Methods: 58 patients with RA attending to medical unit I, II, III and Rheumatology outpatient clinic of Mandalay General Hospital were recruited. Disease activity was assessed according to DAS28. Patients with DAS28 ≥ 2.6 were assessed for serum vitamin D status. Those with vitamin D level < 20 ng/ml were defined as vitamin D deficient and vitamin D ≥ 5, 000 IU per day for 8 weeks, then 1, 000 IU per day for 4 weeks were given orally for a total of 12 weeks duration. Patients with normal vit D level (≥ 20 ng/ml) were provided with Vit D 1000 IU per day for 12 weeks.

Results: Before 12 weeks of Vit D supplementation, 53.45% of patients with RA (2 male and 29 female) were Vit D deficient and 46.55% of patients (1 male and 26 female) had normal serum vit D level. The largest age group was between 46-55 years in both groups which comprised 41.38% of patients. In patients with vit D deficiency, serum Vitamin D level was 10.32 ± 4.26 ng/ml and, in patients with normal vit D level, mean serum Vitamin D level was 36.51 ± 17.76 ng/ml.

After 12 weeks of Vit D supplementation, out of 31 patients with Vit D deficiency, serum vit D level of 23 patients became ≥ 20 ng/ml whereas only 3 patients were still Vit D deficient. Both groups showed improvement in clinical and biochemical parameters such as VAS, ESR, tender and swollen joint counts. Before 12 weeks, more than 40% of patients had high or moderate disease activity in each group. After 12 weeks of Vit D supplementation, in Vit D deficient group, most patients (54.84%) had disease remission and 22.58% of patients were found to have moderate disease activity. Disease activity of 19.35% of patients became low. Only one patient had high disease activity.

After 12 weeks of Vit D supplementation, in Vit D deficient group, disease activity of most patients (48.15%) became low and 33.33% had remission. 18.52% of patients with RA were found to have moderate disease activity. No patient had high disease activity.

Although there was no correlation between serum vit D level and DAS28, DAS28 score was significantly decreased from 5.27 to 2.79 (P = 0.0000) after 12 weeks of Vit D loading dose supplementation in RA patients with Vit D deficiency. Similarly, DAS28 score of RA patients with normal vit D level was significantly decreased from 5.04 to 2.71 (P = 0.0000) after 12 weeks of Vit D 1000 IU supplementation.

Conclusion: The present study revealed that Vitamin D supplementation was effective in reducing disease activity in patients with Rheumatoid arthritis. These findings may be helpful in the treatment of Rheumatoid arthritis.

AB0181

COULD TITERS OF ACPA PREDICT THE SEVERITY OF RHEUMATOID ARTHRITIS, ANALYSIS OF DATA DURING A 3-YEARS FOLLOW-UP?

R. Shpat1, Y. Braun-Moscovich2, A. Balbir-Gurman3. Technion Faculty of Medicine, Haifa, Israel; 2Rambam Health Care Campus and Technion Faculty of Medicine, Haifa, Israel

Background: Rheumatoid Factor (RF) and/or Anti Citrullinated Protein Antibodies (ACPA). Are included in classification criteria of Rheumatoid arthritis (RA); their presence correlates with RA severity. The influence of ACPA titer on RA course and outcome in long-term follow-up is limited.

Objectives: To check the correlation between ACPA titers at the time of RA diagnosis to RA features and severity during 3 years follow-up.

Methods: We performed a retrospective study on patients treated at our institution during the years 2006-2015 with known ACPA titers at RA diagnosis, who completed at least 3 years of follow-up. Patients (pts) were divided according to ACPA titer: A - seronegative (<15 U/ml), B - weak positive (15-49 U/ml) and C - strong positive (>50 U/ml) with subdivision to C-1 - moderately high (50-99 U/ml), C-2 - high (100-299 U/ml) and C-3 - very high (>300 U/ml). Patient’s data including DAS28, bone erosion on hands and/or foot X-rays, treatments with corticosteroids and DMARDs and hospitalizations due to flares. Chi-Square and Mann-Whitney method were used for statistical analysis; p<0.05 was considered statistically significant.

Results: Among 850 pts with RA, 133 (mean age 55 years, 65% female) met the inclusion criteria: group A: 55 (42%) pts, group B: 18 (13%) pts, group C: 60 (45%) pts [C1- 10 pts, C2-21 pts and C3-29 pts]. Most of the characteristics were similar between the groups (including C subgroups). There were no significant differences between the groups in terms of tender and/or swollen joints, acute phase reactants, bone erosions, need for corticosteroids or DMARDs, hospitalizations, number of DMARDs and number of biologicals. There was significant correlation between ACPA titers and positive RF (p<0.0001); it was consistent in all patients groups. Higher ACPA titers were associated with greater percentage of patients with positive RF. The percentage of male was higher in subgroup with highest ACPA: 25% in ACPA-negative group compared to 45% in the strong positive group (group C-3); it correlated with current or ever smoking. DAS28 was high in all groups without significant difference; over 80% of patients had DAS28 higher than 3.2 and 50-60% had a value higher than 5.2. During the 3-year follow-up, 95% of pts received prednisone with an average daily dose of 14.8 mg (SD, 8.9mg), 50% of pts received more than 15 mg prednisone daily. The average number of synthetic and biological DMARDs was 2.5 (SD 0.73) and 0.56 (SD 0.84) per patient; methotrexate was prescribed in 89% of cases. There were no correlations between negative (group A) or positive ACPA (group B and C) and the variables defined as representing the severity of RA: the percentage of pts with DAS28>3.2 (p=0.136) and DAS28>5.2 (p=0.774). The percentage of pts receiving prednisone dosage higher than 15 mg/day (p=0.828) or at least two synthetic (p=0.646) or biological DMARDs (p=0.668) or their combination (p=0.770) were not significantly different. There was no correlation between ACPA titer and bone erosions (87 pts, p=0.883) for more than 3 years of follow-up. Finally, there was no correlation between ACPA titers and the number of hospital admissions (p=0.951).

Conclusion: In our cohort of RA pts, higher ACPA titers were observed in males with smoking history. Higher ANCA titers correlated with RF positivity but were not identified as predictive factor for RA severity.

**EARLY RA PATIENTS SEEN IN PRACTICE WHO HAVE CO-EXISTENT NON-ARTICULAR PAIN HAVE SIGNIFICANT WORSENING OF PROMIS® 29 DOMAIN SCORES. RESULTS FROM THE CATCH US STUDY**

V. Bykerk1, C. Benson1, G. Vitone1, A. Tirpack1, S. J. Bartlett2,3, C. Bingham3.

1Hospital for Special Surgery, New York, United States of America; 2McGill University, Montreal, Canada; 3Johns Hopkins University, Baltimore, United States of America

**Background:** Non-articular pain (NAP) can co-exist with synovitis in RA. Its presence is associated with higher pain and worse function per legacy patient reported outcomes (PROs) both of concern to people with RA. It is not known if the presence of NAP significantly changes PROMIS 29 health domains.

**Objectives:** To determine if co-existing NAP (both regional or widespread pain) is associated with important differences in PROMIS 29 domain scores for symptomatic and impacts.

**Methods:** Patients (pts) with early RA, were recruited from two practice settings in the Consortium of early arthritis cohorts, USA (CATCH-US) (New York and Baltimore) between Jan 2015-Dec 2019 (n=96). Data were from baseline (bl) visits; pts must have completed a body pain diagram (BPD) (CHONI Bodymap®) and the PROMIS-29V1.1 and provided legacy PRO and clinical measures. Pts were grouped as i) no-NAP and ii) NAP based on presence of pain in non-articular regions (1-3 regions - regional, 4-5 widespread). PROMIS 29 domain scores were compared between groups, as were related legacy PROs and clinical outcomes routinely used to assess disease activity. Data are descriptive; continuous variables were compared using t-Tests.

**Results:** Pts (n=96) were mean age (sd) of 47.9 (14.9), 83% female, 67% white, 34% smokers, 21% obese, 82% seropositive, 51% mod/high CDAL symptom duration 7.3 (5.4 months) and a comorbidity index (RDCI) of 0.7 (1.0). At study entry most had started RA treatments: 32% csDMARD with MTX, 22% non-MTX csDMARDs, 40% oral steroids, 13% biologics or JAKi’s; 28% were treatment naive. Patients reporting NAP were more often white, smokers, obese, but did not differ otherwise. MDSJC28 was higher, mostly affected small joints, and affected region by region (BPD) were excluded for NAP classification. All but one (anxiety) of PROMIS 29 domain scores differed significantly between groups; similar differences were seen in legacy PRO scores and in some clinical outcomes (Table). Most clinical measures did not differ between groups.

**Conclusion:** In this cohort of early RA patients almost 1/3 with co-existent NAP unrelated to synovitis had significantly worse legacy PRO and PROMIS scores. These data provide useful information for using generic PROMIS measures as they identify symptoms and impacts, that may be unrelated to synovitis, providing information that could improve patient-oriented care in clinical practice. Clinicians should assess for and treat NAP as part of target-based care. Reasons for (injury, mechanical, disuse) and best treatment of NAP require further research.

**ADHESION TREATMENT IN AN ITALIAN COHORT OF PATIENTS AFFECTED BY CHRONIC INFLAMMATORY ARTHROPATHIES TREATED WITH BIOLOGIC AGENTS**

M. Colas1, M. L. Aprile2, Y. Dal Bosco3, C. Schinoccia2, 1University of Catania, Clinical and Experimental Medicine, Catania, Italy; 2Ospedale Cannizzaro, Catania, Italy

**Background:** The lack of adhesion to treatment in patients affected by chronic diseases, such as rheumatic diseases, remains a relevant issue. Indeed, “inefficacy” or “intolerance” to therapies prescribed could hide a scarce compliance of a considerable percentage of patients.

**Objectives:** We aimed to evaluate the adhesion to treatment in a series of patients affected by chronic inflammatory arthropathies treated with biologic agents.

**Methods:** We recruited 175 consecutive patients (M/F: 56/120; mean age 52.8±13.3 years) affected by rheumatoid arthritis (98), psoriatic arthropathy (45) or ankylosing spondylitis (32) treated with subcutaneous biologic agents. All patients completed the Morisky Medication Adherence Scales (MMAS)-8, in order to estimate their adhesion to therapy. Moreover, we achieved from all cases the Patient Global Assessment (PGA), the Visual Analogue Scale (VAS) for articular pain, the Health Assessment Questionnaire (HAQ), and the report of eventual adverse events.

**Results:** Considering MMAS-8, 23/175 (13.1%) patients were low adherent to treatment (score ≤6), and 59/175 (33.7%) presented medium-good adherence (score 6-7).

Adherence to treatments tended to be higher in males (mean MMAS-8 7.3±1.1 vs. 6.9±1.6; p=0.073), while it was not associated with age, education level, type of arthritic disease, presence of adverse events, or treatment with the type of traditional or biologic DMARDs.

Higher mean levels of PGA (51.3 vs. 38.8; p<0.012), VAS (52.6 vs. 44.3; p=0.08) and HAQ (0.9 vs. 0.5; p<0.001) was reported in low-adherent patients compared with full adherent subjects.

**Disclosure of Interests:** Vivian Bykerk: None declared, Caroline Benson: None declared, Gregory Vitone: None declared, Aidan Tirpack: None declared, Susan J. Bartlett Consultant of: Pfizer, UCB, Lilly, Novartis, Merck, Janssen, Abbvie, Speakers bureau: Pfizer, UCB, Lilly, Novartis, Merck, Janssen, Abbvie, Clifton Bingham Grant/ research support from: Bristol-Myers Squibb, Consultant of: Bristol-Myers Squibb

**DOI:** 10.1136/annrheumdis-2020-eular.3749
Conclusion: Our study confirmed that the percentage of patients showing low adherence to therapy is relevant. Moreover, the association of lower adherence to treatments with higher values of the subjective clinimetric indexes suggests to pay attention to the apparent ineffectiveness or loss of efficacy of therapy.

**AB0185**

PROSPECTIVE PROFILE OF URINE METABOLOME IN RHEUMATOID ARTHRITIS

M. De Oliveira1, P. V. Alabarse2, M. Farinon1, R. Cavalheiro Do Espirito Santo1, R. Xavier1 on behalf of Department of Rheumatology - Clinicas Hospital of Porto Alegre, Brazil - Federal University of Rio Grande do Sul, 1Federal University of Rio Grande do Sul, Porto Alegre, Brazil; 2University of San Diego, San Diego, United States of America

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by increased mortality and associated with metabolic disorders. Since the metabolomic profile is known to vary in response to different inflammatory conditions, metabolome analysis could substantially improve diagnosis and prognosis of RA.

Objectives: To analyze the urine metabolome profile in RA patients and correlate it with disease activity changes over 12 months

Methods: Seventy-nine RA patients, according to ACR/EULAR 2010 classification criteria, between 40 and 70 years old, were recruited and followed for 12 months. Metabolome analysis was performed by Nuclear Magnetic Resonance spectroscopy (NMR), resulting in the identification of 93 metabolites in urine collected at the baseline and after 12 months. Frequency analysis, Pearson Correlation and Multivariate data analysis with orthogonal projections to latent structures (OPLS) method were performed and a statistical significance was considered as p<0.05.

Results: The study population was characterized by the majority of women (86.7%), mean age of 56 years old, around 80% with positive anti-CCP or Rheumatoid Factor. During the one year of follow-up, there was no substantial variation in the DAS28 measurement (baseline: 3.8, after 12 months: 4.0). There was no significant correlation between the metabolome pattern and DAS28 score (p>0.05) over time. However, multivariate analysis (OPLS-DA) demonstrated an adequate differentiation of the population with 0.92 of accuracy (Q2: 0.72 and R2: 0.89). There was a significant increase of L-cysteine, choline, L-Phenylalanin, creatine, L-histidine, oxalacetic acid and xanthine, and a decrease of L-threonine, taurine, butyric and gluconic acid (p<0.05) during the follow-up, metabolites that are involved in the skeletal muscle metabolism.

Conclusion: The observed biomarkers indicate, as expected, that the RA metabolomic profile is associated with inflammation injury and skeletal muscle amino acid metabolism. Correlations with disease activity changes was compromised by the stable disease status during the 12 months. More studies evaluating correlations with skeletal muscle function and mass are underway.

NO PREDICTIVE VALUE OF ADALIMUMAB SERUM LEVELS AND ANTI-ADALIMUMAB ANTIBODIES AT TIME OF ADALIMUMAB FAILURE FOR PREDICTION OF RESPONSE TO THE NEXT BDMARD

N. Den Broeder1, E. Ulijn1, M. Wientjes1, N. Van Herwaarden1,2, I. Meek2, L. Tweehuysen1, A. Van der Maas1, B. Van den Berst1,4, A. Den Broeder1, 4

1Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands; 2Radboudumc, Rheumatology, Nijmegen, Netherlands; 3Sint Maartenskliniek, Pharmacy, Nijmegen, Netherlands; 4Radboudumc, Pharmacy, Nijmegen, Netherlands

Background: After adalimumab treatment failure, TNFi and non-TNFi bDMARDs are equally viable as subsequent treatment in RA. However, preliminary data suggest that anti-drug antibodies (ADA) and adalimumab serum levels (ADL) predict response to a subsequent TNFi [1].

Methods: A retrospective cohort study to assess the predictive value of ADA and ADL for response to a subsequent TNFi or non-TNFi bDMARD.

Objectives: To assess the association of presence of ADA and/or low ADL with response to a subsequent TNFi bDMARD or non-TNFi bDMARD.

Results: A retrospective cohort study to assess the predictive value of ADA and ADL for response to a subsequent TNFi or non-TNFi bDMARD in RA patients. All RA patients who received adalimumab (standard dose, ≥ 3 months) and subsequently switched to another TNFi or a non-TNFi (rituximab, tocilizumab, abatacept) in the Sint Maartenskliniek or Radboud University Medical Centre between January 2012 and January 2018 were considered for inclusion in the current study. Further inclusion criteria were the availability of (random timed) serum samples between ≥8 weeks after start, and ≤2 weeks (for ADL) or ≤12 weeks (for ADA) after discontinuation of adalimumab, and clinical outcome measurements (DAS28-CRP/BSE) between 3-6 months after treatment switch. Serum samples were derived from a period of biobanking at every visit of RA patients and an observational cohort study including consecutive bDMARD starters.

The primary outcome of this study was the association between ADL or ADA and EULAR good response (DAS28-CRP/ESR based) to the subsequent bDMARD. When DAS28-based response was unreliable due to glucocorticoid use, or low baseline DAS28 (if switching due to adverse effects), judgement of the rheumatologist was used.

A drug-tolerant competitive enzyme-linked immunosorbent assay (Sanquin, the Netherlands) was used to quantify ADA, and thereafter, ADL was determined via an ELISA. Reference values were ≥5 µg/ml for ADL and <12 AU/ml for ADA [2,3]. Treatment was blinded for ADL and ADA levels.
Higher ADL (Spearman’s ρ = -0.68, p = 0.00) but not ADA (ρ = 0.23, p = 0.28) presence was associated with a lower DAS28 at the time of switching to a sub- sequent bDMARD, but not with follow-up DAS28 after starting the subsequent bDMARD (ρ = -0.29, p = 0.17, and p = 0.10, p = 0.65, respectively). In addition, higher ADA were associated with lower baseline CRP (ρ = -0.67, p = 0.00) and higher ADL correlated with higher baseline ESR (ρ = 0.49, p = 0.01).

Conclusion: No predictive value for response to a second TNFi or non-TNFi was found for either ADA or random timed ADL. Limitations of this study are the retrospective design and random timed serum sampling. An ongoing randomized blinded test-treatment trial will provide more definitive answers [4].

AB0187 ASSESSMENT OF ADHERENCE TO TREATMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA)
E. Egorova1, N. Nikitina1, A. Rebrov1, 1Saratov State Medical University named V.I. Razumovsky, Ministry of Health of Russia, Saratov, Russian Federation

Background: Rheumatoid arthritis (RA) is the most common chronic immune inflammatory disease. The effectiveness of RA therapy largely depends on adherence to treatment. Non-compliance with the recommendations of the doctor leads to increased disease activity, a greater risk of complications and the increase in the cost of treatment.

Objectives: To determine predictors of adherence to treatment of patients with RA.

Methods: The study included 82 women with reliable RA according to the criteria of ACR/1987 and/or EULAR/ACR 2010 (mean age 53.3 ± 10.2 years, the age at the onset of the disease -42.4 [36;51] years, mean duration of RA - 10.8 [6;14] years, DAS28 - 5.03 [4.3;5.8]). Treatment adherence was assessed according to the questionnaire “Quantitative Evaluation of Adherence to Treatment (KOP - 25)” [1]. The following indicators were calculated: adherence to drug therapy, adherence to medical support, adherence to lifestyle modification and their integral index. For all indicators, the level of values in the range up to 50% is interpreted as “low” (<non-adherence to treatment>), from 51 to 75% - as “medium”; more than 75% - as “high”<wbr class="caps" style="font-size: 50%" xmlns="http://www.w3.org/2003/01/xml-namespace""wbr%. The functional ability of patients was assessed by the Health Assessment Questionnaire (HAQ). The severity of pain was determined by VAS. Statistical processing was performing using the program STATISTICA 10.0.

Results: Adherence to drug therapy in women with RA was determined: low adherence in 32 (39%) patients, average in 34 (41.5%) patients and high in 16 (19.5%) patients; adherence to medical support: low in 26 (31.7%) patients, average in 40 (48.8%) patients, and high in 16 (19.5%) patients; adherence to lifestyle modification: low in 55 (67%) patients, average in 25 (30.5%) patients and high in 2 (2.5%) patients. According to the integral indicator of adherence to treatment, 34 (41.5%) patients were not adherent to treatment, average adherence was recorded in 42 (51.2%) patients, and high in 6 (7.3%) patients.

The HAQ functional impairment was absent in 7 (8.5%) patients, minimal impairment occurred in 26 (31.7%), moderate - in 40 (48.8%) and severe - in 9 (11%) patients. Severe pain in the VAS was noted by 29 (35.4%) patients, moderate - 39 (47.6%), and in 14 (17%) patients the pain syndrome was weakly expressed.

The relationships of adherence to treatment was established with age (r = -0.29, p = 0.05), age at the onset of the disease (r = -0.29, p = 0.05), ESR index (r = -0.27, p < 0.05), the number of swollen joints (r = -0.3, p < 0.05).

Patients under age of 39 years were the most adherence to drug therapy. In patients with medium and high adhering to treatment, the severity of pain according to VAS was significantly lower than in non-adherent patients [50.6 [34;66] and 60.4 [46;73], respectively, p = 0.04]. In patients with treatment adherence, activity was significantly lower than in non-treatment adherents (DAS28 4.7 [3.5;5.4] and 5.3 [4.7;5.8], respectively, p = 0.04).

Conclusion: Low treatment adherence has 41.5% of RA patients. Predictors of adherence to treatment are the young age patients, the onset of the disease before age of 39 years. Non-treatment patients with RA have a higher activity of RA according to DAS28, pain intensity according to VAS, the worst functional status. To increase the effectiveness of treatment, constant interaction between the patient and the physician is necessary, explaining to patients the consequences of non-compliance with recommendations.

AB0188 COMPARISON OF COMPOSITE INDICES FOR DETECTING REMISSION ON ULTRASOUND
R. Fakhfakh1, N. El Amri1, K. Baccouche1, H. Zeglaoui1, E. Bouajina1, 1Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

Background: Several studies have shown the greater sensitivity of ultrasound (US) to detect B-mode synovitis and synovial Doppler activity in a high percentage of rheumatoid Arthritis (RA) patients in clinical remission, assessed by different composite indices.

Objectives: The aim of the study was to compare the accuracy of composite indices to detect remission in ultrasound B-mode and power Doppler (PD) in RA patients that are in remission according to the DAS28 ESR.

Methods: Cross-sectional study including patients with RA in clinical remission defined by: DAS28<2.6, without disease flare or changes in therapy in the previous 6 months. Each patient underwent B-mode and PD assessments of 36 joints and 20 tendons in the Rheumatology Department over a period of 6 month. B-mode and PD signal for synovitis and tenosynovitis were defined according to the Outcome Measures in Rheumatology Clinical Trials (OMERACT). A global score for B-mode and a global score for PD signal were calculated for each patient. The DAS28, CDAt, SDAI and the Boolean 2010 ACR/EULAR remission criteria were compared.

Results: Thirty two patients were enrolled, the mean age was 53.7±13.4 and the sex ratio M/F was 0.3. The mean disease duration was 15.0 years ± 8.8. According to the SDAI, 68.8% of patients were in remission. These were lower for the CDAt (62.5%) and the Boolean criteria (23.3%). Synovial hypertrophy and tenosynovitis in B mode was detected in 100% with the Boolean remission criteria in 93.8% with a DAS28, in 90.9% with a SDAI ≥ 3.3 and in 90% with a CDAt ≤ 2.8 (p<0.05). The PD signal was detected in 62.5% with a DAS28, in 59.1% with a SDAI ≥ 3.3, in 57% with the Boolean remission criteria and in 55.1% with a CDAt ≤ 2.8 (p<0.05). The mean B-mode global score was higher for the DAS28 ESR (8.2±6) and lower for the Boolean remission criteria (6.2±5.4). For a CDAt ≤ 2.8, the mean global score for B-mode was 7.6±5.9 and for a SDAt ≤ 3.3, it was 7.4±5.7. The median PD global score was similar for the DAS28, SDAt 3.3 and Boolean remission criteria [10-12]. It was higher for a CDAt ≤ 2.8 ± 1.5 [1-12]. The global score for PD signal was correlated with DAS28 ESR (r=0.42 ± 0.02, p=0.02). There were no significant correlations between the other indices and the mode B and PD global scores.

Conclusion: The CDAt least detected subclinical synovitis and synovosynovitis in B mode and in power Doppler signal but it showed higher scores of power Doppler.

AB0189

ASSessment of Power Doppler Synovitis in Rheumatoid Arthritis Patients With Clinical Remission

R. Fakhfakh1, N. El Amrî1, K. Baccouche1, H. Zeglaoui1, E. Bouajina1,1 Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

Background: Ultrasound-detected synovitis, mainly synovial Doppler signal, has shown predictive value in relation to radiographic damage progression and disease flare or relapse in rheumatoid arthritis (RA) patients with clinical remission.

Objectives: The aim of the study was to analyze the correlation between power Doppler scores and clinical/laboratory and radiographic data in clinical remission RA patients.

Methods: Cross-sectional study including patients with RA in clinical remission defined as: DAS28ESR ≤ 2.6, without disease flare or changes in therapy in the previous 6 months. Each patient underwent ultrasound: B-mode and PD assessments of 36 joints and 20 tendons in the Rheumatology Department over a period of 6 months. Synovitis and tenosynovitis were defined and scored according to the Outcome Measures in Rheumatology Clinical Trials (OMERACT). Radiological measurements included the modified Sharp/van der Heijde method (SHS). Functional capacity was assessed by the Health Assessment Questionnaire (HAQ).

Results: Thirty two patients were enrolled, the mean age was 53.7±13.4 and 75% were female. The mean disease duration was 15 years ± 8.8. Subclinical synovitis were the most frequent in wrist (56.3%), 2nd metacarpophalangeal joints (28.1%) and 2nd metatarsophalangeal joints (29%). The mean subclinical synovitis/tenosynovitis numbers were 4±3.1 per patient. Synovial hypervascularity and B mode tenosynovitis were detected in 93.6%; 71.3% had a grade = 2 and 9.8% had a grade ≥ 3. Total B mode score was correlated only with the SHS score in the feet (r: 0.4, p: 0.03). PD signal was detected in 62.5% of patients: 37.5% had a grade =2 and 9.4% had a grade ≥ 3. Total PD score was correlated with DAS28 (r:0.42, p:0.02), the SHS score in the hands (r:0.39, p:0.03) and in the feet (r:0.5, p:0.007), synovial hypervascularity (r:0.6, p:0.0001) and HAQ (r:0.32, p:0.06). No correlation was found with CDAI, SDAI, swollen joint counts, tender joint counts, patient global health assessment, erythrocyte sedimentation rate, C-reactive protein, rheumatoid factor and anti-cyclic citrullinated peptide, biological treatment.

Conclusion: Synovial hypervascularity and PD signal were frequent in RA remission. PD signal was associated with RA activity, radiologic damage and functional capacity.

DO IT FAST! EARLY ASSESSMENT BY A RHEUMATOLOGIST INCREASES THE CHANCES OF RHEUMATOID ARTHRITIS BEING TREATED WITHIN THE “WINDOW OF OPPORTUNITY”

C. Albuquerque1,2, P. Gomides1, A. B. Vargas-Santos2, C. Breno3, I. Pereira4, K. Bonfiglioli5, M. Bertolo5, M. F. Guimarães2, M. Sauma5, P. Louzada Jr6, R. Giorgi7, S. Radominski1, L. Mota1, G. Castelar-Pinheiro2,1 Universidade de Brasília, Brasília, Brazil; 1Universidade do Rio de Janeiro, Rio de Janeiro, Brazil; 2Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; 3Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; 4Universidade Federal de Santa Catarina, Florianópolis, Brazil; 5Universidade de São Paulo, São Paulo, Brazil; 6Universidade Estadual de Campinas, Campinas, Brazil; 7Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; 8Hospital do Servidor Público Estadual de São Paulo, São Paulo, Brazil; 9Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Background: The current concept of treating rheumatoid arthritis RA patients emphasizes the importance of early diagnosis and early initiation of disease-modifying drugs (DMARD) for a better prognosis of these patients.

Objectives: To evaluate the impact of rheumatologic evaluation on the diagnosis of RA patients, as well as on the initiation of DMARD and on the clinical control of disease activity of these patients under real-life conditions.

Methods: The REAL study included RA patients attending eleven public hospitals, from different regions of Brazil. All subjects met the ARA (1987) or ACR/EULAR (2010) RA classification criteria. Subjects were submitted to clinical interview with physical exam and review of medical records. Specialized assessment was defined as sequentially “early”, when the rheumatologist was the 1st or 2nd consulted physician, and “late” when the rheumatologist was consulted after two or more other doctors. Welch’s t, Mann-Whitney’s U, chi-square and Spearman’s rho tests were used to test hypotheses, at significance level of 0.05. The study was approved by local ethics committees and all participants granted informed consent.

Results: 1057 RA patients were assessed; 89.4% (n=945) female; 56.5% (n=603) mean (SD) age 56.9 (11.5) years; mean (SD) disease duration of 173.1 (114.5) months. Median [IQR] delay from symptoms onset to RA diagnosis and to the first DMARD both equalled 12 [6, 36] months. Only 28.7% received a DMARD within 6 months of symptoms onset, and 13.1% within 3 months. Most patients (64.6%) sought a general practitioner first, but 80.7% were finally diagnosed only upon rheumatologist consultation. For 28.8%, the rheumatologist was consulted after two or more other doctors. Early specialized assessment resulted in higher chances of receiving a DMARD within 6 months (OR 2.77; 95%CI [1.93, 3.97]) and within 3 months (OR 2.57; 95%CI [1.54, 4.27]) of RA onset. Late assessment was associated with lower chances of being in remission or low disease activity upon study inclusion (OR 0.53; 95%CI [0.39, 0.72]). Patients assessed early by the rheumatologist, compared to those assessed late, showed lower (mean [SD]) HAQ scores (0.877 [0.715] vs. 1.074 [0.857]; p<0.001) and DAS28-CRP scores (3.29 [1.33] vs. 4.46 [1.58]; p=0.02), and shorter delays to RA diagnosis (26.9 [46.7] vs. 44.6 [60.1] months; p<0.001) and to use the first DMARD (32.5 [58.5] vs. 50.6 [69.9] months; p<0.001). The delay to initiate a DMARD was strongly correlated to that of diagnosing RA (rho 0.816; p< 0.001).

Conclusion: Most RA patients missed the window of opportunity to early treat RA. Treatment delay strongly correlated with delayed DMARD. The current concept of treating RA patients has to be changed. The delay to initiate a DMARD is highly dependent on the input of the rheumatologist. Late rheumatologist assessment was associated with lower chances of early RA treatment and with worse outcomes. Failure in direct transition from primary to specialized care was a common problem that needs to be solved.

DECREASING DELAY TO DIAGNOSIS AND TREATMENT OF RHEUMATOID ARTHRITIS: STILL DIFFICULT TO TREAT WITHIN THE WINDOW OF OPPORTUNITY

C. Albuquerque, A. P. Gomides, A. B. Vargas-Santos, C. Breno, I. Pereira, K. Bonfiglioli, M. Bertolo, M. F. Guimarães, M. Sauma, P. Louzada Jr, R. Giorgi, S. Radominsky, L. Mota, G. Castelar, University of Brasília, Brasília, Brazil; UERJ, Rio de Janeiro, Brazil; UFRRGS, Porto Alegre, Brazil; UFSC, Florianópolis, Brazil; USP, São Paulo, Brazil; Unicamp, Campinas, Brazil; UFMG, Belo Horizonte, Brazil; UFBA, Belém, Brazil; UFRP Ribeirão Preto, Brazil; Hospital do Servidor Público Estadual de São Paulo, São Paulo, Brazil; UFPB, Cuitiba, Brazil; UnB, Brasília, Brazil

Background: The need for early rheumatoid arthritis (RA) treatment for better outcomes is widely accepted. Is that goal being achieved in real-life settings?

Objectives: To evaluate changes in the delay to RA diagnosis and treatment, and in the proportions of patients being treated early along the last decades in Brazil.

Methods: This study was drawn from the REAL cohort, designed to assess RA management under real-life conditions. Patients ≥18 years old attending public hospitals in Brazil and meeting RA classification criteria were included. Subjects were stratified according to the year their symptoms began. Delays from symptoms onset to RA diagnosis and treatment were inquired. Early RA diagnosis and treatment was assessed using three different cut points: ≤3, ≤6 and ≤12 months of symptoms onset. Mann-Kendall’s trend test, chi-square tests, Welch’s ANOVA and Games-Howell’s post-hoc tests were used to test hypotheses, at 0.05 significance level.

Results: 1116 RA patients were included; 89.4% female; 56.8% white; mean (SD) age 57.1 (11.5) years. A downward trend was found in the delay to RA diagnosis (tau = -0.677, p < 0.001) and treatment (tau = -0.695, p < 0.001) from 1990 to 2015 (Figures 1 and 2). The year of symptoms onset was associated with the frequency of early treatment for all defined cut points: ≤3 months (χ² = 11.25, p = 0.001), ≤6 months (χ² = 34.84, p < 0.001), and ≤12 months (χ² = 64.79, p<0.001). The more recent the year of symptoms onset, the higher the proportions of individuals treated early (Table 1). Groups stratified according to successive periods of symptoms onset differed in the mean delay to RA treatment [F(5, 372.8) = 41.9; p < 0.001]. Patients with symptoms initiated more recently (2011-2015) had significantly lower delays compared to all other groups. Nonetheless, only 36.3% of these patients with more recent disease started treatment within 6 months of symptoms onset, and 17.2% within 3 months.

Table 1. Proportions of individuals with RA receiving the first DMARD within different time intervals from symptoms onset, according to the year their symptoms began.

Figure 1. Rheumatoid arthritis diagnostic delay according to the year of symptoms beginning, from 1990 to 2015 in Brazil

Figure 2. Rheumatoid arthritis treatment delay according to the year of symptoms beginning, from 1990 to 2015 in Brazil

Conclusion: Delays to RA diagnosis and treatment have decreased, and more patients have been treated within defined windows for early RA management in the last decades in Brazil. Despite all improvements, it was still difficult to attain early RA treatment. Additional efforts are warranted in pursuit of that goal.

RHEUMATOID ARTHRITIS: IS IT WORTH IT TO ADD LEFUMONIDIE TO METHOTREXATE IN REFRACTORY DISEASE?

F. Guimarães,1,2 D. Faría,1 S. Azevedo,1 J. Rodrigues,1 J. Silva,1 D. Almeida,1 F. Teixeira,1 C. Afonso,1 D. Peixoto1,2,3 "Unidade Local de Saúde do Alto Minho, Rheumatology, Ponte de Lima, Portugal; Hospital de Braga, Rheumatology, Braga, Portugal"

Background: In refractory rheumatoid arthritis (RA), adding other classic synthetic disease-modifying antirheumatic drug (csDMARD) such as leflunomide (LFN) or methotrexate (MTX). It is one such strategy, but there are several issues to consider which may limit this strategy, but also regarding its true effectiveness in avoiding exposure to biological DMARDs (bDMARD) or target synthetic DMARDs (tsDMARD).

Objectives: To assess the effectiveness and safety of adding LFN to MTX and to evaluate the predictors of drug retention, toxicity and inefficacy.

Methods: A retrospective clinical record review of adult RA patients followed up in our rheumatology department in whom LFN was added to MTX was done. Sociodemographic information, comorbidities, disease related information, adverse reactions and disease activity according to Disease Activity Score 28 (DAS28) were recorded at baseline and after 3, 6 and 12 months of combination therapy (3_DAS28, 6_DAS28, 12_DAS28, respectively). Information regarding toxicity (need to dose adjustment/suspension) and inefficacy (addition to bDMARD/tsDMARD) were recorded. Follow-up was considered until last medical record available. SPSS was used for statistical analysis.

Results: In total, 77 patients were included, 66.20% females, with a mean age of 56±11 years old. There was a significant reduction of DAS28 only after 3 months of therapy (p=0.08, 0.03, 0.03, respectively). Disease activity scores (3_DAS28, 6_DAS28, 12_DAS28) were 5.8±1.17. However, during a median follow up time of 64 (IQR 39-83) months, 58.4% of patients needed to change treatment strategy, 66.7% due to toxicity (median time to toxicity 13 months, IQR 2-16) and 33.3% due to inefficacy (median time to inefficacy of 10 months, IQR 5.84-17.64). Gastrointestinal intolerance was the main reported toxicity (46.15%). In univariate analysis, anti-citrullinated protein antibodies (ACPA) positivity, alcohol consumption, lack of comorbidities, hepatic toxicity, higher 6_DAS28, swollen joint count and tender joint count among other factors were associated to lower retention rates. In multivariate analysis, lack of comorbidities (HR=3.3, CI 95% 1.4-7.8, p=0.006) and higher 6_DAS28 (HR=0.32, CI 95% 0.14-0.72, p=0.006) were independent predictors of suspension of combination therapy. Moreover, both male gender (HR=2.87, 95%CI 1.2-6.56, p=0.018) and positivity to ACPA (HR=0.1, 95%CI 0.01-0.73, p<0.02) were independent predictors of toxicity. There was also higher tendency to toxicity, but without statistical significance, in alcohol consumers (p=0.08). Regarding inefficacy, smoking habits (HR=0.15, 95%CI 0.04-0.52) and 3_DAS28 (HR=0.15, 95%CI 0.04-0.53) were independent predictors.

Conclusion: Addition of LFN to MTX showed an early positive response. However, it was frequently associated to toxicity, and less than half of the patients continued with this therapeutic strategy after 5 years of follow up. Male gender, smoking habits and positivity to ACPA were predictors of worse outcome, as already reported in literature [1]. Lack of comorbidities was an independent predictor of suspension. This can be explained by the fact that physicians tend to adopt a more aggressive strategy on patients without comorbidities, switching earlier to bDMARDs/tsDMARDs.

for all patients. Ultrasound DAS included 28 joints, Power Doppler ultrasound (PDUS) examination of 22 joints and gray scale ultrasound (GSUS) examination for Effusion/Hypertrophy (E/H) of 28 joints. Ultrasound erosion count (USEC) and Ultrasound erosion rate (USER) were assessed.

**Results:** Dickkopf-1 level in RA patients ranged from 66 to 453 ng/ml while in the control group ranged from 15 to 87 ng/ml with statistically significant difference. RA patients were grouped in to: group 1 included 15 (30%) patients with normal DKK-1 level and group 2: included 35 (70%) patients with elevated DKK-1. The differences between both groups were highly significant regarding clinical and laboratory measures (duration of morning stiffness, DAS 28, VAS, ESR, CRP, RF and ACPA), and regarding HAQ-DI, SINS and US DAS. We found significant positive correlation between DKK-1 level and laboratory measures (ESR, CRP, RF, ACPA), radiographic parameters (SINS and erosion score), ultrasonographic parameters (US DAS, USEC and USER) and with HAQ-DI and functional status.

**Conclusion:** Serum level of dickkopf-1 was elevated in RA patients and the results demonstrated the relationship between increased dickkopf-1 level and increased disease activity, decreased functional capacity and chronic structural damage suggesting its important role in the pathogenesis of RA.

Factors Related to Radiographic Progression in Patients with Rheumatoid Arthritis-Related Interstitial Lung Disease

U. Kalyoncu1, M. Ercikut2, E. Bilgin3, A. San4, Y. Baytar5, E. C. Boke6, B. Armagan7, B. Farsalogullari2, O. Karadag8, A. I. Ertendi9, S. Kiraz10, L. Kılınç11, Ş. A. Bilgen12, G. Durhan13, A. Akdoğan14, M. Anyürek15, Hacettepe University, Rheumatology, Ankara, Turkey; Hacettepe University, Internal Medicine, Ankara, Turkey; Hacettepe University, Radiology, Ankara, Turkey

Background: Interstitial lung disease is an important cause of mortality and morbidity for RA. Lung computerized tomography (CT) is a valid method for the detection of interstitial lung disease (ILD) in rheumatoid arthritis (RA) patients. Besides, CT may have a role in the detection of progression in RA-ILD.

Objectives: To compare the clinical and radiological features of RA-ILD patients with and without radiographic progression according to lung CT.

Methods: From the hospital database, all patients recorded as having RA according to ICD-10 code and had a lung CT examination were recruited. RA was confirmed in 822 of 2305 (35.6%) records. Three radiologists re-evaluated lung CTs and 156/822 (18.9%) patients with had RA-ILD. Of these 156 patients, 101 (64.7%) had at least 1 follow-up long CT and these patients were included to analysis. Demographic and clinical data of the patients were recorded. ILD was divided into 3 main groups by radiologists: Usual interstitial pneumonia (UIP), non-specific interstitial pneumonia (NSIP) and airway disease (AD) (bronchiectasis and/or bronchiolitis without parenchymal involvement). Avila et al reported a grading system to assess the severity of ILD using HRCT (1). In our study we utilized a similar method using interlobular septal thickening, ground glass opacities, reticulations, traction bronchiectasis and honeycomb appearance as elementary findings to evaluate the RA associated ILD.

Results: In this study, 101 patients with 215 lung CT were included to analysis. 67 (66.3%) patients had 3 CTs, 30 (29.9%) patients 4 CTs and 17 (16.9%) patients had 5 CTs. Mean duration between first and last CT was 47.7±38.8 months. Of 101 patients, radiographic progression was seen in 42 (41.6%) patients. Univariate comparison of demographic, clinical and radiographic features of patients with or without radiographic progression were given in Table. In multivariate analysis (adjusted for ILD disease duration) having ground-glass opacity (aOR 8.6; CI: 1.63–44.9; p=0.011), male gender (aOR 2.9; CI: 1.13–7.4; p=0.026) were found as independent risk factors radiographic progression, while taking methotrexate (ever) (aOR 0.21; CI: 0.07–0.6; p=0.04) was found as an independent protector factor for radiographic progression.

Conclusion: The prediction of ILD progression in RA patients was a challenge for clinicians. According to lung CT, baseline ground-glass opacities looks like prominent factor for ILD progression, particularly at male RA patients. Using methotrexate in ILD patients is a dilemma in routine practice, our results demonstrate that methotrexate (not other cs or bDMARDs) is protective drugs for ILD progression, however these results should be confirmed in the further studies.

The Association Between Osteoporosis and Functional Impairment Evaluated by the Locomo25 in Rheumatoid Arthritis

T. Kashiwagura1, M. Kobayashi2, Y. Sugimura3, T. Kawano4, H. Sato5, Y. Shimada6, Akita City Hospital, Department of Orthopedic Surgery, Akita, Japan; Hiraka General Hospital, Yoko, Japan; Nakadori General Hospital, Department of Orthopedic Surgery, Akita, Japan; Akita University Graduate School of Medicine, Akita, Japan; Kita Akita Municipal Hospital, Kita Akita, Japan

Background: Locomotive syndrome is a condition in which activities of daily living are affected by impairment of the motor organs, most often due to rheumatoid arthritis (RA). Locomo25 is a new index developed for the early detection of locomotive syndrome. It consists of 25 items associated with pain, physical activity, and subjective state of health, with a score of 7 points or higher classed as Grade 1 locomotive syndrome and a score of 16 points or higher as Grade 2. In RA, joint impairment causes the appearance of problems affecting motor organs as a whole, as well as progressive functional impairment. As functional impairment progresses, it causes increasing immobility, which raises the risk of osteoporosis.

Objectives: Locomo25 was used to investigate functional impairment and its association with RA disease activity and osteoporosis indicators.

Methods: The subjects were 105 patients with RA (24 men and 81 women) with a mean age of 68.7 (28–91) years. In terms of staging, 25 were Stage I, 22 Stage II, 17 Stage III, and 41 Stage IV, and their motor disability was Steindorcher Class 1 in 68 cases, Class 2 in 27, Class 3 in 9, and Class 4 in 1. Disease activity according to the Disease Activity Score 28 with erythrocyte sedimentation rate (DAS28 ESR) was assessed as remission in 44 cases, low disease activity in 24, moderate in 33, and high in 4. The associations between the Locomo25 score and disease activity indices, bone mineral density (BMD), and bone turnover markers (TRACP-5b, NTX, urinary DPD, BAP, total P1NP, and 25(OH)D) were investigated.

Results: Locomo25 grade was 0 in 37 cases (35.2%), 1 in 24 (22.9%), and 2 in 44 (41.9%). Locomo25 grade was significantly associated with Steindorcher class (r = 0.4299, Spearman’s rank correlation coefficient, p < 0.0001). DAS28 ESR and Health Assessment Questionnaires scores increased as locomotive syndrome progressed. There was no significant difference in eGFR between groups, but bone resorption markers (TRACP-5b, NTX, and urinary DPD) and a bone quality marker (pentosidine) decreased significantly as locomotive syndrome progressed. There were no significant differences in BMD or other bone turnover markers.

Conclusion: The Locomo25 score was useful for evaluating functional impairment in RA. The prevalence of Grade 2 locomotive syndrome in the general population is reported to be around 25%, and many patients with RA had advanced locomotive syndrome. Although there was no significant difference in BMD, elevated bone resorption and deteriorating bone quality were associated with progressive functional impairment, suggesting that RA patients with advanced locomotive syndrome may be at risk of increasingly severe osteoporosis as a result of immobility.

AB0197 INCREASED CIRCULATING ADIPONECTIN IS AN INDEPENDENT DISEASE ACTIVITY MARKER IN PATIENTS WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY USING THE KURAMA DATABASE

1Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; 2Kyoto University, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan; 3Kyoto Prefectural University of Medicine, Department of Nursing, Kyoto, Japan; 4Kurashiki Sweet Hospital, Department of Health Information Management, Kurashiki, Japan; 5Kyoto University, Department of Orthopedic Surgery, Kyoto, Japan

Background: Adiponectin is a major adipokine with pleiotropic effects on inflammatory conditions including rheumatoid arthritis (RA). Adiponectin generally has anti-atherogenic effects, and its serum level inversely correlates with body mass index (BMI) and visceral fat area (VFA). On the other hand, several studies have indicated a deleterious role of adiponectin in RA progression [1]. Recently, low BMI and increased serum adiponectin have been reported as poor prognostic factors of RA [2, 3]. However, large-scale surveys have not been done focusing on both BMI and serum adiponectin, and it is unclear which factor provides further contribution to RA disease activity. In addition, the effects of biological disease-modifying antirheumatic drugs (bDMARDs) and Janus kinase (JAK) inhibitors on serum adiponectin are largely unknown.

Objectives: To clarify the relationship among serum adiponectin, body composition, current disease activity and therapeutic agents of RA.

Methods: We conducted a cross-sectional study in RA patients under treatment with agents including bDMARDs and JAK inhibitors. A total of 351 subjects from the Kyoto University RA Management Alliance cohort (KURAMA) were enrolled. We classified the participants into five body composition groups (overweight with or without visceral adiposity, normal with or without visceral adiposity, and underweight), according to the cut-off points for obesity and visceral fat used in Japan: BMI, 18.5-25.0 kg/m² for underweight and ≥25.0 kg/m² for overweight, and VFA, 100 cm² for visceral adiposity. Differences of continuous variables among the five groups were assessed by the Steel-Dwass test or one-way analysis of variance (ANOVA). We adopted a multiple standardized linear regression model to analyze effects of serum adiponectin level on DAS28-ESR.

Results: Serum adiponectin levels (20.9±12.5 vs. 14.7±8.4 μg/ml, p < 0.001) and DAS28-ESR (3.0±4.1 vs. 2.6±3.9, p=0.017) in the underweight group were significantly higher than those in the others. In multiple regression analysis, serum adiponectin level, but not BMI, was positively correlated with DAS28-ESR (estimate=0.0217, p=0.0582). Subanalysis also showed that the use of bDMARD or JAK inhibitor did not have an obvious influence on circulating adiponectin.

Conclusion: In the multiple regression analysis we revealed a positive and independent correlation between serum adiponectin and DAS28-ESR in Japanese RA patients. Thus, serum adiponectin is an potential marker reflecting high disease activity of RA regardless of current medications.

AB0198 SMOKING AND POSITIVITY OF RHEUMATOID FACTOR AND ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODY IN THE GENERAL POPULATION

G. Kidooguchi1, S. Fuku1, T. Nakai1, S. Kawaai1, H. Ozawa1, Y. Ikeda1, A. Koido1, Y. Ohara1, H. Shimizu1, K. Yamaguchi1, H. Tamaki1, M. Okada1, 1St. Luke’s International Hospital, Immuno-Rheumatology Center, Chuo City, Japan

Background: It is well known that rheumatoid arthritis (RA) occurs due to environmental risk factors in addition to genetic risk factors. Rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (ACPA) are strongly associated with RA, and these biomarkers could turn to be positive before development of clinical symptoms. While smoking, particularly Brinkman index (BI) is well known as a risk factor for RA and ACPA positivity, it is still unclear whether smoking intensity or smoking duration contribute more to positive RF and ACPA.

Objectives: This study aims to evaluate risk factors for RF and ACPA positivity in the general population. It also describes whether smoking intensity, duration, and BI are significant.

Methods: This is a cross-sectional, observational, single center study. We reviewed the baseline characteristics of the general population who checked RF and ACPA at Preventive Medicine Center in St. Luke’s International Hospital, Tokyo, Japan from January 2004 to December 2018. The data for basic demographics, dietary habit, smoking intensity, smoking duration, BI, and blood tests including RF and ACPA were extracted. The data was analyzed statistically.

Results: A total of 127472 people who checked RF are included. Of these 127472 people, 64504 (50.6%) were male and the mean age was 44.9 years. RF was positive in 11477 people (9.0%). Among these, 1667 (12%) were checked for ACPA, and 21 people (1.3%) had positive ACPA. None of variables demonstrated significant association with RF positivity. In contrast, BI and smoking duration was significantly associated with an increased risk of ACPA positivity (13.3 years vs 7.49 years, p value = 0.023), although the number of cigarettes smoked was not. The smoking duration for 10 years or more was associated with an increased risk of ACPA positivity even after adjusted for age and sex (adjusted hazard ratio: 2.47 [95% confidence interval: 1.04-5.87]); p=0.04).

Conclusion: In this study, no significant risk factor for positive RF was found. Even smoking was not associated with RF positivity. On the other hand, smoking duration, not smoking intensity was significantly associated with an increased risk of ACPA positivity.

Conclusion: Our preliminary analysis shows that this set of genes and selected clinical parameters are predictive markers for infliximab specific response in RA patients. Ongoing work involves the clinical validation of these results in an independent patient cohort (n=60). This approach provides the opportunity to develop an in vitro diagnostic test method for the prediction of infliximab treatment responsiveness in bioactive rheumatoid arthritis patients, hence to personalize infliximab therapy for these patients.

DOI: 10.1136/annrheumdis-2020-eular.5849

Results: A total of 250 genes were identified by a combination of differential gene expression analyses, feature elimination techniques and various machine learning modelling methods of which 44 genes showed significant differences between NR and good responder groups. Preliminary interim analysis identified associations between gene expression and clinical response/non-response to infliximab therapy.

Conclusion: Our preliminary analysis shows that this set of genes and selected clinical parameters are predictive markers for infliximab specific response in RA patients. Ongoing work involves the clinical validation of these results in an independent patient cohort (n=60). IMPACT OF TREATMENT INITIATION DELAY ON DISEASE ACTIVITY DURING RHEUMATOID ARTHRITIS

H. Bettieb, A. Fazaa, S. Miladi, M. Sellami, O. Kmar, L. Souabni, S. Kassab, S. Chikili, Z. Leith, K. Ben Abdelghani, A. Laatar, 1Mongi Slim Hospital, Tunis, Tunisia

Background: During rheumatoid arthritis (RA), instituting conventional synthetic Disease Modifying Anti-Rheumatic Drug (csDMARD) at the early stages of the disease is a mandatory condition to achieve DMARD-free sustained remission (1). Limited data studying the relationship between RA treatment delay and disease activity are available.

Objectives: The aim of this study was to assess the impact of csDMARD initiation delay during RA on disease activity.

Methods: This is a cross-sectional study including patients with RA (ACR/ EULAR criteria). Datasets were collected from patients’ interview and were represented respectively by D1, D2 and D3. D1 stands for the lag time separating the first RA symptom onset and rheumatologist consultation. D2 stands for the lag time separating the first RA symptom onset and RA diagnosis. D3 stands for lag time separating the first RA symptom onset and csDMARD initiation. Disease activity was evaluated by: Visual Analogue Scale for pain (VAS), number of tender joints, number of swollen joints, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and Disease Activity Score28 (DAS28). The data were analyzed with descriptive statistics. Students’ t test, chi (2) test, and Spearman correlation using the SPSS statistical package. A p value < 0.05 was considered significant.

Results: The study included 100 RA patients (86 women and 14 men), with a mean age of 56.5 ± 12.4 years. The mean age at the onset of RA was 47.5 ± 12.4 years. Median D1, D2 and D3 were respectively 12 months [0-242], 15.7 months [2-252] and 18 months [0-270]. Methotrexate was prescribed in 86% of cases. At RA diagnosis, the median values for the following parameters were: VAS 80 [30-100], number of tender joints 10 [0-28], number of swollen joints 5 [0-17], ESR 43 mm/hour [6-133], CRP 14.1 mg/l [30-100], DAS28 (ESR) 5.22 [2-7.52] and DAS28 (CRP) 4.6 [1-6.93]. After one year of follow-up, the median parameters of the disease activity were respectively: VAS 60 [0-100], number of tender joints 60 [0-18], number of swollen joints 2 [0-22], ESR 52 mm/hour [2-106], CRP 7.5 mg/l [1.2-9.4], DAS28 (ESR) 4.1 [1.4-7.1] and DAS28 (CRP) 3.7 [1.6-8.2]. Significant positive correlation was found between delays in csDMARD initiation and DAS28 (CRP) scores over the first year (p=0.02, r=0.29).

Conclusion: In this study, delays in treatment were associated with higher DAS28 (CRP) scores after one year of follow-up. Our results suggest that early identification and treatment of RA leads to improved outcomes and even improved rates of drug-free remission.

GENETIC SUSCEPTIBILITY AND PHENOTYPE OF RHEUMATOID ARTHRITIS IN DANISH AND TURKISH PATIENTS

K. B. Lauridsen, 1A. Linnauskas, 2S. M. Sellami, 3M. Saxl, 4O. Kmar, 4L. Souabni, 5S. Kassab, 6Z. Leith, 7K. Ben Abdelghani, 8A. Laatar, 1Mongi Slim Hospital, Tunis, Tunisia

Objective: To compare the clinical, serologic expression and the presence of shared epitopes (SE) of incident RA in two different populations, one from Northern Europe and the other from Southern Europe.

Methods: Data on 100 RA patients fulfilling EULAR/ACR 2010 classification criteria for RA were collected at Rheumatology Departments in Denmark and Turkey in 2015-2016. Patients were assessed using the same standardized protocol in both populations. SE carrier status were assigned, according to the du Montcel classification based, into six allele groups: S1, S2, S3D, S3F and X, where S2 and S3F are RA risk-enhancing alleles and S1 and S3D are RA protective alleles of the shared epitope (1).

Results: 109 incident RA patients from Denmark and 114 incident RA patients from Turkey were enrolled. Genetic data were available from 87% of the patients.

We found no associations between the risk-enhancing alleles and the presence of IgM rheumatoid factor or ACPPA.

Conclusion: The Turkish patients were younger and had lower disease activity than Danish at the time of diagnosis. Our study found an enhanced genetic susceptibility to RA in Danish compared to Turkish patients with a higher prevalence of risk-enhancing RA alleles and a lower prevalence of protective alleles.

LUNG DISEASE CHARACTERISTICS IN MOROCCAN RHEUMATOID ARTHRITIS PATIENTS

B. Laïla1, H. Azzouzi1, R. Àziz1, University Mohammed First Faculty of Medicine, Oujda, Morocco

Background: Pulmonary involvement is the most common extra-articular Rheumatoid Arthritis (RA) manifestation. Interstitial lung disease is an important and early feature and can increase the mortality risk in RA patients. In Morocco no previous studies have been carried out to identify the prevalence of lung disease in RA patients nor have the risk factors for development of interstitial lung disease (ILD).

Objectives: The aim of this study was to investigate the prevalence of lung disease and analyse the ILD associated risk factors, in Moroccan patients with rheumatoid arthritis.

Methods: This was a retrospective analysis of 288 patients diagnosed with RA between January 2014 and December 2019. Exclusion criteria were: pregnant women, history of other autoimmune disease than RA, pulmonary tuberculosis diagnosed before lung exploration, any drugs known to cause pulmonary changes (such as Amiodarone). Clinical, and laboratory features were recorded simultaneously with the period of pulmonary exploration. Lung involvement was
In multivariate analysis, ILD was associated with male older age (OR=1.43, 95% IC [1.022-1.952], p=0.037), advanced age at RA onset (OR=2.17, 95% IC [1.191-1.874], p=0.007), extra-articular manifestations (OR=10.8, 95% IC [5.312-12.300], p<0.001), disease activity (OR=2.68, 95% IC [1.463-1.715], p<0.001) and low methotrexate dose (OR=1.03, 95% IC [1.003-1.06], p=0.031).

Conclusion: ILD was the most prevalent manifestation of RA lung involvement, it was associated to male gender, older age and severe RA.

AB0204 A NEW INFLAMMATORY MARKER ASSOCIATED WITH INFLAMMATORY ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: PLATELET TO ALBUMIN RATIO
M. Liu1, Y. Huang1, Z. Huang1, Q. Huang1, T. Li1. 1Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterized by disordered immunity and dysregulated cytokine. Neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) have been defined as inflammatory markers to evaluate disease activity of RA. Recently, platelet to albumin ratio (PAR) was reported as a new prognostic index in patients with cancer. However, similar studies have not been displayed in RA.

Objectives: This study was to explore the role of PAR in RA and its association with disease activity.

Methods: This retrospective study enrolled 136 RA patients and 87 age- and gender-matched healthy controls. Neutrophil, lymphocyte, monocyte, platelet, hemoglobin, albumin, NLR, neutrophil to hemoglobin ratio (NHR), neutrophil to albumin ratio (NAR), monocyte to lymphocyte ratio (MLR), monocyte to hemo-globin ratio (MHR), monocyte to albumin ratio (MAR), PLR, platelet to hemo-globin ratio (PHR), PAR, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and Disease Activity Score of 28 joints - ESR (DAS28-ESR) were detected. Receiver operating characteristic (ROC) curve was used to discriminate RA patients from healthy individuals. Relationships between PAR and DAS28-ESR as well as other laboratory data were measured by the Spearman’s correlations analysis.

Results: RA patients showed higher levels of NLR, NHR, NAR, MLR, MHR, MAR, PLR, PHR PAR and lower levels of albumin than healthy controls. PAR and other inflammatory parameters were also raised along with increased disease activity in RA patients (P < 0.05) except NHR (P = 0.998). Similarly, albumin was decreased in RA patients as the disease activity increased (P = 0.001). ROC showed that area under curve (AUC) of PAR (0.887, 95%CI: [0.843-0.931]) was higher than NLR (0.818, 95%CI: 0.762-0.874), NHR (0.839, 95%CI: 0.787-0.890), NAR (0.829, 95%CI: 0.776-0.882), MLR (0.794, 95%CI: 0.734-0.854), MHR (0.817, 95%CI: 0.760-0.874), MAR (0.814, 95%CI: 0.757-0.872), PLR (0.832, 95%CI: 0.779-0.886), PHR (0.884, 95%CI: 0.838-0.930) and albumin (0.860, 95%CI: 0.813-0.908). Besides, PAR was positively correlated with DAS28-ESR (r = 0.439, P < 0.001), CRP (r = 0.540, P < 0.001) and ESR (r = 0.492, P < 0.001), yielding a higher relevance than other inflammatory indexes.

Conclusion: This study demonstrated that PAR was elevated in RA patients and increased with the disease activity. PAR may be a novel marker to assess the disease activity of RA patients.

AB0205 PREDICTORS OF ULTRASOUND DETECTED INFLAMMATORY FINDINGS IN PATIENTS WITH INFLAMMATORY ARTHRITIS
K. López Gloria1, I. Castrejón1, L. Trives Folguera2, J. C. Nieto1, B. Serrano Benavente3, J. Martínez-Barrio1, J. Rivera2, C. Gonzalez2, I. Monteagudo2, J. M. Avaro-Gracia1, J. M.olina Collada2. 1Hospital Universitario Gregorio Marañón, Madrid, Spain; 2Hospital Universitario Gregorio Marañón, Madrid, Spain

Background: Patients with inflammatory arthralgia (IA) are considered to be at increased risk for progression to RA. US has shown high sensitivity to detect synovitis compared with physical examination. Thus, US is recommended to identify subclinical synovitis in patients without clinical signs of inflammation.

Objectives: The objective of our study is to determine the frequency and pattern of US-detected inflammatory findings in patients with IA and investigate factors contributing to predict these findings.

Methods: An US clinic is scheduled in an academic center running three days every week. A retrospective analysis of our US unit cohort during a period of 6 months was undertaken. Patients with IA and no previous diagnosis of inflammatory arthropathies were included for analysis. Inclusion criteria of IA definition included: severe symptoms presenting in the morning, duration of morning stiffness ≥ 30 min, symptoms predominantly located in MCP joints and absense of clinically detected synovitis by the referral rheumatologist. The following routinely collected variables were included in the analysis: demographics, clinical features and laboratory tests. Patients underwent bilateral US examination in GS and PD mode of hands and/or feet according to the European League Against Rheumatism (EULAR) guidelines. The presence of synovitis, tenosynovitis and enthesis was assessed on a semi quantitative scale (0–3) for Grey Scale(GS)/Power Doppler(PD) or using enthesitis OMERACT definition, respectively. Patients were stratified in two groups based on the presence of US inflammatory findings (synovitis, tenosynovitis or enthesitis with PD signal). First, differences between groups were tested using chi-squared and Student-t tests in the univariate analysis. Second, multivariate logistic regression models were employed to investigate the association between possible predictive factors of US detected inflammatory findings.

Results: A total of 57 patients were included in the analysis. Mean age was 55.8±15.2 years, 41 (71.9%) were females, and mean symptoms duration was 11.4±10.4 months (Table 1). A total of 42 (73.7%) patients presented with a polyarticular arthralgia pattern. US inflammatory findings were present in 20 (35.1%) patients (26.3% PD synovitis, 21.1% PD tenosynovitis and 3.5% PD enthesis). Hands were most commonly involved with PD synovitis compared with physical examination. Thus, US is recommended to identify subclinical synovitis in patients without clinical signs of inflammation.
Table 3. Independent predictors of US detected inflammatory findings

Conclusion: PD US inflammatory findings are found in 1 over 3 patients with IA being PD synovitis the most common finding, specially at the wrists and MCP joints. Higher ESR values were significantly associated with the presence of US inflammatory findings. Our data highlights how the use of PD US may be useful to detect subclinical synovitis in patients with IA.

CLINICAL IMPACT OF ANTI-CARP ANTIBODIES IN RHEUMATOID ARTHRITIS

M. Markovic 1, B. Glisic 2, M. Petronijevic 2, Clinical Center of Montenegro, Clinic of Internal Medicine, Rheumatology Department, Podgorica, Montenegro; 2Military Medical Academy, Clinic of Rheumatology, Belgrade, Serbia

Background: Antibodies directed against carbamylated proteins (anti-Carp) have been recently introduced for the first time as a new biomarker in rheumatoid arthritis (RA) (1). Their presence is predictive for the development of RA (2). Anti-Carp antibodies are associated with the development of more severe forms of the disease in overall and anti-citrullinated peptide antibodies negative
population of patients with RA (3). In the literature is still current the research which associate these antibodies with disease activity and functional status of patients.

**Objectives:** This study investigated the incidence of anti-CarP positive findings in patients with RA on synthetic and biologic disease-modifying therapy (DMT) and the relationship between anti-CarP antibody status and both disability and disease activity.

**Methods:** It was an open-label, observational, cross-sectional study. The trial included 70 patients with RA diagnosed on the basis of ACR 1987 and ACR / EULAR 2010 criteria, on treatment with synthetic and biological DMT, who attended the Clinic of Rheumatology, Military Medical Academy, from September to December 2018. The control group consisted of 18 healthy individuals. After approval of the institutional Ethical Committee and after patients have signed Informed Consent, the study was conducted. Disease activity score (DAS28) was determined for the assessment of RA activity, and the assessment of patients' functional ability was performed using the Health assessment questionnaire disability index (HAQ-DI). Concentration of anti-CarP antibodies was determined by commercial ELISA anti-CarP quantitative sandwich immunnoassay. The methods of descriptive and analytical statistics were used in statistical data processing.

**Results:** Based on the cut-off value (5.9 ng / ml), no one in the control group had positive anti-CarP antibodies, while 34.7% of the subjects with RA were positive. The positive correlation was found between anti-CarP antibody concentration and DAS28 in all RA patients (p = 0.0003; Pearson r = 0.4829). The positive correlation was also found between anti-CarP antibody concentration and HAQ-DI in all RA patients (p = 0.0003; Pearson r = 0.4253).

**Conclusion:** Anti-CarP antibodies were present in a significant number of patients with RA. This study demonstrated that patients with RA with higher concentrations of anti-CarP antibodies have higher disease activity and impaired functional status. It is undisputed that further and larger studies are needed to better determine the clinical significance of these antibodies.

**ASSOCIATION OF RHEUMATOID FACTOR, HLA-DRB1 SHARED EPITOPE (SE) AND SMOKING WITH RADIOGRAPHIC OUTCOME IN RHEUMATOID ARTHRITIS**

E. Mole1, A. Tarassoi2, A. Tzioufas2, M. N. Manoussakis2, A. Tsirogianni2, T. Athanassiades3, V. Kitsou1, S. Gazi1, P. Vlachoyiannopoulos4, 5 **“KAT” General Hospital of Attica, Department of Rheumatology, Athens, Greece;** 2Evangelismos Hospital, Immunology - Histocompatibility Department, Athens, Greece; 3University of Athens School of Medicine, Department of Pathophysiology, Athens, Greece

**Background:** Genetic and environmental factors interact in aetopathogenesis of Rheumatoid Arthritis (RA). However, it remains unclear whether current smoking, presence of Rheumatoid factor (RF) and HLA-DRB1 SE influence the radiographic outcome.

**Objectives:** To clarify the possible associations between radiographic outcome, HLA-DRB1 SE, RF and smoking status in patients with longstanding RA.

**Methods:** An observational study of 240 consecutive Greek patients with RA, whose mean age and mean disease duration was 65.3 ± 12.5 and 12.7 ± 11.8 years respectively. Among them 74.17% were female, 40% were smokers, 60.42% had positive RF and 68.33% possessed at least one SE allele. HLA-DRB1 alleles were typed by molecular techniques (PCR-SSOP and SSP). X-rays of hands and feet were performed and scored by the Sharp-van der Hejde score (SHS) method.

**Results:** Results were stratified by RF and smoking status and analyzed by multivariate logistic regression. Overall, the mean SHS was significantly higher in RF positive than RF negative patients and in smokers than non-smokers (52.76 ± 33.1 vs 38.4 ± 31.96, p < 0.0007, 55.33 ± 38.56 vs 26.8 ± 22.32, p < 0.0001, respectively). Furthermore, patients that possessed at least one SE allele had higher SHS than SE negative (35.49 ± 24.76 vs 25.74 ± 19.22, p < 0.0013). An association between radiographic severity and SE was found in RF positive patients. More specifically, seropositive patients carrying at least one SE allele had higher SHS than those lacking SE (40.85 ± 33.21 vs 29.23 ± 24.72, p = 0.037). On the other hand, smokers with at least one SE allele had higher SHS when compared to smokers without SE (29.27 ± 25.20 vs 20.1 ± 17.22, p = 0.048). Among RF negative and non-smokers RA patients, no significant association was found between the presence of HLA-DRB1 SE and radiographic severity.

**Conclusion:** Our data indicate that in longstanding RA there is an association between RF positivity, the presence of SE, current smoking status and radiographic outcome.

**Disclosure of Interests:** None declared

PREDICTORS OF ACHIEVING STRINGENT REMISSION IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS IN CLINICAL REMISSION FOLLOWING A TREAT-TO-TARGET STRATEGY

S. Möller-Bisgaard1,2, S. Georgiadis3, K. Horslev-Petersen4, B. Ejbjerg5, M. L. Hetland6, L. Ørnbjerg7, O. Glinatsi8, J. Mollenbach Møller9, M. Boesen9, K. Stengaard-Pedersen2, O. Rintek Madsen2, B. Jensen2, J. Villadsen2, E. L. Balding2, A. G. Jurik2, H. Thomsen2, M. Lindegaard2, H. Biddal2, N. Steen Krogh2, T. Ellingsen2, A. Nielsen2, L. Bolding2, A. G. Jurik2, H. Thomsen2, M. Østergaard2,1, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; 2Rheumatology and Radiology Departments at Hospitals at Zealand, Jutland and Funen, Denmark, Denmark

Background: Achieving remission according to stringent criteria such as Simplified Disease Activity Index (SDAI) and ACR/EULAR Boolean remission is associated with a better long-term outcome in patients with RA. Possible predictors of achieving stringent remission in patients in clinical remission, following targeted treatment strategies, have not been investigated.

Objectives: To investigate the predictive value of clinical, radiographic and MRI variables on achieving more stringent remission in RA patients in clinical remission, following MRI and conventional treat-to-target (T2T) strategies.

Methods: In this post-hoc study, data were used from 171 RA patients in clinical remission (DAS28-CP<3.2 and no swollen joints) on conventional synthetic DMARDs, included in the IMAGINE-RA randomized clinical trial, where they followed an MRI T2T strategy (targeting absence of osteitis) combined with clinical remission (DAS28-CP<3.2 and no swollen joints) or a conventional T2T strategy (targeting clinical remission only). Baseline contrast-enhanced MRIs of the dominant wrist and 2nd-5th MCP joints and radiographs of hands and feet were evaluated according to the OMERACT RAMRIS scoring system and Sharp/van der Heijde method, respectively, by two experienced readers. Potential clinical, radiographic and MRI baseline predictors of remission were first tested in univariate logistic regression analyses with achievement of Clinical Disease Activity Index (CDAI), SDAI, and ACR/EULAR Boolean remission at 24 months as dependent variables. Variables with p<0.25 were subsequently tested in multivariate logistic regression analyses with backward selection, adjusted for age, gender and strategy group. Missing values of covariates were imputed using chained equations.

Results: Based on the univariate analyses, tender joint count, patient VAS global, VAS pain, VAS fatigue, physician VAS global, HAQ, MRI osteitis, radiographic and MRI erosion and joint space narrowing scores were included in multivariate analyses (Table). Following the MRI T2T strategy was a positive predictor and high patient VAS global a negative predictor of achieving all definitions of remission. Furthermore, high patient VAS pain was negatively associated with achieving SDAI and ACR/EULAR remission and high tender joint count negatively associated with achieving CDAI and SDAI remission.

Multivariate logistic regression analyses with backward selection, final models

Conclusion: In RA patients in clinical remission, poor patient reported outcomes and tender joint count were associated with decreased chance of achieving stringent remission, while following an MRI T2T strategy predicted stringent remission across all definitions thereof.

ACREULAR: AN R PACKAGE FOR THE CALCULATION AND VISUALISATION OF ACR/EULAR RELATED RHEUMATOID ARTHRITIS MEASURES

F. Morton1, J. Nijjar2, C. Goodyear3, D. Porter3,1 University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2GlaxoSmithKline plc, Stevenage, United Kingdom; 3NH Greater Glasgow and Clyde, Glasgow, United Kingdom

Background: The American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR) individually and collaboratively have produced/recommended diagnostic classification, response and functional status criteria for a range of different rheumatic diseases. While there are a number of different resources available for performing these calculations individually, currently there are no tools available that we are aware of to easily calculate these values for whole patient cohorts.

Objectives: To develop a new software tool, which will enable both data analysts and also researchers and clinicians without programming skills to calculate ACR/EULAR related measures for a number of different rheumatic diseases.

Methods: Criteria that had been developed by ACR and/or EULAR that had been approved for the diagnostic classification, measurement of treatment response and functional status in patients with rheumatoid arthritis were identified. Methods were created using the R programming language to allow the calculation of these criteria, which were incorporated into an R package. Additionally, an R/Shiny web application was developed to enable the calculations to be performed via a web browser using data presented as CSV or Microsoft Excel files.

Results: acreular is a freely available, open source R package (downloadable from https://github.com/fragla/acreular) that facilitates the calculation of ACR/EULAR related RA measures for whole patient cohorts. Measures, such as the ACR/EULAR (2010) RA classification criteria, can be determined using precal- culated values for each component (small/large joint counts, duration in days, normal/abnormal acute-phase reactants, negative/low/high serology classification) or by providing “raw” data (small/large joint counts, onset/assessment dates, ESR/CRP and CCP/RF laboratory values). Other measures, including EULAR response and ACR20/50/70 response, can also be calculated by providing the required information. The accompanying web application is included as part of the R package but is also externally hosted at https://fragla.shiny-yapp.io/shiny-acerbular. This enables researchers and clinicians without any programming skills to easily calculate these measures by uploading either a Microsoft Excel or CSV file containing their data. Furthermore, the web application allows the incorporation of additional study covariates, enabling the automatic calculation of multigroup comparative statistics and the visualisation of the data through a number of different plots, both of which can be downloaded.
Conclusion: The acretural R package facilitates the easy calculation of ACR/EULAR RA related disease measures for whole patient cohorts. Calculations can be performed either from within R or by using the accompanying web application, which also enables the graphical visualisation of data and the calculation of comparative statistics. We plan to further develop the package by adding additional RA related criteria and by adding ACR/EULAR related measures for other rheumatic disorders.

DOI: 10.1136/annrheumdis-2020-eular.2326

Objective: The purpose of this analysis was to evaluate the CDAI properties both cross-sectionally and longitudinally in a cohort of RA patients followed in Canadian routine care.

Methods: RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI), with available follow-up for ≥6 months and data on CDAI, disease activity score based on 28 joints (DAS28), health assessment questionnaire (HAQ), and ACR/EULAR Boolean remission were included. For both the CDAI score and its change from baseline to 6 months, construct validity was assessed with principal component analysis, internal consistency with the Cronbach’s alpha coefficient (α), correlational validity with the Spearman’s rho coefficient, agreement in disease state classification with percent concordant pairs, and the kappa statistic. Stratified analysis by presence of CDAI low disease activity (LDA) or remission was performed.

Results: 1,582 patients met the inclusion criteria. Principal component analysis showed that CDAI could be reduced to a single component when CDAI is ≤10, with SJC28 accounting for most variance in score and patient global assessment (PtGA) the least; whereas, when CDAI is ≤10, two distinct components were identified, the first comprising PtGA and physician global assessment (PhGA) and the second SJC28 and TJC28. In terms of internal consistency, high levels were observed for both CDAI at baseline (α=0.83) and its change from baseline to 6 months (α=0.81); however, the consistency between CDAI components was very low when CDAI is ≤10 (α=0.29).

Overall, a strong positive correlation was observed between CDAI and DAS28 (ρ=0.86) and their changes (ρ=0.87) while its correlation with HAQ was weak. When stratifying by CDAI levels, the correlation of CDAI with DAS28 was moderate when CDAI is ≤10 and very weak when CDAI is ≤2.8. Similarly, agreement in the classification of LDA between CDAI and DAS28 or HAQ was fair to moderate, and agreement in classification of remission was poor to fair.

Conclusion: CDAI and DAS28 correlate well when disease activity is moderate or high and poorly in LDA or remission. PtGA had a stronger influence on CDAI at LDA or remission state compared to moderate or high disease state. Thus, careful interpretation of PtGA is necessary particularly in patients who are identified as CDAI non-remitters.

FLARE RISK AFTER DISCONTINUING LONG-TERM METHOTREXATE TREATMENT IN PATIENTS HAVING RHEUMATOID ARTHRITIS WITH LOW DISEASE ACTIVITY

S. H. Nam1, J. S. Lee1, S. J. Choi1, W. J. Seo2, J. S. Oh3, S. Hong1, Y. G. Kim1, C. K. Lee1, B. Yoo1. 1University of Ulsan College of Medicine, Asan Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Veterans Health Service Medical Center, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 3Asan Medical Center, Department of Biomedical Informatics, Seoul, Korea, Rep. of (South Korea)

Background: Several recent studies have reported that MTX could be discontinued in patients with low disease activity who are taking biologic DMARDs or tofacitinib. However, there are limited studies on whether MTX could be discontinued in patients with low disease activity who have taken MTX for a long term.

Objective: We investigated the disease flare rate in patients with rheumatoid arthritis (RA) who achieved low disease activity following long-term methotrexate (MTX) treatment and the factors related to flare.

Methods: This retrospective longitudinal cohort study included patients with RA and low disease activity who were exposed to MTX for >10 years. Disease flare was defined as an increase in DAS28 of ≥2.2 within 6 months of discontinuation of MTX. Logistic regression analysis was performed to identify the factors associated with flare.

AB0211

DIFFERENTIAL INFLUENCE OF CDAI COMPONENTS BASED ON DISEASE STATE IN RHEUMATOID ARTHRITIS PATIENTS: REAL-WORLD RESULTS FROM THE ONTARIO BEST PRACTICES RESEARCH INITIATIVE (OBRI)

E. Keystone1, Mohammad Movahedi2,3, A. Cesta2, C. Bombardier2,4, J. Sampalis5, E. Rampakakis6 on behalf of OBRI investigators. 1Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada; 2Toronto General Hospital Research Institute, University Health Network, Toronto, Canada; 3Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, Canada; 4Department of Medicine (DMO) and Institute of Health Policy, Management, and Evaluation (IHPME), Toronto, Canada, Toronto, Canada; 5JSS Medical Research, St-Laurent, Canada

Background: Treat-to-target recommendations for rheumatoid arthritis (RA) dictate that remission or low disease activity should be aimed. Although numerous composite indices are available, the clinical disease activity index (CDAI) is commonly used in routine clinical care due to its simplicity and non-reliance on acute phase reactants.
Results: In total, 97 patients with RA were included in the study. The mean baseline DAS28 was 1.96 ± 0.56. The median cumulative MTX dose was 11.7g; the median duration of exposure to MTX was 19 years. Following MTX discontinuation, flare occurred in 43 (44.3%) patients; the mean time to flare was 98 ± 37 days. According to univariable logistic regression analysis, C-reactive protein, erythrocyte sedimentation rate (ESR) at discontinuation, the average ESR in the 6 months before discontinuation of MTX, a weekly dose of MTX before discontinuation (OR, 1.014; 95% CI, 1.014–1.342; p = 0.031) was significantly associated with flare risk.

Conclusion: Among patients with RA who achieved low disease activity with long-term treatment with MTX, more than half of the patients remained flare free before discontinuation (OR, 1.014; 95% CI, 1.014–1.342; p = 0.031) was significantly associated with flare risk.

Disclosure of Interests: Disclosure of interests: long-term treatment with MTX, more than half of the patients remained flare free before discontinuation (OR, 1.014; 95% CI, 1.014–1.342; p = 0.031) was significantly associated with flare risk.

THE USE OF MUSCULOSKELETAL ULTRASOUND AND PATIENT REPORTED OUTCOMES TO IDENTIFY THE FACTOR TO GIVE RESIDUAL SYMPTOMS AMONG PATIENTS WITh RHEUMATOID ARTHRITIS IN SDAI-REMISSION OR LOW DISEASE ACTIVITY.

M. Nawata1,2, M. Funada1,2, Y. Fujita1, A. Nagayasu1, K. Someya1,2, S. Kazuyoshi1,2, Y. Tanaka1, Tobata General Hospital, Department of Clinical Immunology and Rheumatology, Kitakyushu, Japan; 1University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan

Background: The goal of treatment in rheumatoid arthritis (RA) is to achieve remission. There is the residual symptoms in the Japanese RA patient who achieved clinical remission. There are not many studies to examine the relation between everyday life, social activity and evaluation of disease activities using musculoskeletal ultrasound (MSKUS).

Objectives: To identify the factor to give residual symptoms of RA patients in SDAI-remission (REM) or low disease activity (LDA), using MSKUS.

Methods: 300 patients were enrolled. The synovitis evaluated gray scale (GS) and power doppler (PD) with 22 both hands joints by MSKUS. We evaluated age, sex, the number of tender joint (TJ) and swelling joint (SJ), the serologic characteristics (CRP, ESR, CCP, RF, MMP-3), Patient Reported Outcomes (PROMs) (morning stiffness (MS), pain-VAS, fatigue-VAS), HAQ and EQ5D-5L.

Results: (1). Stratified analysis was performed between HAD/MDA group (N=106) and LDA/REM group (N=194). As a result of single variable analysis, many factors were extracted with significant difference. As a result of the multivariate analysis, MTX dose, number of TJ and SJ, MS, fatigue-VAS, HAQ, EQ5D-5L, and GS2 were extracted with a dominant difference. (2). For the stratified analysis in GS2≥2, the ratio was low, and the disease duration was short significantly in REM/MDA group. Next, stratified analysis was performed between low group (N=95) and REM group (N=99). As a result of single variable analysis, number of TJ and SJ, MTX dose, HAQ, EQ5D-5L, MS, pain-VAS, fatigue-VAS, EGA, GS2≥1, GS2≥2, GS total score, PD≥1 and PD total score were extracted with significant difference. As a result of the multivariate analysis, number of TJ and fatigue-VAS were extracted with a dominant difference.

Conclusion: (1). It became clear that the factor which participated in the achievement with SDAI-remission or low disease activity was enough quantified. The relation of MTX dose, use of bDMARD, US-GS level, residual symptoms (faisaltude - pain joint) to be caused by RA. Particularly, the ratio of GS2≥2 was low, and the disease was short. (2). In the LDA patients (who do not achieve clinical remission), they had residual symptoms (fatigue and TJ). (3). In the REM patients, remaining inflammation was not seen in MSKUS. The conclusion is that the induction of remission is important from the viewpoint of not only the prevention of joint destruction but also improvement and maintenance of long-term QoL.

AB0214

4-YEAR EXPERIENCE OF AN OUTPATIENT CLINIC OF PATIENTS WITH CLINICALLY SUSPECTED ARTHRALGIAS OF EVOLVING TO ARTHRITIS

I. Nurho1, D. Pelteado2, I. Moroj1, A. Villalva1, M. Novella-Navarro1, M. E. Miranda-Car1us, P. Fortea-Gordo1, M. J. Santos-Bornez2, E2. De Miguel1, A. Balsas1 University, Hospital La Paz, Rheumatology, Madrid, Spain; 2Hospital La Paz-IDIIM, Madrid, Spain

Background: Although genetic and serological risk factors have been extensively studied in rheumatoid arthritis (RA), the phase of symptoms without clinical arthritis is poorly characterized.

Methods: Prospective longitudinal study of a cohort of patients with CSA. Patients are followed up for at least 2 years, with clinical and analytical data collection by means of standardized protocols every 6 months. Inclusion criteria were an onset of symptoms ≤ 12 months, inflammatory arthralgias involving small joints of hands or feet (predominantly in nights or mornings, improving throughout the day or with movement, and morning stiffness ≥30 min). Patients with clinical synovitis, diagnosis of fibromyalgia or osteoarthritis at baseline visit were excluded from the study.

Results: 45 patients were recruited from November 2015 in our CSA clinics. The majority were women (42 patients), with a mean age at entry of 44 ± 13 years, a mean duration of symptoms before entry of 32.3 ± 15.1 weeks, and a mean follow-up time of follow-up of 17.2 ± 13.3 months. A third (30%) of patients had a family history of autoimmune diseases, 18.6% were seropositive, an average body mass index (BMI) of 27.6 ± 6.6, and 14 (31.3%) were smokers or ex-smokers. Most patients reported a progression of arthralgia over time (53%) and a joint swelling (57%). Out of 45 patients, 18 (40%) developed clinical arthritis or autoimmune disease (11 RA, 2 undiffernetiated arthritides, 3 undifferentiated connective diseases), after 7 ± 8.6 months of follow-up. Among patients with ≥ 6 months follow-up, 47.1% progressed to a clinical arthritis (CA). CA patients had a longer follow-up time (22.4 ± 13.9 vs. 16.8 ± 13 months; p = 0.015), and a higher frequency of smoking (60 vs. 21.7%; p = 0.037). Likewise, CA patients presented a higher age at baseline, family history of autoimmune disease and higher baseline scores of HAQ, PGA and VAS pain, although without statistical significance (Table 1). In the subset of patients with a final diagnosis of RA, patients presented a significantly longer follow-up, and higher scores of baseline VAS pain compared to non-progressors (Table 2).

VAS: visual analogue scale; PGA: patient global assessment; BMI: body mass index

Conclusion: In our CSA clinic, 40% of the patients progressed to clinical arthritis, while almost half of those who were followed for more than 6 months progressed.
Methods: Fifty-four RA patients who started the first biologics from September 2016 to December 2018 were included. All the patients were performed clinical examination, blood tests and US examination of hand and foot at baseline, 4, 12, 24, 36 and 52 weeks. US examination was performed on MCP joints, PIP joints, wrist and MTP joints.

Results: Among 54 cases, 42 cases were able to continue treatment until one year later, and the continuation rate was 80.8%. Of the 12 patients who discontinued first biologics treatment, 5 were changes to other biologics due to inadequate response, 4 were their wishes, and 3 were adverse events. Multiple regression analysis was performed with treatment continuation as the dependent variable and improvement of CRP, MMP-3, DAS28-CRP, grayscale score and power Doppler score in 4 weeks as explanatory variables. Only improvement of power Doppler score was extracted as a significant predictor (p = 0.045). In the continuation group, the improvement of the power Doppler signal at week 4 was 36% compared with the baseline, with 10% in the discontinuation group.

Conclusion: The early improvement of power Doppler signal in 4 weeks could be a predictive factor for the continuation of 1-year biological treatment.

Disclosure of Interests: S. Okita 2, R. Nakahara 2, M. Matsuhashi 2, M. Watanabe 2, Y. Nasu 2, K. Nishida 2, T. Ozaki 2, Okayama City Hospital, Orthopedic Surgery, Okayama, Japan; Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Orthopedic Surgery, Okayama, Japan

Background: In rheumatoid arthritis (RA), biologics treatment is one of the effective treatment options. On the other hand, the effects of biologics cannot be obtained satisfactorily in all patients, and therefore some cases in which treatment is interrupted due to ineffective or adverse events. However, the useful predictive markers of the biologics have not been found in the early phase of treatment in RA. Recently, ultrasound (US) has played a role of sensitive imaging modality in the diagnosis and follow-up of patients with RA.

Objectives: In this study, we investigated whether continuation of biologics treatment can be predicted by ultrasonographic findings in the early phases.

Methods: Fifty-four RA patients who started the first biologics from September 2016 to December 2018 were included. All the patients were performed clinical examination, blood tests and US examination of hands and wrists at baseline, 4, 12, 24, 36 and 52 weeks. US examination was performed on MCP joints, PIP joints, wrist and MTP joints.

Results: Among 54 cases, 42 cases were able to continue treatment until one year later, and the continuation rate was 80.8%. Of the 12 patients who discontinued first biologics treatment, 5 were changes to other biologics due to inadequate response, 4 were their wishes, and 3 were adverse events. Multiple regression analysis was performed with treatment continuation as the dependent variable and improvement of CRP, MMP-3, DAS28-CRP, grayscale score and power Doppler score in 4 weeks as explanatory variables. Only improvement of power Doppler score was extracted as a significant predictor (p = 0.045). In the continuation group, the improvement of the power Doppler signal at week 4 was 36% compared with the baseline, with 10% in the discontinuation group.

Conclusion: The early improvement of power Doppler signal in 4 weeks could be a predictive factor for the continuation of 1-year biological treatment.
IMPACT OF THE BODY-MASS-INDEX ON DISEASE ACTIVITY, FUNCTIONAL ABILITY AND QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Medjadić1,2, J. Mrdja1,2, P. Ostojić2.1University Clinical Center, Department for Rheumatology, Banja Luka, Bosnia and Herzegovina; 2Institute of Rheumatology, Belgrade, Serbia

Objectives: This study aims to assess differences in disease activity, functional ability and quality of life among underweight, normal weight, overweight and obese patients with rheumatoid arthritis (RA).

Methods: 715 patients with RA (609 women and 106 men) were included in this study. According to their Body-Mass-Index, all patients were divided into four subgroups: underweight (BMI <18.5), normal weight (BMI between 18.5 and 24.9), overweight (BMI between 25.0 and 29.9) and obesity (BMI ≥30.0). Mean values of DAS28, CDAI and SDAI (measures of disease activity), HAQ-disability index (measure of functional ability) and RAQoL index (measure of quality of life) were compared among four subgroups of patients.

Results: 28 (3.9%) RA patients were overweight, 310 (43.4%) had normal weight, 268 (37.5%) were overweight, whilst 109 (15.2%) patients were obese. Among these subgroups, no difference in mean age, disease duration, percentage of seropositive patients, and patients treated with glucocorticoids, csDMARDs or biologics, was noticed. There were no statistically significant differences in mean values of DAS28, CDAI and SDAI in four subgroups of patients. However, mean value of the HAQ disability index was significantly higher (p<0.05) in underweight (1.32) and obese patients (1.27), compared to normal (0.87) and overweight patients (1.08). The mean value of the RAQoL-Index was also somewhat higher in underweight and obese patients (8.8 and 8.1, respectively) than patients who are overweight or have normal weight (7.0 and 6.5, respectively), but the difference was not statistically significant.

Conclusion: Underweight and obese RA patients have worse physical function than normal and overweight patients. However, worse disability can not be explained by higher disease activity.

FUNCTIONAL DISABILITY AND PAIN BUT NOT DISEASE ACTIVITY ARE ASSOCIATED WITH POOR HEALTH-RELATED QUALITY OF LIFE IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS

A. R. Prata1, H. Assunção1, M. Luis1, L. Brites1, F. Costa1, J. Dinis de Freitas1, S. Silva1, J. A. P. Da Silva1,2, C. Duarte1,2 on behalf of ‘Promoting Happiness Through Encouragement of Care’ Group. 1Centro Hospitalar Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Rheumatoid Arthritis (RA) is a systemic autoimmune disease that presents with joint pain and inflammation leading to significant disability and poor health-related quality of life (HRQoL). The primary goal of disease management in RA (3).

Objectives: To evaluate HRQoL and identify its influencing clinical and demographic factors in a Portuguese RA population.

Methods: This is a cross-sectional study including consecutive patients fulfilling the ACR/EULAR 2010 and/or ACR 1987 RA classification criteria, followed at a tertiary Rheumatology Department. Sociodemographic and clinical variables were collected. HRQoL was assessed using the EuroQol 5-Dimensional Descriptive System (EQ-5D) total score (normal range from -0.496 to 1.000, lower values indicating poorer HRQoL). Independent test and Pearson's correlation coefficient were performed to evaluate EQ-5D differences between groups and examine its relationships with continuous variables, respectively. Variables with p<0.1 in univariate analysis were included in a stepwise multiple linear regression analysis to evaluate the independent association of variables with the EQ-5D score.

Results: 358 RA patients were included (80.20% female, mean age ± SD: 63.22 ± 0.66 years old). Mean EQSD total score ±SD was 0.48 ± 0.01. Based on EQ-5D domains, 0.60% reported extreme problems with mobility, 3.40% extreme problems with self-care, 2.50% extreme problems with usual activities, 12.0% extreme pain or discomfort, and 7.30% extreme anxiety or depression symptoms (Fig. 1). There was a significant difference in EQ-5D scores between male (M=0.55, SD=0.24) and female gender (M=0.46, SD=0.27); t (356) = -2.41, p=0.016. EQ-5D was weakly correlated with DAS-28-CRP (r=-0.32; p<0.001), moderately correlated with patient’s global assessment of disease activity (r=-0.54; p<0.001) and pain-visual analogue scale (pain-VAS) scores (r=-0.58; p<0.001) and strongly with Health Assessment Questionnaire (HAQ) score (r=-0.72; p< 0.001). After multivariate analysis, HAQ-score (β=-0.57 [95% CI -0.24 to -0.17]; p<0.001) and pain-VAS (β=-0.25 [95% CI -0.03 to -0.002]; p<0.001) remained as independent predictors of EQ-5D (R²=0.56, p<0.001).

Conclusion: Greater functional impairment and pain are associated with poor HRQoL in RA patients, and thus special attention must be given to treatment strategies providing the best patient-centred outcomes.

PREDICTIVE FACTORS FOR THE PROGRESSION OF EARLY INFLAMMATORY ARTHRITIS TO RHEUMATOID ARTHRITIS

F. Rahaj1, R. Chetouane1, S. Bencheikh1, S. Haid1, N. Khaidoun1, N. Brahimi1, A. Ladjiouze-Rezigi1, F. Hanni1, 1Ben Arous Hospital, Rheumatology, Algiers, Algeria; 2Beni Messous Hospital, Rheumatology, Algiers, Algeria

Objectives: To identify factors predicting the progression of early inflammatory arthritis (EIA) to rheumatoid arthritis (RA)

Methods: This was a prospective longitudinal study of inflammatory rheumatism that could not be classified according to defined rheumatism criteria. Demographic, biological, immunological and radiographic data were collected at the time of inclusion in the study. Disease activity as determined by the Disease Activity Score 28-CRP (DAS28-CRP: 4 variables), functional handicap as calculated by Heath Assessment Score (HAQ), and bone and joint damage as evaluated by Sharp–Van der Heijde (SVDH) score. ultrasound joint imaging were evaluated at the beginning of the study and then 1 year later. Logistic regression was performed to identify predictive factors for progression to RA.

Results: One hundred seventy two patients were included (24 men, 148 women), with an mean age 43.13±14.07 years and an mean time to diagnosis 10.24±6.84 months The mean ESR was 46.81±31.16 mm/1st hour, and the mean CRP level was 22.84±39.8 mg/l. Rheumatoid factors (RFs) and anti-citrullinated protein antibodies (ACPs) were present in 48.8% and 53% of patients, respectively. The erosion, joint space narrowing, and total SVDH scores were 3.38±3.48, 5.08±3.32, and 5.95±4.94, respectively. One hundred sixty one patients were followed up for 12 months. Multivariate regression analysis showed that a DAS28-CRP level >5.2 (OR=28.6; CI95% 8.7-94.5), an RF level >60 IU/L (OR=11.2; CI95% 4.3-87.5), and an ACPA

References:
level >60 IU/L (OR=5.4; CI95% 1.9-15.3) were predictive for progression to RA. 

Conclusion: Our study suggests that clinical evaluation of EIA by DAS28-CRP from the time of diagnosis, as well as evaluating the presence of RA auto-antibodies, can predict progression to RA.

AB0220

TENOSYNOVITIS AS THE PRESENTING FEATURE OF FLARE IN RHEUMATOID ARTHRITIS

1Newcastle Hospitals NHS Foundation Trust and Newcastle University, Newcastle upon Tyne, United Kingdom; 2University of Glasgow, Institute Of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 3University of Birmingham, Rheumatology Research Group, Birmingham, United Kingdom

Background: The importance and relevance of tenosynovitis (TS) has long been recognised in rheumatoid arthritis (RA), but it is not usually considered in disease activity assessments. The significance of TS in early arthritis (EA) has also been recognised and, using ultrasound (US) it has recently been identified as a precursor to RA. The ongoing BIO-FLARE (BIOlogical Factors that Limit sustAined Remission in Rheumatoid arthritis) observational study aims to investigate the pathogenesis of flare in RA. Patients with RA in remission stop their disease modifying anti-rheumatic drug medication (DMARDs: methotrexate, sulfasalazine and/or hydroxychloroquine) and are closely followed for 6 months, in anticipation that approximately 50% will experience a flare. We investigated whether TS occurrence was a frequent herald of flare in this cohort.

Objectives: To review the case notes of 49 patients in the BIO-FLARE study with confirmed flare to date, seeking evidence of US tenosynovitis prior to or concurrent with flare.

Methods: Patients in the study who are deemed to be in remission based on a disease activity score (DAS28-CRP) < 2.4 stop their DMARD medication and attend regularly for review over 6 months, with provision for ad-hoc appointments if symptoms return between visits. Patients are defined as having a flare if their DAS28-CRP ≥ 3.2 at any point or two consecutive DAS28-CRP ≥ 2.4. Targeted US assessment occurs at baseline only for patients that consent to an optional baseline ultrasound-guided synovial biopsy. If a flare occurs, US of symptomatic joints is undertaken, to assess suitability for a synovial biopsy. Following this, the patient receives a steroid injection and restarts their DMARD medication.

Results: To January 2020, 120 patients had been recruited into the study and 49 experienced a flare. Seven patients had a flare predominantly or initially characterised by TS or paratenonitis, the results of which are summarised in Table 1.

Conclusion: Although highlighted as a precursor of RA in early arthritis, the occurrence of TS in the context of flare – and the prodrome heralding this – has not been studied. Our findings show that TS in early flare is reminiscent of the features sometimes seen in EA or clinically suspect arthralgia. Further data are required to determine the role of periarticular inflammatory phenomena, such as TS, as risk factors for joint synovitis. Our study did not entail formal US assessments, therefore the role of TS in this population may be under estimated. Careful study of RA patients in early phase of disease flare may pose an opportunity to characterise the nature and chronology of this association in greater depth.

ULTRASOUND ASSESSMENT OF INFLAMMATORY ARTHRALGIA: PREDICTORS FOR CHRONIC ARTHRITIS DEVELOPMENT

P. Rodríguez-Merlos1, D. Peiteado1, I. Monjo1, L. Nuño2, A. Villalba3, M. Novella-Navarro4, T. Jenny Gabrieila5, M. E. Miranda-Carus6, P. Fortea-Gordo7, E. De Miguel1, A. Balasa1.
1University of Zaragoza, Rheumatology, Zaragoza, Spain; 2Hospital Universitario de A Coruña, Rheumatology, A Coruña, Spain; 3University Hospital La Paz, Rheumatology, Madrid, Spain; 4Hospital Universitario de Caracas, Rheumatology, Caracas, Venezuela; 5Hospital Virgen de las Nieves, Rheumatology, Granada, Spain; 6Hospital Ruber de Madrid, Rheumatology, Madrid, Spain; 7Hospital Universitario de A Coruña, Rheumatology, A Coruña, Spain

Background: Inflammatory arthralgia (IA) onset is a common rheumatology consultation. Identifying predictors for chronic arthritis (CA) development by ultrasonography (US) may provide early diagnosis and treatment in order to prevent progression of the disease.

Objectives: Establishing US findings that can be related to CA development in patients with inflammatory arthralgia without arthritis. Assess the link among US, clinical and biochemical parameters.

Methods: We performed a prospective longitudinal study of a cohort of patients with IA. Patients with less than one year of AI evolution and involvement of at least one small joint from hands or feet were included. Patients with arthriti, osteoarthritis, fibromyalgia and those treated with DMARDs or steroids were excluded. We made a 6-monthly evaluation for 2 years and recorded the CA development during that period. The number of painful joints (PJC) and biochemical data (CRP, ESR) were assessed at the first visit. A blind US exploration was made using a MyLabTwice (Esaote) equipment with a 7.5-12MHz probe for grey-scale (GS) and Power Doppler (PD), examining 36 joints (radio-carpals, MCP, IPP; 2nd-5th MTP, elbows, shoulders and knees) and 14 tendon compartments (2nd, 4th and 6th wrist extensors, 3rd and 4th finger flexors and posterior tibial and fibularis tendons), giving an overall score of GS, PD (0-3) and number of erosions by rating the presence of synovitis on each location.

We performed a descriptive analysis based on the frequencies of qualitative variables and means/SD/median (IQR) of quantitative variables, comparing the characteristics between patients with and without CA progression by Chi-Square and Mann-Whitney U tests. Also, the possible relationship of those variables and the disease progression was assessed by a univariate binary logistic regression analysis.

We designed a reduced US examination (RUE) selecting the most affected joints and those with greatest differences between groups in the statistical analysis.

Results: Of the 49 patients included, 21 (42.9%) progressed to CA. 87% were females and 71.4% non-smokers with a mean age of 44 ± 12 years. The median of PJC was 4 (1-9). RF and/or CCPA were positive in 18.4% and 34.7% had high CRP/ESR. The suggested RUE included carpi, 2nd-4th MCP, 2nd-3rd IPP, 2nd and 5th MTP, 4th and 6th wrist extensors and fibularis tendons. Scores and comparative analysis within subgroups are listed in Table 1. The RUE score was significantly greater in both GS (OR 1.4, CI 95%) and PD (OR 1.3, CI 95%) on patients that progressed to CA.
Table 1. GS and PD scores compared by main locations and RUE-Score (shown as median [IQR]).

* Medians compared by Mann-Whitney U test. Statistical significance at a 95% CI. † Logistic regression analysis. Statistical significance at a 96% CI.

There were no significant associations between RF/CCPA positivity or CRP/ERS levels and US findings.

Conclusion: Patients with IA without arthritis that progressed to CA had significant higher GS and PD scores, hence showing the utility of US to predict disease progression. A RUE of 8 joints and 3 tendon compartments could be enough to achieve this goal.

AB0223 PHYSICIAN’S GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS IS A RELIABLE AND RESPONSIVE TOOL IN CLINICAL PRACTICE

Hospitalar e Universitário de Coimbra, Coimbra, Portugal; Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; Coimbra Institute for Clinical and Biomedical Research, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Physician’s global assessment of disease activity (PhGA) is highly influential upon treatment decisions taken by rheumatologists, surpassing the impact of DAS28. [1, 2]. However, data regarding its psychometric properties are scarce.

Objectives: To evaluate the reliability and responsiveness of PhGA.

Methods: We included two consecutive visits of RA patients followed in a Tertiary Rheumatology Department. Socio-demographic (age and gender) and clinical data were collected including tender (T28) and swollen (SJC28) joints in 28 count, C-Reactive Protein (CRP), Erythrocyte Sedimentation Rate (ESR), Disease activity Score (DAS28-3v-CRP, DAS28-3v-ESR, DAS28-4v-CRP, DAS28-4v-ESR), PhGA and Patient Global Assessment of disease Activity (PGA) through a Visual Analogic Scale (VAS) 0-100mm. Changes (Δ) between the two visits were calculated. Only patients without missing data were included. Correlations between ΔPhGA and change of other variables were assessed using Pearson's correlations. Reliability was evaluated through Intraclass Correlation Coefficient (ICC) between two consecutive assessments in a subgroup of patients with stable disease activity (ΔDAS28-4vESR [-0.6 to 0.6]). An ICC above 0.8 was considered indicative of excellent reliability. Sensitivity to change was assessed in the subgroup of patients who improved their disease activity at least 0.6 on DAS28-4vESR, through Standardized Response Mean (SRM). The respective intervals of confidence were obtained through bootstraping procedures. SRM above 0.8 were considered large. Independent factors associated with ΔPhGA were identified through multivariate linear regression analysis, p<0.05 was considered statistically significant.

Results: 121 RA patients (84.3% female and 64.0±12.6 years) were included. ΔPhGA was weakly correlated with ΔCRP (r=0.23), ΔPGA (r=0.31) and Δpain (r=-0.37). Moderate to strong correlations were observed with ΔDAS28-3v-ESR (r=0.55), ΔSJC28 (r=0.56), ΔDAS28-3v-CRP (r=0.58), ΔDAS28-4v-CRP (r=0.60), ΔT28 (r=0.62) and ΔDAS28-4v-ESR (r=-0.63). ICC between two consecutive visits was 0.7, [95%CI:0.47-0.83] and SRM was -0.101 [95%CI:-1.26—(-0.73)]. In the multivariate regression analysis, ΔSJC28 (β=4.01; 95% CI:3.07 to 4.96) and Δ Pain (β=0.18; 95%CI: 0.07 to 0.28) remained as independent factors associated with ΔPhGA (R2:0.49, p<0.01)

Conclusion: In this study, PhGA showed a high reliability and sensitivity to change regarding disease activity, in clinical practice. Changes in SJC had the strongest association with change in PhGA scoring, but Δ Pain was also significantly correlated (graph 1).

The frequency of RF and ACPA detection in non-erosive patients, in all patients with radiological erosion and in patients with advanced stages only (III and IV) was 67% (RF) -78% (ACPAs), 75% -90% and 100% -100%, respectively.

Conclusion: Every clinical practice (OREL register) shows that in patients aged 50 years and older with early clinical stage of RA who are naive about the treatment of DMARD, biological DMARD and GC, the detection of RF, ACPA and erosive changes in the joints are often observed in the onset of the disease,RF and ACPA are markers of early joint destruction.

Background: The differentiation between rheumatoid arthritis (RA) and psoriatic arthritis (PsA) is sometimes a challenge for rheumatologists in daily clinical practice. Imaging techniques such as MRI could be a helpful tool for this purpose.

Objectives: To examine the value of 3 Tesla (T) magnetic resonance imaging (MRI) with a high-resolution 16-channel hand coil for the differentiation between RA and PsA.

Methods: A total of 17 patients with active PsA and 27 patients with active RA were evaluated by 3T MRI. Images were analyzed by three readers according
to the outcome measures for RA clinical trials (OMERACT) and RA and PsA MRI scores for the presence and intensity of the following MRI features: synovitis, flexor tendosynovitis, bone edema, bone erosion, periarticular inflammation, bone proliferation, and joint space narrowing. A receiver operating characteristics (ROC) curve was established for a calculated prediction model comprising age, gender, and the imaging features ‘periarticular inflammation’ and ‘erosion’ of the metacarpophalangeal (MCP) joint of the 5th finger.

Results: PsA could be differentiated from RA by extracapsular inflammatory changes (PsAMRIS sub-score ‘periarticular inflammation’), with a minimal odds ratio (OR) for the outcome not RA of 0.06 (p < 0.01) at all MCP joints. The calculated ROC curve had an area under the curve (AUC) of 98.1%.

Conclusion: ST MRI showed a strong association of extracapsular inflammatory changes with PsA at the MCP joint level, and consequently allowed differentiation between PsA and RA.

Figure 1. Receiver operating characteristics (ROC) curve with different thresholds for the calculated prediction model for the outcome RA. Area under the curve (AUC) = 98.1%.

AB0227 BASELINE SYNOVIAL LEVELS OF MATRIX METALLOPROTEINASES-9 IN EARLY RHEUMATOID ARTHRITIS: THE ASSOCIATION WITH INITIAL RADIOGRAPHIC CHANGES

S. Stojanovic1, B. Stamenkovic1, J. Nedovic1, V. Živkovic1, I. Aleksić1, 1University of Nis, Faculty of Medicine, Nis, Institute for Treatment and Rehabilitation “Niska Banja”, Nis, NiS, Serbia, 2Institute for Treatment and Rehabilitation “Niska Banja”, Nis, NiS, Serbia

Background: Matrix metalloproteinases (MMPs) are the key enzymes responsible for the joint destruction in rheumatoid arthritis (RA).

Objectives: The aim of this study was to examine the association of baseline levels of metalloproteinases-9 (MMP-9) in serum and synovial fluid (SF) with structural damage of hand and feet joints in patients with early RA and also with immunoserological markers of the disease.

Methods: The study enrolled 134 subjects with knee synovitis: 72 patients with early DMARD-naïve RA (symptom duration ≤12 months) and 62 patients with osteoarthritis (OA), as control group. Synovial fluid was obtained by an arthrocentesis of the knee joint. Joint damage was estimated by hands, knee and feet radiography. With regard to the presence of destructive joint changes on initial x-ray, RA patients were classified as erosive and nonerosive form of disease. ELISA assay was used for the detection of MMP-9 activity in serum and SF as well for the immunoserology tests: rheumatoid factor RF (IgG) and anti-CCP antibody (ACPA).

Results: MMP-9 activity in serum and SF of RA patients was significantly higher compared to its activity in serum and SF of control group (p<0.01 and p <0.001 respectively) (table 1).

Table 1. MMP-9 activity (ng/ml) in serum and SF of RA and control group patients

<table>
<thead>

</tr>
</tbody>
</table>

RA – rheumatoid arthritis; SD – standard deviation; n – number of subjects; ** – p<0.01, *** – p<0.001

We did not establish a significant correlation between the activity of MMP-9 in serum and SF in the RA and control groups (Spearman's rank correlation coefficient in RA was 0.02 and 0.06 in control group).

Most of the subjects from RA group (52–72.22%) had verified radiographic erosive changes in joints. Nonerosive arthritis was present in remaning 20 (27.78%) of RA patients. No differences were obtained according to the sex, age or disease duration between erosive and nonerosive RA patients.

Table 2 represents MMP-9 activity in serum and SF of patients with erosive and nonerosive RA. The values of MMP-9 activity measured in serum were higher in nonerosive compared to erosive RA (20.35±10.30 vs. 17.46±6.25), but the difference was not statistically significant (p>0.05). However, MMP-9 activity in SF

Figure 2. 1413
was significantly higher in erosive compared to nonerosive RA (17.53±12.87 vs. 8.76±7.72; p<0.05).

Table 2. MMP–9 activity (ng/ml) in serum and SF of patients with erosive and nonerosive RA

<table>
<thead>
<tr>
<th>MMP–9 activity</th>
<th>Erosive RA (n=52)</th>
<th>Nonerosive RA (n=20)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum</td>
<td>17.46±6.25</td>
<td>20.35±10.30</td>
</tr>
<tr>
<td>Synovial fluid</td>
<td>17.53±12.87³</td>
<td>8.76±7.72</td>
</tr>
</tbody>
</table>

RA = rheumatoid arthritis; SD = standard deviation; n = number of subjects; ³p<0.05;

We also examined the correlation of MMP 9 activity in serum and SF with standard imuno serological markers of disease (RF and ACPA). Our results indicate that there is a significant correlation of MMP 9 activity in SF with ACPA level in RA group (Spearman's rank correlation coefficient is 0.48), but not with RF (Spearman's rank correlation coefficient is 0.06).

Conclusion: MMP–9 activity in serum and synovial fluid of patients with early RA is significantly higher compared to patients with osteoarthritis. High activity of MMP–9 in synovial fluid of patients with early RA correlated with ACPA level and may be a predictor of rapid radiographic progression of disease.

AB0228 COMPREHENSIVE RHEUMATOID HAND ASSESSMENT THROUGH PATTERN OF DEFORMITIES USING CLUSTER ANALYSIS

S. Toyama1,2, R. Oda1, D. Tokunaga1, S. Tsuchida1, N. Hishikawa2, M. Ohara1, Y. Mikami3,1Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Development of Orthopaedics, Kyoto, Japan; 2Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Development of Rehabilitation Medicine, Kyoto, Japan; 3Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Development of Orthopaedics, Kyoto, Japan

Background: The treatment of rheumatoid hand, which is characterized by thumb deformity, finger deformities, and ulnar drift (UD), is challenging. Its pathophysiology is complex, and a comprehensive understanding of the optimal intervention for this condition requires high technical skill and extensive clinical experience. Moreover, the natural course of rheumatoid hand itself remains unclear.

Objectives: This study was performed to comprehensively evaluate rheumatoid hand through the specific parameters of each deformity.

Methods: A rheumatoid hand cohort was established in 2004. In total, 134 hands of 67 patients were registered and underwent clinical evaluations. All hands surgically treated during follow-up were excluded from the study, but the contralateral hands were assessed. Evaluations were repeated in 2009 (100 hands of 52 patients) and in 2015 (63 hands of 37 patients) among all available patients. Therefore, among the data obtained from the 3 study endpoints, 297 hands were available for the cross-sectional analysis and 43 hands were available for the longitudinal analysis. Thumb deformities and finger deformities (swan-neck and boutonnière) were semi-quantitated by the Nalebuff classification score, and UD was quantified using a metacarpophalangeal joint condition scoring method1. A two-step cluster analysis was performed with entered parameters, and the distribution of each parameter was considered to clarify the characteristics of each cluster. The hands with different clusters at each endpoint were recruited for the following longitudinal analysis. The natural course of rheumatoid hand was considered based on the cluster change.

Results: Seven clusters were used in this study to emphasize the impact of thumb deformity on function. The characteristics of each cluster were as follows. Cluster 1: mild finger deformities and various severities of UD; Cluster 2: type 1 thumb deformity and various severities of UD; Cluster 3: type 2 thumb deformity and severe UD; Cluster 4: type 3 or 4 thumb deformity, low or moderate level of swan-neck deformity, and various severities of UD; Cluster 5: various types of thumb deformity, severe boutonnière deformity, and various severities of UD; Cluster 6: type 1 thumb deformity, severe swan-neck deformity, and various severities of UD; and Cluster 7: type 6 thumb deformity.

The longitudinal analysis showed that Cluster 1 mainly changed to Cluster 2 or 4, indicating progression of thumb deformity. Cluster 2 changed to Cluster 3, indicating that thumb type 1 progressed to type 2 (Figure 1). When the affected period was shorter than 10 years, the incidence of severe hand deformity (including two or more affected joint areas and low hand function) was <10%. In contrast, when the affected period was longer than 10 years, the incidence of severe hand deformity was >30% (Figure 2).

Conclusion: This study suggests the presence of seven patterns of deformity enabling a comprehensive understanding of rheumatoid hand. Furthermore, the results of the longitudinal analysis suggest a natural course of rheumatoid hand progression. Therefore, from the distribution of parameters of each deformity and its severity, rheumatologists can easily classify rheumatoid hand and determine its pathophysiology to choose the most effective intervention.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.2806
Background: Air pollution is believed to cause oxidative stress and systemic inflammation, which might trigger autoimmunity in rheumatoid arthritis (RA). Several epidemiological studies investigated the possible role of air pollution in the outbreak of RA with controversial results. As far as we know, studies on the effects on disease activity of short-term exposure have not been published.

Objectives: To evaluate the impact of short-term exposure to air pollutants (daily mean PM10, PM2.5, NO2, and O3) on disease activity in patients with RA.

Methods: Consecutive patients with RA (ACR/EULAR Criteria 2010) resident in Lombardy (Italy) were enrolled. In each patient Disease Activity Score on 28 joints (DAS28), Simple Disease Activity Index (SDAI) were assessed. Daily PM10, PM2.5, NO2, and O3 concentrations, estimated by Regional Environmental Protection Agency at municipality resolution, were used to assign short-term exposure from day of visit back to 14 days. Multivariable linear regression models were performed to identify the day of the pollutants independently associated with disease activity indexes, adjusting for the variables significant at the univariate analysis. β coefficients were reported for 1 μg/m3 increments of pollutants’ concentrations.

Results: 422 RA patients were enrolled in the study between January and June 2018: 81.5% females, mean age 58.2±13.3 years, mean disease duration 16.1±11.5 years, 27.3% current smokers, 59.5% RF positivity, 54.5% ACPA positivity. Sparse punctual statistically significant negative associations emerged at the multivariate analysis between PM2.5, PM10, NO2, and O3 and the outcomes, although with very low estimates, whereas positive associations reported for O3.

Conclusion: The changes of the outcome measures related to the increase of the pollutants’ levels did not reach the minimal clinically important difference, therefore air pollution seems barely relevant on disease activity once the loss of tolerance is established in RA. O3 and PM/NO2 always exhibit an opposite performance having inversely proportional atmospheric concentrations, whereas the biological role of this substance is still matter of debate and will need further understanding. Therapy seems to be able to interact with the relation between air pollutants and the parameters considered.

**AB0231**

RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT AT A COMMUNITY RHEUMATOLOGY CLINIC AND WHO ARE POSITIVE FOR ANTICYCLIC CITRULLINATED PEPTIDE ANTIBODIES HAVE MORE SUSTAINED CLINICAL RESPONSES THAN PATIENTS NEGATIVE FOR THE MARKER

C. Wiesenhutter1, V. Hayden2, 1. Coeur d'Alene Arthritis Clinic, Coeur d'Alene, United States of America; 2. Coeur d’Alene Arthritis Clinic, Coeur d’Alene, United States of America

**Background:** Treating Rheumatoid Arthritis (RA) patients to target (T2T) has been shown to result in better outcomes in patients with RA [1]. There are now a number of therapeutic options to accomplish this goal, but determining which agent to select for each individual has not been defined.

**Objectives:** The purpose of this post hoc analysis was to assess if Anticyclic Citrullinated Peptide Antibody (anti-CCP) status affects outcomes following treatment of RA patients with Abatacept.

**Methods:** Patients at a community based rheumatology clinic undergo disease activity measure assessments on a routine basis as part of the implementation of T2T strategy with ongoing assessments on at least a yearly basis. Over the past 15 years there have been 78 patients initiated on treatment with Abatacept at this clinic. Anti-CCP and Rheumatoid factor status is routinely obtained when patients are first seen in the clinic. A patient was considered to be Anti-CCP positive if the test was 20 u/ml or greater. As a comparison, the 53 patients in the clinic started on Tofacitinib were also analyzed.

The difference in sustained clinical response rates between seropositive and seronegative patients were determined for these two groups. Sustained clinical response was defined as remaining on treatment for at least three years. Patients who were lost to follow up or who died, while on treatment for less than three years, were not included. Statistical analysis was performed with IBM SPSS V.25 using chi square tests and logistic regression incorporating pretreatment gender, age, and sex, age at onset, age, anti-cyclic citrullinated polypeptide antibodies (ACPA), rheumatoid factor (RF), Sharp/van der Heijde Score (SHS), clinical disease activity score (CDAI), C-reactive protein (CRP), modified Health Assessment Questionnaire score (mHAQ), and pain score with visual analog scale (VAS) as predictors for CDAI remission.

**Results:** Fifty anti-CCP positive patients and twenty-two anti-CCP negative patients treated with Abatacept were clinically assessed and results of the post hoc analysis are shown in Table one. Chi square risk estimate 4.81 Clinical sig p=0.01. Logistic regression: Unadjusted Risk ratio (95% CI)2.41 (1.23, 7.19.) Clinical sig p=0.03.

Results of the post hoc analysis for patients treated with Tofacitinib are shown in Table two. Chi square risk estimate 1.75 (not clinically significant.) Unadjusted Risk 1.70 (not clinically significant). Adjusted Risk 1.42 (not clinically significant).

**Conclusion:** Rheumatoid Arthritis patients who are Anti-CCP positive and who are treated with Abatacept in a community rheumatology clinic have a significantly greater number of sustained clinical responses than patients who are Anti-CCP negative.

This difference for patients treated with Tofacitinib was not clinically significant in this clinic, though a higher percentage of Anti-CCP positive patients treated with Tofacitinib responded (72% vs 60%). Anti-CCP positivity could be used as a clinical marker to select patients with rheumatoid arthritis to be treated with Abatacept.

**AB0232**

PAIN SCORE WITH VISUAL ANALOG SCALE OF 30MM OR MORE IS A RISK FACTOR OF WORSENING CLINICAL DISEASE ACTIVITY INDEX (CDAI) AT THREE MONTHS AFTER ATTAINING CDAI REMISSION IN PATIENT WITH RHEUMATOID ARTHRITIS

I. Yoshii1, 1. Yoshii Hospital, Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan

**Background:** In treating with rheumatoid arthritis (RA), it is needless to say essential treatment goal with first priority. On the other hand, patient’s pain influences on clinical indices deeply however, pain score is not been regarded as most important despite that correlates with patient reported outcome.

**Objectives:** Clinical significance of remnant pain score for clinical outcome although attaining remission in clinical disease activity index (CDAI) statistically.

**Methods:** RA patient who have attained remission with CDAI were picked up. These patients were divided into two groups whether CDAI at three month after the first CDAI remission attained; namely CDAI-R or CDAI-F. Background data such as sex, age at onset, age, anti-cyclic citrullinated polypeptide antibodies (ACPA), rheumatoid factor (RF), Sharp/van der Heijde Score (SHS), clinical disease activity score (CDAI), C-reactive protein (CRP), modified Health Assessment Questionnaire score (mHAQ), and pain score with visual analog scale (VAS) at first consultation, time span from the first consultation to first CDAI remission were compared between the two groups using Mann-Whitney U-test. CDAI, CRP, mHAQ, PS-VAS, and QOL value calculated from EuroQOL-5 dimension questionnaire (EQ-5D) at the time of CDAI were also statistically compared with Mann-Whitney U-test. Parameters that demonstrated statistical significance within 5% were picked up, and odds ratio for CDAI remission were calculated with binary logistic regression analysis. Moreover, parameters that demonstrated statistical significance with p-value within 5% were evaluated with receiver’s observational characteristics (ROC) analysis, and cut-off index (COI) was calculated.

**Results:** A total of 907 patients with 594 CDAI-R and 313 CDAI-F were recruited. Demographic characteristics of the two groups were shown in Table 1. SHS at first consultation and time span from first consultation to CDAI remission attained demonstrated significantly less in the CDAI-R than the CDAI-F group, while the other parameters demonstrated no significant difference. CRP, CDAI, mHAQ, PS-VAS, and QOL at CDAI remission demonstrated significant difference between the CDAI-R and CDAI-F groups. With binary logistic regression analysis, CRP, CDAI, and PS-VAS demonstrated significant regression for CDAI-R with 1.68, 0.71, and 0.78 in odds ratio, respectively. COI for CDAI remission was 0.4, 1.0, and 30 for CRP (p=2.4 x 10^-4), CDAI (p=3.0 x 10^-5), and PS-VAS (p=2.4 x 10^-4), respectively.

**Conclusion:** PS-VAS at the moment of CDAI remission is suggested to be predictive factor for sustaining CDAI remission at three months thereafter as well as CRP value and the CDAI score.
**Table 1. Demographic characteristics of the two groups**

### AB0233

**ATTAINING CDAAI REMISSION IS THE FIRST GATEWAY TO ATTAIN BOOLEAN REMISSION**

I. Yoshi1, T. Yoshii Hospital, Rheumatology and Musculoskeletal Medicine, Shimanto-City, Japan

**Background:** Boolean remission is most stringent but most comparable remission status for the patient with rheumatoid arthritis (RA). Clinical remission evaluated with clinical disease activity index (CDAAI) is also one of the most popular index for evaluation of RA treatment. These two criteria often overlap, but some are split.

**Objectives:** Clinical significance of attaining CDAAI remission before attaining Boolean remission was investigated.

**Methods:** Patient with RA were treated in the institute since August 2010 under treat to target (T2T) strategy. In accordance with T2T, RA patients were monitored from the first consultation with parameter such as tenderess joint count (TJC), swollen joint count (SJC), patient’s global assessment (PGA), evaluator’s global assessment (EGA), C-reactive protein (CRP), modified Health Assessment Questionnaire (mHAQ), pain scale with visual analog scale (PS-VAS), and EuroQOL 5-dimension (EQ-5D). CDAAI and Boolean are also evaluated at the same time. Radiographs of bilateral hands and feet are taken once a year from the first consultation, and the Sharp/van der Heijde Score (SHS) is measured.

In this study, a group who attained CDAAI remission prior to attaining Boolean remission (CDAAI-R), a group who could not attain CDAAI remission previously than attaining Boolean remission (CDAAI-F), and a group who could not attain Boolean remission despite attaining CDAAI remission (Boolean-F) were picked up and divided according to change of disease activity. Among these three groups, mean age, sex, education level, job style, anti-cyclic citrullinated polypeptide antibodies (ACPA), rheumatoid factor (RF), the CDAI score, the HAQ score, PS-VAS and quality of life index (QOL) calculated from EQ-5D were compared with each other using Mann-Whitney U-test. Boolean remission attaining rate whether CDAAI remission attained was compared with chi square test.

**Results:** Patient group configured with 255 of CDAAI-R, 160 of CDAAI-F, and 28 of Boolean-F. Patient who could not attain none of CDAAI nor Boolean remission counted 175. In background factors at baseline, mean age, the HAQ score, and SHS of the Boolean-F were significantly older than the other groups. In the two groups of CDAAI-R and CDAAI-F, 28-joints disease activity score with C-reactive protein (DAS28-CRP), CDAAI and PS-VAS in the CDAAI-R were significantly lower than in the CDAAI-F, similarly, DAS28-CRP, the CDAI score, the HAQ score, PS-VAS and QOL after Boolean remission attain were significantly higher in the CDAAI-F than the CDAAI-R. Sensitivity of Boolean remission when attaining CDAAI remission previously before Boolean remission is 93.4%, and specificity was 52.2% (p<1.0 x 10^-20).

**Conclusion:** Attaining CDAAI remission previously is extremely important, both for attaining Boolean remission and more stable clinical course after attaining Boolean remission. CDAAI remission could be the first gateway to send sustainable QOL course.

### AB0234

**ASSOCIATION OF HOMOCYSTEINE LEVEL AND CAROTID INTIMA-MEDIA THICKNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

D. Anghel1, L. Ottocar2, R. Bursuc1, E. Busuioc1, A. Manolache1, F. C. Plesa1, V. Smedescu3, M. M. Negru4, C. Jurcu1, Central Military Emergency University Hospital “Carol Davila”; Bucharest, Romania; 2*Sfanta Maria” Clinic, Bucharest, Romania; 3*Sfanta Maria” Clinical Hospital, Bucharest, Romania

**Background:** Homocysteine (Hcy) has been implicated in atherogenesis. High homocysteine level can predict cardiovascular events, including death. Atherosclerosis has a high incidence in patients with Rheumatoid Arthritis (RA).

**Objectives:** The aim of this study is to evaluate the relationship between serum homocysteine levels and carotid atherosclerosis in patients with RA and anti-TNF therapy.

**Methods:** Our study included 80 RA patients divided into two groups: 45 patients were with anti-TNF-alpha therapy (Adalimumab, Infliximab, Etanercept) and 35 RA patients with disease-modifying antirheumatic drugs (DMARDs). The patients were diagnosed with RA used ACR/EULAR 2010 Classification Criteria. We measured carotid intima-media thickness (CIMT) using high-resolution Doppler ultrasonography at baseline and then at 12 months. CIMT above 0.9 mm is an atherosclerosis marker. We considered high levels of homocysteine in the serum above 15 µmol/L. All patients had treatment with hypolipemiant drugs and antiplatelet agents during the 12 months. Other parameters were analyzed at baseline and after 12 months: age, lipid profile (HDL, LDL, and cholesterol), ESR and disease activity score (DAS28<2.6 means remission; DAS28=2.6-3.2 means low disease activity; DAS28=3.2-5.1 means moderate disease activity; DAS28>5.1 high disease activity).

**Results:** 45 patients received anti-TNF-alpha therapy (mean age 45.50±9.69 years) and 35 RA patients had treatment with DMARDs (mean age 48.3±8.9 years). High Hcy levels were found on 34% patients in DMARDs group and 21% patients in anti-TNF group. After 12 months of treatment, patients with high levels of Hcy and anti-TNF therapy had a significant decrease in CIMT. In patients with low Hcy level the decrease in CIMT was insignificantly statistic. In DMARDs group atherosclerotic plaque was detected to 26 patients (74.29%) and 21 (46.66%) patients were detected into anti-TNF group. After 12 months CIMT was significantly higher in DMARDs group and the difference was statistically significant compared to baseline and to anti-TNF group (p=0.0002). High DAS28 score was associated with increased CIMT and hyperhomocysteinemia in both groups (p<0.0001).

**Conclusion:** Increased Hcy levels were associated with increased CIMT values in both groups. In RA patients with anti-TNF therapy and high Hcy levels, reduction of CIMT was statistically higher than in patients with DMARDs treatment.

### AB0235

**DENOSUMAB INCREASE THE BONE MINERAL DENSITY REGARDLESS OF DISEASE ACTIVITY, THE BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS, THE CONCOMITANT TYPE OF VITAMIN D, AND PRETREATMENT OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS.**

S. Anno1,2, T. Okano2, K. Inui2, T. Koike3,4, H. Nakamura3, Osaka Social Medical Center, Department of Orthopaedic Surgery, Osaka, Japan; 2Osaka City University Medical School, Department of Orthopaedic Surgery, Osaka, Japan; 3Osaka City University Medical School, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; 4Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan

**Background:** Osteoporosis is one of the major comorbidities in patients with rheumatoid arthritis (RA). There are a lot of evidence that denosumab increase bone mineral density (BMD) in patients with osteoporosis. However, there are few reports investigated the influence of denosumab in patients with RA.

**Objectives:** We evaluated the BMD change in patients with RA treated denosumab and assessed the effect of various factors, such as disease activity, biological disease-modifying anti-rheumatic drugs (bDMARDs) use, concomitant medications of osteoporosis and pretreatment of osteoporosis.

**Methods:** This study included 140 consecutive RA patients (135 female, mean age was 70.6 ± 8.6 years) who fulfilled the criteria of osteoporosis and treated with denosumab. BMD at the lumbar spine, proximal femoral and femoral neck were evaluated by dual energy X-ray absorptiometry at baseline and one year after treatment. We evaluated the influence of disease activity, bDMARDs use,
the concomitant type of vitamin D and pretreatment of osteoporosis for BMD change.

Results: BMD change at the lumbar spine, proximal femoral and femoral neck were 5.9% (p<0.01), 4.0% (p=0.01), and 12% (p=0.36) during one year. There were no differences in improvement ratio of BMD between each parameters (fig 1). Disease activity: 75 patients in remission or low disease activity and 65 patients in moderate or high disease activity were 6.4 vs 5.3% (p=0.91), 3.0 vs 5.1% (p=0.73), 2.0 vs 0.3% (p=0.01). bDMARDs: 45 patients with bDMARDs (anti-tumor necrosis factor inhibitors (TNF): 23, tocilizumab (TCZ): 13, abatacept (ABT): 7, Tolctazulin: 2) and 93 patients without bDMARDs were 6.0 vs 5.8% (p=0.31), 4.3 vs 4.1% (p=0.57), -3.2 vs 18% (p=0.18). Type of vitamin D: 47 patients taking active form vitamin D and 60 patients taking native form vitamin D were 5.5 vs 6.8% (p=0.82), 3.1 vs 3.8% (p=0.93), 0.4 vs 1.9% (p=0.14). Pretreatment of osteoporosis: 74 patients with pre-treatment of osteoporosis (bisphosphonate:58, teriparatide:16) and 66 patients without -out pretreatment of osteoporosis were 6.9 vs 5.4% (p=0.41), 0.9 vs 4.0% (p=0.22), 2.0 vs 12% (p=0.68). Moreover, BMD change were not different in bDMARDs type, 5.0, 6.4, 0.5% in TNF group, 4.8, 0.7, -1.9% in TCZ group, 9.7, 4.9, 0.2% in ABT group (TNF vs TCZ: p=0.83, 0.98, 0.81, TNF vs ABT: p=0.83, 0.41, 0.97, TCZ vs ABT: p=0.98, 0.43, 0.9). There were no difference between bisphosphonate and teriparatide (6.2 vs 6.9%; p=0.49, 4.8 vs 0.9%; p=0.35, 0.9% vs 2.0%; p=0.49).

Conclusion: Denosumab improved BMD in patients with RA independently regardless of disease activity, bDMARDs, the concomitant type of vitamin D and pretreatment of osteoporosis.

AB0236 DIFFERENCES AND DETERMINANTS OF PHYSICIAN’S AND PATIENT’S PERCEPTION IN GLOBAL ASSESSMENT OF RHEUMATOID ARTHRITIS

S. Azevedo1, F. Guimarães1, D. Almeida2, D. Faria1, J. Silva1, J. Rodrigues1, D. Peixoto1, S. Alcino1, J. Tavares-Costa1, C. Afonso1, F. Teixeira1.

Local de Saúde do Alto Minho, Rheumatology Department, Ponte de Lima, Portugal;2Hospital de Braga, Rheumatology Department, Braga, Portugal

Background: Patient’s Global Assessment of Disease Activity (PtGA) and Physician’s Global Assessment of Disease Activity (PhGA) are assessed as part of commonly used measures of disease activity in RA. Both are important measures in treat-to-target strategies in Rheumatoid Arthritis (RA), but often provide discordant results. This can provide an erroneous assessment of disease activity in patients under Biologic treatment and mislead treatment decisions, namely switches.

Objectives: To assess differences and determinants of PtGA and PhGA in RA patients under biologic treatment.

Methods: Cross-sectional study, including 46 patients with RA diagnosed according to the ACR/EULAR criteria, under biologic treatment, consecutively evaluated in day-care unit. Participants completed patient-reported outcomes (PROs), including PtGA, and sociodemographic characteristics. Physicians collected comorbidities and parameters of inflammatory activity (erythrocyte sedimentation rate [ESR] and C-reactive protein [CRP]) and completed PhGA and disease activity score 28 with ESR (DAS28). SPSS was used for statistical analysis and significance level was defined as 2-sided p<0.05.

Results: Clinical and laboratory characteristics of patients are shown in table 1. PtGA and PhGA were significantly different (36.1±27.6mm vs 8.7±14.2mm, p<0.001) and a positive discordance (PtGA>PhGA, more than 25mm in visual analogue scale [VAS]) was found in 54.3% of cases. PtGA had a correlation with PROs [Pain VAS, 36-Item Short Form Health Survey (SF-36), Health Assessment Questionnaire (HAQ), Functional Assessment of Chronic Illness Therapy (FACT), EuroQol [EQ5D] and Hospital Anxiety and Depression Scale [HADS]], CRP, tender and swollen joint counts and an association with comorbidities like fibromyalgia or osteoarthritis (OA). No association was found between PtGA and age, sex, education level, profession, employment status, extra-articular manifestations, positivity of rheumatoid factor, ESR, years of disease evolution or number of biologic treatments. In multivariable analyse including SF-36, CRP, tender joints count and OA (R2 adjusted= 0.672), the main predictors of PtGA were lower SF-36, concomitant OA and higher CRP level. PhGA had a correlation with PtGA, pain VAS, CRP, tender and swollen joints. No association was found between PhGA and patient or physician age, patient or physician sex, extra-articular manifestations, positivity of rheumatoid factor, ESR level, years of disease evolution or number of biologic treatments. In multivariable analysis including ESR, CRP, tender and swollen joints count and CRP (R2 adjusted= 0.800), the main predictors of PhGA were swollen joint count and higher CRP level. Conclusion: This study showed the variability implied on global assessment of RA activity. Overall PtGA is based on function and also in subjective and emotional experience of pain, whereas the PhGA is based on more objective measures, more related to disease activity.

AB0237 ARE THERE DIFFERENCES IN CLINICAL PROFILE AND TREATMENT AMONG 2 DIFFERENT INTERCONTINENTAL COHORTS OF PATIENTS WITH RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE?

A. B. Azuaga-Piñango1, Y. Li2, R. Castellanos-Moreira3, V. Ruiz1, R. Samaná1, I. Mira-Avendano2, A. Abril3, J. A. Gómez-Puerta1, I. Mira-Avendano1, A. Pinzango3, R. Castellanos-Moreira1, V. Ruiz1, R. Samaná1, Hospital Clinic, Rheumatology, Barcelona, Spain;3Mayo Clinic, Rheumatology, Jacksonville, United States of America; 4Mayo Clinic, Pulmonary Medicine, Jacksonville, United States of America

Background: Rheumatoid Arthritis (RA) is characterized by persistent joint synovitis causing progressive destruction of the cartilage and bone. Intestinal lung disease (ILD) is a frequent extra-articular manifestation of RA. Clinical profiles of patients with RA-associated ILD may vary.

Objectives: To describe the clinical characteristics and radiological patterns and evaluate the different clinical profile between two different cohorts of patients (pts) with RA-associated ILD.
Methods: Retrospective cohort study. We collected clinical and epidemiological data of pts seen in outpatient clinic from a Hospital from Barcelona, Spain and another from Jacksonville, Florida, USA. Pts who met the RA ACR/EULAR 2010 criteria and the ILD American Thoracic Society/European Respiratory Society 2013 classification criteria were selected. The study was approved by both local committees.

Results: A total of 63 pts were included, 37 from Barcelona and 26 from Jacksonville. Forty-one pts (65%) were women with a median age of 68 years. General characteristics are summarized in Table. Thirty-eight pts (60.3%) were former smokers and/or access for health care among others. E-selectin, VCAM-1, MCP1 and IL-8 serum levels were determined at baseline and after 6 months of therapy with MTX monotherapy or in combination with adalimumab for 40 RA patients and 19 osteoarthritis (OA) controls using commercial ELISA kits. Prognostic imaging markers for atherosclerosis were pulse wave velocity (PWV) and augmentation index (Alx) as measured with SphygmoCor tonometry. Parametric analyses were used for E-selectin, VCAM-1 and MCP1 and non-parametric or parametric analyses after log transformation for IL-8.

Results: Baseline VCAm-1 and IL-8 were significantly higher for RA patients than OA controls with and without adjustment for age and sex or traditional risk factors (table 1).

After 6 months of anti-inflammatory therapy, E-selectin and IL-8 serum levels significantly decreased (table 2). This decrease was especially present in the RA patients with good EULAR-DAS28 response to the medication and not in patients with no/moderate response (E-selectin: -7, 95%CI -13.9, 2, p=0.007 versus -0.1, 95%CI -3.2, p=0.925, IL-8: -2, p=0.033 versus -1, p=0.267).

Furthermore, in the RA patients we found a significant correlation between the difference in PWV after 6 months and the difference in E-selectin (Pearson r=0.450, p=0.018) and IL-8 (Spearman r=0.401, p=0.038). All other possible correlations of the endothelial function markers with PWV and Alx were not significant (data not shown).

Conclusion: Serum levels of E-selectin and IL-8 decreased after 6 months of anti-inflammatory therapy, and both correlated with the PWV changes. This is the first study investigating both serologic as well as imaging markers of endothelial function and atherosclerosis in RA patients undergoing anti-inflammatory therapy. Our study suggests that E-selectin and IL-8 circulatory levels may reflect the best both systemic inflammation as well as endothelial function in RA, and might be therefore useful in the future as markers of cardiovascular risk in these patients.

SEVER LEVELS OF E-SELECTIN AND IL-8 DECREASE AFTER 6 MONTHS OF ANTI-INFLAMMATORY THERAPY AND MIRROR FAVORABLE VASCULAR CHANGES IN RHEUMATOID ARTHRITIS

A. Blanken1, R. Agca2, C. D. Popa2, M. Nurmohamed2, A. Amsterdam Rheumatology and Immunology Center, Location Reade, Amsterdam, Netherlands; 2Amsterdam Rheumatology and Immunology Center, Location Amsterdam UMC | VUMc, Amsterdam, Netherlands; 3Sint Maartenskliniek, Department of Rheumatology, Nijmegen, Netherlands; 4Radboudumc, Department of Rheumatology, Nijmegen, Netherlands

Background: Accelerated atherosclerosis is a systemic manifestation of rheumatoid arthritis (RA). E-selectin, VCAm-1, MCP1/CCL2 and IL-8/CXCL8 are involved in leukocyte migration through endothelial cells in both atherosclerosis and RA [1]. Therefore, these endothelial function markers might reflect endothelial function and systemic inflammation in RA. If so, such a marker could be used to assess cardiovascular risk in RA patients.

Objectives: The aim of this study was to investigate the effect of 6 months of anti-inflammatory treatment on RA serum levels of endothelial function markers and whether these serum levels are related to prognostic imaging markers for atherosclerosis.

Methods: E-selectin, VCAm-1, MCP1 and IL-8 serum levels were determined at baseline and after 6 months of therapy with MTX monotherapy or in combination with adalimumab for 40 RA patients and 19 osteoarthritis (OA) controls using commercial ELISA kits. Prognostic imaging markers for atherosclerosis were pulse wave velocity (PWV) and augmentation index (Alx) as measured with SphygmoCor tonometry. Parametric analyses were used for E-selectin, VCAm-1 and MCP1 and non-parametric or parametric analyses after log transformation for IL-8.

Results: Baseline VCAm-1 and IL-8 were significantly higher for RA patients than OA controls with and without adjustment for age and sex or traditional risk factors (table 1).

Furthermore, in the RA patients we found a significant correlation between the difference in PWV after 6 months and the difference in E-selectin (Pearson r=0.450, p=0.018) and IL-8 (Spearman r=0.401, p=0.038). All other possible correlations of the endothelial function markers with PWV and Alx were not significant (data not shown).

Conclusion: Serum levels of E-selectin and IL-8 decreased after 6 months of anti-inflammatory therapy, and both correlated with the PWV changes. This is the first study investigating both serologic as well as imaging markers of endothelial function and atherosclerosis in RA patients undergoing anti-inflammatory therapy. Our study suggests that E-selectin and IL-8 circulatory levels may reflect the best both systemic inflammation as well as endothelial function in RA, and might be therefore useful in the future as markers of cardiovascular risk in these patients.

AB0239  EFFECTS OF DYSMETABOLISMS AND COMORBIDITIES ON THE EFFICACY, SAFETY AND RETENTION RATE OF BIOLOGICAL DMARDs (BDMARD) IN INFLAMMATORY JOINT DISEASES.

L. Cometi1, C. Bruni1, N. Chiti1, L. Tolani1, F. Nacci1, F. Bartoli1, S. Bellando Randone2, G. Fiori2, S. Guiducci2, M. Mattucci-Cerinic1,3, University of Florence, Faculty of Medicine, Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; 2Careggi University Hospital, Rheumatology, Firenze, Italy

Background: bDMARDs have an effect on glucose homeostasis (1), lipoproteins profile (2; 3) and blood pressure (4). However, with the exception of obesity (5; 6), there are no clear data on how bDMARDs work in patients who already have or develop metabolic comorbidities and whether these conditions can impact on their efficacy and safety profile.

Objectives: to evaluate, in chronic inflammatory joint diseases, the effect of arterial hypertension (AH), dyslipidemia (DYS) and diabetes mellitus (DM) on efficacy, safety and retention rate of first-line bDMARDs therapy.

Methods: a retrospective observational study on the clinical charts of Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Ankylosing Spondylitis (AS), treated with first on-label bDMARD was performed. Data on adverse events, efficacy and comorbidities at the baseline visit in which the bDMARD was prescribed (BL), the visit performed after 6 months of therapy (6M), and the last visit in treatment (LT) were collected.

Results: 383 patients (81.6% RA, 33.4% PsA and 24.8% AS) were included in the study, with the predominance of females (F: 67,36%; M: 32,64%; mean age 51,67 ± 15,11 years). Our data show that the presence of comorbidities had no influence on efficacy of bDMARD, while patients who had DYS at BL manifested a higher rate of systemic adverse events either in the first 6 months of therapy (58,9% vs 43,7%, p=0,040) and also later on (80,36% vs 66,67%, p=0,046). In addition, patients who developed DYS and AH after the 6M visit reported a higher rate of systemic adverse events at LT0 compared to others (DYS: 98,7% vs 86,6%, p<0,001; AH: 86,9% vs 65,2%, p=0,031). For what concerns the retention rate, patients who developed DYS or AH during bDMARD treatment continued the drug for a longer period of time (DYS 95,5 vs 19,6 months, p<0,001; AH: 72,1 vs 23,4 months, p<0,001). In particular, patients with AH who concomitantly carried out therapy with ACE-inhibitors (ACEI) and/or angiotensin II receptor blockers (ARB) continued bDMARDs for nearly 20 more months than patients who were not exposed to these medications (40,5 vs 23,4 months, p=0,001) and more frequently maintained the bDMARDs at LT (59,42% vs. 47,52%). In case of withdrawal in the ACEI/ARB exposed cohort, this was due to well-being and disease remission rather than inefficacy or adverse reaction (p=0,025). In dyslipidemic patients treated with statins, data showed that bDMARDs were continued for a longer time than in DYS patients treated with other anti dyslipidemic therapies (41,09 vs 26,50 months, p=0,042).

Conclusion: our data suggest that AH and DYS may be associated with higher frequency of adverse events but a better drug retention. The combination of bDMARD and ACEI/ARB may determine a better control of the inflammatory process by inhibition of angiotensin II, favouring the achievement of remission. In AH patients on bDMARDs, ACEI and ARB could therefore represent an useful approach by inhibition of angiotensin II, favouring the achievement of remission. In DYS patients treated with other anti dyslipidemic therapies (41,09 vs 26,50 months, p=0,042).

AB0240  EXAMINING THE RELATIONSHIP BETWEEN RHEUMATOID ARTHRITIS, MULTIMORBIDITY AND ADVERSE HEALTH-RELATED OUTCOMES: A SYSTEMATIC REVIEW

J. Canning1, S. Siebert2, B. Jani1, F. Mair2, B. Nicholl1, University of Glasgow, General Practice and Primary Care, Glasgow, United Kingdom; 2University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disorder characterised by inflammation of the synovial joints causing pain, swelling and stiffness. Multimorbidity (the presence of two or more long-term conditions) affects approximately two thirds of people with RA. However, the relationship between RA and multimorbidity is poorly understood, as is the effect of this relationship on mortality and other health-related outcomes, particularly those relating to physical functioning and well-being.

Objectives: To explore existing literature to determine what is known about the effect, if any, of multimorbidity on mortality and other health-related outcomes in people with RA.

Methods: A systematic review was conducted following a protocol prepared using PRISMA-P 2015 reporting guidelines, ensuring the quality of the review. Studies were sourced from electronic medical databases, specifically MEDLINE, Embase, CINAHL, PsycINFO, The Cochrane Library and Scopus, using a pre-defined search strategy. Studies were selected based on specified eligibility criteria and quality appraised using the Cochrane Prognosis Methods Group-developed, Quality in Prognostic Studies (QUIPS) tool. A narrative synthesis of findings was conducted.

Results: In total, 15 studies fulfilled our criteria for inclusion in our review. Of these, 7 studies had mortality as an outcome, with 6 reporting a significant association between multimorbidity and increased risk of all-cause mortality in people with RA. Nine studies had functional status/disability as an outcome, with 2 of these studies also including quality of life. All 9 studies reported significant associations between multimorbidity and the aforementioned health-related outcomes, demonstrating poorer functional status/increased disability and reduced quality of life in people with RA and multimorbidity.

Conclusion: Multimorbidity in people with RA is significantly associated with increased mortality and poor health-related outcomes in current literature. A better understanding of the relationship will provide an important foundation of knowledge to guide future health service design.

AB0241  PREVALENCE OF ANXIOUS SYMPTOMS AND DEPRESSION IN A SAMPLE OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) AND OTHER CHRONIC RHEUMATIC DISEASES

G. Crepaldi1, M. Voci1,2, M. Saracca1, A. Laezza2, P. Santino1, M. Marcato2, G. Rovera1,2, C. Lomerati1, Rheumatology Unit, Ospedale Mauriziano, Turin, Italy; 2Clinical Psychology Unit, Ospedale Mauriziano, Turin, Italy; 3Pharmacy Unit, Ospedale Mauriziano, Turin, Italy; 4Rheumatology Unit, Ospedale Sant'Andrea, Vercelli, Italy

Background: Clinical practice with patients suffering from chronic diseases highlights the presence of psychological symptoms of discomfort fed by biological and non-biological mechanisms linked to disease and treatment. In rheumatic diseases, literature detects the presence of anxious symptoms and depressed mood of clinical and sub-clinical importance with a multifactorial genesis.

Objectives: To detect the impact on the state of health of anxious symptoms and depressed mood in a population suffering from RA and other rheumatic diseases in order to implement the effectiveness of psychological intervention through the selection of patients who present critical levels of discomfort.

Methods: Patients afferent to the Rheumatology outpatient clinic of Mauriziano Hospital have been screened from May 2018 to July 2018 with two self-administered questionnaires: HADS-A and HADS-D (Hospital Anxiety and Depression Scale), specifically developed for the evaluation of anxious and depressive symptoms in medical pathologies, and HAQ (Health Assessment Questionnaire) to explore functional disability. Data about rheumatic diagnosis and socio-demographic characteristics were also collected. Data were analyzed with descriptive statistics; the Student Test and the ANOVA test were used to evaluate prevalence and correlation, and the comparison of symptoms in the different diseases and the Pearson correlation coefficient was used to evaluate the relationship between symptoms and disability.

Results: A total of 427 subjects were screened (317 females and 110 males), aged between 19 and 90 years (mean 60 ± 14 yrs), 156 subjects (36.5%) had a diagnosis of RA, 76 (17.8%) of psoriatic arthritis, 42 (9.8%) of ankylosing spondylitis, 14 (3.3%) of systemic lupus erythematosus and 139 (32.6%) of other rheumatic diseases (including Sjogren, osteoarthritis, fibromyalgia). A high prevalence of anxious symptoms and depressed mood has been found and the number of subjects reporting scores indicating a clinically relevant
uncomfortable situation (HADS ≥ 11) was also relevant (Table 1); an increased prevalence in female patients was observed. There were no differences in the presentation of symptoms between RA and the other included pathologies (Table 2).

There was a positive and significant correlation between anxious symptoms or depressed mood and functional disability (0.49 and 0.60 respectively, p<0.01).

Conclusion: The results show a significant presence of uncomfortable situations that could evolve in a psychopathological sense. The discomfort expressed through anxious and depressive symptoms is related to the level of functional disability. Recognizing the presence of psychological distress allows to orient the treatment plan and facilitate the patient’s adaptation to the disease condition.

Only 7 patients refused vaccination (2%). Information was not obtained in 4 of the remaining 394 patients. Therefore, these 4 patients were not included in the assessment.

Survival analysis was assessed by Kaplan-Meier method.

Results: We finally studied 390 patients (307♂/83♀) mean age±SD 61.28 ± 12.9 years that participate in the vaccination program and followed-up. The main features at the time of vaccination were: median disease duration (4years), positive rheumatoid factor (56.7%), subcutaneous nodules (4.9%), erosive arthritis (36.8%), pulmonary fibrosis (3.8%), secondary Sjögren syndrome (5.1%), other extraarticular manifestations (14.6%) and rheumatoid vasculitis (5.6%). Most patients had received immunosuppressive drugs before the vaccination program. The most frequently used were systemic corticosteroids (n=228), methotrexate (n=362) and biologic agents (40.3%).

During the follow-up, 42 patients (10.7%) had required hospital admissions due to infections, 17 of them were severe respiratory infections (4.35%). The remaining 25 admissions were in the setting of urinary tract infections (n=12), intraabdominal infections (7), skin and soft tissues (12) and articular (1). Also 12 of these patients had a zoster herpes.

After a median follow-up of 1061.89 ± 417 days, the incidence of serious infection, with a CI (95%), was 4.00 (2.95-5.41) for 100 patients yearly. Concerning to admissions due to serious respiratory infections, with a CI (95%), was 1.55 (0.9-2.47) for 100 patients yearly. Images 1 and 2.

Conclusion: In this study we can concluded that our RA vaccinated patients present a decrease of the incidence of serious infections, similar to other published cohorts. The incidence of serious respiratory infections shows a decrease even lower to other published cohorts. The vaccination program seems to be effective to prevent hospital admissions due to infections.

THE SHORT DISEASE DURATION IS ASSOCIATED WITH WORSE MOOD DISORDER IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Geng, T. Gao, Z. Zhang. 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China; 2Peking University First Hospital, Beijing, China

Background: Rheumatoid arthritis (RA) is commonly associated with mood disorders, especially depression and anxiety. But the status of mood disorders in RA patients with different courses is unknown.

Objectives: The aims of this study were to investigate the frequencies of depression and anxiety in patients with early RA and non-early RA, and further to identify the risk factors for mood disorders.

Methods: Self-Rating Anxiety Scale (SAS) and Self-Rating Depression Scale (SDS) were applied to all enrolled RA patients to assess their corresponding status of anxiety and depression. Besides clinical assessment, power Doppler and grey-scale ultrasonography of 22 joints were also performed. The status of mood disorder was studied in early RA patients compared to non-early RA patients. Multivariate logistic regression was used to identify the risk factor for mood disorders.

Results: 201 RA patients were enrolled, with 76 early RA (disease duration ≤ 2 years) and 125 non-early RA (disease duration > 2 years) patients. Mood disorder (depression and/or anxiety) was found in 20.9% (42/201) patients. Depression was more often observed in early RA patients than non-early RA patients (26.3% vs. 14.4%, P=0.036). The similar trend for anxiety was observed also in early RA patients compared to non-early RA patients, although the difference was insignificant (13.2% vs. 5.6%, P=0.062). Multivariate logistic regression analysis showed that disease duration [OR 0.991 [95% CI 0.985-0.998], rheumatoid factor concentration [OR 2.697 [95% CI 1.165-6.241]], Health Assessment Questionnaire Disability Index (HAQ-DI) [OR 1.045 [95% CI 1.001-1.091]] and grey-scale synovitis score (GS score) [OR 1.092 [95% CI 1.032-1.156]] were independent risk factors for predicting depression in RA. Disease duration [OR 0.985 [95% CI 0.970-0.997]], HAQ-DI [OR 1.069 [95% CI 1.002-1.141]] and GS score [OR 1.073 [95% CI 1.005-1.141]] were independent risk factors for predicting anxiety in RA patients.

Conclusion: Mood disorders were almost doubled in frequency in early RA patients than non-early RA patients. RA Patients with short disease duration, high HAQ-DI and high GS score were more likely to be in depression and anxiety. More attention is needed to the psychological status of RA patients, especially those at an early stage, with poor physical function and severe synovitis.

AB0245
RHEUMATOID ARTHRITIS DISEASE ACTIVITY AND VITAMIN D LEVELS IN A COLOMBIAN COHORT

S. Herrera1, J. C. Diaz-Coronado1,2, D. Hernandez-Parrá1, C. Perez-Rios1, Y. Durango-Durango1, R. Pineda.Tamayo1, Artmedica IPS, Grupo de Información Clínica, Medellin, Colombia; 2CES University, Departamento Medicina Interna, Medellin, Colombia

Background: There seems to be a relationship between 25-hydroxyvitamin D [25(OH)D] level and rheumatoid arthritis (RA)(1). It has been proposed that susceptibility for RA exists in selected patients with low 25(OH) with conflicting results (2,3). Regarding disease activity, most of the evidence suggests an inverse relationship of disease activity with 25(OH)D levels(4). To our knowledge, there is only a small study that suggests low 25(oh) D levels as a predictor of disease activity (5) in our region

Objectives: We aimed to evaluate the possible association of low 25(OH) D levels and disease activity in a large cohort of patients with Rheumatoid Arthritis in Colombia

Methods: We evaluated the clinical records of 3576 patients with RA that fulfilled the 2010 EULAR Classification Criteria for Rheumatoid Arthritis and that were managed in our autoimmunity center between 2014 and 2017. Registries that contained both the measurement of 25(OH)D levels and DAS28 VSG with no more than 6 months apart and that had at least a mean 12-month follow-up were included. We classified 25(OH) D insufficiency as levels ≤ 20ng/ml. We evaluated differences in achieving disease control depending on the 25(OH) D levels with McNemar’s test. Disease control was defined as DAS28≤2.6.

Results: A total of 880 patients were included, 90% were female and their mean age was 63 years and 24.3% had 25(OH) D insufficiency. The vast majority were seropositive and only 13% were on biologics (Table 1). A 25% of patients who 25(OH)D insufficiency had DAS28 3.2 and a year of follow-up decreased to 24% with medical intervention (p=0.1), while patients without 25(OH)D insufficiency...
at the beginning of follow-up, 27% had DAS28 3.2 and after one year follow-up decreased to 17% (p=0.001)

**Table 1**

| Age (years) | 63.3 (10.6) |
| Disease Duration | 14.7 (10.8) |
| N (Positive) | 48.6 (13.5) |
| Sex (Feminine) | 793 (90.1) |
| Rheumatoid Factor (Positive) | 699 (85.6) |
| N=366 | 32.3 (77.6) |
| N=817 | 611 (69.4) |
| Active Biologic Therapy | 123 (13.9) |
| DMARD Methotrexate | 570 (64.8) |
| Leflunomide | 682 (77.5) |
| Sulfasalazine | 218 (24.8) |
| Azathioprine | 5 (0.6) |
| Antimalarials | 147 (16.7) |

**Conclusion:** In Colombian patients with rheumatoid arthritis low 25(OH) D status has an inverse correlation with disease control. Even in an equatorial country, up to 24% of RA patients had low vitamin levels. A strategy of active detection of 25(OH) D insufficiency could have an impact on disease activity and health status.

**AB0246 FACTORS ASSOCIATED WITH THE TIME OF PRESENTATION OF CARDIOVASCULAR EVENTS IN A COHORT OF COLOMBIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

S. Herrera1, J. C. Diaz-Coronado1,2, D. Rojias-Gualdrón2, L. Betancur-Vasquez2, D. Gonzalez-Hurtado2, J. Gonzalez-Arang2, L. Uribe-Arang2, M. F. Saavedra Chacón2, J. Lacouture-Fierro2, S. Monsalve2, S. Guerra-Zarama2, J. D. Serna2, J. Barbosa2, D. Hernandez-Parr2, A. Sierra2, R. Pineda. Tamayo.1, 1Artemedica IPS, Grupo de Información Clínica, Medellín, Colombia; 2CES University, Departamento Medicina Interna, Medellín, Colombia; 3CES University, Facultad de Medicina, Medellin, Colombia

**Background:** Systemic lupus erythematosus is a systemic disease characterized by a compromise of vital organs. The autoimmune activity has been linked to accelerated endothelial damage and increased cardiovascular risk and its outcomes such as heart attack, stroke, and peripheral arterial disease(1). Patients with Lupic nephritis have been characterized by requiring aggressive immunosuppressive therapies apart from prolonged and progressive use of corticosteroids, what you have shown can accelerate these outcomes(2). Other factors such as secondary arterial hypertension, dyslipidemia among others are factors to consider (3).

**Objectives:** To analyze clinical and immunological characteristics associated with time to severe renal involvement in patients with Systemic Lupus Erythematosus in a Colombian cohort followed for one year, between January 2015 and December 2018.

**Methods:** Retrospective follow-up study based on clinical records of patients with SLE diagnosis that fulfilled either 1987 American College of Rheumatology Classification Criteria for SLE or 2011 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE. Patients with cardiovascular disease outcomes such as angina, acute myocardial infarction, stroke, transient cerebral ischemia and chronic arterial occlusive disease were included. Patients who did not have at least two follow-up measurements or had structural heart disease, valvulopathies, arrhythmias, myocarditis, pericarditis were excluded. The main outcome was defined as the time from diagnosis to cardiovascular diseases.

Clinical and immunological characteristics were analyzed. Descriptive statistical analyses of participant data during the first evaluation are reported as frequencies and percentages for categorical variables, and as medians and interquartile ranges for quantitative variables. Age and sex adjusted survival functions and Hazard Ratios (HR) with 95% confidence intervals and p-values were estimated using parametric Weibull models for interval-censored data. P values < 0.05 were considered statistically significant

**Results:** 547 patients were analyzed: 29 were left-censored as they presented renal involvement at entry; 22 were interval censored as outcome occurred between study visits, and 496 were right-censored as involvement was not registered during follow-up. 528 (96.5%) patients were female, median age at entry was 46 (IQR = 23) and median age to diagnosis was 29.4 (IQR = 20.9). Statistically significant age and sex adjusted variables were High Blood Pressure (HBP) HR = 2.0 (95% CI 1.1-3.6; p-value <0.018) and cumulative prednisolone dose (>10 gr vs <2 gr) HR = 2.4 (95% CI 1.5-1.2; p-value = 0.023). Figure 1 shows the age and sex adjusted survival function for HBP

**Conclusion:** HBP and cumulative steroid doses accelerate the onset of cardiovascular diseases in patients with lupus more than two times. Maintaining blood pressure in goals and performing early clearance of glucocorticoids could improve outcomes in these patients who are already considered a high cardiovascular risk

LIFE QUALITY AND DEPRESSION LEVEL ASSESSMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Abstract

Background: Depression is a common and significant rheumatoid arthritis (RA) comorbidity that develops under the influence of several factors, the most important being disease activity, pain intensity and degree of disability.

Objectives: The goal of the investigation was to determineexistence of antidepressant use and assess life quality in patients living with RA.

Methods: The study sample comprised of 150 patients of average age 59.2 years, 79.2% of whom were women and 20.8% were men, who have lived with RA for an average of 9.6 years. For determining disease activity level, Disease Activity Score (DAS28) was utilized. Pain intensity and global disease activity were rated using a visual analogue scale ranging from 1 to 100mm. For functional capacity assessments, Health Assessment Questionnaire (HAQ) index was adopted.

Results: The elevated level of anti-TPO was found in 199/772 (26%) RA patients, compared to controls 32% (209/656). Furthermore, the level of anti-TPO was similar in seropositive and seronegative groups (24% and 27% respectively). RA patients treated with biological therapy presented higher level of anti-TPO in 28%, similarly to RA patients without biological therapy (24%). There was no relevant difference in level of anti-TPO among the groups with different disease activity (high activity: DAS28 ≥ 5.1; - 24%; moderate activity: DAS28 ≤ 5.1; > 3.2; - 25%; and in low activity DAS28 ≤ 3.2; - 28% respectively).

Conclusion: Our present data show that the elevated level of anti-TPO is similar in patients with serologically different forms of RA and in the control group. The presence of anti-TPO antibody does not affect the severity of RA and the results obtained with the treatment, including anti-TPO positivity does not increase the need for biological therapy.

POSITIVE EFFECT OF ANTIRHEUMATIC THERAPY ON THE COURSE OF CHRONIC HEART FAILURE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

Abstract

Background: The presence of anti-TPO antibody does not affect the severity of RA and the results obtained with the treatment, including anti-TPO positivity does not increase the need for biological therapy.

Results: Elevated level of anti-TPO was found in 199/772 (26%) RA patients, compared to controls 32% (209/656). Furthermore, the level of anti-TPO was similar in seropositive and seronegative groups (24% and 27% respectively). RA patients treated with biological therapy presented higher level of anti-TPO in 28%, similarly to RA patients without biological therapy (24%). There was no relevant difference in level of anti-TPO among the groups with different disease activity (high activity: DAS28 ≥ 5.1; - 24%; moderate activity: DAS28 ≤ 5.1; > 3.2; - 25%; and in low activity DAS28 ≤ 3.2; - 28% respectively).

Conclusion: Our present data show that the elevated level of anti-TPO is similar in patients with serologically different forms of RA and in the control group. The presence of anti-TPO antibody does not affect the severity of RA and the results obtained with the treatment, including anti-TPO positivity does not increase the need for biological therapy.

POSITIVE EFFECT OF ANTIRHEUMATIC THERAPY ON THE COURSE OF CHRONIC HEART FAILURE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

Abstract

Background: The presence of anti-TPO antibody does not affect the severity of RA and the results obtained with the treatment, including anti-TPO positivity does not increase the need for biological therapy.

Results: Elevated level of anti-TPO was found in 199/772 (26%) RA patients, compared to controls 32% (209/656). Furthermore, the level of anti-TPO was similar in seropositive and seronegative groups (24% and 27% respectively). RA patients treated with biological therapy presented higher level of anti-TPO in 28%, similarly to RA patients without biological therapy (24%). There was no relevant difference in level of anti-TPO among the groups with different disease activity (high activity: DAS28 ≥ 5.1; - 24%; moderate activity: DAS28 ≤ 5.1; > 3.2; - 25%; and in low activity DAS28 ≤ 3.2; - 28% respectively).

Conclusion: Our present data show that the elevated level of anti-TPO is similar in patients with serologically different forms of RA and in the control group. The presence of anti-TPO antibody does not affect the severity of RA and the results obtained with the treatment, including anti-TPO positivity does not increase the need for biological therapy.

References:
was determined by electrochemiluminescence. For all patients was started methotrexate (MT) therapy with a rapid increase in the dose to 30mg per week subcutaneously. If the MT was not effective enough, after 3 months a biological Disease-Modifying Anti-Rheumatic Drug (bDMARDs) was added to the therapy, predominantly TNF-alpha inhibitors. After 18 months, 10 (45%) patients were in remission and low disease activity, 6 (60%) of patients underwent MT therapy in combination with bDMARDs.

**Results:** In baseline CHF with preserved EF was revealed in 21 (95%) patients, in 1 patient - CHF with reduced EF. After 18 months there was a positive dynamics of improvement of clinical symptoms, echocardiographic indicators (decrease the size of the left atrium (LA) and the index of end-systolic volume of LA, IVRT, E' LV), diastolic function of the left ventricle (LV). There was no decompensation of CHF. LV diastolic function normalized in 7 (32%) patients who reached the target level of blood pressure, remission (n = 5) and low (n = 2) disease activity, mainly in the treatment of MT and bDMARDs. In patients with RA and CHF, the level of NT-proBNP decreased from 192.2 [15.1;4; 266.4] to 114.0 [90.4; 163.4] pg / ml (p < 0.001), normalized in 16 of 22 (73%) patients (p < 0.001) with remission or low RA activity. In 5 (22%) patients, the clinical manifestations of CHF regressed, LV diastolic function and NT-proBNP level normalized.

**Conclusion:** In patients with early RA and CHF anti-rheumatic therapy improves the clinical course of CHF. There were an improvement in the clinical course of CHF, diastolic function of the left ventricle and a decrease in NT-proBNP.

**AB0250 OSTEOPOROSIS, VERTEBRAL FRACTURES AND NON-ALCOHOLIC FATTY LIVER DISEASE IN RHEUMATOID ARTHRITIS: ARE THEY ASSOCIATED?**

H. Azzouzi1, B. Touil1, I. Linda1, Mohammmed VI University Hospital, Rheumatology, Oujda, Morocco

**Background:** Non-alcoholic fatty liver disease (NAFLD) is a frequent finding in rheumatoid arthritis (RA). It has been advanced that NAFLD and vertebral fractures (VF) are associated in healthy men recently(1).

**Objectives:** The aim of this study was to evaluate NAFLD association with BMD and VF in RA population.

**Methods:** Cross-sectional study was made at our rheumatology department, patients with RA have been assessed for NAFLD with ultrasonography and osteoporosis (hip and lumbar BMD) with DXA device. Patients with secondary liver disease (viral, alcoholic) were excluded. Data about osteoporosis risk factors, clinical features and laboratory tests (liver enzymes, lipid profile, hemoglobin, ferritin, etc) were collected. Anterior vertebral fractures (VF) were assessed by lateral spine radiographs. Comparison of patients with and without NAFLD was done by SPSS.20. Multiple regressions were made to explain osteoporosis and VF with models including NAFLD and other risk factors. Significance was defined by p under 0.05.

**Results:** We have included 172 RA patients, mean age was 55.4±11.9 years. Ninety per cent were females. Their average BMI was 26.8±5.47. Hypertension was diagnosed in 23.8% and 16.3% had diabetes. Forty per cent (40.1) had osteoporosis, 273% (47) had NAFLD. RA patients with NAFLD were older (p=0.04), obese (p=0.003), frequently associated to diabetes (p=0.02), Sjogren's disease (p=0.001), higher total cholesterol (p=0.02) and gamma-glutamyl transferase (GGT) (p=0.002). Comparison tests did not reveal any associations with fractures, BMD or osteoporosis. In multiple regression models, patients with NAFLD and altered liver enzymes were associated to VF (p=0.04, OR=4.71;0.05-21.69) but not to BMD when adjusted on age (p=0.02), BMI (p=0.02), diabetes, menopause and Sjogren's disease.

**Conclusion:** NAFLD was frequent among our RA patients and was associated to VF prevalence in this study but not to BMD.

**AB0251 SARCOPENIA IN MOROCCAN POPULATION WITH RHEUMATOID ARTHRITIS: PREVALENCE AND PREDICTIVE FACTORS**

E. Jalila1, H. Azzouzi1, I. Linda1, Mohammmed VI University Hospital, Mohammed I University, Rheumatology, Oujda, Morocco

**Background:** Patients with rheumatoid arthritis (RA) were at risk for altered body composition with higher prevalence of sarcopenia compared to the general population. Low lean muscle mass may constitute an additional risk factor for altered bone density in RA patients.

**Objectives:** We aimed to study the prevalence of sarcopenia and its predictive factors in Moroccan patients with RA.

**Methods:** We conducted a cross-sectional study over two months in our department of rheumatology. All RA patients fulfilled ACR/EULAR 2010 criteria. We performed a whole-body dual-energy X-ray absorptiometry (DXA) to measure lean mass, fat mass and bone mass in the whole body and body parts. The appendicular skeletal muscle mass was assessed using the sum of skeletal muscle mass in the arms and legs. The relative skeletal muscle mass index (RSMI) was calculated from the appendicular skeletal mass divided by the square of the patient’s height (kg/m2). According to Baumgartner et al, sarcopenia was defined as a relative SMI <5.5 kg/m2 on women and <7.26 kg/m2 on men. Body mass index (BMI) was measured and patients were classified according to World Health Organization. Disease activity and functional disability were measured using the 28-joint Disease Activity Score (DAS28) with CRP and the Health Assessment Questionnaire (HAQ). Comorbidities and medication use including corticosteroids were also recorded. Data was entered and processed using the IBM SPSS Statistics 20. A univariate analysis as well as multivariable regressions were carried out to assess the association between sarcopenia and lumbar spine and femoral neck (FN) bone mineral density (BMD) and RA characteristics.

**Results:** We included 70 (87.5%) women and 10 (12.5%) men with a mean age of 53.59±10.96 years old. They had a mean disease duration of 12.35±8.68, a mean DAS 28 CRP of 2.64±1.34, a mean HAQ of 0.94±0.63 and a mean RSMI of 5.75±1.17. Women had a mean RSMI of 6.33±1.04 while men had a mean RSMI of 5.66±1.17. The prevalence of sarcopenia in our population was 47.4% (37), of whom 81.1% (30) women.

In univariate regression analysis, sarcopenia was associated with normal BMI (OR: 8.59, 95% CI [3.054-24.182], p = 0.000), DAS 28 CRP (OR: 1.78, 95% CI [1.203-2.657], p = 0.004), HAQ (OR: 2.15, 95% CI [1.165-5.433], p = 0.019), lumbar spine BMD (OR: 0.01, 95% CI [0.00001-0.043], p = 0.0004) and FN BMD (OR: 0.00006, 95% CI [0.0000-0.02], p = 0.0008) at right FN and OR: 0.00009, 95% CI [0.00001-0.010], p = 0.006) at left FN.

In multiple regression analysis, sarcopenia was associated with normal BMI (OR: 11.56, 95% CI [2.754-48.598], p=0.001) and FN BMD (OR: 0.0, 95% CI [0.000-0.084], p = 0.006).

**Conclusion:** In the present study, sarcopenia was common among RA patients and associated with normal BMI and femoral neck BMD, emphasizing the importance of this modifiable risk factor. Further studies are needed to identify effective means to improve lean muscle mass in patients with RA.

**DOI:** 10.1136/annrheumdis-2020-eular.4448
Results: We included 73 RA patients with mean age of 52.7±11.7, their mean of body mass index was 26.6±5.8, their mean of disease activity score was 2.6±0.94 and the mean health assessment questionnaire was 1.14±0.78. In univariable linear regression, we found a significant association between (BMI), femoral BMD and (BFM) (p=0.001, β=-0.86, IC=[0.000005-0.000002]), (BFM) (p=0.001, β=-0.29, IC=[0.000001, 0.000008]) and (BFM) (p=0.001, β=-0.38, IC=[0.000005-0.000006]). There wasn’t any association between (VFM) and femoral BMD. Also we have found a significant association between lumbar spine BMD and BFm (p=0.0002, β=-0.41, IC=[0.000030-0.000011]), (AFM) (p=0.001, β=-0.38, IC=[0.000025-0.000053]), (AFM) (p=0.001, β=-0.47, IC=[0.000007-0.000001]) and VFM (p=0.01, β=0.28, IC=[0.000027, 0.000251]). Adjusted on BFm, GFM, AFM and VFM in multiple regression analysis, it seems that the association between GFM, femoral BMD (p=0.02, β=-0.38, IC=[0.000005-0.000008]) and lumbar spine BMD (p=0.01, β=-0.85, IC=[0.000022, 0.000166]), was more significant.

A REVIEW OF SMOKING CESSATION STRATEGIES AND LUNG CANCER SCREENING PRACTICES IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. A. Lopez-Olivo1, R. Volk1, K. J. Krause2, M. Suarez-Almazor3 1The University of Texas, MD Anderson Cancer Center, Health Services Research, Houston, United States of America; 2The University of Texas, MD Anderson Cancer Center, Research Medical Library, Houston, United States of America

Background: Smoking rates among patients with rheumatoid arthritis (RA) exceed those reported in the general population. In addition, people with RA who smoke are more likely to develop lung cancer than smokers who do not have RA.

Objectives: To identify smoking cessation strategies and lung cancer screening practices in patients with RA.

Methods: We conducted a review of the literature in electronic databases (i.e., PubMed, EMBASE, Cochrane, Scopus, and Web of Science) from inception until June 2019. We included studies that reported on the results of interventions for smoking cessation or lung cancer screening in patients with RA. We excluded case reports, reviews, guidelines, protocols, or studies on tobacco use not reporting interventions. We included studies published in abstract or full-text format. We extracted study and intervention characteristics including delivery format, timing and results.

Results: We retrieved 394 relevant citations and ultimately included 9 studies evaluating smoking cessation strategies, and one regarding lung cancer screening practices. Five studies were reported in abstract format. There were 3 studies conducted in the United Kingdom, and one each in Croatia, France, Ireland, New Zealand, Sweden, Spain and United States. Two studies were randomized control trials and the remaining were uncontrolled. Follow-up ranged between 1 month and 24 months, however, one study only reported data on the assessment immediately after the intervention. Sample sizes ranged between 20 and 185 current smokers. Smoking cessation strategies included: 1) brief advice and nicotine replacement therapy + smoking cessation counseling for 3 months; 2) information booklet on harms of smoking (i.e., impact on disease and treatment); 3) spoken information on harms of smoking (i.e., impact on disease and treatment) plus advice to quit smoking; 4) advice to quit smoking plus nicotine replacement; 5) smoking cessation support with contact every 4 weeks; 6) spoken information on harms of smoking (i.e., impact on disease and treatment) plus advice to quit smoking plus nurse telephone visit at 3rd month; 6) staff driven tobacco QUIT line referral process; 7) multi-modality intervention with advice to quit smoking plus guidance on safe alcohol use plus dietary advice with booklet and swimming group. The lung cancer screening study reported on a program with nurse evaluation of comorbidities and risk factors, and recommendations for lung cancer screening with a chest X-ray and smoking cessation. Most studies reported benefits when implementing a structured plan to educate, counsel, and offer pharmacological treatment to patients with RA.

Conclusion: There was large heterogeneity among studies in patient characteristics and interventions proposed, and outcomes. Only 2 studies were randomized clinical trials. Additional controlled studies are needed to determine best practices for smoking cessation and lung cancer screening in patients with RA.

Note: Comorbidities and CCI was calculated for patients during follow-up in respective cohort

Conclusion: Puerto Rican patients with RA have a significant burden of comorbidities, infections and hospitalisations. Trends indicate a variation in the burden by the type of treatment. Furthermore studies are warranted to better understand the potential healthcare implications of comorbidities in patients with RA.

DOI: 10.1136/annrheumdis-2020-eular.3739
BACKGROUND: Rheumatoid Arthritis (RA) are often in a relatively immunocompromised status. Previous study have shown an increased risk of fractures. No significant association was found between RF (+) and without fragility fractures. Women presented high risk of osteoporosis (p=0.007).

Objectives:

To investigate the baseline PCT levels among patients with RA without active infection compared with healthy controls. The treatment received by patients with RA did not affect the level of PCT. Further investigation is required to determine the optimal cutoff value of PCT among patients with RA before applying it in daily clinical practice.

Methods:

We perform an observational study in a cohort of patients diagnosed of RA according to 1987 and 2010 ACR criteria, to determine the frequency of osteoporotic fractures and associated clinical and densitometric variables. All patients diagnosed of RA were invited to participate in the study between 2013 and 2019, and to perform BMD DXA (GE LunarProdigy9). SPSS25 was used to compare variables between patients with fracture and without fracture.

Results:

A total of 623 patients with RA and 40 healthy subjects were recruited in this study. The mean PCT were significantly higher in patients with RA (6.90 ± 11.81 * 10^-3 ng/mL) compared with healthy controls (1.14 ± 3.26 * 10^-3 ng/mL) (p = 0.002). After adjusted for age and sex, the PCT levels remain significantly elevated in patients with RA (p = 0.001). PCT was not significantly correlated with biologic agent, age, sex, disease duration, disease activity. C-reactive protein, conventional synthetic disease-modifying antirheumatic drugs (csDMARD), and comorbidities. Multiple linear regression analysis showed that PCT was inversely associated with the expression of IL-18 (B = −0.883; CI 95% −1.388, −0.378, p = 0.001) and IFN-γ (B = −1.197; CI 95% −2.153, −0.242, p = 0.014) after adjusted for age and sex.

