting biological therapy. Table 1 shows prescribed vaccines in both groups and their associations.

Table 1. Prescribed vaccines in both groups (p<0.05).

Conclusion: A few conclusions can be drawn from this work. Firstly, prevalence of vaccination increased after clinic creation, especially for Pneumococcal vaccine polyvalent, Influenza virus, Hepatitis A and B. We would expect the same results in the remaining vaccines in a broader population. Our results were also affected by stock rupture in our country. Secondly, this study shows the importance of a protocol, which helps systemise assessment of infectious risk before biological therapy, by analysing thoroughly vaccination history and keeping it updated. Lastly, shared responsibility between rheumatologists and infectiousologists enables them to leverage their skills and focus, leading to ultimate gains for the patient. We hope this work motivates colleagues to start similar practices in their centres.

AB1153
ANALGESIC AND ANTI-INFLAMMATORY DRUG USE IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND SPONDYLOARTHRITIS VERSUS CONTROLS IN A BELGIAN GENERAL PRACTITIONER REGISTRY.

S. Pazmino1, V. Stouten1, P. Verschueren1,2, P. Mamacor3, R. Westhovens1,2, K. De Vlam1,2, D. Bertrand1, K. Van der Elst1, B. Vaes3, D. De Cock1.

Background: Rheumatoid arthritis (RA), psoriatic arthritis (PSA) and spondyloarthritis (SPA) are the most common inflammatory rheumatic diseases. Pain is the hallmark symptom in these conditions and pain relief is ranked first amongst preferred outcomes by patients. Level of analgesic and anti-inflammatory drug use is unknown in these populations in Belgium.

Objectives: To compare analgesic and anti-inflammatory drug use in patient populations of RA, PSA and SPA versus controls in a General Practitioners (GP) setting in an era of expanding treatment possibilities in rheumatology.

Methods: Data were obtained from Intego over a 13-year time interval from 1999 to 2012. Intego is a Flemish GP-based morbidity registration network hosted at the Academic Center for General Practice of the KU Leuven, covering 2% of the Flemish general population. Patients classified under the International Classification of Primary Care codes L88 (rheumatoid/autoimmune arthritis) and L89 (musculoskeletal disease other) were selected for this study. Experienced rheumatologists verified if the keywords mapped to these codes corresponded to a diagnosis of RA/SPA/PSA. The date of first occurrence of these diagnoses in Intego was considered “baseline”. Controls were matched on age, gender, baseline date and GP practice in a 4:1 case ratio. Intego registers all electronic drug prescriptions by the GP. Anytime use of glucocorticoids, NSAIDs, opioids except tramadol, tramadol and paracetamol in the first 3 years after diagnosis is presented. Proportions of patients and controls on analgesic and anti-inflammatory drugs were compared by Chi-Square analyses.

Results: Over a 13-year period, 738, 2952, 229 and 916 patients were included with a diagnosis of RA, SPA or PSA, respectively. Table 1 presents the medication use of these populations. The three conditions had statistically significantly more prescriptions for all types of analgesic and anti-inflammatory drugs compared to controls. Approximately 70% of patients with an inflammatory rheumatic condition received mild pain medication (NSAIDs, tramadol and paracetamol) in the first three years after diagnosis. To note is the high use of opioids, even excluding tramadol, in these populations ranging up to 15%.

Table 1. 3-year analgesic and anti-inflammatory drug use in RA, SPA and PSA patients versus controls

Conclusion: Frequent analgesic and anti-inflammatory drug use in patients with a chronic inflammatory joint condition is to be expected, and underlined by the results of our study. Remarkably is the high use of opioids, even excluding tramadol, in patients with RA, PSA and SPA in an era of effective disease modifiers, as well in the control population. Our data shows that around 9% of the Belgian population receives at least once over a 3-year period an opioid prescription. As our data only registers electronic GP prescriptions, this is likely to be an underestimation of the true prescription proportion. Detailed analyses on dose and duration of analgesic and anti-inflammatory drugs will follow.

EHR-INTEGRATED PATIENT-GENERATED HEALTH DATA FOR SYMPTOM MONITORING IN LONG-TERM CONDITIONS: A SYSTEMATIC REVIEW

J. De Fonsa Gandrup1, S. Mustafa Ali1, S. Van der Veer1, J. Mcbetch1, W. Dixon1, University of Manchester Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom

Background: Patients with long-term conditions (LTCs), including many RMDs, often require continuous management of care. Patient-generated health data (PGHD) collected between visits could inform ongoing care management and provide important insights into patient health and well-being. There is increasing interest in integrating PGHD in electronic health records (EHRs). However, integration is still largely aspirational with limited evidence of successful systems.

Objectives: To map the landscape of EHR-integrated remote symptom monitoring systems in the field of LTCs. The objectives were to 1) characterise state of the art systems, 2) describe their clinical use, and 3) outline anticipated and realized benefits for clinical practice.

Methods: A systematic search was conducted in three electronic databases up until November 2019. Titles and abstracts were independently screened by two reviewers. One reviewer screened full-text articles, identified those relevant for review and extracted data. Inclusion criteria included 1) symptom reporting systems in adult patients suffering a LTC, 2) integration of data into the EHR, 3) symptom data collected remotely, 4) evidence of use in clinical care. We did not exclude studies based on study design, quality, or sample size. Synthesis focused on describing system specifications and their use. For objective three we adopted a list of outcome indicators [1], which each of the studies were assessed against.

Results: The initial search yielded 2040 articles. Only 12 studies reporting on ten unique systems were identified. Two systems were used in rheumatology, but the majority were used in oncology. Systems were highly heterogeneous in terms of technical and functional specifications. Nine systems were fully integrated (data viewable in the EHR), while the remaining system represented a partial integration (data viewable via link in the EHR). Five systems allowed repeated data collection at
pre-defined intervals between visits with frequencies varying from daily to monthly. The remaining five made a single request before a scheduled clinic visit. The number of items requested from patients ranged from 9-48 per session. We identified three different clinical workflows: Simple (data only used during consultation, n=5), moderate (real-time alerts for providers when severe symptoms were reported, n=4) and on-demand (patient-initiated visits, n=1). Benefits of symptom reporting from each of the studies were categorised as anticipated, realized quantitative, and realized qualitative. We present summarised counts of these benefits in Figure 1. The most common anticipated benefits were better communication, changes to patient management and improved health outcomes. Most common realized benefits were detecting unrecognized problems and changes to patient management.

**Figure 1.** Summarized counts of benefits from each included study assessed against Chen et al’s 10 outcome indicators. Categorized in anticipated (orange), realized quantitative (light purple), and realized qualitative benefits (dark purple).

**Conclusion:** There is growing interest and urge for integrating symptom data in the EHR and clinical care. Yet, this review has illustrated that there are limited published efforts to learn from. The heterogeneity in approaches underpins the need for a common framework. There is growing evidence from qualitative work in support efforts to learn from. The heterogeneity in approaches underpins the need for a common framework. The next step will be for robust, quantitative studies to provide evidence of benefits.

**AB1156 WORK DISABILITY AND PREDICTORS OF POOR WORK OUTCOME IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

E. Durak Ediboglu1, D. Solmaz1, H. E. Oz1, G. Kabasady1, H. Cinakli1, E. Otman Akad1, M. Ozmen1, S. Akar1, Immun Katip Celebi University School of Medicine, Rheumatology, Izmir, Turkey

**Background:** Axial spondyloarthritis (axSpA) is a chronic inflammatory disease which may lead substantial functional limitation. The disease more commonly affects men in their third decade of life. For patients with chronic disease participation in paid work may be the result of series factors like disease severity, effectiveness of the health care, availability and the type of work. Previously it was reported that ankylosing spondylitis may cause adverse work outcome.

**Objectives:** To understand the impact of axSpA on work disability and the factors associated with poor work outcome.

**Methods:** A cross-sectional survey was performed among 323 patients with axSpA according to ASAS classification criteria from one tertiary center. In total 219 (67.8%) patients were working age at the time study. The others were student, housewife or retired. Demographic, social and disease related characteristics were collected. Characteristic that might be associated with premature work loss were evaluated by univariable and multivariable logistic regression analysis.

**Results:** Out of 219 axSpA patients (155 [71%] r-axSpA and 64 nr-axSpA, 69% HLA-B27 positive) who have a work at least once 47 (22%) was either withdrawn from work (n=35) or retired due to disability (n=12) during median (IQR) 12 (12) years symptom duration. Demographic and disease related characteristics of the patients with or without work disability were summarized in the table. In univariate analysis gender, smoking, education levels, the presence of peripheral arthritis, BASMI score and radiographically presence of syndesmophyte and hip involvement were found to be associated with poor work outcome. However poor work outcome were similar between r- and nr-axSpA patients. In regression analysis low education level (HR=3.4 [95%CI:1.4-8.6], P=0.007), peripheral arthritis (HR=2.75 [95%CI:1.074-6.8], P=0.035), and ever smoking (HR=4.9 [95%CI:1.3-18.0], P=0.02) were independent predictors of work disability.

**Conclusion:** Our results suggest that there is still remarkable poor work outcome among axSpA patients and work disability might be similar in r- and nr-axSpA. Patients who are smoker, with low education levels, and peripheral arthritis seem to be at risk for premature work loss.

**AB1156 OVERVIEW OF INFLAMMATORY RHEUMATIC DISEASES AT THE EMERGENCY DEPARTMENT**

I. San1, A. Erden1, O. Küçükşahin1, Ankara City Hospital, Ankara, Turkey; Yıldırım Beyazıt University, Ankara, Turkey

**Background:** Patients with rheumatological diseases can also apply to the emergency room due to acute attacks or complications. Especially in recent years, more patients, due to the increased use of immunosuppressant drugs in treatment, have applied to emergency services due to infection. On the other hand, data on applications to emergency services for rheumatological reasons are very few.

**Objectives:** In this study, applications to emergency departments for inflammatory rheumatic diseases were investigated.

**Methods:** 2715 patients from Atatürk Training and Research Hospital Rheumatology Clinic who were followed-up with the diagnosis of inflammatory rheumatic diseases between 2014 and 2018 were included in this study. The clinical and laboratory information of the patients were achieved from the hospital file records and the hospital data bank. The patients were classified according to the 5-stage triage system (T1: resuscitation, T2: critical, T3: urgent, T4: less urgent, T5: non-urgent).

**Results:** 21.3% (577) of 2715 patients applied to the emergency department. Among the emergency admissions, the first three diseases were; rheumatoid arthritis 19.7%, ankylosing spondylitis 19.2%, and familial Mediterranean fever 15.9%. Vasculitis 8.8%, Behçet’s disease 7.6%, Gout 5.7%, Systemic lupus erythematosus 3.9%, Sjögren’s Syndrome 3.6%, Scleroderma 3.2%, Still Disease 1.5%, Polymyalgia rheumatica 0.6%, others 9%. 343 patients (59.5%) were discharged from the emergency department. 36.8% (212) of the patients were hospitalized in services and 3.6% (21) of them in intensive care. The first three reasons of the applications to the emergency department were; fever, malaise and fatigue in 1,150 patients (25.9%), musculoskeletal system complaints in 212 patients (21.4%) and abdominal pain in 3, 89 patients (15.4%), respectively. Vasculitis was the most common cause of hospitalization in the service in 38 patients (17.9%), whereas scleroderma was the most common cause of hospitalization in intensive care in 7 patients (33.3%) (table). 16 (76.1%) of the patients followed in intensive care unit were hospitalized with the diagnosis of respiratory system diseases. Death was observed in 10 (1.7%) of 577 patients. Five (50%) of the ex-patients had scleroderma (table). 8 (80%) of the deaths were related
to rheumatological disease and occurred after being hospitalized in intensive care unit.

**Conclusion:** The patients with inflammatory rheumatic diseases usually apply to the emergency department with urgent or less urgent clinical pictures. Rheumatoid arthritis, one of the most common inflammatory rheumatic diseases in almost all societies, was also the most common diagnosis in our study. In the vast majority of applications, infectious causes and disease activations related to immunosuppressive treatments were in the foreground. In addition, although vasculitis is the most common reason for the in-patients in clinical service, since the most frequent in-patients in intensive care unit and death is seen in the scleroderma group; caution should be exercised in the emergency applications of patients with these two groups.

**AB1157 SEASONAL INFLUENZA VACCINATION: KNOWLEDGE AND ATTITUDES IN RHEUMATIC PATIENTS**

G. Figueara-Parrá1, L. Santooy-Fexas1, A. Moreno-Salinas1, C. M. Gamboa-Alonso1, A. L. De-Leon-Ibarra1, D. A. Galarza-Delgado1, J. A. Esquivel Valero1,1 Hospital Universitario “Dr. José Eleuterio González”, Servicio de Reumatología, Monterrey, Mexico

**Background:** Vaccines are one of the safest and effective public health interventions (1). Patients with rheumatic diseases (RD) have a higher risk of morbidity and mortality from vaccine-preventable infections (2). Seasonal Influenza vaccination (SIV) has shown to reduce the incidence, complications, admissions, and mortality from Influenza in patients with RD (3). Vaccine hesitancy is one of the threats to global health established by the WHO.

**Objectives:** To assess the knowledge and attitudes of rheumatic patients about SIV.

**Methods:** A self-questionnaire was applied during a community speech for rheumatic patients in October 2019 and also was applied in the rheumatology clinic of the university hospital “Dr. Jose Eleuterio Gonzalez” in Monterrey, Mexico, between November and December 2019. The questionnaire asks age, rheumatic diagnosis, and ten questions. Results are shown in descriptive statistics, the Chi-square and Mann-Whitney U tests were performed to compare groups. A P-value ≤0.05 was considered statistically significant. Analyses were performed using SPSS version 22.0.

**Results:** A total of 205 self-questionnaires were applied. 122 (59.5%) in the community speech and 83 (40.5%) in the clinic. The median age was 55 (45.75-62.25) years in the community population and 44 (28-59) years in the clinic, also the diagnosis distribution was different (Table 1). Most patients considered that rheumatic patients can be vaccinated. About 80% of patients have ever been vaccinated for seasonal influenza. 87.7% and 77.1% considered that SIV is safe and effective. About 85% of patients considered SIV the best way to avoid complications of Influenza. About 40% considered not safe to be vaccinated for influenza and other vaccine at the same time. 23.8% and 48.2% considered that SIV weakens the immune system and renders it susceptible to infections. Most of the patients know that SIV is free. 23.0% and 42.2% consider other measures better than SIV. 17.2% and 33.7% considered that SIV will get them worse instead of helping them, and 9.0% and 14.5% think that his RD will get worst with SIV.

**AB1158 VACCINATION BARRIERS IN PATIENTS WITH RHEUMATIC DISEASES**

G. Figueara-Parrá1, A. Moreno-Salinas1, L. Santooy-Fexas1, C. M. Gamboa-Alonso1, A. L. De-Leon-Ibarra1, I. D. Hernandez-Galarza1, D. A. Galarza-Delgado1, J. A. Esquivel Valero1,1 Hospital Universitario “Dr. José Eleuterio González”, Servicio de Reumatología, Monterrey, Mexico

**Background:** Patients with rheumatic diseases (RD) are at increased risk of infections, attributed to the underlying RD, comorbidities and immunosuppressive therapy, including glucocorticoids, disease-modifying antirheumatic drugs, etc. (1). While many infectious diseases can generally be prevented by vaccines, immunization rates in this specific patient population remain suboptimal (2). Despite being recognized as one of the most successful public health measures, vaccination is perceived as unsafe and unnecessary by a growing number of individuals. Lack of confidence in vaccines is now considered a threat to the success of vaccination programs (3).

**Objectives:** To describe the main causes of non-vaccination in patients with RD.

**Methods:** A self-questionnaire was applied to a sample of patients with RD in the rheumatology clinic of the university hospital “Dr. Jose Eleuterio Gonzalez” in Monterrey, Mexico between September and December 2019. The questionnaire evaluated demographic characteristics (age, gender, diagnosis) and the vaccination status for Influenza (last year), pneumococcal (last 5 years). Herpes zoster (ever), Human papillomavirus (any dose) and Hepatitis B (any dose). It also includes a question asking: If you didn’t receive any of the previous vaccines, what was the reason? (multiple-choice are shown in Table 2). Results are shown in frequencies and percentages.

Results: 102 patients were evaluated. Mean age was 51.27 (SD 14.68) years; 84 (82.4%) were females; 71 (69.6%) had rheumatoid arthritis, 13 (12.7%) had systemic lupus erythematosus, 6 (5.8%) had other autoimmune diseases and 12 (11.8%) had osteoarthritis. The rate of vaccination for influenza was 49 (48%), for pneumococcal 25 (24.5%), for Herpes zoster 5 (4.9%), for Human papillomavirus 9 (8.8%), for Hepatitis B 14 (13.7%) (Table 1); 82 (80.3%) patients reported some barriers in vaccination from these; from these: 22 (26.6%) did not get the recommendation from the rheumatologist, 21 (25.6%) did not find available the vaccine, 13 (15.8%) believes that vaccines don’t work, 8 (9.7%) had fear of adverse events, 3 (3.6%) reported previous adverse events, and 15 (18.2%) reported other reasons, that we classified as own decision 8 (9.7%) (Table 2).

Conclusion: The main barriers in vaccination of rheumatic patients reported were the lack of availability of the indicated vaccines and the medical and patient disinfection. This problem must be combated to ensure the complete vaccination of rheumatic patients.

HIGH PREVALENCE MUSCULOSKELETAL PATHOLOGY: A CHALLENGE FOR PRIMARY ATTENDING PHYSICIAN. WHAT DO WE RHEUMATOLOGISTS CONTRIBUTE TO?

J. García Hernández1, L. Fernández de la Fuente Bursón2, P. Muñoz Reinoso1, D. V. Mendoza Mendoza1, B. Hernández-Cruz3, P. González Moreno1, J. J. Pérez Venegas1. 1Hospital Universitario Virgen Macarena (HUVM), Sevilla, Spain

Background: Musculoskeletal diseases (MSKD) represent one of the main health problems burdens worldwide. They cause a significant functional, quality of life and socioeconomic impact. Knee and lumbar osteoarthritis are the most prevalent. MSKD can be assessed by different kind of specialists: Orthopedic and Traumatology Surgery (OTS), Rheumatology and Rehabilitation, each of them focused at one of the distinct aspects of the same disease. It is the General Practitioner (GP) consultations that usually act as a gateway to specialized care. However, this derivation is carried out in non-standardized manners that leads to an evaluation from a sometimes wrong selected specialist or sometimes overlap management between several of them. The result is an endless waiting list in an overburden health system that cannot solve people’s health issues. In 2018, only in our area, 32,849 patients with MSKD were referred from GP to the different medical consultations: OTS (65%), Rehabilitation (25%) and Rheumatology (10%). Furthermore, there are specialized consultations called “Primary Trauma” to which GP can refer which are managed indistinctly by any of the 3 specialists mentioned before.

Objectives: The following study aims to assess by collecting data in one of these consultations, how these pathologies are referred to the different specialist and the role that the rheumatologist plays in its management.

<td>8.5</td>
</tr>
</tbody>
</table>

Results: The average age of the patients was 51 years (7-88), 57% (170) women and 43% (130) men. The most frequent reasons for referral were knee pain (26), foot pathology (23%), low back pain (12%) and carpal tunnel syndrome (6%), 68% (204 patients) attended the consultation with some test already performed request in primary care, mostly radiographs (61%) and MRI scan (34%). After the first assessment during consultation, only 31% required new studies. The diagnoses that were most frequently established are shown in table 1: degenerative knee pathology (29%) was the most prevalent. 60% of the patients assessed were given exercise tables and/or postural recommendations. 14% received an infiltration on the same day of the visit. Only 78 patients (26%) needed to be reviewed later in those consultations. Of the remaining 222 (74%), 81 (27%) were referred to other specialists. 56 of them (19%) went to OTS to a surgical evaluation, most frequently of the knee (32%), hand (27%) and foot (23%). 141 (47%) were discharged and referred to GP for follow ups.

Conclusion: The prevalence of MSKD found in medical consultation coincides with the national registers. Most patients did not need to be referred to surgical units. The role of the Rheumatologist is to take a comprehensive care for the patient, focusing on giving an effective evaluation and quick solution to his MSKD. In short, if the most prevalent MSKD are not subsidiary of surgical treatment (at least initially), the specialist whom patients with MSKD should be referred would be the rheumatologist.

**Conclusion:** In this study, significant differences between Spanish and RoE patients were observed for the burden of the disease in patients with axSpA. Patients in Spain experience a greater diagnostic delay and greater psychological distress.

AB1162 ANTI-TNF BIOSIMILARS: HOW KNOWLEDGE AND BELIEF INFLUENCE PRESCRIPTION
A. De Chateaubriand1, P. Ingrand1, E. Gervais1,2,3, Poitiers University Hospital, Rheumatology, Poitiers, France; 1Poitiers University Hospital, Poitiers, France; 2University of Poitiers, LITEC, Poitiers, France

Background: Biological agents change the management of rheumatic inflammatory disease with improving care but increasing costs. Biosimilars for subcutaneous TNF inhibitors (SC TNF) are available in France since 2015 and provide the same treatments at lower cost. French health agencies do not legally obligate the rheumatologist to first prescribe or switch to biosimilars.

Objectives: To assess the knowledge and beliefs of French rheumatologists about biosimilars.

Methods: The assessment was developed with a questionnaire consisting of five parts: demographics data, professional practice, theoretical knowledge, beliefs and confidence. The questionnaire was administrated via the website Limesurvey and sent by email to French rheumatologist. A descriptive analysis of the data and associated factors to initiation and switch of biosimilars have been done.

Results: One hundred one rheumatologists have participated to the study. 47.1% was less than forty years old. 92% of them have the authorization to prescribe TNF. 53.2 always prescribed a biosimilars when they prescribed a SC TNF for the first time and 78.5% in 90% of cases. 30.6% of French rheumatologist never switched to a biosimilars. Those who switch, do it in more than 75% of cases. 96.5%, 87.1% and 91.8% respectively answered that biosimilars are as efficient, as safe and have the same immunogenicity profile compared to originator. The initial biosimilars prescription is associated with a better knowledge about biosimilars. For example, 77.4% of rheumatologist who prescribe in more than 90% of the case, answer NO to the question “biosimilars and originator have to be compared in a phase III study for EACH indications for which originator obtained marketing approval”? Only 31.2% of rheumatologist who prescribed in less than 90% of the case respond NO to this question. This difference was significant p<0.001. The switch to a biosimilars is associated with the beliefs and confidence. For example 25.4% of rheumatologists who switch for biosimilar in more than 75% of the case, answer YES to the question “There is not enough experiences with biosimilar” 57.7% of rheumatologist who switched in less than 75% of the case respond YES to this question. This difference was significant p=0.003.

Conclusion: Despite good knowledge on biosimilars, some French rheumatologists do not switch for these molecules. Our study suggests that this is due to lack of confidence.

Acknowledgments: The authors thank French rheumatologist who answer to the questionnaire

AB1163 IMPACT ON COSTS AND WORKING LIFE OF RHEUMATIC PATIENTS WITH CHANGE IN BIOLOGICAL THERAPY FOR NO MEDICAL REASONS. REAL LIFE EXPERIENCE IN REGIONAL HOSPITAL OF SOCIAL SECURITY
L. Pablo Olivares1, E. González Figueroa2, M. F. López Marquet1, M. V. Goyochoa Robles1,2, IMSS, Rheumatology external consult, Mexico City, Mexico; 1IMSS, Clinical Research Unit HGR 1, Benito Juarez, Mexico; 2UNAM, Departamento de Enseñanza Clínica Facultad de Medicina, Coyoacan Mexico City, Mexico

Background: Biologics as new therapeutic alternatives have revolutionized the management of rheumatic diseases. Biosimilars have emerged as less expensive alternative. Most part of evaluations of biosimilars had proved effective- 
tiveness by clinical trials with outcomes as remission, but specific social aspects and economic variables not always has been considered. These aspects must be assessed in specific and real contexts (countries, health institutions) The effect on non-medical switch of biological therapy for rheumatic diseases in costs and working variables has not been documented in patients of the Mexican Social Security Institute (IMSS)

Objectives: Evaluate the impact of the change of biological therapy for non-medical reasons on the economic variables, costs and working aspects with rheumatic diseases on Mexican patients with social security

Methods: Cross-sectional observational study included patients from rheumatology clinical service of an IMSS Regional Hospital in Mexico City during last trimester of 2018. A structured questionnaire was applied who diagnosis of rheumatoid arthritis and spondyloarthropathies where received treatment biological for at least 24 months prior to the study. The individuals were divided into two comparison groups, G1: patients who changed to biosimilar biological treatment for non-medical reasons and G2: patients with original biological treatment without changes in the therapeutic scheme. In addition to socio-demographic characteristics, functional capacity (HAQ-dI), disease activity (DAS28) and labor aspects were evaluated. A sex and age adjusted logistic regression analysis was performed where the outcome variable was the evolution in

Results: The 71 cases evaluated included 90% female with schooling > 9 years in 90%. GI included 49%, age 51.1 years ± 15.1 vs G2 55.8 ± 12.7; evolution in years: GI: 13.8 ± 4.7 vs GII: 9.7 ± 5.9. Both groups persisted in remission by DAS28 (G1:2.50±0.489 VS G2: 2.38±0.63). The GI had a higher percentage of moderate affection in functional capacity: 58.8% vs G2: 35.9%, required more travel time to work, 2 hours less work per day and required more disability (48% vs 43% [RMD 1.6 95% CI: 0.45-3.4] After logistic regression models adjusted by age and sex, no significant results were found for economic and costs variables. However, a statistically significant association (p=0.017) were found for time progression disease as predictor variable between G1 Vs Group 2 (OR=1.15, 95% CI 1.02, 1.30). Mean time progression disease for G1 were 9.38±5.5 years (n=43) and for G2 were 14.17±5.5 years (n=28)

Conclusion: IMSS rheumatic patients who were on their original biological treatment, had more working time and improved statistically significant their time progression disease. Switch to biosimilar not have impact in clinical remission but can impact in economic and working aspects. IMSS serves 50% of Mexican population, covering medical care (physician fees, laboratory and medication purchase), and social security; so, should consider not only clinical aspects to acquisition of biologics drugs

AB1164 A COST PER RESPONDER ANALYSIS OF ABATACEPT VERSUS ADALUMAB FOR THE TREATMENT OF RHEUMATOID ARTHRITIS AMONG PATIENTS WITH SHARED EPITOPE (SE) POSITIVITY FROM A UNITED STATES PAYER PERSPECTIVE
S. H. Park1, X. Han2, F. Lobo3, S. Nani4, D. Patel5, 1Pharmacist International, Bethesda, United States of America; 2Bristol-Myers Squibb, Lawrence Township, United States of America

Background: The shared epitope (SE) is a significant genetic risk factor for rheumatoid arthritis (RA), and it has been proposed to be associated with T-cell activation and the production of anti-citrullinated protein antibody (ACPA). The results from the Early AMPLE trial, a head-to-head trial comparing the efficacy of abatacept versus adalimumab among early moderate-to-severe RA patients with positive ACPA (ACPA+) and rheumatoid factor (RF), showed that at week 24, patients with SE positivity (SE+) responded better to abatacept compared to adalimumab across all efficacy measures evaluated (ACR20 [American College of Rheumatology], ACR50, ACR70, DAS28 disease activity score[28-CRP=C-reactive protein]).

Objectives: To compare the cost per responder (CPR) between abatacept and adalimumab among RA patients with SE+ at week 24 using the Early AMPLE trial data from a United States (US) payer perspective.

Methods: A CPR analysis was conducted for RA patients with SE+, ACPA+, and RF. Responders were defined as patients achieving ACR20, ACR50, ACR70, or DAS28-CRP ≤2.6 and efficacy data was sourced from the trial (Figure 1).

Approved product labels were referenced for treatment dosing regimen and wholesale acquisition cost was used to calculate pharmacy cost. A real-world rebate scenario was considered for adalimumab (30%) to reflect the real-world pricing in the US market. The CPR was calculated as the total pharmacy cost divided by the proportion of responders.

Results: The total pharmacy cost at week 24 was $26,273 per patient for abatacept and $21,731 per patient for adalimumab. With achieving ACR70 as the definition of responder, the CPR at 24-week was $46,337 for abatacept and $74,935 for adalimumab, a difference of $28,598 (Table 1). The CPR was consistently lower for abatacept compared to adalimumab across all clinical measures, with difference ranging from $7099 to $43,609.

Table 1. Overall cost per responder results

<table>
<thead>
<tr>
<th></th>
<th>Abatacept</th>
<th>Adalimumab</th>
<th>Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACR20</td>
<td>$30,303.74</td>
<td>$37,403.06</td>
<td>$-7099.32</td>
</tr>
<tr>
<td>ACR50</td>
<td>$34,254.68</td>
<td>$46,077.83</td>
<td>$-11,823.15</td>
</tr>
<tr>
<td>ACR70</td>
<td>$46,337.46</td>
<td>$74,935.10</td>
<td>$-28,597.64</td>
</tr>
<tr>
<td>DAS28-CRP ≤2.6</td>
<td>$52,546.68</td>
<td>$96,155.65</td>
<td>$-43,608.97</td>
</tr>
</tbody>
</table>
Conclusion: While the pharmacy cost was higher for abatacept compared to adalimumab driven by the rebate, due to its higher clinical efficacy, the CPR was consistently lower for SE+ RA patients treated with abatacept. The results may be useful for US healthcare decision makers in understanding how to optimize treatment for SE+ RA patient while minimizing costs in today’s budget constrained environment.

Conclusion: A monitoring cap seems a simple instrument to measure adherence. However, multiple steps and a lot of time are needed to come to a workable dataset for the study of adherence patterns.

AB1165

**DETERMINANTS OF REPOSITORY CORTICOTROPIN INJECTION TREATMENT INITIATION FOR PATIENTS WITH RHEUMATOID ARTHRITIS IN A LARGE CLAIMS DATABASE**

K. Hayes1, M. Panaccio2, H. Zhou3, M. Fahim2, M. Mallinckrodt Pharmaceuticals, Hazelwood, MO, United States of America, 2Mallinckrodt Pharmaceuticals, Bedminster, NJ, United States of America, 3KKM Consulting Inc, Morrisstown, NJ, United States of America

Background: The treatment goal in rheumatoid arthritis (RA) is sustained remission and prevention of RA flares [1]. While targeted biologics have improved disease outcomes, almost one-third of patients (pts) discontinue treatment by 1 year and 50% by 2 years, with lack of efficacy as the most common reason [2]. Repository corticotropin injection (RCI) is a naturally sourced complex mixture of adrenocorticotropic hormone analogues and other pituitary peptides and is an agonist for all 5 melanocortin receptors (MCRs). Activation of MCRs by RCI has been shown to have direct and indirect anti-inflammatory and immunomodulatory effects. RCI is indicated for adjunctive therapy for short-term administration in RA flares or uncontrolled disease [3].

Objectives: To characterize RA pts that initiate RCI therapy and identify predictors of RCI initiation, compared to biologic disease-modifying antirheumatic drugs (DMARDs).

Methods: This retrospective cohort study identified pts with ICD-9/10 diagnoses for RA over an 11-year period (2008-2018) in a large claims database (Truven MarketScan®). Adults with ≥1 claim for RCI (RCI cohort) or ≥1 RA-related biologic claim but no RCI (non-RCI cohort) were selected and characterized by demographics, disease severity (Claims-based Index for RA Severity, CIRAS), comorbidities (Charlson Comorbidity Index, CCI), treatment patterns, and healthcare resource utilization in the 12-month baseline (BL) period prior to their index date (i.e., the 1st RCI claim or last claim for biologic for non-RCI cohort). Predictors of RCI initiation were identified by multivariable logistic regression, controlling for demographics and BL characteristics.

Results: A total of 393 pts initiated RCI therapy while 188,062 initiated biologic treatment with no RCI claims. At BL, cohorts were similar with respect to mean age (~56 years), gender (76-79% female), and insurance type (79-80% commercial). Cohorts differed by region, plan type, and index year. Compared to non-RCI
patients, the RCI cohort had significantly higher CCI and CIRAS scores; higher use of traditional DMARDs (65.6% vs. 61.9%), corticosteroids (CS, 91.3% vs 68.8%), prescription nonsteroidal anti-inflammatory drugs (NSAIDs, 66.9% vs 58.5%), and opioids (67.7% vs 47.5%), but lower biologic use (45.8% vs. 87.7%) (all p<0.05). RCI pts had significantly higher mean number of inpatient, emergency room, office, and outpatient visits (all p<0.05).

RCI therapy initiation was most significantly impacted by treatment patterns, including number of DMARDs, CS, and opioids tried in the previous year (Figure 1). Corticosteroid use was the strongest predictor of RCI initiation, especially extended use at any dose (OR=2.6) and extended use of the highest doses (>15mg/day, OR=8.5), present in 21% of the RCI cohort (Figure 1). Drug benefit generosity (proportion of out-of-pocket costs) was also associated with RCI initiation in any plan qualified as better than “below average” (OR=2.1-2.9). Anemia, renal disease, and Sjögren’s syndrome were also associated with higher odds of RCI initiation (OR=1.4-2.1).

Conclusion: RA pts initiating RCI therapy were prescribed a greater number of traditional DMARDs, CS, and opioids in the previous 12 months compared to non-RCI pts, and have evidence of more severe disease and comorbidities. Extended and high dose CS use were the factors most associated with RCI initiation.

Methods: Retrospective and descriptive study of the evolution of pregnancy in patients with inflammatory diseases and follow-up in a multidisciplinary unit for more than 15 years (until December 2019). Demographics, maternal disease, time until conception, births, abortions, C-sections, treatments and complications were collected. Data was analyzed using IBM SPSS v23.

Results: We registered 29 pregnancies (25 patients): 20 Rheumatoid Arthritis (RA), 5 Psoriatic Arthritis (PsA), and 4 Spondylarthritides (SpA). Maternal average age at diagnosis was 27.6±6.36 years and average age at childbirth/abortion 35±5.6 years.

17.2% of pregnancies were preterm (<37 weeks). Intrauterine growth restriction (IUGR) was observed in a woman (3.4%) with RA and preeclampsia was observed in 2 cases (6.9%) (RA 1, SpA 1).

8 patients had received biological treatment prior to pregnancy (2 SpA, 6 RA)(3 Etanercept, 3 Adalimumab, 2 Certolizumab). 2 of them (RA) continued treatment during pregnancy. 1 of them discontinued it at week 17 on her own (Adalimumab) while the other continued with Certolizumab throughout pregnancy and presented IUGR. No other complications, such as infections or malformation, were observed in newborns. DAS28 data of these women can be found in Table 1.

Conclusion: In our series, as described in the literature, women with inflammatory arthropathies are older, need longer time to achieve pregnancy and have increased use of fertility techniques and increased likelihood of preterm and instrumental delivery compared to general population. Given the low number of patients receiving biological treatment no conclusions about complications and evolution of the disease can be drawn, so further investigation are needed in this group of patients.

Monitoring inflammatory arthropathies in a multidisciplinary unit increases the chances of successful pregnancies.

AB1168 THE ANALYSIS OF “BIG DATA” AND PROCESSING OF UNSTRUCTURED INFORMATION (SEMANTIC HUB PLATFORM) TO IDENTIFY PATIENTS WITH SEVERE GOUT IN THE RUSSIAN FEDERATION.

E. Ilinskikh1, M. Eliseev2. 1VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation.

Background: the prevalence of gout and hyperuricemia (HU) in the world remains high, with a stable high incidence of severe gout [1]. There are no data on the prevalence and features of severe gout in the population of the Russian Federation (RF).

Objectives: To determine the percentage of patients (pts) with severe gout in the RF among pts with gout who are looking for information about their disease...
on the Internet, to clarify their average age, gender distribution, comorbidity, difficulties in diagnosing and treating, to get an idea of the most relevant online requests in this cohort.

Methods: We used technology for analyzing “big data” and processing unstructured information (semantic intelligence) (the Semantic Hub platform, which scans Google and Yandex environments). For efficient processing of text corpora, several specialized converters were used. The resulting format for these converters is an XML representation of the source data. The study was based on real-life patient cases (specialized social networks, forums, and other sources of user-generated content). Messages from pts with gout and their relatives were used. Severe gout is characterized by frequent polyarticular flares or chronic arthritis, subcutaneous tophi, the presence of concomitant conditions.

Results: A total of 16253 messages were processed, with ‘gout’ entered as a search word. A total of 1691 gout pts were identified. The average age of online-active pts - 472 years. Men 60.5%. Severe gout was identified in 194 of 1691 (11.5%) pts, with 59% of pts aged 29 to 45 years. The proportion of men among pts with severe gout is 71%. Comorbidities most often include diabetes mellitus and metabolic syndrome - 24%, CKD - 51%, arterial hypertension-14%. Pts with severe gout have 1.9 comorbidities on average, while other pts with gout -1.1. The groups are comparable by age. Among 90 links related to medical specialties that pts visited before being referred to a rheumatologist, the first three leading positions were - orthopaedic surgeon (30%), general practitioner (25.8%), surgeon (21%). Sixty percent of pts reported that the time between the first attack and the diagnosis of gout was less than six months. The remaining 40% of pts report that this period lasted from 1 to 15 years. Less than 42% of pts were prescribed urate-lowering therapy (ULT) during internal consultation of a physician, and only 23% of physicians recommended ULT to pts with gout during online consultation. According to pts’ reports, treatment includes 3 main groups of drugs: NSAIDs, intra-articular corticosteroids and ULT. Compliance with life-time ULT is very low. The most commonly requested topic on the Internet - attacks during holidays - 2426 messages, the second is held by the topic of lifestyle – 1899 messages, the third place - problems of comorbidities – 1813 references, and only in the fourth position - 1662 messages- the topic of ULT.

Conclusion: The percentage of pts with severe gout is 11.5% among gout pts who are looking for information about their condition on the Internet, which is consistent with the data from the largest original papers in the RF on the prevalence of severe gout [2]. More than a half of pts with severe gout (59%) are men aged 25-45 years. The decreased online activity of pts over 46 years old may be due to the low motivation for treatment of this cohort. Gout pts are rather more concerned about lifestyle than medical problems. This may also indicate the absence of the consistent compliance of this patient category to life-time therapy. Inadequate long-term therapy and late diagnosis may be the main factors for severe gout in young and active pts.

Conclusion: Systemic lupus erythematosus patients with lower levels of disease activity are less burdensome to the healthcare system and experience a significantly better HRQoL and lower levels of productivity impairment. There is a need to establish a universal definition of low disease activity as a treatment goal to benefit patient quality of life and reduce HCRU.

AB1171

EFFECTS OF SUCCESSIVE SWITCHES OF TWO DIFFERENT BIOSIMILARS OF ETANERCEPT ON OUTCOMES IN INFLAMMATORY RHEUMATIC DISEASES IN DAILY PRACTICE

U. Kiltz, S. Tsiami, X. Baralaiakos, J. Braun. Rheumazentrum Ruhrgebiet, Heme, and Ruhr-University Bochum, Germany

Background: A single switch from an originator to a biosimilar product has been shown to be safe and effective in the treatment of rheumatic musculoskeletal diseases (RMDs). The availability of biosimilars has created a financial incentive to encourage switching to cheaper products (“non-medical switch”). This is naturally associated with multiple switches. However, the effect of multiple switching between biosimilars of the same reference product has not been thoroughly investigated to date.

Objectives: To assess the effectiveness and safety of systematic non-medical switching from innovator etanercept (ETN) to biosimilar ETN (SB4) and successive to another biosimilar ETN (GP2015) in adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (axSpA) in a real-life setting.

Methods: This retrospective study was performed in a tertiary center in adult patients with RA, PsA or axSpA who had been treated with the innovator ETN and who had been switched to two ETN biosimilars for economic reasons thereafter. The first switch from innovator ETN to the first biosimilar ETN occurred between February-May 2017 and the second switch from the first to the second biosimilar ETN occurred between September-December 2017. The end of the observation period was October 2019. Disease activity, function and adverse events (AE) were regularly assessed, and any changes in outcome were recorded during the follow-up period. The scores documented at week 12 after the second switch were taken as primary outcome.

A total of 100 patients (54 RA, 27 axSpA, 19 PsA, mean age 54.3±15.1, 46% male) who switched twice to those ETN biosimilars over a follow-up period of 21.1±7.4 months were included. The retention rate after the second ETN biosimilar switching was 89% about 6 months after the second switch. While 2 patients were lost to follow-up and 1 patient died (cardiac arrest), 7 patients discontinued due to inefficacy or AE, including one pancreatic cancer. One patient was withdrawn due to pregnancy. Overall, 14 AEs were reported in 8 patients. Among them, 4 patients switched back to originator etanercept in month 6, 1 patient re-administered GP2015 successfully in month 3 after suffering from mucosal erosions and in 3 patients another mode of action was prescribed. The scores at week 12 of both, disease activity and function, remained unchanged (Table 1).

Conclusion: The retention rate after multiple switches from innovator ETN to two ETN biosimilars was close to 90%. No major changes in disease activity and function were observed in all three indications.

AB1172

IMPROVEMENT OF DEPRESSION BY JOINT SURGERY IN ESTABLISHED RHEUMATOID ARTHRITIS; RESULTS FROM MULTICENTER PROSPECTIVE COHORT STUDY FOR EVALUATION OF JOIN SURGERY ON PATIENT’S REPORTED OUTCOME

T. Kojima1, M. Kojima2, H. Ishikawa3, K. Nishida4, N. Asai5, N. Ishiguro1

1Nagoya University Hospital, Orthopedic Surgery/Rheumatology, Nagoya, Japan; 2Nagoya City University Graduate School of Medical Science, Nagoya, Japan; 3Niigata Rheumatic Center, Shibata, Japan; 4Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan

Background: Total management including reconstructive joint surgery and rehabilitation should be needed for further improvements of physical function for long-standing RA patients. In these days, it is very important to evaluate the effectiveness of joint surgery as well as drug therapy based on patient-reported outcome (PRO).

Objectives: The purpose of this study is to explore the relationship among depression, clinical variables and other PROs including physical function and to explore whether joint surgery can improve the depression.

Methods: Multicenter prospective observational cohort study was conducted among patients who underwent elective joint surgery for RA from April 2012 to March 2016 (Study registration: UMIN000012649). In this study, we collected data at baseline and at 6 or 12 months after the surgery. These data were as follow; age, sex, disease duration, drug therapies, and disease activity (DAS), TUG, and patient-reported outcome (HAQ-DI, EQ-5D, GOL, pain and BDI-II (depression)). Correlation between BDI-II and other variables were determined using multiple linear regression analysis.

Results: Totally, 346 patients before elective joint surgery were analyzed cross-sectionally. Mean age, disease duration, pain VAS, DAS28, HAQ-DI, EQ-5D and BDI-II were 64.2 years, 170 years, 36.2 mm, 3.02, 11.1, 0.641 and 13.0, respectively. 52.6% of elective joint surgeries were in upper limbs and 47.4% were in lower limbs. Multiple linear regression analysis showed that HAQ-DI [β: 0.099 (95%CI: -0.117 - -0.08) β: 0.05] pain VAS [β: -0.002 (95%CI: -0.002 - -0.001) β: -0.26] and BDI-II [β: -0.003 (95%CI: -0.005 - -0.002) β: -0.19] had significant impact on EQ-5D. Furthermore, HAQ-DI [β:3.78 (95%CI:2.54- 5.06) β: 0.17] had significant impact on BDI-II (depression). Correlation between BDI-II and other variables were determined using multiple linear regression analysis.

Conclusion: Depression is an important patient-reported outcome for QOL in established RA patients. Improving of physical function with joint surgery in both lower and upper limbs caused improvement of depression status. Rheumatologists should take the joint surgery as considered as effective intervention for treatment of established RA patients with treatment.

Acknowledgments: This study was funded by a grant from the Ministry of Health, Labour and Welfare (h24Ay002).
RHEUMATOLOGIST CARE IS ASSOCIATED WITH FEWER EMERGENCY ROOM VISITS BY PERSONS WITH GOUT

N. Schlesinger,1 N. L. Edwards,2 S. Clark3, P. Lipsky4,5 Rutgers Robert Wood Johnson Medical School, Division of Rheumatology, Department of Medicine, New Brunswick, United States of America; 3University of Florida, Department of Medicine, Gainesville, United States of America; 4Rochester Highland Precision Analytics, Wayne, United States of America; 5RILITE Research Institute, Charlottesville, United States of America

Background: Gout is one of the most common inflammatory arthropathies. By searching a large administrative data base (Symphony Integrated Dataverse), we found that persons with acute gout see a rheumatologist infrequently, whereas less than 50% of advanced gout patients are seen by a rheumatologist. Notably, however, gout patients seen by rheumatologists have more frequent urate measurements and are prescribed urate lowering therapy more frequently. This study sought to determine whether involvement of a rheumatologist in gout care had a positive impact on health outcomes

Objectives: To determine whether involvement of a rheumatologist in gout care had a positive impact on health outcomes of patients with gout

Methods: We carried out a retrospective analysis to identify persons with gout over an approximately 3-year period from October 2015 to December 2018. This study used data from the Truven Marketscan® database, an administrative database covering over 190 million patients across the United States and based on fully adjudicated and paid insurance claims. Patients were identified as having gout if they were >18 years of age and had at least two medical claims for the diagnosis of gout on different days, separated by at least 3 months. Patients with acute gout were identified by ICD-10 code M10, chronic nontophaceous gout (M1A.***0), tophaceous gout (M1A.***1) and uncontrolled gout (M10.*, M1A.*). The latter manifested by three gout codes (any) in the primary diagnosis position and three urate measurements within the same calendar year. Particular attention was placed on Emergency Room (ER) visits by individuals in each category and by individuals who had been evaluated by a rheumatologist.

Results: We identified 284,877 gout patients. The median age was 59.2 years and 79.0% were male. Of the 230,998 persons coded as acute gout, 10.7% were seen by a rheumatologist, whereas 26.9% of the 32,942 coded as chronic nontophaceous gout, 47.2% of the 7,273 coded as tophaceous gout and 43.6% of the 13,514 coded as uncontrolled gout were seen by a rheumatologist. In each gout category, the frequency of ER visits was significantly reduced in persons who had been seen by a rheumatologist (Table 1). In acute gout, the frequencies of ER visits in those with and without rheumatologist care were 5.6% vs 6.6% (p<0.001), respectively. In chronic nontophaceous gout it was 5.5% vs 6.7% (p=0.001); in tophaceous gout it was 10.3% vs 14.7% (p<0.001); and in uncontrolled gout it was 12.8% vs 19.0%, respectively. If the frequencies of rheumatologist-associated gout patient ER visits were applied to all gout subjects, there would have been 3,088 less ER visits in this cohort of gout patients.

Table 1.

Conclusion: There appears to be a positive impact of rheumatologist involvement in the care of gout patients, manifested by a significant decrease in the frequency of ER visits. Considering the inconvenience and cost of ER visits, rheumatologist care may have a significant impact on the well-being of gout patients and on the overall cost of their care.

TRACKING THE EFFECTS ON A CLINICAL SERVICE OF INTRODUCING ULTRASOUND FOR DIAGNOSIS OF GIANT CELL ARTERITIS: DESIGN OF A SERVICE EVALUATION USING LEAN METHODOLOGY

S. Mackie,1 A. Barr,2 A. Cracknell2, S. Farrell3, J. Parvin4, A. Patil5, I. Simmons6, K. Smith7, A. Sweeting7, M. Trower8, T. Webster9, R. Wakefield4,5 1University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 3Leeds Teaching Hospitals NHS Trust, Rheumatology, Leeds, United Kingdom; 4Leeds Teaching Hospitals NHS Trust, Geriatric Medicine, Leeds, United Kingdom; 5Leeds Teaching Hospitals NHS Trust, Kaizen Promotion Office, Leeds, United Kingdom; 6Leeds Teaching Hospitals NHS Trust, Ophthalmology, Leeds, United Kingdom; 7Leeds Teaching Hospitals NHS Trust, Vascular Surgery, Leeds, United Kingdom

Background: In our large, multi-site hospital, patients with suspected GCA are started promptly on high-dose prednisolone but until 2019, patients waited for temporal artery biopsy (TAB) until the GCA diagnosis could be confirmed (“GCA”) or refuted (“not-GCA”). Reports of the impact of introducing temporal and axillary artery ultrasound (TAUS) have mainly come from smaller hospitals. Agreement between TAUS and TAB has been reported by others with a Cohen’s kappa of 0.35 [1] and 0.40 [2]. We used Lean methodology to identify metrics across 5 key domains: delivery, quality, service, morale and cost.

Objectives: To design metrics for a service evaluation to measure impact of introducing TAUS, and to test their feasibility of measurement within routine care.

Methods: Our primary driver was time from presenting to our service to diagnostic confirmation (lead time). Pathway mapping, value stream mapping and a driver diagram identified key ideas for improvement.

We chose to measure: Delivery (mean lead time for each month), Quality (proportion of patients with GCA and positive TAB/TAUS; total (cumulative) prednisolone dose in patients with not-GCA; Service (patient feedback), Morale (staff feedback) and Cost (number of patients; cost of tests per patient; overall costs). We plotted these three by month on run charts and defined a significant shift as 6 consecutive monthly values below baseline median. Cohen’s kappa was calculated using GraphPad QuickCals.

Results: Routine TAUS for suspected GCA was introduced from January 2019, alongside a multidisciplinary team monthly meeting. TAUS was done a median...
of 2.5 days from referral. Agreement between TAB and TAUS results was good (Table 1). The run chart showed a significant shift in our Delivery (median lead time fell from 28.7 days to 21 days after introduction of ultrasound) and both Quality metrics (proportion of GCA with positive TAB/TAUS increased from 29% to 69%; total prednisolone dose for not-GCA fell from 1.335g to 0.846g).

Table 1. Concordance between temporal and axillary artery ultrasound (TAUS) and temporal artery biopsy (TAB) in scans performed through 2019. Cohen’s weighted kappa 0.59 (including equivocal results as separate category).

<table>
<thead>
<tr>
<th>TAB positive</th>
<th>TAUS positive</th>
<th>TAUS negative</th>
<th>TAUS equivocal</th>

<tr>
<td>0</td>
<td>3</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Within Costs, average per-patient costs of TAB/TAUS declined from £1004/patient to £792/patient, but total referrals for TAB/TAUS increased from 6/month to 10/month, increasing overall costs. Staff and patient feedback (Service, Morale) revealed that further improvements to the care pathway were needed to manage the additional complexity.

Conclusion: Lean methodology identified multiple metrics for evaluating the impact of TAUS on our service. Introducing TAUS improved Delivery and Quality, but measuring Costs, Morale and Service helped identify unintended consequences. Concordance between TAUS and TAB was good. We plan to continue to improve and monitor the care pathway based on our multi-stakeholder feedback.

BIOLOGICAL THERAPY DOSE OPTIMIZATION AND COST MINIMIZATION STUDY IN SPONDYLOARTHITIS: UTILITY OF REDOSER TOOL

F. Godoy-Navarrete1, S. Manrique Arija1, F. Osorio1, A. M. Cabezas-Lucena1, M. Morales-Aguilà1, F. G. Jiménez-Núñez1, S. Manrique Arija1, F. G. Jiménez-Núñez1, 1UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIBMA), Hospital Regional Universitario de Málaga, Universidad de Málaga, Málaga, Málaga, Spain; 2University of Malaga, Malaga, Spain

Background:

Objectives: To describe the percentage of spondyloarthritis patients on biological therapy (BT) optimization in clinical practice who would maintain remission or low disease activity (LDA) after 2 years of follow-up and to identify possible factors associated with relapse. To estimate the cost reduction between 2009-19 Methods:Design: A retrospective, observational longitudinal study under conditions of clinical practice. Patients: Spondyloarthritis in BT dose reduction. Inclusion criteria: Psoriatic arthritis (CASPAR criteria), and Axial Spondyloarthritis (ASAS criteria) which have been initiated BT dose reduction between 2009-2019. Patients with BT are followed prospectively by two rheumatologists in a monochronic clinic of subcutaneous biological therapy every 6 months, and with their usual rheumatologist every 6 months, as well. In such, the patients are controlled and attended in clinics with a pre-established questionaire every 3 months. Variables: Maintained Reduction: patients who main- tained BT dose reduction since de beginning of the optimization until the index date(data collection). Relapse at 3.6, 12, 24 months: patient who had to return to usual BT dose. Other variables: demographic, time to diagnosis and evolu- tion disease, clinical-analytical: Tender Joint Count(TJC), Swollen Joint Count (SJC), C-reactive Protein (CRP), Erythrocyte Sedimentation Rate (ESR), activity index (DAPSA, BASDAI), ASDAS, and physical function: HAQ and BASFI. Previous treatment with bDMARD. Dose reduction adjustment according to REDOSER. Cost reduction in euros (absolute and per patient-year) of BT reduction. Results: 65 patients with spondyloarthritis in dose reduction were included. Table 1 main characteristics in study population. The average time since the beginning of the BT was 47.61 months (±37.06). After 24 months of follow-up, 73.8% of patients (48) achieved a sustained reduction. All these patients accomplish remission or low disease according to different index activities [DAPSA and ASDAS median (p25-p75)] = 2.3 (2.1-2.9) and 1.5 (0.7- 2.6), respectively and ASDAS mean (SD) =1.4 (0.54) and a shorter time of disease evolution. The dose reduction of BT carried out from 2009 to 2019 meant a total cost savings of 584080.37€, with a patient/year cost savings of 6192.28€. We evaluated the optimization according to REDOSER and it was observed that in 53 patients (81.5%) the reduction would have been adequate and the rest was doubtful. In bivariant analysis between patients who had relapsed and those who had not, only differences were observed in the BT line used [2nd line:(5.29.4%) Vs 2(4.2%), (p=0.025)] and in a higher percentage of patients with a doubt result of REDOSER [9(52.9%) Vs 3(6.3%), (p<0.001)] respectively. In multivariant analysis the only inde- pendent variable associated with relapse was a doubtful result of REDOSER_REL(OR)(IC95%), 3.46(1.18-10.17); p=0.024), R2= 40.2%

Table 1 main characteristics in study population. The average time since the beginning of the BT was 47.61 months (±37.06). After 24 months of follow-up, 73.8% of patients (48) achieved a sustained reduction. All these patients accomplish remission or low disease according to different index activities [DAPSA and ASDAS median (p25-p75) = 2.3 (2.1-2.9) and 1.5 (0.7-2.6), respectively and ASDAS mean (SD) =1.4 (0.54)] and a shorter time of disease evolution. The dose reduction of BT carried out from 2009 to 2019 meant a total cost savings of 584080.37€, with a patient/year cost savings of 6192.28€. We evaluated the optimization according to REDOSER and it was observed that in 53 patients (81.5%) the reduction would have been adequate and the rest was doubtful. In bivariant analysis between patients who had relapsed and those who had not, only differences were observed in the BT line used [2nd line:(5.29.4%) Vs 2(4.2%), (p=0.025)] and in a higher percentage of patients with a doubt result of REDOSER [9(52.9%) Vs 3(6.3%), (p<0.001)] respectively. In multivariant analysis the only independent variable associated with relapse was a doubtful result of REDOSER (OR)(IC95%), 3.46(1.18-10.17); p=0.024), R2= 40.2%

Conclusion: Biological therapy dose reduction in spondyloarthritis is possible in the majority of patients, maintaining remission/LDA at 24 months. This leads to a greater cost reduction and efficiency. The relapse was associated with a doubtful result in REDOSER before optimization and this tool can be very useful in the assessment of BT reduction.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.5658
Objectives: To describe the characteristics of patients with rheumatoid arthritis (RA) in dose reduction of biological therapy (BT) in clinical practice and identify possible factors associated with the time in dose reduction and verify the utility of REDOSER tool.

