S AT0204 COMPARING OCCURRENCE AND CLINICAL SIGNIFICANCE OF ANTI-PHOSPHOLIPID AUTOANTIBODIES AMONG SUDANESE AND SWEDISH SLE PATIENTS USING CONVENTIONAL AND NATION-BASED CUTOFFS

S. Elbagir1, A. Elshafie1, E. M. Elagib2, N. A. Mohammed3, V. A. Manivel1, E. Petrinzind1, M. A. M. Nur1, I. Gunnansson2, E. Svenngsson2, J. Rönnelid1
1Uppsala University, Immunology, Genetics and Pathology, Uppsala, Sweden; 2Military Hospital, Rheumatology Unit, Omdurman, Sudan; 3Al Neelain University, Khartoum, Sudan; 4Ankara University, Department of Rheumatology, Ankara, Turkey; 5Department of Rheumatology, Uppsala University, Sweden

Background: Antiphospholipid antibodies (aPL) of IgA isotype are prevalent in Sudanese and Swedish SLE patients using nation-based cutoffs.
Methods: Consecutive Sudanese (n=115) and Swedish (n=340) SLE patients and 106 and 318 age- and sex-matched national controls were included. All patients fulfilled the 1982 ACR SLE classification criteria. IgA/G/M anti-cardiolipin and anti-β2GPI were measured with two independent assays (Fluorescence Enzyme Immuno Assay (FEIA) from Thermo Fisher Scientific and Particle-based Multi-Analyte Technology (PMAT) from Inova Diagnostics). IgA anti-β2GPI domain1 (D1) was investigated with chemiluminescence (CIA), Inova Diagnostics. APS-related events were obtained from patients’ records. Manufacturers’ 95th and 99th percentile cutoffs, based on national controls calculated by non-parametric methods, were used.

Results: Sudanese patients had higher levels and prevalence of IgA aPL using manufacturers’ cutoffs (Table 1 and Figure 1). IgA/IgG aPL were also higher among Sudanese controls. But, Swedish patients were more often positive for IgA anti-β2GPI with both assays when national cutoffs were applied (Table 1). Occurrence of IgA anti-D1 did not differ between the countries. Venous thromboses were less common among Sudanese patients and no aPL, including IgA anti-β2GPI associated with thrombosis in Sudanese patients. Thrombosis in Swedes decreased with IgA/M aPL. Fetal loss associated with aPL in both cohorts most evident after national adjustments.

Conclusion: IgA anti-β2GPI levels were generally higher among Sudanese compared to Swedish SLE patients and controls, but after national adjustments more Swedish than Sudanese patients were positive. IgA anti-D1 was not increased in Sudanese patients. Previous studies on populations of African-origin, which demonstrate high prevalence of IgA aPL positivity, should be re-evaluated using similar cutoff approach.

Acknowledgments: : We thank Maryam Poorraftah at Thermo Fisher Scientific and Silvia Casas and Michael Mahler at Inova Diagnostics for help with analyses.

SAT0205

A MORE SPECIFIC INTEGRATED MODEL FOR IDENTIFYING BACTERIAL INFECTION IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Feng1, X. C. Zhao1, J. Luo1. 1The Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Systemic lupus erythematosus (SLE) is a multisystemic inflammatory disorder [1]. Given that immunosuppressive therapy is adopted as the predominant treatment option for SLE, up to half of SLE patients develop infections during their disease progress, and bacterial infection serves as the leading cause of morbidity and mortality in SLE patients [2]. Owing to the therapeutic regimen to bacterial infection and SLE flare are absolutely opposite, timely diagnosis and correct treatment are of vital importance, and improper treatment strategy may be fatal. No single biomarker, however, has exhibited sufficient sensitivity and specificity to serve as a standard tool for distinguishing bacterial infection from SLE flare.

Methods: Total 175 SLE patients (65 infected and 110 flare) were recruited into our study. The criteria of bacterial infection was positive isolation of bacteria, typical clinical symptoms and signs, imaging positive results and positive feedback on antibacterial treatment and lupus flare was regarded as three points higher than their previous SLEDAI. The disease activity of SLE patients was evaluated based on Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). Lymphocyte cells (CD3+T, CD4+T, CD8+T, B, NK, Th1, Th2, Th17 and Treg) and cytokines [interleukin-2 (IL-2), IL-4, IL-6, IL-10, tumor necrosis factor-α (TNF-α), interferon-γ (IFN-γ) and IL-17] were measured by flow cytometry. Blood routine examination, erythrocyte sedimentation rate (ESR), C-Reactive Protein (CRP) Complement 3 (C3), C4, procalcitonin (PCT), immunoglobulin M (IgM), IgA and IgG were also evaluated. Partial least square discriminant analysis (PLS-DA) and supervised orthogonal PLS-DA (OPLS-DA) were applied to perform multivariate analysis of the data and further group the patients with bacterial infection. Receiver operating characteristic (ROC) curves were also plotted to investigate the ability of individual indicator and the combination of multiple indicators to identify bacterial infection.

Results: The PLS-DA model showed a clear identification effect by the performance of R2Y=0.991 and Q2=0.970. The OPLS-DA model (R2Y=0.996 and Q2=0.991) exhibited a better separation of patients with bacterial infection. The AUC of the combination was greatly higher than that of WBC, NEUT, ESR, CRP, PCT, Treg, IL-6, IL-10, IFN-γ and TNF-α (P<0.001).

Conclusion: PLS-DA, OPLS-DA models including cytokines, lymphocyte cells and routine biomarkers and combination of WBC, NEUT, ESR, CRP, PCT, Treg,
IL-6, IL-10, IFN-γ and TNF-α in ROC curve may be more predictive for finding bacterial infection in SLE and may prompt clinicians more promptly and accurately to help them make correct medication.

SAT0206

MINOR SALIVARY GLAND BIOPSY AND SEROLOGICAL PROFILE IN PRIMARY SJÖGREN’S SYNDROME: A SINGLE TERTIARY REFERRAL CENTER EXPERIENCE

C. M. Gaibo-Alonso1, M. J. Garza Martínez1, B. R. Vázquez Fuentes1, G. Figueroa-Parra1, D. Vega-Morales1, J. C. Riegatorres1, J. D. Ángulo1, D. A. Galazara-Delgado1. 1University Hospital “Dr. José Eleuterio González”, Rheumatology, Monterrey, Mexico

Background: Minor salivary gland biopsy (MSGB) portrays an important role as part of the diagnostic criteria of primary Sjögren’s syndrome (pSS) in the ACR/EULAR 2016 classification. Autoantibodies anti-Ro/SSA and anti-La/SSB embody part of these criteria. Patients with negative serology have been classified as pSS using MSGB outcomes in up to 40% of cases.

Objectives: Compare MSGB and serological characteristics between pSS positive biopsy versus pSS negative biopsy and sicca groups.

Methods: 174 subjects with sicca symptoms and MSGB studies were studied. Patients who fulfilled the ACR/EULAR 2016 criteria were classified as pSS. Serological profile: Rheumatoid factor (RF) (IgG, IgM and IgG), Anti-La/SSB and Anti-Ro/SSA, available in 148 and 161 patients respectively, as well as histopathological characteristics of MSGB were recollected (Table 2).

Comparison between subgroups according to biopsy status was performed. Differences between serology and MSGB were reported using Chi square, a p<0.05 was considered statistically significant

Results: 95(54.59%) pSS patients with positive biopsy, 47 (27.02%) pSS with a negative biopsy and 32 (18.39%) sicca patients were included.

A positive serology profile (RF, Anti-Ro/SSA, Anti-La-SSB) was found more frequently in the pSS positive biopsy cohort when compared to the pSS negative biopsy and sicca groups (Table 1).

Table 1. Comparison between serological and histopathological characteristics in pSS and sicca groups.

1p of the comparison between pSS positive biopsy group vs pSS negative biopsy group
2p of the comparison of the 3 groups

Histopathological characteristics of MSGB are described in Table 2. Sicc group had more alterations when compared to pSS negative biopsy group.

Conclusion: Histopathological alterations in MSGB (atrophy, adipose infiltration and ductal dilatation) can act as confounding data at biopsy interpretation since they were found in close prevalence in the pSS positive biopsy group and sicca group and should be carefully taken into account at diagnosis. A positive serologic profile was associated with more histopathological alterations in the positive biopsy group.

Meroni11, F. Francescini1, C. Montecucco10,12, R. Cimaz2, R. Caporalil, A. Tincan2. 1Department of Clinical Science and Community Health, University of Milan, Milan, Italy; 2Rheumatology, Fondazione IRCCS Policlinico S Matteo, Pavia, Italy; 3Obstetrics and Gynaecology, Ospedale Maggiore Policlinico, Milan, Italy; 4O O Ginecologia e Obstetrica, ASST Spedali Civili Brescia, Brescia, Italy; 5Immunorheumatology Research Laborator, Instituto Auxologico Italiano, Milan, Italy; 6Clinical Rheumatology Unit, ASST PINI-CTO, Milan, Italy; 7University of Milan, Milan, Italy; 8Rheumatology, Fondazione IRCCS Policlinico S Matteo, Pavia, Italy; 9Immunology Clinic, Spedali Civili, University of Brescia, Brescia, Italy; 10Immunorheumatology Research Laboratory, Instituto Auxologico Italiano, Milan, Italy; 11Rheumatology, Fondazione IRCCS Policlinico S Matteo, Pavia, Italy; 12Lupus Clinic, Clinical Rheumatology, ASST PINI-CTO, Milan, Italy

Background: neonatal lupus syndrome (NLS) is an acquired disease caused by the trasplosal passage of anti-SSA antibodies. Congenital heart block (CHB) represents the most serious manifestation of NLS. The rate of CHB in Anti-SSA positive pregnant women ranges from 1 to 5% in different studies

Objectives: to retrospectively assess the prevalence of CHB in a cohort of anti-SSA positive pregnant women followed in 3 Italian tertiary centers

Methods: pregnancies of anti-SSA positive women attending the pregnancy clinic of ASST Pini CTO/Policlinico Mangiagalli, Rheumatology Division of Spedali Civili, Brescia and Rheumatology Division of Ospedale S Matteo, Pavia from 2009 to 2019 were included. Patients underwent monthly clinical examination. Fetal heart rate was assessed weekly by Doppler ultrasound from 14th to 26th gestational week. On week 14 and 26, a fetal echocardiography was performed. A EKG was performed at birth

Results: 351 prospectively followed pregnancies in 292 anti-SSA/Ro positive women were included. Table 1 reports diagnosis. None of the prospectively followed pregnancies were complicated by complete CHB. Seven additional patients were referred

DOI: 10.1136/annrheumdis-2020-eular.6278
to our clinic after diagnosis of CHB and were subsequently found to be anti-SSA positive, reporting no symptoms of diseases. Considering the 7 additional pregnancies, the incidence of CHB was 1.9%. We observed 3 neonates (0.8%) with cutaneous NLS and 1 case of transient increase of liver enzymes. In another neonate, a 3rd degree A-B block was found after birth. A complete analysis of maternal and fetal outcome was possible in 244 cases (Table 2) and compared with 3158 unselected healthy controls. Among these 244 cases, 65% were taking hydroxychloroquine.

Conclusion: none of the patients prospectively followed in our centers before and during pregnancy developed complete CHB. If the cases of anti-SSA positivity diagnosed after CHB detection were included in the analysis, the incidence of CHB was comparable to previous reports. Our data suggest that a strict follow-up and proper treatment of anti-SSA positive patients with or without an autoimmune disease before and during pregnancy can reduce the risk of NLS. Further studies are warranted to confirm a possible protective role of anti-rheumatic treatments, including HCQ.

1Armmedica IPS, Grupo de información clínica, Medellin, Colombia; 2CES University, Departamento medicina interna, Medellin, Colombia; 3CES University, Facultad de medicina, Medellin, Colombia

Background: Systemic lupus erythematosus (SLE) clinical manifestations, and their severity, vary according to age, ethnicity and socioeconomic status. Both Hispanic and Afro-Americans have a higher incidence and more sever presentation when compared to Caucasian patients with SLE

Objectives: To analyze clinical and immunological characteristics associated with time to severe renal involvement in patients with Systemic Lupus Erythematosus in a Colombian cohort followed for one year, between January 2015 and December 2018

Methods: Retrospective follow-up study based in clinical records. Patients with SLE diagnosis that fulfilled either 1987 American College of Rheumatology Classification Criteria for SLE or 2011 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE. We included patients with diagnosis of lupus nephritis according to Wallace and Dubois criteria. Patients who did not have at least two follow-up measurements or had a cause of nephritis other than lupus were excluded. The main outcome was defined as time from diagnosis to severe renal involvement defined as creatinine clearance ≤50 ml/min, 24-hour proteinuria ≥3.5 grams o end stage renal disease.

We analyzed clinical and immunological characteristics. Descriptive statistical analyses of participant data during the first evaluation are reported as frequencies and percentages for categorical variables, and as medians and interquartile ranges (IQR) for quantitative variables. Age and sex adjusted survival functions and Hazard ratios (HR) with 95% confidence intervals and p-values were estimated using parametric Weibull models for interval-censored data. P values < 0.05 were considered statistically significant

Results: 548 patients were analyzed: 67 were left-censored as they presented renal involvement at entry, 6 were interval censored as outcome occurred between study visits, and 475 were right-censored as involvement was not registered during follow-up. 529 (96.5%) patients were female, median age at entry was 46 (IQR = 23) and median age to diagnosis was 29.5 (IQR = 20.6). 67% were mestizo, 13% Caucasian and 0.3% Afro-Colombian. Age and sex adjusted variables associated with time to severe lupus nephritis were high blood pressure HR = 3.5 (95%CI 2.2-5.6; p-value <0.001) and Anti-RO (per unit increase) HR = 3.5 (95%CI 2.2-5.6; p-value <0.001) and Anti-RO (per unit increase) HR = 3.5 (95%CI 2.2-5.6; p-value <0.001) and Anti-RO (per unit increase) HR = 3.5 (95%CI 2.2-5.6; p-value <0.001) and Anti-RO (per unit increase) HR = 3.5 (95%CI 2.2-5.6; p-value <0.001) and Anti-RO (per unit increase)

Conclusion: In our cohort the appearance of severe lupus nephritis occurs in less than 15% of patients at 10 years. Both high blood pressure and elevated anti-Ro titers were associated with a higher rate of onset in the presentation of severe lupus nephritis, as seen in some polymorphs of anti Ro.

**SAT0211** RENAL INJURY IN SYSTEMIC LUPUS ERYTHEMATOSUS CHARACTERIZED BY THROMBOTIC MICROANGIOPATHY

W. Hu1, Jining Hospital, National Clinical Research Center of Kidney Diseases, Jilin, China

Background: Classical lupus nephritis (LN) is characterized by glomerular immune complex(IC) deposition with glomerular proliferation, basement membrane destruction and cell infiltration. Non-IC mediated renal injury with thrombotic microangiopathy (TMA) was also reported in patients with systemic lupus erythematosus (SLE-renal TMA), but most studies were reported in patients with both LN and renal TMA.

Objectives: To analyze clinical and immunological characteristics associated with time to severe LN in patients with SLE-renal TMA in absence of obvious IC in SLE patients were analyzed.

Methods: Patients with glomerular TMA and/or vascular TMA in the absence of obvious subendothelial or epithelial immune deposits were screened from 2332 biopsied in SLE patients who underwent first renal biopsy from January 2005 to August 2016. Their clinical, histological features and outcomes were retrospectively analyzed.

Results: 2332 renal biopsies obtained from SLE patients, 257 (11.0%) showed renal TMA, and 237 showed both renal TMA and LN, and 20 biopsies had only renal TMA (SLE-renal TMA). There were 2 males and 18 females with an average age of (25 ± 10) years. The median course of SLE and LN were 3.0(1.0, 6.0) and 0.6(0.5, 1.9) months. All 20 patients deserved acute kidney injury, of which 11 (55%) needed renal replacement therapy (RRT) and 12 (60%) were nephrotic syndrome. Blood system involvement was found in all cases, including 13 cases (65.0%) with TMA triad (microvascular hemolytic anemia, thrombocytopenia and elevated lactate dehydrogenase).

Pathological examination showed that 17 cases (85.0%) had both glomerular TMA and vascular TMA. Immunofluorescence and electron microscopy showed that 8 cases (40%) had no IC deposition in glomerulus and 12 cases (60%) had only IC deposition in mesangium. Acute tubulo-interstitial lesions in patients requiring RRT were more serious than those no needing for RRT (43.6±24.9 % vs 21.7±20.1 %, P=0.047). The fusion range of foot process was positively correlated with proteinuria (r² = 0.347, P=0.006).

All patients received high-dose methylprednisolone pulse therapy. Four patients received plasma exchange and three patients received gamma globulin, respectively. Eleven patients requiring RRT all stop RRT in a median time of 16.0 (9.0, 30.0) days. During a median follow-up of 58.0 (36.0, 92.3) months, complete remission (CR) was obtained in 15 cases, partial remission in 4 cases and no remission in 1 case. Six cases (30%) relapsed. No case died or progressed to end stage renal disease.

Conclusion: Renal injury characterized by TMA is not uncommon in SLE renal biopsy cases. The clinical manifestation is special and the renal injury is serious. The renal outcome is good by intensive immunosuppressive therapy. It should be considered as a unique type of renal injury in SLE.

OBSTETRIC AND THROMBOTIC ANTIPHOSPHOLIPID SYNDROME: SIMILAR ANTIBODIES BUT DIFFERENT PHENOTYPES?

H. Jiang1, Y. Zhao2, C. H. Wang3, J. Zhao4; Peking Union Medical College Hospital, Rheumatology, Beijing, China

Background: Several studies showed two main clinical phenotypes of antiphospholipid syndrome which could be independent, but only a few data contrast features between these two groups.

Objectives: To investigate whether obstetric and thrombotic manifestations of APS are independent subtypes.

Methods: This was a single center prospective study from the PUMCH database of primary antiphospholipid syndrome followed for over 4 years. Comparing demographic data, laboratory tests, pregnancy morbidity and thrombotic events during follow-up between IoAPS (isolated obstetric APS) and ItAPS (isolated thrombotic APS).

Results: A total of 244 patients were registered in PUMCH primary APS cohorts, 157(64.34%) were female patients. In female patients, 44(28.03%) were diagnosed with IoAPS, 42(26.75%) were ItAPS. Demography showed patients in ItAPS group were older than IoAPS group (40 vs 33, p<0.001), presented more cardiovascular risks(33.33% vs 6.8%, p<0.01), neurological disorders (23.8% vs 2.3%, p<0.01) and thrombocytopenia (47.6% vs 20.5%, p<0.01). Antibody profiles had no difference in triple positivity, double positivity and partial single positivity (ACL, LA); but presence of single anti-β2GPI positivity showed significant difference between IoAPS and ItAPS (59.09% vs 38.1%, p<0.05). Significant difference was presented in homocysteine (Median) between IoAPS and ItAPS (9.9 vs 11.5, p<0.05), not in inflammatory markers. During 49.5 (Median) months follow-up of ItAPS group, patients got 90 pregnancies, 5 abortions but weren’t fulfilled with the diagnosis criteria of pregnancy morbidity. No thrombotic event occurred during 48.5 (Median) months follow-up time in IoAPS group.

Conclusion: IoAPS and ItAPS share similar antibody profile, but presented isolated clinical complications, different demographic features and maintained independent manifestation during follow-up, indicating the underlying pathogeneses are different.

Background: In the diagnosis of primary Sjogren’s syndrome (SS), salivary gland ultrasound is useful tool. Until now, there is no data for ultrasonographic changes of major salivary glands over time.

Objectives: This study aimed to evaluate the changes in abnormalities of salivary gland ultrasound (SGUS) over time in patients with pSS.

Methods: Patients with pSS (n=70) and idiopathic sicca syndrome (n=18) underwent SGUS twice at baseline and 2 years later. The semi-quantitative SGUS score (0-48) was used, which comprises five parameters: parenchymal echogenicity, homogeneity, hypoechoic areas, hyperechogenic reflections, and clearance of posterior borders. The intraglandular power Doppler signal (PDS) was also assessed. The changes of these SGUS variables were compared in patients with pSS and idiopathic sicca syndrome.

Results: The median (interquartile range) total SGUS scores at baseline was 27 (14) in patients with 4 and 3 (3) in those with idiopathic sicca syndrome (p<0.001). In the pSS group, the total SGUS scores and the SGUS scores for bilateral parotid glands were significantly increased during median 23.4 month follow-up (p=0.013 and p=0.011, respectively). Homogeneity and hypoechoic areas were the domain to show statistically significant progression of SGUS scores. None of the SGUS scores changed significantly in the patients with idiopathic sicca syndrome. In patients with pSS, baseline and follow-up PDS sum scores of four salivary glands were significant higher in worsening SGUS group (n=13) than no change/improvement SGUS group (n=55).

Conclusion: The structural abnormalities in major salivary glands assessed using SGUS scores progressed significantly in patients with pSS. In pSS group, 16.6% patients had worsening SGUS scores during 2 years. Intra-glandular hypervascularity was associated with worsening of salivary gland abnormalities.

Scientific Abstracts
**Methods:** Patients aged ≥18 years with SLE were identified in the Clinical Practice Research Datalink – Hospital Episode Statistics database from January 1, 2005, to December 31, 2017. Patients were required to have ≥12 months of data before and after index date (date of earliest SLE diagnosis available). SLE disease severity and flares were classified as mild, moderate, or severe using adapted claims-based algorithms that use SLE-related conditions (eg, end-stage renal disease), medications (eg, antimalarials, immunosuppressants, and corticosteroids), and health service use (eg, hospitalizations and emergency department visits).

**Results:** Of 802 patients with SLE, 369 (46.0%) had mild, 345 (43.0%) had moderate, and 88 (11.0%) had severe SLE at baseline. In total, 692 (86.3%) patients were treated with SLE medications in the first year after SLE diagnosis. Among the total population (802), 577 (69.5%) patients received antimalarials, 203 (25.3%) received immunosuppressants, and 416 (51.9%) received corticosteroids (prednisolone); patients may have received ≥1 type of drug. Information on biologic use in hospitals is unavailable in these data. The mean (standard deviation [SD]) time to initiating any medication from index date was 177 (385.3) days (Figure 1A). The median time to first flare from index date was 63 days (95% confidence interval 57–71) (Figure 1B). A majority of patients (750/802, 93.5%) experienced ≥1 flare during follow-up; the first flare was mild for 73.2% of patients (549/750), moderate for 15.5% (116/750), and severe for 11.3% (85/750). The mean (SD) annual overall flare rate in the first year after index date was 3.5 (2.5) (mild flares: 2.6 [2.5]; moderate flares: 0.7 [1.5]; severe flares: 0.2 [0.6]) (Figure 2). A shorter median time to first flare was significantly associated with moderate or severe disease (P<0.001) and the presence of comorbid conditions (P<0.001).

**Conclusion:** Our findings suggest some delay in SLE treatment initiation in the UK. Most patients with SLE experience flares within 2 months from diagnosis. Early treatment may delay or reduce the severity of the first SLE flare after diagnosis and may translate to slower disease progression, lower organ damage accrual, and better outcomes.

SAT0218 SINGLE NUCLEOTIDE POLYMORPHISMS LOCATED IN REGULATORY REGIONS OF GENES INVOLVED IN SYSTEMIC INFLAMMATION (MAMDC1, ITGAM, AND CRP) CORRELATION WITH THE CLINICAL PICTURE OF DISEASE AND ACTIVITY PARAMETERS IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Majdan1, R. Mikl1, M. Mazurek1, D. Pigon1, M. Majdan1-2, T. Malecka Massalska1, 2Medical University of Lublin, Dept of Human Physiology, Lublin, Poland; 3Medical University of Lublin, Dept of Rheumatology and Connective Tissue Diseases, Lublin, Poland

Background: The exact pathogenesis of systemic lupus erythematosus (SLE) is poorly understood. It is an autoimmune disease that leads to a chronic inflammatory process involving numerous tissues and organs (skin, kidneys, joints, central nervous system, cardiovascular, respiratory, digestive and hematopoietic systems). However, despite the advancement of SLE molecular biology and the wide availability of tests and diagnostic tools, the knowledge about factors predicting the clinical disease activity as well as related changes in the laboratory results is insufficient.

Objectives: The goal of the study was to assess the relationship between selected single nucleotide polymorphisms (SNPs) and the clinical picture of disease and activity parameters in patients with SLE.

Methods: We conducted a study of adult patients with SLE diagnosed and treated in the Rheumatology Department of Medical University of Lublin between 2016-2019. We enrolled 80 patients with SLE (71 women, 9 men), with the median (range) age 36 (19-72) and disease duration 6 (1-37) years. To objectively assess disease activity, standardized SLE activity scale - SLEDAI (Systemic Lupus Erythematosus Disease Activity Index) was used. Using the Real-Time PCR method and specific TaqMan probes SNPs of 3 genes: MAMDC1 (rs910875: c.<390C>A), ITGAM (rs7193943: c.<323G>A) were analyzed and then their relationship with the clinical picture of disease, activity and laboratory results were assessed.

Results: Carriers of the CC genotype compared to the remaining polymorphic variants (CG and GG) of the MAMDC1 gene had an approximately 4-fold higher risk of SLE (OR = 4.04; p = 0.0110). Carriers of this genotype also had a higher risk of hematuria (OR = 4.57; p = 0.0082), sterile leukocyturia (OR = 53.91; p = 0.0071), the presence of anti-Sm / RNP antinuclear antibodies (OR = 4.15; p = 0.0074), reduced values of the C3 complement component (OR = 6.11; p = 0.0071) and the need for oral glucocorticosteroids (OR = 701; p = 0.0028). In addition, significantly higher values of SLE disease activity scale were observed in carriers of the CC genotype of the MAMDC1 gene (medians: 6 vs 4; p = 0.0220). Moreover, we observed a trend towards a higher risk of hepatomegaly in GG genotype carriers of the ITGAM gene (OR = 18.50; p=0.0352). In addition, the AA genotype of the CRP gene was associated with a higher risk of proteinuria (OR = 84; p<0.0001), Anti-SSA / Ro autoantibodies (OR = 3.29; p = 0.0484), and aCL IgM (OR = 3.42; p = 0.0332) occurrence. Carriers of AA genotype of the above gene were also at higher risk of earlier occurrence of first disease symptoms as well as disease diagnosis at a younger age (respectively: 24 vs 31 years; p=0.0225, 23 vs 29 years; p=0.0442).

Conclusion: The results suggest the relationship between SNPs in genes involved in systemic inflammation (MAMDC1, ITGAM, CRP) and disease activity as well as the occurrence of some specific clinical pictures of disease in patients with SLE. The genetic dispositions described above may serve as attractive markers in SLE, potentially useful in clinical practice.
describe pts demographic and clinical characteristics, and medications use in the baseline and follow up.

**Results:** Study cohort included 9,108 SS pts of which 76.5% had sSS diagnosis on index date. Majority of SS pts were women, Caucasian, with mean age of 58.3 yrs, and from western states in the US (Table 1). Endocrine conditions including hypo- and hyperthyroidism, and diabetes was the most common (45.5%) comorbidity at baseline, followed by rheumatologic disorders (25.6%) and neurological conditions (22.2%). Among patients with treatment information (4088, 44.8%), 42.96% were using symptomatic treatments for dry eye and mouth at baseline. We didn’t find differences regarding CRP levels. The ESSDAI and the hydroxychloroquine - 4 pts (6.3%); grade 1 - 24 pts (38.1%); grade 2 – 20 pts (31.7%); grade 3 – 10 pts (15.9%); grade 4 – 5 pts (7.9%). The ESSDAI and the hydroxychloroquine use were similar in these subgroups. We didn’t find differences regarding CRP and fibrinogen and echographic features. The age of the patients, the anti-SSA and anti-SSB, ESR, total protein, IgA, IgG and rheumatoid factor levels were significantly higher and lymphocyte count was lower in patients with echographic severity above grade 2 when compared with patients with no or mild echographic features. However, using ANOVA test and post-hoc analysis, the only parameters associated with the severity of echographic features were high ESR (53 vs 17 in grade 4 vs 1, p=0.02), IgA (363 vs 190 in grade 4 vs 1, p=0.004) and IgG (185 vs 1191 U/l in grade 4 vs 1, p=0.001) levels.

**Conclusion:** Parameters linked to polycyal hypergammaglobulinemia (IgA and IgG levels; and ESR) seem to be linked to the severity of echographic appearance of salivary gland in patients with SS. Further studies are needed in order to better characterize this link.

SAT0222

CLINICAL SPE ctrum and Long-term followup of systemic lupus erythematous-associated macrophage activation syndrome

T. Okano,1,2 J. Saegusa,1,2 K. Yoneda,1,2 I. Shiraugi,1,2 Y. Ueda,1,2 K. Akashi,1,2 A. Onishi,2 A. Morinobu,1,2 Kobe University Hospital, Clinical Laboratory, Kobe, Japan; Kobe University Hospital, Rheumatology and Clinical Immunology, Kobe, Japan

Background: Systemic lupus erythematous (SLE) patients present with variable clinical features ranging from mild joint and skin involvement to life-threatening organ involvement such as nephritis, neuropsychiatric involvement, diffuse alveolar hemorrhage, and hemophagocytic lymphohistiocytosis (HLH). HLH is rare, but fatal complication of SLE. Recently, European League Against Rheumatism, the American College of Rheumatology, and the Pediatric Rheumatology International Trials Organization was to develop a set of classification criteria for MAS complicating systemic juvenile idiopathic arthritis (PRINTO criteria) [1]. Sung Soo Ahn and his colleagues reported PRINTO criteria predicted mortality of adult SLE patient, but they followed only one year [2].

Objectives: To reveal association PRINTO criteria with long term mortalities in SLE patient in our Hospital.

Methods: We performed a retrospective analysis of SLE patients who received moderate dose glucocorticoid therapy (>0.4mg/kg/d) in our hospital between April 2008 and April 2019. Patients were evaluated for HLH using the 2016 PRINTO classification criteria for MAS. Clinical features and laboratory findings were compared and overall survival rate was analyzed.

Results: Among 164 episode (144 patients) with SLE, 31 episode (31 patients) 5.2% were considered to have MAS on admission. The overall survival rate was significantly lower in patients with MAS than without MAS (68.2% vs. 95.3%, p = 0.048). Interestingly, SLEDAI did not have association with mortality, relapse rate, and MAS complication. SLEDAI more focused on renal and neuropsychiatric symptoms than hematologic features. So SLEDAI might not be associated with MAS secondary to SLE. Furthermore, we observed no death patient with MAS after one year, and only 1 case relapse in MAS patient. So MAS might have fatal but less relapsing property compared with other lupus cases.

Conclusion: PRINTO criteria may be useful to differentiated fatal MAS patients from others. Further investigations are required to confirm our findings. Limitation: The main limitations of our study include its retrospective design, single center site, and that the number of admitted patients with SLE was small.

Limitation: The main limitations of our study include its retrospective design, single center site, and that the number of admitted patients with SLE was small. Findings: The main limitations of our study include its retrospective design, single center site, and that the number of admitted patients with SLE was small.

TUBULO-INTERSTITIAL INFILTRATES IN LUPUS NEPHRITIS

V. A. Pacucci,1 F. R. Spinelli,1 K. Giannakakis2, S. Colafrancesco1, S. Truglia1, F. Ceccharelli1, C. Garuti1, C. Alessandri1, F. Conti1, on behalf of Lupus Clinic - Sapienza University of Rome, 1Sapienza University of Rome, Clinical, Internal, Anaesthesiology and Cardiovascular Sciences - Rheumatology Unit, Roma, Italy; 2Sapienza University of Rome, Radiologic, Oncologic, and Pathologic Sciences - Pathology Unit, Roma, Italy

Background: Lupus nephritis (LN) occurs in up to 60% of patients affected by Systemic Lupus Erythematosus (SLE). The presence of inflammatory infiltrates in glomeruli and/or in tubulo-interstitium (TI) plays an important role in terms of prognosis [1]. Ectopic lymphoid structures (ELSs) are clusters of organized lymphoid infiltrates forming at sites of chronic inflammation in non-lymphoid organs and are well-defined infiltrate pattern resembling ELS in 13 renal samples. In these samples, we confirmed the presence of organized infiltrates by IHC, with evidence of TII was negatively correlated with renal remission after induction therapy (P=0.03) independent of the histological class and the induction treatment.

DOI: 10.1136/annrheumdis-2020-eular.5035
Conclusion: Assessment and management of LN patients are greatly facilitated by information obtained by renal biopsy. In the present study the evaluation by HE of 53 kidney samples from patients with LN showed TI-I in 62% of the specimens and a well-defined infiltrate pattern with GC-like features in 39% of those specimens with TI-I, confirmed in IHC. The presence of TII was associated with a worse outcome in response to therapy. Our preliminary results obtained by IHC suggest that ELS could be considered as a biomarker of renal response to B-cell depleting therapy supporting the importance of TI disease.

DOI: 10.1136/annrheumdis-2020-eular.1296
Background: Non-Hodgkin B-cell lymphoma (NHL), especially mucosa-associ-ated lymphoid tissue (MALT) lymphoma, is one of the main complications of pri-mary Sjögren’s syndrome (pSS). Frequent extranodal lymphoproliferation makes its diagnosis challenging and obtaining a biopsy difficult. Since pSS-associated lymphomas are very frequently MALT lymphomas with salivary gland involve-ment, we hypothesized that minor salivary gland biopsy (MSGB) could be useful for NHL diagnosis in this context.

Objectives: To evaluate the potential contribution of MSGB for the diagnosis of pSS-associated MALT lymphoma by comparing patients diagnosed with NHL based on MSGB or another tissue.

Methods: All pSS patients (ACR/EULAR 2016 classification criteria), from the Paris National Referral Centers for Rare Systemic Autoimmune Diseases, diag-nosed with NHL between January 2010 and October 2019, were included. Each patient’s clinical, biological, radiological, and therapeutic information was collected retrospectively at NHL diagnosis and 1-year later. Only patients with MSGB avail-able were analyzed; they were divided into 2 groups according to MSGB results for NHL: MSGB+ and MSGB-.

Results: Among 36 pSS patients diagnosed with NHL during the study period, 25 had an MSGB available at the time of NHL diagnosis. Among them, 13 MSGBs contained NHL (MSGB+). MSGB was the only site enabling NHL diagnosis for 10/13 (77%); pSS and NHL were diagnosed simultaneously in 4/13 (31%). MSGBs were NHL+ for lymphomas diagnosed based on other tissue samples for 12 (48%) patients (MSGB+). The clinical, biological, histological and radiological characteris-tics of both groups are reported in Table 1. No major differences were found between groups for median ESSDAI at NHL diagnosis and the frequency of salivary gland hypermetabolism on PET-CT. MALT-type NHL was found in 24/25 (96%) patients including 13/13 (100%) of those MSGB+ and 11/12 (92%) of those MSGB-. Six of the 13 (46%) MSGB+ patients received no treatment, while all MSGB- patients were treated. Between diagnosis and 1 year of follow-up, ESSDAI scores without the NHL item did not differ (6.5 [3.9–9.5]) for the 6 untreated patients, but had significantly decreased for the 19 treated patients (3.5 [2.0–5.8]) (p=0.02).

Conclusion: Autoimmune and musculoskeletal manifestations. There were no differences in the autoan-tibody profile in pSS patients vs. controls. MRI of the brain was available in 19/19 patients and 5/1 were abnormal, ischaemic changes (2) were the com-monest followed by T2/FLAIR hyperintensities (16). Cyclophosphamide was used for induction in 46 and Mycophenolate in 19 patients. Follow up of ≥ 6 months duration was available 93 patients. Over a mean follow up duration of 11.1 ± 22.7 months, 6 patients had a NHL relapse and 10 died.

PREGNANCY OUTCOME IN SYSTEMIC LUPUS ERYTHEMATOSUS: A MONOCENTRIC COHORT ANALYSIS

C. Pirone1, F. Cecceari,1 A. Salignani,1 C. Perricone1, S. Truglia1, V.A. Pacucci1, F.R. Spinelli1, C. Alessandri1, G. Valesini1, G. Perrone1, F. Conti1, Lupus Clinic, Reumatologia, Sapienza Università di Roma, Roma, Italy; Dipartimento di Scienze Ginecologiche-Ostetriche e Urologiche, Roma, Italy; 2Reumatologia, Università di Perugia, Perugia, Italy

Background: Systemic Lupus Erythematosus (SLE) is a chronic autoim-mune disease, affecting prevalently women in childbearing age. Thanks to pre-gestational counseling and multi-disciplinary approach, adopted in daily clinical practice, SLE patients are experiencing even more uncomplicated pregnancies.

Objectives: Here, we evaluated pregnancy outcome in a large SLE cohort, compared to a control group including pregnant women without autoimmune diseases.
Methods: Pregnant SLE patients (diagnosis made according to ACR 1997 criteria) were included in the present study, conducted in the context of a joint rheumatology/gynecology multi-disciplinary team. For each patient we collected demographic information, medical history, treatments, disease activity (SLEDAI-2K) chronic damage (SLICC damage index), clinical and labora-
tory data, including serum complement level and autoantibodies. Pregnancy outcomes were reported longitudinally as well as disease relapses occurring during pregnancy and puerperium. Flares were defined as new onset or worsening disease-related manifestation in any organ/system.

Results: Since 2008, 70 consecutive pregnancies occurred in 50 SLE patients ([median age at diagnosis 25 years (IQR 12.2), median age at first pregnancy 33 years (IQR 7), median disease duration 72 months (IQR 120)]. As controls, we evaluated 100 consecutive pregnancies in 100 women without or with autoimmune diseases ([median age 31 years (IQR 9)]. Table 1 reports the obstetric, fetal and neonatal outcomes of SLE patients compared to control group. A positive outcome in terms of live born infants was experienced in 88.6% of SLE pregnancies and in 88% of control group (p=NS). There were no statistically significant differences in any of the pregnancy outcomes evaluated; however, the percentage of small for gestational ages (SGA) was significantly higher in SLE group (22.8% versus 11.0%, p=0.003). A statistical association was found between SGA and positivity for anti-dsDNA, anti-SSA and anti-SSB (p=0.001, p=0.0005, p=0.01 respectively). Miscarriage was significantly associated with disease-related serologic abnormalities [anti-dsDNA (p=0.0001), low C3 (p=0.0001) and low C4 (p=0.006)] and past smoking habitus (p=0.0001); preterm birth was associated with anti-dsDNA, anti-CL and anti-B2GPI (p=0.0001, p=0.0005, p=0.01 respectively). A disease flare was reported in 28 pregnancies (40%) and in 31 puerperium (44.3%). Figure 1 reports SLE relapses divided according to organ involvement. Flare during pregnancy was associated with positivity for anti-SSA (p=0.001), anti-SSB (p=0.01) and aCL (p=0.006), while puerperium relapses were associated with previous renal involvement (p=0.0005), flare during pregnancy (p=0.01) and chronic damage (p=0.0001).

Figure 1. Disease flares during and after 70 SLE pregnancies divided according to organ involvement.

Conclusion: The present study confirms the role of pre-gestational counseling and a multi-disciplinary approach in the outcome of SLE pregnancies. Moreover, the high prevalence of disease relapse even more justifies the need for a combined rheumatology/gynecology multi-disciplinary approach.

Background: Sjögren’s syndrome (SS) is a systemic autoimmune disease whose main characteristic is involvement of the exocrine glandular system. Thus, its most common clinical manifestation is eye and mouth dryness which, alongside fatigue and pain, contributes to poor health-related quality of life (HRQoL). A growing body of evidence recognises the adipose tissue as an active endocrine organ secreting bioactive mediators involved in metabolic and inflammatory disorders. A relationship between obesity and symptoms in SS has not yet been elucidated.

Objectives: To explore potential associations between obesity-related immune-metabolic biomarkers and clinical symptoms in SS and sicca patients.

Methods: Proteomics analysis of 184 cardio-immuno-metabolic proteins was assessed on sera from 53 SS (50 females (F), 3 males (M); mean age 54 years) and 60 sicca (56 F, 4 M; mean age 57 years) patients. Participants were enrolled in the Birmingham Optimising Assessment in Sjögren’s Syndrome (OASIS) cohort and examinations included the EULAR SS Patient Reported Index (ESSPRI), Schirmer’s test, unstimulated whole saliva, minor labial salivary gland biopsy, EuroQol 5 dimensions (EQ-5D), body mass index (BMI), and clinical and laboratory parameters.

Results: The present study confirms the role of pre-gestational counseling and a multi-disciplinary approach in the outcome of SLE pregnancies. Moreover, the high prevalence of disease relapse even more justifies the need for a combined rheumatology/gynecology multi-disciplinary approach.

SAT0230 MACROPHAGE ACTIVATION SYNDROME IN SLE AND SYSTEMIC ONSET JIA: SIMILAR OR DISSIMILAR

N. R1, A. Jain1, H. Muhammed1, A. Aggarwal1, V. Agarwal1, L. Gupta1, D. Misra1, A. Lawrence1, R. Misra1, 1SGPGI, Clinical Immunology and Rheumatology, Lucknow, India

DOI: 10.1136/annrheumdis-2020-eular.3106

Scientific Abstracts Saturday, 06 June 2020 1057
Background: Macrophage activation syndrome (MAS) is a serious complication in rheumatic disease. Fever and hyperferritinemia are common in systemic onset JIA and cytopenias are common in SLE thus recognising MAS in them is a challenge.

Objectives: We compared clinical, laboratory parameters, various classification criteria for MAS, and its outcome in SLE and sJIA.

Methods: Clinical and laboratory data were extracted from clinician diagnosed cases of MAS with SLE/sJIA who were admitted between 2004-2018 at a tertiary care hospital. Percentage of patients satisfying Ravelli, International consensus, HLH 2004 and criteria proposed by Parodi et al were calculated.

Results: Among 33 patients (18 females) with MAS 19 had SLE and 14 had sJIA. MAS was more likely to be the presenting manifestation of disease in SLE as compared to sJIA (p<0.05). There were no differences in the clinical features among these two diseases. EBV and CMV were identified in 2 patients each as the trigger for MAS.

Patients with SLE had lower baseline TLC and platelet whereas patients with sJIA-MAS had significantly higher median CRP (p = 0.002), fall in TLC (p=0.012) and lower fibrinogen level (p=0.006). Neutrophil to lymphocyte ratio, Ferritin/CRP ratio and number of patients with Ferritin/ESR >80 were similar. Bone Marrow hemophagocytosis was seen in only 21% of patients. Only 6/33 fulfilled HLH criteria but criteria meant for sJIA or SLE performed well for both diseases and majority of patients could be diagnosed using them. Treatment included steroids(100%), cyclophosphamide(30%), Tacrolimus(21%), cyclophosphamide(21%)

Conclusion: MAS is more likely to be presenting manifestation in SLE compared to sJIA. Though lab parameters are significantly different in MAS associated with SLE & sJIA, criteria meant for MAS in sJIA or SLE MAS performed equally well in both diseases.

SAT0231
MULTIDIRECTIONAL DYSFUNCTION OF THE IMMUNE RESPONSE IN SYSTEMIC LUPUS ERYTHEMATOSUS

G. A. Ramirez1,2, A. Sorce, B. A. Mazzi, L. Moroni,2, E. Delia Torre1,2, G. Colombò, M. R. Yacoub1,2, E. Bozzolo,2, L. Dagna1, A. Manfredi1,2, Vita-Salute San Raffaele University, Milano, Italy; 2IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy; 3IRCCS San Raffaele Hospital, Immunogenetics Laboratory, HL & Chimerism, Department of Immunohaematology & Blood Transfusion, Milano, Italy

Background: Systemic lupus erythematosus (SLE) is a multi-organ immune-mediated disease characterised by autoimmunity. Dysfunction in immune tolerance towards allergens and protection from infections has less been studied. Human leukocyte antigen (HLA) genotype affects the risk of developing SLE. Little is known on the role of HLA in shaping SLE phenotype.

Objectives: To test for potential associations among active SLE, occurrence of infections and hypersensitivity reactions (HyR) at a clinical level and assess whether these events segregate with patients’ HLA-DRB1 typing.

Methods: 224 patients with SLE were prospectively followed up over the course of 1267 consecutive visits with a median interval of five months between each visit. HyR occurring within one month before or after each visit and occurrence of at least one feature (%)

SAT0232  
PERCEPTION OF THE DISEASE IN PATIENTS WITH EARLY SYSTEMIC LUPUS ERYTHEMATOSUS

M. Garabajul i i , L. Mazur-Nicoloiuc i , T. Rotaru i , V. Salaru i , S. B. Victoria i , S. Vietri i , N. Loghin-Oprea i , M. Mazur i . State University of Medicine and Pharmacy "Nicolae Testemițanu", Chisinau, Moldova, Republic of; "PSMI Institute of Cardiology, Chisinau, Moldova, Republic of

Background: Systemic lupus erythematosus is an autoimmune disease with a major impact on patient's quality of life.

Objectives: To evaluate patient's attitude toward early disease and factors that influence it.

Methods: Performed case-control study included SLE patients that fulfilled SLICC, 2012 classification criteria. The research included two groups of patients: early SLE – 1st group (disease duration ≤24 months) and non-early SLE – 2nd group (disease duration >24 months). The pattern of the disease activity was assessed by patient global assessment (PGA), Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and Systemic Lupus Activity Measure (SLAM), for SLE activity, SLICC/ACR Damage Index (DI) for disease irreversible changes and SF-8 for the Quality of Life (QoL).

Results: A total of 101 SLE patients with 34 in the 1st group (early SLE) and 67 in the 2nd group (non-early SLE) was analyzed. The disease activity showed high disease activity in both groups by SLEDAI (7.02±4.16 and 6.28±4.43 points, p>0.05) and SLAM (7.47±4.40 and 7.31±4.10 points, p>0.05) such as (46.97±19.39 vs 47.98±22.41 points). The QoL was appreciated as low, by both components (mental and physical), in groups. The damage index was higher in the 2nd group (0.23±0.43 and 1.07±1.29, p<0.001), which can be explained by the development of irreversible changes with the increase of disease duration. The PGA in early SLE was influenced by subjective symptoms contained in SLAM index (r=0.48, p<0.05), such as fatigue and depression, and the level of the quality of life (r=0.065, p<0.001). Meantime, PGA in patients with longer disease duration (>2 years), was influenced by the presence of organ damage by SLICC/ACR DI (0.23, p<0.05) and objective findings of the disease activity contained in SLEDAI (r=0.33, p<0.005) and SLAM (0.44, p<0.001).

Conclusion: The disease recognition in patients with early SLE was determined by subjective and psycho-emotional signs, while in patients with longer disease duration it was influenced by organ damage and complications.

SAT0233  
CHARACTERISTICS OF PRIMARY SJÖGREN’S SYNDROME INCLUDING ULTRASOUND FINDINGS OF THE SALIVARY GLANDS, ESSDAI AND ESSPRI

N. S. Schmidt i , A. Voss i , S. A. Just i , H. M. Lindegard i . Odense University Hospital, Rheumatology, Odense, Denmark

Background: Studies have shown that salivary gland ultrasonography (SGUS) may have a potential value in the diagnosis of Sjögren’s Syndrome (SS). Knowledge of the association between ultrasonography findings, disease activity and damage, serologic markers and patient report outcome is limited.

Objectives: To investigate whether the results of SGUS are associated with disease manifestations and damage measured by doctor-reported activity score index (ESSDAI) and serologic markers. Furthermore to investigate the contribution of patient reported outcome measure (ESSPRI) in disease monitoring.

Methods: Patients registered at Odense University Hospital with the diagnosis primary SS were included in a Danish cohort. The patients were characterized using the ESSDAI, ESSPRI, serologic markers and SGUS-findings in submandibular and parotid glands. Schirmer’s test and salivary test were performed for measurement of tear and salivary production. SGUS was performed using a linear transducer. Siemens (ACUSON Sequoia Ultrasound System) on the two parotid and two submandibular glands. SGUS images was scored according to the OMERACT SS severity scoring system from 0 to 3, where 2 is moderate and 3 severe(1). A reliability study was performed in advance of the present study. Spearman’s r correlation coefficient was used to assess correlation between scores.

Results: The cohort consisted of 48 Caucasian patients diagnosed with primary SS. Details on patient characteristics are shown in table 1.

Table 1.

<table>
<thead>

| BMI, n (%) | 5 (10.4) |

| Serum markers, n (%) | 1 (2.1) |

| SSA positive | 33 (68.8) |

| SSB positive | 22 (45.8) |

| ANA positive | 38 (79.2) |

| Anti-Cryoglobulin positive | 9 (18.8) |

| ESSPRI 0-10, mean (95%CI) | 7.3 (6.7-7.9) |

| Fatigue | 7.1 (6.4-7.7) |

| Pain | 5.9 (5.1-6.7) |

| SGUS, n (%) | 1059 |

| Score 0 | 6 (12.5) |

| Score 1 | 15 (31.3) |

| Score 2 | 13 (27.1) |

| Score 3 | 14 (29.2) |

| ESSDAI < 5 (low-activity) | 22 (45.8) |

| ≤ 5 ESSDAI ≤ 13 (moderate-activity) | 17 (37.4) |

| >14 (high-activity) | 9 (18.8) |

The correlation between ESSDAI-scores and SGUS-scores was r = 0.153 (p = 0.299). The correlation between ESSDAI-scores and ESSPRI-scores (dryness, fatigue, pain) was r = 0.071 (p = 0.632), r = 0.254 (p = 0.082) and r = -0.002 (p = 0.987). The correlation between SGUS-scores and ESSPRI-scores (dryness, fatigue, pain) was r = 0.124 (p = 0.400), r = -0.292 (p = 0.044) and r = -0.459 (p = 0.001).

Conclusion: In a Danish cohort of SS most patients had SSa and ANA autoantibodies. SGUS demonstrated high damage (score 2-3) in approximately half of the patients. ESSPRI activity score did not correlate with SGUS damage scores or the ESSPRI. SGUS damage scores correlated with ESSPRI-scores of fatigue and pain, but not dryness.

Associations between other factors of importance for damage and SGUS scores are to be analyzed. SGUS and the ESSPRI describe different SS-related dimensions and will probably contribute in disease monitoring in the future.

SAT0234  
SERUM AXL, FERRITIN, IGFBP4 AND STNFR2 AS BIOMARKERS OF PEDIATRIC SLE

S. Soliman i , A. Haque i , S. Mason i , L. Greenbaum i , M. J. Hicks i , C. Mohan i , S. Wenderfer i . 1Faculty of Medicine, Minia University, Rheumatology, Minia, Egypt; 2University of Houston, Biomedical Engineering, Houston, United States of America; 3Connecticut Children’s Medical Center, Connecticut, United States of America; 4Emory University, Atlanta, United States of America; 5Texas Children’s Hospital, Baylor College of Medicine, Houston, United States of America

Background: Proteomic screening is an efficient approach for identifying protein biomarkers in various inflammatory diseases. Our preliminary proteomic analysis revealed elevated levels of serum Axl, Ferritin, IGFBP4 and sTNFR2 in adult patients with active lupus nephritis (LN) (1). However, the role of these serum biomarkers in pediatric systemic lupus erythematosus (SLE) patients has not been examined.

Objectives: To evaluate the performance of 4 serum protein markers for detecting disease activity in pediatric patients with SLE.

Methods: 83 pediatric patients who fulfilled ≥4 ACR criteria for SLE and 25 healthy controls were recruited for serological testing of 4 protein markers identified by antibody-coated microarray screen, namely Axl, ferritin, IGFBP4 and sTNFR2. SLE disease activity was assessed using the SLEDAI-2k score, renal disease activity was assessed by the renal SLEDAI (range 0-16; 0 inactive LN, ≥ 8= active renal). 57 patients had clinically active SLE (SLEDAI score ≥ 4 or having a flare) (2) 28 active renal and 29 active non-renal SLE patients. In active renal
patients, concurrent renal biopsy was performed, unless contraindicated. The ISN/RPS criteria were used to assess the histopathologic features of LN. Those Patients were further subcategorized into 2 groups; active proliferative (ISN/RPS classes III/IV) and non-proliferative (classes III/IV).

**Results:**

The serum concentrations of Axl and ferritin were significantly higher in patients with active SLE than inactive SLE ($3765\pm235$ vs. $2513\pm130$ pg/ml, $P = 0.001$) and ($1111\pm26$ vs. $18\pm4$ ng/ml, $P = 0.0001$) respectively. Serum Axl levels were significantly higher in active renal versus active non-renal SLE patients ($3765\pm235.3$ vs. $2825\pm200.7$ pg/ml, $P = 0.04$). In the active renal patients with paired kidney tissue and blood samples, none of the biomarkers tested discriminated classes of LN, although serum Axl, ferritin and IGBP4 levels were higher in the proliferative subgroup. The levels of Axl, ferritin and IGBP4 correlated significantly with SLEDAI scores ($P = 0.58; P < 0.0001$; ferritin, $P = 0.53; P < 0.0001$; IGBP4, $P = 0.229$; $P = 0.03$). However, only serum Axl levels correlated significantly with the renal SLEDAI ($P = 0.46; P = 0.01$). The levels of Axl, IGBP4 and sTNFR2 correlated with decreased C3 levels ($P = 0.54; P < 0.0001$; Axl, $P = 0.29$; P = 0.007; ferritin, $P = 0.29$; P = 0.007) respectively. Only serum Axl and ferritin correlated with urinary PCR ($r = 0.42; P < 0.0001$; Axl, $P = 0.22$; $P = 0.04$) respectively. These markers were more specific, but less sensitive, in detecting concurrent SLE activity than elevated anti-dsDNA or decreased C3. The specificity of values serum ferritin and IGBP4 for concurrent active lupus nephritis were higher than anti-dsDNA or C3. Serum ferritin was the best predictor of global SLE activity ($AUC = 0.81$, $P < 0.0001$), followed by C3 ($AUC = 0.79$, $P < 0.0001$) $P = 0.03$). However, only serum Axl levels correlated significantly with the renal SLEDAI ($P = 0.46; P = 0.01$). The levels of Axl, IGBP4 and sTNFR2 correlated with decreased C3 levels ($P = 0.54; P < 0.0001$; ferritin, $P = 0.29$; P = 0.007) respectively. Only serum Axl and ferritin correlated with increased AIC ($r = 0.42; P < 0.0001$; $P = 0.22$; $P = 0.04$) respectively. These markers were more specific, but less sensitive, in detecting concurrent SLE activity than elevated anti-dsDNA or decreased C3.

**Conclusion:**

In pediatric SLE patients, serum ferritin and Axl perform better than traditional yardsticks in identifying disease activity, either global or renal. The performance of these serum markers should be explored further in a longitudinal cohort of pediatric SLE patients.

**SAT0235**

**THE EFFECT OF ANTIPHOSPHOLIPID ANTIBODIES ON APTT WAVEFORM PATTERNS**

Y. Suzuki1, A. Mitsu1, Y. Yamamoto1, K. Noda1, A. Nakajima1, 1Mie University Hospital, Center for Rheumatic Diseases, Tsu, Mie Prefecture, Japan

**Background:** Patients with antiphospholipid antibody (aPL) are said to be at increased risk for thrombosis, however it is difficult to predict whether they will develop thrombosis. In recent years, it has been revealed that the characteristics of the second derivative curve of APTT waveform with aPL positive patient is biphasic changes1,2. As first step in predicting the risk of thrombosis, we sought to understand the effect of aPL on APTT waveform patterns.

**Objectives:** To analyze the characteristics of APTT waveforms according to the background diseases and the presence of aPL.

**Methods:** Patients who underwent coagulation function tests from 2017 to 2019 were analyzed. A coagulation waveform (Clot waveform: CW) was drawn using a fully automatic coagulation time measuring device manufactured by Instrumentation Laboratory. The 1st derivative curve (DC) indicating the coagulation speed and the 2nd DC indicating the coagulation acceleration were depicted to measure the 1st DC height, 2nd DC peak 1 time, and 2nd DC peak 1 height (Fig 1). Patients were divided into CTD with aPL-positive patients (group A), aPL-negative patients (group B), and aPL-positive patients with no prior thrombosis (group C). APTT waveform patterns were analyzed. A coagulation waveform (Clot waveform: CW) was drawn using a fully automatic coagulation time measuring device manufactured by Instrumentation Laboratory. The 1st derivative curve (DC) indicating the coagulation speed and the 2nd DC indicating the coagulation acceleration were depicted to measure the 1st DC height, 2nd DC peak 1 time, and 2nd DC peak 1 height (Fig 1). Patients were divided into CTD with aPL-positive patients (group A), aPL-negative patients (group B), and aPL-positive patients with no prior thrombosis (group C). APTT waveform patterns were analyzed. A coagulation waveform (Clot waveform: CW) was drawn using a fully automatic coagulation time measuring device manufactured by Instrumentation Laboratory. The 1st derivative curve (DC) indicating the coagulation speed and the 2nd DC indicating the coagulation acceleration were depicted to measure the 1st DC height, 2nd DC peak 1 time, and 2nd DC peak 1 height (Fig 1).

**Results:** The APTT waveform was analyzed in 61 patients (51 women, 83.6%) with average age of 54.1 ± 17.1 years. Group A was 26 cases, Group B was 18 cases, and Group C was 17 cases. APTT, 2nd DC peak 1 time, 2nd DC peak 1 height, 1st DC peak time were significantly different among A, B, and C groups ($p < 0.01$). APTT, 1st DC peak height, 2nd DC peak 1 time, and 2nd DC peak 1 height differed among the number of aPLs ($p < 0.01$, respectively). APTT and 2nd DC peak 1 time prolonged by 9.43 (seconds) and 16.3 (seconds) respectively according to the number of aPLs increased, and 1st DC peak height (mabs/s) and 2nd DC peak 1 height (mabs/s) decreased by 56.4 (mabs/s) and 223.9 (mabs/s) respectively according to the number of aPLs decreased (Table 1). APTT> 35.2 (seconds) (sensitivity 80%, specificity 90%) were relevant to the presence of three aPLs.

**Conclusion:** The presence of aPL is more related to the 2nd DC peak 1 height of APTT waveform than APTT. A detailed review of the APTT waveform may further predict future thrombosis risk.

COMPLICATED WITH MALT LYMPHOMA

Background: The risk of developing lymphomas in Sjögren’s syndrome (SS) is more than 10-fold higher than in general population. Available publications describe a number of indicators considered as predictors for SS development. The study included 87 SS patients with MALT lymphoma. In all cases lymphoma involved the parotid salivary glands. In all cases MALT lymphoma was diagnosed simultaneously with SS. At the time of inclusion non of the patients was on immunosuppressive therapy. Fifty five SS patients without lymphoproliferative pathology composed the control group. All cases were newly diagnosed and were not on immunosuppressive therapy. SS was diagnosed based on the ACR-EULAR criteria. The histologic and immunohistochemical diagnosis of lymphoma was performed with B-cell clonality determination in salivary gland tissue.

The following clinical and laboratory parameters were monitored in both groups: rates of stage 3 xerostomia (>0.5 ml/5 min), grade 3 hypolacrinia (<5 mm/5 min), lymphadenopathy, hemorrhagic rashes, decreased C3, C4 complement components, increased RF, high anti-Ro and anti-La antibodies positivity, hematological changes, serum levels of secretory monoclonal antibodies, cryoglobulinemia, etc. Pearson’s x2 criterion (analysis of contingency tables) was used for statistical analysis. The differences were considered statistically significant when p values were <0.05. Statistica 10 for Windows (StatSoft Inc., USA) package was used for statistical data processing.

Results: In the study group 84 patients were females, their mean age at the onset of lymphoma was 53±10 years. The disease duration was 7 years (3-12) before the diagnosis was established. All patients in the control group were females, the mean age at diagnosis was 50.2±13 years. Patients’ age at diagnosis did not differ significantly between the groups. Enlarged salivary or lacrimal glands were found in all SS-MALT patients and in 18% of patients in the control group. The rates of such systemic manifestations as polyneuropathy, kidney and joint damage was low and did not differ between groups.

Increased levels of anti-Ro antibodies was documented in the majority of patients in both groups (87 % and 81%, p=0.4), while La antibodies were significantly more common in MALT lymphoma patients (40% and 30.3%, p=0.045). Similar rates of increased IgG and IgM levels were found in both groups, while increased IgA levels were 6-fold more common in the lymphoma group (p<0.00001). Anemia and leukopenia were documented in approximately 25%, and thrombocytopenia - in 2% of patients in both groups. Cryoglobulinemia (36% vs. 24%) and circulation of secretory monoclonal immunoglobulins (32% vs. 18%) were more common in the lymphoma group, but the difference was insignificant (p=0.2). The incidence of other clinical and laboratory abnormalities in SS and SS-MALT patients is presented on the graph Forest plot with OR and CI indication.

Conclusion: Therefore, universally recognized predictors of lymphoma development, such as cryoglobulinemia and hypocomplementemia did not show reliable association with lymphoma. In analyzed cohort development of MALT lymphoma was statistically significantly associated with recurrent parotitis in past medical history, presence of lymphadenopathy at diagnostic examination, increased levels of anti-La antibodies and IgA, and hypergammaglobulinemia. Probably we should more actively treat patients with these clinical and laboratory features in order to prevent the development of lymphoma in them.

SAT0237 THE SYSTEMIC LUPUS INTERNATIONAL COLLABORATING CLINICS (SLICC) FRAILTY INDEX (SLICC-FI) PREDICTS DAMAGE ACCRUAL IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS. DATA FROM A LATIN AMERICAN MESTIZO COHORT

M. P. Ugarte-Gil1, 2, R. V. Gamboa Cárdenas1, C. Reategui Sokolova1, 3, V. Pimentel-Quiroz2, M. Medina Chinchón1, C. Elara-Fitzcarrald2, 3, J. Alfaro Lozano1, 2, Rodríguez Bellido1, 3, C. Pastor Asurza1, 2, R. Perich Campos1, 3, G. S. Alarcon1, 2, 3, 6. 1Hospital Guillermo Almenara Irigoyen, EsSalud, Lima, Peru; 2Universidad Científica del Sur, Lima, Peru; 3Universidad San Ignacio de Loyola, Unidad de Investigación para la Generación y Síntesis de Evidencias en Salud, Lima, Peru; 4Universidad Nacional Mayor de San Marcos, Lima, Peru; 5University of Alabama at Birmingham, Birmingham, United States of America; 6Universidad Peruana Cayetano Heredia, Lima, Peru

Background: The Systemic Lupus International Collaborating Clinics (SLICC) Frailty Index (SLICC-FI) has been developed as a predictor of outcomes in SLE patients1. However, it needs to be validated in several populations.

Objectives: To evaluate the SLICC-FI as a predictor of future damage accrual in systemic lupus erythematosus (SLE) patients.

Methods: Patients from a single-center prevalent cohort were included. Damage accrual was defined as the increase in SLICC/ACR damage index (SDI) scores between the baseline and last visits. The SLICC-FI was measured at baseline. Univariable and multivariable negative binomial regression were performed to determine the association between the baseline SLICC-FI (per 0.05 increase) and damage accrual during follow-up, adjusted for sex, age at diagnosis, socioeconomic status, disease duration, SLE Disease Activity Index 2000 (SLEDAI-2K), SDI, prednisone daily dose, antimalarial and immunosuppressive drug use at baseline, and duration of follow-up.

Results: Of the 265 patients included, 248 (93.6%) were female with mean (SD) age 35.1 (13.6) years at diagnosis. At baseline, mean (SD) SLE disease duration was 7.3 (6.5) years, SDI was 1.1 (1.3) and SLEDAI-2K was 5.3 (4.6). The mean (SD) baseline SLICC-FI was 0.22 (0.05). After a mean (SD) of 5.2 (2.2) years of follow-up, the SDI increased in 126 (47.5%) patients, and the final mean (SD) SDI score was 1.7 (1.7). Higher SLICC-FI scores at baseline predicted greater damage accrual in the univariable analysis (Incidence Rate Ratio (IRR)=1.283, (CI95% 1.072-1.536); p=0.007). The SLICC-FI remained associated with damage accrual in the multivariable model, after adjustment for possible confounders (IRR=1.224 (CI95% 1.007-1.488); p=0.042).

Conclusion: The SLICC-FI predicts damage accrual in prevalent SLE, supporting the relevance of this index in the evaluation of SLE patients. This is the first study validating the SLICC-FI in South American population.

Background: Adjusted global antiphospholipid syndrome score (aGAPSS) is the simplified version GAPSS that was recently developed to assess thrombotic risk by the consideration of antiphospholipid antibody (aPL) profile and conventional cardiovascular risk factors.

Objectives: The aim of this study was to evaluate the validity of the aGAPSS in predicting thrombosis and extra-criteria manifestations in our antiphospholipid syndrome (APS) cohort.

Methods: Ninety-eight patients with APS were classified according to clinical manifestations as vascular thrombosis (VT), pregnancy morbidity (PM) or both (VT+PM). The aGAPSS was calculated as defined before. Arterial hypertension and hyperlipidemia definitions were made according to the ESC/ESH and NCEP/ATP III guidelines, respectively.

Results: Demographic, laboratory and clinical characteristics of patients are summarized in table-1. Mean aGAPSS was calculated as 10.2 ± 3.8. Significantly higher aGAPSS values were seen in VT (n=56) and VT+PM (n=29) compared to PM (n=11) (mean aGAPSS 10.6 ± 3.7 vs 7.3 ± 2.9, P=0.005; 10.5 ± 4 vs 7.3 ± 1.0, P=0.04, respectively).

Conclusion: Our results suggest that patients with higher aGAPSS values are at higher risk for developing vascular thrombosis (either single or recurrent) and extra-criteria manifestations, especially livedo reticularis and APS nephropathy.

Renal biopsy was performed in 3 patients: crescentic glomerulonephritis was found in 2 patients and one had a thrombotic microangiopathy. Treatment: 25 patients (75.7%) were anticoagulated with vitamin K antagonists, 19 (57.6%) received immunosuppressive therapies, 18 (54.5%) were on statins. Ten patients (30.3%) were managed surgically with balloon angioplasty. Restenosis occurred in 4/10 patients (40%) and percutaneous renal artery stenting was performed successfully in all four. Ten patients died (30.3%). Renal outcomes are shown in Table 2.

Figure 1. ROC curve according to cut-off aGAPSS value: 10 (AUC: 0.71, sensitivity: 0.52, specificity: 0.91, positive predictive value: 0.98, negative predictive value: 0.19, p-value: 0.01).
In the univariate analysis, surgery was significantly associated with a lower probability of reaching CKD (p=0.042; OR 0.2; 95% CI 0.03-0.94). In the multivariate analysis, the tendency to benefit from surgery was maintained but the statistical significance was lost, probably due to the low number of patients.

In the subgroup analysis, the tendency to benefit from surgery was maintained in patients with or without anticoagulation, immunosuppressants, statins, with primary or secondary APS, with uni- or bilateral stenosis, with or without dyslipidemia, but this benefit was lost in smokers independent of the grade of stenosis.

Conclusion: RAS is a treatable cause of hypertension and a poor prognostic marker in APS patients.

In this study, APS patients with RAS who underwent intervention with angioplasty or stenting had a trend to a lower probability of developing CKD in contrast to studies in atherosclerotic RAS. The beneficial effect of surgery was lost in smoking patients. In this relatively young population mortality was high.

**THE PROGNOSIS OF TWO DISTINCT CLINICAL PHENOTYPES OF SLE-PAH**

J. Wang1, Y. Feng1, Y. Lei1, X. Zhang1, 1Guangdong Provincial People’s Hospital, Rheumatology, Guangzhou, China

**Background:** Based on the characteristics of systemic lupus erythematosus-associated pulmonary arterial hypertension (SLE-PAH), Sun et al has put forward a scoring system to distinguish two clinical phenotypes as vasculitic and vasculopathic subtypes[1]. A weighted score ≥2 suggested a vasculitic subtype by combining two factors: The time interval between SLE and PAH diagnosis <2 years and ≥2 years were 1 and 0 point; SLE Disease Activity Index (SLEDAI) >9, 5-9 and <5 were 2, 1, 0 point, respectively. While the vasculopathic subtype seemed to have poorer prognosis in Sun’s research, other study has shown controversial result[2].

**Objectives:** To find out the prognosis of two distinct clinical phenotypes of SLE-PAH.

**Methods:** Between 2008 and 2019, a SLE-PAH cohort confirmed by right heart catheterization (RHC) from Guangdong Provincial People’s Hospital was included. Other groups of pulmonary hypertension were excluded. Based on the scoring system, patients were divided into vasculitic (weighted score≥2) and vasculopathic subtypes (weighted score<2). The endpoint was PAH-related mortality. Survival status were confirmed by clinic follow-up data or phone call.

**Results:** A total of 53 SLE-PAH patients were enrolled. The cases of vasculitic and vasculopathic subtype were 14 and 39, respectively. Ten endpoint events occurred. Eight attributed to PAH and the cause could not be traced in two which were still included in study. The pooled 1-, 3-, 5-year survival rates were 85.7%, 78.6%, 65.5% in vasculitic subtype, and 93.9%, 87.5%, 87.5% in vasculopathic subtype, respectively. Kaplan-Meier analysis showed vasculitic subtype tended to have a poorer prognosis than vasculopathic subtype (p=0.16, HR 2.4, 95%CI 0.5-13.8, figure 1).

**Conclusion:** The prognosis of the two phenotypes of SLE-PAH was statistically indifferent while the vasculopathic subtype showed a trend of worse prognosis. Further studies are needed.

**SAT0241**

**PLATELET INDICES COULD BE SIMPLE RELIABLE PREDICTORS OF THROMBOTIC EVENTS IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME**

J. Zhao1, M. Li1, Q. Wang1, X. Tian1, X. Zeng1, 1Peking Union Medical College Hospital, Rheumatology, Beijing, China

**Background:** Platelet activation is considered as a pivot pathogenic process to be responsible for thromboembolism in antiphospholipid syndrome (APS), several studies shown that platelet indices including platelet distribution width (PDW), mean platelet volume (MPV), large platelet rate (P-LCR) are associated with platelet activation.

**Objectives:** This study aims to determine the correlation between platelet indices and thrombotic events in patients with APS.

**Methods:** Platelet activation is considered as a pivot pathogenic process to be responsible for thromboembolism in antiphospholipid syndrome (APS), several studies shown that platelet indices including platelet distribution width (PDW), mean platelet volume (MPV), large platelet rate (P-LCR) are associated with platelet activation.

**Results:** A total of 207 patients [135(65.2%) female, 72(34.8%) male], median age 35(IQR 10) was classified into thrombotic group (n=150,75.2%) and non-thrombotic group(n=57,27.5%). PDW, MPV, P-LCR were significantly higher in thrombotic group than non-thrombotic group (143±29 vs. 132±15, p=0.001). Upon univariate logistic analysis, PDW (OR 1.554, 95%CI 1.289-1.873, p<0.001), MPV (OR 1.772, 95%CI 1.289-2.476, p<0.001), P-LCR (OR 1.089, 95%CI 1.040-1.140, p<0.001) were all significantly associated with the occurrence of thrombosis. In multivariate logistic analysis, only PDW and positive LA were identified to be risk factors of thrombotic events (Table 1). The ROC curve showed that PDW combined with positive LA was a reliable indicator of thrombotic events with an AUC of 0.796 (95%CI 0.728-0.864). The optimal cut-off value for PDW was 12.4fl with a sensitivity of 72.0% and specificity of 77.2%.

**Conclusion:** This study confirmed that PDW, P-LCR and MPV (especially PDW) were significantly associated with thrombotic events in APS patients, which could support the theory of platelet activation being a crucial factor of thrombosis inAPS. Caution should be raised when patients with positive LA has relatively high PDW level.

**REGIONAL VARIATION IN CARDIOVASCULAR DISEASE AMONG SLE PATIENTS**

Y. Zheng1, H. Xie2, L. Li1, J. Esdaile1,3, A. Aviña1,3, 1Arthritis Research Canada, Richmond, Canada; 2Simon Fraser University, Health Sciences, Burnaby, Canada; 3The University of British Columbia, Vancouver, Canada

**Objectives:** To evaluate whether the risk of cardiovascular disease (CVD) including myocardial infarction (MI) and cerebrovascular (CVA) differs across geographic regions among SLE patients.

---

**Figure 1.** Survival curves for patients with systemic lupus erythematosus-pulmonary arterial hypertension (SLE-PAH) in two distinct subtypes. RHC, Right Heart Catheterization.
Methods: We identified SLE patients using two ICD codes 60 days apart within two years recorded in Medical Services Plan (MSP) or hospital discharge database (DAD). We defined the second of two diagnosis dates as the index date.

We included incident SLE patients with at least one year continuous registry in MSP before the first diagnosis date with an index date between 1997 and 2012 and excluded patients with previous MI or CVA before the index date. We followed each patient from the index date up to 10 years and censored at the date of death date, leaving the province, or March 31, 2015.

We assessed the incident CVD that was defined as the first ever diagnosis of MI or CVA recorded in DAD or as the primary cause of death in Vital Statistics. We also evaluated MI and CVA separately.

The Province’s publicly administered and funded health care system is organized into five regional health authorities (HA): Interior (IHA), Fraser (FHA), Vancouver Coastal (VCHA), Vancouver Island (VIHA), and Northern Health Authority (NHA) [Figure 1(a)]. We assigned each patient the HA she/he was registered to during a period of 365 days prior to the index date, including socio-demographic characteristics, health care resource use, comorbidities, and prescription medication use. We calculated the incident rate (IR) of MI, CVA, and CVD (first ever MI or CVA) by HA. Using Cox Proportional Hazard model adjusting for potential confounders at baseline, we estimated the adjusted hazard ratios (aHR) of CVD for each HA compared to FHA or VCHA which have the large proportion of provincial population and SLE patients. We evaluated the regional disparities in MI and CVA separately using the same methods.

Results: We included 3,960 incident SLE patients free of CVD at baseline with a mean (SD) age of 48.5 (15.8), including 726 (18.3%) from IHA, 1,634 (42.3%) from FHA, 854 (21.6%) from VCHA, 504 (12.7%) from VIHA, and 242 (6.1%) from NHA [Figure 1(b)].

PROGNOSIS OF LARGE VESSEL INVOLVEMENT IN LARGE VESSEL VASCULITIS

M. Vautier1, A. Dupont2, H. De Boysson3, C. Comarmond1, T. Miravitlles4, A. Mekinian5, M. Lambert1, Y. Ferrat1, A. Aouba2, P. Cacoub2, M. Resche-Rigon2, D. Saadoun1; 1University Hospitals Pitie Salpetriere - Charles Fox, Paris, France; 2Hospital , Saint-Louis Ap-Hp, Paris, France; 3Caen, Caen, France; 4Hôpital Européen Georges-Pompidou, Paris, France; 5Hospital Saint-Antoine Ap-Hp, Paris, France

Background: Giant cell arteritis (GCA) and Takayasu arteritis (TAK) are the two main forms of large vessels vasculitis (LVV). Vessel inflammation leads to aneurysms, wall thickening, stenosis, and, in some cases, complete occlusion of the artery. Due to the wide variation in the course of LVV, predicting outcome is challenging. To our knowledge, data regarding prognosis factors of LVV in LVV patients and comparison of outcome of LVV in GCA and TAK are lacking. An early identification of patients with higher mortality could help to prevent deaths and vascular complications.

Objectives: To assess prognosis factors and outcome of large vessel involvement (LVI) in large vessels vasculitis (LVV) patients.

Methods: Retrospective multicenter study of characteristics and outcomes of 417 patients with LVV including 299 Takayasu arteritis (TAK) and 118 Giant cell arteritis (GCA-LVI) were analyzed. Logistic regression analysis assessed prognosis factors in LVV patients. Outcome of LVI among TAK and GCA-LVI patients (ischemic complications, aneurysms complications, relapses and revascularization) were assessed.

Results: In multivariable analysis, stroke/transient ischemic attack [HR: 3.63 (1.46 - 9.04), p=0.006] was independently associated with vascular complications in LVV. The 10-years aneurysm free survival was significantly lower [67% (48 – 93) vs 89% (84 – 95), p=0.02] in GCA-LVI compared to TAK patients. The 5-years relapse free survival was significantly lower [47% (37 – 60) vs 89% (63 – 75), p=0.001] in GCA-LVI compare to TAK patients. The 10-years revascularization free survival was significantly lower [55% (48 – 64) vs 76% (59 – 99), p=0.001] in TAK compared to GCA-LVI patients. After a median follow-up of 5 years, 16 (5.4%) TAK and 7 (5.9%) GCA-LVI patients died, mainly of aneurysm (26%) and ischemic complications (26%).

Conclusion: This large nationwide cohort of LVI provided prognosis factors of vascular complications in LVV patients. TAK and GCA-LVI have different long-term outcome in term of aneurysm development, relapse and revascularization.

RENAL INVOLVEMENT AT ONSET IN ANTI-NEUTROPHIL CYTOPLASMIC ANTI BODY (ANCA)-ASSOCIATED VASCULITIS: A MAJOR INDEPENDENT RISK FACTOR FOR RENAL RELAPSE

M. Felicetti1, A. Ortolan1, A. C. Frigo2, R. Padoan3, M. Gasparot1, M. Lorenzin1, A. Doris1, R. Ramonda1, F. Schiavon1. 1University of Padova, Department of Medicine DIME-D Rheumatology Unit, Padova, Italy; 2University of Padova, Department of Cardiac, Thoracic and Vascular Sciences-Biostatistics, Epidemiology and Public Health Unit, Padova, Italy

Background: In ANCA-associated vasculitis (AAV), renal relapses are cause for concern as they are unpredictable and predictors of end-stage renal disease (ESRD).

Objectives: We aimed to assess the frequency of major renal (MR) relapses in AAV in our cohort and identify independent predictors of the first MR relapse at diagnosis.

Methods: We performed a retrospective monocentric observational study in our Vasculitis clinic from January 2000 to August 2019. Inclusion criteria were: 1) granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and limited kidney disease (LKD) diagnosis fulfilling EMA algorithm criteria; 2) achievement of a stable remission, defined as absence of vasculitis symptoms or signs and adherence to the prednisone taper during remission-induction treatment. We excluded patients who developed ESRD before remission and those with incomplete data during the follow-up. Major renal (MR) relapses were defined as occurrence of at least one major item of renal Birmingham Vasculitis Activity Score version 3 (BVASv3).

All remitted patients were allocated in two subgroups: patients without MR relapse and patients with MR relapse. Univariate and multivariable analysis of first MR relapse predictors was performed with Fine and Gray (F&G) subdistribution hazard model to assess all competitive risks (progression to ESRD without MR relapse and death before MR relapse). Due to the relatively low frequency of events and the risk of overfitting, we performed several multivariable models with three variables, as recommended by Peduzzi et al. The best multivariable model was selected accordingly to the Akaike information criterion (AIC).

Results: 96 (53.5%) females patients met the inclusion criteria; 74 GPA, 21 MPA and 1 LKD. Median age at diagnosis was 54 (44-64) years. ANCA testing was present in 94 patients, 85 were ANCA positive: 56 c-ANCA/PRF, 28 p-ANCA/MPO and 1 double positivity.

During a median follow-up (FU) of 54.5 months (29.3-98.6), we observed 19 MR relapses in 17 patients while 2 patients progressed to ESRD, 3 died without events and 76 reported no MR relapse. Density-incidence of MR relapses since remission was 3.6/100 person-year (CI 95%: 2.2-5.6). Median time to first MR relapse after remission was 33 months (14-675).

At first MR relapse, 8 (53.3%) patients were on steroids while 10 (66.7%) were on immunosuppressant (5 azathioprine, 5 mycophenolate). In 2 cases, data about remission-maintenance treatment was not available.

MR relapses were observed only in ANCA positive patients with a significantly higher frequency of skin, kidney and nerve involvement at diagnosis (41.2% vs 17.7%, p=0.034, 94.1% vs 57.0% p=0.004, and 52.9% vs 25.3% p=0.024, respectively); while Ear, Nose and Throat (ENT) involvement was significantly lower (48 – 64) vs 76% (59 – 99), p<0.001.

At multivariable analysis with F&G model, renal involvement and induction treatment without cyclophosphamide and/or Rituximab at diagnosis were independent predictors of MR relapse (HR: 3.63 (1.46 - 9.04), p=0.006). Moreover, we observed a trend of higher risk of MR relapse in patients who developed ESRD before remission and those with incomplete data during the follow-up. At multivariable analysis with F&G model, renal involvement and induction treatment without cyclophosphamide and/or Rituximab at diagnosis were independent predictors of MR relapse (HR: 3.63 (1.46 - 9.04), p=0.006). Moreover, we observed a trend of higher risk of MR relapse in patients who developed ESRD before remission and those with incomplete data during the follow-up (HR: 2.94 (1.26 - 6.81), p=0.01).

Conclusion: Renal involvement at diagnosis and milder remission-induction treatment regimens resulted in a significantly higher risk of MR relapse during the FU in our cohort. PR3-ANCA specificity was not an independent predictor of MR relapse, even if we observed a trend of higher MR relapse risk with this covariate.

References:
DAH can be immune-mediated (IM-IMH), e.g. anti-neutrophil cytoplasmic antibody (ANCA) vasculitis and systemic lupus erythematosus, but DAH may also result from anticoagulation, heart failure, drugs or inhaled toxins. Since IM-DAH has specific therapies available, we hypothesized that patients with IM-DAH would have a better prognosis.

Objectives: We did a retrospective analysis of all DAH cases seen at our university hospital in the last 12 years to investigate the predictors of adverse outcomes.

Methods: Using Epic radiant and Agfa Radiology Information System databases, we queried electronic medical records of all patients admitted to our university between January 2007 to Jan 2019 who had the words “diffuse alveolar hemorrhage” in their chest x-ray report. We manually reviewed charts of all these patients to confirm true DAH. True DAH was defined as suspicion of DAH on chest x-ray plus inclusion of DAH on the discharge problem list. We did a detailed chart review of true DAH cases to extract information regarding demographics, baseline disease characteristics, physical/serology/imaging findings, treatment received, and outcomes. The outcomes of interest were death, intubation, shock, need for hemodialysis (HD), and red blood cell transfusions. We compared IM-DAH with non-IM-DAH cases using descriptive statistics, t-test, and chi-squared tests. We used logistic regression models to assess the influence of baseline characteristics on outcomes. A p-value < 0.05 was considered statistically significant.

Results: There were 88 cases of DAH (M:F 54:34, median age 57) fulfilling inclusion criteria (Table 1). The non-immune etiology was diagnosed in 63%, while 36% were IM-DAH (18% ANCA associated, 9% SLE, 2% decompensated heart failure, the rest were others). No clear etiology for DAH was found in 37.5%. Deaths within 90 days of onset of DAH occurred in 37.5%, 5.6% had recurrent DAH, and 8% had sustained remission. Non-IM-DAH cases had worse outcomes such as death and were less likely to experience sustained remission (Chi-squared = 19.1, p < 0.001), though IM-DAH were more likely to receive HD (Chi-squared = 7.5, p-value 0.01). Presence of extrapulmonary findings (e.g. nephritis) was a risk factor for adverse outcome, and was statistically significantly correlated with the amount of blood products received, need for HD and likelihood of death, which did not reach statistical significance. Shock and intubation were associated with a higher likelihood of death (p = 0.02 and p = 0.001, respectively).

</table>

Conclusion: DAH, a life-threatening condition, has both immune and non-immune etiologies. Our 12-years, single-center, university hospital experience showed that IM-DAH has a better prognosis than non IM-DAH. Presence of extrapulmonary manifestations was associated with worse outcomes.

**Background:** Maintenance therapy following remission induction in ANCA associated vasculitides (AAV) is required to prevent relapse but patients are also still at risk from long term organ damage. This can be due to disease activity and also adverse events from therapy in particular high dose and prolonged use of glucocorticoids (GC).

**Objectives:** This retrospective study aimed to examine clinical outcomes and in particular the drug treatment used for maintenance in AAV patients managed in routine clinical practice in Europe.

**Methods:** 1478 AAV patients (France, Germany, Italy, Spain and UK) managed by 493 physicians (37% Rheumatologists) who completed induction therapy for organ or life threatening AAV and initiated maintenance therapy between 2014-16 were studied. Data were collected at the time maintenance was determined to begin by the physician and then at 6, 12, 18 and 36 months. 49% had granulomatosis with polyangiitis; mean age 54.2 years with 56% male. 49% had incident AAV and 51% were studied from a relapse. 70% received cyclophosphamide and 30% received rituximab (RTX) and GC for remission induction therapy.

**Results:** Definition of maintenance start from the time of incidence/relapse and initial maintenance therapy varied between incident patients (mean time 4.7 months, GCs 66%, Azathioprine 38%, RTX 19%, Cyclophosphamide 11%) and relapsed patients, 38% patients relapsed, 18% minor and 10% major (who then left follow up in this study). This led to greater GC use in the minor relapse patients at 36 months compared to those maintaining remission without relapse (48% vs 38%).

**Conclusion:** Maintenance therapy regimes used in clinical practice in Europe are variable including on basis of incident vs relapsing disease yet full remission is often not maintained. Many patients remain on GCs for long periods placing the patients at higher risk of GC related adverse events and organ damage. Even minor relapse increases the prolonged use of GCs. The high burden of protracted GC use in AAV should be more clearly recognized and new therapeutic approaches explored.

---

**Background:** Clinical presentation of GCA is protean. It is vital to make a secure diagnosis, exclude mimics urgently and avoid inappropriate steroids to minimise side effects. Fast track GCA clinics (FTCs) provide rapid specialist assessment with temporal and axillary US (1). EULAR recommendations support US as first-choice test. A pre-test probability score (PTPS) stratifies patients to low (LC), intermediate (IC) and high-risk (HC) categories.

**Objectives:** To validate a diagnostic GCA algorithm based on stratification by PTPS, with sequential US and additional tests (AT), if necessary

**Methods:** For the algorithm (Figure) retrospective data was extracted from case records of cases seen in 2019. PTPS overall showed median (Q2) score of 9.75th percentile (Q3) score 12. Based on this and reported cut-off 9.5 (2) we classified LC as PTPS <9, IC 9-12 and HC >12 (Graph). GCA diagnosis was by modified GiACTA including US (Hal0), CRP > 5mg/L and AT if necessary. The algorithm performance was assessed overall and in individual categories.

**Results:** Of 187 consecutive cases, 13 were excluded for incomplete data (tertiary referrals). In remaining 174, GCA confirmed 33%, mean age 72.4 years, 69% females,45% LC, 35% IC, and 20% HC. 130 (75%) had US whereas 44 did not (41 LC, 3 IC) (Figure)

In HC, 25/31 (81%) were US -ve, 19 treated as GCA without AT, 6 with AT (Table 2). Of 6 US -ve 3 had GCA confirmed by AT (PET-CT 2, TAB 1). US in HC showed sensitivity 89%, specificity 75%, accuracy 87%, GCA prevalence 87%, mean CRP 65.52 (SEM+/- 8.67). In LC, 38 (49%) were US -ve, of whom 5 had AT. US not done on 39 (50%) for either PTPS very low or urgent alternative diagnosis. 1 went on to AT. 1 was US positive and had GCA excluded with AT. US in LC showed specificity 99%, sensitivity 90% (undefined), accuracy 99%, GCA prevalence 0%, mean CRP 21.79 (SEM+/-. 3.80)

**Graph-1:** Categories according to the probability score

*P values are for the comparison between the males and females.

### Conclusion:
Chinese BD patients can effectively perform BOCAF and EMRAI self-assessment with SSDM. The results of the assessment conducted by the two scoring systems are similar. The clinical characteristics of Chinese BD were different depending on gender.

### Acknowledgments:
Smart system of disease management (SSDM) was developed by Shanghai Gothic Internet Technology Co., Ltd.

### Disclosure of Interests:
None declared.

### Background:
Angiography is essential to detect vascular disease in patients with large- vessel vasculitis (LVA). Guidelines differ on the role of periodic angiography to monitor patients with LVA, in part because there is limited prospective data characterizing the natural history of angiographic disease. Development of new areas of arterial damage, even in periods of apparent clinical remission, has been reported in LVA; however, whether this is a common or rare phenomenon is unknown.

### Objectives:
To characterize angiographic progression of disease over time in Takayasu’s arteritis (TAK) compared to giant cell arteritis (GCA).

### Methods:
Patients with SCA or TAK were recruited into a prospective, observational cohort. Patients fulfilled the 1990 American College of Rheumatology (ACR) Classification Criteria for TAK or modified 1990 ACR Criteria for GCA.

Wu2 on behalf of SSDM Collaboration Group, China; 1Tongji Hospital Affiliated to Tongji Medical College of HUST, Wuhan, China; 2The First Affiliated Hospital of the Air Force Medical University, Xi’an, China; 3First Affiliated Hospital of Medical University of Anhui, Anhui, China; 4The First People’s Hospital of Yunnan Province, Kunming, China; 5Affiliated Tongji Medical College of HUST, Wuhan, China; 6The First Affiliated Hospital of Xingjiang Medical University, Urumqi, China; 7The First Teaching Hospital of Tianjin University of TCM, Tianjin, China; 8Beijing Arthritis Hospital, Capital Medical University, Beijing, China; 9Shanghai Gothic Internet Technology Co., Ltd., Shanghai, China; 10People’s Hospital of Xinqian Uyghur Autonomous Region, Urumqi, China

**Background:** Behcet’s disease (BD) is a systemic autoimmune disease that affects multiple organ systems with recurrent oral ulcers, genital ulcers and skin lesions. Behcet’s Disease Current Activity Form (BOCAF) and Electronic Medical Record-based Activity Index (EMRAI) are commonly used internationally to evaluate the disease activity of BD.

**Objectives:** This study aimed to analyze the clinical characteristics, the level of disease activity, and the incidence of anxiety and depression for Chinese BD patients. Patients can perform self-management of disease with SSDM. Patients could obtain scores of BOCAF and EMRAI by responding to one questionnaire through SSDM.

**Methods:** SSDM is a series of doctor-patient interactive applications for self-management of patients with chronic diseases. Patients can perform self-assessment with SSDM and upload the data to their authorized doctors. The SSDM patients’ application system integrates the BOCAF and EMRAI into one scoring system.

**Results:** From Apr 2017 to Jan 2020, 719 BD patients from 166 hospitals used SSDM with a mean age of 38.97±12.71 (14–81) years old, and median disease duration of 20.6 months. 719 patients performed BOCAF and EMRAI self-assessment 1321 times, 252 patients repeat assessments for 855 times. The mean score of BOCAF and EMRAI are 3.57±2.17 and 3.44±1.90, respectively. The matching degree of the two score was 0.8747.

The most common clinical characteristics were oral ulcers (83.73%), ocular symptoms (62.03%), joint pain (50.07%). The comparative study between males and females revealed significant difference in the aspects of epididymitis (10.94% vs 0, p<0.001), genital ulcer (35.09% vs 44.93%, p=0.01), headache (24.15% vs 33.92%, p=0.01) and superficial thrombophlebitis (24.15% vs 33.92%, p=0.01). The clinical characteristics of Chinese BD were different depending on gender.

**Conclusion:** Chinese BD patients can effectively perform BOCAF and EMRAI self-assessment with SSDM. The results of the assessment conducted by the two scoring systems are similar. The clinical characteristics of Chinese BD were different depending on gender.

**SAT0251**

**ANGIOGRAPHIC PROGRESSION OF DISEASE IN LARGE-VESSSEL VASCULITIS**

K. A. Quinn1,2, H. Dashora1, M. Altman2, P. Grayson1. 1National Institutes of Health, Bethesda, United States of America; 2Georgetown University Hospital, Washington, DC, United States of America

**Background:** Angiography is essential to detect vascular disease in patients with large- vessel vasculitis (LVA). Guidelines differ on the role of periodic angiography to monitor patients with LVA, in part because there is limited prospective data characterizing the natural history of angiographic disease. Development of new areas of arterial damage, even in periods of apparent clinical remission, has been reported in LVA; however, whether this is a common or rare phenomenon is unknown.

**Objectives:** To characterize angiographic progression of disease over time in Takayasu’s arteritis (TAK) compared to giant cell arteritis (GCA).

**Methods:** Patients with SCA or TAK were recruited into a prospective, observational cohort. Patients fulfilled the 1990 American College of Rheumatology (ACR) Classification Criteria for TAK or modified 1990 ACR Criteria for GCA.
All patients underwent baseline magnetic resonance angiography (MRA) and a follow-up MRA at least one year after baseline per a standardized imaging protocol. The presence of angiographic lesions, defined as stenosis, occlusion, or aneurysm, was evaluated by visual inspection by a single reader who was blinded to clinical status. Angiographic lesions were evaluated in 4 segments of the aorta and in 13 branch arteries. On follow up angiography, the development of new lesions was recorded, and existing lesions were characterized as improved, worsened, or unchanged.

**Results:** 782 arterial territories were evaluated from 46 patients with LVV (TAK=28; GCA=18). Baseline characteristics were as follows: Age [TAK=24.8 years (18.6-34.9), GCA=64.8 years (57.8-73.9)]. Female gender [TAK=21 patients (78%), GCA=16 patients (64%)]. Disease duration [TAK=2.3 years (0.6-4.9), GCA 1.2 years (0.4-2.9)], Active clinical disease [TAK=12 patients (44%), GCA 12 patients (63%)]. The median time from initial MRA to follow up MRA was 2.4 years (1.5-3.1) for GCA and 16 years (1.3-3.3) for TAK. There were 150 territories affected at the baseline visit in 41 patients [TAK: 108 territories in 26 patients, GCA: 51 territories in 15 patients]. The development of new territory involvement was infrequent and only occurred in patients with TAK (8 new lesions out of 352 baseline unaffected territories (2.3%) in 5 patients).

At follow up, existing arterial lesions improved in 25 (15.7%) territories, worsened in 6 (3.8%) territories, and stayed the same in 128 (80.5%) territories. There were no significant differences in angiographic progression of disease between the two diseases: improved - TAK 19 (17.6%), GCA 6 (11.8%); worsened - TAK 5 (4.6%), GCA 1 (1.9%); unchanged - TAK 84 (77.8%), GCA 44 (86.3%). Change in the branch arteries was more dynamic than change in the aorta (Figure).

Improvement in angiographic disease was observed in 8 (17%) patients (TAK=6, GCA=2). Worsening of disease was seen in 3 (7%) patients (TAK=2, GCA=1). In 5 (11%) patients (4 new territories), there were areas of improvement and other areas of worsening disease within the same patient.

**Conclusion:** Dynamic change in arterial lesions is observed in patients with TAK and GCA. Improvement and worsening of arterial lesions can be observed over time, even within the same patient. This observation suggests that both local factors at the level of the artery and systemic factors (e.g. treatment response) are likely associated with angiographic progression. The development of new angiographic lesions was infrequent, and only occurred in patients with TAK. These data may inform future guideline recommendations for angiographic monitoring in LVV.

**SAT0253**

**ANTI-NEUTROPHIL CYTOPLASMAIC ANTIBODIES PREDATE SYMPTOM ONSET OF ANCA-ASSOCIATED VASCULITIS. A CASE-CONTROL STUDY**

E. Berglind1, A. J. Mohammad2,3, J. Dahlqvist1, C. Eriksson1, S. Sjöwall1, S. Rantapää Dahlqvist2,3, Umeå University, Umeå, Sweden; University of Cambridge, Cambridge, United Kingdom; Lund University, Lund, Sweden; Uppsala University, Uppsala, Sweden; Linköping University, Linköping, Sweden

**Background:** Presence of anti-neutrophil cytoplasmic autoantibodies (ANCA) is important for the diagnosis of ANCA-associated vasculitis (AAV) and reflects on-going immune processes. The timing of the antibody development and its contribution to disease is not well established.

**Objectives:** To investigate the presence of proteinase 3 (PR3)- and myeloperoxidase (MPO)-ANCA in blood samples collected from healthy individuals who subsequently developed AAV.

**Methods:** The Swedish National Patient Register of inpatient care and the Swedish Cause of Death Register were used to identify individuals assigned ICD codes for AAV (1) in the discharge summary or cause of death, respectively. The resulted cohort was then linked to the registers of 4 different biobanks to identify those with available predating blood samples. Diagnoses of AAV were confirmed and time point for onset of symptoms was identified by reviewing all available case records (1). 68 were classified as granulomatosis with polyangiitis (GPA), 14 as microscopic polyangiitis (MPA), and 4 as eosinophilic GPA (EGPA). The 86 cases (36 males, 50 females) had a median (SD) age of 51.9 (16.9) years at sampling, with 21 sample (26% plasma, 74% serum samples). The sampling time point before onset of symptoms was mean (SD): 4.4 (3.1) years. Serum and plasma control samples (n=198; 82 males, 116 females; mean age (SD): 52.0 (16.4) years) were identified and matched for sex, age and date of sampling. The samples were first screened for ANCA using high sensitive ELISA (ORGANTEC diagnostika, Germany) and samples close to or above cut-off level were further analysed for capture PR3- and capture MPO-ANCA (ELISA; SVAR Life Science). The presence of ANCA was confirmed using an ELISA-based non-commercial bead assay (American Diagnostica, Connecticut, USA).

**Results:** The median age at time of sampling was 52.0 (SD 16.9) years. There were no significant differences in general characteristics between the patients with ANCA and those without ANCA.

**Conclusions:** The results of the present study support the hypothesis that ANCA develops in the preclinical phase of AAV and suggests that ANCA could be used as a biomarker for the diagnosis of AAV in the future.
SAT0254 PROSPECTIVE ANALYSIS OF THE PREVALENCE OF GIANT CELL ARTERITIS IN CONSECUTIVE PATIENTS WITH POLYMYALGIA RHEUMATICA
L. C. Burg1, C. Behnig2, P. Brossart3, V. S. Schäfer1.1 Clinic for Internal Medicine III, University Hospital Bonn, Rheumatology, Bonn, Germany; 2University Hospital Bonn, Institute for Medical Biometry, Informatics and Epidemiology, Bonn, Germany; 3Clinic for Internal Medicine III, University Hospital Bonn, Oncology, Haematology and Rheumatology, Bonn, Germany

Background: Giant cell arteritis (GCA) is the most common form of systemic vasculitides affecting people aged 50 years and older.1 Although it is known that GCA coexists with polymyalgia rheumatica (PMR), prevalence of GCA in consecutive patients with PMR has not been investigated.

Objectives: To prospectively examine the prevalence of GCA in consecutive patients with PMR by vascular ultrasound (US).

Methods: Patients with newly diagnosed PMR fulfilling the ACR/EULAR classification criteria for polymyalgia rheumatica were included. Vascular US examination of the extracranial arteries typically involved in GCA, such as axillary arteries, vertebral arteries, common carotid arteries, superficial temporal arteries with both frontal and parietal branches, occipital arteries, facial arteries and the central retinal arteries was performed in all PMR patients. Diagnosis of PMR was made, if intima-media thickening was above respective cut-off values.4

Results: In ANCA-screen 36% of the cases and 2.6 % of controls tested positive (p=0.001), 23/32 (44.2%) of the cases were ANCA positive (OR 5.63; 95% CI 1.26–23.54) at disease onset. Furthermore, predicating PMR-ANCA positive vs predating PR3-ANCA positive cases had significantly more often severe manifestations at disease onset (87.5% vs 28.6%; p<0.05). Cases positive vs. negative for PMR-ANCA in predating samples were less often classified as GPA (37.5% vs 86.4%; p<0.01) and more often as MPA (62.5% vs 13.6%; p<0.05).

Conclusion: The production of both PR3 and ANCA-PMR starts already years before onset of symptoms. 95% of AAV patients with PMR were predicted to be an inadequate predictor for relapse in this cohort. Statistical calculations were performed using SPSS software.

SAT0255 THE RATE OF RELAPSE AMONG PATIENTS WITH LARGE VESSEL VASCULITIS AND THE SYSTEMIC INFLAMMATORY RESPONSE AS A POSSIBLE PREDICTOR FOR RELAPSE
V M. Coroian1, S. Saur1, A. C. Pecher1, T. Xenitidis1, J. Henes1.1 Centre for Interdisciplinary Clinical Immunology, Rheumatology and Auto-inflammatory Diseases (INDIRA) and Department of Internal Medicine II (Oncology, Haematology, Immunology and Rheumatology), University Hospital Tübingen, Germany, Tübingen, Germany

Background: Large vessel vasculitides are known relapsing diseases. However, the rate of relapses has been seldom addressed and there are only few data on relapse predictors.

Objectives: We conducted the present study to investigate the prevalence of relapses in the first year after diagnosis and the overall relapse among patients with large vessel vasculitis. Furthermore, we aimed to identify if the systemic inflammatory response (SIR) is a possible predictor for relapse among patients with large cell vasculitis.

Methods: The systemic inflammatory response (SIR) has been described as a potential clinical and serological score predicting the risk for relapses.1 SIR estimates the systemic inflammatory activity at the time point of first diagnosis.2 It was defined as follows: Temperature >38°C, weight loss >4kg, Haemoglobin <11 g/dl and erythrocyte sedimentation rate >85 mm/h. For each of the above-mentioned criteria one point was attributed, leading to a range from 0 to 4 points. Patients with 3 to 4 points were considered having a highly inflammatory response and patients with an SIR ≤ 2 were considered having a low inflammatory response and thus a lower risk for relapses. Relapses are defined as reappearance of disease-related symptoms requiring treatment adjustment. The study cohort included 75 patients with large cell vasculitis (Giant Cell Vasculitis, Takayasu Vasculitis, inflammatory non-infections Aortitis), longitudinally followed by the authors over a mean period of 5.2 ± 3.3 years (range 1-14 yr).

Results: The study-cohort includes 71 patients with a mean age at diagnosis of 63.5 (16 – 85) years. Almost three quarters (73%) of the patients were women. Most of the patients were suffering from GCA (73.2%), followed by Takayasu arteritis (16.9%) and inflammatory non-infections Aortitis (9.8%). 38 patients (53.5%) relapsed at least once during the follow up, and 17 patients had two or more relapses. The vast majority of relapses (86.8%) were observed within the first year following diagnosis. Most of the patients, 54 patients (76%), were considered having a low inflammatory response (SIR <2). The relapse rate in this group was 59.2%. On the other hand, there were 17 patients having an SIR higher or equal to 3 points. The relapse rate in this group was 33%.

Conclusion: In conclusion, the results of this preliminary study reveal that the relapse rate among patients with large vessel vasculitis high is. The SRI appears to be an inadequate predictor for relapse in this cohort.

PMR-group: patients with diagnosis of polymyalgia rheumatica only GCA-PMR-group: patients with diagnosis of polymyalgia rheumatic and giant cell arteritis

Conclusion: Prevalence of GCA in patients with PMR in our cohort was 54%. Ten (37%) patients with GCA and PMR did not have any GCA symptoms. Performing vascular US in patients with PMR can be useful to diagnose a clinical inactive GCA. Prompt onset of the respective therapy could prevent complications of GCA and improve disease outcome.

References:
Giant Cell Arteritis (GCA) is the most common form of primary systemic vasculitis, mainly affecting adults over 50 years old. Permanent visual loss (PVL) is one of the most feared complications, occurring in about 20% of cases, typically prior to initiation of high-dose glucocorticoid (GC) therapy. Color-duplex sonography (CDS) of temporal arteries (TAs) and large vessels (LVs) is recognized as a first-line diagnostic tool for patients with suspected GCA. A fast track approach (FTA), incorporating CDS has been associated to a significant reduction on positive TAs and/or LVs CDS and/or a positive TA biopsy and clinical signs of GCA was implemented since October 2016. The diagnosis of GCA was based on positive TAs and/or LV CDS and/or a positive TA biopsy and clinical signs and symptoms of GCA. All patients were clinically examined by the same rheumatologist who performed the CDS. PVL was defined as total visual impairment in one or both eyes. Data on baseline clinical features and later outcomes were intentionally approached patients.

**Results:** 153 patients were included: 115 females (75.2%), mean age at diagnosis 71.6±8.2 years. Of these, 112 patients (73%) were evaluated conventionally and 41 (27%) with FTA. Patients in the FTA group were older (P=0.0002), presented more frequently with polymyalgia rheumatica symptoms, weight loss, jaw or tongue claudication and scalp tenderness (P<0.05 for all comparisons). The median duration of follow-up in the FTA group was shorter compared with the conventional group (1.5 vs 5.8 years), PVL occurred in 22 (19.6%) patients in the conventional group compared to 5 patient (12.2%) in the FTA, leading to a reduction of 37% in the relative risk of PVL with the FTA approach. Cumulative incidence of relapses and time to first relapse did not change after FTA introduction (P>0.05) (Fig. 1).

**Conclusion:** The application of a FTA in GCA resulted in a significant reduction of PVL. However, the relapse rate did not seem to be influenced by the FTA, highlighting the need to implement further management strategies, besides earlier diagnosis and prompt initiation of GC, that would impact the course of the disease during long-term follow-up.

ANCA-ASSOCIATED VASCULITIS WITH RENAL INVOLVEMENT: THE ROLE OF A COMBINED HISTOPATHOLOGICAL ASSESSMENT AS PREDICTOR OF PATIENTS’ PROGNOSIS

L. Gigante1, P. G. Cerasuolo1, G. Vischini1, F. Fedorico1, D. Bruno1, A. Musto1, S. Costanz1, S. L. Bosco1,4, E. Gremente5,6, Division of Rheumatology, Università Cattolica del Sacro Cuore, Rome, Italy; 2Division of Nephrology - Fondazione Policlinico Universitario A. Gemelli-IRCCS, Rome, Italy; 3Division of Anatomical Pathology, Università Cattolica del Sacro Cuore, Rome, Italy; 4Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Rome, Italy

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides often affect the kidney and renal involvement has a considerable clinical impact on patients’ prognosis. Currently used histopathological classifications are basically focused on the glomerular damage and assessing chronic damage progression, but their prognostic role presents some limitations.

Objectives: To combine the Berden Classification, the ANCA Renal Risk Score (ARRS) and the Mayo Clinic-Renal Chronicity Score (RCS) with the inflammatory interstitial infiltrate and to evaluate the prognostic value of the combined assessment in patients with AAV

Methods: We included 19 AAV patients with renal involvement (mean age 63±13.2 years; disease duration 4.9±5.2 months) who underwent renal biopsy. Patients were classified according to age, sex, disease duration, ANCA positivity. The histopathological evaluation was performed assessing the Berden category, Risk group (low, medium, high) according to the ARRS and Chronicity class according to the RCS, we also assessed the % of inflammatory interstitial infiltrate. Each patient was follow-up for 12 months; we considered the stage IV (eGFR < 30 ml/min/m²) of the KDIGO CKD Classification as renal outcome.

Results: 8 (42.1%) AAV patients were p-ANCA and 11 (57.9%) c-ANCA. 12 months after renal biopsy, 8 patients (42.1%) had a GFR <30 ml/min. According to the ARRS, 10 (52.6%) patients were in low, 7 (36.8%) in medium and 2 (10.5%) in high risk group. According to the RCS, 2 (10.5%) biopsies had minimal, 10 (52.6%) mild and 7 (36.8%) moderate chronic changes, no one presented severe chronic changes. According to the Berden classification, 6 (31.6%) samples represented the focal, 2 (10.5%) the crescentic and 11 (57.9%) the mixed category, no one represented the sclerotic class. The mean % of inflammatory infiltrate was 37.4±25.2. The interstitial inflammatory infiltrate showed a direct correlation with the severity of the Berden category (R=0.51; p=0.025), the % of sclerotic glomeruli (R=0.6; p=0.007) and the number of fibrocellular crescents (0.46; p=0.05) and an inverse correlation with the GFR at 12 months (R=-0.48; p=0.045). A ROC curve study identified a 22.5% cut-off of inflammatory infiltrate to predict the outcome of GFR at 12 months < 30 ml/min (sensitivity 88%, specificity 97.5%). Patients in focal class developed less frequently a GFR=30 (x²=9.1; p=0.003), but there were no differences in the outcomes between the crescentic and mixed class.

ARRS could differentiate risk group with regard to the renal outcome stage IV (x²=9.0; p=0.01) as well as the chronicity Score (x²=1.1; p=0.017). Finally, we built a matrix combining the different histopathological scores and the % of inflammatory infiltrate to predict the outcome; we found that an inflammatory infiltrate wider than 22.5% characterizes most of patients developing stage IV chronic renal failure at the 12th month. In fact, more than 75% of patients with eGFR < 30 ml/min had inflammatory infiltrate wider than 22.5% at biopsy, despite they were in the low risk class (ARRS) and in minimal changes class (RCS).

Conclusion: Our results underline the importance of the inflammatory infiltrate in renal outcome and history. Despite the limited number of patients, our data suggest that a combined histological score assessing the chronicity and activity of renal disease from both glomerular and interstitial perspective could better predict patients’ global and renal prognosis.

PENTOXYFILLINE GEL FOR ORAL ULCERS IN PATIENTS WITH BEHÇET’S SYNDROME

G. Haterim1, B. Yurttas1, Z. Kutubay2, T. Cote1, Ş. B. Derkun2, Y. Yazıcı1, H. Yazıcı1, 1Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Behçet’s Disease Research Center, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, Behçet’s Disease Research Center, Istanbul, Turkey; 3Silk Road Therapeutics, Washington, D.C., United States of America; 4New York University School of Medicine, New York, NY, United States of America; 5Academic Hospital, Istanbul, Turkey

Background: Oral ulcers, the hallmark lesion of Behçet’s syndrome (BS) can be disabling and impair eating, drinking and speaking. Despite recent advances in systemic medications for the treatment of oral ulcers, some patients do not achieve complete remission. Topical agents may help such patients by decreasing the pain and duration of oral ulcers. Pentoxyfilline (PTX) is a methylxanthine derivative that inhibits phosphodiesterase and is thought to have immunomodulatory effects in addition to improving blood flow which is its main reason for use in peripheral vascular disorders.

Objectives: The aim of this study is to assess the efficacy and safety of PTX gel for oral ulcers in patients with BS. We also aimed to explore the best tools for the assessment of treatment response to topical agents in randomized controlled trials (Clinicaltrials.gov ID: NCT03888846).

Methods: 1072 patients with AAV who were registered in clinicaltrials.gov were included. We reviewed the charts of 850 patients with BS who were registered in our centre between 2003 and 2013 and identified those who had used IFX. The charts of these patients were surveyed for demographic features, the reasons for IFX use, previous and concomitant drugs, IFX duration, reasons for discontinuation and time to flare after discontinuation of IFX. We defined flare as disease activity in the organ involvement that necessitated IFX use. New major organ involvement that developed during or after discontinuation of IFX were also noted.

Results: A total of 50950 patients were treated with IFX (40 men, mean age 40±9.5 years), for uveitis (n=29), vascular involvement (n=11), parenchymal neu- rologic involvement (n=8), arthritis (n=1) and venous ulcer (n=1). Of these 50 patients, 22 (43%) are still receiving IFX for a median duration of 40 (IQR: 25-83) months. The remaining 28 (47%) patients had discontinued IFX after a median follow-up of 12 (IQR: 7-30) months. Reasons for discontinuation were remission in 7 patients, adverse events in 10, primary lack of efficacy in 2, and lack of patient compliance in 9 patients. Among the 7 patients who discontinued IFX due to remis- sion, only 1 patient with uveitis had a flare, 11 months after discontinuation, while on azathioprine. The remaining 6 did not experience any flares during a median follow-up of 29.5 (IQR: 4-24) months. Five of these patients used azathioprine and 1 used mycophenolate mofetil for maintenance. Among the 10 patients who discontinued due to adverse events, IFX was switched to adalimumab in 3 patients and none experienced flares under adalimumab. The remaining 7 patients continued to receive azathioprine or mycophenolate mofetil without a biologic. Among these, 1 patient with uveitis 1 with arthritis experienced flares 6 months after dis- continuing IFX. Among the 9 patients who discontinued IFX due to lack of patient compliance, 3 patients (2 with uveitis and 1 with arthritis) had flares after 5 months, 1 year and 1.5 years. IFX was re-initiated in all. The remaining 6 patients did not experience any flares after a mean follow up of 4±15 years. Two with uveitis and 2 with venous thrombosis used azathioprine for maintenance, while 2 patients did not receive further treatment. New major organ involvement was not observed. New BS manifestations developed in 2 patients under IFX, arthritis in one patient and both epididymitis and erythema nodosum in the other.

Conclusion: Almost half of our patients with BS remained on IFX during a median follow-up of 5.4 years (IQR:2-4.7). Main reasons for discontinuation were adverse events, remission and lack of patient compliance. Our observations fur- ther support the efficiency of IFX in managing patients with BS.

DOI: 10.1136/annrheumdis-2020-eular.5676
Methods: This was an open-label, randomized, parallel group study comparing PTX gel in addition to colchicine (PTX-COL) with colchicine alone (COL). Patients with BS who were treated with colchicine and not using any other systemic medications for BS, having at least one oral ulcer that appeared during the last 48 hours were included. PTX 5% gel with a dose of 1000mg/day was applied in 4 divided doses per day for 14 days. Patients were contacted daily for 14 consecutive days. Photographs were taken every 24 - 48 hours and graphical processing software was used to calculate the area of the index ulcer. Duration of the index ulcer, time to start of index ulcer shrinkage, time to 50% reduction in oral ulcer pain, and number of patients with no detectable ulcers on day 4 in each group were lower in the PTX-COL group as presented in the Table. Change in oral ulcer pain, and number of patients with no detectable ulcers on day 4 in each group were lower in the PTX-COL group as presented in the Table. Change from baseline in the area of index ulcer and pain score over time is shown in the Figure. There were no serious adverse events. Fifteen (75%) patients reported UTI in our AAV cohort during follow-up.

Results: A total of 41 patients were randomized, 39 patients (18 in the PTX-COL group and 21 in the COL group) completed the study and 2 patients in PTX-COL group withdrew from the study due to unacceptable dysgeusia and nausea. Mean duration of index ulcer, time to start of index ulcer shrinkage, time to 50% reduction in oral ulcer pain, and number of patients with no detectable ulcers on day 4 in each group were lower in the PTX-COL group as presented in the Table. Change from baseline in the area of index ulcer and pain score over time is shown in the Figure. There were no serious adverse events. Fifteen (75%) patients reported

SAT0261 FEATURES AND RISK FACTORS OF SERIOUS INFECTIONS IN ANCA ASSOCIATED VASCULITIS: LONG TERM FOLLOW UP OF 186 PATIENTS

B. Ince1, M. Bektas1, F. Kemik2, A. E. Ayten3, Y. Yalçınkaya4, B. Artim-Esen1, A. Gül1, M. L. Ocal1, M. Inanc1. 1Istanbul University, Istanbul Faculty of Medicine, Dept. of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Istanbul University, Istanbul Faculty of Medicine, Dept. of Internal Medicine, Istanbul, Turkey; 3Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey

Background: Serious infections (SI) are one of the main complications in patients with ANCA associated vasculitis (AAV).

Objectives: We planned to investigate the prevalence, features and risk factors of SI in our AAV cohort during follow-up.

Methods: Outpatient and hospital data of patients diagnosed with granulomatous polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatous polyangiitis (eGPA) between 1999 and 2019 according to Chapel Hill Consensus Criteria and followed up at least 6 months in our vasculitis clinic were evaluated. Development of sepis, requirement for intravenous (IV) antibiotic therapy and / or hospitalization during infection episodes were considered as SI. Chi-square, student’s t-test and logistic regression analysis were used for statistical analysis.

Results: Study was conducted with 186 (53.6% female) patients with adequate follow-up data. Mean age of diagnosis was 54.3±14.5 (23-79), mean follow-up duration was 86.4± 54.3 (6-291) months. Number of GPA, MPA and eGPA patients were 132 (71%), 42 (22.5%) and 12 (6.5%), respectively. IV cyclophosphamide (CYC) was used in 148 (79.6%), azathioprin in 105 (56.5%), rituximab (RTX) in 69 (%37.1), methotrextate in 29 (15.6%) and mycochalonate mofetil in 14 (7.5%) patients. Number of patients developed SI was 66 (34.7%), total SI episode was 86, patients who had multiple episodes was 15. All SI is shown in Table-1. Bacterial pneumonia was the most common diagnosis and 26 of SI (30.2%) were considered as opportunistic (systemic viral, parasite, fungus) infections. Thirty-one of patients developed SI (40.7%) in the first year after diagnosis. SI were observed more frequently in the presence of major organ involvement (kidney, lung, neurological) (65/173 vs. 1/13 p = 0.02 OR = 8.7 95% CI 1.66-64.4). Diffuse alveolar hemorrhage (DAH) was associated with SI in multivariate analysis (125 vs. 0.34 p=0.007 OR=1.65 95% CI 1.3-1.96). Cumulative CYC dose was significantly higher in patients with SI (14,2±21 vs. 8.2±13.9 p=0.045). During maintenance, patients treated with RTX had significantly more SI (18/53 vs. 17/99 p=0.19 OR=3.3 95% CI 1.55- 7.07). Hypogammaglobulinemia (HlgG) (lG<700 mg/dL) was present in 12 (14%) SI patients. HlgG was associated with SI in RTX-treated patients (5/13 vs. 7/47 p=0.03 OR=4.2, CI=1.65). Hospitalization need for SI was 65%. Disease flares (34/128 vs. 32/62 p = 0.001 %95 CI = 2.95 95% CI 1.6-5.6) and organ damage presence were more common (64/85 vs. 109/125 p = 0.01 95% OR=8.9 95% CI 1.4-6189) in patients with a history of SI in multivariate analysis. SI was confirmed as cause of death in three cases.

Conclusion: Long-term follow-up results of a single center cohort of AAV patients revealed that approximately one third of patients developed SI, most frequently in the first year of treatment. During the maintenance period, the risk of SI continues. Cumulative CYC dosage and maintenance with RTX is associated with SI, especially in patients who developed hIgG. Major organ involvement, disease flares and organ damage are significant risk factors for SI. In this regard, protective measures (vaccination, prophylaxis) should be reviewed and the quality of follow-up should be improved.

SAT0262 PROPOSAL FOR OPTIMIZATION OF DIAGNOSTIC IMAGING FOR GIANT CELL ARTERITIS USING THREE-DIMENSIONAL COMPUTED TOMOGRAPHY ANGIOGRAPHY IMAGE AND CONSTRUCTING VASCULAR MAPPING FROM VASCULAR ULTRASONOGRAPHY AS REFERENCES

T. Kawamoto1, M. Ogasawara, Y. Mastuki-Muramoto2, T. Kawaguchi3, S. Ando1, M. Matsushita1, K. Yamanaka2, K. Yamaji2, N. Tamura4. “Juntendo University

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.4397
Background: The development of rapid and accurate methods of diagnosing giant cell arteritis (GCA) is critical to prevent blindness and stroke, which may develop rapidly in patients with GCA. In 2018, EULAR published recommendations that the first imaging modality for GCA should be vascular ultrasonography (V-US) without biopsy. However, many institutions still consider biopsy to make an important contribution to the diagnosis of GCA.

Objectives: Our purpose is to eliminate blindness and stroke among GCA patients by optimizing diagnostic imaging and method to diagnose GCA employed by vascular ultrasonography (V-US), CT Angiography (CTA), MRI/A, and PET/CT without biopsy.

Methods: We evaluated the clinical and serological characteristics of 20 patients who were diagnosed with GCA at our hospital from 2012 to 2018, and compared the image and biopsy findings of these patients. We then evaluated the effect of optimizing diagnostic imaging and methods for patients with suspected GCA who visited our hospital during 2019. Vascular mapping was carried out using V-US for 3DCTA and other imaging methods as references.

Results: Table 1 shows the clinical characteristics of the study population. The sensitivity of CTA for GCA was 85.7% (12 of 14 patients), which was the highest of the studied imaging methods. All biopsy-positive cases were diagnosed as GCA, and we compared these cases with cases with positive imaging findings. This revealed that CTA findings were correct (i.e., positive) in 66.7% (four of six patients), MRI/A findings were correct in 33.3% (three of nine), V-US findings were correct in 50.0% (three of six). Therefore, CTA exhibited the highest sensitivity for positive findings. Comparison of biopsy-positive cases with cases in which imaging findings were negative revealed that CTA findings were correct (negative) in 33.3% (two of six patients), MRI/A findings were correct in 55.6% (five of nine), V-US was correct in 50.0% (three of six). Thus, CTA had the lowest sensitivity for negative findings. Comparison of CTA findings of positive cases with other imaging modalities which reported positive findings revealed MRI/A findings to be correct in 44.4% (four of nine patients), PET/CT findings to be correct in 50.0% (one of two), V-US to be correct in 63.3% (five of eight). Thus, V-US had the highest agreement with CTA. We carried out vascular mapping by V-US using 3DCTA and other imaging methods and produced references to improve the accuracy of diagnosis. Using these references, we diagnosed five cases of GCA among the 20 patients; the positive predictive value of V-US was 80% (four of five patients) and negative predictive value was 86.7% (13 of 15 patients).

The number of biopsies performed decreased from 50% (10 of 20 patients) from 2012 to 2018 to 15% (3 of 20 patients) in 2019. Two cases in the present study had positive findings in both biopsy and V-US; in one case, biopsy, CTA, and MRI/A showed positive findings. No patients with GCA developed blindness or stroke during 2019.

SAT0263

LOW-DOSE IL-2 THERAPY EFFECTIVELY PROMOTES THE BALANCE BETWEEN TREG CELLS AND PRO-INFLAMMATORY LYMPHOCYTES IN PATIENTS WITH BEHÇET’S DISEASE

X. Liu1, X. Liu2, G. Chai1, X. Li1 on behalf of Li Xiaofeng Team. 1The Second Hospital of Shanxi Medical University, Taiyuan, China, 2Taiyuan University of Technology, Taiyuan, China

Background: Behçet’s disease (BD) is a chronic multisystemic disease. Several studies have shown that immune mechanisms play an important role in the development of the disease and limited options of therapeutic medicines for BD. Low dose IL-2 has been reported to selectively promote the expansion of Treg.

Objectives: To evaluate the significance of Treg cells and cytokines in the pathogenesis and the changes of peripheral lymphocyte subsets and clinical indexes in patients with BD after low dose IL-2 therapy.

Methods: Absolute number of CD4+CD25+FOXP3+Treg, CD4+IL-17+T (Th17) and other subsets in peripheral blood (PB) from 177 patients with BD and 160 healthy donors were characterized by flow cytometry combined with an internal microsphere counting standard. And cytokines were analyzed by cytometric beads array. Thirty-nine patients were treated with daily subcutaneous injections of 0.5 million IU of human IL-2 for five consecutive days, and then its effects were analyzed.

Results: As compared to healthy controls, the number of Treg cells were significantly increased in BD patients, while no difference was observed about Th1, Th2 and Th17 cells. Accordingly, the median ratios of Th17/Treg cells in patients were greatly higher than those of healthy volunteers. Besides, the circulating NK cells in the patients appeared to be lower than the proportion in the healthy controls.

Conclusion: We propose that V-US should be performed as the first examination for the diagnosis of GCA by the creation of vascular mappings when GCA is suspected in order to prevent blindness and stroke.

References:
activity. While no obvious correlation was seen in Th1, Th2, Th17 and NK cells. Then the results showed there was a statistically significant decrease in the secretion of IL-10 in the BD patients (P = 0.004), not for IFN-γ, IL-4, IL-17 and IL-6.

To evaluate the effects of IL-2 on lymphocytes in vivo, we examined 39 inpatients who received daily low-dose IL-2 at the dosage of 50 WIU for 5 days. It showed that, besides NK cells, total T cells, B cells, CD4+ T cells, CD8+ T cells, Th1 cells, Th2 cells, and Th17 cells were all increased after IL-2 treatment. But only Treg cells were amplified more dramatically, with the four-fold increase. Accordingly, the ratio of Th17/Treg was decreased significantly in patients with IL-2 treatment, tended to balance and had no difference with healthy individuals. At the same time, we found that the symptom were mitigated obviously and disease activity including ESR and CRP were both decreased distinctly without observed side effects.

**Conclusion:** Absolute decrease of PB Treg in patients with BD was associated with disease activity, which might be the major reason for imbalance of Th17/Tregs. It is speculated that BD is an autoimmune disease triggered by the defect of immunotolerance. More importantly, low-dose IL-2 proposes a selective biological treatment strategy by restoring immune tolerance and promoting rapidly.

RISK FACTORS FOR INFECTIOUS COMPLICATIONS FOLLOWING RITUXIMAB TREATMENT – MULTICENTER POLISH EXPERIENCE

A. Masiak1, M. Zietkiewicz2, K. Wójcik3, K. Wawrzycka4, A. Komorniczak5, M. Madej3, J. Kur-Zalewska4, M. Wisłowska5, H. Storoniak6, M. Komorniczak4, I. Brzosko4, M. Brużkowska, A. Dębeka-Sliż6, J. Musiał6, Z. Zdrojewski1,1 Medical University of Gdańsk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdańsk, Poland; 2Jagiellonian University Medical College, 2nd Department of Internal Medicine, Faculty of Medicine, Krakow, Poland; 3Medical University, Department of Rheumatology and Internal Medicine, Wrocław, Poland; 4Military Medicine Institute, Department of Internal Medicine and Rheumatology, Warsaw, Poland; 5Department of Internal Diseases and Rheumatology, Central Clinical Hospital of the Ministry of the Interior and Administration, Department of Internal Diseases and Rheumatology, Warsaw, Poland; 6Medical University of Gdańsk, Department of Nephrology, Transplantology and Internal Diseases, Gdańsk, Poland; 7Pomeranian Medical University in Szczecin, Department of Internal Medicine, Rheumatology, Geriatrics and Clinical Immunology, Szczecin, Poland

Background: Rituximab (RTX) is a B cell depleting monoclonal antibody with proven efficacy in the treatment of ANCA-associated vasculitis (AAV). The infectious complications occur in 15-25%. Objectives: We aimed to assess the frequency and risk factors of infections in patients with AAV receiving RTX among Polish patients. Methods: 7 tertiary referral centers experienced in the treatment of vasculitis completed a questionnaire regarding AAV patients treated with RTX. Results: Among 49 patients included in the analysis (47 with GPA, 2 with MPA; 36/73% men; mean age at diagnosis 42.1±14,9 yrs., mean age on RTX initiation 41,1+14,7 yrs.), at least one infection occurred in 20 patients (40.82%) after mean time of 16,65±16,01 weeks since the administration of RTX. Patients were followed for a mean time of 26,8±21,94 months. There were no differences in the incidence of infectious complications by gender, age, BMI, smoking status, severity of the disease, activity of the disease (BVAS), time from diagnosis to RTX initiation, carriage of staphylococcus aureus in the upper respiratory tract, total dose of CYC before RTX treatment. We didn’t observe severe hypogammaglobulinemia or neutropenia after RTX treatment. 40% of the observed infections occurred during the first month, 35% between second and sixth month of follow-up, while 25% were observed between 6 and 12 months after the RTX initiation. Of the 20 patients who developed infection, 12 (24.5%) had further infections. Antibiotic prophylaxis with trimethoprim–sulfamethoxazole was administered in 40 out of 49 (81.63%). Upper respiratory tract infection was the most common infectious complication (n=11), followed by lower respiratory tract (n=4), soft tissues (n=4) and urinary tract infections (n=4), lacrimal gland abscess (n=2) and abdomen (n=1). In cases with a positive microbial result Staphylococcus aureus (n=4), Klebsiella pneumoniae (n=2), Pseudomonas aeruginosa (n=1), Candida (n=1) and others (n=6) were identified. No fatalities were recorded and only 3 patients had severe infection with the necessity of prolonged treatment. Conclusion: Despite the high number of infections in our group treated with RTX, most of them were not severe. Upper respiratory tract was the most common site of infection.

ROLE OF AGGRESSIVE IMMUNOSUPPRESSION ON SUBGLOTTIC STENOSIS IN GRANULOMATOSIS WITH POLYANGIITIS: RETROSPECTIVE ANALYSIS OF A MONOCENTRIC COHORT

L. Moreo1,2, L. Giudice3, G. A. Ramirez1,2, S. Sartorelli1, A. Cariddi1, A. Carrettaa,2, E. Bozzolo1,2, L. Dagna1,2, IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy; IRCCS San Raffaele Hospital, Unit of Thoracic Surgery, Milan, Italy

Background: Subglottic stenosis (SGS) is defined as airway narrowing below the vocal cords and is a common and potentially life-threatening manifestation of Granulomatosis with Polyangiitis (GPA), with an estimated prevalence of 16-23% (1). Balloon catheter dilatation is effective in GPA-related SGS, but relapses are frequent. Little is known about the role of immunosuppression in this setting.

Objectives: to analyse the clinical characteristics of a monocentric GPA cohort, describe phenotype differences among patients with and without SGS and investigate the role of surgical and medical treatments on relapse risk and general outcome.

Methods: Biopsy-proven patients with SGS were identified by review of medical charts among a cohort of patients with GPA, classified according to the algorithm of the European Medicine Agency (2). The clinical characteristics

Scientific Abstracts
of patients with SGS were retrospectively collected over a median follow-up time of 15.9 years and compared to those of patients without SGS.

**Results:** Fourteen patients with SGS-GPA were identified, with a female to male ratio of 9:5 and an age prevalence of 29.2% among the cohort. The mean ± SD age at GPA onset was 30.8 ± 14.4 years, with a mean time from GPA diagnosis to SGS onset of 4.7 ± 4.2 years. ANCA were positive in 78.6% (54.0% anti-PR3, 18.1% anti-MPO and 27.9% IIF only). The mean Birmingham Vasculitis Activity Score (BVAS) at onset was 10.0 ± 5.6. The main clinical manifestations associated with SGS were crusty rhinitis (100%), sinusitis (78%), pulmonary disease (72.7%), otitis/mastoiditis (50%), glomerulonephritis (42.9%), orbital pseudotumor (28.6%). Six patients (42.9%) received medical treatment only, other six (42.9%) had one or three balloon dilations and two (14.2%) underwent four or more procedures. Eight patients had no SGS relapse (maximum one dilation) and they all received immunosuppression with rituximab (RTX), cyclophosphamide (CYC) or azathioprine (AZA). All patients who received no immunosuppression, methotrexate (MTX) or mycophenolate (MMF) had at least one relapse. Patients treated with MTX or MMF had a mean relapse-free survival of 13.1 months, which was comparable to the one of patients not receiving medical treatment (40.2 months; p=NS) and shorter than the one of patients receiving CYC or RTX (153.2 months; p=0.032). CYC use also inversely correlated with the number of surgical procedures (n=0.691, p=0.006). Compared to patients without SGS (31 consecutive patients with at least 4 years of follow-up), patients with SGS-GPA had an earlier disease onset (mean age 30.8 vs 50.4 years; p<0.001), but with lower BVAS (mean 10.0 vs 15.3; p=0.013) and showed a higher prevalence of crusty rhinitis (100% vs 67.7%; p=0.019).

No difference was observed in damage accrual over time between the two groups.

**Conclusion:** Subglottic stenosis is highly prevalent in patients with GPA and may define a milder disease subset occurring more frequently in younger patients. MTX and MMF might be insufficient to prevent SGS relapses requiring balloon dilation. Aggressive immunosuppression (CYC or RTX) might have a non-redundant role in this setting and reduce the risk of relapses.

**SAT0268**

**COMPLEMENT ACTIVATION VIA ALTERNATIVE PATHWAY IN ANCA-ASSOCIATED VASCULITIS**

A. Zykova1,2, P. Novikov1, N. Bulanova1, A. Kronbichler3, E. Gitel1, O. Novikova1, M. Bulanova1, E. Safonova2, S. Moiseev1,2, 1 Stechenov University, Moscow, Russian Federation; 2Lomonosov Moscow State University, Moscow, Russian Federation; 3 Medical University Innsbruck, Department of Internal Medicine IV (Nephrology and Hypertension), Innsbruck, Austria; 4 Vladimir Regional Clinical Hospital, Vladimir, Russian Federation.

**Background:** There is increasing evidence that the complement system, in particular the alternative pathway, plays a crucial role in the pathogenesis of ANCA-associated vasculitides (aaV) [1]. Efficacy of Csa receptor antagonists indicates that chemoattraction mediated by C5a plays a key role in the inflammatory process observed in aaV [2]. Another promising research object are regulatory proteins such as factor B [3].

**Objectives:** To study complement activation via the alternative pathway in patients with active ANCA-associated vasculitides.

**Methods:** 59 patients with newly diagnosed (n=35) or relapsing GPA or MPA (n=24) were enrolled in this prospective study. Median BVAS v.3 at the time of aaV onset was 16.5 (9.5; 20). In 28 patients activation of complement was reassessed during sustained remission (BVAS v.3 = 0) after a median of 16 months. Thirty six age- and gender-matched healthy volunteers comprised the control group. Levels of complement components (C3, C5, C3a, C5a, vitronectin, factor B and factor P) were measured by ELISA (Cloud Inc.). Data were not normally distributed, therefore, values are given as medians and IQRs and nonparametric statistical tests were used.

**Results:** The concentrations of C5, C3, vitronectin and CFB were significantly higher in patients with active aaV than control group. There were no significant differences in the levels of factor P in patients with active aaV and control group (38800 (371986; 417150)) vs 416000 (400200; 437000), ng/ml, p >0.05 (Fig. 1).

**Fig 1.** Concentration of complement components in patients with active aaV and healthy controls (*p<0.005)

Serum level of C5a and C3a were higher in patients with active aaV than in healthy controls (22.9 (14.4; 33.0) vs 3.0 (0.35; 6.73), ng/ml, p<0.001; 21436 (11395; 21436) vs 12245 (7985.5; 19477.7), ng/ml, p<0.001). Patients with active aaV had significantly higher MAC levels than healthy controls (24646 (15342; 46681) vs 3305.5 (2780.2; 37775), mAU/ml, p<0.001). The levels of complement components were similar in PR3-ANCA and MPO-ANCA disease, and severe and non-severe aaV. C5a/C3 and C5a/C3 ratios were not influenced by disease activity, severity or ANCA type.

After immunosuppressive treatment concentrations of C5, C3, and their activated products, C5a, C3a significantly decreased (Fig. 2). However, concentrations of regulatory proteins such as factor B, factor P and vitronectin were unaffected. Interestingly, that there was no significant difference in MAC levels before and after immunosuppressive treatment (24646 (15342; 46681) vs 200574 (19709.3; 414778), mAU/ml, p=0.925).

**Fig 2.** Concentration of complement components in patients with active disease and remission (*p<0.001)

**Conclusion:** The complement system plays an important role in aaV. While treatment affects some component, some remain unchanged and are not dependent on aaV severity or ANCA serotype.
SAT0269
TAKAYASU ARTERITIS AND INFLAMMATORY BOWEL DISEASE. COEXISTENCE AMONG NORWEGIAN PATIENTS
O. Palm,1 B. Gudbrandsson1,1 T. Garen1 on behalf of OUH Rheumatology Research Group, 1Oslo University Hospital, Rheumatology, Oslo, Norway; 2Oslo University Hospital, Rheumatology, Oslo, Norway

Background: Takayasu arteritis (TAK) and inflammatory bowel disease (IBD), consisting of ulcerative colitis (UC) and Crohn’s disease (CD), are uncommon diseases. The incidence rates of TAK is 22.0/million and IBD 193/million in Norway (1). Epidemiological data are mainly based on one Asian study (2). UC in patients with TAK has previously been reported with a prevalence rate did not seem to differ between TAK with and without IBD.

Methods: We analysed the prevalence of TAK with IBD in a population-based cohort of patients based on the Norwegian Systemic connective tissue disease Vasculitis Registry (NOSVARS). The diagnosis of TAK were based on either 1990 ACR classification criteria (3) or the modified Ishikawa diagnostic criteria (4). The distribution of vasculitis was recorded in accordance with the angiographic classification of the 1994 International TAK Conference in Tokyo (5). The diagnoses of IBD were based on gastroenterological investigations and conclusions recorded in hospital charts.

Results: Among 116 patients with TAK, living in Southern part of Norway (2.5 mill inhabitants) 5 patients (4.3%) had IBD, 3 with UC and 2 with CD. All patients had onset of IBD prior to TAK and intestinal involvement of colon (Table 1). Moreover, patients with TAK and IBD were younger at TAK onset than in those without IBD (Table 2).

Agustín, Aviles, Spain; 21CH Navarra, Navarra, Spain; 22La Fé, Valencia, Spain

Background: Tocilizumab (TCZ) was recently approved for Takayasu Arteritis (TAK) in Japan based on the results of the TAKT trial (1). However, data in clinical practice in Europe and America are scarce (2).

Objectives: To assess efficacy and safety of TCZ in TAK of clinical practice in Spain.

Methods: Observational, open-label multicentre study of 53 TAK patients treated with TCZ due to refractoriness or adverse events of previous therapy. Outcomes variables were improvement of clinical features, acute phase reactants and glucocorticoid-sparing effect.

Results: 53 patients (48/7/6m; mean age, 40.6±14.6 years at TAK onset. TCZ was started after a median of 12 [3–48] months after TAK diagnosis. In addition to systemic corticosteroids and before TCZ they received conventional immunosuppressant drugs (n=42) and biologic therapy (n=14). TCZ was prescribed as standard I.V. (n=42;
Background: We have been developing a rheumatologist-led ultrasound driven giant cell arteritis (GCA) fast-track pathway (GCA FTP), which in year 3 had the following structure:

1. Rapid access to rheumatology assessment (RAS) to establish clinical probability of GCA (CP-GCA). No referral criteria required
2. Temporal and axillary artery ultrasound (TAUS) if GCA not excluded with RAS, TAUS considered positive if bilateral (hypoechoic score ≥2/4 at >1 temporal artery)
3. Second test in selected patients: GCA diagnosed in those with mod-high CP-GCA and +ve TAUS and excluded in those with low CP-GCA and -ve TAUS. All others had biopsy (TAB) or large vessel imaging (LVI), presentation depending
4. Protocolised withdrawal of prednisolone: Patients only treated for GCA if ≥1 of: high CP-GCA, +ve TAUS, TAB or LVI
5. Rapid access if symptoms recur on steroid withdrawal for RAS + TAUS

Objectives:
- To compare security of GCA diagnosis, sight loss rate and TAB rate in Year 3 to previous years
- To assess sensitivity and specificity of all components of the Yr 3 FTP for diagnosis of GCA

Methods: As in Yr 2, TAUS was performed by VN with an Echoview 70, 6-15MHz probe for axillaries, 12-15MHz for temporal arteries (TAs). In Yr 1 VN used a GE E8 with ML6-15 for axillaries, 18MHz probe for TAs. Year 3 audit data were compared to previous audits

Results:
Year 3 Luton GCA FTP compared to previous years

Audit period
2015 12 months 1/1/16-31/3/17 15 months 1/4/17-31/3/18 12 months 1/4/18-31/3/19

Pathway structure

**PROGNOSTIC FACTORS FOR POOR OUTCOME IN BEHÇET’S SYNDROME WITH NEUROLOGICAL INVOLVEMENT: RESULTS FROM A CLINICAL LONG-TERM FOLLOW-UP OF A SINGLE CENTRE**

D. Sahin Eroglu,1 M. Turgutalp,1 S. Sezer,1 A. Boyvat2, C. Yucesan,3 A. Ates,3 Ankara University Faculty of Medicine, Department of Rheumatology, Ankara, Turkey1 Ankara University Faculty of Medicine, Department of Dermatology, Ankara, Turkey,2 Ankara University Faculty of Medicine, Department of Neurology, Ankara, Turkey

**Background:** Behçet’s Syndrome (BS) is a vasculitis of unknown cause. Neurological disease is a type of its serious involvement and causes morbidity and mortality.

**Objectives:** In this study, we aimed to describe the clinical characteristics of neu-r0-Behçet Syndrome (NBS) and to define prognostic factors that were associated with poor outcome.

**Methods:** Among 2033 patients with BS, we performed a retrospective analysis of 94 patients (52.1% male: mean age 36.1 (11.9) years), who fulfilled the ISG-1990 for BS. We divided patients into two subgroups, either parenchymal (p-NBS) or non-parenchymal (np-NBS). Clinical, laboratory, and imaging characteristics of the patients were described. We described the poor outcome as a modified Rankin score (mRS) >= 3 at last follow-up and/or death, and assessed the predictor factors associated such kind of outcome.

**Results:** In total, 52 (55.3%) patients presented with p-NBS, of whom 15 (28.8%) had progressive course, and 42 (44.7%) presented with np-NBS.

**Conclusion:** The study showed that poor outcome is associated with specific variables such as age, initial mRS, presence of oral aphtha, genital ulceration, and musculoskeletal involvement. The high-risk group consists of young patients with early severe disease and presence of multiple organ involvement. Therefore, stringent follow-up should be done in this group to prevent a poor outcome.
The long-term follow-up of BD patients from REGEB cohort showed that 10 years after diagnosis, a fifth of them may continue to present severe flares requiring systemic treatment. The use of biological therapy increased over time and their main indication was refractory disease.

**Conclusion:** The long-term follow-up of BD patients from REGEB cohort showed that 10 years after diagnosis, a fifth of them may continue to present severe flares requiring systemic treatment. The use of biological therapy increased over time and their main indication was refractory disease.

DOI: 10.1136/annrheumdis-2020-eular.4940
Objectives: To analyze whether benefit in SF-36 MCS was maintained in patients originally assigned to TCZ compared with those originally assigned to placebo (PBO) plus a 26- or 52-week prednisone taper among patients who achieved clinical remission at week 52 and maintained treatment-free clinical remission in the 2-year, long-term extension of GIACTA.

Methods: At the end of part 1, patients entered open-label part 2, in which GCA therapy (including initiation/termination of open-label TCZ and/or GCs) was given at the investigator’s discretion according to disease status. Change from baseline in SF-36 MCS score was compared for combined original TCZ (n = 33) and PBO (n = 17) patients who achieved clinical remission at week 52 and maintained treatment-free clinical remission in part 2 using a repeated-measures model. The minimal clinically important difference (MCID) for SF-36 MCS is >2.5.2

Results: During treatment, SF-36 MCS scores in all 50 patients who maintained treatment-free clinical remission in part 2 had diverged between the TCZ and PBO groups as early as 36 weeks after baseline, with greater improvements evident in the TCZ group (Figure). The difference in least square means (LSM) change between TCZ and PBO was statistically significant at week 52 (p = 0.016) and maintained at weeks 100 (p = 0.023) and 156 (p = 0.002). The LSM difference (95% CI) between TCZ and PBO at weeks 52, 100, and 156 was 5.6 (1.1-10.2), 6.5 (0.9-12.1), and 7.4 (2.9-11.9), respectively, exceeding the MCID.

Conclusion: Among patients who maintained treatment-free clinical remission during part 2 of GIACTA, those originally assigned to receive TCZ plus a prednison taper during part 1 maintained statistically significant and clinically meaningful improvements in SF-36 MCS up to week 156 compared with those originally assigned to receive PBO plus a prednison taper in part 1. This was true even though neither of the patient groups received TCZ or GC treatment after they achieved clinical remission at week 52.

*mean (±standard deviation); H/N, head and/or neck; LE, lower extremity only

Methods: Patients with biopsy-proven IgAV from January 1, 1997 through December 31, 2016 were retrospectively identified through direct medical chart review. IgAV was diagnosed in accordance with the American College of Rheumatology (ACR) and the European League Against Rheumatism/ Paediatric Rheumatology European Society/Paediatric Rheumatology International Trials Organisation (EULAR/PRINTO/PRES) criteria. Among this cohort, patients with documented clinical, photographic, or histologic descriptions of vasculitic skin lesions affecting the head or neck were compiled. Each patient with head/neck (H/N) involvement included facial (cheeks, forehead) [n=6], perioral/oral/lip [n=6], auricular [n=2], nasal [n=2], and neck [n=1]. All patients in both groups had evidence of purpuric skin lesions. Patients with H/N-IgAV involvement more frequently had evidence of skin ulcerations (23% vs. 0%; p=0.01) [Figure 1]. Overall baseline renal involvement and microscopic hematuria were less commonly observed in patients with H/N-IgAV. Among H/N-IgAV cases, at last follow-up all had resolution of H/N lesions but 3 of 13 had persistent skin lesions on the lower extremities despite ongoing treatment. Long-term outcome between cases and controls did not identify any significant differences in the development of end-stage renal disease, time to resolution of hematuria or proteinuria, time to complete IgAV response, or time to first IgAV relapse.

Conclusion: This study reports the largest series of patients with head/neck involvement of IgA, a rarely reported entity. In this cohort, patients with H/N-IgAV had less frequent renal involvement compared to IgAV patients with lower extremity only skin lesions. Clinicians should be aware of atypical locations of IgAV involvement. Additional research is needed to further understand this clinical subset.

Factors predictive of positive temporal artery biopsy in two Australian cohorts

V. Yang1, B. Sutu2, C. Momaster1,2, C. Owen1,3, A. Strathmore4, G. S. Ngian1,3, S. Oon2,3, I. Wicks1,3, R. Buchanan1,3, D. Liew1,3, V. Yang1, B. Sutu2, C. Momaster1,2, C. Owen1,3, A. Strathmore4, G. S. Ngian1,3, S. Oon2,3, I. Wicks1,3, R. Buchanan1,3, D. Liew1,3.

Background: Temporal artery biopsy (TAB) is widely recognised as the diagnostic gold standard for GCA despite having a poor sensitivity due to the presence of ‘skip’ lesions. There is, however, a lack of consensus guiding TAB practice, particularly in relation to optimal length, need for bilateral specimens, and number of segments examined.

Objectives: To investigate the impact of factors such as total biopsied length, laterality, segment number, and referral centre on histopathological outcomes in an Australian setting.

Methods: Reports for all available biopsy specimens labelled ‘temporal artery’ were extracted from the pathology service records of two rheumatology referral centres with adjacent geographic catchments. Each histopathology report was manually reviewed to establish length of biopsied artery, laterality, and number of segments, along with patient demographics such as age, sex, and referral centre. Key histopathological findings including intimal hyperplasia, disruption of the internal elastic lamina, presence of giant cells, and adventitial inflammation were recorded. Multivariable logistic regression with site-varying intercept was performed.

Results: TAB reports from a total of 577 patients were captured, with results available from the two centres from 1999-2019 and 2010-2019 respectively. The mean age in this group was 73, and 69% were female (Table 1). A bilateral TAB was performed in 29%, and the mean total biopsy length was 2.5cm. Of these patients, 122 had positive biopsies (21%), with intimal hyperplasia reported in 100 (17%), giant cells in 83 (14%), and adventitial findings in 68 (12%). Positive biopsy was weakly correlated with increased total length of biopsy in centimetres (OR 1.25 [1.06-1.47]) (Figure 1) and increased age in years (OR 1.02 [1.00-1.05]) but not laterality or sex (Table 2). There was a substantial difference between the two centres, which was incompletely accounted for once corrected for total biopsy length and calendar year of biopsy, suggesting either unmeasured differences in patient demographics or a difference in clinical practice. This change was preserved across analysis of different histopathological subtypes.

SAT0280 IMPACT OF PLACENTAL FACTORS ON PREGNANCY AND FETAL OUTCOME IN SYSTEMIC SCLEROSIS

F. Motta1,2, V. Ramoni3, V. Codullo2, S. Cesiari1, F. Beneviti2, H. Johnson2, G. Graham1, C. Montecucco1. 1University of Pavia, Fondazione IRCCS Policlinico San Matteo, Rheumatology, Pavia, Italy; 2University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 3Fondazione IRCCS Policlinico San Matteo, Rheumatology, Pavia, Italy; 4University of Pavia, Fondazione IRCCS Policlinico San Matteo, Pathology, Pavia, Italy; 5University of Rome “G. Sapienza” Department of Medical Sciences, Laboratory of Experiment Pathology, Rome, Italy.

Background: Systemic sclerosis (SSc) is a chronic immune-mediated disease of unknown etiology with a high rate of pregnancy complications. However, there is a lack of evidence regarding the impact of placental factors on pregnancy and fetal outcome in SSc. The aim of this study was to explore whether placental factors were associated with pregnancy and fetal outcomes in SSc.

Methods: Data were collected from a prospective cohort study conducted in two Italian universities between 2013 and 2020. The study population included women with SSc and women with systemic lupus erythematosus (SLE) who were pregnant at least once. For each pregnancy, placental factors were collected and pregnancy outcomes were recorded. The placental factors included placental protein 14 (PP14), placental growth factor (PGF), placental growth factor isoform 1 (PGF1), and placental growth factor isoform 2 (PGF2).

Results: A total of 100 pregnancies were included in the study. The majority of pregnancies were with SSc (67%), followed by SLE (33%). The most common placental factor was PP14, followed by PGF, PGF1, and PGF2. The pregnancy outcomes were divided into three categories: normal (43%), premature (25%), and preterm (32%). The placental factors were significantly associated with pregnancy outcomes. For example, patients with PP14 levels >10 ng/mL had a higher risk of preterm delivery compared to patients with PP14 levels ≤10 ng/mL (OR 2.5, 95% CI 1.0-5.9).

Conclusion: Placental factors were associated with pregnancy and fetal outcomes in SSc. Further studies are needed to confirm these findings and to explore the mechanisms underlying these associations.
Biopsies from at risk SSC patients showed limited TGF-beta induced increase in collagen and SMA expression, similar to SSc fibroblasts.

Conclusion: Although pilot in nature, this study suggests that patients “at risk” already show biomarker signs of SSc both in their sera, at skin biopsy and fibroblast level. Longitudinal studies on patients at this stage of pre-clinical disease may inform on the stratification strategies for imminent progression to clinical manifestations, and offer both insights on pathogenesis of clinical signs and a window of opportunity for delaying the onset clinical intervention trials.

SAT0282 ASSOCIATION BETWEEN A VARIANT OF THE SRPS5 SPlicing FACTOR GENE AND SYSTEMIC SCLEROSIS IN AN ITALIAN POPULATION

E. Romani1, M. Marenzi1, J. Kosaka-Wegiel2, B. S. Fioretti1, I. Rosa3, E. Sticho1, S. Guiducci1, S. Bellando-Randone1, L. Ibbà-Manneschi1, M. Matucci-Cerinic1, E. Sticchi1, S. Guiducci1, S. Bellando-Randone1, L. Ibbà-Manneschi1, M. Maturacci-Cerinic1, University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy; Jagiellonian University Medical College, Department of Medicine, Cracow, Poland

Background: In systemic sclerosis (SSc), alternative splicing of the last exon ( exon 8) of vascular endothelial growth factor (VEGF)-A pre-mRNA is a key element in the switch from proangiogenic to antiangiogenic VEGF-A isoforms. The mRNA-binding protein serine/arginine protein 55 (SRPS5, also known as SFR56) is a key regulatory splicing factor that promotes distal splice-site selection in the exon 8 region of VEGF-A pre-mRNA and subsequent upregulation of the exon 8b-containing VEGFb antiangiogenic isoform. Overexpression of both VEGFb and SRPS5 has been implicated in SSC-related angiogenesis impairment and peripheral vascular damage. Moreover, differential splicing of the VEGF-A gene has been shown to be critical for development of pulmonary fibrosis. Of note, previous studies reported the lack of sequence variations in the VEGF-A alternatively spliced region, while a single nucleotide polymorphism (SNP) in the SRPS5 gene (rs2235611) has been associated with susceptibility to disturbed ocular angiogenesis in proliferative diabetic retinopathy.

Objectives: This case-control pilot study examined the possible implication of SRPS5 rs2235611 SNP in the genetic predisposition to SSc susceptibility and clinical phenotype.

Methods: A total population of 872 white Italian individuals (414 SSc patients, 458 controls) was studied. All patients were classified as limited and diffuse cutaneous SSc (lcSSc and dcSSc, respectively) and were clinically evaluated for the presence of autoantibodies (antitrombomere, anti-ScC70 antibodies), pulmonary fibrosis and digital ulcers. The SRPS5 rs2235611 SNP was genotyped by TaqMan Real-Time PCR.

Results: SRPS5 rs2235611 genotype distribution and allele frequency were similar in SSc and healthy controls, though a trend toward significance was observed for genotype distribution (p=0.07). The SRPS5 rs2235611 AA genotype significantly influenced the predisposition to SSc (OR 2.55, 95% CI 1.11 to 5.57,
SOLUBLE GUANYLATE CYCLASE REDUCED THE GASTROINTESTINAL FIBROSIS IN BLYEOMYCIN-INDUCED MOUSE MODEL OF SYSTEMIC SCLEROSIS

Background: Systemic scleroderma (SSc) is a chronic autoimmune-mediated connective tissue disorder. Although the etiology of the disease remains under-mind, SSc is characterized by fibrosis and proliferative vascular lesions of the skin and internal organs. SSc involves the gastrointestinal tract in more than 90% of patients. Soluble guanylate cyclase (sGC) is used to treat pulmonary artery hypertension (PAH), and has been shown to inhibit experimental skin fibrosis.

Objectives: The aim of this study is to investigate whether bleomycin (BLM)-treated mice show gastrointestinal fibrosis, and find a therapeutic strategy to the lesion.

Methods: Female C57BL/6J mice were treated with BLM or normal saline by subcutaneous implantation of osmotic minipump. These mice were sacrificed on day 28 or day 42. Gastrointestinal pathologies were examined by Masson Trichrome staining. The expression of fibrosis-related genes in gastrointestinal tract were analyzed by real-time PCR, and the levels of collagen in the tissue was measured by Sirius collagen assay. To evaluate peristaltic movement, the small intestinal transport (ITR%) was calculated as [Dyeing distance×(Duodenum-Appendix)] -1 ×100 (%). We treated BLM-treated mice sacrificed on day 42 than the mice sacrificed on day 28. The ITR% was found to be significantly lower in BLM-treated mice, suggesting that BLM induces esophageal fibrosis in C57BL/6J mice, and treatment with sGC improves the BLM-induced gastrointestinal lesion.

Conclusions: This was the first study to investigate the gastrointestinal fibrosis in BLM-treated mice. We demonstrated that sGC treatment significantly reduced fibrosis of esophagus and intestine in BLM-treated mice, by histological examination and Sirius collagen assay.

Background: Calcinosis cutis is a major daily challenge to patients with long-standing systemic sclerosis (SSc), negatively affecting their quality of life. Unfortunately, treatment options are very limited due to lack of understanding of the pathogenetic process. Currently, calcinosis cutis is only detected at its irreversible end-stage. Early detection of calcinosis cutis could putatively allow early disease-modifying interventions and monitor treatment effects.

Objectives: The aim of the current study is to assess the feasibility of visualising “active” micro-calculifications with 18-F Sodium Fluoride (NaF) PET scanning, compared to low-dose CT in patients with clinically overt calcinosis cutis.

Methods: This was a cross-sectional, observational, pilot study. All patients met 2013 ACR/EULAR criteria for SSc. Patients underwent a whole body NaF PET/low-dose CT scan, scanned 90 minutes post-injection. (Sub)cutaneous calcifications were described and assessed on NaF PET, which was compared to CT images by two independent investigators.

Results: A total of 10 female patients with limited cutaneous SSC [median age 56 years (IQR 52-66), median disease duration 17 years (8-19), PAH 10%, I LD 20%] were included, and compared to 10 controls [70 years (65-73)]. NaF uptake showed normal distribution throughout the skeletal bones, arterial tree, and visceral organs, which was comparable between patients and controls. Additionally, NaF uptake was visible in the skin of all SSc patients, but in none of the controls. Cutaneous NaF uptake largely correlated with clinical calcifications. Most common sites of cutaneous NaF uptake were finger (6 patients) and knees (7 patients). Only 5% of the NaF positive lesions were not accompanied by visible calcifications on CT. Furthermore, of all calcified lesions seen on CT, 51% showed uptake on NaF PET. Small lesions (<1 cm), were generally only visible on CT, due to lower resolution of NaF PET.

Conclusion: Imaging of “active” calcinosis cutis in limited cutaneous systemic sclerosis is feasible using NaF PET scanning. Most clinically overt calcifications and half of those seen on CT were positive for NaF uptake. Whether these “active” calcifications behave differently in terms of faster progression, clinical complaints, and infection risk, and whether these are potentially suitable for disease modifying interventions is subject to future study.
**Conclusion:** Combining a diverse analysis of BAL proteins with the rich dataset available from SSc-ILD patients participating in SLS I, the study findings suggest the involvement of distinct biologic pathways, inter-related networks, and specific biologic signatures associated with unique radiographic features of ILD. The relationship of these factors to other SSc disease features, patient outcomes and as predictors of treatment responses will be studied in future analyses.

**AMPLIFICATION OF THE PRO-FIBROTIC JAK2-STAT3 SIGNALLING AXIS BY TGFb-INDUCED EPigenetic SILENCING OF SOCS3**

C. Dees1, S. Poetter2, Y. Zhang1, C. Bergmann1, X. Zhou1, M. Luber2, E. Karouzakis3, A. Ramminger4, O. Distler1, G. Schett1, J. Distler1.

1Friedrich-Alexander-University (FAU) Erlangen-Nürnberg, Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany; 2Department of Rheumatology, Center of Experimental Rheumatology, University Hospital of Zurich, Zurich, Switzerland

**Background:** Tissue fibrosis caused by a pathological activation of fibroblasts is a major hallmark of systemic sclerosis (SSc). Epigenetic gene silencing of anti-fibrotic genes is thought to play a central role to establish the persistently activated phenotype of fibroblasts independent of external stimuli such as TGFβ, which has been identified as key-mediator of fibroblast activation.

**Objectives:** The aims of the present study were to investigate whether the aberrant activation of JAK2-STAT3 signaling in fibroblasts might be caused by epigenetic silencing of SOCS expression and whether re-establishment of the endogenous, SOCS-dependent control of JAK/ STAT signaling may prevent aberrant fibroblast activation and ameliorate tissue fibrosis.

**Methods:** The methylation status of SOCS3 in fibroblasts was evaluated by methylation-specific PCR and MeDIP assays. 5-aza-2-deoxycytidine (5-aza) and siRNA was used to inhibit DNA methyltransferases (DNMTs) in vitro and in vivo. Knockdown and overexpression experiments served to analyze the mechanism of action in cultured fibroblasts. Fibroblast-specific knockout mice were additionally used to analyze the role of SOCS3 and DNMTs in vivo.

**Results:** Chronically increased levels of TGFβ reduced the expression of SOCS3 in normal fibroblasts to a level also found in SSc fibroblasts. Consistently, the expression of SOCS3 was severely downregulated in skin of SSc patients compared to healthy individuals with only minor differences between limited and diffuse cutaneous SSc. Methylation analyses demonstrated a prominent promoter hypermethylation of SOCS3 in SSc fibroblasts and in normal fibroblasts exposed to persistently high levels of TGFβ. Increased DNMT activity and a time-dependent induction of DNMT3A and DNMT1 expression upon chronic exposure to TGFβ resulted in promoter hypermethylation of SOCS3. Knockdown of SOCS3 induced an SSc-like phenotype in normal dermal fibroblasts with increased activation of JAK2-STAT3 signaling, enhanced expression of myofibroblast markers, increased collagen release, and aggravated experimental tissue fibrosis with increased activation of JAK2-STAT3 signaling. This effect was mimicked by overexpression of mutant JAK2 with mutations in the SOCS3 binding motif. Vice versa, forced overexpression of SOCS3 reduced TGFβ-mediated fibroblast activation and ameliorated the endogenous activation of SSc fibroblasts. Pharmacological inhibition or selective knockdown of DNMTs restored the normal expression of SOCS3, reduced fibroblast activation and collagen release, blocked STAT3-responsive transcription, and exerted potent antifibrotic effects in bleomycin- and TBRII-β-induced dermal fibrosis. In addition, treatment with 5-aza or knockdown of either DNMT1 or DNMT3A induced regression of established fibrosis.

**Conclusion:** These findings identify a novel pathway of epigenetic imprinting of fibroblasts in fibrotic disease with translational implications for the development of new targeted therapies in fibrotic diseases. We demonstrate that abnormally high TGFβ signaling in fibrotic diseases perturbs the epigenetic control of STAT signaling by DNMT-induced silencing of SOCS3 expression. Our data might thus strengthen the scientific rationale for targeting DNA methylation in fibrotic diseases.

**CHARACTERIZATION OF ANTI-AMINOACYL tRNA SYNTHETASE AUTOANTIBODIES IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES**

C. Pregen1,2, A. Notarnicola1, C. Hellström3, E. Wigen1,2, C. Cerqueira1, P Nilsson1, I. E. Lundberg1, H. Persson3, S. Gräslund1,2, P. J. Jakobsson1,2.

**Background:** Idiopathic inflammatory myopathies (IIM) are rare chronic inflammatory diseases associated with high mortality and morbidity [1]. One sub-group of IIM, anti-synthetase syndrome (ASS), is characterized by the presence of autoantibodies that target aminoacyl (t)RNA synthetases (aaRS), together with specific clinical manifestations such as myositis, interstitial lung disease (ILD), arthritis, mechanic’s hand, Raynaud’s syndrome and fever [2]. The most common anti-aaRS autoantibody, anti-Jo1 targetting histidyl tRNA synthetase (HisRS), is reported in up to 20-30% of patients with IIM, and up to 90% of patients with myositis and ILD [3, 4]. Besides Jo1, there are today seven other identified autoantigens within the aaRS family.

**Objectives:** A large part of patients with IIM, including individuals with clinical manifestations indicating ASS, test seronegative to all known myositis specific autoantibodies. However, these patients could potentially harbor autoantibodies...
against targets not tested for in clinic. In this study, we aimed at extending the detection of autoantibodies by including all cytoplasmic aaRS in the analysis of patients with IIM. We hypothesized the existence of new potential autoantigens with unknown protein function.

Methods: The presence of anti-aaRS autoantibodies was determined using a multiplex suspension bead array assay on 242 IIM patients from the Karolinska University Hospital myositis cohort. A panel of 186 recombinant constructs, representing 57 proteins that included full-length or partial sequence overlaps between constructs of all cytoplasmic aaRS as well as other myositis related proteins, were coupled to magnetic color-coded beads and each plasma sample was tested against the complete antigen panel.

Results: By the use of this multiplex method we identified patients with autoantibodies against many of the tested aaRS. Autoantibodies binding to HisRS have previously been shown to bind with higher reactivity to the WHEP domain of HisRS and this was also confirmed in this study. We confirmed reactivity against three of the other aaRS tested for in the clinic (PL-12, PL-7, and EJ). In addition, we identified patients positive for anti-Zo-, KS- and HA, autoantibodies usually not screened for in routine. Finally, our data indicates that there are autoantibodies binding to other aaRS than the previously known eight autoantigens, which will be presented.

Conclusion: In this study, we could detect autoantibodies in plasma from patients with IIM, both against the most common aaRS autoantigens, but also against other aaRS that are usually not tested for in clinic. We conclude that it is important to continue the studies of anti-aaRS autoantibodies, and their correlation to clinical manifestations, and in the long run also include more aaRS autoantigens in clinical practice.

THE INS AND OUTS OF EPIDERMAL DYSFUNCTION IN SYSTEMIC SCLEROSIS (SSC): RESULTS FROM A NOVEL TISSUE ENGINEERED EPIDERMAL EQUIVALENT FROM SSC KERATINOCYTES

B. Russo1, J. Borowczyk-Michalowska1,2, W.H. Boehncke2, N. Brembilla1,2, C. Chizzolini1. 1Pathology & Immunology School of Medicine, University of Geneva, Geneva, Switzerland; 2Department of Dermatology, University Hospital and School of Medicine, University of Geneva, Geneva, Switzerland

Background: Skin fibrosis is a hallmark of systemic sclerosis (SSc). It is commonly accepted that vascular damage, immune system activation and, abnormal fibroblasts-to-myofibroblasts differentiation are pathological capital features. Nevertheless, recent evidence portrays a potential role of the epidermis in the pathogenesis of SSc skin fibrosis. We hereby present the first study to demonstrate the potential role of epidermis dysfunction in the progression of skin fibrosis in SSc, and its effect on dermis homeostasis. Using a novel epidermal equivalent reconstituted from SSc keratinocytes.

Methods: Primary keratinocytes and fibroblasts cell lines were generated from skin biopsies obtained from 6 SSc and 6 healthy donors (HD), upon informed consent and ethical approval. Epidermal equivalents (EE) were generated from 4 SSc and 6 HD keratinocytes. Skin and EE expression of the mitotic marker Ki67, of the differentiation markers (K10, involucrin, filaggrin, loricrin), and activation markers (K6, K16) was evaluated by immunohistochemistry. The transcriptomic profile of SSc keratinocytes in monolayer or stratified in EE was identified by RNAseq analysis. EE conditioned medium was used to stimulate fibroblasts. The fibroblast production of interleukin (IL)-6, IL-8, matrix metalloproteinase (MMP)-1, type-1 collagen (coll-I), and fibroblastin was assessed by ELISA.

Results: Compared to HD, immunohistochemistry revealed that SSc epidermis is characterized by aberrant premature differentiation and enhanced expression of activation markers associated with a lower mitotic rate of basal keratinocytes. Of interest, EE reconstituted from SSc keratinocytes reproduced most of the abnormalities observed in SSc epidermis. RNAseq analysis revealed that SSc keratinocytes, either cultured in monolayer or in EE, have a distinct transcriptic profile compared to their HD counterpart, characterized by the downregulation of genes from the HOX family. The supernatant of EE enhanced the production of IL-6, IL-8, MMP-1, col-I, and fibroblastin by HD fibroblasts (p<0.05). Except for col-I and fibroblastin, this effect was 2-fold higher in the presence of supernatant from EE reconstituted by SSc keratinocytes. Neutralization experiments indicated that IL-1 was, at least in part, responsible for keratinoctye-dependent fibroblasts activation.

Conclusion: We established a novel epidermal equivalent tissue engineered from SSc keratinocytes, that recapitulates the in vivo characteristics of SSc epidermis. Our preliminary data suggest that SSc keratinocytes have an intrinsic altered program of differentiation, possibly due to the downregulation of some HOX genes. This altered phenotype is associated with increased production of mediators that stimulate fibroblasts production of inflammatory cytokines. In this scenario, we may hypothesize that SSc epidermis participates in modifying the dermis environment, favoring the development of chronic inflammation and fibrosis.

HIGH SERUM MYOSTATIN LEVELS SUGGEST ACCELERATED MUSCLE SENESCENCE IN ACTIVE IDIOPATHIC INFLAMMATORY MYOSITIS

A. Anuja1, M. Singh1, M. K. Rai1, H. Singh1, V. Agarwal1, L. Gupta1, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Background: Inflammation is the forerunner to fibrosis and premature ageing in various systemic diseases. Hence it seems plausible that idiopathic inflammatory myopathies (IIM) may exhibit accelerated senescence too.

Objectives: Hence we investigated the Myostatin: Follistatin system in the serum as a reflection of early senescence in myositis as compared with healthy and diseased controls.

Methods: Patients with inflammatory myositis (ACR/EULAR criteria) presenting to the wards and outpatient clinic between December 2017 to August 2019 were recruited. Those with active infection, pregnancy, renal dysfunction or chronic kidney disease were excluded. Apart from patient and disease variables, activity and damage were assessed using standard IMACS score set measures. Patients in inception cohort were additionally followed up at 1 and 6 months. Myostatin and follistatin were estimated in sera using ELISA (R&D systems, USA). Juvenile myositis and young adults (18-40 years) were subsequently analyzed separately. Non-parametric tests were used for paired and unpaired analysis. Results expressed as median.

Results: 95 myositis (8 Juvenile myositis, 26 DM, 10 PM, 29 Overlap, 2 NAM 1 CAM and 19 ASS) patients (23 Male and 72 Female) with median age 38 (24.5-46.0) years and disease duration 0.9 (2.3-5.1) years were included. Serum Myostatin was lower in IIM than in healthy control (HC) (153.5 vs. 243.6 p=0.001, Fig 1A) but higher in IIM as compared with disease controls (153.5 vs 86.1, p=0.0174 Fig 1B). Serum myostatin was comparable between juvenile and adult myositis and in the various subsets of adult myositis (Fig 1 C and D). Myostatin levels were higher in active as compared with inactive myositis in young adults (211.7 vs. 158.9, p=0.0149, Figure 1E).

**THE ROLE OF X-LINKED INHIBITOR OF APOPTOSIS PROTEIN (XIAP) IN SYSTEMIC SCLEROSIS**

**C. Bergmann**, **L. Hallenberger**, **B. Merlevede**, **C. Dees**, **C. W. Chen**, **O. Dieter**, **G. Schett**, **J. Distler**. 1Department Internal Medicine III, Rheumatology, Erlangen, Germany; 2University Hospital of Zürich, Zürich, Switzerland

**Background:** Pathologic activation of fibroblasts is a central feature of fibrotic tissue disease in Systemic Sclerosis (SSc). Although individual key signaling pathways of fibroblast activation such as transforming growth factor β (TGFβ) and WNT/β-catenin signaling have been identified, the consequences of the concomitant upregulation of these pathways and their crosstalk are incompletely characterized. Given the high medical need, the identification of mutual activation and amplification loops of profibrotic signals is essential to identify novel candidates for therapeutic antibodies. XIAP (X-linked inhibitor of apoptosis protein) is a ubiquitously expressed member of the IAP protein family which are implicated in the regulation of various cellular functions and tissue turnover. XIAP was recently described to be implicated in WNT/β-catenin signaling and TGFβ signaling.

**Objectives:** The aim of this study is to characterize the role of XIAP in fibrotic disease.

**Methods:** XIAP-expression was analyzed by qPCR, IF and Western blot. XIAP was targeted pharmacologically and with siRNA. The activation of WNT/β-catenin signaling was assessed by analyses of WNT target genes, by TOPflash/FOPflash luciferase reporter assay and in reporter mice. In vivo, XIAP inhibition was analyzed in two different models of fibrosis.

**Results:** The expression of XIAP is increased in the skin of SSc patients compared to healthy individuals with a particular prominent expression in fibroblasts. The overexpression of XIAP is more pronounced in SSc patients with diffuse and active skin fibrosis compared to SSc patients with limited and inactive disease. The overexpression of XIAP is also reflected in several experimental fibrosis models: the model of scleroderma-like graft versus host disease, the model of bleomycin induced skin fibrosis and Topoisoasme I induced fibrosis (Topo II mice). TGFβ induces the expression of XIAP in vitro and in vivo and treatment with the TGFβ1 receptor antagonist SD208 reverses the TGFβ induced expression of XIAP. Inhibition of XIAP with embelin or siRNA reduces the TGFβ induced activation of fibroblasts with reduced collagen release and reduced expression of myofibroblast markers. In addition, XIAP inhibition reverted the activated fibroblast phenotype in SSc fibroblasts with reduced expression of stress fibers and αSMA. The antifibrotic effects of XIAP inhibition occurred in non-toxic doses as demonstrated by MTT and by TUNEL staining. In vivo, inhibition of XIAP reduced skin fibrosis in the models of bleomycin induced skin fibrosis and in Topo-II induced skin and lung fibrosis as evaluated by analysis of dermal thickening, dermal hydroxyproline content and by analysis of myofibroblast differentiation. Mechanistically, XIAP inhibition reduced the activation of WNT/β-catenin signaling as demonstrated by TOPflash reporter assays and by the analysis of WNT target genes.

**Conclusion:** XIAP is upregulated in SSc fibroblasts and murine SSc models in a TGFβ-dependent manner and promotes fibroblast activation by fostering canonical WNT signaling. Our data suggest that XIAP mediates an amplification loop between TGFβ and WNT/β-catenin signaling. Inhibition of XIAP may thus be a novel approach to target aberrant WNT/β-catenin signaling in fibrotic diseases.

**EXOSOMES DERIVED FROM PLASMA OF SYSTEMIC SCLEROSIS (SSC) PATIENTS AND FROM SSC CULTURED FIBROBLASTS CONTAIN PRO-FIBROTIC miRNA SIGNATURES AND COULD INDUCE MYOFIBROBLAST DIFFERENTIATION IN VITRO**

C. Corallo1, M. Cutoio2, S. Soldano2, E. Selvi1, F. Bellisai2, N. Giordano1.

1University of Siena, Sclerodermia Unit, Department of Medicine, Surgery and Neurosciences, Siena, Italy; 2IRCSc San Martino Polyclinic Hospital, University of Genoa, Rheumatology, Genoa, Italy

**Background:** Exosomes generated great resonance in the last few years due to their important roles in different biological pathways and diseases, including systemic sclerosis (SSc) (1). They are lipid-like nanovesicles containing biomarkers, such as proteins, lipids, macromolecules and nucleic acids, including microRNA (miRNA) (2). Exosomes are implicated in intercellular communication by fusing and releasing their cargo into the target cells (3).

**Objectives:** In the present study, we evaluated the potential of exosomes deriving from SSc plasma patients or generating from cultured SSc fibroblasts to drive the fibrotic signaling in the disease.

**Methods:** Exosomes were isolated from plasma of n=10 SSc patients and from n=10 control subjects. Exosomes were also purified from cell culture supernatants of SSc fibroblasts and of control fibroblasts. Exosome size and concentration were assessed by Nanosight Particle Tracking Analysis (NTA) and by transmission electron microscopy (TEM). The content of anti-fibrotic (let-7a, 146a, 200a, 223a) and pro-fibrotic (150, 155) miRNAs was assessed in all the plasma-derived and cell culture-derived exosome populations by semiquantitative real time PCR. Finally, isolated exosomes were used to stimulate control dermal fibroblasts in culture. Gene expressions (COL1A1, ACTA2 and TAGLN) were assessed by quantitative real time PCR (qRT-PCR) and protein levels (type-I-collagen, α-SMA and SM22) by immunofluorescence (IF).

**Results:** Exosomes isolated from SSc plasma samples showed higher concentration (3.3x1010±1.1x1010 particles/mL) compared to those isolated from control plasma ones (1.5x1009±0.4x1010 particles/mL) (p<0.01). The exosome size did not differ between SSc and control plasma samples and ranged from 50nm to 150nm. Similar results were obtained with exosomes generated from fibroblast cultures: the concentration was higher in SSc fibroblasts (1.1x1010±0.2x1010 particles/mL) than in control ones (0.4x1010±0.1x1010 particles/mL) (p<0.05) with no significant differences in size distribution. The content of all anti-fibrotic (let-7a, 146a, 200a, 223a) miRNAs was decreased in exosomes coming from both SSc plasma samples and from SSc fibroblasts with respect to control plasma samples (p<0.05) and to control fibroblasts (p<0.05). On the contrary, the pro-fibrotic (150, 155) miRNAs were significantly upregulated in exosomes deriving from SSc plasma samples and from SSc fibroblasts, with respect to control plasma samples (p<0.05) and to control fibroblasts (p<0.05). Finally, only exosomes coming from SSc plasma samples or SSc fibroblast cultures were able to induce pro-fibrotic gene (COL1A1, ACTA2 and TAGLN) and protein (type-I-collagen, α-SMA and SM22) expression in control fibroblasts. No pro-fibrotic induction was seen in presence of exosomes isolated from control plasma samples or control fibroblast cultures.

**Conclusion:** This study demonstrates that plasma from SSc patients contains higher concentration of exosomes compared to plasma from control subjects and SSc-derived exosomes contain specific pro-fibrotic miRNA signatures that can induce myofibroblast differentiation in vitro. These results suggest that exosomes could be fibrotic drivers towards non-affected areas in vivo, and they might represent novel targets for precision medicine treatments in SSc.

**IL33 ACTIVATES FIBROBLASTS AND INDUCES SKIN FIBROSIS IN SYSTEMIC SCLEROSIS**

X. Wu1, B. Ming1, L. Dong1, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Rheumatology and Immunology, Wuhan, China

**Background:** Systemic sclerosis (SSc) is a chronic immune-mediated autoimmune disease that is characterized by fibrotic changes of the skin and internal organs, which in turn leads to distortion of tissue structure and gradual loss of organ function. So far, there is still no treatment allows full recovery from this severe disorder. Therefore, it is of great social significance to study the pathogenesis of this disease and find new targets for treatment. Interleukin 33 (IL-33), which is a potent inducer of type 2 immune response, has been confirmed to be involved in the development and progression of multiple fibrotic diseases. However, the role and mechanism of IL-33 in SSc-related fibrosis remains unclear.

**Objectives:** To clarify the role of interleukin 33 (IL-33) and its receptor Suppression of tumorigenecity 2 (ST2) in the skin fibrosis of SSc, so to provides a new target for the treatment of fibrosis in patients with SSc.

**Methods:** The levels of IL-33 and ST2 was analysed in human samples, murine models of SSc and in cultured fibroblasts by immunohistochemistry and immunofluorescence. The functional role of IL-33 was evaluated by detecting changes...
in proliferation, migration, and activation of fibroblasts stimulated with recombi-
nant IL-33 protein. MAPK and NF-κB signalings of fibroblasts were assessed by
western blotting and analyses of target genes. The role of IL-33 in skin fibrosis
was analysed in IL-33 deficient mice (il33−/−) and wild-type controls injected with
bleomycin or NaCl.

Results: The expression of IL-33 and its receptor ST2 were up-regu-
lated in skin lesions of SSc patients (Fig 1 A-C) and bleomycin-treated
mice(Fig1 D-F). Compared to the healthy skin, the skin from SSc patients
expressed more ST2 on fibroblasts membrane(Fig 1 B-C). IL33 induces
MAPK and IκBα activation in human dermal fibroblast(Fig 2 A), and pro-
mote proliferation, migration and production of collagen of human dermal
fibroblasts, but not the release of inflammatory factors(IL-6, MCP-1)(Fig2
B-G). Mice deficient for IL33 are protected from bleomycin-induced dermal
fibrosis (Fig3).

Conclusion: IL33 promotes skin fibrosis by activating fibroblasts, and IL33/ST2
may be an important target for the treatment of fibrosis in patients with SSc.

**Background:** Polymyositis (PM) is a chronic inflammatory myopathy that impairs
muscle functions. While the treatment with glucocorticoids (GC) has been the
cornerstone of the treatment for PM to suppress immune-mediated muscle injury,
some patients suffer from glucocorticoid-induced myopathy during the treatment,
which further deteriorates the muscle weakness. It has been reported that sig-
ificant disability and muscle weakness persist in a quarter of the patients even
after successful treatment with the immunosuppressive therapy. Ultimately, new
therapeutic strategies to preserve and recover muscle strength as well as to
suppress immune-mediated muscle injury are needed. Glucagon-like peptide-1 (GLP-1) is a peptide hormone with a variety of functions. Although GLP-1 receptor (GLP-1R) agonists have been developed as an anti-diabetic therapy to promote insulin secretion, emerging data suggest that they have pleiotropic actions including anti-inflammatory effects and suppression of muscle wasting. We presumed GLP-1R agonists have beneficial effect on PM to preserve and recover muscle strength.

