Conclusion: Analysis of the burden of disease and the use of medical resources in newly identified EGPA patients revealed that EGPA patients require hospitalizations and AHVs, in addition to exposure to high doses of OCS. The appropriate medication for the treatment of EGPA to reduce burden on patients may need consideration the pathophysiological state of EGPA patients.

METHOTREXATE FOR ESOPHAGEAL GRANULOMATOSIS WITH POLYANGIITIS IN REAL WORLD DATA

T. Shoda1, T. Takeuchi2, K. Nagai1, J. Konma1, S. Arawaka1, Yodogawa Christian Hospital, Clinical Immunology and Rheumatology, Osaka, Japan; 2Osaka Medical College, Internal Medicine (4), Osaka, Japan

Objectives: To investigate the treatments of eosinophilic granulomatosis with polyangiitis (EGPA) and evaluate the usage of methotrexol in clinical settings.

Methods: The subjects were consecutively EGPA patients who were hospitalized and treated at our department and the Rheumatology, Department of Internal Medicine IV, Osaka Medical College between 2002 and 2018. Their clinical data, treatments, and courses were examined, and the usage of methotrexol was evaluated.

Results: Of 49 EGPA patients, 41 could be analyzed (14 males and 27 females, mean age of onset: 56.4 years). The percentage of positive ANCA was 31.7%, and affected sites were peripheral nerve (92%), central nervous system (17%), skin (51%), ENT (39%), lungs (29%), heart (22%), digestive organs (12%), and kidneys (15%). Remission induction therapy was performed with PSL (41 cases, 100%), PSL pulse (16 cases, 39%), IVCy (17 cases, 41%), RTX (4 cases, 10%), IVIG (22 cases, 54%), AZA (22 cases, 54%), MTX (4 cases, 10%), MMF (2 cases, 5%), MIZ (1 case, 2%), and MEPO (1 case, 2%). Maintenance therapy was performed with PSL (41 cases, 100%), AZA (21 cases, 51%), MTX (6 cases, 15%), MMF (2 cases, 5%), MIZ (3 cases, 7%), and MEPO (10 cases, 24%). In 10 patients who received methotrexol, the percentage of positive ANCA was 40%, and the median dose of PSL was reduced from 9.5mg to 5.5mg after administration. Neither relapses nor adverse events occurred in patients who had received methotrexol.

Conclusion: Methotrexol reduced the dose of steroids and improved tolerability in EGPA patients with or without ANCA.

FR10220

EFFICACY OF ADJUVANT METHOTREXATE IN PATIENTS WITH GIANT CELL ARTERITIS TREATED WITH TOCILIZUMAB PLUS PREDNISONE TAPERING: SUBANALYSIS OF THE GIACTA TRIAL

S. Mohan1, J. Han1, J. H. Stone2, Genentech, South San Francisco, United States of America; 2Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, United States of America

Background: There is conflicting evidence regarding the efficacy of methotrexate (MTX) in giant cell arteritis (GCA).1,2 The benefit of adjunctive treatment with MTX remains to be determined in these patients. Data are presented from a subanalysis of the 52-week, double-blind, randomized controlled GIACTA trial in a subgroup of patients with GCA who received MTX in addition to tocilizumab (TCZ) or placebo (PBO) in combination with prednisone tapering.

Objectives: Assess the efficacy of adjunctive MTX in patients with GCA.

Methods: In part 1 of GIACTA, patients were randomly assigned to TCZ administered subcutaneously every week (QW) or every other week (Q2W) plus 26-week prednisone tapering or PBO plus 26-week (PBO+26) or 52-week (PBO+52) prednisone tapering.3 MTX could be initiated at a stable dose during screening, continued during the double-blind period, and reduced or discontinued at the investigator’s discretion according to disease status. Efficacy was determined as the achievement of sustained remission (absence of GCA flare and C-reactive protein <1mg/dL, from weeks 12 to 52 and adherence to the prednisone taper).

Results: During part 1 of GIACTA, 28 of 250 (11%) treated patients received adjunctive MTX for a median duration of 52.1 weeks: 14 of 149 (9%) TCZ-treated patients received MTX for a median of 51.9 weeks. Baseline characteristics (Table 1) were balanced between patients who received and did not receive MTX, except for longer disease duration and a higher proportion of patients with relapsing GCA among those who received MTX. The MTX-treated patients tended to have lower prednisone doses at baseline. The median cumulative glucocorticoid dose received over 52 weeks was similar between PBO-treated patients who received MTX and those who did not (3033mg and 3872mg, respectively) and between TCZ-treated patients who received MTX and those who did not (1339mg and 1862mg, respectively). Sustained remission was achieved by 6 of 14 (43%) patients treated with TCZ + MTX and by 76 of 135 (56%) patients treated with TCZ without MTX (Figure 1). None of the 14 PBO + MTX-treated patients achieved sustained remission, whereas 16 of 87 (18%) patients who received PBO without MTX achieved sustained remission (among all patients in the primary analysis,8 82 of 149 [55%] in the TCZ groups and 16 of 101 [16%] in the PBO groups achieved sustained remission). The mean annualized relapse rate at 52 weeks was not different between the MTX-treated and MTX-untreated groups for the TCZ (0.76 with MTX vs 0.47 without MTX; p = 0.2549) or PBO (1.89 vs 1.46; p = 0.4611) groups (p values based on t tests). Rates of adverse events per 100 patient-years were numerically higher in MTX-treated than MTX-untreated patients: 1267 and 858, respectively, in the TCZ groups and 1331 and 952, respectively, in the PBO groups.