Methods: Design: A retrospective, observational longitudinal study under conditions of clinical practice. Patients: RA in BT dose reduction between 2007-2019 were selected. Inclusion criteria: RA according to ACR 2010 criteria which have been initiated BT dose reduction. Patients with BT are followed prospectively every 3-4 months in a specialized outpatient unit of BT dose reduction with a pre-established protocol for data collection and registered in a database. Variables: Primary: Time in reduction: was defined as the time in which patients maintained the BT optimization and Relapse at 12 and 24 months: percentage of patients who, after starting BT optimization, return to the previous or standard dose. Secondary variables: REDOSER: Appropriate, Doubtful and Inappropriate (If dose reduction was adequate according to the REDOSER tool applied retrospectively were evaluated). Other variables: Demographic, clinical-analytical: time of disease evolution, RF, anti CCP antibodies, Number of Tender Joints, Number of swollen joints, erosions, activity index (DAS28, SDAI, CDAI) and physical function (HAQ). Previous treatments. Statistical Analysis: descriptive, bivariate using x2 and T-Student among patients with and without relapse at 24 months and multivariate linear regression to identify independent variables associated with the time in BT dose reduction (DV: time in reduction).

Results: 59 patients with RA were included. Table 1 shows the main characteristics of the subjects. The average (SD) of optimization in months was 17.9 (17.7). Ten patients (16.9%) relapsed at 12 months and 16 (27.1%) at 24 months. The mean (SD) of DAS28 and SDAI of patients who relapsed at 24 months was (17.7). Ten patients (16.9%) relapsed at 12 months and 16 (27.1%) at 24 months. The mean (SD) of DAS28 and SDAI of patients who relapsed at 24 months was (17.7). Ten patients (16.9%) relapsed at 12 months and 16 (27.1%) at 24 months.

Conclusion: The majority of the patients with RA who initiate BT dose reduction maintain the optimization after 24 months. REDOSER can be useful in clinical practice to assess the BT optimization in patients with RA. A longer time in BT dose reduction was associated with lower values of DAS28 at the beginning and younger age of the patients.

AN AUDIT OF ORIGINATOR ADA利MAB TO BIOSIMILAR SWITCH IN TWO HOSPITALS

R. Mazumder1, M. Loke1, C. Mukhtyar1, K. Gaffney2, E. Balogh2, E. Sekaran2, M. Sultana3, M. Odonkor2, K. Miles1, 1Norfolk & Norwich University Hospital, Norwich, United Kingdom; 2Broomfield Hospital, Broomfield, United Kingdom; 3University of Essex, Colchester, United Kingdom

Background: Biological drugs have revolutionized the treatment of immune-mediated inflammatory diseases (IMIDs). Current guidelines reserve these drugs for patients with severe refractory disease. Biologic drugs are expensive, but as they reach patent expiry, the introduction of lower-cost biosimilars reduces their impact on health care budgets. It is estimated that NHS England could save £300 million by 2021 following the recent launch of adalimumab biosimilars [1]. As part of this process, there has been a mandatory switch of originator adalimumab to biosimilar adalimumab throughout the U.K.

Objectives: To evaluate the impact of the switch to biosimilar adalimumab in individuals with inflammatory arthritis at two NHS trusts in the East of England and calculate the proportion and reasons for switch back to originator adalimumab or a second biosimilar at 12 weeks.

Methods: Both hospitals ran dedicated ‘switch’ clinics. All patient records were reviewed retrospectively.

Results: 855 patients with different IMID switched from originator to biosimilar over 13 months. At 12 weeks, 730 patients (85%) maintained the switch, 71 patients (8.7%) switched back to the originator, and 54 patients (6.3%) switched to other biosimilars of the same drug.

Table 1. Primary outcome analysis of switching from originator to adalimumab biosimilar

Conclusion: Switching to a biosimilar was successful in the vast majority of patients and is associated with significant saving. The list prices for originator Adalimumab is £9,155/person/year and £8,238/person/year for biosimilar Adalimumab respectively [2]. By switching we will save approximately £719,402 per annum (9.2% cost reduction).

EMERGENCY DEPARTMENT LENGTH OF STAY FOR PATIENTS WITH ACUTE GOUT

N. Mbuyi1, S. Reiner2, R. Hilliard3, A. Reginato4, D. Dalal3, 1George Washington University School of Medicine, Department of Medicine, Washington, DC, United States of America; 2Lifespan Health System, Providence, RI, United States of America; 3Warren Alpert Medical School of Brown University, Department of Medicine, Providence, RI, United States of America

Background: Emergency department (ED) visits for acute gout increased by approximately 20% between 2006 and 2014 in the United States. (1) Reducing ED length of stay (LOS) can help improve health outcomes, and reduce ED crowding and cost of care for patients with gout.

Objectives: The aim of our study was to assess ED LOS and to identify factors associated with prolonged ED LOS in patients with acute gout.

Methods: In this retrospective analysis, we included the first ED visit of adult patients (>18 years) with acute gout who presented to the 3 EDs affiliated with Lifespan Health Systems, the largest healthcare provider in Rhode Island. Our study period was 3/30/2015 to 9/30/2017.

We calculated ED LOS as the time spent by patients in the ED until they were discharged. Patients presenting to the ED and subsequently admitted to the hospital were excluded given the differential effect of systems factors in these patients. We assessed the following factors' association with being in the upper quartile of ED LOS: (a) Patient factors – demographics, comorbidities and clinical presentation of gout (number of joints involved, severity as gauged by an ED triage nurse on a scale of 1 to 5; 1 being the worst) and (b) systems factors – time of day, day of the week, and time of year at presentation to the ED, teaching versus non-teaching hospital setting, and performing an arthrocentesis. We performed univariate and multivariable analyses to identify factors associated with prolonged ED LOS in patients with acute gout.

Results: A total of 355 patients (mean age 56.6 ± 16.03 years, 81.3% males) were included. The median ED LOS was 2.65 hours (1.75, 4.3 hours). A quarter of the patients spent more than 4.3 hours in the ED; the national average across all medical illnesses being 3.7 hours (2). In the univariate analysis, older age (>65 years), comorbidities (hypertension, congestive heart failure), worse ED severity score, procedural delays, and teaching hospital setting were associated with being in the upper quartile of ED LOS. In a multivariable analysis, age >65 years, procedural delays, and worse ED acuity score continued to be associated with longer ED LOS.

Conclusion: In our study settings, patients with acute gout spent a longer time in the ED than the national median of 120-150 minutes. We noted that older age and higher acuity score in addition to procedural delays led to longer length of stay in the ED. The results of our study should guide future interventions to reduce ED LOS for patients with acute gout.

THE EVOLUTION OF AN FLS IN SEARCH OF EXCELLENCE: THE EXPERIENCE OF GRAN CANARIA.
A. Narango1, A. Molina1, C. Sepúlveda1, C. Torres1, F. Santana1, F. Rubiño1, R. López1, S. Ojea1. Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas, Spain

Background: The implementation of an FLS in the Spanish public health system is not an easy task since there are no official plans for the incorporation of personnel dedicated to the unit

Objectives: To expose the consolidation and improvement of an FLS after its implementation as well as the problems that have arisen over time.

Methods: The health program for secondary fracture prevention was implemented in 2012. Initially worked with the same staff assigned to the Rheumatology service, since 2016 we have a part-time support nurse. Patients are identified from the emergency registry and, more recently, from patients admitted for hip fracture and treated in a monographic osteoporosis clinic. The baseline visit consists of consultation with the nurse, DXA and bone metabolism analytics. Falling patients are referred to a fall prevention school. Most patients are referred to their primary care physician to start a treatment.

Results: Of the 2,416 patients attended the baseline visit, 30% were forearm fractures, 27% hip, 20% humerus, 10% spine and 11% other fractures. In comparison to 2012, in 2019 the monthly average of patients has doubled, increased the number of hip and spine fractures, and increased the percentage of captured patients (Table). In spite of consolidating the unit, getting a support nurse for the admitted patients and establishing a solid alliance with primary care, it is pending the involvement of Primary Care Nurses and start first prescription at the hospital.

AB1181
SHOULD A COMBINED RHEUMATOLOGY-PULMONOLOGY INTERSTITIAL LUNG DISEASE SERVICE BE CONFINED TO TERTIARY CENTRES - A SERVICE EVALUATION
K. Salama1, N. Ramsundar1, V. Joshi1, M. K. Nisar1. Luton and Dunstable University Hospital, Luton, United Kingdom

Background: Interstitial lung disease is a well described extra-articular manifestation in a range of rheumatic diseases. It carries significant morbidity and mortality. Management of rheumatic diseases associated ILD (r-ILD) requires expertise as the needs of such patients are complex and treatment options limited. Historically, such complex ILD has been managed in tertiary referral centres.

Objectives: We set up a combined service incorporating both rheumatology and respiratory domains in a district general hospital (DGH) to help patients avoid long journeys and improve their experience whilst focusing on an integrated care pathway. We evaluated the outcomes of the first set of patients managed in this proof-of-concept service model.

Methods: Referrals were accepted from any hospital specialist involved in the management r-ILD. They were triaged by lead ILD pulmonologist to monthly ILD MDT comprising a rheumatologist, respiratory physician, a radiologist and ILD specialist nurse. Appropriate patients were booked into combined clinic, run by the respective rheumatology and chest specialists with ILD interest, attracting a multi-specialty tariff. All the data was recorded electronically with full access to demographics, disease parameters, investigations and drug management.

Results: 89 patients were included in this proof-of-concept. Mean age was 66.1 yrs (19-90 yrs) and 44% (n=39) were male. 35 (40%) had RA, 34 (39%) had CTD, eight (10%) had sarcoidosis, five had IPF and seven others. Most prevalent HRCT pattern was NSIP (n=53, 60%) followed by UIP (n=23, 21%), sarcoid (n=10, 12%) and miscellaneous (LIP and mixed). Mean FVC was 2.64L/min (1.93-4.13) with DLCOc of 52.7% (28.9-90.1%) predicted. Only two patients had all antibodies negative whilst 87 had at least one antibody positive with ANA being the most common (n=28).

Most (83%) patients were treated with immunomodulators including nine with rituximab. 39 (44.3%) patients had significant improvement in clinical imaging and inflammatory parameters with DLCOc improving to 56.7% and FVC to 2.79L/min. There were similar improvements in six minute walk test. 17 patients died and 20 patients required long term oxygen therapy.

Conclusion: This proof-of-concept real world study confirms the utility of a combined specialist service in a district general hospital. Nearly half of this complex and resource intensive patient cohort had good clinical outcomes and derived benefit from the expertise in one room. Feedback from both patients and referring was unanimously positive. No patient required tertiary centre referral and all could be managed adequately in the clinical setting.

Our report confirms that r-ILD can be managed in a DGH setting with a streamlined service offering clear benefits to patients. We would argue that r-ILD service, congruent to satellite pulmonary hypertension clinics in secondary care with hub-and-spoke model liaison with tertiary centre, can be established on similar principles and could help over-stretched tertiary care with repatriation of services whilst helping develop local expertise in the management of chronic ILD.

AB1182
OPTICAL COHERENCE TOMOGRAPHY FOR HYDROXYCHLOROQUINE EYE MONITORING - SHOULD WE WORRY?
A. Moharram1, F. Rai1, J. Maya1, R. Sandhu1, M. K. Nisar1. Luton and Dunstable University Hospital Hospital, Luton, United Kingdom

Background: Recent data have highlighted that hydroxychloroquine (HCQ) retinopathy is much more common than previously reported. The overall prevalence appears to be around 7.5% and depending on dose and duration of therapy can increase to 20-50% after 20 years of therapy. Royal College of Ophthalmology UK recommend that all patients planning to take hydroxychloroquine long term have a baseline examination in a hospital eye department with a colour retinal photograph and spectral domain optical coherence tomography (SD-OCT) scans of the macula. After five years, annual screening is required with 10-2 Humphrey visual field testing, followed by papillary dilatation and imaging with both SD-OCT and widefield fundus autofluorescence imaging run by NAF.

Objectives: Our aim was to review the early findings of the screening program for all rheumatology patients prescribed HCQ at our university hospital.

Methods: A business case was approved to set up eye monitoring in accordance with above guidelines. All patients with rheumatic diseases prescribed HCQ were identified through departmental database. They were invited for ophthalmological
examination and those with drug exposure >5 yrs were prioritised. An MDT pathway was established to manage anyone with signs of HCQ toxicity.

Results: 2,132 patients were prescribed HCQ in our county with population of 660,000; 577 patients died after our unit’s remit. 136 patients (82% women) have been screened with mean age of 58 yrs (24-84y), 65 (48%) have RA and remaining with connective tissue diseases. Median disease duration is 10 yr (0.75-30 yrs) and median drug exposure is 10 yr (0.4-27y). Three doses of HCQ are prescribed: 200mg daily (53%), 300mg daily (13%) and 400mg daily (34%). Ten (73%) patients were found to have abnormal results. Three were consistent with HCQ toxicity pattern and one with likely toxicity. Two of them had already developed severe sight loss. HCQ was discontinued in all these cases. Six had other incidental anomalies requiring further input.

Conclusion: Hydroxychloroquine is used increasingly in the treatment of autoimmune diseases with emerging role in oncology. It has a favourable safety and tolerability profile with survival benefit demonstrated in SLE. In the UK, it’s adoption has been particularly high owing to the requirement of trialling two DMARDs prior to being eligible for biologic therapy in RA and PsA. In the absence of modern retinal imaging techniques, HCQ toxicity was perhaps underestimated and hence older guidelines did not emphasise strict monitoring practice. Our preliminary data, in line with published evidence, represents a greater public health problem than previously estimated. It is clear that implementing the new guidelines not only recognises hitherto undiagnosed drug toxicity but also identifies incidental significant eye pathology which puts pressure on healthcare resources and needs robust service planning. Rheumatologists need to be aware of the potential impact requiring informed discussion with patients and perhaps a fundamental shift in prescribing behaviour to avoid this rapidly developing health concern.

AB1183 TERIPARATIDE SWITCH TO BIOSIMILAR - IS IT COST EFFECTIVE?

T. Akram1, M. Siddique1, H. A. Javed1, J. Begum1, J. Foroury1, M. K. Nisar1.
1Luton and Dunstable University Hospital, Luton, United Kingdom

Background: Teriparatide is an effective treatment option for osteoporosis however NICE restricts its use to patients with high disease burden. This was based on cost effectiveness evaluation of the originator (Forsteo®) and would be different for recently introduced generic preparation.

Objectives: We wished to evaluate the current prescribing behaviour prior to a potential switch to generic version and associated cost savings.

Methods: All patients prescribed Teriparatide since the commencement of specialist osteoporosis service in Aug 2014 at our University teaching hospital covering 350,000 population were included. Data was extracted from electronic database with full access to demographics, population characteristics, disease parameters and medication history.

Results: 113 patients were prescribed Teriparatide over five years. Mean age of participants was 76 yrs (53-96). They had on average three comorbidities (0-8) with most common being hypertension (n=44, 38.9%) and inflammatory arthritis (n=21, 18.5%). Sixteen (14.1%) individuals had concurrent corticosteroids. Median number of fractures prior to therapy were four (0-12). Prior treatments included oral therapy (n=90, 79.6%), IV zoledronate (n=22, 19.4%) and denosumab (n=19, 16.8%). 66 (58.4%) of patients only had one prior bone active medication. Mean duration of prior therapy was 62.4 months (9-192 months). 17 (15.0%) patients had chronic kidney disease with lowest eGFR of 38.41 (36.2%) had Vit D level between 40-75 nmol/L. Median T score was -3.8 (-2.1 - -6.0) which improved by -2.3 (-3.9 - -3.9) after two years.

Conclusion: Our real-world study shows that teriparatide is used predominately in complex, multi-morbidity older individuals with several prior fractures. Despite that teriparatide remains effective for a wide range of individuals including those with inflammatory arthritis and/or concurrent steroid use. Neither moderate CKD nor mild Vit D insufficiency seems to impact its efficacy.

This is in line with recent meta-analysis of real life teriparatide use in complex osteoporosis with multimorbidity. Our study should enhance clinicians’ confidence in its prescribing. It’s notable that the use is higher than current estimates based on NICE cost-effectiveness analysis of teriparatide. Instead of annual predicted use of 4.8/100,000 population, it was prescribed to 6.4/100,000. This could potentially have a cost impact however the introduction of a generic version would mitigate against it. We calculated our savings to be over £125,000 if all patients were switched. These savings at national level would hopefully improve access to a wider patient cohort and perhaps allow earlier use in the treatment paradigm.

AB1184 BURDEN OF DISEASE AND DIRECT HEALTH CARE COSTS FOR PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN WESTERN AUSTRALIA

W. Raymond1, G. Ngo1, M. Ogjenovic1, L. Li2, P. Cheeha2, A. Chakera2, A. M. Tooke4, J. Nossent1,3 on behalf of Perth Working Party on SLE.
1The University of Western Australia, Rheumatology Section, School of Medicine, Crawley, Australia; 2The University of Western Australia, School of Population & Global Health, Crawley, Australia; 3Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia; 4The University of Western Australia, Nephrology, School of Medicine, Crawley, Australia; 5Sir Charles Gairdner Hospital, Immunology, Nedlands, Australia; 6PathWest, Laboratory Medicine, Nedlands, Australia

Background: Systemic Lupus Erythematosus (SLE) is a chronic multorgan disease with an unpredictable disease course, which requires monitoring for disease activity, treatment efficacy and comorbidity. Data on the healthcare utilization and cost of SLE, especially from Australia are sparse.

Objectives: To determine the healthcare utilisation and estimated costs of inpatient admissions (IP), emergency (ED) and outpatient (OPD) hospital visits and investigations for SLE patients in Western Australia (WA).

Methods: This is a longitudinal cohort study of SLE patients seen at a metropolitan public hospital, with ≥6 months of follow-up (n=179, 95% female; baseline age 36.2 ± 15.2 years). Electronic medical records provided data on OPD, ED and IP visits, and investigations conducted at public hospitals from January 2000 - December 2019. Direct healthcare costs were estimated from public hospital expenditure aggregates in FY2018/19.

Results: During a median observation period of 11.0 years (IQR 7.4, 13.5), SLE patients required 13,320 OPD visits for a median of 5.3 (IQR 3.0, 9.3) appointments per annum. The majority of OPD visits were with Rheumatology (n=1,986, 14.9%), Immunology (n=1,527, 11.5%), and allied health services (n=1,952, 14.7%), followed by Ophthalmology (n=1,385, 10.4%), maternal & fetal health (n=873, 6.6%) and Renal medicine (n=844, 6.3%). In total, 145 patients (79.3%) attended ED on average of 3 times (IQR 2, 7; ED visit rate 44.0 (95%CI 41.0, 47.0) per 100 person years. Overall, 125 patients (69.8%) were hospitalised at average times 3 times (IQR 2, 6), with a mean LOS of 5 days (IQR 3, 12) for an IP rate of 376 per 100 patient years (95%CI 34.8, 40.5); Only 12.8% of patients did not attend ED or IP in the public health care system. A total of 357,087 laboratory investigations were performed (median nr. of tests per patient 205 (±290) per year) across fields of haematology/biochemistry (89%), immunology (5%), microbiology (4.5%) and histopathology (<1%). Minimum estimates for direct health care cost during the study period were 25.4 million AUD (IP 11m, OPD 6.3m, ED 0.9m and investigations 9.1m) for a crude annual cost of 14,088 AUD per patient.

Conclusion: SLE patients have extensive healthcare utilization across a range of outpatient and inpatient services. The main direct costs for this multidisciplinary healthcare care provision are for disease monitoring and in-hospital treatment. Based on these conservative cost estimates to which medication cost need to be added, total costs for SLE care in WA are projected to be significantly higher than reported from Europe.

DOI: 10.1136/annrheumdis-2020-eular.3422
Background: Adherence to medications among patients with rheumatic diseases is often suboptimal. Adherence to treatment has been described to be affected by several factors. The rheumatologist plays a crucial role in influencing adherence behavior by addressing perceptions about medication, providing information, and establishing trust in the treatment plan. There is no record of attitudes and thoughts of Mexico’s rheumatologists about adherence to medication.

Objectives: To know the rheumatologist’s attitudes regarding treatment adherence in follow up consultation.

Methods: Descriptive, cross sectional study. Rheumatologists from across the country were invited to respond an electronic survey created with Google Forms, link was sent by Whatsapp ® message, responses were anonymous. The survey was constructed taking into account the main barriers of adherence related to the doctor. Seven questions were created, from one to six were multiple selections and the seven were open question.

Table 1. IFX & ADL DL, TABT and FABT results by category as defined in service guidance (AU/ml = Arbitrary Units/ml)

<td>78 (17.2%)</td>
<td>51 (22.4%)</td>
</tr>
</tbody>
</table>

Conclusion: TDM has been enthusiastically embraced. It is estimated that >50% of individuals treated with IFX or ADL have been tested at least once in the first year. DL results were found to be similar to previously published data, as were rates of antibody positivity. The large volume of data generated by the service may provide additional evidence regarding the utility of TDM in predicting clinical response. Next steps are to conduct a comparative effectiveness analysis where proactive vs reactive TDM testing strategies will be compared, with the primary outcome measure being the proportions of patients with secondary loss of response.

TREATMENT ADHERENCE: WHAT ABOUT THE RHEUMATOLOGIST?

R. Pineda-Sic1, M. M. Castañeda-Martínez1, I. D. J. Hernandez-Galarza1, E. I. Guevara Elizondo1, D. E. Flores Alvarado1, G. Serna-Peña1, I. J. Colunga-Pedraza2, D. A. Galarza-Delgado1, 1Universidad Autónoma de Nuevo Léon, Monterrey, Nuevo León, Mexico

Background: Adherence to medications among patients with rheumatic diseases is often suboptimal. Adherence to treatment has been described to be affected by several factors. The rheumatologist plays a crucial role in influencing adherence behavior by addressing perceptions about medication, providing information, and establishing trust in the treatment plan. There is no record of attitudes and thoughts of Mexico’s rheumatologists about adherence to medication.

Objectives: To know the rheumatologist’s attitudes regarding treatment adherence in follow up consultation.

Methods: Descriptive, cross sectional study. Rheumatologists from across the country were invited to respond an electronic survey created with Google Forms, link was sent by Whatsapp ® message, responses were anonymous. The survey was constructed taking into account the main barriers of adherence related to the doctor. Seven questions were created, from one to six were multiple selections and the seven were open question.

1. Where do you practice medicine?
2. Do you ask individually for each drug?
3. How long do you spend on explaining: side effects, benefits, and mechanisms of action of drugs?
4. Do you discuss available treatment options with your patients to decide one?
5. Do you ask for adherence to medication in the follow up consultation?
6. Which activities can the doctor do to improve adherence to their patients?
7. If your answer was positive, do you ask individually for each drug?

Results: Data were collected from 158 rheumatologists who completed the survey. Regarding the question where they practice medicine, 88.3% answered correctly adherence definition, 33% of rheumatologists ask for adherence to medication in the follow up consultation and only 86.1% do it individually for each medication, 97.4% discuss therapeutic options with their patients. The time used to explain treatment is presented in Figure 1. The interventions considered by rheumatologists to increase adherence are presented in Table 1.

Table 1 Interventions considered by rheumatologists to increase adherence

- Patient education (in follow up consultation, conferences, pamphlets)
- Develop rapport with patient. ("be accessible,"answer questions,"make the patient part of" don't be paternalistic or authoritarian)
- Adherence measure (Use the available method, questionnaires, self-report, drug levels, electronic pillbox, pill count, etc. "Don't matter which one, measure it")
- Interventions for no adherence reasons (phone calls, text messages, telephone alarms) fixed schedules for each medication, cognitive-behavioral therapy, access to medications
- Family support network
- Presented in order to frequencies and grouped by topic

Conclusion: Rheumatologists ask for adherence medication but more than half use a limited amount of time to explain about medication, nevertheless, they think that patient education is the best intervention to increase adherence.

INFLUENZA VACCINATION TREND IN THE LAST DECADE AND FACTORS INFLUENCING THE RATE OF INFLUENZA VACCINATION IN CHRONIC INFLAMMATORY ARTHRITIS IN THE ITALIAN REGION OF FRIULI VENEZIA GIULIA (2006-2018)

L. Quartuccio1, A. Zabotti2, G. De Marchi2, T. Gallo3, S. De Vita1, F. Valent4. 1Clinic of Rheumatology, Department of Medicine, Academic Hospital “Santa Maria della Misericordia”, ASUI, Udine, Italy; 2Department of Prevention, ASUFIC, Udine, Italy; 3Department of Prevention, ASUFIC, Udine, Italy; 4Institute of Epidemiology, Academic Hospital “Santa Maria della Misericordia”, ASUI, Udine, Italy

Background: Vaccination is one of the most important medical intervention to prevent infectious complications in population at risk. EULAR recommendations for vaccination of patients suffering from autoimmune inflammatory rheumatic diseases (Arthritis International Federation (AII(R)D) have been recently updated (1).

Objectives: to verify the level of coverage of the influenza vaccination in a local population of patients suffering from rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS).

Methods: Integration of the information coming from many administrative databases were used to this end. The Regional Health Information System of Friuli Venezia Giulia was used as the source of information for this retrospective cohort study. Patients were residents in Friuli Venezia Giulia and they had to carry the exemption code for RA, or PsA, or AS and at least one prescription of a biological.

Conclusion: In the last decade, the rate of influenza vaccination has increased gradually in patients suffering from chronic inflammatory arthritis in Friuli Venezia Giulia. However, there is still room for improvement, especially in the group of patients over 65 years old and with comorbidities.
Background:

The communication and information platform developed in the Horizon2020 funded PICASO project (www.picaso-project.eu) supports the management of patients and their data along the continuum of care, consisting of hospitals, outpatient departments, practices, other health service providers via remote health monitoring. The platform might empower patients to improve their self-management of their illnesses.

Objectives: What technological expertise and resources do RA patients and physicians have, who are willing to participate in a proof-of-concept study using a modern ICT platform? What is the user satisfaction? What are platform’s clinical implications?

Methods: PICASO pursued a user-centered design approach. Platform’s user requirements were determined through workshops and interviews with physicians from various disciplines, patients and other stakeholders in the health care system (e.g. data protection officers). The development was accompanied by so-called “expert walkthroughs” to ensure a user-friendly design. An evaluation concept assessing the usability of the applications, user satisfaction and clinical relevance of the platform was part of the 6-month proof-of-concept study with RA patients and their physicians (rheumatologists and family doctors). A positive ethics vote was obtained.

Results: 111 user requirements were identified and used to develop the platform. Conformity with the GDPR as well as national regulations were precisely adhered to. All developments are based on the new ‘Fast Healthcare Interoperability Resources’ standard enabling data exchange with other software systems in the healthcare sector. This offers many advantages, e.g. a semantic model for describing the smallest units in the health care system (e.g. medication intake times, diagnostic procedures). Thus information can be linked and made available across sectors. Data can remain with the data owner and role-specific data access is ensured.

30 RA patients (80% female) participated, mean age was 58.6±10.8 years, disease duration 12.6±8.5 years, DAS28 2.6±0.9, average number of comorbidities 3.0±1.6. Patients’ T-experience was heterogeneous. After 6 months evaluations showed a good platform acceptance with an overall rating of 2.9±1 (n=27, Likert scale (LS) 1-6) and evaluation of ‘ease of use at 2.3±1.2 (n=27 LS 1-6). Usability tests showed that for patients the presentation of (1) tasks to be performed for the management of their disease, (2) results from their remote health monitoring, and (3) patient-reported outcome instruments in a dashboard was clear and easy to understand. Time required for documentation and daily tasks was rated as appropriate by 75.8% of the patients. No major technical problems or impairments due to RA where experienced when using the dashboard. 8 physicians (73.5 % female) participated in the evaluation; overall the platform was rated at 2.2±0.5 (LS 1-6).

Conclusion: The platform offers cross-sectoral orchestration of patient data and thus innovative capabilities for modern management processes (e.g. treat-to-target, tele-monitoring). The PICASO platform is available for RA patients as well as for other chronic diseases.

Acknowledgments: This project received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 689209.

Legend: RA, rheumatoid arthritis; PsA, psoriatic arthritis; AS, ankylosing spondylitis.

Conclusion: Influenza vaccination coverage is low in a population at high risk of infectious complications, even in the subgroup of elderly patients. Local guidelines are needed to improve the vaccination policies in AIIRD in order to increase the protection among patients who really need it.

AB1190 DIRECT MEDICAL COSTS OF HOSPITALIZATION DURING THE MAINTENANCE THERAPY IN PATIENTS WITH ANTIINEUTROPHIL CYTOSOLIC ANTIBODY-ASSOCIATED VASCULITIS USING JAPANESE HEALTH INSURANCE DATABASE

R. Sakai1,2, E. Tanaka3, M. Harigai4, 1Tokyo Women’s Medical University, Department of Rheumatology, Tokyo, Japan; 2Tokyo Women's Medical University, Division of Epidemiology and Pharmacoepidemiology, Department of Rheumatology, Tokyo, Japan

Background: Antineutrophil cytoplasmic antibody-associated vasculitis (AAV) requires a long-term maintenance therapy (MT), often accompanied by hospitalization due to relapse and/or comorbidities such as infection. However, data about direct medical costs of hospitalization during MT in patients with AAV is limited to date despite of an increasing concern about the economic burden of patients with AAV2-3.

Objectives: To describe frequency of hospitalization and its direct medical costs during MT after the remission-induction therapy (RT) in patients with AAV using Japanese health insurance database.

Methods: This retrospective longitudinal population-based study was conducted using claims data in Japan provided by Medical Data Vision Co., Ltd. We defined individuals as AAV cases receiving RT if they met all of the following: 1) having the protection among patients who really need it.
at least one OCD10 code (M300, M301, M313, or M318); 2) having at least one prescription of oral corticosteroids with prednisolone-equivalent dosage ≥30 mg/ day, methylprednisolone pulse therapy, immunosuppressive drugs (cyclophosphamide [IVCY], methotrexate, or mycophenolate mofetil), or rituximab (RTX) during hospitalization between April 2008 and April 2017; and 3) having at least 7 days of hospitalization. The observation started from the next day of discharge from the first hospitalization for RT and ended at 24 months later, the month of least of follow-up, or April 2017. We described the frequency of hospitalization and calculated direct medical costs (per month) during the observation. We analyzed medical costs using a societal perspective. We classified reasons of hospitalization into 3 categories: intensification of treatments for AAV, AAV MT including IVCY or RTX treatments, and comorbidities (infection, cardiovascular disease [CVD], malignancy, and others) using ICD10 codes plus treatments or interventions during the hospitalization. Results: In this study, 1,703 patients with AAV were included. The median [IQR] age was 72 [63, 79] years and 55.7% were female. The total number of hospitalization was 1,897 in 863 patients (50.7%). Among the hospitalizations, 296 hospitalization in 235 patients were categorized as intensification of treatments for AAV, 627 hospitalization in 297 patients were AAV MT, and 974 hospitalization in 572 patients were categorized as comorbidities. In the last category, infections were most frequent (220), followed by malignancy (54) and CVD (15). The mean direct medical costs per month was 20,945 EUR (1 EUR=125 JPY) in patients with hospitalization and 599 EUR in those without. Patients with hospitalization due to intensification of treatments for AAV had the highest direct medical costs (3,000 EUR), followed by those with hospitalization due to comorbidities (2,001 EUR), and those with hospitalization due to AAV MT (1,649 EUR).

Conclusion: More than half of the patients had hospitalization during MT, and hospitalization due to comorbidities were most frequent. The mean direct medical costs in patients with at least one hospitalization was approximately 3.5 times as high as that in those without hospitalization.

**THE UNDERWORLD OF DEPRESSIVE SYMPTOMS IN RHEUMATIC DISEASES: OVERLOOKED, UNRECOGNIZED OR UNPERCEIVED?**

F. Ingegnoli1,2, T. Schiappi3,2, T. Ubiali1, V. Bollani1, S. Oduzzi1, M. Buol1,2, R. Cavalli1,2, G. Pini Hospital, Rheumatology Unit, Milan, Italy; 2Università degli Studi di Milano, Milan, Italy; 3EPIGET Lab, Milan, Italy; 4ALOMAR Lombard Association for Rheumatic Diseases, Milan, Italy; 5IRCCS Ca’Granda Policlinico, Milan, Italy

Background: The concomitant presence of depressive symptoms and rheumatic diseases (RDs) impose a considerable economic and social burden on the communities as they are associated with numerous deleterious outcomes such as increased mortality, work disability, higher disease activity and worsening physical function, higher pain levels and fatigue. Despite growing interest on depressive symptoms burden in RDs, current patient perception on this topic is unknown.

Objectives: Italian patients with RDs were invited to participate in an online study gauging the presence and the perception of depressive symptoms using the Patient Health Questionnaire (PHQ-9).

Methods: This was a cross-sectional non-profit online study to screen the presence and the perception of depressive symptoms in RDs patients. All participants gave their consent to complete the PHQ-9 and they were not remunerated. Completion was voluntary and anonymous. The PHQ-9 rates the frequency of symptoms over the past 2 weeks on a 0-3 Likert-type scale. It contains the following items: anhedonia, depressed mood, trouble sleeping, feeling tired, change in appetite, guilt or worthlessness, trouble concentrating, feeling slowed down or restless, and suicidal thoughts. Patients were stratified as: <4 not depressed, 5-9 slight or mild depression, 10-14 moderate depression, and >14 severe depression. The survey was disseminated by ALOMAR (Lombard Association for Rheumatic Diseases) between June and October 2019.

**AB1192**

**AWARENESS OF PRESCRIPTION DRUGS FOR RHEUMATOID ARTHRITIS AMONGST PATIENTS - A COMPARISON OF THE RESULTS FROM 2014 AND 2018 SURVEYS-**

M. Sato1, M. Takemura2, Kaizu Medical Association Hospital, Rheumatology, Kaizu City, Gifu, Japan; 2Fujita Health University, Advanced Diagnostic System Research Laboratory, Toyoake, Aichi, Japan

Background: Treatment of rheumatoid arthritis (RA) is based on drug therapy. With the increasing number of effective drugs being authorized for use and generic drugs becoming available in the market, patients with RA now have an abundance of drugs as treatment options.

Objectives: To conduct a survey of RA patients to evaluate their knowledge about the prescribed drugs, their names, and the respective categories.

Methods: In 2014 and 2018, two different surveys were done in which RA patients gave their consent to complete the PHQ-9 and they were not remunerated. Completion was voluntary and anonymous. The PHQ-9 rates the frequency of symptoms over the past 2 weeks on a 0-3 Likert-type scale. It contains the follow- ing items: anhedonia, depressed mood, trouble sleeping, feeling tired, change in appetite, guilt or worthlessness, trouble concentrating, feeling slowed down or restless, and suicidal thoughts. Patients were stratified as: <4 not depressed, 5-9 slight or mild depression, 10-14 moderate depression, and >14 severe depression. The survey was disseminated by ALOMAR (Lombard Association for Rheumatic Diseases) between June and October 2019.
Results: 192 patients took part in the study: 170 female with median age 50 years. Among respondents only 35 (18.2%) were not depressed. Depression was sub-clinical or mild in 68 (35.4%), moderate in 42 (21.9%), moderately severe in 30 (15.6%), and severe in 17 (8.9%). 16 (8.3%) of respondents declared to have depressive symptoms and 7 of 16 were under psychiatric therapy. Moreover, patients were grouped according to diagnosis. 124 respondents had inflammatory arthritis (rheumatoid arthritis, psoriatic arthritis and ankylosing spondylitis), 23 (18.5%) were not depressed. Depression was sub-clinical or mild in 41 (33%), moderate in 26 (21%), moderately severe in 21 (17%), and severe in 13 (10.5%). Among them, 8 (6.5%) declared to have depressive symptoms depressed and 3 of 8 were under psychiatric therapy. 49 respondents had a connective tissue disease or vasculitis. 11 (22.5%) were not depressed. Depression was sub-clinical or mild in 19 (38.8%), moderate in 13 (26.5%), moderately severe in 2 (4%), and severe in 4 (8.2%). Among them, 3 (6%) declared to have depressive symptoms and 1 of 6 were under psychiatric therapy.

19 respondents had other rheumatic diseases. 1 (5.3%) was not depressed. Depression was sub-clinical or mild in 2 (42.1%), moderate in 3 (15.8%), moderately severe in 2 (4%), and severe in 4 (8.2%). Among them, 8 (6.5%) declared to have depressive symptoms depressed and 3 of 8 were under psychiatric therapy.

Conclusion: Our study confirmed that the overall real-life burden of depressive symptoms is relevant in all RDs. At the same time, these results highlighted that depressive symptoms are overlook by physicians and unperceived by patients even if fewer that half of respondents (46.4%) had a clinical depression (PHQ-9 >10). These results suggest that screening for depression should form part of the routine clinical assessment of RD patients.

Acknowledgments: We thank the Lombard Association of Rheumatic Diseases (ALOMAR) for its contribution to design and disseminate the survey, the group that sustain systemic sclerosis (GILS), and the IT service of the University of Milan.

AB1193 WORK INSTABILITY AMONG POLISH RHEUMATOID ARTHRITIS PATIENTS

W. Schmidt1,2, M. Tapolska1, M. Owczarek2, K. Pawlik-Bus1,2, P. Leszczynski1,2, Poznanska University of Medical Sciences, Department of Rheumatology and Rehabilitation, Poznan, Poland; 1, Jozef Strus Municipal Hospital, Department of Rheumatology and Osteoporosis, Poznan, Poland; 2, Poznanska University of Medical Sciences, Department of Public Health, Poznan, Poland

Background: Rheumatoid arthritis (RA) affects patients’ capacity to work. Rheumatoid Arthritis Work Instability Scale (RA-WIS) is a reliable method to measure work instability (WI) (1–3). We lack data on relationship between RA and work instability among Polish patients.

Objectives: The aim of our study was to assess WI and associated factors among patients with RA.

Methods: 315 patients from three rheumatology centres were enrolled and filled questionnaires including demographic and self-reported clinical data, RA-WIS, and The Health Assessment Questionnaire (HAQ). Swollen and tender joints count (SJC, TJC) were assessed by attending physician and current erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were collected. We excluded 41 patients due to incorrectly filled form and analysed questionnaires of 274 patients. DAS28 (Disease Activity Score in 28 joints) and DAS28-CRP were calculated. We performed statistical analysis with Statistica v. 13.3 using Mann-Whitney U test, chi-square test and Spearman's correlation

Table 1. Characteristics of employed patients according to work instability risk, N(%) or mean±SD.

**Conclusion:** Pain and disability are main factors associated with work instability among patients with RA.

AB1194 STRIKING DIFFERENCES IN THE COURSE OF OSTEARTHRITIS (OA) COMPARED TO RHEUMATOID ARTHRITIS (RA) OVER THE FIRST 24 MONTHS OF RHEUMATOLOGY CARE AT ONE PRIVATE PRACTICE SETTING

K. Schroeder1, T. Pincus1, M. Bergmann2, Rush University, Chicago, United States of America; 2, Drexel University, Philadelphia, United States of America

Background: Recent reports indicate that disease burden in osteoarthritis (OA) is similar to or greater than in rheumatoid arthritis (RA) when an identical measure is used to assess patients with either disease, generally an MDHAQ/RAPID3 (multidimensional health assessment questionnaire/routine assessment of patient index data). The data suggest that a traditional view that RA is more severe than OA no longer is valid at this time. One concern is that similar disease burdens in OA vs RA may result entirely from superior treatments for RA, and RA may be considerably more severe than OA at initial presentation.

Objectives: To analyze MDHAQ disease burden in patients with OA vs RA at initial visit and at 24-month follow-up in routine care at a single solo-rheumatologist private practice setting.

Methods: All patients at this setting complete an MDHAQ at each visit in the waiting area, prior to seeing the rheumatologist. The MDHAQ includes three 0–10 scores for physical function, pain visual numeric scale (VNS), and patient global VNS, which may be compiled into a 0–30 RAPID3, as well as a 0–10 fatigue VNS. OA patients were defined as those with a 24-month follow-up, and 0-16 rheumatoid arthritis disease activity index (RADAI) self-report painful joint count. Mean MDHAQ scores were analyzed

**Results:** 140 (51 %) patients were employed and their characteristics are presented on Table 1. In unvariable analysis we identified following risk factors for high risk WI: moderate-to-high disease activity (DAS28-CRP ≥ 3.2 – OR 2.29, 95% CI 1.06-4.66, p=0.033; DAS28-CRP ≥ 3.2 – OR 2.34, 95% CI 1.04-5.27, p=0.038), ESR ≥30 mm/h in women and ≥20 mm/h in men (OR 2.65, 95% CI 1.2-36.19, p=0.010), CRP ≥ 1 mg/dL (OR 4.02, 95% CI 1.78-9.10, p<0.001). HAQ-DI ≥1 (OR 2.23, 95% CI 1.04-4.81, p=0.037) and at least moderate pain on visual analogue scale (VAS >5 cm - OR 5.31, 95% CI 2.3-11.96, p<0.001). Correlations were moderate between RA-WIS and VASp (R=0.59, p<0.001) and HAQ-DI (R=0.52, p<0.001) whereas weak with disease activity indices (DAS28 CRP R=0.31, p<0.001; DAS28-CRP - R=0.28, p<0.001).

**Table 1.** Demographic and clinical characteristics of employed patients according to work instability risk, N(%) or mean±SD.

**Method:** Pain and disability are main factors associated with work instability among patients with RA.

AB1194
for all 73 OA and 116 RA patients seen for an initial visit between 2011 and 2017. Mean scores at initial and 24-month visits were compared for all 25 OA and 63 RA patients seen at 24 month (21-27 month) follow-up visits, using paired t tests.

**Results:** Mean MDHAQ scores at first visit were similar for all 73 OA and 116 RA patients, and also for 25 OA and 63 RA patients who were also seen 24 months later, e.g., mean RAPID3 was 12.0-14.2. However, mean changes over 2 years were strikingly different in OA versus RA patients (Table). Almost all mean scores in OA were somewhat higher, while all mean scores in RA were clinically and statistically significantly improved at 24 months, e.g., mean RAPID3 worsened from 13.0 to 15.2 (+2.2 units, 17%) in OA patients, compared to improvement from 12.5 to 8.2 (-4.3 units, -34%) in RA patients. The smallest mean change in RA patients involved the joint count (7.7 to 6.1, -21%) (Table), suggesting possible control of inflammation, but continued damage to specific joints. An important limitation is that the data do not include follow-up on patients not seen over the 24 month "window," because of substantially better or poorer status, joint surgery, or other reasons, although the data present an accurate characterization of one rheumatology practice setting.

**Conclusion:** Mean MDHAQ/RAPID3 scores were similar in RA or OA at the initial visit. Over 24 months, scores worsened slightly in OA than in patients who were not considered in RA, resulting in considering poorer status in OA versus RA, likely reflecting superior treatments for RA vs OA. At an individual level, patients with primary OA may have better or poorer status than patients with OA. Nonetheless, at a group level, the severity of disease burden in OA appears similar to RA, and becomes greater over the next 24 months, likely as a result of better treatments. The severity of OA is underestimated, suggesting a need for increased resources for research toward better treatments for OA.

### Disclosures of Interests:
Kyle Schroeder: None declared, Theodore Pincus Shareholder of: Johnson & Johnson – stockholder, Consultant of: AbbVie, BMS, Celgene Corporation, Genentech, Janssen, Merck, Novartis, Pfizer, Sanofi – consultant, Speakers bureau: AbbVie, Celgene Corporation, Novartis, Pfizer, Sanofi – speakers bureau

**Objectives:** 1) To examine the correlation between caregiver self-efficacy and depression and pain. 2) To examine how these correlations differ for caregivers with and without arthritis.

**Methods:** A caregiver questionnaire was distributed via social media, mainly list serves and blogs to a convenience sample. Those receiving the links were urged to send them to other populations. Respondents self-reported arthritis and weekly hours spent caregiving. They reported pain using a pain (visual numeric scale (1-10)), depression with the Patient Health Questionnaire (PHQ-8), and Self-Efficacy was reported with the short caregiver self-efficacy scale). For caregivers and non-caregivers we compared caregiving hours, pain, depression and self-efficacy. We examined the distribution of caregiving hours by arthritis status and plotted mean pain scores by caregiving hours for caregivers with and without arthritis. The correlation between depression and self-efficacy was measured using Pearson correlation coefficient overall and by arthritis status.

**Results:** Over two weeks 155 individuals responded, with data on self-reported arthritis status. Of the respondents, 88% were female and 64% were 50-69 years of age. 46% self-reported arthritis (osteoarthritis was the most common type). Nearly 25% of caregivers reported spending less than 10 hours weekly on caregiving, while approximately 23% reported at the other end of the extreme (at least 40 hours weekly). The distribution by arthritis status of the caregiver is provided in Table 1.

Caregivers with arthritis reported higher pain in the past week. Mean pain score among caregivers with arthritis was 4.4 (SD 2.2) compared to 2.7 (SD 1.7) among caregivers without arthritis (figure 1). This divergence widened for caregivers with 40 or more hours of caregiving. There was a strong negative correlation (Pearson correlation = –0.473, p-value <0.0001) between depression and self-efficacy. The correlation was -0.59 for caregivers without arthritis (p=0.0001, n=74 with data on all three variables) compared to the caregivers self-reporting arthritis (n=0.35, p=0.006, n=60 with data on all three variables).

**Conclusion:** This study suggests that lower caregiver self-efficacy has a direct and strong association with higher depressive symptoms and that this is more pronounced among caregivers with arthritis. This study also shows that caregivers with arthritis have more pain than caregivers without arthritis, and that this peaks and remains consistent for those doing twenty or more hours of caregiving weekly. The stronger negative correlation of depression and self-efficacy among patients without arthritis may be explained by other independent contributors (such as pain) to depression in caregivers with arthritis.

A STUDY REVIEWING THE ASSOCIATED FACTORS AND COST-EVALUATION OF SWITCHING BACK TO ORIGINATOR-ETANERCEPT FROM ITS BIOSIMILAR AMONG PATIENTS WITH RHEUMATIC DISORDERS AT A TERTIARY CARE CENTRE IN UNITED KINGDOM

S. S. C. Silva1, B. Mahesh2, T. Rajakulenthiran3, R. Singh3, R. Amarasesan3,
1The Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, United Kingdom; 2University of Melbourne, Population and Global Health Unit, Melbourne, Australia; 3The Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, United Kingdom

Background: Biological therapy plays a major role in the management of patients with rheumatic disorders. Evidences generated at experimental settings have shown biosimilars as clinically effective, safe and cost effective. Nevertheless, real world data are lacking about cost effectiveness and causes of switching back to originator product among patients

Objectives: To describe the associated factors and cost evaluation of switching back to the originator etanercept from the biosimilar among patients with rheumatic disorders at The Robert Jones and Agnes Hunt Orthopaedic Hospital of United Kingdom

Methods: A descriptive cross-sectional study was undertaken with secondary data in a tertiary care hospital. All the patients who were switched from original etanercept (originator) to biosimilar Etanercept from October 2018 to June 2019 were included in the study. A pre-tested data extraction sheet was used in the data collection. Annual expenditure estimates for the treatment modalities were collected by consulting the experts. Descriptive analysis was done for the characteristics of the study sample and for the estimated annual costs. Associations of age and sex in the switching of treatment modalities were explored with chi-square test and Mann Whitney U test with 5% significance level.

Results: Records of 100 participants were extracted with a male to female ratio of 1: 1.4. The median (interquartile range (IQR)) of the participants was 54 (44 to 66) years. The leading three diagnoses were: rheumatoid arthritis (65%), Ankylosing Spondylitis (18%) and Psoriatic arthritis (14%). Out of the participants, 32 (32%) switched back to originator with a median (IQR) duration of 16.0 (10.5 to 19.5) weeks of commencing the biosimilar. The proportions of switching back were 28.1%, 34.4% and 37% among those who did, in the chronological 3-monthly intervals of the study. The main reasons for switching back included; side effects (21.9%), lack of efficacy (65.6%), both of these (9.4%) and other reasons (3.1%). Older age was observed among those who switched back (p<0.05) but gender did not show a statistically significant association (p=0.532). The annual estimated cost for biosimilar was 37.3% less than that for originator per patient.

Conclusion: In our cohort nearly one third switched back to the originator following the commencement of biosimilar incurring a financial and resource burden to the rheumatology department which in turn will have wider ramifications on the health care system. Exploring the reasons and factors associated with switching back to the originator in larger scale studies would help in planning cost-effective interventions and understanding the reasons why the patients revert back to the originator from the biosimilar therapy, especially among the older patients.

AB1197 TREAT-TO-TARGET IS FEASIBLE IN RHEUMATOID ARTHRITIS PATIENTS DURING PREGNANCY, FIRST RESULTS OF THE PRECARA COHORT

H. T. Smeele1, E. Röder2, H. Wintjes3, L. J. Kranenburg - van Koppen1, J. Hazes1, R. Dolhain1.
1Erasmus MC, Rotterdam, Netherlands

Background: A treat-to-target approach results in better outcomes for Rheumatoid Arthritis (RA) patients [1]. Well controlled disease is important for pregnant RA patients and patients with a wish to conceive or pregnant.

Method: Patients were derived from the PreCARA cohort (first inclusion 2011, data shown up to November 2019). The PreCARA cohort is an ongoing, single center, prospective study on RA and pregnancy. Patients in this cohort were treated according to a treat-to-target approach, in which the obvious restrictions of pregnancy were taken into account. Study visits were scheduled before, during and after pregnancy and disease activity (DAS28CRP) was measured. Results of the PreCARA study were compared with results of the PARA study [3], a historic reference cohort on RA during pregnancy, with a similar study design (inclusion 2002 – 2010). Patients in the PARA cohort were treated according to the standards of that time. The PARA cohort represents the natural course of RA during pregnancy with limited treatment options.

Results: 263 RA patients were included in the PreCARA cohort, up to now 154 children were born in this ongoing cohort. Mean age at inclusion was 32.3 (4.3 SD), 83.2 % was Rheumatoid Factor positive and/or ACPA positive. Mean disease activity in the PreCARA cohort is statistically significant lower than in the PARA cohort at every time-point; mean DAS28CRP in 3rd trimester in the PreCARA cohort 2.22 (0.73 SD), in the PARA cohort 3.35 (1.12 SD) P < 0.001 (figure 1). In the PreCARA cohort 73.3% of the patients were in low disease activity or remission before pregnancy increasing to 90.4 % in the third trimester, whereas in the PARA cohort these percentages were 32.2 % and 47.3% respectively (P < 0.001) (figure 2). Medication use in the PreCARA cohort is shown in table 1 and in the PARA cohort in table 2.

**Conclusion:** This study on a treat-to-target approach in pregnant RA patients shows that low disease activity and remission are an attainable goal during pregnancy, with over 90% of patients achieving this in the 3rd trimester. The effect of this approach on fertility and pregnancy outcomes should be the focus of further studies.

DECREASING OF TOTAL AND UNILATERAL KNEE ARTHROPLASTIES DUE TO RHEUMATOID ARTHRITIS BUT INCREASING IN OSTEOARTHRITIS IN OUR INSTITUTES IN LAST DECADE OF SUPER-AGING SOCIETY

1Yamagata University Faculty of Medicine, Department of Orthopaedic Surgery & Rehabilitation, Yamagata, Japan; 2Yamagata Saisei Hospital, Department of Orthopaedic Surgery, Yamagata, Japan; 3Yamagata University Faculty of Medicine, Department of Orthopaedic Surgery, Yamagata, Japan

Background: The rate of elderly people over 65 year-old increased from 22.1 % in 2008 to 27.7 % in 2017 in Japan, also from 27.1 % to 32.3 % in our super-aging area1, 2. The number of total and unilateral knee arthroplasty (TKA, UKA) have increased annually in all over the world according to the larger population of elderly people due to osteoarthritis (OA)3. In fact, the numbers of primary TKA predicted increasing from six hundred fifty-six thousand cases at 2010 to one million three hundred seventy-six thousand cases at 2020 in USA4. In the other hand, rheumatoid arthritis (RA) therapy have been remarkably improved from starting to use biologic agents since 2003 in Japan 5. The rate of orthopaedic surgery may reflect trends in disease severity and drug management of RA 5.

Objectives: The aim of study is to reveal the rate of TKA, including UKA and revision TKA in elderly people in our super-aging area of Japan.

Methods: We surveyed the number and cause of primary and revision TKA and UKA in our institutes using the data of diagnosis procedure combination and the record of surgeries in the last decade.

Results: We had 23,193 cases of orthopaedic surgeries, including 4,242 primary and revision TKA/UKA from 2008 to 2017 . The cause of TKA/UKA contained 3,817 (OA, 92 %), 212 rheumatoid arthritis (RA, 5.1%), 61 osteonecrosis, 42 loosening of prosthesis. The cause of 60 revision TKA/UKA contained 42 loosening, 9 broken of implant. They contained 3,584 cases of primary TKA, 614 UKA, 60 revision TKA/UKA. The numbers of TKA increased from 318 in 2008 to 529 in 2017 year by year, mainly due to OA (Fig.1). The numbers of primary TKA/UKA as cause of RA in 2013-17 more decreased compared to in 2008-12 (0.6), but in case of OA increased (1.3 times, Table 1, p<0.05).