**Objectives:** To examine the effect of a GLP-1R agonist on C protein-induced myositis (CIM), a murine model of polymyositis, in monotherapy or in combination with prednisolone (PSL).

**Methods:** Muscle specimens of PM patients and CIM were examined with immuno-histological staining for the expression of GLP-1R. The therapeutic effect of PF1801 (ImmunoForge), a GLP-1R agonist (5mg/kg body weight (BW)/day), in monotherapy or in combination with PSL (20mg/kg BW/day) on CIM was examined for grip strength, muscle weight and histological muscle inflammation.

**Results:** GLP-1R was expressed on the plasma membrane of muscle cells of PM patients and CIM. The expression levels were high in the area where inflammatory infiltrates were observed. The treatment of CIM with PF1801 in monotherapy or in combination with PSL suppressed the CIM-induced decrease in grip strength on day 14. The combination therapy with PF1801 and PSL ameliorated the CIM-induced muscle weight loss in quadriceps, while the monotherapy with PF1801 or PSL did not. The histological analysis of muscle specimens on day 14 of CIM revealed that the muscle inflammation was suppressed by the treatments with PF1801, PSL, or the combination of PF1801 and PSL. None of the mice in the combination therapy group developed histologically evident myositis, while the myositis was observed in 90%, 40% and 40% of the mice in vehicle treated group, PF1801 treated group, and PSL treated group, respectively. The necrotic area of the muscle in CIM was also reduced in the mice treated with PF1801, PSL, or the combination of PSL and PF1801. The CIM-induced increase in spleen weight was suppressed by PF1801, PSL, or the combination of PSL and PF1801. The additive effect of PSL and PF1801 on the suppression of CIM-induced increase in spleen weight was observed.

**Conclusion:** PF1801 ameliorated CIM-induced muscle weakness and muscle inflammation in CIM. The combination therapy with PF1801 and PSL ameliorated CIM-induced muscle weight loss. PF1801 could be a novel therapy to recover muscle weakness and to suppress muscle inflammation in PM.

**SERUM LEPTIN LEVELS IN SYSTEMIC SCLEROSIS PATIENTS WITH ELECTROCARDIOGRAPHIC ABNORMALITIES**

G. Pellegrino1, K. Stefanantonii1, F. Facioni1, C. Angelieri1, V. Gigante2, R. Badagiacca3, C. D. Vizza1, S. Morelli1, E. Rosato1, V. Riccieri2. 1Sapienza University of Rome, Department of Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy; 2Sapienza University of Rome, Department of Translational and Precision Medicine, Rome, Italy; 3Sapienza University of Rome, Department of Translational and Precision Medicine, Rome, Italy

**Background:** Electrocardiographic (ECG) abnormalities are described in 25-75% Systemic Sclerosis (SSc) cases and they are associated with other systemic manifestations as well as with a worse prognosis. There is an increasing need for clinical and laboratory biomarkers to ameliorate the diagnostic and therapeutic approaches to patients with ECG abnormalities, due to their actual low sensitivity and specificity. Adipokines are circulating proteins that appear dysregulated in SSc and leptin in particular is synthesized in response to inflammatory conditions and seems to play a proinflammatory and pro-fibrotic action in SSc. Interestingly, many studies in the last years have underlined its role in the cardiac remodeling mechanisms and in the development of cardiac fibrosis in other chronic diseases.

**Objectives:** Aim of our study is to evaluate the role of leptin in the development of cardiac rhythm disorders (CRD) during SSc. Furthermore, by the analysis of the clinical and demographic parameters of our SSc patients, we tried to define other possible features associated with increased serum leptin concentration.

**Methods:** We included eighty-five SSc patients, fulfilling the 2013 ACR/ EULAR classification criteria, attending the Regional Rare Disease Center of Policlinico Umberto I of Rome. Fifty presented significant CRD at non-invasive diagnostic techniques (12 Lead ECG, 24-hour Holter ECG). Demographic, clinical, conventional cardiovascular risk factors were examined; instrumental and laboratory assessments were obtained, together with ECG recordings. Thirty-five SSc patients without pathologic finding at ECG traces, matched for demographic and clinical features, were recruited as the control group. In all cases, after obtaining written informed consent, blood samples were taken to measure serum levels of leptin using an ELISA assay (Life Technologies-Italy).

**Results:** The fifty SSc patients with CRD (mean age 51±15 years; F:M:41:9) had pulmonary fibrosis (PF) in 32 cases (64%) and a BMI ≥25kg/m² in 22 (44%) while in the control group of thirty-five SSc patients (mean age 49±16 years; F:M:33:2) PF was found in 15 (43%) and a BMI ≥25kg/m² in 9 (35%). We detected significantly higher median values of serum leptin in SSc patients with CRD compared to the control group (12027 pg/ml IQR 12314 versus 6392 pg/ml IQR 7103; p 0.0009). Additionally, SSc patients with a BMI ≥25kg/m² (31 cases) as well as those with PF (47 cases) showed a significantly higher median serum leptin levels compared to those with BMI <25kg/m² (13161 pg/ml IQR 13610 versus 8187pg/ml IQR 8255; p 0.0008) and those without PF (11740 pg/ml IQR 11940 versus 7616 pg/ml IQR 7855; p 0.0079).

**Conclusion:** To our knowledge this is the first report on high serum levels of leptin in SSc patients with CRD that also confirms its increase in those cases where BMI ≥25kg/m² and PF according to scientific literature data. The role of leptin in the pathogenesis of SSc remains unclear although it is already known its involvement in the development of cardiac fibrosis during other chronic diseases. On the basis of these results we speculate on leptin involvement in the pathogenesis of CRD during SSc, although further studies are needed with larger cohort of patients.

**DIFFERENTIAL PHENOTYPES OF DISEASE-SPECIFIC AUTO-REACTIVE B CELL RESPONSES IN PATIENTS WITH SYSTEMIC SCLEROSIS**

C. Wortel1, N. Van Leeuwen2, M. Boonstra3, R. Toes1, T. Huizinga1, J. De Vries-Bouwstra1, H. J. Scherf4, Leiden University Medical Center, Leiden, Netherlands; 1Leiden University Medical Center, Leiden, Netherlands.

**Background:** Systemic Sclerosis (SSc) carries the highest mortality burden among the rheumatic diseases. >95% of SSc patients harbor autoantibodies. Anti-topoisomerase antibodies (ATA) and anti-centromere antibodies (ACA) are the most prevalent, mutually exclusive in individual patients, associate with distinct disease phenotypes and predict disease. Whether and how these auto-reactive B细胞 responses contribute to disease, however, is currently unclear.

**Objectives:** To delineate phenotypic and functional characteristics of anti-topoisomerase and anti-centromere specific B cell responses in individual patients with SSc.

**Methods:** Peripheral blood mononuclear cells (PBMC) obtained from ATA- and ACA-positive SSc patients were cultured without stimulation or in the presence of CD40L-expressing fibroblasts, IL-21 and BAFF. In addition, PBMC were depleted of circulating plasmablasts (CD19+CD20-CD27++) by fluorescence activated cell sorting (FACS), and isolated plasmablasts were cultured separately. ATA- and ACA-IgG and -IgA were measured in culture supernatants by ELISA. B cell
subsets were defined by flow cytometry. Healthy donors and patients with rheumatoid arthritis served as controls.

**Results:** We observed that ATA- and ACA-positive SSc patients harbour circulating B cells that secrete either ATA-IgG or ACA-IgG upon stimulation, depending on their serotype. In addition, we noted spontaneous secretion of ATA-IgA and, more remarkably, extensive secretion of ATA-IgA in ATA-positive patients. This degree of spontaneous, antigen-specific IgA secretion was specific for the ATA response in ATA-positive patients, while spontaneous ACA-IgA secretion was undetectable in the ACA-positive patient group. FACs experiments showed that spontaneously ATA-IgA secreting B cells were primarily present in the plasmablast compartment.

**Conclusion:** Our findings demonstrate that ATA-positive SSc patients harbour an activated ATA-IgG and ATA-IgA B cell response, as indicated by the spontaneous secretion of both ATA isotypes by circulating plasmablasts. Remarkably, the ACA B cell response was far less active and lacked the active IgA component which suggests a difference in the triggers driving these autoreactive B cell responses in patients. Moreover, the remarkable ATA-IgA secretion points towards a potential mucosal origin of the ATA response.

**SAT0298**

**IS INTERLEUKIN 6 A FACTOR OF FIBROGENESIS IN DERMAL FIBROBLASTS?**

A. S. Siebuhr1, P. Juhl1, M. Karsdal1, A. C. Bay-Jensen1.

1Nordic Bioscience, ImmunoScience, Herlev, Denmark; 2Nordic Bioscience, R&D, Herlev, Denmark

**Background:** Interleukin 6 (IL-6) is known to have both pro- and anti-inflammatory properties, depending on the receptor activation. The classical IL-6 signaling via the membrane bound receptor is mainly anti-inflammatory, whereas signaling through the soluble receptor (sIL-6R) is pro-inflammatory/pro-fibrotic. However, the direct fibrotic effect of IL-6 stimulation on dermal fibroblasts is unknown.

**Objectives:** We investigated the fibrotic effect of IL-6 + sIL-6R in a dermal fibroblast model and assessed fibrosis by neo-epitope biomarkers of extracellular matrix proteins.

**Methods:** Primary healthy human dermal fibroblasts were grown for up to 17 days in DMEM medium with 0.4% fetal calf serum, ficoll (to produce a crowded environment) and ascorbic acid. IL-6 [1-90 nM]+sIL-6R [0.1-9 nM] alone or in combination with TGFβ [1 nM] were tested in three different donors. TGFβ [1 nM], PDGF-AB [3 nM] and non-stimulated cells (w/o) were used as controls. Tocilizumab (TCZ) with TGFβ + IL-6 + sIL-6R stimulation was tested in one donor. Collagen type I, III and VI formation (PRO-C1, PRO-C3 and PRO-C6) and fibronectin (FBN-C) were evaluated by validated ELISAs (Nordic Bioscience). Western blot analysis investigated signal cascades. Gene expression of selected ECM proteins was analyzed. Statistical analyses included One-way and 2-way ANOVA and area under the curve analysis.

**Results:** formation by the end of the culture period. The fibroblastic and collagen type VI signal were consistent between the three tested donors, whereas the formation of type III collagen was only increased in one donor, but in several trials. Type I collagen formation was unchanged by IL-6 + sIL-6R stimulation. The gene expression of type I collagen was induced by IL-6 + sIL-6R. Western blot analysis validated trans-signaling by the IL-6+sIL-6R stimulation with TGFβ, as the biomarker level was either decreased or increased compared to TGFβ alone. In two studies the type I collagen level was synergistically increased by IL-6 + sIL-6R + TGFβ, whereas another study found the level to be decreased compared to TGFβ alone. The gene expression of fibronectin and type I collagen was increased with TGFβ +IL-6+sIL-6R compared to TGFβ alone.

Inhibition of IL-6R by TCZ in combination with IL-6 + sIL-6R did only decrease the fibronectin level with the lowest TCZ concentration (p=0.03). TCZ alone decreased the fibronectin level in a dose-dependent manner (One-way ANOVA p=0.0002).

**Conclusion:** We investigated the fibrotic response of dermal fibroblasts to IL-6 + sIL-6R stimulation. IL-6 modulated the fibroblast level and modulated the collagen type III formation level in a way that is dose-dependent manner. In combination with TGFβ, IL-6 decreased collagen type I and IV formation and fibronectin. However, in this study inhibition of IL-6R by TCZ did not change the fibrotic response of the dermal fibroblasts. This study indicated that IL-6 did not induce collagen formation in dermal fibroblasts, except type III collagen formation with high IL-6 concentration.

**PROLIFERATION, MIGRATION AND CONTRACTION ARE DIFFERENT BETWEEN TGFβ AND PDGF STIMULATED DERMAL FIBROBLASTS**

A. S. Siebuhr1, S. F. Madsen1, M. Karsdal2, A. C. Bay-Jensen1, P. Juhl1.

1Nordic Bioscience, ImmunoScience, Herlev, Denmark; 2Nordic Bioscience, R&D, Herlev, Denmark

**Background:** Systemic sclerosis has vascular, inflammatory and fibrotic components, which may be associated with different growth factors and cytokines. Platelet derived growth factor (PDGF) is associated with the vasculature, whereas tumor necrosis factor beta (TGFβ) is associated with inflammation and fibrosis. We have developed a fibroblast model system of dermal fibroblasts for anti-fibrotic drugs testing, but the effect of the fibroblasts mechanistic properties are unknown.

**Objectives:** We investigated different mechanical capacities of PDGF and TGFβ treated human healthy dermal fibroblasts in the Siau setting.

**Methods:** Primary human healthy dermal fibroblasts were grown in DMEM medium containing 0.4% fetal calf serum, ficoll (to produce a crowded environment) and ascorbic acid for up to 17 days. A wound was induced by scratching the cells at 0, 1, 3 or 7 days after treatment initiation. Wound closure was followed for 3 days. Contraction capacity was tested by creating gels of human fibroblasts produced collagen containing dermal fibroblasts and contraction was assessed at day 2 by calculating the percentage of gel size to total well size. Collagen type I, III and VI formation (PRO-C1, PRO-C3 and PRO-C6) and fibronectin (FBN-C)
were evaluated by validated ELISAs (Nordic Bioscience). Gene expression was analyzed after 2 days in culture. Statistical analyses included One-way ANOVA and student’s t-test.

**Results:** Generally, PDGF closed the wound in half the time of w/o and TGFβ, when treatment and cells are added concurrently or scratched one day after treatment initiation. When treatments were added 3 or 7 days prior to scratch, the cells treated with PDGF had proliferated to a higher degree than w/o and TGFβ. A consequence of this, was that when cells scratch the sheet of cells produced was lifted from the bottom and fold over itself, leaving a much greater scratch than in the other treatments. However, despite this increased gap the PDGF treated cells closed the wound at the same time as w/o and TGFβ, confirming the results of the cells scratched at day 0 and 1.

Inhibition of contraction by ML-7 of otherwise untreated cells inhibited contraction significantly compared to untreated cells alone (p=0.0009). Contraction was increased in both TGFβ and PDGF treated cells compared to untreated cells (both p<0.0001). TGFβ+ ML-7 inhibited the contraction to the level of w/o (p=0.0024), which was only 35% of ML-7 alone. In the contraction study the cells were terminated after 2 days of culture, thus prior to when biomarker of ECM remodeling is usually assessed. However, FBN-C was detectable and a significant release of fibronectin by TGFβ and PDGF compared to w/o was found in the supernatant (both p<0.0001). The gene expression of FBN was only increased with TGFβ (p<0.05), and not PDGF. ML-7 alone tended to decrease FBN-C and in combination with TGFβ the FBN level was significantly decreased compared to TGFβ alone (p<0.0001). However, the level of TGFβ+ML-7 was significantly higher than ML-7 alone (p=0.038).

TGFβ increased the gene expression of most genes assessed, except Col1a1. PDGF increased the gene expression of Col3a1, Col5a1 and Col6a1 above the critical fold change of 2, but only significantly in Col5a1 and Col6a1 (both p<0.05).

**Conclusion:** This study demonstrates that TGFβ and PDGF have different mechanical capacities in human healthy dermal fibroblasts; TGFβ increased gene expression of ECM related genes, such as collagens and have increased FBN release in the supernatant already 2 days after initial treatment. PDGF has increased contraction, proliferation and migratory capacities and less expression of ECM related genes and proteins.

**SAT0300**

**SERUM FROM “EARLY” SYSTEMIC SCLEROSIS PATIENTS ALREADY INDUCES THE ALTERNATIVELY ACTIVATED MACROPHAGE PHENOTYPE (M2) IN CULTURED HUMAN MONOCYTES**

1. Research Laboratory and Academic Division of Clinical Rheumatology, Dept. Internal Medicine, University of Genova, Genoa, Italy; 2.Sclerodermia Unit, Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy; 3.Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Belgium

**Background:** Alternatively activated (M2) macrophages seem to play a role in the fibrotic process of systemic sclerosis (SSc) as potential inducers of tissue fibrosis through their secretion of specific cytokines and chemokines, such as interleukin-10 (IL-10), macrophage derived chemokine (CCL-22) and pro-fibrotic metalloproteases (i.e. MMP9) (1-3).

**Objectives:** To investigate the presence of circulating cells belonging to the monocyte lineage showing an M2 phenotype in SSc patients (pts) and possible correlation with the clinical parameters of the disease. Moreover, to investigate if the treatment of cultured monocytes isolated from healthy subjects with serum derived from early SSc pts may induce their in vitro polarization into M2 macrophages.

**Methods:** Fifty female SSc pts (mean age 64±13 yrs), fulfilling the EULAR/ACR criteria, and 27 gender-matched healthy subjects (HSs, mean age 57±7 yrs) were considered at the Rheumatology Division of Genoa University after written informed consent. Nailfold videocapillaroscopy (NVC), serum SSc-related antibodies and skin involvement were investigated. Circulating cells belonging to the monocyte populations (CD45+and CD14+ cells) were characterised by flow cytometry using specific surface markers of M2 phenotypes (CD204+CD163+). In SSc pts had been under stable treatment regimen for at least six months. Cultured monocytes, isolated by negative selection from peripheral blood mononuclear cells (PBMCs) of 8 HSs, stimulated for 48 hrs with 10% of serum of lcSSc pts with “Early” NVC pattern, as well as serum of dcSSc pts with “Active” and “Late” NVC patterns. Cultured monocyte human cell line (THP1) was differentiated into macrophages (5ng/ml of phorbol myristate acetate) and then stimulated with SSc sera. The expression of CD204, CD206 (M2 markers) and CD68 was investigated by immunocytochemistry, whereas MMP3 secretion was investigated by zymography. Statistical analysis was performed using Mann-Whitney and Kruskal-Wallis tests, and correlations were explored by bivariate Pearson’s analysis.

**Results:** In SSc pts the percentage of circulating M2 cells (CD14+CD204 “CD163”CD206) was significantly increased compared to both HSs and SSc pts not under immunosuppressive treatment (p<0.05). However, no correlation with skin involvement and SSc-related antibodies was observed. Cultured macrophages stimulated with SSc serum expressed CD204 and CD206 markers compared to the macrophages stimulated with HS serum (CD204 and CD206 double negative cells). Of note, the ability to express M2 markers was already evident in cultured macrophages stimulated with “Early” NVC SSc serum and their expression even increased in macrophages stimulated with “Active” and “Late” NVC sera together with the secretion of MMP9. Same results were observed also in cultured THP1-derived macrophages.

**Conclusion:** The study confirmed that SSc pts are characterized by a significant increase of circulating M2 cells, suggesting their possible involvement in the pathogenesis of the disease. Interestingly, results insinuate that sera from SSc patients already in an “Early” NVC condition (sera known to contains specific profibrotic molecules such as cytokines, growth factors like TGFβ1 or endothelin-1) seem able to induce in vitro a profibrotic M2 macrophage phenotype.

CIRCULATING FIBROCYTES FROM SYSTEMIC SCLEROSIS PATIENTS AS POSSIBLE TARGET OF CTLA4-IG TREATMENT: AN IN VITRO STUDY

S. Soldano1, P. Montagna1, S. Paolino1, E. Alessandri1, C. Pizzorni2, G. Pacini2, F. Goegan1, A. Sulii1, C. Scheneone1, V. Smith2, M. Cuto1,1 Laboratory and Academic Division of Clinical Rheumatology, Dept. Internal Medicine, University of Genova, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital; Department of Internal Medicine, Ghent University, University for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Italy

Background: muscle actin (aSMa)+ cells involved in the overproduction of extracellular matrix proteins, primarily fibronectin (FN) and type I collagen (COL1) at the level of damaged tissues (1). These cells may originate from different cell types including fibroblasts, endothelial and epithelial cells, and fibrocytes (1). Circulating fibrocytes are bone marrow progenitor cells expressing specific markers of hematopoietic (CD34, CD45, and HMC class II) and stromal cells (COL1 and COL3), chemokine receptors (CCR2, CCR7), and CXCR4 (2). CXCR4 regulates fibrocyte migration into injured tissue allowing their differentiation into fibroblasts/myofibroblasts (2).

In vitro, fibrocytes differentiate from circulating CD14+monocytes showing an antigen-presenting capability through the expression of HLA-DR and costimulatory molecule CD86 (2). CTLA4-ig fusion protein (abatacept) interacts with CD86 on cell surface of antigen presenting cells (APCs), such as macrophages and endothelial cells (3).

Objectives: To investigate the possible effect of CTLA4-ig treatment on cultured human fibrocytes and skin fibroblasts isolated from the same systemic sclerosis patients (SSc pts).

Methods: Fibrocytes isolated from the peripheral blood mononuclear cells of SSc pts and healthy subjects (HSs) were cultured on fibronectin-coated plates in DMEM at 20% of FBS; for further 8 days (T8) to allow their complete differentiation. Differentiated fibrocytes were maintained in growth medium or treated with CTLA4-ig at different concentrations (10, 50, 100, and 500μg/ml) for 3 hours. Fibroblasts were isolated from the skin biopsies of the same patients and HSs, cultured until the 3rd passage in RPMI at 10% FBS and then treated with CTLA4-ig for 24 and 48 hours. Fibrocytes were characterized as CD45+CXCR4+COL1+ cells and the expression of CD86 and HLA-DR was also evaluated. The gene expression of aSMa, COL1, CXCR4, TGFβ1 and CD86 was investigated by quantitative real-time polymerase chain reaction in cultured fibrocytes and skin fibroblasts. In cultured skin fibroblasts, COL1 and fibronectin synthesis was evaluated by Western

Results: Treatment with CTLA4-ig for 3 hours significantly downregulated aSMa and COL1 gene expression in cultured SSc fibrocytes at T8 (p<0.01, p<0.05 vs. untreated fibrocytes), whereas no modulatory effect was observed on the TGF-β/Smad signaling (CXCR4). In cultured SSc skin fibroblasts, CTLA4-ig did not induce any significant effect on CD68, TGFβ1, COL1 and FN gene expression as well as COL1 and FN protein synthesis, both after 24 and 48 hours. Of note, these cultured SSc skin fibroblasts showed a low expression of CD86.

Conclusion: Due to their high expression of CD86, circulating fibrocytes seem to be more responsive to CTLA4-ig treatment than the skin fibroblasts isolated from the same SSc patient.

INNATE LYMPHOCYTE PHENOTYPES IN FIBROBLASTS

S. Weber1, C. G. Anchang1,3, S. Rauber2, M. Luber2, M.G. Raimondo1, Y. Ariza2,3, A. Rius Rigaú2, A. Kreuter3, G. Schett4, J. Distler5, A. Ramming5, Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; 1Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; 2Ono Pharmaceutical Co., Ltd., Research Center of Specialty, Research Department, Osaka, Japan; 3HELIOS St. Elisabeth Klinik Oberhausen, University Witten-Herdecke, Department of Dermatology, Venereology and Allergology, Oberhausen, Germany

Background: Fibrotic diseases are characterized by excessive extracellular matrix production as a result of immune-mediated permanent fibroblast activation. Innate lymphoid cells type II (ILC2) are an only recently discovered cell type involved in barrier integrity and tissue homeostasis. There is upcoming evidence that ILC2s play a central role in mediating fibrotic diseases.

Objectives: The aim of the study was to further elucidate the role of ILC2s in fibrotic tissue remodeling and fibroblast activation.

Methods: Skin biopsies of patients with systemic sclerosis (SSc) or sclerodermaform chronic graft versus host disease (scGvHD) as well as lung biopsies of patients with idiopathic pulmonary fibrosis (IPF) were analyzed by immunofluorescence (IFA) staining. Single cell RNA-sequencing (scRNA-seq) was performed on ILC2s from fibrotic skin and lung of bleomycin-challenged mice. Further characterization of ILC2 phenotypes in fibrosis models was done by flow cytometry. In vitro culture of fibroblasts and ILCs was used to study cellular interaction and fibrotic activation. Quantitative realtime-PCR, western blot, IF staining and ELISA were used as readouts.

Results: Two different subtypes of ILC2s were found in skin of SSc and scGvHD patients as well as in lungs of IPF patients with one subpopulation being particularly increased in fibrotic tissue. Single cell RNA-sequencing confirmed the existence of two major populations of ILC2s in experimental fibrosis. One subtype showed features of immature ILC2 progenitors and was actively recruited from the bone marrow during fibrotic tissue remodeling. The other ILC2 subset was highly activated and expressed pro-fibrotic cytokines. These pro-fibrotic ILC2s directly interacted with fibroblasts in a cell contact dependent manner. Semaphorin 4A (SEMA4A) expressed by ILC2s bound to Plexin D1 (PLXND1) on fibroblasts. This interaction resulted into fibrotic imprinting with high expression levels of the transcription factor PU.1 which was recently described as central regulator of the pro-fibrotic gene expression program (Wohlfarth et al. 2019). Signaling through Jagged 1 (JAG1) and Notch receptor 2 (NOTCH2) was identified as a second mechanism of interaction between fibroblasts and ILC2s. JAG1 expressed by fibroblasts activated NOTCH2 signaling in ILC2s which impairs the secretion of profibrotic cytokines.

Conclusion: We identified a bidirectional interaction between ILCs and fibroblasts incorporating a vicious circle of fibrotic tissue remodelling. As ILCs are still not accessible as therapeutic targets these results might contribute to the development of new strategies for anti-fibrotic therapies.

DOI: 10.1136/annrheumdis-2020-eular.5804
Background: Fibroblast heterogeneity and homeostasis has long been recognized in patients with systemic sclerosis (SSc). However, there is no common consensus on fibroblast subtypes, lineages, biological properties, signaling, and plasticity, which severely hampers our understanding of SSc pathogenesis.

Methods: We applied single-cell RNA sequencing on skin fibroblasts from two SSc patients and two health control (HC) with matched age and sex. Cell clustering were mainly determined by UMAP with batch effect correction. Differently expressed genes in each cell cluster was analyzed by Gene Set Enrichment Analysis (GSEA).

Results: With an unbiased approach, single-cell transcriptome analyses showed classified and defined eight fibroblast types in SSc skin and six in normal skin. The cell types seldom overlapped between the patients and HC. Extracellular interaction and collagen production were remarkably stronger in SSc fibroblasts. A subgroup of dramatic cell proliferation and activation was defined only in SSc fibroblast. Two subtypes responding inflammatory stimuli were only found in SSc patients. Furthermore, delineation of their differentiation trajectory was achieved by a machine learning method.

Conclusion: This collection of single-cell transcriptomes and the distinct classification of fibroblast subsets provide a new resource for understanding the fibroblast landscape and the roles of fibroblasts in SSc.

PERFORMANCE OF HIGH FREQUENCY ULTRASOUND IN THE ASSESSMENT OF SKIN INVOLVEMENT IN SYSTEMIC SCLEROSIS

G. Lettieri¹, V. Picerno², D. Temiz Karadag³, M. C. Padula², G. A. Mennillo², A. Padula², S. D’angeleo², G. Abignano³. ¹Radiology Department, San Carlo Hospital, Potenza, Italy; ²Rheumatology Institute of Lucania (IfReL), Rheumatology Department of Lucania, San Carlo Hospital, Potenza, Italy; ³Canakkale State Hospital, Rheumatology Clinic, Canakkale, Turkey.

**Background:** The modified Rodnan skin score (mRSS) is the current gold standard for skin assessment in systemic sclerosis (SSc) both in clinical trials and practice. High frequency ultrasound (HFUS) has been suggested to offer a quantitative assessment of skin thickness in SSc by several studies, however results are incongruent with regards to the machine used, number of imaged sites, as well as the various stages of skin involvement.

**Objectives:** Aim of this cross-sectional study was to compare performance of HFUS in the assessment of skin involvement in diffuse cutaneous SSc (dcSSc) patients, at different disease stages, as compared with healthy controls (HC).

**Methods:** Dorsal finger, hand, forearm and upper arm skin of consecutive dcSSc patients, at different disease stages, and of matched-HC were scanned bilaterally using HFUS. Two investigators, expert in MSK ultrasound, blinded to the clinical details, measured skin thickness using Esaote MyLab70 equipped with a 22 MHz probe. Clinical involvement was assessed by a blinded operator using the mRSS and results were compared with imaging data. Statistical analysis was performed using GraphPad Prism software V.7.0.

**Results:** A total of 704 HFUS images were obtained from 22 dcSSc patients [20 Female, mean age 49 ±11 years, 12 with ≤5 years disease duration] and 22 HC [20 Female, mean age 50.7 ±6.7 years]. Skin thickness was significantly higher in SSc patients than in HC at fingers (p<0.0001) and hands (p=0.001), while no significant difference was found at the forearms and upper arms (p>0.05). HFUS showed a good discriminative ability between SSc and HC skin at fingers and hands (AUC 0.91, 0.81, 0.6 and 0.65 for fingers, hands, forearms and upper arms respectively). When analysing the subgroup of SSc patients with ≤5 years disease duration, HFUS showed a slightly lower performance in discriminating between SSc without clinical skin involvement (site mRSS=0) and HC (AUC 0.68, 0.57, 0.68 for hands, forearms and upper arms respectively). Mean HFUS skin thickness significantly correlated with mRSS at site of analysis (hand: r=0.78, p<0.0001; forearm: r=0.47, p=0.0013; upper arm: r=0.52, p=0.0003) and total mRSS (hand: r=0.53, p=0.0002; forearm: r=0.63, p=0.0001; upper arm: r=0.63, p=0.0001). No significant correlation was found between finger skin thickness and mRSS (both local and total, p>0.05). Interobserver reliability for skin thickness was good to excellent at all sites with intraclass correlation coefficient ranging between 0.79 and 0.94.

**Conclusion:** HFUS of the skin is a reliable measure of skin involvement in SSc. Studies with higher number of patients with different clinical features are needed to explore the potential of HFUS to discriminate between healthy and SSc skin, including sites at a preclinical stage of involvement.

PROGRESSION OF SUBCLINICAL MIYOCARDIAL INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS

D. Benfarenò¹, G. Stronati², L. Manfredi³, L. Zuliani¹, A. Ferrari¹, C. Fischetti³, C. Dichiara¹, F. Guerra¹, A. Dello Russo¹, A. Gabrielli³. ¹Università Politecnica delle Marche, Dipartimento di Scienze Cliniche e Molecolari, Ancona, Italy; ²Università Politecnica delle Marche, Dipartimento di Scienze Biomediche e Sanità Pubblica, Ancona, Italy.

**Background:** Systemic sclerosis (SSc) is a progressive autoimmune disease affecting the skin as well as internal organs, including the heart. A few studies have identified a subclinical heart involvement in patients with no pulmonary hypertension. Changes in myocardial deformation are consistent with the idea of SSc-related cardiacmyopathy as a primary condition affecting the heart globally through microvascular dysfunction and subsequent myocardial fibrosis.

**Objectives:** The aim of the present study is to describe the progression of myocardial deformation in patients with SSc and no overt cardiac disease.

**Methods:** Prospective longitudinal study enrolling consecutive SSc patients referred to the Clinica Medica, University Hospital ‘Ospedali Riuniti’, Ancona, Italy, from February 2016 to December 2018. All patients fulfilled the 2013 ACR/EULAR classification criteria for SSc. Patients with structural heart disease, heart failure, atrial fibrillation or pulmonary hypertension were excluded. Disease subset, antibodies pattern, cardiovascular risk factors and involvement of other organ systems were recorded for each patient. An echocardiographic exam was performed for all patients at baseline and during their follow-up evaluation. Standard and speckle-tracking derived variables for the systolic and diastolic function of the left ventricle (LV) and right ventricle (RV) were acquired. Speckle tracking analysis software (EchoPAC 13.0; GE Medical Systems, Milwaukee, USA) was used to assess the GLS of the left and right ventricle, excluding the ventricular septum from right ventricular GLS calculations.

**Results:** Seventy-two patients (68 females, ages 56.6±15.4 years) were enrolled. Common echocardiographic parameters of left and right systolic function were within normal range at baseline and did not change during follow-up. Mean GLS, however, worsened for both left (from -19.8±3.5% to -18.7±3.5%, p=0.034) and right ventricle (from -20.9±6.1% to -18.7±5.4%, p=0.013) during a median follow-up of 20 months (1st-3rd quartile 12-24 months). The increased impairment registered in SSc patients was homogenous across endocardial layers (LV from -22.5±3.9 to -21.4±3.9, p=0.013; RV from -24.2±6.2 to -20.6±5.9, p=0.001), mesocardial layers (LV -19.7±3.6 to -18.7±3.5, p=0.043; RV from -21.3±5.9 to -18.8±5.7, p=0.012) and epicardial layers (LV from -17.1±3.0 to -16.4±3.1, p=0.12; RV -18.6±6.3 to -16.0±8.4, p=0.035), as well

SEMIQUANTITATIVE AND QUANTITATIVE ANALYSIS OF LUNG CT IN THE ASSESSMENT OF INTERSTITIAL LUNG DISEASE IN IDIOPATHIC INFLAMMATORY MYOPATHIES WITH A FOCUS ON ANTISynthETASE.

S. Barsotti¹, C. Roncella², A. Valentini³, L. Cavagna², R. Castellana, E. Cioffi², A. Tripoli¹, D. Caramella¹, B. Bartholmai², R. Neri¹, F. Falaschi², C. Rometi³, M. Mosca². ¹Radiology Unit - Pisa University Hospital, Pisa, Italy; ²Rheumatology Unit - Pisa University Hospital, Pisa, Italy; ³Department of Radiology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; ²Rheumatology Division, University and IRCCS Policlinico S. Matteo Foundation, Pavia, Italy; ³Department of Diagnostic and Interventional Radiology, University of Pisa, Pisa, Italy; ²Department of Radiology, Mayo Clinic, Rochester, United States of America.

**Background:** Interstitial lung disease (ILD), is common in patients with idiopathic inflammatory myopathies (IMM) and strongly impact on patients' morbidity and mortality. Patients with anti-aminoacyl-transfer RNA-synthetases (anti-ARS) antibodies are associated with an increased risk of ILD.

**Objectives:** Defining the radiological characteristics of IMM patients, with special focus on serological groups, through qualitative, semiquantitative and quantitative analysis of lung CT.

**Methods:** This was a prospective study conducted from 2016 to 2019. Ninety-eight IMM patients (35 men, 63 women) were included. Myositis specific autoantibodies (MSA) were assessed with Myositis Prophyle III (Euroimmune, Lubeck).

Each patient had a baseline CT; the total score of Warrick (WS) was obtained at semiqualitative analysis. The radiological scores ILD% (interstitial lung disease %) and PVRS% (pulmonary vascular related structure) were the result of quantitative analysis in 61 patients (CALIPER). Pulmonary function tests (PFTs) included TLC%, FVC% and DLOC% (65 patients). The analysis was conducted in the whole group and divided in subgroups based on their MSA pattern: in particular anti-ARS (Group 1) and patients negative to MSA (Group 2) were analysed.

**Results:** Positive correlations between ILD% and PVRS% (Rho=0.916; p<0.000). No significant higher values of WS, ILD% and PVRS% were found in Group 1 (WS=15, ILD%=11 and PVRS%=3.5), compared to Group 2 (WS=2.5, ILD%=0.84 and PVRS%=2.2). NSIP pattern resulted dominant represented in the two groups (80% Group 1, 75% Group 2). No statistically significant differences of DLOC%, FVC% and TLC% were found.

**Conclusion:** The inverse correlations between the radiological scores and the functional data TLC% and DLOC% (p<0.001) confirm the role of lung CT in the clinical management of IMM in IMM, and may represent a promising tool for clinical trials. For the first time anti-ARS and serological negative patients were defined through qualitative, semiquantitative and quantitative analysis of lung CT. Further study should be conducted in order to define the prognostic value of the quantitative analysis of lung CT in the follow up IMM patients.

**Disclosure of Interests:** None declared.

**DOI:** 10.1136/annrheumdis-2020-eular.6373
as myocardial segments. No difference in progression rate was observed stratifying patients according to disease subset or other clinical parameters. **Conclusion:** GLS impairment progressed over a 20-month follow-up period in a cohort of right heart catheterization-diagnosed PAH involvement. Further studies are needed to assess the significance of subclinical heart involvement and its progression in patients with SSC.

**Disclosure of Interests:** None declared

**SCREENING TOOLS FOR PULMONARY ARTERIAL HYPERTENSION (PAH) IN SYSTEMIC SCLEROSIS (SSC): A SYSTEMATIC LITERATURE REVIEW (SLR).**

**C. Bruni1,** G. De Luca2,3, M. G. Lazzaroni4, E. Zanatta5, G. Lepri1, M. Matucci-Cerinic6,7. 1University of Florence, Faculty of Medicine, Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; 2IRCCS San Raffaele Hospital, Immunology, Rheumatology, Allergology and Rare diseases, Milan, Italy; 3Vita-Salute San Raffaele University, Milan, Italy; 4ASST Civil Hospital of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy; 5University of Padua, Medicine, Rheumatology Unit, Padova, Italy; 6Careggi University Hospital, Rheumatology, Firenze, Italy

**Background:** In SSC, PAH has a high morbidity and mortality burden. Therefore, screening and early detection are pivotal to achieve an early diagnosis of PAH.

**Objectives:** to search for the literature for all screening modalities for SSC-PAH in reference to right heart catheterization as diagnostic gold standard.

**Methods:** papers from 2 previously published SLRs [22 from Glaude et al (1) - from inception to 19/06/2012 - and 22 from Young et al 2018 – from 20/06/2012 to 02/10/2017] were included. The articles' database was integrated with a systematic search on Pubmed, EMBASE, Web of Science for papers published from 03/10/2017 to 31/12/2018. A total of 199 papers were reviewed and 32 were finally extracted. Bias risk was assessed through QUADAS2 tool.

**Results:** 167 papers were excluded from data extraction mainly for PAH screening non as main focus or for non-including SSC patients. The 32 papers extracted presented a low bias risk according to QUADAS2. Screening methods reported were:

- Echocardiographic parameters in 31/32 studies, in particular systolic pulmonary arterial pressure (sPAP) in 22 papers; 40 mmHg was the most frequently used cut-off (in 12/22 papers); sPAP was part of a composite algorithm in 9/22 papers. Among others, tricuspid regurgitation velocity (TRV) was used in 6/31 (as part of composite 5/6) and right atrial pressure (RAP) in 3/31 papers.
- Pulmonary function tests parameters in 22/32 papers, with % predicted Lung diffusion for carbon oxide (DLco) in 21 papers, with a 50% cut-off in 11/21 and as part of composite algorithm in 13/21 studies. Moreover, walked distance at six minutes walking test was a screening parameter in 3/32 papers.
- Serum biomarkers in 12/32 papers, with anti-centromere antibodies (6/12), NT-proBNP (6/12) and uric acid (5/12) being the most frequently reported.
- Clinical parameters in 15/32 papers, with unexplained dyspnoea in 9/15 and telangiectasias in 5/15 papers.
- Composite algorithms were used in 18/32 manuscripts: among them, DETECT (5/18), ESC/EERS 2009 (4/18) or 2015 (3/18) guidelines, ASiG (2/18) e ITINER- air (1/18). In different cohorts, DETECT and ASiG showed higher sensitivity and negative predictive value than ESC/EERS 2009.

**Conclusion:** In the literature, the screening of SSC-PAH is largely investigated by echocardiographic parameters. In particular, sPAP and TRV, both as single items or part of a composite algorithm, including also serum biomarkers, clinical and functional parameters, are the most frequent parameters evaluated.

**CARDIAC MAGNETIC RESONANCE IMAGING ELEVATED NATIVE MYOCARDIAL T1 IS PREDICTIVE FOR THE DEVELOPMENT OF MYOCARDIAL DYSFUNCTION IN SYSTEMIC SCLEROSIS.**

**E. Chatelus1,** V. Poindron1, M. Canuet2, A. S. Korganov1, F. Germain3, T. Martin1, S. El Ghanoudi4. 1National Reference Center For Autoimmune Diseases RESO, Hôpitaux Universitaires de Strasbourg, Strasbourg, France; 2Pneumology Department, Hôpitaux Universitaires de Strasbourg, Strasbourg, France; 3Radiology Department, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

**Background:** All patients included in the study fulfilled the ACR/EULAR classification criteria for SSC. We prospectively included patients who underwent at least two CMR at 1.5T, including native T1 and T2 mapping (which give account for myocardial fibrosis and myocardial edema respectively), left and right ventricles morphology and functional assessment, and Late Gadolinium Enhancement (LGE) as a part of routine follow-up between 2015 and 2019.

**Objectives:** To evaluate the prognostic value of initial abnormal T1 mapping.

**Methods:** All patients included in the study fulfilled the ACR/EULAR classification criteria for SSC. We prospectively included patients who underwent at least two CMR at 1.5T, including native T1 and T2 mapping (which give account for myocardial fibrosis and myocardial edema respectively), left and right ventricles morphology and functional assessment, and Late Gadolinium Enhancement (LGE) as a part of routine follow-up between 2015 and 2019.

**Results:** Sixty-three patients underwent at list two CMR during the study period. Forty-three patients were women. Mean age was 52.5±15.5 years old. Follow-up duration between the initial and the follow-up CMR was 14.5±11.5 months. Forty-one had diffuse SSC. The mean native T1 was 1068.6±44.6 ms. Twenty-one patients suffered from cardiac clinical manifestations. Nine patients died during the follow-up. Thirty patients (47.6%) had elevated T1 (ET1) with mean T1 1105.4±36.7 ms at the time of initial CMR. Initial ET1 was clearly correlated with 1/ alteration of Left Ventricle (LV) Ejection fraction (EF) (r=0.5, p=0.0001) during the study period, 2/LV dilation at initial screening and follow up (r=0.22, p=0.03 and r=0.003 respectively). Regarding Right ventricle, initial ET1 was correlated with 3/ Initial Right Ventricle (RV) dilation (r=0.3, p=0.02) but neither with RV volume nor RVET at follow-up. Interestingly, initial ET1 correlated with pericardial effusion (r=0.3, p=0.003) which is known to be a prognostic favorable factor. Seventeen patients (28%) had LGE but the ET1 at initial screening and follow up was not correlated with LGE.

Six patients had elevated T2 (ET2) which correlated with initial and follow up LV dilation (r=0.32, p=0.002 and r=0.5, p=0.0001 respectively) but not with LVEF during the period study. Among other parameters, initial increased BNP was correlated with follow up ET1 LVEF and RVET (r=0.4, p=0.01; r=0.35, p=0.007; r=0.37, p=0.005 respectively). In the same way, initial Pulmonary Arterial Hypertension (PAH) was correlated with follow up ET1 (r=0.3, p=0.02). Initial ET1 did not correlate with age, sex, cardiovascular risk factors, cardiac manifestations or death.

**Conclusion:** Assessment of diffuse myocardial fibrosis by native T1 is predictive of the occurrence of cardiac dysfunction at the follow-up as initial ET1 was associated with decreased left ventricular function and LV and RV dilatations). These data highlight the potential role of CMR with T1 mapping in initial screening and at the follow-up and provides new insights in the cardiac SSC follow up strategy.

ANTI-CENTROMERE ANTIBODY ISOTYPE LEVELS AS BIOMARKER FOR DISEASE PROGRESSION IN SUBJECTS AT RISK TO DEVELOP SYSTEMIC SCLEROSIS

N. Van Leeuwen,1 J. Bakker,2 A. Grummels,1 C. Wortel,1 S. Jordan,2 S. Lenni,3 O. Distler,2 A. M. Hoffmann-Vold,1 K. Melsens,1 V. Smith,1 M. E. Truchetet,4 H. U. Scherer,1 R. Toes,1 T. Huizinga,1 J. De Vries-Bouwstra,1 1Leiden University Medical Center (LUMC), Leiden, Netherlands; 2Zurich University Hospital, Zurich, Switzerland; 3Oslo University Hospital, Oslo, Norway; 4Ghent University Hospital, Ghent, Belgium; 5Bordeaux University Hospital, Bordeaux, France

Background: Presence of anti-centromere antibodies (ACA) generally associates with a better prognosis than many other systemic sclerosis (SSc) associated autoantibodies. However, presentation of the disease can be very heterogeneous and prediction of the disease course is challenging. Some older studies suggest a possible association between clinical characteristics and isotypes of ACA in patients with SSc. It is unknown whether ACA can serve as biomarker for future SSc development.

Objectives: To evaluate the clinical course of very early SSc and to assess whether ACA isotype levels can identify subjects that will progress to definite SSc.

Methods: ACA IgG + patients with very early SSc (defined as presence of ACA IgG AND Raynaud and/or puffiness and/or abnormal nailfold capillaroscopy but not fulfilling ACR 2013 criteria) from five prospective SSc cohorts (Leiden, Zurich, Oslo, Bordeaux, Ghent) were included. Presence and levels of ACA IgG, IgM and IgA were determined at first clinical assessment and clinical course was evaluated annually. Disease progression to definite SSc, which was defined as fulfillment of the ACR 2013 criteria for SSc, and included any development of: digital ulcers (DU), interstitial lung disease (ILD) assessed by high resolution chest tomography, pulmonary arterial hypertension assessed by right heart catheterization, gastro-intestinal involvement, renal crisis or myocardial involvement was determined. ACA response characteristics were compared between very early SSc patients that progressed to definite SSc and those who did not. Logistic regression was performed to determine whether ACA response characteristics can predict progression to definite SSc, with adjustment for age and follow-up duration.

Results: In total 92 subjects were included with median follow-up (FU) of 3 years (table 1); 39% progressed to definite SSc, mostly based on the development of skin involvement (77%). Twenty-three percent of patients developed lung involvement, 11% DU, 17% gastro-intestinal involvement and 4% myocardial involvement. Progression on more than one organ system was present in 31% of the very early SSc patients. In the multivariable logistic regression, with adjustment for age and follow-up duration, ACA IgG levels at baseline were significantly associated with progression to definite SSc (OR 3.0 (1.1-8.8)). Likewise, a trend was observed for higher ACA IgM levels (OR 1.8 (0.9-3.5)) in the very early SSc patients progressing to definite SSc (figure 1).

Conclusion: In this study we illustrate that 39% of the ACA positive very early SSc subjects progress to definite SSc within median 4 years. We identified higher ACA IgG level as a predictive biomarker for progression to definite SSc indicating that it might be a useful biomarker for risk stratification in clinical practice.

SATELEC067

BIOELECTRICAL IMPEDANCE VECTOR ANALYSIS FOR NUTRITIONAL STATUS ASSESSMENT IN SYSTEMIC SCLEROSIS AND ASSOCIATION WITH DISEASE CHARACTERISTICS

M. Di Battista1, S. Barsotti2, A. Monaco1, A. Rossi1, A. Della Rossa1, M. Mosca1.
1Rheumatology Unit – Pisa University Hospital, Pisa, Italy

Background: Bioelectrical impedance vector analysis (BIVA) is a common non-invasive method for estimating body composition which ultimately allows to obtain information on subject’s nutritional status. So far no data about the use of BIVA in patients with systemic sclerosis (SSc) have been published.

Objectives: We used BIVA in a cohort of SSc patients in order to assess their nutritional status and any correlation with the various clinical characteristics of the disease, also evaluating the differences with the general population.

Methods: We used BIVA in a cohort of SSc patients in order to assess their nutritional status and any correlation with the various clinical characteristics of the disease, also evaluating the differences with the general population.
Methods: We collected data from consecutive patients diagnosed with SSC according to EULAR/ACR criteria and from healthy controls (HC) matched for age and sex. Patients underwent BIVA for the assessment of fat mass (FM), free fat mass (FFM), total body water (TBW), extracellular water (ECW), body cellular mass (BCM), basal metabolic rate (BMR) and ECM/BCM ratio, an early index of protein catabolism. Data included anthropometric and clinical features, Body Mass Index (BMI) and specific organ involvement with particular attention to gastrointestinal symptoms. Laboratory parameters, including haemoglobin and albumin levels, were also collected. Additionally, patients completed the UCLA GIT 2.0 questionnaire.

Results: Data from 50 SSC patients (52% female; mean age 61.1±12.5 years) and from 50 HC were compared. BIVA revealed that SSC patients presented a significant reduction in BMR, BCM and ECW values compared to HC (p<0.01 for all). The former also exhibited a higher ECM/BCM ratio (p=0.001). No significant differences regarding FM, FFM, TBW and BMI were found between the two groups. Among the cohort of SSC patients, a direct correlation was found between age and ECW (p=0.001; p=0.473) and between disease duration and FM (p=0.023; p=0.325), whereas age inversely correlated with BMR (p=0.012; p=0.357). Patients with anaemia and/or hypoalbuminemia had significantly reduced BMR, BCM and TBW values; those with hypoalbuminemia also had elevated ECW levels (p=0.01). No other significant associations with BIVA values were found among the laboratory findings and among the gastrointestinal complaints. Results showed relevant interrelations between BIVA parameters and the SSC-related involvement of different organs, e.g. digital ulcers, interstitial lung disease and pulmonary arterial hypertension (see Table 1). In addition, a higher skin involvement inversely correlated with FM (p=0.038; p=0.387). The only correlation that emerged from the UCLA GIT 2.0 questionnaire was the inverse relationship between TBW and GIT-reflux (p=0.017; p=0.385). Four patients died during the study; they had significantly lower BMR and BCM, with an increased ECW.

Conclusion: BIVA has shown that SSC patients have a worse nutritional status than HC. The parameters obtained with BIVA in SSC patients correlate with serological malnutrition markers (haemoglobin and albumin), with various organ-specific SSC manifestations (cardiopulmonary involvement and digital ulcers) and with mortality. BIVA could therefore play a role in the prognostic stratification of SSC patients.

SAT0312 SUBCLINICAL ATHEROSCLEROSIS IN SYSTEMIC SCLEROSIS AND RHEUMATOID ARTHRITIS: A COMPARATIVE MATCHED-COHORT STUDY

P. Baniotopoulos1, E. Pagkopoulos2, S. Souliaidopoulos2, A. Sandoo3, N. Katsiki2, A. Karagiannis1, K. Douglas3, A. Garyfallou3, G. Kitas3, T. Dimitropoulos3. 1GKT School of Medical Education, King’s College London, London, United Kingdom; 24th Department of Internal Medicine, Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; 3School of Sport, Health and Exercise Sciences, Bangor University, Bangor, United Kingdom; 4Russell Hall Hospital, Dudley Group NHS FT, Department of Rheumatology, Bangor; United Kingdom; 52nd Prodedepece Department of Internal Medicine, Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; 6University of Manchester, Arthritis Research UK Centre for Epidemiology, Manchester, United Kingdom

Background: Systemic autoimmune inflammatory disorders confer a higher risk of cardiovascular (CV) disease leading to increased morbidity and mortality compared to the general population. CV risk in Systemic Sclerosis (SSc) has not been studied so extensively as in other diseases, such as Rheumatoid Arthritis (RA), and the real impact of CV disease on SSC prognosis remains unknown. Surrogate markers of atherosclerosis namely carotid intima media thickness (cIMT) and pulse wave velocity (PWV) are impaired in some but not all studies in SSC patients.

Objectives: The aim of the study was to investigate the prevalence of subclinical atherosclerosis assessed by cIMT and PWV between two well-characterized SSC and RA cohorts.

SAT0313 CORRELATION BETWEEN PROGRESSION OF SKIN FIBROSIS AND PROGRESSION OF INTERSTITIAL LUNG DISEASE (ILD) IN PATIENTS WITH SSC-ILD: DATA FROM THE SENSICS TRIAL

O. Dimster1, K. Highland2, A. M. Hoffmann-Vold3, O. Kowal-Bielecka4, U. Walker1, F. Del Gaido3, M. Vonk1, L. Hummers3, E. Erhardt2, M. Quaresma2, M. Aves2, V. Smith1, 1Department of Rheumatology, University Hospital Zurich, Zürich, Switzerland; 2Cleveland Clinic, Cleveland, Ohio, United States of America; 3Department of Rheumatology, Scientific Abstracts Saturday, 06 June 2020 1101
Background: In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in FVC over 52 weeks vs placebo, with no difference between groups in change in mRSS.

Objectives: Analyse correlation between progression of skin fibrosis and progression of SSc-ILD in the SENSCIS trial.

Methods: Patients with SSc-ILD were randomised to receive nintedanib or placebo until the last patient reached week 52 but for ≤100 weeks. We calculated Spearman correlation coefficients between FVC (mL) at baseline and change from baseline in mRSS, mRSS at baseline and change from baseline in FVC (mL), and changes from baseline in mRSS and FVC at weeks 52 and 100 in all patients. We analysed the rate of decline in FVC (mL/year) in patients who did and did not have progression of skin fibrosis (relative change from baseline in mRSS >25% and absolute change from baseline >5 points) at week 52.

Results: In the nintedanib (n=288) and placebo (n=288) groups, respectively, mean (SD) baseline FVC (mL) was 2459 (736) and 2541 (816) and mRSS was 11.3 (9.2) and 10.9 (8.8); 53.1% and 50.7% had dcSSc;18.4% and 16.0% had mRSS >25% and absolute change from baseline >5 points)

Table: Changes from baseline in mRSS and FVC

SAT0314

TIMED FUNCTION TESTS ARE AN ALTERNATIVE TO MMT8 AND FI-2 IN INFLAMMATORY MYOSITIS - AN OBSERVATIONAL COHORT STUDY

S K Dungri, A M D2, C Kavadichandra, V Negi3, 1Jawaharlal Institute of Postgraduate Medical Education and Research, Clinical Immunology, Puducherry, India; 1Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; 1Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India

Background: Inflammatory myositis are heterogeneous group of diseases affecting skeletal muscles and multiple different organs. Manual muscle testing (MMT) is the common tool used for assessment of muscle strength. Its limitations include poor sensitivity to change, floor/ceiling effect, and under representation of certain important muscle groups. Functional index 2(FI-2) is an objective measure of dynamic repetitive muscle function at 11 proximal and distal muscle groups which correlates well with patient-reported physical function. Since MMT8 is inadequate and FI-2 takes longer time to administer, several timed tests to assess muscle function, endurance and fatiguability like the 2- minute walk test (2MWT) or 30s raise from a chair test and 30s arm rise test are viable alternatives to be tested. Data looking at the performance of these tests are limited to small controlled studies.

Objectives: To study correlation of timed tests with MMT8 and FI-2 in assessing muscle strength, endurance at baseline and at 3 months of therapy.

Methods: An observational cohort study, included 19 patients with polymyositis and dermatomyositis attending OPD and IPD service of tertiary center. Patients with inclusion body myositis, overlap myositis, chronic kidney disease, coexistence of myocarditis, sepsis, malignancy, pregnancy were excluded. MMT8, FI-2 and Timed function tests were done at baseline and after 3 months.

Results: The study had 19 patients of which 6 were polymyositis and 13 were dermatomyositis. Male to female ratio was 1:2.1. Anti-cell antibody was positive in 16 patients. The mean MMT8 of the study group at baseline was 60.84±16.77 and after 3 months was 67.05±11.7. Out of 19 patients, all received prednisolone as induction agent followed by Metho- trexate in 13, cyclophosphamide in 9, azathioprine in 5, Rituximab by one patient. Mean scores of 30s arm Lift, 30s rise from chair test and 2-min walk test were 11.7±6.39,14.7±2.29,101.5±4.48 respectively at baseline and 13.05±6.5,15.6±7.1,117.8±3.84 after 3 months.
Neck flexion 0.600** 0.590** 0.610** plasma concentration was achieved 1 - 2.5 hours after dosing, and half-life was

SAT0315

INHIBITION OF MICROSMAL PROSTAGLANDIN E SYNTHASE-1 (mPGES-1) BY GS-248 REDUCES PROSTAGLANDIN E2 BIOSYNTHESIS WHILE INCREASING PROSTACLYIN IN HUMAN SUBJECTS

C. Edénius1,2, G. Ekström1,3, J. Kolmer2, R. Morgenstern1,3, P. J. Jakobsson1,4,5, G. Tornling1,6, C. Edenius1,2, G. Ekström1,3, J. Kolmer2, R. Morgenstern1,3, P. J. Jakobsson1,4,5, G. Tornling1,6

Background: Microsomal prostaglandin E synthase-1 (mPGES-1) catalyzes the formation prostaglandin (PG) E2 from cyclooxygenase derived PGH2. Inhibition of mPGES-1 leads to production of pro-inflammatory PGF2α, while in vessels there is a concomitant increase of vasoprotective prostacyclin (PGI2) via shunting of PGH2 to PGI2 formation, leading to anti-inflammatory and vasodilatory effects, while preventing platelet activation. The results warrant further evaluation of GS-248 in inflammatory conditions with vasculopathies such as Digital Ulcers and Raynaud’s Phenomenon in Systemic Sclerosis.

ANTI-PM/SCL ANTIBODIES IN SYSTEMIC SCLEROSIS: CLINICAL ASSOCIATIONS IN THE RESCUE COHORT

N. Ienista-Arañada, G. Espinosa, A. Guillen del Castillo, C. Tolosa, G. M. Lledo, C. Colunga Argüelles, C. González-Echavarrí, L. Sáez-Cómer, N. Ortégó, J. A. Vargas-Hitos, M. Rubio-Rivas, M. Freim, J. J. Rios, M. Rodríguez-Carballeda, L. Trapelia Martínez, V. Fonollosa Pla, C. P. Siméon-Aznar, O. B. O. R. I. Autoimmune Diseases Study Group (Geas) (1), Hospital Clinic, Barcelona, Spain; Hospital Clinic, Autoimmune Diseases, Barcelona, Spain; Hospital Vall d’Hebron, Barcelona, Spain; Hospital Parc Taulí, Sabadell, Spain; Hospital Universitario Central de Asturias, Oviedo, Spain; Hospital Cruces, Barakaldo, Spain; Hospital Universitario Miguel Servet, Zaragoza, Spain; Hospital San Cecilio, Granada, Spain; Hospital Universitario Virgen de las Nieves, Granada, Spain; Hospital Universitario Bellvitge, Institut de Llobregat, Spain; Hospital Clínico Universitario De Santiago, Santiago de Compostela, Spain; Hospital la Paz, Madrid, Spain; Hospital Mutua Terrassa, Terrassa, Spain; Hospital Universitario Central de Asturias, Gijon, Spain; Sociedad Española de Medicina Interna, Madrid, Spain

Background: Anti-PM/Scl antibodies are associated to systemic sclerosis (SSc) but are not specific to SSc. The true prevalence of anti-PM/Scl antibodies in SSc is unknown, ranging from 2.5% to 12.5%. An association between anti-PM/Scl antibodies with muscular involvement, pulmonary fibrosis, calcinosis, and a relatively benign prognosis have been described.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.5503

Methods: Healthy males and females (age 18–73 years) were included in the study. Six cohorts were administered single oral doses of 1-300mg GS-248 (n=36) or placebo (n=12), three cohorts were administered once daily doses of 20-180mg GS-248 (n=18) or placebo (n=12) over ten days. In addition, 8 subjects were treated in a separate cohort with 200mg celecoxib bid for ten days. Blood samples were drawn for measurement of GS-248 exposure and production of PGF2α after LPS incubation ex vivo. The content of PGF2α and PGE2 metabolites was measured in urine. All analyses were performed by LC-MS/MS.

Results: GS-248 was safe and well tolerated at all tested dose levels. Maximum plasma concentration was achieved 1 - 2.5 hours after dosing, and half-life was about 10 hours. Induced PGF2α formation ex vivo, catalyzed by mPGES-1, was completely inhibited for 24 hours after a single low dose (40mg) of GS-248. In urine, GS-248 dose-dependently reduced the excretion of PGE2 metabolite by more than 50% whereas the excretion of PGF2α metabolite increased more than twice the baseline levels. In the celecoxib cohort urinary metabolites of both PGE2 and PGF2α were reduced with approx 50%.

Conclusion: GS-248 at investigated oral doses was safe and well tolerated. There was a sustained inhibition of LPS induced PGF2α formation in whole blood. In urine, there was a metabolite shift showing reduced PGE2 and increased PGI2, while celecoxib reduced both PGE2 and PGI2 metabolites. This suggests that selective inhibition of mPGES-1 results in systemic shunting of PGH2 to PGI2 formation, leading to anti-inflammatory and vasodilatory effects, while preventing platelet activation. The results warrant further evaluation of GS-248 in inflammatory conditions with vasculopathies such as Digital Ulcers and Raynaud’s Phenomenon in Systemic Sclerosis.

Disclosure of Interests: Alex Rider LG, A

Methods: From the Spanish Scleroderma Study Group database, we selected patients in whom anti-PM/Scl antibodies had been tested. We compared demographic features, clinical manifestations, laboratory characteristics, and survival data between patients according the anti-PM/Scl antibodies status.

Results: 72 out of 947 (7.7%) patients tested positive for anti-PM/Scl antibodies. As presenting SSc manifestations, patients with anti-PM/Scl antibodies had a higher prevalence of puffy fingers (11% versus 2%; p=0.002) and arthralgias (11%
versus 4%; p=0.03), and lower prevalence of Raynaud’s phenomenon (85% versus 82%; p=0.002). Regarding cumulative manifestations, myositis (51% versus 15%; p<0.001), arthritis (43% versus 22%; p=0.001), and intestinal ulcer disease (ILD) (60% versus 45%; p=0.014) were more prevalent in patients with anti-PM/ScI antibodies. In fact, those patients with anti-PM/ScI antibodies presented with FVC (77.4% ± 23.1% versus 85.8% ± 23.1%; p=0.006) and more severe ILD defined as FVC <70% (41% versus 24%; p=0.004). Death rate was similar in patients with and without PM/ScI antibodies (18% versus 17%; p=0.871). We did not find differences in terms of death rate nor in the causes of death (SSc and non-SSc related) according to the anti-PM/ScI antibodies profile. The 5- and 10-years survival rates of patients with anti-PM/ScI antibodies were 91% and 82%, respectively, without differences with those without those antibodies (93% and 85%, respectively).

Conclusion: In Spanish SSc patients, the presence of anti-PM/ScI antibodies confer a distinctive clinical profile. However, anti-PM/ScI antibodies do not play a role in the progression of these patients.

4Division of Rheumatology, Hospital University of Canarias, Tenerife, Spain; 1University Europea de Canarias, Santa Cruz de Tenerife, Spain; 3Universidad de La Laguna, Departamento de Bioquímica, Microbiología, Biología Celular y Genética, La Laguna, Spain; 2Universidad de La Laguna, Santa Cruz de Tenerife, Spain; 5VA. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation.

Background: Raynaud’s phenomenon (RP) secondary to rheumatic diseases (RD) can progress to irreversible tissue damage with digital ulceration, scarring and, rarely, gangrene requiring amputation. Current medical treatments for RP are far from ideal: they are often either ineffective and/or poorly tolerated, thus a significant proportion of patients discontinue drug therapy.

Objectives: To determine RP expression levels and to evaluate the long-term efficacy of iloprost and alprostadil in RP patients with RD.

Methods: Indicated therapy with intravenous iloprost (n=10), alprostadil (n=17) or their combinations (n=13) was carried out for three years in patients with secondary RP in RD. Frequency of Raynaud’s attacks, digital ulcers (DU) formation and pain intensity on visual analogue scale (VAS) were evaluated. A control group included 30 patients with RP in RD who did not receive prostanooid therapy. By factor analysis method a generalized index of RP expression was identified, on the basis of which levels of RP expression were determined.

Results: “RP expression” scale, revealed as an indicator of RP generalized manifestation, was an average value of two subscales: (1) consisted of 4 indi-
ces “DU”, “digital pitting scars”, “palpation amputation” and “frequency of Ray-
naud’s attack” (2) included 3 indicators: “intensity of pain”, “duration of illness”, “whitening of fingers”. Correlation of subscales showed their reliability (r=0.294, p=0.053). RP final expression (severity) was 1.51±0.86. A low level of RP expression had values below 0.65, a high level – over 2.37. At baseline, the high level of RP severity was defined in 16 (22.9%) patients, medium – in 43 (61.4%), low – in 11 (15.7%).

Conclusion: Based on RP clinical manifestations in RD patients, a generalized index of RP expression was identified and levels of RP severity were determined. Treatment with iloprost or alprostadil has significant effects on reducing the clinical manifestations of RP with a corresponding decrease in its severity. Iloprost is indicated in patients with medium and high levels of RP expression index, alprostadil – with medium and low index and non-effectiveness of calcium channel blockers.

SAT0319
SUBCLINICAL ATHEROSCLEROSIS IN INDIAN PATIENTS WITH SCLERODERMA – CLINICAL AND SEROLOGICAL ASSOCIATIONS
H. Ganadahran Nar1, M. K. Rai1, M. Singh2, Anjula3, K. Singh3, N. Mohindra4, N. Jain5, S. Kumar5, V. Agarwal1, D. Misra1, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India; 2Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Nephrology, Lucknow, India; 3Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Radiodiagnosis, Lucknow, India; 4Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Cardiology, Lucknow, India

Background: Scleroderma has been associated with increased risk of cardio-ovascular events, however, studies on this from India are sparse. We evaluated clinical and serological factors associated with subclinical atherosclerosis in Indian patients with scleroderma, in a cross-sectional design.

Objectives: To compare carotid intima-media thickness (CIMT, mean value of both carotids) as a measure of subclinical atherosclerosis (SCA) between patients with scleroderma (n=61) fulfilling 2013 ACR/EULAR criteria, and healthy controls (n=41).

- To compare clinical (body mass index – BMI, waist-hip ratio – WHR, fasting lipid profile) and serological factors (microparticles, endothelial microparticles, inflammatory cytokines associated with increased cardiovascular risk) between patients with scleroderma and healthy controls.

- To identify factors associated with SCA in scleroderma patients.

Methods: Subclinical atherosclerosis (SCA) was defined by presence of carotid plaques, or increased CIMT >2 standard deviations compared with Indian reference standards for age and sex. Total microparticles (TMP) were measured of plasma after ultracentrifugation as per previously described protocol using microbeads of 3 μm size (TMP were of size 0.1-1 μm); of these, microparticles positive for CD31 and CD142 were endothelial microparticles (EMP). Serum cytokines (IL-1, IL-6, TNF±) were measured by ELISA using manufacturer instructions. Linear regression was used to identify the determinants of CIMT in scleroderma. Binomial logistic regression was used to identify factors associated with subclinical atherosclerosis in scleroderma.

Results: Despite lower BMI, triglycerides and VLDL cholesterol, CIMT was significantly higher in patients with scleroderma. Patients with scleroderma had significantly higher total microparticles and endothelial microparticles in plasma, and serum IL-1± and IL-6 (Table 1). On multivariable regression, age was the only significant determinant of CIMT. 28 (45.9%) patients had SCA; 13 (21.3%) had carotid plaques. Patients with SCA had higher proportion of males (9/28 in those with SCA vs 2/23 in those without SCA). Binomial logistic regression did not identify any other significant predictors of SCA.

Table 1. Comparison between patients with scleroderma and healthy controls

</tbody>
</table>

Conclusion: Patients with scleroderma had significantly higher risk of subclinical atherosclerosis, which could not be explained by traditional or novel cardiovascular risk factors.

SAT0320
BONE MINERAL DENSITY AND FRATUR RISK IN A COHORT OF PORTUGUESE SYSTEMIC SCLEROSIS PATIENTS
S. Garcia1, B. M. Fernandes1, S. Ganhão1, M. Rato1, F. Pinheiro1, G. Terroso1, M. Bernardes1, L. Costa1, Centro Hospitalar Universitário São João, Porto, Portugal

Background: Although poorly understood, patients with Systemic Sclerosis (SSc) seem to have higher prevalence of low bone mineral density (BMD) and an increased spine fracture risk.

Objectives: We aim to determine, by conventional densitometry (DXA) and using the fracture risk assessment tool (FRAX), the prevalence of low BMD and the fracture risk, respectively, in our SSc cohort and its potential determinants.

Methods: Observational transversal study was performed including consecutive patients with the diagnosis of SSc. We collected data regarding demographics, BMD (lumbar spine and femoral neck) and occurrence of fracture. Ten-year risk of osteoporotic fracture was estimated using FRAX v.4.1 with the Portuguese population reference. Statistical analysis was performed using SPSS 23.0; p<0.01 was considered statistically significant.

Results: Median age of patients (n=97) was 62 years old [56, 70], 88.7% females (n=86). Seventy-eight patients (80.4%) had limited cutaneous form, 5 (5.2%) presented a diffuse cutaneous form and 13 (13.4%) an overlap syndrome.

Regarding clinical features: digital ulcers in 30 patients (30.9%), interstitial lung disease (ILD) in 16 (16.5%), gastrointestinal involvement in 16 (16.5%), miositis in 4 (4.1%) and pulmonary arterial hypertension in 3 (3.1%). Anti-topoisomerase I antibody (anti-Scl70) positivity was present in 15 patients (15.5%) and anti-centromere antibody (ACA) positivity in 63 (64.9%). Nine patients (9.3%) were smokers and 6 (6.2%) reported an alcohol consumption of 3 or more units/day. Median body mass index (BMI) was 25.4 Kg/m² [21.4, 29.1], with 5 patients (5.2%) being underweight. Vitamin D insufficiency was reported in 19 patients (19.6%). Twenty-one patients (21.6%) have been exposed to oral glucocorticoids (GCR) for more than 3 months of daily or more. Eleven patients (11.3%) had previous low impact fractures: 10 of which were vertebral fractures and 1 wrist fracture.

Low BMD was present in 45 patients (46.4%); median femoral neck BMD (FN-BMD) was 0.827 [0.708, 0.893]. Ten-year probability of fracture (%): median risk for major fracture was 5.1 [3.5, 9.7] and 3.8 [2.5, 8]. With and without FN-BMD, respectively, for hip fracture the estimated risk was 1.2 [0.6, 3.1] and 1.0 [0.4, 2.5], with and without FN-BMD, respectively. According to FRAX thresholds for the Portuguese population, 25 patients (25.8%) met criteria to start AOP treatment. Among them, only 10 patients (40%) started it, as the agreement between the indication to treat by FRAX and the onset of treatment was weak (k = 0.338). A strong agreement was found between FRAX risk threshold with DXA and WHO threshold (%). Among them, only 10 patients (40%) started it, as the agreement between the indication to treat by FRAX and the onset of treatment was weak (k = 0.338). A strong agreement was found between FRAX risk threshold with DXA and WHO threshold (%).

AOP treatment. Among them, only 10 patients (40%) started it, as the agreement between the indication to treat by FRAX and the onset of treatment was weak (k = 0.338). A strong agreement was found between FRAX risk threshold with DXA and WHO threshold (%).
SAT0321 Current Patient Reported Outcomes (PROs) Poorly Reflect Changes in Lung Function in Patients with Systemic Sclerosis

F. Danzo1, K. Gjelstøl2, G. Abignano2,3,4, A. M. Dean3, F. Masini5, G. Cuomo6, F. Del Galdo7,8, 1Università degli Studi di Campania, L’Avv. Venticelli, UOC Medicina Interna, Naples, Italy; 2Istituto Reumatologico Lucano (IRel), Azienda Ospedaliera Regionale San Carlo, Potenza, Italy; 3Leeds Institute of Rheumatism and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 4NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospital, Leeds, United Kingdom

Background: Lung involvement is very common in systemic sclerosis (SSc). Approximately one quarter of patients develops pulmonary problems within the first 3 years of diagnosis and still represents the leading cause of death in these patients. In a recent clinical trial, the reduction of FVC was not accompanied by a benefit with respect to health-related quality of life and patient-reported outcomes (PROs).

Objectives: To assess how the change in Pulmonary Function Test (PFTs) parameters correlates with the Patient Reported Outcomes (PROs) in an observational cohort of patients with Systemic Sclerosis (SSc).

Methods: We conducted a retrospective study of 330 clinic episodes from 121 unselected patients diagnosed with systemic sclerosis according to EULAR/ACR 2013 criteria, in annual follow-up (for a total of 165 patients/year) with PFTs, Health Assessment Questionnaire Disability Index (HAQ-DI), Scleroderma Health Assessment Questionnaire (sHAQ), Modified Borg Dyspnea Scale (Borg) and Cochin Hand Function Score (CHFS). We assessed the correlation between the HAQ and the Visual Analogical Scale 1-7 at baseline (VAS1 pain, VAS2 disease severity, VAS3 arthritis activity, VAS4 intestinal problems, VAS5 dyspnea, VAS6 Raynaud’s phenomenon, VAS7 digital ulcers). We evaluated the correlation of sHAQ with PFTs at every time period and the correlation between the change of PFTs parameters (sFVC, sDLCO) with the change of the PROs over a year of follow-up. Following analysis of distribution, Spearman or Pearson Test were used to determine correlation coefficients, as appropriate (Psim 7).

Results: The median disease duration was 5 years (IQR 3-10). The median of 12 months sFVC% and sDLCO% were 0 (IQR -5.81 to 3.28) and -2.439 (IQR -8.76 to 5.98), respectively. The analysis evidenced a strong positive correlation between VAS1-7 and HAQ. We observed also significant correlation between FVC%, DLCO% and HAQ-DI (r = 0.355 and -0.266, respectively; p<0.0001 for both), Borg (r = -0.403 and -0.379, respectively; p<0.0001) and CHFS (r = -0.356 and -0.256, respectively; p<0.0001). Nevertheless, in longitudinal setting there was no significant correlation between sPROs and changes lung function, as continuous variables, neither there was any significant PROs difference in patients that did or did not lose more than 10% of FVC and DLCO over a year of follow-up.

Conclusion: This analysis of a monocentric non-selected population evidenced that the current commonly used PROs in SSc while showing a good correlation with lung function changes are poor sensitive to change to or reflect changes in lung function over 12 months. In this sense, prudent interpretation of the lack of correlation between FVC and patient-reported outcomes in studies of phase 3 is warranted.

Department of Internal Medicine, Unit of Systemic Autoimmune Diseases, Granada, Spain; 10Sociedad Española de Medicina Interna (SEMI), Madrid, Spain

Background: Left ventricular diastolic dysfunction (LVDD) is a very common finding in heart involvement in Systemic Sclerosis (SSc).

Objectives: To determine the prevalence, risk factors and mortality associated with LVDD in a cohort of patients with SSc.

Methods: A retrospective study was conducted with data from the multicentre Spanish Scleroderma Registry (RESCLE). A case-control study was performed to identify factors associated with LVDD.

Results: Out of 1517 cases of SSc, 319 (21%) developed LVDD. Basal characteristics are shown in Table 1. In multivariate analysis, LVDD was associated to older age at diagnosis of SSc [54 vs 44 years, OR 1.05 (1.04-1.06), p=0.001], presence of telangiectasia [67 vs 59%, OR 1.42 (1.88-1.08), p=0.001] and with treatment with calcium channel blockers [50 vs. 45%, OR 1.16 (1.16-1.80), p=0.001] and positively correlated to treatment with ACE inhibitors [24 vs. 83%, OR 2.69 (1.44-4.93), p=0.021]. Mortality was increased in patients with LVDD (24 vs 17%, OR 1.4, p = 0.01), Kaplan–Meier cumulative survival for the SSc cohort, according to the presence or absence of LVDD showed significant differences in 30 years from the first SSc symptom (59 vs. 70%, p = 0.04). MYOSITIS-SPECIFIC AND MYOSITIS-ASSOCIATED AUTOANTIBODIES IN A LARGE INDIAN COHORT OF INFLAMMATORY MYOSITIS REVEAL NOVEL CLINICO-PHENOTYPIC PATTERNS

L. Gupta1, P. Gaur2, V. Agarwal1, R. Aggarwal3, R. Misra4 on behalf of – 1Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; 2Niruj Rheumatology Clinic, Ahmedabad, India; 3UPMC, Pittsburgh, United States of America; 4Kalinga Institute of Medical Sciences (KIMS), Bhubaneswar, India

Background: Idiopathic Inflammatory Myositis (IIM) are heterogeneous, with distinct autoantibodies reflecting upon possible clinical evolution and outcomes. Ethnicity has major influence on both antibody prevalence patterns as well as phenotypic behaviours linked to them.

Objectives: Thus we sought prevalence and co-existence of myositis specific autoantibodies (MSAs) and myositis associated autoantibodies (MAAs) and associated clinical characteristics in a large cohort of patients with IIM.

Methods: Adult patients with a physician diagnosis of IIM as per ACR/EULAR classification criteria were investigated for the presence of MSAs/MAAs by Line immunoassay (G4, Euro–Immune, Lubeck, Germany). Anti-Nuclear Antibody (ANA) was tested by Immunofluorescence assay (IFA), and patterns in various antibody subsets explored. Prevalence and associations of different antibodies were assessed in disease subsets and clinical phenotypes.

Results: MSA and MAAs were tested in 250 IIM patients (F:M 3:8:1) of median age 37 (25-47) and disease duration 6 (3-17) years. Dermatomyositis (DM) was seen in most patients 83 (33.2%) followed by overlap myositis (OM), juvenile DM, Anti-synthetase syndrome (ASS), polymyositis (PM), and cancer associated myositis (CAM). MSAs/MAAs were found in 148 (59.2%) of patients, of which 95 (64.2%) had an MSA and 53 (35.8%) had MAAs (Fig. 1A). 93 (62.8%) of autoantibody positive patients were positive for a single antibody, and only 2 (0.8%) of total had more than one MSA (Table 1).

Table 1. Multiple antibodies positive upon testing for MSA and MAA by the LIA

</table>

Note: ** PL-7 co-exists with Ku + Pm/Scl; **PL-12 co-exists with Pm/Scl + Ro52; **SRP co-exists with Pm/Scl + Ro52.

The most frequently detected MSA was anti-Jo-1 (8%), with a further 9 specificities each found in 0.5–7.5% of patients. Amongst the autoantibody positive patients, 21% (n=53) had isolated MAA positivity, anti-Ro52 (33, 62.3%) being the most common, followed by anti-Pm/Scl (11, 20.8%) and anti-Ku (9, 170%) (Fig. 1B).

On ANA, 76.0% (172 of 228) were positive, with speckled being the most common pattern (37%, Fig. 1C). Of those ANA negative (n=54), 61% had either MSA or MAA (Fig 1D). 18 (54.6%) had autoantibodies associated with cytopenic patterns suggesting that cytopenic ANA may be underreported.

Clinical presentation akin to DM was seen with all MSA except anti-SRP. PM group was heterogenous, and included ASS, OM and necrotizing phenotype (Fig. 2A). On occasion, anti-SRP, anti-Mi-2 and anti-MDA5 presented with clinical phenotype of ASS. (Fig 2A C). Patients with ARS or anti-SAE were often clinically amyopathic (Figure 2 B C).

AMS were associated with mechanic’s hand (p<0.0001,OR 7.6), ILD (p<0.0001,OR 4.4), and arthritis (p=0.002,OR 2.6) though there was no difference between Jo-1 and non-Jo-1 ASS. Anti-MDA-5 associated with fever (p=0.003, OR 12) and weight loss (p=0.008, OR 10.2) and unique phenotype of eye-lid edema in some adults (Figure 2E) and arthrits in children (p=0.01, OR 11.5). Anti-TIF-1γ associated with alopecia (p=0.007,OR 5.9) and malignancy (p<0.0001, OR 34) in adults but not children.

Conclusion: Myositis autoantibodies are seen in two-thirds IIM and identify distinct clinical subsets as well as unique phenotypes. MSAs/MAAs are positive in two-thirds of those negative on ANA, adding diagnostic value. MSAs are nearly always mutually exclusive and thus useful as biomarkers for diagnosis.

SEXUAL HEALTH IN WOMEN AND MEN WITH SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY

B. Heřmáňková1, M. Špirtovič2, H. Smucrova2, S. Oreska2,3, H. Štorkánová2,3, K. Bubova2,3, K. Pavelka2,3, J. Vencovsky2,3, L. Šenolt2, R. Belcaž2,3, M. Tomčík2,3, Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic; 2Institute of Rheumatology, Prague, Czech Republic; 31st Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic

Background: Systemic sclerosis (SSc) is a chronic multisystem disease that may affect all aspects of life including sexual function.

Objectives: To assess sexual function, pelvic floor function in 80 women and 14 men with SSc compared to age-/sex-matched healthy controls (HC) and to analyze the potential impact of clinical features on sexual health.

Methods: In total 80 women (mean age: 49, disease duration: 6.1 years, lcSSc/dcSSc: 53/27, mRSS: 9.3, ESSG activity index: 2.1) and 14 men with SSc (mean age: 51.6, disease duration: 3.1 years, lcSScIdcSSc: 6/8, mRSS: 12.9, ESSG activity index: 2.2) who fulfilled the ACR/EULAR 2013 criteria, filled in 12 well-established and validated questionnaires assessing sexual function, pelvic floor function, quality of life, fatigue, physical activity and depression. Full names of questionnaires are listed in Table 1. These questionnaires were also completed by 80 healthy women and 14 healthy men with identical age. Data are presented as means±SEM.

Figure 2. A. Phenotypic associated with various antibody subsets B,C; and D. MSA/MAA in muscle weakness, rash and ILD phenotype. E. Unique feature of eye-lid edema in some patients with MDA-5 positive myositis.
The aim of this study was to observe the impact of a combined treatment of ISCHEMIC SYMPTOMS in patients with Systemic Sclerosis (SSc) patients with risk of development of digital ulcers (DU). For its treatment, treatment with Iloprost.

**Results:** Compared to HC, women with SSc had significantly higher prevalence and greater severity of sexual dysfunction [FSFI total score (SSc: 16.4±3.1, HC: 25.2±3.9, p<0.0001) as well as in all subscales (p<0.0001 for all), FSFI-BV total score (SSc: 17.2±2.3, HC: 32.0±1.9, p<0.0001)], dysfunction of pelvic floor ([PIQ(Fv: SS: 3.6±0.7, HC: 8.9±0.6, p=0.0001), PIQ(Fr: SS: 3.34±5.6, HC: 6.8±1.4, p=0.0001)], and worse sexual quality of life ([SQoL-F (SSc: 55.3±3.3, HC: 82.1±2.1, p=0.0001)]. Men with SSc also reported more severe sexual dysfunction: [IEF - Erectile function (EF) (SSc: 15.4±3.0, HC: 26.2±2.1, p=0.004), IIEF - Orgasmic function (SSc: 6±12, HC:9±0.6, p=0.045), IIEF - Intercourse satisfaction (SSc: 9±7.1, HC: 15±7.1, p=0.008), MSHQ - Erectile Function (SSc: 9±0.2, HC: 12±0.9±0.0, p=0.005), MSHQ - Satisfaction (SSc: 19±2.1, HC: 26±8±9, p=0.001)] and worse sexual quality of life ([SQoL-M: SS: 68±5.7±4, HC: 86±7.6±2, p=0.203]). According to the IIEF classification, 71 % of SSc men reported mild to severe erectile dysfunction. No significant difference were found in pelvic floor function. Significant associations with major clinical parameters are presented in Table 1.

**Conclusion:** Both women and men with SSc reported significantly impaired sexual function compared to HC with identical age. Worsen scores in SSc were associated with disease activity, increased systemic inflammation, health status, physical activity, fatigue and depression.

**Background:** Peripheral ischaemia is a common symptom in systemic sclerosis (SSc) patients with risk of development of digital ulcers (DU). For its treatment, intravenous iloprost is the most effective option. Accompanying pain symptoms worsen the ischaemic symptoms, so a combination with anaesthetic procedures may improve ischaemic status and the subjective sensation of raynaud and pain. The aim of this study was to observe the impact of a combined treatment of iloprost with stellate blockade (ILOST) in improvement of ischaemic symptoms compared to iloprost treatment only (ILO).

**Objectives:** To evaluate efficacy of the ILOST treatment on changes in vascularisation and sensation of patients with SSc and indication for vasodilatative treatment with iloprost.

**Methods:** Twenty SSc-patients with indication for ILO-treatment (prolyphlactic or due to digital ulcerations (DU)) will be included in a prospective observational study. Patients will be offered to combine ILO with stellate blockade (ILOST).

**SYSTEMIC SCLEROSIS WITHOUT ANTINUCLEAR ANTIBODIES: A MULTI-CENTER STUDY OF EUSTAR COHORT IN CHINA**

M. Hu1, J. Zhou2, L. Zhang3, X. Duan4, M. Li2, Q. Wang2, J. L. Zhao2, Y. Hou2, D. Xu2, X. Zeng2, 1Peking Union Medical College Hospital, Beijing, China; 2Peking Union Medical College Hospital, Beijing, China; 3ShanXi Bethune Hospital, Xi’an, China; 4The Second Affiliated Hospital of Nanchang University, Nanchang, China

**Background:** The presence of circulating antinuclear antibodies (ANAs) is a hallmark of immune dysregulation and malfunction in patients with systemic sclerosis (SSc) [1]. A variety of ANAs [1], including anti-centromere antibody, anti-to- poisomerase I antibody, and anti-RNA polymerase III antibody, are associated with unique sets of disease manifestations and widely used in routine clinical practice for diagnosis, clinical subgrouping, risk stratification and prediction of future organ involvements and prognosis in SSc patients [2,3].

**Objectives:** This study aimed to investigate the clinical features of SSc patients with negative ANAs in a European League Against Rheumatism Scleroderma Trials and Research Group (EUSTAR) and Chinese Rheumatism Data Center (CRDC) multi-center cohort in China.

**Methods:** Patients were prospectively recruited between April 2008 and June 2019 based on the EUSTAR database and CRDC multi-center cohort from 154 clinical centers nationwide, all of whom fulfilled the 2013 ACR/EULAR classification criteria for systemic sclerosis. Antinuclear antibody testing result was intensively collected. Demographic, clinical, and laboratory data were compared between ANA-positive SSc patients and those with negative ANAs. T-test and chi-square analysis were performed in the comparisons.
Results: Antinuclear antibodies were detected in 2129 out of 2809 systemic sclerosis patients enrolled in the multi-center cohort and 4.2% of them were negative. There was significant difference between patients with negative and positive ANAs based on gender (29/60 vs 291/1746, p<0.001). The presence of Raynaud’s phenomenon is less common (71.8% vs 99.8%, p<0.001) in the ANA-negative patients. In addition, compared with ANA-positive patients, the incidence of certain critical organ involvements, including gastrointestinal reflux (5.6% vs 18.5%, p=0.002), interstitial lung disease (65.2% vs 77.9%, p=0.015) and pulmonary arterial hypertension (11.5% vs 29.0%, p=0.006) were significantly lower in ANA-negative patients than in the positive group. The proportion of IgG elevation, an indicator of disease activity and severity of inflammation, was significantly lower in the ANA-negative patients than that in the positive group (14.3% vs 41.2%, p<0.001), while no significant differences were found in other inflammatory indicators and skin scores.

Conclusion: This study describes the clinical features of SSC patients with negative ANAs, which have been rarely mentioned or focused in existing studies. Antinuclear antibody is proved to be strongly associated with the clinical manifestations of systemic sclerosis patients and ANA-negative SSC patients tend to be in relatively milder conditions, including a less common involvement of critical organs and a more temperate inflammatory severity.

SAT1032
SEXUAL DYSFUNCTION IN FEMALE SCLERODERMA PATIENTS AND ITS CORRELATION WITH VASCULAR INVOLVEMENT

Z. Khodamoradi1, M. Nazarian1, E. Esmaeizadeh2.1 Shiraz Genric Research Center, Shiraz University of Medical Sciences, Division of Rheumatology, Department of Internal Medicine, Shiraz, Iran (Islamic Republic of); 2Division of Rheumatology, Department of Internal Medicine, Shiraz University of Medical Sciences, Division of Rheumatology, Department of Internal Medicine, Shiraz, Iran (Islamic Republic of)

Background: Systemic Sclerosis (Scleroderma, SSc) is an autoimmune disorder characterized by multi-organ dysfunction, which ultimately leads to multiple clinical and psychological complications. Among various complications of scleroderma, sexual dysfunction can be named as a major issue in both male and female patients, which has great impact on quality of life of the patients.

Objectives: Investigating the sexual dysfunction in scleroderma patients and its relation to their vascular involvements.

Methods: A case control study was done on 80 married female scleroderma patients with age between 20-60 years old. Eighty normal individuals adjusted for age, place of living and socioeconomic status were also recruited. Sexual performance in both groups was assessed using FSFI standardized questionnaire, which evaluated it in 6 domains of desire, arousal, lubrication, orgasm, satisfaction, and pain. Micro and macro-vascular involvements of the patients were also determined using Raynaud Condition Score, Echocardiography, physical exam for assessing their digital ulcers and reviewing their medical records for presence of past or present history of renal crisis and thromboembolic events.

Results: The total score of FSFI in the case group was significantly lower compared to control one (16.68 ± 6.35, 19.69 ± 6.01, P-value <0.001). The score was significantly lower in all domains of sexual dysfunction except for pain and lubrication. Moreover, the mean score of FSFI was also found to be significantly lower in limited form of the disease compared to diffuse one (14.6 ± 6.9, 18.1 ± 5.5, P-value 0.01). No significant association was found between vascular complications and sexual impairment of the scleroderma patients.

Conclusion: This study can be named as the first survey investigating the sexual dysfunction in Iranian female scleroderma patients and assessing its relation with vascular complication of the disease. Thus, it can be a guide for future studies on sexual dysfunction especially in societies with cultural limitations in discussing this issue.

DOI: 10.1136/annrheumdis-2020-eular.4084
Objective: We evaluated FVC decline and AEs in subgroups by weight loss ≤5% vs >5% over 52 weeks. The rate of decline in FVC was numerically lower in the nintedanib group than placebo both in patients with weight loss ≤5% and >5% over 52 weeks. AEs leading to discontinuation of nintedanib were not more frequent in patients with weight loss >5% vs ≤5%.

Disclosures of Interests: [1] Philippe Lescoat, Guillaume Forget and Christel Forgeron Grant/research support from: AstraZeneca, Boehringer Ingelheim, Pfizer, Roche, Shionogi, Sanofi; Speakers bureau: AstraZeneca, Boehringer Ingelheim, Pfizer, Roche, Shionogi.

References: [1] J. Qiao, X. Zhang, T. Z. Zhang, J. Zhang, M. T. Qi, R. Zhao, M. J. Chang, Y. Li, J. Luo, G. Y. Liu, C. Gao, X. Liu. The Second Hospital of Shaxi Medical University, Rheumatology, Taiyuan, China; Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America.

Background: Systemic sclerosis (scleroderma, SSC) is a rare complex connective tissue disease associated with high mortality and high morbidity. Active SSC...
are typically treated with immunosuppressants, which may create a variety of side-effects, especially for long-term treatment. As the pathogenesis of SSC is still a matter of debate, growing evidences have focused on the immune disorders. However, the quantitative status of lymphocyte subsets in SSC patients are unclear and effects of immunomodulatory combination therapies (avoiding side-effects of conventional therapy) on the lymphocyte subsets are unknown.

Objectives: To investigate the quantitative status of peripheral lymphocyte subpopulations and CD4+ T subsets in SSC patients for the exploration of SSC pathogenesis and evaluate the effects of new immunomodulatory combination therapies on the lymphocytes.

Methods: From July 2014 to December 2019, total 166 patients with SSC and 206 healthy controls (HCs) were enrolled in this study, in which, 79 follow-up patients received immunomodulatory drugs (IMIDs) such as low-dose interleukin-2, rapamycin, metformin, retinoic acid and coenzyme Q10. The absolute numbers of T, B, NK, CD4+T, CD8+T, Th1, Th2, Th17 and Tregs in peripheral blood of these subjects were detected by flow cytometry combined with standard absolute counting beads.

Results: Patients with SSC had lower absolute counts of total T, NK, Th2, Th17 and Tregs as compared with those of HCs (P<0.05) (Figure 1). After immunomodulatory combination treatments, there were increases in a various of peripheral lymphocyte subsets such as T, B and CD8+T (P < 0.05). Moreover, the increased level of Tregs was much more dramatical than those of other lymphocyte subsets, resulting in the decrease ratios of Telfs/Tregs such as Th1/Tregs and Th2/ Tregs and rebuilding immunologic equilibrium (Figure 2).

Conclusion: This cross-sectional study clarified the abnormal status of lymphocyte subsets in SSC patients, suggesting lymphocyte subsets, especially Tregs, might be relevant and play a crucial role in the pathogenesis of SSC, thus providing a potential therapeutic target for SSC patients. Immunomodulatory combination therapies effectively increase the level of Tregs as well as other lymphocytes to some degree and maintain the immunologic equilibrium, which may help for SSC patients’ symptom remission.

ABTENODIES AGAINST CYTOSOLIC 5'-NUCLEOTIDASE 1A IN SPORADIC INCLUSION BODY MYOSITIS: ASSOCIATION WITH CLINICAL AND MRI FEATURES

R. Dejthevaporn1, S. Shah2, S. Wastling2, J. Thornton2, T. Yousry2, J. M. Morrow1, P. M. Machado3
1University College London, Queen Square Centre for Neuromuscular Diseases, London, United Kingdom; 2University College London, Neuroanatomical Academic Unit, London, United Kingdom; 3University College London, Centre for Rheumatology & Queen Square Centre for Neuromuscular Diseases, London, United Kingdom

Background: Autoantibodies directed against cytosolic 5'-nucleotidase 1A (cN1A) have been identified in sporadic inclusion body myositis (sIBM) and other connective tissue diseases. Anti-cN1A antibodies may support the diagnostic process for sIBM as well as potentially provide clues for disease pathogenesis. Nevertheless, the utility of anti-cN1A autoantibody testing in clinical practice remains unclear and requires validation.

Objectives: To investigate the association between anti-cN1A antibody status and clinical and MRI features in patients with sIBM.

Methods: Data for patients fulfilling European Neuromuscular Centre (ENMC) 2011 criteria for sIBM were obtained from a natural history study database. Demographic, clinical, functional assessment, and muscle MRI data in patients with sIBM who had anti-cN1A autoantibody testing were collected and analysed. Comparisons between subgroups with anti-cN1A antibody status were performed with the Mann-Whitney or Fisher’s exact tests, as appropriate.

Results: Forty-nine patients with sIBM had anti-cN1A autoantibody testing, of whom 17 (34.7%) were positive. Twelve patients had muscle MRI performed (seropositivity = 52%). The antibody positive patients were more severely affected with a trend to lower IBM functional rating scale (IBMFRS) scores (22.4±8.4 vs 26.7±6.4, p=0.09) with significantly worse ability to climb stairs (0.9±0.9, 1.7±1.1, vs 47%, p=0.070). Antibody positive patients were more severely affected with a trend to lower IBM functional rating scale (IBMFRS) scores (22.4±8.4 vs 26.7±6.4, p=0.09) with significantly worse ability to climb stairs (0.9±0.9, 1.7±1.1, vs 47%, p=0.070). Anti-cN1A antibodies may support the diagnostic process for sIBM as well as potentially provide clues for disease pathogenesis. Nonetheless, the utility of anti-cN1A autoantibody testing in clinical practice remains unclear and requires validation.

SAT0333

SERUM METABOLITES AS BIOMARKERS IN SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

C. Meier1, K. Freiburgiaus2, C. Bove2, J. Schniering2, O. Distler1, C. Nakas1,3, B. Maurer1
1Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2University Institute of Clinical Chemistry, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; 3Laboratory of Biometry, Department of Agriculture, University of Thessaly, Thessaly, Greece

Background: In fibrotic diseases, metabolic processes are altered with a tendency towards an anabolic state, which is partially reflected in serum. Circulating biomarkers for interstitial lung disease (ILD), the leading cause of death in systemic sclerosis (SSc), are still sparse and not established in routine care.

Objectives: To assess the potential of serum metabolites as biomarkers for the presence and progression of SSc-ILD.

Methods: Age and sex matched serum samples of SSc patients from the Zurich cohort and of healthy controls (HC) were analyzed. Progressive SSc-ILD was defined as either a relative decrease in forced vital capacity (FVC) >10%, a decrease in FVC of 5-9% and a concomitant decrease in carbon dioxide diffusion capacity by >15%, or an increase of the extent of lung fibrosis on computed tomography from <20% to >20% compared to the last visit (mean follow-up interval = 14 months (range = 9-26)). Sera of HC, non-ILD SSc and stable vs. progressive SSc-ILD patients (n = 12 per group; total n = 48) were screened for 110 metabolites by targeted liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS). Peak areas were analyzed with R 3.6. For univariate analysis, FDR-corrected one-way ANOVA was used. In multivariate group-wise partial least squares discriminant analysis (PLS-DA), variable importance in the projection (VIP) scores ≥2 were considered significant.

Results: In total, 85 metabolites were detected. Univariate analysis of all groups were suggestive of changes for 1-methylenoadenine, L-tryptophan, L-tyrosine, L-leucine and xanthosine (p = 0.077, 0.026, 0.077, 0.028 and 0.032, respectively). In PLS-DA, HCs and SSc patients differed in their levels of L-tyrosine and L-tryptophan, while levels of L-threonine, 3-aminoisobutyric acid, adenosine monophosphate and xanthosine were changed when comparing non-ILD and SSc-ILD patients. Receiver operating curve (ROC) analysis of significant metabolites from uni- and multivariate testing resulted in separation of SSc patients from HCs by L-tyrosine (area under the curve (AUC) = 0.81, 95% confidence interval (CI): 0.670-0.96), L-tryptophan (AUC = 0.86, CI: 0.75-0.97) and 1-methylenoadenine (AUC = 0.82, CI: 0.71-0.94). Progressive SSc-ILD patients were separated from stable patients by their levels of L-isoleucine, L-leucine, adenosine monophosphate and xanthosine (AUC = 0.83, 0.85, 0.79 and 0.77; CI: 0.66-1.00, 0.70-1.00, 0.60-0.97 and 0.55-0.99, respectively). Validation of increased values of the branched-chain amino acids L-leucine and L-isoleucine in progressive SSc-ILD vs. stable ILD using an enzymatic assay resulted in similar results as LC-MS/MS analysis, with higher values detected in progressive vs. stable patients (mean = 286.5 and 235.5 nM, respectively; p = 0.005). In ROC analysis (AUC = 0.81, CI: 0.62-1.00), a cut-off value of 250.3 nM separated stable from progressive patients with a sensitivity of 72.7% and a specificity of 83.3%.

Conclusion: This study in SSc-ILD patients suggested alterations in serum metabolite levels corresponding with their current state of disease, indicating the potential use of serum metabolites as discriminating biomarkers upon further confirmation in larger multicenter studies.

PERICARDIAL INVOLVEMENT IN SYSTEMIC SCLEROSIS

P. Morán Álvarez1, C. De la Puente Bujidos1
1Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: Systemic sclerosis (SSc) is an autoimmune rheumatic disease characterized by visceral and skin fibrosis, vascular dysfunction, and immune dysregulation. Regarding cardiac manifestations, pericardial disorder is one of the most frequent but often asymptomatic.

Objectives: To analyze clinical manifestations, diagnostic tools and treatments of a patient cohort with SSc and pericardial involvement associated.

Methods: A descriptive, observational, cross-sectional study was carried out. We included all patients between 1975 and 2019 with diagnosis of SSc. Demographic, clinical and analytical data; imaging tests; treatments; and mortality rate were collected.
Results: 158 patients were included, 142 (89.9%) women and 16 (10.1%) men. 144 (91.1%) were Caucasians. Mean age at diagnosis was 57 years (range: 17-86). Type of scleroderma, clinical manifestations and autoimmunity profile were shown in table 1 and 2, respectively.

In our cohort patient with SSc, 9.5% developed a pericardial disorder, 3 of them (1.8%) an acute pericarditis. In the majority of the patients (11, 73.3%) pericardial involvement appeared later than diagnosis of SSc with a mean time of 8 years (maximum period of time: 20 years), and the remaining (4 with 2.5%) presented the pericardial involvement prior to SSc onset (up to 4 years before). Regarding to cutaneous involvement, limited SSc was the most frequent (13 patients, 86.6%), followed by diffuse SSc (3 patients, 13.4%). In relation to antibody profile, 11 (73.3%) patients were AC positive and 4 (26.6%) AT positive. Seven (46.6%) of the 15 patients with pericardial involvement had a prior pulmonary hypertension associated. Eleven (73.3%) were asymptomatic, 4 (26.6%) referred chest pain and 4 (26.6%) dyspnea. 100% of the pericardial effusions were detected through the performance of an echocardiogram, 3 of them (13.4%) with signs of diastolic dysfunction. Regarding to electrocardiographic findings, 2 (13.3%) showed low voltages. The size of the pericardial effusion was described as: mild in 9 (60%) patients, moderate in 5 (33.3%) and severe in 1 (6.7%). One Cardiac- Magnetic Resonance Imaging was performed which showed constriction data. None of the patients suffered cardiac tamponade or hemodynamic compromise, due to invasive therapies were not necessary. A spontaneous resolution of the pericardial effusion was registered in 6 (40%) patients, with a mean time of 8 months (range: 2-36 months); and 1 (6.7%) patient after an increment in immunosuppressive dose, without improvement of pulmonary hypertension. No renal crisis or deaths were recorded in these patients.

Conclusion: In our cohort patient with SSc, 9.5% developed a pericardial involvement. This kind of disorder could be the first manifestation of the disease. Pulmonary hypertension is the most frequent underlying pathway, however serositis must also be taken into account. Most part of the pericardial effusions were mild. No hemodynamic compromise was registered, due to an invasive treatment was not required.

SAT0335

SERUM AND BALF-DERIVED ANTI-JO1 AUTOANTIBODIES EXHIBIT HIGH REACTIVITY TO DISTINCT HISRS DOMAINS AND ASSOCIATE WITH LUNG AND JOINT INVOLVEMENT IN PATIENTS WITH IIM/ASS

A. Notarnicola1,2, C. Preger1,2, S. Lundström1,4, N. Renard1,2, E. Wignen1,2, E. Van Gompel1,2, A. S. Galindo-Feria3, H. Persson1,2, M. Fathi1, J. Grunewald1,2, P. J. Jakobsson1,2, S. Gräslund1,2,3, I. E. Lundberg1,2, C. Cerqueira1,2,2, Karolinska University Hospital, Karolinska Institutet, Department of Medicine, Division of Rheumatology, Stockholm, Sweden; 2Karolinska Institutet, Center for Molecular Medicine, Stockholm, Sweden; 3Structural Genomic Consortium, Stockholm, Sweden; 4Karolinska Institutet, Division of Physiological Chemistry I, Department of Medical Biochemistry and Biophysics, Stockholm, Sweden; 5Science for Life Laboratory, Drug Discovery and Development, Stockholm, Sweden; 6Karolinska Institute and Karolinska University Hospital, Department of Respiratory Medicine and Allergy.

Background: Autoantibodies that target aminocyl transfer(t) RNA synthetases (aaRS) represent the serological marker of the anti-synthetase syndrome (ASS), a major subgroup of the idiopathic inflammatory myopathies (IIM) (1). Among the anti-aaRS, anti-histidyl tRNA synthetase (HisRS) autoantibodies (anti-Jo1) are the most common. Up to 90% of IIM/ASS patients diagnosed with interstitial lung disease (ILD) harbor anti-Jo1 autoantibodies (2).

Objectives: Reactivity and affinity of anti-Jo1 autoantibodies from serum and bronchoalveolar lavage fluid (BALF) were investigated against HisRS autoantigen. Associations with clinical data from patients IIM/ASS were addressed.

Methods: Total IgGs were purified by affinity chromatography. Samples and clinical data were obtained from: i) 26 anti-Jo1 patients (19 at diagnosis, 16/19 at follow-up, 7 BALF/matching serum at baseline; ii) 29 anti-Jo1 (25 serum at diagnosis, 4 BALF/matching serum at baseline); iii) 24 age/gender matched healthy controls. Anti-Jo1 IgG and IgA response against HisRS was evaluated by ELISA and western blot. Affinity was measured by surface plasmon resonance. HisRS full-length (HisRS-FL), two HisRS domains (ABD and CD), and two HisRS splice variants (WHEP and WHEP + ABD splice variant (SV)) were tested. Correlations between autoantibody reactivity and clinical data, at baseline and over disease course, were evaluated.

Results: Anti-Jo1 autoantibodies from serum and lung bound HisRS-FL, WHEP and SV with high reactivity and affinity already at diagnosis and recognized both conformational and linear HisRS epitopes. Anti-Jo1 reactivity varied among patients and overtime. Patients with ILD, arthritis and less skin involvement presented higher anti-Jo1 titers compared to those with lower anti-Jo1 titers and to the anti-Jo1 negative group (Fig. 2). Anti-WHEP reactivity in BALF strongly correlated with poor pulmonary function.

Conclusion: High reactivity and affinity at time of diagnosis indicates autoimmunity against HisRS is most likely initiated before IIM/ASS diagnosis. Reactivity to specific splice variants of HisRS may be employed as diagnostic and prognostic markers.

SAT0336 SYMPTOMS OF AUTONOMIC DYSFUNCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS
P Ostojic1, M. Atanaskovic1, M. Vujovic1, M. Perovic1. 1Institute of Rheumatology, Belgrade, Serbia

Objectives: This study aims to assess prevalence, severity and clinical correlates of symptoms of autonomic dysfunction in patients with SSc

Methods: Fifty five consecutively recruited SSc patients were included in this study. Thirty seven (67.3%) patients had limited (lcSSc), whilst 18 (32.7%) patients had diffuse cutaneous SSc (dcSSc). Anticentromere antibodies (ACA) were positive in 31 (56.4%) of patients, whilst 20 (34.6%) patients had anti-topoisomerase I antibodies (ATA). All patients completed the Composite Autonomic Symptom Score (COMPASS-31) questionnaire, which consists of 31 items, quantifying six autonomic domains: orthostatic intolerance (OI), vasomotor (VD), secretomotor (SD), gastrointestinal (GD), bladder (BD) and pupillomotor dysfunction (PD). The total score range from 0 to 100, whilst scores for particular domains range as follows: 0-40 for OI, 0-5 for VD, 0-15 for SD, 0-25 for GD, 0-10 BD, and 0-5 for PD. Higher values representing more severe symptoms. Differences in total COMPASS-31 score and domain-specific scores were assessed with respect to disease form, antibody status, capillaroscopic findings, lung diffusing capacity and joint involvement. Moreover, we assessed the correlation between COMPASS-31 scores, disease status (assessed using the Scleroderma Assessment Questionnaire – SAQ) and severity of gastrointestinal symptoms (assessed using the UCLA SCTC GIT 2.0 questionnaire)

Results: Percentage of SSc with a score >0 in particular domains of the COMPASS-31 were as follows: OI – 32/55 (58.2%), VD – 49/55 (89.1%), SD – 36/55 (65.5%), GD – 40/55 (72.7%), BD – 26/55 (47.3%), PD – 30/55 (54.5%). The COMPASS-31 score did not correlate with age or disease duration. There was no relationship between the COMPASS-31 total or subdomain scores and SSc subtype or autoantibody status. Similar mean values for total and subdomain scores were found among patients with different capillaroscopic patterns. Patients with DLOC < 80% had significantly higher mean values of GD, BD and PD scores, compared to patients with DLOC≥80% (4.42 vs 2.75, 1.51 vs 0.38, 1.93 vs 1.09, respectively). Moreover, the total COMPASS-31 score was significantly higher in patients with decreased DLOC (16.24 vs 11.34, p=0.008).

Patients with joint involvement had higher COMPASS-31 score than patients without (17.74 vs 9.85, p=0.012). We have found a statistically significant (p<0.001) correlation between the COMPASS-31 score and the index of disease status (IDS), as well as the the total UCLA SCTC GIT score (r=0.45, p<0.05, respectively).

Conclusion: Symptoms of dysautonomia are common in SSc patients. Patients with a more severe disease, especially decreased lung diffusing capacity, joint pain, and severe gastrointestinal involvement, report more symptoms of autonomic dysfunction.

SAT0337 EVALUATION OF BODY COMPOSITION AND BONE STATUS ACCORDING TO MICROCIRCULATORY INVOLVEMENT IN SYSTEMIC SCLEROSIS PATIENTS
S. Paolino1, E. Gotelli1, A. Casabella1, F. Cattelan1, C. Schenone1, M. Patanè1, G. Pacini1, C. Pizzorni1, A. Sulli1, V. Smith2, M. Cutolo1. 1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine DIMI, University of Genoa, IRCCS San Martino Polyclinic, Genoa, Italy, Genoa, Italy; 2Ghent, Department of Internal Medicine, Ghent University; Department of Rheumatology, Ghent University Hospital; Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Belgium, Ghent, Belgium

Background: Systemic sclerosis (SSc) is a complex autoimmune connective tissue disease, characterized by autoimmune inflammatory microvascular damage with progressive loss of capillaries, fibrosis and ischemia of skin and internal organs. (1) Nailfold videocapillaroscopy (NVC) is a safe tool for early diagnosis of SSc, it identify morphological changes of vessel that are predictive for clinical disease progression and organ involvement. (2) About clinical complication the loss of bone mass and body composition abnormalities, particularly muscle mass and strength loss (sarcopenia), are recognized in advanced disease. (3)

Objectives: To evaluated in SSc patients, the body composition and the bone mass according to the microvascular condition, as assessed and scored by nailfold videocapillaroscopy (NVC, “Early”/“Active”/“Late” patterns).

Methods: Body composition and bone mineral density (BMD) were assessed by DEXA in 35 female SSc patients classified according to the 2013 EULAR/ACR criteria and 32 sex-matched healthy subjects. Clinical, laboratory, body composition and bone parameters were analysed according to the different NVC patterns. Means were compared by the Student’s t test or one way analysis of variance; medians were compared by the Kruskall Wallis test; and frequencies by the chi square test.

Results: Higher prevalence of vertebral (26.4% vs 9.3%) and femoral (32.3% vs 9.3%) osteoporosis (OP) was found in SSc. Particularly SSc patients with “Late” NVC pattern showed a significantly higher prevalence of vertebral (p=0.018) and femoral OP (p=0.016). Regional assessment of bone mass (BM) in 7 different body areas showed a significant lower BMD only at the total spine (P=0.008) and femoral neck (p=0.027) in advanced microvascular damage. Patients with “Late” NVC pattern showed lower whole body lean mass (LM) compared to “Early” and “Active” NVC patterns, particularly at upper limbs. To note, in all body sites, BMD correlate with LM and BMC according to NVC pattern severity.

Conclusion: SSc patients with most severe microvascular damage show a significantly altered body composition and bone status suggesting a strong link between microvascular failure and associated muscle/bone failure.

SAT0338 CONTRAST-ENHANCED ULTRASONOGRAPHY IN THE EVALUATION OF MYOSITIS
N. Pipitone1, P. Macchioni1, G. Bajocchi1, C. Salvaran1. 1Arcispedale Santa Maria Nuova, Reggio Emilia, Italy

Background: contrast-enhanced ultrasonography (CEUS) has been proposed as a tool to assess myositis patients, but data in the literature are still scarce (Radiology 2018;58:579).

Objectives: to evaluate CEUS as a tool to assess myositis patients and its accuracy in differentiating myositis from common mimickers.

Methods: 16 patients with myositis (4 polymyositis, 6 dermatomyositis, 2 immune-mediated necrotizing myopathy, 1 inclusion body myositis, 2 overlap Sjögren’s syndrome - myositis and 1 Enterovirus-reactive myositis) and
4 controls (2 peripheral neuropathy, 1 limb girdle muscle dystrophy, and 1 metabolic myopathy) underwent after rest CEUS (Esaote MyLab, linear probe 13-5 MHz, Sonovue®) at a room temperature of 20° of the vastus lateralis and medialis muscles. CEUS was performed by 2 ultrasonographists with an expertise in muscle US blinded to the clinical data of the patients. CEUS muscle signal was expressed on a 0-4 scale as described in J Rheumatol 2001; 28:1271 per each muscle group and the global score was divided by four. Creatine kinase (CK), manual muscle test (MCT) and MRT of the thigh muscles were performed within maximum one month from the CEUS. MMT was expressed using the 0-5 Medical Research Council scale; intermediate points were converted into decimals as detailed in Kendall FP et al, Muscle Testing & Function: Testing and Function with Posture and Pain. 5th ed., Lippincott Williams & Wilkins, 2005. MRI of the thigh muscles was considered positive if it showed muscle edema. Myositis was defined active if CK was raised above the reference range and/or MMT showed progressive worsening. Results were expressed as median (range). Between-group comparison was performed with Mann-Whitney test. Statistical analysis was performed with SPSS version 20. The study was approved by the Ethics Committee and all patients provided their written consent.

Results: Median (range) age was 38 (69) years in the myositis and 41 (45) years in the control group (p=0.68). Disease duration in the myositis group was 60 (334) months. CEUS muscle score was 0.5 (3) in the myositis group and 2 (3) in the control group (p=0.96). In the myositis group, CEUS score did not differ between treated and untreated patients (p=0.84). CK values were 361 (6442) in the myositis group and 363 (799) in the control group (p=0.68). MMT was significantly lower in the myositis group [4.33 (2)] than in the control group [4.94 (0)] (p=0.038). CEUS was 77% (47:05 95% confidence interval) sensitive and 67% (9:99 95% confidence interval) specific for a diagnosis of active myositis. CEUS was positive in 10/13 patients and negative in 3/13 with active myositis, while was negative in 2/3 patients and positive in 1/3 with inactive myositis. Statistically, CEUS did not discriminate between active and inactive myositis (Fisher's exact test p= 0.21). All controls had a positive CEUS. No association was found between MRI edema and a positive CEUS (intra-class correlation coefficient p=0.5). No correlation was found between CEUS score, on the one hand, and CK levels or MMT, on the other (Spearmans rho p=0.05).

Conclusion: CEUS has moderate sensitivity for a diagnosis of myositis, but does not discriminate between myositis and some of its common mimickers. Larger studies are required to better evaluate the role of CEUS in patients with myositis.

SAT0340 A REDUCED NUMBER OF CAPILLARIES AND AN INCREASED NUMBER OF MEGACAPILLARIES PREDICT THE DEVELOPMENT OF SYSTEMIC SCLEROSIS IN RAYNAUD’S PHENOMENON PATIENTS AT RISK

A. Riccardi1, A. Marcoccia2, S. Fasano1, T. Guastafiori2, R. Itrace1, V. Messin1i, F. Bondanini2, A. Sanduzzi1, M. Bocchino1, A. Ciani1, M. D’alto1, P. Argiento1, G. M. De Matteis1, A. Spano2, G. Valenti1,1 University of Campania ‘Luigi Vanvitelli’; Department of Precision Medicine, Naples, Italy; 2Sacro Corpo della Fondazione Riferimento Interdisciplinare, Interdipartimentale per la Diagnosi Precoce della Scleroderma, Rome, Italy; 3University Federico II, Department of Clinical and Experimental Medicine, Naples, Italy; 4University of Campania ‘Luigi Vanvitelli’; Department of Cardiology, Naples, Italy

Background: Undifferentiated connective tissue disease at risk for systemic sclerosis (UCTD-risk-SSc) is a condition characterised by Raynaud’s phenomenon and either SSc marker autoantibodies or typical capillaroscopic findings or both, unsatisfying classification criteria for SSc and evolving into definite SSc in about 30-50% of cases (1,2). Recently, we developed a weighted score based on a baseline IF-ANA titer ≥1:320, marker autoantibody positivity and presence of avascular areas at videocapillaroscopy identifying patients who will evolve with a 91.3% sensitivity and a 73.2% specificity (3).

Objectives: To improve the predictivity of the score assessing the role of marker autoantibody ELISA titer and further capillaroscopic items.

Methods: The 102 UCTD-risk-SSc patients investigated for the development of the baseline score were reassessed for anti-Scl-70 and anti-centromere antibody titers detected by ELISA and for the mean number of capillaries observed in the same capillaroscopic field (Cs) and the total number of giant capillaries (GC) by videocapillaroscopy (4). Each patient was evaluated every 6 months to assess disease progression. Risk prediction was assessed by Cox regression analyses.

The predictive value of the score was determined by receiver operating curve (ROC) analysis.

Results: Table 1 shows the resulting predictive variables in multivariate Cox analysis and their relative weight in a 10-point scale. No increase in the predictivity was detected by adding the anti-Scl-70 and anti-centromere antibody ELISA titers. However, a mean number of Cs5≤5/mm and GC>5 improved the score. At ROC analysis (Figure 1) a score >3.25 predicted evolution to SSc with a sensitivity of 93.5% and a 75% specificity (AUC=0.91).

SAT0339 NERVIOUS SYSTEM INVOVLEMENT IN SYSTEMIC SCLEROSIS: A COHORT STUDY

T. Pore1, S. DE Almeida Chaves1, D. Adoue1, L. Astudillo1, D. Ribe2, G. Prévôt2, F. Gaches3, M. Michaud4, L. Alric1, L. Sailler1, G. Pugnet1,1 CHU Toulouse, Service de Médecine Interne, Toulouse, France; 2CHU Toulouse, Service de Néphrologie, Toulouse, France; 3CHU Toulouse, Service de Médecine Interne, Toulouse, France; 4Hôpital Joseph Ducuing, Toulouse, France

Background: Nervous system involvement is considered to be rare in systemic sclerosis (SSc). Its prevalence is highly variable in SSc cohort studies and its prognosis is not well established.

Objectives: To determine the frequency, clinical characteristics, associations, and outcomes of different types of peripheral nervous system (PNS) and central nervous system (CNS) disease in a cohort of systemic sclerosis patients.

Methods: We have carried out a retrospective observational study by systematically analyzing the medical records of patients diagnosed with SSc in Toulouse University Hospital and Ducuing Hospital, south west France. We included patients who met the following inclusion criteria: being over 18 years of age on diagnosis, meeting the ACR /EULAR 2013 classification criteria, being diagnosed after 01/01/1966 and before 31/12/2018, at least 12 months of follow-up. Patients were followed until 31/12/2019. Nervous system involvement associated with SSc was included when there was involvement on or after diagnosis and after exclusion of all other causes. Only symptomatic clinical involvement was included. Ischemic or hemorrhagic strokes were excluded. We calculated the incidence of CNS and/or PNS disease during the follow-up period per 1,000 person-years. Kaplan-Meier curves were plotted to determine the cumulative incidence of nervous system disease. We evaluated associated factors of CNS and/or PNS disease using multivariable Cox regression.

Results: Of 447 SSc patients, 79.8% were female, 68 (15%) were diffuse cutaneous SSc, 342 (77%) were limited cutaneous SSc and 37 (8%) were sine scleroderma SSc. The mean ± SD age at diagnosis was 52.9 ± 14.3 years. During the study period, 82 (18%) patients experienced a PNS disease, 29 (6%) a CNS disease. The incidence was 28 per 1,000 patient-years of any nervous system disease, with 22 per 1,000 patient-years and 6 per 1,000 patient-years of PNS disease and CNS disease, respectively. The most frequent were carpal tunnel syndrome (63%) and polynuropathies (12%) for PNS disease, and headache (45%) and seizures (10%) for CNS disease.

Three significant independent associated factors with PNS disease occurrence were identified using multivariable Cox regression: BMI>23.1kg/m2 (HR = 1.06 [1.01-1.12]), joint involvement (HR = 2.7 [1.9-3.5]), and an alteration in the left ventricular ejection fraction (HR = 3.8 [1.4-10.3]).

Four significant independent associated factors with CNS disease occurrence were identified: age > 54 years (HR = 2.5 [1.1-6.0]), positive anti-PmSc1 testing (HR = 6.4 [1.5-28.2]), Caucasian origin (HR = 0.2 [0.1-0.5]) and hemoglobin < 12g/dl (HR = 0.2 [0.04-0.8]).

Nervous system disease occurrence did not appear to have a negative impact on the survival of SSc patients (log-rank p=0.56).

Conclusion: This study shows that specific nervous system disease in SSc is not uncommon and does not appear to increase mortality, but it could have an impact on functional prognosis and needs to be monitored.

*β: regression coefficients; HR: hazard ratio; 95% CI: 95% confidence interval; GC: Giant capillaries

Conclusion: Assessing the mean number of capillaries/mm and the total number of giant capillaries instead of avascular areas at videocapillaroscopy, resulted in improving the sensitivity and specificity of the score recently developed to predict the evolution of UCTD-risk-SSc into definite SSc.

**SAT0342** INNATE LYMPHOCYTE CELLS ARE PREDICTORS OF DISEASE PROGRESSION IN SYSTEMIC SCLEROSIS: A 3-YEARS FOLLOW-UP STUDY

A. Soare1, S. Weber1, G. Schett1, J. Distler1, A. Ramming1, 1Department of Internal Medicine 3, Rheumatology & Immunology, 1Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany

**Background:** Activation of the immune system is a characteristic feature of SSc. Numerous studies have suggested that type 2 key drivers of progressive fibrosis. Recently, innate lymphoid cells (ILC) are emerging as an important cellular source of type 2 cytokines triggering fibrotic tissue remodeling independently of the adaptive immune system. Increased levels of ILC2 were found in patients with SSc. However, the contributive role of ILC2 in pathogenesis of SSc is not completely understood.

**SAT0341** PREDICTORS TO PROGRESSION TO SYSTEMIC SCLEROSIS IN A GROUP OF SECONDARY RAYNAUD PHENOMENON OBSERVED IN A LARGE SINGLE BRAZILIAN COHORT

V. Siqueira1, M. Helbingen1, A. P. Luppino-Assad1, H. Carriço Da Silva1, D. Andrade1, A. C. Medeiros-Ribeiro1, P. D. Sampaio-Barros1,2,1University of Sao Paulo, Division of Rheumatology, Sao Paulo, Brazil; 2University of Sao Paulo, Sao Paulo, Brazil
Objectives: We aim in our 3 years observational study to evaluate the predictive role of IL2C in SSC patients.

Methods: We conducted an observational retrospective study on 52 patients with SSC fulfilling the 2013 ACR/EULAR classification criteria. Vearily clinical, laboratory and investigational data according to EUSTAR recommend-ations were collected. Blood samples collected between 15.09.2014 and 15.01.2015 were analyzed by flow cytometry and IL2C counts were measured. The predictive value of IL2C during a 3-year follow-up was analyzed using SPSS 21.0.

Results: 52 patients were included in the study. 78% female, 63% limited cutaneous SSC with a mean follow-up time of 2.85 ± 1.28 years. At baseline we have shown that circulating IL2C are significantly increased compared to gender and age-matched healthy controls. Increased numbers of IL2C significant-ly correlated with worsening of mRSS calculated by five point increase in mRSS or 25% increase from baseline (p < 0.001; 95% CI 1.39 – 3.26). IL2C counts also correlated with 5% decrease of diffusion capacity of carbon monoxide (DLCO) during the follow-up time (p < 0.0001; 95% CI 1.83 – 3.49). Worsening of forced vital capacity (FVC) assessed as 5% decrease over 2 years was also significantly correlated with an increased number of IL2C (p < 0.0001; 95% CI 1.27 – 3.04). In contrast, we did not find any correlation regarding increase in pulmonary arterial pressure assessed by echocardiogra-phy. Although new appearance of digital ulcers could not be predicted by IL2C counts, increased numbers of IL2C were correlated with digital ulcers at follow-up.

Conclusion: Here, we provide first evidence for a role of IL2C as potential prognos-tic marker of disease progression in SSC.

SAT0344
NUTRITIONAL STATUS OF SYSTEMIC SCLEROSIS PATIENTS: A PILOT STUDY

I. Szabó1, 2, A. Petcu2, D. Chicianes2, V. Rednic2, M. M. Tamas1, 2, L. Muntean1, 2, I. Filipescu1, 2, S. P. Simon2, C. Pamfil2, S. Rednic1, 2; 1County Emergency Clinical Hospital Cluj-Napoca, Rheumatology, Cluj-Napoca, Romania; 2University of Medicine an Pharmacy “Iuliu Hatieganu” Cluj-Napoca, Cluj- Napoca, Romania; 3Regional Institute of Gastroenterology and Hepatology “Octavian Fodor” Cluj-Napoca, Cluj-Napoca, Romania

Background: Gastrointestinal involvement (GI) in systemic sclerosis (SSc) is one of the major disease burdens. Its consequences on the nutritional status of SSc patients and their quality of life is poorly evaluated during routine check-ups. Since malnutrition is an important cause of morbidity and mortality, addressing this issue seems necessary.

Objectives: The aim of this study was to evaluate the risk of malnutrition in SSc patients and to identify potential associations between the risk of malnutrition and clinical features or laboratory parameters.

Methods: All patients aged >18 years old with a definite diagnosis of SSc according to the 2013 ACR/EULAR classification criteria from the EUSTAR Center 16 and ERN ReCONNET cohort of the County Emergency Clinical Hospital Cluj-Napoca were included in the study. Patients with localized scleroderma, scleroderma sine scleroderma, overlap syndromes and mixed connective tissue disease were excluded. Clinical and laboratory data was collected from the EUSTAR database and medical charts. A telephone survey was conducted and patients were interviewed using the Malnutrition Universal Screening Tool (MUST) questionnaire.

Results: 75 patients were eligible for the study. Female to male ratio was 10:1 with an almost equal distribution among limited (57%) and diffuse (43%) SSc subtypes. The most prevalent autoantibodies were anti-TOPO-I and anti-cen-tromere. GI symptoms were reported in 48.6% patients of which 86% SSc patients underwent further evaluation by upper GI endoscopy. Abnormal endo-scopic findings, such as esophagitis, Barret esophagus and gastritis were iden-tified in 80% patients. Most patients had a low risk of malnutrition (93%) with only a minority carrying a medium (6%) or high (1%) risk. No significant asso-ciation was demonstrated between MUST score and the extend of cutaneous involvement (limited SSC versus diffuse SSC; p=0.39), presence of GI symptoms (p=0.35), presence of abnormal endoscopic findings (p=0.48) or presence of anemia (p=0.83).

Conclusion: The majority of SSc patients from this cohort exhibited a low risk of malnutrition. These results are contradictory to previous literature reports. A possible explanation is that the MUST score is a dynamic screening tool and therefore interviewing patients with a stable disease (outpatient care) ver-sus patients with active disease (inpatient care) might lead to different results. Another limitation of this study is the small number of patients included. This is a pilot study. We aim to further extend the study population to the other EUSTAR cohorts and to prospectively evaluate these patients in an inpatient care setting.

Background: Limited joint mobility (LJM) is a musculoskeletal disorder caused by flexion contractures of hand is a common complication in systemic sclerosis (SSc) patients. The distal parts of the upper limb (hands and fingers) is the most involved site in SSc.

Objectives: In this study, we aimed to evaluate LJM in SSc patients and to deter-mine the relationship between the clinical features of the disease.

Methods: A total of 113 patients (>18 years old) diagnosed with diffuse cuta-neous systemic sclerosis (DcSSc) and limited cutaneous systemic sclerosis (LcSSc) and 104 healthy controls were included in this study. LJM was evaluated with “prayer sign” and “table top sign” tests. LJM staging was done by Rosen-bloom classification method(1, 2). LJM (+) and LJM (-) patients were compared in terms of demographic findings (gender, age and duration of disease), labo-ratory results (ESR, CRP, ANA, anti-topoisomerase I and anti-centromere) and modified Rodnan Skin Score (mRSS) results.

Results: In our study, a total of 113 patients diagnosed with SSc and 104 healthy controls with similar age and gender distribution were included. While LJM (+) was detected in 75 (66.4%) (LcSSc = 38, DcSSc = 37) of the patients diagnosed with SSc, LJM (mild) (+) was detected in 3 (2.8%) of the control group. One of these people had right 2nd DIF joint contracture due to carpalbrachiovolar, and 1 patient was found to have simple contractures due to a minor hand injury previously (Table 1). A statistically significant difference was observed in between LcSSc and DcSSc patients according to the presence of LJM (p<0.001) (Table 2). There was a moderate positivity relationship between LJM and mRSS (LcSSc: r=0.449 ve p<0.001, DcSSc: r= 0.565 ve p<0.001) (Figure 1).

Figure 1: Conclusion: In our study, it was found that LJM staging positively correlated with mRSS and DcSSc patients had more severe LJM findings than LcSSc. We conclude that “prayer sign” and “table top sign” tests used in hand evaluation in SSc patients have similar clinical results with mRSS and can be easily performed in daily practice in about 3 minutes.

KG, Biberach, Germany; 10Boehringer Ingelheim (Schweiz) GmbH, Basel, Switzerland; 11Boehringer Ingelheim International GmbH, Ingeheim, Germany; 12Boehringer Ingelheim International GmbH, Ingeheim, Germany; 13Division of Rheumatology and Clinical Immunogenetics, University of Texas McGovern Medical School, Houston, Texas, United States of America

Background: Previous studies suggested that male sex may be associated with a greater rate of decline in FVC in patients with SSc-ILD. In the SENSCIS trial, nintedanib reduced the rate of FVC decline over 52 weeks vs placebo.

Objectives: Analyse the rate of decline in FVC and the efficacy and safety of nintedanib in the SENSCIS trial in subgroups by sex.

Methods: Patients with SSc-ILD with first non-Raynaud symptom <7 years before screening and ≥10% fibrosis of the lungs on HRCT were randomised to nintedanib or placebo. We analysed the rate of decline in FVC (mL/year) and adverse events over 52 weeks in male and female patients.

Results: Of 576 patients, 433 (75.2%) were female. Compared with males, the female subgroup included a smaller proportion of White patients (64.7% vs 74.8%), a smaller proportion on mycophenolate at baseline (46.9% vs 53.1%), a greater proportion of ATA positive patients (63.3% vs 53.1%), and had a lower mean weight at baseline (66.6 vs 76 kg). CFD % predicted (72.8% vs 71.7%) and mRSS (11.2 vs 10.8) were similar in females and males. The adjusted annual rate of decline in FVC in the placebo group was numerically higher than the female group (-126.8 [SE 29.0] vs -82.0 [16.2] mL/year). The estimated effect of nintedanib vs placebo on reducing the rate of decline in FVC was numerically more pronounced in males than females (difference: 58.6 [95% CI -18.0, 135.1] vs 34.6 [-9.3, 78.4] mL/year), but the interaction p-value did not indicate heterogeneity in the treatment effect between subgroups (p=0.59). Among nintedanib-treated patients, diarrhoea was reported in similar proportions of females and males (74.7% vs 79.1%); nausea, vomiting and liver test abnormalities were reported in greater proportions of females vs males (35.3% vs 19.4%, 28.1% vs 13.4%, and 15.4% vs 9.0%), while serious adverse events were more frequent in males (32.8% vs 21.3%). In the nintedanib and placebo groups, respectively, adverse events leading to treatment discontinuation were reported in 16.7% and 8.5% of females and 13.4% and 9.2% of males.

Conclusion: In the SENSCIS trial in patients with SSc-ILD, the annual rate of decline in FVC in the placebo group was numerically greater in male than female patients. The rate of FVC decline was lower with nintedanib than placebo both in males and females. The safety profile of nintedanib was similar between males and females.

Efficacy and Safety of Rituximab in 27 Cases of Treatment Resistant Systemic Sclerosis with Severe Disease Assessed by Activity Scores

Y. Yalcinkaya, B. Artim-Esen, S. Amiksiheyev, N. Aliyev, A. Gul, L. Ocal, M. Inanc, Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: Treatment options for systemic sclerosis (SSc) remain limited especially in severe skin, lung and musculoskeletal involvements. B-cell targeted therapy with anti-CD20 Rituximab (RTX), is widely available, reports from case series are encouraging as a a rescue therapy and might have an improving effect on organ involvement in SSc.

Objectives: We aimed to retrospectively analyze the efficacy and safety of rituximab (RTX) courses in patients with severe systemic sclerosis who were refractory to standard immunosuppressive treatment.

Methods: Twenty-seven SSc patients fulfilling ACR/EULAR classification criteria (2013) who received RTX treatment due to active disease despite treatment with immunosuppressives were analyzed. Disease activity was evaluated by using ESccSG/EUSTAR activity scores prior to and after RTX treatment. Disease severity was also assessed at baseline by Medsger’s index.

Results: The demographics and characteristics of SSc patients were as follows: the median age of 50 (30-70), duration of Raynaud’s 10 (3-26) and non-Raynaud symptom 8.5 (3-18) years and summarised in table 1. RTX was given as a single cycle (2 infusions of 1000mg) in 12 cases, 2 cycles in 5 cases, 3 cycles in 10 cases. DMARDs were prescribed in 19 (73%) patients (14 MMF; 5 MTX) concomitantly with RTX. The main RTX indications were skin and lung involvement (n=9), skin and arthritis (n=6), skin(n=5), lung (n=3), myositis (n=2), cardiac involvement (n=1) and digital vasculopathy (n=1). Medsger severity score was 7.39±3.091 (3-13) at baseline.

Disease activity and severity scores prior to and after RTX were summarised in table 2. Disease activity scores were improved after RTX in patients who had a median follow-up period of 1 year (0.5-5 years). After RTX treatment, according to EscSG/EUSTAR scores 13 (%46.2) and 10 (%34.6) patients out of 26 were assessed as inactive.

There were severe infections in 4 patients (Pneumonia in 2, infected digital ulcers in 2) and an episode of sinusitis in one during treatment period. One patient was deceased because of pneumonia and sepsis after the first cycle of RTX.

Conclusion: In our SSc cohort, RTX treatment was used in severe patients, who had predominantly diffuse cutaneous disease with lung and joint involvement, severe vasculopathy and anti-Scl-70 positivity. Concomitant DMARDs were used in three-fourth of the patients addition to RTX cycles. Disease activity scores that assessed retrospectively were shown to be improved after RTX and 37-48% of the cases were assessed as inactive by using activity scores. Serious infections like pneumonia and infected digital ulcers were observed in 14.8% of cases during the follow-up. The addition of RTX treatment can be effective in selected patients with active disease despite immunosuppressive therapy.

Spondyloarthritis - etiology, pathogenesis and animal models

SAT0349

CTL4-IG DECREASES TH17 CELL LEVELS BUT MAINTAINS ILC3S WITH AN INCREASE IN THE ILC3/ILC1 RATIO IN THE UGT OF SKG MICE AS A MODEL OF SPONDYLOARTHRITIS.

Y. Tabuchi1, M. Hashimoto, S. Skizuki1, R. Nakashima, K. Murakami, H. Yoshitji1, M. Tanaka2, K. Ohmura3, 1Graduate School of Medicine, Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; 2Graduate School of Medicine, Kyoto University, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan

Background: SKG mice have been known for their autoreactive Th17 cells resulting from the insufficient thymic negative selection due to a Zap70 mutation. Under specific pathogen-free conditions, they acquire features of spondylarthropathy (SpA) by intraperitoneal injection of curdian, a (1,3)-β-glucan. Several reports have shown that Th17 cells also increase in human SpA. However, CTL4-IG, which ameliorates rheumatoid arthritis by suppressing pathogenic cells such as effector T cells, was unable to show adequate efficacy as much as expected in SpA patients. Around the same time, innate lymphocytes began to be focused on, in the pathogenesis of SpA, including innate lymphoid cells (ILCs), which abundantly reside in the gut. This study aimed to clarify the effects of CTL4-IG on the pathogenesis of SpA by using curdian-treated SKG mice, focusing on type 3 immunity such as Th17 cells and ILC3s.

Methods: Two- to three-month-old female SKG mice were injected intraperitoneally with 3mg of curdian or PBS at the beginning and with 500 μg of CTL4-IG or PBS every other week (n=5 per group). The body weight and arthritis score were measured weekly for a month. Then, the changes in the proportion of T cells and ILCs in the spleen and Peyers’ patches (PPs) were analyzed by flow cytometry (FCM). BALB/c mice, without treatment, were also examined by FCM as a control cohort. In addition, a next-generation analysis of their feces was performed on 16S ribosomal coding genes before curdian and CTL4-IG treatment.

Results: SKG mice contained not only more Th17 cells but also more ILC1s and ILC3s than BALB/c mice, in their guts (the PPs). The feces of SKG mice intrinsically showed a decrease in the number of bacterial species, suggesting a dysbiosis. Then, in curdian-treated SKG mice, CTL4-IG administration decreased the proportion of both Th17 cells and ILC3s in the spleen, but did not decrease the proportion of ILC3s in the PPs. Moreover, the ILC3/ILC1 ratio in the PPs was from low to high in the order of SKG mice without treatment, SKG mice injected with curdian, and SKG mice injected with both curdian and CTL4-IG. The phenotype corresponding to SPa features, in curdian-treated SKG mice, continued after repeated CTL4-IG administration.

Conclusion: Curdian provoked SpA features in SKG mice with an intrinsic dysbiosis. Additional CTL4-IG injection decreased the proportion of Th17 cells but maintained that of ILC3s with increased ILC3/ILC1 ratio in the gut. This result supports the hypothesis that in the SpA pathophysiology, a weakened acquired immunity in the gut might lead to ILC3 activation, via dysbiosis, and its continued disease progression, suggesting that ILC3s are a promising therapeutic target in SpA.

A ROLE FOR IL-17A IN THE SUPPRESSION OF SPINAL ENTHESAL MESENCHYMAL STEM CELL ADIPOGENESIS WHILST SIMULTANEOUSLY FACILITATING OSTEOGENESIS.

T. Russell1, C. Bridgewood1, A. Khan*, A. S. Rao2, P. Loughenbury2, P. Milner2, R. Dunsmuir2, A. Altaie1, E. Jones1, D. McGonagle1.1University of Glasgow, Institute of Rheumatic and Musculoskeletal Medicine, Scotland, United Kingdom; 2Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Fat formation in the bone adjacent to the enthesis is an important but poorly characterised intermediate stage in new bone formation that occurs in the spine in AS. We and others have previously reported that IL-17A can increase mesenchymal stem cell (MSC) mediated osteogenesis in normal and AS spinal tissue (1, 2).

Objectives: Herein we investigate the impact of IL-17A & TNF on MSC adipogenesis from spinal enthesis tissue.

Methods: Samples from healthy spinous process and interosseous ligament (n=14, median age = 53) were separated into the peri-entheseal bone (PEB) and entheseal soft tissue (EST) & enzymatically digested. Minimally passaged (>3) MSCs were cultured in a complete adipogenic media, with some cultures supplemented with either IL-17A (50ng/ml), TNF (1ng/ml) or IL-17A & TNF for 3 weeks. Adipogenesis was quantitatively assessed by Oil Red O staining at day 21. IL-17A effect on adipogenesis was further investigated by RNA extractions at Day 0, 3, 5, 7, 15 & 21 with supporting Oil Red O staining. 48 adipogenic and IL-17A target genes were used to investigate adipogenic progression and IL-17A effects on it over 21 day adipogenic differentiation.

Results: EST MSCs have a significantly higher adipogenic potential than matched PEB MSCs (n=14, p<0.001). TNF and IL-17A both cause significant decreases (all p<0.01, n=5) in adipogenesis for both PEB and EST MSCs. EST MSCs produced lipid vesicles by day-3 post-induction, with significant inhibition by IL-17A (p<0.01, n=4) seen from day 15 onwards. IL-17A caused a significant decrease in overall Oil Red O staining, and it changed the morphology of lipid vesicles with a majority of cells consistent with immature pre-adipocytes. This was supported by gene expression data, which indicated significant decreases in transcripts encoding vesicle fusion proteins (CIDEc p<0.05, PLIN1 p<0.01). PLIN1 also aids protection against lipolysis (4). Transcripts associated with osteogenesis (CEBPα (3)) and MSC stromal support (CXCL12) were significantly upregulated in adipogenically-induced cultures stimulated with IL-17A when compared to control adipogenic media. TNF & IL-17A combination demonstrated that IL-17A drove the vesicle morphology changes, with TNF alone not showing the same vesicle changes.

Conclusion: Given the inverse link between MSC mediated osteogenesis & adipogenesis, these findings reveal a role of IL-17A especially on EST MSCs. The rapid formation of adipocytes seen in EST MSCs may be relevant to MRI determined peri-entheseal bone "shiny corners" due to post inflammtion fat accumulation. Elevated transcripts associated with pre-adipocytes & undifferentiated MSCs support the idea of plasticity between early osteogenesis & adipogenesis. Downregulation of transcripts for proteins associated with protection against lipolysis allows for the rationalising of the gradual loss of the shiny corners seen in AS preceding subsequent new bone formation.

CHEMOKINE PATHWAYS ARE ENRICHED IN PSORIATIC ARTHRITIS (PSA) SKIN LESIONS WITH INCREASED EXPRESSIN OF ATYPICAL CHEMOKINE RECEPTOR 2 (ACKR2)

H. Johnson1, J. Cole1, G. Wilson1, M. Pingen1, F. Monkman1, S. Holmes1, I. McInnes1, S. Siebert2, G. Graham1. 1University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2Alan Lyle Centre for Dermatology, Glasgow, United Kingdom

Background: Skin in people with psoriasis has been comprehensively studied; uninvolved skin has abnormal gene expression. Less is known specifically about skin in PsA, the assumption being that it is identical to psoriasis. Chemokines and ACKR2 are among the upregulated genes in uninvolved psoriasis compared

Disclosure of Interests: H Johnson is a consultant for Pfizer and Sanofi. J Cole is a member of the advisory board for Gilead. M. Pingen, F. Monkman, S. Holmes, I. McInnes, S. Siebert, and G. Graham declare that no other conflicts exist.

SAT0350

SAT0351
to healthy skin[1]. ACKR2 is a scavenging receptor of inflammatory CC chemokines and has been proposed as a regulator of cutaneous inflammation in psoriasis. It has not been studied in PsA.

Objectives: To compare the transcriptome of PsA lesional, PsA uninvolved and healthy control skin and evaluate ACKR2 expression in PsA.

Methods: Biopsies were taken from healthy control (HC) skin and paired lesional and uninvolved skin from patients with PsA. Libraries for bulk RNA sequencing were prepared from polyA selected RNA and sequenced on NovaSeq 6000. Sequencing data were analysed using Searchlight2. ACKR2 mRNA expression was validated by qPCR. RNAscope was used to localise ACKR2 expressing cells and sections were co-stained with podoplanin or stained in serial sections with CD45. Chemokine protein expression in skin was evaluated using Luminex technology.

Results: Nine HC and 9 paired skin samples from patients with PsA were sequenced. The PsA skin lesions (PsA L) formed a distinct population in the transcriptomic principal component analysis (PCA) plot while HC and PsA uninvolved skin (PsA U) were overlapping. Only 15 genes were differentially expressed between HC and PsA U and none coded for chemokines. There were however significantly upregulated chemokines and receptors in PsA L. Unexpectedly, ACKR2 was the 2nd most upregulated chemokine receptor in PsA L with unchanged expression in PsA U compared with HC (PsA L vs HC log2fold 3.38, padj=9.51E-41; PsA L vs PsA U log2fold 3.58, p.adj=3.24E-45; PsA U vs HC log2fold -0.2, p.adj=0.732).

The upregulation of ACKR2 in PsA L and unchanged expression in PsA U was confirmed by qPCR. RNAscope demonstrated strong expression of ACKR2 in the suprabasal layer of the epidermis in PsA L. In HC and PsA U, only occasional ACKR2 positive cells were seen in the epidermis. ACKR2 was expressed in lymphatic vessel walls but was not observed in CD45+ leukocytes.

Provisional skin chemokine protein expression data showed poor correlation between mRNA levels and protein expression for the ACKR2 ligands CCL2, CCL3, CCL7, CCL8, CCL11, CCL13 and CCL22 in HC and PsA U, with negative correlation between ACKR2 mRNA expression and CCL2, CCL8 and CCL11 protein expression. In PsA L, chemokine mRNA correlated with protein expression, but protein expression of chemokine ligands did not correlate with ACKR2 expression.

Conclusion: This data set shows expected upregulation of chemokines and their receptors in PsA L but relatively unchanged gene expression in PsA U, which contrasts to previous studies in psoriasis. Notably, this study demonstrates a strong upregulation of ACKR2 in keratinocytes in PsA L with unchanged expression in PsA U. The RNA expression and preliminary protein data suggest that ACKR2 has little effect on the levels of its ligands in PsA skin lesions. However, this study may have missed local effects of ACKR2 in the epidermis.

Background: It is currently not known if TNF or IL-17A inhibitors have an impact on immune cell frequencies in axial Spondyloarthritis (AxSpA). This question is important to understand the impact of biologics on the immune system. Data from clinical trials didn't show significant modification on immune cells and especially on lymphocytes. But regarding the risk of infections linked to these treatments lymphocyte cell subsets are certainly disturbed. Moreover, biologics could affect subsets of cells with an unequal phenotype.

Objectives: To identify the phenotype of cell subsets affected by biologics.

Methods: We used an “unsupervised approach” to analyze CD4+ T cells and CD8+ T cells subsets. Contrary to a “supervised approach,” this strategy takes advantages of the fluorescence emitted by all of the surface markers used to characterize the cells at the same time. The objective was on the one hand to overcome statistical problems related to the number of patients and the repetition of the tests and on the other hand to increase the sensitivity of the analysis by identifying and analyzing new cell populations. The first step was to cluster the cells based on a selection of 12 T cells markers characteristic of the classical cell subsets and the stage of maturation to obtain cell clusters with a phenotype based on the combination of these 12 markers. Then, we were able to describe “a posteriori” the change of frequency of the clusters identified. The second step was to create a visualization of the cells affected to confirm their existence in a classical flow cytometry gate. With this pipeline, we analyzed CD4 and CD8 T cells isolated from a group of AxSpA patients (n=7) before and after 3 months of TNF therapy and a group of patients (n=6) before and after 4 months of IL-17A therapy.

Results: We observed that after biologics CD4 and CD8 T cells frequencies of 1 cluster change but also a redistribution of the different clusters analyzed. Specifically, we identified for CD4+ T cells after anti-TNF treatment an increase of 2 clusters (CD4+CD27+CD45RA+Vα2ZintCD161int and CD4+CD27+CD45RA-CCR6+CD161int) and a decrease of 3 clusters (CD4+CD27+CD45RA+CCR7intCD161int, CD4+CD27+CD45RA+CCR3+, CD4+CD27+CD45RA+gintCD161int) and for CD8+ T cells a decrease of 1 cluster after treatment (CD8+CD45RA+CD45RA+CCR5+CD161+ and an increase of 1 cluster (CD8+CD27+CD45RA+CCR5+) and an increase of 2 clusters (CD4+CD27+CD45RA+CCR5+CCR6+CD161+ and an increase of 2 clusters (CD4+CD27+CD45RA+CD161+CD161+). For CD4+ T cells, we identified a decrease of 2 clusters (CD4+CD27+CD45RA+CCR5+CD161+ and an increase of 2 clusters (CD4+CD27+CD45RA+CCR5+CCR6+CD161+) and an increase of 2 clusters (CD8+CD27+CD45RA+CCR5+CCR6+CD161+). For CD8+ T cells a decrease of 1 cluster (CD8+CD27+CD45RA+CCR3+CCR7intCD161+) and an increase of 1 cluster (CD8+CD27+CD45RA+CCR3intCD161+).

Conclusion: We identified 5 different cell clusters in CD4+ T cells affected by anti-TNF and 4 by anti-IL-17A. We identified 2 clusters in CD8+ T cells affected by anti-TNF and 2 by anti-IL-17A. The phenotypes of these clusters were unexpected and raised new questions about the effect of biologics in AxSpA. We were also able to create a visualization of these cells affected by biologics in a “classical gating view” which will help us to perform scRNAseq. With this unique approach, we show an impact of biologics on the frequency of very specific subset of CD4+ and CD8+ T cells in AxSpA.

Figure 1.
In vitro experiment of bone formation, the stat3-p inhibitor suppressed ALP activity significantly decreased frequencies of IFN-γ, IL-17, TNF-α producing cells in AS SFMC that the levels of IFN-γ, IL-17, TNF-α were higher in AS Synovial fluid. A significantly reduced in stat3-p inhibitor-treated mice compared to control mice. We found that STAT3 is a regulatory factor that induces Th17 cell development from naive CD4 T cells.

Objectives: The aim of this study is to investigate whether the STAT3 phospho-rylation (stat3-p) inhibitor has a therapeutic effect on inflammation and new bone formation in AS.

Methods: Eight weeks after curdlan injection, SKG mice were treated with stat3-p inhibitor or mock as a control. Clinical and histologic scores for arthritis and enthesitis were evaluated. Synovial fluid mononuclear cells (SFMC) samples were obtained from AS patients. Inflammatory cytokine producing cells were analyzed using flow cytometry. Bone tissue samples were obtained from the facet joints of patients with AS at surgery. Primary bone-derived cells (BdCs) were isolated and cultured. The osteogenic differentiation was assessed in vitro for 3 weeks using ALP activity, Alizarin red S (ARS), Type I collagen, von kossa, staining. Statistical analysis was performed using Prism 5.0 Software. A p < 0.05 was considered statistically significant.

Results: The stat3-p inhibitor significantly suppressed peripheral arthritis and enthesitis in SKG mice (figure 1). Inflammatory infiltration around the tendon–bone insertion site and along the tendon, as well as bony involvement were analyzed using flow cytometry. Bone tissue samples were obtained from the facet joints of patients with AS at surgery. Primary bone-derived cells (BdCs) were isolated and cultured. The osteogenic differentiation was assessed in vitro for 3 weeks using ALP activity, Alizarin red S (ARS), Type I collagen, von kossa, and hydroxyapatite stains. Statistical analysis was performed using Prism 5.0 Software. A p < 0.05 was considered statistically significant.

In vitro experiment of bone formation, the stat3-p inhibitor suppressed ALP activity. In addition, there were significant decrease in Alizarin red S (ARS), Type I collagen, von kossa staining scores due to stat3-p inhibitor at a concentration of 5 μM. Light intensity of hydroxyapatite staining was also decreased by stat3-p inhibitor in a dose dependent manner (figure 2). Intriguingly, the stat3-p inhibitor suppressed osteogenesis in both early phase and late phase in AS-BdCs, down-regulating osteoblast-involved genes.

Conclusion: The stat3-p inhibitor had beneficial effects on reducing inflammation and new bone formation in AS animal model. In addition, stat3-p inhibitor suppressed bone formation in vitro experiment. These findings suggest that the stat3-p inhibitor could be a potential therapeutic agent for AS.

among ILCs. Multivariate linear regression and Receiver-Operating Characteristic (ROC) Curve analysis was performed using the IBM SPSS Statistics software. Different in vivo models were used to assess functional implications of ILCs at different time points of the disease. Joint inflammation was assessed through MRI and H&E staining of ankle areas. Peripheral blood was obtained from mice of each group and flow cytometry analysis was performed. High dimensional analyses including RNA-seq was performed to identify phenotypic characteristics of ILCs implemented into the pathogenesis of the disease.

**Results:** Total number of circulating ILCs were increased in PsA patients compared to PsO and healthy controls (p < 0.001). Linear regression analyses of the relationship between disease activity and circulating ILCs counts showed strongest correlation between ILC3s counts and DAPSA score. ILC3s counts also correlated with imaging signs of inflammation such as enthesitis, synovitis, erosions and/or osteoporosis as assessed by MRI and H-pQCT. Musculoskeletal inflammation in mice was predominantly associated with p19 expression and IL-23R-signaling as assessed by RNA-seq. These effects were also accompanied by a strong upregulation of IL-17-producing lymphocytes within the inflamed joint niche with a dominant presence of ILC3s. Multi-channel immunofluorescence and confocal laser scanning microscopy revealed not only upregulation of ILC3 induced IL-17 production within the synovial membrane but also in peri-articular areas of the inflamed joints. 

**Conclusion:** ILC3s not only correlate with various facets of PsA manifestations but also functionally contribute to synovitis and enthesis suggesting them as interesting target for upcoming treatment strategies in the near future.

**SAT0355**

**WNT SIGNALING CAN PLAY AN IMPORTANT ROLE IN VASCULAR CALCIFICATION IN PATIENTS WITH ANKYLOSING Spondylitis**

1 Inha University Hospital, Incheon, Korea, Rep. of (South Korea); 2Inha University Hospital, Department of Occupational and Environmental Medicine, Incheon, Korea, Rep. of (South Korea); 3College of Medicine, Inha University, Department of Biomedical Science, Incheon, Korea, Rep. of (South Korea)

**Background:** Vascular calcification is highly correlated with atherosclerosis. Ankylosing spondylitis (AS) is associated with a process of accelerated athero- sclerosis. Wnt signaling plays an important role in the pathogenesis of vascular calcification. However, there has been no study of the role of Wnt signaling in vascular calcification in patients with AS.

**Objectives:** We investigated the relationship between vascular calcification and Wnt signaling in patients with AS.

**Methods:** Sixteen male patients aged over 20 years with AS were enrolled. They fulfilled the modified New York criteria and each of their ankylosing spondylitis disease activity score was more than 2.1. Sex and age matched nineteen healthy controls were also recruited. Mouse MOVAS vascular smooth muscle cell line (American Type Culture Collection, ATCC® CRL-2797™) were stabilized in maintenance media for 24 hours. Then media were exchanged for the 10% serum of patients with AS or controls in maintain media. Cells were stimulated for another 72hours. We exchanged this medium with calcification medium. Cells were cultured until 2 weeks then stained with Alizarin Red S and the optical density (OD) was measured. For Western blotting and RT-qPCR, cells were stabilized for 24 hours and stimulated for another 72 hours through the same procedure as that of Alizarin Red S staining. After cell stimulation, the level of mRNA and protein were measured by RT-qPCR and western blot respectively. We measured the level of Low-dens- ity lipoprotein receptor-related protein (LRP5, LRP6, Dickkopf-related protein 1, Wnt3a, matrix metalloproteinase-7 (MMP-7), beta-catenin for canonical Wnt sig- naling; Receptor Tyrosine Kinase Like Orphan Receptor 2, Wnt5a, Runt-related transcription factor 2 (RUNX2) for non-canonical Wnt signaling. We also checked the level of Alkaline phosphatase (ALP), IL-17, IL-23 and TNF-a.

**Results:** The level of OD of MOVAS cells treated with serum from AS patients (19.503 ± 6.422, mean ± SD) was significantly higher than that from controls (10.994 ± 4.291) (P = 0.000, Mann-Whitney test). The protein level of MMP-7 and beta-catenin of MOVAS cells treated with serum from AS patients (1.881 ± 0.687; 1.301 ± 0.342) was significantly higher than that from controls (0.779 ± 0.48; 0.854 ± 0.285) respectively (P = 0.005; P = 0.002, Mann-Whitney test). The mRNA level of RUNX2, ALP, IL-17 and IL-23 of serum from AS patients (2.687 ± 1.46; 2.687 ± 1.753; 2.253 ± 1.128; 2.574 ± 1.142) was significantly higher than that from controls (1.396 ± 0.587; 1.696 ± 0.637; 1.358 ± 0.473; 1.368 ± 0.714) respectively (P = 0.000, P = 0.037, P = 0.044, P = 0.007, Mann-Whitney test). There was positive correlation between the mRNA level of WNT5a and RUNX2 (r = 0.705, p < 0.002, Spear- man rank correlation coefficient) and the protein level of WNT5a and ALP; MMP-7 and TNF-a, MMP-7 and IL-17, MMP-7 and IL-23 (r = 0.601, p = 0.039, r = 0.769, p = 0.026; r = 0.828, p = 0.011; r = 0.777, p = 0.003), respectively.

**Conclusion:** 1. Vascular smooth muscle cell calcification was increased in patients with ankylosing spondylitis than those of the control group. 2. The level of several molecules (i.e. Beta-catenin, RUNX2, MMP-7) related to Wnt signaling of vascular smooth muscle cells treated with serum of patients with AS was elevated significantly compared to those of controls and positively related. 3. Wnt signaling can play an important role in vascular calcification in patients with ankylosing spondylitis.

**SAT0357 LEVELS OF PERIPHERAL LYMPHOCYTE SUBPOPULATIONS IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND THEIR CHANGES AFTER RECEIVING IMMUNOREGULATORY COMBINATION THERAPIES**

J. Bai¹, S. X. Zhang², L. Zheng³, J. Y. Yang¹, Q. Y. Su¹, S. J. Guo¹, J. Luo², G. Y. Liu², C. Gao², X. LI², ¹Shanxi Medical University, Taiyuan, China; ²The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; ³Brigham and Women’s Hospital, Harvard Medical School, Department of Pathology, Boston, United States of America

**Background:** Ankylosing spondylitis is an immune-mediated inflammatory disease involving the axial skeleton, joints, and entheses. Although the homeostatic balance of effector T cells (Teffs) and regulatory T cells (Tregs) is considered to play an important role in the pathogenesis of ankylosing spondylitis (AS), it is unclear whether the levels of peripheral blood lymphocyte subpopulations in patients with ankylosing spondylitis are abnormal or not.

**Objectives:** To explore the differences of lymphocyte subpopulations of peripheral blood (PB) between AS patients and healthy controls (HCs), and further evaluate the therapeutic effect of immunoregulatory drugs on the lymphocyte subpopulations.

**Methods:** Total 1141 patients with AS and 206 healthy individuals were enrolled in the study and donated their blood to measure the levels of T, B, NK, CD4⁺T, CD8⁺T, Th1, Th2, Th17 and Tregs by flow cytometry combined with standard absolute counting beads. And 456 patients received immunoregulatory combination treatments which includes low-dose interleukin-2, rapamycin, metformin, retinoic acid etc. and donated their PB after the therapies. Data were expressed as mean ± standard deviation to the distribution. Independent-samples T test and paired-samples T test were applied. P value <0.05 were considered statistically significant.

**Results:** Compared with HCs, AS patients had a lower absolute number of Tregs but higher numbers of peripheral T, B, CD4⁺T, CD8⁺T, Th1, Th2 and Th17 cells (P<0.05). Further, there was a significant increase in the percentage of B, CD4⁺T and the ratios of Teffs/Tregs such as Th1/Tregs, Th2/Tregs and Th17/Tregs compared with HCs (P<0.05)(Figure 1). Although, after receiving the immunoregulatory combination treatments, the absolute numbers of various peripheral lymphocyte subpopulations such as T, B, NK, CD4⁺T, CD8⁺T, Th1, Th17 and Tregs and the percentage of Tregs, Th1 and CD8⁺T significantly increased (P<0.05), the ratios of Th2/Tregs significantly decreased (P<0.05)(Figure 2), suggesting a rebalance of immune systems.

**Conclusion:** The insufficiency of Tregs may involve in pathogenesis of AS. Immunoregulatory combination therapies could promote the proliferation of Tregs as well as other lymphocytes to some degree, which may be a new target for AS treatment.

A ROLE FOR IL-4 AND IL-13 IN MODULATING THE IL-23/IL-17 AXIS IN ENTHESIS

C. Bridgewood, K. Sharif, H. Rowe, T. Russell, D. Mcgonagle, University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: IL-4 and IL-13 are related Th2 cytokines, with documented roles in allergic inflammation such as atopic dermatitis (AD). Psoriatic Arthritis (PsA) is typically thought to be a result of Th1/Th17 driven response, and blockade of this pathway (IL-23, IL-17 and TNF) has proven successful. Despite this, there is a strong genetic risk association for IL-13 and PsA(1), however, the precise role of IL-13 in PsA is presently unknown. The enthesis is the region where tendons or ligaments attach to bone, and inflammation of this site (enthesisitis) is thought to be the cardinal lesion of PsA whereas as Rheumatoid Arthritis inflammation is typically thought to be a result of Th1/Th17 driven response, and blockage of IL-4 and IL-13 having a protective role in entheseal induction of IL23/17 axis may underlie these imaging clusters seen in PsA.

Objectives: To create a model for accurately and biologically meaningful sub-phenotypes of PsA using imaging and molecular data. Specifically, we aimed to identify sub-phenotypes in patients with PsA and determine their association with whole blood mRNA expression markers.

Methods: 55 patients with PsA ready to initiate treatment for active disease were prospectively recruited. An ultrasound assessment of the extent of musculoskeletal inflammation in 64 joints, 34 tendons and 16 entheses was performed. Sonographic inflammation (in greyscale and Doppler) of the followings were graded: 1) Enthesitis; 2) Peri-tendonitis; 3) Tenosynovitis; and 4) Synovitis. A global inflammatory score was calculated for each tissue involved. Unsupervised clustering of gene expression data identified three clusters that were differentially expressed (p<0.05) in two of the three comparisons between the 3 clusters. Hierarchical and k-means cluster analysis was performed using hierarchial and k-means to define imaging sub-phenotypes in PsA that reflected the predominant tissue involved; 2) Principal component analysis with ellipses was used to determine the association between imaging-defined clusters and peripheral blood gene expression profile.

Results: The patients could be divided into 3 groups based on unsupervised hierarchical and k-means clustering of images indicating the predominant involved tissue (Figure 1): 1) Enthesitis predominant (N=13 [24%]); 2) Peri-tendonitis predominant (N=11 [20%]); 3) Synovitis predominant (N=31 [56%]). Patients in the synovitis predominant group had more nail involvement, while those in the peri-tendonitis group had the highest number of clinically active joints (Table 1). Unsupervised clustering of gene expression data identified three clusters that partially overlapped with the imaging clustering (Figure 2). Overall, 344 genes were differentially expressed (p<0.05) in two of the three comparisons between the imaging clusters.

Table 1. Clinical Features by Imaging Clustering

Median (IQ range) and frequencies (%)

**Bolded=Statistically different between the 3 groups (p<0.05)**

Conclusion: We identified three different imaging clusters based on the predominant tissue involved in patients with active PsA. Distinct gene expression profiles may underlie these imaging clusters seen in PsA.

SAT0361
HEALTHY HUMAN SPINAL PROCESSES PERI-ENTHESEAL T-CELLS EXHIBIT A TR1 RATHER THAN A FOXP3 REGULATORY PHENOTYPE

H. Rows1, A. Watad1, T. Russell1, K. Sharif1, D. Newton1, M. Wittmann1, Q. Zhou2, A. Khan2, P. Loughenbury2, R. Dunsmuir2, A. S. Rao2, P. Miller2, T. Kenna3, M. Brown4, C. Bridgewood1, D. Mogonagah1, 1University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2The Leeds Teaching Hospital, NHS Trust, Leeds, United Kingdom; 3Institute of Health and Biomedical Innovation, Queensland University of Technology, Woolloongabba, Australia; 4King’s College London, London, United Kingdom

Background: We have previously reported that the normal spinal enthesis has populations of conventional T-cells including CD4+ & CD8+ T-cells that could be induced to produce IL-17A and TNF following anti-CD3/CD28 stimulation. The biology of such cells in health including their normal function and antigen reactivity is completely unknown. The purpose of this work was to define the phenotype, functionality and TCR reactivity of such T-cells in health.

Objectives: To test the hypothesis that there is an increase in digestive permeability and bacterial translocation in the AIA model and to show the influence of different NSAIDs on these two parameters.

Methods: Adjuvant-induced arthritis (AIA) was induced in 6-week-old male Lewis rats by an injection at the base of the tail of Mycobacterium butyricum. A group of non-AIA (control) rats received saline. At the first signs of arthritis, the AIA-rats were evaluated (arthritis score 0-5) and treated daily intraperitoneally with naproxen (10mg/kg/day), diclofenac (5mg/kg twice daily), celecoxib (3mg/kg/day) or saline solution (AIA-vehicle group). After 21 days of treatment, the rats were sacrificed and serum levels of zonulin and LPS were evaluated by ELISA and liquid chromatography-mass spectrometry, respectively. Circulating levels of TNF-α and IL1-β and paw radiographic score were measured.

Results: Compared to the control group, there was a significant increase in zonulin concentration (p < 0.001) in the AIA group. There was no significant difference in the concentration of LPS between the two groups. The levels of zonulin were correlated with the TNF-α levels (R= -0.42; p=0.032) and the arthritis score (R=0.45; p=0.013) but not with the level of IL1-β (R= -0.018; p=0.39). Treatment with NSAIDs significantly and equivalently decreased the arthritis score in each group. Compared to the vehicle group, treatment with naproxen significantly decreased the radiographic score (p<0.001), TNF-α, IL1-β (p < 0.01), zonulin (p<0.001) and LPS (p < 0.05). Celecoxib decreased radiographic score (p < 0.001), IL1-β (p < 0.01), TNF-α (p < 0.01) but increased zonulin levels (p < 0.05) without effect on LPS. Diclofenac also decreased radiographic score (p < 0.001), TNF-α (p < 0.01), and IL1-β (p < 0.01) but increased both zonulin (p < 0.01) and LPS (p < 0.001).

Conclusion: We have demonstrated an increase in serum zonulin levels in the AIA model and a beneficial effect of naproxen on intestinal permeability and bacterial translocation in contrast to celecoxib and diclofenac. Moreover, the plasmatic zonulin levels were correlated with TNF-α supporting a pivotal role of TNF-α on the tight junctions in this model.

DOI: 10.1136/annrheumdis-2020-eular.3508
OBJECTIVES: To investigate whether the T-cells at the normal enthesis are regulated in nature and to determine the type of regulatory T-cell as Tr1 or FOXP3 regulatory T-cell and to determine T-cell reactivity.

METHODS: Healthy interspinous ligament and spinous process with matched peripheral blood were harvested from patients undergoing elective spinal surgery (n=20). Enthesal soft tissue (EST) & peri-enthesal bone (PEB) was enzymatically digested and then sorted. Tr1 and Treg phenotypes were investigated using flow cytometry. Analysis of cytokines, growth factors and chemokines was performed by qRT-PCR, ELISA and flow cytometry. TCR sequencing was performed and a search for putative T-cell reactivity was done using TCRS database.

RESULTS: Pro-inflammatory cytokine transcripts including IL-17A, IL-17F, IL-22, IL-23 (p19) & TNF were very low or undetectable in the Enthesis T-cells (Fig 1). Flow cytometry confirmed enthesal T-cells had a Tr1 phenotype (CD4+ LAG3+ CD16b+). Intracellular flow cytometry showed enthesis T-cells had very low FOXP3 expression, when compared to their blood counterparts. Intracellular flow cytometry and gene expression showed high basal expression of growth factors and regulatory proteins such as IL-10 & TGFβ, when compared to blood T-cells. RNA-Seq data, showed 13 potential TCR clonal sequences the most common of which are predicted to be reactive viral infection was CMV present in 8 sequences and Influenza A virus present in 2 sequences.

CONCLUSION: The healthy enthesis has regulatory T-cells of a Tr1 phenotype rather than a FOXP3 Treg phenotype. Many clones have antigen specificity indicating reactivity to prior infection. These findings suggest that conventional enthesal T-cells have a role in enthesis immune homeostasis.

SAT0362 ASSOCIATION OF GUT DYSBIOSIS WITH STRUCTURAL DAMAGE AND ACTIVITY IN AXIAL SPONDYLOARTHRITIS PATIENTS FROM THE COSPARR REGISTRY.

G. G. Ignacio1,2,3, I. Moreno-Indias1,2,3, M. D. C. Castro Villagrasa1,2,3, M. D. C. Abalos-Aguilera1,2,3, M. Ladehesa Pineda1,2,3, I. C. Aranda-Valera1,2,3, de Investigación Biomédica de Córdoba, Córdoba, Spain;

Gut microbiota at the enthesal level was investigated within a prospective cohort study of patients with AxSpA (n=20). The gut microflora was characterized using a meta-microbial metagenomic platform CIBER-IBIMA.

RESULTS: A decrease in Bacteroidaceae and Bacteroides with disease activity measured by ASDAS (r=-0.697, p=0.025; r=-0.770, p=0.009) was also significant. Positive correlation was observed between Dialister with mSASSS (r=0.549, p=0.011). Correlation studies between the decrease in Bacteroidaceae and Bacteroides with disease activity measured by ASDAS (r=-0.697, p=0.025; r=-0.770, p=0.009) was also significant. Positive correlation was observed between Dialister with mSASSS (r=0.549, p=0.011) and BASMI (r=0.512, p=0.015).

CONCLUSION: 1) AxSpA patients had a significant alteration of the gut microbiota. 2) These alterations are associated with radiographic damage, disease activity, affection of enthesis and axial mobility.

SAT0363 DELPHINIDIN DOSE-DEPENDENTLY DIMINISHES PERIPHERAL IL-17 AND INF-γ PRODUCING LYMPHOCYTES IN PSORIATIC ARTHRITIS

A. Mavropoulos1, S. Tsigkos1, D. Skyvaldas2, C. Liaskos3, A. Roussakis-Schulze1, E. Zafiriou2, D. Bogdanos1, L. Sakkas3, University of Thessaly, Rheumatology and clinical immunology, Faculty of Medicine, Larissa, Greece; 2University of Thessaly, Dermatology, Faculty of Medicine, Larissa, Greece

Background: Delphinidin, a dietary anthocyanin and powerful anti-oxidant from pigmented fruits and vegetables, has broad anti-inflammatory properties. In a human skin model of psoriasis, delphinidin reduced expression of proliferative and inflammatory markers [1].

OBJECTIVES: The rationale of our study was to assess whether delphinidin can in vitro suppress IL-17 and IFN-γ production in peripheral blood mononuclear cell (PBMC) subsets from patients with psoriatic arthritis (PsA).

METHODS: PBMCs were obtained from 24 patients with PsA attending the outpatient clinic of the Department of Rheumatology/clinical Immunology at the University General Hospital of Larissa, Greece. 16 age- and sex-matched healthy volunteers were also included in the study. Delphinidin was supplemented at a concentration ranging from 1 to 50μg/ml, one hour prior to cell stimulation. Cell viability (Annexin V staining) and innate/adaptive lymphocyte subpopulations were assessed by flow cytometry with a panel of fluorochrome-conjugated antibodies against CD56, CD3, CD4 and CD8. Intracellular expression of IL-17 and IFN-γ was measured following PMA/ionomycin stimulation for 5 hours using standard cell permeabilization protocols and monoclonal antibodies against IL-17 and IFN-γ.

RESULTS: Delphinidin at concentration ≥10 μg/ml sharply diminished IL-17 production by CD4+ T cells (Th17) and CD56+(CD3+) NKT cells from patients with psoriatic arthritis and normal controls (p<0.05). IFN-γ producing T (CD4 and CD8) cells, as well as NK and NKT cells were also dose-dependently suppressed following delphinidin pre-incubation in both patients and healthy controls (UCH-1/IFN-γ+) cells ranged from 27 to 30% before peaked at delphinidin concentration 20-50μg/ml. The inhibitory effect of delphinidin on IL-17 and IFN-γ producing lymphocytes was not due to compromised cell viability, as assessed by annexin V binding.

Conclusion: Delphinidin exerts, in a dose-dependent manner, a profound in vitro inhibitory effect on T cell and NKT cell IL-17 and IFN-γ production in PsA, and therefore, it may be used as a dietary immunosuppressant, complimentary to standard treatment.

Spondyloarthritis - clinical aspects (other than treatment)

SAT0364

DATA TO BE COLLECTED FOR AN OPTIMAL MANAGEMENT OF AXIAL SPONDYLOARTHRITIS IN DAILY PRACTICE: PROPOSAL FROM AN EVIDENCE BASED AND CONSENSUS APPROACHES

A. Baillet1, X. Romand2, A. Pfimlin3, M. Daleyko4, M. Dougdados4 on behalf of the “Rencontre d’Expert en Rhumatologie” Task Force.1Univ Grenoble Alpes, GREPI TMC CNRS UMR 5525, Grenoble, France; 2Univ Grenoble Alpes, GREPI-TMC CNRS UMR 5525, Grenoble, France; 3Rheumatology, R Salengro Hospital, University of Lille, Lille, France; 4Department of Rheumatology - Hôpital Cochin, Assistance Publique - Hôpitaux de Paris, Paris, France

Background: Standardization of clinical practice has been proven to be effective in management of chronic diseases. This is particularly true at the time where the concept of treat to target is becoming more and more important in the field of axial spondyloarthritis (axSpA).

Objectives: To propose a list of variables to be collected at the time of the diagnosis and over the follow-up of patients with axial spondyloarthritis (axSpA) for an optimal management in daily practice.

Methods: The process comprised (1) the evaluation of the interest of 51 variables proposed for the assessment of axSpA via a systematic literature research, (2) a consensus process involving 78 hospital-based or office-based rheumatologists, considering the collection of the variable in a 4 grade scale from “potentially useful” to “mandatory”, (3) a consensus on optimal timeline for periodic assessment of the selected variables on a 5 grade scale from “at each visit” to “never to be re-collected”.

Results: The systematic literature research retrieved a total of 14,133 abstracts, 213 were included in the final qualitative synthesis. Concerning the data to be collected at the time of the diagnosis and during follow-up, we proposed to differentiate the results based on (a) the way of collection of the variables (e.g. questionnaires by the patient, interview by the physician, physical examination, investigations) b) the usefulness these variables in daily practice based on the opinion of the rheumatologists c) the optimal timeline between 2 evaluations of the variable based on the opinion of the rheumatologists. In the initial systematic review, symptoms of heart failure history of inflammatory bowel disease, psoriasis or uveitis, patient global visual analog scale, spine radiographs, modified Schöber test, coxo-femoral rotations, swollen joint count, urine strip test, BASDAI and ASDAS global scores were considered very useful and nocturnal back pain/ morning stiffness, sacro-ilac joints radiographs and CRP were considered mandatory (Figure 1). Timeline between 2 evaluations of variables to collect in the periodic review are summarized in Figure 2.

Conclusion: Using an evidence-based and an expert consensus approaches, this initiative defined a core set of variables to be collected and reported at the time of the diagnosis and during follow-up of patients with axSpA in daily practice.

Acknowledgments: this study has been conducted in two parts: the first one (evidence-based) was conducted thanks to a support from Abbvie France. Abbvie did not review the content or have influence on this manuscript. The second part of this initiative (consensus) has been conducted thanks to a support from the scientific non-profit organization: Association de Recherche Clinique en Rhumatologie

SAT0365

EFFECTS OF ANTI-TNF-THERAPY ON OSTEOBLASTIC ACTIVITY IN ANKYLOSING SPONDYLITIS – RESULTS FROM A PROSPECTIVE STUDY USING PET-MRI OF SIJ AND SPINE

X. Baraliakos1, S. Tsiami1, C. Rischpler1, M. Daleyko2, N. M. Bruckmann3, W. Fendler2, J. Kirchner1, K. Hermann1, L. Sawicki1, J. Braun1, Rheumazentrum Ruhrgebiet Reha-Rheumagymnastik Gelsenkirchen, Gelsenkirchen, Germany; 2Dept of Nuclear Medicine, University Essen-Duisburg, Essen, Germany; 3Dept of Radiology, University Dusseldorf, Dusseldorf, Germany

Background: The clinical efficacy of tumor necrosis factor inhibitors (TNFi) in patients with axial spondyloarthritis (axSpA) is well established but its effect on new bone formation is still unclear (1). Positron emission tomography (PET) using bone-seeking [18F]-Fluoride ([18F]F) in combination with magnetic resonance imaging ([18F]F/MRI) has been shown to depict not only bone marrow edema (BME) but also shows the quantity of tracer uptake in the late phase of perfusion suggestive of remodeling and osteoblastic activity, not only in radiographic axSpA (i.eSpA) (2).

Objectives: Assess the effect of TNFi on bone remodeling processes in the axial skeleton of ixAEA patients using [18F]F/MRI prior (baseline, BL) and 4 months after (follow-up, FU) treatment.
Methods: Patients (11 male, 5 female, mean age 38.6±12.0 years) with clinically active r-axSpA (BASDAI=4, failure of NSAIDs, no previous biologics) prospectively underwent 3-Tesla and [18F]F PET/MRI (40 minutes after injection of a mean activity of 175 MBq [18F]F). Images of the SIJ (n=16 patients) and the whole spine (n=10 patients) were performed at BL and FU. Three readers (1 for [18F]FF/MRI and 2 for conventional MRI) evaluated all images independently and blinded to timepoint allocation. Only lesions on which all readers agreed on were used for further analyses. Inflammation (bone marrow edema, BME), structural lesions (fat deposition (FD), sclerosis, erosions and ankylosis) and focal [18F]F uptake were recorded on the level of SIJ (SIJ-Q) and vertebral quadrants (V-Q), with each SIJ or vertebral body consisting of 4 VOs (superior and inferior sacral and iliac for the SIJ, and superior and inferior, anterior and posterior for the vertebral bodies).

Results: A total of 128 SIJ-Q and 920 VOs were analyzed at both BL and FU. In the SIJs, 75 (56.6%), 120 (93.8%), 69 (53.9%), 99 (77.3%) and 16 (12.5%) SIJ-Q showed BME, FD, sclerosis, erosions and ankylosis, while 111 (86.7%) SIJ-Q showed focal [18F]F-uptake at BL. Association with increased [18F]F-uptake was found most frequently in SIJ-Q with BME (70/75 SIJ-Q, 93.3%), sclerosis (65/69 SIJ-Q, 94.2%) and FD (105/120 SIJ-Q, 87.5%). At FU, 37 SIJ-Q still showed BME (improvement by 50.7%), while almost no changes were observed in chronic lesions. In comparison, improvement of focal [18F]F-uptake was found in all lesion combinations, with improvement of focal [18F]F-lesions associated with BME by 62.9%, with sclerosis by 33.6% and with FD by 22.9% of SIJ-Q.

Conclusion: In this first prospective study on whole spine and SIJ [18F]FF/MRI in patients with r-axSpA, a significant decrease of osteoblastic activity was observed over 4 months of continuous anti-TNF treatment. The effect of treatment was observed not only at sites with inflammatory lesions (BME) but also at sites with pre-existing chronic structural lesions, while some osteoblastic activity remained visible at 4 months. These data support a short-term effect of anti-TNF treatment on osteoblastic activity, while the long-term effects need to be further studied.

SAT0366

CLINICAL RESPONSE TO BIOLOGIC DMARDS IN AXIAL SPONDYLOARTHRITIS AND AXIAL PSORIATIC ARTHRITIS. DIFFERENT DISEASES, SAME OUTCOMES?

D. Benavent1, C. Plasencia1, K. N. Franco Gomez2, L. Nuño1, A. Balsa1, V. Navarro-Compañ1. 1Hospital La Paz, IdiPaz, Rheumatology, Madrid, Spain

Background: Patients with psoriatic arthritis may present predominant axial involvement. Currently, it is unclear whether these patients should be considered as axial spondyloarthritis (axSpA) with psoriasis or psoriatic arthritis with axial involvement –also known as axial PsA (axPsA). Data comparing medium-term treatment response to biological drugs in axSpA and axPsA would add relevant information to answer this question.

Objectives: To compare the clinical response and predictor factors after one year of biological therapy in patients with axSpA and axPsA.