Conclusion: Preliminary data from a small subgroup of patients suggest that adjunctive MTX does not increase the likelihood of sustained remission, reduce disease relapse rate, or improve steroid sparing in patients with GCA. Response rates in TCZ-treated patients appear to be independent of treatment with MTX. The results from this post hoc analysis in a small sample of GCA patients treated with MTX should be confirmed in larger studies.

Giant Cell Arteritis Presenting as Fever of Unknown Origin and Delay in Diagnosis: Analysis of Two Different Decades

R. Talarioc, C. Stagnaro1, F. Ferroc, A. Figliomeni1, L. Caril, M. Mosca1 on behalf of n.1. Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background: Giant cell arteritis (GCA) represents the most common primary vasculitis of the elderly, that usually involves large and medium sized arteries. The wide spectrum of clinical manifestations can extensively vary, from cranial symptoms, such as headache, jaw claudication or visual alterations, to constitutional symptoms, like fever, weight loss or asthenia. Fever of unknown origin (FUO) may sometimes represent the initial symptom of GCA and when it is not associated with other typical GCA features, the diagnosis can be uncleally delayed.

Objectives: The primary aim of the study was to identify the prevalence of GCA patients presenting as FUO. The secondary aims were to identify the delays in the diagnosis and to compare them between the last two decades.

Methods: Epidemiological and clinical data of 274 GCA patients followed in the last 20 years in our Unit were analysed. We quantified the latency period between the onset of signs and symptoms and the final diagnosis of GCA in terms of months.

Results: One hundred and eighty-five patients (49 males and 136 females, mean ± SD age at the onset 71±7 years) had shown at the onset signs and symptoms suggestive of GCA (new onset headache and/or scalp pain 86%, jaw claudication 39%, vision loss 35%, abnormal temporal artery on examination 49%, dizziness 31%) while 89 patients (33 males and 56 females, mean age at the onset 69±4 years) were sent to our attention just for the onset of FUO and for an increase of erythrocyte sedimentation rate and C-reactive protein not otherwise justified. After an extensive work-up aimed at excluding any kind of infection, malignancy or hematological disorder, the patients with FUO performed a temporal artery biopsy (TAB) and/or a 18F-fluorodeoxyglucose positron emission tomography (18F-FDG PET). The results from histology and/or imaging allowed us to perform the diagnosis of GCA in all cases; moreover the PET alterations reported were characterized by a (18)FDG uptake of the aortic arch and its major branches, including the carotid, subclavian, thoracic aorta and, less frequently, the abdominal aorta. Considering the different decades, the mean latency period between the onset of FUO and the diagnosis of GCA was 6±3 months in the decade from 2000 to 2010 and 3±2 months in the last decade, that was significantly higher compared with the mean latency period between the onset of signs and symptoms suggestive of GCA and the definitive diagnosis (3±1 months) in the other patients of the cohort in the first decade. Notably the latency period between the onset of signs and symptoms suggestive of GCA and the definitive diagnosis was more close (2±1 months) to the latency period of diagnosis in FUO presenting GCA in the last decade.

Conclusion: Our data underline that there is a major focus on the diagnosis of GCA, even when the presentation is not typical; this is probably due to the major knowledge reached in the last decade, to an improved sensibilization regarding the different profiles of presentation and surely on the bigger use of 18F-FDG PET in the work-up of GCA patients.

Magnetic Resonance Imaging of Muscle Involvement in Polyarteritis Nodosa

R. D. Vargas Ruiz1, J. A. Gómez Rosero1, C. Muñoz2,3, D. Jaramillo Arroyave2,3,4, L. Hernández2,5, L. A. González2, G. Vásquez2, M. Restrepo Escobar1, A. Vanegas1,2, Universidad de Antioquia, Medellín, Colombia; 2Hospital Universitario San Vicente Fundación, Medellín, Colombia; 3IPS Universidad, Servicios de Salud Universidad de Antioquia, Medellín, Colombia; 4Grupo de Epidemiología y Bioestadística Universidad CES, Medellín, Colombia; 5Clínica Universitaria Bolivariana, Medellín, Colombia

Background: Muscle involvement is frequently reported in polyarteritis nodosa (PAN), mostly as myalgia, muscle swelling, and gait difficulty due to intramuscular arteries involvement, peripheral neuropathy, or myositis with slightly or no elevation of muscle enzymes. Magnetic resonance imaging (MRI) findings of compromised muscles have been reported in isolated cases, mainly as a limited form of PAN, however, muscular involvement patterns in MRI of patients with PAN have been recently described.

Objectives: To describe MRI of legs findings in patients with PAN in a tertiary center from Medellin-Colombia.

Methods: It was performed a retrospective cross-sectional descriptive study of 15 adult patients who were clinically assessed as having PAN and who had undergone MRI of legs between January 2011 and December 2019. Characteristics already informed in previous studies, affected structures (muscle, subcutaneous tissue, and bone) and pattern of hyperintensities were described as diffuse pattern (signal alterations affecting the entire area of the involved muscle), patchy pattern (areas of hyperintensities alternating areas of normal muscle signal intensity), and fluffy nodular pattern or cotton-wool appearance (round hyperintense lesions with fluffy margins centered on blood vessels).

Results: Clinical characteristics: myalgia, especially calf pain, was the most frequent muscular complaint; other clinical manifestations were: constitutional symptoms (80%), arthralgia or arthritis (50%), mono/polynuropathy (33%), subcutaneous nodules (33%), livedo reticularis (20%), lower limbs ulcers (13%), abdominal symptoms (13%), and purpura (7%). MRI findings: bilateral muscular edema was found in all patients (100%), fatty infiltration (20%), edema of the subcutaneous cellular tissue (20%), and muscular atrophy (13%) were also described. A diffuse pattern occurred in 46% (n=7) of patients (figure panel A), a patched pattern (figure panel B) in 46% (n=7), and a fluffy nodular pattern or cotton-wool appearance (figure panel C) in 6% (n=1). The most frequently affected muscular group was gastrocnemius and soleus (67%), followed by anterior tibialis (27%), plantar, long peroneus, first finger flexors, and long flexors only affected in 7%. Bone involvement was found in 53%, being the tibia the most affected, followed by the fibula and the calcaneus. MRI led to guide the site of muscle biopsy to prove histological medium-size vasculitis in half of the patients.