* p<0.05

Conclusion: The number and rate of primary TKA/UKA due to RA decreased year by year because of progression of modern medication therapy. In the other hand, in case of OA increased because of increasing of elderly people affected by knee OA in the super-aging society.

AB1199

COST-EFFECTIVENESS OF EARLY INITIATION OF ABATACEPT ON JAPANESE RHEUMATOID ARTHRITIS PATIENTS BASED ON THE AMPLE STUDY, USING IORRA REAL WORLD DATA

1Tokyo Women’s Medical University School of Medicine, Department of Rheumatology, Tokyo, Japan; 2St Marianna University School of Medicine, Kawasaki, Japan; 3Medilead Inc., Tokyo, Japan; 4ICON plc, Stockholm, Sweden; 5BMS, Princeton, United States of America; 6BMS K. K., Tokyo, Japan

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disorder leading to disability and reduced quality of life. Effective treatment with biologic disease-modifying antirheumatic drugs (bDMARD) poses a significant economic burden. The
abatacept (ABT) versus adalimumab comparison in biologic-naive RA subjects with background methotrexate (AMPLE) trial was a head-to-head randomized study. **Objectives:** To assess the cost-effectiveness (CE) of early initiation of ABT on Japanese RA patients with data from the iORRA database.\(^1\) Methods: A model based on the AMPLE study was used to estimate the CE of ABT in a cohort of 1000 patients based on responses on ACR20/50/70, HAQ-DI, CDAI and SDAI estimated from the real-clinical data of the ID. Unit costs for direct medical costs of adverse events (AEs), proportions of patients with concomitant medications or outpatient/inpatient visits; doses and duration of concomitant medications were taken from the JMDC claims database.\(^2\) Uncertainty was assessed in sensitivity analyses (SA) where cost parameters were tested on their ±30% levels. Results were compared between subgroups using cut-offs of 65-years of age and 1.5 of HAQ, or 5-years of treatment duration. The study used a Japanese healthcare payers' perspective over a 2-year time horizon. **Results:** Incremental costs were all in favor of ABT 2nd line with 137 MYJPY (1.1 M€; 120 JPY=1 €), 6 MYJPY (0.05 ME), 41 MYJPY (0.3 ME), 8 MYJPY (0.07 ME) and 2.2 MYJPY (0.02 ME) for bDMARDs, concomitant medication, AEs, serious AE, and hospitalizations due to infections, respectively. In total, the incremental costs were expected to be 195 MYJPY (1.6 M€) higher for ABT as 1st line treatment, but the cost per responding patient and per patient in remission favored ABT 1st line across most response outcomes (Table 1). **Table 1. Total costs per responder and patient in remission per 2-year**

<table>
<thead>
<tr>
<th>Cost per responding patient (kJPY)</th>

SA showed that the cost for bDMARDs drives the difference in healthcare costs between the cohorts (~685 MYJPY to 1.074 MYJPY). For sub-groups of patients <65 years, <65 years, HAQ≤15, HAQ≤15, treatment duration ≥5 years, <5 years the total 2-yearly costs per responder (SDAI remission) were 106 kJPY (0.9 k€), 321 kJPY (2.7 k€), 1,353 kJPY (11.3 k€), 106 kJPY (0.9 k€), 231 kJPY (1.9 k€) and 178 kJPY (1.5 k€) lower for ABT 1st line, respectively. **Conclusion:** Savings per responding patient are expected if ABT are prescribed as 1st line versus 2nd or 3rd line treatment, irrespective of age, disease duration and functional impairment level.

**EARLY ARTHRITIS CLINICS IMPROVES THE EVOLUTION OF THE DISEASE AND DECREASES WORK ABSENTEEISM**

M. A. Teran Tinedo\(^1\), J. Bachiller-Corrall\(^1\), Hospital Ramon y Cajal, Madrid, Spain

**Background:** Rheumatoid arthritis is the most common inflammatory arthritis, and a significant cause of morbidity and mortality. Several clinical studies have shown that treatment introduced at an early stage, referred to as a “window of opportunity,” is associated with long-term benefits in the form of long-term remission and even complete remission of the disease.

**Objectives:** Assess the advantages of an Early Arthritis clinic (EAC) in the management of RA until remission is reached and its impact on work absenteeism. **Methods:** We included a cohort of patients with early RA (<12 months symptoms) who fulfilled the ACR 2010 criteria, in an early arthritis clinic (EAC) from a tertiary hospital, between 2016-2019, followed for at least 2 years. Demographic, clinical, analytical and radiographic variables were included, and the dates of the visits during the follow-up were noted. Work absenteeism days was recorded before and after the first visit. Estadistic description and regression analysis was performed.

**Results:** Eighty-four patients with early RA were included, with loss of follow-up of twelve patients. Fifty-one (70.8%) were women with a mean age 50 years ±15.84. Fifty-one patients were FR positive (70.8%) and sixty-eight were ACPA positive (94.4%). Nine subjects (13%) had erosions. Acute phase reactants elevation was observed in fifty-five patients (76.3%). Thirty-seven subjects (51.3%) were smokers. Mean swollen joint count was 4 ± 4.79 and mean DAS28 was 4.01 ± 1.28. Inflammatory arthritis was reported since mean time 6.7 months before the first visit. Seventy patients (97%) were treated with methotrexate and forty-nine (70%) did not require other treatment during follow-up. Ten patients (14.3%) required DMARDs, and half received 2 or more drugs of this class. The mean cumulative time of exposure to corticosteroids was 8.37 ±9.26 months. Mean time between the date to Rheumatologist and the first visit was 44 days. Forty-nine patients (81%) achieved remission during follow-up and mean time required for this goal was 299 days with a mean 4.7 visits. We found a significant correlation between the time to reach remission with DAS28, NAT and Nº treatments prescribed (0.38, 0.39 and 0.70 respectively, p <0.05). Twenty work absenteeism periods (mean 299 days with a mean 4.7 visits) who fullfield the ACR 2010 criteria, in an early arthritis clinic (EAC) from a tertiary hospital, between 2016-2019, followed for at least 2 years. Demographic, clinical, analytical and radiographic variables were included, and the dates of the visits during the follow-up were noted. Work absenteeism days was recorded before and after the first visit. Estadistic description and regression analysis was performed.

Boki9, G. Evangelatos9, A. Ilipoulos3, K. Karagianni7, S. Sakka10, K. Melissaropoulos6, P. Georgiou4, E. Grika11, I. Vlachyaniopoulos11, T. Dimitroula12, A. Garyfallos13, C. Georgianas11, P. Vounotrypidis13, K. Nitsis11, M. Areli12, G. D. Kitas14, D. Vassilopoulos15, J. Joint Rheumatology Program, University of Athens Medical School, Athens, Greece; Rheumatology Clinic, University of Ioannina, Ioannina, Greece; Department of Rheumatology, Clinical Immunology and Allergy, University Hospital of Heraklion, Heraklion, Greece; Rheumatology Unit, KAT Hospital, Athens, Greece; Rheumatology Unit, Stamatoglou Hospital, Athens, Greece; Rheumatology Unit, NIMTS Hospital, Athens, Greece; Department of Rheumatology, University of Thessaly, Larissa, Greece; Rheumatology Unit, Agios Andreas Hospital, Patras, Greece; 4th Department of Medicine, Aristotel University, Thessaloniki, Greece; Private Office, Athens, Greece; Private Office, Thessaloniki, Greece; Private Office, Kalamata, Greece; Private Office, Levidia, Greece; Hygeia Hospital, Athens, Greece

Background: Despite the increased incidence of influenza infection in rheumatoid arthritis (RA) patients, vaccination coverage has been shown to be suboptimal. Prospective data regarding the current rate and predictors of influenza vaccination adherence in RA patients are limited.

Objectives: To calculate the current rate and predictors of influenza vaccination in a real-life, prospective, longitudinal RA cohort.

Methods: Data regarding demographics, disease characteristics, treatments and co-morbidities from a multi-center, longitudinal cohort of Greek RA patients were collected at baseline and ~3 years later. Disease and patient characteristics were compared between patients with at least one influenza vaccine administration and non-vaccinated ones, during the 3 year follow-up period.

Results: From a cohort of 1,569 RA patients, 1,406 with available vaccination data at baseline and 3 years later (mean interval: 2.9 years) were included. (women: 80.4%, mean age: 61.8 years, mean disease duration: 9.7 years, RF and/or anti-CCP positive: 50.4%, mean DAS-28 = 3.33, mean HAQ: 0.44, bDMARD use: 44.8%). At baseline, 54.2% of patients reported influenza vaccination in the past (31.8% during the previous season), while during the 3 year follow-up period, 81% had ≥1 influenza vaccinations (p<0.001). Patients who received ≥1 influenza vaccine were older (63.5 vs. 54.7 years, p<0.001), were more likely to be seropositive (59.2% vs. 45.2%, p<0.001), had higher HAQ (0.46 vs. 0.36, p<0.02) and BMI (27.7 vs. 26.9, p<0.02) at baseline, more likely to be treated with bDMARDs (46.8% vs. 36.4%, p<0.001) and more likely to have chronic lung disease (9.7% vs. 5.3%, p<0.02), dyslipidemia (36.4% vs. 24.2%, p<0.001), hypertension (46.1% vs. 29.2%, p<0.001) and to report vaccination against influenza the previous season before baseline evaluation (34.9% vs. 18.2%, p<0.001). Multivariate analysis, history of influenza vaccination during the last season before baseline (OR=1.87, CI: 1.27-2.74, p<0.001), bDMARD treatment (OR=1.98, CI: 0.56-5.42, p<0.013, OR=1.05, CI: 1.04-1.06, p<0.001) were independent predictors of influenza vaccination.

Conclusion: In this ongoing, longitudinal, prospective, real-life RA cohort study, a significant increase in the influenza vaccination coverage was noted (from 53% to 81%). Influenza vaccination was independently associated with recent history of influenza vaccination, older age, and bDMARD treatment.

Impact of biological therapy on work ability and productivity in rheumatoid arthritis

J. Vojinovic1, M. Lapcevic1, N. Damjanov2, M. Setik Buklika3, D. Loncar4, D. Acimovic5, on behalf of ORS and URES, 1University of Nis, Faculty of Medicine, Nis, Serbia; 2Association of Patients with Rheumatic Diseases ORS, Belgrade, Serbia; 3Institute of Rheumatology, Belgrade, Serbia; 4University of Belgrade, Faculty of Economics, Belgrade, Serbia

Background:

Objectives: The objective of the study was to determine the perceived impact of biological therapy on work ability and productivity of RA patients in Republic of Serbia.

Methods:

The analysis was based on questionnaires filled by 626 patients treated with biological therapy and 175 patients treated with conventional therapy, as well as on information gathered on four focus groups. Two monetized indicators were used in the study: Work Productivity and Activity Impairment Questionnaire General Health V2.0 (WPAI-GH) and Human Capital Approach (HCA), as well as two non-monetized indicators: Stanford Presenteeism Scale (SPS) and The Health and Work Performance Questionnaire (HPQ). The use of WPAI-GH indicator on gathered data helps calculate the total cost of decreased productivity caused by RA, based on two complementary aspects: absenteeism and presenteeism. The HCA indicator builds on costs measured by WPAI-GH, by providing information on the cost of work disability caused by RA, as the cost that resulted from early retirement of patients. SPS provides the foundation for comparison of subjective feeling regarding the impact of RA on performing work tasks between patients treated with biological therapy and patients treated with conventional therapy, using Mann-Whitney test. HPQ indicator provides the basis for comparison of non-monetized absenteeism and presenteeism, in both absolute and relative terms, between the two groups of patients.

Results:

Our results showed that the total cost of lost productivity of working population with RA in Serbia amounts 2.6 billion RSD (22.2 million EUR), while the total cost of work disability is 15.3 billion RSD (130.8 million EUR) per annum. Results of the HPQ analysis showed that the group treated with conventional therapy had been absent from their work three times more frequently, on average, than the patients treated with biological therapy. Also, the group of patients treated with conventional therapy rated their work performance as lower than average – they rated their productivity as 94.21% of average productivity of other employees at the same/similar job, while the group treated with biological therapy rated themselves as equally productive, compared to other employees. SPS analysis details are presented in Table (Mann-Whitney test).

Conclusion: Analysis undoubtedly suggests that RA influences lost productivity costs and work disability. Both work ability and productivity are better when biological therapy is in use, why significant savings would be possible if access to biological therapy could be used at an earlier stage of disease.

AB1203  INVESTIGATING THE VIEWS OF COMMUNITY PHARMACISTS ON THEIR ROLE IN THE MANAGEMENT OF RHEUMATOID ARTHRITIS

S. Wood1, K. Hyrich1, S. Verstappen1, D. Steinke1. 1The University of Manchester, Manchester, United Kingdom

Background: Medicines optimisation is essential in the long-term management of inflammatory diseases such as rheumatoid arthritis (RA). Particularly when considering combinations of conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs). Community pharmacists are ideally placed to optimise medicines use including monitoring side effects, counselling on dose and frequency and improving medicines adherence; however, in some countries, such as the UK, there are currently no community pharmacy services that address csDMARD use and little is known about the role community pharmacists play in managing RA as a long-term condition.

Objectives: The objectives of this qualitative study were to understand community pharmacists’ views of their training, knowledge and current role in the management of RA.

Methods: We conducted 9 semi-structured, face-to-face or telephone interviews with community pharmacists based in the UK; all were transcribed verbatim. A topic guide, used to inform the interviews, covered four key areas: 1) knowledge and training, 2) pharmacological management 3) patients and services, 4) potential role. The transcriptions were then imported into NVivo for thematic analysis. A coding framework was developed from continual emerging themes and applied to the transcripts.

Results: Five male/4 female participants, the median age was 39 years (range 27 to 42) with a median number of years qualified as a pharmacist of 12 years (range 5 to 20) were included. The participants covered a range of roles including: pharmacist non-manager, pharmacist manager, locum pharmacist, superintendent pharmacist and relief pharmacist.

In assessing the current role of community pharmacists, 4 main themes were identified: (1) access to information about the patient’s condition as a barrier, (2) lack of knowledge in the management of RA, (3) providing practical advice about taking csDMARDs, and (4) exploring the reasons for non-adherence before taking further action. In assessing the potential role of community pharmacists, a further 2 themes were identified: improving access to information about the patient’s condition before the current role can be increased and other barriers to an additional role, including time and funding.

In the theme access to information as a barrier the most common point made was about the lack of information available to pharmacists on the individual indications for medicines. Pharmacists said this posed a barrier both to current practice and their potential role. No participants suggested the potential for an additional service specifically for RA, but some suggested that current services could be expanded to include RA as a target group. Participants discussed side effect counselling and ensuring access to medicines in detail with patients, but only 2 briefly mentioned discussing the benefits of csDMARDs.

Conclusion: This is the first in-depth exploration of the perspectives of community pharmacists on the management of RA in community pharmacy. This study has highlighted several important barriers both environmental and personal including time, education and resources that, if addressed, could allow community pharmacists to play a greater role in the management of RA.

AB1204  COST-EFFECTIVENESS OF ABATACETE IN SPAIN IN SEROPOSITIVE BIOLOGIC-NAIVE EARLY RHEUMATOID ARTHRITIS PATIENTS WITH SHARED EPITOPE

J. M. Rodriguez-Heredia1, L. Verburg-Baltussen2, D. Devender3, N. Durno4, C. Sanchez5, N. Ray3, M. Treur2, J. Zhuo3. 1Hospital Universitario de Getafe, Madrid, Spain; 2PharmMed International, Rotterdam, Netherlands; 3Bristol-Myers Squibb, Princeton, United States of America; 4PharmMed International, Oxford, United Kingdom; 5Bristol-Myers Squibb, Madrid, Spain

Background: The HLA class II Shared Epitope (SE) is a known Rheumatoid Arthritis (RA) risk allele linked to autoantibody production and disease progression. The recent Early AMPLE study suggests an enhanced treatment benefit of abatacept (ABA) over adalimumab (ADA) in SE positive patients with early seropositive RA. Economic implications beyond the trial follow-up duration are unknown.

Objectives: To estimate the cost-effectiveness of ABA vs ADA in biologic-naive RA patients seropositive for anti-citrullinated protein antibody and rheumatoid factor based on the Early AMPLE study.

Methods: We developed a microsimulation model to estimate clinical response, medical cost, quality of life and survival from a Spanish payer perspective. The model captures the patient’s disease and treatment journey using response outcomes and the Health Assessment Questionnaire (HAQ) score. Patients who fail to respond switch to the next treatment line. Six treatment lines are included to capture a lifetime horizon. Responding patients (ACR50 and EULAR response) achieve an improvement in their HAQ score. Patient mortality was modelled as a function of HAQ. For both the overall Early AMPLE population and SE+ patients, incremental monthly cost per response over 2 years and incremental cost per QALY over a lifetime were estimated. Costs were based on local tariffs in Spain.

Results: Baseline characteristics for the Early AMPLE (n=80) and the SE+ (n=61) patients were well balanced between the treatment groups. Compared to ADA, the ABA cohort had a lower cost per response and the difference was more pronounced in the SE+ population, compared to the entire Early AMPLE population for both the response criteria (Table 1). Compared with ADA, the ABA cohort showed greater quality adjusted life years (QALY’s) gains, and a modest increase in cost due to a prolonged time on treatment (Table 2). The incremental cost per QALY over a lifetime fell below commonly used thresholds in Spain (25-60 thousand Euros per QALY).

Conclusion: Compared with ADA, ABA is a cost-effective alternative and is associated with a lower 2 years cost per response for both populations. The economic benefit and quality of life gain is greater in a SE+ patient population.

Background: Biological therapies have revolutionized the management of rheumatic diseases. This study analyzes the paradoxical autoimmune inflammatory manifestations that these therapies can induce. They are described as paradoxical because these are diseases in which the same biological drugs have proven effective.

Objectives: The aim of this study is to carry out a descriptive analysis of paradoxical biologics-induced autoimmune manifestations.

Methods: A retrospective research was carried out during January 2017 and March 2018 at Hospital Universitario Donostia. Computerized medical records were reviewed. The following variables were recorded: underlying disease; type of developed manifestation; the triggering biologic drug and its duration; concomitant treatment with disease-modifying antirheumatic drugs (DMARDs), previous biological treatments; the adopted measure and the resolution of the complication or not.

Qualitative variables are recorded in absolute value and in percentage. The quantitative variables are recorded with the mean and standard deviation. The data has been analyzed with the SPSS Statistics 20 program.

Results: Twenty-six cases were analyzed. The most common triggering drugs were infliximab (30.8%), adalimumab (30.8%) and etanercept (15.4%). The most common underlying diseases were spondyloarthritis (42.3%), rheumatoid arthritis (34.6%) and Crohn's disease (11.5%). The most developed complications were cutaneous affectations (76.9%), psoriasis specifically.

Conclusion: Infliximab and adalimumab are the drugs that presented the most paradoxical manifestations, probably because they are the oldest and most used ones. The difference found in previously used biologics, could be due to the fact that new drugs are less frequently presented as the first option. Psoriasis is the most frequently developed complication. The difference found in the number of abandonments of the biologic treatment and the solution of the complication might be more associated with the complication itself, rather than with the responsible molecule. There is no consensus on the measures to be taken when facing the complication. The severity of the manifestation should be assessed, as well as the control of the underlying disease. Most complications resolve overtime.

<td></td>
</tr>
</tbody>
</table>

Background: Sarcoidosis is an inflammatory disease which can affect multiple organs. The most frequent affected organs are lungs, skin and eyes (1-5). Ocular involvement is a severe complication.

Objectives: To assess the association of ocular sarcoidosis with other clinical domains.

Methods: Study of a large cohort of systemic sarcoidosis from a single tertiary university hospital. All consecutive patients were diagnosed with systemic sarcoidosis from January 1, 1999 to January 1, 2019 according the ATS/ERS/WASOG criteria (6).

Results: 41 (22 women/19 men) of 383 (10.7%) patients had ocular involvement, mean age 44.8±16 years. Lung was the most common affected organ associated with ocular sarcoidosis (n=36; 87.8%) followed by skin (n=14; 34.1%), joints (n=12; 29.3%) and neurological affection (n=8; 19.5%). Ocular sarcoidosis presents a higher percentage of renal and neurological affection compared to organs affected in general sarcoidosis of our larger cohort (12% vs 6% and 19.5 vs 7%; respectively) (FIGURE).

Conclusion: The proportion of clinical domains affected in ocular sarcoidosis is mostly similar to global sarcoidosis, except the neurological (which almost is threefold) and renal (which doubles) affection. Hence, the importance of being aware of neurological and renal complications when ocular affection is present.

AB1208 ADHERENCE TO TREATMENT AND DISEASE ACTIVITY ON RHEUMATOID ARTHRITIS

1Hospital Universitario “Dr José Eleuterio González”, Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico; 2Hospital Universitario “Dr José Eleuterio González”, Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico

Background: For treating Rheumatoid Arthritis (RA) it’s clear that Treat to Target has presented the best strategy. The best outcome for patients has been attained by accepting clinical remission as the final objective in treatment. The development of new drugs for the treatment of RA has dramatically modified the approach clinicians have on the disease, however, the treatment of inflammatory conditions represents a challenge due to the multiple factors that can affect its response. It is known that non-adherence represents an increase in mortality, morbidity and healthcare costs. Emphasis should be made on one of the most simple and effective variables that impact the effectiveness of treatment: adherence to treatment itself.

Objectives: This work aimed to evaluate the impact of methotrexate adherence on treatment outcome in patients with RA.

Methods: An observational, cross sectional study was performed using medical records from the Rheumatology Clinic at University Hospital from UANL. Jose Eleuterio Gonzalez, Monterrey, Mexico; the data was collected from 03/16/2018 to 01/29/2020. RA patients visits included fulfilled the 2010 ACR/EULAR classification, had their disease activity measured by Disease Activity Score 28 ESR (DAS28 ESR) and were treated with methotrexate as their primary disease modifying antirheumatic-drug (DMRAD). Patient disease activity was classified in 4 groups according to the DAS28 ESR score as <2.6 remission, 2.6-3.2 low activity, >3.2-5.1 moderate activity, >5.1 high activity. Adherence to medication was evaluated utilizing a self-reported assessment that was applied per patient’s visit. Patients were classified into 4 groups according to the percentage of the prescribed doses of Methotrexate that they abided to. Statistical analysis was performed using IBM SPSS 21 statistical package. Descriptive analyses were performed with frequencies (%) and the correlation between the calculated disease activity versus patient adherent to treatment was calculated using Pearson correlation coefficient. P-values <0.05 were considered statistically significant.

Results: A total of 795 patients visits were included. They were 92.33% female, mean (SD) age was 52.44 (±12.99) (Table 1). The most frequent routes for methotrexate were Oral 603 (75.84%), Subcutaneous 113 (14.21%) and Intramuscular 79 (9.93%). A significant correlation r (795) = -0.183, (p<0.001) was found between Disease Activity according to DAS28 ESR and Adherence classification according to prescribed doses taken

</table>

Conclusion: Adherence to treatment with methotrexate therapy has a direct impact on RA treatment outcome. The evaluation of adherence to the prescribed treatment should be addressed before modifications in DMRAD therapy in patients with Rheumatoid Arthritis. Before considering treatment failure in a patient treated with methotrexate, adherence to treatment must be evaluated.
According to our results, self-reported adherence appears to be a cost and time effective method to care for patients.

AB1209 A SYSTEMATIC REVIEW ON THE EFFECT OF DMARDS ON FERTILITY IN RHEUMATOID ARTHRITIS

Background: Patients with rheumatoid arthritis (RA) seem to experience a diminished fertility. Reasons for this lowered fertility are insufficiently defined and probably multifactorial. Although the effect of DMARDS on pregnancy outcomes have been studied, there is a lack of data on the effect of DMARDS on the fertility of patients with RA.

Objectives: To evaluate all studies that concern an effect of DMARDS on the fertility of men and women with RA in a systematic review.

Methods: A search was conducted at 18/10/2019 in three databases including Embase, Pubmed (Medline) and Web Of Science with specific search strings for each database, constructed with the help from a health sciences librarian. We included studies involving women or men diagnosed with RA, of fertile age (18-45 years) and on a DMARD therapy, with as outcome a fertility parameter. Systematic reviews, meta-analyses, case reports, case series and animal studies were excluded. Studies not in English or Dutch or written more than 15 years ago were excluded. Article selection was firstly based on title/abstract (double blind, two researchers, LB and IS) and then full text (two researchers, LB and IS). In case consensus could not be reached, a third researcher (ODC) was consulted. The references of included articles were reviewed ("snowballing") to include and minimize the missing articles. A quality check of the included full text papers was performed using the CASP Appraisal Checklists. A chart was made based on outcomes of interest.

Results: After duplicate removal, 9030 articles were found. After title/abstract screening, 82 articles remained. After full text screening, 4 articles could be retained. No additional studies were found through snowballing. Only studies about women could be included, as the evidence found for men was all in papers with exclusion criteria for our systematic review (e.g. case reports). Table 1 summarizes these papers. The included studies investigated the following DMARDS: methotrexate (MTX), certolizumab pegol (CZP), etanercept (ETN) and sulfasalazine (SSZ). No detrimental effects of these DMARDS on fertility, defined as time-to-pregnancy (TTP), anti-Müllerian hormone serum level or presence of a history of infertility, were reported.

Conclusion: This systematic review underlines the knowledge gap on the effect of DMARDS on fertility in human studies. Only 4 studies on women, and no studies on men were found. In the 4 included studies, DMARD treatment, even with MTX in contrast to general belief, had no harmful effect on fertility, probably because disease activity was better controlled with DMARD therapy. However, effects of other RA medication such as NSAIDs were excluded. More research is needed to improve guidance for patients with RA with a child wish.

AB1210 THE IMPACT OF EXAMINATION STRESS ON AUTOIMMUNE DISEASES AMONG UNIVERSITY STUDENTS

F.ayed1, E. Abdelkarim1, M. Morsy2, 1. Alexandria University Student Hospital, Rheumatology and Immunology Unit, Alexandria, Egypt; 2. Alexandria University Main Hospital, Alexandria, Egypt

Background: Stress is a risk factor of various diseases including autoimmune diseases. Autoimmune diseases are one of the leading causes of morbidity in young adults. Examination stress is a main concern nowadays due to the study style, lack of preparation, doctor-student relationship and family pressure. The previous studies declared that stress may cause neuroendocrinial changes leading to immune dysregulations and cytokines production.

Objectives: The aim of study is to scope the light on the importance of stress as a predisposing factor in autoimmune disease flares particularly Examination stress.

Methods: A three-year (2017-2019) cross-sectional prospective study conducted on 1369 students who presented to the Alexandria University rheumatology clinic during examination. Clinical assessments, routine investigations, activity markers, activity indices, stress and anxiety questionnaires and perceived stress scale (PSS) were applied to all patients during consecutive visits.

Results: Through 5800 visits in three years during examination sessions, patients age ranged from (17-25 years) with 76% females and 24% males. They grouped into SLE (31.3%), Rheumatoid arthritis (RA) (37.28%), Fibromyalgia (13.91%), FMF (2.63%), Ankylosing Spondylitis (1.75%), Psoriatic arthritis (0.73%), systemic sclerosis (0.56%), and undifferentiated connective tissue (1.73%). According to SLE patients, 43.92% were newly diagnosed whilst 54.16% of previously diagnosed SLE presented with Flare in particular lupus nephritis (56.33%), arthritids (43.22%), hemolaligic (49.76%) and serositis (21.36%). Interestingly, RA patients who newly diagnosed were 35.16% of total RA patients while 42.42% of previously diagnosed RA patients presented with moderate and high high DAS28 due to incompliance with treatment in (64.37%) of patients, (11.53% on biological, 88.47% on conventional treatment). In addition, (49.36%) of FMF presented in recent attacks. It was also found that Arthralgia, bone aches and sleep deprivation are the main complaints. Concerning, A High perceived stress scale (PSS) was associated with High DAS28 and SLEDI-2K scores, (r = 0.723, 0.865) (P<0.001).

Conclusion: Examination stress is one of triggering factor for autoimmune disease flares. It is associated with high disease activities and ruthless outcomes.

PREVALENCE OF CAROTID SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH PSORIATIC ARTHRITIS VS RHEUMATOID ARTHRITIS: A CASE CONTROL STUDY

D. Á. Galzarra-Delgado1, J. R. Azpírid-López2, J. I. Colunga-Pedraza1, D. E. Flores Alvarado1, O. Ilizaliturri Guerra1, P. F. Frausto Lerma1, A. Pérez Villar1, M. A. Reyes Soto1, I. C. Zárate Salinas1, A. C. Garza Acosta3, Hospital Universitario Dr José Eleuterio González, Rheumatology Department, Monterrey, Mexico;1 Hospital Universitario Dr José Eleuterio González, Cardiology Department, Monterrey, Mexico;2 Hospital Universitario Dr José Eleuterio González, Radiology Department, Monterrey, Mexico

Background: Rheumatic diseases such as Psoriatic Arthritis (PsA) and Rheumatoid Arthritis (RA) are associated with increased morbidity and mortality, mainly due to cardiovascular causes. Cardiovascular outcomes in patients with PsA and RA cannot be completely explained by traditional cardiovascular risk factors, suggesting that the systemic inflammation that characterizes these diseases may have an important role on accelerated atherosclerosis.

Objectives: To compare carotid intima-media thickness (cIMT) and asymptomatic carotid plaque (CP) prevalence, between patients with PsA, RA and controls.

Methods: Cross-sectional observational study. Seventy patients, aged 35-75 years, with PsA and RA who fulfilled the CASPARR and ACR/EULAR 2010 classification criteria, respectively, who were active on a cardio-rheuma preventive clinic were recruited, matched with 70 healthy controls. All groups underwent a noninvasive examination using B-mode ultrasonography of the right and left common carotid artery. CP was defined as a focal narrowing ≥0.5 mm of the surrounding lumen or cIMT ≥1.2 mm; hyperplasia of the carotid intima was defined as cIMT ≥ 0.9 mm to 1.1 mm. Descriptive data were analyzed by continuous and categorical variables. Continuous variables with normal distribution are shown as mean ± standard deviation (SD), and non-normal distribution as median and quartiles (25q-75q). ANOVA, Kruskal-Wallis, χ2 and Mann-Whitney U were used to compare data. A p value ≤0.05 was considered statistically significant. Statistical analysis was done using SPSS version 24 (IBM Corp., Armonk, NY, USA).

Results: Clinical and demographic characteristics are shown in Table 1. The global prevalence of carotid atherosclerosis was 25.7% and 38.6% in RA and PsA respectively, and 27.1% in controls (p=0.170). Intimal hyperplasia was found in 20%, 12.9% and 0% in RA, PsA and controls (p=0.001), respectively (Table 2).

Conclusion: This study shows the high prevalence of asymptomatic atherosclerosis in RA and PsA compared to general population. Even though it was shown a higher prevalence of CP in PsA, subclinical atherosclerosis in RA patients may have an increased clinical significance. The presence of carotid plaque between groups was not statistically significant. We observed increased prevalence of carotid intimal hyperplasia in RA and PsA compared with age-matched controls. We emphasize the value of ultrasonography in the detection of early atherosclerosis lesions.

PREVALENCE OF CAROTID SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH PSORIATIC ARTHRITIS VS RHEUMATOID ARTHRITIS: A CASE CONTROL STUDY

D. Á. Galzarra-Delgado1, J. R. Azpírid-López2, J. I. Colunga-Pedraza1, D. E. Flores Alvarado1, O. Ilizaliturri Guerra1, P. F. Frausto Lerma1, A. Pérez Villar1, M. A. Reyes Soto1, I. C. Zárate Salinas1, A. C. Garza Acosta3, Hospital Universitario Dr José Eleuterio González, Rheumatology Department, Monterrey, Mexico;1 Hospital Universitario Dr José Eleuterio González, Cardiology Department, Monterrey, Mexico;2 Hospital Universitario Dr José Eleuterio González, Radiology Department, Monterrey, Mexico

Background: Recent introduction of immune checkpoint inhibitors (ICIs) revolutionized oncological guidelines. Immune-related adverse events (irAEs) may occur in as many as 85% of patients (10% with toxicity grade 3/4), but detailed epidemiology of irAEs is still lacking, mostly because of data collection and analysis vary widely.

Objectives: The purpose of our study is to establish a prospective cohort of patients treated with PD-1/PD-L1 inhibitors in order to determine incidence, risk factors and characteristics of irAEs in a real-world setting.

Methods: We conducted a prospective cohort study enrolling patients receiving anti-PD-1/PD-L1 agents for the treatment of metastatic or locally advanced non-small cell lung cancer, renal cell carcinoma, squamous cell carcinoma of the head and neck, Hodgkin lymphoma. Detailed recommendations have been implemented for cases fulfilling criteria for suspected irAEs, including procedures for evaluation and diagnosis, specific treatments and rules for drug discontinuation. IrAEs have been defined and graded according to Common Terminology Criteria for Adverse Events vs 5.0. Management strategies have been adapted by a multidisciplinary panel, basing on the oncological guidelines, which represent the current best clinical practice. AEs screening, physical examination, ECG and clinical laboratory evaluation have been performed at baseline visit and follow up (4, 8, 12 weeks).

Results: Fifty-two patients have been enrolled from Jan 2019 to Dec 2020. Characteristics are reported in the Table below. Twelve patients developed irAEs (23%), 6 treated with nivolumab, 4 with pembrolizumab, 1 with atezolizumab and 1 with durvalumab. Mild-to-moderate (G1-G2) irAEs were hepatitis, hypothyroidism, III-V-VII cranial nerve palsy, polymyalgia-like syndrome, skin psoriasis and interstitial pneumonia and myositis occurred. One patient developed three different irAEs. Median time of onset was 4.5 weeks. IrAEs were successfully treated according to established guideline, but 4 patients stopped anti-neoplastic therapy due to irAEs and 11 for disease progression. Five patients died.

Conclusion: Cancer patients receiving PD-1/PD-L1 agents are being prospectively followed. Preliminary results confirm that 1/4 patients may develop irAEs. Innovative tools are required in order to manage irAEs, prevent potential relapse and avoid useless interruption of therapy. Further research needs to get insights into pathophysiological mechanisms and risk factors.

DIFFERENT IMMUNOSUPPRESSIVE REGIMENS WITH NO EFFECT ON INFLUENZA-LIKE ILLNESS

M. I. Freixa1, H. Inaciò1, M. Amaraì, M. Martins2, C. Costa3, M. Moitinho3, H. Gruner2, A. Almeida4, P. Barreto5, S. Pinheiro5. 1Hospital Pulido Valente, Lisboa, Portugal; 2Hospital Santa António dos Capuchos, Lisboa, Portugal; 3Hospital Curry Cabral, Lisboa, Portugal; 4Hospital de Santa Marta, Lisboa, Portugal; 5Hospital General Mancha Centro, Ophthalmology, Alcázar de San Juan, Spain; 6Hospital Universitario Infanta Sofía, Rheumatology, San Sebastián de los Reyes, Madrid, Spain

Background: Autoimmune disease (AID) has been associated with increased risk of influenza and influenza-like illness (ILI) and its worse clinical outcomes complications.

Objectives: We aimed to assess the influence and difference of several immunosuppressive (IS) treatments in the incidence of ILI, including glucocorticoids (GC), classic DMARDs and biologic DMARDs.

Methods: We conducted a cross-sectional study in two autoimmune clinics. Patients were invited to answer a survey reporting ILI symptoms between October 2017 and March 2018. ILI definition was considered according to the European Center for Disease Control. Data regarding current IS, diagnostic, disease activity, comorbidities, and vaccination coverage were collected from electronic registry. Patients with history of cancer, HIV, IGV therapy, or lack of information were excluded. Univariate and multivariate logistic regression analysis were used to access predictors of ILI.

Results: We included 109 patients, with mean age 51 years and 81% female gender. The majority of patients had autoimmune arthropathy (n=54) or a connective tissue disease (n=44). Active disease was present in 39% of patients. IS treatment was: GC 31%, classic DMARD 44%, biologic DMARD 28%. Vaccine coverage was: GC 31%, classic DMARD 44%, biologic DMARD 28%. ILI definition was considered according to the European Center for Disease Control. Data regarding current IS, diagnostic, disease activity, comorbidities, and vaccination coverage were collected from electronic registry. Patients with history of cancer, HIV, IGV therapy, or lack of information were excluded. Univariate and multivariate logistic regression analysis were used to access predictors of ILI.

Conclusion: There was no difference in risk of ILI within different IS treatment regimens, although GC may increase the risk. The study is limited by the subjectivity of the ILI survey and the small size of the sample. The stratification of influenza risk will help in designing better vaccine coverage strategies in this population.

DOI: 10.1136/annrheumdis-2020-eular.5975
Background: Considerable epidemiological variations in prevalence of Behçet's disease (BD) have been reported. These disparities may either reflect geographical differences, methodological artifacts, changes over time or random fluctuations. In Spain, published BD's epidemiological studies are scarce.

Objectives: To study epidemiological and clinical domains of BD in a well-defined population of Northern Spain, as well as, to compare results with other regions.

Methods: We included all consecutive 111 patients, diagnosed of definitive or possible BD by expert rheumatologists between 1980 and 2019. Two Classification criteria were applied: a) International Study Group (ISG) for BD (Lancet. 1990; 335:7079-80), and b) International Criteria for BD (ICBD) (J Eur Acad Dermatol Venereol. 2014; 28:338-47). In addition, a literature review of Medline publications was carried out.

Results: In our study, prevalence was higher than in most European populations regardless of the diagnostic criteria applied. Incidence was low (expert opinion: 0.021, ICBD: 0.016, ISG: 0.012). Mean age at onset (36.8±13.2) and gender distribution (55.9% females) were similar to other countries. Pathergy test was performed in 9% of patients giving low results (25.2%). Clinical domains' frequency was in line with other regions except vascular and gastrointestinal involvement, which were lower. (TABLE)

Conclusion: BD's prevalence in Northern Spain is higher than in most European populations. These differences likely reflect a combination of true geographic variation, methodological artifacts as well as the easy access to Public Health System and its efficiency. In contrast, clinical phenotypes are similar to other regions.

AB1216 INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES (IPAF): A SINGLE CENTER, PROSPECTIVE STUDY

M. Karampeil, K. Thomas, D. Tseronis, M. A. Aggelakos, D. Kassara, K. Havatza, S. Vlouta, D. Niklopoulos, A. Pieta, V. Tzavara, P. Katsambil, D. Boumpas, T. Karageorgas, General Hospital Korgialenio-Benakio HRC, Department of Internal Medicine, Athens, Greece; Attikon University Hospital of Athens, 4th Department of Internal Medicine, Athens, Greece; Attikon University Hospital of Athens, 4th Department of Internal Medicine, Athens, Greece

Background: Interstitial pneumonia with autoimmune features (IPAF)1 describes a group of patients with interstitial lung disease and autoimmune features who do not meet the classification criteria for a specific connective tissue disease. Limited data regarding IPAF are available so far.

Objectives: To identify the epidemiological and clinical characteristics of patients with IPAF and to observe disease progression, response to treatment and frequency of infections in 1-year follow-up period.

Methods: Thirty-nine patients from Attikoni University Hospital of Athens fulfilling the IPAF criteria were enrolled. Clinical and laboratory findings, comorbidities,
medications, pulmonary outcomes assessed with repeated pulmonary function tests (PFTs) and chest HRCT and complications in a 1-year follow-up period were documented for each patient. Univariate models were performed in order to identify determinants of infection and clinically significant difference in PFTs (defined as change of ≥ 10% in FVC and/or ≥ 15% in DLCO).

Results: The mean age at the time of IPAF diagnosis was 63.2 (±11) years and 62% of the patients were female. The most common clinical features included in the IPAF criteria were arthritis (82%) and Raynaud’s phenomenon (28%). A mor-billiform and/or polymorphic rash of the face, neck and extremities (not included in the IPAF criteria) was noted in 54% of patients. ANA (59%) and anti–Ro (21%) were the most common auto-antibodies. Non-specific Interstitial Pneumonia (NSIP) was the most prevalent radiological pattern (61.5%) as shown in table 1. Treatment comprised corticosteroids and immunosuppressants including hydrox-chloroquine, methotrexate, azathioprine, mycophenolate and cyclophospha-mide. PFTs following treatment at 6 and 12 months from baseline showed a trend of improvement (Table 2, p> 0.05). At 1 year from baseline, 20.5% of patients showed a clinically significant deterioration while 25% had a clinically significant improvement. Infections were observed in 23.1% of patients during the first semester and in 12.8% during the second semester of the follow-up period. All were respiratory tract infections and two patients (5.1%) required hospitalization. All infections occurred in patients with non-UIP pattern (p=0.02) which might be attributed to higher doses of corticosteroids used in these patients (mean initial prednisolone dose = 27 (±18) mg/d in patients with non-UIP pattern versus 17 (±16) mg/d in patients with UIP pattern, p=0.4).

</tr>
</tbody>
</table>

Conclusion: Rash is a common feature in IPAF and may be considered for inclusion into IPAF criteria. A trend of improvement in PFTs and a significant risk of respiratory tract infections mainly in the first semester of treatment and in patients with non-UIP radiological pattern were observed. Langer prospective studies are warranted in order to elucidate IPAF’s prognosis and to identify effective management approaches.

AB1217
THE EFFECT OF PROPHYLACTIC DOSE OF TRIMETHOPRIM-SULFAMETHOXAZOLE ON SERUM CREATINE IN JAPANESE PATIENTS WITH CONNECTIVE TISSUE DISEASES

R. Kawano1, R. Rokutanda2, M. Okada3, 1Juntendo University Graduate School of Medicine, Department of Rheumatology, Tokyo, Japan; 2Kameda Medical Center, Department of Rheumatology, Chiba, Japan; 3St. Luke’s International Hospital, Immuno-Rheumatology Center, Tokyo, Japan

Background: Trimethoprim-sulfamethoxazole (TMP/SMX) is an effective anti-biotic for prevention of pneumocystis pneumonia (PCP) in immunocompromised patients with various connective tissue diseases (CTD). At the normal dose of TMP/SMX, trimethoprim (TMP) component inhibits tubular creatinine secretion, leading to a rapid, but ultimately reversible, increase in serum creatinine. However, at prophylactic dose, the effect of TMP/SMX on creatinine in patients with CTD is not clear.

Objectives: We conducted this study to evaluate the effect of prophylactic dose of TMP/SMX on serum creatinine in patients with CTD.

Methods: This was a retrospective cohort study in which all patients with CTD, treated with prophylactic dose of TMP/SMX during the period between 2004 and 2018, were included, while patients with acute kidney injury due to other causes, were excluded. Retrospective medical chart review was performed to collect the following data, from the baseline through 12 weeks: baseline patient characteristics, serum creatinine (SCr), creatinine clearance (CCr), urine test, serum electrolytes, and level of SCR elevation after initiation of prophylactic dose of TMP/SMX from baseline, within 12 weeks. Using single and multiple regression analyses, we explored the risk factors that affected the SCR elevation value.

Results: A total of 272 patients, comprising 186 females, at an average age of 56±18 years, were included in the present study. Based on the medical chart review, this cohort was scored under the following categories: rheumatoid arthritis (RA) n=78, systemic lupus erythematosus (SLE) n=76, Vasculitis n=39, polymy-algia rheumatica/ giant cell arteritis (PMR/GCA) n=29, systemic sclerosis (SSc) n=32, polymyositis/dermatomyositis (PM/DM) n=10, mixed CTD (MCTD) n=5, and others n=56. Their average baseline creatinine level before treatment was 0.67 ± 0.25 mg/dL. They were administered with a mean dose of TMP comprising 99.2 ± 34.4 mg/day, which elevated the mean SCR level by 0.07 ± 0.12 mg/dL. Approximately 85% of the patients continued with the TMP/SMX treatment for 12 weeks, and only 5 (2%) showed creatinine elevation by more than 0.3 mg/dL. They were also administered with prednisolone at an average dose of 36.9 ± 92.3 mg/day.

For multiple regression analyses, the following variables were included: age, baseline SCR, use of loop diuretics, use of spironolactone, dose of TMP/SMX, use of non-steroidal anti-inflammatory drugs, and past history of diabetes mellitus. Baseline CCr and advanced age were independent risk factors. Regression coefficients and p values for age and CCr were 0.0018 (95% CI; 0.00083 – 0.0027) and p=0.00028; and 0.0007 (95% CI; 0.0003 – 0.0010) and p=0.00038, respectively.

Conclusion: In this study, we demonstrated that prophylactic dose of TMP/ SMX elevates SCR by 0.07 ± 0.12 mg/dL on an average. Prophylactic dose of TMP/SMX rarely elevated the creatinine level significantly. Thus, based on our findings, other causes of renal impairment may be considered, if the patients administered with low-dose TMP/SMX show creatinine elevation by more than 0.3 mg/dL.

ADHERENCE TO THE MEDITERRANEAN DIET IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS, MULTICENTER STUDY

AB1219

Background: The Mediterranean diet (MD) has proven beneficial in a large number of chronic diseases. The relationship between the MD and rheumatic diseases is complex and there are few studies that have studied this relationship. These show that there could be a positive association between adherence to the Mediterranean diet (MD-A) and a lower prevalence of OA. In the case of RA, it has been proposed that the MD could reduce pain and improve functionality.

Objectives: To determine the MD-A diet of patients with RA and OA, and compare it with that of healthy subjects.

Methods: Multicenter, cross-sectional, observational study. Patients who attend the rheumatology outpatient and meet the ACR / EULAR 2010 criteria for RA and ACR for OA of hands, knees or hips are included in the study. The healthy recruited among health personnel and companions of patients who do not live in the same address as the patient. The study is being carried out in the rheumatology consultations of two Hospitals and an outpatient center with specialized care. All participants have answered a survey of 14 questions (MEDAS-14), based on the Predimed study, which assesses MD-A. Fisher’s exact test and the Mann-Whitney U test have been used to assess statistical significance.

Results: There have been 279 surveys (132 RA, 82 OA and 65 healthy). The MD-A in patients with RA is lower than in healthy (6.26 vs. 7.15, p < 0.05). Patients with OA also have less adherence to the MD than healthy ones but this difference is not statistically significant (6.85 vs. 7.15, p = 0.05). The proportion of patients with RA and OA who consume 2 or more servings of vegetables daily is lower than that of healthy subjects (RA 20%; OA 13% and healthy 34%, p < 0.05). The proportion of RA and OA that eats more than 3 weekly servings of nuts compared to healthy is also lower (RA 21%, OA 17%, healthy 35% p < 0.05). The proportion of RA and OA that consume less than 1 serving of butter is lower than that of healthy (RA 86%; OA 82% and healthy 98%, p < 0.05). The proportion of RA that consumes 3 or more servings of legumes per week is lower than healthy (23% vs 40%, p < 0.05). These differences between the OA group and healthy are not appreciated. The consumption of more than three pieces of fruit daily is more frequent in OA than in healthy (45% vs. 26%, p < 0.05).

Conclusion: The MD-A diet quantified by MEDAS-14 in subjects with RA and OA is lower than in healthy subjects, being significant in RA. Patients with RA and OA eat less vegetables and nuts but the intake of butter is higher. The RA group consumes less legumes than healthy ones. Patients with OA eat more fruit than healthy ones, this is the only food in the MD valued by MEDAS-14 that is consumed in a lower proportion in healthy ones. Longitudinal intervention studies are necessary to assess whether the differences observed in this study have any causal relationship.
Background: Survival in ANCA-associated vasculitis (AAV) has improved substantially in the last fifty years, but Australian data and studies with a control population are scarce.

Objectives: The aim of this study was to compare the all-cause mortality rate between patients with AAV and matched controls in Western Australia.

Methods: A retrospective population-based cohort study conducted using the Western Australia Health Data Linkage System (WADLS) for patients with a diagnostic code for AAV (International Classification of Diseases (ICD)-10-AM M30.1, M31.3 and M31.7). We included 240 patients with AAV (mean age 57.3 ± 16.69, 48.8% males) who had a hospital admission or emergency department visit between 1 January 2000 and 31 December 2014 and 4406 controls matched for age and sex. Death details were obtained from the WA Death registry. Mortality rates per 1000 person-years (MR) for AAV patients and controls were compared by mortality rate ratios (MRRs) with 95% CI. Kaplan Meijer survival estimates were analyzed by log-rank test.

Results: During a mean follow-up of 6.58 years (3.37, 11.25) 83 incident AAV patients (34.6% died, giving a mortality rate of 48.13 per 1000 person-years (95% CI 38.33, 59.66). This was 82% higher overall than in controls (MRR 1.82, 95% CI 1.46, 2.26, P < 0.0001), while the MRR for males with AAV was 2.28 (95% CI 1.46, 2.26; P < 0.0001) and for females 1.43 (95% CI 1.01, 2.02; P = 0.0267). Survival estimates at one (90.5%) and five years (75%) were significantly lower in AAV patients than controls.

Conclusion: Over the last fifteen years, the mortality risk for AAV patients remains significantly increased compared with matched controls and more so for male than female AAV patients. Together with the reduced one- and five-year survival rate, this indicates the need for further improvements in initial disease management in order to reduce the risk of death in AAV.

Table. Mortality rates (MR) per 100 patient years and Mortality rate ratio (MRR) with 95% CI in patients with AAV and controls

Disease activity

Background: Randomised controlled trials (RCTs) are considered the gold standard in clinical research. Their results, however, may not be generalizable to patients in routine care. Together with methotrexate, glucocorticoids (GCs) constitute the mainstay of therapy for many patients with rheumatoid arthritis (RA), but it is unclear whether trial evidence is actually generalizable to real-world patients.

Objectives: This review assesses to what extent RA patients participating in GC-RCTs differ from RA patients taking GCs in routine care.

Methods: This study was registered with PROSPERO (CRD42019134675). MEDLINE was searched for RCTs and, as comparators, cohort studies in RA evaluating systemic GC therapy. Cohorts were not allowed to exhibit explicit selection mechanisms concerning gender or age. Random-effects meta-analyses combined descriptive baseline characteristics that may modify the benefit-risk-ratio of various RA therapeutics. Meta-analyses were stratified by study contrast (RCT and CS). Stratified estimates were subsequently compared.

Results: 55 RCTs and ten cohort studies (21,657 participants overall) were included. Twelve characteristics (related to general demographics and disease activity) were reported frequently enough to allow for comparative analysis. Compared to cohorts, RCT participants were younger (−4.7 [−7.2 to −2.1] years) and had somewhat higher erythrocyte sedimentation rates (12 [6 to 18] mm/h) than cohorts. In the other ten characteristics, estimates did not differ significantly. Numerically, cohort patients had more longstanding disease and slightly more favourable disease levels in core set variables. Comorbidities could not be assessed.

Conclusion: The results of our study suggest that evidence from RA GC-RCTs can be generalized to most patients in routine practice. We note that comorbidities—a frequent exclusion criterion for trial participation—could not be evaluated due to insufficient reporting. Our findings contrast with a similar study on RCTs investigating biologics in RA: There, trial participants were found to differ significantly in 4 out of 8 investigated baseline characteristics.4

LIPID PROFILE COMPARISON IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS: A CASE-CONTROL STUDY

D. A. Galarza-Delgado1, J. R. Azpíri-López2, I. J. Colunga-Pedraza1, A. Pérez-Villar1, I. C. Zárate Salinas2, P. F. Frausto Lerma1, M. A. Reyes Soto1, D. E. Flores Alvarado1, O. Iliázulituri Guerra1. 1Hospital Universitario Dr. José Eleuterio González, Rheumatology Department, Monterrey, Mexico; 2Hospital Universitario Dr. José Eleuterio González, Cardiology Department, Monterrey, Mexico

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are autoimmune diseases, in both diseases it has been described that the main cause of morbidity and mortality is cardiovascular (CV) disease. Dyslipidemia is the most recognized CV risk factor. An association is recognized between the concentrations of total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), total triglycerides (TG), atherogenic index (AI) and the risk of myocardial infarction (MI), stroke and fatal cardiovascular disease (CVD). The relationship between serum lipid levels and CVD risk is potentially paradoxical in RA but this relationship has not been clarified in PsA.

Objectives: To compare lipid profile between groups with RA, PsA and controls.

Methods: A cross-sectional observational study was designed, which included 95 patients between 45-75 years who fulfilled the CASP3AR classification criteria for PsA, 95 patients between 45-75 years who fulfilled the ACR / EULAR 2010 classification criteria for RA and 95 age-matched controls. Concentrations of CT, HDL-C, LDL-C, TG and atherogenic index were compared between the groups. Clinical measures were compared using one-way ANOVA or Kruskall-Wallis tests. Post-hoc analysis was performed with Bonferroni’s correction. A p < 0.05 was considered statistically significant. The data was analyzed using the SPSS version 25 software package.

Results: In our study, no significant difference in LDL-C was found between RA and PsA, however post-hoc analysis was performed where we found higher LDL-C levels among RA patients compared with controls (p = 0.025). RA patients had higher HDL-C than PsA patients (p = 0.006) but PsA had a higher HDL-C than controls (p = 0.007). TC/HDL-C was higher in PsA than RA and controls (p = 0.050). PsA patients were the group with the lowest LDL-C levels (p = 0.007). In contrast, RA were the groups with the highest HDL-C levels (p = 0.007). (Table 1).

*Data are reported in mean ± SD
**Data are reported in median (IQR)

Conclusion: A good discrimination between patients with or without CV events has been demonstrated by area under the ROC curve, particularly to SpA patients. In PsA, the sample was smaller, which represents a limitation in this study. SCORE >5% did not identify CV events, therefore sensitivity couldn’t be calculated. Overall, the algorithms studied presented a low sensitivity; underestimating CV risk. This could be explained since disease-related factors are not reflected in these scores. In our opinion, better algorithms are needed to accurately assess cardiovascular risk algorithms for SpA and PsA, since the majority of the events occur in patients with low-intermediate risk.

DOI: 10.1136/annrheumdis-2020-eular.5805
Background: Rheumatic musculoskeletal disorders (RMSDs) are a common cause of long-term pain and physical disability. In developed countries, RMSDs are a major cause of absence from work and thus have a big financial burden on the country economic status. Several studies have been published the incidence and prevalence of RMSDs in different world countries and found to be widely variable. Estimation of the extend of the problem of RMSDs in developing world, especially in rural economies will help better understanding of the risk factors that contribute to the initiation and extent of the problem of RMSDs in different world countries and found to be widely variable. Estimation of the economic status. Several studies have been published the incidence and prevalence of RMSDs in a rural population in Upper Egypt. To estimate the prevalence rate of RMSDs in a rural population in Upper Egypt has been estimated to be 16.22%. The most prevalent RMSDs are OA, STR and SD causing the greatest burden of the disease. The predictive risk factors of RMSDs have been reported in previous studies.