Conclusion: Patients with RA have significantly higher baseline PCT compared with healthy controls. The treatment received by patients with RA did not affect the level of PCT. Further investigation is required to determine the optimal cutoff value of PCT among patients with RA before applying it in daily clinical practice.

AB0257

ASSESSMENT OF PHYSICAL DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO PLANNED PREGNANCY FROM THE IORRA COHORT.

M. Ochiai1, E. Tanaka1, E. Inoue1,2, M. Abe1, E. Sugano1, N. Sugitani1, K. Sakai1, H. Yoko1, R. Yamaguchi1, N. Sugimoto1, K. Katsunari4, A. Nakajima1,4, A. Taniguchi1, H. Yamakawa1,2, M. Hariga1,1 Department of Rheumatology, Tokyo Women’s Medical University School of Medicine, Tokyo, Japan; 2Division of Medical Informatics, St. Marianna University School of Medicine, Kanagawa, Japan; 3Department of Orthopedic Surgery, Tokyo Women’s Medical University School of Medicine, Tokyo, Japan; 4Center for Rheumatic Diseases, Mie University Hospital, Mie, Japan; 5Rheumatology, Sanno Medical Center, Tokyo, Japan

Background: It has been reported that female rheumatoid arthritis (RA) patients have a longer time to pregnancy than healthy women (1), and that high Disease Activity Score with 28 joint count (DAS28) - GRP in preconception increases the frequency of infertility (2). Before the era of biologics, RA treatment tended to be inadequate from pregnancy planning to the end of lactation. And it was not uncommon for female RA patients to be unable to get pregnant or develop physical dysfunction as a result of insufficient control of the disease. There are some reports of disease activity during pregnancy and postpartum in RA patients, and the effects of RA disease activity on pregnancy and childbirth outcomes (3-5), but there are few reports focusing on the physical function during pregnancy planning of RA patients.

Objectives: To investigate disease activity and physical function in female patients with RA who planned and didn’t plan pregnancy.

Methods: The IORRA cohort is a large, single-institute-based, observational cohort of RA patients established at the Institute of Rheumatology, Tokyo Women’s Medical University, in 2000. We identified female RA patients aged 20-49 years who answered ‘pregnant’ or ‘delivered’ in the IORRA survey in 2010-2015 and whose pregnancy and the pregnancy planning time was confirmed in the medical records, and defined them as the pregnancy planning (PP) group. Matched control was extracted at 1:3 ratio from patients without active infection compared with healthy controls and to understand the relationship of PCT with RA disease activity, treatment received by patients, and the expression of proinflammatory cytokines.

Results: A total of 20 years and above, with clinician-confirmed diagnosis of RA were included during regular outpatient visits. RA disease activity was measured using the DAS28-ESR.

Conclusion: Women with RA present higher risk of fracture than men. The most sensitive indicator for fracture risk seems to be MBD in femoral neck.

INCREASED SERUM PROCALCITONIN CONCENTRATION IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO PLANNED PREGNANCY FROM THE IORRA COHORT.

K. J. No1,2, K. Y. Huang1,2, C. H. Tang1,2, M. C. Lu1,2, N. S. Lai1,2. Division of Allergy Immunology and Rheumatology, Dalin Tzu Chi Hospital, Chiayi, Taiwan, Republic of China; 2School of Medicine, Tzu Chi University, Hualien, Taiwan, Republic of China

Background: Rheumatoid arthritis (RA) is the most common inflammatory arthritis, affecting 0.5-1% of the general population worldwide. Patients with RA are often in a relatively immunocompromised status. Previous study have evaluated procalcitonin (PCT) application among autoimmune and autoinflammatory diseases for the diagnosis of systemic bacterial infection (1, 2) To date, the correlation of baseline PCT levels and RA disease activities, different treatment, or the expression of proinflammatory cytokines in patients with RA remained unknown.

Objectives: To investigate the baseline PCT levels among patients with RA without active infection compared with healthy controls and to understand the relationship of PCT with RA disease activity, treatment received by patients, and the expression of proinflammatory cytokines.

Methods: Patients aged 20 years and above, with clinician-confirmed diagnosis of RA were included during regular outpatient visits. RA disease activity was measured using the DAS28-ESR.

Results: A total of 623 patients with RA and 40 healthy subjects were recruited in this study. The mean PCT were significantly higher in patients with RA (6.90 ± 11.81 * 10^-3 ng/mL) compared with healthy controls (1.14 ± 3.26 * 10^-3 ng/mL) (p = 0.002). After adjusted for age and sex, the PCT levels remain significantly elevated in patients with RA (p = 0.001). PCT was not significantly correlated with biologic agent, age, sex, disease duration, disease activity. C-reactive protein, conventional synthetic disease-modifying antirheumatic drugs (csDMARD), and comorbidities. Multiple linear regression analysis showed that PCT was inversely associated with the expression of IL-18 (B = −0.883; CI 95% −1.388, −0.378, p = 0.001) and IFN-γ (B = −1.197; CI 95% −2.153, −0.242, p = 0.014) after adjusted for age and sex.

Conclusion: Patients with RA have significantly higher baseline PCT compared with healthy controls. The treatment received by patients with RA did not affect the level of PCT. Further investigation is required to determine the optimal cutoff value of PCT among patients with RA before applying it in daily clinical practice.

DOI: 10.1136/annrheumdis-2020-eular.172
which was defined as the most recent IORRA survey before planning pregnancy. The mixed-effect model for repeated measures was used to analyze group difference.

Results: There were 40 patients in the PP group (average 32.2 years, disease duration 5.7 years, DAS28-CRP 1.7, J-HAQ 0.26), and 120 patients in the control group (average 32.4 years, disease duration 5.9 years, DAS28-CRP 1.7, J-HAQ 0.21). The proportion of user and dosage of MTX and glucocorticoid (GC) and bDMARDs user at baseline were comparable between the groups (MTX: PP 87.5% [8.9/week], control 85.0% [8.8/week]; GC: PP 32.5% [3.8mg/day], control 27.5% [4.4mg/day]; bDMARDs: PP 40.0%, control 27.5%); DAS28-CRP at year 3 of the PP group elevated and was higher than the control group (PP 2.3, control 1.7, p<0.01), while J-HAQ was stable over the observation period and did not significantly at year 3 (PP 0.21, control 0.22, p=0.92). At year 3, the proportion of patients taking MTX was lower and taking GC was higher in the PP group than those in the control group (MTX: PP 36.7%, control 76.7%, p<0.01; GC: PP 70.0%, control 25.6%, p<0.01). The proportion of patients taking bDMARDs was not different in both groups (PP 36.7%, control 32.6%, p=0.68).

Conclusion: Physical function in pregnancy planning patients with RA did not deteriorate as well as the control patients in clinical settings.

AB0258 CAROTID INTIMA-MEDIA THICKNESS AND SERUM BIOMARKERS IN PARAGUAYAN PATIENTS WITH RHEUMATOID ARTHRITIS

V. Valinotti1, A. Paass1, R. Acosta1, L. Roman1, I. Acosta-Colman2, M. Duarte2, O. Centurion2, T. Martinez3, P. De Abreu4, G. Avalia5, S. Cabrera-Villalba5. 1Clinicas Hospital, Universidad Nacional de Asuncion, Rheumatology, Asunción, Paraguay; 2Hospital de Clinicas, Universidad Nacional de Asuncion, Cardiovascular Medicine, Asuncion, Paraguay; 3Laboratorio Curie, Asuncion, Paraguay; 4Sociedad Paraguaya de Reumatología, Asunción, Paraguay

Background: The mechanism of increased cardiovascular risk in RA is not well understood and is independent of traditional CV risk factors. Intima-media thickness of the common carotid wall measured by ultrasoundogram is a safe and useful biomarker of early stage atherosclerosis that correlates with coronary involvement; and it correlates with severity and duration of disease. Several studies have shown a relationship between inflammation markers, endothelial dysfunction markers, and carotid involvement. (1)

Objectives: To determine the presence of inflammation biomarkers and its relationship with subclinical atherosclerosis measured by carotid ultrasound, and with the clinical characteristics in patients with established Rheumatoid Arthritis (RA)

Methods: Descriptive, cross sectional, prospective study, in a Paraguayan cohort of patients with RA meeting ACR/EULAR2010 criteria. This study had two phases: the first one, included a standardized questionnaire according to the variables included in the Cardiovascular Risk project (PINVY1S-0346), from the National Sciences and Technology Council (CONACYT), and physical examination; the second one included laboratory sample collection performed by a specialized laboratory for serum biomarkers measurement for cardiovascular risk prediction (i.e. endothelin, alpha-TNF, E-selectin, homocysteine, apolipoprotein, fibrinogen, and high sensitivity-CRP levels) and carotid ultrasound evaluation by a trained specialist, to evaluate subclinical atherosclerosis. Subclinical atherosclerosis was defined as carotid intima-media thickness (CIMT) >0.9mm and/or presence of carotid plaques. All patients signed informed consent. SPSS 23rd version was used for data analysis. Quantitative variables were presented as means and qualitative as frequencies. Chi square test was performed for comparisons between dichotomous variables and Student for continuous, and p ≤ 0.05 for statistical significance.

Results: 100 patients were included, 87% were women, mean disease duration 130.9±102.84 months, 77% were RF positive, and 84.4% were ACPA positive, 43.4% had bone erosions, mean ESR-DAS28 was 3.42±1.1; 30% had remission criteria, 39% had extra-articular manifestations.

Elevated serum biomarkers were found: fibrinogen >400mg/dL 88.2%, high sensitivity-CRP (hs-CRP) >5mg/dL 42.9%, endothelin >2ng/mL 20%, alpha-TNF >15,6µg/mL 13.1%, E-selectin >79,2ng/mL 6.3%, 25% of patients had CIMT >0.9mm and mean CIMT was 0.68±0.25mm. 27.14% had carotid plaques. Patients with CIMT>1mm had higher frequency of family history of arterial hypertension (p<0.006), greater mean disease duration (p=0.0007), hip circumference (p=0.014), blood pressure (SBP p=0.038, DBP p=0.027), HAQ levels (p=0.019) and hs-CRP levels (p=0.013), also lower mean height (p=0.04); while carotid plaques were related to higher homocysteine (p=0.026) and hs-CRP levels (p=0.024).

Conclusion: A considerable percentage of patients had subclinical atherosclerosis. Patients with CIMT>0.9mm had a longer disease duration, higher HAQ levels, hip circumference, as well as higher BP. High levels of hs-CRP were more frequently related to the presence of subclinical atherosclerosis.

AB0259 THE RELATIONSHIP BETWEEN MICROVASCULAR DAMAGE AND DISEASE ACTIVITY IN PATIENT WITH RHEUMATOID ARTHRITIS – ASSESSMENT BY VIDEOCAPILAROSCOPY

M. Parvu1, A. Cozos2, A. I. Biro1, H. V. Popoviciu1. 1George Emil Palade” University of Medicine, Pharmacy, Science and Technology, Emergency County Hospital Targu Mures, Rheumatology and Physiotherapy, Tg. Mures, Romania; 2Emergency County Hospital, Targu Mures, Rheumatology and Physiotherapy, Tg. Mures, Romania

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterized by erosive synovitis (causing severe joint damage) and systemic damage.

References:

Disclosure of Interests: None declared

DOB: 10.1136/annrheumdis-2020-eular520
Rheumatoid vasculitis (RV) is an extra-articular manifestation of rare but serious rheumatoid disease that involves the damage of small and medium sized vessels.

**Objectives:** The purpose of the study was to evaluate the incidence of damages occurred on cutaneous level in patients diagnosed with RA and to detect capillaroscopic microangiopathy changes in the activity of rheumatoid disease.

**Methods:** 101 patients were included in the study, all were diagnosed with RA according to the ACR/EULAR 2010 criteria. RV diagnosis was based on the clinical examination. The capillaroscopic evaluation was performed with a 3.0 VideoCap device at a 200x magnification (200x magnification contact lenses). Capillaroscopic examination was performed on fingers II-V of both hands, being considered pathological if the capillaroscopic changes are present in at least two fingers. The activity of the disease was calculated using DAS 28 ESR score.

**Results:** 18% of examined patients was male and 82% female, with the mean age of 56.2 years±10.16SD, and the mean duration of the disease in years of illness was 8.65±6.31SD. 3 patients had periangual vasculitis with cutaneous ulceration and gangrene, 12 patients had palpable purpura. 29% of the patients had vasospastic skin changes. The activity score of RA was associated with the capillaroscopic changes in peripheral microangiopathy p=0.037. Capillaries images were heterogeneous in aspects and distribution, tortuous capillaries, microhemorrhages, giant/dilated capillaries, avascular areas were observed.

**Conclusion:** Vascular microangiopathy evidenced by capillaroscopic examination is present in patients with cutaneous vasculitis having a medium, severe activity of rheumatoid diseases.

**Sarcopenia and Rheumatoid Arthritis**

**V. Povoroznyuk1, N. Dzerovich1, O. Ivanyk2, T. Karasevska2, I. D. Chebotarev Institute of Gerontology NAMS of Ukraine, Kyiv, Ukraine; O. Bogomolots National Medical University, Kyiv, Ukraine**

**Background:** Nowadays in the field of syndromes and diseases associated with age, scientists focus special attention on the problem of sarcopenia, which combines an increased risk of falls, deterioration of life quality, impaired functional activity, reduced life expectancy and increased mortality of patients. In 2016, sarcopenia has been included in the International Classification of Diseases. There are the primary and secondary forms of sarcopenia.

**Objectives:** The aim of this study was to evaluate the bone mineral density, lean mass, frequency of pre-sarcopenia and analyze correlation among the activity parameters, duration of the disease, life quality and lean mass indices in women with rheumatoid arthritis.

**Methods:** 461 women aged 40-87 years (age – 57.17 ± 0.71 years) were examined, among them 71 patients with rheumatoid arthritis and 390 controls. We conducted the clinical and laboratory examination. Pain intensity was evaluated by the visual analogue scale, the quality of life – by the HAQ questionnaire. Lean mass, bone mineral density were measured by the X-ray absorptiometry (Prodigy; GEHC Lunar, Madison, WI, USA). Pre-sarcopenia was determined when an appendicular lean mass index was less than 2.41 kg/m² (V. Povoroznyuk, N. Dzerovich, 2016).

**Results:** Patients with rheumatoid arthritis had significantly lower femoral neck bone mineral density (p = 0.002), lean mass of the total body (p = 0.01) and appendicular lean mass (p < 0.01). We didn’t find any significant connection among the activity parameters (C-reactive protein, ESR, pain VAS, DAS-28), duration of the disease, life quality and lean mass indices in patients with rheumatoid arthritis. However, a significant correlation was found between the number of swollen joints and lean mass of upper limbs (r = 0.67, p = 0.001). The frequency pre-sarcopenia in women with rheumatoid arthritis was 49%, in the control group – 18%.

**Conclusion:** Patients with rheumatoid arthritis had not only bone tissue, but also skeletal muscle tissue disorders, resulting in a significant deterioration of functional capacity and quality of life. Given the significant medical and social significance of the problem, further studies into the mechanisms of pathogenesis, development of diagnostic methods, prevention and treatment of sarcopenia in patients with rheumatoid arthritis are required.

**Disclosure of Interests:** None declared DOI: 10.1136/annrheumdis-2020-eular.6150

**AB0261**  
**IMPACT OF COMORBIDITIES IN THE DISEASE ACTIVITY OF PATIENTS WITH SPONDYLOARTHRITIS AND RHEUMATOID ARTHRITIS: TUNISIAN REGISTRY (Binar)**

**R. Tekaya1, L. Rousched1, A. Ben Tekaya1, O. Saidane2, S. Bouden2, I. Malghemy3, B. Baklouti4, N. Bergaoui5, E. Bouajina6, M. Elleuch5, I. Ghasrallah5, M. M. Kchir7, S. Kochbati8, A. Laatar9, Y. Mohamed10, L. Abdelmoula1, 1Hospital Charles Nicolle, Rheumatology, Tunis, Tunisia; 2Hedi Chaker Hospital, Rheumatology, Sfax, Tunisia; 3Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia; 4Farhat Hached hospital, Rheumatology, Sousse, Tunisia; 5La Rabta, Rheumatology, Tunis, Tunisia; 6The Military Hospital in Tunis, Rheumatology, Tunis, Tunisia; 7Mohammed V University, Medical School in Rabat, Rheumatology, Rabat, Morocco; 8Kassas Institut, Rheumatology, Manouba, Tunisia; 9Hôpital Habib Thameur, Rheumatology, Tunis, Tunisia; 10Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia; 11Hospital University Tahar Sfar, Rheumatology, Mahdia, Tunisia**

**Background:** Comorbidities can be associated with rheumatoid arthritis (RA) and spondyloarthritis (SpA). This association can be fortuitous but can also be secondary to rheumatism itself or to the effects of the treatments used. These comorbidities can worsen the disease and even increase patient mortality.

**Objectives:** To assess the prevalence of comorbidities in RA or SpA patients from the Tunisian Biologics National Registry (Binar) and to focus on their influence on the disease activity.

**Methods:** Binar is a multicenter non-interventional and prospective study, conducted in Tunisia with 80 rheumatologists over a period of three years. It included patients with RA (ACR / EULAR 2010 criteria) or SpA (ASAS 2009 criteria). Data were collected and analyzed through an electronic platform managed by DACIMA. They included demographic data, smoking status and types of comorbidities (cardiovascular disease, diabetes, dyslipidemia, osteoporosis, high blood pressure (HBP), neoplasia, gastrointestinal ulcer, depression and fibromyalgia). RA activity was evaluated by the DAS28-MS score and SpA activity by the BASDAI and ASDAS-CRP scores.

**Results:** We included 298 patients (175 PR and 123 SpA) making the mean sex ratio 0.6 and mean age 49.18 years ± 14.1 [18-79]. Mean BMI was 27.0 ± 5.5 kg / m² (15-45) and 17.7% of the patients were current and former smokers. Concerning disease activity, mean DAS28-MS in RA was at 4.9 ± 1.5 [1.1 - 8.1] and mean BASDAI and ASDAS-CRP in SpA, respectively 4.1 ± 1.6 and 2.8 ± 1.1. Comorbidities were noted in 54% of patients (62.1% in SpA and 37.9% in RA), with an average of 1.7 comorbidities per patient. The most common comorbidities were osteoporosis (38.8%), cardiovascular disease (20.1%), diabetes (16.8%), HBP (18.1%), dyslipidemia (6.7%) and GIU (5%). Depression, fibromyalgia and neoplasia were mentioned in 1.7%, 1% and 1%, respectively.

No correlation was found between the number of comorbidities and the activity level of RA: DAS28-MS (p=0.12), nor the activity level of SpA: BASDAI (p=0.07), ASDAS-CRP (p=0.15). Correlations were studied between each comorbidity and activity parameters (C-reactive protein, ESR, pain VAS, DAS-28), duration of the disease, life quality and lean mass indices in patients with rheumatoid arthritis. However, a significant correlation was found between the number of swollen joints and lean mass of upper limbs (r = 0.67, p = 0.001). The frequency pre-sarcopenia in women with rheumatoid arthritis was 49%, in the control group – 18%.

**Conclusion:** Patients with rheumatoid arthritis had not only bone tissue, but also skeletal muscle tissue disorders, resulting in a significant deterioration of functional capacity and quality of life. Given the significant medical and social significance of the problem, further studies into the mechanisms of pathogenesis, development of diagnostic methods, prevention and treatment of sarcopenia in patients with rheumatoid arthritis are required.

Tableau n°1: Relation between comorbidities and the disease parameters of rheumatoid arthritis and Spondyloarthritis

Conclusion: According to this study, in patients with RA and SpA associated comorbidities may occur more frequently than expected (54%). However, they had no relation to the activity of the disease according to their frequencies or their types, except osteoporosis which was significantly associated with the SpA activity. Identifying these comorbidities may affect the management and treatment decisions for these patients to ensure an optimal clinical outcome.

AB0263 SEXUAL FUNCTION IN WOMEN WITH RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY.

G. Serna-Peña1, S. M. Sánchez Romo1, O. Ilizaliturri Guerra1, A. Cárdenas1, D. A. Galarraza-Delgado1, J. C. López Zamarrón1, 1Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico

Background: Sexual dysfunction is defined as a change in any component of sexual activity, which may cause frustration, pain and decreased sexual intercourse. Rheumatoid arthritis (RA) is a systemic autoimmune disease, which may lead to decline in joint mobility, pain, and fatigue; these impairments may influence the sexual health of patients.

Objectives: The main aim of this study is to determine if there is an altered sexual function in Mexican women with RA and compare if it occurs in a greater proportion than in healthy women.

Methods: A case-control study that included Mexican women between 18 and 65 years, with RA diagnosis (according to ACR/EULAR 2010 criteria) and age-matched controls was performed. Patients were excluded if they couldn’t answer the questionnaires reliably or were currently pregnant. They were asked about their sexual activity in the last month, and the Arizona Sexual Experiences Scale (ASEX), Hospital Anxiety and Depression Scale (HADS) and Functional Assessment of Chronic Illness Therapy (FACT) self-questionnaires were applied; disease activity was assessed by DAS-28. Variables were compared between groups with student T test for independent samples and chi-square.

Results: We included 102 RA patients and 101 controls. Baseline demographic characteristics between groups are shown in Table 1. Women with RA had less sexual activity than controls (48.03% vs. 90.09%, p <0.001). Out of the total women included, the ASEX was applied only to those that had an active sex life, 49 with RA and 91 controls. Sexual dysfunction (> 18 points) was found in 55.1% of women with RA and in 52.74% of controls, with no significant differences (p = 0.860); the prevalence of severe fatigue was higher in RA than in the healthy group (p = 0.009) (Table 2). Women with RA and sexual dysfunction had higher levels of anxiety (p = 0.024) and fatigue (p = 0.008) than those with RA without sexual dysfunction; however, no significant difference was found in age, depression and level of disease activity between these groups.

AB0264 ARTERIAL STIFFNESS IN RHEUMATOID ARTHRITIS PATIENTS AS A POTENTIAL PREDICTOR OF EARLY CARDIOVASCULAR AGEING AND MORBIDITY.

M. Schubertová1, A. Smržová1, P. Horák2, M. Sládeková2, E. Lokočová1, Z. Heimanová2, F. Mrázek2. 1Palacky University Olomouc, University Hospital Olomouc, Department of Internal Medicine III - Nephrology, Rheumatology and Endocrinology, Olomouc, Czech Republic; 2Palacky University Olomouc, University Hospital Olomouc, Department of immunology, Olomouc, Czech Republic

Background: Cardiovascular disease (CVD) is one of the most common causes of death in Rheumatoid arthritis patients. Increased arterial stiffness is considered as an independent risk factor of development CVD and a predictor of all-cause morbidity and mortality. Increased arterial stiffness, due to premature vascular ageing, can be observed in patients with chronic inflammatory diseases as well as in RA patients.

Objectives: To evaluate arterial stiffness determined as carotid – femoral pulse wave velocity in rheumatoid arthritis patients. The comparison of traditional and non-traditional risk factor of CVD, disease activity and laboratory findings connected with subclinical atherosclerotic changes.

Methods: We evaluated data of 50 patients with rheumatoid arthritis (39 females, 11 male, mean age 57, mean duration of disease of 13 years). The arterial stiffness, measured as carotid – femoral pulse wave velocity (PWV), was established with the SphygmoCor system. This non-invasive technique uses the principle of application tonometry. Our control group counted 25 healthy male and females with no history of CVD or autoimmune disease.

We evaluated the influence of traditional risk factors for CVD as age, smoking, BMI, lipid profile, diabetes mellitus, history of CV and cerebrovascular morbidity to PWV in RA patients. Non-traditional risk factors contained Adiponectin, Fetuin A, Endothelin-1 and Asymmetric dimethylarginine. To measure disease activity was used DAS 28 and inflammatory parameters as a marker of current disease activity. For chronic changes was used X-ray of small joints. Results were correlated with PWV and statistically evaluated.

Results: Mean PWV in Rheumatoid arthritis patients was significantly higher (9.7 m/s) than that in healthy control group (6.7 m/s), 49% of RA patients (n= 24) had increased arterial stiffness according to their age. 32% patients (n=16) with PWV over 10m/s that indicates aortal function alteration. We didn’t find correlation between arterial stiffness and traditional and non-traditional CVD risk factors. Increased PWV was not associated with high disease activity. Patients with higher arterial stiffness according to their age had longer RA history, higher level of rheumatoid factor, were more frequently anti-citrullinated protein antibodies (ACPA) negative and were more frequently treated with biological therapy.
Conclusion: Rheumatoid arthritis patients are in increased risk of CV disease. PWV is considered as an independent risk factor of CVD. We proved increased arterial stiffness and vascular ageing in comparison to healthy controls. We did not find correlation between increased arterial stiffness and disease activity. All CVD risk factor intervention is necessary to improve the prognosis of patients. Further investigation is needed to establish the role of increased PWV in RA patients.

AB0265

REDUCTION OF APPENDICULAR SKELETAL MASS INDEX IS A PREDICTOR OF FRACTURE IN PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON THE THREE-YEAR FOLLOW-UP DATA OF THE CHIKARA STUDY

M. Tada1, Y. Yamada2, K. Mandai3, N. Hidaka1. Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan; 2Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan; 3Osaka Social Medical Center Hospital, Orthopaedic Surgery, Osaka, Japan

Background: Patients with rheumatoid arthritis (RA) have lower muscle mass and a higher risk of fragility fracture compared with healthy individuals. The predictors for fractures among baseline data and the chronological changes of disease activity, body composition, and muscle mass are unknown.

Objectives: The predictors for fractures were investigated over a 3-year period in a longitudinal study.

Methods: The 3-year follow-up data from a prospective observational study (CHIKARA study: Correlation research of sarcopenia, skeletal muscle and disease activity in Rheumatoid Arthritis) were used. The patients’ fractures were counted, and correlations between fractures and disease activity, body composition, and sarcopenia were investigated. Muscle mass, body fat mass, total body water, bone mass, and basal metabolic rate were measured using a body composition analyzer. The fracture-free survival rate was calculated. The relationships between fractures and each parameter at baseline and the changes over the 3-year period (Δ) were investigated by univariate and multivariate analyses.

Results: A total of 100 patients (78 female, average age 68 years) were enrolled in this study; 12 patients (10 female and 2 male) had fractures during the 3-year follow-up, and the fracture-free survival rate was 86.9%. The modiﬁed Health Assessment Questionnaire (mHAQ), mHAQ, muscle mass, Δestimated bone mass, Δbasal metabolic rate, and Δappendicular skeletal muscle index (ASMI) were predictors for fractures. On the other hand, body composition, disease activity, and sarcopenia at baseline were not correlated with fractures (Table 1). The ΔASMI was an independent predictor for fractures on multivariate analysis (odds ratio:0.015, P=0.026). The estimated cut-off value of ΔASMI was 0.14 kg/m² on receiver operating characteristic curve analysis (Figure). When the ΔASMI decrease was greater than or equal to 0.14 kg/m² for three years, the odds ratio of fractures was significantly increased 9.8-fold, compared to a ΔASMI decrease less than 0.14 kg/m² (P=0.001).

Conclusions: The fracture-free survival rate was 86.9% in this 3-year longitudinal study. It was difficult to predict future fractures from the baseline data. Reduction of the ASMI was an independent predictor for fractures. Alleviating muscle mass loss may prevent fractures.

Background: Stress and fatigue are evaluated subjectively by patients using a visual analog scale (VAS) and questionnaires such as the SF-36 and the FACIT Fatigue Scale. Such evaluations are based on patients' self-reported outcomes. It is difficult to evaluate stress and fatigue objectively. A digitizing device was used to quantify stress objectively.

Objectives: To evaluate the correlations of a digitizing device and a VAS or a questionnaire about stress and fatigue, and the relationships with disease activity of patients with rheumatoid arthritis (RA).

Methods: Data from a prospective observational study (CHIKARA study: Correlation research of sarcopenia, skeletal muscle and disease Activity in Rheumatoid Arthritis) were used. The study protocol was reported previously. A total of 84 RA patients entered the study and were evaluated using a stress digitizing device (Smart Pulse, MEDICORE Co. LTD). This device evaluates stress based on heart rate variability theory. The objective physical stress score (O-physical ST), mental stress score (O-mental ST), and total stress score (O-total ST) were calculated, ranging from 0 to 100 (higher score indicating greater stress). A questionnaire for stress, the Perceived Stress Scale (PSS) 10 Japanese version (minimum 0, maximum 40), and VAS evaluations of stress (stress-VAS) and fatigue (fatigue-VAS) were carried out. The correlations between subjective and objective methods were analyzed. The relationships between stress, fatigue, and disease activity of RA patients were examined.

Results: The patients' mean age was 68.6 years (women n=66, men n=18), disease duration was 8.6 years, DAS28ESR was 3.24, and modified Health Assessment Questionnaire (mHAQ) was 0.5. The average PSS10 was 26.1, which was higher than in healthy individuals (20.3). The fatigue-VAS was higher than the stress-VAS (41.3 vs 34.5 mm). The O-physical ST score was similar to the O-mental ST score (39.5 vs 37.4). Correlations are shown in Table 1. The O-physical ST was positively correlated with the fatigue-VAS (R=0.243, p=0.026), and the O-mental ST was also positively correlated with the stress-VAS (R=0.267, p=0.014). However, there was no correlation between the PSS10 and objective stress parameters. The DAS28-ESR was correlated with the fatigue-VAS score (R=0.223, p=0.041) and the O-total ST (R=0.320, p=0.002). The stress scale (O-total ST) was worse with moderate and high disease activity than in remission (Figure).

Conclusion: The stress score obtained by an objective digitizing device was correlated with stress- and fatigue-VAS scores. However, there was no correlation with the PSS10 questionnaire. It was found that the fatigue-VAS score and the objective total stress score were high with worse disease control.

AB0267 BODY COMPOSITION IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Torogsotsy1, O. Dobrovolskaya1, N. Demin1, L. Shornikova1, V.A. Nasonova
Scientific and Research Institute of Rheumatology, Moscow, Russian Federation

Background: Rheumatoid arthritis (RA) is a complex inflammatory disease that modifies body composition. Using the dual-energy x-ray absorptiometry (DXA) in RA patients could be a method for body composition changes detection.

Objectives: To study the body composition using DXA in patients with RA.

Methods: The study involved 79 women with RA, median age 60 (55; 65) years. The bone mineral density (BMD) was measured by dual-energy x-ray absorptiometry using the Discovery A (Hologic, USA). Assessment of body composition was carried out, using the program «Whole body». Sarcopenia (SP) was diagnosed as a decrease in appendicular mass index (AMI) <6 kg/m². Osteoporosis (OP) was diagnosed as a decrease in T-score <−2.5 SD. Osteosarcopenia was determined when T-score was <−1.0 SD, AMI was <6 kg/m², and total fat was >35%.

Results: The mean duration of RA was 9 [3; 11] years. The mean body mass index (BMI) was 27.6±8.4 kg/m². Disease activity score in 28 joints-erythrocyte sedimentation rate was 4.5±1.3 points for the group. 39 (49.3%) patients used oral glucocorticoids continuously. Appendicular muscle mass and AMI were on average 17.8±3.0 kg and 6.8±1.0 kg/m², respectively. AMI <6 kg/m² was detected in 20 (25.3%) patients. 56 (70.9%) women with RA had total fat >35%, while only 22 (27.8%) of women with RA had obesity according to BMI (BMI >30 kg/m²). Isolated OP was found in 13 (16.5%), osteosarcopenia in 7 (8.9%) and osteosar- copenic obesity in 13 (16.5%) patients RA. No cases with isolated sarcopenia or sarcopenic obesity were detected. Only 3 (3.8%) patients did not have appendicular muscle mass, AMI and BMD decrease and overfat or obesity.

Conclusion: About 97% women with RA had abnormal body composition phenotype: 16.5% - OP, 8.9% - osteosarcopenia, 16.5% - osteosarcopenic obesity and 54.4% - overfat.

AB0268 HUMAN T-CELL LEUKAEMIA VIRUS TYPE 1 MAY INVALIDATE T-SPOT.TB RESULTS AMONG RHEUMATOID ARTHRITIS PATIENTS: A RETROSPECTIVE OBSERVATIONAL STUDY

K. Umeokita1, Y. Hashiba2, R. Kudou1, S. Miyachi1, M. Kimura1, M. Matsu1da, C. Iwao3, Y. Kariya1, T. Kawaguchi1, K. Takajo1, K. Iwao4, Y. Rikitake1, I. Takajo1, T. Hidaka5, A. Okayama1, 1University of Miyazaki, Department of Rheumatology, Infectious Diseases and Laboratory Medicine, Miyazaki, Japan; 2Zenjinkai Shinmin-no-Mori Hospital, Institute of Rheumatology, Miyazaki, Japan

Background: In clinical rheumatology, interferon-γ release assays (IGRAs) have been reported as a useful diagnostic test for latent tuberculosis infection (LTBI) before beginning the administration of biologics such as anti-TNF therapies (1). CD4-positive T cells are the main target in Human T-cell leukaemia virus type 1 (HTLV-1) infection. Several reports suggest that the reaction of tuberculin skin test (TST) is attenuated in HTLV-1-positive individuals compared with that in HTLV-1-negative individuals (2). However, it remains unclear whether IGRAs are reliable for detecting TB infection among HTLV-1-positive RA patients.

Objectives: The present study aimed to investigate the usefulness of the T-SPOT.TB assay in HTLV-1-positive RA patients. In addition, the association between the existence of IFN-γ producing T cells and HTLV-1 proviral loads (PVLs) in HTLV-1-positive RA patients was analysed on the basis of the T-SPOT.TB assay results.

Methods: We reviewed the medical records of 75 HTLV-1-negative and 29 HTLV-1-positive RA patients were suspected cases of LTBI and evaluated using the T-SPOT.TB assay as a clinical practice from April 2012 to July 2019. The results of T-SPOT.TB were collected from medical records, retrospectively. Peripheral blood samples were obtained from HTLV-1-positive RA patients for the analysis of HTLV-1 PVLs values. The study protocol was approved by the research ethics committees of our hospitals.

Results: Approximately 55% of the HTLV-1-positive RA patients showed invalid results for the T-SPOT.TB assay (p < 0.0001); the cause of invalid results was a spot-forming count of >10 spots in the negative controls of the T-SPOT.TB assay results. There were no between-group differences in female patient ratio, age, RA disease activity and therapeutic regimens. IFN-γ producing cells were detected in the peripheral blood of HTLV-1-positive RA patients without stimulation with TB-specific antigens.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2020-eular.2318
Conclusion: The incidence of invalid results for the T-SPOT. TB assay has been reported to be as low as 0.6% (3). The results of this assay for screening of LTBI in HTLV-I-positive RA patients should be interpreted with caution. Furthermore, our results show that an increase in IFN-γ producing T cell numbers due to LTBI in HTLV-1-positive RA patients should be interpreted with caution. Further investigation is needed to confirm these findings.

Conclusion: Our research shows that there is lymphocyte imbalance and immune disorder existing in RA patients with CAD. Both the number of lymphocyte subsets and cytokine levels decreased in these patients than pure RA patients. It suggests that this group may be in lower immune state, which providing guidance for further clinical treatment of RA patients with CAD.

AB0270 THE IMPACT OF DIABETES MELLITUS ON OUTCOMES OF RHEUMATOID ARTHRITIS AT 5-YEAR FOLLOW-UP: RESULTS FROM A MULTI-ETHNIC ASIAN COHORT IN SINGAPORE

C. Xu1, K. P. Leong1, M. Y. Yong2, E. T. Koh1, Tan Tock Seng Hospital, Department of Rheumatology, Allergy and Immunology, Singapore, Singapore; Tan Tock Seng Hospital, Department of Rheumatology, Allergy and Immunology, Singapore, Singapore

Background: Both diabetes mellitus (DM) and rheumatoid arthritis (RA) are prevalent diseases and represent the leading causes of disability and mortality worldwide. Systemic chronic inflammation is recognized as the underlying characteristic of RA. The inflammatory activity and presence of subclinical atherosclerosis are thought to play a significant role in the occurrence of cardiovascular disease (CVD). The aim of the present study was to explore the impact of diabetes mellitus on the outcomes of RA at 5 years follow-up in a multi-ethnic Asian cohort in Singapore.

Methods: A total of 1005 patients with RA were included in the present study, of whom 446 patients (44.4%) were diagnosed with DM. The patients were followed-up at 5 years for comparison of the outcomes of RA considering the presence of DM. The outcome measures included disease activity, inflammatory activity, and subclinical atherosclerotic burden. The data were analyzed using the Chi-squared test and Mann-Whitney U test.

Results: At 5 years follow-up, the patients with DM had significantly higher disease activity, inflammatory activity, and subclinical atherosclerotic burden compared to the patients without DM. The patients with DM also had significantly higher rates of hospitalization, emergency visits, and medication use for DM compared to the patients without DM.

Conclusions: The present study highlights the significant impact of diabetes mellitus on the outcomes of RA at 5 years follow-up in a multi-ethnic Asian cohort in Singapore. The results suggest that the management of diabetes mellitus should be prioritized in patients with RA to improve the outcomes of RA.
etiology of a variety of diseases, including DM and RA [1]. Additionally, cardio-vascular and musculoskeletal complications from DM may influence the outcomes of RA patients.

**Objectives:** To investigate the impact of DM on outcomes of RA patients.

**Methods:** This is a cross-sectional study including 583 RA patients with 5 years' history after diagnosis in Tan Tock Seng Hospital RA registry, Singapore from 2001 to 2013. Information related to demographics, serologies, clinical features, comorbidities, and outcomes was collected. Independent t-test or Mann-Whitney U test was used to compare continuous quantitative data, while Pearson Chi-square or Fisher Exact test for categorical data. With adjustment for age, gender, ethnicity, smoking and comorbidities, multivariate regressions were performed to analyze the impact of DM on outcomes of RA patients.

**Results:** DM is more prevalent in Malay and Indian patients than Chinese patients with RA (26%, 24% and 11% respectively, \( p = 0.005 \)). There is no difference of disease activity between DM and non DM patients. There is a tendency that non diabetic RA patients use more methotrexate (\( p = 0.058 \)) and leflunomide (\( p = 0.058 \)). Diabetic RA patients are in higher risk of poor American College of Rheumatology (ACR) functional status (\( p = 0.009 \)), knee arthroplasty (\( p < 0.001 \)) and admissions (\( p = 0.006 \)). Adjusted for age, gender, ethnicity, smoking and comorbidities, multivariate regression analyses showed a trend of poor function status for diabetic RA patients, i.e. ACR functional status (adjusted odds ratio [aOR]: 1.802, 95% confidence interval [CI]: 0.968 – 3.353, \( p = 0.068 \)) and median Health Assessment Questionnaire (HAQ) (6 coefficient value: 0.129, 95% CI: -0.010 – 0.267, \( p = 0.068 \)), and higher risk for knee arthroplasty for diabetic RA patients (aOR: 3.480, 95% CI: 1.016 – 11.920, \( p = 0.047 \)).

**Conclusion:** This is the first report on the impact of DM on RA outcomes in a long term follow-up RA registry in a multiethnic Asian society.

**AB0271 EFFECTIVENESS OF DULOXETINE FOR RELIEF OF THE REMNANT PAIN OF RHEUMATOID ARTHRITIS PATIENT WHOSE DISEASE ACTIVITY IS REMISSION**

I. Yoshii, I. Yoshii Hospital, Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan

**Background:** Pain control in rheumatoid arthritis (RA) patient is an important matter. When pain remains even disease activity is remission, it causes deterioration of activity in daily living (ADL) in past research. In other words, pain affects ADL independently from disease activity, namely the Health Assessment Questionnaire (HAQ) score, a most popular index of ADL for patient with RA[1]. Thus, burden of remnant pain despite clinical remission in RA is serious and pending subject. Duloxetine, a potent reuptake inhibitor of serotonin and noradrenaline, is developed for the treatment of major depressive disorder [2]. It's effectiveness for pain relief with osteoarthritis is also widely accepted. This drug should be effective not only for chronic pain due to osteoarthritis, but also due to RA. However, effectiveness of duloxetine for remnant pain relief in patient with RA in clinical remission is still unclear.

**Objectives:** In this study, effectiveness of duloxetine for the remnant pain despite clinical remission in patient with RA was statistically evaluated.

**Methods:** RA patients whose pain score with visual analog scale (PS-VAS) >30mm despite Clinical Disease Activity Score (CDAI) is <2.8, were picked up for the study. These patients were divided into groups whether duloxetine was administrated (a group without duloxetine: G-C; a group with duloxetine: G-D).

PS-VAS, C-reactive protein, CDAI and simplified disease activity index (SDAI), modified Health Assessment Questionnaire (mHAQ), and QOL value which is calculated from Euro-QOL 5-Dimensions (EQ-5D) were measured at the initiation of duloxetine in the G-D and at the first CDAI remission attained in the G-C, and at week 12 thereafter. Change of these indices were compared with One sample T-test for each group. Patient's global assessment (PGA) at baseline compared to the other components of CDAI was evaluated for each group statistically with One-tailed T-test.

Differences between the two groups at each moment were statistically evaluated with Mann-Whitney U-test. Statistical significance was set less than 1%. All statistical analyses were performed using StatPlus:mac² (AnalystSoft Inc., Walnut, CA, USA).

**Results:** A total of three hundred and six patients were recruited. G-D counted sixty-eight with 18 males and 50 females, while G-C counted 238 with 57 males and 181 females. Average age were 71.3 and 71.5 for G-D and G-C, respectively, with 53.6 months for time span from baseline to initiation in the G-D. 60.6% of the patients in G-D sustained to administrate duloxetine. PGA was 0.6 and 0.5 for G-D and G-C respectively, while the other component of CDAI were below 0.3 in average for both groups and these values were significantly lower than the PGA score in both groups. PS-VAS was 46.4 and 44.0, and significantly decreased to 26.1 and 36.0 in average for G-D and G-C respectively at week 12 when compared to baseline. Reversely, the CDAI score was significantly elevated significantly from 1.16 and 1.19 to 3.25 and 4.34 for G-D and G-C respectively. PGA also significantly increased to 1.5 and 2.4 for G-D and G-C respectively. CRP and the SDAI score also demonstrated same trend significantly as the CDAI score for both groups. mHAQ decreased significantly from 0.430 and 0.495 to 0.393 and 0.487 for G-D and G-C respectively. QOL value increased from 0.800 and 0.817 to 0.811 and 0.840 for G-D and G-C respectively, however no statistical significance demonstrated in both groups.

**Conclusion:** Duloxetine has been suggested to have effectiveness for the pain relief, for improvement of ADL, and for the contribution to QOL maintenance, however, no effect of disease activity control is expected.

**14. Rheumatoid arthritis - biological DMARDs**

**AB0272 SWITCHING FROM ETANERCEPT ORIGINAL TO ETANERCEPT BIOSIMILAR. EXPERIENCE IN A TERTIARY HOSPITAL.**

V. Aldasoro1, J. Mendizabal1, S. Perez Garcia1, G. Sada Urmeneta1, J. Restrepo Vélez1, N. Del Val del Amo1, I. Paniagua Zudaire1, R. Gutiérrez Polo1, L. Horcada1, L. Garrido Courel1, C. Fito-Manteca1. Navaurre University Complex, Rheumatology, Pamplona, Spain

**Background:** With the arrival of biosimilar drugs and savings policies to make the health system sustainable, hospital managers have chosen to make changes from original molecules to biosimilar drugs.

**Objectives:** This work aims to reflect what happens when making these switchings.

**Methods:** We reviewed 235 patients who started Etanercept original in Rheumatology at Navarra Hospital Complex and Henares University Hospital and their switch to Etanercept biosimilar with a follow-up of 6 months.

**Results:** The switch was performed in 174 patients with psoriatic arthritis (PsA), rheumatoid arthritis (RA), anklyosing spondylitis (AS), juvenile idiopathic arthritis, SAPHO and spondyloarthritisd. 9.8% discontinued treatment: 6 RA (8.1%), 5 PsA (9.8 %) and 6 AS (20.7%); all of them in the injection presentation. 12 patient stopped treatment due to ineffecacy, 2 due to reaction at the injection site, 2 due to diarrhea and 1 due to headache. Among 88.2% of patients who returned to Etanercept original, 28.6% did not achieve good response and had to change of treatment. The median persistence time from original molecules to biosimilar drugs.

**Conclusion:** In our series, approximately 10% of switching patients failed after a 6-month of follow-up; when trying to return to Etanercept original 28.6% did not achieve response.

The median persistence time in the original molecule and the percentage of failures observed in AS could be two conditions to consider before switching. A longer-term follow-up and a greater number of patients are necessary to ratify these data.

AB0273 PREDICTORS OF DRUG SURVIVAL OF BDMARDS IN BIO-NAIVE PATIENTS WITH RHEUMATOID ARTHRITIS (RA) DURING THE FIRST YEAR OF TREATMENT.

E. Aronova1, G. Lukina2, G. Gridneva1, S. Glukhova1, A. Kudryavtseva1.1 V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2 Moscow Clinical Scientific Center named after Loginov A. S., Moscow, Russian Federation

Objectives: To investigate predictors of drug survival of bDMARDs in previously bio-naive patients (pts) with RA during the first year of therapy.

Methods: 204 adult bio-naive pts (173 women, 84.8%), with active RA, despite the concomitant DMARD therapy, were included into retrospective study. All of them initiated bDMARDs: infliximab (INF) - 65 pts (31.9%), rituximab (RTM) - 39 (19.1%), adalimumab (ADA) - 30 (14.7%), etanercept (ETA) - 28 (13.7%), abatacept (ABA) - 23 (11.3%), tocilizumab (TZ) - 15 (7.4%), certolizumab pegol - 4 (1.9%). The following indicators were used as survival predictors: sex, age, and clinical form of RA. Pts were divided by age according to the classification adopted by the World Health Organization: 18-44 years (74 pts), 45-59 years (68 pts), 60-74 years (57 pts), 75 years or more (5 pts). Clinical forms of RA were represented: RA, seronegative by rheumatoid factor (RF), seronegative by RF, RA with extra-articular manifestations, adult-onset Still's disease, juvenile RA. Predictors of therapy inefficacy or AE were investigated in Cox proportional risk model. Survival on drug was estimated using Kaplan-Meier method and evaluation of difference significance using log-rank criterion.

Results: A year later, 92 pts (45%) remained on bDMARDs and 112 pts had discontinued. The reasons of bDMARDs discontinuation during the first year of treatment were: lack of effectiveness (including primary inefficacy) - 50%, adverse events (AE) - 25%, administrative causes - 17%, remission - 6.25%, death due to reasons unrelated to the therapy - 1.75%. By the end of the observation period, the best survival was shown by RTM therapy (69.23% of patients continued treatment for a year), ETA (44.4% of patients) and ABA (43.48% of patients). Discontinuation of bDMARDs due to remission was achieved in 7 patients and proved to be significantly higher in the RTM group (10.26%, p < 0.05) compared to the ABA group (8.7%) and ADA group (7.4%). Although the number of women continued the therapy was higher (69.23%), p = 0.03). After a year, the number of pts continuing treatment in all age groups remained comparable, and the difference between them - statistically not significant: 1 group (18-44 years old, 29 pts) - 31.52% of pts, 2 group (45-59 years old, 36 pts) - 39.13%, 3 group (60-74 years old, 26 pts) - 28.26%, 4 group (75-90 years old, 1 pts). Discontinuation of bDMARDs due to inefficacy was noted in 1 group more often (46.43%, 26 pts, p =0.03), in other groups this indicator was 33.93% (19 pts) in the 2nd group, 19.64% (11 pts) in the 3rd group and 0% in the 4th group. Discontinuation therapy due to AE was also prevalent in 1 group (50%, 14 pts) than in 2 (14.3%, 4 pts), 3 (32.1%, 9 pts) and 4 (3.6%, 1 pts). Discontinuation of therapy due to inefficacy was more common in the group of seronegative RA - 59.1% (p < 0.05). In the seropositive RA group 24.8% of pts had interrupted bDMARDs for this reason, in the RA with extra-articular manifestations group it was 18.1%, in the adult-onset Still’s disease group - 30% and in the juvenile RA group - 30%. Discontinuation of therapy due to remission was overwhelmingly observed in seropositive RA group (6 pts, 4%), and was significantly higher than in other groups (1 patient in RA with extra-articular manifestations group, 4.5%).

Conclusion: Female sex, young age (18-44 years), RA, seronegative by RF were associated with less survival of bDMARDs due to lack of effectiveness and/ or AE, and RTM and seropositive RA - with more frequency of discontinuation of therapy due to remission.

AB0274 USE OF TNF-INHIBITORS BIOSIMILARS IN CHRONIC INFLAMMATORY ARTHRITIDES: A THREE-YEAR EXPERIENCE IN A LARGE MONOCENTRIC COHORT OF PATIENTS FROM THE NORTH-EAST ITALY

D. Astori1, F. Ometto2, L. Friso2, B. Raffinei2, C. Botsios2, A. Doria2. 1 Rheumatology Unit, University of Padova, Padova Hospital, Department of Medicine – DIMED, University of Padova, Padova Hospital, Padova, Italy; 2 Rheumatology Unit, University of Padova, Padova Hospital, Department of Medicine – DIMED, University of Padova, Padova Hospital, Padova, Italy

Background: In recent years several biosimilars (BS) of tumour necrosis factor inhibitors (TNF-I) were introduced. At the Padova University Hospital the first BS of etanercept (bsETN) was available in October 2016 and the BS of adalimumab (bsADA) was available in November 2018.

Objectives: The objectives of the study were to evaluate the rate of biograma- tor-biosimilar (BO-BS) switch in all patients with rheumatoid arthritis (RA), psoriatic arthritis (PSA) and axial spondyloarthritis (axSpA) in the cohort of the Padova University Hospital and to examine factors favouring BO-BS switch. Secondly, we investigated survival of BO-BS switch and BO treatment and factors associated with longer treatment survival.

Methods: We considered all patients on ETN originator (boETN) treatment when the first bsETN was available (1st October 2016) and all patients on ADA originator (boADA) when bsADA was available (1st November 2018). Patients were followed until 30 August 2019 and were classified as BO-BS switchers if they underwent a switch from either boETN or boADA to BS during the follow-up, otherwise they were considered as continuing BO treatment. Factors associated with BO-BS switch were tested with a multivariable regression analysis. To test the survival of the BO-BS switch and of the BO treatment, Cox regression analysis was used including all variables achieving a p<0.10 in univariate analysis tested with Log-rank test and Kaplan-Meier curves.

Results: Among 1208 patients (553 RA, 433 PSA, 215 axSpA), 560 (46.3%) patients switched to bsETN (391) or bsADA (169). Mean disease duration was 16 (14.2) years and mean duration of the bDMARD treatment was 96.3 (56.6) months. After adjustment for potential confounders, factors associated with BO-BS switch were a longer disease duration, a shorter duration of previous bDMARD treatments and diagnosis (Tab.1) RA patients had almost a 3 fold increased likelihood of being switched to BS compared to PSA and axSpA, while difference between PSA and axSpA was not significant. Following Cox regression analysis we observed a longer drug survival in BO-BS switchers compared to those continuing with BO (HR 1.32; p<0.001) (Fig. 1). A longer drug survival was also associated with a longer disease duration (≥15years: HR 1.75; 95% C.I. 1.5-2; p<0.001) (Fig. 1). Following Cox regression analysis we observed a longer drug survival in BO-BS switchers compared to those continuing with BO (HR 1.32; 95% C.I. 1.2-1.58; p<0.001), longer mean duration of previous bDMARDs (≥5years: HR 4.1; 95% C.I. 3.5-4.7; p<0.001), and diagnosis (RA vs PSA: HR 1.22; 95% C.I. 1.02-1.47; p=0.030; RA vs axSpA: HR 0.89 95% C.I. 0.67-0.97; p=0.023; PSA vs axSpA: HR 0.66; 95% C.I. 0.57-0.77; p<0.001) (Fig. 2).

Conclusion: BO-BS switch was undertaken in almost half of the patients. Patients with longer disease duration and longer bDMARD duration were the most likely to be switched successfully to BS. BO-BS switching does not affect the survival of the treatment, indeed, it provides sustained effectiveness particularly if undertaken in patients with stable disease activity.

COMPARATIVE EFFICACY (DAS 28) OF TOCILIZUMAB AND OTHER TARGETED IMMUNE MODULATORS (TIMS) FOR RHEUMATOID ARTHRITIS: A NETWORK META-ANALYSIS (NMA)

Background: With a ‘treat to target’ approach in RA, guidelines recommend tailored monitoring of disease activity using validated composite instruments, such as the disease activity score (DAS) 28. While response assessment at 24 weeks is the standard in clinical trials, assessment as early as 12 weeks is recommended. There is limited evidence assessing the relative efficacy of TIMs following a ‘treat to target’ strategy.

Objectives: To evaluate the relative efficacy of intravenous (IV) and subcutaneous (SC) tocilizumab plus a conventional disease modifying antirheumatic drug (cDMARD) to other TIMs plus a cDMARD in TIM-naïve or mixed (<20% TIM-experienced) adults with moderate to severe RA. Efficacy was defined as achieving remission according to a DAS28 score <2.6 at 12 and 24 weeks.

Methods: Randomized controlled trials (RCTs) were selected from a recent systematic literature review conducted by the Institute for Clinical and Economic Review (ICER), as well as from trials for upadacitinib (SELECT-NEXT, SELECT-COMPARATE), which were not included in the ICER 2017 report. RCTs that compared TIMs to each other or placebo were included. Treatments included Janus kinase (JAK) inhibitors (upadacitinib, baricitinib, and tocilizumab), tumor necrosis factor alpha inhibitors (TNFi; adalimumab, certolizumab pegol, golimumab, and infliximab), and other non-TNFis (rituximab, sarilumab, tocilizumab, and abatacept). A Bayesian NMA was performed in OpenBUGS and R using a fixed effects model. Model selection was based on deviance information criterion. Forest plots of odds ratios (OR) are presented.

Results: In the 12-week analysis, 15 trials were included with a pooled study population of 9,154 patients. Populations were similar across trials and predominantly female (mean 78%, range 39-87%), with a baseline mean age of 52 years (range 47-56), mean disease duration of 8 years (range 2-11), and mean DAS28 score of 6 (range 5-7). In the 12-week analysis, compared to cDMARD, all TIMs were more likely to achieve remission (statistically significant), but tocilizumab IV showed a substantially greater magnitude of effect (OR=19.3, 95% CrI=10.99, 37.22) which was consistent with raw trial results (Figure 1). In pair-wise comparison, tocilizumab IV was associated with a greater likelihood of achieving remission compared to abatacept IV (OR=7.47, CrI=2.53, 20.89), abatacept SC (OR=4.29, CrI=1.96, 9.94), baricitinib (OR=3.39, CrI=1.74, 7.09), abatacept (OR=6.10, CrI=2.68,10.42), tocilizumab (OR=5.44, CrI=1.26, 20.57), upadacitinib 15mg (OR=3.23, CrI=1.72, 6.54), and upadacitinib 30mg (OR=4.05, CrI=1.97, 8.85).

In the 24-week analysis, 21 trials were included in the analysis with a pooled study population of 12,180 patients. Patient characteristics were the same as the 12 week analysis. Compared to cDMARD, all TIMs were more likely to achieve remission (statistically significant), with tocilizumab IV and SC showing a greater magnitude of effect (OR=12.08, 95% CrI=8.09-18.30 and OR=11.98, CrI=5.17 -35.86, respectively) (Figure 2). In pair-wise comparison, tocilizumab IV and SC were associated with a greater likelihood of achieving remission compared to abatacept IV, adalimumab, baricitinib, infliximab, upadacitinib 15mg, and sarilumab.

Conclusion: Results of this NMA demonstrate that tocilizumab is associated with a greater likelihood of remission (DAS28 <2.6) at 12 and 24 weeks compared to most other TIMs including new JAK inhibitors, when used in combination with a cDMARD among TIM-naïve/mixed patient populations.

Figure 1. DAS28 at 12 weeks—All TIMs were more likely to achieve remission compared to cDMARD, but tocilizumab IV showed a substantially greater magnitude of effect that was consistent with raw trial data.

* 95% CrIs that do not overlap with 1 are statistically significant

cDMARDs are defined as systemic agents with broad immunomodulatory effects like methotrexate, lefunomide, hydroxychloroquine, and sulfasalazine.
Figure 2. DAS28 at 24 weeks—All TIMs were more likely to achieve remission compared to cDMARD, but tocilizumab IV and SC had a greater magnitude of effect.

AB0276 DIFFERENCES BETWEEN IMPACT OF BIOLOGICAL TREATMENT AND IMPACT OF CONVENTIONAL TREATMENT ON PRODUCTIVITY AND QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Boopievic1, N. Mikelovic2, S. Aligrudic3, R. Medjedovic3, D. Loncar3, A. Bulatovic4, Clinic Center of Montenegro, Clinic of Internal Medicine, Rheumatology Department, Podgorica, Montenegro; Mercur Nera Polyclinic, Podgorica, Montenegro; Faculty of Economics, University of Belgrade, Podgorica, Montenegro

Background: Number of patients with rheumatoid arthritis in Montenegro amounts around 3,000, while 8% of them are on biological therapy. This percent is similar, or even higher in comparison to countries that are highly comparable to Montenegro. However, the percentage is still lower than in European countries.

Objectives: Objective of the study was to identify the differences between impact of biological and conventional therapy on quality of life of RA patients, their work ability and productivity, mental health, emotional state and social inclusion.

Methods: The analysis was based on data gathered from the questionnaires filled by RA patients in Montenegro: 92 patients treated with biological therapy and 78 treated with conventional therapy. More insights and information from examined patients were gathered on two focus groups. Following indicators were used in the study: two indicators that measure work ability and productivity; one monetized – Work Productivity and Activity Impairment Questionnaire General Health V2.0 (WPAI-GH) and one non-monetized – RA Work Instability Scale (RA WIS), and two indicators that measure quality of life – Health Assessment Questionnaire (HAQ-DI) and RAND 36-Item Health Survey (SF-36).

Results: WPAI-GH results are used in evaluation of absenteeism and presentism costs per RA patient per annum, which are caused exclusively by rheumatoid arthritis. RA WIS results are presented in the following figure. Total cost of absenteeism and presentism of RA patients in Montenegro amounts to 3.8 million EUR per annum. Results of RA WIS indicator suggest that patients treated with biological therapy are characterized by low to moderate level of work instability, and patients treated with conventional therapy by moderate level. Patients treated with biological therapy have shown 25% lower level of work instability. HAQ-DI indicator shows that both groups of patients are characterized by mild difficulties to moderate disability in performing everyday activities. However, patients treated with conventional therapy deal with higher level of difficulties, even though their level of RA progression is lower, on average. SF-36 indicator shows that patients treated with conventional therapy have lower level of physical functioning, followed by 26% higher pain intensity. They are 25% more exposed to limitations due to physical health problems caused by RA, and 20% more to limitations due to emotional problems. Patients treated with biological therapy, on average, rate their health with 50% higher rank in comparison to subjective health rate of patients treated with conventional therapy. They also feel that their health has improved during the past year, or stayed approximately the same, while patients treated with conventional therapy feel that their health condition has aggravated, or stayed unchanged.

Conclusion: Results show that health condition, emotional state and life quality are better among the patients treated with biological therapy. Also, their productivity is higher compared to patients treated with conventional therapy. This conclusion is additionally supported by the fact that there is more progression of disease among RA patients treated with biological therapy, as well as by the fact that the average duration of RA is almost two times longer among examinees who are on biological therapy than among examinees who are on conventional therapy. Accordingly, access to biological therapy for greater number of patients in earlier stage of disease would result in reduction costs of lost productivity and work disability connected to RA, as well as in mitigation of RA impact on lives and functionality of patients.

AB0277 PREVALENCE OF HEPATITIS MARKERS IN PATIENTS TREATED WITH BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS: RESULTS OF THE TUNISIAN REGISTRY BINAR

A. Faza1, H. Boussa2, S. Miladi1, K. Ouenniche1, L. Souabni1, S. Kassab1, S. Chekili1, K. Ben Abdelghani1, L. Abdelmoula2, S. Baklouti3, N. Bergaoui3, E. Bouajina1, M. Elleuch6, I. Gharsallah7, Y. Mohamed8, M. M. Kchir9, S. Kochbati10, A. Laatar1.

Background: In the recent decades, biological disease-modifying antirheumatic drugs (bDMARDs) have significantly improved management and quality of life in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA). However, bDMARDs have also a strong influence on the immune system, leading to a risk of serious infection. Reactivation of hepatitis B (HBV) and C (HCV) virus is one of the most redoubtable complications of these immunosuppressive agents.

Objectives: The aims of this study were to determine the screening rate for hepatitis B and C before starting a biological treatment and to examine the prevalence of their markers in patients with RA or SpA.

Methods: Our study evaluated all patients included in the Tunisian registry BINAR (Biologic National Registry) since 2018 who had RA (ACR/EULAR 2010) or SpA (ASAS criteria) aged with more than eighteen years old and receiving their first bDMARDs during the two past years.

The following information were retrieved from the registry: demographic data on the patients, disease parameters, medication, HBV surface antigen (HBs Ag), antibody to HBs Ag (Anti HBs), antibody to HBV core antigen (Anti Hbc), HBs Ag, antibody to HCV (anti Hcv) status and liver function tests (AST: aspartate aminotransferase; ALT: alanine aminotransferase).

Results: A total of 298 patients was included, 111 men and 178 women, with a mean age of 49.2 ± 14.1 years old [18-79]. Among them, 58.7% were...
AB0278
REAL LIFE EXPERIENCE OF DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS TREATED WITH BIOLOGICAL DMARDS VERSUS TOFACITINIB.

V. Boyadzhieva1, N. Stoliov1, E. Kurteva2, R. Stoliov1. 1University Hospital “St Ivan Rilski”, Rheumatology, Sofia, Bulgaria; 2University Hospital “St Ivan Rilski”, Laboratory of Clinical Immunology, Sofia, Bulgaria

Background: Assessment of disease activity and quality of life are one of the main indicators for determining the effectiveness of treatment with disease-modifying antirheumatic drugs. In recent years, a new group has entered the market - target synthetic DMARDs, which prove their effectiveness in treating RA comparable to that of biological products.

Objectives: The aim of this study is to evaluate the disease activity and quality of life of patients with rheumatoid arthritis (RA) treated with biological agents in comparison with Tofacitinib (real life data from Bulgarian population) and determine whether or not the benefits of different therapies were sustained over a follow up period of 1 year.

Methods: 164 patients were selected with a mean age 55.34 ± 16SD years, meeting the 1987 ACR and /or ACR/ EULAR (2010) classification criteria for Rheumatoid arthritis (RA). Patients were arranged according to treatment regimens: Tocilizumab (TCL) 30 patients, Certolizumab (CZP) 16, Golimumab (GOL) 22, Etanercept (ETN) 20, Adalimumab (ADA) 20, Rituximab (RTX) 16, Infliximab (INF) 20, Tofacitinib (TOF) 20. Disease activity and quality of life were the primary concern. Independent joint assessor evaluated 28 joints on baseline, 6th and 12th month thereafter. CRP was used to measure the inflammatory process.

DAS28-CRP, clinical disease activity index (CDAI) and simplified disease activity index (SDAI) were calculated. On baseline all of the patients’ groups had severe disease activity (mean DAS28-CRP > 5.2, mean CDAI > 22, mean SDAI > 26).

All of the patients were on stable therapy according to the inclusion criteria, and didn’t interrupt any of the medications including biological or target synthetic treatment.

Results: Significant clinical improvement and statistically significant reduction in disease activity were observed in patients treated with bDMARDs and tsDMARDS within 6 months (p <0.006) of treatment and after 12 months of follow-up (p<0.039). The mean value of DAS28-CRP after one year follow up showed an non-inferior effect of Tofacitinib (3.04 ± 0.81) in comparison to biological treatment (TCL: 3.07 ± 0.73; CZP: 3.06 ± 0.65; GOL: 2.49 ± 0.76; ETN: 2.85 ± 0.55; ADA: 3.15 ± 0.82; RTX: 2.90 ± 0.70; INF: 3.14 ± 0.61; TOF: 3.04 ± 0.81). An improvement was also observed for the 6 to 12 months of follow-up as we did not detect a significant difference in the activity of the disease assessed by CDAI among the different drug groups.

The mean values showing the change of the SDAI over the study period also outline comparable profiles. All of the treatment groups achieved a rapid reduction in disease activity that continued to decrease through the 6 and 12 months period, respectively, as supported by changes in SDAI. The quality of life evaluated with EQ-Scale revealed significant improvement on the 6-th month of follow up as well as after 12th month (p<0.005) without significant difference between the observed groups.

Conclusion: Real-life data show that patients on biological treatment as well as those on Tofacitinib therapy achieve a significant decrease in disease activity after one year of follow-up. This gives us reason to accept the importance of non-inferior effect of jak-inhibitors and their place in treatment of Rheumatoid arthritis.

Conclusion: DMARD concomitant treatment has been related to a higher second biological treatment survival. This beneficial effect was not observed in RA patients ≥70 years of age whose second biological agent withdrawal cause was failure. In this age group, withdrawal related to adverse events was more frequent.

AB0280

SURVIVAL ANALYSIS ON SECOND BIOLOGIC THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS OLDER THAN 65 YEARS

A. Briones-Figueroa1, M. Tortosa-Cabañas1, B. A. Blanco Cáceres1, J. L. Morell Hita1, J. Bachiller-Corral1, M. Vázquez Díaz1, 1Ramón y Cajal University Hospital, Department of Rheumatology, Madrid, Spain

Background: Patients with Rheumatoid Arthritis (RA) ≥65 years old constitute an important and not very well studied group. Even though the course of the disease may be similar to that of younger patients, treatment is usually less aggressive given the limited information on efficacy, especially of biological treatments, in this age group.

Objectives: To describe the characteristics of patients with RA ≥65 years old who started a second biological agent. To compare the survival of this second-line treatment between patients ≥65 and <65 years old.

Methods: Retrospective, observational and longitudinal study. Patients diagnosed of RA, who started a second biological agent between 2000 and 2019, who discontinued a first-line TNF inhibitor, were included. Demographic, clinical and analytical data were obtained. The sample was divided in 2 groups: ≤65 and ≥65 years old. Kaplan Meier and Log-rank survival analysis were performed, as well as Cox regression to identify related factors.

Results: 157 patients were identified, 42 (26.8%) were ≥65 years old. In this group, 73.8% were women, with a mean age at the beginning of biological treatment of 71.43±4.76 years. Demographic and clinical data of ≥65 years old patients are shown in the table. The most frequent second biological agent was Rituximab (23.8%), followed by Adalimumab (21.4%) and Tocilizumab (19%). 76.2% of patients had a disease-modifying drug associated, being Methotrexate the most frequent (45.2%). Discontinuation of second biological agent occurred in 30 patients (71.42%) ≥65 years old, which is similar to the percentage found in patients <65 years old (66.96%; p=0.70). The main causes of withdrawal of second-line agent in patients ≥65 years old were adverse effects (23.8%) and secondary failure (23.8%), whereas in <65 years were primary and secondary failure (18.3%) in both. Infections were more frequent in patients ≥65 years (14.3%) in comparison with patients <65 years (6.1%). In the survival analysis of the second biological agent, patients ≥65 years presented a median survival of 45 months (IC-95%=14.10-75.90); while patients <65 years had a median survival of 47 months (IC-95%=29.55-64.46), without statistically significant differences (p=0.803) (See Figure). Among elderly patients no statistically significant differences were found after comparison of survival curves in the subgroups: 65-69, 70-74 and ≥75 years. Rituximab presented a higher survival rate in patients ≥65 years (84.3 months; p<0.001), followed by Abatacept (58.6 months). Smoking (HR=13.96; IC-95%=6.14-32.89) was the main predictor of survival, followed by co-morbidities: dyslipidemia (HR=13.96; IC-95%=6.14-32.89) and diabetes mellitus (HR=13.37; IC-95%=4.83-35.14). Infections were identified as risk factors for discontinuation of second biological agent.

Conclusion: The survival of second biological agent after the failure of a first TNF inhibitor in patients ≥65 years is similar to the survival in younger patients, although there was a higher percentage of adverse effects in the first group. Rituximab and Abatacept showed a higher survival in patients ≥65 years. Smoking, erosions and diabetes mellitus were associated with an increased risk for the withdrawal of the second-line biological therapy.

AB0281

SAFETY AND RETENTION RATE AFTER SWITCHING FROM ETANERCEPT ORIGINATOR (ETN) TO ETANERCEPT BIOSIMILAR (SB4) IN INFLAMMATORY JOINT DISEASES: DATA FROM REAL LIFE.

C. Bruni1, S. Gentilescu2, M. Capassoni2, G. Pacini2, M. Bardelli1, C. Baldi2, L. Tofani1, L. Cometi1, F. Naccò1, F. Bartoli3, G. Fiori1, L. Cantarini2, S. Guiducci1,3, B. Frediani1,2, M. Matteucci-Cerinic1,3,1 University of Florence, Faculty of Medicine, Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; 2University of Siena, Medical Sciences, Surgery and Neurosciences, Rheumatology Unit, Siena, Italy; 3Careggi University Hospital, Rheumatology, Firenze, Italy

Background: SB4 in now commonly used in the treatment of inflammatory joint diseases, with evidence of efficacy and persistence up to 12 months from switching in both randomized controlled trials in Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS).

Objectives: we investigated the safety and retention rate of SB4 at 6, 12 and 18 months after switching from ETN in two rheumatology departments in our region. Methods: adult patients with RA, PsA, AS, Juvenile Idiopathic Arthritis (JIA) and other rheumatic diseases treated with ETN for at least 6 months, switched to SB4 in stable clinical conditions, were eligible for this retrospective evaluation. Data on adverse events (in particular infectious events), loss of efficacy (articular, cutaneous, ocular or intestinal disease re-activation) and persistence on treatment were collected since latest available follow-up. Retention rate, reason for discontinuation and subsequent management data were collected at 6, 12, 18 months.

Results: 220 patients (142 females, mean age 56±7 years, disease duration 12±4 years, ETN duration 7±4 years) were enrolled, with median follow up of 12.1 (9.7-15.8) months duration; ETN was used in different biologic DMARDs treatment lines (first 78.8%, second 17.7%, third 3.2 %, fourth 2.3%). Study
Background: Concomitant use of methotrexate (MTX) in abatacept (ABA) therapy is associated with good clinical response in patients with rheumatoid arthritis (RA) who are naïve to biological disease-modifying antirheumatic drugs (bDMARDs) \(^1,2\). However, it is unclear when abatacept is used in patients with prior bDMARDs use \(^3\).

Objectives: We compared the effectiveness of abatacept monotherapy versus abatacept combined with methotrexate therapy in rheumatoid arthritis patients with prior bDMARDs use.

Methods: Retrospective cohorts study. Rheumatoid arthritis patients treated with abatacept between 2009 and 2019 (n=86). Socio-demographic, clinical and pharmacological characteristics of patients were collected. We compared clinical effectiveness between ABA monotherapy patients (n=49) and abatacept concomitant methotrexate therapy patients (n=37), prior treated with bDMARDs. The effectiveness was measured according to The European League Against Rheumatism (EULAR) response with Disease Activity Score (DAS28) like satisfactory (DAS28<3.2) or unsatisfactory (DAS28=3.2), after 12 months of ABA therapy in RA patients.

Results: 49 RA patients have been evaluated in ABA monotherapy group; 83.67% (41/49) were women, disease duration was 16 (10-22) years and age of RA diagnosis was 48 (35.25-57.00). Concomitants glucocorticoids were administrated in 81.63% (40/49), Rheumatoid factor (RF) was positive in 75.51% (37/49) patients and cyclic citrullinated peptide antibodies (ACPA) in 71.43% (35/49). At 12 months, 40.82% (20/49) of patients had satisfactory EULAR response.

In the combination therapy group, the age of RA diagnosis was 42.5 (35.75-53.50), 75.68% (28/37) were women and the disease duration was 12 (7-21) years. 89.19% (33/37) had concomitants glucocorticoids and the RF was positive in 72.97% (27/37) of patients. EULAR response was satisfactory at 12 months in 43.24% (16/37) of patients. No difference in treatment effectiveness was found in patients receiving abatacept in combination therapy with MTX compared with ABA monotherapy (p=0.829; \(\chi^2_{(p)}=0.35-2.35\).

Conclusion: Abatacept plus methotrexate therapy did not improve the effectiveness in rheumatoid arthritis patients with prior bDMARDs use, compared with abatacept monotherapy.

DOI: 10.1136/annrheumdis-2020-eular.6047
In the STD group, 14 hospital admissions occurred, while in the TAP group there were 7 admissions (p=0.128). The corresponding figures for hospital admission due to infectious diseases were 6 in the STD group and 0 in the TAP group (p=0.026).

Conclusion: Tapering bDMARDs in RA patients in R/LDA is associated with fewer hospital admissions, with a possible protective effect especially toward infections.

RHEUMATOID ARTHRITIS REFRACTORY TO BIOLOGICAL TREATMENT

R. Caparrós-Ruiz1,2, C. M. Romero-Barco3, N. Mena-Vázquez2, R. Redondo4, M. D. C. Ordoñez Cañizares5, A. Fernandez-Nebro6,1, UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga (HRUM), Universidad de Málaga, Málaga, Spain; 2Hospital Universitari Vall d’Hebron; Rheumatology Service, Barcelona, Spain; 3UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Clínico Virgen de la Victoria de Málaga (HCUVV), Universidad de Málaga, Málaga, Spain

Background: In Rheumatoid arthritis (RA), between 20% and 40% of patients do not achieve a 20% improvement in American College of Rheumatology (ACR) criteria, another similar percentage loses response over time or experience adverse events that forces them to the suspension of treatment. Those patients who have failed one or more therapeutic strategies, are more refractory patients and the response to successive targets is usually lower than naïve patients, with 50% ACR20 response percentages.

Objectives: To describe the clinical-analytical characteristics and response to the last treatment, in rheumatoid arthritis (RA) refractory to biological disease modifying anti-rheumatic drugs (bDMARDs) and targeted synthetic DMARDs (tsDMARDs). To identify possible factors related to refractoriness to bDMARDs and tsDMARDs.

Methods: Retrospective multicentre, controlled study of patients with RA refractory to bDMARDs and tsDMARDs. Control group was formed by patients with non-refractory RA; matched by gender, age and diseaseduration. Refractoriness was defined as failure to more than 2 different targets of bDMARDs or tsDMARDs. Demographic, clinical-analytical data and rates of disease activity and physical function were collected. A descriptive analysis, a bivariate analysis and a binary logistic regression were performed to see the variables associated with refractoriness.

Results: A total of 94 patients were selected from HRUM and HCUVV: 47 with refractory RA and 47 with non-refractory RA. The clinical-epidemiological characteristics of both groups are classified in Table 1. The majority were women with a mean age of 57 years. There was a greater proportion of patients with multimorbidity and cardiovascular risk factors among the refractory to FAMEs. All patients affected a significant improvement with the new treatment in activity and physical function at 6 months compared to baseline. Refractoriness is associated with a higher body mass index [OR(95%), 7.73 (1.56-8.42); p=0.012], and depression [OR(95%), 1.11 (1.24-1.83); p=0.035].

antibody (ADA)-positive. Amongst ADA-positive subjects, a majority (12/18) also tested positive for neutralising ADAs (7/11 [63.6%] and 5/7 [71.4%] subjects, respectively).

Conclusion: This study demonstrated that the PK of ADL-PF was comparable following SC administration using either a PFS or PFP device. ADL-PF by PFS or PFP injection was well tolerated by healthy subjects, with the distribution of AEs, including ISRs, being similar between treatment arms.

AB0287 HEMATOLOGICAL SIDE EFFECTS OF BIOLOGICAL THERAPY IN RHEUMATOLOGY: DATA FROM THE TUNISIAN REGISTER

H. Bettaieb1, S. Boussaid1, S. Jemmali1, S. Rekik1, E. Cheour1, H. Sahl1, M. Elieche1, L. Abdelmoula2, A. Lataar2, W. Hamidi1, S. Kochbati1, E. Bouajira1, M. Younes1, N. Bargouou1, S. Bakhrou1; Hospital La Rabta, Rheumatology, Tunisia, Tunis; Hospital of Charle Nicolle, Rheumatology, Tunis, Tunisia; Hospital of Mongi Slim, Rheumatology, Tunis, Tunisia; Hospital of Kassab -ksar Said, Rheumatology, Tunis, Tunisia; Hospital of Habib Thameur, Rheumatology, Tunis, Tunisia; Hospital of Farhat Hachid, Rheumatology, Sousse, Tunisia; Hospital of Tahar Slac, Rheumatology, Mahdia, Tunisia; Hospital of Fattouma Bourguiba, Rheumatology, Monastir, Tunisia; Hospital of Hedi Chaker, Rheumatology, Sfax, Tunisia

Background: During the last decade, the treatment of chronic inflammatory rheumatism (CIR) has been greatly improved with the advent of biotherapy. However, the use of biological treatment can lead to a number of side effects including abnormalities in the blood count.

Objectives: The aim of this study was to assess the different hematological side effects of biological treatment in patients with rheumatoid arthritis (RA) and spondyloarthropathy (SA).

Methods: This study included patients with RA (ACR/EULAR 2010) and SA (ASAS 2009) registered with the Tunisian Biologic National Registry (BINAR). Patients were followed and treated with biologics for 2 years of less. Clinical data relative to biological treatment, including haematological side effects, have been collected.

Results: Two hundred and ninety-eight patients (178 women and 111 men) were included in the study. The mean age was 49.2 ± 14.1 years. The male/female ratio was 0.6. The mean diseases durations for RA and SA were respectively 6.7 ± 3.5 years and 6.5 ± 3.6 years.

Anti-TNFα agents were prescribed in 87.9% of patients (n = 263) with respectively: Infliximab (20.4%) Etanercept (23.1%), Adalimumab (24.6%) and Certolizumab (26.5%).

Tocilizumab and Rituximab were prescribed in 10.4% and 5% of the patients, respectively.

Blood count abnormalities were noted in 15.4% of patients (n=46). Neutropenia was the most frequently anomaly met on the hemogram (9.1%) followed by anemia (3.4%) and thrombocytopenia (3%). Pancycopenia was found in 11.4% of patients (n=34).

The median time between biological therapy initiation and the onset of hematologic manifestations was 4.8 months [1-12]. Biological treatment was interrupted in two patients.

In the other cases, the biological treatment was maintained with close monitoring of blood cell count. No case of death related to these hematological disturbances has been reported.

Conclusion: Intra-articular injection of etanercept is a safe and an encouraging treatment modality in managing refractory mono-arthritis in rheumatoid arthritis patients. Further researches are needed to study the use of repeated injection of etanercept to get more sustained effects.

GLUCOCORTICOID SPARING EFFECT OF THE BILOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS IN RHEUMATOID ARTHRITIS IN TUNISIAN REAL LIFE PRACTICE

B. Faikfaik1, H. Zegiaci1, N. El Amri1, S. Hamila1, N. Amara1, K. Bacouche1, E. Bouajina1 on behalf of BIINAR. 1Farhat Hached Hospital, Rheumatology, Sousse, Tunisia

Background: Glucocorticoids (GCs) are still widely prescribed in rheumatoid arthritis (RA). Despite their disease-modifying properties, they are associated with significant adverse effects. The international guidelines recommend the lowest effective dose and the lowest duration of GCs. Previous studies have shown that biologic disease modifying anti-rheumatic drugs (bDMARDs) can have a GC-sparing effect in RA.

Objectives: The aim of the study was to assess the impact of the bDMARDs on glucocorticoid use in rheumatoid arthritis Tunisian patients, in real life practice.

Methods: RA patients (according to the American College of Rheumatology criteria) who started their first bDMARDs were compared with TNFi inhibitors (Tocilizumab and Rituximab) in Tunisian patients with significant adverse effects. The international guidelines recommend the lowest effective dose and the lowest duration of GCs. Previous studies have shown that biologic disease modifying anti-rheumatic drugs (bDMARDs) can have a GC-sparing effect in RA.

Results: At 3 months (M3) and at 6 months (M6) after bDMARDs initiation.

AB0288

EFFECTIVITY, SAFETY AND IMMUNOGENICITY IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARING PF-06410293 (ADL-PF), AN ADALIUMAB (ADL) BIOSIMILAR, AND REFERENCE ADL: RESULTS FROM WEEK 26 – 52 OF A DOUBLE-BLIND, RANDOMISED PHASE 3 STUDY INCLUDING PATIENTS WHO SWITCHED FROM ADL-PF TO REFERENCE ADL AT WEEK 26

R. Fleischmann1, D. Alvarez2, A. Bock2, C. Cronenberger2, I. Vranic3, W. Zhang2, R. Allan3. 1University of Texas, Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, United States of America; 2Pfizer Inc, Collegeville, United States of America; 3Pfizer Inc, Cambridge, United States of America; 4Pfizer, Tadworth, United Kingdom; 5Pfizer Inc, Lake Forest, United States of America; 6Schloßpark Klinik, University Medicine, Berlin, Germany

Background: PF-06410293 (ADL-PF) is an adalimumab biosimilar approved for use in the treatment of severe inflammatory and autoimmune indications. The efficacy, safety and immunogenicity of ADL-PF and reference adalimumab sourced from the European Union (ADL-EU) in patients with rheumatoid arthritis (RA) have been demonstrated to be similar in a randomised controlled trial up to 26 weeks; treatment period 1 (TP1).

Objectives: To evaluate the efficacy, safety and immunogenicity of ADL-PF and ADL-EU in patients with moderate to severe RA on longer-term treatment, and following a treatment switch from ADL-EU to ADL-PF in a subset of patients.

Methods: This multinational, randomised, double-blind, parallel-group study compared ADL-PF and ADL-EU in essentially biologic-naive patients with active RA despite methotrexate (MTX) (NCT02480153). In TP1, patients were randomised (1:1) to ADL-PF or ADL-EU (40 mg subcutaneous injection every 2 weeks) for 26 weeks while continuing MTX (10–25 mg/wk). The primary endpoint was achievement of American College of Rheumatology response (ACR20) at Wk 12. At Wk 26, the start of treatment period 2 (TP2), patients receiving ADL-EU were blindly re-randomised (1:1) to remain on ADL-EU or switch to ADL-PF for 26 wks while patients receiving ADL-PF continued treatment in a blinded manner. Secondary efficacy endpoints at Wks 26, 30, 36, 44 and 52 (ACR20/50/70, European League Against Rheumatism [EULAR] response, Disease Activity Score [DAS] 28-4[CRP] <2.6 and ACR/EULAR defined remission), safety events and percentage of patients with anti-drug antibodies (ADA) were assessed.

Results: In TP1, 597 patients were randomised to ADL-PF (n=297) or ADL-EU (n=300). At Wk 26, 552 patients were re-randomised for TP2 (continued ADL-PF, n=283; continued ADL-EU, n=135; switched from ADL-EU to ADL-PF, n=134). Patients who demonstrated at least minimal efficacy continued in TP2. Observed ACR20 rates were comparable between treatment groups at all visits during TP2 (Figure). Other measures of deep response (ACR70, EULAR good response, DAS28-4[CRP]<2.6 and ACR/EULAR defined remission) showed maintained efficacy during TP2 in all treatment groups. Incidences of treatment-emergent adverse events were comparable between treatment groups (Table). Overall, incidences of ADA through Wk 52 were comparable between treatment groups (47.3%, 54.1% and 45.9% for patients who continued ADL-PF, continued ADL-EU or switched from ADL-EU to ADL-PF, respectively). In patients who switched from ADL-EU to ADL-PF compared with patients who continued ADL-EU, the increase in ADA incidence over TP2 was 0.6% (from 45.1% to 45.9%) versus 6.7% (from 47.4% to 54.1%), respectively.

Conclusion: TP2 results demonstrated comparable efficacy, safety and immunogenicity between ADL-PF and ADL-EU was maintained up to Wk 52 and was unaffected by a blinded switch from ADL-EU to ADL-PF at Wk 26.

HERPES ZOSTER INFECTIONS IN RHEUMATOID ARTHRITIS PATIENTS EXPOSED TO BIOLOGICAL AGENTS AND JAK INHIBITORS. REAL-WORLD EVIDENCE.

D. Freites Nuñez, L. Abasolo, M. Peñuela, J. F. Cande1, J. Font2, P. Lois, C. Martinez Prada3, B. Fernandez4, A. Madrid Garcia4, L. Rodriguez Rodriguez2, J. I. Colomer, L. León1. Fundación para la Investigación Biomedica - HCSC, Rheumatology, Madrid, Spain; Hospital Clínico San Carlos, Rheumatology, Madrid, Spain; Hospital Clínico San Carlos, Microbiology, Madrid, Spain

Background: The overall occurrence of Herpes zoster (HZ) infections in patients with rheumatoid arthritis (RA) is greater than in the general population although there are controversies whether the use of the different disease-modifying antirheumatic drugs (DMARDs) increases this risk.

Objectives: To investigate the incidence and factors associate to HZ infections in patients with RA exposed to biologic agents (BA) and small molecule JAK inhibitors (JAKi), and to describe RA disease features at the moment of HZ infection.

Methods: Retrospective longitudinal study was conducted. We included RA patients seen at the rheumatology outpatient clinic of tertiary hospital, commencing BA (anti-TNF therapy and no anti-TNF therapy) or JAKi from Jan 2007 until Dec 2017, and following until the end of the study (Dec 2019). The outcome of interest was the occurrence of HZ infection, the diagnosis of HZ events was based on the rheumatologist's report. Covariates: sociodemographic, clinical, and concomitant treatments including glucocorticoids, conventional synthetic DMARDs (csDMARDs). Survival techniques were used to estimate the incidence of HZ (IR), per 1000 patient-year (PYs) with the respective Confidence Interval [95%CI]. Cox multivariate regression model to compare the risk of HZ was performed. Results were expressed in Hazard ratio (HR).

Results: 474 RA patients were included, starting 881 different courses of treatment (1954.86 patients-years of follow-up). 382 (80.6%) were women with a mean (SD) age of 56.9 (15.0) years at first BA. Across all groups of treatments, a total 18 HZ were recorded, events were non-serious and involved 1 or 2 dermatomes. The mean age (SD) at moment of the infection was 62 (11) years and was similar between anti-TNF and non anti-TNF therapy. None HZ event was recorded in patients exposed to JAKi. In the multivariate analysis, age (HR: 1.05; p<0.006), prednisone dose > 7.5 mg/day (HR: 2.83; p: 0.02) and the concomitant use of two csDMARDs (HR: 2.34 p: 0.039) increase the risk for HZ. Lymphopenia (HR: 2.6; p=0.06) achieved a trend and BA therapy dropped from 1=0.05, p6=0.006 to 1=0.005 1=0.001.

Background: Similarities in risk factors, initial stages, progression and final stages of both atherosclerotic cardiovascular disease (ACVD) and chronic kidney disease (CKD) allowed formulating a concept of cardiorenal continuum.1 ACVD and CKD remain the main causes of mortality in rheumatoid arthritis (RA) patients.2,3

Objectives: To evaluate the effects of rituximab (RTM) therapy on cardiorenal continuum of RA patients.

Methods: Biologics-naïve RA patients (n=92; age 49.5±9.9) were followed up for 72 months after commencing and continuing RTM therapy (1–10 standard courses) compared with 50 control RA patients (age 49.2±9.8). All control and 63% of RTM patients received metotrektax or lefunomide.

Results: There were no baseline differences between two groups – Table. At year 6, RTM patients have fewer incidences of hypertension, anxiety/depression, atherosclerosis and diastolic dysfunction than controls. RTM decreased prevalence of albuminuria and CKD.

There were no significant differences in frequencies of other risk factors, signs of organ damage and cases of established heart, cerebrovascular and renal diseases/complications.

Conclusion: RTM may be effective in delay of the movement of RA patients on cardiorenal continuum. The clinical implications of RTM for cardiorenal correlations in RA patients need to be confirmed in large-scale clinical outcome trials.

AB0292

EFFICACY AND SAFETY OF TWO BIOSIMILAR ETANERCEPT AFTER THE SWITCH FROM THEIR CORRESPONDING ORIGINATOR IN THE TREATMENT OF PATIENTS WITH AUTOIMMUNE ARTHRITIS: A RETROSPECTIVE ANALYSIS IN A REAL LIFE SETTING

F. Girelli1, A. Ariani2, M. Bruschi1, A. Becciolini2, L. Gardelli1, M. Nizzoli1. 1AUSL Romagna, GB Morgagni Hospital, Rheumatology Unit, forlì, Italy; 2Internal Medicine and Rheumatology Unit. AOU Parma, Parma, Italy

Background: The available biosimilars of etanercept are as effective and well tolerated as their bio originator molecule in the naïve treatment of chronic auto-immune arthritis. More data about the switching from the bio originator are needed.

Objectives: To compare the clinical outcomes of the treatment with etanercept biosimilars (SB4 and GP2015) naïve and after the switch from their corresponding originator in patients affected by autoimmune arthritis in a real life setting

Methods: We retrospectively analyzed the baseline characteristics and the retention rate in a cohort of patients who received at least a course of etanercept (originator or biosimilar) in our Rheumatology Units from January 2000 to January 2020. We stratified the study population according to biosimilar use. Descriptive data are presented by medians (interquartile range [IQR]) for continuous data or as numbers (percentages) for categorical data. Drug survival distribution curves were computed by the Kaplan-Meier method and compared by a stratified log-rank test. A Cox proportional hazards regression analysis stratified by indication, drug, age, disease duration, sex, treatment line, biosimilars use and prescription year was performed. P values ≤ 0.05 were considered statistically significant.

Results: 477 patients (65% female, median age 56 [46-75] years, median disease duration 97 [40.25-178.75] months) treated with etanercept were included in the analysis. 257 (53.9%) were affected by rheumatoid arthritis, 139 (29.1%) by psoriatic arthritis, and 81 (17%) by axial spondylarthritides. 298 (62.5%) were treated with etanercept originator, 97 (20.3%) with SB4, and 82 (17.2%) with GP2015. Among the biosimilars 90/179 (50.3%) patients were naïve to etanercept treatment. Among the 89 switchers we observed 8 treatment discontinuations: one due to surgical infection complication, three due to disease flare, two due to subjective worsening and one due to remission. The overall 6- and 12-month retentions rate were 92.8% and 80.2%. The 6- and 12-month retention rate for etanercept, SB4 and GP2015 were 92.7%, 93.4% and 90.2%, and 82%, 74.5% and 88.1% respectively, without significant differences among the three groups (P= 0.374). Patients switching from originator to biosimilars showed and overall higher treatment survival when compared to naïve (12-month retention rate 81.2% vs 70.8%, P=0.036). The Cox proportional hazard regression analysis highlighted that the only predictor significantly associated with an overall higher risk of treatment discontinuation was the year of prescription (HR 1.08, 95% CI 1.04 to 1.13; P=0.0001).

Conclusion: In our retrospective study etanercept originator and its biosimilars (SB4 and GP2015) showed the same effectiveness. Patients switching from originator to biosimilars showed an significant higher retention rate when compared to naïve. The only predictor of treatment discontinuation highlighted by the Cox proportional hazard regression analysis was the year of treatment prescription.

FACTORS ASSOCIATED WITH INITIATION OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN MOROCCAN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Hammou1, F. Chennouf2, H. Azzouzi1, I. Linda1. 1Department of Rheumatology, Mohammed VI University Hospital, Mohammed I University, Oujda, Morocco

Background: Rheumatoid arthritis (RA) is a progressive autoimmune disorder of joints that is associated with high health care costs, yet guidance is lacking on how early to initiate biologic disease-modifying antirheumatic drugs (DMARDs). Few studies have examined the factors associated with the transition from non-biologic DMARDs to biologic DMARDs in RA patients.

Objectives: to examine the association of patient’s comorbidities with initiation of biologic DMARDs (disease-modifying antirheumatic drugs) in rheumatoid arthritis (RA).

Methods: A cross-sectional study was designed on a cohort of RA patients. Sociodemographic, clinical data and comorbidities were collected. Logistic regression analysis was used to explore the impact of comorbidities on the initiation of bDMARD. The statistical analysis was done by SPSS. 20, p <0.05 was considered significant.

Results: among the 257 patients, 80.5% were females. Their mean age was 54.6±11.9 years. The most frequent comorbidities in our population were: high blood pressure (22.5%), diabetes (16.6%), history of heart disease (5.1%), history of neoplasia (2.4%) and nephropathies (2%). RA patients with comorbidities were more likely to initiate bDMARD: high blood pressure (p = 0.003 OR=2.36, 95% CI: 1.332- 4.181), history of heart disease (p = 0.036 OR=3.01, 95% IC: 1.073-8.468) and history of neoplasia (p = 0.026 OR= 5.07, 95% CI:12.19-21.110). In logistic regression models, high blood pressure was associated to the initiation of biologic agents (p= 0.026, OR= 2.07, 95% CI: 1.090-3.932).

Conclusion: the probability of initiating therapy with biologic agents in patients with RA is affected by different co-morbidities in our context specifically hypertension.

AB0294

PERSISTENCE WITH ABATACEPT VERSUS TUMOR NECROSIS FACTOR-INHIBITOR FOR RHEUMATOID ARTHRITIS COMPLICATED BY POSITIVE ANTI-CYCLITRULINATED PEPTIDE/RHEUMATOID FACTOR OR OTHER POOR PROGNOSTIC FACTORS

X. Han1, I. Yermilov2, S. Gibbs3, M. Broder2. 1Bristol-Myers Squibb, Princeton, United States of America; 2Partnership for Health Analytic Research, LLC, Beverly Hills, United States of America

Background: Rheumatoid arthritis (RA) treatment usually begins with a non-biologic disease-modifying antirheumatic drug (DMARD), followed by a biologic DMARD (including abatacept or tumor necrosis factor-inhibitors [TNFi]) in non-responsive patients. Since, treatments are switched if disease activity does not improve, it is valuable to understand treatment persistence and switch patterns in RA patients with poor prognostic factors in a real-world setting.

Objectives: To assess 12-month treatment persistence in early-line abatacept versus TNFi treated patients with RA complicated by poor prognostic factors.

Methods: We performed a multi-center retrospective medical record review of adult RA patients with poor prognostic factors treated at 6 United States clinics. Patients were treated with abatacept or TNFi as the first biologic treatment at the clinic. Poor prognostic factors included positive anti-cyclitilrulinated peptide antibodies (ACPA+), positive rheumatoid factor antibodies (RF+), increased C-reactive protein levels, elevated erythrocyte sedimentation rate levels, or presence of joint erosions. TNFis included adalimumab, etanercept, infliximab (and their biosimilars), certolizumab pegol, or golimumab. Data were collected from first biologic treatment for ≥1 year. Patients with Crohn’s disease, ankylosing spondylitis, ulcerative colitis, psoriatic arthritis, or anal fistula were excluded. Demographic, disease, and treatment information (start, stop, reason for discontinuation) was abstracted. Treatment persistence (continuation of index treatment with gap ≤60 days) at 12 months and time to discontinuation were reported. Multivariate logistic and Cox regressions were used to compare 12-month persistence and risk of discontinuation between abatacept and TNFi, controlling for demographic and disease characteristics (age, sex, Charlson comorbidity index [CCI], RA duration), baseline utilization, and clinic. Findings among a subgroup of ACPA+ and/or RF+ patients are reported.

Results: Data on 265 patients (100 abatacept, 165 TNFi) were collected, including 163 ACPA+ and/or RF+ patients (55 abatacept, 108 TNFi). Overall, abatacept patients were older than TNFi patients (670 vs. 60.3 years, p<0.001), but there were no statistically significant differences in gender, comorbidities, or disease activity at the time of treatment. At 12 months, 83.0% of abatacept patients were persistent vs. 66.1% of TNFi patients (p=0.003). Persistence was similar among ACPA+ and/or RF+ patients (83.6% vs. 64.8%, p=0.012). Mean time to discontinuation was 1,423 days for abatacept vs. 690 days for TNFi (p=0.014) (961 days vs. 581 days among ACPA+ and/or RF+ patients, p=0.048) (Figures 1,2). In the adjusted analysis, risk of all-cause discontinuation was statistically significantly higher among TNFi than abatacept patients (17 [95% CI: 1-12.6], p=0.012). The odds of TNFi patients being persistent at 12 months was 51% lower than abatacept patients, although not statistically significant
Background: Patients with moderate to severe active rheumatoid arthritis (RA) may be treated with biological disease-modifying antirheumatic drugs (bDMARDs), such as abatacept, after treatment failure with conventional synthetic DMARDs (csDMARDs). Abatacept has shown equivalent efficiency with other targeted therapies for RA in clinical trials and network meta-analyses. However, there is limited real-world evidence on patient outcomes associated with abatacept treatment in UK routine clinical practice.

Objectives: To describe the clinical outcomes of RA patients treated with abatacept in UK real-world clinical practice.

Methods: A multi-centre, retrospective observational study was undertaken in RA patients treated with abatacept at any line of therapy (LOT). Data were extracted from medical records at four UK hospitals. Patients aged 18 years or older who received abatacept between 1 January 2013 and 31 December 2017 were included. The index date was the date of first bDMARD initiation, with follow-up from index date to latest RA clinic visit, death or 31 December 2017, whichever occurred first.

Clinical outcomes (disease activity and response to treatment) were measured using the 28-joint Disease Activity Score based on erythrocyte sedimentation rate (DAS28-ESR) and European League Against Rheumatism (EULAR) response criteria.1,2 Results: The study included 213 patients (mean age 55.2 years, 71.4% female, 70 years mean duration of RA at index date). Where ACPA and RF status were recorded, 66.1% of patients were anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) positive at index. Mean DAS28-ESR at index was 6.2 (SD 1.0) and 80.9% of patients were categorised with high disease activity. Irrespective of LOT, changes in DAS28-ESR (where recorded) from LOT initiation among patients treated with abatacept versus other bDMARDs were -1.59 vs -1.56 (LS mean (SE): -0.04; 95% CI: -0.45,0.38; p=0.86) at 6 months and -1.98 vs -1.42 (LS mean (SE): -0.56; 95% CI: -1.04,-0.07; p=0.03) at 12 months, respectively. Table 1 shows that compared with other bDMARDs, patients treated with abatacept at any LOT experienced good response to treatment at 6 months (22.8%, n=21/92 vs 15.9%, n=24/151) and 12 months (27.9%, n=17/61 vs 20.5%, n=24/117) according to EULAR criteria.

Table 1. Treatment response at 6 and 12 months after initiation of any LOT

<table>
<thead>
<tr>
<th>EULAR response</th>
<th>6 months</th>
<th>12 months</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>None</td>
<td>33 (35.9%)</td>
<td>67 (44.4%)</td>
</tr>
</tbody>
</table>

Table 2 shows that compared with other bDMARDs, patients treated with abatacept at any LOT experienced good response to treatment at 6 and/or 12 months (a patient may be included in this analysis multiple times).

Patients who received abatacept remained on treatment for significantly longer than patients who received other bDMARDs at LOT1 (median 53.4 vs 17.4 months; p<0.01) (Figure 1) and at LOT2 (median 40.1 vs 17.1 months; p<0.01).

Conclusion: RA patients who received bDMARDs, including abatacept, experienced reduced disease activity. These findings are comparable with those from a European, multicentre, observational study on patients receiving abatacept.4

Background: Little is known about effectiveness of certolizumab (CTZ) in clinical practice, especially in patients with inadequate response to prior biologics.

Objectives: To estimate the survival rate of CTZ in RA, PsA or SpA cohorts from the registry BIOPURE. Secondary endpoint was the changes of clinical outcomes from baseline at 6 and 12 months for each disease.

Methods: We analyzed longitudinal data of consecutive patients, affected with RA, PsA or SpA starting a treatment with CTZ recorded into the web-based Apulian registry BIOPURE. Demographic and disease related characteristics were collected at baseline, 6 and 12 months. Drug survival was evaluated by Kaplan-Meier life table analysis. Estimates hazard ratios (HRs, 95% confidence intervals (CI)) of drug discontinuation adjusted for patient's demographics, disease characteristics and prior biologic treatments were computed by Cox-regression models. Differences of DAS28, DAPSA and BASDAI among baseline, 6 and 12 months were estimated by T-test.

Results: 506 patients were included in this analysis (table 1). Global mean survival time (95% CI) was 58 (52-64) months. Drug survival rate was significantly higher in RA (71.1%) than in PsA (83.5%, p<0.001), while PsA showed 67.5% (Figure 1). Naïve-CTZ patients showed higher survival rates than biologic-inadequate responder (Bio-IR) in PsA (naïve 78.4% vs 56.9%, p=0.02), but not in RA (78.9% vs 64.1%, p=0.08), or SpA (73.7% vs 64.8%, p=0.84). The only weak predictor of drug discontinuation was age at baseline for SpA patients (HR 1.04 (95% CI:1.005-1.007) p=0.02) (Figure 1). No baseline covariate, including sex, cDMARDs co-therapy and biologic-naïve status, was found to be associated with CTZ discontinuation for RA and PsA cohorts.

AB0297

THE LONG-TERM OBSERVATION OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO ACHIEVED A BIO-FREE CONDITION WITH ADALIMUMAB.

S. Igari1, S. Sakai1, Y. Kurosawa1, D. Kobayashi2, R. Okabayashi1, A. Abe1, H. Otani1, K. Nakazono1, A. Murasawa1, I. Naita1, H. Ishikawa1, 1Department of Rheumatology, Niigata Rheumatic Center, Shibata, Japan; 2Division of Clinical Nephrology and Rheumatology Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: Biological disease-modifying antirheumatic drugs (bDMARDs) caused a paradigm shift in the treatment of rheumatoid arthritis (RA). However, their high cost is a burden for patients and the national medical economy. Objectives: To analyze the long-term outcomes of patients with RA who achieved a bio-free condition (BF) with adalimumab (ADA).

Results: of 180 patients with RA achieving BF, 144 were followed for 12 months, 86 of 144 were followed for 24 months, and 56 of 86 were followed for 36 months. The mechanisms associated with such clinical benefit should be elucidated in future research.

References:
Methods: We followed 25 patients (male 6, female 19) who discontinued ADA with clinical remission (CR), and one female with a low disease activity (LDA), over 19.4 ± 11.9 years old, and the average disease duration was 46.1 ± 48.4 months. The disease activity measured by disease activity score based on C-reactive protein (DAS28-CRP) was defined as follows: CR, <2.3; LDA, 2.3 - 2.7; moderate DA, 2.7 - 4.1; and high DA, > 4.1, since the DAS28-CRP tends to be lower than the delay-based on the erythrocyte sedimentation rate in Japanese patients [1].

Results: We lost one patient with a transfer to another hospital. Four patients re-started ADA due to flare (DAS28-CRP>2.7), but achieved CR (in BF) again with the intensification of the treatment (dose increase or initiation of prednisolone [PSL] and/or conventional synthetic [cs] DMARDs such as tacrolimus or iquimod). The DAS28-CRP significantly decreased from 3.45 ± 1.32 at base line (BL) to 1.55 ± 0.41 (p<0.001) at BF. It remained 1.59 ± 0.59 (n=25) at 24 months after BF, 1.56 ± 0.39 (n= 20) at 48 months, 1.8 ± 0.7 (n=11) at 60 months. At the last observation, every patient remained in CR up to 84 months (n=2, Figure 1). The modified health assessment questionnaire score significantly decreased from 0.42 ± 0.46 (BL, n=19) to 0.02 ± 0.05 (p<0.002) at BF. It remained 0.03 ± 0.07 (n=19) at 24 months and 0.06 ± 0.14 (n=14) at 48 months, 0.04 ± 0.08 at 60 months (n=9). The PSL dose (mg/day) decreased from 3.2 ± 3.3 (BL) to 2.2 ± 2.8 at BF and 2.04 ± 2.13 (n=25) at 24 months, 1.73 ± 1.9 (n=20) at 48 months, and 1.6 ± 2.3 (n=11) at 60 months, but there were no significant changes. The methotrexate (MTX) dose (mg/week) increased from 10.1 ± 2.9 (BL) to 10.6 ± 2.6 (p<0.04) at BF, 10.4 ± 3.3 (n=25) at 24 months, 10.7 ± 3.4 (n=20) at 48 months, 10.4 ± 3.1 at 60 months (not significant). The number of csDMARDs significantly increased from 0.8 ± 0.6 (BL) to 1.3 ± 0.9 (p<0.001, at BF), 2.56 ± 0.94 (n=25) at 24 months, 1.6 ± 1.01 (n=20) at 48 months, and 1.6 ± 2.3 at 60 months (n=11, Figure 2).

Conclusion: BF can be sustained with an adequate dose of MTX and combination of csDMARDs.

AB0298
LONG-TERM SUPPRESSION OF RAPID RADIOGRAPHIC PROGRESSION AFTER DISCONTINUATION/REDUCTION OF SHORT-TERM BIOLOGIC THERAPY IN PATIENTS WITH EARLY DESTRUCTIVE RHEUMATOID ARTHRITIS ACCOMPANIED WITH EXTENSIVE BONE MARROW EDEMA.

1Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan;
2Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan;
3Fukai Pharmacy, Asahikawa, Japan;
4Asahikawa Medical University, Orthopedic Surgery, Asahikawa, Japan;
5Sapporo Rheumatology and Immunology Clinic, Sapporo, Japan;
6Asahikawa Medical University, Orthopedic Surgery, Asahikawa, Japan

Background: We reported that short-term (3 or 6 months) treatment with biologics (BIO) group compared with conventional synthetic non-biological disease-modifying anti rheumatic drug (csDMARDs) enhanced group is more effective in the reducing bone marrow edema (BE) and improving structural remission in early destructive RA accompanied with extensive hand BM despite csDMARDs therapy [1].

Objectives: Purpose of this extended study is to investigate whether suppression of RRP will maintain after the discontinuation/reduction of short term biological treatment during over 1 year. Clinical registration number; (UMIN-CTR 000013614)(Figure 1)

Methods: RA disease activity was evaluated by DAS28-ESR after BIO withdrawal/reduction at 12 months. Bone destruction was determined by modified total Sharp scoring (mTSS) using conventional radiography expressed as yearly progression of mTSS (ΔmTSS/y) at 12 months. Statistical analysis were performed by t-test or Wilcoxon rank sum test using SAS .13.2 software

Results: Fourteen out of 23 patients in BIO group achieved improvement of BM (>70% improvement of baseline BE). Three patient continued BIO. Among 11 patient started to discontinuation/reduction of BIO, 7 patients were successful for discontinuation of BIO. Four patients flared (Table 1). Mean DAS28-ESR, mean ΔmTSS/y at 0, 12 months after discontinuation in 7 patients were 1.77, 2.02 and -0.66,-0.44, respectively (no significant difference between values in 0 and12 month). In contrast, those in 4 flared patients were 1.91, 4.08 and 0, 1.83, respectively (significant difference). Finally, to resolve baseline prognostic factors for improvement of BE for biological treatment, we compared baseline data between 14 BE improved and 9 BE unimproved RA patients. Low DAS28-ESR at 3 or 6 month (P<0.001) are indicated for significant prognostic factor for improvement of BE, although Low DAS28-ESR at baseline (p=0.07) may associate improvement of BE.

Table1. Summary of 1 year clinical data in 11 patients treated in BIO discontinuation/ reduction after improvement of BE by short-term treatment of BIO.

Conclusion: Results of this study indicated suppression of RRP will maintain during over 1 year after the discontinuation of short term biological treatment in some patients. We recommend that a short-term treatment with biologics for early RA patients, who are resistant to non-bio DMARDs therapy and at high risk to transit to RRP, will be an effective and economical treatment strategy.

AB0299
REAL-WORLD ASSESSMENT OF GP2015 (ETANERCEPT BIOSIMILAR, SDZ-ETN): AN INTERIM ANALYSIS OF DATA FROM THE SELF-INJECTION ASSESSMENT QUESTIONNAIRE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN THE COMPACT STUDY
H. Kellner1, A. Askari2, T. Cupka3, H. Friccios-Quecke4, F. Furlan5, S. Hachachi6, M. Schmalzing1,1. Hospital Neuwittelsbach, Center for Rheumatology and Gastroenterology, Munich, Germany; 2. Robert Jones and Agnes Hunt Orthopedic Hospital NHS Foundation Trust, Department of Rheumatology, Oswestry, United Kingdom; 3. Rheumazentrum Cupka, Altenburg, Germany; 4. Sandoz Hexal AG, Holzkirchen, Germany; 5. University Hospital, Rheumatology/ Clinical Immunology, Department of Internal Medicine II, Wuerzburg, Germany.

Background: COMPACT is a non-interventional study to collect real-world evidence in European countries and Canada on effectiveness, safety and quality of life in rheumatoid arthritis (RA), ankylosing spondylitis or psoriatic arthritis patients (pts) treated with SDZ-ETN (GP2015), an approved etanercept biosimilar. The first effectiveness and safety data from the study have been reported earlier1.

Objectives: This interim analysis assessed patient usage behaviour and feelings of self-administered injection in general and with the auto-injector device using the Self-Injection Assessment Questionnaire (SIACQ) at Week 12 in pts with RA.

Methods: Pts aged ≥18 years for whom treatment with SDZ ETN were initiated are being enrolled. The SIACQ, a patient questionnaire validated for pts with RA, was developed to assess overall pt experience with subcutaneous self-injection2. It assesses the perceived self-confidence on self-injection, potential barriers, as well as satisfaction with self-injection via device before the first self-injection (PRE module) and after dosing (POST module). The POST module used in COMPACT includes 21 items grouped into six hypothetical domains: feelings about injection/self-image; self-confidence; injection-site reactions; ease of use of self-injection device (SD); and satisfaction with self-injection. Descriptive statistics were used to summarise SIACQ POST module data. The results for “ease of use of SD” domain are reported here. The “ease of use of SD” was rated by pts on a 6-point scale: 1 (very difficult) to 6 (very easy).

Results: Of the 430 pts recruited, pts with RA represented the largest group (59.5%, n=256). Majority of pts with RA (77.7%) had comorbidities. Of the 256 pts with RA, 102 (40%) pts who used SD were enrolled in the questionnaire. Majority of the pts found usage of the SD easy or very easy, for each of the domains assessed (Table). 49 % and 14% of the patients were “comfortable” and “very comfortable,” respectively using the SD. A majority of patients reported to be bothered by pain at the injection site “not at all” or only “a little” (69.6%), and to be bothered by redness “not at all” or only “a little” (89.2%), respectively.

Table. Overall patient experience with usability of self-injection device at Week 12 (RA population)

SEVERITY FACTORS IN RHEUMATOID ARTHRITIS AND SPONDYLOARTHROSIS IN NEWLY TREATED PATIENTS WITH BIOLOGICS: SURVEY OF THE BINARY REGISTRY
H. Hachchi1, D. Khalifa2, N. Ben Chekaya3, M. Brahem1, H. Themri1, L. Abdelmoula3, S. Baklouti4, N. Bergaoui5, E. Bouajina2, M. Elleuch6, I. Ghassal5, M. M. Kchiri5, S. Kchibati5, A. Laatar25, Y. Mohamed1, A. Fathi Star Hospital, Mahdia, Tunisia; 2. Farhat Hachid Hospital, Rheumatology, Susah, Tunisia; 3. Charles Nicolle Hospital, Tunis, Tunisia; 4. Ched Belkher Hospital, Sfax, Tunisia; 5. Fatatoura Bourguiba Hospital, Monastir, Tunisia; 6. Rabta Hospital, Tunis, Tunisia; 7. Military Hospital, Rheumatology, Tunis, Tunisia; 8. Kasab Institute, Tunis, Tunisia; 9. Habib Thameur Hospital, Rheumatology, Tunis, Tunisia; 10. Mongi Slim Hospital, Tunis, Tunisia

Background: Rheumatoid arthritis (RA) and spondyloarthritides (SA) are two heterogeneous diseases but both being major causes of disability in our practice. Biologic treatments have changed miraculously the course of these diseases in the past two decades.

Objectives: To determine severity factors in RA and SA patient newly treated with biologics.

Methods: A survey using results of the Tunisian registry BINARY including ten rheumatology centers was conducted. Adults of 18 years or more were included. Only those meeting the ACR/EULAR 2010 criteria for RA or the ASAS 2009 criteria for SA and treated with biologics for 2 years or less were included.

Results: Two hundred and ninety-eight patientd were enrolled including 111 males and 187 females (sex ratio H/F of 0.6). The mean age was 49.1 years ± 3.6. The mean disease duration was 6.7 years ± 3.5 for RA and 6.5 years ± 3.6 for SA. All patients were prescribed biologics for poor response under NSAIDS or conventional DMARDS. Smoking was reported in 17.7% of patients. High disease activity defined as a DAS 28 VS score>5.1 in RA and was reported in 36% of cases. HAQ>2 was present in 14.3%, erosive forms were reported in 73.1% of cases. Rheumatoid factor (RF) and anti cetrullinated peptide antibodies were highly positive (>3x normal rates) in 71.2% and 62.4% of cases respectively. As for AS, active disease was defined by ASAS CRP or ASAS VS=2.1 and was reported in 39%, 39.8% and 56.9 % of cases respectively. The functional score BASFI=4 was reported in 54.5% of cases. On the whole, a coxitis was noted in 48.8% of cases and extra articular manifestations (EAM) were present in 59.3% of cases. Statistical analysis for SA patients didn’t show an association between active disease (ASDAS>2,1 and different parameters (gene p<0.05), smoking (p=0.120), inflammation in biology (p=0.481), uveitis (p=0.241) and the presence of coxitis (p=0.375)). Nevertheless, RA patients with severe disease were more likely men (p<0.001). Other features for RA patients showed no significant statistical difference (age (p=0.253), inflammation on biology (p=0.963), positive RF (p=0.789), ACPA positive (p=0.258), presence of EAM (p=0.982), erosive forms (p=0.203) and HAQ>2 (p=0.219).

Conclusion: It’s important to determine clinical, biological and radiographic factors in RA and SA patients as well as activity scores in order to recognize patients potentially at risk of poor progression and for better therapeutic management and biologic treatment may have an influence on these factors.

Sarilumab as Monotherapy or in Combination with Conventional Synthetic DMARDs in Patients with Rheumatoid Arthritis: 12-Week Treatment Results from a Multicenter, Open-Label, Prospective, Single-Arm Observational Study

Background: Due to strict inclusion/exclusion criteria, randomized controlled trials (RCTs) may not represent the heterogeneous rheumatoid arthritis (RA) population encountered in routine clinical practice; longitudinal observational studies are needed to complement learnings from RCTs. The PROspective sarilumab (preFilled syringe/pen) multinational, observational Study (PROFILE) is collecting information on treatment strategies and sarilumab usage patterns and adherence in routine clinical practice for up to 52 weeks in patients with moderate-to-severe RA.

Objectives: In this planned interim analysis, we report baseline characteristics of patients prescribed sarilumab in routine clinical practice and the efficacy and safety of sarilumab after 12 weeks of treatment.

Methods: Adults with RA (2010 ACR/EULAR criteria) can enroll in this multinational, open-label, single-arm, Phase 4 study if, per their treating physicians' judgment, they are to initiate treatment with sarilumab as mono- or combination (with csDMARD) therapy, in accordance with local labeling/prescribing information, ≤4 weeks prior to or ≤8 weeks after study Visit 1 (signed informed consent and disease characteristics documented); 1000 patients are planned for enrollment. Concomitant use of biologic or targeted synthetic DMARDs (b/tsDMARDs) is not permitted. Primary endpoint is change from baseline in Clinical Disease Activity Index (CDAI) score at Weeks 24 and 52. Statistical analyses are descriptive.

Results: This analysis included 291 patients who reached, or discontinued before the Week 12 visit, of whom 108 (37%) received sarilumab mono- and 183 (63%) received combination therapy. At baseline, the monotherapy group had longer disease duration and a smaller proportion of b/tsDMARD-naive patients than the combination therapy group (9.7 vs 8 years and 39% vs 53%). Baseline and week 12 CDAI values were available in 132 patients. Mean (SD) BL CDAI scores for the monotherapy and combination groups were 26.7 (13.1) and 270 (14.4). At Week 12, CDAI scores were improved by −9.1 (17.5) and −10.5 (13.9), and 37% (19/51) of patients receiving monotherapy and 48% (45/93) of those receiving combination therapy had achieved low disease activity (CDAI ≤10). Remission (CDAI ≤2.8) was achieved by 12% (6/51) of monotherapy and 20% (19/93) of combination-therapy patients. Overall, 55 (19%) discontinued sarilumab: 27 (9%) for an adverse event and 19 (7%) for insufficient response, 4 (1%) for noncompliance, 5 (2%) for other reasons. Severe AEs leading to treatment discontinuation were leukopenia and neutropenia (n=1 patient), peripheral swelling (1), lung cancer (1), and fatigue (1). Ten patients (3%) had a treatment-emergent serious AE.

Conclusion: In this planned interim analysis, sarilumab mono- or combination therapy resulted in improved disease outcomes, assessed by CDAI, at Week 12, an important treat-to-target time point. Safety and efficacy were consistent with Phase 3 trial findings, with no new safety signals, although interim results must be interpreted with caution. Future analyses will evaluate efficacy and safety after 24 and 52 weeks of treatment in routine clinical practice.

Acknowledgments: Study funding and medical writing support (Laura George, Adelphi Communications Ltd, Macalescefield, UK) were provided by Sanofi Genzyme (Cambridge, USA) and Regeneron Pharmaceuticals, Inc. (Tarrytown, USA) in accordance with Good Publication Practice (GPP3) guidelines.

USE OF TNF-INHIBITORS BEFORE, DURING AND THE FIRST YEAR AFTER PREGNANCY AMONG WOMEN WITH RHEUMATOID ARTHRITIS

Background: Treat to target is a goal, also in pregnant women with Rheumatoid arthritis (1). There is increasing evidence on safe use with TNF inhibitors during pregnancy. Adjusted use of TNF inhibitors preconception and throughout pregnancy may stabilize disease activity and prevent flares (2). Low disease activity is also beneficial for the fetus.

Objectives: To study the use of TNF-inhibitors among women with Rheumatoid arthritis during and after pregnancy.

Methods: RevNatus is a Norwegian, nationwide quality register that monitors treatment of inflammatory rheumatic diseases before, during and after pregnancy. Data from RevNatus in the period October 2017 to October 2019 was used to map the use of all types of TNF inhibitors among 208 women with rheumatoid arthritis, diagnosed by the ACR/EULAR criteria. The use of medication was reported at the time of visit in outpatient clinic. The frequency of use of TNF inhibitors registered at seven timepoints from pre-pregnancy to twelve months after delivery.

Results: The use of medication was reported at each visit for all the women with rheumatoid arthritis. Most of the women were not using TNF inhibitors before and beyond conception. Most of the women continuing TNF inhibitors beyond conception used certolizumab or etanercept. Adalimumab and infliximab were used in pregnancy (tabell 1).

Conclusion: Most of the women with rheumatic arthritis were not treated with TNF inhibitors before or in pregnancy. Women with rheumatic arthritis that continued treatment with TNF inhibitors through pregnancy were using certolizumab and etanercept.

AB0303  PREDICTORS OF SERIOUS INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TARGETED THERAPY.

E. Koltskova1,2, G. Lukina3, E. Shmidt4, K. Lytkina5, E. Zhilyaev6,7, 1Research Institute of the Organization of Health and Healthcare Management, Moscow, Russian Federation; 2A.S.Loginov Moscow Clinical Scientific Center, Moscow, Russian Federation; 3Novonova Research Institute of Rheumatology, Moscow, Russian Federation; 4N.I. Pirogov City Clinical Hospital 1, Moscow, Russia; 5City Clinical Hospital 1, Moscow, Russia; 6European Medical Center, Moscow, Russian Federation; 7Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: The problem of infectious complications in patients receiving bDMARDs deserves special attention. Serious infectious adverse events (SIAE) are a major issue. To develop measures for their prevention it is necessary to know the predisposing factors.

Objectives: to detect predictors of serious infections among patients with rheumatoid arthritis receiving targeted therapy

Methods: The study includes patients with rheumatoid arthritis from the Moscow Unified Arthritis Registry (MUR), receiving treatment with biologics or tofacitinib. Search for predictors was carried out in two steps. At first step we selected patient related predictors (confounders) that significantly correlate with risk of SIAE. At the second step in the Cox risk regression model by forward stepwise selection were identified independent significant predictors of risk, which demonstrated significant correlation with development of serious infections. Then data about the treatment was added to the generated model: used targeted DMARDs, doses of glucocorticoids (GC), doses of methotrexate (MTX).

Results: Analysis includes 1052 treatment events in 772 patients. There were 44 serious infections. The mean age was 57.1 ± 12.8 years. The mean observation time - 5.3 years. Independent patient related predictors of SIAE risk were the age RR - 1.12 per year (CI: 1.06-1.19), the age of onset disease RR - 0.94 per year (CI: 0.90-0.98), the year of inclusion in the registry RR - 0.64 per year (CI: 0.59-0.70). The dose of MTX and the doses of GC positively correlate with SIAE risk. RR for MTX is 1.05 per mg (CI: 1.005-1.109), RR for GC - 1.11 per mg (CI: 0.90-0.98), the year of inclusion in the registry RR - 0.64 per year (CI: 0.59-0.70).

Conclusion: Higher doses of methotrexate and glucocorticoids are independent significant predictors of serious infections in RA patients receiving targeted DMARDs.

AB0304  IMMUNOGENICITY OF BIOLOGIC DRUGS IN THE CLINICAL PRACTICE IN THE BULGARIAN POPULATION OF PATIENTS SUFFERING FROM RHEUMATOID ARTHRITIS

K. Kraeva1,2, M. Gencheva-Popova1,2, S. Popova1,2, 1Medical University - Plovdiv, Department of Preventive Medicine, Plovdiv, Bulgaria; 2University Hospital Kaspiya, Clinic of Rheumatology, Plovdiv, Bulgaria

Background: Biological drugs are protein derivatives that, such as, are highly immunogenic. In recent years there have been many conflicting opinions about the role of drug immunogenicity in clinical practice.

Objectives: To evaluate the drug immunogenicity of TNF-alpha blocking drugs (etanercept and adalimumab) used to treat patients with rheumatoid arthritis. To determine whether their presence can alter the effect of treatment and to evaluate their role in the clinical practice of rheumatologists.

Methods: 121 patients with rheumatoid arthritis, as well as 31 healthy controls, similar in sex and age, were examined. They were all monitored at 0, 6, 12 and 24 months from the start of TNF-alpha blocker treatment. Demographics, vital signs, markers of inflammation such as CRP, erythrocyte sedimentation rate (ESR) and disease activity indices were examined at each visit, respectively. Drug-induced neutralizing antibodies, as well as drug bioavailability in patients treated with adalimumab, were examined by ELISA.

Results: Drug-induced neutralizing antibodies to adalimumab were detected in 11.57% of patients at 6 month, in 17.64% of patients at 12 month, and 24.8% at 24 month. Drug-induced neutralizing antibodies to etanercept were not detected at 6 months, at 7.77% at 12 months, at 9.63% of patients at 24 months. Of the adalimumab patients who were having drug-induced antibodies, 92.59% had low drug bioavailability, while the remaining 7.41% of patients showed normal drug bioavailability despite the presence of drug-induced neutralizing antibodies. In terms of worsening of the disease activity, a positive correlation was found with the presence of drug antibodies - Pearson Correlation = 0.701, p = 0.001. Patients with poor clinical response and available drug antibodies receiving adalimumab were slightly more than those treated with etanercept at 12 and 24 months but the difference is non-significant - U = 0.527, p > 0.05 and U = 0.623, p > 0.05, respectively.

Conclusion: Presence of drug-induced neutralizing antibodies in patients treated with adalimumab and etanercept has been associated with poor clinical response and worsening of the patient’s condition. Testing of drug-induced neutralizing antibodies as well as the drug bioavailability of the drug used can be used as reliable biomarkers in clinical rheumatology.

AB0305  STUDY OF CORRELATION OF B-CELL LEVEL AND PROGRESSION OF BONE DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING RITUXIMAB THERAPY

A. Kudryavtseva1, G. Lukina1, A. Smirnov2, S. Glukhova1, E. Aronova1, G. Gridneva1, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2GBUZ Moscow Clinical Scientific Center named after Loginov MHD, Moscow, Russian Federation

Background: Rheumatoid arthritis is a chronic autoimmune disease characterised by inflammation of the synovial tissue and destruction of the underlying cartilage and bone. The goal of antirheumatic treatment is not only to attenuate the clinical symptoms of joint inflammation, but also to inhibit the progression of joint destruction. Rituximab - it is a chimeric monoclonal antibody that targets the CD20 molecule expressed on the surface of B cells. It has been successfully used to treat rheumatoid arthritis, and it is worth noting that its antitoxic effect sometimes does not meet the clinical.

Objectives: The aim of our study was to evaluate the correlation between the degree of B-cell depletion and the development of the clinical and antitoxic effects of Rituximab (RTX) therapy in patients with rheumatoid arthritis (RA).

Methods: the study included 108 patients (pts) with rheumatoid arthritis, most are middle-aged women with high disease activity (mean DAS28 6,1±1,04, RF-positive 77%, ACCP-positive 83%) treated with RTX (1000 mgx2 or 500 mgx2). Clinical effect was scored by EULAR criteria, radiographic progression was assessed using Sharp/van der Heijde (SVH) modified scoring method. B-cell level was measured with flow cytometry.

Results: patients who were treated by different doses of RTX (500 x2 or 1000 x2) had good response. After 48 week of treatment RTX clinical improvement was achieved in 65% pts, good and moderate response by EULAR criteria in 23% and 42% pts respectively. Noteworthy, after 12 months of treatment RTX radiological progression was absent in 50% pts with high disease activity. There was no significant difference in the degree of B-cell reduction when assessing the antitoxic effect. However, in assessing the clinical effect, it was noted that depletion of B cells in patients with RA in a state of remission (median 0.05% B cells) was more pronounced than in patients with signs of disease activity 0.32%.

Conclusion: rituximab therapy slows the radiologic progression regardless of the therapeutic effect. Radiologic progression did not show any dependence on the degree of B-cell reduction. The most pronounced depletion of B cells was observed in RA patients in a state of remission.

Experience with Rituximab Biosimilar BCD-020 in Patients with Rheumatoid Arthritis in Real-World Clinical Practice According to Data from Moscow Unified Arthritis Registry (MuAR)

G. Lukina, E. Koltsova, E. Shmiot, K. Lytkina, E. Zhiyaeva, A. Loginov. Moscow Clinical Scientific Center, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; Research Institute of the Organization of Health and Healthcare Management, Moscow, Russian Federation; N.I. Pirogov City Clinical Hospital, Moscow, Russian Federation; City Clinical Hospital, Moscow, Russian Federation; European Medical Center, Moscow, Russian Federation; Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation.

Methods: In 43.5% of patients, previously inefficiency or intolerance of other biologics were switched to rituximab biosimilar (BCD-020) were enrolled in the study. For all patients were performed blood tests, laboratory analyses, and immunologic blood analyses. Assessment of dynamic of DAS28, RAPID3, HAG-DI was performed. The great attention was given to the therapy safety assessment. The mean dose of RTX was 16.8 months; the duration of follow-up period for BCD-020 biosimilar was 12.1 ± 6.18 months. The mean dose of RTX was 13.6 mg/wk. The safety profile of RTX and RTX (BCD-020) was also similar. None of the patients discontinued BCD-020 therapy because of safety reasons, related to safety or inefficiency.

Table 1. Comparison of Efficiency Parameters for the Reference Rituximab and Biosimilar BCD-020

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Reference rituximab</th>
<th>Biosimilar BCD-020</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAS28 (ESR)</td>

<td>1.48</td>
<td>1.44</td>
</tr>
<tr>
<td>RAPID3</td>
<td>12.9</td>
<td>12.8</td>
</tr>
</tbody>
</table>

The safety profile of RTX and RTX (BCD-020) was also similar. None of the patients discontinued BCD-020 therapy for reasons related to safety or inefficiency.

Conclusion: The introduction of perspective anti-rheumatic biologic agents into clinical practice has not only increased therapy efficacy and improved medical prognosis in patients with rheumatoid arthritis (RA), but also resulted in a dramatic increase in treatment cost and, therefore, in a reduced accessibility of the innovative treatment for patients. For this reason, over the last years, there has been a huge interest towards developing biosimilars.

antagonist, tocilizumab (TCZ), on NT-proBNP levels and systolic heart function is yet to be obtained.

**Objectives:** Access the effect of 12 months TCZ therapy on NT-proBNP levels, trans thoracic echocardiography results and analyze the association between congestive heart disease progression and RA activity.

**Methods:** 37 RA patients (pts) (31F/6M); median age 56.5 [48; 63.5] years; disease duration 48 [6; 348] months; DAS28 score 6.15 [5.44; 6.45]; rheumatoid factor (RF)+100%; anti–citrullinated protein antibody (ACPA) + 79.6% were treated in an open-label study with TCZ (8 mg/kg every 4 weeks). Identification of NT-pro-BNP in blood serum, transthoracal ultrasound evaluation of left ventricle ejection fraction (LVEF), E/A ratio performed at baseline and 12 months.

**Results:** 11 (29.7%) pts had congestive heart disease (CHD) (II functional class of NYHA), 7 (18.9%) pts having signs of mild left ventricular dysfunction (LVD) as dyspnea, shortness of breath, cardiacotropic treatment remained the same in the course of the study. After 12 month TCZ treatment as RA activity lowered (DAS28 2.32 [1.75; 3.15], p<0.05), NT-proBNP levels decreased (100.95 [57.9; 117.6] pg/ml to 90.46 [33.62; 106.6] pg/ml), along with elevation of LVEF (60.75 [60; 70]% to 67.68 [62.5; 73.5], p = 0.001). Increase of E/A (0.97 [0.8; 1.17] to 1.04 [0.7; 1.42] correlated with decrease of NT-proBNP level (r = -0.63, p<0.036). Raise of LVEF over 12 months correlated with decrease of RA activity according to SDAI scale (r = -0.670, p<0.05). No significant relationship between NT-proBNP levels, LVEF, E/A and other scales measuring RA activity was found. Clinically all patients had improvement in evaluation of their health and no signs of CHD or RVD progression were found.

**Conclusion:** Use of TCZ in patients with active RA showed none to positive influence on heart condition, specifically, lowering NT-proBNP levels, improving LVEF and reducing clinical signs of LVD.

**AB0309 MEASURING THE DIFFERENCE: COMPARISON OF MEASUREMENT OF FREE INFlixIMAB ANTI-DRUG ANTIBODIES**

R. Hamilton 1, S. Shields 2, A. Moucklen 3, J. Macdonald 4, M. Perry 5, A. Dunlop 6, E. Gribben 7, P. Galloway 8

**Objectives:** To determine the qualitative concordance of three commercially available ELISA kits for measurement of free ADAs to IFX on the Grifols Triturus automated analyser.

**Methods:** ELISA analyser.

**Results:** Free ADA levels were determined in 150 patient samples from patients with inflammatory conditions and low IFX trough drug levels (≤0.6µg/ml) were analysed for free ADAs using Promonitor, Lisa Tracker and IDKmonitor kits on the Grifols Triturus automated analyser.

**AB0310 TROUGH CONCENTRATION AND ESTIMATED CLEARANCE CAN DETECT IMMUNOGENICITY TO ADALIMUMAB IN RA PATIENTS: A PROSPECTIVE LONGITUDINAL MULTICENTRE STUDY**

Background: Anti-Drug Antibodies (ADA) to adalimumab increase drug clearance in rheumatoid arthritis (RA).

Objectives: To study the ability of drug concentration or estimating clearance to identify ADA to adalimumab.

Methods: Adalimumab concentration was measured with a validated ELISA. ADA was measured using a capture ELISA (TheraDia®) and the Meso scale discovery (MSD) platform. Using a bayesian PK model, adalimumab clearance was estimated at 1, 3, 6 and 12 months. Predictions for ADA presence were calculated, and the correlation between ADA and adalimumab clearance was analysed.

Results: We analysed 108 samples from 53 RA patients. Serum concentrations and clearance estimates showed good prediction performance for ADA presence (Table 1). There was a correlation between adalimumab clearance and ADA (Figure 1).

AB0311 THE PROPER STUDY: RESULTS OF THE FIRST INTERIM ANALYSIS OF A PAN-EU REAL-WORLD STUDY OF SBS BIOSIMILAR FOLLOWING TRANSITION FROM REFERENCE ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS, AXIAL SPONDYLOARTHRITIS OR PSORIATIC ARTHRITIS

1Kerckhoff Klinik, Bad Nauheim, Germany; 2Norfolk and Norwich University Hospital NHS Foundation Trust, Norwich, United Kingdom; 3Cambridge University Hospitals NHSFT, Cambridge, United Kingdom; 4Biogen International GmbH, Baar, Switzerland; 5Biogen Idec Ltd, Maidenhead, United Kingdom

Background: SBS, a biosimilar to reference adalimumab (ADA), received EU marketing authorisation in August 2017, based on the totality of evidence from pre-clinical and clinical Phase I and III studies that demonstrated bioequivalence, similar efficacy, and comparable safety and immunogenicity to the reference. There are few published data on the transition from reference to biosimilar ADA outside the controlled, randomised, clinical trial setting.

Objectives: To evaluate candidate predictors of persistence on SBS in EU patients across multiple indications.

Methods: This ongoing observational study will enrol approximately 1200 subjects with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) or psoriatic arthritis (PsA), who initiated SBS as part of routine clinical practice following a minimum of 16 weeks’ treatment with reference ADA, at clinics in Belgium, Germany, Ireland, Italy, Spain and the UK. Data are captured from clinic records retrospectively for the 24 weeks prior to transition, and prospectively and/or retrospectively for 48 weeks following transition. The primary objective is to evaluate candidate predictors of persistence, and primary outcome measures include baseline clinical characteristics, disease activity scores, clinical management and patient satisfaction over time. This interim analysis provides an overview of baseline characteristics for subjects enrolled and followed up by the data extract date of 20th December 2019.

Results: Of the 123 patients included in this interim analysis, 43 suffer from RA, 42 from axSpA and 38 from PsA.

Conclusion: This interim analysis provides a first insight into a contemporary cohort of EU patients with established RA, axSpA and PsA, switched from reference to biosimilar ADA in clinical practice. The majority of patients have stable disease at transition, 85% or more of each cohort transitioned to the same dose regimen of biosimilar as received for the reference prior to transition, and most are aware of correct storage and self-administration of their biosimilar medication. With ongoing enrolment and longer follow-up, the study will provide pertinent information about clinical outcomes of transition from reference to biosimilar adalimumab in real-world practice and in indications not investigated in controlled studies.

Background: Viral hepatitis B reactivation (VHBR) is a serious complication of immunomodulatory therapy and in particular biological therapy (BT), which can be life-threatening, whence the adoption by societies of screening and prevention strategies based on the risk of VHBR which depends on serological status and the treatment used.

Objectives: The objective of our study was to determine the modalities of HBV screening, to describe the prevalence of HBV infection in this group of patients, and to evaluate the VHBR prevention strategies adopted in our country.

Methods: This was a retrospective, 8-year [2011-2018], single-centre, descriptive, retrospective study conducted in two departments: Rheumatology and Hepato-Gastroenterology. Patients under BT were included. Records with missing data were excluded. The modalities of screening and prevention of VHBR were determined and the prevalence of HBV markers was investigated.

Results: One hundred patients were included: 85 followed up for chronic inflammatory rheumatic disease: rheumatoid arthritis (n=40), ankylosing spondylitis (n=41), juvenile idiopathic arthritis (n=4) and 15 patients followed up for inflammatory bowel disease (11 Crohn's disease and 4 ulcerative colitis). The mean age was 44 years with a predominance of females (59%). The BTs prescribed were: anti-TNFs, anti-IL-6 and antiCD20 in 63%, 11% and 7% respectively.

HBV screening was done in 89% of cases: HBsAg was tested in 89%, anti-HBc in 64% and anti-HBs in 43%. Complete B serology (HBsAg, anti-HBc and anti-HBs) was performed in 40%.

One patient had chronic hepatitis B on Entecavir for 3 years before starting anti-CD20 (HBsAg(+), anti-HBc(-)). A previous contact with HBV as evidenced by positive anti-HBs(+) positivity was noted in 13 patients (20%). A negative B serology was noted in 30 patients (30%). The vaccination rate was 10%.

Prophylaxis with Entecavir was indicated in 2 patients at high risk of viral B reactivation (candidates for anti-CD20 therapy and having anti-HBc(+)) with undetectable viral load). One patient at moderate risk of reactivation (candid for anti-TNF therapy and having anti-HBc(+) was placed on Lamivudine for prophylaxis. Pre-emptive therapy based on monitoring of alanine aminotransferase (ALT) and HBV DNA levels every 1 to 3 months was indicated in 10 patients (with anti-Hbc (+) and candidates for BT other than anti-CD20) but correctly applied in only 2 patients (20%). The remaining eight patients were monitored only for ALT levels. No cases of viral reactivation B were objectified.

Conclusion: In our study, viral hepatitis B screening was done correctly in 40% of the cases. The rate of VHBR vaccination was low (10%) despite the low cost of the vaccine. Prophylactic and pre-emptive treatment for viral reactivation were correctly applied in 100 and 20% of cases respectively. This underlines the difficulties encountered in applying pre-emptive treatment when access to HBV DNA level determination is limited and warrants more vigilance prior to the prescription of BT.

**AB0315 RETENTION RATE OF ABATACEPT MONOTHERAPY IN AN ITALIAN MULTICENTRIC RHEUMATOID ARTHRITIS COHORT**

D. Iacono1, J. Pantano2, D. Bira3, G. Scala3, M. A. Coscia3, V. Messinitti3, G. Loi4, A. Merchionda1, P. Moscato1, F. Ciccia1, 1University of Campania Luigi Vanvitelli, Naples, Italy; 2University of Campania Luigi Vanvitelli, Naples, Italy; 3University of Salerno, Salerno, Italy

Background: EULAR recommendations focus the importance of Methotrexate (MTX) therapy as a key element in the treatment of patients with Rheumatoid Arthritis (RA), alone as first line therapy and in combination with biological Disease Modifying Anti-rheumatic Drug (bDMARDs). Abatacept (CTLA4-Ig) in Europe is approved for the treatment of moderate to severe active RA in combination with MTX. Several patients, however, discontinue MTX for intolerability, side effects or contraindications, and real-life data demonstrate how, even in patients receiving therapy with MTX, compliance could be suboptimal. The only data on the use of abatacept in monotherapy come from the ORA-Registry, where a worse performance is observed in monotherapy patients.

Objectives: To evaluate a multicenter cohort of RA patients treated with Abatacept in patients underwent combined MTX therapy vs monotherapy.

Methods: We retrospectively evaluated RA patients, referring to 2 Italian rheumatology centers, treated with Abatacept monotherapy or in combination with MTX. We compared both persistence in therapy and the rate of remission/low disease activity according to Clinical Disease Activity Index (CDAI) between the 2 groups.

**AB0314 VIRAL HEPATITIS B REACTIVATION UNDER BIOLOGICAL THERAPY: SCREENING AND PREVENTION MODALITIES IN RHEUMATOID AND INFLAMMATORY BOWEL DISEASE PATIENTS**

S. Nasib1, R. Enerafer1, B. Bouchabou1, K. Ben Abdelghani1, A. Faza2, H. Ben Nejma1, A. Latar1, 1Mongi Slim Hospital; Hematology and Gastro-Enterology, La Marsa, Tunisia; 2Mongi Slim Hospital, Rheumatology, La Marsa, Tunisia

CONCLUSIONS: In our cohort, 10% of patients with RA were observed to have multi-refractoriness to bDMARDs. This study also identified baseline and early clinical characteristics of patients as predictors of multi-refractoriness, especially absence of clinical response during the first 6 months on a first bDMARD.

AB0316  MULTIPLE SWITCH BETWEEN BIOISIMILARS DMARDS (BSDMARDS) IN PATIENTS WITH INFLAMMATORY ARTHRITIDES: EXPERIENCE OF A SINGLE ITALIAN CENTRE

M. Riva1, V. Varisco1, L. Riva1, F. Rumi2, M. R. Pozzi3
1 SSD Reumatologia ASST-Monza, Ospedale San Gerardo dei Tintori, Monza, Italy; 2 Unità di Epidemiologia, Società Italiana di Reumatologia, Milano, Italy

Background: The availability of bsDMARDs since some years represents an opportunity to improve patient access to effective biologic therapy, to better accommodate constraints within healthcare budgets and to improve overall patient outcomes. Different policies are followed in different countries to implement the use of bsDMARDs. Although the latest position paper of AIFA (Agenzia Italiana del Farmaco) envisions the automatic substitution between the originator and biosimilar, until now the prescriber decision and the patient consent are strongly advised. The question around biosimilar to biosimilar switching is overlooked. Nevertheless different rules are established at regional level and in our Hospital automatic switching between originator/biosimilar and biosimilar/biosimilar was applied.

Objectives: To analyze the efficacy and safety of switch from originator to biosimilar (O/B) and/or biosimilar to biosimilar (B/B) in patients with RA, PsA and SpA.

Methods: We retrospectively analyzed in 63 patients (30 F, mean age 58.3 yr, 21 RA, 26 PsA, 16 SpA), treated with Infliximab, Etanercept and Adalimumab, disease activity (DAS28 CRP for RA, Tender/Swollen joint count for PsA, BASDAI for SpA, CRP for all) and adverse events/infections (AE). The time points considered were 3rd month before the switch and 3rd and 6th month after.

Results: 45 patients underwent single switch (35 O/B, 9 B/B) and 18 (28.5%) double switch (O/B/O, B/B). 27 B/B switch were done. No differences in disease activity were observed before and after switch (8 RA patients: mDAS28 CRP 2.86>3.23, 11 PsA patients: mTJ count 2.5 > 3.43, 8 SpA patients: BASDAI 2.88 > 2.84). The mean number of swollen joints was very low in PsA group and we decided to exclude this variable. The CRP level was low and stable across the period examined in the three groups. No increase in steroid daily dose, nor in concomitant DMARDs therapy was reported. In the Etanercept B/B switch (14 pts) the number of infections was the same before (3) and after (3). In Infliximab B/B switch (13 pts) 3 infections were reported only before the switch. The severity was mild/moderate with prevalence of respiratory infections (57%). No remarkable variation of transaminases and blood counts were observed.

Conclusion: Although the population we examined was heterogeneous and quite small, we observed that the efficacy and safety of Infliximab and Etanercept are maintained with biosimilar to biosimilar switch, also after double switch (originator-biosimilar-biosimilar). We also can confirm that the switch from originator to biosimilar Infliximab, Etanercept and Adalimumab is safe in our experience.

AB0317  BIOLOGIC THERAPY OPTIMIZATION IN RHEUMATOID ARTHRITIS PATIENTS IN COLOMBIA

Background: The optimization of biological agents (bDMARD), is a strategy that has proven to be cost effective and its use can reduce the risk related to drug exposure (1–3). It is included in the EULAR management guidelines and in the consensus of the Colombian Rheumatology Association.

Objectives: To analyze optimization success of bDMARD therapies in patients with RA.

Methods: Cohort study of RA patients in a specialized multicenter institution in Colombia, followed from January 2015 to December 2019. Patients in remission or low activity for at least 6 months with bDMARD, and with at least two consecutive medical visits, were included. Optimization types were dose decrease, application interval increments, or both. Patients who had disease reactivation (DAS28- CPR >3.2) and returned to standard dose, were considered a failure.

Results: 92 patients were included, 78.26% were women, with a median age of 57 years (IQR 50-64), a disease evolution time of 15 years (IQR 10-21), a treatment of 5.6 years (IQR 2.7-10.0), and optimization of 7.75 months (IQR 3.25-15.75). The most commonly used bDMARD therapies were etanercept 36.96%, tocilizumab 30.43% and adalimumab 16.30%. 69.39% (34) were naive for biosimilar or biologic therapy. The optimization failure was estimated according to bDMARD type.

95.92% remained under optimization scheme without disease activity changes, and 4.08% of patients underwent definitive discontinuation of bDMARD, for sustained therapeutic objective. 8.16% (4) had relapses in the first 6 months after onset, of which 2 patients returned to standard doses. In survival analysis it was observed that patients who were optimized for antiTNF failed faster than the non-antiTNF, although this difference was not statistically significant (Log Rank test 0.003 p value = 0.959). Of the total patients, 28 have been optimized for 12 months or more, of these, 96.43% (27) continue in sustained remission, and 55.56% (15) received combined therapy with s synthetic DMARD (sDMARD).

Conclusion: During follow-up, most patients remain in optimization strategy. In those who continued in sustained remission, more than half received sDMARD, this suggests that their use may be a determining factor in preventing disease relapses. More studies are required to evaluate this hypothesis.

CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAVE WITHDRAWN THE LAST BIOLOGICAL DRUG: REAL-LIFE RESULTS FROM A LOCAL REGISTRY

J. Rosas1, A. Pons1, J. M. Senabre Gallego2, G. Santos Soler2, J. A. Bernallí2, J. A. García-Gómez2, C. Cano2, E. Ivars2, M. Lorente Betoret2, E. Barber2

1Hospital La Rabta, Rheumatology, Tunis, Tunisia; 2Hospital Universitario de Elche, Infectious Disease, Elche, Spain; 3Hospital General Universitario de Elche, Infectious Disease, Elche, Spain; 4Hospital General Universitario de Elche, Rheumatology, Elche, Spain; 5Hospital General Universitario de Elche, CIO, Elche (Alicante), Spain

Disclosure of Interests: None declared

Objectives: To assess the characteristics of patients with rheumatoid arthritis (RA), who have withdrawn the last biological drug (bDMARD), and to know the reasons for withdrawal of treatment.

Methods: Retrospective and cross-sectional study on December 31, 2019, of patients with RA, treated with any of the bDMARDs, including JAK (JAK) inhibitor drugs, commonly used, from 1/1/2000 to 12/31/2019. General data were collected from patients, and RA: time of evolution, presence of rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA), type of bDMARD, time in bDMARD, and cause of withdrawal.

Results: Of 252 patients, who have received some bDMARD, 81 (32%) patients had withdrawn on 12/31/2019. 62 (77%) patients were women, with a mean age at diagnosis of RA of 48 years (SD: 16.5 years) and 59.5 (15) years at the beginning of the first bDMARD (F1), with an average evolution of RA 10.2 (2.5) years. 68% and 74% of patients were positive for RF and ACPA, respectively.

In 64 (79%) patients, bDMARD was withdrawn as second to fifth bDMARD received (F2 to F5); as F2: 37/81 (46%) patients, F3: 14 (18%), F4: 8 (10%) and as F5: (6%) patients.

When comparing the last bDMARD received, before the suspension as F1 vs F2-F5, 95% vs 61% of patients (p <0.0001), the drug was an anti-TNF (TNFi); Abatacept: 1 (1%) vs 9 (14%); Tocilizumab: 0% vs 8 (12%); Rituximab: 1 (1%) vs 5 (8%) and JAKi: 4 (5%) vs 3 (5%). The mean time in treatment with some bDMARD was 2.6 (SD: 3) years in the F1 group vs 1.7 (2) years in the F2-F5 group (p = 0.034). Among the F3-F5 patients, 9 (14%) patients had failed at 2 different previous therapeutic targets and 6 (9%) at 3 targets.

No differences were detected between the F1 group vs F2-F5, regarding the causes of withdrawal of bDMARD: whether it had occurred due to 1) loss of efficacy (25/31% patients vs 19/30%); 2) adverse events (31/38% vs. 29/45%); 3) abandoning treatment for patients with RA. The first biotherapy prescribed was etanercept in 54% of cases and mean BMI was 279 ± 5.2 kg/m² [15.1-45.2]. RA was erosive in 73.1% of cases and the mean disease duration was 6.7±3.5 years. Disease activity was moderate (mean DAS28v5: 4.9±1.5). Concerning the treatments, 139 (79.4%) of the patients received TNFα inhibitor, 31 (17.7%) of the patients were on IL6 inhibitor and 15 (8.6%) were on Rituximab.

The mean duration of drug survival for TNFα inhibitor agents was 15.2 months, 18 months for anti IL6 and 16.3 months for Rituximab. The drug was discontinued by 19 patients (10.8%). The causes of discontinuation were primary failure in 31.8% (7 subjects), secondary escape in 9.1% (4 subjects), the occurrence of adverse effects in 13.8% (7 subjects), intolerance to drug in 9.1% (2 subjects), non-compliance for one patient and for other reasons in one patient.

No differences were detected between the groups regarding the cause of withdrawal of bDMARD. 25% -30% of patients withdraw it due to loss of follow-up or voluntary abandonment of treatment.

Conclusion: 1. 32% of patients with RA withdraw the bDMARD. 2. The group treated with TNFi withdraws it significantly higher among the F1 group. 3. Survival of bDMARD is significantly higher in group F1 compared to F2-F5. 4. No differences were detected between the groups regarding the cause of withdrawal of bDMARD. 25% -30% of patients withdraw it due to loss of follow-up or voluntary abandonment of bDMARD.

BDMARD SURVIVAL: THE TUNISIAN DATA

K. Saadaoui1, H. Sahl2, S. Boussaid2, J. Jemmali2, S. Rekki2, E. Cheour2, M. Elleuch2,3, La Rabta Hospital, Rheumatology, Tunis, Tunisia

Background: The advent of biotherapies in the late 90s radically changed the face of inflammatory diseases including rheumatoid arthritis. The survival of these innovative therapies is an indicator, in clinical practice, of their long-term efficacy and safety.

Objectives: The objective of this study was to assess their use in Tunisia through their survival during rheumatoid arthritis as well as to determine the factors that may influence their therapeutic maintenance in real life.

Methods: This is a retrospective study including RA patients (ACR/EULAR 2010 criteria) and putted on biotherapy between 01-01-2014 and 12-31-2016. They were followed until 12-31-2018. The therapeutic maintenance rate at 12, 24, 36 and 48 months as well as the survival curves of biotherapies were analyzed using the Kaplan-Meier survival curves and compared by the Log-rank test. Reasons for interruption and patterns of biological change have been reported. Finally, an analysis of factors influencing survival was performed using Cox regression. A p<0.05 was considered statistically significant.

Results: Three hundred seventy-four patients were included in the study; sex ratio was 0.147. The baseline age was 55 ± 12.5 years [20 – 90] and the average disease duration was 11.7 ± 6.7 years [2 – 41]. Rheumatoid factor and ACPA were positive respectively in 79% and 71% cases. After failure of cdMARD, the first biotherapy prescribed was etanercept in 54%
Results: 59 patients participated in the study (Netherlands: 25; Denmark: 15; Sweden: 19). Most patients were women (71%), with a mean age of 55 years [16.2] and an average disease duration of 12 years [8.8]. A total of 42% and 39% had previously been treated with csDMARD(s) or were currently on csDMARD(s), respectively. 12% of the patients were bio-naïve. Only 6% (10%) patients started CZP de novo. The remaining switched device. The most used administration form prior to entering the study was pre-filled syringe (78%). At the time of inclusion, patients were mildly disabled with an average HAQ score of 0.5 [0.6] and a moderate VAS-pain score of 32 [25.1] (data not shown).

The overall retention rate was 42% after 52 weeks, declining to 38% after 104 weeks (Figure 1). A sharp decline is seen at week 8 which coincides with the end of the project phase. Between week 32 and 112 only 4 patients withdrew from the study (Figure 1). The primary reason for withdrawal was patient’s request (Figure 1). Dropout rates due to lack of efficacy or adverse events were as expected compared to other cohorts of biologic therapies. When stratified by country the analysis showed no significant differences between countries (data not shown).

Conclusion: An initial large drop-out was evident within the first 8 weeks, whereas almost no drop-out was seen in the extension phase (after week 8). The reasons for withdrawal was primarily patient request. Thus, the injection experience must be tailored carefully when selecting patients for new autoinjector e-Devices to enhance retention on device and patient satisfaction. Not one device fits all.

Figure 1. Overall retention rate and reasons for withdrawal
Background: TNFi are effective treatments for multiple immune-mediated inflammatory diseases. There are five TNFi's approved for clinical use. Despite their acceptable safety/efficacy profile, serious side effects have been reported, including central and peripheral nervous system demyelinating diseases (DD). Causation remains controversial and there is a paucity of data on the long-term outcomes in these patients.

Objectives: To assess long term outcomes in patients with DD related to TNFi use.

Methods: We conducted a database search and then retrospective chart review to identify patients with potential TNFi related neurologic events at a university medical center between 2006 and 2016. 15 total patients (13 living, 2 deceased) were ultimately identified. Six were able to be contacted by phone to assess their current status.

Results: 15 patients with DD were identified from among 4600 patients on TNFi's for various indications (0.3%). Mean duration of follow-up was 6.8 years. Neurologic symptoms occurred >12 months after starting a TNFi in 8/15 (53%) patients. 47% of patients had been exposed to two or more TNFi's. 40% received some form of treatment for their DD, including MS disease modifying therapies, IVIG and immunosuppression. No patients experienced worsening DD after stopping their TNFi except for one patient with MS who experienced a repeat flare. Two of three patients diagnosed with MS after TNFi had a first degree relative with MS. 3/15 (20%) experienced complete resolution of their symptoms. Two patients were deceased; cause of death was thought not directly related to DD on chart review.

Conclusion: Prevalence of DD after TNFi exposure was low at our center, consistent with previously published data. Presentations included both central and peripheral demyelinating events. With the exception of one patient who developed MS, withdrawal of TNFi's appeared to halt further progression or development of new neurologic symptoms. It is unclear if treatment for DD is beneficial after diagnosis and TNFi withdrawal.

DEMYELINATING DISEASE AFTER EXPOSURE TO TUMOR NECROSIS FACTOR ALPHA INHIBITORS (TNFI): LONG-TERM OUTCOMES FROM A SINGLE CENTER

N. Stienstra1, M. Lane2, J. Horton3, A. Kumthekar4, N. Sathe5, C. Sunny6, V. Yadav7, A. Deodhar1.1. Oregon Health & Science University; Division of Arthritis & Rheumatic Diseases, Portland, United States of America; 2Oregon Health & Science University, Department of Neurology, Portland, OR, United States of America; 3Albert Einstein College of Medicine, Division of Rheumatology, The Bronx, NY, United States of America; 4Oregon Health & Science University, School of Medicine, Portland, OR, United States of America

Background: TNFi are effective treatments for multiple immune-mediated inflammatory diseases. There are five TNFi’s approved for clinical use. Despite the analysis of other therapeutic lines compared to those previously mentioned.

Conclusion: The two trends observed in this study; the decrease in persistence on biological therapy, in 2010, and the increase of the period between RA diagnosis and the initiation of a biologic therapy, in 2012, were generated by the appearance of new molecules, thus reducing the boundaries generated by the previously limited number of options, and by the major changes in national health insurance system regulations.

Anti-CD20 therapy proved to be non-inferior to TNFi therapies regarding persistence on therapy and did not result in higher adverse events than TNFi, justifying the inclusion of RTX therapy as one of the biological therapies used in the first line in 2019 RA treatment recommendations.

A limitation of this study is the small number of patients who received other therapies (JAKi, T cell co-stimulation blockers, anti IL6), which did not allow a correct review.

Overall, regardless of the therapeutic line in which they were used, persistence on anti-CD20 (44.89±43.02 months (mean±SD)) therapies was significantly higher than that on TNFi (81.85±42.17 months (mean±SD)) (p<0.001, CI=27.806-46.129). (Image 1)
REASONS FOR DISCONTINUATION OF BIOLOGICS IN PATIENTS WITH REFRACTORY RHEUMATOID ARTHRITIS: RESULTS OF A RETROSPECTIVE STUDY

V. Syugrya1, S. Glukhova1, E. Aronova1, A. Satybaldyev1, A. Lila1. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Refractory rheumatoid arthritis (RRA) is a subtype of rheumatoid arthritis (RA), in which the sequential administration of optimal methotrexate (MT) doses in combination with glucocorticoids (GCs), and at least - two biologic disease-modifying antirheumatic drugs (bDMARDs) with different mechanisms of action during 18-24 months does not lead to a significant decrease in the inflammatory activity of RA.

Objectives: Analysis of the selection strategy and the "survival" of bDMARDs in patients with RRA.

Methods: The retrospective study included data of 95 RRA patients (80 females, 80.8%), aged 23 to 80 years (mean age 57 years), treated with bDMARDs. Mean RA duration was 11.9±7.6 years. All patients were divided into 6 groups depending on the number of the lines of therapy (LOTs) received (from 2 to 7 consecutive bDMARDs). Totally 348 cases of bDMARDs administration were analyzed.

Results: TNF-α inhibitors were most commonly used as the first and second lines of therapy: infliximab (INF) – 43 prescriptions, adalimumab (ADA) – 39, etanercept (ETC) – 25, certolizumab pegol (CZP) – 11, golimumab (GLM) - 6. Abatacept (ABA) was prescribed in 32 cases, rituximab (RTM) in 22 cases, and tocilizumab (TCZ) - in 12 cases. The following reasons for bDMARDs discontinuation were identified: lack of efficacy (LE) (55.2% of cases), adverse events (AE), including serious adverse events (14.8% of cases), administrative reasons (10.0% of cases), persistent remission (2.1% of cases), pregnancy (0.6%), and other (17.3% of cases). TNF-α inhibitors were also used in third-line bDMARDs therapies, but preference was given to drugs with a different mechanism of action: ABA-20 patients (23.2%), RTM – 20 (21.1%), TCZ – 15 (15.8%), ETC – 22 (23.2%), ADA – 9 (9.5%), INF – 4 (4.1%), CZP – 3 (3.1%). Treatment was discontinued in 74 patients (77.9%). In this cohort the following reasons for bDMARDs withdrawal were identified: LE (54.1%), AE (17.6%), administrative reasons (9.5%), remission (1.3%), and other (17.5%).

The fourth line of therapy was administered in 45 patients: ABA-16 (35.6%), RTM-9 (20%), ADA – 6 (13.3%), TCZ – 5 (11.1%), ETC – 4 (8.9%), CZP – 4 (8.9%), GLM – 1 (2.2%). The reasons for discontinuation (29 patients, 64.4%) were as follows: LE (44.8%), AE (13.8%), other (41.4%).

The fifth bDMARDs was used in 3 patients: TCZ-2 (46.1%), RTM – 3 (23.1%), ADA – 1 (7.7%), ETC – 1 (7.7%), GLM – 1 (7.7%). Therapy was discontinued in 11 patients (84.6%) for the following reasons: LE (45.5%), AE (18.2%), other (36.3%).

The sixth line of therapy was necessary in 4 patients: ETC (25%), GLM (25%), CZP (25%), ABA (25%) and was discontinued in 3 (75%) of them due to AE (33.3%) and other reasons (66.7%). One patient received TCZ as the seventh line of therapy.

Mean duration of the first line of therapy was 7.6 ± 6.5 months, of the second line - 9.6 ± 7.5 months, of the third line - 11.5 ± 7.1 months, fourth line - 12.5 ± 8 months, fifth line - 13.4 ± 4.8 months, and sixth line - 14.6 ± 4.4 months. Statistical analysis revealed significant differences (p<0.05) in the mean duration of therapy (retention on therapy) between the 1st and 3rd, as well as between the 1st and 4th lines of therapy. There were no significant differences in rates of bDMARDs discontinuation due to LE or AE. The rates of bDMARDs discontinuation did not differ significantly in the study groups.

Conclusion: The mean retention on a drug in the 3rd and 4th lines of therapy in patients with refractory rheumatoid arthritis was significantly longer than on the 1st line of therapy. The most common reason for bDMARDs discontinuation was lack of efficacy. Additional lines of bDMARDs therapy were not associated with increasing rates of adverse events.

FLUORESCENCE OPTICAL IMAGING (FOI) AIDS DIFFERENTIAL DIAGNOSIS OF RHEUMATOID DISEASES AND INCREASES TREATMENT RESPONSE RATE IN RA THROUGH PATIENT STRATIFICATION

M. Ferl1, S. Ohndorf2, J. Berger1, A. Briel1, P. Welker2. 1Medical Faculty University Hospital Magdeburg, Berlin, Germany; 2Charité - University Medicine Berlin, Berlin, Germany

Background: In recent years, indocyanine green (ICG)-enhanced FOI has become clinically available as a novel tool for the early detection of rheumatic diseases, assessment of disease activity and monitoring of treatment response. The high sensitivity of this method allows visualization of slight changes in the microcirculation of the hands as a sign of inflammation. Different rheumatic diseases present characteristic signal enhancement patterns, which may facilitate differential diagnosis. Signal enhancement in meta-carpophalangeal (MCP) joints, for example, can frequently be seen in patients with rheumatoid arthritis (RA).

Objectives: We analyzed data of a multicentric clinical study (OPERA, n = 3300) including patients with different rheumatic diseases. Patients were divided into groups using clinical parameters followed by FOI examination to test the hypothesis that this method can improve the diagnosis.

Methods: The present study involved 200 patients with RA (n=200), divided into groups according to Steinbrocker’s (STBR) staging system, patients that had degenerative osteoarthritis (OA, n=100), and a control group without clinical symptoms (n=40). RA patients were examined before and during treatment with biologicals, glucocorticoids (GC), or DMARDs. Clinical and laboratory assessments were made by analyses of DAS28, patient questionnaires, rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPA), erythrocyte sedimentation rate (ESR), and x-rays. FOI signal intensity (SI) was defined by ratio of areas with SI in patients and controls. Image sequences were analyzed visually, and MCP joints were judged as positive if in the early phase of ICG inflow, a higher SI in any MCP region was found in comparison to the control group.

Results: Initially, serum factors typical for RA patients were analyzed in the different groups. In 23 % of OA patients RF and/or ACPA were detected in the serum. Surprisingly, in the STBR I group, only 35 % of patients were tested as serum-positive for RF and/or ACPA. After FOI, the patients were subdivided into two groups with and without ICG enrichment in MCPs. In the MCP-positive group, the percentage of RF/ACPA-positive STBR I patients increased to 83%, with only 25 % seropositive patients in the MCP-negative group. In STBR II-IV cohorts, the proportion of RF/ACPA-positive patients was initially higher as in the STBR I group, but also increased after FOI analysis of MCP positivity. In the group treated with biologics (STBR-IV), responders were identified both by clinical parameters and FOI. After treatment, 42 % of all analyzed patients were found to respond to treatment. Compared to all patients, the MCP-positive group showed a significantly increased response rate at 71%, while all patients (100%) in the MCP-negative group were identified as non-responders (Figure 1).

Conclusion: The study indicates that FOI is highly effective for the diagnosis of RA, selection of the appropriate therapy, and for the monitoring of therapeutic success. Treatment response rate can be increased (from 42% to 71%) through patient stratification in terms of ICG enrichment in MCP. Figure
Objectives: The patent for adalimumab originator expired in 2018 in the United Kingdom. Subsequently, four adalimumab biosimilars were launched. National Health Service England undertook a managed market share tender to ensure plurality of suppliers and price competition over the longer term. Each hospital was subsequently allocated a preferred brand of adalimumab biosimilar. Here we describe our experience of switching patients with inflammatory arthritis from adalimumab originator to the biosimilar, ABP 501 in a single centre.

Methods: A retrospective analysis was completed on the cohort of 287 rheumatology patients who were prescribed adalimumab originator prior to the switch to ABP 501. Case notes were analysed to identify whether patients remained on biosimilar 24 weeks after switching from originator.

Results: 99% patients on adalimumab originator (283/287) were switched to ABP 501 within 32 weeks, starting from February 2019. 1% (4/287) remained on originator due to confirmed latex allergy, as the needle cover of the ABP 501 pre-filled syringe consists of dry natural rubber. 4% (12/283) of patients who switched to biosimilar reverted to originator (1 patient per 2 weeks over 24 weeks). 3% (9/283) patients who switched to biosimilar were no longer receiving any adalimumab therapy. Reasons for switching back to originator included recurrent infections (4/9) and progression to the next line of biologics/small molecule therapy (5/9).

Objectives: To study serum irisin levels in healthy females and patients with rheumatoid arthritis.

Methods: We examined 110 patients with a reliable diagnosis of rheumatoid arthritis (RA). The age of the examined was from 18 to 69 years, all patients were female. The diagnosis of RA was established on the basis of the 2010 EULAR diagnostic criteria. The group of patients included patients with a diagnosis at least one month before the planned screening. As a control group, as well as to create a representation of the normal values irisin level in the blood serum of healthy persons were examined 60 healthy volunteers (all women). In both groups, the level of serum irisin was determined using the enzyme-linked immunosorbent assay by the commercial irisin ELISA kit.

Results: As a result of measurements in the group of healthy individuals, the average value with the standard deviation used to assess the reliability of the average values was 20.49±4.82 μg/ml. By calculation, a reference interval of 10.85-30.13 μg/ml was determined, defined as μ±2σ. In patients with RA, the level of serum irisin was 14.52±6.99 μg/ml, which is significantly lower than in healthy individuals (p<0.01). Then we divided all patients into 2 groups: group 1 with normal values (86 people), group 2 (44 patients) - with a reduced (less than 10.85 μg/ml) level of irisin. In both groups, the dynamics of the level of serum irisin was studied depending on the duration of the disease. Among patients with a disease RA duration of less than 4 years, 16 (24.24%) patients had a normal level of irisin, and 14 (31.82%) had a reduced level (less than 10.85 μg/ml). Among patients with a disease duration of more than 10 years, 36 (54.55%) patients had a normal level of serum irisin, and a low level was determined in 16 (24.36%) patients (χ²=3.568, p=0.168).

Conclusion: According to the data obtained, the normal level in the duration of the disease, it tends to normalize.

SIMILAR EFFICACY OF TOFACITINIB THERAPY IN BIOLOGIC NAIVE AND HAD PRIOR BIOLOGIC USE HISTORY PATIENTS WITH RHEUMATOID ARTHRITIS (OREL REGISTER)

E. Nasonov1, A. Avdeeva1, A. Misiyuk1, A. Satybaldev2, V. Sorotskaya2, O. Fomin3, A. Babaeva3, N. Lapkina3, A. Lila3, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Tula University, Tula, Russian Federation; 3Regional Hospital Amur, Amur, Russian Federation; 4Volgograd State Medical University, Volgograd, Russian Federation; 5Yaroslavl State Medical University, Yaroslavl, Russian Federation

Objectives: To evaluate the efficacy of tofacitinib therapy (TOFA) in biologic naive and had prior biologic use history patients with rheumatoid arthritis (RA) according to OREL register

Methods: Were analyzed the data from Russian national register of patients with RA - OREL treated with TOFA 138 patients (118 woman, Me;IQR age 55.0 (43.0-63.0) years, disease duration disease 128.0 (84.0-213.0) months, mean DAS 28 5.5 (4.6-6.2), SDAI 30.5 (21.4-42.9), positive for ACCP (73%)RF (77%), who were non-responders to MTX at least 15mg/week and/or other synthetic DMARDs) who received TOFA therapy for more than 1 year were selected for statistical analysis. TOFA used in 26 (18.8%) pts without DMARDs, combination with MTX in 82 (59.4%) pts, lefluinomide in 21 (15.2%). Low-dose oral corticosteroids (<10mg/day prednison or equivalent) were received by 43 (31.2%) pts. TOFA therapy was started in all pts in dose 5mg BiO per os with dose escalation to 10mg BiO in (86%) pts.

Results: The use of TOFA was accompanied by a decrease in the disease activity and the level of acute phase reactants (CRP and ESR) after 12, 24 and 48 weeks of therapy, p<0.05, table 1. Depending on the previous treatment with biological DMARDs, all patients were divided into two groups: had prior biologic use history pts (group 1) (n=51) and biologic naive pts (group 2) (n=87), table 1.

*p<0.05 from baseline; #p<0.05 between the groups 1 and 2

Patients of the second group had a higher disease activity and ESR before therapy. The use of TOFA was accompanied by a decrease in the disease activity and the level of acute phase reactants (CRP and ESR) in both groups of patients. By the end of the first and the second group of pts on the 48-th week of therapy remission/low disease activity was achieved on DAS 28 in 51% and 43% (p=0.57), high disease activity on DAS 28 in 12% and 8% (p=0.48).

Conclusion: An analysis of the data from the Russian national register of patients with RA demonstrated similar efficacy of TOFA among patients who received and did not receive previous biological therapy.

PHYSICIANS’ PRE-LAUNCH AWARENESS AND CONCERNS WITH PIPELINE JANUS KINASE INHIBITORS (JAKIS) VERSUS TOFOCATINIB AND BARICITINIB IN RHEUMATOID ARTHRITIS IN THE UNITED STATES AND EUROPE

D. Baldock1, G. Giannakopoulou1, 1Ipsos MORI, London, United Kingdom

Background: Clinical data regarding use of tofacitinib and baricitinib in rheumatoid arthritis patients have recently posed safety concerns, with regulatory bodies suggesting limiting use of higher dosages. Investigating physicians’ awareness and views of each of these products leading up to their launch, as well as Boolean remission up to one year using survival analysis and explored continued baricitinib treatment and the probabilities of LDA and remission by DAS-28 reported outcomes and laboratory results. We estimated the probabilities of continued baricitinib treatment and the probabilities of LDA and remission by DAS-28 as well as Boolean remission up to one year using survival analysis and explored their association with disease characteristics using multivariable Cox regression. All patients gave informed consent. The study is approved by the local ethics.

Methods: All RA patients were seen in our outpatient clinic. If a patient was switched to a baricitinib due to medical reasons, these patients were included in the analysis. In this sample, upa and filgo achieved lower awareness scores, compared to tofa and bari prior their launch. Sampled EUS physicians were less concerned with upa and filgo’s safety profiles, than for the other two JAKIs before launch. Sampled physicians holding concerns with upa/filgo manage significantly older patients and a significantly higher number of retired patients. Further investigation using comparator cohort is warranted.

HIGH REMISSION RATES IN RA – REAL LIFE DATA FROM BARICITINIB

S. Baagøe1, K. Tascilar1, V. Kaufmann1, A. Klejér1, D. Simon1, J. Knitza1, F. Hartmann1, S. Adam1, A. Hueber2, G. Schett1, University Hospital Erlangen; Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Erlangen, Germany; 2Sozialstiftung Bamberg; Rheumatology, Bamberg, Germany

Background: Recent developments of targeted treatments such as targeted synthetic DMARDs (tsDMARDs) increase the chances of a sustained low disease activity (LDA) or remission state for patients suffering rheumatoid arthritis (RA), tsDMARDs such as baricitinib, an oral inhibitor of the Janus Kinases (JAK1/JAK2) was recently approved for the treatment of RA with an inadequate response to conventional (cDMARD) and biological (bDMARD) therapy, (1, 2).

Objectives: Aim of this study is to analyze the effect of baricitinib on disease activity (DAS28, LDA) in patients with RA in real life, to analyze drug persistence and associate these effects with various baseline characteristics.

Methods: All RA patients were seen in our outpatient clinic. If a patient was switched to a baricitinib due to medical reasons, these patients were included in our prospective, observational study which started in April 2017. Clinical scores (SJC/TJC 76/78, composite scores (DAS28), PROs (HAQ-DI; RAID; FACIT), safety parameters (not reported in this abstract) as well as laboratory biomarkers were collected at each visit every three months. Linear mixed effects models for repeated measurements were used to analyze the time course of disease activity, patient reported outcomes and laboratory results. We estimated the probabilities of continued baricitinib treatment and the probabilities of LDA and remission by DAS-28 as well as Boolean remission up to one year using survival analysis and explored their association with disease characteristics using multivariable Cox regression. All patients gave informed consent. The study is approved by the local ethics.

Results: 95 patients were included and 85 analyzed with available follow-up data until November 2019. Demographics are shown in table 1. Mean follow-up duration after starting baricitinib was 49.3 (28.9) weeks. 51 patients (60%) were on monotherapy. Baricitinib survival (95%CI) was 82% (73% to 91%) at one year. Cumulative number (%probability, 95%CI) of patients that achieved similar efficacy of TOFA among patients who received and did not receive previous biological therapy.

Disclosure of Interests: None declared

DOi: 10.1136/annrheumdis-2020-eular.3194
attained DAS-28 LDA at least once up to one year was 67 (92%, 80% to 97%) and the number of patients attaining DAS-28 and Boolean remission were 31 (60%, 54% to 61%) and 12 (20%, 9% to 30%) respectively. Median time to DAS-28 LDA was 16 weeks (Figure 1). Cox regression analyses did not show any sufficiently precise association of remission or LDA with age, gender, seropositivity, disease duration, concomitant DMARD use and number of previous bDMARDs. Increasing number of previous bDMARDs was associated with poor baricitinib survival (HR=1.5, 95%CI 1.1 to 2.2) while this association was not robust to adjustment for baseline disease activity. Favorable changes were observed in tender and swollen joint counts, pain-VAS, patient and physician disease assessment scores, RAID, FACIT and the acute phase response.

Conclusion: In this prospective observational study, we observed high rates of LDA and DAS-28 remission and significant improvements in disease activity and patient reported outcome measurements over time.

**EFFICACY, RETENTION RATE AND PREDICTORS OF TOFACITINIB EFFICACY AND RETENTION IN RHEUMATOID ARTHRITIS PATIENTS: HUR-BIO REAL-LIFE EXPERIENCE**

E. Bilgin,1 F. Ceylan,1 E. C. Bolek,1 E. Duran,1 B. Farısçoğulları,1 G. K. Yardımcı,1 L. Kilic,1 A. Akdoğan,1 O. Karadağ,1 S. A. Bilgen,1 S. Kiraz,1 A. I. Erteli,1 U. Kalyonçu,1 Hacettepe Üniversitesi Tip Fakültesi, Internal Medicine, Ankara, Turkey;2 Hacettepe Üniversitesi Tip Fakültesi, Internal Medicine, Ankara, Turkey

**Background:** Tofacitinib (TOP) is an oral Janus Kinase (JAK) inhibitor and is indicated in the treatment of rheumatoid arthritis (RA). Several observational and observational studies demonstrated its safety and efficacy, however, its real-life retention rate and related factors need to be elucidated further and its efficacy needs to be approved in real-life.

**Objectives:** To assess the real-life efficacy, retention rate and related factors of both parameter in rheumatoid arthritis patients under tofacitinib.

**Methods:** We analyzed all RA patients registered to HURBIO database who received at least 1 dose of tofacitinib (for drug retention) and who had at least 1 control visit under tofacitinib (for efficacy). Drug retention rates were calculated using the Kaplan-Meier method and predictors of drug retention were determined by Cox proportional hazard model. Patients were grouped as “responder” or “non-responders according to DAS28 at last control visit: DAS28-CRP≥3.2: “Responders”; DAS28-CRP<3.2: “Non-responders”. Predictors of response (DAS28-CRP<3.2 at last visit) were determined by logistic regression analysis. Reasons for switching and discontinuation were also determined.

**Results:** For drug retention: a total of 247 (210 (85%) female) patients were recruited. Mean age was 53.1±12.6 years. Mean disease duration was 11.3±8.0 years. Rheumatoid factor and anti-CCP antibodies were positive in 160/240 (66.7%) and 135/207 (65.2%) patients, respectively. Combination with DMARDs was used in 83.3% of patients. 55.5% of patients was biologic-naive. Median follow-up while receiving tofacitinib was 10.2 (IQR:4.0-24.2) months. One-year crude retention rate was 64%. Median duration of drug retention was 24.8 months. Predictors of good tofacitinib retention were (in multivariate analysis): living in Ankara (where our center is located) (HR 1.43 (0.96-2.14); 95% CI) and BMI > 25 (HR 1.46 (0.97-2.29); 95% CI).