Conclusion: in patients with PAN suspicion who have muscular complaints, especially calf pain, MRI arises as an important diagnostic tool, and also as a guide to muscular biopsy to prove vasculitis. The patterns associated with PAN are diffuse, patched or nodular hyperintensities in gastrocnemius and soleus with or without bone compromise.

uniform. Recently, based on previous clustering analysis and clinical, histological, serological and prognostic aspects three subcategories of AAV have been proposed and named as: non-severe AAV, severe PR3-AAV and severe MPO-AAV [1].

Objectives: In line with these attempts to subcategorize AAV we decided to use latent class analysis (LCA) on a large multicenter cohort of polish AAV patients from POLVAS [2] registry to identify potential new subphenotypes or confirm already proposed ones.

Methods: Latent Class Analysis (LCA) approach was used as a model based clustering method of objects described by dichotomous (e.g., gender: ANCA status – cANCA, pANCA; organ involvement - skin, eye, ENT, respiratory, heart, GI, renal, urinary, CNS, peripheral nerves) and polytomous (number of relapses) variables supported by quantitative covariates (e.g., age at diagnosis, CRP at diagnosis, maximal serum creatinine concentration ever).

Results: Results of LCA on our AAV group returned four class model of AAV subphenotypes, confirming existence of the previously proposed by Mahr at al. [1] and revealed fourth – previously not described clinically relevant subphenotype. To this fourth class - belong patients only with GPA, diagnosed at young age, with multiorgan involvement, high relapse rate and relatively high risk of death.

Table 1. AAV subcategorization – summary of clinical characteristics and ANCA specificity

FR01025

THE CLINICAL FEATURES AND OUTCOME OF VENA CAVA INVOLVEMENT IN BEHÇET’S DISEASE

J. Zhou1, J. Liu1, Y. Wang1, W. Zheng2, 1Peking Union Medical College Hospital, Rheumatology, Beijing, China; 2Peking Union Medical College Hospital, Radiology, Beijing, China

Background: Behçet’s disease (BD) is a systemic disease that can affect vessels of any size and type. However, only limited cases of BD patients with vena cava involvement have been reported.

Objectives: To investigate the clinical features and outcome of vena cava involvement in BD patients.

Methods: We retrospectively reviewed the clinical data of BD patients with vena cava involvement in our institute from August 2001 to October 2019. The treatment and outcome of these patients were also analyzed.

Results: Fifty BD patients with vena cava involvement were included. The median interval between BD onset and diagnosis of vena cava involvement was 2.8 (range 0-19.4) years. Superior vena cava (SVC) involvement was detected in 22 (44.0%) patients, and 21 patients had typical manifestations of SVC syndrome. Inferior vena cava (IVC) involvement was detected in 33 (70.0%) patients, including 7 patients diagnosed with Budd-Chiari syndrome. Seven patients had both superior and inferior vena cava involvement. Forty-five (90.0%) patients had venous involvement other than vena cava, including 19 patients with common iliac thrombosis, 12 patients with common femoral vein thrombosis, 11 patients with external iliac vein thrombosis, etc. For the other BD manifestations, oral ulceration was presented in all patients, followed by genital ulceration (35, 70.0%), Erythema nodosum (27, 54.0%) and pathergy reaction (25, 50.0%). Thirteen (26%) patients had eye involvement. Ten (20%) patients had pleural and/or pericardial effusions. Eleven (22.0%) patients had pulmonary thromboembolism and 4 (8.0%) patients had arterial involvement.
Scleroderma, myositis and related syndromes

FRIDAY, 05 JUNE 2020

Scleroderma, myositis and related syndromes

Inflammatory markers were significantly elevated in 41 (82.0%) patients when the vena cava involvement developed, the mean ESR was 34.0±29.2mm/hr, and the median CRP level was 19.9±(2.1773)mg/L. The mean BDCAP2006 score of all patients was 4.5±1.4. Glucocorticoid was used in 47 (94.9%) patients after vena cava involvement was diagnosed, and cyclophosphamide was the first-choice immunosuppressant. Forty-one (82.0%) patients received anticoagulation treatment. Five patients had received placement of IVC filter, and 3 patients had taken balloon dilation of IVC. With a mean follow up of 4.1±3.8 years, 45 patients (90.0%) achieved clinical improvements, 6 patients (12.0%) had relapse of vascular involvement, 5 patients (10.0%) died. The respective estimated cumulative 1- and 5-years relapse-free rates were 90.9% and 83.1%, and the respective estimated 1- and 5-years survival rates were 95.9% and 90.1%.

Conclusion: Vena cava involvement is a rare complication in BD patients. The prognosis of these patients is relatively optimistic after proper treatment. To the best of our knowledge, our study is the largest cohort of BD patients with vena cava involvement.

OPTICAL COHERENCE TOMOGRAPHY OF THE SKIN DETECTS SCLERODERMA CHANGES IN CLINICALLY UNAFFECTED SKIN: AN OPPORTUNITY FOR EARLY DETECTION OF SYSTEMIC SCLEROSIS

G. Abignano1,2, D. Temiz Karadag1,3, O. Gundogdu1, G. Lettieri1, M. C. Padula1, A. Padula1, P. Emery2, S. D’Angelo2, F. Del Galdo2.