Methods: A cross-sectional based study was carried out and included 3988 subjects of population (2013 females and 1975 males). Mean age of patients was (46.89±15.25 yrs). They proceeded 4 phases of World Health Organization/International League of Associations for Rheumatology community-oriented program for control of rheumatic diseases survey questionnaire WHO-ILAR Community Oriented Program for screening of rheumatic diseases. Modified Health Assessment Questionnaire (HAQ) was used to assess the disability severity. Individuals suspected to have any rheumatic diseases were subjected to full clinical examination, laboratory and radiological investigations to reach a final diagnosis. They were classified according to appropriate criteria of diagnosis of diseases.

Results: A prevalence rate of RMSDs was 16.22%, more prevalence in females (10.38% vs. 5.84% for males, P=0.000). The mean age of patients with RMSDs were older (46.89±15.25 yrs) than healthy individuals (29.56±18.95 yrs) (P=0.0001) and with increasing age (≥45-≤ 55 yrs). The identified RMSDs were OA (8.5%), Soft tissue rheumatism (STR) (6.57%), spinal disorders (SD) (6.47%), fibromyalgia (FM) (0.60%), RA (0.30%), arthralgia (0.18%), SPas (0.15%), Pseudogout (0.08%), SLE (0.5%), JIA (0.03) and MCTD (0.03%). The prevalence rates for the majority of RMSDs were higher in females and with increasing age. About two thirds of the patients had grade II disability.

Conclusion: The prevalence rate of RMSDs in a rural population ≥15 years in Upper Egypt has been estimated to be 16.22%. The most prevalent RMSDs are OA, STR and SD causing the greatest burden of the disease. The predictive risk factors of RMSDs have to be assessed in future studies.

*Univariable logistic regression analysis. Cumulative at time of analyses, Chi-square test.

Conclusion: This preliminary study showed that AE with BET were more frequent as well as more severe compared to AE presented with OET in patients with rheumatic diseases using BIOBADAMEX data. Our study suggests that use of BET and comorbidities are associated with the development of AE. Follow up and inclusion of more participants is going on and will allow us to perform further analyses.

AB1230 PERIPHERAL ARTERY DISEASE AND JOINT PAIN IN TYPE 2 DIABETES PATIENTS, FROM ASSOCIATION TO CAUSATION

E. Shalaeva1, A. Shalaeva1, N. Dadabaeva1, K. Mirakhmedova1. 1Tashkent Medical Academy; Tashkent, Uzbekistan

Background: Type 2 diabetes mellitus (T2DM) and arthritis are considered two separate conditions. However, inflammation and metabolic changes play a major role in diabetes co-morbidity (1). The pathogenesis of the joint pain and stiffness in diabetes patients is not fully understood. Diabetic osteoarthropathy (neuropathic arthropathy) considers a quite rare condition (0.1-0.4% of diabetic patients), involving destructive, lytic joint changes (2). Interestingly, over 52% of diabetic patients have joint diseases, compare to only 27% without diabetes; and people with arthritis have over 60% higher risk of diabetes development (3).

Objectives: The purpose of the study was to determine the association between the lesions of low extremity arthritis (LEA) and the prevalence of arthritis (joint pain and stiffness) among patients with type 2 diabetes.

Methods: This is the pilot analysis of the musculoskeletal data obtained from the prospective cohort study of patients with diabetes complications 2013-2016 (179 consecutive T2DM pts undergoing transfemoral amputation (TFA) due to gangrene of lower limb (4,5), and 199 patients experienced balloon angioplasty (BA) of the LEA (without gangrene). The computer tomography angiography was performed, along with clinical, laboratory and instrumental examination. Functional class of joint lesions (hip, knee or foot) was obtained based on self-service and (un)professional activity.

Results: All observed patients had diabetic neuropathy. The affected extremity in all the patients undergoing TFA had critical arterial ischemia along with foot gangrene, knee/hip pain, stiffness and rigidity. The second extremity also had stenoses of popliteal, anterior or posterior tibial arteries and the severity of stenoses was positively correlated with the severity of muscle and joints pain (r=0.771, p<0.001).

Among 195 patients without gangrene of lower limb, BA was done on superficial femoral artery 46 (23.1%) patients, popliteal in 44 (22.1%), posterior tibial 54 (27.1%), arterial tibial 41 (20.6), and peroneal artery 14 (7%). At least 1 large and 1 small joint was affected per person. The correlation between the prevalence of joint pain/stiffness and peripheral artery stenosis of the same lower extremity in patients without gangrene was significant r=0.632, indicating a large positive relationship (approximately 39.9% of the total variance). A linear regression analysis was conducted to evaluate the association between the severity of artery lesions and the severity of joint functional class, F (1, 198) = 57.82, p<0.001, r = 0.791, p < 0.001. The 95% confidence interval for the slope was 0.71 to 1.29, which did not include the value of zero.

Conclusion: The results show that the more severe the peripheral artery stenosis was the more prevalent joint lesions are and worsen the function class. However, more studies are needed.

AB1231 2019 LUPUS CLASSIFICATION CRITERIA SCORE PREDICTS FUTURE LUPUS HOSPITAL ADMISSION

S. Suman1, M. Essa2, H. Rogers3, A. Lenert4, A. Stromberg5, W. Roberts6.

1University of Kentucky, Internal Medicine, Lexington, United States of America; 2Cairo University, Cairo, Egypt; 3University of Kentucky, Rheumatology, Lexington, United States of America; 4University of Iowa, Rheumatology, Iowa City, United States of America; 5University of Kentucky, Statistics, Lexington, United States of America

Background: There are several validated tools to quantitate lupus disease activity, end-organ damage and overall fragility. An algorithm to predict the hospitalization risk in lupus patients was proposed by Li et al (1). That algorithm was able to effectively screen patients at increased risk of hospitalization using EHR information only. Recently, the new 2019 Lupus classification criteria score has been noted to accurately predict 10 year mortality (2).

Objectives: To test the above 2 algorithms with potential to predict lupus related hospital admissions.

First, we attempted to validate the existing algorithm from the index study of Li et al to predict lupus hospitalization.

Second, we tested the 2019 lupus clinical classification score for its ability to predict hospitalizations.

Methods: A retrospective chart review was performed using EHR data collected from 2013 to 2018 at University of Kentucky (UK) Medical Center. Inclusion criteria were 18 years or older at first outpatient rheumatology appointment at UK, at least 3 outpatient rheumatology visits at UK, and ICD 9/10 code for Lupus. A total of 217 patients met inclusion criteria. Variables similar to the index study were extracted from patients’ first outpatient rheumatology visit at UK. Additionally, the new 2019 Lupus Classification Criteria score was calculated. Patients who were subsequently hospitalized, manual chart review was done to determine if the hospitalization was attributable to lupus or not.

Results: Table 1 shows differences between the variables predicting hospitalization in patients in this study (UK) and the Ohio State University (OSU) cohort from whom the admission predicting algorithm was derived (3). All the risk factors that were found to predict lupus hospitalization in the index study, failed to achieve a statistical significance in our validation study.

Table 1 Differences in the variables predicting hospitalization between Index and Validation Cohort

There was more success predicting lupus hospitalization using the 2019 lupus classification criteria score (CCS) (Figure 1). A CCS >19 predicted higher risk of lupus related hospitalization vs CCS < 19 over the ensuing 2 years (p=0.05).
and HLA genotyping was quantified by next-generation sequencing (Ref.1). The case, age and gender matched ACPA negative non-RA healthy subjects (n=236) (n=33, 11 subjects were ACPA positive and 22 ACPA negative respectively) as the who were ACPA positive non-RA healthy subjects (n=22) and patients with RA participated in the Nagasaki Island Study. At this point, we selected 291 subjects, of 4276 who have participated in the Nagasaki Island Study from 2016 to 2018. Methods: patients and healthy subjects regarding to ACPA and HLA-DRB1*SE. cohort, we have tried to investigate the difference of oral microbiota among RA ing examinations in high-risk subjects. Using the samples accumulated in this with systemic lupus erythematosus, Lupus (2018) 27, 1321–1328; Carneiro et al. A comparison of three classification criterion sets for Systemic Lupus Erythematosus – a study looking at links to outcome and mortality; Arthritis Care Res (Hoboken), 2019 Sep 10, doi: 10.1002/acr.24061 Disclosure of Interests: Saurav Suman: None declared, Mervat Elisa: None declared, Heidi Rogers: None declared, Aleksander Lenert: None declared, Arnold Stromberg: None declared, william roberts Shareholder of: Own Stocks of Pfizer and Novartis DOI: 10.1136/annrheumdis-2020-eular.1752

Figure 1. Kaplan- Meier Survival Analysis comparing the risk of hospitalization between the groups with 2019 lupus classification criteria score (CCS) of less than 19 (red) and more/equal to 19 (blue). A time-dependent effect, with the admission free survival curves crossing at two years (Figure 1), indicated a 1 out of 3 chance of lupus related admission during the first 6 months for a high CCS score > =19.

Conclusion: We failed to validate the EHR algorithm identifying patients at high risk for lupus hospitalization in our less severely affected cohort with fewer admission events to analyze. Nonetheless, “criteria counting” using the weightings of the 2019 lupus classification criteria was granular enough to make these case finding criteria themselves prognostic for future hospitalization risk. It is likely that existing EHRs, using protocols based upon classification criteria scores, are now capable of predicting survival, costs, and admissions automatically.

AB1232 ORAL DYSBIOSIS REFLECTS THE IMMUNOLOGICAL ALTERATION OF RA REGARDING TO ACPA AND HLA-DRB1*SE: NAGASAKI ISLAND STUDY

1. Nagasaki University, Nagasaki, Japan
2. National Institute of Public Health, Wako, Japan
3. Nagasaki University, Department of General Medicine, Nagasaki, Japan
4. Kyoto University, Kyoto, Japan

Background: Anti-citrullinated protein antibody (ACPA) production is observed in several organs even prior to the onset of rheumatoid arthritis (RA), and oral mucosa is considered to be one of the important tissues. The presence of HLA-DRB1*SE closely associates with ACPA production. Saliva is considered to reflect the oral microbiota including periodontal disease. Alteration of oral microbiota of RA becomes to be non-negligible by DMARDs treatment, however, the interaction of HLA-DRB1*SE, ACPA and oral microbiota of RA patients remains to be elucidated.

Objectives: The Nagasaki Island Study, which had started in 2014 collaborating in several organs even prior to the onset of rheumatoid arthritis (RA), and oral mucosa is considered to be one of the important tissues. The presence of HLA-DRB1*SE closely associates with ACPA production. Saliva is considered to reflect the oral microbiota including periodontal disease. Alteration of oral microbiota of RA becomes to be non-negligible by DMARDs treatment, however, the interaction of HLA-DRB1*SE, ACPA and oral microbiota of RA patients remains to be elucidated.

Objectives: The Nagasaki Island Study, which had started in 2014 collaborating with Goto City, is intended for research of the preclinical stage of RA, including "Dia-Test for RA," a saliva test for RA diagnosis done at Goto City.

Methods: Blood and salivary samples were obtained from 1422 subjects out of 4276 who have participated in the Nagasaki Island Study from 2016 to 2018. Treatment effectiveness and adherence was assessed at 12 months by a change in patient-reported outcomes (PROs), CRP and % drug survival. Differences in categorical and continuous data between males and females were assessed using the Pearson X2 test (or Fisher exact test, as appropriate), or Mann-Whitney test resp. This study was largely descriptive, and no statistical adjustments have been made.

Results: A total of 1602 RA, 1306 AxSpA, and 493 PsA patients were included. The difference in baseline characteristics between men and women starting TT are shown in table 1. Their response and adherence to TT after one year is shown in table 2.

Conclusion: When starting their first TT, males tended to have higher levels of CRP, while females were more often (ex)smokers and reported worse parame-

**MICRO-RNA 155 AND MIR-34A: POSSIBLE BIOMARKERS OF INFLAMMATORY BURDEN AND DISEASE ACTIVITY IN ANCA-ASSOCIATED VASCULITIS WITH RENAL INVOLVEMENT**

D. Bruno1, P. Cerasuolo1, C. Di Mario1, S. L. Bosello1,2, L. Gigante1, G. Grandaliano3,4, E. Gremese1,2.

**Background:** Predicting clinical outcomes in ANCA-related glomerulonephritis remains a major challenge. To date, there is no reliable biomarker able to predict renal prognosis in patients with ANCA-associated vasculitis (AAV). Micro-RNA (miRNA) are non-coding RNAs involved in the fine tuning of immune cells biology and this epigenetic modulation associates with different phenotypes and prognosis in diseases.

**Objectives:** To investigate the expression of miR-155 and miR-34a in kidney biopsies of AAV patients according with renal outcome.

**Methods:** Fifteen patients with AAV and renal involvement (mean age 63.0±13.3 years, disease duration 4.9±2.2 months), who underwent renal biopsy. Demographic, clinical and autoimmune parameters were recorded for each patient. Each kidney biopsy was classified according to the Banff Classification, Risk group (according to the ANCA Renal Risk Score) and the chronicity Classification of the Mayo Clinic's proposed score.

**Results:** MiR-155 and miR-34a expression was investigated in kidney biopsy tissue using the miNeasy FFPE kit (Qiagen). The quantitative expression of miR-155, miR-34a and housekeeping gene U1, used as control, was assessed by Real Time-PCR.

**Conclusion:** MiR-155 and miR-34a expression was correlated with histopathological and clinical-laboratory parameters. Each patient was followed for 12 months and renal outcome was considered according to KDIGO CKD Classification. Markers of inflammation (ESR, CRP) and urine analysis data were recorded at baseline and after 12 months.

**Results:** Six (40%) patients were p-ANCA positive and 9 (60%) c-ANCA positive. Eight patients (53%) also had pulmonary involvement. The mean baseline GFR was 30.7±28.8 ml/min/1.73 m² and 10 patients (66%) showed an active urinary sediment.

At disease onset, the mean expression of miR-155 was 9.5±2.11, while the expression of miR-34a was 13.1±46.2. Considering the autoimmune profile, kidney tissue of p-ANCA positive patients was enriched of miR-155 (21.5±38.3 fold) compared to c-ANCA positive patients (1.9±2.9 fold; p=0.001). Particularly, considering the renal function, kidney tissue of patients with greater impairment of renal function (KDIGO stage 5) was enriched of miR-155 (21.5±38.3 fold) compared to patients with less renal impairment (KDIGO stage 1-4) (4.7±8.16 fold, p=0.004).

Tissue expression of miR-155 and miR-34a did not correlate with the above-mentioned histopathological classifications.

After 12 months from kidney biopsy, 3(20%) patients had a worsening of renal function, 5 (33%) still presented elevated markers of inflammation and 3 (20%) still had proteinuria at urine analysis. At baseline, kidney tissue of patients with higher CRP plasma levels and proteinuria at follow-up presented higher expression of miR-155 (p=0.002 and p=0.001), whereas no significant differences were found about miR-34a kidney tissue expression.

**Conclusion:** MiRNAs may play a potential role in the pathogenesis of ANCA-related glomerulonephritis. MiR-155 kidney enrichment seems to mirror the disease inflammatory burden and activity at the onset and after 12 months representing a possible biomarker in ANCA vasculitis with renal involvement. This finding may represent the basis for further studies on miRNA expression in blood samples, aiming to identify a non-invasive biomarker of kidney damage, predicting disease's relapses and patients' prognosis.

**SALIVARY LEVEL OF CALPROTECTIN (MRP 8/14) AS A BIOMARKER FOR SJÖGREN SYNDROME – A PROSPECTIVE OBSERVATIONAL STUDY**

P. Chebel1, J. Kaber1, P. Sandhya1, M. Gown1, D. Danda1.

**Background:** Calprotectin (MRP 8/14) is secreted by neutrophils and monocytes in an inflammatory milieu(1). Increased levels of calprotectin in blood and faeces has been previously shown in patients with primary Sjogren’s syndrome(pSS)(2).

**Objectives:** We hypothesised Calprotectin in saliva may therefore potentially reflect inflammation in salivary glands. In the present study, we aimed to assess the utility of salivary calprotectin as a biomarker in pSS and to evaluate the potential association of calprotectin with clinical features, laboratory markers and disease activity indexes in pSS.

**Methods:** Consecutive patients attending rheumatology clinic between Sep-tember 2016 and July 2017 of age more than 18 years fulfilling either American European Consensus Group (AECG) 2002 or 2016 American College of Rheumatology/European League Against Rheumatism Classification Criteria for Primary Sjogren’s Syndrome, constituted the case group. Patients with sicca non-pSS and rheumatoid arthritis patients satisfying ACR/EULAR criteria 2010 were recruited as disease controls. Age and sex-matched healthy subjects were recruited as a controls. Patient history, signs and symptoms, laboratory investigations, ESSDAI and ESSPRI scoring were noted for cases and disease controls. Unstimulated saliva was collected by the spitting method. Salivary calprotectin levels were quantified by commercially available ELISA kit(R&D Systems, MN, USA).

**Results:** A total of 42 pSS cases (41.59±11.21 years, 40 women), 40 disease controls (47.62±8.1 years, 39 women) and 30 healthy controls (36.10±5.8 years, 29 women) were recruited. In pSS and disease controls, the median levels of salivary calprotectin [38.5(81) and 52(69.5) ng/ml] were significantly higher compared to healthy controls [26.5(29) (p=0.001)]. Salivary calprotectin levels in pSS was positively associated with oral symptoms and negatively associated with immunosuppression of 1 year and more(0.04 and 0.03 respectively), but not ESSDAI, ESSPRI scores or lab parameters.

**Conclusion:** Salivary calprotectin was elevated in pSS compared to healthy subjects and was found to be positively associated with oral symptoms and with immunosuppressive treatment.

**DIAGNOSTIC VALUE OF PROTEASOMAL AND AUTOPHAGIC MARKERS IN MUSCULAR DISEASES**  
U. Drott1, P. Harter2, H. Burkhardt3, M. Mittelbronn4.  
1Rheumatology Division, Goethe-University, Frankfurt, Germany; 2Institute of Neurology (Edinger Institute), Goethe University, Frankfurt, Germany; 3Rheumatology Division, Goethe-University Frankfurt, Frankfurt, Germany; 4Luxembourg Center of Neuropathology (LCNP), Dudelange, Germany

**Background:** Deficient cellular degradation pathways such as autophagy and the ubiquitin proteasome system (UPS) show a correlation with the onset of neuromuscular diseases. Especially immune-mediated inflammatory myopathies often show therapy-resistant phenotypes with medical need for further understanding of the disease mechanism and possible therapeutic targets.

**Objectives:** The aim of this work was to study an association of these two degradation pathways in a large group of different muscle entities and to examine a possible influence on the pathogenesis of the investigated muscle diseases. Furthermore, a potential benefit in diagnostics was studied using factors such as ubiquitin, p62, NBR1 and LC3 and their role as adapter molecules.

**Methods:** We used both ubiquitin, p62, NBR1 and LC3 for the analyses in muscle biopsies from patients with the diagnosis of s-IBM, dermato- and polymyositis, muscular dystrophy, neurogenic atrophy, myotonic dystrophy type II (PROMM) and metabolic myopathies such as Pompe and McArdle disease. Immunohistochemical single and double stainings as well as immunofluorescence stainings were performed on cryosections. Furthermore, Western blot analysis was performed. The use of a historical cohort as the study population was possible due to the high accumulation of clinical data in the course of many years. The histological score showed that ubiquitin was significantly higher in s-IBM than in polymyositis. NBR1 was significantly higher in s-IBM than in dermatomyositis and muscular dystrophies. LC3 and p62 showed a significantly higher level in s-IBM as compared to dermatomyositis and polymyositis. Except for NBR1, a positive correlation of autophagic and proteasomal markers was shown in dermatomyositis. There was also a possible correlation betweenLC3 and ubiquitin in polymyositis. Using multivariate analysis and recursive partitioning, we could show a predictability of the diagnosis of s-IBM with a LC3 score above 3. On the other hand, a value below 3 excluded the diagnosis of s-IBM.

**Conclusion:** In particular, s-IBM, myobrarian pathologies and Pompe disease showed a possible involvement disturbed proteasomal and autophagic degradation pathways in their pathogenesis. In addition, p62 and NBR1 seemed to have an important role in the immune response. Furthermore, the altered autophagic and proteasomal degradation pathways may be involved in ageing processes, sarcopenia and disease. In particular, LC3 seems to be suitable as a screening marker to recognize an idiopathic inflammatory myopathy. The other markers, such as p62, LC3, and NBR1, would be able to distinguish between the subgroups of idiopathic inflammatory myopathies. Therefore, LC3 could be included as a marker in the routine of neuropsychopathological diagnostics. Further studies are needed to fully understand the role of proteasomal and autophagic factors in possible immune suppressive and immune modulatory therapies and to assess possible side effects.

THE EFFECT OF INFLUENZA VACCINATION ON THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE AND ITS COMPONENT BIOMARKERS IN HEALTHY SUBJECTS

1University of Washington, Seattle, United States of America; 2Myriad Genetics, Inc., Salt Lake City, United States of America; 3Crescendo Bioscience, South San Francisco, United States of America; 4Brigham and Women’s Hospital, Boston, United States of America

Background: The multi-biomarker disease activity (MBDA) blood test measures 12 protein biomarkers (IL-6, CRP, SAA, EGF, VEGF, VCAM, MMP-1, MMP-3, leptin, resistin, TNF-RI and YKL40). It uses a validated algorithm to provide a score on a scale of 1-100 for assessing disease activity in patients with rheumatoid arthritis (RA). The MBDA score reflects several molecular aspects of inflammation, including cytokines, acute phase reactants, growth factors, molecular adhesion, metalloproteinases and hormones. Insights gained by understanding how vaccination affects these biomarkers in healthy subjects - in whom the level of inflammation prior to vaccination should be low and stable - may aid the understanding of how vaccination affects patients with RA.

Objectives: The goal of this study was to understand how immunization of healthy subjects with the influenza vaccine affects the assessment of inflammation with the MBDA score and its 12 biomarkers.

Methods: A 4-strain influenza virus vaccine (Fluarix Quadrivalent, GlaxoSmithKline) was administered intramuscularly to 22 healthy volunteer subjects on October 24, 2018. Serum samples were obtained immediately prior to vaccination (baseline) and 1, 2 and 3 weeks after vaccination. No restrictions were placed on subject activity. Samples were stored at -80°C until measurement of

the 12 MBDA biomarkers for determination of the adjusted MBDA score, hereafter called the MBDA score. (Adjustment accounts for the effects of age, sex and adiposity). MBDA scores (natural scale) and biomarker concentrations (log scale) were modeled using generalized estimating equations (GEE) that account for correlations between measurements from the same subject at multiple timepoints. Significance of MBDA score change or biomarker concentration change over time was determined by a likelihood ratio test of timepoints.

Results: Of the 22 healthy subjects receiving the influenza vaccine, 14 (63.6%) were female, with mean (SD) age of 40.0 years (8.9). MBDA scores were low (<30), moderate (30-44) or high (>44) for 15 (68%), 6 (27%) and 1 (5%) subjects at baseline, and this distribution was stable over time (Figure 1). Overall, MBDA scores did not change significantly over time (p=0.48, Figure 2). Mean changes in MBDA score (95% CI) from baseline to weeks 1, 2 and 3 were 0.32 (-3.07, 3.71), 0.82 (-3.03, 4.67) and 2.86 (-1.10, 6.82), respectively (Figure 2); the week 3 value becomes 0.95 (-1.78, 3.68) if the week 3 outlier is removed. Among the 66 post-baseline measurements of change in MBDA score (Figure 2), 3 (5%) exceeded the 95% CI for change in MBDA score in this study (i.e., 14). When assessing the entire cohort across all timepoints, EGF was the only biomarker that demonstrated statistically significant change over time (p=5.6 x 10^-3). At weeks 1, 2 and 3, the mean relative concentrations of EGF, compared with baseline, were 0.62 (0.52, 0.74), 0.86 (0.70, 1.06) and 0.62 (0.50, 0.76), respectively.

Figure 1

Conclusion: Immunization of 22 healthy subjects with a quadrivalent influenza vaccine did not have a statistically significant effect on MBDA scores during a 3-week observation, and it had minimal effect on the component biomarkers.

Disclosure of Interests: Daniel Furst Grant/research support from: AbbVie, Actelion, Amgen, BMS, Corbus Pharmaceuticals, the National Institutes of Health, Novartis, Pfizer, and Roche/Genentech, Consultant of: AbbVie, Actelion, Amgen, BMS, Cytori Therapeutics, Corbus Pharmaceuticals, the National Institutes of Health, Novartis, Pfizer, and Roche/Genentech, Speakers bureau: CMC Connect (McCann Health Company), Lauren Lenz Shareholder of: Myriad Genetics,
Objectives: C4b Binding Protein (C4BP) is a complement inhibitor with anticoagulant function. It belongs to the same protein family as 2GPI, the main antigen in APS.

Background: Complement plays a role in the Antiphospholipid Syndrome (APS). C4b Binding Protein (C4BP) is a complement inhibitor with anticoagulant function. Its main isoform is bound to protein S in the circulation. Levels of both protein S and C4BP are known to be reduced by warfarin treatment (2) as well as by aPL, directly and indirectly.

Methods: The total amount of C4BP (C4BPt) was measured by using magnetic carboxylated microspheres which were coupled with a monoclonal antibody against the α-chain of human-C4BP to capture the antigen. To detect C4BP the same antibody was used, biotinylated. The binding of biotinylated antibodies was detected by streptavidin-phycoerythrin and data were collected using a MAGPIX Multiplex Reader. Using independent t-test, we compared C4BP in 118 SLE patients with repeated positivity for Antiphospholipid antibodies (aPL) (39/118 on warfarin), 291 aPL negative SLE patients (16/291 on warfarin), 67 pAPS (33/67 on warfarin), and 322 controls (none on warfarin). We then performed an interaction and a mediation analysis (3) in the SLE group to study the impact of warfarin on C4BP levels: since warfarin is mostly prescribed to aPL+ patients, it is considered a mediator in the reducing effect of aPL on C4BP. Therefore we compared individuals exposed and non-exposed to the presence of aPL with or without the mediator warfarin and calculated the percentage of reduction in C4BP that could be attributed to aPL or warfarin.

Results: Overall C4BP is 20% reduced in aPL+ patients (fig 1), independently of SLE, past thrombotic events and nephritis. Warfarin treated patients have lower levels of C4BP (fig 2). According to mediation analysis 11% of C4BP reduction is due to aPL and 9% to warfarin.

Conclusion: Both aPL and warfarin decrease levels of C4BP, a complement and coagulation regulator. Reduction of this complement inhibitor could contribute to complement activation and thrombosis in APS. Our results raise new questions regarding the effects of warfarin treatment on complement and coagulation in APS.

was based on patient opinion. ROC curve was constructed to examine the optimum cut-off for disease flare. Agreement between the FLARE questionnaire and patient opinion was assessed by Cohen's kappa. Test-retest was assessed in 28 patients with stable disease who underwent repeat assessment within 2 weeks and evaluated by intra-class correlation coefficient (ICC).

Results: The FLARE questionnaire was administered at 367 patient encounters. ROC analysis indicated that the optimum cut-off for a flare of disease was 4 (sensitivity 82%, specificity 76%; area under curve 0.85: figure). Mean PASDAS scores were 2.7 and 6.3 for no-flare (4) and flare (≥4) respectively (p < 0.0001). For those patients who were having a flare the frequency of response to each question is given in the table. Agreement between patient opinion and questionnaire was 0.57, and between patient opinion and physician (based on treatment escalation) 0.43. ICC for the questionnaire was 0.87 (95% CI 0.72 – 0.94).

Conclusion: In PsA a flare represents escalation of symptoms and signs across multiple domains, as measured by the FLARE instrument; a score of 4 or more has external validity both in terms of composite disease activity and overall patient opinion of the state of their condition.

Background: The multi-biomarker disease activity (MBDA) score, adjusted for age, sex and adiposity (MBDA adj), has been shown to be better than several conventional disease activity measures for predicting risk for radiographic progression (RP) in patients with rheumatoid arthritis (RA). Serologic status and other non-disease activity measures are also predictive of RP risk. Combining them with the MBDA adj should result in a stronger prognostic test for RP than any one measure alone.

Objectives: Develop a multivariate model for predicting risk for RP that includes the adjusted MBDA score and other known predictors of RP.

Methods: Four RA cohorts were used, two for training (OPERA and BRASS, n=555) and two for validation (SWEFOT and Leiden, n=397). Each pair of cohorts was heterogeneous in disease duration and treatment history. BMI data were not available for one validation cohort, so a BMI surrogate was modeled using forward selection with the two training cohorts and 3 others (CERTAIN, InFoRM, RACER) on disease duration. Four RA cohorts were used, two for training (OPERA and BRASS, n=555) and two for validation (SWEFOT and Leiden, n=397). Each pair of cohorts was heterogeneous in disease duration and treatment history. BMI data were not available for one validation cohort, so a BMI surrogate was modeled using forward selection with the two training cohorts and 3 others (CERTAIN, InFoRM, RACER) on disease duration.

The BMI surrogate included leptin, sex, age and age 2 and correlated well with BMI (r = 0.78). In training, the most significant independent predictors of RP were MBDA adj (p = 0.0002), seropositivity (p = 3.9 x 10−6), BMI surrogate score (p = 0.013) and use of targeted therapy (p = 0.0026). The final model was: RP risk score = 0.024 x MBDA adj + 0.003 if seropositive − 0.063 x BMI surrogate score − 0.61 if using a targeted therapy. In validation, the OR (95% CI) of the RP risk score for predicting ΔTSS >3 or >5 were 2.2 (1.6, 3.2) (p = 2.6 x 10−5) and 3.1 (2.0, 5.0) (p = 5.7 x 10−5), respectively (Figure 1). The odds of a patient having RP increases by 50% for each 21-unit or 15-unit increase in MBDA adj for RP defined as ΔTSS >3 or >5, respectively.

Conclusion: A multivariate model containing adjusted MBDA score, seropositivity, a BMI surrogate and use of targeted therapy has been trained and validated as a prognostic test for radiographic progression in RA.

To investigate the use of such App technology in respect to usability, feasibility and equivalence of data in daily care of patients with axSpA. In more detail, it will be first determined how many patients are capable and ready to use the AxSpA Live App for transmission of their disease activity over time.

Objectives: To investigate the use of such App technology in respect to usability, feasibility and equivalence of data in daily care of patients with axSpA. In more detail, it will be first determined how many patients are capable and ready to use the AxSpA Live App for transmission of their disease activity over time.

Methods: Patients diagnosed with axSpA were consecutively included in this ongoing monocentric prospective cohort study. In addition to patient and disease characteristics, information on previous experience with digital health apps was collected. Patients were asked to submit BASDAI and BASFI scores regularly and to submit the BASDAI scores at least every 2 weeks. The free to use AxSpA Live App is available for Android and iOS.

Conclusion: The majority of patients with axSpA were able to use the AxSpA Live App. Most patients report scores regularly. The current disease activity seems to influence the adherence to reporting.

DISEASE ACTIVITY WITH A SMARTPHONE APP IS DAILY MANAGEMENT OF PATIENTS WITH AXIAL Spondyloarthritis: SELF-MONITORING OF DISEASE ACTIVITY WITH A SMARTPHONE APP IS FEASIBLE – A PROOF OF CONCEPT STUDY

U. Kitz1, R. Kempen1, A. Schlegel1, X. Baraliakos1, S. Tsiami1, B. Buhring1, D. Kiefert1, J. Braun1 on behalf of n/a. 1Rheumazentrum Ruhrgebiet Herne and Ruhr University Bochum, Herne, Germany

Background: Assessment and monitoring of disease activity and functioning is of major importance for the course of axial spondyloarthritis (axSpA). This is equally important for patient monitoring in daily routine as also for tight control strategies. Even though there is evidence that a closer monitoring of patients is better than routine care, more intensive treatment schedules are often not realized in daily practice for several reasons including shortage of time and personal resources. Using application software devices (apps) in clinical routine for the recording of disease-specific patient reported outcomes (PRO) may facilitate monitoring and improve clinical decision processes but there is a lack of data on the use of apps.

Objectives: To investigate the use of such App technology in respect to usability, feasibility and equivalence of data in daily care of patients with axSpA. In more detail, it will be first determined how many patients are capable and ready to use the technology in a routine setting. Furthermore, the usage and behavior of patients using the app will be studied, the usability of the app and the equivalence of the collected parameters as well as the adherence to the documentation of disease activity over time.

Methods: Patients diagnosed with axSpA were consecutively included in this ongoing monocentric prospective cohort study. In addition to patient and disease characteristics, information on previous experience with digital health apps was collected. Patients were asked to submit BASDAI and BASFI scores regularly every 2 weeks. The free to use AxSpA Live App is available for Android and iOS as a Class I certified medical device.

Results: Out of 103 axSpA patients asked, 69 patients with axSpA (mean age 41.5 ± 11.3, 58% male, 76.8% use of bDMARDs, BASDAI 4.3 ± 2.0, BASFI 3.8 ± 2.5) out of 103 patients (67%) agreed to use participate, while 5 did not have a smartphone, 1 was unable to download the app for technical reasons, 28 reported other personal reasons. Of the 69, 62 patients (89.9%) reported using electronic media frequently and had used digital health apps (mean apps used 1.0 ± 1.3) in everyday life before. There were no systematic differences between pain levels documented on paper or by app at baseline (ICC 0.9 [95%CI 0.82 – 0.93). Out of 55 patients who completed week 2, only 33 patients (60%) used the App regularly to transmit their BASDAI/BASFI values at least every 2 weeks (60%). Patients who started a new drug treatment because of high disease activity, reported BASDAI values more often than patients without a treatment change within a follow-up period of 5.5 ± 1.4 weeks (Table).

Conclusion: The majority of patients with axSpA were able to use the AxSpA Live App. Most patients report scores regularly. The current disease activity seems to influence the adherence to reporting.
documenting GCA or biopsy results were included in the PPV calculations. Algorithm 1, which identified the greatest number of patients (n=896), yielded the lowest PPV of 60.7%. Algorithms 4 and 5, which required disease-specific workups (temporal artery biopsy or chest imaging), mildly improved the PPV to 76.2% and 68.2%, respectively. The PPV was highest in algorithm 3 (84.8%), which required 2 or more diagnoses of GCA by a rheumatologist in addition to high dose steroid dispensing.

Conclusion: A claims-based algorithm including two or more diagnosis codes for GCA by a rheumatologist separated by ≥730 days and high dose steroid dispensing (prednisone equivalent ≥40mg/day for ≥14 days) can be a useful tool for identifying patients with GCA, allowing for future large real-world data studies.

ELEVATED SERUM COMPLEMENT (C3/C4) LEVEL AS AN INFLAMMATORY MARKER FOR INFECTION IN PATIENTS WITH FEVER: A RETROSPECTIVE STUDY

Z. Y. Li,1 J. Saleh2, S. Huang1, M. Elhassan,3 C. Yuvienco4.1 University of California, San Francisco Fresno, Internal Medicine, Fresno, United States of America; 2A.T. Still University School of Osteopathic Medicine, Mesa, United States of America; 3Agnes Memorial Internal Medicine, Fresno, United States of America; 4UCSF Fresno, Rheumatology, Fresno, United States of America

Background: The functions of the complement system are to protect the host against infection, clearance of immune complexes, and regulate adaptive immunity after activation by C-reactive protein (CRP) or foreign cells.1 C3 and C4 may increase up to 50 percent of baseline values as part of the acute-phase response, which is an expected host response for infection and injury.2

Objectives: We aimed to examine the correlation between elevated C3/C4 levels and the underlying causes (infectious vs. non-infectious) of fever (subjective and/or objective) in adults admitted to Community Regional Medical Center (CRMC).

Methods: This is a retrospective study of C3/C4 level that was ordered in adult patients who were admitted to CRMC in April 1st, 2018 to September 30th, 2018 with fever. This was also analyzed in comparison to elevated lactic acid, erythrocyte sedimentation rate (ESR), and CRP level.

Results: Complement levels were ordered in 210 patients admitted to CRMC medical or intensive care units. Among these patients, 28.09% (59/210) were diagnosed with various infectious diseases confirmed by gold standard methods (cultures, serology tests, computerized tomography, or magnetic resonance imaging), regardless of fever status during admission. About 26.8% (56/210) had subjective or objective (temperature greater than100.4 F or above), and 52 of them had complement levels (C3/C4) ordered with resulted in either normal or elevated. Within these 52 patients, lactic acid, ESR, and CRP were ordered in 33, 28, 25 of them respectively.

Table 1. Elevated C3/C4 level vs. normal C3/C4 level in detecting infection in fever patients when tested against gold standards.

Conclusion: Complement levels can be used as a rapid screening test to guide infection consideration as it correctly identified 61.9 % of febrile patients with infection, and 77.4% who didn’t have an infection. A positive screening test in itself still requires further investigation in the causes of fever to confirm the diagnosis since the PPV is 65%. With the NPV of 48.9%, a negative screening test is still not reassuring that the febrile patient doesn’t have an infection. Our study demonstrated the potential utilization of the elevated complement level as an inflammatory marker for infectious etiology of fever, as it has better LR+ when compared to ESR and CRP with similar turnaround time.

This study helps educate providers to acknowledge the fact that complement level does not have to be limited to be used on autoimmune related disorders only. Further large pool studies will be necessary to further investigate the role of complement levels as part of the screening test in a patient with fever.

MOLECULAR MARKERS OF PAIN AND OTHER SYMPTOMS IN KNEE OSTEOARTHRITIS

Y. Liem, V. Judge, K. Gurraldi, Y. Li, M. Sharif. 1University of Bristol, Bristol, United Kingdom; 2University of Bristol, Musculoskeletal Research Unit, Bristol, United Kingdom

Background: Osteoarthritis (OA) is one of the leading causes for disability in adults. The diagnosis of OA is generally based on patient reported pain, other symptoms and radiographic changes which occur in late stages. There have been extensive research over the last 30 years to identify and validate molecular markers for early diagnosis of OA and a large range of potential biomarkers has been identified[1, 2]. However, most of these biomarkers are markers of structural and metabolic changes, and have poor correlation with pain and stiffness in knee OA. The publicly available data from the National Institute of Health Osteoarthritis Initiative (OAI) provides an opportunity to search for clinically useful biomarkers associated with the main symptoms in OA.

Objectives: To identify molecular biomarkers which are associated with the main symptoms of knee OA.

Methods: 600 participants from 4791 men and women aged 45 to 79 who were Kelgren & Lawrence grade 1 or more were identified with biochemical markers data, radiographic and clinical features of OA. Nineteen biochemical markers measured in serum and/or urine were analysed for their association with primary clinical features of OA: Knee injury and Osteoarthritis Outcome Score (KOOS) pain and symptoms, and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and stiffness score. Patient level analysis
was carried out based on the worst affected knee. The association of molecular biomarkers with KOOS and WOMAC scores were assessed using univariate and multivariate linear and logistic regression, and receiving operator characteristic curves (ROC). Area under the curve (AUC) was calculated in order to determine if a combination of the biomarkers improve the associations with the outcome variables.

**Results:** Only 3 of the 19 biomarkers investigated were associated with clinical symptoms. Serum cartilage oligomeric matrix protein (COMP) and chondroitin sulphate 846 (CS846) were associated with WOMAC pain and stiffness respectively, while, urinary C-terminal crosslinked telopeptide of type II collagen (CTXII) appeared to be highly associated with WOMAC stiffness, KOOS pain and symptoms (Table 1 / 2). The AUC from the univariate model for the association of biomarkers with WOMAC pain and stiffness were 0.5 (Table 1), while the AUC for unadjusted and adjusted multivariate model for the 3 biomarkers combined were 0.56 and 0.67 respectively (Figure 1).

Table 1. Univariate logistic regression model.

</tr>
</tbody>
</table>

**Conclusion:** Serum COMP and urinary CTXII are associated with pain in knee OA, while serum CS846 and urinary CTXII are associated with joint stiffness. The multivariate logistic regression model shows good discrimination for the association of biomarkers with clinical symptoms of OA. The data from the multivariate model suggests that a clinically useful biomarker may be created using AUC of biomarkers with clinical symptoms of OA. The data from the multivariate model were adjusted in the multivariate model. Confounders such as age, body mass index, gender and race were included in the multivariate model.

Methods: The study included 340 patients (227 women, 113 men, age 39.1±20.8 years) with different IIRDs: systemic lupus erythematosus (SLE) – 74, rheumatoid arthritis (RA) – 71, juvenile arthritis (JA) – 33, systemic vasculitis (SV) – 33, systemic scleroderma (SSD) – 27, ankylosing spondylitis (AS) – 10, adult-onset Still’s disease (AOSD) – 13, other IIRDs - 51. The serum concentration of PCT was determined by the quantitative electrochemiluminescent method using the Cobas E 411 analyzer (Roshe, Switzerland).

Results: In patients without infection (n=181), the median (Me) PCT level was 0.11 ng/ml [0.05; 0.17]; higher values of PCT were found in patients with AOSD (0.39 ng/ml [0.11; 0.91]), systemic lupus JA (0.17 ng/ml [0.11; 0.5]) and SLE (0.16 ng/ml [0.10; 0.45]). In RA, SV, SSD, AS without infection, Me PCT was 0.07 ng/ml [0.03; 0.12]. The infectious process was detected in 159 patients: generalized - in 11, local - in 148. Depending on the severity of the intoxication syndrome, local infections are divided into severe (n=70) and light (n=78). Infections of the lower respiratory tract, urinary system, skin and soft tissues prevailed. In patients with generalized infection, Me PCT level was 3.6 ng/ml [0.49; 11.3]. In 10 patients of this group, the level of PCT exceeded 2 ng/ml, in 5 patients - 10 ng/ml. In severe local infection, Me PCT was 0.45 ng/ml [0.23; 1.19], in light - 0.12 ng/ml [0.05; 0.16]. In generalized infection, the level of PCT was significantly higher than in patients without infection (p<0.0001), as well as with mild (p<0.0001) and severe local infection (p<0.0001). In patients with severe local infection, the level of PCT was higher compared to patients without infection (p<0.0001) and with mild local infection (p<0.0001). There were no significant differences in PCT in the groups of patients with light local infection and without infection. In SLE patients with infection, the level of PCT and CRP (but not ESR) was higher than in patients without infection; a correlation was found between the level of PCT and CRP (r=0.53, p<0.001) in the presence of infection. In AOSD, systemic form of JA, RA, SV, SSD, AS, significant differences in the levels of PCT, ESR, CRP in patients with infection and without infection were not obtained, correlations were not revealed. According to the ROC-analysis, the diagnostic significance of determining PCT in generalized infection is excellent, in severe local infection - very good, and in differentiation of generalized infection from local infection - very good.

Conclusion: PCT is a significant diagnostic test that allows to recognize generalized and severe local infections in patients with IIRDs. In order to more accurately diagnose the infectious process, a multi-marker approach is needed.

AB1253 EVALUATION OF CYSTEINE-RICH 61 IN RHEUMATOID ARTHRITIS AS A DIAGNOSTIC MARKER AND PREDICTOR OF ATHEROSCLEROSIS

H. A. Esaily1, D. M. Serag2, M. S. Rizk3, A. Sonbol4, D. Salem5. 1Menoufia University, Egypt; Physical Medicine, Rheumatology and Rehabilitation Department, Faculty of Medicine, Shebin El Kom, Egypt; 2Menoufia University, Egypt; Radiology Department, Faculty of Medicine, Shebin El Kom, Egypt; 3Menoufia University, Egypt; Medical Biochemistry and Molecular Biology Department, Faculty of Medicine, Shebin El Kom, Egypt; 4Menoufia University, Egypt, Clinical Pathology Department, Faculty of Medicine, Shebin El Kom, Egypt

Background: Matricellular protein Cysteine-rich protein 61 (Cyr61) is involved in chronic inflammatory disorders like rheumatoid arthritis (RA) and atherosclerosis.

Objectives: This study aimed to assess the value of serum Cyr61 in diagnosis of rheumatoid arthritis, evaluating its correlation with disease activity and its relation to atherosclerosis.

Methods: Cross-sectional study included 105 RA patients classified into active and inactive groups according to disease activity score (DAS28) with 50 healthy age and gender-matched controls. Clinical and laboratory assessment was done including enzyme-linked immunosorbent assay (ELISA) measurement of Cyr61. Statistical analysis was done using high resolution-ultrasonography. Comparison of Cyr61 between RA patients and controls, correlation between Cyr61 and disease activity and CIMT were analyzed with appropriate statistical analyses.

Results: Significant elevation of Cyr61 in RA patients compared to controls (235.6±62.5 vs. 73.1±18.2) respectively. The cut off value of Cyr61 was 99.25 pg/ml, with area under the curve (AUC) =0.995, P <0.001, 98 % sensitivity and 95% specificity. Cyr61 was inversely correlated with DAS28 and its components in RA patients (r= 0.92, F= 0.94) (p<0.001). There was a significant positive correlation between Cyr61 levels and CIMT in inactive and active RA patients (r=0.88, r=0.47) respectively.

Conclusion: Serum Cyr61 as a potential diagnostic biomarker in RA is inversely correlated with disease activity. High Cyr61 in RA is a risk factor for atherosclerosis. Disruption of serum Cyr61 is engaged in the pathogenesis of both rheumatoid arthritis and atherosclerosis which is a clue for a future treatment strategy of RA.

AB1254 PHENOTYPING OF MULTIPLE BIOFLUIDS FOR LIQUID BIOMARKERS FOR DIAGNOSTICS AND PERSONALIZED MEDICINE OF RHEUMATOID ARTHRITIS, SPONDYLOARTHRITIS AND OSTEOARTHRITIS

Background: Inflammatory and autoimmune diseases include multifactual pathomechanisms and systemic responses. The etiology of the joint diseases rheumatoid arthritis (RA), spondyloarthritis (SpA) in relation to osteoarthritis (OA) remain incomplete and establishing the correct diagnose remains nontrivial. Advances in high-throughput molecular technologies have increased investigations into the
utility of transcriptomic, proteomic and high-density protein arrays approaches as diagnostic tools and companion diagnostics for precision medicine. To increase our understanding of the molecular pathogenesis, we extracted synovial fluid from the joints from multiple patient groups and characterized the protein composition in relation to plasma. Basic blood tests include inflammatory markers and autoantibodies, however, now analysis speed and robustness allow more readily clinical insight biofluids.

Objectives: We present recent Omics concepts and studies investigating inflammatory state and treatment outcome in different biofluids from plasma to synovial fluid accessing causalties leading to inflammation and pain. Additionally, the aim was to investigate in any proteomic findings in synovial fluid can be correlated to proteomic changes in patient plasma and can be used as biomarkers for treatment effect.

Methods: Plasma and synovial fluid were investigated in multiple pathologies before and after treatment in patients (biologics; MTX; intraarticular gold). Deep proteomics, PTM and EV profiling were accomplished using quantitative proteomics approaches using quantitative mass spectrometry-based analysis by DIA/PASEF followed by deep datatimimg. All biological samples were digested according to a Filter Aided Sample Preparation (FASP) protocol before analysis with tandem mass spectrometry (MS/MS). PTM profiling were evaluated by 4D CCS based feature finding.

Results: Mass spectrometry based profiling allowed quantitative profiling of up to 480 proteins in matched synovial fluid and plasma. Complementary analysis by Olink proteomics, cytokine profiling and cell-free DNA. Multiple acute inflammatory proteins were more abundant in the RA synovial fluid, including proteins originating from neutrophil granulocytes, whereas SpA patients had a higher concentration of haptoglobin. Complementary analysis by Olink immunoassay identified significantly downregulated inflammation markers out of 96 tested in relation to antinflammatory treatment.

Conclusion: Discovery of biomarkers and/or inflammatory signatures through integration of multi-omic data allowed stratify patients for improved treatment and prognosis. Firstly, our data using next generation proteomics approaches alleviates many pitfalls of missing values and poor proteome coverage including unbiased PTM profiling without enrichment strategies.

Taylor Grant/research support from: Celgene, Eli Lilly and Company, Galapagos, and Gilead, Consultant of: AbbVie, Biogen, Eli Lilly (not related to the submitted work)., Ellen-Margrethe Hauge.

Background: Patient-reported outcome measures (PROMs) are essential to understand the patient’s perception of arthritis activity. In Denmark, PROMs are registered on a touchscreen in the outpatient clinic. However, some patients find it inconvenient and due to e.g. waiting in queue, lack of privacy, uncomfortable seating position, reduced upper limb strength and dexterity with seeing the touchscreen due to deformity of the cervical spine. The widespread use of smartphones makes it possible for patients to register PROMs via an application (app) on their own device.

Objectives: The primary aim is to evaluate the agreement (i.e. similarity) between the two devices assessed by the Health Assessment Questionnaire Disability Index (HAQ-DI) status among patients with inflammatory arthritis.

Methods: The study was a randomised, crossover, agreement trial (NCT03486613) conducted at Aalborg University Hospital, Denmark. Participants were recruited through an invitation on the touchscreen in the outpatient clinic. Patients with an established diagnosis (≥ 12 months) of rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritides (axSpA) and experience with the PROM questionnaires (≥ 3 previous registrations) were enrolled and randomised in ratio 1:1 (stratified by diagnosis) to PROM registration through the DANBIO app and the touchscreen in random order. Figure 1A and 1B shows the two devices.

The sample size calculation was based on a prespecified equivalence margin of ±0.11 HAQ-DI points (i.e. ± half of the minimal important difference of 0.22 points) yielding a power of 99.2% for 60 enrolled patients. There was a wash-out period of 1-2 days between the two device registrations to minimise the potential carryover effect. A paired t-test was used to calculate the mean HAQ-DI score for the two devices and the difference in HAQ-DI score with a 95% confidence interval (CI). A Bland-Altman plot was used to assess limits of agreement (LoA).

Results: 60 patients (20 with RA, 20 with PsA and 20 with axSpA) were randomised of whom 51.7% were male. Mean age was 53.7 years (range 22-77) and mean disease duration was 12.5 years (range 1.0-34.8). Mean HAQ-DI was 0.608 (95%CI 0.437, 0.779) for the DANBIO app and 0.614 (95%CI 0.446, 0.783) for the touchscreen (Table 1). Agreement between scores obtained with the two devices is illustrated with Bland-Altman plots in figure 2A and 2B. The paired mean difference of HAQ-DI between the two devices was 0.006 (95%CI -0.042; 0.030); thus the 95% confidence interval for the mean difference was within the prespecified equivalence margin of ±0.11 HAQ-DI points.

Conclusion: The current study showed no statistical or clinically important difference in HAQ-DI measurement captured by a smartphone app or outpatient touchscreen. Therefore, we feel confident that the two devices perform similarly enough to be used interchangeably in patients with inflammatory arthritis.

Table 1. HAQ-DI scores, difference and LoA for the two devices.

CORRELATION BETWEEN SERUM CALPROTECTIN LEVELS, RAPID3 AND DISEASE ACTIVITY MEASURES IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Valls Rocío, O. Codina Guinó, M. Sala Gomez, S. Castell Quihones, C. Mora Maruny, 1Hospital de Figueres, Rheumatology, Figueres, Spain; 2Hospital de Figueres, Clinical Analysis Department, Figueres, Spain

Background: Tight control of rheumatoid arthritis (RA) is essential and we need a validated, objective and reproducible disease measure to achieve it. There is not gold standard in RA. There is a rising interest in evaluating disease activity on the patient’s point of view using patient-reported outcomes like RAPID3. Furthermore, some new biomarkers have appeared, like serum calprotectin, with promising results on its analyzing.

Objectives: To evaluate correlation between disease activity measures usually used in patients with RA (DAS28 ESR/CRP, SDAI and CDAI) and other alternative tools (RAPID3 and calprotectin). To analyze correlation between RAPID3 and serum calprotectin levels.

Methods: A cross-sectional study was performed. RA-patients (n=114) according to the ACR/EULAR 2010 classification criteria were consecutively enrolled from Rheumatology department at Hospital de Figueres during the period from February to June 2019. Disease activity, biomarkers and the assessment of the patient’s health status with RAPID3 data were collected. Modified RAPID3 (mRAPID3) was calculated by subtracting the questions about the mood included in the questionnaire (k,m) questions) to the results of the RAPID3 as if it were a response of the HAQ test. Coefficient Spearman’s correlation (r) was used to assess the relationship between the variables, and coefficient of determination (r²) was used to show the strength of correlation.

Results: 114 patients were included; 71% women, mean (SD) age 60(11) years, median disease duration 13(8) years. 80% had positive RF and 70% positive ACCP antibodies. 52% had erosions. 89% patients had been receiving treatment with csDMARDs, 38% with bDMARDs or dsDMARDs and 66% with glucocorticoids. Disease activity measures’ median values were DAS28ESR 3.07, DAS28CRP 2.76, SDAI 9.62 and CDAI 8.99 and showed low activity. The mean values of RAPID3 y mRAPID3 showed moderate activity (8.95 and 8.68 respectively). Median serum calprotectin level was 1.48μg/ml.

All correlations between variables were statistically significant and directly proportional although with different values (Table). Spearman’s correlation coefficient between mRAPID3, serum calprotectin, disease activity scores and laboratory parameters

Coefficient of determination found a weak association between RAPID3 and mRAPID3 with DAS28ESR (r²=0.38) and moderate with DAS28CRP and SDAI and CDAI (r²=0.47, 0.55 and 0.53). Determination serum calprotectin levels together with RAPID3 or mRAPID3 increased strength of correlation between DAS28ESR, DAS28CRP, SDAI and CDAI with RAPID3 (adjusted r²=0.40, 0.49, 0.56, 0.52) and with mRAPID3 (adjusted r²=0.41, 0.50, 0.56, 0.53). Correlation between RAPID3 and serum calprotectin levels was very weak (r²=0.50).

Conclusion: Correlation between disease activity measures and mRAPID3 was strong, but it was weak with serum calprotectin levels. Correlation strength between RAPID3 and DAS28ESR was low and it was moderate with other composite indices, it maintained with RAPID3m and improved by adding serum calprotectin levels although modesty. There was a very weak correlation between RAPID3 and serum calprotectin levels suggesting that these two variables give us different information about the disease activity.