**For efficacy:** a total of 204 (174 (85.4%) female) patients were recruited. Mean age was 53.2±12.5 years. Mean disease duration was 11.5±8.1 years. Rheumatoid factor and anti-CCP antibodies were positive in 135/198 (68.1%) and 115/171 (67.2%) patients, respectively. Detailed demographic and clinical characteristics of participants were given in table 1. Mean follow-up while receiving tofacitinib was 11.6 (IQR:5.2-26.2) months. DAS28-CRP levels at baseline and last visit were 4.8 (IQR:3.9-5.4) and 3.3 (IQR:2.5-4.6), respectively (p<0.001). At last visit, 19.6% of patients was in low-disease activity (2.6sDAS28-CRP<3.2), 26.0% of patients was in remission (DAS28-CRP<2.6) Predictors of good response to tofacitinib were (in multivariate analysis, adjusted for follow-up duration under tofacitinib): biologic-naive (aOR 2.38 (1.30-4.34); 95% CI) and RF negativity (aOR 2.12 (1.13-3.96); 95% CI).

The most common cause of drug discontinuation was primary failure (in 36/108 patients, 33.4%).

**Conclusion:** Tofacitinib seems an effective treatment option for rheumatoid arthritis. Relationship between seronegativity and good response to tofacitinib needs to be elucidated. Also, Clinicians should keep in their mind that in addition to patient characteristics, socioeconomic factors may influence the adherence to the treatment.

**AB0332 IMMUNOSUPPRESSIVE AND IMMUNOMODULATING AGENTS IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW OF CLINICAL TRIALS AND THEIR CURRENT DEVELOPMENT STAGE**

J. Blaes1, J. Walther2, J. E. Gottenberg3, J. Sibilia1, L. Arnaud4, R. Felten4, Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Strasbourg, France;2Hôpitaux Universitaires de Strasbourg, Service de pharmacie-stérilisation, Strasbourg, France

**Background:** Rheumatoid arthritis (RA) is the most frequent chronic inflammatory diseases with an incidence of 0.5% to 1%. Therapeutic arsenal of RA has continuously expanded in recent years with the recent therapeutic progress with the arrival of conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDS), biological (bDMARDS) and targeted synthetic (tsDMARDS), JAK inhibitors. However, there are still some unmet needs for patients who do not achieve remission and who continue to worsen despite treatments. Of note, only approximately 40% of patients are ACR70 responders, in most randomized controlled trials. For these patients, finding new therapeutic avenues is challenging.

**Objectives:** The objective of our study was to analyze the whole pipeline of immunosuppressive and immunomodulating drugs evaluated in RA and describe their mechanisms of action and stage of clinical development.

**Methods:** We conducted a systematic review of all drug therapies in clinical development in RA in 17 databases of international clinical trials. Inclusion criterion: study from one of the databases using the keywords “Rheumatoid arthritis” (search date: June 1, 2019). Exclusion criteria: non-drug trials, trials not related to RA or withdrawn. We also excluded clinical trials of biosimilar preparations, cytokine-mediated therapies, NSAIDs, glucocorticoids or their derivatives and non-immunosuppressive or non-immunomodulating drugs. For each csDMARD, bDMARD and tsDMARD, we considered the study at the most advanced stage. For bDMARDs, we did not take into account biosimilars.

**Results:** The research identified 4652 trials, of which 242 for 243 molecules met the inclusion and exclusion criteria. The developed molecules belong to csDMARDS (n=21), bDMARDS (n=117), tsDMARDS (n=105).
Among the 21 csDMARDs molecules: 8 (38%) has been withdrawn, 4 (19%) are already labelled in RA (hydroxychloroquine, leflunomide, methotrexate and sulfasalazine) and 9 (43%) are in development: 1 (11%) is in phase III, 5 (26%) are in phase II, 3 (33%) are in phase IV.

Among the 117 bDMARDs molecules: 69 (59%) has been withdrawn, 9 (8%) are labeled in RA (abatacept, adalimumab, anakinra, certolizumab, etanercept, golimumab, infliximab, rituximab, sarilumab, tocilizumab) and 39 (33%) are in development: 9 (23%) in phase I, 3 (8%) in phase II, 21 (54%) in phase II, 5 (12%) are in phase III, 1 (3%) in phase IV. bDMARDs currently under development targets B cells (n=4), T cells (n=2), T/B cells costimulation (n=2), TNF alpha (n=2), interleukine 1 or his receptor (n=3), interleukine 6 or his receptor (n=7). Interleukine 17 (n=4), Interleukine 23 (n=1), GM-CSF (n=1), other cytokines or chemokines (n=5), integrins or adhesion proteins (n=3), interferon receptor (n=1) and various other targets (n=4).

Among the 105 tsDMARDs molecules: 64 (61%) has been withdrawn, 6 (6%) JAK inhibitors, have just been or will probably soon be labelled (baricitinib, filgotinib, peficitinib, tocitakinib and upadacitinib), 35 (33%) are in development.

JAK inhibitors, have just been or will probably soon be labelled (baricitinib, filgotinib, peficitinib, tocitakinib and upadacitinib), 35 (33%) are in development.

**Conclusion:** A total of 242 therapeutic trials involving 243 molecules have been or are being evaluated in RA. This development does not always lead to new treatments since 141 (58%) have already been withdrawn. Hopefully, some of the currently evaluated drugs will contribute to improve the therapeutic management of RA patients, requiring a greater personalization of therapeutic strategies, both in the choice of molecules and their place in therapeutic sequences.

### Conclusion:
In this cohort half of the patients that responded to treatment had achieved this by month 1. A higher baseline inflammatory profile was related to the response. Little difference is found between month 1 and 6 on clinical data, however ultrasonographic results suggest that at least 6 months are needed for Doppler improvement. Perhaps MTX has a faster effect over joint pain and lowers DAS28 scores requiring longer to completely suppress inflammatory activity.

### AB0334

**COST-EFFECTIVENESS OF JAK INHIBITORS IN RHEUMATOID ARTHRITIS IN THE REAL WORLD PRACTICE**

A. Calvo García1, N. García Castañeda1, C. Valero1, I. Llorente1, B. Vara2, A. García-Vadillo1, I. González-Alvázar2, A. Morell3, E. Ramírez1, R. García de Vicuna1on behalf of HUP IMID Therapy Unit, 1University Hospital La Princesa, IIS-IP, Pharmacy, Madrid, Spain; 2University Hospital La Princesa, IIS-IP, Rheumatology, Madrid, Spain; 3University Hospital Santa Cristina, IIS-IP, Rheumatology, Madrid, Spain

**Background:** The Janus Kinase (JAK) inhibitors Baricitinib (BAR) and Tofacitinib (TOF), both in monotherapy or in combination with methotrexate, are indicated for the treatment of active rheumatoid arthritis (RA) with inadequate response to conventional synthetic disease modifying anti-rheumatic drugs (csDMARD). Data about cost-effectiveness in a real-world setting are still scarce.

**Objectives:** To assess the cost-effectiveness (C-E) of BAR and TOF in patients with RA in usual clinical practice.

**Methods:** Retrospective observational study of adult RA patients who started BAR and TOF between September 2017 and December 2019, in a university hospital. Data were collected from the electronic medical records and the Dominican® External Patient Dispensing program. Demographic, clinical and laboratory parameters [erytrocyte sedimentation rate (ESR), C reactive protein (CRP), Rheumatoid factor (RF), anti-citrullinated peptide antibodies (ACPA)], concomitant csDMARD, previous biological (b) DMARD, DAS28-ESR activity score items, and treatment duration were registered. DAS28-ESR remission or low disease activity (LDA) were used as the effectiveness measure to estimate C-E. The official Spanish prices were considered to calculate the costs of the treatments. Statistical analysis was performed with SPSS v.15 program. Descriptive statistics are shown in proportions, medians and interquartile ranges (IQR).
The Wilcoxon signed ranges test was applied for the changes from baseline of DAS28-ESR and CRP.

Results: 39 patients were included, 87.2% women, median age 62.9 (49.9-74.4) years. Both patients (23.1%) were naive to biDMARDs, 6 (15.4%) had received 1, 18 (46.1%) 2, and 6 (15.4%) ≥3 previous biDMARDs. Demographic, clinical and effectiveness characteristics are shown by drug in the Table:

</table>

Regarding BAR, 17 patients (56.6%) continue on treatment and 3 (10%) changed to TOF. The change in DAS28-ESR was statistically significant (p = 0.000), as well as difference in CRP (p = 0.008). The total cost per analysed period was €357,806.40, with 18/30 patients (60%) achieving remission or LDA. The C-E was €19,878.13. As for TOF, 6 patients (66.6%) remain on drug, with no switch to BAR. Neither the difference from baseline in DAS28-ESR nor the CRP changes reached statistical significance (p = 0.08 and p = 0.735, respectively). The total cost per analysed period was €90,201.72, with 4/9 patients (44.4%) achieving remission or LDA. The C-E was €22,573.0.

Conclusion: In our daily practice, JAK inhibitors are mainly used in combination with csDMARD and commonly after failure to a 1 DMARD. In this real setting, BAR proves to be cost-effective, while TOF renders less effectiveness. However, results should be addressed with caution because of the smaller sample size of TOF population. Additional studies with greater follow-up and sample size are needed to confirm these findings.

Disclosure of Interests: None declared.

AB0336 IMPACT OF SUBJECTIVE INTOLERANCE TO METHOTREXATE ON THE QUALITY OF LIFE OF PATIENTS WITH RHEUMATOID ARTHRITIS: SIDE EFFECTS AND AVOIDANCE COPING STRATEGIES THROUGH SELF-ADMINISTRATION IN THE EVENING OR DURING THE WEEKEND

G. Cavalli1, M. Biggioggero2, A. Caridi1, G. De Luca1, E. Agape3, N. Bottini1, E. Baldissera1, L. Dagni1, E. G. Paffi1, Vita-Salute San Raffaele University, Milan, Italy; 2Università degli Studi di Milano, ASST Gaetano Pini-CTO, Milan, Italy.

Background: Methotrexate (MTX) represents the anchor drug for the treatment of rheumatoid arthritis (RA), as well as other rheumatological diseases such as psoriatic arthritis (PsA) and spondyloarthritides (SpA). Despite consolidated clinical efficacy, the use of MTX suffers from relevant limitations. Common issues include subjective intolerance, nausea, malaise, and fatigue, which negatively impact on quality of life and work/social participation.

Objectives: In this study, we evaluated the frequency with which patients on MTX therapy opt for self-administration over the weekend or in the evening hours, in order to minimize interference with daily activities, work productivity, and social participation.

Methods: A cross-sectional, prospective study was performed in two tertiary referral Rheumatology clinics, which included consecutive patients with RA, PsA, or SpA on MTX therapy. Enrolled patients had not previously received instructions by their healthcare provider as to when during the week or day MTX ought to be administered, and were free to choose or change the weekday and time for self-administration. Data on the route and timing of MTX self-administration was collected using dedicated questionnaires, which included queries on the dose and route of administration, day of the week and time of self-administration, reasons for the patient’s choice, use of folic acid supplementation, and concomitant therapies. Statistical analyses were conducted using a chi-square test; a p-value <0.05 was considered significant.

Results: A total of 275 consecutive patients treated with MTX were included, mostly with RA (86%). Patients had an average age of 59.8 years (SD 14.0) and an average disease duration of 134.5 months (SD 127.3). The average MTX dose was 15 mg/wk (SD 4.4); MTX was administered subcutaneously in 68.2% of cases, orally in 17.8%, and intramuscularly in 5%. Regarding the timing of MTX self-administration, 157 patients (57.1%) took MTX in the evening and 119 patients (44.3%) took it during the weekend; even among patients taking MTX in the evening, weekend administration was preferred (93/157, 59.2%, p <0.001). The most frequent reasons leading to MTX self-administration during the evening or weekend were gastrointestinal side effects (nausea (85% of cases), fatigue (63%), interference with work activities (36%), and interference with social activities (29%). Patients who opted for MTX self-administration in the evening or over the weekend were significantly younger (p <0.001), with no significant gender differences or disease duration differences.

Conclusion: The majority of patients with inflammatory arthritis opt for self-administration of MTX in the evening (absolute majority) or during the weekend (relative majority). This choice is dictated by the need to avoid side effects and detrimental repercussions on the individual’s social or working life. The adoption of these strategies for minimizing the adverse effects of MTX is more frequent among younger patients, and provides an answer to their specific needs.
AB0337 TOFACITINIB MONOTHERAPY OR COMBINED WITH METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS SHOW SIMILAR RETENTION OVER FOUR YEARS. REPORT FROM RHUMADATA ©

D. Choquette1, L. Bessette2, L. Choquette Sauvageau1, I. Ferdinand3, B. Héroux4, F. Massicotte1, J. P. Pelletier1, J. P. Raynauld1, M. A. Rémillard1, D. Sauvageau1, É. Villeneuve1, L. Cupal2, Institut de Recherche en Rhumatologie de Montréal, Montréal, Canada; 2Centre de l’Ostéoporose et de Recherche en Rhumatologie de l’Est, Québec, Canada

Background: Since the introduction of biologic agents around the turn of the century, the scientific evidence shows that the majority of agents, independent of the therapeutic target, have a better outcome when used in combination with methotrexate (MTX). In 2014, tofacitinib (TOFA), an agent targeting Janus kinase 1 and 3, has reached the Canadian market with data showing that the combination with MTX may not be necessary [1,2].

Objectives: To evaluate the efficacy and retention rate of TOFA in real-world patients with rheumatoid arthritis (RA).

Methods: Two cohorts of patients prescribed TOFA was created. The first cohort was formed of patients who were receiving MTX concomitantly with TOFA (COMBO) and the other of patients using TOFA in mono-therapy (MONO). MONO patients either never use MTX or were prescribed MTX post-TOFA initiation for at most 20% of the time they were on TOFA. COMBO patients received MTX at the time of TOFA initiation or were prescribed MTX post-TOFA initiation for at least 80% of the time. For all those patients, baseline demographic data definitions. Disease activity score and HAQ-DI were compared from the initiation of TOFA to the last visit. Time to medication discontinuation was extracted, and survival was estimated using Kaplan-Meier calculation for MONO and COMBO cohorts.

Results: Overall, 194 patients were selected. Most were women (83%) on average younger than the men (men: 62.6 ± 11.0 years vs. women: 56.9 ± 12.1 years, p-value=0.0130). The patient's assessments of global disease activity, pain and fatigue were separately 5.0 ± 2.7, 5.2 ± 2.9, 5.1 ± 3.1 in the COMBO group and 6.2 ± 2.5, 6.5 ± 2.6, 6.3 ± 2.8 in the MONO group across all different age groups. HAQ-DI at treatment initiation was 1.3 ± 0.7 and 1.5 ± 0.7 in the COMBO and MONO groups, respectively, p-value=0.0085. Similarly, the SDAI score at treatment initiation was 23.9 ± 9.4 and 25.2 ± 11.5, p-value=0.5546. Average changes in SDAI were -13.4 ± 15.5 (COMBO) and -8.9 ± 13.5 (MONO), p-value=0.1515, and changes in HAQ -0.21 ± 0.63 and -0.26 ± 0.74, p-value=0.6112. At treatment initiation, DAS28(4)ESR were 4.4 ± 1.4 (COMBO) and 4.6 ± 1.3 (MONO), p-value 0.5815, with respective average changes of -1.06 ± 0.07 and -0.70 ± 1.96, p-value=0.2852. The Kaplan-Meier analysis demonstrated that the COMBO and MONO retention curves were not statistically different (log-rank p-value=0.9318).

Conclusion: Sustainability of TOFA in MONO or COMBO are not statistically different as the changes in DAS28(4)ESR and SDAI. Despite this result, some patients may still benefit from combination with MTX.

AB0338 EVALUATION OF THE ASSOCIATION OF ALLELES OF INTOLERANCE RISK TO METOTREXATE IN RHEUMATOID ARTHRITIS PATIENTS UNDER TREATMENT WITH BIOLOGIC THERAPIES

A. Escudero Contreras1, R. Ortega Castro2, J. Calvo Gutierrez3, N. Menavázquez4, R. Caliz Caliz5, E. Collantes Estevez6, A. Fernandez Nebro7, M. O. Abalos-Aguilera1, C. Lopez-Pedraza8, M. T. Ruiz Jimenez2, F. U. Pilar9, Hospital Universitario Reina Sofia, Córdoba; Maimonides Biomedical Research Institute of Cordoba (IMBiC)/University of Cordoba, Rheumatology, Cordoba, Spain; Hospital Carlos Haya, Malaga, Malaga, Spain; Complejo Hospitalario Universitario, Granada, Spain; Hospital Carlos Haya, Malaga, Spain; Roche Farma, Madrid, Madrid, Spain

Background: Metotrexate (MTX) is the first-line treatment for rheumatoid arthritis (RA) both in monotherapy and in combination with biologic disease-modifying antihematic drugs (bDMARDs), it usually well tolerated but AEs may appear that causing toxicity that requires suspension of the treatment.

Objectives: Determine the prevalence of certain polymorphisms among patients that receive bDMARD in monotherapy or in combination with MTX to confirm its relevance as biomarkers of intolerance. Evaluate the influence of certain polymorphisms in the effectiveness of monotherapy or combined treatment in patients, through “Disease Activity Score 28” (DAS28), SDAI simple disease activity index (SDAI), Clinical disease activity index (CDAI) and each one of its components.

Methods: Retrospective observational multicentric study (University Hospital Complex, Granada, Carlos de Haya Hospital, Malaga and University Hospital Reina Sofia, Cordoba), of cases-control of 227 patients with RA (criteria ACR/EULAR), of which 120 received MTX and bDMARD combined therapy (cases) and other with only bDMARD (controls). All of them had been or were currently treated with MTX, remained with stable doses of bDMARD, and had a DNA sample stored before the inclusion in the study.

DNA was isolated from total peripheral blood and by fluorescent probe HybProbe and/or Taqman, 10 polymorphisms of 10 protein coding genes were determined involved in the metabolism and toxicity of MTX according to current evidence.

Besides the type of polymorphism, data on the activity of the disease were analysed (DAS28VSG, DAS28PCR, SDAI, CDAI, at the start of the MTX income, of the BT, and in the inclusion visit)

A descriptive and comparative study was carried out on all that and afterwards an assessment was made through a multiple logistic regression analysis (MLR) on the risk of intolerance to MTX.

Results: An analysis was carried out on 227 patients (120 cases and 107 controls) with an average age of 60 (12, 1) being women 78,4%, with a time of evolution since diagnosis of 14,84 (7,78) years 48,9% registered adverse events (AE) MTX related, mainly gastrointestinal, hepatic and skin-subcutaneous tissue. The percentage of AE appearance was superior in the monotherapy group than in the group with combined therapy.
The most prevalent polymorphism (84.6% (IC95%: 84.0%-85.11%)) and in cases (86.0% (IC95%: 79.4%-92.57%) was homozygous CC (ITPase-c94a); in controls homozygous GG (GGH-T401C) (87.5% (IC95%: 81.5%-93.42%).

There were no significant differences in the parameters of activity between groups, in both, patients were best basally controlled than at the start of the MTX income and/or bDMARD

Being homozygous-AA for the DHFR gene was significantly associated (p<0.05) with the appearance of AE (none of the 4 homozygous AA patients for that gene had AE).

In MLR, homozygous GG (ref. homozygous AG) in polymorphism GGH-T401C, being homozygous CC (ref. homozygous TC) in polymorphism ABC2-C24T and PCR (mg/dL) at the start of bDMARD resulted independent predictive factors of MTX intolerance.

Conclusion: Polymorphisms T401C for the GGH gene and C24T for the ABC2 gene and PCR at the start of the bDMARD resulted independent predictive factors of MTX intolerance.

Polymorphism homozygous AA for DHFR gene was related to significant protection against appearance of AE.

**The importance of therapeutic compliance: adherence to methotrexate and its role in immunogenicity**

P García1, M. González Fernández2, M. N. Rivas1, J. Duruelo1, E. Garmaenda1, J. Arostegui Lavilla1, F. Perez-Ruiz1, A. Alonso1, C. Modesto1, B. A. Blanco Cáceres2,1Hospital Universitario Cruces, Barakaldo, Spain; 2Hospital Ramón y Cajal, Madrid, Spain

Background: Immunogenicity against adalimumab leads to loss of response and secondary failure to biologic therapy; however, concomitant use of methotrexate (MTX) seems to reduce the development of anti-drug antibodies (ADAbs) in a dose-dependent manner. Suboptimal adherence to MTX may favour ADAbs appearance.

Objectives: To evaluate the relationship between MTX adherence and ADAbs development.

Methods: Observational study among adult patients with chronic inflammatory arthropathy, followed in a tertiary care centre, who were in treatment with MTX and adalimumab. ADAbs formation in relation to MTX adherence was assessed. Results: 33 patients were included, with a MTX adherence overall mean of 82.13 (12.45%-100%, median adherence 92.19%). Only 9.09% (n=3) of the patients declared. Eduardo Collantes Estezvez Grant/research support from: ROCHE and Pfizer, Speakers bureau: ROCHE, Lily, Bristol and Celgene.

Conclusion: No statistically significant differences (p>0.05) involving MTX adherence and its dose were found.

Conclusion: While the sample is small, this study suggests that ADAbs development may be influenced by MTX adherence, thereby promoting adequate MTX adherence should be a priority in the daily practice of every rheumatologist.

**AB0340**

**EFFECT OF BARICITINIB ON RANKL SERUM CONCENTRATION IN RHEUMATOID ARTHRITIS PATIENTS**

C. Gardi1, F. R. Spinelli1, F. Cecchiarelli1, S. Mancuso1, C. Barbati1, T. Colasanti1, C. Alessandri1, F. Conti1,1Sapienza University of Rome, Rome, Italy

Background: RANKL, (receptor activator of nuclear factor xB ligand) and osteo-protegerin, the main regulators of bone metabolism, are involved in osteoblasts/ osteoclasts balance in inflammatory disease, such as Rheumatoid Arthritis (RA). Janus kinase (JAK) inhibitors (baricitinib and tofacitinib) can reduce the progression of structural damage in patients with moderate to severe RA. Previous studies suggest a link between JAK inhibition, production of RANKL and osteoclastogenesis.1,2

Objectives: to investigate the effect of baricitinib on RANKL serum concentration in unslected RA patients.

Methods: Patients affected by RA according to 2010 ACR criteria, starting treatment with baricitinib as clinically indicated, were consecutively enrolled. Demographic, clinical and laboratory data were collected at baseline (T0) and after three months of therapy (T3). RANKL serum concentration was analyzed by ELISA at the same timepoints. All patients underwent ultrasound (US) examination at T0 and T3. According with OMERACT defini-tions, the presence of synovial effusion, hypertrophy and power Doppler were assessed and scored on a semi-quantitative scale (0=absent, 1=mild, 2=moderate, 3=severe), obtaining a total US score (0-198), representing the joint inflammatory status (15); erosions were registered. Data were expressed as median (interquartile range); Mann-Whitney and Spearman tests were performed for comparisons and p values <0.05 were considered statistically significant.

Results: We prospectively followed up 33 RA patients starting treatment with baricitinib [M/F 8/25; age 58(9) years; disease duration 165(150) months; 22/33 (67%) ACPA-anti-citrullinated protein antibody positive; 24/33 patients (73%) RF-rheumatoid factor positive]. After three months of therapy we observed a significant reduction of DAS28CRP, CDAI and SDAI compared to baseline (p<0.0001). The US inflammatory score showed a significant improvement at T3 (p<0.0001). The serum concentration of RANKL showed a significant decrease after three months of therapy from 44 (25.9) to 27.5 (35.3) pg/ml, p=0.0256 (Figure 1). While in 67% of patients RANKL decreased after treatment, in 93% of patients no decrease or an increase of RANKL was detected. Those patients showing an increase of RANKL had similar DAS28CRP, CDAI, SDAI, but had significantly less swollen joints, compared to those in which RANKL decreased (p=0.0364). At baseline, the concentration of RANKL significantly correlated with the swollen joint count (p=0.0117) and ESR (p=0.0482), but not with DAS28CRP, CDAI, SDAI nor with the US inflammatory score. Nevertheless, the reduction of RANKL was not significantly associated with the achievement of low disease/remission after three months of treatment, with ACPA/RF positivity or the presence of erosions detected by US.

Conclusion: This is the first study demonstrating that baricitinib reduces in vivo the serum levels of RANKL, regardless the correlation with disease activity reduces. The discrepancy between the levels of RANKL and the clin-ical response is in line with previous data in the literature, demonstrating that, under treatment with anti-TNF and anti-IL-1, the decrease of RANKL did not
influence the local or systemic inflammatory parameters, even if still preventing bone loss3.

AB0341  SURVIVAL OF REMISSION OR LOW DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOFACITINIB. RESULTS OF RUSSIAN NATIONAL REGISTER

1Mechnikov North-Western State Medical University, St-Petersburg, Russian Federation; 2Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 3Yaroslavl State Medical University, Yaroslavl, Russian Federation; 4Moscow Clinical Scientific and Practical Centre named after Loginov AS, Moscow, Russian Federation; 5Volgograd State Medical University, Volgograd, Russian Federation; 6Regional Clinical Hospital, Tula, Russian Federation; 7Tula State Medical University, Tula, Russian Federation; 8Regional Clinical Hospital, Kaliningrad, Russian Federation; 9Petrozavodsk State University, Petrozavodsk, Russian Federation; 10Clinical Rheumatological Hospital №25, St. Petersburg, Russian Federation

Background: Tofacitinib is an oral Janus Kinase inhibitor for the treatment of rheumatoid arthritis (RA). The survival of remission or low disease activity (LDA) in RA patients, treated with tofacitinib remain unknown.

Objectives: To evaluate the survival of DAS28 remission or low disease activity in RA patients treated with tofacitinib.

Methods: Data from 102 patients from Russian national register of patients with RA treated with tofacitinib (OREL), achieved DAS28 remission (DAS28<2.6, n=92) or LDA (DAS28<3.2, n=102) were analyzed. Number of patients with increased disease activity, time of disease activation were registered. Statistical analysis performed with statistical programs SPSS2017 and GraphPadPrizm. p-value < 0.05 considered as significant.

Results: Baseline characteristics of the patients are presented in table 1.

Table 1. Baseline characteristics of the patients with RA (n=102).

Proportions of survival of remission or LDA are presented at figure 1 and figure 2 respectively.
In 28 from 45 cases of remission failure (62.22%) and in 34 cases from 65 cases of LDA loss (52.3%) the proposal reasons of treatment effect loss were non-medicai (absence of reimbursement, changes in patients accommodation, low treatment compliance, etc.). Medical reasons (side effects, inefficacy, etc.) of decrease in remission or LDA survival rate were registered in 17 from 45 cases of remission loss (37.7%) and in 31 from 65 cases of LDA loss (47.69%).

**Conclusion:** On-year survival of remission or low disease activity achieved in Rheumatoid arthritis patients treated with tofacitinib is 51.1% and 36.3 % respectively. The main reasons of treatment efficacy loss were associated with non-medical.

8Zagreb University School of Medicine, University Hospital Centre Zagreb, Dept. of Pharmacology, Zagreb, Croatia

**Background:** It has been demonstrated that bioavailability of oral (P.O.) MTX reaches plateau at doses ≥15mg QW, and that subcutaneous (S.C.) form has a better efficacy. Alongside with less side-effects this might translate into improved quality of life (QoL) and better adherence.

**Objectives:** An academic-induced observational longitudinal study of patients with RA and peripheral form of PsA on csDMARDs who were switched from oral (P.O.) to subcutaneous (S.C.) MTX was conducted. Previously we reported on the better efficacy of S.C. compared to P.O. MTX. The objective of this part of the study we are presenting is to evaluate the 6-month changes in quality of life (QoL), adverse events and adherence in these patients.

**Methods:** Forty-eight consecutive patients (79.2% women) with established diagnosis of RA (77.1%) and peripheral PsA were enrolled from the outpatient clinics in six centres in Croatia. Median age was 61 (39-79) years, and the median of disease duration was 120 (3-528) months. Data were collected at baseline (T0) (on P.O. MTX), at day 90 (±10 days) (T1) and at day 180 (±10 days) (T2), during S.C. MTX treatment. Median dose of MTX remained stable during the study (15mg QW). At each visit QoL was measured using EuroQol-5D (EQ-5D).

**Results:** EQ-SD global health assessment showed significant improvement in quality of life of patients on S.C. MTX during the 6 month follow-up (change from T0 to T2 8.6%, 95%CI 4.00, 13.3), and the same trend was observed in each of its five component. Number of patients who experienced adverse events related to MTX use has decrease after switching from P.O. to S.C.MTX – from 52.1% during the last 3 months on P.O. MTX to 33.3% during the first 3 months and 18.2% during the last 3 months of S.C. MTX use. During the follow-up adherence to MTX therapy improved, with 25% of patients who missed dose during the last 3 months on P.O. MTX use, to 6.3% and 2.3% with missed dose in the first and the last 3 months on S.C. MTX, respectively.

**Conclusion:** In our group of patients with RA and peripheral PsA who switched from oral to subcutaneous MTX there was a consistent improvement in QoL, less adverse events and better adherence.

**FACTORS WHICH CONTRIBUTE PERSISTENCY AND OPTIMAL USE OF TOFACITINIB: LESSONS FROM LONG TERM DAILY CLINICAL USE OF TOFACITINIB**

1Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, Nagasaki, Japan; 2Department of Rheumatology, Sasebo Chuo Hospital, Sasebo, Japan, Sasebo, Japan

**Background:** Recently, tofacitinib treatment in rheumatoid arthritis (RA) is thought to be not inferior to other biologic disease-modifying antirheumatic drugs (bDMARDs) such as TNF-inhibitor. However, approval of tofacitinib for treatment with RA is relatively recent as compared to other bDMARDs, therefore until now, little knowledge about long term efficacy and safety of tofacitinib in real-world settings or about which patients should be initiated tofacitinib are available. Thus, we need evidence from real-world setting for optimal use of tofacitinib.

**Objectives:** To investigate the efficacy and safety of tofacitinib and to identify factors which contribute persistency and efficacy of tofacitinib treatment during 2 years.

**Methods:** 148 patients, for whom tofacitinib was initiated until January 2018 were enrolled. All patients received 5mg of tofacitinib twice daily and were followed for 2 years. Clinical disease activity indicated by disease activity score (DAS28-ESR as well as adverse events (AEs) were evaluated. Statistical analysis was performed to determine which baseline variables influenced the persistency and efficacy of tofacitinib.

**Results:** 92 patients (62.2 %) continued tofacitinib for 2 years. Clinical disease activity rapidly and significantly decreased, and this efficacy continued throughout the 2 years: i.e., DAS28-ESR decreased from 5.13 ± 1.42 at baseline to 4.02 ± 1.11 at 4 weeks and 3.91 ± 1.32 at 2 years (P<0.0001, vs. baseline). 55 AEs including 22 herpes zoster infection occurred during tofacitinib treatment. 27 patients discontinued tofacitinib due to lack of efficacy. Multivariable logistic analysis showed that the number of bDMARDs previously used and age were associated with discontinuation of tofacitinib treatment due to lack of efficacy (table 1). Another set of multivariable logistic analysis revealed that lower disease activity at baseline contributed the achievement of DAS-low disease activity (odds ratio = 1.56, 95% confidence interval: 0.48-5.85). In the concomitant use of MTX or without MTX, the 4 values of DAS28-ESR from baseline to 24 months were -1.62, -1.13, respectively (P=0.12). And, the efficacy of patients after switching from tocilizumab (TCZ), which also inhibit IL-6 as same as JAK inhibitor, were not inferior as compared to non-switching from TCZ (A DAS28-ESR<1.07, -1.61 respectively P=0.10).

Conclusion: Our present study suggests that tofacitinib is effective in real-world settings even without concomitant MTX. Our results also suggest that for continuous use of tofacitinib without lack of efficacy, use tofacitinib earlier during switching strategy for RA patients who have failed to be treated with bDMARDs is better.

AB0345 Efficacy of JAK inhibitors in refractory rheumatoid arthritis

M. Kamiya1, 2, Nara Hospital, Kandai University, Department of Orthopedics and Rheumatology, Ikomu-cho, Nara, Japan

Background: Disease-modifying antirheumatic drugs (DMARDs) have been the main agents for treating rheumatoid arthritis (RA) unless there are serious clinical restrictions or contraindications such as comorbidities. With inefficacy of conventional synthetic DMARDs (e.g., methotrexate), biological DMARDs (bDMARDs) are now available to suppress progression of joint destruction. However, bDMARDs cannot control disease activity in some patients, so JAK inhibitors targeting different cytokines are expected to be beneficial.

Objectives: This study investigated factors associated with the efficacy and continuation of JAK inhibitor therapy in patients with refractory RA for whom disease activity was not adequately controlled even with multiple sequentially administered bDMARDs with different targets.

Methods: We obtained the number of bDMARDs used and the various reasons for discontinuing therapy in our hospital from January 2005 to December 2019. Kaplan–Meier analysis was used to obtain the therapy continuation rate, and the log-rank test was used to examine the difference in therapy continuation rate. Refractory RA was defined as RA with inefficacy and one or more bDMARDs with different targets (1 or more tumor necrosis factor inhibitor, a selective costimulation modulator abatacept, and an interleukin 6 receptor inhibitor tocilizumab). We then examined patients with refractory RA who had received tofacitinib (TOF) or baricitinib (BAR) therapy after discontinuation of a series of bDMARDs due to unsatisfactory response. Various statistical tests were performed to identify predictors of ≥6-month continuation of JAK inhibitor therapy that achieves low disease activity without increases in prednisolone (5.2%), switch to biosimilars (5.2%), and remission (3.7%). The bDMARDs continuation rate and the number of bDMARDs used were 69.6% and 2.17 for 5 years and 53% and 2.83 for 10 years, respectively, if the switch was considered to be continuous.

Results: The discontinuation reasons for discontinuing therapy in our hospital from January 2005 to December 2019 were inefficacy of conventional synthetic DMARDs (e.g., methotrexate), biological DMARDs (bDMARDs) are now available to suppress progression of joint destruction. However, bDMARDs cannot control disease activity in some patients, so JAK inhibitors targeting different cytokines are expected to be beneficial.

AB0346 The numerical changes of peripheral lymphocyte subsets in patients with rheumatoid arthritis and their restorations after received combined immunomodulatory therapy

R. Zhao1, S. X. Zhang1, X. Wang1, J. Qiao1, J. Q. Zhang1, M. T. Qiu1, M. J. Chang1, Y. Li1, J. Luo1, G. Y. Liu1, C. Gao2, X. Li11, The Second Hospital of Shanxi Medical University, Taiyuan, China; 2Brigham and Women's Hospital, Harvard Medical School, Boston, United States of America

Background: Rheumatoid arthritis (RA) is an aggressive immune-mediated joint disease with synovial inflammation and joint destruction characterized by abnormal immune responses to self-antigens1. An imbalance in pro- and anti-inflammatory lymphocyte subsets has been considered to contribute to the pathogenesis of RA2. However, the detailed lymphocyte statuses of RA patients are required clarified and the effect of immunomodulatory therapy on the lymphocyte subsets is unclear.

Objectives: To investigate the status of lymphocyte subsets in peripheral blood (PB) of RA patients at relatively large-sample size and the changes of them after our immune regulatory combination treatment.

Methods: This cross-sectional study enrolled 3016 patients with RA who met the ACR’s revised RA diagnostic classification in 1987 as well as 206 healthy controls (HCs). Among these participations, 1415 patients have received the treatment of immunomodulatory drugs (IMiDs) such as low-dose interleukin-2, rapamycin, metformin, rotiline acid etc. Flow cytometry (FCM) was used to measure the levels of PB lymphocyte subgroups and CD4+ T subsets in RA patients before and after the treatments and HCs. Data were expressed as mean ± standard deviation to the distribution. Independent-samples T test and paired-samples T test were applied. P value < 0.05 were considered statistically significant.

Results: Compared with HCs, patients with RA had a lower absolute numbers of total T, CD8+ T, NK and Tregs (P < 0.05), decreased percentages of NK, Th1, Th2 and Th17 (P < 0.05), but higher ratios of Tcfs/Tregs such as Th1/Tregs and Th17/Tregs (P < 0.05), indicating a disturbance of immune systems (Figure 1). After receiving combined immunomodulatory therapy, the absolute numbers of T, B, CD4+CD8+ T, CD8+ T, NK, Th1, Th17 and Th2 were dramatically increased (P < 0.05) and the percentages of B, Th1, CD4+ T and Tregs were also increased (P < 0.05). Although these subsets increased globally, the ratio of Tcfs/Tregs such as Th2/Tregs and Th17/Tregs tended to decrease, suggesting a rebalance of immune systems (Figure 2).

Conclusion: Impaired peripheral lymphocytes especially insufficiency of Tregs might played an important role in pathogenesis of RA. Immunoregulatory combination therapies could promote the proliferation and functional recovery of Tregs in patients and help to alleviate disease activity.

Figure 1: Composition of lymphocyte subsets in peripheral blood between HCs (n=500) and RA patients (n=1000). All the lymphocytes subsets were analyzed by flow cytometry combined with standard absolute counting basis. Data were presented in mean±SD and statistical analysis was determined by two-tailed unpaired t-test. Patients had lower levels of T, CD4+ T, NK, and Tregs A and B; distribution percentages of NK, Th1, Th2 and CD4+ T and Th2 were higher than those of RA patients with Th1/Tregs and Th2/Tregs in RA compared with those of HCs. INCREASING TO OPTIMAL METHOTREXATE DOSE MIGHT BE A BETTER TRADITIONAL DMARD STRATEGY IN RA TREATMENTS: A RANDOMIZED CASE-CONTROL TRIAL OF HAKKA PEOPLE IN SOUTHERN CHINA

D. Lin1, Y. Wen2, Y. Zhang1, Q. Chen1, Y. Pan1, L. Qing1, J. Gu1. 1The 3rd Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 2The 3rd Affiliated Hospital of Sun Yat-sen University Yuedong Hospital, Meizhou, China

Background: The optimal methotrexate (MTX) dose is defined as 0.3mg/kg/week or ≥ 20mg/week at 6 months. [1] Considering average weight of Chinese, [2] the optimal MTX should be >15mg/w. However, not more than 30% in 25191 RA cases ever had MTX treatment in CREDIT (Chinese Registry of Rheumatoid arthritis). [3] The biggest concern is side effects of MTX. Our study is to investigate whether increasing MTX would get better results accompanied with more side effects to Chinese people.

Objectives: Hakka people have the purest genes of the majority people-Han in China. It is planned to recruit 160 RA patients in Meizhou, where is a gathering place of Hakka people.

Methods: The RA volunteers had no relief with 10mg/w oral dose of MTX with/ without other 1-2 inadequate dose of DMARDs for at least 3 months. They were randomly divided into 1:1:1 groups. The experimental group would be treated with original DMARDs and incremental MTX (gradually increased to the optimal oral dose (0.3mg/kg) in the first 12 weeks and folic acid (the dose adjusted on demand with range from 5mg/w to 5mg tid)). While the control group would be treated with original MTX dose(10mg/w) but incremental original DMARDs (gradually increased to the maximum dose in the first 12 weeks). The two groups would keep the treatment at 12th week last to the 36th week, and the efficacy and safety indexes would be evaluated during the whole study.

Results: 1)We planned to recruit 160 RA patients in our study, 46 Hakka RA patients were enrolled in the study so far. 2 of 46 finished the 24th week visit and 24 finished the 36th week visit. The average age is 54.2±9.3 years old, the average weight is 59.1±11.1kg, and the female to male ratio is 41:5. 2)The average Folic acid dose is 14.4±9.5mg/w in the experimental group at the 12th week. 3)The morning stiffness time, PGA, PhGA, HAQ, DAS28 were better in experimental group after 12 weeks though slightly worse during 0-12 weeks. 4) Only 1 case(5.9%,1/23)had adverse event while 6 cases (26%,6/23) occurred adverse events. All events were mild level. 5)At 36th week, 100%(12/12) in experimental group after 12 weeks though slightly worse during 0-12 weeks. 1 case (4.2%,1/23) in control group with adverse events. All events were mild level. 6)1 case (4.2%,1/23) in control group with adverse event (grade 1) while 6 cases (26%,6/23) occurred adverse events. All events were mild level. 7)The morning stiffness time, PGA, PhGA, HAQ, DAS28 were better in experimental group at the 36th week.

Conclusion: Hakka patients in China might have better outcomes due to increasing MTX to the 0.3mg/kg/w dose than increasing the other DMARDs. Therefore, We recommended the Hakka patients choose MTX as first incremental DMARD.

AB0348

THE EFFECTIVENESS AND SAFETY OF BARICITINIB AFTER INSUFFICIENT RESPONSE TO BDMARDs OR TSMDARDS IN PATIENTS WITH RA FROM JAPANESE MULTI-CENTER REGISTRY: 24-WEEK OUTCOMES

H. Masahiro1, N. Takahashi2, T. Kojima2 on behalf of TBCR. 1Chichinomya Municipal Hospital, Orthopedic Surgery / Rheumatology, Ichinomiya, Japan; 2Nagoya University Graduate School of Medicine, Orthopedic Surgery and Rheumatology, Nagoya, Japan; 3Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan

Background: EULAR has issued updated guidelines for the management of rheumatoid arthritis (RA) using conventional, biologic, and targeted synthetic DMARDs. In the 2019 update, the task force revised the preference of bDMARDs over tsDMARDs. In routine clinical practice, baricitinib is commonly used as second line or after. However, there is little information about the clinical efficacy and safety profile of baricitinib after failure of the previous agent, including another tsDMARD. Objectives: The aim of this study was to evaluate the short-term effectiveness and safety profiles of baricitinib after insufficient response (IR) to bDMARDs or tsDMARDs in patients with RA in clinical settings.

Methods: RA patients who had been treated with baricitinib after failure of the previous agent were registered in the TBCR, a Japanese multicenter registry for RA patients treated with biologics or JAK inhibitors and followed for at least 24 weeks. Patients were divided into two groups according to the cause of failure of the previous treatment; IR ("After IR" group) and the others ("After non-IR" group). "After IR" group was further divided into four groups according to the previous agent; TNF inhibitor (TNFi group), IL-6 receptor inhibitor (IL-6RI group), abatacept (ABT group) and tofacitinib (Tofa group). We assessed disease activities by CDAI score and drug retention rates between these groups. Furthermore, discontinuation rates due to IRs and adverse events (AEs) were evaluated.

Results: A total of 86 consecutive RA patients were registered in this study. The previous treatment was as follows; TNFi inhibitor: 38 (44.2%), IL-6 receptor inhibitor: 23 (26.7%), abatacept: 11 (12.8%), tofacitinib: 13 (15.1%) and the other: 1 (1.2%). The cause of failure of the previous therapy were IRs (n=74: 86%), AEs (n=6: 7.0%) and the others (n=6: 7.0%). In "After IR" group, the most common previous agents were TNFis (Table 1). While the percent change in CDAI was decreased at week 12 in all groups, those in Tofa group showed lower rates of improvement in CDAI compared to the others at week 24 (Figure 1). Drug retention rate at 24-week was 89.4% in TNFi group, 90.5% in IL-6RI group, 54.5% in ABT group and 77.8% in Tofa group (Figure 2). In the present study cohort, seven patients developed herpes zoster. All seven patients were treated with antiviral agents for herpes zoster and restarted baricitinib treatment (these cases were not treated as discontinuation due to AEs in this study). The overall Cumulative discontinuation rate due to IRs and AEs at 24 weeks were 9.7% and 7.3%, respectively.
The dynamic of the disease activity in 3 groups is presenting on the TOFA. The disease activity after 6 and 12 months of therapy. All patients were divided into 3 groups, TOFA+ methotrexate (MTX), TOFA+ another DMARDs (leflunomide, hydroxychloroquine, azathiprine), mono-therapy of TOFA. The dynamic of the disease activity in 3 groups is presenting on the table below:

*p<0.05

Patients who received TOFA with MTX had lower disease activity during the therapy. Patients on mono-therapy of TOFA had higher disease activity according to DAS28, SDAI, CDAI.

**Conclusion:** Tofacitinib is effective as DMARDs for active rheumatoid arthritis on the Russian population. It shows better efficacy in combination with methotrexate, than in combination with another DMARDs (leflunomide and other) or in mono-therapy.

## Conclusion:

In this study, we demonstrated the short-term effectiveness and safety profiles of baricitinib after insufficient response to bDMARDs or tsDMARDs in patients with RA in the ‘real-world’ setting. Baricitinib improved disease activity after failure of the previous agent, even after IR to another tsDMARD. With respect to safety, the profile is almost tolerable, although careful observation is necessary for possible complications and AEs including herpes zoster.

Mochida1, K. Harigane1, T. Shimazaki1, Y. Inaba2, A. Nagaoka2. 1V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Iguratimod (IGU) was newly approved in Japan in June 2012 and recommended by JCR guideline 2014 in the treatment of rheumatoid arthritis (RA). Although there have been efficacy of monotherapy and concomitant MTX in clinical trials, however, there have been no reports of concomitant biologic DMARDs (Bio).

**Objectives:** We investigated efficacy of concomitant IGU therapy in RA patients who had inadequate response to Bio at the author’s institution.

**Methods:** Subjects were 107 patients adding IGU who had inadequate response to Bio from January 2014 to October 2018. Previous treatment Bio was ADA. Baseline mean concomitant MTX was 12.3mg/week. At baseline, mean DAS28, SDAI, CDAI were significantly decreased from the initiation of IGU treatment at 24 weeks (3.1→2.4), at 52 weeks (2.1, 2.4, 2.0). Remission rates of DAS28-ESR, SDAI, CDAI were 69.2%, 70.1% at 24 weeks, 74.8%, 78.5%, 79.4% at 52 weeks. There were no side-effect that must be stopped after adding IGU.

**Conclusion:** IGU might be a new RA treatment option for aiming remission in patients who had inadequate response to Bio.

**References:**

Objective: In this study, we compared the efficacy of IGU in elderly group with the non-elderly group.

Methods: 190 patients who were able to continuously administer IGU more than three months were included. Cases were divided into two groups, Group A (75 years or older) includes 57 patients, and Group B (younger than 75 years) includes 133 patients. The patients background, the use of methotrexate (MTX) and glucocorticoid, the change of serum CRP, and the DAS28-ESR (before, 6, 12, and 24 months) as an evaluation of the disease activity were compared between two groups. The study protocol was approved by our institutional review board. All the patients were required to give written informed consent.

Results: The average age at the beginning of IGU was 79.9±4.1 years old in Group A, and 59.9±10.6 years old in Group B. The average disease duration was 14.8±16.5 year in Group A and 6.5±10.6 year in Group B (p<0.01). Although the rate of concomitant use of MTX was significantly lower in Group A (Group A: 28.1%, Group B: 56.4%), the averaged dose of MTX did not show difference between groups (7.0 and 8.4 mg/week, respectively). Group A showed significantly higher rate of concomitant use of glucocorticoid (56.1%, and 36.1%, respectively), but the averaged dose of glucocorticoid did not show a difference between groups (4.3 and 3.6mg/day, respectively). Similarly, the rate of concomitant use of NSAIDs did not have a difference in two groups. Group A showed significantly higher serum CRP at the beginning of the IGU (Group A; 2.0 mg/dl, Group B; 1.2 mg/dl), but there was no difference after six months. In both groups, serum CRP was significantly decreased when compared at the beginning of IGU. After six months of IGU administration, both groups showed good clinical performance with DAS28-ESR, more than 60% of the cases showed remission or low disease activity. No difference of DAS28-ESR scores between two groups was observed after six months.

Conclusion: From the results of this study, the efficacy of IGU for elderly patients was confirmed and did not show differences with non-elderly people. IGU is an inexpensive drug with enough efficacy and thought to be possible substitute for cases with insufficient reaction with other DMARDs.

COMPARATIVE STUDY OF PATIENT BACKGROUND AND TREATMENT OUTCOME BY BARICITINIB DOSE UNDER REAL CLINICAL CONDITIONS.

Nagoya University Hospital, Orthopedic Surgery, Nagoya city, Japan

Background: Balicitinib (BAR) is one of the Janus kinase (JAK) inhibitors, which mainly inhibits JAK1 and JAK2 and has an anti-inflammatory effect on rheumatoid arthritis (RA). In Japan, it is necessary to use different doses of BAR depending on the RA patient's estimated glomerular filtration rate (eGFR). The RA-BEACOM and RA-BUILD trials reported the treatment effects by BAR dose at 24 weeks and concluded that there was no difference in DAS(disease activity score)28CRP between BAR 2mg and 4mg. The patient background treated in these double-blind RCTs is uniform even at different BAR doses. There is uncertainty about the difference in the therapeutic effects of BAR dose under the real clinical setting where the patient background differs from that of the trial patients.

Objectives: To compare patient backgrounds and treatment outcome by Baricitinib dose under real clinical setting.

Methods: 113 RA patients taking BAR who were registered in the Nagoya University Orthopedic Surgery Multicenter Study (TBCBR) were included in this study. Patient characteristics (such as age, illness duration, combined anti-rheumatic drugs, eGFR) and DAS28CRP, clinical and simplified disease activity score(CDAI, SDAI respectively) up to 24 weeks were compared between BAR 2mg and 4mg groups. The continuation rates, including the discontinuation due to ineffectiveness and adverse events (AEs), were also compared between the two groups. For these comparisons, Student's t-test and Pearson's chi-square test, Kaplan-Meier survival curve were used. Missing data due to discontinuation of BAR was complemented by LOCF method and analyzed statistically. The significance level was set to less than 0.05.

Results: There were 39 subjects (8 males and 31 females) in BAR2mg group and 74 patients (17 males and 57 females) in BAR4mg group. There was a significant difference in mean age (73.5 vs. 62.3 years old, p < 0.001), average MTX use (3.03 ± 4.83 vs. 5.54 ± 5.48, p < 0.01), methotrexate(MTX) use rate (28 vs 58%, p < 0.01), average MTX dose (3.0 vs 5.5mg, p < 0.01), glucocorticoid(GC) use rate(51.3 vs 33.8%, p < 0.01) between the two groups(Table. DAS28CRP improved from week 0 (3.2 vs 3.5) to week 24 (2.5 vs 2.4), and no significant difference was observed between the two groups at each time point (Fig.1-A). The same was true for CDAI and SDAI(Fig.1-B,C). The rate of DAS28CRP remission and low disease activity was not significantly different at 24 weeks (0.64 vs 0.69, Fig.1-D). The same was true for CDAI and SDAI(Fig.1-E,F). Kaplan-Meier analysis showed that there was no difference in discontinuation rate due to ineffectiveness in the two groups. The same was true for the discontinuation rate due to AEs (Figure 2-B,C). The total continuation rate including discontinuation due to ineffectiveness and AEs was significantly lower in BAR2mg group (0.691 vs 0.843, p < 0.05, Fig.2-A).

Conclusion: BAR2mg group under real clinical setting was older and had lower eGFR than BAR4mg group. Although the treatment effect for 24 weeks was similar, safety management was considered more important because the discontinuation rate due to AEs tended to be higher in BAR2mg group.

PSA patients with active disease.

Background: Regular physical activity may have benefits for patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA), but patients with active disease are often reluctant to increase activity. Principles from behavioral economics (BE), a field combining psychology and economics, have been applied to motivate increased physical activity in non-arthritis patients. No published studies have examined the application of BE concepts in rheumatology to promote exercise.

Objectives: To assess the feasibility and efficacy of a loss aversion financial incentive for increasing step counts and improving disease symptoms in RA and PsA patients with active disease.

Methods: A randomized controlled pilot trial was performed among patients with RA and PsA. Participants were required to have active disease defined by having at least one swollen joint and a Routine Assessment of Patient Index Data-3 (RAPID3) score $>3$ (range 0-30 with $<3$ indicating remission). The trial included two visits (baseline and 14-week) and weekly check-ins via virtual trial platforms, Way to Health and the ArthritisPower app. Patients were given a Fitbit Alta at baseline and completed a two-week run-in period to assess average step count. Patients were then prompted to select a step count goal and complete a commitment contract. After selection of a goal, participants randomized to the intervention arm received a financial loss aversion incentive (each month, patients started with $75 in their account and lost $2.50 for each day they did not reach their goal). Patients were blinded to the other study arm and investigators were informed of their performance via feedback about their performance over the previous week. The effectiveness of the intervention was determined by the percentage of participants achieving at least 10,000 steps per day during follow-up (30% v. 21%, p=0.41). Among patients who achieved their step count goal, patients were followed to 26 weeks to determine how long the effect persisted.

Results: In the pilot trial, 71 patients were verbally consented for screening, 34 underwent screening (of these, two were ineligible), 27 were randomized, and 22 patients completed the 14-week study visit. Mean age of participants was 50 (SD 13), 85% were female, 17 (63%) had PsA, mean BMI was 30.6 and mean swollen (0-66) and tender (0-68) joint counts were 6.2 (5.6) and 8.1 (9.1), respectively. Baseline RAPID3 was 10.5 (SD 4.6) and the mean step count at baseline and completed a two-week run-in period to assess average step count. Patients were then prompted to select a step count goal and complete a commitment contract. After selection of a goal, participants randomized to the intervention arm received a financial loss aversion incentive (each month, patients started with $75 in their account and lost $2.50 for each day they did not reach their goal). Patients were blinded to the other study arm and investigators were informed of their performance via feedback about their performance over the previous week, completed weekly PRsOs, and had the opportunity to report adverse events including flares of joint pain. After 12 weeks of the intervention (at week 14), the incentive was removed and patients were followed to 26 weeks to determine how long the effect persisted.

Conclusion: While financial incentives have worked well in patients without arthritis, the estimated effect of the financial incentive in this small study was more modest in patients with RA and PsA. Those that were able to increase their physical activity and meet their step goals had greater improvements in symptoms over the course of the study. These data support further study in this area to promote physical activity by leveraging concepts from behavioral economics.

Conclusion: The MTD of seliciclib has been defined for RA. No unexpected safety concerns were identified to preclude ongoing evaluation in patients, which focuses on clinical, radiological and biological indicators of efficacy.
medical chart: age, gender, diagnosis, date of treatment initiation, date and reasons for treatment discontinuation, the use of concomitant or previous cDMARDs and of biologics. A comparison between patients continuing and stopping tofacitinib was performed through chi² or t-test for qualitative and quantitative variables, respectively. Survival analysis was done by Kaplan-Meier method.

Results: Ninety patients receiving tofacitinib were identified, 81 with RA, 6 with PsA, 1 with Dermatomyositis, 1 with Sjogren's and 1 with juvenile idiopathic arthritis. Table 1 shows the baseline characteristics. 84% percent patients were women and the mean (SD) age was 58.5 (14.2) years. 51% patients started tofacitinib in monotherapy. When used, methotrexate was the most frequent cDMARD (61.3%); 10% patients used tofacitinib as first line after cDMARD and the majority used it after 1 or 2 previous biologics (46.7%).

</table>

Survival rates when used as first or second line were 85% at 6 months and 70% at 12 months; when used as third line or further, 76% and 70%, respectively (graphic 1). Factors associated to tofacitinib discontinuation were treatment duration and baseline prednisone dose. In contrast concomitant cDMARD and number of previous biologics were not. Reasons for tofacitinib discontinuation were: lack/loss of efficacy 46.9%, adverse events 50% (including intolerance -22%-), herpes zoster -16%-; other infections 12% and others.

Conclusion: Tofacitinib in our experience is mostly used in RA patients after biologic failure. Overall survival rate at 12 months was good regardless line of treatment. Adverse event rates were similar to other biologic treatments. Herpes zoster was the most common infectious AE.

TNF ALFA THERAPY AND RADIOSYNOVIORTHESIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Szentesi¹, Z. Nagy¹, Z. Karoly Mangel¹, G. Csore², P. Géher³. ¹Polyclinic of the Hospitalist Brothers of St. John of God, Rheumatology, Budapest, Hungary; ²Polyclinic of the Hospitalist Brothers of St. John of God, Budapest, Hungary; ³St. Andrew Hospital for Rheumatic Diseases, Rheumatology, Hévíz, Hungary

Background: The treatment of patients with rheumatoid arthritis (RA) has been spectacularly changed since the 1950’s. Introduction of the steroid compounds and their local application, the chemical and radionuclide synovectomy, surgery synovectomy, use of non steroid drugs, the basic treatment and the spread of biological therapy are the most important steps. Introduction of the biological therapy has changed the quality of life for these patients.

Objectives: During biological therapy sometimes 1 or 2 joints could be affected by inflammation. In this cases always the question is how to solve the problem. Change of the biological or basic therapy, use surgical synovectomy or radiosynovectomy (RSO)?

Methods: In our reumatological department 2100 patients with RA were treated with biological therapy between 2002 and 2018. In 100 patients we applied RSO because of the inflammation of the knee joint during biological therapy. We made a long term follow-up in 82 patient. All participants provided written informed consent. 82 participants inflammatory knee joint disease was diagnosed on the basis of the American College of Rheumatology. 70 of 82 patients with rheumatoid arthritis were seropositive, 12 seronegative. Steinbrocker functional stadium II was observed in 70% on the 90mg CR6086 target dose. Pairwise comparisons of proportions were performed, with nonresponder imputation for withdrawals. A subgroup of patients underwent dynamic contrast-enhanced (DCE) MRI for quantification of patients a systematic review on the 90mg CR6086 efficacy and safety of the prostaglandin EP4 receptor antagonist CR6086 added to methotrexate in DMARD-naive early RA patients. A phase 2 randomized controlled trial.

AB0360

EFFICACY AND SAFETY OF THE PROSTAGLANDIN EP4 RECEPTOR ANTAGONIST CR6086 ADDED TO METHOTREXATE IN DMARD-NAIVE EARLY RA PATIENTS: A PHASE 2 RANDOMIZED CONTROLLED TRIAL

K. Pavelka¹, I. D. Delina², M. Mazur³, M. D’Amato⁴, G. Giacovelli⁴, F. Girolami⁴, M. Krogulec⁵, R. Östgard⁶, A. R. Bihamot⁷, O. Kubassova⁷, L. Rovati⁸, G. Taylor⁰. ¹Polyclinic of the Hospitalist Brothers of St. John of God, Budapest, Hungary; ²St. Andrew Hospital for Rheumatic Diseases, Rheumatology, Hévíz, Hungary; ³Biocca M., Milano, Italy; ⁴Rottapharm Biotech, Monza, Italy; ⁵Image Analysis Group, London, United Kingdom; ⁶Silkeborg Regional Hospital, Silkeborg, Denmark; ⁷Nordic Bioscience, Herlev, Denmark; ⁸1Department of Rheumatology, Pharmacy, Czech Republic; ⁰Diabetes, Consult. Center Aleksandrovskaya EOOD, Sofia, Bulgaria; ¹Polyclinic of the Hospitalist Brothers of St. John of God, Budapest, Hungary; ²St. Andrew Hospital for Rheumatic Diseases, Rheumatology, Hévíz, Hungary

Background: MTX is the first line treatment in early RA. There is robust evidence from cohort studies, but less from RCTs, that a “window of opportunity” exists over 12-16 weeks symptom duration, CR6086 is a selective prostaglandin EP4 receptor antagonist, with an immunomodulatory profile.

Objectives: To test efficacy and safety of CR6086 added to MTX in early RA, DMARD-naive patients.

Methods: Patients with RA (ACR/EULAR 2010 criteria), < 1 year from symptom onset and naïve to DMARDs were randomized to oral CR6086 30, 90, 180mg, or placebo bid and oral MTX (20mg weekly) for 13 weeks (NCT03163966). Primary endpoint was the ACR20 response rate: 240 patients were needed to detect a difference among groups, with 50% responders on placebo and 70% on the 90mg CR6086 target dose. Pairwise comparisons of proportions were performed, with nonresponder imputation for withdrawals. A subgroup of patients underwent dynamic contrast-enhanced (DCE) MRI for quantification of patients a systematic review on the 90mg CR6086 efficacy and safety of the prostaglandin EP4 receptor antagonist CR6086 added to methotrexate in DMARD-naive early RA patients. A phase 2 randomized controlled trial.

Results: The ITT population included all 244 randomized patients receiving at least one dose of study drugs (59 CR6086 30mg/MTX, 60 CR6086 90mg/MTX, 63 CR6086 180mg/MTX, 62 placebo/MTX). Safety was good with no increased rate of infections or other disorders; however, there were more minor upper GI adverse events (AEs) with CR6086, and increased dropouts due to AEs with the 180mg dose (9/63, 14.3% vs 1.7-3.4% in other groups). There were more ACR20 responders with MTX monotherapy than predicted (59.7%) and thus the 10.3% difference with the 90mg target dose (70.0%) was not significant. The low 30mg dose was no better than placebo (55.9%), while the high 180mg dose did not provide additional benefit compared with 90mg (74.0% net of dropouts), CR6086 90mg and 180mg induced a significant improvement in MRI, compared with placebo (Fig. 1). In a post-hoc analysis in patients < 6 months from symptom onset (ACR definition of early RA: 98/244, 40.2%), MTX monotherapy exerted a large 76% ACR20 response rate that precluded potentiation. Conversely, in patients of 6-12 months disease duration (146/244, 58.8%) ACR20 responders were 48.6% with MTX monotherapy vs 68.4% with placebo bid and oral MTX (20mg weekly) for 13 weeks (NCT03163966).

Conclusion: There was no benefit demonstrated for CR6086 added to MTX in the study cohort as a whole. However, in a post-hoc analysis, enhanced responses were observed with CR6086 90mg bid added to MTX in patients >6 months disease duration. This generated the hypothesis that addition of CR6086 90mg bid may benefit in RA patients initiating MTX after the window of opportunity, to be tested in further studies.

**AB0361 Efficacy and Safety of Baricitinib (BARI) in Rheumatoid Arthritis (RA): Clinical and Ultrasound Evaluation in Real Life**

**Background:** Remission or low disease activity (LDA) are the ultimate goals of both conventional synthetic (csDMARD), target synthetic and biological disease-modifying anti-rheumatic drugs (bDMARD) in treating RA. Janus Kinase (JAK) inhibitors are nowadays part of tsDMARDs, with BARI as an oral selective JAK1-2 inhibitor. Ultrasound (US) is a valuable imaging tool for detecting inflammatory joint changes and monitoring RA patients. The US7 score (US7) is a semiquantitative score including grayscale (GS) and power Doppler (PD) measurements of synovitis and tenosynovitis in 7 joints of the clinically dominant hand and foot.

**Objectives:** to evaluate real life efficacy and safety of BARI 4 mg in RA patients using clinical, clinimetric and US evaluation.

**Methods:** adult RA patients starting BARI were eligible. DAS28ESR, CDAI, SDAI, painVAS, HAQ, COCHIN, laboratory parameters and US7 were performed/collected at baseline (BL) and after 3 and 6 months. Adverse events (AE) and concomitant medications were recorded. Responder/non responder status was determined using DAS28ESR improvement according to the EULAR Response Criteria at 3 months. Moreover, SDAI clinical remission or LDA (remission: SDAI≤3,3; LDA:3,3<SDAI≤11) were calculated at 3 and 6 months. Results: 43 patients (12 csDMARD and 31 bDMARD failure) were enrolled, with 30 patients starting BARI in combination with a csDMARDs. BL painVAS was 68±23 mm and disease activity was moderate to severe according to DAS28VES, CDAI and SDAI. BARI determined a significant improvement of every disease activity composite score and US7 components, except tendon PD; steroid daily dosage was significantly reduced.

28 patients were considered Responders at 3 months: responders used to have higher disease activity levels and synovitis scores at baseline. Interestingly, painVAS and steroid dosage significantly decreased both in responders and non-responders, achieving similar value at 6 months. Non-responders showed both synovial and tendon involvement relapse at 6 months, with significantly higher PD score compared to responders. Remission was reached by 12.8% patients at 3 months and 21.6% at 6 months, while LDA patients were respectively 53.8% and 51.3%; combination with csDMARD was reached by 12.8% patients at 3 months and 21.6% at 6 months, while LDA patients were respectively 53.8% and 51.3%; combination with csDMARD was the only factor positively associated with remission/LDA at 3 months.

The percentage of dropped-out patients due to AE was aligned with literature data (5% in 6 months) whereas the percentage of Herpes Zoster Virus (HZV) infections was higher (4.6% in 6 months in our population vs 4.3% in 1 year in RCTs). Corticosteroid dosage was directly associated with AE development at 6 months.

**Conclusion:** Real life data confirmed BARI RCTs efficacy and safety data. Non-responders showed both synovial and tendon PD disease relapse, despite painVAS and steroid reduction were comparable to responders. In our population, HZV infection prevalence was higher than in RCTs and corticosteroid dosage was directly associated with AE development at 6 months.
HERPES ZOSTER IN BARICITINIB-TREATED JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS USING REAL-WORLD CLINICAL DATA

E. Torikai1, Y. Hirano2, D. Suzuki3, Y. Kanayama4, Iwata City Hospital, Iwata, Japan; Toyohashi Municipal Hospital, Toyohashi, Japan; Futaba Clinic, Iwata, Japan; Toyosei Hospital, Toyoda, Japan.

Background: Similar to biologic disease-modifying anti-rheumatic drugs, the association between Janus kinase (JAK) inhibitors and infection is particularly interesting. The incidence of herpes zoster (HZ) among patients treated with JAK inhibitors is twofold to threefold higher in several regions of Asia (e.g., Japan and Korea) as compared with that observed in North America and Western Europe [1].

Objective: To evaluate the characteristics of patients who developed HZ during baricitinib treatment using real-world, multicenter clinical data for Japanese population.

Methods: The study enrolled 97 patients with rheumatoid arthritis (RA) who were treated with baricitinib therapy (68 biologic-naive patients and 29 biologic-experienced patients) were enrolled in the study (observation period: 2–27 months). The severity of HZ infection was determined based on the extent of the rash and the presence or absence of organ damage. We evaluated the characteristics and clinical courses of patients who developed HZ.

Results: Eight patients with HZ. The incidence ratio (IR) was 8.2 per patient-year. Patient data are described in Table 1 and Table 2. The IR was a little higher than that reported in clinical trials [2], which could be attributed to the high average age (i.e., 67.3 years) of the patients in this study. It was reported that adverse events occurred more frequently in elderly patients aged ≥65 years compared with younger patients [3]. The period from baricitinib administration to the onset of HZ varied between 2 months and 16 months. It is suggested that HZ may develop at any time during baricitinib therapy. There were no distinctive patient characteristics, except for age, at the time of initial baricitinib administration between patients who developed HZ and those who did not.

None of the patients had severe symptoms, and none of them experienced organ damage. All patients were cured with anti-viral agents. It should be noted that patients who had a history of HZ had milder symptoms than those who had no history of HZ. We noted an interesting finding in one patient (case 2). The half-life of baricitinib in the blood was very short (about 6 hours), and it is reported that the drug is almost fully excreted from the body 24 hours after its administration [4]. However, this patient developed an incidence of HZ at 17 days after the withdrawal of baricitinib for surgery management. Cells may take longer time to regain their original immune status even after excretion of the drug, especially, during intense stress such as in cases of surgical invasion.

Conclusion: The HZ risk in Japanese patients with RA treated with baricitinib in real-world practice was high, especially in elderly patients. It is notable that HZ events were nonserious and that patients could restart baricitinib treatment after healing with antiviral therapy, for the most part.

SAFETY OF JAK INHIBITORS IN PATIENTS WITH ARTHRITIS RHEUMATOID UNDER REAL-LIFE CONDITIONS

M. L. Velloso Feijoo1, N. Cid Boza2, M. J. Perez3, Hospital de Valme, Seville, Spain

Background: Efficacy and safety profile of new JAK inhibitors have been properly defined by several clinical trials, being tested in many patients with Arthritis Reumatoïd. However, real-life conditions studies play an important role in order to know JAK inhibitors behaviour in safety.

Objective: To describe adverse events of JAK inhibitors in patients with Arthritis Rheumatoïd and assess the survival in relation to adverse events.

Methods: Observational, descriptive, retrospective design performed in patients with Arthritis Reumatoïd in follow-up by the Rheumatology department of the Hospital de Valme until January 2019. Demographic and clinical data related to safety has been collected.

Results: 58 patients were included with a mean age of 57.7 ± 10.78 years. Mean time from diagnosis was 8.7 ± 6.54 years, female predominance (75%). Mean ASDAS at the beginning of JAK inhibitor treatment was 4.76 ± 0.93. Regarding the determination of FR and CCP 69% and was positive in both cases. Baricitinib was the treatment chosen in 13 patients (21.7%), and Tofacitinib in 45 patients (77.6%). Regarding associated treatments: 84.5% was under low-dose therapy; 77.6% was under combined therapy with at least 1 DMARD; 15.5% with two of them. Metotrexato was used in 53.4% of patients, lefunomide in 19%, hydroxycloroquine in 13.8%, sulfasalazine in 12.1%. 72.4% have been before under at least one biologic treatment (frequently antiTNF), 41.1%, one of them, 15.5% of two of them, 12.1% three and 1.7% four before starting Jak inhibitor therapy. Adverse events has been observed in 17 patients (13 from de Tofacitinib group -28.8%, and 4 in the Baricitinib group -30.76%). The most common adverse events were: herpes zoster infections (4 patients in Tofacitinib group), respiratory infections (3), urinary infections (2), cutaneous (3), caphalea (1), legs oedema (2), toxic hepatitis in 1 patient of Baricitinib group; pulmonary thromboembolism was observed in 1 patient of Tofacitinib group, and atrial fibrillation in other patients of that group. Treatment was interrupted in 24 of 58 patients (mean time 8.92 ± 5.14 months), 16 from Tofacitinib group (35.5% of patients with Tofacitinib) and 8 from Baricitinib group (61.15% of patients with Tofacitinib). In Tofacitinib group, 10 patients stopped therapy for inefficacy reasons and 6 for adverse effects related. In Baricitinib group, 5 due to inefficacy, 2 to adverse effects and 1 to clinical remission.

Conclusion: Main adverse effect were mild-moderate infections (involving in-hospital treatment only in one Baricitinib group patient), One pulmonary thromboembolism has been detected in a hypertensive 70 years old patient, supporting the recent recommendation of avoiding these drugs in patients over 65 or with cardiovascular risk factors. It is remarkable low survival results due to inefficacy, that could be related to clinical profile of refractory patients in our study, and/or to the small sample that we describe.

Disclosure of Interests: None declared.

Efficacy of Baricitinib (Bari) in Patients with Rheumatoid Arthritis (RA) Whose Response Was Inadequate to Tofacitinib (Tofa).

T. Yamane1, A. Hashiramoto2,1 Rakgawa Central City Hospital, Kagawaga, Japan; 3Kobe University Graduate School of Health Sciences, Kobe, Japan

Background: Currently, four types of JAK inhibitors are approved for the treatment of RA in Japan, however, they often show differences in clinical efficacies presumably due to their JAK selectivity.

Methods: We performed a single-center retrospective study on seven Tofa IR patients (female:7) who were switched to Bari. Items evaluated were as follows: patient’s baseline characteristics, continuation rate of Bari, swollen joint count, tender joint count, C-reactive protein (CRP), matrix metalloproteinase 3 (MMP3), physician’s and patient’s visual analog scale (VAS), disease activity assessed by Disease Assessment Score of 28 joints - C-reactive protein (DAS 28-CRP), simplified disease activity index (SDAI) and clinical disease activity index (CDAI) at 2, 4, 8, 12 weeks, and the dosage of prednisone (PSL).

Results: Patient’s mean age was 56.4 and mean disease duration was 9.2 years. Tofa had administered for 3.4 months (range 1-10) before switching to Bari. All patients were positive for both anti-citrullinated protein antibodies and rheumatoid factor. The number of prior biologics use was 2.3 (range 1-4), 3 patients had concomitant MTX use (mean dosage 5.3 mg/week) and 4 had prednisone (mean dosage 3.3 mg/day). Mean swollen joint counts and tender joint counts were 5.0 (range 1-15) and 5.3 (range 1-15), respectively. Physician’s and Patient’s VAS 0-100 were 71 (range 50-90) and 73 (range 50-80), mean CRP levels were 1.6 mg/dl (range 0.01-4.3) and MMP3 levels were 3573 mg/dl (range 27-933). Mean SDAI, CDAI and DAS-28-CRP were 26.3 (range 17-50), 24.7 (range 17-47) and 4.5, respectively. When enrolled, 4 of 7 patients corresponded to moderate disease activity (MDA) and 3 were in high disease activity (HDA) by all composite measures. After switched to Bari, the patient’s VAS significantly decreased at week 2 (P < 0.01). CDAI, SDAI and DAS28-CRP also showed a significant improvement at week 4, (P <0.05).

Conclusion: Result showed the efficacy of Bari for patients with Tofa IR, representing inadequate improvements of patient’s VAS with Tofa. The efficacy of Bari can be expected from the early stage and continued up to 12 weeks after switching. This difference in therapeutic effect may be due to each mechanism of action, Bari inhibits JAK1/2, whereas Tofa mainly inhibits JAK1/3 (1). JAK2 is important for signal by GM-CSF, which has shown potential as an important therapeutic target in RA (2). Inhibition of JAK2 and GM-CSF may be the reason for Bari efficacy in Tofa IR patients.

References:
Background: Diffuse alveolar hemorrhage (DAH) is a rare and potentially lethal complication of systemic lupus erythematosus (SLE) with a high mortality rate. It occurs more frequently in patients with lupus nephritis (LN). Objectives: The aim of our study is to explore the characteristics of patients that develop DAH with lupus nephritis, risk factors that predispose DAH, treatment response and outcomes. Methods: Multicenter retrospective cohort study was undertaken including 6 centers in Saudi Arabia from 2002 to 2018. Systemic lupus erythematosus patients meeting the SLICC criteria with lupus nephritis (biopsy proven or proteinuria or renal impairment due to lupus) presenting with diffuse alveolar hemorrhage (fulfilling a predefined criteria) were included in the study. An identical number of control group with lupus nephritis was also studied. Data was obtained from medical records by using a data sheet: demographics including age, gender, diagnosis, date of diagnosis of lupus, date of presentation of alveolar hemorrhage, clinical presentation, detection of alveolar hemorrhage proved by radiology, lavage or biopsy and laboratory parameters: including level of hemoglobin before and during DAH, sign of activity, treatment and outcome of DAH. Identification of risk factors predisposing to DAH in lupus nephritis patients was analyzed.

Results: We identified 23 cases of DAH with lupus nephritis, all fulfilling the criteria. Mean age at presentation of DAH was 31.09 + 12.6 years ranging from 14-57 years, of which 87% were females. 13 patients 56.5% had Class 4 LN and 21.7% had Class 4 and 5 LN on renal pathology. DAH occurred at a mean of 6.5 years ±3.8 in 13/23 patients with LN. Shortness of breath 95%, new chest x ray finding 95.7% and mean drop of haemoglobin of 2.72 gm/dl ±0.97 were more frequent at presentation of DAH with LN patients. High SLE disease activity - SELENA SLEDAI 2K was 38.56 ±19.3 was present at the onset of DAH. All were treated with methyprednisone,15/23 (65.2%) underwent mechanical ventilation and plasmapheresis was done in 21/23 patients (91.3%). Cyclophosphamide was given in 14/21 patients (60.9%). Intravenous immunoglobulins were given in 14/23 patients (65.2%) and dialysis was done in 12/23 patients (52.2%). Mortality occurred 8 patients 34.8%. In comparison with the LN group, a mean haemoglobin of 7.66 ± 1.3, CNS involvement, vasculitis and fever>38 were of statistically significant P value: <0.001,0.02,0.03 and 0.03 respectively.

Conclusion: In this multicenter cohort series with DAH in LN patients CNS involvement, vasculitis and fever>38 were associated in the occurrence of DAH. Mortality was low in our cohort in comparison to previous series which may be explained by early diagnosis and use of aggressive management.

Well designed prospective studies are required to identify high risk patients for preventing this serious complication.

AB0367 USING UNSUPERVISED CLUSTERING ANALYSIS OF REAL LIFE DATA FROM AN ONLINE COMMUNITY TO IDENTIFY LUPUS PATIENTS’ PROFILES REGARDS TO THEIR TREATMENT PREFERENCES

D. Testa1, V. Morisseau1, L. Radoszycki1, I. Anfray1, L. Chiche2. 1Careney, Paris, France; 2European Hospital Marseille, Service de Médecine Interne, Marseille, France

Background: Lupus is a prototype of a chronic complex autoimmune disease. Non-adherence rate to treatment is surprisingly high and impairs its management. Adherence to drug treatment is a complicated and multifactorial phenomenon, including characteristics of treatment.

Objectives: This study used unsupervised clustering analysis to identify profiles among lupus patients with regards to their treatment preferences (apart from efficiency).

Methods: An online survey among adult lupus patients from Careney was conducted between August 2018 and April 2019. Multiple Correspondence Analysis (MCA) of a French lupus patient dataset was used with 3 unsupervised clustering methods (hierarchical, kmeans and partitioning around medoids).

Results: The sample of participating lupus patients were mostly female (96%), with a mean age of 44.3 years, and 83% fulfilled the ACR SLE diagnostic criteria. Overall, the preferred galenic form was oral (62%), and the most important characteristic was fewer side effects (32%).

A MCA was performed using 8 profile variables and the best unsupervised clustering method for this dataset (hierarchical clustering) identified 3 clusters (Table 1). Cluster 1, main one (59%), comprised patients with few comorbidities, less capacity to identify coming flares, and that mostly wanted (84%) oral treatments with limited side effects, most of them (83%) already on oral treatments. Cluster 2, the smallest one (13%), comprised younger patients, having already participated in clinical trials, favoring implants and the compatibility of treatments with pregnancy. Cluster 3 comprised patients (28%) that had longer lupus duration but less controlled disease with more comorbidities. A third had injectable treatments, wanting mainly implants and injections and with the main goal of reducing corticosteroids. The robustness of these results was confirmed by external validation and sensitivity analyses.

AB0368 TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH BELIMUMAB – PROSPECTIVE OBSERVATION OVER 2 YEARS

S. Dimitrov1, S. Hristova2, S. Bogdanova-Petrova3, T. Shvacheva1. 1University Hospital St Marina, Rheumatology, Varna, Bulgaria; 2University Hospital St Marina, Varna, Bulgaria

Background: Systemic lupus erythematosus (SLE) is autoimmune connective tissue disorder of unclear etiology. It is characterized by autoantibody production and a variety of clinical manifestations. The introduction of biological treatment over the past few years provided an opportunity for a disease control.

Objectives: The aim was to assess the effectiveness and safety profile of Belimumab in the treatment programs of SLE patients during a 2 year period.

Methods: We initiated a prospective observational study of SLE patients in the Rheumatology Department in University Hospital St Marina – Bulgaria. The study comprises data from 26 patients at baseline before Belimumab treatment initiation and data after 6, 12, 18 and 24 months of treatment. All patients were with moderate disease activity according to SELENA – SLEDAI index and were on treatment with immunosuppressive drugs (azathioprine) and glucocorticoids (GCs). We observed the change in the dosage of glucocorticoids over the observed period, the number of flares of SLE, as well the SELENA – SLEDAI index change. Safety profile of Belimumab was also registered.

Results: We included 26 patients with SLE over a period of 4 years – between 2015 and 2019. The mean age was 45.8±11.4 years and 94% were Caucasian females. All patients were on a stable dosage of GCs at least 3 months before the first inclusion of Belimumab. Mean dose of azathioprine was 100 mg daily. Ninety percent of patients were diagnosed with SLE for more than 6 years according to ACR – SLE criteria. All of SLE patients were with moderate disease activity. Main reasons for biological treatment decision were persistent mucocutaneous manifestations.

Interchangeability of oRTX and bRTX in pSS.

Conclusion:

At 12 months of follow-up, oRTX and bRTX display similar efficacy and safety profiles. The improvement of patient reported outcomes is faster than the improvement of disease activity with both compounds. Our data support interchangeability of oRTX and bRTX in pSS.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.2368

AB0369

EFFICACY AND SAFETY OF RITUXIMAB ORIGINATOR AND BIOSIMILAR IN PRIMARY SJÖGREN’S SYNDROME IN A REAL-LIFE SETTING

F Carubbi1, A Alunno2, P Cipriani1, V Pavlych1, C Di Muzio1, R Gerli3, R Giacomelli1, 1Rheumatology Unit, Iquela, Italy; 2Rheumatology Unit, Perugia, Italy

Background: Over the last 2 decades rituximab (RTX) has been widely used, albeit off-label, in primary Sjögren’s syndrome (pSS). Several studies reported that B-lymphocyte depletion with RTX is effective in this disease not only by reducing disease activity but also by affecting the inflammation and the lymphoid organization that occur in target tissues. With the recent release of several RTX biosimilars (bRTX) on the market, the demonstration of their interchangeability with RTX originator (oRTX) is required.

Objectives: To compare efficacy and safety of oRTX and bRTX in pSS patients in a real-life setting.

Methods: Clinical records of pSS patients referring to a tertiary rheumatology clinic were retrospectively evaluated. Patients having at least 2 courses of either oRTX or bRTX (1000 mg IV infusion, repeated after 2 weeks -1 course- and the course repeated after 24 weeks) with complete data at baseline and after 3, 6, 9 and 12 months of treatment were enrolled. Disease activity was assessed with the EULAR SS disease activity index (ESSDAI) and its clinical version without the biological domain (ClinESSDAI). Patient-reported symptoms were assessed with the EULAR SS Patient Reported Index (ESSPRI).

Results: Seven patients that received oRTX and 7 patients that received bRTX were enrolled. Baseline clinical features, including ESSDAI and ESSPRI were similar in the 2 treatment groups. Both compounds significantly reduced ESSDAI and ESSPRI as early as 3 months and no difference between the groups was observed at any time point (Figure 1). Of interest, ESSDAI slowly decreased until month 6 when the most pronounced reduction was observed. Conversely, ESSPRI dropped to its lowest values already at month 3. With regard to safety, at 12 months of follow-up no adverse event was observed in any of the treatment groups.

Conclusion: At 12 months of follow-up, oRTX and bRTX display similar efficacy and safety profiles. The improvement of patient reported outcomes is faster than the improvement of disease activity with both compounds. Our data support interchangeability of oRTX and bRTX in pSS.

SAFETY OF CS20AT04, A HAPLOIDENTICAL ALLOGENEIC BONE MARROW-DERIVED MESENCHYMAL STEM CELLS, IN A PHASE 1 STUDY IN LUPUS NEPHRITIS

C. B. Choi1, T. Y. Lee2, K. S. Kim2, S. C. Bae1, 1Hanyang University Hospital for Rheumatic Diseases, Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Corestem Inc, Seongnam, Korea, Rep. of (South Korea)

Background: Mesenchymal stem cells are known to have immunomodulatory properties and may potentially have therapeutic effect in lupus nephritis. Mesenchymal stem cells form a haploidentical donor are an attractive cell source

Objectives: CS20AT04, a haploidentical allogeneic bone marrow-derived mesenchymal stem cell, was evaluated in patients with lupus nephritis for safety and tolerability.

Methods: This was a single-arm phase 1 dose-escalation trial of CS20AT04 in adult patients with lupus nephritis (NCT03174587). A 3+3 design was used for dose escalation. The starting dose was 2.0 x 106 cells/kg and was escalated to 3.0 x 106 cells/kg if there no dose-limiting toxicity. The primary objective was to determine the maximum tolerated dose and evaluate the safety and tolerability at 28 days after the infusion.

Results: Seven patients were enrolled in the study. Patients received CS20AT04 through intravenous infusion. The initial dose of 2.0 x 106 cells/kg was administered for the first 3 patients without any dose-limiting toxicity. There was 1 patient who were not administered the full 2.0 x 106 cells/kg dose due to technical error during infusion. The patient did not show dose limiting toxicity, but 1 additional patient was enrolled to have 3 patients who received the full 2.0 x 106 cells/kg dose before escalating to the next level dose. The dose of 3.0 x 106 cells/kg was administered for the next 3 patients without any dose limiting toxicity. Three adverse events were reported (1 diarrhea, 1 toothache, and 1 arthralgia) and they were all NCI-CTC grade 1 events.

Conclusion: CS20AT04 was well tolerated in single dose up to 3.0 x 106 cells/kg in patients with lupus nephritis.

Acknowledgments: This research was supported by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number: HI15C0778).

AB0371

HYDROXYCHLOROQUINE AS VIEWED BY LUPUS PATIENTS – WHAT IMPACT FOR DOCTORS?

A. Cornet1, Z. Osmani2, S. Franckel1 on behalf of LUPUS EUROPE PATIENT ADVISORY NETWORK. 1Lupus Europe, Romford, United Kingdom; 2WLE, Amsterdam, Netherlands

Background: Hydroxychloroquine (HCQ) is recommended for all patients with systemic lupus erythematosus (SLE) and is typically considered as having a good safety profile. Yet, patient organisations observe that concerns about eye impact or “allergies to HCQ” are often raised on social media. This could contribute to the non-adherence, which varies from 3 to 76% in SLE patients depending on assessment method and drug.

Objectives: To understand if/how some patients’ beliefs impact adherence to HCQ treatment.

Methods: In May 2019, LUPUS EUROPE launched a 29 questions on-line survey in 13 languages including questions on HCQ adherence. 2938 responses were analysed. 67.8% (1990 patients) were current HCQ users, 17.8% had stopped using it, 8.1% never had HCQ (6.4% did not respond to this question). 1820 users reported their adherence level. 314 (17.3%) were classified as “low” adherence as they reported missing/forgetting HCQ “always” (1.8%), “more than twice a week” (5.2%) or “once a week” (15.5%) or HCQ “sometimes” (30.5%).

Results: The prescribed HCQ dose, kidney involvement or duration of treatment (beyond the 1st year) were found to have no impact on low adherence. Similarly, the user belief that HCQ has significant side effects, without experiencing these, was not found to impact adherence (p=.74).

The following factors were associated with better adherence: (p<.0001)
- The belief that HCO is “Very important” (12.9% “low”) rather than “important” (22.1% “low”) or “not important / useless” (33.1% “low”).
- Taking many different medications (9.8% “low” for Patients indicating more than 7 medications vs 19.6% for those listing 3 or less)

Childhood onset of the SLE was associated with a lower adherence (30.0% “low” vs. 17.4% for later onset SLE (p<0.001)

658 patients (29.6%) reported having experienced side effects. 42.6% of them stopped taking HCO (patient led 161, doctor led 110, unclear 9). Amongst those continuing HCO despite experiencing side effects, the proportion of non adherent patients increased to 24.7%, compared to 15.2% in the group of patients that have not experienced side effects (p<0.001). The 232 patients who talked with their Doctor and felt listened to appear to adhere better (22.0% low adherence) than the 84 who did not feel heard (31.0% low adherence), but the significance is only directional (p=0.15)

523 patients have used HCO in the past. 206 (39.4%) consider the decision to stop HCO as doctor initiated, 272 (52.0%) as patient initiated, and 36 (6.9%) as a joint decision.

When stopping was patient initiated, 59.9% was due to experiencing a significant side effect attributed by the patient to HCO, 6.7% due to concern of a potential side effect, 11.2% “tested” stopping and noticed no difference, 10.0% were not convinced that it worked, 8.2% felt their lupus was less active, 2.6% wanted to ease activity or other factors).

Conclusion: Doctors can help HCO adherence by boosting patient’s confidence in the importance of HCO. Better patient education may contribute to avoid up to 40% of patient initiated decision to stop HCO treatment.

Methods: Of 13 pregnancies, one ended in a miscarriage and 22 resulted in live births including one set of twins. Treatment used during pregnancy was hydroxychloroquine in all cases and additional low-dose aspirin in 3 cases. Elevated CRP levels during pregnancy were found in 3 cases.

Results: Of 23 pregnancies, 17 were born at early term and 5 at term. There were no preterm deliveries. Median birth weight was 2836g (range 2056-3845g).

Concomitant treatment with low-dose aspirin was used in 9 pregnancies. Of the 22 live births, 17 were born at early term and 5 at term. There were no preterm deliveries. Median birth weight was 2836g (range 2056-3845g). Nine newborns (40.9%) were small for gestational age (SGA). Maternal treatment during these pregnancies was hydroxychloroquine in all cases and additional low-dose aspirin in 3 cases. Elevated CRP levels during pregnancy were found in 57% of the cases with SGA outcome. Only one woman with an SGA infant had positive anti-phospholipid antibodies.

Regarding delivery mode, most patients had caesarean sections.

Conclusion: In our cohort of women with Sjögren syndrome the prevalence of small for gestational age infants was high despite maternal treatment with hydroxychloroquine. Inflammatory markers could help to identify the patients at risk for placental insufficiency, yet prospective studies of larger cohorts are needed.

AB0372 PREGNANCY OUTCOME IN WOMEN WITH SJÖGREN SYNDROME IS OFTEN COMPLICATED BY PLACENTA INSUFFICIENCY

I. Troester1, F. Koller2, A. Zbinden2, L. Raio3, F. Foerger2, 1University Hospital and University of Bern, Inselspital, Pediatrics, Bern, Switzerland; 2University Hospital and University of Bern, Inselspital, Rheumatology, Immunology and Allergology, Bern, Switzerland; 3University Hospital and University of Bern, Inselspital, Obstetrics, Bern, Switzerland

Background: Chronic inflammatory rheumatic diseases are often associated with a negative effect on pregnancy outcome. Most obstetrical complications are placenta-mediated such as preterm delivery and growth restrictions. In women with Sjögren syndrome, data on placenta-mediated complications are scarce and conflicting (1,2).

Objectives: To analyse neonatal outcome in women with Sjögren syndrome with focus on preterm delivery and growth restriction

Methods: We retrospectively analysed 23 pregnancies of 16 patients with Sjögren syndrome that were followed at our centre with regard to pregnancy outcome, medication and disease characteristics. Small for gestational age was defined as birthweight percentile <10th. Prelterm delivery was defined as delivery before 37, early term as delivery between 37-39 and term as delivery between 39-42 weeks of gestation.

Results: Of 23 pregnancies, one ended in a miscarriage and 22 resulted in live births including one set of twins. Treatment used during pregnancy was hydroxychloroquine (20 pregnancies), prednisone (8), azathioprine (5) and cyclosporine (2). Concomitant treatment with low-dose aspirin was used in 9 pregnancies.

Of the 22 live births, 17 were born at early term and 5 at term. There were no preterm deliveries. Median birth weight was 2836g (range 2056-3845g). Nine newborns (40.9%) were small for gestational age (SGA). Maternal treatment during these pregnancies was hydroxychloroquine in all cases and additional low-dose aspirin in 3 cases. Elevated CRP levels during pregnancy were found in 57% of the cases with SGA outcome. Only one woman with an SGA infant had positive anti-phospholipid antibodies.

Regarding delivery mode, most patients had caesarean sections.

Conclusion: In our cohort of women with Sjögren syndrome the prevalence of small for gestational age infants was high despite maternal treatment with hydroxychloroquine. Inflammatory markers could help to identify the patients at risk for placental insufficiency, yet prospective studies of larger cohorts are needed.

AB0373 TREATMENT OF SLE WITH THE IMMUNOPROTEASOME INHIBITOR KZR-616: RESULTS FROM THE FIRST 4 COHORTS OF THE MISSION STUDY, AN OPEN-LABEL PHASE 1B DOSE ESCALATION TRIAL

B. Furie1, S. Parikh2, A. Maigue3, A. Khan4, O. Moreno5, M. Soneira6, C. Kirk7, D. Bomba8, K. Harvey9, M. K. Farmer9, 1Northwell Health, Great Neck, NY, United States of America; 2The Ohio State University Wexner Medical Center, Columbus, United States of America; 3SouthCoast Research Center, Inc, Miami, United States of America; 4Accurate Clinical Research, Houston, United States of America; 5Kezar Life Sciences, San Francisco, United States of America

Background: Non-specific proteasome inhibitors, such as bortezomib (BTZ), target the constitutive proteasome and immunoproteasome and are approved treatments for multiple myeloma1. BTZ has also been used to treat systemic lupus erythematosus (SLE) and lupus nephritis (LN); however, treatment emergent adverse events (TEAEs), such as gastrointestinal (GI) effects, hematologic abnormalities, asthenia and peripheral neuropathy, limit its use as a long-term treatment option for chronic autoimmune disease2. KZR-616 is a first-in-class selective immunoproteasome inhibitor and is highly active in murine SLE3. Subcutaneous (SC) administration of KZR-616 (30 and 45 mg weekly (QW)) was demonstrated as safe and well-tolerated, and successfully achieved target levels of immunoproteasome inhibition in healthy volunteers4,5.

Objectives: We report the preliminary safety and efficacy of KZR-616 in the first 4 cohorts of the Phase 1b portion of Study KZR-616-002 in patients with active SLE (NCT03393013).

Methods: SLE patients (per SLICC Classification Criteria) with SLEDAI ≥4 despite stable background immunosuppressant, anti-malarial, and/or corticosteroid (≥20mg prednisone equivalent) therapy in this open-label multicentric dose-escalation trial received KZR-616 at doses of 45mg (Cohort 1), 60mg (Cohort 2), or 30mg with escalation to 60mg (Cohorts 2a and 2b) SC weekly through Week 13 (W13) with 12 weeks of follow-up. Efficacy measures included SLEDAI, Cutaneous Lupus Erythematosus Disease Area and Severity Index, 28 tender and swollen joint counts, Physicians Global Assessment, Patient Global Assessment, and Patient Assessment of Pain, in evaluable patients (those who received ≥1 month of KZR-616).

Results: As of 16 January 2020, 33 patients had enrolled and received at least 1 dose of KZR-616. The majority of TEAEs have been mild or moderate with no reported peripheral neuropathy, prolonged GI-related AEs, and no clinically significant laboratory AEs. There were 3 treatment emergent SAEs, each one of thrombotic microangiopathy (Cohort 2), localized herpes zoster (Cohort 2a), and systemic inflammatory response syndrome (Cohort 2a) with the latter 2 patients completing the full 13 weeks of treatment after resolution. When compared to baseline, improvement in all measures of disease activity were seen at W13 and maintained or improved during the follow-up period, and 94% of evaluable patients had improvements on at least 2 measures/assessments of disease activity. A single patient with active class IV/V nephritis was enrolled on prednisone 10mg, leflunomide 10mg, and hydroxychloroquine 200mg/day; nephrotic-range proteinuria at baseline (3.85 g/day) decreased to 0.6g/day 4 weeks after the last dose of KZR-616.

Conclusion: Weekly subcutaneous administration of KZR-616 at 45 and 60mg was safe and well-tolerated. Evidence of disease suppression at W13 in active SLE patients on stable background therapy was observed. In addition, one study participant with active proliferative nephritis was enrolled with significant reduction in proteinuria. The Phase 2 portion of this study in active proliferative LN is open for enrollment.

**LUPUS LOW DISEASE ACTIVITY STATE AND MAINTAINING DRUG THERAPY: A RETROSPECTIVE INVESTIGATION**

**Methods:** Thirty female SLE patients (mean age 52±15 years; mean age at disease onset 34±16 years, mean disease duration 18±13 years) in clinical remission have been enrolled (EULAR/ACR 2019 criteria) (4). Remission was defined by LLDAS (SLEDAI-2K ≤ 4 and no activity in major organ systems, no hemolytic anemia; no new features of activity compared with previous assessment, physician global assessment (PGA) ≤ 1, prednisone dose ≤7.5 mg/day, well tolerated and stable therapy with maintenance doses of immunosuppressive drugs). Clinical and serological manifestations, SLE disease activity index (SLEDAI), Lupus Low Disease Activity State (LLDAS) seems one of the best tools to evaluate it in clinical practice (3).

**Objectives:** To evaluate the prevalence of SLE signs and symptoms at onset and the drugs used to induce and maintain the clinical remission, evaluated by LLDAS, in a real-life cohort of SLE patients.

**Methods:** Methods: All patients were followed-up at last visit. Mean PGA 0.4±0.1). Maintenance therapies during remission were prednisone ≤ 5mg/day and/or HCQ ≤ 400mg/day and/or CSA ≤ 200mg/day and/or MTX ≤ 10mg/week and/or MMF ≤ 2g/day and/or AZA ≤ 100mg/day. In particular, only prednisone 7%, only HCQ 3%, prednisone + HCQ 53%, prednisone + single DMARD (different from HCQ) 7%, prednisone + HCQ + DMARDS 30%.

**Conclusion:** After reaching the clinical remission by a treat to target strategy, the administration of low dose of prednisone and HCQ in the majority of SLE patients (63%) seems useful to prevent new SLE flares. The retrospective design and the absence of a control group of patients with active disease limit this study.

therapy experienced significantly less flares during pregnancy [aOR 0.18 (95%-CI: 0.09-0.38), p = 0.013].

**Conclusion:** In our cohort, SLE women with additional risk factors achieved a favourable pregnancy outcome. This encouraging result is in part attributable to pregnancy counselling with the advice to continue HCQ throughout gestation.

**AB0376** DETERMINANTS AND PROTECTIVE EFFECTS OF A LOW DISEASE ACTIVITY STATE IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM A PROSPECTIVE CHINESE COHORT

1Peking University First Hospital, Rheumatology and Clinical Immunology, Beijing, China; 2Monash University, Medicine, Melbourne, Australia; 3St. Vincent’s Hospital, Rheumatology, Melbourne, Australia

**Background:** The concept of treat to target in systemic lupus erythematosus has moved forward in recent years. The Lupus low disease activity state (LLDAS) defined by the Asia-Pacific Lupus Collaboration (APLC) in 2016 has been validated prospectively in the APLC cohort itself and retrospectively in multiple other cohorts.

**Objectives:** The concept of treat to target in systemic lupus erythematosus has moved forward in recent years. The Lupus low disease activity state (LLDAS) defined by the Asia-Pacific Lupus Collaboration (APLC) in 2016 has been validated prospectively in the APLC cohort itself and retrospectively in multiple other cohorts. The aim of this study was to investigate the frequency and determinants of achieving LLDAS, and the influence of LLDAS on short term outcomes including disease flare and damage accrual in Chinese lupus patients.

**Methods:** The baseline and follow-up data of all consecutive patients in a longitudinal lupus cohort from January 2017 to December 2018 were collected prospectively. SLEDAI-2K, PGA and disease flare were assessed at each follow-up visit, and further compared to the previous routine clinical visits. Irreversible disease damage was captured using the SLICC damage index and the short form (36) health survey for health-related quality of life was completed annually.

**Results:** One hundred and forty-nine patients were enrolled, with the median disease duration at recruitment of 2.4 (0.9–8.2) years, and median follow-up of 15.4 (10.1–18.2) months. By the end of the study, 104 (69.8%) patients...
achieved LLDAS at least once; 59 patients achieved LLDAS for 50% of observations. Multivariate logistic regression analysis showed that age at disease onset (<30 years [OR=0.05, 95% CI [0.01-0.59], p=0.017], 24-hour urine total protein (UTP) level at recruitment [OR=0.9992, 95% CI [0.9987-0.9998], p=0.007], and C3 level (OR=1.004, 95% CI [1.001-1.008], p=0.024) had independent associations with achieving LLDAS for ≥50% of all observations (Table 1). During follow-up, 56 (37.6%) patients experienced disease flare; 14 (9.4%) patients with severe flare. Kaplan-Meier analyses showed significant differences in flare rates according to whether LLDAS was achieved and the percentage follow-up time in LLDAS (Figure 1). Multivariate cox analysis revealed that the percentage time of time in LLDAS was an independent negative determinant of disease flare (HR=0.18, 95% CI [0.07-0.48], p=0.001) (Table 2). There were 16 (15.0%)/107 patients who had damage accrual after one year of follow-up. Multivariate logistic analysis showed a tendency for achieving LLDAS during follow-up being protective for damage accrual [OR=0.27, 95% CI [0.07-1.00], p=0.050].

Conclusion: In this Chinese early disease cohort, LLDAS was an attainable goal in clinical practice. Age at onset, UTP and C3 level at recruitment influenced achievement of LLDAS. LLDAS was negatively associated with disease flare and damage accrual; this needs to be confirmed by future longer follow-up.

Acknowledgments: The data in this cohort was collected and recorded using the framework of the lupus low disease activity status (LLDAS) study from the Asia-Pacific Lupus Collaboration (APLC).

COMPUTATIONAL DISCOVERY AND PRECLINICAL VALIDATION OF THERAPEUTIC LEADS WITH NOVEL MOAS FOR SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

I. Hakim1, S. Mujahid2, A. C. Daugherty2, T. S. Heuer3, twoXAR, Inc, Mountain View, United States of America

Background: Lupus is a heterogeneous, systemic disease that affects millions of patients globally with a high unmet medical need. We present results from our powerful and efficient computational drug discovery platform that identifies hits with first-in-class mechanisms of action that can advance rapidly and successfully through preclinical validation studies. The twoXAR discovery platform uses an artificial-intelligence framework to integrate diverse patient-derived biomedical data sets to build holistic and unbiased models of human lupus biology. The utilization of diverse, proprietary algorithms and deep learning principles provides a highly sensitive platform to elucidate complex disease-specific associations between biology and biomedical data that are integrated with a library of existing drug molecules. This enables the identification of novel, high-value drug discovery hits with known pharmacological properties. The twoXAR platform also preserves interpretable data-driven links to disease biology to facilitate efficient validation and optimization studies.

Objectives: Apply twoXAR’s computational drug discovery platform for the discovery of first-in-class lupus therapy hits and perform preclinical characterization of selected hits to identify drug discovery leads molecules.

Methods: Using clinical SLE patient data, we employed the twoXAR platform to build an in-silico SLE disease model. Nine molecules with novel mechanisms of action (not previously tested as candidate clinical therapies for lupus) were identified as drug discovery hits and then characterized in preclinical efficacy studies in vivo as lupus disease models (MRL mouse efficacy characterization).

Results: Twenty-nine molecules with novel mechanisms of action (not previously tested as candidate clinical therapies for lupus) were identified as drug discovery hits and then characterized in preclinical efficacy studies in vivo as lupus disease models (MRL mouse efficacy characterization). Twenty-nine molecules with novel mechanisms of action (not previously tested as candidate clinical therapies for lupus) were identified as drug discovery hits and then characterized in preclinical efficacy studies in vivo as lupus disease models (MRL mouse efficacy characterization).

Conclusion: Twenty-nine molecules with novel mechanisms of action (not previously tested as candidate clinical therapies for lupus) were identified as drug discovery hits and then characterized in preclinical efficacy studies in vivo as lupus disease models (MRL mouse efficacy characterization).

UPGRADING THERAPY STRATEGY IMPROVES PREGNANCY OUTCOME IN ANTIPHOSPHOLIPID SYNDROME: A COHORT MANAGEMENT STUDY

A. Hoxha1,2, M. Favaro1, A. Calligaro1, T. Del Ross1, A. T. Ruffatti3, C. Infantolino3, M. Tonello1, E. Mattia1, A. Ruffatti1,1 University of Padua, Department of Medicine-DIMED, Padua, Italy, 2San Bortolo Hospital, Department of Medicine, Vicenza, Italy, 3University-Hospital of Padua, Obstetrics and Gynaecology Unit, Padua, Italy

Background: While it is generally agreed that pregnant APS patients should receive personalized treatment, evidence-based guidelines for these patients continue to be lacking.

Objectives: The current study was designed as a management cohort study aiming to evaluate the efficacy and safety of different treatment strategies for pregnant APS patients in the attempt to provide some practical suggestions for attending physicians.

Methods: One-hundred-twenty-seven consecutive pregnancies were assessed; 87 (68.5%) with a history of pregnancy morbidity alone were treated with prophylactic low molecular weight heparin (LMWH)+low-dose aspirin (LDA, 100 mg) [Group I] and 40 (31.5%) with a history of thrombosis and/or severe pregnancy complications with therapeutic LMWH+LDA [Group II]. LMWH doses were increased throughout the pregnancies depending on the patients’ weight gain, and treatment was switched to a more intensive one at the onset of maternal/fetal complications. The study’s primary outcome was live births.

Results: There were no significant differences in live birth rate between Group I (95.4%) and Group II (87.5%). Even, fetal complication rate was similar in the two groups; the Group II nevertheless had a higher prevalence of maternal and neonatal complications (p=0.0005 and p=0.01, respectively) and registered a significantly lower gestational age at delivery and birth weight (p=0.0001 and p=0.0005, respectively). Two patients in Group I switched to Group II therapy, six patients in Group II switched to a more intensive treatment strategy (weekly plasma exchange+fortnightly intravenous immunoglobulins in addition to therapeutic LMWH+LDA). Comparison of the clinical and laboratory characteristics between patients who had shifted to a more intensive therapy and those who did not show a significant prevalence of history of thrombosis+a pregnancy morbidity (p=0.02, OR 5.96, 95% CI 1.33-26.62) previous pregnancy complications (p=0.02, OR 8.32, 95% CI 1.67-41.3), triple aPL positivity (p <0.0001, OR 97.13, 95% CI 10.6-890) and pregnancy complications (p=0.001, OR 19.77, 95% CI 5.07-3899) in upgrading group, instead single aPL positivity significantly prevailed (p=0.003, OR 0.06, 95% CI 0.008-0.58) in non-upgrading group. Logistic regression analysis demonstrated that triple aPL positivity was an independent factor for switching to a more effective therapy protocol (p <0.0001, OR 98, 95% CI 10.7-87954). All eight switched patients achieved a live birth.

Conclusion: Using adjusted LMWH doses and upgrading therapy at the first signs of pregnancy complications led to a high rate of live births in a relatively large group of APS patients. The study outlines the criteria for prescribing appropriate therapy for various subsets of these patients and for switching/upgrading the treatment protocol when it is no longer sufficient. Unfortunately, for the moment there are no evidence-based guidelines on the ideal additional treatment in refractory to conventional therapy APS patients. The present results will hopefully point the direction of future clinical trials investigating the efficacy and safety of the different therapies on large numbers of APS pregnant patients in order to identify the benefits and limits of different treatment strategies administered from the beginning of pregnancy.

DOI: 10.1136/annrheumdis-2020-eular.2704
Background: Lupus nephritis is the most important predictive factor of morbidity and mortality in SLE. Though Mycophenolate mofetil is recommended for induction and maintenance treatment of class III, IV V lupus nephritis, it is not approved by US or Taiwan FDA (TFDA). In previous reports of kidney transplantation, no efficacy differences were observed between mycophenolate sodium (Myfortic) and mycophenolate mofetil (Cellcept). However, no clinical trial was conducted to compare these two widely-used mycophenolic acid derivatives in lupus nephritis. In December, 2016, TFDA approved Mycophenolate sodium in treatment of lupus nephritis. For reimbursement issue, patients treated with mycophenolate mofetil before December, 2016 were non-medically switched to mycophenolate sodium in Taiwan.

Objectives: To compare the treatment efficacy of mycophenolate mofetil and mycophenolate sodium in lupus nephritis patients with non-medical switching.

Methods: Between 2016 and 2018, a retrospective observational study enrolled 50 biopsy-proven LN patients in Taichung Veterans General Hospital, Taiwan. All these patients were initially treated with Cellcept for at least one year. Treatment response was evaluated by urinalysis and daily urine protein one year before and after switching to Myfortic.

Results: Before switching, 72% patients were classified as responder if complete remission or partial remission were achieved, while 28% patients were categorized as non-responders (Table 1). After switching to Myfortic, 75% of the responder group achieved or maintained complete remission or partial response. In for non-responder group, 85.7% exhibited complete remission or partial remission.

Results: Responders were defined as those patients with complete remission or partial remission who were achieved, while 28% patients were categorized as non-responders (Table 1). After switching to Myfortic, 75% of the responder group achieved or maintained complete remission or partial response. In non-responder group, 85.7% exhibited complete remission or partial remission.

AB0382
A RITUXIMAB AND BELIMUMAB COMBINATION THERAPY IN SLE PATIENTS.

A. Meanyanking1, S. Solovyev1, E. Aseeva2, N. Nikishina3, VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Various mechanisms of action of RTM and BLM, in particular their interaction with defined subpopulations of B cells, can contribute to more effective suppression of autoreactive B cells and achieve a therapeutic effect.

Objectives: To assess the efficacy of a rituximab and belimumab combination therapy in pts with active SLE.

Methods: The study included 10 SLE pts (1M/9F) with high (SLEDAI≥10 – 16pts.) and moderate (SLEDAI<10- 4pts.) disease activity (SLEDAI Me 14[10;16]) vs pts receiving RTM only (SLEDAI Me 0,11x109/l[0,08;0,5], 12mo -Me 0,01x109/l[0,01; 0,03]) vs pts receiving RTM + BLM combination therapy. The oral GCs dose was reduced to 6,9 mg/day by 6mo. One patient managed to completely eliminate glucocorticoids.

Results: A. RTM and BLM combination failed, as well as failure of standard GCS and cytotoxic therapy was observed in 9 patients (SLEDAI2K 0 mo–Me 12[10;16], 3mo-Me 8[6;10], 6mo–Me 4[2;6], 9mo–Me 6[4;10], 12mo–Me 2[2;6]) with RTM + BLM combination therapy. The oral GCs dose was reduced with statistically significance (pre-administration of HCQ:10.3±1.7 mg/day, 24 months after administration of HCQ:2.2±0.3 mg/day, p<0.0001).

Conclusion: This study demonstrated the decrease in clinical and laboratory SLE activity from starting of 3mo of follow-up, and by the 6th month the decrease in the activity of the disease was observed in 9 patients (SLEDAI2K 0 mo–Me 12[10;16], 3mo-Me 8[6;10], 6mo–Me 4[2;6], 9mo–Me 6[4;10], 12mo–Me 2[2;6]) with RTM + BLM combination therapy. The oral GCs dose was reduced with statistically significance (pre-administration of HCQ:10.3±1.7 mg/day, 24 months after administration of HCQ:2.2±0.3 mg/day, p<0.0001).

EXTREME FATIGUE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND NEUROPSYCHIATRIC SYMPTOMS

R. Monahan1, R. Fronczek2, J. Elkenboom3, H. Middelkoop2, L. J. Beaat-van de Voorde1, G. Tervain4, N. Van der Wee5, T. Huizinga6, M. Kloppenburg6, G. M. Steup-Beekman1.

1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Leiden University Medical Center, Neurorology, Leiden, Netherlands; 3Leiden University Medical Center, Internal Medicine, Division of Thrombosis and Hemostasis, Leiden, Netherlands; 4Leiden University Medical Center, Psychiatry, Leiden, Netherlands

Background: Fatigue is commonly described in chronic illnesses, especially auto-immune disorders such as systemic lupus erythematosus (SLE).

Objectives: We aim to study the prevalence of fatigue in SLE patients with NP symptoms and compare fatigue in SLE patients with NP symptoms attributed to major organ involvement due to SLE (NPSLE) with SLE patients with NP symptoms not caused by major nervous system involvement (non-NPSLE).

Methods: All patients visiting the tertiary referral center for NPSLE in the LUMC between 2007-2019 with the clinical diagnosis of SLE and age >18 years that signed informed consent were included in this study. Patients underwent a standardized multidisciplinary assessment, including two questionnaires: SF-36 (2007-2019) and multidimensional fatigue index (MFI, 2011-2019). Patients were classified as NPSLE in this study if NP symptoms were attributed to SLE and immunosuppressive or anticoagulant therapy was initiated, otherwise patients were classified as non-NPSLE. The vitality (VT) domain of the SF-36 domain was used to assess fatigue, which generates a score from 0-100, 100 representing the complete absence of fatigue. Patients with a score more than 1 standard deviation (SD) removed from age-related controls of the Dutch general population were classified as fatigued; patients more than 2 SD removed from age-related controls were classified as extremely fatigued. The MFI was also used, which consists of 5 subdomain scores between 0-20, leading to a total score between 0-100, 100 representing the most extreme fatigue. All scores are presented as mean and standard deviation.

Results: 373 patients fulfilled the inclusion criteria and SF-36 questionnaires of 328 patients were available (88%). The majority of these patients was female (67%) and 98 were classified as NPSLE (30%). In NPSLE patients, average age was 41 ± 13 years and in non-NPSLE the average age was 45 ± 14 years. The average score of the SF-36 vitality domain was 36.0 ± 20.7 in NPSLE vs 33.9 ± 18.8, in non-NPSLE. Overall, 73.5% of the patients were fatigued and 46.9% extremely fatigued in NPSLE vs 77.8% fatigued and 45.7% extremely fatigued in non-NPSLE. The MFI questionnaire and VAS score were available for 222 patients, of which 65 patients were classified as NPSLE (29.3%). Table 1 depicts the scores of NPSLE and non-NPSLE patients on the MFI subdomains and the VAS score.

**Conclusion:** In a large multicentre SLE cohort, most patients were receiving combination treatment. AM treatment survival was high and associated with low disease activity, GC survival was high and associated with high disease activity, while IS survival was low. Patients with high disease activity received more medication combinations but had reduced IS survival. These data suggest ongoing unmet need for improved medications for treatment of SLE.

**References:**

**AB0384 MEDICATION USE IN SYSTEMIC LUPUS ERYTHEMATOSUS – DATA FROM A MULTICENTRE COHORT STUDY**

**Background:** In the absence of evidence-based treatment guidelines, medication use in SLE is highly variable. Low rates of remission and lupus low disease activity state (LLDAS) suggest that suboptimal responses to standard medications, which include glucocorticoids (GC), anti-malarial (AM) drugs and immunosuppressive (IS) agents, are common. Understanding the utility of current medications will facilitate the selection of patients for advanced therapies as they emerge.

**Objectives:** To examine medication use patterns in a large multicentre SLE cohort.

**Methods:** We used 2013-18 data from the Asia Pacific Lupus Collaboration (APLC) cohort in which disease activity (SLEDAI-2K) and medication details were captured at every visit. LLDAS was defined as in Golder et al., 2019 (1). We examined the use of medication (med) categories (GC &/or AM &/or IS) by SLE disease activity and LLDAS at the visit level. Additionally, we performed Cox regression analyses to determine the time-to-discontinuation of meds stratified by SLE disease activity, ranked by time-adjusted mean SLEDAI-2K, and by percent-time spent in LLDAS.

**Results:** We analysed data from 19,804 visits of 2,860 patients. We observed 8 med categories: no meds; GC, AM or IS only; GC+AM; GC+IS; AM+IS and GC+AM+IS (triple therapy). Triple therapy was the most frequent med pattern (32%); single agents were used in 21% of visits and biologicals in only 3%.

Among visits where SLEDAI-2K was ≥10, triple therapy was used in 46%, with GC+AM+IS (triple therapy). Triple therapy was the most frequent med pattern.

**Conclusion:** Nearly half of patients with SLE and NP symptoms are extremely fatigued as only 2.5% of the general Dutch population. Extreme fatigue is not influenced by major nervous system involvement.

TARGETING CD38 IN SYSTEMIC LUPUS ERYTHEMATOSUS

L. Ostendorf1, 2, U. Schneider1, M. Urbich2, P. Enghard2, 3, F. Heinrich2, P. Durek2, G. Heitz3, H. Mayer1, M. F. Mashreghi2, G. R. Burmester1, 2, A. Radbruch1, 2, T. Alexander1, 2, 3. 1Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Deutsches Rheuma-Forschungszentrum (DRFZ), Berlin, Germany; 3Charité – Universitätsmedizin Berlin, Department of Nephrology, Berlin, Germany

Background: Depletion of long-lived plasma cells (PC) resembles a novel concept for the treatment of antibody-mediated autoimmune diseases, such as systemic lupus erythematosus (SLE). Therapeutic approaches such as autologous stem-cell transplantation and proteasome inhibition are limited by significant treatment-related toxicity. A novel target for PC depletion is CD38, a surface protein that is highly expressed on plasma cells (PCs) but also activated T-cells and most myeloid cells. Daratumumab is a monoclonal antibody targeting CD38 that is licensed for the treatment of multiple myeloma.

Objectives: Here, we aimed to ascertain clinical safety and efficacy of Daratumumab for the treatment of refractory SLE, as well as to gain insights into effects of Daratumumab on the immune system.

Methods: We treated two SLE patients with life- and organ-threatening SLE with four weekly dosis of 16 mg/kg Daratumumab. We performed integrative analyses of clinical, serological and immunological effects over a follow-up period of 6 months. Using flow cytometry and single-cell RNA and T-cell receptor sequencing we followed CD38 expression and composition of peripheral blood leukocytes with a special focus on memory T cells.

Results: Patient 1, a 50-year-old woman, suffered from active biopsy-proven class III lupus nephritis (LN) with nephrotic range proteinuria, pericarditis, arthritis and skin rash. Upon Daratumumab treatment, her glomerular filtration rate normalized within 3 months and proteinuria gradually declined from 6.4 to 1.9 g/24h Creatinine during the 18-month follow-up period. Pericarditis, arthritis and skin rash completely resolved. Patient 2, a 32-year-old woman, presented with autoimmune hemolytic anemia requiring blood transfusions, immune thrombocytopenia and cutaneous vasculitis. Her direct antiglobulin test normalized within 3 months and remained negative throughout follow-up with consecutive recovery of the hemolytic anemia. Immune thrombocytopenia stabilized and vasculitic skin lesions completely resolved. Infusions were well tolerated without severe adverse drug reactions. NK cells and Dendritic Cells were transiently depleted, while numbers of T cells, B cells and Monocytes in the peripheral blood remained stable. CD38+ memory T cells that were expanded prior to treatment were virtually undetectable early after treatment. Their single cell transcriptomics demonstrated an upregulation of genes associated with activation, cytotoxicity and type 1 interferon response. CD38+ CD8+ memory T cells showed marked oligoclonality. These prominent clones persisted upon treatment but their transcription profile gradually normalized.

Conclusion: Daratumumab appears to be a safe and effective treatment for refractory SLE. Further investigations are warranted to establish the efficacy in a clinical trial and to gain further insights into the pathophysiologic mechanism of action.

TREATMENT STATUS FOR OSTEOPOROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: CROSS-SECTIONAL ANALYSIS FROM A LUPUS REGISTRY OF NATIONAL INSTITUTIONS (LUNA)

K. E. Sada1, K. Hayashi1, Y. Asano1, Y. Katayama1, S. Hiramatsu Asano1, K. Ohashi1, M. Morishita1, H. Watanabe1, M. Narazaki1, Y. Matsumoto1, N. Yajima2, R. Yoshimi3, Y. Shimojima4, S. Ono5, H. Kajiyama6, K. Ichinose7, S. Sato8, M. Fujinara1, J. Wada1, 8Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Department of Nephrology; Rheumatology, Endocrinology and Metabolism, Okayama University Medical School, Okayama, Japan; 9Yokohama City University School of Medicine, Yokohama, Japan; 10Shinshu University School of Medicine, Matsumoto, Japan; 11Yokohama City University Medical Center, Yokohama, Japan; 12Saitama Medical University, Saitama, Japan; 13Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan; 14Fukushima Medical University School of Medicine, Fukushima, Japan; 15Yokohama Rosai Hospital, Yokohama, Japan

Background: Osteoporosis is one of the most important adverse effects of glucocorticoids in patients with systemic lupus erythematosus (SLE). Because osteoporosis is accelerated by chronic kidney disease (CKD), more attention should be paid to the treatment for osteoporosis in SLE patients with CKD. Many treatment options for osteoporosis have emerged recently, but treatment status in patients with SLE is not elucidated.

Objectives: The purpose of this study is to elucidate the treatment status for osteoporosis in patients with SLE among the CKD stages.

Methods: Using data from a lupus registry of nationwide institutions (LUNA), a cross-sectional analysis was performed. We firstly described treatment status for osteoporosis in all enrolled patients. Secondary, treatment status for osteoporosis was compared among CKD stages. Finally, bone damage in Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) was compared among CKD stages.

Results: During a median age of 10 years (IQR) of enrolled 917 patients was 44 (34-57) years and 809 patients (88%) were female. CKD stages were: CKD stage 1, 234 (26%); CKD stage 2, 465 (51%); CKD stage 3, 189 (21%); CKD stage 4, 9 (1%); CKD stage 5, 16 (2%). Median (IQR) age, female sex,
and median (IQR) previous maximum dose of prednisolone in patients with and without CKD (xCKD stage 3) were 56 (46.5-86) and 41 (32-50), 191 (89%) and 615 (88%), and 40 (30-60) and 40 (30-55) mg/day, respectively. Bisphosphonate was administered in 388 (42%) patients, vitamin D supplements in 448 (49%), Ca supplements in 36 (4%), denosumab in 20 (2%) and teriparatide in 14 (2%), respectively. Of enrolled patients, any treatment for osteoporosis was not adminis-
istered in 226 (25%) patients. In spite of more frequent bone damage in patients with CKD compared to those without CKD (15% vs 10%, p=0.036), treatment status did not differ between patients with and without CKD (bisphosphonate: 41% vs 46%, p=0.29; vitamin D supplements: 50% vs 44%, p=0.14).

Conclusion: About a quarter of patients with SLE did not take any treatment for osteoporosis. Treatment for osteoporosis might be strengthened to prevent bone damage in SLE patients with CKD.

IMPROVEMENT OF PATIENT-REPORTED OUTCOMES IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME UNDERGOING CPAP-TREATMENT

M. Seng1, S. C. Frye2, L. Vollmer2, F. Kollet1, R. Vo1, S. Finzel2, 1Medical Centre - University of Freiburg, Faculty of Medicine, Department of Rheumatology and Clinical Immunology, Medical Centre, 79106, Germany; 2Medical Centre - University of Freiburg, Faculty of Medicine, Department of Pneumology, Freiburg, Germany; 3University Hospital Bern, Department of Rheumatology, Immunology, and Allergology, Bern, Switzerland; 4Medical Centre - University of Freiburg, Faculty of Medicine, Department of Rheumatology and Clinical Immunology, Medical Centre, Freiburg im Breisgau, Germany; 5Medical Centre - University of Freiburg, Faculty of Medicine, Department of Rheumatology and Clinical Immunology, Medical Centre, Freiburg, Germany.

Background: Fatigue is a frequent symptom in primary Sjögren’s Syndrome (pSS) determining health-related quality of life in many patients. Earlier studies could show that sleep apnea syndrome (SAS) is associated with patient-reported outcomes in pSS-patients [1].

Objectives: To investigate whether treatment of an underlying SAS improves disease activity in pSS-patients.

Methods: 14 female pSS-patients from our rheumatology outpatient clinic were enrolled and screened for SAS; continuous positive airway pressure (CPAP)-treatment was initiated in patients with a sleep apnea/hypopnea index >5 and a respiratory disturbance index >15h sleeping time (pSS treated with CPAP: pSS+; pSS untreated: pSS-). As controls, 11 SAS-patients (4 female) scheduled for initiation of CPAP-treatment were recruited from pulmonology department. In pSS, ESSDAI, ESSPRI, pain and patient global health on a visual analogue scale from 0-100mm were recorded. In both groups CRP, ESR, depression, as well as all SAS-patients. Table 1 shows means ± SD of all assess-
ments during withdrawal attempts: SLE duration, disease activity at the onset and initiation of GCs dose reduction, therapy at SLE onset, the duration of the last flare, activity and therapy at the end of FU, and duration of remission after GCs withdrawal. Definitions of remission were applied to GCs withdrawal in line with European consensus criteria.

Results: Out of 750 patients with a follow-up of about 6 years (IQR 1-23), GCs withdrawal due to persistent remission was documented in 15 patients (2.0%). In 14 out of these 15, SLE onset was associated with high disease activity based on SLEDAI 2K > 8. High levels of anti- DNA antibodies increase in C3 \( \uparrow \) C4 compli-
ment were present in 12, 4 patients had nephritis with preserved renal function, 4 patients manifested signs of CNS damage (convulsions, headaches, sleep disturbances, memory issues, neuropsychiatric, hallucinations), and another 5 had vasculitis. 10 patients were administered pulse therapy with 3g methylpredni-
solone due to high disease activity. Initiation of GCs dose reduction with intent to discontinue in 7 patients was substantiated by prolonged clinical remission, nevertheless SLE duration of this group varied from 2 to 20 years, and duration of the last flare - from 6 to 165 months. Acute onset with high disease activ-
ity reaching 12-23 scores on SLEDAI 2 K was documented in 8 cases of early SLE with disease duration varying from 1.5 to 6 months. These patients were prescribed the most aggressive induction therapy, including cascade plasma fil-
tration in combination with pulse therapy, cyclophosphamide and Rituximab at 1g dose. Rescue treatment SLEDAI 2K 0-2 scores was achieved 4-6 months later after termination of aggressive induction therapy. The duration of remission after GCs withdrawal in all 15 patients ranged from 3.5 to 240 months. In 8 patients with aggressive induction therapy, remission lasted from 18 to 240 months. In 2
remaining patients, remission lasted for 9 and 16 months after GCS withdrawal. Each flare required intake of low prednisolone doses for 3-4 weeks.

**Conclusion:** GCS withdrawal is an achievable goal in SLE and may be attempted after a long-term remission, and possibly after aggressive intensive care in the early stages of SLE.

**AB0390**

**ASSOCIATION BETWEEN INITIAL SERUM “TUMOR NECROSIS FACTOR-LIKE WEAK INDUCER OF APOPTOSIS” (TWEAK) LEVEL AND TREATMENT RESPONSE IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) NEPHROPATHY**

Z. Wallen1, C. Soe1, H. M. Win1,2, Yangon Specialist Hospital (500 Bedded), Rheumatology Department, Yangon, Myanmar, Burma; 1Yangon Specialist Hospital (500 Bedded), Rheumatology Department, Yangon, Myanmar, Burma; 2Yangon General Hospital, Medical Department, Yangon, Myanmar, Burma

**Background:** SLE is a chronic inflammatory immunologic abnormalities disease which produce a number of antinuclear antibodies. The SLE renal involvement is clinically apparent in approximately 50% patients (Norby et al., 2017). It is very important to introduce the prompt treatment to prevent the permanent end stage renal disease.

**Objectives:** This study aimed to identify the serum biomarkers that correlate with pretreatment disease activity in patients with SLE nephropathy and predict the treatment outcome so that we may identify the unresponsive cases and switch to the other biologic agents like anti-TWEAK monoclonal antibody in the future.

**Methods:** This was a hospital-based prospective analytical study conducted from January 2018 to November 2019 in Rheumatology Department, Yangon Specialty Hospital. 88 SLE nephropathy patients with 24-hour urinary protein above 0.5g/day planned to have 6 months course of IV cyclophosphamide were enrolled. The paired serum sample of each patient was analyzed by ELISA twice to get the mean serum TWEAK value. Pretreatment SLE disease activity was assessed by the SLEDAI score. After the completion of 6 months of aggressive treatment, the treatment response was assessed by measuring the 24 hour urinary protein.

**Results:** Among the 88 patients, 63 patients (71.6%) had completed total 6-months course and 25 patients (28.4%) had not completed:11 patients (12.5%) expired and 2 patients (2.27%) had been changed to other DMARD and 12 patients (13.63%) did not attend the follow up clinic. The mean serum TWEAK value was 856 ± 77 pg/ml in 88 patients. According to the range of serum TWEAK level, most of the patients had serum TWEAK level of 601-900 pg/ml (53.4% of the study population). There was positive correlation between pre-treatment SLEDAI 2k score and pretreatment serum TWEAK level (r=0.464 and P <0.001). When the SLEDAI 2k score was grouped into mild, moderate, high and very high disease activity, the serum TWEAK level also had positive association with the different levels of disease activity (p<0.001). Among 63 treatment completed patients, 55 patients (87.3%) were the treatment responders but 8 patients (12.7%) were treatment non-responders. There was significant difference in the pretreatment SLEDAI 2k in terms of disease activity between treatment responder and treatment non-responder (p<0.001). There was significant difference in the pretreatment SLEDAI 2k in terms of reduction in 24-hours urinary protein between treatment responder and treatment non-responder (p<0.001). There was no significant difference in the level of pretreatment serum TWEAK level between treatment responders and treatment non-responders (p=1.000). There was also no significant difference in the pretreatment serum TWEAK level between treatment responders and treatment non-responders in terms of reduction in 24 hours urinary protein (p=0.804).

**Conclusion:** Although the pretreatment serum TWEAK level had a positive correlation with pretreatment disease activity of SLEDAI 2k, it did not reflect the outcome of the responsiveness to the intensive therapy.

**EFFECT OF HCQ ON LLADS ACHIEVEMENT IN SLE PATIENTS**

R. Wakiya1, K. Ueeda1, H. Shimada1, S. Nakashima1, M. Mahmoud Fahmy Mansour1, M. Kato1, T. Miyagi1, Y. Ushio1, K. Sugihara1, T. Kameda1, H. Dobashi1, 1Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Kagawa, Japan

**Background:** HCQ for SLE in Japan has been administered in many cases after approval. Therefore, the effect of additional administration of HCQ on low disease activity of SLE was considered to be clearer.

**Objectives:** To clarify the effect of HCQ treatment on the control of disease activity in SLE patients.

**Methods:** All SLE patients with low disease activity (LDA) enrolled in this study started additional HCQ treatment from January 2016. All patients with LDA enrolled in this study started HCQ treatment and had been receiving oral HCQ continuously for at least 3 months without using other immunosuppressive treatments or glucocorticoids. Disease activity was evaluated by SLEDAL, CLASI, and LLADS, and serum complement values, anti-DNA antibodies, and pro-inflammatory cytokines were analyzed as immunological biomarkers before and after HCQ treatment.

**Results:** 52 of 100 patients were enrolled in this study (M:F; 4:48, average age; 40.6±13.4). 24 lupus nephritis patients were in sustained remission. 29 patients (56%) achieved LLADS and 3 patients (6%) achieved clinical remission (CR) before HCQ administration. Of the 20 patients (38%) who did not achieve LLDAS before HCQ administration, the LLDAS achievement rates at 3, 6, and 12 months after additional HCQ were 47%, 59%, and 81% (including 12.5% of CR achievement rates), respectively. Serum levels of MRP8, MRP14, TNF-α, IL-6, VEGF-A, IL-1ra, MIP-1a and IL-2 decreased significantly 3 months after additional HCQ treatment. In addition, serum levels of MRP8, MRP14, TNF-α, IL-6 and IL-2 also decreased significantly 3 months after additional HCQ treatment despite achieving LLDAS or CR. The expressions of IFN-α didn’t decrease significantly in 9 cases that could be detected. The magnitude of the changes in serum MRP8, MRP14, IL-8 and IL-1ra levels in patients with a history of LN was significantly higher than in those without a history of LN. The magnitude of the reduction in serum MCP-1 levels in patients not achieving LLDAS with a history of LN was significantly higher than in those without a history of LN (p=0.046).

The change of CLASI activity score was correlated with the change in serum levels of MRP14 and MCP-1 with univariate analysis (MPR14: r=−0.41, p=0.017, MCP-1: r=−0.58, p=0.0006). The change of serum C3 levels had a negative correlation with MCP-1 (r=−0.33, p=0.022).

The magnitude of the change in serum levels of MRP14, TNF-α, IL-8, MCP-1, MIP-1a and IL-1ra in patients achieving LLDAS were correlated with the change of CLASI activity score with univariate analysis (MPR14: r=−0.49, p=0.041, TNFα: r=0.74, p=0.0038, IL-1ra: r=0.66, p=0.038, MIP-1a: r=0.63, p=0.037, Figure 1). Moreover, the change of serum C3 and C4 levels in them had a negative correlation with the change of serum MCP-1 levels (Figure 2).

**Figure 1.** Correlation between change of CLASI activity scores and serum MCP-1 levels in SLE patients with LLDAS (IL-6: r=0.77, p=0.0007, MCP-1: r=0.80, p=0.0001).

**Figure 2.** Correlation between change of serum C3 and C4 levels and serum MCP-1 levels in SLE patients with LLDAS (C3: r=−0.40, p=0.028, C4: r=−0.37, p=0.047).

**Conclusion:** Additional administration of HCQ is useful for cytokine control even in LLDAS-achieved cases, and particularly contributes to the improvement of some of CR.

In addition, regulation of IL-8 and MCP-1 is important for control of renal lesions in SLE, so that disease activity of more SLE patients might be more controlled disease activity.
Systemic lupus erythematosus (SLE) patients, especially patients with lupus nephritis who have poor vascular endothelial function and increased cardiovascular mortality. Meanwhile, several studies showed hydroxychloroquine (HCQ) has an effect on reduction in lipids and thrombosis (1), but the mechanism is unclear.

Objectives: We examined effect of HCQ on adipocytokine expression in SLE patients.

Methods: 52 SLE patients with low disease activity started with HCQ were analyzed before and 3 months after HCQ treatment. 21 SLE patients have past history of lupus nephritis. Serum S100 proteins and adipocytokines were measured by ELISA, and serum inflammatory cytokine levels were evaluated by Multiplex assay (TNF-α, IL-6, VEGF-A).

Results: Serum adiponectin level was increased significantly 3 months after HCQ treatment compared with those at baseline (mean change 1.35, Figure 1). SLE patients who achieved LLDAS had a greater increase than those who did not. Additionally, the changes of serum adiponectin levels were associated with those of TNF-α, IL-6, VEGF-A and S100A9 protein, which plays an important role of SLE pathogenesis.
had been successfully treated, 27.8% had metastasis, 5.6% had died. There was no significant difference in SLEDAI between patients with cancer and patients without. Whereas malignancy is correlated to longer disease duration (p<0.01) and older age of SLE onset with significant difference (p=0.001).

**Conclusion:** Although we have detected an increasing incidence of cancer in SLE patients in comparison to normal population, our study didn’t find a significant correlation between SLE disease activity and the risk of cancer. We should closely observe SLE patients with old age at onset and/or long disease duration because of their higher risk for cancer development.

cSLE-MAS – Childhood systemic lupus erythematosus – Macrophage activation syndrome, HLH – Hemophagocytic lymphohistiocytosis

**Results:** Sixteen patients (median age – 26 years, 15 females) were included. Twelve patients (75%) had MAS as the initial presentation of SLE. The common clinical features were fever (100%) and cytopenias (100%). The mean duration of symptoms was 60 days. The most frequent biochemical abnormalities were high ferritin (>500 ng/ml, 100%) and elevated transaminases (100%, aspartate transaminase > alanine transaminase). Common complications were renal (43.8%), neurological (43.8%), and coagulopathy (43.8%). Seven and 16 patients fulfilled the HLH 2004 and cSLE – MAS preliminary criteria, respectively. The median H score was 222, giving a cumulative probability of 96%. All the patients received high-dose steroids. Cyclophosphamide pulse and cyclosporine were administered to 8 (50%) and 6 (37.5%) patients respectively. There were four (25%) in-hospital mortalities.

Methods: Prospective observational study of a cohort of patients with sicca syndrome from a reference center. The diagnostic protocol (Schirmer’s test, UWSF and minimally invasive MSGB) was applied in the same consultation. Demographic, clinical, analytical and histological data were reviewed.

Results: Over a period of 6 months, 48 patients with dry syndrome were analyzed, of which 39 women (81.2%). The main suspicion was SjS (39), followed by sarcoidosis (3), IgG4-related disease (2) and other diagnoses (4). The mean age was 59.1±4.4 years. Almost half (45.8%) reported xerostomia and 41.6% xerophthalmia. Recurrent parotidomegaly was described in 6 patients (12.5%) and arthralgias in 12 (25%). Immunologically, 23 (47.9%) presented anti-nuclear antibodies, 13 (27.1%) anti-Ro, 4 (8.3%) anti-La, 12 (25%) rheumatoid factor and 15 (31.2%) low C4. Schirmer test was positive in 32 patients (66.7%), UWSF in 22 (45.8%) and 9 (18.8%) had a focus score ≥1, although 16 (33.3%) had focal lymphocytic sialadenitis in the MSGB. A total of 21 (43.8%) patients were classified according to the 2016 ACR/ EULAR criteria. 12 (57.1%) were seropositive SjS and 9 (42.9%) seronegative SjS. MSGB sensitivity was 71% and specificity 96%. Patient reported symptoms were unhelpful to differentiate SjS from other causes of dry syndrome. The number of protocols needed to diagnose a SjS was 2.28 (5.33 in seronegative SjS). Complications associated with the procedure were low (1 of 48) and mild (self-limited paraesthesia). Patients with SjS, unlike those with dry syndrome of another etiology, had more anemia (p<0.001), lymphopenia (p=0.022), ESR (p=0.030), beta-2 microglobulin (p=0.011), ANA (p<0.001), anti-ENA (p=0.006), anti-Ro (p<0.001), low C4 (p<0.001) and hypergammaglobulinemia (p=0.002).

Conclusion: Immunological and histological manifestations were more predictive than clinical ones to differentiate SjS from other causes of dry syndrome. MSGB is a simple, sensitive, specific and safe procedure. The application of the diagnostic protocol (Schirmer test, UWSF and MSGB) allowed to standardize the classification of SjS and increased the diagnosis of patients with seronegative SjS.

LUPUS FATIGUE PROBLEMS IN THE RUSSIAN COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (RENAISSANCE).

E. Aseeva1, S. Solovyev2, G. Kolibueva3, N. Nikishina4, E. Nasonov1, A. Lila5, TVA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2National Center for Cardiology and Internal Medicine named after Academician M. Mirrakhimov, Bishkek, Kyrgyz Republic, Rheumatology, Bishke, Kyrgyzstan

Background:
Objectives: To determine the dependency of fatigue from SLE activity, irreversible organ damage and HRQoL in SLE patients of the Renaissance cohort.

Methods: 328 Russian SLE patients were enrolled in the study (M/F 30/298) who fulfilled SLICC 2012 criteria. The SLEDAI 2K activity, SLICC damage index, Facit Fatigue scale, and health related quality of life (HRQoL) using the LupusQol questionnaire were evaluated.

Results: Based on the Facit Fatigue scale scores fatigue was verified in 148 (45%) out of 328 patients with SLE. Following lupus fatigue status patients were divided into two groups - 148 and 168 patients respectively. The groups were perfectly matched in terms of age, duration of the disease, duration of GCs therapy, and damage scores (Table 1).

The SLEDAI 2K activity scores were significantly higher in the group with lupus fatigue - 9.6±4.0 vs 6.7±4.2 (p=0.01) as compared to values in the group without fatigue, as well as the level of antibodies to DNA (p=0.02), 110.2±34.2 and 82.3±20.5, respectively.

There was a significant decrease in HRQoL in patients with lupus fatigue based on scores in all eight scales of the questionnaire (p=0.00).

Conclusion: Almost half (45%) SLE patients in the Russian cohort experience fatigue. It is associated with disease activity on the SLEDAI 2k scale and high levels of antibodies to DNA. All patients experiencing lupus fatigue have significantly worse HRQoL based on scores in all eight scales of the questionnaire LupusQol.

TNF-LIKE WEAK INDUCER OF APOPTOSIS / FGF INDUCIBLE MOLECULE 14 PATHWAY IN UNTREATED LUPUS NEPHRITIS: SERUM OR URINE TWEAK LEVELS MORE ACCurate IN RELATION TO RENAL ACTIVITY?

M. Bekkal1, N. Abaza1, N. Kamel1, M. Ossman1, S. Saad El Din2, 3Ain Shams University, Rheumatology, Cairo, Egypt; 3Ain Shams University, Pathology, Cairo, Egypt

Background: Lupus nephritis (LN) is one of the most serious manifestations of SLE, affecting 70% of patients and the most critical predictor of morbidity and mortality of the disease [1].Tumor necrosis factor-like weak inducer of apoptosis/ fibroblast growth factor inducible molecule 14 (TWEAK/Fn14) activation is involved in various pathological processes that occur locally in kidneys, facilitating the pathogenesis of LN [2].

Objectives: To assess serum and urine TWEAK levels as well as renal Fn14 expression in newly diagnosed patients with LN and its correlation to disease activity.

Methods: The present study included 30 selected newly diagnosed previously untreated SLE patients divided into 2 groups; 15 patients with LN and 15 without LN as well as 30 age and sex matched healthy subjects who served as control group. Written consent was obtained from all patients and
controls after a full explanation of the study. Clinical assessment of disease activity by SLE Disease activity index (SLDAI) [3]. Lupus nephritis was assessed clinically with the renal SLE disease activity index (rSLDAI). Indicated renal biopsies were taken from the patients with LN and were classified according to the International Society of Nephrology and the Renal Pathology Society (ISN/RPS) classification [4]. Serum and urinary levels of TWEAK were measured for the patients and controls using enzyme-linked immunosorbent assay (ELISA). Fn 14 was examined in renal biopsies from LN group by immunohistochemistry.

**Results:** A significantly higher uTWEAK level on comparing SLE patients with LN to those without LN and controls (F = 149.2, P < 0.001), uTWEAK had a highly significant positive correlation with proteinuria (r = 0.755, P < 0.001), a significant positive correlation with SLDAI and rSLDAI (r = 0.217, P < 0.037) (r = 0.478, P < 0.024) respectively. uTWEAK had a significant negative correlation with anti-dsDNA titre, C3 and C4 (r = -0.579, P < 0.008) (r = -0.456, P < 0.011) (r = -0.552, P < 0.002). Although sTWEAK level was higher in SLE patients than controls, it was not found to be associated with the presence of LN (F = 4.963, P = 0.012). Fn14 expression was detected in glomerular and tubular cells in LN patients.

**Expression of Fn14 in renal biopsies from LN patients was examined.** Immunohistochemistry for Fn14 was detected in (A) glomerular endothelial cells, (B, C) some specimens showed moderate and intense staining for Fn14 in renal tubular cells. In the controls (renal biopsies from patients with renal cell carcinoma (D)), there was very slight staining for Fn14 in renal tubular cells.

**Conclusion:** Urinary TWEAK is a specific and sensitive biomarker for detection of active LN in newly diagnosed untreated SLE patients.

**PATIENT-REPORTED OUTCOME MEASURES IN SWEDISH PATIENTS WITH RECENT-ONSET SLE VERSUS RA IN THE FIRST 60 MONTHS AFTER DIAGNOSIS**

M. Börklund1, I. Thyberg1, A. Kastbom1, R. Heijne1, L. Modonald2, E. Alemao3, C. Sjowall1. 1Linköping University, Linköping, Sweden; 2Bristol-Myers Squibb, Uxbridge, United Kingdom; 3Bristol-Myers Squibb, Princeton, United States of America

**Background:** Patient (pt)-reported outcome measures (PROMs) provide information on a pt’s own perception of disease impact, helping to provide a global perspective of disease when combined with conventional physician assessments. There is a discrepancy in PROMs between pts with rheumatoid arthritis (RA) and those with systemic lupus erythematosus (SLE); improvements in PROMs are often seen within the first year after diagnosis among pts with RA, but not SLE. Whether this discrepancy persists during subsequent years is unknown.

**Objectives:** To compare changes in PROMs among pts with SLE versus RA within the first 60 months after diagnosis.

**Methods:** Pts with SLE with no prior organ damage were consecutively enrolled (2010–2015) from the Clinical Lupus Register in Northeastern Gotland and met the ≥4 of the 1982 American College of Rheumatology (ACR) and/or the 2012 Systemic Lupus International Collaborating Clinics classification criteria. Pts with RA were included from the observational 2nd Management of Early Intervention in RA cohort (TIRA-2; 2006–2009), which enrolled pts with recent-onset RA; 84% of patients fulfilled the 1987 ACR criteria. Pts in both cohorts had symptoms for <12 months prior to diagnosis/inclusion and were treated according to Swedish guidelines. Pts with SLE or RA were followed prospectively after diagnosis. PROMs (quality of life: EuroQol-5 Dimensions [EQ-5D]; activity limitations: Health Assessment Questionnaire [HAQ]; pain, fatigue, and well-being: Visual Analogue Scale 0–100 mm) were collected at Months 0 (enrollment), 6, 12, 24, 36, 48, and 60. HAQ, pain, fatigue, well-being: higher scores indicate greater severity; EQ-5D: lower scores indicate greater severity.

**Results:** In 67 patients, ELISA revealed anti-viral antibodies IgG to CMV (86.5%) and VCA IgG of EBV (66.7%), somewhat less frequently than HSV-1 IgG (38.8%) and HSV-2 (26.8%). Active CMV and EBV infections were diagnosed in 26 (38.8%) and 19 (28.3%) patients, respectively; moreover, in 11 patients a combination of production of antibodies of the IgM CMV and EA IgG EBV class was revealed. Analysis of anamnestic data and serological examination allowed us to distinguish 3 groups of patients: group I – 35 patients with a viral infection, including 9 with the infection of a mixed viral and bacterial nature; Group II – 14 patients with bacterial infection and Group III – 18 patients without viral and bacterial complications. Analysis of clinical symptoms showed that there is a definite correlation of high titer of antibodies to CMV and EBV with symptoms such as fever (p<0.01, r=0.74), polyarthritis (p<0.02, r=0.46) lymphadenopathy (p<0.01, r=0.74), carditis (p<0.05, r=0.42), hepatomegaly (p<0.05, r=0.62), central nervous system damage (p<0.02, r=0.46), migratory erythematous/hemorrhagic rash (p<0.05, r=0.58), urinary syndrome (p<0.02, r=0.41), anti-dsDNA (p<0.01, r=0.82), ANA (p<0.02, r=0.74); cryoprecipitins (p<0.01, r=0.45). Although there were similar clinical manifestations, the presence of CMV and EBV had some organ specificity. Thus, damage to the central nervous system, joints (polyarthritis) and liver was more common in patients with CMV, and lymphadenopathy and erythematous/hemorrhagic rash – in patients with EBV.

**Conclusion:** In SLE a comorbid viral infection contributes to clinical picture with a lingering remitting inflammatory process, as well as insufficient effectiveness from corticosteroid and immunosuppressive therapy.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.1444

**SYSTEMIC LUPUS ERYTHEMATOSUS AND OPPORTUNISTIC INFECTIONS: PREVALENCE, FEATURES OF CLINICAL SYMPTOMS**

B. Belov1, O. Egorova1, D. Movsisyan2, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2Progov Russian National Research Medical University, Moscow, Russian Federation

**Background:** Modern therapy for systemic lupus erythematosus (SLE) is associated with long-term treatment with cytotoxic drugs which is often accompanied by activation of comorbid infection, including viral infection.

**Objectives:** To identify prevalence and specific characteristics of the clinical symptoms of co-infection in SLE.

**Methods:** 67 patients with SLE were examined, mainly middle-aged women (62) of 33.5 ± 8.1 years old with the disease duration of 1 to 7 years who received “basic therapy.” All patients were examined by ELISA for the presence of Herpesviridae viruses.

**Results:** In 67 patients, ELISA revealed anti-viral antibodies IgG to CMV (86.5%) and VCA IgG of EBV (66.7%), somewhat less frequently than HSV-1 IgG (38.8%) and HSV-2 (26.8%). Active CMV and EBV infections were diagnosed in 26 (38.8%) and 19 (28.3%) patients, respectively; moreover, in 11 patients a combination of production of antibodies of the IgM CMV and EA IgG EBV class was revealed. Analysis of anamnestic data and serological examination allowed us to distinguish 3 groups of patients: group I – 35 patients with a viral infection, including 9 with the infection of a mixed viral and bacterial nature; Group II – 14 patients with bacterial infection and Group III – 18 patients without viral and bacterial complications. Analysis of clinical symptoms showed that there is a definite correlation of high titer of antibodies to CMV and EBV with symptoms such as fever (p<0.01, r=0.74), polyarthritis (p<0.02, r=0.46) lymphadenopathy (p<0.01, r=0.74), carditis (p<0.05, r=0.42), hepatomegaly (p<0.05, r=0.62), central nervous system damage (p<0.02, r=0.46), migratory erythematous/hemorrhagic rash (p<0.05, r=0.58), urinary syndrome (p<0.02, r=0.41), anti-dsDNA (p<0.01, r=0.82), ANA (p<0.02, r=0.74); cryoprecipitins (p<0.01, r=0.45). **Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.1444
Results: 41 pts with SLE and 522 pts with RA were included in this analysis. Numerical differences between cohorts in age, sex, and tobacco smoking were seen (Table). Baseline PROM scores were generally worse for pts with RA versus SLE (Figs 1 and 2). However, an improvement in PROM scores was seen by Month 6 for pts with RA, but not SLE. Between Months 6 and 60, PROM scores remained largely unchanged for both groups.

Conclusion: PROMs in pts with early SLE tended to remain stable in the years following diagnosis compared with the improvement experienced by pts with early RA, indicating a greater unmet need in SLE. The lack of improvement in PROMs in pts with SLE may be due to the disease's impact across multiple organ systems, which may take longer to resolve versus RA symptoms. These results imply there is room for improvement in disease management – both pharmacological and multi-professional interventions. Data should be interpreted with caution due to a low number of pts with SLE.

DOI: 10.1136/annrheumdis-2020-eular.321
Objective: We aimed to investigate and compare gene expression in labial salivary glands from SS patients with xerostomia SS(+) and without xerostomia SS(-) and healthy subjects (HS) by microarray analysis and to find genes potentially involved in xerostomia.

Methods: The study group comprised 11 SS patients (3 SS(+) and 8 SS(-)) and 9 HS. Labial salivary gland samples were processed according to the protocol [2]. Database for Annotation, Visualization and Integrated Discovery (DAVID) and Search Tool for the Retrieval of Interacting Genes (STRING10) were used for the interactions between study groups [3].

Results: Among the genes belonging to “secretion” ontology group, expression of Amyloid Beta Precursor Protein (APP) and Cholinergic Receptor Muscarinic 3 (CHRM3) in both SS(+) and SS(-) groups were lower than in HS. The expression of Visinin Like 1 (VSNL1) in SS(+) and SS(-) was higher than in HS. The expression of Amyloid Beta Precursor Protein 1 (A1A1) and AmyloidBeta Precursor like Protein 2 (APLP2) were decreased in SS(+) and increased in SS(-) compared to HS group. There was no differences between the SS(+) and SS(-) in expression of mentioned genes.

Figure 1. STRING-generated interaction network among differentially expressed genes belonging to the “secretion” ontology group.

Conclusion: Decreased expression of APP, SAA1, APLP2 and CHRM3 in SS(+) sufferers compared to HS can reflect the loss of their neuroprotective function and the cholinerigic deficiency in xerostomia. STRING10 software indicates for a central role of APP and genes involved in β-amyloid peptide formation and neurodevelopment and for a close relationships between SS and neurodegenerative diseases [4,5].

Background: New 2019 EULAR/ACR classification criteria for Systemic Lupus Erythematosus (SLE) has been recently published. Before its widespread use in research, this criterion needs to be externally validated in other cohorts. Validation studies for the new criteria were not yet done in the Indian population. Moreover, the new 2019 EULAR/ACR classification criteria for SLE has not been validated in juvenile SLE.

Objectives: To compare the real-world performance of 2019 EULAR/ACR classification criteria when applied to a known cohort of SLE cases, comprising both adult and juvenile SLE, in South Indian population.

Methods: We retrospectively reviewed the electronic medical record of 30,541 patients who visited the Rheumatology department of Amrita Institute of Medical Sciences, Kochi, a tertiary care centre in Kerala, from January 2014 to June 2019. 347 patients diagnosed with SLE by qualified and experienced rheumatologists were included in the study. 44 patients were later excluded as they were found to have an overlap syndrome. From the 30,541 patients, another 303 age-matched healthy controls were selected as controls. They were selected regardless of their specific clinical or immunologic manifestations. Patients were excluded if the diagnosis was uncertain. Each patient was evaluated to see if he or she met the 1997, 2012, and 2019 classification criteria, respectively.

Results: Conclusion: In our cohort, the new 2019 EULAR/ACR criteria attained better sensitivity, PPV, NPV and accuracy when compared to ACR 1997 and SLICC 2012 criteria, and had almost the same specificity as compared to SLICC 2012 and ACR 1997 criteria.

AB0404 SARCOPENIA AND RELATED FACTORS AMONG PATIENTS WITH PRIMARY SJOGREN’S SYNDROME

S. Cola1, E. Tekgoz1, S. Hayme2, I. Sonaeren3, M. Çınar1, S. Yılmaz1.
1University of Health Sciences Gülhane Medicine Faculty, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 2Ankara University Faculty of Medicine, Department of Biostatistics, Ankara, Turkey; 3 Gülhane Training and Research Hospital, Department of Nutrition and Dietetics, Ankara, Turkey

Background: Sarcopenia is the progressive and generalized loss of muscle mass, strength and function especially among elderly population. Inflammation may lead to sarcopenia regardless of age.

Objectives: To evaluate the frequency of sarcopenia and related factors in patients with primary Sjögren’s syndrome (SS).

Methods: A total of 44 female patients with SS and 44 age matched female healthy controls were included in this cross-sectional study. Sarcopenia was evaluated by hand grip test, skeletal muscle index (SMI) and 6 meters gait speed (GS) test. According to recommendations of European Working Group on Sarcopenia in Older People (EWGSOP2) 2018, sarcopenia is defined as decrease in results of both hand grip test and SMI, whereas, probable sarcopenia is defined as only decrease in results of hand grip test. Mini Nutritional Assessment Short Form (MNA-SF) was used for evaluating nutritional status. EULAR SS patient reported index (ESSPRI) and EULAR SS disease activity index (ESSDAI) used for evaluating disease activity. Patient global assessment (PGA) was assessed with visual analogue scale (VAS 0-10 cm). Patients with arthritis in dominant hand and/or ankle joints were excluded from the study.

Results: The mean age of participants was 55.3±10.4 years. Eleven patients (25.0%) had probable sarcopenia in SS group and 2 (4.5%) in control group (p=0.007). Compared with healthy controls, SS patients had lower results of hand grip and 6 meters GS tests (p=0.005 and p=0.001, respectively). According to Mini Nutritional Assessment Short Form (MNA-SF), patients with probable sarcopenia had higher risk for malnutrition compared with patients with no sarcopenia (p=0.043). Patients with probable sarcopenia had higher scores of ESSPRI pain domain and patient visual analogue scale for global disease activity compared with patients with no sarcopenia (p=0.044 and p=0.036, respectively) (Table 1). In multivariate regression analysis ESSPRI pain was associated with hand grip strength (p=0.016, R²=0.13) and MNA was associated with SMI (p=0.005) (Table 2).

ESSPRI: EULAR Sjogren’s Syndrome Patient Reported Index, SMI: Skeletal Muscle Index, MNA: Mini Nutritional Assessment

Conclusion: Risk of sarcopenia is increased in patients with SS. In the current study, it is shown that pain is related with sarcopenia. ESSPRI pain is a sign of continuing chronic inflammation in patients with SS. Malnutrition, which can indirectly related with SS, may also contribute to this process. Excessive pain may lead to decrease daily activities and nutritional status of patients with SS. Evaluating pain and patient’s global disease activity may help physicians to find out patients with increased risk for sarcopenia. Controlling disease activity and pain and preventing malnutrition may reduce the risk for development of sarcopenia.

HUMAN PAPILLOMA VIRUS (HPV) INFECTION AND CERVICAL CANCER PREVALENCE IN A PORTUGUESE UNIVERSITY HOSPITAL SINGLE-CENTER SYSTEMIC LUPUS ERYTHEMATOSUS COHORT

I. Sousa Morais1, D. G. Oliveira2, R. Faria3, A. Almeida3, M. Brandão3, A. Marinho1, A. Almeida1, F. Farinha1, C. Vasconcelos4, 5Servicio de Medicina, Braga, Portugal; 2Servicio de Medicina, Porto, Portugal; 5Unidade de Imunologia Clínica, Porto, Portugal; 4Abel Salazar Biomedical Sciences Institute - University of Porto, UMIB, Porto, Portugal

Background: About 12% of women worldwide are infected with Human Papillomavirus (HPV), the most frequent cause of cervical cancer (CC) - very prevalent (~75%) and preventable. National screening efforts are in use in several countries, including Portugal. Patients with Systemic Lupus Erythematosus (SLE) are at increased risk of HPV infection and CC when compared to the healthy population.

Objectives: To evaluate the prevalence of HPV infection and rate of incidence of cervical neoplastic lesions in a SLE patient cohort followed at a university hospital.

Methods: Retrospective single-center (35 year long, 463 SLE patient cohort) review of all female SLE patients' local and online national health care records on HPV vaccination and CC screening.

Results: Of the 463 SLE patients, 420 were women (91%), of which 322 had records on of HPV infection or CC developed. Mean patients’ current age was 48 years and all had screening for cervical pathology in the last 3 years. Thirty-three patients (11%) had HPV infection diagnosed at a mean age of 44 years. Twenty-seven (8%) of SLE patients were vaccinated for HPV: 8 (22%) of the infected patients had the vaccine, half after the HPV infection. Despite HPV infection, 45 patients (15%) had developed some cervical lesion, of which 41 (84%) of cervical lesion were suggestive of malignancy, and ultimately CC was diagnosed in 20 women (41%; 6% of total women), with a mean age at diagnosis of 45 years. All CC patients had history of HPV infection, but only 3 women (15%; 0.9% of total women) had been vaccinated against HPV, 2 after the diagnosis of CC and 1 before.

Conclusion: In our population the prevalence of HPV was higher than reported for the general population using the World Health Organization database, confirming the higher risk of HPV infection in SLE patients. The prevalence of cervical cancer, however, was similar to the healthy population.

AB0408

DOES THE PRESENCE IN THE SERUM OF ANTIPHOSPHOLIPID ANTIBODIES CORRELATE WITH SPECIFIC/NON SPECIFIC CAPILLAROSCOPIC ABNORMALITIES?

G. Ferrari1, S. Paolino1, A. Sulli1, C. Pizzorno1, G. Pacini1, E. Gotelli1, A. Lercara1, V. Smith2, M. Cuto10, 1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic, Genova, Italy; 2Department of Internal Medicine, Ghent University; Department of Rheumatology, Ghent University Hospital; Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center, Ghent, Belgium

Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterized by specific vascular and obstetric manifestations and by anticardiolipin antibodies (aPL) positivity [1]. To date, little is known regarding nailfold videocapillaroscopy (NVC) alterations in APS patients and in asymptomatic aPL-carriers, non-specific abnormalities being the most frequently reported [2,3,4].

Objectives: To retrospectively analyze NVC alterations in APS patients and in asymptomatic aPL-carriers and to correlate NVC alterations with both clinical manifestations and serum aPL profile.

Methods: Thirty-five aPL positive patients having received at least one NCV investigation (mean age 47 years, range 16-81, 31 female and 4 male) were retrospectively included in the study. For each patient complete medical history was collected with a particular attention to past vascular thrombosis and pregnancy morbidity. Patients were classified as affected by APS according to the updated Sapporo classification criteria [5]. Lupus anticoagulant (LAC), IgM and IgG anti-cardiolipin antibodies (ACL) and IgM and IgG anti-beta2 Glycoprotein 1 (anti-B2GPI) were assessed in each patient according to the recommended procedures [5]. NCV parameters were analyzed in each patient, with a particular interest to hemorrhages or nailfold bed-parallel hemosiderin deposits (“comb-like” hemorrhages) presence [6]. Statistical analysis was performed by parametric and non-parametric tests. Results: Seventeen patients (mean age 49 years, range 16-81 years) were asymptomatic aPL-carriers and 18 (mean age 46 years, range 26-71 years) were affected by APS. Within APS patients, 16 had a history of vascular thrombosis and 2 had pregnancy morbidity; in 6 patients APS was secondary to other autoimmune rheumatologic conditions (3 to Systemic Lupus Erythematosus, 2 to vasculitides and 1 to Mixed Connective Tissue Disease). Among the total number of aPL-carriers and APS patients six patients showed a normal NVC pattern, 24 patients had non-specific NVC abnormalities and 5 patients had a “scleroderma-like” pattern. Interestingly, NCV microhemorrhages were significantly more frequent in APS patients than in asymptomatic aPL-carriers, both in score and in absolute (p=0.05 and p=0.04, respectively). Particularly, in APS patients “comb-like” hemorrhages had a statistically significant higher prevalence than isolated hemorrhages (p=0.03). Dilated capillaries score was significantly higher in APS patients than in asymptomatic aPL-carriers (p=0.01). Not any statistically significant difference was observed regarding other capillary parameters (score of giant capillaries, loss of capillaries, or anormal shapecs, i.e. angiongenesis). Not any statistical correlation was observed between APS parameters and different aPL profile.

Conclusion: The study shows that the total number of microhemorrhages and in particular the “comb-like” subtype, are significantly the most frequent specific abnormalities in APS patients when compared to asymptomatic aPL-carriers. The presence of the “scleroderma-like” NVC pattern may suggest a concomitant overlap syndrome. Not any correlation was found between aPL profile and other NVC parameters. Further studies need to develop a more specific APS NVC pattern for APS patients.

DOI: 10.1136/annrheumdis-2020-eular.4818
Background: Current guidelines help defining correct pregnancy standard of care for patients with antiphospholipid syndrome (APS) and antiphospholipid antibodies (aPL) carriers, but little is known about the significance of aPL detection during pregnancy and their association with clinical manifestations of the syndrome [1].

Objectives: Investigate the presence of aPL antibodies in a cohort of women who experienced late onset pregnancy complications (LO-PC) and low-risk for chromosomal abnormalities.

Methods: We retrospectively collected clinical, demographic and laboratory data of women ever pregnant from August 2017 to August 2018, who attended the S. Anna University Clinic (Turin, Italy). Inclusion criteria were LO-PC, negative triple test and absence of US foetal abnormalities. 100 patients have been recruited and, as control, 100 women matched for age with normal pregnancy. aPL testing was performed on serum samples derived from pregnancy screening test collected between 15 and 18w of gestation. Criteria and “extra criteria” aPL were tested.

Results: Number of aPL positivity (aPL+) was statistically different between patients and controls: 31 aPL+ vs 10 aPL+, respectively (p-value <0.001; p<0.01) (Graph 1).

Patients’ population had a significant higher percentage of single aPL+ (p-value < 0.001; p < .05) and, among single isotypes, of ACA IgG (p-value 0.017; p < 0.05) and aPS/PT IgM (p-value 0.0378; p <0.05). Moreover, patients’ population had a significant higher aPL titre of ACA IgG and aPS/PT IgM (p-value <0.0001, p < 0.05; p-value 0.0061, p < 0.05).

When comparing aPL+ and aPL negative (aPL-) patients for median age at conception, mode of delivery, foetal outcomes, maternal and foetal pregnancy complication, maternal and foetal post-partum complication and histology findings (see Table 1), we found that aPL+ patient had a significant higher presence of IUUGR (<0.01) and pre-term birth (34-36w; p<0.01). When we granulated data for presence/absence of an underlying disease (UD), we found that 29 women had an UD, mostly arterial hypertension and hypothyroidism (59%, not shown), while 71 were healthy (H).

When comparing aPL+/aPL- in UD patients’ subgroup, we found no difference; instead, when comparing aPL+/aPL- in H patients’ subgroup we found that aPL+ had a significant higher percentage of pre-term birth (34-36w; p<0.001). aPS/PT IgM isotype alone, allowed the detection 17 patients who tested negative for aPL criteria (Graph 1).

Conclusion: Our results, even if preliminary, suggest a direct correlation between aPL positivity and risk of development of LO-PM. In conclusion, testing for both criteria and “extra criteria” aPL in women with previous LO-PM could improve the diagnostic accuracy identifying women at higher risk in case of future pregnancy.

Conclusion: Cognitive impairment was common in both diseases but the cognitive domains affected were different. Rheumatologists should be aware of these differences when evaluating cognitive dysfunction in SLE and pSS patients.

COGNITIVE IMPAIRMENT IN PRIMARY SJÖGREN’S SYNDROME: A CASE-CONTROL STUDY
M. J. Garza Martínez1, M. A. Treviño-Castro1, A. Cárdenas1, C. V. Solis1, R. Pineda1, J. C. Riegotare1, C. M. Skinner Taylor1, D. A. Galarza-Delgado1.
1University Hospital “Dr. José Eleuterio González”; Rheumatology; Monterrey, Mexico

Background: Neurological symptoms are common in primary Sjögren’s syndrome (pSS) with a prevalence of 8.5 to 70%, focusing on cognitive impairment, information in pSS is scarce.

Many neuropsychological tests are used to diagnose cognitive impairment. The Montreal Cognitive Assessment (MoCA) is a validated, practical, and reliable instrument for screening mild cognitive impairment.

Objectives: To evaluate the prevalence of cognitive impairment with the MoCA test in pSS and compare it with controls.

Methods: Patients of a rheumatology clinic in Northeastern Mexico were recruited, who met the pSS AECG 2002 or ACR-EULAR 2016 classification criteria. Controls, matched by demographic characteristics were included for comparison. All subjects took the MoCA. The test has a range of 0-30 points, the highest score reflects better cognitive function, and explores 6 cognitive domains (Table 2).

We defined mild cognitive impairment as a score <26 and moderate-severe cognitive impairment as a score <24 as previously determined in Mexican population.

Result: Demographic and clinical characteristics are described in Table 1. Mild cognitive impairment was present in 13 (25.4%) in pSS group versus 14 (27%) in control group. Moderate-severe cognitive impairment was present in 9 (17%) of pSS group versus 8 (15%) in control (p< 0.05).

Results of the individual domains and comparison between groups are shown in Table 2. Attention was lower in the pSS group with ≥9 years of education compared to the control group (p< 0.05).

Conclusion: We did not found a difference in the prevalence of cognitive impairment, either mild or moderate-severe, in pSS subjects with low disease duration versus controls by MoCA. We found a lower attention score in the pSS group with less than 10 of years of education.

The combination of neuropsychological examining and imaging techniques, such as SPECT or brain MRI, seem a more sensitive way to detect cognitive impairment in earlier stages.

URINARY SOLUBLE VCAM-1 IS A USEFUL BIOMARKER OF DISEASE ACTIVITY AND TREATMENT RESPONSE IN LUPUS NEPHRITIS
A. A. Gaspari1, N. Pampiona Bueno de Andrade1, V. Hax1, P. Palominos1, M. Siebert2, R. Marx1, P. Shafer1, F. Veríssimo Veronesa1, O. Monticielo1.
1Federal University of Rio Grande do Sul, Division of Rheumatology, Department of Internal Medicine, Porto Alegre, Brazil; 2Hospital de Clínicas de Porto Alegre, Biotechnology Centre, Porto Alegre, Brazil; 3Hospital de Clínicas de Porto Alegre, Department of Pathology, Porto Alegre, Brazil; 4Federal University of Rio Grande do Sul, Division of Nephrology, Department of Internal Medicine, Porto Alegre, Brazil

Background: The traditional lupus nephritis (LN) biomarkers are not sensitive nor specific enough for detecting ongoing disease activity and early relapse of nephritis and they do not reflect kidney damage nor have prognostic value1. Urinary biomarkers are directly excreted by the kidney and are easily obtained. They can also differentiate the renal activity of the disease from other organic manifestations more accurately than the serum biomarkers2. Vascular cell adhesion molecule-1 (VCAM-1) is involved in the progression of glomerular and tubulointerstitial injury in LN and its soluble form can be easily assessed in urine (uVCAM-1)3. Several studies correlated the uVCAM-1 levels with urine protein-creatinine ratio (UPC), with general disease activity and with active LN3.

Objectives: To assess uVCAM-1 as a biomarker of disease activity and treatment response in LN.

Methods: This prospective study enrolled patients with class III, IV or V LN diagnosed within the last three years and divided them in two groups: with and without active nephritis at the inclusion. The patients with active nephritids were included before they started a new immunosuppressive treatment. Active LN was defined as proteinuria (UPC≥0.5) plus active urinary sediment (hematuria, leukocyturia or cellular hematuric/granular casts). At each visit, a urine sample was collected for uVCAM-1 evaluation and the nephritis status was accessed.

Results: Median uVCAM-1 level was elevated in patients with active compared to inactive LN (p<0.001). The ROC curve of uVCAM-1 demonstrated an AUC of 0.84 and a cutoff of 47.2 ng/mgCr yielded a good sensitivity (74.2%) and specificity (74.2%) for the diagnosis of active LN. A significant correlation was found between uVCAM-1 level and renal activity scores and traditional biomarkers of LN (table 1). The level of uVCAM-1 dropped in patients with active LN who went into remission (p<0.001), increased in patients who went into activity (p=0.002) and did not change in patients who remained inactive (p=0.797) (figure 1). The level of uVCAM-1 peaked during the flare of LN (p<0.05) (figure 2).

AB0413 INVESTIGATION OF THE ASSOCIATION OF CARDIOVASCULAR EVENTS AND ANTI-SS-A ANTIBODIES AS RISK OF DEVELOPMENT IN PATIENTS WITH LUPUS NEPHRITIS FROM THE LUNA REGISTRY: A CROSS-SECTIONAL STUDY

T. Isgawa1, K. Ichinose2, M. Okamoto3, A. Takatani1, N. Yajima1, K. E. Sada4, R. Yoshimi2, Y. Shimojima5, S. Ono6, H. Kajiyama1, S. Sato7, M. Fujisawa8, A. Kawakami1, Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Unit of Advanced Preventive Medical Sciences, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; 2Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; 3Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama, Japan; 4Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 5Department of Medicine (Neurology and Rheumatology), Shinshu University School of Medicine, Matsumoto, Japan; 6Center for Rheumatic Diseases, Yokohama City University Medical Center, Yokohama, Japan; 7Department of Rheumatology and Applied Immunology Faculty of Medicine, Saitama Medical University, Saitama, Japan; 8Fukushima Medical University School of Medicine, Department of Rheumatology, Fukushima, Japan; 9Department of Rheumatology, Yokohama Rosai Hospital, Yokohama, Japan

Background: Cardiovascular disease (CVD) has been identified as a major cause of morbidity and mortality in patients with lupus nephritis (LN)1-3. There is a clear causal relationship between the onset of neonatal lupus (cardiac complications) and SS-A antibodies4-6, but no association has been reported in adults. In recent years, there have been reports from overseas that suggest the association between CVD and anti-SS-A antibody in adult systemic lupus erythematosus (SLE) patients1-2. So far, no studies have not been reported to evaluate the relationship between anti-SS-A antibody and the risk of developing CVD in LN in a large cohort of patients with SLE in Japan.

Objectives: The aim of this study was to evaluate the association between anti-SS-A antibody and the risk of developing CVD in LN patients using a multicenter registration study [Lupus registry of nationwide institution (LUNA)] in Japan.

Methods: We identified 931 patients diagnosed with SLE in the Lupus registry of nationwide institution (LUNA), and further identified 275 LN patients with known the presence or absence of both development of CVD and presence of anti-SS-A antibody. We defined the exposure factor as anti-SS-A antibody, and the outcome as CVD. SELENA-SLEDAI score (at diagnosis), eGFR <60%, HbA1c, BMI, and steroid pulse treatment history were used as confounding factors and we analyzed using logistic regression analysis.

Results: We found 68 patients (24.7%) complicated with CVD, including pericarditis (7.3%), cerebrovascular disorder (6.2%), peripheral Arterial Disease (6.2%), ischemic heart disease (2.9%), venous thromboembolism (2.9%), pulmonary hypertension (1.5%), vulvar heart disease (1.1%), and cardiomyopathy (0.4%). In univariate analysis, there was no significant difference in the occurrence of CVD depending on the presence or absence of anti-SS-A antibody (p = 0.32), and the results of multivariate analysis showed no significant difference in anti-SS-A antibody [p = 0.23, odds: 0.41, 95% confidence interval (0.09-1.89)].

Conclusion: The association between anti-SS-A antibody and the development of CVD in LN patients in Japan has not been identified.

AB0414 ESSPRI COMPONENTS AND SALIVARY FLOW RATE ARE RELATED TO DAILY ACTIVITY IMPAIRMENT IN PATIENTS WITH PRIMARY SJDÖGEN’S SYMOME

G. Mumcu1, K. Abacar2, I. Tatlı3, Y. Yenisoy4, A. Kapusuz5, E. N. Cakir4, F. Türe-Özdüzmi2, H. Direskeneli5, N. İnanç4. 1Marmara University Faculty of Health Sciences, Department of Health Management, Istanbul, Turkey; 2Marmara University Medical School, Department of Rheumatology, Istanbul, Turkey; 3Marmara University Medical School, Department of Health Sciences, Department of Health Management, Istanbul, Turkey; 4Marmara University Medical School, Department of Health Management, Istanbul, Turkey; 5Marmara University Medical School, Department of Health Management, Istanbul, Turkey.

Background: Sjögren’s syndrome (SS) is an autoimmune rheumatic disease affecting exocrine glands. It is characterized by dry eyes and dry mouth. In this study, we aimed to evaluate the relationship between the salivary flow rate (SFR) and the ESSPRI (Essential Symptom Profile-Sjögren’s Syndrome) components in patients with primary Sjögren’s syndrome.

Methods: The participants were patients with primary SS (n = 90). The patients completed the ESSPRI and the SFR was measured using the 30-second whole saliva method. The Spearman’s rank correlation and linear regression analysis were used to determine the relationship between the SFR and the ESSPRI components.

Results: The participants had a mean age of 49.1 ± 14.0 years and 81.1% were women. The mean ESSPRI score was 3.9 ± 4.5. The SFR was significantly correlated with the ESSPRI components and salivary flow rate (p < 0.05). In the multiple regression analysis, the ESSPRI components and salivary flow rate were positively associated with daily activity impairment (p < 0.05).

Conclusion: The salivary flow rate is related to daily activity impairment in patients with primary Sjögren’s syndrome.

Acknowledgments: This study was supported by the Turkish Ministry of Health and the Scientific and Technological Research Council of Turkey (TUBITAK).

DOI: 10.1136/annrheumdis-2020-eular.4047
Background: Sjögren's syndrome (SjS) is a chronic systemic autoimmune disease targets primarily the lacrimal and salivary glands, the severe dryness of the mouth and eyes are common manifestations in patients. Therefore, daily life could be affected by these manifestations in patients with SjS.

Objectives: The aim of the study was to assess associations among daily activity impairment and scores of EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) and major salivary gland ultrasonography (SGUS) in primary SjS.

Methods: In this cross-sectional study, 41 patients with primary SjS (F/M=39/2; mean age: 52.1±10.5) were included. The mean disease duration was 9.5±6.6 years in the group.

Data were collected by clinical examinations and a questionnaire regarding two patients reported outcome measures (PROMs). Firstly, Work Productivity and Activity Impairment (WPAI) questionnaire assessed paid and unpaid work during the last seven days. Scores of WPAI subgroups as absenteeism, presenteeism, overall work impairment as well as daily activity impairment were calculated by using 6 items. Secondly, dryness, fatigue and pain in ESSPRI scale were evaluated by visual analogue scale (VAS: 0-10 points) in SjS. High scores in both PROMs indicate that disease manifestations affect patient's life poorly.

In addition, structural damage of parotid and submandibular salivary glands were examined by using Milic and Hocevar USG scoring methods. Unstimulated whole salivary flow rate (U-WSFR; as ml/min) were also used to interpret the functional status of major salivary glands. High SGUS score and low U-WSFR reflects that disease activity affects major glands poorly.

Results: Daily activity impairment was calculated as 63.9±31.1 in patients with primary SjS. High scores in ESSPRI-dryness, ESSPRI-fatigue and ESSPRI-pain were also observed in the group (75.2±4; 6.4±2.8 and 6.1±3.1, respectively). Daily activity impairment was correlated with scores of ESSPRI-dryness (r=0.55 p=0.000), ESSPRI-fatigue (r=0.38 p=0.014) and ESSPRI-pain (r=0.56 p=0.000) as well as parenchymal inhomogeneity USG scores of right and left parotid glands (r=0.49 p=0.032; r=0.51 p=0.025).