1Rheumatology Institute of Lucania (IREL), Rheumatology Department of Lucania, San Carlo Hospital, Potenza, Italy; 2Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 3Canakkale State Hospital, Rheumatology Clinic, Canakkaile, Turkey; 4Department of Biomedical Engineering, Kocaeli University, Kocaeli, Turkey; 5Radiology Department, San Carlo Hospital, Potenza, Italy

Background: The Very Early Diagnosis Of Systemic Sclerosis (VEDOSS) study has shown that 82% of patients with Raynaud’s Phenomenon, specific ANA positivity and scleroderma pattern at nail fold videocapillaroscopy will fulfill classification criteria within 5 years. This is suggesting that there is a subclinical window of opportunity to diagnose systemic sclerosis (SSc) before clinical manifestations occur. In this scenario, a non-invasive tool to diagnose SSc in clinically unaffected skin might improve the early detection of disease in at-risk patients. Optical coherence tomography (OCT) of the skin has been shown to be a sensitive and accurate biomarker of skin fibrosis in SSc.

Objectives: Here we aimed to assess the ability of skin OCT to “detect” SSc in clinically unaffected skin from a multicentre cohort.

Methods: Dorsal forearm skin of SSc patients and matched healthy controls (HC) was evaluated using VivoSight scanner (Michelson Diagnostics). Mean A-scans (mean OCT signal plotted against depth-in-tissue) were derived and previously described. Minimum Optical Density (MinOD), Maximum OD (MaxOD) and OD at 300 micron-depth (OD300) were calculated. Clinical involvement was assessed by an operator blinded to OCT findings using the mRSS. Receiver-operating characteristic (ROC) curve analysis was carried out for MinOD, MaxOD, and OD300 to evaluate their ability to discriminate between SSc and HC. Statistical analysis was performed using GraphPad Prism version 7.0.

Results: One hundred seventy four OCT images were collected from 87 subjects [43 SSc (39 Female, mean age 49.7±9.1 years) and 44 gender/age-matched healthy controls (HC) (36 Female, mean age 50.2±8.3 years)] in two different SSc centres. All patients fulfilled classification criteria for SSc. OCT measures demonstrated discriminative ability in SSc skin detection with any clinical skin involvement (0-3 at site of analysis) with an AUC of 0.73 (MinOD, 95%CI 0.64-0.81), 0.77 (MaxOD, 95%CI 0.70-0.85) and 0.82 (OD300, 95%CI 0.76-0.89); p<0.0001 for all as previously indicated. Most importantly, all three measures showed comparable performance in detecting scleroderma also in clinically unaffected skin (mRSS=0 at site of analysis), with an AUC of 0.7 (95%CI 0.6-0.81, p=0.001), 0.72 (95%CI 0.61-0.83, p=0.0003) and 0.72 (95%CI 0.61-0.83, p=0.00003) for MinOD, MaxOD and OD300 respectively.

Conclusion: Virtual biopsy by OCT recognises clinically unaffected skin of SSc patients from the HC skin. This is consistent with gene array data showing that scleroderma specific signatures are consistent in affected and clinically unaffected skin. These results inform future studies on at risk patients with clinically unaffected skin which may define a role for OCT in detecting subclinical SSc.

FR01227

A USABILITY SURVEY OF WRIST MOUNTED DISPOSABLE HEAT PAD ON RAYNAUD’S PHENOMENON IN PATIENTS WITH CONNECTIVE TISSUE DISEASES

N. Azuma1, T. Furukawa1, Y. Shimaa, K. Matsua, 1Hyogo College of Medicine, Division of Diabetes, Endocrinology and Clinical Immunology, Nishinomiya, Japan; 2Osaka University Graduate School of Medicine, Department of Thermo-therapeutics for Vascular Dysfunction, Suita, Japan

Background: For patients with connective tissue diseases (CTD), vasodilators are used to treat Raynaud’s phenomenon (RP), they are difficult to control only by medication. Although physicians recommend the use of a portable handwarmer or gloves to patients with CTD presenting with RP, sustained heat-retention effects cannot be obtained from them because the patients’ daily life-related activities prevent their continued use. Since the wrist mounted disposable heat pad maintains the degrees of freedom of the hands and fingers and can remain usable during the daily activities, we considered this heat pad as a useful and highly practical heating method for CTD patients presenting with RP.

Objectives: To investigate the usability and changes in symptoms resulting from the use of the wrist mounted disposable heat pad in CTD patients presenting with RP.

Methods: Subjects were 23 outpatients with CTD presenting with RP (23 females, mean age 62.6 years; mean duration following the onset of RP 10.3 years; 12 systemic sclerosis, 5 mixed connective tissue disease, 5 Sjögren’s syndrome, and 1 systemic lupus erythematosus) who had used the wrist mounted disposable heat pad (put the pad in a specifically designed holder and wrap it around wrist joint (max. temperature 42 degrees Celsius, heat-retention time 6 hours)). We investigated through interviews with them the use situations, usability, and changes in RP. During their using the heat pad, medication and daily life-related precautions against RP continued to be implemented as before.