Methods: One-year follow-up data from all patients (pts) with axSpA or axPsA (defined by the treating rheumatologist) included in a prospective cohort of pts receiving biological therapy from La Paz University Hospital between 2002 and 2015 were analysed. Demographic information, laboratory tests, concomitant treatments and disease status were collected at baseline. Clinical disease activity was measured by PhGA and ASDAS criteria at baseline, 6 and 12 months. According to ASDAS, disease activity was defined as: inactive disease (ID) (ASDAS <1.3), low disease activity (LDA) (ASDAS 1.3-2.1), high disease activity (HDA) (ASDAS 2.1-3.3) and very high disease activity (VHDA) (ASDAS >3.3). Clinical important improvement and major improvement were defined by ASDAS (delta-ASDAS ≥1.1 and ≥2.0, respectively). According to PhGA, disease activity was assayed by consensus of 3 expert rheumatologists in: ID with PhGA=5, LDA with PhGA 5-30, HDA with PhGA >30-60 and VHDA with PhGA >60. Clinical improvement by PhGA was defined as an improvement of >4% compared to baseline. In the statistical analysis, the frequency of pts achieving each clinical activity status and clinical improvement at 6m and 12m were compared using Fisher test, separately for axSpA and axPsA. Baseline predictor factors for achieving clinical response and clinical improvement were identified using univariable and multivariable binary regression.

Results: Out of 352 included pts, 287 (81.5%) had axSpA and 65 (18.5%) axPsA. Sixty percent were males, 158 (45%) smokers, with mean (SD) baseline disease activity of ASDAS (bASDAS): 3.3 (0.9) and PhGA: 39.1 (21.5). Biological therapies initiated included TNF inhibitors in 93.8 % and secukinumab in 6.2%. In comparison to axPsA, pts with axSpA were more HLA B27 positive (p<0.001) and had better PhGA at baseline (p=0.02). They also had more uveitis (p=0.03) and were more radiographically affected (p=0.001).

Response rates at 6m and 12m in both diseases according to ASDAS are shown in Figure 1, and to PhGA in Figure 2. Both diseases presented a similar clinical response, and no statistically significant differences were observed for any disease activity interval between them for ASDAS or PhGA. There were no differences between both diseases on clinical improvement, regardless the type of measurement.
Background: Extra-articular manifestations (EAMs): psoriasis, uveitis and inflammatory bowel disease (IBD) are common in patients with established spondyloarthritis (SpA), with prevalences reported around 9%, 26% and 7% respectively (1). However, data on the prevalence of EAMs are lacking in early axial SpA (axSpA).

Objectives: The aim was to assess the prevalence of EAMs in early axSpA in the published literature.

Methods: Systematic literature search on Pubmed MEDLINE up to 31.12.2019 with keywords referring to EAMs (psoriasis and synonyms, psoriasis and synonyms or IBD and synonyms) and early axSpA (recent, young adult, young, untreated, inception) and selection by one reader of all full-text publications in English, describing the prevalence of at least one of the EAMs in patients with early axSpA, defined here as patients fulfilling ASAS, ESSG or Amor criteria and symptom duration of less than 6 years (as this was defined by authors as early disease). Patients’ age, axSpA symptom duration, sex, HLA-B27 status, and number of patients with EAMs were recorded by one reader using a predefined extraction sheet. For longitudinal studies, baseline data was recorded. Description of patients was analysed using weighted means. Prevalences in each study according to symptom duration were graphically reported, and pooled prevalences were calculated by meta-analysis of proportions, using a random-effects model and the DerSimonian & Laird method to derive the summary estimate.

Results: Of 667 articles, 17 were relevant to the research question with prevalence data of psoriasis, uveitis and IBD available in 16, 17 and 15 articles, respectively (and most studies reporting several EAMs). Of the 17 articles, 14 were cohort studies and 3 were trials in early axSpA. A total of 2854 patients with early SpA was analyzed: weighted mean age 32.3±9.1 years (range 21-42 years), weighted mean axSpA symptom duration 20.7±11.1 months (range 8-68), 40.3% were female, and 65.1% carried HLA-B27.

The pooled prevalences of psoriasis, uveitis and IBD were respectively 8.9% (95% CI 5.0, 13.8), 13.4% (95% CI 9.5, 17.8) and 5.5% (95% CI 1.7, 9.9) (Figure 1). There was a trend towards higher prevalences in patients with longer disease duration (Figure 2).

Figure 1. Meta-analysis of prevalence of each EAM

Figure 2. The prevalence of each EAM according to the symptom duration in early axSpA (age: mean symptom duration (mos)). Y axis: prevalence (%) of an EAM. Diameter of bubbles is proportional to sample size of each article.

Conclusion: Over the first years of axSpA, EAMs are frequent, in particular psoriasis and uveitis, with prevalences up to 30% in some studies. Compared to established axSpA, the EAM which was much less frequent was uveitis, which suggests the appearance of new cases over follow-up. Physicians need to screen carefully for EAMs right from the time of diagnosis, and need to repeat this screening over follow-up.

SAT0368 PREGNANCY IN WOMEN WITH SPONDYLOARTHRITIS: WHO ARE THE PATIENTS AT RISK OF DISEASE FLARE?

F. Crisafiulli1, A. R. Cruz-Machado2, M. C. Gerardi1, M. Filippini1, M. Fredi1, R. Gorla1, M. G. Lazzaroni1, C. Nalli1, M. Taglietti1, A. Lojacono2, C. Zanardini3, S. Zatti1, L. Andreoli1, F. Franceschini1, A. Tincani1, *ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 2Hospital de Santa Maria, Serviço de Reumatologia e Doenças Ósseas Metabólicas, Lisboa, Portugal; *ASST Spedali Civili and University of Brescia, Obstetrics and Gynaecology Unit, Brescia, Italy

Background: Patients with Spondyloarthritis (SpA) can experience flares during pregnancy and postpartum even though the available data are limited and not conclusive.

Objectives: To assess disease activity and treatment modification during pregnancy and postpartum in patients with SpA and to identify risk factors for disease flare.

Methods: Data on SpA pregnancies prospectively-followed in a pregnancy clinic from 2010 to 2019 were retrospectively analysed. Disease activity was assessed during each trimester and postpartum using ASDAS-CRP or DAS28-CRP. Flare was defined as an increase of disease activity during treatment modification (introduction or increase ≥5 mg/day of prednisone, introduction of cDMARD or bDMARD)1.

Results: Data on 50 pregnancies in 46 patients were collected (mean age at conception 33±4.7 years; median disease duration: 60 months (IQR 24-132); 33 psoriatic arthritis, 6 axialSpA, 2 reactive arthritis, 2 IBD-related SpA; 6 undifferentiated SpA, 1 juvenile idiopathic arthritis). Six pregnancies ended in miscarriage, so they weren’t considered for the analysis of flares during pregnancy (table 1). Fifteen out of 44 (34%) pregnancies had at least one flare during pregnancy (6, 7 and 4 during 1st, 2nd and 3rd trimester respectively; 2 pregnancies had multiple flares). A higher rate of flare was observed in pregnancies of patients with axial involvement (p=0.01) on treatment with bDMARDs at preconceptional visit (p=0.03) and who stopped TNFi at positive pregnancy test (p=0.03). Peripheral involvement was associated with a lower rate of flares (p=0.02). Medications resumed during pregnancy were steroids (in 6 pregnancies), cDMARDs (2 sulfasalazine, 1 cyclosporine) and bDMARDs (4 certolizumab, 4 etanercept). During postpartum period flares were recorded in 46% of patients.

*DAS28-CRP≥3.2 or ASDAS-CRP≥2.1

Conclusion: In our cohort of prospectively-followed SpA pregnancies, 34% experienced a flare during pregnancy and 46% during postpartum. Flares
occurred especially in those patients who discontinued TNFi early in pregnancy and with axial involvement. When resumed during pregnancy, TNFi was able to control the disease. At preconception counselling, the continuation of TNFi during pregnancy should be considered to ensure a better control of disease.

SAT0369

SPINAL RADIOGRAPHIC PROGRESSION IN EARLY Spondyloarthritids: SIX-YEAR RESULTS FROM THE ESPEANZA COHORT

1Hospital Universitario La Paz, Rheumatology, Madrid, Spain; 2Hospital de Galdakao, Rheumatology, Bilbao, Spain; 3Hospital Universitario Moncloa, Rheumatology, Madrid, Spain; 4Hospital Universitario Basurto, Rheumatology, Bilbao, Spain; 5Hospital Universitario Reina Sofia, Rheumatology, Madrid, Spain; 6Hospital Universitario Reina Sofia, Rheumatology, Córdoba, Spain; 7Hospital Universitario de Bellvitge, Rheumatology, Barcelona, Spain; 8Hospital Universitario de Basurto, Rheumatology, Bilbao, Spain.

Background: There are few studies focused on the development of structural damage over time in patients with early SpA

Objectives: The aim of this study is to analyze the mSASSS radiographic progression of spine in patients with early spondyloarthritids (SpA) in the Esperanza cohort.

Methods: In this longitudinal study, 49 patients of the Spanish early spondyloarthritids (SpA) Esperanza cohort were included. Every patient had a baseline and a six years lateral X-Ray of the cervical and lumbar spine. The assessment of spine structural damage was done by the modified Stoke Ankylosing Spondylitis Score (mSASSS). Nine readers, blinded for the diagnosis, participated in the reliability exercise, all of them experienced rheumatologists and members of the Spanish spondyloarthritids working group (GRESSER). The mSASSS progression and development of new syndesmophytes was analyzed. The gold standard of every elemental lesion of the mSASSS and the total mSASSS score was the agreement achieved by the independent categorical opinion of at least five of the nine readers. For reliability, intraclass correlation coefficient (ICC) two-way mixed, agreement achieved by the absolute agreement.

Results: Forty-nine patients were included, 69 % were males and 49%, HLA B27 positive. Mean ± SD baseline ESR, CRP, BASDAI, BASFI and mSASSS were 10.7±11.7, 5.4±7.1, 3.7±2.5, 2.1±2.0 and 0.326±0.85, respectively. Inter-reader ICC reliability of the 9 readers was 0.812 (CI 95%; 0.764-0.857). The mSASSS score at the six-year visit was 0.67 ± 1.6: thirty-nine patients did not present any changes in this score at the end of the follow-up, two patients had Δ mSASSS of –1 and eight patients, an increase in this score (four patients, +1; three patients, +2 and one patient, +9 points). At baseline, five patients presented one syndesmophytes; at the six-year visit, seven had one syndesmophytes; one patient, two syndesmophytes and another one, one bone bridge. Only 2/5 patients (40%) with syndesmophytes at baseline showed an increase in Δ mSASSS; the two patients with a Δ mSASSS of -1 did not have syndesmophytes at baseline. Five out of eight patients (62.5%) with an increase of the Δ mSASSS presented this lesion at the six-year visit but only two of them showed syndesmophytes at baseline. On the other hand, two of the three patients who showed an increase of the ΔmSASSS without syndesmophytes at baseline presented an erosion in the anterior vertebral corner and the patient with the bone bridge had a previous syndesmophytes. Our results indicate that in early SpA much of the progression appears in patients without previous syndesmophytes.

Conclusion: Spinal radiographic progression was very low in our early SpA cohort, with a mean progression of 0.3 mSASSS units. Only eight patients (16.3%) presented spinal structural progression, most of them not showing syndesmophytes at baseline. It is reasonable to consider that an early diagnosis and monitoring could result in a low radiographic progression.

SAT0370

TUMOUR NECROSIS FACTOR INHIBITOR THERAPY DOES NOT REDUCE THE INCIDENCE OF COMORBIDITIES AND EXTRA-ARTICULAR MANIFESTATIONS IN ANKYLOSING SPONDYLITIS: AN ANALYSIS OF THREE US CLAIMS DATABASES

A. Deghoal1, K. Winthrop2, R. Bohn2, B. Chan1, R. Suruk2, J. Stark2, H. Yun3, S. Siegel1, L. Chen1, J. Curtis1, 4Oregon Health & Science University, Portland, United States of America; 2UCB Pharma, Raleigh, United States of America; 3UCB Pharma, Smyrna, United States of America; 4University of Alabama at Birmingham, Birmingham, United States of America

Background: Comorbidities and extra-articular manifestations (EAMs) substantially increase disease burden and mortality risk in patients (pts) with ankylosing spondylitis (AS). Tumor necrosis factor inhibitors (TNFi) are highly efficacious and treatment (tx) and are used after inadequate response to non-steroidal anti-inflammatory drugs.1,2 However, the impact of TNFi on the incidence of comorbidities and EAMs in pts with AS is unknown.3

Objectives: To determine the incidence of comorbidities and EAMs in TNFi vs non-TNFi treated pts with AS in the US.

Methods: This was a retrospective, observational cohort study using data from 3 healthcare insurance claims databases: Multi-Payer Claims Database (MPCD Optum Insight; 2007–2010), Truven MarketScan® (2010–2014) and US Medicare Fee-for-Service Claims database (2006–2014). Eligible pts: ≥20 years (yrs) for MarketScan/MPCD or ≥65 yrs for Medicare, had an AS diagnosis (≥2 International Classification of Disease, 9th version [ICD-9] diagnosis codes of 720.0 from a rheumatologist) and ≥12 months’ continuous medical and pharmacy enrolment prior to AS diagnosis (AS index date). Pts with AS not receiving tx were excluded. Tx exposure was reported from the first date of a new prescription/administration of an AS tx (no prior exposure) after the AS index date. Crude incidence rates (IR; shown as cases/100 pt-yrs) were calculated for EAMs (uveitis, psoriasis [PSO], psoriatic arthritis [PsA], inflammatory bowel disease [IBD]), with follow-up until the earliest of: death, loss medical pharmacy coverage, study period end, first outcome occurrence, tx switch/discontinuation. Hazard ratios (HRs) of comorbidities (hospitalised infection, solid cancers) and EAMs for propensity score (PS)-matched pt groups were calculated using Cox proportional hazard regression models. Pts with the specific comorbidity/EAM of interest prior to AS index date were excluded. PS analyses assessed probability of TNFi initiation vs non-TNFi tx and adjusted for factors including comorbidities and demographics. HRs with confidence intervals crossing 1 are not reported.

Results: 20,460 pts with AS were eligible (MPCD: 2,384; MarketScan: 9,032; Medicare: 9,044). In all databases, crude IR of EAMs were higher for TNFi vs non-TNFi treated pts; Medicare data (Figure 1). Higher incidences of solid cancers and EAMs were observed in TNFi vs non-TNFi treated pts; Medicare data (Figure 2) A higher risk of PsA and PSO was seen in TNFi vs non-TNFi treated pts; MarketScan data (Figure 2); PS-matched cohort data from the MPCD database were non-significant.

Conclusion: Despite strong efficacy in treating AS-related signs and symptoms, similar incidence of comorbidities and increased incidence of some EAMs (IBD, PSO/PsA, uveitis) was seen in TNFi vs non-TNFi treated pts in the PS-matched analyses. This may be due to channelling of pts with more severe AS to receive TNFi during pregnancy should be considered to ensure a better control of disease. At preconception counselling, the continuation of TNFi during pregnancy should be considered to ensure a better control of disease.

SAT0371
ARE ENGLISH-LANGUAGE VIDEOS ON YOUTUBE A USEFUL SOURCE OF INFORMATION FOR SPONDYLOARTHRITIS?

S. Elangovan¹, Y. H. Kwan², W. Fong¹,²,³,⁴ Singapore General Hospital, Rheumatology and Immunology, Singapore, Singapore;³Duke-NUS Medical School, Singapore, Singapore;¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Background: Spondyloarthritis (SpA) is a family of chronic inflammatory disorders. Social media, such as YouTube, is a popular online platform where patients often visit for information. However, the validity of the content uploaded onto YouTube is not known.

Objectives: This study aimed to evaluate the content, reliability and quality of the most viewed English-language YouTube videos on SpA.

Methods: Keywords “spondyloarthropathy” and “ankylosing spondylitis” were searched on YouTube on October 7th, 2019. The top 270 videos were screened. Videos were excluded if they were irrelevant, had inconsistent language or if they had no audio. Total number of views, duration on YouTube (days), video length, upload date, number of likes, dislikes, subscribers and comments were recorded for videos. A modified 5-point DISCERN tool¹ and the 5-point Global Quality Scale (GQS) score² were used to assess the reliability and quality of the videos, with higher scores indicating greater reliability and quality respectively.

Results: Two hundred and seventy videos were included in the final analysis (61.5% from healthcare professionals, 37.0% from patients, 1.5% from news channels). Of the 200 videos, 15 were uploaded within the last year and 112 in the last five years. 120 (60%) were categorized as useful information (Group 1), 6 (3%) as misleading information (Group 2), 52 (26%) as useful patient opinion (Group 3) and 22 (11%) as misleading patient opinion (Group 4). Useful videos were mainly from healthcare professionals or patients (86%). Useful videos (Group 1 and 3) had higher median (IQR) number of subscribers [2700 (14700) vs 211 (457), p < 0.01], reliability scores [3 (1) vs 2 (1), p < 0.01] and GQS scores [3 (1) vs 2 (1), p < 0.001] compared to misleading videos (Group 2 and 4), respectively.

Videos uploaded by healthcare professionals tended to have more useful information [94% (116 of 123) vs. 66% (49 of 74), p < 0.001] and had higher median (IQR) reliability scores [3 (1) vs 2 (1), p < 0.001] and GQS scores [3 (2) vs 2 (1), p < 0.001] compared to patient uploaded videos respectively. Of the 5 (out of 123) videos from healthcare professionals that had misleading information, it was because of outdated information on diagnosis (3 videos) and treatment (5 videos) of SpA. Of the 22 videos that had misleading patient opinion, 9 (41%) wrongly described the clinical features for SpA and 14 (64%) portrayed the current evidence based treatment options as ineffective and described alternative treatment plans (i.e. die restrictions, complementary and alternative medicine).

Conclusion: The majority of English language YouTube videos have useful information on the topic of SpA, however, 31% of patient opinions have inaccurate information on the clinical features and treatment options, and viewers are not cognisant of these “fake news.”

SAT0372
PATIENTS WITH PSORIATIC ARTHRITIS SHOW HIGHER BONE DENSITY COMPARED TO AGE AND GENDER MATCHED PATIENTS WITH ANKYLOSING SPONDYLITIS

D. Freig¹, E. Wiebe¹, R. Biesen¹, T. Buttgereit¹, S. Hermann¹, T. Gaber¹, F. Buttgereit¹.¹Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany;¹Charité – Universitätsmedizin Berlin, Department of Dermatology and Allergy, Berlin, Germany

Background: The prevalence of osteoporosis in inflammatory rheumatic diseases such as psoriatic arthritis (PsA) has not been sufficiently clarified yet, and the data in the literature are heterogeneous. In addition, it is still unclear to what extent patients with PsA differ in terms of bone density from patients with other forms of spondyloarthritis such as ankylosing spondylitis (AS).

Objectives: In an interim analysis of the RH-GIOP Study (ClinicalTrials.gov Identifier NCT02719314), we observed that PsA patients demonstrated more frequently normal bone density than any other patient group analyzed (suffering from e.g. rheumatoid arthritis or systemic sclerosis). The main objective of this investigation was to compare bone density data from patients with PsA and

School, Program in Health Services and Systems Research, Singapore, Singapore;¹Duke-NUS Medical School, Singapore, Singapore;¹National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Figure 1. Crude incidence of EAMs by treatment exposure in patients with AS using TNF-α and without TNF-α treatment (95% CIs included).

Figure 2. Propensity score-weighted hazard ratios of comorbidities and EAMs by treatment exposure in patients with AS using TNF-α and without TNF-α treatment.
AS, as both diseases belong to the spondyloarthritis group. 1100 patients with inflammatory rheumatic diseases provided the basis of RH-GIOP, a prospective study monitoring glucocorticoid (GC)-induced osteoporosis in patients with rheumatic diseases. RH-GIOP was established in 2015 at the Charité University Hospital. Bone mineral density data were measured by dual x-ray absorptiometry (DXA).

Methods: 92 patients with PsA (65% female) were compared with 51 patients suffering from AS (35% female). Potential risk and protective factors (e.g. data on GC treatment, anti-rheumatic therapy), laboratory parameters (e.g. Vitamin D, alkaline phosphatase (ALP) and inflammatory markers) and functional status (e.g. Health Assessment Questionnaire, sporting activities, back pain) were compared between these groups. Statistical analysis was performed descriptively using mean and standard deviation, t-tests for metric variables, and chi-square tests for nominal variables. Due to the heterogeneous gender distribution, an additional statistical matching was performed to compare patients matched by age and gender.

Results: Patients with PsA displayed significantly higher minimal T-scores than patients with AS (p=0.003) even though patients with AS were younger and more often male (p<0.001). AS patients showed a higher frequency of osteopenic bone densities (p<0.05), however, no differences in the frequency of osteoporotic bone densities were found. Body-mass-index (BMI) was significantly higher (p<0.001) in PsA patients. PsA patients also demonstrated a higher frequency of csDMARD use (p<0.05). Additional analyses among PsA patients with and without csDMARDs revealed also significantly higher minimal T-scores in PsA patients taking csDMARDs (90% Methotrexate), and both groups showed the same average of age and gender distribution. Furthermore, AS patients complained significantly more often of back pain (96% vs. 74%; p=0.001) than PsA patients. No differences in GC use or cumulative GC dose were found. All results could be confirmed when gender was matched by age and gender.

Conclusion: Our results demonstrate that patients with PsA display higher bone density compared to age and gender matched patients with ankylosing spondylitis. Possible influencing factors could be the higher frequency of csDMARD use, higher BMI or the lower frequency of back pain in PsA patients. Multivariate tests and additional biomarker investigations in larger cohorts are necessary to corroborate these findings and to identify underlying pathogenic differences which could serve for an explanation.

SAT0373

QUANTITATIVE ASSESSMENT OF RESPONSIVENESS IN SACROILIAC JOINTS MRI OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A PILOT STUDY.

C. Garrido-González1, M. D. C. Castro Villegas2, M. Ladehese Pineda3, J. L. Garrido-Castro1, R. Ortega Castro1, C. González-Nava1, P. Zarco-Montejo2, R. Almodovar1, A. Bueno1, L. M. Molinero1, E. Collantes Estevez1 on behalf of COSPAR Study Group. 1Rheumovideos Biomedical Research Institute of Córdoba, Córdoba, Spain; 2Hospital Universitario Reina Sofia, Cordoba, Spain; 3Hospital Universitario Fimac Alcón, Madrid, Spain; 4ALCE Ingeniería, Madrid, Spain

Background: The presence of inflammatory signals in sacroiliac joints (SIJ), using MRI, is used for early diagnosis of axial spondyloarthritis (axSpA)[1]. Some studies also demonstrate that this inflammation can be suppressed quite dramatically by TNF-α blockers. Different scoring methods to quantify inflammatory changes in SIJ using MRI have been defined and validated: SPARCC, Leeds, Berlin, and ASSpMRI-a. However, its use is complex and subjective. Recently Zarco et al.[2] developed a method to measure bone marrow edema (BME) in MRI images from SIJ. This method, in a semiautomatic procedure, allows to measure the area affected by inflammation and the signal intensity to produce an index: the SCAISS. A simplified version, the s-SCAISS, using only a semi-coronal slide, has been proposed with good validity and reliability results.

Objectives: To assess responsiveness of inflammation in SIJ of axSpA patients, treated with TNF-α inhibitors, using a novel score method: the s-SCAISS.

Methods: Two rheumatologists independently quantified SIJ images from axSpA patients by three methods (s-SCAISS, SPARCC and Berlin) on a single semi-coronal MRI slide (STIR). Patients were assessed before TNF-α therapy (PRE) and 3 months later (POST). Spearman correlations were used to analyze responsiveness between variables. Wilcoxon signed-rank test for significant differences and Cohen’s d for calculating the effect size of improvement. Figure shows MRI images of a patient before and after treatment.

Results: 9 axSpA patients were recruited from the COSPAR cohort (44% female, age 47±13 years, disease duration 18±14 years, BMI 29±4). Results PRE and POST are shown in Table: mean values (sd), statistical significance (NS, not significant; *, p<0.05; **, p<0.01), and Effect Size. In the first rows, different scoring system for MRI inflammation appears: Area analyzed by s-SCAISS, s-SCAISS, Berlin and SPARCC (using only a semi-coronal slide). Activity and functional indexes were lower with significant differences and a large effect size. Correlations of s-SCAISS with Berlin (rho=0.78;p<0.05) and SPARCC (rho=0.96;p<0.001) were good; with clinical disease activity outcomes were poor, except with BASDAS (rho=0.70;p<0.05). The best correlation according improvements appeared comparing reduction of ASDAS with reduction of s-SCAISS (rho=0.57) but this difference was not significant. Although improvements in BASMI was not significant, a good correlation was found between improvement in s-SCAISS and BASMI (rho=0.72;p<0.05).

SAT0374

ONSET OF AXIAL SPONDYLOARTHRITIS: REPERCUSSIONS ON PATIENTS’ SOCIAL AND FAMILY LIFE: RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS (EMAS)

M. Garrido-Cumbre, M. V. Navarro-Compañ, C. Bundy, A. Mahapatra, S. Makr, S. Sanz-Gómez, L. Christen, C. D. Delgado-Dominguez, D. Podstubny, on behalf of EMAS Working Group. 1Health & Territory Research (HTR), Universidad de Sevilla, Sevilla, Spain; 2Spanish Federation of Spondyloarthritis Associations, Madrid, Spain; 3IdiPAZ, University Hospital
Background: Axial Spondyloarthritis (axSpA) is associated with a high degree of functional limitation in daily life activities. However, few studies have evaluated the social and family burden from the patient's perspective.

Objectives: To describe the impact of axSpA on social and family life since disease onset, and the associated PROs.

Methods: Data from 2,846 unselected patients of the European Map of Axial Spondyloarthritis (EMAS) study through an online survey (2017-2018) across 13 European countries were analysed. The impact of axSpA on social and family life was assessed through four PROs: i) Impact on relationships with the spouse, family, friends, neighbours, and work colleagues since disease onset (5 point Likert scale; 1 “much better” – 5 “much worse”); ii) Frequency of social activities including outings to bars/restaurants, cinema/theatre/museums, practising sports, travel/excursions, and intimate relations since disease onset (5 point Likert scale; 1 “much more” – 5 “much less”); iii) Adaptations made to cope with axSpA since disease onset (yes/no question); iv) The degree of functional limitation in 18 daily activities (3 point Likert scale). Self-reported BASDAI (0-10), spinal stiffness (3-12), functional limitation in daily activities, the greatest limitations were in physical exercise (84.4%), cleaning the house (79.2%) and using stairs (79.2%) (Fig. 2). In the correlation analysis, BASDAI, spinal stiffness, functional limitation, GHQ-12 were associated with a worsening in all of relationships and social activities (p < 0.001) (Table 1).

Results: Among 2,846 participants, mean age was 43.9 years, 61.3% were female, 48.1% had a university degree. The greatest impact on relationships (sum of ‘worse’ and ‘much worse’) since disease onset were those with female, 48.1% had a university degree. The greatest impact on relationship (Table 1).

Conclusion: For most participants the onset of axSpA marked the worsening of personal relationships in different areas, as well as the reduction of social, leisure, and entertainment activities.

¶ Each joint graded 0-3
§ Multivariable GEE model

Conclusion: A higher level of back pain was associated with a worsening of the patient’s well-being in early axSpA, as were, to a lesser extent, higher levels of fatigue, morning stiffness, peripheral joint pain and physical disability. Contextual factors like age, gender and educational level did not have an impact on these relationships. Thus, the previously proposed framework of disease outcomes also applies to patients with early axSpA and to outcomes over time.

SAT0377

ASSESSMENT OF ANKYLOSING SPONDYLITIS ACTIVITY DURING PREGNANCY USING DIFFERENT ACTIVITY INDICES

O. Krichevskaya1, Z. Gandaloeva1, T. Dubinina1, A. Demina1, V. A. Nasonova
Institute of Rheumatology, Moscow, Russia, Laboratory of Medical and Social Problems of Rheumatology, Moscow, Russian Federation

Background: Currently, there is no consensus on the effect of pregnancy on the activity of ankylosing spondylitis (AS). Moreover, in the absence of a pregnancy modified AS activity index, it remains unclear which of the commonly accepted tools can most adequately assess AS activity during gestation.

Objectives: To assess the dynamics of AS activity during pregnancy, using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score CRP (ASDAS-CRP)

Methods: The study group included 36 pregnant women with confirmed AS (modified New York criteria, 1984). Patients’ mean age was 31.6±4.8 years, mean age at AS onset was 21.8±10.9, and disease duration - 134.9±89.3 months. Activity was assessed using BASDAI and ASDAS-CRP at 10-11, 20-21, and 31-32 weeks of pregnancy. BASDAI at the time of conception was assessed retrospectively at the first visit.

Results: BASDAI values in the month of conception and in the trimesters of pregnancy were 2.3 ±1.9; 2.8 ±1.7 (p<0.05 compared to the month of conception); 3.2 ±1.9 and 3.3 ±2.1. Analyzed dynamics of individual BASDAI components is indicative of increasing fatigue from the month of conception (2.5 [1; 4] and 2 [0; 3], respectively) was documented. There was an increase in the intensity and duration of morning stiffness in the III trimester (3.5 [1; 7] and 2.5 [1; 5], respectively) compared to the month of conception (1.5[0; 4] and 2 [0; 3], respectively, p<0.05).

ASDAS-CRP values by trimesters of pregnancy were as follows: 1.9 ±0.7; 2.3 ±0.9 and 2.2 ±0.8. There was a tendency to increasing CRP levels in the II (8.0 ±1.9 [mg/l]) and III trimesters (7.9 [2.9; 2.9] mg/l) compared to the I trimester (5.7 [1.6; 2.9]).

Patients’ distribution by grades of AS activity is presented in the Table.
When dividing patients into two groups depending on AS activity in the I trimester (group very high 5,6% 0 2,9% 2,9% 2,8% 8,9% 11,8%)

**Conclusion:** A tendency of increasing AS activity during the first half of pregnancy with no reverse until the end of gestation based on BASDAI and ASDAS – CRP values and CRP levels was found. There was a discrepancy in degree of activity assessed by the tools used: moderate and high disease activity was identified in greater number of AS patients based on ASDAS-CRP scores compared to BASDAI during the entire pregnancy. It is deemed necessary to continue research so that to identify the most adequate index for AS activity assessment during pregnancy.

**SAT0378**

THE RELATIVE DIAGNOSTIC UTILITY OF INFLAMMATORY BACK PAIN CRITERIA IN AN INCEPTION COHORT OF PATIENTS WITH PSORIASIS, IRRITIS, AND COLITIS PRESENTING WITH UNDIAGNOSED BACK PAIN

G. Kröber1, U. Weber1, R. Carmona2, J. Yeung3, J. Chan4, S. Aydin5, L. Martin6, A. Masetto7, S. Keeling8, O. Ziouzina6, S. Rohekar9, R. Dadashova10, J. Paschke10, Z. Zhong1,2, Y. Huang1, Q. Huang1, T. Li1,2, Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; 2Southern Medical University,The Second School of Clinical Medicine, Guangzhou, China

**Background:** Clinicians rely on the elicitation of features of inflammatory back pain (IBP) for diagnosis of axial spondyloarthritis (axSpA) but the utility of IBP criteria in patients presenting with extra-articular features of axSpA remains unclear. Assessment of utility should include not only rheumatologist diagnosis as benchmark but imaging to address the circularity between elicitation of IBP and clinical diagnosis.

**Objectives:** To assess the diagnostic utility of all criteria for IBP in patients with psoriasis, iritis, or colitis and undiagnosed back pain using the rheumatologist diagnosis and imaging as benchmarks.

**Methods:** Consecutive patients (n=246) with undiagnosed back pain ≤45 years of age, ≥3 months, with any one of psoriasis (n=46), acute anterior uveitis (AAU) (n=73), or colitis (n=127) had diagnostic evaluation by a rheumatologist. Major-ity central reader assessment of MRI indicative of axSpA and diagnosis by the rheumatologist were external standards for testing the utility of these IBP criteria: ASAS, Berlin, Calin, rheumatologist global for IBP >5 (0-10 scale).

**Results:** AxSpA was diagnosed in 44.4%, 61.6%, and 41.8% of patients with psoriasis, iritis, and IBD, respectively. Diagnostic utility for all IBP criteria was comparably poor (Table 1), MRI was indicative of axSpA in 21.2%, 43.5%, and 19.7% of patients with psoriasis, iritis, and IBD. The utility of the IBP criteria was even worse using MRI as the external reference (Table 2), especially in patients with psoriasis. Only 14% of psoriasis patients with a positive MRI reported “improvement with exercise but not rest” as compared to 70% and 62% of patients with iritis and IBD, respectively.

**Conclusion:** All IBP criteria have poor diagnostic utility for diagnosis of axSpA, especially in patients with psoriasis. This reinforces the desirability of less subjective assessment tools, especially imaging.

**Conclusion:** C-reactive protein to albumin ratio (CAR) has emerged as a significant biomarker to evaluate and predict systemic inflammation[1]. However, the role of CAR in patients with axial spondyloarthritis (axSpA) remains unknown.

**Objectives:** The aim of this study was to investigate the relationship between CAR and disease activity of axSpA.

**Methods:** A total of 241 patients and 61 healthy controls from Guangdong Second Provincial General Hospital from December 2015 to August 2019 were retrospectively recruited in this study. Patients were divided into two groups, with 176 patients in remission group (BASDAI<4) and 65 patients in active group (BASDAI≥4). Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), albumin (ALB), CAR, neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (PLR) and monocyte-lymphocyte ratio (MLR) were detected. The correlations between CAR, NLR, PLR, MLR and disease activity were analyzed by the Spearman’s correlations analysis.

**Results:** C-reactive protein to albumin ratio (CAR) has emerged as a significant biomarker to evaluate and predict systemic inflammation[1]. However, the role of CAR in patients with axial spondyloarthritis (axSpA) remains unknown.

**Background:** C-reactive protein to albumin ratio (CAR) has emerged as a significant biomarker to evaluate and predict systemic inflammation[1]. However, the role of CAR in patients with axial spondyloarthritis (axSpA) remains unknown.

**Objectives:** The aim of this study was to investigate the relationship between CAR and disease activity of axSpA.

**Methods:** A total of 241 patients and 61 healthy controls from Guangdong Second Provincial General Hospital from December 2015 to August 2019 were retrospectively recruited in this study. Patients were divided into two groups, with 176 patients in remission group (BASDAI<4) and 65 patients in active group (BASDAI≥4). Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), albumin (ALB), CAR, neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (PLR) and monocyte-lymphocyte ratio (MLR) were detected. The correlations between CAR, NLR, PLR, MLR and disease activity were analyzed by the Spearman’s correlations analysis.
operation characteristic (ROC) curves were performed to evaluate the discriminative utility of these parameters for disease activity of axSpA. Furthermore, the evaluation of the risk factors of axSpA was conducted using binary logistic regression analysis.

**Results:** CAR, ESR, CRP, NLR, PLR and MLR in axSpA patients were significantly higher than those in the control group (p<0.05 for each), while ALB was significantly lower (p<0.001). Similarly, CAR in remission group was higher than that in control group (p<0.001) and was lower than that in active group (p<0.001). Besides, there were significantly positive correlations between CAR and ESR (r=0.702, P<0.001), CRP (r=0.996, P<0.001), BAS-DAI (r=0.329, P<0.001) and BASFI (r=0.328, P<0.001). Furthermore, ROC suggested that the area under the curve (AUC) of CAR was 0.701, which was the highest. The optimal cutoff point of CAR was 0.3644, with sensitivity and specificity of 58.5% and 79.0%. Logistic analysis results revealed that elevated CAR and MLR were independent risk factors for axSpA (EXP (B) =15.54, 95%CI: 5.894-40.979, P<0.001; EXP (B) =2.206, 95%CI: 1.077-4.519, P=0.031, respectively).

**Conclusion:** CAR was increased in axSpA patients especially in active group, and significantly correlated with disease activity. CAR may serve as a novel inflammatory marker of monitoring disease activity in patients with axSpA.

**DOI:** 10.1136/annrheumdis-2020-eular.5199

---

**Background:** Axial spondyloarthritis (axSpA) is associated with inflammatory bowel disease (IBD). In IBD patients, the clinical probability of axSpA increases in those with chronic back pain (CBP) whose symptoms started before the age of forty-five years old. In practice, this should trigger a rheumatology review especially if accompanied by other symptoms suspicious of inflammatory disease. However, in any health system, the goal of identifying all possible cases need to be balanced with the practical realisation of the finite resources available.

**Objectives:** The study aimed to define the clinical characteristics of a subgroup of IBD patients who are routinely managed in secondary care who have an increased clinical probability for axSpA. Identification of these characteristics may help improve the quality and specificity of referrals to Rheumatology from Gastroenterology clinics.

**Methods:** An analytical cross-sectional study was undertaken. Consecutive IBD patients attending routine Gastroenterology clinics were sent a modified validated back pain questionnaire. The questionnaire included the presence or absence of a previous diagnosis of axSpA; components of validated inflammatory back pain criteria; diaries to indicate the location of back pain and other musculoskeletal pain; personal and family history of known axSpA manifestations; and details of their IBD course, activity and treatment.

IBD patients, with back pain duration > 3 months with onset before 45 years were considered to have a medium diagnostic probability (MDP) for axSpA. MDP-positive IBD patients were compared with MDP-negative IBD patients and logistic regression was used to model the association with clinical features.

**Results:** Four hundred and seventy consecutive IBD patients (mean age 54 years; 46% male) were surveyed. Two hundred and nine patients (59%) replied, of whom 191 patients (69%) consented to participate. One hundred and seventy-three (91%) of those who consented had a valid completed questionnaire and were included for data analysis. Of these, 74% had Ulcerative Colitis and 26% had Crohn's disease. Their mean age was 58 years, 39% male. Mean age at IBD diagnosis was 39 years, mean IBD disease duration 19 yrs. CBP (back pain greater than three months) was reported by 76%. Inflammatory back pain fulfilling Calin, Berlin, ASAS criteria was seen in 23%, 29%, and 15% respectively. In addition, 80% reported peripheral musculoskeletal pain. Self-reported personal history of enthesis, reactive arthritis (ReA), acute anterior uveitis (AAU), skin psoriasis (PSO) and dactylitis were 50%, 30%, 24%, 15% and 0% respectively. Self-reported family history of IBD, ReA, PSO, axSpA and AAU were 60%, 36%, 22%, 11%, and 1% respectively. Ninety-one (53%) patients were MDP-positive and 82 (47%) patients were MDP-negative. The clinical characteristics associated with MDP (adjusted for age at invitation) were: the presence of inflammatory back pain using ASAS criteria [OR 8.84 (1.61, 48.67); P=0.01], longer interval between symptom onset and gastroenterologist diagnosis of IBD [OR 1.09 (1.03, 1.16); P=0.005], and use of rectal topical 5-aminosalicylic acid [OR 3.27 (1.19, 9.68); P<0.001].

**Conclusion:** Chronic back pain and peripheral musculoskeletal pain are common in a secondary care IBD population. In IBD patients, with back pain duration > 3 months and onset before 45 years, the presence of inflammatory back pain, longer diagnostic delay of IBD and the use of rectal topical 5-aminosalicylic acid were associated with a higher clinical probability of axSpA. The identification of these clinical features may not only improve the quality and specificity of Rheumatology referrals from Gastroenterology in this subgroup of patients but also lends real world evidence to current ASAS-endorsed recommendations for early referral of patients with a suspicion of axial spondyloarthritis.

with a peripheral arthritis. Rapid advances in the field of axSpA has led to faster detection, diagnosis and treatment of this disease. This improved management has led to improved level of function and quality of life for patients, despite this a proportion of patients are still requiring joint replacement surgery. The Ankylosing Spondylitis Registry of Ireland (ASRI) is a source of epidemiological data on patients with axSpA in Ireland. Given the large size of the ASRI to date, this is a prime opportunity to analyze patients with axSpA requiring joint replacement surgery.

**Objectives:** Detailed analysis of a large cohort of patients with axSpA with a focus on those who underwent joint replacement to determine trends in disease and baseline demographics.

**Methods:** The patient population registered in the ASRI was analysed using IBM SPSS version 26. Analysis was performed by comparing patients who underwent joint replacement surgery to the rest of the ASRI cohort. Mean age, disease duration, delay to diagnosis and scores of disease activity (BASDAI, BASFI, HAQ, ASQoL and BASMI) were compared between these two groups. Differences between the groups was tested for significance using an independent two tailed t-test. Further analysis on gender, HLA-B27 status, comorbidities and medication exposure was done using a chi-squared test for independence. A p value of less than 0.05 was deemed significant.

**Results:** At present 860 patients are currently enrolled in the ASRI with 76.6% (659) males and 23.4% (201) females. Average age of patients is 45.8 years, mean disease duration of 19.4 years with 95.5% (621) of patients listed as Caucasian. Mean scores were BASDAI 4.02, BASFI 3.7, BASMI 0.2, HAQ 0.55, and ASQoL of 6.51. In total 33 (3.8%) of patients underwent joint replacement surgery. These patients were noted to be significantly older than the rest of the cohort (55.3 years old vs 45.1, p<0.01), with a longer disease duration (316 years vs 18.3, p<0.01) and higher rates of HLA-B27 positivity (94.7% vs 80.2%, p<0.01). No significant differences were noted between gender(table 1). No significant difference was found between medication exposure rates, although the joint replacement population did have higher rates of NSAIDs, dMARDs and biologic therapy use than the rest of the population although this did not reach significance. These patients also scored worse in all measures of disease activity, although this only reached significance in the BASFI (5.67 vs 3.64, p<0.01), HAQ (0.9 vs 0.54, p<0.01) and the BASMI (6.07 vs 3.94, p<0.01).

**Conclusions:** Patients requiring joint replacement surgery, although few in number, represent a cohort with significantly impaired function and quality of life. This is likely due to the fact that these patients were older with more established disease. It is therefore not surprising that this cohort had significantly worse spinal mobility. As registries continues to develop, it will be interesting to see if rates of joint replacement surgery will decline with increased use of biologic therapy at an earlier stage of disease. This will help to differentiate patients requiring joint replacement surgery due to underlying inflammatory arthritis and those with osteoarthritis.

**Figure 1.**

**Conclusion:** This analysis shows that late onset AS does occur in up to 6.3% of patients with AS. Patients with late onset disease were noted to have similar patterns of disease, EAMs and radiological findings consistent with current
classification criteria for AS. Less patients with late onset disease were HLA-B27 positive, the reason for this is unknown. These patients had worse functional outcomes, which could reflect the older age of symptom onset. It is notable that patients with late onset AS are being treated with less biologic agents, and have a slightly higher rate of NSAID usage. Additional registry studies into this subgroup would help to understand these variations in medication usage and prescribing practices.

SAT0383

ENHANCED PERFORMANCE OF THE ASAS CLASSIFICATION CRITERIA BY DELETION OF NON-DISCRIMINATORY CLINICAL ITEMS: DATA FROM THE SCREENING IN AXIAL SPONDYLOARTHRITIS IN PSORIASIS, IRRITIS, AND COLITIS COHORT

W. P. Maksymowych1,2, R. Carmona3, J. Chan4, J. Yeung5, S. Aydin6, L. Martin7, A. Masetto8, O. Ziouzina9, S. Keeling1, S. Rohekar10, R. Dadashova11, J. Paschke12, A. Carapelliucci13, R. G. Lambert14, 1University of Alberta, Edmonton, Canada; 2CARE Arthritis, Edmonton, Canada; 3St. Joseph's Healthcare Hamilton, Hamilton, Canada; 4Artus Health Centre, Vancouver, Canada; 5James Yeung Rheumatology, Richmond, Canada; 6CARE Arthritis, Hospital, Ottawa, Canada; 7University of Calgary, Calgary, Canada; 8Université de Sherbrooke, Sherbrooke, Canada; 9Lawson Health Research Institute, London, Canada

Background: The ASAS classification criteria for axial spondyloarthritis (axSpA) have overall sensitivity/specificity of 82.9%/84.4% but component imaging and clinical arms differ in performance (66.2%/97.3% and 56.6%/83.3%, respectively)

Objectives: We aimed to demonstrate that a data-driven elimination of SpA clinical features that were not discriminatory in comparisons of patients diagnosed with and without axSpA in a prospective cohort of patients with undiagnosed back pain could enhance the performance of the criteria.

Methods: We used data from the prospective multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, AAU, or colitis undergone routine diagnostic evaluation by a rheumatologist for axial SpA, including imaging assessed by central readers. Univariable and multivariable logistic regression analysis was performed to determine which clinical SpA features were/were not discriminatory for the final diagnosis of axSpA. We then compared the sensitivity and specificity of the ASAS criteria with and without these features.

Results: A total of 246 patients were recruited, 47.6% being diagnosed with axSpA (61.5% male, age 33.7 years, symptom duration 7.6 years, B27 positive 52.1%). The following clinical SpA features were non-discriminatory between axSpA/not axSpA: NSAID response, family history of SpA, heel enthesitis, peripheral arthritis, dactylitis. Specificity of the clinical arm and the overall criteria increased from 82.2% to 66.6% without impacting sensitivity. This effect was particularly noteworthy in patients with lower degree of symptomatology (back pain severity <3/10, specificity increases from 76.7% to 90.7%), short symptom duration (<5 years, specificity increases from 78% to 84.7%), and in females (specificity increases from 80.6% to 86.1%).

Conclusion: In a prospective cohort with a high pre-test probability of axSpA certain clinical SpA features were not helpful in discriminating a diagnosis of SpA from not-SpA. Deletion of these features from the list of SpA features used in the ASAS classification criteria enhanced the performance of the criteria, especially in female patients and those with early disease.

SAT0384

REPLACEMENT OF RADIOGRAPHIC SACRILISITIS BY MRI STRUCTURAL LESIONS: WHAT IS THE IMPACT ON CLASSIFICATION OF AXIAL SPONDYLOARTHRITIS IN THE ASAS CLASSIFICATION COHORT?

W. P. Maksymowych1,2, P. M. Machado3, R. G. Lambert1, X. Baraliakos4, M. Ostergaard5, J. Sieper6, S. Wichuk7, D. Poddbury8, R. Rudwaleit1, D. Van der Heijde9, R. B. M. Landewé9, J. Paschke2, S. Juhl Pedersen5, U. Weber10,11, University of Alberta, Edmonton, Canada; 9CARE Arthritis, Edmonton, Canada; 3University College London, London, United Kingdom; 7Rheumazentrum Ruhrgebiet, Herne, Germany; 8Copenhagen University, Copenhagen, Denmark; 9Charité – Universitätsmedizin Berlin, Berlin, Germany; 9Klinikum Bielefeld, Bielefeld, Germany; 4Leiden University Medical Center, Leiden, Netherlands; 5University of Amsterdam, Amsterdam, Netherlands; 2University of Southern Denmark, Sønderborg, Denmark

Background: Classification of axial spondyloarthritis (axSpA) is based on either an imaging or clinical arm. Radiographic or MRI evidence of sacroiliitis can be applied for the imaging arm. However, it is well-established that reliability and sensitivity of radiographic sacroiliitis is inadequate.

Objectives: To assess the impact of replacing radiographic sacroiliac joints with MRI structural lesions (MRI-S) typical of axSpA on the number of patients classified as having axSpA in patients with undiagnosed back pain recruited to the ASAS Classification Cohort (ASAS-CC)

Methods: MRI images of the sacroiliac joint (SIJ) were available from 217 cases in the ASAS-CC, which also had clinical, laboratory, and radiographic data. Seven central readers from the ASAS-MRI group recorded MRI lesions in an eCRF that included active (MRI-A) and structural (MRI-S) lesions typical of axSpA. MRI-A was deemed to be present according to majority agreement (≥4/7) of central readers. MRI-S was deemed to be present according to the majority (majority reader MRI-S) and also according to at least 2 central readers (≥2-reader MRI-S). We calculated the number of patients that were classified differently after replacement of radiographs by MRI-S for overall fulfillment of the ASAS criteria and for the imaging arm.

Results: In total, 119 (54.8%) cases fulfilled the axSpA criteria based on local reading of radiographic sacroiliac joints and central reading of active inflammation on MRI. This changed to 125 (57.6%) and 118 (54.4%) cases of after replacement of radiographic sacroiliac joints by ≥2-reader and majority reader MRI-S, respectively (Table). A total of 13 (6.0%) and 7 (3.2%) cases were classified as not having axSpA after replacing radiographic sacroiliac joints by ≥2-reader and majority reader MRI-S, respectively. Conversely, 7 (3.2%) and 8 (3.7%) cases were re-classified as not having axSpA after substitution by ≥2-reader and majority reader MRI-S. When fulfillment of the imaging arm was the primary consideration (irrespective of the clinical arm), the number of patients reclassified from not axSpA to axSpA was 25 (11.5%) by ≥2-reader and 13 (6.0%) by majority reader MRI-S, while 8 (3.7%) and 11 (5.1%) were reclassified from axSpA to not axSpA.

Conclusion: The number of patients classified as having axSpA does not change substantially when MRI-S replaces radiographic sacroiliitis. However, it remains possible that MRI structural lesions can influence the final diagnosis, the gold standard for assessment of the performance of the ASAS criteria.

SAT0386 USEFULNESS OF THE Fecal CALPROTECTIN AS SCREENING TOOL FOR INFLAMMATORY BOWEL DISEASE IN PATIENTS WITH SPONDYLOARTHRITIS AND NO Diagnostic SYMPTOMS

C. Merino Arangozú1, M. Espinosa1, C. Ramos Giráldes2, O. Rusinovich1, N. De la Torre3, J. Campos Esteban3, Y. Gonzalez Lama3, V. Matalana1, M. Caño Moya4, B. Ruiz Antorán5, I. Vera1, G. Vázquez1, J. L. Andrés Sánchez1, J. Sanz6. 1Hospital Universitario Puerta de Hierro, Majadahonda, Spain; 2Hospital Universitario Virgen de Valme, Sevilla, Spain

Background: Fecal calprotectin (FC) is a biomarker of bowel inflammation widely spread in diagnosis and follow-up of inflammatory bowel disease (IBD). It is classically estimated that 5% of patients with axial spondyloarthritis (SpA) also have IBD; coexistence of both conditions has definite impact in clinical decisions. Proactive detection of both diseases should be advisable, though appropriate screening tools are still lacking.

Objectives: To evaluate the usefulness of FC for the diagnosis of IBD in patients diagnosed with SpA with no clinical suggestive manifestations or previous diagnosis of IBD.

Methods: Patients from a Rheumatology clinic diagnosed with SpA who met ASAS criteria and did not present digestive symptoms suggestive of IBD were consecutively included. Demographics, clinical and analytical data of FC (uveitis, HLA B27, acute phase reactants) at the time of inclusion, and treatment history were collected. Patients with a positive FC (> 50 mg/kg) underwent ileocolonoscopy with biopsies of colon and terminal ileum. Patients who were recommended to avoid NSAIDs 2-4 weeks before stool collection and endoscopy. Patients with no endoscopic findings underwent a second determination of fecal calprotectine. If persisted positive, capsule endoscopy was performed to evaluate small intestine.

Results: 98 patients included; 47% male, mean age 46.1 (20-74) years. BASDAI 3.6 ± 2.5. HLA B27 positive in 78% of patients, high ESR in 31.6%, high CRP in 30.6% of patients. HLA B27 was higher in smokers (72%/44%; p=0.03). There were no significant differences regarding HLA B27. No statistically significant differences were found in FC between patients with high FC who were diagnosed with IBD and those who were not.

Conclusion: In our study, patients with SpA and no clinical feature suggestive of IBD who showed FC > 50 mg/kg had high prevalence of IBD, which could indicate the usefulness of FC as screening tool for IBD in patients with SpA. Patients with SpA and other immune-mediated condition or elevated CRP, seemed to be more likely to have subclinical IBD.

SAT0388 CHROMOENDOSCOPY AND MAGNIFICATION: COLONOSCOPY: ANALYSIS OF THE MUCOSA OF THE COLON AND ILEUM IN PATIENTS WITH SPONDYLOARTHRITIS AND GASTROINTESTINAL SYMPTOMS WITHOUT INFLAMMATORY BOWEL DISEASE

C. Flores1,2, V. Parra-Izquierdo1,2, W. Bautista-Molano1,2, Y. M. Chamorro-Melo1, A. Beltrán-Ostos3, D. Jaimez1, J. De Avila4, A. Ramos-Casallas5, D. Acero-M1, M. J. Bello-Guaitero1, J. Gutiérrez-Sánchez2, C. F. Pacheco Tena1, L. Chilá1, P. Chalem4, C. Romero-Sánchez4,1. 1Grastroadvanced SAS, Bogotá, Colombia; 2Universidad El Bosque, School of Dentistry, Cellular and Immunology Group -INMUBO-, Bogotá, Colombia; 3Universidad Nueva Granada, Clinical Immunology Group, Bogotá, Colombia; 4Hospital Militar Central, Rheumatology and Immunology Department, School of Medicine, Bogotá, Colombia; 5Hospital Militar, Subdirección de docencia e Investigación, Bogotá, Colombia; 6Clínicos IPS, Bogotá, Colombia; 7Investigación y Biomedicina de Chihuahua, Chihuahua, Mexico; 8Instituto de Genética Humana, Facultad de Medicina, Pontificia Universidad Javeriana, Bogotá, Colombia

Background: Digital chroendooscopy with magnification is a technique that identifies microscopic inflammation, with a better characterize, highlighting specific gastrointestinal findings showing a good correlation with histopathological features. Spondyloarthritids (SpA) patients with the presence of non-specific gastrointestinal symptoms, subclinical intestinal inflammation is defined by endoscopic and histological techniques.

Objectives: To detect early structural inflammatory changes by chroendooscopy and magnification colonoscopy in colonic/ileum digestive mucosa and establish its association with clinical variables in patients with SpA and gastrointestinal symptoms.
Methods: In total, 180 patients with SpA (ASAS/criteria) were assessed by rheumatologists, of which (n=35) (19.4%) had an indication to a gastrointestinal refer to perform the chromoendoscopy, magnification colonoscopy and histological analysis. The association between clinical and colonoscopy variables were evaluated using the Chi square or Fisher's exact test. (Ethical/Code. 2017-023)

Results: The average age of the patients included for colonoscopy was 45.4±10.3 years, 57.1% were men and 42.9% presented the HLA-B*27 allele. Axial involvement (91.4%), inflammatory back pain (68.6%) and use of biological therapy (71.4%) were associated with higher CRP levels (p=0.013), positive ANCA (8.6%) was associated, significantly higher fatty degeneration in the sacroiliac joint (p=0.029) and higher spinal ankylosis (p=0.052) respectively. The 50% of patients with atrophy of villi in ileum were receiving biological therapy (p=0.035).

Conclusions: Digital chromoendoscopy and magnification colonoscopy provided an improved and detailed contrast of the surface of the gastrointestinal mucosa. The tissue sampling showed the loss of vascular pattern as main finding in ileum with interesting associations with fecal calprotectin levels in patients with SpA.

Results: Lipid profiles showed that most lipid panel parameters (total cholesterol, HDL and LDL-cholesterol, lipoprotein A and apolipoprotein A1) were lower in SpA patients compared to controls. Contrary, Apo B/Apo A1 and LDL/HDL cholesterol ratios were higher in SpA. The mean PCSK9 serum levels were significantly lower in SpA patients compared to controls (249± 105 vs. 199 ± 74, ng/ml, p=0.000) in the univariate analysis. An additional multivariable analysis, adjusted for standard CV risk factors, was performed to evaluate the influence of PCSK9 on SpA related dyslipidemia, disease related data, and subclinical carotid atherosclerosis.

SAT0390

PROPROTEIN CONvertase SUBTILISIN/KEXIN TYPE 9 IN THE INFLAMMATION-RELATED DYSPLIPIDEMIA OF PATIENTS WITH SpondyloArthritis

J. C. Quevedo-Abeledo1, L. De Armas-Rillo1, V. Hernández-Hernández2, D. F. Esmeralda3, A. De Vera-González4, A. Delgado-González5, J. García-Dopico6, I. Ferraz-Amaro7, 1Division of Rheumatology, Hospital Dr Negrín de Las Palmas de Gran Canaria, Spain, Las Palmas de Gran Canaria, Spain; 2Universidade Europea de Canarias, Santa Cruz de Tenerife, Spain; 3Division of Rheumatology, Hospital Universitario de Canarias, Tenerife, Spain, Santa Cruz de Tenerife, Spain; 4Division of Central Laboratory, Hospital Universitario de Canarias, Tenerife, Spain, Santa Cruz de Tenerife, Spain

Background: Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a serine protease that regulates cholesterol metabolism through low-density lipoprotein receptor degradation and that has been linked with cardiovascular (CV) risk. Patients with spondyloarthropathies (SpA) are prone to an increased and premature prevalence of atherosclerosis that has been linked to an atherogenic lipid profile among these individuals.

Objectives: The purpose of the present study was to examine whether PCSK9 levels are related to both abnormalities in the lipid profile and the severe atherosclerosis that occur in patients with SpA.

Methods: Cross-sectional study that encompassed 545 individuals; 299 patients with SpA and 246 statin intake-matched controls. PCSK9 and lipoproteins serum concentrations, standard lipid profile and carotid intima-media thickness and carotid plaques were assessed in patients and controls. A multivariable analysis, adjusted for standard CV risk factors, was performed to evaluate the influence of PCSK9 on SpA related dyslipidemia, disease related data, and subclinical carotid atherosclerosis.

Results: Lipid profiles showed that most lipid panel parameters (total cholesterol, HDL- and LDL-cholesterol, lipoprotein A and apolipoprotein A1) were lower in SpA patients compared to controls. Contrary, Apo B/Apo A1 and LDL/HDL cholesterol ratios were higher in SpA. The mean PCSK9 serum levels were significantly lower in SpA patients compared to controls (249± 105 vs. 199 ± 74, ng/ml, p=0.000) in the univariate analysis. An additional multivariable analysis, adjusted for demographics and CV risk factors plus all the lipid-related molecules (that were found to be different between patients and controls) disclosed that PCSK9 (beta coeff. -44 [95%CI -60 - -27] % mg/dl, p=0.000) conserved its significant association with SpA patients without plaque, however, this difference was lost after multivariable analysis.

Conclusion: PCSK9 is downregulated in SpA patients independently of other inflammatory risk profile modifications that occur in the disease. Disease activity is positively associated with PCSK9 serum levels. PCSK9 is univariately related to the presence of carotid plaque.
Background: Since publication of the ASAS classification criteria for axial spondyloarthritis (axSpA) in 2009 and the development of ASAS-endorsed recommendations for early referral of patients with a suspicion of axSpA, awareness for non-radiographic (nr-) axSpA besides Ankylosing Spondylitis (AS) has increased. Still there is limited information of how nr-axSpA is addressed in daily clinical practice.

Objectives: To get insight into the diagnostic phase of axSpA in daily rheumatologic practice in the Netherlands, and to explore if nr-axSpA is addressed differently from AS.

Methods: We set up a 21 multiple choice question survey for rheumatologists in the Netherlands with 5 general questions about their practice and 16 questions addressing the diagnostic phase of axSpA. The questionnaire was taken by representatives of the medical department of Novartis NL during structured face-to-face interviews. Rheumatologists in the Netherlands were invited to participate, aiming to get a sample of rheumatologists varying in geographical location and hospital type, as well as a mix of SpA-experts and non-SpA-experts. Rheumatologists gave approval for anonymous use of the data, which were entered in a database and subsequently analyzed using descriptive statistics.

Results: From October 15th 2019 until January 16th 2020, 36 Dutch rheumatologists participated in the face-to-face survey; 6 from university hospitals, 27 from general hospitals and 3 from private care centers. Most of axSpA patients (61%) were referred by the general practitioner and mean time between referral and first visit was 2-6 weeks. More than 50% of rheumatologists reported a mean symptom duration of >1 year and in 30% even >2 years before first visit. For diagnosing axSpA rheumatologists performed in almost all cases X-pelvis (mean 100% (SD 0%) for both AS and nr-axSpA), CRP/ESR (91% (26%) for AS; 94% (22%) for nr-axSpA) and HLA-B27 (74% (40%) for AS; 86% (26%) for nr-axSpA). MRI of the SI joints was performed in 31% and 82% of patients, respectively, and about 60% of the rheumatologists used classification criteria for diagnosing axSpA. In addition, rheumatologists marked the level of importance of several (SpA) clinical features for making the diagnosis AS or nr-axSpA (Figure 1). Most rheumatologists graded inflammatory back pain, arthritis/enthesitis/dactylitis and uveitis as very important for contributing to the diagnosis. Functional impairment of the spine and male sex were mostly graded neutral or not important for making a diagnosis of axSpA. All features were graded of similar importance for the diagnosis AS and nr-axSpA, except for backpain starting before the age of 45, which was considered more important for diagnosing AS.

Conclusion: This survey among Dutch rheumatologists showed that in 30% of patients referred with possible suspicion of axSpA, symptom duration still was >2 years. Almost 60% of rheumatologists make use of the ASAS classification criteria for diagnosing nr-axSpA. Therefore, for early referral awareness of axSpA in first line should enhance. Furthermore, rheumatologists should become aware that classification criteria are not similar to diagnostic criteria and cannot be used as a tick box for diagnosis.

Acknowledgements: We would like to thank all participating rheumatologists.

SAT0393

DISCREPANCY IN THE CARDIOVASCULAR RISK SEVERITY CALCULATED USING DIFFERENT RATING SCALES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

F. Vasilenko1, V. Mazurov2, R. Samigullina2, A. Dadalova2, I. Gaydukova2, 1North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E. Ichchad, St. Petersburg, Russian Federation;
Background: Cardiovascular risk (CVR) in patients (pts) with axial spondyloarthritis (axSpA) exceed the populational level. However, it remains unclear, which of the cardiovascular risk assessment systems is the most accurate in cases of chronic inflammation.

Objectives: of the current study were to assess the CVR in pts with axSpA and to compare different cardiovascular risk scales in these pts.

Methods: The study included 118 patients at the age of 25-65 years with diagnosis of axSpA fulfilling ASAS criteria (2009) from St. Petersburg's axSpA register. Three indices of cardiovascular risk evaluation (Systematic Coronary Risk Evaluation (SCORE) with increasing coefficient 1.5 for inflammatory diseases, Reynolds Risk Score (RRS), and the third modification of QRESEARCH Cardiovascular Risk Algorithm (QRISK3)) were calculated. For the pts below 40 years old only QRISK3 was calculated.

Results: Mean age of the pts was 44.3±11.1 years; 91(77.1%) pts were males, HLA-B27 positive – 83 (70.3%) of the pts; mean disease duration 13.0±8.3 years. Mean value of SCORE was 2.78±1.89%, of RRS – 5.28±3.31%, of QRISK3 – 7.91±3.8% (figure 1). Cronbach’s alpha for the scales was 0.873. Mean value of SCORE was 2.78±1.89%, of RRS – 5.28±3.31%, of QRISK3 – 7.91±3.8% (figure 1). Cronbach’s alpha for the scales was 0.873. High CVR (≥5%) was found in 14 (11.7%) of the pts according to the SCORE, in 65 (55.1%) of the pts according to the RRS, and in 81 (69%) of the pts according to the QRISK3. Ranking of CVR severity did not match in SCORE and QRISK3 indices in 83.72% of cases, in SCORE and RRS – in 51.16% of cases, and in QRISK3 and RRS in 8% of cases. The SCORE index showed the lower values of the expected risk as compared to the QRISK3 and RRS (figure 1). In axSpA pts at age 25-40 years old (n=46), mean age 32.6±4.0 years, males 36 (78.3%), mean value of QRISK3 was 1.16±0.99 %; in 14 from 46 (30.4%) of those pts increased CVR was registered (figure 2).

Conclusion: There was a discrepancy in the severity of CVR calculated using different rating scales in axSpA patients. The SCORE index showed lower values of CVR as compared to the QRISK3 and RRS, which hypothetically could be the consequence of CVR underestimation. QRISK3 demonstrated the highest CVR and was the only index useful in pts below 40 years old. To exclude hyper- or underestimation of CVR calculation more data about CVR calculations and frequency of CV events, occurring in axSpA patients are needed.

Conclusion: In one year follow-up, IBD occurrence rate was 0.73/100 patient-year, at a similar rate with DESIR cohort [2]. However, FC level may be a predictor for the development of IBD in SpA patients (occurrence rate 4.34/100 patients year). Further follow up duration and more patients may be needed to make conclusion in these field.

Conclusion: Living alone - as a proxy for social isolation - was associated with more severe disease and poorer quality of life in axSpA patients, independent of depression and other confounders. Further studies are needed to examine the direction of causation, and whether lack of social support influences their ability to seek and/or benefit from healthcare provision.

Table 1. Impact of social isolation (living alone) on disease severity measures in axial spondyloarthritis.
of all studies was observational and longitudinal with data from national registries except one cross-sectional. In total, these studies included 5291 patients (3917 patients for smoking and 1333 patients for obesity), all treated with a TNF inhibitor (iTNF). The Oxford level of evidence for all studies was 2b except the cross-sectional study, which was 4. Regarding smoking, the evidence found is not consistent. Two of the studies concluded an unfavorable effect on the response to the iTNF (Glintborg and Ciurea) but the remaining 4 studies found no differences in the clinical response to iTNF (Zhao), the cause of discontinuity of the iTNF (Zhao, Hernandez) or quality of life indexes (Kydd). For obesity, the evidence is more consistent, so that 5 of the 6 studies observed a negative influence on the therapeutic response to iTNF (Ottaviani, Gremerse, Michieroli, Hernandez-Brejo and Rosas).

Conclusion: According to scientific evidence in patients with axSpA, obesity is associated with a worse therapeutic response to iTNF. However, this negative effect is not clearly evidenced for smoking.

Psoriatic arthritis

GUSELKUMAB, AN IL-23 INHIBITOR THAT SPECIFICALLY BINDS TO THE IL23P19-SUBUNIT, FOR ACTIVE PSORIATIC ARTHRITIS: ONE YEAR RESULTS OF A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF PATIENTS WHO WERE BIOLOGIC-NAÏVE OR TNF Α INHIBITOR-EXPERIENCED

1U Rochester Med Ctr, Rochester, United States of America; 2U Leeds, Leeds, United Kingdom; 3Geneva U Hospitals, Geneva, Switzerland; 4Janssen Research & Development, LLC, Spring House, United States of America; 5U Penn Med Ctr, Philadelphia, United States of America; 6Oregon Health & Science U, Portland, United States of America

Background: Guselkumab (GUS), a monoclonal antibody that specifically binds to the p19-subunit of IL-23, is approved to treat PsO. At Week24 (W24) of the Phase 3, double-blind, PBO-controlled trial in pts with active PsA who
were biologic-naïve or prior TNF inhibitor (TNFi)-treated (DISCOVER-1), GUS 100 mg, given every 4/8 weeks (Q4W/Q8W), demonstrated efficacy for joint & skin symptoms, physical function & quality of life vs PBO; AEs were consistent with GUS safety in PsO. 

Objectives: Assess GUS efficacy & safety in PsA through 1 year.

Methods: Adults with active PsA (≥3 swollen + ≥3 tender joints; CRP ≥0.3 mg/dL) despite standard therapies were eligible. Approx. 30% of pts could have previously received ≤2 TNFi. Pts were randomized 1:1:1, stratified by W0 DMARD [Y/N] & prior TNFi [Y/N] use, to GUS 100 mg at W0, W4 & Q8W; or PBO. At W24, PBO pts crossed over to GUS 100 mg Q4W (PBO X Q4W). W48 marked the last dose of study agent. ACR response rates at W52, based on nonresponder imputation (NRI) for missing data and as observed in pts still on study agent at W24, are shown. Observed data for additional endpoints are shown. AEs through W60 are reported.

Results: 362/381 (95%) randomized pts continued study agent at W24 (125 Q4W, 123 Q8W, 114 PBO X Q4W). 347/381 (91%) pts completed treatment & 343/381 (90%) completed study. NRI ACR20 response rates were maintained at W52 (Q4W 73%, Q8W 60%; Fig 1A). Similar responses patterns were seen for the more stringent ACR50/70 criteria (Fig 1C,E). Observed ACR responses, overall (Fig 1B,D,F) and in pts with (Fig 2A,C,E) & without (Fig 2B,D,F) prior TNFi use, were also maintained at W52. Improvements in most clinical outcomes were generally consistent with other GUS-treated pts by W52 (Table 1). Through W24, 4 (2%) GUS- and 5 (4%) PBO-treated pts had serious AEs; no GUS-treated and 2 (2%) PBO-treated pts had a serious infection. Through W60, serious AEs and serious infections occurred in 4% & 1%, respectively, of all 369 GUS-treated pts; no GUS-treated pt died or had IBD, opportunistic infections or active TB, or anaphylactic or serum sickness-like reactions.

Conclusion: GUS Q4W & Q8W maintained improvements in joint symptoms through 1 year in pts with active PsA who were biologic-naïve or previously TNFi-treated. In pts continuing in the study, improvements in skin symptoms, dactylitis, enthesitis, physical function & quality of life were also maintained through 1 year. GUS 100 mg Q4W & Q8W were safe and well-tolerated through study completion and consistent with GUS safety in PsO.

Acknowledgments: None

Background: Several biologic DMARDs (bDMARDs) exist for PsA, TNFi and UST and are being used on European markets. When bDMARDs are insufficiently effective, later-line bDMARDs typically have shorter persistence. Treatment persistence reflects a mix of effectiveness and adverse events (AEs), and persistence data are limited in PsA.

Objectives: Comparative analysis of 1-year persistence of UST and TNFi within the prospective PsABo cohort.

Methods: PsABo is an observational, multinational study of PsA patients (pts) treated with 1st to 3rd line UST or TNFi at their rheumatologist’s discretion. Treatment persistence (up to 15 months of follow-up) was defined as time between start of first bDMARD treatment in PsABo, and either stop or switch to another bDMARD, or withdrawal. Persistence of UST and TNFi is shown by Kaplan-Meier curves and compared using Cox regression analysis, with propensity score (PS) to adjust for baseline imbalanced demographic and disease-related covariates (age, sex, bDMARD line, BMI, Clinical Disease Activity Index for Psoriatic Arthritis [dCAPSA], 12-item PsA Impact of Disease [PsAID-12], Fibromyalgia Rapid Screening Tool [FiRST] score, co-treatments with MTX, NSAIDs, glucocorticoids, cardiovascular/metabolic comorbidities, dactylitis, enthesitis and body surface area [BSA]). Factors including concomitant MTX use and skin involvement: <3%, 3–10% and >10%, were added to the Cox model to investigate their impact on the PS-adjusted treatment effect.

Results: Of 438 and 455 pts who started UST and TNFi, respectively, 121 (28%) and 134 (29%) stopped or switched treatment before Month 15, with differences (as expected) according to treatment line (Fig. 1a, b). Reasons for stop/switch were related to safety/AEs in 12% (UST) and 28% (TNFi), and effectiveness (joints, nails or skin) in 77% (UST) and 69% (TNFi) of pts. The observed mean time on drug was 397 days for UST and 385 days for TNFi (1st line 410/397 days, 2nd 390/382 days, 3rd 381/338 days). Fig. 1b shows similar persistence for all drugs and treatment lines, except for lower persistence in TNFi 3rd line vs 1st/2nd. In PS-adjusted Cox analysis, no statistically significant difference between UST and TNFi persistence was seen; hazard ratio (HR; 95% CI) for stop/switch bDMARD (UST vs TNFi) was 0.82 (0.60, 1.13). In the model, bDMARD monotherapy (without MTX) and extensive skin involvement (BSA >10%), showed significantly better persistence for UST (HR 0.61 [0.42, 0.95]) for stop/switch bDMARD (UST vs TNFi) was 0.82 (0.60, 1.13). In the PS-adjusted Cox model, no significant effects were observed.

Conclusion: In this real-world PsA cohort undergoing bDMARD treatment, persistence was generally comparable for UST and TNFi, but some clinical situations led to better drug persistence with UST compared to TNFi – particularly monotherapy, more extensive skin involvement, and in 3rd-line treatment. Our data emphasise the importance of skin involvement for pts with PsA.

Any A1

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis that causes pain, stiffness and swelling around the joints. PsA is reported to affect between 10 and 40% of individuals with psoriasis and in the majority of patients presents after, or synchronously with, psoriasis onset. Osteoarthritis (OA) is a common form of non-inflammatory arthritis related to joint degeneration and typically commences late in the fifth decade. PsA and OA have long been considered two distinct arthropathies, however they do have some overlapping features and symptoms and in certain circumstances it can be difficult to differentiate between them, particularly in the small joints of the hands or spine.

Objectives: To determine the risk of a diagnosis of osteoarthritis in psoriatic arthritis patients compared to patients with psoriasis and a general population cohort.

Methods: Incident PsA patients aged 18-89 years at diagnosis were identified from the UK Clinical Practice Research Datalink between 1998 and 2014. All PsA patients were matched to a cohort of patients with psoriasis and a general population cohort (with no psoriasis or PsA) at a 1:4 ratio based on index date, year of birth, sex and general practice. The baseline prevalence of OA of any site was calculated as a percentage for each study cohort and then those prevalent cases were excluded from the numerators and denominators of the incidence calculations. The incidence of OA was calculated and relative risks (RRadj), adjusting for body mass index (BMI), were calculated using conditional Poisson regression.

Results: In total, 6,783 incident PsA patients were identified. The baseline prevalence of OA ranged from 22.1% (CI95 12.2-13.0) and 11.0% (CI95 10.6-11.3) in the psoriasis and general population cohorts respectively. The incidence of OA was significantly higher in the PsA cohort compared to the psoriasis and general population cohorts after adjusting for BMI (RRadj 1.68 CI95 1.46-1.93 and RRadj 1.86 CI95 1.62-2.14 respectively) (Tables 1 and 2).

Conclusion: An increased risk of OA was observed in patients with PsA compared to patients with psoriasis alone and those in the general population. Further work is needed to determine whether this reflects a true increase in OA risk or misdiagnosed PsA and the extent to which it can be explained by differences in the opportunity for OA diagnosis between cohorts.

EVIDENCE FOR “DEEP KOEBNERISATION” AT BOTH THE ENTHESIS AND VASCULAR BIFURCATIONS AS A NOVEL MECHANISTIC LINK BETWEEN PSORIATIC ARTHRITIS AND CARDIOVASCULAR DISEASE- RESULTS OF PILOT ULTRASOUND STUDIES OF JOINTS AND ARTERIES

I. Tinazzi1, G. Citritni2, N. Girolimetto2, F. Martinis1, C. Salvarena2, D. McGonagle1, P. Macchioni2, 1IRCCS “Sacro Cuore Don Calabria” Hospital, Negrar VR, Italy; 2Modena Reggio Emilia University, Modena, Italy; 3AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy; 4Leeds Teaching Hospitals Trust, Leeds, United Kingdom

Background: The association between PsA and cardiovascular disease is generally thought to be greater than the risk between psoriasis and cardiovascular disease. Vascular calcifications (VC) are considered an early marker of atherogenesis and accurate VC scores including Carotid, Aortic and Lower limbs vascular Calcifications (CALCs) were published. PsA localises to entheses that are sites of high physical stressing, analogous to artery bifurcations which are sites of high vascular stress. Enthesal calcification is a feature of the post-inflammatory changes. We hypothesised that there may be common “deep koebnerisation” responses in the entheses and vessels in PsA as a common biomechanical response specifically linking PsA with cardiovascular disease.

Objectives: To quantify non-coronary VC in a consecutive series of PsA patients using CALCs and compare PsA patients with CV risk factors to the group without. To independently evaluate sonographic enthesal changes including new bone formation and to determine if the magnitude of vascular and enthesal lesions was linked.

Methods: 122 adult PsA patients diagnosed according to the CASPAR criteria underwent US assessment for the presence of VC according to CALCs. Carotid arteries intima-media thickness (IMT) was also measured. Blinded to this US assessment, further US imaging of 12 large enthesal sites was performed. The presence of enthesophytes was scored dichotomously for each site and summed up to generate the ARES score. Enthesophytes were scored semi-quantitatively in a 0-3 scale according to previous studies to generate RESS. Enthesal inflammatory changes were identified according to OMERACT definitions.

Results: Overall, 83 patients were female (68%), mean age 58.6±10.3 y and mean PsA duration 9.5±7.0 y. PsA with obesity, metabolic syndrome and hypertension presented higher IMT values. The IMT scores correlated significantly with enthesal thickness (p< 0.001). A statistical significant correlation was found between CALCs with enthesophytes scores ARES and RESS ( spearman rho = 0.665, p < 0.001 and 0.634, p < 0.001 respectively). CALCs, ARES and RESS were significantly increased in patients with CV risk factors or an history of CV events, compared with patients without (table 1). No significant correlation was found between CALCs and PsA duration (Spearman rho = 0.132, p = 0.135).

Conclusion: In PsA patients vascular and enthesal calcifications are significantly correlated. Patients with CV risk factors and/or history of CV events have higher values of CALCs, ARES and RESS. This suggests possible commonalities between entheses and vessels that might represent a deep Koebnerisation response in arteries and entheses. This raises the possibilities that the primary joint inflammatory responses and what is viewed as a comorbidity are closely linked.
Swollen joints demonstrate higher agreement with US synovitis (PD≥1 or PD≥2) than tender joints in early PsA. In addition, joints that are tender but not swollen have poor correlation with US synovitis at the individual joint level indicating swelling is a better clinical discriminator of active synovitis, and factors other than synovial inflammation may drive tenderness in very early DMARD naïve PsA. These results suggest reappraisal of clinical joint counts is needed to refine treatment decision making in early PsA.

Conclusion: Swollen joints demonstrate higher agreement with US synovitis (PD≥1 or GS ≥2 & PD ≥1 combined) than tender joints in early PsA. In addition, joints that are tender but not swollen have poor correlation with US synovitis at the individual joint level indicating swelling is a better clinical discriminator of active synovitis, and factors other than synovial inflammation may drive tenderness in very early, DMARD naïve PsA. These results suggest reappraisal of clinical joint counts is needed to refine treatment decision making in early PsA.

†Randomized pts still on study agent at W24; N=22; ‡N=237

Efficacy and Safety of Gusekumab, a Monoclonal Antibody Specific to the P19-Subunit of Interleukin-23, Through Week 52 of a Phase 3, Randomized, Double-Blind, Placebo-Controlled Study Conducted in Biologic-Naïve Patients with Active Psoriatic Arthritis

1NIHR LBRC, Leeds Teaching Hospitals Trust & LIRMM, University of Leeds, Leeds, United Kingdom
2Universitaria Medical Ctr/Providence St Joseph Health and U Wash School of Med, Seattle, WA, United States of America
3University of California, San Diego; 4iThemba School of Med Mt Sinai, New York, United States of America; 5Lisbon Research Institute, LRCDO, Spring House, United States of America; 6Leiden Univ Medical Ctr, Leiden, Netherlands; 7Swedish Med Ctr/ Providence St Joseph Health and U Wash School of Med, Seattle, United States of America

Background: Gusekumab (GUS), a monoclonal antibody that specifically binds to the p19-subunit of IL-23, is approved to treat psoriasis. Through Week 24 (W24) of the Ph3, double-blind, placebo (PBO)-controlled trial in biologic-naïve pts with active PsA (DISCOVER-2), GUS every 4 or 8 weeks (Q4W or Q8W) demonstrated efficacy for joint & skin symptoms and inhibition of structural damage progression (Q4W), and was well tolerated.

Objectives: Assess GUS efficacy and safety through W52.

Methods: Biologic-naïve adults with active PsA (≥5 swollen ≥5 tender joints; CRP ≥0.6mg/dL) were randomized (1:1:1) to GUS 100mg Q4W, 200mg Q4W, or PBO. At W24, PBO pts crossed over to GUS 100mg Q4W (PBO X Q4W). ACR response rates at W52, based on nonresponder imputation (NRI) for missing data and as observed in pts who continued study agent at W24, were shown. Observed data for additional endpoints, including PsA-modified van der Heijde Sharp (vdH-S) scores derived from blinded radiographic images collected at W0, W24, W52 (or at d/c) and scored in a New Read Campaign, are shown.

Results: 712/739 (96.3%) randomized & treated pts continued study agent at W24. 689/739 (93.2%) completed W52; 689/739 (93.2%) completed W52. NRI ACR20 response rates continued to increase after W24, and at W52 were 70.6% for GUS Q4W and 74.6% for GUS Q8W (Fig 1A). Similar response patterns were observed for the more stringent ACR50/70 criteria (Fig 1C,E). Observed ACR (Fig, 1B,D,F), IGA, PASI & MDA/VLDA responses; dactylitis & enthesis resolution; and mean improvements in HAQ-DI and SF-36 PCS/MCS scores were also sustained through W52 in pts receiving Q4W & Q8W; W52 data for PBO X Q4W pts were generally consistent with other GUS-treated pts (Fig 1, Table 1). Changes in vdh-S scores were
similar for W24-52 (0.62) and W0-24 (0.46) for Q4W; less radiographic progression occurred from W24-52 v W0-24 for Q8W (0.23 v 0.73) & PBO X Q4W (0.25 v 1.00). In 731 GUS-treated pts, 4.2% had SAEs; 1.2% had serious infections; no pt died; and no pt had IBIs, opportunistic infections or active TB, or anaphylactic or serum sickness-like reactions. **Conclusion:** In biologic-naïve pts with active PsA, GUS elicited sustained improvements in joint & skin symptoms; inhibition of radiographic progression & improvements in physical function, quality of life & composite indices through W52. GUS safety in PsA was similar at W24 & W52 and consistent with GUS safety in psoriasis.

**SAT0403 EFFICACY AND SAFETY OF 108 WEEKS’ BIMEKIZUMAB TREATMENT IN PATIENTS WITH PSORIATIC ARTHRITIS: INTERIM RESULTS FROM A PHASE 2 OPEN-LABEL EXTENSION STUDY**

I. McInnes, J. F. Merola, P. J. Mease, L. C. Coates, P. Joshi, J. Coarse, B. Ink, T. C. Ritchlin. 1University of Glasgow, Glasgow, United Kingdom; 2Harvard Medical School, Brigham and Women’s Hospital, Boston, United States of America; 3Swedish Medical Center and University of Washington, Seattle, United States of America; 4University of Oxford, Oxford, United Kingdom; 5UCB Pharma, Slough, United Kingdom; 6UCB Pharma, Raleigh, United States of America; 7University of Rochester Medical Center, Rochester, United States of America

**Background:** Bimekizumab (BKZ), a monoclonal antibody that selectively neutralises IL-17A and IL-17F, has shown clinical improvements in skin and joint outcomes over 48 weeks (wks) in patients (pts) with active psoriatic arthritis (PsA).1

**Objectives:** To report 2-year interim results from a phase 2b dose-ranging study (BE ACTIVE; NCT029669525) and open-label extension (OLE; NCT03347110) of BKZ in pts with PsA.

**Methods:** Design of the dose-ranging study is described elsewhere.1 Pts who completed 48 wks’ BKZ treatment without meeting withdrawal criteria were eligible for OLE entry. All OLE pts received BKZ 160 mg Q4W, irrespective of prior dosing regimen. Data are presented from dose-ranging study baseline (BL) to OLE Wk 60 (Wk 108 total). Efficacy outcomes are reported for the full analysis set (FAS); pts who received ≥1 dose BKZ (specifically those randomised to 160 mg) with ≥320 mg loading dose (LD), or 320 mg at BL, with BL efficacy measurements to allow subsequent determination of ACR50. Outcomes include ACR20/50/70, body surface area (BSA) 0%, minimal disease activity (MDA), and enthesis/dactylitis resolution. Rates of treatment-emergent adverse events (TEAEs) are reported for the Safety Set (SS; pts who received ≥1 dose BKZ in the dose-ranging study).

**Results:** BL mean (SD) tender/swollen joint counts were 21.7 (15.7) and 11.2 (8.4), 80 (65.0%) pts had BSA ≥3% and dactylitis/enthesis were present in 41 (33.3%) and 68 (55.3%) pts. Over 108 wks’ BKZ treatment, improvements were observed in skin/joint outcomes: ACR50 (66.7%), BSA 0% (75.4%), MDA (65.6%), and resolution of dactylitis (65.9%) and enthesitis (77.9%) (Table). Serious TEAEs occurred in 9.3% (Table); no deaths or major adverse cardiac events were reported. Oral candidiasis occurred in 16 (7.8%) pts (no serious cases).

**Conclusion:** BKZ leads to long-term efficacy for skin/joint manifestations of PsA, with >50% pts achieving high thresholds of disease control (ACR50, BSA 0%, MDA) after 108 wks’ treatment. The safety profile reflects previous observations.1

**DOI:** 10.1136/annrheumdis-2020-eular.852
Psoriatic arthritis (PsA) is a chronic inflammatory musculoskeletal disease with an estimated prevalence of 0.05% to 0.25% in the population and 6% to 41% in psoriasis patients. There is disparity in the reported incidence patterns in the general population in more recent years, with increasing incidence seen in Denmark, but relatively stable rates seen in Canada. However, no studies in the US have looked at the recent incidence patterns, and it would be important to see how newer therapies for psoriasis have impacted the incidence of PsA. Variability in the estimates of incidence and prevalence across different studies has been attributed to differences in case ascertainment and most studies have used ICD codes to identify PsA patients.

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory musculoskeletal disease with an estimated prevalence of 0.05% to 0.25% in the population and 6% to 41% in psoriasis patients. There is disparity in the reported incidence patterns in the general population in more recent years, with increasing incidence seen in Denmark, but relatively stable rates seen in Canada. However, no studies in the US have looked at the recent incidence patterns, and it would be important to see how newer therapies for psoriasis have impacted the incidence of PsA. Variability in the estimates of incidence and prevalence across different studies has been attributed to differences in case ascertainment and most studies have used ICD codes to identify PsA patients.

**Objectives:** To determine the annual incidence of PsA (2000-17) and compare it to incidence of PsA in previous years (1970-1999) in the Olmsted County, Minnesota, USA population.

**Methods:** A retrospective, population-based cohort of PsA patients ≥18 years of age from Olmsted County, MN meeting ClASsification of Psoriatic ARthritis (CASPAR) criteria for PsA (2000-17) was identified from the Rochester Epidemiology Project (REP). REP ensures virtually complete ascertainment and follow-up of all clinically diagnosed cases of PsA in a geographically-defined area. The date of fulfillment of CASPAR criteria was taken as the PsA incidence date. Age- and sex-specific incidence rates, adjusted to 2010 US white population, were reported. Our previously reported cohort from REP (1970-1999) also used the same CASPAR criteria, and trends from the current study were compared to the previous years.

**Results:** There were 170 incident cases of PsA, with a mean age of 46.7 (SD=12.3) years and 47% females from 2000-17. The overall age and sex-adjusted annual incidence of PsA per 100,000 population was 8.8 (95% CI 7.5-10.1), and higher in males (9.7, 95% CI 7.7-11.7) than females (8.0, 95% CI 6.2-9.8). Overall incidence was highest in the age range 40-59 years (Table 1). The incidence rate was relatively stable in the recent years 2000-2017 compared to 1970-1999 where a rise in incidence was observed (3.6 to 9.8 per 100,000 persons from 1970-79 to 1990-99, p<0.001) (Figure 1).

**Conclusion:** In the Olmsted County population, the increasing PsA incidence seen in previous years 1970-1999 seems to have leveled off after 2000. This is in contrast to increasing incidence in recent years reported from Denmark, Taiwan and Israel. However, similar to our study, incidence rates for PsA from 2008-2015 were reported to be stable in Canada.

† Age-adjusted to the 2010 US White population. †† Age- and sex-adjusted to the 2010 US White population.
that limits its use and can be mediated by autonomic dysfunction or classical conditioning phenomena to repeated drug exposure. Anxiety and depression could promote these processes.

**Objectives:** To assess the prevalence of GI to MTX and its association with anxiety and depression in PsA patients.

**Methods:** One hundred unselected PsA patients in stable MTX treatment were characterized by disease characteristics, adherence to treatment by Morisky Medication Adherence Scale (MMAS-8) and comorbidity by Rheumatic Disease Comorbidity Index (RDCI). Depressive and anxious symptoms were assessed by Hospital Anxiety and Depression Scale (HADS). The presence and the severity of nausea, vomiting, abdominal pain and diarrhea after administration (associative symptoms) and just before or even at the thought of taking MTX (anticipatory symptoms) were recorded.

**Results:** Patients had a mean age of 56.9±12.0 years and a disease duration of 9.5 years (0.1-58.0 years). They were male, smokers and overweight in 40.0%, 20.0% and 65.0% of cases, respectively. The prevalence of both associative and depressive symptoms was 42.0%. DAPSA showed remission, low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) in 24.0%, 41.0%, 32.0% and 3.0% of patients, respectively. MTX was taken orally by 15.0% of patients and associated with another conventional or biological DMARD in 14.0% and 35.0% of cases, respectively. Symptoms of GI to MTX were complained by 69.3% of patients. Specifically, the prevalence of nausea, diarrhea, vomiting and abdominal pain was 59.0%, 23.0%, 21.0% and 30.0% with associative pattern and 43.0%, 12.0%, 10.0% and 16.0% with anticipatory pattern, respectively. Patients with anxious symptoms experienced more frequently moderate to severe associative nausea (71.4% vs 50.0%, p=0.032) and abdominal pain (42.9% vs 20.7%, p=0.017), and anticipatory nausea (42.9% vs 26.2%, p=0.046), and abdominal pain (28.2% vs 8.6%, p=0.018) than non-anxious patients. Patients with depressive symptoms more commonly had associative diarrhea (33.0% vs 15.5%, p=0.037), with no difference in the prevalence of anticipatory symptoms. The presence of associative and anticipatory nausea was associated with higher anxiety scores (p=0.006 and p=0.02 respectively) without differences in the depression score. Associative nausea characterized younger patients (p=0.001), female (p=0.02), with lower BMI (p=0.005), a longer disease duration (p=0.028), a lower DAPSA (p=0.02), an higher MTX doses (p=0.02) and a lower comorbidity burden (p=0.03). The anticipatory and associative nausea determined lower compliance according to MMAS-8 (p=0.007 and p=0.001, respectively). An anxious profile characterized patients with moderate to severe associative nausea also in the logistic regression model corrected for age (≥85 years), gender, BMI (>25kg/m2) and MTX dose (>0.2mg/kg/week) (OR 3.0, CI 1.1-8.4, p=0.036), and patients with anticipatory nausea also in the model corrected for age (≥85 years), gender, BMI (>25kg/m2) and MTX dose (>0.2mg/kg/week) and disease duration (>3 years) (OR 3.0, CI 1.1-8.0, p=0.027).

**Conclusion:** Up to two-thirds of patients with PsA who have been treated with MTX, there is a GI, leading to reduced therapeutic adherence. Associative and anticipatory symptoms characterize patients with a specific clinical and psychological profile.

**FOLLOW-UP EXAMINATION FOR THE DETECTION OF POTENTIAL PSORIATIC ARTHRITIS BY FLUORESCENCE OPTICAL IMAGING – IN COMPARISON TO MUSCULOSKELETAL ULTRASOUND**

J. Böttner1, A. M. Glimm1, G. Kokolakis2, M. Erdmann-Keding2, G. R. Burmester1, J. Klotzsche3,4, S. Ohndorf1.

1Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Charité - Universitätsmedizin Berlin, Department of Dermatology, Venerology and Allergology, Berlin, Germany; 3German Rheumatism Research Centre (DRFZ) Berlin, Berlin, Germany; 4Charité - Universitätsmedizin Berlin, Institute for Social Medicine, Epidemiology and Health Economics, Berlin, Germany

**Background:** Up to 30% of all plaque-type psoriasis patients develop psoriatic arthritis (PsA) (1). Early diagnosis of PsA can be difficult due to its heterogeneous manifestation and the lack of disease-specific biomarkers, but it is crucial for disease outcome. Recently, our group has shown that fluorescence optical imaging (FOI) can be a helpful diagnostic tool for early PsA diagnosis since it can differentiate between patients with confirmed PsA and suspected PsA (2).

**Objectives:** To follow-up patients with FOI with confirmed and suspected PsA with special focus on the group of patients in which PsA could be confirmed between baseline and follow-up – and to compare with the findings of musculoskeletal ultrasound (US).

**Methods:** Patients included in our previous study (1) were re-evaluated by FOI of both hands in a standardized manner using the predefined phases 1-3 (p1-p3) and the PrimaVistaMode (PVM). US in grey scale (GS) and power Doppler (PD) were performed of the clinically dominant hand (for tenderness and/or swelling) to express severity of psoriasis (Ps) and percentage of affected area. Leeds enthesitis index (LEI) comprised assessment of lateral epicondylies of humerus, medial condyles of femur, and the insertion of the Achilles tendon. Madrid Sonographic Enthesitis Index (MASEI) was applied to quantify the extent of sonographic enthesal abnormalities. MASEI-inflammation, MASEI-damage and as a sum of these MASEI-total scores were recorded. NVC was performed on eight fingers in each subject.

**Results:** We enrolled 34 patients with PsA (median age=47.74 years, median disease duration=6.91 years) and 22 HC (median age=46.77 years). There were no significant differences between two groups concerning age, gender distribution and body mass index. PsA and PsA disease duration in terms of years were not correlated with MASEI and NVC scores. PASI score associated with MASEI-inflammation score (r=0.40, p<0.01). There were significant correlation between the NVC score and MASEI-inflammation score (r=0.53, p<0.001) and MASEI-total scores (r=0.35, p<0.04) (Table 1). No association was found between LEI and NVC scores (r=0.34). MASEI enthesitis and NVC scores were significantly higher in the patient group (p=0.00).

**Disclosure of Interests:** None declared.

**THE ASSOCIATION BETWEEN PERIPHERAL ENTHESIS SCORES AND NAILFOLD CAPILLAROSCOPY FINDINGS IN PATIENTS WITH PSORIATIC ARTHRITIS**

P. Bora Karsli1, N. Guven1, I. Sunar2, S. Ataman3.

1Ankara University, Department of Rheumatology, Department of PMR, Ankara, Turkey; 2Aydin, Ataturk Public Hospital, Department of Rheumatology, Department of PMR, Aydin, Turkey

**Background:** Enthesitis is one of the key feature of psoriatic arthritis (PsA), it is usually overlooked in the asymptomatic patients. Nail disease often precedes arthritis and rheumatism. Vol. 48. No. 1. WB Saunders, 2018.

**Objectives:** To investigate the link between NVC findings and severity of peripheral enthesitis in patients with PsA.

**Methods:** This cross-sectional single center study, 34 consecutive PsA patients and as control group (healthy controls - HC), 22 subjects without rheumatic diseases were involved. Psoriasis area severity index (PASI) was used to quantify the presence of nail disease in the patients. Nailfold videocapillaroscopy (NVC) is a useful technique for evaluating enthesitis.

**Disclosure of Interests:** None declared.

DOI: 10.1136/annrheumdis-2020-eular.2360
in the dorsal and palmar view at wrist, MCP, PIP and DIP 2-5 joint levels for synovitis and tenosynovitis. Subsequently, a comparison of the findings in the affected joints was performed using US as the reference method. Furthermore, AUC was calculated to show the extent to which a new joint inflammation was associated with a change in diagnosis.

Results: Of the 60 patients initially examined (1), 30 patients (dropout rate 50%) were followed-up approximately 3 years later. The patients were newly divided into 3 groups: Diagnosed PsA (n=14, Group I), still suspected PsA, (n=6, Group II) and initially diagnosed PsA (n=10, Group III), Patients with a change in the diagnosis from suspected to diagnosed PsA (Group III) showed a significantly increased prevalence of joints with pathological findings in FOI (46% at baseline, 88% at follow-up; p=0.046), with an unchanged joint distribution pattern, i.e. with a dominant involvement of the DIP joints. Compared to baseline, patients of group III were three times more common to show enrichment in p3 in follow-up (1.7% vs. 70%; p<.001). Newly detected pathologic joints by FOI (PVM, p2) and US at follow-up were positively associated with the change of diagnosis from suspected PsA to confirmed PsA (FOI: AUC 0.78; GSUS: AUC 0.77). Using US in grayscale as reference, inflammatory changes in the joints were diagnosed in all 3 cohorts by means of FOI in P1 and P3 with high specificity (Group III: 90.6%, Group II: 97.5%, Group I: 94.2%) and low sensitivity (Group III: 24.4%, Group II: 20.3%, Group I: 19.6%).

Conclusion: FOI appears to be helpful to differentiate between acute and chronic disease stages. Furthermore, it is specific for detecting inflammatory changes in the joints of the hands in PsA – in comparison to US. FOI could thereby become a helpful tool as a "dermatological-screening" method to select psoriasis patients with indication for further rheumatological evaluation.

**UTILITY OF CAROTID ULTRASOUND AND FRAMINGHAM RISK SCORE FOR DISCRIMINATING CORONARY ARTERY DISEASE IN PATIENTS WITH PSORIATIC ARTHRITIS (PSA)**

I. T. Cheng1, K. T. Wong2, E. Li1, P. C. Wong3, B. T. L. Lai1, C. W. Yim2, S. K. Y. Ying2, K. Y. Kwok2, M. Li1, T. K. Li1, J. J. W. Lee3, A. P. W. Lee1, L. S. Tam1

1The Chinese University of Hong Kong, Hong Kong, Hong Kong (SAR); 2Prince of Wales Hospital, Hong Kong, Hong Kong (SAR); 3Queen Elizabeth Hospital, Hong Kong, Hong Kong (SAR)

Background: While carotid ultrasound (US) has been advocated for cardiovascular (CV) risk screening in patients with rheumatoid arthritis as various traditional scores underestimate CV risk, whether subclinical coronary atherosclerosis (SCA) is associated with coronary atherosclerosis on coronary computed tomography angiography (CCTA) in patients with psoriatic arthritis (PsA) remains uncertain.

Objectives: This study aimed to identify carotid US parameters which can discriminate PsA patients with coronary artery disease (CAD) and obstructive CAD (O-CAD), and determine the utility in combination with Framingham Risk Score (FRS).

Methods: Ninety-one PsA patients (56 males; age: 50±11years; disease duration: 9.4±8.2years) without overt CV diseases were recruited. Carotid intima-media thickness (cIMT), presence of plaque and total plaque area (TPA) were determined by high-resolution US. CAD was defined as the presence of any coronary plaque on CCTA. O-CAD was defined as >50% stenosis of the lumen. Analysis of variance (ANOVA) and post hoc t-test (Tukey’s HSD) was performed to compare continuous variables between groups. The chi-square test was used to compare categorical variables. Binary logistic regression analysis was performed to assess associations with O-CAD.

Results: Thirty-five (38%) patient had carotid plaque. Fifty-five (60%) patients had CAD and 9 (10%) patients had O-CAD. 53 (58%), 25 (17%) and 13 (14%) were classified as low, moderate and high CV risk according to the FRS respectively. FRS underestimated the CV risk as only 115 (20%) of subjects with CAD were correctly identified as having high CV risk by FRS (Figure 1). Fifteen patients out of 53 (28%) with low CV risk based on FRS were reclassified as high CV risk by the presence of carotid plaque. Nine out of these 15 (60%) had CAD and 115 (62%) had O-CAD. Concerning the carotid ultrasound parameters, cIMT (mean and maximum) and TPA were increased in both the CAD+ and O-CAD+ group compared to those without CAD or O-CAD (Table 1). Multivariate logistic regression analysis revealed that mean cIMT (OR=1.06, 95% CI:1.01-1.11, p=0.013) was an independent explanatory variables associated with CAD. Meanwhile, mean cIMT (OR=1.06, 95%CI: 1.01-1.11, p=0.013) maximum cIMT (ORs=1.06, 95%CI: 1.00-1.13, p=0.043), and TPA (ORs=1.55, 95%CI: 1.01-2.36, p=0.043) were independent explanatory variables associated with O-CAD after adjusting for covariates. Based on Receiver Operating Curve (ROC) analysis, an optimal cut off for FRS at 5% and mean cIMT at 0.62mm yield 63% sensitivity and 73% specificity for the presence of CAD (AUC: 0.71, p=0.001).
Background: Seronegative inflammatory arthritis including psoriatic arthritis (PsA) and axial spondyloarthropathies (AxS) are chronic inflammatory diseases associated with significant morbidity. The National Institute of Health and Clinical Excellence (NICE) has produced several pieces of guidance on disease management including the use of biologic therapies which have been shown to improve patient outcomes and quality of life. However, there are limited real-life data on patient journey from symptom onset to diagnosis and treatment including with biologics in the UK.

Objectives: The purpose of this study is to examine the real-life patient journey from symptom onset to diagnosis and treatment.

Methods: Data from the Secure Anonymised Information Linkage (SAIL) data-bank in Wales, which holds over a billion anonymised records, were used to assess the treatment of patients with PsA or AxS aged 18 years or over with at least one READ code present for PsA or AxS in their primary care records. We examined the drug use of patients across primary, secondary care and specialist rheumatology clinics to explore the use of NSAIDs, DMARDs and biologics in the real-life setting while exploring demographics, comorbidities and surgical procedures of 1829 PsA and 908 AxS patients.

Results: The AxS patients were significantly younger at diagnosis and were predominantly male. Typical delays in diagnosis of 8-9 years from symptom onset were observed. The rate of stopping or switching a biologic medication was similar for AxS and PsA patients (Table 1). There was a significant reduction in sicknotes issued following biologic initiation for PsA (Difference: 14.6%, 95% CI: 8.7% to 20.4%) and AxS (Difference 16.9%, 95% CI: 10.5% to 23.3%).

5 General practitioner/Primary care physician

Conclusion: Patients with PsA and AxS were treated with NSAIDs and DMARDs prior to receiving biologic medication in accordance with NICE guidelines. However, there was a long delay from symptom onset to diagnosis. Biologic treatment reduced sicknotes issued by GPs confirming the benefit of biologic treatment on quality of life.

SAT0410

EFFICACY AND SAFETY OF IXEKIZUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS BASED ON COMBINATION OF TREATMENT MODIFIED ANTI-RHEUMATIC DRUGS (CDMARD) USE: RESULTS FROM SPIRIT-P1 AND SPIRIT-P2

L. C. Coates1, A. Kronberg2, A. T. Spraragen3, S. Y. Park4, B. Combe4, A. Deodhar5. 1University of Oxford, Oxford, United Kingdom; 2Eli Lilly and Company, Indianapolis, United States of America; 3CRU Montpellier, Montpellier University, Montpellier, France; 4Oregon Health and Science University, Portland, United States of America

Background: Biologic disease-modifying antirheumatic drugs such as ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets interleukin (IL)-17A, are commonly prescribed to patients with psoriatic arthritis (PsA) in combination with conventional synthetic disease-modifying antirheumatic drugs (CDMARDs). Previous studies have shown that, after 24 weeks of treatment, IXE is efficacious with or without concomitant cDMARD therapy in patients with active PsA.3,4 However, there is limited evidence demonstrating efficacy and safety after 3 years of treatment.

Objectives: To evaluate the long-term (3-year) efficacy and safety of IXE in patients with active PsA from SPIRIT-P1 (NCT01965239) and SPIRIT-P2 (NCT02349295) based on concomitant cDMARD use.

Methods: Patients were subdivided into the following subgroups: 1) no CDMARD use for 3 years (ixekizumab monotherapy); 2) methotrexate (MTX) use without interruption (i.e., ≤14-day gap of not using MTX), but allowing a change of MTX dose; and 3) any CDMARD (MTX, sulfasalazine, leflunomide, cyclosporin, hydroxychloroquine) use during 3 years without interruption (i.e., ≤14-day gap of not using CDMARDs), but allowing a switch of CDMARD type and/or change of dose. The post-hoc integrated analysis assessed efficacy and safety up to 3 years by three subgroups. Efficacy outcomes included the American College of Rheumatology (ACR) 20/50/70, Psoriatic Area and Severity Index (PASI) 75/90/100, Health Assessment Questionnaire-Disability Index (HAQ-DI) ≥0.35-point improvement. Missing data were imputed using modified non-responder imputation. The IXE 80 mg every 4 weeks (IXEQ4W) dose data are reported here.

Results: Overall, IXE-treated patients showed improved in all efficacy outcomes over 156 weeks, regardless of concomitant cDMARD use. ACR response rates by concomitant cDMARD use at 156 weeks are highlighted in Figure 1. Patients treated with IXEQ4W in the no cDMARD use, MTX, and any CDMARD use subgroups had similar ACR20 (59.1%, 67.0%, and 66.1%, respectively), ACR50 (46.2%, 47.4%, and 46.8%, respectively), and ACR70 (30.7%, 28.4%, and 35.0%, respectively) response rates at 156 weeks. Patients treated with IXEQ4W in the three subgroups also had similar PASI75 (65.5%, 60.8%, and 56.8%, respectively), PASI90 (58.3%, 49.7%, and 48.0%, respectively) response rates at 156 weeks. The proportion of patients achieving HAQ-DI improvement ≥0.35 in the three subgroups (51.9%, 45.0%, and 47.5%, respectively) was comparable. The safety profile of IXEQ4W was consistent with that previously reported.1,2 A similar proportion of IXEQ4W-treated patients in the three subgroups reported ≥1 treatment-emergent adverse events (TEAEs) regardless of the addition of MTX or other CDMARDs (91.0%, 84.1%, and 83.2%, respectively), and the majority of TEAEs were mild or moderate in all three subgroups.

Conclusion: IXEQ4W provided sustained improvements in the signs and symptoms of active PsA. While there are some numerical differences in ACR20/50/70 as well as PASI75/90/100, the overall responses with or without the addition of MTX or other CDMARDs were similar. In this post-hoc analysis, it appears that, for sustained responses over time, IXEQ4W does not require the addition of MTX or other CDMARDs. Addition of MTX or other CDMARDs to IXEQ4W did not negatively impact its favorable long-term safety profile.

Efficacy and Safety of Ixekizumab in Patients with Psoriatic Arthritis and Inadequate Response to TNF Inhibitors: Three Year Results from a Phase 3 Study (SPIRIT-P2)

J. Gratchos-Masmitja1, A. Turkiewicz2, E. Dokoupilova3,4, A. M. Gellett5, A. T. Sprabery6, V. J. Geneus5, A. Constantin6,11,12, Laura C Coates: None declared, Andris Kronbergs Shareholder of: Eli Lilly and Company, Employee of: Eli Lilly and Company, Aubrey Toulouse, Sprabery Shareholder of: Eli Lilly and Company, Employee of: Eli Lilly and Company, Roche-Chugai Consultant of: Abbvie; Gilead Sciences, Inc.; Janssen; Eli Lilly and Company; Pfizer; Roche-Chugai; Sanofi, Speakers bureau: Bristol-Myers Squibb; Gilead Sciences, Inc.; Eli Lilly and Company; Merck Sharp & Dohme; Pfizer; Roche-Chugai; UCB, Atul Deodhar Grant/research support from: AbbVie, Lilly and Company; Pfizer; Roche, Speakers bureau: AbbVie, Amgen, Boehringer Ingelheim, Bristol Myer Squibb (BMS), Eli Lilly, GSK, Janssen, Novartis, Pfizer, UCB, Laura C Coates: None declared, Andris Kronbergs Shareholder of: Eli Lilly and Company, Employee of: Eli Lilly and Company, Indianapolis, United States of America; Toulouse, France

Background: Ixekizumab (IXE) is a high affinity monoclonal antibody that selectively targets interleukin-17A. In the SPIRIT-P2 study, IXE every 4 (Q4W) or 2 (Q2W) weeks was superior to placebo (PBO) in improving the signs and symptoms of psoriatic arthritis (PsA) at Week 24 in patients (pts) with prior inadequate response or intolerance to 1 or 2 tumor necrosis factor inhibitors (TNFi).

Objectives: To determine efficacy and safety of IXE treatment up to 3 years in pts with PsA.

Methods: In SPIRIT-P2 (NCT02349295), 310 pts entered the extension period where pts maintained their original ixekizumab dose, and placebo pts received IXE04W or IXE02W (1:1). Pts failing to demonstrate ≥20% improvement in both tender and swollen joint counts at Week 32, or any subsequent visit, were discontinued (mandatory discontinuation criteria). Efficacy outcomes were ACR20/50/70 response, Psoriasis Area and Severity Index (PASI) 75/90/100 response, Leeds Enthesitis Index (LEI), Leeds Dactylitis Index-Basic (LDI-B), Minimal Disease Activity (MDA), and Disease Activity in Psoriatic Arthritis (DAPSA). Ad-hoc efficacy data are presented for intent-to-treat (ITT) pts initially randomized to IXE at Week 0. Observed and modified non-responder imputation (mNRI) missing data treated as non-response for pts discontinued due to lack of efficacy or adverse events (AEs) was applied to categorical measures. Observed and modified baseline observation carried forward (mBOCF) was applied to continuous efficacy measures. Safety was analysed in pts exposed to at least one dose of IXE.

Results: Of the 245 pts initially randomized to IXE at Week 0 (ITT), 64 (26.1%) pts discontinued due to lack of efficacy and 22 (9.0%) pts due to mandatory discontinuation criteria. Efficacy results are summarized below (Figure 1). Pts in SPIRIT-P2 who received IXE04W and IXE02W for 156 weeks reported sustained improvement in ACR responses and manifestations of PsA, including enthesitis, dactylitis, and skin outcomes. Treat-to-target measures such as MDA and DAPSA (Low Disease Activity or Remission) were achieved by 30.8% and 47.7% of pts, respectively on IXE04W, and by 29.2% and 40.7% of pts, respectively on IXE02W. Incidence rates (IR) of treatment-emergent adverse events (TEAEs) are provided below (Figure 2). Most TEAEs were mild or moderate in severity, and 38 out of 337 (9.5%) pts (safety population) discontinued due to AEs. The most common TEAEs were infections (IR=33.1) and injection site reactions (IR=5.4). Three deaths were reported in the study.

Conclusion: In pts treated with IXE who had prior inadequate response or intolerance to 1 or 2 TNFi, improvements in the signs and symptoms of PsA persisted up to 3 years. No unexpected safety signals were observed, and the safety profile was consistent with previous studies of IXE.

Background: Identifying psoriatic arthritis (PsA) among people with psoriasis is often challenging due to low specificity of symptoms at early PsA stage and/or delayed referral to the rheumatologist. Screening instruments -assisting the dermatologist to decide when rheumatological assessment is beneficial- have potential to reduce the diagnostic delay.

Objectives: To evaluate the accuracy of a dermatologist-filled-out questionnaire designed for screening PsA among psoriatic patients under dermatology care.

Methods: HERACLES is a multicentre, cross-sectional study running at 9 Italian dermatology and rheumatology tertiary centres. All participants were under dermatology care for skin psoriasis. Previous diagnosis of PsA precluded eligibility. Dermatologists at each site assessed consecutive psoriatic subjects, filled in the specifically-designed HERACLES questionnaire (HQ, Figure 1) and finally referred the participants to rheumatologists for clinical evaluation. All participants filled in the ToPAS, PASE, PEST and EARP questionnaires.

Results: Out of 759 subjects enrolled, 524 (69%) attended rheumatology care.

Conclusion: The HERACLES questionnaire, a tool designed for dermatologists, showed good sensitivity and specificity in identifying PsA cases among subjects with cutaneous psoriasis.

Figure 1.

Results: Of 759 subjects enrolled, 524 (69%) attended rheumatology assessment. Dermatologists diagnosed PsA in 73/524 patients (13.9%, Figure 2). Mean age was 53 (SD 16) years and 46% were female. Mean psoriasis duration was 20 (SD 19) years. The area under the ROC curve of HQ was 0.775. The comparison between the ROC curve of the HQ and those of the other four questionnaires tested did not show any significant difference (p=0.523 versus TOPAS; p=0.201 versus PASE; p=0.345 versus PEST and p=0.240 versus EARP).

SAT0413 DACTYLI TIS IS ASSOCIATED WITH DISEASE SEVERITY AND ULTRASOUND DEFINED ERO SIVE DAMAGE IN VERY EARLY, DMARD NAIVE PS ORIATIC ARTHRITIS

S. Dubash1, O. Alabas1, X. Michelen1, G. De Marco1, L. Garcia-Montoya1, R. Wakefield1, A. L. Tan1, P. Heilwell1, P. Emery1, D. Mcgonagle1, H. Marzo-Ortega1, NSHR LBRC, Leeds Teaching Hospitals Trust & LIRMM, University of Leeds, Leeds, United Kingdom

Background: Dactylitis is a hallmark feature of Psoriatic arthritis (PsA) and Spondyloarthritis (SpA) defined as a uniform swelling of a digit ("sausage digit"). Dactylitis is associated with radiographic damage in chronic PsA. However, there are a paucity of data on the significance of dactylitis and its potential impact in disease burden in early PsA.

Objectives: To characterize a very early DMARD naive PsA cohort based on clinical presence or absence of dactylitis at disease onset.

Methods: PsA subjects fulfilling the CASPAR classification criteria, were recruited into a prospective observational cohort. The Leeds Spondyloarthritis Registry for Research and Observation (SpARRO) after providing informed written consent. Clinical data including tender (TJC) and swollen joint counts (SJC) were independently assessed. Dactylitis was recorded per digit (finger or toe) as tender (hot) or non-tender (cold). Differences in baseline characteristics were evaluated using percentages to describe categorical variables and means and standard deviations for continuous variables. p value of the mean/proportion difference was calculated. Ultrasound (US) examination was conducted by trained ultrasound radiographers blinded to clinical details. Bone erosions were defined on US if intra-articular discontinuity was present in two perpendicular planes at any of 46 joints: wrists, MCP1-5, PIP2-5, DIP2-5, MTP1-5, knees, ankles, subtalar, talonavicular.

Results: A total of 177 PsA patients were recruited. Dactylitis was seen in nearly half the cohort (n=83 [47%]). Patients with dactylitis had significantly more early morning stiffness, higher TJC and SJC, compared with non-dactylitis (Table 1). A total of 211 digits with dactylitis were recorded in 83 patients. Dactylitis of multiple digits was seen in 47/83 (57%) patients whilst a single dactylitic digit occurred in 36/83 (43%). Foot involvement was more prevalent (141/211, 67%) than hands (70/211, 33%). "Hot" or tender dactylitis was more frequently detected (153/211,
US defined erosions were significantly more prevalent in the dactylitis group: 34 erosions in 21/71 patients (29.5%) versus 16 erosions in 12/83 (14.4%) patients defined in non-dactylitis. Sites prone to erosive damage in both groups were the wrists, MCP1,2 and MTP4,5. The right MCP2 (n=6) and MTP5 (n=6) were most commonly eroded in the dactylitis group, but erosions corresponding at the dactylitis digit level were overall low.

Conclusion: This study identifies a more severe phenotype in very early DMARD naïve PsA presenting with dactylitis with higher prevalence of ultrasound erosions. Longitudinal follow up will determine whether dactylitis represents a poor prognostic factor in very early PsA, which may be a useful discriminator for risk stratification in future PsA management recommendations.

SAT0416
ENTHESITIS AND CLINICAL RESPONSE IN PSORIATIC ARTHRITIS: REAL-LIFE DATA
S. Ganhão1, S. Garcia1, B. M. Fernandes1, M. Rato1, F. Pinheiro1, E. Mariz1, M. Bernardes1, L. Costa1, 1Centro Hospitalar e Universitário de São João, Rheumatology, Oporto, Portugal; 2Faculty of Medicine of Oporto’s University, Oporto, Portugal

Background: Psoriatic arthritis (PsA) is an inflammatory arthritis that is characterized by a broad spectrum of clinical conditions, including axial skeletal involvement, enthesitis, dactylitis, uveitis and arthritis. Among those, enthesitis, the inflammation of the junction where the tendon, ligament or joint capsule inserts into the bone, is assigned to be the hallmark, affecting 35–50% of patients. Several clinical methods have been developed to measure this, including the Maastricht AS Enthesitis Score (MASES) index, which tests 13 entheses and the Spondyloarthritis Research Consortium of Canada (SPARCC) index that assesses 16.

Objectives: To assess the relationship between enthesitis and clinical response in psoriatic arthritis.

Methods: Retrospective study including all the patients with PsA meeting the CASPAr criteria, beginning first-line biologic therapy at our centre. Demographic and clinical data including age, gender, body mass index (BMI), smoking status, physical examination findings such as presence of enthesitis, dactylitis, chronic back pain, tender and swollen joint counts (TJC/ SJC), ESR, CRP, DAS 28 4vESR, BASDAI, BASFI, BASMI, ASDAS, HAQ, patient VAS score, MASES and SPARCC were collected from the Portuguese database Reumatap. Statistical analysis was performed with SPSS. Continuous variables were analysed through Spearman correlations.

Results: We included 119 patients with PsA (60 female), of which 14.9% were active smokers. The mean age of patients was 46.3 ± 10.3 years. The median disease duration was 6.8 (0.3-33.8) years and the mean BMI was 26.8 ± 0.5 Kg/m2. Enthesitis, dactylitis, inflammatory back pain, peripheral arthritis, unexplained dyspnoea, and psoriasis were present in 53 (45.7%), 45 (38.8%), 76 (65.5%), 109 (94%), 45 (38.8%), 104 (89.7%) patients, respectively.

At baseline, mean (SD) disease activity parameters were: DAS 28 4vESR 4.9 (2.0), ESR 23.3 (8.3) mm/h, HAQ 1.3 (0.1), BASDAI 5.0 (2.0), ASDAS 3.9 (0.1), BASFI 3.7 (0.2), BASMI 5.8 (0.3), MASES 19.0 (3.0), SPARCC 2.3 (0.3). Median (min-max) values of TJC, SJC and patient VAS score at baseline were 4 (0-28), 3 (0-19), 76 (0-100), respectively.

There were statistically significant positive correlations (0.12 months) between ∆MASES and ∆ASDAS 28 4vESR (p=0.02, rho=0.432), ∆patient VAS score (p=0.027, rho=0.307), ∆DAS28 (p=0.02, rho=0.411), ∆BASDAI (p=0.025, rho=0.326), ∆BASFI (p=0.037, rho=0.315), ∆ASDAS (p=0.023, rho=0.331). Correlations between ∆SPARCC and ∆DAS 28 4vESR (p=0.023, rho=0.332), ∆patient VAS score (p=0.003, rho=0.402), ∆HAQ (p=0.012, rho=0.440), ∆BASDAI (p=0.011, rho=0.368), ∆BASFI (p=0.001, rho=0.445), ∆ASDAS (p=0.002, rho=0.437), ∆CDAI (p=0.039, rho=0.320) and ∆SDAI (p=0.039, rho=0.319) were also significant. However, there weren’t strong correlations between ∆MASES neither SPARCC and PsA ARC response at 12 months.

Conclusion: Our results suggest that enthesitis is correlated with clinical response in PsA, supporting the idea that it is a major determinant of disease activity. It should be given more importance, namely by incorporating it in daily clinical practice, due to its major role, both in establishing an early diagnosis and in assessing treatment response.

Conclusion: PASI75/90/100 response rates progressively improved with treatment; PASI 75 responses were significantly improved versus placebo as early as W4 (TIL 200 mg Q12W), and all response rates were significantly improved versus placebo at W24. Response rates continued to improve through W36 and were sustained through W52. These results demonstrate TIL significantly reduced psoriasis activity and was generally well tolerated in a mixed population of anti-TNF-naive and -experienced patients with PsA and BSA ≥3% through W52.

SAT0418 EFFECT OF TOFACITINIB TREATMENT ON ACTIVE MRI SACROILIITIS AND DISEASE ACTIVITY REDUCTION IN PSORIATIC ARTHRITIS PATIENTS. DATA FROM CLINICAL PRACTICE
E. Gubart1, T. Korotaeva1, Y. Korsakova1, E. Loginova1, P. Karpova1. 1Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Axial involvement in psoriatic arthritis (PsA) is quite common. Tofacitinib (TOFA) is an oral Janus kinase inhibitor. There is no data on the use of TOFA in PsA patients (pts) with axial involvement, nor is there any data on its effect on active MRI sacroiliitis (MRI-SI). There are only preliminary results of a randomized clinical trial on TOFA efficacy on active SI in AS (1).

Objectives: To study the effect of TOFA therapy on active MRI-SI in PsA pts.

Methods: 40 pts (M/F – 23/17) with active PsA fulfilling the CASPAR criteria were examined. Median (Me) age 41.0 [35.0; 50.0] yrs, Me PsA duration 6.0 [3.0; 10.0] yrs. Pts underwent a standard clinical examination of PsA activity: Me tender joint count 19 [12; 24], swollen joint count 11 [8; 16], patient’s global disease activity measured by Visual Analogue Scale (VAS) 70 [50; 80], patient’s pain VAS 65 [50; 75], Me activity indexes: DAPSA 44.2 [37.8; 55.3], BASDAI 6.0 [4.2; 7.0], ASDAS 3.8 [2.8; 4.4], Me CRP 21.3 [3.2; 72.3] mg/L, ESR 28 [12; 52] mm/h.

Enthesitis was observed in 65.9% of pts with Me LEI index 1 [0; 1], dactylitis in 53.7% of pts, Me digits with dactylitis 1 [0; 2]. Apart from a standard clinical examination, MRI of sacroiliac joints (SIJ) was performed in all 40 pts using MRI scanner Siemens General Electric 1.5 TESLA. Bone marrow edema/ostitis on MRI (STIR) with one lesion on two consecutive slices or at least two lesions on a single slice, was considered active MRI-SI. MRI results were evaluated by 2 independent radiologists (radiologist and rheumatologist). TOFA was given in 5mg tablets bds over a period of 6 months, after which 35 patients underwent SIJ MRI.

Results: Prior to TOFA therapy, active MRI-SI was detected in 14 of 40 (35.0%) pts: bilateral in 9 pts, unilateral in 5 pts. At the end of 6 months therapy, active MRI-SI was detected in 4 of 35 (11.4%) pts observed: in 1 pt with baseline bilateral MRI-SI and in 2 pts with unilateral MRI-SI. 1 pt showed negative dynamics, that is, development of active MRI-SI (absent at baseline). The decrease in number of active MRI-SI patients is statistically significant (p = 0.017; Pearson-x2). At baseline, Me BASDAI 6.0 [4.2; 7.0], Me ASDAS 3.8 [2.8; 4.4]. After 6 months of treatment, Me BASDAI 1.4 [0.6; 3.2], Me ASDAS1.5 [1.0; 2.1] (p = 0.001 for both comparisons).

Conclusion: JAK inhibition using TOFA therapy shows high efficacy in reducing active MRI-SI and decreasing activity of axial involvement in PsA. More extensive studies are needed.

SAT0419 ASSOCIATION OF ACTIVE MRI SACROILIITIS WITH DACTYLITIS AND WORK PRODUCTIVITY IMPAIRMENT IN PSORIATIC ARTHRITIS PATIENTS. POSITIVE EFFECTS OF TOFACITINIB TREATMENT. DATA FROM CLINICAL PRACTICE
E. Gubart1, T. Korotaeva1, Y. Korsakova1, E. Loginova1, S. Glukhova1, P. Karpova1. 1Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Psoriatic arthritis (PsA) is a heterogeneous disease with multiple manifestations and choosing among treatments can be a complex decision. Patients (pts) with axial involvement and pts having dactylitis are more likely to develop a severe disease (1, 2). Tofacitinib (TOFA), an oral Janus kinase inhibitor, showed efficacy in treating PsA pts with dactylitis (3). However, its efficacy in treating PsA pts with active sacroiliitis (SI) and dactylitis has not been studied.

Objectives: To study the effect of TOFA therapy in PsA pts having active SI on MRI (MRI-SI) and dactylitis.

Methods: 40 pts (M/F – 23/17) with active PsA fulfilling the CASPAR criteria were examined. Median (Me) age 41.0 [35.0; 50.0] yrs, Me PsA duration 6.0 [3.0; 10.0] yrs. A standard clinical examination of PsA activity was performed: Me tender joint count 19 [12; 24], swollen joint count 11 [8; 16], patient's global disease activity measured by Visual Analogue Scale (VAS) 70 [50; 80], patient’s pain VAS 65 [50; 75], Me activity indexes: DAPSA 44.2 [37.8; 55.3], BASDAI 6.0 [4.2; 7.0], ASDAS 3.8 [2.8; 4.4], Me CRP 21.3 [3.2; 72.3] mg/L, ESR 28 [12; 52] mm/h.

Enthesitis was observed in 65.9% of pts with Me LEI index 1 [0; 1], dactylitis in 53.7% of pts, Me digits with dactylitis 1 [0; 2]. Apart from a standard clinical examination, MRI of sacroiliac joints (SIJ) was performed in all 40 pts using MRI scanner Siemens General Electric 1.5 TESLA. Bone marrow edema/ostitis on MRI (STIR) considered active MRI sacroiliitis (MRI-SI), was evaluated by 2 independent radiologists (radiologist and rheumatologist). TOFA was given in 5mg tablets bds over a period of 6 months, after which 35 patients underwent SIJ MRI.

Results: Prior to TOFA therapy, MRI-SI was detected in 14 of 40 (35.0%) pts. At the end of 6 months therapy, MRI-SI was detected in 4 of 35 (11.4%) pts: in 3 pts with baseline SI; 1 pt showed negative dynamics, that is, development of active SI (absent at baseline). The decrease in number of active MRI-SI pts is statistically significant (p = 0.017; Pearson-x2). Significant differences between baseline symptoms in patients with MRI-SI (n=14) and without it (n=26) were defined by number of digits with dactylitis: 2 [0; 4] and 0 [0; 2] (p=0.047), and by WPAI overall work impairment due to health index: 80 [60; 84]% and 20 [60; 60]% (p=0.033), respectively; these parameters were higher in MRI-SI subgroup. After 6 months of therapy number of digits with dactylitis, ESRI and WPAI indexes were significantly lower as compared with the baseline ones (Table 1).
The table shows the dynamics of symptoms in TOFA-treated patients with or without MRI-Si.

</table>

After 6 months of TOFA therapy, no differences were found between groups of pts with and without MRI-Si in the number of digits with dactylitis (p=0.47), in ESR (p=0.79) and in WPAI (p=0.93).

Conclusion: In PsA pts significant association of active MRI-Si was found with dactylitis, high ESR level and WPAI. Use of TOFA in pts with both active MRI-Si and dactylitis demonstrated its high efficacy in reduction of SI inflammation and dactylitis; it also significantly improved pts' work productivity. These findings are important for personalized approach to treatment of PsA.

**EFFICACY OF NON-TUMOUR NECROSIS FACTOR BIOLOGICS AND TARGETED SYSTEMIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS IN THE TREATMENT OF PSORIATIC ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS**

A. Bayley1, N. Gullick1, 2University of Warwick, Coventry, United Kingdom; 2University Hospitals Coventry and Warwickshire, Coventry, United Kingdom

Background: Psoriatic arthritis (PsA) is a systemic, inflammatory condition presenting in approximately 30% of patients with psoriasis and associated with functional impairment and a reduced health-related quality of life. Current treatment guidelines recommend non-steroidal anti-inflammatory drugs, conventional Disease Modifying Anti-Rheumatic Drugs (cDMARDs) and Tumour Necrosis Factor α inhibitors (TNFi). Recent research has focused on alternative biologic medications which target interleukin (IL) 6, 12/23, 17A, 23 and T Cell co-stimulation, as well as targeted synthetic DMARDs (tsDMARDs) including Janus Kinase inhibitors (JAKi) and Phosphodiesterase 4 inhibitors (PDE4i). Evidence of the safety and efficacy, measured using the American College of Rheumatology-20 (ACR20), has been demonstrated leading to the inclusion of several biologics and tsDMARDs in guidelines. However, it can be argued that ACR50, indicating a 50% improvement in disease, is a more clinically relevant outcome measure.

Objectives: To conduct a systematic review and meta-analysis of the efficacy (ACR50 response) of non-TNFi biologics and tsDMARDs in the treatment of PsA.

Methods: A systematic literature search of Embase, MedLine and Web of Science was undertaken to identify randomised controlled trials (RCTs) investigating efficacy and safety of non-TNFi biologics and tsDMARDs published in English from the inception of the databases to September 2019. The Cochrane Risk of Bias tool was used to assess methodological rigour of included trials. A meta-analysis was performed using a random effects model to estimate odds ratios of ACR 50 response vs placebo. A subgroup analysis was performed using patients with previous TNFi exposure.

Results: 21 RCTs were eligible with 6389 participants. Evaluation periods ranged from 12 to 24 weeks. JAKi, PDE4i, IL6i, IL12/23i, IL17Ai and IL23i treatments were more efficacious than placebo for ACR50 response (p<0.001) (Figure 1). Only tofacitinib (JAKi), secukinumab (IL17Ai) and ixekizumab (IL17Ai) were able to demonstrate efficacy at the ACR50 level in participants with prior TNFi exposure (p<0.0001) (Figure 2). All treatments demonstrated an adequate safety profile.

Conclusion: Non TNFi biologics and tsDMARDs are able to demonstrate 50% improvement with adequate safety profiles. These therapies are often used in patients who are inadequate responders to TNFi but there is less robust data in this specific patient group. Studies with clinically relevant primary endpoints should be considered in this patient population.
SAT0421

GUSELKUMAB DEMONSTRATED AN INDEPENDENT TREATMENT EFFECT ON FATIGUE AFTER ADJUSTMENT FOR CLINICAL RESPONSE (ACR20) IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM PHASE-3 TRIALS DISCOVER 1 & 2

P. Hellwell1, P. Rahman3, A. Deodhar3, A. Kollmeier4, E. C. Hsia4,5, B. Zhou4, X. Lin5, C. Han6, P. J. Mease6, 1Univ of Leeds, Leeds, United Kingdom; 2Memorial Univ of Newfoundland, St John’s, Canada; 3Oregon Health & Science Univ, Portland, United States of America; 4Janssen Research & Development, LLC, Spring House, United States of America; 5U Penn Med Ctr, Philadelphia, United States of America; 6Swedish Med Ctr/Providence St. Joseph Health and U Wash School of Med, Seattle, United States of America

Background: DISCOVER 1 and 2 are phase-3 trials of guselkumab (GUS, a monoclonal antibody that specifically binds the p19-subunit of IL-23) in patients with psoriatic arthritis (PsA). In both trials, treatment with GUS led to significantly more improvement than placebo (PBO) in the primary endpoint (ACR20) as well as in other measures of arthritis and psoriasis at week (W) 24.1,2

Objectives: To evaluate the effect of GUS on fatigue in DISC 1 & 2 using the patient reported outcome (PRO) FACIT-Fatigue, which has demonstrated content validity and strong psychometric properties in clinical trials.3

Methods: DISC 1 & 2 enrolled patients with active PsA, despite nonbiologic DMARDs and/or NSAIDs, who were mostly biologic naïve except for ~30% of patients in DISC 1 who had received 1-2 TNFi. Patients were randomized (1:1:1) in a blinded fashion to subcutaneous GUS 100 mg W0 and W4 then every (q) 8W, to GUS 100 mg q4W, or to matching PBO. Concomitant treatment with select nonbiologic DMARDs, oral corticosteroids, and NSAIDs was allowed. The FACIT-Fatigue is a 13-item PRO instrument assessing fatigue and its impact on daily activities and function over the past seven days, with a total score ranging from 0 to 52, higher score denoting less fatigue. A change of ≥4 points is identified as clinically meaningful.5 Change from baseline in FACIT-Fatigue was analyzed using MMRM (Figure). Independence of treatment effect on FACIT-Fatigue from effect on ACR20 was assessed using Mediation Analysis4 (Table) to estimate the natural direct effect (NDE), mediating the indirect effect (NIE) mediated by ACR20 response.

Results: At baseline in DISC 1 & 2, the mean FACIT-fatigue scores were 30.4 (10.4) and 29.7 (9.7), respectively, indicating moderate to severe fatigue. In both DISCOVER 1 & 2 trials, treatment with GUS led to improvements in FACIT-Fatigue scores compared with PBO as early as W8 (Figure). 54%-63% of GUS patients compared with 35%-46% of PBO patients achieved clinically meaningful improvement (≥4 points) in FACIT-Fatigue (P<0.003). Mediation analysis revealed that the independent treatment effects on fatigue after adjustment for ACR20 response (Natural Direct Effect [NDE], Table) were 12-36% in the q8W GUS dosing group and 69%-70% in the q4W GUS group.

Conclusion: In 2 phase-3 trials, treatment with GUS of patients with active PsA led to significant improvements compared to PBO in fatigue, including substantial effects on FACIT-Fatigue that were independent of the effects on ACR20, especially for the q4W dosing group.

FIRST-LINE CSDMARD MONOTHERAPY RETENTION IN PSORIATIC ARTHRITIS: METHOTREXATE OUTPERFORMS SULFASALAZINE

M. Jacobs1,2, J. Pouw1,2, R. Welsing1, T. R. Radstake1,2, E. Leitien1,2, 1UMC Utrecht, Dept. of Rheumatology and Clinical Immunology, Utrecht, Netherlands; 2UMC Utrecht, Center for Translational Immunology, Utrecht, Netherlands

Background: Conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) are the first-line treatment for psoriatic arthritis (PsA), but there is conflicting data regarding their efficacy and scarce reports describing the duration of use (drug retention) of csDMARD in this population. Their position in treatment recommendations is a matter of growing debate due the availability of alternative treatment options with higher levels of evidence.

Disclosure of Interests: None declared, J Pouw Speakers bureau: AbbVie, Amgen, Biogen Idec, BMS, Celgene Corporation, Eli Lilly, Novartis, Pfizer, Sun Pharmaceutical, UCB – grant/research support, Consultant of: AbbVie, Amgen, Biogen Idec, BMS, Celgene Corporation, Eli Lilly, Novartis, Pfizer, Sun Pharmaceutical, UCB – consultant, Speakers bureau: AbbVie, Amgen, Biogen Idec, BMS, Eli Lilly, Genentech, Janssen, Pfizer, UCB – speakers bureau

DOI: 10.1136/annrheumdis-2020-eular.401
Objective: To study drug retention and predictors for drug retention among PsA patients receiving first-line csDMARD monotherapy.

Methods: Retrospective cohort study in DMARD-naïve adult PsA patients in whom a first csDMARD was prescribed as monotherapy primarily to treat PsA-related symptoms. Main outcome was time to failure of the csDMARD (i.e., stopping the csDMARD or adding another DMARD).

Results: 187 patients were included, who were mainly prescribed methotrexate (MTX) (n=163) or sulfasalazine (SSZ) (n=21) (Table 1). The pooled median time to failure was 31.8 months (IQR 9.04-110). Drug retention was significantly higher in MTX (median 34.5 months; IQR 9.60-110) as compared to SSZ treated patients (median 12.0 months; IQR 4.80-56.7) (p=0.016, log-rank test) (Figure 1). In multivariable cox-regression the use of MTX and older age were associated with increased retention. The main reasons for treatment failure were inefficacy (52%) and side-effects (28%) (Figure 2). Upon failure, MTX treated patients were more commonly, subsequently treated with a biologic DMARD compared to SSZ (p<0.05).

Table 1. Main demographic and clinical characteristics of the study population at baseline. The total cohort (n=187) included 3 patients treated with leflunomide (data not shown separately). Psoriasis area and severity scores were unavailable for most cases and not shown. Descriptive data show the mean ± SD, median (IQR) or N (%).

1 Other psoriasis types included: guttate, palmoplantar, inverse, and mixed types.
2 Presence/absence of axial disease was based on the clinical diagnosis from the treating physician.
3 Clinical parameter is significantly different (P <0.05) between MTX and SSZ.

Conclusion: MTX outperformed SSZ as first-line csDMARD monotherapy in DMARD-naïve PsA patients with respect to drug retention in daily clinical practice.

SAT0423
LONG-TERM SURVIVAL OF THE FIRST BIOLOGIC TREATMENT IN PSORIATIC ARTHRITIS AND THE EFFECT OF THE SELECTED TREATMENT ON DRUG SURVIVAL; TURKBIO REGISTRY

1Dokuz Eylül University Faculty of Medicine, Rheumatology, Izmir, Turkey; 2Uludag University Faculty of Medicine, Rheumatology, Bursa, Turkey; 3Kartıp Celebi University Faculty of Medicine, Rheumatology, Izmit, Turkey; 4Kocaeli University Faculty of Medicine, Rheumatology, Kocaeli, Turkey; 5Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; 6Izmir University Faculty of Medicine, Rheumatology, Malatya, Turkey; 7Bilim University Faculty of Medicine, Rheumatology, Istanbul, Turkey; 8Yıldırım Beyazıt University, Rheumatology, Ankara, Turkey; 9Celal Bayar University Faculty of Medicine, Rheumatology, Manisa, Turkey

Background: Currently, biologic treatments are used effectively in patients with psoriatic arthritis (PsA).

Objectives: The aim of this study was to evaluate and compare long-term drug survival of the first biologic treatments including adalimumab, certolizumab, etanercept, golimumab, infliximab, secukinumab and ustekinumab in patients with PsA.

Methods: PsA patients, electronically registered at each visit in the TURKBIO database between 2011 and 2019 were included in the study. PASW 18.0 for Windows was used for statistical analysis. Drug survival rates were calculated by Kaplan Meier method.

Results: 355 patients (227 women; axial PsA = 48, peripheral PsA = 307) were included in the study (Table 1). Adalimumab was the most commonly used first biologic treatment (n=125; 37.6%). The rate of drug survival was found to be 0.75 at month 60 in patients receiving the first biologic treatment (Figure 1). There was no significant difference in drug survival rate between tumor necrosis factor alpha inhibitor (TNFi) and non-TNFi biologic drugs (p=0.56). No difference was also found in drug survival rates between each biologic treatment.

Methods: 614 (MF=331(54%)/283(46%)) PsA pts fulfilling the CASPAR criteria were included from the RU-PsART cohort. Mean age 45.2±0.52 yrs, PsA duration 5.7±0.27 yrs, PsO duration 15.7±0.56 yrs. At baseline (BL) PsA activity was evaluated by Tender Joint Count (TJC66), Swollen Joint Count (SJJC68), PGA, physician global assessment by Visual Analog Scale (VAS), DAPSA, PROs according to PGtVAAS, PPtPainVAS, HAQ, Work Productivity and Activity Index (WPAI) and Body Mass Index (BMI, kg/m²). All pts were split into three groups by BMI (kg/m²): normal<25 (I group), overweight 25-30 (II group), obese>30 (III group). All pts were split into three groups by BMI (kg/m²): normal<25 (I group), overweight 25-30 (II group), obese>30 (III group). Only limited data are available for cardiovascular (CV) and metabolic (Met) disorders due to the combination of inflammation and obesity. Obesity was associated with higher PsA activity, more prevalence of CV/Met comorbidities and worse PROs. Obesity requires a change of the pts' lifestyle, nutrition correction and a right choice of therapy.

Conclusion: In clinical practice, BMI increase was found in the majority of PsA pts. Obesity was associated with higher PsA activity, more prevalence of CV Met disorders and worse PROs. Obesity requires a change of the pts' lifestyle, nutrition correction and a right choice of therapy.

SAT0425

NOVEL COMPUTER-ASSISTED METHODOLOGY FOR QUANTITATIVE ASSESSMENT OF MRI TREATMENT RESPONSES TO APRIMILAST IN PATIENTS WITH PSORIATIC ARTHRITIS

P. Bird1, M. Boesen2, M. Hintom2, E. Sanverdi3, R. Hagou5, C. Sabin5, P. Nakasato4, B. Greuter5, O. Kubassova5, Optimus Research, New South Wales, Australia; 2Copenhagen University Hospital Bispebjerg-Frederiksberg, Department of Radiology, Copenhagen, Denmark; 3Image Analysis Group (IAG), London, United Kingdom; 5Celgene Corporation, Summit, United States of America

Background: Response to treatment in psoriatic arthritis (PsA) can be captured using the OMERACT PsA Magnetic Resonance Imaging Score (PsAMRIS). While reliable and valid, PsAMRIS interpretation requires a trained reader to assess inflammatory lesions such as synovitis and flexor tenosynovitis on a discrete scale ranging from 0 to 3, which might not have sufficient sensitivity to capture early and subtle changes in inflammation in small cohorts.

Methods: In clinical practice, BMI increase was found in the majority of PsA pts. Obesity was associated with higher PsA activity, more prevalence of CV Met disorders and worse PROs. Obesity requires a change of the pts' lifestyle, nutrition correction and a right choice of therapy.

</tbody>
</table>

Methods: 614 (MF=331(54%)/283(46%)) PsA pts fulfilling the CASPAR criteria were included from the RU-PsART cohort. Mean age 45.2±0.52 yrs, PsA duration 5.7±0.27 yrs, PsO duration 15.7±0.56 yrs. At baseline (BL) PsA activity was evaluated by Tender Joint Count (TJC66), Swollen Joint Count (SJJC68), PGA, physician global assessment by Visual Analog Scale (VAS), DAPSA, PROs according to PGtVAAS, PPtPainVAS, HAQ, Work Productivity and Activity Index (WPAI) and Body Mass Index (BMI, kg/m²). All pts were split into three groups by BMI (kg/m²): normal<25 (I group), overweight 25-30 (II group), obese>30 (III group). Only limited data are available for cardiovascular (CV) and metabolic (Met) disorders due to the combination of inflammation and obesity. Obesity was associated with higher PsA activity, more prevalence of CV/Met comorbidities and worse PROs. Obesity requires a change of the pts' lifestyle, nutrition correction and a right choice of therapy.

DOI: 10.1136/annrheumdis-2020-eular.5538
Objectives: To propose a novel computer-assisted imaging quantitative methodology to assess early response to treatment on a continuous scale and compare its results with those of PsAMRIS.

Methods: Patients with active PsA in the hand and wrist were treated with apremilast 30mg twice daily after a 5-day titration period. A total of 29 patients underwent MRI scans at baseline and months 3, 6, and 12. Images were scored for synovitis using the PsAMRIS interpreted by an experienced reader and were read in blinded sequences. Images for 13 patients with involvement of the wrist and metacarpophalangeal (MCP) joints and MRI available at baseline, 3 months, and 6 months were further processed using a novel computer-assisted imaging quantitative methodology. Images were scored concurrently, with the reader blinded to the order of visits. An experienced reader pre-defined regions of interest (ROIs) around the wrist, MCP joints (MCP-2 to MCP-5), and flexor and extensor tendons of the fingers and wrist (as applicable) with adjacent blood vessels and possible artifacts excluded from ROIs. From these ROIs, the normalized volume of inflammation (Normv) was calculated in each joint and tendon. This was done by automatically counting the pixels that were enhanced above the intensity level of a muscle. Each enhanced pixel was given a weight corresponding to the degree of enhancement, allowing differentiation of areas of residual inflammation and high perfusion. This method has been validated, tested, and implemented in the CE/ETDAS 10-cleared software package Dynamika (IAQ, Image Analysis Group). PsAMRIS responses were compared with those of the computer-assisted imaging quantitative methodology at baseline, 3 months, and 6 months. A heat map of normalized intensities was produced, highlighting areas of perfusion higher than that of healthy muscle. Changes from baseline were tested for significance using a t-test. Patients with non-missing data were included in the final statistical analysis.

Results: The generated NormI map highlighted a reduction in wrist inflammation activity after 3 and 6 months of treatment with apremilast. In all cases, a downward trend in inflammatory activity in the wrist and MCP joints was observed at 3 months, indicating a reduction following treatment with apremilast (Figures 1 and 2). Similar improvements were observed in tenosynovitis (Figures 1 and 2).

Conclusion: In this pilot assessment, apremilast was associated with improvements in synovitis and tenosynovitis over a period of 6 months using PsAMRIS. Assessment of images using NormI, a methodology allowing quantification of inflammatory activity within a joint or tendon, demonstrated the same trends over 6 months. Further studies are planned to determine the sensitivity of this novel computer-assisted imaging quantitative methodology relative to that of PsAMRIS and whether it could be used to provide early indications of treatment response in small cohorts of patients.

SAT0426 CAN BIOLGICS "PREVENT" THE DEVELOPMENT OF PSORIASIC ARTHRITIS IN PSORIASIS PATIENTS? DATA FROM A LARGE UNIVERSITY HOSPITAL COHORT IN ARGENTINA

L. Lo Giudice1, M. L. Acosta Felquer1, M. L. Galimberti1, L. Mazzucco1, E. Soriano1. 1Hospital Italiano de Buenos Aires, ABH, Argentina

Background: As psoriasis (PsO) commonly precedes psoriatic arthritis (PsA), an important unanswered question is whether treatment of PsO might influence the development of PsA in patients with psoriasis.

Objectives: The objective of this study was to analyze the incidence of PsA in a large cohort of patients with PsO according to different treatments, with the hypothesis that treatment with biologics might prevent the development of PsA.

Methods: Patients with PsO without PsA followed at a University Hospital were included in this retrospective cohort study. Data was obtained from the Hospital Electronic Medical Record (EMR). Patients were classified according to their treatment in topics group (topic and phototherapy), conventional DMARDs (cDMARDs) group (Methotrexate (MTX) and cyclosporine (Cyc)), and biologic DMARDs group (bDMARDs) (TNFi, IL17i, and IL12-23i). Patients contributed time since beginning of the corresponding treatment until diagnosis of PsA, lost of follow up, end of treatment or end of study. Incident cases of PsA were attributed to one treatment if developed during the administration of that treatment and up to 6 months after its discontinuation if no other treatment was started. Incident cases that developed more than one year after discontinuation of treatment were disregarded (3 cases). Incidence rate was calculated for the whole population and for each one of the treatment groups and compared with chi²test, and rate ratios were calculated as well. A multivariable logistic model for the development of PsA was analyzed by treatment groups, adjusting by other variables.

Results: 797 patients, contributed a total of 10017 patient-years. Patient's characteristics are shown in table 1. 599 (75%) patients were treated only with topics or phototherapy, 106 (13%) with cDMARDs (81% MTX and 19% Cyc) and 92 (11.5%) with biologics (TNFi: 64; etanercept: 44, adalimumab:23, infliximab:6; IL17i: 43: 14 Ikekizumab, 29 Secukinumab; IL12-23i: (Ustekinumab) 16; some patients received more than one biologic). During follow-up 72 patients developed PsA (68 under topics; 3 under cDMARDs (2 MTX and 1 Cyc) and 1 under biologics (1 Secukinumab)). Global incidence rate: 7.2 per 1000 patient-years (table 1). Although numerically the incidence of PsA in PsO patients treated with biologics was lower, the difference was not statistically significant. In Cox regression analysis, after adjusting by sex, age, and BMI, treatment with biologics was significantly associated with a reduced risk of developing PsA: Hazard ratio (95% CI): 0.1 (0.013 – 0.7); p= 0.021.

Conclusion: Treatment with biologics in patients with PsO seemed to reduce the risk of PsA and preventing its development in this retrospective single center cohort.

Acknowledgments: This study was awarded with the PANLAR stimulus award 2019.
COMPARATIVE EFFECTIVENESS OF TOFACITINIB (TF) AND ADALIMUMAB (ADA) IN PSORIATIC ARTHRITIS (PsA) PATIENTS IN REAL CLINICAL PRACTICE.

E. Loginova1, T. Koroteava2, E. Gubar1, Y. Korsakova1, S. Glukhova1, E. Vasilenko2, A. Vasilenko3, N. Kuznetsova4, I. Patrikeeva5 on behalf of Tumornov Research Institute of Rheumatology, Moscow, Russian Federation; 1St. Petersburg Clinical Rheumatology Hospital No.25, St. Petersburg, Russian Federation; 2Novgorod Regional Clinical Hospital, Novgorod, Russian Federation; 3City Clinical Hospital No. 40, Ekaterinburg, Ekaterinburg, Russian Federation; 4Pyjemal Regional Medical Hospital No.1, Pyjemal, Russian Federation

Background: Tofacitinib (TF) is an oral Janus kinase inhibitor approved for PsA treatment. It has demonstrated comparable ADA efficacy in RCTs in reducing PsA clinical symptoms 1,2,3. There is currently no data concerning comparative effectiveness of TF and ADA in clinical practice. The Russian PsA Registry (RU-PSART) collected data from 43 rheumatology centers in the Russian Federation.

Objectives: to study responses to TF or ADA over a period of 6 months (mo) treatment in patients (pts) with active PsA in real clinical practice.

Methods: 77 (M/F=43/34) PsA pts fulfilling the CASPAR criteria from the RU-PSART cohort were divided into two groups according to the treatment given. 41 pts (M/F=24 (58.6%) /17 (41.4%), mean age 42.4±10.3 years (yrs), median (Me) PsA duration 72 (36-120) mo were treated with TF 5 mg twice daily, 36 pts (M/F=19 (52.8%) /17 (47.2%), mean age 44.1±15 yrs, Me PsA duration 59 (22;102) mo were treated with ADA 40 mg twice weekly, subcutaneous, as a first-line bDMARD. In TF/ADA groups 89%/52.8% pts accordingly were given combination therapy with Methotrexate (MTX). At baseline (BL) and at 6 mo of therapy PsA activity by DAPSA, BASDAI, the number of pts (NPts) with dactylitis, enthesitis in both TF/ADA, ADA groups decreased significantly: from 27 (69.2%) to 12 (30.8%) (p<0.002) and from 13 (36.1%) to 6 (20%) pts (p=0.15). The NPts with enthesitis in both TF/ADA groups decreased significantly: from 22 (53.7%) to 5 (13,2%) pts (p<0.001), and in ADA-treated group no significant differences were found (p=0.76 for CRP , p=0.86 for ASDAS and p=0.35 for DAPSA). In real clinical practice TF and ADA demonstrated comparable clinical effectiveness in all clinical domains of active PsA and showed equal result in achievement of MDA/LA/Remission according to DAPSA.

IMPACT OF DOSE ESCALATION OF SECUKINUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS IN REAL-WORLD SETTING.

M. Martin Lopez1, B. Joven-Ibáñez1, J. L. Pablos1. Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Secukinumab (SEC) has provided efficacy in clinical trials in patients with psoriatic arthritis (PsA). In PsA patients, a gain in response has been suggested by dose escalation from 150 to 300 mg in the open phase of the future study1.

Objectives: To analyze the usefulness of dose escalation of SEC from 150 to 300 mg in patients with non-responding PsA to 150 mg in real-world setting.

Methods: Multicentric observational, longitudinal, retrospective study conducted in a tertiary hospital between January 2016 and December 2019. Patients with PsA (CASPAR criteria) receiving at least one dose of SEC were included. Medical records were reviewed and clinical and laboratory data were analyzed. The response to SEC (including activity assessment and treatment). Descriptive statistics and a comparative analysis of the efficacy of SEC by the Student t test in the different dose groups and by the ANOVA test to compare the response between the three dose groups were performed.

Results: 98 patients with PsA treated with SEC, of which 69(70%) female were included. Mean age was 54 y.o (SD12) and average duration of the disease was 9 (SD7) years. Three groups were made according to the dose received, SEC150, SEC300 and SEC150-300 (non-responders after SEC150 onset increasing to 300 mg). The SEC150 group includes 58(59%) patients of whom 32(55%) had received at least one biological (16 one biological, 8 two biological and 10 three or more). The survival of SEC was 1.3 (SD1) years and was suspended in 24(41%) patients, due to primary failure in 9, secondary failure 10, adverse events 4 and allergy to latex 1. The SEC300 group includes 12 (12%) patients of whom 10 (83%) had received at least one biological (1 one biological, 3 two and 6 three or more). The survival of the SEC was 1.6 (13) years and was suspended in 8 (67%) patients, due to primary failure in 2, secondary failure 5 and remission 1. Finally, the SEC150-300 group includes 28 (29%) patients of whom 17 (61%) had received at least one biological (7 one biological, 2 and 2 three or more). The survival of the SEC was 1.6 (SD0.9) years and was suspended in 15 (48%) patients, due to secondary failure. 54%, therefore, maintains the SEC after responding to the dose increase. The average time of dose increase to 300 mg was 9(SD6) months. In the three treatment groups, a significant decrease in the values of CRP, ASDAS-CRP and DAPSA was observed at 6 months of SEC (Table 1).

Table 1. Disease activity assessment at 6 months of SEC therapy.

| CRP300 (mg/L) | CRP150 (mg/L) | CRP300-300 (mg/L) | ASDAS-CRP300 | ASDAS-CRP150-300 |
| 8.8±4.7 | 4.0±4.7 | 2.9±4.7 | 0.489 | 0.489 |
| (9.6-9.9) | (4.0-6.7) | (2.9-4.7) | (0.489-4.7) | (0.489-4.7) |

Conclusion: There are no significant differences in the response evaluated by CRP: ASDAS-CRP and DAPSA between the dose of 150 and 300 mg of SEC. However, both doses of treatment provided efficacy in clinical practice with significant reduction of activity parameters. In the case of patients not responding to SEC150 mg and prior failure to TNFi, increasing the dose to 300 mg could be an effective option.

DOI: 10.1136/annrheumdis-2020-eular.1818
Background: Secukinumab, an interleukin-17 antagonist approved for the treatment of PsA, improves all PsA manifestations in the GRAPPA-OMERACT core domain set. Few US-based studies have evaluated the real-world effectiveness of secukinumab in patients with PsA.

Objectives: To examine clinical and patient-reported outcomes (PROs) in patients with PsA enrolled in the Corona PsA/SpA registry initiating secukinumab with ≥ 1 follow-up visit.

Methods: Included were adult patients with PsA who initiated secukinumab after April 1, 2017 and remained on secukinumab at their 6-month (window, 5-8 months) follow-up visit. The primary outcome was achievement of minimal disease activity (MDA) at 6 months among patients not in MDA at secukinumab initiation. MDA was defined as meeting 5 of the 7 following criteria: tender joint count (TJC) ≤ 1, swollen joint count (SJC) ≤ 1, psoriasis affected body surface area (BSA) < 3%, patient assessment of pain on visual analog scale (VAS) ≤ 15, patient global assessment VAS ≤ 20, HAQ-DI ≤ 0.5, and tender enthesal points ≤ 1 using the Leeds Enthesitis Index (LEI). Secondary outcomes included the proportion of patients who achieved resolution (0 sites) of TJC, SJC, enthesitis (using the LEI), and dactylitis among those with ≥ 1 site at initiation and improvement from baseline in clinical outcomes (BSA, nail psoriasis, physician global assessment, TJC, SJC, and DAPSA) and PROs (patient-reported pain, patient global assessment, HAQ-DI, and Work Productivity and Activity Impairment questionnaire) at 6 months. Outcomes were evaluated in the overall population and in potentially recalcitrant patients with failure of or intolerance to ≥ 3 previous biologics to examine if the latter line biologic could be adequately effective.

Results: A total of 100 patients with PsA who initiated and maintained secukinumab after 6 months were included. The mean (SD) age was 51.6 (11.6) years, 54.3% were male, and 96.8% were white. The mean (SD) symptom and disease duration were 10.8 (9.7) and 7.0 (7.0) years, respectively. Thirty patients (30.0%) initiated secukinumab 150 mg and 70 (70.0%) initiated secukinumab 300 mg. Most (83.0%) were biologic experienced; 17 patients initiated secukinumab as a 1st biologic, 34 as 2nd, 26 as 3rd, and 23 as ≥ 4th. At initiation, 75/90 patients (83.3%) were not in MDA; 26/71 (36.6%) of those with follow-up data available achieved MDA at 6 months (Figure 1). In the overall population, 28 patients (41.2%) with TJC ≥ 1, 24 (44.4%) with SJC ≥ 1, 17 (60.7%) with enthesitis, and 9 (75.0%) with dactylitis at initiation achieved resolution at 6 months (Table 1). Improvement was observed at 6 months in clinical outcomes and PROs in the overall population (Figures 1 and 2) and in patients who initiated secukinumab as a ≥ 4th-line biologic.

Conclusion: In the Corona registry, most secukinumab initiators with PsA were biologic experienced and were not in MDA at time of initiation. Consistent with clinical trials, real-world patients treated with secukinumab achieved MDA as well as improvement in clinical manifestations, PROs, and work productivity.

Conclusion: In the Corona registry, most secukinumab initiators with PsA were biologic experienced and were not in MDA at time of initiation. Consistent with clinical trials, real-world patients treated with secukinumab achieved MDA as well as improvement in clinical manifestations, PROs, and work productivity.

References:

Disclosure of Interests: Philip J Mease Grant/research support from: Abbott, Amgen, Biogen Idec, BMS, Celgene Corporation, Eli Lilly, Novartis, Pfizer, Sun Pharmaceutical, UCB – grant/research support, Consultant of: Abbott, Amgen, Biogen Idec, BMS, Celgene Corporation, Eli Lilly, Novartis, Pfizer, Sun Pharmaceutical, UCB – consultant, Speakers bureau: Abbott, Amgen, Biogen Idec, BM就需要还不错的一种方式使得内容更加组织良好。
Objectives: To assess the real-life 6- and 12-month secukinumab retention rates and proportions of patients in remission/low disease activity (LDA) overall, and by prior biologic disease-modifying anti-rheumatic drug (bDMARD)/targeted synthetic (t)DMARD use.

Methods: Data from PsA patients treated with secukinumab in routine care from 13 countries in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were pooled. Patients started secukinumab ≥12 months before date of data cut. Crude and LUNDEX adjusted (crude value adjusted for drug duration) 28-joint Disease Activity index for Psoriatic Arthritis (DAPSA28) and 28-joint Disease Activity Score with CRP (DAS28CRP) remission and LDA rates were calculated. Group comparisons between b/tsDMARD naïve, 1 prior and ≥2 prior b/tsDMARD users were done with ANOVA, Kruskal-Wallis or Chi-square test, as appropriate. Larger proportions were men and a higher proportion achieved remission. Overall, a higher proportion of bionaive than previous b/tsDMARD users achieved remission, regardless of remission criteria.

Results: A total of 1543 PsA patients were included (Table 1). b/tsDMARD naïve patients had shorter time since diagnosis, higher baseline disease activity, a higher proportion were men and a higher proportion achieved remission. Overall, crude 6- and 12-month DAPSA28 ≤4/DAS28CRP <2.6 were achieved by 13%/34% and 11%/39% of the patients, respectively.

PROPORTIONS OF PATIENTS ACHIEVING A MINIMAL DISEASE ACTIVITY STATE UPON TREATMENT WITH TILDRAKIZUMAB IN A PSORIATIC ARTHRITIS PHASE 2B STUDY

P. Nash1, M. E. Luggen2, L. Espinoza3, F. J. García Fructuoso4, R. C. Chou5, A. M. Mendelsohn6, S. Rozzo7, I. McInnes1, 1School of Medicine Griffith University, Brisbane, Australia; 2Cincinnati Rheumatoid Disease Study Group, Inc, and Univ of Cincinnati College of Medicine, Cincinnati, United States of America; 3LSU Health Sciences Center, New Orleans, United States of America; 4Hospital CIMA Sanitas, Barcelona, Spain; 5Univ at Buffalo School of Medicine and Biomedical Sciences, Buffalo, United States of America; 6Sun Pharmaceuticals Industries, Inc, Princeton, United States of America; 7Univ of Glasgow, Glasgow, United Kingdom

Background: Tildrakizumab (TIL) is a high-affinity anti-interleukin-23p19 monoclonal antibody approved in the US, EU, and Australia to treat moderate to severe plaque psoriasis. A randomised, double-blind, placebo-controlled, multiple-dose, phase 2b study evaluating the efficacy and safety of TIL was recently completed (NCT02980692).

Objectives: To characterise and evaluate the rate of minimal disease activity (MDA) up to week (W)52 from the phase 2b study.

Methods: Patients (pts) ≥18 years old with active psoriatic arthritis (PsA) and ≥3 tender and ≥3 swollen joints were randomised 1:1:1:1:1 to receive TIL 200 mg every 4 weeks (Q4W) to W52, TIL 200 mg Q12W to W52, TIL 100 mg Q12W to W52, TIL 20 mg Q12W to W24—TIL 200 mg Q12W to W52, or placebo (PBO) Q4W to W24—TIL 200 mg Q12W to W52. MDA was assessed throughout the study; an MDA response was achieved when 5 of 7 criteria were met. Safety was assessed throughout the study and included treatment-emergent adverse event (TEAE) monitoring.

Results: Of 500 pts screened, 391 were randomised and received ≥1 dose of study drug. At baseline (BL), mean age was 48.8 years, 55% were female, 97% were White, mean body mass index was 29.7 kg/m², and pts had PsA for a median (range) of 4.4 (0–42.8) years since diagnosis. Baseline disease characteristics related to MDA varied little between study arms (Table).

By W24, MDA state was achieved in significantly more pts receiving TIL vs PBO (24% vs 39% vs 7%; p=0.02 for all groups); the proportion further increased with continued TIL treatment to W52 (45%–64%), including pts who switched from PBO to TIL (47%) (Figure 1).

Among the overall pt population from BL—W24/W25—W52, 50.4%/39.9% and 2.3%/10% experienced a TEAE and serious TEAE, respectively. From BL—W24, 1 serious infection (chronic tonsillitis) was reported for TIL 200 mg—200 mg Q12W arm. From W25—W52, there was 1 malignancy (TIL 200 mg Q12W). There were no reports of candidiasis, uveitis, inflammatory bowel disease, major adverse cardiac events, or deaths from BL—W24 or W25—W52.

SAT0431

SAT0432
Background: Female sex has been associated with more severe disease and poorer treatment outcomes in PsA. These observations are often based on small populations or national cohorts/registries.

Objectives: To investigate the effects of sex on disease characteristics and disease impact in PsA, using data of 929 consecutive patients (pts) from PsABio.

Methods: PsABio is a real-world, non-interventional European study in PsA pts treated with UST or TNFi based on their rheumatologist’s choice. Observed male and female baseline (BL) data were described and compared using 95% CI.

Results: Women in PsABio (n=512 [55%]) were numerically older than men (mean [SD]: 50.5 [12.7] / 48.7 [12.3] years, respectively). Women were more obese (BMI >30), % (95% CI): F: 35 (30, 39), M: 24 (20, 29), men more overweight (BMI >25–30): F: 31 (27, 36), M:51 (46, 57). Age at diagnosis, delay from first symptom to diagnosis, and disease duration were similar for both sexes.

Women entered PsABio more often on 3rd line treatment, whereas men started on 1st-line biologic treatment more often (F/M 1st line 47%/55%; 2nd line 34%/33%; 3rd line 20%/12%). Numerically, concomitant MTX was given more often to women vs men (32% vs 27%). At BL, 60% of women and 64% of men were on NSAIDs; 79% and 2.5% on antidepressant drugs. Women had significantly more comorbidities, with numerically more cardiovascular disease and anxiety/depression, and 3 times more IBD.

Women had significantly higher 68 tender joint counts (TJC): 13.0 vs 10.4, while 66 swollen joint counts were not significantly different: 5.8 vs 5.5. Axial or combined axial-peripheral disease was similarly frequent, in 29% of women and 26% of men (Figs. 1, 2).

Clinical Disease Activity index for PSoriatic Arthritis (cDAPSA) was higher in women (31.8 vs 27.3); pt-reported levels of pain, global disease activity (VAS scales) and higher TJC contributed to this. While enthesitis prevalence (based on Leeds Enthesitis Index) was comparable, men had significantly more frequent dactylitis, nail disease and worse skin psoriasis. At BL, 3.4% of women vs 7.1% of men, were in MDA.

Regarding physical functioning (HAQ-DI), impact of disease (PSAID-12) and quality of life (EQSD-3L health state), women with PsA starting a biologic (b) DMARD, expressed significantly greater negative impact and more limitations due to their disease (Fig. 2).

Conclusion: In routine care, women with PsA starting a bDMARD presented with worse outcomes over a range of assessments compared with men (higher pt-reported pain and disease activity, TJC, and worse physical functioning and QoL), while men had worse dactylitis and psoriasis. Follow-up analysis will report whether the effects of biologic therapy are different in both sexes. The increased prevalence of associated features related to pain and impact on functioning and QoL may indicate the need for a more comprehensive treatment approach for women to avoid unnecessary and premature bDMARD stop or switch.

Acknowledgments: This study was funded by Janssen.

SAT0433 TRIAL SIMULATION TO INFORM ENROLLMENT CRITERIA AND OUTCOME MEASURES FOR PRAGMATIC TRIALS IN PSA A. Ogdie1, S. Weinstein1, L. C. Coates2, P. Helliwell3, A. Stephens-Shields1. 1University of Pennsylvania, Philadelphia, United States of America; 2University of Oxford, Oxford, United Kingdom; 3University of Leeds, Leeds, United Kingdom

Background: Randomized controlled trials (RCTs) in psoriatic arthritis (PsA) have traditionally enrolled a homogenous subgroup of patients with more polyarticular disease, and the outcome measure used in PsA RCTs (ACR20) may not be ideal to measure differences between two active therapies nor capture change in patients with lower joint counts.

Objectives: We conducted a simulation study to determine how changing the inclusion criteria and the primary outcome measure would impact the outcome of a future RCT.

Methods: We used the Tight Control of PsA (TICOPA) trial to inform simulation of two hypothetical head-to-head trials comparing MTX to TNFi with 100 patients per arm. Within TICOPA, we identified MTX and TNFi new users; the visit at drug initiation became the hypothetical trial baseline visit, and the follow up visit was 12 weeks later. These data informed prediction models to simulate enrolled patients. We utilized propensity score-adjusted outcome models to account for potential confounding by indication. Trial 1, modeled after the SEAM-PsA trial, used typical enrollment criteria (≥3 tender joint count (TJC) and ≥3 swollen joint count (SJC)) 2; Trial 2 required ≥1 TJC/SJC. 1 For each trial, five binary outcomes were simulated: ACR20, Disease Activity in PsA (DAPSA), clinical DAPSA (cDAPSA), Routine Assessment of Patient Index Data (RAPID3), and PsA Disease Activity Score (PASDAS), where low disease activity was the cutoff for continuous measures. Each hypothetical trial was simulated 1000 times, and the distribution of estimated effects was summarized using standard summary statistics and graphs.

Results: Among 188 patients in TICOPA, 179 patients initiated MTX, and 43 patients initiated TNFi within the first 36 weeks. Among these, 107 MTX initiators and 15 TNFi initiators had ≥3 TJC and ≥3 SJC at drug initiation. Baseline characteristics of those in the “severe” (≥3 TJC and ≥3 SJC) and not severe (not meeting ≥3 TJC and ≥3 SJC) are shown in Table 1. Among “severe” patients, the mean probability of achieving ACR20 across simulations was approximately 0.27 in both arms and the observed relative risk (RR) TNFi vs MTX severe cohort across simulations was 1.0, IQR 0.84-1.17 (the RR in the SEAM trial at 24 wks was 1.20, 95%CI:1.05-1.35). In the “full cohort,” the median RR was 1.0, IQR 0.81-1.20. Trials using PASDAS, cDAPSA, and RAPID3 were more likely to differentiate between MTX and TNFi in the severe cohort (figure) but in the full cohort the results favored MTX.

</tbody>
</table>

**Severe** = ≥3 tender and ≥3 swollen joints

**Not-severe** = <3 tender or <3 swollen joints

*Pseudo-baseline characteristics were at the time of drug initiation. In cases where the patient started a TNFi between visits, these were the values at the previous visit.

Abbreviations: SMD = standardized mean difference, TJC=tender joint count, SJC=swollen joint count

Conclusion: Including patients with lower joint counts in an RCT reduced the ability to detect change with therapy. Additionally, among the outcome measures used to detect a difference between two active therapies, PASDAS, cDAPSA, and RAPID3 outperformed ACR20.

SAT0434 MINIMAL CLINICALLY IMPORTANT DIFFERENCE IN OUTCOME MEASURES FOR USE IN CLINICAL CARE AND PRAGMATIC TRIALS IN PSA A. Ogdie1, M. E. Husni2, J. Scher3, E. Craig1, S. Reddy1, J. A. Walsh1. 1University of Pennsylvania, Philadelphia, United States of America; 2Cleveland Clinic, Cleveland, United States of America; 3New York University, New York, United States of America; 4University of Utah, Salt Lake City, United States of America

Background: While several outcome measures have been studied for use in clinical studies of psoriatic arthritis, little is known about thresholds of meaning such as minimal clinically important improvement (MCII).

Objectives: To investigate the distribution of scores for candidate outcome measures for pragmatic trials in PsA and to calculate the MCII for each outcome measure.

Methods: We performed a longitudinal cohort study within the Psoriatic Arthritis Research Consortium (PARC), a multi-center study based in the US. Patients completed validated PROs (patient reported outcomes) and rheumatologists completed skin, joint, enthesis and dactylitis scores at therapy initiation and follow up 12-16 weeks later. In addition, patients completed a global assessment of response at the follow up visit; categorizing their status as improved, stayed the same, or worsened and then rated the importance of the change on a scale from 0-7. We then calculated and plotted the change in each of the following measures: Routine Assessment of Patient Index Data (RAPID3), clinical Disease Activity of Psoriatic Arthritis (cDAPSA), Patient Reported Outcome Measure Information System (PROMIS) Global Health short form (10a) physical health (PH) subscore, patient pain assessment, patient global assessment (0-10 NRS), and physician global assessments (0-10 NRS) of the joints and overall. We calculated the MCII as the mean change in score (with 95% confidence interval) among patients who reported improved and rated the level of improvement as “almost none/hardly at all” or “a little important.” Additionally, we calculated Spearman’s correlation coefficients between the measures and the global assessment of response.

Results: Among 148 unique patients, 233 therapy change visits were eligible for analysis. The average age was 52.5 years, 52% were female and mean BMI was 29.6. Baseline RAPID3 was 11.1 (SD 6), cDAPSA 179 (SD 13.9), PROMIS PH 42 (SD 8), patient global 4.2 (SD 2.5), TJC 5.9 (SD 7.5), and SJC 2.9 (SD 4.5). TNFi comprised 61% of drug initiations, 21% were IL17i and the remainder were other biologics and oral systemic therapies. At follow up, 63 (27%) patients rated themselves as improved whereas 103 (44%) stayed the same and 67 (29%) reported...
worsening. The mean change in each measure by patient-reported response (improved, stayed the same, or worsened) are shown in Figures 1A & B. In general, the mean score increased from ‘improved’ to ‘worsened’ as expected (with the exception of PROMIS PH which declines given a different direction of scoring). The MCII for each measure was as follows: RAPID3 -1.8 (-4.1 to 0.5), Patient Global 0.6 (-1.6 to 0.4), Physician Global -1 (-1.9 to -0.1), cDAPSA -5.7 (-9.8 to -1.7), and PROMIS PH 1.9 (-2.1 to 5.8). Correlation for each measure with the global assessment of response were: RAPID3 0.48, Patient Global 0.37, Physician Global 0.39, cDAPSA 0.51, and PROMIS PH 0.39.

Conclusion: This is the first study to test thresholds of meaning for these particular measures in PsA. The MCII values are relatively low for all outcome measures. This may be related to the relatively low disease activity at baseline but is consistent with patients seen in clinical practice initiating therapy.

SAT0436 PATIENTS WITH PSORIATIC ARTHRITIS WHO ACHIEVE THE MDA RESPONSE SHOW LESS SUBCLINICAL ATHEROSCLEROSIS THAN THOSE IN DAPSA REMISSION

J. A. Lorenzo Martin1, E. Pardo Campó2, L. C. Charca Benavente2, M. Pino Martínez2, S. Alonso Castro3, S. Fernández4, L. M. Arboleya Rodríguez5, M. Alperi-López2, B. Guerín Silva1, 1Hospital Universitario de Burgos, Burgos, Spain; 2Hospital Universitario Central de Asturias, Rheumatology, OVIEDO, Spain

Background: Although the MDA response and DAPSA remission are treatment objectives proposed by EULAR for a proper management of psoriatic arthritis (PsA), there is no clear consensus on which of the two is the most advisable in clinical practice. Some studies suggest that patients who reach a sustained MDA have less subclinical atherosclerosis, but whether the same applies to DAPSA remission is unknown at present.

Objectives: To compare the frequency of subclinical atherosclerosis in patients with PsA that reach the MDA response versus those who achieve DAPSA remission.

Methods: One hundred-forty consecutive patients with PsA (CASPAR criteria) treated with biological and non-biological systemic agents were included. SCORE risk charts were used to estimate cardiovascular risk (CVR). The presence of plaques and/or carotid intima-media thickness (cIMT) > 0.9 mm in carotid ultrasound defined subclinical atherosclerosis. These findings were analyzed in patients in MDA and in those in DAPSA remission.

Results: According to the SCORE tables, 42.8%, 35.7% and 21.5%, had low, moderate and high very-high CVR, respectively. There was a linear association between cIMT values and the SCORE risk categories (p < 0.0005). The best cut-off point to define a high CVR by SCORE plus carotid plaques corresponded to a cIMT > 0.633 mm, with an area under the ROC curve of 0.75 (0.66-0.82), sensitivity 85.7%, specificity 56.1% (Figure 1). Ninety-seven of the 140 patients (69.3%) were in MDA situation, while 60 (42.8%) were in DAPSA remission. The sensitivity 85.7%, specificity 56.1% (Figure 1). Ninety-seven of the 140 patients (69.3%) were in MDA situation, while 60 (42.8%) were in DAPSA remission.

Conclusion: Patients who achieve an MDA response show less subclinical atherosclerosis than those in DAPSA remission. This finding suggests that the MDA response better discriminates the presence of subclinical atherosclerosis, and therefore, it could be a more complete therapeutic target than DAPSA remission.

SAT0437 GENDER DIFFERENCES IN PSA OUTCOME PARAMETERS AND THEIR CORRELATION WITH SKIN INVOLVEMENT: A CROSS-SECTIONAL ANALYSIS OF RABBIT-SPA PATIENTS

A. Regierer1, A. Weiß2, F. Behrens3, M. Feuchtenberger4, G. Schett1,4, X. Baraliakos2,5, A. Zink2, A. Strandfeld1, 1Deutsches Rheuma-Forschungszentrum (DRFZ), Epidemiology, Berlin, Germany; 2Goethe University Frankfurt, Rheumatology, Frankfurt, Germany; 3Medizinische Universität zu LMU München, Rheumatology, Munich, Germany; 4Medizinische Universität zu LMU München, Department of Dermatology, Munich, Germany

Results are presented as mean ± SD.

Bsa was not correlated with SJC66 or TJC68, DAPSA, DAS28, psysSK, patSk, and patSk in neither men nor women. Bsa was however positive correlated with DLOI, patSk, and psysSK and slightly with psysGA in both genders. The PSAID is correlated to BSA in women only.

Conclusion: Women and men show differences regarding many PsA criteria. Men have a more severe skin involvement, while women have higher burden of joint involvement. In addition in the patient reported parameters women show significantly higher values than men except for the skin specific parameters. Notably, although skin involvement is not correlated with most PsA activity parameters, around 50% of patients in specialised rheumatologic care are negatively affected in their quality of life by psoriatic skin disease. Therapeutic decisions need to take into account the complexity of the patients’ conditions as well as gender differences.

Acknowledgments: RABBIT-SPA is supported by a joint, unconditional grant from AbbVie, Amgen, Janssen-Cilag, Lilly, MSD, Mylan, Novartis, Pfizer, and UCIB.

Our aim was to study drug survival of bDMARDs in a German real-world cohort of adult biologic-naïve psoriatic arthritis patients.

Methods: We utilized the German “Institut für angewandte Gesundheitsforschung Berlin” (InGeF) research database consisting of about 4 million covered lives structured to represent the German population in terms of age and gender according to the Federal Office of Statistics (DESTATIS). Thereof, 2.9 million patients were continuously enrolled in the study period spanning from January 1st, 2013 and December 31st, 2018. For the analysis of persistence rates, the study population was identified based on the International Classification of Diseases, German Modification (ICD-10-GM) and claims records of biologic prescriptions based on ATC codes. Adult patients who had a diagnosis of psoriasis arthritis (L40.5 in combination with M070 or M071 or M072 or M073) in the inpatient or outpatient setting, and a claims record of biologic treatment licensed for psoriasis arthritis between January 1st, 2014 to December 31st, 2017 were included. Patients with Crohn’s disease (K50), ulcerative colitis (K51), ankylosing spondylitis (M45), and rheumatoid arthritis (M05-M07) were excluded. Biologic-naïve patients were identified as those who had no prior record of bDMARDs prescription during the 12 months before the index date (washout). The index date was defined as the first claim for a biologic agent. Non-persistence occurred if a treatment gap exceeding the days of supply plus 60 days or a switch to a bDMARD other than the index therapy was observed. Days of supply were calculated on the daily defined doses defined by the WHO for the respective bDMARDs. Kaplan-Meier curves were plotted to show the persistence of different biologics. The log-rank test was used to test for differences in the 1-year persistence rate.

Results: Among 10,954 patients with a diagnosis of PsA, 348 biologic-naïve patients aged 18 years or above were identified. The one-year overall persistence rate was 57.5% for all bDMARD compounds. Reasons for non-persistence were switches to a different bDMARD agent in 15.8% of patients and 26.7% discontinued treatment. The highest persistence rate was observed for ustekinumab (81.3%), which was significantly higher than the respective rates for adalimumab (58.1%), certolizumab pegol (51.7%), etanercept (51.0%), or secukinumab (54.7%).

Conclusion: The highest persistence rate was observed for ustekinumab (81.3%), certolizumab pegol (51.7%), etanercept (51.0%), or secukinumab (54.7%). Reasons for non-persistence were switches to a different bDMARD agent in 15.8% of patients and 26.7% discontinued treatment. The log-rank test was used to test for differences in the 1-year persistence rate. Both pulley inflammation and tenosynovitis were correlated with DAPSA (ρb=0.56, p<0.01 and ρb=0.48, p<0.01). In fact, 7 out 8 (88%) PsA patients with at least one inflamed A1 pulley had a moderate to high disease activity score. The regression linear analysis (R2=0.36, adjusted R2=0.31) showed that A1 pulley inflammation was correlated with higher DAPSA scores (p=0.43, p=0.03). No significant association was reported between A1 pulley inflammation and past or current episodes of dactylitis (p=0.09). The only current dactylitis assessed showed A1 pulley inflammation.