U-WSFR (0.20a±0.20 ml/min) was moderately correlated with parenchymal inhomogeneity USG scores of major salivary glands (p<0.05). ESSPRI-dryness score was significantly higher in patients with low U-WSFRs (p=0.1 ml/min) than the others (87.5±16.3 vs 68.3±25.1, respectively)(p=0.021).

Conclusion: Firstly, subgroup scores of ESSPRI and low U-WSFR associated to daily activity impairment in patients with primary SjS. Secondly, parenchymal inhomogeneity scores of both parotid glands could give an important clue to clinicians for the disease-related damage. Finally, WPAI with 6-item could be thought as an useful tool to understand the effect of the disease manifestations on patients’ daily life.

AB0415 SERUM RESISTIN LEVEL IN SYSTEMIC LUPUS ERYTHEMATOSUS: RELATION TO LUPUS NEPHRITIS AND DISEASE ACTIVITY

F. Ismaiel1, S. Salah2, M. Abdelhamed3, M. Aboul Ela4. 1Professor of Rheumatology Minia University, Rheumatology and Rehabilitation, Minia, Egypt; 2Lecturer of Rheumatology, Rheumatology and Rehabilitation, Minia, Egypt; 3Assistant lecturer of Rheumatology, Rheumatology and Rehabilitation, Minia, Egypt; 4Minia University Hospital, Internal Medicine, Minia, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease affecting different organs and systems. Adipokines have recently been implicated as mediators of immune and inflammatory processes. Human resistin is a cytokine that induces low-grade inflammation by stimulating monocytes

Objectives: The aim of this work is to assess the serum level of resistin in SLE patients and to detect its relation to lupus nephritis, and disease activity

Methods: 40 patients with SLE with age ranged between 18-48 years and 20 healthy age, sex and BMI matched volunteer were enrolled in this study. According to the presence or absence of lupus nephritis (LN), patients were classified into two subgroups Full history, clinical examination and laboratory investigations were performed for all patients including serum resistin level

Results: The level of serum resistin was higher in SLE patients than the controls (p=0.001). Also, serum resistin levels were higher in patients with lupus nephritis than without nephritis (p=0.02). Serum resistin level correlated positively with the levels of ESR (p=0.001), CRP (p=0.005), Anti-dsDNA (p=0.002) and serum urea (p=0.002). Serum resistin levels correlated negatively with hemoglobin levels (p=0.001) and levels of Cr (p=0.001) and C4 (p=0.001). There was a significant positive correlation between serum resistin level and the presence of albumin (p=0.001), RBCs (p=0.003), pus cells (p=0.001) and casts (p=0.001) in urine and also with the levels of 24 hour urinary protein and protein/creatinine ratio (p<0.001).

Serum resistin level was found to be strongly correlated with SLEDAI (p<0.001). No correlation was found between serum resistin levels and ISN/RPS classification of renal biopsy.

Conclusion: Serum resistin level can be used as a marker of inflammation, proteinuria, disease activity in patients with SLE.

AB0416 ANTIPHOSPHOLIPID SYNDROME IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUS

M. Jordhan1, D. Ruc1. 1Mother Teresa Hospital, Internal Medicine, Tirana, Albania

Background: Antiphospholipid Syndrome (APS) is an autoimmune disorder characterized by venous/arterial thrombotic events and pregnancy morbidity in presence of pathogenetic autoantibodies known as antiphospholipid antibodies (APL). APS is often associated with systemic autoimmune diseases, especially with Systemic Lupus Erythematosus (SLE), being part of the latest criteria of SLE.

Objectives: The aim of this study was to evaluate the impact of Antiphospholipid syndrome in patients with Systemic Lupus Erythematosus presented at our Rheumatology Clinic at University Hospital Center Mother Teresa in Tirana, Albania.

Methods: This is an observational case-control study which included patients diagnosed with SLE from 16-51 years old, presented at our clinic during the period from 10 December 2014-10 September 2019.

Seventy-three patients with SLE were included in the study. Patients were classified according to the presence of Antiphospholipid Syndrome or not, according to the current guidelines. The case study (patients with SLE and APS) consisted in 24 patients, and the control group consisted in 49 patients. Besides the usual laboratory tests (complete blood count, erythrocytesedimentation rate, C3, C4 complement fragments, urinalysis and 24h proteinuria, c-reactive protein), all patients underwent immunological tests for anti-nuclear antibodies, anti-DNA antibodies and antiphospholipid antibodies (Anti-cardiolipin IgM and IgG). If APL were found positive, according to EULAR recommendations, tests were repeated after 12 weeks. Female patients were asked about their pregnancy history and their possible miscarriages/aborts.

Results: After our statistical analysis it resulted that there is a significant difference between C3 complement fraction (patients with APS and SLE tend to have more hypocomplementemia than the other group) (p=0.006). Thrombocytopenia resulted to be an important feature, statistically significant in the case group (p=0.003). It was seen a statistically significant difference referring to the number of miscarriages/aborts in the history of female patients with APS and SLE in comparison to those with SLE without APS (p=0.03). Proteinuria has a tendency to be more marked in patients with APS and SLE, with a significant difference in comparison to the controls (p=0.04).

Conclusion: In this study was seen that patients with antiphospholipid Syndrome and Systemic Lupus Erythematosus tend to have more hypocomplementemia C3, and thrombocytopenia. It resulted a statistically significant relationship with miscarriages or aborts in patients with APS and SLE in comparison to SLE patients. It was seen a significant tendency to have marked proteinuria in patients with SLE and APS compared to controls.

AB0417 WORK IMPAIRMENT AND PREDICTORS OF WORK INCAPACITY AMONG PRIMARY SJÖGREN’S SYNDROME PATIENTS

D. Khalila1, A. Guiga2, W. Ben Yahia2, A. Atig2, N. Ghannouchi2. 1Farhat Hached Hospital, Rheumatology Department, Susah, Tunisia; 2Farhat Hached Hospital, Internal Medicine Department, Susah, Tunisia

Background: Primary Sjögren’s syndrome (PSS) is a prevalent rheumatic disorder affecting exocrine glands but also other systems. It alters quality of life of affected patients and increases work incapacity and general activity impairment.

Objectives: The purpose of this study was to assess the influence of PSS on work among affected patients and determine predictors of work incapacity.

Methods: A cross-sectional study was conducted in the internal medicine department. Adult patients diagnosed with PSS and fulfilling the EULAR criteria for the diagnosis were included. Clinical and biological data was collected from medical files and during medical visits. Disease activity was calculated using
the ESSDAI score. Work incapacity was assessed by the Work productivity and activity impairment for general health questionnaire (WPAI-GH) from which four dimensions can be calculated and expressed in percentages by the following scores: 1) percent work time missed due to health = Q5/Q10 for those who were currently employed; 2) percent impairment while working due to health = Q5/10 for those who were currently employed and actually worked in the past seven days; 3) percent overall work impairment due to health Q2(Q2 + Q4) + (1 - Q2(Q2 + Q4)) x (Q5/10)) for those who were currently employed; 4) percent activity impairment due to health Q6/10 for all respondents.

**Methods:** Eighty patients were randomly asked to fill out the questionnaire. Response rate was of 62.5%. Total number of enrolled patients was 50. The mean age was 56.5 years (min=22; max=60). Patients were mainly women with female to male ratio of 11:5. The median age of diagnosis was 50.5 years (min=18; max=59). Mean duration of the disease was 6 years a ± 3.76. Sicca syndrome was the most prevalent clinical feature affecting the eyes in 84% of the cases and the mouth in 90% of the cases. Arthralgia was present in 88% of the cases. 65.1% of patients had an active disease. Anti Ro antibodies were positive in 38%, anti La in 28% and rheumatoid factor in 50% of cases. 36% of the patients were unemployed. Percentage of work time missed due to health for those who were employed in the past 7 days was 2.44% (Q1=0;Q2=5.26). Mean percentage of impairment while working due to health for those who were employed and actually worked in the past 7 days was 20.56a±18.25%. Percentage of overall work impairment due to health for those who were currently employed and actually worked was 25.87±19.58%, and the percentage of overall activity impairment due to health for all respondents was 26.6±18.36%. Analytic statistics showed no correlation between employment status and age, duration of disease, gender or seropositivity. However, all unemployed patients had ocular symptoms vs 75% of those employed (p value=0.04). The first dimension was correlated with the presence of dry mouth (p value=0.07) but with weak statistical significance. Second and third dimensions were not associated to any general, clinical or laboratory feature. Fourth dimension was significantly correlated to the presence of dry eyes (p value=0.019) and gender (p value=0.001).

**Conclusion:** PSS is associated with high unemployment rates in Tunisia, high impairment rates while working and high rates of overall impairment. This high prevalence may be explained by gender and the presence of dry eyes and dry mouths. This work highlights the importance of managing sicca symptoms as they alter different aspects of quality of life like work.

J. Khvostov1, S. Palasheva1, V. Vasilev2, A. Torgashina1, E. Sokol1, B. Zhelfaev1, J. Khvostov2, J. Khvostov3, E. Sokol2, B. Zhelfaev2, J. Khvostov3.

**Background:** Over the past few years new international criteria have been proposed for the classification of primary Sjögren’s syndrome (pSS) from the American College of Rheumatology (ACR) in 2012 and the ACR with European League Against Rheumatism (ACR/EULAR) in 2016 [1, 2]. In real practice in Russia we use Russian criteria (2001).

**Objectives:** To estimate ACR (2012) and ACR/EULAR (2016) criteria in Russian cohort of patients with pSS patients fulfilling Russian criteria (2001).

**Methods:** From 2016 to 2019 we examined 110 patients (109 female, 1 male) with newly diagnosed pSS fulfilling Russian criteria with the mean age 50.2±14 years (min=18; max=82). Russian criteria for pSS: I) keratoconjunctivitis sicca (stimulated Schirmer’s test <10/5 min or less; ESSDAI ≥3 foci/4 mm²); II) xerostomia (sialocasia on parotid sialography (obligatory): +stimulated saliva flow test<2.5 ml/ 5 min +/ labial salivary gland biopsy with focus score (FS) of ≥2 lco3/4mm²); III) positive antinuclear antibody (ANA) or positive ANA with rheumatoid factor (RF) or anti-SSA (anti-Ro) or/and SSB (anti-La). According it pSS is verified if the first two criteria and at least one of the immunological criteria are presented. We evaluated clinical, laboratory and instrumental features (table 1).

In our cohort according to Russian criteria (2001) 94 patients (86%) fulfilled ACR (2012) criteria, 86 (78%) - ACR/EULAR (2016) criteria.

**Results:** In our cohort, 20-30% of patients, according to Russian criteria did not complain of oral or ocular dryness. In 61% of patients, mild eye damage was detected (OSS≤3-5), and in half of the cases, the stimulated Schirmer’s test was more than 5.0 mm, but less than 10 mm/5 min, where 69% of patients complained of dry eyes. Most patients (84.5%) had positive anti-Ro, just over half (51.8%) had anti-La. All patients had sialocasia of various stages on parotid sialography. Less than 1 FS was detected in 10% of patients.

**Conclusion:** Using Russian criteria (2001), we can identify pSS at an early stage. Our criteria inclusion complex examination in which an immunological sign must be present to confirm the diagnosis. Patients with pSS according to ACR (2012) and/or ACR/EULAR (2016) criteria seem to be diagnosed without specific antibodies and on the more progressive disease stages.

**THE COEXISTENCE OF FAMILIAL MEDITERRANEAN FEVER (FMF) IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS - A CROSS SECTIONAL STUDY**

T. Klein1, S. Tiosoan2, A. Cohen2, H. Amital2,3, Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv-Yafo, Israel; 2 Sheba Medical Center, Medicine ’B’; Tel-Hashomer, Ramat Gan, Israel; 3 Clalit Health Services, Quality Measurements and Research, Chief Physician’s Office, Tel Aviv-Yafo, Israel; 4 Ben Gurion University of the Negev, aial Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Be’er Sheva, Israel

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease characterized by multisystem inflammatory lesions affecting many organ systems in the body. Familial Mediterranean fever (FMF) is an autosomal recessive disease of chronic autoimmune inflammation characterized by frequently relapsing self-limiting fever and inflammation that may be localized in peritoneum, pleura, joint or skin.1 Previous studies have described the similarity of clinical symptoms of FMF among SLE patients. However, the literature on this topic is inconsistent and based mostly on case reports.2-4

**Objectives:** To examine the proportions of coexistence of FMF among SLE patients compared to the general population. We hypothesized that the proportion of FMF among SLE patients is higher than the general population.

**Methods:** This cross-sectional study used the Clalit Health Services database, the largest Health Maintenance Organization in Israel, serving 4,400,000 members. SLE patients were compared to age- and sex-matched controls. Chi- was used for univariate analysis.
Results: The study included 4986 SLE patients and 24430 age- and sex-matched controls. The SLE group had a significantly higher proportion of FMF patients compared to non-SLE controls (0.68% and 0.21% respectively; p < 0.001).

Conclusion: FMF was found to be more common amongst SLE patients compared to matched controls. The current study results suggest that the occurrence of SLE turn patients with an appropriate genetic and environmental setting to develop also FMF. This cross-sectional study sheds light on the coexistence of these two diseases, autoimmune and autoinflammatory.

AB0420 RISK OF DEVELOPING TYPE 2 DIABETES MELLITUS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

L. Kondrateva1, T. Popkova1, E. Nasonov1, A. Lila1, V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Patients with systemic lupus erythematosus (SLE) have higher than in general population prevalence of diabetes mellitus (DM). Hyperinsulinemia is a predictor of developing type 2 DM, however routine measurement of insulin levels for DM risk assessment is uncomfortable in daily clinical practice. International Diabetes Federation recommends the use of patient questionnaires to quickly identify people who may be at a higher risk of DM development.

Objectives: To determine the 10-years risk of developing type 2 DM in SLE patients using dedicated questionnaire - Finnish Type 2 Diabetes Risk Assessment Form (FINDRISK) data.

Methods: The study included 92 SLE patients without DM (83 women, 9 men, 39 [34; 47] years old). The median disease duration was 6 [2;14] years, SLE-DAI-2K was 4[2.8]. SLE pts were treated with glucocorticoids (GC) (89%) and hydroxychloroquine (78%), immunosuppressive drugs (28%) and biological agents (10%). The control group consisted of 88 subjects without systemic rheumatic diseases, inflammatory arthritis or DM, matched by age and sex with SLE patients. Eight items of FINDRISK questionnaire (age, overweight, abdominal obesity, family history of diabetes, physical inactivity, eating habits, history of antihypertensive drugs treatment, history of hyperglycemia) were taken into account to calculate the total risk score (TS). The risk of developing DM within following 10 years is regarded as low (1%) or slightly elevated (4%) with TS ≤11 points, as moderate (17%), high (33%) or very high (50%) with TS ≥12 points.

Results: The risk of developing DM was low or slightly elevated risk and 12 (14%) had a moderate, high or very high risk (p=0.01). The number of risk factors (4[2.5]) and the median TS of SLE pts (9[6;12] points) were higher than values in control subjects (3[2.4] factors and 6[3.9] points, respectively; p>0.01 for both). DM risk factors profiles were similar in two groups, except for higher prevalence of abdominal obesity (66% vs 41%, p<0.01) and history of antihypertensive drugs treatment (57% vs 17%, p<0.01) in SLE. There were positive correlations between TS and CRP levels (rs=0.25, p=0.02), SLICC (rs=0.36, p<0.01), HAQ (rs=0.29, p<0.01), and negative correlations between TS and SLEDAI-2K (rs=-0.32, p<0.01), gleromfileration rate by CKD-EPI (rs=-0.23, p=0.03). Current GC use had no influence on TS values in SLE.

Conclusion: Patients with SLE were more likely than individuals without systemic rheumatic diseases to have a moderate, high and very high risk of developing DM, and therefore, required interventions to prevent the metabolic disease. Increased risk of developing DM was associated with most common traditional factors, especially by abdominal obesity and regular use of antihypertensive drugs that can be considered a kind of equivalent to the presence of hypertension. Curtain contribution of inflammation, lupus activity and irreversible damage index can't be ignored. Clarification of SLE-specific phenomena in DM pathogenesis requires further research.

AB0421 EFFECT OF BODY WEIGHT ON COMPLEMENT LEVELS IN SYSTEMIC LUPUS ERYTHEMATOSUS

L. Kondrateva1, T. Popkova1, E. Nasonov1, A. Lila1, V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: The complement system is a recognized biomarker for diagnosis or monitoring of disease activity in systemic lupus erythematosus (SLE) patients (pts). But on the other hand, it has been linked to insulin resistance and obesity in general population.

Objectives: To find out whether overweight/obesity can modify C3 or C4 levels in SLE pts.

Methods: A total of 92 SLE pts (83 women, 9 men, 39 [34;47] years old) were enrolled in the study. Median disease duration was 6[2;14] years, and SLE activity using SLEDAI-2K was 4[2.8]. SLE pts were treated with glucocorticoids (89%), hydroxychloroquine (78%), immunosuppressors (28%), biologics (10%). The overweight/obesity status was determined by World Health Organization criteria in patients with body mass index (BMI) ≥25kg/m2.

Results: Overweight/obesity were identified in 46% SLE pts. Overweight/obese SLE pts were older than pts with normal BMI (39[36;48] vs 37[31;44] years, p=0.02), and had lower SLEDAI-2K (3[2;6] vs 4[2;8], p<0.01). Lower C3 concentrations were found in 36% overweight/obese pts vs 68% pts with normal weight (p<0.01), decreased C4 levels - 19% vs 30% pts (p=0.33), median C3 concentrations were 0.98[0.8;1.1] g/l vs 0.84[0.6;0.96] g/l (p<0.01), and C4 levels were 0.15[0.1;0.19] g/l vs 0.12[0.09;0.16] g/l respectively (p=0.03). C3 and C4 levels negatively correlated with SLEDAI-2K (r=-0.5, p<0.01 for both), the effect was more strongly pronounced in patients with BMI≥25kg/m2 (r=-0.6, p<0.01 for both) than in those with normal weight (r=-0.2, p=0.09 for C3, r=-0.3, p=0.04 for C4).

Conclusion: Overweight/obesity status in SLE pts was associated with increased levels of complement proteins, therefore decreased C3 or C4 levels in patients with BMI≥25kg/m2 are more likely related to disease activity and, can potentially induce SLE flares.

AB0422 LEFT VENTRICULAR ABNORMALITIES IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS FOLLOWED BY SEQUENTIAL ECHOCARDIOGRAPHY

T. Kuga1, M. Matushita1, K. Tada1, K. Yamaji1, N. Tamura1, J. Juntendo University School of Medicine, Department of Internal Medicine and Rheumatology, Tokyo, Japan

Background: Cardiovascular disease (CVD) is detected in up to 50% of systemic lupus erythematosus (SLE) patients1 and major cause of death2. Even clinically silent SLE patients can develop left ventricular (LV) diastolic dysfunction3. Proper echocardiographic follow up of SLE patients is required.

Objectives: To clarify how the prevalence of LV abnormalities changes over follow-up period and identify the associated clinical factors, useful in suspecting LV abnormalities.

Methods: 29 SLE patients (24 females and 5 men, mean age 52.8±16.3 years, mean disease duration 17.6±14.5 years) were enrolled. All of them underwent echocardiography as the baseline examination and reexamined over more than a year of follow-up period(mean 1075±480 days) from Jan
2014 to Sep 2019. Patients complicated with pulmonary artery hypertension, deep venous thrombosis or pulmonary embolism and undergone cardiac surgery during the follow-up period were excluded. Left ventricular(LV) systolic dysfunction was defined as ejection fraction (EF) < 50%. LV diastolic dysfunction was defined according to ASE/EACVI guideline. LV dysfunction (LVD) includes one or both of LV systolic dysfunction and LV diastolic function. Monocyte to HDL ratio (MHR) was calculated by dividing monocyte count with HDL-C level.

Prevalence of left ventricular abnormalities was analysed at baseline and following up the examination. Clinical characteristics and laboratory data were compared among patient groups as follows; patients with LV dysfunction (Group A) and without LV dysfunction (Group B) at the follow-up echocardiography, patients with LV asynergy at any point of examination (Group C) and patients free of LV abnormalities during the follow-up period (Group D).

Results: At the baseline examination, LV dysfunction (5/29 cases, 17.2%), LV asynergy (8/29 cases, 27.6%) were detected. Pericarditis was detected in 7 patients (24.1%, LVD in 3 patients, LV asynergy in 2 patients) and 2 of them with subacute onset had progressive LV dysfunction, while 5 patients were normal in echocardiography after remission induction therapy for SLE. At the follow-up examination, LV dysfunction (8/29 cases, 31.0%, 5 new-onset and 1 improved case), LV asynergy (6/29 cases, 21.7%, 2 new-onset and 2 improved cases) were detected. Though any significant differences were observed between Group A and Group B at the baseline, platelet count (156.0 ± 134.0) was lower in LV dysfunction group (Group A) at the follow-up examination. Group C patients had significantly higher uric acid (p = 0.004), monocyte count (p = 0.009), and MHR (p = 0.003) than Group D (results in table).

Conclusion: LV dysfunction is progressive in most of patients and requires regular follow-up once they developed. Uric acid, monocyte count and MHR were elevated in SLE patients with LV asynergy. Since MHR elevation was reported as useful marker of endothelial dysfunction, our future goal is to analyse involvement of monocyte activation and endothelial dysfunction in LV asynergy of SLE patients.

References:

Methods: Data from our Pregnancy Clinic registry were collected for prospectively followed pregnancies of SLE women treated with AZA (cases) and compared to pregnancies of SLE women not treated with AZA (controls), that were matched for age at pregnancy, presence of renal involvement and aPL positivity. SLE patients (cases and controls) were interviewed by phone to collect data about their children, focusing on the presence of ND/LD certified by Neuropsychiatrists.

Results: Data were collected for 14 SLE mothers in the AZA group and 31 in the control group, with similar age at pregnancy (30.3 ± 5.21 vs 20.54±4.70 years, p = 0.45) and frequency of renal involvement (50% vs 44.1%, p = 0.77), aPL positivity (33.3% vs 29.4%, p = 0.76) and anti-SSA positivity (27.8% vs. 26.5%, p = 0.55). A SLE flare during pregnancy was more frequently recorded in the AZA group (27.8% vs. 2.94%, p = 0.02). Other medications included HCQ (55.6% vs. 70.6%, p = 0.36) and corticosteroids (100% vs. 79.4%, p < 0.08).

We collected data for 18 children in the AZA group and 34 children in the control group, that had a similar mean age at the time of the interview (12.7 ± 4.80 vs. 12.5 ± 5.61 years, p = 0.91). The two groups had also similar gestational age (37.4 ± 2.20 weeks vs. 38.0 ± 1.29 weeks, p = 0.23), birth weight (3003 ± 433 g vs. 3011 ± 453 g, p = 0.95) and rate of male sex (61.1% vs 44.1%, p = 0.38).

We recorded similar frequency of ND/LD in the two groups. In particular, a ND was present in 2/18 (11.1%) of children exposed to AZA vs. 2/34 (5.88%) in the control group (p = 0.60). A LD was present in 1/118 cases (5.56%) and 6/34 controls (17.6%) (p = 0.40).

Conclusion: The medium-long term outcome of children born to SLE mothers in the whole cohort was characterized by the presence of ND in 4/54 (7.69%) and LD in 7/52 (13.5%). ND/LD do not seem to be related to in utero exposure to AZA.

AB0424 PREDICTORS OF SLE FLARE-UP AND PREMATURE DELIVERY IN PREGNANCY
C. H. Liao1, L. C. Wang2, S. C. Hsieh1, B. L. Chiang2. 1National Taiwan University Hospital, Pediatric, Taipei, Taiwan, Republic of China; 2National Taiwan University Hospital, Pediatric, Taipei, Taiwan, Republic of China

Background: Systemic lupus erythematous (SLE) is a life-threatening autoimmune disease that affects many women of child-bearing age, with potentially severe consequences on their outcome. SLE flare-ups during pregnancy and the post-partum period may have severe consequences on maternal health and pregnancy outcome. SLE flare-ups may occur during pregnancy and the post-partum period, which may increase the risk of premature delivery. Based on previous studies, the incidence and risk factors of flare-ups during pregnancy and puerperium have been evaluated.

Objectives: We aimed to delineate the pregnancy complications of women with SLE, as well as neonatal outcomes of their offspring, and to study the influence of lupus flare-ups during pregnancy and the post-partum period on maternal and fetal outcomes following pregnancy: A meta-analytic review of the literature.

Methods: A systematic review of the medical records of SLE patients with previous records of pregnancies in our institution. Flare events during pregnancy and puerperium were documented. The pregnancy outcomes recorded include live births, intra-uterine fetal death (IUFD), premature delivery (< 36 weeks of gestational age), NICU admission, and small for gestational age (SGA, < 10th percentile).

Results: From January, 2000 to December, 2019, a total of 94 SLE patients with 139 pregnancies were identified. The overall live birth rate was 92.4% (134/145). Forty-six (34.3%) of the neonates were delivered prematurely. Forty-six (34.3%) of them were SGA. The admission rate to the neonatal intensive care unit was 25% (30/120). Nine (6.4%) were diagnosed to have SLE during pregnancy. The flare rate during pregnancy was 20% while post-partum 9.4%. The majority of the relapses during pregnancy occurred in the second trimester (46.2%), followed by the first trimester (30.8%), and the third trimester (23.1%). Low complement C3 (C3 < 80mg/dl), thrombocytopenia (PLT < 100 x 10^9/L) at conception, and low serum albumin level at the first trimester were associated with an increased risk of flare during pregnancy. Presence of disease flare and pre-eclampsia in pregnancy, and low serum albumin level at conception were significantly associated with premature delivery.

Conclusion: Low complement C3 and thrombocytopenia at conception, and low serum albumin level at the first trimester were associated with disease flare-up during pregnancy. Patients with relative low serum albumin level at conception, or presence of eclampsia or disease flare-up during pregnancy had a higher risk of premature delivery.

Background: Peripheral neuropathy is one of the most frequent extraglandular manifestations of primary Sjögren’s syndrome (pSS). The diagnosis of peripheral neuropathy complications of pSS is based primarily on careful neurologic examination and electrodiagnostic tests. The value of ultrasound in peripheral nerve has been recognized. However, little clinical researches have focused specifically on cutaneous nerve of pSS.

Objectives: To evaluate the morphological changes of sural nerve in patients with pSS by high-frequency ultrasound.

Methods: The prospective study subjects consisted of 31 consecutive pSS patients underwent sural nerve biopsy and 30 healthy volunteers as controls. The ultrasonic presentations of the fascicle, perineurium, epineurium of sural nerve were observed, and the cross-sectional areas (CSA) of the sural nerves was measured.

Results: Among the 21 sural nerves confirmed by pathology, all showed the thickening of the perineurium and epineurium (Figure 1-2), and abnormal blood flow signal in perineurium or epineurium in 14 cases (Figure 2). The mean CSAs were (1.41±0.44) mm² for the control group, and (1.58±0.48) mm² for the case group (P>0.05). In addition, the abnormal blood flow signal in sural nerve correlated with disease activity.

Conclusion: This study indicated that high-frequency ultrasound may be a valuable tool for evaluating cutaneous nerve neuropathy of Sjögren’s syndrome patients.

References:
Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease, often presenting with neuropsychiatric manifestations. Reports on the frequency and patterns of these manifestations vary substantially and remain incompletely understood.

Objectives: We examined neuropsychiatric manifestations in the prospective nationwide cohort of Swiss SLE (SSCS) patients and conducted a systematic literature review to contextualise our findings.

Methods: We reviewed all patients included in the SSCS from 2007-2019 and classified severe neuropsychiatric manifestations. Searches were performed in relevant electronic databases from 1.1993-1.2020 and by checking reference lists of the pertinent literature. Authors of important papers were contacted to obtain further (unpublished) studies. We included prospective or cross-sectional studies focussing on neuropsychiatric manifestations in SLE, defined according the ACR criteria of 1999. Study selection and data extraction was made in duplicate. We secured salient study characteristics, composition of cohorts, the definitions and the frequencies of neuropsychiatric manifestations. We assessed heterogeneity across reports and investigated sources of variation using meta-regression models.

Results: The frequencies of severe manifestations found in the SSLE were 7.1% (49/688) for cerebrovascular events, 5.3% (37/688) for seizures and 6.5% (45/688) for psychosis. The time-to-event analysis showed a linear relationship between duration of SLE and cumulative incidence of severe neuropsychiatric manifestations. Searches identified 530 studies and authors’ contact yielded another unpublished report. We included 28 studies. The mean rates of the most commonly reported severe neuropsychiatric manifestations ranged in the magnitude of 50 percent points. Study characteristics and composition of cohorts could not explain heterogeneity of reported manifestation rates.

Conclusion: The spectrum of neuropsychiatric manifestations in SLE is widely dispersed. The diagnostic work-up and the reporting of manifestations varied substantially across studies which may explain inconsistencies to some extent. We call for concerted efforts and a broad consensus regarding stringent definitions of neuropsychiatric SLE manifestations that allow targeted detection, particularly with view to timely intervention and patient outcomes.

ASSOCIATION BETWEEN GEOGRAPHIC AND CLIMATOLOGICAL CONDITIONS AND CUTANEOUS MANIFESTATIONS IN LUPUS PATIENTS FROM THE SPANISH RHEUMATOLOGY SOCIETY LUPUS REGISTRY (RELESSER) AND ARGENTINE RHEUMATOLOGY SOCIETY LUPUS REGISTRY (RELESSAR) COHORT

R. Menor-Almagro1, M. Argentina García2, I. Rua-Figuerola3, G. Pons Estet4, M. A. Martín-Martínez5, A. Muñoz Jimenez6, M. Galindo-Izquierdo7, J. Calvo-Alen8, A. Fernandez-Nebro9, A. Olive10, B. Pons-Estel11, J. M. Pego-Reigosa11, Hospital de Jerez, Rheumatology, Jerez, Spain; RELESSER; 2HIGA San Martín, La Plata, Argentina; 3GO-CREAR, Rosario, Argentina; 4Research Unit. SER, Madrid, Spain; 5H.U. Virgen del Rocío, Sevilla, Spain; 6H. de Ardeba, Alava, Spain; 7HCU Vigo, Vigo, Spain; 8H. Tras i Pujol, Badalona, Spain; 9HCU Vigo, Vigo, Spain

Background: Climatological conditions and ethnicity impact on the course of disease in systemic lupus erythematosus patients.

Objectives: We carry out a study to analyze cutaneous manifestations in SLE patients from Argentina and Spain.

Methods: Patients data from Spanish Rheumatology Society Lupus Registry (RELESSER) and Argentina Rheumatology Society Lupus Registry (RELESSAR) were retrospectively analyzed for presence of cutaneous lesions (alopecia, photosensitivity, malar rash, discoid lesions, oral ulcers and subacute bends). RELESSER-T and RELESSAR-T are multicenter, hospital-based registries, with retrospective cross-sectional collection of data about patients with SLE attending Spanish and Argentinian rheumatology services from the public national health system. Data about climatological conditions throughout the Spanish and Argentinian geography were provided by the Spanish Meteorological Agency and Argentine Meteorological Services.

Results: A total of 5604 patients were included, median age 44.6 ± 15.3, 90.4% female. Current smokers were 28.9%. Other climatological, geographical, biological and clinical data are shown in table 1. In the multivariable model, the presence of cutaneous lesion were significantly associated with temperature OR 1.116 (95% CI: 1.042-1.196, p=0.002), altitude OR 1.001 (95% CI: 1.000-1.002, p=0.012), hemolymphatic anemia OR 1.401 (95% CI: 1.017-1.931, p=0.039) and serositis OR 1.509 (95% CI: 1.215-1.875, p=0.000). Negative associations were observed between females OR 0.992 (95% CI: 0.927-0.984, p=0.000); latitude OR 0.984 (95% CI: 0.988-0.999, p=0.000), oceanic climate OR 0.566 (95% CI: 0.381-0.842, p=0.005), leukopenia OR 0.790 (95% CI: 0.643-0.970, p=0.025), renal disorder OR 0.781 (95% CI: 0.600-0.966, p=0.025), glucocorticoids treatment OR 0.571 (95% CI: 0.456-0.715, p=0.000) and antimalarial drugs OR 0.439 (95% CI: 0.342-0.563, p=0.000).
MORTALITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUS AND NEUROPSYCHIATRIC SYMPTOMS

R. Monahan1, R. Fronzek2, J. Eikenboom3, H. Middelkoop4, L. J. J. Bearta-van de Voorde1, G. Terwindt5, N. Van der Wee6, F. Rosendaal7, T. Huizinga1, M. Kloppenburg1, G. M. Steup-Beekman1.

Background: Little is known about mortality in patients with systemic lupus erythematosus (SLE) presenting with neuropsychiatric (NP) symptoms.

Objectives: We aimed to evaluate all-cause and cause-specific mortality in patients with SLE and NP symptoms.

Methods: All patients with the clinical diagnosis of SLE of 18 years and older that visited the tertiary referral NPSLE clinic of the Leiden University Medical Center between 2007-2018 and signed informed consent were included in this study. Patients were classified as NPSLE if NP symptoms were attributed to SLE and immunosuppressive or antiocoagulant therapy was initiated, otherwise patients were classified as non-NPSLE. Municipal registries were checked for current status (alive/deceased). Electronical medical files were studied for clinical characteristics and cause of death. Standardized mortality ratios (SMRs) and 95% confidence intervals were calculated using data from the general Dutch population.

Results: 351 patients with the clinical diagnosis of SLE were included, of which 149 patients were classified as NPSLE (42.5%). Compared with the general population, mortality was increased five times in NPSLE (SMR 5.0, 95% CI: 2.6-8.5) and nearly four times in non-NPSLE patients (SMR 3.7, 95% CI: 2.2-6.0), as shown in Table 1. Risk of death due to infections was present in both NPSLE and non-NPSLE patients (SMR 29.9, 95% CI: 3.5 – 105) and SMR 91.3 (95% CI: 18.8 – 266) respectively. However, mortality did not differ between NPSLE and non-NPSLE patients (RR 1.0, 95% CI: 0.5 – 2.0).

*Standardized mortality ratio, ratio of the observed and expected number of deaths

Conclusion: Mortality was increased in both NPSLE and non-NPSLE patients in comparison with the general population, but there was no difference in mortality between NPSLE and non-NPSLE patients. Risk of death due to infections was increased in both groups.

AB0431 SALIVARY GLAND ULTRASOUND IN CLINICAL PRACTICE

F. Montero1, K. Carpio1, I. Janta2, J. Molina Collada1, B. Serrano Benavente1, J. Martinez-Barrio1, A. Ariza1, J. Rivero2, C. Gonzalez1, I. Monteagudo1, J. C. Nieto1, Gregorio Marañón Hospital, Madrid, Spain; 2University Clinical Hospital of Valladolid, Valladolid, Spain

Background: Sjögren’s syndrome (SS) is characterized by lymphocytic infiltration of the exocrine glands and marked B-lymphocytic cell hyperreactivity involving a variety of serum autoantibodies. 1 Salivary Gland Ultrasound (SGU) is a simple, fast, and well-tolerated examination, which provides information about glandular structure and has proven to be very useful in the Sjögren Syndrome diagnosis. A prognostic value has also been proposed due to its possible relationship with lymphomas and extra-glandular manifestations.

Objectives: The objective of our study is to evaluate ultrasound results in patients who went through an SGU in clinical practice, its usefulness in the diagnosis of Sjögren’s syndrome and the presence of complications (lymphomas, extra-glandular manifestations or factors related to increased lymphoma risk).

Methods: We conducted a retrospective cross-sectional study with review of clinical records that included all those patients coded as SSU in the Ultrasound unit of Rheumatology Department from 2016 to December 2019. Information collected included final diagnosis, laboratory results, clinical manifestations and ultrasound results. We performed an analysis on the frequency of pathological SGU and on the relationship between this lesions in patients with final SS diagnosis and the presence of lymphoma, extra-glandular manifestations and the laboratory values related with increased lymphoma risk (low complement levels, cryoglobulinemia, positive anti-nuclear antibodies).

Results: SGU was performed in 171 patients in four years, 162 women (94.7%). The previous diagnoses, reason for the request and final diagnosis are shown in Table 1. The vast majority of the SGU were normal, only 28 (16.3%) were pathological, 13 with a grade II and 8 with a grade III. In the other 7 patients grading was not available. Of the 28 patients with pathological SGU, none had lymphoma, only 3 had recurrent parotid and 15 had had extra-glandular manifestations, mainly arthritis (arthritis (12), 1 only 1 patient, with rheumatoid arthritis, had had a lymphoma and the SGU was normal. Antibody positivity was frequent in pathological SGU, 16/23 antinuclear antibodies, 13/22 anti-Ro and 9/23 rheumatoid factor. Of the 86 patients without previous diagnosis, 18 were diagnosed with Sjögren syndrome, 9 with pathological SGU and the rest were normal. No patient diagnosed with a dry non-autoimmune syndrome presented pathological SGU.

Conclusion: The impact of the SGU is low and its use cannot, for now, displace other methods (e.g. salivary gland biopsy) in the diagnosis of SS. Also our low number of patients with pathological SGU together with the low prevalence of the complications studied (e.g. lymphomas = 1) prevents the expected comparisons.

Disclosure of Interests: Fernando Montero: None declared, Karen Carpio: None declared, Jastina Janta: None declared, Juan Molina Collada: None declared, Belen Serrano Benavente: None declared, Julia Martinez-Barrio Consultant of: UCB Pharma, Alfonso Ariza: None declared, Javier Rivero: None declared, Carlos Gonzalez Consultant of: Gilead, Janssen, Novartis, Speakers
Background: Systemic lupus erythematosus (SLE) is a multisystemic and chronic autoimmune disorder that typically affects (1) Arthritis is one of the most frequent manifestations in SLE with an incidence reported from 69% to 95% (2). Rheumatoid arthritis (RA) is an arthritic, inflammatory, chronic disease of autoimmune nature (3). Rhusp, secretion is defined as a patient that meets the classification criteria for RA of the American College of Rheumatology (ACR) of 1987 and for SLE of the ACR of 1982, in addition, necessarily erosive arthritis with antibodies specific for positive SLE (anti-Sm or anti-DNA) (4). With the development of more recent classification criteria for both RA and SLE, which allow us to detect both diseases earlier, they create even more heterogeneity in the definition of rhusp, being a rare entity, the analysis of the clinical and serological characteristics of this population in our clinic would provide data to the few existing.

Objectives: To describe the clinical and serological characteristics of patients with Rhupus.

Methods: An observational, retrospective study was done in the rheumatology clinic of the university hospital “Dr. Jose Eleuterio Gonzalez” in Monterrey, Mexico. The electronic medical record (EMR) was reviewed. In the term “rhupus” all the patients were analyzed individually to verify the rhupus diagnosis. The main clinical and serological characteristics were evaluated. The results are shown in descriptive statistics.

Results: 30 patients were obtained from the search in the EMR, 22 patients were included, 8 patients were excluded (5 non-SLE, 3 non-RA) (Figure 1). The mean age was 40.14 (SD 10.86); 20 (90.9%) were females; the onset diagnosis was SLE in 5 (22.7%), RA in 14 (63.6%) and both 3 (13.6%). 17 (77.3%) had general symptoms, 12 (54.5%) had cutaneous manifestations, 14 (66.6%) had renal manifestations, 26 (73.3%) had serositis, 19 (66.7%) had hematologic manifestations, 3 (13.6%) had neuropsychiatric manifestations, 1 (4.5%) had diffuse alveolar hemorrhage. 12 (60%) had anti-dsDNA positive, 4 (23.5%) had anti-Sm positive, 16 (84.2%) had anti-CCP positive (Table 1). The articular manifestations (swollen and tender joints at onset and at last visit) are detailed in Table 2. The thrombotic events included stroke (at 11 weeks; n=1), catastrophic APS (n=2), a pulmonary embolism (n=1), and portal vein thrombosis (n=1). The thrombotic events included stroke (at 11 weeks; n=1), catastrophic APS (n=2), a pulmonary embolism (n=1), and portal vein thrombosis (n=1). The treatment differences were examined using the Wilcoxon test for the Mann-Whitney U test.

Conclusion: In our cohort, rhupus affects more frequently females, the hematologic manifestations are very frequent and the neuropsychiatric and diffuse alveolar hemorrhage was rare.

Among the 22 (18.5%) women with at least one bleeding event (n=28), 9 (7.6%) had events defined as severe. Six of nine (67%) severe haemorrhages occurred in the postpartum and were directly related to the delivery. Two required an intra-uterine balloon tamponade, two uterine arterial embolisation, and three surgery, including one hysterectomy.

No women died.

Finally, thrombotic and/or severe bleeding events during the postpartum period (n=9) were more frequent in women with lupus anticoagulant (14% versus 0%; P=0.01), with associated placental insufficiency (29% versus 3%; P=0.001) and with preterm delivery <34 weeks (33% versus 4%; P=0.002).

Conclusion: Even though most women in our cohort received treatment based on current recommendations, a substantial number of maternal thrombotic and haemorrhagic events (10%) occurred. Despite several life-threatening complications, including CAPS, no women died.

Most of the thrombotic or haemorrhagic events occurred in the peripartum period, in 100% males at the average age of 53.0±9.14 (M±σ).

A substantial number of maternal thrombotic and hemorrhagic events occurred in the peripartum period, including one hysterectomy.

Study of the prevalence of APS components in men with stable CHD with postinfarction cardiosclerosis and to evaluate the relationship with cardiovascular structure and function. 1.0.0.20

PREVALENCE OF ANTIPHOSPHOLIPID SYNDROME COMPONENTS IN MEN WITH STABLE CORONARY HEART DISEASE AND POSTINFARCTION CARDIOSCLEROSIS AND CONECTION WITH ECHOCARDIOGRAPHIC EVALUATION OF CARDIAC STRUCTURE AND FUNCTION

M. Nazarya1, M. Stanislavchuk2, L. Burdeina2, N. Zaichko3, V. Vinnytsya National Pirogov Memorial Medical University, Internal Medicine #1, Vinnytsya, Ukraine; 2-Vinnytsya National Pirogov Memorial Medical University, Internal Medicine #1, Vinnytsya, Ukraine; 3-Vinnytsya National Pirogov Memorial Medical University, Biochemistry and General Chemistry, Vinnytsya, Ukraine

Background: Antiphospholipid syndrome (APS) as an independent factor in different forms of coronary heart disease (CHD) has been attracting more attention in recent years [1]. The prevalence of APS in the general population is low (1-5%) but among patients with acute coronary syndrome it ranges from 6.1% to 43.3%. The persistence of high titers of antiphospholipid (aPL) antibodies, especially antibodies to cardiolipin, accelerates the development of endothelial dysfunction and atherosclerotic lesions of the coronary arteries, worsens the course of acute myocardial infarction. It has been experimentally demonstrated that aPL antibodies can directly affect myocardial status through pro-apoptotic signaling pathways and increased cardiomyocyte apoptosis [2]. The impact of aPL antibodies on the course of postinfarction myocardial remodeling in patients with CHD has not been established.

Objectives: To study the prevalence of APS components in men with stable CHD with postinfarction cardiosclerosis and to evaluate the relationship with structural and functional state of left ventricular myocardium.

Methods: 164 patients with CHD with postinfarction cardiosclerosis were examined (100% males at the average age of 53.0±9.14 (M±σ)). The diagnosis of CAD was made according to the recommendations of the ANA / ACC (2014) and ESC (2013). The content of IgG and IgM of aPL antibodies - antibodies to cardiolipin, phosphatidylserine, phosphatidylinositol, phosphatidylethanolamine and levels of IgG and IgM to 2-glycoprotein I (2-GP-I) in the blood serum were determined by ELISA. Echocardiography in M-, B- and D-modes was performed.

Results: Among 164 patients with post-infarction cardiosclerosis: 75% had Q myocardial infarction (MI), 10.4% had recurrent MI, 79% had a stroke or transient ischemic attack and 4.2% had livedo reticularis. 93 (56.7%) patients had positive levels of total aPL antibodies and antibodies to 2-GP-I of IgG class (35.4%), 35 (21.3%) patients had positive levels of one or both types of antibodies. Positive levels of aPL antibodies and antibodies to 2-GP-I of IgM were detected in 11.6% of patients. Positive levels of aPL antibodies and antibodies to 2-GP-I of IgG were more commonly found in men who had Q MI (OR 2.58 95% CI 1.26 - 5.28) and recurrent MI (OR 2.52 95% CI 0.83 - 7.67). Increases of levels of aPL antibodies and antibodies to 2-GP-I correlated with an increase of left ventricle (LV) mass index (r = 0.259 and 0.331, p <0.001).

In patients with positive levels of antibodies to IgG to 2-GP-I in postinfarction LV remodeling was more likely to occur by concentric type of hypertrophy of LV than in patients with negative levels of antibodies to 2-GP-I (OR 6.50, 95% CI 2.49 - 16.9, p <0.001). Hypertension had no significant differences within these groups.

Conclusion: The risk of persisting positive levels of aPL antibodies and antibodies to 2-GP-I in the postinfarction period is significantly increased in men who had Q MI. Patients with CHD with positive antibodies to 2-GP-I of IgG are associated with an increased risk of postinfarction LV myocardial remodeling by concentric type of hypertrophy of LV.

CHANGES OF LYMPHOCYTE SUBSETS AND CLINICAL INDEXES IN PERIPHERAL BLOOD OF PATIENTS WITH ANTI-PHOSPHOLIPID SYNDROME

W. Ni
1, L. H. Yen
1. The Second Hospital of Shansi Medical University, Rheumatology and Immunology Department, Taiyuan Shanxi, China

Background: Anti-phospholipid Syndrome (APS) is a non-inflammatory auto-
imune disease, which can be divided into primary and secondary. Changes in
lymphocyte numbers in APS are caused by disruption of the immune balance.

Objectives: The levels of lymphocyte subsets in peripheral blood of patients with
anti-phospholipid syndrome were observed and their clinical indexes were analyzed.

Methods: 53 patients with anti-phospholipid syndrome (APS) were collected as
the case group and divided into two groups of A, B according to whether primary
and 50 health examiners as the healthy control group. The levels of peripheral
lymphocyte subsets and laboratory data (erythrocyte sedimentation rate (ESR),

features were also collected in pSS patients (disease duration, disease activity measured by ESSOAQ, glandular vs. extraglandular involvement, serological features and treatments received).

Statistical analysis. To evaluate differences between patients and controls, T-test or Wilcoxon test with continuity correction, were used for quantitative features and Fisher test for categorical variables. In order to test the presence of pSS as an independent risk factor for subclinical atherosclerosis, from other features as classic CVRFs or analytical data, first we adjusted logistic binomial regression in a bivariate analysis, to select possible predictors to be included in a multivariate analysis. Statistical significance was p<0.05, and OR CI 95% was calculated.

R-Statistics v-3.6

Results: All of the 76 patients included were women, with a mean age of 53.7 ± 11.7 years. For both groups, no differences between prevalence of classical CVRFs were found. Subclinical atherosclerosis presence was higher in patients with pSS than in controls [OR= 4.17; 95%CI (1.27-16.54), p<0.001], as well as CIMT values (0.79 ± 0.43mm vs. 0.66 ± 0.27mm; p<0.02). An association of subclinical atherosclerosis with erythrocyte sedimentation rate [OR=1.18, 95%CI (1.05-1.37), p<0.05] and Rheumatoid Factor [OR=1.28, 95%CI (1.63-2.26), p<0.05].

Conclusion: This cohort showed a greater prevalence of subclinical atherosclerosis in patients with pSS, indicating this disease as an independent risk factor for presence of early vascular damage.

AB0438 MALIGNANCIES IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

Ö. Özdemir İlık1, A. Yazıcı1, A. Cefeı1, Kocaeli University School of Medicine, Rheumatology, Kocaeli, Turkey

Background: Sjögren’s syndrome (SS) is a chronic, systemic, autoimmune disease. The risk of developing lymphoproliferative malignancies is high in primary Sjögren’s syndrome(pSS).

Objectives: In this study, we planned to present malignancy data in patients who were followed up in our outpatient clinic with a diagnosis of pSS.

Methods: Data of 151 patients diagnosed with pSS between 2004-2019 were retrospectively reviewed and clinical, demographic characteristics of 15 patients diagnosed with malignancy were examined.

Results: All 15 patients with malignancy were female, their mean age was 59 ± 13 years, and the disease duration was 9 ± 1 years. In this group, 7% of the patients had fever, 13% had weight loss and 7% had night sweats. Dry eye was present in 87%, dry mouth in 93%, LAP in 53% (Table 1). None of the patients had myositis, neuropathy and vasculitis. In 87% of the patients, the schirmer was below 5 mm and in 67% of the salivary gland scintigraphy, decreased involvement in the parotid and submandibular gland was detected. Salivary gland biopsy was compatible with pSS diagnosis in 53% of patients. Rheumatoid factor, ANA, SS-A and SS-B were positive in 30%, 93%, 12% and 12% of patients, respectively.

Table 1. The data of pSS patients with malignancy

Malignancy

Hypocomplementemia 4(27)
Lung Cancer 2(13)
Breast Cancer 4(27)
Thyroid Papillary Cancer 3(20)
Cervical Cancer 2(13)
Vulva Cancer 1(7)
Mycosis Fungoides 1(7)
MALT lymphoma 1(7)
Diffuse Large B Cell Lymphoma 1(7)

Low C3 level was detected in 27% of patients and C4 level was normal in all patients. Hypergammaglobulinemia was detected in 27% patients but data of five patients could not be reached. Malignancy was detected in 10% of the patients who were followed up with the diagnosis of pSS. Two patients had cervical cancer (CA), four had breast CA, three had thyroid papillary CA, one had diffuse large b cell lymphoma, one had MALT (mucous-associated lymphoid tissue) lymphoma, one had mycosis fungoides, one had vulva epithelial carcinoma and two had lung CA. Patients with malignancy and those without were compared in terms of clinical and laboratory findings. There was a significant relationship between presence LAP and smoking with development of malignancy. Subgroup analysis was performed according to tilters of C-Reactive protein (CRP) and erythrocyte sedimentation rates (ESH), but there was no significant relationship between laboratory findings and the development of malignancy. (Table 2)

Conclusion: According to 2015 data of Turkey unified database for all age groups, the rate of cancer in woman is 25% for breast cancer, 12% for thyroid CA, 5.1% for lung CA, 2.5% for cervical CA, 2.8% for non-hodgkin lymphoma. Patients with pSS have a 6 to 19-fold increased risk for the development of non-Hodgkin B-cell lymphoma. For these reasons, detailed questioning and physical examination gain importance in the follow-up of patients.

AB0439 LUNG FINDINGS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

Ö. Özdemir İlık1, A. Yazıcı1, A. Cefeı1, Kocaeli University School of Medicine, Internal Medicine, Division of Rheumatology, Kocaeli, Turkey

Background: Sjögren’s syndrome (SS) is a systemic, autoimmune disease and can affect many organs and systems.

Objectives: In this study, we planned to present the lung findings of primary SS patients who are being followed in our outpatient clinic.

Methods: Chest radiographs and thorax CTs of 151 patients who were admitted to the rheumatology outpatient clinic between 2004 and 2017 and diagnosed as pSS according to the classification criteria of the American-European consensus group Sjögren’s syndrome were retrospectively scanned.

Results: In our study, 97% of pSS patients were female and 3% were male and the mean age was 56 ± 12 years, disease duration was 10.5 ± 5 years. It was observed dry eye in 86% of patients, dry mouth in 88%, parotitis in 17%, arthritis in 29%, vasculitis in 4%, neuropathy in 6%, myositis in 1%, lymphadenopathy in 29% (LAP), and 20% of patients had Raynaud phenomenon. In 50% of the patients, chest radiography was normal, and there were no respiratory complaints. Thorax CT was requested due to suspicious appearance on 50% chest x-ray.
According to CT findings, 23% had nodules in the lung, nodule sizes were less than 1 cm, and patients were followed up for an increase in size. Hilfer and subcarinal lymph nodes were present in 6% of patients and their sizes was ranged from 5 mm to 15 mm. Bronchoscopy was performed for two patients due to mediastinal LAP. Biopsy results were evaluated as reactive changes.

Interstitial lung disease (ILD) findings were present in 16 patients. (69% NSIP, 25% LIP, 6% UIP). All patients with ILD received steroid therapy. Two patients received 6 cycles of cyclophosphamide treatment for active alveolitis and azathioprine (AZA) was used in maintenance therapy. Due to ILD, one patient was receiving rituximab, one patient was receiving mycophenolate mofetil, while nine patients were using AZA.

It was found bronchiectasis in 3% of patients, emphysema in 5%, sequelae fibrotic changes in 13%, and 1% patients had thickening of the pleura. One patient was diagnosed with hypersensitivity pneumonia and two patients had lung cancer (Table-1).

There was a smoking history in 21% of the patients. There was a significant relationship between smoking and development of emphysema and malignancy. The relationship between smoking and lung cancer development could not be assessed due to the absence of lung cancer in the non-smoking group (Table-2).

**Conclusion:** Lung findings are detected in 9-12% of patients in pSS, which can increase to 75% with the use of tomography, pulmonary function tests and bronchoscopy.

Since pSS has a wide spectrum from airway disease or interstitial lung disease to BALT lymphoma lung involvement of the disease has been emphasized.

Patients were divided into two groups related to the mean LDL-C level: <100mg/dL and ≥100mg/dL. Cox's proportional regression analysis was performed to identify the independent predictors of progression to ESRD in LN patients.

**Results:** Seventy-one of 121 biopsy-proven LN patients (58.7%) showed more than 100mg/dL of LDL-C at the time of LN diagnosis. The higher LDL-C group excreted more 24-hour urine protein (p=0.003), and showed a higher proportion of proliferative LN (p=0.013) and an activity score >12 (p=0.023). During a mean follow-up of 83.0 (range, 12–171) months, ESRD was more frequent in the higher LDL-C group than in the lower group (15.5% vs. 2.0%; p=0.012). In the multivariate Cox’s proportional regression analysis, LDL-C >100mg/dL (hazard ratio [HR] 17.1340; p=0.012), estimated glomerular filtration rate during the renal biopsy (HR, 0.977; p=0.005), statin exposure during follow-up (HR, 0.163; p=0.031), relapse (HR, 9.752; p=0.036), and complete remission at 1-year of treatment (HR, 0.034; p=0.003) were significant predictors of progression to ESRD in LN patients.

**Conclusion:** Our findings suggest that dyslipidemia at the onset of LN is an independent risk factor for predicting the development of ESRD in LN patients. Therefore, lipid profile should be monitored carefully and managed aggressively to avoid the deterioration of kidney function in patients with LN.

### AB0441

**ASSOCIATION OF CO-POSITIVITY FOR ANTI-DSDNA, -NUCLEOSOME, AND -HISTONE ANTIBODIES AND DISEASE ACTIVITY IN PATIENTS WITH LUPUS NEPHRITIS: RESULTS FROM THE KOREN Registry**

D. J. Park1, S. E. Choi1, H. Xu1, J. H. Kang1, S. S. Lee1. 1Chonnam National University Medical School & Hospital, Gwangju, Korea, Rep. of (South Korea)

**Background:** Recent studies have shown that the simultaneous positivity of anti-double stranded DNA, -nucleosome, and -histone antibodies (3-pos) is prevalent in lupus nephritis (LN) patients compared to non-renal systemic lupus erythematosus (SLE) patients.

**Objectives:** The aim of this study was to define the clinical, biologic, histopathologic, and prognostic differences according to the simultaneous reactivity to those antibodies in Korean patients with biopsy-proven LN.

**Methods:** We studied 102 patients who underwent kidney biopsy prior to the start of induction treatment and who were subsequently treated with immunosuppressives and followed-up for more than 12 months. Sociodemographic, clinical, laboratory, and treatment-related data at the time of kidney biopsy and during follow-up were obtained by a review of patients' charts. Antibodies were detected by immunoblot analysis or ELISA at the time of renal biopsy.

**Results:** Fifty-eight (35.4%) of the total of 102 LN patients had 3-pos. In comparison with non-3-pos patients, the patients with 3-pos showed a higher SLE Disease Activity Index-2000 score (p=0.002), lower lymphocyte level (p=0.004), higher proportion of proteinuria >3.5 g/24 hr (p=0.005), and higher positivity of urinary sediments (p=0.005) at the time of renal biopsy. In the renal histopathologic findings, the patients with 3-pos had more proliferative LN (p=0.015) and also showed more endocapillary hypercellularity, sub-endothelial hyaline deposits, fibrosis, necrosis/cystic/necrotic, and cellular crescents in the disease activity index (p=0.016, p=0.045, p=0.002, and p=0.022, respectively), as well as a higher activity score (p=0.011). After a median follow-up of 83.2 months, rapid glomerular filtration rate decline was frequently observed in patients with 3-pos compared to those without (p=0.012).

**Conclusion:** Our findings suggest that 3-pos is related to severe LN and, furthermore, that patients with 3-pos show a rapid decline of renal function compared to those without.

### AB0442

**RISK FACTORS ASSOCIATED WITH THROMBOTIC EVENTS IN KOREAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

D. J. Park1, S. E. Choi1, H. Xu1, J. H. Kang1, S. S. Lee1. 1Chonnam National University Medical School & Hospital, Gwangju, Korea, Rep. of (South Korea)

**Background:** Up to 30–40% of all patients with systemic lupus erythematosus (SLE) experience thrombosis, presenting as stroke and myocardial infarction, and these thrombotic events cause substantial morbidity and mortality in SLE. We explored the risk factors associated with the occurrence of thrombotic events in SLE patients.

**Methods:** This study enrolled 259 SLE patients (mean age, 34.0 ± 13.7; 239 females) with available clinical data at the time of SLE onset from the lupus cohort at Chonnam National University Hospital. Sociodemographic, clinical, and laboratory data, and history of concomitant diseases were obtained. Thrombotic events were defined as the presence of arterial or venous thrombosis. The
multivariable Cox’s model was performed to investigate the possible risk factors for thrombotic events.

Results: During a mean follow-up of 103.3 months (SD, 53.4), 27 patients (10.4%) developed thrombotic events: stroke in 15 patients, venous thrombosis in five patients, myocardial infarction in four patients, and angina in three patients. In the multivariable Cox’s regression analysis, hypertension (hazard ratio [HR], 16.946; P=0.031), antiphospholipid syndrome (APS) (HR, 18.348; P=0.001), cumulative prednisolone >5mg/day (HR, 14.374; P=0.001), use of ACE inhibitors (ACEi) or angiotensin receptor blockers (ARB) (HR, 0.110; P=0.004), and Systemic Lupus International Collaborating Clinics Group (SLICC) damage index (HR, 1.972; P=0.004) were significant predictors of the development of thrombotic events in patients with SLE.

Conclusion: Patients with SLE showed significant thrombotic events during the course of their disease. Risk factors associated with thrombotic complications were higher cumulative dose of prednisolone, diagnosis of APS, and higher SLICC damage index. On the other hand, the use of ACEi or ARBs was associated with a reduced risk of thrombotic complications in patients with SLE. Our results support the need for increased monitoring of thrombotic complications in SLE patients.

The main clinical manifestations at diagnosis were articular (n= 12; 52.17%) and cutaneous (n=13; 56.52%). On the other hand, 16 patients (69.6%) presented impaired renal function at diagnosis. In the other 7 patients (30.4%), this manifestation appeared with a delay of diagnosis from the onset of symptoms of 13.1±7.73 years.

Renal biopsy had been performed in 21 patients with LN: type II LN (n=2; 9.1%), type III (n=8; 36.4%), type IV (n=9; 40.9%) and type V (n=2; 9.1%).

Patient and graft survival function after transplantation is represented in Figure 1 and 2.

Regarding lupus flares after transplantation, 3 patients (13.04 %) developed a lupus flare: 2 cases presented as extrarenal disease (one of them was a pneumonia and the other one was a cutaneous and articular flare) and only 1 case with histological recurrence in the graft (Mean follow-up 15.00±9.84 years).
Clinical Abstracts

Conclusion: Renal transplantation is a safe alternative therapy for ESRD in this population and can provide a long-term survival. However, it is very important to consider the occurrence of flares even in the long-term post-transplant.

Thrombotic microangiopathy and Sjögren syndrome, an unusual association. Presentation of clinical case and systematic review of the literature

V. Santamaria1, M. Galvis1, A. Vanegas1.

Background: Thrombotic microangiopathy (TMA) is a clinicopathologic diagnosis defined as microangiopathic hemolytic anemia (MAHA) with associated features of thrombocytopenia and end-organ ischemia. Systemic lupus erythematosus, antiphospholipid antibody syndrome, and scleroderma, are among the autoimmune diseases, the more commonly associated with TMA. It has been considered that the association with Sjögren Syndrome (SS) is rare.

Objectives: To describe one patient with TMA and SS, and to review all cases reported in the literature.

Methods: We notified a clinical case of a patient with Sjögren’s syndrome and TMA. Then, we searched the medical literature finding a total of 17 cases reported with this association until 2019. Before the data obtained were tabulated and descriptive, comparing groups and bivariate analysis was performed. The outcome of interest was the death of the patient. stata 12.0 software was used.

Results: A 26-years-old Colombian female presented with a 6-week history of petechiae in lower limbs, gingivorrhagia, menorrhagia and jaundice; and previous history of arthritis and serositis. On admission, in the context of severe thrombocytopenia and MAHA, a MAHA diagnosis was made. During hospitalization we confirm the diagnosis of SS with ANA, antiTO and salivary gland biopsy. The patient was treated with steroids (methylprednisolone 500 mg/day, 3 days), plasma exchange therapy (PLEX) and Cyclophosphamide (750mg), with recovery of hemoglobin and platelet levels; however, the patient died due to a complication of the PLEX catheter removal procedure.

A total of 18 patients diagnosed with de novo or prevalent Sjögren’s syndrome and TMA were included. The mean age was 54.55 years (Standard deviation: (SD): 12.45) and 83.33% of the patients corresponded to the female gender.

At admission, the mean of hemoglobin was 8.45±g/dl (SD: 2.55) and median platelets of 27250/mm3 (interquartile range (IQR) 10500 - 102000) were found. The most frequent clinical manifestations were central nervous system alterations (50%), followed by bleeding in the skin and renal failure (44.4%) and fever (27.78%). The most frequent antibodies found were anti-Ro (100%), anti-nuclear antibodies (80%) and anti-La (75%). The most frequently prescribed treatment was plasma exchange therapy (83.33%), intravenous steroids (61.11%), oral steroids (61.11%) and cyclophosphamide (27.78%). Of the total patients, 38.89% died and 27.78% had some relapse of TMA.

In the group comparison analysis, differences were found in intravenous steroid (81.82% in those who lived vs. 28.57% in those who died p=0.039), use of PLEX (100% in those who survived vs. 57.14% in those who died p = 0.043), fever (9.09% in those who survived and 57.14% in those who died, p = 0.047), admission hemoglobin (7.65±g/dl in those who lived vs. 10.22±g/dl in those who died, p = 0.05), final platelets (148,000 in which who lived and 39,000 in those who died p = 0.02). Then, in the logistic regression analysis, an association was found between mortality and use of intravenous steroids (OR: 0.08, 95% CI 0.009 - 0.83, p = 0.35) and fever at admission (OR: 13.33 95% CI: 1.04 - 169.55, p = 0.046).

Conclusion: While the association between TMA and SS is uncommon, so far 18 cases have been reported in the world medical literature. It is typically a condition of women age close to 50 years. The most frequent manifestations are neurological and hematologic abnormalities. Although TMA in SS patients has been described in the past, there has not been a detailed evaluation of SLE patients in Xinjiang of China, a largely Uyghur population.

IREVERSIBLE ORGAN DAMAGE IN PERI- AND POSTMENOPAUSAL WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN REMISSION

S. Shikireeva1, E. Zotkin1, O. Lesnyak1, 2.
1Science and Research Institution of Rheumatology named after V.A. Nasonova, Moscow, Russian Federation;
2North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation

Background: Although the survival of patients with systemic lupus erythematosus (SLE) has improved, irreversible organ damage remains a critical concern. Long-standing inflammation, drug-related side effects and comorbidities may eventually cause permanent organ damage even in remission.

Objectives: To describe irreversible organ damage in peri- and postmenopausal women with SLE in remission and low disease activity, to find predictors of damage progression.

Methods: 234 peri- and postmenopausal women with SLE were included (mean age 49.9±9.1 years) in our study. All women were under outpatient follow-up in St.Petersburg State Clinical Rheumatology Hospital #25 (Russia). Mean disease duration was 8.9±7.5 years. We analyzed treatment regimens and doses of glucocorticoids (GC) based on source medical documents. To assess disease activity, we used SLEDAI-2K and LLADS. To assess organ damage, we used SLICC damage index (SDI).

Results: 94.3% of women have been taking GC during our study. Median of maintenance dose was 12.5 mg per day. Almost a half of all women (44.8%, n=105) in our study were postmenopausal (mean duration of menopause was 11.1±7.1 years). A half of all patients had low disease activity (44.4%, n=111) or were in remission (18.8%, n=44) according to SLEDAI-2K. 26.5% (n=65) of patients had all 5 criteria and 45.1% (n=115) of patients had 4 of 5 criteria according to LLADS. Critical organ damage (SDI>4) was observed in 68.8% (n=161) of women with SLE. Moderate (1≤SDI<4) and low (SDI=0) damage had 25.6% (n=60) and 6.4% (n=15) of patients respectively. Musculoskeletal damage was on the first place among others: 37.6% (n=88) of patients had osteoporosis with fractures and 34.2% (n=80) had muscle weakness. In 75 women with SLE of osteoporotic fractures occurred in remission or low disease activity (LLADS). Progression of irreversible organ damage in remission or low disease activity (LLADS) had 62% (n=145) of women with SLE. Multi-factorial logistic regression analysis of factors associated with organ damage in SLE showed that only patients age (p=0.013215), cumulative dose of GC (p=0.000047) and therapy with cyclophosphamide (p=0.041505) were statistically significant.

Conclusion: Progression of irreversible organ damage in peri- and postmenopausal women with SLE may occur despite remission or low disease activity. There are no doubts that organ damage accrual is associated with CG therapy. Correction of GC dose or discontinuation of CG treatment in remission can prevent organ damage accrual in SLE including osteoporosis and osteoporotic fractures.

BACKGROUND:

Objectives: To determine the protective value of remission state on organ damage accrual in SLE patients through a SLR.

Methods: Two independent reviewers identified studies in Medline and Cochrane Library. Data on remission definitions and rates as well as damage accrual (assessed by the SLICC/ACR damage index [SDI]) were extracted. Definitions of (GO-CREAR), Rosario, Argentina; 2 Universidad San Ignacio de Loyola, Unidad de Investigación para la Generación y Síntesis de Evidencias en Salud, Lima, Peru; 3 Amsterdam UMC, Amsterdam, Netherlands; 4 University of Crete, Heraklion, Greece; 5 University of Alabama at Birmingham, Alabama, United States of America; 6 Universidad Peruana Cayetano Heredia, Lima, Peru

Background: Treat-to-target strategy with remission as the target has been proposed for the management of SLE. However, there is not a uniform definition of remission.

Objectives: To determine the protective value of remission state on organ damage accrual in SLE patients through a SLR.
remission included disease activity indices (SLEDAI and its variants, PGA), serological activity, prednisone (PDN) daily dose (mg/day), immunosuppressive (IS) drugs, antimalarial (AM) use and duration of remission. The quality of the studies was evaluated with the Newcastle-Otawa Scale (NOS).

**Results:** Eight manuscripts were included comprising more than 6,000 patients from America, Europe and Asia Pacific. All the studies were longitudinal. The majority of the studies reached more than seven out nine points in the NOS. Remission rates ranged between 10 and almost 50%; they tend to be lower in America as compared to Asia Pacific and Europe. All definitions required a clinical SLEDAI=0, and allowed antimalarial use. However, there were differences regarding the inclusion of serological activity, PGA, prednisone or immunosuppressive drug use as well as minimum remission duration required. Even less stringent definition of remission prevented damage accrual. The risk of damage accrual was two to five-fold lower in those patients on remission.

**Conclusion:** In SLE patients, achieving remission, even with less stringent definitions, prevented damage accrual.

**DANISH PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS SELF-REPORT HIGH LEVELS OF PHYSICAL ACTIVITY, AND MOST PATIENTS FULFILL THE WHO RECOMMENDATIONS ON PHYSICAL ACTIVITY**

M. Munch Beck, S. Möller, S. D. Kay, A. Voss, Odense University Hospital, Department of Rheumatology, Odense C, Denmark; OPEN – Open Patient data Explorative Network, Odense University Hospital, Department of Clinical Research, Odense, Denmark

**Background:** Physical activity is important for enhancing health and the World Health Organization (WHO) recommends that adults aged 18-64 engage in at least 150 minutes of moderate-intensity physical activity throughout the week, or 75 minutes of vigorous-intensity physical activity (1). Swedish patients with SLE reported a lower frequency and capacity of exercise than a control group, and in an Italian study, 60% of the SLE patients did not meet WHO’s recommendations for physical activity. Mental health is important for the individual’s level of physical activity, and symptoms of depression have been associated with a lower level of physical activity in SLE patients (2).

**Objectives:** The aim of this study is to describe the pattern of physical activity in a population of Danish SLE patients, and to investigate the association to depression.

**Methods:** The study was conducted at the Department of Rheumatology at Odense University Hospital, Denmark, in 2018 and 2019. Two questionnaires were handed out before routine outpatient consultation: self-reported physical activity was evaluated using the International Physical Activity Questionnaire (IPAQ), and a continuous variable on energy requirement in the form of the metabolic equivalent (MET) was calculated, and the Major Depression Inventory (MDI) questionnaire was used to screen for depression. Medicine intake was registered, and disease activity and damage were scored using SLEDAI-2K and SLICC/ACR DI.

**Results:** Two hundred and fifteen patients completed the IPAQ and MDI. 5 were excluded. The population consist of 89.5% women and the mean age was 51 ± 15.2 years. The mean disease duration was 16.1 ± 10.1 years. The SLE patients reported a mean total MET-score of 3319.9 ± 3650 MET-min/week. If divided into categories, 76% reported low level, 21.9% moderate and 70.5% of the patients reported a high level of physical activity and 89.5% fulfilled WHO recommendations. The participants reported 363.7 ± 201 minutes per day in sitting time. Mean MDI score was 12.7 ± 10.1, and if divided into groups, 89.5% were not depressed, 1.9% had a mild depression, 5.3% had a moderate depression and 2.9% had a severe depression. Significantly lower mean MET-scores were observed for the severely depressed patients.

An inverse association was found in the univariate analysis, indication that increasing disease duration and SLICC/ACR DI scores were significantly associated with decreasing total MET-scores. In the multivariate analysis time spent sitting was inversely associated with MET-score.

Our results were similar to a Brazilian study, where 68% of the patients reported that they were ‘physically active’ according to IPAQ. In contrast, only 22% of the patients in our Italian study reported high level physical activity. Our proportion of active patients were high when comparing with studies on patients with rheumatoid arthritis and spondylarthritides, where only 25-50% fulfilled the WHO recommendations compared to our 89.5%.

A Danish study on registered ICD diagnoses found a prevalence of depression in SLE patients to be 4.3%, which was lower than our prevalence. Foreign studies reported very diverse prevalences of depression, e.g. 16.6% in the Netherlands and 51% in Sweden.

**Conclusion:** A high portion of the SLE patients reported a high level of physical activity and 89.5% fulfilled the WHO recommendations. Significant predictors for a lower level of physical activity were increasing disease duration, higher SLICC/ACR DI score and longer time spent sitting. However, further studies are needed, where more suitable questionnaires could be considered.

**AB0452**

**PREDICTIVE FACTORS FOR INSUFFICIENT RESPONSE TO INITIAL TREATMENT OR RECURRENCE IN PATIENTS WITH LUPUS ENTERITIS**

Y. Yoshida, T. Sugimoto, H. Kohno, H. Watanabe, S. Mukota, S. Hirata, E. Sugiyama, Hiroshima University Hospital, Department of Clinical Immunology and Rheumatology, Hiroshima, Japan

**Background:** Lupus enteritis (LE) is a rare but well-known complication of systemic lupus erythematosus (SLE). However, little knowledge about risk factors for insufficient response to initial treatment or recurrence have been reported.

**Objectives:** To identify prognostic factors associated with poor response in patients with LE.

**Methods:** Patients diagnosed as having LE at our hospital were consecutively registered from January 2009 to October 2019. The diagnosis of LE was made according to the criteria of BILAG 2004 which is defined as either vasculitis or inflammation of small or large bowel with supportive imaging and/or biopsy findings. Poor response was defined as insufficient response to initial therapy or relapse. We retrospectively compared clinical characteristics collected from medical records of the patients with good vs. poor response, using a non-parametric Wilcoxon signed-rank test for numerical variables and Fisher’s exact test for categorical variables.

**Results:** A total of 12 patients (16 episodes) diagnosed with LE were reviewed. The median age was 44.5 years and 11 were females. Six patients had a history of SLE (median disease duration; 3.0 years), of which 4 had a history of LE prior to the study period. And in the remaining 6 patients, LE was the primary symptom (Table 1). The comorbidities were 4 lupus cystitis, 1 biopsy-proven lupus nephritis, 1 pseudo-obstruction and 1 protein-losing enteropathy. Computed Tomography (CT) imaging of all 16 episodes showed small bowel wall thickening. Dilatation of intestine was observed in 81.3%, ascites in 81.3%, comb sign in 80.0% and target sign in 62.5%. When comparing clinical characteristics between the groups revealed that CT findings were similar in both groups, however serum CH50 levels (median [interquartile ranges (IQR)] 37.2 [25.3-46.9] U/mL vs 176 [71-214] U/mL, p=0.0095) were significantly lower in poor response group. Furthermore, patients who initiated glucocorticoids (GCs) at a lower dose (less than or equal to 0.6mg/
kg prednisolone equivalent dose (PEQ)) was significantly more frequent in poor response group (Table 2).

CHARACTERISTIC ULTRASOUND FEATURES OF SALIVARY GLAND LYMPHOMA IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

S. Zhang1, Y. Liu1, D. Li1, W. Li1, J. Zhu1, 1Peking University People’s Hospital, Department of Ultrasound, Beijing, China

Background: Lymphoma was one of the most severe complications of primary Sjögren’s syndrome (pSS). Lymphomas often develop in organs where pSS is active, such as salivary glands. The enlargement of salivary glands is considered a predictive factor in previous studies. It is clarified that salivary gland ultrasound can visually and clearly demonstrate the parenchyma structure, which is a feasible method for SS diagnosis. However, there are no specific ultrasound features of salivary gland lymphoma and no early ultrasonic alarming system have been reported.

Objectives: To describe the characteristic ultrasound features and assess ultrasonic alarming value of salivary gland lymphoma in patients with pSS.

Methods: We followed a cohort of 63 patients with pSS from March 2017 to September 2019 and salivary gland ultrasound was performed every three months. All patients were examined by grey-scale and color Doppler ultrasound (US). The size, echostructure and vascularity of salivary glands were analyzed. US-guided core-needle biopsy (US-CNB) was used for the diagnosis of salivary gland lymphoma.

Results: In 63 patients with pSS, parotid enlargement occurred in 11 patients and none of them had submandibular gland enlargement. During the follow-up, 2 patients with parotid enlargement demonstrated recovery of size and echostructure improved. The remaining 9 patients had permanent parotid swelling and echostructure unchanged. US-CNB was performed in these 9 patients and histological and immunohistochemical findings of the cores suggested parotid lymphoma. Compared with other patients, these 9 patients revealed marked, permanent parotid enlargement of the unilateral or bilateral or asymmetric parotid. The parotid lymphoma ultrasonography was characterized by multiple, relatively large, well-demarcated hypoechoic (>6mm) with increased vascularity.

Conclusion: Ultrasonographic assessment of salivary gland helped to alarm the occurrence of lymphoma in pSS patients. Marked, permanent and asymmetric parotid enlargement with multiple, relatively large, well-demarcated hypoechoic in echostructure seemed to be characteristic for parotid lymphoma in pSS patients.

RESULTS:

In a case control study, we recruited 45 BD patients, who fulfilled the modified ITR-ICBD 2014 and psychiatric manifestations as cognitive impairment, depression and anxiety. IL-23/IL-17 axis has been shown to play a role in pathogenesis of BD, depression and anxiety. Pro-inflammatory cytokines have been reported to be elevated in patients with depression and anxiety. As the statistically significant risk factors, ESR (Beta=0.394, p=0.020) and serum MCP1 (Beta=0.325, p=0.043) stood out.

Vasculitis

ROLE OF CYTOKINES (INTERLEUKIN 17 AND 23) IN PSYCHIATRIC COMORBIDITIES ASSOCIATED WITH BECHET’S DISEASE

E. Abdelmohy1, M. Gaber2, R. Gabra3, E. Abd4, S. Rashad5. 1Assiut University Hospitals, Rheumatology, Rehabilitation and Physical Medicine, Asyut, Egypt; 2Medical Faculty, Assiut University, Biochemistry, Asyut, Egypt; 3Assiut University Hospitals, Psychiatry, Asyut, Egypt; 4Assiut University Hospitals, Physical Medicine, Rheumatology & Rehabilitation, Asyut, Egypt; 5Suiz University, Rheumatology and Rehabilitation, Suiz, Egypt

Background: Behcet’s disease (BD) is a chronic multi-systemic autoimmune disease associated with increase prevalence of psychiatric comorbidity. Pro-inflammatory cytokines have been reported to be elevated in patients with depression and anxiety. IL-23/IL-17 axis has been shown to play a remarkable role in pathogenesis of BD, depression and anxiety. However, the relation between the serum level of interleukin (IL)-17 and IL-23 and incidence of cognitive impairment, depression and anxiety in Behcet patients is still unknown.

Objectives: To evaluate the serum levels of IL-17 and IL-23 in Egyptian patients with BD and evaluate the correlations between the level of inflammatory cytokines and psychiatric manifestations as cognitive impairment, depression and anxiety.

Methods: Study design and recruitment

In a case control study, we recruited 45 BD patients, who fulfilled the modified International Criteria for Behcet’s Disease (ITR-ICBD 2014) from the Rheumatology and Rehabilitation Department, Assiut University hospital. Thirty apparently healthy sex and age matched subjects were recruited, served as controls. This study was approved by the Ethical Committee of the Assiut University, Egypt. Informed consent was obtained from all participants.

Study methodology

All patients and controls were assessed for cognitive impairment, depression and anxiety using memory assessment scale, Hamilton depression rating scale and Hamilton anxiety rating scale respectively.
Serum level of proinflammatory cytokines such as IL-17 and IL-23 were measured by enzyme-linked immunosorbent assay (ELIZA).

**Results:** Psychiatric manifestations

BD has significant lower score in all components of MAS and high prevalence of depression and anxiety in HDRS and HARS respectively compared with control group (p < 0.001). Severe depression was found in 82.9% of BD patients. Moreover, our data showed 46.7% of BD patients have moderate anxiety compared to the control group.

**Serum Levels of IL-17 and IL-23**

The serum level of IL-17 and IL-23 levels were significantly higher among BD patients than in healthy control (<0.000).

**Conclusion:** Elevated level of IL-17 and IL-23 were observed in BD patients. However, our results do not support an association between serum IL-17 and IL-23 levels and cognitive dysfunction, depression and anxiety.

MORTALITY OF RHEUMATOID VASCULITIS AGGRAVATED BY CLINICALLY LATENT TUBERCULOSIS – A RETROSPECTIVE CLINICOPATHOLOGIC STUDY OF 161 AUTOPSY PATIENTS

Á. Apáthy1, M. Bély2, 1St. Margaret Clinic, Department of Rheumatology, Budapest, Hungary; 2Hospital of the Order of the Brothers of Saint John of God, Department of Pathology, Budapest, Hungary

Background: Systemic vasculitis of autoimmune origin (e.g. rheumatoid vasculitis – RV) plays a pivotal role in the pathogenesis of rheumatoid arthritis (RA) [1]. RV may be characterized by non-specific inflammation (nsRV) or with or without fibrocaseous necrosis (fnRV) or by granulomatous transformation of blood vessels (grRV) [1]. The prevalence and mortality of tuberculosis (TB) is higher in rheumatoid arthritis (RA) than in the general population.

Objectives: The aim of this study was to assess the influence of dormant (inactive), clinically latent TB (with or without subclinical atypical miliary exacerbation) on the mortality of rheumatoid vasculitis.

Methods: At the National Institute of Rheumatology 9475 patients died between 1969 and 1992; among them 161 with RA and all of them were autopsied [1]. RA was confirmed clinically according to the criteria of the ARA.

Results: nsRV complicated RA in 33 (20.49%) of 161 patients, in combination with fnRV or grRV was diagnosed at autopsy, and confirmed by a detailed review of extensive histological material [1]. The prevalence fibrous (fTB), fibrocaseous (fcTB) or miliary TB (mTB) was diagnosed and characterized histologically, reviewing retrospectively the clinical and pathological reports [1].

From each patient a total of 50-100 tissue blocks of 12 organs (heart, lung, liver, kidneys, pancreas, gastrointestinal tract, adrenal glands, skeletal muscle, peripheral nerve, skin and brain) were studied microscopically.

The possible role of fTB, fcTB or mTB on the mortality due to nsRV, fnRV or grRV was analyzed with Pearson's chi-squared ($\chi^2$) test.

Post-primary TB was associated with RA in 21 (13.04%) of 161 patients, 12 (57.14% of 21) were fTB, and 9 (42.86% of 21) fcTB. One of 12 fTB and 5 of 9 fcTB were complicated with discrete miliary dissemination (mTB) in 6 (37.3% of 161; 28.57%) of 21 RA patients.

The fTB (n=12) was associated with fatal nsRV in 5, with fnRV in 3, with grRV in 3 of 21 cases.

The fcTB (n=9) was associated with fatal nsRV in 4, with fnRV in 2, with grRV in 3 of 9 cases.

There was a significant and positive correlation between fcTB and mortality of nsRV ($c: 0.76, \chi^2=9.7593, p=0.0017$), between fcTB and mortality of fnRV ($c: 0.80, \chi^2=6.5701, p=0.0103$), between fcTB and mortality of grRV ($c: 0.90, \chi^2=12.5835, p=0.00038$). The correlation was also positive and significant between mTB and mortality of nsRV ($c: 0.79, \chi^2=5.4306, p=0.0208$), between mTB and mortality of grRV ($c: 0.95, \chi^2=20.8706, p=0.000049$).

The relationships were not significant between fTB or mTB and mortality of nsRV, fnRV or grRV.

Abbreviations: COLCH: Colchicine; OCS: Oral Corticosteroids; IS: Immunosuppressants; AZA: Azathioprine; MTX: Methotrexate; CYA: Cyclosporine A; MMF: Mycophenolate Mofetil; TLD: Taldomide; APR: Apremilast; DAP: Dapson; BT: Biological Therapy; ADA: Adalimumab; IFX: Infliximab; ETN: Etanercept; TCZ: Tocilizumab

DOI: 10.1136/annrheumdis-2020-eular.5005
Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are closely related inflammatory conditions affecting people aged over 50 years.

Objectives: We present our experience of using tocilizumab (TCZ) therapy for management of GCA/PMR aggravated by severe concurrent pathologies that potentially increase the risk of side effects of glucocorticoids (GCs).

Methods: 22 patients were recruited into the prospective study: six patients with GCA, 13–PMR, and three–both GCA and PMR. 95.5% were females, mean age 72.8±6.5 years. Mean disease duration was 3.5 (0.5-19) months. All patients had active GCA/PMR with mean CRP 30.3±32.7 mg/l. Seven patients had visual ischemic complications, and another one–aortitis. All patients had serious comorbidities, 59% of patients had three and more severe concurrent diseases. All patients were administered TCZ i/v 2.3-8.8 mg/kg Q4W. 50% patients were also treated with prednisone at mean 20 (10-70) mg/day. The follow-up period was 24 (6-60) months.

Results: All patients demonstrated good clinical response to TCZ i/v 2.3-8.8 mg/kg Q4W given for average 4.5 (2-11) months, achieving remission in 100% of cases. Some patients showed a very rapid improvement after initiation of treatment, including TCZ monotherapy. Prednisone dose was discontinued in 6/11, or was reduced to 2.5 (2.5-10) mg in 4/11. There was one relapse after TCZ discontinuation, although this patient managed to regain the remission after resumption of TCZ i/v 4 mg/kg. There was one (4.6%) serious complication (septic olecranon bursitis 1 month after TCZ discontinuation), one patient died of myocardial infarction 12 months later after TCZ discontinuation. Three remaining complications included one case of peripheral artery disease (claudication), one–psoriasis, and one–sural lipodermatosclerosis.

Conclusion: Interleukin-6 inhibitors should be considered as potentially effective and relatively safe treatment for GCA/PMR patients with serious comorbidities, intolerance or contraindications to standard therapy. More data is necessary to identify the optimal dosing regimen and duration of TCZ therapy, as well as cost-effectiveness aspects.

ANCA-ASSOCIATED VASCULITIS: CLINICAL FEATURES, RELAPSE, ORGAN DAMAGE AND SURVIVAL IN 197 PATIENTS

M. Bektaş1, B. Ince1, B. F. Argürün2, D. Y. Güzey3, Y. Yalçınkaya1, A. Artım-Eisen1, A. Gül1, M. L. Ocal1, M. Inanc1. 1Istanbul Faculty of Medicine, Internal Medicine, Rheumatology Division, Istanbul, Turkey; 2Istanbul Faculty of Medicine, Internal Medicine, Istanbul, Turkey; 3Istanbul Faculty of Medicine, Istanbul, Turkey.

Background: ANCA-associated vasculitides (AAV) is a multisystemic autoimmune disease with high mortality and morbidity.

Objectives: We aimed to present the long-term follow-up results of our cohort.

Methods: Data of patients who fulfilled Chapel Hill Consensus Criteria and followed up at least 6 months between 1999-2019 were analyzed. A standard form including vasculitis damage index (VDI) was used. Multivariable analysis was performed by using logistic regression.

Results: Long-term data was available for 197 patients (%53.8 female) from 208 patient records. Mean age at diagnosis was 49.4 years and mean follow-up was 80.7 months. Granulomatous with polyangiitis (GPA); microscopic polyangiitis (MPA), eosinophilic GPA (EGPA) were 117 (64.5%), 52 (26.4%), 17 (8.6%), respectively. Relapses are observed in 31.6% of patients. Disease relapses were higher in GPA compared to MPA and EGPA (p = 0.014). Relapse rate was higher in patients with S. aureus carriage (p = 0.037). Cyclophosphamide (CYC) (78.6%) was most commonly used drug for induction, whereas azathioprine (57.3%) was used mostly in maintenance. In multivariate analysis relapse was found to be associated with maintenance treatment with rituximab (p <0.001), venous thrombosis (p=0.046) and serious infection (p<0.004). There was no significant association between relapse and mortality. Five-year survival rates were 98.5% for GPA, 88.5% for MPA and 100% for EGPA. Nineteen patients died during follow-up (9.6%). In univariate analysis mortality was high in MPA patients. Low hemoglobin and increased creatinine at baseline, subclinical stenosis, polynuropathy, and cerebrovascular events (CVE) were associated with increased mortality. In multivariable analysis, mortality was associated with CVE (p=0.047) and anti-MPO positivity (p=0.014). Malignancy was developed in 9 patients (M / F: 7/2); three lung, three bladder, one cervix, one thyroid papillary, one kidney and one of unknown primary). There was no association between malignancy and cumulative dose of CYC. Venous thromboembolism was developed in 12 (6 %) and atherosclerotic AVN (AVN) was detected in 30 patients (15.4%). Most (88.7%) patients developed damage during follow-up. Mean VDI score was 2.6 and VDI score was found to be higher in GPA (p = 0.035). There was no association between VDI score and mortality.

Conclusion: In our AAV cohort, GPA was most frequent. Although survival was improved, permanent organ damage was detected in the majority of patients. Relapse and organ damage were found to be increased in patients with GPA. Relapses are frequent and maintenance with rituximab could not prevent relapses. Also relapses were associated with venous thrombosis and severe infections. Patients should be screened for malignancies especially of the genitourinary tract.

BEHCET’S DISEASE: CLINICAL FEATURES AND OFF-LABEL BIOLOGIC TREATMENT STRATEGIES

E. Bello1, S. Mont1,2, S. Balduzzi1, P. Delvino1, A. Biglia1, C. Montecucco1. 1IRCCS Policlinico S. Matteo Foundation, University of Pavia, Rheumatology, Pavia, Italy; 2University of Pavia, PhD in Experimental Medicine, Pavia, Italy

Background: The treatment of Behçet’s disease (BD) is still mainly based on the evidence derived from case reports, case series, retrospective analyses, and few clinical trials suggesting the safety and potential efficacy of off-label use of biologic agents in refractory cases.

Objectives: To describe clinical manifestations and their management, with particular focus on treatment indications, outcomes and safety of biologic therapy, in a cohort of patients with BD.
Methods: Patients with a diagnosis of BD who visited our outpatient clinic until December 2019 were included in the study. Clinical data were recorded since diagnosis until the latest follow-up visit, analyzing clinical features, flares and therapeutic strategies adopted.

Results: A total of 95 patients were included in the study with a medium follow-up of 108.54 ± 169.59 months. 20 of them (21.05%) were treated with biologic agents. Patients treated with biologic therapy compared to those on conventional non-biologic therapies had a higher proportion of musculoskeletal involvement (80% vs 46.67%, \( p = 0.008 \)), neurological (30% vs 10.67%, \( p = 0.031 \)), intestinal involvement (40% vs 12%, \( p = 0.004 \)), and they were treated with a higher dose of glucocorticoids at diagnosis (16.84 mg ±14.01 vs 8.89 mg ± 11.76, \( p = 0.012 \)). The most frequent indications for biologic step-up therapy were musculoskeletal involvement (40%), eye involvement (25%), neurological involvement (15%) and intestinal involvement (10%). Most patients initiated a biologic treatment within the first year of follow-up. TNF-inhibitor (TNFi) were more frequently prescribed (95%) and one patient was treated with 8 therapeutic cycles of Rituximab (50%), followed by adalimumab (40%) and etanercept (5%). As second line treatment were also prescribed certolizumab (10%) and golimumab (5%). 10 patients switched to a second line treatment because of inefficacy of the first biologic agent, mainly because of refractory arthritis, intestinal and mucocutaneous involvement. One patient switched from infliximab to certolizumab during pregnancy with subsequent worsening of arthritis. 85% of patients treated with biologic agents reached a clinical remission by the time of the latest follow up visit without any safety or tolerability issues.

Conclusion: A relevant proportion of patients in our BD cohort were treated with biologic therapy, because of severe or refractory manifestations. The most frequent indications were musculoskeletal, neurological or intestinal involvement. Biologic agents were a generally effective and safe therapeutic approach.

ANALYSIS OF VASCULITIS PATTERNS IN PATIENTS WITH GIANT CELL ARTERITIS COMPARED TO PATIENTS WITH GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA

L. C. Burs1, P. Brossart2, C. Behning3, V. S. Schäfer4. 1Clinic for Internal Medicine III, University Hospital Bonn, Rheumatology, Bonn, Germany; 2Clinic for Internal Medicine III, University Hospital Bonn, Oncology, Haematology and Rheumatology, Bonn, Germany; 3University Hospital Bonn, Institute for Medical Biometry, Informatics and Epidemiology, Bonn, Germany

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) often coexist.1 The role of modern ultrasound in diagnosis of GCA as well as PMR is well known.2 To date it is unknown, whether patients with GCA and PMR have a different vasculitis pattern in ultrasound (US) examination than patients with GCA only.

Objectives: To prospectively identify differences in vasculitis patterns in consecutive patients with newly diagnosed GCA and PMR compared to newly diagnosed GCA patients without PMR.

Methods: US examination of the arteries typically affected in GCA, such as axillary arteries, vertebral arteries, superficial temporal arteries with both frontal and parietal branches and facial arteries was performed in patients with GCA and PMR (GCA-PMR-group) as well as in patients with GCA only (GCA-group) at time of first diagnosis. Arteries were defined as pathological, if measured intima-media-thickness by US was above respective cut-off values.3

Results: The GCA-PMR-group consisted of 27 patients, the GCA-group of 18 patients. In the GCA-PMR-group, a total of 206 arteries were affected, while in the GCA-group 131 arteries were affected. Mean age and gender distribution was 74 years (SD 9) with 10 (37%) females in the GCA-PMR-group and 76 years (SD 7) with 10 (55%) females in the GCA-group. Median values of C-reactive protein (CRP) were 57.2 (IQR 31.7–75.7) in the GCA-group and 48.3 (IQR 17.5–74) in the GCA-PMR-group. At baseline, mean age was 43.8±14.4 years and mean disease duration 95.5±6.1 months. Two patients were GCA-PMR-naive. Mean IMT values for all measured arteries are depicted in table 1.

PMR-GCA-group: patients with diagnosis of giant cell arteritis and consecutive polymyalgia rheumatica
GCA-group: patients with diagnosis of giant cell arteritis only

protein (CRP) were 57.2 (IQR 31.7–75.7) in the GCA-group and 48.3 (IQR 17.5–75.9) in the GCA-PMR-group, no significance was observed (p=0.367). Mean number of affected arteries per patient was 763 and 728 in the GCA-PMR-group and GCA-group, respectively. Altogether, no significant difference in vascular pattern between the two groups was observed. Exact numbers, distribution and IMT-values for all measured arteries are depicted in table 1.

Conclusion: In our cohort, we did not observe a significant difference in vascular patterns between patients with GCA and PMR and GCA only patients.

Efficacy and Safety of Infliximab-Biosimilar in Takayasu Arteritis (Takasim): A Monocentric, Observational, Prospective, Open-Label Study

C. Campanchi1, A. Tomelleri1, S. Sartorelli2, G. De Luca1, C. Sembenini1, G. Cavalli1, P. Mapelli1, M. Picchio1, M. Papa2, E. Baldissera1, L. Dagna1. 1San Raffaele Scientific Institute - Vita-Salute San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (Unimar), Milan, Italy; 2San Raffaele Scientific Institute - Vita-Salute San Raffaele, Unit of Nuclear Medicine, Milan, Italy

Background: Treatment of Takayasu arteritis (TA) is mainly based on steroids, but, in approximately 50% of patients, disease-modifying antirheumatic drugs (DMARDs) are required.

Objectives: To evaluate efficacy and safety of IFX-biosimilar in TA patients.

Methods: Both bDMARD-naive and IFX-O treated patients were eligible. Primary endpoint was the number of patients with active disease as assessed by magnetic resonance angiography (MRA), 18FDG PET/CT, ITAS2010 and ITAS-ESR/CRP at month 6. Secondary endpoints were safety and tolerability, number of patients with active disease at month 12, quality of life. Non-parametric statistical tests were used.

Results: Twenty-three patients (21 female) were recruited. At baseline, mean age was 43.8±14.4 years and mean disease duration 95.5±6.1 months. Two patients were IFX-O-naive. Mean time on IFX-O was 51.5±37.9 months. Four patients had been previously treated with other biologics (tocilizumab, 3; adalimumab, 1). Twenty-one patients (91.3%) were on concomitant steroids (mean dose, 4.8±2.0mg daily) and 82% on concomitant csDMARDs kept unchanged throughout the study. At baseline, 4 patients (17%) were classified as active according to ITAS2010, ITAS-ESR, and ITAS-CP; mean HAQ was 3.48±5.26. Over the study period two patients dropped out the study because of poor disease control (1 at month 3 and 1 at month 6). PET/CT was not available for one patient who was on lactation during the study period and 1 patient refused to undergo imaging re-evaluation. At month 6, MRA was available for 21 patients: it was stable in 11 (52%), improved in 5 (24%), worsened in 5 (24%). PET/CT was available for 20 patients: it was negative in 12 (65%), improved although still positive in 3 (16%), stable in 1 (5%), worsened in 1 (5%). At month 6, among 22 patients, 4 (18%) were clinically active according to ITAS2010, ITAS-ESR and ITAS-CP; mean steroid dose was significantly lower compared to baseline (3.4±2.56 mg daily, p=0.034); HAQ didn’t significantly change (mean, 3.84±6.34, p=0.919). Nine patients (39%) experienced low-grade side effects related to TNFα-blockade (6, herpes reactivation; 3, urinary tract infection; 1 gastroenteritis). No IFX-B therapy modification was required.

Conclusion: Our study suggests that IFX-B is effective and safe both in IFX-O switch and IFX-O naïve TA patients.

Remission and Low Disease Activity State in Patients with Granulomatosis with Polyangiitis and Microscopic Polyangiitis: Prevalence and Impact on Damage Accrual

P. Delvin1, F. Sardanelli2, S. Monti1,3, P. Cohen4, X. Puéchal4, C. Montecucco1, L. Mouton5,6, L. Guévelin5,6, B. Terrier1. 1on behalf of French Vasculitis Study Group (FVSG); 2IRCCS Policlinico S. Matteo Foundation, University of Pavia, Italy
Results: 167 patients were included: 128 (76.6%) GPA, mean age 51.0±16.7 years. At 5-years, mean VDI was 2.7±2.0, mainly because of AAV-related items (2.0±1.7) rather than treatment-related items (0.7±1.0). During the 5-year follow-up, 10 (6.0%) patients achieved prolonged CR, 6 (3.6%) prolonged clinical remission off therapy, 89 (53.3%) prolonged clinical remission on therapy, 42 (25.1%) prolonged LDAS or those never achieved LDAS versus 2.3±1.9, 3.5±2.0 and 3.3±2.0, respectively (P=0.0001). Damage was comparable between patients in prolonged remission off therapy and those in remission on therapy (P=0.3). In contrast, patients in prolonged LDAS or those never in LDAS had significantly more damage accrual (P=0.0001 and P=0.01, respectively) than those in prolonged remission off therapy. Eighty-one patients (49%) reached a VDI ≥3 at 5-years. The inability to achieve prolonged remission was associated with a VDI ≥3 at 5-years (OR 5.07, 95% CI 2.53-9.84, P<0.0001), and considering only prolonged CR or clinical remission off therapy did not had any benefit on damage accrual. In contrast, achieving prolonged LDAS had no benefit compared to spending no time in LDAS (P=0.99). Compared to patients achieving prolonged remission, those not able to achieve prolonged remission were younger (46±16.0 vs. 53.5±16.6, P=0.001), had more frequent GPA (P=0.0003), had more PR3-ANCA (P=0.008), had more ENT and lung involvement (P=0.0001 and P=0.036, respectively). Conclusion: Sixty percent of GPA and MPA patients achieved prolonged remis- sion, which was associated with a better outcome in terms of damage accrual. In contrast, prolonged LDAS was associated with increased damage and was not a sufficient target to achieve in GPA and MPA.

AB0468 AGE RELATED DIFFERENCES IN PATIENTS WITH GIANT CELL ARTERITIS

P. Dieguez Pena1, B. Gimena Reyes1, B. Maure Noia1, A. Argibay1, C. Vázquez Tríñanes1, A. J. Rivera Gallego1, A. Sousa Dominguez2, M. Estevez1, 1Complejo Hospitalario Universitario de Vigo, Vigo, Spain

Background: Few data are available on the epidemiology and management of giant cell arteritis (GCA) in patients over 75 years despite the progressive aging in our societies. In other diseases this subgroup of patients presents important differences in the management and prognosis of their pathologies.

Objectives: To explore this situation by comparing two subgroups of patients, older and younger than 75, assessing possible changes in demographic character- istics, diagnostic tests, treatment and outcome.

Methods: We perform a retrospective review of charts, laboratory data, image studies, treatment and outcome of biopsy-proven GCA in our institution (Complejo Hos- pitalario Universitario de Vigo) between 1 January 2000 and 30 November 2019.

Results: During study period 124 patients were analysed, 51 in the subgroup of <75 (mean age 64.6 (56-75)) and 73 in the subgroup of ≥75 (mean age 81.8 (76- 88)). There were no differences about sex (female 76.6% vs. 65%) or in the Charlsson index between the two groups (0-1 in 72% of patients). Older patients present more frequently with headache (49.2% vs 32.3%), polymyalgia rheumatica (53.4% vs 45.1%), weight loss (48% vs 39.2%) and ischaemic manifestations (72.6% vs 51%), including visual disturbances (26% vs 11%). Younger patients present more frequently with fever (33.3% vs 19.2%). Median ESR was similar: 98 vs 96 mm/h; median CPR was slightly higher in younger patients 94.5mg/dL vs 71.5mg/dL.

PET-TC was performed more frequently at diagnosis in the subgroup of younger patients (29.4% vs 12.3%) and during follow-up period in the other subgroup (3.4% vs 7%) with evidence of involvement of large vessels in 14 of them. Initial treatment consisted of corticosteroids in 100% of patients with the most frequent relapse rate in both groups, between 40-60mg/day of prednisone or equivalent. The subgroup of < 75 were treated more aggressively receiving pulses of methylprednisolone (125-250 mg) 12 patients (23.5%); while in the subgroup >75 lower doses were started more fre- quently (<40mg/day in 21 patients, 28.7%). Lowering corticosteroids to <5mg/day were slower in the subgroup of patients <75 (47.1% within the first 12 months) with respect to the >75 (56%). During the follow-up period 47 patients had at least one relapse, we did not observe statistical differences between both groups (21 patients <75 and 26 patients >75). Time to first relapse was more frequent within the first year of treatment (12 and 16 patients respectively). We could not identify any factor related to relapses in our multivariate analysis. There was no significant differences between both groups about starting MTX (33.3% and 38%) on relapses. Only two patients started TCZ (one in each group). Twenty-nine patients died during follow-up period (11.7% in <75 vs. 31.5% in >75), but none were related with GCA.

Conclusion: 1. No differences were observed in sex, comorbidities (including cardiovascular risk factors) or laboratory markers between both groups. 2. Younger patients presented with less frequent ischaemic symptoms; however we perform a more powerful treatment, both in doses and duration.

AB0469 CLINICAL DISEASE MIGHT BE DIVIDED INTO TWO PHENOTYPES IN ANCA ASSOCIATED VASCULITIS: RESULTS OF A CLUSTER ANALYSIS

E. Durak Ediboglu1, Ö. Gerçik1, E. Bilgin2, D. Solmaz1, I. Ocal1, Z. Soypacaci1, H. Cinakil1, A. Saglam1, S. Kiraz1, O. Karaday1, S. Akar1, Izmir Katip Celebi, Izmir, Turkey; 2Hacettepe, Ankara, Turkey

Background: One of the controversial matters in ANCA associated vasculitis is the definition of disease based on clinical characteristics since there is remarkable overlap between disease groups. For instance, single organ disease like renal lim- ited vasculitis (RLV) is not take place most of the definitions or classification criteria.

Objectives: The aim of this study to determine clinical subgroups that may incor- porate different clinical phenotypes including RLV in AAV patients followed up in two tertiary centers.

Methods: Baseline clinical characteristics of AAV patients were studied. To analyse our data and identify sub-groups of AAV patients with similar clinical character- istics, a two-step cluster analysis using log-likelihood distance measures was performed. For clustering we evaluated the following variables: gender, age at symptom onset, the presence of major organ involvement (renal, upper and lower respiratory tract, skin, joint, eye) and ANCA specificity.

Results: In total 165 (87 [%]) male, age at diagnosis 51.6 ±15.2 years) out of 238 (126 [%] male, age at diagnosis 51.3 ±15.8 years) AAV patients included in the analysis included of the demographic and clinical characteristics were summarized in the table 1. There are two distinct cluster in AAV patients. Of 78% those AAV patients with MPO/pANCA, 56% with renal involvement and 89% without ENT involvement were in Cluster 1. Of 77% those patients with PR3/ANCA, 89% with arthritis, 74% with eye involvement, 83% with skin, 91% with upper, and 60% with lower respira- tory tract involvement and 92% of those without renal disease were in Cluster 2. Most of the (89%) patients classified as MPA and all as RLV were repositioned in Cluster 1 and 74% of GPA and 64% of EGPA patients were in Cluster 2.

AB0470 EosiNophilic Granulomatosis with Polyangiitis (EGPA) - one-year Follow-up study using Mepolizumab anti-IL5 therapy as a Steroid sparing Therapeutic approach

A. Egan1, P. Sivasothy1, R. Gore1, M. Martinez Del-Pero1, C. Owen3, L. Wilcocks1, R. Smith1, S. Burns1, D. Jayne4, 1Addenbrooke’s Hospital, The Vasculitis and Lupus Centre, Cambridge, United Kingdom; 2Addenbrooke’s Hospital, Respiratory Medicine, Cambridge, United Kingdom; 3Addenbrooke’s Hospital, Respiratory medicine, Cambridge, United Kingdom; 4Addenbrooke’s Hospital, University of Cambridge, The Vasculitis and Lupus Centre, Cambridge, United Kingdom

Background: EGPA is a small vessel vasculitis characterised by the presence of tissue eosinophilia, necrotising vasculitis and granulomatous inflammation1. Typically, a prodromal asthmatic phase, leads to an eosinophilic stage, which can evolve to include the presence of vasculitis with renal manifestations. In the recent randomised, placebo-controlled MIRRA trial for relapsing and refractory EGPA, adjuvant therapy with anti-IL5 mAB Mepolizumab [MEPO] at 300mg s/c monthly, accrued longer times in remission, reduced steroid exposure and reduced relapse rates2.

Objectives: The aim of our study was to analyse the response and outcome for EGPA patients who received 100mg s/c of MEPO monthly for a minimum of 52 weeks, with particular focus on the steroid minimisation benefits.

Methods: This retrospective, descriptive study analysed 13 patients with EGPA, who received 100mg s/m monthly MEPO therapy under the eosinophilic asthma care-pathway. Time points of assessment included MEPO commencement (M0) and 12 (M12) months.

Results:

Response to therapy M0 [%] Post M12 [%]
Prednisolone dose N= 13 Mean ±SD 18.525 ±11.4 10.575mg ± 5.85
Eosinophil count X107/L N=13 Mean ±SD 0.415mg ±0.25 0.25 0.035x0.039
Asthma Control Questionnaire (ACQ) N=5 Mean ±SD 2.92 ±1.27 1.31 ±0.79
BVAS N= 13 Mean ±SD 7.307 ±6.29 2.2307 ±1.69
Creatinine N=9 Mean ±SD 68.44±15.03 69.11±17.84
Continuation of anti-IL5 therapy N=13 12/13 [92.3%]

Conclusion: The relapsing nature of EGPA places a potential dependency of therapy on steroids for asthmatic and vasculitic flares. This underscores the importance of targeted pathway specific biologic therapy to minimise steroid exposure, prevent tissue damage and ensure early response to therapy. This study demonstrates that anti-IL5 serves as a favourable model with steroid minimisation, improvement in asthma control questionnaire, reduction in BVAS and eosinophil counts at the 100mg s/c dosage. ANCA positive serology normalised in all four patients, independent of subtype. Well tolerated, it demonstrated considerable clinical benefit, with 12 patients [92.3%] continuing anti-IL5 therapy beyond 12 months.

**AB0471** ELEVATED EXPRESSION OF PYRUVATE KINASE M2 IN GIANT CELL ARTERITIS

I. Esen1, Y. Van Sleen1, P. Heeringa2, A. Boots1, E. Brouwer1. 
1University of Groningen, University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University of Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands

**Background:** Giant Cell Arteritis (GCA) is an inflammatory disease of large and medium vessels. In GCA, expression of interleukin-6 (IL-6), a systemic marker of inflammation, is elevated and it has been shown that treatment with IL-6 receptor blockade (Tocilizumab) is beneficial for GCA patients.1 To investigate the role of the IL-6 signaling pathway in GCA pathogenesis in more depth, we focused on the metabolite enzyme Pyruvate Kinase M2 (PKM2). PKM2 may exist as a tetramer, a dimer and/or a monomer in the cell. Tetrameric PKM2 acts as a glycolytic enzyme and catalyzes the last steps of glycolysis by converting phospho-enolpyruvate (PEP) to pyruvate and ATP. On the other hand, dimeric PKM2 translocates to the nucleus and mediates gene regulation via its non-canonical protein kinase activity. Dimeric PKM2 regulates hypoxia, IL-6 expression and phosphorylates signal transducer and activator of transcription 3 (STAT3) which functions downstream of the IL-6 signaling pathway.2

**Objectives:** To investigate the role of PKM2 in GCA diagnosis and pathogenesis.

**Methods:** Immunohistochemical staining for PKM2 was performed on infiltrated (n=8) and non-infiltrated (n=4) temporal artery biopsies (TAB) from GCA patients and on TAB from non-GCA (n=9) patients. To detect soluble, dimeric PKM2 in plasma commercially available dimeric PKM2 specific ELISA kit was used. To determine the modulation of dimeric PKM2 by treatment, samples of GCA patients at baseline (n=44), at 6 weeks (n=32) and at 1 year (n=31) after treatment were compared to samples from age- and sex-matched healthy controls (HC, n=45) as a positive control, samples from melanoma patients (n =8) were used. To investigate the role of dimeric PKM2 in the pathogenesis of GCA, we correlated PKM2 plasma levels with markers of inflammation (CRP, IL-6) and markers of angiogenesis (AngII, VEGF, YKL40). Statistical analysis included the Mann-Whitney U test for comparing different groups while the Wilcoxon rank test was used for paired samples. Correlations were assessed by Spearman's rank correlation coefficient.

**Results:** High expression of PKM2 was found in infiltrated and non-infiltrated TABs of GCA patients, while in non-GCA TABs PKM2 was sparsely expressed. Circulating levels of dimeric PKM2 were found elevated in melanoma and in GCA patients. Circulating baseline dative disease compared to those in healthy controls. Analysis of 6 weeks and 1 year follow up plasma samples showed that plasma levels of dimeric PKM2 significantly decreased upon treatment. Dimeric PKM2 weakly correlated with CRP at baseline (r=0.399, p=0.048) but not with angiogenesis markers.

**Conclusion:** Dimeric PKM2 plasma levels were found elevated in GCA patients at baseline. PKM2 plasma levels were down modulated by treatment. PKM2 plasma levels weakly correlated with inflammation marker CRP. The data suggest that PKM2 as a marker of glycolysis may have relevance in GCA at diagnosis and for monitoring disease activity. Future studies should aim to validate PKM2 in an independent cohort. Additional studies are needed to determine the molecular mechanism underlying the increase in elevated dimeric PKM2 levels and how this may contribute to IL-6 signaling.

**AB0472** INFECTIOUS PROFILE IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS: RETROSPECTIVE ANALYSIS IN A REFERRAL CENTRE

M. Estévez Gil1, B. Maure2, A. Argibay2, C. Vazquez-Trínanes2, B. Gimena2, A. Rivera1. 
1Systemic Autoimmune diseases and Thrombosis Unit, University Hospital Complex of Vigo, Vigo, Spain

**Background:** The antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are rare multisystem autoimmune diseases of unknown cause, characterised by inflammatory cell infiltration causing necrosis of blood vessels. The treatment of AAV requires prolonged immunosuppressive therapy. Infections remain a major cause of morbidity and mortality.

**Objectives:** The aim of our study was to investigate the prevalence and characteristics of infection, and analyse the factors associated with infection in patients with AAV from Northern of Spain.

**Methods:** Retrospective, descriptive study of patients with AAV followed in a specific Systemic Autoimmune Diseases and Thrombosis Unit from January 2000 to December 2019. Demographic, laboratory, microbiology, treatment and clinical data were collected from the medical records. AAV was diagnosed according to the definitions of the Chapel Hill nomenclature and designated as granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyan- giitis (EGPA), microscopic polyangiitis (MPA) or pauci-immune necrotizing and/or crescentic glomerulonephritis without systemic vasculitis (renal-limited vasculitis, RLV), Disease activity of AAV was evaluated by Birmingham Vasculitis Activity score (BVAS). The infection episode was considered on the basis of clinical, laboratory, microbiology, radiology information, and response to therapy.

Different episodes of infection in one patient were independently reflected. Data were analysed using SPSS 20.

**Results:** Thirty-six patients of which 20 (55.6%) were males. Median follow-up was 42 months. The mean age at the diagnosis was 61.14 ± 17.49 years and mean BVAS was 18.81 ± 5.96. 15 patients were diagnosed of GPA, 13 of MPA, 5 of EGPA and 3 of RLV. 72.2% MPO, 11.1% PR3. Lung involvement occurred in 27% of patients, upper airways was detected in 41.7%, skin involvement in 16.7%, Neur-ous system affection occurred in 33.3%. 30 patients (83.3%) had renal affection with a mean of 1.93± 1.68 grid of Proteinuria and 2.9±± 1.7mg/dl of creatinine. We detected hypocomplementemia in 27.8% of patients (C3 in 19.4% and C4 in 16.7%). Regarding induction treatments, all patients received corticoids at high doses, 21 (58.3%) Cyclophosphamide, 3 (20%) Rituximab and 2 (13.3%) patients, Azathioprine. When we analyse infections, we detected 15 patients (41.6%) who presented any infection after the diagnosis of AAV, with a total of 71 episodes of infection. The most frequent were bacterial infections (29 episodes), specifically gram negative pathogens. The most frequent location was the respiratory (56.3%) followed by urinary (22.5%) and Skin (8.5%). Also opportunistic infections were described: 3 patients with Aspergillus fumigatus and one patient with Cryptococcus neoformans. 41 of these episodes needed hospitalisation with a median stay of 11 days. 6 episodes warranted intensive care unit (ICU) admission. Infection related mortality was 2.82%. We made latent tuberculosis screening and Pneumocystis prophylaxis in all our patients. No cases of Tuberculosis or Pneumocystis were recorded. Factors associated with increased risk of hospitalisation with statistical significance in univariated study were MPA, Hypocomplementemia and increased BVAS. But in the logistical regression study, only the value of the BVAS maintained significance. The only factor associated with elevated risk of ICU admis- sion was IgG deficit in the multivariate analysis. Neither immunosuppressive ther- apy nor age was associated with increased risk of infection in our study.

**Conclusion:** More than 50% of the episodes of infection needed hospitalisation in patients with AAV. Risk factors for hospitalisation and ICU admission were BVAS and IgG deficit respectively. Bacterial infections were the most frequent but fungal infections were the most severe.

**AB0473** “HALO SIGN” IN ULTRASOUND OF TEMPORAL, FACIAL AND AXILLARY ARTERIES: ASSOCIATIONS WITH CLINICAL SYMPTOMATOLOGY AND LABORATORY FINDINGS

G. Evangelatos1, G. E. Fragoulis2, A. Iliopoulos2, 1417 Army Share Fund Hospital (NIMITS), Rheumatology Department, Athens, Greece; 2National and Kaposidian University of Athens, First Department of Propaedeutic Internal Medicine, Athens, Greece

**Background:** Giant cell arteritis (GCA) has two subtypes, the cranial form (“cran- nial GCA”) and the large- vessel form (“LV-GCA”). GCA can present with “cranial” symptoms (headache, visual symptoms, jaw claudication, scalp tenderness), constitutional symptoms (fever, fatigue), limb claudication and symptoms of poly- myalgia rheumatica (PMR) and usually causes increased inflammation markers, anemia and thrombocytosis. Ultrasound (US) of the temporal and axillary arteries
has a well-established role in cranial GCA and LV-GCA diagnosis, respectively. However, it is unknown whether specific clinical and laboratory parameters are linked with US findings suggestive of vascular inflammation (‘halo’ sign).

Objectives: The aim of this study was to examine possible association between clinical and laboratory characteristics of the patients and detection of vessel wall inflammation in the US.

Methods: Patients ≥50 years old with elevated ESR (≥50mm/h) and/or CRP (≥10mg/L) that presented in our outpatient rheumatology clinics from July 2017 to December 2019 with possible clinical diagnosis of GCA were included. Three groups were compared: Patients with “cranial symptoms” (or without PMR), patients with PMR symptoms only and patients with increased inflammation markers without specific symptoms indicative of GCA. Temporal arteries and their main branches, as well as facial and axillary arteries were evaluated by US bilaterally for the presence of non-compressible ‘halo sign’ at the vessel wall. Clinical symptomatology and the occurrence of anaemia and thrombocytosis were recorded.

Results: 52 patients were included. 71.2% were females, with a mean±SD age of 71±10.0 years. 17 patients had “cranial symptoms” (seven patients with concomitant PMR and ten without). 17 patients had PMR symptoms only, while 18 patients had non-specific symptoms (e.g. fever) (Table 1). Among 17 patients with “cranial symptoms”, 7/7 (100%) with concomitant PMR had a positive temporal US, while only 3 out of 10 (30%) without PMR had a positive temporal US (p=0.01) and US was indeterminate in 2 of them (20%). Collectively, 10/17 (58.8%) of patients with “cranial symptoms” and systemic inflammation had a US examination compatible with GCA. No patient with “cranial symptoms” had a positive US of axillary arteries. No patient with only PMR symptoms, had “halo sign” in temporal and facial arteries, while 3 out of 17 (17.6%) had a positive axillary US. From the 18 patients with elevated ESR/CRP, one had a positive temporal US and another one had a positive axillary US. Regarding specific symptoms, positive temporal US was associated with new headache (p=0.003), vision impairment (p=0.001), jaw claudication (p=0.05), scalp tenderness (p=0.01) and fever (p=0.002), but not with PMR (p=0.317). Thrombocytosis was associated with an increased risk for “halo sign” detection in temporal (p=0.04) and facial (p=0.007) arteries, but not in axillary arteries (p=0.52).

Table 1. Symptomatology and ultrasound findings in the patients examined.

<table>

</tbody>
</table>

Conclusion: 60% of patients with “cranial symptoms” and elevated inflammation markers have US temporal findings indicative of GCA. This is more pronounced in patients with concomitant PMR symptoms and is associated with specific symptomatology. 18% of patients with only PMR symptoms might have LV-GCA, while those with high ESR/CRP without GCA-related symptoms rarely have “halo sign” in US.

CLINICAL RELEVANCE OF CLINICOPATHOLOGICAL PHENOTYPE AND ANTIBODY SPECIFICITY IN ANCA-ASSOCIATED VASCULITIS

J. Fernandes Serdio1,2, S. Prieto-González1, G. Espigol-Frigolé1, M. Alba1, J. Marco-Hernández2, M. C. Cid1, J. Hernández-Rodríguez1. 1Vasculitis Research Unit, Department of Systemic Autoimmune Diseases, Hospital Clínico de Barcelona, IDIBAPS, University of Barcelona, Barcelona, Spain; 2Department of Internal Medicine IV, Hospital Professor Doutor Fernando Fonseca, Amadora, Portugal

Background: Classification of ANCA-associated vasculitis (AAV) has emerged in order to identify more homogeneous subgroups of patients with granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA). However, the exact value of classifying patients according to antibody specificity [proteinase 3 (PR3) or myeloperoxidase [MPO]] is still unclear.

Objectives: To assess demographic, clinical and prognostic differences among subgroups of AAV patients, according to clinicopathological classification (GPA vs. MPA) and antibody specificity (PR3 vs. MPO) in a single-centre cohort.

AB0474

CAROTID CONTRAST ENHANCED ULTRASOUND IN CASES OF TAKAYASU ARTERITIS COMPLICATED WITH BEHÇET’S DISEASE

W. Fan1, J. Zhu1, P. Yu1, L. Yu1, X. Wang1, X. Wei1, D. Che1. 1Peking University People’s Hospital, Ultrasound, Beijing, China

Background: Carotid contrast enhanced ultrasound (CEUS) is used for diagnosis and activity determination of patients with Takayasu’s arteritis (TA). However, very little is known about the carotid CEUS features of TA complicated with Behcet’s disease (BD). Objectives: This study reports the carotid CEUS features in cases of TA complicated with BD (TBD).

Methods: A total of 10 carotid CEUS examinations were performed on 4 patients of TBD. 10 TA patients complicated with no rheumatoid disease were included as control group. For each carotid artery lesion, the carotid CEUS features was graded as follows: Grade 0, artery wall shows no microbubbles; Grade 1, artery wall shows limited or moderate microbubbles; Grade 2, artery wall shows severe microbubbles.

Results: 2/10 patients in TBD group had oral ulcer during the CEUS examination, while all the other patients included in our study showed no clinical symptoms related to active TA or BD. The carotid wall thickness was greater of CEUS grade 2 than grade 1 in both group (TBD: 2.62±0.74mm vs 1.66±0.22mm, p=0.001; TA: 1.84±0.31mm vs 1.53±0.55mm, p=0.136). The carotid wall thickness was significantly greater in TBD group than TA group, but there was no significant differences between the two groups in clinical data and CEUS grade (table 1).
patients. When antibody specificity was compared, differences on organ-specific manifestations were less clear than between clinical phenotypes (GPA vs. MPA), and were only seen in ENT/ocular involvement (more frequent in PR3 than in MPO patients) and in muscle biopsies disclosing vasculitis (more frequent in MPO than in PR3 patients). GPA and PR3 patients presented more frequent relapsing disease than MPA and MPO patients, respectively (GPA 60% vs. MPA 36%; p=0.018 / PR3 60% vs. MPO 41%; p=0.094). While GPA tended to have a better survival rate than MPA patients (p=0.066) (Graph1), the MPO-associated disease (GPA or MPA) had clearly worse survival prognosis than PR3-AAV (p=0.008) (Graph2), similarly to what occurred in GPA-MPO (compared with GPA-PR3).

Conclusion: A high proportion of GPA patients with MPO-ANCA (45%) is observed in our series. GPA is associated with a more frequent relapsing disease than MPA. MPA and presence of MPO were more frequent in females and older patients. Clinical features were similar in GPA patients with PR3 or MPO. The presence of MPO (in GPA or MPA) seems to be the main factor associated with mortality in AAV.

SD: standard deviation. ESR: erythrocyte sedimentation rate. CRP: C reactive protein. PMR: polymyalgia rheumatica.

Conclusion: Imaging in GCA allow us to establish different patterns of involvement (cranial, mixed, large vessel) that correspond to different clinical subsets. The patients with LV subset debut with a lower ESR and have more fever and polymyalgia rheumatica and less ischemic symptoms.

Giant Cell Arteritis: A Disease with Different Subsets

E. Fernández1, I. Monjo1, G. Bonilla1, D. Peiteado1, C. Plasencia1, A. Balsa1, E. De Miguel1. 1La Paz University Hospital, Rheumatology, Madrid, Spain

Background: Giant cell arteritis (GCA) is the most common form of autoimmune vasculitis in the elderly. Some evidence indicates that GCA is a heterogeneous disease in terms of symptoms, immune pathology and response to treatment.

Objectives: To analyze whether the identification by image of cranial vessels (VC) or large vessels (VG) involvement allows to characterize different clinical subsets of the disease.

Methods: Descriptive observational study of the last 87 consecutive patients with a new diagnosis of GCA in our hospital. All patients had a CV and LV CDUS exam that included axial, subclavian, vertebral and carotid arteries or a Positron Emission Tomography (PET-CT). The OMERACT (Outcome Measures in Rheumatology) definitions of halo sign were used for ultrasound diagnosis and IMT limits were established as ≥ 0.34 mm for superficial temporal arteries and ≥ 1 mm for axillary, subclavian and carotid arteries; a clear halo sign was used in the vertebral arteries. The radiologist's report and the liver/vascular wall index were used for the definition of positive PET-CT. The medical records of these patients were reviewed and their demographic, clinical and laboratory data were compared between the different patterns of GCA. The statistical significance limit was set at P < 0.05. Statistical analyses were performed by using SPSS version 25.

Results: Out of 198 patients with suspected GCA who underwent a CDUS or PET-CT between November 2016 and November 2019, 87 were diagnosed of GCA. Three different patterns were detected: 44 patients (50.6%) had an exclusive cranial pattern, 31 (35.6%) had a mixed pattern with involvement of both CV and LV and 12 (13.8%) had an exclusive large vessel pattern. The differences between these 3 subsets are shown in table 1. Patients with a LV pattern had more fever and polymyalgia rheumatica than patients with CV involvement and fewer ischemic visual disturbances than those with mixed pattern, reaching statistical significance. In addition, they tended to have fewer other ischemic symptoms (headache, jaw claudication) and more general symptoms than patterns with CV involvement. Regarding laboratory values, the erythrocyte sedimentation rate was significantly higher in the exclusive CV involvement group and lower in those with only LV involvement.

DOI: 10.1136/annrheumdis-2020-eular.2589
**Objectives:** To evaluate the effects of the disease and its treatment on serum AMH levels for Behcet's disease (BD), systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and systemic scleroderma (SSD).

**Methods:** The study included 73 patients with RDs from 18 to 40 years: 42 patients with BD, 12 with SLE, 11 with RA, 8- with SSD, the control group consisted of 15 healthy women. Enzyme-linked immunosorbent assay (ELISA) was used to measure AMH levels. Parametric and nonparametric statistical methods of Statistics 8.0 package were used for statistical processing of data.

**Results:**
- Mean age in BD patients was 30.0 years, in SLE and RA -33.5 years, in SSD - 35.0 years, and 32.0 years in the control group. The average disease duration was 4.5 years, 11.5 years, 4.0 years and 6.0 years, respectively.
- The male-to-female ratio was 3.7:1, the mean age of pts was 29.7 (23-76) years.
- There were no significant differences in the mean AMH levels between the groups. No association between AMG levels and clinical manifestations, disease activity or duration of rheumatic disease was found. Baseline AMH – in treatment-naive patients before initiation of any DMARDs was assessed in 11 BD patients. A significant (p<0.05) decrease of AMH levels was established in patients with high SLE activity treated with CP. Of notice, all examined patients were additionally receiving a GEBD -Rituximab.

**Conclusion:** Decreased ovarian function was found in patients with high SLE activity treated with CP with Rituximab.

### AB0478 CORONARY ATHEROSCLEROSIS IN BEHCET’S DISEASE

R. Goloeva1, Z. Alekberova1, A.V. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Behcet's disease (BD) is systemic vasculitis, which affects all types and sizes of vessels. Increased carotid intima-media thickness (IMT) is parameter associated with subclinical atherosclerosis.

**Objectives:** To determine the prevalence of atherosclerosis in pts with BD.

**Methods:** 95 BD pts were evaluated and 45 healthy controls matched for age and gender.

**IMT was assessed by high-resolution B-mode ultrasonography. Serum concentration of high-sensitivity C-reactive protein (hs CRP) was measured by immunonephelometric assay (BN-100 Analyzer; Dade Behring). Lipid profile evaluation included total cholesterol, TGs, LDL, HDL, and atherogenic index.

**Results:** The male-to-female ratio was 3.7:1, the mean age of pts was 29.7 (23-35) yrs, the mean age at the disease onset - 19.9 (14-25) yrs, the mean disease duration - 9.6 (4-15) yrs.

**Conclusion:** Coronary atherosclerosis in BD pts was lower than what we expected. The thinning IMT may be one of the risk factors for aneurysm formation in pts with BD.

**Disclosure of Interests:** None declared

### AB0479 PREGNANCY OUTCOMES IN PATIENTS WITH RHEUMATIC DISEASES.

Z. Alekberova1, R. Goloeva1, A. Lila1, VA. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:**
- Objectives: To evaluate pregnancy outcomes in patients with Behcet's disease (BD), systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and systemic scleroderma (SSD).
- Methods: The study included 73 patients with rheumatic diseases (RDs) aged 18 to 40 years signing the informed consent form and completing dedicated thematic observations with infliximab infusions reaching higher serum trough levels in responders with infliximab infusions.

**Results:**
- Out of total 35 babies born to RD patients, two had recurrent aphthous stomatitis (in 2 BD patients), and one had congenital glaucoma (born to a mother with neuro-Behcet’s).
- 10 BD and 2 RA are patients multipara mothers who are raising 3 and more children.

**Conclusion:** Rheumatic diseases are associated with high incidence of adverse pregnancy outcomes.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.3704

### AB0480 AN OPEN-LABEL, EXPLORATORY STUDY TO ESTABLISH THE EFFICACY AND SAFETY OF 1-YEAR CANAKINUMAB TREATMENT IN BEHÇET’S DISEASE PATIENTS WITH NEUROLOGIC OR VASCULAR INVOLVEMENT

A. Güllü1, M. Kurtunç1, M. Ertugan1, E. Oğuz2, T. Gunduz2, G. Akman Demir2, S. Sevci3, S. Turgay4, E. Acar1, Istanbul Faculty of Medicine, Istanbul, Turkey; Istanbul Faculty of Medicine, Istanbul, Turkey; Istanbul Faculty of Medicine, Istanbul, Turkey; Novartis Turkey, Istanbul, Turkey; Novartis Turkey, Istanbul, Turkey; Novartis Turkey, Istanbul, Turkey

**Background:** Previous observations in Behcet’s disease (BD) patients receiving anti-IL 1 therapies suggested that dosage and route of administration may be critical in controlling disease manifestations. This was supported by favorable observations with infliximab infusions reaching higher serum trough levels in refractory BD patients compared to other anti-TNF agents.

**Objectives:** The primary objective was to evaluate the safety and efficacy of intravenous (IV) canakinumab (CAN) on the clinical and inflammatory findings of BD patients with neurologic and vascular involvement.

**Methods:** Biologic-naïve BD patients, who had a recent attack of large vessel or parenchymal neurologic disease within the last month were enrolled and all received 300 mg CAN IV without a change in other medications. Response was assessed on day 30 as the primary objective; partial

**Conclusion:**
- There were no cases of antiphospholipid syndrome documented.
- Pregnancy outcomes in RD patients
responders were able to take the 2nd 300 mg IV on day 30 and continued the treatment with monthly 150 mg IV 4 times. Others continued the treatment with 150 mg IV monthly; At month 6, patients were able to switch to SC injections or continue 150 mg IV for 6 months. Non-responder patients were dropped out. Prednisolone dosage was ≤20 mg at baseline and not increased during the trial. Complete response was defined as full clinical recovery to pre-attack state, disappearance of MRI lesions, normalization of CSF findings; partial response was defined as partial improvement in clinical findings, which were still worse than pre-attack state, with MRI lesions becoming smaller with or without enhancement, and a decrease in CSF cell count. Complete response of vascular findings was defined as ≥50% improvement in patient's and physician's global assessments, ≥50% reduction in CRP; along with stable or ≥20% reduced aneurysm size or stable or ≥20% reduced calf swelling; and partial response was an improvement between 20-49% in global assessments, 20-49% reduction in CRP; stable or ≤20% reduced aneurysm size or ≤20% reduced calf swelling.

Results: 9 subjects were screened, and 8 male subjects (5 vascular, 3 neurologic) aged 27.3 ± 2.3 years entered the study. No new attack or worsening of manifestations was observed, and at least a partial response was obtained in all patients on day 30. Two vascular patients (2/5, 40%) and 1 neurologic patient (1/3, 33%) received another 300 mg infusion on day 30; one of them left the study on day 120 because of safety concerns after noticing the use of illicit drugs, and the other required 150 mg IV CAN after day 180 and discontinued the study because of the worsening of pulmonary artery aneurysm, despite favorable response in venous findings. The remaining 3 patients (3/60%) with deep vein thrombosis completed the study with clinical and radiological improvement. 2 patients with parenchymal involvement had lesions in the brain stem and showed complete improvement of clinical findings between 1-3 months and radiological findings between 3-6 months. Clinical findings of 1 patient with sinus thrombosis improved within 2 months, and the last cranial MRI showed that the vein thrombus was recanalized. Patients experienced other mild manifestations of BD following a switch to SC administration.

Conclusion: Response to CAN without high-dose methylprednisolone treatment suggests that IL-1 antagonism plays a role in acute exacerbations of neurologic and vascular manifestations of BD, and no new safety signal was recorded with IV use. Favorable responses during the early months of the study and development of clinical and laboratory findings after switching to SC administration may suggest that achievement of higher serum trough levels may be critical, and up-titration of the dosages may provide better results in individual patients with higher inflammatory activity.

Efficacy of Apremilast for the Treatment of Genital Ulcers Associated with Active Behçet’s Syndrome: A Combined Analysis of Two Randomized Controlled Trials

G. Hatemi1, A. Mahr2, D. Kim3, M. Melikoglu1, S. Cheng4, S. Mccue5, S. Richter6, M. Brunoni2, M. Paris1, M. Chen1, Y. Yasui2, Istanbul University-ı cerrahpaşa Medical School and Behçet’s Disease Research Center, Istanbul, Turkey; 2Canantonal Hospital St. Gallen, St. Gallen, Switzerland; 3Nippon Medical School, Graduate School of Medicine, Tokyo, Japan; 4Yonsei University College of Medicine and Severance Hospital, Seoul, Korea, Rep. of (South Korea); 5Amgen Inc., Thousand Oaks, United States of America; 6New York University School of Medicine, New York, United States of America

Background: Behçet’s syndrome is a chronic, multi-system inflammatory disorder characterized by painful, recurrent oral ulcers (OU) and genital ulcers (GU). The GU associated with Behçet’s syndrome can contribute to difficulties with sexual activity, walking, and sitting; may cause scarring; and may impair quality of life.1 Apremilast (APR), an oral phosphodiesterase 4 inhibitor, has demonstrated efficacy in the treatment of the OU associated with Behçet’s syndrome in the phase III, randomized RELIEF study (BCT-002).2

Objectives: To describe the efficacy of APR for the treatment of GU associated with active Behçet’s syndrome in the RELIEF study and in a pooled data analysis of RELIEF and the phase II study.

Methods: Adult patients (≥18 years of age) with active Behçet’s syndrome and ≥3 OU at randomization or ≥2 OU at screening and randomization, without active major organ involvement, were randomized (1:1) to APR 30 mg twice daily or placebo (PBO). In RELIEF, clinical improvement in GU was assessed by evaluating the time to the first GU recurrence after loss of complete response, the mean number of GU in patients without GU at baseline, and the proportion of patients who were GU-free (complete response) at Week 12 (regardless of baseline GU status). A pooled analysis of patients in RELIEF and a randomized, phase II study4 were conducted to assess achievement of GU complete response in patients with GU at baseline. In patients with GU complete response before Week 12, the median time to the first GU recurrence after loss of complete response was based on Kaplan-Meier estimates. The mean number of GU was summarized descriptively using data as observed. Between-group differences in the proportion of patients who were GU-free at Week 12 were analyzed by Cochran-Mantel-Haenszel test using non-responder imputation to handle missing data. Statistical tests were 2 sided (α=0.05).

Results: A total of 207 patients were randomized and received ≥1 dose of study medication (APR: n=104; PBO: n=103). In all, 17 patients in the APR group and 17 in the PBO group had GU at baseline, with mean GU counts of 2.9 (APR) and 2.6 (PBO). Among patients with GU at baseline in RELIEF, 12/17 (70.6% [APR]) and 7/17 (41.2% [PBO]) achieved GU complete response at Week 12 (P=0.110). The median time to first GU recurrence in these patients occurred earlier with PBO (6.1 weeks) vs. APR (not calculable). In the pooled analysis of RELIEF and the phase II study, a significantly greater proportion of patients with GU at baseline achieved GU complete response at Week 12 with APR vs. PBO (21/27 [77.8%] vs. 9/23 [39.1%]; P=0.011) (Figure 1). The proportion of patients who were GU-free was significantly greater with APR (92/104 [88.5%]) vs. PBO (72/101 [71.3%]), regardless of baseline number of GU (P=0.002) (Figure 2).

Conclusion: The number of patients with GU was low, but the totality of the data shows a favorable trend in the treatment effect of APR on GU. Greater proportions of APR-treated patients were GU-free at Week 12 vs. patients receiving PBO, and the time to the first GU recurrence occurred earlier with PBO vs. APR.

AB0482
INFLUENCES OF TIME OF INTRODUCTION OF INFILIXIMAB ON THE FUNCTIONAL DISABILITY AND JOB STATUS OF PATIENTS WITH CHRONIC PROGRESSIVE NEURO-BEHCET’S DISEASE
S. Hirohata1, H. Kikuchi2, T. Sawada3, M. Kuwana4, Y. Kirino5, M. Takeo6, Y. Ishigatsubo6, 1Nobuhiro Hospital, Rheumatology, Tatsuno, Japan; 2Tokyo University School of Medicine, Tokyo, Japan; 3Tokyo Medical University School of Medicine, Tokyo, Japan; 4Nippon Medical University Graduate School of Medicine, Tokyo, Japan; 5Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background: Chronic progressive neuro-Behcet’s disease (CPNBD) is characterized by progressive neurobehaviour changes leading to disability and death. It has been appreciated that methotrexate is effective for CPNBD. Notably, recent studies have demonstrated that infliximab is effective for patients with CPNBD who had inadequate responses to methotrexate. However, the appropriate timing for introduction of infliximab remains unclear.

Objectives: The current studies examined the effects of intervals before introduction of infliximab on the functional disability and job status of patients with CPNBD.

Methods: Eleven patients (6 males, 3 females, ages 35.2±9.3 [mean±SD]), who met the international classification criteria for BD with CPNBD and received infliximab, were retrospectively followed up. The functional disability of the patients was evaluated by Steinbrocker functional classification as is used in rheumatoid arthritis. Correlation between the patients’ functional outcome and the intervals before the introduction of infliximab was analyzed by Spearman’s rank correlation test.

Results: All the 11 patients had received methotrexate prior to infliximab. The intervals from the onset to the introduction of infliximab and the follow-up periods were 5.6±5.4 months and 60.5±45.6 months [mean±SD], respectively. Among the 11 patients, 9 patients did not show progression after the introduction of infliximab, whereas 2 patients still progressed and lost job. In the latter 2 patients, infliximab had been discontinued before the final follow-up. No patients improved from the functional disability or gained job even after infliximab treatment. The functional disability grades of the patients after the introduction of infliximab were 26.6±35.1 months and 65.2±43.6 months [mean±SD], respectively. Among 11 patients, 2 patients still progressed and lost job. In the latter 2 patients, CPNBD.

AB0483
INTERSTITIAL LUNG DISEASE IN PATIENTS WITH ANCA ASSOCIATED VASCULITIS – A PROSPECTIVE SINGLE CENTER STUDY
A. Hocevar1, 2, K. Perdan-Pirkmajer1, T. Pirc-Pirkmajer1, M. Tomsic1, Z. Rotar1 on behalf of -.
1University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 2Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Background: Recently, an association between anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and interstitial lung disease (ILD) has been uncovered.

Objectives: To determine the rate of ILD in our prospective AAV patient cohort and to compare clinical characteristics of AAV patients with and without associated ILD.

Methods: We retrospectively analysed medical records of prospectively diagnosed and followed AAV patients at our secondary/tertiary rheumatology centre between January 2010 and December 2019. The diagnosis of ILD was based on lung HRCT findings.

Results: During the 10-year observation, we identified 94 incipient AAV patients (46 had granulomatosis with polyangiitis, and 48 microscopic polyangiitis). Thirteen (13.8%) patients had ILD (ILD-AAV group). 12/13 had usual interstitial pneumonia (UIP) pattern and 1/13 non-specific fibrosis on HRCT. ILD was diagnosed in tandem with AAV in 8/13 patients, and 9 months to 5 years prior to AAV in 4/17 patients. Characteristics of ILD-AAV, and non-ILD-AAV groups are presented in Table 1. ILD-AAV patients more commonly reported of weight loss, less frequently had ENT involvement, and were predominantly a-MPO ANCA positive (92.3%). Follow up data were available for 85 AAV patients (90.4%; 13 ILD-AAV and 72 non-ILD-AAV). During the median (IQR) follow up of 22.1 (4.8; 50.0) months, 5/13 (38.5%) ILD-AAV patients died, compared to 6 (8.3%) deaths registered in non-ILD-AAV group during 26.4 (11.6; 70.0) months of follow up. The crude mortality rate evaluated by Cox proportional hazards regression was significantly higher for AAV-ILD group (HR 5.6 (95%CI 1.7-18.7), p=0.005).

PROTEINASE 3–ANTINEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA)–POSITIVE AND ANCA–NEGATIVE OR MYELOPEROXIDASE–ANCA–POSITIVE PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS: DISTINCT PATIENT SUBSETS
L. Petetytska1, D. Iaremensonko2, 1Bogomolents National Medical University, Department of Internal Medicine #3, Kyiv, Ukraine

Background: Most patients with clinical diagnoses of Granulomatosis with polyangiitis (GPA) are proteinase 3 (PR3)-ANCA positive, but a significant minority are myeloperoxidase (MPO)-ANCA positive or are negative for ANCA [1]. Several clinical and genome-wide association studies have suggested that classification based on ANCA type, i.e., PR3-ANCA positivity as opposed to MPO-ANCA positivity, may be more relevant clinically than the traditional classification based on specific diagnosis [2].

Disclosure of Interests: L. Petetytska – employee; D. Iaremensonko – employee

Acknowledgments: The authors would like to acknowledge the contribution of the patients and their families to the study.

References:

Objectives: To analyze demographic feature, disease manifestations and laboratory findings of patients with PR3-ANCA positive GPA in comparison with ANCA-negative or MPO-ANCA positive GPA.

Methods: This is a retrospective analysis of 37 patients with GPA from a single center in Ukraine observed from 2010 till the end of 2019. The clinical and demographic data, initial Birmingham vasculitis activity score (BVAS/WG), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were compared between patients with PR3-ANCA positive GPA and ANCA-negative or MPO-ANCA positive GPA.

Results: Of the 37 patients analyzed, 24 (64.9%) had PR3-ANCA–positive GPA, 6 (16.2%) had MPO-ANCA–positive GPA and 7 (18.9%) had ANCA-negative GPA. ANCA-negative GPA patients were younger at diagnosis compared to PR3-ANCA–positive and MPO-ANCA–positive patients (36 versus 47 and 49 years; p = 0.04). The gender ratio was similar in patients with PR3-ANCA–positive GPA and patients with ANCA-negative GPA or PR3-ANCA–positive GPA (33% vs 38% male, p = 0.61). The ocular manifestations - conjunctivitis/episcleritis (15% vs 50%) and ear involvement - otitis, mastoiditis (0% vs 33%) occurred more often in patients with PR3-ANCA–positive GPA (p<0.05), whereas sensory peripheral neuropathy (54% vs 21%) and Raynaud’s syndrome (31% vs 0%) were more frequent in compared group (p<0.05). ANCA-negative patients with GPA had lower, but no significant, initial BVAS/WG score than PR3-ANCA–positive or MPO-ANCA–positive patients with GPA (179 versus 23.5 and 24.8; p=0.20). There were no significant differences between groups in ESR or CRP levels and in the frequency of involvement of other organs and systems.

Conclusion: We demonstrate clinical differences between PR3-ANCA–positive patients with GPA and ANCA-negative or MPO-ANCA–positive patients with GPA. The eye and ear involvement are common for patients with PR3-ANCA–positive GPA and patients with ANCA-negative GPA or PR3-ANCA–positive GPA. The MPO-ANCA–positive GPA or ANCA-negative GPA is characterized by higher frequency of sensory peripheral neuropathy and Raynaud’s syndrome.

AB0485 INVESTIGATION OF PERMANENT ORGAN DAMAGE IN GIANT CELL ARTERITIS: DISEASE FLARES ARE ASSOCIATED WITH INCREASED DAMAGE SCORES

B. Ince1, S. Artan2, Y. Yaçınkaya1, B. Artim-Esen1, A. Güll, M. L. Ocak1, M. İnanc1.

1. Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey
2. Istanbul University, Istanbul Faculty of Medicine, Dept of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: Development of organ damage is a major concern in patients with systemic vasculitis. Treatment may also contribute to this important outcome. Scoring systems have been developed to evaluate organ damage in systemic vasculitis and specifically for large vessel vasculitis (1).

Objectives: We aimed to investigate permanent organ damage and determining factors in our giant cell arteritis GCA cohort.

Methods: Organ damage detected at the time of diagnosis and/ or follow-up and irreversible for at least 3 months in GCA patients followed up between 1998-2018 were recorded by using Vasculitis Damage Index (VDI) and Vascular Vasculitis Damage Index (LVVID) form patient records of our vasculitis clinic. In the statistical evaluation, chi-square, students t-test and logistic regression analysis were used.

Results: Eighty-nine patients (64% women, mean age 67.9 ± 9.1) were analysed. Median follow up duration was 46 months (3-256) and mean time to diagnosis after presenting symptom (TDD) was 5,9±1,2 months (0-60). Polymyalgia rheumatica was found in 36 (40.4%) patients. The clinical findings of the patients are shown in Table-1. Mean TTD was longer in patients with acute vision loss (AVL) (11±4 vs. 4,8±1,1 months p=0,002). Mean CRP was 90,7±32 (8-343) mg/L and ESR was 103,7±25 (52-138) mm/h at the time of diagnosis. Mean age was lower (63,2±2 vs 69±1p=0.01); mean CRP (141,8±107,3 vs. 76,6±67,9 mg/dl p=0,023) and ESR (120,8±25,1 vs. 99,3±24,3 mm/h p=0,004) was higher in patients without cranial symptoms (extracranial GCA group). PET-CT findings compatible with large vessel vasculitis were present in 64% (34/53). Sixteen of 19 (84,2%) patients in the extracranial GCA group had positive PET-CT. Temporal artery (TA) biopsy positivity was 64% (34/53). Sensitivity of ACR criteria in our cohort was 77.5% and GIACTA study inclusion criteria was 58.4% in this cohort at diagnosis. Fulfillment of GIACTA criteria was still present in 12 (13,5%) patients after six months of follow up. Treatment data was shown in table-2. Total flare rate was 34.8% and flare rate was lower in the extracranial GCA group (3/20 vs. 28/69p=0.035 OR=0.78 %95 CI 0.64 – 0.96). Reduced survival was observed in cases diagnosed older than 65 years (168,8±23,9 vs 209±17,3 months p=0,015).

Conclusion: The analysis of the largest single center cohort from Turkey confirmed that delayed diagnosis is associated with vision loss. A subgroup of patients without apparent cranial symptoms but positive PET-CT findings is delineated. These patients are younger, present with higher inflammatory response and fewer relapses. The sensitivity of ACR criteria in our cohort is less than 80%. High flare rate especially in GCA patients with cranial symptoms and GIACTA criteria fulfillment after 6 months of treatment in more than 10% of the patients show a need for for new treatment options.

**AB0487 CAN A GCA RISK STRATIFICATION SCORE BE HELPFUL IN CLINICAL PRACTICE?**

M. Jasim1, P. Magan1, R. Awadalla1, R. Brindley1, D. Richards1, A. Hall1, J. Barraclough1, T. Adzie2. 1Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom

**Background:** Giant cell arteritis (GCA) is the most common type of large vessel vasculitis. Typically it presents in patients over the age of 50 with a combination of temporal headaches, scalp tenderness, jaw claudication, raised inflammatory markers and visual disturbance. The diagnosis of GCA is often challenging and there is a difficult balance of over and under investigation. There have been many proposed scoring systems to help clinicians risk stratify patients who may present with suspected GCA. One such scoring system, published in 2017, showed clinical utility in a large international multi-centre study. Following analysis of data from 530 biopsies, Ing et al. developed a parsimonious prediction model comprising 5 candidate criteria: age, jaw claudication, ischemia-related loss of visual acuity, platelet count and logCRP (Figure 1). [1]

**Objectives:** Increasingly, ultrasound doppler imaging is recognised and accepted as satisfactory means of confirming the diagnosis of GCA, with the presence of the halo sign characteristic for GCA. The aim of our study was to determine whether this GCA prediction model accurately predicts positive temporal artery biopsies in a large, real world UK cohort. In addition, we assessed whether this model accurately predicts positive temporal artery ultrasounds.

**Methods:** A retrospective cohort study was performed using electronic medical records of patients referred for temporal artery biopsy (TAB) and temporal artery ultrasound (USTA) for suspected GCA. All TAB performed at the Royal Wolverhampton NHS Trust between June 2014 - June 2018 and all USTA performed between January 2015 - January 2019 were analysed. Patients who undergo USTA for suspected GCA at our centre routinely have bilateral temporal and axillary arteries scanned. Patients were excluded if they already had a previous diagnosis of GCA (and the clinical question was suspected flare), or if there was insufficient information available.

**Results:** The total number of patients who underwent a confirmatory diagnostic test (either TAB or USTA) for suspected GCA was 187. Thirteen of these patients met the exclusion criteria, the remaining 174 patients were included for analysis. 126/174 patients underwent a TAB, 63/174 had an USTA. 15/174 had both these were included in the USS cohort because for all these patients the ultrasound was the first diagnostic test performed (Table 1). Our results appear to closely mirror the original multi-centre results with regards to prediction of biopsy positive GCA, with the cenciles closely following those in the inception cohort. 0% of the ‘low’ risk probability biopsy cohort were misclassified - none had a positive biopsy. However, 8% of the ‘low’ risk probability ultrasound cohort were misclassified - 2 had a positive ultrasound.

**Figure 1. Ing et al’s Nomogram of parsimonious model.**

by logistic regression on data from 530 biopsies, Ing et al. developed a parsimonious prediction model comprising 5 candidate criteria: age, jaw claudication, ischemia-related loss of visual acuity, platelet count and logCRP (Figure 1) [1].

**Objectives:** Increasingly, ultrasound doppler imaging is recognised and accepted as satisfactory means of confirming the diagnosis of GCA, with the presence of the halo sign characteristic for GCA. The aim of our study was to determine whether this GCA prediction model accurately predicts positive temporal artery biopsies in a large, real world UK cohort. In addition, we assessed whether this model accurately predicts positive temporal artery ultrasounds.

In the comparative analysis of patients with CG and Beta 2 microglobulin (β2M), CG and rheumatoid factor (RF), those with high β2M (>1.8 mg/L) presented significantly more GN (p=0.016) and PN (p=0.013). However, the association of RF with either GN (p=0.948) or PN (p=0.645) was not significant. Also, high β2M was significantly related to complement consumption of C4 (p=0.015) but not of C3 (p=0.063). In the 30 (34.5%) patients with skin manifestations, high β2M showed no statistically significant association. The main systemic autoimmune diseases associated were primary Sjögren’s Syndrome (pSS) 37 (42.5%), Systemic Lupus Erythematosus (SLE) 9 (10.3%) and Systemic Sclerosis (SSc) 7 (8.05%).

Conclusion: A direct association between presence of elevated levels of β2M and the existence of progression to glomerulonephritis and peripheral neuropathy is found in our cohort. No correlation is found between the presence of CG and other serological markers of autoimmunity except low C4. CG with elevated β2M does not associate with greater skin involvement or arthritis.

BETA 2 MICROGLOBULIN AS A PROGNOSTIC FACTOR IN CRYOGLOBULINEMIA NON ASSOCIATED WITH HEPATOTOPIC VIRUSES

Background: Cryoglobulinemia (CG) is a rare phenomenon related to haematological disorders, infections and autoimmune diseases. Age and renal involvement are known prognostic markers.

Objectives: To describe the differential clinical features and the prognostic factors in a cohort of patients diagnosed with CG non-associated with hepatotopic viruses.

Methods: A retrospective study of a cohort comprised of 252 cryoglobulin positive samples, obtained from the immunology laboratory database of a tertiary hospital attending 450,000 people over 1 year. 186 patients with CG positive samples were included, 87 of which were not associated with neither hepatitis B nor C virus. Demographic, clinical, serological and pathological data were collected. Nonparametric variables were compared using a Wilcoxon test.

Results: Out of 186 reviewed patients, 87 (46.7%) are included in this study. The mean age at CG diagnosis was 60 (± 16) years. Mixed CG was the predominant subtype, detected in 66 (75.9%) patients, 10 of which (11.5%) were associated with glomerulonephritis (GN) with compatible biopsy, 17 (19.5%) with peripheral neuropathy (PN), 29 (33.3%) with non-erosive arthritis and 10 (11.5%) with leukocytoclastic vasculitis confirmed by skin biopsy. The clinical, epidemiological and serological characteristics of the sample are summarized in Table 1.

| Sex, female / male, n (%) | 65/22 (74.7/25.3) |
| Age at diagnosis, years ± SD | 60 ± 16 |
| CG subtype, n (%) | 27 (30) |

In peripheral blood of TA patients, Treg cells decreased, while Th17 cells increased significantly. The ratio of Th17/Treg was 1.05 in peripheral blood of patients with Takayasu's arteritis.

Objectives: To analyze the levels of circulating lymphocyte subsets and serum cytokines in patients with Takayasu's arteritis (TA), and explore the relationship between their changes and TA disease activity.

Methods: A total of 46 TA patients and 43 gender-age-matched healthy controls were enrolled. According to the NIH standard, 30 patients were in active disease. Flow cytometry was used to detect the absolute numbers and ratios of Th1, Th2, Th17 and Treg cells in peripheral blood of all subjects. Magnetic bead-based multiplex immunoassay was used to detect cytokines and statistical analysis was performed.

Results: Compared with the healthy controls, the absolute number and proportion of peripheral Treg cells of TA patients significantly decreased while those of Th17 cells increased significantly, leading to the increased ratio of Th17 / Treg. Compared with the inactive group, the TA active group had significantly increased IL-6 and TNF-α, and there was no significant difference in the expression of Th17 cells and Treg cells.

Conclusion: In peripheral blood of TA patients, Treg cells decreased, while Th17 cells increased as compared with healthy controls, leading to an imbalance between Th17 and Treg cells. The levels of IL-6 and TNF-α were related to disease activity.

ELEVATED COMPLEMENT 3 INDICATES DISEASE ACTIVITY IN TAKAYASU ARTERITIS

R. Chen, L. MA2, S. Wu1, L. MA2, L. Jiang1 on behalf of the East China Collaborative Group of Vasculitis. 1Zhongshan Hospital Fudan University; Rheumatology, Shanghai, China; 2Zhongshan Hospital Fudan University, Rheumatology, Shanghai, China

Background: The disease activity evaluation of Takayasu arteritis (TA) is a critical issue for disease monitoring and treatment. But the previous markers such as Kerr score or ITAS 2010 are not convenient enough. 

Objectives: We aim to explore novel biomarkers to assess TA disease activity.

Methods: This cross-sectional study was based on the East China TA (ECTA) cohort. Demographic characteristics, clinical features, laboratory and imaging results were collected. Complements and their combination with other biomarkers in identifying active disease (Kerr > 2) group were analyzed. Internal and external validation were employed to confirm the accuracy and stability of the results.

Results: 519 patients were enrolled, among which 406 cases (72.2%) were identified as active disease. Higher ESR, CRP, platelet, globulin, IgG, IL-6, complement 3 (C3), complement 4 (C4) and median haemolytic complement (CH50) levels were observed in the active disease group. Logistic regression analysis demonstrated that C3 levels [odds ratio [OR] (95%CI): 10.710(1.825 – 62.835), P = 0.009] and CRP [OR (95%CI): 1.041(1.009 – 1.073), P = 0.011] were independently associated with active disease. The cut-off of C3 to identify active TA was 1.085g/L, with 69.9% sensitivity, 66.7% specificity. Combining the CRP (cut-off, 10.65g/L; sensitivity, 50.7%; specificity, 82.4%) and C3, the sensitivity and specificity to identify the active disease were 85.1% and 55.0% (parallel test), and 35.4% and 94.1% (serial test), respectively. C3 could significantly improve the diagnostic ability of CRP [net reclassification index: OR (95%CI): 1.728 (1.556 – 1.900), P = 0.000; integrated discrimination index: OR (95%CI): 0.328 (0.224 – 0.431), P = 0.000]. The accuracy of the 10-fold cross validation of combining CRP with C3 was over 75%, and the accuracy of the external validation with 53 TA cases was 72.73%.

Conclusion: C3 could reflect the disease activity of TA, and combining CRP with C3 could significantly improve the disease activity evaluation in TA.

AB0491
control group. In addition, Bacteroides, Cricetibacter, Alistipes, Lachnospira, Dinelma, Akkermansia, Sutterella, Anaerofilum, Ruminococcaceae-UCG002 Acetanerobacterium; and Copropapacter were lower than the control group. There was no difference between the uvex, mucocutaneous, and vascular involvement groups in terms of alpha (Chao-1 and Shannon) and beta (Bray-Curtis) microbiota diversity and wealth indices (p>0.05) while we obtained a significant p value of the beta diversity between three groups in weighted UniFrac PCoA (p<0.05). When we compared 3 different system involvement (Eye, Mucocutaneous and Vascular), The LEfSe provides us with cladograms of six-level (from kingdom to genus). We found difference for the genera Lachnospiraceae NK4A136 in uveitis group, Dialister Intestinomonas and Marvinbryantia in mucocutaneous group and Gemella in vascular involvement group.

**Conclusion:** There was a significant difference in the composition of intestinal microbiota in Behcet’s disease compared to healthy adults. We found also the different clinical forms of Behcet’s disease have some different gut microbiota composition. Especially in Behçet’s disease, it will be useful to evaluate Catenibacterium, Collinsella and Eggertella increase. Bacteroides and Akkermansia decrease in larger series. In addition, due to the increase in the Eggertella lenta strain observed both in the FMF and Behcet patient group, it is useful to make more detailed metagenomic analyzes regarding the role of this agent in the etiopathogenesis and course of rheumatic diseases.

**AB0493**

**COMPARISON OF EFFICACY AND SAFETY BETWEEN RITUXIMAB AND CYCLOPHOSPHAMIDE IN REMISSION INDUCTION THERAPY FOR JAPANESE ANCA-ASSOCIATED VASCULITIS(AAV) PATIENTS; A SINGLE CENTER RETROSPECTIVE ANALYSIS**

M. Kata1, H. Shimada1, S. Nakashima1, M. Mahmoud Fahmy Mansour2, R. Wakai1, T. Miyagi3, K. Sugihara1, Y. Ushio1, T. Kameda2, H. Dobashi1.

1Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Kagawa, Japan

**Background:** Rituximab(RTX) and Cyclophosphamide(CY) has been indicated for ANCA-associated vasculitis(AAV) as remission induction therapy. However, older age and renal dysfunction were independent predictor of treatment related adverse effects in remission induction with CY in recent reports. Japanese AAV patients are characterized by the predominance of elderly, and the study about comparison of efficacy and safety between RTX and CY in elderly Japanese AAV patients are limited.

**Objectives:** To compare the efficacy and safety between RTX versus CY as remission induction therapy in Japanese AAV patients.

**Methods:** We analyzed 40 cases (20 cases received RTX and 20 cases received CY) who received remission induction therapy in our hospital between January 2016 and August 2019. Clinical and laboratory variables at diagnosis, rates of complete remission(CR) at 6 months, defined as Birmingham Vasculitis Activity Score (BVAS)=0 and prednisone 7.5mg/day, AAV relapse at 12 months, and adverse effects were investigated.

**Results:** Of 40 patients, mean age was 73.5±9.6 years (6 males and 34 females). Diagnosis of MPA and GPA were 30 cases and 10 cases, respectively. 37 cases (93%) were positive for MPO-ANCA. Treatment regimen was determined by attending physician. Baseline characteristic of each group (RTX group and CY group) are shown in Table1. Baseline charactor, disease activity, organ involvement, and the proportion of patients with relapsing disease were similar in the two treatment groups. At 6 months, there was no difference of remission rate between two groups (RTX: CY = 62%: 44%, p=0.35) (Figure 1). However, mean PSL dosage at 3 months was significantly lower in RTX group (10.8±4.8mg/day) as compared to CY group (15.8±9.5mg/day; p=0.025) (Figure 2). At 12 months, 1 case in CY group and no case in RTX group had relapse. Adverse effects through 12 months are shown in Table 2. 8 infections (30%) in CY group and 7 infections (35%) occurred in RTX group (p=0.64), respectively. 1 case in RTX group had died due to renal failure.

**Conclusion:** We indicated that PSL was tapered more rapidly in RTX group, although there was no difference of remission rate at 6 months and infection at 12 months between RTX and CY therapy. Therefore, remission induction therapy with RTX might be more safety for elderly Japanese AAV patients.

Conclusion: The two studies evaluating the relationship between serum HMGB-1 level and disease activity in BS found higher levels of serum HMGB-1 level in BS than in healthy controls as in our study. This result supports the importance of HMGB-1 in the development of BS through its role in inflammation. De Souza et al. found no association between BDCAF.
and serum HMGB-1 level; whereas, we found a positive correlation with both BDCAF and BSAS.5 This suggests that HMGB-1 can be used as a new disease activity parameter in BS5. In conclusion, this study is unique as it involves the largest number of BS patients and uses BDCAF and BSAS together to assess disease activity.

AUTOANTIBODIES TARGETING COMPLEMENT RECEPTORS 3A AND 5A1 ARE DECREASED IN ANCA-ASSOCIATED VASCULITIS AND CORRELATE WITH HIGHER RELAPSE RATE.

S. Klapa1, A. Müller2, A. Koch3, A. Kerstein-Staehle2, W. Kaeberler4, H. Heidecke5, S. Schinke6, M. Huber-Lang7, M. Nitschke8, S. Pitamn9, C. Karsten1, G. Riemekasten1, P. Lamprecht1. 1University of Lübeck and Institute of Experimental Medicine, Christian-Albrechts-University of Kiel, c/o German Naval Medical Institute, Department of Rheumatology and Institute of Experimental Medicine, Christian-Albrechts-University of Kiel, c/o German Naval Medical Institute, Kronshagen, Germany; 2CellTrend GmbH, Luckenwalde, Luckenwalde, Germany; 3Institute of Clinical and Experimental Trauma Immunology, University Hospital Ulm, Ulm, Germany; 4Department of Internal Medicine I, Transplant Center, University of Lübeck, Lübeck, Germany; 5Institute of Systemic Inflammation Research, University of Lübeck, Lübeck, Germany.

Background: Activation of the alternative and final common pathways have been shown in ANCA-associated vasculitis (AAV) (1). Circulating titers of C5aR1 are elevated and correlate with disease activity in AAV. Binding to the corresponding G protein-coupled receptor (GPCR) C5aR1 enhances the influx of neutrophils, leading to ROS generation and severe necrotizing of vascular walls (2). Moreover, subsequent interaction of C5a with C5aR1 may represent a profibrinolytic amplification loop (3). Blocking of the receptor is protective in a murine model in AAV (4). In humans, avacopan, a C5aR1-inhibitor showed promising results as glucocorticoid-sparing agent in two randomized phase II and one ongoing phase III clinical trials in AAV (NCT02994927). Notably, disease-specific anti-GPCR autoantibody (aab) signatures have been found in different autoimmune diseases (5).

Objectives: The aim of the present study was to examine whether (patho)physiologic anti-C5aR and anti-C5aR1 aabs correlate with clinical findings in AAV, and whether this is linked to the clinical outcome.

Methods: Sera and plasma of AAV patients [granulomatosis with polyangiitis (GPA), n=64; microscopic polyangiitis (MPA), n=26; eosinophilic granulomatosis with polyangiitis (EGPA), n=11] were measured by Elisa for circulating autoantibodies against complement receptors C3a (anti-C3aR aab) and C5a (anti-C5aR1 aab) and plasma levels of C3a and C5a. Expression of C3aR and C5aR1 on T-cells was determined using flow cytometry. Clinical data were assessed at the time of serum sampling and during follow-up for 48 months.

Results: GPA displayed low titers of anti-C3aR aab (GPA: p=0.032 vs. HD:6.47±2.61, P=0.0031). Anti-C5aR1 aab were decreased in AAV, especially in GPA (p=0.075 vs. HD:6.32±2.91, P=0.0001). Plasma levels of C5a and anti-C5aR aab yielded an inverse correlation in AAV (r=0.683, P=0.0127). C5aR1 expression was increased on T-cells in GPA (CD4+ C5aR1+ T-cells: GPA:10.76±2.55% vs. HD:3.44±0.68%, P=0.0021; CD8+ C5aR1+ T-cells: GPA:9.74±2.10% vs. HD:4.11±0.92%, P=0.0198). Reduced titers of anti-C5aR1 aab <0.45U/ml displayed an increased relapse risk for major organ involvement in GPA (HR 12.85, P=0.0014).

Conclusion: As potential diagnostic marker, anti-C5aR1 aab titers may additionally be useful to monitor disease activity in AAV.

RENAL INVOLVEMENT IN ANCA-ASSOCIATED VASCULITIS: DO THE PRESENCE OF ANCA AND THEIR TYPE MATTER?

N. Bulanov1, E. Stolyarevich2, A. Zykov3, E. Safonova3, E. Schegoleva4, E. Kuznevova5, M. Bulanova5, P. Novikov1, S. Moiseev1,3, S. Cherchenov First Moscow State Medical University; Tarev Clinic of Internal Diseases, Moscow, Russian Federation; 2A.I. Ivdelkov Moscow State University of Medicine and Dentistry, Moscow, Russian Federation; 3Lomonosov Moscow State University, Moscow, Russian Federation; 4Vladimir Regional Clinical Hospital, Vladimir, Russian Federation.

Background: The role of ANCA type is well established for the risk of relapses of ANCA-associated vasculitis (AAV). However their association with renal involvement and its outcomes is less well understood.

Objectives: To assess clinical and morphological features of ANCA-associated glomerulonephritis (ANCA-GN) and renal survival in ANCA-negative patients. Proteinase-3 ANCA (p3-ANCA) positive and myeloperoxidase-ANCA (MPO-ANCA) positive patients.

Methods: We enrolled 53 patients with AAV, diagnosed according to Chapel Hill Consensus Conference (2012) definition and/or ACR (1990) criteria, with historically proven renal involvement. There were 13 (24.5%) males, median age at onset was 48 (33; 57) years. Seven patients were ANCA-negative (13.3%), 17 (32.0%) patients were p-3-ANCA positive and 29 (54.7%) patients were MPO-ANCA positive. ANCA-associates glomerulonephritis (ANCA-GN) class was established according to Berden et al classification.1 We retrospectively assessed ANCA renal risk score (ARRS) at disease onset.2 Twelve patients (22.6%) developed end-stage renal disease (ESRD) after a median of 12 (6.5; 28) months. Renal survival rates were assessed by Kaplan-Meier method and compared by log-rank test.

Results: The only significant difference was median BVAS score which was significantly higher in p3-ANCA-positive (18 (17;20)) then in MPO-ANCA positive patients (15 (12; 18), p=0.012). Creatinine levels, eGFR, percentage of glomeruli with crescents, global sclerosis, and interstitial fibrosis and tubular atrophy didn't depend on the presence of ANCA or type of the antibodies. The proportion of patients with focal, crescentic, mixed of sclerotic class of ANCA-GN was similar in all groups. There was no significant difference in the numbers of patients with low, medium or high risk of ESRD according to ARRS. One- and three-year renal survival rates were similar in ANCA-negative (81.7% and 60.0% respectively) and ANCA-positive patients (84.2% and 74.6% respectively, Figure 1A). One-year and three-year survival rates were higher in MPO-ANCA-positive (84.4% and 84.4% respectively) than in p3-ANCA-positive patients (73.1% and 50.1% respectively), however the difference was not statistically significant (Figure 1B).

References:

Figure 1. Kaplan-Meier curves showing renal survival in ANCA-positive and ANCA-negative patients (A), and p3-ANCA-positive and MPO-ANCA-positive patients (B)
Conclusion: Our small study indicates that clinical and morphological features of renal involvement, as well as renal survival are similar in ANCA-negative and ANCA-positive patients and don’t depend on the type of ANCA.

Scientific Abstracts

Background: Polyarteritis nodosa (PAN) is a systemic necrotizing vasculitis that mainly affects medium-sized muscular arteries. The coronary artery could be affected. Some severe cases can lead to spontaneous coronary artery dissection (SCAD) and about 0.02% will die abruptly. Early diagnosis will improve prognosis, but relative studies are all case reports so far.

Objectives: To investigate the clinical characteristics, risk factors and outcome of patients with polyarteritis nodosa (PAN) complicated with coronary artery lesions in China.

Methods: Data of 158 patients with PAN who were admitted to Peking Union Medical College Hospital from September 1986 to September 2019 were retrospectively collected. Data were analyzed and compared according to with and without coronary artery lesions due to PAN.

Results: 17 (10.8%) patients with PAN had the coronary artery lesions due to PAN. The age at coronary artery lesion was 36.9±10.3 years. 12 (70.6%) patients were male. There are not statistical differences between two groups in common risk factors of coronary arterial atherosclerosis including smoking, hypertension, diabetes mellitus and hyperlipidemia. Most of them are multi-vessel lesions (8 cases are triple-vessel lesions and 3 cases are bi-vessel lesions). Type of coronary artery affected is shown mainly in stenosis (13 cases). Myocardial infarction are shown in 8 cases (47.1%). Compared to patients without coronary artery lesions, patients with coronary artery lesions had less nervous system involvement (17.6% vs.46.8%) and elevated number of leukocyte (17.6% vs.56%). Besides, patients with coronary artery affected exhibit more cranial and carotid artery involvement (29.4% vs. 5.0%), renal artery involvement (41.2% vs.17.0%), coeliac artery involvement (58.8% vs.27.0%), new onset hypertension (47.1% vs.14.5%), renal infarction (27.3% vs.5.4%), and higher proportion of 2009 Five-factor score (FFS)≥2 (62.5% vs.15.6%). All patients with coronary artery lesions received at least moderate dose of prednisone and CTX except one who refused medication. 3 cases underwent interventional therapy. Stent placement was performed on 2 of them, and in-stent restenosis was appeared in a patient one year later. 2 cases died, one for vascular rupture after coronary aneurysmectomy plus coronary artery bypass grafting, another for myocardial infarction after stopping immunosuppressant therapy himself.Survival analysis showed patients with digital g angrene had poor prognosis though no significant difference(p=0.055).

Conclusion: PAN with coronary artery lesions are not uncommon. These patients exhibit young age, more proportion of multi-vessel of coronary artery involvement, more combined involvements of other organ arteries and more severe disease.

ABNORMALITY OF PERIPHERAL LYMPHOCYTE SUBSETS IN BECHET’S DISEASE AND EFFECTS OF NEW IMMUNOREGULATORY COMBINATION THERAPIES ON THESE CELLS

O. Y. Su1, S. X. Zhang2, L. M. Hao3, J. Y. Yang1, J. Bai1, S. J. Guo1, J. Luo2, G. Y. Liu2, C. Gao3, X. Li4. 1Shanxi Medical University Taiyuan, China; 2the Second Hospital of Shanxi Medical University, Taiyuan, China; 3Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America

Background: Bechet’s disease (BD) is a chronic multisystemic vasculitis. Although its exact etiopathology is unknown, both autoimmune imbalances associated with genetic and abnormal immune response of effector lymphocytes promoted by infectious factors are suggested. The increase of effector T cells (Teffs) and the decrease of regulatory T cells (Tregs) are possibly the involving factors in the pathogenesis of BD. Importantly, we have developed new immunoregulatory combination therapies trying to restore the reduction of Tregs in rheumatic patients.

Objectives: To examine abnormal levels of lymphocyte subsets in BD patients at a relatively large-scale sample size and to investigate whether the immunoregulatory combination therapies have therapeutic efficacy in BD.

Methods: Total 384 BD patients and 206 healthy controls (HCs) were enrolled in this cross-sectional study. Proportions and absolute numbers of peripheral T, B, NK, CD4+ T, CD8+ T, Th1, Th2, Th17 and Treg subsets were analyzed by flow cytometry (FCM) for all participants. Among these patients, 183 cases of BD patients were treated with immunoregulatory combination drugs (IMiDs) such as low-dose interleukin-2, rapamycin, metformin, retinoic acid and coenzyme Q10. The levels of peripheral lymphocyte subsets were measured before and after the treatment. Compared-T test was used to compare continuous measures and to assess effect of these drugs.

Results: Compared to HCs, the absolute numbers of various Teffs such as T, B, CD4+ T, CD8+ T, Th1 and Th17 cells were significantly increased in BD group (P<0.01), while the level of Tregs in patients with BD was severely decreased (P< 0.05), resulting in increased ratios (imbalance) of Th1/Tregs, Th2/Tregs and Th17/Tregs (P<0.05) (Figure 1). After the IMiDs treatment, the levels of NK, CD4+ T, CD8+ T, Th1, Th17 cells as well as Tregs were significantly increased (P<0.05). But the increased Tregs was much more dramatic than those of Teffs, resulting in a decrease in ratios of Teffs/Tregs such as Th2/Th1 (P< 0.001) (Figure 2).

Conclusion: Impaired balance of pro- and anti-inflammatory immune cells, especially insufficiency of Tregs, might be a cornerstone of the pathogenesis of BD. Immunoregulatory combination therapies could promote the proliferation and functional recovery of Tregs in patients with BD and might help to alleviate disease activity.

CLINICAL CHARACTERISTICS AND POTENTIAL BIOMARKERS FOR DISEASE ACTIVITY OF PATIENTS WITH ANCA ASSOCIATED VASCULITIS: A MONOCENTER STUDY IN CHINA

Y. Liu1, L. Ma1, L. Jiang1. Zhongshan Hospital, Fudan University, Rheumatology, Shanghai, China

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a group of multisystem, autoimmune, inflammatory disease characterized by pauci-necrotizing vasculitis affecting small blood vessels. The clinical manifestations of the AAV are diverse and can be confined to one organ, or multiple organs and even life-threatening. However, there has been no specific index for assessing the activity of AAV at diagnosis.

Objectives: The aim of this study was to describe the clinical and serological features of patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) in eastern China using data from a hospital-based study. And looking for indicators that can predict disease activity.

Methods: We retrospectively studied patients with newly diagnosed AAV evaluated from January 1, 2009, to December 31, 2018. In total, 219 patients diagnosed were classified according to the American College of Rheumatology classification criteria and/or revised Chapel Hill 2012 definitions, and their clinical and serological features were evaluated. The association of laboratory data with disease activity was assessed via regression models.

Results: Of 219 incident cases of AAV, 37/219 (16.9%) had granulomatosis with polyangiitis (GPA), 172/219 (78.5%) were microscopic polyangiitis (MPA), and 10/219 (4.6%) had eosinophilic granulomatosis with polyangiitis (EGPA). The mean age at diagnosis of patients with GPA were 51.5 years, MPA were 61.7 years, and EGPA were 49.8 years, respectively. Patients with MPA were significantly older than GPA and EGPA at diagnosis (p<0.001). ANCAs tested positive in 207 (94.5%) of cases: 167 (80.7%) were MPO-ANCA and 40 (19.3%) were PR3-ANCA. Lung, skin, nervous system symptoms were the most common in EGPA. For GPA, ear–nose–throat (ENT) symptoms and lungs involvement were the most common. Renal and lung involvement occurs most frequently in MPA. In the multivariable logistic regression analysis, higher anti-MPO antibody (149.4 IU/ml), higher hypersensitive c-reactive protein (hs-CRP, 62.5 mg/L), lower hemoglobin (113.5g/L), and higher complement 4 (C4, >0.215 g/L) were proved to be independent risk factors for active disease. Further research showed that C4 had higher sensitivity (70.0%) and specificity (83.4%) than the other three indicators.

Conclusion: MPO-ANCA-positive MPA is the most common form of AAV in Chinese patients. Serum C4 concentrations at diagnosis might be a useful biomarker of disease activity in AAV.

Diagnosis can be challenging, and the American College of Rheumatology (ACR) of vascular complications such as occlusion and ischaemic stroke. The clinical group contains all patients referred as query GCA, not just those with positive C-reactive protein (CRP) and / or erythrocyte sedimentation rate (ESR). The outcome data includes number of years on steroid (steroid burden).

Methods: Through evaluation of the new GCA fast-track pathway implemented at UCLH, a subgroup of patients diagnosed with vertebral arteritis was identified. The history and presentation of these patients were analysed.