Results: Many patients had no knowledge of the heat pad (n=17, 73.9%). The most common wearing time of the heat pad was 5–6 hours (n=8, 34.8%). As for scenes of wearing the heat pad, patients who wore the pad when being out of the home accounted for the highest proportion (n=16, 69.6%), and as follows: at home (n=6, 26.1%), during kitchen work (n=3, 13.0%), and during housework (n=2, 8.7%). 17 patients (73.9%) replied that usability was “good” and 18 (78.3%) replied that usability was “better” compared with conventional measures. Moreover, many patients (n=16, 69.6%) replied that RP and associated symptoms had become reduced or alleviated. No patients replied that RP and associated symptoms had become exacerbated or severer. In terms of advantages of using the heat pad, patients who replied that the site on which the pad was mounted was felt to be warm accounted for the highest proportion (n=8, 34.8%), and those who replied that sites other than where the pad was mounted (such as fingertips, hands, and arms) were also warmed accounted for virtually the same proportion (n=7, 30.4%). Over 60% of the patients (n=14, 60.9%) replied that symptoms associated with RP (skin color, cold sensation, and pain) had become reduced or disappeared. In terms of disadvantages of using the heat pad, patients who replied that it was bothersome to use the pad accounted for the highest proportion while other patients made replies referring to cost and bad appearance. No significant accident occurred and as many as 17 patients (73.9%) replied that they would like to continue to use the heat pad in the future.
Conclusion: There have been few reports evaluating the usefulness of a heat pad for RP. The wrist mounted disposable heat pad was thought to be a heating method having the potential to achieve high levels of usability and practicality on CTD patients presenting with RP. Given that the heat pad alleviated RP or caused sites other than where the pad was mounted to be felt warm even though it did not directly heat the hands and fingers, the pad seemed to have usefulness attributed to the heating of the wrist. Although the heat pad seems to be an excellent method for addressing RP in patients daily lives, we hope that this heat pad will be evaluated on a larger number of patients with the addition of objective indices.

FRIO228
TOFACITINIB IN THE TREATMENT OF SKIN AND MUSCULOSKELETAL INVOLVEMENT IN ADULT PATIENTS WITH EARLY SYSTEMIC SCLEROSIS, EVALUATED BY ULTRASOUND

R. Karalilova1,2, T. Sapundzhieva1,2, A. Batalov1,2, M. Matucci-Cerinic9, A. Batalov1,2, 1Medical University of Plovdiv, Department of Internal Diseases, Plovdiv, Bulgaria; 2University Hospital ‘Kaspela’; Rheumatology Clinic, Plovdiv, Bulgaria; 3University of Florence, Division of Rheumatology, Florence, Italy

Background: The whole management of systemic sclerosis (SSc) remains to be defined while trials mainly focus on the treatment of different organ involvement and disease-modifying treatments are still not available.

Objectives: To assess the safety and efficacy of tofacitinib (TOF) treatment on skin and musculoskeletal involvement as compared to methotrexate (MTX) treatment in patients with early SSc.

Methods: In this 52-week, prospective, investigator-initiated, open-label, single-centre study, 66 patients with SSc were enrolled. Thirty-three patients received 5mg of oral TOF twice a day; and thirty-three received 75-10mg of MTX weekly. The primary outcome measures were: skin fibrosis improvement at week 26, assessed by the reduction in skin thickness - evaluated by the modified Rodnan skin score (mRSS) and the ultrasound (US) measured skin thickness; improvement in the musculoskeletal involvement, assessed by the reduction in the joint and tendon score (US10SSc score); and adverse events from baseline to week 26. The dynamics in the outcome measures within each group were examined through Wilcoxon tests and between-group comparisons were performed through Mann-Whitney U and Chi-square tests.

Results: At baseline, both groups of patients had similar median scores with no significant differences on all measures: mRSS (p = 0.589), US measured skin thickness (p = 0.822), and US10SSc score (p = 0.918). At week 26, significant differences were observed between the two treatment groups as the TOF treated patients showed a greater reduction in mRSS and musculoskeletal manifestations. In the TOF group, the median mRSS score decreased by 50% from 24 to 12 (IQR = 7.50) versus a smaller decrease of 8.70% in the MTX group, from 23 to 21 (IQR = 8.00), p < 0.001. The median US measured skin thickness in the TOF treated patients decreased by 12.87% from 1.71 to 1.49 (IQR = 0.31) versus a decrease of 4.73%, from 1.69 to 1.61 (IQR = 0.52) in the MTX group, p = 0.040. The US10SSc median score in the TOF group decreased by 56.25% from 16 to 7 (IQR = 6.50) versus a decrease of 12.5% in MTX group from 16 to 14 (IQR = 10.50), p < 0.001. There was no significant difference between the groups in the number of adverse events from baseline to week 26. No cases of herpes zoster and deep vein thrombosis were observed in the TOF group.

Conclusion: The data show that in early SSc TOF may lead to a significant improvement of skin thickness, measured with the mRSS and US, and of the musculoskeletal involvement, measured by the US10SSc score. TOF has also shown a satisfactory safety profile.

THE IMPACT OF SYSTEMIC SCLEROSIS ON BODY IMAGE PATIENTS

L. Brites1, F. Costa, L. Saraiva1, A. R. Cunha2, J. A. P. Da Silva1, T. Santiago1,2, M. J. Salvador1,2,3, Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Centro Hospitalar Baixo Vouga, Aveiro, Portugal; 3Faculdade de Medicina de Coimbra, Coimbra, Portugal

Background: Satisfaction with body image has a major impact in quality of life. Systemic sclerosis (SSc) is a can result in disfiguring physical changes.