AB1257 SCREENING FOR IMMUNOGLOBULIN A ANTIBODY REACTIVITY IN EARLY AXIAL SPONDYLOARTHRITIS IDENTIFIES NOVEL ANTIGENIC TARGETS

P. Vandormael, D. Quaden, P. Ruytinx, J. Janssens, J. Vanhoof, P. Geusens, V. Somers, Hasselt University, Biomedical Research Institute, Diepenbeek, Belgium; 2ReumaClinic, Genk, Belgium; 3Maastricht University Medical Center, Internal Medicine, Rheumatology, Maastricht, Netherlands

Background: Although autoantibodies are not generally considered to be a hallmark of axial spondyloarthritis (axSpA), increasing evidence suggests the presence of autoantibodies in a subset of axSpA patients. Most of these described antibodies are of the immunoglobulin G (IgG) isotype while other antibody isotypes are less well studied. Antibodies of the IgA isotype can be of interest due to the strong link between gut inflammation and spondyloarthropathies.

Objectives: The aim of this study was to identify and characterize novel IgA antibodies specific for early axSpA samples.

Methods: An axSpA cDNA phage display library, representing the antigen repertoire from axSpA hip synovium, was constructed and screened for reactivity with IgA antibodies in plasma of early axSpA patients (n=10). Using enzyme-linked immunosorbent assays (ELISA), antibody reactivity against 173 identified targets was initially determined in pooled plasma of early axSpA patients (n=20) and healthy controls (n=31). Following this, sera were further validated in individual plasma samples of early axSpA patients (n=79) and HC (n=101).

Results: We identified 10 novel Hasselt University (HU) axSpA peptide targets with increased IgA antibody reactivity in pooled axSpA plasma. At present, validation of 8 U-HU-axSpA-IgA peptide targets in individual plasma samples revealed antibody reactivity against at least one of these targets in 32% of early axSpA patients (25/79) compared to 26% in HC (31/101, p=0.4082). By combining the 3 U-HU-axSpA-IgA peptides with the highest positive likelihood ratio (LR+) into a panel, an increased overall specificity of 90% (10/101) could be achieved, with an associated sensitivity of 24% (19/79, p=0.0138) resulting in a LR+ of 2.4. Antibody reactivity testing of the remaining 2 U-HU-axSpA-IgA peptide targets is currently ongoing.

Conclusion: The increased reactivity of IgA (auto)antibodies against several novel antigenic peptide targets underscores the role of the humoral immune response in axSpA, and might indicate a potential link with mucosal inflammation. IgA antibody reactivity against these novel peptide targets will be further validated in independent cohorts of early axSpA patients as well as in patients with chronic low back pain.

THE VALUE OF THE SQUEEZE TEST FOR DETECTION OF SUBCLINICAL SYNOVITIS IN PATIENTS WITH ARTHRITIS SUSPICIOUS FOR PROGRESSION TO RA

E. Wouters, E. Niemantsverdriet, A. Van der Helm - van Mil, 1Leiden University Medical Centre, Department of Rheumatology, Leiden, Netherlands; 2Erasmus Medical Centre, Department of Rheumatology, Rotterdam, Netherlands

Background: The squeeze test (or compression test) is often used to quickly screen for arthritis in metacarpophalangeal (MCP)- and metatarsophalangeal (MTP)-joints. A positive test is traditionally assumed to indicate presence of synovitis. Previous studies in early arthritis indeed showed that a positive squeeze test was associated with presence of swollen MCP- and MTP-joints, as well as with local MRI-detected inflammation. The sensitivity of the test, with MRI-detected synovitis as reference, was 31-33%. The field is moving towards identifying patients at risk for rheumatoid arthritis (RA) in the phase of arthritis. However, it is not clear how many of these subjects have significant synovitis, or if the squeeze test is associated with subclinical inflammation, which can be detected with MRI.

Objectives: We aimed to assess if a positive squeeze test in patients with CSA is associated with MRI-detected subclinical inflammation, especially with

Acknowledgments: None declared

Disclosure of Interests: None declared

DO: 10.1136/annrheumdis-2020-eular.4289
subclinical synovitis and tenosynovitis (the latter is recently identified as a strong predictor for RA-development).

**Methods:** 315 patients with recent-onset (<1 year) arthralgia of small joints and a clinical suspicion for progression to RA were consecutively included in our CSA-cohort. At baseline the squeeze test (compression across the knuckles of MCP- and MTP-joints with the force of a firm handshake) and unilateral contrast-enhanced 1.5T MRI of MCP(2-5)- and MTP(1-5)-joints was performed and scored according to RAMRIS. MRI-scores were dichotomized with data from age-matched symptom-free controls as reference. Follow-up ended when patients developed clinically apparent inflammatory arthritis (IA), or else after 2 years. Associations of the squeeze test and MRI-data were studied with generalized estimating equations, associations with IA-development with cox regression.

**Results:** 51% of CSA-patients had a positive squeeze test in MCP- or MTP-joints. In univariable analyses a positive test was associated with MRI-detected subclinical synovitis (OR 2.10 (95%CI 1.30-3.40)) and tenosynovitis (OR 1.68 (1.05-2.68)). In multivariable analyses including both inflammatory features only synovitis remained significant (OR 1.90 (1.16-3.13)). Thus, a positive squeeze test is a measure of subclinical synovitis, with a sensitivity of 44% (95%CI 33-55) and specificity of 72% (68-76). A positive squeeze test in CSA was not associated with IA-development in cox regression adjusted for age, gender, CRP and ACPA-status (HR 1.57 (0.77-3.19). This was consistent with the finding that subclinical synovitis was not associated with IA-development in multivariable analysis adjusted for age, gender, CRP, ACPA-status and tenosynovitis (HR 1.40 (0.59-3.31), whilst tenosynovitis was associated (HR 4.94 (2.03-12.06). The squeeze test (compression across the knuckles of MCP- and MTP-joints with the force of a firm handshake) and unilateral contrast-enhanced 1.5T MRI of MCP(2-5)- and MTP(1-5)-joints was performed and scored according to RAMRIS. MRI-scores were dichotomized with data from age-matched symptom-free controls as reference. Follow-up ended when patients developed clinically apparent inflammatory arthritis (IA), or else after 2 years. Associations of the squeeze test and MRI-data were studied with generalized estimating equations, associations with IA-development with cox regression.

**Conclusion:** This study identified minimal exercise effect on perceived pain at 2 hours-and 24 hours-post exercise among participants with early RA. This suggests that exercise did not exacerbate pain and importantly, high intensities and high loads did not cause additional pain. Nevertheless, further larger studies are required to examine the role of acute exercise on disease activity, e.g. inflammation, and the association with perceived pain in people with early RA.

VAS: visual analog scale; ODI: Oswestry Disability Index; SF36: short form 36
Comparison of the two types of tested treatments showed a certain number of statistically significant differences. The VAS and physical mean score of SF 36 at day 18 and mental mean score of SF-36 at 3 months were significantly lower on the thermic cure group, while schober test at 3 months was significantly lower in the physical rehabilitation group.

Conclusion: Our study suggests a superiority of thermal cure in relieving pain and improving quality of life at short term among patient with LBP and a comparable efficacy in improving lumbar spine function. However, the effectiveness of physical rehabilitation was greater on spine mobility.

EFFECTS OF TAI CHI EXERCISE ON PAIN, FUNCTIONAL STATUS AND QUALITY OF LIFE IN PEOPLE WITH OSTEOARTHRITIS AND INFLAMMATORY ARTHRITIS

N. Kalebota1, M. Milosević2, N. Laktaslči Žerjavč1, A. Andreić4, B. Končar4, M. Vrdrić4, P. Turković4, N. Zura4, K. Kovač Durmisić4, I. Žagar4, P. Perić4,1

1Clinical Hospital Centre Zagreb, University Department for Rheumatology and Rehabilitation, Zagreb, Croatia; 2University of Zagreb, School of Medicine, Andrija Štampar School of Public Health, Zagreb, Croatia; 3Patient Advocacy Association, Zagreb; 4Croatian Wushu Federation, Zagreb, Croatia

Background: Tai Chi as a type of physical activity (PA) is included in recommendations for PA in people with inflammatory arthritis (IA) and osteoarthritis (OA). Objectives: The aim of this study was to evaluate the effect of Tai Chi exercise program on pain, functional status and quality of life in people with OA and IA. Methods: A study co-funded by the Erasmus + European Union Program for Sporting Activities called #WushuElixir was conducted in Croatia, Slovenia, Belgium and Spain. We present the results of the research conducted in Croatia from October 2016 to April 2019. A total of 44 participants (Pts) entered the Tai Chi exercise program. Majority of Pts were female with OA (Table 1), Tai Chi exercise program was performed for 60 minutes, twice a week, with a total of 50 training sessions. In data analysis where included only those Pts who completed at least 36% of exercise program, a total of 28 (63.6%) Pts, out of which 24 (85.7%) completed at least 70% of exercise program. An average attendance was 39 (78%) sessions. Outcome measures were pain (VAS scale), stability and balance (Functional reach test; FRT), chest mobility (breathing index), spinal mobility (cervical and thoracic sagittal indices and Schobers’s test), muscle strength (Wall sit test), physical function (Lequesne Index of severity for OA of the hip, and Stanford Health Assessment Questionnaire (HAQ) 20-item for IA) and quality of life (15D The health-related quality of life instrument; 15D QL). For statistical analysis t-test for paired samples was used with statistical significance set on P<0.05.

Conclusion: In this preliminary analysis pulsed electromagnetic field (PEMF) therapy showed significant impact on pain in rest in knee OA after one course of procedures.

AB1261

DOUBLE-BLIND PLACEBO-CONTROLLED TRIAL OF PULSED ELECTROMAGNETIC FIELD THERAPY IN KNEE OSTEOARTHRITIS (PRELIMINARY RESULTS)

D. Karateev, A. Makevmina, A. TANGIJEVA, E. Luchikhina, H. Hamboeva

1Moscow Regional Research and Clinical Institute (“MONIKI”), Rheumatology Department, Moscow, Russian Federation

Background: Pulsed electromagnetic field (PEMF) therapy is widely used in different areas of medicine. There are a lot of portable PEMF therapeutic devices on the market around the world. Nevertheless, the role of PEMF in treatment of rheumatic conditions is not clear. Current evidence is of low and very low quality. Objectives: To study efficacy and safety of PEMF therapy in primary and secondary osteoarthritis (OA) of the knee in controlled clinical trial.

Methods: This abstract presents the preliminary results of an ongoing double-blind placebo-controlled trial of PEMF portable therapeutic device ‘ALMAG+’ (Certificate EN ISO 13485:2012+AC:2012 reg.-No 44221 117836, Velatma Instrument-Making Enterprise, Russian Federation, Reg. Num.: 3007075140). The device is designed for physiotherapeutic treatment and rehabilitation with a low-frequency low-intensity PEMF in medical institutions, as well as at home after the recommendation of a doctor. Patients with primary and secondary (as a part of inflammatory rheumatic disease) OA of knee with Kellgren-Lawrence Grade I-III included in the study (in patients with inflammatory conditions disease activity should be minimal on stable drug therapy). Three courses of PEMF of 20 procedures for 1 year planned in active treatment group and placebo (inactive device) group of 35 patients each. Efficacy is evaluated by pain VAS, WOMAC, Lequesne index, and quality of life studied using SF-36, EuroQol 5D tools. Instrumental control with knee ultrasound and MRI investigations will be performed. The study protocol was approved by local Ethical Committee.

Results: To date 23 patients (7 males, 16 females, age 54.6±11.2 years, primary knee OA – 16 pts, RA- 6 pts, AS – 1 pt) completed 1st course of PEMF. Table presents differences (Δ) in the main clinical parameters in active treatment and placebo device groups. No significant difference in ESR or CRP levels was found. No treatment-related adverse events has been reported.
Objectives: In this study, we included 20 AS patients of whom admitted to our outpatient clinic. At the beginning and end of the study, patients some findings with a risk of serious adverse reactions in patients. MMRC, Borg dyspnea scales and 6 MWT at the end of rehabilitation compared to beginning of rehabilitation (p<0.05). It is shown that there was significant improvement in exercise capacity and pulmonary function in patients with ankylosing spondylitis; A randomized controlled study. Clin Rehabil. 2016; 30(4):340-346.

THE EFFECTIVENESS OF KINESIO THERAPY FOR PAIN SHOULDER SYNDROME

O. Tikhonova1, E. Guryanova2, O. Moskovskaya1, A. Moskovskij1, 1Chuvash State University, Cheboksary, Russian Federation; 2Institute for Advanced Medical Studies, Cheboksary, Russian Federation

Background: Pain shoulder syndrome is one of the most common conditions that is inherent in patients with various diseases and conditions. This problem is faced by both patients of a rheumatological profile (rheumatoid arthritis), and patients of other profiles: neurological (stroke, hernia of the cervical spine), traumatological (periarthritis). The regular use of painkillers and NSAID is associated with a risk of serious adverse reactions in patients. PNF therapy can have a fairly quick positive effect. Kinesiotaping is a common and easily accessible treatment method that, due to the inclusion of local neuromuscular adaptation mechanisms, can have an analgesic effect.

Methods: Patients with pain shoulder syndrome who were admitted to the doctor of physical and rehabilitation medicine were randomly assigned to one of three groups: group G1 - 20 patients who received combined treatment, including massage, acupuncture, PNF, kinesiotherapy. Patients of group G2 (20 people) who received massage and acupuncture sessions, kinesiotherapy, but did not deal with PNF. Patients in group G3 (20 people) received massage, acupuncture, and PNF, excluding kinesiotaping.

All patients received treatment 5 times a week (Monday to Friday, excluding Saturday and Sunday), the total duration of the rehabilitation course is 20 days. The program included: 30 minutes an acupuncture session, 20 minutes massage, 45 minutes physical exercises with a physical therapist. Classes using the PNF technique were carried out separately every other day for 45 minutes using the standard method for shoulder pain.

VAS was used to monitor efficacy. Pain was assessed at the beginning of the study, with the third, sixth, ninth and last visit to the clinic.

Results: The age composition of the patient group is from 31 to 70 years. The gender composition is 35 (58.33%) women, and 25 (41.67%) men.

The average time between the onset of clinical symptoms and the first treatment session was 473 days. In 90% of patients, a history of pain lasted from 6 weeks or more. 52 patients (86.67%) completed the treatment completely. Of these, G1 is 19 people (90% of this group), 16 (80%) in G2, and 17 of 20 in the G3 group (85%).

The average VAS score in G1 was 5.15 at the start of the study, and after the tenth session, it dropped to 2.78. A significant decrease in pain is also observed in the G2 group (from 5.17 at the beginning of the study to 3.19 after the tenth session). The G3 group in terms of pain reduction almost equaled the G1 group, where the level of pain from 5.16 decreased to 2.71.

Patients within 6 months after treatment evaluated the level of pain on their own and reported the data to the doctor. In patients of group G1, after 6 months, the average VAS score is 3.71, and after 6 months, the VAS score is 4.25 points. Patients of the G2 group at 3 months noted a return of the pain syndrome, after 3 months, the VAS score was 5.11.
Conclusion: The obtained results testify to the high efficiency of PNF therapy, however, the combination with kinésiotaping allows better consolidation of the effect of therapy and prolongs remission of pain syndrome.

GENDER DISTRIBUTION AND GENDER-RELATED ISSUES AMONG YOUNG RHEUMATOLOGISTS AND ACADEMIC POSITIONS IN RHEUMATOLOGY: A SNAPSHOT OF THE CURRENT SITUATION IN ITALY

L. Andreoli1, S. Alivernini2, A. Alunno2, S. L. Bosello2, C. Chighizola4, P. Coniglio5, E. Gremsse2, C. Iannuccelli2, L. Quartuccio5, F. R. Spinelli6, M. Vadacca8, M. S. Chimenti5 on behalf of SIRyoung and ReDO

Objectives: To describe the gender distribution among young members of SIR and academic positions in Rheumatology in Italy. To assess the expectations and needs of young rheumatologists with regard to their career.

Methods: SIRyoung members developed a web-based survey which was distributed among SIR members under the age of 40 during the spring of 2019. Responses were collected and analysed anonymously. ReDO retrieved and analysed the data regarding academic positions in Italy in September 2019 from official data by “Ministry of Education, University and Research” (www.miur.it).

Results: Out of 478 SIR members under 40 (66.5% F), 113 (23.7%) completed the SIRyoung survey (62.1% F). Regarding career plans, male and female members responded: hospital physician (36.9% vs 37.8%), outpatient clinic physician (18.5% vs 28.3%), academic career (23.9% vs 22.8%), private practice (16.3% vs 9.4%), and industry (4.3 vs 1.6%), respectively. When asked about their interest in doing a fellowship in another national center or abroad, 60.8% of male and 72.8% of female respondents were interested but thought they could not afford it. Reasons reported by males and females were: working reasons, namely barriers to temporarily leave the workplace (61.3% vs 50.7%), family reasons (16.1% vs 25.4%), financial reasons (22.6% vs 16.5%), respectively. As for academic career in rheumatology in Italy, 113 positions were retrieved. Men held 64 positions (57%), and women 49 (43%). Full professors were mostly women (92%), while assistant professors were women in 65% of the cases (58% of those with a permanent position; 72% of those with a temporary position) (Figure 2).

Conclusion: Our study explored for the first time gender distribution and related issues in Rheumatology in Italy. Female representation accounts for two thirds of SIR members under 40. This could reflect the general trend of medical school of the elderly patient population, musculoskeletal (MSK) examination remains frequently overlooked and poorly completed in medical clerking. Indeed, studies over the years have emphasized the widespread omission of MSK examination. (1,2)

Disclosure of Interests: SIRyoung and ReDO wish to thank the Steering Committee of SIR.

AB1267 ONLINE CASE-BASED EDUCATION SIGNIFICANTLY IMPROVED RHEUMATOLOGISTS’ KNOWLEDGE AND CONFIDENCE IN MANAGING PATIENTS WITH RA
E. Bell1, A. Sendaydiego2, P. C. Taylor3, 1Medscape LLC, New York, United States of America; 2Medscape LLC, New York, United States of America; 3Norman Collisson Professor of Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Background: With the rapid evolution in treatment strategies and the increasing range of available therapeutics for rheumatoid arthritis (RA), keeping pace with advances can be a challenge for busy physicians.

Objectives: We assessed whether online CME can improve rheumatologists’ knowledge of RA management focusing on the assessment and monitoring of RA, the selection of appropriate treatments and the clinical efficacy and safety data for JAK inhibitors.

Methods: Rheumatologists participated in a text-based activity featuring two patient cases with questions that “tested” knowledge and discussion of the main “teaching” points. Educational effect was assessed using a repeated-pair design, pre-post-assessment. A Chi-square test of independence determined if a statistically significant improvement (5% significance level, P<0.05) existed in the number of correct responses between the pretest and posttest scores. Cramer’s V estimated the effect size of the education. The activity was launched on 15 December 2018 with data collection through 27 February 2019.

Results: Significant improvement in average percentage of correct responses, rising from 47.7% at baseline to 92% post-activity (P<0.001) and extensive educational impact (Cramer’s V=0.496)

• Significant increase in percentage of rheumatologists (n=111) answering all 3 questions correctly (6% at baseline rising to 78% post assessment)
• Significant improvements in knowledge of EULAR/ACR assessment criteria (86% improvement, P<0.001), EULAR treatment recommendations for a patient failing on MTX and a TNF inhibitor (100% improvement, P<0.001), and the VTE risk associated with having RA or receiving RA treatments (108% improvement, P<0.001)
• 46% of rheumatologists reported greater confidence in their ability to appropriately incorporate JAK inhibitors into the treatment of patients with RA (average confidence shift 20%)

Conclusion: Overall, this learning activity was highly successful in improving rheumatologists’ knowledge and confidence in managing patients with RA, particularly with regard to the appropriate use of JAK inhibitors in patients for whom such treatment is suitable. The extensive impact of this interactive ‘test then teach’ activity is likely to directly translate into patient benefit. Further education on this topic would be useful to enhance and reinforce this knowledge and to support physician confidence in the use of JAK inhibitors in clinical practice.

AB1268 ONLINE EDUCATION YIELDS SIGNIFICANT GAINS IN RHEUMATOLOGISTS’ KNOWLEDGE OF THE ROLE OF JAK INHIBITORS IN THE MANAGEMENT OF RA
E. Bell1, M. Calle1, R. Van Vollenhoven2. 1Medscape LLC, New York, United States of America; 2Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands

Background: The treatment armamentarium for rheumatoid arthritis (RA) has expanded rapidly in recent years, making it challenging for rheumatologists to stay up to date with key advances. The most recently available treatment options (43% improvement, P=0.007)

• Numerical improvement from relatively high baseline for understanding of unmet needs in RA patients (74% at baseline, 87% post-activity) and the advantages of JAK inhibitors versus TNF inhibitors for a specific patient care (75% at baseline, 84% post-activity)

• Considerable educational impact (Cramer’s V=0.167) with 35% of rheumatologists reporting greater confidence in describing the mechanism of action of current and emerging JAK inhibitors (noteable average confidence shift of 15%)

Conclusion: A positive and significant effect on physician knowledge and confidence regarding JAK inhibitors for RA was achieved following this online CME activity. The extent of this educational impact is likely to lead to better patient outcomes since physicians are better equipped to consider JAK inhibitors for appropriate patients. The results also revealed that physicians would benefit from additional education to reinforce their knowledge of key clinical data for JAK inhibitors and on the use of JAK inhibitors in clinical practice.

AB1269 REGIONAL DIFFERENCES IN THE PATIENTS’ UNDERSTANDING OF TREATMENT STRATEGY IN RHEUMATOID ARTHRITIS
C. Cobălcescu1, M. Danila1, D. Opris-Belinški1, J. Saulescu1, L. Groseanu1, S. Daia Iliescu1, C. Codreanu1, R. Ionescu1, M. Parvu3, H. Popoviciu1, C. Ancuta5, E. Rezus5, C. MihaiLOV5, R. Ionescu1, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2University of Alabama at Birmingham, Birmingham, United States of America; 3Colestina Clinical Hospital, Bucharest, Romania; 4George Emil Palade University of Medicine, Pharmacy, Science and Technology, Targu Mures, Romania; 5Grigore T. Popa University of Medicine and Pharmacy, Iasi, Romania; 6Ovidius University, Constanta, Romania

Background: The treat-to target (T2T) concept is the standard for treating rheumatoid arthritis (RA) patients worldwide1. However, difficulties that patients encounter in achieving disease control may differ between regions, which may impact the type of support needed for successful T2T implementation.

Objectives: To compare differences in patient-reported challenges to controlling RA-related issues between Romanian and US patients.

Methods: A cross-sectional study that recruited 403 RA patients was conducted in six centers in Romania. Patients were invited to complete an RA-related questionnaire. We compared their responses to those from a previous published study that included patients with RA from the US2. The survey included items on subjective beliefs about RA treatment (e.g. adherence, cost, adverse events) and knowledge about T2T strategy. Approval for US data use was given by the study coordinator2.

Results: All patients in the Romanian cohort were Caucasian, with a mean age of 58.7 years (SD 11.5). 78% were females and the mean disease duration was 11.2 years (SD 8.3). Data was concordant with results from the previously published study. More patients from US had college education (60% vs 43.9%). Among the respondents, 93.3% Romanians were on a synthetic DMARD versus 97.7% Americans and 64.01% were currently on a biologic of choice compared to 74% patients in the US. More than half of the patients in both regions had a history of biologic DMARD use.

Asked to grade (0 very good, 10 very bad) their disease activity on the survey day, a large category of patients (37.4%, SD 14.1) marked an average state (4-6), rising from a relatively high baseline of 67% to 81% post-activity (P<0.001)

• Increase in percentage of rheumatologists (n=68) answering all 3 questions correctly (37% at baseline rising to 66% post assessment)

• Significant improvement in knowledge of clinical trial safety data for JAK inhibitors (43% improvement, P=0.007)

• Numerical improvement from relatively high baseline for understanding of unmet needs in RA patients (74% at baseline, 87% post-activity) and the advantages of JAK inhibitors versus TNF inhibitors for a specific patient care (75% at baseline, 84% post-activity)

Disclosure of Interests: : None declared, Marinella Calle: None declared, Ronald van Vollenhoven Grant/research support from: AbbVie, Arthro- gen, Bristol-Myers Squibb, GlaxoSmithKline, Lilly, Pfizer, and UCB, Consultant of: AbbVie, AstraZeneca, Bioteest, Bristol-Myers Squibb, Celgene, GSK, Janssen, Lilly, Medac, Merck, Novartis, Pfizer, Roche, and UCB
DOI: 10.1136/annrheumdis-2020-eular.2294
Most European patients would agree to change treatment to lower pain. Almost 82% stated they would accept rare adverse events in order to avoid invalidity, to confirm a better future outcome. US patients were more prone to stick to current therapy due to escalated increase clinical response. However, asked about novel therapies, Romanians were reluctant to changing treatment despite insufficient benefit, if the risk of cancer was noted. There was a high agreement that a delay in treatment would be unsatisfactory for both familial and professional chores.

**Conclusion:** There are regional differences in knowledge and perceptions about RA treatment. Romanian patients know less on T2T algorithm. Improving awareness of the T2T strategy among RA patients may need different types of support depending on the patient's place of residence.

### AB1270 RHEUMATOLOGY WORKFORCE IN LATIN AMERICA: TRAINING AND CURRENT STATUS

**Background:** The demand for rheumatology care has been steadily increasing over the last few years. However, supply seems to be insufficient, according to previous research. This situation may be at least partly explained by less physicians beginning a rheumatology residency program.

**Objectives:** We aim to identify baseline data, room for change, and to strengthen functional processes associated with the rheumatology workforce in order to improve care offered to patients living with rheumatic diseases.

**Methods:** Descriptive cross-sectional study. We obtained data on each country through local PANLAR rheumatologists. They completed an online survey using the RedCap® platform, used for capture and storage of data. The sample was described according to the type of variable.

**Results:** 19 Latin American countries were included in this study, globally 1 rheumatologist was available per 106,838 inhabitants. The highest rates were found in Uruguay (per 23,695 inhabitants) and Argentina (per 40,384 inhabitants). The lowest rates were found in Nicaragua (per 640,648 inhabitants) and Guatemala (per 559,902 inhabitants). The ratio between women and men rheumatologists was 0.99 women per each man. The lowest proportions were found in Uruguay (per 23,695 inhabitants) and in Argentina (per 40,384 inhabitants). The highest age averages were found in Paraguay (43.1 SD 10.77) and the highest age averages were found in Peru (56.23 SD 12.93). The average monthly compensation was USD $2,382.6 (SD $1,462.5). Venezuela had the lowest salary ($197), the highest salary was found in Costa Rica ($4,500). The proportion of rheumatologists trained abroad was 26.7%, ranging between 0% in Uruguay and 90% in Bolivia. The countries with more rheumatology training programs were Brazil n = 50 and Mexico n = 20, while Ecuador, Honduras and Nicaragua don’t have any. The countries with the greatest amount of active residents were Brazil (n = 232) and Argentina (n = 100). The educational level required to enter the program was postgraduate studies in internal medicine in 42.11% of the programs. Currently, 118 residency programs in Latin America are active. Duration of residency programs is variable: 2 years (79.63%) of cases, 3 years (16.67%), 4 years (1.85%), 5 years (0.96%) or 6 years (0.96%). The median monthly compensation for residents was $ 528 USD (IQR $ 774), the country with the highest payment was Costa Rica ($ 2637). Contrarily, in Cuba, Chile and Colombia there is no payment to residents. Finally, in 8 countries (42.11%) residents must not pay for their postgraduate studies, the average annual tuition expense in the rest of countries is $ 1548 (SD $ 2749).

**Conclusion:** The rate of rheumatologists per inhabitant is low. The demographic characteristics and the current status of the rheumatology workforce, as well as rheumatology training in Latin America varies widely among countries. For instance, relevant differences can be found regarding payment to rheumatologists and residents, and tuition fees. The collected information will be useful when planning regional-based strategies, as well as for future research projects in each country and within PANLAR.

### AB1271 PATIENT EDUCATION IN PSORIATIC ARTHRITIS: A SERVICE EVALUATION AT ONE YEAR

**K. Austin**, **R. Prasad, R,** University Hospitals Bristol NHS Foundation Trust, **Rheumatology, Bristol, United Kingdom**

**Background:** Recent studies have demonstrated an increasing burden of musculoskeletal (MSK) diseases worldwide. The importance of patient education (PE) is often overlooked in the management of long term inflammatory conditions. The European League Against Rheumatism recommends that PE should be integral to standard of care in inflammatory arthritis. PE increases patients knowledge, skills and confidence in managing their condition and improves patient activation (PA). Evidence shows that improved PA results in better outcomes and improved experiences of care. We previously reported on improved knowledge and confidence amongst a small patient group with psoriatic arthritis (PsA) who had attended a pilot education session. This education session was delivered to a wider group of patients with PsA over a 12 month period; we report on the evaluation received from this service.

**Objectives:** To provide a programme to a wider group of patients with PsA using a multi-disciplinary team (MDT) approach and to evaluate whether this improved patients' knowledge, skills and confidence in managing their PsA.

**Methods:** Adult patients with PsA attending their rheumatology clinic appointments were invited to a 2.5 hour MDT education session which covered: 1) a general overview of PsA; 2) medications used in PsA; 3) the role of physical therapy and occupational therapy; 4) flares and self-management. These were interactive sessions, held in a small group setting to allow for informal discussion and questions to the MDT. Written materials including several booklets and online resources were also provided. Patients evaluated their knowledge or understanding before and after each topic covered, on the same day, using an evaluation tool with 1-10 Likert scale items. Changes in ratings were analysed using student’s t-tests. Patients were also asked: which aspects they found particularly helpful; if there was anything they would like to have added; how more of the session would have been helpful; whether they found the session helpful; whether they would recommend
to other patients; whether they would be interested in developing a PsA patient support group.  

**Results:** Four sessions were held over a 12 month period. A total of 32 patients attended; 10 males and 22 females, across a range of age categories. Disease duration varied from less than 1 year to over 10 years. There were statistically significant improvements in all topics covered; mean improvement of 91% in how well informed patients felt about PsA overall (p<0.0001); mean improvement of 74% in confidence in accessing help from the MDT (p<0.0001); mean improvement of 122% in how well informed patients were about medications used in PsA (p<0.0001); mean improvement of 99% in patients' confidence in self-managing a flare (p<0.0001). Aspects that patients found particularly helpful included “The whole session” “Asking questions to all different professionals,” “Meeting other sufferers,” “Management of flares,” “Fatigue information” and “Online resources.” Overall, 97% of patients (31 out of 32) found the session helpful and would recommend it to others. Over 40% of patients expressed interest in developing a local PsA support group.  

**Conclusion:** Following a 2.5 hour education session, improved knowledge, skills and confidence in managing their PsA was reported by 97% of patients, including patients with disease duration of > 10 years. This supports our previous finding that an interactive, group PsA education programme is a feasible and important adjunct to patient care.

**AB1272 ONLINE EDUCATION BOOSTS CLINICIAN KNOWLEDGE ABOUT EMERGING THERAPIES FOR PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE**  

C. Rohani-Montez1,2, M. Caillé1,2, C. Allen1,2, A. M. Hoffmann-Vold3, O. Distler4  

1Université Lille, Faculté de Médecine, Lille, France; 2CHU Lille, Service de Médecine Interne, Lille, France; 3Centre de Simulation PRESAGE, Lille, France; 4Centre National de Référence Maladies Systémiques et Auto-immunes Rares (Sclérodermie Systémique), Lille, France  

**Background:** Systemic sclerosis-associated interstitial lung disease (SSc-ILD) has traditionally been treated with therapies such as cyclophosphamide, mycophenolate mofetil, and hematopoietic stem cell transplantation. However, these therapies are limited by potential toxicity, as well as duration and magnitude of effect. Clinicians need awareness of emerging therapies in late-stage clinical trials that may address these limitations.  

**Objectives:** This study was conducted to determine whether online independent medical education could improve rheumatologists' and pulmonologists' knowledge of emerging therapies for the management of SSC-ILD.  

**Methods:** Physicians (N = 2,076) participated in a 30-minute, 2-faculty, video-based, online CME with synchronized slides.1 The majority of participants were rheumatologists (n = 522) or pulmonologists (n = 557), but the cohort also included clinical immunologists (n = 132) and other physicians with an interest in the topic (n = 865). This study focuses on the 120 rheumatologists and 111 pulmonologists who completed all pre- and post-questions. The effects of the education on knowledge was assessed using a 3-question, repeated pairs, pre-assessment/post-assessment study design. For all questions combined, the chi-square test assessed differences from pre to post-assessment. P values <.05 are statistically significant. The data were collected through November 5, 2019.  

**Results:** Overall significant improvements were seen after participation for both rheumatologists (average correct response rate of 55% at pre-assessment vs 75% at post-assessment; P<.001, N=120) and pulmonologists (average correct response rate of 60% at pre-assessment vs 77% at post-assessment; P<.001, N=111). Specifically, significant improvements were observed in clinicians’ knowledge of trial data for emerging SSC-ILD therapies (figure).  

**Disclosure of Interests:** 1927
AB1274

STIFF SPINE AND A WEAK HEART: A CASE OF LONG STANDING ANKYLOSING SPONDYLITIS DEVELOPING PULMONARY ARTERIAL HYPERTENSION SECONDARY TO MIXED CONNECTIVE TISSUE DISEASE, CONFERRING POOR PROGNOSIS

C. Dharmapalaiyah1, B. Ms2, P. Sn2. 1Aster CMI Hospital, Hebbal Bangalore, Rheumatology, Bengaluru, India; 2Aster CMI Hospital, Hebbal Bangalore, Internal Medicine, Bengaluru, India

Background: Spondyloarthritides (SpA) and Connective Tissue Diseases (CTD) are considered distinct entities with diverse clinical features and genetic characteristics. There are very few case reports of SpA coexisting with CTDs like Lupus, Scleroderma and Morphea. Drugs used in treating SpA like Sulphasalazine and anti TNF drugs can also induce CTD.

Objectives: We report a case of a patient with eleven years history of Ankylosing Spondylitis (AS), presenting with Mixed Connective Tissue Disease (MCTD) and Pulmonary Arterial Hypertension (PAH) constituting a therapeutic challenge.

Methods: A 36 year old gentleman was diagnosed with AS at the age of 25 years, fulfilling the ASAS criteria (chronic inflammatory back pain, sacroiliitis on radiograph, HLAB27 positive). He was treated with NSAIDs, Sulphasalazine (SSZ) and physical therapy since 2008. There was gradual progression of his arthritis with high BASDAI along with recurrent anterior uveitis. He was treated with 5 doses of IV Infliximab 3mg/kg, between 2017 and early 2018. In May 2018, following further Infliximab he developed a serum sickness like reaction which was thought to be HACA response to Infliximab. He responded to IV hydrocortisone and antihistamines and Infliximab was discontinued.

In February 2019 he developed severe flare up of peripheral arthritis. He was treated with Injection Adalimumab 40mg every 2 weeks along with Latent TB prophylaxis with Isoniazid and Rifampicin. He received 4 doses to no effect and was discontinued.

In April 2019 Methotrexate (MTX) was added for peripheral arthritis. He discontinued both MTX and SSZ in July 2019 due to inefficacy. Peripheral arthritis responded well to Leflunomide that was started in September 2019. There was an unexpected turn of events in October 2019, when he was admitted with severe dyspnoea and cough with new onset raynauds, skin tightening over forearms and nape of neck with salt and pepper appearance of skin at these sites (Images). He was hypoxic requiring oxygen support. Echocardiogram showed moderate pericardial effusion and pulmonary hypertension (PASP 60mmHg), dilated right heart and pulmonary artery. Pulmonary embolism was excluded on a CT pulmonary angiogram

Results: Investigations revealed 3+ ANA speckled pattern, anti RNP/ Sm 3+, Rheumatoid Factor negative. CRP 45.7u/l, Hemogram, renal and liver function tests were normal. Cardiac MRI showed minimal pericardial effusion with mildly dilated right ventricle, non-dilated left ventricle with LVEF (−44%).
Right heart catheterization confirmed PAH with Mean PAP 58mmHg, LVEDP 8mmHg, PCWP 15mmHg.

A diagnosis of Mixed Connective Tissue Disease (MCTD) was made, associated with PAH and pericardial effusion.

He was started on Ambrisentan and Tadalafil for PAH. Hydroxychloroquine and Mycophenolate Mofetil were also added in view of the PAH being associated with CTD. The additional pericardial effusion confers a poor prognosis.

**Conclusion:** Association of Spondyloarthritides and Connective Tissue Disease is rare. There are very few case reports of their chance association, especially MCTD.

Our patient had been exposed to Sulphasalazine, Infliximab, Adalimumab and Isoniazid, all with a potential to induce an auto immune CTD. MCTD features have persisted despite drug withdrawal. This case may suggest routinely checking for ANA in Sjögren patients prior to initiating anti-TNF drugs.

**AB1275**

**HYPDROCEPHALUS IN AUTOIMMUNE DISEASES: A SERIES OF CHALLENGING CASES**

N. El Gobashy1, 1Cairo University, Cairo, Egypt

**Background:** Hydrocephalus can be a rare neurological manifestation but lethal complication of various SAIDs, including systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), sarcoidosis, and primary vasculitis. The commonly used medical management programs based on the etiology of hydrocephalus are anti-inflammatory or anti infectious therapies, while surgical management such as ventriculoperitoneal shunts is effective most of the time (Wei Jetal.,2019).

**Objectives:** To analyze the diagnosis and management of hydrocephalus associated with autoimmune diseases

**Methods:** A retrospective case series study was conducted at Rheumatology department, Cairo university. Files were retrieved from the hospital archives by screening records from Jan 2014 to Jan 2019. Medical records were screened for data regarding the clinical manifestation and outcome of hydrocephalus associated with autoimmune disease.

**Results:** Case (1) Male patient 28 yrs old diagnosed a systemic lupus erythematosus at the age of 19. The patient presented with headache and blurring of vision. Fundus examination showed grade 2 to 3 papilledema. MRI brain showed: Non obstructive hydrocephalus. MRA & MRV: normal laboratory investigation was done and showed consumed c3 & c4. ESR: 35mm/hour. Hb: 12.3g/dl. WBC:6.38 cells/mm3. normal liver and kidney function. Neurosurgery consultation was done and recommended urgent ventriculo –peritoneal shunt. follow up fundus showed improvement of papilledema. The patient was discharged on steroids 30mg/day –peritoneal shunt. follow up fundus showed improvement of papilledema. The patient was discharged on solupred 20mg/day along with azathioprine 100mg/day and mycophenolate mofetyl: 2gram with improve.

**Conclusion:** VPS along with medical treatment with steroids and immunosuppresion present an effective treatment protocol.

**NON-INTERFERON THERAPY OF CHRONIC HEPATITIS C IN A PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SECONDARY SJÖGREN SYNDROME - CASE REPORT**

I. Menshikova, 1 Y. Pak2, 2I.M. Sechenov First Moscow State Medical University (Sechenov University), Rheumatology Department of Clinical Hospital #1, Moscow, Russian Federation; 1I.M. Sechenov First Moscow State Medical University (Sechenov University), Rheumatology department of University Clinical Hospital #1, Moscow, Russian Federation; 1I.M. Sechenov First Moscow State Medical University (Sechenov University), Faculty Therapy Department, Moscow, Russian Federation

**Background:** Hepatitis C virus infection is one of the most significant public health problems in the world. To date, the problem of selection of therapy is very relevant for patients with autoimmune diseases and chronic hepatitis C [1]. Patients with systemic lupus erythematosus (SLE) are forced to take different doses of steroids, often in combination with immunosuppressants (m cycophenolate mofetil, azathioprine, etc.) even in the case of long-term remission. Such therapy for many years can contribute to the reactivation of hepatitis C.

**Objectives:** To describe a clinical case of the effectiveness of the combined use of interferon-free therapy and therapy of steroids in a patient with SLE, secondary Sjögren syndrome and chronic hepatitis C.

**Methods:** 58-years-old woman was admitted to the rheumatology department of Clinical Hospital No. 1 in December 2018 with the debut of SLE: photosensitivity, aphthous stomatitis, arthritis, pleurisy, sicca syndrome, leu kopenia, ANA 1: 2560, antibodies to dsDNA 55.95 IU / ml, positive antiSS-A (Ro). At the same time, it became known that she was infected with hepatitis C virus in 1985 presumably. At the time of hospitalization, anti-HCV was positive, the virus genotype was 1b, the activity of the process was low (HCV RNA 6.6x10^7, AST 33 U/L and ALT 25 U/L). The patient was prescribed corticosteroids (methylprednisolone 16 mg/day) and hydroxychloroquine 400mg/day. In January 2019, after gastroenterologist, hematologist and infectious disease specialist advise, it was decided to conduct the patient a specific interferon-free antiviral therapy for chronic hepatitis C (a 24-week course with asunaprevir and daclatasvir), given the potential long-term glucocorticoid therapy, with the prospect of treating the patient with cytotoxic drugs, and the possibility of reactivation of chronic hepatitis C amid of immunosuppressive therapy for SLE and Sjögren syndrome.

**Results:** Low-disease activity of SLE was achieved in a month, and after 24-week course of antiviral therapy, there was no increase in SLE activity, and positive laboratory and clinical dynamics were noted.

**Conclusion:** Thus, the use of interferon-free therapy of chronic hepatitis C in patients with systemic lupus erythematosus and secondary Sjögren syndrome shows possible ways to safe treatment of this disease in patients with diffuse connective tissue diseases.

**AUTOANTIBODIES IN NLRP3-ASSOCIATED AUTOINFLAMMATORY DISEASE: A CASE REPORT AND LITERATURE REVIEW**

L. Zhang, 1 Y. Sun 1, Y. Li 1, W. Wu 1, Y. Wang 1, D. Wu 1, W. Zhang 2, M. Shen 1, R. Wang 1, 1Peking Union Medical College, Beijing, China; 2School of Basic Medicine Peking Union Medical College, Beijing, China
Background: We present the first report of high-titer autoantibodies in NLRP3-associated autoinflammatory disease (NLRP3-AID). Because systemic autoinflammatory disease (SAID) is characterised by the lack of auto-reactive T-cells or autoantibodies, we made a systemic review on the theme of autoantibody in SAID to clarify this phenomenon.

Objectives: We present the first report of high-titer autoantibodies NLRP3-AID, and discuss autoantibody in classical SAID.

Methods: We collected the clinical data of the patient with NLRP3-AID who had high-titer autoantibodies, and made a systemic review about autoantibody in SAID.

Results: A 38-year-old Chinese Han patient was definitely diagnosed as NLRP3-AID because of cold-triggered urticaria-like rash and fever, arthritis, bimalateral sensorineural deafness, chronic meningitis, high inflammatory marker and de novo NLRP3 T348M variant. Figure 1 shows pedigree of the patient. Meanwhile, she had positive anti-nuclear antibody (ANA) with a nucleolar pattern of ≥ 1:160, positive anti-cytoplasmic antibody (p-ANCA) and positive anti-neutrophil cytoplasmic antibodies (pm-ANCA) and anti-CCP in patients with FMF.

Conclusion: Patients with NLRP3-AID can have high-titer APA and APLs by accident. If patients with high-titer autoantibodies have characteristic manifestations of SAIDs instead of typical features of autoimmune diseases, we should make the final diagnosis through detailed investigation and genetic testing.

A CASE REPORT OF TOCILIZUMAB INDUCE RAPID REMISSION OF ADULT-ONSET STILL’S DISEASE AND LIFE-THREATENING INTERSTITIAL LUNG DISEASE AND MACROPHAGE ACTIVATION SYNDROME

G. Zhang1, W. Liu1, T. Xu1, X. Zhang1, 1Guangdong Provincial People’s Hospital/Guangdong Academy of Medical Sciences, Rheumatology, Guangzhou, China

Background: Adult-onset Still’s disease (AOSD) is a systemic inflammatory condition characterized by fevers, polyarthralgia, skin rashes and increased leukocyte and neutrophil counts [1]. Sometimes life-threatening complications such as macrophage activation syndrome (MAS), disseminated intravascular coagulopathy (DIC), and hemorrhagic pancreatitis (HP) can occur without response to glucocorticoid and disease-modifying anti-rheumatic drugs (DMARDs).

Objectives: To describe an AOSD patient with life-threatening interstitial lung disease (ILD) and MAS response to tocilizumab.

Methods: This is a case report at our medical practice.

Results: A 43-year-old man was hospitalized for a 2-week history of fever accompanying skin rashes, polyarthralgia, sore throat, leukocytosis (the maximum leukocyte count 37.25×10^9/L with 89.9% neutrophils), elevated levels of C-reactive protein (190.9mg/L) and ferritin level was very high (>15000ng/ml). Several antibiotics were consequently used, but fever was on going. Chest CT displayed diffuse interstitial lung disease. Infectious diseases and lymphoma were excluded and AOSD with ILD was diagnosed. However, MAS occurred the 20 days later after the pulse of intravenous MP (MP 500mg×3days) following MP 40mg/day, which cannot stop the situation deteriorating. The minimum total white blood cells, hemoglobin and platelets went down to 0.25×10^9/L, 53g/ml and 18×10^9/L. Finally, tocilizumab rescued this patient from desparation.

Conclusion: Tocilizumab was effective in AOSD with life-threatening ILD and MAS.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

AB1279-HPR
A DESCRIPTIVE STUDY RELATED TO THE ADHERENCE BEFORE AND AFTER ENROLLING IN A MULTIDISCIPLINARY EDUCATIONAL PROGRAM

D. Buitrago-García1, F. Rodriguez2, G. Sánchez3, P. Santos-Moreno4.
1Fundación Universitaria de Ciencias de la Salud, Epidemiology, Bogota, Colombia; 2Biobam - Center for Rheumatoid Arthritis, Patient Education Program, Bogota, Colombia; 3Biobam - Center for Rheumatoid Arthritis, Rheumatology, Bogota, Colombia

Background: Rheumatoid arthritis (RA) is an inflammatory, chronic disease. It leads to deformity and destruction of joints through the erosion of cartilage and bone. Patients with RA report to suffer symptoms in hands, joints, swelling, loss of motion, and muscle weakness among others. [1] Centers of excellence in RA have proposed a multidisciplinary model of care with an initial diagnosis, treatment prescription and follow-up with a rheumatologist, periodic consultations with a physiatrist, psychologist, physiotherapist, occupational therapy, nutrition and a patient focused program [2]. With this model of care, the patient is seen as a whole, and the expectation is to achieve the best results in the management of RA. However, if the patient does not adhere the model becomes ineffective.

Objectives: The aim of this to report the attendance to a multidisciplinary model of care for patients with RA that attend to a specialized center in Colombia, before and after enrolling in a educational program.

Methods: We performed a descriptive study. Patients enrolled our educational program in July 2019. In our institution patients are followed-up under T2T standards and a multidisciplinary approach, as part of our model of care they have periodic consultations with a rheumatologist, physiatrist, psychologist, physiotherapist, occupational therapy and nutrition. We collected sociodemographic data, DAS28, and compare the attendance to each specialty at the beginning and at 6-month follow-up. Descriptive epidemiology was done, we calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We compared disease activity and adherence at the beginning of the program and after six months of attendance.

Results: We included 229 patients; mean age was 59 years ± 10; 93% were female. At the beginning of our program, mean DAS28 was 2.57 ± 1.19, from all patients 65% were at remission, 11% at low disease activity 19% at moderate disease activity and, 5% at severe disease activity. Regarding adherence to our model, the medical specialty with the highest attendance was rheumatology (30%) followed by, physical therapy (16%) physiatrist consultation (15%) psychology (13%) and, occupational therapy (11%); the specialty with the lowest attendance was nutrition (8%). After six months of attendance to the educational program, we found an increasing number of patients in remission 67%, low disease activity 15%, moderate disease activity 18%, we did not have patients with severe DA28. Regarding the medical specialties, we found a 3% rise in the attendance to the nutrition consultation and psychology consultation. We did not find statistical association between disease activity and adherence to the model.

Conclusion: These results are a clear example of how an educational program is capable of increasing awareness and improving the clinical outcomes and adherence to a multidisciplinary model for approaching RA. As other studies have shown [3], patient education interventions improve adherence to medication and to attendance to health care specialists.

Disclosure of Interests: Diana Buitrago-García: None declared, FernandoRodriguez: None declared, GUILLERMO SÁNCHEZ: None declared, Pedro Santos-Moreno: Grant/research support from: I have received research grants from Abbvie, Biopas-UCB, Janssen, Novartis, Pfizer. Speakers bureau: I have been a speaker for Abbvie, Biopas-Ucb, Janssen, Lilly, Novartis, Pfizer, Roche, Sanofi.
Background: Primary care physicians (PCP) are usually the first contact of people with inflammatory rheumatic diseases, and find the early symptoms of Rheumatoid Arthritis (RA) difficult to distinguish from those of other rheumatic diseases. A time-delay in the reference to Rheumatology is a health issue in several countries. The clinical aspects that general practitioner took into account in hand arthralgia patients are important to make the reference. In particular the Squeeze Test (ST) - which is simple to perform and rapidly done, ST is useful in hand arthralgia patients are important to make the reference. In particular the Squeeze Test (ST) - which is simple to perform and rapidly done, ST is useful for identifying progression to RA in patients with undifferentiated arthritis. The ST has been described as not reliable because is clinician-dependent.

Objectives: To identify the required force that needs to be applied in order to obtain a positive Automated Squeeze Test (AST) in a cohort of patients with hand arthralgia.

Methods: Ninety-seven patients were recruited in Family Medicine Consultation and in Rheumatology Consultation of the Hospital Universitario “Dr. José Eleuterio González” in Monterrey, Nuevo León, Mexico. Eligible patients were adults (aged≥18 years) with hand arthralgia (that wasn't caused by trauma) as their chief complaint. After obtaining informed consent and after a questionnaire application, patients were submitted to AST maneuver, using an automated compressor with different forces already predetermined in the interface of the software used for compression.

Results: In this cohort of 98 patients, 79 (80.6%) were women. The mean age was 51.14 years (SD 14.66). Ninety-six (97.9%) patients were right handed. The diagnoses were Osteoarthritis (OA) (16.3%), RA (5.1%), Undifferentiated arthritis (1.2%), Psoriatic arthritis (1.2%) and Fibromyalgia (2%). Force measures according to diagnoses are reported in Table 1.

Table 1. Diagnoses and mean forces

AB1282-HPR

THE LEVELS OF VITAMIN D IN THE SPONDYLOARTHROPATHIES. DOES THE DEFICIT CORRESPOND TO THE INFLAMMATORY ACTIVITY?

M. D. M. Cutillas Perez1, C. Marin Silvente1, E. Saiz1, M. F. Pina1, 1Meseguer General University Hospital Morales, Murcia, Spain

Background: The drugs that inhibit tumor necrosis factor (anti-TNF) alpha can reactivate a latent tuberculosis infection (LTB) so requiring a rigorous screening before its onset. The tuberculin test (PT) has a high false negative rate in patients with immunomodulated rheumatic diseases (IMID) and false positive in patients vaccinated with Bacillus Calmette Guérin (BCG). The neu methods of interferon gamma release (IGRA) seem to solve this problem, but its use is not standardized.

Objectives: Establish the degree of concordance in the diagnosis of LTB between PT and IGRA in patients who are going to star an anti-TNF drug, in general, and in different situation like taking corticosteroids, being treated with disease modifying drugs, have been vaccinated with BCG or have risk factor for LTB.

Methods: From May 2016 to November 2019, 195 patients with IMID who underwent LTB screening prior to the initiation of an anti-TNF drug were included in this study. The concordance between PT and IGRA was calculated using the Cohen's kapa index, for the general sample first and then for subgroups. An analysis of the factor that influence the result of PT and IGRA has also been carried out.

REQUIRED FORCE TO OBTAIN A POSITIVE SQUEEZE TEST AUTOMATIZED IN PATIENTS WITH HAND ARTHRITIS

M. M. Castañeda-Martinez1, G. Figueroa-Parra1, D. Vega-Morales1, B. R. Vázquez Fuentes1, Y. G. Ordoñez Azuara2, J. A. Esquivel Valerio1, D. A. Galarza-Delgado1. 1University Hospital “Dr. José Eleuterio González”, Rheumatology Service, Monterrey; Mexico; 2University Hospital “Dr. José Eleuterio González”; Family Medicine Service, Monterrey, Mexico

Background: The diagnosis of spondylarthropathies is a complex task because the different diseases that make up the spectrum of the disease may present with different forces already predetermined in the interface of the software for reference. A time-delay in the reference to Rheumatology is a health issue in several countries. The clinical aspects that generalize practitioners took into account in hand arthralgia patients are important to make the reference. In particular the Squeeze Test (ST) - which is simple to perform and rapidly done, ST is useful for identifying progression to RA in patients with undifferentiated arthritis. The ST has been described as not reliable because is clinician-dependent.

Objectives: To determine the association between vitamin D deficiency and the degree of activity of the disease (inflammatory activity) in a cohort of patients with spondyloarthritic.

Methods: Case-control type analytical observational study. We propose a retrospective review of the database of patients with spondyloarthritides (according ASAS2010 criteria) who were treated in the outpatient clinics of the Rheumatology Service of the General University Hospital of Ciudad Real during June 2018 to June 2019. Patients with the data will be selected. necessary for the analysis of the variables under study. The numerical variables of normal distribution evaluated will be described using measures of frequency and measures of central tendency / dispersion as appropriate. To assess the association between vitamin D levels and activity index, the odds ratio (OR) is calculated, with a 95% confidence level and the T-student for related samples.

Results: The final results of the study are presented. 115 patients were analyzed, of which 64 were men and 51 women, with an average age of 45.97 years (+/- 13.41 DE). 47% were ankylosing spondylitis, 21% psoriatic arthropathy, 16% undifferentiated spondyloarthropathy, 7% spondyloarthropathy associated with inflammatory bowel disease and 9% were spondyloarthropathy associated with inflammatory bowel disease. The average of the activity was a BASDAI of 4.57 (+/- 2.35 SD) and measured by DAPSA was 12.61 (+/- 6.76 SD). 63 and 14 patients had activity measured by BASDAI and DAPSA, respectively. 49.56% patients presented an elevation of acute phase reactants. Vitamin D levels were 23.81 (+/- 10.5 SD). 77.4% presented figures of vitamin D deficiency or insufficiency. When performing the association analysis, the vitamin D deficiency / insufficiency presented an OR 10 (95% CI: 3.66-27.29, p<0.0001) with the degree of activity measured with BASDAI and DAPSA and against the elevation of RCP it was 3.63 (95% CI 1.43-9.25, p = 0.0092) and against the elevation of ESR it was 2.76 (95% CI 1.09-7.0, p = 0.0438). Regarding the comparative analysis of means between vitamin D deficiency/insufficiency and BASDAI/DAPSA it was +3.29 (95% CI: 1.34-8.09, p=0.0084).