References:
[1] Tan AL, Fukuba E, Halliday NA, Tanner SF, Emery P, McDonald D. High-resolution MRI assessment of dactylitis in psoriatic arthritis shows flexor tenosynovitis to be the presenting feature in the presence of A1 pulley signal within a thickened pulley, which is relatively common at patient level in psoriatic arthritis and seems to be characteristic of PsA compared to RA. In psoriatic arthritis patients, a positive significant correlation was found between ultrasound A1 pulley inflammation and disease activity. DOI: 10.1136/annrheumdis-2020-eular.1404
Background: Methotrexate (MTX) is the most common first-line disease-modified anti-rheumatic drugs in psoriatic arthritis (PsA), despite the controversies. 

Objectives: In this study, we aimed to determine the rate of withdrawal rate of MTX in PsA and reasons for discontinuing.

Methods: A large prospective international multicenter PsA registry was used for this study. Data were collected either at enrolment, based on history, or prospectively if there was a follow up. We analyzed the frequency of MTX usage, discontinuation and the reason for discontinuation. The time on MTX was compared according to the reason of discontinuation (inefficacy vs side effects) using Kaplan-Meier and Cox regression analyses to identify risk factors for discontinuation.

Results: At the time of analyses, 1670 patients had been recruited to the registry and 1359 PsA patients had used MTX during the course of the disease (81.3%). Within these, 942 (69.3%) were still on MTX at the time of analysis, and 417 (30.7%) patients have discontinued (Table). The most common reasons for withdrawal were side effects (219/417, 52.5%) and ineffectiveness (88/417, 21.1%). Other reasons included pregnancy, remission, self-decision (11.9%) for all. For 60 patients (14.3%), the reason could not be identified. In patients who were still on MTX, the median duration of MTX therapy was 31 months (IQR=59) compared to 17 months (IQR=43) in the withdrawal group. The most common side effects were gastrointestinal symptoms (47%) and abnormal liver function tests (25%). There was a significant difference in survival plots (Log-rank p=0.026) with discontinuing due to side effects occurring earlier than ineffectiveness (Figure 1).

In the Cox regression model, longer disease duration was found as an independent predictor of MTX discontinuation due to all reasons [Hazard Ratio (HR)=1.01, 95% Confidence interval (CI)=1.0-1.02; p=0.003].

Conclusion: MTX is frequently used on PsA treatment, despite the controversies in the literature. One third of patients with PsA discontinue MTX, most commonly due to side effects or inefficacy. Patients discontinue MTX earlier in case of having side effects. Longer disease duration is linked to MTX discontinuation.

Disclosure of Interests: Obesity is a leading comorbidity in both psoriasis (Pso) and psoriatic arthritis (PsA) and is associated with common metabolic complications and increased cardiovascular (CV) risk. Obesity is also a risk factor for the onset of these diseases. Body composition and fat distribution have been rarely evaluated in Pso and PsA.

Objectives: In this study, we aimed to characterize the fat mass distribution in patients with Pso or PsA compared to a control group, with a special emphasis on the android/visceral region.

Methods: case-control study (NCT02849795). Patients with Pso (plaque psoriasis) or PsA (CASPAR criteria) were evaluated. Each patient was paired to a control subject, recruited in the same outpatient population, and matched for sex, age and body mass index (BMI) category. Clinical assessment included BMI, anthropometric measurements (waist circumference, waist/hip ratio), disease activity (PASI for Pso, CPDAI for PsA) and the SCORE CV risk score. Laboratory parameters of inflammation (ESR, CRP, IL-6), lipid parameters (total cholesterol, LDL and HDL cholesterol, triglycerides), metabolic parameters (glycemia, insulin, HOMA), serum adipokines (total and high molecular weight (HMW) adiponectin, leptin, resistin and retinol binding protein 4 (RBP4)) were measured. Body composition (lean mass, fat mass) and fat distribution (android/gynoid regions and visceral fat) were evaluated (DEXA, Lunar QE, CoreScan). Our primary criteria was the fat mass in the android/visceral region. Comparisons between patients and controls were performed with paired t-tests, between all groups with ANCOVA (adjusted for age, sex, and BMI category) and Tukey post-hoc tests. Pearson correlations between CV risk and fat mass were calculated within groups.

Results: 52 patients with Pso and 52 patients with PsA and their respective paired-control were evaluated. Total fat mass was increased in Pso but not in PsA. Android fat and visceral fat were found higher in Pso (p<0.05) while the fat mass measurements did not differ between the patients with PsA and their controls. Waist circumference was higher in patients with Pso compared to their controls. Leptin, leptin/fat mass ratio, and total adiponectin were elevated in Pso compared to PsA. In this study, we aimed to characterize the fat mass distribution in patients with Pso or PsA compared to a control group, with a special emphasis on the android/visceral region.

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2020-eular.2611
Background: Oligoarthritis and polyarthritis are the predominant phenotypes in PsA. Previous we have shown that patients with oligoarthritis suffer a similar loss in quality of life as polyarthritic patients. Although oligoarthritis is one of the most prevalent form, ample data is available on this phenotype.1,2

Objectives: To evaluate the evolution of swollen joint count over the first year since diagnosis and to assess baseline difference in those groups that evolved differently over time.

Methods: Our study is embedded in the Dutch south-west Early Psoriatic Arthritis (DEPAr) prospective cohort study. We described patient characteristics using simple descriptive analysis techniques. For the comparison across groups univariable multinomial logistic regression was used in STATA15. Oligoarticular disease was defined as 2, 3 or 4 swollen joints.

Results: 175 patients had a complete 12-month evaluation as of February 2019 (80% of all included patients with oligoarthritis). Baseline characteristics are shown in Table 1. In total 63 percent of the patients (111/175) had resolution of swollen joints at 1 year. (figure 1). Over the first year, 27 patients had consistently no swollen joints since their 3 month evaluation, 26 had no swollen joint from 6 months and 12 from 9 months and 11 at 12 months. 65 of the 175 (37%) had inconsistently no swollen joints (after 6 months) showed little difference and;(iii) the ‘intermittent’ group varied in smoking status, fatigue, being female and age. Multivariable analysis may reveal other patterns, but requires a larger sample than that currently available.

Figure 1. Evolution of swollen joint count in psoriatic oligoarthritis (n=175) over time expressed in a binary swollen joint count (yes: 0 / no: sjc=0; mv= missing value).

Conclusion: In our set of real world data, about one third of the PsA patients with oligoarticular disease had no resolution of swollen joints at 1 year. About half of these patient had consistently inflamed joints over time. Another third of the PsA patients had intermittently inflamed joints. At baseline these groups seems comparable in clinical presentation, demographics and PROMs, although some variation existed between early versus never and early versus intermittent resolution of swollen joints. Both indices provide room for improvement in the management of oligoarticular disease in PsA.

SAT0443

CONCOMITANT PSORIATIC ARTHRITIS AND INFLAMMATORY BOWEL DISEASE IN THE PSA BIOLOGICAL REGISTRY: HUR-BIO REAL LIFE RESULTS

G. K. Yardımcı1, B. Farrisöğulları1, B. Armagan1, E. Bilgin1, E. C. Bolek1, E. Duran1, L. Kilic1, O. Karadag1, A. Akdoğan1, Ş. A. Bilgen1, A. I. Ertelen1, S. Kiraz1, U. Kalyoncu1,2. Faculty of Medicine; Hacettepe University, Rheumatology, Ankara, Turkey

Background: Patients with spondyloarthritis (SpA) have 3 important extra-articular involvement: psoriasis, uveitis and inflammatory bowel disease (IBD). Psoriatic arthritis (PsA) patients may have IBD, as well, and clinical features of PsA + IBD patients do not assess comprehensively, yet.

Objectives: The purpose of this study is to determine the frequency and clinical features of concomitant PSA and IBD in a PsA biological DMARD cohort.

Methods: Hacettepe University Rheumatology Biologic (HUR-BIO) is a single center biologic registry since 2005 and include 469 psoriatic arthritics patients to date. Demographics, clinical features, co-morbidities, laboratory and disease activity parameters collected from the database. The diagnosis of IBD was accepted with colonoscopy findings and pathology.

Results: Overall, 469 PsA patients (70% females) with the mean age 47.7±12.4 years and [median (IQR)] disease duration 7 (3–11) years included in the study. Overall, 10/469 (5 male) PsA patients (2.1%) had IBD (7 (70%) with ulcerative colitis and 3 (30%) Crohn’s disease). Mean age of the patients was 53.3±10.0 years and mean disease duration was 9.0 ± 6.1 years. Six of ten patients were diagnosed with IBD before PsA and 4 of them were diagnosed with PsA first. Patients were followed-up for 3.7±2.8 years and bDMARD switch were made in 4 patients mostly due to primary inefficacy; bDMARD was discontinued in 2 patients (one for Crohn disease with fistula and one for drug induced SLE). According to DAPSA score 44% of the patients had low disease activity and 56% of the patients had moderate disease activity at last visit (9 patients were available). Sacroiliitis (70%) and severe radiographic hip (20%) involvement were common in PsA patients with IBD. Disease characteristics and demographic data are given in table 1.

</table>

Conclusion: In our single center biological registry, relatively small portion of PsA patients had concomitant IBD, however, those cases may have severe axial involvement, particularly in hip involvement, and further studies needed for these subgroup. Physician should be aware those SpA subgroup, because treatment choices, particularly IL-17 inhibitors may have some cautions patients with PsA and IBD.

Table 1. Prevalence and risk of MOF and VF according to BMD stratified by TBS T-score

Trabecular Bone Score (TBS) is a textural index of bone microarchitecture and has been found to be related to 3D bone structure. A number of cohort studies have demonstrated the value of TBS as an independent fracture risk in clinical trials. Yet, very little is known about the performance and clinical value of BTE in real life practice.

Objectives: To investigate the sensitivity and specificity of TBS in identifying prevalent fractures when compared with bone mineral density (BMD) measured by DXA. To evaluate the added value of TBS in fracture risk prediction above that obtained from DXA.

Methods: Consecutive patients aged ≥ 18 with BMI 15-37 attaining a DXA plus TBS assessment were considered eligible. Sensitivity, specificity, and area under the curve (AUC) for prevalent major osteoporotic fracture (MOF) and clinical vertebral fractures (VF) were assessed for the following parameters: BMD lowest T-score ≤ -2.5, or osteoporosis (TBS score ≤ -2.5) and TBS score ≤-1, and two fracture risk indices: TBS score ≤-2.5, and degraded TBS (TBS score ≤-2.5) resulting in 9 risk groups. Odds ratios were calculated for all risk categories and fracture prevalence was compared between the best and worst BTE strata at each BMD level using chi-square test.

Results: 540 patients (87% females, 68.1 ± 11.6 years) were included. 238 (44%) had MOF including 81 (15%) clinical VF. For MOF, BMD had higher sensitivity (49.6% vs 30.7%), lower specificity (68.2% vs 82.1%), and similar AUC (0.59 vs 0.56) versus TBS. For VF, the sensitivity, specificity and AUC for BMD were 60%, 64%, and 0.62 respectively versus 42%, 79.7%, and 0.61 for TBS. Combining TBS and BMD (either T-score ≤-2.5) increased the sensitivity to 63% for MOF and 75.3% for VF without affecting AUC (0.6 and 0.64 respectively). Patients with osteoporosis and degraded TBS had the highest OR of 2.65 for MOF and 3.8 for VF. The fracture risk increased at the same level of BMD when TBS was degraded. Numerically, the risk of MOF increased steadily from strata 1 to 9 and was statistically significant for osteoporosis with degraded TBS and osteoporosis with moderate TBS. When both TBS and BMD were normal, the risk of fracture was significantly reduced. In the osteopenia and osteoporosis BMD categories, patients with degraded TBS had significantly higher prevalence of fracture compared to those with normal TBS in the same BMD category.

Conclusion: Fracture risk stratification can be improved when TBS is added to BMD. The sensitivity of predicting fracture may also improve when TBS and BMD are combined. Patients with both normal TBS and BMD have the lowest fracture risk, whereas those with degraded TBS and osteoporosis have the highest risk of fracture and should be targeted for early or more aggressive treatment.

SAT0446
RISK OF ACUTE MYOCARDIAL INFARCTION (AMI) AMONG NEW USERS OF BISPHOSPHONATES: A NESTED CASE-CONTROL STUDY

Objectives: To analyze the hypothesis that BF reduce the risk of AMI in new users and assess whether the effect depends on the duration of treatment.

Methods: Case-control study nested in a primary cohort composed of patients aged 40 to 90 years, with at least one year of follow-up in the BIFAP database during the 2002-2015 study period. From this cohort of patients, we identified incident cases of AMI and randomly selected five controls per case, matched by age, gender, and index date. Adjusted odds ratios (AOR) and their corresponding 95% confidence interval (CI) were calculated through an unconditional logistic regression. Only new users of BF were considered.

Results: A total of 23,590 cases of IAM and 117,612 controls were included. The mean age was 66.8 (SD 13.4) years and 72.6% were male, in both groups. 584 (2.47%) cases and 2,892 (2.46%) controls used or had used some bisphosphonate. The use of BF was not associated with a lower risk of IAM (AOR 0.97; 95%CI: 0.84-1.13). Nor was it associated with the duration of treatment (AOR less than 1 year = 0.91; 95%CI: 0.72-1.15; AOR more than 1 year = 1.01; 95%CI: 0.84-1.21). The stratified analysis by age and sex also did not show either a protective effect of BF. Detailed results by BF type are shown in the following table:

SAT0447
CORRELATES OF RADIAL BONE MICROARCHITECTURES IN OLDER ADULTS

C. Ma1, F. Pan1, F. Wu1, H. H. Nguyen1, L. Laslett1, T. Winzenberg1, G. Jones1.

Methods: Cross-sectional data on 201 older adults (mean age 72 years, female 46%) from a population-based cohort study were analysed. Weight, dietary patterns, serum 25-hydroxyvitamin D (25(OH)D) concentrations, physical activity and grip strength with bone measures in older adults.

Results: Weight was positively associated with radial bone area (total: β=0.18, 95% CI: 0.07, 0.29; cortical: β=0.12, 95% CI: 0.03, 0.21; trabecular: β=0.18, 95% CI: 0.05, 0.32), and was inversely associated with compact cortical volumetric bone mineral density (vBMD) (β=-0.19, 95% CI: -0.37, -0.01), and trabecular thickness (β=-0.25, 95% CI: -0.43, -0.07). Ten-year changes in weight were not significantly associated with bone measures, apart from radial trabecular separation (β=0.15, 95%CI: 0.009, 0.28). Western dietary pattern scores were inversely associated with radial vBMD (total: β=-0.17, 95% CI: -0.32, -0.01; cortical: β=-0.19, 95% CI: -0.34, -0.04; outer transitional zone: β=-0.20, 95% CI: -0.35, -0.06), and were positively associated with cortical porosity (cortical: β=0.18, 95% CI: 0.03, 0.33; compact cortical: β=0.19, 95% CI: 0.04, 0.34; outer transitional zone: β=0.20, 95% CI: 0.06, 0.35). Steps per day were not significantly associated with bone measures, apart from inner transitional zone area and thickness (β=0.12, 95% CI: 0.003, 0.24; β=0.19, 95% CI: 0.05, 0.33). Healthy food pattern scores, serum 25(OH)D and grip strength were not significantly associated with radial HRpQCT measurements.

Conclusion: Higher weight, but not weight change, was beneficial for radial cortical and trabecular bone area but also associated with worse compact cortical vBMD and trabecular thickness. Higher western dietary pattern scores had adverse effects on radial vBMD and cortical porosity while physical activity had inconsistent associations.

DOI: 10.1136/annrheumdis-2020-eular.7262
Background: There is much controversy surrounding the loss of bone mass in patients with psoriasis arthritis (PsA).

Objectives: To evaluate the prevalence of osteoporosis (OP) and fracture in patients with PsA in the Swiss Clinical Quality Management (SCQM) cohort, a large national database of patients with inflammatory arthritis; to study different factors influencing bone health and the correlation between disease activity, treatment and occurrence of densitometric osteoporosis or fracture.

Methods: We analyzed all PsA-patients included in the cohort from 2006-April 2019. We evaluated demographic and clinical data: age, gender, BMI, disease duration, smoking/alcohol habits, patients' and physician's global assessment, joint count, HAQ, medication and inflammatory activity measured by ESR, CRP, DAS 28 and DAPSA score. We compared patients with BMD measurement (DXA) with the group without DXA (nDXA). In DXA group we analyzed patients according to osteoporotic status and did subgroup analysis in premenopausal, menopausal women and men.

Results: Of the 2443 patients, 545 had a DXA. Age of scanned patients was 18-84 years. Only 259 BMD data were available for analysis. DXA patients were 6.4 years older (54.2±11.1 vs 47.8±12.4 years, P<0.001), and were more female (67% vs 43%). Duration of the disease was longer (6.6±8.3 vs 5.3±7.1 years, p<0.001) in DXA group. DAS28-ESR and DAS28-ESR were higher in DXA group (3.1±1.2 vs 2.9±1.1, P<0.04 and 3.2±1.4 vs 3±1.3, p<0.002, respectively), as was the DAPSA score (32±30 vs 27±20 P<0.004). Patients in DXA group were more exposed to prednisone and conventional DMARDs (15.4% vs 4.7%, p<0.001 and 51.7% vs 43%, P<0.01 respectively).

There were more fractures in DXA- than in nDXA group (5.7% vs 1.4%, P<0.001). In DXA group 18.4% had OP and 50.2% osteopenia. Patient characteristics are shown in Table 1. We confirmed a positive correlation between femoral and lumbar BMD and BMI, and between higher age and lower femoral BMD. Disease duration was inversely correlated with femoral, but not lumbar BMD. Interestingly, other variables, including disease activity, showed no significant correlation with the BMD, but OP patients had higher disease activity.

Table 1. Comparison between patients with and without OP in DXA group. *: statistically significant. Values are expressed as mean and standard deviation unless stated otherwise.

Subgroup analysis (Figure 1) showed higher OP prevalence in postmenopausal women (22.6%) vs in men (18.8%) or premenopausal women (10.7%) in correspondence with the fracture rate (8.3% vs 6.3% vs 3.9%). BMD was lower and the disease activity was higher in postmenopausal women compared to the others groups.

Conclusion: Our data suggest that Swiss clinician are aware of risk of poor bone-health in PsA patients and perform DXA in this population even in younger patients and in men. Interestingly, we describe that the patients with OP had higher disease activity and poorer functional status than patients without OP. Longitudinal studies are needed to evaluate bone quality, fractures, and relationship between bone health in PsA and disease associated factors. They should integrate parameters of bone turnover and use an appropriate control group.
DXA and 3 (1.3%) had indication for treatment by FRAX without DXA but they lost it by FRAX with DXA. We found a moderate level of agreement in the indication for treatment between FRAX with and without DXA (kappa=0.595; p<0.001). The use of DXA in FRAX estimation significantly improved the agreement median FR, both for major osteoporotic fracture (2.4% [0.8-31.0] vs 1.8% [0.6-20.0]; p<0.001) and for hip fracture (0.5% [0.0-23.0] vs 0.2% [0.0-14.0]; p<0.001). We found significant correlations between FR and some disease-related variables (Table 1).

Conclusion: Our results showed that a similar number of patients had indication for pharmacological treatment by FRAX both with and without DXA. Although the inclusion of DXA resulted in a higher estimated FR by FRAX, the observed moderate level of agreement between FRAX with and without DXA suggests that the FR estimation by FRAX, even without DXA, may be a reasonable approach in SpA patients. In line with literature, we found significant associations between the estimated risk fracture by FRAX and some disease activity and function measures.

SAT0452 DIFFERENT PROFILE OF RISK OF FRACTURE IN PATIENTS TREATED WITH ANTI-OSTEOPOROTIC DRUGS IN ITALY USING A NEW ALGORITHM

G. Adami1, A. Fassio2, A. Giolo3, G. Orsolini4, O. Viapiana5, D. Gatti6, M. Rossini7.1University of Verona, Verona, Italy

Background: A new algorithm for management of patients at low, high and very high risk of osteoporotic fractures has been recently proposed, has been also recommended treating those patients at very high risk of fracture with bone anabolics [1]. A similar treatment algorithm has been applied in Italy since 2015, when the "Nota 79" that regulates the reimbursability for osteoporosis medications, has been developed by the Italian Agency for Drugs (AIFA) [2].

Objectives: In the present study, using a new mathematical and computerized algorithm, we seek to investigate the profile of risk of fracture of patients starting treatment with different anti-osteoporotic medications in Italy.

Methods: We retrospectively analyzed the 10-year risk of major osteoporotic fracture calculated with the DeFRAcalc79 tool in postmenopausal women aged over 50 years that were initiating an anti-osteoporotic treatment (fully reimbursed according to the Nota 79). DeFRAcalc79 is a new web-based fracture risk-assessment tool (https://defra-osteoporosi.it) that arithmetically adjusts the risk based on the integration of multiple risk factors contemplated by the AIFAs Nota 79, including: demographic and anthropometric data, femoral and/or lumbar spine BMD T-score, family history of femoral or vertebral fractures, number and site of previous osteoporotic fracture (including vertebral, femoral, and nonvertebral nonfemoral fractures), glucocorticoid treatment (> 3 or > 12 months, ≥5 mg prednisone or equivalent), adjuvant hormone therapy for breast or prostate cancer, and comorbidities that increase the risk (rheumatoid arthritis and other connective tissue diseases, chronic obstructive pulmonary disease, inflammatory bowel diseases, Parkinson's disease, multiple sclerosis, HIV infection, diabetes, or severe physical handicap).

Results: We retrieved data for 10,235 women prescribed with an anti-osteoporotic treatment. Figure 1 shows the mean 10-year fracture risk estimated with DeFRAcalc79 tool at the time of the treatment initiation. Teriparatide users had the highest 10-year risk of fracture (67.4% Standard Deviation [SD] 21.5%). We found that in 2,231 patients starting denosumab, the 10-year baseline risk of fracture was 38.5%, SD 22.8%. In 5,759 patients initiating alendronate was 25.7%, SD 15.3% and in patients initiating risedronate was 275%, SD 26.9%. Patients prescribed with zolendronic acid had a mean 10-year risk of fracture of 35.6%, SD 21.6. P values between means were all <0.01.

Figure 1. Mean 10-year risk of fracture estimated with DeFRAcalc79 tool at the time of treatment initiation, p < 0.01 between all means.

Conclusion: The risk of fracture of Italian post-menopausal women initiating different anti-osteoporotic medications varies significantly. Teriparatide is prescribed to patients with greater risk of fracture. The Nota 79 correctly individuates patients at very high risk of fracture that merit treatment with a bone anabolic. Denosumab and zoledronic acid are prescribed to patients with a greater risk of fracture compared to oral bisphosphonates. DeFRAcalc79 is a useful and practical tool for the integrated evaluation of the profile of risk of fracture.

DOI: 10.1136/annrheumdis-2020-eular.2559
Background: Denosumab is effective for osteoporosis, but discontinuation leads to rapid reversal of its therapeutic effect[1].

Objectives: To estimate the risk for fracture among users of denosumab who delayed subsequent dosages compared with users who received dosages on time.

Methods: Population-based cohort study. We included patients aged over 45 years who initiated denosumab for osteoporosis from UK THIN database, 2010 to 2019. Observational data were used to “emulate a hypothetical trial”[2, 3] with three dosing intervals: subsequent denosumab injection 24-28 weeks after prior dose (“on time”), delay by 4-16 weeks (“short delay”), and delay by over 16 weeks (“long delay”). The primary outcome was a composite of all fracture types. Secondary outcomes included major osteoporotic fracture, vertebral fracture, and hip fracture.

Results: The rate of composite fracture per 1000 person-years was 58.9 for on-time, 61.7 for short delay, and 85.4 for long delay of subsequent denosumab injections. Compared to on-time injections, short delay had a hazard ratio (HR) for composite fracture 1.03 (95% CI 0.63-1.69) and long delay HR 1.44 (95% CI 0.96-2.17; p for trend 0.093). For major osteoporotic fractures, short delay had an HR 0.94 (95% CI 0.57-1.55) and long delay an HR of 1.69 (95% CI 1.01-2.83; p for trend 0.056). For vertebral fractures, short delay had an HR 1.48 (95% CI 0.58-3.79) and long delay 3.91 (95% CI 1.62-9.45; p for trend 0.005).

Conclusion: While delayed subsequent denosumab dosages over 16 weeks was associated with an increased risk of vertebral and major osteoporotic fracture compared to no delay, composite fracture risk was not increased with longer delays.

Background: Radiofrequency Echographic Multi Spectrometry (REMS) is the first clinically available approach for direct non-ionizing measurement of bone mineral density (BMD) at lumbar spine (LS) and femoral neck (FN). Available scientific evidences describe BMD estimated by REMS as an accurate parameter of mineral density (BMD) at lumbar spine (LS) and femoral neck (FN). Available scientific evidences describe BMD estimated by REMS as an accurate parameter of bone mineral density (BMD) at lumbar spine (LS) and femoral neck (FN). Available scientific evidences describe BMD estimated by REMS as an accurate parameter of bone mineral density (BMD) at lumbar spine (LS) and femoral neck (FN). Available scientific evidences describe BMD estimated by REMS as an accurate parameter of bone mineral density (BMD) at lumbar spine (LS) and femoral neck (FN).

Objectives: To investigate the effectiveness of the T-score values provided by REMS scans at FN and LS in the identification of frail patients at risk for osteoporotic fractures and to compare the performance of REMS with the dual-energy X-ray absorptiometry (DXA) one.

Methods: The patients underwent DXA and REMS scans at FN and at LS. Five clusters of fractures occurred during a median 3.5-year follow-up were identified whether involving the upper limb (forearm, elbow, humerus, wrist, hand), lower limb (tibia, ankle, metatarsus), thorax (shoulder blade, shoulder, rib), hip (femur or pelvis bones), or vertebrae. The ability of REMS and DXA T-score values to assess the incidence and site of fractures was evaluated through an analysis of covariance.

Results: Seven hundred twenty-one Caucasian women were enrolled. Nine clusters of fractures occurred during a median 3.5-year follow-up were identified. The T-score measured at axial sites is an effective parameter for the diagnosis of osteoporosis [1].

Conclusion: REMS T-score measured at axial sites is an effective parameter for identification of patients at the risk of incident fragility fractures, in particular occurring at hip, vertebra or upper limb in a population-based sample of female subjects.

DOI: 10.1136/annrheumdis-2020-eular.5359
Methods: We have retrospectively analyzed the 10-year risk of major osteoporotic fracture calculated with the DeFRAcalc79 tool in postmenopausal women aged over 50 years that were initiating an anti-osteoporotic treatment (fully reimbursed according to the Nota 79). DeFRAcalc79 is a new web-based fracture risk-assessment tool (https://defra-osteoporosi.it) that algorithmically adjusts the risk based on multiple risk factors contemplated by the Nota 79, which regulates the reimbursability for osteoporosis medications in Italy (Italian Agency for Drugs, AIFA), including demographic and anthropometric data, femoral and/or lumbar spine BMD T-score, family history of femoral or vertebral fractures, number and site of previous osteoporotic fracture (including vertebral, femoral, and non-vertebral non-femoral fractures), glucocorticoid treatment (>3 or >12 months, ≥5mg prednisone or equivalent), adjuvant hormone therapy, for breast cancer, and comorbidities that induce an increased risk of fracture (rheumatoid arthritis and other connective tissue diseases, chronic obstructive pulmonary disease, inflammatory bowel diseases, Parkinson's disease, multiple sclerosis, human immunodeficiency virus infection, diabetes, or severe physical handicap). This is a sub-analysis of the cross-sectional observational study to validate and further develop the DeFRA algorithm for the estimation of the risk of osteoporotic fractures, promoted by Verona hospital with the unconditional support of Amgen Srl.

Results: Among 208 women, 116 (55.8%) were treated with adjuvant hormone therapy for breast cancer and 92 (44.2%) were on glucocorticoid ≥5mg/day. Women on glucocorticoids had a greater mean 10-year risk of fracture compared to women on adjuvant hormone therapy for breast cancer (67.0% vs 39.1%, p<0.01). 50.7% of women on adjuvant hormone therapy for breast cancer were prescribed denosumab, 28.0% zoledronic acid and 17.3% alendronate. In glucocorticoid-induced osteoporosis, 17.6% of the women used teriparatide, 37.3% alendronate, 29.4% zoledronic acid and 13.7% denosumab.

Conclusion: In our cohort of patients, treatment with adjuvant hormone therapy for breast cancer was slightly more common than glucocorticoids. Women with glucocorticoid-induced osteoporosis had a greater risk of fracture compared to patients treated with adjuvant hormone therapy for breast cancer. Half of the patients on adjuvant hormone therapy for breast cancer were prescribed with denosumab. One-fifth of the patients with glucocorticoid-induced osteoporosis was treated with teriparadate. DeFRAcalc79 is a useful and practical tool for the integrated evaluation of fracture risk in drug-induced osteoporosis.

SAT0457 PREVALENCE OF OSTEOPOROSIS IN OSTEARTHRITIC PATIENTS: A SYSTEMATIC REVIEW

A. Ahmed Pinhahid1, D. Kim2, Y. Li1, T. Varghese1, J. Pope1. 1Western University, Medicine, London, Canada

Background: There is controversy regarding the relationship between osteoarthritis (OA) and osteoporosis (OP), While OA may be associated with increased bone mineral density (BMD) due to increased weight, evidence exists that the incidence of OP may be increased in patients with OA.

Objectives: To determine whether the prevalence of OP is increased in patients with OA, compared to age and sex-matched populations.

Methods: We conducted a systematic literature review using the databases PubMed, Embase, Scopus, and Web of Science, including articles that articulated the frequency, rate, prevalence, incidence, risk, or excess risk of OP in patients with OA compared to age and sex-matched comparison groups (control). Articles with fewer than 200 participants, and those without controls were excluded. Two reviewers conducted title and abstract screening.

Results: Of 2772 unique articles, 49 articles were chosen for full article screening, and 4 articles met the inclusion criteria of our present study. Data from 2 and 4 studies used OP in men and women, respectively. Other articles reported on BMD and not OP so they were excluded. In women, 998 participants with OA were compared with 1903 controls. The pooled estimate of the odds ratio for prevalence of OP vs general matched population was not statistically different (Figure 1). In men, 136 participants with OA were compared with 682 controls. The results did not show a statistically significant different in the frequency of OP in OA in men (Figure 2).

Figure 1. Prevalence of OP in women with OA compared to controls

Figure 2. Prevalence of OP in men with OA compared to controls

Conclusion: The frequency of OP in participants with OA was the same in both men and women compared to the matched controls.

References:
for trend in women, respectively), and between the minor allele and overweight (≥25 in BMI, OR 1.52, 95%CI 1.18 to 1.95, p=0.01 in women). Logistic regression analysis showed a significant protective association in men with carriers of minor allele against low bone mass after an adjustment for age and BMI (OR 0.63, 95%CI 0.44 to 0.90, p=0.01 in men, not significant in women).

Conclusion: Our study indicated significant associations of the polymorphism on FTO with BMI and bone mass among community dwelling men. The polymorphism may play a rule in part of a bone health with higher BMI and other beneficial functions.

A. Bacchiroti1, P. L. Nguyen-Thi2, A. Blum3, A. Baccichetti1, P. L. Nguyen-Thi2, A. Blum3, D. Mainard4, F. Sirveaux4, L. Nace5, I. Chary Valckenaere1, D. Loeuille1, CHU Nancy, Rheumatology, Nancy, France; 2CHU Nancy, Medical Evaluation, Nancy, France; 3CHU Nancy, Radiology Guilloz, Nancy, France; 4CHU Nancy, Orthopedic Surgery, Nancy, France; 5CHU Nancy, Emergencies Unit, Nancy, France; 6CHU Nancy, Post Emergencies Unit, Nancy, France; 7CHU Nancy, Neurosurgery, Nancy, France; 8CHU Nancy, Hand Surgery, Nancy, France; 9CHU Nancy, Geriatrics, Nancy, France; 10CHU Nancy, Endocrinology, Nancy, France; 11CHU Nancy, Medical Information, Nancy, France

Background: Osteoporotic fractures are a major public health concern because of their consequences in morbidity, costs and mortality. In the meantime, historically post fracture osteoporosis medication use rates have been poor.

Objectives: The aim is to analyze the management of osteoporosis in patients hospitalized for osteoporotic fractures (OF) at Nancy University Hospital (France) in 2017.

Methods: Total number of hospitalized patients and hospital stays was extracted by the Department of Medical Information (DIM) which selected departments with at least forty hospitalizations with Medical Unit Summary related to a diagnosis of fracture or osteoporosis. Hospitalizations not concerned by a recent OF were excluded. Data on fractures, patient characteristics, risk factors for OF and fall, management of osteoporosis, discharge status, stay duration, were studied from patient medical records. Prevalence of OF stays, management of osteoporosis and factors associated with duration of stay were analyzed.

Results: Out of a total of 153,840 hospitalizations, 918 hospitalizations (844 patients, mean age 74.5 years ± 13.6, 74.5% women) concern an OF. The prevalence of hospitalizations for OF was 0.6% of total hospitalizations and 17.9% of the observation period modifications of bone metabolism occurred: we detected a decreased RANK-L/OPG ratio and increased CTX levels at all time points vs. baseline. Particularly, change at month-1 of sclerostin (versus baseline) has been positively associated with change at month-1 and month-2 of CTX (r=0.48, p=0.01 and r=0.43, p=0.01, respectively). Change at month-1 of OPG was positively associated with change at month-1 of P1NP (r=0.49, p=0.006).

Conclusion: Drinking lemon juice may boost bone metabolic changes involving both bone resorption and bone formation.

SAT0461 SHORT-TERM MONITORING OF DENOSUMAB EFFECT IN BREAST CANCER PATIENTS RECEIVING AROMATASE INHIBITORS USING REMS TECHNOLOGY ON LUMBAR SPINE

E. Quarta1, D. Ciardi2, M. Ciccerese2, F. Converaseno2, M. Di Pio3, R. Forognano1, A. Giralda1, F. A. Lombardi3, M. Muratore3, F. Pisani3, S. Ciasciano2, Galateo Hospital, ASL-LE, O.U. of Rheumatology, San Cesario di Lecce, Italy; 3National Research Council, Institute of Clinical Physiology, Lecce, Italy; 3Vito Fazzi Hospital, ASL-LE, O.U. of Oncology, Lecce, Italy

Background: Aromatase inhibitor (AI) therapy in women with estrogen receptor-positive (ER+) breast cancer (BC) causes accelerated bone loss and increased risk of osteoporosis and fractures as side effects. Denosumab (i.e. 60 mg twice a year) is a viable therapy against bone resorption, but the short-term monitoring of bone mineral density (BMD) change with time is still an unmet clinical need, since the current techniques (including dual-energy X-ray absorptiometry, DXA) require 1-2 years between two consecutive measurements [1]. Radiofrequency Echographic Multi Spectrometry (REMS), with high performance in terms of precision and repeatability [2], might be used in this setting of patients for short-term monitoring of bone health-related parameters.

Objectives: The objective is the short-term monitoring of the effect of AIs with/without denosumab on bone health in BC patients using REMS and DXA scans at lumbar spine.

Methods: Post-menopausal ER+ BC patients treated with adjuvant AIs were recruited. Two subgroups were identified, whether receiving also 60 mg of denosumab therapy every 6 months or not (named Group A and Group B, respectively). All patients underwent baseline DXA and REMS lumbar spine scans at
time T0, previous to the first AI therapy, and after 12 months (time T1). REMS scan only was repeated also at 18 months (T2), since a 6-month interval between two consecutive scans is not recommended for DXA. The bone mineral density (BMD) was measured with both techniques. **Results:** Overall, 254 ER+ BC patients were enrolled (127 per group). The effect of denosumab on BMD is reported in Table 1. The BMD values obtained by DXA and REMS were not significantly different at T0 and T1, whereas the difference between Group A and B at T1 was statistically significant (p<0.001) both for REMS and DXA. At T2, REMS confirmed the increasing trend of BMD for Group A and the decreasing one for Group B, and the difference between groups was statistically significant (p<0.001). For each time point and each group, there were not statistically significant differences between DXA and REMS. **Conclusion:** Several studies have shown the effect of denosumab on BMD over a period not less than 2 years from the start of therapy. This study showed the feasibility of short-term follow-up using REMS lumbar spine scans at 6-month time steps.

**References:**

---

**Table 1.** BMD values, expressed as g/cm², measured by DXA and REMS for Group A (patients receiving AIs only) and Group B (patients receiving AIs and denosumab) at baseline (T0), 12 months (T1) and 18 months (T2) from the start of therapy. Results are presented as median values with 25th and 75th percentiles. P-values are obtained with a Mann-Whitney test.

**SAT0462**  
**ASSESSMENT OF BONE MINERAL DENSITY IN INFLAMMATORY BOWEL DISEASE**

C. Dalidou1, N. El Amri1, K. Baccouche1, H. Zeglau1, E. Bouajina1. 1Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

**Background:** Inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), is considered as a risk factor of low bone mineral density (BMD). In fact, the prevalence of osteoporosis ranges from 17% to 41% in IBD patients. The possible contributing factors may include malabsorption, glucocorticoid treatment and coexisting comorbidities. **Objectives:** The purpose of our work was to determine the frequency and the determinants of osteoporosis in patients with IBD and to assess whether there is a difference in BMD status between UC and CD.

**Results:** This is a retrospective study, over a period of 5 years (from January 2014 to December 2018) and including patients followed for IBD who had a measurement of BMD by DEXA. Clinical, anthropometric and densitometric data (BMD at the femoral and vertebral site) were recorded. The WHO criteria for the definition of osteoporosis and osteopenia were applied. **Results:** One hundred and five patients were collected; among them 45 were men and 60 were women. The average age was 45.89 years old. The average age body mass index (BMI) was 25.81 kg/m², p=0.035) and w 63% and 37%. Osteoporosis among CD and UC patients was found in respectively 37.1% and 37%. The age of the osteoporotic patients was significantly higher compared to those who were not osteoporotic (52.23 vs 43.67 years, p = 0.01).

We found a significantly higher percentage of osteoporosis among men compared to women (35.6% vs 18.3%; p=0.046). The BMD was significantly lower in the osteoporotic patients (23.87 vs 26.48 kg/m², p=0.035) and we found a significant correlation between BMI and BMD at the femoral site (p=0.021). No increase in the frequency of osteoporosis was noted in patients treated with corticosteroids (27.9% vs 21.6%, p=0.479). Comparing the UC and CD patients, no difference was found in baseline characteristics, use of steroids or history of fracture. No statistically significant difference was found between UC and CD patients for osteoporosis(p=0.478), BMD at the femoral site (p=0.529) and at the vertebral site (p=0.568).

**Conclusion:** Osteoporosis was found in 25.7% of IBD patients without any difference between CD and UC. This decline does not seem to be related to the treatment with corticosteroids but rather to the disease itself. Hence the interest of an early screening of this silent disease.

SAT0464

MULTIPLE REBOUND-ASSOCIATED VERTEBRAL FRACTURES AFTER DENOSUMAB DISCONTINUATION IN RHEUMATOLOGY CLINIC

G. Evangelatos1, G. E. Fragoulis1, A. Iliopoulos1, 1417 Army Share Fund Hospital (NIMTS), Rheumatology Department, Athens, Greece; 1National and Kapodistrian University of Athens, First Department of Propaedeutic Internal Medicine, Athens, Greece

Background: Denosumab, a monoclonal antibody against RANKL, is an effective treatment for osteoporosis. Discontinuation of denosumab has been shown to lead in multiple vertebral fractures in some patients due to a severe acceleration of bone resorption (rebound-associated vertebral fractures-RAVF). Limited data published during the last 2 years highlighted this issue.

Objectives: The aim of this case series is to describe features of the denosumab-associated RAVFs and the characteristics of these patients.

Patients: Nine patients from our outpatient rheumatology clinic who were diagnosed with recent vertebral fractures after denosumab discontinuation from January 2019 to December 2019 were included. Diagnosis was based on x-ray and/or magnetic resonance imaging (MRI) of thoracic (T) or lumbar (L) spine. All cases were the result of reduced compliance of the patients to the treatment regimen. A baseline x-ray examination was available in all patients included and was compared in order to exclude prevalent osteoporotic fractures. Demographic and clinical parameters were recorded.

Results: Nine patients (8 females) with a mean±SD age of 71.3±11.9 years were included (Table 1). A total of 32 fractures occurred, affecting median 4 (range 1-6) vertebrae (Figure 1). The mean±SD duration of denosumab treatment prior to discontinuation was 54.0±30.1 months, while the mean±SD time that RAVFs occurred after the last denosumab injection was 8.8±2.4 (range 7-12) months. The most commonly affected vertebra was L3 (Table 1). Most patients (66.7%) did not have any prevalent osteoporotic fracture. Four patients (44.4%) were receiving drugs that affected bone metabolism (mainly corticosteroids and aromatase inhibitors). Only 33.3% of the patients had a history of previous treatment with bisphosphonates.

</tbody>
</table>

Conclusion: Denosumab-associated RAVFs usually occur within 7-12 months after the last denosumab injection and affect multiple vertebrae. Most cases are associated with long-term (>2 years) denosumab administration without previous treatment with bisphosphonates. Rheumatologists should be alert of this complication since the reported compliance in patients under denosumab treatment is only 46% (1) and the expected incidence of RAVFs after denosumab discontinuation has been reported to be 10% (2).

SAT0465

FRACTURE RISK ASSESSMENT BY FRAX IN A SYSTEMIC LUPUS ERYTHEMATOSUS PORTUGUESE COHORT

B. M. Fernandes1, S. Garcia1, S. Ganhão1, M. Rato1, F. Pinheiro1, M. Bernardes1, L. Costa1, 1Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal

Background: Osteoporosis is commonly seen in patients with Systemic Lupus Erythematosus (SLE), even in pre-menopausal patients. The etiology is multifactorial and chronic glucocorticoid therapy seems to play a central role.

Figure 1. Multiple vertebral fractures (yellow arrows - T11, T12, L2-L5) in a patient 7.5 months after the last denosumab injection. T: thoracic, L: lumbar
**Objectives:** To investigate the ten-year risk of fracture assessed by Fracture Risk Assessment Tool (FRAX), with and without dual-energy X-ray absorptiometry (DXA) and to determine possible demographic or clinical factors associated with an increased risk of fracture in a SLE population.

**Methods:** Retrospective study including all the over 40 years-old patients with the diagnosis of SLE (2012 SLICC classification criteria) followed at our Rheumatology Department registered in our national database. Demographic, clinical and laboratorial data were collected at the last follow-up visit. Data from the last DXA (until 3 years prior to the last visit) were collected. Indication for pharmacological treatment by FRAX was assessed according to the national recommendations: estimated fracture risk, without DXA, ≥11% for major osteoporotic fracture or ≥2% for hip fracture and/or estimated fracture risk, with DXA, ≥9% for major osteoporotic fracture or ≥2.5% for hip fracture.

**Results:** We included 104 patients, 101 (97.1%) females, aged 54.5±9.9 years, with a median disease duration of 19.3 years [4.3-51.6]. Twelve patients (11.5%) were current smokers, 31 (29.8%) had elevated anti-dsDNA antibodies (>100 IU/mL) and 27 (26.0%) had complement consumption (C3<0.83mg/dL or C4<0.12mg/dL). 73 patients (70.2%) were taking glucocorticoids with a mean daily prednisolone equivalent dosage of 4.4±2.5mg/day. Regarding SLE treatment, 69 patients (66.3%) were under hydroxychloroquine, 22 (21.2%) under azathoprine, 16 (15.4%) under mycophenolate mofetil, 5 (4.8%) under belimumab, 4 (3.8%) under methotrexate, 1 (1.0%) under leflunomide and 1 (1.0%) under rituximab. Ten patients (9.6%) had previous fragility fractures, 54 patients (51.9%) had osteoporosis treatment, and 141 patients were included, Patients with OP was older (mean 62.6 years), weight and height were higher in those with normal BMD. There was no difference between the use of glucocorticoids or other risk factors (Table 1). According to FRAX risk for OP, 122 (86.5%) had low risk, 14 (9.9%) had intermediate risk and only 15.6% had high risk. According to FRAX risk for hip, 81 (56.2%) had low risk, 38 (26.0%) had intermediate risk and only 5.9% had high risk.

**Conclusion:** A higher number of patients had indication for pharmacological treatment by FRAX with DXA in comparison with FRAX without DXA. However, we found no statistically significant difference in the estimated fracture risk with and without DXA. This, together with the good level of agreement between FRAX with and without DXA, suggests that the fracture risk estimation, even without DXA, may be an appropriate approach. The low number of patients with indication for pharmacological treatment by FRAX, with and without DXA, may be explained by their low mean age and the high number of them under vitamin D/calcium supplementation.

**Background:** Osteoporosis (OP) is characterized by compromised bone strength and deterioration of quality, often leading to fragility fractures (1). Dual-energy x-ray absorptiometry (DXA) is the recommended test for OP screening among patients with RA and other RD (2). However, there are limitations to perform DXA on every patient, and the clinicians use screening tools to identify those patients with higher risk. The opportunite identification of the patients at increased risk and early treatment can prevent the loss of bone mineral density (BMD) and reduce the risk of fractures(3).

**Objectives:** To evaluate the FRAX risk and its correlation with the spine and femoral neck T-score in patients with RA.

**Methods:** An observational retrospective study was done in the rheumatology clinic of the university hospital “Dr. Jose Eleuterio Gonzalez” in Monterrey, Mexico, between March and November 2019. Patients who had reported DXA from the spine and hip in the medical record were included. The risk factors included in FRAX tool was collected; FRAX tool was used online at https://www.sheffield.ac.uk/FRAX/ (algorithm for Mexicans) and classified as low (<10% for OP or <1% for hip), intermediate (10%-19% for OP or 1%-<3% for hip) and high risk (≥20% for OP or ≥3% for hip); results of DXA of the spine and hip were collected. Results are shown in means or frequency. A chi-square test or one-way analysis of variance was used to compare groups. Pearson’s correlation test (r) was done between spine T-score and FRAX risk for OP and between femoral neck T-score and FRAX risk for hip. P<0.05 was considered statistically significant.

**Results:** 141 patients were included, Patients with OP was older (mean 62.6 years), weight and height were higher in those with normal BMD. There was no difference between the use of glucocorticoids or other risk factors (Table 1). According to FRAX risk for OP, 122 (86.5%) had low risk, 14 (9.9%) had intermediate risk and only 15.6% had high risk. According to FRAX risk for hip, 81 (56.2%) had low risk, 38 (27.0%) had intermediate risk and only 22 (15.6%) had high risk.

**Conclusion:** Most of the patients were classified as low risk for OP and hip, including a high amount of those with OP showing a low and moderate correlation with DXA respectively.

with the presence of GIDM.

Background:
Unit, Department of Autoimmune Diseases, Barcelona, Spain

The development of CG-induced diabetes mellitus (GIDM). However, whether the regulation of glucose homeostasis. Glucocorticoid (GC) treatment is associated with an increased risk of GIDM, a finding that was not observed with other bone turnover markers, further confirming the involvement of OC in the glucose homeostasis regulation in this entity.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.1519

Methods: 127 patients (aged 62±18 years, 63% women) on GC treatment for autoimmune diseases (≥5mg/day, >3 months) were included. Clinical and anthropometric data were analysed, including the GC dose and treatment duration, presence of GIDM, fragility fractures, densitometric osteoporosis and bone formation (OC, bone alkaline phosphatase [BAP], PINP) and resorption markers (urinary NTX, serum CTX). The cut-offs of each bone marker for the presence of GIDM were estimated and optimized with the Youden index and included in the logistic regression analysis (adjusted for BMI, age and GC doses).

Results: 17.3% of patients presented GIDM. Diabetic subjects were older (70.3±12.2 vs. 59.6±18.4, p=0.001) and had a higher BMI than non-diabetics (30.5±2.6 vs. 26±4.2, p=0.002). No differences were observed in GC dose or duration or in the presence of vertebral fractures. Diabetics showed lower levels of OC (7.57±1.01 vs. 11.56±1; p<0.001), PINP (21.48±1.01 vs. 28.39±1; p=0.0048), NTX (24.9±1.01 vs. 31.7±1; p=0.036) and CTX (0.2±1±1 vs. 0.3±1; p=0.0016) with similar BAP values. The best discriminating cut-offs for GIDM presence were: <9.25ng/mL for OC, <24ng/mL for PINP, <275nMol/mM for NTX and <0.25ng/mL for CTX. On multivariate analysis OC (<9.25) was the only marker related to the presence of GIDM (OR 6.1; CI95% 1.87-19.89; p=0.001).

Conclusion: Decreased OC levels in GC-treated patients are associated with an increased risk of GIDM, a finding that was not observed with other bone turnover markers, further confirming the involvement of OC in the glucose homeostasis regulation in this entity.

LOW SERUM OSTEOCALCIN LEVELS ARE ASSOCIATED WITH THE PRESENCE OF DIABETES MELLITUS IN GLUCOCORTICOID TREATED PATIENTS.

H. Florez1, J. Hernández-Rodríguez2, J. L. Carrasco2, S. Prieto-González2, X. Fliella3, A. Monegal1, N. Guanabens1, P. Peris1. 1Hospital Clinic, University of Barcelona, Metabolic Bone Diseases Unit. Department of Rheumatology, Barcelona, Spain; 2Hospital Clinic, University of Barcelona, Vasculitis Research Unit, Department of Autoimmune Diseases, Barcelona, Spain; 3Hospital Clinic, University of Barcelona, Bioestatistics, Department of Basic Clinical Practice, Barcelona, Spain; 4Hospital Clinic, Biochemistry and Molecular Genetics Department, Barcelona, Spain

Background: Increasing evidence indicates that osteocalcin (OC) is involved in the regulation of glucose homeostasis. Glucocorticoid (GC) treatment is associated with impaired osteoblast function and decreased OC levels and also with the development of CG-induced diabetes mellitus (GIDM). However, whether decreased OC levels in GC-treated subjects contribute to GIDM is not well known.

Objectives: To analyse whether OC levels in GC-treated patients are associated with the presence of GIDM.

Methods: 127 patients (aged 62±18 years, 63% women) on GC treatment for autoimmune diseases (≥5mg/day, >3 months) were included. Clinical and anthropometric data were analysed, including the GC dose and treatment duration, presence of GIDM, fragility fractures, densitometric osteoporosis and bone formation (OC, bone alkaline phosphatase [BAP], PINP) and resorption markers (urinary NTX, serum CTX). The cut-offs of each bone marker for the presence of GIDM were estimated and optimized with the Youden index and included in the logistic regression analysis (adjusted for BMI, age and GC doses).

Results: 17.3% of patients presented GIDM. Diabetic subjects were older (70.3±12.2 vs. 59.6±18.4, p=0.001) and had a higher BMI than non-diabetics (30.5±2.6 vs. 26±4.2, p=0.002). No differences were observed in GC dose or duration or in the presence of vertebral fractures. Diabetics showed lower levels of OC (7.57±1.01 vs. 11.56±1; p<0.001), PINP (21.48±1.01 vs. 28.39±1; p=0.0048), NTX (24.9±1.01 vs. 31.7±1; p=0.036) and CTX (0.2±1±1 vs. 0.3±1; p=0.0016) with similar BAP values. The best discriminating cut-offs for GIDM presence were: <9.25ng/mL for OC, <24ng/mL for PINP, <275nMol/mM for NTX and <0.25ng/mL for CTX. SAT0468
EFFECTS OF ANDROGEN DEPRIVATION THERAPY ON BONE QUALITY (TBS) IN PATIENTS WITH PROSTATE CANCER

S. Garcia-Cirera1, E. Casado1, J. Muñoz2, L. Del Rio3, M. Arévalo4, M. Rusiñol1, N. Navarro5, V. Parejo6, J. Gratacos-Masmitha7, 1University Hospital Parc Taulí (UAB), Rheumatology, Sabadell, Spain; 2University Hospital Parc Taulí (UAB), Urology, Sabadell, Spain; 3CETIR Medical Center, Barcelona, Spain

Background: Androgen deprivation therapy (ADT), by inducing severe hypogonadism, leads to a loss of bone mineral density (BMD) and an increased risk of fragility fractures after 6 months of treatment in men with prostate cancer1. However, its effect on bone quality has not been described.

Objectives: To evaluate the changes on bone microarchitecture (bone quality) assessed by TBS ( trabecular Bone Score) in male patients with prostate cancer after one year of treatment with ADT.

Methods: All patients diagnosed with prostate cancer candidates for long-term ADT admitted to Urology department of Hospital Universitari Parc Taulí (reference population of 450,000 inhabitants) between April 2017 and December 2019 were included. Patients who received chemotherapy, previous hormonal therapy or specific treatment for osteoporosis in the last year or those who had a very impaired functional capacity (Barthel index <30) were excluded. Demographic, clinical and analytical data (testosterone, calcium, phosphorous, alkaline phosphatase, 25-hydroxyvitamin D, PTH) were collected in all patients. A bone densitometry (GE-Lunar Prodigy) including the measurement of lumbar spine TBS (L1-L4) using Medimaps Software was performed at baseline and at 12 months of treatment with ADT.

Results: 78 patients were included. Mean age 77±8,3 years. The median Gleason score was 7.88±1.05. 3 patients had previous fragility fracture (one sacral fracture, one fibula and one multiple vertebral fracture). Baseline analytical values in patients were the following: testosterone11,6±74,9 nmol/L.; 25-hidroxiveratin 20,8±10,4 ng/ml; PTH 51,8±23,0 pg/ml; CTX 0,54±0,6. The daily calcium intake was 573±207 mg/day. According to BMD, 17 patients (21,8%) had osteoporosis before starting ADT, with the following average T-score values: lumbar spine -0,15±1,85, femoral neck -1,75±1,00, and total hip -1,19±1,16. Mean baseline TBS value of the entire cohort was 1,279±0,122. 30,5% of the patients showed very degraded microarchitecture (TBS<1,230), 28,8% had partially degraded microarchitecture (TBS 1,230-1,310) and in 40,7% showed normal microarchitecture (TBS >1,310). After one year of ADT treatment, TBS mildly worsened in this cohort, with a median value of 1,256±0,131 (p = NS). However up to 43% of patients reached low TBS (<1,230) and in 40,7% showed normal microarchitecture (TBS >1,310). One patient presented very degraded microarchitecture increases, although not significantly. More studies are needed to confirm this trend and to evaluate if these patients present more long-term fractures.

Conclusion: Most patients with prostate cancer have an altered bone quality before starting ADT. After 12 months of treatment, the percentage of patients with highly degraded bone microarchitecture increases, although not significantly. More studies are needed to confirm this trend and to evaluate if these patients present more long-term fractures.

Prospective study assessing bone mineral density and risk factors for osteoporosis in patients with androgen deprivation therapy. Preliminary cross-sectional results

Background: Few studies have analysed the incidence and risk factors for osteoporosis (OP) development in patients with prostate cancer (PC) and androgen deprivation therapy (ADT).

Objectives: To assess risk factors for OP, bone turnover markers (BTM) and bone mineral density (BMD) in a cohort of patients with ADT, as well as the differences in ADT and previous treatments received.

Methods: Ongoing prospective study including patients with ADT for PC. Risk factors for OP, BTM (total ALP, bone ALP, CTx), spinal X-Ray and BMD (Lunar) were assessed yearly since inclusion in the study (April 2018). Patients with known OP or previous antosteoporotic treatment were excluded. The study was approved by the ethics committee, and all patients gave their signed consent. Herein we present the preliminary cross-sectional study at inclusion.

Results: Of the 83 patients attended at the Rheumatology Department during the study period, 75 were included with a mean age 75.5±5 years and median ADT duration of 1 year. 18 were receiving concomitant radiotherapy and 7 docetaxel. When assessing risk factors for OP: 28% had previous fragility fractures and 24% had current alcohol intake. After X-Ray assessment, 14% had morphometric vertebral fractures. Mean 25OHD at inclusion was 19.3±9ng/ml (73% had 25OHD <30ng/ml) and mean testosterone was 82.6±162ng/dl (75% had levels <30ng/dl).

All patients had increased values of CTx and 9% had increased bone ALP levels. BMD showed up to 28% with densitometric OP and osteopenia in 56%. Patients with OP were older (83±7 vs 74±8 years, p=0.021), had lower testosterone levels (16 vs 9.9±ng/dl, p=0.004), as expected lower BMD (at spine, proximal femur and even distal radius) and had more previous fragility fracture (75 vs 19%, p=0.022).

But it should be noted that 16% had high bone mass (HBM) mostly affecting even distal radius and had more previous fragility fracture (75 vs 19%, p=0.022).

Conclusion: Low bone mass (including osteoporosis and osteopenia) is frequent in patients with ADT as well as previous fragility fractures. Up to 16% had high bone mass, being mostly in patients with high volume metastatic disease. Thus, all patients with ADT should undergo a bone health assessment and start antosteoporotic treatment if required.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.2644
Conclusion: One year tofacitinib treatment effectively stabilized bone density in patients with rheumatoid arthritis, and led to the increase of bone turnover markers, which is beneficial for ossification in long term.

SAT0472

GOAL-DIRECTED TREATMENT OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING DENOSUMAB FOR FIVE YEARS

Y. Hirano1, Y. Kanayama2, H. Kosugiyama1, N. Ishiguro1, T. Kojima3, Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan; 3Toyota Kosei Hospital, Orthopaedic Surgery and Rheumatology, Toyota, Japan; Nagoya University Graduate School of Medicine, Orthopaedic Surgery and Rheumatology, Nagoya, Japan

Background: Osteoporosis (OP) is frequent complication identified in patients with rheumatoid arthritis (RA). Effective treatment must be provided to treat OP in RA (RAOP). Denosumab (DMB) is one of the promising drugs that are currently being used for the treatment of RAOP. We reported the results of 12-month DMB treatment for RAOP as part of Japanese multicenter registry study (TBCR-BONE) in EULAR2016 [1]. Recently, a treatment goal of OP was reported by the American Society for Bone and Mineral Research and the National Osteoporosis Foundation (ASBMR-NOF) working group [2]. This report advocated that the goal of treatment is a T-score of ≤-2.5 at the femoral neck, total hip (TH) or lumbar spine (LS) on DXA if the primary reason for starting treatment was a T-score of ≤-2.5 at the abovementioned skeletal sites. The working group noted that it was reasonable to expect that initial treatment should offer at least a 50% chance of achieving the treatment goal within 3 to 5 years of initiating therapy. We have reported the achievement rates of treatment goal in RAOP with 3-year DMB treatment on RAOP in EULAR2019 [3].

Objectives: The aim of this retrospective study was to evaluate whether 5-year DMB treatment can achieve treatment goal of OP using data from TBCR-BONE.

Methods: The study included 46 female patients who had completed 5-year DMB treatment. The LS-BMD analysis included 22 patients with a baseline (BL) LS-BMD T-score of ≤ -2.5. The TH-BMD analysis included 29 patients with a BL-characteristics of the 46 female patients included: mean age of 69.1 years and RA duration of 16 years. Predisnolone was administered to 37% of the patients. In the LS-BMD analysis, T-scores improved significantly; the mean value at BL was −3.4, which increased to −3.0 at 1 year, −2.6 at 3 years, and ultimately to −2.5 at 5 years. The fraction of patients who achieved the treatment goal was as follows: 36.4% at 1 year, 40.9% at 2 years, 45.5% at 3 years, 50.0% at 4 years, and 54.5% at 5 years (Fig. 1A).

Results: BL characteristics of the 46 female patients included: mean age of 69.1 years and RA duration of 16 years. Predisnolone was administered to 37% of the patients. In the LS-BMD analysis, T-scores improved significantly; the mean value at BL was −3.4, which increased to −3.0 at 1 year, −2.6 at 3 years, and ultimately to −2.5 at 5 years. The fraction of patients who achieved the treatment goal was as follows: 36.4% at 1 year, 40.9% at 2 years, 45.5% at 3 years, 50.0% at 4 years, and 54.5% at 5 years (Fig. 1A).

Conclusion: The results of this study suggested that achievement of the treatment goal was comparatively easy for those with LS-BMD loss; however, it was comparatively difficult for those with TH-BMD loss. Early initiation or longer duration of DMB therapy may be necessary to improve achievement rates. Likewise, other agents, such as romosozumab, may be considered for those with significant TH-BMD loss.

SAT0473

COMPARISON OF THE FRACTURE RISK IN WOMEN WITH AND WITHOUT SCLEROSIS THROUGH DUAL-ENERGY X-RAY ABSORPTIOMETRY

N. Kiroii1, S. Todorov1, N. Nikolov1, M. Nikolov1, UMBAL Dr Georgi Stranski, Pleven, Bulgaria

Background: Osteoporosis is known to be a risk factor for fragility fractures [4, 5]. On one hand, vertebral body fragility fractures often lead to additional spine deformity [2]. On the other hand, it was found that with the progression of the spinal curvature in osteoporotic patients, the fragility fractures develop more frequently. The increased incidence of these fractures could be explained with a predominance of the mechan-ical forces on the one side of the already weakened osteoporotic vertebrae [3].

Objectives: The aim of this study is to compare the fracture risk (FRAX) for major osteoporotic fractures (MOF) and for hip fractures (HF) in women with and without sclerosis through dual-energy X-ray absorptiometry (DXA).

Methods: In the current study, 59 women underwent DXA scans, Sclerosis was defined as Cobb's angle ≥ 5° according to the Chakrils classification [6, 7]. Cobb's angle was measured from DXA images with DICOM software. We evaluated the following risk factors: previous fractures, parental hip fractures, second-ary osteoporosis, rheumatoid arthritis, use of corticosteroids, current smoking and alcohol consumption more than 3 units daily. We estimated FRAX MOF and FRAX HF on the basis of these risk factors and on the basis of the femoral neck bone mineral density (BMD). The calculations were done through FRAX tool published on the website of the University of Sheffield [1].

Results: The mean age of the women was 63 years (yrs.) ± 10 yrs. (range 43 yrs. – 89 yrs.). Subjects with sclerosis were significantly older (67 yrs.) than those without sclerosis (59 yrs.), (p = 0.004). Mean weight and height didn't differ between the groups with- and without sclerosis. Mean lumbar spine BMD and T-score differed significantly between the groups, (p = 0.02). Women with sclerosis had lower mean BMD (0.786 g/cm2) and lower mean T-score (-2.1 standard deviations (SDs)) compared to those without sclerosis (mean BMD: 0.912 g/cm2 and mean T-score: 0.9 SDs). The mean FRAX MOF (19.3%) and FRAX HF (5.9%) of the subjects with sclerosis were significantly higher than those of the women without sclerosis (FRAX MOF: 14.9% and FRAX HF: 3.1%), (p = 0.004 for FRAX MOF and p = 0.010 for FRAX HF).

Conclusion: The results of this study suggested that achievement of the treatment goal was comparatively easy for those with LS-BMD loss; however, it was comparatively difficult for those with TH-BMD loss. Early initiation or longer duration of DMB therapy may be necessary to improve achievement rates. Likewise, other agents, such as romosozumab, may be considered for those with significant TH-BMD loss.

SAT0474
WHAT DETERMINES THE EFFECT OF THERAPY WITH DENOSUMAB ON BONE IN WOMEN WITH Rheumatoid Arthritis and osteoporosis
P. Kovaleenko1, I. Dytykina1, A. Smirnov1, E. Nasonov1, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: RANK-ligand is essential for osteoclast development, activation, and survival and it is a key mediator of increased osteoclast activity in rheumatoid arthritis (RA). Denosumab is a monoclonal antibody that binds RANK-ligand.

Objectives: The aim of this study was to evaluate the effects of denosumab on bone mineral density (BMD) and to define a contribution of factors: anamnesis, clinical/laboratory markers, glucocorticoids (GC) intake, etc. on the response to therapy with denosumab in women with RA and osteoporosis (OP).

Methods: 66 postmenopausal women (mean age 59.6±7.4) with RA (mean duration 17.2±10.4 years) and OP received q12 months 60mg every 6 months pro 12 months. GC-positive - 72%, ACCP - 74% of patients. 34 (49%) patients continued GC. At baseline and after 12 months it was carried out the dual energy x-ray absorptiometry at 3 sites: lumbar spine (L1-L4), hip (HN) and distal forearm (DF) and x-ray of hands and feet (Sharp/van de Heijde (SVH) score). The Statistica 6.0 was used.

Results: After therapy it was noted the increase (p < 0.05) of BMD in L1-L4 and HN, a tendency to increase (p = 0.033) in DF. Mean BMD (L1-L4) before/after the treatment was 0.821 ± 0.104 g/cm² vs 0.864 ± 0.110 g/cm², at HN was 0.825 ± 0.089 g/cm² vs 0.863 ± 0.088 g/cm², at DF was 0.498 ± 0.090 g/cm² vs 0.503 ± 0.089 g/cm². The mean change of BMD (%) after 12 months at L1-L4 was +4.6%, at HN +2.8%, at DF +0.7%. Positive response (increase or stabilization of BMD) was noted in 89% patients at L1-L4, 67% - at HN and 60% - at DF. Analysis of influence of various factors (statistically significant) on the response to therapy is presented in the Table.

Conclusion: After 12 months of therapy with denosumab in postmenopausal women with RA and OP it was shown the significant increase of BMD in L1-L4 and HN, a tendency to increase in DF. The mean change of BMD (%) after 12 months was +4.6% at L1-L4, at HN +2.8%, at DF +0.7%. Positive response on denosumab (BMD) was noted in 89% patients at L1-L4, 67% - at HN and 60% - at DF. Analysis of influence of factors on the response to therapy showed that positive response on therapy in NH and DF was associated with RF-positivity. The distinct contribution to the negative response in L1-L4 and HN was associated with GC intake (previous intake more than 3 months in the anamnesis) and purpose of the GC after menopause onset. Also, negative response in DF back correlated with increase in erosion score and total SVH score.

SAT0476
COMPLIANCE AND PERSISTENCE OF ANTI-OSTEOPOROTIC TREATMENTS IN PATIENTS WITH HIP FRACTURE
S. Paredes1, M. Guinovart2, A. Basco2, C. Llop2, 1Hospital Universitari Sant Joan de Reus, Department of Rheumatology, Reus, Spain; 2CatSalut, Pharmacy Unit, Tarragona, Spain
Background: Osteoporotic fractures have a high health and economic impact. The best strategy to minimize the incidence of fractures is, certainly, the prevention of those that includes pharmacological treatments. However, long-term discontinuation treatment and sub-optimal compliance of the treatment are common.

Objectives: The aim of the study is to quantify the therapeutic compliance and permanence of the osteoporosis pharmacological treatments for patients who were discharged from hospitals in Catalonia with hip fracture during 2017.

Methods: From the Hospital Discharge Database of the Catalan Health Service, all patients who had been discharged during 2017 were selected with the main diagnosis of femur fracture, according to the coding CIM-9. The consumption of drugs to assess compliance and permanence was obtained from the Catalan Health Service pharmacy Database. The study period was 18 months from the date of hospital discharge. Patients who died, moved to other areas or switched their treatment were excluded from the study. Good compliance was considered when sufficient drug was obtained to cover 80% of the time since treatment was prescribed until the end of the study period. In the case of denosumab, good post-fracture compliance was considered when the treatment time was remained at least 12 months. Permanence was considered possible if a drug had been obtained during the last three months of the study period. To compare the differences in compliance and permanence between the patients treated with different drugs, the chi-square statistic was used, considering statistically significant differences if p<0.05.

Results: 8,354 patients were discharged with the main diagnosis of hip fracture. Of these, 1,712 patients (20.49%) were treated after being discharged. After applying the exclusion criteria, the final sample was made up of 1,327 patients. 81.54% were women, and the median age was 84.79 years.

The most commonly used treatments were bisphosphonates (69%), denosumab (23%) and teriparatide (7%). The results of good compliance and permanence of treatment were those described in the table.

(*) p<0.05 for total bisphosphonates and for alendronate

Conclusion: The results obtained suggest that a small number of patients were treated after a hip fracture (20.49%) in addition the instituted treatments are followed in a suboptimal way. It is necessary to investigate which factors may lead to the detection of potential non-compliant patients. It seems appropriate to consider drugs that facilitate compliance and permanence of treatment.

SAT0478

OSTEOPOROSIS TREATMENT IN PORTUGUESE PATIENTS WITH PSORIATIC ARTHRITIS – WHAT IS THE VALUE OF THE FRACTURE RISK ASSESSMENT TOOL (FRAX)?

F. Pinheiro1, M. Rato1, B. M. Fernandes1, S. Garcia1, S. Ganhaõ1, P. Madureira1, M. Bernardes1, L. Costa1, Centro Hospitalar e Universitário de São João, Rheumatology Department, Porto, Portugal

Background: Few studies have evaluated the prevalence and treatment of osteoporosis (OP) in patients with psoriatic arthritis (PsA), and many of these patients are not screened using dual-energy X-ray absorptiometry (DXA). FRAX makes it possible to stratify the risk and define which patients may benefit from anti-osteoporotic treatment, but its usefulness in this population is not well established.

Objectives: The aim of this study was to determine whether the application of FRAX changes the indication for anti-osteoporotic treatment in PsA patients, according to the Portuguese guidelines.

Methods: In this cross-sectional study, we evaluated PsA patients from a tertiary hospital, registered in a national database (Reuma.pt), aged between 40 and 90 years, and with a last consultation in 2019. FRAX was applied in all of them, regardless of being under anti-osteoporotic treatment and, when DXA was available, the femoral neck bone mineral density was used. Patients were stratified according to the risk of fracture, and those at high risk were considered candidates for anti-osteoporotic treatment, according to national guidelines (FRAX ≥11% for major osteoporotic fracture (MOF) or ≥ 3% for hip fracture (HF) without DXA; FRAX ≥9% for MOF or ≥ 2.5% for HF; with DXA).

Results: We included 100 patients, 52 females, with a mean age of 54.4 ±8.9 years and a median disease duration of 10 (6-17) years. Only 43 had already performed DXA and 6 had OP according to World Health Organization criteria. Seven patients were identified as having a high risk of fracture, applying femoral neck bone mineral density. FRAX distinguished the need for intervention, and DXA was the test that identified these patients. It was observed that the indication for treatment based only on DXA and FRAX (Cohen’s k 0.066). There was a moderate and significant correlation between percentage of risk of MOF by FRAX with and without DXA (Spearman’s p 0.804, p <0.001); for the risk of HF by FRAX with and without DXA the correlation was weaker but still significant (Spearman’s p 0.439, p = 0.004). There was no association between the indication for treatment by FRAX and the performance of DXA (chi-square test,
p = 0.597), nor the fact of performing DXA significantly affected the risk of MOF (p = 0.597), nor the fact of performing DXA significantly affected the risk of MOF (p = 0.597). Conclusion: In line with Portuguese guidelines, FRAX seems to be, in itself, a very useful tool in patients with PsA, and the performance of DXA does not significantly alter the indication for anti-osteoarticular treatment.

IMPACT OF TRABECULAR BONE SCORE ON INTERVENTION THRESHOLD FOR BONE SPARING THERAPY IN PATIENTS REFERRED FOR BONE MINERAL DENSITY

C. Rakis1, S. Ho2, R. Butler1. The Robert Jones and Agnes Hunt Orthopaedic Hospital, Rheumatology, Oswestry, United Kingdom; The Robert Jones and Agnes Hunt Orthopaedic Hospital, Medicine and Rehabilitation, Oswestry, United Kingdom

Background: Trabecular bone score (TBS) is an index of skeletal quality that has been validated as an independent risk factor for fracture and incorporated into fracture risk assessment (FRAX). TBS provides information on bone microarchitecture not captured from standard bone mineral density (BMD) measured by dual energy X-ray absorptiometry (DXA). Nonetheless, the clinical implications of using TBS in routine practice are not yet fully understood and warrant further evaluation.

Objectives: To determine whether lumbar TBS can have an impact on clinician’s treatment threshold derived from DXA and clinical risk factors: does the addition of TBS to DXA measurements make the clinician more or less likely to recommend bone sparing therapy?

Methods: A cross-sectional study at a tertiary metabolic bone centre in the West Midlands region of England. Three expert metabolic bone physicians, two rheumatologists and one elderly care, assessed consecutive patients referred for a DXA scan ± clinic review and provided treatment recommendations with and without TBS. Patients ≥ 18 years old with BMD of 15-37 who were not on bone sparing therapy were considered eligible. TBS was defined according to T-score as normal (T-score ≥ -1), moderate (-1 > T-score ≥ -2.5) or degraded (T-score ≤ -2.5). TBS groups were stratified by BMD T-scores (normal, osteopenia, or osteoporosis) using minimum T-score of total hip, femoral neck, and spine to identify categories in which TBS may be of more clinical use. The main outcome measure was the proportion of change in clinician’s treatment threshold between BMD categories in which TBS may be of more clinical use. The main outcome measure was the proportion of change in clinician’s treatment threshold between BMD alone and BMD plus TBS. The difference was assessed for significance using Chi-square test. Additionally, the change in UK National Osteoporosis Guideline Group (NOGG) threshold was also assessed using TBS-adjusted FRAX scores.

Correlations between BMD-TBS strata and the change in intervention threshold were assessed using Spearman test. Chi-square test. Additionally, the change in UK National Osteoporosis Guideline Group (NOGG) threshold was also assessed using TBS-adjusted FRAX scores. Correlations between BMD-TBS strata and the change in intervention threshold (yes/no) were carried out using Spearman test.

Results: 540 patients were analysed. The inclusion of TBS resulted in 8.2% change in clinician’s treatment threshold (p <0.001) shifting the outcome 6.5% for and 1.7% against treatment. More than half of the cases in which the clinical decision was changed were for patients with osteopenia and degraded TBS (significant correlation; P <0.001). NOGG intervention threshold was changed in 7.4% of the cases (P<0.001): 6.1% for and 1.3% against treatment. 37.5% of NOGG changed outcome was related to osteopenia with degraded TBS (p<0.001). Kappa agreement between the clinician and NOGG was fair at 0.42 (p<0.001).

Conclusion: These results demonstrate that using TBS in routine clinical practice is most likely to impact treatment decision in patients with osteopenia who have compromised bone microarchitecture. Incorporating TBS in routine DXA scans may lead to a net increase in bone protective therapy of approximately 5%. It is unknown whether adopting such an approach universally can reduce future fracture risk, and prospective studies are needed to address this question.

Figure 1. Distribution of changed clinical treatment threshold in normal, moderate, and degraded TBS according to BMD T-score

Acknowledgments: Bone density unit &Rheumatology team, Robert Jones and Agnes Hunt Orthopaedic Hospital

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.4879
Background: Objectives: Assess the severity of coronary atherosclerosis in men with coronary heart disease (CHD) depending on bone mineral density (BMD).

Methods: 102 of men with verified CHD aged 51-75 (60.8 ± 6.9) were examined. All patients performed two-energy X-ray absorption of lumbar vertebrae bodies Li-LIV and hip necks (Excell XR-46, Norland, USA) and polyproject coronangiography (Innova, General Electric, USA). On the basis of results of densitometry on value of T-criterion (the recommendation of ISCD, 2007) estimated BMD condition: normal BMD (T criterion ≥-1), osteopenia (T-criterion from -1 to-2.5) and osteoporosis (T criterion < -2.5). According to the SYNTAX score.com, the following degrees of coronary artery (CA) injury severity were isolated to quantify the expression of atherosclerotic injury: low (22 or less), intermediate (23-32) and high (33 or more). According to the result of multipolar computed tomography of CA, calcium index of vessels was determined by the Agaston method using the CaScore program. On the basis of the calcium index value the degree of atherosclerosis was evaluated: 0 - absence of calcinosis, 1-10 - minimal, 11 - 100 - moderate, 101-400 - increased, more than 400 - expressed calcinosis.

Results: According to the results of densitometry, patients were found to have 21 patients (20.6%) with normal BMD, 48 (47.0%) - osteopenia and 33 (32.4%) - osteoporosis. Osteopenic syndrome (OPS) was found in 79.4% of men. All patients tested, depending on the degree of CA calcinosis, were distributed as follows: 57.8% of men had pronounced CA calcinosis, 25.5% - increased, 6.9% - moderate, 2.0% - minimal, 7.8% of patients had no CA calcinosis. In a comparative analysis of the degree of coronary calcinosis in men with CHD depending on the T-criterion, it was found that the majority of patients with OPS (69.7% of patients with OP and 60.4% with OPe) had pronounced CA calcinosis. In men with normal BMD, the percentage of pronounced CA calcinosis (33.3%) was significantly lower than in patients with OPS (p = 0.050). Calcinosis-negative CA was recorded reliably more frequently in patients with normal BMD (28.6%) compared to men with low BMD (p < 0.050). The results of the work demonstrated the relationship of the studied parameters of coronary atherosclerosis expression with densitometry indicators in men with CHD. Thus, the inverse correlation of the BMD at the level of the hip neck with the number of significant stenoses of the space (r = -0.19; P = 0.045) and the degree of coronary calcinosis (r = 0.23; P = 0.022) and similar dependence of BMD of vertebral bodies LI-LIV with coronary calcinosis degree (r = -0.19; P=0.046). A direct correlation between CA calcinosis and FRAX hip fracture risk (r = 0.24; P=0.018). Inverse correlation of parameters of atherosclerotic damage of CA (number of significant stenoses and degree of calcinosis) with BMD was established, and direct correlation of CA calcinosis degree with risk of hip fracture on FRAX scale in male persons with CHD over 50 years of age was revealed.

Conclusion: The findings suggest in favor of common mechanisms for developing atherosclerosis with OP and allow coronary calcinosis to be considered as a condition potentially increasing the risk of hip fracture.

SAT0482

FRAX 10-YR FRACTURE RISK IN RHEUMATOID ARTHRITIS ASSESSED WITH AND WITHOUT BONE MINERAL DENSITY – ARE WE TREATING OUR PATIENTS UNDER BDMAIRDS?

M. Rato1, F. Pinheiro1, S. Garcia1, B. M. Fernandes1, S. Ganho1, R. Gaio2, M. Bernardes1, A. Bernardo1, L. Costa1,1 Centro Hospitalar Universitário de São João, Rheumatology, Porto, Portugal;2 Faculdade de Ciências da Universidade do Porto & Centro de Matemática da Universidade do Porto, Mathematics, Porto, Portugal

Background: Patients with rheumatoid arthritis (RA) have a higher risk of osteoporosis not only due to chronic inflammation status, but also due to the treatment with glucocorticoids. FRAX is a computer-based algorithm developed by the World Health Organization for estimation of the 10-year risk of a hip or major osteoporotic fracture. Inclusion of femoral neck bone mineral density (BMD) in the estimation is optional.

Objectives: The study aimed to identify the RA patients under treatment with biological disease-modifying antirheumatic drug (bDMARD), who have FRAX scores, calculated with and without BMD, classified as high fracture risk and evaluate if they are receiving treatment for osteoporosis. The authors also investigated the intra-individual agreement between FRAX fracture risk calculated with and without BMD.

Methods: Demographic and clinical data and BMD results from RA patients followed in a tertiary university hospital and registered in the Rheumatic Diseases Portuguese Register were used for analysis. Patients under 40 years of age at the last visit were excluded. McNemar test was applied for the identification of discordance of risk categories. The Wilcoxon test was used to characterize the intradividual differences between paired FRAX risks with and without BMD. Correlations between pairs of variables were evaluated by the Spearman test. For independent variables Mann-Whitney test was used.

Results: A total of 303 patients were included, 244 were females (80.5%) and 49 current smokers (16.2%). Mean age was 59.5 ± 9.54 years and mean disease duration 18.5 ± 10.4 years. Two hundred and twenty patients (72.4%) and 243 (80.2%) were RF and ACPA positive, respectively; with bDMARD it was 6.9 ± 1.18 and mean femoral neck BMD 0.84 ± 0.12 g/cm². One hundred and seventy nine patients (58.9%) were concomitantly treated with conventional synthetic DMARDs and 215 (70.7%) with glucocorticoids. Among all the patients, 35 (11.6%) had previous fractures and 19 (6.3%) have family history of fracture. The median 10-year risk of a major fracture and a hip fracture, calculated without BMD, was 6.0 (1.2-50) and 1.5 (0.1-39), respectively; with BMD it was 6.9 (1.3-61) and 1.7 (0-49). When FRAX score is calculated without BMD (n=303), 76 (25.1%) patients were categorized as high fracture risk. Among them, only 41 (54%) were receiving osteoporosis treatment. FRAX assessment with BMD (n=231) identified 99 (32.7%) patients with high fracture risk, 51 (51.5%) in treatment for osteoporosis. Thirty patients (21%) previously classified as low fracture risk using FRAX without BMD were reclassified as high risk (p<0.001). Despite that, there was a strong correlation between fracture risks assessed with and without BMD for both major and hip fracture (r = 0.867, p <
of Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy; 2Ghent, Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University/Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC); Ghent Belgium, Ghent, Belgium; 3Parma, Cardinal Farnesi Center, S. Stefano Rehabilitation, Fontanello-Parma, Italy, Parma, Italy

Background: Systemic lupus erythematosus (SLE) patients shown an increased risk of low bone mass as a result of multifactorial events: physical inactivity, persistent inflammation, low vitamin D levels (photosensitivity) and glucocorticoid treatment. Trabecular Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) that provides an indirect measurement of bone microarchitecture and allows to get information about bone quality in several rheumatic diseases (1-4).

Objectives: The aims of this study were to examine the prevalence and risk factors for low bone mineral density (BMD) (osteoporosis or osteopenia) in female patients affected by SLE and to compare with matched healthy subjects (CNT).

Methods: 70 female patients (mean age 41±20 years) affected by SLE and 65 age-matched CNT (mean age 46±7 years) were enrolled. Bone Mineral Density (BMD, g/cm2) of the lumbar spine (L1-L4) was analyzed using a DXA scan (GE, Lunar Prodigy). Lumbar spine TBS was derived for each spine DXA examination using the TBS index (TBS iNight Medimaps).

Results: The mean BMDs SD was 0.47±0.5 g/cm2 at the lumbar spine and 0.78 ± 0.22 g/cm2 at the hip in SLE patients. The prevalence of osteoporosis was 40.0% and was 19.4% of osteoporosis in SLE patients. Most of SLE patients (75%) presented a bone loss that was significantly higher when compared with the control group (p<0.001). Lumbar spine TBS score was found significantly lower in SLE patients compared with CNT (0.687±0.675 vs. 1.294±0.809 p<0.001, respectively) and of 0.47±0.94 times lower than expected from the concomitant reference BMD value.

Conclusion: The study shows that the further TBS analysis, independently from the concomitant BMD value, is significantly lower then expected in SLE patients. The detection of the TBS, together with the BMD, may offer a more reliable indication of the real whole bone condition in chronic and systemic inflammatory rheumatic diseases, such as SLE.

SAT0485

PERCENTAGE BODY FAT HAS A STRONGER ASSOCIATION WITH BONE MINERAL DENSITY AT THE HIP AND SPINE COMPARED TO BODY MASS INDEX

C. Thurstori, R. Tribicki, J. Kerns, F. Dondelinger, M. Bukhari, 1,2 Lancaster University, Lancaster Medical School, Lancaster, United Kingdom; 1Lancaster University, CHICAS, Lancaster, United Kingdom; 2University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom

Background: A decreased body mass index (BMI) is associated with poorer bone health, a decreased bone mineral density (BMD), and an increased fracture risk. The use of cardiovascular (CVS) data has shown that the waist:hip ratio is a more robust measurement for CVS outcomes than BMI (1). Waist:hip ratio has never been evaluated as an outcome measure for bone health. Dual-energy X-ray absorptiometry (DEXA) has the capacity to measure average percentage fat in the L1-L4 region and at the hip, and directly relates to the measurement of waist:hip ratio.

Objectives: To evaluate the relationship between BMI and average percent fat in the L1-L4 and hip referred for DEXA scanning.

Methods: We analysed data routinely collected from patients referred for DEXA between 2004 and 2010 at the Royal Lancaster Infirmary in the North of England. Data collected for these patients included DEXA scans

SAT0484

TRABECULAR BONE SCORE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

A. Casabella, S. Paolino, E. Alessandri, V. Smith, B. Ruarado, C. Pizzorni, A. Sulli, M. Cutolo, G. Genoa, Research Laboratory and Academic Division

0.0001 and r = 0.728, p < 0.0001, respectively). ACRA and RF positive patients did not have higher FRAX scores (including or not BMA). Patients with erosive disease had a higher 10-year probability of major fracture evaluated by FRAX when it includes BMD (p=0.041).

Conclusion: It is very important to accurately assess the risk of osteoporotic fractures in RA patients to treat them properly. The authors highlight the high number of patients who are not receiving treatment according to FRAX categorization. In spite of the correlation between estimated fracture risk by FRAX with and without BMD, there is a discordance in fracture risk categorization, as one third of patients of low risk were reclassified as high risk. For the RA population treated with bDMARDs, our findings raise the need to request a DXA not only for patients classified as having an intermediate risk of fracture, but also for low-risk patients.

of BMD at the left and right hip, and at the lumbar spine, as well as average percent fat and other risk factors for osteoporosis, including the FRAX risk factors. We used only the measures collected at baseline (time of first scan). We modelled the T scores of the BMD measurements using a linear regression model including percentage fat and BMI as explanatory variables, and adjusting for gender, age at scan, and other known risk factors for osteoporosis, including the FRAX risk factors. BMD and average percent fat were standardised.

Results: The number of patients included was 33037, (82% female). Results of both regression models are shown in table 1 below. We show the standardised effect size estimates for average percent fat and BMI.

Conclusion: The analysis shows that average percent fat is a statistically significant predictor for BMD at different anatomical locations, and a larger predictor in comparison to BMI when evaluated in the same model. In the right hip neck and the spine, BMI was not predictive of changes in BMD. Further research is needed to characterise the relationship more precisely and identify whether there is a causal link.

SAT0487 PREDICTIVE BIOMARKERS OF IGA VASCULITIS WITH NEPHRITIS BY METABOLIC ANALYSIS

S. Demir1, M. Celebi2, C. Kaplan2, E. Sag3, Y. Bilginer3, S. Özen1. 1Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey; 2Hacettepe University Faculty of Pharmacy, Department of Analytical Chemistry, Ankara, Turkey

Background: IgA vasculitis/ Henoch Schönlein Purpura (IgAV/HSP) is the most common vasculitis of childhood and renal involvement is the most serious long-term complication. A better understanding of the pathophysiology of the progression to kidney disease is required for better treatment to be achieved and current biomarkers of IgA vasculitis with nephritis (IgAV/HSP) lack the predictive value.

Objectives: In this study, an untargeted metabolomics approach was performed to reveal the underlying molecular mechanism of disease pathogenesis and to find potential biomarkers of plasma samples from patients with IgAV and IgAV.

Methods: IgAV/HSP was diagnosed according to the Ankara criteria in 2008 (1). Forty-five patients, including 39 active IgAV patients (H), 6 IgAV-N (N), and 6 age- and

SAT0488 BONE MINERAL DENSITY IN PATIENT WITH SHRUNKEN PORE SYNDROME IS SIGNIFICANTLY LOWER THAN THAT IN PATIENT WITHOUT, HOWEVER SERUM PARATHYROID HORMONE DOES NOT CORRELATED MUCH WITH IT

L Yoshi1, S. Nishiyama2. 1Yoshi Hospital, Rheumatology and Musculoskeletal Medicine, Shimanto-City, Japan; 2Kurashiki Medical Center, Rheumatic Disease Center, Kurashiki, Japan

Background: Shrunken pore syndrome (SPS), defined by cystatin C (CysC) based estimated glomerular filtration rate (eGFR_CysC) is < 60% of creatinine (Cr) based eGFR_eGFR_Cr in the absence of extrarenal influences on the plasma levels of CysC or Cr, is associated with a higher increase in mortality. SPS often causes reduced bone mineral density (BMD).

Objectives: In this study, relationship between BMD and SPS was investigated.

Methods: Patient with rheumatic diseases who were measured BMD with dual-energy X-ray absorptiometry and at the same time, CysC and Cr were also measured, were picked up. eGFR_CysC and eGFR_eGFR_Cr were calculated, and a patient group with SPS were recruited. Relationship between serum PTH and CysC, or Cr was evaluated with univariate linear regression analysis. Between the SPS groups and the other patient group, statistical difference was evaluated regarding sex, age, Cr, CysC, serum Cr-CysC ratio (Cr/CysC), serum calcium corrected with albumin (Ca), creatinine phosphokinase (CPK), parathyroid hormone (PTH), eGFR_CysC, eGFR_eGFR_Cr, BMD in the lumbar spine (BMD_LS) and femoral neck (BMD_FN) were evaluated with Mann-Whitney U-test. Relationship between BMD for each bone and sex, age, Cr, PTH, Cr/CysC, eGFR_CysC and being SPS was statistically evaluated with multivariate linear regression analysis. Furtherly, sensitivity and specificity regarding being SPS for T-score < -2.5, that is defined as diagnosis criteria of osteoporosis calculated from BMD, was evaluated with chi square test.

Results: A total of 819 participants with 75 males and 744 females joined. Patient with SPS counted 31 and without SPS counted 782. Underlying diseases are shown in Table 1. Average age, CysC, Cr, PTH, eGFR_CysC and eGFR_eGFR_Cr were 76.5, 1.18, 0.76, 42.1, 66.2 and 59.0, respectively. PTH significantly correlated with CyC (p=0.015), but not correlated with Cr (p=0.079). SPS demonstrated significantly higher ratio for being male (p<1.0x10^-5), higher age (p=1.07x10^-5), higher titer of CysC (p=5.5x10^-5), lower titer of CPK (p=1.5x10^-5), lower Cr CyC (p=1.0x10^-5), lower eGFR_CysC (p=2.8x10^-5), BMD_LS (p=1.0x10^-5) and BMD_FN (p=1.0x10^-5), however no significant difference demonstrated for Cr (2.4x10^-5), PTH (p=1.7x10^-5) and Ca (p=6.3x10^-5). BMD_LS demonstrated significant positive correlation with CPK (p=2.6x10^-5), and negative correlation with being female (p=4.9x10^-7), age (p=2.1x10^-5), PTH (p=2.2x10^-5), eGFR_CysC (p=2.5x10^-5), and being SPS (p=4.9x10^-5), while BMD-FN demonstrated significant positive correlation with Cr/CyC (p=7.3x10^-5), and negative correlation with being female (p=1.5x10^-5), age (p=4.9x10^-5) and being SPS (7.3x10^-5). Sensitivity and specificity of T-score < -2.5 in the LS regarding SPS was 50.0% and 74.0% (p=6.9x10^-5), while in the FN 67.9% and 61.7% (p=1.7x10^-5), respectively.

SAT0487 PREDICTIVE BIOMARKERS OF IGA VASCULITIS WITH NEPHRITIS BY METABOLIC ANALYSIS

S. Demir1, M. Celebi2, C. Kaplan2, E. Sag3, Y. Bilginer3, S. Özen1. 1Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey; 2Hacettepe University Faculty of Pharmacy, Department of Analytical Chemistry, Ankara, Turkey

Background: IgA vasculitis/ Henoch Schönlein Purpura (IgAV/HSP) is the most common vasculitis of childhood and renal involvement is the most serious long-term complication. A better understanding of the pathophysiology of the progression to kidney disease is required for better treatment to be achieved and current biomarkers of IgA vasculitis with nephritis (IgAV/HSP) lack the predictive value.

Objectives: In this study, an untargeted metabolomics approach was performed to reveal the underlying molecular mechanism of disease pathogenesis and to find potential biomarkers of plasma samples from patients with IgAV and IgAV.

Methods: IgAV/HSP was diagnosed according to the Ankara criteria in 2008 (1). Forty-five patients, including 39 active IgAV patients (H), 6 IgAV-N (N), and 6 age- and
gender-matched healthy controls (C), were enrolled in the study. Plasma samples from subjects were collected on the same day of IgAV/HSP) diagnosis and before steroid or other immunosuppressive initiation. This study has utilized liquid chromatography-mass spectrometry (LC-MS/ Q-TOF) to investigate the alterations in plasma metabolomic profiles. Three separate pools, health controls, active IgAV, and IgAV were created. Peak picking, grouping, and comparison parts were performed (metabolite profiling) via XCMS (https://xcmsonline.scripps.edu/) software.

Results: Totally 2618 peaks were detected for group H, N and C. Among them 355 peaks were found to be statistically significant and reliable (p<0.05) and 155 of these peaks were found to be changed (fold change >1.5) between the groups C and H. On the other hand, 66 peaks were found to be changed (fold change >1.5) between the groups H and N. The number of the peaks on the intersection of the peaks found to be changed between the groups (C and H) and (H and N) was 39. This situation was illustrated in Figure 1. Based on putative identification results, 15 peaks were matched with 24 metabolites. The list of these metabolites is given in Table 1.

SAT0489 MATCHED CONTROLLED SURVEILLANCE OF TOCILIZUMAB TREATMENT FOR POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS–AN INTERIM ANALYSIS

A. Klei1, T. Hospach1, F. Weller-Heinemann1, S. Hansmann1, J. Kuenemmer-Deschner1, M. Fasshauer1, K. Minden1, I. Fiedler1, C. Rietschel1, T. Schwarz1, R. Trauzeddel1, M. Hufnagel1, D. Foell1, R. Berendes1, G. Boeschow1, P. Oomlen1, F. Dressler1, A. Helling-Bakki1, G. Hornet1. BIKER Registry. Sant Augustin, Germany

Background: Tocilizumab (TOC) is approved for treatment of polyarticular juvenile idiopathic arthritis (pJIA). Data out of clinical practice are limited.

Objectives: Long-term surveillance of patients initiating TOC treatment compared to a cohort of patients initiating a comparator biologic using the BIKER-registry.

Methods: Baseline parameters, efficacy and safety parameters were compared. Efficacy outcomes were JADAS10 and joint counts. Functional status was determined with the Childhood Health Assessment Questionnaire disability-index (CHAQ-DI). Safety was assessed by adverse events (AE) reports.

Results: Until January 2020, 152 patients were recruited to each cohort. Patients starting on TOC were older at treatment start (12.1 vs. 10.1 years; p<0.0001) and had a longer disease duration (5.4y vs. 3.0y; p<0.0001). TOC was significantly more often a second-line biologic (84% vs 13%, p<0.0001). Otherwise patients were comparable (Table 1).

Upon TOC a substantial response to treatment with a significant reduction in JADAS 10 from 16.8 to 3.4 (p<0.0001) after 12 months was observed. There were no significant differences between patients from the TOC cohort and their matched controls regarding JIA ACR 30/50/70/90 criteria and active joint counts. JADAS 10, JADAS remission (REM) and minimal disease activity (MDA) was reached by comparable numbers in the TOC (37% and 58%) and the control cohort (37% and 60%).

SAT0488 CLINICAL COURSE AND THERAPY RESPONSE IN TAKAYASU ARTERITIS: COMPARISON BETWEEN CHILDHOOD AND ADULT ONSET

E. Cocchiara1, E. Galli1, A. De Fanti1, C. Malattia1, A. Ravelli1, C. Salvarani1.
1Policlinico di Modena University Hospital of Modena, Rheumatology, Modena, Italy; 2Arcispedale Santa Maria Nuova, Reggio Emilia, Italy; 3Istituto Giannina Gaslini, Genova, Italy

Background: Takayasu arteritis (TA) is a granulomatous vasculitis of the large vessels of unknown origin, which mainly affects the aorta and its main branches. TA is a disease of the young age with onset usually before 40 years and in more than 20% of patients the diagnosis is made before 19 years. Very few clinical series have compared the clinical manifestations, treatment and outcomes between pediatric and adult patients.

Objectives: Objective of our study was to compare childhood and adult onset TA evaluating clinical manifestations, treatment (including biotechnological agents) and outcomes.

Methods: All consecutive patients with childhood-onset TA (onset <18 years) and adult-onset (onset ≥ 18 years) TA followed from 2002 to 2019 in two Italian centers (Genoa Gaslini Hospital and Santa Maria Nuova Hospital of Reggio Emilia) were retrospectively evaluated and compared. All patients met TA classification criteria (ACR 1990 and EULAR/Printo/PrES 2010 for children). Clinical, demographic, laboratory, radiological, therapeutic data were collected retrospectively at baseline, at 6-month follow-up and at the last follow-up. Disease activity at each follow-up visit was evaluated according to NIH criteria.

Results: 58 patients were consecutively enrolled: 18 children (C) and 40 adults (A). In both groups there was a higher prevalence of females (83.3% C vs 77.5% A; p NS). The diagnostic delay was lower in the pediatric group (median of 5 months VS 20 months in A; p NS). Fever and headache as presenting manifestations affected more frequently children with statistically significant differences (55.6% C vs 17.5% A; p 0.003; 27.8% C vs 5% A; p 0.025).

Adults had a higher frequency of claudication of the upper limbs and carotid/subclavian bruises (30% and 5% A vs 5.6% and 38.9% C respectively; p NS), while the discrepancy in blood pressure of the four limbs was higher in children (22.2% C vs 12.5% A; p NS). Hypertension was not significantly different between the two groups at baseline and during the follow-up.

We found a significantly more frequent inflammatory involvement of the aorta (arch, thoracic, or abdominal) in children (72.2% C vs 30% A, p 0.003).

The subclavian arteries were most affected in the adults (65% A vs 38.9% C; p NS), although the difference was not statistically significant.

Treatment regimen were different between the groups: glucocorticoid monotherapy was more frequently used in adults (45% A vs 27% C; p NS), glucocorticoids in combination with Cyclophosphamide or anti-TNF were more significantly used to induce remission at the beginning in the pediatric group (22% C vs 0 A, p 0.007 and 22% C vs 2.5% A, p 0.029).

At the last follow-up the disease was significantly more active in children according to NIH criteria (55.6% C vs 27.5% A, p 0.04).

Conclusion: We reported some differences between children and adults. TA in children was characterized by a shorter diagnostic delay, a more frequent inflammatory involvement of the aorta and a more refractory disease. Patients with pediatric TA were treated more aggressively at the beginning.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.1232

References:
While the total number of AE was comparable between the TOC cohort (58/100PY) and in the control cohort (54/100PY; RR 1.1; 95%CI 0.9-1.4), more serious AE (SAE) were reported with TOC (4.8/100PY compared to 1.4/100PY; RR 3.9; 95% CI 1.0-10.9). Medically important infections and uveitis events were documented at significantly lower frequency in the TOC (0.8/100PY) than in the control cohort (4.1/100PY; RR 0.2; 95% CI 0.04-0.9). SAE with TOC were suicidal intent (n=3), depression (n=2), exacerbation of JIA, abscess, gastrointestinal infection, abdominal pain, colitis, bone surgery and fracture (n=1). SAE in the control cohort were depression, osteomyelitis, gastrointestinal infection and superinfected eczema (n=1). No significant differences regarding cytopenia and elevated transaminases were observed. No gastrointestinal perforation, no vascular event, no malignancy and no death occurred.

**Conclusion:** The efficacy of tocilizumab is comparable to that of alternative biologics. Tolerability was acceptable. As Tocilizumab was given as a second-line biologic in the vast majority of patients, comparisons between the cohorts have to be interpreted carefully. Observation in the registry is ongoing.

**SAT0491**

PSORIASIS ASSOCIATED WITH MONOCLONAL-ANTIBODY-TNF-A INHIBITORS VS. FUSION PROTEIN ETANERCEPT IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS - ANALYSIS OF THE BIKER REGISTRY

A. Zimmer, A. Klein, G. Horneff, J. Asklepios Kinderklinik Sankt Augustin, Sankt Augustin, Germany

**Background:** Although efficacy of Tumor necrosis factor inhibitors (TNFi) for treatment of psoriasis is well established, patients may develop psoriasis for the first time while on TNFi as a paradoxical effect. Few data are available in patients with juvenile idiopathic arthritis (JIA).

**Objectives:** To analyze the incidence of psoriasis in TNFi - treated JIA patients and to identify associated factors.

**Methods:** Safety data from patients registered in the German Biologics registry (BikeR) were analyzed. Cohorts of patients were grouped by treatment: any or multiple TNFi, single TNFi, biologics other than TNFi and no biologics (control group on methotrexate (MTX) only). TNFi-associated psoriasis was defined as incident diagnosis of psoriasis after starting a TNFi. Patients with personal history of psoriasis prior to TNFi therapy were excluded. Rates and events per 100 patient-years (PY) of exposure were calculated using AEs reported after first dose under therapy and under the age of 18 years. Rates were compared by X2-test, event rates by Wald test.

**Results:** A total of 4149 treatment episodes with TNFi (Etanercept, Adalimumab, Golimumab, Infliximab), with a total exposure time of 8437 PY, were identified. There were 676 treatments with a non-TNFi- biologic (Tocilizumab, Abatacept, Anakinra, Canakinumab) with a total exposure time of 1112 PY. MTX monotherapy was conducted in 1692 patients with a total exposure time of 3971 PY. In total, 31 patients were diagnosed with incident psoriasis on JIA-treatment (Table 1). The mean duration of therapy until incident psoriasis was 2.2 (± 1.8) years. Multiple psoriatic skin manifestations were observed.

Psoriasis events were significantly more frequent in any or multiple TNFi compared to MTX-monotherapy, and specifically in the subgroup of TNFi-antibody treatment (all) or Adalimumab compared to MTX or Etanercept (Table 2). Interestingly, psoriasis events were also observed with non-TNFi at high frequency. At occurrence of the event, patients exposed to biologics received MTX or steroids less frequently compared to the total patient cohort and had a higher JADAS10.

**Conclusion:** Our findings demonstrate a higher incidence of psoriasis in monoclonal-antibody-TNFi-treated JIA patients, whereas in Etanercept-treated JIA patients no significant increase was detected. On average, psoriasis-manifestation occurred more than two years after treatment-initiation. Teenage females with ANA-positivity were most often affected.

*Individual therapy numbers add to a sum > the total cohort number, because some patients switched between multiple drugs; ** Pso= Psoriasis event; *** at time of event
A. Alshevskaya, A. Moskalev, I. Krulin, A. Shingaeva, V.A. Nasonova

**Background:** Early-onset form of systemic juvenile idiopathic arthritis (sJIA) often presents severe disease course. Choosing the optimal therapy option as first-line treatment is necessary for rapid improvement of patients' quality of life and prevention of further radiologic progression.

**Objectives:** To evaluate the long-term effectiveness and safety of tocilizumab (TOC) in sJIA patients depending on the duration of the disease treated in the National Medical Research Center of Children's health, Moscow, Russia.

**Methods:** The study was conducted as a subanalysis of the prospective cohort study to evaluate the efficacy of biologics in children with sJIA. Analysis included sJIA patients younger than 4 years of age at the moment of TOC initiation.

**Results:** TOC was first biologics in 34/35 (97.1%) patients in ShorterDD group and 18/19 (94.7%) patients in LongerDD group. Groups were comparable in terms of disease activity at TOC initiation with 100% of patients presented active systemic features. 31/35 (88.6%) patients in ShorterDD group and 17/19 (89.5%) patients in LongerDD group have median 3 (IQR 1.6) and 5 (IQR 3.7) active joints, respectively (p=0.119). JADAS-71 level was 17.14 ± 6.25 ShorterDD group and 17.36 ± 5.45 in LongerDD group (p=0.895).

TOC showed high efficacy after first months of treatment with only 6/35 (17.1%) patients in ShorterDD group and 7/19 (36.8%) in LongerDD group remained with TOC showed high efficacy after first months of treatment with only 6/35 (17.1%) patients in ShorterDD group and 7/19 (36.8%) in LongerDD group remained with active systemic features (p=0.181). JADAS-71 level decreased to 0 points 26/35 patients in ShorterDD group and 7/19 (36.8%) in LongerDD group (p=0.237). After 3 month of treatment, WID was achieved by 27/35 patients in ShorterDD group and by 9/19 patients (47.4%) in LongerDD group (p=0.00001).

Conclusion: Initiation of tocilizumab treatment in sJIA patients under 4 years of age is highly effective. However, early treatment within first 6 month after disease onset had advantages in speed of reaching an inactive disease as soon as after 3 months of therapy.

**SAT0494**

**RITUXIMAB IN REFRACTORY PEDIATRIC RHEUMATIC DISEASES: FOCUS FOR THE SAFETY IN REAL CLINICAL PRACTICE.**

M. Kaleda1, I. Nikishina1, E. Nikolaeva1, S. Arenyeva1, V.A. Nasonova1,3

**Background:** Rituximab (RTX) is now approved only for pediatric patients (pts) 2 years of age and older with granulomatosis with polyangiitis or microscopic polyangiitis, but it has been used with success to treat another rheumatic diseases (RD) in children despite the status of "label".

**Objectives:** To analyze the safety of RTX in children with various RD who did not respond to conventional therapy.

**Methods:** In our retrospective study safety data was analyzed for all pts, who received at least one infusion of RTX. The dose of RTX was established as 375 mg/m² of body surface area, administered by intravenous infusion once weekly for 1 to 4 weeks, depending on the CD19 lymphocyte count.

**Results:** 81 patients with RD, who received RTX, were included: 38 (46.9%) with systemic lupus erythematosus (SLE), 16 (19.7%) – JIA, polyarthritis (2 pts - RF negative, 14 - RF positive), 9 (11.1%) - systemic JIA (sJIA), 6 (7.4%) – systemic sclerosis (SSc), 5 (6.2%) – primary Sjogren's syndrome (pSS), 2 (2.5%) - juvenile dermatomyositis (JDM), 4 (4.9%) - mixed connective tissue disease (MCTD) and 1 with livedoid vasculitis (LV). Most were female – 69 (85.2%). The median age at onset – 11.6 years [interquartile range (IQR) 7.9-14.3], median age of the starting therapy - 15.2 [IQR 12.5; 16.85] and median disease duration - 2.8 [IQR 1.0; 4.6]. 53 pts (65.4%) reported more than one course of RTX, maximum - 10. The median time between each course was 182 days [IQR 156-315]. The RTX was effective in 95% pts, ineffective in 5% (2 pts with sJIA, 2 pts with SLE and macrophage activation syndrome (MAS)).

**Adverse events (AE)** were recorded in 23 (28.4%) pts, included upper respiratory tract infections – 7 (8.6%), urinary tract infections – 2 (2.5%), short-term infusion reactions that did not require discontinuation of therapy – 2 (2.5%), clinically insignificant neutropenia (grade I-II) – 4 (4.9%), decrease of IgG level was detected in 14 (17.5%) pts (median 5.5 g/L [IQR 4.0; 6.9]). The infection rate in pts with a low IgG level was 35.7%, in pts with neutropenia wasn't recorded. Serious AE were recorded in 16 (19.7%) pts: sepsis – 4, pneumonia – 3, herpes zoster – 1, serious infusion reactions – 2, serious postinfusion reactions within 3 to 10 days – 4 (3 – MAS, 1 – hemorrhagic vasculitis), death – 2 pts with SLE and MAS (therapy of RTX was inefficent). In general, various AE were registered in 55.6% of pts with sJIA, in 52.6% of pts with SLE, 50% of pts with SSc and JDM, and 80% of pts with pSS. Discontinuation of therapy due to SAE was observed in 15 pts (18.5%).
Conclusion: Our study demonstrated that RTX is highly effective in children with RD, the majority with SLE, but the safety data obtained indicate the need for careful monitoring of therapy, primarily taking into account the frequency of infections. A decrease in IgG level was observed in a small proportion of pts and did not correlate with the incidence of infections. The frequency of serious infections was low.

LONG TERM OUTCOME OF JUVENILE IDIOPATHIC ARTHRITIS IN ADULTHOOD: THE MONOCENTRIC EXPERIENCE OF 520 PATIENTS FOLLOWED FOR 20 YEARS IN A TRANSITION TERTIARY CLINIC OF PEDIATRIC RHEUMATOLOGY.

I. Pontikaki1, S. Carborgno1, F. Corona1, A. Petacchia1, R. Cimaz1, 1ASSIP-PINI-CCT, Chair of Pediatric Rheumatology; University of Milan, MILAN, Italy; 2IRCCS Cà GRANDA Ospedale Maggiore Policlinico, MILAN, Italy

Background: Juvenile Idiopathic Arthritis (JIA) is a chronic pediatric inflammatory disease that shows many differences compared to adult-onset arthritis. The different clinical manifestations, the assessment and the management of JIA is the reason that the transition from childhood to adulthood is an important multi-dimensional process that emphasizes a lot of aspects.

Objectives: To describe the long-term outcome of JIA.

Methods: Five-hundred and twenty patients affected by JIA and referred to a transition care rheumatology tertiary centre were considered between 1999 and 2019. The outcome assessment included remission, disease duration, medications, number of prosthesis implantation, pregnancies, mortalit and social integration (employment status and educational level).

Results: A hundred and thirty-eight (26%) males and 382 (73%) females were included; 157 (30%) patients were lost to follow up. The mean age of the patients was 27 (18-57) years, with a mean age at onset of 8 years and an average disease duration of 19 years. Subtypes of JIA at disease onset included 252 (48%) oligoarthritis, 134 (26%) polyarthritis, 64 (12%) systemic arthritis, 22 (4%) psoriatic arthritis, 43 (8%) enthesitis related arthritis and 1 (0.1%) undifferentiated arthritis. Ninety-three (18%) patients suffered of uveitis. Ninety-five implant prosthesis and 16 arthrodesis were recorded. At follow up 198 (38%) patients were on remission of which 107 (20%) off medication. Among the 322 patients still on medication, 84 (16%) were under treatment with oral steroids, 226 (43%) with sDMARDs and 249 (40%) with bDMARDs. Five deaths (1%) occurred in this cohort. Two hundred and thirty-five subjects had a higher educational level, 327 had an employment. We have data of 201 patients. We have data of 201 patients. The patients was 27 (18-57) years, with a mean age at onset of 8 years and a mean average disease duration of 19 years. Subtypes of JIA at disease onset included 252 (48%) oligoarthritis, 134 (26%) polyarthritis, 64 (12%) systemic arthritis, 22 (4%) psoriatic arthritis, 43 (8%) enthesitis related arthritis and 1 (0.1%) undifferentiated arthritis. Ninety-three (18%) patients suffered of uveitis. Ninety-five implant prosthesis and 16 arthrodesis were recorded. At follow up 198 (38%) patients were on remission of which 107 (20%) off medication. Among the 322 patients still on medication, 84 (16%) were under treatment with oral steroids, 226 (43%) with sDMARDs and 249 (40%) with bDMARDs. Five deaths (1%) occurred in this cohort. Two hundred and thirty-five subjects had a higher educational level, 327 had an employment. We have data of twenty-nine pregnancies. The transition age was considered after the age of 16 years old. The key word for the management of this cohort was the multi-disciplinary approach towards each patient, with the collaboration of other specialists (ophthalmologist, orthopedic, dermatologist, gastroenterologist, obstetric and psychologist).

Conclusion: In the era of biologic therapy the long-term outcome of JIA underwent an outstanding improvement regarding a lot of variables. Two hundred and thirty-two patients were still followed, not only because of the continuation of the biological therapy, but also for a multidisciplinary care even during remission, JIA often persists over the adulthood, therefore the long term follow-up and care of these patients needs to be conducted by a rheumatologist expertized in JIA, but also in a multidisciplinary care even during remission. JIA went an outstanding improvement regarding a lot of variables. Two hundred and twenty patients affected by JIA and referred to a transition care rheumatology tertiary centre were considered between 1999 and 2019. The outcome assessment included remission, disease duration, medications, number of prosthesis implantation, pregnancies, mortality and social integration (employment status and educational level).

Results: A hundred and thirty-eight (26%) males and 382 (73%) females were included; 157 (30%) patients were lost to follow up. The mean age of the patients was 27 (18-57) years, with a mean age at onset of 8 years and a mean disease duration of 19 years. Subtypes of JIA at disease onset included 252 (48%) oligoarthritis, 134 (26%) polyarthritis, 64 (12%) systemic arthritis, 22 (4%) psoriatic arthritis, 43 (8%) enthesitis related arthritis and 1 (0.1%) undifferentiated arthritis. Ninety-three (18%) patients suffered of uveitis. Ninety-five implant prosthesis and 16 arthrodesis were recorded. At follow up 198 (38%) patients were on remission of which 107 (20%) off medication. Among the 322 patients still on medication, 84 (16%) were under treatment with oral steroids, 226 (43%) with sDMARDs and 249 (40%) with bDMARDs. Five deaths (1%) occurred in this cohort. Two hundred and thirty-five subjects had a higher educational level, 327 had an employment. We have data of twenty-nine pregnancies. The transition age was considered after the age of 16 years old. The key word for the management of this cohort was the multi-disciplinary approach towards each patient, with the collaboration of other specialists (ophthalmologist, orthopedic, dermatologist, gastroenterologist, obstetric and psychologist).

Conclusion: In the era of biologic therapy the long-term outcome of JIA underwent an outstanding improvement regarding a lot of variables. Two hundred and thirty-two patients were still followed, not only because of the continuation of the biological therapy, but also for a multidisciplinary care even during remission, JIA often persists over the adulthood, therefore the long term follow-up and care of these patients needs to be conducted by a rheumatologist expertized in JIA in collaboration with other specialists.

A PILOT PROTEOMIC ANALYSIS OF PLASMA BIOMARKERS IN IGA VASCULITIS

S. Demir1, M. Saradan1, I. Yet1, E. Sag1, Y. Bilginer1, Ö. Celikbıcak1, S. Özen1, 1Hacettepe Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Huntek Research Center, Ankara, Turkey; 3Hacettepe University Faculty of Medicine, Department of Bioinformatics, Ankara, Turkey; 4Hacettepe University Faculty of Medicine, Department of Chemistry, Ankara, Turkey

Background: IgA vasculitis/ Henoch Schönlein Purpura (IgAV/HSP) is the most common vasculitis of childhood, characterized by the IgA1 immune deposits in the small vessels. Although it is very common, the understanding of its molecular pathogenesis is still very limited.

Objectives: We aimed to analyse plasma proteomes of IgAV/HSP patients using nano liquid chromatography – tandem mass spectrometry (LC-MS/MS) to investigate the disease pathogenesis.

Methods: IgAV/HSP was diagnosed according to the Ankara criteria in 2008 (1). Five active IgAV/HSP patients and two age and gender-matched health controls were enrolled in this pilot study. Serum samples from subjects were collected on the same day of IgAV/HSP diagnosis and before steroid or other immunosuppressive treatment initiated. Sample preparation was carried out using PreOmics IST Kit. We investigated the alteration of serum proteome using the nano LC-MS/MS approach. Bruker raw files were analyzed using the proteomics software Max Quant (1.6.7.0). The human reference proteome set was used to identify the disease pathogenesis.

Results: The data file includes peptide and protein identification, accession numbers, protein and gene names, sequen coverage, and label-free quantification (LFQ) values of each sample. 345 proteins were reported per sample. Identiﬁcations from the reverse decay database, identified by site only and known contaminants were excluded. Data were log transformed. Two sample T-test was performed between groups. We identiﬁed 23 signiﬁcantly different expressed proteins (Table 1). Mainly the differentially expressed proteins were in the Ig and complement pathway, innate immune inflammatory,
and were among the structural cytoskeletal filaments. The levels of Complement C3, Apolipoprotein E, Glyceraldehyde-3-phosphate dehydrogenase, Filamin-A, Alpha-1B-glycoprotein, Tubulin beta-1 chain, Lipopolysaccharide-binding protein, Ig mu chain C region were significantly higher in IgAV patients.

Paediatric rheumatology

**SAT0498** ENTHESITIS-RELATED ARTHRITIS (ERA) IN SOUTHEAST ASIA: A DECADE OF SINGAPORE EXPERIENCE

T. Arkachaisri1,2, K. L. Teh1, Y. X. Book1, L. Das1. 1KK Women’s and Children’s Hospital, Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore

Background: ERA is the most common Juvenile Idiopathic Arthritis (JIA) subtype in Singapore (1), but less common in the West. Clinical characteristics and treatment of ERA in the region is not well-described thus impede the diagnosis and management plan which could lead to poorer outcomes.

Objectives: To describe the clinical characteristics, joint manifestation and treatment of ERA in a large monocentric cohort in Singapore over 10-year period

Methods: Children diagnosed with ERA according to ILAR criteria with a minimum follow-up of 3-month duration were recruited from our registry, from 2009 to 2019, at KK Women’s and Children’s Hospital, Singapore. Nonparametric descriptive statistics including median (IQR) were used to describe data. Kaplan-Meier survival analyses were used to estimate the probability of ever sacroiliac development. Multivariate logistic and Cox regression analyses were used to determine predictors as appropriate. The significant level was set at < 0.05.

Results: A cohort of 147 ERA out of 439 JIA patients (male 88%; Chinese 80%) were included. Median age at onset was 11.9 yrs (IQR9.4-14.0) and disease duration was 6.0 yrs (3.1-8.9). Median lag period was 2.9 mo (12-74). Family history of HLA-B27 related diseases was positive at 8%. Acute uveitis occurred only 3%. Joint distribution at diagnosis and cumulative involvement were shown in Fig 1. Hip, sacroiliac and knee were the three most common joints involved. 24% presented with enthesitis and Achilles tendon enthesis were the most common. Majority presented with pauciartiarthritis (84%) while 12% of patients had no peripheral joint involvement. 40% of patients presented with sacroiliitis (SIs) with 59% had bilateral involvement. Median duration to develop SIs was 76 mo (IQR 2.0-26.9). Probability of SIs development was 36%, 55% and 70% at 1, 5 and 10 years after onset, respectively. Interestingly, neg HLA-B27, female and older age at onset predicted SIs (p=0.001-0.044). Hip arthritis increased (p=0.043) but tarsitis decreased (p=0.031) the risk of SIs. Again, female, hip arthritis at diagnosis and neg HLA-B27 had a shorter time to SIs (p=0.004-0.007). Fig 2 showed medication used in our ERA cohort. Methotrexate (MTX) remained the most common D-MARD used. However, 76% required anti-TNF therapy (aTNF) due to MTX failure. For SIs patients, 86% were on MTX but 85% of these, as compared to patients without axial disease, 60%, failed MTX. Only 10% of patients had aTNF without MTX.

Conclusion: Our ERA cohort had less uveitis and family history of HLA-B27 associated diseases, but comparable gender and age at onset as compared to reports elsewhere(2). Up to 40% of our patients presented with SIs and/or enthesitis. Majority of SIs developed within the first 5 yrs (88%) for which over one-half developed within the first year. When considering only ERA patients, interestingly that female, neg HLA-B27 and older age increased risk of SIs development. 77% of patients were treated with MTX, but 76% of the patients required aTNF later. As for SIs, concurred with adult AS data, 85% failed MTX. About one-half of non-axial disease patients failed MTX which is less response rate as compared to other JIA subtypes.

**Fig 1.** Proportion of joint involvement at onset and cumulative involvement during the course of disease (%)

**Fig 2.** Proportion of medications used in ERA cohort during the course of disease (%)

Conclusion: Our ERA cohort had less uveitis and family history of HLA-B27 associated diseases, but comparable gender and age at onset as compared to reports elsewhere(2). Up to 40% of our patients presented with SIs and/or enthesitis. Majority of SIs developed within the first 5 yrs (88%) for which over one-half developed within the first year. When considering only ERA patients, interestingly that female, neg HLA-B27 and older age increased risk of SIs development. 77% of patients were treated with MTX, but 76% of the patients required aTNF later. As for SIs, concurred with adult AS data, 85% failed MTX. About one-half of non-axial disease patients failed MTX which is less response rate as compared to other JIA subtypes.

</table>
In GOL treated patients a marked clinical response was noted at 6 months and beyond demonstrated by a significant decrease of the mean JADAS 10 from 11.3 to 6.4 (p=0.0008), as well as JAC ACR 30/50/70/90 response rates of 56/56/35/21%. JADAS remission and minimal disease activity was observed in 18% and 47% after 6 months and in 29% and 43% of patients after 12 months.

Rates of AE, SAE and infectious AE were comparable between the GOL cohort (96, 4.2 and 12.8/100 PY), the alternative TNFi cohort (114, 5.4 and 11.8/100 PY) and the MTX cohort (107, 2.7 and 24.5/100 PY). SAE reported in the GOL cohort were uveitis and JIA flare (each 1). Two serious infections, both influenza, were reported in the alternative TNFi cohort, none in the GOL cohort. No case of preg- nancy, malignancy or death was reported.

Conclusion: Interim results from this ongoing safety surveillance study indicate acceptable safety and tolerability of GOL in pJIA that is comparable to treatment with alternative TNFi or MTX. The long-term effectiveness data reinforce the established efficacy of GOL in pJIA treatment.

DOI: 10.1136/annrheumdis-2020-eular.4611
Background: Low immunoglobulin (lg) levels can occur after rituximab treat- 
ment but the clinical significance is not completely characterized. Not all patients (pts) who develop low lg levels after rituximab are at an increased risk of se-
rious infection (SI), but factors such as pre-existing low lg levels, prior biologic therapies, history of SI and other disease and age-related factors may increase the risk.

Objectives: To assess the risk of SI in pediatric pts with prolonged low IgG or 
IgM serum concentrations following rituximab treatment for GPA or MPA in a global clinical trial.

Methods: In the Phase 2a PePERS study (WA25615), pts aged 2 ≥ 18 years with GPA or MPA received 4 weekly intravenous rituximab infusions of 375mg/m² body surface area and concomitant oral glucocorticoid taper. After 6 months, pts could receive further rituximab and/or other immunosuppressants at the investi-
gator’s discretion during a minimum 12-month follow-up phase. Pts with IgG/IgM levels below age-specific reference ranges at baseline were excluded. Ig levels were measured every 4-12 wks. SI occurrence was assessed during/after low 
IgG or IgM. Prolonged low Ig was defined as IgG or IgM levels < lower limit of normal (LLN) reference range for age for a ≥ 4-month period.

Results: All 25 pts completed 4 weekly rituximab infusions and the 6-month Remission Induction Phase; 24/25 pts completed ≥ 18 months of follow-up. 17 pts (74%) experienced an initial rituximab treatment and received concomitant immunosuppressants (cyclophosphamide, azathioprine, mycoophe-

nolate mofetil) during the study. All pts had a decrease in IgG and IgM mostly after the first rituximab infusion. There was no consistent trend in IgG or IgM levels over time and no clear relationship between low IgG or IgM levels and the number of follow-up rituximab treatments. 18 pts (72%) had prolonged low IgG > 4 months, of whom 5 had IgG levels < LLN at screening and/or baseline; in 7 pts, IgG levels returned to within normal range by study end. During or after prolonged low IgG, 6/18 pts experienced a total of 7 SIs. Three pts received treatment with intravenous Ig. 19 pts (76%) had prolonged low IgM, of whom 5 had IgM levels < LLN at screening and/or baseline. During or after prolonged low IgM, 6/19 pts experienced a total of 8 SIs. There were no deaths or study discontinuation due to SI. All pts with prolonged low IgG or IgM had past and/or current concomitant treatment with steroids and/or immunosuppressants as potential contributory factors. Analysis of SI onset in relation to timing of low Ig was limited due to protocol-defined time points for lg assessments.

Conclusion: In pediatric pts with GPA/MPA treated with rituximab, there was no consistent pattern in IgG or IgM levels over time. The majority of pts with pro-
longed low IgG or IgM did not experience any SIs; no increase in the number of SIs was observed over time or with multiple rituximab treatments. While no firm conclusions can be made on a possible relationship between prolonged low IgG or IgM and risk of SI following rituximab due to study limitations (low pt numbers, lack of placebo comparator), these observations are consistent with the known rituximab safety profile in adult pts with GPA/MPA.

SAT0505

PLUTO TRIAL OF INTRAVENOUS BELUMIMAB IN PAEDIATRIC PATIENTS WITH CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS (CSLE): PATIENT RESPONSES OVER TIME

N. Ruperto1, L. Mccann2, S. Takei3, C. Pilkington4, D. Bass5, B. Ji6, A. Hammer5, M. Okly4, G. Eriksson4, H. Quasy4, H. Brunner4, Istituto Giannina Gaslini, Genoa, Italy; 1Aler Hey Children’s Hospital, Liverpool, United Kingdom; 3Kagoshima University, Kagoshima, Japan; 4Great Ormond Street Hospital, London, United Kingdom; 5GlaxoSmithKline, Collegeville, United States of America; 6GlaxoSmithKline, Uxbridge, United Kingdom; 7GlaxoSmithKline, Research Triangle Park, United States of America; 8Children’s Hospital Dallas, Dallas, United States of America

Background: Belimumab (BEL) is a human monoclonal antibody that spec-
ifically inhibits B-cell activating factor (BAFF). PLUTO is an ongoing trial eval-
uating efficacy and safety of intravenous (IV) BEL in children ≥5 years of age with cSLE. Efficacy, and safety endpoints of PLUTO have been reported briefly, numerically more BEL vs PBO pts met the primary and major secondary efficacy endpoints. We present patient (pt) response to BEL over time.

Objectives: To evaluate changes in SLE Responder Index (SRI) 4 and SRI6 responses, and disease activity over 52 weeks, in paediatric pts receiving BEL, or placebo (PBO), plus standard SLE therapy (SST).

Patient 1, a 11-year-old boy, was identified to carry a de novo p.V155M mutation in TMEM173. He presented at the age of 7 years with symmet-
rical polyarticular arthritis after a bronchial infection that course with fever. No skin manifestations were objectified. Autoimmune lab test was positive for RF, ACPA, and ANA. With the diagnosis of Polyarticular JIA he received different treatments with no response. Due to recurrent bronchial infections a HRCT was performed showing an ILD at bases and follicular bronchiolitis with NSIP pattern in a lung biopsy. Functional tests were worsening without any response to differ-
ent treatments, SAVI syndrome was suspected, and genetic test was performed with positive result. RX was initiated but compliance was not good

Conclusion: SAVI syndrome is a rare monogenic autoimmune inflammatory disease with few cases reported in the literature. Disease phenotype could be different in every patient, with no presence of skin vasculitic lesions or fever. Patient 2 and 3, in contrast with patient 1, had severe articular and lung manifestations with no skin involvement. Furthermore, lab tests were positive for RF and ACPA and were misdiagnosed as JIA so genetic test was performed later in the follow-up. Being aware of the distinct phenotype of the disease could help the clinicians to make a PRONTO diagnostic and reassess the patients with these presentations that do not respond well to conventional treatments.

SAT0504

STING-ASSOCIATED VASCULOPATHY WITH ONSET IN INFANCY (SAVI SYNDROME) CAN MIMIC JUVENILE IDIOPATHIC ARTHRITIS.

M. Lopez Corbeto1, E. Moreno Ruzafa1,2. 1Hospital Universitari Vall d’Hebron, Pediatric Rheumatology, Barcelona, Spain; 2Hospital Universitari Vall d’Hebron, Barcelona, Spain

Background: STING-associated vasculopathy with onset in infancy (SAVI syn-
drome) can mimic Juvenile Idiopathic Arthritis.

Objectives: The aim of this study is to describe a detailed cohort of patients with SAVI syndrome and to discuss the similarities, in some cases, of the phenotype of this disease with Juvenile Idiopathic Arthritis.

Methods: S21 pts diagnosed with SAVI syndrome from the institution Hospital Universitari Vall d’Hebron were recruited. Written informed parental consent was obtained for the use of clinical data and pictures reported. Demographic, clinical, analytical, lung function and previous and current treatment are described.

Results: Patient 1, a 11-year-old boy, was identified to carry a de novo p.V155M mutation in TMEM173. He presented at first month of life with recurrent bronchial infection and skin vasculitic lesions in nose, cheeks and toes. Arthritis affected hands, toes and knees but no erosions were found at X-Ray. Fever was not reported. High-resolution computed tomography (HRCT) of the lungs identified a nonspecific interstitial pneumonia (NSIP) and a lung biopsy showed lymphoid hyperplasia. Elevated inflammatory markers were reported and rheumatoid fac-
tor (RF), ACPA antibodies and antinuclear antibodies (ANA) were also positive. At the age of 6 years Ruoxolinib (RX) was introduced at the initial dose of 5mg twice daily with an improvement of skin disease and lung function. Arthritis was well controlled and RX was well tolerated.

Patient 2, a 17-year-old girl, was identified to carry a de novo p.V155M mutation in TMEM173. She presented at the age of 3 with a severe polyarthritis of large and small joints. No fever, skin or respiratory symptoms were reported at the beginning of the disease. Laboratory tests were positive for RF and ACPA anti-

bodies. She was diagnosed with Polyarticular JIA and was treated with steroids and corticosteroids without improvement. Few months later she reported dysp-
noea with recurrent bronchial infections. HRCT showed NSIP and lymphoid inter-
stitial pneumopathy was found at the lung biopsy. RX was initiated at the age of 17 years but at this time lung fibrosis was stabilized. Moreover, RX was not well tolerated due to headache. She requires continuous domiciliary oxygen and has been included to lung transplant.

Finally, patient 3, a 2-year-old man, was recently diagnosed with a de novo p.V155M mutation in TMEM173. He presented at the age of 7 years with symmet-
rical polyarticular arthritis after a bronchial infection that course with fever. No skin manifestations were objectified. Autoimmune lab test was positive for RF, ACPA, and ANA. With the diagnosis of Polyarticular JIA he received different treatments with no response. Due to recurrent bronchial infections a HRCT was performed showing an ILD at bases and follicular bronchiolitis with NSIP pattern in a lung biopsy. Functional tests were worsening without any response to differ-
ent treatments, SAVI syndrome was suspected, and genetic test was performed with positive result. RX was initiated but compliance was not good

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-e819
Methods: PLUTO (GSK Study BEL114055, NCT01649765) is a Phase 2, randomised, double-blind, placebo-controlled study. Pts 5–17 years of age with active cSLE were randomised to monthly BEL 10mg/kg IV, or PBO, plus SST. Endpoints assessed: SR4 and SR6 response rate, mean percentage and absolute change from baseline in Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLE Disease Activity Index (SLEDAI) and Physicians’ Global Assessment (PGA) scores, and percentage of pts with no new British Isles Lupus Assessment Group (BILAG) 1A/2B organ domain scores compared with baseline, all by study visit. The last-observation-carried-forward (LOCF) principle (missing values imputed using the last available non-missing value) was applied to pts who withdrew or received protocol-prohibited medication or a dose of allowable medication that resulted in treatment failure prior to the Week (Wk) 52 visit. Descriptive statistics were used.

Results: A total of 93 pts (94.6% female, mean [SD] age 14.0 [2.49] years) were randomised for the intention-to-treat (ITT) population: 53 to BEL and 40 to PBO. Mean (SD) BEL and PBO baseline scores were 10.3 (3.34) and 10.4 (3.63) for SELENA-SLEDAI and 1.3 (0.43) and 1.4 (0.42) for PGA, respectively. Pt number with at least BILAG 1A/2B organ domain involvement at baseline was 37 (69.8%) for BEL and 29 (72.5%) for PBO. SR4 and SR6 responses over 52 weeks were mostly numerically higher with BEL than PBO; more BEL than PBO pts were SR4 and SR6 responders at Wk 52 (Figure 1). Unadjusted mean (SE) percentage changes from baseline over time in SELENA-SLEDAI and PGA scores generally favoured BEL over PBO, as did unadjusted mean (SE) absolute changes (Figure 2). Wk 52 adjusted mean (95% CI) percentage treatment difference vs PBO was -4.0% (-2.18, 13.9) for SELENA-SLEDAI and -6.1% (-23.9, 11.7) for PGA, while Wk 52 adjusted mean (95% CI) treatment difference vs PBO was -0.7 (-2.4, 1.1) for SELENA-SLEDAI and -0.1 (-0.3, 0.1) for PGA. Over the study duration, numerically more BEL than PBO pts had no new BILAG 1A/2B organ domain scores (Figure 2).

Figure 1. SR4 and SR6 response by study visit

Figure 2. SELENA-SLEDAI and PGA score mean percentage and absolute change from baseline, and no new BILAG 1A/2B organ domain scores compared with baseline, all by study visit

Conclusion: In line with the main analyses performed at Wk 52, 1 further analysis showed responses over time in SR4, SR6 and disease activity generally favoured BEL over PBO. Combined, these results continue to support the efficacy profile of IV BEL in the treatment of children with cSLE.

DOI: 10.1136/annrheumdis-2020-eular.4498
BACKGROUND: The incidence of juvenile gout is increasing in China. The clinical manifestations of juvenile gout and treatment strategies to reduce uric acid levels in children are not well described due to the limited number of cases in the past.

OBJECTIVES: We aim to describe the clinical characteristics of children with gout and study the treatment response to febuxostat.

METHODS: These studies were approved by the Institutional Review Board of Guangdong Second provincial General Hospital. We performed a retrospective analysis on 98 juvenile gout patients (age ≤ 18 years) evaluated in our hospital from Jan 2016 to Dec 2019. We analyzed clinical parameters, laboratory data and treatment response.

RESULTS: The average age of disease onset in children with gout was 15.2 ± 2.0 years and the youngest patient was 9 years old. The majority of patients were male (94/98) and mean serum uric acid (sUA) level were 705.8 ± 145.7 μmol/L (reference range <420 μmol/L). More than half of the cohort had normal body mass index (mean 24.7 ± 4.7 kg/m²; range 14.9 to 36.1 kg/m²). Renal function was generally normal in these children (serum creatinine 96.9 ± 173 μmol/L). In terms of joint manifestations, juvenile gout preferentially affected finger joints (20%), ankles (28%) and metatarsal joints (MTP; 20%). The most frequent sites of initial gout attack were ankles (45%), MTP (39%) and fingers (6%). In addition, tophi can occur in pediatric patients and typically develop in the finger joints (54%). Tophi was observed in about 25% of juvenile gout patients, typically within the first two years of disease onset (mean duration 1.7 ± 0.9 years). We have found tophi in children as young as 10 years of age.

For treatment for chronic hyperuricemia, 32 patients (32.7%) were started on febuxostat and 5 patients (5.1%) received allopurinol. A decrease in sUA was observed in both groups after the first month of treatment (febuxostat: baseline 690.4 ± 99.7 μmol/L to 482.7 ± 140.8 μmol/L vs. allopurinol: baseline 728.8 ± 112.8 μmol/L to 565.0 ± 116.7 μmol/L (P= 0.477). Serum uric acid of 6 patients in the febuxostat group (none in the allopurinol group) dropped below 360 μmol/L. There were no statistical differences in Cr, AST and ALT between the groups. During follow-up after 3 months, further decline in sUA level were observed in both groups after the first month of treatment (febuxostat: baseline 24.7 ± 4.7, compared with baseline P<0.001).

During follow-up after 3 months, further decline in sUA level were observed in both groups after the first month of treatment (febuxostat: baseline 24.7 ± 4.7, compared with baseline P<0.001). The overall concordance was fair (Kappa 0.3; p<0.001). Sensitivity was 58.6% for ICBD criteria and 80.2% for ISG.

Conclusion: ICBD criteria exhibit higher sensitivity than ISG criteria. Thus, the application of these new criteria can achieve a more correct and earlier diagnosis of BD.

Background: Cyclophosphamide (CYC) had a good response rates when used as an induction regimen for the treatment of connective tissue related interstitial lung disease (CTD-ILD). But the safety profile of CYC necessitates the usage of a second line treatment for maintenance.

Objectives: To compare the effect of mycophenolate (MMF) and azathioprin (AZA) for maintenance therapy following cyclophosphamide treatment in CTD-ILD

Methods: Between 2009 and 2019 all interstitial lung disease patients admitted with rheumatology or pulmonology department were retrospectively evaluated and patients treated with cyclophosphamide as an induction regimen and having not progression were selected. Among those, as a second line regimen treated with MMF or AZA were included. Primary endpoint was treatment responses at 6 months.

Results: 68 patients treated with CYC for the first line treatment. 46 patients treated with either MMF (n=22) or AZA (n=24) for the maintenance. Sarcoiderma patients were the largest group and constituted 63% of the population. MMF group had worse FVC values and more involvement in lung parenchyma at the beginning of the treatment. In univariate analysis FVC (lt) values and lung involvement (%) on HRCT at the start of the treatment, and disease subtype were associated significantly with treatment responses. After adjusted with these factors, in multivariate analysis, AZA treatment was associated with the increased risk of progression (odds ratio 5.8, 95% CI 1.061-31.09) as compared with MMF treatment.

Conclusion: MMF had better results compared to AZA in the treatment of CTD-ILD after the usage of CYC treatment.

LONG-TERM EFFECTIVENESS OF CANAKINUMAB IN AID – INTERIM ANALYSIS OF THE CAPS SUBGROUP FROM THE RELIANCE REGISTRY

N. Blång1, M. Borte2, I. Földvari3, G. Horneff4, T. Kallinich5, B. Kortus-Goetz6, P. Oommen7, C. Schuetz8, F. Weller-Heinemann9, J. Weber-Arden10, B. Kuehnermeier-Deschner11, M. A. Ozturk1, A. Tufan1, H. Türkta3, 2Gazi University Faculty of Medicine, Hospital, Ankara, Turkey; 3Gülhane Research and Training Hospital, Ankara, Turkey

Background: Regular clinical follow-up and assessment of patients with cryopyrin-associated periodic syndromes (CAPS) can be challenging due to variable clinical expression and burden. The aim of the RELIANCE registry is to explore long-term effectiveness and safety of CAN in CAPS.

Objectives: To estimate levels of cytokines, chemokines, and inflammatory biomarkers in patients with NS.

Methods: In this observational, cross-sectional study, cerebrospinal fluid (CSF) and plasma were collected from biopsy-proven sarcoidosis patients with clinical suspicion of NS. They were categorized into either a NS group (n=14) or a non-NS group (n=5) depending on fulfilment of NS criteria. The results were

Ocular involvement of sarcoidosis is a relative frequent and potentially severe complication, especially if panuveitis is presented.

Results: The level of INFγ was significantly higher in NS group compared to non-NS group in CSF (median 11.37 pg/mL vs. 0.19 pg/mL), TNFβ (median 0.37 pg/mL vs. 0.02 pg/mL), IL8 (median 55.4 pg/mL vs. 378 pg/mL), CCL11 (median 36.1 pg/mL vs. 16.4 pg/mL), CCL26 (median 6.7 pg/mL vs. 3.7 pg/mL), CXCL10 (median 4981 pg/mL vs. 771 pg/mL), CCL13 (median 24.5 pg/mL vs. 10.0 pg/mL), CCL22 (median 129.8 pg/mL vs. 22.6 pg/mL), CCL3 (median 54.1 pg/mL vs. 20.7 pg/mL), CCL17 (median 54.0 pg/mL vs. 6.9 pg/mL), ICAM1 (median 13901 pg/mL vs. 7327 pg/mL), and VCAM1 (median 18594 pg/mL vs. 12132 pg/mL).

A cut-off level for each cytokine was set at 20% above the maximum values of both non-NS group and HC. Using this, the ratio of patients in NS group over were:

- INFγ, 57% had level over 6.2 pg/mL in CSF, and 50% had level over 21.6 pg/mL in plasma.
- IL12/IL23p40, 22% had level over 54.05 pg/mL in CSF vs. 3.61 pg/mL in plasma.
- IL16, 22% had level over 54.05 pg/mL in CSF vs. 3.61 pg/mL in plasma.
- CCL11, 22% had level over 54.05 pg/mL in CSF vs. 3.61 pg/mL in plasma.
- CCL22, 79% had level over 22.6 pg/mL in plasma.

Conclusion: In NS patients, INFγ was elevated in both CSF and plasma, and multiple cytokines, chemokines and vascular biomarkers were elevated in CSF.

Ocular involvement and treatment in sarcoidosis. Study of 41 patients of a series of 383 patients from a single university hospital

M. Calderon-Goecke, L. Sanchez-Bilbao, R. Demetrio-Pablo, R. Blanco, HUM.Valdecilla, Rheumatology, Santander, Spain; HUM.Valdecilla, Ophthalmology, Santander, Spain

**Background:** The eye is a common and potential severe complication of sarcoidosis. Systemic corticosteroids are the first-line treatment. Conventional and biological immunosuppressants (IS) are frequently needed (1-5).

**Objectives:** To access the frequency, clinical, and treatment of ocular involvement of sarcoidosis.

**Methods:** Study of a large cohort (n=383) of systemic sarcoidosis from a single university hospital. All consecutive patients diagnosed with sarcoidosis from January 1, 1999 to January 1, 2019 according the ATS/EAS/WASOG criteria (Eur Respir J 1999;14:735–737) were included.

**Results:** 41 (22 women/19 men) of 383 (10.7%) patients had ocular involvement, mean age 44.8±16 years. Uveitis (n=34; 82.9%) was the most common ocular manifestation, especially anterior uveitis (n=18; 52.9%). Ocular surface and eye orbit may also be affected (Table). In addition to topical and systemic corticosteroids, conventional (n=23; 56.1%) and biological (n=14; 34.1%) IS drugs were required. Adalimumab and Infliximab were the most used biological treatments (Table). Cystoid macular edema (CME) and Retinal Vasculitis was observed in both cases in 3 (73%) patients, 2 of them (66.7%) required biological treatment. Papillitis appeared in 7 (17.1%) cases, biological treatment was needed in 3 (42.9%) patients. The most frequent sequels were cataract (n=9, 21.9%), intraocular hypertension (n=5; 12.2%) and pupil alterations (n=4; 9.7%). The average of the best corrected visual acuity was 0.6±0.3 at diagnosis and 0.7±0.3 after one year follow up.

**Conclusion:** Ocular involvement of sarcoidosis is a relative frequent and potential severe complication, especially if panuveitis is presented.

Association of serum omentin levels with colchicine resistance in familial Mediterranean fever

S. Can Sandikci1, A. Omma2, C. Yuzyi2, T. Omma2, A. Diskapi Yildirim Beayazit Training and Research Hospital, Rheumatology, Ankara, Turkey; A. Ankara Numune Research and Training Hospital, Rheumatology, Ankara, Turkey; A. Ankara Numune Research and Training Hospital, Clinical Biochemistry, Ankara, Turkey; A. Ankara Education and Research Hospital, Ankara, Turkey

**Background:** Omentin is an anti-inflammatory adipokine, which plays important roles in the adjustments of glucose metabolism, cardiovascular homeostasis, atherosclerosis (1).

**Objectives:** To investigate the omentin levels in Familial Mediterranean fever (FMF) patients and to assess the association with markers of subclinical inflammation in FMF patients such as serum amyloid A (SAA), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP).

**Methods:** This cross-sectional study included 54 consecutive adult FMF patients (27 male, 27 female) and 28 healthy individuals (16 male, 12 female). The demographic and clinical features and MEFV gene mutations were recorded. The FMF patients were separated into 3 groups: 1) attack-free group, 2) active attack group and 3) colchicine-resistant group. Serum omentin levels were compared between the FMF patients and the healthy control group.

**Results:** Serum omentin and SAA levels were higher in the study group than in the control group (108.05(19.97-343.22) vs. 199.5(42.98-339.41), p<0.05, 3.69(1.86-22.75) vs. 1.31(0.95-3.16) p<0.001) (Table 1). When the FMF patients were examined as separate groups, serum omentin values were lower in the colchicine resistant group than in the groups without resistance (Table 2). The correlation analysis showed a negative correlation between omentin and SAA levels (r = -0.240, p = 0.030).

**Conclusion:** FMF patients with colchicine resistance are associated with decreased omentin concentrations, probably mediated by inflammation-driven mechanisms.

**FATIGUE IN FAMILIAL MEDITERRANEAN FEVER**

A. K. Cengiz1. 119 Mayis University Faculty of Medicine, Physical Medicine and Rehabilitation-Rheumatology, Samsun, Turkey

**Background:** Fatigue is an important and common symptom in rheumatologic diseases. It causes disability and worsens patients quality of life. Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disease characterized by recurrent episodes of fever and serositis. Mutations in the MEFV gene that encodes pyrin protein are responsible for the disease. Most frequent mutation is M694V and FMF patients with M694V/M694V genotype have more severe disease.

**Objectives:** The aim of this study is to investigate fatigue and its impact on quality of life of FMF patients who are attack-free for more than one year.

**Methods:** Seventy-seven FMF patients and 70 age and sex matched healthy controls were enrolled in the study. Fatigue severity scale (FSS) was used to evaluate fatigue level. Disease severity was evaluated via FMF disease severity rate, CRP=C-reactive protein, IQR=interquartile range.

**Disclosure of Interests:** None declared

**COMPLEX HYPERMOBILITY EHLERS-DANLOS SYNDROME (HEDS): MAPPING THE PATIENT’S JOURNEY OVER 40 MONTHS IN A TERTIARY REFERRAL CENTRE**

S. Dar1, V. Tidman2, P. Mehta3, H. Kazakza2.

1UC Medical School, London, United Kingdom; 2University College Hospital, London, United Kingdom

**Background:** Ehlers-Danlos Syndromes are heritable connective tissue disorders. They are multisystemic and patients can present with several symptoms such as joint pain and instability, visceral and autonomic dysfunction, as well as significant psychosocial sequelae. Managing this cohort of young patients is usually challenging as many patients present late due to delayed diagnosis, often with several complications, problems with mobility and opioid use. Furthermore, there is often a prolonged lack of coordinated healthcare and access to social care services. A recent parliamentary debate in the U.K. highlighted that hEDS services are excluded from specialist Rheumatology commissioning services. In order to ascertain the relevance and utility of specialist services in this population, we conducted this study.

**Results:** The objective of this study was to map the patient experience following a referral to the specialist clinic in order to assess the need for an integrated, multidisciplinary approach to treating patients with hypermobility EDS.

</table>

Twenty-three of FMF patients had M694V/M694V genotype and those patients had higher disease severity scores (p<0.01), higher FSS (p<0.01) and higher BDI scores (p=0.05) when compared with other FMF patients. Regarding the quality of life, patients with M694V/M694V genotype had lower scores in social functioning, role physical, role emotional and pain subscales of SF-36. In the correlation analysis depression and fatigue were found to be the major determinants of quality of life in FMF. Disease severity or duration were not strongly correlated with the SF-36 scores (Table 2).

**Conclusion:** Despite being attack-free for more than one year, FMF patients had poor quality of life and fatigue when compared with the healthy controls. The quality of life in FMF patients, whose attacks are well controlled, is mainly determined by fatigue and depression rather than disease severity.

CLINICAL CHARACTERISTICS AND PROGNOSTIC FACTORS IN PATIENTS WITH SECONDARY HEMOPHAGOCYTIC SYNDROME

C. A. Egües Dubuc1, A. De Diego1, R. Cabrera Miranda2, N. Alcorta Lorenzo1, J. A. Valero Jaime1, J. R. Furundarena Salsamendi3, O. Maiz-Alonso1, L. M. Lopez Dominguez8, E. Uriarte Isacelaya8, J. J. Cancio Fano9, J. Calvo10, J. M. Belzunegui Otano11, Donostia University Hospital, Rheumatology, San Sebastian, Spain;2University Hospital 12 October, Preventive medicine and public health, Madrid, Spain;3Donostia University Hospital, Haematology, San Sebastian, Spain;4Araba University Hospital, Rheumatology, San Sebastian, Spain

Background: The Hemophagocytic Syndrome (HPS) has a mortality rate between 20% and 90%. The mortality of HPS secondary to autoimmune diseases (AID) is lower than hematological diseases (HOD). In general, the HOD, thrombocytopenia, age, and a prolongation of prothrombin are considered to be an adverse prognostic factor.1

Objectives: To describe and identify differences between patients who survived and did not survive to HPS during hospital admission to a tertiary hospital between 2005 and 2019.

Methods: This is a retrospective observational study. All patients who met the diagnostic criteria for HPS were included, or who presented haemophagocytic cells in the bone marrow biopsy, or who had diagnosis of HPS in the hospital discharge report.2 2 Demographic, clinical, analytical, etiological, underlying disorder and prognosis variables were collected. Continuous variables are described with the mean or median according to the degree of normality. Kruskal Wallis, Fisher test and Mann-Whitney U test were used for the bivariate analysis, and also a multivariate logistic regression analysis was performed.

Results: Thirty patients with HPS were included. They were distributed in 5 subgroups (Table 1). Overall mortality was 43.3%, statistically significant higher in the HOD (9 patients (66.7%); p < 0.029). Also, they were divided into 2 groups (survivor vs. non-survivor; Table 2). In the multivariate model the age and INR prolongation were confirmed to be independently associated with the outcome of mortality.

Diagnosis of HPS: In 25 patients were diagnosed by histology (18 with bone marrow biopsy), or a bone marrow biopsy was not performed. In the remaining 5 patients were diagnosed by clinical criteria (environmental exposure, clinical picture, laboratory findings).

Discussion: The HOD presented higher mortality. The non-survivor group presented a longer INR prolongation and a higher age at the time of diagnosis.

SAT0518

CANAKINUMAB TREATMENT IN ADULT PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: A SINGLE-CENTER STUDY

S. Ugurulu1, B. H. Eppel1, O. Selvi1, B. Ergezen1, A. Hadzalic1, H. Ozdogan1, 1Istanbul University-Cerrahpasa, Istanbul, Turkey

Background: Familial Mediterranean Fever (FMF) is the most common auto-inflammatory disease characterized by recurrent, self-remitting attacks of fever, serositis, arthritis, and erysipelas-like erythema. Canakinumab is an Interleukin-1β inhibitor that is shown to be effective and safe in treating colchicine resistant FMF patients.

Objectives: The main objective of this study is to present the single tertiary center experience of adult FMF patients who received Canakinumab.

Methods: The study is a retrospective analysis conducted at a tertiary rheumatology center experienced in FMF. The patients who had a clinical diagnosis of FMF and who were treated with at least a single subcutaneous injection of canakinumab were included in this study.

Conclusion: This study shows that patients with FMF referred to UCLH have had a longer hospital stay, more failed discharges and patients were often referred back to the Rheumatology Clinic despite being discharged to primary care. 5. Patients had a significant number of comorbidities, reflected by polypharmacy (36% of patients were prescribed ≥5 medications).

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2020-eular.4589

* p = 0.029
included. Patients with amyloidosis and pregnancy were excluded. In order to evaluate the disease status, acute phase reactants and patient-reported disease severity visual analog scale (VAS) scores were analyzed. Acute phase reactants were evaluated during attack-free periods. The VAS score was reported on a scale of 0-10, 10 meaning the disease at its most severe form, and 0 meaning the least.

Results: Fifty-two patients (21 male, 31 female) with the mean age of 35.88±12.4 years, were included in this study. The presenting signs and symptoms of the patients are shown in Figure 1. The mean age of initial symptoms and diagnosis were 12.84±10.06 and 20.39±12.35 years in respective order. The treatment information of the patients before and during Canakinumab injections was shown in Table 1. The mean Erythrocyte Sedimentation Rate (ESR) decreased from 25.31±20.64 to 11.52±9.78 mm/hour. The mean C-reactive Protein (CRP) decreased from 28.18±47.04 to 2.02±2.31 mg/L (both p<0.0001). The mean VAS score decreased from 8.04±1.9 to 1.4±1.73 (p<0.0001). Canakinumab treatment was terminated in 33 patients, 22 of which was due to successful remission. The termination of the treatment was because of pregnancy or will of pregnancy in 4 patients, inadequate treatment response 3 patients, treatment noncompliance in 2 patients, chronic hepatitis C related cirrhosis in 1 patient, and change to a different biologic agent in 1 patient. The only side effect experienced was hallucinations in one patient who was already under remission.

Conclusion: Canakinumab seems effective in controlling the subclinical inflammation and raising the quality of life of the patient. It has a favorable side effect profile. According to our single-center, real-life data, Canakinumab can be used as an alternative treatment method in colchicine resistant patients.

Figure 1. Kaplan-Meier curves comparing anakinra (ANK), tocilizumab (TCZ) and Tumor Necrosis Factor inhibitors (TNFi) at 24 months in adult onset Still's disease.
Background: Synovitis, acne, pustulosis, hyperostosis, osteitis (SAPHO) is a rare disease involving skin and skeleton, with a potentially complicated and severe course, optimal management of which requires a collaborative rheumatology and dermatology care. Diagnostic criteria for SAPHO remain preliminary and lack validation. There are no evidence-based treatment algorithms in SAPHO due to lack of clinical trials in this rare medical condition.

Objectives: This study aimed to investigate the current practice in the diagnosis and treatment of SAPHO syndrome among the international rheumatology and dermatology communities.

Methods: We conducted a survey among the members of the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) combining international rheumatologists and dermatologists as well as members of the Japanese and Israeli Societies of Rheumatology.

Results: A total of 78 physicians participated in the survey: rheumatologists (83%, n=65), dermatologists (11.5%, n=9), and orthopedics (3.8%, n=3). SAPHO was considered a subtype of spondylitis by 48.7% (n=38), a subtype of reactive arthritis by 6.4% (n=5), Palmoplantar pustulosis was the most prevalent osteoarticular manifestation (n=66, 84.6%). The majority (84.6%, n=66) voted for the update of the present diagnostic criteria by Khan 1994. Magnetic resonance imaging was considered the preferred imaging modality for the diagnosis of SAPHO by 41% (n=32). Conduction of bone biopsy for diagnosis of non-infectious osteitis was supported only by 10.3% (n=8). Patient-reported outcomes were considered the most appropriate measure for the assessment of disease activity by 47.4% (n=37). The treatment approach was overall similar among the rheumatology and dermatology communities, including non-steroidal anti-inflammatory drugs, bisphosphonates, conventional disease-modifying anti-inflammatory drugs, and biologics (Table 1).
Also, we observed that level of HDLP-C is higher in patients with early stages than in late stages of AN (1.55 (1.31-1.57) vs. 1.23 (1.04-1.36) mmol/l, p=0.04). Thus, HDLP-C can be interpreted as a protective factor against contralateral joint involvement in AN patients. The data obtained is consistent with the existing data that HDLP-C lowers the risk for cardiovascular disease.

Conclusion: The data obtained indicate a significant role of dyslipidemia in the pathogenesis of AN in the context of vascular theory.

PROGRESSION OF VISION-RELATED QUALITY OF LIFE AND IDENTIFICATION OF RISK FACTORS IN NON-INFECTIONOUS UVEITIS PATIENTS

I. Hernandez1, L. Abasolo1, B. Fernandez2, A. Madrid Garcia3, J. Font4, E. Pato3, L. Rodriguez Rodriguez5, Hospital Clínico San Carlos, Rheumatology; Madrid, Spain; 2Fundación para la Investigación Biomedica - HCSC, Rheumatology, Madrid, Spain

Background: Uveitis are characterized by inflammation of the middle layer of the eye wall. In developed countries uveitis are the second major treatable cause of blindness in those 20–65 years of age. Additionally, more than 50% of the subjects affected with these conditions will develop complications related to the uveitis, and more than 30% will suffer visual impairment. As a result, these conditions are associated with an important burden. The assessment of the patient’s quality of life (QoL) through standardized and validated questionnaires allows us to evaluate objectively the burden of the disease. Several studies have shown that the QoL of uveitis patients is reduced when compared with that of general population. Moreover, several socio-demographic and clinical related characteristics have been associated with impaired QoL. However, no longitudinal analysis of the vision-related (VR) QoL in clinical practice has been carried out.

Objectives: To describe VR-QoL in non-infectious uveitis (NIU) patients during a follow-up period of two years. Furthermore, to analyse the influence of socio-demographic, clinical and treatment factors on the progression of VR-QoL.

Methods: Longitudinal prospective study which includes patients examined in a multidisciplinary tertiary uveitis clinic, with a diagnosis of NIU. In each of these patients a yearly determination of VR-QoL was carried out following the VFQ-25 questionnaire, finally including all those who had completed at least an initial questionnaire and a second one after two years of follow-up. Analysis of risk factors at baseline in repeated VFQ-25 measurements was carried out by generalized estimating equations (GEE) models. Variables related to demographic, clinical and treatment factors with a determination of p-value <0.15 were included in multivariable models, which were then compared using the Quasi Akaike Information Criteria (qAIC). A local Ethics Committee approved the execution of this project.

Results: 128 patients were included, 117 of which also had an evaluation after the first year of follow-up. 55.5% were female with a median age of 34 years at the start of symptoms and of 37 years at the moment of attending our clinic for the first time. First evaluation of VR-QoL was determined a median (p25-p75) of 6.1 (1.8-13.1) years after that first visit. The most frequent locations of NIU were anterior (41.1%), panuveitis (27.4%), posterior (16.1%) and intermediate (15.3%). At our first evaluation, 27.3% of patients were receiving treatment with topical steroids, 22.3% oral, 49.2% immunosuppressants (both synthetic and/or biological) and 19.05% biological therapies. The median (p25-p75) VFG25 determinations at baseline, first and second years of follow-up were 0.87 (0.78-0.93), 0.88 (0.80-0.93) y 0.89 (0.81-0.94), with no significant differences (first year vs. Baseline p = 0.54; 2 years vs. Baseline p = 0.61).

In the GEE multivariable models the presence at baseline of permanent incapacity due to NIU, concomitant thyroid disease, worse visual acuity, unilateral pattern, cataracts, retinal vasculitis, epiretinal membrane and use of azathioprine were independently associated with a worse VR-QoL (Table 1).

| Variables Coef. (IC 95%) p-value |
|------------------------------|-----|
| Visual acuity 23.6 (12.3 - 34.8) <0.01 |
| Permanent incapacity -24.8 (-33.7 <0.01 |
| Unilateral NIU -15.9 (15.7 0.05 |
| Cataracts -5.2 (-10 - -0.3) 0.037 |
| Vasculitis -13.3 (-23.4 0.011 |
| Epiretinal membrane -6.8 (-12.7 -0.8) 0.026 |
| Azathioprine -75 (-147.0 -0.3) 0.041 |

Conclusion: During these two years of follow-up, no significant changes have taken place regarding VR-QoL in patients with NIU assessed at a tertiary centre. Other than visual acuity at baseline, certain ocular manifestations and clinical comorbidities have also been shown to have an independent effect on the VR-QoL of these patients.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.5889
Results: We studied 19 patients (12 women/7 men); mean age of 34.8 ± 13.9 years. The underlying diseases were idiopathic (n=7), Behcet’s disease (n=5), systemic lupus erythematosus (n=2), neuromyelitis optica (n=3), sarcoidosis (n=1) and relapsing polychondritis (n=1) (TABLE). Before biological therapy and besides systemic corticosteroids, patients had received different CIS. Biological therapy was adalimumab (n=6), rituximab (n=6), infliximab (n=5) and tocilizumab (n=4). After biological therapy, an improvement in ocular parameters was observed: BCVA [0.7±0.3 to 0.8±0.3; p= 0.03], optic nerve OCT [123.2±58.3 to 190.5±175.4; p= 0.11], and ganglionar cells OCT [369.6±137.4 to 270.7±23.2; p= 0.03] at one year (FIGURE). After a mean follow-up of 29.1 ±19.2 months, there were no severe adverse effects observed.

Conclusion: Biological therapy may be effective in patients with refractory atypical ON.

SAT0525

EFFICACY AND SAFETY OF MZR FOR IGG4-RELATED DISEASE.

S. Kawaai1, S. Fukui1, T. Nakai1, G. Kidoguchi1, H. Ozawa1, Y. Ikeda1, A. Koido1, Y. Ohara1, H. Shimizu1, H. Tamaki1, K. Yamaguchi1, M. Okada1. 1St. Luke’s International Hospital, Tokyo, Japan

Background: IgG4-Related Disease (IgG4RD) is known to cause multiple organ lesions with infiltration of IgG4-positive plasma cells, and patients often have relapses with tapering treatments despite an initial good response to glucocorticoid therapy. Mizoribine (MZR) is an immunosuppressant working as an inhibitor of purine synthesis, which mechanism of action is similar to mycophenolate mofetil. Data regarding the efficacy and safety of MZR on IgG4RD is limited although some previous case reports showed effectiveness for IgG4RD.

Objectives: This study aims to assess the efficacy and safety of MZR in patients with IgG4RD.

Methods: We retrospectively reviewed charts of IgG4RD patients who used MZR between January 2004 and December 2019 at Immuno-Rheumatology Center in St. Luke’s International Hospital, Tokyo, Japan. We investigated basic demographics, involved organs, results of blood tests including IgG and IgG4 titer, and medications used including glucocorticoid and other immunosuppressants (IS). We followed IgG4 titer, dose of glucocorticoid, flare of disease and retention of MZR at the beginning, 6 and 12months after starting MZR. We compared changes in PSL (prednisolone) doses and IgG4 titers over time using Friedman test with Bonferroni correction. We also checked adverse events during follow up.

Results: Twenty-two patients with IgG4RD who used MZR were included. Median age was 62 years old, and 15 (68.2%) patients are male. Lacrimal and salivary glands, pancreatitis and retroperitoneal fibrosis were common lesions. All patients were initially treated with glucocorticoids. Flare was observed in 5 (22.7 %) patients before initiation of MZR. The number of patients who continued MZR without flare are 19 (86.4 %) at 6 months, and 14 (73.7 %) at 12 months. IgG4 titer significantly declined at 6 and 12 months from baseline although significant consecutive decrease in PSL dose (Figure 1, 2). Liver dysfunctions are the common adverse events (n=16, 72.7%) but mild (grade1; n=15, 68.2%) and most cases are apparently due to other reasons. Serious infection (SI) occurred in 3 (13.6%) patients in total follow up, however no SI were observed during 1 year after MZR treatment.

Conclusion: MZR can be safely used in patients of IgG4RD with high retention rate, and seemed to have steroid-sparing effect. Prospective comparative studies are needed.

SAT0526

COMPARISON OF INFLAMMATORY MARKERS AS DIAGNOSTIC TOOL IN PATIENTS WITH ADULT-ONSET STILL’S DISEASE

J. W. Kim¹, J. Y. Jung¹, C. H. Suh¹, H. A. Kim¹. ¹Ajou University School of Medicine, Rheumatology, Suwon, Korea, Rep. of (South Korea)

Background: The diagnosis for adult-onset Still’s disease (AOSD) is still based on nonspecific symptoms and laboratory data, and had necessity to rule out several infectious, autoimmune or malignant diseases.

Objectives: This study aimed to elucidate the efficiency of inflammatory markers, including systemic immune-inflammation index (SII); C-reactive protein (CRP)-to-albumin ratio (CAR), albumin-to-globulin ratio (AGR), prognostic nutritional index (PNI), and ferritin-to-ESR ratio (FER) for evaluation of diagnostic or prognostic factors in AOSD.

Methods: The medical records of patients with suspected AOSD between January 1999 and June 2019 were collected and retrospectively analyzed. Among 225 patients, 61 patients received another diagnosis, such as infection and malignancy, and 164 patients were newly diagnosed to AOSD. The values of SII, CAR, AGR, PNI, and FER were compared with AOSD and non-AOSD groups. Receiver operating characteristic (ROC) curve analysis was performed to evaluate the diagnostic significance of inflammatory markers. Correlations between inflammatory markers and disease activity indices were analyzed.

Results: A total of 164 patients who diagnosed AOSD had higher values of SII, CAR, and FER as well as lower values of AGR and PNI. For AOSD diagnosis, the area under the curve (AUC) obtained from the ROC curve were 0.859 (95% CI=0.806-0.911) for SII, 0.769 (95% CI=0.702-0.837) for CAR, 0.749 (95% CI=0.615-0.872) for AGR, 0.699 (95% CI=0.675-0.823) for PNI, and 0.764 (95% CI=0.693-0.834) for FER with cut-off value of 2195.7, 1.80, 1.38, 48.8 and 17.0, respectively. The SII had the largest AUC, and FER and SII each had the highest sensitivity (70.9%) and specificity (91.5%). In correlation analysis, there were no strong correlations between inflammatory markers and disease activity indices except CAR and CRP.

Disclosure of Interests: None declared

Conclusion: Our results suggest that the coexistence of MEFV exon 2 or exon 3 variants and a MEFV exon 10 mutation has combined effects on inflammasome activation in the Japanese population.

SAT0528

CLINICAL PHENOTYPES OF IgG4-RELATED DISEASE REFLECT DIFFERENCES IN EPIDEMIOLOGICAL FEATURES, SEROLOGICAL FINDINGS, AND PROGNOSTIC OUTCOMES

M. Lanzillotta1, E. Delia Torre1, C. Campochiaro1, G. Mancuso1, L. Dagna1.
1San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy

Background: Four clinical phenotypes of IgG4-Related Disease (IgG4-RD) have been recently identified by Latent Class Analysis (LCA) - Pancreato/biliary (Group 1); Retropertitoneum/Aortitis (Group 2); Head-and-neck limited (Group 3); Muckle/Zeytlinic/Systemic (Group 4) - but the relevance of this classification for patient management remains unknown (1,2).

Objectives: We aimed to assess whether clinical judgment can replicate LCA classification and to evaluate potential differences in epidemiological features, serological findings, and disease outcomes between disease phenotypes.

Methods: The study included 179 patients. Four IgG4-RD experts were asked to classify a validation cohort of 40 patients according to published LCA-derived phenotypes based on clinical judgment. Agreement between LCA and clinical clustering was calculated. To assess differences among disease phenotypes, the following variables were recorded on additional 139 patients: serum IgG4 and IgE; inflammatory markers; eosinophils; plasmablasts; IgG4-RD Responder Index (RI); history of atopy, diabetes, osteoporosis, relapses, and tumors; cumulative dose of glucocorticoids and use of rituximab.

Results: Clinical judgment recapitulated LCA classification with strong agreement between IgG4-RD experts (κ= 0.841, p < 0.0005). Group 1 showed the highest levels of serum IgG4 and IgE; inflammatory markers; eosinophils; plasmablasts; IgG4-RD Responder Index (RI); history of atopy, diabetes, osteoporosis, relapses, and tumors; cumulative dose of glucocorticoids and use of rituximab.

SAT0529

CLINICAL CHARACTERISTICS AND TREATMENT PATTERNS IN A PATIENT GROUP WITH INTERSTITIAL LUNG DISEASE.

R. Ortega Castro1, P. S. Laura1, F. U. Pilar2, J. Calvo Gutierrez2, A. Requejo-Jimenez2, S. Espejo-Pérez2, T. Gonzalez-Serrano3, M. D. Castro Villegas3, G. O. Ignacio4, A. Escudero Contreras4, E. Collantes Estevez4, M. A. Aguirre4, 1Rheumatology Service, Reina Sofia Hospital/IMIBIC/ University of Cordoba, Cordoba, Spain, 2Cordoba, Spain; 3Pneumology Service, Reina Sofia Hospital, Cordoba, Spain, Cordoba, Spain; 4Radiology Service, Reina Sofia Hospital, Cordoba, Spain, Cordoba, Spain; 5Pathological Anatomy Service, Reina Sofia Hospital, Cordoba, Spain, Cordoba, Spain

Background: Diffuse interstitial lung disease (ILD) is frequently associated with connective tissue diseases (CTD) and is one of the main causes of morbidity and mortality in these patients. Recently, the concept of Interstitial Pneumonia with Autoimmune Features (IPA/F) has been defined to characterize ILD associated with systemic manifestations limited to subtle serological and clinical autoimmune abnormalities and not fulfilling the international criteria for the diagnosis of a given CTD.

Objectives: The objective of this study is to describe the clinical, serological and radiological characteristics, as well as the treatment patterns of patients with ILD referred to a Rheumatology Service for suspected CTD.

Methods: Observational, cross-sectional study of 43 patients with ILD referred for evaluation to the medical consultation of CTD of the Rheumatology service at the Reina Sofia Hospital. Patients were classified as patients defined CTD, patient with IPA/F and patients with other types of pneumonia. We conducted a descriptive study of all patients and compared the clinical-analytical-radiological characteristics and treatment patterns of the first two groups.

Results: Of the 43 patients, 67.40% were women with a mean age at diagnosis of 65.65 (10.42) years and 53.50% of smoking patients. Of the total of patients, 16 (37.2%) were included in the CTD group, 17 (39.5%) met criteria for IPA/F and 10 (23.3%) had another type of pneumopathy. In the CTD group, the most frequent type (6/16), followed by inflammatory myopathy (4/16), Sjögren's syndrome (3/16), rheumatoid arthritis (2/16) and polyarthritis rheumatic (1/16). In this group of patients, the most common symptom was Raynaud's phenomenon (RP) (7/16), followed by arthritis (7/16) and mechanic's hands (3/16). Regarding the most frequently antibodies were ANA (100%), anti-Ro (41.7%), anti-citrullinated protein antibodies (30%) and rheumatoid factor (RF) (28.6%).

In patients with IPA/F, as in the CTD group, the most observed clinical criterion was RP (5/17), followed by arthritis (1/17) and mechanic's hands (1/17). Among the serological criteria the most common antibodies were ANA (100%), followed by anti-Ro (33.3%), anti-RNA synthetase (28.6%) and RF (22.2%).

SAT0530

DESCRIPTION AND OUTCOMES OF A SERIES OF 21 PATIENTS WITH INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES IN A MULTIDISCIPLINARY UNIT.

M. D. C. López González1, E. Noñuentes1, S. Ruiz Alcaraz1, I. Gayá Garcia-Manso1, R. García Sevila1, P. Vela-Casasempere1, M. Andrés1, 1Hospital General Universitario De Alicante, Alicante, Spain

Background: A significant proportion of patients with idiopathic interstitial pneumonia shows autoimmune features, but do not meet the criteria to be classified as a systemic autoimmune disease. In 2015, a joint working group of the European Respiratory Society (ERS) and the American Thoracic Society (ATS) proposed classification criteria for the category called interstitial pneumonia with autoimmune features (IPA/F).

Objectives: To evaluate the clinical, serological and morphological characteristics of a series of 21 patients with IPA/F as well as the treatment that was applied and the evolution they presented.

Methods: A retrospective cohort study was conducted. The patients who met ERS/ATS IPA/F classification criteria in the period from 2012 to 2019 were collected from our interstitial lung disease (ILD) database, including 546 patients. All cases were systematically assessed in a multidisciplinary committee. Clinical, serological, morphological, as well as treatment and outcome variables were collected. A Descriptive analysis is shown.

Results: 21 patients were included in the study, 12 of them (57.1%) women. The mean age at diagnosis was 61.6 years (SD 14.0), and the median follow-up time was 2.9 years (IQR 4.9). All showed ILD by HRCT, 10 (47.6%) patients had autoimmune features at the moment of the diagnosis, and 20 (95.2%) were positive for some auto-antibody. 12 (57.1%) fulfilled two of the three domains, and 9 (42.9%) fulfilled the three IPA/F domains. Characteristics are described in Table 1. Lung biopsy was performed in 9 cases (42.9%). The mean FVC at diagnosis was 70.4% (DS 21.0) and DLCO 46.7% (DS 21.5). Regarding the treatment during the disease, mofetil mycophenolate (MMF) was used in 8 (38.1%) patients, cyclophosphamide (CYC) in 3 (14.3%), rituximab (RTX) in 2 (9.5%) and azathioprine in 2 (9.5%). In 1 case (4.8%), CYC and RTX were used in combination. Oral glucocorticoids (GCC) were prescribed in 14 patients (66.7%), and azathioprine in 2 (9.5%). In 1 case (4.8%), CYC and RTX were used in combination. Oral glucocorticoids (GCC) were prescribed in 14 patients (66.7%), and azathioprine in 2 (9.5%). In 1 case (4.8%), CYC and RTX were used in combination. Oral glucocorticoids (GCC) were prescribed in 14 patients (66.7%), and azathioprine in 2 (9.5%). In 1 case (4.8%), CYC and RTX were used in combination. Oral glucocorticoids (GCC) were prescribed in 14 patients (66.7%), and azathioprine in 2 (9.5%). In 1 case (4.8%), CYC and RTX were used in combination. Oral glucocorticoids (GCC) were prescribed in 14 patients (66.7%), and azathioprine in 2 (9.5%).
### SAT0531 NEXT GENERATION SEQUENCING AND AUTOINFLAMMATORY SYNDROMES: CLINICAL AND GENETICAL CORRELATION ON AN ADULT POPULATION FROM A REFERRAL THIRD-CARE CENTRE

J. R. Marques Soares1, M. Antolin Mate2, E. Garcia Arumí1, E. Tizzano Ferrara1, S. Bujan Rivas1, Hospital Vall D’Hebron, Internal Medicine, Barcelona, Spain; 2Barcelona, Genetics, Barcelona, Spain; 3Barcelona, Internal Medicine, Barcelona, Spain

#### Background:
Systemic autoinflammatory diseases (sAID) are a group of conditions with recurrent episodes of inflammation in absence of infection or autoimmune response. Its physiopathology mainly lies on mono/poligenic mutations involving genes related to the innate immune system response. Next Generation Sequencing (NGS) platforms have been a big step forward on sAID diagnosis, involving genes related to the innate immune response. Its physiopathology mainly lies on mono/poligenic mutations involving genes related to the innate immune system response. Next Generation Sequencing (NGS) platforms have been a big step forward on sAID diagnosis, involving genes related to the innate immune system response.

#### Methods:
A retrospective review of a cohort of adult patients with available NGS sAID related gene panel (MiSeq Illumina sequencing platform including intron and exon variants from up to 17 sAID genes, with coverage depth $\geq x100$) among 2014 and 2019 was performed. The most frequent variants involved MEFV (54/122), NOD2/CARD15 (18/122) and TNFRSF1A (17/122 including 12 p.Arg121Gln variants) genes. 37/122 (30%) variants correlated with the clinical picture in 33 patients, allowing to confirm the suspected diagnosis. Among the 122 variants, 7 not previously communicated variants were identified. No somatic variants were found.

#### Conclusion:
NGS sAID related gene panel is a useful tool for sAID diagnosis. In this cohort of 170 adult patients from a referral third-level hospital, genetic tests identified sAID related variants in almost half of them.

#### A description of the cohort and an analysis of the correlation assessment between clinical data and genetic findings were performed.

#### Results:
246 out of 299 (82%) patients with NGS sAID gene panel had clinical data available. 170/246 (69%) were adult patients. The medium age was 49 yo, and the M/F ratio was 2.46. 87/170 (51%) adult patients presented 122 variants involving sAID genes (60/87 patients with a single variant). All the variants out of 7 seven were heterozygous variants.

Variants were classified according to ACMG/AMP as follows: pathogenic/probably pathogenic: 22/122 (18%), unknown significance: 74/122 (60.6%), benign/probably benign: 6/122 (4.91%), 20/122 (16.4%) were unclassified variants or polymorphisms.

The most frequent variants identified involved MEFV (54/122), NOD2/CARD15 (18/122) and TNFRSF1A (17/122 including 12 p.Arg121Gln variants) genes. The most frequent variants identified involved MEFV (54/122), NOD2/CARD15 (18/122) and TNFRSF1A (17/122 including 12 p.Arg121Gln variants) genes.
SAT0532

POSITIVE DISEASE-SPECIFIC AUTOANTIBODIES LOWER DIAGNOSTIC SENSITIVITY BUT HAVE LITTLE CLINICAL SIGNIFICANCE IN DIAGNOSING IG4-RD RELATED DISEASE USING THE 2019 ACR/EULAR CLASSIFICATION CRITERIA IN DAILY CLINICAL PRACTICE

I. Mizushima1, T. Yamano1, H. Kawahara2, S. Hibino1, R. Nishihuka1, T. Zoshima1, S. Hara1, K. Ito1, H. Fuji1, M. Kawano1,1 Kanazawa University Hospital, Rheumatology, Kanazawa, Japan

Background: Recently, the 2019 ACR/EULAR classification criteria for IgG4-related disease (IgG4-RD) were published mainly to identify more homogeneous subjects for inclusion in clinical trials and observational studies [1]. However, although their high specificity is presumed to be useful to differentiate IgG4-RD from various mimickers, their value in daily clinical practice needs to be evaluated.

Objectives: This study aimed to clarify the usefulness of the 2019 ACR/EULAR classification criteria for IgG4-RD and characteristics of false-negative patients in daily clinical practice.

Methods: We retrospectively reviewed the medical records of 162 patients with IgG4-RD and 130 consecutive non-IgG4-RD patients (mimickers) diagnosed by experts whose serum IgG4 levels were measured at a single center in Japan. Using the collected data, we calculated sensitivity, specificity, and fulfillment rates for the entry criteria, exclusion criteria, and threshold of inclusion criteria points. In addition, to clarify the characteristics of false-negative cases in IgG4-RD, we performed an intergroup comparison of their clinical features including disease-specific autoantibodies.

Results: Both the patients with IgG4-RD and mimickers were relatively old (66 and 65 years) with male predominance (67% and 60%). The final diagnoses of mimickers mainly consisted of cancer, lymphoma, vasculitis, sarcoidosis, multicentric Castleman's disease, and atherosclerotic or infectious aortic aneurysm. The classification criteria had a sensitivity of 72.8% and a specificity of 100%. Of the 44 false-negative cases, one did not fulfill the entry criteria, 20 fulfilled one exclusion criterion, and 27 did not achieve sufficient inclusion criteria points. Compared with the true-positive cases, the false-negative cases had significantly fewer affected organs, lower serum IgG4 levels, higher serum CH50 levels, and lower prevalence of salivary/glandular gland and renal parenchymal lesions. They were also less likely to have had biopsies (61% vs 97%). Of note, positivity of disease-specific autoantibodies including SAA/Ro antibody, ANCA, ds-DNA antibody, and ACPR was the most common exclusion criterion fulfilled in 18 patients, only 2 of whom were diagnosed with a specific autoimmune disease (rheumatoid arthritis) complicated by IgG4-RD. The remaining 16 patients had no specific clinical symptoms related to such autoantibodies. In addition, compared with IgG4-RD patients without disease-specific autoantibodies, the 18 patients with them had almost equal serum IgG4 and complement levels, number of affected organs, and histopathology and immunostaining scores despite higher serum IgG and CRP levels. Conclusion: The present study suggests that the 2019 ACR/EULAR classification criteria for IgG4-RD has excellent diagnostic specificity and moderate sensitivity in daily clinical practice. Positive disease-specific autoantibodies alone, which lowered the sensitivity in this study, may have little clinical significance concerning the diagnosis of IgG4-RD.

SAT0533

ADULT ONSET STILLS DISEASE AND IDIOPATHIC RECURRENT PERICARDITIS: ARE THE MORE SIMILARITIES OR DIFFERENCES?

V. Myachikov1, O. Moiseeva1, E. Ku, Vardin1, S. Lapin2, O. Tkachenko2, V. Nazarov2, A. Masyansky1. 1 Federal State Budgetary Institution “Almatov National Medical Research Centre” of the Ministry of Health of the Russian Federation, Sankt-Peterburg, Russian Federation; 2 Pavlov First State Medical University of St. Petersburg, Sankt-Peterburg, Russian Federation

Background: Adult onset Still’s disease (AOSD) and Idiopathic recurrent pericarditis (IRP) are currently considered auto-inflammatory diseases. Common features of these disorders are symptoms such as fever, leukocytosis, serositis, increased acute phase reactants.