Objectives: Our aim was to determine the impact of systemic sclerosis on body image using the Satisfaction with Appearance Scale (SWAP). (1)

Methods: Cross-sectional study including patients satisfying the 2013 American College of Rheumatology criteria for SSc diagnosis, aged ≥ 18 years, treated in a tertiary Rheumatology Department. Demographic and clinical data were collected from Reuma.pt and clinical records. All patients provided informed consent and fulfilled SWAP questionnaire, which consists of 14 questions in 4 subscales: satisfaction with facial appearance, satisfaction with non-facial appearance, social discomfort due to appearance and perceived social impact of appearance. Patients rate each item on a numerical rating scale from 1 (strongly disagree) to 7 (strongly agree). Scores for the facial and non-facial appearance range from 0-24 and scores for the social discomfort and perceived social impact subscales range from 0-18. Total SWAP score can range from 0-84 and higher values indicate greater dissatisfaction with appearance and poorer body image. A descriptive analysis was used to summarize demographic and clinical data; categorical variables were described using frequencies; and continuous data using mean and standard deviation. Correlation between variables [Rodnan, age, disease duration, Hospital Anxiety and Depression Scale (HADS) and Short Form Health Survey (SF36)] and SWAP score was tested with Pearson or Spearman coefficient, as appropriate. Scores of SWAP and its subscales in preclinical, limited and diffuse forms of SSc were compared using ANOVA test. Analyses were performed with SPSS Statistics, V.21 and p<0.05 was considered statistically significant.

Results: We enrolled 38 patients, 84.2% (n=32) female, with mean age 60.3±14.5 years and mean disease duration 13.3±5.6 years. All but one were caucasian. Fifty percent (n=19) had a limited form, 26.3% (n=10) had preclinical SSc and 23.7% (n=9) had a diffuse form of SSc. Regarding the autoantibodies, 5.3% (n=2) had anti-PM antibodies and 2.6% (n=1) had anti-Scl-70 antibodies. The median of Rodnan scores was 4 (IQR 0-9). The total mean SWAP score was 44.8±12.5 with worse results at “Satisfaction with facial appearance” subscale (mean score 14.4±6.1). There is no statistically significant difference between facial and non-facial appearance subscales in preclinical, limited and diffuse forms of SSc were compared using ANOVA test. Analyses were performed with SPSS Statistics, V.21 and p<0.05 was considered statistically significant.

Conclusion: We found no significant differences between preclinical, limited or diffuse forms. SWAP scores were not significantly correlated with the total Rodnan score, age or disease duration. Contrary to our expectations SWAP did not show any relationship with depression, anxiety (HADS) or quality of life (SF-36).

THE 2009-2019 SURVIVAL AND MORTALITY PREDICTORS IN A LARGE MULTICENTRE SYSTEMIC SCLEROSIS COHORT

F. Cacciapaglia1, E. De Lorenzi2, A. Corrado3, L. S. Bollero2, M. Fornaro1, F. Montini1, L. Ursu1, L. Verardi2, A. Altomare3, F. P. Cantatore2, E. Gremsere2, F. Iannone1,1Rheumatology Unit, Department of Emergency and Organ Transplantations - University and AOU Policlinico of Bari, Bari, Italy; 2Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy; 3Rheumatology Unit, Department of Medical and Surgical Sciences - University of Foggia, Foggia, Italy

Background: Systemic sclerosis (SSc) is one of the connective tissue diseases with the poorer prognosis and disease-related causes, particularly pulmonary fibrosis, PAH and cardiac involvement, accounting the most deaths.

Objectives: This multicentre study aimed to evaluate the global survival and any predictor of mortality in a large multicentric cohort of SSc patients.

Methods: We performed a retrospective analysis examining the medical records of our longitudinal SSc cohorts with a median (IQR) follow-up of 11 (6-18) years from 3 Scleroderma Units since January 2009. All clinical, laboratory and instrumental findings have been recorded and analyzed using Chi-squared tests, Kaplan-Meier curves, log-rank tests, and Cox proportional hazards models.

Results: Data from 750 SSc patients (91.9% female; mean (SD) age at first Non-Raynaud symptom 48.4 (15.3) years, median (IQR) disease duration 3 (0-8) years; diffuse cutaneous involvement 162 (21.6%) patients fulfilling the 1980 ARA and/or 2013 ACR/EULAR classification criteria, were collected. All patients were positive for ANA, anti-Topo-I Abs were found in 235 (31.3%) and Cenp-B Abs in 300 (40%) patients. 98 (13.1%) patients were positive to other Abs (Anti-RNA polymerase III, anti-Pm/Scl) and anti-ENA were negative/unknown for 117 (15.6%) patients. Intestinal lung disease (ILD) was present in 202 (26.9%), pulmonary arterial hypertension (PAH) was found in 29 (3.9%), and 50/750 (6.7%) patients presented pulmonary hypertension combined with ILD (PH-ILD). The overall 10-years survival was 93.1% and, it was significantly impaired by the presence of ILD, PAH or PH-ILD (Figure). The univariate analysis showed that female gender, higher age at first Non-Raynaud symptom, earlier referral to a tertiary Scleroderma center, absence of any ENA antibodies, and PH-ILD presence were survival predictors. After multivariate analysis, the significance of PH-ILD was lost [Table]. Disease duration, basal Rodnan skin score, smoking, renal or gastrointestinal comorbidities, NYHA functional class, steroid or immune-suppressive treatments did not reach the statistically significance.

Conclusion: Our study demonstrated a global 10-years survival rate over 93%. Male patients and rapid evolution of Non-Raynaud symptoms represent the main death predictors in our SSc cohort. A rapid referral to a tertiary rheumatological centre and early treatment with effective agents are associated to a better prognosis.

Table. Prognostic factors for 10-years survival at univariate and multivariate analysis.