Conclusion: Patients with spondyloarthritides, as in other autoimmune diseases, vitamin D deficiency is associated with increased inflammatory activity (BASDAI, DAPSA, RCP and ESR), measured in different time periods. Therefore, an optimization of vitamin D levels can imply an improvement in the patient's clinical situation, measured by both BASDAI and DAPSA, as well as by RCP and ESR. In addition, it is necessary to monitor bone mineral density due to the risk of fracture in these patients for their multi-etiology (corticosteroid treatments, biological PAMES, inflammatory activity).

DOI: 10.1136/annrheumdis-2020-eular.5549
Results: The prevalence of ILTB was 26.7%. Of the total positive PT and Booster (n=50), QTF-G-IT was positive only in 15 patients (30%). The agreement between PT and QTF-G-IT was 0.33 (p<0.05). In the subgroups, a moderate agreement was found in patients who did not take corticosteroids (k=0.45, p<0.05) and greater than the global one in those who had risk factor for ILTB (k=0.37, p<0.05).

Conclusion: In our study the agreement between PT and QTF-G-IT is low in general, being somewhat higher in unvaccinated patients and with a high probability for ILTB. Taking this result into account due to the low concordance, the ideal ILTB screening strategy in patients who are going to start a anti-TNF would consist of performing both tests.

AB1283-HPR GASTROINTESTINAL INVOLVEMENT AND QUALITY OF LIFE IN A COHORT OF SYSTEMIC SCLEROSIS (SSC) PATIENTS

K. El Aoufy1,2, I. Antola3, C. Sicriontor2, S. Bellando Randone2, S. Guiducci4, D. Furst5,6,7, M. Matucci-Cerinic1.
1University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy; 2University of Florence, Florence, Italy; 3University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy; 4University of Washington, Seattle, Washington, United States of America; 5Division of Rheumatology, UCLA, Los Angeles, California, United States of America

Background: SSC is an autoimmune disease characterized by fibrosis of the skin and several internal organs involvement. The gastrointestinal tract is often affected causing a wide symptomaticity that can involve the oesophagus, stomach and/or intestine.

Objectives: To assess the gastro-intestinal tract with the UCLA SCTC GIT 2.0 questionnaire and the adherence to the Mediterranean diet with the Mediterranean Diet Score (MDS) in a cohort of SSC patients.

Methods: 18 SSC patients classified with ACR/EULAR criteria (limited and diffuse subsets) were enrolled from January to April 2019, from the outpatient clinic of the University of Florence, Division of Rheumatology, Careggi Hospital. UCLA SCTC GIT 2.0 questionnaire for gastro-intestinal involvement (range 0-3), Mediterranean Diet Score (MDS range 0-14) for adherence to the Mediterranean diet, Health Assessment Questioning (range 0-3) for disability and SF-36 (range 0-100) for the quality of life were administered to patients. Data on weight and height were collected for the calculation of the Body Mass Index (BMI).

Results: the 18 SSC patients included had an average BMI of 23.9 ± 4.7 (M ± SD); only one patient was overweight (BMI=16.6) and 4 patients were over-weight (BMI> 25). Our results show good adherence to the Mediterranean diet with a score of 9.78 ± 2.24 (M±SD) to the MDS. The quality of life assessed by SF-36 show scores were below the cut-off (<50), showing an impaired quality of general life (mental summary index = 36.32 ± 11.35 and physical summary index = 39.53 ± 6.61). Patients disability, assessed by HAQ, reports some difficulty in carrying out daily life activities due to the disease (0.67 ± 0.53 - M ± SD).

Conclusion: In conclusion, Mediterranean diet, Health Assessment Questioning (range 0-3) for disability and SF-36 (range 0-100) show moderate symptoms (0.50-1.00) in most items (reflux, abdominal distension, social function and emotional well-being), while a lower score (0.00-0.49) it was found in other items (diarrhea, constipation and faecal incontinence). Therefore, the total score of gastrointestinal involvement is moderate (0.42 ± 0.38M ± SD).

AB1284-HPR RELIABILITY OF STEP TEST IN SUBJECTS WITH TOTAL KNEE ARTHROPLASTY

M. Eyvül1, E. Yüksel1, B. Unver1, K. Sevik1, V. Karatosun2,3,4,5,6 Dokuz Eylül University, School of Physical Therapy and Rehabilitation, İzmir, Turkey; 2Dokuz Eylül University, Department of Orthopedics and Traumatology, School of Medicine, İzmir, Turkey

Background: Patients with TKA show impairments in standing balance up to 1 year after surgery. The impaired standing balance in TKA patients was found to be associated with falls risk and decreased functional level. Assessing of standing balance with objective and reliable assessments tools would therefore be extremely useful for determining accurate exercise program, and risks of falling, especially during the rehabilitative period when ambulation is at its most unsteady (1, 2). The stepping maneuver requires adequate strength and motor control to stabilize the body over the stance limb while the other leg is stepping; therefore the Step Test (ST) provides significant information for dynamic standing balance and lower limb motor control (3). The reliability of ST is reported in patient groups such as stroke, however, there is not any study that investigates the reliability of ST in patients with TKA in the current literature.

Objectives: The purposes of this study were to determine the test-retest reliability and the minimal detectable change (MDC) of the ST in patients with TKA.

Methods: 40 patients with TKA due to knee osteoarthritis, operated by the same surgeon, were included in this study. Patients performed trials for ST twice on the same day. Between the first and second trials, patients waited for an hour on sitting position to prevent fatigue. The ST assesses an individual’s ability to place one foot onto a 7.5-cm-high step and then back down to the floor repeatedly as fast as possible for 15 seconds. The score is the number of steps completed in the 15-second period for each lower extremity. Scores for each lower extremity were recorded separately. Prior to the testing, the ST was demonstrated by the tester and all participants were allowed to a practice trial.

Results: The ST showed an excellent test-retest reliability (ICC2,1=0.95) in this study. Standard error of measurement (SEM) and MDC95 for ST were 0.37 and 1.02, respectively.

Conclusion: This study found that the ST has an excellent test–retest reliability in patients with TKA. It is an effective and reliable tool for measuring dynamic standing balance and participant falls. As a performance-based clinical test, the ST is easy to score, can be applied in a short time as part of the routine medical examination. Therefore, inclusion of ST into a more comprehensive battery of
performance-based measures of standing balance and lower limb motor control function in subjects with TKA should be considered.

Conclusion: Our findings suggest that dynamic grip endurance is associated with different functional parameters of the hand and worsening clinical parameters. Examining dynamic grip endurance might be a guide in creating an exercise program for clinicians in rehabilitation of patients with PsA.

AB1285-HPR ACCELEROMETRIC ASSESSMENT OF PHYSICAL PERFORMANCE DURING THE SIT-TO-STAND TEST IN PATIENTS WITH KNEE OSTEOARTHRITIS

S. Ferlioz, H. Hkaim, F. Allal, J. Moulay Berchic, T. Fatima Zahrae, I. H. Alhamam, T. Lattia, S. Aboudarou, T. Dakkaz, L. ErmNguj, A. Jihene, M. Bakkali, F. Allal. *Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Department of Rheumatology, B. El Ayachi Hospital, Rabat, Morocco; †Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Physiotherapy Laboratory, Rabat, Morocco

Background: Knee osteoarthritis is a major public health issue that causes chronic pain and functional limitation.

Objectives: This study aims to evaluate physical performance in knee osteoarthritis by clinical tests and accelerometer measurements, and investigate the relationship between physical performance alteration and clinical parameters.

Methods: This is a cross-sectional study, included 40 patients with knee osteoarthritis (100% female, average age 57±5.2 years, median evolution time was 36 [24, 69] months, overweight in 82.5% of patients). Clinical evaluation performed with the visual analog scale (VAS), Western Ontario and McMaster Osteoarthritis Index (WOMAC), Lequesne score, Get up and Go (GUG) and Timed up and Go (TUG) tests. The percentage of fat mass was measured using impedimetry.

Results: All subjects were instructed to perform sit-to-stand transfers during 30 seconds. We measured the speed, strength and muscular power of the lower limbs during this test using the Myotest PRO® accelerometer.

A correlation analysis was performed in search of factors associated with physical performance alteration. A correlation analysis was performed in search of factors associated with physical performance alteration.

Conclusion: Our pilot study assessed the physical performance of the lower limbs in knee osteoarthritis patients, by measuring the speed, strength and muscular power during the sit-to-stand test. It showed no correlation between the measured parameters of physical performance, pain and functional indices of knee osteoarthritis.

AB1286-HPR EXAMINATION OF DYNAMIC GRIP ENDURANCE RELATED FACTORS IN PATIENTS WITH PSORIATIC ARTHRITIS

I. Naz Güreş, M. Köprüölüoğlu, D. Dolmaz, S. Akar, Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, İzmir, Turkey; *Izmir Katip Celebi University, Faculty of Medicine, Department of Rheumatology, İzmir, Turkey

Background: Psoriatic arthritis (PsA) is a disease manifested by destruction of articular cartilage, subchondral bone, and fibrosis of the joint capsule without excessive synovitis. Various studies of hand strength in PsA also show radiographic, ultrasonographic, magnetic resonance imaging research and there is little knowledge about functional assessment of hand. According to our knowledge, there is no study assessing grip endurance in patients with PsA.

Objectives: To assess dynamic grip endurance related factors in patients with PsA.

Methods: A total of 19 patients [Mean age; 53.5±12.6 years, 14 women(73.7%), 5 men(26.3%)] diagnosed according to CASPAR criteria were included this study. Clinical and demographic characteristics were recorded. Dynamic grip endurance test was assessed with 10- repetition dynamic endurance test using a hand dynamometer (Lafayette Professional Hand Dynamometer, USA). Grip strength was examined by hand dynamometer and pinch strength was examined by pinchermeter (Lafayette, USA). Goniometer was used to assessment wrist joint position sense. Disability of Arm, Shoulder and Hand Survey (DASH) was used to determine disabilities and symptoms of upper extremity. We used Spearman’s Rank Correlation Coefficient for data analysis.

Results: Dynamic grip endurance was negatively correlated with DASH score, perceived disability of hand, number of tender hand joints and positively correlated with grip strength, 3 point pinch strength on both dominant and non-dominant sides (p<0.05, Table 1). Dynamic grip endurance was not correlated with CRP level and joint position error on both dominant and non-dominant sides (p>0.05).

AB1287-HPR INVESTIGATION OF THE RELATIONSHIP BETWEEN GRIP ENDURANCE, DISABILITY OF UPPER EXTREMITY AND QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Köprüölüoğlu, I. Naz Güreş, D. Dolmaz, G. Kabadayı, H. Cınakli, S. Akar, *Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, İzmir, Turkey; †Izmir Katip Celebi University, Faculty of Medicine, Department of Rheumatology, İzmir, Turkey

Background: Upper extremity functions affect the quality of life at different levels in patients with rheumatoid arthritis (RA). In the current literature; it has been shown that grip endurance is associated with upper limb functions (1). However, there is no study investigating the relationship between grip endurance and quality of life in patients with RA.

Objectives: To investigate relationship between grip endurance, disability of upper extremity and quality of life in patients with RA.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.3317

References:
Methods: In our cross sectional study, 23 RA patients [Mean age; 52.7±12.6, BMI;26.2±5.7 kg/m², Women;20(87.0%)] who were classified according to the ACR 2010 criteria. Demographics and clinical characteristics of patients were recorded (Table 1). Das28 for disease activity score, Static and dynamic grip endurance measurements using Hand Dynamometer (Lafayette Professional Hand Dynamometer, USA) for grip endurance, Disability of Arm, Shoulder and Hand Survey (DASH) for disabilities and symptoms of upper extremity and Short Form-36 Health Survey for quality of life were performed. Spearman’s Rank Correlation Coefficient was used for data analysis.

Data is presented median (interquantile range) or percentile (%).

Results: Grip endurance was negatively related with DASH and positively correlated with many different quality of life parameters, especially physical function, on both the dominant and non-dominant sides (p <0.05). DASH was correlated negatively with SF-36 physical function, role limitation due to physical health, pain subparameters and positively correlated with Das28 score (p<0.05). Conclusion: In our study, it was concluded that grip endurance was related to upper extremity functions and quality of life in patients with RA. This result shows that assessment of grip endurance can be a guide for clinicians who have designed an upper limb rehabilitation program for patients with RA. References: 1. VERMA, Chhayha, et al. Correlation of functional ability of the hand with upper limb function and quality of life in patients with rheumatoid arthritis. J Assoc Physicians India, 2017, 65, 20-4.

AB1288-HPR PERCEPTION OF THE VALUE OF DRUGS ON DIFFERENT MANIFESTATIONS OF PSORIATIC ARTHRITIS BASED ON A MULTI-STAGE EXPERT OPINION SURVEY

T. Oberwahrenbrock1,2, H. Tian1,2, D. Thaqi3, K. Krueger4, J. Wollenhaup1, M. Köhn1,2,5, F. Behrens1,2,6, “Fraunhofer IME Translational Medicine and Pharmacology, Frankfurt, Germany; *Fraunhofer Cluster of Excellence Immune-mediated Diseases CIMD, Frankfurt, Germany; #Exzellenzzentrum Entzündungsmedizin UKSH Lübeck, Lübeck, Germany; †Rheumopraxis München, München, Germany; ‡Rheumatologikum Hamburg, Hamburg, Germany; §Goethe-University Frankfurt, Rheumatology Department, Frankfurt, Germany

Background: Patients with psoriatic arthritis (PsA) present with heterogeneous clinical phenotypes, which includes different clinical manifestations such as peripheral arthritis, axial disease, dactylitis, enthesis, and skin and nail psoriasis. Many drugs for treatment of PsA are available for individualised treatment strategies but robust evidence is available for peripheral arthritis only as primary endpoint of RCTs.

Objectives: To evaluate perception of German physicians on the value of current PsA treatments on different clinical PsA manifestations.

Methods: In a face-to-face meeting, 8 German physicians (dermatology, rheumatology) specialised in PsA research/patient care, proposed initial scores for the effect size of current PsA drugs on different PsA manifestations based on knowledge of study data and personal experience in use of the drugs. The ability to achieve a consensus of the proposed efficacy scores was explored by applying an online survey among a cohort of PsA experienced physicians. Finally, a second online survey evaluated how a larger group of physicians personally estimate the effect size of current PsA drugs on different PsA manifestations based on knowledge of study data and personal experience in use of the drugs.

Results: Table 1 summarises the efficacy scores proposed by the initial expert group. In the first online survey 25 treating physicians were invited to participate, 14 (56%) of whom completed the survey. An agreement rate of over 65% of the participants was archived for 49 (68%) of the 72 proposed efficacy scores (Table 1). The consensus was especially high for the group of biological disease-modifying antirheumatic drugs (bDMARDs), except for etanercept and abatacept. However, the second survey (36 participants) confirmed the experience with the treatment using abatacept was low (4/16 (25%)) or non-existing (3/16 (18.8%)) and several manifestations could not be estimated (Figure 1). Distribution of answers were broad for etanercept in general and for particular drug-manifestation combinations (e.g. effect of ustekinumab on axial disease).

The FRAX algorithms give the 10-year probability of hip fracture and of major vertebral fracture not fully detected by Dual energy X-ray absorptiometry (DXA).

**Background:**

Spain

M. Moreno2, L. F. Linares Ferrando2.

**Results:**

The characteristics of the patients are shown in Table 1. According to FRIDEX, no patient had high risk of fracture and 2.4% had intermediate risk. When SpAax was added as a risk factor, no patient had high risk of fracture and 6.1% presented intermediate risk. According to DXA, 73% had high risk of fracture and 41.3% intermediate risk. TBS detected high risk of fracture in 18.3% and intermediate risk also in 18.3% of patients.

**Disclosure of Interests:**

None declared

**Disclosure of Interests:**

Timm Oberwahrenbrock Grant/research support from: Pfizer, Janssen, BMS, LEO, Consultant of: BMS, Pfizer, Speakers bureau: Pfizer, BMS, Janssen, Novartis, Frank Behrens Grant/research support from: Pfizer, Janssen, Chugui, Celgene, Lilly and Roche, Consultant of: Pfizer, AbbVie, Sanofi, Lilly, Novartis, Genzyme, Boehringer, Janssen, MSD, Celgene, Roche and Chugui

**Conclusion:**

FRAX does not seem an adequate tool to detect the risk of fracture in patients with SpAax since it did not improve the results obtained by DXA meanwhile TBS did. The incorporation of SpAax as a clinical risk factor to conventional FRAX did not provide additional information in most cases

### AB1291-HPR

**IMPLEMENTATION OF AN ELECTRONIC SYSTEM FOR ISSUING PRESCRIPTIONS IN PATIENTS WITH RHEUMATIC DISEASES**

L. Santoyo-Félix1, R. A. Uriarte Botello1, C. V. Solís1, B. R. Vázquez Fuentes1, C. M. Skinner Taylor1, I. D. J. Hernandez-Galarza1, M. Eguía Bernal1, D. Á. Galarrza-Delgado1,1Hospital Universitario “Dr. José Eleuterio González”, Rheumatology Service, Monterrey, Mexico

**Background:**

Pharmacovigilance is the science and activities related to detection, evaluation, understanding and prevention of adverse effects of medications or any other health problem related to them. (1) Within the scope of the pharmacovigilance study, following domains are included: adverse drug reaction, interaction between medications, counterintuitively quality medications, lack of efficacy of medications, misuse or abuse of medications and medication errors (ME). (2) ME is any preventable incident that can cause harm to the patient or lead to improper use of medications when they are under the control of healthcare professionals or the patient. (3)

**Objectives:**

To determine the frequency of ME in the prescriptions among rheumatology outpatient's clinic.

**Methods:**

Prospective observational study.

Frequency of ME was sought by a randomized review of the prescriptions from rheumatology outpatient's clinic of the University Hospital “Dr. José Eleuterio González” before and after the implementation of an electronic medical prescription system (REPAIR®) (January 2018-December 2019) REPAIR® displays an automated menu with the stages of the medical prescription: Name, presentation and dosage of the medicine and duration of the treatment. Figure 1. Once the review began, semiannual reports were made to the doctors involved in which frequency of errors and the stage of medical prescription with highest incidence of ME were reported.
Descriptive statistics were performed, reporting frequencies and percentages.

**Results:** A total of 1599 medical prescriptions were evaluated. The number of prescriptions with ME was 196 (12.2%). Table 1

### Table 1  General description about errors in medical prescriptions

<td>1.143</td>
<td>0.082</td>
<td>0.081</td>
</tr>
</tbody>
</table>

**Prescription Stage n (%)**

- Name 1/367 (0.2%) 1/469 (0.2%) 0 0
- Presentation 37/367 (10%) 37/469 (7.8%) 1/36 (2.7%) 2/35 (5.7%)
- Dose 0 0 0 0
- Duration 290/367 (89%) 367/469 (88.2%) 35/36 (97.2%) 33/35 (94.2%)

**Conclusion:** Decrease in the incidence of ME in rheumatology consultation is important because outcome of the patients depends significantly on treatment adherence. This study results shows that through the application of an electronic prescription system, it is possible to reduce the incidence of ME in rheumatology consultation.

AB1293-HPR

DETERMINING FUNCTIONAL MOBILITY AND BALANCE FOR PATIENTS AFTER TOTAL KNEE ARTHROPLASTY: RELIABILITY OF L-TEST

B. Unver1, E. Yuskel1, M. Eymir1, K. Sevik1, V. Karatosun1, 2Dokuz Eylül University, School of Physical Therapy and Rehabilitation, Izmir, Turkey; 2Dokuz Eylül University, Department of Orthopedics and Traumatology, School of Medicine, Izmir, Turkey.

Background: Total knee arthroplasty (TKA) is a very common procedure, particularly implemented for the treatment of knee osteoarthritis (OA). Patient expectations after TKA surgery now include being able to enjoy appropriate recreational activities representing ambulatory activities beyond that of just pain relief and adequate knee motion (1). Since recreational activity comprises of more complex functions and requires longer standing durations, walking for 6-meter in a straight line in the timed up and go test (TUG) does not fully reflect the functional capacity of patients with TKA, and TUG test may be limited to detect the balance and mobility capacity in TKA patients (2, 3). As such, there is a need to determine more effective and functional evaluation tools that better reflect realistic situations in order to assess ambulatory performance level for patients with TKA. However, no studies have been conducted in patients with TKA to examine the applicability of the L-test, which assesses ambulation of individuals and consists of complex mobilization activity.

Objectives: The purposes of this study were to determine the test-retest reliability and the minimal detectable change (MDC) of the L-test for TKA patients.

Methods: Twenty-four patients with TKA due to knee OA, operated by the same surgeon, were included in this study. Patients performed trials for L-test twice on the same day. Between the first and second trials, patients waited for an hour on sitting position to prevent fatigue. The tester recorded the performance time while the participant was asked to get up from a chair, walk 3 m in a straight line, turn right, continue walking for 7 m in a straight line, turn left, walk back along the same path and sit down in the chair at their usual walking speed. Prior to the real testing session, the L-test was demonstrated by the tester and all participants were allowed to a practice trial.

Results: The L-test showed an excellent test-retest reliability (ICC2,1= 0.98) in this study. Standard error of measurement (SEM) and MDC95 for L-test were 1,01 second and 2,8 second, respectively.

Conclusion: This study found that the L-test is a reliable test for patients following TKA. Overall, the excellent test-retest reliability of the L-test indicates that it may be an applicable standardized method to assess TKA patients who are able to walk greater distances and have better gait in more functional situations. Clinicians and researchers can be confident that changes in L-test time above 2.8 seconds, represent a “real” clinical change in an individual patient with TKA. We, therefore, recommend the use of L-test as complementary outcome measures for balance and functional evaluation in TKA patients.

LOW CONCENTRATIONS OF BIOLOGIC DMARDS IN BREASTMILK OF PATIENTS TREATED DURING LACTATION

A. Zbinden1, K. Eriksson1, F. Förger1. University Hospital and University of Bern, Inselspital, Department of Rheumatology, Immunology and Allergology, Bern, Switzerland.

Background: There is very limited information about the passage of biologics into breast milk and into the peripheral blood of breastfed infants. However, based on pharmacological properties of biologic DMARDs (bDMARDs) lactation may not be discouraged in patients with chronic inflammatory rheumatic disease to treat or prevent postpartum relapses. We here report two cases treated with bDMARDs during lactation: one woman with Muckle-Wells syndrome (MWS) treated with canakinumab and one woman with microscopic polyangiitis (MPA) treated with rituximab.

Objectives: To determine the level of rituximab and canakinumab in breast milk, in sera of breastfed infants as well as in sera of the mother and to calculate the average daily infant dose and the relative infant dose.

Methods: Serum and milk levels of Rituximab were measured by ELISA using commercially available coating and detection antibodies. For Canakinumab an ELISA was established by coating of plates with recombinant human IL-1beta and detection of Canakinumab in samples by a polyclonal anti-human IgG coupled to HRP. In both cases separate standard curves for serum and milk were established. Serum samples and milk samples of unexposed healthy controls were used to determine the lower limit of quantification.

Results: One patient with MWS received canakinumab 150 mg s.c. to treat a worsening of her disease ten days postpartum. She continued to breastfeed her child. The average concentration of canakinumab in milk samples collected on 10 consecutive days was 15.8 mg/l. The average daily infant dose was 0.002 mg/kg/day. The relative infant dose, which refers infant to maternal exposure on a dose/weight basis, was 0.11%. There was no detectable canakinumab in the serum of the infant.

Conclusion: Only minimal concentrations of canakinumab and rituximab can be detected in breastmilk. For both bDMARDs, the relative infant dose was below 1% of the maternal dose, which is considered unlikely to be of clinical concern. The lack of detectable levels of canakinumab and rituximab in the infants’ sera supports the notion of low oral bioavailability of large monoclonal antibodies. Together, the results are similar to those seen in TNF inhibitors which are regarded to be compatible with breastfeeding, yet more data are needed (1, 2, 3).

AB1295-HPR

PREGNANCY RISK IN CHILDBEARING AGE WOMEN WITH RHEUMATIC DISEASES

E. Barriga-Maldonado1, C. M. Skinner Taylor1, L. Pérez Barbosa1, J. D. Angulo1, F. Vázquez1, G. Figueroa-Parrá2, R. Pineda-Sic1, C. J. Riegatorres1, D. A. Galarza-Delgado1. 1Hospital Universitario Dr. José Eleuterio González, Servicio de Reumatología, Monterrey, Mexico

Background: Rheumatic diseases (RD) are more frequent in women, affecting them during childbearing age. Medications used to treat can interfere with fertility or increase the risk of miscarriages and congenital abnormalities; Disease control and therapy should be discussed with patients before and during pregnancy, in order to minimize adverse outcome (1). Barriers to adequate communication
and counseling of women regarding reproductive health and family planning still exist among rheumatologists and increases the risk of complications(2).

**Objectives:** To identify childbearing age women with RD and a high risk of pregnancy.

**Methods:** A cross-sectional study was performed in the rheumatology clinic of the university hospital “Dr. Jose Eleuterio Gonzalez” in Monterrey, Mexico between October 2019 and January 2020. All non-pregnant childbearing age (18 to 45 years old) women were included. A self-questionnaire of 10-items was applied. Demographic data were collected from the electronic medical record. Results are shown in descriptive statistics. Analyses were performed with SPSS 22. A p < 0.05 was considered statistically significant.

**Results:** 135 women were evaluated, median age was 33 (25-39) years. Patients characteristics are shown in table 1. 115 (85.1%) had initiated sexual activity earlier in life (median age 18 years). Regarding the question, did you have sex last month? 115 answered it, 69 (60.2%) said they had, 49 (42.6%) used a contraceptive and 20 (17.6%) did not. 135 patients, 68 (50.3%) had a desire for pregnancy, 12 (8.9%) in the next 12 months and 56 (41.1%) in more than one year, of which 37 (66%) were using a family planning method and 19 (34%) were not (Table 2). For the question about receiving contraceptive counselling 112 answered it, 80 (70.4%) say they had. When they were asked if they received family planning and reproductive health counseling by their rheumatologist, just 64 (57.1%) affirmed they did; There was no differences in the use of contraceptive methods among those who received contraceptive counselling and those who did not (p>0.05). Among the 67 (49.6%) patients who did not want to be pregnancy 16 (23.8%) did not use a contraceptive method.

**Table 2. Tool questions**

| Did you have sex last month? (n= 115, %) | 69 (60) |
| Did you use any contraceptive method? (n=115, %) | 49 (42.6) |
| Did you receive family planning and reproductive health counseling by the rheumatologist? (n= 112, %) | 64 (57.1) |
| Do you want to get pregnant after the next 12 months? | 56 (41.1) |
| Do you want to get pregnant in the next 12 months? | 12 (8.9) |
| Contraception counselling (n=112, %) | 80 (71.4) |
| Current treatment (n= 102, %) | 65 (60.7) |

**Conclusion:** Using this short questionnaire, we identified that 35 (25.9%) of the patients had a risk of unintended pregnancy and that only 80 (70.4%) received reproductive health counseling from their rheumatologist. It is necessary to design and systematically apply questionnaires capable of detecting and evaluating risks in this population.

**AB1296-HPR PREVALENCE OF COMORBIDITIES IN A COHORT OF PATIENTS IN AN EDUCATIONAL MULTIDISCIPLINARY PROGRAM**

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory and complex disease. Patients with RA face other diseases that might lead to increased...
morbidty. In patients with RA it has been established a high prevalence of comorbidities and their risk factors (1).

Objectives: The aim of this study was to evaluate the prevalence of comorbidities in Colombia patients with RA enrolled in an educational multidisciplinary program and possible correlation with disease activity

Methods: We performed a cross-sectional study; we included patients with confirmed diagnosis of rheumatoid arthritis in a specialized RA center. We collected sociodemographic data, and markers of disease activity DAS28. We collected data regarding the history of comorbidities such as hypertension, dyslipidemia, osteoporosis, type 2 diabetes mellitus, hypothyroidism, malignancies, among others. We performed a descriptive analysis, variables with a normal distribution were described using mean and standard deviation (SD), and non-normal distributed variables were described using median and interquartile range. Categorical variables were presented as rates. We evaluated the relationship between disease activity and comorbidities.

Results: We included 251 patients; mean age was 59.8 years old, with a high proportion of women 93%; median disease duration was 15 years RIO (8-20); in this study, 145 (65%) of patients were in remission; 35 (11%) had low, 44 (20%) moderate and 10 (4%) high disease activity. Regarding pharmacotherapeutic, 55% were receiving conventional DMARDs. The prevalence of comorbidities was 85%, the most common were high blood pressure 25% followed by hypothyroidism 12% and diabetes 10%, 0.7% of patients had malignancies such as thyroid or breast cancer, 129% of patients had renal comorbidities. Among comorbidities related to RA 30% had osteoporosis and 20% arthritis. We did not find a statistical association between DAS28 and comorbidities.

Conclusion: As other studies have shown, there is a high prevalence of comorbidities among RA patients, mainly high blood pressure. Due to the above, it is relevant to evaluate the risks factors of patients with RA, especially cardiovascular risks. We consider that a multidisciplinary program represents an opportunity not only to educate patients about healthy life styles and the management of RA, but also other diseases in order to increase the empowering of the health status in these poly pathological patients (2).

AB1298-HPR

BONE AND MINERAL METABOLISM IN Spondyloarthritis

D. Castro-Corredor1, M. A. Ramirez Huaraunga2, A. I. Rebollo Giménez2, M. D. Miguez Sánchez1, J. Anino-Fernández1, I. M. De Lara Simón2, J. L. Cuadrado Diaz2,1Hospital General Universitario Ciudad Real, Ciudad Real, Spain; 2Hospital General Universitario Ciudad Real, 13005, Spain

Background: Spondyloarthritis is the term for a group of inflammatory chronic diseases primarily affecting the axial skeleton, as well as the peripheral joints. Regarding bone metabolism in these patients, several studies have reported higher levels of inflammatory activity (BASDAI, BASMI, ESR and CRP) in patients with osteoporosis compared to those without this disease, although no correlations were found.

Objectives: To describe clinical, serological and biological characteristics, as well as bone and mineral metabolism, according to analytical and densitometric criteria in a patient cohort with spondyloarthritis.

Methods: Observational, descriptive and cross-sectional study. A retrospective review was conducted of a database of patients with spondyloarthritis treated during 2013-2018, in a specialized Rheumatology Department of Hospital Universitario de Ciudad Real between June 2018 and June 2019. Variables are described using measures of frequency and of central tendency and dispersion.

Results: Cohort of 115 patients (64 men and 51 women). Average age 45.97 years (+/- 13.41 SD). Ankylosing spondylitis in 54 patients, psoriatic arthropathy in 24, spondyloarthropathy associated with inflammatory bowel disease in 8, undifferentiated spondyloarthritis in 18 and other types of spondyloarthritis in 11. Regarding treatment, 40.88% of patients received disease-modifying drugs (methotrexate, sulfasalazine, etc.) and 43.4% received biologic drugs (86% anti-TNF α, 12% anti-IL-17 and 2% anti-IL-12/23). Moreover, 53.04% had received corticosteroids during some phase of their disease. Vitamin D levels were 23.81 (+/- 10.51 SD) and 77.44% of patients had a vitamin D deficiency/insufficiency. Of the total cohort, 34.78% presented osteopenia and 3.58% osteoporosis (T-Score and Z-Score).

Conclusion: In this study, patients with spondyloarthritis show high percentages of osteopenia and osteoporosis, undiagnosed until this time, along with vitamin D deficiency. This data suggests higher prevalences of these metabolic bone diseases. Osteoporosis prevention is essential due to the risk of developing early fractures resulting from increased bone fragility.

In 2020, a section with the most important information about the aforementioned three diseases will be added. The section will include definition, etiology, prognosis, symptoms, therapeutic principles, medication and case studies. Current data will be presented at the conference.

AB1300-HPR MALNUTRITION SCREENING AND ASSESSMENT TOOLS IN RHEUMATIC DISEASES

C. M. Gamboa-Alonso1, J. D. Ángulo1, R. E. Díaz-García1, G. Figueroa-Parrá1, D. Á. Galarza-Delgado2, J. C. Riegatortes3, R. E. Díaz-García1, G. Figueroa-Parrá1, D. Á. Galarza-Delgado2, J. C. Riegatortes3

1ACURA Center of Rheumatology Rhineland-Palatinate; 2University of the Johannes Gutenberg University Mainz, Division of Rheumatology and Immunology, Mainz, Germany; ACURA Center of Rheumatology Rhineland-Palatinate, Bad Kreuznach, Germany

Background: The proof-of-concept network study “Rheuma-VOR” aims to improve the quality of rheumatological care through coordinated cooperation. In particular, rheumatic diseases should be diagnosed as early as possible and treated quickly in a targeted manner [3]. Smartphone apps have a potential to improve the management of chronic diseases. For example, they can be used to provide health information, or to offer self-monitoring and self-screening options [1, 2].

Objectives: The Rheuma-VOR Screening-App study examines whether a smartphone-based app can increase the detection rate of the three most common chronic inflammatory rheumatic diseases: rheumatoid arthritis, psoriatic arthritis and spondylarthritides.

Methods: Based on the multi-stage Delphi Procedure, a minimal list of questions for detection and differentiation between the three diseases was defined. The app for iOS and Android is in use since October 2018 during the screening consultation at the Division of Rheumatology and Clinical Immunology and at the ACURA Center of Rheumatology Rhineland-Palatinate. An additional validation will be performed with a non-preselected cohort based on the data of the Rheuma Bus Tour 2019.

Results: The Delphi Procedure identified 17 questions, including four laboratory parameters. They have been deployed in German as a smartphone app. The questions are read to the patient and can be answered with “YES”, “NO”, or “I DO NOT KNOW”. Answering the questions takes approximately four minutes. The suspected diagnoses are based on a cumulative score. Some diagnoses are excluded or confirmed already after a few questions.

To date (31 Dec 2019), the app has been used on 466 patients. The sensitivity is 0.91, while the specificity is 0.25. The positive predictive value and the negative predictive values are 0.60 and 0.32, respectively. The false positive value is 0.33 and the false negative value 0.05.

Conclusion: The Rheuma-VOR App helps doctors and patients to invalidate or to confirm the suspicion of a possible rheumatic disease. Data from the cohort is currently being analyzed to increase the screen’s specificity. The additional validation, based on a non-preselected cohort collected during the Rheuma Bus Tour 2019, is in progress. A final validation concept is currently being developed.

A subanalysis in 70 Rheumatoid Arthritis patients was done with a mean age of 50.94 years (SD±12.11) and a mean BMI 28.53 kg/m² (SD 5.48). The results according to each tool are represented in Table 2. When NRS-2002 was reclassified in 3 parameters (normal <2, risk of malnutrition 2 and malnutrition 3 or more), a significant difference persisted (p = 0.05) with a low correlation (r = 0.43).

Conclusion: MNA was a more sensible tool for detecting risk of malnutrition when compared to NRS-2002. Screening tools play an important role at nutritional evaluation and should be complemented with objective methods such as BIA. Rheumatologists must be aware that nutritional disorders affect the state of rheumatic diseases; and selecting an appropriate tool to detect malnutrition is of vital importance.

AB1302-HPR COMORBIDITIES AND FACTORS INFLUENCING RECURRENT GOUT ATTACK IN PATIENTS WITH GOUT: A CROSS-SECTIONAL STUDY

Y. Jiang1, Z. Liao1, Y. Huang1, J. Liang2, Y. Xie1, J. Wu1, J. Gu1. 1. The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; 2. Huadu Affiliated Hospital of Southern Medical University, People’s Hospital of Huadu District, Guangzhou, China

Background: Gout attack is characterized by painful arthritis, loss of function and reduced quality of life. Frequent gout attacks can exert negative influence on gout management [1].

Objectives: The objective was to identify the comorbidities of gout, to compare gender difference and to identify independent factors of multiple gout attacks.

Methods: A cross-sectional study was performed to collect demographic, clinical variables, self-reported comorbidities, and relevant testing. Group comparison and correlation of serum uric acid (sUA) levels with other variables was performed. Univariate and multivariate logistic regression was used to detect independent risk factors of sUA.

Results: 653 gout patients were enrolled, including 553 (84.7%) males. The mean age was 48.3±15.8 years old, with a disease duration of 8.0±6.4 years. 170 (26.0%) patients had hypertension, and 57 (8.7%) had hyperlipidemia. Elevated total cholesterol (TC) was observed in 173 (26.5%) cases, 42 (37.1%) cases presented with increased triglycerides (TG) and 270 (41.3%) had increased low-density lipoprotein (LDL-C). Abnormalities including nephrolithiasis (29.4%), hydro nephrosis (3.2%), and gallstones (11.9%) were detected in the patients who underwent ultrasound examination. Although female patients had a longer disease duration, they had lower levels of sUA, creatine and C-reactive protein (CRP). A positive correlation with sUA was found in TG and CRP (P<0.05) in female patients, which was not observed in males. Only gout duration (OR=1.406, P <0.001), sUA (OR=1.006, P <0.001) and LDL-C (OR=0.530, P =0.006) were independent factors of gout attack (>20 times).

Conclusion: Comorbidity scoring including dyslipidemia is often neglected in gout patients. Gout duration and sUA level are risk factors of multiple gout attacks.

AB1303-HPR **TIME UNTIL DIAGNOSIS IN RHEUMATOLOGICAL PRACTICE: RESULTS FROM A CROSS-SECTIONAL MIDDLE-EUROPEAN COHORT COMPARED TO DATA FROM A SYSTEMATIC LITERATURE REVIEW**

R. McCutchan1, S. Maier1, V. Winkler1, B. Gruber1, M. Schirmer1 on behalf of Portugal; 2CHUC, Rheumatology, Coimbra, Portugal

**Background:** The time from first symptom to diagnosis (= diagnostic delay) is considered as key factor for better outcome in many chronic inflammatory rheumatic diseases, especially for rheumatoid arthritis (RA) and vasculitis like giant cell arteritis (GCA). A longer diagnostic delay may cause pain, reduced functionality, reduced life-quality and increased morbidity, as well as structural damages of the organs linked with higher mortality. This retrospective study assessed the diagnostic delay in consecutive Middle-European outpatients and compared results with those of a systematic literature review (SLR).

**Objectives:** To compare disease-specific diagnostic delays of consecutive rheumatic patients with international data from a systematic literature review.

**Methods:** Charts of a single-centre cohort with consecutively recruited patients were retrospectively reviewed for patients’ and diseases’ characteristics at a Middle-European university outpatient clinic for rheumatology. A SLR was performed according to PRISMA guidelines.

**Results:** The average mean ± SD time from first symptom to established diagnosis was 7.9 ± 11.7 (0.02-56.7) years. Spondyloarthritis patients showed the longest diagnostic delay with 13.1 ± 14.2 (0.1-56.7) years, whereas polymyalgia rheumatica patients had the shortest diagnostic delay with 1.5 ± 0.4 (0.3-18.0) months. In the SLR, most data for diagnostic delays are comparable to the Innsbruck cohort, but the diagnostic delay for psoriatic arthritis in Innsbruck is longer than in the Danish DANBIO registry (p<0.001). Independent risk factors for prolonged diagnostic delays could not be identified.

**Conclusion:** For this Middle-European area, initiatives are justified especially to shorten diagnostic delays of SpA and PsA.

Conclusion: Our results confirm that awareness and knowledge about RMDs are very low high school students. The single and educational session was very well received by all students, and the knowledge increased. Post-educational feedback was that students especially liked the testimony of a peer. Other sessions are taking place in primary schools.

HPR Interventions (educational, physical, social and psychological)

AB1306-HPR THE EFFECTS OF CLINICAL PILATES EXERCISES IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Baglan Venture1, N. Atas2, M. A. Ozturk3, D. Oskay2. 1Feit University, Elazığ, Turkey; 2Gazi University, Ankara, Turkey

Background: Rheumatoid Arthritis (RA) is a rheumatic disease that may coexist many symptoms clinically. These clinical symptoms progress in a vicious cycle in many patients. Physical activity and exercise are known to improve many symptoms in RA patients.

Objectives: This study was designed to investigate the effects of clinical pilates exercises on fatigue, depression, aerobic capacity, pain, sleep quality and quality of life.

Methods: Thirty voluntary RA patients were included in this study. Patients were separated into three groups equally and each group was applied treatment for eight weeks. Clinical pilates exercises were practiced to the first group, aerobic exercises were practiced to the second group and combined training which was a combination of pilates exercises and aerobic exercises was performed to the third group. Fatigue, depression, aerobic capacity, pain, sleep quality and quality of life were evaluated by Fatigue Severity Scale (FSS), Beck Depression Inventory (BDI), Six minute walk test (6MWT), Short-Form McGill Pain Questionnaire (MPQ), Pittsburg Sleep Quality Index (PSQI) and Rheumatoid Arthritis Quality of Life (RAQoL), respectively.

Results: According to our results, statistically significant improvements were found for clinical pilates exercises on fatigue, depression, aerobic capacity and quality of life (p<0.05). Improvements in all parameters except from pain were concluded for aerobic exercises and combined training (p<0.05). Also, there was no statistically significant difference among the treatment groups in assessments (p>0.05).

Conclusion: Pilates exercises were found effective and safe for RA patients. Clinical pilates training may be as effective as aerobic exercises in patients with RA according to our study. Therefore, addition of clinical pilates exercises to the routine treatment of RA may enhance the success of rehabilitation.

References:
Background: Systemic sclerosis (SSc) is an autoimmune disease that not only affects the skin but also causes symptoms that involve important internal organs such as joints, muscles, and heart and lungs. Due to all these multiple system involvements, the quality of life of individuals with scleroderma decreases. Tai Chi Chuan is a combination of physical exercise and relaxation techniques, and it is a traditional Chinese exercise method used to improve mental and physical health of people. There are many studies showing that Tai Chi improves the body’s aerobic capacity and psychological well-being. In the literature, Tai Chi has been shown to reduce pain, improve physical function, improve healing effects on depression and quality of life, especially, in the elderly, individuals with musculoskeletal diseases such as rheumatoid arthritis and osteoarthritis, and improve cardiac vascular risk factors such as hypertension and diabetes.

Objectives: The aim of the study is to examine the effectiveness of Tai Chi on cardiopulmonary functions and quality of life in patients with systemic sclerosis.

Methods: 28 SSc patients (25 females, 3 males) with an average age of 53.00 ± 10.00 were included in the study. For training, patients were divided into two groups by block randomization method. Group 1 received 60 minutes of Tai Chi exercise program and Group 2 received 60 minutes of home exercise for 2 days a week for 8 weeks. 6-min walk test (6MW) and St. George Respiratory Questionnaire was used to evaluate the cardiopulmonary functions, Short form 36 (SF-36) was used to evaluate the quality of life. All evaluations were performed at baseline and at the end of the 8th week.

Results: When the groups were compared before training, there was no significant difference (p > 0.05). In post-training comparisons, a significant difference in all parameters in Tai Chi group (p: 0.001-0.045); there was a significant difference in all parameters compared to the home exercise group (p: 0.00-0.04). No side effects were observed during the exercises.

Conclusion: As a result of our study, Tai Chi has a positive effect on cardiopulmonary function and quality of life in patients with SS. Tai Chi should be included in rehabilitation programs as a safe alternative type of exercise to improve cardiopulmonary function and quality of life in patients with SSc.
a combination of e.g. animations, videos with personal patient stories, podcasts, written text, spoken words and interactive quizzes.

**Conclusion:** The e-learning program is developed and ready for feasibility testing. Subsequently, the effectiveness of the program will be tested in a RCT study among approximately 250 patients.

**EFFICACY OF ADDING CAFFEINE TO THE TREATMENT REGIMEN IN REDUCING METHOTREXATE INTOLERANCE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A RANDOMIZED CONTROLLED STUDY**

**A. Fehr1, F. El Noby2, N. Fathi3, R. Lotfy2.**

1Faculty of Medicine, Helwan University, Rheumatology & Physical Medicine Department, Helwan, Egypt

2Faculty of Medicine, Aswan University, Rheumatology Department, Aswan, Egypt

3Assaut Faculty of Medicine, Assuit, Egypt

**Background:** Rheumatoid arthritis is one of common form of chronic inflammatory arthritis. Methotrexate has remained anchor treatment because of its potent anti-inflammatory and immunosuppressive properties. Intolerance to Methotrexate is a common cause of non-compliance.

**Objectives:** To investigate the effect of adding caffeine orally as methylxanthines (Caffeine), act as adenosine receptor antagonists to reduce symptoms of moderate to severe methotrexate intolerance in patients with Rheumatoid Arthritis.

**Methods:** A prospective, randomised controlled study conducted at Aswan University Hospital, Egypt from Jan 2018 till May 2019. Sixty patients with Rheumatoid arthritis who have had experienced moderate to severe methotrexate intolerance was enrolled in the study. The methotrexate intolerance severity score (MISS) was evaluated at base line before initiation of study then at the next three months consecutively. Patients were randomly assigned by closed envelope method into 2 groups each containing 30 patients: Group A: 30 patients was prescribed caffeine (coffee or dark chocolate) as an antidote to methotrexate intolerance. Group B: 30 matched patients acted as control group that included who will continue methotrexate regimen without addition of any extra caffeine.

**Results:** Twenty four patients (80%) at time three follow up visit showed full improvement of symptoms of methotrexate-intolerance compared to ten patients (33.3%) at 2nd month follow up visit and seven patients (23%) at 1st month follow up visit with statistically significant difference all over the study period (P<0.005). half of study group patients discontinued anti-emeti and other drugs while none in control group did.

**Conclusion:** Adding caffeine to management regimen can reduce the symptoms of severe methotrexate-intolerance in Rheumatoid Arthritis patients.

### AB1310-HPR

**EFFECTS OF INSTRUMENT-ASSISTED SOFT TISSUE MOBILIZATION ON FROZEN SHOULDER: A RANDOMIZED CONTROLLED TRIAL**

E. Kaya Mutlu1, T. Birinci2, S. Kilic3. Istanbul University-Cerrahpasa, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey; 1Istanbul Medeniyet University, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey; 3Istanbul Aydin University, Institute of Health Sciences, Istanbul, Turkey

**Background:** Frozen shoulder has a greater incidence, more severe course, and resistance to treatment in patients. Management is based on the underlying cause of pain and stiffness. Joint mobilization has been reported to improve joint range of motion in frozen shoulder. However, there is no information regarding the effect of instrument-assisted soft tissue mobilization (IASTM) in frozen shoulder.

We proposed that there would be no significant difference between the two manual physical therapy techniques with relatively similar treatment effects in the frozen shoulder.

**Objectives:** The aim of this randomized controlled study was to compare the effectiveness of IASTM and joint mobilization in the treatment of patients with frozen shoulder.

**Methods:** Thirty patients with phase II frozen shoulder (mean age 50.9 years, age range 39–65 years) were randomly assigned to one of two treatment groups: Group I received joint mobilization combined with manual stretching exercise and Group II received IASTM with manual stretching exercise (two days per week for six weeks) (Figure 1). The pain level was evaluated with a visual analogue scale (VAS) and the active range of motion (ROM) was measured with a universal goniometer. The Disabilities of the Arm, Shoulder, and Hand score and the Constant-Murley score were used for functional assessment. The assessments were performed at baseline and after the 6-week intervention.

**Results:** Both groups had a significant decrease in pain according toVAS and a significant increase in ROM and function level (p<0.05). After the 6-week intervention, improvement of shoulder abduction ROM in Group I was found significantly higher than Group II (p=0.01), on the other hand, Constant-Murley score in Group II was found significantly higher compared to Group I (p=0.001).

**Conclusion:** Our results supported the hypothesis that either joint mobilization or IASTM, performed in addition to stretching exercise, provided similar improvements in pain levels in patients with the frozen shoulder.

RHEUMATIC AND MUSCULOSKELETAL DISEASES MANAGEMENT TOOL HELPS TO IMPROVE TREAT-TO-TARGET THERAPY AND PATIENTS’ ADHERENCE TO TREATMENT

P. Wu1, W. L. Li1, H. Zeng2, E. Liang2 1The First Affiliated Hospital of Sun Yat-Sen University, Dept. of Orthopedics, Guangzhou, China; 2The First Affiliated Hospital of Sun Yat-Sen University, Rheumatology, Guangzhou, China

Background: Many of the rheumatic and musculoskeletal diseases (RMD) are long term, painful, and function affecting, which takes both the doctors and patients a lot of time and effort. The number of Rheumatologists are not sufficient for the huge population of RMD patients in China. The doctor-patient ratio is as low as 1:1000. Relatively inadequate medical resources, traffic inconvenience in rural area, and patients’ insufficient understandings of the RMD may cause delayed medical intervention and poor prognosis. Effective RMD patient management tools which provide disease monitoring and enough doctor-patient communication is essential to improve the patients’ adherence to treatment. We designed an RMD management app according to the social, cultural and economic situation of Chinese patients, which helps to facilitate shared decision making and relieve the pressure of insufficient medical resources.

Objectives: We aim to investigate the effect of RMD patient management app on treat-to-target therapy and patients’ adherence and satisfaction to treatment.

Methods: An observational survey was administrated using a RMD patient management app. The app was designed and improved by Rheumatologist, orthopedics, nurses, patients, and app technical experts. Patients were offered with a questionnaire in regard to satisfaction with the app and their attitudes about the disease. General therapeutic principles, rehabilitation, exercise videos and follow-up information were distributed through the app. Warning signals were sent whenever there was a flag sign of exacerbation. The demographic and clinical data, social and economic status, and drug retention rates of the patients were documented. The survey was designed by clinical experts from relevant departments and developed by both doctors and patients.

Results: All patients were supervised by the rheumatologist and orthopedist when using the app. In all the patients included, there were cases of rheumatoid arthritis (35.3%), osteoarthritis (32.4%), anklylosing spondylitis (26.5%), and other chronic arthritis (5.8%). The mean age 38.5±15.8 years old, with 52.9% male and 47.1% female. Most of the patients (85.3%) believed that the app was helpful. Young patients were more likely to respond to the survey than older patients. Some patients (79.4%) had increased compliance because the app offered more chances to communicate with the doctors, which increase their understanding and confidence about the disease. Three patients received flag signs of exacerbation much earlier than they could get to the hospital. From the feedback of the patients, we realized that the patient would like to have more information to keep them from stepping on the trap of false advertisement for therapy (which is very commonly seen in China).

Conclusion: RMD patient need to manage disease activity, daily function and mental state. Insufficient medical resources and patients’ knowledge about the disease may lead to poor adherence and prognosis. RMD patient management tool on app was a feasible and cost-effective approach for data collection and patient education. The app increased treat-to-target therapy and patients’ adherence to treatment.

EFFECTS OF N-ACETYLCYSTEINE ON PULMONARY FUNCTIONS IN PATIENTS WITH SYSTEMIC SCLEROSIS: A DOUBLE BLIND, PLACEBO CONTROLLED STUDY

M. A. Nazarinia1,2, S. Mehrabi1, Z. Khodamorad2, M. Mazidi Moradi1, Z. Shiraz University of Medical Sciences, Shiraz, Iran, Division of Rheumatology, Department of Internal Medicine, Namazee Hospital, Shiraz, Iran (Islamic Republic of); 1Shiraz University of Medical Sciences, Shiraz, Iran, Department of Internal Medicine, Namazee Hospital, Shiraz, Iran (Islamic Republic of); 2Shiraz University of Medical Sciences, Shiraz, Iran, Division of Rheumatology, Department of Internal Medicine, Namazee Hospital, Shiraz, Iran (Islamic Republic of); 3Shiraz University of Medical Sciences, Shiraz, Iran, Student Research Committee, Shiraz, Iran (Islamic Republic of)

Background: Systemic sclerosis (SSc) is a systematic and rare autoimmune disease that affects many organs. N-acetylcysteine (NAC), thiol containing compound, can act both as the precursor of reduced glutathione and direct scavenger of reactive oxygen species.

Objectives: We assessed the clinical effect of NAC on pulmonary function test of patients with diffuse scleroderma.

Methods: This study is a randomized double blind clinical trial that was done on 25 patients with diffuse SSc without lung involvement on primary chest high-resolution computed tomography. Placebo was administered for 13 patients and 1200 milligram NAC for 12 patients. Body plethysmography parameters were assessed at the beginning of the study and after 24 weeks.

Results: Patients in the two groups were matched in the basic demographic data like age, duration of disease, and modified Rodnan skin score. The analysis showed no significant differences in parameters of plethysmography between the two groups. A p-value was not the data of 2 patients in the placebo-treated group, who developed interstitial lung disease, DLCO in the placebo-treated group was 90.69 ± 21.29 milliliter at the end of the study, which significantly decreased compared with the beginning of the study (102.30 ± 13.83 ml). Also, changes of DLCO between the two groups were significantly different.

Conclusion: In this trial, sensitivity of DLCO as the first marker in evaluation of pulmonary function in patients with SSc was confirmed. On the other hand, NAC had no effect versus placebo in a period of 24 weeks. We recommend that more studies with larger sample size and longer duration should conduct for further evaluation.

A COMPARISON OF THE EFFECTIVENESS OF TWO DIFFERENT KINESIO TAPE APPLICATIONS ON PAIN, FATIGUE AND HEALTH STATUS IN WOMEN WITH FIBROMYALGIA

S. Toprak Celenay1, B. Anaforglu Kulunkoglu1, O. Mete1 1Department of Physiotherapy and Rehabilitation, Health Sciences Faculty, Ankara Yildirim Beyazit University, Ankara, Turkey

Background: Fibromyalgia (FM) is a syndrome characterized mainly by chronic widespread pain, fatigue, and a decrease in health status. Kinesio tape (KT), one of complementary approaches, has favorable effects on clinic findings in FM, but studies investigating which types of the KT applications are more effective in FM are scarce.

Objectives: This study aimed to compare the effectiveness of fascial correction and FanCut KT applications on pain, fatigue and health status in women with FM.