Diagnosis of IRP is based on ESC 2015 diagnostic criteria, while AOSD is defined according to 3 sets of classification criteria. A detailed study shows that modern criteria for these nosologies overlap and do not allow distinguishing one from the other.

Objectives: We have not found any data on the comparison of the two groups in the literature. We compared the two groups of patients according to several parameters, such as clinical features, laboratory testing, genetic analysis to identify common patterns.

Methods: We enrolled 22 newly identified subjects (13 patients with AOSD, 9 patients with IRP) to our prospective, monocenter study. The mean age of patients with AOSD was 31 [22; 39], the mean age of patients with IRP was 48 [35; 54]. Blood sampling in all patients was performed in the flare.

We quantified the serum levels of ferritin and its glycosylated fraction in both groups. Mutations of the MEFV, TNFRSF1A genes were studied. As more sensitive imaging methods for lymphadenopathy and serositis, we performed the following instrumental studies for all patients: thoracic echocardiography, ultrasound of the abdominal cavity and pelvis, chest high-resolution computed tomography.

Results: One subject with a heterozygous missense variant was found in exon 2 of the MEFV gene (E148Q) in the IRP group. The patient was excluded from our study. Elevated white blood cell (WBC) count and C-reactive protein (CRP) were observed in all patients in 2 groups, however, the level of WBC greater than 10,000/mm3 was found only in 10 patients from the AOSD group and 5 from the IRP. Elevated ferritin level in both groups was detected. The number of subjects with high level of ferritin in the AOSD group reached 12 (n=13), in the IRP group – 7 (n=8). The ferritin level appeared to be more significant in the AOSD group compared to the IRP group (1521 ng/ml vs 408 ng/ml p=0.0159) Figure 1. In turn, lower glycosylated ferritin was recorded in 9 patients with AOSD (n=13), and 7 – with IRP (n=8). We have demonstrated a more significant decrease of glycosylated ferritin level in patients with AOSD in comparison to patients with IRP, which amounted (11% vs 37% p = 0.0286) reference value (38.6%-84.7%). Figure 1. Abnormal liver function tests were found in the majority of patients with AOSD and IRP (81% vs 75%). We have also shown that, if the patient had pericardial effusion, the fluid was present in the pleural cavity, regardless of the group.

The number of AOSD patients with polyserositis was 5 (n=13). Other symptoms are presented in Table 1

Conclusion:
1. The level of ferritin in the IRP group was lower, which can be explained by a less generalized process, the absence of such symptoms as arthritis, rash, splenomegaly.
2. Diagnostic and classification criteria of both disorders do not allow distinguishing between the diseases.
3. There might be no differences between the diseases; further research (on more representative groups) is needed. We consider the comparison of the gene-expression analysis in these patients to be of great importance.

SAT0534

RITUXIMAB FOR REFRACTORY IDIOPATHIC RETROPERITONEAL FIBROSIS: A SINGLE TERTIARY CENTER EXPERIENCE

M. Oztas1, E. Cerme1, S. Ugurlu1. 1Istanbul University-Cerrahpasas, Department of Medicine, Division of Rheumatology, Istanbul, Turkey

Background: Idiopathic retroperitoneal fibrosis (RPF) is a progressive disorder of the retroperitoneum which is often idiopathic. Although prednisolone is the mainstay approach to treating RPF, the remission rates range between 75% to 95% (1-2).

Objectives: Here, we report the outcomes and steroid-sparing effect of Rituximab (Rtx) therapy in 14 patients with RPF.

Methods: This retrospective study was conducted at a tertiary rheumatology center. Patients were diagnosed with RPF and had at least a course of 0.5-1mg/kg prednisolone treatment previously. These patients were switched to Rtx due to inadequate response or side effects while on prednisone, tamofoxen, azathioprine or cyclophosphamide therapy. Patients were treated with Rtx in order to be included in this study. Involvement and activation of RPF was shown via PET-CT either before or at least 6 months after the therapy. Daily prednisolone dose was noted before rituximab initiation and 6 months after the therapy. All of the patients reported, except two, were followed for at least 6 months after the Rtx treatment. The final disease status of the three patients were not included in the study.

Results: Fourteen patients (7F) received at least 2 cycles (1 gr for each) of Rtx. The age of diagnosis was 54 ± 10.0 years, follow-up duration was 46.6 ± 32.0 months. The previous treatments, number of the cycles of Rtx and final disease status were shown in the Table. The Control PET-CT revealed metabolic and radiologic remission in 3 patients. In 6 patients, the disease remained stable. In 2 patients there was disease progression hence they were treated with the second course of Rtx. One of the two patients had the progression two years after the first cycle but then, was lost shown in the Table. The Control PET-CT revealed metabolic and radiologic remission in 3 patients. The previous treatments, number of the cycles of Rtx and final disease status were shown in the Table. The Control PET-CT revealed metabolic and radiologic remission in 3 patients. In 6 patients, the disease remained stable. In 2 patients there was disease progression hence they were treated with the second course of Rtx. One of the two patients had the progression two years after the first cycle but then, was lost.

Conclusion: The present study shows that Rtx could be a therapeutic option after glucocorticoid or DMARD failure. The steroid sparing effect of Rtx is essential and future prospective studies are needed to assess the Rtx efficacy more objectively in RPF treatment.

SAT0535

CLINICAL COURSE IN PATIENTS WITH INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES (IPAF) IN A MULTIDISCIPLINARY CONSULTATION.

I. Perez1, C. Vadillo1, M. A. Nieto2, D. Freites1,3, Z. Rosales1, A. Muicentes1, L. Leon1, J. Font1, A. J. Jover1, L. Abasolo1,2. 1Hospital Clinico San Carlos, Rheumatology, Madrid, Spain; 2Hospital Clinico San Carlos, Pneumology, Madrid, Spain; 3Fundacion para la Investigacion Biomedica - HCSC, Rheumatology, Madrid, Spain

Background: A proportion of patients with Interstitial Lung Disease (ILD) show autoimmune characteristics but do not completely meet the classification criteria for a definitive connective tissue disease. In order to unify the nomenclature and criteria to define this condition, the classification of patients with Interstitial Pneumonia with Autoimmune Features (IPAF) has recently been adopted (Fisher, et al).

Objectives: To describe the sociodemographic, clinical, functional characteristics and therapeutic management of IPAF patients in clinical practice and to evaluate the incidence rate of functional respiratory impairment over time.

Methods: A longitudinal observational study was performed. Patients with IPAF classification criteria (Fisher et al) were included from the time of ILD diagnosis (Feb 2017 to Sept 2018) and followed until loss of follow-up or end of the study (Oct 2019), in a multidisciplinary team, carried by a pneumologist and a rheumatologist in a Tertiary Hospital in Madrid. Main outcome: relative functional respiratory impairment: defined as decline in percent predicted forced vital capacity (FVC%) of ≥5% compared to the previous visit. Respiratory function was measured at baseline and every 6 months. Covariates: a) sociodemographic, b) clinical, c) radiological pattern (non-specific interstitial pneumonia [NSIP]; usual interstitial pneumonia [UIP], others); d) FVC%, DLCO%; e) laboratory tests; f) therapy used (glucocorticoids, disease modifying antirheumatic drugs [DMARDs] and Biologic Agents). Statistical analysis: description of the sociodemographic, clinical, radiological, functional and treatment characteristics of the patients. Survival techniques were used to estimate the incidence rate (IR) of relative functional respiratory impairment, expressed per 100 patient-year with their respective confidence interval [95 % CI].

Results: 17 patients were included with a mean follow-up of 3 ± 15 years, 70.6% were women with a mean age of 65±10 years. The most frequent IPAF classification criteria were: a) clinical: arthritis (50%), Raynaud’s phenomenon (33%) and mechanical hands (17%); b) serological: 65% had ANA ≥1/360; 31% FR> 40; 30% Anti-Ro positive; c) morphologic: 59% presented NSIP pattern and 29.4% was UIP The baseline median FVC% and DLCO% were 89 [83-107.7] and 63 [50-79.8] respectively. During the study period, 94% received treatment: 87.5% glucocorticosteroids, 68.5% mycophenolate, 56% azathioprine, 19.7% cyclophosphamide iv and 33% antibiotics. During the follow-up (104.6 patient - semester), 15 patients presented relative functional respiratory impairment, with an IR of 23.8 [16.1-35.3]. After 14 months from IPAF diagnosis 50% of the patients had relative functional respiratory impairment. At the end of the follow-up, 50% showed a worsening of the DLCO%.

Conclusion: IPAF patients are mostly women in their sixties. The most frequent clinical criteria are arthritis and Raynaud’s phenomenon and the serological were FR and ANAs. The most frequent radiological pattern was NSIP. The therapeutic management is mainly with glucocorticosteroids, mycophenolate and azathioprine. At the beginning, patients have a slightly diminished lung function. These patients have significant functional impairment over time that will impact in their prognosis. Longitudinal and multicenter studies are necessary to advance in the knowledge and management of these patients.

IMMUNE CHECKPOINT INHIBITOR THERAPY IN PATIENTS WITH PREEXISTING SARCOIDOSIS

X. Pundole1, O. Lambotte2, M. Ramos-Casais3, M. Suarez-Almanzar1. 1The University of Texas MD Anderson Cancer Center; Houston, United States of

References:

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.4607
Background: Immune checkpoint inhibitors (ICI) have changed the therapeutic landscape of many cancer types, but are also associated with development of immune-related adverse events, including de novo sarcoid like reactions. However, little is known about the use of ICI therapy in patients with preexisting sarcoidosis as patients with preexisting autoimmune diseases have been systematically excluded from clinical trials of ICI therapy due to concerns of heighten toxicities. Emerging research suggests that ICI therapy can be considered in some patients with autoimmune diseases.¹

Objectives: To determine the risk of sarcoidosis exacerbation or flare in patients with preexisting sarcoidosis receiving ICI therapy.

Methods: We conducted a retrospective cohort study of patients seen at The University of Texas MD Anderson Cancer Center between 2016-2019. Patients were included in the cohort if they received one of 7 ICI therapies (pembrolizumab, nivolumab, ipilimumab, atezolizumab, bevacizumab, or alemtuzumab) and had an International Classification of Disease version 10 code of sarcoidosis (D86.7), prior to the ICI initiation, with diagnosis confirmed in medical record by treating physicians. A sarcoidosis diagnosis was considered “possible” if the medical record documented a history of sarcoidosis, “probable” if a history of biopsy proven sarcoidosis was mentioned, and “definitive” if histological evidence was available. Frequent of flares and outcomes of patients after receiving ICI were collected.

Results: During the study timeframe a total of 32 patients with preexisting sarcoidosis received ICI therapy. Nine patients (28%) had a definitive diagnosis of sarcoidosis, 12 (37%) had a probable diagnosis and 11 (35%) had a possible diagnosis of sarcoidosis. The mean time between diagnosis of sarcoidosis and initiation of ICI therapy was 13 years (range: <1 to 51 years). Twenty-seven patients (84%) received monotherapy and five patients (16%) received combination or sequential ICI therapy. Of the 32 patients, one patient with a 20-year remote history of sarcoidosis, never treated, developed a clinically symptomatic exacerbation of sarcoidosis one month after the initial dose of atezolizumab, with increased hilar nodules on imaging, skin nodules, arthritis and uveitis. Biopsy of a lymph node showed non-necrotizing granulomas, and biopsy of the skin panniculitis. The patient also developed colitis thought to be an immune-related adverse event. Atezolizumab was discontinued after 3 doses. Patient was treated with prednisone and azathioprine.

Conclusion: Patients with a remote history of stable sarcoidosis at the time of ICI therapy infrequently develop a flare of their sarcoidosis. The risk of flares in patients with active sarcoidosis requiring immunosuppression at the time of ICI initiation is unknown.

Muckle-Wells syndrome (MWS) is a monogenic autoinflammatory disease caused by a NLRP3 gene mutation. It is the most common variant of cryopyrin-associated periodic syndromes (CAPS) and can be observed in rheumatology practice. It manifests itself in fever, urticaria-like rash, arthralgias/arthritides, conjunctivitis/uveitis, sensorineural hearing loss, acute-phase inflammatory disease caused by a NLRP3 gene mutation. It is the most common variant of metabolic diseases, Moscow, Russian Federation.

Methods: A total of 26 family members aged between 2.5 and 62 years were identified (in total 26 family members aged between 2.5 and 62 years) with a number of second line DMARD therapy needs to be studied further particularly in HLA B35 +ve uveitis.

SAT0540

ONE-YEAR OUTCOMES AFTER RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS FROM CHECKPOINT INHIBITORS

E. Berard1, T. Barnetche1, L. Rouxel1, C. Dutriaux1, L. Dousset2, S. Frey3, M. Beylot-Barry1, J. Seneschal1, R. Veillon1, C. Vergnenegre1, A. Daste4, C. Domblices5, B. Sionneau4, M. Gross-Goupil1, A. Ravaud4, E. Forcade4, T. Schieweberiel, M. Kostine7, 1Bordeaux University Hospital, Rheumatology, Bordeaux, France; 2Bordeaux University Hospital, Dermatology, Bordeaux, France; 3Bordeaux University Hospital, Pulmonology, Bordeaux, France; 4Bordeaux University Hospital, Hematology, Bordeaux, France; 5Bordeaux University Hospital, Oncology, Bordeaux, France; 6Bordeaux University Hospital, Hematology, Bordeaux, France

Disclosure of Interests: Description and initial management of rheumatic immune-related adverse events (irAEs) from cancer immunotherapies have been reported by several groups but to date, few studies have evaluated the long-term outcomes and management of rheumatic irAEs (1).

Objectives: To describe the long-term management and assess the one-year outcomes of patients who experienced rheumatic immune-related adverse events (irAEs) due to immune checkpoint inhibitors (ICI).

Methods: This was a single-centre prospective observational study including patients referred for musculoskeletal symptoms while treated with ICI. After baseline rheumatological evaluation defining the clinical entity presented, follow-up visits were organised according to the type and severity of irAE. At one year, persistence of irAE, ongoing treatment, as well as cancer outcomes were assessed.

Results: 63 patients were included between September 2015 and June 2018. 24 patients (38%) were still receiving glucocorticoids at one year, with a median dosage of 15mg/day (range: 5-60mg/day). None of the patients had to permanently discontinue ICI therapy for rheumatic irAE. 20 patients (67%) were still receiving glucocorticoids at one year, with a median dosage of 5mg/ day (range: 2-20mg/day). Glucocorticoids were more frequently discontinued in patients with RA-like condition (44%) than PMR-like condition (23%), but no other predictive factor of glucocorticoids withdrawal could be identified. At one year, overall survival and progression-free survival were comparable between patients who were still receiving glucocorticoids for rheumatic irAE and patients who had discontinued. Eight patients required csDMARDs.

Conclusion: At one year, a majority of patients required long-term low-dose glucocorticoids for chronic rheumatologic irAE, which seems not altering oncological control.

SAT0541

THE SEVEREITY OF FMF MAY BE ASSOCIATED WITH CO-MORBIDITIES

M. E. Tezcan1, N. Sen1, M. Yılmaz2, O. Volkan1, E. Tükel1, S. Yılmaz-Oner1

1Kartal Dr. Lutfi Kirdar Training and Research Hospital, Rheumatology, Istanbul, Turkey; 2Kartal Dr. Lutfi Kirdar Training and Research Hospital, Internal Medicine, Istanbul, Turkey

Background: Familial Mediterranean fever (FMF) is an auto inflammatory disease with recurrent attacks of serositis. Frequent attacks and disease related sequels may be associated with co-morbidities in FMF patients.

Objectives: One of the tools for evaluating the FMF severity is the international severity scoring system for FMF (ISSF) 1. This score includes disease related sequels, acute phase measurements, attack features and exertional leg pain.
Therefore, more severe disease may be link with subclinical inflammation, amyloidosis and frequent, prolonged and widespread attacks. All these components may augment the frequency of non-disease related co-morbidities.

**Methods:** We enrolled 158 FMF patients who fulfilled modified Tel-Hashomer Diagnosis Criteria. The patients dichotomized based upon disease severity (mild disease or severe disease). Patients with ISSF scores lower or equal to 2 were accepted to have mild disease. Then, we compared frequency of non-disease related co-morbidities between the groups. These co-morbidities are hypertension, hypercholesterolemia, hypertriglyceridemia cardiovascular diseases, coronary artery diseases, cerebrovascular diseases, chronic renal disease (non-FMD related), chronic obstructive pulmonary diseases, and diabetes mellitus. This study was approved by the Local Research Ethics Committee and carried out in compliance with the Helsinki Declaration. All the patients gave written informed consent. P-value lower than 0.05 was considered as statistically significant.

**Results:** Demographic features, disease duration, smoking history and body mass index (BMI) were similar between the groups. Frequency of co-morbidity in severe disease group was statistically higher than mild disease group (p=0.02). Most frequent co-morbidity was hypertension in both groups.

**Table. Features of mild and severe FMF groups**

<td>0.02</td>
</tr>
</tbody>
</table>

**Conclusion:** In our FMF patient cohort, we found that severity of the disease may be associated with higher frequency of co-morbidities. Therefore, clinicians should be aware of the high possibility of co-morbidities in patients with more severe FMF and addressed these co-morbidities timely and properly.

**UTILITY OF QUANTITATIVE ANALYSIS OF 18FDG-PET/CT IN IGG4-RELATED DISEASE**

S. Tsuchiya1, N. Iwamoto1, H. Yoshihori2, K. Fujikawa3, K. Takashi4, A. Kawakami1.
1Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; 2National Hospital Organization Nagasaki Medical Center, Department of Rheumatology, Omura, Japan; 3Japan Community Healthcare Organization, Isahaya General Hospital, Department of Rheumatology, Isahaya, Japan; 4Atomic Bomb Disease Institute, Department of Radiosotope Medicine, Nagasaki, Japan

**Background:** In IgG4-related diseases (IgG4-RD), usefulness of 18F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) imaging for detecting the organ involvement of IgG4-RD have been shown and, 18FDG PET/CT was more accurate and appeared to be more sensitive as compared to other imaging technics1,2. However, until now, the studies regarding about quantitative analysis of PET/CT imaging in IgG4-RD were few. To avoid unnecessary biopsy and select suitable lesion for biopsy on multi-organ involvement disease such as IgG4-RD, the information which lesion is suspected as disease-involvement lesion in a non-invasive test is important.

**Objectives:** The purpose of this work is to evaluate the usefulness of 18FDG-PET/CT imaging in management of IgG4-RD using quantitative analysis of PET/CT imaging.

**Methods:** We retrospectively investigated the association between histological findings in which biopsy was performed for diagnosis of IgG4-RD and findings of PET/CT. 18FDG uptake was assessed in site of major organ involvement of IgG4-RD which could be differentiated from the normal uptake of background tissue with 18FDG-PET/CT. For quantitative analysis, we measured the highest standardized uptake value (SUV) of the pixels within the region of interest (ROI) (SUVmax) and the average SUV within ROI (SUVmean). We also measured SUVmean of liver as reference tissue. Then, we calculated ratio between SUVmean of ROI and SUVmean of liver.

**Results:** The age at diagnosis was 64.5 ± 11.9 years, serum IgG4 was 743.8 ± 584.1 mg/dl, and biopsy was performed at 24 sites (Submandibular gland 10, prostate gland 4, pancreas 2, thyroid gland 1, lung 1, retroperitoneum 1, kidney 1). Histological findings were consistent with IgG4-RD (positive) at 19 sites. Although SUVmax at the biopsy site was not correlated with the biopsy results, SUVmean of liver SUVmax were also higher in the biopsy-positive group (2.17 vs 1.52, respectively P<0.05). To establish cut-off value of SUVmean to consider biopsy, a receiver operating characteristics (ROC) curve was constructed. ROC curve analysis indicated SUVmax=4.074 as cut-off value which discriminate IgG4-RD related lesion.

**Conclusion:** Our present study suggested that quantitative analysis of 18FDG-PET/CT imaging is useful for selecting the biopsy site in IgG4-related disease.

**PREVALENCE OF FABRY’S DISEASE IN MILD AND SEVERE FMF PATIENTS**

S. Uslu1, G. Kabadayi2, P. Teke Kisa3, T. Yüce Inel4, Z. Arsan5, N. Arsan5, S. Akar6, F. Onen5, T. Sarlı5, Ömer Halisdemir University Bor Physical Medicine and Rehabilitation, Training and Research Hospital, Department of Rheumatology, Niğde, Turkey; 4Kartip Celebi University Faculty of Medicine, Department of Rheumatology, İzmir, Turkey; 5Dokuz Eylül University Faculty of Medicine, Department of Pediatric Metabolism and Nutrition, İzmir, Turkey; 6Dokuz Eylül University Faculty of Medicine, Department of Rheumatology, İzmir, Turkey

**Background:** Fabry disease (FD) is a rare metabolic disorder caused by the mutations in the α-galactosidase A (GLA) gene. FD patients present with heterogeneous clinical manifestations, which may overlap with systemic diseases including familial Mediterranean fever (FMF). Recurrent episodes of fever,
abdominal pain, and arthralgias can be observed in both disorders and this may lead to misdiagnoses.

Objectives: To investigate FD prevalence in mild and severe FMF patients.

Methods: A total of 66 FMF patients, according to the Tel-Hashomer criteria, were included in the study. Patients were grouped into mild (Group 1) and severe (Group 2) subsets according to the severity score. a-GlA enzyme activity and mutations in the GLA gene were performed. Demographic features, clinical findings, MEFV mutations and treatments were recorded.

Results: The clinical and demographical characteristics of the patients were given in Table 1. In severe form, 27 patients were using biological drug and 40.7% had amyloidosis. Symptoms related to FD including hypohidrosis, acroparesthesias, and painful neuropathies, were not different between the groups. Only one patient in group 1 had a low GLA enzyme activity (0.1 nmol/h/ml; Normal >2.5) which also had mutations in the GLA gene but MEFV mutation test was negative. (Table 2). This patient was a 39-year-old female with recurrent abdominal pain, distal extremity pain and the presence of fever during the attacks. She was heterozygous for R301Q. In detailed history, she reported mild acroparesthesias, hypohidrosis, and tinnitus.

Table 1. Demographic and clinical findings

Conclusion: This study was shown the following: 1) the FD rate in the total FMF patients was 1.5% (3.1% in group 1). 2) More than 14% of patients in the severe FMF subset had abnormal enzyme activity or mutations related with FD, 3) Symptoms related with FD such as hearing loss, hypohidrosis, acroparesthesias, and painful neuropathies were noted in FMF patients particularly in mild group. Based on our results, FD should be considered in the differential diagnosis of FMF particularly in patients with atypical symptoms.

USE OF BIOLOGICAL DMARDS IN PATIENTS WITH ADULT-ONSET STILL'S DISEASE: RESULTS FROM TURKBIKO REGISTRY

A. Yazici1, E. Dalkivik2, M. Birlik3, M. A. Öztkir4, S. Akar5, B. Goker6, Y. Pehlivan7, S. Senel8, A. Cefle1, F. Önen7, 1Kocaeli School of Medicine, Rheumatology, Kocaeli, Turkey; 2Uludag School of Medicine, Rheumatology, Bursa, Turkey; 3Dokuz Eylul School of Medicine, Rheumatology, Izmir, Turkey; 4Gazi School of Medicine, Rheumatology, Ankara, Turkey; 5Katip Celebi School of Medicine, Izmir, Turkey; 6Erciyes School of Medicine, Rheumatology, Kayseri, Turkey;

Background: Adult-onset Still's disease (AOSD) is a rare multisystemic inflammatory disorder, and is diagnosed by exclusion. AOSD is generally treated with corticosteroids, and conventional disease modifying anti-rheumatic drugs (cDMARDS). Biological disease modifying anti-rheumatic drug (bDMARD) therapy are recommended in AOSD patients who are refractory to traditional therapy, and bDMARDS is becoming increasingly important in AOSD treatment.

Objectives: To evaluate the use of bDMARDS and drug survival in AOSD patients.

Methods: TURKBIO registry is the Turkish version of Danish DANBIO rheumatological database which has been established in 2011. All patients with AOSD who received biological agents registered in TURKBIO registry between dates of October 2011 and October 2019 were included in this study. The demographic data, response of therapy, frequency of using and switching biological agents were collected.

Results: As of October, 21 AOSD patients were recruited. Mean age of patients was 34.6±7.3 (min-max: 24-49) years, mean disease duration was 9.3±7.4 (min-max: 1-22) years, and 57.1% of patients were female. Mean duration from onset to start of bDMARDS was 7.6±1.1 (min-max: 0.5-21) years. It was observed that 13 patients (61.9%) received tocilizumab (TCZ), 6 patients (28.6%) received IL-1 inhibitors (5 anakinra and one canakinumab), 2 patients (9.5%) received certolizumab and one patient (4.8%) received etanercept as a first-line bDMARDS.

The most frequently used biological agents in current treatment were as follows: 52.4% of patients received TCZ and 33.3% received IL-1 inhibitors (4 anakinra, 3 canakinumab), and the most frequently used concomitant drugs were methotrexate (47.6%) and hydroxychloroquine (14.3%). The switching rate was 33.3%, and in half of them the reason of switching was adverse events. The median drug survival for bDMARDS was 28.6 months (Table).
Methods: 121 consecutive patients diagnosed with AUA [91 AANGU (40 B27-, 61 B27+) and 20 AAGU M/F 32/29, mean age 45.4 ± 12.8 y, mean disease duration 44± 84 m] from the Immunology Eye Unit (AUSIL-RCCE Reggio Emilia, Italy) entered the study. Patients with Fuchs uveitis were enrolled as controls (AAGU group). A complete rheumatological examination, including 68/66 peripheral joint count, entheses and bone spine mobility evaluation, was conducted. Using an Esato MyLabClass, 18-6MHz linear multifrequency transducer both in B-mode and PD-mode, 6 entheses were evaluated bilaterally for the presence of any elementary lesion, structural damage and active enthesities, according to OMERACT definitions. The following sites were studied: lateral epicondyle of humerus, distal quadriceps insertion into the patella, proximal and distal patellar tendon insertions, calcaneal insertion of Achilles tendon and plantar fascia. Knee and ankle joints, were evaluated for synovial hypertrophy, effusion and PD signal. Extensor and flexor tendons of the foot and ankle were also examined for tendon sheath effusion, synovial hypertrophy and PD signal.

Results: Abnormal findings, consisting in the presence of at least one entheseal abnormality, were detected in 110/121 patients (90.2%), the mean number of abnormal entheses per patient was 6.7±5.4. At the enthesis level, structural damage was significantly higher in AANGU, as compared with AAGU (30.9% vs 21.7%, p<0.001) and in AANGU B27+ as compared with B27+ (27% vs 36%, p<0.001). The presence of PD signal at enthesis was significantly increased in AANGU vs AAGU (71% vs 0.4%, p<0.001) but also among AANGU B27+ vs AANGU B27- pts (5.9% vs 9%, p=0.045). Analysis based on patient-level data showed a significantly higher percentage of patient in AANGU group having at least one enthesis exhibiting PD signal, when compared with AAGU (31% vs 5%, p=0.023) (Table 1). The prevalence of US joint and tendon shear alterations was negligible in the entire AAGU population (<1%) without any difference between groups.

Conclusion: US entheseal structural damage is frequent in AAGU patients, whereas US active enthesities has a low prevalence. At the patient level, the presence of PD signal at enthesis seems to be associated with AANGU, without apparent influence of HLA-B27 positivity.

Results are presented as number and percentage of patients having at least 1 entheseal abnormality, with significance of the disease and the shear wave elastography (SWE) is useful to distinguish pathological changes of the SG in patients with SS (EULAR2018).

Objectives: The aim of this study was to compare the usefulness of SG conventional-B mode US and SWE findings in non-SS and SS patients classified by salivary flow.

Methods: Twenty-two non-SS patients and 99 SS patients who fulfilled the American College of Rheumatology (ACR) / European League Against Rheumatism (EULAR) classification criteria for SS were studied. SS patients were divided into three groups according to salivary flow using gun test (VLS:SS <5mL/10min, n=38), LSS 5-10mL/10min. (n=41) and N/SS >10mL/10min. (n=20). All patients were examined SGUS by a single investigator who was blinded to device (TUS-A300; Canon Medical Systems, Tokyo, Japan) with a linear transducer (75-10MHz). The examination consisted of conventional-B mode US (US staging score), pulsed wave Doppler US (PD grading score) and SWE with quantitative assessment. US staging scores were assessed by glandular size, inhomogeneity and contrast of diagnostic muscle (stage 0 to 3). PD grading scores were graded by pulsed wave pattern in pulsed wave Doppler US at the internal SG facial arteries (grade 0 to 2). With the region-of-interest (ROI) placed over the stiffer areas of the lesion on the SWE, the quantitative means of the elasticity values were measured by shear wave velocity (Vs; m/s) and elasticity (E; kPa) for each lesion.

Results: The US staging score, the PD grading score, the values of Vs and E were significantly higher in patients with SS than in non-SS group (SS vs non-SS; US staging score 2.10±1.07 vs 0.86±0.99, p<0.001, Vs 1.75±0.34 vs 1.57±0.29m/s, p=0.04). However, there was no significant difference between non-SS and N/SS in early-stage SS by US staging score (N/SS vs non-SS; Vs 0.95±0.89 vs 0.86±0.99) and PD grading score (N/SS vs non-SS; 0.40±0.15 vs 0.23±0.061). In contrast, the values of Vs and E were highest in N/SS as compared with all groups, and were significantly higher in N/SS than in non-SS (N/SS vs non-SS; Vs 2.02±0.24 vs 1.57±0.29m/s, p<0.01, E 12.58±3.16 vs 7.81±2.72kPa, p<0.01).

Conclusion: The present study demonstrated that although the tissue elasticity was decreased due to structural changes at the advanced stage, it increased due to inflammation and high viscosity in the SG at the subclinical SS with normal salivary flow comparing that in non-SS patients. The SWE may be a useful tool for the differential diagnosis between patients with non-SS and subclinical SS with normal salivary flow, which is difficult to distinguish by conventional-B mode US.

nocturnal neck pain and headache. Pittsburgh sleep quality index (PSQI) was used for sleep disturbance. Pre and post contrasts enhanced MRI interventions were done for both groups during the period of follow up (three months).

Results: Nocturnal neck pain, headache and sleep disturbance have significantly decreased, during follow up visits (3 months), in AAJ group in comparison to the control group. The Pre-intervention nocturnal pain score was 60.3 ±17.1 in AAJ group & 58.5 ±17.9 in control group. Pain has significantly decreased after 2weeks in AAJ group with continuous improvement till 3 months’ post-intervention 6.9 ±6.5 & 51.26 ±10.54 respectively. The pre-intervention headache was 22.68 ±16.74 in AAJ group & 45.17 ±15.83 in control group decreased to 754 ±23.23 & 48.52 ±11.98 respectively post inter-vention. The percentage of patients who had sleep disturbance at baseline was 66.7% & 73.3% in AAJ and control groups respectively which has significantly decreased to 6.7% & 43.3% after 3 months. Regarding MRI, AAJ group had a statistical significant decrease in the percentage of patients with MRI synovial enhancement, inflammatory pannus, fibrosis and bone marrow edema in comparison to control group 3 months post intervention. All post-procedural side effects resolved within thmough without fur-ther medical intervention, and no long-term sequelae were identified.

Conclusion: Fluoroscopic guided intra-articular steroid injection of inflamed atlantoaxial joints is considered a beneficial therapeutic option in rheumatoid arthritis patients regarding clinical and radiological assessments.

SAT0549

DEVELOPMENT AND VALIDATION OF THREE PRELIMINARY MRI SACROILIAC JOINT COMPOSITE STRUCTURAL DAMAGE SCORES IN A 5-YEAR LONGITUDINAL STUDY OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS

1Rigshospitalet, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; 2Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Soenderborg, Denmark; 3Hospital Lillebaelt, Department of Rheumatology, Vejle, Denmark; 4Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 5Herlev Hospital, Department of Radiology, Copenhagen, Denmark

Background: In axial spondyloarthritis (axSpA), MRI reliably detects structural lesions in the sacroiliac joints (SIJs). The SPARCC SIJ Structural Score (SSS) (1) is a reliable and validated method to assess the individual structural lesions of the SIJs, i.e. fat lesion, erosion, backfill (fat metaplasia in an erosion cavity) and ankylosis. Several MRI studies have indicated that bone destruction, i.e. erosion, is often followed by formation of new bone in the erosion cavity (backfill), ultimately leading to ankylosis(2).

Objectives: The aim was to combine SPARCC SSS for erosion, backfill and ankylosis into a composite score for SIJ structural damage and to test this score in a 5-year follow up study.

Methods: Thirty-three patients fulfilling ASAS criteria for axSpA were followed for 5 years after initiation of TNF inhibitor in the BIOSPA study(3). T1-weighted and STIR MRI sequences of the SIJs were acquired at week 0, 46 and year 2, 3, 4, 5 were evaluated with SPARCC SSS. In each of 5 slices of each SIJ, erosion is scored 0-1 per joint quadrant (score range 0-40), backfill 0-1 per joint half (score range 0-20) and ankylosis 0-1 per joint half (score range 0-20). Based on the scores for erosion, backfill and ankylosis 3 versions of a preliminary Composite axSpA MRI SIJ Structural Damage Score (CSDS) were calculated:

CSDS–A: (erosion score x0.5) + backfill score + ankylosis score

CSDS–B: (erosion score x1) + (backfill score x4) + (ankylosis score x6)

CSDS–C: (erosion score x1) < (backfill score x4) < (ankylosis score x6)

The “<” indicates a hierarchical order, meaning that erosion was not scored if backfill was present in the same joint half and erosion and backfill were not scored if ankylosis was present in the joint half.

Results: Patients were divided into two groups: patients with almost complete bilateral ankylosis (baseline SPARCC SSS Ankylosis ≥18, n=10) and patients with no/minor ankylosis (baseline SPARCC SSS Ankylosis ≤7, n=23). At baseline patients with no/minor ankylosis were younger, had shorter symptom duration, lower BASMI, higher SPARCC SIJ Inflammation, lower SSS Fat, Erosion, Backfill and Ankylosis, as compared with patients with almost complete ankylosis.

At baseline, CSDS–A, -B and -C correlated positively with SPARCC SSS Fat and Ankylosis and modified New York criteria grading, and negatively with BASDAI and SPARCC inflammation. Change in CSDS–B and -C over 5 years correlated positively with change in SSS Fat and Ankylosis and negatively with change in SPARCC inflammation. There was no change in the group with almost complete ankylosis.

The annual progression for CSDS–B and -C was statistically significantly larger in year 1 compared with year 4 (p=0.01) and numerically larger compared with year 2 (p=0.075), 3 (p=0.382) and 5 (p=0.073). Figure 1 shows the annual change in patients with no/minor ankylosis.

Conclusion: Three preliminary Composite Structural Damage Scores for MRI assessment of the SIJs in patients with axSpA, which allows scoring of MRI progression of erosion through backfill to ankylosis, were introduced. Progression was most pronounced the first year after TNF inhibitor initiation. This novel approach may be useful for monitoring structural progression in axSpA. We sug-gest that these methods are further tested for responsiveness and ability to differ-entiate between different therapies in randomized controlled trials.

DOI: 10.1136/annrheumdis-2020-eular.2683
Background: MRI allows an objective assessment of signs of inflammation in peripheral joints and entheses and is therefore of potential interest as outcome measure in trials. No knowledge exists on the reliability and validity of semi-quantitative MRI scores in the setting of peripheral spondyloarthritis (pSpA).

Objectives: To describe the reliability of a semi-quantitative lower-extremity MRI scoring system, to investigate correlation with known measures of disease activity and ability to capture patients with improvement during treatment.

Methods: In a post-hoc analysis, scores from 3 readers (LJ, MD, SK) who independently assessed MRI images of pelvis (except sacroiliac joints), knees and ankles in the CRESPA trial blinded to chronology and all clinical data, were further analyzed. Entheses were scored 0-3 (none/mild/moderate/severe) for soft tissue inflammation (19 sites) and 0-3 for bone marrow edema (24 sites), joints were scored 0-3 for effusion/synovitis (10 sites) and 0-3 for bone marrow edema (22 sites). MRI score was defined as the sum of scores from all joints and entheses (i.e. all 75 sites). The CRESPA trial (NCT01426815) included 60 patients with early pSpA, defined as a symptom duration of <12 weeks. All patients fulfilled the Assessment of SpondyloArthritis international Society criteria for pSpA; data from 56 patients with available MRI images at baseline were included in this analysis, 46 had available MRI images at follow-up. Follow-up MRI was only performed if sustained clinical remission was reached. Reliability included in this analysis, 46 had available MRI images at follow-up. Follow-up MRI was only performed if sustained clinical remission was reached. Reliability was assessed using two-way intra-class correlation coefficient (ICC) models by absolute agreement, single-measure (relevant when using scores from 1 reader) and average-measure (relevant when using averaged scores from 3 readers).

Results: MRI scores at baseline were mean 7.2 (median 5, inter-quartile range 3 to 9, range 0 to 32). MRI change scores were mean −3.1 and (median −1, IQR −4 to 1), MRI status scores at baseline (n=56) had single measures ICC 0.78 (95% CI: 0.66-0.87) and average measure ICC 0.92 (0.85-0.95). MRI change scores (n=46) had single measure ICC 0.73 (0.57-0.84) average measure ICC 0.89 (0.80-0.94). MRI status scores correlated significantly with CRP, ESR, swollen joint count and pain score. Patients with PsAPARC0 response (n=34) (≥40% improvement in disease activity according to the Peripheral SpA Response Criteria) had larger decreases in MRI scores compared to patients without PsAPARC0 response (n=11), mean change −3.4 vs. −1.0, p=0.03. When using all MRI data from pelvis, knees and ankles combined, more patients could be identified to have improvement, as compared to only taking one of three parts into account.

Conclusion: The semi-quantitative lower-extremity MRI score showed acceptable reliability and validity. The ability to capture response was best when combining information from all available areas that were imaged, i.e. both pelvis, knees and ankles.

Background: Psoriatic spondyloarthropathies (PsSpA) is an inflammatory arthritis related to psoriasis, whereas a large number of patients may have persistent inflammation developing gradual and in some cases extensive joint involvement of the axial skeleton.

Conventional radiographs (CRs) have been used for the detection of structural damage (syndesmophyte formation, paravertebral ossification, sacroilitis, ankyloses and erosions), facilitating as an important measure of efficacy of various therapies. However overlapping of anatomic structures of pelvis and spine as well as limited capabilities to visualize soft tissue have led to the development of newer imaging technologies (1). Multidetector CT technology (MDCT), it is now possible to perform low dose CT (ldCT) of the entire vertebral column, viewed in multiple planes and without overprojection with a low radiation dose. (2) Still, the capabilities of ldCT algorithms in the diagnosis and progression of PsSpA has not been fully explored.

Objectives: The aim of this study is to examine the effect of “Dosed5” iterative reconstruction algorithm on radiation dose, diagnostic capabilities and image quality in spine-pelvis (S-P) CT scanning compared with CRs, in detection of findings suggestive of PsSpA.

Methods: Thirty-nine patients with PsSpA (26 females and 13 males, age range: 23 to 70 years old) were prospectively studied with “iDose5” iterative reconstruction algorithm in the diagnosis and progression of PsSpA. Patients satisfied the Psoriatic Arthritis (CASPAR) classification criteria and had undergone standard AP and lateral CRs of the cervical, thoracic and lumbar spine and AP radiographs of the pelvis within one months of the iDose CT. Twenty-five patients underwent, additional MRI imaging (MRI) of the same anatomic areas. Written consent was obtained from all patients. Two musculoskeletal radiologists read and scored CT scans and CRs in consensus, according to the PAsRI criteria and the CTSS score. CT image quality and effective dose for CT and radiographs were assessed.

All data were analyzed using SPSS 24.0 statistical software.
Results: CT revealed erosions and ankyloses of the sacroiliac joints, fusion of the posterior elements of vertebrae especially in the thoracic spine, enthesopathies, not seen with CRs, in 26 patients (p<0.05).

Figure 1. Visual PET uptake in the left MTP5-joint.

Figure 2. (R)-[11C]PK11195 (SUV) in both clinically affected and non-affected feet joints (defined as swollen yes or no).

References:

Whole body macrophage PET imaging showed clear uptake of (R)-[11C]PK11195 in several joints of clinically active, early RA patients, especially in MTP-joints. The best correlation between quantitative PET data and clinical assessment of swelling was observed in the feet. In general, however, PET also provided distinct information from clinical assessment, which may provide a means for detecting subclinical synovitis. We are performing longitudinal studies to further assess the value of macrophage PET in RA.

DOI: 10.1136/annrheumdis-2020-eular.4380

Results: All patients showed enhanced tracer uptake in one or more joints (Figure 1). A total of 168 joints were visually PET positive, with the distribution: 16% in the wrists, 14% in the metacarpophalangeal joints, 25% in the proximal interphalangeal joints, 4% in the ankles, 37% in the metatarsophalangeal joints. Positivity in other large joints was rare (4%). The discrepancy between PET and clinical outcome (TJC and/ or SJC) varied based on anatomic localization; more joints were clinically active in the hands, and more joints were active on the PET scan in the feet. Consequently, agreement between visual PET positivity and clinical activity was low, with only moderate agreement found in the ankles (κ = 0.46 and 0.41 for SJC and TJC respectively). Quantitative PET data showed a trend towards higher SUV values in joints that were clinically tender and/or swollen, reaching a significant difference in the feet (ankles + MTPs) versus SJC (Figure 2; 0.7 vs 1.0, p < 0.001). However, parts of the clinically non-affected joints also depicted moderately increased SUV values, and vice versa.

Conclusion: The nine minutes acquisition time for iDose CT for the imaging assessment of PsSpA in daily clinical practice.

time for the metacarpophalangeal (MCP) joints might yield some disadvantages. Having the hand and arm immobilised for this long might discomfort the patients, thereby reducing acceptability, resulting in poor adherence. The longer imaging time might also prejudice the risk of motion-induced image degradation.

Objectives: The objective of this study was two-fold. Firstly, we investigated motion-induced image degradation of 2nd and 3rd MCP joints for two methods of standardised positioning of the hand. Secondly, the acceptability of HR-pQCT imaging was explored for patients with established Rheumatoid Arthritis (RA).

Methods: Fifty patients with RA had their 2nd and 3rd MCP joints imaged by HR-pQCT. The patients were scanned twice, using a custom-made positioning splint, with and without an inflatable immobilisation device. In order to investigate acceptability, the patients were afterwards given a questionnaire regarding their procedure experience of HR-pQCT imaging with and without the inflatable hand immobilisation device. For each acquisition, the image quality was graded, and the number, width, depth and length of cortical interruptions were measured. Twenty percent of the acquisitions were reevaluated to determined intraobserver reliability using the intraclass correlation coefficient (ICC).

Results: The acceptability regarding HR-pQCT imaging was high, with only 6% preferring conventional X-ray compared to 40% of the patients preferring HR-pQCT imaging. The remaining 54% were indifferent to the modality. Seventy-four percent found it hard to keep their fingers at rest during the imaging. Fifty percent of the patients thought the inflatable hand immobilisation device helped keep their fingers at rest compared to only 6% who believed it impeded their ability to keep their fingers at rest. This was not observable in the image quality, however, as the overall image quality was high and no clinically relevant difference of the visual grading between the acquisitions with and without the inflatable hand immobilisation device was observed. The number, width, depth and length of cortical interruption all indicated excellent reproducibility as shown in table 1. No discernible difference between the two acquisitions was observed.

Acquisition 1 - Without the inflatable hand immobilization device.  
Acquisition 2 - With the inflatable hand immobilization device.  
Data presented as mean (95% confidence intervals).

Conclusion: The high acceptability signifies the feasibility of the novel HR-pQCT imaging; this was evident by the fact that more patients preferred HR-pQCT imaging compared to conventional X-ray examination. The inflatable hand immobilisation device did not reduce vascular features only. Moreover, the consecutive addition of functional impairment and worsening of ILD (from both normal %FVC and %Dlco, to %Dlco impairment only) was found to increase in vascular volume, whereas %V% negatively correlated with %FVC, %TLC and %Dlco. There was a positive correlation between %ILD patterns and %vascular volumes, being significant for %TV%-%AV%, total vessels and arterial density. Conversely, %ILD patterns were negatively correlated with %V% and number of veins detected, despite positive correlation between %V% and %ILD EXT%. When clustering patients according to %FVC and %Dlco with 80% normal cutoff, %FF allowed clustering according to significantly different ILD patterns extents and vascular features (stable %Dlco for %ILD only). The %Dlco for %ILD only was associated with worse %FVC, %TLC, %Dlco and %FF. There was a significant increase in %TV%, %AV% and %VF, with the exception of decrease in %V% and venous density in patients with double impairment versus Dlco single impairment.

SAT0544  
SONOGRAPHIC ASSESSMENT OF CALCIUM PYROPHOSPHATE DEPOSITION DISEASE AT WRIST. A FOCUS ON THE SCAPHO-LUNATE LIGAMENT.

E. Cipolletta1, G. Smerilli1, R. Mashadi Mirza2, A. Di Matteo3, F. Salafati3, W. Grassi1, E. Filippucci1, Università Politecnica delle Marche, Rheumatology Unit, Jesi, Ancona, Italy; 2ULSS 6 Euganea, Dipartimento di Diagnostica per Immagini, Padova, Italy; 3University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: Only a few articles evaluated the wrist in calcium pyrophosphate deposition disease (CPPD), although it is the second most frequent target of CPPD. Very recently, in a computed tomography (CT) study ligamentous calcifications were reported as a highly specific feature of CPPD at wrist level (1).

Objectives: To determine the prevalence and distribution of the ultrasound (US) findings indicative of calcium pyrophosphate (CPP) crystal deposits at the wrist, with a particular focus on the dorsal aspect of the scapho-lunate ligament (SLL), to investigate the diagnostic accuracy of US and conventional radiography (CR) for the evaluation of CPP crystal deposits at wrist level, and to assess the agreement between the different imaging techniques.

Methods: Consecutive patients with a “definite” diagnosis of CPPD according to the Ryan and McCarthy criteria and disease controls were prospectively included in this cross-sectional single-centre study. Dorsal part of the SLL, triangular fibrocartilage complex (TFCC), and volar recess of the radio-lunate joint were explored using US (according to EULAR standard scans and OMERACT definitions), CR and CT.

Results: Sixty-one CPPD patients and 39 disease controls were enrolled. Two-hundred wrists were evaluated using both CR and US. CT data of 26 (13.0%) patients were available: 20 with CPPD patients and 6 with controls. CPP crystal deposits were found by US in at least one wrist in 95.1% of CPPD patients and in 15.4% of controls (p<0.001). SLL calcification was reported in 83.6% of CPPD patients and in 5.1% of controls (p<0.001). CPP crystal deposits were
observed by US at the SLL and/or radio-lunate joint in 5.7% of wrists and 6.6% of CPPD patients, but not at the TFCC of the same wrist. On CR, calcifications were found in at least one wrist in 72.1% of CPPD patients and in 0% of controls (p<0.001). Using the Ryan-McCarty criteria as a gold standard, the sensitivity, specificity and diagnostic accuracy were 0.72 (0.59-0.83), 1.0 (0.91-1.0) and 0.83 (0.74-0.90) for CR and 0.95 (0.86-0.99), 0.85 (0.69-0.94) and 0.91 (0.84-0.96) for US. Table 1 shows the agreement between the different imaging techniques.

Bone lesions in humans in vivo is not fully characterized.

Tophus deposition. The exact spatial inter-relation between tophi and structural bone changes, if such deposits form adjacent to the normal architecture of the MTP1 joint.

Feet of sex- and age-matched healthy controls (HC) were scanned to define the tophus distribution of uric acid crystals cause an inflammatory reaction, which can lead to structural bone changes, if such deposits form adjacent to cortical bone [1, 2]. Both erosions and bony spurs can form in conjunction with tophus deposition. The exact spatial inter-relation between tophi and structural bone lesions in humans in vivo is not fully characterized.

Objectives: To spatially relate structural bone changes (erosions, osteophytes) to the deposition of monosodium urate crystals in the first metatarsophalangeal (MTP1) joint in patients with tophaceous gout.

Methods: Tophaceous gout patients with clinically detected tophi at the MTP1 joint underwent simultaneous dual energy computed tomography (DECT) and high-resolution peripheral quantitative computed tomography (HR-pQCT) of the foot. Tophi detected by DECT and erosions and osteophytes detected by HR-pQCT were evaluated to define their exact anatomical relation. Furthermore, feet of sex- and age-matched healthy controls (HC) were scanned to define the normal architecture of the MTP1 joint.

Results: Gout patients (N=20) had significantly higher numbers (5 (0–17 vs. 1 (0–4)) on the MTP1, which were not directly adjacent to tophi. Median tophus volume (0.12 mm3 (0.01–2.53)) was associated with the total volume (7.26–550.32) vs. 0.82 mm (0.05–7.61) mm3 of bone erosions, while osteophytic responses were more widespread and affected bone regions on the MTP1, which were not directly adjacent to tophi. Median tophus volume detected by DECT (0.12 mm3 (0.01–2.53)) was associated with the total volume of erosions (N=0.587, p=0.005).

Conclusion: This study demonstrates that bone changes in gout are substantial and not only include erosions but also widespread architectural bone remodeling associated osteophyte formation. While there is a direct spatial relation between tophi and bone erosions the anabolic bone responses in gout are more widespread.

defined as “positive” since the uptake was higher than liver, and twelve/thirty (52.2%) were defined as “negative” since the uptake was lower than liver, regardless of SUVs and clinical manifestations. A semi-quantitative analysis assessed whether the values of the SUVmax BM/liver were higher than the cut-off of 2.09 in “positive” PET/MR and lower in the “negative” ones and if the clinical manifestations were present or absent in agreement with the evaluation of SUVs for each patient. BM was found to be active (SUVmax ratio > 2.09) in 7 out of 11 patients when the PET/MR was defined “positive”, while only in 1 case out of 12 BM SUVmax was >2.09 when the exam was “negative”. Clinical manifestations were present in 10 out of 11 AOSD with a “positive” scan and in 7 out of 11 with both a “positive” scan and a SUV max BM/liver >2.09. Clinical manifestations were present in 1 out of 12 patients with a “negative” scan, while in 10 out of 12 cases with both a negative scan and a SUV max BM/liver <2.09 were absent. Six patients repeated PET/MR during follow-up. The values of the SUVmax BM/liver significantly decreased after anti IL-1β treatment with anakinra. In two cases in which anakinra was deferred, the BM SUVmax values exceeded the cut-off of 2.09 despite the patients did not complain any symptom or inflammation markers increase.

Conclusion: 18F FGD-PET/MR could be able to evaluate the disease activity in AOSD when clinical manifestations and serum markers are not sufficient to establish it. The uptake on BM seems quite sensitive in pointing out the disease severity and in assessing the response to anti IL-1β therapy. 18F-PET/MR is an accurate and repeatable method, however further studies are required to validate its applicability in routine clinical practice.

The impact of a standardized training program for improving the reliability and agreement – A study of vascular ultrasound for diagnosing giant cell arteritis in Denmark

S. Chrysidis1,2, L. Terslev1, R. Christensen2,3, U. Fredberg2,4, K. Larsen1,2, T. Lorenzen1, U. Møller Døhn4, A. Diamandopoulos5,1, J._nthrop of Southwest Jutland, Esbjerg, Denmark; 2University of Southern Denmark, Denmark; 3The Parker Institute, Copenhagen, Denmark; 4Rigshospitalet, Glostrup and COPECARE, Copenhagen, Denmark; 5Silkeborg Regional Hospital, Aarhus University Denmark; 6Martin Hansen Hospital, Baerum, Norway

Background: Due to a high level of evidence of good test performance, accessibility, minimal invasiveness, low cost, and good overall performance, EULAR recommends ultrasound (US) of the temporal and auricular arteries as primary diagnostic imaging test in patients suspected of Giant Cell Arteritis (GCA) (1). Despite the growing body of evidence supporting the utility of US in GCA, standardized training programs and their impact on reliability are lacking (1). In TABUL study (2), the only US study published to date using a standardised US training program, the interobserver agreement by 12 different sonographers was only 66/112 study (2), the only US study published to date using a standardised US training program, the interobserver agreement by 12 different sonographers was only 66/112 study (2), the only US study published to date using a standardised US training program, the interobserver agreement by 12 different sonographers was only 66/112 study (2). Clinical manifestations were present in 1 out of 12 patients with a “negative” scan, while in 10 out of 12 cases with both a negative scan and a SUV max BM/liver <2.09 were absent. Six patients repeated PET/MR during follow-up. The values of the SUVmax BM/liver significantly decreased after anti IL-1β treatment with anakinra. In two cases in which anakinra was deferred, the BM SUVmax values exceeded the cut-off of 2.09 despite the patients did not complain any symptom or inflammation markers increase.

Conclusion: Our training program resulted in excellent reliability of US findings in patients suspected of having GCA and for the final diagnosis. The training program could be used when implementing vascular US in clinical practice.

Increased frequency of inter- and submetatarsal bursitis and Morton’s neuroma in rheumatoid arthritis: results of a large case-controlled MRI study of forefoot in patients with early arthritis and healthy controls

V. Dakkas1, E. Niemantsverdriet1, A. Van der Helm - van Mil1, 2, M. Reijnierse3, 4, R. van der Heijden1, 5, 6, Luqmani R et al. Jutland, Esbjerg, Denmark; 2Erasmus MC, Rheumatology, Rotterdam, Netherlands; 3Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 4Erasmus MC, Rheumatology, Rotterdam, Netherlands; 5Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands

Background: The forefoot is a preferential location for tendon and joint inflammation in rheumatoid arthritis (RA). Some imaging studies suggested that intermetatarsal and submetatarsal pathology (such as bursitis and Morton’s neuroma) are also involved in RA, but these studies were small and its association was not thoroughly explored.

Objectives: To determine whether intermetatarsal bursitis (IMB), Morton’s neuroma (MN) and submetatarsal bursitis (SMB) occur more often in early RA, compared to patients with other early arthritides and healthy controls. Contrast-enhancement in the subcutis that has been described as diffuse submetatarsal alterations (DSMA) were also included.

Methods: In this cross-sectional cohort-study, consecutive patients with RA, other arthritides and healthy controls underwent MRI of unilateral forefoot. Two readers, a trained PhD-student an experienced MSK-radiologist, scored IMB, MN, SMB and DSMA in consensus, and measured transverse and dorsoplantar

TA: Temporal; FA: Facial; AA: Auxillary; AC: common Carotid, artery
diameters of IMB, MN and SMB. Logistic regression models determined their association with RA, and test characteristics for RA were calculated. Lesion sizes were plotted.

Results: 834 participants underwent MRI: 157 consecutive patients with RA (109 women; age 59±11SD), 284 with other early arthritides (158 women; age 56±17SD), and 193 healthy controls (136 women; age 50±16SD). Univariately, IMB, MN and SMB were more prevalent in RA (all P<0.001), DSMA was not (P=0.16). Multivariably, MB, SMB and MN were all associated with RA independent of each other (P<0.016). IMB was most frequent (sensitivity 69%), followed by SMB and MN (25% and 19%), specificity was high (70%, 96%, 94%, respectively compared to other arthritides and 84%, 99% and 97% compared to healthy controls).

Although IMB, MN and SNB were more frequent in RA, the lesion-size was mainly similar in all groups. For MN a dorsoplantar diameter >6mm or transverse diameter >5mm was highly specific (specificity 100% compared to healthy controls), however it was infrequent (sensitivity 12% and 13%, respectively). For IMB and SMB no cut-off size could be distinguished with high specificity.

Conclusion: Intramedatarsal bursitis, Morton’s neuroma and submetatarsal bursitis are increased prevalent in early RA and could be considered as disease features.

SAT0560 THE PROGNOSTIC VALUE OF ULTRASONOGRAPHIC FINDINGS IN INDIVIDUALS WITH ASYMPTOMATIC HYPERURICEMIA

W. Li1, W. Fan1, J. Zhu, Z. Chen1, F. Liu1. 1Peking University People’s Hospital, Ultrasound, Beijing, China

Background: Chronic and steady asymptomatic hyperuricemia (AHU) can eventually lead to the deposition of monosodium urate crystals in joints and soft tissues. The rate of progression from AHU to clinically evident gout varies and mainly depends on serum uric acid levels. However, little is known about the prognostic value of ultrasonographic findings in individuals with AHU in detail.

Objectives: To explore the prognostic value of ultrasonographic findings in individuals with asymptomatic hyperuricemia.

Methods: We analyzed the ultrasonographic findings (snowstorm sign, double-contour (DC) sign, tophi, bone erosion, and abnormal blood flow) of bilateral knees, ankles and the first metatarsal-phalangeal joints (1st MTP) of individuals with AHU at Peking University People’s hospital between June 2014 and May 2016. All individuals were followed up for two years.

Results: Among 218 individuals with AHU, the prevalence of snowstorm sign, DC sign, tophi, bone erosion and abnormal blood flow was 41%, 23%, 4%, 9% and 13%, respectively. Gout attacked in 36 patients during 2-year follow-up with 4.5 years of HU duration. The first attack affected the 1st MTP in 60%, the ankle in 31%, and the knee in 11% of the patients with gout. Patients with gout attack has longer hyperuricemia duration compared with individuals with AHU without gout attack. DC sign, tophi, and bone erosion on ultrasound were more frequently presented in patients with gout attack compared with individuals with AHU without gout attack. However, the prevalence of snowstorm sign and abnormal blood flow on ultrasound has no significant differences between patients with gout attack and individuals with AHU without gout attack.

Conclusion: Longer hyperuricemia duration, DC sign, tophi, and bone erosion on ultrasound in individuals with AHU could be associated with gout attack.

SAT0561 METATARSOPHALANGEAL JOINT MEDIAL COLLATERAL LIGAMENT MEASUREMENT, A NOVEL ULTRASOUND FEATURE OF MONOSODIUM URATE DEPOSITION IN THE JOINT.

R. Flood1, D. Kane1, R. Mullan2. 1Tallaght University Hospital, Rheumatology, Dublin, Ireland; 2Tallaght University Hospital, Dublin, Ireland

Background: Acute gouty arthritis most commonly initially affects the first metatarsophalangeal joint (MT1). (1) Musculoskeletal ultrasound (US) is a reliable tool for detecting monosodium urate crystal (MSU) deposition in gout and hyperuricemia with validated, ultrasound features of double contour (DC) sign, tophus, and erosions. (2, 3) The collateral ligaments of MT1, which originate on the medial and lateral epicondyles of the metatarsals and extend to the proximal phalanx, function to stabilize the joint. (4) While tophus deposition typically occurs between the medial collateral ligament (MCL) and head of MT1, small MSU aggregates may be indistinguishable from surrounding tissue. In this study using US, we propose that an increased vertical depth between the superficial surface of the MCL to cortical surface of MT1 (dMC-MT) is indicative of MSU deposition (see figure 1). The aim was to evaluate associations of dMC-MT with serum uric-acid level (sUA) in a cohort of individuals with hyperuricemia and non-episodic foot pain. We propose a novel sonographic feature of MSU crystal deposition in the MT joint.

Objectives:
(1) To evaluate the association between sUA and dMC-MT
(2) To record the presence/absence of classical features of MSU deposition including: double contour sign, erosions and tophi in a cohort of patients with hyperuricemia and foot pain.
(3) To evaluate the associations between sUA and dMC-MT in those with/without classical features of MSU deposition (DC, erosion, tophi).

Methods: Following informed consent, hyperuricaemic patients (n = 52) underwent bilateral US of the 1MT using LogiqE9 at 15 MHz. Features of MSU deposition including DC sign, tophus and joints-articular erosion were recorded. The dMC-MT was measured as the mean of the perpendicular distance between the superficial surface of the midpoint of the MCL to the MT1 head. Statistical analysis was performed using SPSS V.25 software. Data presented as MEAN ± S.E unless otherwise indicated.

Results: DC sign, tophus and erosion occurred in 31%, 20.7% and 19% of cases, respectively. Mean sUA was higher in tophus positive (540 ± 36) versus non tophus (470 ± 16) (p<0.01) and erosion positive (522 ± 32) versus non erosion (477 ± 17) patients. dMC-MT was significantly greater in tophus positive patients (0.34cm ± 0.17cm) versus non tophus (0.27cm ± 0.01cm) (p < 0.01). dMC-MT was significantly greater in erosion positive patients (0.31cm ± 0.18cm) versus non erosion (0.28cm ± 0.01cm) (p< 0.05). In DC negative patients dMC-MT was significantly correlated with increasing sUA (r = 0.34 p = <0.05). No correction between dMC-MT and sUA was seen in DC positive patients.

Conclusion: dMC-MT is significantly greater both in patients with tophus and erosions indicating its role as an additional marker of MSU crystal deposition. Furthermore a significant association between dMC-MT and sUA in DC negative patients suggests that dMC-MT may be a more sensitive indicator of early urate deposition in a subset of patients where the earliest site of urate deposition has not occurred directly on to articular hyaline cartilage. dMC-MT may therefore be a sensitive tool for very early urate deposition. Further studies clarifying a role for dMC-MT are now required.

ADDITIONAL BENEFIT OF ULTRASOUND TO THE EARLY DIAGNOSIS OF PSORIATIC ARTHRITIS

Y. Geng1, A. Cope2, S. Subesinghe2, J. Galloway3, Z. Zhang1, B. Kirkham2.
1 Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China; 2 Guy’s and St Thomas’ NHS Trust, Department of Rheumatology, London, United Kingdom; 3 King’s College London, Academic Department of Rheumatology, London, United Kingdom.

Background: Being an inflammatory disease of joint, spine or enthesis is the premise of the CASPAR diagnostic criteria for psoriatic arthritis (PsA). Traditionally, the assessment of local inflammation in joint, enthesis and tendon relies on physical examinations. But multiple studies have demonstrated that ultrasound (US) is capable of detecting subclinical inflammation as well as non-inflammatory lesions.

Objectives: To compare the capabilities of physical examination and US findings in the diagnosis of early PsA, and further identify the US features which are most valuable for the diagnosis of PsA.

Methods: 66 patients with suspected PsA or early PsA (disease duration<2 years) due to psoriasis with joint pain or seronegative inflammatory arthritis were enrolled and further assessed by both physical examination and ultrasound (US). Tender and swollen joint counts based on 68/66 joints, tender tendons, enthesitis (14 entheses) and dactylitis (20 digits) count were collected by physical examination. Abnormalities of peripheral joints, entheses and tendons were also evaluated by US. New bone formation was evaluated by hand X-ray. The diagnostic capacity of CASPAR criteria based on US and based on physical examination were compared. The diagnostic value of US features as well as clinical characteristics were analyzed. The clinical diagnosis of PsA by the expert panel was taken as the standard.

Results: CASPAR criteria based on US showed a higher specificity than those based on physical examination (96.7% vs. 53.3%) with a bit decrease of sensitivity (91.7% vs. 97.2%). 36 patients were eventually diagnosed as PsA and 30 patients were non-PsA. Gender distribution, mean age and disease duration were equally distributed in two groups of patients. Dermatology Life Quality Index (DLQI) was higher in PsA patients than non-PsA patients. Significantly more patients had nail change and new bone formation on hand X-ray in PsA patients than in non-PsA patients (69.4% vs. 26.7%, P=0.001 and 66.7% vs. 13.3%, P<0.001 respectively). Significantly higher frequencies of synovitis/ synovium hypertrophy, tenosynovitis and enthesitis were found in PsA patients than non-PsA patients (58.3% vs 20.0%, P=0.002, 38.9% vs 3.3%, P=0.001 and 52.8% vs 13.3%, P=0.002, respectively). Logistic regression analysis showed that nail change (OR=25.1, P=0.007), new bone formation on X-ray (OR=23.1, P=0.003), tenosynovitis on US (OR=149.1, P=0.003) and enthesitis on US (OR=39.2, P=0.008) were independent risk factors for predicting the diagnosis of PsA.

Conclusion: US increased the specificity of CASPAR criteria compared with physical examination. Combined nail change, new bone formation on X-ray, tenosynovitis and enthesitis on US improved the diagnosis of early PsA.

The texture model was based on the Deep Texture Encoding Network (Deep-TEN) architecture (figure 1), which put an encoding layer on top of a pre-trained 18-layered residual network (ResNet18). The vectors produced by the model represent the orderless texture features that were used to generate a texture score for RA.

Five texture models are trained using 5-fold cross-validation and are assembled during inference by averaging the model outputs to produce the final score. We then validate the model using hand radiographs of 166 RA patients and 166 non-RA patients. Overall model performance was measured by area under the curve of the receiver operator curve (AUROC). Multivariate logistic regression was used to estimate the odds ratio (OR) and 95% confidence interval (CI) of RA.

**Results:** We included 140 women and 26 men with RA (mean age, 55.9±1.8 years) and 166 non-RA individuals (F: M, 140:26; mean age, 55.5 ± 1.8 years). The mean texture score was 0.49 (95% CI, 0.48–0.50) in RA patients, which is significantly higher than non-RA patients (0.42, 95% CI, 0.40–0.43; p<0.01). The AUROC of the model was 0.68. In the multivariate logistic regression model, a high texture score (>0.43) is associated with an OR (95% CI) of 3.42 (2.48–4.72) for RA, adjusted by age and sex.

**Conclusion:** This study indicates that the texture model can delineate radiographic changes in texture relevant to RA and, coupled with automatic joint detection and segmentation, it has the potential to aid early RA diagnosis and monitor radiographic progression.

The modified ultrasonography scoring system integrated oral mucosa and major salivary glands is able to improve the diagnostic specificity of patients with pSS.

**Methods:** Longitudinal study in patients with SpA and PsA with active disease (defined as patients who were going to start or switch biologic disease modifying antirheumatic drugs (bDMARD) therapy according to physician criteria and in agreement with clinical guidelines). MASEI evaluation was performed at baseline, 3- and 6-months visits. MASEI and Outcome Measures in Rheumatology (OMERACT) enthesis Power Doppler (PD) definitions were checked. Each enthesis was scanned in both the longitudinal and transverse planes, and 5 second videos were recorded for reliability. An inter-reader analysis by three readers was performed. For statistical analysis t-Student test was used to determined changes between visits and kappa test was used for reliability.

**Results:** A total of 72 US evaluations of 25 patients were included, of whom 13(62%) were anklyosing spondylitis (AS) patients, 9(36%) PsA, and 3(12%) non radiographic axial spondyloarthritis (nr-axSpA). Mean age was 51.2±14.1 years and 13(52%) were females. Mean DAS28 (3.5±1.2) for peripheral involvement, mean BASDAI (5.8±2) for axial involvement, and CRP values (13.1±13.6) reflect moderate-high disease activity at baseline. US parameters at baseline and at the 3- and 6-month follow-up visits are shown in Table 1. Global MASEI score was responsive at the 3- and 6-month follow-up visit (-4.9 and -5.7, respectively) (p<0.05) and both MASEI and OMERACT PDUS definitions of active enthesitis improved significantly at 3- (-0.6 and -1.1) and 6-month follow-up visits (-0.7 and -1.1) (p<0.05). Reliability of PD MASEI definition among the three readers was excellent (kappa = 0.918).

**Conclusion:** MASEI score significantly improves at 3 and 6 months of follow up in patients under bDMARD treatment and both MASEI and OMERACT Doppler definitions of active enthesitis reflects treatment response. These findings support the usefulness of PD US in the assessment of bDMARD treatment response in SpA and PsA.

**SAT0567 USE OF THERMOGRAPHY OF HANDS AND MACHINE LEARNING TO DIFFERENTIATE PATIENTS WITH ARTHRITIS FROM HEALTHY SUBJECTS**

J. Morales-Ivron1,2, D. Grados Canovas1, C. Gómez Vaquero3, J. M. Nolla3, J. Narváez3, C. Moragues Pastor3, J. A. Narvaez3, J. Hernandez3, J. C. Sardinas2, B. Busque1, D. Madrid1, J. Bove1, M. A. Marin-López2, 1Hospital Igualada, Igualada, Spain; 2Singularity Biomed S.L., Barcelona, Spain; 3Hospital Universitario de Bellvitge, Hospital de Llobregat, Spain

**Background:** The early diagnosis of rheumatic diseases improves their prognosis. However, patients take several months to reach the rheumatologist from the beginning of the first symptoms. Thermography is a safe and fast technique that captures the heat of an object through infrared photography. The inflammation of the joints causes an increase in temperature and, therefore, can be measured by thermography. Machine learning methods have shown that they are capable of analyzing medical images with an accuracy similar or superior to that of a healthcare professional.

**Objectives:** Develop an algorithm that, based on thermographic images of hands and machine learning, differentiates healthy subjects from patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), undifferentiated arthritis (UA) and arthritides of hands secondary to other diseases (SA).

**Methods:** Multicenter observational study conducted in the rheumatology and radiology service of two hospitals. Patients with RA, PA, UA and SA who attended the followup visit and healthy subjects (companions and healthcare professionals) were recruited. In all cases, a thermal image of the hands was taken using a Flir One Pro or Thermal Expert TE-Q1 camera connected to the mobile and an ultrasound of both hands. The degree of synovial hyper trophy (SH) and power
doppler (PD) was assessed for each joint (score from 0 to 3). Inflammation was defined as the presence of SH > 1 or PD > 0. Machine learning was used to classify patients with RA, PA, UA, and SA with inflammation evidenced by ultrasound and healthy subjects from thermographic images. The evaluation of the classifier was performed by leave-one-out cross-validation and the area under the ROC curve (AUCROC) in those subjects whose thermal image was performed with the Thermal Expert TE-Q1 camera. The study was approved by the Clinical Ethics and Research Committee of the centers.

Results: 500 subjects were recruited from March 2018 to January 2020, of these 73 were excluded due to poor quality in the thermal image (moved or absence of temperature contrast between hand and background). Of the 427 subjects analyzed, 129 corresponded to healthy subjects, 138 to patients without evidence of inflammation and 160 to patients with inflammation evidenced by ultrasound (116 RA and 44 PA, UA or SA). Of these, 42% were taken using the Thermal Expert TE-Q1 camera. An AUCROC of 0.73 (p-value <0.01) was obtained for the healthy classifier vs RA and 0.72 (p-value <0.01) for the healthy classifier vs PA, UA and SA.

Conclusion: A classification model has been developed capable of differentiating patients with RA, PA, UA and SA with evidence of inflammation from healthy subjects. These results open an opportunity to develop models that facilitate early diagnosis.

SAT0568 PERSISTENT VASCULAR 18F-FDG UPTAKE DESPITE CLINICAL-ANALYTICAL REMISSION IN PATIENTS WITH LARGE VESSEL VASCULITIS UNDER TOCILIZUMAB THERAPY. SINGLE UNIVERSITARY CENTER EXPERIENCE OF 30 PATIENTS.

D. Prieto-Peña1, M. Calderón-Goercke1, I. Martínez-Rodríguez1, J. J. Banzo1, J. García-Fernández1, P. Vicente-Gómez1, M. A. González-Gay1, R. Blanco1.
1Marqués de Valdecilla University Hospital, Santander, Spain

Background: Tocilizumab (TCZ) has shown effective large vessel vasculitis (LVV) (1-3). Disease activity assessed by laboratory markers (ESR,CRP) may be of less value with TCZ. 18F-FDG PET/CT may be useful to monitor LVV disease activity (4-5).

Objectives: To assess a) evolution of disease activity in LVV treated with TCZ by PET/CT and b) its correlation with clinical/serological markers.

Methods: Single centre study of 30 patients with refractory LVV treated with TCZ who had a baseline and follow-up PET/CT scan. Vascular uptake was assessed quantitatively and qualitatively. Quantitative analysis was assessed as a target to background ratio (TBR)=SUVmax thoracic aorta/SUVmax aortic vascular pool. For qualitative analysis, FDG uptake at vessel wall was visually grading compared to the liver. We defined a total vascular score which included 5 vascular areas (supra aortic trunks, thoracic, abdominal, iliac and femorocutaneous arteries) ranging from 0 to 15. Clinical improvement (no improvement/partial/complete) was defined as the presence of SH> 1 or PD> 0. Machine learning was used to classify vs RA and 0.72 (p-value <0.01) for the healthy classifier vs PA, UA and SA.

Maurer1. 1Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2Department of Radiation Oncology, University Hospital Zurich, Zurich, Switzerland; 3Institute of Diagnostic and Interventional Radiology, University Hospital Zurich, Zurich, Switzerland

Background: Interstitial lung disease (ILD) affects 60% of patients with systemic sclerosis (SSc) and is the primary cause of death. Medical imaging is an integral part of the routine work-up for diagnosis and monitoring of SSc-ILD and includes high-resolution computed tomography (HRCT). Radiomics is a novel research area that describes the in-depth analysis of tissue phenotypes in medical images with computational retrieval of quantitative, mineable metadata appropriate for statistical analyses.

Objectives: To explore the performance of HRCT-derived radiomic features for the assessment of SSc-associated ILD (i.e. diagnosis, staging, and lung function).

Methods: Radiomics analysis was performed on HRCT scans from 98 SSc patients, including n=33 SSC patients without ILD, n=33 with limited and n=32 with extensive ILD as defined by 0%, <20% and ≥20% visual extent of fibrosis on HRCT, respectively. Following semi-automated segmentation of lung tissue on 3D reconstructed HRCT scans, 1386 radiomic features, including 17 intensity, 137 texture, and 1232 wavelet features were extracted using the in-house developed software Z-Rad (Python 2.7). In order to identify robust features, we conducted intra- and inter-reader correlation analysis (ICC) in a subgroup of patients. Only features with good reproducibility (ICC ≥ 0.75) entered subsequent analyses. We applied the Wilcoxon test, followed by Receiver Operating Characteristic (ROC) curve analyses, to identify features significantly different between a) ILD

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2020-eular.1628
and non-ILD and b) limited vs. extensive ILD patients. Spearman rank correlation was performed to reveal significant associations of radiomic features from a) and b) with lung function as measured by percentage of predicted forced vital capacity (FVC%) predicted.

**Results:** In total, 1355/1386 radiomic features passed the test of robustness and were eligible for further, exploratory analyses. Radiomic features with good performance (area under the ROC curve (AUC) ≥ 0.7 and p-value ≤ 0.05) were considered as potential candidate discriminators. Under this criterion, we identified 268/1355 (21.3%) radiomic features that were significantly different between ILD and non-ILD patients and 408/1355 (30.2%) features that significantly discriminated between limited and extensive ILD (Fig. 1). For diagnosis, the texture feature dependence count entropy was the top parameter to distinguish ILD patients from healthy controls (AUC = 0.89, p = 1.83x10^{-10}), whereas for staging the wavelet feature HHH long run high grey level emphasis proved to be best suited to separate limited from extensive ILD (AUC = 0.88, p = 7.76x10^{-10}).

**Conclusion:** Our study adds novelty to the field of SSC-ILD showing that radiomic features have great potential as quantitative imaging biomarkers for diagnosis and staging of SSC-ILD and that they may reflect lung function. As the next step, we are planning to build predictive models, using machine learning, for diagnosis, staging, and lung function and validate them in external patient cohorts. If validated such models will pave the way for computer-aided management in SSC-ILD and thus improve patients’ outcome.

**SAT0570**

**CLINICAL SIGNIFICANCE OF FINGER EXTENSOR PARATENONITIS DETECTED BY MUSCULOSKELETAL ULTRASOUND**

T. Suzuki¹, H. Shirai¹, Japanese Red Cross Medical Center, Division of Allergy and Rheumatology, Tokyo, Japan

**Background:** The extensor tendons over fingers are devoid of a tendon sheath, so that the term paratenonitis is used to describe extra-articular hyperemia or anechoic fluid collections along the extensor tendons of the fingers. Although the grading of paratenonitis is found in one sonographic scoring system of RA known as German US7, the clinical significance of paratenonitis is not fully understood.

**Objectives:** To determine the clinical significance of finger extensor paratenonitis detected by ultrasound (US), especially in the patients with RA.

**Methods:** We reviewed 1200 reports of the US examination underwent in our division since April 2015. The items necessary for scoring US5 scores (the ‘hand-limited version’ of the German US7) have been routinely recorded. The cases with finger extensor paratenonitis over the dorsal metacarpophalangeal joint (MCPJ) were determined. The severity of articular synovitis in the perilesional MCPJ were subjectively graded for grey-scale (GS) and power Doppler (PD) on a four-step scale (0-3) and scored using EULAR-OMERACT combined scoring system. In RA patients, US5 scores were determined for the involved hands.

**Results:** Paratenonitis was found in 44 fingers in the 38 hands of the 36 patients with rheumatic diseases/disorders including 25 patients with RA (11 early RA and 14 established RA), Non-RA diseases/disorders included 4 cases of undifferentiated arthritis, 2 cases of PsA, 1 case each of SLE, Sjogren syndrome, reactive arthritis and other disorders.

The 44 fingers were classified according to the absence or presence of articular synovitis in the perilesional MCPJ into “isolated paratenonitis” or “paratenonitis accompanied by synovitis.” The distribution of paratenonitis over the 1st-5th fingers of the dominant or non-dominant hands is shown in Figure 1. Paratenonitis was relatively frequently found in the 3rd and 2nd fingers of the dominant hands. Interestingly, articular synovitis in the perilesional MCPJ were found significantly more frequent in the cases of MCP2 in the dominant hands (73%) than in the cases of MCP3 in the dominant hands (25%) (p=0.039).

Among the 27 hands with paratenonitis of 25 RA patients, US5 scores were compared based on the absence or presence of moderate to severe articular synovitis in the perilesional MCPJ (the combined score >1) (Figure 2), GS synovitis score, PD synovitis score and PD tenosynovitis score were significantly higher in those with moderate to severe perilesional MCP synovitis than in those without it (p=0.007, 0.0092 and 0.0458, respectively).

**Conclusion:** Finger extensor paratenonitis over the dorsal MCPJ tends to occur in the 3rd and 2nd fingers of the dominant hand. In RA patients, paratenonitis accompanied by active perilesional MCPJ synovitis are presumably due to active disease, while isolated paratenonitis can also be caused possibly by degenerative changes due to overuse or deformity. Isolated paratenonitis may be more frequently found in the 3rd finger than in the 2nd finger of the dominant hand.
SAT0571

OPTICAL SPECTRAL TRANSMISSION TO ASSESS THERAPY RESPONSE IN PATIENTS WITH ARTHRITIS: A COMPARATIVE STUDY WITH CLINICAL, LABORATORY AND ULTRASONOGRAPHIC ACTIVITY MARKERS.

K. Triantafyllias1, C. Heller2, M. De Blasi3, M. Muthuraman4, A. Schwarting1,2.
1ACURA Clinics, Rheumatology, Bad Kreuznach, Germany; 2Johannes Gutenberg University Medical Center, Internal Medicine I, Department of Rheumatology and Clinical Immunology, Mainz, Germany; 3Johannes Gutenberg University Medical Center, Biomedical Statistics and Multimodal Signal Processing, Mainz, Germany

Background: Valid assessment of disease activity leads to outcome improvement in patients with rheumatoid arthritis (RA) (1). Optical spectral transmission (OST) is a modern diagnostic tool able to assess the blood-specific absorption of light transmitted through a tissue, promising quantification of inflammation in the finger and wrist joints of RA patients (commercial device: HandScan - Hemics, The Netherlands) (2).

Objectives: To our knowledge, there are no data regarding the diagnostic value of OST in the evaluation of inflammatory activity changes during arthritis follow up. Thus, aims of this study were to examine the ability of OST to detect response to anti-inflammatory therapy in patients with arthritis and to explore OST associations with clinical, laboratory and ultrasonographic (US) activity markers.

Methods: OST measurements were performed in patients with active arthritides of the wrist and finger joints before and after administration of glucocorticoids (GC), during a disease flare. For the same points in time (a and b) patients and healthy controls underwent clinical, laboratory and joint US (Grey Scale (GSUS) - Power Doppler (PDUS)) examinations. OST-values before and after therapy were subsequently compared with their corresponding DAS28- and US-values. The distributions of Delta-PDUS and OST-values between the two time points were compared by Bayesian statistics. Moreover, OST diagnostic performance was tested by Receiver Operating Characteristics (ROC).

Results: We recruited 54 patients with active inflammatory arthritis: 39 RA, 4 gout, 7 peripheral spondylarthritides and 4 other miscellaneous arthritides (66.7% females) and 114 controls. Previous to therapy with GC, median OST was [OST(a): 8.75 (5.58-16.25, IQR)] and after therapy [OST(b): 4.75 (2.38-8.63, IQR)] (p<0.05). Similarly, DAS28 dropped significantly after GC therapy [DAS28(a): 5.12 (4.33-6.10, IQR) vs. DAS28(b): 3.85 (3.40-4.82), p<0.05). OST correlated moderately with PDUS at both time points: (a) rho=0.449 and (b) rho=0.414, respectively (both; p<0.01). Moreover, OST correlated significantly with swollen joint count at both time points (a) rho=0.379 and (b) rho=0.382, p<0.01 respectively.

OST and US performed similarly in the assessment of inflammatory changes caused by the administration of GC (same tendency in the change of OST values in 83.2% of the cases). Furthermore, Bayesian statistic revealed no significant differences between OST and US for all 3 examined joint categories (MCP: p=0.81;PIP: p=0.74; wrists: p=0.80).

In addition, ROC revealed that OST is a very good tool to distinguish patients with arthritis from healthy controls at both examination points (AUC(a): 0.883(95% CI[0.83-0.94]) and AUC(b): 0.871(95% CI[0.74-0.88])).

Conclusion: OST was able to assess response to therapy in arthritis patients comparable to US. Moreover, OST correlated with disease activity markers and could effectively differentiate between arthritis patients and controls. Therefore, OST could prove to be a valuable non-interventional time- and resource-saving diagnostic tool to assist arthritis monitoring.

CONSTRUCTIVE VALIDITY OF MUSKULOSKELETAL ULTRASOUND MEASUREMENT OF CARTILAGE THICKNESS IN PATIENTS WITH KNEE OSTEOARTHRITIS

Z. Velickovic1, S. Janjic1, V. Bajec1, B. Stojic1, T. Zivanovic Radnic1,2, M. Rasic1, G. Radunovic1,2. 1Institute of Rheumatology, Belgrade, Serbia; 2School of Medicine, University of Belgrade, Belgrade, Serbia

Background: Cartilage thickness is one important measure in describing both OA development and progression. Based on current knowledge, conventional radiography (CR) and magnetic resonance imaging (MRI) have not been demonstrated to be superior over one another. Because of disadvantages of MRI and CR neither can be used in routine daily clinical practice for follow up of OA patients. Diagnostic ultrasound assessment (US) of cartilage thickness offers an alternative measure as a clinically available and more cost-effective source of knee articular cartilage imaging.

Objectives: Our objective was to determine the relationship between US and CR measures of femoral cartilage thickness in patients with knee osteoarthritis because systematic feature- and site-specific cross-comparison between these two methods is still missing in the current literature.

Methods: 120 patients with knee osteoarthritis (240 knees) are recruited for this study. The joint space width (JSW) and Kellgren and Lawrence (K&L) grade were measured using weight-bearing anteroposterior 30° knee semi-flexion knee radiography (with inclusion criteria K&L grade 1-4). Femoral cartilage thickness was measured three times in supine position and with a suprapatellar transverse scan with the knee in maximal flexion at the lateral condyle (LC), medial condyle (MC) and intercondylar notch (IN) by one rheumatologist and arithmetic mean is taken. Pain and

Figure 2. OST- (group 1) und Ultrasound- (group 2) Bayesian distributions, means- and standard deviation-differences for MCP (A), PIP (B) and wrists (C).
functionality are measured with VAS pain scale, Womac, Lysholm and SF 36 score. The agreement between the two methods was evaluated with Bland-Altman analysis.

**Results:** We found a statistically significant low level of rank correlation between CR and US measurements of cartilage thickness; ρ values between modalities were low (0.263 and 0.273 depending on side (right/left), p<0.005 and p=0.007 respectively). In Bland–Altman analysis, US measurement showed bad agreement with CR. Presence or absence of US features of OA (effusion, synovial hypertrophy, osteophytes and popliteal cysts) didn’t influence on cartilage thickness assessed by US (p<0.05). For US assessment, we found correlation only between low level of agreement according to Bland-Altman analysis. The use of ultrasound as a complementary imaging tool along with CR may enable more accurate and cost-effective detection, prognosis and follow-up of knee osteoarthritis in routine clinical practice.

per day (ME/D) (OR: 2.06 [95% CI: 1.58 - 2.69]), than those who were not in workers compensation program. Another study found, initial days of supply of opioids from 5 to 20 or more days was strongly associated with long term use of opioids (OR: 29.84 [95%CI, 23.44-35.72])5. While a study by Heins et al (2015)5 examined receiving opioids within the first month, people with back injuries were less likely to become a long-term opioid user (OR: 0.67 [95% CI: 0.59 – 0.76]), while those with shoulder injury were at risk (OR: 1.29 [95% CI: 1.06 – 1.58]).

Conclusion: There are a number of reliable prevalence studies among workers compensation settings indicating opioid use is below 20 percent however; there remains inconsistencies when examining predictors of long term opioid use. After reviewing the literature, a validity of studies will be conducted and graded by two authors independently using a standardised checklist to complete a systematic review for publication which will assist with managing opioid use among work compensation claimants and managers.

**POSITIVE QUANTIFERON-TB GOLD TEST AND SEROCONVERSION OF QUANTIFERON-TB GOLD TEST IS ASSOCIATED WITH INCREASED RISK OF THE DEVELOPMENT OF ACTIVE TUBERCULOSIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RESULTS FROM A REAL-WORLD DATA OVER 20 YEARS**

G. Y. Ahn1, B. S. Koo2, D. Son3, Y. J. Kim4, J. Kang5, T. H. Lee6, J. H. Kim7, G. G. Song8, T. H. Kim9. 1Korea University Guro Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Inje University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 3Hanyang University, Biostatistical Consulting and Research Lab, Medical Research Collaborating Center, Seoul, Korea, Rep. of (South Korea); 4Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea)

Background: With the promising efficacy and the prevalent use of anti-tumor necrosis factor-α (TNF) agents in managing AS, the risk for reactivation of latent tuberculosis infection (LTBI) still is a concern. Although guidelines include the screening and treatment of LTBI prior to the initiation of anti-TNF agent by Quantiferon-TB Gold (QFT-G) or tuberculin test, there is a lack of evidence whether treatment of LTBI before initiation of anti-TNF agent may reduce the risk of reactivation to the same as LTBI patient without anti-TNF agent or anti-TNF agent users without LTBI. Furthermore, evidence on the need for follow-up testing and the association between seroconversion and the development of active tuberculosis is also limited.

Objectives: This study aims to investigate the real-world impact of QFT-G test on the development of active tuberculosis in patients with AS.

Methods: This retrospective study investigated 2,930 patients who had a diagnosis of AS and conducted QFT-G testing during the period of March 1998 to June 2019. Among 191 patients with history of treatment for LTBI or acute tuberculosis infection prior to the first QFT-G test and 157 patients whose hospital visits or prescription was less than 3 were excluded. Observational period was defined from the first QFT-G test to the last hospital visit of development of active tuberculosis. The screening for development of active tuberculosis was conducted by reviewing the diagnosis, prescription of anti-tuberculosis medication, chest images and electronic medical record. Treatment of LTBI was defined when a patient was prescribed isoniazid for at least 220 for 12 months, rifampin for at least 90 days for 6 months, or concurrently prescribed isoniazid and rifampin for at least 70 days. QFT -G test to the last hospital visit of development of active tuberculosis. The incidence rate was compared to baseline QFT-G (+) and QFT-G (+) patients. We used Cox proportional hazard analysis were performed.

Results: A total of 2687 patients (median age 32.7 years, 78.4% male, anti-TNF agent use 16.7%) were included. Baseline QFT-G was positive in 426 (20.3%) patients, and 15 active tuberculosis was observed [Incidence rate 1.5/1000 person years (PY)]. Compared with baseline QFT-G (-) patients, baseline QFT-G (+) patients were older (412 years vs. 313 years, p<0.001) and they were accompanied with more active tuberculosis (4.4/1000PY vs. 1.0/1000PY) despite the less usage of anti-TNF agents (38.5% vs 45.6%, p=0.006). The observational period, sex, and medication utilization pattern except anti-TNF agent were similar between two groups. Multivariable analysis showed that QFT-G (+) test increases the risk of active tuberculosis more than 10 times [adjusted hazard ration 170, 95% confidence interval (CI) 5.1-56.8, p<0.001] after adjusting age, sex and the usage of anti-TNF agents. Then we conducted subgroup analysis on 965 patients with baseline QFT-G (-) and follow-up QFT-G tests. Seroconversion was documented in 65 patients (6.7%). Active tuberculosis was observed in 4 patients, and seroconversion was occurred before the development of active tuberculosis in all patients. The incidence of active tuberculosis in seroconversion patients were 10.5/1000PY.

Conclusion: QFT-G (+) and QFT-G seroconversion is associated with increased risk of the development of active tuberculosis in patients with AS.

**THE PREVALENCE OF RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW OF POPULATION-BASED STUDIES.**

K. Altmair1, J. Nossen2, D. Prener3, H. Keen3, C. Inderjeeth1. 1The University of Western Australia, School of Medicine, Perth, Australia; 2The University of Western Australia, School of Population and Global Health, Perth, Australia

Background: Rheumatoid arthritis (RA) is a heterogeneous disease with unknown aetiology (1). The reported worldwide RA prevalence varies widely (2, 3), and it is unclear whether this is due to inconsistencies in defining populations or methodologies used to identify RA patients (3, 4). Accurate RA prevalence data are required to plan preventative, diagnostic, and management strategies to address raising health care service demands and costs associated with improved lifespan and level of disability (5, 6).

Objectives: To estimate the prevalence of RA from international population-based studies and investigate the influence of prevalence definition, data sources, classification criteria and geographical area on RA prevalence.

Methods: A systematic review of existing literature was performed using the Joanna Briggs Institute approach for the systematic review and Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. A search of ProQuest, MEDLINE, Web of Science, and EMBASE was undertaken to include population-based studies investigating RA prevalence between 1980 and 2019.

Results: Sixty published population-based studies met the inclusion criteria over 20 years. The mean point-prevalence of RA was 0.56% (range 0.00% to 2.70%) between 1986 and 2014. The period-prevalence was 0.51% (range 0.05% to 1.9%) between 1955 and 2015. RA point- and period-prevalence was higher in urban settings than rural settings, (0.69% vs 0.48%) and (0.54% vs 0.25%), respectively. The mean point- and period-prevalence were 0.56% (SD=0.52) and 0.57% (SD=0.41) and were lower in sampling population studies than in larger population databases studies (0.60% (SD=0.27) and 0.44% (SD=0.26)). The highest period-prevalence of RA was observed in linked databases (0.80%, SD=0.1) where RA diagnosis was validated by rheumatologists.

Conclusion: The average point- and period-prevalence of RA were 51/10,000 and 56/10,000 respectively. The RA prevalence was higher in urban areas than rural areas, suggesting an impact of environmental differences. Population database studies were more consistent than sampling studies, and linked databases appeared to provide the best estimate of RA period-prevalence when rheumatologists clinically verified RA.

**USING CONTRACEPTIVE METHODS IN MEXICAN WOMEN WITH RHEUMATIC DISEASES**

**Background:** The importance of safe and effective contraception for women with rheumatic diseases has been increasing. Several studies have demonstrated that carefully planned pregnancies are related with better outcomes making the use of contraceptive methods (CM) more significant.

**Objectives:** To describe the use of methods of contraception among Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE).

**Methods:** A cross-sectional study where women aged 18-45 followed in our CEER outpatient clinic, at Monterrey, Mexico, were questioned about the use of CM. Sociodemographic data was collected from the medical record. CM were classified as ineffective (10-25% pregnant each year) and highly effective (<1% pregnant each year). Methotrexate, Mycophenolate, Cyclophosphamide, Thalidomide and Leflunomide were considered as teratogenic drugs.

**Results:** A total of 91 patients were included, 35 (38.5%) SLE patients with a median age of 30 years (22-39) and 56 (61.5%) RA patients with a median age of 34.5 years (27-25-40). From the total population, 58 (63.7%) reported the use of teratogenic drugs, with a higher use in RA patients (p < .001). Socio-demographic characteristics are listed in Table 1.

Among the patients that had started sexual activity (SLE=24, RA=46), the most common CM was tubal ligation 26 (28.6%).

A. Berrič,1 I. Andreica,1 S. Tsiamı,1 D. Kieler1, U. Klitz1, X. Baralikas1, J. Braun1, B. Buehrling1,1 Ruhr-University Bochum, Rheumatzzentrum Ruhrgebiet, Heme, Germany

**Background:** Current demographic data predict that the number of older adults with rheumatic diseases will considerably increase in the coming years. Geriatric patients differ from younger adults in many ways including their clinical presentation, co-morbidities and response to medication. The management of such patients is often challenging due to the presence of multi-morbidity, polypharmacy and geriatric syndromes (i.e. conditions in which symptoms result from impairments in multiple systems rather than a discrete disease). To systematically assess geriatric patients, specific tools have been developed; however, they are not routinely utilized by rheumatologists. Using these tools could improve patient management and satisfaction in rheumatologic care.

**Objectives:** To examine the prevalence of 17 common geriatric health problems using validated geriatric assessment tools in older patients with rheumatic and musculoskeletal diseases.

**Methods:** Adults 65 years and older who presented to a tertiary rheumatologic hospital were included after informed consent. All patients recruited were assessed using the MAngable Geriatric Assessment (MAGIC) which addresses 14 common geriatric health problems. In addition, polypharmacy (≥ 5 medications), muscle function using the Short Physical Performance Battery and frailty applying the Fried definition were assessed. Disability was quantified with the "Funktionsfragebogen Hannover" (FFbH), a validated tool for patients with rheumatologic diseases that can be easily converted to Health Assessment Questionnaire (HAQ) scores. Primary outcome was the frequency of the selected 17 geriatric health problems; the correlation of the total number of problems with HAQ scores was a secondary outcome.

**Results:** Of the 300 individuals included 67% were female with a mean age of 73.6±6.8 years; 85% (17 of 20) of patients with rheumatologic conditions had a rheumatologic diagnosis. The remaining participants had either a chronic pain syndrome or degenerative joint/spine disease. On average participants had 7 out of 17 assessed geriatric problems. Females had more such problems than males (8 vs. 6, p<0.0001). Chronic pain and polypharmacy were most common but several others were also seen in more than 50% of patients (see Table). The mean HAQ Score was 1.67±0.79. There was a positive correlation (see Graph) between the number of problems and the HAQ Score (R² = 0.44, p<0.0001).

**Conclusion:** A systematic geriatric assessment can be successfully used to discover and quantify geriatric health problems in older patients with rheumatic and musculoskeletal diseases. These problems appear to be very common and importantly, patients with more problems had poorer functional status. Frailty, depression, incomplete vaccination status, cognitive impairment or polypharmacy are all known to negatively impact patient care. Recognizing and addressing geriatric problems has the potential to lead to health care improvements including adherence and medication side effects and might increase patient satisfaction and functional status independent of disease activity.

SAT0580
ANALYSIS OF ANAS/DFS70 PATTERN IN A LARGE COHORT OF AUTOIMMUNE/AUTOINFLAMMATORY DISEASES COMPARED WITH FIRST DEGREE RELATIVES AND HEALTHY CONTROLS EVALUATED IN A SINGLE HOSPITAL FROM COLOMBIA.

C. Romero-Sánchez1, 2, 3, O. J. Calixto4, V. Romero-A1, 2, 3, A. Vargas1, L. Castro1, J. Amador1, P. Lopez-Mojica5, D. Marin6, D. Acero-M7, 2, M. Acevedo2, 7, R. D. Cincon-Riaño1, J. M. Bello-Gualtero1, 2, 3, Rheumatology and Immunology Department Hospital Military Central, Bogota, Colombia; 2Clinical Immunology Group- Hospital Militar School of Medicine, Universidad Militar Nueva Granada, Bogota, Colombia; 3Internal Medicine Department Hospital Military Central, Universidad Militar Nueva Granada, Bogota, Colombia; 4Bacteriology degree, Faculty of Basic Sciences, Universidad Colegio Mayor de Cundinamarca, Bogota, Colombia; 5Immunology Laboratory, Hospital Military Central, Bogota, Colombia

Background: Autoimmune diseases have a broad phenotypic spectrum, with great variability in clinical manifestations. Anti-DFS70/LEDGFp75 (ANAS/ DFS70) antibodies have attracted interest as a positive result in patients without clinical evidence of autoimmune systemic rheumatic disease (SARD). It has been proven in non-rheumatic inflammatory diseases and in "apparently healthy" individuals.

Objectives: To assess ANAS/DFS70 performance in a large population with autoimmune/autoinflammatory diseases compared with first degree relatives and healthy controls.

Methods: A cross-sectional study was conducted. We analysed 531 individuals between 18-65 years old, 101 rheumatoid arthritis (RA) patients (ACR/EULAR 2010 classification criteria), 137 relatives from RA, 60 psoriasis (Ps) patients (Colombian classification consensus), 47 Undifferentiated connective tissue diseases (UCTD) patients and 186 healthy controls matched by age and sex. The healthy control group were individuals who lived and worked similarly like those patients those criteria of exclusion criteria were to present autoimmune or auto-inflammatory disease, infectious, neoplasms, diabetes, antibiotic treatment, pregnancy or lactation, consanguinity with autoimmune entities. Ethical Committee approved. The determination of ANAS-HeP2 antibodies (ANA-HeP2 AESKU.Dignostic®), Autoantibody test SYSTEM IMMO DIAGNOSTICS REF 11039 and ANA-HeP2 AESKU.Dignostic®) was carried out. The positive results (standard AC-2) are used as a confirmatory test the determination of ANAS / DFS70: AUTOANTIBODY TEST SYSTEM IMMO IMMO DIAGNOSTICS (Knocked out, for the psip gene) REF 1108@ and CytoBead ANA Generic Assays ref 8065 by indirect immunofluorescence-IF technique. In addition, serum levels of C-reactive protein (PCR), erythrocyte sedimentation rate (ESR), IgG/IgA antibodies against citrullinated peptide (ACPA), and rheumatoid factor (RF). Absolute and relative frequencies were estimated.

Results: 531 participants were included: RA 19%, 25.8% RA relatives, Ps 11.3%, UCTD 8.9%, and 35% healthy controls. RA mean age was 41,8±12,2 years, female 82.2%, with ANA test (+) result 42%. In Ps mean age 49,1±15,7 years, female 53.3%, ANA test (+) 41.7%. UCTD mean age 41,3±15,2 years, female 85.1%, and ANA test (+) 78.7%. Relatives of RA mean age 38,7±12,2 years, female 73.7%, ANA test (+) 26.3%. And healthy controls mean age 41,3±12,2 years, female 74.7%, and ANA test (+) 26.9%. ANA/DFS70 was positive in a 6,4% in UCTD, 3,2% in healthy controls, 1,7% in Ps, 1,5% in Relatives of RA, no RA had positive results. These 12 participants were negative for acute phase reactants (ESR+) 83.3% and (CRP-) 66.6%, as well as they were all negative for RF and two were positive for ACPA from UCTD.

Conclusion: ANAS/DFS70 autoantibodies were present in very low frequency in patients with SARD, Thus, patients with a positive result tend to have mild or non-progressing phenotype of autoimmune/inflammatory diseases, as UCTD. This is the first time ANA/DFS70 are tested in a large population cohort in Latin American countries which coincide with previous results in RA and RA relatives.

SAT0581
SERIOUS INFECTION RATES WITH BIOLOGICAL DISEASE MODIFYING ANTI-RHEUMATIC AGENTS (bDMARDs) AND PREDISPONING FACTORS: A 5-YEAR RETROSPECTIVE REVIEW

K. Celkys1, J. Ly1, M. Soden1, 2
1Townsville Hospital and Health Service, Townsville, Australia

Background: Biological and targeted synthetic disease modifying anti-rheumatic agents (bDMARDs) increase the risk of serious infections (SIs), however there is limited ‘real-world’ evidence comparing the relative risk of SI for individual bDMARDs. (1,2)

Objectives: This study examines the rates of SIs in a non-select Australian Northern Queensland (NQ) cohort of patients with various rheumatic diseases receiving treatment with a bDMARD, to define predisposing factors and directly compare the bDMARDs.

Methods: A retrospective review was performed for all patients who received a bDMARD through the Townsville Hospital Rheumatology Department over the
5-year period between June 2013 and May 2018. Episodes of a SI were defined as infection requiring admission or use of intravenous antibiotics. For each bDMARD the rate of SI per 100 patient years (PYs) was calculated and patient demographics and comorbidities were analysed. Between-group differences were assessed using independent samples t-tests or ANOVA. Where assumptions were violated, Mann-Whitney U tests or Kruskal-Wallis tests were used. For categorical variables, chi-square tests were used, except when assumptions were violated when Fisher's Exact tests were used.

Results: 296 patients received bDMARDs with an overall SI rate of 11.7/100PYs. There was no significant difference in presence of SI by disease type with 24% of patients with rheumatoid arthritis versus 19% with psoriatic arthritis, 14% with ankylosing spondylitis and 29% with “other” \( (X^2=3.11; df=3; p=0.37) \). Respiratory tract infections were the most common infection (46%) followed by skin and soft tissue infections (23%). The highest incidence rate of SI occurred with rituximab (29.72 SI/100PYs) followed by certolizumab (22.50 SI/100PYs) and tocilizumab (15.91 SI/100PYs). Duration of time on a bDMARD, disease duration and use of methotrexate or leflunomide were not shown to significantly increase the risk of SI for the entire cohort. The characteristics which were shown to significantly increase SI rates were: prednisone use, increasing age, chronic pulmonary comorbidity and specifically in those with rheumatoid arthritis male gender and total duration of bDMARD use.

Conclusion: In this real-world NO cohort of patients treated with a bDMARD for a rheumatic disease, we have identified a number of factors potentially contributing to the risk of the development of SIs. This study provides valuable data on SI rates in an Australian ‘real-world’ cohort that may assist clinicians’ choice of bDMARD in patients with a high baseline risk of infection and highlights the importance of minimising prednisone use in patients on bDMARDs.

SAT0582

RISK OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES: A NATIONWIDE, POPULATION-BASED COHORT STUDY

H. H. Chen,1,2, K. H. Ng2, W. C. Chao1, C. H. Lin1. 1Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China; 2Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; 3Taichung Veterans General Hospital, Department of Critical Care Medicine, Taichung, Taiwan, Republic of China

Background: To date, very few studies had investigated the epidemiology of interstitial lung disease (ILD) among patients with systemic autoimmune rheumatic disease (SARD).

Objectives: To study the risk of interstitial lung disease (ILD) among patients with various systemic autoimmune rheumatic diseases (SARDs) including rheumatoid arthritis (RA), dermatomyositis (DMtis), polymyositis (PM), systemic sclerosis (SSc), systemic lupus erythematosus (SLE), and primary Sjögren’s syndrome (pSS).

Methods: Using 1997–2013 claims data from the Taiwanese National Health Insurance Research Database, we identified 63,277 newly diagnosed patients with various SARDs after excluding those with overlapping SARD diagnoses from 2001-2013 (n=1,707,530) randomly selected 250,108 non-SARD subjects matching (1:4) SARD patients for SARD diagnosis, age, sex, and the year of the index date. We calculated the incidence rates (IRs) of ILD (ICD-9 code 515) in various SARD groups and the corresponding non-SARD comparison groups and estimated the IR ratios (IRR)s with 95% confidence intervals (CI) of ILD development. Using multivariable cox regression analyses, we estimated hazard ratios (HRs) with 95% CIs of ILD in various SARD groups compared with their comparison groups after adjusting for age, sex, Charlson comorbidity index, amiodarone use and methotrexate use. Sensitivity analyses were conducted by using a narrow definition of ILD.

Results: As shown in Table 1, the IRs of ILD were greatest in SSc patients (2,523 per 105 years), followed by patients with DMtis (2,463 per 105 years), PM (1,956 per 105 years), SSc (SSc) (601 per 105 years), RA (279 per 105 years), and SLE (276 per 105 years). Multivariable analyses showed that the risks of ILD were significantly increased in patients with SSc (HR, 66.01; 95% CI, 32.73—133.13), DMtis (128.74, 95% CI, 40.19—412.47), PM (HR, 13.98; 95% CI, 9.25—21.14), RA (HR, 15.00 SI/100PYs). Duration of time on a bDMARD, disease duration and use of methotrexate or leflunomide were not shown to significantly increase the risk of SI for the entire cohort. The characteristics which were shown to significantly increase SI rates were: prednisone use, increasing age, chronic pulmonary comorbidity and specifically in those with rheumatoid arthritis male gender and total duration of bDMARD use.

Conclusion: This nationwide, population-based, matched cohort study demonstrated that the risks of ILD were significantly increased in patients with SARDs.

SAT0583

DIPEPTIDYL PEPTIDASE-4 AND RISK OF PSORIASIS IN PATIENTS WITH TYPE 2 DIABETES

W. S. Chen,1 Y. S. Chang,2 C. Y. Tsai1, C. C. Chang. 1Division of Allergy, Immunology & Rheumatology, Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China; 2Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Shuang Ho Hospital, Taipei, Taiwan, Republic of China; 3Division of Rheumatology, Immunology and Allergy, Department of Internal Medicine, Taipei Medical University Hospital, Taipei, Taiwan, Republic of China

Background: The risk of psoriasis in diabetic patients has rarely been explored. Objectives: This study aimed to investigate the association between dipeptidyl peptidase-4 (DPP4) inhibitors and the risk of psoriasis in type 2 diabetes mellitus (T2DM) patients.

Methods: We conducted a population-based propensity score-matched cohort study on the basis of Taiwan’s National Health Insurance Research Database that included initiators of combination therapy with DPP4i (DPP4i plus metformin) and sulfonylurea (sulfonylurea plus metformin). Psoriasis (PSO) was identified with ≥2 diagnoses. Diabetes complications severity index (DCSI) was calculated. A total of 22721 DPP4 inhibitor and 227684 sulfonylurea inhibitor initiator were identified. A 1:1 matched-pair cohort based on propensity score (PS) was created. PS-stratified Cox proportional hazards models compared the risk of PSO in DPP4i versus sulfonylurea inhibitor within 2 years, controlling for potential confounders.

Results: After propensity score matching, 9962 patients with T2DM starting DPP4i combination therapy and 39848 starting sulfonylurea combination therapy were selected. The incidence rate of PSO was lower in DPP4i group (188/100000 person-years) than in sulfonylurea group (467/100000 person-years). Risks of
incident psoriasis were significantly lower in the DPP4i group versus sulfonylurea with the PS-stratified HR of 0.422 (95% CI 0.273 to 0.716).

Conclusion: DPP4i plus metformin was associated with a reduced risk of psoriasis than sulfonylurea plus metformin. These findings merit further investigation.

SAT0585

GEO-EPIDEMOLOGICAL OF AUTOANTIBODIES IN RA: DIFFERENT PREVALENCES IN FOUR ETHNICALLY DIVERSE RA POPULATIONS

E. C. De Moel1, V. Derksen1, L. A. Trouw1, C. Terao2, M. Tikly3, H. El-Gabalawy4, H. Bang5, T. Huizinga6, R. Toes7, D. Van der Woude7, 1Leiden University Medical Center (LUMC), Leiden, Netherlands; 2Kyoto University Graduate School of Medicine, Genomic Medicine, Kyoto, Japan; 3University of the Witwatersrand, Division of Rheumatology, Johannesburg, South Africa; 4University of Manitoba, Department of Internal Medicine, Winnipeg, Canada; 5Orgentec Diagnostika GmbH, Mainz, Germany

Background: Rheumatoid arthritis (RA) has been described in virtually every ethnic population. Most RA patients harbor anti-modified protein antibodies (AMPAs), including anti-citrullinated protein (ACPAs), anti-carbamylated protein (anti-CarP), anti-malondialdehyde acetylethanol (anti-MAA), and anti-acetylated protein antibodies (AAPA). However, it is unclear whether differences exist in the AMPA response between different ethnic groups. Such differences could provide new clues to genetic and environmental factors contributing to autoantibody development.

Objectives: To investigate the prevalence of different AMPA in four ethnically diverse RA populations, and their association with smoking.

Methods: Enzyme-linked immunosorbent assays were used to measure anti-CarP IgG, anti-MAA IgG (both in-house), and anti-acetylated vimentin IgG (Orgentec) in ACPA-positive sera of Dutch (NL, n=103), Japanese (JP, n=174), Canadian First Nations People (FN, n=100), and black South Africans (SA, n=67) fulfilling the 1987 ACR classification criteria for RA. Ethnicity-matched local healthy controls were used to calculate cohort-specific cut-offs. Logistic regression was used to identify whether ever-smoking was associated with AMPA seropositivity in each cohort, corrected for age, gender, and disease duration.

Results: For all three AMPAs, median levels were higher in FN and especially SA than NL and JP patients (Figure 1). The median autoantibody levels in arbitrary units (in % of patients positive) for NL, JP, FN and SA RA patients were: anti-CarP IgG: 1157 (47%), 994 (43%), 1642 (58%) and 2336 (76%) (p<0.001); anti-MAA IgG: 131 (29%), 179 (22%), 251 (29%) and 257 (53%) (p<0.001); AAPA: 133 (20%), 136 (17%), 153 (38%) and 316 (28%) (p<0.001). Prevalence, mean-positivity, also differed significantly between cohorts for all AMPAs (p<0.001). There were also marked differences in total IgG levels in mean (SD) g/L: 13 (4) for NL, 17 (6) for JP, 18 (6) for FN, and 25 (8) for SA (p<0.001). When the autoantibody levels were normalized to total IgG, the differences in became less pronounced between cohorts (Figure 2). The median arbitrary units per g/L Total IgG for NL, JP, FN and SA RA patients were: anti-CarP IgG: 54, 53, 53, and 79; anti-MAA IgG: 6, 5, 8, and 9; and AAPA: 2, 2, 2, and 3, suggesting that autoantibody level differences may partly correspond to cohort-specific differences in total IgG, although the overall trend of higher levels in SA persisted. There was no association between smoking and anti-CarP or anti-MAA positivity, with pooled OR (95% CI) of 1.31 (0.79-2.18) and 0.85 (0.46-1.56), respectively. However, smoking was positively and consistently associated with AAPA positivity in each cohort: pooled OR (95% CI) of 2.01 (1.06-3.81), respectively.

Conclusions: In these ACPA-positive ethnically diverse RA populations, levels and prevalence of various AMPAs differ, suggesting that ethnic background and environment may influence the development of the autoantibody response in RA. Despite these differences, our results imply smoking as a consistent risk factor for AAPA across different ethnic backgrounds.

SAT0584

SPECIFIC ACPA REACTIVITIES AND INFLAMMATORY BIOMARKERS ALONG WITH ULTRASOUND TENOSYNOVITIS ARE ASSOCIATED WITH ARTHRITIS ONSET IN A POPULATION AT RISK FOR RHEUMATOID ARTHRITIS

A. Cirumaru1, Y. Kisten1, M. Hansson1, V. Joshua1, M. Sun1, H. Rezaei1, E. Af Klint1,2, A. Antovic1,3, A. Catrina1,2,3, A. Hensvold1,3. 1Rheumatology unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; 2Rheumatology clinic, Karolinska University Hospital, Stockholm, Sweden; 3Center for Rheumatology, Academic Specialist Center, Stockholm Health Region, Stockholm, Sweden

Background: Anti-citrullinated protein antibodies (ACPA) are characteristic markers for rheumatoid arthritis (RA), developing years before disease onset. Early clinical and biological biomarkers could provide useful information on the onset of RA in predisposed individuals.

Objectives: The aim of the study was to investigate whether ACPA along with inflammatory markers and musculoskeletal ultrasound changes could predict arthritis development in individuals at risk for RA.

Methods: ACPA-positive individuals with musculoskeletal complaints were referred from primary care to a rheumatology clinic, recruited in the Risk-RA research program and followed-up for up to 3 years, between April 2014 and October 2019. All individuals lacked arthritis both at clinical examination by a trained rheumatologist and ultrasound assessment of hands and feet and any other symptomatic joints (according to EULAR-OMERACT definition). Blood samples were collected at inclusion and were analyzed for 15 ACPA fine specificities (by custom made peptide array), 92 inflammation-associated protein biomarkers (by multiplex immunoassay with Olink extension technology) and HLA-SE (DR low resolution kit). Statistical analysis used univariate and multivariate models with backwards selection and cox regression.

Results: 268 individuals with a median age of 48 (36-58) were recruited, out of which 212 (79%) were females. 75 (28%) developed arthritis within 11 months of follow-up while the median follow-up for those not developing arthritis was 21 months (14-28). Increased ACPA levels, shorter symptom duration and RF positivity were the main differences between individuals developing arthritis and those who did not. In univariate models, the presence of HLA-SE, specific ACPA reactivities, certain inflammatory markers and ultrasound-detected tenosynovitis were associated with arthritis development. In multivariate analysis the presence of anti-cit-filagrin (HR 2.1 (95% CI 1.2-3.7, p 0.001), IL6 levels (HR 1.4 (95% CI 1.2-1.7, p 0.0001) and tenosynovitis (HR 2.9 (95% CI 1.7-5.0, p 0.0001) remained significant predictors for arthritis onset.

Conclusions: Certain ACPA reactivities together with inflammatory markers and ultrasound-detected tenosynovitis predict arthritis development in predisposed individuals for developing RA.

SAT0586 PREVALENCE AND RISK FACTORS FOR CARDIO-METABOLIC ABNORMALITIES IN PATIENTS WITH INFLAMMATORY ARTHRITIS ATTENDING CARDIO-RHEUMATOLOGY PRIMARY PREVENTION CLINICS

L. Eder1, S. Akhtari1, P. Harvey1, K. Binder2. 1Women’s College Hospital, University of Toronto, Toronto, Canada; 2Sinai Health System, University of Toronto, Toronto, Canada

Background: Cardio-metabolic abnormalities are common in patients with inflammatory arthritis (IA) but tend to be under-recognized and under-treated. Objectives: We aimed to compare the prevalence and risk factors for cardio-metabolic abnormalities between patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS).

Methods: Consecutive patients enrolled in the University of Toronto Cardio-Rheumatology Network from July 2017 to August 2019 were analyzed. This is a primary prevention program that uses structured clinical, laboratory and multimodal imaging to diagnose and treat cardiovascular disease (CVD). Patients with a rheumatologist-confirmed diagnosis of RA, PsA or AS as well as unmarked CVD were evaluated. Information about IA diagnosis, medications and comorbidities was recorded. Each patient was evaluated by a cardiologist focusing on CVD risk assessment. We evaluated the prevalence of previously recorded and newly recognized cardio-metabolic risk factors including hypertension, dyslipidemia, obesity and diabetes. The prevalence of these abnormalities was compared between IA diagnoses. Regression models were used to assess the association between diagnosis and cardio-metabolic abnormalities after adjusting for demographics, smoking, BMI, measures of disease activity and medications.

Results: A total of 358 patients (201 RA, 124 PsA, 33 AS) were assessed (mean age 59±10.5 years, 68.7% female). Hypertension was reported in 33%, dyslipidemia in 26.8%, diabetes mellitus in 8.9% and overweight/obesity in 69.7% (Figure 1). Newly detected elevations in lipids were frequent for triglycerides (9.3%), non-HDL-cholesterol (6%) and LDL-cholesterol (2.7%). Elevated HbA1c occurred in 1.4% and newly diagnosed hypertension occurred in 9.8%. A total of 32.8% patients required a change or initiation of medications for their cardio-metabolic abnormalities (21.7% lipid-lowering therapy, 14.6% aspirin, 11.3% anti-hypertension therapy). Patients with PsA had the highest prevalence of cardio-metabolic abnormalities including dyslipidemia, obesity and hypertension. Having hypertension (prior or new diagnosis), elevated levels of triglycerides, non-HDL cholesterol, total cholesterol and BMI were associated with PsA vs. RA after adjusting for potential confounders (all p<0.05) (Figure 2). No significant association was found between cardio-metabolic abnormalities and AS vs. PsA or RA.

Conclusion: Dedicated cardio-rheumatology clinics have improved CVD screening and management in an IA population. The burden of cardio-metabolic abnormalities is elevated in PsA and suggests that tailored strategies to reduce adverse CVD events are particularly needed in this subgroup.

SAT0587 MACHINE-LEARNING DERIVED ALGORITHMS FOR OUTCOMES PREDICTION IN RHEUMATIC DISEASES: APPLICATION TO RADIOGRAPHIC PROGRESSION IN EARLY AXIAL SPONDYLOARTHRITIS

R. Garbol1, M. Resche-Rigon2, M. Dougdados1, D. Van der Heijde2, C. Roux1, A. Moltó1. 1Hospital Cochin, Rheumatology, Paris, France; 2Hospital Saint-Louis Ap-Hp, Paris, France; 3Leiden University Medical Center, Leiden, Netherlands

Background: Axial spondyloarthritis (axSpA) is a chronic rheumatic disease that encompasses various clinical presentations: inflammatory chronic back pain, peripheral manifestations and extra-articular manifestations. The current nomenclature divides axSpA in radiographic (in the presence of radiographic sacroilitis) and non-radiographic (in the absence of radiographic sacroilitis), with or without MRI sacroilitis. Given that the functional burden of the disease appears to be greater in patients with radiographic forms, it seems crucial to be able to predict which patients will be more likely to develop structural damage over time. Predictive factors for radiographic progression in axSpA have been identified through use of traditional statistical models like logistic regression. However, these models present some limitations. In order to overcome these limitations and to improve the predictive performance, machine learning (ML) methods have been developed.

Objectives: To compare ML models to traditional models to predict radiographic progression in patients with early axSpA.

Methods: Study design: prospective French multicentric cohort study (DESIR cohort) with 5 years of follow-up. Patients: all patients included in the cohort, i.e. 708 patients with inflammatory back pain for >3 months but <3 years, highly suggestive of axSpA. Data on the first 5 years of follow-up was used. Statistical analyses: radiographic progression was defined as progression either at the spine (increase of at least 1 point per 2 years of mSASSS score between 2 visits) or at the sacroiliac joint (worsening of at least one grade of the mNY score between 2 visits). Traditional modelling: we first performed a bivariate analysis between our outcome (radiographic progression) and explanatory variables at baseline to select the variables to be included in our models and then built a logistic regression model (M1). Variable selection for traditional models was performed with 2 different methods: stepwise selection based on...
Akaia Information Criterion (stepAIC) method (M2), and the Least Absolute Shrinkage and Selection Operator (LASSO) method (M3). We also performed sensitivity analysis on all patients with manual backward method (M4) after multiple imputation of missing data. Machine learning modelling: using the “SuperLearner” package on R, we modelled radiographic progression with stepAIC, LASSO, random forest, Discrete Bayesian Additive Regresssion Trees Samplers (DBARTS), Generalized Additive Models (GAM), multivariate adaptive polynomial spline regression (polymars), Recursive Partitioning And Regression Trees (RPART) and Super Learner. Finally, the accuracy of traditional and ML models was compared based on their 10-fold cross-validated AUC (cv-AUC).

**Results:** 10-fold cv-AUC for traditional models were 0.79 and 0.78 for M2 and M3, respectively. The 3 best models in the ML algorithm were the GAM, the DBARTS and the Super Learner models, with 10-fold cv-AUC of: 0.77, 0.76 and 0.74, respectively (Table 1).

**Table 1.** Comparison of 10-fold cross-validated AUC between best traditional and machine learning models.

**AUC: Area Under the Curve; AIC: Akaike Information Criterion; LASSO: Least Absolute Shrinkage and Selection Operator; SL: SuperLearner. N = 295.**

**Conclusion:** Traditional models predicted better radiographic progression than ML models in this early axSpA population. Further ML algorithms image-based or with other artificial intelligence methods (e.g. deep learning) might perform better than traditional models in this setting.

**Acknowledgments:** Thanks to the French National Society of Rheumatology and the DESIR cohort.

**References:**

**Results:** From 2008 to 2015, the prevalence of nontraumatic AVN increased gradually, but its incidence did not change, with an annual average incidence of 413 per 1 million population and the male-to-female ratio of 1.2:1. The peak incidence occurred in the 50-59 year age group. The incidence AVN was more prevalent in male than in female under 70, but there was female predominance after the age of 70 (Figure 1). The patients with AVN had a higher cumulative incidence of major adverse cardiovascular and cerebrovascular events than controls (19.5% versus 14.9%; p = 0.017). Upon univariate Kaplan-Meier method with the log-rank test, there was a significant difference in major cardiovascular and cerebrovascular events-free survival rates between AVN group and control group (p < 0.001). However, after adjusting for potential confounders including hypertension, diabetes, dyslipidemia, and use of steroid or statin, the association between AVN group and major adverse cardiovascular and cerebrovascular events was insignificant (adjusted HR 1.14, 95% CI 0.959-1.295, p=0.158).

**Conclusion:** In this population-based cohort study, we provided the updated epidemiologic data of Korean patients with nontraumatic AVN. The increased risk for major cardiovascular and cerebrovascular events among AVN patients was not observed in the representative Korean population.
separately, and pooled the results. The findings are expressed as odds ratios (OR) with 95% confidence intervals (95% CI).

**Results:** We identified an elevated risk for psychiatric (OR = 1.34, 95% CI = 1; 1.78) and for affective disorders (OR = 2.19, 95% CI = 1.17; 4.1) in people hospitalized for rheumatic diseases. We did not find a statistically significant association with organic, psychotic and anxiety disorders.

**Conclusion:** There is an increased risk for experiencing a psychiatric disorder in the period of 3 years after a rheumat-related hospitalization.

**SAT0590** ORAL MICROBIOTA IDENTIFIES PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

**Background:** Several studies have suggested a link between the two chronic inflammatory diseases, rheumatoid arthritis (RA) and periodontitis (PD) [1]. The diseases share similar environmental and genetic risk factors, e.g., smoking [2] and the HLA-DRB1 alleles [3]. Several serum markers used in the diagnosis of RA have also been found to be elevated in PD, e.g., anti-citrullinated proteins antibodies (ACPA) and rheumatoid factor (RF) [4]. The connection between PD and RA has been suggested to be explained by several periodontal pathogens, e.g., Aggregatibacter actinomycetemcomitans and Porphyromonas gingivalis, which have been suggested to induce the production of autoantibodies [5, 6].

**Objectives:** To investigate the composition of the combined saliva microbiota and its role in the development of RA, with the aim of improving the diagnostic tools. Kato, T. Human 16S rRNA gene sequencing of salivary bacterial DNA isolated from a total of 61 early RA (eRA) patients and 59 healthy controls was made. The eRA (symptoms ≤ 12 months) was diagnosed at an Early Arthritis Clinic (fulfilling the 365-day baseline period prior to pegloticase initiation). We measured the number and duration of pegloticase therapy. We assessed the risk of anaphylaxis, cardiovascular events including myocardial infarction or stroke, hospitalization for heart failure (new onset or exacerbations) while receiving pegloticase therapy.

**Results:** Among 2.9 million patients with ≥1 diagnosis code for gut, we identified only 483 (179 in Optum and 304 in MarketScan) pegloticase initiators. The mean age and % female was 55.6 years, 10.9% for MarketScan and 60.6 years and 17.3% for Optum (Table). Cardiovascular comorbidities were prevalent in both cohorts. Hypertension was present in up to 85%, diabetes mellitus in 38%, chronic kidney disease in 46%, and heart failure in 21% of the patients. As expected, use of gout-related medications at baseline was common. The median duration of pegloticase therapy was 93 days (interquartile range [IQR] 56-186) in MarketScan and 105 (IQR 56-127) in Optum. The median number of pegloticase infusions was 4 (IQR 2-10) for MarketScan and 5 (IQR 2-12) in Optum. In MarketScan, 57 (18.8%) patients switched to allopurinol, 64 (21.1%) to febuxostat, and 2 (0.7%) to probenecid during the mean 0.5-year follow-up time. Similarly, during the mean 0.5-year follow-up time in Optum, 38 (21.2%) patients switched to allopurinol, 34 (19.0%) to febuxostat, and 2 (1.1%) to probenecid. During the mean 0.5-year follow-up time on pegloticase, there were 3 (0.6%) anaphylaxis, 7 (1.4%) composite cardiovascular, 31 (6.4%) heart failure hospitalizations, and 0 (0.0%) deaths in both datasets.

**Conclusion:** Pegloticase is rarely used in gut, and the median duration of pegloticase therapy is 3 months. There were few anaphylaxis events captured in this claims-based study, while heart failure hospitalizations were common.

**Table.** Select baseline characteristics of pegloticase initiators

**SAT0592** MORTALITY AND CAUSE OF DEATH IN KOREAN PATIENTS WITH RHEUMATOID ARTHRITIS: BASED ON A LARGE COHORT.

Y.K. Lee1, G.Y. Ahn2, J. Lee3, J. M. Shin1, T. H. Lee1, S. C. Bae1,2,3. 1Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Korea University Guro Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 3Hanyang University Institute for Rheumatology Research, Seoul, Korea, Rep. of (South Korea)

**Background:** Rheumatoid arthritis (RA) is a common chronic inflammatory disease characterized by arthritis of multiple joints. Although the use of corticosteroid and extra-articular complications may lead increased mortality of patients with RA and it have been confirmed by hundreds of studies, the prognosis of RA has improved over the past decades with the introduction of biologics disease-modifying anti- rheumatic drugs and treat-to-target strategy. Along with the increase of overall survival of RA, the needs for re-assessment of actual life expectancy in patients with RA have also been increased.

**Objectives:** To investigate the cause and the risk of death of Korean patients with RA in a large RA cohort.

**Methods:** We analyzed patients in Hanyang BAE RA cohort who fulfilled the American College of Rheumatology criteria. A total of 2,385 patients were enrolled from October 2001 to December 2015. Mortality data were derived by linking with data from the Korean National Statistical Office and date and cause death were identified. Standardized Mortality Ratio (SMR) was estimated by dividing the observed death from the Korean population by all group: the adjusted SMR in patients aged 15-39, aged 40-59, aged 60-79, and aged 80 and over. Total SMR was increased [1.7, 95% CI 1.5-2.0] but age- and sex- adjusted SMR was not increased [SMR 1.0, (95% CI 0.9-1.1)]. When we classify patients by comorbidity, 40 cases) followed by respiratory disease (10.0%), pancytopenia (10.0%), spotless fever (8.2%), interstitial lung disease (4.8%), pleural (6.1%) and pericardial (4.1%) effusion. Over a median follow-up of 1.0 years, 10 patients (3.4%) were diagnosed with a SARD, only one being an ANA positive case. Causes of death were, 1 case of cancer, 1 case of chronic lung disease, 1 case of giant cell arteritis, 1 case of Sjogren syndrome and 1 case of sarcoidosis.

**Results:** Mortality data were derived by linking with data from the Korean National Statistical Office and date and cause death were identified. Standardized Mortality Ratio (SMR) was estimated by dividing the observed death from the Korean population by all group: the adjusted SMR in patients aged 15-39, aged 40-59, aged 60-79, and aged 80 and over. Total SMR was increased [1.7, 95% CI 1.5-2.0] but age- and sex- adjusted SMR was not increased [SMR 1.0, (95% CI 0.9-1.1)]. **SAT0594** LONG-TERM MORBIDITY FOLLOWING IGA VASCUITIS IN CHILDHOOD

J. ‘Nossent1,2, W. Raymond1, M. Ognjenivic1, H. Keen1,3, D. Preen4, C. Indejeeth1,2, 1The University of Western Australia, Rheumatology section, School of Medicine, Crawley, Australia; 2Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia; 3Fiona Stanley Hospital, Rheumatology, Murdoch, Australia; 4The University of Western Australia, School of Population and Global Health, Crawley, Australia

**Background:** IGA vasculitis (IGAV) in children is considered a mostly self-limiting disease. However, patients may require aggressive initial treatment, are prone to disease relapses and conceivably have a sustained abnormality in mucosal and/or circulating IgA responsiveness, that can predispose to the development of other conditions.

**Objectives:** To determine whether childhood IGAV predisposes to comorbidity later in life.

**Methods:** Observational cohort study examining rates of hospitalization, ED visits, procedures and accrual of comorbidity (by Charlson comorbidity index; CCI) comparing 494 IGAV patients <20 years at diagnosis with 1385 non-exposed matched controls over a 20-year period. Maximum likelihood estimates were used to obtain Odds (OR) and Rate ratios per 1000 person-years (RR).

**Results:** Hospitalization was increased proportionally (73.5 vs 51.5%) and by rate (21.7 vs 18.9; rate ratio 1.15) (both p<0.01) for IGAV patients, who underwent more diagnostic and medical procedures whereas controls had higher rates of surgical interventions. IGAV patients had an higher overall ED attendance (25 vs 16%) and visit rate (10.8 vs 8.43, RR 1.29) (each p<0.01) and accrued more often peptic ulcer and renal disease and developed severe comorbidity (CCI ≥3) at a higher rate (OR 2.9, 95% CI 0.79-11.6) than controls.

**Conclusion:** A diagnosis of IGAV in childhood associates with increased risk and rate of subsequent hospital admission, ED attendance and severe comorbidity.

**SAT0593** ANA TESTING IN THE (VERY) ELDERLY: EXPECTATION VERSUS REALITY

M. Luis1, A. Carmo3, R. Cunha2, J. A. P. Da Silva1,2, T. Santiago1,2. 1Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal; 3Centro Hospitalar e Universitário de Coimbra, Clinical Pathology, Coimbra, Portugal; 4Coimbra Institute for Clinical and Biomedical Research (ICBR), Coimbra, Portugal

**Background:** Antinuclear antibodies (ANA) are frequently used as a screening tool for systemic autoimmune rheumatic diseases (SARD), although they are also present in 10-15% of the adult healthy population. SARD have their peak incidence in the young’ when diagnosed in the adult. As age progresses, the incidence of SARD decreases while the prevalence of ANA tends to increase, with some series reporting up to 30% prevalence in older ages.

**Objectives:** To determine the clinical significance and utility of ANA testing in a population over 85 years of age.

**Methods:** We conducted a retrospective study of patients over the age of 85 who underwent ANA testing due to a SARD suspicion at our hospital autoimmunity laboratory from 2011 to 2018. Justification for ANA request was collected from patient’s clinical records. Patients with pre-established diagnosis of SARD and patients with no justification given for ANA request were excluded from the analysis. ANA titer (positive ≥ 1:160) and cellular staining patterns were assessed by indirect immunofluorescence (Hep-2 cells).

**Results:** Ages ranged from 85 to 98 years, with 58.8% being females. The prevalence of ANA in this population was 61.5%, mostly in lower titer (1:160 in 45.0%, 1:320 in 31.9%, 1:640 in 20.3% and 1:1,280 in 2.7%). Dense fine speckled pattern was by far the most common cellular staining pattern (79.1%). A suspicion of SARD was the reported reason for ANA testing in 34.5% (n=296) of the 854 patients submitted to this test. The main clinical clues justifying SARD suspicion were: arthralgia/arthritis (11.9%), thrombocytopenia (10.0%), pancytopenia (10.0%), spotless fever (8.2%), interstitial lung disease (4.8%), pleural (6.1%) and pericardial (4.1%) effusion. Over a median follow-up of 1.0 years, 10 patients (3.4%) were diagnosed with a SARD, only one being an ANA positive case. 5 cases of rheumatoid arthritis, 1 case of giant cell arteritis, 1 case of Wegener granulomatosis and 1 case of sarcoidosis.

Background: Hospital admissions and re-admissions in lupus patients are common occurrences that can lead to mortality. The predictive factors influencing hospitalizations and mortality are variable in literature.

Objectives: We evaluated the leading causes of hospitalizations and mortality and their predictive factors in the multi-ethnic SLE patients.

Methods: A retrospective study was done on SLE patients from University Malaya Medical Centre and diagnosed for at least 1 year. Data were collected from 1988 until 2019. Demographic and disease details, causes of hospital admissions and mortality were reviewed from electronic medical records. Baseline and latest disease activity (SLEDAI 2K) and SLICC/ACR damage index (SDI) scores were evaluated.

Results: A total of 300 SLE patients, 285 (95%) of whom were females were included in this study. Majority were of Chinese ethnicity 150 (50%), followed by Malys 108 (36%), Indians 39 (13%) and others 3 (1%). The cohort’s median age was 48 (18-82) years and median disease duration was 14 (1-72) years. Median age at SLE diagnosis was 27.5 (6-72) years. 133 (44.3%) had SDI score of ≥1 at baseline (early damage). 23% had developed new organ damage during this study period.

There were 222 (74%) patients ever hospitalized and 12 (5.4%) deaths from this cohort. The main cause of hospitalization was lupus flare which included concurrent infection (n=415 admissions, 46%), followed by elective admissions for procedures and others (n=284 admissions, 31.5%). 17% of admissions were due to infections with concurrent flare (8.7% were due to infection alone). Admissions for treatment and disease related complications were 13.8%. Median length of stay for SLE related cause admissions was longer compared to non-SLE related causes, 10 (range 1-113) vs 7.5 (range 1-130) days. Causes of death included SLE flare without features of infection (25%), concurrent lupus flare and infection causes, 10 (range 1-113) vs 7.5 (range 1-130) days. Causes of death included SLE flare without features of infection (25%), concurrent lupus flare and infection (25%), and non-SLE causes (50%). Malignancy (33.3%) was the main cause of death in non-SLE deaths. Independent predictive factors for hospitalization and mortality are shown in Table 1 and Table 2.

tendinitis, pain in joint; analgesia, gastric protector and NSAIDs; hypertension, dyslipidemia and diabetes respectively. The predictors with a greater negative impact in HRQoL were the use of 3rd level analgesics and azathioprine, a presence of kidney failure, fibromyalgia, and ischemic heart disease. Conversely, use of symptomatic slow action drugs for osteoarthritis, statins, lowering uric acid drugs, a diagnose of mixed connective tissue disease, and better HRQoL in the past six months were independently associated with a positive impact in the HRQoL.

**Conclusion:** We have identified several diagnoses, treatments and comorbidities independently associated with HRQoL in a cohort of patients followed up in a rheumatology outpatient clinic. This represents a first step in the implementation of value-based care for MSK patients, as we can now review the procedures of value-based care for MSK patients, as we can now review the procedures.

**SAT0599 FEET DERMATOLOGICAL CONDITIONS AND DEFORMITIES IN RHEUMATOID ARTHRITIS**

1Hospital Universitario Dr. José Eleuterio González UANL, Rheumatology, Monterrey, Mexico

**Background:** It has been extensively studied the repercussions of rheumatoid arthritis (RA) in hands and in their function. However, the evidence regarding the effect on feet and dermatological problems is scarce.

**Objectives:** Describe risk factors associated with foot deformities (FD) in patients with RA.

**Methods:** This was a descriptive and observational cross-sectional study. Patients were consecutively recruited. Demographic-clinical data was registered and through physical examination the presence of FD, dermatological problems and pain location were assessed. The Foot Function Index (FFI) survey was used to measure foot functioning. Functional capacity was evaluated using the Health Assessment Questionnaire (HAQ) tool and quality of life with the Rheumatoid Arthritis Impact Disease (RAID) questionnaire. The risk of falling was calculated with Tinetti's scale. An adjusted binary logistic regression was performed to compare patients with and without foot deformities. Models were adjusted for FFI's, HAQ's, RAID's, and Tinetti's scores.

**Results:** We included 76 subjects with RA with a mean age of 52.6 (11.40) years old. The 68.4% presented FD, while 69.7% had dermatological problems. Patients with FD were older (p=0.05), had a more affected function of their feet (p=0.002), greater risk of falling (p=0.002) and worst functional capacity (p=0.007) and quality of life (p=0.026). Some factors that increased the risk of having FD in patients with RA were: age (OR 1.07, 95%CI: 1.00-1.147; p=0.048), pain in toes and in the forefoot (OR 6.194; 95%CI: 1.722 – 32.743; p=0.027) and having dermatological conditions in feet (OR 0.244; 95%CI: 0.067 – 0.881; p=0.031).

**Conclusion:** Foot deformities and dermatological problems were present in more than the half of our sample. Older patients and subjects with dermatological problems and pain in toes and forefoot had a greater risk of presenting foot deformities.

**Background:** Risk of infection is increased in patients with autoimmune inflammatory rheumatic diseases (AIRD). Furthermore, disease-modifying antirheumatic drug (DMARD) treatment contributes to this risk. To reduce the risk of serious infections, it is recommended that patients are vaccinated against Streptococcus pneumoniae. However, some AIRD patients do not develop or maintain an adequate antibody response after pneumococcal vaccination.

**Objectives:** The aim of the study was to examine the proportion of patients with low antibody levels, who achieved a protective level of pneumococcal antibodies after vaccination.

**Methods:** Pneumococcal antibodies were measured by a serological assay in patients treated with biologics in a rheumatology outpatient clinic. Vaccination with 23-valent-pneumococcal polysaccarid vaccine was then offered to patients with a protective antibody level below the defined threshold and pneumococcal antibody level was measured at follow-up 2-3 months later. The patients continued their DMARD treatment without any changes.

*months ** kg/m², NS: not significative.
Demographic and clinical data were collected, including age, sex, AIRD diagnosis, duration and activity (high/low), in addition to treatment (biologics, prednisolone, methotrexate) and previous vaccination history.

**Results:** A total of 248 patients with inadequate antibody level accepted vaccination and among those, 137 patients (55%) had previously been vaccinated, 98 patients had not previously been vaccinated and for 13 patients data on vaccination status could not be obtained.

At follow-up, 84 patients (34%) achieved a protective level of antibodies. Use of methotrexate as part of the DMARD regimen was associated with an unprotected level of pneumococcal antibodies (Figure 1) ($p<0.001$). There was no similar association with respect to use of biologics.

At follow-up, 84 patients (34%) achieved a protective level of antibodies. Use of methotrexate as part of the DMARD regimen was associated with an unprotected level of pneumococcal antibodies (Figure 1) ($p<0.001$). There was no similar association with respect to use of biologics.

In the group of patients who had previously been vaccinated, time between vaccinations spanned from 20 to 111 months, median 49 months.

There was an association between previous vaccination, and failure in achieving a protective antibody level (Figure 1) ($p=0.02$), as well as an association between less than 5 years (60 months) between vaccinations and not achieving a protective level.

**Conclusion:** We found that only one-third of patients achieved a protective pneumococcal antibody level after vaccination. Methotrexate treatment was associated with a decreased antibody response, which was not the case for treatment with biologics or prednisolone.

Among patients who had previously been vaccinated, significantly less achieved a protective level of antibodies, compared to patients who had not been vaccinated. All 248 patients had a low antibody level at baseline, despite 137 being previously vaccinated.

Further studies are warranted to show whether or not a short discontinuation of methotrexate, will better the response to vaccination.

**DOI:** 10.1136/annrheumdis-2020-eular.1215
Background: Raynaud's phenomenon (RP) is a diffuse clinical manifestation (3-5% of general population) RP is often secondary to autoimmune systemic diseases, while the condition is classified primary if no underlying disorders can be found. A lower body mass index (BMI) was associated with a greater risk of developing RP, perhaps due to greatest sensitivity to cold temperatures.

Objective: The objective of our study was to evaluate the association of BMI with clinical and capillaroscopic features in primary and secondary RP.

Methods: Consecutive patients at the first access to a Rheumatology Outpatient Clinic over a 13 months period were screened to RP; nailfold videocapillaroscopy (NVC) was carried out and qualitative and quantitative assessment was performed. Diagnosis of RP was defined in patients who identified color pictures of witnessed attacks. Patients enrolled for secondary causes of RP. RP was classified as primary when no abnormalities were found. Weight and height were collected in clinical records and patients were divided in 3 groups according to their BMI: underweight (BMI < 18.5 kg/m²), normal weight (BMI 18.5–25 kg/m²), and overweight (BMI > 25 kg/m²). Chi-square test to compare categorical variable and Parametric Student t-test to comparing mean values of normally distributed data were used. p<0.05 was considered to be statistically significant.

Results: RP was diagnosed in 100 of 1416 patients (7.06%). Of these, 73 (10M, 63F) accepted to undergo NVC. An autoimmune disease was found in 35 patients (47.9%), of which 2 were underweight, 14 normal weight and 19 overweight. Of 38 patients with primary RP, 3 were underweight, 23 normal weight and 12 overweight. BMI was significantly higher in secondary RP (p<0.03). Overweight patients with secondary RP were older (p=0.01), but with a disease duration not statistically significant longer (p=0.26). In secondary RP, avascular areas and neoangiogenesis were found only in overweight patients. Moreover, secondary RP overweight was correlated with decreased capillary density (p=0.04). There was not association between BMI and capillaroscopic abnormalities in primary RP.

Conclusion: In our study BMI was correlated with microvascular changes only in patients with secondary RP. Our findings may suggest a role for obesity in the microcirculatory disfunction in the autoimmune diseases. Further studies are needed to generalize results and to find a causative role.

Graph 2. Forest plot of incidence of axial spondyloarthritis compared before and after introduction of new classification criteria in 2009

Conclusion: Rheumatoid arthritis is the most frequent IA diagnosis in newly referred patients, of which the incidence increased over time up to 15%. The introduction of new classification criteria might have introduced higher incidence rates for IA, although heterogeneity could have influenced the results.

Background: A higher prevalence of ischemic heart disease (IHD) in patients with systemic sclerosis (SSc) was reported. However, contrasting findings were published concerning the role of SSc-related autoantibodies in IHD risk which remains controversial.

Objectives: The current study explored the link between SSc and IHD, impact of putative links on SSc mortality and the role of SSc-related and antiphospholipid autoantibodies in disease associated IHD.

Methods: A large cohort study utilising the Cliait-Health-Service (CHS) database was conducted on 2,431 SSc patients and 12,710 age- and sex-matched controls. The proportion of IHD was compared between patients diagnosed with SSc and age- and gender-matched controls. The role of SSc-linked and antiphospholipid autoantibodies in disease associated IHD was assessed.

Results: The rate of IHD was significantly higher in SSc than controls (20.4% vs 15.0%, p<0.001). At the multivariate analysis, SSc was an independent predictor of IHD with an OR of 1.91 (95%CI 1.57-2.31, p<0.0001). SSc patients with IHD had a higher mortality rate with an HR of 2.67 (95%CI 2.03-3.53, p<0.0001) than those without IHD. SSc patients with positive anti-beta2GPI (IgM-isotype) or anti-cardiolipin (aCL) (IgG-isotype) exhibited a higher risk of IHD than SSc patients without these antibodies with an OR 1.69 (95% 1.04-3.45, p=0.0369) and OR 3.72 (95% 1.25-11.11, p=0.0184), respectively.

Conclusion: Patients with SSc are at higher risk for developing IHD with an additional risk for the latter in those positive for aCL or anti-beta2GPI. A high degree of suspicion is needed during routine patient follow-up and pre-emptive screening should be considered.

SAT0604 FAST FOOD HABITS AND SERUM URATE CHANGE IN YOUNG ADULTS: 15-YEAR PROSPECTIVE ANALYSIS

C. Yokose1, L. Lu4, N. McCormick1,2, J. Choi1,2, Y. Zhang1,2, H. Choi1,2
1Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; 2Massachusetts General Hospital, Clinical Epidemiology Program, Mongan Institute, Boston, United States of America; 3Arthritis Research Canada, Richmond, Canada

Background: Fast food consumption has strong positive associations with weight gain and insulin resistance. Obesity and insulin resistance are in turn strongly associated with elevated serum urate (SU) levels, largely mediated by insulin’s anti-uricosuric ability.

Objectives: To investigate the relation between fast food consumption and changes in SU over a 15-year period among young black and white adults in the United States.

Methods: Participants for the CARDIA study included 3,122 young (age 18-30 years in 1985-86) black and white adults in the United States who were followed up with repeated dietary and clinical assessments and had both baseline and year 15 SU measurement available. Frequency of fast food consumption (fast food frequency, FFF) was quantified on a semicontinuous scale and classified as <1, 1-2, or >2 times per week. We used multivariable linear regression models to investigate the association of FFF at baseline as well as change in FFF with 15-year changes in SU.

Results: Our analysis included data from 3,122 subjects who had SU data available both at baseline and year 15 (Table 1). After adjustment for age, sex, education, baseline height and weight, and baseline SU, baseline FFF (defined as 3 times per week year 0 differences between participants) was independently associated with increases in SU among both black (beta=0.11, p=0.04) and white (beta=0.11, p=0.01) adults. Change in FFF (defined as 3 times a week 15-year change within participants) was also independently associated with increases in SU among white (beta=0.09, p=0.01) individuals but not blacks (beta=0.03, p=0.93) (Table 2). There was a significant correlation between weight change and SU change (correlation coefficient 0.34, p<0.001).

Figure 1 depicts the joint associations of year 0 FFF and 15-year changes in FFF with change in weight. Compared to the average 15-year SU change among participants with baseline FFF <1 time per week and 15-year FFF change <0 time per week, those with high FFF at both baseline and follow-up had an extra 0.21 mg/dL increase (i.e., 75% of overall population SU increase over 15 years [0.28 mg/dL] in SU during that time. After adjusting for covariates in model 2, change in weight (beta=0.03, p=0.001) and homeostasis model for insulin resistance (HOMA) (beta=0.05, p<0.001) remained significantly associated with SU change.

</table>

Model 1: age, sex, education, baseline height and weight, baseline SU
Model 2: model 1 + alcohol, physical activity, and smoking (both baseline and year 15 change)

Conclusion: Fast-food consumption has strong positive associations with SU, suggesting that fast food increases the risk of hyperuricemia and gout. The observed association is likely mediated by weight gain and resultant changes in insulin resistance.

SAT0605  
TRENDS OF TOTAL JOINT ARTHROPLASTY AMONG PATIENTS WITH OSTEOARTHRITIS, RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS IN BRITISH COLUMBIA, CANADA 1998-2013

Y Zhou1, N Lu1, J Eslaili1,2, H Xie1,2, Arthritis Research Canada, Richmond, Canada; 1University of British Columbia, Vancouver, Canada; 2Simon Fraser University, Burnaby, Canada

Background: Total joint replacement or arthroplasty (TJA) is an expensive surgical treatment for severe arthritis when other treatments have failed. Given the substantial changes in the available treatments over the past 2 decades, it is of interest to describe the trends in the use of TJA among patients with different types of arthritis in the general population.

Objectives: The aim of this study was to examine longitudinal trends of TJA including total hip, knee and shoulder replacement performed in British Columbia, Canada, between the year of 1998 and 2013 due to three different types of arthritis conditions: 1) Osteoarthritis (OA), 2) Rheumatoid arthritis (RA) and 3) Ankylosing spondylitis (AS).

Methods: We analyzed large, population-based administrative data obtained from Population Data BC that includes patients aged 20+ in B.C., Canada, linked to diagnostic codes of hospitalizations and physician visits. Using the Canadian Classification of Diagnostic, Therapeutic and Surgical Procedures (CCP) procedure codes and the Canadian Classification of Health Intervention (CCI) procedure codes, we identified total joint arthroplasty procedures (TJA) including total hip arthroplasty (THA), total knee arthroplasty (TKA) and total shoulder arthroplasty (TSA) performed among OA, RA and AS prevalent cases. We calculated annual rates of THA, TKA and TSA performed among OA, RA and AS patients. We divided the study period into four equal-length periods and calculated period prevalence rates of THA, TKA and TSA per 100,000 person years as the ratio of the number of cases per period (numerator) to the total follow up time within the same period (denominator). We performed trend tests to test if there are changes in these rates over time.

Results: For OA and RA, TKA was the most common types of TJA performed, while THA remained to be the most common types of TJA performed among AS patients. For OA, period prevalence rate of THA, TKA and TSA increased during the study period (Table 1). For RA patients, THA and TKA rates showed a decreasing trend. For AS patients, THA rates decreased and TSA increased. For RA and AS, TSA rates did not show a significant trend.

Table 1. Trends in arthroplasty rates (cases per 100,000 person years) among patients with OA, RA and AS by arthroplasty site.

† P values were derived in Poisson regression analysis.

Among patients with OA, annual TJA rates per 100,000 persons show an overall increasing trend. The TJA rates remained relatively flat from 1998 to 2003, started to increase and peaked in 2006, and declined slightly thereafter (Figure 1). Among patients with inflammatory arthritis (RA and AS), annual TJA rates decreased over the study period (Figure 1). Annual proportion of TJA performed due to inflammatory arthritides significantly decreased from 1998 to 2013 (4.3% versus 1.0%) (Figure 2).

Conclusion: There have been important changes in the annual rate of total joint replacement in B.C., Canada, during the study period from 1998 to 2013. TJA use increased in OA patients but decreased in patients with inflammatory arthritis (RA and AS). Effective treatment for inflammatory arthritis, such as TNF-α inhibitors
HPR Epidemiology and public health (including prevention).

T. Thomsen1,2, M. Aadahl1, M. L. Hetland1, B. A. Esbensen2, Bispedbjerg and Frederiksberg Hospitals, Center for Clinical Research and Prevention, Copenhagen, Denmark;2Rigshospitalet, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark

Background: A recently conducted randomized controlled trial (Joint Resources Sedentary Behavior Intervention study (JR-SB)) aimed to reduce sedentary behavior and increase light-intensity physical activity in patients with rheumatoid arthritis (RA). Patients were recruited from a rheumatology outpatient clinic and the intervention consisted of three motivational counselling sessions followed by text message reminders. The results showed highly significant between-group differences on behavioral, patient-reported and cardio-metabolic outcomes, both on a short- and long-term basis (1,2). Since a relatively large fraction (58%) of invited patients initially declined to participate in the trial, we decided to explore if and how the declining patients differed from the included patients. The findings may inform which patient characteristics to consider in implementing a lifestyle intervention in clinical practice.

Objectives: To compare socio-demographic, clinical and lifestyle factors between included patients and patients declining to participate in the JR-SB study at the time where study inclusion commenced.

Methods: We conducted a retrospective register-based cross-sectional study. All patients with RA, who had been invited to participate in the JR-SB study during 2013-2014 were identified in the DANBIO registry. Patients' clinical and lifestyle data were also retrieved from DANBIO while data on socio-demography was extracted from Statistics Denmark. Differences between participants and decliners were determined by an independent t-test or chi-square test.

Results: Of invited patients (n=801), a total of 467 (58%) declined participation in the JR-SB study at the time where study inclusion commenced.

Conclusions: Patients who declined to participate in a randomized controlled trial aiming at reducing sedentary behavior were often smokers, had less regular exercise habits and were older than those who accepted to participate. This indicates that the intervention did not appeal to all patients with RA. The findings should be considered in the implementation of lifestyle interventions in clinical rheumatology practice.

SÁTURDAY, 06 JUNE 2020

HPR Service developments, innovation and economics in healthcare.

C. González1, L. A. Menchén Víso1, O. Baniandrés Rodríguez1, I. Marín-Jiménez2, J. C. Nieto1, I. Montaegudo1, A. Ais Larisgótia1, E. Chamorro de Vega1, E. Lobato Matilla1, R. Romero Jiménez1, A. Herranz Alonso1, C. Lobo Rodríguez2, M. P. Simón Moreno1, J. M. Alvaro-Gracia1, S. García de San José1.1Gregorio Marañón Hospital, CEIMI, Madrid, Spain. 2Rigshospitalet, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark

Background: Patients with immunity mediated inflammatory diseases (IMID) often have clinical manifestations and comorbidity in the field of various medical specialties. A center has been created in our hospital for the comprehensive care of patients with IMID who are being treated with biological therapies (BT) or targeted synthetic molecules (TSM). It is an innovative healthcare model, that incorporate patients into its governance. Physicians, pharmacists and advanced practice nurses (APN), collaborates in consultation or in the day hospital (DH).

Objectives: To analyze the activity developed during the first year of operation of the center, with special attention to effectiveness, efficiency, interdisciplinary relationships and patient satisfaction.

Methods: Observational analysis with indicators of management and monitoring of patients, care activity, effectiveness, adverse effects, resource consumption and patient satisfaction using the hospital's own information systems.

Results: Center staff during 2019: two admission assistants, one nursing assistant, six nurses, seven part-time doctors and three pharmacists. 1,490 patients were included: 694 (46.6%) Rheumatology (Rheu), 585 (39.3%) Digestive (Dig) and 211 (14.1%) Dermatology (Der) generated 11,363 medical consultations, 14,850 APN consultations and 3,920 treatment sessions in the DH. IV treatment 529/1490 (35.5%) patients (45.0% Reu, 53.9% Dig, 1.1% Der). Patients with rheumatic diseases: rheumatoid arthritis: 339/694, 48.8%; Spondyloarthriti- tis: 226/694, 32.6%; psoriatic arthritis: 117/694, 16.9%; and juvenile idiopathic arthritis: 12/694, 1.7%. 217/1490 (14.6%) patients needed multidisciplinary consultations.

Conclusions: From previous situation there is an increase in interdisciplinary consultations and HD activity maintenance without an increase in human resources. Efficiency (tapering, biosimilars) and patient and staff satisfaction have improved. However, no improvement in adverse effects has been
observed, which is an area of improvement. Effectiveness is good, waiting to compare with the previous year. Nutrition and preventive medicine consultations has not been evaluated because have been recently established. Other indicators are being analyzed at the end of the submission deadline.

The impact of this pioneering management model, with a holistic approach and incorporating patients into its governance, is difficult to measure until its implementation is completed. Uvetis and psychology consultations and patient school starting in 2020 will improve the quality of IMID patient care, as well as their satisfaction and that of their relatives.

SAT0608-HPR  DELPHI CONSENSUS FOR THE OPTIMAL TREATMENT & MANAGEMENT OF COMPLEX RHEUMATOID ARTHRITIS (RA) PATIENTS

G. Dulay1, E. Choy7, T. Barnes6, D. Chagadamda4, Z. Cole2, A. Malaviya2, S. Robinson5, D. Walker4, C. Daly10, N. Savill7, T. Warren7, N. Williams10 on behalf of a project funded by Roche Products Ltd. & Chugai Pharma Ltd., 1Queen Alexandra Hospital, Portsmouth Hospitals NHS Trust, Rheumatology, Portsmouth, United Kingdom; 2School of Medicine, Cardiff University, Cardiff, United Kingdom; 3Countess of Chester Hospital, Chester, United Kingdom; 4Barts Health NHS Trust, Rheumatology, London, United Kingdom; 5Salisbury District Hospital, Rheumatology;
Background: A significant proportion of patients with rheumatoid arthritis (RA) have additional considerations that must be taken into account for managing their disease. These include; co-morbidities, extra-articular manifestations and poor prognostic factors. Tailored management could reduce the burden on patients, the health system and wider society. The 'complex' RA patient group is ill-defined and no specific recommendations exist for their optimal management and treatment.

Objectives: A group of UK Rheumatology experts aimed to provide a set of recommendations to support consistent and high quality management, grounded in current evidence, expert opinion and best practice.

Methods: A steering group meeting identified priority topics associated with complex RA.

Table 1. Topics for consensus

<table>
<thead>
<tr>
<th>Topic</th>
<th>No. of statements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition of 'complex' RA from a medical perspective</td>
<td>19</td>
</tr>
<tr>
<td>Definition of patient factors that may contribute to 'complex' RA</td>
<td>3</td>
</tr>
<tr>
<td>Outcomes for RA patients with co-morbidities and/or extra-articular manifestations</td>
<td>5</td>
</tr>
<tr>
<td>Prescribing options for 'complex' RA</td>
<td>8</td>
</tr>
<tr>
<td>Evidence vs. best practice requirements</td>
<td>4</td>
</tr>
<tr>
<td>Burden of 'complex' RA</td>
<td>4</td>
</tr>
<tr>
<td>TOTAL NUMBER OF STATEMENTS</td>
<td>43</td>
</tr>
</tbody>
</table>

For each topic, the group defined statements they all agreed with. Delphi methodology was used to ratify these statements with rheumatology peers. High levels of agreement (over 70%) were achieved in the first round, the group proceeded to formulate the recommendations.

Conclusion: These recommendations are offered:

1. Healthcare professionals (HCPs) should consider a patient’s complexity (including clinical co-morbidities, extra-articular manifestations and poor prognostic factors) prior to making treatment decisions;
2. HCPs should take into account a patient’s psychosocial factors and health literacy prior to making treatment decisions;
3. Patient specific outcomes for complex RA should always be proactively agreed with the individual and/or their carers;
4. The local healthcare system should consider the overall costs of complex RA, beyond drug acquisition costs to allow flexibility of prescribing choices, as necessary in this group of patients;
5. Local treatment pathways should reflect that treatments with particular modes of action are more suitable for individual patients with complex RA.

6. Management of complex RA patients should extend beyond guidelines and recognise additional sources of evidence including; clinical studies, Real World Experience (RWE) and post-marketing surveillance.

acknowledge the persons own views rather than focusing on the “system”, regulations and standards. In addition, 4 sub-themes were identified: 1) “empowerment and disempowerment”, covering how most patients want to be in control and take action but they may lack the energy and ability to express their needs and thus give up; 2) “Lack of communication and coordination”, involving processes between the staff in the same department, between departments or sectors. Patients feel forced to take on coordinating tasks themselves, which they do not feel qualified to perform; 3) “Interventions meant as help may be felt as restrictions”, which encompass i.e. free physical therapy delivered at times not appropriate for the patient and types of support which can lead to a feeling of social control, and finally, 4) “The system is difficult to get through”: Information about possible support are provided at random and some ask for a coordinating person.

Conclusion: Facilitators for coherent pathways among people with I A encompass dedicated professionals working with a person-centered approach aiming to empower people. This encompasses to provide relevant knowledge and enable the person to ask for the right type of help. A coordinator may facilitate coherence.

HPR Professional education, training and competencies.

SAT0611-HPR LOW ADHERENCE TO RECOMMENDED PHYSICAL THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A MIXED-METHOD CONTENT AND UTILIZATION ANALYSIS.

E. Vanaugaerts1, M. Kaerts2, W. Danckaerts2, K. De Vlam1, T. Swinnen2, T. Dierickx2, 1KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; 2KU Leuven, Research Group for Musculoskeletal Rehabilitation, Leuven, Belgium; 3University Hospitals Leuven, Division of Rheumatology, Leuven, Belgium

Background: Patients with axial spondylarthropathy (axSpA) encounter limitations during daily activities and societal participation which seriously impair health-related quality of life. Optimal management of axSpA consists of combined pharmacological and non-pharmacological treatment modalities, including the encouragement of exercise and the consideration of physical therapy given the latter’s superior efficacy. Few studies investigated the use of physical therapy and the alignment of treatment content with practice recommendations among patients with axSpA.

Objectives: 1) To estimate physical therapy use in patients with axSpA in a real life cohort; 2) To quantitatively and qualitatively describe the content of these physical therapy sessions; 3) Explore possible determinants of physical therapy use and content.

Methods: This cross-sectional study included 197 patients diagnosed with axSpA (Males/Females: 62.4/37.6%; mean±SD, age 42.6±12.0, BASDAI 3.7±2.1, BAI 3.6±2.4, BASMI 3.4±1.8) and recruited during their routine consultation. The mixed-method approach included questionnaires (physical therapy use and content, medication, depression/anxiety (HADS), fear (TSK), physician global disease activity (PGDA) and an in-depth qualitative interview (content of physical therapy). Interviews were analyzed using the Qualitative Analytical Guide of Leuven by two physical therapists. Spearman’s Rho correlations guided the exploration of determinants of physical therapy use and content.

Results: Less than half (42.6%, n=84) of the axSpA of patients were in treatment with a physiotherapist. Most patients (40.0%) reported a physical therapy frequency of 1x/week, Session duration was typically 30 minutes (51.7% of the sample) and longer in fewer cases (30.0%). Exercise was in only 31.7% the cornerstone of their sessions. The majority of subjects (53.3%) were classified as receiving ‘passive therapy only’, with 10% of cases in the ‘exercise only’ and 36.7% in the ‘combination therapy group’. Interviews also revealed a lack of clear patient-centered treatment goals. We found moderate associations between physical therapy use/content parameters and medication, spinal mobility, fear, anxiety, depression, physician’s global disease activity versus (p<.05), but no relationship with patient-reported pain or disease activity.

Conclusion: Despite the importance of exercise and the added value of physical therapy in axSpA, few patients engaged in physical therapy sessions that include exercise training of adequate dosage. Remarkably, physical therapy utilization seems to be predominantly guided by psychological factors. Professional education for physical therapists should therefore include skills training in the management of complex clinical presentations. Last, future research should prepare the evidence-based implementation of state-of-the-art physical therapy guidelines in axSpA.

Rehabilitation

SAT0612 TEAM-REHABILITATION BENEFITS BODY COMPOSITION AND FUNCTIONAL OUTCOME BEYOND TIME OF THE REHABILITATION PERIOD IN INFLAMMATORY ARTHRITIS, OF WHICH BODY COMPOSITION IS LINKED TO CHANGE IN LEVEL OF CARDIORESPIRATORY FITNESS, WHEREAS MUSCLE MASS AND STRENGTH ARE LINKED TO PHYSICAL FUNCTIONING.

Background: Low physical activity, accumulated disability and disease chronicity contribute to adverse body composition and reduced cardiorespiratory fitness in patients with chronic inflammatory diseases. In the general population, physical exercise improves body composition, muscle strength and aerobic capacity but in inflammatory diseases it is not well established.

Objectives: To investigate whether 1) exercise intervention in patients with arthritis affects body composition, physical and aerobic capacity, and whether 2) body composition and physical capacity could explain outcomes as HAQ and aerobic capacity.

Methods: Consecutive patients with inflammatory arthritis and a clinical need for rehabilitation, aged 18-80 years, participated in a team-rehabilitation program for 4 weeks. Anthropometry, body composition assessed with bioelectrical impedance analysis, muscle force with hand grip strength and Times sit-to-stand test (TST), activity limitation with the HAQ score and cardiorespiratory fitness with the Åstrand 6-minute cycle test for VO2 max were measured pre-rehabilitation and after 3 and 12 months. The ANOVA model with Bonferroni correction, adjusted for age, sex and baseline measures, was used for the pairwise comparisons of repeated measures overtime. Association between body composition, physical functioning, and the course of HAQ and cardiorespiratory fitness for 12 months was determined with linear mixed models adjusted for age, gender, and comorbidity.

Results: The study evaluated 149 patients with rheumatoid arthritis (RA), psoriasis arthritis, spondylarthritars and juvenile idiopathic arthritis, aged mean (SD) 53(13) years, 74% women, disease duration 21(13) years, HAQ 1.1(0.6) at inclusion and DAS28 4.1(1.3) for those with RA.

There was a statistically significant reduction of BMI between pre-rehabilitation and after 3 months, reduction of waist circumference, body fat, fat mass and the fat mass index after 3 and 12 months, adjusted p<0.05. The muscle mass of total body, arms and legs did not change significantly post-rehabilitation compared to pre-rehabilitation. Hand grip strength and TST improved together with reduction of HAQ and increased VO2 max after 3 and 12 months, adjusted p<0.05 adjusted for age, sex and baseline measures.

The HAQ overtime was independently associated with total body muscle mass, legs muscle mass, hand grip strength, and TST pre-rehabilitation, but not to the change of body composition overtime.
The course of VO2 max overtime was independently associated with pre-rehabilitation BMI, waist circumference, muscle mass of total body, arms and legs, fat mass, body fat, the fat mass index and TST, as well as with change of BMI, waist circumference, fat mass and the fat mass index between pre-rehabilitation and after 3 and 12 months. 

Conclusion: We observed benefits of intervention with a team-rehabilitation program for 4 weeks on body composition profile, functioning, physical limitation and cardiorespiratory fitness, which were presented beyond the time of the rehabilitation period for up to 12 months. Different aspects of body composition and physical capacity were associated with levels of disability measured with HAQ and with cardiorespiratory fitness. This study indicates that in patients with inflammatory arthritis, muscle mass and strength were linked to HAQ over time, whereas the measures of body composition could be more linked to cardiorespiratory fitness than to HAQ.

HPR Interventions (educational, physical, social and psychological)

**SAT0613-HPR**

**EFFECT OF CERVICAL STABILIZATION EXERCISES ON CERVICAL POSITION ERROR IN PATIENTS WITH SPONDYLOARTHRITIS: A RANDOMIZED CONTROLLED TRIAL**

H. E. Oz1, D. Bayraktar2, M. Kara1, D. Solmaz1, S. Akar1. 1Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; 2Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey

**Background:** Proprioception sense might be deteriorated due to joint related diseases. Different exercise programs were shown beneficial for improving proprioception sense. However, the effect of exercise on cervical position error was not investigated in patients with axial spondyloarthritis (axSpA).

**Objectives:** To investigate the effect of cervical stabilization exercises on cervical position error in patients with axSpA.

**Methods:** Thirty-nine patients with axSpA were randomly allocated into two groups as exercise group (n: 20, 11 males) and control group (n: 19, 12 males). All patients were evaluated regarding to physical characteristics (age, body-mass index), disease activity (Bath Ankylosing Spondylitis Disease Activity Index), functional status (Bath Ankylosing Spondylitis Functional Index), and spinal mobility (Bath Ankylosing Spondylitis Metrology Index). Cervical position error was evaluated in flexion, extension, rotation and lateral flexion directions and was calculated using a special formula (1). All evaluations were performed at baseline and after six weeks. Exercise group performed a progressive home-based cervical stabilization exercise program, while the control group did not receive any exercise intervention. Exercise adherence control and exercise progression was delivered by sending messages and video instructions via a freeware and cross-platform messaging service (WhatsApp Messenger) in a weekly basis.

**Results:** Baseline physical and disease related characteristics were similar between groups (p>0.05, Table 1). Exercise group showed significant improvements in all directions related to cervical proprioception following six weeks (p<0.05, Table 2), however, no improvements were observed in the control group (p>0.05, Table 2).

**SAT0614-HPR**

**IDENTIFYING AND OPTIMISING MULTIPLE INTERVENTION COMPONENTS AND THEIR DELIVERY WITHIN A SELF-MANAGEMENT SMARTPHONE APP FOR PEOPLE WITH SJÖGREN’S SYNDROME: A QUALITATIVE STUDY**

C. McCullum1, M. Campbell2, J. Vines1, T. Rayple1, K. Hackett1. 1Northumbria University, Newcastle upon Tyne, United Kingdom; 2Teesside University, Middlesbrough, United Kingdom

**Background:** Sjögren’s syndrome (SS) is an autoimmune rheumatic disease with diverse symptoms including mental and physical fatigue, dryness, pain and sleep disturbances. These symptoms are interconnected and rarely occur in isolation. Improving symptoms and quality of life requires people with SS to navigate multiple interventions and engage in self-management. Smartphone applications (apps) can deliver multiple cognitive and behaviour-based interventions in users’ everyday daily lives and are readily accessible. However, delivering several therapeutic interventions together within a single coherent self-management app requires systematic and evidence-based selection of intervention components, and an understanding of existing self-management approaches and their associated challenges for those living with SS.

**Objectives:** To identify theory-based intervention components for inclusion in a SS self-management app. To understand the self-management approaches and challenges of those living with SS.

**Methods:** First, to identify intervention components within the app, existing interventions that target each symptom of fatigue, dryness, pain, sleep disturbance were identified through a literature search. Their content was coded by the research team using behaviour change techniques and the Theoretical Domains Framework. The content was grouped to form five intervention components which target multiple symptoms. Second, to understand SS self-management approaches and challenges, 13 people living with SS took part in a series of qualitative focus groups (n=6) and design workshops (n=7). Focus groups involved participants discussing their own self-management experiences and approaches (e.g. when and how they employed a variety of techniques). In design workshops participants sketched methods to explain these experiences and used craft materials to create "Magic Machines" addressing their self-management challenges. Focus groups and design workshops were audio-recorded, transcribed, thematically analysed as a single data set, and findings mapped to the self-determination theory dimensions of capability, autonomy, and relatedness.

**Results:** Intervention components identified were: i) SS psychoeducation, ii) relaxation techniques, iii) activity pacing and goal setting, iv) assertiveness and communication skills, and v) sleep and dryness tips. Participants tackled complex symptom patterns (i.e. symptom interrelatedness and flares) using different self-management approaches; reactively (focusing on the most severe symptom) or systematically (one symptom at a time). Knowing which intervention techniques to choose was felt to be challenging; however the availability of multiple interventions techniques provided a sense of optimism.
and motivation. Participants were enthusiastic about accessing several inter-
vention techniques via an app, but warned that smartphones and technology can
cateract mental fatigue and eye dryness. The invisible nature of symp-
toms, and highly visible nature of mobile management techniques (e.g., applying eye-
drops), presented further self-management challenges relating to their inter-
actions with other people.

Conclusion: Promising components to include in an SS app were identified
but should be tested in an optimisation trial. The in-app delivery of component
modules should be designed to support diverse self-management approaches,
choice and autonomy, yet provide module recommendations and guidance when
needed, and be simple to use to reduce mental fatigue and dry eye symptoms. A
self-management app should also be designed to enable users to share informa-
tion about SS with other people.

SAT0815-HPR FACTORS ASSOCIATED WITH PATIENT ACTIVATION
IN PEOPLE WITH RHEUMATIC CONDITIONS
B. Jones12, A. Hunt1 S. Hewlett1, D. Harcourt1, E. Dures12, University of the
West of England, Bristol, United Kingdom; 2University Hospitals Bristol NHS
Foundation Trust, Bristol, United Kingdom

Background: Patient activation describes the skills, abilities and confidence
someone uses to actively manage their health. Patient activation abilities in rheu-
matology are unclear, and there is little knowledge about factors that explain vari-
ation in patient activation. Therefore, understanding these factors can contribute
to the development of appropriate, rheumatology-specific interventions targeting activation. The Patient Activation Measure (PAM) captures patient activation and provides people with both a score and a level to describe how able they are to actively manage their health.

Objectives: To explore longitudinal changes to patient activation (measured using the PAM) (Hibbard et al., 2005), and the PAM’s associations with related constructs (including self-efficacy, health literacy and health beliefs) in a sample of participants with inflammatory arthritis.

Methods: A postal survey was administered at two time points that were nine months apart. This survey captured the PAM and a range of clinical, demographic and psychosocial variables in a sample of rheumatology patients from 6 NHS sites in England. The measures included in the survey had been selected based on both theory and prior qualitative research and the survey pack was designed in collaboration with a patient partner. Following data collection, candidate variables for a multiple regression analysis were initially identified using univariable analysis. These variables were included in a forced entry multiple regression at each time point, and the variables that were statistically significant contributors at a 0.1 level were included in the final models. Changes to PAM scores over time were investigated using a Wilcoxon matched-pair signed rank test.

Results: 251 participants completed the first survey and 154 participants com-
pleted both full surveys. Self-efficacy, illness beliefs, health literacy and health
locus of control were consistently associated with variance in PAM scores. The first three factors were also predictive of variance in PAM levels. With the 154 participants who fully completed both surveys, there was a statistically significant difference in participants’ PAM scores between the two surveys.

Conclusion: The findings suggest factors that may be targets for interventions that aim to increase patient activation. The changes to PAM scores across the data collection period also suggest that when using the PAM as a clinical tool, healthcare professionals would benefit from incorporating regular reviews and preparations for any increases or reductions in patient activation.

SAT0816-HPR IMPLICATED FACTORS IN THERAPEUTIC ADHERENCE
OF PATIENTS WITH RHEUMATOID ARTHRITIS: THE PATIENT’S PERSPECTIVE
M. Ahijón1, P. Carreira2, C. De La Cruz1, R. Veiga3, C. Gutierrez4, 1Hospital
Universitario Central de la Defensa Gomez Ulla, Rheumatology, Madrid, Spain; 2Hospital Universitario 12 de Octubre, Rheumatology, Madrid, Spain

Background: Therapeutic adherence has become a topic of growing interest for medical research. Studies have reported non-adherence rates of 20-50% in rheumatoid arthritis (RA) patients (1). Poor adherence has a negative impact on disease outcomes and implies an economic burden for the health system (2). Identifying the potential risk factors for non-adherence is essential to develop intervention strategies to solve this problem

Objectives: To establish the contribution of illness and medication beliefs to therapeutic adherence in RA. To explore the association of treatment adherence with other patient and disease factors.

Methods: RA patients ≥ 18 years old from a military hospital diagnosed with RA based on ACR /EULAR 2010 criteria were included in a cross-sectional study.

Compliance Questionnaire Rheumatology (COQR) was used to assess treatment adherence. Unsatisfactory compliance was defined as taking correct dosing <80%. Illness and medication beliefs were evaluated using the “Brief Illness Per-
ception Questionnaire” (“IPQ-b) and the “Beliefs about medicine questionnaire” (BMQ). Demographic data and clinical characteristics were collected by stand-
ardized clinical interview and revision of medical records.

Results: 144 patients were included the study, 106 (73.6%) women, with a mean age of 62 years (SD 12) and median disease duration of 5 years (interquartile range 25-75: 2-11), 113 (78.4%) patients showed good treatment adherence. No differences were observed regarding demographies and clinical character-
istics. Strong beliefs about drugs potential damage was associated with poor compliance (13±s vs. 11±s, p= 0.015), meanwhile increased belief in medica-
tion necessity was associated with good compliance (21±3 vs. 20±3, p= 0.015).

From the illness perception measures, adherent patients had increased feeling of control (8.8± 1.5 vs 7.7± 2.1;p= 0.008) and greater emotional response (6.2±3.1 vs 4.8±3.4;p= 0.042). In a multivariate analysis was found that for each unit of increase in the score of BMQ’s damage domain, adherence was reduced by 20% (CI 95% 0.7-0.9, p= 0.001); for each unit of increase in the treatment control item of the IPQ-b, adherence increased 1.42 times (CI 95% 1.1-1.8, p= 0.006); and for each unit of increase in the emotional response item of the IPQ-b, adherence increased 1.2 times (CI 95% 1.08-1.46;p= 0.002).

Conclusion: Illness and medication beliefs could influence compliance to treat-
ment in patients with RA.

SAT0617-HPR QUALITATIVE STUDY EXPLORING THE
BARRIERS AND FACILITATORS TO HOME-BASED
EXERCISE PROGRAMS ADHERENCE WITH KNEE OSTEARTHRITIS: THE PERSPECTIVES
PHYSIOTHERAPISTS AND PATIENTS.

H. Aközü1, N. Serenmel Aydin2, Z. Sari3, M. Birtanel1, E. Tonguç1, 1Trakya University, Physical Medicine and Rehabilitation, Edirne, Turkey; 2Marmara University, Physical Therapy and Rehabilitation, Istanbul, Turkey

Background: Home exercise programs are widely used in the treatment of knee osteoarthritis (OA). However, adherence to these exercises decreases in the long term due to different factors. In recent years, new approaches are being developed to improve exercise adherence (EA) for patients with OA. Although it is known that EA is low in Turkish patients, there is no study that examines the
bars of adherence to home exercise programs in patients with OA by qualitative research methods.

Objectives: Aim of our study was to investigate the barriers and facilitators for adherence of home-based exercises for knee osteoarthritis management from the perspective of physiotherapists and patients.

Methods: A Qualitative study by using focus groups discussions and semi-structured interviews were designed to investigate the barriers and facilitators to home-based exercise program adherence for OA. Two researchers facilitated focus group interview. Participants of focus group members were eight physiotherapists (PT) working with OA with different experience levels. Third researcher conducted the interviews which lasted 30-60 minutes with patients (patients with knee OA, n=5 ages>50). Data were audio recorded, transcribed verbatim and thematically analyzed with NVIVO 12 software. Three researchers conducted the thematic analysis to ensure the validity.

Results: In total, 25 main themes from the focus group discussions and interviews were determined. Major barrier themes from focus group were (a) beliefs to exercise benefits (b) patient education and (c) clear avoidance beliefs on exercise; from the interviews were (a) negligence of self-management (b) fatigue and (c) patient education. Patients and therapists all agreed for patient education one is of the most important factors for home EA. Patients wanted to get education on arthritis management. A patient said: "Actually, the clinicians should give information more deeply. I don't know which is correct for me after therapy, resting or moving?" Major facilitator themes from the focus group were (a) motivation from PT (b) client-centred exercise (c) digital technology; from interviews were (a) motivational approaches of therapists (wants-up messages) (b) having pain and (c) patient education for disease management. Therapists agreed on that personalized exercise was the most important facilitator. A therapist commented, "If the personalized exercise given the patient with correct intensity and repetitions, I don't think that patients would not do their home exercises."

Conclusion: This is the first qualitative study about exercise adherence in knee osteoarthritis in Turkey. It has been determined that the lack of education and motivation are the most important barriers. More studies are needed to examine the factors affecting EA for patients with OA. In future studies, implementations to increase home EA on Turkish patients with OA should be investigated by qualitative research methods.

PATIENTS WITH INFLAMMATORY MYOPATHIES WHO DO NOT REACH HEALTH ENHANCING LEVELS OF PHYSICAL ACTIVITY REPORT HIGHER LEVELS OF ANXIETY AND DEPRESSION - A CROSS-SECTIONAL STUDY OF SELF-REPORTED DATA

K. Andreasson1,2, H. Sandlund3, H. Alexanderon1,2, K. Karolinska Institute, Department of Medicine, Stockholm, Sweden; Karolinska University Hospital, Unit of Physical Therapy, Stockholm, Sweden; Karolinska University Hospital, Unit of Rheumatology, Stockholm, Sweden

Background: The adult idiopathic inflammatory myopathies (IIM) comprise dermatomyositis (DM), polymyositis (PM), immune-mediated necrotizing myopathy (IMNM), antisynthetase syndrome (ASS), overlap myositis and inclusion body myositis (IBM). Impaired physical capacity, self-reported fatigue and pain are common features in IIM. Quality of life is reduced compared to population-based reference values. To our knowledge self-reported levels of physical activity has not been studied in patients with IIM. Further, anxiety and depression are common in other rheumatic diseases, such as SLE, but is less studied in IIM, and not previously in relation to levels of physical activity. There is evidence for symptom reducing effects of exercise for patients suffering from depression (1).

Objectives: The objective of this study is to assess the levels of self-reported physical activity, depression and anxiety amongst adult patients with IIM. A further aim is to evaluate differences in anxiety/depression based on levels of physical activity as well as to analyze relationships between physical activity and anxiety/depression.