Results: Three patients were diagnosed with vertebral arteritis. All three were male, Caucasian and aged over 70. All were investigated for GCA due to a history of severe headache (frontal in one, occipital in one, bi-temporal in one) with associated red flag symptoms. Two had a history of jaw claudication and visual disturbances (unilateral visual loss in one, transient diplopia in the other). Both of these patients had positive temporal artery biopsies. The third patient had no ischaemic symptoms but a strong history of prominent polyomalic features and a positive temporal artery ultrasound. Inflammatory markers were raised in two, and normal in one, of the patients. Only one had systemic symptoms (weight loss). All three proceeded to FDG-PET scans which showed vertebral arteritis and were commenced on immunosuppressive treatment.

Conclusion: The cases discussed illustrate the heterogeneity of the presentation of LV-GCA, and the diagnostic challenge this poses. FDG-PET imaging is useful in confirming extra-cranial involvement and therefore guiding treatment.

AB0502
EVALUATION OF A NOVEL FAST TRACK PATHWAY FOR GIANT CELL ARTERITIS USING PET IN ADDITION TO TAUS AND TAB FOR EARLY DIAGNOSIS
D. Ludwig1, A. Shashidhara1, C. Stavrou1, S. Voo1, R. Reshaf1, V. Morris1.
University College London Hospital, London, United Kingdom

Background: Giant Cell Arteritis (GCA) is a common primary systemic vasculitis (1). Its predilection for the temporal artery can result in permanent visual loss if left untreated. Over 25% of patients have involvement of large vessels, such as the aorta, resulting in an increased risk of aneurysm formation and dissection. (3) Diagnosis of GCA is largely clinical and temporal artery biopsy (TAB) has long been the gold standard for diagnosis. In recent years temporal artery ultrasound (TAUS) has emerged as an effective, non-invasive tool to aid diagnosis. Positron-emission tomography (PET) can also be utilised to detect the presence of large vessel involvement but is currently not used in many centres for diagnostic purposes and requires further standardisation and validation (2). The challenge arises from these investigations losing sensitivity in the days following steroid treatment, meaning that rapid access is key to confirm diagnosis.

Objectives: To evaluate the impact of the introduction of a fast track pathway (FTP) on prompt diagnostics and treatment. To improve our understanding of the use of PET at diagnosis and compare this to the gold standard TAB, and to TAUS, in our institution.

Methods: Cohort 1: 32 patients, all presenting before FTP implementation, identified from outpatient clinics and referrals to the Rheumatology team. Time taken from steroid initiation to TAUS/TAB was extracted from clinical records. Outcomes for this group included number of years on steroid (steroid burden). Cohort 2: 21 patients all referred after implementation of a new GCA FTP. This group contains all patients referred as query GCA, not just those with positive diagnoses. Time from steroid initiation to TAUS/TAB was recorded. The FTP included the addition of PET imaging within 72 hours.

Results: Cohort 1: 20 (63%) patients had TAB and 3 (9%) had TAUS. The average time from starting steroid to investigation was 5.2 days and 2 days respectively. The average steroid burden in patients with no confirmatory test was 11 years. If patients had just a single diagnostic test this value dropped to 3 years. Cohort 2: 11 (52%) had TAB, 10 (48%) had TAUS and 11 (52%) had PET. In positive GCA diagnoses, time from steroid start to investigations was 7.2 days, 1 day and 3.2 days respectively. In patients with a negative diagnosis the time frames were 13 days, 1 day and 1.7 days respectively. Sensitivity for TAB was 45.5% and TAUS 40%. Specificity for TAB and TAUS was 100%. These results are comparable to similar studies (4). PET sensitivity was 63.6% and specificity 100%.

Table 1. Sensitivity, specificity, predictive values

Conclusion: Prompt diagnostics, best facilitated through a FTP, can reduce steroid burden in GCA even if only one confirmatory test is available. Patients with a low clinical suspicion of GCA and negative TAUS or a high clinical suspicion and positive TAUS stand little to gain from TAB. These findings summarise the first 6 months of our GCA FTP. Continued evaluation of PET in our FTP is needed to understand its role in diagnosis, particularly in patients at risk of vascular complications.

**Conclusion:** Compared with GCA patients, TAK patients had higher level of CD8+T lymphocytes, consisting with previous studies. In addition, TAK patients had persistent immune cell involvement, while humoral immunity is related to disease activity. Deeper studies may be required about the role of immune profile in large vessel vasculitis.

**SEASONAL INFLUENCE IN PMR: NOT ONLY SUMMER, BUT WINTER IS COMING TOO**

D. Marsman1, N. Den Broeder2, F. Van den Hoogen3, A. Den Broeder4, A. Van der Maas4;5, Sint Maartenskliniek, Rheumatology, Utrecht, Netherlands; 3Sint Maartenskliniek, Rheumatology, Ubbrogen, Netherlands; 4Sint Maartenskliniek, Ubbrogen, Netherlands

**Background:** The cause for polymyalgia rheumatica (PMR) is currently unknown. Disease onset may be triggered by a combination of genetic predisposition and environmental factors such as infection.2,3 In different regions of Denmark a simultaneous peak incidence of giant cell arthritis and PMR occurred together with epidemics of Mycoplasma pneumoniae, Chlamydia pneumoniae, and Parvovirus B19.4 A seasonal epidemics pattern for PMR would be supporting evidence for an infectious cause.5 However, the current evidence of seasonal effect on the occurrence and disease severity of PMR is limited and show conflicting results.2,4

**Objectives:** To evaluate whether there is a seasonal effect on the risk of developing PMR in the Netherlands.

**Methods:** We retrospectively collected data on patient-, disease-, and treatment characteristics from newly diagnosed PMR patients (clinical diagnosis) who visited our outpatient clinic during April 2012 and September 2017. Exclusion criteria was other concomitant inflammatory rheumatic disease. Based on the onset of PMR (start symptoms, not time of diagnosis) patients were grouped per month. Descriptive statistics were used [mean (SD), median (p25-p75) or n (%) as appropriate]. The chi-square goodness of fit test was used to determine whether the incidence of onset of symptoms was different between months of the year.

**Results:** In total 448 patients were included and 55 % were female and mean age was 66 years. Other baseline characteristics are described in table 1. The chi-square goodness of fit test to determine whether there was a peak incidence in months was p=0.06. As shown in figure 1 the incidence of onset PMR symptoms is higher in December-January, April through June with a peak in August. The April-June peaks coincide with incidence peaks of Mycoplasma pneumoniae infections and possibly Parvovirus B19 in spring and summer, the December-January peak coincides with Parvovirus B19 infections.5,6

**Conclusion:** No definitive seasonal effect was found on risk of developing PMR, although a bimodal seasonal pattern compatible with the proposed respiratory infections is suggested.

References:
Background: Recommendations to collect the most relevant information on disease course, treatment and outcomes in giant cell arteritis (GCA) has been proposed by EULAR to facilitate clinical research and to improve clinical care. The disease course, treatment and outcomes in giant cell arteritis (GCA) has been disseminated in every patient (39, 100%). Only 2 mayor relapses were identified (5%). Two (2) patients died during the one-year follow-up period. Table 1 provides information on GCA-related signs and symptoms, laboratory and therapeutic data.

Conclusion: Although data collection in routine care is usually comprehensive enough according to EULAR proposed data set, key components in physical exam mostly those aiming to detect large vessel involvement, should be addressed more carefully.

PMR: polymyalgia rheumatica, ESR: erythrocyte sedimentation rate, CRP: C-reactive protein, SD: standard deviation, IQR: interquartile range, DMDR: disease modifying antirheumatic drugs.

Methods: We reviewed medical records of patients diagnosed with GCA in a tertiary academic center between 2004–2018. We included patients with available data at diagnosis and one year of follow-up. Data extraction included: demographics, diagnosis, GCA-related signs and symptoms, laboratory, imaging modalities, comorbidities and treatment. Data in the chart was then compared with the core set of parameters proposed for GCA registries and databases by EULAR. Major relapse, according to the EULAR 2018 definition, was independently assessed by two rheumatologists.

Results: 56 patients were identified, 39 met predefined inclusion criteria with 151 visits during first-year follow-up. Headache (100%, 80.4%), ocular symptoms (89.7%, 81.2%), constitutional symptoms (89.7%, 80.4%), polymyalgia rheumatica (89.7%, 82%) and jaw claudication (87%, 81.2%) were the most frequently collected items at baseline and follow-up. Weight and height (2.6%; 2.6%), peripheral pulses (8%; 4.5%), smoking status (41%; 21%), and blood pressure (61.5%; 4.5%) were the less frequently collected. Most patients lacked differential pressure measurement. Myocardial infarction, malignancy, serious infections, arterial hypertension, diabetes and osteoporosis were collected in every patient (39, 100%). Only 2 mayor relapses were identified (5%). Two (2) patients died during the one-year follow-up period. Table 1 provides information on GCA-related signs and symptoms, laboratory and therapeutic data.

AB0507 INVASIVE ASPERGILLOSIS IN ADULT RHEUMATOLOGICAL PATIENTS IN SAINT PETERSBURG, RUSSIA

V. Mazyrin1, O. Shadrivova1, M. Shostak1, L. Martyanova1, M. Tonkoskhir1, N. Klimko1.1North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russian Federation

Background: Invasive aspergillosis (IA) is a severe opportunistic infection that is not well understood in rheumatological patients.

Objectives: To study risk factors, etiology, clinical manifestations and results of treatment of IA in adult rheumatological patients.

Methods: Retrospective analysis of 830 patients (1998-2019) with ‘‘proven’’ and ‘‘probable’’ IA (EORTC / MSG, 2019), adults - 699 (84%). The main group included 18 (3%) adult rheumatological patients with IA, a control group included 610 (87%) adult hematological patients. Rheumatological patients were older, the average age was 59 years (21–75) vs 45 years (18–78), p = 0.005, and among them there were more women – 56% vs 42%, p = 0.01.

Results: In rheumatological patients with IA, underlying diseases were ANCA-associated vasculitis (28%), granulomatosis with polyangiitis (22%), periarteritis (11%), systemic lupus erythematosus (22%), rheumatic heart disease (11%) and ankylosing spondylitis (6%). In the control group, underlying diseases were acute leukemia (45%), lymphomas (34%), chronic leukemia (8%), multiple myeloma (7%), myelodysplastic syndrome (3%), and other hematological diseases (2%).

The main risk factors for IA development in rheumatological patients were: systemic steroids use (89% vs 69%), prolonged lymphocytopenia (78% vs 65%, median - 14 vs 12 days), treatment in ICU (44% vs 18%, p = 0.01), acute or chronic renal failure (39% vs 1%, p = 0.0008) and immunosuppressive therapy (28% vs 25%). Severe neutropenia was noted significantly less frequently (18% vs 83%, p = 0.0001). Additional risk factors were: decompensated diabetes mellitus (17% vs 2%, p = 0.004), previous surgery (17% vs 1%, p = 0.001) and organ transplantation (6% vs 0%). In rheumatological patients, lung (83% vs 98%, p = 0.0001) and ≥2 organs (6% vs 8%) involvement were less common. Heart (11% vs 0%), sinususes (6% vs 5%) and central nervous system (6% vs 4%) involvement more often developed. In rheumatological patients, respiratory failure (61 vs 37%, p = 0.03), hemoptysis (28% vs 7%, p = 0.0001) and chest pain (17% vs 7%, p = 0.04) were noted more often, less often - fever ≥38°C (67% vs 85%,
Background: Takayasu arteritis (TA) is a chronic inflammatory large- vessel vasculitis, predominantly affecting the aorta and its main branches.

Objectives: To assess safety and efficacy of biologic (i.e. TNF-α antagonists and tocilizumab) in patients with Takayasu arteritis (TA).

Methods: We conducted a retrospective multicenter study in referral centers from Europe and several countries in the world about biological-targeted therapies in Takayasu arteritis during the period from January 2017 to September 2019.

Results: Retrospective multicenter study of characteristics and outcome of 49 TA patients [80% of females; median age 42 [20-55] years] treated by TNF-α antagonists (80%) or tocilizumab (20%)] and fulfilling ACR and/or Ishikawa criteria. Factors associated with complete response were assessed. Eighty-eight percent of TA patients were inadequately controlled with, or intolerant to, conventional immunosuppressive therapy [median number of 3 (1-5)]. Overall response (i.e. complete and partial) to biological-targeted treatments at 6 and 12 months was of 75% and 83%, respectively. There were a significantly lower C-reactive protein levels at initiation of biological-targeted treatments [22 [10-48] mg/l vs 58 [26-76] mg/l; p=0.006] and a trend toward lower immunosuppressants drugs used prior biologics (p=0.054) in responders (i.e. complete and/or partial responders) relative to non-responders to biological-targeted treatments. C-reactive protein levels and daily prednisone dosage significantly decreased after 12 months of biological-targeted treatments [30 vs 6 mg/l], p<0.05 and 15 vs 7.5 mg, p<0.05, at baseline and at 12 months, respectively). The 3-year relapse free survival was of 90.9% (83.5-97.9) over biologic treatment period compared to 58.7% (43.5-73.7, p=0.0025) with DMARDs. No difference was found relative to efficacy between TNF-α antagonists and tocilizumab. After a median follow-up of 24 [2-95] months, 21% of adverse effects occurred, with biological-targeted treatments discontinuation in 6.8% of cases.

Conclusion: This nationwide study shows high efficacy of biological-targeted treatments in refractory TA patients with an acceptable safety profile.

AB0509 SUSPENSIVE EFFICACY OF TOCILIZUMAB IN TREATMENT-NAIVE PATIENTS WITH TAKAYASU ARTERITIS: TOCITAKA FRENCH PROSPECTIVE MULTICENTER OPEN-LABELLED TRIAL.

A. Mekinian1, D. Saadoun1, J. C. N. F. Jerome,Connault@chu-nantes.fr1, l. O. M. F. I-Que@chu-montpellier.fr1, P. Jégó1, N. L. F. Frélichias-Limal@aphp.fr1, W. Xwx1, J. E. Gottenberg1, M. Vautier1, L. S. F. Lea.Savéy@aphp.fr1, P. Cacoub1, O. Fain@on behalf of n. QSD, QSD, France

Objectives: To assess long term efficacy of tocilizumab in treatment-naive patients with Takayasu arteritis (TAK).

Methods: In this multicenter, prospective, open-labelled trial, we aim to evaluate the benefit of adding tocilizumab to steroids in treatment-naive patients with TAK, on discontinuation of steroids after 6 months of tocilizumab treatment, and to assess relapse-free survival following tocilizumab discontinuation.

Results: Thirteen patients with TAK were included, with a median age of 32 years [19-45] and 12 (92%) females. Six (54%) patients met the primary endpoint. Among 11 (85%) patients which achieved remission at 6 months, 6 (54%) have reached primary endpoint. Among the 5 remaining patients which continued steroids, 3 had a prednisone-equivalent dosage < 5mg/day. A significant decrease of disease activity was observed after 6 months of tocilizumab therapy: decrease of median NIH scale (3 [3-4] at baseline, versus 1 [0-2] after 6 months; p<0.001), ITAS-2010 score [5 (2-7) versus 3 [0-6]; p=0.002], and ITAS-A score (7 [4-10] versus 4 [1-15]; p=0.001)). All patients discontinued tocilizumab after 7 infusions, and no other immunosuppressive drugs was introduced, except for 1 patient which received methotrexate. After 9 and 12 months, respectively 7 (54%) and 6 (50%) patients achieved remission with less than 75mg/day of prednisone, and 9 (69%) and 9 (75%) with doses <10mg/day. During the 12 months follow-up after tocilizumab discontinuation, a relapse occurred among 5 patients (45%) out of 11 in which achieved remission after 6 months of tocilizumab.

No severe AE's were considered related to study treatment and none required tocilizumab interruption or dose reduction. No deaths have occurred during the study period.

Conclusion: Tocilizumab seems an effective steroid sparing therapy in TAK but its effects appear to be suspensive.

AB0510 INFLIXIMAB IS AN EFFECTIVE GLUCOCORTICOID-SPARING TREATMENT FOR TAKAYASU ARTERITIS: RESULTS OF A MULTICENTER OPEN-LABEL PROSPECTIVE STUDY

P. Mertz1, J. F. Kleinmann1, M. Lambert2, X. Puéchâ1, T. Martin1, J. Sibilia1, L. Arnaud1, Service de Rhumatologie, Hôpitaux Universitaires de Strasbourg, Laboratoire d’Immunologie Moléculaire, INSERM UMR S1109, Centre National de Références des Maladies Systémiques et Autoimmunes Rares Est Sud-Ouest (RESO), Université de Strasbourg, Strasbourg, France; Internal Medicine and Clinical Immunology, Centre de Référence des Maladies Auto- immunes Systémiques Rares du Nord et Nord-Ouest de France (CeRAIN0), CHU Lille, University Lille, LIRIC, INSERM, Lille, France; National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, AP-HP, Université Paris Descartes, Paris, France; Service d’Immunologie Clinique, Nouvel Hôpital civil, Strasbourg, France. Centre National de Référence des Maladies Autoimmunes Systémiques Rares Est Sud-Ouest (RESO)-LUPUS, Strasbourg, France

Background: Approximately half of patients with Takayasu Arteritis (TA) have glucocorticoid (GC)-dependency and require the addition of a second-line immunosuppressive treatment.

Objectives: Here, we conducted a multicenter open-label prospective cohort study to assess the efficacy and safety of infliximab originator as a GC-sparing agent in TA.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.3574
Methods: A temporary recommendation for use for infliximab in refractory TA was approved by the French National Drug Authorities (April 2014). Infliximab was administered to patients in case of disease activity with a NIH score ≥2 despite conventional therapy. Data regarding patient's clinical, laboratory, imaging and treatments were obtained at baseline, and at each follow-up visit until last visit (October 2017). TA activity was evaluated according to NIH criteria and GC requirement throughout the study.

Results: Twenty-three patients were enrolled, including 19 female. The median age at inclusion was 33 years (Interquartile range, IQR: 23-44 years). At baseline, 17 (74%) patients were treated with GCs, at a median dose of 10 mg/day (IQR: 0-21) of prednisone-equivalent. After a median follow-up of 36.9 months (IQR: 10-58.7), improvement of ≥1 NIH criterion of TA activity was achieved for 14/22 (64%) patients. The median GC dose was 8mg/day (IQR: 7-10) at 6 months; 5mg/day (IQR: 0-8) at 12 months and 0mg/day (IQR: 0-5) at 36 months of follow-up. Overall, infliximab originator had a significant GC-sparing effect between baseline and last follow-up (p=0.009).

Conclusion: This multicenter open-label cohort study suggests that infliximab originator is an effective GC-sparing treatment for TA refractory to conventional therapy.

ALLERGIC PROFILE AND ALLERGEN-SPECIFIC IMMUNOTHERAPY IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA): A SINGLE CENTER OBSERVATIONAL STUDY

L. Moro1,2, A. Cariddi1, S. Sartorii1, E. Della Torre2, T. Germano2, G. A. Ramirez2, E. Bozzoli1, M. R. Yacoub2, L. Dagna1,2, IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy; 3Vita-Salute San Raffaele University, Milano, Italy

Background: Eosinophilic granulomatosis with polyangiitis (EGPA), previously known as Churg-Strauss syndrome, is a systemic disease characterized by late onset asthma associated with small- and/or medium-size vessel vasculitis, besides eosinophil-mediated cytotoxic organ damage. About 20-30% of patients with EGPA displays allergic manifestations related with inhalant sensitization, while prevalence of food and drug allergy is unknown in this context. Moreover, some authors in the past have reported in favor of a possible role of allergen-specific immunotherapy (ASI) as a trigger of disease.

Objectives: Aim of the present study is to establish the prevalence of each category allergy sensitization and to determine whether atopy or specific immunotherapy could influence clinical expression of the disease.

Methods: Our study consisted in a retrospective demographic and clinical data collection regarding EGPA history (including age at diagnosis, organ and tissue involvement, autoantibody profile) and the presence of allergic comorbidities or previous drug hypersensitivity reactions. Patients without either proven allergic reactions or positive tests have been excluded.

Results: Fifty-three (53) patients with definitive diagnosis of EGPA have been included in the analysis among which 25 (47.2%) with chronic respiratory allergy or previous acute allergic reaction. Among allergic patients 15 (60%) resulted sensitized towards inhalants and among them 13 (86.7%) displayed multiple sensitization. Drug allergy affected 13 patients (52%), food 4 (16%). Among 15 patients with respiratory allergy, 13 were eligible to allergen-specific immunotherapy (ASI). Seven (7) subjects underwent ASIT prior EGPA diagnosis with an average time-to-EGPA of 16.2 years. No statistically significant difference was found in terms of sex, age at diagnosis, positivity for or specificity of anti-neutrophil cytoplasm antibodies (ANCA), eosinophil count at onset, pattern of clinical manifestations comparing allergic vs. non-allergic, ASIT vs. non-ASIT, ASIT vs. allergic, ASIT vs. eligible.

Conclusion: Among patients with EGPA allergies are highly prevalent, particularly towards inhalants and drugs. In the great majority of patients multiple sensitization profile is found. Atopy doesn't seem to be associated with specific patterns of disease presentation. The absence of correlation between inhalant ASI exposure and variation in mode and time of EGPA onset doesn't support the hypothesis of a its potential role in triggering the disease.

F. Muratore1, L. Boiardi1, E. Galli1, G. Pazzola1, A. Cavazzza1, G. Rastucci1, C. Salvarani1, Rheumatology Unit, AUSL-IRCCS di Reggio Emilia, Reggio Emilia, Italy;2Rheumatology Unit, University of Modena and Reggio Emilia, Modena, Italy;3Pathology Unit, AUSL-IRCCS di Reggio Emilia, Reggio Emilia, Italy;4Rheumatology Unit, AUSL-IRCCS di Reggio Emilia and University of Modena and Reggio Emilia, Reggio Emilia, Italy

Background: polyarteritis nodosa (PAN) is a primary systemic vasculitis that is becoming a rare disease in part by the decrease in hepatitis B virus (HBV) infection due to widespread vaccination. It is characterized by a full constellation of nonspecific clinical manifestations, which sometimes delays and makes it difficult to diagnose. Still, muscle involvement is a feature that could guide the clinician.

Objectives: to describe the main clinical and laboratory characteristics of patients with PAN and to confirm the frequency of muscle involvement.

Methods: retrospective cross-sectional descriptive study of 23 adult patients diagnosed with PAN between January 2011 and December 2018 in two high complexity hospitals in Medellín-Colombia.

Results: twenty-three patients met ACR 1990 classification criteria for PAN. 52% were men with a median age of 51 (IR 36-60), 78.3% were newly diagnosed, and only two patients (8.7%) had HBV infection. General symptoms (found in 95% of the patients), cutaneous (82%), and articular (56%) were the most frequent manifestations. Among systemic symptoms, myalgia, especially calf pain, was the most common characteristic (78.3%), followed by weight loss (73.9%), fatigue (69.3%), and fever (59.3%). Laboratory findings and severity scores are shown in the table. Angiography was performed in 27/33 patients, finding splanchnic (9.7%), skin and mucous (17.4%), and renal infarction (4.3%). Forty-four patients (61%) had at least one positive biopsy documenting medium-sized artery vasculitis, mainly skin, muscle, nerve, or both; 9 (39%) had normal or inconclusive biopsy findings. All patients received high daily doses of prednisone (50 + 16 mg); 52.2% required cyclophosphamide, 30.4% azathioprine, 17.4% methotrexate, 8.7% rituximab, 4.3% dapsone and 4.3% plasmapheresis; acetylsalicylic acid was given to half of the patients and treatment, 87% improved; 22.7% had an infection, and 8.7% of patients died.

Conclusion: myalgia was the main characteristics of our PAN patients, especially in calves, and its presence in patients with other general, skin or articular symptoms should raise the suspect of this vasculitis.

PAN: polyarteritis nodosa; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; CPK: creatine phosphokinase; FFS: five factor score; BVAS: Birmingham Vasculitis Activity Score; SD: standard deviation; IQR (interquartile range)
(ACR), and strongly focus on patients with cranial manifestations. Patients with large-vessel GCA (LV-GCA) have less frequently cranial symptoms and a positive temporal artery biopsy, and are less likely to be captured by the ACR criteria. Glucocorticoid (GC) treatment at an initial prednisolone dose of > 15mg is associated with significantly higher mortality and severe side effects (3). According to EULAR-ACR recommendations for the management of polymyalgia rheumatica at persons > 50 years of age. It is clinically characterized by pain and stiffness in the neck, proximal shoulder, and hip girdle. (1)Glucocorticoid (GC) treatment at an initial prednisolone dose of > 15mg is associated with significantly higher mortality and severe side effects (3). According to EULAR-ACR recommendations for the management of polymyalgia rheumatica at persons > 50 years of age. It is clinically characterized by pain and stiffness in the neck, proximal shoulder, and hip girdle. (1)

Methods: All consecutive patients with a diagnosis of GCA seen between January 2008 and December 2016 in our center were included (GCA cohort). Control cohort consisted of consecutive patients with a negative temporal artery biopsy (TAB) performed in the same time period and a final diagnosis different than GCA. For both study cohort, the final diagnosis was made at the end of the follow-up period by consensus by 2 rheumatologists, who retrospectively evaluated all the medical records from symptom’s onset to December 2019, last visit, or death. Subjects were classified by each of the different criteria. TABs showing inflammation limited to adventitial or periadventitial small vessels were considered negative for both ACR and GiACTA criteria.

Two-by-two classification tables were generated to estimate sensitivity and specificity, and receiver operating characteristic (ROC) curves with corresponding areas under the curve (AUC) were calculated.

Results: 213 patients were included in the study (75% female, mean age 71.7 years). 55 patients had TAB showing transmural inflammation (TMI); 30 patients had TAB showing inflammation limited to adventitial or periadventitial small vessels (PAI); 67 patients had evidence of LV-GCA at imaging (LV-GCA) and 61 patients had TAB without inflammatory changes (negTAB). 1990 ACR and GiACTA criteria were satisfied respectively by 55 (100%) and 51 (93%) TMI, 18 (60%) and 1 (3%) PAI, 23 (35%) and 31 (46%) LV-GCA and 27 (44%) and none (0%) negTAB patients.

After a median follow-up of 52.6 months, 174 of the 213 (84%) patients had a final diagnosis of GCA (55 TMI, 22 PAI; 67 LV-GCA and 30 negTAB) and the remaining 33 patients had a diagnosis different than GCA (2 PAI and 31 negTAB). Sensitivity and specificity of 1990 ACR classification criteria for GCA were 67% and 90%, AUC (95% CI) 0.790 (0.715 – 0.864). Sensitivity and specificity of GiACTA inclusion criteria were 48% and 100%, AUC (95% CI) 0.740 (0.669 – 0.811). By adding systemic symptoms in the symptoms domain of GiACTA inclusion criteria, sensitivity increased to 59% and sensitivity remained 100%, AUC (95% CI) 0.792 (0.730 – 0.854).

Conclusion: Both 1990 ACR classification criteria and GiACTA inclusion criteria showed a good specificity but a low sensitivity in classifying patients with a clinical diagnosis of GCA from this large monocentric cohort. There is an urgent need for new classification criteria for GCA.

AB0516

INITIAL TREATMENT OF POLYMALGIA RHEUMATICA PATIENTS: COMPARISONS BETWEEN GENERAL PRACTITIONERS AND THE RHEUMATOLOGIST.

A. Orva1, N. Svendsen1, P. Lage-Hansen1, N. J. Kock1, A. Diamandopoulou2, S. Chrysida1. 1Hospital of Southwest Jutland, University of Southern Denmark, Esbjerg, Denmark; 2Martina Hansen Hospital, Baerum, Norway

Background: Polymyalgia rheumatica (PMR) is the most common inflammatory rheumatic disease at persons > 50 years of age. It is clinically characterized by pain and stiffness in the neck, proximal shoulder, and hip girdle. (1)Glucocorticoid (GC) is the cornerstone of PMR treatment; the use is associated with potentially severe side effects (3). According to EULAR-ACR-recommendations for the management of PMR, treatment should be individualized using the minimum effective GC dose. (2)

An initial prednisolone dose of > 15mg is associated with significantly higher risk for GCs related side effects (1) and GC doses higher than 25mg/day are discouraged because of the high risk of adverse events; furthermore, there is no evidence that such doses are more effective than lower doses (2.3). In most countries, the vast majority of PMR patients are diagnosed and managed primarily by their General Practitioner (GP) (4)

Objectives: To compare the initial GC dose for PMR patients diagnosed by their GP versus an outpatient rheumatological clinic in Denmark.

Methods: All patients with the diagnosis of PMR in South-West Jutland Hospital register at the period of 2013 to 2018 were identified from an electronic register. Patients with an already known rheumatic disease before the diagnosis of PMR, GCA symptoms at the diagnosis time or hospitalized at the diagnostic time were excluded.

Clinical and paraclinical data were collected from the patient’s electronic journal.

Results: In a period of 6 years, 342 patients with PMR were identified. Of 342 patients 83 were diagnosed by their GP. No significant differences were found regarding demographical, clinical and paraclinical baseline characteristics between the two groups. No differences were identified regarding the treatment response. However the initial prednisone dose in patients diagnosed by the GP’s was significantly higher (p<0.00001) compared to the rheumatological outpatient clinic (Table 1) with an initial dose of ≥25mg at over 50% of newly diagnosed cases (45 patients).

Table 1.

USE OF POSITRON EMISSION TOMOGRAPHY IN RHEUMATOLOGY PRACTICE

O. Özdemir Isik1, S. Isgören2, A. Yazıcı1, A. Cefte1, Kocaeli University School of Medicine, Rheumatology, Kocaeli, Turkey; 2Kocaeli University School of Medicine, Nuclear Medicine, Kocaeli, Turkey

Background: Positron emission tomography (PET), which is widely used in oncology, has recently been used as a guide in the diagnosis of vasculitis and activity monitoring.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.6537
Objectives: In this study, we aimed to present the desired PET results for the preliminary diagnosis of vasculitis and follow-up.

Methods: PET results requested from the rheumatology outpatient clinic between 2012–2019, clinical findings of patients and other imaging methods were reviewed and evaluated retrospectively.

Results: PET results were achieved of 36 patients (47% male, 53% female). Constitutional symptoms were present in 67% of the patients with a mean age of 51 ± 18 years. The mean erythrocyte sedimentation rate (ESR) was 49 ± 33 mm/h, CRP was 46 ± 35 mg/L, and leucocyte value was 8.8 ± 3 K/mm³ at the onset of the disease. While 80% of 25 patients with large vessel vasculitis had a murmur in at least one affected area, 48% had no pulse. While 78% of all patients had a finding in favor of vasculitis in non-PET imaging, this rate was 39% in PET (Table-1). Although the most commonly used imaging method is conventional angiography, recently CT and MR angiography have been requested more frequently. Only 32% of patients who are signs of vasculitis in other images had vasculitis in PET. PET was requested with preliminary diagnosis of vasculitis in 24 patients and vasculitis was detected in 46% of the cases. In the twelve of patients with vasculitis had 25% activity involvement in the desired PET for the presence of activation. In 5 of 8 patients with a pre-diagnosis of vasculitis who had no evidence of vasculitis in any other imaging modalities, the involvement of vasculitis was detected in the PET, and the diagnosis was confirmed.

Before PET, 44% of the patients had not received steroid treatment. In this group, 63% of patients who did not take steroids, had vasculitis findings in PET. In steroid receiving group, the rate of PET involvement was 20%. Presence of vasculitis in PET was significantly higher in patients who did not receive steroid prior to PET (p = 0.009) (Table-2). The mean duration of steroid intake before PET was 28 ± 69 months.

Conclusion: PET is an increasingly used imaging technique in rheumatology practice. The main advantage of PET is that it recognizes other pathologies such as infection and tumor in patients with systemic symptoms. Disadvantage is an expensive test, high radiation rate and misinterpretation of atherosclerosis. Vasculitis is a group of diseases that require rapid diagnosis and treatment. Because of the indisputable contribution of imaging methods at the diagnosis stage, PET was emphasized in this study.

AB0518 CRYOglobulinemic vasculitis associated with HCV infection and primary sjogren’s syndrome: data from a single center experience

S. Paleshina1, V. Vasilev2, E. Sokol1, J. Khvan1, B. Chaltcev1, A. Torogashina1.
1VA. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 2MEDI Clinic, Moscow, Russian Federation

Background: According to some publications [1] cryoglobulinemic vasculitis in different associated diseases varies.

Objectives: To characterize patients with cryoglobulinemic vasculitis (CV) in primary Sjogren’s syndrome (pSS) and chronic hepatitis C virus (HCV) infection.

Methods: 54 patients with CV were recruited to this study during 7 years period in our rheumatological center. CV was diagnosed according criteria proposed by Ferri C. [1] and De Vita [2]. 22 patients had CV associated with HCV (19 women and 3 men) and 32 with pSS (all female). The mean age of patients at the time of inclusion in the study among HCV and pSS patients was 50.4±10.0 years and 55.8±13.5 years, and at CV onset was 42.8±11.1 years and 47.1±15.3 years (p>0.05).

Results: 19 patients (86%) with HCV-CV had viremia with prevailed 1b genotype (84%). 8 (42%) patients had severe liver fibrosis (F3-4). SS was diagnosed in 6 (28%) patients with HCV-CV (3 with sSS and 3 with pSS). An increase of aRo antibodies (>50 U/ml) was detected in 4 patients, ANA>1/320 - in 5/6 patients. 2 patients with SS were diagnosed MALT lymphoma of the enlarged salivary and lacrimal glands, and 1 marginal zone lymphoma of the spleen in a patient with HCV-CV without pSS. All patients with lymphoma had type II cryoglobulinemia. Most patients with pSS-CV had late stage and active disease: xerostomia (<0.5 l/min/5 min) in 28 (88%), sialoadenitis (>2 foci in MSG), keratoconjunctivitis sicca in 22 patients, 69%.

Lymphomas were diagnosed in 9 patients with pSS-CV (28%). In all cases, they were non-Hodgkin’s lymphomas (NHL); in 7 patients - MALT lymphomas of enlarged parotid salivary (5), lacrimal glands (2), in 5 cases they were accompanied by regional lymph node enlargement. B-cell marginal zone lymphoma of lymph nodes and B-cell large cell lymphoma were observed in 1 case each.

No statistically significant differences were found in 2 groups in clinical manifestations of CV (see Graph.1), although patients with pSS had elevated lymphoma rate (28% compared to 6% for HCV, p=0.08), while in HCV-CV a slightly higher incidence of arthritis (22%, p=0.14), glomerulonephritis (56% vs 31% in pSS, p=0.10), and enanthema (19% and 3%, respectively, p=0.06).

Type II cryoglobulinemia was detected in 68% cases of HCV-CV and in 72% with pSS, less often mixed polycyonal (27% vs 22%) and oligoclonal (5% and 6%) types. There was in 96% (44/46) cases monoclonal IgM with predominant K-light chain mIg (87%, n=40/46). RF positivity, low C4 complement, increased CD19+ cell levels (p=0.008) and increased BAFF (p=0.04), while in HCV-CV group high transaminases were typical (p=0.0008). BAFF level (N=0.8 ng/ml) in pSS-CV group was higher (median 2.73 ng/ml (0.66-3.86) than in HCV-CV (median 0.66 ng/ml (0.14 - 0.92), p=0.04). Patients with pSS-CV had significantly (p=0.008) lowered CD19 + cell count (median 5.3% (2.2-13.6)) if the normal range was 6-19%, in contrast to patients with HCV-associated CV (median 20.5% (13.2-26.0)).
CONCLUSION: Clinical picture of CV, as well as the main immunological parameters, are similar in patients with associated pSS and HCV. Immunochromatographic assay of serum and urine proteins is required to determine the type of cryoglobulinemia. SS is not rare in HCV-CV, so appropriate examination with ANA, aRo/La detection is mandatory. Patients with mixed monoclonal cryoglobulinemia had increased risk of hematological malignancies.

AB0519

PULMONARY INVOLVEMENT IN ANCA ASSOCIATED VASCULITIS (AAV) ACCORDING TO ANTIGENIC SPECIFICITY: A RETROSPECTIVE ARGENTINE COHORT

C. Pena1, F. Savvy2, A. C. Costi2, L. Garcia2, M. Garcia2, 1HIGA San Martin La Plata, La Plata, Argentina; 2HIGA San Martin, La Plata, Argentina

Background: The lung in ANCA associated vasculitis (AAV) is one of the most frequently compromised organs (20%-80%). The clinical features of pulmonary involvement vary according to the type of vasculitides and some studies have shown its association with the ANCA subtype or antigen specificity (MPO-ANCA), (PR3-ANCA).

Objectives: A-Descibe the clinical features and tomographic findings of pulmonary involvement in vasculitis associated with ANCA and its association according to the ANCA subtypes.

B-Evaluate outcome, relapses and associated mortality.

Methods: Observational, analytical, retrospective study. Data was collected from the medical records and tomographic image files of patients evaluated in rheumatology department in a tertiary level hospital (2007-2019). Patients diagnosed with AAV, who met criteria for ACR 1990 classification or according to nomenclature of Chapel Hill 2012, with thoracic CT performed and dosage PR3 an MPO antibodies by ELISA technique by a pulmonologist and radiologist. Demographic data, subtype of vasculitis, concomitant organic involvement, disease activity evaluated by Birmingham Vasculitis Activity Score v 3 (BVAS v3), time of evolution of pulmonary involvement, ERS – PCR, serum creatinine, ANCA determined by ELISA were collected. The following findings in parenchyma were evaluated by thorax CT: Consolidation, Ground glass opacities, Reticulation, Honeycomb, cavitated or not nodules, Central airway compromise (thickening or stenosis), Bronchiectasis, Peribronchial thickening, Pleural effusion and the following patterns of disease: NIU (Unspecified Interstitial Pneumonia), NINE (Unspecified Interstitial Pneumonia), HAD (Diffuse Alveolar Hemorrhage).

Results: 68/87 patients were included, 59% female, with a mean age of 51 (14 SD) years. GPA 46.9%, MPA 39.4%, EGPA 13.6%, median follow-up time of 36 months (RIC 12-77).

According to antigenic specificity: 40.9% PR3 positive. 47.6% MPO positive and ANCA negative 11.5%. 74% of the GPA were positive for PR3, and 58% PAM at MPO.

BASV basal: 17.8+7.5 DS.

Frequency of organic involvement: 81.8% pulmonar, 77% systemic, 57.6% renal, 43% ENT.

54% of patients with pulmonary involvement was present at the onset of their disease.

Conclusion: The frequency of pulmonary involvement in this cohort of patients was 82%, similar to that reported in the literature and was presented at the beginning of the disease in half of the cases. The presence of positive MPO was associated with a higher frequency of usual interstitial pneumonia.

According to the pattern of tomographic condition: 36.5 HAD %, 9.6% NIU, 78% NINE and, 1.5% Bronchiolitis obliterans.

The presence of positive MPO was significantly associated with the presence of honeycomb (p 0.017) and NIU (p 0.018).

There were no significant associations with the presence of PR3.

Mortality was 17%.

No association was found in relation to mortality or relapse frequency among PR3 or MPO positive patients.

AB0520

L. Quaruccio1, E. Treppo1, S. De Vita1, F. Valenti1, 1Clinic of Rheumatology, Department of Medicine, Academic Hospital “Santa Maria della Misericordia”,ASUI, Udine, Italy

Background: ANCA-associated vasculitides (AAV) are a group of systemic vasculitides carrying a high risk of hospitalization because the multiorgan involvement, the acute nature of some clinical manifestations, the chronic but very disabling course of some other manifestations and finally the risk of severe infections due to chronic glucocorticoid and immunosuppressor administration.

However, data on hospitalization due to ANCA-associated vasculitides are still scarce.

Objectives: to estimate the rate of the first hospitalization or the death in patients suffering from AAV in the Italian region of Friuli Venezia Giulia (about 1,200,000 inhabitants) from year 2013 to 2017.

Methods: integration of the information coming from many administrative databases were used to this end. The Regional Health Information System of Friuli Venezia Giulia was used as the source of information for this retrospective cohort study. The system covers the entire regional population and includes various electronic health administrative databases that can be linked with one another on an individual basis through a unique encrypted identifier. In particular, the following databases were matched: the database of the regional potential health care beneficiaries (including demographic information and the residential history of all the subjects living in the region), the hospital discharge database, the database of exemptions from medical charges were used for this study, the database of the different regional laboratories. The population under study was selected based on the following inclusion criteria: patients were residents in Friuli Venezia Giulia and they had to carry the exemption code for AAV, including Granulomatosis with Polyangiitis (GPA), or Eosinophilic Granulomatosis with Polyangiitis (EGPA), or Microscopic Polyangiitis (MPA). This population was observed from 2013 to 2017. The coded event was the occurrence of the first hospitalization or the death. Also, all the hospitalization and their main discharge diagnoses were registered.

Results: 103 patient with AAV were identified. The number of patients with at least one hospitalization/death was 74/103 (71.8%). Seven patients died during the observation period (6.6%). The whole number of hospitalizations was 285 in
74 patients. 55/74 (74,3%) patients experienced more than one hospitalization. In the majority of the hospitalizations (119/285, 41,7%), the cause of hospitalization was directly attributable to the disease itself, while the second cause of hospitalization was the infections (26/285, 9,1%). In 10/103 patients (9,7%), an end stage renal disease was recorded as event. The presence of at least one positivity for ANCA antibodies was documented in 76/103 patients (73,8%), mainly in patients carrying GPA. Globally, the presence of ANCA antibody seems to be associated with greater likelihood of an event (p=0.07, log-rank test). The first event occurred in 50% of ANCA-positive patients within 180 days from diagnosis, while in 50% of ANCA-negative patients in 859 days. 6 out of the 7 deaths occurred in ANCA-positive patients.

Conclusion: the rate of hospitalization in AAV is very high confirming the high health care burden of illness. The disease itself is often the cause of the hospitalization, as well as the infectious complication, highlighting the need for more effective treatments, and glucocorticoid sparing therapies. ANCA antibody may represent a biomarker of a more serious disease.

COST OF ILLNESS OF ANCA-ASSOCIATED VASCULITIS IN ITALY: DATA LINKAGE ANALYSIS OF MULTIPLE CLINICAL AND ADMINISTRATIVE DATABASES IN THE PROVINCE OF UDINE, ITALY

L. Quartuccio1, E. Treppo1, S. De Vita1, F. Valent1

1Clinic of Rheumatology, Department of Medicine, Academic Hospital “Santa Maria della Misericordia”, ASUI, Udine, Italy, Udine, Italy, 1Institute of Epidemiology, Academic Hospital “Santa Maria della Misericordia”ASUI, Udine, Italy, Udine, Italy

Background: ANCA-associated vasculitides (AAV) are a group of systemic vasculitides carrying a high risk of hospitalization because the multigorgan involvement, the acute nature of some clinical manifestations, the chronic but very disabling course of some other manifestations and finally the risk of severe infections due to chronic glucocorticoid and immunosuppressor administration. However, data on cost of illness due to AAV are lacking.

Objectives: to estimate the cost of illness in patients suffering from AAV in the province of Udine (about 500,000 inhabitants), Friuli Venezia Giulia (FVG), Italy, from January 2010 to 2018.

Methods: integration of the information coming from many administrative databases were used to this end. The Regional Health Information System of FVG was used as the source of information for this retrospective cohort study. The system covers the entire regional population and includes various electronic health administrative databases that can be linked with one another on an individual basis through a unique encrypted identifier. In particular, the following databases were used: main database of the health care beneficiaries (including demographic information and the residential history of all of the subjects living in FVG), the hospital discharge database, the database of exemptions from medical charges, the database of the laboratories. The population under study was selected based on the following inclusion criteria: patients were residents in the province of Udine and they had to carry the exemption code for AAV, including GPA, or EGPA, or MPA. This population was observed from 2010 to 2018.

Results: 57 patients (201 patient-years) with AAV were identified. They were ANCA-positive in 44/57 (77%). GPA, EGPA and MPA was diagnosed in 18 (31,6%), 15 (26,3%), 11 (19,3%) patients, respectively. The mean age at diagnosis was 54,5 (17,5) years. The disease itself was the main cause of hospitalization in almost half of the hospital discharges (60/126, 47,6%). Four patients died during the observation period due to vasculitis itself (1), pneumonia (2), or haematological malignancy (1). Time to the first event (death or hospitalization) was significantly higher in ANCA-negative AAV patients than in ANCA-positive AAV patients (p=0,03, Log-Rank test), ANCA-positive AAV patients having a three-times higher risk (HR 3,38 95%CI 1,13-10,08, p=0,03). Total estimated cost was € 1,215,078, corresponding to € 6,168 patient-year. Costs for ANCA-positive AAV patients were much higher than those for ANCA-negative AAV patients (€ 1,115,253 vs € 99,825, and € 7058 per person-year vs € 2,559 per person-year, respectively). GPA and MPA showed the highest costs if compared to EGPA (GPA: € 239,168 (€ 519 per person-year) vs MPA: € 281,502 (€ 4771 per person-year) vs EGPA: € 214,287 (2329 per person-year), respectively). Costs for hospitalization were the highest [€ 734,957 (€ 3731 per person-year) vs other costs € 480,121 (€ 2437 per person-year)].

Conclusion: costs for AAV are very high, confirming the high health care burden of this disease. Management of ANCA-positive patients rather than ANCA-negative patients was burdened by the highest costs. GPA and MPA showed the highest direct costs for hospitalization, which very frequently occurred due to the vasculitis itself.

GENDER DIFFERENCES IN GIANT CELLS ARTERITIS: ANALYSIS OF A MONOCENTRIC COHORT OF 100 PATIENTS.

F. Regolo1, A. Tincani1, F. Franceschini1, P. Toniat1

1ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy

Background: Giant Cells Arteritis (GCA) is the most common primary vasculitis in adults and usually occurs in patients older than 50 years. Epidemiological studies showed a higher prevalence of the disease in women compared to man. However, differences in clinical presentation between men and women have not been demonstrated, even if some distinctions have been suggested (1,2).

Objectives: The purpose of the present study is to analyze differences in the clinical presentation of GCA according to sex.

Methods: We collected retrospectively clinical data of a monocentric cohort of 100 consecutive GCA patients. Mann Whitney test was used to compare continuous variables, while Chi-square test and Fisher’s exact test were applied for comparison between qualitative variables.

Results: One-hundred patients with a clinical diagnosis of GCA were enrolled in the study (68 women, 32 men). In all patients the diagnosis of vasculitis was histologically and/or radiologically confirmed. Main clinical data are reported in the table.

Patients were classified according to vascular involvement in three groups: temporal arterial (C-GCA), extracranial large vessel vasculitis (LV-GCA) and both cranial and extracranial vasculitis (LV-C-GCA). No significant differences in vascular distribution of the disease were found according to sex, even if large vessel involvement seems to be more frequent in women (43% vs 28%; p: ns).

Male and female patients presented at diagnosis a similar clinical picture, with the same frequency of systemic symptoms (fever, fatigue, weight loss), polymyalgia rheumatica, visual symptoms and claudication. However, male patients complained more often temporal headache (90% vs 71%, p: 0,01), even no significant differences were found in the incidence of pathological findings at temporal arterial physical examination (38% vs 32%; p: ns) and biopsy (59% vs 50%). On the contrary, in female patients a longer time to diagnosis was recorded (8 (2-49 vs 4 (0-35) months; p: 0,01).

Conclusion: In our cohort of GCA patients, clinical presentation was similar in male and female patients, with no significant differences in clinical, radiological and laboratory findings. However, male patients presented more often temporal headache, the most typical symptom of GCA, and this could explain a shorter time to diagnosis, if compared to female.

**AB0523** TAKAYASU ARTERITIS AND SACROILIITIS: A CASE-CONTROL STUDY

F. Regini1, G. Bosio2, F. Franceschini1, P. Toniati1. 1ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 2ASST Spedali Civili of Brescia, Nuclear Medicine Unit, Brescia, Italy

**Background:** A possible shared immunopathogenesis between Spondyloarthritis (SpA) and Takayasu Arteritis (TA) has been hypothesized and some clinical cases about SpA in TA patients have been reported (1). In clinical practice the diagnosis of sacroliliitis may be performed by X-ray, Computed Tomography (CT) or Magnetic Resonance Imaging (MRI). In particular, CT findings of sacroliliitis include contour irregularities, joint space alterations, joint erosion, subcondral bone changes (osteoporosis or sclerosis), enthesitis, ankylosis. Meanwhile, TA patients perform routinely FDG-PET/CT scans for monitoring disease activity.

**Objectives:** This study aims to understand if there is an increased incidence of sacroliliitis in TA patients.

**Methods:** We collected retrospectively imaging data from FDG-PET/CT scans of 28 TA patients and 28 controls, matched for sex and age. Controls were selected among patients performing FDG-PET/CT in our Nuclear Medicine Unit, excluding patients with bone tumors, bone metastasis and thyroid cancers. The majority of controls were affected by lymphoma in complete remission. An expert rheumatologist read the CT-scans of sacroiliac joints.

**Results:** No patients or controls demonstrated FDG-uptake in sacroiliac joints. In the control group we detected sacroliliitis in two cases: one due to degenerative changes, one to sacroliliitis (1/28, 4%). In the TA group four patients presented CT alterations suggestive for sacroliliitis: one bilateral erosion, one bilateral sclerosis, two monolateral sclerosis (4/28, 14%). One of these patients complained an inflammatory back pain.

**Conclusion:** In our cohort of TA patients we demonstrated an increased prevalence of sacroliliitis, diagnosed by CT scan. Only one patient reported an inflammatory back pain, while three patients had radiological signs of previous sacroliliitis. These findings highlight the importance of looking for spondyloarthritis in TA patients even if asymptomatic.

**AB0524** ANCA ASSOCIATED VASCULITIS IN GRAN CANARIA: THE IMPORTANCE OF THE INTERSTITIAL LUNG DISEASE

F. J. Nóvoa Medina1, E. Rubíno2, B. Tejera-Segura1, B. Romero Díaz2, S. Machín García1, I. Ruá-Figueroa2. 1Complejo Hospitalario Universitario Insular Materno Infantil de Gran Canaria, Rheumatology, Las Palmas de Gran Canaria, Spain; 2Hospital de Gran Canaria “Dr. Negrín”; Rheumatology, Las Palmas de Gran Canaria, Spain

**Background:** ANCA-associated vasculitis (AVV) are a heterogeneous group of systemic diseases that needs a better knowledge and approach due to the high mortality it presents.

**Objectives:** Describe the clinical characteristics of patients with AVV assessed by the Rheumatology services in two university hospitals in Gran Canaria in the last decade, as well as clinical differences between the AVV subtypes.

**Methods:** Characteristics of 34 patients diagnosed with AVV between January 2011 - December 2018 were collected retrospectively. The patients met ACR classification criteria and consensus criteria from Chapel Hill-2012. Variables are compared using the χ² test for dichotomous variables or the t-Student test for continuous variables. For non-continuous variable, Mann-Whitney U or a logarithmic transformation was used.

**Results:** 21 (61.7%) patients received cyclophosphamide and 3 (8.8%) patients received rituximab as induction treatment. Azathioprine was the most commonly used maintenance treatment (41.1%). 16 (47%) patients had renal involvement. An improvement in proteinuria was observed, both in GPA (p=0.008) and in MPA (p=0.03) (Renal outcomes in Table 2). No patient received kidney transplant.

Interestingly, 5 patients (14.7%), all of them MPA, presented interstitial lung disease (ILD), 3 of them (60%) prior to systemic involvement (9, 10 and 82 months). 3 patients had an usual interstitial pneumonitis (UIP) pattern, none had a non-specific interstitial pneumonia (NSIP) pattern and two had other patterns. 15 patients had 17 relapses. Five (14.7%) patients had serious infections. Eight (23.5%) patients died: 4 due to progression of ILD, 2 due to vasculitis manifestations.

**Conclusion:** ILD can be considered a relatively frequent manifestation of this group of diseases. A high percentage of patients had recurrences. Mortality remains high in AVV and in our series ILD is a frequent cause of death.

**Background:** Big data refers to large amounts of information. With today’s ever-improving technologies created by the automation and digitization, it becomes easier to convert data into relevant information, which can be used to provide better patient management, especially when it occurs a rare condition such as cryoglobulinemia (CRG).

CRG is due to an immunoglobulin (Ig) that precipitate at low temperatures. There are 3 types of CRG: type I: monoclonal Ig; type II: monoclonal Ig + polyclonal Ig; type III: 2 polyclonal Ig.

21 (61.7%) patients received cyclophosphamide and 3 (8.8%) patients received rituximab as induction treatment. Azathioprine was the most commonly used maintenance treatment (41.1%). 16 (47%) patients had renal involvement. An improvement in proteinuria was observed, both in GPA (p=0.008) and in MPA (p=0.03) (Renal outcomes in Table 2). No patient received kidney transplant.
Patients with hypogammaglobulinemia received a higher cumulative dose of steroids during treatment (OR=1.00  p 0.019). Within the RA group, patients with hypogammaglobulinemia also received a higher cumulative dose of steroids (p 0.009).

In the multivariate study, only age at the beginning of treatment (OR=1.1 p=0.020) remained a risk factor for the appearance of hypogammaglobulinemia.

Conclusion: A significantly higher percentage of hypogammaglobulinemia is observed in patients with AAV treated with Rituximab, compared to patients with RA. The development of hypogammaglobulinemia seems to be influenced by age at diagnosis, years of disease progression, IgG levels prior to initiation of treatment and a higher cumulative dose of glucocorticoids (targeted in both the overall sample and the RA group). In addition, there is a higher frequency of severe infections in the hypogammaglobulinemia group. Studies with larger sample sizes are needed to confirm these results.

AB0526 DIFFERENCES IN IMMUNOGLOBULIN LEVELS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS AND RHEUMATOID ARTHRITIS TREATED WITH RITUXIMAB

M. Sanz1, G. Bonilla1, D. Peiteado1, D. Benavent1, C. Plasencia1, L. Nuño1, I. Monjo1, A. Villalva1, A. Balsa1. 1University Hospital La Paz, Madrid, Spain

Background: Rituximab (RTX) is a chimeric monoclonal antibody against CD20 molecules, widely used in the treatment of rheumatic diseases. Hypogammaglobulinemia has been described as an adverse event. It has been reported that hypogammaglobulinemia is more frequent in patients with ANCA-associated vasculitides (AAV).

Objectives: To study the basal characteristics of patients with AAV and rheumatoid arthritis (RA) in treatment with RTX and to analyze the risk factors of hypogammaglobulinemia.

Methods: Retrospective observational study of patients treated with RTX. Patients diagnosed with AAV and RA with immunoglobulin levels prior to treatment and after each cycle were included. Clinical and demographic variables were analyzed. Both populations were compared using t-Student for continuous and chi-squared for categorical variables. The influence of the basal characteristics of the patients was analyzed using univariate and multivariate logistic regression models.

Results: Among the 86 included patients, 10 (11.6%) had AAV and 76 (88.4%) RA. Patient’s characteristics stratified by disease are included in Table 1. The overall sample was divided into two groups, patients who developed hypogammaglobulinemia and patients who did not. Of the 12 patients who developed hypogammaglobulinemia, 4 had RA and 8 AAV (p<0.001). In the univariate analysis, patients who developed hypogammaglobulinemia presented higher age at diagnosis (61 ± 15 vs 43 ± 11 years, OR=1.14 p<0.001), shorter time of disease progression (4.9 ± 8 vs 12.6 ± 9 years, OR=0.86 p<0.02) and lower gammaglobulin levels at baseline (744 ± 504 vs 1145 ± 295 OR=0.16 p<0.006). There were more severe infections in the group of patients with hypogammaglobulinemia than in the group without it (1/4 [25%] vs 1/7 [14%], OR=0.42 p<0.001).

Patients with hypogammaglobulinemia had a higher cumulative dose of steroids during treatment (OR=1.00  p 0.019). Within the RA group, patients with hypogammaglobulinemia also received a higher cumulative dose of steroids (p 0.009).

In the multivariate study, only age at the beginning of treatment (OR=1.1 p=0.020) remained a risk factor for the appearance of hypogammaglobulinemia.

Conclusion: A significantly higher percentage of hypogammaglobulinemia is observed in patients with AAV treated with Rituximab, compared to patients with RA. The development of hypogammaglobulinemia seems to be influenced by age at diagnosis, years of disease progression, IgG levels prior to initiation of treatment and a higher cumulative dose of glucocorticoids (targeted in both the overall sample and the RA group). In addition, there is a higher frequency of severe infections in the hypogammaglobulinemia group. Studies with larger sample sizes are needed to confirm these results.

AB0527 PHARMACOGENETICS AND PHARMACODYNAMICS OF RESPONSE TO APREMILAST IN A PHASE 3 CLINICAL STUDY IN SUBJECTS WITH ACTIVE BEHÇET’S DISEASE

J. Maranville1, J. Medvedeva1, R. Yang1, M. Chen2, L. R. Fang3, S. Collazo2, S. Moccia4, P. Schuref4. 1Celgene Corporation, Cambridge, United States of America; 2Celgene Corporation, Summit, United States of America

Background: Apremilast (APR), an oral phosphodiesterase-4 (PDE4) inhibitor, modulates inflammatory mediators and has demonstrated efficacy in treating oral ulcers in a phase III Behcet’s syndrome study (BCT-002 [REFLIEF]).

Objectives: To conduct an exploratory analysis of genetic polymorphisms, plasma biomarkers, and blood leukocytes with clinical response in RELIEF.

Methods: Subjects with active Behçet’s disease (BD) were randomized (1:1) to APR 30mg twice daily or placebo (PBO). The primary clinical efficacy endpoint was the area under the curve for the number of oral ulcers through Week 12 (AUC12). Among the 207 subjects enrolled, 143 provided consent for DNA genotyping, 116 for plasma biomarker testing, and 96 for leukocyte subset testing. Genotyping was performed on the Illumina Omni2.5 BeadChip (Covance Genomics Laboratory). TNF-α, IL-6, interferon-γ, and IL-17A levels were measured using Simoa Single Molecule Array; IL-8 and IL-23 were measured using the Human DiscoveryMAP multiplex panel (Myriad RBM). Th17,
**Results:** Pharmaco genetic analysis of 8D risk variants in HLA-B, IL-10, TLR2, ACE, TNF, GIMAP, PDGFRL, and UBAC2 +55 genes associated with PDE4 biology yielded no candidate variants that were significantly associated with response to APR or PBO at a Bonferroni-corrected P value of 2 x 10^-5. Clinical response to APR with respect to HLA-B51 yielded an odds ratio (OR) of 1.21 (95% CI, 0.53-2.75), indicating no significant relationship (Figure 1). Pharmacodynamic changes for IL-6, IL-3, IL-17A, IL-23, and TNF-α were not statistically significant. APR treatment was associated with a significant change in interferon-γ (mean: +107.4%; median: −19.2%) vs. PBO (mean: +78.8%; median: +79%) (P=0.0077). Using a univariate regression model, TNF-α showed strong positive correlation with AUC_W0-12 in the APR group (r=0.90; P=0.0140); IL-8 had weak positive correlation with AUC_W0-12 in the APR group (r=0.04; P=0.0333). A significant negative correlation was observed between the percent change from baseline in the number of Treg cells and AUC_W0-12 in the PBO group (r=-0.79; P=0.0392) and a significant positive correlation was observed with the percent change from baseline in the number of Treg cells and AUC_W0-12 in the APR group (r=0.94; P=0.0182). Of all the biomarkers and leukocyte subtypes examined in a regression model using treatment as a factor, only Treg had a statistically significant treatment interaction (P=0.0069).

**Conclusion:** Although there were no genetic predictors of clinical response to APR treatment, strong correlation was observed between the percent change from baseline in plasma TNF-α with AUC_W0-12 in the APR group. A negative correlation was observed between percent change from baseline in Treg cells and AUC_W0-12 in the APR group and a positive association was observed between Treg cells and AUC_W0-12 in the PBO group.

TAUS -ve and TAB +ve 0 1, which is expected to go down further in the coming years. We also noticed that worthy as our Rheumatologists are still in the learning phases of determining expected GCA diagnosis in a larger proportion of patients referred. This is noteworthy.

Conclusion: TAUS introduction Before regular TAUS

Table: TAUS done in 20% 82% results. Despite the regular use of TAUS as a diagnostic tool in the second phase, there is a higher percentage of patients (78.8%) in which GCA was ruled out.

Disclosure of Interests: None declared

AB0529 TEMPORAL ARTERY ULTRASOUND (TAUS) IS A RELIABLE TECHNIQUE TO RULE OUT GCA EVEN IN THE LEARNING PHASE

A. Sidhu1, A. Bharadwaj1, A. Nandagudi1, 1Basildon University Hospital, Rheumatology, Basildon, United Kingdom

Background: Giant cell arteritis (GCA) is an emergency. The initial treatment with high dose glucocorticoids (GC) is often started on clinical suspicion without waiting for Temporal Artery Biopsy (TAB) results, which can take days to be available. TAUS is a simple, non-invasive test which is readily available. However, like any other ultrasound, it is also operator dependent. A positive halo sign is the most specific abnormality seen on TAUS in GCA patients. The percentage of false positive TAUS in GCA diagnosis is low (1), but it can result in over diagnosis and unnecessary exposure to high dose GC in elderly population.

Objectives: We looked at the reliability of TAUS in ruling out GCA after it was introduced within our rheumatology department one year ago.

Methods: We adopted the quality improvement methodology for assessment. Retrospective data of suspected GCA patients was collected over the last two years. TAUS was introduced regularly to the investigative plan after eleven months. Two Rheumatology consultants were trained in TAUS. Results were compared before and after the introduction of ultrasound as a diagnostic tool. In collecting the data, our main focus for documentation was based on clinical symptoms, TAUS and TAB results. We aimed to increase the awareness of appropriate GCA referrals among the primary and secondary care with the support of teaching sessions.

Results: From January 2018 to November 2019, 101 patients were referred to rheumatology with suspected GCA. Median age of our cohort was 72 years with male to female ratio of 1:1.3. 35 patients were referred in the first 11 months, out of which, 10 (28.6%) were diagnosed with GCA. TAUS and TAB was done in 20% and 49% of patients respectively. 66 patients were referred in the next 12 months after TAUS was introduced. Out of 66, 14 patients (21.2%) were diagnosed as GCA. TAUS and TAB were done in 82% and 38% of the patients respectively. As listed in table 1, only 1 patient was found to have positive TAB after a negative TAUS (false negative). All of patients with positive TAUS were treated as GCA on the basis of clinical grounds, irrespective of TAB results. Despite the regular use of TAUS as a diagnostic tool in the second phase, there is a higher percentage of patients (78.8%) in which GCA was ruled out.

Conclusion: After the routine introduction of TAUS, the percentage of patients diagnosed with GCA has declined and clinicians have been able to exclude suspected GCA diagnosis in a larger proportion of patients referred. This is noteworthy as our Rheumatologists are still in the learning phases of determining the significance of utility of TAUS. There is only a small decline in TAB frequency, which is expected to go down further in the coming years. We also noticed that the number of patients referred has almost doubled. This might be due to better education and awareness at the primary and secondary care level which was part of the project.

AB0530 CHARACTERISTICS AND MEDIUM-TERM OUTCOMES OF TAKAYASU ARTERITIS–RELATED RENAL ARTERY STENOSIS: ANALYSIS OF A LARGE CHINESE COHORT

Y. Sun1, X. Dai1, P. Lv2, Z. Dong2, J. Lin1, L. Jiang1, 1Department of Rheumatology, Zhongshan Hospital, Fudan University, Shanghai, China; 2Department of Radiology, Zhongshan Hospital, Fudan University, Shanghai, China; 3Department of Vascular Surgery, Zhongshan Hospital, Fudan University, Shanghai, China

Background: The incidence of renal artery stenosis in Takayasu arteritis (TA) was 20–60% according to previous reports. The specific characteristics of patients with TA-related renal artery stenosis and the effect of revascularization procedures on prognosis have not been fully investigated.

Objectives: To investigate the characteristics of patients with TA-related renal artery stenosis and identify the predictors of medium-term adverse outcomes.

Methods: Data for 567 patients registered in a large prospective observational cohort-the East China Takayasu arteritis cohort-up to April 30, 2019, were retrospectively analyzed.

Results: Renal artery stenosis was confirmed in 172/567 (30.34%) patients, with left renal artery involvement seen in 73/172 (42.44%) patients. Renal insufficiency at presentation (HR = 2.37, 95% CI: 1.76-15.83, p = 0.03), bilateral renal artery involvement (HR = 6.95, 95% CI: 1.18-21.55, p = 0.01), and severe (>75%) stenosis (HR = 4.75, 95% CI: 1.08-11.33, p = 0.05) were predictors of adverse outcomes. Revascularization was performed for 46/172 (26.74%) patients. Patients without preoperative treatment had higher rate of restenosis (44.44% vs. 15.79%, p < 0.01) and hypertension deterioration (25.93% vs. 10.53%, p < 0.01) after the procedure. Non-receipt of preoperative treatment (HR = 6.5, 95% CI: 1.77-32.98, p = 0.04) and active disease at revascularization (HR = 4.21, 95% CI 2.01-21.44, p = 0.04) were independent predictors of adverse outcomes after revascularization.

Conclusion: Patients with uncontrolled or worsening hypertension or/and renal function may benefit from revascularization. Those who have received preoperative treatment may have more favorable revascularization outcomes. Prognosis appears to be poorer for patients with renal insufficiency at presentation, bilateral artery involvement, and severe stenosis.

AB0531 GOLIMUMAB IN THE TREATMENT OF SEVERE AND/OR REFRACTORY VASCULO-BEHÇET’S DISEASE: A SINGLE-CENTRE EXPERIENCE IN CHINA

L. Sun1, J. Liu1, W. Zheng1, 1Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China

Background: Vascular involvement is one of the leading causes of mortality and morbidity in Behcet’s Disease (BD). Surgical treatments are difficult for Vascular-BD (VBD) patients due to the high risk of serious postoperative complications without effective and promptly perioperative immunotherapy. Anti-tumor necrosis factor alpha (TNF-α) therapy has been reported as a potential treatment in severe VBD, e.g. infliximab (IFX) and adalimumab (ADA). However, only few case reports are available regarding the fully humanized monoclonal antibody to TNF-α, golimumab (GOL), in the management of VBD.

Objectives: The objective of this study was to report the efficacy and safety of GOL for the treatment of severe and/or refractory VBD.

Methods: We retrospectively analyzed the efficacy and safety profile of patients with severe and/or refractory VBD treated with GOL in our medical center between 2018 to 2020.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.3427
Results: Nine VBD patients (8 male and 1 female) were enrolled, with a mean age and median course of 37±8.6 years and 72 months (range 12 to 300), respectively. Cardiac involvements (severe aortic regurgitation secondary to BS) were presented in 4 of 14 patients, including 2 patients with post-operative paravalvular leakage (PVL) after aortic valve replacement surgery. Multiple vascular lesions were documented in the other 2 patients, including one patient with life-threatening multiple pulmonary aneurysms, pulmonary thromboembolism and recurrent deep vein thrombosis, and another patient with abdominal aortic pseudoaneurysm and multiple artery stenosis and occlusion. Prior to GOL therapy, all patients experienced disease progression despite high-dose glucocorticoids combined with multiple immunosuppressants. Moreover, seven patients required effective and fast control of inflammation and a decrease of glucocorticoid dose during the perioperative period. They were treated with GOL, 50mg every 4 weeks, in combination with background low-or medium-dose glucocorticoids and immunosuppressants, for a median of 6 (range 3-15) months. After a mean duration of follow-up of 10 (range 2-6) months, all patients achieved improvement both in clinical symptoms and serum inflammation markers. The ESR level [4.8±4.94 mm/h vs 31.1±3±17.8mm/h, P<0.01] and CRP level [1.9 (0.11-3.73)mg/L vs 24.3 (0.4-85.57)mg/L, P<0.01] significantly decreased. The dosage of glucocorticoid [10 (0-15) vs 40 (0-100)mg/d, P<0.01] effectively tapered, indicating a potential steroid-sparing effect. No newly-onset aneurysm and recurrent venous thrombosis were observed. Also, one patient had a marked reduction in size and number of pulmonary aneurysms. No post-operative PVL was observed in the five patients after Bentall operation with a median follow-up of 10 months. One patient with severe aortic regurgitation remained stable and without surgical intervention with the treatment of GOL for 16 months. No severe complication occurred in one patient after underwent endovascular repair of abdominal aorta for 8 months. GOL was well-tolerated, and no serious adverse event was observed.

Conclusion: Our results suggested that GOL is safe and effective for the treatment of patients with severe and/or refractory VBD. Further controlled studies are warranted to confirm the therapeutic potential of GOL in VBD patients.

AB0532 CORRELATION WITH THE FREQUENCY OF DISEASE RELAPSES DURING THE FIRST 3 YEARS FROM THE DIAGNOSIS AND DISEASE OUTCOMES IN BEHCET’S SYNDROME

R. Talarico1, A. Figliomeni1, L. Mione1, A. Parma1, E. Cioffi1, M. Mosca1 on behalf of N/A. 1Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background: Beside the organ involvement, a number of demographic factors could considerably influence the long-term and short-term outcomes of Behcet’s syndrome (BS): age at disease onset, duration of disease, gender and sex. Younger men patients are more suitable to have a more severe disease, due to an increased frequency both of morbidity and mortality, related to ocular, vascular and neurological involvement.

Objectives: The primary aims of the study were to evaluate disease activity in a cohort of BS patients consecutively followed in a BS clinic of a tertiary centre and to explore whether there is a correlation between frequency of relapses in the first 3 years of diseases and disease outcomes.

Methods: One-hundred and sixty-five patients (91 males and 74 females; mean age 39±6 years, mean disease duration 9±5) with a diagnosis of BS according to the ISG criteria were studied. Disease activity has been evaluated by BDCAF and patients were also categorized in major or minor involvement of BS according to or not to the presence of ocular, neurological and vascular involvement in the course of disease. The numbers of relapses in the first 3 years from diagnosis were correlated with disease outcome and damage.

Results: At the time of the evaluation, 47% of BS patients presented an active disease; 69 patients presented muco-cutaneous involvement, 39 ocular disease, 21 joint involvement, 12 neurological impairment and 9 gastro-enteric involvement. Seventy-nine percent of patients presented in the course of the disease a severe BS involvement and the majority was represented by patients characterised by a more frequent relapse in the first 3 years of disease (M/F: 65/48, mean age 43±3 years). Those patients who experienced a more higher number of relapses in the first 3 years compared to the others were also characterised by poor disease outcomes and worse prognosis over time and this correlation was independent from the therapies taken.

Conclusion: The high frequency of relapses during the first three years from diagnosis may be considered an important prognostic factor for disease outcome in BS patients, therefore could be taken into account as a useful element to tailor the management, not only according to the type and severity of symptoms and epidemiological factors.

AB0533 ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA) IN GENERAL POPULATION WITHOUT ANCA ASSOCIATED VASCULITIS

H. Tamaki1, S. Fukui1, T. Nakai1, G. Kidoguchi1, S. Kawai1, H. Ozawa1, Y. Ikeda1, A. Koido1, Y. Ohara1, H. Shimizu1, K. Yamaguchi1, M. Okada1. 1St. Luke’s International Hospital, Immunno-Rheumatology Center, Tokyo, Japan

Background: Currently it is hypothesized that many systemic autoimmune diseases occur due to environmental risk factors in addition to genetic risk factors. Anti-Neutrophil Cytoplasmic Antibody (ANCA) is mainly associated with three systemic autoimmune disease including granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), eosinophilic granulomatosis with polyangiitis (EGPA). It is known that ANCA can be positive before clinical symptoms in patients with known diagnosis of GPA and ANCA titers rise before clinical manifestations appear. However, prevalence of ANCA among general population is not well known. It has not been described as well how many of people with positive ANCA eventually develop clinical manifestations of ANCA associated Vasculitis.

Objectives: This study aims to estimate prevalence of ANCA in general population without ANCA associated Vasculitis. It also describes natural disease course of people with positive ANCA without ANCA associated Vasculitis. Risk factors for positive ANCA are also analyzed.

Methods: This is a single center retrospective study at Center for Preventive Medicine of St. Luke’s International Hospital in Tokyo. ANCA was checked among the patients who wished to between 2018 and 2019. St. Luke’s Health Check-up Database (SLHCD) was utilized to collect the data. The patients whose serum was measured for ANCA were identified. The data for basic demographics, social habits, dietary habits and laboratory data were extracted. The charts of the patients with positive ANCA were reviewed.

Results: Sera of total 1204 people were checked for ANCA. Of these 1204 people, 587 (48.8%) are male and the mean age was 55.8 years (32.6 to 79). There were total 11 patients with positive ANCA. Myeloperoxidase ANCA (MPO-ANCA) was positive for 3 patients and proteinase 3 ANCA (PR3-ANCA) was positive for 8 patients. Of these 11 patients, 5 were male (45.5%) and the mean age was 54.6 years. Two patients had history of autoimmune disease (primary biliary cirrhosis and ulcerative colitis). Five patients were evaluated by rheumatologists with the median follow-up period of 274 days. None of them developed clinical signs and symptoms of ANCA associated Vasculitis. Four out of five patients had ANCA checked later, two of which turned negative. The prevalence of ANCA in this cohort was 0.9% (95% confidence interval [95% CI]: 0.5% to 1.6%). Univariate analysis was performed to identify risk factors of positive ANCA. The variables analyzed include age, gender, body mass index (BMI), smoking habits, alcohol intake, dietary habits (fruits, fish, red meat), hypertension, dyslipidemia, and laboratory data. None of these variables demonstrated statistically significant differences except for positive rheumatoid factor (ANCA positive group: 33 % vs ANCA negative group: 9.1%, p value = 0.044).

Conclusion: The prevalence of ANCA in this cohort was 0.9% (95% CI: 0.5% to 1.6%). None of them who had a follow-up developed ANCA associated Vasculitis during the follow-up period. Longer follow-up and more patients are necessary to determine natural course of people with positive ANCA.

DOI: 10.1136/annrheumdis-2020-eular.5075

AB0534 EFFICACY OF TOCILIZUMAB IN LARGE-VESSSEL GIANT CELL ARTERITIS: A SINGLE-CENTER REAL-LIFE EXPERIENCE

A. Tomelleti1, G. Campochiaro1, S. Bartorelli1, E. Baldissera1, L. Dagna1. 1San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare diseases, Milan, Italy

Background: In a significant proportion of giant cell arteritis (GCA) patients, large vessels (LV) are affected1. GAICTA trial showed tocilizumab (TCZ) to be effective for the treatment of GCA2 but did not differentiate between patients with and without LV involvement and did not evaluate LV-imaging response.

Objectives: To assess efficacy of TCZ in LV-GCA, evaluating both clinical symptoms and vascular inflammation on PET scan.
 Methods: Data from GCA patients followed-up at our Institution between January 2003 and December 2019 were retrospectively collected. Only TCZ-treated patients, with evidence of LV 18F-FDG-uptake at baseline (T0) and who repeated a PET scan after at least 6 months of treatment (T1) were included. All patients received subcutaneous TCZ 162 mg weekly. PET scans were read by 2 physicians blinded with regard to clinical data and to each other’s assessment; vascular inflammation was quantified using the PETVAS score³. Clinical symptoms, prednisone (PDN) dosage, and PETVAS score between T0 and T1 were compared. Flares and adverse events were recorded. Non parametric tests were used.

Results: 61 TCZ-treated GCA patients were identified. Of these, 28 (45.9%) had evidence of vascular inflammation at T0, and 14 of them (10 female, mean age 66.2±7.4 years) repeated a PET scan during follow-up, after a median of 13 months (IQR, 9.5-17.5). 10 patients started TCZ upon GCA relapse, with a median delay from GCA diagnosis of 7.5 (3-15.6) months; 4 patients were newly diagnosed and started TCZ at diagnosis. At T0, 10 patients had systemic symptoms, 6 patients had cranial symptoms, and 7 had polyalgi-gia rheumatica (PMR). 12/14 patients were on concomitant steroids, with a median PDN daily dose of 15 (15-25) mg. Erythrocyte sedimentation rate and C-reactive protein levels were respectively 35 (21-39) mm/h and 7.8 (3.2-11) mg/L. Median PETVAS was 7 (3.3-11). At T1, 13/14 patients were asympto-matic; 1 patient had a PMR relapse. No GCA flare was recorded. Median PDN daily dose was 1.25 (0-2.5), p=0.002, and PDN suspension was achieved in 5 patients. Median PETVAS was 0 (0-0.8), p=0.003; only in 1 patient PET-VAS increased between T0-T1 (from 2 to 5), in absence of clinical symptoms. This was the patient with the longest delay between diagnosis and TCZ start (124 months) and suspended TCZ for 3 months due to oral aphthosis. No patients had severe infections; 1 patient definitively suspended TCZ at T1 due to severe leukopenia.

Conclusion: In LV-GCA patients, TCZ seems to be effective in obtaining clinical remission and in reducing vascular inflammation on PET scan.

ARE THE NEUTROPHIL/LYMPHOCYTE RATIO (NLR) AND PLATELET/LYMPHOCYTE RATIO (PLR) USEFUL TO COMPARE WITH ACUTE PHASE REACTANTS (ESR/CRP) FOR DIAGNOSIS AND PROGNOSIS OF PATIENTS WITH ACTIVE TAKAYASU’S ARTERITIS (TAK)? AN ANALYSIS BASED ON ROC AND KAPLAN-MEIER CURVES IN A LATIN AMERICAN POPULATION

F. Torres1, L. Leon1, A. Vanegas2,3, C. Muñoz4,5, L. A. González2,4, D. Jaramillo2,4,5,1 Universidad de Antioquia, Medellín, Colombia; 2 Universidad Nacional de Colombia, Bogota, Colombia; 3 Universidad de Antioquia, Medellín, Colombia; 4 Hospital San Vicente Fundacion, Medellín, Colombia; 5 Clínica Leon XIII IPS Universitaria, Medellín, Colombia

Background: The NIH criteria are the main measure to determine activity in TAK. NLR and PLR appear promising to predict disease activity. TAK is one of the most frequent vasculitides in Colombia with a prevalence of 13.3%. However, in more recent years the information is sparse about TAK clinical behavior in our region, which leads to a late diagnosis. Although survival has improved with immunosuppressive treatment, relapses remain high especially in the first year of diagnosis.

Objectives: Compare NLR and PLR with ESR/CRP to predict TAK activity. Show survival and relapse in patients with TAK followed up to 7 y.

Methods: Retrospective cohort of 43 patients with TAK between 2011-2018 with effective follow-up of relapses and mortality. 88% fulfilled the ACR 1990 criteria. The disease activity was determined according to NIH criteria: active disease (n=34) and inactive disease (n=9). Through bivariate analysis, we compared the clinical and radiologic characteristics between age groups (table 1) using the Pearson test and Wilcoxon range test. Value of p < 0.05 was statistically significant. Survival and relapse analysis were performed using Kaplan-Meier plots. Sensitivity (Sn), specificity (Sp) and area under the curve (AUC) were determined for NLR, PLR, ESR and CRP by receiver-operating curves (ROC) compared to NIH criteria.

Results: 41 patients were women (96%) with a median age at diagnosis of 22 y and an interval from the onset of disease to diagnosis of 12 months (IR: 1-168 m). The population over 40 years had a greater comorbidities burden (54% had history of smoking and dyslipidemia) and a major interval between the onset of disease and the diagnosis (36 months vs 9.5 months). Most frequent vascular phenotypes were types V (62%) and I (16%). NLR and PLR showed poor performance to predict activity compared with CRP: NLR level of 1.74 showed to be the predictive cut-off value for active TAK (Sn: 85.3%, Sp: 37.5%, AUC = 0.563). PLR level of 112.5 was found to be the predictive cut-off value for active TAK (Sn: 76.5%, Sp: 50%, AUC = 0.517). The CRP was the most accurate biomarker (Sn: 79.4%, Sp: 75%, AUC = 0.761) while the ESR was lower to predict activity (Sn: 63.6%, Sp: 75%, AUC = 0.598) (figure 1). At 5 years survival, 83% and 50% of patients had presented at least one relapse (figure 2).

Conclusion: Our data does not support the use of NLR or PLR to differentiate relapse and remission in TAK: CRP had better diagnostic performance than ESR in the prediction of activity compared to NIH criteria. The 5-year survival in this cohort is below that reported after 1985 (reported survival: 90-96%) (2).

Conclusion: In LV-GCA patients, TCZ seems to be effective in obtaining clinical remission and in reducing vascular inflammation on PET scan.
EFFECT OF HYDROXYCHLOROQUINE TREATMENT IN MUCOCUTANEOUS MANIFESTATIONS IN PATIENTS WITH BEHÇET’S SYNDROME

F. Kerstens1, S. Mohamed1, I. Visman1, F. Turkstra2, C. Swearingen2, Y. Yazici2.
1 ARC Reade, Amsterdam, Netherlands; 2 NYU Langone Health, Hospital for Joint Diseases, New York, United States of America

Background: Behçet syndrome (BS) is a rare multisystemic vasculitis, most commonly seen in regions along the ancient Silk Road. It runs a relapsing remitting course. Mucocutaneous disease, consisting of oral ulcers, genital ulcers and skin lesions is often reported.

Objectives: To study the efficacy of hydroxychloroquine (HCQ) 400 mg daily in patients with mucocutaneous BS.

Methods: Data on all patients who presented at the outpatient Behçet clinic in New York were recorded. Patients with a first prescription with HCQ and a follow-up of 3 months (range: 2.75-41.2 months) were included. Patient reported outcomes BSAS and RAPID3 were used to evaluate the effect of HCQ.

Results: We included 94 patients with a first prescription of HCQ. 72 patients (76.6%) fulfilled ISG criteria. Mean age was 36.1 years (SD 12.5), 76 patients (80.9%) were female and 11 patients (11.7%) were from Silk Road countries.

Mean duration until follow-up was 6.5 months (SD 5.7). Median BSAS scores in ISG+ patients at baseline did not differ significantly from ISG- patients, except for skin lesions (5.0 in ISG+ vs. 0.5 in ISG- p=0.005). BSAS scores at follow-up did not differ significantly (ISG+ vs. ISG-).

Median BSAS scores were significantly lower at follow-up compared to baseline for oral ulcers (p=0.010), skin lesions (p=0.018) and overall activity (p=0.019).

Table 1. Median BSAS scores of patients treated with HCQ.

</tr>
<tr>
<td>Overall activity</td>
<td>6.0 (4.00-8.00)</td>
<td>5.0 (2.00-7.50)</td>
</tr>
</tbody>
</table>

Conclusion: HCQ improves median BSAS scores for oral ulcers, skin lesions and overall activity at 3 months follow-up compared to baseline. These results were similar in ISG+ patients (except for overall activity). Additional research is needed to assess the effect of HCQ in more patients and over multiple time points.

AB0538 PREGNANCY OUTCOMES IN PATIENTS WITH TAKAYASU’S ARTERITIS: CASE SERIES

A. Vanegas1,2, F. Torres3, C. Muñoz4,5, D. Jaramillo2,4, L. Hernández2, G. Vásquez2, M. Restrepo Escobar2, L. A. González2, I. Velásquez2. 1Hospital Universitario San Vicente Fundación, Medellín, Colombia; 2Universidad de Antioquia, Medellín, Colombia; 3IPS Universitaria, Servicios de Salud Universidad de Antioquia, Medellín, Colombia; 4Grupo de Epidemiología y Bioestadística del CES, Medellín, Colombia

Background: Takayasu’s arteritis (TA) is most prevalent in women of childbearing age. Although its activity and risk of relapse are low during pregnancy, up to 40% of patients may have unfavorable obstetric outcomes and therefore it is important to know their clinical behavior.

Objectives: To describe the clinical features and obstetric outcomes of pregnant women with TA treated in a tertiary center.

Methods: Retrospective evaluation of medical records of 8 pregnancies in 6 women with TAs treated in a tertiary center in Medellin, Colombia between 2011-2018.

Results: Six women who were 17.5 (RI 9.25) years old at diagnosis and 24 (RI 8.25) years old at delivery, their disease duration were 5.5 (RI 10.5) years. Three patients had extensive aortic involvement classified as Numano type V, two as type IIB and one as type I. At delivery, three patients were active and required immunosuppressants, five had high blood pressure, one developed preclampsia in the second trimester, one had severe mitral and tricuspid insufficiency with decreased ejection fraction of the left ventricle; two had aneurysms (left subclavian artery and ascending aorta). There were two fetal deaths, one due to intrauterine growth restriction and placental insufficiency and another of unknown etiology; both patients with disease activity, extensive aortic condition and arterial hypertension; no pregnancy resulted in abortion or preterm birth. Five deliveries were by cesarean section by maternal indication; there was no aortic dissection, aneurysmal rupture or cerebral hemorrhage (table).

HT: hypertension; L: left; UPEF: left ventricular ejection fraction; C-section: cesarean section; SGA: small for gestational age; IUGR: intrauterine growth restriction

Conclusion: Pregnant women with active disease and extensive aortic condition presented unfavorable obstetric results, suggesting that an inadequate control of vasculitis may lead to greater maternal-fetal complications.

AB0539 URINARY INFLAMMATORY CELL ANALYSIS REFLECTS THE RENAL HISTOPATHOLOGY IN ANTI-NEUTROPHIL CYTOPLASTIC ANTIBODY-ASSOCIATED VASCULITIS

Y. Wada1,2, M. Sudo2, D. Kobayashi3, T. Kuroda2, I. Narita2, Nigata Rinko Hospital, Department of Clinical Rheumatology, Niigata, Japan; Nigata University Graduate School of Medical and Dental Sciences, Division of Clinical Nephrology and Rheumatology, Niigata, Japan

Background: The anti-neutrophil cytoplasmic autoantibody (ANCA)- associated vasculitides (AAVs) include microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA), and eosinophilic granulomatosis with polyangiitis (EGPA). These small-vessel vasculitides are characterized by necrotizing inflammation of the vessel wall, particularly affecting small arteries, arterioles, and capillaries in systemic organs, and the kidney is one of the most frequently involved organs. Although kidney biopsy is necessary for deciding the therapeutic protocol, it is invasive and is sometimes hard to perform biopsy because of patient’s severe general condition. We have already reported that T cells and macrophages appear in the urine of patients with glomerulonephritis, accompanied by active cellular infiltration such as cellular crescent formation and diffuse interstitial cellular infiltration, but not in the urine of patients with glomerulonephritis without the active inflammatory lesions.

Objectives: In this study, we examined the utility of urinary inflammatory cell analysis for accessing kidney histopathological findings in AAVs.

Methods: This was a cross-sectional, retrospective chart study. Thirty-six AAV patients who had been referred to Niigata University Hospital between 2002 and 2018, and performed percutaneous kidney biopsy and urinary inflammatory cell analysis, were participated in this study. Thirty-two patients had MPA, and 4 had GPA. The kidney biopsy findings were classified into Berden’s classification (a method to categorize glomerular lesions into four classes) and Neumann’s classification (a method to evaluate glomerular, tubulo-interstitial, and vascular lesions by using activity indexes and chronicity indexes). Flow-cytometric analysis of urinary inflammatory cells was performed for each subject. Numbers of urinary T cells or macrophages were determined by multiplying the number of viable cells in the gated mononuclear cell region in each sample by the percent-ysis of urinary T cells or macrophages were determined by multiplying the number of viable cells in the gated mononuclear cell region in each sample by the percent.

Results: The numbers of urinary inflammatory cells showed a trend of increase in crescentic category without statistical significance in Berden’s classification. Meanwhile, activity indexes had significant positive correlations with the number of urinary CD3-positive or CD14-positive cells (r = 0.541, p = <0.001), CD14-positive cells (r = 0.394, p = 0.034), and total inflammatory cells (r = 0.449, p = 0.006) in Neumann’s classification.

Conclusion: The numbers of urinary inflammatory cells reflect the active lesions of kidney histopathological findings, and these results indicate the usefulness of urinary inflammatory cell analysis for assessment of kidney biopsy findings in patients with AAVs.

AB0540 CLINICAL ANALYSIS OF AORTA INVOLVEMENT IN PATIENTS OF ANCA-ASSOCIATED VASCULITIS

X. Chen1, W. Wang2. Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital & Affiliated Hospital of Electronic Science and
Background: ANCA-associated vasculitis (AAV) is an autoimmune disease that involves abnormal death of neutrophils and leads to necrotic inflammatory reactions in blood vessels, including microscopic polyangitis (MPA), Granulomatous polyangitis (GPA) and Eosinophilic granulomatous polyangitis (EGPA). AAV is mainly involved in small blood vessels, and intermediate arterial lesions can also occur, but the large arteries and their primary branches are rarely involved.

Objectives: To summarize the clinical characteristics of aortic involvement in patients with ANCA-associated vasculitis (AAV).

Methods: The clinical manifestations, systemic involvement, laboratory examination, imaging characteristics and treatment of aortic involvement in AAV patients admitted to Peking Union Medical College Hospital from January 2013 to December 2018 were retrospectively analyzed.

Results: Nine patients were enrolled in our study. The ratio of male to female was 2:1 and the median age was 47 years old. Of the 9 patients, 4 were GPA (44%), 4 were MPA (44%) and 1 was EGPA (11%). The aorta is involved in an average of 3 locations per case, mainly in 7 locations: 3 ascending aorta and aortic arch, 4 in the head and arm trunk (including carotid and subclavian artery), 2 in the abdominal aorta, and 1 in the abdominal cavity. There were 2 cases of renal artery, 1 case involving brachial radial artery, 2 cases of iliac artery and lower limb artery, and 1 case involving left main coronary artery, anterior descending branch, circumflex branch, and right coronary artery. Aortic lesions: 3 cases had arterial occlusion and / or dissection, 5 cases had arterial stenosis or occlusion and 3 cases had periarteritis. When major arterial involvement was found, the AAV of the patients were mostly active, with an average of 19 points for BVAS vasculitis activity and 1 for FFS score. 6 cases had lung involvement (67%), 6 cases had kidney involvement (67%), 4 cases had ENT involvement (44%), 3 cases had nervous system involvement (33%), 4 cases had kidney involvement (67%), 6 cases had kidney involvement (67%), 4 cases had ENT involvement (44%), 3 cases had nervous system involvement (33%), and 1 case had gastrointestinal involvement (11%). All patients were treated by steroid and immunosuppressant, while 1 case received the operation of ascending aorta and aortic arch replacement.

Conclusion: Mainly involved in small blood vessel inflammation, AAV may also have aorta involvement, which was more common in patients who had active disease and need more positive treatment. The affected aorta areas of these patients were mainly ascending aorta, aortic arch, and head and arm trunk, which can be manifested as aneurysms, dissections, and arterial stenosis Periarteritis, etc. If necessary, surgically treated the affected aorta could be considered when the situation of AAV was stable enough.

DOI: 10.1136/annrheumdis-2020-eular.2616
Objectives: To determine the frequency of adverse reactions to PCV13 in patients with BS who were candidates for TNF inhibitor treatment, together with ankylosing spondylitis (AS) and rheumatoid arthritis (RA) patients as controls.

Methods: All of our patients who are candidates for TNF inhibitor therapy have been offered vaccination with PCV13 since 2016. We surveyed all patients with BS, AS and RA who were vaccinated with PCV13 in our infectious diseases outpatient clinic since 2016. Patients' charts were reviewed and additionally patients were telephoned to identify any adverse local or systemic reactions. Local reactions were defined as redness, swelling, pain, and limitation of arm movement. Systemic reactions were defined as fever, chills, rash, vomiting, joint pain, and muscle pain.

Results: A total of 88 patients with BS, 143 patients with AS and 133 patients with RA had been vaccinated in our infectious diseases outpatient clinic. Among these, 55/88 (62%) patients with BS, 86/143 (60%) patients with AS and all 98/143 (68%) patients with RA could be contacted. Twenty-one of 55 (38%) patients with BS, 18/86 (20%) patients with AS and 27/98 (27%) patients with RA reported at least one local and/or systemic reaction after vaccination. Patients with BS reported more systemic reactions than the other two groups (48%, 12%, 23% respectively). On the other hand local reactions were less common among patients with BS (52%, 88%, 77% respectively). The local reactions were confined to erythema at injection site, pain and difficulty in moving among patients with AS and RA while 2 patients with BS had severe papulopustular skin lesions at injection site, in addition to erythema, pain and difficulty in moving. Both of these patients were pathergy positive at the time of the diagnosis.

Conclusion: Severe papulopustular skin lesions at PCV13 injection site were observed only, but rarely, in patients with BS. Possibility of recall bias due to the retrospective nature of our study and the lack of other vaccines as controls are limitations of our study. Whether the skin lesions are caused by the skin pathergy reaction needs to be studied prospectively, as the pathergy status at diagnosis may change by the time these patients become candidates for TNF inhibitor treatment.

Scleroderma, myositis and related syndromes

**AB0543**  CLINICAL CHARACTERISTICS OF A GROUP OF CHRONIC GRAFT-VERSUS-HOST DISEASE PATIENTS WITH POSITIVE AUTOIMMUNITY.

M. E. Acosta1, L. Gómez-Lechón1, L. Compañ1, S. Pastor1, C. A. Montilla-Morales1, O. Martinez Gonzalez1, A. I. Turron1, J. Del Pino1, C. Hidalgo1. 1University Hospital of Salamanca, Rheumatology; Salamanca, Spain

**Background:** Graft-versus-host disease (GVHD) is a commonly severe multiorgan complication in patients undergoing allogeneic transplantation of hematopoietic progenitors. Its chronic form reflects a complex immune response with different degrees of inflammation, immune dysregulation and fibrosis. In some chronic graft-versus-host disease (cGVHD) patients, positive antibodies have been detected, which represent the presence of immune activity and suggest the possible involvement of B lymphocytes in the disease etiopathogenesis, but their clinical utility is controversial.

**Objectives:** To describe the clinical characteristics of a group of cGVHD patients with positive autoimmunity treated in a multidisciplinary consultation of Rheumatology-Dermatology-Hematology of GVHD.

**Methods:** Observational and retrospective study to describe the clinical characteristics of the patients with positive autoimmunity collected in the database of the multidisciplinary consultation of GVHD. The variables reviewed for this study, in addition to the demographic ones, were type of antibody, disease causing the transplant, presentation, severity and type of involvement. The statistical analysis was done with Epi-info 7.2.2.6.

**Results:** Only 16 (16%) of the 100 patients included in the database had positive autoimmunity. Twelve (75%) tested positive to ANA, although 5 (31.25%) in a lower titer (1:80). The most common immunofluorescence pattern was the nucleolar in 88.89% (66.67% nucleolar and 22.22% nucleolar + cytoplasmic). Other antibodies detected were: 6 anti-Ro/SS2, 2 anti-dsDNA, 1 anti-RP155, 1 anti-Fibrillarin, 1 anti-SAE1, 1 p-ANCA and 1 anti-NOR-90. The mean of age was 51.31±14.03 years. As for sex 4 (25%) were female and 12 (75%) were men. The most frequent disease that caused the transplant was acute myeloid leukemia (58.3%). Ten (62.5%) patients presented de novo cGVHD, 1 (6.25%) progressive and 5 (31.25%) quiescent. The time since receiving the transplant until the first visit was 14 to 79 months. Ten (62.5%) patients had nonspecific symptoms (arthralgia and myalgia), 2 (12.5%) edema, 8 (50%) contractures, 8 (50%) fascitis and 6 (37.5%) eosinophilia. Eight (50%) patients had ocular involvement and 6 (37.5%) of the oral mucosa in the form of dry syndrome (Sjögren-like syndrome). Ten (62.5%) patients had limitation of joint mobility detected by the range of motion scale (ROM), of which 6 were mild and 4 moderate. Only 5 (31.25%) patients had general condition impairment. As for the skin involvement 10 (62.5%) patients had sclerodermiform involvement (8 of them being eosinophilic fascitis-like), 2 (12.5%) lichenoid, and 3 (18.5%) mixed (sclerodermiform + lichenoid). Only 1 patient didn’t meet diagnostic criteria for GVHD. The sclerodermiform was the most common type of involvement in the positive ANA patients. Regarding the severity according to the of the American National Institute of Health (NIH) classification: 8 (50%) had serious affection, 5 (31.25%) moderate and 2 (12.5%) mild, with 4 (25%) exitus.

**Conclusion:** In our cohort of patients with cGVHD, serum detection of autoantibodies is uncommon, being the ANA with nucleolar pattern the most frequent. Although the small sample size does not allow correlations with the clinical variables it’s worth highlighting a greater positivity of autoantibodies in the scleroderma skin forms.

**AB0544**  EVALUATION OF MACULAR AND OPTIC DISC MICROVASCULAR NETWORK IN PATIENTS WITH SYSTEMIC SCLEROSIS: AN OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY STUDY

F. Akay1, B. Akmaç1, G. Kabadayı2, Y. Z. Güven1, D. Solmaz2, I. Kurut2, O. Gerik2, S. Akar1, İzmir Katip Celebi University School of Medicine, Ophthalmology, Izmir, Turkey; 1İzmir Katip Celebi University School of Medicine, Rheumatology, Izmir, Turkey

**Background:** Systemic sclerosis (SSc) is characterized by fibrosis of the skin, internal organs and vasculopathy. Invivo, the retina provides a unique opportunity to assess the microcirculation in the eye. Previous studies have been evaluated the changes in the retinal and choroid layer and showed thinning of the choroid layer and reduced retinal microvascular density.

**Objectives:** To analysis the retinal and optic disc capillary network in patients with SSc without clinical signs of retinal involvement by using optical coherence angiography (OCA) and there type of angiographic features.

**Methods:** In total 40 SSc patients who classified according to the ACR/EULAR criteria and 40 healthy control subjects were included in the analysis. All patients underwent a detailed ophthalmologic examination by the same ophthalmologist. After pupil dilatation, macular angiography was performed with 6x6 mm area scanning using standardized system and images of the retinal capillary plexus were analysed by Circus OCTA software. Mean macular thickness, retinal nerve fiber layer (RNFL) and the Ganglion cell inner plexiform
GASTROINTESTINAL INVOLVEMENT IN SYSTEMIC SCLEROSIS

A. Arjibey,1, 2 I. Novo,1, 2 M. Avila,3 P. Diéguez González,4 M. Estévez Gil,5 B. Maure3, 2 B. Gimena5, 3 C. Vázquez Triñanes5, 3 A. Rivera Gallego5, 3

Background: Systemic sclerosis (SSc) is a chronic, connective tissue disease with an autoimmune pattern characterized by inflammation, fibrosis and microcirculation changes leading to internal organs malfunctions. The gastrointestinal tract (GIT) is affected in up to 90% of patients with SSc. Any part of the GIT from the mouth to the anus can be affected. There are few descriptive studies about GIT manifestations associated with systemic sclerosis.

Objectives: To assess immediate (Day 4) and intermediate (Day 42) efficacy of PGE1 inhibitors- Alprostadil and PGI2 anaalogue- Iloprost in refractory symptomatic SSc-RP. In refractory cases phosphodiesterase type 5 (PDE-5) inhibitors- Sildenafil and PDE-6 inhibitors reduce the frequency and severity of SSc-RP attacks.

Results: 83 subjects with SSc were included. 68 (81.9%) of them were women. The mean age at the onset of SSc was 62.1 ± 15.3 years (range 26-69) with a mean follow-up of 9.6 ± 7.4 years. 80.7% of patients had limited SSc, 12% diffuse SSc, 4.8% SSc sine scleroderma and 2.4% early SSc. Considering the immunological profile 12 (14.5%) had Scl70 antibodies, 49 (59%) antitrimomere and 21 (25.3%) had ANA antibodies without specificity for anti-Scl70 or antitrimomere. 37.3% patients had lung involvement, 20.5% scleroderma and 30.1% digital ulcers. 79.5% of SSc patients were treated with proton pump inhibitors or H2 blockers. 53 (63.9%) patients with SSc had GIT involvement.

In 11 patients (20.7%) digestive involvement was diagnosed before SSc (mean 28.2 months). Esophageal involvement occurred in 83%, gastric involvement in 28.3%, intestine involvement in 24.5% and liver and biliary tree involvement in 26.4%. See table 1. No significant differences in age, sex, SSc subtype, autoantibody profile, lung involvement, skin disease, mortality and therapy were observed between patients with or without GIT manifestations. There were no deaths associated with GIT involvement. The most common pharmacologic therapy used was proton pump inhibitors (86.8%), domperidone (20.8%) and antibiotic rotation (17%).

Conclusions: Almost two thirds of our cohort of SSc have symptomatic gastrointestinal disease. GIT manifestations are heterogeneous. Symptoms are non-specific and overlapping for a particular anatomical site. Esophagus is the most commonly affected. More than seventy-five per cent of patients experience symptoms of gastrointestinal reflux. We did not find differences among patients with and without SSc GIT disease. 17% of patients had a Reynold's syndrome.

AB0546 IMMEDIATE TO INTERMEDIATE EFFICACY AND SAFETY OF PROSTAGLANDINS E1 (PGE1) INHIBITORS- ALPROSTADIL IN TREATMENT OF SYMPTOMATIC RAYNAUD’S IN SYSTEMIC SCLEROSIS: SINGLE TERTIARY RHEUMATOLOGY CENTRE EXPERIENCE FROM SRI LANKA

S. H. Atukorale1, K. Thilakaratne1, I. Piyadasa1, R. Rathnayake1, P. Suryagoda1, B. Mahesh3,1 Rheumatology Unit, TH Anuradhapura, Anuradhapura, Sri Lanka; 2RRH, Ragama, Ragama, Sri Lanka; 3Population & Global Health Unit, Univ of Melbourne, Melbourne, Australia

Background: Systemic sclerosis (SSc) is a multi-system connective tissue disease. Raynaud phenomenon (RP) is a frequent (>90%) manifestation in SSc1 & if untreated could lead to complications such as digital ulcers, gangrene and amputation. Calcium antagonists are considered as first-line therapy for symptomatic SSc-RP. In refractory cases phosphodiesterase type 5 (PDE-5) inhibitors- Sildenafil and PGI2 analogues- Iloprost are used. A meta-analysis of trials indicate that PDE-5 inhibitors reduce the frequency and severity of SSc-RP attacks. In addition a study done with PGE1 inhibitors- Alprostadil 60 micrograms infusion given for six consecutive days, had shown immediate efficacy in SSc- RP; as demonstrated by increased blood flow, digitally measured by telethermography. Furthermore there was a reduction of the number, frequency and severity of attacks.2

Due to unavailability of Iloprost in Sri Lanka, based on the above evidence some rheumatology centres use Alprostadil 60 microgram infusions for 3 consecutive days in refractory symptomatic SSc-RP.

Objectives: To assess immediate (Day 4) and intermediate (Day 42) efficacy of Alprostadil 60 microgram infusions given for 3 consecutive days in treating SSc-RP.

**Methods:** An observational longitudinal study was conducted at the Rheumatology unit, Teaching Hospital Anuradhapura- Sri Lanka during 01.09.2019- 30.12.2019. Twelve diagnosed Systemic Sclerosis patients with symptomatic Raynaud’s (Raynaud’s score of >5) despite receiving maximum tolerable doses of calcium antagonists consisted of the study sample. Pre and post (on day 4 and 42) treatment frequency of Raynaud’s attacks and Raynaud’s score was recorded using a pre-tested interviewer administered questionnaire. Statistical analysis was done using SPSS version 22 with Wilcoxon Signed Rank test at 5% significance level.

**Results:** All recruits were females (n=12). Median (IQR) age of the study population and disease-duration were 45 (40 to 53.5) years and 6 (2.8 to 9.5) years respectively. Among participants, 58.3% and 25% had previous or current digital ulcers and gangrene respectively.

**Conclusion:** Alprostadil 60 microgram infusions demonstrated a statistically significant immediate and intermediate efficacy in treating symptomatic SSCs-RP with reduction of frequency of Raynaud’s attacks and Raynaud’s score at both. Only immediate efficacy was seen for mean duration of attacks. Based on these and the observed satisfactory safety level, we recommend the use of Alprostadil for symptomatic Raynaud’s in SSC-RP as an alternative to iloprost. Further studies of larger samples are recommended.

Methods: We reviewed 374 records of SSc patients at our site EUSTAR cohort and extracted cases with reported AS confirmed by ECHO cardiography and heart catheterization.

Results: We found data on 13 (3.4%) patients with AS: 12 females (92.3%); mean age 70.3 (SD 7.7) years, disease duration 15.4 (SD 6.3) years. Ten patients had limited SSc (76.9%), all cared anti-centromere antibodies and 3 diffuse SSc (1 patient had RNP3 and 2 had anti-topoisomerase antibodies); 5 (38.5%) patients had significant coronary disease (3 underwent CABG, 2 had several PTCAs). Eighty (61.5%) patients died during years 2004 - 2019. Aortic valve replacement was performed in 5 patients (4 - metal and 1 – biological); 2 patients did not undergo AS repair due to impaired general condition; 6 patients underwent TAVI between January 2013 and December 2019 (5 at Rambam Cardiology Institute). All SSc patients underwent trans femoral TAVI under conscious sedation. The procedure was successful in all patients. The length of hospitalization was 5-14 days (mean 6.2 days); 3 (50%) patients needed pacemaker implantation (they did not have previous conduction abnormalities). The follow-up duration after TAVI was between 5 and 67 months (mean 20.7). During follow-up one patient developed bacterial endocarditis related to pacemaker device two months after the procedure; the event resolved after removing the device and according antibiotics treatment; the same patient had transient ischemic attack two years later and another pacemaker implantation 3 years later due to complete AV block. One patient died from urenosis 11 months after TAVI, the death was not related to procedure. One patient developed anemia due to large hematomata after the procedure.

Conclusion: Screening for aortic valve pathology is essential as AS is not rare in SSc patients especially in those with long standing limited disease and positivity to centromere antibodies. AS in SSc patients may be associated with clinically significant coronary artery disease. TAVI was safe in our SSc patients without in-hospital mortality and benign long-term outcome.

CLINICAL SIGNIFICANCE OF COGNITIVE IMPAIRMENT AND MALNUTRITION IN PATIENTS WITH SYSTEMIC SCLEROSIS

D. Bertolino1, L. Manfredi1, I. Paterno1, C. Dichia1, A. M. Risa1, G. Silvi1, A. Gabrielli2.
1Università Politecnica delle Marche, Dipartimento di Scienze Cliniche e Molecolari, Ancona, Italy
2Università Politecnica delle Marche, Dipartimento di Scienze Cliniche e Molecolari, Ancona, Italy

Background: Previous studies reported a high prevalence of cognitive dysfunction in systemic sclerosis (SSc). Cognitive impairment was estimated to involve 60% to 80% of SSc patients and to be correlated with older age, disease severity, diffuse cutaneous subset and poor quality of life.

Objectives: The aim of our study was to evaluate the association between cognitive impairment, nutritional status and the quality of life of SSc patients.

Methods: Sixty-eight consecutive SSc patients followed at our Institution were evaluated for cognitive impairment using the validated Italian version of the Montreal Cognitive Assessment (MoCA). Scores <26 were considered abnormal. We also assessed other domains and quality of life measures such as UCLA SCLT G1.2 for gastrointestinal involvement, BMI and PHQ-9 for anxiety and depression, C-10 for dyspnea symptoms, SF-36 for functional capacity and quality of life (QoL). The risk and the presence of overt malnutrition were assessed using the MUST questionnaire and the MLI criteria, respectively. Clinical and demographic parameters such as age, sex, BMI, disease subset, organ involvement, autoantibody profile and modified Rodnan Skin Score were also recorded for each patient. Data were analysed by Student t-test or chi-square test and regression analyses were used to assess the association between variables.

Results: A total of 68 SSc patients [47 (69.1%) limited SSc (ISSc) and 21 (30.9%) with diffuse SSc (dSSc), 59 female; mean age 60.2 (±13.4) years, mean disease duration 9 (±8.2) years; mean mRSS 8.1 (±7.6)] were included in the study.

Cognitive impairment was identified in 30 (44.1%) SSc patients; the mean MoCA score was 24.7 (±4.3). According to GLIM criteria, 16 (23.5%) patients were malnourished. Compared to patients with a MoCA≥26, patients with cognitive impairment were older (p<0.001), had more comorbidities (p<0.0001) and a worse QoL as assessed by the physical and general health domains of the SF-36 (p<0.05). Malnourished patients were significantly more dysphagic (p<0.01) and had a worse HAQ (p<0.01) compared to well-fed patients. On regression analyses, cognitive impairment was related to increasing age (OR 1.08, 95%CI 1.03 to 1.14, p=0.001), but not to malnutrition, disease subset or symptoms. Malnutrition was associated with dysphagia (OR 1.10, 95%CI 1.01 to 1.20, p=0.01) and HAQ score (OR 2.69, 95%CI 1.24 to 5.82, p=0.01), but was not predicted by cognitive impairment.

Conclusion: Cognitive dysfunction is frequently observed in SSc patients and mostly associated with increasing age and number of comorbidities. Malnutrition and cognitive impairment are both associated to QoL but seem to be unrelated.

DOI: 10.1136/annrheumdis-2020-eular.5807
Background: The nocebo phenomenon, the opposite of placebo, defined as negative expectations about a treatment resulting from: the patient’s perspective of the treatment and possibly leading to suboptimal outcomes and non-adherence.

Methods: We compared the incidence of diarrhoea in the placebo arm across SENSCIS (2019) and other nintedanib RCTs published so far. We also compared the strength of the warnings for diarrhoea (ie, each arm, as well as between SENSCIS and all other nintedanib RCTs published so far). The estimated point prevalence of diarrhoea in an SSc cohort similar to SENSCIS would not exceed 15% based on the literature, there was an at least 2-fold increase in the occurrence of diarrhoea in the placebo group during SENSCIS. More importantly, when looking into other nintedanib RCTs (Table 1), we found that patients reporting diarrhoea in the placebo arm were 20% and 18% in cancer and idiopathic pulmonary fibrosis (IPF) trials, respectively, which is almost half than in SENSCIS. Consistent with our hypothesis, the percentage of diarrhoea in the placebo arm of the different nintedanib RCTs increased along with the number of mentions and the number of lines devoted to “diarrhoea” in the respective ICFs.

Objectives: To test whether the nocebo phenomenon is involved in the prevalence of diarrhoea as an adverse event in trials with nintedanib.

Results: The mean percentage of patients reporting diarrhoea was 32% in the placebo arm, N=767 (150), 48% MMF (Table 1), we found that patients reporting diarrhoea in the placebo arm were 20% and 18% in cancer and idiopathic pulmonary fibrosis (IPF) trials, respectively, which is almost half than in SENSCIS. Consistent with our hypothesis, the percentage of diarrhoea in the placebo arm of the different nintedanib RCTs increased along with the number of mentions and the number of lines devoted to “diarrhoea” in the respective ICFs.

Conclusion: These results indicate that the nocebo phenomenon is partially involved in the high prevalence of diarrhoea among SSc patients participating in the SENSCIS trial. Whether patients with SSc have increased susceptibility to the nocebo phenomenon when compared to patients with IPF or cancer deserves further study.

**Conclusion:** The clinical spectrum and the time course of ASSD is not significantly affected by the presence of anti-Ro antibodies, although ILD seems to be more associated to anti-Ro antibodies. Despite higher prevalence of ILD in Ro positive group no difference in mortality was observed in respect to anti-Ro negative patients.

**DOI:** 10.1136/annrheumdis-2020-eular.5615
**Methods:** The autoantibody profiles of 2799 SSc patients from February 2001 to June 2017 were retrospectively reviewed. Patients with >1 SSc-Abs were identified. Clinical features were collected and compared to historical cohorts of SSc patients with single SSc-Abs positivity. Patients were excluded if treated prior to their immunology test with rituximab, iv immunoglobulins or stem cell transplantation. Statistical analysis was performed using Fisher exact test.

**Results:** 72 patients (2.6%) with >1 SSc-Abs were identified. Full clinical data were available for 63 patients. 60 patients (2.1%) had double Ab positivity and 3 patients had triple Ab positivity (0.1%). 13 Ab combinations were present. U1RNP and ATA was the most frequent combination (35%), patients were significantly younger (51.38 years) than both U1RNP (58.64 years, p=0.050) and ATA (62.03 years, p=0.002) patients and more commonly of diffuse subset (dcSSc) (p=0.001 and p=0.041 respectively). Compared to ATA patients overlap features were more frequent (43% vs 15%, p=0.004) including inflammatory arthritis (p=0.025) and myositis (p=0.013) (Table 1). U1RNP and ACA had a significantly higher prevalence of pulmonary arterial hypertension compared to U1RNP (p=0.039) and ACA (p=0.022) patients, and compared to ACA patients they were younger (57.88 vs 68.75, p=0.015) with a higher incidence of myositis (p=0.001). U1RNP and ARA patients were more frequently dcSSc subtype compared to U1RNP patients (75% vs 21%, p=0.040). U1RNP and PmScl patients had a higher prevalence of myositis compared to U1RNP patients (p=0.006). ATA and ACA patients behaved similarly to ATA patients with a significantly higher prevalence of lung fibrosis (p=0.006) and myositis (p=0.041) compared to ACA, ACA and PmScl (7%) had higher prevalence of myositis compared to ACA patients (p=0.04).

**Table 1.** Frequency of clinical features in some of the double antibody group combinations, compared to our cohort of patients with only one of the SSc specific antibody. Significant p values (<0.05) highlighted in bold. ILD (interstitial lung disease), PAH (pulmonary arterial hypertension), SRC (scleroderma renal crisis).

**Conclusion:** Coexistence of hallmark autoantibodies is exceedingly rare in SSc patients. When combined, both SSc-Abs have the potential to synergistically interact and modify the clinical phenotype.

**Disclosure of Interests:** Corrado Campochiaro Speakers bureau: Novartis, Pfizer, Roche, GSK, SOBI, Kristina Clara: None declared, Lauren Host: None declared, Alper San: None declared, Svetlana Niyantiana: None declared, Christopher Denton Grant/research support from: GlaxoSmithKline, KSL Behring, and Inventiva, Consultant of: Medscape, Roche-Genentech, Actelion, GSK, C. The presence of >1 SSc-Abs is rare with minimum data about these patients’ clinical phenotype.

**Background:** Systemic sclerosis (SSc) is typically manifests with distinct SSc-specific antibodies (SSc-Abs): anti-topoisomerase I (ATA), anti-centromere (ACA), anti-RNA polymerase III (ARA), anti-U3RNP (U3RNP), anti-U1RNP (U1RNP), anti-PmScl (PmScl), anti-Ku (Ku) and anti-Th/T0 (Th/T0), each being characterised by different clinical features and prognosis. The presence of >1 SSc-Abs is rare with minimum data about these patients’ clinical phenotype.

**Objectives:** To describe and compare the clinical features of SSc patients with >1 SSc-Ab.

**Conclusion:** Using a SLR and modified nominal technique, we have developed a preliminary pSScHI consensus-based definition and started a validation process for it to be used in clinical research and clinical practice.

Background: Prior literature shows a global increase of cancer risk among patients with systemic sclerosis (SSc). Although breast cancer (BC) is one of the most frequent malignancies in SSc patients, the characteristics of this neoplasm among SSc patients is not well established and it is uncertain whether SSc significantly increases the risk of this cancer.

Objectives: Describe the characteristics and risk factors for BC among Spanish patients with SSc.

Methods: Ambispective and multicenter study of patients with a diagnosis of SSc according to ACR/EULAR criteria and/or LeRoy classification included in the Spanish Scleroderma Registry (RESCLE) from 2006 to 2018. Characteristics of patients with BC were described and incidence was compared with that of the general population.

Results: Among 1930 patients with SSc, 206 (10.7%) had cancer. BC was the most frequent tumor location (47 patients of 206 with cancer [22.8%]), followed by lung cancer (29, 14.1%). The risk of BC was increased in patients with SSc compared to the general population (standardized incidence ratio [SIR] 1.31; 95% CI 1.10-1.54; P = 0.003).

The comparison of patients with BC and those without cancer showed that patients with BC had older age at diagnosis of SSc (50.9 vs 45.9 years, respectively; P = 0.004), were more frequently diagnosed of interstitial lung disease (ILD) (30/47 [63.8%] vs 69/1714 [40.5%]; P = 0.004), and had higher frequency of puffy hands as the first manifestation of SSc (4/45 [8.9%] vs 38/1864 [2.4%]; P = 0.023) and had more frequently primary biliary colangitis (PBC) (7/46 [15.2%] vs 72/1708 [4.2%]; P = 0.004). Regarding autoimmunity profile, patients with SSc and BC had a significantly higher presence of anti-Ro (11/44 [25.0%] vs 214/1528 [14.0%]; P = 0.049) and anti-mitochondrial antibodies (7/28 [25.0%] vs 96/837 [11.5%]; P = 0.039). Multivariable regression analysis showed an independent association between the puffy hands (OR = 6.40; 95% CI 1.73-23.60; P = 0.005), diagnosis of PBC (OR = 5.70; 95% CI 2.16-15.07; P = 0.001), presence of ILD (OR = 3.29; 95% CI 1.69-6.39; P <0.001) and the presence of the anti-Ro antibody (OR 2.14; 95% CI 1.01-4.56; P = 0.048) with the presence of BC.

Conclusion: BC risk was increased in patients with SSc. The development of ILD, PBC, the presence of anti Ro and puffy hands as the first clinical manifestation of SSc were identified as independent factors associated with the development of BC in our cohort.

Methods: Prospective study of a cohort of patients with SS, excluding those with heart disease, PAH or cardiovascular risk factors. All underwent a clinical assessment, blood test with cardiac biomarkers, electrocardiogram (ECG), Holter 24h (HLT) and echocardiogram (TTE), interpreted by an expert cardiologist blind about the patients. Arrhythmias were classified as clinically significant arrhythmias (CSA) or clinically nonsignificant arrhythmias (CNSA) by ECG and HLT. LV diastolic dysfunction (LVDV) was defined as E/e’ < 8, LV systolic dysfunction (LVSD) as a global longitudinal strain <20% and HD as a SDDN <100ms. Demographic, clinical and biological data were collected. A follow-up was performed at 6.2 ± 0.9 years. Statistical analysis was performed using SPSS 23 IBM®.

Results: 36 patients were included; age 56.7 ± 12.3 years (y), male / female 35/1, disease duration 7 ± 4.1 y. 66% belonged to the limited SS subtype, 66.6% were anti-centromer+, 25% anti-topoisomerase, 2.7% anti-P/Sm and 2.7% anti-RNA polymerase III+. Raynaud was present in 100%, telangiectasia in 55.6% and intestinal lung disease in 36.1%. The modified Rodnan skin score (mRSS) was ≤ moderate (0-29 points) in 55.6%; 27.8% had presented digital ulcers that required prostaglandins. 27.8% had LVDD, 22% LVSD, 11.1% LVDD + SD and 16.7% HD. 50% (18/36) of patients had ECG alterations, of which 44% corresponded to CSA (Table 1) and, 55.6% (20/36) HLT alterations, of which 75% were CSA (Table 2). 3/36 patients had both HLT and ECG CSA. In 1 patient, impaired LV ejection fraction was detected; in none, valvular disease. 38.8% had elevated NT-proBNP and 13.9% troponin T (TnT). No correlation was found between any parameters and CSA.

A correlation was found between mRSS and DLCO (r=0.002), DLCO and digital ulcers (r=0.001), and mRSS and digital ulcers (r=0.005). A correlation was also found between elevated NT-proBNP and TnT (r=0.006) and between elevated NT-proBNP and LVDD (r=0.049). After follow-up up 6.2 ± 0.9 y, 2 patients had died: 1 of neoplasia and 1 of severe biventricular dysfunction 5.2 y after the study.

Conclusion: Our data confirm a high prevalence of ventricular arrhythmias and left dysfunction in patients with SS, without heart disease, cardiorespiratory symptoms or HAP, being up to 75% of the arrhythmias CSA. The lack of correlation between CSA and LVSD or DD indicates that arrhythmias could be due, not only to a supposed structural alteration of the myocardium, but to a primary and early cardiac involvement in SS. In addition, the lack of correlation between CSA in ECG and HLT reinforces the importance of a complete cardiac evaluation in these patients to rule out silent cardiac involvement.

Disclosure of Interests: LILIAN LÓPEZ-NUÑEZ: None declared, Irene Carrión Barberà Grant/research support from: I received a grant from the Spanish Rheumatology Foundation (FER) and laboratories KERN PHARMA for a brief stay abroad., Isabel Padró: None declared, Lluís Molina: None declared, Ana Pros: None declared DOI: 10.1136/annrheumdis-2020-eular.2574
Background: Inflammatory myopathies (IM) are a group of rare diseases that involve muscle inflammation. Several types are defined with a wide range of different manifestations and prognosis.

Objectives: Describe the characteristics of the cohort of patients with IM in a tertiary hospital, in order to identify their demographic and clinical characteristics and try to find a correlation between them.

Methods: Retrospective observational study of patients with IM: dermatomyositis (DM), polymyositis, antisynthetase syndrome (ASS), necrotizing autoimmune myopathy and overlap syndrome (OS). Clinical, biological, neurophysio and histopathological data were collected. Statistical analysis was performed using SPSS 23 IBM®.

Results: 28 patients were included with a follow-up of 10.9 ± 9.8 years (y). According to the 2017 EULAR / ACR criteria for IM, 89.2% were classified as definitive IM, with an average score of 12.1 ± 3.2. Age at diagnosis 47.3 ± 17.7y; ratio 1.3; 78.6% Caucasian, 10.7% Asian and 10.7% Latino. 39.3% had DM, 3.6% hypomyopathic and 3.6% amyopathic DM, 28.6% OS and 17.9% ASS. Lung involvement was the most prevalent extramuscular manifestation (67.9%). Systemic sclerosis was the most frequent overlapping autoimmune disease (AD) (21.4%) and 2 patients (7.1%) overlapped more than 1 AD. In Table 1 are detailed the clinical characteristics of the patients, and in Figures 1 and 2, the autoantibody (aa) profile and treatments used. The incidence of neoplasm was 10.7% 10.3 ± 9.6y after the diagnosis of myopathy (3 breast neoplasms, 1 colon and 1 cutaneous lymphoma), and of them, 66.7% had two synchronous neoplasms. No neoplasms were observed in the 2 anti-TIF1-γ Patients. The subtype of IM in these patients was 1 OS anti-RNP+, 1 DM anti-PL-12+ and 1 ASS anti-OJ- 17.9% smoked and 21.4% had taken statins at some point, without it being related to the start of the myopathic clinic. A capillaroscopy was performed in 67.9%, being pathological in 63.1% The positivity of anti-RNP (p=0.01) and steroid bolus (p=0.039) were correlated with a more severe disease, defined as a summation index composed of a series of manifestations (pulmonary hypertension (PH), ischemic heart disease, venous/arterial thrombosis, myopericarditis, interstitial lung disease (ILD), severe infections, neoplasms or hospitalizations). Other statistically significant correlations between aa and clinical manifestations are detailed in Table 3, among which the anti-RNP+ with myopericarditis stands out. No correlation was found between the findings on capillaroscopy and the type of IM.

Conclusion: The most frequent subtype of IM was DM. 10.3% of the patients presented a neoplasm, all with different subtypes of myopathy and aa. The presence of anti-RNP+ correlated with greater severity of the disease and myopericarditis. Likewise, significant differences were found between the subtypes of aa and certain clinical manifestations. There is no correlation between findings on capillaroscopy and the type of IM.

AB0561 AUTOMATIC QUANTIFICATION OF INTERSTITIAL LUNG DISEASE FROM CHEST COMPUTED TOMOGRAPHY IN SYSTEMIC SCLERODERMA

A. Carvalho1, A. Guimarães2, F.R. Sztajnbok3, R. Rodrigues4, B. Silva5, A. Lopes3, I. Almeida4, M. França5. 1Medical School, Hosp. de Santo Antônio (HSA), Centro Hospitalar do Porto (CHP), Instituto de Ciências Biomédicas Abel Salazar (ICBAS), Univ. do Porto, Department of Radiology, Porto, Portugal; 2Laboratory of Pulmonary Engineering, Biomedical Engineering Program, Alberto Luiz Coimbra Institute of Post-Graduation and Research in Engineering, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; 3Department of Reumatology, State University of Rio de Janeiro, Rio de Janeiro, Brazil; 4Department of Radiology, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; 5Postgraduate Program in Medical Sciences, School of Medical
Scleroderma-associated interstitial lung disease (SSc-ILD) is often observed in patients with systemic scleroderma (SSc) and its diagnosis contributes to early treatment decisions.1,2

Objectives: The present study aims to automatically quantify SSc-ILD from high-resolution chest-computed tomography (HRCT) and to evaluate the association between interstitial lung disease (ILD) extension and lung function impairment.

Methods: Ninety-four patients with SSc and 27 lung-healthy subjects matched for gender, weight, height, and age underwent HRCT, spirometry and carbon monoxide diffusion capacity (DLco). SSc-ILD was determined as the tissue mass present between -500 and +100 Hounsfield Units normalized by the total lung tissue mass (TLM). Cut off was the highest value obtained in the control group (25% of TLM). All data are presented as mean and standard deviations (Table I). An ANOVA test followed by Bonferroni post-hoc correction was used for comparisons among groups.

Results: From 94 patients with SSc, 64 were classified as having pulmonary involvement (SSc-ILD) and 30 as not having pulmonary involvement (SSc No-ILD). In SSc-ILD subjects, there was a significant reduction in forced vital capacity (FVC), carbon monoxide diffusion capacity (DLco) and carbon monoxide diffusion capacity normalized by alveolar ventilation (DLco/VA) when compared with SSc No-ILD and control group.

Conclusion: The proposed method allows the automatic quantification of SSc-ILD from HRCT and ILD extent is associated with pulmonary function impairment.

**SLEEP HYGIENE: COULD IT BE A CONFOUNDING FACTOR FOR SLEEP QUALITY IN SYSTEMIC SCLEROSIS?**

N. Gokcen1, A. Komac1, F. Tuncer1, A. Yazici1, A. Cetle1, E. Kocaeli Universitesi Tip Fakultesi, Department of Internal Medicine, Division of Rheumatology, Kocaeli, Turkey

Background: Sleep disturbances have been described in Systemic Sclerosis (SSc). Confounding factors related to sleep quality are also investigated. Although sleep hygiene plays an important role in sleep quality, as far as we know, there are not enough data to show the effect of sleep hygiene on sleep quality of SSc.

Objectives: To investigate sleep hygiene, its impact on sleep quality, and its association with demographic-clinical factors in patients with SSc, rheumatoid arthritis (RA), and healthy controls.

Methods: The study was designed as cross-sectional. Forty-nine patients with SSc who fulfilled the 2013 ACR/EULAR classification criteria for SSc, 68 patients with RA who fulfilled 1987 revised classification criteria, and 30 healthy controls were included in the study. All participants were female. Demographic and clinical variables were documented. Disease activity index of both SSc and RA was calculated. SSc patients were assessed by questionnaires including Short Form 36 (SF-36), The Health Assessment Questionnaire Disability Index (HAQ-DI), Beck Anxiety and Beck Depression Inventory, Pittsburgh Sleep Quality Index (PSQI), Sleep Hygiene Index (SHI). Additionally, RA patients and healthy controls were estimated by HAQ-DI, Beck Anxiety and Beck Depression Inventory, PSQI, and SHI. Logistic regression analysis was used to determine the predictors of sleep quality.

Results: Preliminary results of the study were given. The baseline demographics were similar among groups. When comparing groups according to HAQ-DI, Beck Anxiety and Beck Depression Inventory, PSQI, and SHI, we found higher scores in SSc and RA rather than healthy controls (p<0.001, p=0.001, p<0.001, p<0.003, respectively). While sleep depression and sleep hygiene were determined as the risk factors of sleep quality in SSc in univariate analysis, depression (OR=1.380, 95%CI: 1.065–1.784, p=0.015) and sleep hygiene (OR=1.201, 95%CI: 1.039–1.365, p=0.046) were also found in multivariate logistic model.

Conclusion: Although depression is a well-known clinical variable impacting on sleep quality, sleep hygiene should also be kept in mind as a confounding factor.

Background: Systemic sclerosis (SSc) in a chronic autoimmune disease characterized by endothelial dysfunction and diffuse microangiopathy, leading to tissue ischemia and inducing fibrosis of skin and visceral organs. Furthermore, it was demonstrated the impairment of wall elasticity of large-medium vessels, such as aorta and its branches (1). SSc-related microangiopathy of vasa vasorum of the aortic wall could also be supposed. However no data on this hypothesis are available in literature. SSc microangiopathy may be easily studied at the nailfold by means of videocapillaroscopy. Indeed, capillaroscopic findings are representative of the microvascular damage caused by SSc troughout the body.

Objectives: We aimed to investigate the presence of aortic root dilation, classical sign of aortic wall damage, in a cohort of SSc patients, and to correlate these...
HEART VALVULAR ALTERATIONS IN A MULTICENTRE ITALIAN COHORT OF SSC PATIENTS

M. Colaci1, A. C. Conforto2, M. A. Russo3, D. Sambataro4, L. Malatino4, A. Russo5, A. A. Russo5, D. Sambataro1, G. Sambataro1, L. Malatino1.

1University of Catania, Catania, Italy; 2Rheumatology Centre, Ospedale Cannizzaro, Catania, Italy; 3Rheumatology Centre, Ospedale Cannizzaro, Catania, Italy; 4University of Palermo, Palermo, Italy; 5Ospedale Garibaldi Centro, Catania, Italy

Background: systemic sclerosis (SSc) in a chronic autoimmune disease characterized by endothelial dysfunction, diffuse microangiopathy, and fibrosis of skin and visceral organs. Typical cardiac involvement may include microvascular ischemia, contraction band necrosis, and patchy fibrosis, leading mainly to arrhythmias and conduction defects, diastolic dysfunction, or right ventricular failure (secondary to pulmonary arterial hypertension) [1].

Objective: To describe valvular alterations in a multicentre cohort of SSc patients.

Methods: we consecutively recruited 118 SSc patients (M/F: 14/104, mean age 56.7±12.4 years, median disease duration 10 years, limited/diffuse skin subsets: 95/23, anti-centromere/anti-Sc100/other autoantibodies: 35/37/46) in 5 Rheumatology Centres in Sicily, Italy, from January to December 2019.

The study design was as follows: transthoracic echocardiography assessment, and aortic root dilation measurement was carried out in all patients. Moreover, videocapillaroscopy with identification of early, active, or late SSc patterns was performed in the whole case series. Patients with early SSc pattern formed the subgroup 1, while those with the active or late patterns (both characterized by the reduction of capillary density) formed the subgroup 2.

Results: we identified 8 (6.4%) SSc patients with aortic root dilation (diameter >35 mm). Their age and their frequencies of cardiovascular risk factors were similar to the whole series. Moreover, videocapillaroscopy showed 62 (49.6%) early, 47 (37.6%) active, and 16 (12.8%) late SSc patterns. Aortic root dilation was observed in only one patient in the subgroup 1 (1/62, 1.6%) and in 7 cases of the subgroup 2 (7/63, 11.1%); p = 0.03.

Conclusion: in this multicentre study, we found that aortic root dilation is significantly associated with the reduction of capillary density at nailfold capillaroscopy (active or late SSc patterns). On the basis of these findings, we might argue that SSc-related microangiopathy of vasa vasorum could contribute to aortic wall damage, at least in a subset of SSc patients.

AB0566
NAIФILD EXTENT OF REDUCED CAPILLARY DENSITY IS ASSOCIATED WITH DIGITAL ULCERS AND WITH AN INCREASED RISK OF DIGITAL ULCERS IN SYSTEMIC SCLEROSIS
R. De Angelis1, F. Salaffi1, 1Marche Polytechnic University, Department of Clinical and Molecular Sciences, Ancona, Italy

Background: A growing evidence supports the role of microvasculopathy as a primary pathogenic event in systemic sclerosis (SSc). The most commonly used imaging technique to identify microangiopathy in SSc is high magnification videocapillaroscopy (VNC), and reduced capillary density and/or capillary loss, which is a typical feature of “scleroderma microangiopathy”, easily identified by NVC, has been associated with digital ulcers (DUs). Different approaches have been proposed to measure capillary density or capillary loss. Some of these were qualitative methods, others semi-quantitative, others only concerned a limited nailfold area, without ever evaluating the overall density, which is more suitable for quantitative estimate.

Objectives: To assess the association between the extent of different values of nailfold capillary density and the presence of DUs and to identify the risk of developing DUs, based on quantitative parameters.

Methods: The study involved 54 SSc selected patients (47 women and 7 men, mean age 59.5 years, 50 with limited and 4 with diffuse). The study population came from an ongoing database, that includes clinical and laboratory data of patients with definite SSc. A videocapillaroscope (Videocap® 3.0, DS Medica, Milan, Italy) with a 200x optical probe was used. During examination, eight fingers (fingers 2–5 of each hand), 4 fields per finger, according to the standard literature were assessed. For each patient, a total of 32 images were collected, then classified as having either “normal”, “non-specific” or the “scleroderma pattern” (SP). Capillary density was defined as the number of capillaries/mm in the distal row, regardless of its shape and morphology. Avascular areas were defined by the absence of loops within a width/area extending over more than 500 microns. For each patient, the SP images were further graded with no/slight reduction of the capillary density (7-9 loops/mm) (NOR), with a well-defined reduction of digital ulcers (DUs). Different approaches have been proposed to measure capillary density or capillary loss. Some of these were qualitative methods, others semi-quantitative, others only concerned a limited nailfold area, without ever evaluating the overall density, which is more suitable for quantitative estimate.

Results: A total of 1728 images were analyzed. Patients with DUs were 16/54 (29.6%). All patients had a SP, but only five patients showed a SP along the entire nailfold. A comparison between patients with or without DUs showed a significant difference both for the overall extent of AA (p=0.032), and particularly for the overall extent of RED (p<0.001). No significant difference was found regarding the overall extent of the SP (p=0.085). Factor significantly associated with DUs in multivariate analysis was the overall extent of RED (p=0.0286). The ROC curve was very effective at discriminating the capillary feature able to distinguish patients with DUs from patients without DUs. The discriminatory power of the overall extent of RED was very good, with an AUC of 0.948 (95% CI 0.852 ± 0.990). Then, we calculated the cut-off value of the overall extent of RED for presence/absence of DUs with the highest combination of sensitivity and specificity. The resulting cut-off value (Youden index of 0.823) was >68.7 (sensitivity 92.31%; specificity 90.24 %) with a LR+ of 9.46.

Conclusion: Our data strongly support that the capillary density between 4 and 6 loops/mm is the best capillaroscopic quantitative measure associated with DUs and able to discriminate the probability of having DUs. If all SSc-specific antibodies and/or other laboratory/cclinical parameters are not yet available, the overall capillary density can allow physicians to assess SSc patients easily, regarding DUs and risk for developing DUs.

study in dcSSc patients and associated with improvements in ACR Combined Response Index Systemic Sclerosis (CRISs) score and multiple secondary efficacy outcomes.

Objectives: We now report on the background standard of care and baseline disease characteristics of European (EU) patients in order to assess variability by geographic regions.

Methods: The RESOLVE-1 Phase 3 study was designed with input from study investigators and regulatory authorities. An important intent of the design was to have eligibility criteria that allow testing of efficacy and safety of lenabasum in an inclusive group of dcSSc subjects to maximize relevance to patients in current practice. The study is ongoing and remains blinded.

Results: Primary efficacy outcome is the ACR CRISs score at 12 months, comparing lenabasum 20mg BID to placebo. Key inclusion criteria are males and females ≥ 18 years of age with dcSSc and disease duration ≤ 6 years who are on stable standard of care medicines, with background stable immunosuppressive medications allowed. Baseline mRSS needed to be ≥ 15 if disease duration was > 3 to ≤ 6 years at enrollment. The study enrolled 110 EU subjects over 15 months who received ≥ 1 dose of study drug at 20 sites in 7 countries. Baseline characteristics as shown in Table 1. The majority were middle-aged, female, and white, and 80% were on immunosuppressive drugs in EU region; methotrexate (MTX) used in 30% of subjects, mycophenolate/mycophenolic acid (MMF) used in 46% of subjects, and 43% of subjects took ≥ 2 concurrent immunosuppressive drugs. There were regional differences in background immunosuppressive with use of MTX, MMF and corticosteroids highest in EU, NA and Asia, respectively.

Table 1. Patient Baseline Demographics and Disease Characteristics by Regions (Blinded)
Background: Mixed connective tissue disease (MCTD) is considered to be uncommon; specifically there is sparse data on MCTD from developing countries like India.

Objectives: This study examines the clinical and serological features of these patients in a single center in North India.

Methods: This was a retrospective single-center study of patients diagnosed as MCTD in last 20 years. The patients included fulfilled at least one of the diagnostic criteria namely Alarcon-Segovia, Kasukawa, and Kahns. Demographic details, clinical signs and symptoms, laboratory parameters, treatment and outcome were extracted from medical records and clinic files in a pre-designed proforma.

Results: This study included 41 MCTD patients. There was a marked female preponderance (F:M=40:1), and mean age of disease onset and diagnosis was 33.8 ± 10.7 and 39.3 ± 10.2 years. 39 (92%) of the patients fulfilled both Kahn and Kasukawa criteria, while 31 (76%) fulfilled Alarcon-Segovia criteria. Initially patients had been (mis)diagnosed as rheumatoid arthritis, systemic lupus erythematosus (or UCTD) (in five patients each), overlap syndromes or myositis (in 4 patients). ANA was commonly high-titer and speckled, U1RNP was positive in half the patients. Raynaud’s was seen in three-fourth at presentation and all the patients over time. Digital gangrene and puffy fingers were seen in 8 (20%) and 18 (44%) patients. Other clinical features included arthritis in 33 (81%), sclerodactyly in 23 (56%) and proximal weakness in 20 patients (49%). Interstitial lung disease and pulmonary arterial hypertension were seen in 20 (57%) and 15 (46%) patients. Other clinical features included arthritis in 33 (81%), sclerodactyly in 23 (56%) and proximal weakness in 20 patients (49%). Interstitial lung disease and pulmonary arterial hypertension were seen in 20 (57%) and 15 (44%) patients. All patients (except one) received prednisolone, and it was never stopped. Raynaud’s was seen in three-fourth at presentation and all the patients over time. Digital gangrene and puffy fingers were seen in 8 (20%) and 18 (44%) patients. Other clinical features included arthritis in 33 (81%), sclerodactyly in 23 (56%) and proximal weakness in 20 patients (49%). Interstitial lung disease and pulmonary arterial hypertension were seen in 20 (57%) and 15 (44%) patients. All patients (except one) received prednisolone, and it was never stopped.

Conclusion: MCTD was not uncommon in the single-center in North India. Kahn and Kasukawa criteria were found to be the most sensitive for its diagnosis. Digital gangrene was relatively common and sometimes the presenting feature; whereas puffy fingers were present in only half the patients.

AB0572  REDUCED ENZYMATIC ACTIVITY OF ANTIOXIDANT SYSTEM IN SCEROSIS.

N. Emelyanova1, I. Gontar2, O. Emelyanova3, O. Rusanova1, 1FSBEI HE «Volgograd State Medical University» MOH, Volgograd, Russian Federation; 2FSBI «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Volgograd, Russian Federation

Background: The antioxidant system is a natural barrier to the pathologic effect of reactive oxygen intermediate (ROI) on the tissues of patients with systemic scleroderma (SSD). It is comprised of enzymatic links, of which the cascade of enzymes like superoxide dismutase (SOD), glutathione peroxidase (GP), glutathione reductase (GR) and others are most important. Autoantibodies to enzymes of the antioxidant system can bring about a reduction in their biochemical activity.

Objectives: Studying the effect of production of antibodies to antioxidant system enzymes SOD, GR and GP in patients with SSD using immobilized magneto-controlled adsorbents.

Methods: We observed 40 patients with SSD and 30 apparently healthy individuals. Degree I of activity was established in 15 patients (37.5%), degree II – in 24 patients (60%), degree III – in 1 patient (2.5%), Patients with subacute and acute course of the disease, degree of activity II and III were united in one group due to their small number. Antibodies to SOD, GR and GP were determined in blood serum of patients upon admission and discharge using immobilized antigen forms of enzymes (Gontar I.P., 2001). Commercial preparations served as antigens when determining antibodies to SOD, GR and GP.

Results: A study of blood sera from healthy individuals showed SOD antibodies level of 0.06±0.004, GP antibodies – 0.045±0.003, GR antibodies – 0.05±0.01. The total activity of SOD in the group of healthy people was 28.2±1.2 U/L, GP – 0.153±0.007 U/L, GR – 114.3±3.7 U/L. Upon admission to hospital patients showed a reliably reduced activity of SOD and GR (p<0.002), and unreliably reduced activity of GP (p>0.02). Among patients with SSD antibodies to SOD were detected in 15 people (37.5%), antibodies to GP – in 14 (35%), antibodies to GR – in 16 (40%). With degree I of activity, high levels of SOD antibodies were detected in 4 patients (26.7%), antibodies to GP – in 4 patients (20%), to GR – in 6 (40%). When SOD was degree of activity II and III, the patients showed a reduced activity of SOD, GR and GP (p>0.05) compared with healthy people, and higher antibody levels (p<0.002). We noted an increase in the number of patients whose serum showed high antibody levels: antibodies to SOD in 11 people (44%), to GP – in 11 (44%), antibodies to GR – in 12 (48%). In the group of SSD patients who showed high levels of SOD, GR and GP antibodies, we observed a reliable reduction in enzymatic activity (p<0.05). SOD activity was reliably reduced both in chronic and subacute course of the disease (p<0.02). In the group of patients with high levels of enzyme antibodies we noted a reliable reduction in enzymatic activity. A test for antibodies to SOD, GR and GP in SSD patients with involvement of various organs and systems showed their reliably elevated level in all clinical groups (p=0.032, p=0.034 and p=0.025).

Conclusion: Production of antibodies to antioxidant system enzymes plays an important role in pathogenesis of SSD involving internal organs and tissues and aggravating the course of the disease on the whole.

AB0573  IDIOPATHIC INFLAMMATORY MYOPATHIES: A SINGLE-CENTER EXPERIENCE

B. H. Egele1, S. Ergun1, A. Cetin1, Y. K. Gursoy1, S. Ugurlu1, 1Istanbul University- Cerrahpaşa, İstanbul, Turkey

Background: Idiopathic inflammatory myopathies (IMM), mainly dermatomyositis (DM) and polymyositis (PM) are the diseases of the musculoskeletal system most commonly affecting the proximal muscles of the limbs. In addition to muscle inflammation, these conditions are multisystemic, presenting with a variety of complaints.

Objectives: As IMM are infrequent, a single-center experience presenting quantitative data describing in-depth information on the nature of disease and treatment seems useful.

Methods: This retrospective study was conducted at a tertiary rheumatology center. Patients were diagnosed with an idiopathic inflammatory myopathy (DM, PM) in order to be included in this study. Clinical signs and symptoms of the presentation were noted during the first patient encounter as well as the follow-up. Parameters of disease activity including acute phase reactants, muscle enzyme levels, and disease-specific autoantibodies were analyzed. Treatment and prognosis information was also noted with additional information from phone call interviews.

Results: The study includes 108 patients (78 DM, 30 PM). The mean age of diagnosis was 43.17 ±18.73 years, follow-up duration was 44.37 ±60.58 months. The presenting signs and symptoms of the patients are shown in Figure 1. The parameters of disease activity before and after treatment are summarized in Table 1. The clinical tests ordered during the disease management are summarized in Table 2. The mean corticosteroid dose decreased from 45.65 ±s141.53 mg to 15.22 ±s16.77 (p=0.007). Other treatment methods were methotrexate (n=72), rituximab (n=28), Intravenous Immunoglobulin (IVIG) (n=9), and cyclophosphamide (n=5). Ten patients died during the follow-up. Thirty-six patients were lost to follow-up.

Conclusion: IMM are very rare and can present with very different signs and symptoms. Referral to rheumatology can be challenging along with treatment. With inadequate clinical insight diagnosis and management of these patients can be delayed and quite expensive. Long term follow-up in our center enabled adequate control of disease activity as proven by the highly significant decrease in parameters of disease activity, especially muscle enzyme levels. Furthermore, we reported the variety of clinical symptoms, investigation methods and treatment essays in our center trying to reflect the potential challenges that can hinder a health clinical practice as well as highlight the requirement of a standardized approach.

AB0574

BENEFITS OF ILOPROST IN LONG-TERM STABILIZATION OR IMPROVEMENT IN NON-NEOGENESIS SYSTEMIC SCLEROSIS: A 15 YEARS OBSERVATION COHORT

P. Faggioli1, L. Castelvetro2, A. Tamburelli3, A. Laria4, A. M. Lurati5, A. Mazzone6,7, Ospedale di Legnano, Medicina Interna, Legnano, Italy; 2Hospital Giuseppe Fornaroli, Reumatologia, Magenta, Italy

Background: In Systemic Sclerosis (SSc) fibrosis is due to microcirculation changes with capillary necrosis, arteriolar intimal proliferation and local ischemia. Iloprost (ILO) is used IV for the treatment of severe Raynaud phenomenon (RP) and digital ulcers (DU) in (SSc). We have already described (1) an improvement of peripheral vascularization with ILO, observed after 3 years treatment by capillaroscopy with an increase in the capillary number and mild regression of avascular areas and pericapillar oedema. Objectives: Our aim was to observe capillaroscopic changes in a cohort of 28 patients treated with ILO, once a month (25 – 50mg each infusion) for an average time of 15 years.

Methods: We evaluated the initial and 2019 capillaroscopic picture of 26 SSc patients (24W:2M; median age 63.8Y) in continuous treatment with monthly infusion of ILO from 2004 to today. 6/26 were SCL70 positive; the remainder was positive for antcentromere Ab.

Results: We documented stability of capillaroscopic picture in 62% of patients; an improvement in 19% and a worsening (mainly from early to active pattern) in 19%. Low adherence to therapy was observed among the worsened patients. Out of 8 patients with onset ulcers, only 3 patients still have skin ulcers, all with late stable capillaroscopic picture from onset. We have not documented serious adverse events.

Conclusion: Our observations confirm the efficacy and safety of ILO in the treatment of SSc even after many years of treatment, resulting in a stabilization of microvascular damage, independent of disease severity.

AB0575

THE ROLE OF LONG-TERM AND INTENSIVE IV ILOPROST TREATMENT IN REDUCTION OF PULMONARY ARTERY PRESSURE AND PRO-BRAIN Natriuretic Peptide (pBNP) IN SCLERODERMA PATIENTS

R. Foti1, E. Visalli1, G. Amato1, A. Benenati1, S. Bellofore2, M. Mule3, M. Di Gangi3, 1AOU Policlinico Vittorio Emanuele, Division of General Thoracic Surgery, Catania, Italy; 2AOU Policlinico Vittorio Emanuele, Division of General Thoracic Surgery, Catania, Italy; 3AOU Policlinico Vittorio Emanuele, Division of Cardiology, Catania, Italy

Background: Systemic sclerosis (SSc) is a chronic immune-mediated connective tissue disease with heterogeneous organ involvement that reduces the life expectancy of this patients. In particular cardiopulmonary manifestations, such as pulmonary arterial hypertension (PAH), are currently the primary cause of death. In patients with SSc, PAH is the cause of death in 30% of cases. In SSc patients, PAH develops in 18% of patients and increases to 30% in patients with diffuse disease. SSc with PAH is associated with a worse survival compared to patients with SSc without PAH. Methods: A total of 68 SSc patients (58F; 52.88 ± 12.6 years) were included in the study. Patients were divided into two groups: Group A (33 patients) received IV ILO therapy for 2 years, and Group B (35 patients) received IV ILO therapy for 4 years.

Results: The results of the present study showed that IV ILO therapy significantly decreased the pulmonary arterial pressure (PAP) and pro-brain natriuretic peptide (pBNP) levels in both Group A (β = 0.001) and Group B (β = 0.001). The improvement in PAP and pBNP levels was significant in both groups, with a p-value of less than 0.05. The improvement was more pronounced in Group B, with a p-value of less than 0.01. Conclusion: IV ILO therapy is an effective treatment for reducing pulmonary arterial pressure and pro-brain natriuretic peptide levels in SSc patients. This study supports the use of IV ILO therapy as a potential treatment for PAH in SSc patients.

AB0576

INCIDENCE AND CLINICAL MANIFESTATIONS OF RAYNAUD’S PHENOMENON IN RHEUMATIC DISEASES

I. Gaisin1, Z. Bagautdinovna1, R. Valeeva1, N. Maximova1, O. Desinova1, R. Shayakhmetova1, I. Sabelnikova2, A. Tukmacheva2, L. Gibadullina2, N. Barueva1, E. Agareva1, O. Yochikurova1, T. Bragina1, K. Alexandrova1, E. Reutova1, 1Izhevsk State Medical Academy, Izhevsk, Russian Federation; 2Clinical Diagnostic Centre of the Udmurt Republic, Izhevsk, Russian Federation; 3UA, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Raynaud’s phenomenon (RP) is a common clinical manifestation of rheumatic diseases, characterized by episodic color changes in the fingers and toes in response to cold exposure. RP is more frequent in women and is associated with other systemic autoimmune diseases, such as systemic lupus erythematosus (SLE), scleroderma (SSc), and dermatomyositis (DM). Objectives: The aim of this study was to determine the incidence, clinical features, and outcomes of RP in patients with rheumatic diseases.

Methods: A retrospective analysis of medical records of 50 patients with RP diagnosed at the Department of Rheumatology, Izhevsk State Medical Academy, Izhevsk, Russian Federation, between 2010 and 2020. The demographic data, clinical characteristics, and outcomes of RP were recorded.

Results: Among the 50 patients, 27 (54%) had SLE, 15 (30%) had SSc, 6 (12%) had DM, and 2 (4%) had mixed connective tissue disease (MCTD). The median age at diagnosis was 42 years (range: 18-65 years). The median duration of RP was 5 years (range: 1-20 years). The most common clinical manifestations of RP were episodic double-color change, consisting of pallor and cyanosis, pallor and erythema, or cyanosis and erythema. Some patients reported an unusual sensitivity of fingers to cold. The incidence of RP in patients with SLE was higher than in patients with SSc and DM.

Conclusion: RP is a common clinical manifestation of rheumatic diseases, with a higher incidence in patients with SLE. Further studies are needed to investigate the role of RP in the prognosis and management of rheumatic diseases.
The frequency of RP attacks was detected more than once a day in 44 (42%) patients. In 73% of cases, RP did not show signs of deep digital ischemia. Digital ulcers (active) were observed in 13 (12.3%) patients, fractures in a finger area – 23 (21.9%), digital scars – 15 (14.2%), phalangeal amputations – 7 (6.6%).

**Conclusion:** Patients with RD and secondary RP most often have SSC (55%), less often – SLE (17%), RA (6%), DM (3%). In SSC and SLE patients, Raynaud's reddening of fingers to cold is less common than in other RD. In SSC, two-/three-phase changes of fingers color in the cold are more frequent than single-phase changes. In SLE, fingers turn blue in the cold more often than in SSC.

**Acknowledgments:** Professor LP Anan’eva, Professor RT Alekperov

**Background:** Systemic sclerosis (SSc) patients have an increased risk for atherosclerotic cardiovascular disease (CVD), possibly mediated by inflammatory and fibrotic mechanisms. However, pathogenesis of accelerated atherosclerosis in SSc remains to be elucidated. Endothelial dysfunction is the key initial event in atherosclerosis. Predictors for rapid evolution of cardiovascular complications would be highly desirable for CV risk stratification. This study aims to assess endothelial function and atherosclerosis in SSc, in context of markers of inflammation and vascular function in SSc patients.

**Objectives:** To assess endothelial function and atherosclerosis in SSc in context of markers of inflammation and vascular function in SSc patients.

**Methods:** A cross-sectional study was performed in 20 SSc patients meeting the 2013 European League Against Rheumatism (EULAR) and American College of Rheumatology (ACR) classification criteria and 18 healthy controls matched for age and sex. Flow-mediated dilatation (FMD) assessed by AngioDefender and CIMT measured ultrasonographically. Disease-specific measures included: Disease duration, Modified Rodnan Skin Score (mRSS), EUSTAR activity score in SSc. We also assayed markers of inflammation, including C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), proinflammatory cytokines (interleukin IL-1, IL-6, and IL-17), and endothelial dysfunction including lipsid, serum nitrite and TBARS (marker of oxidative stress). Quality of life measured by Scleroderma Health Assessment Questionnaire (SHAQ).

**Results:** FMD is significantly lower in SSc patients compared with controls (6.13±0.35% vs. 9.12±0.25%, p<0.05). CIMT is significantly higher in SSc patients compared with controls (0.71±0.04 cm vs. 0.53±0.01 cm p<0.05). Compared with controls, SSc patients had significantly (p<0.05) elevated mRSS, EUSTAR score, ESR, CRP, IL-1, IL-6, IL-17, nitrite, TBARS and SHQA whereas HDL levels are significantly reduced in SSc compared with controls (p<0.05). In SSc, FMD inversely correlated with EUSTAR score, mRSS, IL-6 (Fig. 1A), serum nitrite (Fig. 1B), TBARS (Fig. 1C) and CIMT (Fig. 1D). CIMT positively correlated with age (Fig. 2A), disease duration, CRP (Fig. 2B) and IL-17 (Fig. 2C) and inversely correlated with HDL (Fig. 2D) (p<0.05).

**Conclusion:** In the present study, FMD and CIMT are impaired in SSc, indicating endothelial dysfunction and accelerated atherosclerosis, respectively. EUSTAR score, mRSS, IL-6, serum nitrite, CIMT and TBARS predicted endothelial dysfunction. Age, disease duration, CRP, IL-17, HDL and impaired FMD predicted accelerated atherosclerosis. SSc-related inflammatory mechanisms (IL-6, IL-17) and markers of vascular function (CRP, serum nitrite and TBARS) may all be involved in the development of vascular disease in SSc. Cytokine-triggered inflammation mediated by nitrite and TBARS is associated with endothelial dysfunction and accelerated atherosclerosis in SSc. These markers would possibly serve as predictors of endothelial dysfunction and atherosclerosis and more importantly therapeutic targets to prevent premature atherosclerosis and cardiovascular disease in SSc.

Background: Aminophenone (AMI) is a bioflavonoid compound, classically used for “capillary disorders”. In vitro AMI interferes with adhesion molecules (≤ELAM-1 and sVCAM-1) and with vascular endothelial cadherin degradation thus defending vascular permeability. Moreover, it counteracts vasconstriction, downregulating endothelin-1 production at a gene level (1-3). In vivo AMI ameliorates clinical symptoms of several clinical conditions, above all Raynaud’s phenomenon (RP), either primary or secondary to systemic sclerosis (SSc), as demonstrated by a recent six-month study (4).

Objectives: To evaluate long-term tolerability of standard dosage of AMI in a real-life cohort of SSc patients with secondary RP.

Methods: Seventy-eight SSc patients (mean age 65±13 years; mean disease duration 9.7 years) treated with AMI due to active RP were enrolled (ACR/EULAR 2013 criteria). They were taking various concomitant treatments, including aspirin, calcium-channel blockers, cyclic intravenous iloprost, immunomodulators, endothelin receptor antagonists. SSc patients performed periodic clinical assessments and blood tests on average every four months per clinical practice. Duration of AMI administration, side effects, and self-assessment of Raynaud Condition Score (RCS) in a scale from 0 (absence of pain) to 10 (in tolerable pain) were retrospectively taken into account.

Results: Duration of AMI administration was between six and sixty-seven months (mean 31±20 months). AMI was administered at 75 mg bis in die dosage, as standard initial posology. At baseline, mean RCS was 7.3±0.8. After 3 months of treatment sixty-four patients (82%) yet referred a subjective improvement of RCS (3.5±0.8, p=0.03), whereas 14 patients (18%) were unchanged or worsened (RCS 1±0.4, p=0.10). In this last group, posology was increased to 75 mg thrice in die, with a satisfactory amelioration in further nine patients (93%,6) (RCS 4.0±0.6 p=0.04), while five patients (6,4%) definitively discontinued therapy for subjective ineffectiveness within six months. Patients referred a sustained improvement of RCS along the observational period (31±20 months) (last RCS 3.7±0.7, p=0.03 vs baseline). During the follow-up, five patients (6,4%) referred headache as side effect: three of them had to reduce AMI posology to 75 mg per day, while maintaining clinical benefits. Periodic blood tests did not reveal any significant alteration attributable to AMI. No other side effects related to the drug appeared during the treatment period.

Conclusion: AMI shows an acceptable medium-long-term tolerability along with sustained efficacy in the management of SSc-related RP, without disabling side effects. However, the retrospective design, the absence of a placebo-control group and the concomitant standard therapy limit the results, and a randomized controlled trial for AMI use in the management of SSc-related RP is desirable.

Scientific Abstracts
Results: Males were significantly older at symptom onset (p=0.007) and at first center visit (p<0.009). There were no differences regarding disease duration at first visit or the interval between the onset of Raynaud syndrome and other non-Raynaud manifestations (p=0.06). Male patients were significantly more likely to have ever smoked (p=0.001), males more often had severe or end-stage peripheral vascular involvement (p=0.01), Modified Rodnan skin score (mRSS) was significantly higher in males (p=0.004). We found no difference regarding musculoarticular involvement, except for digital contractures (p=0.001) and tendon friction rubs (p=0.044). Males more often had interstitial lung disease (ILD) (p=0.013) which was also more frequently severe or end-stage (p=0.003). Car- dial involvement was more common in males: pulmonary hypertension (PHT) (p=0.018), arrhythmias (p=0.012), left ventricle ejection fraction<45% (p=0.014). The frequency of scleroderma renal crisis (SRC) was higher in males (p=0.025). Gas- trointestinal involvement did not differ between groups ESCG (European Scle- roderma Study Group) disease activity scores were higher in males (p=0.001). The isolated presence of antitopoisomerase-1 or anticientromere antibodies did not differ between groups. Mortality rate was similar between sexes, although male sex is a independent predictor for the death associated with ILD, SRC, arrythmias

In multivariate analysis, male sex was independently associated with a higher risk of diffuse cutaneous subtype (OR: 1.56, [1.35 to 1.84]; p<0.001), a higher frequency of severe vascular disease (OR: 1.38, [1.11 to 1.67]; p=0.001), severe digital contractures (OR: 1.92, [1.68 to 2.42]; p=0.001), interstitial lung disease (OR: 1.22, [0.9 to 1.47]; p=0.001), ILD involvement (OR: 1.56, [1.22 to 2.1]; p=0.001) and SRC (OR: 3.31, [1.87 to 5.620]; p<0.003). In the longitudinal analy- sis, after a mean follow-up of 7.2 (±2.6) years, male sex was predictive of new onset of scleroderma renal crisis (HR: 3.66, [1.82 to 4.86]; p=0.006) and heart failure (HR: 1.9, [1.36 to 3.18]; p=0.01). Conclusion: In essence, the disease prophyte in females is that of younger age of onset, longer disease duration at first center visit, less severe peripheral vascular involvement, the most frequent cause of death being PHT. In contrast, males are older at onset, present earlier in their disease, have dcSSc, more severe peripheral vascular disease, higher mRSS, more frequent and severe ILD, more frequent heart involvement, higher risk of PHT and SRC, the most common cause of death being ILD. These results raise the point of including sex in the management and the decision-making process.

AB0581 HIGH PREVALENCE OF TUBERCULOSIS IN ADULTS AND CHILDREN WITH IIM AS COMPARED WITH SLE: RETROSPECTIVE DATA REVIEW FROM A LARGE HOSPITAL AT A TERTIARY CARE CENTER IN INDIA.

L. Gupta1, A. Zanwar2, R. Aggarwal3, A. Lawrence4, D. Misra5, V. Aggarwal6, R. Misra7, A. Aggarwal8 on behalf of -
1Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India;
2Y P Dal Hospital, Navi Mumbai, India; 3University of Pittsburgh Medical Center (UPMC), Division of Rheumatology and Clinical Immunology, 15260, United States of America; 4Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; 5Kalinga Institute of Medical Sciences (KIMS), Bhubaneswar, India

Background: Infections are the most common cause of morbidity and mortality in idiopathic inflammatory myositis (IIM). India is endemic for Tuberculosis (TB) with a prevalence of 2.3% cases per thousand population.

Objectives: Thus, we studied the prevalence of TB in our cohort of IIM patients and compared with that in systemic lupus erythematosus (SLE).

Methods: Medical records from paper charts and electronic medical records were reviewed for adults and juvenile patients with SLE (ACR criteria 1997) and IIM (Bohan and Peter criteria 1975) first presented at a tertiary care hos- pital in India from 1989 to 2016. Clinical variables including disease character- istic variables, the frequency, site, duration and complication of active TB as well as dose of corticosteroids and other immunosuppressive drugs were extracted retrospectively from the medical records. Descriptive statistics were used to describe the cohort and TB characteristics. Chi-square and t-test were used to evaluate association of TB with clinical diagnosis as well as medica- tion data.

Results: There were 167 (132 adults and 35 juvenile) IIM and 280 (131 adults and 149 juvenile) SLE in our cohort. Active TB occurred in 24 (14.4%) of all IIM cases (18, 13.6% adults; 6, 17.1% juvenile) as compared to 18 (6.4%) of all SLE cases (6, 6.1% adults; 10, 6.7% juvenile, p-value <0.01). Of all the TB in myositis, most often it was seen in Dermatomyositis (n=11, 45.8%) followed by Polymy- ositis (5, 20.8%), and occasionally in Overlap myositis (3, 12.5) and juvenile dermatomyositis (1, 4.1%).

Considering an annual TB rate of 211 per 100,000 of the general population, the risk of developing active TB was 62-fold higher in patients with IIM and 27-fold higher in those with lupus. Patients with IIM had higher odds of developing TB as compared with Lupus (odds ratio 2.86 (CI 1.5-5.47), p=0.007). Amongst 24 IIM patients with TB, 10 had pulmonary TB and 14 had extra-pul- monary TB. The median glucocorticoid dose at the diagnosis of TB was 0.25 (0.1-0.5) mg/kg/day. Half the cases of active TB occurred during inactive myositis. Seventeen patients with active TB were followed up over 27 months (8-184), with remission of TB in all cases but required prolonged courses of Anti-Tuberculous Therapy (ATT) in 25% cases with 10 ATT related adverse events in 8 patients and 5 patients with relapse of myositis due to lowering of immunosuppression.

Conclusion: Patients with IIM have higher prevalence of active TB as com- pared with SLE patients. The risk is highest in patients with Dermatomyositis possibly related to high doses of steroids. Extra-pulmonary forms of TB are more common, and patients commonly require prolonged course of ATT and may suffer relapses of myositis during ATT. Screening for latent TB may be useful in IIM patients before prescribing steroids and other immunosuppressive drugs.

AB0582
DIAGNOSING SYSTEMIC SCLEROSIS WITH PHOTOACOUSTIC AND HIGH-FREQUENCY ULTRASOUND IMAGING

B. Kersten1, K. Daoud2, C. H. M. Van den Ende1, F. Van den Hoogen1, C. De Korte1, M. Vonk1, R. Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; 2Radboud University Medical Center, Radiology and Nuclear Medicine, Nijmegen, Netherlands

Background: Vasculopathy is already evident in early systemic sclerosis (SSc); Raynaud’s phenomenon and typical nailfoldcapillaroscopic findings are part of the criteria of very early diagnosis of SSc (VEDOSSs) (1). As not all early SSc patients have alterations in their nailfoldcapillaries, there is need for other diagnostic tools. Photoacoustics/PA and high-frequency ultrasound (HFUS) might be able to fulfill this need (2). The former can measure the oxygen saturation of hemoglobin by using short pulsed laser light while the latter can provide high-resolution images that allow measuring skin thickening distal from DIP joint, which could be used to determine skin involvement early.

Objectives: We hypothesize that photoacoustics and high-frequency ultrasound can distinguish (early) SSc patients from individuals with primary Raynaud’s phenomenon (PR) by measuring the oxygenation (by PA) of the fingertip and skin thickness (by HFUS).

Methods: In our cross-sectional study, we compared measurements of the third finger in (early)SSc patients with individuals with PR and healthy volunteers. Smoking and beta-blockage were exclusion criteria. The level of oxygenation (by PA) and skin thickness (by HFUS) were compared between groups. Nailfoldcapillaroscopy was performed on all subjects and analyzed for the pattern.

Results: Thirty-one adult subjects participated in this study: twelve patients with SSc, 5 patients with early SSc, 5 volunteers with PR and 9 healthy volunteers. Smoking and beta-blockage were exclusion criteria. The level of oxygenation (by PA) and skin thickness (by HFUS) were compared between groups. Nailfoldcapillaroscopy was performed on all subjects and analyzed for the pattern.

Conclusion: Our results demonstrate that photoacoustic and high-frequency ultrasound can distinguish between (early)SSc and PR in both oxygenation saturation and skin thickening. In a larger prognostic study we want to determine the value of photoacoustic and high frequency ultrasound in diagnosing earlySSc.

AB0583
COMPARISON OF THE RITUXIMAB (RTM) IN MONOTHERAPY REGIMEN AND CYCLOPHOSPHOMIDE (CYP) EFFICACY AND SAFETY IN SYSTEMIC SCLEROSIS (SSC) WITH INTERSTITIAL LUNG DISEASE (ILD)

O. Koneva1, L. Ananieva1, L. Garzanova1, O. Desinova1, O. Ovsyannikova1, M. Starovoytova1, 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: CyP is considered as a drug of choice for the treatment of ILD in the patients with SSc. However, the use of CyP leads to rather limited and transient improvement of the pulmonary fibrosis. RTM is considered as a promising therapeutic agent for treatment of ILD in the patients with SSc. However, the limited number of RTM-treated patients, considerably different dose regimens, cumulative doses, and observation periods does not allow univocal conclusions on RTM efficacy or definitive recommendations on RTM use in the patients with SSc.

Objectives: To compare the impact of CyP and RTM a single-agent therapy on SSc clinical manifestation and activity, and the safety of these agents in the open-label prospective non-randomized study.

Methods: 71 patients with the confirmed SSc diagnosis and ILD evidence based on multispinal computed tomography findings were enrolled into the study. All patients received low-dose and moderate-dose glucocorticoids regimens. Group A (n=35) received RTM as a single therapy agent over the follow-up period 13.3±2.3 months in a total dose 1.35±0,5g (the patient’s average age was 45.0±15 years, with female proportion 80%; SSc duration 6.3±2.3 years; diffused/localized forms 1.3±1). Group B (n=36) received parenteral CyP for 12±6 months at total dose 10.6±5g (the patients’ average age was 47±12 years, females 92%, SSc duration 5.0±4.8 years, diffused/localized forms 1.6±1). The age, gender proportion, SSc form and SSc duration, FVC, were similar in the both groups. The time courses of FVC, modified skin count (mRss, points), activity index (ESCvG, points) were assessed in the both groups.

Results: The glucocorticoids starting dose that patients received at the time of inclusion in the study was significantly higher in group B compared to group A (p=0.03). Only after a year of CyP therapy, the dose of glucocorticoids was reduced to the starting dose in group A.
In Groups A and B the therapy was associated with significant decrease in mRs(2) (p=0.02 and 0.009, respectively) and EScSG (p=0.00017 and 0.000165, respectively).

Evaluation of FVC time course in Groups A and B revealed significant FVC increase (p=0.002 and 0.034, respectively), with median increment about 5%. The 10% FVC increase and decrease was similar in both groups.

The therapy was better tolerated in RTM-treated group: during RTM therapy adverse reactions emerged in significantly lower proportion of the patients (4/11%) compared with CyP-treated group (19/33%), p=0.0000.

Conclusion: Both agents effectively alleviated skin induration and EScSG, and significantly improved FVC. However, the glucocorticoids doses that needed to be used during anti-B cell therapy were significantly lower compared to CyP treated patients. The RTM single therapy was better tolerated compared to CyP.

Background: Clinical profile of myositis differs in respect of the setting. We present a single center experience from a community based referral center. 

Objectives: STUDY CLINICAL PROFILE OF INFLAMMATORY MYOSITIS (IM) 

Methods: We present data from 114 patients of connective tissue disorders (CTD) with dominant Inflammatory Myopathy (IM) evaluated in CRD where we have patient database since 1996. Standard investigations & ELISA, immunoblot and nephelometry to assay autoantibodies (AAb) were done. Data extraction done from 2005-2017 

Results: 36 and 28 patients respectively diagnosed as dominant idiopathic dermatomyositis (DM) and polymyositis (PM); remaining 41 patients showed overlap (OCTD). Mean onset age range 33-40 years in each subset with women dominance. Exclusive proximal muscle involvement seen 64% DM, 67% PM and 43% OCTD. 12 of OCTD showed classical DM rash. Raynaud’s phenomenon was seen in 38% (25% DM, 10% PM, 65% OCTD). 83% OCTD showed inflammatory polyarthritis; DM 29% and PM 42%. Two patients DM also diagnosed malignancy (ovarian CA). 25% DM, nil PM and 31.7% OCTD showed CT based lung findings. Mean creatinine phosphokinase at diagnosis were DM 1580, PM 2239 & OCTD 830. EMG required in 48 patients confirmed diagnosis (DM 17, PM 16 and OCTD 15). Seven patients with diagnostic dilemma/ poor therapy response required muscle histopathology confirmation. 59% DM,69% PM and 84% OCTD were seropositive ANA positive in each subset. 59% DM,67% PM and 43% OCTD. 12 of OCTD showed classical DM rash. Raynaud’s phenomenon noted in 9 patients. 

Conclusion: Overlap CTD with myositis seems more common profile than DM or PM. Response to therapy was satisfactory with steroids and methotrexate being the mainstay. Rituximab is a promising biological agent in chronic resistant cases.

DOI: 10.1136/annrheumdis-2020-eular.5768
Background: Idiopathic inflammatory myopathies (IIM) are featured by a series of clinical presentation such as proximal muscle weakness, increased serum levels of creatine kinase and other muscle enzymes and involvement of other organs and systems [1-3], which results in high morbidity and early mortality [2]. We have known the changes of the level of Th17 and Treg cells in IIM in previous studies [4-6]. However, whether infection affects lymphocyte subsets or not and whether the effect of low-dose interleukin-2 (IL-2) can be influenced by the use of immunosuppressants or not are still unclear.

Objectives: The study aimed to explore the changes of lymphocyte subsets in patients of IIM with or without important organ infection, and the restoration of Th17/Treg after receiving treatment with low-dose IL-2.

Methods: A total of 118 IIM patients were enrolled and classified into infection group and non-infection group based on the important organ infection. Of them, 48 cases were treated with low dose IL-2 (5.0*10^5 IU for 5 days). The absolute number of peripheral total T, CD4+ T, CD8+ T, NK, Th1, Th2, Th17 and Treg cell subsets were analyzed by flow cytometry combined with absolute counting beads. Clinical data, laboratory examinations and the levels of peripheral lymphocyte subsets were analyzed retrospectively.

Results: In these patients, especially in the infection group, the absolute number of T, CD4+ T, CD8+ T, NK, Th1, Th2, Th17 and Treg cells were significantly decreased as compared with that in the healthy controls, which were significantly increased by low dose IL-2 (especially Treg cells treatment). The levels of ESR, LDH and HBDH and the ratio of Th17/Treg were significantly lower than those before IL-2 treatment (Z = 2.237, 2.083, 2.140, 3.663, P = 0.025, 0.037, 0.039, 0.000). The 48 cases who received IL-2 treatment were divided into 2 groups according to whether they used immunosuppressants. There was no significant difference in the absolute number of T, B, CD4+ T, CD8+ T, Th1, Th2, Th17 and Treg cells, the proportion of Th17 and Treg cells and the ratio of Th17/Treg between the 2 groups (P > 0.05).

Conclusion: Global decrease in lymphocyte subsets was found in IIM patients, especially those who had important organ infection. A significant re-balance of Th17/Treg was observed after receiving treatment with low-dose IL-2. Furthermore, the restoration of lymphocyte subsets showed similar degree after treatment with or without immunosuppressants. Low-dose IL-2 may become a potential therapy for IIM patients. The mechanism of lymphocyte decrease in IIM is required further to study.

Conclusion: The most frequent autoantibody was anti-Jo-1, which is consistent with the literature. Interestingly, patients with anti-PL-P usually described as having a younger age at diagnosis in Jo1 positive patients and remarkably more than severe lung disease, in our series do not have it. Additionally, we found a trend with the literature. Interestingly, patients with anti-PL-P, usually described as having the most frequent autoantibody was anti-Jo-1, which is consistent with the literature. Consistent with the literature, we found a trend with the literature. Interestingly, patients with anti-PL-P, usually described as having Jo1 positive patients and remarkably more than severe lung disease, in our series do not have it. Additionally, we found a trend with the literature.

Table 1. Demographic and clinic characteristics of our cohort. Regarding treatment, 21 patients were taking Mycophenolate, 16 patients required cyclophosphamide and 6 patients rituximab. No patient in our cohort died due to interstitial lung disease.

Conclusion: The data obtained are consistent with what is collected in the medical literature. The subtype of sclerosis more related to ILD was diffuse SS. The most frequent antibody was anti-SCL 70. Regarding the treatment, the most used in ILD in our center was the mycophenolate. From our sample analyzed when applying the likelihood ratio (RV) a value of 47,186 is obtained, which has an associated probability of 0, which is less than 0.05, leads to reject the null hypothesis (there is no dependence between antibodies and type of radiological pattern of ILD in SS), concluding that there is dependence between the analyzed variables.

After this analysis, we can conclude that in our sample there is a relationship between the type of interstitial pneumopathy pattern and the antibody present in patients with SS.

AB0592 NAILFOLD CAPILLARY ABNORMALITIES PREDICT INTERSTITIAL LUNG DISEASE (ILD) COMPLICATION IN SYSTEMIC SCLEROSIS PATIENTS

Nailfold capillary abnormalities are considered a hallmark of systemic sclerosis (SSc), and their presence has been associated with an increased risk of interstitial lung disease (ILD). However, the relationship between nailfold capillary abnormalities and ILD remains to be fully elucidated.

Background: Nailfold capillary abnormalities are a common feature in SSc and are predictive of disease severity and organ involvement. They are thought to be indicative of microvascular damage and endothelial dysfunction, which are hallmark features of SSc.

Methods: We performed a retrospective analysis of clinical and radiological data from patients with SSc seen at our institution over a 5-year period. We evaluated the presence of nailfold capillary abnormalities and correlated it with the development of ILD. We also assessed the impact of treatment interventions on the progression of nailfold capillary abnormalities and ILD.

Results: Of the 100 patients included in the analysis, 40 had nailfold capillary abnormalities. The presence of nailfold capillary abnormalities was associated with a higher risk of developing ILD (OR: 3.4, 95% CI: 1.5-7.7). Treatment interventions, including oral and intravenous corticosteroids, had a significant impact on the progression of nailfold capillary abnormalities and ILD.

Conclusion: Nailfold capillary abnormalities are predictive of ILD in SSc and should be used as a tool for monitoring disease activity and tailoring treatment strategies.

AB0591 ANALYSIS OF A COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS AND INTERSTITIAL LUNG DISEASE

Background: Systemic sclerosis (SSc) is a chronic connective tissue disease characterized by inflammation, vascular injury, and fibrosis. Interstitial lung disease (ILD) is a common complication in SSc, affecting up to 50% of patients with limited or diffuse disease.

Objectives: The primary objective of this study was to analyze the clinical characteristics and outcomes of a cohort of SSc patients with ILD. Secondary objectives included assessing the role of autoantibodies in the development of ILD and evaluating the effectiveness of different treatment strategies.

Methods: We performed a retrospective chart review of 100 consecutive patients with SSc seen at our institution between 2010 and 2019. Data were collected on demographics, disease characteristics, and treatment outcomes. Autoantibody status was also recorded.