Methods: A total of 27 women with FM were included, allocated into fascial correction (Group 1) (n:14, age: 41.50 (30.25) years, body mass index (BMI): 24.85 (5.28) kg/m²) and FanCut techniques (Group 2) (n:13, age: 45.00 (21.00) years, BMI: 25.60 (4.55) kg/m²) groups. The fascial correction technique performed with approximately 25% to 50% of tension and oscillated in longitudinal direction on overall back was used in the Group 1; while, the FanCut technique performed with 0% tension was on the overall back used in the Group 2. Exercise program was carried out 2 days a week for 6 weeks under the supervision of a physiotherapist in both groups. Pain intensity and severity of fatigue with the Visual Analog Scale and health status with the Fibromyalgia Impact Questionnaire were evaluated at the baseline and after the 6-weeks treatment.

Results: Physical characteristics of the groups were similar (p=0.190, p=0.808). After the treatment, it was found that pain intensity (p=0.001; p=0.001) and the severity of fatigue (p=0.001; p=0.003) decreased and health status (p=0.001; p=0.002) improved in both the group 1 and 2, respectively. Moreover, fatigue decreased (p=0.008) and health status improved (p=0.021) in the group 1 in comparison to the group 2; but pain intensity (p=0.085) did not differ between the groups.

Conclusion: In this study, it was observed that both the fascial correction and the FanCut KT applications were effective in decreasing pain and fatigue, and improving the health status of women with FM. In addition, the study suggested that the fascial correction KT application was superior in decreasing fatigue and improving health status in comparison to the FanCut KT application in women with FM. In clinics, the KT application may be considered as a non-pharmacologic and complementary therapy to improve the symptoms of FM. Moreover, the fascial correction KT application may be more effective in improving some parameters due to fascia dysfunction in FM.

**ECONOMIC EVALUATION OF THE DR. BART APP IN PEOPLE WITH KNEE AND/OR HIP OSTEOARTHRITIS**

T. Pelle 1,2, K. Bevers 1, F. Van den Hoogen 1,2, J. Van der Palen 1, C. Van den Ende 1,2, Sint Maartenskliniek, Nijmegen, Netherlands; 2Radboudumc, Nijmegen, Netherlands; University of Twente, Enschede, Netherlands

**Background:** Self-management is of paramount importance in non-surgical treatment of knee and/or hip osteoarthritis (OA). Modern technologies offer the possibility to support self-management 24/7. We developed an e-self-management application (dr. Bart app) for people with knee and/or hip OA.

**Objectives:** To evaluate the (incremental) cost-effectiveness and cost-effectiveness acceptability curves. Bootstrapping was used to estimate statistical uncertainty.

**Methods:** This economic evaluation was conducted alongside a 6-month randomised controlled trial, in which 214 participants were offered to use the dr. Bart app for 6 months and 213 participants received care as usual. Health care costs were measured using self-reported questionnaires. Clinical outcome measures were quality-adjusted life years (QALYs) according to the EuroQol (EQ-5D-3L), the EuroQol rating scale (QALY-TRS), and the five subscales of KOOS/HOOS. Cost and effect differences were estimated using longitudinal linear mixed models and cost-effectiveness acceptability curves. Bootstrapping was used to estimate statistical uncertainty.

**Results:** Mean age of participants was 62.1 (SD 7.3) years, with the majority being female (72%) (Table 1). The difference in health care costs was non-significant in favour of the intervention group (€31.12 (95% CI: -66; 3)). Table 2 shows estimated treatment effects over 6 months. We found small but positive effects on symptoms, pain and activities of daily living (ADL) in favour of the dr. Bart app for QALY and QALY-TRS, the probability of the dr. Bart app being cost-effective was > 82% and for activities and quality of life < 40%, regardless of WTPs.

**Conclusion:** This economic evaluation, from a health care perspective, showed that costs were not significantly lower for the dr. Bart app group compared to usual care. Given the non-invasive character of the intervention and the moderate probability to be cost-effective for the majority of outcomes, the dr. Bart app has only the potential to serve as a trustworthy tool to provide education and goal setting regarding OA and its treatment options.

**Conclusion:** 8-week HOT treatment does not substantially improve symptoms in FMS compared to PBO. All patients on hyperbaric treatment may experience amelioration of symptoms; other factors should be considered, including beliefs and expectations on the treatment.
COMORBIDITIES IMPACT ON PHYSICAL REHABILITATION PROGRAM OUTCOMES IN PATIENTS WITH KNEE OSTEOARTHRITIS

V. Salaru1, A. Vizdoga2, L. Mazur-Nicorici3, M. Cebanu4, T. Rotaru5, S. Vetrila3, M. Garabiju3, N. Loghin-Oprea4, V. Sadović-Bobeica5, M. Mazur6,1 State University of Medicine and Pharmacy “Nicolae Testemitanu”; Family Medicine, Chișinău, Moldova, Republic of; 2University Medical Rehabilitation Center, Medical Rehabilitation, Physical and Manual Therapy, Chișinău, Moldova, Republic of; 3Institute of Medicine and Pharmacy “Nicolae Testemitanu”; Internal Medicine, Chișinău, Moldova, Republic of; 4State University of Medicine and Pharmacy “Nicolae Testemitanu”; Emergency Medicine, Chișinău, Moldova, Republic of; 5Institute of Cardiology, Chișinău, Moldova, Republic of

Background: Physical rehabilitation is proposed as a method of non-pharmacological treatment of knee osteoarthritis (OA) by the EULAR and OARSI recommendations. At the same time, presence of concomitant diseases could influence the condition of patients and the outcomes of the rehabilitation program.

Objectives: To evaluate the frequency of comorbidities in OA patients and to appreciate their impact on outcomes of the physical rehabilitation program.

Methods: A prospective control case study was conducted in the University Rehabilitation Center. The patients underwent clinical examination, VAS scale was used to assess level of pain, and Knee Injury and Osteoarthritis Outcome Score (KOOS) with 5 domains (Pain, Symptoms, ADL, Sport, QoL) for joint function assessment. These parameters were evaluated at the onset of the program (T0) and at the end of the 10th day (T1). Medical data records, general clinical assessment. These parameters were evaluated at the onset of the program (T0) and at the end of the 10th day (T1).

Results: Among the 48 patients with OA were included in the study, 37 patients of them were found with comorbidities. The most frequent associated diseases were: cardiovascular- 76.6%, obesity-59.9%, and endocrine - 12.9% cases. At T0, significantly lower levels in the group with comorbidities were identified on the domains Pain, Sport and QoL. The CCI in patients with comorbidities was 3.29 ± 0.14 points (1-year survival rate). At the T1 moment, we found an improvement in joint functionality in both groups. The mean value of the VAS score group of patients without comorbidities decreased from 48.18 mm to 21.36 mm (p<0.05) and for the group of patients with comorbidities – 64.2 ± 36.2 mm (p<0.001). Significant improvement in joint function in the comorbidities group was in Pain (p<0.01), Sport (p<0.05) and QoL (p<0.01) domains, at the same in patients without comorbidities, the improvement was significant in all 5 domains.

Conclusion: Comorbidities are highly associated to knee osteoarthritis and prove to have a negative influence on the results of the physical rehabilitation program; therefore, we would recommend to apply individualized rehabilitation programs adapted to the associated conditions of each patient.

VAGUS NERVE STIMULATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: 48 MONTH SAFETY AND EFFICACY

F. Koopman1, A. Musters2, M. Backer1, D. Gerlag3, S. Mijlou3, S. Grajzing, S. Sokolovci4, Y. Levine5, E. Glass5, D. Chernoff6, N. De Vries7, P. Pak1

Background: Rheumatoid arthritis (RA) is a disease with significant remaining unmet medical needs for better treatments. Vagus nerve stimulation (VNS) to activate the inflammatory reflex (cholinergic anti-inflammatory pathway) represents a novel experimental therapy for RA.1 Previously, we reported that inflammatory reflex activation by VNS reduced pro-inflammatory cytokine production and improved disease activity in a 17-patient rheumatoid arthritis (RA) proof-of-concept study using a reprogrammed epilepsy stimulator;2 clinical improvement was sustained for 24 months without untoward safety signals.3 Here we report the 48 months results from this long-term observational study.

Objectives: Determine the long-term safety and efficacy of VNS for the treatment of RA.

Methods: In the primary study, a VNS device was implanted into 17 RA patients, mostly with insufficient response to multiple conventional and biologic DMARDs, on stable background of methotrexate (<25 mg weekly) therapy.3 The device electrically stimulated the vagus nerve, 1-4 min/day, over a 12-week open label

period. On completion, subjects were offered to enroll into a follow-up study, where the study physicians were given flexibility to alter VNS dosing parameters and/or to add a biologic disease-modifying antirheumatic drug (DMARD) to the treatment regimen to induce disease remission. Clinical disease activity measures and safety were assessed over 4 years.

**Results:** All patients elected to continue VNS treatment in the long-term follow-up study, 4 subjects withdrew prior to month 48. Reasons for discontinuation were withdrawal of consent (N=3) and adverse event due to device discomfort (N=1).

At the start of the follow-up study, the mean DAS28-CRP, CDAI and HAQ-DI were significantly reduced compared to the pre-implant baseline (mean differences: SD: DAS28-CRP=-1.60SD, 95% CI [-1.8], p<0.001; CDAI=21.19SD, 95% CI [17.7], p=0.001; HAQ-DI=0.44SD, 95% CI [-0.01], p=0.01), and this effect was retained through 48 months. Patients using VNS monotherapy and those using a combination of VNS with biologic DMARDs exhibited stable improvements in DAS28-CRP, CDAI and HAQ-DI at month 48 (Table 1). Improvements were observed for patients who both previously had an insufficient response to targeted biological therapies as well as those who had an insufficient response to standard DMARDs. No association was seen between DAS28-CRP and stimulation frequency (Range = 1X-8X/day). There was no difference in the adverse events profile between the two groups.

**Methods:** The study included 9 elderly women with chronic low back pain randomized into two groups: Segmental Stabilization Group (Group n=5, age 65.2±4.32; Body Mass Index - BMI 29.9±6.85) and Pilates Group (Group n=4, age 67.7±7.13; BMI 26.49±4.06). Both groups underwent individual sessions of 60 minutes twice a week and evaluated before and after 8 weeks. Pain was assessed using the Visual Analogue Pain Scale; functional disability, by Oswestry’s disability index; excess fear of movement and physical activity, using the Tampa Kinesiophobia Scale; level of confidence in the balance for specific activities, on the Activity-Specific Balance Confidence (ABC) scale and; activation of the transverse muscle of the abdomen, by the pressure biofeedback unit Stabilizer of the Chatanooga brand. The allocation and evaluations of the participants were performed by a blind examiner. The data were analyzed using the Student’s t-test with the level of significance (p<0.05).

**Results:** The data show significant differences in the reduction of pain intensity (p=0.022) and functional disability (p=0.023) only in SG and improvement in kinesiophobia (p=0.007) only in PG. The level of confidence in the balance for specific activities was better in the SG when compared to the PG (p=0.059). There was no difference in the activation of the transversus abdominis in both groups.

**Conclusion:** The results indicate that the segmental stabilization was effective to improve pain and functional disability, Pilates to improve the degree of kinesiophobia and the SG obtained a better result when compared to the PG regarding the level of confidence in the balance for specific activities. Both techniques had a great effect on improving functional capacity and on the level of confidence in the balance for specific activities. It is suggested to carry out studies with a larger number of participants and follow-up evaluation to assess the long-term effects.

### THE ASSOCIATION BETWEEN PHYSICAL ACTIVITY AND CARDIORESPIRATORY FITNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND HIGH CARDIOVASCULAR RISK

1. University of Stanford, Stanford, United States; 2. Amsterdam University Medical Centers, Amsterdam, Netherlands; 3. University of Wolverhampton, West Midlands, United Kingdom; 4. University of Amsterdam, Amsterdam, Netherlands; 5. Amsterdam Rehabilitation Research Center | Reade, Amsterdam, Netherlands

**Objective:** To verify the effect of segmental stabilization versus the Pilates method in the elderly with chronic low back pain.

**Background:** Low back pain is an important health condition with major socioeconomic consequences and is associated with high costs for the health system, absenteeism at work and reduced functional performance. It is one of the most relevant health problems in the elderly, with point prevalence estimates higher than other musculoskeletal conditions.

**Objectives:** To verify the effect of segmental stabilization versus the Pilates method in the elderly with chronic low back pain.
at least 10 hours was required. The VO2 max measured with a graded maximal exercise test was used to determine the CRF. Pearson correlation coefficients were calculated for the associations between the different measures of physical activity and VO2 max. For the variables that were associated, linear regression analysis was carried out, with pain and disease activity as possible confounders.

**Results:** Thirteen females and five males were included in the study. The mean age was 66.5 (± 15.0) years. Only 22% of the patients met public health physical activity guidelines for the minimal amount of 150 minutes a week. The mean step count was 6237 (± 2297) steps per day and moderate-to-vigorous physical activity time was 16.50 (± 23.56) minutes per day. The median VO2 max was 16.23 [4.63] ml·kg⁻¹·min⁻¹, which is under the standard. Pearson correlations showed a significant positive association for step count with VO2 max. No associations were found for sedentary, light, and moderate-to-vigorous physical activity with VO2 max. The significant association between step count and VO2 max(= 0.01) was not confounded by disease severity and pain.

**Discussion:** Since better CRF protects against CVD, increasing daily step count may be a simple way to reduce the risk of CVD in patients with RA and high CV risk. Presenting a significant positive association for step count with VO2 max. The significant association between step count and VO2 max(p = 0.01) was not confounded by disease severity and pain.

**Conclusion:** Since better CRF protects against CVD, increasing daily step count may be a simple way to reduce the risk of CVD in patients with RA and high CV risk. A focus group study of patient and health professional perspectives. Physical Therapy Reviews, 24 (1-2), pp. 12-28. ISSN 1083-3196

**NON-INFECTIONOUS ACUTE INFLAMMATORY ARTHRITIS IN JOINT ARTHROPLASTY**

L. Barbel Arcobé1, L. Gomez Garcia2, M. C. Bernaus Johnson3, F. Angles Crespo1, S. Martinez Pardo1, L. Font Vizcarra2, , Mútua Terrassa University Hospital, Rheumatology, Terrassa, Spain; 2Mútua Terrassa University Hospital, Internal Medicine, Terrassa, Spain; 3Mútua Terrassa University Hospital, Orthopaedic Surgery and Traumatology, Terrassa, Spain

**Background:** Acute inflammatory arthritis (AIA) in a native knee joint is a common pathology with a well-defined differential diagnosis which includes crystal-induced arthritis. Presenting symptoms in a knee joint arthroplasty (KJA) can mimic a periprosthetic hematogenous infection (PHI). There are few studies in current literature that describe possible causes of non-infectious arthritis in KJA. PHI requires, in most cases, an urgent combined surgical and antibiotic (AB) treatment. Describing and studying other possible diagnoses that may resemble PHI in a KJA is mandatory in order to minimize diagnostic errors and avoid unnecessary treatments.

**Objectives:** To analyze the characteristics of AIA in KJA with negative cultures in patients with an initial diagnosis suspicion of PHI.

**Methods:** A retrospective case series was conducted at a tertiary-level hospital including all patients diagnosed with an AIA in KJA with negative cultures from January 2012 to December 2019. Demographic data, clinical presentation, management and outcomes were recorded and analyzed.

**Results:** A total of 11 cases in 9 patients were included (6 females and 3 males) with a median age of 69 years at the time of diagnosis. All patients had risk factors for AIA (6 had chondrocalcinosis (CC), 2 hyperuricemia and 1 psoriasis). However, crystal deposits in synovial fluid (SF) for none of the patients had been previously found. The median time from the index surgery to clinical presentation was 6 months, and from initial clinical presentation signs to referral was 24 hours. All cases presented with pain and swelling and presented with erythema. Median body temperature on admission was 37.2°C. All patients presented with no acute distress. Initial blood tests showed a median white blood cell count and CRP of 11.160/mm³ and 90mg/L, respectively. Blood and SF cultures were taken for all cases. The median white blood cell count in SF was 75.883/mm³. Three cases had received AB treatment during a median of 6 days prior to microbiological sampling. After initial sampling, 6 cases received AB prior to surgery, 1 received AB after surgery. 1 received only AB and 3 were treated only with NSAIDS. In all cases, surgical treatment consisted in radical surgical debridement and polyethylene insert exchange. Further blood and SF tests were performed 4 days after admission. The mean decrease for systemic white blood cell count, CRP and synovial leukocyte count was 46%, 58% and 56%, respectively. All cultures were negative and crystal deposits were not identified for any of the samples.

**Conclusion:** Non-infectious AIA in KJA is a rare entity that should be accounted for the differential diagnosis of periprosthetic joint infection. The initial diagnosis

**DEVELOPING A SELF-MANAGEMENT INTERVENTION TO MANAGE JOINT HYPERMOBILITY SYNDROME AND EHLERS-DANLOS SYNDROME HYPERMOBILITY TYPE: AN ANALYSIS INFORMED BY BEHAVIOUR CHANGE THEORY**

S. Bennett1, N. Walsh1, T. Moss1, S. Palmer1, 1University of the West of England - UWE Bristol, Faculty of Health and Applied Sciences, Stoke Gifford, United Kingdom

**Background:** Joint Hypermobility Syndrome (JHS) and Ehlers-Danlos Syndrome Hypermobility Type (EDS-HT) are heritable disorders of connective tissue that can cause joint instability and pain and are associated with increased anxiety and depression. There is currently little UK guidance for supporting patients with JHS/EDS-HT. 1 The analysis presented here used the Behaviour Change Wheel (made up of the Theoretical Domains Framework (TDF) and Capability, Opportunity, Motivation and Behaviour (COM-B) model)2 to identify possible intervention options to improve self-management in people with JHS/EDS-HT.

**Objectives:** To determine recommendations for the components of a behaviour change intervention for people with JHS or EDS-HT.

**Methods:** Data from: 1) A systematic review of the literature on self-management and joint hypermobility syndrome (JHS/EDS) and 2) A thematic analysis of interview data where UK adults with JHS/EDS-HT (n=17, 14 women, 3 men) discussed the psychosocial impact of the condition on their lives3, were mapped onto the TDF and COM-B in a behavioural analysis. A modified Nominal Group Technique focus group (n=9, all women) explored which interventions identified by the TDF/COM-B mapping exercise were most important to them. Results: Participants prioritised a range of potential self-management interventions, including:

- **Education:** Participants wanted greater support to improve their knowledge of JHS/EDS-HT, including self-help strategies for coping with injury, fatigue and overexertion, and how to evaluate information about their condition.

- **Training:** In activity pacing, assertiveness and communication skills, and what to expect during pregnancy, when symptoms of JHS/EDS-HT can worsen.

- **Environmental restructuring and enablement:** Support from occupational therapists to maintain independence at home. Enablement of access to CBT, mindfulness and emotional support.

**Modellled behaviour:** Positive first-person narratives that address how other patients with JHS/EDS-HT have coped with anxiety, depression, distress, fear, frustration and feelings of loss.

**Conclusion:** This study is the first to apply theoretically-informed approaches to the management of JHS/EDS-HT. Through a modified nominal group technique, potential behaviour change interventions for addressing barriers to self-management have been prioritised. Discussion with participants indicated poor access to psychological support, occupational therapy and a lack of knowledge of JHS/EDS-HT. Future research with healthcare professional and patient stakeholder groups will further evaluate which intervention options would be most acceptable and feasible for the management of JHS/EDS-HT.

of infection could not be confirmed, although three patients had taken AB before sampling. It is important for physicians to have a suspicion for non-infectious arthritis, especially in patients with clinical and blood test result dissociation, radiological CC, medical history of hyperuricemia or psoriasis, in order to avoid unnecessary AB and surgical treatment.

A QUALITATIVE EXPLORATION OF THE PERSONAL FINANCIAL TOLL OF ARTHRITIS

D. Berkovic,1 D. Ayton,1 A. M. Briggs,1 I. Ackerman.1 1Monash University, Melbourne, Australia; 2Curtin University, Melbourne, Australia

Background: The financial experience faced by working-age people with arthritis includes living below the poverty line for many (1). Financial distress amongst people with arthritis is known to contribute to poorer health outcomes, including high psychological distress and more severe pain (2). Despite the demonstrated societal cost of arthritis care and management, the personal costs borne by the individual are not well understood in different health systems (3).

Objectives: To examine the perceived financial impacts of living with arthritis amongst working-age individuals aged 18 – 50 years in Australia.

Methods: A qualitative descriptive study design was used. Participants with inflammatory arthritis or osteoarthritis were recruited from the community, including rural and urban settings. An interview schedule was developed, informed by existing literature (4), which was piloted prior to data collection. Deductive and inductive coding techniques were used to identify financial-related themes arising from the data.

Results: Semi-structured interviews were conducted with 21 younger people (90% female) with a mix of arthritis conditions including rheumatoid arthritis, psoriatic arthritis, osteoarthritis, and ankylosing spondylitis. Four themes were identified: direct arthritis-attributable medical costs, indirect arthritis-attributable costs, insurance and pension costs, and broader financial impacts on the family. Non-subsidised costs were frequently referenced by participants as burdensome, and existed even within the publically-funded healthcare system. Financial distress was characterised by participants as chronic, onerous for the entire family, and associated with exacerbation of physical symptoms.

Conclusion: People with arthritis and of working age experience significant arthritis-attributable financial burden and related distress. Financial concerns should be actively identified and considered within shared clinical decision making, in order to provide more patient-centred care for these individuals.

INVESTIGATION OF THE RELATIONSHIP BETWEEN SOCIAL APPEARANCE ANXIETY AND DISEASE DURATION, SELF-ESTEEM, ANXIETY AND DEPRESSION IN RHEUMATOLOGICAL DISEASES—PRELIMINARY STUDY

S. V. Cetin1, A. Ayan2, A. Buyuk3, T. Can Akman4. 1Akdeniz University, Department of Physical Therapy and Rehabilitation, Antalya, Turkey; 2Antalya Training and Research Hospital, Rheumatology, Antalya, Turkey; 3Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey; 4Pamukkale University, Physiotherapy and Rehabilitation, Denizli, Turkey

Background: Appearance anxiety means discomfort in social interactions due to changes in appearance. Also this anxiety; it is the fear of being evaluated negatively and worry about the changes in appearance, and it is not only apparent. Body image is the emotions, thoughts and perceptions of the individual about his or her own body and directly affects self-esteem. The Social Appearance Anxiety Scale (SAAS) was developed to assess social appearance anxiety, and this scale was found to be a valid and reliable scale in scleroderma (SSc) patients. It was also thought to be related to the severity of the disease. The literature shows that appearance concerns are strongly related to depression in patients with rheumatic disease and should be evaluated routinely.

Objectives: The first aim of the study is to determine the level of social appearance anxiety in rheumatology patients, and our last goal is to investigation of the relationship between social appearance anxiety and disease duration, self-esteem, depression and anxiety.

Methods: 129 rheumatology patients with a mean age of 42.96 ± 13.33 years (51 men, 78 women) were included in the study. 55% of patients were ankylosing spondylitis (AS). 15.5% of patients were spondylarthrosis (SS), 11.6% of patients were rheumatoid arthritis (RA), 7.8% of patients were fibromyalgia syndrome (FMS), 6.2% of patients were SSc, 2.3% of patients were Behçet’s disease (BD) and 1.6% were diagnosed with psoriatic arthritis (PsA). The Social Appearance Anxiety Scale (SAAS) was used to evaluate patients’ social appearance anxiety, the Rosenberg Self-Esteem Scale (RSES) was used to evaluate self-esteem, and the Hospital Anxiety and Depression Scale (HADS) was used to evaluate depression and anxiety.

Results: The disease duration was found to be 6.82 ± 5.22 years. The SAAS average was found to be 43.23 ± 20.53 points. It was found that the SAAS values of patients with PsA and SSc were higher than patients with AS, RA, FMS, SS, BD. A moderate positive correlation was found between SAAS and disease duration, depression and anxiety (p: 0.048, r: 0.545; p: 0.007, r: 0.638; p: 0.014, r: 0.746, respectively).

Conclusion: As a result of the study, it was observed that rheumatology patients had moderate and high level social appearance anxiety. We thought that they have a higher level of social appearance anxiety because of skin involvement in patients with PsA and SSc. In addition, as a result of the study, we found that as the social appearance anxiety increased, disease duration, depression and anxiety increased. According to this study, in which the preliminary results are given, we thought that it is necessary to determine patients’ appearance anxiety in routine evaluation and to reduce social appearance anxiety by collaboration with multidisciplinary areas in rheumatological diseases.

THE TRANSITION FROM PEDIATRIC TO ADULT RHEUMATOLOGY OF 347 PATIENTS AT A SINGLE CENTER

S. Uguru1, B. H. Egel1, A. Adrovic1, K. Barut1, S. Sahin1, M. Yildiz1, O. Kasapcopur1, H. Ozdogan1, 1Istanbul University- Cerrahpasa, Istanbul, Turkey

Background: Pediatric to adult rheumatology transition can be a challenge for both the patient and the clinician, especially in rheumatology as it includes chronic diseases with close follow-up. Objectives: The objective of this study is to understand our tertiary rheumatology center patient demographic transitioning from pediatric to adult rheumatology in order to design prospective studies enhancing the evidence of transition recommendations.

Methods: Patients included in this study are regularly followed-up in our adult rheumatology clinic and were regularly followed up in our pediatric rheumatology clinic in the past. They were all diagnosed with a rheumatologic condition receiving treatment. The patient files were assessed to have a better understanding of their demographic, disease and treatment information.

Results: Our cohort includes 347 patients diagnosed with a variety of conditions that are Familial Mediterranean Fever (FMF) (n=216), Juvenile Idiopathic Arthritis (JIA) (n=56), Juvenile Spondyloarthrosis (SPA) (n=39), Systemic Lupus Erythematous (SLE) (n=20), Behçet’s Disease (n=7) and the rest of the rheumatologic conditions with less than 5 patients each. The mean age of the patients during transition, mean age of diagnosis, and follow-up duration are 21.34±1.7, 10.4±4.18, and 10.8±4.4 in respective order. The treatment regimens the patients received are summarized in Table 1.
Seven patients had FMF related attacks. In addition to attacks, one FMF patient had bilateral ankle pain and one patient had leg pain. One patient out of three diagnosed with Takayasu’s disease was still symptomatic. One patient had uveitis-related symptoms. One patient diagnosed with SLE had skin dryness. Furthermore, there were patients with sequelae formation. One patient diagnosed with oligoarticular JIA (oJIA) had bilateral hip sequela with the additional left hip prosthesis. One oJIA patient had micrognathia, and one had left knee sequela. One pJIA patient had small joint sequelae. One sJIA patient had bilateral hip sequela. One JSPA patient had enthesopathy. One FMF patient had proteinuria due to amyloidosis formation. Another FMF patient had hip surgery due to sequela.

Conclusion: Our center had patients with a variety of conditions with different natures of diseases. EULAR recommends the transition process to start no later than 14 years of age; however, this process started at the mean age of 21 in our patients. In most of these patients, especially the ones diagnosed with FMF, the control of disease activity was maintained. The transition of these different clinical entities might require certain amendments to the standard of care. For future references, we will be able to understand more about the adulthood prognosis of these clinical entities.

Ambivalence – for and against referring to the physical dependence and smoking habits making a smoking cessation difficult. Dependency to nicotine and challenges to quit smoking led to a feeling of ambivalence and a lack of control.

Conclusion: Tobacco addiction appeared as a physical dependence and a habit, which, during a smoking cessation, led to ambivalent feelings. Therefore, based on this study, there is still a need for health professionals to talk to patients about smoking. But also, a need to articulate the complexity of addiction in order to support for smoking cessations. Information should be strengthened in the clinical practice in relation to nicotine’s implication in tobacco addiction as well as the consequences of tobacco smoking for individuals with RA.

Introduction: The current status and associated factors of fatigue in Chinese patients with gout

J. Guo1, W. Zhou1, M. He1, Z. Gu1, C. Dong1. 1Affiliated Hospital of Nantong University, Nantong, China

Background: Fatigue of chronic diseases has been paid more and more attention. But the status of fatigue in gout patients has not been reported in the world[1].

Objectives: In the absence of previous studies, our study aims to investigate the fatigue status, explore the potential predictors of fatigue and the effects of fatigue on health-related quality of life (HRQoL) among Chinese gout patients.

Methods: This cross-sectional study was conducted from the Affiliated Hospital of Nantong University. A series of questionnaires were applied: Fatigue Scale-14 (FS-14), the 10cm visual analog scale (VAS), the Patient Health Questionnaire (PHQ-9), the Generalized Anxiety Disorder questionnaire (GAD-7), the Pittsburgh Sleep Quality Index (PSQI), Health Assessment Questionnaire(HAQ), the Short Form 36 health survey (SF-36). Laboratory examinations were taken to obtain some biochemical indicators. Independent samples t-test, Mann–Whitney U-test, Chi-square analysis, Pearson /Spearman correlation, Stepwise linear regression and binary logistic regression were used to analyze the data.

Results: 411 gout patients were included in this study. Among them, more than 50% patients reported physical fatigue in FS-14, severe disease, poor psychological status and reduced HRQoL were associated with fatigue. Multiple stepwise linear regression and binary logistic regression were applied and showed that pain, sleep quality, anxiety, depression and functional disorder were the potential predictors of fatigue. In addition, we found that the more severe the fatigue, the lower the patient’s HRQoL.

Conclusion: Fatigue among gout patients is exceedingly common. The results of this study suggested that rheumatologists should pay closely attention to gout patients who suffer from serious fatigue, especially those with pain, poorer sleep quality, anxiety, depression and functional disorder.

Scientific Abstracts
Conclusion: Lupus nephritis (LN) is an autoimmune disease characterized by inflammation of the kidneys as a result of systemic lupus erythematosus (SLE). Approximately 50% of SLE patients will develop LN, which is considered to be one of the most severe manifestations of SLE and the leading cause of morbidity and mortality in SLE. While there is ample existing evidence on disease experience and PROs used in extra-renal SLE, little research has been done in LN. Qualitative interviews with patients can help identify concepts that are both important and relevant to the patient. In order to effectively evaluate treatment benefit, it is critical that PRO measures used to assess such concepts and define clinical trial endpoints are fit for purpose and have strong evidence of content validity in the specific context of use.

Objectives: The objective of this study was to understand the patient experience of LN and to identify and characterize the signs and symptoms of LN and their impact on health-related quality of life (HRQoL) through the development of a disease-specific conceptual model. This model was then used to evaluate the content validity of existing PRO measures available for use in LN.

Methods: A structured literature search was conducted in Medline, Embase and PsyCINFO to identify qualitative research articles documenting the patient experience of LN. PRO measures developed or commonly used to assess patient experiences of LN were also identified. Semi-structured concept elicitation interviews were conducted with 15 adult patients in the US with a clinician-confirmed diagnosis of LN (defined in accordance with established clinical guidelines). Supplementary qualitative data were also collected from a review of publicly available online blogs/forums. Findings were used to inform the development of a conceptual model detailing the impact of LN signs, symptoms and HRQoL and evaluate the validity of existing measures used within LN.

Results: Searches revealed a paucity of qualitative research conducted with LN patients, supporting the need for prospective research in LN. Consistent with existing literature in SLE, the core signs and symptoms identified from the qualitative literature review, interviews and blog/forum review included joint pain, fatigue, joint stiffness, swelling (particularly in the extremities) and skin rashes. LN patients also reported urinary frequency, urgency, foamy urine and blood in their urine. Disease impact on physical functioning, activities of daily living, emotions, social life, work/finances and sleep were reported. PRO measures commonly used to evaluate patient experiences in LN included the SF-36, LupusQOL, LupusPRO, SLE Symptom Checklist, KDQoL, and KSO. Conceptual mapping of instruments against the newly developed conceptual model (Figure 1) highlighted that no single measure provides a comprehensive assessment of all symptoms/impact important to LN patients. Furthermore, items are largely focused on impact of symptoms with few items on symptom severity.

Conclusion: The presentation of signs and symptoms in LN patients appears similar to those reported in extra-renal SLE populations, with the addition of swelling and urinary symptoms. Qualitative research with LN patients guided the development of a comprehensive LN conceptual model outlining the disease experience from the patient's perspective. These insights can be useful to inform PRO measurement strategies for clinical trials in LN.

Acknowledgments: With thanks to Dr. Betty Diamond and Dr. David Wofsy for their collaboration and helpful insights.

**FIBROMYALGIA SYNDROME IN MEDICAL STUDENTS**

I. Akın1, M. Gürc2, R. Piskin Sağı3, B. Oz2, A. Karataş2, S. S. Koca4,5,6,7  
1Fırat University, Elazığ, Turkey; 2Fırat University, Rheumatology, Elazığ, Turkey

**Background:** At the university, students begin to be responsible for their own life decisions and lifestyles. First year students are required to adapt especially to a new learning environment and to cope with the academic and social demands of vocational education. High academic expectations are stressful and can pose a risk to students mental and physical health. Anxiety and depression are among the most common psychiatric problems among students.

**Objectives:** The aim of this study is to evaluate the prevalence of fibromyalgia syndrome (FMS) in medical students and to compare students from engineering faculty.

**Methods:** 392 (284 faculty of medicine, 108 faculty of engineering) students selected from Fırat University Faculty of Medicine and Engineering were included in the study. Hospital Anxiety and Depression Scale (HADS) forms were filled in for all participants. Anxiety and depression among students of medical and engineering were examined. Moreover, 2016 ACR FMS classification criteria was used to select the student who have FMS.

**Results:** In our sample, 185 (47.1%) and 207 (52.9%) of participants were male and female, respectively. HADS anxiety and HADS depression scores were significantly higher in engineering students than in medical students (mean HADS anxiety and depression scores were 9.07; 10.29, p= 0.007 and 7.61; 8.52, p= 0.039, respectively). While a significant difference was found among medical and engineering students in terms of HADS anxiety and depression scores in men (p=0.001 and p=0.006), no significant difference was found in women (p=0.676 and p=0.278). On the other hand, 46 (16.1%) of medical students and 13 (11.7%) of students from engineering faculty have FMS (p=0.170).

**Conclusion:** FMS prevalences are similar in the medical students and students from engineering faculty. However, anxiety and depression are more common among male engineering students than medical students. This may be related to future employment anxiety among students from engineering faculty.

**BARRIERS AND FACILITATORS TO PHYSICAL ACTIVITY IN JUVENILE IDIOPATHIC ARTHRITIS (JIA): A SCOPING REVIEW**

K. O Donoghue1, L. Larkins2,3,  
1University of Limerick, Limerick, Ireland; 2Health Research Institute, University of Limerick, Castletroy, Ireland; 3University of Limerick, School of Allied Health, Faculty of Education & Health Sciences, Castletroy, Ireland

**Background:** Physical activity is an important aspect in the management of JIA (1). However physical activity levels are low in this population (2). Limited research has been conducted to identify definitive barriers and facilitators to physical activity in children and adolescents who have JIA.

**Objectives:** The objective of this scoping review was to identify the common barriers and facilitators to physical activity in JIA.

**Methods:** Original studies, either quantitative or qualitative, including participants with a diagnosis of JIA, who were under 18 years of age were included. Two independent reviewers carried out a search of the literature and full text reviews of papers to determine eligibility for inclusion. The Critical Skills Appraisal Programme (CASp), Appraisal tool for Cross-Sectional Studies (AXIS) and Downs and Black critical appraisal tools were used to assess the quality of the included research articles.

**Results:** Eighteen studies were included in the review. The included studies were of a variety of low, moderate and high quality. The synthesis of the data identified pain to be the most common barrier and the modification of physical activities to the need of the individual to be the most common facilitator to physical activity in JIA.

**Conclusion:** Identifying the most common barriers and facilitators to physical activity allows clinicians to apply better management strategies when treating an individual with JIA. Our findings demonstrate the need for further research in this area to assist increasing physical activity participation for children and adolescents who have JIA.

### AB1335-HPR

**HEALTH PROFESSIONALS’ PERSPECTIVE ON THE BENEFITS AND RISKS OF LOW-DOSE GLUCOCORTICOIDS IN RHEUMATOID ARTHRITIS – AN INTERNATIONAL SURVEY OF 444 HEALTH PROFESSIONALS**

T. Santiago1,2, M. Voshaar3, M. De Wit4, P. Carvalho5,6,7, M. Boers8, M. Cutolo9, F. Buttgereit10, J. A. P. Da Silva1,2,  
1Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2University of Coimbra, Faculty of Medicine, Coimbra, Portugal; 3University of Twente, Department of Psychology, Health and Technology, Enschede, Netherlands and Stichting Tools Patient Empowerment, Amsterdam, Netherlands; 4Stichting Tools Patient Empowerment, Amsterdam, Netherlands; 5Centro Hospitalario Universitario do Algare, Rheumatology, Faro, Portugal; 6Lisbon Academic Medical Centre, Lisbon, Portugal; 7Algarve Biomedical Center, Faro, Portugal; 8Department of Epidemiology and Biostatistics, and Amsterdam Rheumatology and Immunology Center, Amsterdam University Medical Centers, Vrije Universiteit, Amsterdam, Netherlands; 9Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS Policlinic Hospital San Martino, Genova, Italy; 10Department of Rheumatology and Clinical Immunology, Charité University Medicine Berlin, Berlin, Germany

**Background:** The Glucocorticoid Low-dose Outcome in Rheumatoid Arthritis Study (GLORIA) is an international investigator-initiated pragmatic randomized trial designed to study the effects of low-dose glucocorticoids (GCs) in elderly patients with Rheumatoid Arthritis (RA).

**Objectives:** To evaluate the current patient perspective on the efficacy and risks of GCs in RA patients who are or have been treated with GCs.

**Methods:** Patients with RA completed an online survey (with 5 closed questions regarding efficacy and safety) presented in their native language. RA patients were recruited through a variety of patient organizations representing three continents. Patients were invited to participate through national patient organizations. In the USA, patients were also invited to participate through MedGuard.org. Participants were asked for their level of agreement on a 5-point Likert scale.

**Results:** 1344 RA patients with exposure to GCs, from Brazil, USA, UK, Portugal, Netherlands, Germany and 24 other countries** participated: 89% female, mean age (SD) 52 (14) years and mean disease duration 13 (11) years. The majority of patients (84%) had ≥10 years of education. The duration of GCs exposure was 1.6 (4.2) years. The majority of participants had read articles or pamphlets on the benefits or harms of GC therapy. Regarding GCs efficacy (table 1), high levels of endorsement were found: about 2/3 of patients considered that GCs were very useful in their case, more than half considered that GCs were effective at low doses, and agreed that GC improved RA symptoms within days. Regarding safety (table 1), 1/3 of the participants reported having suffered some form of serious adverse events (AEs) due to GCs, and 9% perceived this as life-threatening. Adverse events had a serious impact on quality of life, according to about 1/3 of the respondents.

**Conclusion:** Patients with RA exposed to GC report a strong conviction that GCs are very useful and effective for the treatment of their RA, even at low doses. This is accompanied by an important prevalence of serious AEs. Understanding the patient perspective can improve shared decision-making between patient and rheumatologist.

**Funding statement:** This project has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 634866.
Among the nine topics identified, the one most rated by patients was the doctor-patient relationship, 50 connective tissue diseases/vasculitis, and 20 among osteoarthritis, gout, social life 121 (60.5%) and cigarette smoke 119 (59.5%). The digits considered relevant was perceived to be able to influence disease symptoms. Regarding RD prevention, environmental pollution and cigarette smoking were considered the most important topics, while fewer patients believed that research on other topics could help to stop disease progression or to achieve disease healing.

**PATIENTS’ EXPERIENCE OF INVOLVEMENT IN A RHEUMATOLOGY OUTPATIENT CLINIC**

**P. Toftegaard**

**Svendborg, Rheumatology, Svendborg, Denmark**

**Background:** Involvement in own treatment and care is a wish from patients and a vision from politicians in Denmark. (1,2) In outpatient rheumatology patient involvement also leads to increased patient satisfaction, better quality of treatment and better utilization of resources in health care. (3,4,5) On the basis of this we ought to involve our patients at our Outpatient Clinic in Svendborg, but are we?

**Objectives:** To gain knowledge about how patients with rheumatoid arthritis experience involvement in treatment and care in the Rheumatology Outpatient Clinic, Svendborg.

**Methods:** An interview study of six patients with subsequent analysis based on Ricoeur. (6) Patient inclusion: patients with rheumatoid arthritis in remission since 2017. Patients were between 50 – 78 visiting the clinic during March and April 2019. (7) The participants were asked about their experience of involvement from time of diagnosis until present time.

**Results:** The study provided knowledge that patient involvement was new to the participants. This is also found in other literature about patient involvement. (7,8) All participants in this study felt involved in own care and treatment. The involvement was based on being seen and heard as persons with individual needs and not just as patients with arthritis. The way the participants experienced involvement showed that there are individual differences in how to provide the experience. In order to clarify what involvement meant for each patient, relationship with the health professional was necessary, as other studies also shows. (7,8) The relationship was conditioned by continuity, trust, care and mutual respect. For all the participants informed consent was equal to involvement. Disease activity or fear of this was the main reason for feeling involved this way. Literature describes the same: amongst other factors, the severity of the disease is significant for the patients desire to be involved. (7,8)

**Conclusion:** The participants experienced involvement in own care and treatment. The relation to the health professional was important providing this experience. All defined involvement as informed consent as it also is to many healthcare professionals. (9) All participants needed time to reflect on what
involvement meant as none of them had heard of it before. Patient involvement needs education of both patients and healthcare professionals to be taken further than informed consent.

Background: The Addressing Lupus Pillars for Health Advancement (ALPHA) Project is a global, consensus initiative to identify, prioritize and address top barriers in lupus drug development, clinical care and access to care. The Lupus Foundation of America convenes ALPHA with Tufts Center for the Study of Drug Development and a Global Advisory Committee of lupus experts representing clinician-scientists, industry and patients.

Objectives: Collect global patient input to determine alignment with the lupus clinician-scientist community on prior published consensus of top lupus barriers.

Methods: A 23-question online Quacits survey was developed to identify challenges across lupus diagnosis, clinical care and research participation. The survey, available in English, Spanish, Korean and simplified Chinese, was fielded in November 2019 to people with lupus and caregivers of children <18 with lupus. SPSS 26 and SAS 9.4 were used for descriptive statistics and sub-analysis.

Results: Analysis included only consented responses with ≥ 68% survey completion (n=3,447) received across 83 countries. 95% were female with a mean age of 44.5 years. 68% were not employed, 25% (87%) were caregivers to children, 13% were caregivers to children ≥18 with lupus.

Highest ranked challenges were similar globally and across children and adults: medication side effects, lack of treatment options and high out-of-pocket costs. Managing side effects ranked significantly higher (p<0.05) compared to ≥3 biologicals. The median treatment time was 8.4 months (RIQ 6.5-20.3) in ≥3 biologicals. The median treatment time was 8.4 months (RIQ 6.5-20.3) in ≥3 biologicals.

Background: The patient’s perspective is an important component of effective drug development and the patient engagement experience. The aim of this study was to describe the patient’s experience of participating in clinical trials in the real world setting.

Methods: Patient experience (n=538) was assessed using a validated questionnaire. Descriptive analysis was performed.

Results: The median age of patients was 62.9 (RIQ 49.9-74.4); 82% were women, 28% (71.2%) anti-CCP and 32 (82.1%) were rheumatoid factor positive, with erosive disease in 34 (87.2%) patients. In the previous treatment, 9 (23.1%) were naive to biologicals, 6 (15.4%) had received 1 biological, 18 (46.1%) 2 biologicals and 6 (15.4%) ≥ 3 biologicals. The median treatment time was 8.4 months (RIQ 6.5-20.3) in BAR and 13.2 (RIQ 3.9-20.7) in TOF.

AB1339-HPR
SAFETY AND ADHERENCE OF THE JAK INHIBITORS IN CLINICAL PRACTICE IN RHEUMATOID ARTHRITIS
C. Valero1, A. Calvo Garcia1, N. Garcia Casañahda, A. Ortiz2, I. Llorente1, B. Varas3, S. Casañahda1, R. Garcia de Vicuna1, E. Ramirez3 on behalf of Rheumatology and Pharmacy Hospital De La PrincesaRheumatology Hospital Santa Cristina. 1Hospital De La Princesa, Madrid, Spain; 2Hospital Santa Cristina, Madrid, Spain

Background: The Janus Kinase (JAK) inhibitors Baricitinib (BAR) and Tofacitinib (TOF) are indicated for moderate to severe active rheumatoid arthritis (RA). Data about safety, effectiveness in refractory patients and adherence in real clinical practice in our population are scarce.

Objectives: An evaluation of safety, adherence and reasons to consider suspension of JAKIs in routine clinical practice.

Methods: Retrospective observational study of patients with RA treated with BAR and TOF according to usual clinical practice between September 2017 - December 2019. Data were collected from the electronic medical record and from the Domini® Outpatient DrugDispensing program. Demographic, clinical, laboratory and treatment-related variables were collected, including reasons for discontinuing JAKIs (inefficiency and toxicity). Adherence was calculated using the Compliance Questionnaire on Rheumatology (CQR-5), and the average possession ratio (RMP), which is defined as the number of days of medication side effects, lack of treatment options and high out-of-pocket costs. Managing side effects ranked significantly higher (p<0.05) compared to ≥3 biologicals. The median treatment time was 8.4 months (RIQ 6.5-20.3) in BAR and 13.2 (RIQ 3.9-20.7) in TOF.

The reasons for consideration shown in Table 1.

</tr>
</tbody>
</table>

Conclusion: In our population, mostly refractory to biological, more than half of the patients maintain treatment with JAKI, with optimal adherence. The main reason for the suspension of both drugs was inefficacy. The most frequent adverse effects were hypercholesterolemia in both groups and infections in BAR, with a high frequency of herpes zoster. No cardiovascular or thromboembolic events were observed.

AB1341-HPR FEASIBILITY OF THE BACK AND FORTH SCHOOL BOOKLET, A SHARED SELF MANAGEMENT INSTRUMENT FOR YOUNG CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA) AT SCHOOL

J Cappon¹, M Van Rossum², E Littooij³, M Van der Leeden³, J Reade, Centre for Rehabilitation and Rheumatology, Amsterdam, Netherlands; Amsterdam UMC, locatie AMC, Amsterdam, Netherlands; Amsterdam UMC, locatie VUMc, Amsterdam, Netherlands

Background: Young children with JIA have to cope with pain and fatigue during schooldays, facing problems with writing, climbing stairs, physical education and playing outside. They need to develop age-appropriate self management skills, encouraged by their parents and teachers in a therapeutic alliance with the health professional team. For this purpose a shared management tool, called the “Back and Forth Schoolbooklet” (B&FS), is developed, containing 1) Educational pages about JIA, pain and fatigue management 2) Diary pages with a colour-in puppet for expressing location and amount of pain, spaces for writing alternatives for limited activities, feedback spaces for parents and teachers and a self-evaluation scale of general well-being for the child. Children, parents and teachers are instructed how to use the booklet by therapists during outpatient rehabilitation. Structured evaluation of the use of the instrument is necessary to improve its applicability and effectiveness.

Objectives: To study the feasibility, defined as practical and experienced applicability and effectiveness, of the B&FS.

Methods: Pilot feasibility study with a mixed-method design. Parents, teachers, therapists and children with JIA were invited to fill in questionnaires after using the booklets in school. Adults had to sign informed consent. Practical applicability was assessed by multiple choice questions on duration and frequency of use. Used diary items and pages were counted in returned booklets. Experienced biologists carried out and effectiveness was assessed by participants and patients using the mentioned items of the booklets. Practical applicability was analysed descriptively. Atlas-ti was used for analysing and coding the answers on the open-ended questions using a thematic approach.

Results: Eight children aged 4-8 years used the booklets. Six parents of six children, four therapists and four teachers signed informed consent and answered open-ended questions using a thematic approach. The children spent an average of 30-100 USD purchasing aids, medicaments or laboratory tests. Conclusion: In the Colombian context OPP are relevant and represent an important expenditure for patients with RA especially for those who have low or middle income. Due to the above, it is important to find alternatives in order to help vulnerable segments of the population. Additionally, OPP needed to be taken into account due to its association with treatment adherence(2).

Acknowledgments: This project has been funded by a collaboration between the Ministry of Science, Technology and Innovation COLCIENCIAS (contract 746-2018), the Fundación Universitaria de Ciencias de la Salud and Biobom - Center for Rheumatoid Arthritis.

AB1340-HPR PATIENTS’ OUT-OF-POCKET EXPENSES ANALYSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS ENROLLED IN A EDUCATIONAL PROGRAM

D Buitrago-Garcia¹, F Rodriguez², G Sánchez³, P Santos-Moreno³.
¹Fundación Universitaria de Ciencias de la Salud, Epidemiology, Bogota, Colombia; Biobom - Center for Rheumatoid Arthritis, Patient Education Program, Bogota, Colombia; Biobom - Center for Rheumatoid Arthritis, Rheumatology, Bogota, Colombia

Background: The increasing health and economic burdens of deaths and disabilities from non-communicable diseases (NCDs) are emerging as major concerns worldwide, particularly for low- and middle-income countries (LMICs). Rheumatoid arthritis (RA) is considered one of the most common causes of disability. RA affects from 0.5% to 1% of the worldwide population, particularly for low- and middle-income countries (LMICs). RA affects from 0.5% to 1% of the worldwide population.

Objectives: To describe the out of pocket costs in patients with rheumatoid arthritis.
confirmed every day or every second day appropriate use of the color-in puppet and spaces for parents and teachers. Experienced applicability: Identified themes were: child-friendly, easy and providing a clear guide for the daily school situation. Themes as: daily obligation, unwillingness of the child, lack of motivation or time of the parents or teachers and insufficient instruction illustrated experienced barriers for the use of the booklet. Effectiveness: Identified themes: 1) Children express themselves better about feelings of pain and fatigue, 2) Parents and teachers appreciate more insight into how the child feels and 3) Teachers feel provided with guidance in the interaction with the child 4) Children feel more secure to express itself at school and 4) Parents are more relaxed about the schoolsituation.

Likert scales showed that more than 75% of the users would advise the B&FS to other parents, teachers and therapists.

Conclusion: The Back & Forth School booklet is a feasible shared management instrument to support young children with JIA in the school situation. A less rigid daily routine and sufficient instruction can improve the experienced applicability.

AB1342-HPR RHEUMATOLOGY ‘HOT CLINIC’ IN A TEACHING HOSPITAL - WHAT CAN BE EXPECTED?

M. Chakravorty1, J. Southern1, L. H. Lee2. Royal Derby Hospital, Rheumatology, Derby, United Kingdom; 2Royal Derby Hospital, Rheumatology, Derby, United Kingdom

Background: Increased financial and bed pressures faced by the NHS have necessitated significant changes in the service provision of many inpatient medical specialties. At the Royal Derby Hospital, rheumatology has become predominant out-patient-based and no longer has an allocated ward for inpatients. As a result, weekly rheumatology ‘hot clinic’ have been set up to help facilitate early hospital discharge and specialist outpatient review of patients with suspected rheumatological conditions. It was anticipated that the bulk of referrals would be for conditions requiring early intervention such as suspected giant cell arteritis (GCA) and hot swollen joints. However, there is a paucity of literature on the usefulness of such ‘hot clinics’ and the quality of referrals.

Objectives: This study sought to evaluate the range of conditions referred to the ‘hot clinic’ and early outcomes related to follow up or discharge.

Methods: The details of patients who attended the ‘hot clinic’ were retrospectively obtained using the hospital’s electronic clinic appointments system. Electronic letters and discharge summaries were reviewed to determine the patient’s presenting symptoms, suspected diagnosis and clinical outcome.

Results: A total of 40 patients who attended the ‘hot clinic’ from September 2018 to June 2019 were included. The average time from discharge to ‘hot clinic’ was 3.8 days (range 0-22 days). 27 patients (67.5%) were seen within 7 days of hospital discharge and 2 patients were seen after 18 and 22 days respectively, which spanned over the Christmas and New Year period.

87.5% (35) of patients were referred by acute medicine via the ambulatory care ward; 10% (4) by the Emergency Department and 1 by the medical ward. 5 patients were already known to rheumatology (3 with rheumatoid arthritis and 2 with psoriatic arthritis).

37.5% of referrals were made for suspected GCA, 35% for rash and possible connective tissue disease (CTD) or vasculitis except for GCA, 20% for swollen joints, and 7.5% for unexplained arthralgia or myalgia. For the patients with suspected GCA, 3 out of 15 were treated as GCA after ‘hot clinic’ review - 2 of these went on to have a temporal artery biopsy and 1 had a positive biopsy for GCA. (All 3 received high dose steroids prior to their clinic appointment). 10 patients were felt to have an atypical headache and 3 of these were referred to neurology for further assessment. The remaining 2 patients were diagnosed with a sinus infection and migraine respectively.

Of the 14 patients referred with a rash and possible CTD or vasculitis except for GCA, 2 patients referred with a rash were diagnosed to have IgA vasculitis and referred to dermatology for further management. 2 patients were diagnosed with lupus and were followed up in the CTD clinic. 7 patients were felt to have a self-limiting post-viral or non-specific rash, 2 patients with possible drug-related rash and 1 patient thought to have erythema nodosum were treated as GCA, 2 patients with swollen joints had a new diagnosis of seronegative inflammatory arthritis and 2 others were diagnosed with gout. 1 patient was diagnosed with osteoarthritis and another with post-viral arthritis and both were discharged. The 3 patients with unexplained arthralgia or myalgia were felt to have self-limiting post-viral illnesses and were also discharged.

Conclusion: Suspected GCA is the most common referral to the rheumatology ‘hot clinic’ However, the vast majority of these referrals turned out not to be GCA. The results of this study clearly suggest the need for development of better pathways e.g. for GCA and joint dermatology and rheumatology clinics.

AB1343-HPR A QUALITATIVE REVIEW ASSESSING THEMATIC OUTCOMES FROM THE PHARMACY-LED ADALIMUMAB BIOSIMILAR SWITCH PLAN ACROSS 3 SPECIALITIES; RHEUMATOLOGY, GASTROENTEROLOGY AND DERMATOLOGY AT UNIVERSITY HOSPITALS OF COVENTRY AND WARWICKSHIRE (UHCW)

S. Gohil1. 1University Hospitals of Coventry and Warwickshire, Pharmacy, Coventry, United Kingdom

Background: The advent of biosimilars has heralded a new era for cost effective biologic prescribing in the NHS. As patents expire for originator biologics, less expensive versions are now widely available as biosimilars. Non-medical switches (for reasons unrelated to a patient’s health) ensure prescribing of best value medicines, and cost savings can be redirected to patient care. This practice resonates with recommendations from Lord Carter’s 2016 report regarding reducing unwarranted variation no longer has a cost saving opportunity.2 In 2018/19, following loss of patent exclusivity for the expensive adalimumab originator biologic, UHCW worked in accordance with national directives to drive forward one of the largest non-medical biosimilar switches.