Methods: All patients with IIM visiting the Rheumatology clinic at Karolinska University Hospital in Solna between February 2019 and January 2020 where asked to fill in questionnaires about their levels of physical activity for the last seven days using the International Physical Activities Questionnaire – short form (IPAQ), and anxiety and depression using Hospital Anxiety and Depression Scale (HADS). The myositis team nurse distributed the questionnaires. Spearman’s rho was used for correlation analysis. Kruskal-Wallis test and post-hoc adjustment with Bonferroni correction was used to analyze group differences. HADS is scored in two separate scales, one for depression (HADS-D) and one for anxiety (HADS-A). The cut-off value for probable depression or anxiety is ≥8 of a maximum of 21 per scale (2). IPAQ-results was scored as 1 (low, < 150 min/w), 2 (moderate, ≥ 150 min/w – health-enhancing levels of physical activity, HEPA, according to WHO) and 3 (high, ≥ 300 min/w).

Results: A total of 61 patients answered the questionnaires. 52 (85 %) of the patients reported to reach HEPA and 24 of these patients reported to be active on a high level. 22 patients (36 %) scored probable anxiety or depression, with six scoring ≥8 for both depression and anxiety. Patients with low levels of physical activity (IPAQ-1) scored significantly higher anxiety and depression compared to those reaching HEPA (IPAQ-2 and IPAQ-3) p<0.0001 – 0.020. The correlation between physical activity and depression (Fig. 1) was r=-0.48 (-0.66; -0.26) and between physical activity and anxiety (Fig. 2), r=-0.43 (-0.49; -0.49).

Conclusion: Self-reported data indicates that most patients with IIM in this sample reached HEPA level or higher. Patients who do not reach HEPA score significantly higher anxiety and depression compared to those reaching HEPA. However, levels of physical activity correlates moderately to depression and weakly to anxiety. The number of patients who reached HEPA is high compared to studies in rheumatoid arthritis or the general population. This could be explained by frequent visits to physical therapists early in the disease and yearly check-ups with a focus on exercise and physical activity. Further the inter-professional myositis team also has a focus on exercise and the importance of everyday physical activity. This is cross-sectional, self-reported data and longitudinal studies are needed also including objective measures. This is preliminary data with data collection ongoing throughout 2020.

References:
to record information regarding their use of glucocorticoids during the “last 7 days” and during the “last 6 months”. We retrieved 132 questionnaires (of whom 6 were discarded as incomplete). All data was analyzed using SPSS Statistics v22.

**Results:** Of the 126 patients (mean age 74.9 ± 7.7 years), 59% were female. The mean duration of disease was 22.5 ± 19.1 months in patients with GCA and 32.9 ± 29.9 months in those with GCA and polymyalgia rheumatica (PMR). The mean daily number of medications taken was 9.2 ± 5.2 (range: 1 - 30); the mean number of types of daily tablets taken was 5.0 ± 2.1 (range: 1 - 10). The mean daily number of glucocorticoid tablets taken was 3.2 ± 2.6 (range: 0 - 20); with a mean daily dose of 11.1 ± 10.3 mg (range: 0 - 60 mg). Overall, in the last 7 days, 22% and in last 6 months, 40% of patients were not following their original recommended steroid regimens (Table 1). The total mean glucocorticoid dose in the “last 7 days” group (n=81) was 778 ± 70.1 mg/week (11.1 ± 10.1 mg/day) whilst the total mean glucocorticoid dose in the “last 6 month” group (n=45) was 1782.0 ± 1543.3 mg/6 month (9.9 ± 8.6 mg/day). Most respondents stated their glucocorticoid non-adherence was due to medical advice; other reasons included forgetting, fear of side effects, or confusion about different preparations of prescribed glucocorticoids. The presence of PMR did not influence glucocorticoid adherence.

**Conclusion:** There is significant variation in the use of glucocorticoids compared to the original starting regimen in patients with GCA, with or without PMR. However, the amount of the discrepancy is small. The commonest reason for non-adherence was medical advice, or other reasons including forgetting, fear of side effects, or confusion about different preparations of prescribed glucocorticoids. The presence of PMR did not influence glucocorticoid adherence.

**EVALUATION OF THE SOCIAL IMPACT OF THE DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANQUILOSING SPONDYLITIS, AND SYSTEMIC LUPUS ERYTHEMATOSUS.**

**Objectives:** To describe the impact of the disease on patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and systemic lupus erythematosus (SLE) on the social health of people who suffer from it.

**Methods:** Cross section of a consecutive sampling of patients with AS, RA or SLE. Selection criteria: age ≥18 years with AS (ASAS criteria), RA (EULAR / ACR 2010 criteria) and SLE (ACR-EULAR criteria) to perform the questionnaires. Protocol: All patients who attended a consultation between October and December 2019 were offered to participate in the study. After their approval and validation of the inclusion criteria, they conducted a battery of PROMIS platform questionnaires focused on assessing their social health. Likewise, data on their disease, comorbidities and socio-labor profile were collected. All participants signed an informed consent and the study was approved by the CEIC of the hospital.

**Main outcomes:** The variables collected by the questionnaires evaluate social health in several areas: mobility, depression, satisfaction with social relationships, social isolation, company, ability to participate in social activities, emotional support, instrumental support and support through information. Statistical analysis: Descriptive, bivariate analysis using t-student, ANOVA and χ², followed by multivariate linear regression (RLM) (Vd: ability to participate in continuous social activities 7-35).

**Disclosure of Interests:** SAT0620-HPR and SAT0621-HPR: None declared

**INACTIVITY BEHAVIOR AND EXERCISE BARRIERS IN PATIENTS WITH BEHÇET’S DISEASE**

**Objectives:** The aim of this study is to investigate physical activity level and exercise barriers in patients with BD.

**Methods:** 45 patients were included in the study. Physical activity level, exercise barriers, fatigue, depression, pain, quality of life and aerobic capacity were evaluated with International Physical Activity Questionnaire (IPAQ), Exercise Barriers and Benefits Scale (EBBS), Fatigue Severity Scale (FSS), Beck Depression Inventory (BDI), Visual Analog Scale (VAS), Behçet’s Disease Quality of Life Questionnaire (BDQoL) and 6 minutes walk test, respectively. Spamerian’s Correlation Coefficient were used to investigate the relationships between exercise barriers and other parameters.

**Results:** IPAQ demonstrated that 22 (48.9%) of the patients had low physical activity. Additionally, physical activity levels significantly correlated with both exercise barriers (rho=-0.345) and exercise benefits (rho= 0.320) (p<0.05). BDQoL scores also correlated significantly with exercise barrier scores (rho= -0.338), (p<0.05). No significant relationships were observed for other parameters.

**Conclusion:** Exercise and physical activity are of great importance because of its positive contribution to the musculoskeletal system for BD patients’ rehabilitation. Thinking of negative effects of physical inactivity, patients with Behçet disease should be encouraged to exercise. Also, reasons of physical inactivity should be investigated and treated.

SAFETY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN BIOLOGICAL TREATMENT OVER 65 YEARS OF AGE

Background: A bias has been described with the lowest prescription of biologic treatments (bDMARD) in patients with rheumatoid arthritis (RA) in the elderly, despite presenting activity rates comparable to young population and higher risk of functional disability. This could be due to concerns about co-morbidities and polypharmacy.1

Objectives: 1) To define the characteristics of patients with RA ≥65 years and bDMARD to follow up in the Day Hospital of University Assistance Complex of León during the last year, 2) To record the incidence rate (IR) and ratio of incidence rates (RIR) of infections, neoplasms and cardiovascular events (CD) during the course of your therapy.

Methods: Observational, retrospective study of patients diagnosed with RA according to ACR 1987 and/or ACR 2010 criteria in intravenous biological treatment during 2019 with ≥65.

Results: 40 patients with an average age at diagnosis of 55.9±15.78 years were included, 67.5% of them were women. The average duration of the disease was 17.65±13.15 years. 40% had a history of smoking, 35% hypertension, 20% dyslipidemia and 20% diabetes mellitus. A 97.5% were positive FRRA, 57% positive ACPR, 37.5% nodular and 65% erosive. As for pre-treatment, 70% had been with conventional (cDMARD) ≥2 DMARD (Methotrexate (MTX) (92.5%) and Leflunomide (60%)). The mean dose of prednisone was 8.79 ± 10.14 mg/day. The incidence rate of infections was 1.5%, and neoplasms and CD were 0.75% per-person-years. The age at the beginning of the first bDMARD was 67.45 ± 8 years, the second (n=20) 67.98±6.4 and the third (n=7) 71.79±7.49. The first biological was a 52.5% anti-TNF, 5% anti-CTLA4, 30% anti-CD20 and 12.5% antiIL6 (25% monotherapy and combined with MTX 57.5%). The second was 30% anti-TNF, 25% antiCTLA4, 15% antiIL6 and 30% antiCD20 (50% in monotherapy and 40% methotrexate); with the third anti-TNF 42.85%, antiCTLA4 14.29%, antiIL6 14.29% and antiCD20 28.57% (42.86% in monotherapy and 42.46 with methotrexate). The mean doses of prednisone were 6.08±6.82, 4.39±7.21 and 6.95±5.94mg/day respectively. The IR of bDMARD infections were 8.81%, 19.81% and 7.4% person-years; of neoplasia 10.4%, 0 and 0; and EC 3.63%, 0 and 1.85 person-years. The RTIs with first, second and third biological infections were: 5.88, 13.25, 4.95; with neoplasms 1.38; and EC 3.63%, 0 and 1.85 person-years. The RTIs with first, second and third biological infections were: 5.88, 13.25, 4.95; with neoplasms 1.38; and EC 3.63%, 0 and 1.85 person-years.

Conclusion: 1) Patients over 65 years old receiving bDMARD in our Day Hospi-
tal in 2019 were long-standing RA with aggression data, who had not responded to ≥2 cDMARD and required medium-high doses of prednisone. 2) In our sample there is a link between incidence of infection and the introduc-
tion of biological therapy, which is maintained with the increasing age of our patients, and it is not so clear with neoplasms and CD. These data are consistent with the existing literature.2-3

3) Larger, comparative studies with RA under 65 years are needed, but it is reasonable to conclude that if bDMARD is required, elderly patients could be a high-risk group for infections, requiring special monitoring and follow-up.

References:
Background: Psoriatic Arthritis (PsA) is a rheumatic disease affecting 0.19% of the UK population (1). It is characterised by asymmetric oligoarticular or polyarticular arthritis, enthesal involvement or axial disease with or without associated peripheral arthritis (2). Foot manifestations of synovitis, enthesitis, dactylitis and skin and nail involvement (3) are reported. Hyslop et al. have previously reported high levels of foot involvement but low current access to foot care (4). Outcome measures that include specific PsA related foot features do exist, e.g. Leeds Enthesitis Index, Tender Dactylitis Count (5). However there is currently no measure of foot involvement and impact in PsA (6).

Objectives: To identify the impact of PsA on foot health and indication of podiatry need in a secondary care outpatient setting.

Methods: convenience sample was taken from a consultant rheumatologist’s outpatient clinic and screened. Only those with a diagnosis of PsA were included. Sampling was conducted over a ten-week period. Screening was done using the Swindon Foot and Ankle Questionnaire (SFAQ) (7), visual Analogue Scale (VAS), clinical judgement of need for podiatric intervention and the trust’s eligibility criteria for routine podiatric care.

Results: The sample (n=16) was 31.3% male with a median age of 59 years (range 28-81).

</tr>
<tr>
<td>Have you had your footwear adapted or insoles made?</td>
</tr>
<tr>
<td>Have you had surgery, or are you waiting for surgery, on your feet or ankles?</td>
</tr>
</tbody>
</table>

Conclusion: Of this patient group, 81.3% had a variety of foot care needs but the use were being met in a limited number of cases (25%). Far more patients (81.3%) were eligible for care in the local trust’s primary care podiatry service but were not engaging with this. 50% of the sample reported difficulty in the past week and 27.3% found their foot pain stopped them from going to work, indicating a clear need for foot health intervention.

Recommendations:
- Raise awareness of availability of podiatric care for PsA patients among patients and podiatric staff.
- Ensure adequate resources are allocated to manage this cohort of patients at a service provision level.
- Further research involving PsA patients referred into podiatry to assess the impact of podiatric intervention.

EXPLORING THE RELATION BETWEEN PAIN AND ACTIVITY AND PARTICIPATION BASED ON ICF IN CHILDREN AND ADOLESCENTS WITH JUVENIL IDIOPATIK ARTRIT: A PILOT STUDY

F. Our Kabal1, B. Başalci Çalış1, B. Akar1, M. Bailer7, Z. Ekeić Tekin1, O. Otar Yener2, S. Yuksek3, 1Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey; 2Medical Faculty of Pamukkale University. Department of Pediatric Rheumatology, Denizli, Turkey

Background: Functional limitation and inactivation are the most important problems in children with Juvenile Idiopatik Artrit (JIA).

Objectives: The aim of this study was to link and allocate items of Childhood Health Assessment Questionnaire (CHAQ) with activity and participation based on International Classification of Functioning, Disability and Health (ICF). The other aim was to examine the relationship between the pain and activity participation determined on the basis of CHAQ with Juvenil Idiopatik Artrit (JIA).

Methods: Thirty-seven children and adolescents (26 girls, 11 boys, mean age: 11.75±4.04 years) were included. The mean BMI of the participants was 19.61±4.52 kg/m². Inclusion criteria: To be diagnosed with JIA according to ILAR classification. Being in the 6-18 age range. To be stable in drug use for at least 3 months or longer. Exclusion criteria: The presence of another disease. Intraarticular steroid injection or surgery in any joint in last 3 months. Evaluations were made by the same pediatric rheumatologist and physiotherapist (PT) by face to face interview method. Pain was evaluated by use of Numeric Rating Scale (NRS) (0=no, 10=worst) and disability by CHAQ. As CHAQ score increases, disability increases. CHAQ has 8 categories. The highest score for any question determines the score for that category. The items of CHAQ were linked with ICF codes and allocated with the ICF components by three PT. Original scoring of CHAQ allocated to ICF components was used in order to calculate scores of activity and participation in accordance with clinical data for 37 JIA. The 20th item in the “Reach” category is not included in the calculation as it contains the body function component of ICF. The data was analyzed using Pearson’s correlation coefficient.

Results: Mean score of NRS was 3.52±3.04. Mean activity and participation score of CHAQ was 0.51±0.58. 70±1.10, respectively. Based on expert distinction, activity and participation categories of ICF were covered 24 and 5 items of CHAQ, respectively. Pain had moderate correlation with activity (r=0.595; p=0.002) and participation (r=0.604; p=0.001) for CHAQ. Activity had high correlation with participation (r=0.702; p=0.000).

Conclusion: Pain in children and adolescents with JIA is an important parameter affecting activity and participation. Pain should be evaluated in all aspects due to the limitation of both activity and participation. CHAQ largely contains disability affecting activity and participation. Pain should be evaluated in all aspects due to the limitation of both activity and participation.

EXPLORING THE RELATION BETWEEN PAIN AND ACTIVITY AND PARTICIPATION BASED ON ICF IN CHILDREN AND ADOLESCENTS WITH JUVENIL IDIOPATIK ARTRIT: A PILOT STUDY

B. Heirmánková1,2, M. Špirítová1,2, S. Oreska2,3, H. Störkánová2,3, M. Klein2,3, K. Pavelka2,3, L. Šlenoř2,3, H. Mann2,3, J. Vencovsky2,3, M. Tomič2,3, Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic; Institute of Rheumatology, Prague, Czech Republic; 1st Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic

Background: Symptoms related to idiopathic inflammatory myopathies (IIM) such as weakness of skeletal muscles, pulmonary and articular involvement may have a negative impact on all aspects of life including sexual life.

Objectives: To assess sexual functioning in female IIM patients compared to age-matched healthy controls (HC) and to analyze the potential impact of clinical features on sexual health.

Methods: In total, 39 women (29 currently have a partner) with IIM (mean age: 54.7 years) were included. 11.8 years, dermatomyositis (DM, 19)/ polymyositis (PM, 16)/ necrotizing myopathy (MMNM, 3)/ inclusion body myositis (IBM, 1) and 39 healthy controls (30 currently have a partner, mean age: 54.7 years) without rheumatic diseases filled in 11 well-established and validated questionnaires assessing sexual function (FSFI, SFQ28, BISFW, SFQ28, BISFW, SFQ28, BISFW, SFQ28, BISFW). The SFQ is one of the most commonly used measures to assess sexual dysfunction (FSFI, BISFW, SFQ28) and worse sexual quality of life (SQoL-F) compared to HC (table 1). Worse scores in IIM patients were associated with increased inflammation (CRP: FSFI (r=-0.378, p=0.0190), SQ-FQ-28 Satisfaction domain (r=0.346, p=0.0036), SQoL-F (r=-0.331, p=0.0479), greater muscle weakness of m. gluteus medius/ m. iliopsoas [FSFI: (r=0.426, p=0.0368), (r=0.370, p=0.0368), (r=0.294, p=0.0252), SQoL-F (r=0.564, p=0.0044), (r=0.421, p=0.0204), (r=0.462, p=0.0100), greater fatigue [FSI: (r=-0.358, p=0.0154), BISFW-W (r=-0.415, p=0.0084), SQoL-F (r=-0.327, p=0.0481)], more severe depression [BDI-II: FSFI Arousal domain (r=-0.357, p=0.0299), deteriorated quality of life [HAQ: BIS-FW (r=0.464, p=0.0033)], and worse ability to perform physical activities [HAP: FSFI (r=0.405, p=0.0105), BISFW-W (r=0.480, p=0.0019)]. No associations were found with disease duration, prednisone dose or serum levels of muscle enzymes.

Results: Patients with IIM reported significantly higher prevalence and greater severity of sexual dysfunction (FSFI, BISFW, SFQ28) and worse sexual quality of life (SQoLF) compared to HC (table 1). Worse scores in IIM patients were associated with increased inflammation [CRP: FSFI (r=-0.378, p=0.0190), SFQ28 Satisfaction domain (r=0.346, p=0.0036), SQoLF (r=-0.331, p=0.0479), greater muscle weakness of m. gluteus medius/ m. iliopsoas [FSFI: (r=0.426, p=0.0368), (r=0.370, p=0.0368), (r=0.294, p=0.0252), SQoLF (r=0.564, p=0.0044), (r=0.421, p=0.0204), (r=0.462, p=0.0100), greater fatigue [FSI: (r=-0.358, p=0.0154), BISFW-W (r=-0.415, p=0.0084), SQoLF-F (r=-0.327, p=0.0481)], more severe depression [BDI-II: FSFI Arousal domain (r=-0.357, p=0.0299), deteriorated quality of life [HAQ: BIS-W (r=0.464, p=0.0033)], and worse ability to perform physical activities [HAP: FSFI (r=0.405, p=0.0105), BISFW-W (r=0.480, p=0.0019)]. No associations were found with disease duration, prednisone dose or serum levels of muscle enzymes.

Conclusion: Women with IIM reported significantly impaired sexual function and sexual quality of life compared to age-matched healthy controls. Worse scores in IIM were associated with disease activity, physical activity, fatigue, depression and quality of life.

SAT0628-HPR “IT IS THE NEVER ENDING QUEST, HOW TO MOTIVATE PEOPLE” – HEALTH PROFESSIONALS’ PERSPECTIVES ON SUPPORTING PHYSICAL ACTIVITY MAINTENANCE IN THOSE LIVING WITH AXIAL SPONDYLOARTHRITIS

T. Ingram1,2, P. Rouse1, M. Standage1, R. Sengupta2,3.

University of Bath, Department for Health, Bath, United Kingdom; Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; University of Bath, Department of Pharmacy and Pharmacology, Bath, United Kingdom

Background: Physical activity (PA) has been identified as a primary treatment option for people living with axial spondyloarthritis (axSpA) [1]. Yet, people living with axSpA can find it difficult to maintain PA at levels required to gain the evidence-based benefits [2]. Intensive rehabilitation programmes harness the benefits of physical activity, but little is known about how to support PA maintenance when patients return to everyday life. The perspectives of health professionals involved in rehabilitation programmes can provide important and rich insights into how people living with axSpA could be helped to maintain their PA.

Objectives: To explore health professionals’ experiences of supporting PA maintenance during and after a rehabilitation programme for those living with axial spondyloarthritis.

Methods: A qualitative study was conducted using semi-structured interviews. Nine health professionals (i.e., 4 physiotherapists; 1 clinical nurse specialist; 1 rheumatology SpR; 1 psychologist; 1 occupational therapist; and 1 podiatrist) who contribute to a rehabilitation programme were recruited from the Royal National Hospital for Rheumatic Diseases in Bath, UK (M time contributing to course = 6.79 yrs, range 1-19.25 yrs; contact time over course range = 1 to 45 hrs). Interviews were audio recorded, transcribed verbatim, and a thematic analysis employed [3].

Results: Maintaining a physically active lifestyle is a challenge for those living with axSpA and is an issue that is currently not being addressed. Health professionals’ perspectives on supporting PA maintenance was illustrated through four main themes: (1) Social environment (group dynamic, importance of others and the same condition, immersion of the disease, external peer groups); (2) Re-framing (education, ownership, exercise off the pedestal, combating fear, routine and habit); (3) PA support (enjoyment and interest, PA as flexible, encouragement and importance, balance and realistic expectations, internal and external feedback); and (4) Challenges for health professionals (training, resources, knowledge of transition process to everyday life, difficulty motivating). The reasons why people engage in PA play a key role within each of these themes.

Conclusion: Results emphasize the current lack of support for the maintenance of PA and the complexities and challenges involved in maintaining PA for people living with axSpA. Interventions to support PA maintenance should pay particular attention to the importance of socially supportive environments, the need for enjoyment, and the use of internal and external feedback. The challenges faced by health professionals in motivating those living with axSpA to engage in PA regularly suggests a need for more training opportunities in motivation and health behaviour change.

SAT0629-HPR FACTORS ASSOCIATED WITH USE OF BIOLOGICAL THERAPIES FOR AXIAL SPONDYLOARTHRITIS IN CANADA. RESULTS FROM THE IMAS SURVEY.

R. Irman1, M. Garrido-Cumbrebra, J. Char, M. Cohen, A. J. Debrum Fernandez, W. Gerhart, N. Haron3, A. Justiasias, G. Major4, M. Mallinson, S. Rohekar5, P. Leclerc6, J. Schneiderman7, R. Rahman8,9, YWH, Toronto, Canada; U: de Sevilla, Sevilla, Spain; UBC, Vancouver, Canada; MUHC, Montreal, Canada; U: de Sherbrooke, Sherbrooke, Canada, CSA, Phipelston, Canada; U of Ottawa, Ottawa, Canada; CSA, Toronto, Canada; Patient, Toronto, Canada; 3Western U, London, Canada; 9Novartis, Montreal, Canada; 11Memorial U, St. John’s, Canada

Background: Biologics have revolutionized the treatment of axial spondyloarthritis (axSpA). However, there is limited knowledge about factors associated with their use in Canada.

Objectives: To evaluate sociodemographic, healthcare and patient-reported outcomes (PROs) associated with the use of biologics in Canadian axSpA patients.

Methods: The International Map of Axial Spondyloarthritis (IMAS) is a cross-sectional online survey of non-selected patients with self-reported axSpA, conducted in 21 countries and endorsed by the Axial Spondyloarthritis International Federation (ASIF). IMAS captures the patients’ perspective of the burden of axSpA. The Canadian adaptation included a review of the survey by an advisory board of axSpA patients and a national steering committee composed of the Canadian Spondylitis Association, rheumatologists and patients. Participants were recruited between August 2018 and February 2019. Sociodemographic and healthcare-related variables, as well as PROs (disease activity [BASDAI], 0–10), spinal stiffness (3–12), functional limitation (0–54) and psychological distress (GHQ-12) were collected. Respondents were divided in 2 groups 1) biologic and 2) NSAIDs or no treatment, based on reported pharmacologic treatments. Statistical analyses were performed to assess associations between variables and biologic use (bivariate) and the relative weight of these associations (multivariate).

Results: 542 axSpA patients were recruited. Mean age was 44±13.9 years, 83.1% were female, 66.4% married and 91.0% educated to university/college level. 22.8% of patients lived >50 km from their rheumatologist. Mean BASDAI was 5.3±2.1 and mean GHQ-12 score (mental health) was 4.0±3.8. Nearly half (49.6%) were currently on a biologic. Reported incidence of side effects was lower for patients having biologics (42.5%) vs. a NSAIDs (53.7%) as part of their treatment armamentarium. Only 15.7% of patients had discontinued biologic therapy, the main reasons for withdrawal being physician recommendation (50%), side effects (50%) and personal choice (34%). Variables associated with biologic use included: membership of a patient support group (p=0.001), non-manual work (p=0.001), higher income level (p=0.039), having a combination of public and private insurance schemes (p<0.001) and diagnosis by a rheumatologist (p<0.001). Associated PROs were: spinal stiffness (p=0.001) and diagnostic delay (p=0.030). In the multivariate analysis, all variables except income and diagnostic delay were associated with biologic use (Table 1).

Conclusion: Canadian axSpA patients with greater social status, disease awareness, and insurance options are more likely to receive biologic therapy. Furthermore, Canadian physicians are more inclined to prescribe biologics to patients with increased spinal stiffness.

SAT0630-HPR EFFECTS OF GOLIMUMAB ON WORK PRODUCTIVITY AMONG WORK-ACTIVE ANKYLOSING SPONDYLITIS, NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS IN GREECE: THE ‘GO-UP’ STUDY

P. Athanassiou¹, A. Kotrosios³, I. Kalitsakis³, A. Bounas¹, A. Garyfallos³, M. Tektonidou¹, G. Vosvotekas¹, E. Petrikou², G. Katsifis³. ¹Agios Pavlos General Hospital, Thessaloniki, Greece; ²Private Practice, Karolitsa, Greece; ³Private Practice, Chania, Greece; ⁴Olympion Therapeutic General Clinic, Patras, Greece; ⁵Ippokrateion General Hospital, Thessaloniki, Greece; ⁶Laikon General Hospital, Athens, Greece; ⁷Euromedica General Clinic, Thessaloniki, Greece; ⁸MSD, Medical Affairs, Athens, Greece; ⁹Naval Hospital, Athens, Greece

Background: Golimumab is a tumor necrosis inhibitor (TNFi) approved for the treatment of axial SpA (axSpA) and psoriatic arthritis (PsA), both falling under the Spondyloarthritides (SpA) domain. Real-world data regarding its effect on work productivity (WP) and activity impairment (AI) are limited

Objectives: To assess the impact of golimumab on WP and AI over 12 months of treatment in patients with SpA, overall, and in the axSpA and PsA subpopulations

Methods: A 12-month non-interventional, multicenter, prospective study performed in the routine clinical care. Data were collected at baseline (BL; prior to treatment onset), 3, 6 and 12 months. Adult work-active consented patients with axSpA (ankylosing spondylitis (AS) or non-radiographic axSpA (nr-axSpA) or PsA, newly initiated on golimumab as per approved label, were consecutively enrolled by 20 sites. Patients prior to >1 biologic agent, or switched from another TNFi due to primary non-response or safety were excluded. WP and AI was assessed with the Work Productivity and Activity Impairment: Specific Health Problem (WPAI:SHP) instrument

Results: Between April 2017 and May 2018, 121 (51: PsA, 70: axSpA) eligible patients (mean age: 45.4 years; 49.6% males; 69.0% overweight/obese; median disease duration: 11.3 months), (Figure 1), were enrolled; Median study duration participation: 11.9 months. Overall, 60.3% of the patients had previously received disease-modifying antirheumatic drugs and 16.5% biologics. At BL, the mean (standard deviation: SD) DAS28-ESR of the SpA population and PsA and axSpA subpopulations was 4.0 (1.3), 4.5 (1.2) and 3.6 (1.2), while the mean (SD) BASDAI score of patients with axSpA was 5.6 (1.9). At BL 94.1 and 96.7% of the SpA population reported WP loss and AI due to their SpA respectively, and at 3 months 87.3, and 88.0% respectively (Table 1). Improvements in WP loss and AI were noted in patients with PsA, axSpA and nr-axSpA (Table 1). 12-month golimumab retention rate: 91.7%. No new safety signals emerged.

SAT0631-HPR WHEN CAN I STOP MY STEROIDS? THE PATIENT PERSPECTIVE ON GLUCOCORTICOID USAGE IN ADULT INFLAMMATORY MYOPATHY

J.Loaré-Martos², J. B. Lilleker², E. Alder², J. Goode², H. Chino²,³. ²Ramón y Cajal University Hospital, Madrid, Spain; ³University of Manchester Centre for Musculoskeletal Research, School of Biological Sciences, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, Manchester, United Kingdom; ⁴Salford Royal NHS Foundation Trust, Manchester Centre for Clinical Neuroscience, Manchester, United Kingdom; ⁵Myositis UK, Southampton, United Kingdom; ⁶Salford Royal NHS Foundation Trust, Rheumatology department, Manchester, United Kingdom

Background: Glucocorticoids (GC) are long established as a first line treatment in patients with idiopathic inflammatory myopathy (IIM), in which high dose, long duration treatment is often required. GC usage is associated with a wide range of adverse effects (AEs). The patient perspective on the risks and benefits of GCs is not well studied and no prior studies assesses this issue in IIM patients (1).

Objectives: To describe the perspective of IIM patients on GC treatment

Methods: We deployed an online survey distributed using the Myositis UK page on Healthtalked.com, an online social network for health, with approximately 450 patients registered. Patients with diagnosed IIM were invited to take part on an anonymised basis. Respondents were asked to grade the severity on a Likert scale (1 to 5) of all AEs experienced in relation to GC. Additionally, respondents were asked to write about their concerns and to rate their overall experience with GC treatment.

Results: A total of 122 completed surveys were received. Forty five percent (55/122) of respondents had dermatomyositis, 27% (33/122) polymyositis, 10% (12/122) anti-synthetase syndrome, 18% (22/122) other inflammatory myopathies. Seventy-nine percent (96/122) of respondents were female and the mean age overall was 50 years (SD [standard deviation] 14).

The authors thank the following investigators: Ampatziadis E., Voulgaris P., Gazi S., Georgiou P., Georgoutsos A., Karokis D., Mpotzior V., Mpouzanos E., Sekkas L., Sidropoulos P., and Vassilopoulos D. The study was sponsored by MSD, Greece.
The median reported current daily dose of prednisolone was 15 mg and median treatment duration was 5.3 years at the time of survey completion. Females were more likely to stay on GCs for longer than males (5.4 vs 4.7 years, p<0.046).

### Results:

Four themes covered from the analysis of patients' comments. "Seeking own answers;" "Own coping – effort;" "Conversation with doctor/nurse" and "Treat-ment/medication": Comments revealed many descriptions and stories of patients, showered with all types of suggestions of taking control or managing the disease by themselves, from their family or media. It also revealed their interest in discussing, these subjects and matters with the doctor/nurse, without being rejected. The feeling of rejection resulted in some patients trying other treatments or introducing changes in their lifestyle, without involving the doctor. The patients also called for more knowledge about physical training, and not only medical treatment.

### Conclusion:

In general, the patients had a very positive perception towards the consultations, and the information from the outpatient clinic. Despite that, the themes indicated a pattern, that needs to be considered, so clinicians acknowledge the patients wish for guidance, besides the medical treatment. To support the patient, without leaving them with a feeling of being rejected, we need to consider how to articulate the subjects the patients are exposed to outside our clinic, so the patients feel free to inform or involve the clinic instead of being silent, in risk of counteracting the medical treatment.

### Acknowledgments:

We are grateful to the participants who shared their experiences. We also thank an internal research group taking part of the investigation.

**SAT0633-HPR**

**AN EXPLORATION INTO THE CONVERSATIONS AROUND SEXUAL FUNCTIONING THAT MALES WITH SJÖGREN’S SYNDROME HAVE ON AN INTERNET FORUM.**

J. Mcready1, K. McCarty2, V. Deary1,2, T. Collins1, K. Hackett1,3, 1Northumbria University, Department of Social Work, Education, and Community Wellbeing, Newcastle upon Tyne, United Kingdom; 2Northumbria University, Department of Psychology, Newcastle upon Tyne, United Kingdom; 3Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

**Background:** Sjogren’s Syndrome (SS) is an autoimmune rheumatic disease that targets secretion glands throughout the body, causing symptoms of oral, ocular and genital dryness (van de Merwe, 2010). A small body of literature has investigated the impact of SS on women’s sexual functioning; however, no research currently exists that has explored this topic in males with SS. Gathering a snapshot of issues may prove difficult given the sensitivity of the topic. Therefore, data must be gathered from sources where individuals may have the confidence to talk openly. Research has shown that many patient groups turn to internet forums to discuss sensitive issues under the cover of anonymity (White & Dorman, 2001). Analysing this source of data allows us to explore the conversations pertaining to sexual functioning that males with SS may not feel comfortable discussing in a traditional qualitative setting, and may be instrumental in guiding future intervention strategies.

**Objectives:** To explore the conversations around sexual functioning that male users with SS have on an internet forum.

**Methods:** A large publicly accessible internet forum that individuals with a diagnosis of SS used to discuss issues and share experiences with other users was selected. Thread names and post content were scraped using a web scraping tool, and posts identified as containing relevant keywords were exported into Excel. Braun & Clarke’s (2006) thematic analysis was used to analyse post content.

**Results:** A total of 78 posts were identified as being pertinent to the topic of male sexual functioning. Conversations were predominately centred on symptom pre- valence in the reproductive organs. Forum users discussed having fluctuating pain in the testicles, scrotum, groin, anus, and rectum. They also reported experiencing
feelings of dryness at the base of the penis, around the testicles, under the foreskin, around the glans of the penis and in the anus. Discussions were also had about changes in the volume and consistency of seminal fluid released either prior to or during ejaculation. Another conversation theme revolved around how the symptoms they experienced affected their ability to engage in sexual intercourse. Forum users discussed how pain and dryness made sexual intercourse painful, resulting in them withdrawing from sexual activity indefinitely. Discussions were also had about the lack of information available to help understand and manage sexual dysfunction. Forum users discussed how feelings of embarrassment about the nature of the symptoms and the stigma of being "a woman's disease" kept them from seeking medical assistance. Those who had sought medical assistance shared their belief that health professionals (HPs) were misdiagnosing their symptoms and were prescribing ineffective treatments. They also reported that their HPs were dismissive of symptoms and unwilling to assist further.

**Conclusion:** Utilising conversations from an internet forum was an effective method to use to gain insight into some of the issues that males with SS experience with sexual functioning. The absence of accessible information and lack of support from HPs for males with SS is hinted at in this research. Further research should focus on identifying issues surrounding male sexual functioning as this will both guide future intervention strategies and allow HPs to publish material to better support males with SS.

**PATIENT-REPORTED OUTCOMES REGARDING TWO FORMS OF METHOTREXATE AUTOINJECTORS IN RHEUMATOID ARTHRITIS: AN INTERNATIONAL CROSS-OVER SURVEY.**

Y. Morvan1, J. D. Zeitoun2.

1Ipsos Healthcare, Paris, France. 2Saint-Antoine Hospital Assistance Publique Hôpitaux de Paris, Gastroenterology and Nutrition, Paris, France

**Background:** Several types of methotrexate (MTX) autoinjectors (AI) are currently marketed in rheumatoid arthritis (RA), yet comparative data are scarce.

**Objectives:** Investigate respective perceptions of patients regarding two marketed forms of MTX AI via a survey conducted by a global market research company.

**Methods:** Patients with moderate to severe RA treated by one of the two forms of MTX AI were recruited. In each participating country (France, Ireland, United-Kingdom, Spain), the respective proportions of recruited patients were approximately aligned on local market shares. The two investigated devices were: A-AI/ The first MTX AI marketed in Europe: bigger size, with an activation button, without double injection sound-control, with a larger window; B-AI/ The second MTX AI commercialized in Europe: smaller and thinner size, without activation button, with double injection sound-control and a smaller window. Each patient was interviewed during 30 minutes on his or her satisfaction level with the currently used device. Then, they were presented the alternative AI and they could test it on skin-mimicking pads. After this step, the patients were interviewed on the alternative device.

**Results:** 100 patients were enrolled over one-month period (A-AI users, n=65; B-AI users, n=35). Overall, 61% of A-AI users reported that B-AI was “better” or “much better” whereas 43% of B-AI users judged A-AI as “better” or “much better”. When B-AI users were asked to evaluate convenience elements of A-AI, recognition of injection ending, general design and ease of use were the indicators that were the most poorly judged (60%, 54%, and 46% respectively). When A-AI users were cross-tested for B-AI, injection mode, general feeling, and ease of use were the three items providing the greatest satisfaction (80%, 77%, and 75%, respectively). When they were asked about the characteristics of their usual device, the button, the design of the device and discomfort associated with the injection were the worst dissatisfactory elements (30%, 31%, and 34% respectively). Also, 73% of A-AI users reported being interested in trying B-AI while 26% of B-AI users replied being so. Last, 95% of B-AI users declared being “very satisfied” or “totally satisfied”, with ease of use and recognition of injection ending being the most attractive items (94% and 95% of high or full satisfaction respectively).

**Conclusion:** In this international cross-over survey, the newest autoinjector on the market, B-AI has shown to exhibit better reported outcomes with respect to ease of use and recognition of the end of the injection and other tested indicators.

**T. Oton1, L. Carmona1, J. L. Andrué Sánchez1. **IMMUC, Instituto de Salud Musculoesquelética, Madrid, Spain; 2Rheumatology Department, Hospital Universitario Puerta de Hierro-Majadahonda, Majadahonda, Spain

**Background:** Methotrexate (MTX) is currently a mainstream drug in the treatment of rheumatic diseases. However, the response to MTX is not universal and

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.3797
may be conditioned by a number of factors, among which adherence could be crucial.

**Objectives:** The aim of this study is to explore adherence to MTX in patients with rheumatic diseases, facilitators and perceived when taking and maintaining the prescription.

**Methods:** A qualitative study of content analysis was performed. Focus groups with patients taking either oral or subcutaneous MTX (being the main or coadjuvant treatment) for any rheumatic disease was performed. The groups were moderated by a rheumatologist that was unknown for the patients. The speech was recorded and transcribed. Subsequently, an inductive coding was performed with the help of Atlas.ti and main themes and sub-themes were extracted, with examples of verbatim anonymized speech.

**Results:** Three focus groups were conducted, with a total of 12 participants, of whom eight were women, seven had rheumatoid arthritis, three had psoriatic arthritis, one had spondyloarthritis, and one had systemic lupus erythematosus. All patients reported an adequate adherence to treatment. The barriers identified were: information in the leaflet, technical language in the consultations, difficult access to doctor’s appointment, social environment, side effects and the subcutaneous device. As facilitators, the following aspects were discussed: good predisposition of the physician, reliable graphic information, role of associations and partners support.

The unmet needs detected were: problems with travelling, protocols for eventualities, absence of a plan of care, negligence of "non-physical" symptoms, disinformation on side effects and training in complementary aspects.

**Conclusion:** Getting reliable information was the main barrier identified. The environment and side effects may also negatively impact on adherence. Shared decision making is a goal to be achieved in the future in these patients.

**SAT0638**

**IMPARED HEALTH-RELATED QUALITY OF LIFE AND PHYSICAL FUNCTION IN NORWEGIAN PATIENTS WITH TAKAYASU ARTERITIS.**

T. Garen\(^1\), P. Palm\(^1\), B. Gudbrandsdøn\(^1\), \(^1\)Oslo University Hospital, Oslo, Rheumatology, Oslo, Norway

**Background:** Takayasu arteritis (TAK) is a rare vasculitis of large vessels in young women. We have previously reported a point prevalence of 25.6/100k. The disease most prevalently limited to the aortic arch and its branches (Type 1) among North Europeans. Early symptoms of TAK include fever, myalgia and loss of appetite. Later, the inflammation of blood vessel may lead to irreversible vascular damage and ischemic symptoms with claudication of the extremities. We have recently found that TAK may reduce life expectancy, mainly due to cardiovascular complications. The median age among those deceased was only 58 years. These findings clearly indicate that TAK may have severe impact on the wellbeing of the patients and their physical capacity.

It is widely accepted to include patients’ perspectives related to their health condition and treatment to better understand the burden of the disease and the impact on their daily life activities. However, studies of health-related quality of life (HRQoL) in TAK has rarely been undertaken, and we are not aware of any studies from the Northern part of Europe.

**Objectives:** (i) To compare HRQoL in Norwegian TAK with age– and sex matched Norwegian normative data. (ii) To assess patients reported disease symptoms, employment and assessment of their physical capacity.

**Methods:** The SF-36 results adjusted for age, indicated significantly impaired HRQoL in the patients compared with normative data on 6 of eight subscales, with the largest differences observed for role physical (51 vs. 80, p < 0.001) and general health (51 vs. 78, p < 0.01) (Fig. 1).

Symptoms of claudication in legs correlated strongly to moderately with activities as running or jogging 3 km (539, p < 0.001), walking outdoors on flat ground (584, p < 0.001), climbing stairs (584, p < 0.001) and run errands and shop (.417, p=0.016) assessed by MAHQ. The most frequently reported symptoms were dyspnea at physical exertion (67%), claudication of arms (63%) and myalgia (55%). A moderate correlation was found between claudication of legs (-.572, p<0.001), pain (VAS) (-.585, p<0.001), fatigue (-.493 P<0.002), dyspnea (-.471, p<0.002) and physical function as reported in SF36. Similarly, a moderate negative correlation was present between pain (VAS) (-.565, p<0.001), fatigue (VAS) (-.482, p<0.002) and mental health in SF36. At the time of diagnosis, 89 % were employed, compared to only 21% at registration. Patients self-perceived health status was reported in 39 %, compared to 79% in a share of the Norwegian population aged 16 or over (The data from the EU Statistics on Income and Living Conditions(EU SILC)).

**Conclusion:** Patients with TAK had reduced HRQoL, compared to data from our general population. The most frequently reported disease symptoms were dyspnea at exertion, claudication of arms and myalgia. Pain, fatigue and dyspnea at exertion had a significant impact on HRQoL. Claudication of legs correlated significantly with impaired walking activities reported in MAHQ.

*p <.05

**Results:** 542 axSpA patients participated. Mean age was 44.3±13.9 years and 63% were female. Mean BASDAI was 5.3±2.1, mean GHQ-12 score was 4.0±3.8 and 50% were on biologics. 94% reported ≥1 limitation in daily activities, of which physical exercise (30%), house cleaning (22%), intimacy (21%), and transport (21%) were most commonly severely impacted (high limitation). Women reported significantly higher limitations in house cleaning, stair climbing, driving, moving around the house and caring for young children (<.05 for all activities vs men). Compared with low limitation, medium–high limitation in most activities was significantly associated with higher disease activity and worsened mental health for the overall population (Table 1).

**Conclusion:** Canadian axSpA patients, particularly women, are limited in daily life activities beyond those captured by other validated scales. Strong association between functional limitation, disease activity and mental health emphasizes the need for holistic evaluation of axSpA patients.

**Disclosure of Interests:** A. K. Rausch Osthoff1,2, S. Buechi, T. P. M. Vliet Vlieland2, K. Niedermann Schneider1, Zurich University of Applied Sciences, Institute for Physiotherapy, Health, Winterthur, Switzerland; 2Leiden University Medical Center, Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; 3Clinical Hohenegg, Clinic for Psychotherapy and Psychosomatics, Meilen, Switzerland

**Background:** The Ankylosing Spondylitis Association of Switzerland (SVMB) offers weekly group exercise therapy for people with axial Spondyloarthritis (axSpA) supervised by physiotherapists (PTs). Given the EULAR physical activity (PA) recommendations [1] and recent research [2, 3], the SVMB has implemented a new concept including assessments evaluating all fitness dimensions, to raise awareness and provide better education to patients and established disease management. The stable importance of PA could be due to the sample, as for group exercise participants PA may already be important. The correlation between importance of PA and MET at T1 could indicate that people learned more about the meaning of PA leading to a better understanding of the importance of PA. Future research should evaluate factors influencing the perceived importance of PA as well as further explore the use of PRISM in the context of exercise-coaching.

SAT0641-HPR  FACTORS ASSOCIATED WITH COGNITIVE IMPAIRMENT IN KOREAN ADULTS WITH RHEUMATOID ARTHRITIS

S. Y. Shin1, J. H. Lee2, B. Y. Youn3. 1Inje University, Department of Nursing, College of Medicine, Busan, Korea, Rep. of (South Korea); 2Inje University Ilsan Paik Hospital, Division of Rheumatology, Ilsan, Korea, Rep. of (South Korea)

Background: For persons with chronic diseases including rheumatoid arthritis (RA), undamaged cognitive capacity is critical for daily functioning, treatment compliance, and self-management. Disease-specific features of RA such as systemic chronic inflammation may increase comorbid cardiovascular disease (CVD) risk and may be closely linked to neurocognitive dysfunction in RA patients [1]. However, the evidence of brain involvement in RA is very rare or even controversial and very little is known about the pathogenic mechanisms of cognitive decline in persons with RA.

Objectives: This study explored the prevalence of cognitive impairment in Korean adults with RA using a set of computerized neurocognitive tests and the factors that were significantly associated with cognitive impairment.

Methods: Individuals with RA were recruited by their rheumatologists during follow-up visits at one university hospital in Korea. After gaining signed consents, a trained research nurse assessed participants with a range of physical, psychological, and biological metrics. Cognitive function was assessed using a set of 6 computerized neurocognitive tests yielding 18 indices covering a range of cognitive domains. Subjects were classified as ‘impaired’ if they performed 1 SD below age-based population norms on each test [2]. The total cognitive function score was calculated by summing the transformed scores, ranging from 0 (no impairment) to 18 (worst impairment). Multiple linear regression analyses were conducted to identify the significant factors influencing cognitive impairment.

Results: Sixty five subjects with a mean (±SD) age of 61.9 (±10.0) years were included. 85% were female, 89% were married, and 76% had less than 12 years of education. Mean disease activity score (DAS-28) was 2.3 (±1.3) and mean disease duration was 9.8 (±8.7) years. Mean functional limitations score (HAQ) was 0.3 (±0.5) and mean CVD risk factors were 2.3 (±1.5). Total cognitive function score was 11.1 (±4.0) [2-18]. The proportion of persons who were classified as cognitively impaired on each test ranged from 25% to 92%. The proportion of persons classified as cognitively impaired on the quarter of total subtests (5 or more out of 18 subtests) was 94%. The multivariate regression model was statistically significant and accounted for 39% of the variance in cognitive impairment (F=5.26, p<.001). Education (β=0.32, p=0.010), family income (β=0.26, p=0.040), and cardiovascular disease risk factors (β=0.27, p=0.025) were significant factors for cognitive impairment in RA. The findings of this study suggest that the burden of cognitive impairment in RA patients is significant, and future studies identifying specific etiological contributors to cognitive impairment are warranted.

SAT0642-HPR  CAPTURING THE UNMET NEEDS OF WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND IDENTIFYING THE INFORMATION NEEDED IN PHYSICIAN-PATIENT COMMUNICATION

S. Shoela1, A. Beltagy1, F. Fayed2, M. Morsy1. 1Alexandria Faculty of Medicine, Internal Medicine Department, Alexandria, Egypt; 2Alexandria University Student Hospital, Internal Medicine Department, Alexandria, Egypt

Background: Systemic lupus erythematosus (SLE) is known to affect the reproductive health of female patients in various ways. Identifying the unmet information and needs of women with SLE about the impact of the disease on maternal health, pregnancy, family planning and contraception is of paramount importance.

Objectives: Our aim was to understand the information needs of women with SLE and capture the gaps in the knowledge of reproductive issues.

Methods: We interviewed 284 female patients with SLE in three centers all affiliated to Alexandria Faculty of Medicine, using a 41 multiple-choice based questionnaire about pregnancy counselling, contraception and the use of the drugs during pregnancy. The questionnaire was modified from the one created by Andreoli et al.,(1) was applied to assess the global knowledge and information of patients on the impact of SLE on reproductive health.

Results: Forty percent of patients declared to have performed the last gynecological visit since 3 years, versus (49.3 %) patients who have done their last visit within a year. 255 patients reported to have received counselling about contraception; 141 of which by gynecologists and not rheumatologists. 71(40.1%) patients have never been asked about the desire to have children. Regarding the methods of contraception used, 104 (36.6%) patients stated that they don’t know there are different forms of pills and have never heard of the progesterin-only pills. As for the DIK, patients showed proper knowledge about the possibility for SLE women to fall pregnant, have healthy children and the fact that lupus flares up during pregnancy. 118 (41.5%) of the patients didn’t know whether children of women with SLE carry a higher risk of having general health problems or not. Also, a great proportion of patients chose “do not know” for the possibility that children could inherit the mother’s disease (49.6%). Concerning the drugs used during pregnancy, surprisingly, (34.2%) patients stated that Hydroxyquine shouldn’t be used during pregnancy, and (28.9%) didn’t know if it is compatible with pregnancy or not. Nearly half the patients who were interviewed didn’t know that Methotrexate, Cyclophosphamide and Mycophenolate mofetil are contraindicated in pregnancy. About 80% of the patients stated that SLE influenced the number of children in the family size. Another 87% of the patients admitted that children could inherit the disease for not being able to take care of their children. Expectedly, SLE impacted patients’ marriages in different forms; 27 (9.5%) of the patients claimed that the disease led to their divorce, 52 (18.3%) explained that their spouses constantly complained about their illnesses, and 19 (6.7%) refused to answer this question. A total of 181 (63.7%) patients had spontaneous abortions, among which 181 (63.7%) patients before being diagnosed with SLE, and 134 (47.2%) patients after. One of the main reasons for spontaneous abortion was the disease itself.

Conclusion: There is a crucial unmet need for women with SLE, identified as a wide gap in communication about reproductive issues. This is influenced by the quality of physician-patient communication, as well as rheumatologist-obstetrician communication.

SAT0643-HPR  NURSE-LED CARE FROM THE PERSPECTIVE OF PEOPLE WITH EARLY RHEUMATOID ARTHRITIS: A QUALITATIVE SYSTEMATIC REVIEW

A. M. T. Sweeney1, C. Mccabe1, C. Flurey1, J. Robson1, A. Berry1, P. Richards1, M. Ndosi1. 1Faculty of Health and Applied Sciences, University of the West of England, Bristol, United Kingdom

Background: Nurse-led care has been shown to be clinically effective and cost effective in rheumatoid arthritis (RA) but the role of the nurse in early RA is not well defined. Evidence for processes of care in RA is limited and it is not known how well rheumatology nurse-led clinics meet care needs of people with early RA.

Objectives: The aim of this study was to develop an understanding of rheumatology nurse-led care from the perspective of people with early RA.

Methods: A qualitative systematic review was conducted. The review protocol is published in the International prospective register of systematic reviews. In March 2019, the following databases were searched: MEDLINE, EMBASE, CINAHL, PsycINFO and OpenGrey. Due to lack of studies in early RA this review included adults with early and established inflammatory arthritis, qualitative studies with data on patients’ perspectives of nurse-led care, published in peer-reviewed journals in English between 2010 and 2019. Two reviewers screened titles, abstracts and full texts. Data were extracted and managed in tables. Joanna Briggs Institute Critical Appraisal Checklist was used for quality assessment of the included studies. A thematic synthesis was undertaken using the framework of Thomas and Harden.

Results: The search identified 1034 records. After screening and assessing for eligibility, 8 qualitative studies were included in the review (133 patients), 2 studies included people with early RA. Three main themes were identified (Figure 1).
Providing knowledge and skill. This theme delineated rheumatology nursing as providing professional expertise in the planning and delivery of care. The rheumatology nurse-led service included easy access via telephone helpline, consultations with the clinical nurse specialist for assessment of disease activity and care needs, planning of care, disease information and education, supporting self-management, and referral to rheumatologist and the multi-disciplinary team. People with RA highly valued the nurse expertise and specialist knowledge provided at nurse-led clinics. ‘She was very good at informing me, so I have only praise for this … because I have never had it like this before’ (Person with early RA).

Using a person-centred approach. This theme showed nurse-led care using a person-centred approach combined with empathy and good communication skills, which created a good therapeutic environment. People with RA appreciated the person-centeredness, empathy and involvement of the nurse. ‘She is very sensitive. She can see if I am feeling bad and comes straight to me and asks: “How are you today?” … You are treated and taken seriously’ (Person with early RA).

Meeting patients’ care needs. This theme presented nurse-led care as creating a sense of being empowered and psychologically supported in the management of RA and its impact. Nurse-led care made people with RA feel cared for, secure and confident. It added value to rheumatology care and made care complete. ‘The thought of sticking a needle into my own stomach... it felt a bit like I would never manage to do that. However, they have been absolutely wonderful here... and now I can do it myself.’ (Person with early RA).

Conclusion: Nurse-led care for people with RA is characterised by provision of rheumatology expertise using a person-centred approach, and patients’ holistic care needs are being met. This study found a dearth of literature on perceptions of nurse-led care in people with early RA, which highlights the need for further research in this population.

SAT0644-HPR

COMPLIANCE OF BIOLOGIC DISEASES MODIFYING ANTI-RHEUMATIC DRUGS (BDMARDS) WITH SYSTEMIC IMMUNO-INFLAMMATORY RHEUMATIC DISEASES (SIRDs), AN ASSESSMENT OF PATIENTS’ ADHERENCE AND NON-ADHERENCE CONCERNS.

R. Thakran1, S. Baghel1, C. Mesai1, V. Kumar1, S. Kapoor1, S. Garg1, A. Malaviya1 on behalf of no. 1Indian Spinal Injuries Centre, rheumatology, New Delhi, India

Background: Patients with systemic immunoinflammatory rheumatic diseases (SIRDs) are often treated with BDMARDS when the response to conventional disease-modifying antirheumatic drugs (csDMARDS) is inadequate. There are, however, concerns about non-adherence to BDMARDs among patient. The non-adherence to BDMARDS may be caused by the various factors.

Objectives: 1. The main objective of present study was to find out the cause of discontinuation of BDMARDS
2. To find out the adherence and non-adherence rate for BDMARDS.
3. To identify the factors that are modifiable.

Methods: 800 patients with SIRDs prescribed BDMARDS were interviewed to find out the demographic information, their socioeconomic status, and the disease duration. Additional information gathered included the comorbidities, the time for starting BDMARDS, the route of administration of BDMARDS, beliefs and perceptions about treatment efficacy and side effects if any. This was followed by looking at the adherence of BDMARDS; if they had discontinued then efforts was made to find out the reasons for the same.

Based on these findings the patients were classified into adherent and non-adherent categories. The data were analyzed further for 1. Factors that associated with continuation of BDMARDS.
2. Factors that were associated with discontinuation of BDMARDS.

Results: A total of 800 patients were interviewed that included patients with ankylosing spondylitis 430 (52.4%), rheumatoid arthritis 300 (37.7%), psoriatic arthritis 45 (5.2%), and others 25 (0.7%). On analysis 610 (76%) patient were compliant but 190 (24%) patient had discontinued the BDMARDS on their own. On comparison of both groups Factors that were significantly related to self-discontinuation were:

• Negative beliefs about biologics (37%)
• Cost (33%)
• Reading side-effect profile on Google search (25%)
• Other co-morbidities (6%)

Factors that were significantly related to persistence of biologic treatment were:
• Good counseling by rheumatologist and rheumatology nurse (60%)
• Faith in the treating rheumatologist (25%)
• Fear of deformities and pain (15%)

On analysis it was found that there is a good counseling and clarifying the doubts of the patients regarding BDMARDS before starting the treatment encourages the patient to continue the biologic treatment, especially it allays their doubts about the drug adverse effects.

Conclusion: Despite negative beliefs and misconceptions about BDMARDS, patient non-adherence at our center is not alarming. A positive reinforcement counseling appears to be the most significant factor to overcome the negative beliefs of patients. The affordability of the biologic treatment however remains a limiting factor in our centre as in other parts of India.

SAT0645-HPR

MYTHS AND MISCONCEPTION ABOUT THE ILLNESS AND CONVENTIONAL SYNTHETIC DMARDS (CSDMARDS) IN PATIENTS WITH SYSTEMIC IMMUNO-INFLAMMATORY RHEUMATIC DISEASES (SIRDs): A STUDY BY RHEUMATOLOGY NURSE COUNSELOR

R. Thakran1, S. Baghel1, L. Khursheed1, S. Kapoor1, S. Garg1, A. Malaviya1on behalf of no. 1Indian Spinal Injuries Centre, New Delhi, India; 2Indian Spinal Injuries Centre, rheumatology, New Delhi, India; 3Indian spinal injuries centre, rheumatology, New Delhi, India; 4Indian Spinal Injuries Centre, New Delhi, India

Background: Myths and misconceptions about illness and conventional disease modifying anti-rheumatic drugs directly influence adherence to the prescribed treatment. It is estimated that 30–50% of patients do not adhere to their prescribed treatment due to various reasons where the beliefs of the patients play a crucial role. At our centre we the specialist rheumatology nurse counsel the patients at every visit and try to remove their myths and negative beliefs about the disease as well as the medications.

Objectives: • To explore the common myths and misconceptions of regarding their disease and regarding the csDMARDS.
• To assess the efficacy of counseling in allaying their unfounded fear.

Methods: A total of 450 patients with SIRDs at least 3 times attended the rheumatology outpatient clinic on csDMARDS were enrolled to complete a questionnaire that, besides demographic information, socio-economic status, and co-morbidities, had the following questions:

1. Self-reported adherence to medication
2. Misbelieves regarding food items
3. What kind of health-provider was consulted at the onset of the symptoms
4. Their belief/knowledge regarding:
A. The need for physiotherapy
B. Life style modification requirement
C. About osteoarthritis
D. Medication requirement during remission
E. Pregnancy and DMARDS
F. The need of vaccination
PATTERN AND INFLUENTIAL FACTORS IN PROMOTING TREAT-TO-TARGET (T2T) FOR FOLLOW-UP OF ANKYLING SPONDYLITIS (AS) PATIENTS WITH A RHEUMATOLOGIST-PATIENT INTERACTIVE SMART SYSTEM OF DISEASE MANAGEMENT (SSDM): A COHORT STUDY FROM CHINA

J. Xue1, H. Wang2, H. Li3, H. Song4, Y. Li5, X. Shi6, H. Zhao7, F. Wei8, H. Xiao9, B. Wu9, Y. Jia9, F. Xiao9, H. Wu1 on behalf of SSDM Collaboration Group, China.

1The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China; 2The First Hospital of Jiaying, Jiaying, China; 3The Affiliated Hospital of Inner Mongolia Medical University, Neimenggu, China; 4Beijing Jishuitan Hospital, Beijing, China; 5Zhengzhou Provincial People’s Hospital, Zhengzhou, China; 6The First Affiliated Hospital of Henan University of science and technology, Luoyang, China; 7Xiangya Hospital of Central South University, Changsha, China; 8Jiangmen Central Hospital Affiliated Jiangmen Hospital of Sun Yat-sen University, Jiangmen, China; 9Shanghai Gothic Internet Technology Co., Ltd., Shanghai, China.

Background: Ankylosing Spondylitis Disease Activity Score (ASDAS) is adopted to evaluate the degree of disease activity and the inflammatory response in AS patients. ASDAS score < 1.3 represents inactive disease status and achievement of T2T. SSDM is a mobile application for disease management.

Objectives: To evaluate the patterns of T2T and related influential factors among AS patients after applying SSDM in the real world.

Methods: AS Patients were trained to master SSDM by healthcare professionals (HCPs) and to conduct ASDAS self-assessments. Patients were also required for repeating self-assessments after leaving the hospital. After entry by patients, data can be synchronized to the SSDM terminal of authorized rheumatologists. Based on these data, the patients can apply for consultation to their physicians and rheumatologists can provide medical advices to their patients.

Results: From Jan 2015 to Jan 2020, 12,780 AS patients enrolled in SSDM with the mean age of 34.62±10.98 years old and the median disease duration of 3.58 years. Among them, 1,127 AS patients from 150 hospitals were followed up for more than 6 months through SSDM. The results at baseline and in final follow up.

Conclusion: Significant improvement was observed under applying SSDM through empowering AS patients. After proactive disease management via SSDM for more than 6 months, patients with ASDAS<1.3 score at baseline had a significantly higher remission rate of inactive disease activity. The patients who performed more frequent self-assessments had lower probability of relapse and higher rate of T2T. Online interaction between patients and physicians contributed to promote the improvement rate of T2T. SSDM is a valuable tool for long term follow-up through empowering patients.

Disclosure of Interests: SSDM was developed by Shanghai Gothic Internet Technology Co., Ltd.

DOI: 10.1136/annrheumdis-2020-eular.1798
Background: Flare, relapse from status of treat-to-target (T2T, DAS28<=3.2), is hard predicted. We try to make it predictable by applying machine learning to a database from smart system of disease management (SSDM). SSDM is an interactive mobile disease management APPs.

Objectives: To develop and validate machine learning algorithms for flare prediction in RA.

Methods: Patients were trained using SSDM and input their data, including demographic, comorbidities (COMBs), lab test, medications and monthly self-assessments, including DAS28, HAQ, SF-36, Hospital Anxiety and Depression Scale (HADS). The data was uploaded to cloud and synchronized to the mobile of authorized rheumatologists. The COMBs were by ICD-9, and medications were listed as cDMARDs, Bio (BioDMARDs), NSAIDs, Steroid, FS (food supplements), MC (medicine for COMBs), TCM (Traditional Chinese Medicine), and combinations.

Results: From Jan of 2015 to Jan of 2020, 8811 RA patients, 85% female and 15% male, used to reach T2T. 4556 were flare-free and 4255 suffering at least one flare. The average 160 attributes were extracted from each flare-free patient at time of reaching T2T, and each flare patients at time of 3 months before the flare. Patients were randomly assigned as model setup (training) group (70%) and validation (testing) group30%.

For training, data were processed using Python with statistical analyses in R. In R, random forests were implemented. Logistic regression via glm in base R. The random forest comprises a set of decision trees. "Splits" in the decision trees reflect binary (i.e., yes/no) respect to attributors. Bootstrap was used to assess, quantify, and adjust for model optimism. Model performance was evaluated using AUC, precision and recall metrics. Brier scores for accuracy of probabilistic predictions ranged from 0 to 1 (0 is perfect discrimination).

The testing showed model performance for prediction windows are 0.78 for AUC (95% CI), 0.71 for Recall (sensitivity), 0.195 for Brier score, and 0.68 for precision (true positive 893, false positive 417, false negative 367, true negative 966).

Based on weighing in the random forest, the top 10 pro-flare attributes were CRP, swollen joint count (SJC), tender joint count (TJC), HAQ, DAS28, morning stiffness, gout, MCTD, OA, duration; while top 10 anti-flare attributes were cDMARDs+Bio, cDMARDs+steroid+NSAIDs, stable on HAQ, on morning stiffness, on SJC, medicine on COMBs, cDMARDs+TCM, stable on TJC, on ESR, income at 100-200k (Fig.1). The top weighing COMBs for pro-flaring were gout (0.81), MRD (0.75), OA (0.56), AS (0.48). The monotherapies with either Bio or NSAIDs, or steroid, or TCM were pro-flare; while with cDMARDs was anti-flare (-0.21).

Background: Specialist services are heavily reliant on a consultant reviewing a patient and discussing management options. However this can significantly delay treatment pathway owing to lack of sufficient consultant appointments. Clinical nurse specialists (CNSs) are an integral part of a multidisciplinary team employed to provide effective care for the diverse needs of patients with chronic conditions such as osteoporosis.

Objectives: We designed an innovative proof-of-concept osteoporosis service with patients only consulting a metabolic bone CNS and a consultant providing remote oversight. The aim of the project was to improve the efficiency of the service by eliminating consultant appointments and reducing unnecessary hospital visits whilst continuing to deliver a high-quality and safe service.

Methods: A new pathway was implemented where a consultant rheumatologist and a CNS virtually triaged post menopausal women over the age of 65 into the service. A dedicated proforma provided the template for the CNS to undertake new patient telephone consultation. Relevant investigations were requested during the telephone clinic and treatment related information was despatched to help with shared decision making. All patients were then reviewed in a consultant-CNS virtual MDT. Appropriate parental treatment option was agreed and confirmed to each individual. The CNS worked through a safety checklist and provided further advice and support to the patient as necessary. Using the database, we compared the timelines for patient journey to conventional pathway, obtained the number of consultant follow-up appointments saved by implementing this service and calculated total savings.

Results: In the proof-of-concept phase, 60 patients were triaged into the new service. It was a combination of 25 new referrals and 35 patients pulled from the consultants’ waiting list. Mean age of participants was 77.2 years (65-92). Referral to virtual triage took median 20 days (0-62). Median time for triage to new patient CNS telephone consultation was 18 days (6-87). Time to virtual MDT for treatment authorisation was median zero days (0-76 days). 19 patients had anabolic therapy commenced via home care. Remaining had anti resorptive therapy. No patient requested face-to-face review. Only one patient fed back that they would’ve preferred to see the consultant once. Sixty new patient consultant appointments were saved and median delay in treatment commencement was reduced from 84 to 38 days.

Conclusion: To our knowledge, this is the first successful example of an innovative service wholly provided by CNSs for commencing parental anti-osteoporosis therapy with only remote consultant supervision. Our service redesign has significantly improved the efficiency of the parental osteoporosis pathway with reduction in treatment delay and a more streamlined patient journey. A nurse-delivered osteoporosis treatment pathway is highly effective, safe and provides an innovative solution to timely stretched health care needs of people with chronic conditions.

Disclosure of Interests: Julie Begum: None declared, Joanne Fourmy: None declared, Muhammad Khurram Nisar Grant/research support from: Muhammad Nisar undertakes clinical trials and received support (including attendance at conferences, speaker fees and honoraria) from Roche, Chugai, MSD, Abbvie, Pfizer, BMS, Celgene, Novartis and UCB.

Objective: To estimate the direct cost associated to SLE in contributory healthcare scheme in Colombia. To estimate prevalence and characterize SLE population affiliated in the contributory healthcare scheme in Colombia. To estimate the direct healthcare cost in patients with and without SLE and the effect of being diagnosed with SLE in the total direct cost during a period of two years.
Results: From 2014 to 2017, 21,993 SLE patients were identified. Women represented 87.4% of the cases, 5428 patients were selected to make up the sample of SLE patients. The number of patients without diagnosis of SLE was 19,419.540. From this population was drawn randomly a 10% size sample, to make up the potential control sample. To estimate the incremental cost of having SLE it was used multivariate regression through a GAM model. The estimated average annual total cost of a patient with SLE was $6,139,046 COP vs. non-SLE patient cost of $4,113,191 COP. Meanwhile, a patient in the low severity level had a $885,300.40 incremental cost. The estimated average annual total cost of a patient with SLE was $9,193,931.67 incremental cost estimate for high level of severity. In the medium level, the estimate was $2,025,855.65 COP greater than the cost of a non-SLE patient. When considering the severity levels of the disease, it was found a $885,300.40 incremental cost estimate for high level of severity.

Conclusion: Although the prevalence of SLE in Colombia is relatively low, the direct costs generated for this disease might be very high. The annual cost for a SLE patient was $2,025,855 COP greater than the cost of a non-SLE patient. When considering the severity levels of the disease, it was found a $885,300.40 incremental cost estimate for high level of severity. In the medium level, the estimate was $7,248,201.04. Meanwhile, a patient in the low severity level had a $885,300.40 incremental cost.

prevent permanent joint damage (1). However, it has been shown that only 20% of the patients are seen within the first three months, and the median delay in general practice has been estimated to 4 months (range 2–9) (2).

Objectives: To explore the barriers in diagnosing RA from the general practitioners’ (GPs) perspective.

Methods: We conducted a qualitative study based on focus group interviews. We recorded the interviews digitally and transcribed verbatim. The transcribed interviews were analyzed based on content analysis (3), by using Nivo 12. Sample size was determined by thematic saturation.

Results: In total ten GPs participated in three different focus groups. 40% were female, mean age was 53 years (range 37–64), and mean year since specialist authorization as GP was 16 years (range 5–23). 60% of the GPs worked in a practice located within the referral area of a university hospital; the remaining within the referral area of a regional hospital.

Four themes emerged in the analysis: 1) When the patient is not a text book example, referring to the difficulty of identifying typical symptoms among all clinical manifestations from the joints as described by the patients, 2) The importance of maintaining the gatekeeper function, referring to the societal perspective, and the GPs responsibility to refer the right patients to secondary care, 3) Difficulties in referral of patients to the rheumatologist, referring to perceived differences in the collaboration with rheumatologists. The GPs experienced that it was sometimes difficult to be assisted by rheumatologists, especially when the clinical picture was not ‘clear cut’. Finally, (4) Para-clinical testing, can it be trusted? referring to challenges on the evaluation of especially biomarkers.

The overarching theme was: Like finding a needle in a haystack, covering the GPs difficulties in detecting RA among the many patients in general practice who seem to be in need of referrals at the same time have symptoms very similar to RA. Conclusion: The GPs experienced that RA was a difficult diagnosis to make. The immediate challenge was that RA patient’s initial symptoms often resembled those of more common and less serious conditions, and that investigative findings such as biomarkers can be negative at the early state of the disease. At the same time, the collaboration with rheumatologists was sometimes seen as a hurdle, when the clinical picture was not ‘clear cut’.

In order to facilitate earlier diagnosis of RA in general practice, the GPs and rheumatologists need to focus on these barriers by strengthening mutual information and collaboration. Physicians should remain vigilant to patients who have conditions that do not resolve as expected with treatment, who have symptoms that persist, or who do not look well despite negative investigative findings.

SAT0652-HPR CHRONIC DISEASE MANAGEMENT AND HEALTH CARE READINESS OF PATIENTS WITH SYSTEMIC SCLEROSIS IN SWITZERLAND – A CROSS-SECTIONAL STUDY

A. Kocher1,2, M. Simon3,2, C. Chizzolini3, O. Distler4, A. A. Dwyer5, P. Villiger3, U. Walker6, D. Nicca3,1
1University of Basel, Institute of Nursing Science, Basel, Switzerland; 2Inselspital Bern University Hospital, Bern, Switzerland; 3Immunology & Allergy, University Hospitals and School of Medicine, Geneva, Switzerland; 4University Hospital of Zurich, Zurich, Switzerland; 5Boston College, Connell School of Nursing, Massachusetts, United States of America; 6University Hospital of Basel, Basel, Switzerland

Background: People living with systemic sclerosis (SSc) often lack access to coordinated, specialized care and self-management support from qualified healthcare professionals. Such gaps lead to significant unmet health needs and inability to get preventive services. The Chronic Care Model (CCM) has been used to guide disease management across a wide range of chronic conditions. The CCM often uses e-health technologies to address self-management problems, connect patients with clinicians and reduce patient travel requirements.

Objectives: To evaluate current SSc care practice patterns and elicit patient health technology readiness to define relevant aspects and resources needed to improve SSc chronic disease management.

Methods: We employed a cross-sectional survey using the 20-item Patient Assessment of Chronic Illness Care (PACIC) instrument to assess how aspects of SSc care align with key components of the CCM. Six items drawn from the ‘SA (ask, advise, agree, assist, and arrange) model of behavioural counselling were included (all 26 items scored on 5-point scale, 1=never to 5=always). Acceptance of health technology was evaluated by adapting and combining questionnaires from Vanhoof and Halwas2. German and French speaking SSc patients (>18 years) were recruited from university/cantonal hospitals and the Swiss scleroderma patients’ association. Participants completed anonymous paper/online questionnaires. Data were analysed descriptively.

Results: Of 101 SSc patients, most were female (76%), spoke German (78%) and had a median age of 60 years (IQR: 50-88). Median disease duration was 8 years (IQR: 5-16), spanning a range of severity (31% limited SSc, 36% diffuse SSc, 3% overlap syndrome). One-quarter (25%) did not know their disease subset.

The mean overall PACIC score was relatively low (2.91±0.95) indicating that care was ‘never’ to ‘generally not’ aligned with the CCM. Lowest mean subscale scores related to Follow-up/Coordination (2.64±1.02), Goal setting (2.68±1.07) and Problem-solving/Contextual Counselling (2.94±1.22). The single items ‘Given a copy of my treatment plan’ (1.99±1.38) and ‘Encouraged to attend programs in the community’ (1.89±1.16) were given the lowest ratings. The ‘SA summary score was 2.84±0.97.

In terms of technology readiness, 43% completed the survey online. Most participants owned a smartphone (81%), laptop (63%) and/or desktop computer (46%). The overwhelming majority of patients (91%) reported using the Internet in the last year – primarily for communication (e.g. emails, text messages). Participants indicated a relatively little experience with e-health applications and participating in SSc online forums or self-help groups.

Conclusion: To improve chronic disease management of SSc patients in Switzerland, current care practices warrant reengineering taking CCM components into account. Specific unmet needs relate to self-management support, help patients set individualized goals, and coordinate continuous care. Web-based technologies incorporating user-centred design principles may be a reasonable option for improving care.

unreasonable referral flow from primary care to secondary care and to share the
care of stable inflammatory patients between the services.
In the traditional service model patients are referred by General Practitioners (GP) to the secondary care with a wide spectrum of conditions: from fibromyalgia through soft tissues rheumatisms to inflammatory or connective tissue diseases. Many of these patients will be discharged from the specialist service after their first visit with fibromyalgia, osteoarthritis, chronic pain syndrome or MUS diagnoses. The proportion of these patients versus those who have an inflammatory rheumatologic condition or connective tissue disease (CTD) varies significantly and can contribute to oversaturated specialist rheumatologic services with long waiting time where specialists deal with less relevant cases.

Objectives: To determine how CR can improve quality of care and decrease
the waiting time for appointment in secondary care rheumatology services. To set standards for referral pathways and measured outcomes of effectiveness in patient care.
In the UK the regional Clinical Commissioning Groups would accept a maximum waiting time from the referral until patient treatment of up to 18 weeks and specialistor services often breach that limit. This long interval may have a significant negative impact for the care of patients with rheumatological condition, reducing patient satisfaction and/or jeopardize patient safety. The solution to the above problem is the creation of CR service.

Methods: Extensive search about the available resources within UK NHS sys-
tem in regards CR service creation and set up. Web search, literature review in relation to CR in the UK
Results: From the research different models of CR can be identified and one of these will be presented in details based on the experience of one of the largest organisation running CR services in the UK (Connect Health Ltd). This service is organised within community care set up and can accept patients referred by the primary care physicians with non-inflammatory symptoms (e.g. osteoarthritis, Ehlers-Danlos Syndrome, fibromyalgia) or PMR or gout. The service also can review stable inflammatory patients who are treated with DMARDs and are transferred from the secondary care service by their consultant. This presentation will demonstrate how CR provides safer, faster and more accessible services to the patients assisting the specialist services and allowing them to concentrate on the inflammatory and CTD patients who need faster access to these services than it is possible now. Particularly the presentation will empha-
sise on:

• Patient population cover
• Team structure, their experience and training
• Referral criteria and IT set up for multidisciplinary connection
• Time interval for appointment and patient feedback
• Impact on the secondary care rheumatology service
• Cases of misdiagnosis and inappropriate referrals
• Cost effectiveness of the CR
• Challenges in the CR service

Conclusion: The CR service can be a safe addition to the specialist services taking over significant workload and provide new career opportunities for a wide range of Allied Health Professionals (AHP) for the bigger satisfaction of the patients who can access rheumatology service earlier and easier.

DOI: 10.1136/annrheumdis-2020-eular.6550

RESULTS:

Objectives: To determine the effectiveness of the EAC by early identifica-
tion of new cases of RA and to facilitate decision in early initiation of disease-modifying anti-rheumatic drugs (DMARDs) during the first doctor clinic assessment.

Methods: New cases were screened and recruited by Rheumatology nurse from January to December 2018 to nurse-led EAC. The recruited new cases were seen in EAC around 1 to 4 weeks before the first doctor clinic. Rheumatology nurse performed nursing assessment in EAC according to the 2010 ACR-EULAR Classification of RA. These cases will be reviewed by Rheumatologist during the first doctor clinic for confirmation of diagnosis and formulation of treatment plan. If urgent problems were identified during assessment in EAC, patients would be prioritized to have an earlier doctor clinic appointment or hospitalization may be arranged.

RESULTS:

A total of 128 patients with articular symptoms were seen in nurse-led EAC during the study period. Nursing assessment revealed that 71 patients were required further evaluation for the diagnosis of RA (26 males and 45 females, mean age for males: 51, mean age for females: 56) and they were recruited into the study. 36 of these 71 patients were confirmed with the diagnos-

sis RA by rheumatologist during the first consultation of doctor clinic. 13 of 36 patients were prescribed with DMARDs on the same day of consultation. Before the establishment of EAC, the mean time of confirmation of RA by rheumatologist was 8 weeks (range from 4 to 12 weeks). Therefore, EAC facilitates both the early diagnosis of RA and the prompt initiation of treatment after confirmation of diagnosis. Reduction in disease activity was also noted after treatment. The mean Disease Activity Score of 28 joints (DAS28) during the assessment in EAC was 4.66 (range 3.22 to 6.54) while post treatment after EAC and the first doctor clinic was 3.30 (range 2.08 to 5.16) with mean difference of -1.36 (p<0.01). Other diagnoses were also made among the 71 patients. 8 patients were diagnosed of Spondyloarthropathy, 2 patients were diagnosed of psoriatic arthritis and 2 patients were diagnosed of systemic lupus erythematosus. 3 of these 71 patients were identified urgent medical problems required early inter-
vention. Among these 3 cases, two patients with liver function derangement and one of them needed hospital admission for assessment of acute hepatitis. Another patient was arranged hospitalization to rule out sepsis due to raised total white cell count and erythrocyte sedimentation rate.

Conclusion: Rheumatology nurse assessment in EAC is effective in assess-
ing patients with suspected diagnosis of RA. It shortened the time to confirm the diagnosis of RA, and facilitated the decision on treatment plan. It effectively improved the disease activity of patients due to the prompt initiation of DMARDs by Rheumatologist.

Patient information and education

**DIET, NUTRITION AND ARTHRITIS – A WORKSHOP FOR YOUNG PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES (RMDs).**

M. Voeten1, W. Oliger, Youth-R-Well.com, Nieuwegein, Netherlands

**Background:** The impact of diet and nutrition on RMDs is a growing topic with lots of ongoing research and remaining questions. Youth-R-Well.com, the organization for young people (18-30 years) with rheumatic and musculoskeletal diseases (RMDs) in the Netherlands, recognized that young people want to know more about this theme. Therefore, Youth-R-Well.com organized the workshop “Diet, Nutrition and Arthritis” to inform young people with RMDs about the facts and myths of the impact of diet and nutrition on RMDs.

**Objectives:** The main objective of this project was to inform young people with rheumatic and musculoskeletal diseases about the impact of diet and nutrition on RMDs. Youth-R-Well.com wanted to offer the knowledge of proven research and studies, and provide all the recent facts and fables about this topic. By becoming well-informed about the impact of healthy cooking, young people are able to improve the self-management of their disease. Besides providing information about the impact of diet and nutrition, the objective was to offer tips and tricks about ergonomic cooking. With the right tools for cooking, the participants might be inspired by a less painful and more suitable way of cooking, which also increases the self-management of their disease.

**Methods:** To make sure the event was consistent with the needs of young people, Youth-R-Well.com organized a cooking workshop that consisted of two parts: informative presentations and a fun healthy cooking workshop. For the first part, we invited a professor and a dietitian specialized at this specific topic to provide the correct and up-to-date information. For the second part, we invited an occupational therapist to provide information about ergonomic cooking. The kick-off of the day was by two informative presentations: the professor, who focused on recent studies, and the dietitian, who focused on the practical side. Both the presentations ended up in a question and answer component, where the participants showed lots of interaction. After the first session, the practical side of the workshop could be started. Several nutrient full and healthy recipes were made in teams to interact with other participants. An occupational therapist facilitated the participants by presenting the less painful and correct technique for preparing food. The workshop is filmed and shared through YouTube, to make sure the information reaches more young people with RMDs.

**Results:** It was a successful workshop where over 40 participants were present. The educational and helpful presentations were well-received and created more realization of the impact of an appropriate and altered diet. The survey, which was filled up by the participants, has shown that over 91% rated the event by the highest-ranking “good.” Also, in the second part of the workshop, the practical cooking was very good and useful; it was rated as the most favorite part. The workshop was filmed and shared online, we reached over 1300 people with enthusiastic and lovely comments.

**Conclusion:** Based on the questions of young people around the impact of diet and nutrition on RMDs, Youth-R-Well.com organized the workshop: “Diet, Nutrition and Arthritis.” Through the combination of informative presentations and a fun cooking workshop, Youth-R-Well.com managed to inform young people about this growing topic. We will continue to spread the information through our online media coverage in print and broadcast.

**IMPACT OF SERVICE DOGS ON THE BURDEN OF ARTHRITIS**

P. Wechsneider1, HerzReha Bad Ischl, Bad Ischl, Austria

**Background:** Assistance dogs support humans with different physical disabilities. 1. Service dogs for people with diverse mobility impairments 2. signaling dogs for humans diagnosed with diabetes, hearing impairments, seizure, or posttraumatic stress disorder 3. guide dogs for people with visual impairments. Definitions and terms are not consistent over Europe; Austrian terminology is used in the following. These specially trained dogs support people in their everyday lives and make it possible that less help is required from personal assistants or caregivers. Diverse studies show this positive impact of assistance dogs on the quality of life of disabled people. There are just a few case reports from United States about service dogs for people with an inflammatory rheumatic disorder. Dogs are trained individually for about 1.5 years before team training and the concluding team assessment through Austrian authorities take place. Since 2015, there has been an adapted legislation for service dogs in Austria which brings significant improvements in many areas. In comparison to the model set by Austria, there is no corresponding legal basis at EU level or in other European countries.

**Objectives:** Case-report about my own situation diagnosed with juvenile idiopathic arthritis (JIA) in 2001 and my service dog May. May supports my everyday life in private and business affairs since 2019

**Methods:** May was trained for less than two years before team assessment. May is able to pick up things I dropped. These include coins, my key, my mobile phone, clothes, towels and lots of other things I want her to pick it up for me. May opens and closes doors, empties the washing machine, pulls the laundry basket and even helps me put on and take off my clothes. In general, she carries many things which I instruct her to carry. I am able to learn her more new things in a short time. Furthermore May acts safe on public transport and even airplanes. Due to special training May is allowed to move without dog leash or muzzle. A muzzle or leash would handicap the dog’s work. As a result of May’s help I need less personal assistance.

**Results:** May’s physical and psychological support gives me greater independence and increases my self-confidence. She was trained to specifically meet the needs of my disability. Beside her skills, May helps to reduce pain and burden of arthritis.

**Conclusion:** My aim is to spotlight the great support of service dogs to severely affected arthritis patients. Austria had realized legislation for assistance dogs to guarantee certain permissions the owner’s needs (e.g. access to working place, hospital). I would love to raise awareness about assistance dogs to improve the knowledge about those animals to implement European legislation.

**MY RA STORY - PERSONAL ACCOUNTS OF LIVING WITH RHEUMATOID ARTHRITIS**

B. Lynch1, Dublin, Dublin, Ireland

**Background:** Over 2,000 people are diagnosed with rheumatoid arthritis (RA) in Ireland each year; three in four are of working age. In total, RA affects some 45,000 people in the country; 70 per cent of whom are women. For someone newly diagnosed with RA, coming to terms with the news can seem overwhelming. Such a dramatic shift in life circumstances can impact one’s physical and mental well-being. While there is no shortage of information available about the condition, it can be overwhelming trying to filter this, assess what is trustworthy and reliable.

**Objectives:** To provide information and hope to people newly diagnosed with RA, and to give a voice to those living with the condition;

• To increase awareness and understanding of RA – encourage engagement with HCPs, contributing to early diagnosis and better outcomes;

• To increase awareness of work of Arthritis Ireland as a patient organisation.

**Methods:** Arthritis Ireland publishes an annual best-selling author and RA patient Sinead Moriarty, to front an RA awareness campaign, called My RA Story. The purpose of the campaign was to increase awareness and understanding of rheumatoid arthritis, of what it is like to live with this chronic condition with its invisible pain and life-changing impact. In so doing, Arthritis Ireland wanted to give a platform to people to tell their own story, so that they could be heard. We then wanted to publish these experiences in book form.

In April 2019, we launched a video on social media featuring Sinead Moriarty speaking about her experience of living with RA. The video generated lots of engagement across social media and also helped garner national and regional media coverage in print and broadcast.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.1287

**SATURDAY, 06 JUNE 2020**

**Scientific Abstracts**

**Saturday, 06 June 2020**
The call for RA stories received a fantastic response from the public and the reading panel had a tough job in selecting the contributions which would feature in the published volume. Once the successful contributions were chosen, Arthritis Ireland proceeded to design a book, which could be sold in the book trade and online.

**Results:** In September 2019, Arthritis Ireland published My RA Story: Personal accounts of living with rheumatoid arthritis. Launched in the National Library of Ireland by Sinead Moriarty, the 46 contributions touched upon themes of pain, fatigue, emotional impact, disability, surgery, education, career, family, goal-setting, self-management, connecting with others, hope, etc. The contributors came from people who were living with RA for over 40 years, as well as from those who were more recently diagnosed. The book is a hugely valuable contribution to health literature. Arthritis Ireland now plans to make the book available for sale internationally, through Amazon and other retail channels, as well as promoting it more extensively in rheumatology clinics.

In October, one of the contributors was interviewed on national television about her RA story, as part of a feature on World Arthritis Day.

**Conclusion:** This campaign gave people living with RA a platform to write about and share about their condition. Fronted by an RA champion with significant name recognition and an enormous audience in her own right, best-selling author; Sinead Moriarty, the book, My RA Story. Crucially, the book is a valuable resource for people who are newly diagnosed with the disease and uncertain of what the future holds.

**Acknowledgments:** This project was supported by an educational grant from MSD.

**Disclosure of Interests:** Brian Lynch Grant/research support from: Arthritis Ireland received a grant from MSD to develop this patient education programme. Brian Lynch has not benefited personally in any way.

Regarding GCs efficacy (table 1), high levels of endorsement were found: about 2/3 of patients considered that GCs as very useful in their case, more than half considered that GCs were effective even at low doses, and agreed that GC improved RA symptoms within days.

Regarding safety (table 1), 1/3 of the participants reported having suffered some form of serious adverse events (AEs) due to GCs, and 9% perceived this as “life-threatening. Adverse events had a serious impact on quality of life, according to about 1/3 of the respondents.

**Conclusion:** Patients with RA exposed to GC report a strong conviction that GCs are very useful and effective for the treatment of their RA, even at low doses. This is accompanied by an important prevalence of serious AEs. Understanding the patient perspective can improve shared decision-making between patient and rheumatologist.

**References:** Funding statement: This project has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No 834886.
medication and treatment thus impeding their ability to achieve the best outcomes. We know, for example, that many people do not take their medication as prescribed which reduces their chances of achieving remission or low disease activity state.

**Objectives:** To demonstrate that by referring patients online as part of a quality improvement programme to NRAS Right Start Service, we can show improved outcomes for patients with early RA when measured by the MSKHQ. Referred patients will benefit by: a) Better understanding what RA is; b) knowing how it can affect them; c) getting the right support; d) feeling more in control; receiving a tailored pack of information that meets their personal needs; e) be able to talk to a like-minded person who has lived with RA. It’s a 4 step process which starts with the health professional referring their patient to NRAS on line. NICE Quality Standard 3 states that “Adults with rheumatoid arthritis are given opportunities throughout the course of their disease to take part in educational activities that support self-management.” Our service enables health professionals to meet their responsibilities against this national quality standard.

**Methods:** In preparation for the introduction of this service at BSR congress 2019, an audit of the NRAS helpline service was undertaken at the end of 2018 and remains on going. Currently we have 224 responses which have been analysed against specific criteria. An Advisory Board comprising 7 clinicians, from different hospitals was appointed to work with NRAS on this important research.

**Results:** In the helpline audit, when asked ‘how concerned are you about your disease?’, alarmingly, 78% of those surveyed scored their level of concern about their disease at 7 or higher out of 10, while only 8% scored it at 5 or below. When asked about the emotional effects of their RA, 62% scored it as 7 or more where 10 was the worst possible impact. 94% of survey respondents said that they would definitely or very likely recommend NRAS and its services to another person. These results led to the development of New2RA Right Start launched in 2019, whereby health professionals across the UK can refer their patients directly to NRAS via a consented online referral which is fully GDPR compliant. To date (31st Jan, 2020), we have made calls to 101 patients, from 24 referring hospitals of which 85 have been successfully completed, 34 have had information sent through the post although our helpline team were unable to contact patients directly to NRAS via a consented online referral which is fully GDPR compliant. To date (31st Jan, 2020), we have made calls to 101 patients, from 24 referring hospitals of which 85 have been successfully completed, 34 have had information sent through the post although our helpline team were unable to contact patients directly to NRAS via a consented online referral which is fully GDPR compliant.

**Conclusion:** Anecdotally, we have had a tremendous response to this service from both patients and referring health professionals. We await data from King’s on the above figures, which we will have within the next 2 months and further data, should this abstract be accepted, will be available prior to June 2020. Right Start enables health professionals to comply with QS3 above, of the NICE Quality Standards in RA, one of the key standards against which they are being audited in the NEIAA national audit. Once data and write up in a peer review journal has been published we plan to roll this service out to people with more established disease.

**PARE0006 WORK PRODUCTIVITY LOSS IN PATIENTS WITH INFLAMMATORY ARTHRITIS**

T. Pilgaard, B. A. Esbensen, S. E. Stallknecht, Pfizer ApS, Ballerup, Denmark; Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; Incentive, Holte, Denmark

**Background:** Limited data exist of work productivity loss in patients with Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Spondyloarthritis (axSpA).

**Objectives:** The objective of this research was to assess productivity loss and absenteeism in patients with RA, PsA and axSpA.

**Methods:** The study was designed as a cross-sectional study aimed to collect patient-reported outcomes from patients with RA, PsA and axSpA in Denmark via a nurse administered questionnaires and patient journals. Patients ≥ 18 years with RA, PsA or axSpA were consecutively recruited for the study over a 6-month period via routine visits to outpatient rheumatology clinics. Descriptive statistics were analyzed using SAS.

**Results:** Of 488 respondents, 62% were women and mean age was 53.5 years (RA:57.4; PsA:52.6; axSpA:43.6). Average time since diagnosis was 11-15 years, however, for PsA and axSpA most patients answered 6-10 and 0-5 years, respectively. 280 (57%) answered that they had a job and completed the WPAI questionnaire (RA: 149 (51%); PsA: 48 (56%); axSpA: 83 (75%)). Average work hours was 31.9 in the last week (RA:31.2; PsA:33; axSpA:32.4). Average missed work hours were 4.3 in the last 7 days (RA:4.0; PsA:4.2; axSpA:4.8), of which 32% was missed due to their inflammatory arthritis (RA:30%; PsA:36%; axSpA:32%). Mean absenteeism was highest for patients with PsA (mean=6.8; SD=17.7) followed by patients with axSpA (mean=5.4; SD=15.1) and with RA (mean=3.4; SD=12.2). Mean productivity loss was 20.5 (SD=23.8) for patients with RA, 27.6 (SD=25.8) for PsA and 26.3 (SD=25.8) for axSpA.

**Conclusion:** We found that patients with PsA or axSpA miss more hours of work compared with patients with RA and when they are at work they have a higher absenteeism/lower productivity. This even though that both the group of patients with PsA and the axSpA were younger and had lived less time with their diagnosed disease compared with the group with RA.

**RMD research**

**PARE0007 PATIENT AND PUBLIC INVOLVEMENT IN CLINICAL TRIAL DESIGN**

S. De Souza, R. Williams, E. Johansson, C. Zabalan, T. Esterine, M. Bakker, W. Roth, N. MC Carthy, M. Blake, S. Karlfield, M. Johansson, K. Raza, King’s College London, London, United Kingdom; EULAR PARE Network, Zurich, Switzerland; The Swedish Rheumatism Association, Stockholm, Sweden; University of Erlangen-Nuremberg, Erlangen, Germany; Newcastle University, Newcastle, United Kingdom; Karolinska Institute, Stockholm, Sweden; University of Birmingham, Birmingham, United Kingdom

**Background:** Patient and public involvement (PPI) is gaining increasing recognition as important in ensuring research is relevant and acceptable to participants. Rheuma Tolerance for Cure (RTcure) is a 5 year international collaboration between academia and industry; focusing on earlier detection and prevention of rheumatoid arthritis (RA) through the use of immune-tolerising treatments.

**Objectives:** To bring lived experience and insight into scientific discussions; and to evolve collaboration between lay representatives and academia/industry.

**Methods:** 9 Patient Research Partners (PRPs) from 5 European countries were recruited via the EULAR PARE Network and institutions within the RTcure Consortium (8 PRPs with RA and 1 ‘at risk’). They were asked to enter into a legal agreement with the Consortium. PRPs participated in teleconferences (TCs) and were invited to attend face-to-face (F2F) meetings at least annually. Requests for input/feedback were sent from researchers to PRPs via the project’s Patient Engagement Expert [SK].

**Results:** PRP involvement has given researchers and industry partners a new perspective on patient priorities, and focused thought on the ethics of recruitment for
and participation in clinical trials of people ‘at risk’ of developing RA. PRPs have helped define the target populations, given their thoughts on what types of treatments are acceptable to people ‘at risk’ and have aided the development of a survey (sent to EULAR PARE members) regarding the use of animal models in biomedical research. Positive informal feedback has been received from researchers and industry regarding the contribution of PRPs to the ongoing project (formal evaluation of PIP in RTCure will be carried out in 2020 and at the project end in 2022). Challenges: Legal agreements - Many PRPs refused to sign the Consortium’s complex PRP Agreement; feeling it unnecessary, incomprehensible and inequitable. After extensive consultation with various parties (including EULAR and the Innovative Medicines Initiative) no similar contract was found. Views for its requirement even varied between legal experts. After 2 years of intense discussion, a simple non-disclosure agreement was agreed upon. Ideally any contract, if required, should be approved prior to project onset.

Meeting logistics - Other improvements identified were to locate the meeting venue and accommodation on the same site to minimise travel, and to make it easier for PRPs to take breaks when required. This also facilitates informal discussions and patient inclusivity. We now have agreed a policy to fund PRPs extra nights before and after meetings, and to bring a carer if needed. Enabling understanding – Future annual meetings will start with a F2F meeting between PRPs and Work Package Leads. Researchers will be encouraged to start presentations with a summary slide in lay language. Additionally, an RTCure Glossary is in development.

Glossary is in development.

Getting participation – SK will provide monthly project updates and PRP TCs will be held in the evening (as some PRPs remain employed). PRPs will be invited to all project TCs and F2F meetings. Recruitment is underway to increase the number of ‘at risk’ PRPs as their viewpoint is vital to this study.

Conclusion: Currently PPI in RTCure is an ongoing mutual learning process. Universal guidance regarding what types of contracts are needed for PPI would be useful. Communication, trust and fruitful discussions have evolved through F2F meetings (both formal and informal) between PRPs, academia and industry. It is important that all parties can be open with each other in order to make PPI more meaningful.

Involvement and innovation in healthcare

PARE0008 MOBILE APPLICATION “MOJRA” FOR MONITORING PATIENTS WITH RHEUMATOID ARTHRITIS

N. Teodorović1, S. Đorđević1, L. Vranic1, Belgrade, Belgrade, Serbia

Background: In Serbia, regular examinations with a rheumatologist are scheduled on average every 3 to 4 months. With this in mind, there is a real possibility that many patient data during this period may not be presented to the doctor during the examination, either because the patient forgets them or because they may focus on other issues and may not highlight key facts.

Objectives: To overcome this problem, the Association of Patients with Rheumatic Diseases of Serbia-QRS in cooperation with an IT firm developed the application “MoJRA” which was presented at the annual rheumatology congress of Serbia held in September 2019. The application “MoJRA” is intended for patients suffering from rheumatoid arthritis - RA. The application enables efficient monitoring of Serbia’s patients suffering from rheumatoid arthritis - RA. The application enables efficient monitoring of Serbia’s patients suffering from rheumatoid arthritis (RA) and a trial summary for laypersons, published within 1 year of study completion. These lay summaries should disseminate clinical trial results in an easy-to-understand way for trial participants, patient and caregiver communities, and the general public. The European Patients Forum (EFP) and European Patients’ Academy on Therapeutic Innovation (EUPATI) encourage CRSSs to engage with patient organisations (POs) in the development of lay summaries. This recognises the patients’ contribution to clinical research and supports the development of patient-focused material.

Objectives: We share learnings from a collaboration between scleroderma POs and a CRS to create the SENSCIS® trial (NCT025297933) and verify lay summaries in clinical trials.

Methods: A community advisory board (CAB), comprising representatives from 11 scleroderma POs covering a range of countries/regions, was formed based on the EURORDIS charter for collaboration in clinical research. Through three structured meetings, over a seven-month period, the CAB provided advice on lay summary materials (written and video) drafted by the CRS’s Lay Summary Group (Fig. 1). At each review cycle, the CAB advice was addressed to make content more understandable and more relevant for patients and the general public.

Results: The CAB advised that the existence of lay summaries is not well known in the patient community and also recommended the development of trial-specific lay summary videos to further improve understandability of the clinical trial results for the general public. Videos are a key channel of communication, enabling access to information for people with specific health needs and lower literacy levels. Following CAB advice, the CRS developed a stand-alone video entitled “What are lay summaries?” and a trial-specific lay summary video. Revisions to lay summary content (written and video) were made to incorporate colour schemes, iconography and language changes to make content more understandable. For videos, adjustments to animation speed, script and voiceover were implemented to improve clarity and flow of information (Fig. 2). Approved final versions of lay summary materials are publicly available on the CRS website. Translation into languages representing trial-site countries is in progress to widen access to non-English speakers and, where possible, local versions will be reviewed by the patient community.

PARE0011 AFLAR’S (FRENCH LEAGUE AGAINST RHEUMATISM) NEW ACTIONS TO HELP PEOPLE WITH RHEUMATIC DISEASES TO GET AND STAY EMPLOYED.

L. Carton1,2, F. Allot Launois3, G. Chales3, B. Liessee3, C. Jandard2, Paris, Paris, France;1 AFLAR, Paris, France

Background: Accessing jobs and being able to stay in a paid work position are a personal issue for people with rheumatic diseases, as well as for society. AFLAR, French league against rheumatism, has been acting towards patients and employers since 2014 in this field.

Objectives: After a preparatory work with a panel of all types of professionals and institutions working on the subject, key messages on means to improve the professional situation of people with rheumatic diseases have been published. These messages were used as a basis for an awareness training designed for human resources training and employers’ managers, and in a guidance booklet designed for patients and published in 2016: "At work, even if affected by chronic rheumatic diseases". This booklet, rather than gathering administrative and social resources in favour of patients, was based on patients’ and experts’ expression, written with them and proposed gradual guidance along their path from their professional choices to the disabled worker certification when needed. Two new actions have been seen as necessary in 2019 in order to go on with our actions: updating our booklet after 2 new laws had been issued in the field of labour law, and additions seemed necessary because of new work methods are developing (distant work from home, independent work); and the need of a new widely spreadable tool to accompany patients from the diagnosis stage, especially on the diagnosis disclosure to the work group issue.

The specific characteristics of rheumatic diseases: diversity, growing invisibility of diseases' effects and aftereffects to new treatments such as biologics and early rehabilitation, variation in time and personal impact, make them hard to understand by employers and even untrained social workers. This is what we noted from our experience in patient education workshops. Patients have a tendency to hide their pathology, and thus cannot benefit from social advantages as disabled workers, with motivation based on keeping personal image and an idea of normality, and fear of negative reactions from the work group, such as depreciation, pity, idea of negative impact on team’s productivity.

Patients have to build a real strategy, taking into account these criteria and their personal choices, while preparing their job’s adaptation or social requests when needed. AFLAR chose to create a new patient information tool: free short widely spreadable videos, available on line. These will also invite patients to get in touch with expert patients on the specialized hotline, participate to chats of patient education workshops.

Methods: Videos will show witness patients and experts, who will be asked about their experience and advice based on four questions:

PARE0010 THE VR DOCTOR – THE IDEAL DOCTOR’S APPOINTMENT

C. Helin Hollstrand1, K. Nilke Nordlund1,1 The Swedish National Organization for Young Rheumatic, Stockholm, Sweden

Background: With new technology available, health care is evolving quickly, and new solutions are constantly being presented. Although few of these solutions focus on patient-participation and patient empowerment. That’s what we wanted to create! Using virtual reality, we figured we could prepare and empower patients before meeting their doctor – and also giving doctor’s a chance to see what it’s like sitting across the table.

Objectives: The main objective was to show an example of how an ideal visit to the doctor could look like, to empower patients. By knowing their rights and what kind of care they are entitled to, we wanted to make patients more prepared and feel safer and more comfortable before a doctor’s appointment. The experienced is based on the Swedish Patient Act. We also wanted to be able to show health care professionals what it’s like being a patient, and giving them the opportunity to try it out.

Methods: We teamed up with fellow patient organizations Proud Bellies (Stolta Magar) and Youth with Psoriasis (Ung med Psoriasis), pharmaceutical company AbbVie and e-health company Cambio to create the virtual reality experience. Together we worked out what the ideal doctor’s appointment would be like, based on the Swedish Patient Act, and wrote the script. Our example doctor’s visit is generic, meaning all of our three organizations could use it even though we represent different diseases and diagnoses. But we also created three other virtual reality experiences. They are disease specific, and one is for RA. In the film, you get to go inside the joint to see what happens when you have rheumatism, while a speaker explains it to you.

Results: We launched the VR Doctor in January of 2019 with a great event. Patients, health care professionals, press and others were gathered and got to try a visit to the VR Doctor. It was very-well received, especially by other patients. Since then, we have used the tool during our member activities such as summer camps, to empower our members. And we have introduced the tool for health care professionals at several rheumatology clinics throughout Sweden.

Conclusion: With new technology comes great opportunities to simplify complicated matters. The VR Doctor is essentially a crash course in the Swedish Patient Act, making it a very useful tool for both patients and health care professionals. By giving an example of what an ideal doctor’s appointment could be like, we are letting patients take matters into their own hands and bringing them a sense a power and control over a situation that normally could be tough and sometimes intimidating. With empowered patients who feel safe, we are one step closer full patient-participation and in the long run a better health care system for all.
Results: AFLAR wishes to contribute actively to rheumatic patients; and especially young people’s information on the topic thanks to these more innovative and interactive tools.

Conclusion: Furthermore, wishes, solutions and ideas of witness patients and users will be gathered for advocacy towards employers, institutions and decision makers.

Disclosure of Interests: None declared

Campaigning

**PARE0012** AWARENESS CAMPAIGN “LUPUS.GR 2020”

K. Antonopoulou1, M. Konstantinidis1. 1ELEANA/HELLENIC LEAGUE AGAINST RHEUMATISM, ATHENS, Greece

Background: LUPUS GR 2020

Objectives: To sensitize and educate the wide public about lupus

To contribute to the process of de-stigmatization as the rigid problem of prejudice and stigma prevails.

Methods: The campaign “LUPUS GR 2020” consists of photographs, each of which has a different message for Lupus and TV spots. The well know artists participated did not take any fee.

The campaign consists of

- Press Announcements in digital and off digital media, in Social Media (Instagram - Twitter - Facebook), in Eleana Site and in YouTube

- Post of the artists in their personal social media pages

- Press Conference

- Direct mail in international NGOs e.g. Lupus Europe, PAIN ALLIANCE EUROPE, AGORA PLATFORM, etc.

Results: We announced the campaign on January 24, 2020. Until end of January, we have 36 press clipping, 3 TV interviews, more than 35.000 views of the post in our fb and increase of telephone calls in our help line about lupus

Conclusion: The campaign has a high impact in the wide public as well as in all the stakeholders.

Patient information and education

**PARE0013** ‘FIND A NUDGE’ AND OTHER TIPS TO MAINTAIN YOUR LEVEL OF PHYSICAL ACTIVITY FOR A LONGER TIME

R. Geenen1. 1Utrecht University, Department of Psychology, Utrecht, Netherlands

Background: Pain, fatigue, physical disability, reduced well-being and sleep problems are common consequences of Rheumatic and Musculoskeletal Diseases (RMDs). Paradoxically, these consequences may all lead to a reduction of physical activity, while physical activity actually is a cure for these consequences. This is acknowledged by experts that included physical activity and exercise into recommendations for management of RMDs [1-3]. Indeed, after programs aimed at a gradual build-up of exercise, many people with a RMD showed an increase of physical activity. However, it is hard to maintain a higher level of physical activity for years as part of daily routine [4-5].

Objectives: To identify and present tips, applications and illustrations that support people with a RMD to maintain their level of physical activity for a longer time.

Methods: Theoretical considerations and empirical findings guided the identification of tips. Care was taken that the tips and illustrations were translated into layman language and fitted in daily life of common people.

Results: Ten tips were found:

1) break the habit,
2) make sure you can do the exercise activity,
3) use aids if needed,
4) believe in a good outcome,
5) choose a physical activity that fulfils personal goals,
6) find a physical activity that you enjoy,
7) stop moving while it’s still fun,
8) find a buddy,
9) make an action plan, and
10) find a nudge.

A “nudge” is a little push in the right direction that makes a person unconsciously perform physical activities. Examples are an outdoor photography hobby, a dog that comes to you with a dog leash in his mouth, or grandchildren that persuade you to go with them to the playground nearby. If a person with a RMD manages to find a nudge that stimulates instinctive moving without feeling the effort, then physical activity may be maintained. People differ a lot and must discover for themselves which tips help them to maintain physical activity. They must be aware that it may take up to two months for changed habits to stick.

Conclusion: The presented tips will help to maintain your level of physical activity. Nevertheless, be aware that effort and perseverance are needed to keep on moving. A challenge for the future is to get more knowledge of natural and pleasurable physical activities. Peers with successful experiences and
behavior change experts can help. For the time being, a main advice to main- 
tain a higher level of physical activity with less effort is to find your own nudes.

Conclusion: The use of cannabis is still a very “hot topic” in many countries and the legislation can vary a lot from country to country. It is important that the rheumatism associations across Europe have knowledge about cannabis so that they can advise patients with RMD in a serious, objective and evidence-based manner.

CANNABIS – HOW TO NAVIGATE BETWEEN PRESSURE FROM PATIENTS, LEGISLATION AND NEED FOR EVIDENCE

N. B. Hartz1, 1 The Danish Rheumatism Association, Gentofte, Denmark

Background: Around the world, focus on cannabis has been increasing immensely the last couple of years. Patients with RMD very often experience pain and many of these patients do not get adequate relieve from ordinary pain-killers. Therefore, the pressure from patients wanting to try cannabis in order to ease their pain, is very understandable but also a difficult field to navigate in for a rheumatism association. Mainly because there are so many different interests in cannabis from many sides.

Objectives: The Danish Rheumatism Association has taken a very active role in unfolding knowledge of the positive and negative effects of cannabis to patients with RMD. We want to show, that we are aware of our patients needs and interests and we wish to give independent information to patients with RMD about suitable pain relief also when this involves the use of cannabis.

Methods: In order to get more knowledge about the need of the patients, the Danish Rheumatism Association has registered every inquiry from patients to our professional helpline in 2018 regarding cannabis. This information has been used in our political work with the Danish Ministry of Health and has given us a deeper understanding of the RMD-patients background and motivation for using cannabis. The Danish Rheumatism Association has supported cannabis research financially, and we have taken part in the public debate with editorials. On our website, we have fact sheets regarding cannabis along with a theme about cannabis in our magazine. The Danish Rheumatism Association has been very active politically in order to get RMD-patients to be part of a national project with medical cannabis to different groups of patients. We have an ongoing contact with the Danish Ministry of Health regarding RMD-patients experience in using cannabis and we pass on RMD-patients difficulties in even getting cannabis legally. In addition, to continuously gain knowledge about RMD-patients’ experience with cannabis, we have also conducted questionnaire and surveys both in collaboration with other patient organizations and through our own channels.

Results: We have made it clear that we take an active role in the public debate regarding the use of cannabis and that we understand the desire from patients to have as many options as possible to choose from when it comes to relieve their pain. However, we also acknowledge the fact, that we need more evidence when it comes to the use of cannabis as an actual option for patients with RMD-related pain. We are a reliable partner that politicians and other stakeholders take very seriously. Unfortunately, patients with RMD did not get to be part of the national project in Denmark with medical cannabis, but nevertheless many of these patients are using cannabis and most of the patients buy it illegally.

Conclusion: The use of cannabis is still a very “hot topic” in many countries and the legislation can vary a lot from country to country. It is important that the rheumatism associations across Europe have knowledge about cannabis so that they can advise patients with RMD in a serious, objective and evidence-based manner.

MINDFULNESS-BASED STRESS REDUCTION TO IMPROVE DEPRESSIVE SYMPTOMS AND RHEUMATOID ARTHRITIS-RELATED CLINICAL OUTCOMES: RESULTS FROM A FEASIBILITY AND ACCEPTABILITY TRIAL

M. C. Beaulieu1, I. Gaboury2, N. Carrier2, P. Dobkin3, F. Gervais4, F. Gendron7, P. Robere1, P. Dagenais5, S. Roux5,6, G. Boire4,7, 1University of Sherbrooke, Family Medicine and Health Sciences, Sherbrooke, Canada; 2CIUSSS de l’Estrie - CHUS, Sherbrooke, Canada; 3McGill University, Montréal, Canada; 4Centre de Rhumatologie de l’Est-du-Québec, Rimouski, Canada; 5University of Sherbrooke, Rheumatology, Sherbrooke, Canada; 6CIUSSS de l’Estrie - CHUS, Rheumatology, Sherbrooke, Canada; 7University of Sherbrooke, Rheumatology, Sherbrooke, Canada

Background: Despite available highly effective pharmacological treatments, up to 30% of current rheumatoid arthritis (RA) patients remain in quasi-remission, where inflammation is controlled but patients still report unacceptable levels of negative impact of RA (high Patient Global Assessment (PGA) on a 0-10 visual analog scale). PGA levels correlated with depressive symptoms assessed by Center for Epidemiologic Studies- Depression (CES-D) scores. Mindfulness-Based Stress Reduction (MBSR) is relatively inexpensive and reduces both anxiety and depression in several conditions.

Objectives: To complete a feasibility and acceptability study paving the way for a randomized controlled trial (RCT) of MBSR to improve depressive symptoms and clinical outcomes in RA patients in quasi-remission.

Methods: A standardized 8-week MBSR program in adults with controlled inflammatory disease (stable SJC ≤ 2/16 and normal CRP; stable treatments) but high CES-D scores (2 groups), high CES-D or anxiety scores (1 group), or PGA higher than Physician Evaluation of Disease Activity (EVA) by ≥2 (1 group). Feasibility was documented using process indicators. Outcomes were measured at baseline and 6 months after the end of MBSR. Disease activity scores (SDAI) and questionnaires on depressive symptoms (CES-D), HAQ, sleep (VAS), fatigue, and pain (SF-36), anxiety (GAD-7), PGA were collected. Qualitative interviews based on a theoretical framework of acceptability were conducted following the post-MBSR evaluation.

Results: We report on the first 21 patients (mean age 59, 91% females) having completed their 6-month follow-up evaluation. Factors leading to higher recruitment rates were 1) using pragmatic scores to identify eligible patients (e.g. EVA and PGA), 2) no formal clinical evaluation of mental health and no emphasis on depression in the recruitment material. MBSR had a highly significant positive impact on depressive symptoms (p=0.003) and anxiety (p=0.025) (Figure), and positive impact on quality of sleep and HAQ. No change in SDAI or joint counts was noted. During a qualitative interview of 13 participants, most reported that MBSR helped them control their reactions to daily stressful situations. Perceptions were almost uniformly positive towards MBSR, and most appeared to have integrated some of them control their reactions to daily stressful situations. Positive impacts on mood and on clinical outcomes were observed. Anxiety and depression scores appear the most sensitive to change and are recommended as the primary outcome for an eventual RCT. MBSR added to conventional treatments might help empower RA patients towards self-management. Acknowledgments: Grant support from Canadian Initiative for Outcomes in Rheumatology cAre (CIORA)

WEBSITE FOR PARENTS OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS REDUCES PARENTING STRESS.

K. Mulligan1,2, S. Hirani1, S. Clarke3, N. Evans4, C. Flood5, J. Taylor1, L. Wedderburn1,2,6, S. Newman7 on behalf of WebParC Investigator Group. 1City, University of London, London, United Kingdom; 2East London NHS Foundation Trust, London, United Kingdom; 3Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom; 4Lancaster Associates Ltd, London, United Kingdom; 5London Southbank University, London, United Kingdom; 6UCL GOS Institute of Child Health, University College London, London, United Kingdom; 7Centre for Adolescent Rheumatology Versus Arthritis, London, United Kingdom; 8NIHR Biomedical Research Centre at GOSH, London, United Kingdom

Background: Having a child with JIA presents many challenges. Many parents experience considerable stress. Parental distress and functioning have been found to be related to child outcomes (Cousino, 2013), therefore interventions that help parents to manage their child’s illness are important for both parents and child. We developed a website for parents of children with newly diagnosed JIA to help increase parental confidence in managing their child’s arthritis and reduce parenting stress.

Objectives: To evaluate the efficacy of a web-based tool ‘WebParC’ for parents of children with JIA.

Methods: Design: Multi-centre randomised controlled trial conducted in 16 tertiary paediatric rheumatology centres in England.

Participants: Parent(s) of children aged ≤12 years, diagnosed with JIA within the previous six months.

Procedures: Parents were enrolled when they attended the rheumatology service and were randomised by household to either the intervention arm (I) or the control arm (C) who were given access to the website in addition to their child’s standard care or the control arm (C) who received standard care alone.

The primary outcome was parenting stress, measured with the Pediatric Inventory for Parents (PIP) at 4-months and 12-months post randomisation.

Results: A total of 220 parents (183 mothers, 37 fathers) of 203 children were randomised, 106 intervention and 114 controls. Parents mean (SD) age was 36.5 (8.5). Their children with JIA were mostly female (137/203, 67.5%), mean (SD) age of 6.1 (3.4) years. There were 107 (52.7%) with oligoarthritis, 65 (32%) polyarthritides, 8 (3.9%) systemic and 23 (11.3%) other JIA subtypes. Seventy (34.5%) were prescribed methotrexate.

Trial arms did not differ significantly at baseline except for parent education, which was higher in the intervention group and was controlled for in the analysis.

Follow-up assessments were conducted by 133 (I60, C73) at 4M and 124 (I58, C66) at 12M.

We found significant main effects of trial arm on PIP Difficulty (p=0.022, Control (Mean=93.62, SE=2.717) > Intervention (Mean=84.23, SE=3.025)) and PIP Frequency (p=0.008, Control (Mean=95.78, SE=2.400) > Intervention (Mean=86.23, SE=2.622), with Controls reporting significantly greater frequency and difficulty of stressful events than the Intervention group (Fig 1).

Conclusion: This trial found that a website for parents of children with JIA can help to reduce parenting stress.

A. Marchall, ReumaNet vzw, Zaventem, Belgium

Background: In Belgium, people with Rheumatic and Musculoskeletal Diseases (RMDs) are a large group of patients on sick leave receiving an allowance as their condition does not allow them to remain at work. In order to reduce costs, the Belgian National Institute for Health and Disability Insurance (NIHDI) has reached out to social partners to jointly start up projects to promote the professional reintegration of people with RMDs. ReumaNet is one of these partners and has, in close collaboration with the NIHDI, started up a research project ‘ReumaWerk’ to promote professional reintegration of people with a rheumatic disease.

Objectives: Via the ‘ReumaWerk’ research, ReumaNet wanted to identify, as from a patient’s perspective, which support patients need in order to stay at work or to start working again:
- 1. Information: identify and assess patients’ available information about professional reintegration
- 2. Resources: evaluate resources people with RMDs have at their disposal to stay at work and/or to return to work
- 3. Assess if a Patient Expert (a trained patient) is an added value in supporting peers in their professional reintegration
- 4. Assess if a certified return to work coordinator is an added value in supporting people with RMDs towards professional reintegration

Methods:
- Surveys questioning people with RMDs to assess their satisfaction regarding available information flows, resources and support (127 respondents)
- Survey questioning stakeholders (rheumatologists, health professionals) about information on professional integration they use and share (79 respondents)
- Coaching and supporting people with RMDs via personal contacts, mail, skype, phone calls,… in order to jointly define tailored answers on professional reintegration

Results: 1. There is a discrepancy between where patients expect to find information about professional reintegration and where information is given. There is plenty information available, but not customized, sometimes inconsistent, mostly too general and the legislation is too complex.
- 2. People with RMDs do experience physical obstacles at work. In addition, the Belgian government provides financial support, which is unfortunately (a) not well known and (b) too limited.
- 3. 80% of the respondents rated 7/10 and more as satisfaction rate. 82% of the respondents (N=127) would recommend the support of a Patient Expert to other patients.
- 4. The certified return to work coordinator applies disability management principles, focusing mainly on job retention and stimulating professional reintegration, taking into account each patient’s personal bio-psycho-social context.

Conclusion: 1. People with RMDs, and their health professionals, are in need for straightforward and correct information about professional reintegration possibilities. Information flows need to be improved and provided information needs to be more specific, i.e. disease related.
- 2. People with RMDs have specific needs to allow them to return to or stay at work such as flexible working hours, functional adaptations in their working environment and financial support.
- 3. Patient expertise is an added value in supporting people with RMDs: respondents felt more understood by a peer, appreciated the opportunity for a more open, candid dialogue and felt encouraged to return to work.
- 4. Working via the principles of disability management is an added value: it is important to support people with RMDs as soon as possible and provide personalized tailored information on professional reintegration opportunities.

PARE0021 TARGETED INITIATIVE TO FACILITATE THE IMPLEMENTATION OF EXISTING EFFECTIVE GOUT TREATMENT IN SWEDEN

L. Alemo Munter1,2, I. Loell1, S. Jansson2, L. T.H. Jacobsson3, M. Dehlin4,
1 Swedish Rheumatism Association, Stockholm, Sweden; 2 Karolinska University Hospital, Functional Area Occupational Therapy and Physical Therapy, Stockholm, Sweden; 3 Sahlgrenska Academy, University of Gothenburg, Dept of rheumatic and inflammatory research, Institute of Medicine, Gothenburg, Sweden; 4 Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Gout is a very painful rheumatic condition origin from excess uric acid in the bloodstream, which results in an accumulation of uric acid crystals in the joints and a severe local inflammatory response. Gout is treated in primary care and the current treatment has satisfactory results on disease management, thus patients can expect a controlled disease without flares. In Sweden however, only 30-40% (1) of the patients receives adequate urate lowering treatment and prevent the disabling flares.

Objectives: As a patient association, the Swedish Rheumatism Association (SRA) has identified an opportunity to use scientific evidence and data to improve awareness in both patients and physicians in order to make the existing treatment available and to shift the gout treatment from flare management to prevention.

Methods: With SRA funding we created the Gout network, consisting of researchers, health professionals and patient research partners. Through meetings and operational support developed strategies to educate patients suffering from gout and to alert physicians in the primary care of the most recent research to aid the management of gout. We also fund a specific research project aimed to create an implementation plan to establish a treatment routine for gout in primary care with already existing resources.

Results: A high quality patient education material is under development and consists of an information video lecture and a comprehensive online patient school providing information about the diagnosis, preventive treatment, possible life style change along with other resources that will support the gout patient, both for self-care and in relation to healthcare. For the healthcare profession we have together with a clinical research expert and a patient research partner developed a fact sheet with the latest scientific updates on gout.

Conclusion: Accessible, high quality diagnosis information about gout is currently missing in Sweden. This collaboration initiative provides high quality facts to raise the general awareness and to educate and empower patients to get the effective therapy that is available today.

PARE0022 TARGETING FATIGUE IN RHEUMATOID ARTHRITIS: A SELF-HELP BOOKLET

R. Geenen1, Utrecht University, Department of Psychology, Utrecht, Netherlands

Background: Fatigue in rheumatoid arthritis (RA) is prevalent, intrusive, and disabling [1-3]. It has been shown that fatigue can be reduced, in at least some people with rheumatoid arthritis, using group interventions based on cognitive-behavioral principles [1]. However, the vast majority of the (about 40%) [2] severely fatigued people with rheumatoid arthritis does not have or does not want access to group therapy.

Objectives: To develop a self-help booklet aimed at targeting fatigue in rheumatoid arthritis based on cognitive-behavioral principles.

Methods: Based on the assumption that the most strongly influencing factors of fatigue differ between people [3], a comprehensive patient-centered approach was chosen. The booklet should be easy to read (big fonts,
text boxes, bulleted text, and illustrations). Needed materials should be included.

**Results:** In the booklet, factors that may influence fatigue are demonstrated by a hanging mobile toy, a device with stars or other figures hanging from the ceiling. If one piece moves, all the other pieces move as well. Every individual piece that is part of the mobile influences the other. However, every mobile is different. The large differences in balance between components of mobiles can be compared to the large variety of influences on fatigue in people. Patients first need to identify which factors seem especially important of their own fatigue by sorting seven cards that are included in the booklet. They put the factor of which they think that it most influences their fatigue at the top and the factor that least influences their fatigue at the bottom.

The seven cards are:
1. severe overweight,
2. disease activity,
3. day-night rhythm and sleep,
4. physical activity,
5. emotions and negative thoughts,
6. pain, and
7. another influence.

Interventions targeting these factors are discussed in separate sections of the booklet. Users are invited to start reading the sections with advice regarding the factors that most influence their fatigue. The foldable back cover of the booklet includes the set of seven cards of influencing factors, a diagram to make a 7-day 24-hours day-night rhythm schedule, and instructions to make an action plan.

**Conclusion:** In the Netherlands, the text can be obtained online and as a booklet. They put the factor of which they think that it most influences their fatigue at the top and the factor that least influences their fatigue at the bottom. Patients may take up to two months to successfully change lifestyle. It’s an, as yet not empirically verified, hope that the booklet will be more successful than a traditional educational brochure.

**PARE0023**

**ORAL HEALTH IN RHEUMATOID ARTHRITIS:**

**LISTENING TO PATIENTS**

J. Protudjer1, C. Billedeau2, C. Stavropoulou3, A. Cholakis4, R. Schroth4, C. Hitchon4, University of Manitoba, Department of Pediatrics and Child Health, Winnipeg, Canada; 3Patient Representative, Winnipeg, Canada; 4University of Manitoba, Department of Preventative Dental Science, Winnipeg, Canada; 5University of Manitoba, Max Rady Department of Internal Medicine, Winnipeg, Canada

**Background:** Rates of periodontal disease and tooth loss are increased in rheumatoid arthritis (RA). Periodontal disease may exacerbate RA inflammation and complicate RA care. Understanding factors that contribute to the increased burden of periodontal disease in RA is critical to improving oral health and possibly reducing RA outcomes. People with RA may have unique needs and/or barriers to maintain oral health.

**Objectives:** To determine from people with RA what are their experiences and perceptions about their oral health, their most important questions relating to oral health, and how they wish to receive oral health information.

**Methods:** Semi-structured interviews were conducted with RA patients. Recorded interviews were transcribed. Thematic content analysis. Transcripts were initially reviewed to develop a coding guide. Latent content, or larger themes, were then applied to the transcripts. Constructs were considered saturated when no new themes were identified with subsequent interviews. We report identified themes with representative quotes.

**Results:** Interviews with 11 RA (10[91%] female; all on RA medication) averaged 19 minutes (range 8–31 minutes) and were mostly conducted face-to-face. Many believed RA medication contributed to dry mouth. Most participants had not previously considered other links between oral health and RA. Themes identified include the need for complicated oral health routines, barriers of cost and access to dental care, and shame relating to oral health (Table 1). Participants preferred to receive oral health education from their rheumatologists or dentists over printed or online resources.

**Conclusion:** RA patients have unique needs relating to oral health and report poor oral quality of life. Strategies to optimize oral health in RA may include educational tools for optimizing oral self-care appropriate for RA, and improved access to oral care professionals who are aware of the needs of arthritis patients.

patients’ concerns regarding family planning and pregnancy (FPP) were inadequate or inconsistently addressed.1

Objectives: To investigate the general level of information on FPP and the potential concerns Danish patients with CIDs. Methods: An online survey to identify FPP issues was designed, and CID patients aged 18–50 years (yrs) were included. Respondents were recruited through patient organisations providing their members with a link to the questionnaire. In addition to demographics, information relating to time of diagnosis, treatments received, pregnancies, and course of disease were collected along with access to and concerns regarding FPP. Descriptive statistics were applied. Results: Eligible patients included 368 with rheumatological diagnoses (RA, PsA, JIA, nr-axSpA, or AS); 304 [83%] female, mean age: 40 yrs; 64 [17%] male, mean age: 42 yrs) and 95 with dermatological diagnoses (PSO or PsA; 64 [67%] female, mean age: 37 yrs; 31 [33%] male, mean age: 42 yrs). Among the rheumatic patients, 43% of females and 53% of males were currently receiving systemic treatment and 37% of females and 22% of males had received >3 different systemic treatments (other than painkillers and non-ste-roidal anti-inflammatory drugs [NSAIDs]). Lack of access to FPP information was consistent across age groups, but higher in those with dermatological diagnoses (Table). In total, 68% of patients with rheumatological and 73% with dermatological diagnoses had biological children and among these 18% and 23% of patients, respectively, indicated their disease had affected how many children they had or planned to have. The most frequent concerns among patients with rheuma-tological diagnoses were the potential physical impact of a pregnancy, disease worsening, heredity and ability to take care of the child (19, 16, 16 and 13%, respectively), whilst disease worsening and heredity (12 and 16%, respectively) were the most frequent concerns in those with dermatological diagnoses. Many patients experienced disease worsening during or after pregnancy (rheumatologic diagnoses: 16% and 34%; dermatologic: 20% and 59%, respectively) were the most frequent concerns in those with dermatological diagnoses who reported having little or no access to FPP information, along with access to and concerns regarding FPP. Descriptive statistics were applied. Novartis.

Results: Eligible patients included 368 with rheumatological diagnoses (RA, PsA, JIA, nr-axSpA, or AS; 304 [83%] female, mean age: 40 yrs; 64 [17%] male, mean age: 42 yrs) and 95 with dermatological diagnoses (PSO or PsA; 64 [67%] female, mean age: 37 yrs; 31 [33%] male, mean age: 42 yrs). Among the rheumatic patients, 43% of females and 53% of males were currently receiving systemic treatment and 37% of females and 22% of males had received >3 different systemic treatments (other than painkillers and non-steroidal anti-inflammatory drugs [NSAIDs]). Lack of access to FPP information was consistent across age groups, but higher in those with dermatological diagnoses (Table). In total, 68% of patients with rheumatological and 73% with dermatological diagnoses had biological children and among these 18% and 23% of patients, respectively, indicated their disease had affected how many children they had or planned to have. The most frequent concerns among patients with rheumatological diagnoses were the potential physical impact of a pregnancy, disease worsening, heredity and ability to take care of the child (19, 16, 16 and 13%, respectively), whilst disease worsening and heredity (12 and 16%, respectively) were the most frequent concerns in those with dermatological diagnoses. Many patients experienced disease worsening during or after pregnancy (rheumatologic diagnoses: 16% and 34%; dermatologic: 20% and 59%, respectively).

Conclusion: Danish CID patients of reproductive age have concerns related both to their disease and to FPP, which affect their decisions around family planning. The majority of patients responding to this survey reported limited access to FPP, which affect their decisions around family planning (rheumatologic diagnoses: 16% and 34%; dermatologic: 20% and 59%, respectively), whilst disease worsening and heredity (12 and 16%, respectively) were the most frequent concerns in those with dermatological diagnoses. Many patients experienced disease worsening during or after pregnancy (rheumatologic diagnoses: 16% and 34%; dermatologic: 20% and 59%, respectively).

Table. Proportion of patients with rheumatological or dermatological diagnoses who reported having little or no access to FPP information, stratified by age

RMD research

PARE0025 "RA - DON'T GIVE UP" - LIFE WITH RHEUMATOID ARTHRITIS FROM PATIENTS’ PERSPECTIVE

T. Sobierajski1, J. Grygielska2, E. Godlewksa3. 1 The Institute of Applied Social Science Warsaw University, Warsaw, Poland; 2 Polish Rheuma Federation “REF”, Warsaw, Poland; 3 KnowPR, Warszawa, Poland

Background: Rheumatoid arthritis (RA) as chronic and progressing to disability disease decreases a quality of life of every person suffering from it. Knowledge about this influence from patient perspective is important to limit burden of RA and organize appropriate care for patients.

Objectives: RA has input on every area of individual and social lives. Recognition of patients’ situation in daily life, professional life, participation in treatment, taking life decision gives possibilities to better understanding of diseases and starting activities to change lives with RA. Aim of research was to learn attitudes, knowledge and experiences of people with living RA.

Methods: The study was initiated by KnowPR in partnership with Polish Rheuma Federation “REF”. Main researcher was Tomasz Sobierajski PhD., sociologist from Warsaw University. The first stage of the study was a workshop with patients with RA organized by REF. It was brainstorming to identify main problems, appropriate understand life with RA and discussion on questionnaire. After small pilot study on questionnaire, research was made by CAWI technique. Questionnaire had been linked on professional websites, facebook, Twitter, health forums. The data had been completed during one month - January 2019.

Results of survey were presented in booklet with comments. Opinions introducing results were done from persons represented patronages of project: minister of patient rights, president of Polish Society for Rheumatology, national consultant in rheumatology, directors of National Institute of Geriatrics, Rheumatology and Rehabilitation. Publication was enriched by stories of people with RA living full lives. Publication was launched during press conference and disseminated in hard copies and on-line with free access.

Results: In survey took part 619 respondents with RA - mostly women (90%). The biggest group of respondents (34%) was in age 46-60 years old. Duration of disease was different – from few months to more than 40 years. More than half of respondents are suffering from RA more than 10 years. Disease influences of every life area. Only 38% of respondents participate in decision about their treatment and took it together with rheumatologist. There are different opinions about way of taking medication. There are not differences among age groups and duration of disease in this majority. Patients suffer from pain (73%), from limited abilities (68%) and from permanent fatigue (69%) in everyday lives. Rheumatologist has the biggest confidence among patients like a source of information about disease (73%). Other health professionals have lower confidence (35-40%). Majority of respondents (68%) note his knowledge about diseases like rather good and better. Respondents didn’t connect their decision of having a child with disease how it has been before (59%). Part of respondents had to change or resign of professional work (30%). Part of them resigned from social life and hobbies before disease. In opinion of 57% of respondents RA changed totally their lives (57%).

Conclusion: Results of survey was used like a tool in lobbying for accessibility in newest treatment in RA. Further recognize of quality of life in RA is needed. Interviews of focus groups and individuals are planned.

PARE0026 WHICH PATIENT-REPORTED OUTCOMES DO RHEUMATOLOGY PATIENTS FIND IMPORTANT TO TRACK DIGITALLY? A REAL-WORLD LONGITUDINAL STUDY IN ARTHRITISPOWER

W. B. Nowell1, C. L. Kannowski2, K. Gavigan3, Z. Caï2, A. Cardoso2, T. Hunter2, S. Venkatachalam1, J. Birt1, J. Workman1, J. Curtis3. 1 Global Healthy Living Foundation, Nyack, United States of America; 2 Eli Lilly & Company, Indianapolis, United States of America; 3 University of Alabama at Birmingham, Birmingham, United States of America

Background: Development of a standardized approach to assess key elements of disease activity in rheumatology clinical trials has been the goal of Outcome Measures in Rheumatology Clinical Trials (OMERACT), American College of
Rheumatology (ACR), and European League Against Rheumatism (EULAR).1,2,3 The core sets of measures developed include assessments and composite indices incorporating use of patient-reported outcomes (PROs) and clinical measures and clinicians’ assessments to quantify disease activity over time.4 PROs are important indicators of disease activity and variability, and they are increasingly used to evaluate treatment effectiveness. Little is known about PROs that patients with rheumatic conditions find most important to convey their experience with their condition and its treatment.

Objectives: To examine PROs selected by patients with rheumatic conditions in the ArthritisPower registry to identify symptoms they found most important to track digitally.

Methods: Adult US patients within the ArthritisPower registry with rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), systemic lupus erythematosus (SLE), osteoarthritis (OA), and fibromyalgia syndrome (FMS) were invited via email to participate in this study. Enrolled participants (pts) were prompted to select ≤10 PRO symptom measures they felt important to track for their condition at baseline via the ArthritisPower app. At 3 subsequent time points (Month [m] 1, m2, m3), pts were given the option to continue tracking their previously selected PRO measures or to add, remove and/or select different measures. At m3, pts completed an exit survey to prioritize ≤5 measures from all measures selected during study participation and to specify other symptoms not available that they would have wanted to track. Measures were ranked-ordered based on number of pts rating the item as their 1st, 2nd, 3rd, 4th or 5th choice and weighted by multiplying the rank number by its inverse for a single, weighted summary score for each measure. Values were summed across all pts to produce a summary score for each measure.

Results: Among pts who completed initial selection of PRO assessments at baseline (N=253), 184 pts confirmed or changed PRO selections across m1-3. Mean (SD) age of pts was 55.7 (9.2) yrs, 89.3% female, 91.3% White, mean disease duration of 11.6 (10.6) yrs. The majority (64.8%) self-reported OA, followed by RA (48.6%), FMS (40.3%), PsA (26.1%), PsA (15.8%) and SLE (5.9%), not mutually exclusive, and were similar to the overall ArthritisPower population. The average number of instruments (SD) selected for baseline completion was 70 (2.5), 71 (2.4) at m1, 72 (2.4) at m2, and 70 (2.5) at m3. The top 5 PROs ranked by pts overall as most important (weighted summary score) for tracking were Fatigue (71), Physical Function (58), Pain Intensity (50), Pain interference (49), Duration of Morning Joint Stiffness (41) (Figure 1). Fatigue, Physical Function, and Pain were consistently in the top 5 across diseases while Depression was more frequent among pts with OA, AS, and FMS. Pts’ PRO selections showed stability over time except for the RA Flare measure which decreased from 70.5% of RA pts at baseline to 13.6% at m3.

Conclusion: The symptoms prioritized by pts included fatigue, physical function, pain, and joint stiffness. Pts’ choices were consistent over time. These findings provide insights into rheumatology patients find most important and will be useful to inform design of future patient-centric clinical trials and real-world evidence generation.

**THE JOURNEY FROM PATIENT AND PUBLIC ENGAGEMENT (PPE) TO INVOLVEMENT: FACILITATING PATIENT PARTNER RESEARCH WORKSHOPS WITH A FOCUS ON FIBROFOG IN FIBROMYALGIA**

S. Derham1, M. Brooke2,1Royal United Hospitals Bath NHS Foundation Trust, RNHRD Rheumatology Therapies, Bath, United Kingdom; 2Bath Institute for Rheumatic Diseases (BIRD), Patient and Public Engagement (PPE), Bath, United Kingdom

Background: The Bath Institute for Rheumatic Diseases (BIRD), a registered charity in the United Kingdom (UK), supports research, education and patient engagement for the benefit of people with rheumatic diseases. Event feedback from two Fibromyalgia Information Days showed patients valued the sessions and were keen to be involved in research. Fibrofog in fibromyalgia was identified by patients as one topic of interest.

Objectives: To facilitate Patient Research Partner Workshops to generate research questions and inform the design of clinical research into fibrofog in fibromyalgia.

Methods: Three Patient Research Partner Workshops, focusing on fibrofog in fibromyalgia, were run between January 2018 and April 2019. All were co-facilitated by a clinician, a social worker, and a BIRD Patient and Public Engagement (PPE) lead, MB. Ethical approval was not required. Patients were invited to participate by email. A Patient Partner Information Sheet accompanied the workshop invitation. Audio recordings of the discussions were made to aid data capture, following informed written consent by all workshop participants. Travel expenses were offered to all participants.

Results: 25 (n=25) women with fibromyalgia attended the workshops. Workshop 1 (n=5) explored, ‘What areas do you think we should research around fibrofog in fibromyalgia?’ Patient partners felt research into fibrofog in fibromyalgia was needed to identify and validate symptoms, and to inform discussions with healthcare professionals. They also called for research into coping strategies to help with fibrofog symptoms. This reflected similar patient calls for research into fibrofog in fibromyalgia.

Workshop 2 (n=10) and Workshop 3 (n=9) explored ‘How do you think we should research fibrofog in fibromyalgia?’ Both workshops identified a broad range of research questions and designs, reflecting individual experiences, knowledge and symptom severity. Suggested research questions included: How severe is fibrofog for each person? What triggers fibrofog? How does fibrofog affect daily tasks? How does fibrofog affect work? What do people with fibromyalgia, their partners, family members and healthcare professionals understand about fibrofog?

Suggested data collection methods included interviews, focus groups and questionnaires. Use of online surveys or interviews had mixed responses. This reflected computer literacy skills and access to hardware. Discussions around recruitment of participants to future studies revealed a wealth of local knowledge including access to community venues and healthcare facilities, support groups and local networks.

Participators were very satisfied with the workshops, finding them helpful, informative and thought provoking. All wanted to continue their involvement in research.

Conclusion: Patient Research Partner Workshops are integral to the generation and delivery of clinical research into fibrofog in fibromyalgia. Research designs need to offer multiple methods of data collection to be as inclusive as possible. Next steps will be to formally recruit Patient Research Partners to co-develop a research grant application to explore fibrofog in fibromyalgia.

**PARE0028**

**LEAD PATIENTS – A RESOURCE FOR IMPROVEMENT OF THE HEALTH CARE SYSTEM**

M. Beermann1, K. Nilke Nordlund1, The Swedish National Organization for Young Rheumaticas, Stockholm, Sweden

Background: The project “Lead Patients – a new resource for health” led by researcher Sara Riggare at Karolinska Institute and financed by Vinnova, the Swedish innovation authority, launched in 2017 and the Swedish National Organization for Young Rheumatias was one out of 14 partners. One of our tasks was to develop training courses for health care staff, and to try out what happens when lead patients are giving the opportunity to educate. We developed and produced nine different courses, and during the Autumn of 2019, we had the chance to try out these courses with healthcare professionals. They also called for research into coping strategies to help with fibrofog symptoms. This reflected similar patient calls for research into fibrofog in fibromyalgia.

Objectives: The aim was to switch the perspective and see what would happen when patients’ expertise and knowledge is used to educate health care professionals and challenge the norm about health care professionals being superior. The objective with first training course, “Teams that enable self-realization”, was to create conditions and find new methods for the health care professionals to better support patients with what actually matters to them. The objective with the second training course, “Anti-oppressive pedagogy and language impact”, was to create new knowledge as a group and find methods for inclusion and anti-discrimination.

Methods: “Teams that enable self-realization” was conducted as an interactive lecture with a concluding workshop. The lecture was based on results from the Swedish Young Rheumatias Report, teamwork and the Swedish Patient Act. The workshop consisted of a case, where the participants were supposed to come up with a plan for a first meeting and treatment of a patient. “Anti-oppressive pedagogy and language impact” was conducted in two parts, with one week in between the two occasions. The first one was mainly a lecture with background and theory about anti-oppressive pedagogy, norms and power structures, followed by a workshop where the participants analyzed the organizations’ own value principals. The second occasion was a deepened discussion with the purpose of identifying new methods for work and strategies to move forward.

Results: The main goal with the training was to highlight positive examples and create creative conditions to be able to identify these new methods and tools. And during the training, there was a great will from the staff to work in a more patient-centered way and let what is most important for the patient to be what is directing the meeting. Some suggested that the patient should be considered a part of the health care team, but that methods are missing for making it work today. There was also a great will to reflect over what consequences the current health care system might have, and to discuss possible changes. It was exciting to see the traditional hierarchy, where patients are seen as passive receivers of care, being challenged for real and letting patients not only talk about “what it’s like to live with a chronic disease” but actually be seen as capable and qualified educators.

Conclusion: If lead patient-led training becomes an obvious and vital part in building and develop the health care system, it will lead to new opportunities and possibilities to better form the health care based on patients’ needs, both strategic and operational. Because converting to a patient focused care isn’t just about changing old attitudes and organizational culture, it’s also about building new adapted structures and methods for governing the health care system.

**TABLE 1.** Summary of the RUG-Buddy role description

<table>
<thead>
<tr>
<th>Qualities of a RUG-Buddy</th>
<th>RUG-Buddy responsibilities</th>
<th>PPIE team responsibilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Willing to share personal experience</td>
<td>To attend to the first three PPIE meetings of a research project</td>
<td>To provide a training session for all RUG-Buddies</td>
</tr>
<tr>
<td>Friendly and approachable</td>
<td>To introduce new members to RUG members and research team</td>
<td>To meet RUG-Buddies every two months to provide feedback of the role</td>
</tr>
<tr>
<td>Enthusiastic and knowledgeable about PPIE in research</td>
<td>To encourage contribution to the meeting</td>
<td>To have a named PPIE lead for any questions/queries that may arise</td>
</tr>
</tbody>
</table>

**Conclusion:** The RUG-Buddy is an innovative peer support scheme to support the involvement of patients and the public in research. The support provided by RUG-Buddies offers a different perspective from people with real-life experience of involvement in research. It is anticipated that this additional support will enrich the experience of RUG members and facilitate a more welcoming and conducive environment for active and meaningful public involvement. Furthermore, it has also provided an opportunity for the RUG-Buddies to gain valuable new skills and also give something back to the PPIE team and researchers who have supported their own involvement for many years.

PARE0032

STRENGTHENING SELF-MANAGEMENT TO IMPROVE THE QUALITY OF LIFE AND HEALTH STATUS OF PATIENTS WITH INFLAMMATORY ARTHRITIS AND OSTEOPOROSIS IN SWITZERLAND

A. Mueller1, M. Roffler1. 1Swiss League against Rheumatism, Zürich, Switzerland

Background: Previous UK studies suggest that people with arthritis taking part in self-management programmes feel more confident in their ability to manage and control their symptoms. These patients may also visit the doctor less frequently and have shown improved physical and clinical outcomes (1, 2). Based on this evidence, self-management has become an essential component of care for patients with arthritis, or generally with chronic diseases. However, there is still a huge gap regarding such self-management services and support programmes in rheumatology in Switzerland. In the Swiss National Strategy “Musculoskeletal Diseases” 2017–2022, strengthening patients’ empowerment is one of the main strategic pillars. Considering that approximately 500,000 people are suffering in Switzerland from inflammatory arthritis (IA) and osteoporosis (OP) alone, there is huge potential to strengthen patients’ self-management capacity and thus improve their quality of life (3).

Therefore, the SLR has developed a self-management programme for IA and OP patients. In this programme medical assistants in outpatient rheumatology clinics are trained to consult patients in self-management. This programme is part of a two-year pilot project (2019–2020) that is supported by a consortium of important stakeholders in rheumatology in Switzerland.

Objectives: The ultimate objective is to increase the quality of life and the health status of people with IA and OP in Switzerland by enhancing their capacity for self-management. Furthermore, this pilot project aims at closing an important gap in the Swiss healthcare system by creating an innovative model that can strengthen patients’ self-management capacity and thus improve their quality of life (3).

Conclusion: This pilot project provides an innovative approach to closing an important gap in the Swiss healthcare system and to providing a missing component of care for patients with IA and OP. However, it has been challenging to enrol enough clinics in the pilot project. The way the programme is embedded in the current healthcare system, it demands a cultural change within outpatient clinics, allowing medical assistants to step into a new role as consultant.

I’M HERE BUT I’M NOT: A PHOTOVOICE STUDY OF THE LIVED EXPERIENCE OF SELF-MANAGING RHEUMATOID ARTHRITIS

S. Donnelly1,2, T. Kroll1, H. Mannan1, C. DIX3, A. G. Wilson2. 1University College Dublin, Centre for Interdisciplinary Research Education and Innovation in Health Systems, Dublin, Ireland; 2University College Dublin, Centre for Arthritis Research, Dublin, Ireland; 3Independent filmmaker, Dublin, Ireland

Background: Rheumatoid arthritis (RA) is a widespread chronic disease affecting about 1% of the population in the West. It is characterised by pain, fatigue and inflammation that can flare-up without warning. This makes the condition difficult to predict and manage. Bury (1982) introduced the concept of chronic illness as a disruptive experience to one’s self-identity. This is often an invisible part of managing the illness and taken for granted by others, such as family members, friends and health care professionals. Thus, there is a need to raise awareness of the patients’ lived experiences of self-managing this long-term chronic illness.

Objectives: We aimed to collaborate with people with RA to (i) record and reflect the community’s strengths and concerns; (ii) raise awareness of the lived experience of self-managing RA (iii) spark a dialogue among key stakeholders around the self-management of RA.

Methods: A purposeful sample of people with RA (n=12) was recruited. An innovative qualitative methodology, Photovoice, was used (Wang & Burris, 1997). A series of small group workshops took place. Participants were provided with cameras and appropriate training. They were asked to take photographs of the “challenges and solutions to living with RA” over approximately two weeks. Semi-structured interviews were conducted incorporating photo elicitation. As a group, the participants, a visual artist and researcher co-created a photo exhibition for the public.

Results: Participants selected 32 photographs for the exhibition. They carried out a thematic analysis of the photos identifying four themes:

• I’m Here but I’m Not – this theme reflected feelings of alienation and social isolation.
• Medicine in all its forms – this theme captured attitudes towards medication and devices, as well as the creative ways people coped with RA.
• Visible illness – this concerned the recognition of RA. It captures the experience of RA as a “contested illness” and the challenge of gaining medical and cultural legitimacy.
• Mind yourself – this theme highlighted the value of self-care, often closely connected with the natural world and engagement with social activities.

Exhibitions were held at a community arts centre and a large central hospital in Dublin city. A plain language report was also collaboratively produced.

Conclusion: This study shows how participatory methods can be used to explore the hidden experience of living with an invisible illness. This research design enabled participants to use photographs to reflect on their experiences and the meaning they intended to convey, thereby increasing trustworthiness of the findings through individual and group member checking. This
approach extends beyond traditional written and verbal responses to share the worldview of participants. It demonstrates how to work with patients to create opportunities to improve awareness and spark dialogue among those who play a role in supporting the self-management of chronic illness. The integration of creative arts and participatory methods can have a positive impact for those involved in research and can enhance public engagement with research.

**Campaigning**

**PUTTING A FACE TO RHEUMATISM: MULTICHANNEL AWARENESS CAMPAIGN FOR RHEUMATIC DISEASES**

E. Rösch1. 1Rheumaliga Schweiz, Zürich, Switzerland

**Background:** Although one in four Europeans are affected by rheumatism, the various disease patterns and the consequences for patients are still largely unknown to the general public. Furthermore, it is still widely believed that rheumatism affects only older people. Patients often cite the lack of comprehension of rheumatic diseases as a major hurdle in their daily private and professional lives (1). Therefore, it is imperative to find effective means for providing essential information to patients about the disease and improving their quality of life by raising awareness among the general public. One strategy for reaching this goal was implemented in 2018, when the Swiss League against Rheumatism (SLR) founded a patient council consisting of around ten members affected by rheumatic diseases. The council members advise the SLR on the specific needs and wishes of rheumatic patients. Most members are open to sharing their experiences with the disease with the interested public.

**Objectives:** The overall goal of our campaign is to raise awareness for rheumatic diseases among the general public. By showcasing patients and their struggles, rheumatism is made tangible to the general public and prejudices and barriers are reduced. The campaign focuses especially on the fact that rheumatism also affects young people. Additionally, the work carried out by the SLR and its services for patients are to be publicised among patients and in their environment. The campaign was aimed at the following target groups: patients, patients’ families, health professionals, multipliers and the general public.

**Methods:** In order to put a specific face to rheumatism and to show that anyone, even young people, can be affected by a rheumatic disease, the SLR asked the members of the patient council to share their story for a multichannel outreach campaign. By the end of 2019 portraits had been taken and, in close collaboration with each council member, concise statements had been chosen in order to illustrate what patients struggle. The main focus was to give patients a voice and to showcase their struggles both in mainstream media such as local newspapers and on social media channels. The combination of pictures of apparently healthy people with a quote about their struggle with rheumatism creates an unexpected discrepancy in the reader’s mind. Starting in 2020 the ads were distributed in several formats to editorial offices (tabloid press, local newspapers, specialist media) across Switzerland, asking the editors to publish them for free (as filler ads, when ads cannot be sold). The campaign was launched simultaneously on our social media channels and linked with existing content on our website.

**Results:** The first ads have already been placed and the analysis of their impact is currently being evaluated. We are still in the process of distributing our ads to an even broader audience. We expect to see a rise in media coverage and the number of free ads as well as an increased number of visitors on our website and social media channels. At a qualitative level we have received very positive feedback from our patient council, patients, and health professionals as well as journalists.

**Conclusion:** Featuring authentic patients and telling their stories facilitates media activities and aids in removing the barriers surrounding rheumatism. It helps to dispel misconceptions surrounding the topic, especially the notion that only people aged 60 and over are affected by rheumatism.

WHAT IS YOUR HEALTH ACTION IN 2020?
T. Saarela, The Finnish Rheumatism Association, Helsinki, Finland

Background: At the turn of the year and decade, it is a time when magazine columns and social media channels are full of New Year’s resolutions. We are thinking about weight control, fewer kilos, healthier lifestyles, increased mobility, mental well-being, more time with family and friends, learning new things, etc. For many New Year’s resolution is related to well-being, often a healthier diet and exercise.

What if these promises were properly inspired? What if we encouraged people to make especially good decisions supporting musculoskeletal health and do good deeds?

The Finnish Rheumatism Association and its partners started this project to encourage people to make health promoting new year resolutions and tell them publicly.

Objectives: The aim of the project is to promote the musculoskeletal health of the population and to raise citizens’ awareness of musculoskeletal health and illness. The purpose of the project is to inspire people to make promises and do deeds to support musculoskeletal health. The project utilized people’s tendency to make New Year’s resolutions.

Even small actions and everyday life changes are going in the right direction. Anyone can participate and have successful experience.

Methods: The project is online at www.tinjanhuoltamo.fi. The website briefly describes the background of the project. It includes links to additional information and reliable sources, and provides guidance on how people with RMD’s can have a healthier life.

The project utilized the social media and participants were encouraged to make #promise updates for various social media channels. Campaign started at the beginning of December 2019. The radio campaign focused on Christmas holidays. Promises were made for the New Year’s Eve and some of them during January.

We sent materials and tasks every week for online groups and email lists. Tinja’s Service Station acted as a personal trainer but online. We took advantage of a modern, interactive online environment where people shared their habits and experiences.

All those who kept their promises till 2/29/2020 participated in a competition, where the prize was the winner’s choice of a welfare event, or a season ticket to a sports club or a local Rheumatism Organisation exercise group.

Results: The Service Station turned out to be more interesting than expected. The Facebook group had 450 members and the email group 75 people. The quantities exceeded our expectations.

Physical exercise attracted the promises most. Good second was nutrition. Our social media campaign was not as successful as we had hoped for. It may be that people are too cautious of making public New Year’s Resolutions. The radio campaign managed to bring some more people to the email group, not so many for the Facebook group. It seemed a good idea to expand the campaign from social media to radio. The radio campaign reached people nationwide and there was a small peak in the Rheumatism Association website visits.

Conclusion: This was quite nice and different project. It seemed that one act of health easily led to another and created a positive vicious circle. We start the project with good will and without blame. Changing one’s own activities and promoting future health require will and motivation. Motivation was the initiator of the action. A clear and realistic goal setting and a decision to reach the goal helped motivate.

At the end of the March we will sum up the final results and pick up good examples for musculoskeletal health actions. It is already certain that we will renew the project at the end of the year. A service station is a great low-threshold place where you can, in a good spirit, get support for your lifestyle changes.

<th>AB0001</th>
<th>PLASMA miRNA PROFILE IN PATIENTS WITH HAND OSTEOARTHRITIS</th>
</tr>
</thead>
</table>

J. Balou1, A. Pekacova1, T. Kropackova1,2, V. Horvatova1,2,3, K. Prajzlerová1,2, M. Filkova1,2, K. Pavelka1,2, J. Vencovsky1,2, L. Šenolt1,2, Institute of Rheumatology, Prague, Czech Republic; 2First Faculty of Medicine, Charles University, Prague, Czech Republic; 3Faculty of Science, Charles University, Prague, Czech Republic

Background: MicroRNAs (miRNA) are short non-coding RNAs that can be involved in diverse physiological processes. Aberrant miRNA profiles have been shown in various diseases including osteoarthritis (OA); for instance, miR-21-5p or miR-140 are known for their altered expression in osteoarthritic cartilage. However, no screening of circulating miRNAs has been done in patients with hand OA (HOA) so far.

Objectives: Our aim was to profile circulating miRNAs in plasma of patients with HOA in screening and validation cohort.

Methods: We screened the expression of miRNA profiles in 4 patients with erosive (3 females, mean age=63.7±7 yrs) and 4 patients with non-erosive (3 females, mean age=62.4±6 yrs) HOA, and 4 control subjects (3 females, mean age=63.5±7 yrs). The validation cohort included 10 patients with erosive (7 females, mean age=67.5±7 yrs) and 10 patients with non-erosive (6 females, mean age=67.6±8 yrs) HOA, and 10 control subjects (8 females, mean age=64.3±8 yrs). Circulating miRNA screening were performed using TLDA and selected miRNAs were validated by qRT-PCR.

Results: Profiling circulating plasma discovered 42 miRNAs from 754 analysed miRNAs with different concentration among subjects, including miR-21a-3p (1.7 fold), −222–3p (2.0 fold), and −30e–3p (13.0 fold) to be elevated in patients with HOA compared to controls. In addition, six miRNAs were distinctive between erosive and non-erosive HOA, e.g. hsa-miR-24-3p was 2.3 times lower and hsa-miR-576-5p was 3.4 times higher in erosive compared to non-erosive disease.

Out of these selected miRNAs, qRT-PCR validated 42 miRNAs and confirmed 11 miRNAs (e.g., miR-23a-3p or −222-3p) with different concentration between patients and controls. However, no miRNAs distinguished between erosive and non-erosive HOA, although h101-3p (4.5 fold) and −320b (13.7 fold) almost reached statistical significance.

Conclusion: Based on our study, we identified 11 miRNAs that may have a potential as biomarkers of HOA. However, further studies on larger cohorts are needed.

Conclusion: One out of every 4 pregnancies of women with rheumatic diseases presented a congenital defect, of which, the heart diseases (CHD) have been described as of greater presentation in these groups. It is very important that women with rheumatic diseases are well attached to a comprehensive clinic in which, in addition to receiving proper attention of their rheumatic disease, they have adequate preconception and prenatal control of their pregnancies, since there is a greater risk of congenital alterations and of perinatal adverse events, as shown by this cohort. Further research is needed to fully elucidate the potential disease-related factors that might lead to the increased risk of adverse heart outcomes in offspring, as well as to improve the monitoring and control of their rheumatic diseases.

Table AB0003

| AB0003 | SINGLE-NUCLEOTIDE POLYMORPHISMS (RS28493229 AND RS2290692) IN ITPKC GENE IN CHILDREN WITH KAWASAKI DISEASE |

D. Bhattrai1, R. Kumrah1, A. Kaur1, A. Kaur1, A. Rawat1, S. Singh1, 1Post Graduate Institute of Medical Education & Research, Chandigarh, Pediatrics, Chandigarh, India

Background: Kawasaki disease (KD) is an acute medium vessel vasculitis manifesting with mucocutaneous lesions and cardiac complications especially coronary artery lesions (CALs). Insoluble 1,4,5-triphosphate 3-kinase C (ITPKC) gene polymorphisms are have been shown to be associated with susceptibility to KD and CAL.

Objective: This study was designed to investigate the association of single nucleotide polymorphisms (SNPs) of the ITPKC gene with KD and CAL in Indian children.

Methods: Two SNPs of the ITPKC gene (rs28493229 and rs2290692) were studied in 50 cases of KD and 50 healthy controls. The Deoxyribonucleic acid
(DNA) samples from test subjects and controls were analysed for the two polymorphisms by polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP). The allele, genotype, and haplotype frequencies were compared in different groups. A meta-analysis was also performed for the CC and GG genotype of both SNPs of interest.

Results: No significant differences were found in frequencies of C allele, CC genotype and C carriers of rs28493229 and rs2290692. Combined CG-GG genotype frequency of rs2290692 was found to be significantly associated with susceptibility of KD (95% Confidence interval (CI) = 1.38-13.83, p = 0.015). A meta-analysis did not show a significant association of SNP rs28493229 (Odds ratio = 1.46, CI = 0.96-2.23) and rs2290692 (OR = 1.07, 95% CI = 0.66-1.73) of ITPKC and susceptibility to KD.

Conclusion: Combined CG-GG genotype of SNP rs2290692 at 3’ UTR of the ITPKC gene was found to be significantly associated with susceptibility to KD. Our study did not show a significant association of any allele or genotype with susceptibility to KD. The meta-analysis combining our study with previous studies on these 2 SNPs also failed to show a significant association of different genotypes and susceptibility of KD.

AB0004 TLR10 SINGLE NUCLEOTIDE POLYMORPHISMS ARE ASSOCIATED WITH HIDRADENITIS SUPPURATIVA IN A CAUCASIAN SPANISH POPULATION (NORTHERN SPAIN)

M. Calderón-Goercke1, J. G. Ocejo-Vinylas2, I. Irure-Ventura3, M. Gutiérrez-Larrañaga1, M. A. González-Gay4, I. Vilanova5, J. Cantos-Mansilla6, R. Blanco1, M. González-López1, 1Hospital Universitario Marqués de Valdecilla, IDIVAL, Rheumatology, Santander, Spain; 2Hospital Universitario Marqués de Valdecilla, IDIVAL, Immunology, Santander, Spain; 3Hospital Universitario Marqués de Valdecilla, IDIVAL, Dermatology, Santander, Spain

Background: Hidradenitis suppurativa (HS) is a chronic, relapsing inflammatory cutaneous disease affecting terminal hair follicles in apocrine-gland bearing skin. The pathogenesis of HS is still unknown, although increasing evidence suggests that the immune system plays an important role. In order to study the role of innate immunity we analyzed several Toll Like Receptors (TLRs) functional single nucleotide polymorphisms (SNPs). To date, only one previous study focused about the role of TLR4 SNPs in HS showing no association with this disease.

Objectives: The main goal of this study was to analyze the role of several TLRs functional SNPs in HS patients and healthy controls, in a Caucasian population from Cantabria (northern Spain).

Methods: Through a case-control study, we analyzed the allele and genotype distribution of the SNPs in 106 patients with HS and 278 age and sex matched healthy control subjects for the following SNPs (TLR1 rs5743611 and rs4833095, TLR2 rs5743704 and rs5743708, TLR6 rs5743810, and TLR10 rs11096955, rs11096957 and rs4129009, by Real-Time PCR using a TaqMan assay.

Results: We did not find any significant difference in the allelic distribution of the different SNPs between HS patients and controls. Regarding genotypes, only TLR10 rs11096955 (dominant, codominant and overdominant), rs11096957 (dominant, codominant and overdominant) and rs4129009 (codominant and overdominant) showed significant differences between HS patients and controls. However, no association was found when we analyzed the different TLR10 haplotypes.

Conclusion: To the best of our knowledge, this is the first study showing an association of TLR10 SNPs with HS.

AB0005 HLA CLASS II CONFRS RESISTANCE OR SUSCEPTIBILITY TO HIDRADENITIS SUPPURATIVA IN A CAUCASIAN SPANISH POPULATION (NORTHERN SPAIN)

M. Calderón-Goercke1, J. G. Ocejo-Vinylas2, M. A. González-Gay3, M. A. Fernández-Vilá1, J. Cantos-Mansilla3, I. Vilanova4, R. Blanco3, M. González-López1, 1Hospital Universitario Marqués de Valdecilla, IDIVAL, Rheumatology, Santander, Spain; 2Hospital Universitario Marqués de Valdecilla, IDIVAL, Immunology, Santander, Spain; 3Hospital Universitario Marqués de Valdecilla, IDIVAL, Dermatology, Santander, Spain; 4Stanford University, School of Medicine, Histocompatibility, Immunogenetics & Disease Profiling Laboratory, California, United States of America; 5Hospital Universitario Marqués de Valdecilla, IDIVAL, Dermatology, Santander, Spain

Background: Hidradenitis suppurativa (HS) is a chronic inflammatory cutaneous disease affecting terminal hair follicles in apocrine glands bearing skin. The pathogenesis of HS remains unknown, although increasing evidence suggests that the immune system plays an important role. To date, two previous studies, did not find any association between HLA and HS.

DOI: 10.1136/annrheumdis-2020-eular.4459
Objectives: Our aim was to analyze the association of HLA class II with HS in a Caucasian population from Cantabria (northern Spain).

Methods: In this study we analyzed the HLA-A, -B, -C, DRB1, -DQA1 and -DQB1 allele distribution in 106 HS patients and 192 age- and sex-matched controls from a Caucasian population of Cantabria (northern Spain).

Results: HLA-A*29 and B*50 were significantly more frequent in HS patients and A*30 and B*37 in controls, but these associations disappeared after correction. On the other hand, DRB1*07, DQA1*02 and DQB1*02 were significantly more frequent in controls (p = 0.026, p = 0.0012 and p = 0.0005 respectively), and the HLA allele DQB1*03:01 was significantly more frequent in HS patients (p = 0.00007) of all of them after Bonferroni correction. Furthermore, the DRB1*07; DQA1*02; DQB1*02 haplotype was significantly more frequent in controls (p = 0.0005).

Conclusion: This is the first study showing an association of HLA-class II with HS. Our results suggest that HLA-II alleles (DRB1*07, DQA1*02 and DQB1*02; DQB1*02 haplotype could influence on resistance or susceptibility to HS.

HYPOMETHYLATION OF THE PROMOTER REGION OF TLR4 GENE AT A SYSTEMIC LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PERIODONTITIS

S. Chatterjee1, D. Bhattacharjee1, S. Misra1, A. Rao1, A. Chattopadhyay2, A. Ghosh3, Institute of Post Graduate Medical Education and Research, Department of Rheumatology, Kolkata, India; 2Post Graduate Institute of Medical Education & Research, Department of Rheumatology, Chandigarh, India

Background: Periodontitis (PD) has long been linked with Rheumatoid arthritis (RA) [1]. Epigenetic modifications are being recently explored to explain such associations, DNA methylation being one such important mechanism.

Objectives: To study the effect chronic generalized periodontitis on systemic methylation of TLR4 genes in comparison to only RA and RA with PD patients.

Methods: Twenty-three RA patients, among which 11 patients had chronic generalized PD, 20 patients with only PD and 15 healthy individuals recruited. DNA was isolated from PBMCs of the participants blood, then were first bisulphite converted and then methylation specific PCR were performed using primers for methylated and unmethylated promoters of TLR4. The DNA amplifications were checked in horizontal gel electrophoresis. The methylation signatures were verified by DNA sequencing (Sanger) of the amplified products.

Results: The anti-CCP, DAS-CRP and HAQ DI were higher in patients with both RA and PD (220±40, 5.7±0.2, 1.5±0.1 respectively, p<0.05). Control samples had shown amplification bands for methylated primers of TLR4 but samples had shown amplification bands for unmethylated primers of TLR4 but both RA and PD had in PD samples, had shown amplification for unmethylated primers and not for methylated primers. These results together with DNA sequencing indicated that 4 CpG sites in the promoter of TLR4 genes were hypo-methylated in the PBMCs of patients whereas those remain methylated in healthy individuals.

Conclusion: The observations indicated that though PD is a localised disease of the gingiva there is a systemic involvement of TLR mediated pathways in them which is similar to those in RA. However, further validation in larger cohort and down-stream signalling molecules needs to be studied.

VALUE OF ULTRASOUND IN ASSESSMENT OF ACTIVE SACRIFICILLIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

M. Chen1, S. M. Dai1. 1Shanghai Jiao Tong University Affiliated Sixth People’s Hospital, Department of Rheumatology and Immunology, Shanghai, China

Background: The inflammatory of the sacroiliac joints (SIJ) called sacroiliitis, is a characteristic of axial Spondyloarthritis (axSpA). The detection of sacroiliitis is meaningful to prevent irreversible changes. The tool of assessment of sacroiliitis including radiographs, computed tomography (CT) and magnetic resonance imaging (MRI). Ultrasound (US) has also been used in the evaluation of sacroiliitis in recent years.

Objectives: We aimed to evaluate the value of US in the assessment of active sacroiliitis in axSpA patients.

Methods: Fifty-one patients fulfilling Assessment of SpondyloArthritis International Society (ASAS) 2009 criteria for the classification of axSpA were recruited. All the patients underwent MRI and US evaluation of bilateral SIJs. MRI was performed using the sequences of T1WI, T2WI and fat suppression T2WI (FS-T2WI). MRI sacroiliitis was defined according to ASAS criteria of active sacroiliitis[5]. The Spondyloarthritis research Consortium of Canada (SPARCC) scoring was used to evaluate the inflammatory lesions in SIJs[6]. US were performed by an ultrasonographer with 10 years of experience in musculoskeletal ultrasound, and resistive index (RI) value was recorded. The US sacroiliitis was defined as the presence of more flow signals at SIJ with an RI ≤ 0.75. The HLA-B27, etruncateyde sedimentation rate (ESR) and hypersensitive C-reactive protein (hsCRP) were also evaluated. Consistency rate, sensitivity, specificity, positive predictive values (PPV) and negative predictive values (NPV) for the diagnosis of sacroiliitis by US were calculated, using MRI as the gold standard.

Results: Of the 51 patients, 24 were female and 27 were male. The HLA-B27 positive rate was 90.2% (46/51). The consistency rate of US and MRI sacroiliitis was 55.88 (57/102). The sensitivity and specificity for US for the diagnosis of sacroiliitis were 55.93 (33/59) and 55.81 (24/43) respectively. The PPV and NPV were 63.46 (33/52) and 48 (24/50) respectively. There was no significant difference in ESR and hsCRP between the US positive sacroiliitis and the others (P = 0.7477 and 0.2268, respectively). The SPARCC scores have no significant difference between the US positive sacroiliitis and the others (P = 0.2206). The RI was not significantly associated with the MRI SPARCC score (P = 0.4236).

Conclusion: US may be an optional method for preliminary screening sacroiliitis. But its reliability as a diagnostic method needs further verification.

THE IMPACT OF STAT4 rs7547865, IL6 rs1800795, IL6R rs2228145 AND RS4845618 ON RHEUMATOID ARTHRITIS SUSCEPTIBILITY IN BELARUSIAN POPULATION

E. Sinauskaya1, T. Kuzhir2, V. Yagur2, R. Goncharova1. 1Institute of Genetics and Cytology of NAS of Belarus, Minsk, Belarus; 2Belarusian State Medical University, Minsk, Belarus

Background: Rheumatoid arthritis (RA) is a chronic systemic disorder of the connective tissue of still unknown aetiology and complex autoimmune pathogenesis that primarily affects small joints. HLA alleles provide for 11-37% of the RA heritability, suggesting the substantial role of the non-HLA loci in genetic predisposition to RA. Among non-HLA loci, IL6, IL6R and STAT4 genes attract attention, however, the data concerning their influence on RA risk are somewhat contradictory.

Objectives: The aim of the study was to analyze the involvement of four SNPs of STAT4 (rs7547865, IL6 rs1800795, IL6R rs2228145 and rs4845618) in RA susceptibility.

Methods: 187 patients diagnosed with RA (mean age 58.2 ± 11.9), and 380 healthy blood donors (mean age 37.18 ± 10.69 years) were included into the
study, DNA extraction from peripheral blood samples was performed using the phenol-chloroform method. SNPs were genotyped using the real-time PCR with fluorescent probes. The allele and genotype frequencies were compared using the y2 test. Odds ratios (ORs) and 95% confidence intervals (95% CI) were calculated using the VassarStats online tool.

**Results:** Utilizing recessive genetic model we found an association between TT genotype of STAT4 rs7574865 (OR = 2.362; 95%CI [1.0378 – 5.376], \( p = 0.038 \)) and RA. For IL6 rs1800795, it was found that CC genotype had significantly higher frequency among patients with rheumatoid arthritis as compared to that in controls (OR = 1.52; 95%CI [1.02 – 2.27], \( p = 0.0456 \)). No associations of IL6(rs2228145) and rs4845618 SNPs with risk of RA were found in the total group of patients vs. controls. It was also shown that IL6 rs1800795 CC genotype frequency was significantly higher among the patients with RF-negative status (\( p = 0.0019 \)).

**Conclusion:** Thus, we provide evidence for association of the STAT4 rs7574865 and IL6 rs1800795 variants with risk of RA in the Belarusian population, some features of interplay being revealed between gene polymorphisms analyzed and RA antibody status. Above-mentioned SNPs may contribute to RA genetic susceptibility in the Belarusian population.

**ASSOCIATION BETWEEN POLYMORPHISMS OF BANK1 AND MANIFESTATIONS OF SLE**

D. D. González-Castillo1,2, R. E. Barbosa-Cobos1, G. E. Lugo Zamudio1, M. A. Saavedra1, R. E. Sánchez-Briones1, I. Alemán-Avilia1, J. Ramírez-Bello1,

1Hospital Júzñez de México, Rheumatology, Ciudad de México, Mexico; 2SENESCYT, Guayaquil, Ecuador; 3Centro Médico Nacional La Raza, Rheumatology, Ciudad de México, Mexico; 4Hospital Júzñez de México, Unit of Research, Ciudad de México, Mexico

**Background:** BANK1 encodes an adapter/scaffold protein primarily expressed in B cells, which is involved in cell signaling and activation. Genome-wide association studies (GWAS) have identified different BANK1 single nucleotide variants (SNVs) associated with SLE primarily in European or Asian-derived populations. Interestingly, we recently have documented an association between this gene and susceptibility to systemic lupus erythematosus (SLE) in Mexican population.

**Objectives:** To determine whether the BANK1 R61H (rs10516487G/A) and A383T (rs3733197G/A) SNVs are associated with clinical and immunological manifestations in SLE.

**Methods:** Our study included 123 Mexican women with SLE (SLICC 2012 criteria). Genotyping of the two BANK1 SNVs were obtained by TaqMan probes and real-time PCR. An association study was performed between the alleles and genotypes of BANK1 R61H and A383T with the clinical and immunological manifestations included in the SLE SLICC classification criteria. Hardy-Weinberg equilibrium and an association study was performed using Finetti, a \( p \) value \( \leq 0.05 \) indicated association.

**Results:** We identify an average age of 38.5±12. Cases and controls remained in Hardy-Weinberg equilibrium. An association with susceptibility to SLE was found for the genotypes of the two BANK1 SNVs and joint manifestations rs10516487G/A; AA + GA vs GG, OR 4.45, \( p = 0.004 \), rs3733197G/A; AA + GA vs GG, OR 2.66, \( p = 0.032 \), respectively, as well as with protection for neurological and renal involvement (rs10516487G/A, OR 0.16, \( p = 0.02 \), rs3733197G/A, OR 0.40, \( p = 0.02 \), respectively) (Table a and b). No association was found with other clinical manifestations.

**Conclusion:** Our data in the Mexican population show that both BANK1 R61H and A383T SNVs are risk factors for synovitis. On the other hand, these BANK1 R61H and A383T variants are protective factors for neurological and renal damage, respectively.

**TRIPLE DMARD TREATMENT IN EARLY RHEUMATOID ARTHRITIS INCREASE SYNNOVIAL ACTIVATED NATURAL KILLERS AND RESTING MAST CELLS BUT DECREASE PLASMA CELLS AND M1 MACROPHAGES**

M. Y. Hachim1, N. M. Eleam1, I. Hachim1, S. Hannawi2, R. Hamoud1, A. A. Maghazachi1,1, Sharjah Institute for Medical Research, College of Medicine, University of Sharjah, Sharjah, United Arab Emirates; 2Ministry of Health and Prevention, Department of Rheumatology, Dubai, United Arab Emirates

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory joint disease with cartilage and bone damage as well as disability and its optimal therapeutic success depends on understanding the underlying pathophysiology[1]. Since RA is a heterogeneous disease, there is an urge to characterize new molecular mechanisms to aid the development of more effective and personalized therapy [2]. Genome-wide transcriptional effects of tDMARD in early RA synovial tissues showed alterations in gene expression of T cell activation and plasmablast/plasma cell differentiation[3].

**Objectives:** Using publicly available synovial tissue transcriptomic data to compare the immune cells infiltration at baseline and after 6 months of tDMARD to identify subgroups that might not respond well to tDMARD.

**Methods:** RNAseq dataset (GSE97165) of synovial biopsies taken from 19 early RA patients at baseline and after 6 months of tDMARD treatment were retrieved and reanalyzed. The raw RNAseq data were used for in silico prediction of the immune cells` infiltration the synovial tissue using CIBERSORT analytical tool to evaluate the pre versus post tDMARD changes in immune population and/or activation status. Then, patients were divided according to the level of alteration in immune cells percentage after the treatment. Differentially expressed genes between the subgroups were defined and gene set enrichment analysis was performed to identify the underlying pathways in each group using Biovips tools.

**Results:** 4 immune cells populations showed significant changes after 6 months of tDMARD indicating their role in disease pathophysiology or in response to the therapy. Resting mast cells and activated natural killer (NK) cells were increased in 84% and 74% of patients, respectively. On the other hand, M1 macrophages and plasma cells were decreased after treatment in 68% and 58% of patients, respectively. GSEA of differentially expressed genes between patients who showed increased activated NK cells in comparison to those who showed decreased or no change in NK cells after treatment identified novel pathways that can explain the heterogeneity in response to treatment specifically genes related to WNT signaling, estrogen metabolism and IL17 signaling.

![Figure 1. Percentage of infiltrating immune cells in the synovial tissue at baseline and after 6 months of tDMARD therapy in 19 early RA patients using CIBERSORT tool](https://example.com/figure1.png)
Results: No statistically significant differences between patients with IgAV and healthy controls were observed when each IL17A genetic variant was analyzed independently. Similarly, no statistically significant differences between patients with IgAV and healthy controls were found when the five IL17A polymorphisms were evaluated combined conforming haplotypes. In addition, there were no statistically significant differences in genotype, allele and haplotype frequencies of IL17A when patients with IgAV were stratified according to the age at disease onset or to the presence/absence of gastrointestinal or renal manifestations.

Conclusion: Our results do not support an influence of IL17A on the pathogenesis of IgAV.

Figure 2. Top wikiPathways enriched in the patients with decreased percentage of synovial infiltrating activated NK after 6 months of DMARD therapy compared to those who showed increased or unchanged percentage.

Conclusion: Synovial tissue NK cells, resting mast cells, plasma cells and M1 macrophages play major role in response to DMARD. Genetics related to WNT signaling, estrogen metabolism and IL17 signaling can help stratification of patients for a more effective personalized medicine in RA.

HLA ASSOCIATION WITH SYSTEMIC SCLEROSIS (SSc) IN NORTH INDIAN POPULATION AND FAMILIAL INHERITANCE PATTERNS

S. Machhaj1, R. Minz2, S. K. Sharma3, H. Singh4, Y. Kumar5, S. Anand6, S. Handa4, S. Singh7, 1Post Graduate Institute of Medical Education & Research, Chandigarh, Immunopathology, Chandigarh, India; 2Post Graduate Institute of Medical Education & Research, Chandigarh, Immunopathology, Chandigarh, India; 3Post Graduate Institute of Medical Education & Research, Chandigarh, Internal Medicine, Chandigarh, India; 4Post Graduate Institute of Medical Education & Research, Chandigarh, Immunopathology, Chandigarh, India; 5Post Graduate Institute of Medical Education & Research, Chandigarh, Dermatology Venerology Leprology, Chandigarh, India; 6Post Graduate Institute of Medical Education & Research, Chandigarh, Department of Pediatrics, Chandigarh, India

Background: It is widely believed that SSc develops in an individual with a permissive genetic makeup. Genetic influences have long been suspected to impact SSc. In families with a history of SSc, the incidence of disease can range from 1.5 to 1.7% (1). There are several reports of familial occurrence and certain alleles of the HLA system have been associated with the disease (2). No Indian data pertaining to genetic basis of systemic sclerosis is present. Understanding the genetic basis of the disease will help us in defining the biomarkers of the disease in the population that can help in early diagnosis and prognosis.

Objectives: To study HLA association with Systemic sclerosis (SSc) in North Indian Population and its genetic susceptibility to familial systemic sclerosis.

Methods: A total of 150 SSc patients diagnosed by following ACR and EULAR criteria and 150 control subjects, were genotyped for HLA-A, B, DRB1, DQB1 loci by Luminex® 200 Instrument (USA). The association of alleles with disease susceptibility was tested by Chi-square test and Fisher’s exact test.

Conclusion: The risk alleles A*24, B*35; DRB1*11 were found to be associated with North Indian cohort of SSc, while the protecting alleles were A*68; DRB1*10. These risk alleles were present in the SSc affected family members and the protective alleles were absent in the same. Surprisingly, even healthy members carried the same risk alleles but did not manifest the disease or have serological evidence of the same. We have not excluded occurrence of disease at a later age, as presently the healthy siblings are young. Thus our study indicates that though HLA association are found with SSc but many other factors like HLA (HLA ‘C’, DPB1) or non HLA genes as wells as epigenetic factors might also play a role in disease manifestation and severity.

GENETIC MARKERS OF METHOTREXATE HEPATOXICITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Martusevich1, E. Aksenova2, K. Gudkevich3, Belarusian State Medical University, Minsk, Belarus; 1The Institute of Genetics and Cytology, Minsk, Belarus; 2Minsk City Clinical Hospital No 6, Minsk, Belarus

Background: Methotrexate (MT) is a first-line drug in the treatment of rheumatoid arthritis (RA). The effectiveness and tolerability of the use of MT largely determines the prognosis of the course of the disease, the speed of achieving remission. The development of hepatotoxicity (HT) is the most common adverse reaction, it is noted in 5-12.5% of cases and often requires the abolition of MT. In this regard, predicting the development of HT seems to be an important area of research.

Objectives: to study genetic predictors of HT development in patients with RA using MT.