Results: Of the 100 patients, 40 had ILD. The most common autoantibodies associated with ILD were anti-centromere (10%) and anti-Scl-70 (20%). Treatment with immunosuppressants, such as cyclophosphamide and methotrexate, was associated with a significant reduction in the progression of ILD.

Conclusion: Our study highlights the importance of early recognition and aggressive management of ILD in SSc. Further research is needed to identify the optimal treatment strategies for this disease.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.4857
Methods: We enrolled SSC patients without PH from January 2016 to December 2019 in our institution. SSC patients were diagnosed according to EULAR classification criteria in 2013. ILD was detected by chest CT scans. We assessed severity of ILD with pulmonary function tests (PFT). Abnormal PFT was defined as vital capacity (%VC) or diffusion capacity (DLCO) < 70%. NFC abnormalities were detected with “OptiPiX capillaroscopy Clinic 1.7×” and the number of capillaries was measured per 1mm in 2nd to 5th fingers of both hand. We defined enlarged and giant capillaries as >30 µm and >50 µm, respectively.

Results: We enrolled 59 SSC patients (64 females, 5 males). Mean age is 65.0 ± 8.0 years. Thirty-one patients (52.5%) were complicated with ILD. Mean capillary counts were 6.6/mm. The number of patients with each NFC abnormalities (enlarged capillaries, giant capillaries, microhemorrhages, ramified, avascular areas) are 42, 32, 48, 38, and 33 cases, respectively. Two cases did not have NFC abnormalities. SSC patients with giant capillaries had fewer ILD complications (p < 0.05, odds ratio 0.183 [0.059 – 0.57]). Other NFC abnormalities were not associated with ILD in SSC patients. We inspected %VC of 23 patients and DLCO of 20 patients with ILD. Eleven patients had abnormal PFT (5 patients had abnormal %VC and 9 patients had abnormal DLCO). Most of them had not enlarged capillaries than patient with normal PFT (odds ratio 0.11 [0.016 – 0.81]). Other NFC abnormalities including giant capillaries were not associated with abnormal PFT.

Conclusion: We investigated the relationship between NFC abnormalities and ILD complications in SSC patients. NFC abnormalities are associated with ILD complications and severity of ILD. It was suggested that no giant capillary in SSC patients may predict ILD complication. Moreover, no enlarged capillary may predict the severe ILD.

**AB0593**

**DOES REALLY EXIST MIXED CONNECTIVE TISSUE DISEASE?**

L. Montolio-Chiva1, J. Narváez2, M. Pascual1, J. H. Park1, A. V. Orenes Vera1, E. Flores1, J. J. Alegre-Sancho, I. Castellví1, J. M. Nolla2, 1Universitary Pefor Doctor Hospital, Valencia, Spain; 2Universitary Bellvitge Hospital, Barcelona, Spain

Background: Currently, most authors accept that mixed connective tissue disease (MCTD) is an independent entity, although there are those who argue that it is actually an overlap syndrome with an undifferentiated early phase of another systemic autoimmune disease (SAD).

Objectives: To analyze the long term evolution of a series of patients with MCTD.

Methods: Observational, retrospective and multicenter study in patients with MCTD (diagnostic criteria of Alarcón-Segovia et al), followed for a minimum of 2 years.

Results: Fifty-five patients (49 women) with a median age at diagnosis of 38±14 years and with a follow up time (median) of 101 months (range, 24-237 months with a total of 501.2 patient-years) were identified.

At the end of the follow-up period, only 27% (15/55) of the patients kept on fulfilling MCTD criteria. In the remaining 73% (40), 40% (22) had been differentiated to systemic lupus erythematosus (SLE), 13% (7) to systemic sclerosis (SSc) and 20% (11) developed an overlap syndrome [SSc+SLE in 8 cases and SSc+rheumatoid arthritis (RA) in 3]. In 8% of these patients, a secondary Sjögren’s syndrome was diagnosed during the follow-up period. The average score in patients who met the EULAR/ACR 2013 criteria for SSc was 11 (minimum 9 - maximum 16) and the average time elapsed from the diagnosis of MCTD to meet SSc criteria was 64.4 months (interquartile range [IQR] 25-75%: 10-127 months).

Applying the 2012 SLICC criteria, only 24 patients of those initially diagnosed as MCTD ended up meeting SLE criteria. The average score in these patients was 5.6 (4-9) and the average time elapsed from the diagnosis of MCTD until fulfilling the SLICC criteria was 59 months (IQR 25-75%: 6-28). When we apply the new ACR/EULAR 2019 criteria, the percentage of patients who meet SLE criteria increased to 30%, with an average score of 17.3 (10-38). The average time elapsed since the diagnosis of MCTD until meeting the new SLE criteria was reduced to 17 months (IQR 25-75%: 0-10).

In the multivariate study, the presence of sclerodactyly (OR: 2.91; IC 95% 1.90 - 4.1, p= 0.001) and esophageal involvement (OR: 2.05; IC 95% 1.14-3.66, p=0.016) were associated with the evolution to SSc. Any predictor of evolution to SLE was identified.

Conclusion: Only slightly more than a quarter of patients initially diagnosed as MCTD maintain this diagnosis during the follow-up. The majority, ended up evolving towards another SAD, fundamentally SLE and SSc. The new ACR/EULAR 2019 criteria seems to be more sensitive than the SLICC 2012 criteria for diagnose SLE in these patients.

**AB0594**

**EFFECTIVENESS OF RITUXIMAB IN CDSPMARDS-RESISTANT ACTIVE MIXED CONNECTIVE TISSUE DISEASE**

L. Montolio-Chiva1, J. Narváez2, J. J. Alegre-Sancho1, J. Lluch Ponsa, A. Y. Orenes Vera, I. Vázquez-Gómez1, M. Mora1, X. González2, C. Marzo1, J. Rodríguez1, M. Romero1, J. M. Nolla2, 1Universitary Pefor Doctor Hospital, Valencia, Spain; 2Universitary Bellvitge Hospital, Barcelona, Spain

Background: Objectives: To evaluate rituximab (RTX) effectiveness and safety in treating patients with refractory mixed connective tissue disease (MCTD).

Methods: Open observational study including patients with refractory MCTD (active disease despite treatment with glucocorticoids and csDMARDs) from two third-level hospitals who had been treated with RTX (off-label use) from January 2001 to December 2019.

Results: Thirty-three patients (all women) were included, with a mean age of 32 years (SD: 10, range 17-50) and a median time of evolution of the disease of 55 months (SD: 34.3; range 5-98 months). The main indication for initiating treatment with RTX was refractory arthritis (100%), most of the times accompanied by other features of the disease including shrinking lung syndrome (2), fibrosing progressive non-specific interstitial pneumonia (FP-NSIP) (1), recurrent serositis (2), glomerulonephritis (GMN) (2), lymphadenitis (1) and immune thrombocytopenic purpura (ITP) (1). All patients were treated with RTX at rheumatoid arthritis dosage while the baseline immunosuppressive treatment (methotrexate, azathioprine, mycophenolate, leflunomide or tacrolimus) remained unchanged. Hydroxychloroquine was also associated in 8 of the patients. The follow-up time (median) after starting RTX was 118 months (range, 65-177 months, with a total of 132.6 patient-years of follow-up) and the mean number of cycles of treatment was 4.2 (range, 1-15), with a variable interval (from 6 to 12 months). After the first RTX cycle, a partial or complete response was achieved in 92% of the patients. A significant improvement in the mean DAS28-ESR was observed (initial: 4.56 ± 1.6 / final: 2.21 ± 0.85; p=0.008). In all but one patient, who had previously failed to 2 anti-TNFα
Methods: useful when associated with skin ulcers. However, little attention has been paid to local treatment, which is especially mainly involves the use of systemic therapies, which often have limited efficacy. Background: these with zinc oxide cream edges due to the ointment preparation, which was resolved by protecting adverse effect has been detected, except for slight maceration of the wound calcinosis foci and partial or complete healing of the ulcers together with an are available for 8 patients, who have been on TST a median time of 9 months and SSc were included: 2 patients with diffuse SSc (DcSSc), 6 with limited or tumoral calcinosis which had been refractory to systemic treatment with diltiazem, colchicine, zoledronate, rituximab, and/or acenocoumarol and had or tumoral calcinosis (2), gestational desire (2) sustained remission (1). RTX was withdrawn because of primary failure (1), recurrent bacterial infec-tions (2), gestational desire (2) sustained remission (1). Conclusion: According to our preliminary results, RTX seems to be effective and relatively safe in patients with csDMARDs-resistant active MCTD. Disclosure of Interests: I. Torner Hernández1, A. Sendra-García1, V. Núñez-Monje1, L. Montolío-Chiva1, A. V. Orenes Vera1, I. Vázquez-Gómez1, E. Flores Fernández2, A. Martínez-Ferrer1, E. Valls-Pascal1, D. Ybáñez-García1, J. J. Alegre-Sancho1. 1Hospital Universitari Dr Peset, Rheumatology, Valencia, Spain Background: Treatment of calcinosis associated with systemic sclerosis (SSc) mainly involves the use of systemic therapies, which often have limited efficacy. However, little attention has been paid to local treatment, which is especially useful when associated with skin ulcers. Objectives: To show our experience with topical sodium thiosulfate (TST) for the treatment of calcinosis-associated cutaneous ulcers in patients with SSc. Methods: Descriptive analysis of a case series of patients with SSc and calcinosis-associated skin ulcers treated with TST. Wound management procedure: wounds and perilesional skin cleaning and dissection is performed and, if needed, additional debridement. TST is compounded at 25% w/o emulsion, for extensive calcinosis, or as beeler-base or cold-cream ointment, for limited wounds are then covered with a polymeric foam dressing. This cure in moist healing environment shows some advantages over the dry cure (exudate control without damaging the perilesional skin, protection against contamination, and reduction of the needed cures, healing time and pain). Results: Nine patients (7 women) with calcinosis-associated skin ulcers and SSc were included: 2 patients with diffuse SSc (DcSSc), 6 with limited SSc (LcSSc) and 1 with overlap syndrome. Median age was 60 years (IQR 20), 6 patients had localized wounds and 3 had extensive involvement and/or tumoral calcinosis which had been refractory to systemic treatment with diltiazem, colchicine, zoledronate, rituximab, and/or acenocoumarol and had suffered recurrent superinfections. Follow-up results of more than 3 months are available for 8 patients, who have been on TST a median time of 9 months (IQR 8.25). They have shown clinical improvement (disappearing of many calcinosis foci and partial or complete healing of the ulcers together with an improvement in pain, function, quality of life and satisfaction of the patients). Radiological improvement was also observed in 1 case. No TST related adverse effect has been detected, except for slight maceration of the wound edges due to the ointment preparation, which was resolved by protecting these with zinc oxide cream Conclusion: In our experience, treatment with TST for calcinosis-associated skin ulcers in patients with SSc is an effective, safe and easily implementable therapeutic alternative in clinical practice. Torner Hernández1, A. Sendra-García1, V. Núñez-Monje1, L. Montolío-Chiva1, A. V. Orenes Vera1, I. Vázquez-Gómez1, E. Flores Fernández2, A. Martínez-Ferrer1, E. Valls-Pascal1, D. Ybáñez-García1, J. J. Alegre-Sancho1. 1Hospital Universitari Dr Peset, Rheumatology, Valencia, Spain AB0596 PREDICTORS, LONG TERM CLINICAL AND TREATMENT OUTCOMES IN SOUTH ASIAN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOSITIS: A SINGLE CENTER STUDY A. Nair1, R. Goel1, P. Chebbi2, A. Mathew2, A. Ganapatii1, G. Rebekah2, B. Yadav2, J. A. J. Prakash2, D. Danda2, J. Mathew2. 1Christian Medical College, Clinical Immunology and Rheumatology, Vellore, India, 2Christian Medical College, Vellore, Biostatistics, Vellore, India, 2Christian Medical College, Vellore, Microbiology, Vellore, India Background: Idiopathic inflammatory myositis (IM) are a heterogeneous group of immune-mediated disorders with varied presentations and multiple organ involvement. Data on long term outcome among South Asian patients with IM is sparse. Objectives: To study the long term clinical outcome, treatment responses and factors predicting outcome among adult patients with IM. Methods: Patients diagnosed as ‘Idiopathic Inflammatory Myositis’ under the department of Clinical Immunology and Rheumatology at CMC, Vellore, India were screened retrospectively. Patients aged 18 years and above, satisfying Bohan and Peter criteria, having follow up of one year or more with at least two outpatient or inpatient visits between January 2010 and April 2019 were included in this study. Those patients with connective tissue disease associated- myositis were not included. Details on muscle weakness, extramuscular involvement, muscle enzymes and treatment administered were recorded at baseline, 3, 6, 12, 18, 24 months and yearly thereafter. After assessing their cumulative response, categorization of patients into complete and partial responders was done. Complete responders were defined as patients with persistent muscle power of more than 4/5 and/or MMT ≥ 80% if any as well as muscle enzymes less than twice the upper limit of normal without any documented flares during the entire follow up period. Patients not satisfying the said criteria were grouped as Partial responders. Disease free survival duration was also analyzed. Results: Out of 310 patients of IM identified, 187 (60.3%) patients satisfied the inclusion criteria. Women were 2.2 times more than men and mean age at symptom onset was 35.7±12.6 years. Dermatomyositis was the predominant myositis subtype seen. All patients were put on steroids with the mean dose being 45.9 ± 18.6 mg/day. At baseline, the key immunosuppressants used were methotrexate in 44.9% and mycophenolate in 37.6% patients. The median fol-low up duration was 48 (25-80) months. An associated malignancy was diagnosed in 3.2% after a median duration of 24.5 months. Five patients expired after a median duration of 60 months from diagnosis. Normal muscle power was attained in 76.1% patients and 88.6% were vocational by the last follow up visit. Steroids were discontinued in 56.7% patients after a median duration of 24 months (p=0.0002). Discontinuation of the immunosuppressant was fea-sible in 10.2% patients after a median duration of 44 months. Assessment of

IS administration was associated with male gender, ILD, a-Scl-70 positivity, ACA-negativity and U disease in iSSc, and with ACA-negativity and a higher mRSS in dSSc. Multivariate logistic regression analysis showed that IS treatment could be predicted by ACA-negativity in iSSc patients (Exp(B) = 0.317, p = 0.012) and younger age in dSSc patients (Exp(B) = 0.974, p = 0.002).

Conclusion: Over the past decade, there has been a trend to prescribe IS more often, especially MTX, and earlier in dSSc patients. MMF has gained favour over CYC. Autoantibody status was the most consistent predictor whether a patient is likely to take IS over the course of the disease.

The increasing use of immunosuppressants in early systemic sclerosis

R. Park, T. Nevskaya, M. Baron, J. Pope on behalf of CSRG Investigators.

1University of Western Ontario, London, Canada; 2University of Western Ontario, Rheumatology, London, Canada; 3McGill University, Montreal, Canada

Background: Immunosuppression (IS) remains the main treatment for progressing skin involvement, active intestinal lung disease (ILD) and underlying inflammatory joint (U) or muscle disease in systemic sclerosis (SSc).

Objectives: This study investigated the pattern and trends in immunosuppressive agent use in patients with early SSc diagnosed before and after 2007 to determine whether the changes in the preferred type and combination of IS, timing and predictors of administration took place over the past decade.

Methods: 397 SSc patients from Canadian Scleroderma Research Group (CSRG) database (183dcSSc, 214 icSSc) who had baseline and follow-up visits within 3 years (1.8±0.8) after disease onset were included: 82% females, age at diagnosis 53±13 years, disease duration 1.6±0.8 years. Organ involvement was assessed by modified Rodnan skin score, Medsger Disease Severity Score (DSS) and CSRG definitions using bivariate, chi-squared, ANOVA, and adjusted regression analyses.

Results: 115 dcSSc patients (63%) and 62 icSSc (29%) received IS, most commonly methotrexate (MTX) (72% dcSSc and 52% icSSc), followed by mycophenolate mofetil (MMF) and cyclophosphamide (CYC). Within the patients receiving IS, monotherapy prevailed (77% dcSSc and 66% icSSc); CYC and azathioprine were the preferred choice of IS more frequently in icSSc compared to dcSSc (p=0.006 and p=0.02, respectively). In dcSSc, IS were predominantly prescribed at years 2 and 3 after the onset of first non-Raynaud’s phenomenon (RP) manifestation, when about half of the patients received IS. The proportion of icSSc patients receiving IS was significantly lower and distributed more equally through the first three years. After 2007, dcSSc patients received IS more often (74% vs 50%, p=0.001), especially MTX (p=0.02) and MMF (p=0.05), and earlier (peaked at 2 years after disease onset)(Table 1).

Authorisation and governance

Background: Interstitial lung disease (ILD) is a frequent complication of systemic sclerosis (SSc) and is often progressive and has a poor prognosis. A restrictive ventilatory defect could suggest ILD either alone or in combination with pulmonary arterial hypertension.

Nowadays, Early-SSc is well defined as preliminary stage of SSc. Patients who meet criteria for Early-SSc could benefit from an early diagnosis of pulmonary involvement.

Objectives: Our aim was to assess the pulmonary function in patients diagnosed of Early SSc.

Methods: Retrospective observational study of a wide and unselected series of patients diagnosed as Early-SSc from a single university hospital from 2012 to 2019. Patients were classified as Early-SSc following Le Roy criteria. Despite this, patients already did not meet 2013 ACR/EULAR classification criteria for SSc.

We reviewed pulmonary function through conventional spirometry and diffusion capacity of lung for carbon monoxide (DLCO).

Results: We included 56 patients with a mean age of 52.3±12.1 years (96.4% women; 3.6% men).

At the diagnosis of Early-SSc, no one of our patients evidenced a restrictive ventilatory pattern. DLCO was below normal limits in 18 patients (32.1%). Small airway obstruction expressed according decreased maximal (mid-) expiratory flow (MMEF) 25-75 was present in 24 patients (42.8%). After a mean follow-up period of 38.3±2.4 months, 29 (51.8%) patients fulfilled 2013 ACR/EULAR classification criteria for SSc. The average time between diagnosis of Early-SSc and achieve SSc classification was 24.4±1.8 months. The remaining 27 patients continued classified as Early-SSc.

An analysis of the subgroup of patients which progressed to SSc showed that DLCO was decreased in 15 of those 29 patients (51.7%) and 18 of 29 patients (62.1%) presented decreased MMEF 25-75. Comparing with the subgroup of patients which not progressed to SSc were significant differences (Decreased DLCO: 51.7% vs 11.1%; p=0.02 and decreased MMEF 25-75: 42.8% vs 22.2%; p=0.05).

The analysis of pulmonary function of the subgroup of patients continued classified as Early-SSc after follow-up period did not show significant changes after follow-up.

Conclusion: In our study, a third of the patients classified as Early-SSc presented at diagnosis abnormal values of DLCO and/or signs of small airway obstruction without the presence of a restrictive ventilatory pattern. Moreover, this pulmonary dysfunction was significantly more frequent in patients who progressed to definitive SSc. Patients which remains classified as Early-SSc did not experience significant changes.

Our results support the concept that pulmonary function was impaired in Early-SSc and that I should probably be considered for future Early-SSc classification criteria.
AB0599 TREATMENT OF REFRACTORY DERMATOMYOSITIS WITH TOFACITINIB

K. Riggie1, A. Patel2, R. Aggarwal3. 1University of Virginia, Charlottesville, United States of America; 2University of Virginia, Charlottesville, United States of America; 3University of Pittsburgh, Pittsburgh, United States of America

Background: Dermatomyositis (DM) is a systemic, autoimmune disease affecting the skin and proximal skeletal muscles. A subset of DM patients present with subclinical or resolved muscle involvement but continue to have skin disease. In these cases, first and second line treatments including glucocorticoids are sometimes insufficient for controlling the disease, necessitating escalation of treatment. Several recent studies have investigated the response of Tofacitinib, an oral Janus Kinase inhibitor approved for the treatment of rheumatoid arthritis, in DM patients and patients with inflammatory skin diseases.

Objectives: Due to the reported ability of JAK inhibitors to suppress type 1 interferon (IFN) signaling, which is suspected to be upregulated in DM, we evaluated the efficacy of treatment with Tofacitinib in four refractory DM patients.

Methods: Four patients with dermatomyositis without evidence of current muscle involvement began treatment with Tofacitinib 11 mg daily after they had failed or had adverse effects to first and second line immunosuppressive agents. Their medical records were reviewed at 0, 3, and 6 months, with improvement measured using the Cutaneous Dermatomyositis Disease Area and Severity Index (CDAI) activity score. Throughout their treatment they were additionally monitored for improvement in markers of inflammation and the necessity for concomitant treatments. Patients were monitored for adverse effects to Tofacitinib treatment.

Results: All four patients within the case series showed significant improvement of their cutaneous disease activity (CDAI scores improved by 8-15 points) over the first 6 months, with three of the four having achieved minimal clinically improved difference of ≥ 5 point by three months. Based on the CDAI, three of the cases’ disease classification changed from moderate-to-severe disease to mild disease. The last patient initially presented with mild disease. Other outcomes noted included improved pruritus in 3 patients and improvement of calcinosis in 1 patient. One patient was additionally able to stop concomitant treatment with prednisone and IVIG at 3 and 6 months, respectively. This patient had been on daily prednisone for 4 years. Only other patient on prednisone was on low dose of 3mg daily. The patients all had normal muscle exams prior to treatment with Tofacitinib. No worsening muscle involvement or adverse effects were noted with Tofacitinib use.

Conclusion: Tofacitinib is believed to play a role in the inhibition of IFN signaling pathways that are overactive in dermatomyositis. All four patients within this retrospective study showed significant improvement of cutaneous disease with Tofacitinib use.

AB0600 THE EFFECTS OF HYPERBARIC OXYGEN THERAPY TO QUALITY OF LIFE AND STATE OF MICROCIRCULATION IN PATIENTS WITH SYSTEMIC SCLEROSIS - A PILOT STUDY

S. Pavlov-Doljanovic1, V. Koletic2, N. Vujasinovic Stupar2, N. Damjanov3. 1Institute of Rheumatology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; 2Centre for Hyperbaric Medicine, Belgrade, Serbia

Background: Many treatments have been tried in therapy systemic sclerosis (SSc) patients but use of hyperbaric oxygen therapy (HBOT) is very limited.

Objectives: To assess the effects of HBOT to quality of life and state of microcirculation in SSc patients.

Methods: 18 female patients aged 29-68 years (mean 57 years) with limited SSc and digital or leg ulcers were included in this work. The HBOT protocol comprised 20 sessions 5 days/week, 60 min, 100% oxygen at 2.2 ATA. The treated patients were evaluated at baseline and after 20 HBOT sessions. Evaluation consisted of physical examination, capillaroscopy, pulmonary function tests, biochemical analyses, socio-demographic and clinimetric questionnaires: Systemic Sclerosis Questionnaire (SySQ) and Health Assessment Disability index Questionnaire (HAQ-DI).

Results: Mean value (before: after, mean [range]) for SySQ [15.5 (4-48) vs 9.0 (3-31)], HAQ-DI [0.60 (0-2.88) vs 0.35 (0 -1.75)], erythrocyte sedimentation rate [21 (4-42) vs 12 (3-27)], forced vital capacity (96.61±14.44% vs 115.94±16.69%), diffusing lung capacity of carbon monoxide (73.61±6.63% vs 87.33±9.30%) significantly improved after HBOT sessions (p<0.001). There was no significant changes in the total number of capillaries (325 vs 338, p=0.235), mean number of enlarged capillaries (21 vs 27, p=0.182), giant capillaries (14 vs 14, p=0.235) and ramified/bushy capillaries (14 vs 13, p=0.178) before and after HBOT. All patients had digital ulcers, and 5 patients had bilateral lesions (digital and leg ulcers). Mean size of ulceration before HBOT was 12x11mm, and after therapy was 4x4mm (p<0.001). Three patients had digital gangrene. Amputation was not necessary in any.

Conclusion: Our data confirm the efficacy of HBOT in treating SSc patients. Further studies are required to evaluate the protocol and to understand the duration of the clinical effect.

Department of Medicine, San Giovanni di Dio Hospital, Florence, Italy, Florence, Italy.

Abstract: Anti-3-hydroxy-3-methylglutaryl-coenzyme A reductase myopathy is a new entity, which has been clearly associated to statin use, even if it can be diagnosed in patients without a history of exposure to statin or even in the childhood (1). The objective of the study is to describe the efficacy of a triple therapy regimen consisting in high-doses of intravenous immunoglobulins (IVIG), methotrexate (MTX), and glucocorticoids (GC) in 16 patients with Anti-HMGCR myopathy enrolled in 6 specialized centers.

Methods: A total of 16 patients with anti-HMGCR myopathy (7 females; 9 males) were enrolled. Mean (±standard deviation) age at the onset of disease was 72.4±10.3 years old. All patients were diagnosed having anti-HMGCR myopathy. [Anti-HMGCR antibodies were measured by chemiluminescence assay (Bio-Flash, Inova, CA)]. Median follow-up was 29.5 months (interquartile range: 15.75-60 months). Anti-HMGCR antibodies were available in the follow-up in 8/16 patients.

Results: Thirteen out of 16 patients (81.3%) had been exposed to statin (1/13 to red rice), 3/16 (18.7%) were not exposed. As induction therapy, 11/16 patients (68.7%) were treated with triple therapy (high-dose IVIG, MTX and GC), 2/16 with double therapy (high-dose IVIG and GC), 2/16 have been treated with GC alone, the patient exposed to red rice resolved only with red rice suspension. Clinical remission and normalization of CPK values within month +24 were obtained in all the patients. All the patients were in remission at the last follow-up. Gradual improvement started soon from the first month, and among the 13 patients treated with an aggressive immunosuppressive therapy (GC (13/13), and methotrexate (11/13), 9/13 normalized the CPK value within 6 months. Clinical and laboratory response was accompanied by significant decrease or normalization of the anti-HMGCR antibody titer. All the patients were neither taking GC (56.3%), or were taking low doses of GC (43.7%) at the last follow-up. Four patients had stopped GC within 6 months. No serious side effects were recorded. After persistent remission, a maintenance immunosuppressive therapy was then administered. Only 3 relapses in 3 different cases were recorded, all of them during drug-free remission in long-term follow-up. Reinduction was again effective in all.

Conclusion: Anti-HMGCR myopathy is a rare and serious myopathy which usually affects older people during statin treatment. After statin suspension, a rapid and sustained remission can be achieved by induction with a triple aggressive therapy consisting in medium-to high-doses of GC, high-dose IVIG, and MTX (3). GC should be tapered as soon as possible. Relapse appears infrequent during maintenance treatment. Monitoring anti-HMGCR antibody titer may be clinically relevant.

Systemic Sclerosis: Subclinical Atherosclerosis and Mortality

M. Retueru-Guerrero1, M. Martin Lopez1, B. Joven-Ibañez2, J. L. Rosales2, P. Carreña1, 1Hospital Universitario 12 de Octubre, Madrid, Spain; 2Hospital Rambla, Santa Cruz de Tenerife, Spain

Background: Rheumatic diseases are associated with accelerated atherosclerosis, and an increase in cardiovascular morbidity and mortality. This process is mediated by classic cardiovascular risk factors (CVRF), chronic inflammation and atherogenic treatments such as corticosteroids. In Systemic Sclerosis (SSc) cardiovascular complications have increased in recent decades, although the studies on subclinical atherosclerosis (sATS) in SSc show discordant results.

Objectives: To evaluate prospectively the relationship between subclinical atherosclerosis, cardiovascular morbidity and mortality in patients with SSc.

Methods: 120 consecutive patients with SSc who attended their medical regular review during November and December 2011 were included. We evaluated the presence of plaques and measured the right CCA IMT by B doppler US for the detection of sATS (IMT > 0.9mm and/or presence of plaque), review of classic CVRF and estimation of Medsger severity and EUSTAR activity index. Patients have been followed for 8 years, with at least annual consultation. In retrospect, the SSc SCT damage index, published in 2019, was obtained at the time of inclusion in the study. The clinical characteristics of the patients are collected since 1990 in a Prospective Longitudinal Observational Study (PLOS). Descriptive analysis was performed, using contingency tables for qualitative variables, and comparison of means for quantitative variables. The relationship between clinical characteristics, mortality, cardiovascular events (CVE), activity, severity and damage index, and sATS, was analyzed using binary logistic regression, adjusting for age and sex.

Results: 120 patients with SSc were included (93% female, age 60 ± 12 years). 42 of these patients (35%) had subclinical atherosclerosis. Age was statistically significant higher in patients with sATS compared to those without it (67.9±11.5 vs. 56.1±10.4 years, p <0.001). We found no differences between groups in activity, damage and severity index (Table 1). Patients with sATS had higher levels of ESR and CRP, but the difference was not confirmed after adjusting for age (*). During the 8 years of follow-up, 9 CVE in 7 patients (5.8%): three myocardial infarction, one transient ischemic accident, one angor, one intermittent claudication and three refractory heart failure. The incidence of severe CVE was more than double in patients with SSc (10.25% vs. 3.7%), but the difference was not significant. We found no relationship between the mortality of any cause, or the occurrence of CVE, with sATS, in the 32 patients who died during the follow-up, 3 due to CVE (9.4%). The results are similar when we analyze only the presence of plaques.

Table 1. Relationship between clinical characteristics and activity, severity and damage index with the presence of accelerated atherosclerosis.

Conclusion: In our study subclinical atherosclerosis is not related to higher mortality in patients with SSc, but it does seem to influence the occurrence of cardiovascular events. In addition, our results suggest that SSc does not influence the onset of accelerated atherosclerosis.

PGDF AS A POTENTIAL BLOOD MARKER IN DSSC

K. Romanowska-Prochnicka1,2, A. Wajda3, A. Paradowska-Gorycka3, A. Felis-Giermi4, E. Walczuk3, M. Olesi

Background: PDGF is a potential important factor in the pathogenesis of scleroderma. PDGF is almost undetectable in healthy skin or lung. Immunohistochemical studies have revealed increased presence of PDGFα and PDGFβ receptors in scleroderma skin biopsies.

Objectives: The aim of this study was to determine the mRNA level of IFNα1, IL-4, TGFβ1, TGFβ2, PDGFα, PDGFβ, TNFα in whole blood in SSC patients in the aspect of clinical

Methods: A group of 14 patients (50% were women) with systemic sclerosis based on EULAR / ACR 2013 criteria was included in the study. The modified Rodman Skin Score (mRSS) was evaluated by same assistant at the beginning of the study and six months later. Dlco, Hrct, echocardiography and NFC were measured. Gene expression was determined using validated TaqMan probes in qPCR. Constitutive mRNA level of selected genes was analyzed using ∆Ct method. Comparision between different groups of patients was determined using non-parametric Mann-Whitney U test. Correlation was analyzed using non-parametric Spearman test.

Results: The mean age of the patients was 50 ± 15.66. 100% of patients had organ involvement as pulmonary fibrosis. 78% - had changes -features of ground glass. 64% of patients had mild mRSS-1-10 skin involvement, 36% had moderate to severe skin involvement. In SSC patients TGFβ1 and IFNα1 revealed the highest level of expression in comparison to other analyzed genes. Additionally, very high and significant correlation between TNFα and TGFβ1 (r=0.57 ± 0.004) has been noted. High and significant correlation between mRNA PDGFβ and TNFα levels have been observed. We did not reveal significant differences in analyzed genes expression when compare limited and diffuse SSC. Nevertheless, patients with dSsc were characterized by higher level of IFNα1 (almost 2 times) and TGFβ1.

On the border of significance higher PDGFα mRNA level was observed in dSSc patients when compared to iSSc. Average PDGFα expression is higher in SSC patients with ScI70 presence than in patients without ScI70 (p=0.04). In the aspect of clinical parameters, patients with ESR ≤12/mml revealed almost 6 times higher level of IFNα1 (p≤0.01) in comparison to the patient with ESR>12/mml.

Patients with mRSS above 10 points revealed significantly higher of IFNα1 expression is higher in SSc patients with non-active HRCT. Nevertheless these two groups did not differ in ESR or OB parameter.

AB0604

EVALUATION OF PATIENTS WITH ANTISYNTHETASE SYNDROME AND INTERSTITIAL LUNG DISEASE BASED ON THE RADILOGICAL PATTERN

A. Ruiz Roman1, J. A. Rodriguez Portael, 1Hospital Virgen del Rocío, Rheumatology, Seville, Spain; 2Hospital Virgen del Rocío, Pneumology, Seville, Spain

Background: Antisynthetase syndrome is an autoimmune rheumatologic disease characterized by the presence of specific antibodies that are known as antisynthetase antibodies and with a varied clinic, including arthritis, myositis or interstitial lung disease (ILD), among others. ILD is the manifestation that associates the highest morbility / mortality and can occur with different characteristic radiological patterns: usual interstitial pneumonia (UIP), non-specific interstitial pneumonia (NSIP), organizing pneumonia (OP)

Objectives: To describe the clinical, serological and prognostic characteristics of patients with antisynthetase syndrome with interstitial pulmonary involvement (ILD) based on their radiological pattern.

Methods: Retrospective descriptive study of patients with a clinical diagnosis of antisynthetase syndrome in which they show positive for some antisynthetase antibody and with clinical follow-up of at least 6 months in a reference center consultation between the period from January 2008 to September 2019. In those patients who presented interstitial lung involvement clinical, analytical and prognostic variables were evaluated (including spirometry) based on the radiological pattern presented by high-resolution computed tomography (HRCT) of the chest

Results: 32 patients (24 women and 8 men) were included in the study, 7 cases (21.9%) did not present pulmonary involvement, while the remaining 25 cases (78.1%) presented with interstitial lung involvement. Of the patients diagnosed with ILD, 4 cases (12.5%) had an intermittent pattern of UIP 17 cases (53.1%) had an interstitial pattern of NSIP and another 4 (12.5%) interstitial pattern of OP. From an analytical point of view, the most frequent antisynthetase antibody in our sample was antiJo1 with 29 cases (96.9%) and less frequently the antiPL12 antibody with 2 cases and antiPL7 with 1 case. The specific characteristics depending on the type of EPID pattern are summarized in Table 1.

Conclusion: ILD is a frequent and serious manifestation that can occur in patients with antisynthetase syndrome, which may have different radiological patterns. In our series, the most observed radiological pattern has been the NSIP pattern with 68%. The pattern most associated with the Ro 52 antibody was the UIP pattern and the NSIP pattern. As for the group that required the largest numbers of drugs (including biological therapy) it was the NSIP pattern. When evaluating changes in respiratory function tests, the pattern that shows a tendency to improve over time is organized pneumonia with improvement of the DLCO, FVC, FEV1, FEV1 / FVC, while the UIP pattern pattern a worsening of the DLCO and the FVC.

CLINICAL PROFILE AND CHEST HIGH-RESOLUTION COMPUTED TOMOGRAPHY (HRCT) FINDINGS IN PATIENTS WITH CONNECTIVE TISSUE DISEASES AND INTERSTITIAL LUNG DISEASE: EXPERIENCE OF A SINGLE REFERENCE RHEUMATOLOGY CENTER

I. Pest, L. Muntean1, M. M. Temase1, I. Felenes1, L. Damian1, I. Filipescu1, S. P. Simon1, C. Parmit1, C. M. Marinescu2, M. A. Man3, C. Cautak4, S. Rednic5, 1Emergency Clinical County Hospital, Rheumatology, Cluj-Napoca, Romania; 2Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; 3Emergency Clinical County Hospital, Radiology,
Background: Intestinal lung disease (ILD) is a common manifestation of connective tissue diseases (CTDs), and is associated with significant morbidity and mortality. Chest high-resolution computed tomography (HRCT) play an important role in the diagnosis of ILD and may provide prognostic information.

Objectives: We aimed to characterize the clinical profile and chest HRCT abnormalities and patterns of patients diagnosed with CTDs and ILD.

Methods: In this retrospective, observational study we included 80 consecutive patients with CTDs and ILD referred to a tertiary rheumatology center between 2015 and 2019. From hospital charts we collected clinical data, immunologic profile, chest HRCT findings, HRCT patterns were defined according to new international recommendations.

Results: Out of 80 patients, 64 (80%) were women, with a mean age of 55 years old. The most common CTD associated with ILD was systemic sclerosis (38.8%), followed by polymyositis (22.5%) and rheumatoid arthritis (18.8%). The majority of patients had dyspnea on exertion (71.3%), bibasilar inspiratory crackles were present in 56.3% patients and 10% had clubbing fingers. Antinuclear antibodies (ANA) were present in 78.8% patients, and the most frequently detected autoantibodies against extractable nuclear antigen were anti-Scl-70 (28.8%), followed by anti-SSA (anti-Ro, 17.5%), anti-Ro52 (11.3%) and anti-Jo (7.5%). Intravenous cyclophosphamide therapy for 6-12 months was used in 35% of patients, while 5% of patients were treated with myophenolate mofetil.

The most frequent HRCT abnormalities were reticular abnormalities and ground glass opacity. Non-specific interstitial pneumonia (NSIP) was identified in 46.3% CTDs patients. A pattern suggestive of usual interstitial pneumonia (UIP) was present in 32.5% patients, mainly in patients with systemic sclerosis. In 21.3% patients the HRCT showed reticulo-nodular pattern, micronodules and other abnormalities, not diagnostic for UIP or NSIP pattern.

Conclusion: Nonspecific interstitial pneumonia (NSIP) is the most common HRCT pattern associated with CTDs. Further prospective longitudinal studies are needed in order to determine the clinical and prognostic significance of various HRCT patterns encountered in CTD-associated ILD and for better patient management.

AB0606 SYMPTOMIC SCLEROSIS – ARE PATIENTS WITH CALCINOSIS DIFFERENT FROM THOSE WHO DO NOT HAVE IT?
B. Samboes, D. Fonseca, R. Vieira, T. Videira, A. Alexio, P. Pinto, M. Guerra 1
1Centro Hospitalar Vila Nova de Gaia, Rheumatology, Vila Nova de Gaia, Portugal

Background: Systemic Sclerosis (SS) is a heterogeneous disease with a broad range of organ involvement. Calcinosi is a common problem and although it may affect almost any body tissue, it is typically seen in the limbs. 1 Its presence relates with higher risk of digital ulcers and infection. 2 It is still unknown whether patients with calcinosi also have other clinical features that differentiate them from the remaining.

Objectives: To determine the prevalence of calcinosi in a SS cohort and to evaluate if its presence relates with specific clinical features.

Methods: A cross-sectional study was conducted evaluating a cohort of SS patients. Plain radiographs were taken to assess calcinosi at elbows, hands, knees and feet. Clinical data was obtained and analyzed using IBM SPSS Statistics 26.0.

Results: We included 25 patients, 21 females [n= 21 (84%)], median (min, max) age was 58 (27, 75) years-old. Regarding disease classification, 18 (84%) had limited SS, 4 (16%) had diffuse SS, 3 (12%) had overlap syndrome and 2 (8%) had early SS. Ten (40%) patients had radiological calcinosi in at least one site, seven of which (70%) were subclinical. The most affected areas were knees and hands [n=6 (24%)]. Table 1 summarizes the clinical characteristics of patients with and without calcinosi. Limited SS was significantly more prevalent in the calcinosi group [n=9 (90%) vs. n=7 (46.7%); p=0.04]. All patients had Raynau phenomenon [n=10 (100%) vs. 15 (100%)]. Current or past digital ulcers [n=5 (50%) vs. n=6 (40%); p=0.697], telangiectasias [n=9 (90%) vs. n=11 (73.3%); p=0.615], pulmonary hypertension [n=2 (20%) vs. n=1 (6.7%); p=0.550] and esophageal involvement [n=6 (60%) vs. n=6 (40%), p=0.428] were more frequent in the calcinosi group but with no statistical significance. Although late capilarscopic pattern was more frequent in the calcinosi group, there was no statistical significance difference [n=4 (40%) vs. n=1 (6.2%); p=0.121]. Sensitivity for centromere-B antibodies was more frequency in the calcinosi group but with no statistical significance [n=7 (70%) vs. n=8 (53.3%); p=0.678].

Conclusion: The prevalence of calcinosi was similar to that reported in literature (18-49%). This study confemed the association, already found in previous studies between calcinosi and the limited form of SS and raises attention for the importance of calcinosi radiographic screening since there was a high prevalence of subclinical calcinosi. 1 Although there were some clinical differences between patients with and without calcinosi, given the small cohort, statistical significance was not obtained. Larger studies are needed to increase statistical power.

AB0607 MYOSITIS-RELATED INTERSTITIAL LUNG DISEASES: CLINICAL FEATURES, BIOMARKERS AND AUTOANTIBODIES IN LATINOAMERICAN PATIENTS
S. M. Sánchez Romo 1, G. G. Sánchez Mendieta 1, M. A. Villarreal-Alarcón 1, I. D. J. Hernandez-Galarza 1, D. A. Galarza-Deigado 1, 1Hospital Universitario Dr. José Eleuterio Gonzalez UANL, Rheumatology, Monterrey, Mexico

Background: The lung is one of the most common extra-muscular targets in idiopathic inflammatory myopathies (IIM) and interstitial lung disease (ILD) is a prevalent and often devastating manifestation of IIM. 1 Objective: To know the frequency of autoantibodies associated with IMM-ILD biomarkers, and their relation with clinical features in patients with IIM.

Methods: Adults with IIM were enrolled in a retrospective way. Demographics, clinical and laboratory features were registered. The determination of antibodies was performed by the Immunoblot technique with Euroimmun kit. Patients without a myositis antibody panel were excluded. The diagnosis of ILD was based on HRCT. Patients with anti-MDA5 antibodies and with anti-Ro-52 antibodies associated with anti-ARS were considered as high risk group, those with anti-ARS, anti-U1-RNP, anti-Pm/ Sc and anti-Ku antibodies as moderate risk and those with anti-Mi2, anti SRP and anti TiF1 antibodies as low risk. 2

Results: Demographics characteristics are shown in table 1. We included 36 patients. Dermatomyositis (DM) was described in 69.4%, polymyositis (PM) in 16.7% and antinuclepherase syndrome (AAS) in 13.9%. Out of the total of our patients, 30.6% had interstitial lung disease. The most frequent autoantibody was Anti Ro52 in 13 (36.1%) patients and 44.4% were in the high risk group. We analyzed our patients by the presence or absence of ILD and we found that
anti-MDA5 antibodies were more frequent in IMM-ILD group (p=0.006). In our IMM-ILD group we compared the autoantibodies with the clinical and serological features and we found that patients with IMM-ILD and anti Ro-52 antibody had more frequency of heliotrope rash (p=0.045) and those with IMM-ILD and anti-Jo1 antibody had a higher level of CK (p<0.001).

Conclusion: Anti-MDA5 antibodies were more frequent in our IMM-ILD group than in IMM without ILD group. Almost half of our patients were in a high risk group, which means they need an early immunosuppressive treatment. In our IMM-ILD patients we found an association between the presence of anti Ro-52 antibody with heliotrope rash and of anti-Jo1 antibody to a higher level of CK.

CARDIAC VESSELS CALCIFICATION IN A COHORT OF SYSTEMIC SCLEROSIS PATIENTS:
THE POSSIBLE ROLE IN VASCULOPATHY AND HEART ABNORMALITIES.
S. Sciacca1, C. Rotondo1, A. Corrado1, L. Giardullo1, S. Stefania1, A. Altomare1, F. P. Cantatore1. University of Foggia, Rheumatology Unit, Foggia, Italy

Background: Cardiovascular disease is the leading cause of morbidity and mortality worldwide. Myocardial calcifications have been related with cardiovascular diseases (CVD) such as focal wall motion abnormalities and arrhythmias. The impact of vascular calcifications is under investigation in order to define the risk of cardiovascular events. The relationship between cardiac calcification and systemic sclerosis (SSc) has not been investigated.

Objectives: The aim of the study is to evaluate the frequency of different patterns of cardiac calcification in SSc patients, and to correlate them to other CVD risk factors.

Methods: We analyzed thoracic-CT scanners of 35 SSc patients (88% female, aged 478±12.9, disease duration 12.8±5.9) to determine the location and extension of vascular and cardiac calcification. All recruited patients fulfilled the 2013 ACR/EULAR classification criteria for SSc. No one patients had renal failure, cardiomyopathy, myocarditis, history of cardiac surgery or radiotherapy.

Results: We found myocardial vessels calcifications (MCv) in 37% SSc patients, aortic wall calcifications (ACw) in 60% SSc patients, cardiac valve calcifications (CV) in 28% SSc patient and heart wall calcifications (HCw) in 20%.

The SSc patients with almost one calcification had older age (65±9.8 vs 50±8.8; p=0.001) and higher values of circulating NTproBNP (336±83.5 vs 144±2±187.8; p=0.04) compared to those without.

In particular, the SSc patients with MCv and with uric acid (5.3±1.5 vs 4.1±1.3; p=0.05), higher rate of PAH (25% vs 0% ; p=0.037), arrhythmia (38.5% vs 9%; p=0.036) and higher prevalence of CENP-B antibodies (46% vs 4%; p=0.01) compared to patients without MCv.

The SSc patients with MCv had higher frequency of arrhythmia (33% vs 0%; p=0.016) and longer disease duration (15.5±9.9 vs 8.8±5.8; p=0.03).

Conclusion: All patterns of calcifications may be related mostly with the older age. Myocardial vessels calcifications have been found in a high percentage of SSc patients and in particular in those with PAH and positive for anti CENP-B. Furthermore, myocardial vessels calcifications could be associated to the higher occurrence of arrhythmia. More studies are needed to assess the importance of vascular calcification as a part of the vascular involvement in SSc.

THE SPECTRUM OF ANTINUCLEAR ANTIBODIES IN PATIENTS WITH SYSTEMIC SCLEROSIS POSITIVE FOR ANTI-U1RNP
R. Shayakhmetova1, L. P. Ananyeva1, O. Koneva1, M. Starovoytova1, O. Ovyanikova1, O. Desina1, L. Garzanova1, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Patients with systemic sclerosis positive for anti-U1RNP have special clinical picture and disease progression. The autoimmune profile in this group is poorly understood.

Objectives: The purpose of our work was to study the level of major autoantibodies in patients with systemic sclerosis positive for anti-U1RNP.

Methods: The study included 80 patients (71 women and 9 men, mean age 44.5±14 years) positive for antibodies to RNP and meeting the criteria of the systemic sclerosis (ACR/EULAR 2013). Patients were examined for autoantibodies: RF, ACCP, ACA, anti-Scl70, anti-RNA3-III, anti-Ro, anti-La, anti-dsDNA, anti-Sm, ACL, anti-Jo1. 44 patients were examined in dynamics in 24 months.

Results: In the study group the clinical picture was dominated by inflammatory muscularoskeletal lesions (synovitis and myopathy), skin manifestations were poorly expressed. Intestinal lung disease was detected in 68% of cases. Overlaps (34%) with other rheumatic diseases (rheumatoid arthritis, systemic lupus erythematosus) and combination with Sjogren’s syndrome (32.5%) were frequently noted. Other antibodies were often detected: commonly - RF (31%), anti-Ro (38%), anti-dsDNA (42%), rarely - anti-Sm (11%), ACCP (8%), anti-La (8%), ACA (6%), anti-Scl70 (6%), AKL (2%). Anti-Jo1 and anti-RNA3-III were not detected at all. In patients with systemic sclerosis highly-positive for anti-U1RNP (more than 2 upper normal limits) RF, anti-Ro, anti-dsDNA were significantly more common in comparison with low-positive(p=0.00). In dynamics 80% of patients maintained anti-U1RNP, while other autoantibodies were detected with the same frequency. In patients with initially low titer of anti-U1RNP, their disappearance was noted.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.5746
Conclusion: Patients with systemic sclerosis positive for anti-U1RNP differ in the predominance of inflammatory musculoskeletal manifestations and frequent combination with Sjogren’s syndrome and overlaps. Highly positivity for anti-U1RNP is accompanied by a persistent increase in RF, anti-Ro, anti-dsDNA

AB0610 SEASONAL VARIATION IN IDIOPATHIC INFLAMMATORY MYOPATHIES INCIDENCE AND PRESENTATION: A RETROSPECTIVE STUDY IN BEIJING AND HONG KONG

H. Su1, X. Shen1, T. L. V. Wong3, R. Ho1, T. Li5, X. Lu3 1Chinese University of Hong Kong, New Territories, Hong Kong (SAR); 2China Japan Friendship Hospital, Beijing, China; 3Kwong Wah Hospital, Kowloon, Hong Kong (SAR); 4Queen Elizabeth Hospital, Kowloon, Hong Kong (SAR); 5Queen Mary Hospital, Hong Kong, Hong Kong (SAR)

Background: Seasonal patterns of disease onset and severity in idiopathic inflammatory myopathies (IIMs) as a whole are conflicting [1-3]. In recent years, over 10 myositis-specific antibodies (MSAs) have been identified. They are able to divide patients into homogenous subgroups and inform on prognosis [4].

Objectives: The objective of the study was to investigate the seasonal variation of onset of IIMs characterised serologically.

Methods: This was a multi-centred retrospective observational study. Consecutive Chinese patients with IIMs admitted to the rheumatology wards of the participating major regional hospitals in Beijing and Hong Kong from July 2013 to June 2018 were recruited. The diagnosis of IIMs was based on the Bohan and Peter’s criteria with definite or probable cases being included [5]. Patients with clinically amyopathic disease must have the typical Gottron’s papules or heliotrope rash as determined by rheumatologists or dermatologists, and with no symptoms or signs of muscle involvement according to Sontheimer [6]. Patients with juvenile myositis, inclusion body myositis, cancer-associated myositis and myositis associated with other connective tissue disease were excluded. A commercial line blot immunoassay kit (EUROLINE) was used to detect the MSAs.

Results: All together 495 patients were studied. The mean age of the patients at disease onset was 48.1 years (S.D. 13.3). There was a female predominance (68.3%). The subgroups of IIMs were: dermatomyositis (61.0%), polymyositis (21.8%), clinically amyopathic dermatomyositis (12.9%), immune mediated necrotising myopathy (3.8%) and nonspecific myositis (0.4%). No particular seasonal pattern in disease onset was observed in IIM patients as a whole (Figure 1) or in any classical subgroups. However, significantly more patients with any one MSA had their disease started in the first half of the year (p=0.007) as shown in Figure 2. Patients with either anti-synthetase or anti-MDA5 antibodies, which are associated with interstitial lung disease, had more frequent disease onset from November to February, which might coincide with the local flu season. It was also found that MSA positivity was associated with infection of the patient (p=0.005). Further analyses showed that patients with MSAs which are typically associated with severe skin disease (MDA5, TIF1g, NXP2, SAE) had more hospitalisation from April to September where excessive sun exposure is more frequent in PH group too (p=0.016). These pts showed higher incidence of ventricular dilatation only in PH subjects. Furthermore, interesting significant values were obtained during follow-up regardless of treatments.

Conclusion: Apparent seasonal patterns were noticed in our ethno-serologically defined IIM patients. Certain environmental factors, particularly infection or UV exposure, could be potential triggers. Our findings could shed light on the identification of etiologic factors and enhance our understanding of disease pathogenesis.

AB0611 STRAIN ANALYSIS OF THE RIGHT VENTRICLE USING 2D-SPECKLE TRACKING ECHOCARDIOGRAPHY IN A COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS

A. Spinnella1, P. Macrìpo1, E. Cocciarà1, E. Galli1, F. Lumenti1, L. Magnani2, F. Coppì1, A. V. Mattioli1, R. Rossi1, G. Boriani1, C. Salvarani1, D. Giuggioli1, 1Clinicino of Modena University Hospital of Modena, Modena, Italy; 2Arcipressa Santa Maria Nuova, Reggio Emilia, Italy

Background: Systemic Sclerosis (SSc) is a rare and life-threatening connective tissue disease with multiple organ impairment. Cardio-pulmonary involvement is common: pulmonary fibrosis, pulmonary hypertension (PH), and electrical disorders are the most serious complications and causes of increased mortality.

Objectives: We evaluated features related with the onset and development of PH in a cohort of SSc patients. We further studied eocardiographic abnormalities, by means of 2D-speckle tracking echocardiography (STE) with specific reference to the right ventricular strain measure (RV-strain).

Methods: We analyzed data from 50 SSc patients (pts) referred to our University-based Rheumatology Centre and SSc Unit from January 2007 to June 2019 (F/M 45/5; lc/dcSSc 45/5; mean age 59.20±14.357 years; mean disease duration 12.08±8.75 years). All pts underwent general and cardio-pulmonary assessment in our Cardio-Rheumatology Clinic. The following parameters were considered: blood exams, in particular inflammation indexes, uric acid test and serum autoantibodies; pulmonary function tests; high resolution scan of the lungs (HRCT); standard electrocardiogram (EKG) and RV-strain measured by 2D-STE. These examinations were performed according to clinical picture and current methodologies. We compared SSc subjects with (10/50) and without (40/50) PH diagnosis during follow-up regardless of treatments.

Results: SSc pts with PH didn't show significant alterations concerning RV-strain if compared with pts without PH (p=0.707). Nevertheless, RV-strain value was modified in relation to TAPSE alterations in all pts but this data correlated with right ventricular dilatation only in PH subjects. Furthermore, interesting significant values about dilatation of right and left atria (p<0.007, p=0.048), dilatation of inferior vena cava (p=0.037) and right ventricle (p=0.023) were observed. Left ventricular hypertrophy (p=0.012) as well as valvular insufficiencies (mitral and aortic) were more frequent in PH group too (p=0.016). These pts showed higher incidence of
skin ulcers (p=0.0001), higher values of blood pressure (p=0.004), elevated uric acid levels (p=0.027) and anti-centromere antibodies positivity (p=0.0001).

Conclusion: Our research provides further evidence of the prognostic value of echocardiographic findings in SSc subjects, with focus on PH. Population enlargement is ongoing in order to identify more accurate results about RV-strain, considering the efficacy of PH treatments on cardiac contractility. Speckle tracking echocardiography proves to be a sensitive, low-cost, non-invasive and reliable tool to detect early cardiac impairment in SSc, full of potential future prospects.

AB0612 SHORT-TERM REVERSIBLE IMPROVEMENT IN EARLY-PHASE ELEMENTS OF NAILFOLD CAPILLARY ABNORMALITIES IN PATIENTS WITH SYSTEMIC SCLEROSIS BY INTRAVENOUS CYCLOPHOSPHAMIDE (IVCY)
T. Sugimoto1, S. Hirata1, H. Kohn1, H. Watanabe1, Y. Yoshida1, S. Mokuda1, E. Sugiyama2. 1Hiroshima University Hospital, Clinical Immunology and Rheumatology, Hiroshima, Japan

Background: Nailfold capillary abnormalities are one of representative signs in systemic sclerosis (SSc). However, previous reports about changes in nailfold capillary by immunosuppressive therapy have been limited. Especially, there have been no reports about short-term changes in nailfold capillary abnormalities.

Objectives: To clarify whether intravenous cyclophosphamide (IVCY) treatment for SSc patients can improve nailfold capillary abnormalities in half a year.

Methods: Among patients diagnosed as having SSc according to the 2013 ACR/ EULAR classification criteria at our hospital from May 2018 to December 2019, those who treated with IVCY for intestinal lung disease (ILD) were consecutively registered. All patients received IVCY six times. Nailfold capillary abnormalities on eight fingers including both second to the fifth fingers were observed with a nailfold videocapillaroscopy (NVC). Each finger was evaluated for enlarged capillary, giant capillaries, hemorrhage, loss of capillary, disorganization of the vascular array, and capillary ramification. Quantitative scoring was performed on a scale of 0 to 3 in accordance with the ratio of each of them. NVC tests were evaluated before IVCY treatment intervention and after IVCY. In all cases, the evaluation of NVC after IVCY treatment was performed 6 months after the administration day. Skin changes were evaluated by modified Rodnan's total skin thickness score (mRSS) at performing NVC. Anti-centromere antibodies, anti-Scl-70 antibodies, anti-RNA polymerase III, and anti-RNP antibodies were measured. Pulmonary function tests (PFTs) including forced vital capacity (FVC) and diffusing capacity of the lung for carbon monoxide (DLCO) were performed before and after IVCY. The statistical significance of the differences between means of two groups was evaluated by paired t-test. A p level of 0.05 or less was considered statistically significant.

Results: Five patients were included. The mean age was 59 years and 4 patients were female. High dose corticosteroids were used in 2 patients (40%). Anti-RNA polymerase III was positive in 2 patients (40%), anti-Scl-70 antibody was positive in 1 (20%), and negative test for any specific antibodies was in 2 (40%). Changes in mRSS, which were total scores of 8 fingers, were as follows: Enlarged: 18.8±8.3 to 12.4±13.3 (p=0.0677). The cases with improved mRSS scores, which were total scores of 8 fingers, were as follows: 16.8±8.3 to 12.4±13.3 (p=0.0677). The cases with improved NVC findings were consistent. The mean FVC before and after IVCY was 9.88±3 mL/min/mmHg and 9.58±2 mL/min/mmHg, respectively.

Conclusion: Nailfold capillary abnormalities in patients with SSc could be improved in half a year with IVCY. Especially, early phase elements including enlargement, giant, and hemorrhage were specifically reversible.

AB0613 AUTONOMIC NEUROPATHY AND ITS PREDICTORS IN SYSTEMIC SCLEROSIS
A. Sylgja1,2, N. Garg3, D. Gera3. 1Cardio Rheuma Division, Healing Touch City Clinic, Chandigarh, India; 2Fortis Multispeciality Hospital, Internal Medicine and Rheumatology, Mohali, India; 3Chitkara University, Chitkara College of Pharmacy, Rajpura, Punjab, India

Background: Systemic sclerosis (SSc), a chronic autoimmune disease, is associated with autonomic neuropathy. Autonomic neuropathy, especially cardiovascular autonomic neuropathy (CAN) is significant risk predictor of sudden cardiac death. However, its relationship with disease specific measures remains unexplored in SSc.

Objectives: To assess cardiovascular autonomic neuropathy and sudomotor function and its predictors in systemic sclerosis.

Methods: In this cross-sectional study, 16 SSc patients meeting the 2013 European League Against Rheumatism (EULAR) and American College of Rheumatology (ACR) classification criteria and 15 age and sex-matched healthy controls were recruited. Cardiovascular autonomic function assessed by five cardiovascular reflex tests according to Ewing. Peripheral sympathetic autonomic function assessed by FDA approved Sudoscan (Impeto Medical, Paris) through measurement of electrochemical skin conductance. Disease-specific measures (Disease duration, Modified Rodnan Skin Score (mRSS), EUSTAR activity score), and inflammatory measures (ESR, CRP) were determined. Quality of life measured by Scleroderma Health Assessment Questionnaire (SHAQ).

Results: Systemic sclerosis patients had significantly impaired parasympathetic [Heart rate response to deep breath (HRD) (Fig. 1A), Heart rate response to standing (HRS) (Fig. 1B) and Heart rate response to valsalva manoeuvre (Fig. 1C)] and sympathetic [BP response to hand grip (BPH) (Fig. 1D)] function as compared to healthy controls. Scleroderma patients had significantly impaired sudomotor function (p<0.05) as compared to healthy controls. Levels of mRSS, EUSTAR score, ESR, CRP and SHAQ were significantly higher in SSc patients as compared to healthy controls (p<0.05).

Parasympathetic (HRD & HRS) dysfunction inversely correlated with ESR, CRP and mRSS. Sudomotor function positively correlated with mRSS, disease duration and CRP.

Conclusion: CAN and Sudomotor function are significantly impaired in SSc. Parasympathetic dysfunction is more pronounced than sympathetic dysfunction in SSc. CAN and Sudomotor dysfunction are associated with disease-duration, skin-score, ESR and CRP. These could serve as potential predictors of Cardiovascular Autonomic neuropathy and sudomotor dysfunction in SSc.

AB0614 METHOTREXATE DOESN’T LOWER THE RISK OF DEVELOPING INTERSTITIAL LUNG DISEASE IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES WITH JO-1 ANTIBODIES.

P Szczesny1, K. Swierkocka1, A. Felis-Giemia1, M. Oleśniska1, National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Connective Tissue Diseases, Warsaw, Poland

Background: In patients with idiopathic inflammatory myopathies (IIM) most commonly found autoimmune against histidine–RNA synthetase (anti-Jo-1) is associated with development of interstitial lung disease (ILD), which has been regarded as a serious mortality factor.

Objectives: To assess if methotrexate as an initial steroid sparing agent lowers the risk of developing ILD in Jo-1 positive patients diagnosed with IIM.

Methods: Medical records of IIM patients treated in a referral clinic in capital city of Poland between 2008 and 2018 were reviewed. Inclusion criteria were: fulfillment of ACR/EULAR 2017 classification criteria for IIM, positivity of anti-Jo-1 antibodies in the EUROLINE test, introduction of corticosteroids equivalent to ≥0,5mg of prednisone. Exclusion criteria: insufficient data on disease course, history of IIM <18 months.

Results: 29 patients were included for this analysis. ILD was present at the onset in 52% (n:15) patients. Other 14 patients were treated initially with corticosteroids ≥0,5mg/kg along with methotrexate up to 25mg/week. In all 14 patients methotrexate was well tolerated and led to successful reduction of steroid dose. However, ILD attributed to the primary disease appeared in follow up in 50% (n:7) of the patients. Sixty percent of patients were SSC-related (pulmonary cause<n=11), cardiac cause<n=6>, gastrointestinal involvement (GI, n=3), renal crisis [n=2] and others [n=4]).

Conclusion: Our study shows that methotrexate in dose up to 25mg/week doesn’t lower the risk of developing ILD in Jo-1 positive IIM patients in the long term suggesting that other medication should be used as a first line treatment for this group.

AB0615 MORTALITY AND CAUSES OF DEATH AMONG ROMANIAN SYSTEMIC SCLEROSIS PATIENTS

A. Petcu1, M. M. Tamas1,2, L. Muntean1,2, S. P. Simon1,2, I. Filipescu1,2, L. Damian2, D. C. Leucuta2, 1Helioglu Hatice Tan2, 1Juliu Haticeanu University of Medicine and Pharmacy, Cluj-Napoca, Romania; 2Emergency County Clinical Hospital, Cluj-Napoca, Romania; 3Juliu Haticeanu University of Medicine and Pharmacy, Department of Medical Informatics and Biostatistics, Cluj- Napoca, Romania

Background: Systemic sclerosis (SSc) is associated with an increased risk of death compared to the general population. Survival in SSc patients has improved significantly over the last 20 years with a decrease in renal involvement as a cause of early death and an increase in death caused by cardiopulmonary involvement (1,2), Causes of death in SSc patients have not been described in a Romanian cohort so far.

Objectives: To study the causes of death in patients with SSc prospectively followed-up from 2002 to 2018 in a single tertiary centre from Romania.

Methods: The cohort consists of 197 patients who fulfill the American College of Rheumatology/EULAR 2013 criteria for SSc. We examined the data of patients who had died during follow up. Patients were reviewed at least twice a year and the cause of death was classified as SSC-related or nonSSC-related.

Results: Of 197 SSc patients (87.8% females), 47.7% had diffuse SSc and 52.2% had limited SSc. The mean age at diagnosis was 47 (SD 12) years and mean follow up duration was 6.75 years. There were 41 deaths (20.8%). Survival rate was substantially lower in men (P <0.003). The mean age at the time of death in those with diffuse SSc was lower compared to those with diffuse SSc but the disease onset was similar. Sixty percent of patients were SSc-related (pulmonary cause<n=11), cardiac cause<n=6>, gastrointestinal involvement (GI, n=3), renal crisis [n=2] and others [n=4]).

Conclusion: In our cohort the main causes of death were lung and cardiovascular involvement. Deaths occurred early after the onset of the disease and the survival rate was significantly reduced among men. Multivariate analysis showed that age at onset of Raynaud phenomenon, male gender, diffuse disease form, presence of tendon friction rub [HR 4.54], digital ulceration [HR 3.54], epistaxis [HR 2.07] and cardiovascular involvement [HR 3.68], use of corticosteroids[HR 2.13] and cyclophosphamide [HR 2.02] were associated with poor prognosis in multivariate analysis.

AB0616 REDUCED BONE MINERAL DENSITY IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: A LONGITUDINAL STUDY

Y. K. Tang1, H. Soi1, T. L. V. Wong1, H. T. Pang1, V. Lao1, M. L. Yip2, Kwong Wah Hospital, Kowloon, Hong Kong (SAR); 2TWHs Integrated Diagnostic and Medical Centre, Kowloon, Hong Kong (SAR)

Background: Reduced bone mineral density (BMD) leads to fragility fracture which is associated with a significant morbidity and excess mortality [1,2]. Patients with idiopathic inflammatory myopathies (IIM) should be at a heightened risk of reduced BMD as a result of the systemic inflammation, reduced mobility and corticosteroid use [3]. A previous cross-sectional study demonstrated a high prevalence of osteoporosis (23.7%) and osteopenia (47.4%) in a cohort of IIM patients [4]. However, longitudinal data are lacking.

Objectives: To assess the BMD of IIM patients longitudinally and to investigate the factors associated with accelerated bone loss.

Methods: This is a single centered observational study. Existing adult Chinese patients with IIMs who had serial BMD measurements done were recruited. The diagnosis of IIMs was based on the Bohan and Peter’s criteria with definite or probable cases being included [5]. Patients with clinically amyopathic disease must have the typical Gottron’s papules or heliotrope rash as determined by rheumatologists or dermatologists, and with no symptoms or signs of muscle involvement according to Sontheimer [6]. BMD was measured by dual energy X-ray absorptiometry (DEXA). Clinical variables thought to be associated with bone health were documented.

Results: All together 28 patients were studied. The mean age of the patients at disease onset was 46.1 years (S.D. 12.2). There was a female predominance (92.9%). The subgroups of IIMs were: dermatomyositis (39.3%), polymyositis (25.3%), clinically amyopathic dermatomyositis (21.4%) and immune mediated necrotising myopathy (14.3%). Only a minority of the patients smoked (11%). None of them drank regularly. About one fifth were considerably underweight. All patients have been exposed to systemic corticosteroid, while 82.1% of them were still on it between the two scans with 32.1% even on high dose (>0.5mg prednisolone/kg/day). Three out of the 28 patients (10.7%) was found to be osteoporotic at baseline and 17 patients (60.7%) were osteopenic.

Follow-up DEXA were performed mostly 5 to 10 years after the initial scan. Despite 8 patients (28.6%) were given active anti-osteoporotic medication, the bone health deteriorated significantly. The mean baseline neck of femur BMD dropped from 0.711 to 0.657 g/cm² (p=0.042) on follow-up, while the total
lumbar BMD from 0.951 to 0.905 g/cm² (p=0.036). The T-score in 11 patients (39.3) reached osteoporotic range at the second DEXA. Together with the patients with osteopenia, 76.6% of the IIM patients had reduced BMD at the follow-up scan. Actually, 5 patients (17.9%) already had one episode of fragility fracture. The use of high dose corticosteroid in between the 2 scans was found to be associated with a greater degree of mean BMD loss in the hip (-0.171 vs -0.007 g/cm², p=0.007).

Conclusion: Reduced BMD is prevalent in patients with IIM. Follow-up study revealed significant worsening of bone health. High dose corticosteroid use might be especially detrimental. Liberal assessment of BMD and use of anti-osteoporotic drugs in IIM patients are advisable. Prompt use of steroid-sparing agents to minimize steroid exposure may also be helpful.

OPTICAL COHERENCE TOMOGRAPHY IN THE ASSESSMENT OF SKIN FIBROSIS IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY

D. Temiz Karadağ1, A. Yaziç1, A. Komac1, Y. Erez2, M. Birlik2, A. Akdoğan3, A. Sari2, B. Farisogullari1, G. Kimyon2, 3, A. Arslan5, E. Koc2, S. S. Koca1, A. Karacab, N. Kasifoğlu2, E. Alpaslan7, A. Çeltik1, Kocaeli University School of Medicine, Rheumatology, Kocaeli, Turkey; 2Dokuz Eylül University School of Medicine, Rheumatology, İzmir, Turkey; 3Hacettepe University School of Medicine, Rheumatology, Ankara, Turkey; 4Hatay Mustafa Kemal University School of Medicine, Hatay, Turkey; 5Çukurova University School of Medicine, Adana, Turkey; 6Fatih University School of Medicine, Rheumatology, Elazığ, Turkey; 7Eskisehir Osmangazi University School of Medicine, Microbiology, Eskisehir, Turkey

Background: Serum autoantibodies closely reflect patterns of organ involvement and disease progression in systemic sclerosis (SSc). The entire autoantibody profile is less well defined in many cohorts and the data regarding their clinical associations and frequencies is limited.

Objectives: To determine the autoantibody profile of patients with SSc, as well as their clinical associations, in well-characterized inception-cohort with disease duration less than 3 years.

Methods: Serum samples of 100 patients out of 105 enrolled in the study were analyzed for ANA patterns with indirect immunofluorescence (IIF) assay. Insufficient HEp-20-10/pigeon liver mosaic IIFT kit. sera of 96 patients were subjected to commercial line immunobssay to quantify autoantibodies against 13 different autoantigens.

Results: 92 (92%) out of 100 patients were positive for ANA by IIF (Table 1). The speckled staining was the most pattern followed by nuclear in 10 patients, centromere in 4, reticular in 1, nuclear in 2 and homogenous in 1. At present (n=96) patients were positive for at least 1 autoantibody by immunobssaying Table 2.

Disease-related autoantibody positivity was found in 22 patients (22%). Twenty-two (49%) of patients with antiTopo I, 12 (44%) of the patients with anti-CEP and 4 (22%) of the patients with antiRNP/PR were single positive.

There was no difference in terms of the clinical findings when the patients with single and coexpression of these antibodies were compared. The distributions of the most frequent autoantibodies are shown in Figure 1. Intestinal ulcers disease was more frequent in the patients positive for anti-Topo I (78.8%) and anti-RNAP/PR (27.3%). One of the two patients with breast cancer was anti-RNAP/PR positive and none of the patients have diagnosed scleroderma renal crisis. Anti-Topo I was more common in patients with dcSSc (75%) and anti-CEP in lcSSc (46.4%).

AB0620 EFFECTIVENESS OF RITUXIMAB IN PATIENTS WITH EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS. A MULTICENTER ANALYSIS.

J. Vázquez-Gómez1, J. Návárez2, J. Lluç Pons3, M. Aguilar-Zamora4, L. Montblío-Chiva5, A. V. Orenes Vera6, E. Flores7, E. Valls-Pascual1, D. Ybañez8, A. Martínez-Ferrer9, A. Sendra-García10, I. Torner Hernández11, V. Núñez-Monje12, J. J. Alegre-Sancho13, 1Servicio de Reumatología, Hospital Universitario Dr Peset, Valencia, Spain; 2Servicio de Reumatología, Hospital Universitario de Bellvitge, Barcelona, Spain; 3Servicio de Reumatología, Hospital de Sagunto, Valencia, Spain; 4Fundación para el Fomento de la Investigación Sanitaria y Biomédica de la Comunidad Valenciana (FISABIO), Servicio de Reumatología y Farmacia, Hospital Universitario Dr Peset, Valencia, Spain

Background: Rituximab (RTX) is effective in improving skin affection in patients with diffuse cutaneous systemic sclerosis (DCSSc). However, there are few data on early use of this drug.

Objectives: To evaluate RTX effectiveness for skin disease in patients with DCSSc of less than 3 years of evolution.

Methods: Multicenter, observational and retrospective study. Patients with DCSSc starting RTX within 3 years since first non-Raynaud symptom were recruited. Demographic variables, time of disease duration at the beginning of RTX, immune pattern and time on RTX treatment were collected. Effectiveness was defined as modified Rodnan skin score (mRSS) improvement. Evaluations were done by the same experienced rheumatologist. Patients subjective perception of skin hardening and/or tightness was evaluated. mRSS changes from baseline to 6 and 12 months after RTX beginning and, later on, to the last available observation were analysed using Wilcoxon test. Statistical analysis was performed with SPSS 20.0.

Results: 11 patients (8 women) were recruited from 2 university hospitals. Median age was 48 years (IQR 22). Median time since diagnosis to RTX beginning was 12 months (IQR 8), 5, 3 and 2 patients presented ATA +, RNAPIII + and Ro-52 +, respectively. Median duration of RTX treatment was 12 months (IQR 68). Median baseline mRSS was 15.5 (IQR 18). Median mRSS after 6 and 12 months of RTX treatment and at last available mRSS evaluation was 15 (IQR 13), 14.5 (IQR 13) and 11 (IQR 16), respectively, mRSS showed statistically significant improvement at 6 (29%, IQR 37) and 12 months of RTX treatment (35%, IQR 34) and, thereafter, at last available observation (39%, IQR 51), compared to basal mRSS. Most patients reported subjective improvement at 6 (9 of 10 continuous parameters and multivariable analysis using logistic regression analysis. Receiver operating characteristic (ROC) curve analysis was examined to obtain the cut-off level. Survival was examined using Kaplan-Meier method and Log-rank test.

Results: Twenty-one patients were involved. Eight were deceased and 13 were survived. The deceased group had a higher ratio of male (75% versus 25%, p = 0.018). All deceased cases were with RPIP and 67% in the survived cases. Levels of serum ferritin (4490 versus 646 ng/mL, p = 0.0026), CRP (2.1 versus 0.9 mg/dL, p = 0.0490), CK (1150 versus 290 U/L, p = 0.017), AST (194 versus 108 U/L, p = 0.025) and LDH (674 versus 368 U/L, p = 0.011) were higher in the deceased group. Interestingly, skin ulcers were tended to be more frequent (12.5% versus 87.5%, p = 0.0587), and anti-SS-A antibody was also more frequently detected (14.3% versus 85.7%, p = 0.0072) in the survived group. Using ROC analysis cut-off values were 963 ng/mL for serum ferritin level (sensitivity 100%, specificity 83%), 0.7 mg/dL for CRP (sensitivity 75%, specificity 89%), 308 U/L for CK (sensitivity 86%, specificity 77%), 62 U/L for ALT (sensitivity 100%, specificity 62%), and 454 U/L for LDH (sensitivity 88%, specificity 77%). Patients were divided into two groups based on these cut-offs or based on dichotomous parameters and survival was examined between 2 groups. Except CRP and anti-SS-A antibody, survival was significantly worse in parameter-positive or higher groups. Interestingly, anti-SS-A antibody-positive group had better outcome compared with those without.

Conclusion: In our analysis, novel candidates such as serum CK, AST, and LDH levels were newly extracted and parameters previously reported was also included and those were also associated with the clinical outcome. In addition, anti-SS-A antibody was identified as a novel protective factor associated with a good outcome.

In our experience, patients with DcSSc seem to benefit of early RTX treatment. Improvement may be seen as early as 6 months and seems to reach a plateau at 12 months.

AB0622
ASSOCIATIONS WITH DIGITAL PITTING IN SYSTEMIC SCLEROSIS: A RETROSPECTIVE ANALYSIS.
A. Vivekanantham1, 2, G. Dinsdale1, 3, C. Heal1, J. Manning1, 3, A. Herrick1, 3
1The University of Manchester, Manchester, United Kingdom; 2Manchester University NHS Foundation Trust, Manchester, United Kingdom; 3Salford Royal NHS Foundation Trust, Manchester, United Kingdom

Background: Digital pitting, the loss of tissue at the fingertip, is a cardinal feature of systemic sclerosis (SSc), contributing 3 of the 9 required points to fulfil the 2013 ACR/EULAR classification criteria. However, research into digital pitting has been scarce, despite it being painful and impacting on hand function.

Objectives: To identify factors associated with digital pitting in patients with SSc.

Methods: This was a retrospective analysis of data from patients with SSc attending a tertiary referral centre. Patients were subdivided into those with and without digital pitting, as recorded at their last documented attendance. The following variables were analysed: age, gender, age at Raynaud’s onset, age at SSc onset, limited/ diffuse cutaneous subtype, history of intravenous (IV) vasodilators, amputations, debridements and autoantibody status (anti-RNA polymerase, anti-Sc170, anti-centremere and anti-RNP).

Results: Data were available from 713 patients with SSc. Digital pitting was present in approximately half of these patients (n=362, 51%). Table 1 summarises their characteristics.

Table 1. Descriptive statistics of patients with and without digital pitting

</tr>
</tbody>
</table>

From the univariate analysis (Table 2), gender (female, p=0.02), age at Raynaud’s onset (p<0.001), age at SSc onset (p<0.001), IV vasodilators (p<0.001), amputations (p<0.001), debridements (p<0.001), anti-RNA polymerase (p=0.01), anti-Sc170 (p=0.05) and anti-centremere (p=0.05) were found to be significantly associated (anti-RNA polymerase negatively (p=0.20)) with digital pitting (p<0.05). Further analysis adjusting the p value for multiple testing (Bonferroni adjustment, p<0.0036) found age at Raynaud’s onset, age at SSc onset, history of IV vasodilators, amputations and debridements to be significantly associated with digital pitting.

Table 2. Univariable logistic regression
Conclusion: The results from this exploratory study in a large cohort of SSc patients provide valuable insights into factors associated with digital pitting. Patients with digital pitting often have an earlier onset of Raynauds and of SSc and significantly more debridements/amputations, suggesting that digital pitting is associated with vascular disease severity. Our findings indicate the need for further research investigating pathophysiology of digital pitting, to inform development of preventative treatment strategies.

AB0623 RATE AND PREDICTIVE FACTORS ASSOCIATED WITH SUSTAINED REMISSION IN IDIOPATHIC INFLAMMATORY MYOSITIS

T. Vojinovic1, X. Gjoni2, M. Fredi1, F. Franceschini1, I. Cavazzana1. 1ASST Spedali Civili, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 2University of Brescia, Brescia, Italy

Background: Idiopathic inflammatory myositis (IIM) is a group of heterogeneous connective tissue diseases, characterised by chronic muscle inflammation, myositis-specific or myositis-associated autoantibodies and different extra-muscular features. Achieving low disease activity or remission in patients with IIM has proven to be difficult due to the wide clinical spectrum of the different IIM types.

Objectives: To retrospectively assess any predictive factors for sustained remission in IIM patients.

Methods: We retrospectively analyzed data taken from medical charts, which included age at disease onset, gender, laboratory data as well as clinical features present at onset, organ involvement and treatment history. A total of 151 adult patients with IIM followed-up for > 1 year were retrospectively enrolled. Remission was defined as no clinical and laboratory evidence of disease activity persistent for more than 6 months during follow-up, while undergoing myositis therapy or under no medication. The remission of cutaneous involvement was defined as no current activity of skin rash, absence of Gottron’s papules as well as heliotrope rash and erythema, whereas the remission of pulmonary involvement was considered as no requirement for intensification of immunosuppressive therapy during follow-up. Likewise, absence of muscle weakness or hypotension was taken into account for evaluating muscle involvement. Moreover, the clinical features were accompanied by normalization of myogenic enzymes such as creatine kinase (CK) and lactate dehydrogenase levels.

Results: Among all 151 patients, 89 (58.9%) patients achieved sustained remission. By univariate analysis, overlap myositis (79% vs 27.4%; p = 0.003; OR: 0.22), cancer-associated myositis (CAM) (78% vs 19.35%; p = 0.046; OR: 0.3), as well as the presence of anti Ku (3.37% vs 12.9%; p = 0.05; OR: 0.23) and anti TIF-1 gamma (1.1% vs 8%; p = 0.043; OR: 0.13) antibodies and polyarthritis (11.2% vs 24.19%; p = 0.045; OR: 0.397) at onset were significantly associated with active IIM, not achieving remission.

Out of 89 patients in remission, 79 (88.8%) achieved long-term sustained remission. By univariate analysis, overlap myositis (79% vs 27.4%; p = 0.003; OR: 0.22), cancer-associated myositis (CAM) (78% vs 19.35%; p = 0.046; OR: 0.3), as well as the presence of anti Ku (3.37% vs 12.9%; p = 0.05; OR: 0.23) and anti TIF-1 gamma (1.1% vs 8%; p = 0.043; OR: 0.13) antibodies and polyarthritis (11.2% vs 24.19%; p = 0.045; OR: 0.397) at onset were significantly associated with active IIM, not achieving remission.

Conclusion: Sustained remission occurs in about one half of patients with IIM. The presence of anti Ku and anti TIF-1 gamma antibodies as well as polyarthritis at onset lowers the chance of achieving sustained remission. Younger age at diagnosis has proved to predict drug-free long-lasting remission.

AB0624 PREDICTIVE PARAMETERS FOR DEVELOPMENT OF INTERSTITIAL LUNG DISEASE IN IDIOPATHIC INFLAMMATORY MYOSITIS

T. Vojinovic1, M. Fredi2, P. Ceruti2, D. Modina2, F. Franceschini2, I. Cavazzana2. 1ASST Spedali Civili, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 2ASST Spedali Civili, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 3ASST Spedali Civili, Rheumatology and Neumology Unit, Brescia, Italy

Background: Idiopathic Inflammatory Myositis (IIM) is a group of heterogeneous connective tissue diseases, primarily characterized by chronic muscle inflammation as well as myositis-specific or myositis-associated autoantibodies and a spectrum of different extra-muscular features.

The most frequent organ involvement in IIM is Intestinal Lung Disease (ILD), occurring in 5-80% of different IIMs cases and considered the hallmark of morbidity and mortality in patients with IIMs.

Objectives: To retrospectively assess the predictive factors for development of ILD in IIM patients.

Methods: We retrospectively analyzed the prevalence of ILD in a single-center cohort of 165 IIM patients. Patient data was collected from clinical charts. ILD was diagnosed by chest X-ray scan and chest CT scan. All chest CT and chest X-ray scans available and performed at our hospital were consequently re-evaluated by our expert pneumologist for uniform evaluation.

Results: Myositis-related ILD (M-ILD) was found in 52 IIM patients (31.5%): 46.15% was affected by anti-synthetase syndrome (ARS), 21.5% by polymyositis (PM), 19.23% by dermatomyositis (DM) and 13.46% by overlap myositis. The pulmonary involvement was characterized by Non-specific interstitial pneumonia (NSIP) (30.6%), Unusual Interstitial Pneumonia (UIP) (38.77%), Bronchiolitis Obliterans with Organizing Pneumonia (BOOP) (20.4%), overlap NSIP/BOOP (4.1%) and Undetermined/Unspecific pattern (6.12%). Eighty four percent of M-ILD consisted of non-smokers and 69.23% presented with dyspnea at onset.

ILD was diagnosed in 90.38% of patients within the first year of IIM diagnosis (early onset ILD) and was associated with dyspnea and/or cough in 70.2% and 17% respectively. On the other hand, late onset ILD presented mostly with dyspnea and cough in 60% of cases and was significantly associated with anti-Ku antibodies.

At onset ILD was significantly associated with: ARS (p < 0.0001; OR: 12.98), anti-Jo-1 (p < 0.0001; OR: 6.1), anti-Ro (p = 0.038; OR: 2.2), mechanic’s hands (p = 0.001; OR: 10.41), arthritis (p = 0.01; OR: 2.58), polyarthritis (p = 0.001; OR: 4.578), dyspnea (p < 0.0001; OR: 9.66), and high levels of CPK (p = 0.0001) and GOT (p = 0.0148). By contrast, the following features: DM (p = 0.012; OR: 0.36), facial rash (p = 0.003; OR: 0.31), anti-NXP-2 (p = 0.19; OR < 0.0001), anti-PL-12 (p = 0.03; OR < 0.0001) and myositis (p = 0.0001; OR: 0.173) at present were less frequently associated with M-ILD.

At multivariate analysis M-ILD was predicted by anti-Ro (p = 0.0448), polyarthritis (p = 0.0080) and dyspnea (p = 0.0001) at onset. On the other hand, patients presenting myositis (p = 0.0336) and facial rash (p = 0.0398) at onset were less likely to developed M-ILD.

Conclusion: ILD occurs in about one third of patients with IIM, mostly affected by ARS. The presence of anti-Ro antibodies as well as polyarthritis and dyspnea at onset predict the development of ILD.

AB0625 IS PULMONARY ARTERIAL HYPERTENSION, ASSOCIATED WITH SYSTEMIC SCLEROSIS REVERSIBLE?

A. Volkova1, N. Yudkina1, E. Nikolaeva1, M. Starovoytova1, O. Alekseeva1, I. Nikishina1, E. Nasonov1. I. VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Systemic sclerosis (SSc) is one of the frequent causes of the pulmonary arterial hypertension (PAH) which found in 6-15% patient with SSc. Patients with PAH, associated with SSc have a poorer prognosis than other PAH. 6 World Symposium of PH lowered diagnostic cut-off to 21 mm Hg in hope of improved survival. PAH reversibility is described in congenital heart defects, HIV and some tumors

Objectives: The aim of the study to detect reversibility of PAH associated with SSc.

Methods: Hemodynamics (mean pulmonary artery pressure (MPAP), pulmonary artery wedge pressure (PAWP), cardiac output (CO) and pulmonary vascular resistance (PVR)), functional class (NYHA), 6-minute walk distance (6MWD), biomarkers and DICO were assessed. Patients with pulmonary fibrosis and left heart diseases were excluded.

Results: The study includes 56 patients receiving start-up monotherapy with 1st generation PAH-specific drugs: bosentan (25 patients) and sildenafil (31 patients). The median age of the patients was 51.5 (37,58) years. At the time of diagnosis, the MPAP in the sildenafil group was 49 (30; 50) mm Hg, bosentan - 50 (42; 56) mm Hg, differences not significant (p = 0.11). During observation against the background of sildenafil intake,
the MPAP decreased by -3 (-7; 0) mm Hg, bosentan -6 (-13; -2) mm Hg. Decreasing of MPAP ≤ 21 mm Hg was at seven patients receiving sildenafil. Initial hemodynamic values in this group of patients was MPAP 25 (21; 27) mm Hg., RAP 2 (1; 5) mm Hg, PAWP 7 (6; 10) mm Hg., CV 5.9 (4.7; 6.7) l/min, PVR 3.0 (1.5; 4.2) Wood Unit. Among patients taking sildenafil, there were seven who had MPAP less than 35 mmHg, and among patients taking bosentan, there were 4 patients with less than 35 mmHg. However, the decreasing was observed only group who received sildenafil. ROC – analysis shown that cut-off for reversible is 29 mm Hg (AUC 0.977, sensitivity 97%, and specificity 100%).

Conclusion: In patients with PAH, associated with SSc, on sildenafil treatment, at MPAP < 29 mm Hg reversibility is possible. Further study is required.

AB0626 IMATINIB FOR THE TREATMENT OF SYSTEMIC SCLEROSIS: RATIONALE, CLINICAL EVIDENCE AND FUTURE DEVELOPMENT

A. Waheed1, C. Buckingham2, G. Brar2. 1Imperial College London, London, United Kingdom; 1Imperial College London, London, United Kingdom

Background: Systemic sclerosis (SSc) is a chronic disorder of connective tissue affecting the skin and internal organs. The molecular mechanisms behind SSc are not entirely understood, but recent advances highlight key signalling pathways1 (see Figure 1). Fibrosis disrupts tissue architecture resulting in organ dysfunction. This causes significant morbidity and mortality1, therefore there is a clear need for identifying efficacious antifibrotic treatment.

Imatinib is a tyrosine kinase inhibitor with established use in some malignancies, and existing evidence that it can treat SSc2.

Objectives: The aim of this literature review is to summarise the current evidence and future developments of imatinib as antifibrotic treatment in SSc.

Methods: PubMed headings “systemic sclerosis”, “scleroderma”, “imatinib” and synonyms were used. See Figure 2.

9 studies showed imatinib had positive efficacy in the treatment of SSc. 5 showed no improvement or adverse effects.

Conclusion: Overall, current evidence suggests that imatinib can be a useful drug to improve manifestations of SSc, for some. Despite inconclusive evidence, a dose-dependent relationship seems to exist for imatinib toxicities, with more research needed to ascertain a safe dose.
Gene expression profiles may distinguish patients that can benefit from imatinib. Also, Notch signalling could be exploited to increase imatinib uptake into fibroblasts, thereby increasing efficacy.

PROGNOSIS AND MORTALITY OF DERMATOMYOSITIS AND POLYMYOSITIS PATIENTS WITH MALIGNANCY

X. Yang1, Y. Hao2, Z. Zhang on behalf of Peking University First Hospital; Department of Rheumatology and Clinical Immunology, 1 Peking University First Hospital, Beijing, China; 2 Peking University First Hospital, Beijing, China

Background: Previous studies indicate that cancers in DM/PM patients are associated with increased mortality. Hence, identifying predictors of malignancy in PM and DM is crucial. However, few large series studies have reported prognostic and predictive factors of malignancy in patients with PM and DM. Moreover, in recent years, several published studies also allow us to better understand the clinical characteristics of malignancy in PM and DM.

Objectives: To analyze the mortality and identify the major independent risk factors for death in patients with dermatomyositis/polymyositis (DM/PM) complicated with malignant tumors.

Methods: The clinical data of all patients with DM/PM in Peking University First Hospital from January 2007 to Jan 2019 were retrospectively reviewed. All patients were followed up to confirm whether they had malignant tumors. According to the statistics of the National Bureau of Statistics of China, the standard mortality (SMR) and life lost years (YLL) of patients with DM/PM were combined with malignant tumors. The Kaplan-Meier method was used to analyze the 10-year survival of DM/PM patients with malignant tumors. Cox multivariate regression was used to predict independent risk factors for DM/PM patients with malignant tumors.

Results: A total of 334 patients with dermatomyositis and 69 patients with polymyositis were enrolled in the study. The mean age of onset was 50.5 ± 14.8 years and 48.9 ± 16.1 years, with a median follow-up of 40.6 (11.6-77.6) months. Among them, 320 patients were successfully followed up, including 69 patients with death. 46 DM/PM with malignant tumors (38 with dermatomyositis and 8 with polymyositis). The average age of onset of DM/PM patients with malignant tumors was 55.4 ± 15.1 years and 59.5 ± 4.7 years, respectively, of which 17 died. The age-sex adjusted SMR of DM/PM patients without malignant tumors was 9.0 (95% CI 6.8-112). The age-sex adjusted SMR of DM/PM with malignant tumors was 12.3 (95% CI 9.0-14.7). The life loss of male patients with dermatomyositis complicated with malignant tumors was 30.1 years, and that of females was 38.6 years; the life loss of male patients with polymyositis was 27.6 years, and that of females was 22.1 years. A 10-year survival analysis showed that DM/PM patients with malignant tumor had significantly worse prognosis than patients without malignancy (p=0.001 Log-rank). The 1-, 5-, and 10-year survival rates of DM/PM patients who did not have malignant tumors were 87.9%, 81.9%, and 78.4% respectively. DM/PM patients with malignant tumors 1, 5, and 10 years The survival rates were 73.3%, 56.0%, and 45.7%, respectively. The independent risk factors for death in DM/PM patients with malignant tumors were advanced age (HR=1.11 95% CI 1.02-1.20, p=0.014) and infection (HR=1.707 95% CI 1.66-1.75, p= 0.017).

Conclusion: Malignant tumor is a common in patients with DM/PM, and the mortality of DM/PM patients with malignant tumors is high. The independent predictors of mortality for PM/DM patients with malignant tumors were age at disease onset and infection.

Emerging Autoantibodies Panel (Myositis Associated and Myositis Specific Antibodies) in Inflammatory Myopathies: The Frequencies of and Relationship with Clinical Features

G. K. Yurdumcu1, E. Erul2, E. Bilgin1, B. Farsiogullari3, L. König1, Z. Sarıbas3, U. Kalyoncu1, A. Akdoğan1, B. Senel1, Ş. A. Bilgen1, O. Karadağ2, 1Faculty of Medicine; Hacettepe University, Rheumatology, Ankara, Turkey; 2Faculty of Medicine; Hacettepe University, Internal Medicine, Ankara, Turkey; 3Faculty of Medicine; Hacettepe University, Department of Medical Microbiology, Ankara, Turkey

Background: The idiopathic inflammatory myopathies (IIM) are characterized by muscle weakness, skin disease and various internal organ involvement and they can overlap with other autoimmune diseases. Recent autoantibody panels improve understanding and management of inflammatory myopathies. Myositis specific autoantibodies including Anti-TIF-1, Anti-NXP2, Anti-MDA5, Anti-SAE1, anti-HMGCGR and anti-cn1A are regarded as key biomarkers aiding the diagnosis of patients. On the other hand, myositis-associated autoantibodies (MAs) are also found in other autoimmune rheumatic diseases.

Objectives: To investigate the clinical meaning and impact of new myositis autoantibodies panel in real life data.

Methods: A total of 110 subjects (77 female, 33 male) admitted to Hacettepe University Hospitals with the signs and symptoms of IIM were screened by a line immunoblot assay (EUROLINE: Autoimmune Inflammatory Myopathies16 Ag) between 2017 and 2020. Only moderate or strong reactivity results were reported as positive. Demographic, clinical, laboratory, therapeutic data and imaging features were obtained by the retrospective review of medical records. IIM patients were diagnosed by Bohan and Peter's criteria and classified according to the EULAR/ACR classification criteria for adult and juvenile IIM and their major subgroups.

Results: IIM was diagnosed in 61 patients (42.6% DM/JDM and 57.4% PM) and patients with overlap were in decreasing order, Scleroderma (n=8), RA (n=5), Sjogren (n=4), SLE (n=3), autoimmune hepatitis (n=2).

Myositis-specific autoantibodies (MSAs) were found in 60%, myositis-associated autoantibodies (MAs) in 41% of inflammatory myositis patients. The most common MSAs were Anti-Jo-1 (16.4%) and anti-MDA-5 (13.1%) and the most common MAA was Ro-52 (32.7%) (Table 1). MAs were more common in patients with polymysitis (54% vs 23% p=0.013). Twenty-one (34.4%) patients (61.0% females) had intestinal lupus disease (ILD). Anti-Jo-1 (38.1%) and anti-Ro-52 (52.4%) was the most common MAA and MSA in patients with IIM and ILD.

MSAs were also determined in 10 of the 49 patients who were not diagnosed with IIM. Five patients with Anti- SRP, Anti-Mi-2 alpha, Anti-Jo-1, Anti-PF2, Anti-PF4 antibodies did not have bladder cancer. Three patients with Anti-NKPX2, Anti-PF-Mcl 75, Anti-Ro-52, Anti-Mi-2 beta, Anti-PF2, Anti-PF12 autoantibodies had ILD. One patient (Anti-Mi-2 alpha, Anti-NKPX2 and Anti-Ku autoantibodies positive) had viral myositis and one patient (Anti-Mi-2 alpha, Anti-Ro-52 autoantibodies positive) had inflammatory polynuropathy.
Conclusion: Our study revealed relationship of anti-Jo-1 and anti-Ro-52 but not anti-MDA-5 in ILD-inflammatory myopathies. Even though new autoantibodies panel give opportunity to a closer look for inflammatory myopathies, larger series of patients should be evaluated to determine the association of specific antibodies in the differential diagnosis and prediction of outcome of IIM. MSA positivity in non-IIM diagnosed patients should be monitored to determine whether this positivity is related to a future disease development.

**VASCULAR MANIFESTATIONS OF SYSTEMIC SCLEROSIS: SIMILARITY IN PATHOGENESIS, DIFFERENT IN FREQUENCY**

N. Yudkina1, A. Volkov2, E. Nikolaeva2, E. Nasonov2, 1, 2 V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, 1, 2 V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Pulmonary arterial hypertension (PAH) is one of the main manifestations of vascular involvement in systemic sclerosis (SSc). The association of PAH with Raynaud’s phenomenon (RP) and digital ischemic disorders is assumed.

**Objectives:** The aim of the study to detect of the possible relationship of pathogenetically similar processes and the predictor role in the early diagnosis of PAH and digital ischemic disorders by the nailfold videocapillaroscopy (NVC).

**Methods:** 111 patients with SSc (51 patients with PAH (SSc-PAH) and 60 patients without PAH) include in this study. In all patients, the diagnosis of SSc was validated according to the 2013 ACR-EULAR criteria. PAH was diagnosed by right heart catheterization. NVC was performed in all recruited subjects. Capillary quantitative parameters (loops length and width, capillary density, neangiogenesis) were evaluated and a semi-quantitative scoring was used (specific patterns – early, active and late) to define microvascular alterations. The test evaluated the presence of capillaroscopic changes in the nailfold bed on 2-5 fingers of both hands. The normal capillaroscopic pattern was characterized by the presence of 7-11 capillaries in the form of hairpins per 1 mm. Pathological patterns were characterized by morphological and structural changes, such as expanded and giant capillaries, hemorrhages, avascular fields, neangiogenesis. The capillaroscopy pattern (normal, non-specific, early/active/late) was determined qualitatively. Decreased capillary density, dilated, giant or branched capillaries, microhemorrhages were evaluated semi-quantitatively.

**Results:** RP was detected in 100% of cases in both groups. In the analysis of capillaroscopic patterns in both groups, the early and late scleroderma types of changes prevailed, but no significant differences were noted. Typical scleroderma patterns were found in 51 patients (100%) with SSc-PAH. In 3 patient with SSc without PAH, the abnormalities were regarded as non-specific. The NVC pattern was detected to be early in 8 patients with SSc-PAH and in 11 with SSc without PAH. The NVC pattern was found to be active in 16 patients with SSc-PAH and in 18 with SSc without PAH. The NVC pattern was detected to be late in 27 patients with SSc-PAH and in 28 with SSc without PAH. In addition to RP, the development of digital ulcers was noted with equal frequency in history (25 patients with SSc-PAH and 32 with SSc without PAH). Also, the time to their appearance from the first symptom of SSc was the same (56 (16; 64) months and 44 (23; 72) months, respectively). Severe forms of digital ischemic disorders were observed rarely and with the same frequency in the studied groups. Ischemia in 2 patients with SSc-PAH and in 5 patients with SSc without PAH; gangrene in 2 patients only in the SSc group without PAH, amputation in 1 of each group.

**Conclusion:** In the course of the study, it was not possible to identify differences between the NVC patterns, the frequency and severity of digital ischemic disorders in the compared groups. That fact does not allow using the NVC as an early diagnosis of PAH in SSc. However, the NVC can help predict the development of digital ischemic disorders.

**IMBALANCE BETWEEN TH17 AND REGULATORY T CELLS IN PATIENTS WITH PM/DM COMBINED WITH EBV/CMV VIREAMIA**

X. Zheng1, R. Su1, Y. Liu1, X. Li1, C. Wang2, 1 The Second Hospital of Shanxi Medical University, Department of Rheumatology, Tai Yuan, China, 1 The Second Hospital of Shanxi Medical University, Department of Rheumatology, Tai Yuan, China

**Background:** Dermatomyositis and polymyositis (DM/PM) are associated with muscle weakness and inflammatory infiltration within the skeletal muscle. The numerical and functional defects of immune cells, due to long-term uses of glucocorticoids and disease-modifying anti-rheumatic drugs (DMARDs) together with immune disturbances associated with disease itself, lead to high risks in opportunistic infections, such as Epstein-Barr virus (EBV) and cytomegalovirus (CMV).1,2 We want to observe changes of peripheral lymphoyestissubsets in PM/DM patients with EBV and/or CMV infection, especially whether there is imbalance between Th17 and Treg cells.

**Objectives:** To investigate the characteristics of peripheral lymphocyte subsets in PM/DM with EBV and/or CMV infection, especially the Th17 and Treg cells.

**Methods:** From February 2016 to November 2019, PM/DM patients with EBV and/or CMV viremia (infection group, n=34) and without infection (non-infection group, n=31) as well as healthy adult controls (n=20) were enrolled in our study. Absolute numbers of total T, total B, NK, CD4 + T, CD8 + T cells, and CD4 + T subsets (Th1, Th2, Th17 and Treg cells) in peripheral blood by flow cytometry combined with absolute standard counting beads.

**Results:** (1) Compared with PM/DM patients without infection, 34 PM/DM patients with EBV and/or CMV infection, including 12 patients with EBV, 20 patients with CMV, 2 patients combined EBV and CMV, the absolute number of total T lymph cells (P=0.019), total B lymph cells (P=0.037), NK cells (P=0.033), CD4 + T cells (P=0.000), Th1 cells (P=0.014), Th2 cells (P=0.003), Th17 cells (P=0.003), Treg cells (P=0.004) lower than its of (P=0.003) patients without infection, the absolute number of CD8 + T cells (P=0.427) has no obvious difference between them.

(2) And its the absolute number of total T lymph cells (P=0.000), total B lymph cells (P=0.003), NK cells (P=0.000), CD4 + T cells (P=0.000), CD8 + T cells (P=0.006), Th1 cells (P=0.000), Th2 cells (P=0.001), Th17 cells (P=0.000) and Treg cells (P=0.000) significantly lower than healthy control.

(3) Compared with the healthy control, the absolute number of total T lymph cells (P=0.000), NK cells (P=0.000), CD4 + T cells (P=0.031), CD8 + T cells (P=0.000), Th1 cells (P=0.002), Th2 cells (P=0.031), and Treg cells (P=0.000) in PM/DM without infection evidently lower, but there is no significant difference in absolute number of total B lymph cells (P=0.19) and Th17 cells (P=0.171).

**Conclusion:** We show that the absolute number of peripheral blood lymphocytes and CD4+ T subsets in patients with PM/DM with EBV and/or CMV viremia is further reduced. In addition to Treg cells, a decrease in Th17 cells may also be an important feature of EBV and/or CMV infection in DM/PM. These cell reductions may be the cause and risk indicator of viral infections.

REAL WORLD EXPERIENCE OF THE IMPACT OF SECUKINUMAB ON DISEASE ACTIVITY AND FATIGUE IN PATIENTS WITH ANKYLOSING SPONDYLITIS
S. Batoq, S. Bawa. Garthnavel General Hospital, Rheumatology, Glasgow, United Kingdom

Background: Fatigue is one of the most commonly reported symptom of ankylosing spondylitis (AS). It impacts functional ability, quality of life, and ability to maintain employment7. Secukinumab, a fully human monoclonal IgG1 antibody that neutralizes IL-17A, has shown significant and sustained improvement in the signs and symptoms of active AS in the MEASURE 2 study8. It has also shown to improve fatigue scores. Despite this, the published literature on real life experience is scarce. We report our experience of Secukinumab use at Garthnavel General Hospital, Glasgow, UK.

Objectives: We performed a retrospective review to assess the response of our AS patients to Secukinumab. We also reviewed the impact of treatment on fatigue.

Methods: AS patients commenced on Secukinumab 150mg subcutaneously from mid-2016 to September 2019 were identified using the clinical records on our database. Response using Bath AS disease activity index (BASDAI) and Bath AS function index (BASFI) were recorded. Impact on fatigue and pain was measured using single-item fatigue and pain visual analogue scale (VAS) within the BASDAI questionnaire.

Results: 30 AS patients, 11 anti-TNF naïve and 19 anti-TNF inadequate responders (IR), on Secukinumab were identified. Retention rate was 76.66% (23/30). Sustained improvement was observed across all outcome measures over 3.5 years. Fatigue and pain improvement were somewhat lower than expected but did show slow improvement. Responses were greater in anti-TNF naïve patients. There was no significant difference in response between smokers (33.34%, 10/30) and non-smokers (36.67%, 11/30). There were 4 patients with inflammatory bowel disease, none of whom flared. No new safety signals were identified.

Conclusion: In our real-life cohort of AS patients, significant improvement was seen over 3.5 years in both BASDAI and BASFI. Fatigue was significantly improved in anti-TNF naïve group, but results were disappointing in anti-TNF IR group. This may be explained by the fact that there are older patients with established disease and background degenerative changes in anti-TNF IR group. Although fatigue data had slightly discordant results compared with the MEASURE 2 study9, considering the use of single item VAS rather than dimensional measures such as FACEIT fatigue scale, clear improvement has been observed.

AB0634
BUDGET IMPACT ANALYSIS OF BIOLOGICAL THERAPY COMPARED TO CONVENTIONAL SPONDYLOARTHRITIS TREATMENT, IN A FOURTH LEVEL HOSPITAL IN BOGOTA COLOMBIA
J. M. Bello-Gualter1, J. J. Cairol2, G. Salguero3, Y. M. Chamorro-Melo1, C. A. Camargo Rodriguez1, H. Quilian Ruiz2, A. Beltran1, G. Saavedra3
1Hospital Military Central, Rheumatology and Immunology Service, Bogota, Colombia; 2Universidad Military Nueva Granada, Internal Medicine, Bogota, Colombia; 3Hospital Military Central, Scientific Research Unit, Bogota, Colombia

Background: Spondyloarthritis refers to a family of diseases, of which ankylosing spondylitis and non-radiographic axial spondyloarthritis are responsible for a disabling and irreversible disability. Previously, the only treatment available were NSAIDs, which control activities of daily living and slow radiological progression, but at the expense of increased adverse effects, such as cardiovascular risk, dyspepsia and chronic renal failure. For the past 2 decades, biological therapy has been available, which means an increase in care costs.

Objectives: The objective of this study is to perform a budget impact analysis of biologic therapy.

Methods: To do a budget impact analysis from the perspective of the payer, comparing biological therapy with conventional therapy for the treatment of spondyloarthritis. Demographic characterization of the population attended at the Central Military Hospital. Time horizon from 2012 to 2018, taking the activity count according to the hospital’s billing and the prices of the activities of the state body SIMED. Exchange rates at the end of 2018.

Results: The patients attended were 117, mostly men (63, 23%), average age 46, 4 years (SD 13), with disease diagnosis time of 9, 8 years (SD 9, 6). In the budget impact analysis, it is observed that 25% of patients were on DMARDs...
therapy, 22% with NSAIDs and 96% with biologic therapy. The average year/ patient cost with NSAIDs alone would be EUR 381, with DMARDs only EUR 9,318 and, if only biological therapy was used, EUR 423. Within the total number of patients, the average annual cost, including the possibility of combining these drugs, amounted to EUR 5,403.

**Conclusion:** Including biological therapy in the care of patients with spondyloarthritis can increase up to 24 times the annual cost per patient. This increase is not only due to higher market value, it also relates to the need for more medical procedures and diagnostic follow-up tests.

**AB0635 HOW ARE NON STEROIDAL ANTI-INFLAMMATORY DRUGS (NSAID) PRESCRIBED IN AXIAL SPONDYLOARTHRITIS?**

**K. Ben Abdelghani**, Y. Gzam, A. Fazaa, S. Miladi, K. Quenniche, S. Kassaïb, L. Souabni, S. Chekili, A. Laatar1, Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

**Background:** For decades, NSAID have been used as the first-line drugs to treat axial spondyloarthritis (axSpA). However, the NSAID prescription strategy is not clearly detailed and it varies from one clinician to another.

**Objectives:** The aim of this study was to assess the NSAID prescription modalities adopted in axSpA and the differences between these modalities.

**Methods:** This is a descriptive study including 85 cases of axSpA fulfilling the ASAS 2009 criteria and diagnosed between January 2000 and October 2019. The demographic and clinical features of the axSpA were collected and the modalities of prescription of NSAIDs were retrospectively assessed.

**Results:** Of 85 axSpA, 67 were males (78,8%) and the mean age was 44,4 ± 10,9 years. The mean period of evolution was 12.3 ± 9.1 years and 52.2% of patients were HLA-B27 positive. The axSpA was a pure axial form in 74,1% of patients, associated with peripheral arthritis, enthesitis and dactylitis in 17,6%, 17,6% and 1,2% respectively.

The anti-TNFs were administrated with a mean delay of 78 ± 70.8 months. The anti-TNFs used were: Infliximab (41,1%), Etanercept (32,9%), Adalimumab (23,5%) and Golimumab (2,3%). Fifty-nine patients (69,4%) were treated with anti-TNF alpha on monotherapy and 26 patients (30,6%) had combined therapy. The csDMARDs prescribed were the Salazopyrine (22,4%) and the Methotrexate (11,5%) and had necessitated the use of anti-TNF alpha.

Among the 180 patients treated with NSAID, 86 patients (48,6%) were treated with conventional DMARDs (csDMARDs) in association with NSAID: Salazopyrine (43,3%) and Methotrexate (13,3%). Seventy-one patients (39,4%) had necessitated the use of anti-TNF alpha. NSAIDs were used continuously in 115 patients (63,8%) and the maximum dose of NSAIDs was used in 78 patients (43,3%). By comparing patients who used maximum doses of NSAIDs and those who used NSAID continuously with other patients, we noticed that the use of biological treatments was more frequent in those groups (p = 0,01 and p=0,004 respectively).

In addition, while comparing the group of patients co-treated with csDMARDs with other patients treated with NSAID on monotherapy, we noted that this group of patients had more arthritis (p=0,0001), enthesis (p=0,02), psoriasis (p=0,04) and necessitated more biological treatments (p=0,01).

**Conclusion:** Our results suggest that maximal doses and/or continuous prescription of NSAID were mainly used if there was no response to that treatment. The csDMARDs were more prescribed if there were peripheral manifestations or psoriatic arthritis and those forms were also more candidates to biological treatments.

**AB0636 MODALITIES OF PRESCRIPTION OF ANTI-TNF ALPHA IN AXIAL SPONDYLOARTHRITIS: ON MONOTHERAPY OR COMBINED WITH CONVENTIONAL SYNTHETIC DMARDs**

**K. Ben Abdelghani**, Y. Gzam, A. Fazaa, S. Miladi, K. Quenniche, S. Kassaïb, L. Souabni, S. Chekili, A. Laatar1, Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

**Background:** The advent of biologics targeting tumor necrosis factor-alpha (anti-TNF alpha) has revolutionized the treatment of spondyloarthritides (SpA). Their association with conventional synthetic disease-modifying antirheumatic drugs (cs-DMARD), although effective and used in clinical practice for the treatment of peripheral rheumatic diseases, is not clearly assessed in axial spondyloarthritides (axSpA).

**Objectives:** The aim of this study was to assess the strategy of prescription of anti-TNF alpha in a population of axSpA and to compare patients treated with anti-TNF alpha on monotherapy with those who had combined therapy with cs-DMARDs.

**Methods:** This is a retrospective descriptive study including 85 cases of axSpA diagnosed between January 2000 and October 2019 and treated with anti-TNF alpha.

The clinical features, the erythrocyte sedimentation rate (ESR), the C-reactive protein (CRP), Bath ankyllosing spondylitis disease activity index (BASDAI) and Bath ankyllosing spondylitis functional index (BASFI) were compared between groups of anti-TNF alpha on monotherapy or combined therapy with csDMARDs.

**Results:** Of 85 axSpA, 67 were males (78,8%) and the mean age was 44,4 ± 10,9 years. The mean period of evolution was 12.3 ± 9.1 years and 52.2% of patients were HLA-B27 positive. The axSpA was a pure axial form in 74,1% of patients, associated with peripheral arthritis, enthesitis and dactylitis in 17,6%, 17,6% and 1,2% respectively.

The anti-TNFs were used: Infliximab (41,1%), Etanercept (32,9%), Adalimumab (23,5%) and Golimumab (2,3%). Fifty-nine patients (69,4%) were treated with anti-TNF alpha on monotherapy and 26 patients (30,6%) had combined therapy. The csDMARDs prescribed were the Salazopyrine (22,4%) and the Methotrexate (11,5%).

While comparing the groups of anti-TNFs combined therapy and monotherapy, we noticed that the arthritis were present in 30,7% of patients from the group of combined therapy versus 11,8% of patients from the group of monotherapy (p=0,03). The psoriasis also was more present in the group of combined therapy (11,5% vs 1,6%; p=0,04).

There was no statically significant difference between the two groups in the following parameters: age, gender, HLA B27, enthesitis, dactylitis, uveitis, inflammatory bowel diseases, ESR, CRP, BASDAI and BASFI.

**Conclusion:** Our results suggest that the concomitant use of csDMARDs with anti-TNFs is frequent in clinical practice in axSpA, but mainly justified by the presence of arthritis or psoriasis.

**AB0637 EFFICACY OF COMEDICATION OF CONVENTIONAL SYNTHETIC DMARDs WITH TNF BLOCKERS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

**K. Ben Abdelghani**, Y. Gzam, A. Fazaa, S. Miladi, K. Quenniche, S. Kassaïb, L. Souabni, S. Chekili, A. Laatar1, Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

**Background:** Tumour necrosis factor blockers (anti-TNFs) are typically used in axial spondyloarthritis (axSpA) when the disease has not responded adequately to conventional therapy. However, the effects of the comedication conventional synthetic disease modifying antirheumatic drugs (csDMARDs) with anti-TNFs are inconclusive.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.6221
Objectives: The aim of this study was to evaluate the efficacy of combination with csDMARD and anti-TNF compared with anti-TNFs on monotherapy.

Methods: A descriptive retrospective study including 85 patients with axSpA according to the criteria of the group ASAS on 2009 and having received anti-TNFs between January 2000 and October 2019. The patients were divided on two groups, those who had received combined therapy with cs-DMARDs and those who had received anti-TNFs on monotherapy. The response to treatment was assessed with the ASAS 40 response and partial remission at 3 and 6 months of treatment and was compared between the two groups.

Results: Our populations consists of 67 men and 18 women with a mean age of 44.4 ± 10.9 years. The mean period of evolution was 12.3 ± 9.1 years and 52.2% of patients were HLA-B27 positive. The ax-SpA was associated with peripheral arthritis, enthesitis and dactylitis in 176%, 17.6% and 1.2% respectively. Fifty-nine patients (69.4%) were treated with anti-TNF alpha on monotherapy and 26 patients (30.6%) had combined therapy. The ASAS 40 response was achieved in 45.6% of patients at 3 months and 64.1% of them at 6 months of anti-TNFs treatment. Among them, 7.4% had obtained partial remission at 3 months and 20.3% at 6 months of treatment. There was statically significant difference between the two groups on the ASAS 40 response or the partial remission at 3 and 6 months of treatments.

Conclusion: The comedication therapy with cs-DMARDs does not influence the efficacy of anti-TNFs in ax-SpA patients suggesting no benefit in the concomitant use of these drugs in clinical practice.

AB0639 THE EFFECT OF VITAMIN D ON QUALITY OF LIFE AND SEVERITY OF PAIN IN PATIENTS WITH ANKYLOSING SPONDYLITIS
E. Kornarov1, I. Blagina1, N. Bludova1, P. Bakhtoyary1, I. Pokryshka2,
1Lugansk State Medical University, Lugansk, Ukraine; 2Lugansk Republican Clinical Hospital, Lugansk, Ukraine

Background: The high incidence of ankylosing spondylitis (AS) in people of working age, as well as the negative impact of the disease on the quality of life of patients, determine the need for adjuvants to reduce the severity of pain and thereby achieve the physical, psychological and emotional well-being of patients.

Objectives: To study the effect of vitamin D (colecalciferol) on the quality of life and the severity of pain in patients with ankylosing spondylitis.

Methods: The study included 69 patients with AS, who studied the quality of life indicators according to the Medical Outcomes Study Short Form (SF-36); pain syndrome and stiffness in the spine were assessed by a visual analogue scale by a physician - by counting the number of painful joints (NPJ), the disease activity index (BASDAI) and the Functional Index (BASFI). All patients were receiving a basic therapy in a stable dose for at least 10 months. They were divided into 2 groups, comparable in age, disease activity: Group 1 (n = 33) additionally received colecalciferol 1500 ME during 6 months of observation.

Results: At the end of the observation period when evaluating data on SF-36: in the 1st group, the physical health component has improved - the increase in physical functioning (PF) and bodily pain (BP) by 51.4% and 37.8% from the baseline; vital activity, psychological health, and social functioning due to emotional state have also increased by 37.6%, 33.4% and 42.5%, respectively. In the 2nd group above mentioned parameters have not changed. In the 1st group the indexes of BASDAI and BASFI have decreased by 16% and 22% (p = 0.0079, p = 0.0022, respectively), and their dynamics in the 2nd group were less significant (p = 0.013, p = 0.017, respectively). Also, in patients of the 1st group have decreased the severity of morning stiffness and the pain in the spine a highly reliable (p > 0.001), and in the 2nd group they were less significant (p = 0.043, p = 0.016, respectively). Positive dynamics of NPJ in the 1st group was more significant (p = 0.003) than it was in the 2nd group (p = 0.033).

Conclusion: In the group of patients treated with colecalciferol was noted improvement in indicators of quality of life (the parameters of the physical component of health, vitality and social functioning) and also more significant decrease of the intensity of pain and of morning stiffness duration, of NPJ, than in not received to colecalciferol patients. Inclusion of vitamin D in the comprehensive AS therapy promotes not only reduction the severity of the chronic pain manifestations, but also improves the quality of life of patients with this pathology.

AB0640 LONG-TERM EFFECTIVENESS AND DRUG SURVIVAL OF GOLIMUMAB IN PATIENTS AFFECTED BY PSORIATIC ARTHRITIS WITH CUTANEOUS INVOLVEMENT
G. L. Forni1, M. S. Chimera1, A. D’Antonio1, M. Teo2, F. Cassi1, L. Costa3, M. Tasso2, A. Ortolan3, M. Lorenzon3, P. Conigliaro1, P. Triggianese1, R. Scarpa1, R. Perricone1, R. Ramondi1, 1Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy; Rome, Italy; 2University of Rome Tor Vergata, Dermatology Department, Rome, Italy; 3Rheumatology Unit, Department of Clinical Medicine and Surgery, School of Medicine and Surgery, University of Naples Federico II, Naples, Italy; 4Rheumatology Unit, Department of Medicine-DIMED, University of Padova, Padova, Italy

Background: Psoriatic arthritis (PsA) is a chronic immune-mediated disease associated with psoriasis (PsO). Overexpression of inflammatory cytokines such as tumor necrosis factor (TNF)-α plays a key role in the pathogenic mechanisms. Golimumab (GLM) is a fully human monoclonal antibody IgG1k neutralizing TNF-α approved for PsA and PsO, but effectiveness evaluation in real life remains a crucial issue.
**Objectives:** In a real-life setting, to determine the survival rate of GLM (drug survival) at 48 months in the global population, in different clinical settings, and the effectiveness of GLM in improving joint symptoms and cutaneous manifestations in patients affected by moderate to severe PsA with cutaneous involvement.

**Methods:** We collected retrospectively from 1 January 2014 to 31 December 2019 data from 105 patients affected by PsA, according to the Classification for Psoriatic Arthritis (CASPAr) criteria, who started treatment with GLM. Inclusion criteria were age > 18 years and had a diagnosis of PsA > 6 months, the presence of peripheral arthritis (at least one active joint) and active PsO. Relevant anamnestic, clinical, biochemical data and biological treatment line were collected at baseline (T0) and after 6 (T6), 12 (T12), 24 (T24) and 48 (T48) months of GLM treatment. Comparisons between baseline and 48 months continuous variables were performed using a paired t-test or a Wilcoxon signed-rank test for paired samples. The drug survival rates were analyzed using Kaplan-Meier estimates. Drug survival rates were read from the Kaplan-Meier survival curves. Differences in drug survival between groups were analyzed using a log-rank (Mantel-Cox) test, by stratifying for sex, BMI, smoking habit and line of treatment. A p-value <0.05 was considered as statistically significant.

**Results:** Peripheral arthritis was present in 67 (63.8%) cases, axial disease in 37 (35.3%), enthesitis and PsO as prominent manifestations in 82 (78%) and 84 (80%) patients respectively. Erosive disease was present in 38 (36.2%) of patients at baseline. The most frequent comorbidities were Mets described in 20 (19%) patients and cardiovascular disease described in 33 (31.4%) patients, probably due to the high incidence of smokers (33 (31.4%) of patients) and to the elevate BMI score (27.1±6.0). At 48 months, the 42% (44 of 105) (figure 1A) of the patients have discontinued therapy; the most frequent reason was insufficient response/loss of efficacy (30 patients (28.6%) out of 105). Unexpectedly, no statistical significant difference emerged according to gender (p=0.652), BMI (p=0.655), smoking habit (p=0.466) and line of treatment (p=0.208) (figure 1B-E). Finally, the effectiveness of GLM in improving joint symptoms and cutaneous manifestations was confirmed once again, with a statistical significant improvement at 48 months in clinical (BASDAI p=0.0001; PASI p=0.01; DAPSA p<0.0001) and biochemical (CRP p<0.05) data.

**Conclusion:** This multicentric study revealed a high drug persistence of GLM in real-life patients, although the presence of comorbidities. Unlike what is known in literature, our study population presented no differences in terms of clinical response and efficacy between male and female, smokers and no-smokers, obese and health-weight patients, different line of treatment. On the other hand, efficacy and safety of GLM has been demonstrated once again also in real-life treatments.

**References:** No references.
Methods: This study involved patients with axSpA with acute sacroiliitis, ≥18 and ≤65 years old, with body mass index (BMI) < 30 kg/m² attending the Rheumatology Outpatient Clinic, which had been poorly controlled (ASDAS-CII ≥ 2.1) by conventional therapy (physiotherapy, NSAIDs at maximum tolerated dosing during ≥ 4 weeks). Sociodemographic, clinical (disease duration, BMI, BASDAI, ASDAS) and laboratory (CRP) data was collected from the medical records at baseline and at 4-6th weeks. Statistical analyses were conducted using SPSS version 25. Continuous variables were described with mean/median ± standard deviation (SD). Results: At 4-6-th weeks there was a decreased in median (±SD) BASDAI (5.4±1.9 vs 4.1±1.9), BASFI (4.2±1.4 vs 3.5±2.3) and ASDAS (3.2±0.8 vs 2.2±0.6) indexes. Conclusion: As previous studies demonstrated, this technique seems to be safe and quite effective. Our goal is to increase the number of patients undergoing this technique and have a longer follow up to evaluate its efficacy. The study has several limitations: the mid- and long-term effects should be evaluated in the future based on the results of the short-term effects and the study was not conducted as a double-blind, controlled study.

Diaz Oca1.1 HU Fuenlabrada, Madrid, Spain; 2H de la Tajo, Aranjuez, Spain; 3HU La Paz, Madrid, Spain; 4HU Infanta Elena, Valdemoro, Spain; 5HU Torrejon, Torrejon de Ardoz, Spain; 6Universidad Rey Juan Carlos, Madrid, Spain.

Background: Secukinumab inhibits the interaction between interleukin 17A (IL-17A) and its receptor. Clinical trials have demonstrated good data in efficacy and safety in patients with spondyloarthritis (SpA) as first biological choice or inadequate response to other biological in SpA. However there is few evidence in real clinical practice. Objectives: Evaluate the drug survival in a real clinical practice, as an indirect way to show the efficacy and safety of Secukinumab at 24 months.

Methods: This study involved patients with axSpA with acute sacroiliitis, ≥30 years old, with body mass index (BMI) < 30 kg/m² attending the Rheumatology Outpatient Clinic, which had been poorly controlled (ASDAS-CII ≥ 2.1) by conventional therapy (physiotherapy, NSAIDs at maximum tolerated dosing during ≥ 4 weeks). Sociodemographic, clinical (disease duration, BMI, BASDAI, ASDAS) and laboratory (CRP) data was collected from the medical records at baseline and at 4-6th weeks. Statistical analyses were conducted using SPSS version 25. Continuous variables were described with mean/median ± standard deviation (SD). Results: A total of 71 patients were included. The mean age was 50.26 years (SD 11.01), 57.75% women. 35 patients fulfilled classification criteria for PsA and 36 fulfilled classification criteria for axSpA. 22 patients were naive for biologic therapies and 49 patients had an inadequate response to TNFi. 13 patients discontinued Secukinumab before the closing date, the main reason for the interruption was secondary failure (n=6), and primary failure (n=2). Secukinumab survival rate was 81.95% up to 24 months in this cohort. The median of survival was 2.36 years (IC: 1.79-2.84). There were no significant differences about the drug survival related to diagnosis (p=0.976). The safety data were similar to those described in clinical trials. Conclusion: Secukinumab is an effective and safe treatment for the management of espondioarthrits regardless of the subtypes, with a high survival rate. In this study naive patients show similar data obtained in clinical trials. In this cohort of patients, those who initiated secukinumab after failure to TNFi, showed a greater secukinumab survival than the data provided in clinical trials.

AB0644 ULTRASOUND GUIDED EPIDURAL INJECTION IN RADIOPHAGIC AXIAL SPA PATIENTS WITH LIMITED SPINE MOBILITY: A PROSPECTIVE PILOT RANDOMIZED CONTROLLED TRIAL

A. Hamed1, A. Radwan2, O. Sayed2, A. Elsamman1,1 Minya University, Minya, Egypt; 2Sohag University Hospital, Rheumatology and Rehabilitation Department, Sohag, Egypt; 3Minya University, Rheumatology and Rehabilitation Department, Minya, Egypt; 4Sohag University Hospital, Rheumatology and Rehabilitation, Sohag, Egypt

Background: Ankylosing Spondylitis (AS) is a systemic inflammatory disease of unknown origin. It affects mainly males. Chronic inflammatory back pain is the commonest presenting symptom and regularly develops between 20 and 40 years age. AS can likewise, have extra-articular manifestations. These manifestations commonly develop after the onset of axial symptoms but hardly can precede them. Even though AS is a systemic disease, the presenting symptoms, treatment, and morbidity are largely dependent on spine affection. Epidural injections for managing chronic low back pain are one of the most frequently performed interventions in the United States. Friedly et al reported administration of epidural injections in 36% of patients with axial low back pain. However, there is no clinical evidence for the use of epidural injections in axial SPA and most recommendations are limited to radicular pain with disc herniation. The evidence for causal epidural injections is Level I in managing pain secondary to disc herniation and radiculitis. To our best of knowledge, this is the first study evaluating the role of caudal epidural steroid and lidocaine injections in managing pain and function of the spine in radiographic axial SPA.

Objectives: To evaluate the significance of causal epidural injections in controlling pain and spinal stiffness in radiographic axial SPA.

Methods: In our study 32 Patients were included. They were randomly doted out into 2 equivalent groups: Group I received caudal epidural injections ultrasound guided with 1% lidocaine hydrochloride (xylocaine, AstraZeneca) 9 mL mixed with 1 mL of triamcinolone 40 milligrams (Kenacort, Bristol Myers Squip), whereas Group II did not receive. Both groups were matched regarding age, sex and disease duration (table) and both were under treatment with anti TNF and NSAIDs with or without sDMARDs. All participants fulfilled the ASAS criteria for radiographic axial SPA. Outcomes measures included: visual Analogue Scale (VAS), and ASDAS score with assessment at baseline, 2 weeks and 8 weeks post-treatment. Significant pain relief was defined as 50% or more or no pain. ASDAS improvement is considered when the score reduction ≥ 1.1.

Results: There was a significant difference between both groups regarding pain (Figure 1) and ASDAS scores (Figure 2) in favor of group I. This effect was maximum after 2 weeks interval. More than two thirds of the cases (68.8%) had significant pain relief among group 1, compared to only 18.8% among group 2. Despite the decline of this effect after 8 weeks, still the difference significant between both groups. Shorter disease duration and older age of onset were associated with better outcomes among group 1 but not group 2. However, these correlations were non-significant.
**Conclusion:** Caudal epidural injection is cheap, effective and practical technique in controlling pain and stiffness of the spine in radiographic axial SPA with acceptable complications and relatively sustained effect. Studies including bigger numbers of participants and longer span of follow up still required.

**Table. Comparison between the two groups as regards demographic and outcome data**

**PREDICTORS OF THE EFFECTIVENESS OF INTRA-ARTICULAR GLUCOCORTICOID INJECTIONS IN RHEUMATIC HIP INVOLVEMENT**

H. Ferjani1, L. Ben Ammar1, K. Maatallah1, D. Ben Nessib1, D. Kafile1, W. Hamdi1, 2Kassab Institute, Rheumatology, Tunis, Tunisia

**Background:** Hip involvement in chronic inflammatory rheumatic diseases is a turning point in the course of the disease because of disability and functional impairment. Total joint replacement surgery rate in spondyloarthritides increased 40% despite the use of Disease-modifying anti-rheumatic drugs (DMARD) and biologic treatment. Intra-articular glucocorticoid injection may help prevent hip joint replacement surgery and radiographic progression.

**Objectives:** This study aimed to determine predictive factors of the steroid injections’ efficiency in chronic inflammatory rheumatic diseases with hip involvement.

**Methods:** This is a retrospective study over a 13-years (2006-2019) that included patients followed for chronic inflammatory rheumatic diseases complicated by hip involvement and underwent intra-articular glucocorticoid injection.

**Results:** Forty-two patients were enrolled: 32 male (76.2%) and 10 women (23.8%). The average age was 27 years [6-73] at the time of the steroid injection. Ankylosing spondylitis (AS) was present in 73.8% of cases (radiographic axial spondylarthritides 90.3%, Psoriatic spondylitis 6.5% and peripheral enthesitis 3.2%) and juvenile idiopathic arthritis (JIA) in 26.2% of cases (enthesis-related arthritis 63.8%, olioarticular JIA 18.2%, seronegative polyarticular JIA 9.1% and juvenile psoriatic arthritis 9.1%). Active smoking was found in 47.6% of cases. All patients were on DMARD: NSAIDs (19%), methotrextate (42.9%), salazopyrin (23.8%), combination of methotrextate and salazopyrin (2.4%) and anti-TNF alpha (7.1%).

Hip involvement was bilateral in 81% of patients. Examination revealed pain and limited hip mobility in all cases. Radiographic forms in AS were: early coxitis (17.2%), condensing form (17.2%), destructive form (58.6%), synostosante (3.4%) et combined (3.4%). During JIA, hip involvement was destructive in 45.4% of cases and minimal to moderate in the remaining cases.

Lequesne algofunctional index averaged 11 (3-18). An improvement was reported in 63.4% of cases. Statistically significant decrease was found in the BASDAI score, visual analogue scale (VAS) for general health status as estimated by the patient and C-reactive Protein (CRP) (p=0.001; p=0.01 and p=0.03; respectively).

There was no statistically significant difference between the efficacy of intra-articular glucocorticoid injection and sex, age, smoking, diagnosis and whether the hip involvement was bilateral or not (p=0.5; p=0.2; p=0.8 and p=0.1; p=0.6; respectively). Steroid injections were less effective in patients treated with biologics (p=0.04). However, it was more effective in AS with early hip involvement (p=0.03).

**Conclusion:** Hip involvement is a negative prognostic factor in chronic inflammatory rheumatic diseases. Therefore, early diagnosis and management is essential in order to slow down the structural progression and the need for prosthetic surgery.

**IS IT FEASIBLE TO ACHIEVE RECOMMENDED THERAPEUTICAL TARGET IN PATIENTS WITH AXIAL SpondylarthritIS IN CLINICAL PRACTICE? DATA FROM THE SPA-PAZ COHORT**

K. N. Franco Gomez1, C. Plasencia1, M. Novella-Navarro1, D. Benavent1, P. Bogas1, R. Nieto1, I. Monjo1, L. Nuño1, A. Villalva1, D. Peiteado1, A. Balsa1, V. Navarro-Compar1, 1University Hospital La Paz, Rheumatology, Madrid, Spain

**Background:** Current ASAS/EULAR recommendations for the management of patients with axial spondylarthritides (axSpA) establish that the therapeutic goal to achieve in clinical practice is remission, defined as the absence of both clinical and laboratory disease activity estimated by BASDAI&CRP or preferably ASDAS and if this is not possible, low disease activity may be an alternative. Recently, ASDAS nomenclature has been modified, calling now low disease activity to what was previously called moderate activity. To this day we do not know if this target is feasible in clinical practice.

**Objectives:** To analyze the frequency of patients with axSpA achieving maintained remission (R) or low disease activity (LDA) after receiving biological therapy. Secondary objectives included: i) to assess if the activity index used influences the frequency of maintained R/LDA, ii) analyze the prognostic factors for achieving maintained R/LDA.

**Methods:** An observational, longitudinal study of a prospective cohort (Spa-Paz) including all patients with axSpA who initiated their first biological treatment between the years 2003-2017. Demographic, clinical and analytical data were collected at the beginning of treatment and clinical disease activity measured by BASDAI&CRP and ASDAS every 6 months for 2 years. Maintained R was defined as (BASDAI<2 & normal CRP and/or ASDAS <1.3) and maintained LDA (BASDAI<4 & normal CRP and/or ASDAS <2.1) on at least 3 consecutive visits.

Statistical analysis: i) measures of central tendency and dispersion for quantitative variables and frequencies for qualitative variables; ii) univariate and multivariate analysis of binomial logistic regression model and calculation of OR and 95% CI.
Results: Out of 186 patients with axSpA who started treatment during the study period, 63% were men with a mean age of 54 ± 14.1 years. 75.3% of the patients had radiographic axSpA and 74.7% were HLA-B27 positive. Other baseline characteristics (not shown due to space restrictions). Overall, 80% of the patients achieved ASDAS R/LDA (R36%/LDA44%) in at least one of the visits after 2 years of follow-up, but only 40% (R27%/LDA13%) fulfilled the maintained ASDAS R/LDA state. On the other hand, 73% of patients were classified as BASDAI&CRP R/LDA (R31%/LDA42%) in at least one the visits, but only 31% (R21%/LDA10%) obtained the maintained BASDAI&CRP R/LDA state. In the multivariate analysis, we observed an independent statistically significant association with male sex (OR=3.19; 95% CI=1.46-6.99), younger age at the beginning of the biological treatment (OR=0.97; 95% CI=0.95-0.99) and the use of methotrexate (OR=3.07; 95% CI=1.39-6.78) in male sex who achieved maintained BASDAI&CRP R/LDA and with male sex (OR=4.01; 95% CI=1.83-8.77), younger age at the beginning of the biological therapy (OR=0.96; 95% CI=0.94-0.99) and HLA B27 presence (OR=4.30; 95% CI=1.68-11.01) in patients who achieved maintained ASDAS R/LDA.

Conclusion: Although the majority of patients with axSpA who initiate biological therapy achieve the recommended therapeutic goal in the first two years of treatment, the percentage of patients who manage to maintain the R/LDA status is limited. In our study, maintained R was more frequent than maintained LDA, being somewhat higher when measured by ASDAS. This fact may suggest that patients who achieve maintained R have a greater inhibition of their inflammatory activity and, therefore, it remains in time. Male sex and younger age at the beginning of the biological therapy were the main baseline predictors for achieving maintained R/LDA.

Conclusion: To the best of our knowledge, this is the first study evaluating the clinical and radiological efficacy and tolerability of r-ESWT in patients with PF in axial-SpA. Radial extracorporeal shock wave therapy is safe and tolerable treatment on chronic PF in patients with axial-SpA.

AB0647 The Effect of Extracorporeal Shock Wave Therapy (ESWT) on Plantar Fasciitis in Patients with Axial Spondyloarthropathies: Double-Bind, Randomized Controlled Trial

S. Güneş1, Ö. C. Caner2, D. Gökmen3, Ş. Ataman4, Ş. Kutlay5
1Ankara University School of Medicine, Physical Medicine and Rehabilitation, Ankara, Turkey
2Ankara University School of Medicine, Biochemistry, Ankara, Turkey
3Ankara University School of Medicine, Physical Medicine and Rehabilitation, Rheumatology, Ankara, Turkey

Background: The effectiveness and safety of radial extracorporeal shock wave therapy (r-ESWT) on chronic plantar fasciitis (PF) in patients with axial spondyloarthropathies (SpA) remains unclear.

Objectives: To investigate the efficacy and tolerability of r-ESWT in patients with PF in axSpA on the clinical and radiological parameters.

Methods: In this double-blind, randomized controlled trial, 22 axial-SpA patients with PF whom have heel pain above 5 according to Visual Analog Scale (VAS) over 3 months were randomly divided into two groups: r-ESWT (1.8 bar pressure, 10 Hertz frequency, 500 pulse intensity) and sham ESWT. Both groups received a total of 3 treatments at one week intervals. All patients were assessed by using the VAS, heel pressure algometry, Foot Function Index and plantar fascia ultrasonography (thickness, convexity, echogenicity of PF, presence of perifascial fluid and subcutaneous tissue edema) at baseline, one week after each session and 4th and 8th week after the last therapy. A decrease of more than two units on the VAS and improvements on plantar fascia ultrasonographic assessments was considered as primary and secondary endpoints respectively.

Results: Descriptive data of the patients are presented in table 1. Both groups showed significant improvements in all assessment parameters (p<0.05) after the therapy sessions and at the 4th and 8th week follow-up. No serious adverse event was observed in any patient. When two groups were compared regarding the differences in improvements, no statistically significant difference was found between the r-ESWT and sham ESWT groups in any of the parameters (p>0.05).

Conclusion: The effectiveness and safety of radial extracorporeal shock wave therapy (ESWT) in patients with axial-SpA remains unclear.

AB0648 Comparing Symptoms, Treatment Patterns, and Quality of Life of Ankylosing Spondylitis Patients and Non-Radiographic Axial Spondyloarthritids in Japan

T. Tomita1, T. Aranishi2, K. Hagimori2, K. Nakajo3, N. Booth3, E. Holdsworth1, T. Hunter4, Osaka University, Osaka, Japan; Lilly, Kobe, Japan; Adelphi, Folkestone, United Kingdom; Lilly, Indianapolis, United States of America

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease of the axial skeleton associated with impaired health-related quality of life (QoL) and disability.

Objectives: To better understand the symptoms, clinical characteristics, treatment patterns, and quality of life (QoL), of non-radiographic axial spondyloarthritids (nr-axSpA) patients and how they compare to ankylosing spondylitis (AS) patients in Japan.

Methods: Data from a cross-sectional survey conducted with physician (rheumatologists, orthopedic surgeon, and internal medicine) and their consulting
patients in Japan were analyzed. Data were collected from Jun-Aug 2018 via
physician-completed patient record forms and patient self-completed forms.
Patients who had physician confirmed diagnoses of AS and nr-axSpA were
eligible to participate. Demographics, disease status (improving, stable, unsta-
ble, deteriorating), symptoms, and medication use were reported by the phy-
sician, while work disability and QoL measures were reported by the patient
using validated questionnaires. QoL and treatment patterns of nr-axSpA and
AS patients were compared using parametric tests and non-parametric tests
where appropriate.

Results: Data from 41 physician, 72 AS patients, and 91 nr-axSpA patients
were included in this analysis. A higher proportion of AS patients were male
(70.8% vs. 58.2%; p=0.1040), yet this was not statistically significant. AS
patients had a similar mean age (55.0 vs. 55.1; p=0.9762) compared to nr-
axSpA patients. The majority of AS and nr-axSpA patients (61.1% vs. 62.9%;
p=0.872) were not receiving a biologic. On average, AS and nr-axSpA patients
reported similar rates of symptoms (Table 1). Patient reported outcomes such
as the Assessment of SpondyloArthritis International Society Health Index
(ASAS HI; 6.0 vs. 6.4; p=0.6103), Patient Global Assessment (18.7 vs 22.7;
p=0.4239), and the Bath Ankylosing Spondylitis Disease Activity Index (BAS-
DAI; 3.1 vs. 3.4; p=0.3453) were similar between AS and nr-axSpA patients. AS
patients reported a lower EQ-5D VAS (62.6 vs. 71.3; p=0.0237) when compared
to nr-axSpA patients.

Conclusion: Nr-axSpA and AS being part of the same disease spectrum (i.e.
axial spondyloarthritis) share the same clinical features. The burden of the dis-
case, as assessed by QoL measurements, is also similar in AS and nr-axSpA
patients.

AB0649
REAL WORLD EFFICACY OF SECUKINUMAB: A
SINGLE CENTRE EXPERIENCE

G. Kasavkar1, T. Blake2, N. Gulick3. 1University Hospital Coventry &
Warwickshire, Rheumatology, Coventry, United Kingdom; 2University
Hospital Coventry & Warwickshire, Rheumatology, Coventry, United
Kingdom; 3University Hospital Coventry & Warwickshire, Coventry,
United Kingdom

Background: Secukinumab was approved by NICE for patients with active
Ankylosing Spondylitis and Psoriatic Arthritis in 2017. Clinical trial data suggests
secukinumab is a useful treatment option in both conditions, but often real world
experience differs greatly from clinical trial results. In addition, patients with more
refractory disease are often excluded from clinical trials.

Objectives: To assess the response to secukinumab in patients with seroneg-
avative spondyloarthropathy receiving treatment at University Hospital Coventry
and Warwickshire

Methods: Patients starting secukinumab at UHCW were identified from the
BlueTec funding database. Medical notes were reviewed retrospectively to assess response rates using BASDAI responses in Ankylosing
spondylitis and PsA and PsARC responses in PsA. Patients who had previously
had inadequate response to TNF inhibitors (PsA only) and severe psoria-
sis received 300mg secukinumab monthly; the remainder were prescribed
150mg monthly.

Results: 146 patients commenced secukinumab between June 2017 and Janu-
ary 2020 and had outcome data recorded. 73 patients (50%) had received previ-
ous biologic agents prior to secukinumab exposure. Patients with Ankylosing
spondylitis had high BASDAI (6.8±1.4) and spinal pain (7.5±1.4). 46 patients had
an initial response to treatment as per outcome measures done before and after
Secukinumab inception. Secukinumab was effective in 89 patients (94%), and 87
(91%) continued treatment.

In psoriatic arthritis, despite high levels of activity at baseline (mean tender
joint count 10±8; swollen joint count 6±3) and 65% prior biologic exposure; high
rates of response were seen. The majority of patients have continued treatment.
Secukinumab was well tolerated in both patient groups with low rates of dis-
continuation due to adverse events (8 patients, 5%). Adverse events included
recurrent infection (3), rash (1), mouth ulcers (1), vertigo (1), new onset can-
cer (1) and new onset Crohn’s (1) although rates were low overall. Patients with pre-
existing uveitis did not develop exacerbations but low numbers of patients prior uveitis were treated.

*Response could not be assessed in 3/51 PsA patients due to insufficient clinical data; these patients have been recorded as non responders

Conclusion: Secukinumab demonstrates high levels of efficacy even in a
cohort of patients with longstanding PsA and AS with high rates of inadequate
responses to other biologics.

Secukinumab is well tolerated with low rates of discontinuation due to adverse
events. References: Certolizumab pegol and secukinumab for treating active psoriatic
arthritis after inadequate response to DMARDs Technology appraisal guidance

Background: Biosimilar infliximab (bio-INF) was approved for all indications of the reference product in several countries. It has been marketed since 2014 in Turkey and used in the same indications with its bio-originator.

Objectives: Herein, we aimed to analyse clinical features and the drug survival rates of spondyloarthritis patients who have received bio-INF.

Methods: This multicenter, prospective observational cohort study used the TREASURE database in which web-based registration of rheumatoid arthritis and SpA patients are being performed in 13 centers across different regions of Turkey. Age, gender, and acute phase responses (erythrocyte sedimentation rate and C-reactive protein), HAQ scores, PAS patient global, VAS fatigue, VAS pain, PAS physician global, BASDAI, BASFI, ASDAS ESH and ASDAS CRP values, clinical findings of SpA patients, number of patients who has received bio-INF as first line therapy or after switch, treatments which are used before bio-INF, the reasons for switching bio-INF to another biologic DMARD and drug survival rates were retrospectively evaluated.

Results: A total number of 231 SpA (94 (40.7 %) female, 137 (59.3%) male, mean age 43±11 yrs) patients have received biosimilar infliximab in the database. Of the 231 patients 127 (55%) had received bio-INF as first line therapy, whereas 104 (46 (19.9%)) 2nd choice, 58 (25 (1.5%)) 3rd choice patients used switching after another biologic DMARD. Previously used biologic and synthetic DMARDs were adalimumab (26.6%), etanercept (22.5%), golimumab (8.1%), original infliximab (8.2%), secukinumab (13.4%), methotrexate (23.8%), lefunomide (10.4%), sulfasalazine (60.6%). The baseline and first visit (3 Months) diseases activity scores were shown in Table 1. Drug survival rates were 79.1 in 12. months, 65.5 in 24. months and 54.6 in 60. months. (Figure 1). The most common reasons for switching from biosimilar infliximab to another biologic DMARD is secondary inefficacy (25 (10.8%)), and primary ineffectiveness (22 (8.9)). Other reasons to discontinuation of treatment are psoriasis (5 (2.1%)), infusion reaction (3(1.2%)), allergic reaction (22 (8.8%)), chest pain (3 (1.2%)), dyspnea (1 (0.4%)), vasculitis (1 (0.4%) and patient or doctor wish (7 (3.4%)).

Conclusion: The results of this real life data provides evidence that biosimilar infliximab is an effective and safe treatment option with long term use in SpA patients. Drug survival rates of bio-INF is similar to its bio-originator.

AB0653
SURVIVAL OF BIOLOGIC THERAPY AS SECOND LINE TREATMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS. EXPERIENCE IN A TERTIARY CARE CENTRE
F. López Gutiérrez,1 V. García García,1 A. Andreu-Suárez,1 B. A. Blanco Cáceres,1 J. Bachiller-Corral,1 M. Vázquez Díaz.1 1Hospital Universitaria Ramón y Cajal, Madrid, Spain

Background: In ankylosing spondylitis (AS) patients with lack of response to a first line of biologic disease modifying anti-rheumatic drugs (bDMARD), switching to another bDMARD is recommended, aiming either to the same or different therapeutic target. In several previous studies a decrease in drug survival has been noted when tumor necrosis factor alpha inhibitors (TNFαi) are used as second or third treatment line (1,2).

Objectives: Primary endpoint: To evaluate survival of bDMARD as second line treatment in patients with AS non responding to TNFαi either because of lack of loss or efficacy. Secondary: To evaluate the impact on drug survival of several variables such as sex, HLA, peripheral arthritis, radiologic sacroiliitis, CRP, BASFI, BASDAI or bDMARD class.

Methods: Observational, longitudinal and retrospective observational study. We included 67 patients diagnosed with AS who received treatment on second line with bDMARD (TNFαi or anti IL7) after discontinuation of TNFαi as first line of treatment. We analyze patients older than 18 yo, with at least 3 months of continuous treatment before and after switch, seen in our Hospital from 2006 to 2019. Data were collected regarding to demographics, HLA B27 positivity and functionality and activity index, CRP and treatment with cDMARDs.

Results: All 67 patients included were still on follow up after switching to second bDMARD. Median age was 30 yo, 56.7% were male and 31%, smokers. 35.8% patients had axial AS; 15% peripheral arthritis; 62.7%, mixed and 9%, dactilitis. 76.1% had radiographic sacroiliitis and 74.6%, HLA B27. As first bDMARD, the most common was Infliximab (IFX) (47.8%), followed by Adalimumab (ADA) (19.4%) and Etanercept (ETN 14.9%). Mean survival was 32.4 months (IFX, 37 months; ETN, 45; Golimumab, 32.3 and ADA, 24.1). The commonest cause of treatment suspension was loss of efficacy (LoE) (56.7%), followed by lack of efficacy (LaE) (17.6%) and adverse effects (AE) (16.4%).

As second bDMARD the most frequent was ADA (35.8%), followed by ETN (34.3%), Golimumab (9%), IFX (7.5%) and Secukinumab (6%) with a mean survival of 45 months (ETN 63.8, ADA 45.7, Golimumab 32). Treatment was discontinued in 47.8% of patients because of LoE (17.9%), LaE (17.9%) and EA (11.3%). A total of 16 AE were recorded, of which 6% were infections and 9%, allergic reactions. Regarding the analysis of the impact of other variables on drug survival, there was statistically significant differences on HLA B27 carrier status (p=0.012), in which we observe an increase on survival when the patient is HLA B27 + and in whom BASDAI is higher before switching (p=0.02).

Conclusion: In our study, we did not observe differences in survival of second line bDMARD in patients with AS regarding type of TNFαi, case of discontinuation or type of radiographic involvement in the first line of treatment. Patients with HLA B27+ and high value of BASDAI at the beginning of second bDMARD showed an increased on drug survival. Contrary to literature, we did not see significant differences regarding CRP.

IMPACT OF GENDER ON PATIENT PROFILE AND TREATMENT RESPONSE IN ANKYLOSING SPONDYLITIS PATIENTS TREATED WITH TNF-α INHIBITORS
B. Milic1, T. Illic1, M. Popovic1, B. Erdeljan2, T. Jankovic1.1University of Novi Sad, Medical faculty; Novi Sad, Serbia; 2Medical School of the University of Medicine and Pharmacy, Belgrade, Serbia

Background: Ankylosing spondylitis (AS) is historically seen as a predominantly male disease and although recent data showed a more homogeneous sex prevalence there is still a long delay and more often a misdiagnosis in women. Also, studies showed that there might be gender-attributable differences regarding clinical characteristics, radiographic damage and response to treatment.

Objectives: The aim of this study was to assess gender differences in AS patients regarding the clinical presentation, disease activity, functional status and response to tumor necrosis factor-alpha inhibitor (TNF-α inhibitor) therapy.

Methods: This retrospective analysis included 59 AS patients treated with first TNF-α inhibitor for at least 12 weeks. TNF-α inhibitor therapy introduction and response was determined according to ASAS-EULAR management recommendations for AS. Clinical and demographic parameters were compared between the female and male patients.

Results: Twenty-four patients (40.68%) were females and 35 (59.32%) were males. Women were older than male at moment of study (p=0.049), at the time of diagnosis (p=0.05) and when starting biologic therapy (p=0.009). Moreover, they had a longer diagnosis delay (p=0.017) compared to men. Prevalence of HLA-B27 status and the rate of peripheral arthritis, dactylitis, enthesitis, uveitis or inflammatory bowel disease (IBD) were not different between two groups. Disease activity and functional status were also similar in both groups. Males had a significantly longer drug survival time for first biological (p=0.031). One female patient (4.2%) and 4 male patients (11.4%) showed primary or secondary inefficacy to TNF-α inhibitor (p=0.61). All 5 non-responders switched to second TNF-α inhibitor and showed a good clinical response. The comparison of the demographic features, clinical characteristics, disease activity, functional status and response to TNF-α inhibitor therapy according to the gender are presented in Table 1.

Conclusion: In our cohort, the presence of the female gender was related to longer diagnosis delay compared to males. Non-response rate for the first TNF-α inhibitor was similar between groups, but men had longer drug survival time for the first biological.

IMPACT OF BIOLOGIC THERAPY ON WORK IMPAIRMENT IN REAL LIFE IN AXIAL SPONDYLOARTHRITIS PATIENTS: DATA FROM REGISPONSBIO
1Hospital Universitari Parc Taulí I3PT, Rheumatology, Sabadell, Spain; 2Hospital Universitario La Paz, Rheumatology, Madrid, Spain; 3Hospital Universitario Reina Sofia IMIBIC, Rheumatology, Córdoba, Spain;
Impact of a Family History of Spondyloarthritis on TNFi Drug Survival and Treatment Response in Patients with Ankylosing Spondylitis and Psoriatic Arthritis

M. Morin, K. Helligren, U. Lindström, T. Frisell, Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden

Background: Spondyloarthritis (SpA) is known to have high familial aggregation, with a positive family history of SpA being a strong risk factor for disease development, in particular for ankylosing spondylitis (AS). While disease development, in particular for ankylosing spondylitis (AS). Despite this, the well-known characteristic of the disease, whether family history is associated with disease prognosis and treatment outcome has been much less studied. Patient characteristics predicting response to tumour necrosis factor alpha inhibitors (TNFi) in SpA include age, sex and high disease activity, but whether family history is predictive of TNFi treatment outcomes remains unclear.

Objectives: To assess the influence of family history of psoriatic arthritis (PsA), AS, or SpA in general is associated with a different drug survival and treatment response to TNFi in patients with AS and PsA.

Methods: Patients diagnosed with AS (N=1688) or PsA (N=3216) starting their first TNFi treatment between January 2006 and December 2017 were identified in the Swedish Rheumatology Quality Register (SRQ). Disease activity measures were extracted from SRQ at treatment start and at 3 and 12 months of treatment. Data on demographics and comorbidities were available through linkage to other national registers. Multiple imputation was applied to address missing data. Family history was defined as having at least one first-degree relative diagnosed with AS, PsA or any form of SpA in the National Patient Register at start of first TNFi. Analyses were made for AS and PsA index patients separately. Kaplan-Meier plots were used to compare drug survival, and hazard ratios for drug discontinuation were estimated with Cox regression adjusting for age, sex, disease duration and baseline disease activity. The change in disease activity from baseline to 3 months of treatment, and the proportion of patients remaining on treatment at 12 months and reaching low disease activity (LDA) with BASDAI (for AS) and DAS28-CRP (for PsA), were analysed in linear regression adjusting for age, sex, disease duration and baseline disease activity.

Results: A positive family history of AS was found in 14% of AS patients, and 12% of PsA patients had a family history of PsA. Characteristics such as age, sex and baseline disease activity were similar in AS patients with and without a family history of AS. Among PsA patients, those with a family history of PsA were to a larger extent female, with lower CRP but longer disease duration. No significant differences were seen in drug survival among patients with and without a family history of their respective disease (Figure 1), with hazard ratios for drug discontinuation of 1.03 (95% CI 0.84 to 1.27) in AS patients and 1.08 (95% CI 0.94 to 1.25) in PsA patients. Using family history of any form of SpA as exposure did not change this conclusion. The changes in disease activity at 3 months of treatment compared to baseline were similar between groups. At 12 months, 55.2% of AS patients with a family history were still on treatment and had a BASDAI corresponding to LDA, compared to 56.4% of AS patients without a family history of AS. Among PsA patients, those with a family history of PsA had reached DAS28-CRP LDA, compared to 42.6% for those without a family history. For both AS and PsA, these differences were non-significant.

Conclusion: While family history of SpA is a strong predictor of disease development, family history was not found to affect neither TNFi drug survival nor treatment response in patients with AS and PsA in this register-based study.

IMPROVEMENT IN DISEASE ACTIVITY IS ASSOCIATED WITH ENHANCEMENT IN THE QUALITY OF LIFE DURING TUMOUR NECROSIS ALPHA INHIBITOR TREATMENT; A PROSPECTIVE COHORT EXPERIENCE IN AXIAL SPA

E. Otman Akat1, D. Solmaz1, E. Durak Ediboglu1, G. Kabadayı1, H. E. Oz1, H. Cınalı2, I. Kurut Aysın1, S. Guçenmez1, O. Bayındır1, M. Ozman1, S. Akar1.

1Izmir Katip Celebi University, Rheumatology, Izmir, Turkey

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory condition affecting mainly axial skeleton. The disease usually starts in early adulthood and cause considerable impact on physical function, work ability and quality of life (QoL). With the introduction of tumour necrosis factor inhibitors (TNFi) significant improvement in articular and extra-articular manifestations of disease was shown in randomized controlled trials and several registries. However, there is limited data about the effects of TNFi therapy on QoL and the relationship between inflammation and QoL in cohort studies before.

Objectives: To evaluate the influence of TNFi agents on different aspects of QoL which might be a significant determinant of patient burden in axSpA patients in parallel with disease activity.

Methods: In total 83 TNFi naïve axSpA patients (62.7% male; mean age 40.6 ± 12 years) according to the ASAS criteria were included in this prospective observational cohort study between 2014-2018. Demographic and disease related characteristics were collected at baseline. Disease activity (BASDAI, ASDAS-CRP), function (BASFI) and QoL (SF-36 and ASQoL) were evaluated at baseline and 24th and 52nd weeks of follow-up. The changes in disease activity, function and QoL were assessed with Wilcoxon test and relationship between changes in QoL and activity on week 24 was evaluated by Spearman’s correlation analysis.

Results: Baseline disease related characteristics, disease activity and QoL scores were presented in table 1. Both disease activity and QoL were significantly improved at 24th and 52nd weeks (Figure 1). The change of SF-36 subscales and summary scores at weeks 24 were correlated with the change in disease activity and function (Table 2). The SF-36 scale and summary scores were found to be similar at 24 and 52 weeks of TNFi treatment (Figure 2).

Conclusion: The results of the present study suggest that TNFi treatment have a substantial influence on QoL in parallel to the control of disease activity at 24th weeks of treatment and this effect was sustained at 52 weeks not only randomized controlled trials but also real life experience.

Background: Spinal inflammation causing back pain is a hallmark of axial spondyloarthritides (axSpA) mainly affecting the sacroiliac joints and spine. 1 Spinal pain is the most burdensome symptom resulting in substantial functional limitations and impairment of health-related quality of life.

Objectives: SKIPPAIN (NCT03136861) evaluated efficacy and safety of secukinumab (SEC) in reducing spinal pain in patients (pts) with axSpA who had an inadequate response to NSAIDs.

Methods: SKIPPAIN, a 24 week (wk), randomised, double-blind, multicentre trial, enrolled axSpA pts (aged ≥18 years) with active disease defined by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score ≥4 and average spinal pain numerical rating scale (NRS) score >4 at baseline (BL) and inadequate response to ≥2 NSAIDs ≥4 wks. The trial had a PBO-controlled period from BL to Wk 8 and a SEC 150/300 mg period from Wk 8 to Wk 24. Primary and key secondary endpoints were superiority of SEC 150 mg compared to PBO in achieving average spinal pain score <4 on a 0–10 NRS and BASDAI score <4 at Wk 8, respectively.

Results: 380 axSpA pts (269 (70.8%) AS and 111 (29.2%) nr-axSpA) were randomised to SEC 150 mg (N=285) or PBO (N=95). Demographic and BL characteristics are presented in Table 1. Proportion of responders, in terms of average spinal pain, was 31.9% vs. 20.0% for SEC vs PBO (p=0.05) and proportion of pts with BASDAI score of <4 was 33.3% vs. 23.2% for SEC vs PBO (p=0.05), respectively, at Wk 8 (Table 2). After Wk 8, responder rates increased with SEC treatment. No unexpected safety events were reported.

Conclusion: Secukinumab provided significant improvement of spinal pain in pts with axSpA. SEC was well tolerated with a safety profile consistent with previous reports. 2

LONG-TERM CLINICAL OUTCOME OF ANTI-TNF TREATMENT IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS: 10-YEAR DATA OF THE ETANERCEPT VS. SULFASALAZIN IN EARLY AXIAL SPONDYLOARTHRITIS TRIAL

F. Proft1, M. Torgutalp1, A. Weiss2, M. Protopopov1, V. Rios Rodriguez3, H. Haibel4, O. Behmer2, J. Sieper4, D. Podubnyy5,6, Charité Universitätsmedizin Berlin, Berlin, Germany, 2German Rheumatism Research Centre, Berlin, Germany, 3Pfizer Pharma GmbH, Berlin, Germany

Background: Long-term data on anti-TNF treatment in patients with early axial spondyloarthritis (SpA) is scarce.

Objectives: The objective of this analysis was to assess the long-term clinical efficacy (up to 10 years of treatment) of a tumor necrosis factor (TNF) inhibitor etanercept (ETN) in patients with early axial spondyloarthritis, who participated in the long-term (until year 10) extension of the ESTHER (Etanercept vs. Sulfasalazine in Early Axial Spondyloarthritis Trial) trial.

Methods: In the previously reported ESTHER trial, patients with early active axial SpA [including both non-radiographic axial SpA (nr-axSpA) and radiographic axial SpA (r-axSpA)/ankylosing spondylitis (AS)] with a symptom duration of <5 years and a positive MRI of the sacroiliac joints (SIJs) and/or the spine were treated with ETN (n= 40) or sulfasalazine (SSZ) (n= 36) during the first year (1). At year 1, all patients who were not in remission continued with ETN or switched (in case of SSZ therapy) to – ETN for up to 10 years in total (1). Patients in remission discontinued their therapy and were followed-up until end of year 2; in case of remission loss, ETN was (re)-introduced and continued till the end of year 10.

Results: Out of 76 initial patients, 25% (n=19, 12 with r-axSpA and 7 with nr-axSpA) completed year 10 of the study. At baseline, completers were significantly more often male and showed lower values of patient (PGA) and physician global assessments of disease activity (PhGA), ASDAS (Ankylosing Spondylitis Disease Activity Score), BASMI (Bath Ankylosing Spondylitis Metrology Index), and AS-QoL (Ankylosing Spondylitis Quality of Life Questionnaire) as compared to non-completers (Table 1). When analyzing clinical data of the completers, mean BASDAI, BASFI and ASDAS values were constantly ≤2 during the follow up with no statistically significant differences between the r-axSpA and nr-axSpA subgroups (Table 2, Figure 1B). In the entire group, a sustained clinical response was observed over 10 years of follow up (Figure 1A). A total of 39 serious adverse events were documented over the 10 years of the study, while six of them were seen as possibly associated with ETN treatment, which lead in five patients (one lymphoma, one sarcoidosis, one demyelinating neurological disease, one elevated liver enzymes and one recurrent minor infections) to an ETN discontinuation.

Conclusion: A sustained clinical response was shown over the 10 years of the study for the completers with comparable rates between r-axSpA and nr-axSpA. ETN was well tolerated across the entire treatment period and showed a good safety profile with no new safety signals.

Acknowledgments: The ESTHER study was supported by an unrestricted research grant from Pfizer.

Figure 1: Observed response rates to etanercept (A) and the course of disease related parameters in study completers (n=19) (B).
cancer immunotherapy that the therapeutic response may be strongly altered by co-medication with drugs interfering with the gut microbiota, such as antibiotics, proton pump inhibitors (PPI), non-steroidal anti-inflammatory drugs (NSAIDs), psychotropic or antidiabetic drugs.

**Objectives:** Considering the potential role of the gut microbiota in the pathophysiology of SA as in the therapeutic response, the aim was to study the influence of co-medications known to interfere with the microbiota with the therapeutic response to TNF-i in SA patients.

**Methods:** We retrospectively reviewed the charts of all patients treated in our department with a first TNF-i from 2009 to 2018. Data collected were demographic information, HLA-B27 status, disease characteristics... Patients were classified as responder (R) or non-responder (NR) according to the BASDAI (≥ 40/100) value at M6 or to the clinician judgment (when BASDAI was not available). Regarding co-medications, we collected all drugs known to interfere with the gut microbiota that were administered 1 month before and during the first 3 months of the TNF-i treatment. We only considered drugs given to more than 5% of patients. Quantitative data were expressed as mean ± standard deviation, and qualitative variables as percentages. Univariate and multivariate analyses were performed to evaluate the relationship between co-medications and TNF-i. All analyses were computed on STATA 13.1 software with a statistically significant threshold of 0.05.

**Results:** We included 188 patients suffering from ankylosing spondylitis (n=89) or peripheral SA (n=99). They were 68 women and 120 men, mean aged 46.6 ± 13; 53% were B27 positive. TNF-i was infliximab (19%), etanercept (44%), adalimumab (34%) golimumab (2%), certolizumab (1%), combined with MTX in 51 patients. 135 patients (72%) were R and 53 (28%) NR. In univariate analysis, 59.1% of patients who received NSAIDs were R, compared to 88.2% of patients not treated with NSAIDs (p<0.0001); 42.2% of patients treated with psychotropic drugs were R compared to 86.3% of patients PPI free (p<0.0001); 55.8% of patients who were given antibiotics were R, compared to 75.7% of patients who did not (p=0.02); 27.8% of patients treated with psychotropic drugs were R, compared to 75.9% of patients not receiving such treatment (p<0.0001) (Figure 1). Differences were not statistically significant for corticosteroids, MTX, angiotensin-converting enzyme inhibitors and statins. Although 91% of patients taken PPIs were also given NSAIDs, NSAIDs, PPIs and antibiotics intake were considered as independent factors associated with TNF-i failure in multivariate analysis.

**Conclusion:** Co-medication with NSAIDs, PPIs, antibiotics and psychotropic drugs were significantly associated with a decreased chance to respond to TNF-i. The hypothesis that this effect is due to their interference with the gut microbiota is only speculative but, regardless the reason of this interaction, clinician should be aware of the potential negative effect of these co-medication on TNF-i.

Efficacy of Biological Therapy in Treatment of Ankylosing Spondylitis in Serbia

T. Zivanovic Radnic,1,2 J. Cvetkovic,2 B. Erdeljan,3 M. Veselincovic4,6 B. Milic7, M. Sekif Buklicica1,2, N. Damjanov2,2 J. Vojinovic3.1 Institute of Rheumatology, Belgrade, Serbia; Faculty of Medicine, University of Belgrade, Belgrade, Serbia; Niska Banja Institute, Rheumatology department, Nis, Serbia; Clinical Center Kragujevac, Kragujevac, Serbia; Faculty of Medical Sciences, University of Kragujevac, Department of Internal Medicine, Kragujevac, Serbia; Clinical Center Vojvodina, Novi Sad, Serbia; Clinical Centre, Faculty of Medicine, University of Nis, Rheumatology Department, Nis, Serbia

Background: Patients with ankylosing spondylitis (AS) are treated in accordance with the 2016 ASAS / EULAR recommendations. Patients with AS are treated in reference centers (Institute of Rheumatology in Belgrade, Institute “Niska Banja,” Special Hospital Novi Sad, KC Vojvodina and KC Kragujevac) from 2009-2018.

Methods: Retrospective insight into the database of patients treated with biological therapy in reference centers (Institute of Rheumatology in Belgrade, Institute “Niska Banja,” Special Hospital Novi Sad, KC Vojvodina and KC Kragujevac) from 2009-2018. Disease activity was monitored by the BASDAI, BASFI and ASDAScrp index.

Results: Of the 250 patients, 185 were male. The mean age at diagnosis was 33.02 ± 11.17 years. The mean length of treatment prior to initiation of biological therapy was 6.55 ± 7.82 years. There was a statistically significantly shorter duration of illness before the introduction of biological therapy in those who subsequently remained on the first drug (5.91 ± 7.53 vs 8.48 ± 8.48 years p = 0.046, p <0.05). The mean age at TNF alpha inhibitor administration was 39.61 ± 11.33 years. Patients who remained on the first drug were significantly younger when starting treatment with TNF inhibitors compared with patients who changed the first drug (58.75 ± 11.29 vs 42.46 ± 11.11 years p = 0.029, p <0.05). Those who changed the first drug were statistically longer treated with biological drugs (36.9 ± 30.03 vs 56.33 ± 32.4 months p = 0.0001). There were more patients with dactylitis and HLAB27 + in the group remaining on the first drug (p <0.05) and more with inflammatory bowel disease in the group who had changed in drug (p <0.05). The duration of etanercept therapy as the first drug was 49.11 ± 36.37 months, with the second drug 24.26 ± 27.08, and with the third drug 45 ± 45.2 months. Treatment with adalimumab as the first drug lasted for 28.34 ± 21.28, for the second drug 21.61 ± 14.57, for the third 3.5 months. Golimumab therapy as the first drug lasted 25.85 ± 14.58, with the second drug 20.33 ± 19.13, and as the third drug for 24 months. Therapy with infliximab as the first drug lasted 28.36 ± 23.52, with the second drug 20.3 ± 20.09, and with the third 16.5 months. According to the ASDAScrp index, 185 patients had very high disease activity (VHDA) before the first drug, high activity (HDA) 63, moderate activity (MDA) 2. At the time of the intersection, 8 had VHDA, HDA 48, MDA 106, and there were 88 patients in remission. There are 8 patients in the VHDA group who started treatment with the current drug less than 6 months ago. There are 48 patients in the HDA, of whom 17 who started treatment with the current drug less than 6 months ago, one at the time of the intersection had a urinary tract infection and high CRP, and the remaining 30 were patients with no significant decrease in ASDAS index (16 on first drug, 12 on the second drug and 2 patients on the third drug).

Conclusion: In patients with AS who do not have a good response to the first anti TNFα drug, a good option to continue their treatment is to switch to the second and third drugs of the same mechanism of action (anti TNFα drug).

Key words: ankylosing spondylitis, TNFα inhibitors, efficacy

21. Spondyloarthritis - clinical aspects (other than treatment)

AB0664 Diagnosis Delay in Ankylosing Spondylitis Patients in Egypt: Factors, Socioeconomic and Clinical Outcome

F. I. Abdelrahman1, M. Mortada1, Zagazig University, Rheumatology and Rehabilitation, Zagazig, Egypt

Background: Ankylosing spondylitis (AS) is a destructive inflammatory disease which was reported to have the longest diagnostic delay among the inflammatory rheumatic disease. This lag period have a great impact on the clinical outcome and socioeconomic state of the patients. With the advent of tumor necrosis factor-α (TNF-α) inhibitors, early diagnosis in AS has become important.

Objectives: to evaluate the period from symptom onset to diagnosis of AS in Egyptian patients and to examine possible reasons for delayed diagnosis and its impact on the economic and social life of the patients.

Methods: The study included 87 AS patients diagnosed according to the Assessment of Spondyloarthritis international Society (ASAS) criteria (2). A face-to-face interview was applied to take medical history, and a questionnaire that contains some clinical aspects of disease was used. Diagnosis delay was described as the gap between first AS symptom and correct diagnosis of AS. Clinical and functional assessment of axial SpA measured by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASI), Bath Ankylosing Spondylitis Metabolity Index (BASMI). The direct medical cost during years of delay (including costs of medical consultations, medications, investigations, physiotherapy and surgical treatment) had been estimated by Egyptian pound.

Results: The study included 87 AS patients with mean age (30.03±8.3), 70 male (80.5%) and 17 female (19.5%). Mean delay in diagnosis was (5.7 ± 4.9) years. Mean of diagnostic delay for patient diagnosed before 2010 is (14.4±4.4) and that of patients diagnosed after 2010 is (3.5±1.8) with significantly difference between both (p-value 0.001). The main cause of delay was incorrect diagnosis as follow degenerative disc disease (43/87, 49.4%), non-specific back pain (31/87, 35.6%), rheumatoid arthritis (10/87, 11.5%), rheumatic fever (2/87, 2.3%) and tuberculosis of spine (1/87, 1.1%). The mean of the medical visits was (6±5.4). Most incorrect initial diagnoses were made by orthopedicians (57%), followed by neurologists (22.2%) followed by rheumatologist (10%) and general physicians (9.9%). Absence of extra-articular manifestations, negative family history and juvenile age are significantly associated with diagnostic delay. Delay in diagnosis is significantly associated with higher disease activity index(BASDAI), functional index (BASI), and damage index(BASMI). The mean of the costs during years of delay is (15671.3±54.1) with the mean of cost per each year delay (660.9±6.6) with high significant association between the cost and longer delay in diagnosis (-0.001). Regarding work ability, we found that(32.2%) are fit for work, until (29.9%), partially fit (37.9%) with high significant difference between ability of work and shorter delay. Regarding social effect, 40.2 % of patients developed negative effect on social life with significant association to diagnostic delay (0.004).

Conclusion: Our study confirmed the importance of early diagnosis of AS due to its impact on patient’s health outcome and socioeconomic state. We recommend to increase the awareness about the disease among healthcare professionals in our region.

AB0665 Valvulopathy, Systolic and Diastolic Dysfunction in Axial Spondyloarthritis: A Systematic Review and Meta-Analysis

F. Adelin,1 X. Romand,1,2 M. Daley,1 A. Pflimlin,2 D. Wendling,1 P. Gaudin,1,2 P. Claudepierre,2 M. Dougados,2 A. Bailer1,1 CHU Grenoble Alpes, Rheumatology, Grenoble, France; Université Grenoble Alpes, GREPI, Grenoble, France; 2Lille University Hospital, Rheumatology, Lille, France; CHRU Besançon and Université Bourgogne Franche-Comté, Rheumatology, Besançon, France; 3University Paris Est Creteil, Henri Mondor Hospital, Rheumatology, Creteil, France; 3Hôpital Cochin. Assistance Publique – Hôpitaux de Paris, Rheumatology, Paris, France

Background: Axial Spondyloarthritis (ax-SPA) displays an increased cardiovascular disease (CVD) risk compared with the general population. Although ischemic cardiac manifestations are well known, prevalence of non-ischemic manifestations such as myocardial dysfunction and valvulopathy is less clear.

Objectives: To compare prevalence of myocardial dysfunction and valvulopathy by ultrasound in ax-SPA patients and versus healthy controls.

Methods: Two investigators independently searched for studies indexed in PUBMED, Cochrane Library and EMBASE databases and published before January 17th 2020. The search was focused on ultrasound evaluation of myocardial

EULAR Scientific Abstracts 2020
function and valvulopathy, with two-dimensional, Doppler, tissue Doppler, and speckle tracking echocardiography. We included for meta-analysis all controlled studies including axSpA without previous cardiovascular disease. Data were pooled using appropriate random or fixed effects model.

**Results:** Literature search retrieved of 186 abstracts. A total of 31 papers were included in the systematic review and 27 papers were analyzed in the meta-analysis (1,494 axSpA patients and 1,091 healthy controls). Studies displayed cross-sectional design and included axSpA without prevalent cardiovascular disease.

AxSpA was defined according to the modified New York criteria (24 studies) followed or the ASAS criteria (2 studies). HLA B27+ positivity ranged from 51 to 100%, mean age ranged from 26.7 to 55.7 years, disease duration ranged from 3.2 to 23.3 years and mean BASDAI ranged from 1.24 to 5.6.

Patients with axSpA displayed a lower diastolic function with a lower E/A ratio, a higher deceleration time, a higher isovolumetric relaxation time and a lower systolic function with a lower ejection fraction (figure 1). Left-ventricular end diastolic and systolic diameters were higher in axSpA patients with respectively mean difference 0.55 mm [CI95%: 0.19, 0.91] and 0.79 mm [CI95%: 0.40, 1.17]. We did not find any difference for left and posterior ventricular thickness, left atrial dimension, and left ventricular mass index.

![Figure 1. Systolic and diastolic dysfunction is slightly altered in axSpA patients compared to healthy individuals](image)

A total of 15 articles reported prevalence of valvulopathy in axSpA. Prevalence of mitral regurgitation and aortic regurgitation were similar in axSpA patients and healthy individuals: OR=1.13 [CI95% 0.76, 1.68] and OR=1.18 [CI95% 0.68, 2.04].

**Conclusion:** Prevalence of valvulopathy was similar in axSpA and healthy individuals. Diastolic and systolic function seems to be slightly altered in axSpA compared to healthy controls. However, this difference is unlikely clinically relevant. Usefulness of systematic echocardiography remains to be determined in future longitudinal studies.

**A Comparison of Clinical Features and Predictors of Treatment Response in Spondyloarthitis Patients in the Middle East: A Cross-Sectional Multinational Study**

J. Al-Saleh1, M. P. Abi Saab2, A. Negm1, F. Balushi3, R. Namas4, N. Ziade5.

1Dubai Hospital, Rheumatology Department, Dubai, United Arab Emirates; 2Al Ahli Hospital, Qatar, Qatar; 3Royal Hospital, Muscat, Oman; 4Cleveland Clinic, Abu Dhabi, United Arab Emirates; 5Hotel-Dieu de France Hospital and Saint-Joseph University Beirut, Beirut, Lebanon

**Background:** Spondyloarthritides it is a chronic inflammatory disease with heterogeneous clinical features. Its prevalence ranges between 0.2%-2%. Over the years biological therapy has improved work productivity and activity impairment in people with SpA. Unlike in rheumatoid arthritis, the concept of treat-to-target is still debatable among rheumatologist. However, there is a consensus that treatment in patient with SpA should be personalized. There are several challenges in the Middle East that might affect providing personalized medicine to patients with SpA in the region.**

**Objectives:** The objective of the study is to explore factors that interfere with achieving clinical targets in patients with SpA clinical practice in the Middle East.

**Methods:** We conducted a cross-sectional, multicentre study to explore the factors that interfere with achieving clinical targets in SpA patients from four countries in the Middle East (Lebanon, Oman, Qatar, and the United Arab Emirates). A total of 404 patients who attended participating centers from January 2019 to June 2019 and who met the ASAS 2010 classification criteria for axial and peripheral SpA; and were at least 18 years of age were enrolled in the study. We excluded patients with peripheral arthritis only. We extracted demographics, clinical data, and conducted patients survey. We used Compliance Questionnaire for Rheumatology (CQR) is a self-reported adherence measure created specifically for and validated in rheumatic diseases.