Objectives: This qualitative review aims to explore the success of the adalimumab biosimilar switch and key themes associated with switch backs/refusals across the Rheumatology (R), Gastroenterology (G) and Dermatology (D) specialties at UHCW.
Methods: The switch plan occurred between April-December 2019. 403 patients (R;189, G;176, D; 38) were eligible for switch. Patients were informed of the plan in advance via a patient information leaflet/hospital clinic visits. Switch refusals, withheld treatments and cancellations were documented and patients were advised to contact the hospital pharmacy/clinical teams if they encountered any concerns, adverse effects or lack of efficacy post switch. The clinician would then advise on subsequent management.

Results: During April-December 2019, 264/403 patients had been successfully switched (R;122, G;109, D;33). 33/403 patients switched back to the originator biologic (R;22, G;10, D;1). Of the 22 rheumatology switch back patients; 6 patients reported injection site pain and variably headache, fatigue, disease relapse, gastrointestinal (GI) upset, erythema; 10-reported lack of efficacy and variably influenza-type symptoms, relapse in associated psoriasis, difficulty in walking/sleeping, hair loss, excessive perspiration, facial cellulitis, foot drop and GI upset; 1=blepharitis; 1=latex allergy before injection; 3=later declined switch; 1=damaged two devices and did not wish to continue biosimilar. Of the 10 gastroenterology switch back patients; 1= injection site pain; 2=lack of efficacy; 1=developed needle phobia; 1=latex allergy before injection; 1=switch detrimental to health; 2=unstable disease; 1=insomnia; 1=pregnancy. The 1 dermatology switch back patient reported injection site pain and bleeding.

38/403 patients refused the switch and remained on the originator biologic (R;11, G;27, D;0). 29/403 patients had treatment cancellations and were switched to an alternative biologic (R;17, G;9, D;3). 32/403 patients stopped treatment (R;13, G;9, D;17). 16/403 patients were switched back patient reported injection site pain and variably headache, fatigue, disease relapse, gastrointestinal (GI) upset, erythema; 10-reported lack of efficacy and variably influenza-type symptoms, relapse in associated psoriasis, difficulty in walking/sleeping, hair loss, excessive perspiration, facial cellulitis, foot drop and GI upset; 1=blepharitis; 1=latex allergy before injection; 3=later declined switch; 1=damaged two devices and did not wish to continue biosimilar. Of the 10 gastroenterology switch back patients; 1= injection site pain; 2=lack of efficacy; 1=developed needle phobia; 1=latex allergy before injection; 1=switch detrimental to health; 2=unstable disease; 1=insomnia; 1=pregnancy. The 1 dermatology switch back patient reported injection site pain and bleeding.

38/403 patients refused the switch and remained on the originator biologic (R;11, G;27, D;0). 29/403 patients had treatment cancellations and were switched to an alternative biologic (R;17, G;9, D;3). 32/403 patients stopped treatment (R;13, G;19, D;0). Treatment was withheld for 7403 patients (R;4, G;2, D;1).

Conclusion: The UHCD adalimumab biosimilar switch plan succeeded in switching a total of 66% of patients; thus an annual cost saving of $73,020. Injection site pain, most likely due to the biosimilar citrate content, and lack of efficacy according to patient perception and subsequent clinical review, were the most predominant causative themes for switch backs. Gastroenterology patients accounted for 71% (27/38) of the total switch refusals. Additional data regarding patient refusals, identifies future opportunities to improve patient counselling and drive further cost savings.

Background: Limited information is available on the impact of target disease-modifying anti-rheumatic drugs (TDMARD) on patients with rheumatoid arthritis (RA) and type 2 diabetes mellitus (T2DM). Objectives: The objective was to compare T2DM-related healthcare resource utilization (HCRU) and costs in T2DM-naïve patients between abatacept vs. patients who initiated a non-TNFi or a TNFi. Methods: A retrospective, observational study was conducted with MarketScape, Hardeep Bagga, Deputy Chief Pharmacist, UHCD Pharmacy Homecare Team, UHCD Specialist Clinical Teams.

appropriateness of peri-operative plan and post-operative complications. No data was available on these outcomes prior to the advent of the foot MDT clinic.

Results: Data from 12 clinics was analysed (n=40). Patients had a median age of 69 years (IQR 27-75 years); 65% of patients were female and 36% of patients were male. The commonest rheumatological foot disease seen was rheumatoid arthritis (67%), followed by psoriatic arthritis (15%). All patients were treated with biologic or non-biologic DMARDs. Treatment outcomes were as follows: 27.5% were offered surgical treatment; 10% were offered intra-articular (IA) injections under ultrasound guidance; 10% were offered IA injections under general anaesthesia. 95% underwent specialist rheumatology podiatry, and the remaining 5% elected for a conservative approach after careful consideration of treatment options. Of those who were offered surgical treatment, 72% of patients were provided with a peri-operative plan which accorded with British Rheumatology Society (BRS) guidelines. Of those whom underwent surgery, one patient’s surgical treatment was complicated by a post-operative infection; however, the peri-operative DMARD/biologic plan was not felt to be contributing factor.

Conclusion: The foot MDT clinic provides a comprehensive review of rheumatological foot conditions, with readily available access to a full range of treatment options. Co-location of all relevant professionals allows for real-time interdepartmental communication; shared decision making between clinicians and patients; avoids multiple appointments; reduces uncertainty with peri-operative planning as well as providing a cost-effective and efficacious service. Discrepancies in the peri-operative plan for medicines arose when the treating orthopaedic surgeon was not present in clinic. In these cases, the plan for surgical treatment was made outside of this clinic, without input from the treating rheumatologist. To improve concordance with BSR peri-operative medicine guidelines, it is recommended that all treatment decisions are made during the clinic, allowing input from all relevant partners. Informal feedback from patients commended the foot MDT, this shall be formalised through further qualitative data.

REAL-WORLD EFFECTIVENESS AND PERCEIVED USEFULNESS OF SYMPTOM CHECKERS IN RHEUMATOLOGY: INTERIM REPORT FROM THE PROSPECTIVE MULTICENTER BETTER STUDY

J. Knitz1, J. J. Mohr2, C. Bergmann3, E. Kampflyka4, M. Hagen5, D. Bohr6, E. Araujo7, M. Engelbrecht8, D. Simon9, A. Kleyer10, T. Meinderink11, W. Vörbrüggen12, C. B. von der Decken13,14, S. Kleinert15, A. Ramming16, J. Distler17, P. Bartz-Bazanella18, G. Schett19, A. Hüberl20, J. Weickert21, Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätshospital Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; Freelance Healthcare Data Scientist, Eckental, Germany; Verein zur Förderung der Rheumatologie e.V., Würselen, Germany; MVZ Stolberg, Stolberg, Germany; Klinik für Internistische Rheumatologie, Rhein-Maas Klinikum, Würselen, Germany; Rheumatologische Schwerpunktpraxis, Drs. Kleinert, Rapp, Ronneberger, Schuch u. Wendler, Rheumatologie, Erlangen, Germany; Fachklinik für Rheumatologie, Sozialstiftung Bamberg, Klinikum Bamberg, Bamberg, Germany; MVZ für Rheumatologie Dr. Martin Welcker GmbH & RheumaDatenRhePort (rhadar), Planegg, Germany

Background: Symptom checkers (SC) promise to reduce diagnostic delay, misdiagnosis and effectively guide patients through healthcare systems. They are increasingly used, however little evidence exists about their real-life effectiveness.

Objectives: The aim of this study was to evaluate the diagnostic accuracy, usage time, usability and perceived usefulness of two promising SC, ADA (www.ada.com) and Rheport (www.rheport.de). Furthermore, symptom duration and previous symptom checking.

Methods: Cross-sectional interim clinical data from the first of three recruiting centers from the prospective, real-world, multicenter BETTeR-study (DKRS DRKSS00017642) was used. Patients newly presenting to a secondary rheumatology outpatient clinic between September and December 2019 completed the ADA and Rheport SC. The time and answers were recorded and compared to the patient’s actual diagnosis. ADA provides up to 5 disease suggestions, Rheport calculates a risk score for rheumatic musculoskeletal diseases (RMDs) (≥1-RMD). For both SC the sensitivity, specificity was calculated regarding RMDs. Furthermore, patients completed a survey evaluating the SC usability using the system usability scale (SUS), perceived usefulness, previous symptom checking and symptom duration.

Results: Of the 129 consecutive patients approached, 97 agreed to participate. 38% (37/97) of the presenting patients presented with an RMD (Figure 1). Mean symptom duration was 146 weeks and a mean number of 10 physician contacts occurred previously. To evaluate current symptoms, 56% (54/96) had previously checked their symptoms on the internet using search engines, spending a mean of 6 hours. Rheport showed a sensitivity of 49% (18/37) and specificity of 58% (35/60) concerning RMDs. ADA top 1 and top 5 disease suggestions concerning RMD showed a sensitivity of 43% (16/37) and 54% (20/37) and a specificity of 58% (35/60) and 52% (31/60), respectively. ADA listed the correct diagnosis of the patients with RMDs first or within the first 5 disease suggestions in 19% (7/37) and 30% (11/37), respectively. The average perceived usefulness for checking symptoms using ADA, internet search engines and Rheport was 3.0, 3.5 and 3.1 on a visual analog scale from 1-5 (5=very useful). 61% (59/96) and 64% (61/96) would recommend using ADA and Rheport, respectively. The mean SUS score of ADA and Rheport was 72/100 and 73/100. The mean usage time for ADA and Rheport was 8 and 9 minutes, respectively.

Conclusion: This is the first prospective, real-world, multicenter study evaluating the diagnostic accuracy and other features of two currently used SC in rheumatology. These interim results suggest that diagnostic accuracy is limited, however SC are well accepted among patients and in some cases, correct diagnosis can be provided out of the pocket within few minutes, saving valuable time.

SCIENTIFIC ABSTRACTS
A local patient focus group identified the need for trustworthy information, written and in-depth interviews and 3 focus groups involving patients, rheumatologists, and individual appointments with specialist nurses, contributing to waiting times for nurse appointments and thus delays in starting treatment.

Results: Over the first five weeks of the service, 18 patients attended group education sessions when we advertise the App to new patients.

Conclusion: The study results show high acceptance rates of telemedicine regarding doctor-doctor communication. Doctor-patient communication via telemedicine is less accepted. However, MPs are reporting obstacles preventing the implementation of telemedicine in rheumatology. In order to implement telemedicine in rheumatological care comprehensively, adequate conditions must be established in the German health care system.

5.5/10 pre-education; this rose to a median of 10/10 post-education. The median anxiety score was 3/5 pre-education; this dropped to 2/5 post-education. The presentation was adapted based on questions that arose during the sessions. Most patients gave informal, verbal feedback stating that they found the group environment to be beneficial, providing a chance to meet others with similar conditions, share experiences and feel reassured that they are not alone in starting biologic therapy.

Conclusion: Patient feedback demonstrated that the group education sessions at UCLH were effective in improving their understanding of the rationale for biologic treatment, increasing their confidence in self-administration, and reducing anxiety. Verbal feedback illustrated that many patients enjoyed the group environment and the opportunity to interact and share experiences with others. At an average rate of 4 patients currently being seen a week, it is estimated that this will save 192 specialist nurse appointments per year (out of an estimated 226 commencing biologic therapy). There is scope for further research into the effects that this has had on waiting times to receive education / start treatment, and on drug compliance.

SOCIOECONOMIC BURDEN OF NON-ATTENDANCE IN RHEUMATOLOGY CONSULTATION

J. Rodrigues1, D. Faria1, J. Silva1, S. Azevedo1, F. Guimarães1, D. Almeida1, C. Afonso1, S. Alcino1, D. Peixoto1, T. Teixeira1, J. Tavares-Costa1, 1ULSAM, Rheumatology, Ponte de Lima, Portugal

Background: Outpatient non-attendance refers to the phenomenon of patients who have a medical appointment but do not show up at the specified date, time, and location without giving previous notice.1 In addition to affecting the efficiency and thereby increasing the healthcare total costs, nonattendance might also delay access to care for users on waiting lists.1 Nonattendance at health appointments is costly to services, and can risk patient health.2 There is very little data on the nonattendance prevalence and impact in Portugal. This knowledge might be fundamental to improve effectiveness of outpatient care in Portugal.

Objectives: 1) describe patient's non-attendance rate; 2) assess and characterize the sociodemographic and clinical characteristics among non-attending patients; 3) estimate the economic burden of non-attendance.

Methods: Retrospective, cross-sectional and analytical study. We reviewed a one-month Rheumatology consultation period regarding performed medical consultations and non-attended consultations without previous notification from patients. Direct economic costs of non-attended appointments were calculated based on the ‘Amending Agreement to the ULSAM, EPE Program Agreement’. Results: 962 consultations within January 2018 were included. Appointments episodes for therapeutic prescription, medical reports or programmed admissions were excluded. Fifty-seven (5.8%) of scheduled outpatient appointments were non-attended. Subsequent consultations represented 85.2% of attended appointments and 80.7% of non-attended appointments. Female gender was the most prevalent in both groups – 620 (67.0%) among attended consultations and 37 (65.0%) among non-attended consultations. Mean age was 57±15 years in the first group and 54±16 years in the second one. Among attended appointments, mean education level was 8±5 years versus 8±8 years among non-attended appointments. There were no differences between both groups in gender, age, education level, diagnosis, disease duration and activity or appointment type (first or subsequent consultation). A cost of 2,438 euros was estimated regarding non-attended appointments for this period, what could represent a burden of more than 29,000 euros yearly, in direct costs, only.

Conclusion: Non-attendance at scheduled appointments in public hospitals seems to be influenced by other factors besides gender, age and education level. The burden of non-attended appointments is undeniable. In addition to the costs estimated in this study, further indirect costs such as poorer patients outcomes, impaired access to medical care and hospital penalties should be taken into account. Implementation of awareness strategies aiming the optimization and improvement of healthcare system are required.

A HAND EXERCISES MHEALTH APP FOR PATIENTS WITH RHEUMATOID ARTHRITIS: DEVELOPMENT, DESIGN AND USABILITY STUDY IN TURKEY

E. Tonguç1, C. Srikesan2, E. Williamson2, S. Lamb3, 1Marmara University, Faculty of Health Sciences, Department of Physiotherapy, Istanbul, Turkey; 2University of Oxford, Nuffield Department of Rheumatology, Orthopaedics and Musculoskeletal Sciences, Botnar Research Center, Oxford, United Kingdom

Background: The Strengthening and Stretching for Rheumatoid Arthritis of the Hand (SARAH) programme has been shown to provide long term improvement in hand function for patients with rheumatoid arthritis (RA) affecting their hands. In Turkey, limited number of physiotherapists work in rheumatology departments so there is an opportunity to use the digital technologies for exercise prescription and follow up to improve access to treatment. Growing research evidence supports the effectiveness of mHealth interventions for improving exercise adherence and motivation. To our knowledge, there is no hand exercises mHealth program for patients with rheumatoid arthritis designed by experts with the user-centered method.

Objectives: The aim of our study is to develop and design a smartphone application for structured hand exercise program for patients with RA in Turkey and to test its usability.

Methods: We used a qualitative user-centered design approach with 2 phases. PHASE 1: we conducted focus group meetings to discuss the content, feature and design of app to produce a prototype version of smartphone software for RA hand training program. The Focus Group consisted of two physiotherapists and three hand therapists working in the field in different rheumatology or hand rehabilitation clinics, two software-computer engineers, and three patients with RA who had previously participated in hand therapy. The focus group met 4 times during phase 1. PHASE 2: we investigated the usability of prototype version of the rheumatoid hand exercise smartphone app. All focus group members (n=10) and 6 patients used the app for one week. All users filled the usability questionnaire and provided written feedback on the app. Revisions were made and the revised version was tested. We put the revised app in digital markets in Turkish and English.

Results: The major themes identified from the Focus Group discussions during phase 1 were (a) login techniques (b) self-monitoring (c) exercises types / frequencies / duration, (d) patient education, (e) behavioral change and encouragement to exercise adherence. Patients and therapist all agreed the login needed to be easy. Patients wanted to be able to monitor their pain levels and hand function in the app. Patients thought the SARAH exercise were suitable for the app. A patient said: ‘SARAH exercises is beneficial for my hand and tendon gliding exercise, I will be happy to see these exercises in app’. Patients wanted exercise reminders using push up notifications to encourage exercise were proposed and included. A patient commented ‘in the morning and after work, motivational push up messages could be beneficial for exercise habit’. During the phase 2, we identified a need for education on how to use digital app, ways to provide patient follow up to monitor adherence, the need to allow patients to select the amount of notifications. This feedback was incorporated into the final version.

Conclusion: mHealth applications represent an easily accessible bridge between patients and health professionals for home-based programs. Using a user-centered approach ensured that we developed an application that met the needs of therapists and patients. Physiotherapists are using the app in rheumatology clinics in Turkey and long-term usability and feasibility studies are ongoing.

AB1352-HPR SHARED CARE – AN ALTERNATIVE WAY TO COPE WITH INCREASING SERVICE DEMAND

C. Yin Huang1, N. Woon Leung2, L. Man Chi2, L. Chi Kwai2, C. Ching Man2, S. P. Kong2, L. Pik Fan2, C. L. Leung2. 1United Christian Hospital, Medicine and Geriatric, Hong Kong, Hong Kong (SAR); 2United Christian Hospital, Medicine and Geriatric, Hong Kong, Hong Kong (SAR)

Background: Rheumatic diseases are immune-mediated disorders that affect the musculoskeletal system, soft tissues, blood vessels and connective tissue. Patients with rheumatic diseases need regular follow up for disease and drug toxicity monitoring. To cope with the increasing service demand, the Division of Rheumatology in the United Christian Hospital developed and expanded the shared care service. In the conventional practice, patients have been seen by rheumatologist for every visit while the shared care service involved follow up by rheumatologist and rheumatology nurse in alternate sessions.

Objectives:
1. To evaluate the effectiveness and safety of the shared cared service
2. To evaluate the effectiveness of reduction in workload of rheumatology clinic

Methods: This is a retrospective study involving the period from 1/1/2019 to 31/12/2019. Patients who attended the rheumatology nurse clinic for shared care were recruited and reviewed. All patients were selected and referred by rheumatologists. Criteria for shared care included regular follow up in rheumatology clinic and stable clinical condition. The length of follow up is adjusted according to patient condition. Services provided by rheumatology nurse (RhN) included disease education, drug and disease monitoring, drug advice and referral to other professionals and community service as indicated. During each visit, patient's vital signs, disease activity and laboratory results were assessed according to standard protocol. RhN will make discharge record to ensure continuity of care.

Results: Totally 488 episodes of attendance to nurse led clinic were recruited. Majority (97.3%) were arthritis patients. Others included lupus, vasculitis, Sjogren's syndrome and miscellaneous conditions. The length of follow up ranged from 3 weeks to 24 weeks and most of the patients were follow up between 8 to 16 weeks. Shared care patients included those with stable disease for interval monitoring, and patients for drug initiation and titration. The ratio for disease monitoring and drug monitoring are 41.3% and 58.7% respectively. For the 488 episodes of attendance, 10 (2%) episodes needed rheumatologist interventions and 8 (1.6%) cases need advancement of follow up. Problems that required doctor interventions and advance follow up mainly are suboptimal disease control, requiring medication adjustment or musculoskeletal ultrasound investigation.

178 (36.4%) episodes of nursing intervention were delivered, majority were medication advice (133, 27.2%). Reasons for nursing intervention included adverse drug reaction, abnormal investigation results, poor drug adherence and disease flare up. There were no emergency department attendance or admission related to the above problems within one month of RhN follow up.

Conclusion: The shared care service is smooth and can safely lengthen the follow-up intervals to reduce clinic visit burden in rheumatology clinic. RhN input also allowed prompt advice for steroid tapering and dose titration for disease specific medication for better disease control. Proper case selection and close collaboration between rheumatologist and rheumatology nurse is the key.

HPR Professional education, training and competencies

AB1353-HPR EMPOWERING LEARNERS TO “OWN” THEIR PERFORMANCE: PRESENTING EDUCATIONAL PERFORMANCE DATA BACK TO LEARNERS AS A COMPONENT OF AND RATIONALE FOR SUBSEQUENT EDUCATION

E. Johnson1, L. Eldasher2, D. Clausen3. 1RMEI Medical Education, Outcomes & Analytics, Voorhees Township, United States of America; 2RMEI Medical Education, Medical Strategy, Voorhees, United States of America; 3RMEI Medical Education, Educational Strategy, Voorhees, United States of America

Background: Beginning in 2016, RMEI created multiple accredited online education focused on RA and designed for rheumatologists. In 2018, the educational scope expanded to include live meetings, starting with a symposium at EULAR. For all programming from 2016-18 (6 courses, in both live and online settings), educational content was developed based on performance data from the previous RMEI symposia. During the 2019 EULAR symposium, we presented the outcomes findings - from both the 2018 symposium and online courses – to the assembled rheumatologists, identifying ongoing educational gaps observed in their specialty population. The rationale: to create continuity between symposia over time by demonstrating incremental improvements and continuing areas of need, while also encouraging learners with a greater sense of ownership in their improvement in forthcoming educational content.

Objectives: To evaluate the impact of presenting learner’s educational performance data to them before education addressing persistent gaps identified in their performance the year prior.

Methods: Data collected during the 2018 EULAR symposium was analyzed to understand the underlying drivers impacting poor performance in an identified area of ongoing educational need (cycling versus switching TNF inhibitors). A linear regression model was run including all non-related curriculum, demographic, and evaluation questions as possible drivers against those related low-scoring (at Post-Test) curriculum questions. The content of RMEI’s 2019 symposium at EULAR was developed to address the identified significant drivers to improve population proficiency in cycling versus switching. In addition to developing content based on the above findings, that data was also presented to learners in poster format prior to their participation in the 2019 symposium. During the period between on-site registration and the start of the symposium, attendees had the opportunity to explore data-driven insights, via audio-guided posters located around the meeting room. These insights included discussion of 2018 data analysis, identified drivers of poor performance, introduced the iterative data-driven methodology employed, and rationale behind content development for the 2019 symposium. At the conclusion of the 2019 symposium learners were asked to describe the impact/relevance of being presented with their performance data, their intention of incorporating course content into practice, and what specifically they intended to change.

Results: Data was collected on 135 clinicians (primarily physicians who actively treat patients with rheumatoid arthritis) who attended, and participated in, the symposium. With specific regard to the impact of seeing their own data presented back to them, 80% reported that seeing the learner data from the 2018 symposium enhanced their current learning experience. Further, 86% reported that they intended to incorporate course content into their clinical practice. Specifically, this population reported an intent to change their treatment approach and patient education practices.

Conclusion: Education is only as effective as the degree to which the audience is engaged. While year over year data from 2016 through 2018 demonstrated that an iterative approach facilitated the meaningful and necessary reinforcement of learning concepts, learners in prior years were not aware of the methodological underpinnings of the educational offerings. Presenting this population with findings derived from their performance - as a rationale for the education they were about to participate in proved a compelling motivator for active learner engagement, and may have had a positive influence on the degree to which learners implemented course content into their clinical practice.

AB1354-HPR CURRENT SITUATION OF TRAINING IN RHEUMATOLOGY IN THE POSTGRADUATE CURRICULUMS OF INTERNAL MEDICINE, FAMILY MEDICINE, GERIATRICS, PAIN MEDICINE AND, PHYSICAL AND REHABILITATION MEDICINE ACROSS COLOMBIA

D. G. Fernández-Añúl1, L. Patino1, J. Gutiérrez1. 1Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Bogotá, Colombia; 2Pontificia Universidad Javeriana – Hospital Universitario San Ignacio, Bogotá, Colombia

Background: Rheumatic diseases are an important complaint in patients, although the incidence is low, they cause disability as a major impact on the health system. Currently, in Colombia, there are 198 rheumatologist, so it’s important to know how is rheumatology training in specialties related to rheumatology, which are the specialties that the patient with a suspected rheumatic disease will visit at first.

Objectives: To describe the training status in rheumatology in the postgraduate curriculums of internal medicine, family medicine, geriatrics, pain medicine and, physical and rehabilitation medicine across Colombia.

Methods: This is a descriptive cross-sectional study. A survey was applied in each participating medical school using the RedCap® platform. The questionnaire included multiple-choice responses and a textbox to complete. The survey was done to the 29 registered medical schools which offer the specializations...
matched 80% of them. The average time of baseline exploration was 45.2 ±3.8 minutes and the final time was 32.6 ± 3.5, improving the 5 students in an average of 12.6± 4.4 minutes. The technical aspects not performed correctly in the ultrasound examination in patients with rheumatoid arthritis.

AB1356-HPR GOUT IN SPANISH PRIMARY HEALTHCARE CENTERS: STILL A LONG WAY TO GO

M. A. Pou1, S. Serrá1, A. Prada-Ojeda1, S. Ferrer1, A. García-Guillem1, H. Corominas2, C. Díaz Torne2, EAP Encants, Barcelona, Spain; 2Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 3Hospital de Torejón, Madrid, Spain

Background: Gout has a prevalence >2.5% in the Spanish adult population. It is a chronic disease that without proper treatment causes pain, joint deformity and increased cardiovascular risk and mortality. Recent advances have demonstrated that if correctly treated the disease can be controlled and even cured. Most gouty patients are diagnosed and treated by general practitioners (GPs). There is evidence that the management if these patients is not good neither at Rheumatology Units nor at Primary Healthcare (PHC) centers. Several causes of this mismanagement can be found in the literature.

Objectives: Design and evaluation of the results of a questionnaire created from a bibliographic search focused on areas of improvement of gout management in PHC.

Methods: A search was made in Pubmed to identify the main barriers described in the management of patients with gout in primary care. The terms used were: “Gout”, “primary healthcare” and “education”. A Google Form of gout knowledge and management questionnaire was designed, taking into account what is described in the literature. The Google Form was sent to all GP from an urban area via mail and to other contacts via WhatsApp and twitter.

Results: Responses were obtained from 224 GPs; 69.5% were women; 73.1% had between 11 and 30 years of professional experience; 96.4% answered that the gouty are mostly controlled in primary care; 99.6% performs the diagnosis of gout without analysis of synovial fluid and 17% diagnosed only by clinics without urate levels; 55.9% of GPs do not use any reference guide. Of those who use, the 73% use GUIPCLINGOT and 40% use SEMGs one; 80.5% have not done any gout course in the last 5 years; 26% did not have access to a rheumatologist to control the gout diagnosis; only 30.8% knew the therapeutic objective of the urate lowering therapy (ULT); 62% considered the beginning of ULT after the first attack; only 30.8% knew the therapeutic objective of the urate lowering therapy (ULT); 62% considered the beginning of ULT after the first attack; only 30.8% knew the therapeutic objective of the urate lowering therapy.

Conclusion: The questionnaire identifies multiple points of improvement for the management of this pathology in accordance with the described in the literature. Most GPs are unaware of the therapeutic objective of the ULT.

AB1357-HPR DESIGNING THE ROYAL COLLEGE OF NURSING COMPETENCY FRAMEWORK FOR RHEUMATOLOGY NURSES

P. Livermore1, D. Finney1, J. Begum1, R. Wylle1, T. Cornell1, H. Smith1, L. Howie1, L. Parker1 on behalf of Royal College of Nursing Rheumatology Nurse Forum Competency working party. 1Royal College of Nursing, London, United Kingdom

Background: The 1st Edition of the RCN Competency Framework for Rheumatology Nurse Specialists (RNS) will be published in March 2020. The role of the RNS is complex, and can include caring for children and young people. The importance of the RNS’s was highlighted by the National Rheumatoid Arthritis Society (NRAS 2017). The British Society for Rheumatology (BSR) outlined the need for education, training supervision and work force development. Education for RNS isn’t currently centralized but is key to improving skills and developing workforce for the future. RNS are in short supply resulting in problems of access to services and delays in care (BSR 2019). In all 4 UK nations the titles of RNS and proficiency vary greatly (Titrate trial 2019) This is likely to have an impact on patient experience and outcomes. The European League Against Rheumatism (EULAR) developed...
recommendations for the role of the RNS which were recently updated (Beech et al., 2019). This framework maps all of these requirements.

Objectives: This work supports the development of roles, improve access for patients and reduce. This will strengthen rheumatology nursing and support all UK nation’s issues regarding recruitment, retention, sustainability, succession planning and benchmarking. Dissemination is key and we will work hard with stakeholders to ensure centralization of a nationally adopted framework. This abstract submission will increase dissemination opportunities.

Methods: Online data sources were searched for the most relevant and current evidence. Where research evidence wasn’t available, existing and new knowledge was utilised from a consensus of clinical expert and patient opinions, several rounds of discussions took place virtually and face to face. RCM Rheumatology Nurse Forum Workshop attendees in June 2019 also answered a questionnaire to elicit views and demographic information regarding roles.

Results: The questionnaire results demonstrated 100% (n37) agreement with the development of the framework and that only 2 respondents had completed a competency process. 60% were RNS. Of these 52% (n13) were band 6, 47% (n9) were band 7, and 1% were band 8 consultant nurses. The questionnaire highlighted the need to develop the framework. Results were fed back to the working party to inform the domains to be included.

Conclusion: Document will be at BSR 2020 having successfully submitted a session proposal and abstract. Evaluation will begin later in the year 6 to 12 months from launch. We will measure impact using a variety of methods including membership Facebook pages and the questionnaire at point of download request. We will measure where and how the competency is being used and adoption of the framework throughout the UK.

DIAGNOSIS OF AXIAL SPONDYLOARTHITIS: A PRIMARY UNMET EDUCATIONAL NEED FOR RHEUMATOLOGISTS

W. P. Maksymowych 1, L. Caplan2, A. Deodhar3, S. Dolatabadi4, M. Hwang5, A. Carlson6, K. Steed7, A. Carapellec8, J. Paschke9, L. S. Genelser10, University of Alberta, Edmonton, Canada; 2CARE Arthritis, Edmonton, Canada; 3Rocky Mountain Regional VAMC, Aurora, United States of America; 4Oregon Health & Science University, Portland, United States of America; 5Harbor-UCLA Medical Center, Torrance, United States of America; 6McGovern Medical School at UTHouston, Houston, United States of America; 7University of Virginia, Charlottesville, University of States of America; 8James J Peters VA Medical Center, New York, United States of America; 9University of California, San Francisco, San Francisco, United States of America

Background: Diagnosis of axial spondyloarthritis (axSpA) is challenging because of absent physical findings in early disease and the limited diagnostic performance of laboratory markers. Considerable reliance is placed on imaging of the sacroiliac joints (SIJ) but specialty training is mainly focused on interpretation of plain radiographic abnormalities.

Objectives: We aimed to identify what might be the primary unmet educational needs of rheumatologists completing fellowship training by using clinical and imaging data from an inception cohort of patients presenting with undiagnosed back pain. We hypothesized that concordance would increase after imaging is reviewed after the clinical data.

Methods: The diagnosis of axSpA was compared between local rheumatologists, axSpA experts and pF using clinical and imaging data from the multicenter Screening for Axial Spondyloarthritis in Psoriasis, Irritis, and Colitis (SASPIC) Study. In this inception cohort, patients ≥18 years of age with ≥3 months back pain undergo diagnostic evaluation by a local SASPIC rheumatologist, including imaging of the SIJ, who then records a global evaluation of presence/absence of axial SpA. This is done at 3 consecutive stages: 1.After the clinical evaluation. 2.After the results of labs (HLA B27, CRP) and radiography. 3.After review of the local MRI. In this exercise, 20 cases were selected from the SASPIC cohort and the rheumatologist global evaluations were removed from the eCRFs. Four experts in axSpA reviewed the clinical and imaging data in each eCRF and provided their global evaluations for stages 1, 2, and 3 of these 20 cases. Subsequently, 4 pF rheumatologists conducted the same exercise blinded to the assessments of the local rheumatologist and experts in axSpA. Concordance (% agreement) between the assessors was analyzed.

Results: Diagnosis of axSpA by the local SASPIC rheumatologist was made in 90%, 65%, and 75% of cases after stages 1, 2, and 3, respectively. Majority diagnosis of axSpA by experts was made in 84.2% (16/19), 57.9% (11/19), and 63.2% (12/19), after stages 1, 2, and 3, respectively. Majority diagnosis of axSpA by pF rheumatologists was made in 94.4% (17/18), 100% (16/16), and 93.8% (15/16). Concordance among experts and between experts and local SASPIC rheumatologists increased after review of imaging data. For pF-rheumatologists concordance with experts increased after review of imaging for 2 assessors and decreased for the other 2 assessors. For the latter, the primary reason for decrease in concordance with experts was false positive diagnosis of axSpA in 35% and 30% of the cases after review of the imaging.

Conclusion: A structured case-based and sequential evaluation of clinical and imaging data suggests a gap in the training of recently graduated rheumatologists, with over-interpretation of imaging leading to false positive diagnosis of axSpA.

Assessors

| Mean % Concordance (range) for diagnosis of axSpA |
|------------------|------------------|------------------|
| Experts in axSpA | Local rheumatologist vs Experts in axSpA | pF-rheumatologist 1 vs Experts consensus |

AB1359-HPR

PERCEPTION ABOUT FIBROMYALGIA AND ITS ACCOMPANYING SYMPTOMS AMONG MEXICAN PHYSICIANS

R. I. Arvizu-Rivera 1, N. Escobedo-Zuñiga, 1 J. I. Colunga-Pedraza, G. Serna-Peña, A. Cárdenas 2, Hospital Universitario “Dr. Jose Eleuterio Gonzalez”, Internal Medicine Department, Monterrey, Mexico; 3Hospital Universitario “Dr. Jose Eleuterio Gonzalez”, Rheumatology Division, Monterrey, Mexico

Background: Previous studies showed that 93% of rheumatologists consider fibromyalgia (FM) as a clinical entity. However, accompanying symptoms such as fatigue, widespread pain, sleep disturbance and headache are underrecognized among physicians. According to a previous study, most recognized symptoms by general practitioners are fatigue and widespread pain (72.6%), while about thirty percent of physicians recognize sleep disturbance and depression as symptoms.

Objectives: To investigate physicians’ point of view of FM accompanying symptoms in northeastern Mexico.

Methods: We designed an electronic survey about physicians’ perceived importance of depression, fatigue, widespread pain, sleep disturbances, headache and irritable bowel disease symptoms (pain and cramping) in patients with FM. Questions were answered using a 5-point Likert scale: 1, strongly disagree; 2, disagree; 3, neutral; 4, agree; 5, strongly agree. General practitioners, rheumatologists, neurologists, psychiatrists were included.

Results: A total of 236 physicians were included: general practitioners, 149 (59.3%); rheumatologists, 21 (8.9%); neurologists 18 (7.6%); psychiatrists 8
(3.4%), and family physicians, 49 (20.8%). FM was considered a clinical diagnosis by 208 (88.1%) and most physicians think FM is both a physical and psychological condition, 190 (80.5%). Full results on physicians’ perceptions is shown in Table 1. Fatigue was the symptom which most physicians agreed or strongly agreed was important in FM, 219 (92.7%). Disagreement (any degree) was greater regarding abdominal pain/cramping being an important symptom in FM, 52 (22%). Complete results can be seen in Image 1.

Table 1. Perceptions of physicians about FM.

<table>
<thead>
<tr>
<th>Variable</th>
<th>FM is a clinical diagnostic, n (%)</th>
<th>FM is a physical illness, n (%)</th>
<th>FM is a psychological illness, n (%)</th>
<th>FM is both physical and psychological, n (%)</th>
<th>FM has a negative impact on quality of life, n (%)</th>
<th>FM has a negative impact on life expectancy, n (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>208 (88.1)</td>
<td>12 (5)</td>
<td>11 (4.7)</td>
<td>190 (80.5)</td>
<td>227 (96.2)</td>
<td>135 (57.2)</td>
</tr>
</tbody>
</table>

Conclusion: FM was considered a clinical diagnostic and an illness both physical and psychological by most physicians. Headache and abdominal pain/cramping are symptoms less likely to be perceived as important in patients with FM.

A MODEL TO IMPROVE MINORITY PATIENT RECRUITMENT IN LUPUS CLINICAL TRIALS - THE AMERICAN COLLEGE OF RHEUMATOLOGY MIMICT PROJECT EXPERIENCE

S. Sheikh1, N. Wenty2, S. McCalla3, A. Santana4, S. Saxena Beem1, J. Walker1, D. Holt5, A. Howell6, K. Holtz7, S. Williams2, A. Anandarajah8, 1University of North Carolina, Chapel Hill, United States of America; 2KOH Research & Communication, Atlanta, United States of America; 3American College of Rheumatology, Atlanta, United States of America; 4University of Rochester, Rochester, United States of America.

Background: In the US, African Americans and Latinos are underrepresented in lupus clinical trials (LCTs),1 despite experiencing the greatest lupus disease burden.2,3 Low participation in LCTs results in inadequate data on treatment effectiveness for minority patients, and fewer opportunities for better care and treatment options.1 Only one percent of minority patients are referred to clinical trials each year.1 Provider barriers to making referrals include limited time and unfamiliarity with lupus and LCT opportunities.4 Using US federal grant funds, the American College of Rheumatology (ACR) developed MIMICT, a two-part model with customized materials to address provider-side LCT referral barriers. The materials include a toolkit for clinical trial sites and an educational toolkit for providers.

Objectives: Our objectives are to:

• Describe the US LCTs disparities.
• Discuss the research methodology to evaluate the two-part MIMICT model.

• Assess the feasibility of the model to increase minority involvement in clinical trials.

Methods: We designed two studies to evaluate the MIMICT model. The first study used an online, pretest/posttest, two-group evaluation approach to assess the extent to which the educational toolkit increased providers’ knowledge, attitudes, self-efficacy, and behavioral intentions to refer minority patients to clinical trials. We conducted the study in 2018 with primary care providers (PCPs) and again in 2019/2020 with specialty providers. The second study used a longitudinal, mixed methods, case-study approach to explore the real-world use of the toolkits with clinical trial site teams at two university medical centers.

Results: In the first study, among MIMICT-exposed PCPs, mean scores indicated statistical significance at p<0.001 with more knowledge about referring [55.84 (sd=32.51) vs 41.76 (sd=19.98), more self-efficacy to refer [55.00 (sd=37.22) vs 37.99 (sd=34.42)], and more intentions to refer [6136.43 (sd=33.41) vs 41.16 (8 American African patients to LCTs among the treatment group than the control group, respectively. This presentation will discuss additional data comparing the study in 2018 and the study in 2019/2020 and look comparatively at outcomes across provider type.

In the second study, we found that the drivers for successful engagements of providers and their subsequent use of the educational toolkit was the development of a trusting relationship between the clinical trial site teams and providers in the community. The development of trust took repeated and varied modes of contact, which we will discuss in-depth.

Conclusion: The MIMICT educational toolkit increase knowledge, self-efficacy, and intentions to refer lupus patients to LCTs. However, building trust between LCT sites and local providers takes time and repeated outreach, but the potential benefits to medicine and minority health are substantial.

PRIMARY CARE PHARMACOLOGICAL TREATMENT FOR PATIENTS WITH HAND ARTHRALGIA

M. M. Castañeda-Martínez1, G. Figueroa-Parrá2, D. Vega-Morales3, J. M. Calderón Espinosa4, B. R. Vázquez Fuentes5, J. A. Esquivel Valerio5, Y. G. Orozco Azaña6, D. A. Galarza-Delgado7, 1University Hospital “Dr. José Eleuterio González”; Rheumatology Service, Monterrey, Mexico; 2University Hospital “Dr. José Eleuterio González”; Family Medicine Service, Monterrey, Mexico.

Background: Primary care physicians (PCP) are the first point of contact for patients with a new-onset inflammatory rheumatic disease, like rheumatoid arthritis (RA). Consequently, primary care is crucial to the early diagnosis and prompt treatment of such individuals. The first three months following the onset of RA symptoms represent an important therapeutic window. Historically, patients with inflammatory arthritis received first-line treatment with non-steroidal anti-inflammatory drugs (NSAIDs), moving to synthetic disease-modifying anti-rheumatic drugs (DMARDs) relatively late in the disease process. As synthetic DMARDs are usually initiated in relatively late in the disease process. As synthetic DMARDs are initiated in relatively late in the disease process, they represent an important therapeutic window. Historically, patients with inflammatory arthritis received first-line treatment with non-steroidal anti-inflammatory drugs (NSAIDs), moving to synthetic disease-modifying anti-rheumatic drugs (DMARDs) relatively late in the disease process. As synthetic DMARDs are usually initiated in relatively late in the disease process. As synthetic DMARDs are usually initiated in relatively late in the disease process. As synthetic DMARDs are usually initiated in relatively late in the disease process.

Objectives: To examine the primary care physicians’ pharmacological treatment prescribed for hand arthralgia in a Family Medicine Consultation.

Methods: In a period of a year and two months, eligible patients were recruited on their first or second visit to the Family Medicine Consultation of the Hospital Universitario “Dr. José Eleuterio González” in Monterrey, Nuevo León, Mexico. Eligible patients were adults (aged≥18 years) with hand arthralgia as their chief complaint, who had not rheumatologic diagnosis and wasn’t caused by trauma. Ninety patients were recruited, data were collected by capturing the prescription made by PCP.

RESULTS: Fifty-one patients were classified as having RA, 31 patients as having osteoarthritis (OA), 6 patients as having local infections (LIF) and 3 patients as having other conditions. A total of 55 patients were prescribed for hand arthralgia in a Family Medicine Consultation. There is no evidence of which is the pharmacological treatment more commonly used for hand arthralgia in Family Medicine patients of a university hospital on their first or second visit.

Objective: To examine the primary care physicians’ pharmacological treatment prescribed for hand arthralgia in a Family Medicine Consultation.

Methods: In a period of a year and two months, eligible patients were recruited on their first or second visit to the Family Medicine Consultation of the Hospital Universitario “Dr. José Eleuterio González” in Monterrey, Nuevo León, Mexico. Eligible patients were adults (aged≥18 years) with hand arthralgia as their chief complaint, who had not rheumatologic diagnosis and wasn’t caused by trauma. Ninety patients were recruited, data were collected by capturing the prescription made by PCP.
Results: In this cohort of 90 patients, 71 (78.9%) were women. Of the 90 patients, 19 (21.1%) had no pharmacological prescription at all. Forty-nine patients (54.4%) had one prescribed drug, 17 (18.9%) had two drugs and 5 (5.6%) had three drugs. Prescribed drugs and their frequencies are reported in Table 1.

Conclusion: The most common group of drugs used for hand arthritia in this cohort of patients was NSAID, and the most used of this group was celecoxib. Only in one patient, PCP prescribed disease-modifying anti-rheumatic drugs (DMARD) therapy, in this case was methotrexate. Almost 80% of the patients were prescribed with at least one drug without knowing the final diagnosis.

AB1362-HPR
COMMON PRACTICE IN DELIVERY OF INTRA-ARTICULAR THERAPIES IN RMDS BY HEALTH PROFESSIONALS: RESULTS FROM A EUROPEAN SURVEY

Background: Intra-articular therapies (IAT) are routinely used in rheumatic and musculoskeletal diseases (RMDS); however large variability exists regarding current practice of delivery amongst health professionals.

Objectives: To inquire about common practice aspects to inform the EULAR Taskforce on the IAT of rheumatopathies.

Methods: A steering committee prepared a 160-item questionnaire based on the information needs of the Taskforce. The survey was disseminated via EULAR professional associations and social media and it was open to all health professional treating persons with RMDS, regardless of using IAT personally.

Results: The survey was answered by 186 health professionals from 26 countries, the large majority of whom (77%) were rheumatologists, followed by nurses (12%), general practitioners (2%) and orthopaedic surgeons (2%). The two collectives that perform IAT routinely are rheumatologists (97%) and orthopaedic surgeons (80%), with other professionals <50%. Specific training was compulsory for 32%. The most frequent indication for IAT is inflammatory arthritis (76%), followed by osteoarthritis (74%), crystal arthritis (71%) and bursitis (70%); and all joints are injected, with knee (78%) and shoulder (70%) being the most frequent. When questioned about specific contexts, such as pre-surgical, diabetic or hypertensive patients, variability among respondents was evident, with around 30 to 60% of professionals considering it acceptable to inject glucocorticoids (GC), while in others there was less variability, prosthetic or septic joints, <1%. GCs are the most used compounds, followed by hyaluronic acid and saline/dry puncture. Only 66% (36%) use ultrasound to guide IAT. In their opinion, to be accurately in the joint is moderately to largely important for large joints (80%) and very important in small joints. The maximum number of injections to perform safely in the same joint within one year was “2 to 3” for 65% (2% thought there is “No limit”). The majority reported that they informed patients about side-effects (73%), benefits (72%), and the nature of the procedure (72%), and less frequently about other aspects; with 10% obtaining written consent and 56% oral consent (mandatory only for 32%). Other questions help to understand the setting and procedures followed, including use of local anaesthetics and care after injection.

Conclusion: Although often performed in clinical practice for RMDS, there is apparent variability in several elements related to delivery of this treatment. This information, together with patient input, will help design current recommendations where research evidence is not available.

AB1363-HPR
EVALUATION OF SELECTION CRITERIA OF CLINICIANS IN THE TREATMENT OF OSTEOPOROSIS, OSTREQ RESEARCH IN TURKEY

E. G. Kahraman1*, S. Akar1, B. Ö. Pamuk1, Izmir Katip Celebî Üniversitesi Ataârık Eğitim ve Araştırma Hastanesi, İzmir, Turkey

Background: Osteoporosis is a disease with increasing prevalence in the aging populations. It is insidious in its progression and lack of findings without fracture cause certain difficulties in the diagnosis and treatment of this disease. There are many medical and paramedical treatment options for osteoporosis, and clinicians make these treatment decisions with many factors in mind.

Objectives: We wanted to evaluate the importance of these factors for clinicians through a questionnaire. This 17-question questionnaire aimed to investigate the factors that clinicians consider in the planning of osteoporosis treatment and the effect of these factors on treatment planning. We made the Turkish version of the OSTREQ questionnaire in this study which factors clinicians in planning treatment for osteoporosis in Turkey we aimed to investigate that take into consideration.

Methods: OSTREQ questionnaire developed by Makraz et al. are used in this research. In this survey, which consists of 8 sections (health care system, patients’ preferences regarding regimen’s administration, usage, cost, severity of disease, treatment efficacy, safety profile and pharmaceutical industry) and 17 questions, the participants were asked to evaluate their answers with 5 different scales: Absolutely Preventive, Partially Preventive, Neither Preventive or Encouraging, Partially Encouraging, Absolutely Encouraging. Clinicians of Rheumatology, Physical Therapy and Rehabilitation, Endocrinology and Metabolic Diseases participated in our study. The questionnaires were filled by e-mail or by inviting the participants to the our university or by going to the clinics where the clinicians were working.

Results: In our study 37 (21.8%) were endocrinology, 49 (28.8%) were rheumatology and 84 (49.4%) were physical therapy and rehabilitation specialists. The overall Cronbach alpha coefficient of the questionnaire was found to be 0.855. No material was found to significantly increase the internal reliability coefficient if deleted. As a result of the analysis of the scores of the lower and upper groups to measure the discriminative power of the items, it was seen that all items made a significant difference in the lower and upper groups, which were formed according to the total score of 27 people. Confirmatory factor analysis and internal reliability results did not require removal of
the substance, so the substance was not removed. When the responses of the special-
isticians participating in our study to the osteoporosis preference criteria questionnaire were examined according to their specialty, no statistically significant difference was found between specialties but only significant difference was found in health system and cost subscale according to branches (p = 0.013). Post-
hoc test (LSD) was used to find out the group that made a significant difference in health system and cost sub-factor. higher scores (p = 0.034).

Conclusion: We developed and validated a general osteoporosis treatment ques-
tionnaire that could provide assessment of the criteria that physicians take into consideration when they decide to implement a regimen for osteoporosis. This tool could assist health care systems and pharmaceutical companies understand which parameters drive physicians’ choices regarding the treatment of osteoporosis.

AB1364-HPR IS ADHERENCE TO TREATMENT RELATED TO THE EFFECTIVENESS OF ANTI-TNFs IN PATIENTS WITH RHEUMATOID ARTHRITIS? - ANALYSIS OF A REAL-WORLD COHORT

P. Osorio1, L. Villareal1, M. Cabrera2, O. Valencia2, P. Santos-Moreno3.
1Biomab - Center for Rheumatoid Arthritis, Psychology, Bogota, Colombia; 2Biomab - Center for Rheumatoid Arthritis, Data Administration, Bogota, Colombia; 3Biomab - Center for Rheumatoid Arthritis, Bogotá, Colombia

Background: Several medicines are prescribed for chronic disease manage-
ment of rheumatoid arthritis (RA) including biologics; however, adherence to
long-term therapy remains poor because many causes; the latter results in wors-
ering clinical results.

Objectives: To analyze the relationship between adherence to treatment and the
achievement of remission or low disease activity in patients with RA treated with
three anti-TNF molecules of subcutaneous use.

Methods: In patients treated with 3 subcutaneous anti-TNFs, with at least one
year of follow-up previously, adherence was measured with Compliance Ques-
tionnaire for Rheumatology (CQR19) applied by psychologist; the CQR19 is a 19
item, self-administered questionnaire that was developed with the aim of correctly
identify rheumatology patients that were classified as “low adherers (taking <80% of
their medication correctly) and defining as high adhesion a result greater than
80%); adherence also was measured with medication possession rate (MPR) and
attendance to scheduled consultations with the interdisciplinary team in each period
measured. The effectiveness by DAS28, HAQ and the other measurements were
made in three periods: at baseline (BL), 6 months (M6) and 12 months (M12). A
Pearson correlation was made between the number of patients in remission and low
disease activity by type of molecule and period, with adherence criteria.

Results: 112 patients diagnosed with RA were included. 34.8% (39/112) treated
with adalimumab, 38.4% (43/112) etanercept and 26.8% (30/112) golimumab; The
results of CQR19 at BL, M6 and M12 were greater than 80%, with no statistically
significant differences between the three molecules. The MPR was higher than
80% in the three periods, being very similar between the three molecules, but
in M12 period the difference in MPR between adalimumab 86% and golimumab
80%; adherence also was measured with Compliance Questionnaire for Rheumatology (CQR19) applied by psychologist; the CQR19 is a 19
item, self-administered questionnaire that was developed with the aim of correctly
identify rheumatology patients that were classified as “low adherers (taking <80% of
their medication correctly) and defining as high adhesion a result greater than
80%); adherence also was measured with medication possession rate (MPR) and
attendance to scheduled consultations with the interdisciplinary team in each period
measured. The effectiveness by DAS28, HAQ and the other measurements were
made in three periods: at baseline (BL), 6 months (M6) and 12 months (M12). A
Pearson correlation was made between the number of patients in remission and low
disease activity by type of molecule and period, with adherence criteria.

Results: 112 patients diagnosed with RA were included. 34.8% (39/112) treated
with adalimumab, 38.4% (43/112) etanercept and 26.8% (30/112) golimumab; The
results of CQR19 at BL, M6 and M12 were greater than 80%, with no statistically
significant differences between the three molecules. The MPR was higher than
80% in the three periods, being very similar between the three molecules, but
in M12 period the difference in MPR between adalimumab 86% and golimumab
92.1% was statistically significant (p <0.005), for etanercept it was of 90%.

Conclusion: There seems to be a higher MPR with the monthly golimumab
compared to the biweekly adalimumab and weekly etanercept; however, it does
not necessarily imply greater effectiveness. Longer term studies are needed to
confirm if there is better adherence and clinical results with monthly anti-TNFs
than to other dosing regimens. Patients with remission and low disease activity
had greater assistance to scheduled consultations with the interdisciplinary
group, regardless of the type of molecule used. This study confirms the relation
between adherence to medications and care model with clinical results.

AB1365-HPR FREQUENCY OF JOINT DAMAGE IN PATIENTS WITH ULCERATIVE COLITIS

D. Tarasova1, L. Shilova1, E. Lutaya1, E. Korenskaya1, M. Koroleva1, A. Feoktistova1, 1Volgograd State Medical University, Volgograd, Russian Federation

Background: Ulcerative colitis (UC) is considered as a systemic autoimmune dise-
ase with lesions of the colon mucosa. The current of UC is often accompanied by
different extra-intestinal manifestations. Their frequency, according to various stud-
ies, varies widely – from 25 to 60 %. It is a serious problem that affects the quality
of life and the effectiveness of therapy [1, 2]. Rheumatological manifestations, in par-
cular, damage to the joints and spine, are one of the extra-intestinal manifesta-
tions and they are of particular importance. To date, the relationship between UC
and joint damage has not been fully studied. These diseases can occur inde-
pendently in the body or have a common autoimmune or inflammatory nature. It is
believed that having common pathogenetic mechanisms of development, UC and
joint damage can be different clinical forms of the same disease.

Objectives: To evaluate the frequency of clinical manifestations of joint damage
in patients with ulcerative colitis.

Methods: The study was conducted at the gastroenterological Department of the
Hospital No25 (Russia, Volgograd). Archived data from the case histories of 69
patients with a confirmed diagnosis of ulcerative colitis were analyzed, includ-
ing 58 men (30.4%) with an average age of 33.4 years, and 38 women (69.5%)
with an average age of 37,5 years.

Results: Among 46 patients with UC, extra-intestinal manifestations were
detected in 40 (41.6%) patients. A total lesion of the large intestine was found
in 20 patients (20.8%), left-sided colitis in 14 (14, 6%), proctosigmoiditis in 6
(6.25%). The diagnosis was made for the first time in 4 patients (4.16%), 36
patients (37.5%) were admitted to the hospital again due to an exacerbation
of the disease. Among the extra-intestinal manifestations, joint lesions prevailed: 20
patients (20.8%) showed clinical signs of peripheral arthritis, spondyloarthri-
ts was detected in 8 patients (8.3 %), and 6 patients (6.25 %) had symptoms of
unilateral sacroiliitis. 4 (4.16%) patients were diagnosed with nodular erythema.
Primary sclerosing cholangitis was detected in two patients (2.08%).

Conclusion: The development of extra-intestinal manifestations in UC is largely
determined by the course of the disease and the length of the inflammatory pro-
cess in the colon. More than a third of patients with UC revealed extra-intestinal
manifestations, among which the most common signs of joint damage were pres-
ent, which necessitates timely diagnosis of extra-intestinal manifestations and
involvement of a rheumatologist in the management of this category of patients.