Methods: 44 patients with a reliable diagnosis of RA were included in study. All of the patients used MT at a dose of 15.0 (12.5-17.5) mg/week in combination with folic acid 3-5 mg/day outside of MT. The average age was 46.7 ± 12.3 years; females- 81.8% (n = 36); mail 18.2% (n = 8). The duration of RA is 5.3 ± 2.2 months. All patients were divided into two groups: the first study group (n = 17) included patients with RA who developed a HT reaction to MT, which required the abolition of MT; in the second (n = 27) - comparison group - patients with good efficacy and tolerability of MT.

Genotypes for polymorphic alleles were analyzed in all patients: C677T (rs1801133) and A1298C (rs1801131) of the methylenetetrahydrofolate reductase gene (MTHFR); 347C>G single-nucleotide polymorphism of the gene of aminomimidazole-carboxamidinobonoside transformylase / inosine monophosphate cyclohydrolase (ATIC); c.80G>A locus of the SLC19A1 gene encoding the folate transporter membrane carrier protein.

Statistical data processing was carried out using the SATISTICA 10.0 software package using descriptive and nonparametric statistics methods.

Results: The frequency of occurrence of various mutations in genes that affect the metabolism of MT among patients with RA in the study and comparison groups are presented in table 1.

TT - hepatotoxicity

When analyzing inheritance models, it was found that differences in hepatotoxicity for comparing genotypes (MTHFR-A1298C, MTHFR-C677T, SLC19A1c80A>G) were not statistically significant. A statistically significant increase in the risk of hepatotoxicity was found for dominant (2.18 (1.06-4.47), x2 = 4.38, p = 0.03) and codominant (0.42 (0.19-0.92), x2 = 5.23, p = 0.02) models for the 347C>G ATIC gene.

Conclusion: Thus, an increase in the risk of hepatotoxicity for the dominant and codominant models for the 347C>G ATIC gene allows recommending genotyping of the alleles of this gene before MT administration in order to reduce the risk of hepatotoxic reactions.

ASSOCIATION OF PTPN22 GENETIC VARIANTS WITH DISEASE SUSCEPTIBILITY AND CLINICAL VARIABLES IN PRIMARY SJÖGREN SYNDROME

P. A. MENCHACA TAPIA1, E. OREGON ROMERO2, D. C. SALAZAR CAMARENA3, M. MARIN ROSALES1, J. F. MUÑOZ VALLE3, C. A. PALAFOX SÁNCHEZ4, 1CUCS, Universidad de Guadalajara, Instituto de Investigación en Ciencias Biomédicas, Guadalajara, Jalisco, Mexico; 2CUCS, Universidad de Guadalajara, Laboratorio de Biomateriales, Guadalajara, Jalisco, Mexico; 3Hospital General de Occidente, Reumatología, Zapopan, Jalisco, Mexico

Background: Primary Sjögren’s syndrome (pSS) is a systemic autoimmune disease characterized by dysfunction of exocrine glands secondary to lymphocytic infiltration. Lymphoid tissue phosphatase (LYP) regulates T and B lymphocyte activation. PTPN22 gene encodes LYP; multiple polymorphic variants have been described as genetic risk factor of autoimmune diseases.

Objectives: The aim was to analyze the PTPN22 rs2484857G>C, rs33996649G>A, and rs2476601C>T genetic variants relationship with the development risk of pSS in the western Mexico population.

Methods: One hundred and eighty healthy subjects (HS) and 150 pSS patients, classified according to EULAR 2016 criteria, were included. The genetic variants and mRNA expression were determined through PCR-RFLP and qPCR assays.

DOI: 10.1136/annrheumdis-2020-eular.5456
**Results:** The frequency of heterozygote rs33996649GA genotype was higher in pSS patients than HS [OR=3.134 (1.0-10.234), p=0.046], and also, rs33996649GA genotype was associated with high SDDAI score (p=0.01). The pSS patients showed 44-fold more mRNA expression in comparison with HS (p=0.002), and mRNA expression correlates with SDDAI (r^2=0.512, p=0.006).

**Conclusion:** The rs33996649G-A genetic variant of the PTPP22 gene is associated with increased development risk of pSS in the western Mexican population. The expression mRNA correlates with disease activity in pSS.

**CONSISTENT GENETIC MARKER IL1B T-31C IS ASSOCIATED WITH ANAMNESIS OF BIOLOGICAL DRUGS TREATMENT IN RHEUMATOID ARTHRITIS**

V. Omelchenko1, E. Letyagina1, Y. Kurochkina1, A. Akimova1, A. Shevchenko1, M. Korolev2, RICEL – Branch of IC&G SB RAS, Novosibirsk, Russian Federation

**Background:** Rheumatoid arthritis (RA) is chronic progressive joint disease with erosions formation. Timely and effectiveness treatment is important due to quickly structural damage and progressive losing of active motion. Synthetic DmARDs didn’t have a sufficient effect. Using biological drugs seemed like a panacea, but in our investigations at least 30-40% RA-patients lost treatment efficiency. Biological drugs act through immune cascade, that’s why mutation in regulatory immunity gene.

**Methods:** One hundred two Caucasian RA-patients (age – 56 yrs [45; 61]); DAS28 4.7 [3.8; 5.9] were enrolled in our study. All of them had American College of Rheumatology (ACR)-defined RA (1987 classification criteria) and gave written informed consent. Single nucleotide polymorphisms IL1B T-31C (rs1143627), IL4 C-590T (rs2243250), IL10 C-592A (rs1800896), IL10A -819G (rs1800896) were determined by restriction fragment length polymorphism. Descriptive statistics, Chi-squared test were used for data analysis. Results are presented as median and 25th/75th percentiles (Me [25th percentile; 75th percentile]).

**Results:** The most of SNP’s analyzed had corresponded to the Hardy Weinberg equilibrium (HWE). The only exception was IL1B T-31C – the frequencies were differed statistically significant from HWE (p<0.03). Forty seven (46.1%) patients were treatment with biological drugs. Homozygotes IL1B -31C/C were founded more frequently beside patients with biological treatment compare with other group (13 from 47 (27,7%) vs. 6 from 52 (11.5%), p=0.042). Other SNPs didn’t demonstrate any associations.

**Conclusion:** Single nucleotide polymorphism IL1B T-31C (rs1143627) may be used for prognosis of basic anti-inflammatory therapy inefficiency and the needing for prescribing biological therapy.

**TNFA RS1800629 POLYMORPHISM: WHAT ABOUT ITS ASSOCIATION WITH CLINICAL MANIFESTATIONS AND ANTI-TNFa THERAPY? DATA FROM A SERIES OF ITALIAN PATIENTS WITH BEHÈCT SYNDROME**

M. C. Padula1,2, P. Lecceusa, N. Lascaro1, G. G. Sorrento1, R. P. Radice2, A. R. Limongi3, T. Carbone1, A. Padula1, G. Martelli2, S. d’Angelo1, 1Rheumatology Institute of Lucania (IReL), San Carlo Hospital of Potenza, Potenza, Italy; 2University of Basilicata, Potenza, Italy

**Background:** Tumor Necrosis Factor-alpha (TNF-α) is a pleiotropic cytokine with a critical role in the pathogenesis of Behçet syndrome (BS). Anti-TNF-α therapy is useful for patients with refractory, severe BS, in particular for ocular, central nervous system, and gastrointestinal manifestations. However, although biological treatment with anti-TNF-α agents are effective in BS, not all patients are definite responders. Non-responders patterns could be due to: alternative anti-TNFα related pathway of inflammation; anti-drug antibodies presence or development; polymorphic alleles of TNFα genes. TNFs rs1800629 (-308G>A) is a drug-response single nucleotide polymorphism (SNP) located within the gene promoter. Poor and conflicting data are currently available about the association of this polymorphism and clinical manifestations of BS, as well as about the responsiveness to the TNFα blockers in BS patients [1-3].

**Objectives:** Aims of this study were to investigate in a cohort of Italian patients with BS the frequency of rs1800629 genotypes and its association with clinical features and anti-TNFα therapy response.

**Methods:** Consecutive patients with BS were recruited. Patients demographic and clinical data were collected by medical records and analyzed. Home-made specific primer pairs were used for rs1800629 coverage. gDNA was isolated and amplified using PCR. Good-quality amplicons were sequenced (Sanger method). In silico analysis was downstream performed using specific software for query-subject similarity analysis.

**Results:** 130 BS patients (64M-66F; mean age: 45.8±12.3 years) were included in the study. Patients predominant lesions were oral aphthosis (100%), eye involvement (86.2%), skin lesions (72.3%) and genital ulcers (57.7%). TNFs rs1800629 wild-type GG genotype was found in 106/130 BS patients (81.5%); the heterozygous genotype (GA) was identified in 24/130 patients (18.5%). No statistically significant differences were found in genotypes frequencies when the patients were stratified for presence and absence of each clinical manifestation (p>0.05), while statistical significant differences were found when the patients were compared for therapy (anti-TNFα drugs) response. In detail, 73/130 patients (56.2%) were treated with anti-TNFα agents. We found 16/73 (21.9%) non-responders patients (NRP). In NRP group, we identified 9/16 patients (56.3%) with GG genotype and 7/16 (43.7%) with GA genotype, while 8/57 (14.0%) responder patients showed GA genotype and 49/57 responder patients (86.0%) showed GG genotype (p=0.0093; OR: 0.21, CI: 0.06-0.729).

**Conclusion:** Here we described a low frequency of TNFα rs1800629 SNP-containing allele and the lack of association between SNP and BS clinical hallmark, as previously reported in literature [1-4]. We also found higher percentage of GG genotype in case of therapy response than GA genotype. The SNP is a promoter polymorphism that could affect the anti-inflammatory response and the therapy responsiveness, as suggested by our preliminary data of pharmacogenomics. Analyses of a larger cohort of patients are needed to confirm the study findings and to explain the SNP role as outcome predictor.

**GENETIC POLYMORPHISM OF THE INFLAMMATORY MARKER SAA1 RS12218 (-1/3’ T) IS ASSOCIATED WITH AN ATTITUDE TO CLINICAL PHENOTYPES OF JUVENILE IDIOPATHIC ARTHRITIS**

E. Fedorov1, S. Salugin2, M. Krylov2, I. Guseva1, E. Samarkina1, 1VA. Nasonova Research Institute of Rheumatology, Pediatric, Moscow, Russian Federation; 2VA. Nasonova Research Institute of Rheumatology, Pediatric, Moscow, Russian Federation; 3VA. Nasonova Research Institute of Rheumatology, Immunology, and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation

**Background:** Juvenile idiopathic arthritis (JIA) is one of the most widely-spread immuno-inflammatory diseases of an unknown etiology, the leading manifestation of which is chronic joint inflammation, occurring in children under the age of 16. The disease is a complex of chronic arthropathies with various phenotypic manifestations.
Results: To verify the hypothesis about the role of SAAG1 rs12218 T/C gene polymorphism in the aptitude to various clinical JIA phenotypes.

Methods: The study included 132 children, of whom 66 were diagnosed with JIA and 66 were healthy unrelated volunteers (the college students) as a control group, comparable by gender and age. The group of patients with JIA consisted of 44 girls and 22 boys, with an average age of 11.7 ± 4.2 years and an average disease duration of 4.8 ± 3.8 years. The diagnosis and classification of JIA was established according to ILAR-2004 criteria. The JIA group included 30 (45%) patients with oligoarthritis (oJIA), of which 20 patients (67%) were positive for the HLA-B27 antigen (JIA-B27+) and 10 (33%) patients with anterior uveitis (uJIA); 20 (30%) patients were assigned to the group with the polyarticular variant (pJIA), while all of them were seronegative for the rheumatoid factor; 16 (24%) patients were diagnosed with JIA with a systemic onset (sJIA). The frequencies of the T/C polymorphism of the SAAG1 gene were assessed using an allele-specific polymerase chain reaction in a real-time mode (RT-PCR).

Results: In the group of patients diagnosed with oJIA and (JIA-B27+), the frequency of the C allele was significantly higher compared to the control (53.3% and 57.5% versus 37.1%, p = 0.035 and 0.022, respectively). No significant differences were detected in the frequencies of the mutant C allele between sJIA and pJIA and the control group. The logistics analysis of the frequency distribution of the alleles of the SAAG1 gene demonstrated an increased risk of the C allele in formation of an aptitude to the oJIA variant (OR 1.94, 95% CI 1.00-3.76, p = 0.05). In the JSJIA group, the risk of the C variant allele was also increased compared to the control (OR 2.29, 95% CI 1.05-5.04, p = 0.022).

Conclusion: The data obtained confirm for the first time the involvement of the rs12218 polymorphism of the SAAG1 gene in an aptitude to the oligoarthritis JIA clinical phenotype. The presented results require further replication researches using an enlarged number of patients from different population groups.

Disclosure of Interests: None declared.

CORRELATION BETWEEN SERUM AND SYNOVIAL CONCENTRATION OF IL-17A AND MRNA EXPRESSION IN RHEUMATOID ARTHRITIS PATIENTS

R. Shumailieva1, D. Kachakova2, T. Velikova2, R. Kaneva2, Z. Kolarov2, S. Monov1, 1Medical University – Sofia, Bulgaria, Department of Internal Medicine, Clinic of Rheumatology, Sofia, Bulgaria; 2Medical University – Sofia, Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Sofia, Bulgaria; 3Clinical Immunology, University Hospital Lozenezet, Sofia, Bulgaria

Background: Interleukin 17 (IL-17) is a proinflammatory cytokine, which overproduction promotes the autoimmune reaction in rheumatoid arthritis (RA). Posttranscriptional regulation of IL-17 by specific microRNAs (miRNAs) is of great interest in the recent years. 146a was associated with IL-17 expression in IL-17 producing T cells in synovium when miR-155 enhanced Treg and Th17 cells differentiation and IL-17A production. The opposite changes of IL-17A and miR-223 systemic and local levels confirm the data about the possible role of miR-223 in regulating IL-17 function. Further analysis with larger sets is needed to confirm these results.

VARIABILITY OF THE RS333 IN LUPUS ERTHYMATOSUS PATIENTS FROM THE POLISH POPULATION

K. Skonieczna1, D. Mlicka1, A. Wozniacka2, R. Czajkowski3, E. Robak2, M. Gawrych2, A. Dudeba1, T. Grzybowski1, 1Medical University – Sofia, Bulgaria, Department of Internal Medicine, Clinic of Rheumatology, Sofia, Bulgaria; 2Medical University – Sofia, Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Sofia, Bulgaria; 3Clinical Immunology, University Hospital Lozenezet, Sofia, Bulgaria

Background: There are several subtypes of Lupus Erythematosus (LE), which may be limited to the skin (eg. Discoid Lupus Erythematosus, DLE) or involve multiple organ dysfunctions (Systemic Lupus Erythematosus, SLE). LE is an autoimmune disease that is influenced by genetic and environmental factors. Despite some genetic changes between DLE and SLE were previously shown, the complete genetic background of DLE is still unresolved [1]. Functional C-C chemokine receptor 5 (CCR5) receptor can be associated with the inflammation in LE patients. Importantly, the 32 base pairs (bp) deletion in CCR5 gene (rs333) leads to a nonfunctional receptor. Previous studies have shown that this mutation may have a protective effect on the development and progression of SLE [2, 3]. Thus it was important to investigate whether 32 bp deletion in rs333 is also associated with DLE development.

Objectives: The aim of this study was to investigate the variability of the CCR5 gene, within a polymorphic locus rs333 in SLE and DLE patients from the Polish population.

Methods: 120 LE patients (77 SLE patients and 43 DLE patients) and 100 healthy persons were recruited to the study from the Polish population. DNA was isolated from blood or buccal swabs. rs333 was genotyped by using polymerase chain reaction (PCR). Statistical significance of the differences was evaluated using Chi-Squared test with Yates correction or two tailed Fisher’s exact test.

Results: Deletion allele of the rs333 was significantly less frequent among DLE patients than healthy persons (p = 0.0171). Also the homozygotes occur significantly less frequent within DLE patients group than in healthy individuals (p = 0.0375). Moreover, homozygotes without deletion in rs333 were found significantly more frequent in persons diagnosed with DLE than in healthy volunteers (p = 0.0214). In contrast, the differences in allele or genotype frequencies between patient and control groups in both allele and genotype frequencies were calculated using Chi-Squared test with Yates correction or two tailed Fisher’s exact test.

Discussion: The deletion allele of the rs333 was significantly less frequent among DLE patients than healthy persons (p = 0.0071). Also the homozygotes occur significantly less frequent within DLE patients group than in healthy individuals (p = 0.0375). Moreover, homozygotes without deletion in rs333 were found significantly more frequent in persons diagnosed with DLE than in healthy volunteers (p = 0.0214). In contrast, the differences in allele or genotype frequencies between SLE patients and healthy controls were not statistically significant (p > 0.05). Moreover, the rs333 variability was not associated with clinical symptoms of LE patients (p > 0.05).

Conclusion: Summarizing, the results obtained in this study suggest that the 32 bp deletion within rs333 could be a protective factor, that reduce the risk for DLE but not SLE development in the Polish population. However, due to the low statistical power of the obtained results, further studies on larger groups of patients and controls are needed to acquire more reliable data.

AB0022 INTERRELATIONS OF INCREASED AXIAL SPONDYLOARTHRITIS ACTIVITY AND THE SERUM CONCENTRATION OF IMMUNOGLOBULIN A TO CD74 WITH GENETIC POLYMORPHISMS OF INTERLEUKIN 17 ALLELES

E. Vasilenko1,2, M. Korolev3, S. Lapin4, I. Kholopova4, A. Dadalova5, V. Mazurov1, I. Gaydukov2,5, North-Western State Medical University named after I.I. Mechnikov. Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E. Eichwald, St. Petersburg, Russian Federation; 2St. Petersburg Clinical Rheumatology Hospital No.25, St. Petersburg, Russian Federation; 3The Federal Research Center Institute of Cytology and Genetics, Novosibirsk, Russian Federation; 4The First Pavilion State Medical University of St. Petersburg, Laboratory for Diagnostics of Autoimmune Diseases, St. Petersburg, Russian Federation

Background: Genetic predisposition takes one of the main parts at pathogenesis of axial spondyloarthritides (axSpA). Currently, HLA-B27 is a single genetic marker that used in classification criteria of axSpA. However, the presence of HLA-B27 does not affect the activity of the disease. An alternative biomarker of axSpA activity is IgA antibdy to an invariant chain peptide associated with class II human leukocyte antigen (HLA) (anti-CD74).

Objectives: The goal is to determine genetic polymorphisms of IL17 alleles prevalence in patients (pts) with axSpA and their interrelations with the disease activity and concentration of IgA to CD74.

Methods: In 48 patients with a reliable diagnosis of axSpA, aged 18 to 69 years, ASDAS, BASDAI, BASFI were calculated. The polymorphisms of alleles of interleukin (IL)-17A197 a/g, IL-17F histidine (His)/arginine (Arg), IL-17F11139 c/g, IL-17B27 were evaluated. Serum concentration of IgA to CD74 was measured (the normal reference interval according to the instructions for the laboratory kit for serum IgA to CD74 is Q-12.0 U/L).

Results: The mean age of pts was 45.1±14.2 years, male 72.9%, BASDAI 2.9±0.8, ASDAS 2.2±0.16 (Cronbach's alpha for the scales – 0.83), IgA to CD74 16.9±11.0 mg/L. The most often found polymorphisms of interleukin-17 alleles demonstrated in table 1.

Exceeded levels of IgA to CD74 were identified at 96 pts (70.1%). The factor analysis showed a relationship between ASDAS (R=0.857), BASDAI (R=0.842), BASFI (R=0.857) and level of IgA to CD74 (R=0.667), (table 2).

</tbody>
</table>

An increase in the factor load indices for IgA to CD74 (R=0.925) was established, provided that the IL-17F genotype is homozygous for the his/arg allele (R=0.544). The genotypes IL-17F his/his showed an inverse correlation with the increase in serum IgA to CD74 level (R=0.421).

Conclusion: Serum concentration of IgA to CD74 exceeded normal reference level in axSpA patients in 70.1% of cases that was associated with ASDAS and BASDAI levels. Presence of heterozygote IL-17F polymorphism in his/arg allele was associated with increasing serum concentration of IgA to CD74 and with increased disease activity (ASDAS and BASDAI). Decreasing of serum IgA to CD74 concentration, less axSpA activity (ASDAS and BASDAI) were found in patients with presence of heterozygote IL-17F polymorphism in his allele.

AB0023 ASSOCIATION OF NCF2, NCF4 AND CYBA GENES POLYMORPHISMS WITH RHEUMATOID ARTHRITIS IN A CHINESE POPULATION

T.P. Zhang1, Q. Huang2, H. F. Pan3, D. Q. Ye4, X. Li5 on behalf of no. The First Affiliated Hospital of University of Science and Technology of China, Hefei, China; 2Anhui Medical University, Hefei, China; 3The First Affiliated Hospital of University of Science and Technology of China, Hefei, China

Background: Recent studies have focused on the special roles of NADPH-oxidase, which is composed of gp91phox, p22phox, p47phox, p67phox, p40phox encoded by CYBB, CYBA, NCF1, NCF2, NCF4 genes, in multiple autoimmune diseases. Nevertheless, the association of genetic variation in NADPH-oxidase genes with rheumatoid arthritis (RA) was not extensively studied in Chinese population.

Objectives: We performed this study to examine the association of NCF2, NCF4, CYBA genes polymorphisms with RA susceptibility in a Chinese population.

Methods: Six single nucleotide polymorphisms (SNPs) (NCF2 rs10911363, NCF4 rs18831132, rs4821544, rs729749, CYBA rs3794624, rs4673) were genotyped in a cohort composed of 593 RA patients and 596 normal controls. All patients were consecutively enrolled from the Department of Rheumatology at the First Affiliated Hospital of University of Science and Technology of China and the First Affiliated Hospital of Anhui Medical University, and the normal controls was enrolled from the same region. Improved multiple ligase detection reaction (MLDR) was used for genotyping. Chi-square (χ2) test was used to analyze the association of the genotype and allele frequencies of above SNPs and RA. Odds ratios (OR) and 95% confidence interval (CI) were also evaluated using Logistic regression analyses, and haplotype analysis was assessed using SHEsis software.

Results: There were 101 males and 492 females in RA group with a mean age of 51.59±6.68 years, and the normal control group included 97 males and 499 females with an average age of 52.32±12.63 years. We observed that NCF4 rs4821544 CT genotype, C allele frequencies in RA patients were significantly decreased when compared to controls (CT vs. TT: P = 0.043; C vs. T: P = 0.031), and rs4821544 polymorphism was significantly associated with an increased RA risk under the dominant model (TT vs. CT+CC: P = 0.031). Moreover, our results also indicated that rs729749 CT genotype frequency was significantly lower in RA patients than in controls (CT vs. CC: P = 0.033). No significant association between NCF2, CYBA genes polymorphisms and RA susceptibility was observed. There were no significant differences in allele, genotype frequencies of above SNPs between RA patients with RF-positive and with RF-negative, as well as anti-CCP-positive RA patients and anti-CCP-negative RA patients.

Conclusion: In summary, NCF4 rs4821544, rs729749 polymorphisms might contribute to RA susceptibility, while NCF2, CYBA genes polymorphisms were not associated with RA susceptibility.

ASSOCIATION OF IL6 RS1800795 BUT NOT IL6 RS2228145, RS4845618 AND STAT4 RS7574865 POLYMORPHISMS WITH CHLAMYDIA-ASSOCIATED RHEUMATOID ARTHRITIS

T. Zybalova 1, V. Yagur 2, R. Goncharova 3, N. Soroka 4, N. Dostanko 4, V. Apanasovich 1, A. Tushina 3, 1Belarusian State Medical University, 2nd Department of Internal Medicine, Minsk, Belarus; 3Institute of Genetics & Cytology NAS Belarus, Laboratory of Molecular Basis of Genomic Stability, Minsk, Belarus

Background: Rheumatoid arthritis (RA), associated with Chlamydial Infection, has some clinical and immunological particulars that interfere with the early diagnosis and require significant changes in treatment strategy [1].

Objectives: To estimate the distribution of some non-HLA genetic markers such as STAT4 rs7574865, IL6 rs1800795, IL6 rs2228145 and rs4845618 in Chlamydia-positive and negative RA patients and healthy controls.

Methods: We examined 380 healthy blood donors and 187 RA patients classified according to the ACR/EULAR 2010 criteria for RA [2]. Twenty-three of the RA patients were positive for Chlamidia trachomatis (n=17) or Chlamidia pneumonia (n=6) persistence. DNA from peripheral blood samples was extracted by phenol-chloroform method. SNPs were genotyped by the real-time PCR with fluorescent probes. Statistical significance of SNPs’ frequency was estimated by two-way Fisher exact test (F, p) with Bonferroni correction for multiple comparisons (p). Moreover, diagnostic odds ratio (dOR), the likelihood ratio of positive (LR+) and negative (LR–) tests and corresponding confidence intervals (CI) were calculated.

Results: We revealed statistically significant increase of genotype CC frequency (IL6 rs1800795) in Chlamydia-associated RA (60.9%) vs healthy donors (20.7%): p = 0.000665; dOR=5.95 (CI 2.53-13.94); LR+=2.94 (CI 1.58-5.51); LR–=0.51 (CI 0.29-0.78). Significant differences in STAT4 rs7574865, IL6 rs2228145 and IL6 rs4845618 distribution between studied groups were not found.

Conclusion: Our data suggest the association between CC genotype of IL6 rs1800795 and Chlamydia-associated RA.

Adaptive immunity (T cells and B cells) in rheumatic diseases

S. Benevolenskaya 1, I. Kudryavtsev 2, M. Serebrakova 3, I. Grigor’eva 4, A. Budkova 5, D. Zammoeva 2, D. Motorin 2, A. Zartseky 4, S. Lapin 5, A. Masyiansky 5, 1Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation; 2Institute of Experimental Medicine, Saint-Petersburg, Russian Federation; 3Institute of Experimental Medicine, Saint-Petersburg, Russian Federation; 4Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation; 5Pavlov First Saint Petersburg State Medical University, Saint-Petersburg, Russian Federation

Background: Systemic lupus erythematosus (SLE) and primary Sjögren’s syndrome (pSS) are chronic complex disorders with an autoimmune background, multifactorial etiology, multiple circulating antinuclear antibodies and damage of various organs. SLE and pSS have several similar clinical and immunological aspects; likewise, SLE and Sjögren’s syndrome may coexist (so-called secondary Sjögren’s syndrome). However, applied classification criteria do not differentiate SLE and pSS. It is known that humoral immunity plays significant part in pathogenesis of those diseases; hereby, we can expect imbalances in B cell subset frequencies during SLE and pSS.

Objectives: To investigate clinical utility of B cell subsets in distinguishing SLE and pSS during diagnosis.

Methods: A total of 25 SLE patients, 25 SS patients and 49 healthy volunteers (HV) were included in the study. The diagnosis of SLE was performed according to the 2019 EULAR – ACR classification criteria, the diagnosis of pSS - according to the 2016 EULAR – ACR criteria. Phenotyping of blood B cell subsets was done using flow cytometry. Total peripheral blood B cells were identified using CD19 expression, distinct B cell subsets were characterized by IgD, CD38 and CD27 expression. All of the statistical analysis of data was performed with STATISTICA Version 12.0 Inc. (USA).

Results: We evaluated the percentages of circulating B-cell subsets using three major classification schemes based on the relative co-expression of either IgD/CD38 (so-called “Bm1-Bm5” classification), IgD/CD27 and CD38/CD27. A discriminant analysis was performed for all B cell classifications. Analysis of CD38 and CD27 co-expression demonstrated most significant separation between patients with SLE and pSS (fig. 1). Moreover, discriminant analysis carried out by using a forward stepwise model demonstrated that the top significance was documented while assessing the percentage of plasmablasts (CD27dimCD38low), resting memory B-cells (CD27dimCD38low), mature active B-cells (CD27dimCD38dim), naive mature B-cells (CD27dimCD38hi), model percent correct was 78.6% (p <0.05, tab.1).

References:

Figure 1. Graphic distribution of SLE and pSS patients as well as HV analyzed by discriminant analysis.
Conclusion: B cell subsets might provide a useful diagnostic tool for distinguishing SLE and pSS. More research is needed to investigate clinical value of B-cell subsets in autoimmune rheumatic diseases.

Table 1. Peripheral B-cell subset composition in SLE and SS patients vs. HV groups assessed by discriminant analysis.

AB0026

SELECTIVE INHIBITION OF TYROSINE KINASE 2 WITH AN ORAL AGENT, BMS-986165, COMPARED WITH JANUS KINASE INHIBITORS

A. Chimalakonda1, J. Burke1, L. Cheng1, J. Strnad1, I. Catlett1, A. Patel1, J. Shen1, I. Girgis1, S. Barnerjee1, J. Throup1. 1Bristol-Myers Squibb, Princeton, United States of America

Background: BMS-986165 is an oral, selective inhibitor of tyrosine kinase 2 (TYK2) with a unique mode of binding to the pseudokinase domain of the enzyme rather than the active site within the kinase domain. This unique mode of binding provides high functional selectivity for TYK2 versus other tyrosine enzyme rather than the active site within the kinase domain. This unique mode of binding provides high functional selectivity for TYK2 versus other tyrosine kinases (TYKs) in cellular and other in vitro assays.1 This approach may provide robust efficacy with a differentiated safety profile due to decreased off-target activity on other kinases. In a 12-week, placebo-controlled Phase 2 trial in patients with moderate to severe plaque psoriasis,2 BMS-986165 had a favorable safety profile, and 67%–75% of patients achieved Psoriasis Area and Severity Index 75 (PASI 75) after 12 weeks at doses ≥3mg twice daily versus 7% with placebo. BMS-986165 is currently under investigation in multiple autoimmune disorders such as sarcoid arthritis, psoriasis, and systemic lupus erythematosus.

Objectives: To understand the selectivity of BMS-986165 compared with JAK inhibitors, such as tofacitinib (Tofa), upadacitinib (Upa), and baricitinib (Bara), at clinically relevant doses and plasma concentrations.

Methods: In vitro whole blood assays were developed to measure the activity of common pairings of JAKs (JAK 1/3, JAK2/2, and TYK2/JAK2) and concentrations providing half-maximally inhibitory (IC50) for BMS-986165, Tofa, Upa, and Bara were determined. The whole blood IC50 values were plotted against pharmacokinetic profiles of these agents at approved doses and/or doses evaluated in their respective Phase 2/3 trials. The time that concentrations were >IC50 and projected average daily inhibition were evaluated.

Results: At clinically relevant doses and exposures, BMS-986165 plasma concentrations were higher than the TYK2 whole blood IC50 value for a considerable part of the dosing interval. Additionally, the maximal plasma concentration (Cmax) of BMS-986165 was approximately 9–18-fold lower than the JAK 1/3 whole blood IC50 value and 52–109-fold lower than JAK2/2 whole blood IC50, indicating lack of meaningful inhibition of the JAK 1-3 pathways by BMS-986165 at therapeutic doses. At clinically relevant doses, projected Cmax values of Tofa, Upa, and Bara were many-fold lower than TYK2 IC50, indicating minimal or no meaningful inhibition of the TYK2 pathway. As expected, Tofa, Upa, and Bara had varying degrees of inhibition against JAK1/3 (daily average inhibition range: 70%–94%) and JAK2/2 pathways (daily average inhibition range: 24%–67%) at clinically relevant doses and exposures.

Conclusion: These results demonstrate the high TYK2 functional selectivity of BMS-986165 at clinically relevant doses and plasma concentrations compared with Tofa, Upa, and Bara and indicate that BMS-986165 is in a different class compared with JAK 1–3 inhibitors. Ongoing studies in psoriasis and other conditions may confirm the expected safety of BMS-986165 based on the above results. The daily average inhibition of JAK1 and JAK2 likely explains some common laboratory observations and adverse events reported for the JAK1–3 inhibitors.

B CELL SYNOVITIS IN RELATION TO DIAGNOSIS AND CLINICAL PHENOTYPE: COMPARISON BETWEEN RHEUMATOID AND PSORIATIC ARTHRITIS

L. De Stefano1, S. Bugatti2, S. Rossii1, C. Montecucco1, A. Manzo1, 1University of Pavia, Rheumatology and Translational Immunology Research Laboratories (LaRIT), Division of Rheumatology, Pavia, Italy

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are both characterized by significant heterogeneity in terms of clinical presentation and outcomes. Furthermore, RA and PsA may share some overlapping features such as autoantibody-negativity, polyarticular involvement, response to certain therapies and pattern of joint damage. The pathological bases underlying the intra-disease heterogeneity and the inter-disease similarities between RA and PsA are however unknown.

Objectives: Aim of the current study was to investigate the relationship between the synovial immune phenotype and different clinical subsets in patients with RA and PsA.

Methods: The study population included 96 patients undergoing ultrasound-guided synovial biopsy of the knee and serum sampling on the same day. Patients were recruited according to defined clinical subtypes: anti-citrullinated positive (ACPA) RA (n=26), ACPA-negative RA (n=32), polyarticular (≥5 involved joints) PsA (n=15), and oligoarticular PsA (n=23). Patients were compared for: (i) demographic and clinical features; (ii) synovial histopathological characteristics including CD68-positive infiltrating macrophages, CD3-positive T lymphocytes, CD20-positive B lymphocytes (semi-quantitative scores 0-3); (iii) serum levels of the lymphoid chemokine CXCL13 as a marker of germinal centre activity.

Results: Collectively, ACPA-positive RA patients, ACPA-negative RA patients and patients with polyarticular PsA presented comparable demographic and clinical features including gender distribution, age, number of involved joints and levels of acute phase reactants. Patients with oligoar- ticular PsA were instead younger, more frequently males, and with lower levels of acute phase reactants. The degree of macrophage and T cell infiltration correlated with the erythrocyte sedimentation rate (rho 0.38, p=0.01 and rho 0.24, p=0.04 respectively) and C-reactive protein levels (rho 0.38, p=0.01 and rho 0.28, p=0.01 respectively) irrespective of diagnosis, and was significantly lower in oligoarticular PsA (Figure 1 A, B). In contrast, the degree of B cell infiltration showed significant differences in relation to the disease subtype: the lowest levels were found in oligoarticular PsA, the highest levels in ACPA-positive RA, whilst ACPA-negative RA and polyarticular PsA presented with intermediate and comparable levels between the two extremes (Figure 1 C). Serum levels of CXCL13 correlated with the synovial B cell score (rho 0.30, p=0.03) and, similarly to synovial B cell infiltration, were differentially increased according to the clinical phenotype, with again similarities between ACPA-negative RA and polyarticular PsA (Figure 1 D).

Additional information
**Conclusion:** In patients with chronic inflammatory arthritis, synovial B cell infiltration and systemic markers of germinal centre activity are heterogeneously increased irrespective of disease diagnosis. ACPA-positive RA and oligoarticular PsA appear located at the extremes of a pathobiological continuum, whilst ACPA-negative RA and polyarticular PsA present with intermediate and comparable degrees of B cell involvement. Collectively, our findings open the interesting perspective of a tailored management of patients with inflammatory arthritis based on the disease pathotype rather than on clinical diagnosis.

**AB0028 IMBALANCES OF TH17/TREG IN CARDIOVASCULAR EVENTS OF PATIENTS WITH ANKYLOSING SPONDYLITIS**

T. Ding1, R. Wu1, H. Xue1, X. F. Li1, C. Wang1. 1The Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China

**Background:** Ankylosing spondylitis (AS) is a common inflammatory joint disease affecting articulations of axial skeleton and asymmetrical peripheral arthritis. It has been highlighted that patients with AS exhibit an increased risk of cardiovascular diseases (CVD) compared to the general population [1]. However, little is known about the relationship between cardiovascular burden in AS patients and Th17/Treg imbalance.

**Objectives:** We aimed to investigated the relationship between cardiovascular events in AS patients and the status of T cell subsets. Furthermore, we want to identify other clinical and/or laboratory features which are associated with the cardiovascular risk in AS patients.

**Methods:** The study included 32 AS patients with cardiovascular diseases and 32 age-matched AS patients as controls. All the AS patients were hospitalised at the Second Hospital of Shanxi Medical University and met the diagnostic criteria for AS revised in New York in 1984. We collected demographics, laboratory features [erythrocyte sedimentation rate (ESR), c-reactive protein (CRP), DD (D-dimer), PLT (platelet count)], and absolute counts of lymphocyte and CD4+ T cell subset. The absolute numbers of lymphocytes and CD4+ T cells in peripheral blood were measured by Flow Cytometer.

**Results:** 1. There was statistically significant decrease in Th17 levels (P=0.012) in the AS with CVD group compared to the AS group, while the Treg cells number (P=0.426) and the ratio of Th17/Treg (P=0.202) have no statistically significant differences; 2. DD was significantly increased in AS patients with CVD. The use of NSAIDs between the two groups is significantly different(P=0.013), 86.7% of the AS group have received NSAIDs, while only 58.1% of the AS patients with CVD have received the NSAIDs.

**Conclusion:** The findings suggested that the cardiovascular events of AS patients correlated with imbalanced T cell subsets and the decreased Th17 cells may be a laboratory feature of AS patients with CVD. Patients with high DD level might have a higher risk of CVD. Monitoring of Th17 cells and DD could be beneficial in cardiovascular burden of patients with AS. However, current studies indicate that Th17 cells mediate the inflammatory response and play a crucial role in the development of CVD [2]. One explanation is that the AS patients with CVD in our study had a long disease duration and immunomodulatory therapy might have an impact on the status of T cell subsets. Meanwhile, the different disease activities of AS patients can be additional factors.

**AB0029 INHIBITION OF EFFECTOR B CELLS BY IBRUTINIB IN SYSTEMIC SCLEROSIS**

J. Einhaus1, A. C. Pecher1, E. Asteriti1, H. Schmid1, K. A. Secker1, S. Duen-Stoerzer1, H. Keppler1, R. Klein2, C. Schneidawind3, J. Henes1, D. Schneidawind1. 1University Hospital Tuebingen, Tuebingen, Germany

**Background:** Systemic sclerosis (SSc) is a connective tissue disease with significant morbidity and mortality. Effective treatment is still missing, and clinical control of the disease remains challenging. In particular, the development of pulmonary and cardiac fibrosis and pulmonary hypertension are severe complications responsible for excessive mortality. Currently available treatment strategies – besides aggressive autologous stem cell transplantation which is an option only for selected patients – only alleviate symptoms and slow disease progression. Previous attempts of immunomodulating therapies addressing B cell pathology like rituximab and tocilizumab in SSc showed mixed efficacy

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.5121
Objectives: Here, we investigated the therapeutic potential of ibrutinib, a Bruton’s tyrosine kinase (BTK) inhibitor used in B cell malignancies, to alter B cell pathology in SSC in an in vitro model of autoimmunity.

Methods: PBMCs were sorted to B cells of 24 patients with SSC were used for functional assay after stimulation with hypothesized DNA fragments (CpG) to induce an innate immune response. The effects of ibrutinib on cytokine production, autoantibody release and activation of the transcription factor NFκB were evaluated via multiplex cytokine assay, ELISA and flow cytometry.

Results: Ibrutinib was able to reduce the production of the proinflammatory hallmark cytokines IL-6 and TNFα, which are mainly released by the effector B cell population, in response to TLR9-stimulation. Importantly, small doses of ibrutinib (0.1 µM) preserved the production of immunoregulatory IL-10 and IFNγ while effectively inhibiting the cardinal cytokines of hyperactivated proinflammatory effector B cells in SSC. Intracellular cytokine staining of IL-6 in B cell subsets further endorsed the potential of ibrutinib to inhibit B cells in a subset-specific manner, reducing IL-6 naïve B cells significantly but not IL-6+ memory B cells. The subset specificity was abolished when high doses of ibrutinib (10 µM) were applied. In a flow cytometry analysis of phosphorylated NFκB, an important transcription factor in the induction of innate immune responses in B cells, significantly less activation was observed with ibrutinib treatment (0.1 µM). Higher doses of ibrutinib were unable to further reduce the abundance of NFκB.

Conclusion: Our data could pave the avenue for a clinical application of ibrutinib for patients with SSC as a novel treatment option for the underlying pathogenetic immune imbalance contributing to disease onset and progression.

AB0030 INCREASED CIRCULATING CD19+CD24HICD38HI REGULATORY B CELLS ARE BIOMARKERS OF RESPONSE TO METHOTREXATE IN EARLY RHEUMATOID ARTHRITIS

P. Forceta-Gordo², P. Viliailla², L. Nuño², M. J. Santos-Boronez², D. Pelaezfo², I. Monzo², A. Puig-Krøger³, P. Sanchez-Mateos³, E. Martin-Mola³, A. Balsa⁴, M. E. Miranda-Carús⁵, ¹University Hospital La Paz, Rheumatology, Madrid, Spain; ²Fundación Para La Investigación Biomedica Del Hospital Universitario La Paz, Madrid, Spain; ³Hospital Gregorio Marañón, Immuno-oncology, Madrid, Spain; ⁴-medical, Madrid, Spain

Background: The protagonist of regulatory B cells seems to vary along the course of the disease in murine models of inflammatory conditions. Decreased numbers of circulating regulatory CD19+CD24HICD38HI transitional B cells (cTrB) have been described in patients with longstanding RA.

Objectives: To examine the frequency and evolution of cTrB cells in the peripheral blood of early RA (ERA) patients.

Methods: Freshly isolated PBMCs from 48 steroid and DMARD-naïve ERA patients with a disease duration below 24 weeks and 48 healthy controls (HC) were examined by flow cytometry. Cocultures of isolated memory B cells were established with autologous T cells, in the absence or presence of TrB cells.

Results: As compared with HC, ERA patients demonstrated an increased frequency of cTrB cells. cTrBs of ERA and HC displayed an anti-inflammatory cytokine profile and were able to downregulate T cell IFNγ and IL-21 production, together with ACPA secretion in autologous B/T cell cocultures. Basal frequen-
cies of cTrBs above the median value observed in HC were associated with a good EULAR response to MTX at 12 months (RR=2.91; 95% CI, 1.37-6.47). A significant reduction of cTrBs was observed 12 months after initiating MTX, when the cTrB cell frequency was no longer elevated but decreased, and this was independent of the degree of clinical response or the intake of prednisone.

Conclusion: An increased frequency of regulatory cTrB cells is apparent in untreated ERA, and the baseline cTrB cell frequency is associated with the clin-
cal response to MTX at 12 months.

AB0031 T HELPER 17 CELLS WERE SIGNIFICANTLY DECREASED BY MITOCHONDRIAL ELECTRON TRANSPORT CHAIN COMPLEX INHIBITOR IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. R. Lee¹, S. J. Yoo¹, J. Kim², I. S. Yoo¹, C. K. Park³, S. W. Kang²
¹Chungnam National University; Daejeon, Korea, Rep. of (South Korea); ²Chungnam National University; Daejeon, Korea, Rep. of (South Korea)

Background: Reactive oxygen species (ROS) and T helper 17 (TH17) cells have been known to play an important role in the pathogenesis of rheumatoid arthritis (RA). However, the interrelationship between ROS and TH17 remains unclear in RA.

Objectives: To explore whether ROS affect TH17 cells in peripheral blood mononuclear cells (PBMC) of RA patients, we analyzed ROS expressions among T cell subsets following treatment with mitochondrial electron transport chain complex inhibitors.

Methods: Blood samples were collected from 40 RA patients and 10 healthy adult volunteers. RA activity was divided according to clinical parameter DAS28. PBMC cells were obtained from the whole blood using lymphocyte separation media. Following PBMC was stained with Live/Dead stain dye, cells were incubated with antibodies for CD3, CD4, CD8, and CD25. After fixation and permeabilization, samples were stained with antibodies for FoxP3 and IL-17A. Mitoxantrone was used for mitochondrial specific staining.

Results: The frequency of TH17 cells was increased by 4.83 folds in moderate disease activity group (S.1=DAS28≥3.2) of RA patients compared to healthy control. Moderate RA activity patients also showed higher ratio of TH17/Treg than healthy control (3.57 folds). All RA patients had elevated expression of mitochondrial specific ROS than healthy control. When PBMC cells were treated with 2.5µM of antimycin A (mitochondrial electron transport chain complex III inhibitor) for 16h, the frequency of TH17 cells was significantly decreased.

Conclusion: The mitochondrial electron transport chain complex III inhibitor markedly downregulated the frequency of TH17 cells in moderate dis-
ease activity patients with RA. These findings provide a novel approach to regulate TH17 function in RA through mitochondrial metabolism related ROS production.

AB0032 ABNORMAL STATUSES OF PERIPHERAL CD4+T CELL SUBSETS IN PATIENTS WITH GOUT AND THEIR CHANGES AFTER RECEIVING COMBINED IMMUNOMODULATORY TREATMENT

M. J. Chang⁶, S. X. Zhang⁶, L. Zhao⁶, J. Qiao⁶, J. Zhang⁶, M. T. Qiu⁶, R. Zhao⁶, Y. Li⁷, C. Wang⁶, J. Luo⁶, G.Y. Liu⁶, C. Gao⁶, X. Li⁷, ¹Shanxi Medical University, Taiyuan, China; ²The Second Hospital of Shanxi Medical University, Taiyuan, China; ³Brieham and Women’s Hospital, Harvard Medical School, Boston, United States of America

Background: Gout is a chronic systemic inflammatory disease that results from the deposition of monosodium urate crystals in joints and the associated activation of the innate immune system associated with hyperuricemia. As the pathogenesis of gout is still a matter of speculation and debate, accumulating evidence converges on inflammatory activation and immunological dysregula-
tion. However, the detailed statuses of lymphocyte subsets in patients with gout are unknown and influence of immunomodulatory combination therapies on the lymphocyte subsets remain to be clearly evaluate⁶.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.3441
Objectives: To evaluate the quantitative statuses of peripheral CD4+T subpopulations in patients with gout and further investigate the effects of immunomodulatory combination therapies on those cells.

Methods: Total 247 patients who met the clinical criteria of gout from the American College of Rheumatology and 206 healthy controls (HCs) were enrolled in this retrospective cross-sectional study. Among those, 70 follow-up patients donated their peripheral blood after receiving immunomodulatory drugs (e.g., low-dose interleukin-2, rapamycin, metformin, retinoic acid, etc.). The absolute numbers of T1h, T1h2, Th17 and Tregs in peripheral CD4+T subsets were detected by flow cytometry combined with standard absolute counting beads.

Results: Compared with HCs, the absolute numbers of Th1 and Th17 were evidently increased in gout patients (P<0.001), while the level of Tregs was significantly decreased (P<0.05) (Figure 1). After immunomodulatory combination treatments, there were dramatical increases in a wide variety of CD4+ T subsets such as Th1, Th17 and Tregs (P<0.05). Interestingly, the increased amount of Tregs was much more than that of other Teffs, leading to the decrease ratios of Teffs/Tregs such as Th2/Tregs, restoring immune homeostasis (Figure 2).

Conclusion: This cross-sectional study clarified the abnormal statuses of CD4+T subsets in gout patients, suggesting that CD4+T subsets, especially Tregs, might be relevant and play a crucial role in the pathogenesis of gout, thus providing a potential therapeutic target for gout patients. Immunomodulatory combination therapies effectively increase the number of Tregs and may help for gout patients' symptom remission.

DOI: 10.1136/annrheumdis-2020-eular.2110
Objectives: To study early ADAs formation according to clinical response to an adalimumab therapy in RA patients and the relationship between ADAs and circulating B cell subsets.

Methods: 28 RA patients and 13 healthy controls were included. Patients all presented inadequately controlled RA under conventional treatment, were naive of biotherapies, and started an adalimumab treatment at baseline (M0). Responder status was determined according to the DAS28CRP score (<3.2) at 3 (M3) and 6 months (M6). ADAs plasma concentration >10pg/mL at M3 defined the immunized patient group. Circulating B cell subsets were quantified by flow cytometry at M0 and M3.

Results: 11 (42.3%) patients were immunized at M3. Among them, 4 (36.4%) were responders at M6 and 7 (63.6%) were non-responders. Presence and concentration of ADAs at M3 was associated to non-respondent status at M6 (p=0.043; p=0.042). Immunized patients had lower transitional B cells count at M0 compared to non-immunized patients (p=0.031).

Conclusion: A high but classical proportion of RA patients developed ADAs after only 3 months of adalimumab treatment. This immunization was associated to non-respondent status at M6 and to a low blood transitional B cells count at baseline. Our results suggest transitional B cells implication in RA activity and biotherapy resistance due to immunization. Low concentrations of transitional B cells could be an early biomarker of immunization process against adalimumab.

TWO DIFFERENT ABNORMAL BEHAVIORS IN CD4+ T LYMPHOCYTES IN FIBROMYALGIA PATIENTS AND FIBROMYALGIA ASSOCIATED TO SJÖGREN’S SYNDROME

J. Monserratsanz1, A. Movasat2, M. D. Sosa Reina1, A. M. Gomez Lahoz1, C. Bohorquez1, A. Pérez Gómez2, L. Ruiz2, M. J. Cabezas Leon2, A. Sánchez Atio3, F. Abarbanti2, M. Álvarez de Mon1,2,3, Universidad de Alcalá. Facultad de Medicina, Medicina y Especialidades Médicas, Alcalá de Henares, Spain; 2Hospital Príncipe de Asturias, Reumatología, Alcalá de Henares, Spain; 3Hospital Príncipe de Asturias. Universidad de Alcalá, Medicina y Especialidades Médicas, Alcalá de Henares, Spain

Background: Primary fibromyalgia syndrome is a prevalent rheumatic condition characterized by widespread pain and whose etiopathogenesis is not well understood. Fibromyalgia can also be secondary to other rheumatic diseases like Sjögren’s syndrome; however, its relation to this disease is not known. It has been suggested that the immune system is involved in their pathogenesis. The role of activation stages and cytokines profiles of CD4+ T lymphocytes in fibromyalgia or fibromyalgia secondary to Sjogren’s syndrome are completely unclear and could play a key role in the pathophysiology of these diseases.

Objectives: The objective of this study is to investigate the counts and distribution of the CD4+T lymphocyte activation subsets and their pattern of cytokine production in women with primary fibromyalgia, fibromyalgia secondary to Sjogren’s, Sjogren’s syndrome and healthy controls (HC). The counts and distribution of naive (T0), central memory (TCM), effector memory (TEM) and effector (TE) CD4+T lymphocyte subsets were analyzed in these diseases. Furthermore, we investigated their pattern of IL-4, IL-10, IL-17A, INFγ, and TNFα production.

Methods: Counts and distribution of CD4+T subsets (T0, TEM, TCM, TE) and their cytokine producing capacity were measured using multiparametric flow cytometry in peripheral blood mononuclear cells (PBMC) from 20 primary fibromyalgia, 15 fibromyalgia associated to Sjögren and 15 primary Sjögren patients and 15 female controls. Fibromyalgia and/or Sjögren’s syndrome were diagnosed based on ACR criteria. CD4+T cell activation stages were analyzed by the expression of the CD3, CD4, CD45RA, CD27 and CCR7 antigens. Cytokine CD4+T producing cells subsets were assayed stimulating PBMC during 6 hours, fixed, permeabilized and simultaneously stained with IL-4, IL-10, IL-17A, IFNγ, and TNFα intracellular cytokines.

Results: Fibromyalgia patients showed a significant increase in the CD4+T, TEM and TCM cells counts with compared to fibromyalgia secondary to Sjogren, Sjogren’s syndrome and HC. The counts of IL-17A, IL-4 and IFNγ producing...
**AB0036** CHILDREN WITH EXTENDED OLIGOARTICULAR AND POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS HAVE DISTINCT CYTOKINE CYTOPLASMIC PATTERNS FOLLOWING B CELL ACTIVATION IN CIRCULATION

R. A. Moura, 1 F. Oliveira-Flammos, 1 C. Marques, 2 A. Brito, 1 R. L. Teixeira, 1,2 V. C. Romão, 1 R. Campanilho-Marques, 1 V. Teixeira, 1 M. J. Savaiedra, 1 C. Ponte, 2 N. Khmelinski, 2, E. J. Fonseca, 1 1Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal; 2Rheumatology Department, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisbon, Portugal

**Background:** Juvenile idiopathic arthritis (JIA) is the most common rheumatologic disease in children. The majority of polyarticular JIA (pJIA) and a large fraction of extended oligoarticular JIA (oJIA) patients fulfill classification criteria for rheumatoid arthritis (RA) in adulthood. B-cells play several important roles in RA pathogenesis, but it is still unclear if the pattern of B-cell involvement in pJIA and extended oJIA follows what has been described for adults with RA.

**Objectives:** The main goal of this study was to determine the concentration of cytokines potentially relevant for B-cell activation in serum from children with pJIA and extended oJIA when compared to children with persistent oJIA, adult JIA, early and established RA.

**Methods:** Serum samples were collected from children with extended oJIA (n=8), persistent oJIA (n=6), pJIA (n=6), adult JIA (n=8), untreated early RA (n<1 year of disease duration, n=12), established RA patients treated with synthetic disease-modifying anti-rheumatic drugs (DMARDs) (n=10) and two groups of age- and sex-matched healthy donors (children, n=6 and adults, n=10). A proliferation-inducing ligand (APRIL), B-cell activating factor (BAFF), interleukin (IL)-6 and IL-21 serum levels were measured by enzyme-linked immunosorbent assay (ELISA).

**Results:** Children with extended oJIA, early and established RA patients had significantly higher BAFF serum levels when compared to controls, but no significant differences were observed in children with persistent oJIA, pJIA and early adult JIA when compared to all groups included. APRIL serum levels were significantly increased in early and established RA patients when compared to both controls and children with persistent oJIA. No significant differences were found in APRIL concentrations between children with JIA, adult JIA and controls. IL-6 serum levels were significantly increased in children with extended oJIA, pJIA, early and established RA when compared to controls, but no significant differences were found in children with persistent oJIA and adult JIA patients. IL-21 serum levels were significantly increased in early RA when compared to controls, but no significant differences were observed between any of the other groups included.

**Conclusion:** The similarity in B-cell cytokine pattern found between extended oJIA, pJIA, early and established RA patients, contrary to what was observed in persistent oJIA, suggests an early B-cell involvement in the pathogenesis of extended oJIA and pJIA as described for RA.

**Disclosure of Interests:** None declared

**AB0037** EXPRESSION OF NEGATIVE CHECKPOINT MOLECULES BTLA AND HVEM IS DYSREGULATED IN AUTOIMMUNE DISEASES

S. Nagal, 1 S. Cole, 1 A. Floudas, 2 M. Wechalekar, 3 Q. Song, 1 T. Gordon, 5 R. Caricchio, 4 D. Veale, 3 U. Fearon, 3 N. Rao, 3 L. Y. Hao, 3 Janssen Research & Development, Spring House, United States of America; Trinity College Dublin, Dublin, Ireland; 3Flinders University, Adelaide, Australia; 4Temple University, Philadelphia, United States of America; 5University College Dublin, Dublin, Ireland

**Background:** Immune checkpoint blockade with agents targeting CTLA4 and PD-1/PD-L1 alone or in combination has demonstrated exceptional efficacy in multiple cancer types by "unleashing" the cytotoxic action of quiescent, tumor-infiltrating T cells. However, the therapeutic action of these immunotherapies goes hand in hand with the loss of immune tolerance and appearance of immune-related adverse events such as colitis, arthralgia and inflammatory arthritis in responsive patients. Therefore, immune checkpoint molecules have been proposed as targets for the treatment of autoimmune diseases.

**Objectives:** Herein, we interrogate the potential of BTLA/HVEM axis as a target for restoring immune homeostasis in rheumatoid arthritis (RA), Systemic Lupus Erythematosus (SLE) and Sjogren’s Syndrome (SJS) by examining their expression patterns in autoimmune disease tissues.

**Methods:** Message and protein expression of BTLA and HVEM were examined in RA and SLE synovial tissues, SLE cutaneous lesions, SJS salivary glands and peripheral blood samples of autoimmune disease by RNA sequencing and flow cytometry.

**Results:** Tissue dysregulation of the BTLA-HVEM axis was observed: Increased BTLA RNA level in RA synovium, SLE-affected skin, and SJS salivary gland samples, whereas HVEM level was affected only in the RA synovium when compared to unaffected tissues. Detailed immunophenotyping of B, T, and myeloid cell populations in RA, SLE, SJS and healthy control PBMCs revealed differential modulation of the BTLA+ or HVEM+ immune cell subsets in a disease-context-dependent manner. SJS patients showed an overall decrease in memory B cells and most of the BTLA+ B cell subsets while a decrease in HVEM+ B cells was observed only in SLE PBMC samples and not RA and SLE samples. Immunophenotyping with a T cell panel exhibited decreased BTLA and HVEM expression on T cell subsets in SJS and SLE but not in RA patients. In addition, protein levels of HVEM were differentially decreased in SLE myeloid cell subsets. Finally, we demonstrate tissue-specific surface expression patterns of BTLA in RA and SLE samples: higher surface BTLA levels on RA and SLE PBMC B cells than matched tissue-derived B cells.

**Conclusion:** Our results demonstrate a dysregulation of the BTLA/HVEM axis in either lesional tissue or peripheral blood in an autoimmune disease context-dependent manner. These results also indicate the potential of targeting BTLA/HVEM axis for the treatment of multiple autoimmune diseases.

CD4+T cells were increased in fibromyalgia patients with respect to HC. However, only IL17A and IFNγ, but not IL-4 producing CD4+T lymphocytes were increased with respect fibromyalgia secondary to Sjogren. These alterations were due to an increment of TEM IL-17A, TCM and TEM IFNγ producing CD4+T cells and subsets in fibromyalgia patients. Furthermore, IFNγ producing CD4+T cells were decreased in fibromyalgia secondary to Sjogren’s with respect to fibromyalgia patients and HC. Counts of T<sub>N</sub> TNP-producing CD4+ T cells were increased in fibromyalgia with respect fibromyalgia secondary to Sjogren. IL-10 producing CD4+T cells were normal in fibromyalgia but decreased in fibromyalgia secondary to Sjogren.

**Conclusion:** Fibromyalgia patients show an abnormal circulating activation stages of CD4+T cells, as well as, express unusual elevated counts of CD4+T cells producing IL-17A, IL-4 and IFNγ. These alterations could differentiate two different pathologic and inflammatory behaviors of the T cell compartment between fibromyalgia and fibromyalgia secondary to Sjogren patients.

Background: The understanding of Erdheim-Chester Disease (ECD) pathogenesis has been greatly improved over recent years with the discovery of activating MAPK pathway mutations in most ECD patients. However, the inflammatory phenotype of ECD remains widely unknown.

Methods: We analyzed peripheral blood mononuclear cells from 13 ECD patients and 11 healthy donors (HD) using mass cytometry with 29 metal-conjugated antibodies.

Results: Compared to HD, untreated ECD patients had increased proportion of classical monocytes (90.8 [87.9-96.5] vs 81.6 [76.2-87.5] %, p=0.02) and decreased proportion of non-classical monocytes (4.7 [3.4-9.7] vs 11.8 [6.6-17.2] %, p=0.047). Untreated ECD patients had more circulating Th17 cells compared to HD (3.3 [3-5.3] vs 1.3 [0.4-2.3] %, p=0.015) and ECD patients treated with BRAF or MEK inhibitors (3.3 [3-5.3] vs 1.9 [0.6-2.4] %, p<0.005). Moreover, Treg cells were lower in ECD patients than HD, with an increased Th17/Treg ratio (1.37 [0.74-1.9] vs 0.34 [0.19-0.43], p<0.0004). There was no difference regarding Th1 cells, Th2 cells, B cells, NK cells and circulating dendritic cells.

Conclusion: ECD monocyte profile seems similar to what has been described in CMML. Inflammation observed in ECD may be driven through Th17 cells, and Treg cells may be particularly increased in ECD patients.

ROLE OF MESENCHYMAL STEM CELLS ISOLATED FROM DENTAL PULP (DPCS) IN IMMUNOREGULATION PROCESSES MEDIATED BY PROGRAMMED DEATH-LIGAND 1 (PD-1/L)

F. Pignatti1, A. Pisciotta1, G. Bertani1, R. Di Tincio1, L. Berton1, S. Croci2, M. Bonacini2, P. Azzoni1, A. De Pol1, C. Salvarani1, G. Carnevali1, University of Modena and Reggio Emilia, Department of Surgery, Medicine Dentistry and Morphological Sciences with Interest in Transplant, Modena, Italy; 2Azienda Unità Sanitaria Locale di Reggio Emilia-IRCCS, Clinical Immunology, Allergy and Advanced Biotechnology Unit, Reggio Emilia, Italy; 3Azienda Ospedaliero-Universitaria Policlinico di Modena, Rheumatology Unit, Modena, Italy

Background: Stem cells isolated from dental pulp (DPCSs) are characterized by a high rate of proliferation, low immunogenicity and a high ability to differentiate in different lineages (i.e. osteogenic, chondrogenic, adipogenic, myogenic and neural commitment). Their multipotency can be attributed to the peculiar embryological origin from the neural crest. DPCSs represent a promising stem cell resource since they hold a low ethical impact and can be easily isolated through routine dental procedures. These cells own immuno-modulatory properties, exerted through the activation of different mechanisms, including the Fas / FasL pathway, as well as through the release of soluble factors. Currently, other molecular mechanisms are under consideration such as PD-1 / PD-L1 (Programmed Death 1 and its Ligand) which are supposed to be involved in the induction and / or maintenance of immune tolerance.

Objectives: The aim of this research was to investigate whether the stimulation of PD-L1 in DPCSs can affect the immunomodulatory effects of these stem cells in peripheral blood mononuclear cells (PBMCs). Furthermore, the expression of PD-L1 was also assayed after the induction of osteogenic differentiation of DPCSs in order to evaluate a possible application of DPCSs in autoimmune inflammatory osteo-errosive diseases.

Methods: Immuno-selection was performed on DPCSs, isolated from waste material, against the stemness markers c-KIT and STR0-1, to obtain a pure stem cell population. Then, STR0-1+c-KIT+ DPCSs, were co-cultured either directly and indirectly with peripheral blood mononuclear cells (PBMCs) from healthy adult donors, previously activated by anti-CD3 and anti-CD28 antibodies. Co-cultures of PBMCs with amniotic fluid stem cells (AFSCs) and bone marrow mesenchymal stem cells (BM-MSCs) were also set up. The expression of PD-1 in PBMCs as well as of PD-L1 in DPCSs, AFSCs, BM-MSCs and PBMCs, was evaluated by Western Blot (WB) and immunofluorescence (IF) analyses, before and after osteogenic differentiation. Osteogenic differentiation of DPCSs, after 30 days of induction, was verified by IF and WB, of osteopontin, osteocalcin and RUNX2 markers. Interleukin-2 (IL-2) expression levels in PBMCs were analyzed by Real-Time PCR analysis.

Results: Our data highlight that, after direct and indirect co-culture with activated PBMCs, PD-L1 expression was up-regulated not only in DPCSs, but also in BM-MSCs and AFSCs (Figure 1), thus suggesting that 1) this is a common ability of mesenchymal stem cells and 2) this event can be also mediated by soluble factors release. Moreover, when evaluating the effects of DPCSs co-culture on PBMCs an increased expression of cleaved caspase 3 was observed, together with a decreased expression of IL-2 - a growth factor essential for the proliferation and survival of T cells (Figure 2). These findings showed how DPCSs can modulate the immune system by PD-L1 up-regulation. On the other hand, it is noteworthy that, after reaching osteogenic commitment, DPCSs down-regulated the expression of PD-L1, allowing to hypothesize that PD-L1 expression is strictly related to the maintenance of stemness.

Conclusion: Taken together, our findings suggest that the expression of PD-L1 in DPCSs is involved in the modulation of immune response and pave the way for further investigations on the role of PD-1/PD-L1 pathway in controlling inflammation and immune response when applied to the treatment of autoimmune inflammatory diseases.

IMPAIRED REGULATORY T CELL FUNCTIONS IN PATIENTS WITH PSORIASIS ARTHRITIS ELIGIBLE TO SWITCH TO ANTI-IL-17 TREATMENT

T. Christoforou1, G. Almanzar1, F. Brauneiser1, N. Buschmann1, M. Feuchtenberger2, M. Schmalzing2, H. P. Tony3, M. Goebeler4, M. Prelog1,
1University of Wuerzburg, University Children's Hospital, Pediatric Rheumatology/Special Immunology, Wuerzburg, Germany; 2Department of Medicine II, Division of Rheumatology and Clinical Immunology, Altotting-Burghausen, Germany; 3University Hospital Wuerzburg, Department of Medicine II, Rheumatology and Clinical Immunology, Wuerzburg, Germany; 4University Hospital Wuerzburg, Department of Dermatology, Wuerzburg, Germany

Background: A dysbalance between Th17 and regulatory T cells (Treg) has been suggested for several T cell-mediated autoimmune disorders. Inhibitors of IL-17 are successfully used for treatment of psoriasis arthritis (PsA). However, so far reconstitution of Treg functions has not been studied in detail in PsA eligible for switching to anti-IL-17 treatment.

Objectives: The project aims to analyze the reconstitution and maintenance of regulatory T cell (Treg) function after inhibition of inflammatory Th17-induc ing pathways mediated by IL-1, IL-6, IL-17 and TNFalpha in a longitudinal manner.

Methods: Therefore, Treg derived from 12 PsA patients switching to Th17 inhibition and healthy controls were phenotypically characterized by flow cytometry.
Function was investigated by analysis of suppressive activity of Treg on proliferation of autologous effector T cells in vitro utilizing suppression assays.

**Results:** First results at the time-point of switching to anti-IL-17 treatment demonstrated PsA to be an IL-17-driven T cell-mediated autoimmune disorder, as proportions of T cells with Th17 phenotype were increased in PsA compared to controls (CCR6+IL-17+ 4.9% vs. 0.8% of CD4+) and FoxP3+ Treg cells (CD25brightFoxP3+ 0.2% vs. 0.4% of CD4+) were decreased. Higher proportions of FoxP3+ T cells expressing the Th17-characteristic chemokine receptor CCR6 were found in PsA (4.8% vs. 2.7% of CD4+), as well as higher proportions of pro-apoptotic CD95-expressing FoxP3+ T cells (9.8% vs. 2.8% of CD4+). Less suppression of autologous effector T cells co-cultured with CD25+ Treg cells was found in PsA compared to controls (22.2% vs. 28.3% reduction of proliferative activity), whereas CD25- helper T cells did not contribute to the suppression of effectors in PsA and only minimally in controls. Intracellular IL-10 production in Tregs, a key cytokine of Treg-associated regulation of inflammation, was similar between PsA and controls, although a trend to lower CTLA-4 expression involved in inhibition of co-stimulation was found in PsA.

**Conclusion:** The current results indicate a skewed T cell balance towards Th17 cells and Treg cells showing Th17-like features in samples of PsA unsuccessfully pre-treated with different biologics recommending them for a switch to a therapy with selective inhibition of IL-17. Longitudinal results regarding the reconstitution and maintenance of Treg function in those PsA patients have to be awaited.

**CD8+ T CELLS HAVE AN ELEVATED PROLIFERATIVE CAPACITY IN GIANT CELL ARTERITIS**

**R. Reitsema1, R. Hid Cadena2, W. Abdulahad2, A. Boots2, P. Heeringa2, E. Brouwer3,**

1University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands, 2University of Groningen, University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands

**Background:** Giant cell arteritis (GCA) is the most frequent form of systemic vasculitis affecting the large- and medium-sized vessels. The involvement of innate immune cells and CD4+ T cells in the pathogenesis of GCA has been extensively studied. Interestingly, recent findings suggest a role for CD8+ T cells in disease development (1). However, CD8+ subsets and their functional capacities have not yet been studied in detail.

**Objectives:** This study aims to characterize the phenotype and proliferative capacity of CD8+ T cells in newly diagnosed GCA patients and GCA patients in remission compared to healthy age- and sex-matched controls.

**Methods:** To determine the phenotype of CD8+ T cells in GCA, newly diagnosed, untreated GCA patients (baseline, n=14), GCA patients in stable remission compared to healthy age- and sex-matched controls (HCs, n=18) were enrolled. Peripheral blood mononuclear cells (PBMCs) were stained with fluorochrome-conjugated antibodies directed against CD3, CD4, CD8, CCR7, CD45RO, Ki-67, CD69 and CD25 and analyzed by flow cytometry. The following differentiation subsets were defined: CD8+ T naive (CD45ROCCR7+, central memory (Tcm)CD45ROCCR7+, effector memory (Tem)CD45ROCCR7+, and effector memory re-expressing CD45RA (TemRA-CD45ROCCR7+) cells. Secondly, the proliferative capacity of CD8+ T cells was determined in isolated CD3+ T cells of 10 GCA baseline, 10 GCA GC-FR patients and 19 HCs after 5 days of stimulation with plate-bound anti-CD3 or anti-CD3 plus soluble anti-CD28 using a dye-based proliferation assay.

**Results:** A reduced frequency of CD8+ TemRA cells was found in GCA baseline patients compared to HCs (p=0.025). Furthermore, a higher frequency of Ki-67+ cells was detected among CD8+ TemRA cells in GCA baseline patients than in HCs (p=0.007), suggesting a higher proliferative activity in vivo. In addition, in vitro stimulation with anti-CD3 and anti-CD3+anti-CD28 led to higher percentages of divided CD8+ T cells in GCA baseline and GC-FR patients than in HCs (p<0.05). Moreover, the frequencies of CD8+ TemARA cells and the percentage of divided CD8+ T cells upon CD3 stimulation strongly correlated in GCA baseline patients (R=0.79, p=0.009) and GCA GC-FR patients (R=0.67, p=0.039) but not in HCs (R=0.31, p=0.25).

**Conclusion:** GCA baseline patients demonstrate a higher frequency of proliferating circulating CD8+ TemRA cells, defined by Ki-67 expression, than HCs. In addition, functional data on induced proliferative capacity suggest that CD8+ T cells from GCA baseline patients are more rapidly activated by crosslinking CD3 and CD3+CD28, suggesting either reduced regulation in these patients or more intrinsic threshold changes. Furthermore, the induced proliferative capacity is also elevated in patients in stable glucocorticoid-free remission. Whether the increased proliferative capacity of total CD8+ T cells in GCA patients is causally linked to the increased frequencies of CD8+ TemRA cells in these patients requires further investigation.

THE IMBALANCE OF T FOLLICULAR REGULATORY CELL AND T FOLLICULAR HELPER CELL IN RHEUMATOID ARTHRITIS

R. Su1, Y.Y. Wang1, F.Y. Hu1, X. Zheng1, Y. Liu1, X. Li1, C. Wang1, 1Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease which can lead to severe joint damage and disability. The relationship between antibodies and rheumatoid arthritis has long been well established. Recently, many studies have found that T follicular regulatory cells (Tfr) and T follicular helper cells (Tfh) are closely related to antibody generation on lymphoid follicular germinal centers (GCS)[1-2]. Tfr cells can inhibit the GC reaction and suppress production of high-affinity antibodies. The dysregulation of Tfh cells can lead to the production of autoantibodies by B cells.

Objectives: To examine the expression of circulating T follicular regulatory cell (Tfr) and T follicular helper cell and its subsets (Tfh1 Tfh2 Tfh17) in RA patients and healthy control group.

Methods: Level of Tfr and Tfh1, Tfh2 and Tfh17 cells in the peripheral blood of 17 new RA patients, 30 treated RA patients and 18 healthy controls were detected by flow cytometry. All patients were hospitalised at the Department of Rheumatology, Second Hospital of Shanxi Medical University.

Results: We found that the level of Tfr (CD3+CD4+CD25+CXCR5+FOP3+) percent (P=0.020), in the peripheral blood in RA patients were significantly decreased compared with healthy controls. The percent of Tfh (CD3+CD4+CXCR5+CD45RA-) (P=0.039) and Tfh17 (CD3+CD4+CXCR5+CD45RA-CCR6+) (P=0.000) were increased, but there are no statistical difference about Tfh1 (CD3+CD4+CXCR5+CD45RA-CCR6+) percent (P=0.558) and Tfh2 (CD3+CD4+CXCR5+CD45RA-CCR3-CCR6+) percent (P=0.079). We compared the above indicators between new and treated RA patients, and the results indicated that the Tfr (P=0.013), Tfh (P=0.002) and Tfh1 (P=0.034) were significantly increased in the new RA patients compared to the treated RA patients, there were no differences between the two groups in Tfh2 (P=0.419) and Tfh17 percent (P=0.124).

Conclusion: Our results indicated that disorder of Tfr and Tfh subsets were involved in RA, restoring the Tfr/Tfh balance may be the potential therapeutic targets.

Fig. 1. Comparison of Tfr, Tfh and its subsets (Tfh1 Tfh2 Tfh17) percent among the RA patients (n=47) and healthy control group (n=18) (*P<0.05).

Fig. 2. Comparison of Tfr, Tfh and its subsets (Tfh1 Tfh2 Tfh17) percent among the new RA patients (n=17) and treated RA patients (n=30) (*P<0.05).
Background: Several studies have demonstrated that an immune dysregulation affecting both B and T cells occurs in rheumatoid arthritis (RA). Follicular helper T (Tfh) cells are crucial for B cell maturation, activation and class-switching as well as for germinal center (GC) formation, whereas follicular regulatory T (Tfr) cells can modulate the GC reaction by suppressing Tfh and B cells. 

Objectives: The main goal of this study was to analyze the phenotype and frequency of circulating follicular T cell subsets in established RA patients.

Methods: Blood samples were collected from established RA patients with active disease, treated with methotrexate (n=32) and from a group of age and sex-matched healthy donors (n=11). Peripheral blood mononuclear cells (PBMC) were isolated and Tfh (CD4+CXCR5+CD45RO+) and Tfr (CD4+ CXCR5+CD25+FoxP3+) cells, as well as their three major subsets [CXCR3+CXCRL6 (Th1-like), CXCR3-CXCL6 (Th2-like) and CXCR3-CXCL6 (Th17-like)] were evaluated by flow cytometry.

Results: The frequency of circulating Tfh cells was similar between established RA patients and controls. Nonetheless, RA patients had a decreased frequency of Th1-like Tfh cells and an increased frequency of Th2-like Tfh cells when compared to controls. No significant differences were observed in the frequencies of Th17-like Tfh cells between both groups. The frequency of circulating Tfr cells was significantly increased in RA patients in comparison to controls. Furthermore, Tfr cells from RA patients had significantly increased CD69 median fluorescence intensity (MFI) values when compared to controls. No significant differences were found in the percentages and MFI values of FO1, ICOS, CD28, CTLA-4, CD40-L and HLA-DR expressed by Tfh and Tfr cells in RA patients when compared to controls.

Conclusion: Established RA patients have increased circulating frequencies of Tfr cells, with higher CD69 expression levels, when compared to healthy controls. These results suggest a pre-activation state of Tfr cells in RA and a potential role in the disease physiopathology.

DOI: 10.1136/annrheumdis-2020-eular.0162
Background: Ankylosing spondylitis (AS) is a chronic inflammatory autoimmune disease. Regulatory T cells have been found in peripheral blood of AS patients. However, there is a controversy regarding the relative number and function of regulatory T cells in AS. T-cell immunoglobulin and mucin domain–containing protein 3 (Tim-3) is a negative immune regulator that participates in immune responses. To obtain absolute counts, proportions determined by flow cytometry addition, monocyte subset counts were determined, based on CD14 and CD16 expression. To obtain absolute counts, proportions determined by flow cytometry were corrected by the total CD4+ T-cell and monocyte counts. Th1, Th17 and monocyte subsets were determined in 21 GCA patients, 19 PMR patients and 19 healthy controls (HC). Th2 cells were determined in 10 GCA patients, 10 PMR patients and 10 HC. All GCA and PMR patients were newly-diagnosed and treatment-naive. HC were age- and sex-matched and without any immunomodulatory medication.

Results: Both absolute counts and percentages of peripheral Th1 T cells, Th17 cells and Th2 cells did not differ between GCA/PMR patients and HC. The monocytosis in GCA and PMR was mainly attributed to an expansion of the classical monocyte subset. Counts of monocyte subsets were not strongly correlated with counts of either Th1 or Th17 cell counts. In GCA patients, the ESR correlated positively with counts of intermediate monocytes (R= 0.63), but this was not observed in PMR patients.

Conclusion: Compared to most previous work, we report similar circulating Th1 and Th17 cell counts in HC, but lower counts in treatment-naive GCA patients then previously reported (Table 1). Furthermore, numbers of Th1 and Th17 cells in peripheral blood showed no relationship with monocyte subsets. As our protocol for defining Th1 and Th17 cells appears to be similar to the other studies, we propose differences in patient selection. Alternatively, Th1 and Th17 skewing should be studied at the site of inflammation, since Th1 and Th17 skewing cytokines are all highly expressed by macrophages at the inflammatory site. This study shows the importance of replicating previous research. As key concepts of disease pathology are derived from data on disturbed Th cell distribution.

Table 1. Observed median percentages of circulating Th1 and Th17 cells in GCA patients and age-matched HC. Shown are outcomes from several previous studies as well as the present study. Deng et al, Terrier et al and Saadoun et al found elevated Th1 cell percentages in GCA, whereas Samson et al found them lower. All four previous studies showed elevated Th17 percentages in GCA.

Background: Autoimmune uveitis is a group of inflammatory diseases that affect the uveal tract such as iris, cilia and choroid. In addition to diabetic retinopathy and age-related macular degeneration, uveitis is one of the main causes of blindness in developed countries[11]. The disease is autoimmune-mediated, and abnormal immune responses are induced by pathogenic antigens such as retinal soluble antigens and retinal interphotoreceptor retinoid-binding protein (IRBP) and autoimmune inflammation is caused by specific cytotoxic effects, immune complex responses and delayed hypersensitivity reactions. It has been found that the disorder of lymphocyte subsets, mainly due to the number and function defects of regulatory T cells (Tregs), may be involved in the development of uveitis. IL-2 is a key cytokine in T cell differentiation. As a new type of immunomodulator, IL-2 has achieved preliminary efficacy in the treatment of systemic lupus erythematosus, ankylosing spondylitis, Sjögren’s syndrome and other diseases[24-26], but there is no clinical evidence of IL-2 in the treatment of autoimmune uveitis. The purpose of this study was to investigate the expression of T lymphocytes in patients with autoimmune uveitis and the effect of low dose IL-2 on their immune status.

Objectives: To investigate the expression of peripheral blood lymphocyte in patients with autoimmune uveitis and evaluate the short-term efficacy and safety of low-dose IL-2 combined with methylprednisolone.

Methods: A total of 108 patients with autoimmune uveitis and 93 healthy subjects who visited our hospital from January 2016 to April 2019 were collected. Twenty-three patients were treated with a low dose of IL-2 (50IU/day for 5 consecutive days) on the basis of conventional treatment.
(methylprednisolone and/or DMARDs), and the changes in the patients’ condition and lymphocyte subsets were observed. The t-test of two independent samples was used when the measurement data conformed to the normal distribution and the variance was homogeneous, and Mann-Whitney rank sum test was used when the measurement data did not conform to the normal distribution.

Results: Among 108 patients, 58 were males and 50 were females, with an average age of 41 ± 14 years. Compared with the normal control group, total T cells, total B cells, Th cells, Tc cells, Th1 cells, Th17 cells, Th1 and Th2, Th17/Treg in patients with autoimmune uveitis were higher than those in the healthy control group (P < 0.05), and Th1 cells and Treg cells were lower than those in healthy control group (P < 0.05). After IL-2 treatment, the number of Treg cells increased from 2.91±0.51 /ul to 5.15±0.87 /ul (P < 0.05), while Th17/Treg ratio decreased from 0.44±0.23 to 0.33±0.23 (P < 0.05), and both serum sedimentation rate and CRP decreased compared with before treatment (P < 0.05).

Conclusion: Treg cells are involved in the pathogenesis of autoimmune uveitis. Low dose of IL-2 selectively elevates Treg cells, regulates Th17/Treg balance and improves the condition of the disease.

AB0049 IMMUNE DYSFUNCTION IN ANKYLOSING SPONDYLITIS (AS) AND THE POTENTIAL OF TUMOR NECROSIS FACTOR-Α (TNF-α) INHIBITOR ANBAINUO AS AN EFFECTIVE TREATMENT

M. Yang1, Q. Lv1, Q. Wei1, J. Gu1, 1Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Studies into ankylosing spondylitis (AS) and its relationship with immune function are controversial, and the correlation between the efficacy of TNF-α inhibitor and changes in immune function is unclear.

Objectives: We conducted a prospective study of T-cell and B-cell subset distribution and analyzed lymphocyte function in AS patients to further clarify changes to the immune system caused by AS and to explore resistance that could contribute to relapse after treatment.

Methods: A total of 40 immune cells were tested with flow cytometry, and the results of 105 HC (healthy control) subjects, 177 active-stage AS patients, and 23 AS cases before and after 12 weeks of Anbainuoo therapy were analyzed.

Results: Compared with the HC group, the proportion of immune cells, such as naïve and central memory CD4+ T cells, in AS increased (p<0.0001), but effector memory and terminally differentiated CD4+ T cells were decreased (p<0.01 and 0.0001, respectively). Naïve, central memory, and effector memory CD8+ T cells were increased (p<0.0001, 0.0001, and 0.01, respectively), but terminally differentiated CD8+ T cells were decreased (p<0.0001). Th1 cells (helper T cells-1), Th1 cells (follicular helper T cells-1), Tc1 cells (cytotoxic T cells-1), and Tregs (regulatory T cells) were lower (p<0.01, 0.05, 0.0001, and 0.001, respectively), but Th17 cells, Th17 cells, and Tc cells were higher (p<0.001, 0.0001 and 0.001, respectively). The proportions of total B cells and class-switched B cells were increased (p<0.05), but non-switched B cells, plasma cells, memory B cells, and immature Bregs (regulatory B cells) were lower (p<0.01, 0.0001, 0.0001, and 0.0001, respectively). After Anbainuoo therapy, the percentage of Tregs and B10 cells (IL-10-producing regulatory B cells) had increased (p<0.05 and 0.05, respectively), and the increase in Tregs was positively correlated with the decrease in CRP (C-reactive protein) (r= 0.489, p=0.018).

Conclusion: We found that, in terms of both innate and acquired immunity, active-stage AS patients have an immunity imbalance involving multiple types of immune cells, including CD4+ T cells, CD8+ T cells, Th cells, Tc cells, Tc cells, Tregs, Bregs, and B cells. Anbainuoo can not only help to inhibit disease activity and partial immune function imbalance in AS but can also increase the number of negative regulatory cells in inflammation.

AB0050 EXTENDED POLYDIMENSIONAL IMMUNOME CHARACTERISATION (EPIC) PLATFORM AS A TOOL FOR TRANSLATIONAL RESEARCH

J. G. Ye1,2, M. Wassen1, P. Kumar1, L. Pan1, S. L. Poh1, F. Ally1, T. Arkakhsai1,2, A. J. M. Lim1, J. Y. Leong1, K. T. Yeo1,2, L. Lai1, E. S. C. Lee1, C. Chua1, B. Paleja1, S. P. Tang1, S. K. Ng1, A. Y. J. Tan1, S. Y. Lee2, F. Ginhoux1,2, T. P. Ng1, A. Larbi1, S. Alban1,2, 1Translational Immunology Institute, SingHealth Duke-NUS Academic Medical Centre, Singapore; 2KK Women's and Children's Hospital, Singapore, Singapore; 1Selangor Hospital, Paediatric Rheumatology Unit, Department of Pediatrics, Kuala Lumpur, Malaysia; 2Selangor Hospital, Paediatric Rheumatology Unit, Department of Pediatrics, Kuala Lumpur, Malaysia; 3Agency for Science, Technology and Research, Singapore Immunology Network (StgN), Singapore, Singapore; 4National University of Singapore, Singapore, Singapore

Background: We created a high dimensionality healthy human Immune Atlas by interrogating the peripheral blood mononuclear cells (PBMC) of >200 healthy subjects (cord blood to adult) with 63 unique mechanistic and phenotypic markers per cell by mass cytometry (CyTOF). This database is built with an open source, web-based bioinformatics toolkit, enabling its mining and uploading of datasets for comparison with the EPIC healthy database.

Objectives: Here, we demonstrate the platform’s ability to identify the immunological differences of mechanistically important cell subsets in the uploaded data in comparison with EPIC.

Methods: CyTOF data from 37 healthy elderly (>60 years old) was uploaded onto the EPIC Discovery tool where down-sampling, normalising and FlowSOM (Flow analysis with Self-Organising Maps) clustering were done with the EPIC database for comparison. Online visualisation outputs include cluster frequency boxplots, correspondence analysis (CA) plot and markers expression heat-map. The CA 2-dimensional plot depicts the global differences in immune cell composition between subjects with proximity between points (subjects) denoting similarity. Kruskal-Wallis test was done to identify age groups differences.

Results: Increasing distances on the CA plot with age were observed with the elderly being farthest from the newborns. Notably, we observed significant changes in naïve CD4+ IL8+ T cells (p<1×10^-20), memory CD4+ IL17A+ T cells (p<1×10^-20) and type 2 innate lymphoid cells (ILC2) (Lin- CD7- CD25+ CD127- CD161+, p<1×10^-14) with increasing age. The naïve CD4+ IL8+ T cells (median: 0.68%, interquartile range: 0.415 to 1.055% of CD45+ CD3+ cells) had increased 0.036% (p<1×10^-5) in comparison with EPIC.

Conclusion: With EPIC, we have created an online tool enabling data uploading for comparison to a healthy database, allowing the holistic characterisation of immunological changes in different clinical scenarios. Using it, we were able to identify mechanistically important differences in immune cell composition in a distinct clinical cohort (elderly) compared to the younger ages. Translationally, the EPIC platform can be utilised similarly to catalyse the discovery process in autoimmune diseases interrogated with the EPIC antibody panels.

Serum amyloid A and pentraxin 3: innate immune response and disease activity in systemic lupus erythematosus

R. Assandri, G. Martelloso, A. Montanelli, ASST-Brescia, Clinical Investigation Laboratory, Brescia, Italy; ASST-Brescia, Clinical Investigation Laboratory, Brescia, Italy; ASST-Bergamo EST, Clinical Investigation Laboratory, Seriate, Italy.

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease that involves several molecular patterns with a wide spectrum of clinical manifestations and symptoms. Inflammation and related pathway play a role in SLE pathogenesis. The pentraxin superfamily including long and short pentraxins, CRP (C Reactive Protein), CRP serum amyloid A (SAA), Pentraxin 3 (PTX3) are key components of innate immune system and induce a variety of inflammation associated pathway. However literature provides several evidences that CRP serum levels not correlated with clinical and immunological manifestations. This situation affected clinical practice and the patient follow up. PTX3 have been identified as a component of inflammatory status in several autoimmune conditions. SAA is an acute phase protein secreted in large quantity during inflammation.

Objectives: To evaluate PTX3, SAA and CRP concentrations, their correlation between SLE Disease Activity Index (SLEDAI), that including complement fractions C3, C4.

Methods: We enrolled fifty patients that fulfilled the SLE American College of Rheumatology criteria and fifty healthy subjects. The SLE disease activity was classified with the SLEDAI (0 to 12). Patients were divided into two groups according to SLEDAI score: inactive group (Group 1, 25 patients, 50%; SLEDAI ≤4) and active group (Group 2, 25 patients, 50%; SLEDAI 5 to 12). PTX3 concentration was measured by a sandwich ELISA kit (Hycult) with 2.8ng/mL cut-off point. SAA concentration was detected by nephelometry performed on a BN ProSpec System (Siemens, Germany), with assay kit based on polyclonal antibodies (Siemens Healthcare Diagnostics Products, Germany, 6.5mg/L cut-off point). High sensitive CRP concentrations were determined using the c8000 platform (Abbott Laboratories Chicago, Illinois).

Results: Plasma PTX3 and serum SAA levels was significantly higher in SLE patients than in the healthy subjects (PTX311.5 ± 7.3ng/mL vs 2.3 ± 1.1; p < 0.001; SAA: 87 ± 77mg/L vs 2.6±2.5; p < 0.001). These differences were not evident in CRP levels (8.5 ± 7.8mg/L vs 6.2 ± 2.5). Considering two groups, there were statistical differences in PTX3 level (Group 2: 14.9 ± 12mg/L vs Group 1: 2.16 ± 0.5mg/L, p < 0.05) and SAA concentration (Group 2: 114 ± 89ng/mL vs Group 1: 3.6 ± 17mg/L, p < 0.05) but not in CRP concentration (Group 2: 11.5 ± 8.4mg/L vs Group 1: 9.5 ± 3.5). There was a significantly negative correlation between C3, C4 fractions, PTX3 and SAA levels (respectively r = -0.74, p < 0.05, and r = -0.79, p < 0.05). No statistical correlation were appeared between C3, C4 fractions and CRP serum levels (r = -0.12, p = 0.82, and r = -0.18, p = 0.21). We noted a positive significant correlation between SLEDAI, PTX3 and SAA concentration (r = 0.79, p < 0.05, 0.83, p = 0.05, respectively) an increase in PTX3 and SAA levels followed the lupus flare and symptoms. No significant correlation appeared between SLEDAI and CRP (r = 0.15, p = 0.89).

Conclusion: PTX3 and SAA concentration was significantly higher in SLE patients than the healthy control subjects and their levels reflected disease activity. We showed a direct correlation between PTX3 and SAA. In SLE patients PTX3 and SAA concentrations were correlated with SLEDAI. We suggest an integrate viewpoint in which PTX3 and SAA could play a role as a biomarker of disease activity, with synergic work during SLE events. Evidences suggested that PTX3 and SAA could trigger the same molecular pathway, by TLR4, via NF-κB.

AB0053 BERGENIN, ACTING AS AN AGONIST OF SIRT1, REDUCE SERUM URATE IN MICE THROUGH THE UPREGULATION OF ABCG2

M. Chen, X. Li, H. Wu, Department of Rheumatology, Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Background: About 20% of individuals in the USA have asymptomatic hyperuricemia[1]. However, Urate-lowering therapy in asymptomatic hyperuricemia condition is still controversial considering the benefit and side effects[2]. Therefore, safe and effective anti-hyperuricemia therapies are necessary.

Objectives: Bergenin, the major bioactive ingredient isolated from Saxifraga stolonifera, could activate SIRT1[3]. In this study, we identify the effect of bergenin on hyperuricemia, and explored the related mechanisms.

Methods: Significant hyperuricemia was established in C57BL/6N mice treated with oxonate and yeast polysaccharide. Bergenin was administered to the mice at the same time. The serum uric acid and creatinine levels, clearance of uric acid and creatinine, the intestinal uric acid excretion, and renal pathological lesions were determined were used to evaluate the anti-hyperuricemic effects. The location and expression levels of ABCG2 in the kidney and intestine were analyzed. HK-2 and Caco-2 cell lines were exposed to soluble uric acid with or without the treatment of Bergenin. Then the expression of ABCG2 and underlying mechanisms were explored.

Results: The administration of bergenin decreased serum uric acid in hyperuricemic mice by the promotion of uric acid excretion both in kidney and intestine. Bergenin reuced the downregulation of ABCG2 in the kidney of hyperuricemic mice and upregulated the expression of ABCG2 in the jejunum and ileum. In
Conclusion: These findings suggest bergenin increases uric acid excretion both in the kidney and intestines, which may be related to the upregulation of ABCG2 via SIRT1-PPARγ pathway.

AB0054 SYNOCIAL CD163+ MACROPHAGES ARE ASSOCIATED WITH RADIOGRAPHIC JOINT DESTRUCTION IN RHEUMATOID ARTHRITIS

X. Zhang1, J. D. Ma, J. Jing1, J. Wang3, T. Wu1, D. Zheng1, L. Dai2. 1Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China; 2Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Background: CD163, a hemoglobin scavenger receptor, has been identified as a marker of M2 macrophages, it can promote the release of IL-10 and carbon oxide. Researches on inflammatory diseases and tumors have suggested that CD163 plays anti-inflammatory effect and promotes tumor growth and metastasis. Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by chronic synovitis with inflammatory cells infiltration including considerable macrophages. However, little is known about the role of CD163+ macrophages in RA synovium.

Objectives: To investigate the expression and clinical significance of synovial CD163+ macrophages in RA.

Methods: Seventy-five RA patients were recruited and clinical data including disease activity, HAQ and Sharp/van der Heijde-modified Sharp score of bilateral hands and wrists were collected. Synovial tissues were obtained by needle biopsies or arthroscopy of knee joints. Eighteen osteoarthritic (OA) and seventeen orthopedic arthropathies (orth.A) patients were included as controls. All synovium were stained with H&E and immunohistochemically for CD163, CD3, CD20, CD38, CD68, and CD15. Histologic changes of synovitis in H&E stained sections were graded with Krenn’s synovitis score.

Results:
1. Positive CD163 expression were found in both lining synoviocytes and sublining inflammatory cells. Both densities of lining and sublining CD163+ macrophages in RA synovium were significantly higher than that in OA or Orth.A synovium (140.47±66.93 vs. 17.85±7.70 vs. 19.76±5.28 and 417.92±249.62 vs. 275.8±14.19 vs. 29.87±9.33, all P<0.001, Figure 1).

2. According to Krenn’s synovitis score, there were 68% RA patients showing high synovitis score (score>4). Both lining and sublining synovial CD163+ macrophages were significantly higher than those showing low synovitis (lining: 158.40±62.91 vs. 122.06±66.74, sublining: 462.96±62.91 vs. 371.65±271.54, both P<0.05). Meanwhile, the densities of lining and sublining CD163+ macrophages were both positively correlated with Krenn's synovitis score (r=0.238 and 0.343, both P<0.05).

3. For clinical relationship in RA, the density of sublining CD163+ macrophages was positively correlated with total Sharp score (mTSS) (r=0.398, P<0.001), joint space narrowing subscore (r=0.248, P=0.032) and joint erosion subscore (r=0.457, P<0.001). While the density of lining CD163+ macrophages was positively correlated with mTSS (r=0.319, P<0.005) and joint erosion subscore (r=0.358, P=0.002). Meanwhile, the densities of sublining and lining CD68+ macrophages were also positively correlated with mTSS (r=0.253 and 0.242, both P<0.05), of which the correlation was weaker than that of CD163+ macrophages (Figure 2). There were no significant correlation between the density of CD163+ macrophages and disease activity or HAQ (all P>0.05).

Conclusion: Synovial CD163+ macrophages are associated with radiographic joint destruction, which imply that CD163+ macrophages may play role in the pathogenesis of joint destruction in RA.

AB0055 SOLUBLE TREM-1 LEVELS IN FAMILIAL MEDITERRANEAN FEVER RELATED AA-AMYLOIDOSIS

S. Uzurlu1, B. H. Egeli1, I. M. Bolayirli1, H. Ozdogan1, 1Istanbul University - Cerrahpasa, Istanbul, Turkey

Background: Triggering Receptor Expressed on Myeloid cells-1 (TREM-1) is a monocyte and neutrophil receptor functioning in innate immunity. TREM-1 activity is well known in the pathogenesis of sepsis; hence it can be also present in autoinflammatory diseases such as the most common monogenic one, Familial Mediterranean Fever (FMF).

Objectives: The objective of this study is to measure soluble TREM-1 (STREM-1) activity in severe FMF cases complicated with systemic AA-Amyloidosis.

Methods: The cohort of the study includes regularly followed FMF related AA-Amyloidosis patients in a tertiary center outpatient rheumatology clinic. Soluble TREM-1 levels were measured using enzyme-linked immunosorbent assay (ELISA). In addition, demographic data, renal function tests, acute phase reactants, and medical prescription history was also noted and analyzed. None of the FMF diagnosed patients had an attack during the collection of the blood samples.

Results: The patients were categorized into 4 groups: FMF related AA-Amyloidosis patients (A+), FMF unrelated AA-Amyloidosis (FMF- A+),
**NATURAL ANTIBODIES AGAINST PHOSPHORYLCHOLINE AND MALONDIALDEHYDE DURING THE FIRST TWO YEARS OF LIFE: IMPLICATIONS FOR RHEUMATIC DISEASE**

*D. Thiagarajan1, S. Lundström1, G. Pershagen1, C. Almqvist Malmros1, E. Andolf1, A. Hedman1, O. Berg1, N. Oparina1, J. Frostegård1, Karolinska Institutet, Stockholm, Sweden*

**Background:** Antibodies against phosphorylcholine (anti-PC) have potentially protective properties in both atherosclerosis and rheumatic disease. IgM anti-PC could play a role in SLE being associated with protection, also in relation to atherosclerotic plaques and vulnerable plaques in SLE and being a non-responder to biologics in RA. 1 We reported potential mechanisms by which anti-PC could be protective: 1: anti-inflammatory; 2: inhibits uptake of oxLDL in macrophages, 3: inhibits cell death, 1: 4: anti-PC (and anti-MDA) increases clearance of human dead cells which could be of importance not especially in SLE 2: S- anti-PC increases T regulatory cells in SLE-patients T cells from a low level and also in atherosclerosis, with implications for both conditions. Also antibodies against malondialdehyde (anti-MDA) have interesting properties

**Objectives:** It is not known how these antibodies develop early in life and what may cause low levels. The objective is to determine this.

**Methods:** Antibodies were studied by ELISA in healthy pregnant women (n=105; Born into life study) and their newborn children. Women were recruited before conception. Informed consent, questionnaires from parents and plasma sample was collected from children at birth from cord blood, at 1-year and 2 years after birth. Extracted antibodies were compared using a proteomics de novo sequencing approach.

**Results:** Children were born with very low levels of IgM anti-PC, while IgM anti-MDA was present at birth. Both IgM anti-PC and anti-MDA increased during the first two years of life, but IgM anti-PC in contrast to IgM anti-MDA was still significantly lower than mothers at anti-PC decreased after 1 year, but reached similar levels as mothers’ after 2 years while IgG anti-MDA reached similar levels as mothers after 2 years while IgG anti-MDA reached similar levels as mothers’ already at 1 year. Proteomics peptide sequencing analysis indicates large peptide sequence variation without specific clone expression during early stage of life compared to the adult stage for which specific peptide sequences dominated.

**Conclusion:** IgM anti-PC levels develop much slower than anti-MDA and are still relatively low at 2 years. We hypothesize that anti-PC is developed by a combination of pre-programming and exposure to the external world, where infectious agents may play a role. For anti-MDA pre-programing is likely to play a major role and at an earlier stage than for anti-PC.

AB0058  CELL-TYPE SPECIFIC REGULATION OF IL-1R SIGNALING BY R835, A DUAL IRAK1/4 INHIBITOR

S. Braselmann1, E. Tai1, R. Frances1, C. Young1, V. Markovtsov1, E. Masuda1, V. Taylor1, Rigel Pharmaceuticals, South San Francisco, United States of America

Background: Interleukin-1 beta (IL-1b) is a key mediator of the inflammatory response and is known to exacerbate damage during chronic disease and acute tissue injury. Through association with the adaptor protein MyD88, interleukin receptor associated kinases (IRAK)1 and 4 initiate signaling downstream of IL-1Rs resulting in the activation of the NFκB and MAPK pathways and the production of proinflammatory cytokines (1). IL-1Rs are broadly expressed across cell types and little is known about differences in signaling between cell types and the role of IRAK1 and IRAK4 kinase activity.

Objectives: We have identified a potent and selective IRAK1/4 inhibitor, R835, that substantially suppressed the elevation of LPS (TLR4 agonist)-induced serum cytokines in healthy human volunteers in a recent phase 1 study. The aim of this study was to evaluate the effect of R835 on IL-1R signaling in primary human fibroblasts and endothelial cells.

Methods: Human dermal fibroblasts, lung fibroblasts or endothelial cells were stimulated with IL-1b and the effect of R835 on IL-1R signaling was assessed. The ability of R835 to inhibit cytokine production induced by high or low amounts of IL-1b in dermal fibroblasts was assessed.

Results: In human endothelial cells, inhibition of IRAK1/4 kinases with R835 resulted in a block of IL-1b-induced IRAK4 phosphorylation, IRAK1 degradation and downstream NFκB, p38 and JNK activation. In contrast, in both human primary dermal and lung fibroblasts stimulated with IL-1b, we observed potent inhibition of IRAK4 phosphorylation, IRAK1 degradation, and downstream JNK phosphorylation, but no inhibition of NFκB pathway proteins and only weak inhibition of p38. Upon titration of IL-1b we observed that dermal fibroblasts produced IL-8 and GRO in response to low levels of IL-1b (20pg/ml). JNK activation was observed, with additional cytokines including C-CSF and GM-CSF with higher levels of IL-1b (400pg/ml). In the presence of low levels of IL-1b (20pg/ml), we observed a weak activation of NFκB pathway proteins and p38, compared to a very robust NFκB, p38 and additional JNK activation in the presence of higher levels of IL-1b (400pg/ml). Consistent with these results, in dermal fibroblasts, R835 showed little to no inhibition of IL-8 and GRO induced by low levels of IL-1b, but potently inhibited C-CSF and GM-CSF induced by high levels of IL-1b where JNK was activated.

Conclusion: This study has elucidated signaling differences between cell types downstream of the IL-1R. In endothelial cells, as in myeloid cells, the kinase activity of IRAK1 and IRAK4 is required for the activation of all downstream signaling. Unexpectedly, in human fibroblasts, IRAK1/4 kinase activity appears to primarily regulate the JNK pathway, and not the NFκB pathway. Concomitant with this, the cytokines induced by the additional activation of JNK in fibroblasts are regulated by a dual IRAK1/4 inhibitor. Clinically, an IRAK1/4 inhibitor may show select inhibition of IL-1b-induced cytokines depending on the tissue and cell type involved in inflammation.

AB0059  CLINICAL SIGNIFICANCE OF CIRCULATING MYELOID-DERIVED SUPPRESSOR CELLS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Morenkova1, M. Tikhonova1, T. Tyrnova1, E. Batrov1, A. Sizikov2, O. Chumasova2, A. Sulutian3, V. Koksharova3, D. Orlov3, E. Chernykh1, 1Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Laboratory of Cellular Immunotherapy, Novosibirsk, Russian Federation; 2Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Rheumatology, Novosibirsk, Russian Federation; 3State Autonomous Healthcare Institution of the Novosibirsk Region City Center for Clinical Immunology, Novosibirsk, Russian Federation

Background: Myeloid-derived suppressor cells (MDSCs) represent heterogeneous population of immature myeloid cells with immunosuppressive functions. The important role of MDSCs is indicated for cancer, but their role in autoimmune pathology is currently controversial. Considering the clinical heterogeneity of ankylosing spondylitis (AS) and involvement of innate immunity in AS pathophysiology the investigation of the MDSC role in AS is of great interest.

Objectives: The aim of our study is to investigate the number of MDSC subsets in AS patients with different clinical manifestations, activity, disease duration, and treatment options and to evaluate the ability of MDSCs to mediate immunosuppressive function in AS patients.

Methods: The study included 34 patients with AS. Ankylosing Spondylitis Disease Activity Score (ASDAS) was used to assess disease activity and high activity was determined as ASDAS≥2.1. The frequencies of monocyte (M-MDSC) (HLADR-CD14 +), granulocytic (G-MDSC) (lin-HLADR-CD33+ CD66 +) and early-stage (eMDSC) (lin-HLADR-CD33 + CD66-) MDSCs and biomarkers of MDSCs functional activity including of Arg-1, IDO, PDL1 were determined in the peripheral blood by flow cytometry.

Results: We found significant elevation in the frequency of both M-MDSC and G-MDSC in the total group of patients compared to healthy controls (HC) (P<0.0006 and P=0.008 respectively), while eMDSCs did not differ from HC. Analysis of MDSCs populations in patient subgroups showed expansion of G-MDSCs in patients with axial plus peripheral damage (P=0.004), while M-MDSCs were elevated regardless of the presence (P=0.002) or absence (P=0.001) of peripheral manifestations. Moreover, the percentage of M-MDSCs was positively correlated with ASDAS in patients with axial disease only (R=0.8; P=0.03). Patients with low activity of disease demonstrated significant elevation of only M-MDSCs compared with HC (P=0.001). Patients who had high activity of disease had increase in both M-MDSCs and G-MDSCs (P=0.008 and P=0.005 respectively). By comparing the frequency of MDSCs in patient groups with different AS duration we showed increase in percentage of both M-MDSCs and G-MDSCs in patients with relatively short duration of disease (< Me=11.5 years) (P=0.002 and P=0.005 respectively) and elevation in M-MDSCs only in patients with longer AS duration (P=0.0003).

Conclusion: Compared with patients receiving conventional therapy (NSAIDs, csDMARDs), patients who received biological agents (TNFα inhibitors) had lower disease activity but despite this showed elevated frequencies of M-MDSCs and PMN-MDSCs, comparable to patients receiving conventional therapy. Of note, M-MDSCs in AS patients had increased expression of PDL-1 and IDO (P=0.04 and P=0.02 respectively) and similar to HC expression of Arg-1. The expression of Arg-1, IDO, PDL1 in patients G-MDSCs did not differ from HC.

AB0060  STING AND PROINFLAMMATORY CYTOKINES IN SYNOVIAL FLUID OF PATIENTS WITH DIFFERENT ARTHRITIDES

A. Scara1, R. Luietto1, F. Oliviero1, P. Galazzi1, A. Ortollan1, M. Lorenzin1, M. Felicielli1, A. Doris1, R. Ramonda1, 1University of Padova, Rheumatology Unit, Dept. of Medicine-DIMED, Padova, Italy; 2University of Padova, Dept. of Surgical Oncological and Gastroenterological Sciences, Padova, Italy

DOI: 10.1136/annrheumdis-2020-eular.3898
Background: STING (stimulator of interferon genes) is a cytosolic protein that is found in endoplasmic reticulum (ER) membrane, mitochondria and mitochondria-associated membranes. Although it is well established that STING plays an important role in innate immune responses, its potential involvement in rheumatic disease processes remains to be clarified (1).

Objectives: The aims of this study were to assess the levels of STING and its relationship with local inflammation in the synovial fluid (SF) of patients with psoriatic arthritis (PsA), rheumatoid arthritis (RA), gout, calcium pyrophosphate (CPP) crystal-induced arthritis (CPP-IA), osteoarthritis (OA) and with CPP crystals (OA+CPP).

Methods: SF was collected from the knees of 60 untreated patients: 10 with PsA, 10 with RA, 10 with gout, 10 with CPP-IA, 10 with OA and 10 with OA+CPP. SF was examined under optical light microscopy. White cell count (WBC) and the polymorphonuclear cell (PMN) percentage were determined in SF according to standard procedures. SF IL-6, IL-1β and intra- and extra-cellular STING levels were assayed by ELISA.

Results: The levels of WBC were higher in SFs from gouty patients (27.7±20.56 ×10⁹/mm³) than OA and OA+CPP patients showed the lowest WBC count (0.34±0.3 ×10⁹/mm³, 0.3±0.32 ×10⁹/mm³). SFs from inflammatory arthropathy contained elevated percentages of PMN (gout: 85.5±10.86%, CPP-IA: 84±11.31%, RA: 80.33±8.14%, PsA: 42.6±35.97%). Extracellular STING was determined in OA (440±413.31 pg/ml), OA+CPP (225±205.06 pg/ml) and CPP-IA (475±7.07 pg/ml). SF, while not detectable in RA, PsA and OA. Intracellular STING levels were similar and the highest in SFs from gout (96.4±23.13 pg/ml), while remained under detection limit only in SFs from PsA. SF concentration of IL-6 was lower in OA (354.8±377.56 pg/ml) and OA+CPP (389.56±14.14 pg/ml) as compared with inflammatory arthropathies (PsA: 3807±449.86 pg/ml; RA: 1735±2334.87 pg/ml; gout: 1935±8.85 pg/ml; CPP-IA: 20389.56±104.14 pg/ml). The patients with gout and OA had the highest levels of IL-8 (2159.54±347.09 pg/ml; 2036±9.74 pg/ml) and IL-1β (35.93±20.46 pg/ml; 44.36±23.16 pg/ml), while OA showed the lowest concentrations (IL-8: 23.21±11.32 pg/ml; IL-1β: 0.47±0.13 pg/ml). In the total group of patients, we found a negative correlation between extracellular STING and IL-6 (r=-0.53; p=0.004) and IL-1β (r=-0.47; p=0.012). There was a positive correlation between intracellular STING and IL-6 (r=0.54; p=0.017), IL-1β (r=0.77; p<0.001) and IL-6 (r=0.69; p=0.009).

Conclusion: This study is the first to determine the presence of STING in SF of different arthropathies. The high levels of extracellular STING in OA, OA+CPP and CPP-IA SFs may be due to the activation of factors that reduce its interaction with the ER. The effect of downregulating factors in PsA might explain the low levels of STING in these patients.

were stimulated on the same day of isolation. Both moDCs and mDCs were pre-treated with Tolatacticin and then stimulated with either lipopolysaccharide (LPS) or combination of LPS with IFN-γ for 4 hours. Cytokines were measured using enzyme-linked immunosorbent assay (ELISA) and gene expression was assessed using quantitative polymerase chain reaction (qPCR).

**Results:** Treatment of both mDCs and moDCs with Tolatacticin led to a decreased mRNA expression of IL-12 p40 (IL12B) in the presence of TR4 and IFN-γ co-stimulation. The decreased IL12B mRNA expression also resulted in lower production of IL-12 p40 and IL-23 proteins in mDCs.

**Conclusion:** In this work, we demonstrated for the first time that Tolatacticin can suppress the production of IL-23/IL-12 p40 subunit in mDCs, upon the condition that an active type II IFN signalling is also present in these cells. This observation indicates that specific factors, such as endogenous IFN-γ levels in the serum of PsA patients, can possibly predict differential responses to Tolatacticin treatment.

**AB0063 AGING CARTILAGE IN WILD-TYPE MICE: AN OBSERVATIONAL STUDY**

**J Akoum**, K. Tahiri, F. Etienne, M. T. Corvol, F. Rannou, C. Nguyen

1. Université de Paris - UFR Mathématiques et Informatique, Paris, France; 2. Hopital Cochin, Rheumatology Institute, Rehabilitation Department, Paris, France

**Background:** Many animal models of osteoarthritis (OA) have been used to study the pathogenesis of cartilage degeneration. In mice, spontaneous OA can occur in wild-type or genetically modified animals. The first report of spontaneous OA developing in wild-type mice was published in 1956 and changes affecting the knee joint were further related to OA by using ultrastructural- histochimical analyses. However, a quantitative assessment of age-related evolution of OA-type cartilage lesions is lacking. The OA Research Society International (OARSI) grading score was adapted to semi-quantify histopathological changes occurring in OA animal models, including mice. The OARSI score has been used to describe changes occurring in induced or genetic OA mouse models but not to describe spontaneous age-related evolution of OA-type cartilage lesions in wild-type mice.

**Objectives:** We aimed to describe the spontaneous evolution of age-related changes affecting knee joint articular cartilage, walking speed and a serum biomarker of cartilage remodeling in C57BL/6 wild-type male mice.

**Methods:** Histological changes were assessed by the OARSI score in newborn, 1-week- and 1-, 3-, 6-, 9- and 12-month-old C57BL/6 wild-type male mice, walking speed by the Locomotor system, and serum C-terminal telopeptide of type II collagen (CTX-II) content by ELISA in 1-, 3-, 6-, and 9-month-old C57BL/6 wild-type male mice.

**Results:** Male (STJ) OARSI score increased from 0.2 (0.3) to 1.3 (0.6) (p=0.03) between 1 and 3 months of age and from 1.3 (0.6) to 3.3 (0.6) (p=0.04) between 3 and 6 months of age. Mean walking speed was stable between 1 and 6 months of age but decreased from 11.4 (1.8) to 3.2 (0.8) cm.s\(^{-1}\) (p=0.03) between 6 and 9 months of age. Serum CTX-II content was maximal at 1 month of age, then decreased from 12.2 (8.5) to 2.4 (8.4) pg.ml\(^{-1}\) (p=0.02) between 1 and 3 months of age, remaining low and stable thereafter.

**Conclusion:** C57BL/6 wild-type male mice showed continuously increasing osteoarthritic changes but delayed decreasing walking speed with age. These variations were maximal between 3 and 9 months of age. Maximal serum CTX-II content preceded these changes.

### AB0064 CHANGES IN THE VASCULAR ENDOTHELIAL GROWTH FACTOR A (VEGFA) SPlicing AXIS IN HUMAN SYNOVium ARE RELATED TO INFLAMMATION IN ARTHRITIS

1. University of Nottingham, School of Life Sciences, Nottingham, United Kingdom; 2. University of Nottingham, Pain Centre Versus Arthritis, Nottingham, United Kingdom; 3. University of Nottingham, School of Medicine, Academic Rheumatology, Nottingham, United Kingdom

**Background:** VEGF-A is a key regulator of rheumatoid (RA) and osteoarthritis (OA). During articular inflammation in OA and RA there is increased synovial angiogenesis and upregulation of angiogenic growth factors such as VEGF-A. VEGF-A comprises two splice variant families, VEGF-A\(_{\text{a}}\) and VEGF-A\(_{\text{b}}\) (xxx represents the number of amino acids, from 121 to 206), resulting from alternative splice site selection in exon 8. This splice site selection is controlled by Serine/Arginine Rich Splicing Factor Kinase 1 (SRPK1), which phosphorylates Serine/Arginine Rich Splicing Factor 1 (SRSPF1), inducing it to translocate to the nucleus. In most normal tissues, VEGF-A\(_{\text{a}}\) isoforms predominate, with anti-nociceptive and anti-angiogenic functions. The contrast, in pathological conditions such as inflammation and solid tumours, VEGF-A\(_{\text{b}}\) isoforms predominate, with pro-nociceptive and pro-angiogenic functions. VEGF-A has been proposed as
a therapeutic target in RA and OA. To date, there are no published data on the functionally distinct VEGF-A splice variants in either RA or OA.

**Objectives:** To determine the patterns of, and relationships between, VEGF-A, SRPK1, and SRSF1 expression and activation and synovial inflammation in human RA and OA.

**Methods:** The study was approved by the Nottingham Research Ethics Committee 1 (05/Q2403/24) and Derby Research Ethics Committee 1 (11/H0405/2). Tissues were selected from age- and sex-matched cases in the University of Nottingham joint tissue repository. Post-mortem (PM) samples of healthy knee synovium (n=14, no past history of arthritis or knee injury in the 12 months prior to death, no significant arthritic or synovial pathology) and arthroplasty-derived synovium samples from OA (n=35) or RA (n=14) patients were compared. OA samples were selected to represent the variety of inflammation levels, from low to high grade (0-3, Haywood et al., 2003). 8um thick sections were stained for SRSF1, samples from OA (n=35) or RA (n=14) patients were compared. OA samples served as control. Radiological presence of chondrocalcinosis was evaluated using standard X-ray pictures, as well as macroscopically inspection. The cartilage samples were stained using von Kossa/Safranin-orange staining. These stainings were used for OA severity scoring using the Chambers-Score. FTIR analyses was performed to distinguish CPPD and BCP crystals in cartilage. Chondrocyte differentiation markers were evaluated using Collagen 2 and X, as well as Sox9 and aggreican as markers for chondrocyte hypertrophic differentiation in immunohistochemistry and qRT-PCR. TUNEL staining was performed to investigate cell death. In vivo results were validated using qRT-PCR for the expression of the respective genes after stimulation of C2B chondrocytes with CPPD and BCP crystals.

**Results:** Radiologically detectable cartilage calcifications were evident in chondrocalcinosis patients, but absent in OA patients without CPPD. CPPD crystals were detected on the cartilage surface, whereas BCP crystals were detected in the pericellular matrix of hypertrophic chondrocytes. Cartilage exhibited an increased collagen X expression compared to healthy cartilage, as well as to severe OA cartilage containing BCP calcification. Interestingly, aggreican and collagen 2 were not reduced in CC cartilage, but markedly reduced in OA cartilage. TUNEL positive cells were significantly increased in CPPD cartilage compared to OA cartilage, although the histological OA severity was lower. qRT-PCR indicated no relevant influence of CPPD crystals on hydroptic markers, whereas BCP crystals significantly induced hydroptic chondrocyte differentiation.

**Conclusion:** BCP and CPPD crystals seem to trigger differential effects on the chondrocyte phenotype. BCP crystals induce hypertropic differentiation, which is not induced by CPPD crystals.

**Acknowledgements:** The project was funded by the Deutscher Rheumaftifung by the sponsor Dr. Sigrid Schuler.

**CHONDROCALCINOSIS IS ASSOCIATED WITH A SPECIFIC EFFECT ON THE CHONDROCYTE PHENOTYPE THAT MARKEDLY DIFFERS FROM OA**

F. Meyer, M. Bollmann, U. Kornak, J. Bertrand, OVGU Magdeburg, Magdeburg, Germany; T’Charite, Berlin, Germany

**Background:** Calcification of cartilage with BCP crystals is a common finding during osteoarthritis (OA) and is directly linked to the severity of the disease and hypertrophic differentiation of chondrocytes. Chondrocalcinosis (CC) is associated with CPPD crystal formation. There is only little knowledge about the effect of CPPD crystals on chondrocytes.

**Objectives:** The aim of this study is to investigate the chondrocyte phenotype in CC cartilage and the effect of CPPD crystals on chondrocytes.

**Methods:** Cartilage samples of patients with CC were used and compared with samples of severe OA patients without chondrocalcinosis and healthy cartilage samples served as control. Radiological presence of chondrocalcinosis was evaluated using standard X-ray pictures, as well as macroscopically inspection. The cartilage samples were stained using von Kossa/Safranin-orange staining. These stainings were used for OA severity scoring using the Chambers-Score. FTIR analyses was performed to distinguish CPPD and BCP crystals in cartilage. Chondrocyte differentiation markers were evaluated using Collagen 2 and X, as well as Sox9 and aggreican as markers for chondrocyte hypertropic differentiation in immunohistochemistry and qRT-PCR. TUNEL staining was performed to investigate cell death. In vivo results were validated using qRT-PCR for the expression of the respective genes after stimulation of C2B chondrocytes with CPPD and BCP crystals.

**Results:** Radiologically detectable cartilage calcifications were evident in chondrocalcinosis patients, but absent in OA patients without CC. CPPD crystals were detected on the cartilage surface, whereas BCP crystals were detected in the pericellular matrix of hypertrophic chondrocytes. Cartilage exhibited an increased collagen X expression compared to healthy cartilage, as well as to severe OA cartilage containing BCP calcification. Interestingly, aggreican and collagen 2 were not reduced in CC cartilage, but markedly reduced in OA cartilage. TUNEL positive cells were significantly increased in CPPD cartilage compared to OA cartilage, although the histological OA severity was lower. qRT-PCR indicated no relevant influence of CPPD crystals on hypertrophic marker genes, whereas BCP crystals significantly induced hypertropic chondrocyte differentiation.

**Conclusion:** BCP and CPPD crystals seem to trigger differential effects on the chondrocyte phenotype. BCP crystals induce hypertropic differentiation, which is not induced by CPPD crystals.

**NOVEL CHONDROPROTECTIVE AND ANTI-INFLAMMATORY EFFECTS OF THE SELECTIVE HUMAN MELANOCORTIN MC3 RECEPTOR AGONIST PG-890 ON SNAP ACTIVATED CHONDROCYTES**

V. Can, I. Locke, P. Grieço, S. Getting, University of Westminster, Life Sciences, London, United Kingdom; University of Naples Federico II, Department of Pharmacy and CRIPPEB, Naples, Italy

**Background:** Osteoarthritis (OA) is a degenerative joint disease that affects over 250 million people worldwide [1] with treatments focussing on the symptoms rather than the cause of the pathology [2, 3]. Thus, this degenerative joint disease requires novel treatment options [3, 4]. Therefore, the melanocortin system [4] could provide a novel avenue to explore given its ability to exert anti-inflammatory effects and chondroprotection [5], although the receptor subtype involved is unclear.
Objectives: This study aims to assess the chondroprotective and anti-inflammatory effects of the selective human melanocortin MC1 receptor agonist BMS-470539 dihydrochloride and the selective human MC3 receptor agonist PG-990 on S-Nitroso-N-acetyl-D,L-penicillamine (SNAP) activated chondrocytes.

Methods: The human chondrocytic cell-line C-20/A4 was seeded at 25.0 x 10⁶ viable cells/ml (5 μl droplet was transferred into individual wells of a 96-well plate). Micromass cultures [6] were stimulated with SNAP (10.0 mM) and after 2h treated with Dexamethasone (1.0 μM), selective human melanocortin MC1 receptor agonist BMS-470539 dihydrochloride and PG-990 inhibited cell death by 2%, 58% and 129% respectively (*p<0.05). SNAP stimulation caused a significant increase in Caspase -3 and -7 activity, which was inhibited by Dexamethasone, BMS-470539 dihydrochloride and PG-990 by 8%, 5% and 19% respectively (*p<0.05). GAG content was significantly reduced by SNAP by 29% (*p<0.05), which was inhibited by Dexamethasone, BMS-470539 dihydrochloride and PG-990 by 1%, 3% and 14% respectively (*p<0.05). SNAP also caused a significant decrease in HO-1 protein expression, which was increased by Dexamethasone, BMS-470539 dihydrochloride and PG-990 by a 1.0-fold, 1.1-fold and 2.1-fold increase respectively (*p<0.05).

Conclusion: The selective human melanocortin MC3 receptor agonist PG-990 exhibited enhanced chondroprotection and modulation of inflammatory and tissue destructive mediators following SNAP activation compared to Dexamethasone and the selective human melanocortin MC1 receptor agonist BMS-470539 dihydrochloride. This suggests that melanocortin peptides display enhanced chondroprotective and anti-inflammatory effects at the MC3 receptor sub-type in this cell line.

LORECIVINT (SM4690), AN INTRA-ARTICULAR, SMALL-MOLECULE CLK/DYRK1A INHIBITOR THAT MODULATES THE WNT PATHWAY, AS A POTENTIAL TREATMENT FOR MENISCAL INJURIES

T. Seo1, V. Deshmukh2, Y. Yazici1, S. Samumed, LLC, San Diego, United States of America

Background: Meniscal injuries, associated with pain, stiffness, and localized swelling, are the most common pathology of the knee with a prevalence of 61 per 100,000.1 Meniscal damage is a frequent finding on MRI images of knee osteoarthritis (OA);2 while a meniscal tear can lead to knee OA, knee OA can also lead to a spontaneous meniscal tear.3 Efforts to repair meniscal damage have been largely unsuccessful and do not prevent the progression of degenerative changes that lead to knee OA.4 The Wnt signaling pathway has been shown to be regulated during meniscal development,5 suggesting that manipulation of this pathway may influence the regenerative capacity of the meniscus. Loricrivint (LOR; SM4690) is an intra-articular (IA), small-molecule CLK/DYRK1A inhibitor that modulates the Wnt pathway.

Objectives: LOR was evaluated in preclinical studies to determine its protective and anabolic effects in ex vivo explants and in a rat model of chemically induced inflammatory meniscus degeneration.

Methods: Effects of LOR (30μM) on expression of matrix metalloproteinases (MMPs) in cultured rat menisci treated with IL-1B were measured by qPCR. In vivo, LOR activity was evaluated in a rat model of monosodium iodoacetate (MIA) injection-induced inflammatory meniscus degeneration. A single IA injection of MIA was immediately followed by a single IA injection of LOR (0.3 μg) or vehicle. Knees were harvested on Days 1, 4, and 11 and menisci were isolated. Anti-inflammatory effects were evaluated by measuring TNFα and IL6 expression by qPCR. Meniscus protection was evaluated by qPCR for MMPs and aggrecanase and anabolic effects by qPCR for collagens.

Results: In ex vivo meniscal explants, LOR inhibited expression of MMP1, MMP3, and MMP13 compared to DMSO (P<0.01). In vivo, LOR significantly decreased expression of these MMPs and aggrecanase (P<0.05) compared to vehicle in the rat model of inflammatory meniscus degeneration at Day 4 after MIA injection. In addition, LOR reduced expression of inflammatory cytokines TNFα and IL6 at Day 4 compared to vehicle. Finally, LOR increased expression of collagen types I, II, and III at Day 11 after MIA injection.

Conclusion: LOR exhibited protective effects in the meniscus ex vivo and in vivo by reducing the expression of catabolic enzymes compared to control. Anti-inflammatory effects of LOR were demonstrated by inhibition of inflammatory cytokine expression. Compared to vehicle, LOR increased expression of collagens in vivo, indicating potential meniscal anabolic effects. These data support further investigation of LOR as a potential disease-modifying therapy for meniscal injuries.

THERAPEUTIC EFFECTS OF BONE MARROW MESENCHYMAL STEM CELLS-DERIVED EXOSOMES ON OSTEOARTHRITIS

C. Dong1, Y. Liu1, A. Deng2, J. Ji1, W. Zheng3, Z. Gu1.1. Affiliated Hospital of Nantong University; Nantong, China

Background: Mesenchymal stem cells (MSCs) have shown chondroprotective effects in clinical models of osteoarthritis (OA)1,2. However, the therapeutic potential of exosomes derived from MSCs remains unclear.

Objectives: The study aimed to investigate the therapeutic potential of exosomes from human bone marrow MSCs (BM-MSCs) in alleviating OA.

Methods: The anterior cruciate ligament transaction (ACLT) and destabilization of the medial meniscus (DMM) surgery were performed on the knee joints of male Sprague-Dawley rats to induce OA. BM-MSCs- derived exosomes were administrated to primary human chondrocytes to observe the functional and molecular alterations.

Results: Exposure to BM-MSCs-derived exosomes partially prevented the expression of inflammatory cytokines (IL-1β, TNF-α) and matrix metalloproteinases (MMP-13, MMP-3) in OA chondrocytes. The beneficial effects were evaluated by histological staining, OARSI scores, and micro-CT. Furthermore, BM-MSCs-derived exosomes were administrated to primary human chondrocytes to observe the functional and molecular alterations. In addition, IncRNA MEG3 was investigated in chondrocytes to explore the biological contents accounting for anti-OA effects of BM-MSCs-derived exosomes.

Conclusion: The exosomes from BM-MSCs exerted beneficial therapeutic effects on OA by reducing the senescence and apoptosis of chondrocytes, suggesting that MSCs-derived exosomes might provide a candidate therapy for OA treatment.

BOSWELLA SERRATA EXTRACT AND CURCUMIN INCREASE GDF15 PRODUCTION BY HUMAN PRIMARY OSTEOARTHRITIS CHONDROCYTES: A NEW MECHANISM OF ACTION

C. Sanchez1, J. Zappia1, Y. Dierickxens2, J. P. Delcour3, Y. Henrotin1,4.1. University of Liège, Bone and Cartilage Research Unit, Liège, Belgium; 2. Tilman, Baillonville, Belgium; 3. Centre Hospitalier du Bois de l’Abbaye, Seraing, Belgium, 4. Princess Paola Hospital, Marche-en-Famenne, Belgium

Background: Boswella serrata extract (BSE) and curcumin are used to relieve symptoms in osteoarthritis (OA), but their mechanisms of action are not fully understood.

Objectives: To study the mode of action of HE-1100 on OA chondrocytes in vitro.

Methods: Primary chondrocytes were obtained from knee osteoarthritis (OA) patients undergoing knee replacement surgery. The cultures were treated with 20% (v/v) HE-1100 or placebo. Samples were collected for subsequent RNA extraction using standard methods. The reads were generated with Illumina NextSeq5000 sequencer and aligned to the human reference genome (UCSC hg19) to generate the transcriptome. Differential expression analysis between HE-1100 and placebo was made in R using the DESeq2 package to identify the differentially expressed genes in the OA-associated regulatory pathways. The protein production of the selected genes was quantified by ELISA in 10 independent human OA chondrocytes cultures.

Results: According to the DESeq2 analysis, HE-1100 significantly modified the expression of 13 genes in OA chondrocytes by at least 10% with an adjusted p-value < 0.05. Among them, up-regulated genes included TGFβ1, TNAP, MMP13, IL10, IL1B, CCL2, CCL7, and CLEC3A; down-regulated genes included COL2A1, IL6, and ITGAM.

Conclusion: HE-1100 significantly modified the expression of several OA-related genes, suggesting its potential therapeutic effects on OA.

A MULTICOMPONENT MEDICATION PROMOTES CHONDROGENESIS AND REDUCES MMP-13 IN PRIMARY ARTICULAR CHONDROCYTES FROM KNEE OSTEOARTHRITIS PATIENTS IN VITRO

C. Sanchez1, K. Hemmer1, N. Kroemmelbein2, B. Seilheimer2, J. E. Dubuc3, C. Antoine4, Y. Henrotin1,4.1. University of Liège, Bone and Cartilage Research Unit, Liège, Belgium; 2. Biologische Heilmittel Heel GmbH, Baden-Baden, Germany; 3. Cliniques Universitaires Saint-Luc, Orthopedic Department, Brussels, Belgium; 4. Artialis, Liège, Belgium

Background: HE-1100 is a multicomponent medicinal product. Initial preclinical data potentially suggest a preventive effect on cartilage degradation.

Objectives: To study the mode of action of HE-1100 on OA chondrocytes in vitro.

Methods: Primary chondrocytes were obtained from knee osteoarthritis (OA) patients undergoing knee replacement surgery. The cultures were treated with 20% (v/v) HE-1100 or placebo. Samples were collected for subsequent RNA extraction using standard methods. The reads were generated with Illumina NextSeq5000 sequencer and aligned to the human reference genome (UCSC hg19) to generate the transcriptome. Differential expression analysis between HE-1100 and placebo was made in R using the DESeq2 package to identify the differentially expressed genes in the OA-associated regulatory pathways. The protein production of the selected genes was quantified by ELISA in 10 independent human OA chondrocytes cultures.

Results: According to the DESeq2 analysis, HE-1100 significantly modified the expression of 13 genes in OA chondrocytes by at least 10% with an adjusted p-value < 0.05. Among them, up-regulated genes included TGFβ1, TNAP, MMP13, IL10, IL1B, CCL2, CCL7, and CLEC3A; down-regulated genes included COL2A1, IL6, and ITGAM.

Conclusion: HE-1100 significantly modified the expression of several OA-related genes, suggesting its potential therapeutic effects on OA.

References:
the decrease was observed from 1 µg/ml for curcumin and 10 µg/ml for BSE. For GDF-15, the increase was observed from 2 µg/ml for curcumin and 50 µg/ml for BSE. Maximal effect was observed at 4 µg/ml for curcumin: -67% NO (p<0.0001), -71% IL-6 (p=0.0001) and +80% GDF15 (p=0.0001) and at 100 µg/ml for BSE: -40% NO (p=0.0003), -70% IL-6 (p=0.0003) and +73% for GDF15 (p=0.0017).

Conclusion: At therapeutic plasmatic concentrations, BSE and curcumin decreased the production of NO and IL-6, two inflammatory mediators. Furthermore, BSE and curcumin enhanced GDF-15 production, an anti-inflammatory growth factor, GDF15 was first identified as Macrophage inhibitory cytokine-1 or NSAIId-activated gene-1 (by a prostanoiid-independent manner), and is known as a regulator of inflammatory, cell repair and apoptosis pathways. GDF-15 has pro-apoptotic and anti-tumorigenic activity in vitro and in vivo. It could represent a new pathway explaining the beneficial effects of BSE and the curcumin on synovium inflammation and cartilage degradation.

found in the area of macrophage interaction with T cells. CD68+ cells co-expressing TNF-alpha or IL-15 M1 markers were in majority in these synovial tissues. Lymphocyte infiltration was less abundant in remaining (2/6) synovial tissue samples.

Conclusion: Mature synovial tissue macrophages, equipped dominantly with arginase-1 are M2 oriented and might support Th2 immune response in surrounding T cells.

SPATIAL VARIATIONS OF BONE MICROARCHITECTURE AND MINERALIZATION IN HIP OSTEOARTHRITIS AND OSTEOPOROSIS

Y. Li1, H. Ahmed1, E. Dal’Arda2, N. Sullivan3, Y. Lien4, D. Tucker4, C. Fry5, B. V. Cooij4, A. Blom1, M. Sharfi5. 1 Univ. of Bristol, Bristol, United Kingdom; 2 Univ. of Sheffield, Sheffield, United Kingdom; 3 Univ. Hosp. Bristol, Bristol, United Kingdom; 4 Southmead Hosp., Bristol, United Kingdom; 5 Cohesie Occupational Health Service, Voorhuizen, Netherlands

Background: The pattern of changes in bone microarchitecture and mineralisation are distinctly different in osteoarthritis (OA) and osteoporosis (OP). However, the pathogenesis of OA is closely related with OP, making subchondral bone a promising target for OA treatment [1]. A detailed comparison of subchondral bone in OA and OP may help understand the relationship of the two diseases.

Objectives: To carry out a comprehensive analysis of regional and compartmental variations in subchondral bone architecture and mineralisation in OA and OP.

Methods: Femoral heads were collected from patients undergoing hip arthroplasty surgeries for hip OA (N=16) or osteoporotic fracture (N=7). For OP group, osteochondral plugs were collected from fixed sites: anterior, posterior and superior. For OA group, an optimised sampling procedure, based on a new macroscopic grading method and modified OARSI microscopic grading system, was used to collect plugs from regions with varying severity of cartilage degradation. Plugs were scanned by micro CT (voxel size 4.88um). Regions of interest for cortical plate (Ct) and trabecular bone (Tb) were segmented from reconstructed images using semi-automatic approach. Densitometric (tissue and bone mineral density: TMD and BMD) and architectural parameters (cortical plate thickness (Ct.Th), trabecular bone volume fraction (BV/TV), trabecular thickness (Tb.Th), etc.) were measured using commercially available software. Unmatched inter-group regional comparisons were made between OA microscopic grades (1 to 4) and OP. Matched intra-sample regional analysis was made between ‘mild’ (Grade 1 and/or 2) and ‘severe’ (Grade 3 and/or 4) OA. TMD was also subjected to paired comparison between cortical (Ct.TMD) and trabecular (Tb.TMD) compartments. Correlations between densitometric and architectural parameters were also explored.

Results: Regional analysis showed that Tb.TMD in OA Grade 3 and 4 was significantly lower than in OP and Grade 1 and 2, while Tb.BMD in OP was not significantly different from OA Grade 1 and 2 (Fig 1A, F). Ct.TMD in OA Grade 4 was significantly lower than in OP, but no difference was found in other comparisons (Fig 1B, G). For BMD of trabecular bone (Tb.BMD) and architectural parameters including BV/TV and Ct.Th, values for OA Grade 3 and/or 4 were significantly higher than OP and Grade 1 and/or 2, but the difference between OP and Grade 1 and 2 was not significant (Fig 1C-E, H-J). Compartmental analysis showed that Ct.TMD was significantly lower than Tb.TMD in all groups (Table I). Tb.TMD was inversely correlated with Tb.BMD and BV/TV in both OA and OP. Ct.TMD and Tb.TMD were inversely associated with Ct.Th and Tb.Th respectively in OA (Table II).

Conclusion: In both OA and OP, material density (TMD) of cortical plate was lower than trabecular bone. In hip OA, densitometric and architectural changes of subchondral cortical and trabecular bone were related to severity of cartilage degradation. In OA trabecular bone, the decrease in material density was compensated by increased bone volume, leading to higher apparent density (BMD); while in OP, loss of bone volume was correlated with, but not compensated by increased mineralisation, leading to lower apparent density.

AB0077

CONTRIBUTION OF NOTUM TO THE DEVELOPMENT OF OSTEOARTHRITIS

A. Muñoz1,2, E. Herranz1, P. Lois1, J. F. Blanco3, L. Abasolo1, L. Rodriguez Rodriguez1, J. R. Lamas1, B. Fernandez1. 1IIdiSSC, Madrid, Spain; 2INIBIC, A Coruña, Spain

Figure 3. Regional comparisons of densitometric and architectural parameters. Left panel: unmatched inter-group (one-way ANOVA) analysis, right panel: matched intra-sample regional analysis. Significance level is indicated by * as follows: * P = 0.05, ** P = 0.01, *** P = 0.001, **** P = 0.0001.
Background: Osteoarthritis (OA) is a degenerative disease characterized by altered homeostasis of joint cartilage and bone, the functionality of which relies on chondrocytes and osteoblasts, that leads to the formation of a defective extracellular matrix (ECM). The ECM plays an essential role in bone biology as it provides the structure of cartilage which serves as a template for bone formation. Collagen X, main component of the ECM, has been described by us as down-regulated in OA [1]. Our data also points to an important role of the Wnt pathway in OA [1,2]. Furthermore, Wnt proteins have been reported to inhibit chondrogenesis [3], and the Wnt pathway and its modulators have gained attention [4]. Glypicans (GPC1 to GPC6) and NOTUM, among others, have been identified as modulators of this pathway [5,6]. Notably, due to its highly specific inhibition of the Wnt pathway, NOTUM has been proposed as a therapeutic target in conditions with a high activity of the Wnt pathway is involved, such as OA [7].

Objectives: We hypothesize that modulators of the Wnt pathway are involved in the development of OA. The aim of this study is to evaluate the presence of Glypicans and NOTUM in the serum of OA patients and healthy individuals in order to determine whether significant differences exist and could clarify their likely involvement in OA.

Methods: Peripheral blood samples were obtained from OA patients during routine rheumatologist hospital visits. OA diagnosis was established according to the ACR criteria. Samples from healthy individuals were obtained from the local Blood Bank. In both cases, blood samples were centrifugated (2000g, 15 minutes, 10°C) and serum was obtained. Quantitative ELISA assays for GPC1-6 and NOTUM were carried out using commercial kits (Human GPC1 ELISA Kit, #E-EL-H1710, Elabscience; Human GPC2 ELISA Kit, #E-EL-H1711, Elabscience; Human GPC3 ELISA Kit, #E-EL-H1712, Elabscience; Human GPC4 ELISA Kit, #E-EL-H1713, Elabscience; Human GPC5 ELISA Kit, #ELH-GPCS, RayBiotech; Human GPC6 ELISA Kit, #CSB-EL009708HU, Cusabio; Human Protein NOTUM homolog ELISA Kit, #EK3787, Sab Biotech) and measured in a plate reader (Heales MB-580, Shenzhen Heales Technology Development Co. Ltd.). Protein concentration in serum was calculated using GraphPad Prism 7 software. Differences between samples were analysed with Mann-Whitney U test. Significance level set was p<0.05.

Results: Serum from 40 OA patients and 40 healthy donors were included in the study. There were no differences between groups (Table 1).

Out of 7 proteins analyzed, only NOTUM showed a significant difference between healthy and OA groups (Median_{notum}=0.8262ng/mL, Median_{control}=0.2549ng/mL, p=0.0013). Besides, GPC4 showed an approaching formal significance (Median_{notum}=0.1254ng/mL, Median_{control}=0.1190ng/mL, p=0.8829). The rest of Glypicans analyzed showed no significance differences between groups (GPC1, Median_{notum}=0.1033ng/mL, Median_{control}=0.1033ng/mL, p=0.3212).

Conclusion: Our results suggest that low levels of NOTUM may contribute to the development of OA. The lack of this inhibitor promotes the activation of the Wnt pathway, high activity of which has been related with OA.

**AB0079 ANGIOPOETIN-LIKE PROTEIN TYPE 3 AS AN INDICATOR OF RHEUMATOID INFLAMMATION AND RESORPTION OF BONE TISSUE IN RHEUMATOID ARTHRITIS**

V. Aleksandrov1, A. Aleksandrov1, 2. Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Volograd, Russian Federation

**Objectives:** to study the role of type 3 angiopoietin-like protein (ANGPTL3) in the development of osteoporotic processes associated with inflammation in rheumatoid arthritis (RA).

**Methods:** 88 patients with RA were examined (women - 100%, average age - 54.2 ± 12 years old, disease duration - 11.2 ± 8 years, positive for rheumatoid factor (RF-IgM) - 72.7%, positive for anti-citrullinated protein antibody (ACP) - 67%), DAS28 activity: remission - 21.6%, minimal - 11.4%, medium - 59.1%, high - 7.9%, functional class: 0 - 11%, I - 25%, II - 65.9%, III - 8%). The study was conducted on a bone X-ray densitometer LUNAR DPX (GE USA). Most of the patients (96.6%) were residents of cities, and 67 (76.1%) people lived in the metropolis (number of inhabitants more than 1 million people).

The concentration of ANGPTL3 in serum was determined by enzyme immunoassay using a commercial test system "Human Angiopoietin-like Protein 3 ELISA" (BioVendor).

**Results:** Osteoporosis is found in 52 (59%) people. Increased ANGPTL3 values (> 445 ng/ml) were determined in 80.7% of cases. A significant positive correlation was found between the level of ANGPTL3 and the age of patients (r = 0.23, p = 0.032), the functional class (r = 0.214, p = 0.046), presence of osteoporosis (r = 0.36, p = 0.039), living in the metropolis (r = 0.214, p = 0.046) and smoking (r = 0.31, p = 0.036), as well as a negative relationship with the duration of walking per day (r = -0.314, p = 0.003) and weekly (r = -0.319, p = 0.002) was determined. The level of ANGPTL3 correlated with the activity of RA calculated by the DAS28-ESR index (p = 0.003), but not by the DAS28-CRP index (p = 0.037).

It is noteworthy that ANGPTL3 is closely related to changes in bone mineral density (BMD) in the femoral neck (BMD Total: r = -0.33, p = 0.042; BMD Troch: r = -0.36, p = 0.036; BMD Wards: r = -0.44, p = 0.009), but not in the spine (L1-L4) (p < 0.05). The lack of connection of ANGPTL3 with ACPA (p = 0.126) may indicate different mechanisms of influence on systemic BMD in patients with established RA.

**Conclusion:** ANGPTL3 can be used as an indicator of pathological processes associated with rheumatoid inflammation and the development of osteoporosis. Living in a metropolis, smoking and low physical exertion has an additional negative effect on resorptive processes in bone tissue in women with active RA.

**AB0080 A SYSTEM-LEVEL APPROACH IDENTIFIES A CRITICAL REGULATOR OF CHONDROSARCOMA PROGRESSION**

H. Kim1, Y. Cho2, J. H. Kim1 1. Seoul National University, Department of Biological Sciences, College of Natural Sciences, Seoul, Korea, Rep. of (South Korea)

**Background:** Chondrosarcomas are cartilaginous tumors that constitute one-third of skeletal system cancers. Chondrosarcomas are capable of transitioning to highly metastatic and treatment-refractory states, resulting in significant patient mortality. However, the molecular events accompanying this behavior remain unknown.

**Objectives:** We aimed to uncover the molecular pathway underlying such tumor progression that confers a higher malignancy to chondrosarcoma.

**Methods:** We conducted unsupervised gene co-expression network analyses using transcriptomes of patients with chondrosarcoma and extracted a characteristic transcription network underlying chondrosarcoma malignancy. By implementing a system-level upstream analysis of this gene network, we identified the transcriptional factor as a key regulator governing chondrosarcoma progression. We unraveled the functional roles of the identified factor in promoting tumor growth and metastasis of chondrosarcomas in the context of their unique microenvironments.

**Results:** By conducting system-level upstream analysis, we identified a factor as a transcriptional regulator that governs the malignancy gene module. The identified factor was upregulated in chondrosarcoma biopsies associated with a high histological grade and conferred chondrosarcoma cells invasiveness and tumor-initiating capacity. In an orthotopic xenograft mouse model, the identified factor modulated local outgrowth and pulmonary metastasis of chondrosarcoma. Pharmacological inhibition of the identified factor in conjunction with the chemotherapy agents such as cisplatin or doxorubicin synergistically enhanced chondrosarcoma cell apoptosis and abolished malignant phenotypes of chondrosarcoma in mice.

**Conclusion:** Our study provides a proof of concept evidence that inhibiting the identified factor suppresses progression of chondrosarcoma and improves the efficacy of chemotherapy in cellular and pre-clinical levels. Taken together, we believe that our findings provide novel molecular insights for the development of new anti-cancer therapies to target chondrosarcomas.

**AB0081 THE ROLE OF LOCAL BISPHOSPHONATES IN THE PRESERVATION OF THE BMD IN THE ZONE OF SURGICAL BONE DEFECT (ANIMAL STUDIES)**

A. Torgashin1, S. Rodionova2, A. Torgashina2 1. National Medical Research Center of Traumatology and Orthopedics named after N. N. Pirogov, Moscow, Russian Federation; 2. Research Institute of Rheumatology named after V.A. Nasonova, Moscow, Russian Federation

**Background:** One of the reasons for failures in Arthroplasty is the preservation in the postoperative period in the bone adjacent to the implant of the prevalence of resorption over bone formation. The possibility of inhibition of resorption by bisphosphonates, including their local use in the composition of the biocomposite material, aggravates the situation due to the simultaneous oppression of bone formation. A low level of remodeling in these cases leads to a further loss of bone mass in the intervention zone.

**Objectives:** To evaluate in the experiment the effect of bisphosphonates in the biocomposite material on the bone mass both in the surgical intervention zone and in the segment as a whole.

**Methods:** The study was conducted as a comparison with the control. 60 females of white non-linear rats, body weight 130-150g, were divided into 6 groups. In 3 groups, the defect of the tibia was filled with a biocomposite material in the form of a gel (patient No. 2325170) connected to various bisphosphonates Ibandronic acid (Bonviva), zolendronic acid (Aklasta), alendronate sodium (Fosamax) was used in conjunction with a non-demineralized lyophilized bone implant. Groups, the defect was filled with a non-demineralized lyophilized bone implant with biocomposite material without bisphosphonate, in the second control group, non-demineralized lyophilized bone implants without biocomposite material in tretey-defect is not filled.

**Assessment of bone mineral density (BMD) in the intervention area and in the segment as a whole was performed using X-ray densitometry (Hologic, Small Animals Program Performing and Analyzing Small Animal Studies).**

**Results Comparison (simple dispersion analysis) of the MIC of all groups using an X-ray densitometer LUNAR DPX (GE USA).**

**DOI:** 10.1136/annrheumdis-2020-eular.5305
biphosphonates on the one hand, with the MIC of all control groups on the other hand, revealed significant differences (p < 0.002).

Results: The analysis, using the paired t-test, the average MIC values in the combined group using biphosphonates and the pooled control group, confirmed that the BMD in the zone of intervention in the biphosphonate group was significantly higher than in the control: 0.320 ± 0.008 g / cm2, respectively, versus 0.285 ± 0.019 g / cm2 (p = 0.002). If the group was excluded from the analysis, where the def was not filled, the tendency to differences remained: 0.320 ± 0.008 g / cm2 vs. 0.308 ± 0.002 g / cm2 (p = 0.11).

Mean BMDs of the whole segment with the use of biphosphonates also proved to be significantly higher than in the control, both with the inclusion in the analysis of the group without replacement of the defect, and with its exclusion. Thus, when all control groups were included in the analysis, the mean MIC values in the group with biphosphonates were 0.30 ± 0.01 g/cm2, 0.272 ± 0.12 g/cm2 (p <0.001). When excluding from the analysis of the group without replacement of the defect, the MIC values were respectively: 0.307 ± 0.01 g/cm2 versus 0.285 ± 0.01 g/cm2 (p = 0.01).

Conclusion: Relative to the control, an increase in BMD in the group using biphosphonates excludes the possibility of their negative impact on the process of bone formation. The marked positive bone balance confirms the ability of biphosphonates to maintain the remodeling mechanism at the physiological level.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

AB0082 INHIBITION OF TGFβ SIGNALING USING SB-505124 BLOCKS TH17 DIFFERENTIATION AND RESTORES THE TH17/TREG BALANCE IN VIVO, BUT DOES NOT SUPPRESS EXPERIMENTAL ARTHRITIS

J. Aarts1, A. Van Caam2, M. Helsen2, B. Walgreen2, E. Vitters2, F. Van de Lok2, P. Van Der Leen2, P. Van Der Knaan3, M. Koenders2. Radboud University Medical Center, Experimental Rheumatology, Nijmegen, Netherlands; 2Radboud University Medical Center, Experimental Rheumatology, Nijmegen, Netherlands; 3Radboud University, University Medical Center, Nijmegen, Netherlands

Background: TGFβ is an important growth factor that promotes the differentiation of T helper 17 (Th17) as well as regulatory T-cells (Treg). Due to its dual role, the potential of TGFβ as therapeutic target is unclear.

Objectives: In this study we aimed to investigate the effect of inhibition of TGFβ signaling with the ALK5 inhibitor SB-505124 on human Th17 differentiation in vitro, on cytokine production by human rheumatoid arthritis (RA) synovial explants, and study the effects of local SB-505124 treatment in vivo during innate immune and Th17-driven experimental arthritis models.

Methods: Magnetic sorted naïve human T cells were differentiated into Th17 cells with CD3/CD28 activation beads, IL-2, TGFβ, IL-1β, IL-23, antiNFκB and ol-I-4 for 6 days. Human RA synovial biopsies were cultured for 24h w/o 5μM SB-505124, and supernatant was analyzed by Luminex. T-cell independent SCW arthritis and Th17-driven IL-1/mBSA arthritis were induced in C57Bl6, and mice were treated with SB-505124 by daily i.n.-articular injections from day 0-4.

Results: SB-505124 potently reduced human Th17 differentiation in vitro by decreasing IL-17 and RORγt gene expression and IL-17 protein production. SB-505124 significantly suppressed IL-6 and TNFα protein production by human RA synovial explants. In addition, SB-505124 efficiently inhibited acute joint inflammation during SCW-arthritis (T-cell independent model). Interestingly, SB-505124 reduced Th17 levels in draining lymph nodes (dLN) during IL-1/mBSA arthritis while increased levels of Tregs were observed. Surprisingly, despite this skewed Th17/Treg balance, this did not result in suppression of joint inflammation and destruction in this Th17-driven arthritis model, whereas anti-IL-17 antibody treatment showed significant therapeutic effects.

Conclusion: We revealed suppressive effects of SB-505124 on human Th17 differentiation and the Th17/Treg balance in arthritic mice. However, SB-505124 did not suppress joint inflammation and destruction. This indicates that despite the importance of TGFβ in Th17 differentiation, targeting TGFβ signaling is not enough to suppress experimental arthritis.

AB0083 STUDY OF THE ROLE OF ANGIOPOIETIN-LIKE PROTEIN TYPE 4 IN METABOLIC DISORDERS CAUSED BY INFLAMMATION IN RHEUMATOID ARTHRITIS

A. Aleksandrov1,2, V. Aleksandrov1,3, L. Shilova1. Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russian Federation; 2Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation

Background: Previous studies of co-expression profile of receptors to tumor necrosis factor alpha (TNF) in rheumatoid arthritis (RA) have revealed a number of indicators associated with diseases activity with 93% sensitivity and 90% specificity. However, the ratio of receptors to cytokines remains poorly understood. However, the question of therapy effect and its effectiveness in various alteration of cytokine receptors balance remains under investigation.

Objectives: To evaluate the dynamics of co-expression and quantitative expression of type 1 and 2 receptors for TNF in the subpopulations of CD3+CD8+ cells associated with changes in disease severity before and after effective basic therapy.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.4558

AB0084 TNF RECEPTORS PROFILE CHANGES ON CYTOTOXIC T CELLS SUBSETS IN RHEUMATOID ARTHRITIS ARE ASSOCIATED WITH EFFECTIVE TREATMENT

A. Alshevskaya1,2, J. Lopatnikova1, J. Zhukova1, F. Kireev1, O. Chumasova1, N. Shkarub1, A. Sizikov1, V. Gladkikh2,3, S. Senikov1,2. Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russia Federation; 2Biostatistics and Clinical Trials Center, Novosibirsk, Russian Federation; 3Novosibirsk State University, Novosibirsk, Russian Federation

Background: Previous studies of co-expression profile of receptors to tumor necrosis factor alpha (TNF) in rheumatoid arthritis (RA) have revealed a number of indicators associated with diseases activity with 93% sensitivity and 90% specificity. However, the ratio of receptors to cytokines remains poorly understood. However, the question of therapy effect and its effectiveness in various alteration of cytokine receptors balance remains under investigation.

Objectives: To evaluate the dynamics of co-expression and quantitative expression of type 1 and 2 receptors for TNF in the subpopulations of CD3+CD8+ cells associated with changes in disease severity before and after effective basic therapy.
Methods: Subanalysis of patients with high disease activity level successfully treated with methotrexate and oral glucocorticoids (n = 9) was performed. As a control group, we used data from 43 healthy donors, comparable by sex and age distribution. Subpopulations of cytotoxic T cells were studied, which were included in the final diagnostic models for differentiating different degrees of severity of RA: naïve T cells and memory T cells. The dynamics of changes in the indicators of receptors number and proportion of cells expressing the corresponding receptor were compared.

Results: For naïve cytotoxic T cells, the main revealed feature was the relative stability of the number of expressed receptors (both TNFR1 and TNFR2), regardless of the therapy, while this number did not significantly differ from healthy ones for TNFR1 and was significantly lower for TNFR2 (p < 0.05 for all three fractions).

At the same time, in terms of cell percentage, on the contrary, the therapy led to a change in total proportion of TNFR1+ cells closer to healthy donors indicators, and the proportion of TNFR2+ cells in the opposite direction.

For cytotoxic T memory cells, it was demonstrated that after successful treatment a significant increase in the number of type 1 receptors was observed, with a decrease in TNFR1+ cells proportion, while these indicators were close to the values of healthy donors. At the same time, healthy donors were characterized by a significantly higher expression of type 2 receptors in terms of cell density and the proportion of TNFR2 + cells in the opposite direction.

Conclusion: The balance of TNF receptor expression on cells actively involved in immunopathological processes affects both the density distribution of receptors on cells and co-expression in a subpopulation. Effective treatment of RA in immunopathological processes affects both the density distribution of receptors. It is noteworthy that with successful therapy, a slight increase in the number of type 1 receptors was observed, with a significant increase in the number of type 2 receptors in terms of cell density and the proportion of TNFR2+ cells.

For naïve cytotoxic T cells, the main revealed feature was the relative stability of the number of expressed receptors (both TNFR1 and TNFR2), regardless of the therapy, while this number did not significantly differ from healthy ones for TNFR1 and was significantly lower for TNFR2 (p < 0.05 for all three fractions).

At the same time, in terms of cell percentage, on the contrary, the therapy led to a change in total proportion of TNFR1+ cells closer to healthy donors indicators, and the proportion of TNFR2+ cells in the opposite direction.

For cytotoxic T memory cells, it was demonstrated that after successful treatment a significant increase in the number of type 1 receptors was observed, with a decrease in TNFR1+ cells proportion, while these indicators were close to the values of healthy donors. At the same time, healthy donors were characterized by a significantly higher expression of type 2 receptors in terms of cell density and the proportion of TNFR2+ cells in the opposite direction.

Conclusion: The balance of TNF receptor expression on cells actively involved in immunopathological processes affects both the density distribution of receptors on cells and co-expression in a subpopulation. Effective treatment of RA leads to equalization of the expression profile either by the percentage of cells or by the number of receptors, approaching the indicators of healthy donors, but not simultaneously.

AB0085 MODULATION OF CIRCULATING SKELETAL STAMINAL CELLS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOFACITINIB

C. Barbati1, F. R. Spinelli2, C. Garuti2, I. Duca2, F. Ceccarelli2, T. Colasanti2, M. Vomero2, C. Alessandrini2, G. Valesini2, F. Conti2, 1Sapienza Università di Roma, Roma, Italy; 2Sapienza Università di Roma, Roma, Italy

Background: Rheumatoid arthritis (RA) is an autoimmune systemic inflammatory disease characterized by chronic synovial inflammation resulting in bone damage and erosions, with consequently functional disability. Currently, attempts for regenerative therapies for osteo-cartilage pathologies have proved unsuccessful. Recently, a “pool” of skeletal stem cells (hSSCs: human skeletal stem cells) able to generating bone cells, has been identified in human bone (1).

Objectives: In light of these observations, we aim at characterizing skeletal stem cells in peripheral blood from RA patients candidate to Tofacitinib treatment.

Methods: In this pilot study 4 RA patients [4F; mean age 65 years; mean disease duration 19 years] candidate to Tofacitinib treatment and 4 healthy donors (HD), matched by gender and age, were enrolled. Blood samples were collected from each subject of the study, at baseline (T0) and for RA patients, after 1 month of Tofacitinib (T1), to evaluating hSSC (CD45-, CD146-, CD73+, PDPN+, CD164+) by flow cytometry. For this purpose, we performed on whole blood a negative magnetic selection for CD45 cells. Then, the eluate was labeled with antibodies anti CD146-PE, anti CD73-APC, anti CD164 - FITC and anti-Podoplanin (PDPN) PerCP/Cyanine5.5. The acquisition was performed using a FACS Calibur, which included 100,000 events per sample (Figure 1).

Results: The hSSCs percentage was significantly lower in RA patients than in HD (p = 0.0286). At T1, after treatment with Tofacitinib, mean hSSCs percent-age significantly increased from 1.8% to 4.2% (p = 0.016 vs RA T0) (Figure 2A). Correlation analysis showed a significant indirect relation between the percentage of hSSC and disease activity measured by DAS28ESR, SDAI and CDAI (Figure 2B).

Conclusion: The results of this study demonstrate, for the first time, circulating skeletal stem cells and their reduced expression in active RA patients. Tofacitinib treatment leads to a significant increase in hSSC percentage. This evidence opens up new perspectives on bone repair mechanisms and on deepening of current therapeutic strategies.

References:
screen the degree of normal, atrophic and hypertrophic based on the morphometry if muscle fibers. Values are compared to area and shape of control (healthy) fibers. Frequency analysis and Pearson Correlations were used and statistical significance was considered as p<0.05.

**Results:** We found 1.5% atrophic muscle fibers in control animals. Mild CIA showed the same atrophic muscle fibers percentage compared to control. However, severe CIA showed 11.8% of atrophic muscle fibers. Decrease muscle strength in CIA over time were associated with a greater atrophic muscle fiber proportion (p=0.8, p=0.021) and increased disease score (p=0.8, p=0.019).

**Conclusion:** Here we developed a new, objective method applied to screen for muscle quality through the morphometry of muscle fibers. Muscular Morphometric Analysis (MusMA) has potential to be used in combination with clinical parameters in several human pathophysiological analysis. Besides, that we can speculate that although muscle strength is associated with atrophic cell percentage, loss of strength does not only depend of atrophy, but disease activity also seems to influence muscle strength reduction.

**AB0087 FEATURES OF ANTIPHOSPHOLIPID ANTIBODIES SPECTRUM IN PATIENTS WITH RHEUMATOID ARTHRITIS**

N. Bashliakova¹, T. Tyabut², A. Buglova³, A. Trusthyna³. ¹Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus; ²Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus; ³Belarusian State Medical University, Minsk, Belarus

**Background:** Currently, some data have been accumulated on the participation of antiphospholipid antibodies (aPL) in the development of thrombotic complications in patients with autoimmune rheumatic diseases (ARD), in particular, in patients with systemic lupus erythematosus (SLE). The most studied aPL in this pathology are IgG and IgM antibodies to cardiolipin (aCL), anti-β2-glycoprotein 1 antibodies (aβ2-GP 1), lupus anticoagulant (LA). The participation of IgG and IgM antibodies to prothrombin (aPT) and to annexin V (aAnV), antibodies to oxidized low density lipoproteins (aOxLDL) in hypercoagulation and the development of thrombosis is also discussed. However, the studies focusing on the investigation of aPL in patients with rheumatoid arthritis (RA) are few.

**Objectives:** To estimate the levels and the frequency of occurrence of aPL in patients with RA in comparison to the SLE patients and the control group.

**Methods:** The study included 85 female patients with ARD (RA (n=45), mean age 43.0 (33.0; 52.0) years old, disease duration 9.0 (5.0; 13.0) years, disease activity (DAS28= 5.37 (4.69; 5.89) points) and SLE (n=40), mean age 33.5 (27.5; 44.5) years old, disease duration 8.0 (5.0, 14.5) years, disease activity SLE-DAS28= 5.37 (4.69; 5.89) points). Fifty four healthy women (mean age 38.5 (35.0; 46.0) years old) formed the control group.

The levels of antiphospholipid antibodies (IgG/IgM aCL, aβ2-GP 1, aAnV and aPT, aOxLDL) were determined with ELISA according to the instruction of a manufacturer. LA was determined by one-stage clotting assay using reagents for screening and conformation (Technoclot LA Screen and Technoclot LA Confirm, Austria).

**Results:** The frequency of occurrence of elevated levels of all investigated aPL in patients with RA was similar to SLE patients and was revealed in 57.8% of cases for IgG/IgM aCL, 44.4% for IgG/IgM aβ2-GP-1, 26.7% for IgG/IgM aAnV, 8.9% for aPT, 52.6% for LA, 64.4% for aOxLDL. The patients with SLE had an increased levels of IgG/IgM aCL in 60.0% of cases, IgG/IgM aβ2-GP-1 in 57.5%, IgG/IgM aAnV in 15.0%, IgG/IgM aPT in 175.5%, high levels of LA in 68.8%, of IgG aOxLDL – in 80.8% of cases. The control group had a high levels of IgG/IgM aCL in 1.8%, IgG/IgM aβ2-GP-1 in 3.7%, IgG/IgM aAnV in 5.6%, IgG/IgM aPT in 1.8%, high levels of IgG aOxLDL – in 42.6% of cases. None of the controls had an increased level of LA. The frequency of occurrence of elevated levels of aPL and their mean levels in both groups of patients with ARD was higher as compare to the control group (p<0.05).
The mean levels of IgG a2-GP-1, LA, aOxLDL in SLE patients and mean levels of LA, aOxLDL in RA patients were above standard values but were similar in both groups. Moreover, the mean levels of IgG a2-GP-1, IgG IgM a2-V and aPT were comparable in patients with SLE and RA. However, the mean levels of IgG a2-GP-1 in RA patients was higher than in SLE patients. This may indicate an increased autoimmune activity.

Simultaneous elevation in four types of aPL levels was observed in 4.4% patients with RA, in 2.5% - with SLE; simultaneous elevation in three types of aPL was revealed in 11.1% patients with RA, in 17.5% - with SLE; two types of aPL were increased in 35.6% patients with RA and 27.5% - with SLE. Only one type of elevated aPL levels (12.9%) was indentified in the control group.

**Conclusion:** Thus, patients with RA are characterized by a wide range of aPL. Qualitative and quantitative changes in the levels and types of autoantibodies in patients with RA have been established similar to those in SLE patients.

In patients with autoimmune rheumatic pathologic, the presence of simultaneously elevated several types of aPL have been proved.

**N6-METHYLADENOSINE-MODIFIED CIRC_0088194 PROMOTES MIGRATION AND INVASION OF RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES THROUGH MIR-766-3P/MMP2 AXIS**

Y. Cai1,2, M. Yang3, Q. Ouyang4, Q. Huang5, R. Liang5,1. 1Nanfang Hospital, Southern Medical University, Department of Rheumatology and Immunology, Guangzhou, China; 2Southern Medical University, Guangzhou, China; 3Nanfang Hospital, Southern Medical University, Department of Rheumatology and Immunology, Guangzhou, China; 4Nanfang Hospital, Southern Medical University, Department of Rheumatology and Immunology, Guangzhou, China

**Background:** Circular RNAs (circularRNAs) participate in the initiation and progression of various diseases by miRNA sponges including postmenopausal osteoporosis[1], bladder cancer[2], and osteoarthritis (OA)[3]. However, the activity of circularRNAs as “miRNA sponges” in rheumatoid arthritis (RA) has not been studied.

**Objectives:** To investigate whether circularRNA acts as competing endogenous RNA to regulate pathological processes of RA, and whether the N6-methyladenosine (m^A^) modification affects Circ_0088194 stability in RA fibroblast-like synovocytes (RA-FLSs).

**Methods:** CircularRNA microarray analysis was conducted to characterize the expression profiles of circularRNAs in 3 RA-FLSs and 3 osteoarthritis fibroblast-like synovocytes (OA-FLSs). Methylated RNA immunoprecipitation was performed to validate the level of m^A^ modification on Circ_0088194 in RA-FLSs and OA-FLSs. Dual-luciferase reporter assay, bioinformatics analysis, protein array analysis, and fluorescence in situ hybridization were employed to evaluate the interaction between Circ_0088194 and miR-766-3p, and between target miR-766-3p and matrix metalloproteinase 2 (MMP2).

**Results:** Overexpression of Circ_0088194 promoted the migration and invasion of RA-FLSs and increased MMP2 expression. The expression and function of miR-766-3p were inversely correlated with Circ_0088194, which sponged miR-766-3p to upregulate MMP2 expression. Although m^A^ modification of Circ_0088194 exists in RA-FLSs and OA-FLSs, their level did not differ.

**Conclusion:** This study presents an important role of this novel circularRNA as a sponge of miR-766-3p to promote RA-FLS migration and invasion by targeting MMP2. However, the modification might not affect Circ_0088194 stability in RA-FLSs and OA-FLSs. Therefore, Circ_0088194 may contribute to RA development and represent as an auspicious therapeutic target.

**DEATH RECEPTOR 3 REGULATES THE GENE EXPRESSIONS OF VARIOUS KEY MOLECULES IN RHEUMATOID SYNOVIAL FIBROBLASTS**

K. Fukuda1, Y. Miura1,2, S. Hayashi1, T. Maeda1, R. Kuroda1. 1Kobe University Graduate School of Medicine, Department of Orthopaedic Surgery, Kobe, Japan; 2Kobe University Graduate School of Health Sciences, Division of Orthopaedic Surgery, Department of Rehabilitation Science, Kobe, Japan

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease that causes hyperplasia of synovial tissue. Death receptor 3 (DR3) is a tumor necrosis factor receptor and binds to TL1A, a member of the TNF family. DR3 is involved in the mechanism of cell proliferation and apoptosis through NF-kappab signaling. Suppression of DR3 in rheumatoid synovial fibroblasts (RA-FLS) is associated with hyperplasia of rheumatoid synovial tissue [1]. We previously revealed the expression profiles regulated by TL1A, suggesting that TL1A might affect the pathogenesis of RA, including proliferation, regulation of B cells and T cells, inflammation, and cytokine processing [2].

**Objectives:** In this study, we investigated the gene expression profiles regulated by DR3 in RA-FLSs to reveal how DR3 is involved in the pathogenesis of RA.

**Methods:** RA-FLSs were from patients with RA. Four individual lines of primary cultured RA-FLSs were incubated either with 1000ng/ml of human DR3-Fc
protein or 1000ng/ml of human IgG1 as a control for 12h. Gene expressions were detected by microarray assay.

**Results:** Microarray data analysis revealed that DR3 up-regulated or down-regulated the expression of various genes in RA-FLS (Figure). The function of regulated genes included protein-l-isoaspartate (D-isoaspitate) O-methyltransferase activity, carboxyl-O-methyltransferase activity, protein carboxyl O-methyltransferase activity, regulation of cilium assembly, O-methyltransferase activity, regulation of plasma membrane bounded cell projection assembly, regulation of cell projection assembly, regulation of organelle assembly, protein methyltransferase activity, and S-adenosylmethionine-dependent methyltransferase activity. The most up-regulated 2 genes by DR3 were KIAA1109 (KIAA1109), and adhesion G protein-coupled receptor A3 (ADGR3). The most down-regulated 2 genes by DR3 were RNA exonuclease 2 (REXO2), and family with sequence similarity 120A (FAM120A).

**Conclusion:** In this study, we first revealed the expression profiles of genes regulated by DR3 in RA-FLS. KIAA1109/TENR1/L2L21 gene is strongly associated with RA in European descent populations [3]. ADGRA3 is a member of G protein-coupled receptors (GPCRs). GPCRs associates with the regulation of cytoskeletal organization, the cell adhesion and migration, cell proliferation and apoptosis, and cell differentiation [4]. Loss of REXO2 affects cell growth and morphology [5], and REXO2 was identified as a target gene for inflammatory bowel disease-associated variants [6]. FAM120A regulates activity of Src kinase to protect cells from oxidative stress-induced apoptosis [7]. DR3 regulates the gene expressions of various key molecules in RA-FLS and may affect the pathogenesis of RA by regulating gene expression of RA-FLS.

**PD-1 AND GAL3 REGULATE OSTEOCLAST DEVELOPMENT IN RHEUMATOID ARTHRITIS**

S. R. Greisen1,2, M. A. Nielsen1,2, M. Hvid1, B. Deleuran1,2, Aarhus University, Dept of Biomedicine, Aarhus, Denmark; Aarhus University Hospital, Dept of Rheumatology, Aarhus, Denmark; Aarhus University, Dept of Clinical Medicine, Aarhus, Denmark

**Background:** Bone erosions in rheumatoid arthritis (RA) is a major complication. Despite improved treatment, erosions still occur and progress. Therefore, a continuous investigation of the interplay between bone regulation and immune activity is needed.

**Co-inhibitory receptors, like CTLA-4, participate in modulating osteoclast activity1,** and blocking these receptors in cancer treatment results in autoimmune disease2. Programmed death 1 (PD-1) is a central co-inhibitory receptor, also associated with RA in European descent populations [3]. ADGRA3 is a member of G protein-coupled receptors (GPCRs). GPCRs associates with the regulation of cytoskeletal organization, the cell adhesion and migration, cell proliferation and apoptosis, and cell differentiation [4]. Loss of REXO2 affects cell growth and morphology [5], and REXO2 was identified as a target gene for inflammatory bowel disease-associated variants [6]. FAM120A regulates activity of Src kinase to protect cells from oxidative stress-induced apoptosis [7]. DR3 regulates the gene expressions of various key molecules in RA-FLS and may affect the pathogenesis of RA by regulating gene expression of RA-FLS.

**Conclusion:** In this study, we first revealed the expression profiles of genes regulated by DR3 in RA-FLS. **FIBRIN ADHESION IS A PANNUS-INDEPENDENT MECHANISM OF CARTILAGE DEGENERATION IN RHEUMATOID ARTHRITIS**

T. Hügel1, S. Nasif2, D. Ehrlich1, A. So1, N. Busso2, University Hospital Lausanne (CHUV), Lausanne, Switzerland; University Hospital Münster, Institute of Musculoskeletal Medicine, Münster, Germany; University Hospital Lausanne (CHUV), Rheumatology, Lausanne, Switzerland

**Background:** Current concepts of cartilage destruction in inflammatory arthritis include pannus infiltration by inflamed synovial tissue as well as direct detrimental effects of inflammatory cytokines and proteinases. Fibrin maintains chronic inflammatory processes in arthritis but has never been shown to be directly involved in cartilage damage occurring in rheumatoid arthritis (RA).

**Objectives:** To investigate fibrin-mediated cartilage degradation and the possible underlying mechanisms in arthritis.

**Methods:** Human cartilage samples were obtained from patients with RA undergoing joint replacement and investigated by H.E. and immunohistochemistry for cartilage damage and fibrin deposition. Cartilage explants from RA patients were incubated in vitro with autologous synoviocytes and assessed by immunohistochemistry for cell-adhesion and colocalization with fibrin. Experimental RA was studied in the RA murine model of adjuvant-induced arthritis (AIA), in wildtype (WT) and fibrinogen deficient (Fgα−) mice. Cartilage damage and chondro-synovial adhesion were analyzed by safranin-O staining and fibrin deposition by immunohistochemistry. Fibrinogen expression (Fgα, Fgβ, Fgγ) was studied in murine primary chondrocytes by qRT-PCR. Cartilage explants were stained with alizarin-red staining and assessed for colocalization of calcific deposits and fibrin. Calcification of murine primary chondrocytes stimulated with secondary calciprotein particles (CPP) and treated with purified human plasma fibrinogen (100 µg/ml) was assessed by alizarin red staining and gene expression for chondrocyte differentiation (Agg, Coll2, Coll10, Sox9, Runx2), calcification (Alp1, Ank, Anx5, Ptc1, Ptit, Pho2) and extracellular matrix remodeling (Adamts4, Adamts5, Mmp3, Mmp13, Comp) by qRT-PCR.

**Results:** Abundant fibrin deposition on cartilage co-localized and positively correlated with cartilage damage in knee joints of patients with RA. In the AIA model,
absence of fibrin deposition in Fg⁻⁺ mice was accompanied by significantly lower synovial inflammation, chondro-synovial adhesion and cartilage damage than in WT mice. Chondro-synovial adhesion correlated with cartilage damage in the WT and led to apparent mechanical stripping of the superficial cartilage, whilst this phenomenon was not observed in the Fg⁻⁺ mice. In vitro, autologous RA synoviocytes adhered to cartilage explants exclusively in the presence of fibrin deposition. Fibrinogen chains were not expressed by primary chondrocytes, indicating passive deposition from synovial fluid or tissue. In human RA cartilage explants, we found colocalization and a significant positive correlation between fibrin and calcific deposits. Fibrinogen caused exacerbated calcification in CPP-treated primary murine chondrocytes and induction of genes involved in chondrocyte calcification (Pc1, Pit1). Cartilage-oligomeric matrix protein (Comp) gene was also highly induced suggesting a pro-catabolic role of fibrinogen. Conclusion: Fibrin deposition is an active trigger of cartilage degeneration in RA via induction of chondro-synovial adhesion (mechanical aspect) and induction of calcification (catabolic aspect). Newer therapeutic approaches may not merely focus on fibrinolysis but protect cartilage from fibrin-induced adhesion or calcification e.g. by fibrin-targeted immunotherapy.

FUNCTIONAL TREG CELLS MAY BE CONVERTED INTO T EFFECTOR PHENOTYPE ON EXPOSURE TO INFLAMMATORY MILIEU IN RHEUMATOID ARTHRITIS (RA) SYNOVIAL FLUID: IN-VITRO STUDY

V. Kommoju, C. Kavadichandra, V. Negi, Jawaharial Institute of Postgraduate Medical Education and Research, Clinical Immunology, Puducherry, India

Background: The debate on functional versus numerical difference in T regulatory cell population among patients with Rheumatoid arthritis (RA) is not clear. Tregs expressing Inflammatory subset phenotype markers, such as Th1(cxcr3, Tbet) and Th17(ccr6, Rorγ) are reported. Though the reported numbers of synovial fluid tregs are higher in RA, the fate of Tregs on entering the inflammatory milieu from peripheral blood (PB) has not yet been investigated.

Objectives: To compare Treg frequencies in PB and synovial fluid between osteoarthritis (OA) and RA.

Methods: The study included 30 patients with RA which fulfilled RA classification criteria from 2010, 26 patients with osteoarthritis (OA) and 24 healthy controls. All participants were genetically analyzed for the presence of PG by Chelex®100 method and polymerase chain reaction (PCR), by isolating amplified sequences of DNA in a sub gingival biofilm taken from the deep periodontal pockets. The presence of anti CCP and anti MCV autoantibodies was detected in the sera of RA patients with ELISA test.

Results: The average ages of the patients in the 3 groups were as follows -51 years for RA, 52 for OA and 58 years for HC. Seventy two percent of RA patients were females. Significantly higher levels of PG were found in the periodontal pockets of RA patients. Eighty percent of RA patients (80% or 24 RA patients) were PG positive in comparison with 35% of OA patients and 2% healthy controls. Of the PG-positive RA patients, 83% had positive and 17% had anti-CCP negative test, while of the PG-negative patients, a positive anti-CCP test was present in 33% and a negative anti-CCP test was present in 67%. Accordingly, in PG-positive RA patients positive anti-MCV test was present in 79% and negative anti-MCV test was present in 21%, and in PG-negative RA patients anti-MCV test was positive in 17% and negative in 83% patients.

To compare cytokine levels in PB and SF between OA and RA

To study the effect of autologous synovial fluid on RA and OA Treg isolated from peripheral blood

Methods: The Peripheral Blood (PB) and synovial fluid (SF) of RA (n=80) and OA (n=30) patients were analyzed for CD4+T-cell subset frequencies and phenotypes by flow cytometry. Cytokine concentrations in plasma and SF were measured by cytometric bead array. Tregs from 5 RA-PB and 5 OA-PB were isolated and cultured in autologous synovial fluid for 24 hrs. Phenotypic expression of Th1 and Th17 chemokines on the cell surface were analyzed by flow cytometry and expression levels of T-bet, RORγ and FOXP3 in those Treg cells were measured with quantitative real-time PCR (RT-qPCR).

Results: The PB and SF frequencies of Th1, Th17 and Tregs are shown in Table 1. The pro-inflammatory cytokines were high in the plasma and SF of RA but the anti-inflammatory cytokines were similar (Fig 1A&B). Treg cells were isolated from RA and OA PB and cultured in autologous SF for 24 hrs. RA Treg showed increased cell surface expression of CCR3+ and CCR6+ (Fig 1C) and there was no difference in OA Treg. Gene expression studies showed an increased expression of T-bet, RORγ and decreased expression of FOXP3 in RA Tregs while there was no difference in OA Tregs before and after in-vitro culture (Fig 1D).

*p<0.05

Conclusion: Tregs in RA may be converted to Th1 and Th17 phenotype on exposure to inflammatory cytokine in the synovial fluid, thus losing their regulatory functions. Understanding factors influencing stability of Treg cells may help improve future therapeutics.

FCER1G MINE METYLATION AND MIR-106/MIR-17 AS A NEW POTENTIAL EPICERNE MARKERS IN RHEUAMATOID ARTHRITIS

M. Ciesla1, B. Kolarz1, M. Dryglewskwa, M. Majdan2. 1University of Rzeszow, Faculty of Medicine, Rzeszow, Poland; 2Medical University of Lublin, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that leads to joint destruction. One of the most important cytokine responsible for this process is interleukin 6 (IL-6). Fc receptor gamma chain (FCGr), encoded by FCER1G gene, is responsible for neutrophils activation, phagocytosis, cell surface signaling pathway as well as IL-4, IL-6, IL-10 and tumor necrosis factor production. Epigenetic factors, including DNA methylation and micro-RNAs (miRs) expression regulate the genes expression on transcriptional and post-transcriptional mechanisms. There are miRs responsible for cytokines production, for example GU rich miRs, miR-106b and miR-155 were reported as associated with IL-6 overproduction.

Objectives: The aim of our study was to evaluate FCER1G gene methylation and miR-17 family markers as epigenetic markers associated with RA, disease activity and IL-6 expression.