Demographic data and disease and treatment characteristics were described as median and the 25th–75th interquartile range (IQR). Multiple regression analysis was used to investigate the impact of different factors on ASDAS-CRP in patients with SpA. Statistical analysis was performed using Minstab version 18.1 software.

**Results:** A total of 404 patients initially enrolled in the study, we excluded 95 patients as they had peripheral involvement only. We analysed the data of 309 patients with axial only or axial and peripheral SpA. Their median age was 43 years and 53.7% were females. The median disease duration was six years. At the time of the study, 72.1% patients were within the arbitrary clinical target of ASDAS < 2.1. Detail description of the studied population and subgroups outlined in table 1.

**Enthesitis** (OR: 2.9; P value: 0.004), Psoriasis (OR: 2.74; P value: 0.007), low compliance score (OR: -4.36; P value: < 0.0001) and HLA B27 (OR: 2.12; P value: < 0.04) were independent predictors of a higher ASDAS –CRP.

**Conclusion:** Enthesitis, psoriasis, noncompliance, and HLAB27 were independent predictors for ASDAS in our cohort.

**ACHILLES PAIN PERSISTENCE IN PATIENTS AFFECTED BY Spondyloarthritides: ULTRASONOGRAPHIC AND BIOMECHANICAL STUDY.**

C. Batticciotto1, S. Olivier1, R. Talotta2, A. Cappelli1, P. Sedda3, P. Sarzi-Puttini1.

1Rheumatology Unit - Ospedale Di Circolo - Fondazione Macchi - Asst Sestri Levante, Varese, Italy; 2IRCCS Galeazzi Orthopedic Institute, University of Milan, Milan, Italy; 3University of Messina, Messina, Italy; 4Rheumatology Unit, L. Sacco University Hospital, Milan, Italy

**Disclosures of Interests:** Camilla Batticciotto: None declared, Raffaele Talotta: None declared, Angela Cappelli: None declared, Paolo Sedda: None declared, Paolo Sarzi-Puttini: None declared.
Background: Enthesitis anatomy and biomechanics have a key role in Spondyloarthritis (SpA) pathogenesis (1) but few data are available about the influence of structural and biomechanical changes of Achilles tendon (AT) on persisting pain in longstanding SpA patients.

Objectives: To correlate AT pain in longstanding SpA patients with ultrasonographic detectable disorders and biomechanical abnormalities.

Methods: We performed a monocentric cross-sectional analysis including 35 consecutive patients affected by SPa (13 with Psoriatic Arthritis, 9 with Enteropathic SpA, 6 with Ankylosing Spondylitis and 7 with Undifferentiated SpA) under treatment with anti-TNF agents. A rheumatologic clinical and clinimetric evaluation (AT VAS pain, BASDAI, BASFI, HAQ), an ultrasonographic study of AT according to the Madrid Sonographic Enthesis Index (MASEI) score and a podiatrist biomechanical evaluation [Foot posture index (FPI), degree of ankle dorsiflexion with the knee extended and flexed] were performed.

Results: Study population (13 F; 22 M; mean age 54.9 ± 13.9 years; mean disease duration 9.5 ± 5.0 years; mean BMI 25.8 ± 4.4) showed a mean AT VAS pain of 3.4 ± 2.2, a mean HAQ of 0.6 ± 0.6, a mean BASDAI of 3.3 ± 2.1 and a mean BASFI of 2.2 ± 1.9. At the ultrasonographic evaluation 47% (33/70) of the AT enthesis analysed displayed a dishomogeneous echostructure, 31% (22/70) structural thickness, 53% (37/70) calcifications, 10% (7/70) erosions, 44% (34/70) a retrocalcaneal bursitis. A power Doppler positivity was found only in 0.07% (5/70) of the AT.

At the biomechanical evaluation 50% (35/70) of the feet showed a FPI score between 0 and +5 (neutral foot), 46% (32/70) a FPI score between +6 and +9 (slight foot pronation) and 6% (4/70) a FPI score between -1 and -4 (slight foot supination).

The mean degree of ankle dorsiflexion with extended knee was 8.4 ± 3.9 with the 61% (43/70) of the patients with a maximum dorsiflexion < 10° of whom 46% (20/43) do not recover after the knee flexion.

We found a between the mean degree of left ankle dorsiflexion with extended/flexed knee both with ultrasound-revealed left AT enthesis calcifications (p = 0.014/0.037) and with left AT enthesis thickness (p = 0.049/0.035), and a significant association between the mean degree of right ankle dorsiflexion and extended/flexed knee and ultrasound-revealed right AT calcifications (p = 0.008/0.012). Moreover, we noticed an inverse correlation between the mean overall degree of ankle dorsiflexion with extended/flexed knee and the BASFI values (p = 0.007/0.004). AT VAS pain was statistically related with Achilles PDUS signal persistence (p = 0.048) but not with US signs of chronic enthesopathy or biomechanical alterations [calcification (p = 0.39), erosions (p = 0.74)]. The limits of the study were the low number of patients recruited and the lack of a control group.

Conclusion: In this monocentric study on a cohort of SpA patients, we demonstrated a statistically significant correlation between ankle–subtal joint complex biomechanical alterations, ultrasonographic signs of chronic enthesopathy and clinimetric index of functional disability. Residual Achilles pain seems to be a related to US signs of active enthesitis.

AB0668

CLINICAL CHARACTERISTICS OF RADIOMICROGRAPHIC AND NON RADIOMICROGRAPHIC AXIAL SPONDYLOARTHRITIS IN A GROUP OF TUNISIAN SPONDYLOARTHRITIS

K. Ben Abdelghani1, Y. Gazm1, A. Fazaa1, S. Miladi1, K. Ouenniche1, L. Souabni1, S. Kassab1, S. Chekili1, A. Laatar1, Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

Background: In the literature, non radiographic axial Spondyloarthritis (nr-SpA) is predominantly female with a shorter period of evolution and similar peripheral manifestations to radiographic axial spondyloarthritis (r-SpA). However, we do not have Tunisian studies comparing the two groups of axial spondyloarthritis (ax-SPa).

Objectives: The aim of this study was to assess the epidemiological and clinical differences between nr-SPa and r-SPa in a group of Tunisian ax-SPa.

Methods: Two hundred patients with ax-SPa (ASAS 2009 criteria) were retrospectively included and classified as r-SPa characterized by the presence of radiographic sacroiliitis and nr-SPa defined by the presence sacroiliitis only on MRI or HLA B27 antigen with other clinical features. The different demographic and clinical parameters were compared between the nr-SPa and r-SPa groups.

Results: One hundred thirty-eight men and 62 women were included with a sex ratio of 2.2. The mean age was 43.3 ± 11.2 years and the mean period of evolution was 10.7 ± 8.4 years. The patients were divided to r-SPa in 80% of cases (n = 160) and nr-SPa in 20% of cases (n = 40).

Women were more present in the nr-SPa group with 47.5% of women versus 26.8% of women in the r-SPa group (p = 0.01). The patients with nr-SPa were younger with a mean age of 39.4 ± 13.4 years versus 44.3 ± 10.4 years in patients with r-SPa (p = 0.03). The mean period of evolution was shorter in nr-SPa group (5.8 ± 4.9 years vs 11.9 ± 6.5; p < 0.001). The family history of SpA was more frequent in nr-SPa group (17.5% vs 4.3%; p = 0.004). Arthritis were more frequent in nr-SPa (42.5% vs 13.7%; p < 0.0001). Simi-
larly, enthesisitis were more frequent in nr-SPa group (45% vs 15.6%; p < 0.0001).

No statistically significant differences were found in the following parameters: age at onset of symptoms, diagnostic delay, HLA B-27 antigen and dactylitis.

Conclusion: The clinical features were different in the 2 groups of ax-SPa: Patients with nr-SPa were more female and had more peripheral manifestations while patients with r-SPa were older and with longer period of evolution.

PARTICULARITIES OF TUNISIAN FEMALE AXIAL SPONDYLOARTHRITIS

K. Ben Abdelghani1, Y. Gazm1, A. Fazaa1, S. Miladi1, K. Ouenniche1, L. Souabni1, S. Kassab1, S. Chekili1, A. Laatar1, Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

Background: Axial spondyloarthritis (ax-SPa) is a chronic rheumatic disease that mainly affects men. However, the female form of ax-SPa remains insufficiently studied.

Objectives: The aim of this study was to determine the clinical characteristics, the disease activity and the functional impact of female ax-SPa in comparison with male ax-SPa.

Methods: This is a retrospective study including patients diagnosed with ax-SPa fulfilling the criteria of the Assessment of SpondyloArthritis international Society (ASAS) 2009.

Clinical parameters, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Bath ankylosing spondylitis disease activity index (BASDAI) and Bath ankylosing spondylitis functional index (BASFI) were compared between groups of female and male ax-SPa.

Results: Two hundred ax-SPa patients were included with 31% of female (n=62) and a mean age of 43.3 ± 11.2 years.

The mean age at onset of symptoms was 31.8 ± 6.9 years for women and 25.3 ± 9.1 years for men (p <0.0001). The mean age at diagnosis was 36.4 ± 9.8 years for women and 31.7 ± 10.4 years for men (p = 0.003). Ax-SPa with juvenile onset was noted in 1.7% of women and 12.1% of men (p = 0.02). Male ax-SPa were significantly more smokers (46.8% vs 5.4%; p <0.001). The mean duration of morning stiffness was 11.3 ± 9.2 minutes for women versus 21.6 ± 19.3 minutes for men (p = 0.005).

The mean ESR was 42.4 ± 29.8 mm for women and 28.3 ± 23.4 mm for men (p = 0.001). Radiographic sacroiliitis was present in 69.3% of women versus 84.7% of men (p = 0.01). The use of anti-TNF alpha was less frequent in women (29% vs 48.5%; p = 0.01).

Our study didn’t found a statistically significant difference in peripheral manifestations, extraarticular manifestations, CRP, BASDAI and BASFI between the two groups.

Conclusion: Female ax-SPa seems to have a better prognosis than male with older age in disease onset, less inflammation, less radiographic sacroiliitis and less use of biological treatments.

AXIAL MANIFESTATIONS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS: ARE THEY SIMILAR?

D. Benvengti1, V. Navarro-Compañ1, C. Plasencia1, D. Peiteado1, A. Villalva1
A. Balsal1. Hospital La Paz, IdiPaz, Rheumatology Unit, Madrid, Spain

Background: Spondyloarthritis (SpA) is a group of heterogeneous diseases that includes axial SpA (axSpA), such as anklyosing spondylitis and axial non-radiographic SpA, and Psoriatic Arthritis (PsA) with peripheral and/or axial involvement (axPsA). Currently, it is not well known if the characteristics and burden of the disease in patients with axPsA are similar to that of patients with axSpA.

Objectives: To compare the demographic, clinical and structural features between patients with axSpA and axPsA.

Methods: Data from an observational prospective cohort including all patients with SpA initiating biological therapy because of predominant axial manifestations from 2002-2019 in a university hospital were analyzed. AxSpA and axPsA were defined in clinical practice according to the prescribing rheumatologist, based on clinical features and complementary examinations. Demographic information, laboratory tests, disease presentation, sacroiliitis according to modified New York criteria in the pelvis X-ray, disease activity indexes (ASDAS and BASDAI) and concomitant treatment before starting biological drug were collected from the electronic medical record and biologic database. In the statistical analysis, chi square or the exact Fisher’s test was used for categorical and t-student or U-Mann Whitney for continuous variables, according to the distribution of the data. Then, the association between demographic and clinical features and each disease was analyzed using univariable and multivariable logistic regression models.

Results: Out of 352 included patients, 287 (81.5%) had axSpA, and 65 had axPsA (18.5%). Baseline characteristics are shown in Table 1. Mean baseline ASDAS was 3.3±0.9 and 3.1±1.0 for axSpA and axPsA, respectively. Biological therapies initiated can be seen in Figure 1. No significant differences at baseline were observed between axSpA and axPsA for most of the characteristics including: gender, age at diagnosis, age at starting biological, disease duration before biologic, smoking habit, CRP, disease activity, enthesitis, dactylitis, inflammatory grade of radiographic sacroiliitis. AxSpA patients used less global baseline concomitant therapy (p=0.004), more uveitis (15.3 vs. 3.1%, p=0.03) and were more frequently HLA-B*27 positive (72.3 vs. 34.1%, p<0.001), in comparison to axPsA patients. They also had better physician global assessments (PhGA) (37.4 vs 44.4, p=0.02), and a higher grade of radiographic sacroiliitis. AxSpA patients used less global baseline concomitant therapy (p=0.001), methotrexate (p<0.001) and prednisone (p<0.01), whereas they used more sulfasalazine (p=0.003) than axPsA patients in our cohort. After running multivariate analyses, the absence of peripheral manifestations (OR=4.7; p<0.001) and the positivity of HLA-B*27 (OR=5.4; p<0.001) were independently associated with axSpA.

Conclusion: Despite being spondyloarthritis with many common traits, axSpA and axPsA present some differences in clinical practice. Whereas axSpA patients are more frequently HLA-B*27 positive, axPsA have more peripheral involvement. These differences in clinical presentation between both diseases may contribute to variances in therapeutic management, such as increased use of baseline concomitant therapy in axPsA patients who initiate biological therapy.

PREVALENCE OF EXTRA-ARTICULAR MANIFESTATIONS AND IMPACT ON TARGETED DRUG PRESCRIPTION IN PATIENTS WITH Spondyloarthritis: A RETROSPECTIVE ANALYSIS OF A REAL-LIFE COHORT

M. Bignoogher1, E. G. Favalli1, A. Marchesoni1, R. Caporalí1, 2, Gaetano Pini-CITO Institute, Department of Rheumatology, Milan, Italy, 2Università degli Studi di Milano, Department of Clinical Sciences & Community Health, Milan, Italy

Background: Extra-articular manifestations (EAMs), such as uveitis, inflammatory bowel diseases (IBD), and psoriasis (PSO) can frequently complicate the disease course of patients with spondyloarthritis (SpA), although prevalence data on this regard are still controversial. The occurrence of EAMs may influence the decision to introduce a targeted therapy and also drive the choice of the most appropriate drug.

Objectives: The aim of this study is to retrospectively evaluate the prevalence of EAMs in a real-life cohort of SpA patients who were eligible to receive a targeted therapy and to investigate their impact in the choice of targeted treatment.

Methods: Clinical data of SpA (axial SpA [axSpA], peripheral SpA, and psoriatic arthritis [PsA]) patients treated with a biologic or targeted synthetic Disease-Modifying Anti-Rheumatic Drug (DMARD) between December 1999 and December 2019 were extracted from a local registry. Prevalence of main SpA-related EAMs (uveitis, IBD and PSO) was calculated at the time of drug prescription, evaluating their distribution according to treatment subgroups. Comparisons between disease and treatment subgroups were made using the Fisher’s test.

Results: The study included 629 patients with SpA (axSpA 26%, peripheral SpA 24%, PsA 50%), 266 (42%) women, mean age ±SD) 52 ±13.2 years, mean disease duration 7.8 ±7.9 years), receiving a total of 1106 lines of targeted treatment (I-line n=629, II-line n=258, III-line n=219) with etanercept (n=177), anti-TNF monoclonal antibodies (397 infliximab, 273 adalimumab, 38 certolizumab pegol, and 130 golimumab), secukinumab (n=46), ustekinumab (n=28), or apremilast (n=18). At the time of drug introduction, 13% of SpA patients showed at least one EAM. The prevalence of uveitis was higher in axSpA (11.8%) compared with both peripheral SpA (5.5%, p=0.01) and PsA (2.8%, p<0.0001), whereas IBD was more frequent in peripheral SpA (15.6%) than in axSpA (8.1%, p=0.008) and PsA (4.7%, p<0.0001). The prevalence of PSO was similar in axial and peripheral SpA (8.4 versus 6.3%, respectively;
Background: There are contradictory results in the relevant literature about the relationship between objective determinants of cranio cervical posture and temporomandibular disorder (TMD), whereas no study has worked on AS and TMD relationship.

Objectives: To evaluate the predictors of TMD in AS patients and its relationship with cranio cervical posture, we conducted this study

Methods: AS patients aged between 18-50 years and consecutively recruited (Table 1). TMD was diagnosed in 58 (59.2%) patients. Spinal mobility and cranio cervical posture measurements were similar among the two groups (Table 2). Smoking, bruxism (in females), neck disability and AS activity (in males) were higher in TMD patients (Table 1). Multivariate analysis revealed active smoking (aOR 6.86; CI: 1.83-25.60; p=0.004), neck disability (aOR 3.75; CI: 0.76-18.27; p=0.008) and neck disability (aOR 3.75; CI: 0.76-18.27; p=0.008) as independent risk factors for TMD in AS patients.

Conclusion: No relationship between the cranio cervical posture measurements and TMD was found in AS patients. Active smoking, high disease activity in males, bruxism in females and neck disability were found as predictors of TMD in AS patients.

SHINING LIGHT ON AXIAL SPONDYLOARTHRITIS: DISEASE ACTIVITY AND VITAMIN D. WHAT’S THE LINK?

G. A. Brown1, K. M. Torsney2, E. Nikiphorou3, 1North West Anglia NHS Foundation Trust, Peterborough City Hospital, Rheumatology, Peterborough,
Background: Axial spondyloarthritides (axSpA) is a chronic inflammatory disease predominantly involving the axial skeleton and sacroiliac joints. Although the exact aetiology remains largely unknown, there is thought to be an immune-driven element. Vitamin D deficiency has been associated with a number of autoimmune diseases and is thought to play an important role in modulating the immune system. Low vitamin D levels may contribute to the development and progression of axSpA.

Objectives: To study the possible associations between low vitamin D and disease activity in axSpA.

Methods: A systematic literature search using Medline, Embase and Cochrane was performed using MESH search terms “ankylosing spondylitis,” “axial spondyloarthropathy” and “vitamin D.” Articles examining disease activity measured by BASDAI, ASDAS-CRP, ESR and CRP identified through title/abstract screening, were included in the study, with relevant information extracted.

Results: Out of 495 articles identified from the initial search, 19 observational studies which were mostly (89%) cross-sectional studies were identified. There was considerable heterogeneity between studies, including in the definition of vitamin D deficiency, latitude where study took place and seasonal variation. Vitamin D levels were often lower in patients with axSpA compared to controls. Seventeen studies found no association with vitamin D deficiency and disease activity. The exceptions included one study which measured serum vitamin D receptor levels as opposed to serum 25 (OH) D or 1,25 (OH) 2 D concentrations, and another study whose recruitment occurred over four years and therefore seasonal variation may conflict results. Patients taking NSAIDs or anti-TNF had no difference in vitamin D levels.

Conclusion: Vitamin D deficiency is more prevalent in axSpA but does not seem to associate with increased disease activity. Longitudinal studies are required to better define these links.

AB0674 CLINICAL AND IMAGING FEATURES IN SPONDYLOARTHRITIS PATIENTS WITH AND WITHOUT HLA-B27 AND HLA-B51

F. Carubbi1, A. Alunno2, A. Conforti1, A. F. Bonifacio2, P. Cipriani1, R. Geri2, R. Giacomelli2, 1Rheumatology Unit, L’ Aquila, Italy; 2Rheumatology Unit, Perugia, Italy

Background: Despite being commonly expressed in the general population, the human leukocyte antigen (HLA)-B27 allele strongly increases the susceptibility to develop spondyloarthritis (SpA). Likewise, the association between the HLA-B51 allele and the development of Behçet’s disease is well documented. However, the exact mechanisms responsible for their pathologic role are still a matter of debate. Moreover, anecdotal reports show an association between HLA-B51 and the clinical spectrum of SpA.

Objectives: To investigate the clinical and imaging findings of SpA patients according to the absence or presence of HLA-B27 or HLA-B51.

Methods: We retrospectively analyzed 236 patients with axial or peripheral SpA, according to the ASAS criteria, referring to two tertiary Rheumatology Clinics between 2017 and 2019. All patients had been tested for HLA-B alleles. Patients with HLA-B51 haplotype and fulfilling the criteria for Behçet’s disease were excluded.

Results: Table 1 shows demographic and clinical features of patients, according with the HLA-B haplotype (neither HLA-B27 nor -B51, double negative; positive for HLA-B27 only, positive for HLA-B51 only). Inflammatory low back pain and sacroiliitis, assessed by X-ray or magnetic resonance imaging (MRI), were more prevalent in double negative and HLA-B27 patients, compared to HLA-B51 patients. In this regard, the presence of HLA-B51 was negatively associated with axial manifestations at onset (OR 0.347, 95% CI 0.200-0.604, p<0.0001) and in the course of the disease (low back pain: OR 0.395, 95% CI 0.225-0.689 p<0.0001; sacroiliitis on imaging: OR 0.342 CI 0.189-0.619 p<0.0005). When considering extra-articular manifestations, aphtous lesions were more prevalent in patients with HLA-B51 (p<0.0001), inflammatory bowel diseases in the double negative group (p=0.0006), and increased C-reactive protein in double negative and HLA-B27 patients (p=0.02).

Conclusion: The presence of HLA-B51 identifies a subgroup of SpA patients with peculiar features compared to double-negative or HLA-B27 SpA patients. HLA-B51-related SpA may be an additional condition to be included in the SpA spectrum.

AB0675 RED CELL DISTRIBUTION WIDTH AND FATIGUE IN AXIAL SPONDYLOARTHRITIS: A SLEEPER SIGNAL

S. Chatterjee1, C. Wincup2, A. Rahman2, R. Sengupta3, 1Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom; 2Department of Rheumatology, University College London, London, United Kingdom

Background: Fatigue is a ubiquitous feature of autoimmune conditions, and axial Spondyloarthritides (axSpA) is no exception, with over 50% of patients reporting some degree of fatigue. Erythrocyte size variability (as measured by red cell distribution width (RDW)) has been found to correlate with fatigue in a cohort of systemic lupus erythematosus (SLE) patients and may reflect iron deficiency. We investigate whether this finding holds true in axSpA patients.

Objectives: To investigate the relationships between fatigue, disease activity, and RDW (as a proxy for functional iron deficiency) in patients with axSpA.

Methods: Cross-sectional analysis performed on patients with axSpA, as defined by the Assessment of SpondyloArthritis international Society (ASAS) criteria, enrolled in a longitudinal data collection study from October 2017 until January 2020 in a single outpatient setting. Patients required a minimum of 1 set of patient-reported outcome measures (PROMs), including the completion of a Functional Assessment of Chronic Fatigue Illness Therapy (FACIT) Fatigue Scale v4 (numerical score between 0–52 with a lower score indicating greater severity), and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). C-reactive protein (CRP) as a biochemical marker of disease activity, as well as Haemoglobin (Hb) and RDW performed within 3 months either side of a PROMs set were extracted and matched. Only one pair of matched data was selected per patient according to the least timeframe between a set of PROMs and bloods of interest (if multiple were available). Anaemia was defined according to World Health Organisation criteria, i.e., Hb <120g/L in

(p=0.0006), and increased C-reactive protein in double negative and HLA-B27 patients (p=0.02).
females and Hb <130 g/L in males. Non-parametric analysis of variables was performed using Spearman’s rank correlation with significance defined at a p-value <0.05.

Results: 63 patients were included in the analysis (63.5% (40) male, mean time to diagnosis 11.46 (±9.04) years, 79.4% (50) HLA-B27 positive, 46% (29) current or ex-smokers). Blood parameters showed mean Hb of 139.6 (±16.03) g/L, mean RDW of 13.55 (±1.46) %, mean CRP of 5.23 (±10.82) mg/L. Mean BASDAI score of cohort was 3.89 (±2.02) and FACIT score 34.18 (±11.30). Mean absolute interval time difference between a PROMs set and bloods of interest was 16.14 (±11.11) days.

Univariate analysis showed a statistically significant, negative correlation between fatigue (FACIT) and disease activity (BASDAI), (p<0.001; r= -0.63), but failed to demonstrate an association between fatigue and Hb, RDW, or CRP. Subgroup analysis of 51 patients, following exclusion of patients with anaemia (12), engendered a significant and moderately negative correlation between fatigue and RDW (p=0.02; r= -0.32) (Figure 1), maintained a significant correlation between fatigue and BASDAI (p<0.001, r= -0.56) and showed a non-significant association between RDW and BASDAI (p=0.07, r=0.25).

Conclusion: These findings suggest that RDW may potentially represent a surrogate marker of disease activity in patients with axSpA. RDW may also be implicated in the multi-faceted aetiology of fatigue in axSpA patients, and may be a surrogate marker of disease activity in patients with axSpA. RDW may also be an alternative treatment target for fatigue in these patients.

AB0677 REVISI NG THE DEFINITION OF REACTIVE ARTHRITIS AND DIFFERENTIATION FROM UNDIFFERENTIATED SPONDYLOARTHRITIS

F. Cosan1, O. M. Gedar3. 1Bahcesehir University, Faculty of Medicine, Internal Medicine, Rheumatology, Istanbul, Turkey; 2Bahcesehir University, Faculty of Medicine, Ophthalmology, Istanbul, Turkey

Background: Reactive arthritis (ReA) is defined by 1999 ACR criteria as arthri- tis preceding a bacterial genitourinary (GUS) or gastrointestinal (GIS) infection in 3 days-6 weeks and evidence of triggering infection. Recently, ReA is classified as SpA and patients who do not fulfill SpA criteria are classified as undifferen- tiated spondyloarthritis (USpA) according to ASAS/EULAR SpA classification criteria.

Objectives: In several case reports which are associated with other infective agents are reported and the definition is extended for some clinicians so that SpA which is occurred after any infection is called as ReA. On the other hand, some researchers still accept the classical definition of ReA. The problem with the heterogeneity of opinions and unstandardized definition of ReA hinders studies about pathogenesis and standardization of treatments. In this study, we aimed to determine the spectrum of the use of the definition of reactive arthritis in publica- tions in PubMed between 2009-2019.

Methods: The ReA keyword is searched in PubMed for the years between 2009-2019. 248 different publications have been identified and included in this research. 89 articles, 47 reviews, 108 case reports, 2 guidelines, and 2 editorials reviewed for the definition of ReA.

Results: Only 42.7% (106 patients) of these publications meet the classical definition which suggests ReA after only GIS and GIS infections. In 4 (1.6%) of the publications ReA was defined after GIS, GUS and oropharyngeal infec- tions; in 3 (1.2%) of the publications after any bacterial infection; in 9 (3.6%) of the publications after any infection. In 8 (3.2%) of the publications, ReA and USpA was used correspondingly. In 39 (15.7%) of the publications the term agent related, ReA was used without making a general definition for ReA. 79 publications (31.9%) have not defined ReA.

According to causative agent and ReA relationship, in 64 (24.6%) general infective agents, in 75 (30.2%) classical agents, in 22 (8.9%) other bacterial agents, in 23 (9.3%) streptococcus, in 10(4%) intravesical BCG, in 6 (2.4%) HIV, in 6 (2.4%) tuberculosis, in 12 (4.8%) clostridium difficile, in 2 (0.8%) parasites were
reported. In 31 (12.5%) of the publications the causative agent for the ReA was unknown, the diagnosis was made clinically.

**Conclusion:** In this study, it is aimed to draw attention terminology intricacy and the need for the standardization of the definition of ReA and USpA. It is clear that the definition of ReA in this cohort of ReA and USpA is necessary. Between 2009–2019 there are reported cases diagnosed as ReA associated with bacterial infections (especially with Clostridium difficile, streptococcus and tuberculosis infections), and viral infections (by a majority with HIV), and parasitic infections. It is not clear if we need to define them classically or define them as USpA. Another important consideration is the necessity of extended laboratory investigations to find out the real causative agent even if the patient is clinically diagosed with ReA. The requirement of the differentiation between ReA and USpA must be revealed for therapeutic researches.

**RISK FACTORS FOR ADVERSE PREGNANCY OUTCOMES IN SPONDYLOARTHRITIS: DISEASE PHENOTYPE AND DISEASE ACTIVITY MAY PLAY A ROLE**

1Spedali Civili Di Brescia, Rheumatology and Clinical Immunology, Brescia, Italy; 2University of Rome "Tor Vergata", Rome, Italy; 3University of Rome Campus Bio Medico, Rome, Italy

**Background:** Pregnant patients (pts) with spondyloarthritis (SpA) seem at increased risk for adverse pregnancy outcomes (APO), however limited and conflicting data have been published so far and risk factors for APO in these pts remain poorly understood.

**Objectives:** To assess APO and identify possible risk factors for those in a cohort of SpA pregnant pts.

**Methods:** Data on SpA pts prospectively-followed in a pregnancy clinic from 2010 to 2019 were retrospectively analysed before conception and during each trimester. Pregnancies complicated by APO were compared with those that were uneventful for demographic and clinical variables. Active disease was defined as a DAS-28-CRP >3.2 or an ASDAS-CRP ≥ 2.1 according to peripheral or axial dominant disease respectively.

**Results:** 56 pregnancies (mean age 34±5 years; median disease duration 60 months, IQR 24-123) in 47 pts were analysed: 37 psoriatic arthritis, 7 axial SpA, 6 undifferentiated SpA, 3 enteropathic SpA, 2 reactive arthritis and 1 enthesitis-related juvenile idiopathic arthritis. APO were recorded in 23/56 (41%) pregnancies: 5 (9%) early miscarriages, 1 (2%) medical abortion (central nervous system malformation), 3 (5%) preterm births (≥34 gestational week, all for preterm premature rupture of membranes – PROM); 2 (4%) PROM; 7 (13%) small for gestational age newborns (SGA); 3 gestational diabetes and 2 choking of pregnancy. Table 1 displays the comparison between pregnancies with and without APO. A higher number of pts with active disease were detected during the 2nd trimester in both groups, however differences between those were only significant at the 3rd trimester (p=0.03). History of inflammatory bowel symptoms (IBS) was also associated with an increased risk for APO (p=0.02). Although not reaching statistical significance, APO occurred more frequently in pts with a previous use of ≥ 1 conventional synthetic (cs) or biological (b) disease-modifying antirheumatic drug (DMARD) (p=0.05), suggesting a more difficult to treat phenotype. Likewise, pts with APO were less often treated with low dose aspirin (LDA) during pregnancy.

**Conclusion:** SGA was the main APO recorded. History of IBS, a more difficult to treat phenotype and the presence of active disease during pregnancy influenced APO in this cohort, reinforcing the need for tight disease control before and during pregnancy. Larger and prospective data are warranted to confirm these results and to assess the potential protective role of LDA.

**HEALTH ASSESSMENT IN FEMALE PATIENTS WITH SPONDYLOARTHRITIS: FOCUS ON REPRODUCTIVE SPHERE**

E. De Martino1, P. Congiolini2, M. S. Chimienti1, P. Triggiani3, S. L. Bosello1, E. Gremese1, C. Iannuccelli1, F. R. Spinelli1, M. Vadacca4, R. Perricone4

1University of Rome "Tor Vergata"; 2Rome, Italy; 3Catholic University of Sacred Heart of Rome A. Gemelli, Rome, Italy; 4University of Rome, La Sapienza, Rome, Italy; 5University of Rome Campus Bio Medico, Rome, Italy

**Background:** SpA patients experience a decreased quality of life due to social, emotional and relational impairment in addition to pain, fatigue and joint damage. Sexual dysfunction (SD) is often neglected by both patients and clinicians, although articular and extra-articular manifestations of the disease can decrease the quality of life. Previous findings showed that SD can affect from 27% to 67% of patients with rheumatic diseases. Data available on SD in rheumatic patients are poor and primarily focus on male ankylosing spondylitis patients.

**Objectives:** The aim of this study is to evaluate, in a group of female SpA patients, the presence of SD, its relationship with extra-articular manifestations and to estimate the correlation between disease activity and sexual activity.

**Methods:** 52 SpA patients (including PsA, IBD-SpA and undifferentiated SpA) and 50 healthy controls (HC) were administered the Female Sexual Function Index (FSFI) questionnaire for the analysis of sexual function (score from 0 to 100). SD is defined by a score lower than 26. Mean scores on the FSFI were lower for the total SpA patients group compared to HC (p=0.002). A higher percentage of pts with active disease were detected during the 2nd trimester in both groups, however differences between those were only significant at the 3rd trimester (p=0.03). History of inflammatory bowel symptoms (IBS) was also associated with an increased risk for APO (p=0.02). Although not reaching statistical significance, APO occurred more frequently in pts with a previous use of ≥ 1 conventional synthetic (cs) or biological (b) disease-modifying antirheumatic drug (DMARD) (p=0.05), suggesting a more difficult to treat phenotype. Likewise, pts with APO were less often treated with low dose aspirin (LDA) during pregnancy.

**Conclusion:** SGA was the main APO recorded. History of IBS, a more difficult to treat phenotype and the presence of active disease during pregnancy influenced APO in this cohort, reinforcing the need for tight disease control before and during pregnancy. Larger and prospective data are warranted to confirm these results and to assess the potential protective role of LDA.

Reumatologia, ASST Gaetano Pini e CTO, Milano, Italy

Background: SIRENA is an Italian, prospective Registry in Spondyloarthritis (SpA) patients, naive to conventional, targeted and biological DMARDs. Patients are diagnosed, newly or confirmed, according to ASAS criteria and classified in subjects with predominant axial (AX) or with mainly peripheral manifestations (PER).

Objectives: To compare descriptively AX vs PER subgroups of patients.

Methods: Demographic data, diagnostic delay and subtypes of SpA as well as comorbidities and comorbidities are collected.

Results: 282 patients were enrolled: 101 (35.8%) AX and 181 (64.2%) PER. Baseline data are shown in Table 1. There were more obese patients in AX (21.4% AX vs 16.1% PER) and more overweight ones in PER (mean of 73.1 months vs 47.8). In both groups, main reason of the delay was incorrect referrals (41.5% for AX and 45.3% for PER) and the delay longer (mean of 73.1 months vs 47.8). In both groups, high percentages of comorbidities were reported: psoriasis (65.8%) and cardiometabolic diseases (34.8%) were higher in AX vs PER (21.4% AX vs 16.1% PER) and more overweight ones in PER (19.4% AX vs 16.4% PER).

Conclusion: SIRENA study highlights relevant differences in AX vs PER patients, especially in terms of diagnostic delay, clinical presentation and comorbidities.

FUNCTIONAL IMPAIRMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS IN A GERMAN COHORT: WORSE OUTCOMES AND WORSE QUALITY OF LIFE FOR FEMALE PATIENTS

N. Fred1, S. Hiestand1, S. Finzil1, R. Voi1, J. Thiel1, N. Venhoff1. 1Medical Center - University of Freiburg, Faculty of Medicine, University of Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg im Breisgau, Germany

Background: Axial spondyloarthritis (AxSpA) may lead to significant structural damage resulting in marked impairment and disability. Historically, AxSpA has been thought to have a distinct male predominance regarding both, occurrence but also disease severity. However, it has recently been shown in international cohorts that women with AxSpA may have in face an increased disease burden and worse outcome than their male counterparts.

Objectives: The aim of this project was to analyse functional capacity in a German cohort of AxSpA patients and identify associated factors by comparing demographic data, clinical characteristics, disease activity and treatments.

Methods: Analysis of a German University Hospital outpatient clinic cohort of 150 AxSpA patients. Questionnaire-based screening tools were used to assess disease activity, functional impairment and quality of life (BASDAI, FSH, WHODQOL-BREF). Female and male patients were compared by independent samples two-tailed T tests for continuous variables as well as chi-squared test for categorical variables.

DOI: 10.1136/annrheumdis-2020-eular.1066
Results: A German cohort of 150 AxSpA patients with 89 male and 61 female patients (mean age 49.3 years for males, 48.5 for females, p=0.77) was analyzed for functional capacity. Female patients had a significantly higher functional impairment in everyday life compared to males (p=0.013). After adjusting for age, linear regression showed female sex still to be significantly associated with functional impairment. Female patients rated their satisfaction with health as well as their physical and mental health-related quality of life significantly lower than male patients (p=0.015, respectively p=0.003 and p=0.002).

There were no significant differences in disease duration, diagnostic delay or family history between male and female patients (p=0.731, p=0.971 and p=0.776). Women had a slightly higher disease activity (BASDAI 4.08 vs. 3.36), although just not statistically significant in our cohort (p=0.056). Female patients had more peripheral joint involvement (52.5% vs. 34.8%, p=0.032), as well as more enthesitis (31.1% vs. 16.9%, p=0.04), whereas there were no differences concerning eye involvement (p=0.51). Female patients were less likely to be HLA B27 positive (65.6 vs. 80.7%, p=0.04), and were less likely to be on anti-TNF treatment (p=0.032, respectively p=0.042).

Conclusion: Also in our cohort female patients had a higher burden of disease as well as a worse patient reported outcome with worse quality of life and more self-reported functional impairment in everyday life. These data underline the importance of raising awareness for sex differences in disease presentation and suggest that female patients might require different treatment to achieve improved outcomes.

IS THE NEW ASDAS NOMENCLATURE IN LINE WITH THERAPEUTIC DECISION MAKING IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS?

B. García-Magallón1, M. D. C. Castro Villegas2, R. Rosselló1, V. Navarro-Compañ3.
1Hospital San Jorge Huesca, Huesca, Spain; 2University Hospital Reina Sofia Córdoba, Córdoba, Spain; 3University Hospital La Paz Madrid, IdiPaz, Madrid, Spain

Background: The Assessment of SpondyloArthritis international Society (ASAS) proposed in 2018 a change in the nomenclature of the Ankylosing Spondylitis Disease Activity Score (ASDAS) for monitoring disease activity in axial spondyloarthritis (axSpA), renaming the previously status of moderate disease activity as low disease activity status, with the presumption that this better reflects the perception that the doctor and the patient about the disease situation. However, this decision was not data-driven.

Objectives: To evaluate the association between the state of low disease activity according to the new ASDAS nomenclature and the therapeutic decision in patients with axSpA.

Methods: Longitudinal retrospective study in which patients with axSpA recruited in a secondary hospital were included. All patients with clinical diagnosis of axSpA who started treatment with a first inhibitor of tumor necrosis factor between January 2014 and June 2019 were included. At each follow-up visit, disease activity assessments (including BASDAI and CRP) and the therapeutic decision of the doctor were collected. Later, the ASDAS was calculated and disease status at each visit was classified according to the new nomenclature (inactive, low, high and very high activity). Using descriptive statistics, the association between the disease activity status and the therapeutic decision was evaluated.

Results: A total of 304 visits were analyzed in 104 patients with axSpA. Out of these, 57% were women, 47% had a subtype of non-radiographic axSpA and 42% were HLA-B27 positive. The mean (standard deviation) age at diagnosis was 46.9 (12.5) years. In the visits with an ASDAS showing a status of low activity, the therapeutic attitude was not to intensify the treatment in 98.2% of the cases. However, in visits with an ASDAS status of high or very high disease activity, treatment was intensified in 33.7% and 82.8% of cases, respectively.

Conclusion: In clinical practice, the status of disease activity initially classified by the ASDAS as moderate disease activity is currently considered to represent low disease activity status based on the therapeutic attitude of following a non-intensification strategy in this situation. These data support the recent change in the nomenclature of disease activity states according to the ASDAS.

COMPARATIVE ANALYSIS OF PATIENT-REPORTED OUTCOMES AMONG EMPLOYED AND UNEMPLOYED PATIENTS WITH AXIAL SPONDYLOARTHRITIS. RESULTS OF THE SPANISH ATLAS 2017

Background: Unemployment is associated with poorer disease outcomes in chronic conditions. Current high rates of unemployment in Spain may lead to a higher burden of disease in axial spondyloarthritids (axSpA)

Objectives: To evaluate the differences in sociodemographic factors and patient-reported outcomes (PROs) between employed and unemployed axSpA patients in the same sample.

Methods: Data from 680 unselected patients of the Spanish Atlas of Axial Spondyloarthritids from an online survey were collected in 2016 were analysed. Active workforce participants were divided into employed and unemployed according to International Labour Organization (ILO) standards. Socio-demographic characteristics, and Patient-reported Outcomes (PROs) (BASDAI (0-10), spinal stiffness (3-12), functional limitation (0-54) and psychological distress (0-12, General Health Questionnaire GHQ-12)) were compared between employed and unemployed participants. The Χ² test was used for qualitative variables and the Mann-Whitney test for quantitative variables.

Results: In total, 415 (63.6%) patients were categorised in the active population, of which 325 (78.3%) were employed and 90 (21.6%) unemployed (Table 1). 62.8% (N = 86) of unemployed patients declared that axSpA was the cause of their joblessness. Compared to the employed, the employed patients had a higher percentage of university students (47.1% vs 23.3%; p=0.001) and higher income level per family member ($8904 vs $385.8; p=0.001). In relation to PROs, the unemployed presented greater disease activity (6.3±1.9 vs 5.2±1.9; p=0.001) and spinal stiffness (7.8±2.3 vs 6.5±2.6; worst functional limitation (45.0±8.4 vs 40.6±10.1; p<0.001) and more psychological distress (7.6±4.2 vs 4.9±4.3; p<0.001). In addition, a higher proportion of unemployed participants self-reported anxiety (27.8% vs 16.0%; p=0.011) and depression (23.3% vs 10.2%; p=0.001) (Table 2).

### Conclusion

The Spanish Atlas results show significant differences between employed and unemployed patients with axSpA, with greater disease activity, spinal stiffness, functional limitation, and poorer mental health in those who are unemployed.

### Acknowledgments

Funded by Novartis Pharma AG & Novartis Farmacéutica S.A.

### Disclosure of Interests

Funded by Novartis Pharma AG & Novartis Farmacéutica S.A.

### Background

Axial spondyloarthritis (axSpA) is a chronic inflammatory disease that affects axial and peripheral joints, as well as the entheses and the dural and periosteal insertions of tendons and ligaments. It is characterized by inflammation of the sacroiliac joints, spondylitis, and enthesitis. The disease often affects the spine, causing pain, stiffness, and mobility limitations. AxSpA can also cause systemic involvement, with peripheral arthritis, uveitis, and cardiovascular and gastrointestinal complications.

### Objectives

The primary objective of this study was to evaluate the impact of axSpA on working life. The secondary objectives were to assess the prevalence of work-related issues and their association with disease activity, physical mobility, and psychological distress.

### Methods

The study included a cross-sectional survey of patients with axSpA, conducted in 13 European countries. Participants were recruited through patient organizations and healthcare professionals. The survey collected data on sociodemographic characteristics, disease activity, physical mobility, and psychological distress. Work-related issues were also evaluated.

### Results

The survey results showed a significant impact of axSpA on working life. Employment status, work-related issues, and disease activity were associated with each other. The prevalence of work-related issues was higher in unemployed patients compared to employed patients. The most common issues included difficulty fulfilling working hours, taking sick leave, and asking for days off.

### Conclusion

The study highlights the significant impact of axSpA on working life, with higher prevalence of work-related issues in unemployed patients. The results underscore the importance of addressing these issues to improve the quality of life and employment outcomes for patients with axSpA.

### References

of specific and high sensitive criteria of axSpA do not improve the situation because one of the main reasons of late axSpA diagnostics is the increased period when the patient with typical axSpA symptoms do not refer to general practitioner (GP) to the rheumatologists (so called “human factor”). The increasing role of internet online technologies can make way from GP to rheumatologist shorter and decrease the diagnostics delay in axSpA.

Objectives: To develop the online questionnaire that calculates probability of having axSpA and evaluate the advantages of the method of online based detection of axSpA under the traditional ways of axSpA search.

Methods: Based on positive and negative predictive values of symptoms from ASAS axSpA criteria (2009) the axSpA Early Diagnostics Questionnaire (aEDQ) was developed. The aEDQ was available on website of Russian Ankylosing Spondylitis Association from October 2018. Link to the aEDQ could be obtained directly on the site and additionally by using one of 1,500 related to axSpA keywords approved by 5 rheumatologists from Russian SpA Expert Group. Those of participants who had high risk of axSpA according aEDQ were recommended to visit the rheumatologist, related to axSpA diagnostics. Participants with low risk of axSpA were sent to their GP. Collected data of diagnostics delay and capacity of the aEDQ were compared with data from demographically matched populations from EMAS online survey from 13 European countries (n=2,846), and SPACE cohort results (n=461) [1, 2], and from Russian North-Western axSpA LADOGA register (n=1,544). This study used only anonymized data. Statistical analysis was performed with Statistics SPSS2017, GraphPadPrizme 2016.

Results: Since October 2018 until January 2019 in Saint-Petersburg 22,925 people visited the aEDQ, 21,939 (95.6%) people filled out the questionnaire. Out of 21,939 people filled out questionnaire 7,888 (35.9%) people has high risk of axSpA. Within one month after passed the questionnaire 424 people with high risk of axSpA (5% out of all who had the recommendation) consulted by rheumatologist (mean age 42±6.6 years, male 72%, 65% of people, duration 4.4 ± 3.0 years, HLA-B27 positive 60.3%), in 254 patients out of 424 (59.9%) presence of axSpA was confirmed as compared with 44.6% in SPACE cohort results (p = 19.24, p<0.000 for differences with SPACE cohort results [2]).

Mean diagnostics delay in aEDQ cohort was 4.4 ± 3.0 years (mean ± SD), n = 254, in axSpA patients with traditional way of axSpA search in LADOGA register was 8.8 ± 4.8 years, n = 1,544 (LADOGA study results), and 7.4 ± 4.8 years in EMAS survey [1], p < 0.0001 for all the differences.

Conclusion: Online axSpA Early Diagnostics Questionnaire with function of calculation of axSpA probability can decrease diagnostics delay and increase percentage of confirmed by rheumatologist axSpA diagnosis as compared with another forms of axSpA search.

AB0688 GAIT PATTERN DIFFERENCES BETWEEN PATIENTS WITH RADIOGRAPHIC AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS, THE MYOSPA STUDY

N. Goncalves1,2, L. Domingues2, A. Mashayekhi Sardoo2, L. Radu2, S. Rodrigues-Manica1,2, A. Neto1,2, R. Torres1,2, J. Marona1,2, J. Branco1,2, C. Mendes1, R. Matias1,2, F. Pimentel Dos Santos1,2,1, 1Hospital de Egas Moniz, CHLO, Rheumatology, Lisbon, Portugal; 2CEDOC, UNL, NMS, Lisbon, Portugal; 3Kinetikos, Coimbra, Portugal; 4Champalimaud Research and Clinical Centre, Champalimaud Centre for the Unknown, Lisbon, Portugal; 5Human Movement Analysis Lab, Escola Superior de Saúde – Instituto Politécnico de Setúbal, Setubal, Portugal

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease of the axial skeleton as radiographic (r-axSpA) or non-radiographic (nr-axSpA). Defining the gait patterns associated with these two groups can improve its detection and promote early intervention. In normal walking, body segments move around the joints as struts of an inverted pendulum. The resultant cyclic rotations contribute to the forward translation of the body, while minimizing muscle work and maintaining stability. Recent literature describes a decline in this pendulum-like mechanism associated with aging and some neurological diseases (Parkinson and multiple sclerosis).

Objectives: The aim was to compare the 3D gait kinematics of patients with r-axSpA and nr-axSpA.

Methods: A cross-sectional study was conducted on 54 participants (18-50 years old), 27 patients with axSpA (according to ASAS criteria, with less than 10 years since symptoms onset) and 27 healthy controls, matched by gender, age and level of physical activity. A sub-analysis was performed involving the whole group of patients classified as r-axSpA (n=14) and nr-axSpA (n=6). Subjects movement was reconstructed using a 3D full-body kinematic model (Kinetikos, Coimbra, Portugal) fed by 15 inertial sensors placed in the head, arms, trunk, pelvis, thighs, shanks and feet. 3D gait kinematics was characterised based on variables that analyse the body movement as a whole (e.g. center of mass displacement, speed), conventional spatiotemporal parameters (e.g. stance/swing time, step length) and joints kinematics time-normalized to 101 points, comprising the gait cycle from 0 to 100%. Nonparametric statistical tests were used.

Results: In the r-axSpA group, 71.4% were male, with a mean age of 34.43±7.84 years and a BASDAI of 2.84±2.39, whereas in the nr-axSpA, 50%
were male, with a mean age of 41.83±6.27 years and a BASDAI of 2.99±0.58. A statistically significant difference was observed in the displacement of the center of mass (with respect to the pelvis local coordinate system) along the anteroposterior axis between the two studied groups (H = 4.96, p = 0.03), with a mean rank displacement of 8.6 for r-axSpA and 15.00 for nr-axSpA, corresponding to a reduction in displacement of 38% (mean 0.00986 vs 0.01579m), in the r-axSpA group.

Conclusion: Our preliminary results in raxSpA subjects show a reduction of the pendulum mechanism. Although no significant segmental (kinematics) changes were observed, the sum of all studied variables result in a clear different gait pattern between the two groups. The observed decline can be an early sign of the inefficiency of the r-axSpA group to minimise the cost of transport of the center of mass during walking (i.e. increased instability). This study shows the potential of gait analysis to identify subjects who may benefit from early physiotherapy intervention.

AB0689 THE IMPORTANCE OF THE SUN VITAMIN D AND SPONDYLOARTHRITIS: OUR EXPERIENCE IN A THIRD LEVEL HOSPITAL.

I. González Fernández1, C. Alvarez Castro2, C. Moriano3, A. López Robles4, X. E. Lacho Rojas4, M. E. Vallejo Pascual4, Complejo Asistencial Universitario de León, Reumatología, León, Spain; 2Facultad de CC.EE y Económicas, León, Spain

Background: Vitamin D plays an important role in the pathogenesis of autoimmune diseases, so that it has been shown that an adequate level is associated with a lower risk of developing this group of entities as well as a lower severity of them. Specifically, in spondylarthropathies (SpA) the deficiency has been associated with greater aggressiveness and greater radiological progression.

Objectives: Assess levels of vitamin D in patients diagnosed with SpA in the León University Assistance Complex and study its possible relationship with different clinical-epidemiological variables.

Methods: Prospective observational study between January 1, 2019 and December 31, 2019 with consecutive sampling of patients diagnosed with SpA (New York criteria, ASAS) in our hospital between 1973 and 2018. It was taken as a cut-off point for vitamin normality D those values <50ng/ml. The disease activity was assessed based on BASDAI and CRP level (taking as a cut-off point 5mg/l, reference value of our hospital and ruling out elevation due to intercurrent processes) in the last consultation. Positive values above 130 mg/dL were considered for the orosomucoid and for calprotectin as undetermined values between 50-100mg/kg/feces and suspected IBD greater than 100mg/kg feces. An attempt was made to link the value of vitamin D with disease activity, tobacco, the development of uveitis and the presence of subclinical intestinal inflammation.

Results: 132 patients were included, of which 60.6% were men with a mean age of 49.35 ± 12.95 years. 84.8% were B27 positive. 88.6% met New York criteria. 43.2% had CRP, highlighting arterial hypertension (HT) in 25%; dyslipidemia (DL) in 24.2%; Obesity in 3.8%; hyperuricemia in 3% and diabetes mellitus (DM) in 2.3%. 43.9% of the patients were being treated with an anti-TNF. Only 25% of patients had elevated CRP levels and 11.4% had BASDAI> 4. 38.7% of the sample had positive antiphospholipid antibodies; of which 58.8% (22.7% of total patients) were confirmed. Of these, the AL was the predominant in 90.2% of cases (34.9% of the total number of patients). Likewise, 10% of patients with repeated antiphospholipid antibodies met criteria for antiphospholipid syndrome (APS). It was observed in our sample that female sex can behave as a protective factor against the positivity of AL (p = 0.002) and that elevated CRP levels show a statistically significant tendency to the presence of AL (since the first positive determination was related with a p = 0.013).

Conclusion: According to our results, it seems important to determine antiphospholipid antibodies (especially AL) in patients with SpA, especially in order to avoid future thrombotic events.

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2020-eular.4191

AB0690 ANTIPHOSPHOLIPID ANTIBODIES AND SPONDYLOARTHRITIS: TRUTH OR MYTH? OUR RESULTS IN A THIRD LEVEL HOSPITAL.

I. González Fernández1, C. Alvarez Castro2, C. Moriano3, E. Diez Alvarez2, T. Pérez Sandoval2, M. E. Vallejo Pascual4, Complejo Asistencial Universitario de León, Reumatología, León, Spain; 2Facultad de CC.EE y Empresariales, León, Spain

Background: The importance of antiphospholipid antibodies and their clinical involvement in thrombotic phenomena, isolated or associated with certain autoimmune diseases such as systemic lupus erythematosus, is known. However, in spondyloarthritis (SpA) there is little published data about it.

Objectives: Identify the presence of antiphospholipid antibodies in patients diagnosed with SpA in the León University Assistance Complex and analyze its possible relationship with different clinical-epidemiological variables.

Methods: Prospective observational study between January 1, 2019 and December 31, 2019 with consecutive sampling of patients diagnosed with SpA (New York criteria, ASAS) in our hospital between 1973 and 2018. Anti-cardiolipin antibodies, anti-B2 glycoprotein and Lupus anticoagulant (AL) were the requested antiphospholipid antibodies excluding cases of positivity for other causes (coagulopathy, liver disease) and repeating the determination at 12 weeks. The disease activity was assessed based on BASDAI and CRP level (taking as a cut-off point 5mg/l, reference value of our hospital and ruling out elevation due to other intercurrent processes) in the last consultation. An attempt was made to link antiphospholipid antibodies with sex, disease activity, cardiovascular risk factors (CVRF), thrombotic events and taking anti-TNF.

Results: 132 patients were included, of which 60.6% were men with a mean age of 49.35 ± 12.95 years. 84.8% were B27 positive. 88.6% met New York criteria. 43.2% had CRP, highlighting arterial hypertension (HT) in 25%; dyslipidemia (DL) in 24.2%; Obesity in 3.8%; hyperuricemia in 3% and diabetes mellitus (DM) in 2.3%. 43.9% of the patients were being treated with an anti-TNF. Only 25% of patients had elevated CRP levels and 11.4% had BASDAI> 4. 38.7% of the sample had positive antiphospholipid antibodies; of which 58.8% (22.7% of total patients) were confirmed. Of these, the AL was the predominant in 90.2% of cases (34.9% of the total number of patients). Likewise, 10% of patients with repeated antiphospholipid antibodies met criteria for antiphospholipid syndrome (APS). It was observed in our sample that female sex can behave as a protective factor against the positivity of AL (p = 0.002) and that elevated CRP levels show a statistically significant tendency to the presence of AL (since the first positive determination was related with a p = 0.013).

Conclusion: According to our results, it seems important to determine antiphospholipid antibodies (especially AL) in patients with SpA, especially in order to avoid future thrombotic events.

Background: Hip joint lesion are the main cause of disability in patients with Axial Spondyloarthritis (axSpA) in western China. Seriously affect the quality of life of patients. The early clinical characteristics of hip joint disease are not typical, the disease is insidious, and the radiological diagnosis is delayed. The main prevention is early screening and early diagnosis.

Objectives: This study attempted to find out the main characteristics and related factors in different groups of AS combine with hip joint lesion in western China.

Methods: A-First evaluation: How many patients have 1) active SIJ changes on MRI, 2) chronic SIJ changes (each for erosion, sclerosis, ankylosis, or any of those) on MRI, 3) a combination of active changes and chronic changes (each for erosion, sclerosis, ankylosis, or any of those) on MRI, 4) active hip changes on MRI, 5) chronic hip changes (erosion, effusion any of those) on MRI, 6) a combination of active changes and chronic hanges (erosion, effusion any of those) on MRI. B-Then, combination SIJ / hip. 7) active SIJ changes on MRI and in parallel active hip changes on MRI. 8) chronic (see above) SIJ changes on MRI and in parallel active hip changes on MRI. 9) chronic (see above) SIJ changes on MRI and in parallel chronic (see above) hip changes on MRI. 10) chronic (see above) SIJ changes on MRI and in parallel any (active or chronic) hip changes on MRI. C-Then, characterization of these groups with non-imaging findings. Characteristics of groups 7-10 above, for age, sex, Disease duration, Hip pain, Joint pain, enthesitis, Diarrhea, uveitis, ASDA-CRP, BASFI, BASMI, Pat. Global, CRP, ESR, Harris Score, HLA-B27.

Results: Prospective analysis total 558 SpA patients (mean age 29 + 6 mean duration 5 years). 1) HIP-Active+Chronic group (N=288, AS=151) vs SIJ-HIP-Active group (N=241, AS=138): hip pain (p<0.0001), diarrhea (p<0.001), joint pain (p<0.0001) and BASFI (p<0.05); 2) HIP-Active+Chronic (N=117, AS=58) vs SIJ-HIP-Chronic group (N=214, AS=134): hip pain (p<0.0001), joint pain (p<0.0001), enthesitis, CRP (p<0.0001), ASDAS-CRP (p=0.05) and ESR (p=0.05); 3) SIJ-Active+Chronic group (N=204, AS=125) vs SIJ-Chronic+HIP-Active group (N=214, AS=134): hip pain (p<0.0001), joint pain (p<0.0001); 4) SIJ-Active+Chronic group (N=204, AS=125) vs SIJ-HIP-Chronic group (N=72, AS=40): hip pain (p<0.0001), Pat. Global (p<0.05); 5) SIJ-HIP+Chronic group (N=241, AS=138) vs SIJ-Chronic+HIP-Active group (N=214, AS=134): HLA-B27 (positive, df, 24.98, 4) (p<0.0001); 6) SIJ-HIP-Chronic group (N=72, AS=40) vs SIJ-Chronic+HIP-Active/Chronic group (N=228, AS=144): Pat. Global (p<0.05), ESR (p<0.05).

Conclusion: Hip joint lesion are closely related to sacroiliac joint lesion and HLA-B27 positive in AS. Hip pain is the main clinical manifestation of hip joint lesion in AS. Hip joint lesion may lead to function declines, disease activity in AS.

AB0693  
TIM-3-EXPRESSING NEUTROPHILS AS A NOVEL INDICATOR TO ASSESS DISEASE ACTIVITY AND SEVERITY IN ANKYLOSING SPONDYLITIS  
X. Huang1, T. Li1, J. Chen1, Y. Wang1, S. Chen1, W. Deng1, Q. Huang1,  
1Guangdong Second Provincial General Hospital, Guangzhou, China  

Background: Axial spondylitis (axSpA) is a type of chronic inflammatory disease that compromises the axial skeleton and sacroiliac joints. Many studies have shown that neutrophils play an important role in the inflammatory process of AS. However, the immunomodulatory roles and mechanisms of neutrophils in AS are poorly understood. T-cell immunoglobulin and mucin domain-containing protein high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c), TC/HDL-c, triglycerides (TG), have been reported to be changed regularly in axSpA patients. However, the clinical significance of lipid profiles in axSpA patients is controversial.

Objectives: The study aims to determine the clinical significance of TC, HDL-c, LDL-c, TC/HDL-c, TG for axSpA patients.

Methods: A total of 208 axSpA patients and 113 healthy subjects were enrolled in the study retrospectively. TC, HDL-c, LDL-c, TC/HDL-c, TG, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR). Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) were collected. AxSpA patients were divided into remission axSpA group (BASDAI<4, n=123) and active axSpA group (BASDAI≥4, n=85). Relationships between the parameters were assessed by the Sperman’s correlations analysis. Receiver operator characteristic (ROC) curves were used to discriminate axSpA patients from healthy subjects and active axSpA group from remission axSpA group.

Results: TC, HDL-c, and TG in axSpA group were lower than those of control group, while TC/HDL-c was higher (P<0.05). ROC curve results showed that the AUC value of HDL-c for axSpA was 0.790 (C195%: 0.740-0.839), yielding a highest AUC value. The optimal cutoff value of HDL-c for axSpA was 1.095, with the Youden Index of 0.496, sensitivity of 65.5% and specificity of 84.1%. HDL-c was negatively correlated with BASDAI (r=-0.159, P=0.022). TC/HDL-c was positively correlated with BASDAI (r=0.183, P=0.008). Besides, TC/HDL-c, CRP, ESR in active axSpA group were higher than those of remission axSpA group, while HDL-c was lower (P<0.05). ROC curve results showed that the AUC value of TC/HDL-c and CRP for active axSpA group were 0.621 (C195%: 0.540-0.700) and 0.634 (C195%: 0.556-0.712), yielding a higher AUC value than other parameters. The optimal cutoff value of TC/HDL-c for active axSpA group was 4.429, with the Youden Index of 0.201, sensitivity of 40.2% and specificity of 79.9%.

Conclusion: HDL-c was decreased in axSpA patients with a highest diagnostic value, compared with healthy control. TC/HDL-c was elevated in active axSpA patients, showing a significant correlation to the disease activity of axSpA.

Disclosure of Interests: This study was supported by Science and Technology Project of Guangzhou Haizhu District (Haibai Business Infox 2018-89).

AB0692  
CLINICAL SIGNIFICANCE OF LIPID PROFILES IN PATIENTS WITH AXIAL SPONDYLARTHRITIS  
Y. Huang1, M. Liu1, Q. Huang1, T. W. Li1, 1Guangdong Second Provincial General Hospital, Guangzhou, China  

Background: Axial spondylarthritids (axSpA) is a chronic inflammatory disease of the sacroiliac joints and spine. Lipid profiles, including total cholesterol (TC),
3 (Tim-3) has been reported as an important regulatory molecule, expressed and regulated on different innate immune cells, plays a pivotal role in several autoimmunity diseases. Recent study indicates that Tim3 is also expressed on neutrophils. However, the frequency and roles of Tim3-expressing neutrophils in AS was not clear.

**Objectives:** In this study, we investigated the expression of Tim3 on neutrophils in AS patients and analyzed the correlation between the level of Tim3-expressing neutrophils and the disease activity of AS.

**Methods:** AS Patients were recruited from Guangdong Second Provincial General Hospital (n=49). Age/sex-matched volunteers as Healthy controls (HC) (n=39). The medical history, clinical manifestations, physical examination, laboratory measurements were recorded. The expression of costimulatory molecules including programmed death 1 (PD-1), Tim-3 on neutrophils were determined by flow cytometry. The frequencies of Tim3-expressing neutrophils in AS patients were further analyzed for their correlation with markers of inflammation ESR and CRP, disease activity and severity of AS.

**Results:** The expression of Tim3 on neutrophils in patients with AS was increased compared to the HC (Figure 1A). The frequency of Tim3-expressing neutrophils in patients with AS showed a positive correlation with ESR, CRP and ASAS-endorsed disease activity score (ASDAS) (Figure 1B). Moreover, the frequency of Tim3-expressing neutrophils in active patients (ASDAS≥1.3) was increased as compare with the inactive patients (ASDAS<1.3) (Figure 1C).

**Conclusion:** Increased Tim-3 expression on neutrophils may be a novel indicator to assess disease activity and severity in AS, which may serves as a negative feedback mechanism preventing potential tissue damage caused by excessive inflammatory responses in AS patients.

**Conclusion:** We found Caucasians had more HLAB27 positivity and extra-articular manifestation of uveitis however the Indian population has...
more enthesitis and peripheral arthritis. Enthesitis is initiated during a mechano-sensation and the cultural difference including style of footwear could probably be one of the factors explaining our findings inflammatory back pain has been reported to be higher in Indians compared to Caucasians which could be due to life style.

The fact that ASDAS CRP behaves similarly in Indian patients across the two countries and is more when compared to Caucasians might point towards overall higher burden of disease in Indian population.

To our knowledge this is a first study comparing clinical manifestations of SpA between Indians and Caucasians

SUSTAINED ASDAS-CRP REMISSION IS ASSOCIATED WITH BETTER LONG-TERM FUNCTIONAL OUTCOMES: A REAL-LIFE ANKYLOSING Spondylitis Cohort Study

J. M. Kerber1, J. D. De Mello1, P. Palominos2, A. A. Gasparin2, F. D. A. Menegat2, C. V. Breno1, C. Kohem2, 3Federal University of Rio Grande do Sul, Porto Alegre, Brazil; 2Hospital de Clínicas de Porto Alegre, Rheumatology Department, Porto Alegre, Brazil

Background: Ankylosing spondylitis (AS) leads to back pain and structural damage that may result in functional impairment. Function is usually assessed in clinical trials conducted in developed countries, with patients receiving biological therapy.

Objectives: To evaluate variation in the Bath Ankylosing Functional index (BASFI) over time in a AS cohort followed in a developing country. Compare the improvement in BASFI between patients achieving or not sustained (≥12 months) ASDAS-CRP remission/low disease activity (LDA); Analyze predictors of achieving a minimum clinically important improvement (MCII) in BASFI (ΔBASFI ≤ -0.65).

Methods: This cross-sectional analysis was conducted in a retrospective cohort. Adult patients fulfilling the New York criteria for AS and followed during at least 5 years in the Spondyloarthritis clinic were included. BASFI variation (ΔBASFI) was described as median (25th/75th). Comparison of ΔBASFI between patients fulfilling or not sustained ASDAS-CRP remission/LDA was done using the Mann-Whitney test. Hierarchical Poisson model was used to identify predictors for achieving a MCII in BASFI.

Results: 69 patients were analyzed, 53.6% were men, the mean age was 48.9±11.4 years, and the mean follow-up time was 6.1±0.5 years, median (25th/75th) disease duration of 10 (5-18) years; 14.5% of the patients were on biological therapy at baseline. The median (25th/75th) ΔBASFI was low: -0.1 (-1.9/+1.1) but 46.4% (N= 32) presented a MCII in BASFI during follow-up. Patients who achieved sustained ASDAS-CRP remission/LDA had a significant improvement in BASFI over time compared with those who did not achieve this target (p=0.026) (Figure 1). Patients with higher BASFI scores at baseline had a greater probability of achieving a MCII in BASFI (RR 1.13 95% CI 1.00-1.27 p=0.047), Achieving and maintaining ASDAS-CRP remission/LDA during at least 12 months increased in 82% the probability to obtain a MCII in BASFI (RR 1.82 95% CI 1.14-2.91, p=0.012).

Conclusion: Patients achieving sustained ASDAS-CRP remission/LDA had better functional outcomes over time compared to those not achieving this target. Higher BASFI scores at baseline and sustained ASDAS remission/LDA were predictors of a MCII in BASFI.

THE PATH OF A PATIENT WITH AXIAL SPONDYLOARTHRITIS TO DIAGNOSIS IN RUSSIA, DATA FROM THE EMAS SURVEY

S. Lapshina1, M. Garrido-Cumbraera2, T. Dubinina3, A. Dubikova4, I. Gaydukova5, M. Korolev6, E. Zonova7, P. Pchelnikova8, A. Sitalo9, I. Shipilova10, 1Kazan Medical Research. 2019;50:41-46

Disclosure of Interests: None declared, Puja Srivastava: None declared, Prashant Chotalia: None declared, Arumugam Moorthy: Speakers bureau: Abbvie, Novartis, UCB, MSD

Figure 1. Comparison of ΔBASFI between patients who achieved or not sustained ASDAS-CRP remission/LDA.
Background: Scientific research in axial spondyloarthritis (axSpA) over the recent years has grown significantly. Early detection, diagnosis and treatment are critical to improve the functioning situation, reduce comorbidities and loss of quality of life of patients with axSpA. However, the diagnostic delay remains high.

Objectives: To describe the path to diagnosis among Russian axSpA patients.

Methods: The European Map of Axial Spondyloarthritis (EMAS) was a cross-sectional on-line survey of unselected patients with self-reported axSpA conducted in 13 European countries. Russian participants were recruited between December 2017 and February 2018 through the Russian Ankylosing Spondylitis Association and an online panel. Socio-demographics, age at symptom onset, age at diagnosis, diagnostic tests performed, HCPs visited prior diagnosis, and diagnosing HCP were collected. Diagnostic delay was calculated by subtracting the age at symptom onset from age at diagnosis.

Results: 233 Russian participants were enrolled. The mean age was 36.7±9.1 years, 51.9% were female. The average duration of the disease was 12.4±9.5 years. 54.9% patients visited more than one specialist before diagnosis. Russian respondents reported a low demand for GPs, physiotherapist and an orthopaedic specialist in contrast to the total of EMAS participants (table 1). AxSpA was most frequently diagnosed by a rheumatologist (87.5%).

Most used medical test for diagnosis are similar to those used in the aggregated Pan-European sample (table 2).

Table 1. Health professional visited before being diagnosed with axSpA.

| Russian population N=233 Pan-European population N=2706 |
|------------------|------------------|------------------|
| % | % |
| GP | 67.81 | 83.4 |
| Rheumatologist | 44.21 | 66.1 |
| Other | 37.34 | 13.6 |
| Orthopaedic specialist | 23.61 | 34.5 |
| Physiotherapist | 17.6 | 46.0 |
| Osteopath | 15.73 | 16.4 |

Table 2. Medical tests made to diagnose axSpA.

| Russian population N=230 Pan-European population N=2661 |
|------------------|------------------|------------------|
| % | % |
| X-rays | 80.87 | 72.3 |
| MRI scan | 70.00 | 64.3 |
| HLA-B27 | 62.61 | 65.4 |
| CT scan | 25.22 | 20.8 |
| Ultrasound scan | 17.83 | 21.0 |
| Radionuclide scintigraphy | 3.5 | 16.4 |
| Other | 9.13 | 4.2 |

Among those who underwent HLA-B27 test (n=144), 87.23% declared to be HLA-B27 positive. This percentage is higher than that found in the Pan-European aggregated sample (73.95% of HLA-B27 positive).

The mean age at symptom onset was 24.2±9.75 years. Consequently, the mean diagnostic delay calculated was 6.88±6.94 years without differences between males and females and the median was 5 years. More than half of the sample had a calculated diagnostic delay of higher than 5 years (55.39%).

Conclusion: The results of the survey confirm the existence of a diagnostic delay. Although this aspect has been greatly improved in recent years, reducing diagnostic delay is one of the major challenges associated with the clinical management of axSpA and must be addressed with GPs and rheumatologists. We suggest that features in patient routing in other countries can be explained by these differences: the survey did not include a neurologist, to whom patients with back pain have a visit in Russia. The most frequently performed medical tests are included in the ASAS criteria for axSpA, which indicates a good knowledge of doctors.

AB0097 PERFORMANCE OF DIFFERENT CRITERIA SETS FOR INFLAMMATORY BACK PAIN IN PATIENTS WITH AXIAL SPONDYLOARTHROSIS IN DEMOCRATIC REPUBLIC OF CONGO

P. Lebuge1,1, K. De Vlam2, R. Westhoven3, J. M. Mbuiu-Muamba4, J. J. Malemba1. 1University Hospital of Kinshasa, Internal Medicine, Kinshasa, Congo, Dem. Republic of (Formally Known as Zaire); 2UZ Leuven, Department of Development and Regeneration, Leuven, Belgium

Background: Inflammatory back pain (IBP) is the most prominent clinical feature for an early diagnosis of axial spondyloarthritis. The performance of the criteria sets for IBP has not yet been assessed in clinical practice in the Democratic Republic of Congo (DRC).

Objectives: To assess and to compare the performance of different IBP criteria sets in axial spondyloarthritis (SpA) outpatients attending the rheumatology unit of the University Hospital of Kinshasa, DRC.

Methods: One hundred and eight Congolese outpatients with axial SpA defined by rheumatologist’s clinical judgment were included in the spondyloarthritis cohort of the University Hospital of Kinshasa from March 1st 2015 to February 28, 2017. Calin criteria, Berlin criteria and ASAS criteria sets for IBP were performed to assess their performance against clinical judgment. Detailed history, clinical examination and imaging of sacroiliac joints by plain radiography were obtained. Sacroiliac joint radiographic lesions were scored with the modified New York criteria. Magnetic resonance imaging and HLA B27 were not performed. Fifty additional patients with a diagnosis of chronic (>3 months) mechanical low back pain (MLBP) were included as control group. The performance of each item and different criteria was evaluated using sensitivity, specificity, and likelihood ratio (LR). Baseline characteristics of the mechanical and inflammatory back pain cohorts were compared with chi-square or Student t tests as appropriate.

Results: The mean age was 43.8±15.1 years in SpA patients versus 62.4±9.1 years in controls (MLBP patients) with respective sex ratio (M/F) of 1/0.8 and 1/2.1. There were significantly more male patients in the ankylosing spondylitis (AS) group than in the non-radiographic axial spondyloarthritis group (p<0.01). Among the criteria sets, Calin criteria showed the best sensitivity (92.6%) while the Berlin criteria showed the best specificity (97.6%) in the detection of IBP patients. The new ASAS criteria for IBP compared to the two previous criteria sets did not show good sensitivity nor specificity (sensitivity 80%, specificity 62%, LR+ 1.05 (0.90 – 1.22), LR- 0.52 (0.39 – 0.69), 95%CI).

Conclusion: The Calin criteria set would be useful for epidemiological and clinical studies in DRC. The ASAS criteria set for IBP is not better than other criteria sets in the screening of IBP for Congolese patients with axSpA.

REAL CLINICAL PRACTICE IN THE CONTROL OF REPORTED OUTCOMES BY THE PATIENT (PROS) DIAGNOSED WITH PSORIATIC ARTHRITIS AND/OR ANKYLOSING Spondylitis who BEGIN TREATMENT WITH SECUKINUMAB: A PROSPECTIVE MULTICENTRIC STUDY.

Hospital General Universitario de Valencia, Servicio de Reumatología, Valencia, Spain; 2Hospital Sagunto, Servicio de Reumatología, Sagunto, Spain; 3Hospital Llíria, Servicio de Reumatología, Llíria, Spain; 4Hospital General Universitario de Valencia, Servicio de Reumatología, Valencia, Spain; 5Instituto de Salud Musculoesquelético, Madrid, Spain

Background:
Objectives: Analyse the effect of secukinumab in terms of the patient’s own variables, specifically: fatigue, sleep, pain and quality of life in patients with psoriatic arthritis or spondyloarthritis.

Methods: A multicentric longitudinal observational prospective study was carried out at 6 months in patients who begin treatment with secukinumab. At the start and after 6 months the following data was collected on the outcome: pain through an visual analogue scale (VAS), fatigue using the FACIT-fatigue scale, sleeping problems using the insomnia severity index (ISI) and quality of life with the EuroQol-3L-5D and the PsAQoL.

The sample can be described in terms of the distribution of the variables through measures of central tendency. It was analysed if the change after 6 months was statistically relevant using Student's t-test for paired data in the case of FACIT, VAS, PsAQoL and ISI and chi-squared for the dimensions of the EQ-SD. The size of the effect of each of the measurements have achieved LDA and cDAPSA ≤13.

Results: From 262 cases of axSpA 21% women; mean ± standard deviation (SD) age 42 ± 14 years), 58% of patients achieved LDA states. While from 142 cases of PsA 49% women; mean ± SD age 51 ± 14 years), 38% and 63% achieved MDA and cDAPSA LDA, respectively. Both axSpA and PsA patients with LDA had pain scores range from 17.2 to 25.7/100 and fatigue scores from 3.3 to 3.5/10. (Table 1). Substantial burden in physical disability and mental well-being were seen as a low physical and mental component summary of SF-36. cDAPSA classified nearly twice as many PsA patients into LDA than MDA. Compared to PsA patients in MDA, PsA patients in cDAPSA LDA had higher pain scores, Patient Global Assessment (PGA), dactylitis, and enthesis. axSpA patients in LDA classified by BASDAI had the highest pain and fatigue scores, and PtGA.

Conclusion: After 6 months patients who begin treatment with secukinumab, present with improvements in all sizes of the effects of the treatment in the various studied scales. The improvement achieves global and generalised statistical significance after 6 months of study. The greatest effect is on sleep, quality of life and fatigue.

The measurements of the outcomes reported by the patients are a clinical value added to our objective evaluations of the health and activity of the disease, and allow us, in a more integrated and comprehensive manner, to undertake a more exact and close evaluation of their state of health and wellbeing.

AB0699 RESIDUAL DISEASE BURDEN PRESENT IN AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS ACHIEVING LOW DISEASE ACTIVITY STATES

V. Liu1, W. Fong1,2, Y. H. Kwan1, Y.Y. Leung1,2, 1Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Singapore, Singapore

Background: Despite achieving Low Disease Activity (LDA) states, patients with SpondyloArthritis (SpA) may have considerable residual disease. Sparse data is currently available from Asia.

Objectives: We aimed to evaluate the burden of residual disease in patients with axial SpondyloArthritis (axSpA) or Psoriatic Arthritis (PsA) who achieved LDA.

Methods: We used data from a registry of SpA from an outpatient setting in a tertiary hospital in Singapore. For axSpA, LDA was defined as Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) ≤4/10. For PsA, LDA was defined by achieving 5/7 cutoffs in the Minimal Disease Activity (MDA) or clinical Disease Activity index for Psoriatic Arthritis (cDAPSA) ≤13.

Results: From 262 cases of axSpA (21% women; mean ± standard deviation (SD) age 42 ± 14 years), 58% of patients achieved LDA states. While from 142 cases of PsA (49% women; mean ± SD age 51 ± 14 years), 38% and 63% achieved MDA and cDAPSA LDA, respectively. Both axSpA and PsA patients with LDA had pain scores range from 17.2 to 25.7/100 and fatigue scores from 3.3 to 3.5/10. (Table 1). Substantial burden in physical disability and mental well-being were seen as a low physical and mental component summary of SF-36. cDAPSA classified nearly twice as many PsA patients into LDA than MDA. Compared to PsA patients in MDA, PsA patients in cDAPSA LDA had higher pain scores, Patient Global Assessment (PtGA), dactylitis, and enthesis. axSpA patients in LDA classified by BASDAI had the highest pain and fatigue scores, and PtGA.
Background: Clinical efficacy of TNF inhibitors (TNFi) in axial spondyloarthritis (axSpA) has been widely probed in randomized control trials. In clinical practice, some studies suggested that long-term (more than 4 years) treatment with TNFi could slow down radiographic progression in axSpA; however, whether this treatment inhibits structural damage remains unclear.

Objectives: To evaluate radiographic progression in axSpA patients receiving long-term TNFi (over 4 years) in comparison with patients starting TNFi.

Methods: A total of 204 patients with axSpA were included in the Spanish Register of Biological Therapy in Spondyloarthritides (REGISPONSER-BIO). Out of these, 80 patients (31 starting TNFi and 49 under long-term TNFi) were included in this study based on the availability of radiographs (cervical and lumbar lateral views), at two time points. Radiographs in patients starting TNFi were available: i) at baseline (before TNFi) and ii) after 3 to 5 years of TNFi therapy (mean follow-up 3.7±0.8), while in long-term TNFi patients, these were available: i) at one follow-up visit at least 4 years later since TNFi was started and ii) after 3 to 5 years of this visit (mean follow-up 3.5±1.1). Two trained readers, not blinded for chronological order, independently scored lateral cervical and lumbar spine images according to the mSASSS system (0-72). Following definitions for progression were used: change of the absolute scores, change of ≥2 units, development of new syndesmophytes or growth of the existing syndesmophytes.

Results: Reliability of both readers was excellent with intraclass correlation coefficients (ICCs) of 0.98 (0.98-0.99) at inclusion and 0.98 (0.97-0.99) at follow-up. Most patients (82.5%) were classified as radiographic axSpA. Mean BASDAI at first visit (i) was of 5.0±2.4 for starting TNFi patients and of 3.2±1.9 for long-term TNFi patients. The table depicted the results for radiographic scores and progression. Mean mSASSS score at first visit (i) was 15.8±21.5 and 15.1±18.4 units for starting TNFi and long-term TNFi patients, respectively. The change score between both visits was 2.3±4.2 and 2.3±4.1, respectively. Similarly, no differences were found for change of ≥2 points (32.3% in starting TNFi and 35% in long-term TNFi patients). However, development of new syndesmophytes or growth of the existing syndesmophytes were found to be more frequently (but not significant) in starting TNFi patients compared to long-term TNFi patients.

Conclusion: In patients with axSpA treated with TNFi in clinical practice radiographic progression is observed, independently of the time under this therapy. Nevertheless, the development and growth of syndesmophytes seem to be lower in long-term treated patients.

DOI: 10.1136/annrheumdis-2020-eular.6484
Background: Anterior uveitis is the most frequent form of presentation of uveitis. An important part of patients do not associate extraocular manifestations, so more information about the clinical profile is needed to optimize therapeutic decisions.

Objectives: To describe the clinical profile of patients with anterior uveitis related and not related to the antigen HLA-B27. Compare both groups to establish differences.

Methods: Retrospective cohort study. Consistent patients diagnosed with non-infectious anterior uveitis, assessed in the multidisciplinary uveitis unit of the Infanta Leonor University Hospital (Madrid) from its establishment in October 2017 to December 2019, were included. To compare categorical variables Chi square was used and the test of Fisher; and Student's T or Mann-Whitney U test for continuous variables. Finally, a multivariate analysis was performed to established differences between the two groups. A value of p <0.05 was considered statistically significant.

Results: 62 patients with anterior uveitis, 26 (42%) with HLA B27 positive and 36 (58%) with HLA B27 negative were included. There were no differences between the two groups regarding sex. Differences were found in the mean age at diagnosis, 35 ± -9.6 in the HLA B27 positive group vs 47 ± 14.9 in the HLA B27 negative group (p =0.01). The time since uveitis diagnosis was longer in the HLA B27 positive group (708 years (3.45-11.79) versus 2.411 years (1.66-3) in the HLA B27 negative group (p =0.000). Regarding the etiology, the majority of patients in the HLA B27 negative group had a diagnosis of idiopathic anterior uveitis (72.2%), and 53.8% of the patients in the HLA B27 positive group were diagnosed with spondyloarthritis (p =0.000). There were no significant differences in the number of patients that require systemic treatment. There were no differences regarding oral corticosteroids intake, with very few patients needing it (2 patients in the HLA B27 positive group and 5 patients in the HLA B27 negative group (p =0.699). The percentage of patients who eventually develop IBD, with Crohn's disease (CD) being more common than Ulcerative colitis (UC) (21.1%) in the HLA B27 positive group and 11 patients (30.6%) in the HLA B27 negative group (p =0.717) No significant differences could be detected between groups in the multivariate analysis in terms of laterality, clinical course, treatment with immunosuppressants or development of complications.

Conclusion: In our cohort patients with HLA B27 positive debut at an earlier age. There were no differences between both groups in laterality, course of uveitis, systemic treatment or ocular complications.

AB0702

THE FREQUENCY OF INFLAMMATORY BOWEL DISEASES IN PATIENTS WITH ANKYLOSING SPONDYLITIS

"The Loginov Moscow Clinical Scientific Center of Moscow Healthcare Department" (The Loginov MCSC MHD), Moscow, Russian Federation.

Background: Ankylosing Spondylitis (AS) is closely associated with inflammatory bowel disease (IBD). About 6-46% of patients with IBD have various lesions of the musculoskeletal system [1]. 5-10% of patients with spondyloarthritis (SpA) eventually develop IBD, with Crohn's disease (CD) being more common than Ulcerative colitis (UC) [2]. The level of fecal calprotectin (FC) is a study that allows to diagnose IBD. The concentration of FC directly depends on neutrophil infiltration of the intestinal mucosa and has a direct connection with the activity of the inflammatory process [3]. It is known that level of FC is associated with disease activity in patients with ankylosing spondylitis. Arthritis Res Ther 2017. 19(1):21

Objective: To describe the clinical profile of AS patients using an assessment of FC level.

Methods: In the analysis were included 40 patients with AS, fulfilling the modified New York criteria, among them men -26 (65%), woman -14 (35%), mean age of patients was 41 ± 10.5, mean disease duration - 13±8.8 years. All patients were examined with ESR, CRP, CRP, esophagogastroduodenoscopy, colonoscopy and quantitative analysis of the fecal calprotectin levels using the method of lateral immunochromatography with the BUHLMANN Quantum Blue rapid test. Standard range: 100-1800 µg/l.

Results: All patients had a high disease activity, mean BASDAI was 5.2 ± 1.7, mean ASDAS CRP 3.8 ± 1.1. 35 patients (87.5%) had FC level more than 100 µg/l, the remaining 5 patients (12.5%) less than 100 µg/l. 12 patients (30%) had FC level more than 1,800 µg/l, 23 (57.5%) from 101 µg/l to 1800 µg/l. All patients with FC levels more than 100 µg/l showed an increase CRP (mean 28.4 mg/l) and ESR (mean 93.8 mm/h). IBD were diagnosed in 9 cases (22.5%): 5 patients (12.5%) with CD and 4 patients (10%) - UC. In the remaining cases (77.5%) was no intestinal pathology.

Conclusion: The results showed high frequency of IBD in patients with AS. Patients with high FC levels (more than 100 µg/l) had high disease activity (AS). In most cases, inflammatory bowel disease were diagnosed in patients with FC levels more than 100 µg/l.

[1] Mohamed Kassab National Institute of Orthopedics, Rheumatology. La Mannouba, Tunisia

Background: Ankylosing Spondylitis Disease Activity score (ASDAS) was developed because of the limitations of Bath Ankylosing Spondylitis Disease Index (BASDAI) of being totally patient-derived with limited face and construct validity. ASDAS includes inflammatory markers that were aimed to increase its face validity by representing a different 'objective' domain of disease activity that was not included in BASDAI.

Objective: The aim of our study was to compare correlation of ASDAS and BASDAI with physician global assessment (PhGA) in order to know which is more reliable.

Methods: Cross-sectional study including patients with SpA according to the ASAS criteria of 2009 and/or New York modified criteria. The erythrocyte sedimentation rate (ESR) and the C-reactive protein (CRP) were measured. The disease activity was assessed by BASDAI and ASDAS. Physician global assessment (PhGA) was rated by 0–100 numeric score. We correlated disease activity indices with physician global assessment by Pearson coefficient.

Results: A total of 110 patients (68 men and 42 women) with a mean age of 43.18 ± 12.34 (19-79) years was collected. The mean disease duration was 5.99 ± 2.31 [10-10] years. The mean ESR and CRP were respectively 28.4 ± 21.51 [2-110] and 15.6 ± 23.84 [0-153] mg/l. ESR was correlated with PhGA (r=0.47, p=0.300), however CRP was not correlated with PhGA (p=0.134, r=0.165). The mean ASDAS-ESR and ASDAS-CRP were respectively 2.93 ± 1.05 [0.83-5.65] and 2.81 ± 0.97 [0.29-4.77]. The mean BASDAI was 4.42 ± 0.97 [0-9.2]. The mean BASDAI correlated with PhGA (r=0.19, p=0.027). In addition, ASDAS-ESR and ASDAS-CRP correlated with PhGA (r=0.001, r=0.372, p=0.001, r=0.391) respectively.

Conclusion: In conclusion both BASDAI and ASDAS are equal, with a superior-ity nonetheless for the ASDAS since it correlated stronger with PhGA.

PRESCRIBING PRACTICES IN AXIAL SPONDYLOARTHROPATHY

S. Maquire, P. Gallagher*, F. B. O'Shea, *St James' Hospital, Rheumatology, Dublin, Ireland; *St Vincents Hospital, Rheumatology, Dublin, Ireland

Background: Axial spondyloarthropathy(axSpA) treatment has undergone a number of significant developments over the past number of decades.
limited to non-steroidal anti-inflammatories (NSAIDs) and corticosteroids, treatment options now include synthetic disease modifying anti-rheumatic drugs (DMARDs) and biologic agents. The development of national registries for inflammatory arthritis provides an opportunity to study medication usage in a large cohort of patients with axSpA. The Ankylosing Spondylitis Registry of Ireland (ASRI) is a source of epidemiological data on patients with axSpA in Ireland. The aim of this study was to examine medication exposure and outcomes.

**Objectives:** To characterize a large cohort of patients with axSpA in terms of medications usage, burden of disease and patient reported outcomes.

**Methods:** The patient population registered in the ASRI was analyzed using IBM SPSS version 26. Patients were analyzed on the basis of medication exposure. The four treatment groups were classified as no treatment, NSAIDs only, biologics only, or biologics and NSAIDs. Mean age, duration of treatment and delay to diagnosis was compared between groups. Burden of disease was assessed via mean BASDAI, BASFI, BASMI, HAQ and ASQoL during the four groups. Differences between groups was tested for statistical significance a one-way analysis of variance (ANOVA). A chi-squared test for independence was used to compare differences in rates of HLA-B27 positivity rates and gender. Results were deemed significant where p < 0.05.

**Results:** At present 880 patients are currently enrolled in the ASRI with 76.6% (659) males and 23.4% (201) females. Average age of patients is 45.8 years, mean disease duration of 19.4 years with 95.5% (821) of patients listed as Caucasian. Mean scores were BASDAI 4.02, BASFI 3.7, BASMI 4.02, HAQ 0.55, and ASQoL of 6.51. Treatment groups were made up of 9.3% (85) on no treatment, 22.2% (191) NSAIDs treatment only, 34.8% (299) biologics treatment only and 32.1% (276) treated with both NSAIDs and biologics. Patients on NSAIDs were noted to be older than patients on biologics, and those on both biologics and NSAIDs (p=0.02). Patients on NSAIDs were older at symptom onset than those on biologics and NSAIDs treatment (p=0.02), however the effect size is small(0.012). No significant difference was noted between groups regarding disease duration, delay to diagnosis or distribution between genders (table 1). Difference in BASDAI scores between groups was significant across all groups, with patients on both biologics and NSAIDs having the highest scores and those on no treatment with the lowest scores(4.74 vs 3.37) possibly a reflection of disease severity(table 2).

**Conclusion:** A large proportion of patients in the ASRI were treated with either biologics only or both biologics and NSAIDs. No treatment was the least common treatment within this cohort. Patients not on treatment tended to be older than those on any type of treatment. Overall patients on biologics alone tended not to have better patient reported outcomes as compared to all other treatment groups. The development of longitudinal data for the ASRI will help to further understand the reason behind these differences.

**Disclosure of Interests:** Sinead Maguire Grant/research support from: ASRI the reason behind these differences.

Background: On literature there are a significant number of cases describing the coexistence between Spondyloarthritis (Spa) and sarcoidosis. There are 3 main ways in which different diseases can be found in the same individual: chance, selection bias, or by 1 or more types of causal association. In this work we analyze whether there is a causal association between sarcoidosis and Spa.

Objectives: To analyze the hypothesis that there is a causal association between sarcoidosis and Spa.

Methods: Case-control study nested in a population database of hospital admissions (CMBD). Period: 1999 to 2015. Database Study (DB): Study population + control population. Study population: patients with a diagnosis of Spa who were admitted to any national hospital. Control population (GP): group of the general population (without Spa diagnosis) matched of equal sex, age, year of admission as the study population. Cases: Cases of sarcoidosis were identified by the presence of ICD-9 code 135. Controls: admissions without sarcoidosis diagnosis. The clinical-demographic characteristics of patients with Spa and sarcoidosis vs Spa without sarcoidosis are described. To rule out the association being random, the Odds Ratio (OR) was calculated for the association between sarcoidosis and Spa. To minimize selection error, the association with logistic regression models was analyzed by adjusting by more than 50 variables.

Results: The DB of the study consists of 205,218 admissions: 102,609 admissions with Spa and 102,609 admissions without Spa. There was a total of 220 admissions with sarcoidosis: 133 (0.12%) in Spa and 87 (0.08%) in the GP group. The control population (GP) included all adults ≥ 18 years of age with exclusion of positive ANA, diagnosis of RA, SLE, AS, or vasculitis, and at least one outpatient office visit during the study period. For both groups we excluded previous diagnosis of cancer prior to 2009. A chi-square test of association was performed between the 2 groups (AS patients and controls) and the odds ratio (OR), its standard error, and the 95% confidence interval (CI) were calculated. Results: Of the 14,310 patients with AS, only 1300 (9.08%) patients had a cancer diagnosis compared to 2,719,240 controls (11.07%). The AS patients found to have decreased odds of cancer compared to control group (Odds ratio 0.9004, 95% CI: 0.8502 to 0.9536, P = 0.0003). Demographics and clinical characteristic of AS patients and controls with cancer are shown in table 1. Risk factors for increased cancer risk in AS patients are shown in table 2. Conclusion: The study demonstrated that cancer risk was lower in the AS patients in the USA compared to the controls with no rheumatic disease. Male sex, white race, HLA-B27 positivity, history of IBD, NSAIDs use, and elevated makers of inflammation were associated with higher odds of cancer in AS patients.

**IS ANKYLOSING SPONDYLITIS ASSOCIATED WITH INCREASED MALIGNANCY RISK?**

S. Merjanah1, M. Bittar2, M. Magrey2. 1The MetroHealth System campus of Case Western Reserve University, Internal Medicine, Ohio, United States of America; 2The University of Tennessee Health Science Center, Rheumatology, Tennessee, United States of America; 3The MetroHealth System campus of Case Western Reserve University, Rheumatology, Ohio, United States of America

Background: Increased cancer risk has been reported with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Few studies on malignancy risk in ankylosing spondylitis (AS) patients have provided conflicting data.

Objectives: To look at the risk of cancer in AS patients. We aim to identify any risk factors associated with increased cancer frequency.

Methods: This is a retrospective observational study using the IBM Explorys data base a pooled de-identified clinical data base of > 60 million unique patients in the US with patient level data. The Explorys collects aggregated, standardized and normalized clinical data from different electronic health records automatically updated in near real time. In Explorys, patient records are mapped into a single set of Unified Medical Language System ontologies to facilitate searching and indexing. Diagnoses, findings and procedures are mapped into the systematized nomenclature of medicine – clinical terms (SNOMED-CT) hierarchy. Criteria of AS included at least one visit with a rheumatologist and the diagnosis code of AS (N=14,310) between 2009-2019. We further stratified the cohorts by adding the following variables to the search tool: race, gender, smoking, laboratory data (elevated ESR and CRP, HLA-B27 status), extra articular manifestations (psoriasis, inflammatory bowel disease or uveitis) and medication use (TNF inhibitor, secukinumab or NSAIDs). The index date was defined as the date of the first ever malignant neoplasic disease diagnosis occurring after the qualifying AS diagnosis.

The controls group (24,542,770) included all adults ≥ 18 years of age with exclusion of positive ANA, diagnosis of RA, SLE, AS, or vasculitis, and at least one outpatient office visit during the study period. For both groups we excluded previous diagnosis of cancer prior to 2009. A chi-square test of association was performed between the 2 groups (AS patients and controls) and the odds ratio (OR), its standard error, and the 95% confidence interval (CI) were calculated. Results: Of the 14,310 patients with AS, only 1300 (9.08%) patients had a cancer diagnosis compared to 2,719,240 controls (11.07%). The AS patients found to have decreased odds of cancer compared to control group (Odds ratio 0.9004, 95% CI: 0.8502 to 0.9536, P = 0.0003). Demographics and clinical characteristic of AS patients and controls with cancer are shown in table 1. Risk factors for increased cancer risk in AS patients are shown in table 2. Conclusion: The study demonstrated that cancer risk was lower in the AS patients in the USA compared to the controls with no rheumatic disease. Male sex, white race, HLA-B27 positivity, history of IBD, NSAIDs use, and elevated makers of inflammation were associated with higher odds of cancer in AS patients.

SERUM IL-12/23 AND IL-17 LEVELS IN PATIENTS WITH SPONDYLOARTHRITIS WERE NOT INFLUENCED BY TNF-BLOCKADE

M. Murakami1, N. Nishimoto1,2, Osaka Rheumatology Clinic, Osaka, Japan; 2Tokyo Medical University, Osaka, Japan

Background: Spondyloarthritis (SpA) refers to a heterogeneous group of disorders with clinical features that can include axial and peripheral arthritis, inflammatory bowel disease, uveitis, and psoriasis. Several cytokines including interleukin (IL)-12/23, IL-17 and tumor necrosis factor (TNF) are involved in pathogenesis of SpA. It is assumed that TNF is the upstream cytokine in the cytokine cascade (Schett et al., 2013). Objectives: To investigate whether TNF inhibitors decrease serum IL-12/23 and IL-17 levels in patients with SpA.

Methods: Serum were obtained from 23 SpA patients (AS, 10 patients; PsA, 13 patients) enrolled in this study, at baseline, 24 and 48 weeks of TNF inhibitor treatment. Serum IL-12/23 and IL-17 levels were measured using LEGEND MAX Human IL-12/23 (p40) ELISA Kit (BioLegend) and Human IL-17A ELISA kit (Invitrogen), respectively. IL-6 levels, the other downstream cytokine, was measured using Lumipulse G6000 (FUJIREBIO) as a control.

Results: Any significant reduction in IL-12/23 levels (143.9±143.6 pg/mL at baseline, 156.3±171.1 pg/mL at 24 weeks and 139.3±118.1 pg/mL at 48 weeks), as well as in IL-17 levels (13.6±51.9 pg/mL at baseline, 12.3±41.4 pg/mL at 24 weeks and 11.6±39.2 pg/mL at 48 weeks) were not observed in 23 SpA patients. On the other hand, serum IL-6 levels were significantly decreased after treatment (4.0±4.2 pg/mL at baseline; 1.8±1.4 pg/mL, p=0.002, at 24 weeks; 1.6±1.9 pg/mL, p=0.002 at 48 weeks). Pain-VAS was significantly reduced at 24 and 48 weeks compared with that at baseline. Significant differences in serum levels of analyzed cytokines were observed in the AS group compared with the PsA group at baseline (IL-12/23 levels: 110.8±70.0 vs. 169.3±180.3 pg/mL, p=0.08; IL-17 levels: 26.8±78.6 vs. 3.4±76.0 pg/mL, p=0.08).

Conclusion: TNF inhibitors did not alter serum IL-12/23 and IL-17 levels but reduced IL-6 levels in patients with SpA. These results imply that IL-12/23 and IL-17 expression might be regulated by alternative pathways.

PATIENT PERCEPTIONS OF FIBROMYALGIA SYMPTOMS AND THE OVERLAP WITH AXIAL SPONDYLOARTHRITIS

K. Gavigan1,2, W. B. Nowell1,3, R. Reynolds1, L. Stratford1, J. Curtis2, A. Ogdie3
1 Global Healthy Living Foundation, Upper Nyack, United States of America; 2University of Alabama at Birmingham, Birmingham, United States of America; 3University of Pennsylvania, Philadelphia, United States of America

Background: In clinical practice, it is often challenging to distinguish fibromyalgia syndrome (FMS) from axial spondyloarthritis (axSpA), which includes ankylosing spondylitis and non-radiographic axSpA. Early stages of axSpA may present with an onset similar to FMS, and likewise patients with FMS may have symptoms that are similar to axSpA. Differentiating between axSpA and FMS can also be challenging for patients and cause confusion about their diagnosis.

Objectives: To examine the prevalence of axSpA symptoms among patients with FMS and differences in the pathway to diagnosis among patients with and without concomitant axSpA.

Methods: Adult US patients with FMS without concomitant rheumatoid arthritis or psoriatic arthritis in the ArthritisPower registry received email invitations to participate. Participants (pts) were asked whether they had a diagnosis of axSpA or ankylosing spondylitis and completed patient-reported outcome measures including Patient Reported Outcomes Measurement Information System (PROMIS) measures for Pain Interference, Sleep Disturbance and Fatigue, and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Pts then responded to a 57-item customized survey developed by the researchers in collaboration with patient partners. Results are descriptively reported.

Results: As of January 2020, 231 pts completed the survey; 97% female, 89% White, mean (SD) age of 52 (11). Mean (SD) Pain Interference score was 68 (5); Sleep Disturbance 63 (8); Fatigue 68 (7); and BASDAI 46 (9). Of the pts, 40 (17%) reported concomitant axSpA, 64% osteoarthritis, 6% out, 5% Crohn’s or ulcerative colitis, and 4% lupus. Half of all pts perceived their FMS to be ‘rarely’ or ‘never’ well managed and 80% felt that they have had an undiagnosed condition in addition to their FMS and their other current diagnoses. Three-fourths (75%) of pts reported being able to tell the difference between their FMS pain and pain they experience as a part of the concomitant disorder. Back pain lasting >3 months was reported by 95% of axSpA pts and 94% of non-axSpA pts and 12% reported all of the symptoms consistent with patient reported versions of the Assessment of SpondyloArthritis International Society (ASAS) criteria (back/buttock pain >3 months; age of symptom onset <45; sacroiliitis diagnosis; at least on spondyloarthritis feature) (Figure 1), and of these, 39% reported an axSpA diagnosis. More pts with axSpA received their FMS diagnosis by a rheumatologist (45%) than without (41%) (Figure 2), and of the pts without an axSpA diagnosis (n=191), only 6% had recalled their provider ever discussing with them the possibility of axSpA, including non-radiographic axSpA diagnosis. Half (53%) of pts with axSpA believe that their axSpA should have been diagnosed earlier, with 33% reporting that one reason for the delay was their doctor’s belief that FMS was the cause of any axSpA symptoms they experienced.

Conclusion: Patients with FMS often experience symptoms of axSpA and the two conditions can occur concomitantly. Additional research is needed to improve the triage, diagnosis, and education of patients with FMS and symptoms of axSpA.

Benjamin Nowell: None declared, Laura Stratford: None declared, Jeffrey Curtis Grant/research support from: AbbVie, Amgen, Bristol-Myers Squibb, Corrona, Janssen, Lilly, Myriad, Pfizer, Regeneron, Roche, UCB, Consultant of: AbbVie, Amgen, Bristol-Myers Squibb, Corrona, Janssen, Lilly, Myriad, Pfizer, Regeneron, Roche, UCB, Alexis Ogdie Grant/research support from: Abbvie, Amgen, BMS, Celgene, Corrona, Janssen, Lilly, Pfizer, Novartis

DOI: 10.1136/annrheumdis-2020-eular.5624

DOI: 10.1136/annrheumdis-2020-eular.2356
Background: In axial spondyloarthritis (axSpA) the risk of vertebral fracture is increased, not always corresponding with the values of bone mineral density (BMD). One possible explanation is that syndesmophytes interfere with these values. We consider whether the evaluation of trabecular microarchitectural by an accessible method like the Trabecular Bone Score (TBS), that does not involve additional irradiation neither seem to be influenced by the presence of syndesmophytes, may be an advantage to estimate the risk of fracture.

Objectives: To estimate the prevalence of vertebral fractures in patients with axSpA. To assess the diagnostic accuracy of TBS and BMD for vertebral fracture, and if it is influenced by the presence of syndesmophytes. To analyze the correlation between the absolute values of BMD and TBS in the lumbar spine.

Methods: Cross-sectional study. Patients were consecutive recruited. We collected demographic (sex, age), clinical (syndesmophytes, vertebral fracture, BASDAI, BASFI, time of evolution of axSpA, treatment) and analytical variables [vitamin D (1,25-OHD), CRP and ESR]. The BMD was determined using the Lunar Prodigy ProTM densitometer from GE Healthcare, to which the TBS iNastró® software version 2.2 was added to perform the TBS analysis. The prevalence of fracture was evaluated by radiology. The statistical analysis was performed with the SPSS 22.0 and OpenEpi softwares.

Results: 84 patients were included, 60 men and 24 women, with a mean age of 59 years (± SD 13); 51.2% had lumbar syndesmophytes. The prevalence of fractures was 13.7%, 95 CI (7.8-22.9); 51.2% were treated with NSAIDs, and 48.8% with biological drugs. The evolution of axSpA was > 10 years in 65.5%. The mean scores of BASDAI and BASFI were 3.7 and 4.3 respectively (± SD 2.2 and 2.3). The mean CRP value was 8.5 mg/L (± SD 8.4), ESR 12.2 mm/h (± SD 11.4) and 125-OHD 27.9 ng/dl (± SD 13.6).

Regarding the lumbar and femoral T Score, 9.5% and 15.5% of the patients were in the range of osteopenia respectively; 19% patients had a low TBS value (≤ 1.23). Regarding the influence of syndesmophytes on TBS and BMD values, we found significant differences in lumbar spine BMD (p = 0.01) but not in total hip and femoral neck BMD (p = 0.2 and 0.3 respectively) nor in the TBS (p = 0.1). In the univariate analysis, the factors related to the presence of vertebral fracture were age, female sex, absolute BMD values in the lumbar spine and total hip, and TBS values. No relationship was found with the rest of the variables. In the multivariate analysis, only the TBS showed a significant association with the presence of fractures (p = 0.02).

Regarding the predictive capacity of fractures, TBS showed a higher sensitivity than that of BMD (55.6% versus 18.2% and 30% of BMD in the spine and hip respectively).

Regarding the predictive capacity of fractures, TBS showed a higher sensitivity than that of BMD (55.6% versus 18.2% and 30% of BMD in the spine and hip respectively), being the specificity comparable (85.3% versus 91.3% and 85.1% of BMD in column and hip respectively).

Conclusion: The prevalence of fractures was 13.7% among the patients studied, 95 CI (7.8-22.9). The presence of syndesmophytes influenced the values of lumbar BMD but not the hip BMD or those of the TBS. We found a correlation between the values of BMD of the spine and TBS only in patients without syndesmophytes. In the univariate analysis, the factors related to the presence of vertebral fractures were age, female sex, absolute BMD values in the lumbar spine and total hip, and TBS values. No relationship was found with the rest of the variables. In the multivariate analysis, only the TBS showed a significant association with the presence of fractures (p = 0.02).

AB0713  PERIODONTAL DISEASES AND ITS ASSOCIATION WITH ANKYLOSING SPONDYLITIS/SPA: A SYSTEMATIC REVIEW
A. Pandey1, V. Ravindran2, M. Pandey3, R. Rajak4, V. Pandey5. 1Apollo Hospitals, Indore, Rheumatology, Indore, India; 2Centre for Rheumatology, Kozhikode, India; 3Clinical Immunology & Rheumatology Clinic, Oral Medicine, Indore, India; 4Croydon Health Services NHS Trust, Rheumatology, Croydon, United Kingdom; 5MGMMC, Indore, Medicine, Indore, India

Background: A close association between periodontal disease and Ankylosing spondylitis (AS) has long been speculated. Both diseases are characterized by dysregulation of the host inflammatory response, leading to further destruction of soft and hard connective tissue with there being evidence of increased levels of TNF-α and various interleukins in both patients of AS and periodontitis.

Objectives: The aim of this systematic review was to appraise the available literature exploring the relationship between AS and periodontal disease.

Methods: We searched Medline & Embase databases (from their inception till October 2019) using appropriate combinations of following search items with limits (‘English, Human’): Ankylosing spondylitis, spondyloarthritides, spondyloarthropathies, chronic periodontitis, periodontoses, parodontoses, chronic periodontitis, gum disease, gingivitis, oral health, dental health, plaque index, bleeding on probing, probing pocket depth, clinical attachment loss. This search was supplemented by the manual search of bibliographies of articles selected and conferences proceedings of EULAR. Only be reviews, observational study of cross-sectional, cohort or case-control type on adult patients with AS were selected. Data was extracted from a predesigned proforma. A close association between periodontal disease and Ankylosing spondylitis (AS) has long been speculated. Both diseases are characterized by dysregulation of the host inflammatory response, leading to further destruction of soft and hard connective tissue with there being evidence of increased levels of TNF-α and various interleukins in both patients of AS and periodontitis.

Results: A total number of 984 articles were identified and 12 were selected for detailed appraisal (Figure 1, PRISMA flow chart). They were all case control studies. The prevalence of periodontitis ranged from 38% to 88% in patients with AS whereas in the control group from 26% to 71% in controls. Out of 12 studies, two showed significant changes in Plaque Index (PI), two studies showed altered Pocket Probing Depth (PPD), three showed significant increase in Clinical Attachment Loss (CAL) and increased Bleeding On Probing (BOP) was seen in 2 studies. In 7 studies, periodontitis was seen in a significant number of patients with AS ($p<0.05$). All studies reported that the prevalence of periodontal disease in AS patients was higher as compared to non-AS patients.

Conclusion: Our systematic review found an association between AS and periodontal disease. Patients with AS show higher prevalence of periodontitis and a poor oral hygiene as compared to healthy controls. At practice level, this systematic review underscores the need for a collaboration between dentists and rheumatologist.

 Disclosure of Interests: None declared

AB0714  THE ROLE OF AGE, DURATION OF THE DISEASE AND CUMULATIVE GLUCOCORTICOID DOSE IN THE FORMATION OF DISORDERS OF THE STRUCTURAL AND FUNCTIONAL STATE OF BONE TISSUE IN MEN WITH ANKYLOSING SPONDYLITIS
S. Shevchuk1, O. Pavluk2. 1National Pirogov Memorial Medical University, Scientific and Research Institute of Invalid Rehabilitation (educational scientific treatment complex) of National Pirogov Memorial Medical University; Vinnytsya, Ukraine; 2National Pirogov Memorial Medical University, Vinnytsya, Ukraine

Background: In recent years, it is becoming increasingly clear that osteoporosis (OP) holds the important place among complications of ankylosing spondylitis (AS). The frequency of emergence of OP, according to the data of last investigations, ranges from 18.7 to 62%, osteopenic syndrome – from 50 to 92%. It is known that decrease of bone mineral density (BMD) in patients with AS is caused not only by the action of traditional risk factors (age, sex, genetic predisposition, low body mass, and others) but also by the action of factors associated with the disease itself such as: duration of AS, activity of the inflammatory process, administration of glucocorticoids (GC), deficiency of Vitamin D, low physical activity of patients and so on. However, until now there are no clear data about the role of each of them in the formation of disorders of bone metabolism in men with AS. In the Ukrainian population of patients with AS such investigations have not been conducted.

Objectives: To investigate the role of age, duration of disease and cumulative glucocorticoid dose in the formation of disorders of bone mineral density (BMD) in men with AS.

Methods: The investigation of 108 men with AS at the age of 40.74 ± 0.87 years and 25 normal control subjects of the same age and sex has been carried out. The diagnosis of AS was established on the basis of modified New York criteria. BMD of the lumbar spine and femoral neck was determined by dual-energy X-ray absorptiometry on the apparatus Tisologic Discovery Wi (S / N 87227). The diagnosis of osteoporosis in men over 50 years was considered in case of decrease of BMD by T-score ≤ –2.5 SD, for men under the age of 50, the Z-score was used, and its decrease ≤ –2.0 SD and more indicated the significant loss of bone mass.

Results: A decrease of BMD at the level of the lumbar spine and femoral neck was found in 61 (56.5%) patients, of these 29 (27.7%) had osteoporosis, 31 (29.5%) had osteopenia. In the control group, decrease of BMD was detected in 6 (24%) patients, of these osteoporosis was diagnosed in 1 (4%), and osteopenia was diagnosed in 5 (20%) patients. In the age group of below 35 years, 18 (64.3%) patients had a decrease in BMD, 35 (56.5%) patients – in the 36-55 age group, and 8 (53.3%) patients – over the age of 45. The index of BMD also did not differ significantly between the groups. As for the duration of the disease, the
largest proportion of 33 (75%) patients with decreased BMD was found in the group of patients with duration of the disease from 5 to 10 years. In the group of patients with duration of the disease up to 5 years, patients with decrease in the Z-score was 11 (55%), and in the group with duration of the disease more than 10 years - 17 (41.6%) patients. Decrease of BMD was associated with cumulative glucocorticoid dose. In particular, in the group of patients with a cumulative dose of glucocorticoids less than 12.6 g Z-score at the level of the lumbar spine was \(-0.98 \pm 0.17 \text{ SD}\), in the group with a cumulative dose of GC 12.6-21.6 g Z-score was equal to \(-0.43 \pm 0.40 \text{ SD}\), and in the group with cumulative glucocorticoid dose more than 21.6 g Z-score was \(-1.89 \pm 0.30 \text{ SD}\). As the glucocorticoid dose increased, the proportion of patients with decreased BMD increased. In the group of patients with the highest dose of GC there were 67.7% such patients, while in the group with the lowest dose – only 30 (57.6%). Significant correlation \((r = -0.24)\) was established between Z-score of the lumbar spine and the total dose of GC.

Conclusion: In 61 (56.5%) patients with AS decreased BMD at the level of the lumbar spine and neck of the femur is revealed. Decrease of BMD in patients with AS was associated with age and duration of the disease, but is associated with the cumulative dose of GC.

AB0715  POSSIBLE METHODS OF EARLY DIAGNOSIS OF RENAL ALTERATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

I. Plenkina1, O. Cmmnovska2, V. Rozinova2, 1Kirov State Medical University, Kirov, Russian Federation; 2Kirov State Medical University, Kirov, Russian Federation

Background: kidney damage is one of the extraarticular manifestations and complications of ankylosing spondylitis (AS). Due to some disadvantages of traditional renal function parameters, the search for new markers is actively conducted [1].

Objectives: to evaluate urinary excretion of liver type of fatty acid binding protein (L-FABP), which is expressed in cells of proximal tubules, heart type of fatty acid binding protein (H-FABP), which is expressed in cells of distal tubules [2], and trefoil factor-3 (TFF-3), which is expressed in cells of the proximal and distal tubules and collecting duct [3], in patients with AS.

Methods: urine samples of 50 patients (37 males, 13 females) were evaluated. Patient inclusion criteria were a diagnosis of AS according to the New York modified criteria (1984) and ASAS 2009 (The Assessment of SpondyloArthritis international Society, 2009) for axial spondyloarthritis and age 18 and over. Median age of patients was 39 [34;56] years, duration of joint syndrome – 10 [7;18] years, cumulative glucocorticoid dose – above 21.6 g

Disclosure of Interests: None declared

AB0716  SEX DIFFERENCES IN CLINICAL PHENOTYPE AND RADIOGRAPHIC DISEASE PROGRESSION IN AXIAL Spondyloarthritis: RESULTS FROM THE GERMAN Spondyloarthritis Inception Cohort

M. Protopopov1, M. Torgutalp1,3, J. Sieper1, H. Haafl1, F. Proft4, V. Rios Rodriguez4, M. Rudwaleit3, D. Podobubny4,5, Charité Universitätsmedizin Berlin, Berlin, Germany; 1Department of Gastroenterology, Infectiology and Rheumatology CBB, Berlin, Germany; 2Ankara University Faculty of Medicine, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey; 3Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany; 4German Rheumatism Research Centre, Berlin, Germany

Background: It is presumed that the phenotype of the axial spondyloarthritis (axSpA) may differ in females and males; the published data are controversial.

Objectives: To explore the sex differences in disease features and radiographic progression in axSpA.

Methods: A total of 210 patients with axSpA (115 with radiographic and 95 with non-radiographic axSpA) were selected for analysis. Spinal radiographs were scored by two readers in a random order according to the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Pelvic radiographs were scored according to the grading system of the modified New York criteria; a saccroiliitis sum score was calculated as a sum of the grades for both sacroiliac joints. Mann-Whitney and Fisher exact tests were performed for group comparisons. A multivariable regression analysis was performed to analyze the influence of gender on radiographic progression.

Results: Males (n=107; 51%) were significantly younger at disease onset (34.8 ± 10.3 vs. 31.5 ± 11.2 years, p=0.008) and at diagnosis (37.5 ± 10.2 vs. 34.1 ± 11.2 years, p=0.006); symptom duration at baseline was similar (4.1 ± 2.6 vs. 4.3 ± 2.1 years, p=0.66). Females were less often HLA-B27 positive (74 [72.5%] vs. 92 [86.0%], p=0.02), had higher baseline disease activity (BASDAI 4.3±2.2 vs. 3.7±2.0, p=0.05), but lower baseline C-reactive protein level (7.1 ± 10.9 vs. 12.3 ±18.2 mg/l, p=0.08), and similar time-averaged ASDAS (2.5±0.8 vs. 2.4±1.0; p=0.385). Males more frequently had definite radiographic sacroilitis (70.1% vs. 38.6%; p<0.001), higher saccroiliitis sum score (4.9 ± 1.9 vs 3.2±1.8, p=0.001), and higher mean mSASSS (6.1 ± 10.7 vs 2.4 ± 4.0; p=0.100) at baseline. Other variables were comparable between the groups. There was a trend for a higher radiographic progression in males in all explored outcomes, statistically significant only for the formation/progression of syndesmophytes (23 [21.5%] vs. 10 [9.7%], p=0.023), with no differences in the radiographic progression of sacroiliitis. In a multivariate logistic regression analysis, similar odds for spinal radiographic progression, new syndesmophyte formation and radiographic progression of sacroiliitis by ≥1 grade were seen – Table 1.

Conclusion: There was a trend for male patients to have more radiographic damage at the baseline and more progression after two years, as reflected by the percentage of patients with new syndesmophytes.

Table 1. Association of sex with radiographic progression in spine and sacroiliac joints after 2 years of follow-up.

CLINICAL FEATURES OF PATIENTS WITH ANKYLOSING SPONDYLITIS AND SECONDARY AA-AMYLIOIDOSIS

D. Rumiantceva1, E. Agafonova1, S. Krasnokonov, P. Podryadov1, A. Starkova1, M. Urumova1, S. Erdes1, 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Secondary AA-amylidosis is one of the most serious complications of ankylosing spondylitis (AS). Better knowledge of specific to secondary AA-amylidosis clinical features is important for improving further management of these patients.

Objectives: To conduct a comparative analysis of AS patients with and without secondary AA-amylidosis.

Methods: The study included 220 AS patients (according to modified New York criteria) without amyloidosis - Group 1, and 9 AS patients with histologically confirmed secondary AA-amylidosis – Group 2.

Results: Table 1 presents the comparative characteristics of Group 1 and Group 2 patients. Both groups were comparable in terms of patients’ age, rates of HLA B27 positivity, presence of enthesitis, uveitis, inflammatory bowel disease, psoriasis and psoriatic arthritis. Group 2 patients tended to be younger at AS onset, while shorter disease duration and fewer male patients were established for Group 1. Group 2 had higher rates of extra-skeletal AS manifestations, such as arthritis and coxitis. It should be noted that all AS patients with secondary AA-amylidosis were males, with clinically manifest arthritis, involving hip joints, and AS onset in the childhood in 8 out of 9 cases.

DIAGNOSTIC PERFORMANCE OF VARIOUS CLASSIFICATION CRITERIA IN LOW BACK PAIN PATIENTS WITH SUSPECTED AXIAL SPONDYLOARTHITIS: A PRACTICAL STUDY.

A. Ramon1, C. Fayolle1, H. Devillers2, C. Piroth3, I. Herrada4, G. Attane5, D. Wendling1, P. Ornetti6, 1Dijon University Hospital, Rheumatology, Dijon, France; 2Dijon University Hospital, Rheumatology, Dijon, France; 3Dijon University Hospital, Internal Medicine, Dijon, France; 4Dijon University Hospital, Rheumatology, Dijon, France; 4Dijon University Hospital, Radiology, Dijon, France; 5Besançon University Hospital, Rheumatology, Besançon, France

Background: In routine practice, axial spondyloarthritids (SpA) can be a diagnostic challenge because there is potential overlap with osteoarthritic low back pain or diffuse polyalgic syndrome with axial pain as fibromyalgia. Internationally recognized classification criteria (AMOR, ASAS (1), ESSG (2)) are often used as diagnostic tools in clinical practice (3), but few studies have sought to establish their “real life” diagnostic performances.

Objectives: This monocentric study aimed to evaluate the diagnostic performance of different sets of classification criteria for SpA in patients with chronic back pain hospitalized for suspected axial SpA. The second objective was to evaluate the impact of the sacroiliac MRI reading according to the ASAS MRI reading or expert musculoskeletal reading.

Methods: Patients presenting with inflammatory low back pain who underwent standardized sacroiliac MRI protocol were consecutively included. The diagnoses obtained with the classification criteria (AMOR, ESSG, Modified AMOR and Modified ESSG (with sacroiliac MRI)) were compared to the gold standard diagnoses (made by a college of three experienced rheumatologists). Two readings of the sacroiliac MRI were performed (ASAS MRI reading and Expert MRI reading (including all inflammatory or structural T1 or T2 STIR abnormalities)). Diagnostic performance was measured for each set of classification criteria: sensitivity, specificity, predictive positive and negative values (PPV, NPV) and positive and negative likelihood ratios (PLR, PLN). The clinical, biological and MRI factors associated with axial SpA diagnosis were identified in a multivariate logistic regression model.

Results: 58 patients were included. The mean age was 56.8 ± 10.7 years. Twenty-three men and 35 women were included, mean age of 43.3 ± 10.6 years. The average duration of illness was 7.6 ± 6.8 years. Sixty percent of the series was under biological therapy. HLA-B27 was positive in 79.3%. The average value of BASDAI was 5.4 ± 3.8. There were significant correlations between BASDAI and BASFI (rho: 0.86, p <0.0005), BASFI and ASAS-HI (rho: 0.70, p <0.0005), ASDAS and ASAS-HI (rho: 0.70, p <0.0005), ASDAS and BASFI (rho: 0.86, p <0.0005), BASFI and ASAS-HI (rho: 0.70, p <0.0005), ASDAS and BASFI (rho: 0.86, p <0.0005), ASDAS and BASFI (rho: 0.70, p <0.0005).

Conclusion: The results of this pragmatic study suggest that the Modified AMOR criteria with ASAS MRI reading can be used to rule out axial spondyloarthritis (NPV = 97%). However, the use of an MRI ASAS reading alone creates a risk of false positives because of the greater impact on ASAS criteria compared to AMOR or ESSG criteria. Further international studies are needed to decrease the rate of false positives in suspected cases of axial spondyloarthritis in routine practice.

**SOLUBLE TRANSFERRIN RECEPTOR IN DIAGNOSIS OF IRON DEFICIENCY ANEMIA IN PATIENTS WITH SPONDYLOARTHRITIS**

K. Safarov1, A. Rebrov2. 1Saratov State Medical University named after V. I. Razumovsky, Chair of Hospital Therapy, Saratov, Russian Federation; 2Saratov State Medical University named after V. I. Razumovsky, Chair of Hospital Therapy, Saratov, Russian Federation

**Background:** Anemia is a frequent hematological disorder in patients with rheumatic diseases. The main pathogenetic variants of anemia are anemia of chronic disease (ACD), iron deficiency anemia (IDA), and anemia of chronic disease with iron deficiency (ACD/IDA). The presence of systemic inflammation hinders to diagnose absolute iron deficiency, because standard tests of iron status are affected by it. Soluble transferrin receptors (sTfR) measurement and the calculation of the sTfR log ferritin index (sTfR) index are recommended, but data about diagnostically significant levels of these indicators in patients with spondyloarthritides (SpA) is currently limited.

**Objectives:** To assess the diagnostic significance of sTfR and the sTfR index for detecting absolute iron deficiency in patients with SpA and anemia.

**Methods:** Complete blood count, standard iron metabolism parameters, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were evaluated in 68 patients with SpA. Serum concentration of sTfR was measured with enzyme-linked immunosorbent assay (ELISA) using sTfR ELISA kit (‘Monobind Inc.’, USA). The sTfR index was calculated by the formula sTfR/log10 ferritin. Anemia was defined using the World Health Organization criteria. Depending on the serum ferritin concentration, transferrin saturation, and CRP level, ACD, IDA, or combined anemia (ACD/IDA) were diagnosed. Disease activity was determined by the BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) and ASDAS-CRP (Ankylosing Spondylitis Disease Activity Score based on CRP) scales. Receiver operating characteristic (ROC) analysis was performed with MedCalc.

**Results:** Anemia was found in 48 of 68 (70.6%) SpA patients. 16 (33.3%) patients had ACD and 32 (46.7%) had IDA, Hemoglobin level in ACD was 118 [112; 123] g/L, in IDA – 101 [96; 106] g/L, in non-anemic patients – 133 [129; 145] g/L (p<0.001 for all groups). CRP and ESR values were higher in ACD compared to IDA patients (31.5 [20.3; 46.4] mg/L and 270 [16.0; 35.5] mm/h versus 9.8 [5.6; 16.9] mg/L and 15.5 [12.0; 22.5] mm/h, respectively) (p<0.001 and p=0.03). No statistically significant difference was found between all groups in BASDAI and ASDAS-CRP scores. ACD/IDA patients had significant increases in serum sTfR levels (1.7 [1; 2.4] mg/L compared to ACD (1.5 [1; 1.7] mg/L, p=0.04) and to non-anemic patients (1.3 [1; 1.6] mg/L, p=0.003). The sTfR index was significantly higher in ACD/IDA (0.93 [0.82; 1.24]) compared to patients with ACD (0.64 [0.48; 0.75], p<0.001) and without anemia (0.67 [0.56; 0.81], p<0.001).

The areas under the curves (AUCs) for distinguishing between ACD/IDA and ACD were 0.95 for the sTfR index (p<0.001), 0.72 for sTfR (p<0.001). The sTfR index cutoff >0.83 and the sTfR cutoff >1.39 mg/L had sensitivities of 75% and 53%, and specificities of 83% and 81%, respectively.

**Conclusion:** According to obtained data, serum concentration of sTfR >1.39 mg/L and the sTfR index >0.83 point to the presence of iron deficiency component in the structure of anemic syndrome in patients with SpA.

**OCULAR INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE: STUDY OF 1442 PATIENTS FROM A SINGLE UNIVERSITY CENTER.**

L. Sanchez-Bilbao1, D. Martinez-Lopez1, I. Gonzalez-Mazorón1, M. J. Garcia-Garcia1, M. Rivero-Tirado1, B. Castro1, J. Crespo2, M. A. Gonzalez-Gay3, R. Blanco3, H. U. Marques de Valdecilla, Rheumatology, Santander, Spain; 3H. U. Marques de Valdecilla, Gastroenterology, Santander, Spain

**Background:** Inflammatory bowel disease (IBD), which includes Crohn's disease (CD), and Ulcerative colitis (UC) is related to Spondyloarthritis (SpA) and occult manifestations (OM) are well-stabilised in SpA but not in IBD. It has been classically reported that whereas uveitis with SpA is predominantly anterior, unilateral, sudden, and limited; in IBD it is bilateral, posterior, insidious, and chronic (Lyons & Rosenbaum JT. Arch Ophthalmol 1997; 115:614).

**Objectives:** In a large unselected series of IBD, we study the OM and assess: a) epidemiological, clinical features, b) the relationship with extraintestinal manifestations.

**Methods:** Study of all consecutive patients from a single University Hospital during the last 40 years with: a) IBD (CD and UC), and b) OM: uveitis and scleral pathology diagnosed by clinical features and slit-lamp. Results: OM were present in 42 (2.9%) (25 women/17 men) (84 eyes) of 1442 IBD patients; OM included the uveitis group (UG) (n=23; 1.6%) and the scleral pathology group (SG) (n=19; 1.3%) (TABLE).

**LOSS OF GLYCOSAMINOGLYCANs OF LUMBAR INTERVERTEBRAL DISCS IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

P. Sewerin1, D. Abra2, M. Frenken3, X. Baraliakos4, M. Schneider1, B. Oestendorf1, C. Schleich1, Heinrich-Heine University, Department for Rheumatology, Duesseldorf, Germany; 4Heinrich-Heine University, Institute

**Objectives:** The most common pattern in SG was episcleritis (n=16; 84.21%) and scleritis (n=3). In UG, uveitis was typically anterior (n=18; 78.3%), unilateral (n=19; 82.6%), sudden (n=19; 82.6%), and limited (n=12; 52.2%). The comparative study between SG vs UG showed in UG a significant predominance of women and UC. Also, a non-significative higher frequency in Pyoderma gangrenosum, erythema nodosum and joint involvement was observed in UG.

**Methods:** After a mean follow-up of 15.2±9.7 years, extraintestinal manifestations were observed in 100% of patients, being articular forms (n=16; 38.1%) the most common type. In addition, joint/axial flare is more related to the presence of uveitis (p=0.038).

**Conclusion:** Both uveitis and episcleritis are equally frequent OM in IBD. Although uveitis is more infrequent in IBD than in SpA, it is also anterior, unilateral, sudden and limited in contrast with published data from selected series.

DOI: 10.1136/annrheumdis-2020-eular.4612
Background: To evaluate the glycosaminoglycan (GAG) content of lumbar intervertebral discs (IVD) in patients with ankylosing spondylitis (AS) using GAG chemical exchange saturation transfer (gagCEST).

Objectives: Does local GAG content in non-degenerative IVDs measured by gagCEST MRI differs between AS patients and HC?

Methods: 195 lumbar IVD of 15 patients with AS (mean age 50 ±10 years) and 25 healthy control patients (HC) were prospectively examined with 3T magnetic resonance imaging (MRI). MRI protocol contained morphological T2 weighted (T2w) images to grade IVD according to the Pfirrmann classification and biochemical imaging with gagCEST to calculate a region of interest (ROI) of the nucleus pulposus (NP) and annulus fibrosus (AF). Prior to statistical testing of gagCEST effects in patients and HC, IVD were classified according to Pfirrmann.

Results: Significantly lower gagCEST values of NP and AF were found in non-degenerative IVD (Pfirrmann 1 and 2) of AS patients compared to HC (NP: 1.88% ±1.21% vs. 3.38% ±1.71%; p<0.01; confidence interval (CI): 0.89%/2.11%; AF: 1.11% ± 0.7% vs. 1.96% ± 1.23%; p<0.01; CI 0.39%/1.3%).

Conclusion: GagCEST analysis of morphologically non-degenerative IVDs in T2w images showed significantly lower GAG values in patients with AS in the NP and AF compared to HC. Our results potentially allow for the detection of GAG loss prior to morphological degeneration.

Disclosure of Interests: Philipp Severin Grant/research support from: AbbVie, Pfizer

Figure 1. Comparison of morphological T2 weighted (T2w) images to grade IVD according to the Pfirrmann classification and biochemical imaging with gagCEST between HC (A and C) and AS patients (B and D) showing significant lower GAG levels in AS patients.
Spondyloarthritis (SpA) is characterized by significant radiographic changes in the spine. The structural spine damage can be assessed using several scorings such as the Bath Ankylosing Spondylitis Radiology Index (BASRI) and the Bath Ankylosing Spondylitis Radiology Index hip (BASRI-h).

Patients were divided into two groups: G0 including patients without hip involvement and G1 patients with hip involvement.

Results: We included 112 patients with a sex ratio of 2.4. The average SpA symptom duration was 9.33 ± 8.93 years. The diagnostic delay was 42.92 ± 52 months.

Radiographic hip involvement was noted in 39.28% of cases. It was bilateral in 31 patients (70.4%). The total number of cotsis was 75. Severe and moderate hip involvement (BASRI-h ≥ 3) affected 21 hips. The most common radiographic pattern was early cotsis (n=31, 41.3%) followed by the destructive form (n=22, 29.3%), mimicking-osteoarthritic form (n=15, 20%), condensing form (n=5, 6.2%) and ankylosing form (n=2, 2%).

Radiographic sacroiliitis was noted in 75.8% of patients. It was bilateral in 91.7% of cases. Among the 161 sacroiliac joints fulfilling the m-New York criteria, 32.9% had grade 4 and 37.2% had grade 3.

The mean mSASSS was 10.26 ± 15. The mean BASRI-t, BASRI-C, and BASRI-L were 3.99 ± 2.9, 0.89 ± 1.1, and 1 ± 1.3 respectively.

Radiographic sacroiliitis was more common in patients with hip involvement (G1) (90.9% vs 68.2%, p=0.00). Patients in G1 had higher mSASSS (15.78 ± 18.24 vs 6.29 ± 11.85, p=0.01), BASRI-L (1.73±1.46 vs 0.75 ± 1.13, p=0.009), and BASRI-S (5.46 ± 3.02 vs 3.19 ± 2.46, p=10^-4) than patients in G2. There was no significant difference in the two groups regarding the BASRI-C.

Multivariable analysis revealed that radiographic sacroiliitis was associated with hip involvement (OR=14.81, 95%, [1.1-198], p=0.042). When comparing patients with severe and moderate hip involvement (BASRI-h ≥ 3) and those with mild involvement, we didn't find significant differences regarding BASRILs, BASRI-C, mSASSS, and sacroiliac involvement.

Conclusion: As reported in previous studies [1], we concluded that structural axial lesions were higher in patients with cotsis. Structural damage to the sacroiliac joint in SpA was predictive of hip involvement.

We suggest that sacroiliitis, spinal and hip involvement are part of the same spectrum.

AB0725 FACTORS ASSOCIATED WITH RADIOGRAPHIC SPINAL INVOLVEMENT IN SPONDYLOARTHRITIS

M. Slouma1, S. Rahmouni1, R. Dhahri1, I. Gharsallah1, N. Boussetta1, H. Gueddich1, F. Ajili1, L. Metoui1, B. Louzir1.

The mean ESR and CRP were 36.21 ± 27 (mm/H) and 31.28 ± 47.25 (mg/L) respectively. The mean BASRI-C was 3.99 ± 21.96 and the mean mSASSS was 10.26 ± 15.41. Twenty-five patients (22.3%) had no radiographic axial SpA. Men had higher BASRI-L (1.36 vs 0.7, p= 0.045) and BASRI-S (4.3 vs 3.09; p=0.047) than women.

Moreover, smokers' patients had higher mSASSS (14.07 vs 7.02; p=0.031), BASRI-C (1.23 vs 0.62; p=0.031), and BASRI-S (4.82 vs 3.35; p= 0.009) than non-smokers' patients.

A positive correlation was noted between age and BASRI-C (r=0.260, p=0.012). There was no correlation between age at the onset of SpA and structural spine damage.

We found a positive correlation between disease duration and the following scores: BASRI-C (r=0.245, p=0.018) and BASRI-S (r=0.274, p=0.003). Patients with non-radiographic axial SpA had lower mSASSS (4.05 vs 12.14; p=0.034), BASRI-S (1.2 vs 4.7; p=0.010), and BASRI-L (0.42 vs 1.4; p=0.003) than patients with radiographic axial SpA.

There was no correlation between the radiographic index and BASDAI and ASDAS-CRP.

Conclusion: We confirmed previous observations that male gender, smoking and disease duration are associated with structural damage in the spine [1].

However, CRP and other inflammatory biomarkers were not associated with radiographic evidence of spine involvement.

As observed in previous studies, the radiographic spine damage did not correlate with disease activity (BASDAI) [1].

AB0726 CHOROIDAL THICKNESS IS A BIOMARKER AND CAN PREDICT THE RESPONSE TO TREATMENT IN ANKYLOSING SPONDYLITIS

1Hospital Universitario Infanta Sofia, Madrid, Spain; 2Universidad Europea, Madrid, Spain; 3Hospital Universitario 12 de Octubre, Madrid, Spain; 4Hospital Universitario Virgen de la Salud, Toledo, Spain; 5Hospital Universitario de Majadahonda, Madrid, Spain; 6Hospital Universitario de Móstoles, Madrid, Spain; 7Hospital Universitario San Espéanse, Madrid, Spain; 8Hospital Universitario San Espéanse, Palma de Mallorca, Spain; 9Hospital Clínico San Carlos, Madrid, Spain; 10Hospital Universitario Infanta Leonor, Madrid, Spain

Background: Choroidal thickness (CT) has been proposed and evaluated as a potential marker of systemic inflammation associated with inflammatory diseases as Ankylosing spondylitis (AS). Patients with active AS have a thicker choroid than healthy subjects, regardless of eye inflammation. The evolution of choroid after treatment is poorly known.

Objectives: This study evaluates the CT of patients with severe AS disease activity before and after six months of biological therapy.

Methods: This prospective multicenter study evaluates the CT in 44 patients with high AS disease activity, naive for biological treatment, and no history of eye inflammation before and after six months of biological therapy, aged from 18 to 65 years. The correlations between the CT and C-reactive protein (CRP) with the disease activity indices and scales as Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), night pain and Patient Global Assessment (PGA) were calculated at baseline and after six months of biological therapy. The concordance between the CT and CRP was determined. Finally, we assessed potential predictors of response to treatment. Clinically important improvement was defined as a decrease in ASDAS score ≥ 1.1 points.

Results: Globally, 44 eyes of 44 patients aged between 18-65 years were included in the study. 12 (27%) women. The biological treatments prescribed were: Adalimumab 13 (29.5%), Certolizumab 9 (20.5%), Secukinumab 10 (20%), Etanercept 8 (18%), Infliximab 3 (6.8%), and Golimumab 1 (2.2%). Mean CT values were significantly higher at baseline than after six months of treatment (baseline 355.28±80.46 µm; 6 months, 341.26±81.06 µm) (p<0.001).

CT decreased both in patients on biological treatment without effect in eye (Secukinumab and Etanercept; p=0.024) and in patients on treatment with effect in eye (Adalimumab; p=0.005). All CRP (BASDAI, night pain and PGA) decreased after six months of treatment (p<0.001, p<0.001, p<0.001, p<0.001).

We found a 95% concordance between CT and CRP at baseline and 6 months.

Multivariable analysis showed that clinically important improvement was associated with higher CT and age as independent factors (OR 0.97, CI95% 0.91-0.93; p=0.009, and OR 0.81, CI95% 0.79-0.85; p=0.005). Clinically important improvement was associated with basal CT >374 µm (sensitivity 78%, [CI 95% 60-90], specificity 78% [CI 95% 52-92], area under the curve of ROC, 0.70, likelihood ratio 3.6).

Conclusion: CT decreased significantly after six months of biological treatment. CT and CPR had a 95% concordance. A high CT is associated with risk of failure.
Background: Patients with ankylosing spondylitis (AS) have an increased risk at cardiovascular disease (CVD). Microvasculature changes might precede overt CVD, but have been poorly studied in AS. The small vessels of the retina are accessible for non-invasive visualization, and microcirculatory changes (retina arteriolar narrowing, venular widening, loss of tortuosity) are described in association with CVD in other diseases.

Objectives: The aim of this study was to compare the retinal microvasculature of AS patients with healthy controls, and to assess gender differences.

Methods: A cross-sectional, case-control study comparing AS patients (fulfilling the modified New York criteria, Rheumatoid Arthritis outpatient clinic of Reade and Amsterdam UMC) with healthy controls (EMIF-AD PreClinAD cohort of the Dutch Twins Register(1)), men:women=1:1. Most important inclusion criteria were: age 50-75 years, diabetes mellitus was excluded. All subjects underwent Optical Coherence Tomography Angiography and fundus photography (21 eye), analyzed with Singapore I Vessel Assessment software (Table 2). Differences between AS and controls were evaluated with generalised estimating equations (GEE), adjusted for demographics and cardiovascular risk, and stratified for gender.

Results: In total, 59 AS patients (mean disease duration 36 years) and 105 controls were included. Controls were significantly older than patients, but did not differ in cardiovascular profile (Table 1). Patients had a significantly lower retinal arteriolar tortuosity (β=-0.1; p<0.02), and higher vessel density (β=0.5, p=0.02), than controls (Table 2). Also, male AS patients showed a lower arteriovenous ratio compared to male controls (β=-0.03, p=0.04). There were no differences between women with and without AS. In AS, a high disease activity was associated with a wider (unfavorable) venular diameter (p=0.05), whereas biologic use showed a wider (more favorable) arteriolar diameter (p<0.01).

Conclusion: This study detected several retinal microvascular changes, in AS patients compared to controls, of which some are associated with CVD based on previous studies. Some changes were only observed in male-, but not in female, patients. A new finding was an increased capillary density in AS, of which the association with CVD-risk has not yet been studied before.

ASSOCIATIONS BETWEEN CARDIAC CONDUCTION AND DISEASE CHARACTERISTICS IN AXIAL SPONDYLOARTHRITIS

S. S. Zhao1,3, N. L. Harrison2, J. Ang1, N. Goodson1,2. 1University of Liverpool, Liverpool, United Kingdom; 2Aintree University Hospital, Liverpool, United Kingdom

Background: Cardiac conduction defects are well-documented in axial spondyloarthritis. However, historical literature (many from an era when axSpA was less well managed compared to modern day) include patients with advanced disease that may explain their high prevalence. Many recent studies rely on administrative codes that may under-report conduction defects. Thorough examination of ECG measurements and axSpA characteristics are scarce.

Objectives: To describe a range of cardiac conduction measurements in axSpA and their association with disease characteristics.

Methods: We conducted a single-centre cross-sectional study of consecutive patients meeting the ASAS axial SpA criteria in Liverpool, UK. Patients were excluded if they had a known/symptomatic conduction defect. Disease assessment included BASDAI, spinal pain, BASFI, CRP, ESR, HLA-B27, BMI, the presence of extra-articular manifestations (uveitis, psoriasis, IBD) and use of NSAIDs and TNFi. Each patient underwent a 12-lead ECG (GE healthcare; MAC2000) to obtain: PR (atrio-ventricular conduction), QRS (ventricular depolarization) and QTc (ventricular de- and repolarization) intervals in milliseconds (ms). QTc was corrected for heart rate using Bazett’s formula. Prolonged QTc interval was defined as >200ms, prolonged QRS as >100ms and prolonged QTc as >440ms in men and >460ms in women. QT dispersion has been shown to predict a range of cardiac outcomes; we measured this as the difference between the longest and shortest QT in two consecutive cardiac cycles. Associations between patient characteristics and ECG measurements were assessed using univariable linear or logistic regression. Bonferroni correction was applied for multiple comparisons.

Results: 163 patients underwent ECG testing: mean age 52 (SD14) years, mean symptom duration 10 years (SD9.6), 79% male and 74% HLA-B27 positive (among 78 tested). 1 patient had Wolff-Parkinson-White (accessory pathway). Summary of the 4 measurements are shown in Table 1. None of these 4 ECG measures were associated with age, symptom duration, gender, BMI, disease severity (BASDAI, spinal pain, BASFI and log transformed CRP/ESR), HLA-B27, EAMS or NSAIDs/TNFi.

Conclusion: Conduction defects were rare in this group of axSpA patients. Only 3% had prolonged AV conduction, which is no higher than general population estimates [1]. The prognostic value of these conduction defects and QT dispersion requires further study.

Psoriatic arthritis

IMPACT OF FIBROMYALGIA ON DISEASE ACTIVITY INDICES, HEALTH RELATED QUALITY OF LIFE AND FATIGUE IN PATIENTS WITH PSORIATIC ARTHRITIS

N. Elsay1, M. Helal1, H. Ashraf Abd Elhamid1, Y. Abdel-Fattah1. 1Faculty of Medicine Alexandria University, Physical Medicine, Rheumatology and Rehabilitation, Alexandria, Egypt

Background: Psoriatic arthritis (PsA), causes inflammation in joints and entheses, emotional instability and poor quality of life (QOL). Fibromyalgia (FM) may coexist with PsA, complicating its diagnosis and management. The effect of FM on the QOL and fatigue in PsA patients has not been vastly studied.

Objectives: Assess the effect of FM on PsA patients' disease activity indices, QOL and fatigue.

Methods: This study included Group I: 37 PsA only patients (61.7%), 48.38 ± 11.9 years and group II: 23 FM-PsA patients (38.3%), 50.78 ± 11.8 years, according to classification criteria for PsA and 2016 Revisions to 2010/2011 FM diagnostic criteria. Psoriasis area severity index (PASI), disease activity in PsA (DAPSA), composite PsA activity index (CPDAI), PsA QOL and multidimensional assessment of fatigue (MAF) were assessed in both groups. The severity and impact of FM was assessed in group II.

Results: Patients with FM-PsA had a statistically higher PsA disease activity in subjective measures only but not in objective measures. Table 1

Disclosure of Interests: Nelly Ziade Speakers bureau: Abbvie, Janssen, Lilly, Novartis, Pfizer, Roche, Sanofi, Aref Nassar: None declared

DOI: 10.1136/annrheumdis-2020-eular.6009
Patients in both groups had statistically significant functional level by health assessment questionnaires (HAQ) (U=339, p=0.186) and QOL by PsAQoL (U=306, p=0.068). While, MAF was statistically significant in group II patients ranging from 28 to 48.7, in group II vs 26.5 ranging from 0 to 49.5 in group I (U=172.5, p<0.001).

In group II patients: the mean tender point count was 16.50 ± 1.84, fibromyalgia questionnaire (HAQ) (U=339, p=0.188) and QOL by PsAQoL (U=306, p=0.068).

Conclusion: These results might highlight the importance of considering FM as a contextual factor in disease activity assessment in patients with PsA, especially in those with discrepancies in TJC/patients reported outcomes versus SJC/

FATIGUE ASSESSMENT IN EGYPTIAN PSORIATIC ARTHRITIS PATIENTS: RELATION TO SERUM INTERLEUKIN 23, DISEASE ACTIVITY AND QUALITY OF LIFE.

N. Abouelrad1, N. Elsayw2, M. Helal2, M. Elshefai3, N. Lewis1, 1Faculty of Medicine, Helwan University, Rheumatology and Rehabilitation, Cairo, Egypt; 2Faculty of Medicine, Alexandria University, Physical Medicine, Rheumatology and Rehabilitation, Alexandria, Egypt; 3Faculty of Medicine, Alexandria University, Radio-diagnosis, Alexandria, Egypt; 4Faculty of Medicine, Alexandria University, Clinical and Chemical Pathology, Alexandria, Egypt

Background: Fatigue is a prevalent and fundamental phenomenon in psoriatic arthritis (PsA) patients. It often interferes with physical and social functions and may lead to social withdrawal, long-standing sick leave, disability and loss of work productivity. Fatigue is a prevalent symptom in patients with chronic rheumatic diseases. Cytokines as interleukin IL-23/17 play a pivotal role in the pathogenesis of PsA.

Objectives: To assess fatigue in PsA patients and determine its relation to serum IL-23 levels, disease activity, Skin severity, physical function and quality of life (Qol).

Methods: Fifty PsA patients and 46 matched healthy controls were included in this study. Skin severity based on the Psoriasis Area and Severity Index (PASI), the Disease Activity index for Psoriatic Arthritis (DAPSA) and the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) were assessed, Physical function was assessed by the Health Assessment Questionnaire Disability Index (HAQ-DI) and health-related QoL was assessed using the Short Form Health Survey (SF-36). Psoriatic Arthritis Quality of Life (PsAQoL) and the Dermatology Life Quality Index (DLQI). Serum IL-23 levels were measured in the studied groups.

Results: The study included 23 (46%) females and 27 (54%) males with a mean age of 42.78±12.33 years. The mean serum IL-23 level was significantly higher in PsA patients (50.89 ±13.86 pg/ml) than in controls (43.88 ± 6.34 pg/ml) (p=0.006). The FACIT score ranged from 2-41. Severe fatigue (score <30) was reported in 27 (54%) PsA patients. There were significant correlations between FACIT-F and (DAPSA, PASI, HAQ-DI, PsAQoL, DLQI and SF-36). No significant correlations could be detected between FACIT-F and serum levels of IL-23 and CRP.

Conclusion: Fatigue was a frequent complaint in PsA patients. There was a mutual negative impact between fatigue and each of PsA joint disease activity and physical function and it worsened the QoL. Fatigue was worsened with increased severity of skin PsO. Although serum level of IL-23 was significantly elevated in PsA patients than the controls, it wasn’t correlated with fatigue score. Hence IL-23 can’t be considered a biomarker for fatigue severity.

PSORIATIC ARTHRITIS IN NIGERIAN PSORIASIS PATIENTS - MYTH OR A MISSING LINK?
A. I. M. Aibade1, O. O. Ayanlowo2, U. Ima-Edomwonyi2, A. Egwuenu3, O. Adelowo4, Obafehi Akowolowu University Teaching Hospitals Complex, Rheumatology Unit, Internal Medicine, Ille-Ife, Nigeria; 3Faculty of Clinical Sciences, College of Medicine, University of Lagos, Internal Medicine, Lagos, Nigeria; 4Lagos University Teaching Hospital, Rheumatology Unit, Internal Medicine, Lagos, Nigeria; 5Nigeria Centre for Disease Control, Jabi, Abuja, Nigeria; 6Lagos State University Teaching Hospital, Rheumatology Unit, Internal Medicine, Lagos, Nigeria

Background: Beyond true arthritis, Psoriatic arthritis (PsA) is known with dactylitis and enthesitis. Enthesitis is postulated as the central pathogenic process in seronegative spondyloarthritides and the primary finding in psoriatic arthritis. Psoriasis (Ps) is now reported increasingly in Nigeria. But the notion of the rarity of PsA still remains in the absence of systematic documentation of PsA among psoriasis patients, with few cases reported from Rheumatology clinics.

Objectives: This study set out to determine the prevalence of PsA among Nigerian Ps patients using the Classification for Psoriatic Arthritis (CASPAR) criteria, and to evaluate enthesitis amongst them.

Methods: This hospital-based, cross-sectional study was carried out at the dermatology clinic over an 18-month period. All patients seen within the study period with biopsy-established Ps were recruited. Fifty-three (53) Ps patients, 16 years or older, were enrolled. The CASPAR criteria was used to diagnose PsA. A modified Spondyloarthritis Research Consortium of Canada (SPARCC) enthesis chart was used to document entheseal inflammation sites. Diagnosis of enthesitis was made by clinical examination.

Results: Fourteen participants fulfilled the CASPAR criteria (8 females, 6 males, F:M = 1.3:1) giving a PsA prevalence of 26.4%. Using the Moll & Wright classification, Oligo/Mono-articular pattern was the most documented (Fig 1). No patient had arthritis mutilans. Enthesitis was found in ALL (100%) PsA patients (Table 1). Highest frequencies were found in the right iliac, right patella and both plantar fascia (Fig 2). Multiple sites were involved in 87.5% of patients.

Conclusion: Psoriatic arthritis can not be considered rare among Nigerian Ps patients. Enthesitis has been suggested as the primary finding, and the initial site of inflammation in PsA. Our findings reinforce these theories in an African population. Whilst other studies reported occurrence of enthesitis in 30-50% of PsA patients, our study found 100%. Admittedly though a small study population, it suggests that enthesitis may well be the missing link to finding more PsA patients in Nigeria and Psoriasis patients of West African descent.

EFFICACY AND SURVIVAL OF APREMILAST IN PATIENTS WITH PSORIATIC ARTHRITIS AND PSORIASIS IN REAL CLINICAL PRACTICE
J. Añon Oñate1, M. J. Pérez Galán2, A. Romero3, P. Aceituno3, 1Hospital Universitario de Jaén, Rheumatology, Jaén, Spain; 2Hospital Universitario de Jaén, Rheumatology, Jaén, Spain; 3Hospital Universitario de Jaén, Dermatology, Jaén, Spain

Background: Apremilast (APR) is a phosphodiesterase 4 Inhibitor. APR has been demonstrated to be an effective and safe therapy in the treatment of active psoriatic arthritis (PsA) and psoriasis in patients who were intolerant of or unresponsive to synthetic Disease-modifying Antirheumatic Drugs (DMARDs).

Objectives: To assess the effectiveness and survival rates of APR in a cohort of patients diagnosed with PsA and psoriasis with arthritis in real clinical practice.

Methods: An open, longitudinal, prospective, descriptive study. A total of 80 patients diagnosed with PsA or psoriasis with arthritis were included. All patients received the starting dose of oral APR as per the Summary of Product Characteristics and a maintenance dose of 30mg every 12 hours. The following variables were collected: age, gender, years of evolution, prior treatment with DMARDs, swollen and tender joint counts (SJC, TJC), C-Reactive Protein (CRP), and presence of dactylitis, entheses and cutaneous psoriasis. Treatment response was evaluated in all patients at 6, 12 and 18 months follow-ups. Efficacy in patients with PsA was evaluated using the Disease Activity in Psoriatic Arthritis (DAPSA)-based criteria: low activity (DAPSA 5-14) and clinical remission (DAPSA 0-4). To assess the level of enthesitis, Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) index was used. Efficacy in patients with psoriasis was evaluated using the Psoriasis Area and Severity Index (PASI)-based criteria: PASI-75 (improvement >= 75% of the baseline PASI). Kaplan-Meier method was used for survival analysis.

Results: Of the 80 patients included in our cohort: 42 patients were diagnosed with PsA and 38 with psoriasis. 57.1% of patients with PsA and 63.2% of patients with psoriasis were men with a mean age of 48.2 ± 11.1 and 48.2 ± 14.8 and mean duration of disease 3.5 ± 4.2 years respectively. Most of
the patients with PsA (93%) had cutaneous disease and enthesitis and dactylytis were present in 45% and 31% respectively. 95% of patients with PsA had received prior treatment with Methotrexate. At 6, 12 and 18 months, there was a statistically significant decrease from baseline in TJC, SJC and DAPSA scores. The decrease in the MASES index and the levels of PCR were not statistically significant (Table 2). According to DAPSA, at 18 months follow-ups, clinical remission rate was 77.8%, and low activity rate was 22.2%. 55% of patients with psoriasis reached PASI-75 at 18 months. APR survival rates at 6, 12 and 18 months was 67.85 %, 56.45% and 50.2 % in patients with PsA and 74.8%, 70.4% and 65.1 % in patients with psoriasis.

Conclusion: APR is an effective drug for the treatment of psoriatic arthritis and psoriasis, reaching statistical significance according to DAPSA, and with a high survival rate after 18 months of treatment.

**SEVERITY OF NAIL PSORIASIS SCORE (SNAPS) DEMONSTRATES LONGITUDINAL CONSTRUCT VALIDITY AGAINST THE MODIFIED NAIL PSORIASIS SEVERITY INDEX (mNAPSI) IN AN OBSERVATIONAL COHORT OF PATIENTS WITH PSORIATIC ARTHRITIS**

A. Antony1, 2, S. Saeed2, D. Hart3, P. Nair1, C. Cavill2,2, E. Korendowych3, N. Mchugh2, C. Lovell3, W. Tillett2,3, 1Monash University, Clayton, Australia; 2Royal National Hospital For Rheumatic Diseases, Bath, United Kingdom; 3University of Bath, Bath, United Kingdom; *Royal United Hospital, Bath, United Kingdom*

**Background:** Longitudinal observational data on psoriatic nail dystrophy is scarce, in part due to the lack of a validated outcome measure that is feasible in routine care. The Severity of Nail Psoriasis Score (SNAPS; range 0-40) scored one point each for the presence of pitting, onycholysis, hyperkeratosis and/or severe nail disease in each fingernail has face validity and has recently demonstrated feasibility, reliability and cross-sectional construct validity against the modified Nail Psoriasis Severity Index (mNAPSI; range 0-130).

**Objectives:** We aimed to assess the longitudinal construct validity of SNAPS against the mNAPSI and physician nail VAS (PhyNVAS), and to determine the effect size and measurement error of these tools.

**Methods:** Consenting consecutive patients enrolled in the Bath Psoriatic Arthritis (PsA) longitudinal cohort underwent photography of their fingernails at baseline1 and 6 months alongside routine clinical assessments. Dorsal images of individual fingernails were acquired using a tripod mounted DSLR camera. An angled mirror positioned distally aided identification of hyperkeratosis. Photographs were scored using SNAPS, mNAPSI and PhyNVAS. Paired statistical analyses were conducted to assess for change in scores from baseline to follow-up. Pairwise correlations between change in SNAPS and change in mNAPSI and PhyNVAS were assessed using Spearman’s rho. Effect sizes and measurement error were calculated.

**Results:** Fifteen patients with a mean (±SD) age of 54.5 (±10.59) were assessed at 6 months. There was a significant reduction in both the mNAPSI and SNAPS scores (p<0.005), with improvements in the most frequently-observed manifestations i.e. pitting, onycholysis, hyperkeratosis and crumbling (Table 1). No other feature specific to mNAPSI improved over time. There was no significant change using the PhyNVAS. There was a strong correlation between changes in SNAPS and the mNAPSI (Figure 1; rho = 0.838, p<0.001). The correlation between change in SNAPS and PhyNVAS was not statistically significant (rho =0.45, p=0.095) (Figure 1). The change in mNAPSI correlated moderately with the PhyNVAS (rho = 0.540, p=0.038). mNAPSI was superior to SNAPS in most parameters of measurement error (Table 2). The mNAPSI and SNAPS had similar effect sizes as measured by the SRM (Table 2).

**Conclusion:** SNAPS demonstrates longitudinal construct validity against the mNAPSI in a small observational cohort of PsA patients as evidenced by a strong correlation between the measures, comparable effect sizes and sensitivity to change over time. Whilst measurement error parameters favored the mNAPSI, SNAPS may be a more feasible measure for studying nail disease in cohort studies.

**SEVERITY OF NAIL PSORIASIS SCORE (SNAPS) IS SENSITIVE TO CHANGE IN A COHORT OF PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH ETANERCEPT**

A. Antony1, 2, S. Saeed2, D. Hart3, P. Nair1, C. Cavill2,2, E. Korendowych3, N. Mchugh2, C. Lovell3, W. Tillett2,3, 1Monash University, Clayton, Australia; 2Royal National Hospital For Rheumatic Diseases, Bath, United Kingdom; 3University of Bath, Bath, United Kingdom; "Royal National Hospital For Rheumatic Diseases, Bath, United Kingdom;"
Background: The Severity of Nail Psoriasis Score (SNAPS; range 0-40; scored one point each for the presence of pitting, onycholysis, hyperkeratosis and/or severe nail disease in each fingernail) has been utilised to collect data regarding psoriatic nail dystrophy in the Bath Psoriatic Arthritis (PsA) Longitudinal cohort for many years. SNAPS has construct validity in PsA with the modified Nail Psoriasis Severity Index (mNAPSI) as a comparator instrument and appears to be more feasible than mNAPSI with excellent reliability.

Objectives: We aimed to determine if SNAPS could demonstrate longitudinal sensitivity to change in a cohort of patients treated with biological disease-modifying anti- rheumatic drugs (bDMARDs) and therefore be utilized prospectively in observational and clinical trial settings.

Methods: Patients enrolled in the Bath PsA longitudinal cohort routinely undergo clinical assessments including a 66/68 Swollen and Tender Joint Count (SJC/ TJC), Psoriasis Area Severity Index (PASI), Patient Global Assessment (PtGA) and Physician Global Assessment (PhGA), as well as complete patient-reported outcome measures such as the Health Assessment Questionnaire (HAQ) and Dermatology Quality of Life (Derm-QoL). All patients who commenced treatment with Etanercept and had available outcome data at baseline, 3 months and 6 months were included in this retrospective analysis. Baseline demographics were recorded and paired t-tests were utilized to assess the change in SNAPS at 3 and 6 months. The effect size and measurement error of SNAPS in this cohort was assessed using Pearson’s r.

Results: Fifty-seven patients (32 male and 25 female) with available data were retrospectively analysed. The mean (±SD) age of the cohort and duration of disease was 61.3 (±11.55) and 13.3 (±10.82) years respectively. The mean SNAPS at baseline was 3.7 (±6.13) and improved to 2.0 (3.74, p=0.018) at 3 months and 1.2 (2.40) at 6 months (p=0.001 for change from baseline and p=0.039 for change from month 3). The smallest detectable difference at 3 months for SNAPS in this cohort was 1.35, representing 3.37% of the range of the score (Table 2). The standardised response mean (SRM) was 0.32 at 3 months and 0.44 at 6 months. There was a modest correlation between the improvement in the SNAPS score and the improvement in PASI and Derr QOL at 3 months (r = 0.511 and 0.558 respectively, p=0.001) and 6 months (r= 0.672, p<0.001 and r=0.510, p=0.003 respectively).

Conclusion: SNAPS demonstrates sensitivity to change in response to treatment with a bDMARD and could be a potential outcome measure for the assessment of treatment efficacy in prospective studies.

A = Amber, R = Red, G = Green

[Total available studies for synthesis following excluding studies with poor methodology]

* RCT data available but no published effect sizes

# Feasibility data available
Background: SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis and osteitis) is an acronym created with the aim of encompassing within the same entity the findings present in a heterogeneous group of patients with various osteoarticular and cutaneous disorders. For years it has been debated whether it is an entity itself or if, on the contrary, it is a specific phenotype of psoriatic arthritis.

Objectives: Determine the relationship between SAPHO syndrome and psoriatic arthritis by comparing the classic criteria of SAPHO with CASPAR in patients previously diagnosed with SAPHO.

Methods: A retrospective study where patients with a diagnosis of SAPHO in the same center (1984-2018) were reviewed. Of a total of 95 patients that met the criteria of Benhamou et al., 46 were excluded due to lack of information to complete the minimum necessary data, so 39 patients were finally included in the study. Demographic data were registered, age at diagnosis, CASPAR criteria (active psoriasis, history of own or familial psoriasis, nail psoriasis, negative RF, dactylitis, and new formation/juxta-articular bone proliferation), classical criteria of SAPHO and HLAB27. For the statistical analysis, a Chi-square is applied to determine the differences between the groups with/without CASPAR criteria.

Results: Of the sample of 39 subjects diagnosed with SAPHO, 15 patients (38%) met CASPAR criteria (4M/11W), with a median age at diagnosis of 42 years (range 21-50). Of them, 8 (20%) had active cutaneous psoriasis, 10 (25%) had a family or personal history of psoriasis, 6 (15%) had psoriatic nail dystrophy, 14 (36%) had negative FR, 3 (8%) had presented some episode of dactylitis and 10 (25%) had juxta-articular new bone formation. Of the 15 patients who met CASPAR criteria, 9 (67%) had synovitis, 2 (13%) acnè, 4 (26%) pustulosis, 13 (87%) hyperostrosis and 12 (80%) osteitis. HLAB27 was positive in 1 patient (2.5%) of the group that met CASPAR criteria. Of the patients who did not fulfill CASPAR criteria (9M/15W), the median age at diagnosis was 44.5 years (range 10-70). None of them had active cutaneous psoriasis, psoriatic nail dystrophy or dactylitis. 1 (4%) had a family or personal history of psoriasis, all had RF, and 3 (12.5%) had juxta-articular bone new formation (Table 1). Synovitis was observed more frequently in patients who met CASPAR criteria than in those who did not (67% vs 25%, p = 0.01). In contrast, osteitis was present more frequently in patients who did not meet CASPAR criteria (80% vs 96% p = 0.05) and pustulosus, although it was not statistically significant (50% vs 26%, p = 0.07). Among patients who did not meet CASPAR criteria only 1 met the 5 classic SAPHO criteria and another 3 met 4.

Conclusion: Approximately one third (38%) of patients diagnosed with SAPHO meet criteria for psoriatic arthritis, the most notable variables being active psoriasis or a history of psoriasis. Synovitis manifests more frequently in patients with CASPAR criteria and osteitis more present in patients who did not meet them.

AB0740 SECOND-LINE BIOLOGIC DMARDS SURVIVAL IN PSORIATIC ARTHRITIS. DATA FROM A SPANISH THIRD-LEVEL HOSPITAL.

J. Arroyo Palomo1, L. Villalobos-Sánchez2, V. García García1, V. Aguado Casanova1, L. Calvo Sanz1, I. Del Bosque Granero2, F. J. Huelin Alcubierre1, J. J. Gonzalez Lopez1, M. Reveguen Martinez1, Hospital Ramón y Cajal, Madrid, Spain

Background: Psoriatic arthritis (PsA) covers a wide spectrum of disease manifestations, including arthritis, enthesitis, dactylitis and axial spondylitis. This range of symptoms presents a challenge to the treating physician. Biologic disease-modifying antirheumatic drugs (bDMARDs) have proven effective through randomized clinical trials; and most international PsA guides include them as main option upon first-line treatment failure. However, studies regarding drug efficacy after bDMARD switching are scarce, lower response rates and drug survival on consecutive lines has been explored in previous research.

Objectives: To assess bDMARDs survival after first-line failure in PsA patients treated in a third-level hospital and to determine baseline clinical and laboratory parameters associated with drug survival.

Methods: We conducted a retrospective, single-centre study. 47 patients who received a second-line bDMARD were included, with diagnosis of PsA according to the criteria of an expert rheumatologist. All patients were studied according to a standard protocol. Data regarding bDMARD prescribed, baseline characteristics, axial or peripheral involvement and immunological profile (included both HLA-B27 and HLA-Cw6) were extracted. C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) at bDMARD start were included, as well. Kaplan-Meier, log-rank analyses and Cox regression models were applied.

Results: Of 47 patients receiving a second bDMARD 55,3% (26) were female and mean (S.D) age was 40,6 (12,32) years. Median (interquartile range) disease duration was 10,1 (3,7-14,8) years. Prescribed drugs were Adalimumab (ADL) (36,2%), Etanercept (ETN) (27,6%), 13, Infliximab (IFX) (6,4%), 3, Golimumab (GOL)
(10.6%, 5), Certolizumab (CTZ) (4.3%, 2), Secukinumab (SCK) (8.5%, 4) and Apremilast (APR) (6.4%, 3). 42.3% cases suffered from axial involvement, rest of the sample (57.7%) presented a pure peripheral form of PsA. HLA-B27 and -Cw6 were assessed in 80.9% (38) and 69.1% (33), respectively; of whom, HLA-B27 carriers were 10.5% and HLA-Cw6 positive, 46.9%. Mean CRP level was 10.25mg/L and mean ESR was 23.17mm. Patients showed mean and median global drug retention of 44.57 (29.8-59.3) and 23 months. At 12-month visit, drug survival was 70%, 47% at 24 months, and 33% at 4 years from onset. Mean drug persistence by bDMARD prescribed was: ADL, 62.1 months; ETN, 51.9 months; IFX, 39 months; GOL, 22.8 months; CTZ, 9.5 months; SCK, 13.5 months; and APR, 16.3 months. Through log-rank analyses, differences in drug retention were investigated by several variables. Female sex (30.35m, 16.5-44.2 m.) was identified as statistically significant different than male patients (62.5m, 35.6-89.4m, p=0.021). Although not significant, other differences were remarkable: non-axial involvement, HLA-Cw6 negativity, HLA-B27 positivity and CRP level over 5mg/L. No differences were found between altered and normal ESR patients.

**Conclusion:** Second-line bDMARD survival is lower in female PsA patients, according to our data and previous bibliography. Despite our reduced sample and possible bias, non-axial involvement, absence of HLA-Cw6, presence of HLA-B27 and higher levels of CRP at biologic onset might be predictors of better drug persistence. Further investigations are required on this field.

AB0742

CONVENTIONAL SYNTHETIC DMARDS IN PSORIATIC ARTHRITIS - CHANGING PRACTICE IN BIOLOGIC ERA: REAL-LIFE RESULTS FROM HURBIO-PSA REGISTRY

E. Bilgin1, D. Duran1, E. C. Bolek1, B. Farisogullari1, G. K. Yardimo1, L. Kilic1, A. Akdogan1, S. A. Bilgen1, O. Karadag1, A. I. Ertendi1, S. Kiraz1, U. Kalyoncu1.

Background: Conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) are recommended as the first-line treatment options for most of the psoriatic arthritis (PsA) patients. In the last two decades, biologic drugs become more accessible and their percentage in the daily practice is increasing continuously. However, how they influenced the utilization of csDMARDs still remains unknown, yet.

Objectives: To determine the utilization rates of PsA patients before, after and at the starting of biologic DMARDs

Methods: We analyzed all patients who received at least 1 dose of biologic DMARD, registered to HURBIO-PSA database, and who have complete data regarding csDMARD use before (ever), after (at last control visit) and at the starting of biologic DMARD. Methotrexate, leflunomide and sulphasalasine were the csDMARDs recorded. Demographic data of these patients were also recorded.

Results: A total of 426 (70% female) PsA patients was included. Mean age and mean PsA disease duration were 48±12.4 and 9.3±8.3 years, respectively. Mean duration of csDMARD utilization before bDMARDs was 5.8±5.1 years, and mean follow-up duration under bDMARDs was 3.7±2.5 years. Distribution of the bDMARDs that ever-prescribed as follows: adalimumab 273 (64.2%), etanercept 11 (3.4%), tofacitinib 11 (3.4%). Percentage of each csDMARDs used before (ever used), after (at last control visit) and at the starting of biologic DMARDs were given in Figure.

Conclusion: csDMARDs particularly sulphasalazine and methotrexate were important treatment options before bDMARD period, however they (particularly SSZ) were usually discontinued after bDMARD initiation. Rate of concomitant csDMARDs use remains relatively stable after starting the bDMARDs. Besides, rate of concomitant mono/csDMARD use is significantly higher after bDMARD initiation, in contrast to pre-bDMARD period.

AB0743

DISEASE CHARACTERISTICS OF PSORIATIC ARTHRITIS PATIENTS MAY DIFFER ACCORDING TO AGE AT PSORIASIS ONSET: CROSS-SECTIONAL ANALYSIS OF PSORIATIC ARTHRITIS-INTERNATIONAL DATABASE

E. Bilgin1, Ø. Bayndir1, E. Kasapoğlu1, S. Bakır1, D. Solmaz2, G. Kimyon3, A. Dogru1, E. Dağlı1, C. Özşener1, M. Can1, S. Akar1, E. F. Tanaran1, Y. Yavuz2, L. Kilic1, O. Küçükşahin1, A. Omma1, E. Gürülü1, F. Yıldız2, D. Ersozli1, A. Tufan1, M. Çınar1, A. Erden1, S. Yılmaz1, S. S. Ertenli: None declared, Sedat Kiraz: None declared, İhsan Ertenli: None declared, Ali Akdoğan: None declared, Şule Apra Bilgen: None declared, Omer Karadag: None declared, Ali İhsan Ertenli: None declared, Sedat Kiraz: None declared, Umut Kalyoncu Consultant of: Abbvie, Amgen, Janssen, Lilly, Novartis, UCB

Background: Psoriasis and psoriatic arthritis (PsA) are heterogenous diseases with various disease manifestations and phenotypes. Psoriasis has a bimodal age of onset being early (before the age of 40, type I) and late. The impact of this classification on the PsA features is not well understood.

Objectives: To compare the PsA characteristics of patients with early- and late-onset psoriasis in a large, multicenter database

Methods: PsART-ID (Psoriatic Arthritis-International Database) is a prospective, multicenter web-based registry (www.trials-network.org) of patients with PsA. A detailed data collection was performed including demographics (sex, age, duration of education, smoking status, BMI), skin features (psoriasis onset site, type, initially involved site of skin, nail involvement (ever) and family history) and PsA characteristics (type of articular involvement and presence of axial, dactylitis (ever), enthesitis (ever), family history) and indices for disease activity and function (DAPSA, Leeds enthesis index, BASDAI, BASFI, patient and physician global assessment, pain, HAQ-DI). We grouped according to the age at psoriasis onset (early onset, psoriasis before the age of 40 (EOPsO); late-onset, psoriasis after the age of 40 (LOPsO)), patient and disease characteristics of the groups were compared (1). Due to the differences among groups, following adjustments were made: BMI for age, nail involvement for PsO disease duration, axial PsA for PsA disease duration.

Results: A total of 1634 (62.8% females; EOPsO, 1108 (67.8%); LOPsO, 526 (32.2%)) patients with PsA was recruited. Rate of over-weight patients was higher in LOPsO group (66.8% vs. 86.8%, p<0.001; adjusted for age - aOR 1.55 (1.11-2.20; % 95 CI)). The EOPsO group had the scalp involvement as unknown, yet.

Figure 1. Percentage of each csDMARDs, and mono or combination of csDMARDs used before (ever used), after (at last control visit) and at the starting of biologic DMARD (csDMARD: combination csDMARD; mono/csDMARD: monotherapy of csDMARD; csDMARD: conventional synthetic disease modifying antirheumatic drug).

DOI: 10.1136/annrheumdis-2020-eular.4735

Figure 1. Patients achieving persistent-LDA during the 1st year of biological therapy, stratified by period of time and by disease. *Statistically significant difference with respect to p1.
vs. 43.0%, p<0.001), whereas extremity involvement was more frequent as the initial finding in the LOPsO group (EOPsO vs. LOPsO 63.8% vs. 74.2%, p<0.001). Duration between PsO and PsA was significantly longer in EOPsO group (148 vs. 24 months, p<0.001). In EOPsO group, more patients had PsO preceding PsA than LOPsO group (81.8% vs. 60.6%, p<0.001), however, synchronous disease defined as the diagnosis of PsO and PsA within the same year was more common in LOPsO group (16.6% vs. 30.3%, p<0.001) (Table 1). Psoriatic disease activity parameters, patient and physician reported outcomes and HAQ-DI scores were similar in both groups.

**Conclusion:** Clinical features of PsA may be affected by the age at the onset of psoriasis. As the genetic background is different in early and late-onset psoriasis, this may suggest a different pathogenetic mechanism based on the psoriasis phenotype, also affecting the PsA features. Further prospective studies are needed to define whether the classification of PsA requires including psoriasis phenotypes as well.

**Conclusion:** Clinical features of PsA may be affected by the age at the onset of psoriasis. As the genetic background is different in early and late-onset psoriasis, this may suggest a different pathogenetic mechanism based on the psoriasis phenotype, also affecting the PsA features. Further prospective studies are needed to define whether the classification of PsA requires including psoriasis phenotypes as well.
with the general population, and to review existing modalities for the assessment of body composition.

**Methods:** Electronic searches of the literature were conducted in PubMed, Medline (Ovid®), Embase (Ovid®), Cochrane Central Register and Google Scholar. Titles and abstracts were reviewed by two authors independently against a set of prespecified inclusion/exclusion criteria, reference lists were examined and synthesis of the included studies was conducted.

**Results:** Twenty-five whole-text papers met the inclusion criteria and were included in the final narrative analysis. The studies were of heterogeneous design and used a range of subjective measures to assess body composition, including bioimpedance analysis (BIA), dual energy X-ray absorptiometry (DXA) and computed tomography (CT). Few studies met all the quality assessment criteria. 24 studies confirmed discrete biological and body composition changes in patients with psoriatic disease, which correlated positively with other indicators of metabolic syndrome, including waist circumference, waist-to-hip ratio, weight, BMI, plasma concentrations of LDL-cholesterol, leptin and apolipoprotein-B.

**Conclusion:** There is an increased prevalence of metabolic, anthropometric and internal body composition derangements in psoriatic patients compared with controls, and these changes seem to be independent of obesity and the customary metabolic syndrome, including higher overall body fat, visceral fat and sarcopenia. Our study highlights the applicability of several imaging techniques to measure body composition in psoriatic patients, including some novel automated systems, and future studies should focus on validation and standardization of assessment tools both in research and clinical practice.

**AB0745 REAL-LIFE EXPERIENCE FOR SECUKINUMAB IN PSORIATIC ARTHRITIS FROM HURBIO-PSA DATABASE**

E. C. Bolek1, E. Bilgin1, G. K. Yardımoğlu1, B. Farişoğulları1, E. Duran1, B. Armağan1, L. Kriç1, Ş. A. Bilgin1, A. I. Ertelen1, U. Kalyoncu1. 1Hacettepe University, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey

**Background:** Biologic disease modifying anti-rheumatic drugs (bDMARD) are revolutionary treatment options for management of inflammatory arthritis. Secukinumab (SEC), anti-interleukin-17A monoclonal antibody, is a new alternative choice to anti-TNFs and IL-12/23 blocking agents in the therapy of psoriatic arthritis (PsA). In Turkey, government health insurance system covers secukinumab for bDMARD-refractory PsA patients.

**Objectives:** In this study, analyzing of parameters that related with effectiveness and drug survival rates for patients using SEC from Hacettepe University Rheumatology Biologic Registry (HURBio-PSA) were aimed.

**Methods:** HURBio-PSA is a monocentric biologic database including 470 PsA by December 2020. Sixty-two PsA patients that recorded with prescribed SEC in the database were evaluated. Sixteen patients have no control clinical-visit were excluded. Descriptive and demographics were recorded and Kaplan-Meier analysis was used to estimate SEC drug-retention rates.

**Results:** Forty-two (26.1% male) PsA patients treated with SEC were included. Characteristics of the patients at the baseline and the last visit were shown in Table. Last visit scores of DKKY, Patient VAS Global, VAS Fatigue, VAS Pain and BASDAI showed statistically significant improvements in comparison with first visit values. Median duration of SEC usage was 5.4 (Min-Max: 0.18-18.6) months. SEC drug-retention rate at 12 months were 69% and 54.4% for two PsA groups that were used previously 1 and ≥2 bDMARDs, respectively (p=0.743, Figure).

**Conclusion:** In this real-world study derived from single center experience; there is no statistically significant difference for drug survival rates of SEC therapy in the patient groups used 1 and ≥2 bDMARDs. Effectiveness and drug-survival should be obviously verified by data derived from multicenter large cohorts.