STUDY
TREATMENT OF DIGITAL ULCERS IN PATIENTS WITH SYSTEMIC SCLEROSIS: PROSPECTIVE COHORT STUDY

Sohn Chunghyang University College of Medicine Cheonan Hospital, Cheonan, Korea, Rep. of (South Korea); Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Rep. of (South Korea); Seoul National University Bundang Hospital, Seongnam, Korea, Rep. of (South Korea); Yonsei University Wonju College of Medicine, Wonju, Korea, Rep. of (South Korea); Yonsei University College of Medicine, Seoul, Korea, Rep. of (South Korea); Pusan National University Hospital, Pusan, Korea, Rep. of (South Korea); Chonnam National University Medical School & Hospital, Gwangju, Korea, Rep. of (South Korea); Seoul National University College of Medicine, Seoul, Korea, Rep. of (South Korea).

Background: Digital ulcer (DU) is a common clinical manifestation in patients with systemic sclerosis (SSc). About 70% of patients with SSc experience DUs during the first 10 years, which limit daily activities and may result in digital gangrene or amputation. Several vasoactive/vasodilating agents have been suggested for treatment, but few studies have compared the efficacy of those drugs.

Objectives: The objective of our study was to compare the efficacy of medical treatment for SSc-related DUs, focusing on endothelin receptor antagonist (ERA) and phosphodiesterase-5 inhibitors (PDE5inh).

Methods: In this prospective observational cohort study, we recruited patients who had one or more active SSc-related DUs and newly started or changed a medical treatment for SSc-related DUs from 13 medical centers in South Korea. The primary outcome was to compare the time to resolution of cardinal DU (CU) according to the treatments. The secondary outcomes included changes in the size or number of CU and changes in the number of DUs. CU was defined as the most clinically significant DU chosen by the investigators.

Patients were followed up at every 4 weeks after enrollment until 12 weeks and finally at 24 weeks.

Results: Seventy-one patients were enrolled. Seven patients were excluded due to follow-up loss or withdrawal of consent. A total of 64 patients were analyzed. Seventy-eight percent (n=50) were female. The mean age at enrollment was 49.6 ± 11.6 years, and the mean disease duration was 7.1 ± 5.9 years. Twenty-eight patients (43.8%) were limited SSc. Forty-nine patients (76.8%) started ERA treatment (n=40 for bosentan; n=9 for tadalafil, and n=1 for udenafil). Four patients who started medication other than ERA or PDE5inh classified as other treatment groups. Seventeen patients (26.6%) were on background calcium channel blockers (CCBs). CU healed in 25 patients (39.1%) at 12 weeks and 43 patients (67.2%) at 24 weeks. The mean time to heal CUs were 54.4 ± 22.7 days at 12 weeks and 91.6 ± 49.2 days at 24 weeks. Time to heal CU was comparable among patients on ERA, PDE5inh, and others (p=0.53, figure 1). The CU area was comparable among the three groups at baseline, 12, and 24 weeks. The mean area of CU in patients on ERA at baseline at 12, and 24 weeks was 21.3±19.4 mm², 3.5±3.6 mm², and 4.6±7.7 mm², respectively. The mean area of CU in patients with PDE5inh at baseline at 12, and 24 weeks was 26.2±28.1 mm², 3.5±3.6 mm², and 1.3±4.3 mm². New DUs developed in 4 patients (8.3%) in ERA, whereas 4 patients (40.0%) in PDE5inh at 4 weeks. The use of ERA was significantly associated with less new DU developments than the use of PDE5inh at 4 weeks follow-up (RR for developing new DU patients on ERA, 0.21; 95% CI 0.06-0.70; p=0.02) At 24 weeks follow-up, none of the patients on CCB developed new DUs.

Conclusion: The time to heal CU for ERA and PDE5inh users was comparable in the current study. ERA treatment was associated with reduced new DU occurrence compared with PDE5inh treatment. None of the patients with CCB treatment developed new DU at 24 weeks.

IMPACT AND ADHERENCE TO THE MEDITERRANEAN DIET IN SYSTEMIC SCLEROSIS ITALIAN PATIENTS: CORRELATION WITH GASTROINTESTINAL SYMPTOMS, MOOD DISTURBANCES AND QUALITY OF LIFE

G. De Luca1, G. Nataliello2, G. Abignano3, C. Campochiaro1, D. Temiz Karadag2,3, M. De Santis4, E. Gremsese5, S. L. Bosello6, L. Dagna1, IRCCS San Raffaele Hospital and Vita-Salute University Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; 2Fondazione Polliciico Universitario A. Gemelli - IRCCS, Rheumatology Division, Rome, Italy; 3San Carlo Hospital, Potenza, Rheumatology Institute of Lucania (IREL), Potenza, Italy; 4Canakkale State Hospital, Rheumatology Clinic, Canakkale, Turkey; 5Humanitas Clinical and Research Center - IRCCS, Division of Rheumatology and Clinical Immunology, Rozzano, Italy

Background: Gastrointestinal involvement (GI) is a common feature of systemic sclerosis (SSc) and can be highly disabling, representing a major cause of morbidity and reduced quality of life (QoL). The impact of dietary habits on GI symptoms, mood and QoL has not been extensively evaluated.

Methods: To evaluate the adherence to the Mediterranean Diet (MD) in an Italian multicenter cohort of SSC patients, and its impact on GI symptoms and other disease features, depression, anxiety and overall QoL.