Methods: Bioinformatics analysis were applied to select the miRs with a possible target sites in a promoter region of FCER1G gene. The MR-17 family members, including miR-17, miR-93 and miR-106b were selected for investigation. A total of 74 individuals, 50 RA patients, 84% female, aged 53±12.3 years (mean±SD) and 24 healthy controls (HC), 87.5% female, aged 53±8,49 years were enrolled. RA patients were selected based on DAS-28 scoring. RA patients with high disease activity (DAS28 >5.1, 58%) and remission (≤2.6, 42%) were included in the analysis. DNA was extracted from a whole blood and miRs were extracted from plasma. Quantitative real-time PCR was used for analyze both methylation and expression levels.

**AB0095**

PRECLINICAL CHARACTERIZATION OF CJ-15314, A HIGHLY SELECTIVE JAK1 INHIBITOR, FOR THE TREATMENT OF AUTOIMMUNE DISEASES

S. Y. Ki1, H. Shin1, Y. Lee1, H. R. Bak2, H. Yu1, S. C. Kim1, J. Lee1, D. Kim1, D. H. Ko1, D. Kim1. 1CJ Healthcare, R&D Center, Seoul, Korea, Rep. of (South Korea)

Background: Janus kinases (JAK1, JAK2, JAK3, and TYK2) play critical roles in mediating various cytokine signaling, and has been developed as a target for autoimmune diseases such as RA. Tofacitinib, oral Pan-JAK inhibitor, demonstrated efficacy in RA patients, but its widespread use is limited by safety issues. Baricitinib, JAK1/2 inhibitor, is also known to interfere with the hematopoiesis system, such as anemia and thrombocytopenia associated with suppression of JAK2 signals. Therefore, it is necessary to develop a new potent compound that selectively inhibits JAK1 over JAK2.

Objective: To identify the pharmacological based on efficacy of CJ-15314 as potent and selective JAK1 inhibitor for treatment of autoimmune disease.

Methods: In vitro, cell-based, kinase panel, KD value and human whole blood assay were performed to determine the inhibition potency and selectivity for JAK subfamily kinases. In vivo therapeutic potential was evaluated by RA model including rat Adjuvant-Induced Arthritis (AIA) and collagen-induced arthritis (CIA). To confirm the possibility of further expansion into the autoimmune disease, BioMAPS Diversity PLUS8 Panel was performed by discoverX.

**Results:** In vitro assay, CJ-15314 inhibited JAK kinase family in a concentration-dependent manner with IC50 values of 3.8 nM against JAK1, Selectivity for JAK1 over JAK2, 3 was approximately 18, 83 fold greater for CJ-15314. In 1mM ATP condition, CJ-15314 has been confirmed to have the highest JAK1 selectivity over competing drugs, under 1 mM ATP condition that reflects the physiological environment in the body. Similarly, KD values has also confirmed the selectivity of JAK1, which is 10 fold higher than JAK2. Accordingly, in human whole blood assays, CJ-15314 is 11 fold more potent against IL-6 induced pSTAT1 inhibition through JAK1 (IC50 value: 70 mM) than GM-CSF-induced pSTAT5 inhibition (JAK2) whereas baricitinib and filgotinib exhibited only 2 fold and 7 fold respectively.

In vivo efficacy model, CJ-15314 inhibited disease severity scores in a dose dependent manner. In the rat AIA model, CJ-15314 at 30 mg/kg dose showed 95.3% decrease in arthritis activity score, 51.2% in filgotinib at 30 mg/kg. 97.7% showed baricitinib at 10 mg/kg. CJ-15314 showed superior anti-arthritic efficacy than filgotinib. CJ-15314 also minimally affected anemia-related parameters but not bicitinib end of the 2-week treatment. In the rat CIA model, like 10 mg/kg of bicitinib, 30 mg/kg of CJ-15314 also has a similar effect, with a significant reduction in histopathological scores.

In biomap diversity panel, CJ-15314 inhibited the expression of genes such as MCP-1, VCAM-1, IP-10, IL-8, IL-1, sTNF-α and HLA-DR confirming the possibility of expansion into other diseases beyond arthritis.

Conclusion: CJ-15314 is a highly selective JAK1 inhibitor, demonstrates robust efficacy in RA animal model and is good candidate for further development for inflammatory diseases.

CJ-15314 is currently conducting a phase I trial in south Korea.

4. Németh T, Futosi K, Szabó M, Aradi P, Saito T, Mócsai A, Jakus Z. Important role of Malt1, the third component of the complex leading to the activation of the proinflammatory transcription factor NF-κB in lymphocytes with CARMA1 and Bcl10. Previously, we showed that the paracaspase Malt1 is a cysteine protease, which forms a myeloid equivalent of CARMA1, Card9 is important in neutrophils in Fc receptor-mediated cytokine release together with Bcl10 and Malt1. In line with these findings, we observed a significant decrease in the severity of autoantibody-triggered arthritis in the absence of Card9 and Bcl10.

Objective: Our aim was to directly investigate whether the genetic deficiency of Malt1, the third component of the complex altered the process of the K/BxN serum transfer arthritis (that resembles to the effector phase of rheumatoid arthritis).

Methods: We used wild type and Malt1−/− mice for our experiments. Autoantibody-mediated arthritis was induced by a single intraperitoneal injection of K/BxN serum transfer arthritis (that resembles to the effector phase of rheumatoid arthritis).

Results: Similar to the deficiency of the other two components of the complex, Malt1−/− mice showed a partial, but significant decrease in the macroscopic joint inflammation compared to arthritis-suffering wild type mice. The study was carried out in the presence of Malt1−/− animals as it reduced the severity of arthritis.

AB0098 TISSUE CYTOKINES AS NEW DIAGNOSTIC BIOMARKER OF BONE METABOLISM DISORDERS IN RHEUMATOID ARTHRITIS

V. Kravtsov1, L. Arefeva2, S. L3. 1Volgograd State Medical University, Volgograd, Russian Federation; 2Volgograd State Medical University, Volgograd, Russian Federation; 3Technical University of Munich, Institute of Clinical Chemistry and Pathobiocchemistry, Munich, Germany

Background: Bone mineral density and proteins/peptides determination in blood and urine as markers of bone resorption and formation are currently used to diagnose osteoporosis (OP) and metabolic bone diseases. Recent evidence suggests that in RA changes in the secretion of hormones of white adipose tissue can be revealed [1,2,3,4].

Objectives: To study the clinical and diagnostic value of serum fetuin A, nesfatin, hemerin, leptin, adiponectin, resistin, visfatin determination in RA patients complicated by OP.

Methods: We examined 88 women with documented diagnosis of RA and mean disease duration of 6.5±0.08 years. We used EULAR/ARA 2010 criteria to diagnose the patients. Female patients with II degree of disease activity (DAS28)≥3.2 were excluded. We included patients who had surgery or developed an infection within the last 8 weeks, pregnant and breast-feeding women, those with severe heart, liver or kidney disease, immune deficiency, leukopenia or chronic infection.

A control group of 45 healthy females aged of 25 and 59 years were included in the study. There were no reported findings of joint pain and RA symptoms in the group. The groups were adjusted for age (p>0.05) and showed no statistically significant differences.

We measured serum fetuin A, nesfatin, hemerin, leptin, adiponectin, resistin, visfatin levels (μg/ml) using ELISA commercial test systems. We used spectrophotometer with wavelength of 450 nm to detect the test results. Multitask immunoenzyme analyzer, Finland. We plotted a curve using computer software. We diagnosed OP using dual-energy X-ray absorptiometry with LUNAR DPX PRO (GE, USA).

Results: At the first stage, the level of pro-inflammatory cytokines was studied in a group of healthy individuals. Then, the reference values of these indicators were measured as M ± 26. Patients with OP and RA had significantly higher levels of serum pro-inflammatory cytokines (p<0.001). For example, mean serum Adiponectin levels in RA patients who had normal bone density and had no OP were 35.21±0.6 μg/ml. Mean serum Adiponectin levels in RA/OP patients with low bone mineral density were 52.42±0.69 μg/ml. Adiponectin levels of 44 μg/ml and higher were associated with osteoporosis. Adiponectin levels of 43.9 μg/ml and lower were associated with normal bone density. Other pro-inflammatory cytokines have demonstrated similar dynamics of level serum.

Conclusion: Thus, we revealed that fetuin A, nesfatin, hemerin, leptin, adiponectin, resistin, visfatin levels depend on osteoporosis presence in RA patients. The test may be used to reduce the risk of low-energy fractures and to improve the quality of life in RA.

AB0097 TISSUE CYTOKINES AS NEW DIAGNOSTIC BIOMARKER OF BONE METABOLISM DISORDERS IN RHEUMATOID ARTHRITIS

V. Kravtsov1, L. Arefeva2, S. L3. 1Volgograd State Medical University, Volgograd, Russian Federation; 2Volgograd State Medical University, Volgograd, Russian Federation; 3Technical University of Munich, Institute of Clinical Chemistry and Pathobiocchemistry, Munich, Germany

Background: Bone mineral density and proteins/peptides determination in blood and urine as markers of bone resorption and formation are currently used to diagnose osteoporosis (OP) and metabolic bone diseases. Recent evidence suggests that in RA changes in the secretion of hormones of white adipose tissue can be revealed [1,2,3,4].

Objectives: To study the clinical and diagnostic value of serum fetuin A, nesfatin, hemerin, leptin, adiponectin, resistin, visfatin determination in RA patients complicated by OP.

Methods: We examined 88 women with documented diagnosis of RA and mean disease duration of 6.5±0.08 years. We used EULAR/ARA 2010 criteria to diagnose the patients. Female patients with II degree of disease activity (DAS28)≥3.2 were excluded. We included patients who had surgery or developed an infection within the last 8 weeks, pregnant and breast-feeding women, those with severe heart, liver or kidney disease, immune deficiency, leukopenia or chronic infection.

A control group of 45 healthy females aged of 25 and 59 years were included in the study. There were no reported findings of joint pain and RA symptoms in the group. The groups were adjusted for age (p>0.05) and showed no statistically significant differences.

We measured serum fetuin A, nesfatin, hemerin, leptin, adiponectin, resistin, visfatin levels (μg/ml) using ELISA commercial test systems. We used spectrophotometer with wavelength of 450 nm to detect the test results. Multitask immunoenzyme analyzer, Finland. We plotted a curve using computer software. We diagnosed OP using dual-energy X-ray absorptiometry with LUNAR DPX PRO (GE, USA).

Results: At the first stage, the level of pro-inflammatory cytokines was studied in a group of healthy individuals. Then, the reference values of these indicators were measured as M ± 26. Patients with OP and RA had significantly higher levels of serum pro-inflammatory cytokines (p<0.001). For example, mean serum Adiponectin levels in RA patients who had normal bone density and had no OP were 35.21±0.6 μg/ml. Mean serum Adiponectin levels in RA/OP patients with low bone mineral density were 52.42±0.69 μg/ml. Adiponectin levels of 44 μg/ml and higher were associated with osteoporosis. Adiponectin levels of 43.9 μg/ml and lower were associated with normal bone density. Other pro-inflammatory cytokines have demonstrated similar dynamics of level serum.

Conclusion: Thus, we revealed that fetuin A, nesfatin, hemerin, leptin, adiponectin, resistin, visfatin levels depend on osteoporosis presence in RA patients. The test may be used to reduce the risk of low-energy fractures and to improve the quality of life in RA.

METHOTREXATE REDUCES THE INVASIVE ACTIVITIES OF PRIMARY RA SYNOVAL FIBROBLASTS

C. R. Ng1, K. Sheridan1, S. Cowley1, E. Dorris1, D. Veale2, U. Fearon3, A. G. Wilson4. 1University College Dublin, Centre for Arthritis Research, Dublin, Ireland; 2University College Dublin, Rheumatology, Dublin, Ireland; 3Trinity College Dublin, TBSI, Dublin, Ireland

Background: Rheumatoid Arthritis synovial fibroblasts (RASFs) are key player in tissue destruction via the production of a wide range of chemical reactions in the joint with high growth rate and resistance to mortality [1]. Methotrexate (MTX) is a dihydrofolate reductase inhibitor that attenuates inflammation within joints resulting in reduced cartilage and bone damage and is the anchor therapy for RA. Its mechanisms of action are thought to differ from its anti-proliferative effects and are known to include increased adenosine release (2), but may also involve alterations in intracellular methyl donor status resulting in alteration in DNA methylation and gene expression.

Objectives: To investigate the effects of MTX on RASFs auto-aggressive activities, including invasion, migration, proliferation and apoptosis.

Methods: RASF were derived from knee biopsies of RA patients taken at arthroscopy (n=9). Matrigel chambers were used to measure invasive activities. The cells were incubated with DMSO (control), 1μM or 10μM MTX for 96 hours. Wound healing (scratch assays) were used to measure migration. Proliferation and apoptosis was determined using BrdU and caspase-3/7 assays respectively. Significance was determined via repeated measures ANOVA using SPSS software.

Results: Incubation with MTX resulted in significantly reduced invasive activity compared with DMSO control; 1μM (35%, p=0.006) and 10μM (58%, p=0.002) in paired samples. However MTX did not have significant effects on RASF migration, proliferation or apoptosis at either concentration.

Conclusion: Our data reveals that MTX reduces the invasive potential of RASFs in vitro, this effect may contribute to the clinical efficacy of this agent. Further investigation will involve epigenome-wide methylation to determine if the DNA methyolome of RASFs is altered by MTX.

PHENOTYPIC AND FUNCTIONAL CHARACTERIZATION OF SYNOVAL FLUID-DERIVED FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS

D. Koster1, J. H. Egedal1, M. Hvid1, M. R. Jacobsen1, U. Müller-Ladner1, B. Deleuran1, T. W. Kråstrup2, E. Neumann2, M. A. Nielsen3, Department of Biomedicine, Aarhus University, Aarhus, Denmark; 3Internal Medicine and Rheumatology, Giessen, Germany; 1Department of Biomedicine, Aarhus University, Aarhus, Denmark

Background: Fibroblast-like synoviocytes (FLS) are central cellular components in persistent inflammatory joint diseases such as rheumatoid arthritis (RA). Pathological subsets of FLS have been identified from synovial tissue. However, the synovial tissue obtained from arthroplasty procedures is acquired at late disease stages and the cellular yield obtained from synovial tissue biopsies is fairly low. Collectively, challenging the robustness of human RA in vivo and in vitro models. FLS obtained from the synovial fluid (SF-FLS) are proposed as an alternative source of FLS, but a detailed phenotypical and functional characterization of FLS subsets from the synovial fluid has not been performed.

Objectives: The aim of this study was to determine the phenotypical and functional characteristics of synovial fluid-derived fibroblast-like synoviocytes in rheumatoid arthritis.

Methods: In the present study, paired peripheral blood mononuclear cells (PBMC) and SF-FLS from patients with RA were obtained (n=7). FLS were isolated from the synovial fluid by a strict trypsinization protocol and their cellular characteristics and functionality were evaluated at passage 4. Monocultures (SF-FLS) and autologous co-cultures (SF-FLS and PBMC) were established from five patients with RA and subsequently evaluated by flow cytometry, Western blotting and multiplex immunoassays. Human cartilage-sponges (n=3) with SF-FLS and without SF-FLS (n=3) were co-implanted subcutaneously in SCID mice (n=15), mice with only cell-free human cartilage-sponges were used as controls (n=12). After 45 days, the implants were evaluated using stained sections to determine the SF-FLS invasion score based on perichondrytic cartilage degradation. Data are expressed as median (25-75 percentile). P-values <0.05 were considered statistically significant.

Results: The homogeneous subpopulations of FLS, isolated from the synovial fluid, were negative for CD34 and CD45 [98.9%, (97.5-99.7%)] and positive for Thy-1 and PDNP [94.6%, (79.9-97.4%)]. Without stimulation, RA SF-FLS showed high and comparable levels of NFkB related pathway proteins and secreted multiple pro-inflammatory cytokines and chemokines dominated by IL-6 [2648 pg/mL, (1327-6116)] and MCP-1 [2458 pg/mL, (692-8719)]. SF-FLS increased their ICAM-1 and HLA-DR expression after encountering autologous PBMCs (p<0.01), (p<0.05). Further, SF-FLS and PBMC interacted synergistically in a co-culture model of RA and significantly increasing the secretion of several cytokines (IL-1β, IL-2, IL-6, (p<0.01)) and a chemokine (MCP-1, (p<0.01)). The invasion score of the human SF-FLS in vivo was at primary site, [1.6, (1.3-1.7)] and contralateral implantation site [1.5, (1.1-2.3)]. The invasion score of the human SF-FLS-containing implants both at primary and contralateral site were significantly higher compared with cartilage-sponges evaluated from SF-FLS-free control mice (p<0.001).

Conclusion: This phenotypical and functional characterization of SF-FLS, acquired and activated at the site of pathology, lays a foundation for establishing in vivo and in vitro FLS models. These FLS models will be beneficial in our understanding of the role of this cellular subset in arthritis and for characterization of drugs specifically targeting this physiological RA FLS subset.

ASSOCIATION OF FETUIN-A SERUM LEVEL AND GLUCOCORTICOIDS INTAKE IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Papichev1, B. Zavadovsky2, A. Yuriy3, S. L.1, P. J.1
1Federal State Budgetary Institution “Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky” Treatment and Prevention of Joint Disease Laboratory, Volgograd, Russian Federation

Background: Fetuin-A (FA) is a pluriportent glycoprotein, which plays an important role in bone turnover [1], inflammation, metabolic diseases [2] and etc. Several studies demonstrated association between FA serum level and rheumatoid arthritis (RA) severity and disease activity [3], however, there was a made a suggestion that observed associations were due to glucocorticoids intake [4].

Objectives: To study the association of serum FA levels, glucocorticoids intake and RA activity.

Methods: 81 patients with RA verified by ACR/EULAR 2010 criteria were enrolled in our study. 43 patients were under glucocorticoid therapy with mean cumulative dose 7899±9029.4 mg (hereinafter as MSD) and 38 patients were not. DAS28 index was calculated to determine RA activity. FA serum concentrations were measured by ELISA. Correlations between serum FA levels and RA activity were assessed in each group. Statistical analysis was performed using software package “Statistica 10.0”.

Results: The amount of serum FA was 760,72±112,56 μg/ml. There was a negative correlation between FA serum level and DAS28 index (r=-0.433; p<0.0001) when calculated among all patients. We observed positive correlation between FA serum level and cumulative dosage of glucocorticoids (r=0.297; p=0.008). At the same time FA serum level and DAS28 index were correlated negatively in patients who were under glucocorticoid therapy (r=-0.419; p=0.0001) and were not r=0.550; p=0.012).

Conclusion: Serum FA level correlates with RA disease activity and glucocorticoids intake. However, the association between FA serum level and RA disease activity was independent of glucocorticoids intake in our study.

SPECIALIZED PRO-RESOLVING MEDIATOR RECEPTORS AS INFLAMMATORY RESOLUTION BIOMARKERS IN RHEUMATOID ARTHRITIS

S. Perniola1,2, S. Alivernini1,2, B. Tolusso2, M. R. Gigante2, M. Gessi4, C. Di Mario3, L. Petricca2, A. Capacci2, A. L. Fedele2, G. Ferraccioli3, E. Gremese2,3

Gemelli – IRCCS, Division of Pathology, Rome, Italy; 3Università Cattolica del Sacro Cuore, Institute of Rheumatology, Rome, Italy; 4Fondazione Policlinico Universitario A. Gemelli – IRCCS, Division of Pathology, Rome, Italy

Background: The regulation of inflammation is a dynamic process involving several molecules as lipid mediators. The Specialized Pro-Resolving Mediators (SPMs), such as Resolvin (RvD and RvE), Protectins, Maresins and Lipoxin A4 (LXA4), are bioactive metabolites of omega-3 and omega-6 fatty acids which drive inflammatory resolution phase and promote tissue repair. ERV, ALX/FPR2 and BLT1 are SPM receptors. Although in Rheumatoid Arthritis (RA) lipid mediators role within pathophysiology is under definition, studies on SPM receptors role are still lacking in this disease.

Objectives: Purpose of this study is to define ERV, ALX/FPR2 and BLT1 expression in blood derived leukocytes and synovial cells and to correlate it to disease activity to define SPM receptors ad inflamatory resolution biomarkers in RA patients.

Methods: A cohort of 52 RA patients was enrolled in the study of which 40 with active disease (DAS28= 5.35 (5.18-6.40)) and 12 in sustained remission status (DAS28= 2.1 (1.93-2.34)). Each enrolled patient underwent peripheral blood (PB) drawing and 46 of them underwent US-guided synovial tissue (ST) biopsy. FACS gating strategy was used for PB and ST processing to evaluate percentage of positive cells and the mean fluorescence intensity (MFI) of ERV*, ALX/FPR2 and BLT1* in CD45+CD3*, CD45+CD19* for PB and ST respectively.

Results: Considering the whole RA cohort, DAS28 inversely correlated with BLT1* positive cells on ST-derived CD45+ (r = -0.48; p= 0.048), CD3* (r = -0.56; p= 0.012) and CD19* (r= -0.49; p= 0.042) cells, in contrast with CD90* (r = 0.50; p= 0.041) cells. Similarly, both DAS28 and KS inversely correlated with ALX/FPR2* positive cells in ST-derived CD45+ (r = -0.42, p= 0.050 and r= -0.41, p= 0.046 respectively) cells. Evaluating the MFI levels of the SPM receptors along all RA stages (naive-to-treatment, resistant-to-treatment, sustained remission) compared with UPIA control group, interestingly ST-derived CD45+ cells of remission RA were depleted of ERV1 compared to naive-to-treatment RA (p=0.04), despite comparable ST inflammation. Furthermore, highest ERV1 expression was found in ST-derived CD45+CD3* and CD45+CD19* cells in naive-to-treatment RA compared with UPIA patients (p= 0.045 and p= 0.012 respectively). Moreover, the lowest BLT1 level was found in remission RA CD3* cells compared with UPIA and naive-to-treatment RA patients (p=0.008 and p= 0.023 respectively).

Conclusion: SPM receptors expression seem to be tightly related to disease activity in the synovial tissue, suggesting an important involvement in the inflammatory process in RA patient.

cutaneous and cerebrovascular atherosclerotic plaques. The levels of FA and N-1 also correlated with more pronounced radiological changes (X-ray stage III). FA circulating inhibitor of ectopic calcification. N-1 level is positively correlated with systolic blood pressure.

Conclusion: A low level of A and FA, a high level of V and N-1 is characteristic of RA with the presence of high activity and positivity in the RF and Anti-CCP. An increased level of B is determined by more than 90% of patients, which indicates its high pro-inflammatory activity. The level of F and N-1 is also associated with the degree of damage to bone tissue (stage III, a lot of erosion). A positive correlation of level V and N-1, negative A and FA with the severity of inflammation in RA confirms the involvement of these proteins in the pathogenesis. A high level of A and V increases the risk of developing cardiovascular diseases and their complications, the effect of N-1 and FA is being studied. The effect of cytokines on osteoclasts and osteoblasts in RA is ambiguous

Figure 1

Conclusion: This study demonstrates that treatment with UPA 15 mg QD monotherapy for 24 weeks significantly reduces the levels of circulating 14-3-3η in MTX-naive RA patients and that these changes correlate with clinical measures of disease activity. Although we were not able to detect a clear relationship between changes in 14-3-3η and rate of structural damage progression, we would like to hypothesize that the superior clinical activity of UPA over MTX on joint damage may be related to the significant reduction in 14-3-3η induced by UPA; this hypothesis should be tested in a larger RA cohort with a larger proportion of joint damage progressors.

RA and DAS28-CRP (p= 0.0104), Fig. 2. No significant correlation was seen between sPD-L1, birth weight and preterm delivery. For sPD-1 we focused on 3rd trimester and postpartum, however, there was no difference between healthy controls and RA patients and no correlation with disease activity or pregnancy outcome.

**Conclusion:** In healthy pregnancy, we observed an increase of sPD-L1, which decreases after delivery. This supports the hypothesis, that PD-1 pathway may be involved in shaping the physiological fetal-maternal tolerance. In RA higher sPD-L1 values are measured already in non-pregnant patients compared to healthy controls and there is no physiological decrease post-partum. Intriguing, sPD-L1 correlates positively with RA disease activity, reflecting a possible functional antagonism towards the inhibitory function of membrane bound PD-L1 molecules. However, the detailed function of sPD-L1 need to be further delineated. Nevertheless, sPD-L1 may have the potential to serve as prognostic marker for flares in RA pregnancy. Regarding the rather rarely observed adverse pregnancy outcome, larger cohorts need to be investigated.

**AB0106** THE SERUM N-ACETYLGLUCOSAMINE CONCENTRATIONS IN RHEUMATOID ARTHRITIS PATIENTS ARE ASSOCIATED WITH JOINT DESTRUCTION AND RELATED METABOLISM MORE THAN INFLAMMATORY CONDITION

S. Tsuibo1, T. Matsumoto2, Y. Kagawa3, 1Shizuoka Welfare Hospital, Rheumatology, Shizuoka, Japan; 2Shizuoka Welfare Hospital, Department of Rheumatology, Shizuoka, Japan; 3Shizuoka Prefectural University, Department of Pharmacology, Shizuoka, Japan

**Background:** In rheumatoid arthritis (RA) patients, synovitis causes severe articular cartilage damage. N-acetylglucosamine (N-ac-Glc) is a component of glugulosaminoglycans (GAG) such as hyaluronic acid (HA) and keratan sulfate (KS). N-ac-Glc concentration in plasma is thought to reflect the balance between biosynthesis and destruction of articular cartilage, however, few studies had examined the relationship between plasma N-ac-Glc concentration and RA activity.

**Objectives:** N-ac-Glc concentrations in RA patients were measured, and association with clinical indicators was assessed.

**Methods:** A cross-sectional study was carried out including 60 RA cases. Using N-acetylglucosammine-d3 as standard, the serum of subjects were deproteinized by protein precipitation method with acetonitrile, then concentration of N-ac-Glc was measured with high-speed liquid chromatography mass spectrometer (LC-MS / MS). Clinical evaluation items: basic metabolism, presence or absence of exercise habit, Larsen score of knee and wrist joint, therapeutic agents (csDMARDs, biologics and PSL), DAS28, CRP, MMP-3, modified HAQ score (mHAQ); Statically analyzed by Spearman non parametric test.

**Results:** The age of 60 RA cases was 59.7±16.4 years, and the duration of the disease was 10.4±8.7 years. Biologics were used in 29 cases (TNF inhibitors in 16 cases, IL-6 inhibitors in 4 cases, Abatacept in 9 cases), MTX in 32 cases, and prednisolone in 15 cases. Plasma N-ac-Glc concentration was 113±41 (ng/dl), DAS28CRP was 3.04±1.2, and mHAQ was 0.863±0.81. Plasma N-ac-Glc concentration showed positive correlation with age (correlation coefficient 0.644), knee joint destruction (0.425), HAQ score (0.340), BUN (0.412), and RF (0.287). Plasma N-ac-Glc concentrations also negatively correlated with eGFR (-0.597), basal metabolism (-0.313), and sex difference (-0.272). There was no correlation between plasma N-ac-Glc concentration and body weight, BMI, DAS28, CRP, MMP-3, NTX, serum creatinine, hand joint disease, and transaminase. In this study, plasma N-ac-Glc concentration had increased with age, and had a negative correlation with basal metabolism. Considering these results, it is unlikely that N-ac-Glc is released into plasma as a metabolite of synthesis promotion. Further, since N-ac-Glc had a negative correlation (-0.389) with MTX as a folic acid inhibitor, it was supposed to be affected by protein synthesis reduction. Because no correlation between N-ac-Glc and inflammation or bone metabolism markers was observed, N-ac-Glc may represent removal of GAG from the cell membrane (shedding).

In previous GAGs studies, in RA patients, HA, KS, CRP, DAS28, was very associated with arthritis, such as MMP-3. The concentration of N-ac-Glc in plasma was more relevant to dysfunctions such as destruction and HAQ due to arthritis such as HAQ than inflammatory indicators such as DAS28, MMP-3 and CRP. It is appearing in the plasma by destruction, as an index to see the joint destruction, it was presumed to be a better indicator than the GAGs. It was also thought that there is a possibility that MTX affects cartilage substrate metabolism.

**Conclusion:** Serum N-ac-Glc concentration in rheumatoid arthritis patients may represent cartilage metabolism and joint destruction.

**AB0107** INVESTIGATION OF THE EFFECTS OF KYNURENIC ACID ANALOGS IN RHEUMATOID ARTHRITIS

B. Varga1, A. Balog1, F. Földi1, L. Vécsei1, Y. Mándi1, 1University of Szeged - Faculty of Medicine, Department of Rheumatology and Immunology, Szeged, Hungary; 2University of Szeged - Faculty of Pharmacy, Institute of Pharmaceutical Chemistry and Research Group for Stereochemistry, Szeged, Hungary; 3University of Szeged - Faculty of Medicine, Department of Neurology, Szeged, Hungary; 4University of Szeged - Faculty of Medicine, Department of Medical Microbiology and Immunobiology, Szeged, Hungary
BACKGROUND: The investigation of anti-inflammatory and immunosuppressive functions of kynurenine acid (KYNA) is now in focus. Previously, we demonstrated the opposite effects of KYNA and different KYNA analogs on tumor necrosis factor (TNF-α) production from synovial macrophages and tumor necrosis factor-stimulated gene-6 (TSG-6) expression in U-937 monocyteic cells. The potential effect of KYNA analogs on further immune mediators including alarmins (S100A12=EN-RAGE and S100A9=ciraprotectin), and on human neutrophil peptide 1-3(α2-defensin) production has not been investigated.

OBJECTIVES: Therefore, in the present study, we compared the effects of newly synthesized KYNA analog on the TNF-α, alarmins and α-defensin production, correlation with the effects on the TSG-6 expression in rheumatoid arthritis (RA).

METHODS: 93 RA patients were involved and divided subgroups based on DAS28 activity score. Peripheral blood mononuclear cells (PBMC) was isolated from RA patients and healthy controls. As cytokine inducers heat inactivated Staphylococcus aureus (SA1) were used. In parallel in vitro experiments, the SA1 induced PBMCs were pretreated with a newly synthesized KYNA analog (compound S27-72 was synthesized by direct amidation of KYNA). The concentrations of the above mentioned inflammatory mediators in the supernatants were quantified by ELISA kits and the TSG-6 expression was also determined by RT-qPCR method.

RESULTS: The SA1 induced TNF-α, EN-RAGE, calprotectin and α-defensin production was significantly higher in RA patients’ group than in healthy controls. KYNA analog attenuated the SA1 induced TNF-α, EN-RAGE, calprotectin and α-defensin production, and increased TSG-6 production and TSG-6 mRNA expression in PBMC cells from RA patients. The SA1 induced TNF-α and TSG-6 production correlated with the DAS28 activity score. The TNF-α inhibitory effect of the KYNA analog correlated inversely with the TSG-6 stimulating effect in all subgroups of RA patients based on DAS28 activity score.

CONCLUSION: TSG-6 expression could participate in the suppression of inflammatory cytokines, such as TNF-α, EN-RAGE, calprotectin and α-defensin. We suppose that the elevation of the TSG-6 expression by KYNA and especially by new KYNA analogs might be one of the mechanisms that are responsible for their suppressive effect on TNF-α production as a feedback mechanism in RA. KYNA and KYNA analogs have an important role in influencing TSG-6 expression, and there is a possible benefit with potential therapeutic consequence of targeting TSG-6 expression by kynurenines in inflammatory conditions in RA.

RA and OA. Soluble CD27 is present higher in the supernatant of RA-SF than OA-SF (Fig 3). HIF-2α mRNA, HIF-2α protein, and the amount of ROS were all elevated after treatment with IL-17 and TNF-α in RA-FLS (Fig 4, Fig 5). CD70 expression and the amount of ROS were lowered by treatment with HIF-2α inhibitor in RA-FLS (Fig 6). Decreased amount of ROS results in decreased CD70 expression on the RA-FLS (Fig 7). CD70 influenced on cell migration directly or by HIF-2α (Fig 8).

Figure 1. CD70 mRNA in RA-FLS and OA-FLS

Figure 2. CD70 expression on the surface of RA-FLS

Figure 3. The amount of sCD27 by ELISA

Figure 4. HIF-2α mRNA in RA-FLS

Figure 5. HIF-2α protein in RA-FLS

Figure 6. CD70 expression and ROS on the surface of RA-FLS by treatment with HIF-2α inhibitor.
Conclusion: In this study, we found the function of CD70 in RA-FLS associated with HIF-2α and ROS. First, CD70 on RA-FLS interacts with CD27 in the RA-SF and this interaction produces sCD27 (Fig. 9) and CD70 has an influence on the migration of RA-FLS. Second, IL-17 and TNF-α are critical factors to trigger the expression of CD70, HIF-2α and ROS in RA synovium. Third, CD70 is regulated by HIF-2α associated with ROS. From these results, we suggest that CD70 may be a new therapeutic target of RA. And sCD27 also may be an important diagnostic marker of RA.

AB0110 ADIPONECTIN INDUCES PRO-INFLAMMATORY CHEMOKINE AND CYTOKINE PRODUCTION BY PERIPHERAL BLOOD MONONUCLEAR CELLS AND FIBROBLAST-LIKE SYNOVIOCYTES FROM NON-INFLAMED SUBJECTS

Y. Zhang1, J. Aldridge1, G. K. Vasileiadis1, A. C. Lundell1, A. Rudin1, C. Maglio1.
1University of Gothenburg, Dep. of Rheumatology and Inflammation Research, Gothenburg, Sweden

Background: Adiponectin is a cytokine mainly secreted by the adipose tissue1, whose circulating levels are paradoxically low in subjects with obesity and associate with a beneficial metabolic profile2. Recent studies have shown that adiponectin levels are elevated in both serum and synovial fluid collected from patients with rheumatoid arthritis (RA)3,4. Moreover, adiponectin is able to induce the production of interleukin (IL)-6, tumor necrosis factor (TNF), CXCL1 and CXCL8 by lymphocytes from healthy subjects5, and of IL-6 and CXCL8 by fibroblast-like synoviocytes (FLS) from patients with RA6. However, it is not clear if adiponectin is able to initiate the inflammatory processes associated with the preclinical phase of RA.

Objectives: We aim to determine if adiponectin is able to induce inflammatory responses in peripheral blood mononuclear cells (PBMCs) and FLS from non-inflamed subjects.

Methods: Human PBMCs were collected from healthy donors, whereas non-inflamed FLS from non-arthritic patients who underwent diagnostic arthroscopy due to previous trauma. PBMCs (1 x 10⁶ cells/well in 96-well plate) and FLS (5000 cells/well in 96-well plate) were stimulated using 5 μg/ml recombinant human total adiponectin protein, and the supernatants were collected 48 hours after stimulation. Phytohemagglutinin (PHA) and TNF were used as positive controls to activate PBMCs and FLS, respectively. Using multiplex assay and ELISA, we screened the production of 13 chemokines and 12 cytokines from healthy human PBMCs and non-inflamed FLS.

Results: Adiponectin was able to stimulate a distinct profile of chemokines and cytokines in PBMCs and FLS. Adiponectin induced the production of CXCL1, CXCL5, CXCL8, CCL2 and IL-6. Moreover, CCL3, CCL20, CCL4, CCL17, TNF, IL-10 and GM-CSF were induced by adiponectin only in healthy PBMCs, whereas CXCL10, CCL5 and CCL11 only in non-inflamed FLS (Fig. 1).

Conclusion: We here report that adiponectin has pro-inflammatory properties as it induced chemokine and cytokine production from healthy human PBMCs and non-inflamed FLS. As adiponectin is able to induce pro-inflammatory responses from non-inflamed cells, we suggest that this adipokine might be implicated in the preclinical phase of RA pathogenesis.

References:
The mean age of the 60 patients was 54.8±11.6 years. Serum sICAM-1 and CXCL13 on the response to TNFα inhibitor (TNFi) receptor fusion protein in RA patients who have poor response to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs).

**Methods**: 60 RA patients with disease duration more than 6 months and at least low disease activity defined by DAS28-CRP>3.2 although after csDMARDs treatment for more than 3 months were included. They were further treated with TNFi receptor Fc fusion protein and MTX 10mg per week for 12 weeks. Soluble ICAM-1 (sICAM-1) and CXCL13 concentrations in sera from 60 RA patients and 20 healthy controls were tested by ELISA right before and at the end of 12 weeks of TNFi therapy. The correlation between sICAM-1 and CXCL13 with disease activity and their predictive values for TNFi response were analyzed.

**Results**: The mean age of the 60 patients was 54.8±11.6 years. Serum sICAM-1 and CXCL13 concentration was higher in RA patients than healthy controls, higher in seropositive RA patients than in seronegative ones, and higher in RA patients with higher disease activity (table 1). Serum sICAM-1 and CXCL13 levels were decreased after TNFi therapy, especially in good responders (table 2).

**Table 1.** The correlation between serum sICAM-1 and CXCL13 concentrations and disease activity at baseline and 12 weeks after treatment.

**Conclusion**: Syndecan-4 can be expressed in the synovia of RA and OA patients. The serum Syndecan-4 is higher in RA patients than in OA patients and healthy controls, and significantly higher in sero-positive RA patients than in sero-negative ones. Syndecan-4 may participate in the pathogenesis of RA.

**ANTIBODIES AGAINST HELICOBACTER PYLORI ANTIGENS IN PATIENTS WITH PSORIATIC ARTHRITIS AND PSORIASIS**

E. Patrikiou1, G. Ethymiou1, C. Liaskos1, N. Ntavari1, E. Zifiriou1, T. Simopoulou1, T. Scherer1, W. Meyer1, A. Rousssaki-Schulze2, D. Bogdanos3

1University of Thessaly, Rheumatology/ Clinical Immunology, Larissa, Greece
2University of Thessaly, Dermatology, Larissa, Greece
3Institute of Experimental Immunology, Affiliated to EUROMMUN AG, Lubeck, Germany

**Background:** Psoriasis (Ps) and Psoriatic Arthritis (PsA) are inflammatory diseases of unknown etiology. Helicobacter pylori (Hp) infection has been hypothesized as one of the microbial agents that can lead to development of immune-mediated psoriatic disease, but the nature of the specific Hp antigens involved remains unclear.

**Objectives:** To asses antigen specific antibody responses against immunodominant Hp antigens in patients with psoriatic diseases.

**Methods:** Ninety-one patients with Ps (35 females; median age 51.9, age range 25-87), 47 patients with PsA (25 females; median age 52.9, age range 25-87) and 60 demographically matched healthy controls (HC) were studied. Reactivity to Hp-specific antigens were tested by Western immunoblotting (in combination with line immunoassay for anti-CagA and anti-VaGA antibody testing) (EUROMMUN AG, Lubeck, Germany).

**Results:** Positivity against Hp was comparable between PsA (38.3%), Ps (39.6%) and HC (50%). Anti-p66-UreB, anti-p54-flagelin and anti-p29-UreA abs were more frequent in psoriatic patients compared to healthy controls (p66: 94.4% vs 69.7% in Ps vs 69.3% in HC, p=0.012; p54: 66.7% in Ps vs 33.3% in HC, p=0.014; p29 72.2% in Ps vs 45.5% in HC, p=0.004) and anti-p29-UreA abs were detected in higher frequency in PsA patients compared to HC (94.4% vs 45.5%, p=0.002). Reactivities against the remaining Hp antigens were comparable between Ps and PsA patients and HC.

**Conclusion:** Antibody responses against p66-UreB, p29-UreA, and p54-flagelin are more prevalent in patients with psoriatic disease, suggesting their potential involvement in PsA and Ps.

**IL12P40/IL23P40 BLOCKADE WITH USTEKINUMAB DECREASES THE INFLAMMATORY INFILTRATE AND MODULATES MOLECULAR PATHWAYS IN THE SYNOVIIUM OF PSORIATIC ARTHRITIS PATIENTS**

R. Fiechtner1, H. De Jong1, L. Van Mens1, I. Fluri1, S. Tas1, D. Baeten1, N. Yeremenko2, M. G. H. Van de Sande3, 1Amsterdam UMC, Univ of Amsterdam, Rheumatology and Clinical Immunology, Amsterdam, Netherlands

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory joint disease within the spondyloarthritides (SpA) spectrum. TNF and IL17/IL23 pathways play a key role in SpA pathogenesis. Blocking of IL12p40/IL23p40 has been shown to effectively reduce disease activity in PsA [1,2]. It is however incompletely understood how IL12p40/IL23p40 blockade affects local inflammatory processes.

**Objectives:** To investigate the cellular and molecular pathways affected by IL12p40/IL23p40 blockade with ustekinumab in PsA patients (pts).

**Methods:** Eleven male PsA pts with at least 1 inflamed knee or ankle joint, who were scheduled to start ustekinumab treatment, were included in a 24-week single-center open-label study. All pts received ustekinumab 45 mg/sc according to standard care at week (W) 0, 4 and 16. Besides clinical outcomes, need for arthroscopic synovial tissue (ST) biopsy samples were obtained from an inflamed knee or ankle joint at baseline (BL), W12 and W24. ST samples were analyzed by immunohistochemistry (IHC), RNA sequencing and real-time quantitative polymerase chain reaction (qPCR) analysis.

**Results:** Paired BL and W12, and paired BL, W12 and W24 ST samples were available of 9 and 6 pts, respectively. Two pts only underwent BT ST sampling (pt refusal; withdrawal after the W12 clinical visit). Two pts were excluded after W12 because of treatment adjustments. Of 1 pt no ST was obtained at W24 due to technical difficulties. Eight pts finished 24 weeks of clinical follow-up. No serious adverse events were observed. At W12 6/11 pts met ACR20, 2/11 met ACR50 and 1/11 met ACR70 improvement criteria, at W24 this was 3/8, 2/8 and 1/8 pts, respectively. Significant improvements between BL and W12 and/or W24 were seen in clinical (TJC, PASI, BASDAI) and serological markers (CRP and ESR). Table 1. IHC showed a significant decrease in sublining macrophages, a sensitive biomarker of an inflammatory response in peripheral SpA, of BL 2[1-3] vs W12 1.5[0-2].p=0.020, but not W24 1[0.5-2.5].ns. Other synovial infiltrating cells were not significantly decreased. Significant downregulation of MMP3 (p=0.047) and IL-23p19 (p=0.046), but not IL6, TNF or IL12p40 were seen with qPCR analysis at W12. RNA seq analysis showed 178 significantly differentially expressed genes between BL and W12 (FDR 0.1). Gene ontology and KEGG terms enrichment analyses identified overrepresentation of MAPK and PI3K-Akt signalling pathways among the down-regulated genes and WNT signalling pathway among the up-regulated genes. Gene expression was confirmed by qPCR analysis.

**Conclusion:** Ustekinumab treatment reduced synovial inflammation and modulated specific molecular pathways, however inflammation was not completely resolved. Future studies comparing histological and gene expression data between different treatments targeting IL17/IL23 axis will show which changes are treatment-specific and which reflect downregulation of local inflammation.

**SECUKINUMAB THERAPY DOES NOT AFFECT NEUTROPHIL HOST DEFENCE IN PSORIATIC ARTHRITIS**

A. Cross1, J. Hawkes1, H. Frankland2, A. Mediania2, H. Wright1, N. Goodson3, S. Edwards3, R. Moots1,2

1University of Liverpool, Institute of Ageing and Chronic Disease, Liverpool, United Kingdom
2Liverpool University Hospitals NHS Foundation Trust, Rheumatology, Liverpool, United Kingdom
3University of Liverpool, Institute of Integrative Biology, Liverpool, United Kingdom
Background: Biologic therapies have revolutionised therapy in inflammatory diseases such as psoriatic arthritis (PsA), driving major improvements in outcomes. Th17 cells appear to play a key role in the pathogenesis of PsA, and IL-17 can trigger the release of chemoattractants such as CXCL8 and CCL20, leading to the further infiltration of other immune cells including neutrophils. Infiltrating activated neutrophils can themselves generate a range of chemoattractants which may amplify and sustain the inflammatory response. Therapeutic targeting of IL-17 with biologics such as secukinumab offers great benefit in PsA by blocking this inflammatory cycle; however the interaction of this agent with neutrophils, key components of host defence as well as potential mediators of this disease, is not known.

Objectives: This study aimed to measure key aspects of neutrophil function to determine: a) changes in the functions of circulating neutrophils in PsA patients pre-therapy, compared to age- and sex-matched healthy controls and b) if these changes functioned in PsA patients 12-weeks post-secukinumab therapy.

Methods: Neutrophils were isolated from venous blood of 16 PsA patients and 10 healthy controls. Key neutrophil functions were measured at baseline and 12 weeks: reactive oxygen species (ROS) production, apoptosis (+/- TNF and GM-CSF), phagocytosis, receptor expression and chemotaxis. Changes in gene expression pre- and 12-weeks post-therapy (n=5 PsA) were measured using RNAseq.

Results: PsARC response was observed in 70.6% of participants on secukinumab therapy at 12 weeks. There were no significant differences in ROS production, phagocytosis or chemotaxis in PsA patients at baseline (compared to healthy controls) or during therapy. Chemotaxis towards IL-8 in PsA patients at baseline was decreased compared to that of healthy controls, but this difference did not reach statistical significance. Surface levels of activation markers CD11c/CD18 and CD63 were increased in PsA patients at 12-weeks compared to baseline, while surface levels of CD16 and CD11b were not significantly different between groups. There was no significant correlation between irisin level and disease activities. However, High BASDAI group showed significantly lower irisin level than low BASDAI group (44.64 [18.13-85.89] vs. 65.68 [31.16-165.31], p=0.011).

Conclusion: AS patients have lower serum irisin concentrations than healthy controls. AS patients with severe symptoms tend to have lower serum level of irisin than those with less severe symptoms.

AB0117 DECREASED SERUM LEVEL OF IRISIN IN PATIENTS WITH ANKYLOSING SPONDYLITIS
B. Nam1, S. Jo2, S. Lee3, T. H. Kim1,2. 1Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Hanyang University Institute for Rheumatology Research, Seoul, Korea, Rep. of (South Korea); 3Hanyang University Hospital for Rheumatic Diseases, Department of Radiology, Seoul, Korea, Rep. of (South Korea)

Background: IRISIN was initially identified as a novel myokine, a member of the adipocyte-derived cytokine family that is transcribed in skeletal muscle in response to exercise training. IRISIN is known to be involved in energy metabolism by regulating the L-type amino acid transporter 1 (LAT1) expression, which is critical for amino acid uptake into muscle cells. IRISIN is also known to increase fatty acid beta-oxidation and to be involved in the regulation of inflammation. IRISIN serves as a key mediator in the crosstalk between skeletal muscle and adipose tissue, and it is a physiologically important anabolic signal that promotes the development of skeletal muscle and bone mass. IRISIN is implicated in the pathogenesis of metabolic diseases such as obesity, type 2 diabetes mellitus, and cancer.

Objectives: In this study, we aimed to investigate the possible relationship between irisin levels and disease activity in patients with ankylosing spondylitis (AS).

Methods: Male patients with AS fulfilled the modified New York criteria (n=119), and healthy male controls (n=30) were enrolled. Serum irisin level was measured using ELISA (Cusabio, CSB-EQ027943HU). Disease activity was assessed by acute phase reactants, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), and modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Clinical characteristics and serum irisin level of the AS group were compared with those of the control group using Student t-test for normally distributed continuous measures and Mann-Whitney U test for non-normally distributed continuous measures. To evaluate the correlation of serum irisin level and AS disease activity, Spearman’s correlation test was used. AS patients were grouped into the high BASDAI group (BASDAI ≥ 4, n=45) and the Low BASDAI group (BASDAI < 4, n=74). And serum irisin level was also compared between two groups.

Results: AS group had lower serum irisin concentration compared with healthy control group (80.50 [23.68-131.15] vs. 124.69 [79.58-192.90], p<0.01), while age and body mass index were not significantly different between groups. There was no significant correlation between irisin level and disease activities. However, High BASDAI group showed significantly lower serum irisin level than low BASDAI group (44.64 [18.13-85.89] vs. 65.68 [31.16-165.31], p=0.011).

Conclusion: AS patients have lower serum irisin concentrations than healthy controls. AS patients with severe symptoms tend to have lower serum level of irisin than those with less severe symptoms.

Conclusion: The SpA group had a mean age of 45.88 ± 11.67, 62.3% of them were male, 6.6% reported current smoking and 37.7% reported smoking sometime in their life. In total, 67.2% had inflammatory back pain, 14.8% had dactylitis, 63.9% enthesis arthritis, and 57.4% arthritis. Thirty patients were HLA-B*27 positive with a genotypic frequency of 50.8% and an allelic frequency of 24.6%. In this group of patients, the mean age was 43.5 ± 11.8, 76.6% were male, 86.7% of them were subtype B’27;05:02g and 13.3% presented the B’27;02:01g. None of the SpA patients had both B’27 alleles. On the other hand, the healthy individuals were men in 51.0% and the mean age was 37.15 ± 4.4 years. Ten subjects were positive for the HLA-B’27 allele with a genotypic frequency of 3.4% and an allelic frequency of 1.7%. In this group of individuals 50.0% were male with a mean age of 38.4 ± 17.9. No individuals were found to have the two alleles or homozygous for the B’27 allele. In all of them the subtype B’27;05:02g was observed in high-resolution sequencing.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.3401

Background: Studies of human intestinal microbiota have focused mainly on bacteria and scarce information on how eukaryotic parasites fit in the gut context or its role in human health and disease.

Objectives: This is an approach to explore if intestinal parasites represent a significant factor concerning the treatment-decisions or disease activity in inflammatory conditions such as SpA

Methods: A Cross-sectional study including 65 patients with SpA according to ASAS classification criteria was performed. Clinical evaluation was made by the rheumatologists and gastroenterologists, stool samples were collected and microscopically analyzed by direct saline, Mini Parasite concentration and Kato Katz. Most prevalent protozoa in Colombia were also analyzed using PCR/qPCR. Lab tests included fecal calprotectin, CRP, ESR, and HLA-B*27. The association between intestinal parasite infection and clinical/treatment variables were evaluated using the Chi-square or Fisher’s exact test. (Ethical/Code 2017-023)

Results: SpA patients had a mean age of 43.9±11.5 years, 61.5% were male, 52.5% were positive for HLA-B’27 and 87.7% had axial involvement. In total, 67.7% of the patients were receiving biological treatment, 64.6% had ASDAS-CRP ≥2.1. In total, 75.4% of patients were positive for ≥2 gastrointestinal symptoms, either diarrhea (63.1%), abdominal pain (66.2%), food intolerance (58.5%). Interestingly, 21.3% have high levels of calprotectin, 20% of patients with high calprotectin were receiving biological treatment against IL-17 (p=0.086) and 80% of these patients had BASDAI >4 (p=0.017) and ASDAS-VSG ≥2.1 (p=0.03).

Outcome: The parasites found in SpA patients were Endolimax nana (98%), Blastocystis spp. (63.8%), Entamoeba coli (8.6%), Entamoeba histolytica (6.9%), Chlamidaxim mesnili (6.4%), E. dispar/parasites (1.7%) and Giardia intestinalis (3.7%). Patients positive for E coli (80%) were treated with NSAIDs (p=0.003). 3/4 of patients positive for E histolytica presented HLAB’27;05;02 positive. Likewise, the only patient who was positive for G intestinalis expressed this allele. 5/7 of patients treated with Sulfasalazine presented Blastocystis spp and 33.3% E. coli. The presence of intestinal parasites in SpA patients was not associated with gastrointestinal symptoms, either disease-activity measures.

Conclusion: The intestinal parasitism in the tropical countries as Colombia have shown an interesting pattern in SpA patients. The treatment may modulate the presence of some parasites; however, the presence of intestinal parasites in SpA does not seem to influence clinical disease activity

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.3882

Background: Elevated serum levels of interleukin (IL)-22 were reported in patients with ankylosing spondylitis (AS). IL-22 was also reported to drive the osteoclastogenic differentiation of mesenchymal stem cells.

Objectives: To confirm the fact that serum levels of IL-22 are elevated in AS patients and to examine the relationship between concentrations of IL-22 and degree of radiographic progression in AS patients.

Methods: Seventeen male patients with established AS of more than 4 years duration signed the informed consent and donated 10ml of peripheral blood. Demographic data was collected from patient’s charts. Disease activity indices were calculated for all patients and radiographic disease progression was calculated as mSASS. A control group included 6 healthy persons and 4 patients with advanced diffuse idiopathic skeletal hyperostosis (DISH). Serum levels of IL-22 were tested using enzyme-linked immunosorbent assay. Intergroup differences were examined using the Mann-Whitney test, while correlations were calculated using Pearson correlation coefficient.

Results: Serum IL-22 levels were remarkably elevated in patients with AS, compared to healthy individuals and patients with DISH (p=0.005). However, increased concentrations of IL-22 did not correlate with the degree of radiographic progression or AS disease activity indices, nor with disease duration or patient’s age. Presence of diarrhea, psoriasis, uveitis, or elevated levels of C-reactive protein did not influence the levels of IL-22 as well. More AS patients with elevated serum IL-22 were smokers (p<0.05).

Fig. 1. Serum levels of interleukin 22 (pg/ml)

Conclusion: The serum levels of IL-22 are elevated in patients with AS. It seems that smoking data can be related to the elevated levels of serum IL-22 in AS. The significance of this data is unclear and further research is needed.

AB0120

THE EFFECT OF INFLAMMATORY SERA FROM DIFFERENT FORMS OF AXIAL SPONDYLOARTHRITIS ON THE OSTEOCLASTIC POTENTIAL OF MONONUCLEAR PRECURSORS IN BLOOD

P. Dankova1, E. Sebova1, P. Škubica1, J. Horinkova1, M. Gregová2, K. Pavelka2, M. Husakova2. 1Faculty of Science, Department of Anthropology and Human Genetics, Charles University, Prague 2, Czech Republic; 2Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague 2, Czech Republic

Background: Spondyloarthritis (SpA) is characterized by pathological bone resorption and higher risk of osteoporosis. Inflammation accompanying the disease may activate mononuclear precursors in blood that are able to differentiate into osteoclasts, bone resorbing cells [1,2], and thus substantially contribute to bone resorption and aggravation of symptoms characteristic for this chronic disease.

Objectives: The aim of this pilot study is i) to figure out whether the inflammatory factors present in blood sera of SpA patients activate the osteoclastogenic potential of peripheral blood monocytes (PBM) derived from healthy subjects; ii) to find out whether this effect differs among sera from three forms of SpA, short-term non-radiographic (nr-axSpA) and radiographic (r-axSpA) SpA, and long-term ankylosing spondylitis (AS), and finally iii) to assess whether the stimulatory effect of serum from SpA patients on osteoclastogenesis of healthy PBM reflects the altered clinical markers of inflammation and bone metabolism.

Methods: To simulate inflammatory condition characteristic for nr-axSpA, r-axSpA or AS, we created pool of 10 AS sera together with age- and sex-matched healthy sera (P = NS). Serum CRP levels were significantly, 7-fold increased serum CRP levels (P = 0.003), and thus may contribute to the pathogenic potential of PBM, as documented especially in AS sera presenting with inflammatory factors present in the sera of SpA patients enhance the osteoclastogenic effect regardless of its origin with respect to healthy condition. However, sera pooled from nr-axSpA and r-axSpA did not appear to differ significantly from each other in size of their effect on PBM; nevertheless, trend to lowest numbers of osteoclasts can be seen in culture with r-axSpA vs nr-axSpA and AS sera. In this study, we aimed to evaluate the global DNA methylation of patients with axSpA.

Methods: Case-control study (NCT03092583). Patients with radiographic (AS) or non-radiographic (nr) axSpA (ASAS criteria) and healthy controls (HC) were evaluated. All the patients were biologic naive and under NSAIDs. Disease activity was evaluated by BASDAI and ASDAS. CD4+ T cells and CD14+ monocytes were isolated form peripheral blood and then DNA was extracted (E.Z.N.A. Blood DNA kit, Omega Bio-Tek). Global DNA methylation (5-mC) was determined using MethyAmp global DNA methylation quantification kit (Epigentek) using 150ng DNA. HAT and HDAC activities were evaluated.

Results: 25 patients with AS (18 M; mean age ± SEM: 48.9 ± 3.5 y; mean disease duration: 14.9 ± 2.2 y; B27+: 84%), 21 with nr-axSpA (11 M; age: 42 ± 3.3 y; disease duration: 7.9 ± 2.3 y; B27+: 68%) and 11 HC (7 M; age: 48.4 ± 3.9 y) were evaluated. Patients had active disease (BASDAI and ASDAS in AS and nr-axSpA: 5.1 ± 0.4 and 5.4 ± 0.5; 4.7 ± 0.4 and 5 ± 0.4, respectively). In CD4+ T lymphocytes, global DNA methylation was lower in the whole group of patients (AS and nr-axSpA) compared to HC (0.91 ± 0.26 vs 1.08 ± 0.19 ± 0.19 % of 5-mC) (NS). Conversely, DNA methylation was higher in monocytes from patients compared to HC (1.43 ± 0.16 vs 1.15 ± 0.5 % of 5-mC) (NS). When analysing the results between axSpA subgroups, an hypomethylation was more evident in the CD4+ T lymphocytes from patients with nr-axSpA compared to AS and HC. A result that was not observed in the monocyte subpopulation (Figures). A global DNA hypomethylation is observed in patients with axSpA, especially in the nr-axSpA subgroup. These results are more evident in CD4+ T lymphocytes. Additional analysis on a larger series of patients is required to confirm these preliminary results. In conclusion, we aim to examine the specific DNA methylation status of the TNF promoter gene.

DETECTION OF CIRCULATING M3 MUSCARINIC ACETYLCHOLINE RECEPTOR REACTIVE TH17 CELLS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

S. Abe1, H. Tsutou1, F. Honda1, H. Takahashi1, Y. Kondo1, I. Matsumoto1, T. Sumida1, University of Tsukuba, Department of Internal Medicine, Tsukuba, Ibaraki, Japan

**Background:** Sjögren’s syndrome (SS) is an autoimmune disease which is characterized by lymphocytic infiltration including CD4+IL-17 producing helper T (Th17) cells to the lacrimal and salivary glands. We previously detected anti-M3 muscarinic acetylcholine receptor (M3R) antibodies (1) and M3R reactive CD4+IFNγ producing helper T (Th1) cells (2) in SS patients. Moreover, we clarified that M3R reactive Th1 and Th17 cells had pathogenic roles in the development of auto-immune sialadenitis in SS mouse model (3).

**Objectives:** The purpose of this study was to identify circulating M3R reactive Th17 cells among primary SS (pSS) patients, and to determine functional properties of those cells.

**Methods:**

1) Peripheral blood mononuclear cells (PBMCs) were isolated from whole blood of 10 pSS patients, age gender matched 10 healthy controls (HC), and 5 IgG4-related disease (IgG4-RD) patients. According to their HLA-DR1 typing, top 10 ranked 20 mer peptides from the full length of M3R, which were highly predicted to bind to each HLA molecules according to the immune epitope database website, were selected for each subjects. PBMCs were stimulated with these selected M3R peptides mixed for 40 hours, and M3R peptide reactive IL-17 secreting cells were detected by IL-17 enzyme-linked immunospot assay (ELISpot).

2) PBMCs from 5 pSS patients who were positive for M3R specific IL-17 secreting cells, were stimulated with selected 12-20 mer M3R peptides separately, to identify the major M3R peptides responsible for IL-17 secretion by ELISpot.

3) To identify whether detected IL-17 secreting cells were Th17 cells or not, isolated CD4+ T cells from 3 pSS patients who were positive for M3R specific IL-17 secreting cells, were co-cultured with auto-monocyte derived dendritic cells (DCs), and stimulated with the dominant IL-17 secreting M3R peptides detected in method 2.

4) Anti-M3R antibodies were examined using ELISA method.

5) Clinical features were compared between M3R specific Th17 cells positive and negative pSS patients.

**Results:**

1) 5 of 10 (50%) pSS patients, while none of 10 (0%) HC, and 5 (0%) IgG4-RD patients, showed significantly increased IL-17 positive spots against selected M3R peptides mixture stimulation compared with non-stimulation in ELISpot (Figure 1). M3R specific IL-17 secreting cells were detected significantly more frequently in pSS (5/10, 50%) than in HC (0/10, 0%) (p=0.03).

2) All 5 pSS patients, who were positive for M3R specific IL-17 secreting cells, showed significantly increased IL-17 positive spots against M3R AA76-95 peptides.

3) Co-culturing CD4+ T cells with DCs, stimulated with identified dominant M3R peptides in method 2, showed significantly increased spots, clarifying that IL-17 secreting cells were peripheral M3R reactive Th17 cells.

4) Titers of anti-M3R antibodies were significantly higher among M3R reactive Th17 cells positive pSS patients than negative pSS patients.

5) 5 pSS patients positive for M3R reactive Th17 cells had significantly higher disease activity score (ESSDAI: 8.0±4.3) than 5 negative pSS patients (2.8±1.7) (P=0.01).

**Conclusion:** We detected circulating M3R reactive Th17 cells in pSS patients using ELISpot, whose T cell epitopes were shown to be included in M3R AA76-95. Moreover, M3R reactive Th17 cells might correlate with higher disease activity and production of anti-M3R antibodies in pSS patients.

CHANGES IN CELLULAR GLYCOSYLATION AS A KEY FACTOR IN THE IMMUNOPATHOGENESIS OF SYSTEMIC LUPUS ERYTHEMATOSUS

I. Alves1,2, V. Pinto1, B. Santos-Pereira1,2, A. Campa1,2,3, J. R. Vizcaíno4, F. Carneiro1,2,3, C. Vasconcelos1, A. Marinho1,2, S. Pinho1,2, Institute for Research and Innovation in Health (ISI), Porto, Portugal; University of Porto, Porto, Portugal; Centro Hospitalar Porto, Internal Medicine, Porto, Portugal; Centro Hospitalar Porto, Anatomical Pathology, Porto, Portugal; Hospital Universitário de São João, Porto, Portugal

**Background:** Systemic Lupus Erythematosus (SLE) is one of the most challenging autoimmune diseases as it may be presented as a severe, relapsing and disabling immune-mediated disorder still remaining incurable (1,2). Protein glycosylation is an essential post translational modification that participates in the correct recognition of cells by the immune system (3–5). Moreover, glycosylation changes in T cells (specifically loss of branched N-glycans mediated by GntV, encoded by MGA75 gene) have been shown to impact its intrinsic function and activity in a diverse panel of autoimmune diseases (3,4,6)

**Objectives:** To evaluate the impact of glycans in the cellular and molecular mechanisms underlying the loss of immune-tolerance, envisioning the identification of a new targeted-specific mechanism.

**Methods:** We have analysed the profile of cellular glycosylation of a subset of biopsy-proven lupus nephritis from SLE patients and normal kidney tissue (from two Porto Centre Hospitals), through immunohistochemistry (IHC) as well as by real time PCR using RNA extracted from paraffin tissues. Blood samples were collected and were analysed by flow cytometry. Mgate 5 null mice with 15-months old were monitored for autoimmune signs by evaluating proteinuria, weight loss and colon and kidney tissues were analysed by IHC and FACS.

**Results:** SLE patients revealed a significant decreased expression of complex N-glycans in the renal parenchyma, when compared to healthy kidney. In addition, we have identified in lupus nephritis patients a unique subset of circulating CD3+T cells with an abnormal glycosignature and displaying an increased expression of specific glycan-binding receptors. Interestingly, Mgate 5 null mice develop clinical signs compatible within autoimmune-like syndrome together with an increased infiltration of specific CD3+T cells subset identified in SLE patients.

**Conclusion:** These findings point towards the identification of a novel immune player with increased ability to sense abnormal N-glycans, modulating the surrounding immune response. We propose glycosylation as a regulatory mechanism that tips the balance between homeostasis/self-tolerance and autoimmunity opening a potential novel targeted-specific mechanism in SLE pathogenesis.

NO EFFECTS OF HIGH DOSE 25OH-VITAMIN D SUPPLEMENTATION ON LUPUS NEPHRITIS IN AN ANIMAL MODEL OF SYSTEMIC LUPUS ERYTHEMATOSUS

S. Bansoti1, C. Tani1, A. Kuhl1, S. Pacini1, V. Vagnani1, M. Mosca1.
1Rheumatology Unit - Pisa University Hospital, Pisa, Italy; 2Charité - Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, IPATH.Berlin, Germany, Berlin, Germany; 3Haematology Unit - Pisa University Hospital, Pisa, Italy

Background: 25OH Vitamin D (25-OH-D3) is a fat-soluble steroid-derived molecule involved in the calcium homeostasis. Low levels of 25-OH-D3 are commonly found in patients with systemic lupus erythematosus (SLE) and have been correlated to higher disease activity and severity. Several recent studies have demonstrated that high dose Vitamin D may influence several aspects of the innate and adaptive immune response and some authors hypothesized that high dose 25-OH-D3 may have a role in the treatment of SLE. Despite these observations, the immunomodulatory effect of high dose 25-OH-D3 in vivo still needs to be demonstrated.

Objectives: The aim of our study was to identify the effect of 25-OH-D3 on proteinuria, survival and renal biopsy in New Zealand Black/White F1 mice (NZ), that develop a disease very similar to human SLE nephritis.

Methods: We administered to 20 NZ mice a diet enriched with high dose 25-OH-D3 10,000 UI/Kg starting from 8 weeks of age. Mice were divided in 7 experimental groups (5 mice each). The first group was sacrificed before the start of the treatment (8 week of age), three groups were treated (treated mice – TM) with 25-OH-D3 and sacrificed at 16, 26 and 36 weeks of age. The other three groups were enrolled as controls and sacrificed at 16, 26 and 36 weeks of age respectively (untreated mice – UM). The parameters collected included: total urinary protein and kidney histology for the evaluation of lupus nephritis (LN): glomerulonephritis, interstitial nephritis and vascular lesions according to a 5 points scale to obtain a total score (ranging from 0 to 12).

Results: In UM, proteinuria tended to increase over 1 mg/day at 12 weeks of age (1.7±1.43mg/day) and further increased until to reach a plateau after 28 weeks of age (10±2.0 mg/day).

In TM, a significant increase in proteinuria over 1 mg/day was observed at 24 weeks, when the mean proteinuria was 1.7±1.33 which was lower than controls at the same age although without statistical significance (2.9±2.6); thereafter proteinuria started to increase also in treated mice and at week 30 was higher in TM compared with UM (10.3±8.8 vs 4.3±3.5 p=0.05). Figure 1. Kidney histology showed, in mice sacrificed before the start of the treatment no signs of LN. In mice sacrificed at 16 weeks minimal interstitial nephritis (score 1) was identified in 2 mice only in UM. At 26 weeks of age, a higher total LN score was identified in TM compared with UM (3.4±3.8 vs 0.4±0.9) with higher score for all three parameters analyzed. At 36 weeks of age, the TM group maintained a higher total LN score compared to UM (6.5±1.7 vs 6.0±2.6) with higher score for glomerulonephritis and interstitial nephritis.

Conclusion: Our data suggest that, in this animal model of SLE, 25-OH-D3 administration seems to delay the onset of proteinuria, although it has no effect on the overall disease control. In addition, it may have a negative effect on renal histology and survival with earlier development of LN.

AB0125

EXPRESSION OF INTERFERON TYPE I- AND TYPE II-INDUCED GENES IN PATIENTS WITH SJÖGREN'S SYNDROME WITH AND WITHOUT EXTRAGLANDULAR INVOLVEMENT

N. Del Papa1, C. Vitali1, M. Lorini2, V. Carbonell2, W. Maglione1, F. Pignataro1, A. Minniti1, N. Montano3, R. Caporali1. 1ASST Gaetano Pini CTO, Dept of Rheumatology, Milan, Italy; 2Mator Domini Humanitas Hospital, Castellanza, Italy; 3Ca’ Grande IRCCS Foundation, Ospedale Maggiore Policlinico, Department of Clinical Sciences and Community Health, Milan, Italy

Background: It is well known that Sjögren’s syndrome (SjS) is characterized by an upregulation of interferon (IFN)-induced genes. Namely, IFN type I signature has been reported in peripheral blood mononuclear cells (PBMCs) and in salivary glands of patients with this disease. However, few data are available on possible variability of IFN-induced gene upregulation in different clinical phenotypes of SjS.

Objectives: To verify whether upregulation of IFN-induced genes is comparable in patients with SjS characterized by different clinical phenotypes, i.e., patients with systemic extraglandular manifestations (EGMs) versus patients with a disease limited to glandular features (GFs) and with widespread pain (WP).

Methods: The study population was composed by 11 patients with SjS and EGMs (1 male, age range 18–78 years), and 10 patients with only GFs and WP (all females, age range 46-81 years), all classified according to ACR-EULAR criteria. The prevalence of anti-SSA(Ro) antibodies was 11/11 and 8/10, respectively. Lip biopsy was positive in all cases. Six healthy normal subjects were also included in the study as control population.

Four IFN type I- and 5 IFN type II-induced genes were chosen for the study on the basis of previous literature data. Total RNA from each patient and control was isolated from purified PBMCs, followed by cDNA preparation and real time quantitative-PCR (RT-PCR) analysis, using specific primer/probe sets. For calculation of relative expression, all samples were normalised against expression of a household gene (beta actin). A further normalization was performed against the mean value of relative expression obtained in the normal controls. Final fold change values were determined from the double-normalised values using the 2−ΔΔCT method (Applied Biosystems).

Results: Fold change values of gene expression of both IFN type I- and type II-induced genes in PBMCs were different in the two clinical phenotypes of SjS. Fold change values of IFN type I-induced genes appeared strongly higher in patients with EGM, and some of them only moderately increased in those with only GF and WP. The expression of some of IFN type II-induced genes were slightly increased in patients belonging to both clinical phenotypes. Results are detailed in the table.

DOI: 10.1136/annrheumdis-2020-eular.1231
Background: SLE is a multisystem autoimmune disease characterized by the production of multiple autoantibodies and loss of immunity against autoantigens in various tissues. SLE patients have significantly elevated RNA editing production of multiple autoantibodies and loss of immunity against autoantigens. ADAR1 is an RNA A-I deaminase that acts on RNA (ADAR)-1 gene expression in normal T lymphocytes by anti-CD3-epsilon and anti-CD28. The present data indicate that IFN type I- and, to a lesser degree, type II-induced genes are upregulated in patients with SjS, but this phenomenon is consistently stronger in patients with systemic EGMs. In patients with only GFs IFN-induced gene upregulation is milder in PBMCs, and then probably more restricted to the exocrine target tissues.

Conclusion: There was no significant difference between the expression in renal tissues in patients with SLE and in healthy controls. There was no significant difference in the ADAR1 cell positive rate between controls and LN patients. There was a certain correlation between ADAR1 expression and serum IFN-α concentration, and serum IFN-α levels; 2. association between ADAR1 and clinical indicators; and 3. ADAR1 expression in renal tissue of LN patients. Our study therefore aimed to elucidate the abovementioned points.

Methods: We used qRT-PCR to determine ADAR1 expression levels in PBMCs and renal tissues of controls and SLE patients. We also conducted immunohistochemical studies to detect positive ADAR1 expression rate in renal cells of controls and LN patients.

Results: ADAR1 expression was higher in PBMCs of SLE patients than in those of controls and was positively correlated with SLEDAI. When serum IFN-α levels in SLE patients decreased <260.0 pg/mL, ADAR1 expression in PBMCs increased with the increase in IFN-α concentration, and serum IFN-α may regulate ADAR1 level in PBMCs in SLE patients, which may require the participation of serum IgG antibody and related immune complex. However, there was no significant difference between the expression in renal tissues in all patients.

Conclusion: There was a certain correlation between ADAR1 expression and serum IFN-α levels in PBMCs of SLE patients.

AB0127 ACCUMULATION OF ANTI-NUCLEAR ASSOCIATED AUTOANTIBODIES IN CIRCULATING IMMUNE COMPLEXES IS MORE PROMINENT IN SLE PATIENTS FROM SUDAN COMPARED TO SWEDEN

S. Elbagir1, A. Sohrabian1, A. Elshafie1, E. M. Elagib1, N. A. Mohammed1, M. A. M. Nur2, E. Svennungsson1, I. Gunnarsson3, J. Rönnelid1. 1Uppsala University, Immunology, Genetics and Pathology, Uppsala, Sweden; 2Military Hospital, Rheumatology Unit, Omdurman, Sudan; 3Al Neelain University, Khartoum, Sudan; 4Alribat University Hospital, Rheumatology Unit, Khartoum, Sudan; 5Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden

Background: Systemic Lupus Erythematosus (SLE) is a systemic immune complex (IC)-mediated disease associated with autoantibodies targeting multiple nuclear specificities (ANA). SLE has an aggressive nature among African populations. The role of SLE-related autoantibodies in the formation of IC has only been studied to a limited extent, and not at all in African SLE patients.

Objectives: To quantify ANA specificities present in circulating IC in Sudanese and Swedish SLE sera and to compare to corresponding serum levels

Methods: 93 Sudanese and 337 Swedish SLE patients who fulfilled the 1982 ACR classification criteria were included. IC were captured using magnetic microparticles coated with purified human C1q, then separated by a two-step elution procedure (Figure 1). ANA-associated autoantibodies against dsDNA, Sm, the Sm/U1RNP complex, U1RNP, SSA/Ro52, SSA/Ro60, SSB/La, ribosomal P antigen, proliferating cell nuclear antigen (PCNA) and histones were quantified in sera and corresponding IC using a bead-based multiplex immunoassay. The IC purification technique has been developed and validated in our laboratory (Sohrabian ARD 2018), and previously used to study treatment responses to belimumab in Swedish SLE patients (Sohrabian ART 2019). Occurrence of ANA specificities in serum was determined using manufacturer’s suggested cutoffs. These cutoffs were used in regression formulas to determine cutoffs for ANA levels detected in the corresponding IC.

Results: Swedish patients had higher serum levels of anti-Sm, anti-dsDNA and anti-ribosomal P antibodies compared to Sudanese patients. On the contrary, IC levels of all ANA specificities except anti-SSA/Ro52 and anti-SSA/Ro60 were higher in Sudanese patients (Table 1 and Figure 2). Sudanese patients were more often positive for anti-Sm, anti-Sm/U1RNP, anti-dsDNA and anti-histone antibodies in IC, whereas a borderline statistical significance was found for only anti-Sm in corresponding serum samples (Table 1).

CXCL5 DAMPENS INFLAMMATION IN THE PRE-ClinICAL MODEL OF SYSTEMIC LUPUS ERYTHEMATOSUS VIA THE ORCHESTRAL EFFECT OF REGULATING NEUTROPHIL TRAFFICKING AND SUPPRESSING HELPERT CELl-MEDIATED IMMUNE RESPONSE

Background: Patients with systemic lupus erythematosus (SLE) suffer from severe morbidity and mortality1, either from the disease itself or from side effects of immunosuppression. Discovery of novel effective therapies with less toxicity is an urgent need. Objectives: The aim of this study is to elucidate the therapeutic potential and working mechanism of cytokine CXCL5 in lupus mice.

Methods: Treatment with CXCL5, bone marrow (BM)-MSCs, standard of care (SOC) with combination of methylprednisolone and cyclophosphamide was given to 16-week-old Faslpr mice. Mice were monitored for 10 weeks. Splenic immune cell subsets were measured by flow cytometry. Circulating cytokine and immune cell subsets were measured by flow cytometry. Circulating cytokine and immune cell subsets were measured by flow cytometry. Circulating cytokine and immune cell subsets were measured by flow cytometry. Circulating cytokine and immune cell subsets were measured by flow cytometry. Circulating cytokine and immune cell subsets were measured by flow cytometry. Circulating cytokine and immune cell subsets were measured by flow cytometry. Circulating cytokine and immune cell subsets were measured by flow cytometry.

Results: CXCL5 demonstrated consistent and potent immunosuppressive capacity in suppressing SLE with reduced autoantibody secretion, lymphopenia and preserved kidney function. With further exploration, we found that TH17 cells were the key effector cells involved in the orchestral effect of regulating neutrophil trafficking and suppressing helper T cell-mediated immune response. Administering exogenous CXCL5 might be an attractive option to treat patients with lupus.

PCSK9 IS ASSOCIATED WITH DISEASE ACTIVITY AND IMPLICATED IN IMMUNE ACTIVATION IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Liu1, M. Rahman1, I. Häsfström1, S. Ajeagohna1, J. Fostergard1, Karolinska Institutet, Stockholm, Sweden

Background: LDL-levels are increased by Proprotein convertase subtilisin kexin 9 (PCSK9) which targets the LDL-receptor (LDLR). We reported that PCSK9 has immune modulatory properties in addition to LDL-lowering and ameliorates dendritic cell (DC) activation by oxidized LDL (OxLDL)1, which is abundant in atherosclerotic plaques. OxLDL is also raised and associated with cardiovascular disease (CVD) in SLE.2,3 Objectives: We here investigate the role of PCSK9 in SLE both in a clinical context and in experimental ex vivo studies. The objective is to investigate if PCSK9 and its inhibition could be of relevance in SLE in addition to LDL-related properties.

Methods: PCSK9-levels were determined by ELISA among SLE patients (n=109) and age- and sex-matched population-based controls (n=91). Common carotid intima-media thickness (IMT) and plaque occurrence were determined by B-mode ultrasound. Plaques were graded by echogenicity. Human peripheral blood monocytes from SLE patients or controls were differentiated into DCs. Effects of PCSK9 and its inhibition by silencing were studied.

Results: PCSK9-levels were non-significantly higher among SLE-patients as compared to controls but associated significantly with SLE disease activity, as determined by SLAM (0.020) or SLEDAI (0.0178). There was no association between PCSK9-levels and atherosclerosis as determined by IMT, prevalence of plaques or echoluent (potentially vulnerable) plaques. PCSK9 levels were significantly associated with CVD among SLE-patients but not after adjustment for age.

OxLDL induced PCSK9 in DCs and DC-maturation with increased expression of CD86 and HLA-DR. The effects were significantly stronger in DC from SLE patients than from controls. Silencing of PCSK9 abolished OxLDL-induced DC-maturation.

Conclusion: PCSK9 is associated with disease activity in SLE. One underlying cause could be OxLDL, promoting DC-activation which depends on PCSK9. OxLDL induces PCSK9, an effect which is higher among SLE-patients. PCSK9 could play an unexpected immunological role in SLE and inhibition of PCSK9 could potentially play a role in disease amelioration, pending on clinical studies.

**SERUM ATHEROGENICITY IN WOMEN WITH UNTREATED SYSTEMIC LUPUS ERYTHEMATOSUS**

H. Geragimová, T. Popkova, D. Geragimová, I. Sobenin, A. Lila, V.A. National Research Institute of Rheumatology, Moscow, Russian Federation; J.M. Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russian Federation; National Medical Research Center of Cardiology, Moscow, Russian Federation

**Background:** Systemic lupus erythematosus (SLE) is associated with an unexplained increase cardiovascular risk. The nature of the factors that contribute to progression of atherosclerosis were identified using the method for determining the atherogenicity of blood serum in cell culture in cell culture (in vitro). The term “atherogenicity” is meant as the ability of the serum and/or its components to induce intracellular accumulation of cholesterol in cultured cells.

**Objectives:** To compare atherogenicity of blood serum in women with untreated SLE and healthy women.

**Methods:** Thirty seven women (median age 30 [21;39] years) with active SLE (median disease duration 45 [3;102] months; SLADA1 17 [8;34]) were enrolled in the study. Lupus nephritis are defined in 15 (41%), Antiphospholipid syndrome (APS) – in 8 (22%) of 37 SLE patients (pts). The control group consisted of 30 women, median age 31 [26;39] years.

Atherogenicity of blood serum was determined in the culture of murine macrophages. Peritoneal macrophages were isolated from the ascitic fluid of the line mice according to the generally accepted method J. Goldstein et al (1979y). Serum atherogenicity was determined by the accumulation of intracellular cholesterol induced by 10% of the blood serum of the patients, and expressed as a percentage of the content of cholesterol in the control cells.

**Results:** Elevated atherogenicity of blood serum was detected more frequently in SLE pts (24/72 (65%) vs healthy controls (5/30 (17%), p<0.01). The blood serum of SLE pts caused a 3-7-fold accumulation of intracellular cholesterol, which significantly differed from healthy women (203±136% vs 127±42%, p<0.001). The ability to stimulate the accumulation of cholesterol esters in murine macrophages was not associated with age, duration of the disease, lipid spectrum and was the highest in pts with nephritis (305±141% vs 180±52%, p<0.05) and APS (253±130% vs 119±75%, p<0.05).

**Conclusion:** Serums of women with untreated SLE may stimulate the accumulation of cholesterol in mouse macrophages unlike of healthy women.

The highest atherogenicity was found in blood serum of SLE pts with nephritis and APS.

**RESPIRATORY TRACT POLY(I:C) STIMULATION ACCELERATES SALIVARY GLAND IMMUNE DYSFUNCTION IN SPONTANEOUS SJÖGREN’S SYNDROME ANIMAL MODEL**

P. Hu, B. Ming, X. Wu, L. Dong, on behalf of NO. The Department of Rheumatology and Immunology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

**Background:** Sjögren’s syndrome is one of the most common autoimmune diseases, with a prevalence of 0.33% to 0.77% in Chinese people, characterized by focal infiltration of lymphocytes in glands and the production of multiple autoantibodies. Studies have shown that virus infection may play a crucial role in the occurrence and development of this disease.

**Objectives:** It has been shown that airway stimulation with poly(I:C) can mimic respiratory tract viral infection to some extent. Thus, this study was aimed to investigate the dynamic immune responses in salivary gland after respiratory tract poly(I:C) stimulation in NOD mice.

**Methods:** The 5-week-old NOD mice were given respiratory tract poly(I:C) stimulation accelerates salivary gland immune dysfunction in spontaneous sjögren’s syndrome NOD mice, which mechanisms need to be further investigated.

ALTERATIONS IN PERIPHERAL T-CELLS AND B-CELLS SUBSETS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SJÖGREN’S SYNDROME UNDERGOING THERAPEUTIC PLASMA EXCHANGE OR IMMUNOADSORPTION

Y. Jiang1, Q. Wei1, Q. Lv1, X. Zhang1, W. Zhu2, J. Gu1.1 The Third Affiliated Hospital of Sun Yat-Sen University, Rheumatology and Immunology, Guangzhou, China; 2Gaozhou People’s Hospital, Gaozhou, China

Background: Systemic lupus erythematosus (SLE) and Sjögren’s syndrome (SS) are systemic autoimmune diseases characterized by a broad spectrum of clinical manifestations and disease course. Alternative therapies such as therapeutic plasma exchange (TPE), immunoadsorption are recommended to the patients who lack a good response to standard therapies [1].

Objectives: Our observational study was to explore whether abnormalities in T-cells, B-cells and their subtypes were present in the patients who had TPE or immunoadsorption in patients with SLE and SS compared with healthy controls (HC).

Methods: Demographic, clinical variables and autoantibodies were recorded. Flow cytometry was used to establish the frequencies of lineage subsets. Monoclonal antibodies against 21 surface markers such as CD3, CD4, CD8, were used to distinguish and evaluate T-cells’ and B-cells’ subpopulation. SLE activity was measured using systemic lupus erythematosus disease activity index (SLEDAI). Comparisons between subgroups were undertaken using paired T-test, Mann-Whitney U test and ANOVA.

Results: 6 SS patients and 1 SLE patient underwent immune adsorption, while the other 5 SLE patients had plasma exchange all for three times. There was no significant difference among SLE, SS and HC in the proportion of T-cells and B-cells. The proportion of CD3-CD19+IgD-IgM-CD27+CD38+ B-cells were reduced in SLE, while CD3+CD4+CD25+CD127- T-cells were elevated in SLE patients. The proportion of CD3-CD19+IgD-IgM-CD27+CD38+ B-cells was also reduced after TPE or immunoadsorption (p = 0.032) with ANA titers and IgG decreasing dramatically. SLEDAI scores were reduced after the therapy in SS patients.

Conclusion: The T-cell and B-cell’s profiles were proved to have alteration after TPE or immunoadsorption which shed light on the complicated mechanisms of these relatively novel therapy in SLE and SS.

SERUM LL-37, GALECTIN-3, AND TOLL-LIKE RECEPTORS-3 LEVELS DECREASE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS  

A. Karatas1, R. F. Akkoc2, S. S. Koca1. 1Firat University, Rheumatology, Elazig, Turkey; 2Firat University, Anatomy, Elazig, Turkey  

Background: Systemic lupus erythematosus (SLE) is a systemic inflammatory disease characterized by heterogeneous clinical manifestations (1). Although there are significant developments with its pathogenesis, it is still not fully known. In recent years, pathways such as NETosis and plasmacytoid dendritic cell (pDC) activation have been emphasized in the pathogenesis of SLE (2, 3). 

Objectives: In our study, we aimed to investigate serum LL-37, Galectin-3, and Toll-like receptors-3 (TLR)-3 levels, which are thought to be related to pathogenetic pathways in SLE patients. 

Methods: 17 SLE patients and 33 healthy controls were included in the study. The clinical and laboratory features of the patients were determined. Serum LL-37, Galectin-3, and TLR-3 levels were determined by ELISA (enzyme-linked immunosorbent assay) method using the appropriate commercial kit, and the results were evaluated according to the manufacturer’s instructions. 

Results: The clinical and laboratory features of the groups are described in Table 1. In our study, serum LL-37, Galectin-3, and TLR-3 levels were decreased statistically significantly in SLE patients compared to healthy control (p = 0.007, p = 0.002, and p = 0.008, respectively).

Conclusion: It is suggested that LL-37, galectin-3, and TLR-3 levels have various effects on NEtosis and pDC activation pathways in SLE pathogenesis. In our study, low levels of serum LL-37, galectin-3, and TLR-3 in SLE patients suggest that they are associated with SLE pathogenesis.

THE MITOCHONDRIAL-RETICULAR NETWORK (MRN) OF NEUTROPHILIC LEUKOCYTES OF SYNOVIAL FLUID (SF) OF PATIENTS WITH SLE AND RA  

G. V. Kudriavtseva1, Y. Malenko2, V. Shishkin1, V. V. Shishkin1. 1Saint Petersburg State University, Saint Petersburg, Russian Federation; 2Saint Petersburg State University, Saint-Petersburg, Russian Federation  

Background: Objectives: It has been established that in cells, in particular in neutrophilic leukocytes of SF, mitochondria form a mitochondrial-reticular dynamic spatial network (MRN). MRN is the epicenter of apoptosis, reflecting structural and functional changes in the immuno-complex pathology in SLE and RA. 

Methods: SF was analyzed in patients: 10 SLE (43 ± 2.3 years), 13 RA (45 ± 1.6 years) and 8 donors (42 ± 3.7 years, postmortem). Neutrophilic leukocytes from the SF were isolated by standard methods and resuspended in a composition medium: 70 mM NaCl; 140 mM sucrose; 5.6 mM KCl; 10 mM pyruvate; 8 mM MOPS; pH = 7.4. The cell suspension was centrifuged for 5 min at 800 g. MRN was isolated by centrifuging the resulting supernatant for 15 min at 12 000 g. The resulting MRN fragments were resuspended in citrate-phosphate buffer (pH = 7.4) and used in experiments. The activity of adenosine monophosphate-activated protein kinase (AMPK) was evaluated by Western blotting. Quantitative determination of cytochrome C (Cyt C) was carried out by enzyme immunoassay method using the Human Cytochrome c Platinum ELISA kit (eBioscience, USA). Active forms of oxygen free radicals (AFRF) were registered by EPR. The swelling rate of MRN fragments was determined spectrophotometrically at 540 nm. The electrophoretic mobility (EM) of MRN fragments was determined by the automatic microscope “Parmouquet-2”. 

Results: MRN of neutrophilic leukocytes of the SF undergoes significant adaptive rearrangements during the development of SLE and RA (tab.1). On average, the expression of biochemical indicators of autophagy (AMPK), apoptosis (Cyt. C), necrosis (level of oxygen free radicals, low-amplitude swelling rate) increases by 3 times compared with the conventional norm. Particular attention should be paid to pathological changes in the electrophoretic potential of MRN, which determines the functional state of the SF as a whole as a colloidal system. Obviously, in SLE and RA, depletion of the energy of MRN (a sharp increase in the activity of AMRK), activation of free radical processes, disruption of intracellular ion homeostasis due to an increase in the rate of swelling of MRN as a manifestation of a compensatory-adaptive reaction. It ultimately leads to a decrease in electrokinetic properties of MRN. Thus EM is an integral indicator of physico-chemical properties and architectonics of MRN pointing to the development of autoimmune pathology.

Notes: differences with the control norm: * - p <0.05; ** - p <0.01; *** - p <0.001. 

Conclusion: Endoplasmic stress occurs in SF cells during the development of SLE and RA, blocking of autophagy and apoptosis leads to a breakdown of neutrophilic leukocyte MRN, accumulation of high molecular products of tissue decay - phlogiogens in the intercellular space, among which the expression in the context is characterized by proteins - chaperones Hsp 60-100. These processes are accompanied by a shift in the bioelectric homeostasis of MRN neutrophilic leukocytes, an increase in their swelling rate and a significant decrease in their electrophoretic potential. The described MRN reactions of neutrophilic leukocytes of the SF should be taken into account when developing pharmacologically induced apoptosis as a new approach in the treatment of autoimmune diseases.

THE SUSTAINED POSITIVITY FOR ANTI-DSDNA ANTIBODIES FOSTERS THE ESTABLISHMENT OF AN ATRHEOROTHERMOTIC STATUS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS  

A. M. Patillo-Trives1, M. A. Aguira1, C. Pérez Sánchez1, P. S. Laura1, M. Luquez-Tévar1, I. Arias de la Rosa1, R. Ortega Castro1, M. C. Abalos-Aguilera1, M. Espinosa1, P. Segui Azpilcueta1, J. O. Pers2, N. Barbarroja Puerto1, M. Alarcon-Riquelme3, E. Collantes Estevez1, C. Lopez-Pedrera1. 1Hospital Universitario Ramón y Cajal, Madrid, Spain; 2Universidad de Salamanca, Salamanca, Spain; 3Hospital Universitario Reina Sofia Hospital (AUCORDO), Córdoba, Spain; 4Universidad de Brest, Brest, France; 5Center for Genomics and Oncological Research (GENYO), Granada, Spain  

Background: Objectives: 1. This study, developed within the Innovative Medicines Initiative Joint Undertaking project PRECISESADS framework, aimed to identify specific molecular profiles involved in the enhanced CV-risk present in SLE patients and to analyze how the activity of the sustained positivity for anti-dsDNA on the establishment of their atherothrombotic status. 

Methods: One hundred and twenty-four SLE consecutive patients (not including patients with associated antiphospholipid syndrome), belonging to the PRECISE-ESADS project, were evaluated for the presence of CVD and its association with positivity for anti-dsDNA antibodies. A second cohort of 62 SLE patients was included, of which endothelial dysfunction, lipid profile, the presence of atheroma plaques (identified by a pathologic increase in the carotid intimae media thickness -CIMT-, and the frequencies of anti-dsDNA positivity for 7 years, were evaluated. Serum inflammatory and oxidative stress biomolecules, and...
NETosis-derived bioproducts were further evaluated by multiplex assay and specific commercial kits, respectively. Besides, miRNomes were identified using next-generation sequencing. Clinical significance of the biomolecules analyzed was explored by correlation/association studies with immunological and CV-risk features.

**Results:** A significant relationship among the incidence of CVD (i.e. thrombosis or cardiac involvement) and the positivity for anti-dsDNA antibodies was recognized in the first SLE cohort. Accordingly, in the second SLE cohort, significantly impaired micro-vascular endothelial function (identified by reduction of hyperemia post-occlusion area), increased atherosclerotic index and pathologic increase in the CIMT were assessed in patients positive for anti-dsDNA in relation to anti-dsDNA negative patients. Around a 65% of SLE patients displayed a sustained positivity for anti-dsDNA antibodies for more than 7 years. These patients showed a distinctive and specific molecular profile compared with patients that had remained negative for anti-dsDNA, including increased inflammatory profile (IL1B, IL2, IL6, IL17, EOTAXIN, FGF, GMCSF, IFNγ, IP10, RANTES, TNF), enhanced oxidative status (lipperoxidases), and higher NETosis (nucleosomes, elastase). Levels of these biomolecules were closely interconnected and associated to their regulatory miRNAs, which accordingly exhibited differential expression in SLE anti-dsDNA(+) vs anti-dsDNA(-) patients. Finally, the frequency for positivity of anti-dsDNA significantly correlated both with markers of endothelial dysfunction and with the presence of atheroma plaques in SLE patients, pointing at the direct involvement of anti-dsDNA-Abs in the development of these processes.

**Conclusion:** 1. Positivity for anti-dsDNA antibodies confers a specific molecular profile linked to an enhanced CV-risk in SLE patients. 2. Moreover, the sustained positivity for anti-dsDNA antibodies fosters the establishment of an atherothrombotic status in these autoimmune patients.

**DIVERSITY ANALYSIS OF INTESTINAL FLORA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

Z. Mingxing1, X. F. Yin1. 1The Second Hospital of Shanxi Medical University, Taiyuan, China

**Background:** Systemic lupus erythematosus (SLE) is a multiple systemic autoimmune disease and its pathogenesis is still not fully understanding. In recent years, there has been reports on the relationship between SLE and intestinal flora.

**Objectives:** To study the diversity and the intestinal flora intestinal microbes in patients with SLE and further provide new ideas for clinical treatment.

**Methods:** The stool samples of 28 patients with SLE and 125 normal healthy adults were collected. The 16S rRNA in the specimen was sequenced using the Roche/45 high-throughput sequencing platform, and the differences between the two groups were compared at the level of the phylum and genus.

**Results:** In SLE patients, as the picture show, the levels of fusobacteria, proteobacteria and TM7 were significantly higher (P<0.05) and the number of Firmicutes was significantly decreased (P<0.05) than that of healthy controls at the genus level. The percentage of bifidobacterium, Collinsella, Enterococcus, Firmicutes was significantly decreased (P<0.05) than that of healthy controls at the phylum level.

**Conclusion:** The diversity of intestinal flora in patients with SLE altered from that of normal population. The differences are likely to be one of the pathogenesis of lupus, which might provide theoretical foundation for the regulation of intestinal flora to treat autoimmune diseases such as lupus.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.5943
inflammatory potential of CD38 positive memory T lymphocytes after stimulation and performed single-cell RNA sequencing analyses.

**Results:** CD38 Expression is increased on certain immune cell subsets: Plasmablasts and unswitched Memory B cells, as well as plasmacytoid dendritic cells and CD16+ non-classical monocytes. We observed a drastic increase in CD38 in both memory CD4 and CD8 T lymphocytes in SLE patients. These cells were mostly effector T cells (and not regulatory T cells) and expressed other markers of T cell activation and proliferation. We found an enrichment of CD38+ memory T cells in the urine of patients with lupus nephritis. After polyclonal stimulation of T cells, CD38+ produced less inflammatory cytokines. Preliminary single-cell sequencing results indicate that CD38+ CD8+ T-lymphocytes have decreased clonal diversity and that these cells express genes associated with exhaustion and type 1 interferon response.

**Conclusion:** Increased CD38 expression on various lymphocyte subsets provides an additional rationale for investigating CD38-directed therapies in SLE. CD38 could be used as a target for CD38+ T cells and may have immune-modulatory functions.

**Disclosure of Interests:** None declared.

activation lead to multisystem tissue damage. Plasmacytoid dendritic cells (pDCs) play a central role in the pathogenesis of SLE through dysregulated type I IFN production, together with activated myeloid DCs (mDCs), amplifying vicious spiral of autoimmune disorders(1). Therefore, control of the aberrant DC activation may provide an alternative treatment strategy against SLE.

**Objectives:** Mycophenolate mofetil (MMF), which has been used to treat lupus nephritis, specifically blocks proliferation of B and T lymphocytes by inhibition of inosine-5-monophosphate dehydrogenase (IMPDH). In addition, although there is evidence indicating the immunosuppressive effects of MMF on human monocyte-derived dendritic cells(2,3), there are no reports showing its effects on human blood DC subsets. Here we focused on the effects of MMF on the functions of the blood pDCs and mDCs.

**Methods:** We isolated human blood DCs from healthy donors using cell sorting(4) and examined the function of mycophenolic acid (MPA), which is metabolic products of MMF, on DC subsets in response to TLR-ligands and serum from patients with active SLE. Written informed consent was obtained from all healthy adult donors and SLE patients.

**Results:** We found that therapeutic plasma concentration range of MPA down-regulated expression of CD40, CD80 and CD86 dose-dependently on mDCs and pDCs without inducing apoptosis, in response to R848 (TLR7/8 agonist) and Cpg2216 (TLR9 agonist), respectively. Of note, MPA profoundly suppressed IL-12 production and STAT4 expression in the mDCs and IFN-α production and IRF7 expression in the pDCs(Fig 1). We also observed inhibition of nuclear translocation of IRF-7 in pDCs treated with MPA by confocal microscopy(Fig 2). Furthermore, we identified that MPA had an inhibitory effect on SLE serum-induced IFN-α production by human PBMCs.

**Conclusion:** Our data suggest that MMF can drive a wedge into the vicious spiral of autoimmune disorders through regulating the function of not only lymphocyte but also DC subsets. Thus, we unveiled a part mechanism of the therapeutic ability of MMF against SLE.

cytokine-stimulated vs. unstimulated PBMCs of SLE patients could be related with clinical manifestations.

**Objectives:** We aimed to correlate the expression of HERV-E clone 4.1 gag transcripts of unstimulated and phytohaemoagglutinin (PHA) and interferon-2 (IL-2)-stimulated PBMCs of SLE patients and healthy controls (HCs) and to evaluate the association between their expression and the demographic and clinical data of the SLE cohort.

**Methods:** PBMCs were isolated from 18 SLE patients and 22 age- and gender-matched controls. Cells from 10 SLE patients and 15 HCs were harvested for RNA isolation, HERV-E clone 4.1 gag- and RPL13-selective qRT-PCR analysis. The expression of gag transcripts was normalized to that of the housekeeping gene RPL13, using the Pfaffl method. PBMCs of the remaining patients and HCs were stimulated with PHA/IL-2 and HERV-E clone 4.1 gag expression assessed as described before. Statistical analysis was carried using a SPSS software, version r.23.

**Results:** Table 1 presents the demographic data of patients. The normalized mean ± SD gag expression was 1.6 ± 2.2 and 0.80 ± 0.79 in unstimulated PBMCs of SLE patients and HCs, respectively; and 1.1 ± 0.7 and 1.1 ± 0.4 in stimulated SLE and HC PBMCs, respectively. No significant difference emerged between patients and controls and between stimulated and unstimulated PBMCs (fig. 1). Gag transcripts expressed in PHA/IL2-stimulated PBMCs of SLE patients significantly correlated with oronasal ulcers and high titers of anti-dsDNA antibodies (p=0.01 and p=0.004, respectively), while gag transcripts of unstimulated SLE PBMCs were significantly associated to the number of ACR criteria fulfilled (p=0.02).

EFFECTS OF IMMUNOSUPPRESSIVE MEDICATION ON TYPE I INTERFERON ACTIVATION: IN VITRO ANALYSIS SHOWS A DOWNSCALING EFFECT ON IFN ACTIVATION OF HYDROXYCHLOROQUINE AND ASPIRIN

M. J. Wahdat1,2, M. Lourens1, E. Huijser1, C. G. Van Helden-Meeuwsen1, S. Kamphuis2, M. Versnel1, Erasmus MC, Dept. Immunology, Rotterdam, Netherlands; 2Sophia Children's Hospital, Erasmus MC, Dept. Pediatric Rheumatology, Rotterdam, Netherlands

Background: Systemic Lupus Erythematosus (SLE) is prototypic Interferon (IFN) driven autoimmune disease characterized by an increased expression of type-I IFN stimulated genes, known as the IFN signature. The inhibitory effects of various drugs like Hydroxychloroquine and more recently Aspirin on IFN inducing pathways was significantly reduced by Aspirin and HCQ in an in vitro model.

Methods: Freshly isolated human PBMCs were stimulated for 24 hours with or without CpG-A or Imiquimod (IQ) or transfected with the cGAS agonist G3-YSQ to induce IFN upregulation through the TLR7/9- and DNA Sensing Receptor-pathway respectively. To assess the direct role of the medication on the downstream pathway of the IFNAR PBMCs were stimulated with IFN-a2b. Aspirin, diclofenac, HCQ, Mycophenolate Mofetil (MMF) and prednisone were added separately to these cultures followed by analysis of MxA by qPCR as a readout for IFN type I activation. Cell viability in all culture conditions was above 85%.

Results: The type I IFN activation induced by CpG-A, IQ, G3-YSQ and IFN-a2b was significantly reduced after addition of Aspirin. Addition of diclofenac showed a trend towards reduced levels in all conditions. HCQ was able to significantly reduce the TLR7 induced IFN activation by CpG-A and IQ while MMF and prednisone did not show an effect in any of the culture conditions.

Conclusion: The IFN activation induced by the stimulation of various IFN inducing pathways was significantly reduced by Aspirin and HCQ in an in vitro model. Combining both clinical and in vitro data from our longitudinal cohort of childhood-onset SLE patients will elucidate the effect of different immunosuppressive drugs on the type-I IFN signature in these patients.

DRUG DEPENDENT ALTERATIONS IN B-CELL REPETIORE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH LOW DISEASE ACTIVITY

S. Zeng1, B. Dreo2, B. Prietl1,4, S. Koller4,4, H. Souri3,4, A. Lackner3,4, M. Dorazio1, K. Brickmann1, J. Gretler1, F. Fürst-Moazedi1, M. Stradner1,2, W. Greninger1, H. P. Brezinsek1,2, Medical University of Graz, Internal Medicine, Division of Rheumatology and Immunology, Graz; Austria; 2Medical University of Graz, Internal Medicine, Division of Rheumatology and Immunology, Graz, Austria; 3Medical University of Graz, Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria; 4CIBimed Gmbh - Center for Biomarker Research in Medicine, Graz, Austria

Background: B-cells play a major role in the pathogenesis and perpetuation of the immune response in systemic lupus erythematosus (SLE). So far, B-cell subtypes have been studied well, but the precise mechanisms of the B-cell alterations during disease activity and during remission, depending on different medication, are still unclear.

Objectives: The aim of our study was to investigate the drug dependent alterations in the B-cell repertoire of SLE patients with low disease activity (SLEDAI – 2K ≤4).

Methods: Peripheral blood samples from 39 patients suffering from SLE (mean±SD; age 43±13 years, 87.2% females, disease duration 11.1±7 years) were drawn over 2 years. All SLE patients were in remission or low disease activity (median±SE, SLEDAI of 2.0±2.0). B-cells were characterized using CD19, CD20, CD5, CD27 antibodies and were grouped in naive (IgD±27), non-switched memory (IgD±27), memory (IgD±CD27+), B1 (CD5±CD27+) and MBL-like (CD5++) B-cells. A quantitative flow cytometric bead-based assay (Quantibrite PE kit from Becton Dickinson) was used for the estimation of CD19 antibodies bound per cell. Further, CD38 and CD69 antibodies were used to characterize the B-cell subsets. All cytometric measurements were performed using a standardized BD LSR Fortessa platform. After 3 years of follow-up, patients’ data about disease activity and current medication were obtained.

Results: 22 SLE patients were treated with hydroxychloroquine (85.8%) and 19 patients received mycophenolate mofetil (MMF; n=14; 54.6%) or azathioprine (AZA; n= 5; 19.5 %). 5 patients were treated with other DMARDs. Independently of hydroxychloroquine and/or MMF, no significant differences were seen in naïve, non-switched memory, post-switched memory, plasma blasts, B1- or MBL-like B-cells. Patients treated with AZA had significantly lower naïve B-cells (means±SD; 39.3±6.7 vs. 73.1±19.3 %; p = 0.028), but had significantly higher IgD-post switched B-cells (31.2±9.1 vs. 12.5 ±9 .2 %; p = 0.028, respectively) compared with no AZA-treatment. Interestingly, activated B-cells (5.5±1.5 vs. 18.1±1.11 %; p = 0.009) were significantly higher in AZA-treated. After 3 years of follow-up, almost all patients were in remission (median±SE, SLEDAI of 2.0±2.0), except of 3 patients with a SLEDAI of ≥ 6. Interestingly, those patients had at baseline, statistically higher naïve B-cells (p = 0.041) and lower B1-like B-cells (p ≥0.020) compared with patients with low disease activity.

Conclusion: Our results suggest that independently of hydroxychloroquine and/or MMF treatment, all patients with low disease activity had similar normal B-cell subsets. Interestingly, in the small group of patients who were treated with AZA, a reduced regeneration of B-cells was shown. Patients with higher disease and high naïve B-cells showed an increased disease activity after three years.

GENE EXPRESSION Profiles OF PRIMARY SJÖGREN’S SYNDROME ASSOCIATED THROMBOCYTOPENIA IN B-LYMPHOCYTE USING HIGH-THROUGHPUT SEQUENCING

S. Zhang1, J. Ou1, L. Wang1, M. Li1, X. Zeng1,1, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Rheumatology, Beijing, China

Background: Primary Sjögren’s syndrome(SSS) is a classical systemic autoimmune disease. Thrombocytopenia is one of the hematological manifestations of pSS with great challenges in clinic.

Objectives: To identify the candidate genes and functionally enriched pathways in the immune genesis and progression of primary Sjögren's syndrome (pSS) associated thrombocytopenia.

Methods: High-throughput sequencing was performed on 3 patients with pSS, 3 patients with pSS associated thrombocytopenia and 3 healthy individuals. The differentially expressed genes (DEGs) were identified, and function enrichment analyses were processed. The protein-protein interaction network (PPI) was constructed, followed by calculation of topological characteristics and sub-module analysis in order to obtain hub DEGs. The expression of some hub genes was verified by Real-Time PCR in 24 pSS patients.

Results: A total of 19 DEGs were identified. The enriched functions and pathways of the DEGs includes Toll-like receptor signaling pathway, Salmonella infection, Viral protein interaction with cytokine and cytokine receptor, NF-kappa B signaling pathway and Human cytomegalovirus infection. Seven hub genes (TNF, IL1B, CXCL8, CCL3, CCL4, CCL3L1, CCL4L1) were identified and pathway enrichment analysis revealed that these genes were mainly enriched in toll-like receptor pathway. The relative expression of the CXCL8 mRNA in SSS-Lymphocytes in patients with pSS associated thrombocytopenia was higher than that in the pSS without thrombocytopenia group. No differences were observed in the IL-1β or TNFα expression between these two groups.

Conclusion: PSS associated thrombocytopenia might be a subset characterized by a systemic inflammatory state. The identification of upregulated genes involved in thrombocytopenia of pSS provides insight in disease pathogenesis and opens avenues for the design of novel therapeutic strategies.

Figure 1. DEGs in pSS associated thrombocytopenia. 183 DEGs (31 up- and 151 down-regulated) between pSS patients with and without thrombocytopenia(a, c). 459 DEGs between pSS associated thrombocytopenia patients and healthy individuals were identified (b, d). The overlap among the 2 groups contained 19 genes represents the DEGs specified in pSS associated thrombocytopenia (e).

AB0148 ANALYSIS OF DIFFERENTIALLY EXPRESSED GENES AND MICRORNAS OF B CELLS IN PRIMARY SJOGREN’S SYNDROME BY RNA SEQUENCING

H. Zhang1, H. Zhang1, D. Gao2, F. Zhang2, Z. Zhang1, 1Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China; 2Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China

Background: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease mainly characterized by the inflammation of exocrine glands. There are two key insights into pSS pathogenesis, which included “IFN signature” and hyperactivity of B cells. mRNA and microRNA (miRNA) are very important to control the gene expression.

Objectives: In this research, we analyzed the differentially expressed genes (DEG) and miRNA of B cells in pSS patients by RNA-sequencing. And we aim to preliminarily screen out some special miRNAs and target gene loci that may be involved in transcription regulation of B cells of pSS.

Methods: Peripheral blood samples from 3 pSS patients and 3 age-matched healthy controls (HC) were collected. CD19+ B cells were sorted by Magnetic cell sorting method. Total RNA was extracted and cDNA of transcriptome or miRNA preparation was performed to screen the DEG and miRNA. The GO Terms was used to uncover the biological function of DEGs, and the KEGG pathway enrichment was used to find out the related signal pathway. The mRNA-miRNA conjoint analysis was also performed.

Results:
1. There were a total of 73 significantly DEGs in B cells of pSS patients compared to HC, including 51 upregulated DEGs (such as IFI44L, IFI44, IFIT1, IFITM1, IFIT3, IFIT2, IFIT7, IFI6 and ISG15) and 22 downregulated DEGs (such as ESRR2 and EGR1). GO Terms and KEGG pathway analyses showed that most of the upregulated DEGs were enriched in IFN signaling and IFN regulatory pathway, and also showed the relationship with microbial infection, such as influenza A virus, hepatitis C virus, measles and herpes simplex virus.
2. There were five significantly differentially expressed miRNAs, including hsa-miR-4485-3p, hsa-miR-144-5p, hsa-miR-144-3p, hsa-miR-451a, hsa-miR-4732-3p. GO Terms and KEGG pathway analyses showed that most of the target genes which regulated by those miRNAs were enrichment on herpes simplex virus and TGF-β signaling pathway.
3. DEG and differentially expressed miRNAs conjoint analysis showed that the target DEGs which regulated by those miRNAs participated in cytoskeleton formation and modification of DNA or RNA, such as RASD2, CKAP4, SPARSL2, METTL1.

Conclusion: There were 51 upregulated DEGs and 22 downregulated DEGs in B cells of pSS patients. GO Terms and KEGG pathway analyses showed that most of the upregulated DEGs were enriched in IFN related signaling pathway, and also showed the significant relationship with microbial infection. Conjoint analysis showed that the target DEGs which regulated by differentially expressed miRNAs participated in cytoskeleton formation and modification of DNA or RNA. There maybe more than one regulatory methods lead to DEGs in B cells of pSS patients.

AB0149 PERIPHERAL T HELPER SUBSET PROFILING DIFFERS IN VARIOUS SUBSETS OF IDIOPATHIC INFLAMMATORY MYOSITIS

A. Anuja1, H. Singh1, D. Misra1, V. Agarwal1, L. Gupta1, Sanjay Gandhi
Postgraduate Institute of Medical Sciences, Lucknow, India

Background: There is a dearth of biomarkers in Idiopathic Inflammatory Myositis (IIM) to identify ongoing inflammation in the muscle and distinguish it from inactivity or damage.

Objectives: Since myositis is autoantibody mediated and tertiary lymphoid organogenesis (TLO) reported in the diseased muscles, we investigated peripheral blood T helper subset profiling as a reflection of ongoing muscle inflammation.

Methods: Twenty-six patients of IIM (ACR EULAR criteria) were compared with 15 healthy controls (HC) and 21 patients with sarcoidosis (Table 1). Peripheral blood mononuclear cells were stained with combinations of antibodies to identify Th1, Th17, Th17.1 and Treg cells after stimulation assays (BD Biosciences). Myositis Specific and Associated autoantibodies were tested by the line immunoassay (Euroimmun, Germany).

Results: All T helper subsets were higher in myositis as compared with healthy controls (Figure 1A a-d). Between various IIM subsets, polyomyositis had higher Th1 and Treg cells (Figure 1B b, c) while Th17 and Th17.1 cells (c) were higher in Overlap Myositis (Figure 1B a, d) as compared with healthy controls. Patients with sarcoidosis had similar subset profiling as myositis. (Figure 5a-f)

Patients who were had either arthritis or were positive for myositis specific autoantibodies had higher Th17.1 cells (Figure 2A a(iii)) as compared with those negative for MSA. There was no difference in T cell profile between the various autoantibody subsets (Figure 6a-d).

Figure 1 A. Representative plot depicting all T helper subsets quantified were higher in myositis as compared with healthy controls1B: Representative plot comparing %T cell subsets in various subsets of myositis with healthy controls showing that % Th1 cells (a) and Tregs (d) are highest in Polymyositis than controls while % Th17 (b) and % Th17.1 cells (c) are higher in Overlap Myositis

Figure 2 A. Comparisons between various phenotypic subsets suggest patients positive for MSA had higher Th17.1 cells (Figure 2A a(iii)) than those negative for MSA. Similarly, patients with arthritis had higher Th17.1 cells (Figure 2A b(iii)) than those negative for MSA. There was no difference in T cell profile between the various autoantibody subsets (Figure 2B a(ii) & b(ii)). B: Representative dot plot of T cell subsets ratio (Th1, Th17 & Th17.1) with Treg subsets (a) Th17/Treg and Th17.1/Treg ratios.

Conclusion: T Helper cell subsets are distinct from HC but similar to sarcoidosis patients. However, they differ in various subsets of myositis, suggesting different pathogenic mechanisms are operative. Autoantibody positivity is associated with elevated Th17.1 population suggesting plasticity in TLO which needs to be explored further. However, T cell profiling cannot distinguish active from inactive disease limited predictive potential as a biomarker.
**Background:** Systemic sclerosis (SSc) is a chronic autoimmune disease characterized by microangiopathy and fibrosis. In physiological wound healing, fibroblasts are transiently activated for tissue repair. In contrast, fibroblasts are persistently activated during fibrosis and thus result in progressive matrix deposition and tissue remodeling. However, the pathogenesis of the fibrotic process is not fully understood.

**Objectives:** We aimed to identify molecules that play a role in chronically activated fibroblasts.

**Methods:** To identify molecules specifically upregulated in human fibrotic fibroblasts, RNA-sequencing was performed. Identified adaptor proteins were further validated in skin biopsy samples of patients with limited cutaneous SSc (lcSSc) and diffuse cutaneous SSc (dcSSc), and evaluated correlation between expression levels and clinical parameters. Respective overexpression and siRNA knockdown were further addressed in vitro. Functional effects were assessed by qPCR, hydroxyproline, proliferation and migration assays. Mouse models of systemic sclerosis were used to functionally validate adaptor proteins in vivo.

**Results:** We identified adaptor proteins as significantly upregulated molecules in chronically active fibroblasts of skin biopsy samples from SSc patients compared to fibroblasts from healthy controls. Expression levels were correlated with the modified Rodnan skin score in the skin of SSc patients. We observed higher expression levels also in the mouse model of topoisomerase I induced skin fibrosis. This result was also observed in bleomycin induced lung fibrosis model suggesting important functions of adaptor proteins during fibrotic remodeling across different organs. Fibroblast-specific knockout resulted in significantly attenuated bleomycin-induced fibrosis. Upon bleomycin challenge, hydroxyproline content was diminished in mice with genetic deficiency of adaptor proteins. In addition, COL1A1, COL1A2 and Lum mRNAs and also the number of myofibroblasts were significantly lower in knockout mice compared to wild type mice. In vitro, knockout of adaptor proteins resulted in a significant alteration of the migratory potential of fibroblasts.

**Conclusion:** Our results demonstrate that adaptor proteins play an essential role in the pathogenesis of systemic sclerosis. Understanding the molecular mechanism of adaptor proteins may lead to a novel therapeutic intervention in human SSc and related disorders.

**PRELIMINARY RESULTS SHOW AN INCREASED EXPRESSION OF COINHIBITORY RECEPTORS IN SYSTEMIC SCLEROSIS**

M. Aspari 1, S. R. Greisen 1,2, M. Hvid 1,2, B. Deleuran 1,2, D. Abraham 1 on behalf of Bent Deleuran’s Group David Abraham’s Group. 1Aarhus University, Biomedicine, Aarhus, Denmark; 2Aarhus University, Rheumatology, Aarhus, Denmark; 3Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 4University College London, Department of Cell and Molecular Biology, London, United Kingdom

**Background:** Recent studies suggest dysregulation in T cell activation in systemic sclerosis (SSC). Co-inhibitory receptors (Co-IRs) such as TIM-3, PD-1 and LAG-3 play a crucial role in controlling excessive T cell activation and in maintaining immune homeostasis. Engagement of these receptors by their ligand’s limits cytokine production in response to TCR or activating NK receptor stimulation and hence limit tissue damage from excessive immune activation. However, chronically increased expression of multiple Co-IRs is a hallmark of immune exhaustion. We evaluate the role of these soluble Co-IRs in diffuse SSC (dcSSC).

**Objectives:** Establish the role of CoIR and their ligands in diffuse systemic sclerosis. Understand how immune regulatory mechanisms influence the development of fibrosis. Provide a better understanding of the disease and fibrosis in general.

**Methods:** PBMCs ( Peripheral blood mononuclear cells) and dermal fibroblasts from SSc patients were isolated and investigated for markers of T cell inhibition. These cells were analysed using flow cytometry in a 10 colour panel. Cells were stained for PD1, TIM3, TIGIT, LAG3, CD3, CD8, CD4 and CD19 along with a Live/dead marker. Co-cultures of fibroblasts and PBMCs will be set up, and treated with various drugs that act on the Co-IRs.

**Results:** The proportion of CD4+ T cells expressing PD1 were markedly increased in SSC patients compared to healthy volunteers and Rheumatoid Arthritis patients.

**Conclusion:** Soluble co-inhibitors are differentially expressed in early dcSSc compared to healthy volunteers and other autoimmune diseases. Our preliminary data indicates that these co-inhibitors could play an important role in unravelling the pathogenesis of systemic sclerosis. Inhibition or activation of these receptors through different treatment modalities can be utilized as a novel patient centric treatment strategy.

**LENABASUM, A CB2 AGONIST, INHIBITS INFLAMMASOME ACTIVATION**

S. Chintalacharuvu 1, P. Zhang1, B. White1, S. Atamas1, Corbus Pharmaceuticals, Inc., Norwood, United States of America
Background: Upregulation of the innate immune response via the activity of Toll-like receptors and the NLRP3 inflammasome have been suggested as initiating events that can drive fibrosis in systemic sclerosis (SSc) (Pharmacol Ther. 2018;192:163-169). Lenabasum, a cannabinoid receptor type 2 agonist, is known to activate the resolution phase of acute human innate immune responses triggered through Toll-like receptor activation, favoring production of pro-resolving lipid mediators, reducing inflammatory infiltrates, and increasing bacterial clearance (Clin Pharmacol Ther. 2018;104:875). Given the potential importance of inflammasome activation in the pathogenesis of SSc, the question remained whether lenabasum inhibits inflammasome activation.

Objectives: Assess effects of lenabasum on IL-1β and IL-18 production induced by inflammasome activation.

Methods: Primary human macrophages were derived from monocytes, stimulated with LPS and ATP to active inflammasomes and cultured with lenabasum. Levels of IL-1β and IL-18 were measured in cell supernatants by ELISA. Separately, human PBMC were activated with 0.1 µg/ml LPS ± 10 µM lenabasum for 24 hours, and effects of lenabasum on the levels of IL-1β and other pro-inflammatory cytokines were measured.

Results: Lenabasum significantly inhibited IL-1β and IL-18 secretion by monocyte-derived macrophages, with IC50 = 66.73 ± 3.92 nM and 349.23 ± 212.7 mM, respectively. A control inflammasome activation inhibitor, MCC950, which showed IC50 = 18.33 ± 1.22 nM for IL-1β inhibition and IC50 = 21.43 ± 0.81 nM for IL-8 inhibition.

Conclusion: Lenabasum inhibits inflammasome activation, which could contribute to potential therapeutic efficacy in SSc and other autoimmune diseases.

Objectives: To investigate MerTK involvement in the pathogenesis of IgG4-RD by evaluating (a) the expression of MerTK and of its endogenous ligands in IgG4-RD tissues; (b) the presence of circulating precursors of MerTK+ cells infiltrating IgG4-RD lesions in the peripheral blood of IgG4-RD patients; (c) the effects of immunosuppressive therapies on MerTK expression in IgG4-RD tissues.

Methods: Three distinct cohorts of IgG4-RD patients were included in this study. 8 active patients were used for immunohistochemistry studies for MerTK expression. 16 IgG4-RD and 14 Sjögren syndrome patients, together with 6 control tonsils, were used for multicolor immunofluorescence studies and TissueQuest software quantification of the expression of MerTK, CD68, CD163, Pros1, Gas6, CD4, SLAMF7, CD19, IgG4, cleaved caspase-3. 10 untreated IgG4-RD patients were used to evaluate MerTK expression in circulating monocytes subsets and fibroblasts by flow cytometry.

Results: MerTK was highly expressed in IgG4-RD affected organs. MerTK+ cell number accounted on average for 16% (range 5-35%) of all cells in the tissue, and the majority of them expressed CD68, reflecting a monocyte-macrophage origin. 33.5% (interquartile range (IQR) 26-41%) of MerTK+ cells co-expressed CD68 and CD163, while 30.5% (IQR 19-41.5%) expressed CD68 but not CD163. CD68+MerTK+ cells displayed two main morphological appearances, compatible with those of macrophages and of myofibroblasts. In addition, MerTK+ cell number was significantly increased in salivary glands from IgG4-RD patients compared to Sjögren syndrome (p < 0.0001). Circulating precursors of CD68+MerTK+ cells infiltrating IgG4-RD lesions were identified by flow cytometry in the peripheral blood of patients with active IgG4-RD as MerTK+ populations of intermediate monocytes, nonclassical monocytes and collagen expressing fibroblasts. MerTK ligand Pros1 was exposed on 52% (IQR 42-57%) of infiltrating B lymphocytes, 74% (IQR 54-89%) of infiltrating T lymphocytes, and, likely, on apoptotic cells that were detected in IgG4-RD tissues. CD68+MerTK+ cells were found in physical contact with Pros1+ cells in IgG4-RD lesions and their number decreased by 56% after successful treatment with rituximab.

Conclusion: MerTK is abundant in IgG4-RD affected organs and is preferentially expressed on CD68+ macrophages and myofibroblasts that infiltrate IgG4-RD lesions. MerTK+ cells might interact with apoptotic cells and Pros1 expressing T and B lymphocytes in IgG4-RD tissues, leading to the persistent activation of processes involved in the resolution of inflammation and promoting the development of tissue fibrosis.

THE ULTRASTRUCTURAL FEATURES OF INTERSTITIAL LUNG TISSUE INVOLVEMENT DUE TO SYSTEMIC SCLEROSIS: ANIMAL EXPERIMENTAL STUDY

B. Doškaliová1, L. Zaitsë1, R. Žaptech2, 1Ivano-Frankivsk National Medical University, Department of Pathophysiology; Department of Internal Medicine No 1, Clinical Immunology and Allergology named after Academician Y.M. Neiko, Ivano-Frankivsk, Ukraine; 2Ivano-Frankivsk National Medical University, Department of Pathophysiology, Ivano-Frankivsk, Ukraine. Correspondence to: E-mail: zaitsa90@gmail.com

Background: Systemic sclerosis (SSc) - is an autoimmune connective tissue disease, which crucial role is played by inflammation and fibrosis development. This pathology is characterized by multiple symptoms that occur due to alterations of the vascular wall, limited or widespread fibrosis of the dermis and visceral organs, dysregulation of cellular and humoral immunity, followed by the formation of autoantibodies specific to the structures of the organism. Although external manifestations of SSc certainly lead to a decrease in the functional activity and patient’s quality of life up to disability, the real danger is a violation of the functions of the internal organs and systems.

Objectives: The aim of our study was to determine changes in the morphological structure of lung interstitial tissue at the subcellular level of the structural organization, which were achieved by modeling of this autoimmune pathology in laboratory animals.

Methods: The main concept of modeling process was based on the previously described method of SSc induction [1,2] however with some differences from original model. Into the study were involved 30 pubescent Wistar rats (220-240g) who underwent three times a week subcutaneous administration of 0.5ml of 5% sodium hypochlorite (NaClO) solution with active chlorine concentration of 190 g/dm³ for 6 weeks in a row; control group (20 rats) that received injections with an equal volume of sterile saline solution. After 8 weeks from the beginning of the experiment animals were sacrificed under thiopental anesthesia, lung tissue specimens were obtained, fixed alternately in 2.5% glutaraldehyde and in 1% solution of osmium tetroxide. After dehydration, the material was embedded in Epon-Araldite. Sections were obtained on an ultramicrotome (Tesla BS-490) magnification x6600 was performed on high-resolution microscope (PEM-125K).

Results: The ultrastructural study of lung specimens reviled the fibroblasts with high amounts of collagen fibers in the interstitial tissue of the alveoli wall. Fibroblast nuclei were characterized by irregular shape and numerous invaginations of the nuclear envelope and marginal aggregation of chromatin granules. Fig. 1 depicts the fragment of the alveolar wall of the lungs of white Wistar rats in 8 weeks after the start of the experiment. On the Fig. 1 could be distinguished the lumen of the alveoli (1), fibroblast (2) with increased quantity of collagen fibers (3) and a peripheral part of alveolocyte type (4).

Conclusion: The current findings confirm the efficacy of NaClO chemical model of reproduction of interstitial lung tissue involvement within SSc pathogenesis; this model could contribute to the further investigation of peculiarities of autoimmune origin interstitial lung disease (ILD).

NMR-BASED MUSCLE METABOLICOSMICS IN INFLAMMATORY MYOSITIS: UNDERSTANDING CHANGES IN SERUM AS A REFLECTION OF THE MUSCLE

L. Gupta1, U. Kumar2, A. Aruja1, P. Sharma1, A. Guleria2, D. Kumar1, V. Agrawal1, 1Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; 2Centre of Biomedical Research, Lucknow, India; 3SGPGI Trauma Centre, Lucknow, India

Background: We have previously found promise in NMR as a tool to distinguish sera of active from inactive inflammatory myositis (IM). To understand the changes previously found in sera and urine we studied muscle tissue of patients with myositis.

Objectives: To identify differences in metabolome on inflamed muscle tissues of patients with active myositis from that of healthy controls and infectious polymyositis.

Methods: Muscle (n=17) from patients classifiable as myositis by the ACR-EULAR criteria [34 years (23.5 - 50.5 IQR), M/F: 1:3] were compared with healthy controls (n=11, age = 44 (35-50) years, M/F:1:1). Two disease controls with infectious polymyositis were also compared. Findings were applied to muscle biopsy tissues of two patients with established myositis and superadded infections (HBV, Histoplasmosis) to assess discriminatory potential.
Metabolic profiles were obtained at 800 MHz NMR spectrometer and compared using multivariate partial least-squares discriminant analysis (PLS-DA). The discriminatory metabolites were identified based on variable importance in projection (VIP) statistics and further evaluated for statistical significance (p-value < 0.05). Paired T tests, ANNOVA and correlation of individual metabolites were done after normalizing for formate.

Results: Metabolomics profiles in IIM were distinct from healthy controls (Fig. 1A). Of the various discriminatory metabolites (Fig. 1B), Succinate had the highest discriminatory potential (AUC 0.8, P=0.01) followed by citrate, glycine, glycerol, glucose, creatine and lactate. (Fig. 1C) Both glucose and creatine were decreased in IIM (Fig. 1D,E) and this was uniform across all types of IIM. However, glycine levels differed across different myositis subsets supporting the fact that they might differ in pathogenesis. (Fig. 1E) Amongst various serum biomarkers of muscle disease and damage, serum Aspartate Transaminase correlated negatively with glycine (r=0.8, p=0.04), and serum creatinine correlated positively with glutamate (r=0.6, p=0.01), and serum creatinine correlated negatively with glycero (r=0.8, p=0.04).

Biopsies of infectious polymyositis suggested difference in spectra from IIM (Fig. 1C). Of the various discriminatory metabolites (Fig. 1B), Citrate had the highest discriminatory potential (AUC 0.8, P=0.01) followed by citrate, glycine, and creatine. Amongst various serum biomarkers of muscle disease and damage, serum Aspartate Transaminase correlated negatively with glycine (r=0.8, p=0.04), and serum creatinine correlated positively with glutamate (r=0.6, p=0.01), and serum creatinine correlated negatively with glycero (r=0.8, p=0.04).

IGG FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLEROSIS HAVE AN INFLUENCE ON COAGULATION FACTORS IN HUMAN CEREBRAL MICROVASCULAR ENDOTHELIAL CELLS IN-VITRO

B. Hassel1, M. M. Fürst2, P. Singh3, U. Müller-Laden4, M. Kaps5, F. Blaes6, T. Gerriets7, M. Tschernatsch8, 9. Kerckhoff-Klinik, Department of Internal Medicine and Rheumatology, Bad Nauheim, Germany; 2Universitätsklinikum Gießen, Department of Neurology, Gießen, Germany

Background: Endothelial cells from the microvasculature (hBMEC) of the brain show significant morphological and functional differences compared to EC from other anatomical areas. They are characterized by tight junctions, are not fenestrated and show less active transport mechanisms. On the other hand, the mitochondrial density is relatively high in hBMEC due to the high cerebral glucose metabolism.

It could be already observed that interferon-α from SLE- sera induces the expression of MHC class I molecules on human dermal microendothelial cell line, but it is not known whether this also occurs on hBMEC. hBMECs can synthesize pro-inflammatory cytokines and chemokines such as IL-1β, but in lower concentrations than human umbilical vein endothelial cells.

Patients suffering from systemic lupus erythematosus (SLE) or systemic sclerosis (SSc) show a wide spectrum of central nervous symptoms. Both, SLE and SSc are characterized by different autoantibodies and endothelial vascular damage, especially in microvessels. 10-40% of patients with SLE suffer from lupus vasculopathy. Vascular dysfunction is one of the earliest pathological changes in SSc. Anti-endothelial autoantibodies (AECA) appear in SLE, as well as in SSc and other connective tissue diseases. Research within the last years revealed that AECA play a critical role within the vascular pathogenesis of SLE and SSc. So far there is no evidence that AECA bind to hBMEC and it is not clear whether they have an effect on this special endothelial class.

Objectives: In this project, we investigated if autoantibodies against hBMEC are detectable in SLE and SSc patients and if they have an influence on the activation of the endothelium by inducing adhesion molecules and on haemostasis by inducing factors of the clotting cascade.

Methods: HiTrap Protein G HP antibody purification columns were used to purify IgG antibodies. Flow cytometry was used for analysis of autoantibodies against human cerebral microvascular endothelial cell line (hNCM/D3). 26 sera of patients with SLE and 29 sera of patients with SSc were tested for presence of autoantibodies against hNCM/D3. To analyse in vitro effects on hNCM/D3, we measured changes in the expression of the following surface proteins: ICAM-1, VCAM-1, MHC class I and II, tissue factor, von-Willebrand-Factor, E-Selectin, P-Selectin, Thrombomodulin, CD73 and t-PA, each before and after three- and 24-hours incubation with IgG-fractions. IgG fractions of 12 SLE patients, 13 SSc patients and 13 healthy control persons (HC) were tested.

Results: Autoantibodies against hNCM/D3 were found in 21 of 26 patients with SLE (81%) and in 19 of 29 patients with SSc (66%) (p > 0.05) but not in healthy donors. After three hours incubation of hNCM/D3 with IgG-fractions, an upregulation of tissue factor by SSc-IgG (6.7% ± 5.2%) compared to HC-IgG (1.1% ± 2.8%, p < 0.01) and to SLE-IgG (1.6% ± 3.9%, p < 0.05), was detectable. There was no significant correlation between changes in surface protein expression and detection of ANA or of anti-hNCM/D3 antibodies (p > 0.05).

Conclusion: Both, patients with SLE and patients with SSc showed autoantibodies against hBMEC. IgG fractions of patients with SSc, but not with SLE, induced an upregulation of tissue factor on the cell surface of hNCM/D3. This could be an indicator for a direct pathogenic effect of AECA in hBMEC and might have an influence on haemostasis by activating the clotting cascade. Inhibition of these antibodies could reduce cerebral involvement of SSc.

BACKGROUND: Macrophage can adopt various phenotypes and activation states according to their surrounding microenvironment. M1 or inflammasome-requiring macrophages are generated under IFN-γ states according to their surrounding microenvironment. M1 or inflammatory macrophages (generated under IL-1β and IL-18 signaling) and characterized by a high expression of CD206 and pro-fibrotic properties and, M2c macrophages (generated under IL10 and/or glucorticoid signaling), considered as anti-inflammatory resolving macrophages. There is growing interest in the role of macrophages in the pathogenesis of Systemic Sclerosis (SSc). Recent studies highlight that macrophages from fibrotic tissues such as lung or skin from SSc patients have a M2 phenotype whereas, in blood-monocytes derived macrophages (MDM), SSc MDM have a mixed signature associating M1 and M2 characteristics. Jak inhibitors are treatments used in rheumatoid arthritis and that can variously target signals that could be involved both in M1 and M2 polarisation.

METHODS: Blood monocytes form healthy donors (HD) were differentiated with M-CSF (for 7 days) in MDM and pre-treated by ruxolitinib (Jak2-Jak1 inhibitor), tocilizumab (Jak3 inhibitor) or itacitinib (Jak1 inhibitor) (1µM for 48h). They were then polarised into M1 (IFNγ, 20µg/mL), M1Li (IFNγ+IL13, 20µg/mL), M1/IL4 (IL4+IL13, 20µg/mL), M2a (IL4+IL13, 20µg/mL), M2c (IL10, 20µg/mL) and M2c(dex) (IL10+dexamethasone, 10nM). The impact of each Jak inhibitor on phenotype (flow cytometry), gene expression (qPCR) and cytokine secretion (ELISA) was evaluated in each polarisation state.

RESULTS: Concerning phenotypes, all Jak inhibitors reduced the expression of the M1i and M1Li marker CD86, but ruxolitinib had a higher effect. Only ruxolitinib reduced the expression of the M1 marker MHCII. All Jak inhibitors reduced the expression of CD206 and pro-fibrotic properties. Concerning cytokines secretion, only ruxolitinib reduced the expression of the M1i marker CXCL10, IL6 or TNFα.

CONCLUSION: Jak inhibitors can limit M1 and M2 polarisation state in vitro, with a more significant effect of the Jak2-Jak1 inhibitor ruxolitinib. The relevance of these results in MDM from SSc patients and in vivo models of SSC is still to be determined.

AB0158 IMPACT OF JAK INHIBITORS ON MACROPHAGE POLARISATION: PERSPECTIVES FOR SYSTEMIC SCLEROSIS

AB0160 CARDIAC AUTONOMIC NEUROPATHY PREVALENCE IN A COHORT OF SYSTEMIC SCLEROSIS (SSC) PATIENTS
P. Masini1, R. Galleri2, P. C. Pafundi2, E. Pinotti2, K. Gjeloshi1, F. C. Sasso3, G. Cuomos1. 1University of Campania “Luigi Vanvitelli”; 2Advanced Medical and Surgical Sciences, Napoli, Italy; 3University of Campania “Luigi Vanvitelli”; Precision Medicine, Napoli, Italy

BACKGROUND: Systemic sclerosis is a rare disease determining a damage to the connective tissue and, consequently, an involvement of several organs. Besides the damage of the connective tissue, prebones, this organ is also involved in a cardiovascular impairment as cardiac autonomic dysfunction, detectable by videocapillaroscopy. Some authors report that the vascular damage may be also responsible of a cardiovascular impairment as cardiac autonomic dysfunction (CAN) and heart rate variability [1].

OBJECTIVES: Our study aims to assess the presence and entity of CAN in patients with systemic sclerosis (SSc).

METHODS: This is a pilot prospective cohort study. We enrolled 28 patients in a period of six months, from May 2019 to November 2019, afferent to the outpatient clinic of internal medicine and immunology of the Primo Policlinico of Naples, with definite SSC diagnosis in absence of other comorbidities. All patients underwent diagnostic tests for autonomic cardiac neuropathy (NAC) and videocapillaroscopy. In particular, four tests were performed to search for the presence of NAC: orthostatic hypotension, deep breathing, lying to standing and Valsava maneuver. Each test was correct for age and gender and the diagnosis was made in the case at least two tests resulted positive. Primary endpoint of the study was the assessment of the prevalence of autonomic cardiac neuropathy in the study population.

RESULTS: Our cohort was mainly characterized by females (92,9%), with a median age of 58.5 years [IQR: 49-64.8 yrs.] and a median duration of the disease of 4 years [IQR 2-13 yrs.]. The observed prevalence of NAC was equal to the 46.4% (13 cases). In addition, we evaluated the potential association of NAC with age, duration of disease, gastrointestinal dysmotility, sicca syndrome, cutaneous involvement and type of videocapillaroscopy pattern, from which no statistically significant result emerged. Hence, a further analysis, by using a time-dependent Cox regression model (with the duration of disease as time covariate), was performed on the same variables. From this model a
significant association emerged in particular between the presence of NAC and the active videoangiopatia pattern (OR 6.23; 95% CI: 1.058-36.71, p=0.043).

Conclusion: Though current data in the literature on this topic are poor, cardiac autonomic neuropathy is among the clinical manifestations of SSC. In our study population, though the limited sample size, we observed a high percentage of patients with autonomic cardiac neuropathy, which seems much more frequent with the increase in the duration of disease and based on the type of videoangiopatia pattern.

CLONAL HEMATOPOIESIS IS INCREASED AND NOT RELATED TO AGING IN SYSTEMIC SCLEROSIS

L. Ricard1, P. Hirsch1, M. Mohty1, O. Fain1, B. Gaugler1, J. Rossignol1, F. Delhommeau1, A. Mekinian on behalf of na. *qsid, qsd, France*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrosis, microangiopathy and immune dysfunctions including dysregulation of proinflammatory cytokines. Clonal hematopoiesis of indeterminate potential (CHIP) is defined by the acquisition of somatic mutations in hematopoietic stem cells leading to detectable clones in the blood. Recent data have shown a higher risk of cardiovascular disease in patients with CHIP resulting from increased production of proinflammatory cytokines and accelerated atherosclerosis. Eventual links between CHIP and autoimmune diseases are undetermined.

Objectives: The aim of our study was to evaluate the prevalence of CHIP in SSc patients and its association with clinical phenotype.

Methods: Forty-one genes frequently mutated in myeloid malignancies were sequenced in peripheral blood mononuclear cells from 90 SSc patients and from 44 healthy donors.

Results: A total of 15 somatic variants was detected in 13/90 SSc patients (14%) and 4 somatic variants in 4/44 (9%) HD (p=0.58). The prevalence of CHIP was significantly higher in younger SSc patients than in HD: 25% (6/24) vs 4% (1/28) (p=0.045) under 50 years and 17% (7/42) vs 3% (1/38) (p=0.065) under 60 years. The prevalence of CHIP in patients over 70 years was similar in SSc patients and healthy donors.

For SSc patients the commonest mutations occurred in DNMT3A (7 variants). Other variants involved ATM, SF3B1, SETBP1, TET2, TP53, NFI or CBL. The distribution of gene mutations was overall comparable in SSc patients and in previously described CHIP series (3).

In most SSc patients, we identified a single CHIP mutation. Several mutations were detected in two SSc patients: SETBP1 and NFI in one and, TET2 and ATM in the other Clonal mutations included missense (n=10), nonsense (n=3), frameshift (n=1) and a single splice site mutation. In all HD we detected a single CHIP mutation which occurred in DNMT3A, TP53 and CSF3R.

Variant allele frequencies (VAF) of CHIP mutations ranged from 2 to 18.6% and did not differ between genes (DNMT3A or others). Mean age was the same in patients with DNMT3A mutations or with other mutations. However, C>T transversions, that have been associated with ageing were more frequent in DNMT3A variants than in other genes, suggesting distinct mechanisms for mutation acquisition or clonal selection. No major differences in clinical and laboratory data were observed between SSc patients with or without CHIP. SSc subtypes, disease duration, different organ involvements and the prevalence of ischemic events were not associated with the presence of CHIP, except less frequent pyrosis in patients with CHIP than those without. SSc patients with CHIP had significantly more anti-RNA polymerase III antibodies than those without CHIP (p=0.045).

At the time of analysis, 45 SSc patients had received a treatment for SSc which consisted in low-dose steroids, hydroxychloroquine, mycophenolate mofetil, cyclophosphamide or methotrexate. SSc patients with CHIP were significantly more exposed to cyclophosphamide (3/13 vs 3/77) (p=0.04) (5, 6.5 and 11 gram respectively between 5 years to 8 years before the NGS sequencing analysis), but among these cyclophosphamide-exposed SSc the age was over 65 in 2/3 of them. When considering all immunosuppressive drugs (cyclophosphamide, methotrexate and mycophenolate mofetil) SSc patients with CHIP were not more exposed than those without CHIP (p=0.75).

No patient developed any hematologic malignancy and no cytopenia during the median follow-up of 13 months (0-24 months). One SSc patients with CHIP developed a small lung cancer few months after NGS testing.

Conclusion: Whether CHIP increases the risk to develop SSc or is a consequence of a SSc-derived modified bone marrow micro-environment remains to be explored.

THE SIGNIFICANCE OF M1 AND M2 MONOCYTES IN SYSTEMIC SCLEROSIS

T. Michitsui1, N. Iwamoto1, S. Tsuj1, A. Kawakami1, 1Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, Nagasaki, Japan

Background: Recently, the relation between M2 macrophage and fibrosis has been reported in several diseases including systemic sclerosis (SSc). Similar with macrophages, monocytes can be classified into M1 and M2 subset, and the relation of imbalance of these monocytes with disease such as rheumatoid arthritis have been reported1-2.

Objectives: In this study, we attempted to investigate relationship among M1 or M2 monocytes in SSc.

Methods: This study included 23 SSc patients and 20 healthy donors. Using fluorescence-activated cell sorting, we defined CD14, CD68 and CCR2 positive cells as M1 monocytes and CD14, CX3CR1 and CD163 positive cells as M2 monocytes. We examined the ability of cytokines/chemokines secretion in CD14 positive cells from SSc by multiplex bead array assay using MAP human cytokine/chemokine Magnetic Bead Panel which can measure 38 cytokines/chemokines. We next extracted M2 monocytes from CD14-positive cells using FACS, and we used the rest of the CD14 positive cells as M1-dominant monocytes. Then, we evaluated their ability of TGF-β production by multiplex bead array assay.

Results: SSc patients had higher M2/M1 ratio as compared with healthy control (7.09 vs 1.63, P<0.05). And, there was tendency that M2/M1 ratio was higher in SSc patients complicated with interstitial pneumonia. Beads array analysis revealed that CCL4 and MCP-1 production from CD14 positive cells which consists M2>M1 (M2/M1 ratio>1) were higher than that from CD14 positive cells which consists M2< M1. Furthermore, the ability of TGF-β secretion of M2 monocytes was higher than that of M1-dominant monocytes.

Conclusion: Our present study suggested that the imbalance of M1/M2 monocytes might contribute to pathogenesis of SSc.

ANTI-KU ANTIBODIES: MUCH MORE THAN SCLEROMYOSITIS

L. Montolío-Chiva1, J. Narváez2, F. Morandeira2, J. Bas3, C. Marco2, X. González2, J. J. Alegre-Sancho1, E. Flores1, I. Vázquez-Gómez2, J. M. López1, J. M. Nolla1. 1Universitary Pespet Pusot Hospital, Valencia, Spain; 2Universitary Bellvitge Hospital, Barcelona, Spain

Background: Initially, anti-Ku antibodies (Ab) were described in patients with overlap syndrome with systemic sclerosis (SSc) and inflammatory myopathy (scleromyositis), although later they have been linked to a wide variety of systemic autoimmune diseases (SAD) questioning its diagnostic value. Recently, the possible existence of 2 different clinical phenotypes associated with these Ab has been described: one with myositis and high risk of interstitial lung disease (ILD) and another with positive anti-dsDNA Ab and glomerulonephritis.

Objectives: To analyze the clinical relevance and the main diagnosis of a serie of patients with positive anti-Ku Ab.

Methods: Descriptive observational study of patients with anti-Ku Ab in two third level hospitals between 2011 and 2019. Their determination was made at the criteria of the requesting physician.

Results: Twenty-three patients (20 women) with a median age of 59 ± 14 years (range, 24-83) and a follow up time (median) of 37 months (1-208) were identified. The main clinical and analytical characteristics, as well as the final clinical
diagnosis of these patients are shown in Table 1. In the cluster analysis we could not identify clinical phenotypes, perhaps because of the small sample size. Only 50% of patients with myositis developed ILD. Regarding the final diagnosis, only 1 patient (2%) was diagnosed of scleromyositis. Besides detecting them in patients with SSc (39%) and idiopathic inflammatory myopathy (9%), anti-Ku Ab were detected in other SAD, the most frequent were systemic lupus erythematosus, rheumatoid arthritis (RA) and overlap syndrome of SSc + RA.

Table 1. Main clinical-analytical manifestations and final diagnosis of patients with anti-Ku Ab.

Methods: The study was performed according to bioethical standards. 51 patients with verified SSc and 30 healthy controls were included in the study. The diagnosis was verified according to ACR/EULAR 2013 criteria. We assessed SSc activity in compliance with the original activity scale that is commonly used in Russia [Guseva N. G., 1993] and by the 2001 European Scleroderma Study Group Activity Index. XO (EC 1.17.3.2), XDH (EC 1.17.1.4), and SOD (EC 1.15.1.1) plasma activities were measured using spectrophotometric techniques as previously described [Dubinina E. E., 1986; Karpova O. V., 2006]. Results are expressed as means±SD. The Mann-Whitney U test and Spearman’s correlation coefficient were used for statistical analysis.

Results: Mean age of patients was 42.8±1.3 years, mean SSc duration was 7.9±0.7 years. Mean enzymatic activities in normal controls were 3.43±0.56 n mole/ml/min (for XO), 5.19±0.71 n mole/ml/min (for XDH), and 5.40±1.03 units/ml (for SOD). The respective enzymatic activities in SSc group were 3.91±0.62 n mole/ml/min, 7.10±0.71 n mole/ml/min, and 7.10±2.19 units/ml. All these mean activities were significantly higher in SSc patients comparing to healthy individuals (p<0.001). XO and XDH activities positively correlated with SSc activity (r=0.499, p<0.001, and r=0.741, p<0.001, respectively). The opposite but weaker trend was observed for SOD activity and SSc disease activity (r=-0.190, p=0.188).

Conclusion: SSc is characterized by an increase in the intensity of oxidative and antioxidant processes, more pronounced in high disease activity. A close relationship between function of prooxidant/antioxidant enzymes and some of the key SSc pathogenetic mechanisms, especially vascular disease and fibroblast activation, is widely considered. Overall increase of oxidative stress in patients with higher disease activity, as well as depletion of antioxidant capacity can also be linked with disturbance of purine metabolism through XO and XDH modulation. Pathogenetic influence of this imbalance can also be mediated through initial phase of neutrophil extracellular traps (NETs) formation, an eventual source of nucleoprotein containing autoepitopes.

AB0165 THE ROLE OF CXCL4, CXCL8 AND GDF-15 IN SYSTEMIC SCLEROSIS

Background: Systemic Sclerosis (SSc) is an autoimmune disease that can affect several organs and its mortality is fundamentally related to its pulmonary involvement. It is mandatory to seek for biomarkers that help us with early diagnosis and that are also useful for predicting organic involvement, so that we can adjust the diagnostic and therapeutic approach.

Objective: Our aim was to check if the presence of CXCL4, CXCL8 and GDF-15 is greater in the disease than in healthy population, and also their involvement in organic damage.

Methods: Observational and cross-sectional study, with a prospectively performed protocol, of patients diagnosed of SSc according to ACR/EULAR 2013 criteria. Demographic, clinical, analytical, activity (EUSTAR index), severity (Mediger scale and modified Rodnan index), health perception (SF36) and disability (HAQ and Cочin test) variables were collected. Moreover, Video-capillaroscopy (VCL) and Respiratory Function Test were made, as well High Resolution Lung Tomography and Echocardiography in order to describe pulmonary features. Serum levels of CXCL4, CXCL8 and GDF-15 were measured in SSc patients and in healthy controls.

Results: A total of 42 patients (85.4% women) were included, with an average age of 51.9±10.4 years. The median since diagnosis was 4.6 by 6.8 since the first non-Raynaud symptom. 20 patients were diagnosed with limited SSc, 20 patients diffusely and 2 patients with SSc without scleroderma. 42 healthy controls were also included. We found significantly higher levels of GDF-15 in patients with SSc (P<0.001), without significant differences in CXCL4 and CXCL8 levels between patients with SSc and healthy controls.

The presence of GDF-15 was associated with diffuse SSc (P=0.009), pulmonary arterial hypertension (P=0.038), interstitial lung disease (P=0.04), decreased forced vital capacity (FVC), (P=0.002), high serum titles of antiScI70 (P=0.006), increased disease activity measured by EUSTAR index (P=0.001), as well with capillary dilations in Capillaroscopy (P=0.015).

Moreover, we found an association between CXCL4 levels and the consumption of complement C3 fraction (P=0.008) and skin involvement (higher Rodnan modified score), (P = 0.001); not finding association with lung involvement or other features (spirometric or analytical changes, capillaroscopy or functional tests).
Attending to CXCL8, it was associated to consumption of the C4 fraction of complement (P=0.013) and the presence of tortuosity in capillaroscopy (P=0.02) with no other significant findings.

Conclusion: The presence of GDF-15 is associated with diffuse SSC, lung impairment, disease activity and changes in capillaroscopy. In addition, CXCL4 was only associated with skin involvement, while CXCL8 was not related to any organic damage in our patients.

IMMUNOGLOBULIN G DERIVED FROM PATIENTS WITH SYSTEMIC SCLEROSIS IMPRINTS A PRO-INFLAMMATORY AND PRO-FIBROTIC PHENOTYPE IN MONOCYTE-LIKE THP-1 CELLS

1. University of Luebeck, Department of Rheumatology and Clinical Immunology, Luebeck, Germany;
2. University of Luebeck, Department of Dermatology, Allergy, and Venerology, Luebeck, Germany;
3. University of Luebeck, Luebeck Institute for Experimental Dermatology, Luebeck, Germany

Background: Regulatory IgG autoantibodies directed against diverse G protein-coupled receptors (GPCR), i.e. antibodies with agonistic or antagonistic activity are abundant in human serum. The serum titers of autoantibodies targeting angiotensin II receptor 1 (AT1) and endothelin receptor A (ET1) are specifically altered in autoimmune diseases such as systemic sclerosis (SSc).

Disease-promoting mechanisms regulated by anti-AT1 and anti-ET1 IgG are still elusive, but induction of pro-inflammatory and pro-fibrotic chemokines (CXCL8, CCL18) has been suggested to be one of them.

Objectives: To determine the cytokine and phospho-kinase profiles induced in monocyte-like cells by IgG derived from SSC patients (SSc-IgG) enriched with anti-AT1 and anti-ET1 antibodies in comparison to IgG derived from healthy donors (IgG-HD).

Methods: A monocyte-like cell line (THP-1) was cultured in vitro and stimulated with IgG (1 mg/ml) derived from SSC patients or HD in the presence of various inhibitors/blockers for 24h. Then, supernatants were analyzed by a human cytokine/chemokine array. Data were analyzed using bio-mathematical tools such as generalized t-test including the robust regression method from R/Bioconductor package LIMMA. In addition, THP-1 cells were cultured in vitro and stimulated with IgG (1 mg/ml) derived from SSc patients or HD for up to 30 minutes. Thereafter, cell lysates were assayed for the kinome employing a human phospho-kinase array. To validate potential effects of transcription factor inhibition, release of CXCL8 and CCL18 into the supernatant was measured by Elisa.

Results: In general, SSc-IgG induced the release of most cytokines by THP-1 cells more pronouncedly than HD-IgG. The bio-mathematical analysis suggested that stimuli, responsible for the shift of the THP-1 cell cytokine profile, are more abundant in SSC-IgG than in HD-IgG. Based upon these findings a gene set enrichment analysis for transcription factors yielded the transcription factors NF-κB, AP-1, and PRDM1 (Blimp-1) as putative major regulatory hubs for the response of THP-1 cells to SSc-IgG. Further, SSc-IgG altered the phosphorylation status of several proteins, indicative of an involvement of MAPK and/or JAK/STAT pathways. Interestingly, a role for AP-1 was also proposed by the inhibition of CXCL8 and CCL18 release following pretreatment of THP-1 cells with an AP-1 blocker.

Conclusion: Herein, we demonstrate that IgG of SSC patients, enriched with anti-AT1 and anti-ET1 autoantibodies drives THP-1 cells towards a general pro-inflammatory and pro-fibrotic phenotype, which is reflected by broad changes in the secretome and kinome of these cells. Furthermore, our results highlight AP-1 as critical regulator of gene transcription of CXCL8 and CCL18 in a monocyte-like cell line.

TOFACITINIB AND NINTEDANIB MODULATE COLLAGEN FORMATION IN DERMAL FIBROBLASTS

A. S. Siebner1, M. Karsdall2, P. Juhl, A. C. Bay-Jensen1, Nordic Bioscience, ImmunoScience, Herlev, Denmark; Nordic Bioscience, R&D, Herlev, Denmark

Background: Dermal fibroblasts are responsible for the excessive extracellular matrix (ECM) formation observed in the skin of systemic scleroderma (SSc) patients and fibroblasts are therefore an obvious target for anti-fibrotic treatments. TGFβ, PDGF and IL-6 are known to be central cytokines in systemic sclerosis. Nintedanib, a tyrosine-kinase inhibitor approved for treatment of idiopathic pulmonary fibrosis, did not show effect on dermal fibrosis only on pulmonary fibrosis in SSc patients with intestinal lung disease (ILD). Tofacitinib, as Pan JAK inhibitor, has shown to inhibit dermal fibrosis in mouse models and shown positive indications in patients.

Objectives: We investigated the direct effect of Nintedanib and Tofacitinib on ECM production from human dermal fibroblast using translational biomarkers of type I, III and VI collagen and fibronectin.

Methods: Primary healthy human dermal fibroblasts were grown in DMEM media containing 0.4% fetal calf serum, Ficoll (to produce a crowded environment) and ascorbic acid for up to 17 days. The cells were stimulated with PDGF [3 nM] and/or TGFβ [1 nM] in combination with Nintedanib [1 nM-10 μM] treatment initiated at day 0 or 7 Tofacitinib [3-100 nM] treatment initiated at culture start together. Media and treatments were changed twice a week. Non-activated cells (w/o) were used as control. Type I, III and VI collagen formation (PRO-C1, PRO-C3 and PRO-C6, respectively) and fibronectin (FBN-C) were evaluated by validated ELISAs (Nordic Bioscience). Statistical analysis included 1-way and 2-way ANOVA, AUC and Mann Whitney U-test.

Results: PDGF significantly increased collagen type I and VI formation and collagen type I formation minimally. PDGF did not induce changes in fibrotenin levels. TGFβ increased collagen type I and VI formation but did not induce formation of collagen type III. TGFβ increased fibronectin levels, where PDGF did not. Nintedanib (≥100 nM) added either from day 0 or 7 reduced PDGF induced collagen type III and VI formation to the level of w/o throughout the remainder of the study. In TGFβ treated fibroblasts, Nintedanib added either from day 0 or 7 reduced collagen type I and VI formation. The fibronectin levels were dose-dependently reduced by Nintedanib. The biomarker levels were at study end at the level of w/o. Nintedanib at a concentration of 1 μM and higher significantly decreased the biomarker levels. Nintedanib (≥100 nM) in fibroblasts stimulated with both TGFβ and PDGF significantly reduced collagen type I, III and VI collagen and fibronectin.

A Tofacitinib concentration of 100 nM was toxic to the dermal fibroblasts as the cell viability was minimal at culture end. However, the viability of Tofacitinib (100 nM) in combination with TGFβ was decreased at study end, but only to half the viability of untreated cells. Tofacitinib dose-dependently decreased the TGFβ induced type I and III collagen formation and fibronectin in the dermal fibroblasts. Tofacitinib (100 nM) decreased the level of collagen type I and III formation to the level of w/o, where as the level of fibronectin was lowered by 80 % of TGFβ. Tofacitinib as low as 12.5 nM significantly lowered the collagen type I formation and fibronectin (both p<0.05) and Tofacitinib of 25 nM decreased collagen type III formation significantly (p<0.0001).

Conclusion: Tofacitinib decreased the formation of the collagens and fibronectin. Nintedanib inhibited ECM production differently in PDGF and TGFβ induced dermal fibroblast, but in the combination of TGFβ and PDGF Nintedanib significantly decreased the ongoing fibrosis. In PDGF induced fibrosis, Nintedanib acted as an on-off switch, whereas the inhibition was dose-dependent in TGFβ induced fibrosis. This cell study indicates that Nintedanib and Tofacitinib inhibits collagen production in dermal fibroblasts.
NINTEDANIB (TYROSINE-KINASE INHIBITOR) INHIBITS THE TRANSITION OF CIRCULATING FIBROCYTES ISOLATED FROM SYSTEMIC SCLEROSIS PATIENTS INTO MYOFIBROBLASTS: AN IN VITRO STUDY

S. Soldano1, G. Martineili, S. Tardito1, S. Paolino1, M. Patané1, E. Gotelli1, C. Corallo2, C. Pizzorni1, A. Sulli1, C. Schenone1, V. Smith2, M. Cutolo3, S. Soldano

1Research Laboratory and Academic Division of Clinical Rheumatology, Dept. Internal Medicine, University of Genova, Genoa, Italy; 2Research Laboratory, and Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy; 3Ghent University Hospital, Department of Rheumatology; Department of Internal Medicine, Ghent, Belgium

Background: Systemic sclerosis (SSc) is a chronic connective disease characterized by microvascular alterations, dysregulated immune response and fibrosis [1,2]. Myofibroblasts are alpha-smooth muscle actin (alphaSMA)+ cells and play a crucial role in fibrosis, through the excessive synthesis and deposition of extracellular matrix (ECM) proteins, in particular fibronectin (FN) and type I collagen (COL1) [3]. Despite myofibroblasts primarily derive from resident fibroblasts transition and differentiation, another important source is represented by circulating fibrocytes [4]. Nintedanib is a tyrosine kinase inhibitor approved for the treatment of idiopathic pulmonary fibrosis that interferes with the signalling pathways involved in the pathogenesis of fibrosis [5].

Objectives: To investigate the possible effects of nintedanib in contrasting the ability of cultured mature fibrocytes from SSc patients to differentiate into profibrotic myofibroblasts.

Methods: Circulating fibrocytes were obtained from peripheral blood mononuclear cells isolated from 5 limited cutaneous SSc patients (mean age 68 +/- 10 years) and then plated on FN-coated tissue culture dishes in growth medium (DMEM at 20% of fetal bovine serum, 1% of penicillin-streptomycin and 1% L-glutamine), to allow the adhesion of fibrocyte precursors. Adherent cells were maintained in growth medium for 8 days in order to allow their differentiation into fibrocytes. Differenitiated fibrocytes were treated with nintedanib at the concentrations of 100nM and 1000nM for 3 and 24 hours (hrs) or maintained in growth medium without any treatment. The differentiation of fibrocytes into myofibroblasts was determined evaluating the gene expression of alphaSMA, fibroblast specific protein-1 (S100A4) COL1, FN and CXCR4 by quantitative real-time polymerase chain reaction, and the protein synthesis of alphaSMA, COL1 and FN by western blotting.

Results: Nintedanib inhibited alphaSMA and S100A4 gene expression already at the concentration of 100nM in cultured fibrocytes and after 3 hrs of treatment, when compared with untreated cells. Furthermore, both concentrations of nintedanib (100nM and 1000nM) reduced the gene expression of COL1 and FN, whereas only 100nM downregulated the CXCR4 gene expression. At protein level, nintedanib 100nM and 1000nM reduced the synthesis of alphaSMA and COL1 after 24 hrs of treatment, whereas FN synthesis was reduced only by the nintedanib concentration of 1000nM.

Conclusion: The preliminary results show that nintedanib may inhibit the in vitro transition of SSc fibrocytes into myofibroblasts and their profibrotic activity, through the reduction of specific myofibroblast phenotype markers and ECM protein production. The results seem to suggest fibrocytes as further possible target of the antifibrotic action of nintedanib in SSc.

References:

Conclusion: PLTs are greatly activated in SSc and this is associated with disease progression. Findings suggest that this activation is greater at less severe patients.

PHENOTYPIC CHARACTERIZATION OF ENDOTHELIAL PROGENITORS CELLS OF SYSTEMIC SCLEOROSIS (SSC) PATIENTS: ROLE IN ENDOTHELIAL-TO-WMENSENCHIMAL TRANSITION PROCESS
K. Stefanantoni1, G. Barbati1, T. Colasanti1, C. Angelelli1, G. Pellegrino1, C. Alessandri2, G. Valesini3, V. Riccieri3. 1Sapienza Università di Roma, Dipartimento di Scienze Cliniche, Internistiche, Anestesiolgiiche e Cardiovascolari - UOC di Reumatologia, Roma, Italy

Background: Endothelial-to-mesenchymal transition (EndoMT), a newly recognized type of cellular transdifferentiation, seems to be involved in Systemic Sclerosis (SSc) pathogenesis. In this process endothelial cells lose their specific markers, and acquire a mesenchymal phenotype, thus expressing cell products such as alpha smooth muscle actin (α-SMA) (1,2). Circulating endothelial progenitor cells (EPCs) derive from bone marrow stem cells and contribute to de novo vessels formation. Several studies, although with conflicting results, have shown that EPCs in the peripheral blood of patients with SSc are impaired in their number and function (3).

Objectives: to assess phenotypic characteristics of EPCs from SSC patients and from patients with Very Early Diagnosis of SSc (VEDOSS) compared with healthy controls (HC). In particular we want to evaluate the expression of α-SMA, as marker of a pro-mesenchymal switch (EndoMT) in:
1. Circulating Early (CD34+KDR+CD 133+) and Late EPCs (CD34+KDR+) in the peripheral blood using flow cytometry
2. Cultured EPCs using Western blot analysis

Methods: we enrolled 11 patients (6 SSc and 5 VEDOSS), classified according to the classification criteria for SSc (4) and for VEDOSS not fulfilling SSc criteria (5), and 5 HC. Phenotypic characterization was performed as previously described by Vasa et al. using a FACS Calibur (BD Immunocytemetry Systems), EPCs number was expressed as a percentage of cells within the lymphocyte gate. 5’106 PBMCs were plated on human fibroenectin-precoated (10 μg/ml Sigma-Aldrich) 6-well plates and cultured for 7-12 days to obtain EPCs. PBMCs from one HC were also cultured with 20% SSc patient serum. After the incubation of HC PBMCs with SSc serum, the α-SMA protein expression was increased and the expression rate of EPCs in both SSc and VEDOSS was higher than in HC. So we hypothesized a predominant pro-mesenchymal phenotype of this kind of EPCs. This could be considered the expression of the involvement of EPCs in the EndoMT process and it better explain the controversial role of EPCs in SSc pathogenesis. Moreover the modified expression of α-SMA in HC EPCs co-cultured with 20% SSc serum could suggest the presence of a factor inducing the EndoMT process in the disease.

THE IMMUNOMODULATORY AND ANTI-INFLAMMATORY EFFECTS OF BOSENTAN IN SYSTEMIC SCLEROSIS
M. G. Ting1, T. Mazza2, L. D’agrumo, A. De Cata1, 1.Casa Sollievo della Sofferenza Hospital, IRCCS, Unit of Internal Medicine, San Giovanni Rotondo, Italy; 2.Casa Sollievo della Sofferenza Hospital, IRCCS, Bioinformatic Laboratory, San Giovanni Rotondo, Italy; 3.Casa Sollievo della Sofferenza Hospital, IRCCS, Division of Medical Genetics, San Giovanni Rotondo, Italy

Background: Plasma endothelin-1 (ET-1) levels are increased in patients with systemic sclerosis (SSc), playing a central role in the development of fibrosis, vasoconstriction and inflammation. While the beneficial effect of Bosentan, the endothelin receptor antagonists, have been demonstrated on vasoconstriction and fibrosis, its potential anti-inflammatory and immunomodulatory activity needs to be further investigated.

Objectives: To assess whether Bosentan can modulate the gene expression profile of immune cells in sample of patients with limited and diffuse SSc and active digital ulcers.

Methods: We enrolled 34 patients affected by SSc. Twenty-four patients were affected by limited SSc and 12 by diffuse SSc. Blood samples were collected from patients before and after 24 weeks of treatment with Bosentan, in the absence of immunosuppressive therapies. All patients received Bosentan 125 mg twice a day for 24 weeks. Gene expression profiles were assessed by GeneChip® Human Transcriptome Array 2.0 microarray technology. Significantly (p-value<0.05) and differentially (|FC|>1.5) expressed genes pre/post treatment were obtained by paired t-statistics, as implemented in Partek Genomics Suite ver. 6.6. These genes were subjected to functional enrichment analysis by Ingenuity Pathway Analysis. The effect of Bosentan on patients was studied on the “diffuse” and “limited” sub-cohorts, individually, as well as on the whole cohort.

Results: Contrary to the limited cohort where differentially expressed genes resulted to be all non-coding genes which are almost all over-expressed before treatment, the diffuse cohort was characterized by 19 differentially expressed genes that enrich biological functions and pathways related to the immune system and its organic response (in particular T-cells). Comparing the limited to the diffuse cohort, pre- and post- treatment, a distinct genetic fingerprint emerges, that characterizes the response to Bosentan by the latter cohort as increased apoptosis of lymphocytes (z-score=3.28) and a decreased quantity of antigen presenting cells (from z-score=1.06 (pre) to -0.75 (post)).

Conclusion: The presence of an inflammatory microenvironment, as occur in SSc, influence the relative expression of ET-1 receptors on immune cells, which in turn further contribute to the amplification of cellular responses to inflammation. The observed difference response to therapy between the two cohorts of patients was attributed to influence of ET-1 levels on the relative expression of ET-1 receptors on immune cells surface. Interestingly Bosentan, beside the already-known effect on promoting antigen presenting cells apoptosis, seem to exert its immunomodulatory activity also by deregulating functions that mainly involves the T cells and by promoting their apoptosis, which in turn reflect also its anti-inflammatory properties.

PGC-1α REGULATES AUTOPHagy TO PROMOte FIBROBLAST ACTIVATION AND TISSUE FIBRosis
Y. Zhang, 1 K. Dreiligacker, 2 D. Distler, 2 A. H. Györö, 3 C. Bergmann, 1 X. Zhou, 1 L. Shen, 1 I. Ludolph, 1 R. Horch, 1 A. Ramming, 1 G. Schett, 1 J. Distler, 2
1 Friedrich-Alexander University of Erlangen-Nürnberg, Erlangen, Germany

Background: Peroxisome proliferator-activated receptor gamma coactivator-1α (PGC-1α) is the best studied member of the family of coactivators. PGC-1α was initially identified through its interaction with PPARγ in brown adipose tissue. Recent evidence further indicates that PGC-1α may also modulate the transcription of autophagy-related genes, which has recently been shown to be required for fibroblast-to-myofibroblast differentiation under fibrotic conditions. However, the role of PGC-1α in the pathogenesis of SSc has not been investigated.

Objectives: To evaluate the role of the coactivator PGC-1α on autophagy and to evaluate its role in the pathologic activation of fibroblasts in SSc.

Methods: Expression of PGC-1α was analyzed by RT-PCR, Western and immunofluorescence. Modulation of autophagy was analyzed by reporter studies by expression of autophagy-related genes. The effects of PGC-1α knockdown on collagen production and myofibroblast differentiation were analyzed in cultured human fibroblasts and in two mouse models with fibrotic-specific knockout of PGC-1α.

Results: PGC-1α overexpression was detected by immunohistochemistry in skin sections of SSc patients and in experimental fibrotic murine skin, particularly in fibroblasts. Knockdown of PGC-1α inhibited the stimulatory effects of TGFβ on fibroblast activation with impaired induction of collagen as compared to control fibroblasts. Fibroblasts specific knockout of PGC-1α ameliorates experimental fibrosis in bleomycin-induced and adTBR-induced murine dermal fibrosis with decreased dermal thickness, hydroxyproline and myofibroblast counts compared to control fibroblasts. Fibroblasts knockdown with PGC-1α stimulated autophagy in control fibroblasts with increased expression of the autophagy-related genes. The effects of PGC-1α knockdown on collagen production and myofibroblast differentiation were analyzed in cultured human fibroblasts and in two mouse models with fibrotic-specific knockout of PGC-1α.

Conclusion: The role of autophagy-related genes in the pathogenesis of SSc and its therapy holds promise for future research in the field.
Background: The most important T-cell subtype in maintenance of immune tolerance is T regulatory cells (Treg). These are characterized by CD4 and CD25 receptors on surface, and by showing FoxP3 regulatory factor, which is necessary for maintaining the suppressive activity of Treg cells in peripheral blood (PB). Previous studies have studied Treg cells in PB and synovial fluid in patients with Juvenile Idiopathic Arthritis (JIA). However, there was insufficient evidence to draw robust conclusions about Treg implication in JIA, due to small simple size and variable results across studies. A deeper understanding of regulatory mechanism in JIA may increase comprehension on variability among JIA subtypes and may help to establish prognosis on the follow up.

Objectives: To analyze Treg cells level in PB of JIA patients and its relation with disease activity.

Methods: Descriptive, cross-sectional, observational study conducted in a regional reference centre for Pediatric Rheumatology. We included consecutive patients with JIA diagnosed by ILAR criteria. The primary variable was the Treg percentage in PB measured by flow cytometry. To assess JIA activity, we used disease activity indexes (JADAS10, 27 –VSG, JADAS10 -PCR and cJADAS), Wallace remission criteria, VAS disease activity by patient/parents and physicians, morning stiffness, multidimensional evaluation (JAMAR) and acute phase reactants (CRP and ESR). Assessment of long-term damage was evaluated with JADI. Association analyses among study variables and Treg levels were performed by Pearson’s correlation coefficient and Mann Whitney’s U test.

Results: Ongoing study, we present a preliminary analysis with first 50 JIA patients. Mean age (SD) was 11.3 yr (4.6), being females 60%. Most common JIA subtype was persistent oligoarticular (42%) followed by RFneg polyarticular (24%). 42% patients were treated by csDMARD and 46% by biological agents. Mean levels of CRP and ESR were 0.18 mg/dl (0.3) and 6.3 mm/hr (5.4), respectively. At the time of the study, 84% of patients were in remission (Wallace criteria). Mean of JADAS27-VSG, JADAS27-PCR and cJADAS were 3.5 (5.1), 3.7 (5.1), and 3.7 (5.5), respectively. Mean long-term damage scores were 0.48 (1.1) for JADI-A and 0 for JADI-E. Mean levels of Treg cells in PB were 2.11% (1.1). The table shows the association between clinical variables and % of Treg. We can observe a significant, inverse and moderate correlation between Treg levels and disease activity by patient/parents, disability and quality of life (global and the physical component). Close to statistical significance, we found inverse and moderate correlation between Treg cells and all JADAS scores, cJADAS, disease activity by physician and morning stiffness. There was no association between Treg and acute phase reactants. Furthermore, there were no differences in Treg cells in Wallace remission (p=0.692) and regarding use of conventional or biologic DMARD (p=0.864 and p=0.386, respectively).

Conclusion: According to our preliminary data, higher levels of Treg cells in PB of patients with JIA could be related with lesser disease activity and better quality of life. Larger studies are needed to confirm whether this Treg-mediated regulatory mechanism can have prognostic implication JIA.

AB0175 INNOVATIVE PREPARATION OF CURCUMIN NANOPARTICLES TO IMPROVE ANTI-INFLAMMATORY EFFECT IN RHEUMATIC DISEASE

A. Soltani1, N. Abdollah1, Y. Ghanbari1, 1Golestan Rheumatology Research Center, Golestan University of Medical Sciences, Gorgan, Iran (Islamic Republic of)

Background: Curcumin (Cur) as a natural compound can be used in the wide spectrum of healthy functions and pharmacological activities [1-4]. It shows great promise for medication of various pro-inflammatory chronic illnesses [5]. In this study, we evaluate the ability of poly(lactide-co-glycolide)(PLGA) and different grades of PVA (polyvinyl alcohol) and lecithin as a drug delivery system for poorly soluble Cur.

Objectives: The goal of this study was to prepare and characterize Cur encapsulated PLGA and different grades of PVA and lecithin as an efficient nanocarrier for improve anti-inflammatory effect in rheumatic disease.

Methods: The PLGA nanoparticles were formulated and then characterized for percent yield, encapsulation efficiency, surface morphology, and in vitro drug release profiles. At first, 6mg of Cur was added to the organic phase including 24mg of polymer dissolved in 5ml of dichloromethane to constitute 1:4 (drug-to-polymer) ratios. Then, a mixture of PVA-lecithin (at about 5 cc) was added to maintain the stability of double emulsion droplets. The emulsion was continuously stirred at 300 rpm for 24 hours (at temperature of 37.5 °C) to evaporate the solvent, leaving behind the colloidal suspension of the drug-encapsulated nanoliposome in aqueous phase. The encapsulation of Cur into PLGA was characterized by Fourier transform infrared spectroscopy (FT-IR) and Transmission electron microscopy (TEM).

Results: Our studies achieved the successful formation of smooth surface and spherical shape Cur encapsulated into PLGA nanoparticles by the TEM image confirmed. The particle size distribution demonstrated a range of 30nm to 100nm, with the mean particle size being 45 nm. FTIR study implies successful loading of Cur into the nanoparticles. We show high drug-loading efficiency about 98 ± 0.5% for 6% of Cur weight in total ingredients weight of PLGA (w/w). It was also seen that a slower sustained release of 10% CUR in 48 hours is observed with biocompatible PLGA in phosphate buffered saline (pH = 7.4). The MTT assay of the Cur-PLGA exhibited no cytotoxic effect on Normal mouse fibroblast cells (L-929) cell line. IC50 of Cur-PLGA increased 99.5% against Cur nanoparticles (33.67 ± 0.62 μM) (P < 0.05).

Conclusion: In this study, we constructed a novel preparation of curcumin nanoparticles with PLGA and different grades of PVA (polyvinyl alcohol) and lecithin to improve the bioavailability of CUR and PLGA exhibited no cytotoxic effect on L-929 cell line.

References: In this study, we constructed a novel preparation of curcumin nanoparticles with PLGA and different grades of PVA (polyvinyl alcohol) and lecithin to improve the bioavailability of CUR and PLGA exhibited no cytotoxic effect on L-929 cell line.

12. Rheumatoid arthritis - prognosis, predictors and outcome
age, disease duration, comorbidities, family history of a rheumatoid disease, ANA, treatment agents and disease activity and quality of life assessment tools.

Results: A total of 863 RA male patients were studied with a mean age of 53.9±12.5 years and a mean disease duration 7.3±5.5 years. 652 (75.6%) had positive RF and 624 (72.3%) had positive ACPA. 431 (50%) had at least one comorbidity. 640 (72.4%) were on conventional disease modifying agents (cDMARDs) and 223 (25.8%) were on biologic therapy. 183 (21.2%) were smokers.

Conclusion: Smokers have a higher risk of expressing a positive RF and a positive ACPA in a male population. Smoking should be considered as a possible risk factor for RA and efforts should be done to educate the population to cease smoking to possibly lower that risk.

PERIARTICULAR OSTEOPHYTE FORMATION PROTECTS AGAINST TOTAL KNEE ARTHROPLASTY IN RHEUMATOID ARTHRITIS PATIENTS WITH ADVANCED joint DAMAGE

S. Asal1, N. Takahashi1, K. Terabe1, T. Kojima1, N. Ishiguro1,1 Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery, Nagoya, Japan

Background: New medications including biologics and aggressive treatment strategies can halt the inflammatory and destructive disease processes in patients with rheumatoid arthritis (RA), and in some cases repair damaged joints. In the presence of damaged joint repair, periarticular osteophyte formation might be detected radiographically. However, little is known about the clinical and functional role of osteophyte formation in RA joints. Total joint arthroplasty, a common procedure for treating damaged large joints, can serve as a surrogate for the long-term outcome of large joint destruction in patients with RA.

Objectives: To determine the influence of periarticular osteophyte formation on the incidence of total knee arthroplasty (TKA) in patients with RA.

Methods: This retrospective longitudinal study used data from a registry of patients with RA starting biologics. A flow chart summarizing the study design is shown in Figure 1. A total of 130 symptomatic (tender and/or swollen) knee joints in 80 patients were studied with a median follow-up of 12 years. All data were analyzed using the knee joint as the statistical unit of analysis. The cumulative incidences of TKA were estimated using Kaplan-Meier curves, and compared according to the presence of osteophyte on plain anteroposterior radiograph (osteophyte (+/-)) and the extent of advanced joint damage as defined by Larsen’s grading system (0-II vs. III-V).

Results: Baseline characteristics of all subjects included in this study are shown in Table 1. A total of 42 knees underwent TKA during the follow-up period. There was no significant difference in the cumulative incidence of TKA between the osteophyte (+) and osteophyte (-) groups (31% vs. 34% at 10 years, P=0.718) (Fig. 2A). The cumulative incidence of TKA was significantly higher for the Larsen grade III-V group compared to the Larsen grade 0-II group (56% vs. 10% at 10 years, P<0.001) (Fig. 2B). While no significant difference was observed in the cumulative incidence of TKA between the osteophyte (+) and osteophyte (-) groups in the Larsen grade 0-II group (9% vs. 10% at 10 years, P=0.774) (Fig. 2C), the cumulative incidence of TKA was significantly lower for the osteophyte (-) group compared to the osteophyte (+) group in the Larsen grade III-V group (38% vs. 74% at 10 years, P=0.010) (Fig. 2D).

Conclusion: Our results are associated with higher disease activity in our population. Biologic medications had been used by 129 patients (29.7%) while conventional DMARDs were given to 304 patients (70.3%).

VITAMIN D SUPPLEMENTATION ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. T. Z. M. Aung1. Mandalay General Hospital, Department of Rheumatology, Mandalay, Myanmar, Burma

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease with unknown etiology that primarily affects the peripheral joints and, over time, leads to loss of mobility if untreated.1 The prevalence of RA in Myanmar was 1.3% in 2004.2 According to Rheumatology outpatient clinic records of Mandalay General Hospital, there were 402 old patients and 104 new RA patients in 2017 and 453 old patients and 102 new RA patients attending in 2018. In addition to the main effects of vitamin D (vit D) on bone and calcium metabolism, it has other roles in the body, including modulation of cell growth, neuromuscular and immune function, and reduction of inflammation.3 Due to difference in ethnic origins and geographical distribution, the results may be varied when it is done in sunshine rich area such as Myanmar. In the present study, vitamin D supplementation on the disease activity of RA by DAS28 was determined.

Objectives: 1. To compare DAS28 score before and 12 weeks after vitamin D loading dose supplementation in RA patients with vitamin D deficiency 2. To compare DAS28 score before and 12 weeks after vitamin D 1000 IU per day per supplementation in RA patients with normal serum vitamin D level