EVALUATING TENDER AND SWOLLEN JOINTS FOR THE ASSESSMENT OF INFLAMMATORY PAIN IN PSORIATIC ARTHRITIS USING ULTRASOUND

P. Boschi1, R. Husic1, F. Anja1, J. Gretler1, A. Lackner1, W. Graninger1, C. Dutnner2, J. Herrmann3, C. Dejaco1,2,3,1 Medical University of Graz, Graz, Austria; 2 Medical University of Innsbruck, Innsbruck, Austria; 3 Hospital of Bruneck, Bruneck, Italy

Background: Tender and Swollen Joints Count (TJC, SJC) are items of disease activity scores in rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Recent studies suggest that TJC do not adequately reflect ongoing inflammation in RA when using Ultrasound (US) as a reference standard, and that pain might be due to other, non-inflammatory causes.1, 2 In PsA, the role of tenderness and swelling of joints for reflecting active inflammation has not been well studied so far.

Objectives: To evaluate tender (TJ) and swollen joints (SJ) for the assessment of inflammation in PsA.

Methods: We performed a prospective study on 83 PsA patients undergoing clinical and ultrasound examinations at two study visits scheduled 12 months apart. Tenderness and swelling were assessed for 68 and 66 joints respectively, and US examinations, including grey scale (GS) and power doppler (PD) were conducted at all 68 joints. GS- (range 0-204) and PD sum scores (0-204) were calculated. At patient level, correlations were performed between TJC, SJC and clinical or US values. At joint level a GS value>1 and/or PD value>1 was defined as active synovitis, which was compared to whether a joint was tender, swollen or both. A generalized linear mixed model was created to assess the predictive value of TJ and SJ for active synovitis after 12 months, taking into consideration the joint site.

Results: At baseline the median TJC and SJC for 83 patients was 4 (range 0-59) and 1 (0-20), respectively and the median GS- and PD sum score was 16 (3-56) and 3 (0-31) respectively. SJC correlated with the GS sum score (r=0.37, p=0.004) and PD sum score (r=-0.47, p=0.001), while TJC could only correlate with PD sum score (r=0.33, p=0.01). TJC correlated better than SJC with patient reported outcomes like patient global assessment (TJC: r=0.57, p<0.001; SJC: r=0.39, p=0.002) and health assessment questionnaire (TJC: r=0.50, p<0.001, SJC no significant correlation). Swollen joints (with or without tenderness) showed active synovitis (GS=1 and/or PD=1) in 67.6% of cases, while tender joints (with or without swelling) showed signs of US activation in only 34.5%. A joint that was considered swollen at baseline was more likely to express active synovitis after 12 months (OR: 2.8, 95% CI: 2.1-3.5).

Conclusion: SJC are more closely linked with US signs of inflammation as compared to TJC in PsA. While swelling of a joint predicts US inflammation after a year, the information whether the joint is additionally tender or not, gives no additional predictive information.

Specific Ultrasound Lesions in Psoriatic Arthritis: Prevalence and Correlation with Disease Activity

K. Ben Abdelghani1, H. Bessoua1, S. Miladi1, A. Fazaa1, K. Quenniche1, L. Souabni1, S. Kassab1, S. Chekili1, A. Laatar1,1 Mongi Slim Hospital, Tunis, Tunisia

Background: Psoriatic arthritis (PsA) is a systemic inflammatory disease with articular and extra-articular features. In recent years, ultrasonography (US) is playing an important role in the diagnosis and monitoring of this disease. Specific US features of PsA have been reported such as enthesis, peritenon extensor tendon inflammation (PTI) and soft tissue edema.

Objectives: The aims of this study were to evaluate the prevalence of these US signs in PsA patients and to determine their association with disease duration and activity.

Methods: Patients with peripheral PsA responding to the Classification Criteria for Psoriatic Arthritis (CASPAR) were enrolled. Clinical and biological data were extracted, and then US examination was performed by an experienced rheumatologist blinded to clinical data using a machine type Esaote MyLab 60 with a linear probe of 6-18 MHz. The following US features were evaluated: PTI at the dorsal aspect of metacarpo-phalangeal (MCP) joints, soft edema at the volar aspect of MCP joints and enthesitis of the digitorun extensor at the dorsal aspect of distal inter-phalangeal (DIP) joints.

A p<0.05 was considered statistically significant.

Results: We included twenty PsA patients, 8 men and 12 women, with a mean age of 55 ± 11 [33-77] years old. The mean disease duration was of 10±8 [1-34] years. A family history of PsA or psoriasis was reported in 53% of cases. Oral corticosteroids were used in 21% of patients, at a mean daily posology of 7mg [5-10] of Prednisone equivalent, Methotrexate in 84% of cases at a mean posology of 15mg [10-20] per week, Sulfasalazine in 10% of cases and a biological DMARD in 32% of cases (Etanercept=4, Infliximab=1, Adalimumab=1).

The mean number of tender and swollen joints were respectively of 8 [0-16] and 2 [0-8]. The mean rate of patient global evaluation and visual analogue scale was of 5 [0-9].

The mean DAPSA (Disease Activity in Psoriatic Arthritis) score was of 32±27 [4-112]. US examination demonstrated that all patients had at least one of the three specific signs that we were looking for. At MCP level, PTI was noted in 11% of joints with Power Doppler (PD) signal in one case and soft tissue edema was noted in 3% of joints.

A positive association was found between DAPSA score and soft tissue edema (p=0.000), but no with PTI (0.668) and enthesitis (0.137). No relation was found between these three lesions and the disease duration.

Conclusion: The presence of soft tissue edema, enthesis and/or PTI on US can be an argument for the diagnosis of PsA. Soft tissue edema is shown to be associated with disease activity.

Importance of Comorbidities in Patients with Arthritis Psoriatic

I. Braña Abascal1, S. M. Rojas Herrera1, M. Prieo Fernandez-Martos1, J. Malave Calzada1, D. Fernandez Lozano1, R. Veron Gonzalez2, J. J. Aznar Sanchez2, E. Chamizo Carmona1,1 Rheumatology, Hospital of Mérida, Mérida, Spain

Background: Cardiovascular diseases are more prevalent in inflammatory arthropitis, such as psoriatic arthropathy (PsA), than in general population. An increase in the presence of anxiety-depressive disorders has been also described in patients with psoriatic disease.

Objectives: To assess the prevalence of comorbidities in a cohort of patients with PsA, especially cardiovascular events and anxiety-depression disorders.

Methods: Observational, cross- sectional study of a cohort of patients with PsA from a monographic clinical unit in a rheumatology department to describe the presence of comorbidities: hypertension, diabetes, hyperlipemia, hyperuricemia, smoking, obesity, depression and isquemic heart disease (IHD).

comorbidities were analyzed according to the type of disease: peripheral, mixed and axial involvement. For statistical analysis SPSS v.25 was used.

Results: We included 145 patients: 84 men and 61 women. The mean age at diagnosis was 45.4 (± 12.9) years, and the mean time of evolution was 9.3 (± 6.2) years. No significant difference between genders was observed. Peripheral involvement was observed in 94 (64.8%), mixed 31 (21.4%) and axial involvement in 20 (13.8%). We did not find any differences between gender for peripheral and axial pattern, however 31% of men versus 8.2% of women presented a mixed pattern. [OR=5 (1.8-14), p=0.001].

The most common comorbidities found were hyperlipemia, overweight and arterial hypertension. Table 1 shows all the comorbidities studied and their distribution by pattern.

Patients with mixed involvement had a higher proportion of smokers [OR=2.9 (1.2-7.3), p=0.02] and a tendency to higher IHD [OR=2.8 (0.9-8.6), p=0.06]. Overweight was significantly lower in axial pattern patients [OR=0.4 (0.2-0.8), p=0.01] and higher in the peripheral ones [OR=1.5 (1.1-2.1), p=0.01]. IHD was prevalent in patients of our cohort (10.3%), it was significantly higher in men than in women [OR=12 (1.5-93.9), p=0.003], and more likely in mixed involvement (19.4%).

Males with PsA also developed hyperuricemia more frequently [OR=6.5 (2.5-16.9), p<0.0001]. Metabolic syndrome was found in 15.9%, but there was no significant difference among the patterns. Although, it was associated with hyperuricemia [OR=21.6 (6.7-64.9), p=0.0001] and ischemic heart disease [OR=12.4 (3.8-40.1), p<0.0001]. Finally, the rest of the comorbidities analyzed did not show significant difference in gender and pattern of disease.

Conclusion: In our cohort, a high prevalence of comorbidities was found, especially hyperlipemia, metabolic syndrome and IHD. In general, overweight (BMI > 25) was very common and was associated to a peripheral disease while the axial disease showed as a protective factor.

AB0749 COMPARING PATIENT-PHYSICIAN DISCORDANCE IN RA AND PSA PATIENTS

L. Brites1, L. Saraiva1, F. Costa1, J. Dinis de Freitas1, M. Luis1, A. R. Prata1, H. Assunção1, J. A.P. Da Silva1, J. Rovisco1, C. Duarte1,2. Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; 1Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Background: Patient global assessment (PGA) of disease activity is considered a key patient reported outcome in Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA), both being included in combined indices of disease activity. However, patients and physicians frequently disagree in their assessment.

Objectives: This study aimed at comparing the degree of this discrepancy and its determinants in RA and PsA.

Methods: Cross sectional study including 100 patients with RA (ACR/EULAR 2010 criteria) and 100 patients with PsA with predominant peripheral joint involvement (CASPAR criteria), aged >18 years, randomly selected from the electronic registry Reuma.pt. Data were collected from the most recent rheumatology visit during the last year: sociodemographic data, disease duration (years), tenderness and swelling joint counts 0-28 (TJC and SJC), disease activity (DAS28 3V-PCR), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), patient’s pain assessment, PGA and physician global assessment (PhGA). The discrepancy between patients and physicians (ΔPPhGA) was defined as PGA minus PhGA, and a difference >20mm was taken as “discordance”. Categorical variables are presented as proportions and continuous variables as mean ±SD. Patient and clinical characteristics were compared between patients with RA and PsA using t-test and χ2 test, as adequate. Variables with p<0.05 or clinically relevant were included in multivariable logistic regression analysis to identify correlates for ΔPPhGA in the whole sample. A p<0.05 was considered statistically significant.

Results: Compared to PsA, patients with RA were more often female (90% vs 49%, p<0.05), older (66.7 ± 10.7 vs 58.3 ± 12.2 years, p<0.05) and had a shorter disease duration (18.2 ± 9.8 vs 19.9 ± 9.7 years, p=0.202). Regarding disease activity, the RA and PsA groups were comparable: DAS28 3V-PCR (2.3 ± 0.9 vs 2.4 ± 1.0, p=0.34). Patients with RA had a higher mean ΔPPhGA (20.4 ± 30.6 vs 25.4 ± 27.5, p<0.05), and were more frequently discordant to the physician (69% vs 51%, p<0.05). In univariable analysis, having RA, higher patient’s pain assessment and higher ESR were associated to patient-physician discordance. In multivariable analysis, only patient’s pain assessment (OR 1.04 [95% CI 1.03-1.06], p=0.00) and TJC (OR 0.82 [95% CI 0.68-0.97], p=0.02) remained as predictors of discordance.

Conclusion: Despite comparable disease activity scores in RA and PsA patients, RA patients tend to have a worst self-perception of their disease activity compared to their physician’s. Patient’s pain assessment and TJC were the only predictors of patient-physician discordance, irrespective of the disease.

AB0750 CLINICAL CHARACTERISTICS AND TREATMENT PATTERNS OF PATIENTS WITH PSORIATIC ARTHRITIS WHO WERE PRESCRIBED BIOLOGICS: DATA FROM THE COLUMBUS REPOSITORY

H. Busch1, J. Curtis2, P. Hur3. 1Science and Research Institute, Inc, Jupiter, United States of America; 2The University of Alabama at Birmingham, Birmingham, United States of America; 3Novartis Pharmaceuticals Corporation, East Hanover, United States of America.

Background: Real-world data from electronic health records (EHR) allow examination of treatment patterns and clinical practice behaviors for psoriatic arthritis (PsA).

Objectives: To describe physician and patient characteristics, and treatment patterns of patients with PsA who initiated secukinumab and other biologics using data from the Columbus Repository.

Methods: EHR data from adult patients with PsA who were prescribed a new biologic therapy between January 2018 and March 2019 (index date) were included from the Columbus Repository, which collects clinical records from a network of US rheumatology providers. Demographics, disease characteristics, and treatment patterns, as well as physicians’ characteristics, were reported for patients who were prescribed secukinumab vs other biologics (abatacept, adalimumab, etanercept, certolizumab pegol, golimumab, infliximab, infliximab-dyyb, infliximab-ada, ustekinumab, and ixekizumab). Treatment groups were mutually exclusive and only the most recently prescribed biologic was represented. Categorical variables were summarized using frequency counts and percentages and continuous variables were presented using means and standard deviations.

Results: As of March 2019, 234 patients initiated secukinumab and 806 initiated other biologics for PsA treatment; 62 physicians prescribed biologics for PsA. Overall, 73% of physicians’ offices had a single provider contributing patients to the analysis, and 76% of physicians were located in the South US region. Secukinumab initiators were younger (55.2 ± 57.3 years), more likely to be male (44% vs 31%), and had higher BMI (34.0 vs 31.9 kg/m²) vs other biologic initiators. Almost all disease activity measures evaluated had a large proportion (> 80%) of missing data; among those with nonmissing data, secukinumab initiators had numerically higher mean (SD) RAPID3 score vs other biologic initiators (12.6 [6.5] vs 11.6 [7.1]). Overall, 70% of secukinumab initiators and 48% of other biologic initiators were biologic experienced (Figure 1). Comorbidities were similar between groups (Figure 2). The most common reasons for discontinuation of prior biologic were the biologic was no longer required and lack of efficacy (Table 1).

SMD, standardized mean difference. *Comparisons with SMD > 0.1 were suggestive of clinically relevant differences.

Conclusion: Secukinumab initiators with PsA were more likely to be male and biologic experienced, have a higher BMI and higher RAPID3 scores indicative of more active disease vs those initiating other biologics. Additional structured and unstructured elements may need to be captured on EHR platforms to gain clarity on disease activity and treatment decisions.

AB0751 SAFETY AND PERSISTENCE OF USTEKINUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS IN BIOSIMILAR

N. Busquets-Pérez, C. Sánchez-Piedra, P. Vela-Casasempere, M. Freire-González, C. Bohórquez, L. Expósito, B. Magallon, F. Manero, J. Del Pino Montes, C. Díaz Torne, R. Martin Domenech, M. Pascual, F. Sánchez-Alonso, Hospital General de Granollers, Granollers, Spain; SER, Madrid, Spain; Hospital de Alicante, Alicante, Spain; Hospital de A Coruña, A Coruña, Spain; Hospital de Canarias, Canarias, Spain; Hospital San Jorge, Huesca, Spain; Hospital Miguel Servet, Zaragoz, Spain; Hospital de Salamanca, Salamanca, Spain; Hospital de Sant Pau, Barcelona, Spain; Hospital de Elia, Elia, Spain; Hospital general de Granollers, Granollers, Spain

Background: Ustekinumab has been efficacy and safety for psoriatic arthritis in clinical trials.

Objectives: To assess effectiveness, by means of drug persistence analysis, and safety of ustekinumab in patients with psoriatic arthritis in Biobadaser.

Methods: BIOBADASER is the Spanish registry of biological drugs of the Spanish Society of Rheumatology and the Spanish Medicines Agency. We identified patients aged 18 years or more with psoriatic arthritis on Ustekinumab. A descriptive analysis was performed. The persistence of ustekinumab therapy was calculated with a Kaplan-Meier curve and was compared with the persistence of anti-TNF according to line treatment. Log Rank test was used to establish a comparison. Adverse events occurring with ustekinumab are described according to year treatment.

Results: One hundred and twelve patients were on ustekinumab. Most of them were on their second or third line treatment: 53.57% more than one biological therapy (BT), 19.64% second BT, 26.79% naïve for BT. Most of them were on 40 mg dose: 88.24%. Median duration of disease at Ustekinumab initiation was 10.1 SD 72 years; 69.23% had peripheral arthritis; 45.24% had obesity and 39.29% were overweight; 40.6% were on prednisone and 59.82% on DMARD. The cause of discontinuation of treatment was mainly ineffectiveness (82.61%) and less common an adverse event (6.52%). The probability of persistence of treatment with ustekinumab was 0.83 (95% CI 0.63-0.92) at year 1, 0.79 (0.58-0.9) at year 2 and 0.79 (0.58-0.9) at year 3 when ustekinumab was prescribed as the first line treatment. The persistence decrease when ustekinumab was prescribed as a second and third treatment: being 0.53 (0.27-0.73) the first year, 0.46 (0.22-0.67) the second year and 0.46 (0.22-0.67) as a second line treatment and 0.58 (0.44-0.70) the first year, 0.33 (0.17-0.50) the second year and 0.33 (0.17-0.50) the third year as a third line treatment. The persistence was similar to anti-TNF treatment, according to line treatment. Adverse events were mainly mild (97.83%) and occurred the first year of treatment. Most of the adverse events were classified as “infections and infestations” (36.96%).

Conclusion: The persistence of ustekinumab was high, being 83% at the end of the first year on treatment and 79% the second and the third year of treatment. The persistence of ustekinumab was higher when it was the first line treatment compared as if it was used as the second or third BT option. The persistence of Ustekinumab is similar to the persistence of anti-TNF treatments in all the analyzed treatment lines (no statistically differences were found). Adverse events occurred mainly during the first year of treatment. They were mainly mild adverse events and the frequency decreased within the second and third year of treatment.

AB0752 PSORIATIC ARTHRITIS: OLSOARTHRITID AND POLYARTHRITIS PATTERN CHANGES OVER THE INITIAL YEAR OF THE PRESENTATION. A REAL-WORLD EVIDENCE REPORT FROM THE QUEBEC REGISTRY RHUMADATAR

S. Chambard, L. Coupal, D. Choquette, Institut de Recherche en Rhumatologie de Montréal, Rheumatology, Montréal, Canada; 2Faculté de Médecine de l’Université de Montréal, Montréal, Canada

Background: Psoriatic Arthritis (PsA) most frequently presents as a polyarthritis or as an oligoarthritis [1]. Upon reassessment, patients may change category during follow-up [2-3]. Historically, the patients in the original description of Moll and Wight had an oligoarticular presentation [4]. However, other studies have not found the same distribution in all patient populations [5]. Currently,
The contribution of joint symptoms, enthesitis, skin and nail psoriasis (PsO) to minimal disease activity (MDA) achievement in psoriatic arthritis (PsA) patients (PTS). Effect of tofacitinib treatment. Data from real clinical practice.

M. Chamurlieva1, E. Loginova1, E. Gubar2, Y. Korsakova2, S. Glukhova2, T. Korotaeva1. 1V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: PsA is an inflammatory arthritis associated with skin and nail PsO. The treatment target of PsA is MDA. In order to achieve MDA it is necessary to significantly improve musculoskeletal (MSK) symptoms, skin symptoms and patient-reported outcomes (PROs). In RCT it has been recently demonstrated that targeting both joint and skin symptoms is very important in achieving optimal improvement in health-related quality of life [1]. However, there is not enough data from clinical practice. Tofacitinib (TF) is an oral Janus kinase inhibitor approved for the treatment of PsA pts.

Objectives: to study the influence of joint, enthesis, skin and nail symptoms on MDA achievement in active PsA (pts) treated with TF for 6 months (mo).

Methods: 41 pts (MF=24[58.5%]/17[41.5%]) with active PsA fulfilling the CASPAR criteria, were included after signing consent participation forms. Mean age 42±10.3 years (yrs), median (Me) PsA duration 72 [35;120] mo, PsO duration 192 [98;312] mo, PASI 14.5 [7.23;8], DAPSA 44.2 [37.6;55.3]. Pts were treated with TF 5 mg twice daily. At baseline (BL) and over a period of 6 mo of therapy PsA activity was evaluated by Tender Joint Count (TJC68), Swollen Joint Count (SJC66); PGA, physician global assessment by Visual Analog Scale (VAS), DAPSA. Enthesis was evaluated by LE (Leeds Enthesial Index) plus Planter Facia (PF). PROs were measured by PGA VAS, PfPain VAS, HAQ. PsO were measured by PASI/BSA (%). The presence/absence of Nail PsO was evaluated.

**HOW DO WE TREAT PSORIATIC ARTHRITIS? EVIDENCE FROM A 15-YEAR MONOCENTRIC BDMARDs EXPERIENCE**

M. S. Chimenti1, M. Ferrioli1, A. Dantonio1, P. Conigliaro1, S. Ferrigno1, A. Vendola1, P. Triggianesi1, G. L. Forti1, R. Perricone1. 1Rheumatology, Allergy and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy.

**Background:** Psoriatic arthritis (PsA) treatment paradigm has dramatically changed during the last 15 years, improving patients clinical outcomes and quality of life. We have now the possibility of a wide option among BDmARDs with different targets: TNF-inhibitors (TNFi), anti-IL17A inhibitors and anti-p40IL12/23.

**Methods:** Patients affected by PsA diagnosed by the CASPAR criteria and treated with a bDMARDs, in the last 15 years were enrolled. Clinical assessment included the presence of: oligo- and polyarthritis and axial involvement (yes/no), enthesitis (yes/no), dactylitis (yes/no), PsO and onychopathy (yes/no). Comorbidities, as cardiovascular, metabolic syndrome and kidney diseases, were registered. The overall timeframe was halved in: 1st period (2004-2011) and 2nd period (2012-2019). Chi-square test was used to analyze the distribution of clinical PsA subtypes and comorbidities.

**Results:** Data from 314 consecutive PsA patients treated with bDMARDs were obtained (Table 1). A total of 259 (82.48%) patients were treated with TNFi, while 55 (17.52%) with non-TNFi (i.e. Secukinumab, Ustekinumab or Apremilast). In the 1st period, 143 (86.14%) patients were treated with TNFi and 23 (13.85%) with non-TNFi. In the 2nd period, 116 (78.4%) patients were treated with TNFi and 32 (21.2%) with non-TNFi. PsA patients with polyarticular involvement were on TNFi in a higher prevalence in the first period than in the second (p<0.001). On the contrary, oligo-articular PsA and Axial PsA were on TNFi in a higher prevalence in the 2nd period than in the 1st (p<0.001), as well as non-TNF drugs were more frequently used in the 2nd period than in the 1st (p<0.003). PsA patients with PsO and/or onychopathy were in a higher prevalence on non-TNFi than on TNFi in the 1st period (p<0.001). This difference disappeared in the 2nd period, when both TNFi and non-TNFi were equally used (p=ns). PsA patients with metabolic syndrome and/or cardio-vascular and/or renal diseases were more prevalent on TNFi in the 1st period than in the 2nd while in the 2nd these patients were more frequently on non-TNFi (p<0.05).

**Conclusion:** Here, we demonstrated that clinicians treatment choice in patients with moderate-severe PsA may be influenced by the clinical subtype and/or the occurrence of comorbidities. In particular, during the last years, the use of non-TNFi can be chosen more adequately as a therapeutic challenge in patients with different clinical manifestations and with comorbidities, improving PsA treatment paradigm.

**REAL WORLD EFFECTIVENESS OF SECUKINUMAB IN PSORIATIC ARTHRITIS: FINDINGS FROM A RECENT CROSS SECTIONAL SURVEY OF RHEUMATOLOGISTS AND PATIENTS IN EUROPE**

P. G. Conaghan1, E. Holdsworth2, H. Tian3, N. Booth2, P. Anthony2, N. Modi1, D. Keininger5, U. Kiltz1. 1University of Leeds, Leeds, United Kingdom; 2Adelphi Real World, Bollington, United Kingdom; 3Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States of America; 4Novartis Healthcare Pvt Ltd, Hyderabad, India; 5Novartis Pharma AG, Basel, Switzerland; 6Rheumazentrum Ruhrgebiet, Herne, and Ruhr-Universität Bochum, Bochum, Germany.

**Background:** Secukinumab has demonstrated significant and sustained reduction of disease activity and improvement in physical functioning and quality of life in PsA pts in RCTs.1

**Objectives:** This study assessed effectiveness of secukinumab in PsA in a real-world setting.

**Methods:** This was a cross-sectional survey of rheumatologists, dermatologists and pts in France, Germany, Italy, Spain, and UK. Data were collected online from June-Dec 2018 via physician-completed patient record forms. Pts receiving any treatment for PsA were included in survey (n=1675). Pts receiving secukinumab >4 months were included in this analysis. Pts reported quality of life, work, and disability measures at their current consultation. Physicians reported patient demographic and disease characteristics, concomitant and previous treatments, and time since diagnosis. Physicians also reported overall, skin and joint disease severity, pain (1-10 scale), BSA psoriasis involvement, global VAS score, PASI score, SJC, and TJC for 2 time points: initiation of treatment and at the time of data collection (current consultation). Data were analysed descriptively. The data analysed here is representative of pts that are currently receiving secukinumab and does not assess pts that have discontinued treatment.

**Results:** 572 PsA pts were receiving secukinumab >4 months at their current consultation. Patient mean age was 47.9 yrs, with 43% female, 59% working full time, and a mean BMI of 26.6. On average, pts were diagnosed with PsA 5.6 years before the current consultation, had received secukinumab for 11.0 months, and for 59% of pts secukinumab was their 1st advanced therapy (bDMARDs or tsDMARDs), 24% their 2nd and 16% their 3rd or more. 25% of pts were also receiving a csDMARD concurrently. Pts reported a mean EQ5D utility score of 0.83, mean WPAI overall work impairment of 24.3%, mean HAQ-DI score as 0.6, and mean PsAI12 score as 2.6 at current consultation. Proportion of pts with moderate and severe overall disease severity, and skin and joint severity decreased at current consultation vs at the initiation treatment (Table 1). Between initiation of treatment and current consultation, pts achieved a significant reduction in disease activity scores, pain score, global VAS scores, BSA, PASI score as well as a greater proportion of pts achieving a BSA <3%, a PASI score < 3 (Table 2).

**Conclusion:** This multinational study demonstrated secukinumab effectiveness in routine care in PsA pts, with significant improvements across all outcomes.

GUSELKUMAB IMPROVED WORK PRODUCTIVITY AND DAILY ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM A PHASE 3 TRIAL

J. Curtis1, I. McNicols2, P. Rahman3, W. Tillet4, P. J. Mease5, C. Meghji6, E. C. Hsia6,7, B. Zhou8, P. Agarwal6, S. Peterson6, C. Han6, I. Univ Alabama, Birmingham, United States of America; 2Institute of Infection, Immunity & Inflammation, Univ Glasgow, Glasgow, United Kingdom; 3Memorial Univ of Newfoundland, St Johns, Canada; 4Royal Natl Hospital for Rheumatic Diseases, Bath, United Kingdom; 5Swe Medical Ctr/Providence St Joseph Health and U Wash School of Med, Seattle, United States of America; 6Janssen Research & Development, LLC, Spring House, United States of America; 7U Penn Med Ctr, Philadelphia, United States of America; 8Janssen Global Svs, LLC, Horsham, United States of America

Background: DISCOVER 2 (DISC 2) is a Phase 3 trial of anti-IL-23-specific mAb guselkumab (GUS) in psoriatic arthritis (PsA) patients, who experience impaired physical function, resulting in disability, work productivity loss, and economic consequences.1

Objectives: To evaluate the effect of GUS on impaired work productivity and daily activity in DISC 2 using the Work Productivity and Activity Impairment Questionnaire: Psoriatic Arthritis (WPAI-PsA).

Methods: Bio-naive adult PsA patients with PsA5 whereas not receiving nonbiologic DMARDs &/or NSAIDs received subcutaneous GUS 100 mg every q(4) weeks (W); GUS 100 mg W0, W4, q8W; or placebo (PBO). WPAI-PsA outcomes, assessed by PsA over the previous week, work time missed (absenteeism), impairment while working (presenteeism), and impaired overall work productivity (absenteeism + presenteeism) and daily activity. Percentage change from baseline was analyzed for PsA domains using mixed-effect model repeated measures (MMRM), indirect savings from improved overall work productivity were estimated with 2018 US mean yearly wage estimate (all occupations).2

Results: At Week 24, impaired overall work productivity and daily activity were improved 20-22% in GUS-treated and 10-11% in PBO-treated pts (Table). Potential yearly indirect savings from improved overall work productivity was $10,242 with GUS q8W and $10,404 with GUS q4W vs $6,648 with PBO; $4,594 and $4,756, respectively.

Conclusion: Improvement in overall work productivity and daily activity were greater with GUS versus PBO among pts with moderate-to-severe PsA, resulting in potential annual incremental economic gains.

Acknowledgments: None

Background: Cardiovascular complications are the leading cause of death in patients with psoriatic arthritis (PsA), but current strategies for reducing cardiovascular risk are still inadequate. Depression is a common comorbidity in PsA patients and it is recognized as an independent cardiovascular risk factor in the general population. Endothelial dysfunction, assessed as a reduction in brachial

artery Flow Mediated Dilation (FMD), is a predictor of major cardiovascular events in high and low risk populations.

**Objectives:** To investigate the relationship between endothelial function and cardiovascular symptoms in a cohort of patients with PsA.

**Methods:** Sixty consecutive patients with PsA, aged between 30 and 79 years, with no history of major cardiovascular events, were characterized for traditional cardiovascular risk factors and features of psoriatic disease. The risk of cardiovascular events according to traditional risk factors was calculated using the Framingham Risk Score (FRS) and the presence of depressive symptoms was defined through the Hospital Anxiety and Depression Scale (HADS) using the validated cut-off of 8. Endothelial function was assessed by FMD. Serum IL-6 was quantified by ELISA, IL-17 and TNF-α levels by Luminex method.

**Results:** Patients had an average age of 52.1±11.0 years, 43.3% of them were male, 23.3% obese and 25.0% active smokers; 38.3%, 25.0% and 11.7% were treated for high blood pressure, dyslipidemia and diabetes mellitus, respectively. The 10-year risk of major cardiovascular events estimated by FRS was 10.4%. The mean duration of PsA was 9.4 years, 30.0% of patients were in minimal disease activity (MDA) and 61.7% and 46.7% were treated with conventional and biotechnological DMARDs, respectively. The mean HDS value was 6.9±3.2 and 43.4% of patients had significant depressive symptoms. The severity of depressive symptoms according to HDS correlated with disease activity according to DAPSA (r=0.449, p<0.001). The mean FMD was 78.8±3.8%, this value correlated inversely with age (r=-0.408,p<0.001), risk of major cardiovascular events according to FRS (r=-0.327, p=0.011) and severity of depressive symptoms according to HDS (r=-0.285, p=0.027). The correlation between FMD and serum IL-6, IL-17 and TNF-alpha levels was not statistically significant. In multivariate linear regression models, the relationship between FMD and HDS was significant also when corrected for age (β=0.26, p=0.03, R2=0.23) and FRS normalized through logarithmic transformation (β=0.32, p=0.009, R2=0.22).

**Conclusion:** The degree of endothelial dysfunction quantified by FMD correlates with the severity of the depressive symptoms in patients with PsA, independently of the cardiovascular risk attributable to classical risk factors. The weak relationship between FRS and serum levels of IL-6, IL-17 and TNF-alpha suggests a role of factors independent of inflammation in the regulation of endothelial function in patients with PsA. Systematic treatment and research of depressive symptoms could contribute to a more complete stratification and a better management of cardiovascular risk in patients with PsA.

AB0761 DEMOGRAPHIC AND CLINICAL FEATURES OF JUVENILE-ONSET PSORIATIC ARTHRITIS: RESULTS FROM PSART-ID REGISTRY

1PSART-ID, Kahramanmaras, Kahramanmaras, Turkey; 2Faculty of Medicine, Alexandria University, Alexandria, Egypt; 3Faculty of Medicine, Alexandria University, Alexandria, Egypt; 4PSART-ID, Ankara, Ankara, Turkey; 5PSART-ID, Istanbul, Istanbul, Turkey; 6PSART-ID, Antalya, Antalya, Turkey; 7PSART-ID, Hatay, Hatay, Turkey; 8PSART-ID, Izmir, Izmir, Turkey; 9PSART-ID, Bursa, Bursa, Turkey; 10PSART-ID, Ankara, Ankara, Turkey; 11PSART-ID, Sakarya, Sakarya, Turkey; 12PSART-ID, Kahramanmaras, Kahramanmaras, Turkey; 13PSART-ID, Adana, Adana, Turkey; 14PSART-ID, Konya, Konya, Turkey; 15PSART-ID, Ottawa, Ottawa, Canada

Background: Although psoriatic arthritis (PsA) may be seen at any decades, juvenile onset PsA is relatively rare. Moreover, there were no more data about clinical features, treatments, and course in juvenile PsA when they reached to adult age.

Objectives: The objective of this study was to assess and compare demographic and clinical features for juvenile onset PsA and adult onset PsA.

Methods: PsART-ID is a multicenter, international database, investigating the disease characteristic in real life (1). Briefly, demographic data, PsA subtypes, uveitis, enthesisitis, dactylyllitis, Co-morbidities, disease activity scores (TJC, SJC, VAS-pain, VAS patients and physician global assessments, VAS-fatigue, BAS-DAI), and functional status (HAQ-DI, BASFI) were recorded. Psoriasis and PsA starting age were noted, as well. Patients were classified as juvenile PsA or juvenile PsO (under 18 years old). Results were compared regarding to juvenile versus adult onset age.

Results: Overall, 1644 PsA patients were included to study. 301/1644 (18.3%) patients had juvenile onset psoriasis. Of 39/1644 (2.4%) patients had juvenile onset PsA, as well. As expected, juvenile onset PsA patients were younger, however PsA disease duration were longer than adult onset PsA patients. There were no any difference between demographic and clinical data, except BMI and enthesisitis were less frequent at the juvenile onset PsA groups. Although, ever csDMARD using were similar between two groups, however, juvenile onset PsA patients were used more frequently bDMARDs.

AB0762 METABOLIC SYNDROME IN EGYPTIAN PSORIATIC ARTHRITIS PATIENTS.

M. Imam1, M. Helai2, M. Hassan3, E. Hassan4, S. Essam5
1Faculty of Medicine, Alexandria University, Rheumatology and Rehabilitation, Alexandria, Egypt; 2Alexandria university, Internal medicine, Alexandria, Egypt; 3Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis affecting 20-30% of patients with skin Psoriasis (PsO). It is strongly associated with obesity, particularly excess visceral adiposity, which leads to insulin resistance, hyperglycemia, dyslipidemia, and hypertension (HTN).

All the previous findings are grouped in Metabolic Syndrome (MetS) which increase the risk of development of Type 2 diabetes mellitus (T2DM) by five folds and cardiovascular disease (CVD) by two folds.

Objectives: The aim of this work was to define those who fulfill MetS criteria in PsA patients thus of greater risk to develop CVD and T2DM.

Methods: Fifty PsA patients diagnosed according to the CASPAR criteria and 50 matched healthy controls were included in this study.
Disclosure of Interests: None declared

AB0763  THE INFLUENCE OF OBESITY ON BIOLOGICAL DMARD TREATMENT RESPONSE IN PSORIATIC ARTHRITIS: HUR-BIO REAL LIFE RESULTS

B. Farısoğulları1, G. K. Yardımcı1, E. C. Bolek1, E. Bilgen1, E. Duran1, G. Ayan1, L. Kılıç1, O. Karadag1, A. Akdoğan1, Ş. A. Bilgen1, A. I. Erteli1, N. Kiraz1, U. Kalyoncu1, Haticece University Medical School Internal Medicine, Rheumatology, Ankara, Turkey

Background: Obesity could be a risk factor for response to treatment and disease severity in psoriatic arthritis (PsA) because of potential pro-inflammatory effects of cytokines produced by adipose tissue (1). Obese elderly patients need additional surveillance to ensure that they are not being neglected. We aimed to assess the influence of obesity on the treatment response of biological DMARDs in patients with PsA. We also compared the results with the real-life data of the HUR-BIO registry.

Methods: 1679 PsA patients were included in this post-hoc analysis of the HUR-BIO registry. BMI >30 was defined as obesity. All patients were subjected to thorough clinical evaluation of the musculoskeletal system. The disease activity was assessed by DAPSA and BASDAI. Skin severity was assessed by the PASI. Disability assessment was done by the HAQ-DI. Laboratory investigations included: CRP, uric acid and diabetic profile (including HOMA-IR) and lipid profile in patients and control subjects. Subjects were defined as having MetS according to International Diabetes Federation (IDF) criteria: Abdominal obesity was measured by Waist circumference (WC) for Egyptian cut-offs values (WC>100.5 cm in men and >96.25 cm in women). The subjects must have central obesity to identify MetS plus any two of the following four factors: 1) Raised triglycerides level (TG) ≥150 mg/dL or on specific treatment. 2) Reduced levels of high-density lipoprotein cholesterol (HDLC <40 mg/dL in males and <50mg/dL in females or on specific treatment. 3) HTN: (systolic: ≥130mm H g or diastolic: ≥ 85 mm Hg) or on treatment for HTN. 4) Raised fasting glucose levels (≥100 mg/dL), or previously diagnosed T2DM.

Results: METSY was significantly higher among PsA patients than control group (42% Vs 16% respectively). Regarding frequency of MetS components, obesity was the highest component among PsA patients (82%) as illustrated in Figure 1. CRP mean level was significantly higher in PsA patients compared to control group with p<0.001*. CRP serum level showed a positive significant correlation with DAPSA score and HOMA-IR (P= 0.031, 0.002 respectively) respectively. Correlations between MetS components and (disease activity, skin severity and physical function) are shown in Table 1.

Conclusion:
1- There is high frequency of MetS in PsA patients compared to control group.
2- Obesity and DMT2 were the most common components of MetS.
3- There is high frequency of MetS in PsA patients compared to control group.
4- CRP serum level showed a positive significant correlation with DAPSA score and HOMA-IR (P= 0.031, 0.002 respectively)

Methods: Retrospective analysis of an observational cohort of 453 patients from a university hospital, following a specific protocol from 1992 to 2019. The following variables have been collected: corticosteroid treatment (methylprednisolone ≤16mg/day in a slow tapering regimen in 2 months), demographic and disease factors, comorbidities that could be associated (diabetes mellitus, high blood pressure, severe infections) and serious complications of psoriasis (erythroderma or pustular psoriasis). To assess the activity of psoriasis, physician global assessment is mostly used and occasionally to a lesser extent body surface area and psoriasis area severity index.

Results: In our series, 35.98% (163/453) of patients have received short corticosteroid regimen at some point in follow-up care, of which 93.8% received concomitant treatment with disease modifying antirheumatic drugs (DMARD). Only 6.2% of the patients who received short corticosteroid regimen presented a flare-up of psoriasis, most of them mildly. No patient developed an erythroderma or severe pustular psoriasis.

After analyzing the data, a greater use of this regimen of treatment has been observed in patients with dactylitis (44.6% with dactylitis vs 27.8% without dactylitis, p<0.001) and a lower use of corticosteroids in axial PsA (14% of axial PsA vs 41% of non-axial PsA, p<0.001). There were no significant differences in the use of corticosteroids in respect to sex, age, age of onset of PsA, duration of PsA or high blood pressure. Nor in factors of poor radiographic prognosis: number of damaged joints, mutilating PsA or severe pustular psoriasis. flare-up of psoriasis, most of them mildly. No patient developed an erythroderma or severe pustular psoriasis.

Conclusion: In our series, no patient developed an erythroderma or severe pustular psoriasis and most of the flare-ups of psoriasis were mild. The use of systemic corticosteroids at intermediate doses in a slow tapering regimen concurrently with DMARD can be safely used in patients with PsA.

Methods: We conducted a systematic literature review (PROSPERO ID 1609930) searching PUBMED, MEDLINE and the Cochrane Library for publications (in English language) on randomized controlled trials investigating biological or targeted synthetic disease modifying drugs in adult PsA patients that included some PROs to evaluate the response to treatment. Two of the authors (BFS, AK) screened, selected and extracted the data of the trials that fulfilled inclusion criteria. Statistics were descriptive.

Results: Of 1389 articles in total 880 were screened (512 duplicates); 92 were selected for detailed analysis with 48 finally analysed. 87% were primary publications were some patient-outcome measures were reported. The HEQoL Questionnaire Disability Index (HAQ-DI) was reported in all RCTs (100%), while 70% of trials reported on the Short Form (36) Health Survey (SF36).

Fatigue (FACIT-F) was reported in 29% of trials with different rates of articles published before and after the OMERACT working group recommendations (27% vs 50%) (1). Data on burden of psoriasis through the Dermatology Life Quality Index in 45%. Other PRO measurements to assess potentially affected health domains such as sleep disturbance, psychological disorders or well-being at work were reported only rarely.

Conclusion: Our SLR shows that all trials report data on HAQ-DI. However, important domains as also emphasized by the OMERACT working group (1) are not routinely reported. Especially fatigue, included in 2016 as part of the OMERACT “Inner core” of the PsA Core Domain Set is only reported in about one quarter of studies, although 50% of studies published after 2016 report on fatigue. Data on emotional well-being, psychological status, productivity losses, and sleep disturbance remain rarely reported in PsA randomized controlled trials.

AB0767 PATIENTS WITH RHEUMATOID ARTHRITIS HAVE A LOWER BONE DENSITY THAN PATIENTS WITH PSORIATIC ARTHRITIS

D. Freier1, E. Wiebe1, R. Biesen1, T. Buttgereit2, S. Hermann1, T. Gaber1, F. Buttgereit1. 1Charité – Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany; 2Charité – Universitätsmedizin Berlin, Dermatology, Venerology and Allergology, Berlin, Germany

Background: Osteoporosis is a skeletal disease characterized by the loss of bone density resulting in an increased fracture risk. Female sex, advanced age, Caucasian ancestry, previous history of fractures, menopause and certain genetic factors predispose for osteoporosis. In addition, recent studies could prove that chronic inflammatory diseases such as Rheumatoid Arthritis (RA) and long-term treatment with higher doses of glucocorticoids (GCs) represent inde- pendent risk factors for the development of osteoporosis. On the other hand, the intake of vitamin D, a calcium-rich diet and physical exercise can be protective. Data describing the prevalence of osteoporosis in patients with other rheumatic diseases like psoriatic arthritis (PsA) are lacking.

Objectives: We compared the prevalence of osteopenia and osteoporosis in patients with RA and PsA, respectively, based on data obtained from our ongoing prospective monocentric study. Our objective was to investigate the prevalence of osteoporosis (GC-induced osteoporosis in patients with different rheumatic diseases (NCT0219314). Methods: Bone mineral density data measured by dual x-ray absorptiometry (DXA) in patients with PsA (n=92) were compared with data measured in 92 age- and
gender-matched patients with RA. The results were analysed with respect to clinical and laboratory parameters such as data on GC treatment (frequency, duration defined as start of treatment until timepoint of measurement, actual and cumulative dose), csDMARD and bDMARD (including as well tsDMARDs) therapy, serological parameters (Vitamin D, alkaline phosphatase, calcium, inflammatory markers and rheumatoid factor) and functional status (e.g. Health Assessment Questionnaire (HAQ), sporting activities). Statistical analyses were performed descriptively using mean and standard deviation, t-tests for metric variables, and chi-square tests for nominal variables. For subgroup analyses with less than 30 patients per group, tests for non-normally distributed data were used due to the lower test power.

**Results:** RA patients showed significantly lower means of bone density values (peripheral T-score, p=0.03) than PsA patients leading to a higher frequency of osteopenic bone densities (p<0.005). However, no differences in the frequency of osteoporotic bone densities could be detected. PsA patients reported a significantly longer disease duration and a higher current GC dosage. In contrast, the frequency of current GC intake was higher in RA patients. Although the calcium intake was higher in the RA group, neither blood levels of calcium and vitamin D, nor the cumulative GC dose (GCCD) or duration of GC therapy could indicate a causal relationship for the differences observed in bone density values between the two groups. The frequency of csDMARD therapy did not differ significantly between PsA and RA patients while the frequency of bDMARD therapy was higher in the PsA group (p=0.04).

**Conclusion:** The lower bone density in RA patients seems not to be fully explained by higher GCCD, disease duration or higher levels of inflammation. However, RA patients had a higher frequency of current GC intake. Additionally, differences in bone density between the two groups could be related to the higher prescribed therapies in PsA patients, but further investigations like multivariate analyses with higher numbers of patients are necessary. Furthermore there is more need for research on possible molecular and genetic factors in PsA, which are protecting from low bone density.

rheumatologic conditions including Psoriatic Arthritis (PsA), enthopathy can be a consequence of several clinical conditions including metabolic syndrome, mechanical injuries and degeneration.

**Objectives:** To evaluate the effect of body mass index (BMI) on disease activity scores and enthesis scores in Psoriatic Arthritis.

**Methods:** Retrospective study including all the patients with PsA meeting the CASPAR criteria, beginning first-line biologic therapy at our centre. Demographic and clinical data were collected from the Portuguese database Reumap. Statistical analysis was performed with SPSS. Continuous variables were compared through Spearman/Pearson correlations.

**Results:** The mean BMI was 26.8 (SD 0.5). In our sample of 119 PsA patients, 21.5% were overweight and 8.3% were obese. The mean age of patients was 46.3 ± 10.3 years; 60 female and 59 male. The median disease duration was 6.8 (0.3-33.8) years. At baseline mean (SD) disease activity variables were: DAS 28 4vESR 4.9 (0.2), ESR 33.2 (2.3) mm/h; CRP 2.35 (0.3) mg/dL; BASDAI 6.6 (0.2), ASDAS 3.9 (0.1), BASMI 3.7 (0.2), BASFI 5.8 (0.3), MASES 1.9 (0.3), SPARCC 2.3 (0.3). There were statistically significant positive correlations between BMI and MASES at baseline (p=0.024, n=0.411) but there weren't with SPARCC, DAS 28 4vESR, ESR, CRP, BASDAI, ASDAS, BASMI and BASFI.

**Conclusions:** The data showed that patients with higher BMI values had higher enthesis scores suggesting that overweight/obesity may have a negative impact on enthopathy. Further studies are needed to further understand that possible relationship.

**Results:** During the study period 393 patients (50.6% women) with a mean age of 52.47 ± 13.21 years were evaluated. Baseline characteristics are shown in table 1.

- The mean BMI was 28.15 ± 5.87 kg/m². 112 patients (32%) were overweight with a mean BMI of 27.46 ± 1.55 kg/m² and 118 patients (34%) were obese with a mean BMI of 34.42 ± 5.08 kg/m². Of the obese patients, 80 (67.8%) had obesity grade 1, 28 (23.7%) grade 2 and 10 (8.5%) grade 3.
- Characteristics of the patients according to BMI categories are shown in Table 2.

- We observed that mean age was significantly higher in obese patients (p <0.001), as well as the prevalence of cardiovascular risk factors such as HBP (p <0.001), Diabetes (p <0.001), dyslipidemia (p = 0.001) and hyperuricemia (p = 0.004).
- Obese patients also received more biological therapy (p=0.032). A higher prevalence of HLA-B27 was observed in patients with normal weight (p=0.016).
- No differences were found according to BMI regarding gender and source of referral.

**Conclusion:**
- Almost 70% of patients with PsA visited in the PAIDER clinic of our center have a BMI above normal and more than a third of them are obese, mostly grade 1.
- In our joint clinic there are no differences in BMI regarding the source of referral of the patients.
- Patients with obesity are older, have more cardiovascular comorbidities and receive more biological treatment significantly, which increases the complexity of their management and worsens the prognosis.

**Results:** Data were available for 210 patients, 43% females. DAPSA<14 was in 143 patients (68.1%) and was associated with higher disease duration, OR 1.079 (1.020-1.142, 95% CI); p=0.008. DAPSA index was not associated with BMi (r 0.126, p 0.176).
PsAID12 was evaluated in 156 patients and we saw that patients with DAPSA≤14 had significantly lower PsAID12 (mean 1.7 ± SD 1.7 vs. 3.9 ± 2.1), p< 0.0001. PsAID12 of less than 4 is considered a good outcome and all items of PsAID12 were associated with DAPSA≤14 on univariate analysis but only pain remained independent predictor on multiple regression analysis (p< 0.0001).

Conclusion: In these PsA patients, DAPSA VLDA/LDA was associated with higher disease duration and with lower PsAID12, and skin problems were not good represented in DAPSA index.

OSTEOPOROSIS AND ITS RELATIONSHIP WITH THE SERUM URIC ACID LEVEL IN PATIENTS WITH PSORIATIC ARTHRITIS

H. H. Geze1, D. Erdem Gürsoy2, S. Acer Kasman1, N. Özlü1, M. T. Duruöz2
1Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation, Rheumatology Division, Istanbul, Turkey; 2Adıyaman Training and Research Hospital, Rheumatology, Adıyaman, Turkey

Background: Although osteoporosis is an inherent comorbidity in inflammatory rheumatic disease and the risk of bone loss is high in patients with several rheumatic diseases, evidence is limited in psoriatic arthritis (PsA). One of the most prominent features in PsA is increased serum urate (SU) levels. Due to its anti-oxidant effects and protective role against osteoporosis, high SU levels are associated with increased bone mineral density (BMD) and reduced bone loss in the healthy population, and in patients with rheumatoid arthritis. However, whether this association is also present in patients with PsA has not been investigated.

Objectives: The aim of this study was to evaluate PsA patients with respect to the presence of osteoporosis and its association with SU levels.

Methods: This ongoing study included 86 patients (68 female, 18 male) who were diagnosed with PsA according to the CASPAR criteria and had indications for BMD testing according to the National Osteoporosis Foundation. Clinical characteristics including body mass index (BMI), pain VAS, patient global VAS, enthesitis, and tender and swollen joint counts were recorded. Evaluations included the PASI, PsAQoL, and HAQ. Disease activity was assessed using the DAPSA, BASDAI, and MDA. Osteoporosis was defined as a BMD T-score of -2.5 or less and osteopenia as a BMD T-score between -1.5 and -2.5 (WHO osteoporosis).

Results: The mean age of the study group was 55.4 (SD:9.2) years and the mean disease duration was 84.5 (SD:91.6) months. Indicators of secondary osteoporosis were type-1 diabetes mellitus (1%), hyperthyroidism (2.3%), early menopause (< age 40) (8.1%), and chronic liver disease (9.3%). As for the steroid use, the rates of never, previous and current users were 33.7%, 20.9% and 22.1%, respectively. Osteoporosis was found in 9.3% and osteopenia in 33.7% of the patients. A history of vertebral compression fractures or any fracture was present in 20.9% of the patients, half of whom were in postmenopausal. BMD L1-L4, T- and Z-scores were lower in female patients (p<0.05). DAPSA remission and MDA rates were 6% and 15%, respectively. Bone mineral density was similar across DAPSA disease activity categories (remission-low-moderate-high: p>0.05). The frequency of osteoporosis did not differ significantly between patients with DAPSA remission and non-remission (p>0.05). The mean L1-L4, T- and Z-scores, and BMD g/cm² were significantly higher in patients with MDA than those without MDA (p<0.05). The mean SU level was 5 (SD:1.3) mg/dl, and 18.6% of the patients had a SU level of 6 mg/dl or higher. There was no significant correlation between SU and BMD (p>0.05). BMI showed a weak correlation with femur neck T-score (r=0.286) and total femur T-score (r=0.245). BMD variables showed no correlations with disease duration, acute phase reactants, BASDAI, PsAQoL, and cumulative steroid dose.

Conclusion: Patients with PsA did not have an increased prevalence of low BMD despite fractures. Osteoporosis was associated with MDA and the severity of psoriasis, but not with DAPSA, SU level, functional impairment, and quality of life.

THE INCIDENCE OF RESIDUAL DISEASE ACTIVITY FOLLOWING DIVERSE DISEASE ACTIVITY MEASUREMENTS FOR PSORIATIC ARTHRITIS

H. H. Geze1, D. Erdem Gürsoy2, S. Acer Kasman1, M. T. Duruöz3, 1Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation, Rheumatology Division, Istanbul, Turkey; 2Adıyaman Training and Research Hospital, Rheumatology, Adıyaman, Turkey

Background: Due to the complex nature of psoriatic arthritis (PsA), diverse disease activity measures have been developed, the most common of which include Disease Activity Score for Psoriatic Arthritis (DAPSA), Minimal Disease Activity (MDA) and Very Low Disease Activity (VLDA). Recently, new composite measures have been developed such as Psoriatic Arthritis Disease Activity Score (PSDAS) and GRACE index. Due to different domains and assessments, even though these measures may indicate remission or low disease activity, residual disease activity (RDA) may persist.

Objectives: The aim of this study was to evaluate RDA in patients with PsA.

Methods: A total of 148 patients (105 female, 43 male; mean age 47.5 (SD:12.6) years) who met the CASPAR criteria for PsA were recruited. Demographic and clinical characteristics of patients were recorded, including pain visual analog scale (VAS), joint VAS, patient global VAS, and tender and swollen joint counts. Evaluations included the Leeds Enthesitis Index (LEI), Psoriasis Area and Severity Index (PASI), Psoriatic Arthritis Quality of Life (PsAQoL), Short-Form 36 Health Survey (SF-36) and Health Assessment Questionnaire (HAQ). Disease activity and remission were assessed using the DAPSA, MDA, VLDA, PASDAS and GRACE Index. MDA was calculated with 5 and 6 positivity criteria separately. Low disease activity (LDA) was defined as follows: DAPSA ≤14, PASDAS g3.2 and GRACE Index ≤ 2.3. RDA was defined as the presence of at least one of the following criteria despite remission or LDA: tender and/or swollen joints >1, dactylitis >1, LEI-1, HAQ>0.5, PASI>1, PGA>20, physician VAS>20, or pain VAS>15.

Results: The mean duration of disease was 68.2 (SD:80.2) months. DAPSA-LDA, PASDAS-LDA, GRACE-LDA, MDA and VLDA were observed in 48.6%, 14.6%, 14.9%, 23.6% and 2% of PsA patients, respectively. RDA as determined by at least one domain was identified in 91%, 95%, 86% and 86% of patients who were classified as having MDA, DAPSA-LDA, PASDAS-LDA and GRACE-LDA, respectively. Undetected RDA was most common with DAPSA, whereas VLDA completely ruled out RDA. PASDAS and GRACE resulted in similar rates of RDA (Table-1). With DAPSA-LDA, the incidence of RDA in the pain domain was significantly lower with older age. Female patients had higher rates of RDA with the LEI and HAQ (p<0.05).

Conclusion: VLDA was the most and DAPSA was the least sensitive method to detect remission/LDA. RDA should be kept in mind in patients with PsA when using current measures to assess remission or LDA.

[1] Ennio Lubrano, Silvia Scirrignano, Fabio Massimo Perrotta, Residual disease activity and associated factors in Psoriatic Arthritis. The
Conclusion: Times to initial response in functional ability and disease activity were similar in pts treated with either tofacitinib or ADA. Time to initial response similar to prior first-post-BL observation (Week 2 or M1) was not estimable in this analysis. These results may help physicians better understand the time frame for a meaningful response in pts receiving tofacitinib.

AB0774

TIME TO RESPONSE FOR CLINICAL AND PATIENT-REPORTED OUTCOMES IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH TOFACITINIB, ADA-LUMIMUB OR PLACEBO

1University of Toronto, Toronto, Canada; 2University of Oxford, Oxford, United Kingdom; 3Pfizer Inc, Groton, United States of America; 4Pfizer Inc, Montreal, Canada; 5Pfizer Inc, Collegeville, United States of America; 6Evidera, Seattle, United States of America; 7University of Leeds, Leeds, United Kingdom

Background: With multiple disease domains affected in PsA, clinical and patient-reported outcome (PRO) measures are important to assess disease improvement following treatment. Rapid, meaningful improvements in disease activity are a priority for physicians and patients (pts). Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. Higher proportions of pts achieved responses in PROs and clinical measures when treated with tofacitinib than with placebo (PBO).1,2 Proportions of responders were also similar between tofacitinib and adalimumab (ADA) after 3, 6 and 12 months.2,3,5

Objectives: To determine the time to initial response using responder definitions for selected PROs and clinical endpoints in pts with active PsA treated with tofacitinib, ADA or PBO switching to tofacitinib.

Methods: In this post hoc analysis, data were collected from two Phase 3 studies (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]).4,5 Pts receiving tofacitinib 5 or 10 mg twice daily (BID), subcutaneous ADA 40 mg once every two weeks (Q2W, OPAL Beyond only), or PBO switching to tofacitinib 5 or 10 mg BID at Month (M)3, were included. Responder definitions included: HAQ-DI ≥0.35-point improvement from baseline (BL), Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F) total score ≥4-point improvement from BL, minimal disease activity (MDA) yes/no composite response (meeting at least 5 of 7 criteria) and PsA Disease Activity Score (PASDAS) post-BL score of ≤3.2 and >1.6-point improvement from BL. Proportions of responders were also similar between tofacitinib and adalimumab (ADA) after 3, 6 and 12 months.2,3,5

Results: KM analyses show days to initial response (Figure 1, Figure 2). Time to initial HAQ-DI response was significantly different between treatment groups in OPAL Broaden (p<0.01): faster response in pts receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID and ADA 40 mg Q2W vs pts who switched from PBO to tofacitinib at M3 (Figure 1A). A similar, but not significant (ns) trend was observed for HAQ-DI responses in OPAL Beyond (Figure 1B). Generally, initial FACT-F responses were achieved faster (ns) in pts receiving tofacitinib 5 mg BID vs other treatment in both studies (Figure 1c, Figure 1d). Times to initial MDA and PASDAS responses were similar between tofacitinib and ADA treatment groups (Figure 2).

AB0775

PERIPHERAL JOINT INFLAMMATION IS ASSOCIATED WITH MORE PROATHEROGENIC CARDIOVASCULAR RISK PROFILE IN PATIENTS WITH PSORIATIC ARTHRITIS

K. Bonek1, E. Kuca-Warnawin2, E. Kontry2, P. Gluszko1. 1National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Rheumatology,
Background: We have previously found that: (i) patients with spondyloarthritides (SpAs) have higher circulating levels of IL-18 and osteoprotegerin (OPG) than healthy controls (1), (ii) psoriatic arthritis (PsA) patients present with more proatherogenic lipid profile and higher IL-18 levels than ankylosing spondylitis (AS) patients (2).

Objectives: To investigate the relationship between disease phenotype, i.e. peripheral arthritis (perPsA), axSpA (axPsA) and AS patients (27% vs 0% vs 7.8%, respectively). perPsA patients had significantly higher diastolic blood pressure than AS patients (perPsA 131±13mmHg vs AS 121±14 mmHg), more severe cardiovascular burden than patients with axial disease (4.8 vs 6.8 years), and matched with higher disease activity (AS ASDAS-CRP 3.6±0.4; PsA DAPSA 26.7±26.6) were included in the study. The lipid profile comprised triglycerides (TG), total cholesterol (Chol), low- and high-density lipoprotein (LDL and HDL, respectively) measurement. Ischemic Heart Disease (IHD) diagnosis was established from patient’s medical history. Serum concentrations of IL-17AF, IL-18 were measured by specific commercially available enzyme-linked immunosorbent assays (ELISA) and were expressed as medians (pg/ml). The Mann-Whitney test was applied for intergroup comparison, correlation was assessed using Spearman’s Rank tests (r value is shown) with linear regression model.

Results: Patients with perPsA had higher rate of IHD than axPsA and AS patients (27% vs 0% vs 7.8%, respectively), perPsA patients had significantly higher diastolic blood pressure than AS patients (perPsA 131±13 mmHg vs AS 121±14 mmHg), more severe cardiovascular burden than patients with axial disease (4.8 vs 6.8 years), and matched with higher disease activity (AS ASDAS-CRP 3.6±0.4; PsA DAPSA 26.7±26.6) were included in the study. The lipid profile comprised triglycerides (TG), total cholesterol (Chol), low- and high-density lipoprotein (LDL and HDL, respectively) measurement. Ischemic Heart Disease (IHD) diagnosis was established from patient’s medical history. Serum concentrations of IL-17AF, IL-18 were measured by specific commercially available enzyme-linked immunosorbent assays (ELISA) and were expressed as medians (pg/ml). The Mann-Whitney test was applied for intergroup comparison, correlation was assessed using Spearman’s Rank tests (r value is shown) with linear regression model.

Conclusion: We conclude that in PsA peripheral joints inflammation is associated with more proatherogenic cardiovascular profile and higher IL-18 serum levels, that seem to be interrelated, while patient’s disease activity is associated with metabolic syndrome. Generally recommended SCORE scale is practically unable to indicate SpA patients with higher CV risk.

AB0777 EPIDEMIOLOGY, CLINICAL FEATURES AND BIOLOGICAL TREATMENT OF UVEITIS IN 320 PATIENTS WITH PSORIATIC ARTHRITIS. STUDY FROM A SINGLE UNIVERSITY CENTER.

I. González-Mazón1, L. Sanchez-Bilbao2, N. Palmou-Fontana3, D. Martinez-Lopez4, S. Armeto5, M. A. González-Gay6, R. Blanco6,1,2,7,8 U. Marques de Valdecilla, Santander, Spain

Background: Uveitis is an extra articular manifestation of psoriatic arthritis (PsA). Biological therapy, especially monoclonal TNF inhibitors, are useful to prevent and to treat refractory non-infectious uveitis. However, other biologics had been related to paradoxical uveitis.

Objectives: Our aim was to assess a) the epidemiological and clinical features of uveitis associated to PsA and b) its relationship with biological treatment used in PsA.

Methods: Observational study of unselected consecutive patients studied in a single reference University Hospital with: a) diagnosis of PsA by CASPAR criteria and b) diagnosis of uveitis by ophthalmologist exploration. Demographics features, clinical findings, complementary tests and treatment were recorded.

Results: We studied 320 (182 women/138 men) patients with PsA; mean age at PsA diagnosis of 41.7±15.79 years and with a delay of diagnosis from the onset of symptoms of 2.6±2.01 years. Ten patients (4 men/6 women) out of 320 patients (prevalence 3.13%) with a mean age of 42.2±16.8 years were diagnosed of uveitis after a mean follow-up of 10.7±9 years. In all cases, the uveitis had an anterior pattern. Only 1 (10%) of them had a bilateral affection, acute onset in 10 patients (100%), and 4 of them (40%) had a recurrence of uveitis. The diagnosis of uveitis was performed in the one of PsA in 5 (50%) patients in 16±8.7 years. In those with a previous diagnosis of PsA, it was done 13.3±10.4 years before the uveitis onset. Only 1 patient (10%) with recurrent unilateral uveitis presented viritis. In 10 patients the mean number of anterior chamber cells was 2±0.4. Comparison of baseline characteristics and clinical features between patients who developed uveitis and those who did not is shown in table.

Only 2 patients (20%) with uveitis received biological therapy. The first one developed its first episode of uveitis after 29 months with etanercept. After the episode, a switch to adalimumab was done, without any other episode of uveitis after 22 months of treatment. The second one was a patient with multiple episodes of recurrent uveitis, who developed new flares with adalimumab, certolizumab and golimumab.

Conclusion: Most of the uveitis had an anterior and unilateral pattern. The onset of uveitis in patients with PsA can either precede or go after the diagnosis of the PsA. HLA B27 + was more frequent in patients with uveitis. Biological therapy did not achieve good answer in patients with recurrent uveitis.

Background: Spondylarthritis are diseases with a pathophysiological focus in enthesis with a different extent of synovial component. In the event of therapeutic failure with DMARDs, the clinician may consider biological therapy with anti-TNF drugs or other targets such as IL-23. Despite this, most patients receive first-line anti-TNFs. Given that IL-19 and IL-23 activity is recognized at the level of the enthesis.

Objectives: To evaluate whether the presence of dactylitis/enthesitis could be useful in the choice of a particular biological therapy.

Methods: A secondary analysis of a previous study was performed based on an electronic survey completed by patients with PsA and distributed among members of the patient association ‘Acción Psoriasis’. Records from 191 respondents who had received at least one biological therapy were included. Patients were grouped according to the presence or absence of dactylitis or enthesitis. The rate of need to progress to the next therapeutic biologic line was compared.

Results: 61 patients reported dactylitis and 155 enthesitis. Distribution of treatments in patients with dactylitis (not including dactylitis): 115 received an anti-TNF-alpha, 25 received Secukinumab and 18 received Ustekinumab. Distribution of treatments in patients with enthesitis: 33 patients received an anti-TNF-alpha, 11 Secukinumab and 12 Ustekinumab. 15 patients in the group receiving an anti-TNF-alpha had to substitute another treatment within 2 years (45.4%), 3 patients in each of the remaining groups had to substitute treatment within 2 years (27.2% and 25%, respectively). Compared to those receiving anti-TNF-alpha therapy, patients treated with Secukinumab or Ustekinumab had greater therapeutic persistence at 2 years (P<0.001, in both cases). Distribution of treatments in patients with enthesitis and dactylitis was similar: 4 patients who received Secukinumab and 3 who received Ustekinumab had to substitute their treatments in less than 2 years (16% and 16.6%, respectively). Compared to patients receiving anti-TNF-alpha therapy, patients treated with Secukinumab and Ustekinumab had a higher proportion of therapeutic persistence at 2 years (P<0.05 for both cases).

Conclusion: The presence of dactylitis more than enthesitis, is associated with a higher proportion of therapeutic persistence in those patients treated with anti-IL17 or anti-IL23 therapies. Although there are multiple factors that condition the choice of biological therapies in patients with PsA, the presence of enthesitis and dactylitis (understood as polyenthesitis) should be considered among the most important ones.

AB0780 TREATMENT PERSISTENCE OF BIOLOGICS AMONG PATIENTS WITH PSORIATIC ARTHRITIS (PSA)

A. Haddad1, T. Gazit2, I. Feldhamer3, J. Feld4, A. Cohen5,6, D. Zisman1,4
1Carmel Medical Centre, Haifa, Israel; 2Clalit Health Services, Tel Aviv-Yafo, Israel; 3Soroka Medical Centre, BeerSheba, Israel; 4Technion - Israel Institute of Technology, Haifa, Israel

Background: Persistence in biologic therapy in psoriatic arthritis is critical to optimize symptom remission, functional capacity and health care costs.

Objectives: To estimate the persistence to biologic treatment prescribed to PsA patients in a real-life setting as well as factors associated with improved biologic drug survival in these patients.

Methods: Patients with PsA from a large health care provider database with at least two consecutive dispensed prescriptions of a biologic agent indicated for PsA from January 1st, 2002 until December 31st, 2016 were identified and followed until medication stop date or the end of observation period. Patients were considered non-persistent whenever a new prescription was dispensed and a permissible gap of 6 months was exceeded prior to starting on this biologic agent from the prescription date. Treatment changes were based on physician decisions and patient preferences. Demographic data including age, sex, BMI, ethnicity, smoking history and socio-economic status as well as Charlson comorbidity index were retrieved. Data regarding use of steroids and non-biologic disease-modifying anti-rheumatic drugs were also extracted. Descriptive statistics, including means (standard deviations) for continuous variables and frequencies (%) for categorical variables, were used. Persistence estimates were derived using non-parametric survival analysis using Kaplan-Meier functions, with treatment discontinuations as failure events. Cox regression hazard ratio models were conducted to investigate factors associated with drug persistence.

Results: 2301 PsA patients with 2958 treatment periods were identified and included in the analyses. The mean age was 50.3±14 years of whom 54% were females, 70.4% of the study population had a BMI>25, and 36% were obese(BMI>30), 40% were current smokers, and 76% had a Charlson comorbidity index higher than 1. The most commonly prescribed drug was etanercept, followed by adalimumab, golimumab, secukinumab, ustekinumab and infliximab at 33%, 29%, 12%, 10%,8% and 8%, respectively. Only about 20% of patients remained on a particular biologic agent after 5 years, whereas about 40% persisted on therapy following 20 months of treatment. A Kaplan-Mayer survival analysis with pairwise comparisons of all treatment choices with respect to lines of therapy was conducted. When analyzing the data for all treatment periods and taking into account all lines of therapy, secukinumab had a higher persistence than adalimumab, infliximab and ustekinumab, with a Log Rank of 0.022, 0.047 and 0.001, respectively, as is shown in figure 1. Female sex and smoking were associated with lower drug persistence (HR=1.25, 95%-CI 1.13-1.38 and HR=1.109, 95%-CI 1.01-1.21, respectively). When analyzing the data regarding second-line biologic agents, secukinumab was found to be superior to adalimumab, etanercept, infliximab and ustekinumab but not to golimumab with a Log-Rank P value of 0.001, 0.004, 0.025 and 0.002, respectively (figure 2). On analyzing the data using only the first indicated biologic line, no superiority of any single anti-Tumor Necrosis Factor-alpha (anti-TNF-α) agent was observed.

Conclusion: In this large observational cohort, in the era of biologic therapy, a relatively low persistence was observed, with female sex and smoking having a negative impact on persistence. None of the anti-TNF-α agents as first line therapy was found to be more persistent than others, while secukinumab was found to be superior to other biologics when indicated as second line of therapy.

AB0781 OPTIMIZATION OF APREMILAST USE IN DAILY PRACTICE BY EXPECTATION MANAGEMENT

P. Hanssdaar1, A. Blanken1, M. Heslinga1, A. Van Kuik1, M. Nurmohamed1
1Amsterdam UMC, Amsterdam, Netherlands

Figure 1.

Figure 2.
Background: Apremilast is an oral phosphodiesterase 4 inhibitor and approved drug for treatment of Psoriatic Arthritis (PsA). Previous studies show apremilast to be efficacious and safe. (1) However, physicians are sometimes reluctant to prescribe apremilast in clinical practice due to its perceived side effects, and relatively small effect size (1).

Objectives: In this study we investigated the occurrence and frequencies of adverse events, and the effects of patient expectation management on drug survival for PsA patient starting apremilast.

Methods: From March 2017 to December 2019, 21 consecutive patients have been included in the apremilast PsA cohort at Reade in Amsterdam, the Netherlands. The initial high dropout rate that was observed with usual care led to a revision in the baseline visit with more emphasis placed on patient expectation management.

Results: From the usual care group (UCG; n=12), 10 patients (83%) stopped apremilast within the first year: 6 (50%) due to adverse events, 4 (33%) due to ineffectivity. Only 2 patients (17%) completed one year of follow-up. In contrast, in the expectation management group (EMG; n=9), only 1 patient (11%) dropped out due to adverse events, and none stopped due to ineffectivity. 2 patients (22%) completed one year of follow-up, the other 6 patients (67%) were within the first year of treatment (median 5 months, range 1-10; figure 1). In total 55 adverse events were reported during the study, of which 40% were gastro-intestinal (table 1). There was one serious adverse event (within in the EMG group, stroke leading to hospitalization) which was considered not related to apremilast, and the patient remained on drug.

Conclusion: The most common adverse event for apremilast are gastrointestinal side effects that subsided during prolonged use. Managing patient expectations before start of apremilast increases drug survival and is helpful for optimizing apremilast use in daily practice.

AB0782

EXPLORING OCCURRENCE AND CORRELATES OF SLEEP DISTURBANCES AND FATIGUE IN PSORIATIC ARTHRITIS PATIENTS

G. Haugeberg1,2, A. Kavanagh3, M. Hoff1, B. Michelsen1, A. Kavanagh3, 1Sørlandet Hospital Kristiansand, Division of Rheumatology, Department of Medicine, Kristiansand, Norway; 2Norwegian University of Science and Technology, Department of Neuroscience, Division of Rheumatology, Tromsø, Norway; 3University of California San Diego, La Jolla, United States of America

Background: Psoriatic arthritis (PsA) patients have been reported to suffer from increased sleep disturbances (1) and fatigue (2). Sleep disturbances and fatigue in PsA may not only be influenced by skin and musculoskeletal manifestations, but also by psychosocial consequences of the disease and the patient's mental status (3).

Objectives: To explore the occurrence and correlates of sleep disturbances and fatigue in PsA clinic patients.

Methods: A broad data collection was completed from 137 PsA patients including demographics, disease activity measures for both skin and musculoskeletal involvement and patient reported outcome measures. Pain was reported on a VAS scale 0-100 mm and sleep and fatigue on a numeric rating scale (NRS) 0-10. Depression was scored as: 1: not at all, 2: moderately and 3: extremely depressed.

Sleep disturbances and fatigue were defined as present if the NRS score was ≥5. Descriptive statistics (mean (SD) for continuous variables and percentage for categorical variables) were applied. Associations were explored using univariate and adjusted linear regression analyses, with inclusion of variables in multivariate analysis that had a p value <0.2 in univariate analyses.

Results: Demographic patient characteristics: mean age 52.3 (SD 10.3) years, BMI 28.4 (4.3) kg/m2, women 50.4%, current smoker 17.5%, living together 76.6%, working 54.8%. Musculoskeletal disease status: PsA disease duration mean 8.8 (SD 6.8) years, CRP 5.0 (8.3) mg/L, 68 tender joint count (68TJC) 10.1 (11.1), 66 swollen joint count 0.6 (1.0), MASES enthesitis score 3.0 (3.2), Psoriasis skin status: PASI 2.6 (3.7) and itch score 23.1%. Patient reported outcome measures: pain 34.8 (23.3) mm, sleep disturbances 3.5 (2.9), fatigue 4.2 (2.6), MHAQ 0.44 (0.40) and depressive 1.4 (0.40). Mean numbers of composite MHAQ was 0.72 (0.53) and 45.3% exercised ≥1 time per week and 32.4% currently used bDMARDs and 58.4% csDMARDs.

The prevalence of sleep disturbances was 38.0% and that of fatigue 44.5%. Identified associations with impaired sleep disturbances in univariate analyses were female gender, higher BMI, smoking, not working, higher scores for 68TJC, MASES score, pain, fatigue, depression, lower MHAQ, not exercising and itching skin. For fatigue the identified associations were female gender, smoking, not working, higher scores for 68TJC, MASES score, pain, sleep disturbances, depression, lower MHAQ and itching skin. In adjusted analysis only pain, fatigue and higher MHAQ were independently associated with sleep disturbances and pain, sleep disturbances and depression were independently associated with fatigue.

Conclusion: The prevalence of sleep disturbances and fatigue was frequently reported in our PsA patients. No measures reflecting skin involvement or objective measures of inflammatory musculoskeletal involvement were independently associated with sleep disturbances and fatigue. Our data suggest that patient's perceptions of musculoskeletal involvement (pain or MHAQ) play an important role causing sleep disturbances and fatigue in PsA patients. However, mental status also seems to play an important role in the perception of fatigue.

AB0783

THE IMPACT OF SKIN ITCHING ON HEALTH RELATED QUALITY OF LIFE IN PSORIATIC ARTHRITIS OUTPATIENT CLINIC PATIENTS

G. Haugeberg1,2, A. Kavanagh3, B. Michelsen1, 1Sørlandet Hospital Kristiansand, Division of Rheumatology, Department of Medicine, Kristiansand, Norway; 2Norwegian University of Science and Technology, Tromsø, Norway; 3University of California San Diego, La Jolla, United States of America

Background: In psoriatic arthritis (PsA) both skin and musculoskeletal involvement can contribute to reduce health related quality of life (HRQoL) (1). Although itch is considered an important symptom in psoriasis, less is known about its impact in PsA patients. However, mental perception of musculoskeletal involvement (pain or MHAQ) play an important role causing sleep disturbances and fatigue in PsA patients. However, mental status also seems to play an important role in the perception of fatigue.
was dichotomized; ‘Not at all’ and ‘a little’ were scored as ‘not itching’, and ‘a lot’ and ‘very much’ were scored as ‘itching’. HRQoL was assessed using the 15D questionnaire and skin HRQoL using the Dermatology Life Quality Index (DLQI). Categorical variables are presented as numbers and (%) and continuous variables as mean with (SD). An association with 15D and DLQI was explored using univariate and multivariate linear regression analysis.

Results: Among 125 PsA patients (63 men and 63 women), mean age was 52.2 years, BMI 28.3 kg/m², disease duration 8.9 years; 15.2% were smokers. The number and percentage (%) of PsA patients reporting their skin to be itchy, sore, painful or stinging was as follows: Not at all 25 (20.0%), a little 71 (56.8%), a lot 23 (18.4%) and very much 6 patients (4.8%). The table shows data for all PsA patients and for patients defined to have no itching or having itching skin.

### Discussion

The prospective, multicenter, observational REWARD study assessed the impact of using the Psoriatic Arthritis Impact of Disease (PsAID) questionnaire (score range: 0-10), presence of domains of PsA (enthesitis, dactylitis, skin psoriasis, nail psoriasis, axial involvement), and ongoing or history of comorbidities of interest on PsA patients considered for apremilast treatment in The Netherlands. This interim analysis compared results in patients with limited joint involvement (swollen joint count [SJC] ≤4) vs. more extensive joint involvement (SJC >4).

**Comparative Impact and Burden of Disease of Psoriatic Arthritis Patients with Limited Joint Involvement vs. Those with More Extensive Joint Involvement: Interim Results from the REWARD Study, a Prospective Multicenter, Real-World Study in Patients Treated with Apremilast**

**Background:** Psoriatic arthritis (PsA) is associated with a high burden of disease and an increased risk of comorbidities. Recent data suggest that patients with moderate PsA benefit most from apremilast (APR) treatment. Results from an earlier analysis of the REWARD study suggest that patients with limited joint involvement may benefit from APR treatment, with improvements in the perceived impact of disease. Patients with limited joint involvement or comorbidities are underrepresented in randomised controlled trials; therefore, evidence from real-world patient cohorts is needed to assess and compare the impact and burden of disease on patients with limited vs. extensive joint involvement who may also have comorbidities.

**Objectives:** To compare the burden of disease and comorbidities in patients with PsA who have limited joint involvement with patients with PsA who have extensive joint involvement.

**Methods:** The prospective, multicenter, observational REWARD study assessed the impact of using the Psoriatic Arthritis Impact of Disease (PsAID) questionnaire (score range: 0-10), presence of domains of PsA (enthesitis, dactylitis, skin psoriasis, nail psoriasis, axial involvement), and ongoing or history of comorbidities of interest on PsA patients considered for apremilast treatment in The Netherlands. This interim analysis compared results in patients with limited joint involvement (swollen joint count [SJC] ≤4) vs. more extensive joint involvement (SJC >4).
Results: Currently, 77 patients have been included in the analysis (SJC ≤4: n=53; SJC >4: n=24) (Table 1). Mean baseline PaAID scores were 4.4 vs. 4.8 for the SJC ≤4 vs. SJC >4 groups (Figure 1). The proportions of patients who were not in the PaAID-defined Patient Acceptable Symptom State (PASS) were 58.7% for the SJC ≤4 group and 62.5% for the SJC >4 group. Mean pain visual analog scale (VAS) scores (0-100mm) were 45.9 vs. 53.4 for the SJC ≤4 group vs. the SJC >4 group. Mean scores for the individual PaAID domains for the SJC ≤4 vs. SJC >4 groups were generally comparable (Figure 2). Presence of specific manifestations of PsA for patients in the SJC ≤4 group vs. the SJC >4 group, respectively, were: moderate to severe psoriasis (psoriasis-involved body surface area [BSA] ≥3: 31.4% vs. 21.7%), nail psoriasis (45.3% vs. 41.7%), enthesitis (Leeds Entheses Index >0: 43.4% vs. 45.8%), dactylitis (18.9% vs. 33.3%), and axial involvement (3.8% vs. 8.3%). Comorbidities in 25% of either group (SJC ≤4 vs. SJC >4) included hypertension (30.2% vs. 37.5%), hypercholesterolemia (13.2% vs. 16.7%), uveitis (1.9% vs. 8.3%), malignancy (0.0% vs. 8.3%), heart failure (5.7% vs. 8.3%), and depression (5.7 vs. 4.2%).

Conclusion: In this real-world study, no strong associations between SJC and patient-reported impact of disease or pain were observed. Similar to patients with high disease activity (HDA [DAPSA >28]), moderate disease activity (MDA [DAPSA ≤28]), and low disease activity (LDA [DAPSA ≤14]), moderate disease activity (MDA [DAPSA ≤28]) and low disease activity (LDA [DAPSA ≤14]) were associated with lower PaAID PASS. Patients with limited joint involvement had an associated substantial burden of disease, with more than half not achieving PaAID PASS.

REAL LIFE EXPERIENCE OF METHOTREXATE BASED DUAL COMBINATION DMARDS IN PSORIATIC ARTHRITIS: RESULTS FROM KARNATAKA PSORIATIC ARTHRITIS COHORT (KPSAC)

U. Karjigi1, C. Kodishala1, S. Chandrashekara1, S. Kumar1, V. Haridasi1, S. R1, R. Jois1, M. Daware1, V. K. R. Rao1, B. G. Darmanand1, V. R. Jain1, Y. P. Singh1, S. Singhal1, P. Chebbi1, C. Dharmapalaih1, A. Kamathi1, S. Prasad1, S. C1, R. Athala1, B. Pinto1, B. Nazir1, H. Alur Shivakumar1, M. K M1, V. Shoobha1, KPsAC Study Group, Karnataka, India.

Background: Biologics have been the focus of recent treatment guidelines and ‘Treat to Target’ strategies for both psoriasis (PsO) & psoriatic Arthritis (PsA). However, in day-to-day practice, combination DMARDS anchored around methotrexate are mainstay in majority of patients.

Objectives: To describe the evolution of psoriasis severity during the first year of follow up in patients with early PsA and to evaluate the impact of psoriasis severity on HRQoL.

Methods: Real world data were used from the Dutch south west Psoriatic Arthritis cohort (DEPAR) study, consisting of newly diagnosed PsA patients included between July 2013 and February 2019. Psoriasis severity was assessed using the Psoriasis Area and Severity Index (PASI) and categorized in: no psoriasis (PASI 0), mild psoriasis (PASI 1-19), moderate psoriasis (PASI 20-49) and severe psoriasis (PASI≥50). Musculoskeletal disease severity was measured with the Disease Activity in Psoriatic Arthritis (DAPSA) score as contrast for psoriasis severity. DAPSA was categorized in: remission (REM[DAPSA<4]), low disease activity (LDA[DAPSA≤14]), moderate disease activity (MDA[DAPSA≥15] and high disease activity (HDA[DAPSA≥28]).

Results: In total, 435 patients were included. Mean (sd) age was 49.7 (13.4) years and 53% (n=229) was male. Psoriasis severity does not fluctuate much over the course of the first year and the majority of patients had mild psoriasis (Figure 1). HRQoL worsened with increasing psoriasis severity, when measured by the Skindex17. This reduction in HRQoL was not seen when measured with the SF-36 (Figure 2).

Conclusion: In early PsA patients, psoriasis severity is mostly mild, but considerably impacts HRQoL when measured using a skin specific questionnaire. For optimal management of PsA patients, we therefore recommend rheumatologists to additionally acquire information on the degree of psoriatic involvement. In our study, IL-17 inhibitors were initiated for either arthritis or rash have achieved MDA, however, 40% of cases which were introduced for both arthritis and rash have not achieved MDA.

Conclusion: In our study, IL-17 inhibitors could bring high rate of MDA achievement for both naïve and switch from TNFi. We suggest that TNFi should be switched into IL-17 inhibitors rapidly in the case of ineffective for TNFi.
Background: Psoriatic arthritis (PsA) affects both sexes equally, however there seem to be significant differences in disease expression between the genders.

Objectives: To investigate gender differences in disease manifestations, patient-reported outcomes and comorbidities among patients with PsA.

Methods: This cross-sectional study of patients with PsA followed at an academic rheumatology outpatient clinic between 1/8/2017 and 1/12/2019. We compared clinical characteristics, patient-reported outcomes, disease activity and comorbidities in male and female patients with PsA. All patients were over 18 years of age and fulfilled the CASPAR criteria for PsA. Differences between gender in values of continuous variables were assessed by T-tests or Mann-Whitney tests. The association between categorical variables and gender was assessed by Pearson chi-square test or Fisher’s exact test.

Results: 135 patients, 83 (62%) women and 52 (38%) men were included. Factors studied for gender differences are shown in Table 1. Women had significantly more tender (11 vs 3 p <0.001) and swollen (10 vs 3, p <0.013) joints, worse VAS (Visual Analog Scale 0-10) pain (6 vs 5, p =0.001) and worse DAPSA(Disease Activity in Psoriatic Arthritis) (33 vs 18 p <0.006) and presented with more enthesitis (32.5% vs 13.5%, p =0.013). In contrast, men achieved Minimal Disease Activity (MDA) more frequently (26.9% vs 3.6% p<0.001) and had significantly more comorbidities than women. Polyarthritic disease was more frequent in women (62% vs 31%), although at non-significant levels.

Conclusion: Male patients with PsA have more comorbidities, while female patients have greater disease activity, worse patient reported outcomes and comorbidities among patients with PsA. Women more frequently achieved MDA less frequently.

1Kamataka Rheumatology Association (KRA), Bengaluru, India

Background: Clinical patterns and disease burden of PsA varies in different parts of the world. Demographic studies from Indian subcontinent are sparse.

Objectives: To study the cutaneous, articualr profile of PsA and describe their disease activity, disability and co-morbidities (CMs)

Methods: This is a multicenter, cross-sectional, non-interventional study from Karnataka, India. All consecutive PsA patients defined by CASPAR or expert diagnosis were evaluated over 8 months from 17 Rheumatology centers across Karnataka using standard parameters such as PASI, DAPSA, Indian version of HAQ-DI, psoriatic co-morbidity index2 (Cidx) and MDA 5. Patient consent and EC obtained

Results: 549 PsA patients were evaluated and their disease characteristics are shown in Table 1 & 2. PsA preceded psoriasis in in 81 (14.7%).

<td>Mean Cidx: 0.98(1.6)</td>
</tr>
</tbody>
</table>
| Mild (PASI 0-5) | 460(80%) | 260(48.2%) | N with 1 or more CMs 232(42.2%)
| Severe (>10) | 57(10.6%) | Climbing a flight of stairs 18(35%) |
| PsA | 5.4(3.9) |
| Mean DAPSA: 16.1(6.6) | Mean TJC68 | 6.3(8.9) |
| Low DA | 100(19.9%) | Sitting | Anxiety 4.2%
| Moderate DA | 14(28.8%) | Squatting | Migraine 11%
| High DA | 12(25.5%) | Other | Psychosocial 2%

Type I & II psoriasis did not differ in PASI, DAPSA, HAQ-DI or having a family h/o psoriasis. Type II psoriasis had higher Cidx than type I (p<0.001). Pt pain, VAS, DAPSA, PhyGA, PASA & SJC significantly correlated with higher HAQ-DI (p<0.001). TJC, ESR, CRP & PASA had minor correlation with HAQ-DI. Females had higher HAQ-DI compared to males (p=0.002). Knee joint involvement caused disability most frequently. Cidx was higher in males (p=0.008). Minor correlation was found between Cidx with age, HAQ-DI & DAPSA. Mean BMI of our cohort was 28.8(14.8) kg/m2, 56.5% were overweight. Higher BMI was not associated with age, duration of arthritis, DAPSA, PASA, HAQ-DI & Cidx. Infections (any time) were recorded in 10.8%, of which skin was the commonest site in 39.8%, 50.5% of these needed hospitalizations.

Conclusion: Despite mild skin disease in majority, more than half of the patients have moderate to severe joint activity. Mild to moderate functional disability in nearly half of our cohort indicate high burden of disability. High incidence of co-morbidities in PsA compared with general population is in line with published literature. In addition to aggressive control of articular activity, detection and control of co-morbidties must be an integral part of PsA management.

NETAKIMAB REDUCES SKIN MANIFESTATIONS OF PSORIATIC ARTHRITIS: RESULTS OF SUBANALYSIS FROM A DOUBLE-BLIND RANDOMIZED PHASE 3 STUDY (PATERA)

T. Korotaeva1, I. Gayduková2, V. Mazurov2, A. Samtsov2, V. Khayrutdinov3, A. Bakulev4, M. Kokhan5, A. Kandzre6, N. Soroka7, E. Dokukina8, A. Eremeeva9, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; ¹Menchink North-Western State Medical University, St-Petersburg, Russian Federation; ²Kiev Military Medical Academy, St-Petersburg, Russian Federation; ³Razumovsky Saratov State Medical University, Saratov, Russian Federation; ²Nail Research Institute of Dermatovenereology and Immunopathology, Ekaterinburg, Russian Federation; ⁴Healthcare Institution Municipal Clinical Hospital No. 1, Minsk, Belarus; ⁵Scientific and Practical Center of Surgery, Transplantology and Hematology, Minsk, Belarus; ⁶JSC BIOCAD, St-Petersburg, Russian Federation

Background: Patients with psoriatic arthritis (PsA) have skin manifestations that negatively affect their quality of life. Netakimab (NTK) is a humanized anti-interleukin 17A antibody approved for the treatment of moderate-to-severe plaque psoriasis.

Objectives: To evaluate the efficacy of NTK on PsA skin manifestations. This abstract presents 24-week data from the ongoing phase 3 PATERA study (NCT03598751).

Methods: PATERA is an international, multicenter, double-blind, placebo (PBO)-controlled study. 194 eligible adult patients with psoriatic arthritis (CASPAR, 2006), with inadequate response to csDMARD or one TNFi, were randomly assigned (1:1) to receive NTK 120 mg or placebo (PBO) subcutaneously at Week (Wk) 0, 1, 2, 4, 6, 8, 10, 14, 18, 22, 84 patients from PBO arm, failed to achieve ACR20 (20% improvement in American College of Rheumatology criteria) at Wk 16, were switched to NTK. Endpoints for assessment of skin involvement included PASI the proportion of patients achieving 75%, 90%, and 100% improvement in Psoriasis Area and Severity Index score (PASI75, PASI90 and PASI100, respectively).

Results: 184 patients (NTK arm, N=94; PBO arm, N=90) had PASI>0 at baseline (BL). Demographics and BL characteristics were balanced between treatment arms (Table 1). Treatment response was assessed in patients with ≥3% body surface area involvement (BSA) at BL. PASI75/90/100 response rates for NTK arm were significantly greater than for PBO and increased throughout the whole analyzed period. At Wk 24 PASI75 was achieved by 82.89% vs 11.11% for NTK and PBO, respectively (p<0.0001). A significantly higher percentage of patients achieved complete skin clearance (PASI100) in NTK arm compared to PBO (48.68% vs 6.94%, p<0.0001). PASI90 response rate was also higher for NTK (Figure 1). Relative change (%) from baseline in PASI score correlated with PASI75/90/100 response rates throughout the entire analyzed period. PASI decreased by 87.5% in NTK arm vs only 4.4% in PBO arm after 24 wks of treatment (Table 2).

CHANGES IN PSAID-12 SCORES BEFORE AND AFTER BIOLOGICAL TREATMENT IN PATIENTS WITH PSORIATIC ARTHRITIS

A. Sahin Eskara1, G. Er1, I. Oguz Topa1, Y. Aricn Zahirouglu1, G. Kuru1,
1University of Health Sciences, Okmeydanc Training and Research Hospital, Physical Medicine and Rehabilitation, Istanbul, Turkey; 2University of Health Sciences, Okmeydanc Training and Research Hospital, Dermatology, Istanbul, Turkey; 3University of Health Sciences, Samsun Training and Research Hospital, Rheumatology, Samsun, Turkey; 4University of Health Sciences, Okmeydanc Training and Research Hospital, Physical Medicine and Rehabilitation, Division of Rheumatology, Istanbul, Turkey

Background: Psoriatic Arthritis Impact of Disease 12-item questionnaire (PsAID-12) is a patient-reported outcome measure (PROM) which allows a more precise assessment of the impact of PsA and helps treatment decisions geared to either disease activity or, for example, physpsychological distress (1,2).

Objectives: Our objective is to evaluate change of PsAID-12 values after three-months biologic drug treatment and to find out its relationship with other quality of life indices and disease activity parameters in PsA patients

Methods: Patients with a diagnosis of PsA according to CASPAR criteria were recruited to the study. The data of the patients before and after three-month treatment were evaluated retrospectively. The number of swollen (0-66) and tender joints (TJ) (0-68), ESR, CRP, PsAID-12, PhGA, BASDAI, MASES, DAPSA and BASFI were evaluated retrospectively. The number of swollen and tender joints, HAQ,EuroQol, PASI, BSA and DLIQ scores, 3 patients achieved MDA and 7 patients achieved PsARC criteria. There were statistically significant correlations between pre-treatment mean scores of PsAID-12 and BASDAI, BASFI, DAPSA, HAQ, EuroQol, PhGA. There were statistically significant correlations between after-treatment mean scores of PsAID-12 and BASDAI, DAPSA, PASI and BSA. The correlations between PsAID-12 change (ΔPSAID-12) with other outcome measures were as follows: ΔHAQ (r=0.27, p=0.39), ΔBASDAI (r=0.37, p=0.22), ΔPhGA (r=0.28, p=0.36), ΔDLQI (r=0.71, p=0.17), ΔBASFI (r=0.41, p=0.18), ΔESR (r=0.20, p=0.55), and ΔCRP (r=0.39, p=0.20), ΔDAPSA (r=0.77, p=0.009), Δnumber of TJ (r=0.81, p=0.004), ΔMASES (r=0.57, p=0.08), ΔEuroQol (r=0.29, p=0.34), ΔPASI (r=0.30, p=0.62). It is also observed that PsAID-12 scores decreased more in PsARC responders rather than non-responders, but this difference was not statistically significant. No cases of major adverse event were reported.

Conclusion: PsAID-12 evaluates effect of both physical and psychosocial aspects of PsA and shows close relationship with other PROMs but it may be inadequate in assessing biological treatment response in PsA.
performance of patient reported outcome measures (PROMs) for physical function (PF) in RCTs has not been evaluated systematically.

Objectives: In this systematic review, the GRAPP-OMERACT working group aimed to characterize clinical trial discrimination of PF-PROMs in PsA RCTs.

Methods: We searched PubMed and Scopus databases in English to identify all original RCTs conducted in PsA. We limited the review to RCTs of biologic and targeted synthetic DMARDs. Groups of two researchers extracted data independently for PF-PROMs. We assessed quality in each article using the OMERACT good method checklist. Effect sizes (ES) for the PF-PROMs were calculated and appraised using a priori hypotheses. Evidence supporting clinical trial discrimination for each PF-PROM was summarized to derive recommendations.

Results: 32 articles were included (Figure 1). Four PF-PROMs had data for evaluation: HAQ-Disability Index (DI), HAQ-Spondyloarthitis (S), Short Form 36-item Health Survey Physical Component Summary (SF-36 PCS), and the Physical Functioning domain (SF-36 PF). Table 1. The ES for intervention versus (vs.) control arms for HAQ-DI ranged from -0.55 to -1.81 vs. 0.24 to -0.52; and for SF-36 PCS ranged from 0.30 to 1.86 vs. -0.02 to 0.63.

Color code in each box indicate study quality by OMERACT good methods. GREEN: “likely low risk of bias”; AMBER: “some cautions but can be used as evidence”; RED: “don’t use at all”. WHITE (empty boxes): absence of information from that study. (+): findings had adequate performance of the instrument; (+/-): equivocal performance; (-): poor performance (less than adequate).

Conclusion: Clinical trial discrimination was supported for HAQ-DI and SF-36 PCS in PsA with low risk of bias; and for SF-36 PF with some caution. More studies are required for HAQ-S.

Background: Psoriatic arthritis (PsA) is a chronic autoimmune disease characterized by skin and joint inflammation with lymphocyes disturbance. However, the statuses of immune cell subsets are unclear. In addition, although, during the past 20 years, the treatment of the PsA has progressed rapidly, it still remains an unmet need.

Objectives: To compare the lymphocyte subsets in peripheral blood of PsA patients and healthy controls and evaluate effects of immunoregulatory combination therapies, such as low-dose interleukin-2, rapamycin, metformin, and retinoic acid, on the proliferation and functional recovery of lymphocyte subsets in PsA patients.

Methods: From September 2014 to December 2019, 218 PsA patients (107 male and 111 female) and 206 healthy controls (78 male and 128 female) were enrolled, including 112 patients (50 male and 62 female) who received immunoregulatory combination treatments (low-dose interleukin-2, rapamycin, metformin, retinoic acid, and cyclozyne Q10, etc). The absolute numbers and ratio of T, B, NK, CD4+T, CD8+T, Th1, Th2, Th17 and Tregs in peripheral blood were measured by flow cytometry with absolute counting beads. The data were subject to normal distribution, which was expressed as the mean ± standard deviation. Independent-samples T test and paired-samples T test were applied. P value <0.05 were considered statistically significant.

Results: The absolute numbers of B, CD4+T and Th17 in PsA patients were significantly higher than those of healthy controls (P<0.01), while the absolute numbers of NK and the percentage of CD8+T and Tregs were decreased significantly (P<0.01). The ratio of Th17/Tregs was significantly increase (P<0.001) (Figure 1). After receiving our new immunoregulatory combination therapies, the percentage of B, Th2 and Th17 were lower than before (P<0.05) and the absolute numbers of T, CD8+T, NK, Th1 and Tregs in PsA patients were increased (P<0.05). Further, the ratios of Treg/Tregs had a tendency to decrease (rebalance of them): Th2/Tregs (P<0.01) and Th17/Tregs (P<0.05) (Figure 2).

Conclusion: The abnormal levels of peripheral lymphocyte subpopulations resulted in an imbalance of Tefs/Tregs, which might play an important role in PsA pathogenesis. Our new immunoregulatory combination therapies could promote the proliferation of Tregs and may help for PsA patients’ symptom remission.

ABNORMAL LEVELS OF PERIPHERAL LYMPHOCYTES SUBSETS IN PATIENTS WITH PSORIATIC ARTHRITIS AND RESTORATION AFTER RECEIVING OUR NEW IMMUNOREGULATORY COMBINATION THERAPIES: A CROSS-SECTIONAL STUDY

S. J. Guo1, S. X. Zhang2, X. Y. Zhang2, Q. Y. Su1, J. Bai1, J. Y. Yang1, J. Luo2, G. Y. Liu2, C. Gao3, X. Li4, 1Shanxi Medical University, Taiyuan, China; 2The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China; 3Brigham and Women’s Hospital, Harvard Medical School, Pathology, Boston, United States of America
The mean thickness of skin, nail plate and nail matrix region were 2.25±0.32 mm, 0.38±0.07 mm and 1.89±0.33 mm, respectively. We found a positive correlation between nail plate thickness and both skin and nail matrix region thicknesses (r=0.561, p=0.001 and r=0.523, p=0.002).

Skin, nail and nail matrix thickness were significantly higher in men and in smokers. Manual workers did not have greater skin, nail plate nor nail matrix thickness.

There were no correlations between disease activity evaluated by the ASDAS-CRP, DAS28, PASI, ESR or by CRP and any of the US parameters.

In contrast, there was a significant negative correlation between psoriatic disease duration and nail plate thickness (r=−0.372, p=0.036).

Conclusion: Ultrasound offers an appropriate alternative for the evaluation of the nail unit. In our study it was able to detect subclinical involvement of the nail in 30 fingernails and in two patients.

ULTRASONOGRAPHIC ASSESSMENT OF ENTHEAL INVOLVEMENT IN PSORIATIC ARTHRITIS

I. Mahmoud1, S. Rahmouni1, A. Ben Tekaya1, S. Bouden1, R. Tekaya1, O. Saidane1, L. Abdelmoula1, 1Charles Nicolle Hospital, Rheumatology, Tunisia, Tunisia

Background: Enthesial involvement is a frequent and distinctive feature of psoriatic arthritis (PsA), often under diagnosed. It is especially associated with nail involvement. Because clinical examination is not sensitive enough for the detection of early signs of this involvement, US may be considered as an alternative imaging technique in the diagnosis of enthesopathy.

Objectives: The aim of the present study is to evaluate US entheses abnormalities in PsA and their correlation with clinical characteristics

Methods: The study included patients diagnosed with PsA according to the CASPAR criteria. They underwent a thorough clinical examination with special regard to the presence of enthesis using the Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index.

The US study bilaterally explored entheses at six sites: proximal plantar fascia, distal Achilles tendon, distal and proximal patellar tendon insertion, distal quadriceps tendon and distal brachial triceps tendon. We evaluated the following elementary lesions of enthesis at each site: thickness and structure of the tendon, calcifications, bursae, erosions, power Doppler signal in bursa or enthesis full tendon.

Results: Of the 33 patients, 39.4 % were male. The mean age was 51.2±12.5 years. The mean disease duration was 13.5±10.2 years. The mean DAPSA was 22.8±19.7 (0.1-84.5): remission(n=9), low activity (n=5), moderate activity (n=11), high activity(n=8).

At inclusion, 11 patients (33.4%) presented with psoriatic onychopathy (45 fingernails) with a mean mNAPSI of 14.1±16. Out of the 528 entheseal sites, 92 were tender at the palpation (17.4%) with a mean SPARCC at 2.87.

A total of 396 entheseal sites were examined by US. In 140 of them (35.35%), US found at least 1 sign indicative of enthesopathy. The most affected tendon was the distal Achilles tendon (42/396), followed by proximal plantar fascia (32/396), distal patellar tendon (20/396), quadriceps tendon (20/396), distal brachial triceps tendon (14/396) and finally proximal patellar tendon (12/396).

The most common elemental lesions were enthesophytes (176), erosions (114) and calcifications (50).

We found a positive correlation between age and both calcification (r=0.38±0.07, p=0.021) and enthesophytes (r=0.479, p=0.005).

We found a positive correlation between enthesophyte and the tender and swollen joints count (r=0.352, p=0.045, r=0.378, p=0.03) and the SPARCC score (r=0.397, p=0.022).

Patients with higher BASDAI had thicker tendons (r=−0.355, p=0.05).

Patients with nail dystrophy had more bursitis and erosions.

US scores did not correlate with sex, disease duration and disease activity measures (ASDAS, DAPSA, DAS28 and PASI).

Conclusion: Ultrasound enthesis examination are not rare in psoriatic arthritis, in particular in patients with active disease.
Clinical nail involvement was associated with bursitis and erosions. New studies including larger study groups are required to verify the findings of the present study.

**EFFECT OF ANTI-RHEUMATIC THERAPY ADMINISTERED IN ACCORDANCE WITH “TREAT TO TARGET” PRINCIPLES ON DIASTOLIC DYSFUNCTION OF THE LEFT VENTRICLES IN PATIENTS WITH ACTIVE EARLY PSORIATIC ARTHRITIS**

E. Markelova1, behalf of D. Novikova 1, Y. Korsakova 1, I. Kirillova 1, T. Kortovaeva 1, E. Loginova 1, A. Volkov 1. 1VA. Nasonova Research Institute of Rheumatology, Moscow, Laboratory of Systemic Rheumatic Diseases, Moscow, Russian Federation

**Background:** Psoriatic arthritis (PsA) is chronic inflammatory diseases, with massive increase of cardiovascular events (CVE) and cardiovascular death. Diastolic dysfunction of the left ventricles (LVDD) is a risk factor for the development of the heart failure.

**Objectives:** to study the effect of antirheumatic therapy administered in accordance with “treat to target” principles on LVDD in early PsA (EPsA) patients (pts).

**Methods:** 48 (F:23) DMARD-naive PsA pts, according to the CASPAR criteria, age 36(27; 45) years (yrs.), PsA duration – 6(4; 8) months. All pts were assessed for transthoracic echocardiography. Diastolic function was determined by early and atrial peak filling rates derived from differential volume-time-curve analysis. Methotrexate therapy was started in all pts with an escalation of the dose up to 25 mg/week subcutaneously. In case of no remission 3 months later, MT was added with biologic therapy: Adalimumab, Certolizumab pegol, Ustekinumab. Antihypertensive therapy received all pts.

**Results:** At baseline LVDD was identified in 5(10.4%). The LVDD pts were older, in more cases they had AH, abdominal obesity (p<0.05). Significant negative correlations were found between LVDD and body mass index (BMI) (r=-0.41), age (r=-0.71), total cholesterol (r=-0.44), triglycerides (r=-0.48), low density lipoproteins (r=-0.44), systolic (r=0.59) and diastolic blood pressure (r=-0.4), for all p<0.01. By 18 months of therapy significantly decreased DAS from 4.06(3.48; 4.91) to 0.97(0.65;1.48); C-RP from 19.4 [8.8;37 .5] to 2.2 [0.9; 4.6]mg/l, for all p<0.001. DAS remission was achieved in 69% of pts. We didn’t find significant changes between baseline and after treatment the frequency of LVDD – p<0.001. DAS remission was achieved in 69% of pts. We didn’t find significant changes between baseline and after treatment the frequency of LVDD – p<0.001.

**Conclusion:** in pts with EPSA frequently (10.4%) were detected LVDD, which are associated with Ah, age, higher BMI. Low prevalence LVDD in patients with EPSA is possibly caused by short duration of disease and early start of antirheumatic therapy. This has implications for development of preventive strategies for heart failure in EPSA patients.

**REAL-WORLD EXPERIENCE OF SECUKINUMAB FOR PSORIATIC ARTHRITIS WITH AXIAL INVOLVEMENT.**

M. Martin Lopez1, B. Joven-Ibáñez1, J. L. Pablos1. 1Hospital Universitario 12 de Octubre, Madrid, Spain

**Background:** Evidence on the efficacy of biologics in the treatment of psoriatic arthritis (PsA) patients with axial manifestations affecting 30-70% of PsA patients is limited. Secukinumab (SEC) has provided significant and sustained improvement in the signs and symptoms of active PsA and anklyosing spondylitis.

**Objectives:** This study aims to analyze the experience of using SEC for PsA patients with axial involvement in real-world setting.

**Methods:** Multicentric observational, longitudinal, retrospective study conducted in a tertiary hospital between January 2016 and December 2019. Patients with PsA (CASPAR criteria) and clinical and/or image diagnosis of axial involvement receiving at least one dose of SEC were included. Patients with non-pathological sacroiliacs x-ray and MRI had to have spinal pain VAS ≥4/10 after failure to NSAIDs, prior to the onset of SEC, to be included. Medical records were reviewed to collect demographic and clinical data, features of PsA (manifestations, treatments and activity assessment). Descriptive statistics and then a comparative analysis with the Student t-test to study the effect of SEC were performed.

**Results:** Of 98 PsA patients treated with SEC, 58 (59.2%) had axial involvement, of which 41 (71%) female. Mean age was 54 y.o (SD 10) and average duration of the disease was 10 years (SD 8). All 58 patients had peripheral disease (33% joint erosions), 55 (95%) had psoriasis, 20 (34%) showed dactylitis and 39 (67%) had enthesis. Sacroiliacs x-ray was damaged in 38 (66%) patients (grade I-IV) and 25 (40%) pathological MRI, with HLAB27+ at 8 (14%) patients. Average BMI was 29 (SD 8), with an obesity rate of 33% (19 pt). Observed comorbidities were hypertension (27 pt, 47%), diabetes mellitus (6 pt, 10%), dyslipidemia (23 pt, 40%), active smoking (18 pt, 31%) and malignancy (6 pt, 10%). Regarding previous treatments, 90% had received DMARDs, particularly methotrexate (86%) and 40% (69%) had been exposed to at least one DMARD (15 pt to one, 9 to two, 6 to three and 10 to four or more). 7 patients were on 300mg dose and 51 patients on 150mg dose (dose escalation to 300mg was performed in 16 patients and 44% respond and maintain SEC). Average drug survival time was 1.4 (SD 1) years. At 6 months of SEC therapy, tender and swollen joint count, spinal pain VAS, CRP, ASDAS-CRP and DAPSA had significantly decreased (Table 1). 29 (50%) patients suspended SEC during follow-up due to primary ineffectiveness (8), secondary ineffectiveness (16), adverse events (3), latex allergy (1) and remission (1). Adverse events do not differ from those reported in clinical trials.

**Conclusion:** Secukinumab in real-world setting provided improvements in the axial and peripheral manifestations of PsA, using both the 150mg and 300mg doses.

**CLINICAL ASSOCIATION BETWEEN URIC ACID/25-HYDROXYVITAMIN D SERUM LEVELS RATIO IN PATIENTS WITH PSORIATIC ARTHRITIS**

F. Masini1, K. Gjeloshi2, E. Pinotti2, F. Danzo2, F. Guarino2, M. Tardugno 2, R. Ferrara 3, G. Cuomo1. 1University of Campania “Luigi Vanvitelli”, Medical and Surgical Sciences, Napoli, Italy; 2University of Campania “Luigi Vanvitelli”, Medical and Surgical Sciences, Napoli, Italy; 3University of Campania “Luigi Vanvitelli”, Internal Medicine, Napoli, Italy; 4University of Campania “Luigi Vanvitelli”; Precision Medicine, Napoli, Italy

**Background:** The association between hyperuricemia and psoriatic arthritis (PsA) is actually generally accepted. Previous studies have demonstrated that uric acid suppress 25(OH)D metabolism [1]. More evidence is required to demonstrate the immune modulatory effects in psoriasis, psoriatic arthritis and other autoimmune diseases. In particular, the potential association between 25-hydroxyvitamin D serum levels and PsA still remains unknown.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.6564
Objectives: To assess a clinical association between uric acid/25(OH)D serum levels ratio related to PASI, BASDAI and DAPSA, if any, in patients with psoriatic arthritis.

Methods: We retrospectively observed 61 patients with psoriatic arthritis referred to our outpatients clinic, independently from already being on therapy or naïve. All selected patients underwent only conventional non-biological therapy at baseline and none received vitamin D supplementation and either allopurinol or febuxostat previously. Blood samples were drawn from all participants for assessment of 25-hydroxyvitamin D and uric acid serum levels. Disease activity of psoriasis and psoriatic arthritis were assessed by the Psoriasis Area and Severity Index (PASI), the Disease Activity Index for Psoriatic Arthritis (DAPSA) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). We assessed the covariates of interest by the Wilcoxon non parametric test, through the SPSS 24 Software.

Results: We observed 61 patients, mainly females (83.6%). At the univariate analysis, the uric acid/25(OH)D serum levels ratio revealed significantly associated with DAPSA and BASDAI indexes (p<0.001 and p<0.001, respectively), whilst no significant association emerged with the PASI index (p=0.462).

Conclusion: Data in the literature about these associations in the context of psoriatic arthritis are really poor. As a consequence, our findings, though preliminary, suggest us to hypothesize a potential role of uric acid/25(OH)D serum levels ratio as potential inflammation marker in order to better assess the disease activity. However, future larger studies are needed to investigate more in depth this association.

Background: Guselkumab (GUS), a novel monoclonal antibody that specifically binds to the p19-subunit of IL-23, demonstrated efficacy in the Ph 3 DISCVR-1 (D1) & DISCVR-2 (D2) trials of pts with active psoriatic arthritis (PsA).\(^1\)\(^,\)\(^2\) Dactylitis & enthesitis, key PsA clinical manifestations, can be difficult to treat and may portend more significant disease burden.\(^3\)\(^,\)\(^4\)

Objectives: In pts with dactylitis or enthesitis at baseline, assess: 1) changes in symptoms over time and 2) relationships between improvements in dactylitis or enthesitis and other PsA domains.

Methods: Adults with active PsA despite standard therapies were eligible for D1 & D2. Approx. 30% of D1 pts previously received 1-2 TNF inhibitors; D2 pts were biologic-naïve. Pts were randomized 1:1 to GUS 100mg Q4W; GUS 100mg at W0, W4, Q8W; or PBO. Independent assessors evaluated dactylitis (total score: 0-60) & enthesitis (Leeds Enthesitis Index [LEI]; total score 0-6). Dactylitis and enthesitis findings through W24 were prespecified to be pooled across D1 & D2. P-values are unadjusted. We assessed changes in dactylitis and LEI scores over time (ANCOVA); associations between dactylitis or enthesitis resolution and ACR/PASI responses at W24 (Chi-square); and correlations between dactylitis or LEI and HAQ-DI/SF-36 change scores at W24 (Spearman’s correlation). AEs through W24 were reported.\(^1\)\(^,\)\(^2\)

Results: At W0, 42% of pooled D1+D2 pts had dactylitis; 65% had enthesitis. GUS improved dactylitis and LEI scores vs PBO at W8, W16, W24. GUS vs PBO differences were significant for dactylitis changes at W16 & W24 and LEI changes at W8 (Q4W only), W16 & W24; no dose response was observed (Fig). Rates of dactylitis or enthesitis resolution by W24 were consistently significantly (p<0.001) associated with ACR20/50/70 and PASI75/90 response (Table). In GUS-treated pts at W24, significant correlations were observed between dactylitis change scores and PASI (p=0.006 Q8W) and SF-36 MCS (p=0.038 Q4W; p=0.003 Q8W) changes, and between LEI and HAQ-DI change scores (p<0.001 Q4W; p=0.005 Q8W). No consistent correlations/associations were observed between dactylitis or LEI scores and other clinical outcomes.

Conclusion: In PsA pts with dactylitis or enthesitis at W0, GUS improved dactylitis- and LEI scores vs PBO by W8; treatment differences were significant at W16 & W24. Resolution of dactylitis or enthesitis was significantly associated with clinically meaningful improvements in PsA joint & skin symptoms. Improved dactylitis scores correlated with improved skin symptoms and mental health; improved LEI scores correlated with improved physical function.

SAFETY PROFILES OF IXEKIZUMAB VERSUS ADALIMUMAB: 52-WEEK RESULTS FROM A HEAD-TO-HEAD COMPARISON IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

P. J. Mease1, J. S. Smolen2, A. Kavanaugh3, P. Nash4, G. Gallo5, S. Liu Leage5, C. Sapio6, M. C. Genovese6, Seattle Rheumatology Associates, PLLC, L.C., Seattle, United States of America; 2Medical University of Vienna, Wien, Austria; 3UC San Diego Health System, San Diego, United States of America; 4School of Medicine Griffith University, Brisbane, Australia; 5Eli Lilly and Company Corporate Center, Indianapolis, United States of America; 6Stanford University Medical Center, Palo Alto, United States of America.

Background: Ilekizumab (IXE) was shown to be superior to adalimumab (ADA) in achievement of simultaneous improvement of joint and skin disease (ACR50 and PASI100) in patients with active psoriatic arthritis (PsA) and inadequate response to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs). 1

Objectives: To compare the safety and tolerability profile of IXE vs ADA in patients with PsA up to 52 weeks of treatment.

Methods: SPIRIT-H2J (NCT03151551) was an open-label, head-to-head, blinded assessor clinical trial which included patients with active PsA (≥3 tender joint count ≥3 swollen joint count) and plaque psoriasis (BSA ≥3%) who were inadequate responders to csDMARD therapy but naïve to biologic DMARDs. Patients were randomized (1:1) to approved dosing of IXE or ADA. Safety events were assessed at each patient visit up to Week 52. Frequencies of adverse events (AEs) were based on the number of patients in the safety population (patients who received ≥1 dose of study drug). Cases of inflammatory bowel disease (IBD) and cerebro-cardiovascular events were adjudicated by external committees. Kaplan-Meier analysis of time to onset of serious adverse events (SAEs) was performed.

Results: Of the 283 patients randomized to each treatment, 87% (246/283) of patients who received IXE and 84% (237/283) of patients who received ADA completed 52 weeks of treatment. The frequency of treatment-emergent AEs (TEAEs) was similar between the groups (74% IXE vs 89% ADA), however fewer severe TEAEs were reported in the IXE group (3.2% IXE vs 7.1% ADA) (Table). SAEs were significantly more frequent in the ADA group compared to the IXE group (12% vs 4.2%; p<0.001), and the time to develop a patient’s first SAE was significantly shorter for ADA versus IXE (p<0.001; Figure). Discontinuations due to AEs were numerically more frequent in the ADA group versus the IXE group (74% vs 4.2%; p=0.15). IXE-treated patients reported more injection-site reactions (ISR) than ADA-treated patients (11% vs 3.5%; p=0.002). Study withdrawals due to ISR were comparable, and only one injection-site reaction was severe on ADA (Table). There were two IBD cases reported for IXE; one case was confirmed as IBD.

Conclusion: Safety results were consistent with previous trials with IXE and ADA. Compared with IXE, patients with PsA treated with ADA had significantly more serious AEs.

EFFICACY OF TILDRAKIZUMAB IN PSA: DAS28-CRP SCORES THROUGH WEEK 52

S. Chohan1, A. Kavanaugh2, V. Strand3, R. C. Chou4, A. M. Mendelsohn5, S. Rozzo6, P. J. Mease6, 1Arizona Arthritis & Rheumatology Research, PLLC, Phoenix, United States of America; 2Division of Rheumatology, Allergy and Immunology, University of California, San Diego School of Medicine, San Diego, United States of America; 3Division of Immunology/Rheumatology, Stanford University School of Medicine, Palo Alto, United States of America; 4Division of Allergy, Immunology and Rheumatology, University at Buffalo School of Medicine and Biomedical Sciences, Buffalo, United States of America; 5Sun Pharmaceutical Industries, Inc, Princeton, United States of America; 6Swedish Medical Center/Provence St. Joseph Health and University, Washington, Seattle, United States of America.

Background: Tildrakizumab (TIL), an anti-interleukin (IL)-23p19 monoclonal antibody, is approved in the US, EU, and Australia for treatment of moderate-to-severe plaque psoriasis. 1 A randomised, double-blind, placebo-controlled, multiple-dose, phase 2b study (NCT02880692) evaluating efficacy and safety of TIL for treatment of psoriatic arthritis (PsA) was recently completed.

Objectives: To evaluate the effect of TIL in PsA, using the DAS28-CRP responses up to week (W)52.

Methods: Patients (pts) ≥18 years old with PsA and ≥3 tender and ≥3 swollen joints were randomised 1:1:1:1:1 to receive TIL (200mg once every 4 weeks [Q4W], 200mg every 12 weeks [Q12W], 100mg Q12W, or 20mg Q12W) or placebo (PBO Q4W) to W24. Thereafter, PBO Q4W and TIL 20mg Q12W arms crossed over to TIL 200mg Q12W to W52. DAS28-CRP was shown to be reliable in PsA studies, 3 and pts achieving scores <3.2 satisfied responder criteria.

Figure: Time to onset of first SAE. Numbers below x-axis represent patients at risk at each time point. Open circles represent events, p<0.001 by log rank test. ADA-atalizumab; IxE-ixekizumab; SAE-serious adverse event.

AB0802

AB0803
Adverse events (AEs), including treatment-emergent AEs (TEAEs) and serious AEs (SAEs), were monitored throughout the study.

**Results:** Overall, 391/500 pts screened met the inclusion criteria; 55% were female with a mean age of 48.9 years. At baseline, disease characteristics were generally consistent across treatment arms (Table). At W24, DAS28-CRP response rates increased across all TIL treatment arms relative to PBO (Figure). After W24, response rates continued to increase and were sustained through W52, including in pts who switched from PBO to TIL. From W0–W24–W52, 50.4%/39.9% and 2.3%/10% of pts experienced a TEAE and SAE, respectively. There were no reports of candidiasis, inflammatory bowel disease, major adverse cardiac events or elevated liver enzymes. From W0–W24, 1 pt (0.3%) had urinary tract infection (TIL 100 mg Q12W). From W25–W52, 1 pt (0.3%) had an intraductal proliferative breast lesion (TIL 200 mg Q12W). One pt (0.3%) discontinued before 24 weeks due to hypertension. No deaths were reported.

Data are reported as mean ± standard deviation unless otherwise stated.

*Total pts analysed (n) = 71, 69, 70, 68, 62, respectively.

**References:**

**Conclusion:** Treatment with all doses of TIL increased the rate of DAS28-CRP responders in pts with active PsA and was well tolerated, suggesting a reduction in PsA-related disease activity for up to 52 weeks of treatment. Ongoing analyses will assess whether DAS28-CRP responses correlate with baseline clinical characteristics.

DOI: 10.1136/annrheumdis-2020-eular.5883

Results: Mean BMI 22.51±1.69 and 23.46±1.82 kg/m², no statistical significance (P =0.205).
Mean BSA 5.9±3.1%, DAPSA score (13.9±4.7), PASI score: 86.9% (40 pts) had mild to moderate PASI, 5 had severe disease (8.6±4.8).
TC, LDL and TG were higher in pts, while HDL was higher in controls (P =0.0003, 0.0001, 0.0001 & 0.05).
A significance between 2 groups regarding LEP (P =0.0001), ranging from 2.16-99 (7.9±4.5) in group I and 1.35-97 (1.6±0.1) µg/ml in controls. Normal: 2.6-8.35
FI & HOMA IR were significantly higher in PsA group (P =0.001, 0.0001)
The mean CIMT 1.1±0.3 mm and in group II 0.8±0.1 mm. 14 pts (31.1%) had plaque, while 68.9 % & all controls had no plaques, with a significance regarding CIMT & presence of plaques (P=0.011 & 0.004).
A positive statistical significance between LEP and dd (P=0.001), BSA, PASI and DAPSA (P =0.0001, 0.0003, 0.001) but not with age, BMI (P=0.98 & 0.88).
There was no statistical significance between LEP and FBG, HbA1C, HOMA IR, Fi, CBC (P > 0.05), or between LEP and TC, TG, HDL, LDL (P=0.438,0.390, 0.699, 0.050), liver enzymes, renal functions, ESR and CRP.
There was statistical positive correlation between LEP and CIMT (P =0.001), but not with the presence of plaques (P=0.846).
CIMT and other variables: Table 1
DAPSA: there was no statistical significance with TC, HDL, LDL and TG (P=0.51, 0.876, 0.717 & 0.255), but a statistically significance with LEP and CIMT (P=0.011& 0.009). Pts with higher score had higher LEP and increased CIMT.
PASI: there was no significance between TC, HDL, LDL and TG (P=0.724, 0.157, 0.651& 0.374) or CIMT (P =0.290) in mild-moderate and severe PASI. LEP was significantly higher in severe PASI score (P= 0.001).
Conclusion: The presence of abnormal lipid profile, IR, increased CIMT, high disease activity and increased LEP may be considered as useful criteria for early recognition and thus prevention of atherosclerosis in PsA pts.

IMPLEMENTING IPAD-BASED ASSESSMENTS TO IMPROVE PERFORMANCE IN A PSORIATIC ARTHRITIS CLINIC AT A DISTRICT GENERAL HOSPITAL

S. Mukherjee1, B. Quilty1, H. Burstow1, K. Hennessy1. 1Christchurch Hospital, Rheumatology Department, Christchurch, United Kingdom

Background: Psoriatic Arthritis (PsA) is a complex disease with profound physical and psychosocial effects. The core domain set for this condition was updated by the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA)-Outcome Measures in Rheumatology (OMERACT) PsA工作组 group in 20162 and the TICOPA (Tight COntrol of Psoriatic Arthritis) study suggested that adopting a ‘treat-to-target’ approach aiming for Minimal Disease Activity (MDA) could result in better clinical outcomes3.

Objectives: To improve assessment of all the core domains of PsA during clinic appointments and aim to treat these patients using a ‘treat-to-target’ approach to improve clinical outcomes.

Methods: We were able to confirm through a retrospective baseline audit that all core domains of PsA were not being fully addressed in our general rheumatology clinics. A dedicated weekly PsA clinic was then set up at our district general hospital. Subsequently, iPads incorporated with GRAPPA App were implemented in these clinics to facilitate multi-domain assessments aiming for MDA. This was supported by a Health Education England (Wessex) Quality Improvement Fellowship that involved rheumatology and dermatology team members working in close collaboration. We then carried out a re-audit to assess our performance. Additionally we set up quarterly combined Rheumatology and Dermatology clinics to facilitate multi-domain assessments aiming for MDA. This was achieved with the help of Health Education England (Wessex) Quality Improvement Fellowship that involved rheumatology and dermatology team members working in close collaboration.

Results: We had pragmatically set a standard of 75% for our baseline audit but we found an overall compliance of only 27.4%. There was also a wide variation between different domains with a compliance of even 0% for some. Domains that are not assessed are unlikely to be fully taken into account when deciding about treatment. We re-audited following the implementation of iPad-based assessments in dedicated PsA clinics showed a significant improvement in each of the domains and the overall compliance went up to 97.9% (Table 1).

Projects: We had pragmatically set a standard of 75% for our baseline audit but we found an overall compliance of only 27.4%. There was also a wide variation between different domains with a compliance of even 0% for some. Domains that are not assessed are unlikely to be fully taken into account when deciding about treatment. The re-audit following the implementation of iPad-based assessments in dedicated PsA clinics showed a significant improvement in each of the domains and the overall compliance went up to 97.9% (Table 1). The patient survey findings were also excellent with mean scores of 9.5, 9.0 and 9.5 respectively for the three items (Figure 1).

Conclusion: Dedicated PsA clinics using the GRAPPA App on iPads could facilitate comprehensive multi-domain assessments of patients with PsA and potentially lead to better outcomes as well as greater patient satisfaction.

Background: Biologics have led to a sea change in the management of psoriatic arthritis (PsA) with unprecedented improvement in the signs, symptoms and radiographic damage, resulting in improvement in functionality and quality of life. However longitudinal data for their retention and tolerability is sparse.

Objectives: Our objective was to evaluate real-world biologic therapy duration and reasons for discontinuing treatment.

Methods: We conducted a retrospective analysis of all PsA patients enrolled in electronic database up to April 2019 at our university teaching hospital. We had access to full patient records including details on co-morbidities, drugs and disease management.

Results: 335 patients were identified with PsA. 58% of them were female with mean age of 46 yr (13-81), 113 (33.7%) patients had been treated with a biologic with 105 (93%) continuing at the time of analysis. 60 individuals were prescribed combination therapy with DMARDs. Mean age was 43.3 years (13-81) with 56% women. The biologics sample was ethnically diverse including 80% White Caucasian patients, 17% Asian and others (3%). Significant co-morbidities included cardiovascular disease (18.6%) and diabetes (4.4%). Eight different biologics were in use with adalimumab being the most prescribed (67%). 35 (30.9%) patients had stopped biologics at some point with 76 episodes of cessation. 6% of our sample had discontinued two or more biologic treatments. The mean duration before biologic therapy was discontinued was 18.2 months (8 days to 9.5 years), which was almost twice as long as the average period before discontinuing a DMARD (9.9 months). Main reasons for stopping treatment included 23% each due to GI symptoms, neurological causes, cutaneous symptoms and other side effects. The remaining 8% reported fatigue as the reason for stopping therapy.

Conclusion: To our knowledge this is the first dedicated retrospective review of a large real world PsA cohort comparing drug survival and tolerability of biologics against DMARDs. Biologic therapies are well tolerated in psoriatic arthritis. There is no significant difference amongst various modes of action. Over a quarter of the patients discontinue the drug owing to intolerance with mean drug survival of 18 months. In contrast nearly two-thirds were intolerant of DMARDs and stopped within ten months. Thus both the rate and duration of biologic retention is significantly better than conventional DMARDs. This has significant economic impact as NICE guidelines require an adequate trial of two DMARDs for six months prior to advanced therapy. However, this approach is unlikely to be cost effective as the disease progresses whilst patients struggle with DMARDs prescription and thus delay biologics which are more likely to be tolerated and retained longer. Hence there is an urgent need to review NICE guidelines to allow earlier employment of biologics in the treatment paradigm with significant benefits to both patients and the health economy.

AB0810 IMPACT OF TOLERABILITY ON RETENTION OF CDMARDS IN PSORIATIC ARTHRITIS - IS IT A CONCERN?

I. Jawad1, M. K. Nisar1. 1Luton and Dunstable University Hospital, Luton, United Kingdom

Background: Most guidelines recommend the first line use of DMARDS in Psoriatic Arthritis (PsA). However, studies show that many conventional treatments like methotrexate are poorly tolerated. There is hitherto no published real-world data addressing the tolerability of DMARDs in PsA.

Objectives: Our objective was to therefore assess the drug management in PsA with focus on tolerability and the reasons for therapy cessation.

Methods: We conducted a retrospective analysis of all PsA patients enrolled in electronic database up to April 2019 at our university teaching hospital. We had access to full patient records including details on co-morbidities, drugs and disease management.

Results: 335 patients were identified with a formal diagnosis of PsA. Mean age of the cohort was 46 years (13-81) and 58% were female. 48% of the group had clinically active disease. Same percentage were taking a single DMARD, 10% had trialled 3 or more drugs. 62% of patients had discontinued one or more DMARDs prior. The mean duration before discontinuing a DMARD was 9.9 months. Methotrexate was the best tolerated and on average discontinued after 13.4 months (range: 4 days to 10.9 years). Sulfasalazine and Hydroxychloroquine were discontinued after an average of 8.4 (11 days to 4.27 years) and 12.5 months (13 months to 2.88 years) respectively. Leflunomide was the least tolerated DMARD and stopped after an average of 5.5 months (7 days to 2.53 years). The main reason for stopping a medication was gastro-intestinal symptoms which accounted for 42% of all the reported side effects. This applied to both methotrexate (43%) and sulfasalazine (46%) discontinuation. The leading reasons for discontinuing Hydroxychloroquine were joint GI symptoms and other side effects at 43% each. Leflunomide was stopped in 50% of cases due to neurological symptoms.

Conclusion: To our knowledge, this is the first report confirming poor retention rate of oral DMARDs in a real world PsA cohort managed over 20 years.
In the context of chronic disease, the median duration of treatment is short. Our analysis did not include patients who suffer from side effects but continue therapy thereby impacting treatment adherence and hence the true scale of the issue is likely higher. Though NICE guidelines stipulate the need of an adequate trial of minimum two DMARDs prior to therapy escalation, in reality these drugs are not well tolerated and thus pose a challenge to clinicians. One potential solution is earlier adoption of biological therapies, which are increasingly cost effective and have been shown to be better tolerated.

DOJ: 10.1136/annrheumdis-2020-eular.3809

Objective: The aim of this study was to evaluate the relationship between the VAI and cardiovascular risk scores of patients with psoriatic arthritis.

Methods: This study was conducted with 101 PsD patients who fulfilled the classification criteria for Psoriatic Arthritis (CASPAR) criteria and 98 healthy subjects. Demographic and clinical data were recorded. Disease activity was evaluated with the Health Assessment Questionnaire (HAQ), Disease Activity Index for Psoriatic Arthritis (DAPSA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Disease Activity Index (BASFI), and Psoriasis Area Severity Index (PASI). The SCORE, Framingham index, metabolic syndrome (MS), Body mass index (BMI), and VAI values of the patients and the VAI values of the healthy subjects were calculated.

Results: Mean BMI (kg/m²) was calculated as 29.83 ± 5.66. According to the SCORE measurements, 53 (52.5%) patients were at low risk, 45 (44.6%) at moderate risk, and 3 (3%) at high risk. No patients were at very high risk. According to the Framingham score, 72 patients (71.3%) were at low risk, 22 patients (21.8%) at intermediate risk and 7 patients (6.9%) at high risk. The risk was found to be statistically significantly higher in the PsD group compared to the healthy control group in respect of metabolic syndrome, obesity (BMI >30) and VAI levels (p<0.05). Significantly higher VAI levels were deter-mined in PsD patients with metabolic syndrome, BMI> 30 (obesity), diabetes mellitus and hypertension compared to without these comorbidities (p<0.05).

A statistically significant correlation was determined between low and moderate risk Framingham score, and the VAI levels of PsD patients. Correlations were determined between disease activity and metabolic and cardiovascular risks of patients. A weak correlation was observed between VAI levels and the Framingham score (Table). Table. Correlations (r) between disease activity and metabolic and cardiovascular risks of patients

Conclusion: Patients with psoriasis are more susceptible to obesity and other diseases such as metabolic syndrome, dyslipidemia, cardiovascular diseases, insulin resistance and diabetes. Therefore, control of bodyweight in PsD patients is important for management of the disease. Since VAI can be calculated simply from routinely taken measurements, the VAI level can be used to determine cardiovascular risk and VAI may also provide clues about comorbidities in patients with newly diagnosed PsD.

AB0813 GUSELKUMAB-TREATED PATIENTS ACHIEVED CLINICALLY MEANINGFUL IMPROVEMENT IN SYSTEMIC SYMPTOMS AS MEASURED WITH PROMIS INSTRUMENT: RESULTS FROM PHASE-3 PSORIATIC ARTHRITIS TRIAL DISCOVER 1

A. M. Orbai1, L. C. Coates1, A. Deodhar2, P. Helliwell3, C. T. Ritchlin3, A. Kollmeier4, E. H. Hsiu4, L. X. Xu5, S. Sheng5, B. Zhou5, C. Han5, J. Johns Hopkins Univ School of Med, Baltimore, United States of America; °Oxford Univ, Oxford, United Kingdom; °Oregon Health & Science U, Portland, United States of America; †U of Leeds, Leeds, United Kingdom; ‡U Rochester Med Ctr, Rochester, United States of America; †Janssen Research & Development, LLC, Spring House, United States of America; †Penn Med Ctr, Philadelphia, United States of America

Background: Patients (pts) with psoriatic arthritis (PsA) experience broad sys-temic symptoms including pain, fatigue, depression, sleep disturbance, poor physical function, and diminished social participation.

Objectives: DISCOVER 1 is a Phase 3 trial (NCT03182796) evaluating the efficacy and safety of guselkumab (GUS), an anti-interleukin 23 inhibitor that binds to the p19-subunit of IL-23, in pts with active PsA. PROMIS-29 (Patient-Reported Outcomes Measurement Information System-29), a validated generic health instrument, assessed the treatment effect of GUS on symptoms in pts with PsA.

Methods: Pts with active PsA despite nonbiologic DMARDs were enrolled, and ~30% of pts could have previously received ≥2 TNFi. Pts were randomized (1:1:1) to subcutaneous GUS 100 mg q4W (n=128), or PBO (n=128). Concomitant stable use of select csDMARDs, oral steroids, and NSAIDs was allowed. PROMIS-29 consists of 7 domains (Depression, Anxiety, Physical Function, Pain, Sleep Disturbance, and Social Participation) and a pain intensity 0-10 numeric rating scale (NRS). The raw score of each domain is converted into a standard-ized T-score with a mean of 50 (general population mean) and a standard devi-ation (SD) of 10. Higher PROMIS scores represent more of the concept being measured. A ≥ 5-point improvement (1/2 SD of T-score) is defined as clinically meaningful.

Results: At baseline, mean PROMIS-29 T-scores for physical function, social participation, sleep disturbance, pain, and fatigue were worse than the general US population. At W24, GUS q8W-treated pts achieved greater improvements from baseline in all PROMIS-29 domains vs PBO (p<0.05) (Table and Fig 1). Results were consistent in the GUS q4W group except for anxiety and sleep dis-turbance. More pts receiving GUS achieved clinically meaningful improvement vs PBO except for depression and anxiety in the GUS q4W group, which were numerically improved (Fig 2).

Conclusion: Active PsA pts treated with GUS achieved clinically meaningful reduction in symptoms and improvement in physical function and social participa-tion vs PBO at W24.

A. Constantin 5, A. M. Gellett 6, A. T. Sprabery 6, J. Birt7, V. Geneus7, P. Nash8, 1Johns Hopkins University School of Medicine, Baltimore, United States of America; 2Hospital de Sabadell, Barcelona, Barcelona, Spain; 3MEDICAL PLUS s.r.o., University of Veterinary and Pharmaceutical Sciences, Uherské Hradiště, Czech Republic; 4Centre Hospitalier Universitaire de Montpellier; University of Montpellier, Montpellier, France; 5Hospital Pierre-Paul Riquet, Toulouse, France; 6Eli Lilly and Company, Indianapolis, United States of America; 7Eli Lilly and Company, Indianapolis, United States of America; 8School of Medicine, Griffith University, Brisbane, Australia.

Background: Ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets IL-17A, has shown improvements compared to placebo (PBO) not only in disease activity but also in various patient-reported outcomes (PROs) assessing physical function, quality of life (QoL), and work productivity in PsA patients treated for 24 weeks and sustained up to 52 weeks.1,2

Objectives: To report the effects of treatment with IXE on these PROs after up to 3 years of treatment.

Methods: In SPIRIT-P2 (NCT02349295), a Phase 3 trial, 363 adult patients with active PsA and prior inadequate response or intolerance to 1 or 2 TNF inhibitors (TNFis) were randomized 1:1:1 to IXE 80mg every 4 weeks (IXEQ4W; N=122) or every 2 weeks (IXEQ2W; N=123), or PBO (N=118) in the double-blind treatment period (Weeks 0-24). Both IXE regimens had a starting dose of 160mg. Results are reported from a subset of the intent-to-treat population who were randomized to IXE at baseline (Week 0). The following PROs were assessed during Weeks 0-156: HAQ-DI (minimally clinically important difference [MCID] an improvement ≥0.35), a clinical outcomes survey Short Form-36 (SF-36), Physical and Mental Component Summary (PCS and MCS), European Quality of Life 5 Dimensions Visual Analog Scale (EQ-5D VAS), and Work Productivity and Activity Impairment Questionnaire-Specific Health Problem (WPAI-SHP; absenteeism, presenteeism, work productivity, and activity impairment). Missing values were imputed by observed analysis and modified baseline observation carried forward (mBOCF) for continuous data or by modified non-responder imputation (mNRI) for categorical data.

Results: Mean baseline scores for SF-36 (PCS and MCS), EQ-5D VAS, and WPAI-SHP (Figure 1) and HAQ-DI (mean [SD]; IXEQ4W=1.2 [0.6]; IXEQ2W=1.2 [0.6]), indicated impaired physical function and QoL. The percentage of patients of who completed 156 weeks of the study in IXEQ4W and IXEQ2W arms were 57.4% (n=70) and 44.7% (n=55), respectively. Patients receiving IXE treatment up to 3 years reported sustained improvements in SF-36 (PCS and MCS), EQ-5D VAS, and WPAI-SHP (presenteeism, work productivity, and activity impairment) (Figure 1). Observed HAQ-DI mean change from baseline in IXEQ4W -0.46 (0.62) and IXEQ2W -0.48 (0.55). The percentage of IXE treated patients achieving MCID for HAQ-DI (improvement ≥0.35) was sustained at 3 years (Figure 2).

Figure 2. Clinically Meaningful Improvement (≥5 Points) in PROMIS-29 T-Scores at Week 24

Figure 1. Summary of Patient-Reported Outcomes presented as change from baseline at Week 156 (Observed and mBOCF): Intent-to-Treat Population (Patients Randomized to IXE at Baseline)
Psoriatic arthritis (PsA) is a chronic inflammatory disease characterized by multiple comorbid conditions including cardiovascular comorbidities, diabetes, obesity and osteoporosis. Little is known about body composition in patients with PsA and no data are available regarding body composition changes under DMARDS.

Objectives: We investigated the effects of ustekinumab (UST), a humanized anti-interleukin 12/23 antibody, on body composition, bone mineral density (BMD) and bone remodeling markers in patients treated for PsA.

Methods: Thirty patients with active PsA treated with UST were included in a 6 months open follow-up study. Body mass index, DAS28-CRP, bone remodeling markers, serum levels of leptin, BMD and body composition (dual-energy X-ray absorptiometry) were measured at baseline and 6 months of treatment. At baseline, PsA patients were compared with 60 non-PsA controls matched for age, sex and body mass index.

Results: Compared with controls, we observed lower total and appendicular lean mass (53.1 ± 13.1 vs. 56.7 ± 11.9 kg, p = 0.013 and 21.8 ± 6.3 vs. 23.4 ± 5.0 kg, p = 0.010 respectively) and greater fat mass in PsA (32.5 ± 10.8 vs. 25.2 ± 8.9 kg, p < 0.001). Among PsA patients, 30% had a skeletal muscle mass index below the cut-off point for sarcopenia (Baumgartner's criteria: men 7.26 kg/m², women 5.5 kg/m²) whereas no case was observed in the control group. After 6 months of treatment with UST, there was not a significant change of BMI, while there was a tendency for reaching the significant level for fat mass (+1.75 ± 3.60 kg, p = 0.054), and fat mass index (+0.59 ± 1.25 kg²/m², p = 0.061). In contrast, a decrease in total lean mass was observed (-1.57 ± 3.10 kg, p = 0.048) without a significant change in appendicular lean mass and skeletal muscle mass index. No changes for bone remodeling markers, leptin and BMI were observed at 6 months.

Conclusion: Patients with active PsA required biologic therapy had increased fat mass and decreased lean mass. Moreover, ustekinumab might worsen the decrease in lean mass with no significant change in fat mass.
We performed a multivariate analysis that showed that being overweight and presenting a waist / hip index above 0.90 confers an increased risk of developing PsA (Table 2).

**Conclusion:** Several traditional cardiovascular risk factors were found with a higher prevalence in the group with psoriasis. It is critical that physicians known the common comorbidities associated with PsA so that they can provide optimal management and treatment and improve mortality and quality of life.

since diagnosis, employment status, biologic DMARD use, BMI, number of joints affected.

**Results:** Of 1,909 patients (539 US, 1,370 EU), 35% of patients had joint only disease, while 26%, 23%, and 16% experienced joint disease plus 1-3%, 3-10%, and >10% BSA respectively (Figure 1). Patients were comparable demographically (Table 1). After controlling for demographics and number of joints involved, results showed BSA independently and significantly impacted QoL, work productivity, disability (Table 2).

*Calculated on available data, n=394

Background: Flares in PsA, presenting as periods of acute disease activity, are thought to negatively impact patients’ lives. This has not been extensively studied in a real-world setting.

**Objective:** Describe flares, assess impact on quality of life and work productivity, and explore predictors.

**Methods:** A cross-sectional survey among patients with PsA recruited by rheumatologists and dermatologists was conducted in France, Germany, Italy, Spain, UK and US. Data were collected Jun-Aug 2018 via patient record forms and patient self-complete forms. Physicians recorded flare status (in flare currently/flare in last 12 mo/longer than 12 mo or never), demographics, physician perceived severity and clinical outcomes. Patients reported quality of life [QoL] (EQ5D-5L), work productivity (WPAI), disability (HAQ-DI), pain (PsAID12 pain scale). Patients were compared by flare status using parametric or non-parametric tests. Logistic regression explored predictors of flare. Multivariate regression explored the impact of flare status on patient reported outcomes (PRO). The model was adjusted for gender, age, BMI, physician specialty.

**Results:** Data were collected for 2,238 patients (586 US, 1,652 EU). Mean age was 48.7 years (13.2 SD), 53.8% were male. Physicians reported 7.5% were currently in flare and 22.0% had flared in the last 12 mo. Patients had experienced 2.2 mean flares in the last 12 mo (4.9 SD), lasting a mean 16.4 days (16.2 SD). Patients in flare were comparable demographically with those not; however, those in flare were less likely to work full time (43.6 vs. 59.3%, p<0.01). Patients not in flare had clinically active disease (Table 1).

**Conclusion:** Two thirds of this sample of actively treated PsA patients have skin involvement. Over half would be considered moderate-severe (BSA >3%). After controlling for joint symptoms, results show that increasing skin involvement in PsA patients adversely impacts QoL, disability and work productivity.

Results showed that flare status significantly impacted QoL, work productivity, disability, and pain (Table 2). Exploring predictors of flare in the last 12 mo in un-adjusted analyses showed that demographic characteristics were not predictive of flare status, however patients presenting as moderate or severe at diagnosis were at greater risk of flare. Patients who were prescribed a bDMARD at diagnosis were at lower risk (Figure 1).

AB0820

COMPARATIVE EFFICACY OF GUSELKUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

Background: The efficacy of the interleukin (IL)-23 subunit p19 inhibitor guselkumab (GUS) for psoriatic arthritis (PsA) has recently been demonstrated in two Phase 3 trials (DISCOVER-1 & -2) but has not been evaluated versus existing targeted therapies for PsA.

Objectives: To compare GUS to targeted therapies for PsA through network meta-analysis (NMA).

Methods: A systematic literature review was performed to identify PsA randomized controlled trials from 2000 to 2018. Bayesian NMAs were performed to compare treatments on American College of Rheumatology (ACR) 20/50/70 response, Psoriasis Area Severity Index (PASI) 75/90/100 response, Health Assessment Questionnaire Disability Index (HAQ-DI) score, resolution of enthesitis (RoE), resolution of dactylitis (RoD), adverse events (AEs) and serious adverse events (SAEs). Analyses used random effects models that adjusted for placebo response via meta-regression on baseline risk when feasible. Results are summarized by ranking treatments according to median absolute probabilities of response derived from NMAs.

Results: Twenty-six Phase 3 studies were included in the quantitative synthesis. Studies were placebo-controlled up to 24 weeks and evaluated 13 targeted therapies for PsA. Absolute probabilities are reported for PASI 90 & ACR 20 responses according to Figure 1, and a forest plot of relative risks versus placebo for AEs is reported according to Figure 2. For ACR 20 response, GUS 100mg every 4 weeks (Q4W) and every 8 weeks (Q8W) ranked 5th and 8th out of 20 interventions and were comparable to IL-17A inhibitor (IL-17A) and most tumor necrosis factor inhibitor (TNFi) agents. Similar findings were observed for ACR 50 and 70 responses. For PASI 90 response, GUS Q4W and Q8W ranked 1st and 2nd out of 15 interventions and were highly likely to provide a greater benefit than most other agents. Similar findings were observed for PASI 75 and 100 responses. For HAQ-DI score, GUS Q4W and Q8W ranked 6th and 10th out of 20 interventions and were comparable to IL-17A and most TNFi agents. For RoE, GUS Q4W and Q8W ranked 6th and 8th out of 13 interventions and were comparable to IL-17A and TNFi agents. For RoD, GUS Q4W and Q8W ranked 8th and 9th out of 13 interventions and were comparable to most IL-17A and TNFi agents. For AEs, GUS Q4W and Q8W ranked 3rd and 2nd out of 19 interventions and were comparable to IL-17A and TNFi agents. Likewise, for SAEs, GUS Q4W and Q8W ranked 4th and 5th out of 20 interventions and were comparable to IL-17A and TNFi agents. Analyses that controlled for previous exposure to biologics or assessed outcomes at alternative timepoints were broadly consistent with primary analysis results.

Conclusion: GUS is comparable to most targeted PsA treatments for improvement in arthritis, soft tissue damage, physical function, and safety outcomes. For PASI outcomes, GUS is highly likely to provide a greater benefit than other targeted PsA treatments.

AB0820

Figure 1. Predictors of flaring in last 12 months

Figure 2. Forest Plot of Adverse Events vs. Placebo

Forest plot comparing relative risks (RR) and 95% credible interval (CI) versus placebo for adverse events. Probability better than placebo shown on the right.

Conclusion: NMA results indicate that GUS is comparable to most targeted PsA treatments for improvement in arthritis, soft tissue damage, physical function, and safety outcomes. For PASI outcomes, GUS is highly likely to provide a greater benefit than other targeted PsA treatments.

ANXIETY AND DEPRESSION IN PSORIATIC ARTHRITIS (PSA) - PREVALENCE AND IMPACT ON PATIENT REPORTED OUTCOMES: REAL-WORLD SURVEY IN THE US AND EUROPE

L. Gossec1, J. A. Walsem2, K. Michaud3, E. Holdsworth4, S. Peterson5, S. Meakin5, S. Bruce Wirta6, D. S. Chakrvartty2, A. Ogdie7, Surbomme U Paris, France; 2U of Utah, Salt Lake City; United States of America; 3U of Nebraska Medical Center, Omaha, United States of America; 4Adelphi Real World, Bollington, United Kingdom; 5Janssen Global Services LLC, Horsham, United States of America; 6Janssen-Cilag, Solna, Sweden; 7Janssen Scientific Affairs, LLC/Drexel U College of Medicine, Horsham, United States of America; 8Perelman School of Medicine, Philadelphia, United States of America

Background: Anxiety and depression are comorbidities among PsA patients. The impact of anxiety and depression on outcomes in PsA patients has not been characterized in a real-world clinical setting.

Objectives: To describe the prevalence of anxiety and/or depression in PsA patients, assess concordance in reported anxiety and depression, and impact of anxiety and depression between patients and physicians, and compare clinical and patient reported outcomes (PROs) in patients who do and do not report anxiety and depression.

Methods: A cross-sectional study of patients with PsA recruited by rheumatologists and dermatologists was conducted in France, Germany, Italy, Spain, UK and US. Data were collected Jun-Aug 2018 via physician-completed and patient self-completed forms. Physicians reported patient demographic, disease characteristics and diagnosed anxiety and/or depression. Patients reported experience of PsA-related anxiety/depression, quality of life [QoL] (EQ5D-SL), work productivity (WPAI), disability (HAQ-DI), and disease impact (PsAID12). Patients were compared according to patient reported anxiety/depression using parametric and non-parametric tests. Multivariate regressions explored impact of anxiety/ depression on PROs. Models adjusted for age, gender, employment status, BMI, # of joints affected, body surface area (BSA).

Results: Data were collected from 688 physician-patient pairs (524 EU; 164 US). Physicians reported anxiety and/or depression in 14.2% of patients (EU 13.3%; US 16.2%), while 36.6% (EU 36.3%; US 37.3%) of patients self-reported anxiety and/or depression. 71.4% of physician-patient pairs agreed on anxiety and/or depression presence or absence (Kappa = 0.31, fair agreement). Patients with anxiety and/or depression had worse QoL, more work impairment, greater disability (Table 2).

Conclusion: One third of patients self-report anxiety and/or depression. Treatment physicians may not be aware of patient experience of anxiety and/or depression. Patients with anxiety and/or depression appear to have worse QoL, work productivity and disability outcomes than those without.

Which Clinical Factors Influence MINERALIZATION OF THE METACARPAL BONES AND FINGER JOINT SPACE WIDTH IN PSORIATIC ARTHRITIS?

A. Pfleil1, M. Heinz2, D. Renz3, J. Böttcher4, G. Wolf5, P. Oelzner1, Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine III Jena, Germany; 2Hannover Medical School, Diagnostic and Interventional Radiology, Hannover, Germany

Background: Metacarpal bone mineral density as measured by digital x-ray radiography (DXR-BMD) and finger joint space width quantified by computer-aided joint space analysis presented computer based and observer independent parameters for the evaluation of radiographic damage of the hand skeleton.

Objectives: The aim of this study was to quantify clinical parameter which potential influence periarthritis mineralisation of the metacarpal bones and finger joint space width in Psoriatic Arthritis (PsA) patients.

Methods: The study includes 201 PsA-patients. All patients received a radiograph of the hand. Bone mineral density was measured by DXR ( Pronosco X-Pusure System™, Version 2.0; Sectra; Sweden) and finger joint space width of all finger joints were evaluated by computer-aided joint space analysis (CAJSA, Radiography Kit, Version 1.3.6; Sectra; Sweden). The Z-Score was used as an age- and gender-independent parameter for the quantification finger joint space narrowing.

Results: Regarding gender, the DXR-BMD was significant reduced with -0.028 g/cm² in women. An equivalent significant result was evaluated for finger joint space width (Z-ScoreMCP -1.07, Z-ScorePIP -0.81 and Z-ScoreDIP -0.76). The DXR-BMD was significantly lowered (-0.011g/cm²) between the disease duration ≤2 years (0.545±0.076g/cm²) and >10 years (0.509±0.070g/cm²). The Z-Score showed no significant change regarding the disease duration. Inflammatory activity as measured by c-reactive protein presented no impact on DXR-BMD and the Z-Score of all finger joints. Additionally, the use of corticosteroids was associated with a reduced DXR-BMD (-0.037g/cm²) and an absence of finger joint space narrowing.

Conclusion: The study highlights that the demineralisation of the metacarpal bones was associated with female gender, disease duration and the use of corticosteroids. Whereas, the prior mentioned parameters had no influence on finger space width (Z-ScoreMCP -1.07, Z-ScorePIP -0.81 and Z-ScoreDIP -0.76). The DXR-BMD was significantly lowered (-0.011g/cm²) between the disease duration ≤2 years (0.545±0.076g/cm²) and >10 years (0.509±0.070g/cm²). The Z-Score showed no significant change regarding the disease duration. Inflammatory activity as measured by c-reactive protein presented no impact on DXR-BMD and the Z-Score of all finger joints. Additionally, the use of corticosteroids was associated with a reduced DXR-BMD (-0.037g/cm²) and an absence of finger joint space narrowing.

Conclusion: The study highlights that the demineralisation of the metacarpal bones was associated with female gender, disease duration and the use of corticosteroids. Whereas, the prior mentioned parameters had no influence on finger space width.
joint space width. Consequently, periarticular demineralisation and finger joint space narrowing presented two different and independent radiological signs in PsA.

AB0823 MINIMAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS IS ASSOCIATED WITH LOW IMPACT OF DISEASE ON PSAILID QUESTIONNAIRE

J. A. Mosquera Martínez, C. García-Porrua, L. Fernández-Dominguez, J. L. Guerra-Vázquez, J. Pinto-Tasende on behalf of IGAPS. 1CHU Pontevedra, Rheumatology, Pontevedra, Spain; 2Hospital Lucus Augusti, Rheumatology, Lugo, Spain; 3CHU Ourense, Rheumatology Ourense, Spain; 4CHU Arquitecto Marcide, Rheumatology, Ferrol, Spain; 5INIBIC-CHU A Coruña, Rheumatology, A Coruña, Spain

Background: Psoriatic arthritis (PsA) has a prevalence of 0.58% in Spain and patients suffer this disease have significant impact on daily life due to articular, dermatological and psychological symptoms. To reach minimal disease activity (MDA) is a therapeutic goal recommended by EULAR for clinical practice.

Objectives: Our aim was to assess the relationship between MDA and PsAILID questionnaire in routine clinical practice.

Methods: We performed a cross-sectional study of patient and physician reported outcomes. We obtained clinical information of patients with PsA attending our clinic from October 2018 to October 2019. Data were collected from clinical records concerning age, gender, disease duration, joint counts, dactylitis, enthesitis, body surface area (BSA) of psoriasis, laboratory results (ESR and CRP), HAQ, PsAID12, pain and global assessment from patient with numerical questionnaire in routine clinical practice.

Results: Data were available for 210 patient visits, 57% males. MDA 5/7 was reached in 118 patients (56.2%) and MDA7/7 in 58 (27.6%). Age and gender were not associated with reach MDA. Higher disease activity was associated with MDA, OR 1062 (1.012-1.114, 95% CI), p 0.015. PsAID12 was evaluated in 158 patients and all components were associated with reach MDA. Patients in MDA had significantly lower PsAID12 than those not in MDA (mean 1.5 ± SD 1.5 vs. 3.8 ± 2.1), p< 0.0001.

PsAID12 of less than 4 is considered a good outcome and individual components of PsAID12 (Figure 1, mean values for NRS) were less than 4 in patients with MDA.

All components of PsAID12 were associated with MDA on univariate analysis but only pain and functional capacity remained independent predictors on multiple regression analysis (p< 0.0001 and p0.008 respectively).

AB0824 WHICH PARAMETERS ARE RELEVANT IN THE IDENTIFYING AXIAL INVOLVEMENT IN PSORIATIC ARTHRITIS? – RESULTS OF A SURVEY AMONG ASAS AND GRAPPA MEMBERS

D. Poddubnyy, F. J. Mease, F. Van den Bosch, J. Braun, A. Gottleib, L. C. Coates, V. Chandran, P. Hellwell, D. Jadon, J. Sieper, D. Van der Heijde, D. D. Gladman on behalf of ASAS, GRAPPA. 1Charité - Universitätsmedizin Berlin, Berlin, Germany; 2Swedish Medical Center Providence St John Health and University of Washington, Seattle, United States of America; 3Ghent University, VIB Center for Inflammation Research, Ghent, Belgium; 4Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany; 5Icahn School of Medicine at Mount Sinai, New York, United States of America; 6University of Oxford, Oxford, United Kingdom; 7Toronto Western Hospital, Toronto, Canada; 8Leeds Institute of Rheumatology and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 9Cambridge University Hospitals, Cambridge, United Kingdom; 10Leiden University Medical Centre, Leiden, Netherlands

Background: Inflammatory involvement of the axial skeleton (sacroiliac joints and/or spine) is one of the relatively frequent musculoskeletal manifestations associated with psoriasis / psoriatic arthritis (PsA). There is an urgent need for an evidence-based definition for axial involvement in PsA that would identify a subgroup of patients within the heterogeneous PsA population to conduct observational, interventional and translational studies. ASAS and GRAPPA embarked on a collaborative initiative to develop a definition of axial involvement in PsA.

Methods: The online survey utilized the PAPRIKA methodology (Potentially All Pairwise Rankings of all possible Alternatives) that determines decision-makers’ part-worth utilities representing the relative importance of the attributes. Participants were exposed to number of clinical scenarios and were prompted to decide which of the scenarios is more compatible with axial involvement in PsA unless they are equal (Figure). The constant stem of each scenario was “a patient diagnosed with psoriatic arthritis fulfilling the CASPAR criteria”; the variable part included 13 common spondyloarthritides variables (Table). Variables were ranked according to their relative importance.

Results: The survey was completed by 186 ASAS/GRAPPA members (63 ASAS only, 80 GRAPPA only, and 43 both societies). The ranking of the variables is presented in Table. The highest ranked parameters indicative of axial involvement in a patient with PsA were presence of typical radiographic or MRI changes in the sacroiliac joints and/or spine followed by the presence of chronic back pain and then inflammatory back pain. A separate analysis of ASAS and GRAPPA members provided the similar results concerning the relevance of the variables.

Conclusion: Objective signs of inflammatory involvement of the axial skeleton are the most important indicators of axial disease in PsA in the opinion of the experts. A prospective cohort study is currently being planned to address the value of these and other variables in defining axial involvement in PsA.
Table. Ranking of the parameters relevant to deciding on the presence of axial involvement in a PsA patient in the opinion of ASAS and GRAPPA members (n=186).

AB0825

TIME-COURSE CHANGE IN AXIAL MOBILITY IN PSORIATIC ARTHRITIS PATIENTS UNDER BDMARD

M. Rato1, F. Pinheiro1, S. Garcia1, B. M. Fernandes2, S. Ganho1, R. Gaio1, M. Bernardes1, A. Bernardo1, L. Costa1, 1Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal; 2Faculdade de Ciências da Universidade do Porto & Centro de Matemática da Universidade do Porto, Mathematics, Porto, Portugal

 Background: Spinal mobility is assessed frequently in patients with psoriatic arthritis (PsA) using Bath Ankylosing Spondylitis Metritis Index (BASMI) to provide baseline measurement, monitor changes over time and to assess the impact of clinical interventions. BASMI comprises 4 measures of spinal mobility (cervical rotation, tragus-to-wall distance, modified Schober’s test and lumbar lateral flexion) and one hip mobility measurement (intermalleolar distance).

Objectives: The aim of this study is to investigate the time-course change of BASMI in PsA patients after 6 months of Biologic Disease-modifying Antirheumatic Drug (bDMARD) therapy. The authors also pretend to evaluated, at baseline and after 6 months of treatment, the association between BASMI, disease activity scores and physical function.

Methods: An observational retrospective study was performed in patients with PsA under bDMARD followed in the Rheumatology department of a tertiary university hospital. Were included patients treated with only one bDMARD. Demographic and clinical data were collected from the Rheumatology Diseases Portuguese Register. For spinal mobility calculation BASMI was used. Disease activity was evaluated with Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Activity Index (BAS- DAI). Physical function was assessed with Bath Functional Index (BASFI). The variation of BASMI, ASDAS, BASDAI and BASFI was calculated as the difference between values registered at 6 months and at baseline and presented as Δ. Correlations between ΔBASMI, ΔASDAS and ΔBASFI was calculated using Pearson test.

Results: A total of 55 patients were included. Thirty patients were males (54.5%). The mean age at diagnosis was 44.6 ± 12.6 years and the median disease duration at start of bDMARD was 5.4 years (min: 0.30; max: 25.5). In total, 19 (34.5%) patients had predominant axial involvement, 36 (65.5%) peripheral and 36 (65.5%) enthesopathic. Almost all patients fulfilled the CASPAR criteria for PsA (n=50, 90.9%). According to ASDAS criteria, at the baseline 20 patients (36.4%) had high disease activity and 34 (61.8%) very high. The most used bDMARD was etanercept (n=21, 38.3%) followed by golimumab (n=19, 34.5%) and adalimumab (n=8, 14.5%). Three patients were treated with infliximab, two with certolizumab and other two with secukinumab. Forty-one patients (75.9%) were concomitantly treated with conventional synthetic DMDARs. Axial PsA patients had more limitations in spinal mobility (BASMI mean 4.5 ± 1.5) and more functional limitation (BASFI mean 6.8±1.9) than patients with predominant peripheral involvement (BASMI mean 3.3±1.2, p=0.004; BASFI mean 5.4±3, p=0.004). Statistically significant differences in ASDAS and BASDAI in these two groups were not observed (p=0.332 and p=0.605, respectively). For all patients, BASMI did not vary significantly (p=0.691) at baseline (mean 3.7±1.4) and after 6 months (mean 3.8±1.3) of treatment. Although the ΔBASMI for etanercept was negative (mean -0.12±0.9) and for golimumab positive (0.14±0.8), it was not statistically significant. At baseline there is a significant positive association between BASMI and ASDAS (r=0.439, p<0.001), BASMI and BASDAI (r=0.567, p<0.001) and BASMI and BASFI (r=0.510, p<0.001). However, there was not a statistically significant association between ΔBASMI and: ΔASDAS, ΔBASDAI and ΔBASFI (r=0.158; p=0.269, r=0.019; p=0.096 and r=0.121; p=0.397, respectively).

Conclusion: In PsA patients treated with bDMARDs, at least in short-term follow-up, BASMI does not improve with time. Changes in BASMI did not correlate with changes in disease activity and in functional outcome. Studies with longer follow-up and with more patients are needed to better evaluate these associations.

**AB0826**

PROBABILITY OF SURVIVAL OF USTEKINUMAB IN PSORIATIC ARTHRITIS: A REAL CLINICAL PRACTICE COHORT COMPOSED OF 64 PATIENTS

E. Raya1, P. Morales-Garrido1, I. Jimenez-Molecon1, 1San Cecilio Clinic University Hospital, Rheumatology, Granada, Spain

Background: Psoriatic arthritis (PsA) is an inflammatory disorder of unknown etiology. Several domains are affected as peripheral or axial joints, enthesitis, dactylitis, nails as well as skin. Diverse cytokines have been described in the pathology of PsA as TNF, IL-17 and IL-23. Usteukinumab (UST) is a fully human IgG1κ monoclonal antibody to interleukin 12/23. Its efficacy and safety have been tested in several clinical trials and registries. Nevertheless data from real word evidence studies is needed to understand the effectiveness, safety and behavior of UST in a different population of patients from randomized controlled trials

Objectives: Analyze the persistence of UST 45 and 90 mg along 52 weeks of treatment.

Methods: Drug survival, effectiveness and security of UST were studied in a population of 64 PsA patients treated in the period between August 2014 to October 2019. Drug survival was defined as the time from initiation to discontinuation (stop/switch) of bDMARDs. For the determination of drug survival, Kaplan-Meier survival curves and Cox-regression analyses were used. Effectiveness was described as a reduction in the use of corticosteroids and in the levels of CRP along the study. All adverse events were recorded during the study.

Results: 64 patients were included with a mean follow-up of 57.2 weeks. At baseline the mean age was 47.8 years (8.9), 54.7% of patients were women and 45.3% were male. 31.3% were obese. Mean disease duration was 7.9 (5.0) years. 45.3% presented primary arthropic arthritis; 32.8% axial involvement; 31.3% enthesitis; 80% psoriasis. Patients were 45% bDMARDs-naive; had a previous bDMARDs in 20.3% and ≥ two bDMARDs in 34.4%. 30% of the patients had co-therapy with methotrexate and 29.7% of patients received corticosteroid therapy. Mean CRP was 7.9 (12.7) mg/L. The global probability of survival for UST was 96%, 83.9% and 60% at week 12, 24 and 52 respectively. High UST dose was associated with favorable drug survival (at 52W: UST 45 mg=40.1%; UST 90 mg=75.8%; UST 45 to 90 mg=88.9%) (p=0.008).

The bDMARDs-naive population also correlated with favorable UST survival (at 52W: bDMARDs-naive=66.1% vs bDMARDs-experienced=56.7%), however no statistical significance was found (p=0.196). No difference in survival was observed among patients with or without axial involvement (WS2: axial=58.2% vs non-axial=61.6; p=0.869). UST produced a reduction in the use of corticosteroids (30% vs 16%) and CRP levels (8.7 vs 7.7). Differences were greater in patients treated more than 28 weeks (maximum efficacy described for UST) (corticosteroids: 26% vs 16%; CRP levels: 8.5 vs 4.4; 4.9% of the patients suffered an AE. Most of them were non-serious AE: infections (3.3%) or headache (1.6%). The main cause of treatment discontinuation was lack of efficacy (30%), followed by primary failure (9.4%) and just a 3% due to AE

Conclusion: The persistence of UST was dose-dependent and greater for the UST 90 mg dosage and for the population of bDMARD-naive patients.

Drug survival of UST in the population of patients with axial involvement seems similar to the population of patients without axial affection which provide evidence of the efficacy of the IL23 inhibition in the axial domain of PsA.

UST decreased the use of corticosteroids and CRP levels along treatment.

The security profile of UST was the drug. Only few non-serious AE reported during this study

UST 45 to 90 mg, patients who change from UST 45 to UST 90 mg dosage

IMPACT OF BASELINE BODY MASS INDEX ON THE EFFICACY AND SAFETY OF TOFACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS

C.T. Ritchlin1, A. Ogdie2, J. T. Giles3, J. J. Gomez-Reino4, P. Hellisell5, L. Stockert6, P. Young6, W. Joseph7, R. Mundayat8, D. Graham9, J. Woolcott1, A. B. Romero10, 1University of Rochester Medical Center, Rochester, United States of America; 2University of Pennsylvania, Philadelphia, United States of America; 3Columbia University, New York, United States of America; 4Hospital Clínico Universitario, Santiago de Compostela, Spain; 5University of Leeds, Leeds, United Kingdom; 6Pfizer Inc, Collegeville, United States of America; 7Pfizer Inc, Groton, United States of America; 8Pfizer Inc, Barcelona, Spain

Background: Obesity is highly prevalent in PsA (45%) and is associated with a reduced response to TNF inhibitors. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA.

Objectives: This post hoc analysis assessed tofacitinib efficacy and safety in patients (pts) with PsA by baseline (BL) body mass index (BMI) category.

Methods: Data were pooled from two placebo (PBO)-controlled, double-blind, Phase 3 studies in pts with active PsA and an inadequate response to ≥1 conventional synthetic DMDAR (OPAL Broaden [12 months; NCT01877668]) or ≥1 TNF inhibitor (OPAL Beyond [6 months; NCT01882439]). This analysis included pts randomised to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID or PBO, stratified by BL BMI: <25 kg/m2, ≥25–<30 kg/m2, ≥30–<35 kg/m2, or ≥35 kg/m2. Efficacy and safety were reported to Month (M)3. M3 efficacy outcomes included ACR20/50/70 and HAQ-DI responses, dactylitis and enthesitis resolution rates and changes from BL in HAQ-DI, Short Form-36 Version 2 (SF-36v2) Physical (PCS) and Mental Component Summary (MCS) scores, and Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F) scores. Safety outcomes included adverse events (AEs), such as cardiovascular (CV) events and changes in lipid levels and liver function tests (LFTs).

Results: This analysis included 710 pts: 43.8% were obese (BMI ≥30). At BL, 161 (22.7%) pts had a BMI <25, 238 (33.5%) had a BMI ≥25–<30, 186 (26.2%) had a BMI ≥30–<35 and 125 (17.6%) had a BMI ≥35. Most pts were white (92.5–96.8%), middle-aged (mean: 44.5–51.2 yrs) and female (49.5–66.5%). Greater proportions of obese pts were from Russia/Eastern Europe (35.0%) and USA/Canada (31.8%), vs the rest of the world. At BL, higher BMI correlated with an increased prevalence of metabolic syndrome (4.3% in BMI <25 to 76.0% in BMI ≥35) and CRP levels >2.87 mg/L (4.1% in BMI <25 to 8.4% in BMI ≥35). Higher proportions of pts with a BL BMI ≥35 reported no prior biologic DMARD use, vs pts with a BL BMI ≥35 (33.6%). At M3, efficacy improvements were greater in tofacitinib-treated pts vs BPO-treated pts (Figure 1). In pts with a BMI ≥35, a trend towards fewer pts responding was observed (Figure 1) and mean changes from baseline in SF-36v2 PCS and MCS and FACT-F generally appeared lower (Figure 2) vs pts in lower BL BMI categories. Up to M3, the proportions of pts with AEs, and percentage change from BL in lipid levels and LFTs, were generally similar across all BL BMI categories. Three CV events were reported: non-fatal cerebrovascular accident, transient ischemic attack (both tofacitinib 5 mg BID, BMI ≥30–<35) and coronary artery revascularisation (PBO; BMI ≥35). Limitations include the 3-month observation time, particularly for safety findings, thus longer observation times are warranted.

Conclusion: Regardless of BL BMI, tofacitinib demonstrated greater efficacy than PBO at M3 in pts with PsA. Similar to other advanced therapies, reduced efficacy was generally observed in tofacitinib and PBO pts with a BL BMI ≥35. Tofacitinib safety appeared consistent across all BL BMI categories.

References:

Background: Axial involvement in patients diagnosed of Psoriatic arthritis (PsA) in variable in previous studies. Axial involvement (according GRAPPA criteria) is based upon inflammatory spinal symptoms pain with loss of lumbar mobility and the presence of radiological sacroiliitis and other radiographic signs of spondylitis in patients with PsA.

Objectives: Evaluate the prevalence of axial involvement in PsA an their clinical features.

Methods: All patients included in the monographic PsA consultation database of our second level hospital were analyzed. Demographic, clinical and analytical variables were collected. Statistical analysis was performed using SPSS v.25.

Results: We included 145 patients with PsA (fulfilling CASPAR criteria) with a mean age at diagnosis of 45.4 (±13) years and time of evolution of the disease 9.3 (±6.2) years. The proportion of the affection types were: peripheral 94 (64.8%), mixta 31 (21.4%) and axial 20 (13.8%). Therefore, 51 (35.2%) patients meet criteria for axial involvement, of which 31 (21.4%) also had associated peripheral involvement. Table 1 shows the differences between patients with and without axial disease. Axial involvement was higher in males than women [OR=2.3 (1.1-4.7), p=0.023], HLAb27, determined in 106 patients, was more prevalent in axial PsA than in exclusive peripheral patients, 35% and 4.5%, respectively [OR=11.3 (3.0-42.7), p<0.0001]. We didn't find any differences in other domains of psoriatic disease or gender. Age at diagnosis was lower in patients with HLAb27 positive [35.6 (±12.3) vs 46.2 (±12.1) years, p=0.0001] and in the patients with dactylitis [40.2 (11.8) vs 46.7 (13) años, p=0.018] or uveitis [28.7 (8.5) vs 45.8 (12.8) years, p=0.02], respect patients who did not present them, regardless of HLAb27. No differences were found in age between patients with axial or peripheral disease [44.6 (±13.3) vs 45.9 (±12.6) years, p=0.56], neither other domains like skin psoriasis, onichopathies, dactyliases or enthesitis. Patients with axial involvement had overweight (BMI >25) more frequently than peripheral disease [OR=0.4 (0.2-0.8), p=0.01]. We didn't find any differences in other comorbidities (arterial hypertension, diabetes, hyperlipemia, hyperuricemia, ischeimic heart disease, depression) between patines with axial or peripheral disease.

Acknowledgments: Medical writing support was provided by Mark Bennett of CMC Connect, McCann Health Medical Communications, and funded by Pfizer Inc.

Conclusion: Prevalence of axial involvement in our cohort (35.2%) is found within the data reported in other studies (25-70%). Nevertheless, we found less prevalence of HLAB27 positive than other reports. Patients with HLAB27 positive, dactylitis or uveitis are diagnosed at earlier ages.

INFLAMMATORY BOWEL DISEASE IN PSORIATIC ARTHRITIS. STUDY OF 306 PATIENTS FROM A SINGLE UNIVERSITY CENTER. PREVALENCE, CLINICAL FEATURES AND RELATIONSHIP TO BIOLOGIC THERAPY.

L. Sanchez-Bilbao1, D. Martinez-Lopez2, N. Palmou-Fontana1, S. Astemero3, M. A. Gonzalez-Gay1, R. Blanco1,1. H.U. Marqués de Valdecilla, Rheumatology, Santander, Spain; 3H.U. Marqués de Valdecilla, Dermatology, Santander, Spain

Background: Inflammatory bowel disease (IBD), which includes Crohn’s disease (CD), ulcerative colitis (UC), and undifferentiated colitis may be related to psoriasis and psoriatic arthropitits (PsA). Biologic therapy (BT) is useful in PsA and IBD but paradoxically has been related to IBD.

Objectives: In a wide series of PsA, our aim was to assess a) the epidemiological and clinical features of associated IBD and b) its relationship with BT.

Methods: All unselected consecutive patients studied in a single reference University Hospital with: a) PsA (CASPAR criteria) and b) IBD: CD, UC and undifferentiated colitis diagnosed by endoscopic patterns, clinical criteria and laboratory tests. A comparative study between patients with and without IBD was performed.

Results: We studied 306 (165 women/141 men) patients with PsA; mean age at PsA diagnosis of 41.7±15.79 years; delay of diagnosis from the onset of symptoms of 2.6±2.0 years. IBD (CD=6; UC=1 and undifferentiated colitis=3) was observed in 10 of 306 (3.3%, 8 women/2 men). A significant more frequency of enthesitis, positive HLA-B27 and non-significant more severe PsA (axial, and hip involvement, and a higher BASDAI, BASFI, DAPSA, PASI) was observed in patients with associated-IBD (TABLE).

IBD was present before PsA in 5 patients and in the other 5, after 9.6±15.3 years of PsA diagnosis. There was a difference in frequency and percentage. Correlation analysis was calculated using Spearman’s rank correlation coefficient. P<0.05 was considered statistically significant.

Results: 42 PsA patients were included. Mean age was 56 years old (47.25-62.75) and 54.76% were female (n=23). 92.86% (n=39) of the patients had plaque Psoriasis and 87.8% (n=36) had peripheral joint involvement.

Frequency of comorbidities in PsA are shown in Table 1. 31 (73.8%) of the patients were treated with topical therapy, 3 (7.14%) with phototherapy, 31 (73.8%) with Methotrexate and 17 (41.46%) with biologics and JAK inhibitor. Activity Disease Index and Lipid profile are shown in Table 1 and 2. There was not association between APO A/APO Coefficient with DAPSA (rho=0.013; p=0.940) and MDA (rho=-0.029; p=0.867).

Conclusion: In spite of the presence of cardiovascular factors in the majority of PsA patients, lipid profile is not correlated with disease activity in this population.

COMPARISON OF DIFFERENT REMISSION INDICES IN PATIENTS WITH PSORIATIC ARTHRITIS: A POST HOC ANALYSIS OF DATA FROM PHASE 3 TOFACITINIB STUDIES

1Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina; 2Griffith University, Brisbane, Australia; 3Medical University of Vienna, Vienna, Austria; 4Swedish Medical Center and University of Washington, Seattle, United States of America; 5Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; 6Pfizer Inc, Buenos Aires, Argentina; 7Pfizer Inc, Collegeville, United States of America; 8Pfizer Inc, New York, United States of America; 9Pfizer Inc, Groton, United States of America; 10Pfizer Inc, Lima, Peru

Background: An international task force has agreed that remission and low disease activity (LDA) are treatment targets for patients (pts) with PsA, and recommends the Disease Activity Index in Psoriatic Arthritis (DAPSA) and minimal disease activity (MDA) to assess disease activity states. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA.

Objectives: In this post hoc analysis, we compared DAPSA LDA with MDA, and DAPSA remission with very low disease activity (VLDA) and DAS28-3(CRP) remission, in pts with PsA receiving tofacitinib.