Results: 265 patients (94.7% females; age 55.8±13.6 years; disease duration 9.1±7.0 years; diffuse SSC 31.8%; SSc±70+ 33.5%; ulcers 23.4%; ILD 29.4%; BMI 23.7±4.4 Kg/m²); obese 13.1%, overweight 23.4%, underweight 4.9% were enrolled. Overall MD adherence was moderate (75 ± 19) according to MEDAS and it correlated with QueMD score (4.53 ± 1.96) R= -0.133, p=0.032 and general S-HAQ items (bowel: R= -0.202, p=0.01; Raynaud: R= -0.217, p=0.001; ulcers: R= -0.207, p=0.01). MD adherence directly correlated with lung function (MEDAS: R= -0.202, p=0.005) and reduced QoL, both for GI (constipation at USG: R= -0.133, p=0.032) and general S-HAQ items (bowel: R= -0.202, p=0.01; Raynaud: R= -0.217, p=0.001; ulcers: R= -0.207, p=0.01). MD adherence directly correlated with the severity of reported upper GI symptoms according to both scales (RDQ-GERD: R= -0.263, p=0.001; USG: R= -0.263, p=0.001) and general S-HAQ items (HAQ: R= -0.136, p=0.032; severity R= -0.233, p=0.001; bowel: R= -0.135, p=0.04; breath: R= -0.133, p=0.03; ulcers: R= -0.132, p=0.037). Results were confirmed after exclusion of psychiatric (11.7%) and fibromyalgic (15.5%) patients.

Conclusion: Unsatisfactory MD adherence is associated with a low mood, impaired QoL, work impairment, GI and vascular symptoms in Italian SSC patients. The promotion of a healthy lifestyle could positively impact on QoL and disease status of SSC patients. The promotion of a healthy lifestyle could positively impact on QoL and disease status of SSC patients.

A HIGH NEMO SCORE IN VIDEOCAPILLAROSCOPY IS PREDICTIVE OF FUTURE DEVELOPMENT OF DIGITAL ULCERS IN PATIENTS WITH SYSTEMIC SCLEROSIS

N. Del Pia et al. P. Pignataro, W. Magliione, A. Minniti, D. Sambataro, G. Sambataro, G. Valentini, C. Vitali, R. Caporali, ASST Gaetano Pini-CTO, Rheumatology Dep., Milan, Italy; 2University of Catania, Dept. of Clinical and Experimental Medicine, Internal Medicine Unit, Section of Rheumatology, Catania, Italy; 3University of Catania, Dept. of Clinical and Experimental Medicine, Regional Referral Center for Rare Lung Disease, Catania, Italy;
MINNEAPOLIS, United States of America

Methods: 145 monotherapy and combination therapy with plerixafor in healthy volunteers. Lises HSCs in mice and non-human primates. The combination promises to be a biologic that activates CXCR2 on neutrophils, and with plerixafor rapidly mobilises HSCs in patients with simultaneous and 2h stagger dosing after plerixafor. Median peak CD34+ cell mobilisation with plerixafor and one grade 2 back pain with MGTA-145 at 0.075 mg/kg that resolved within minutes.

Results: Monotherapy of MGTA-145 mobilised CD34+ cells within minutes and peaked within 1 hour post MGTA-145 (median 11 CD34+ cells/L, a 7-fold increase vs baseline). White blood cells and neutrophils followed a similar pattern. Importantly, markers of neutrophil activation were relatively unchanged (≤2-fold vs baseline).

MGTA-145 combined with plerixafor increased CD34+ cell mobilisation, whether given simultaneously or 2h after plerixafor (Fig. 1A). Mobilisation was highly enriched for CD34+CD90+CD45RA- HSCs, which tracked closely with the total CD34 count. At the 0.03 mg/kg dose with 2h stagger, median peak CD34+ peripheral blood mobilisation was ≥40 cells/L in Part B. On a second consecutive day of dosing, MGTA-145 + plerixafor mobilises HSCs to levels comparable to day 1. Initial data from the ongoing Part D show that sufficient numbers of cells (median 4.3 x 10^6 CD34+ cells/kg) for transplant were collected in a single day. Preliminary data from NSG mouse transplant studies of those mobilised HSCs in part D show higher engraftment rates of MGTA-145 + plerixafor mobilised HSCs, compared to G-CSF-mobilised HSCs.

Conclusions: NEMO score is not only a valid tool to assess the level of DA in the course of SSC, but this NVC parameter could also be used as a good predictor of the future development of IDUs in patients with this disease.

Disclosure of Interests: Niccolletta Del Papa: None declared, Francesca Pignataro: None declared, Antonina Minniti: None declared, Domenico Sambataro: None declared, Gianluca Sambataro: None declared, Wanda Maglione: None declared, Domenico Sambataro: None declared, Francesca Pignataro: None declared, Gabriele Valentini Grant/research support from: BMS, MSD, NOVARTIS, LILLY, PFIZER, ABBVIE, CELGENE, Claudio Vitali: None declared, Roberto Caporali Consultant of: AbbVie; Gilead Sciences, Inc.; Lilly; Merck Sharp & Dohme; Celgene; Bristol-Myers Squibb; Pfizer; UCB; Speakers bureau: Abbvie; Bristol-Myers Squibb; Celgene; Lilly; Gilead Sciences, Inc; MSD; Pfizer; Roche; UCB

Figure. Peripheral blood mobilisation after plerixafor + 0.03 mg/kg MGTA-145 in healthy subjects with simultaneous and 2h stagger dosing after plerixafor. Dotted line: previously reported CD34+ counts with plerixafor alone mobilisation (Chen et al, Blood Advances. 2018).

MGTA-145 monotherapy was well tolerated with no significant adverse events (AEs). Grade 1, transient lower back pain that dissipated within minutes was reported. The combination of MGTA-145 with plerixafor was well tolerated, with some subjects experiencing grade 1/2 gastrointestinal AEs commonly observed with plerixafor and one grade 2 back pain with MGTA-145 at 0.075 mg/kg that resolved within minutes.

Conclusions: MGTA-145 monotherapy was well-tolerated and induced rapid mobilisation of significant numbers of HSCs. CD34+ cell mobilisation with MGTA-145 + plerixafor was immediate and superior to plerixafor alone. These data suggest that the combination can enable the collection of sufficient HSCs for transplant in one day without the need for G-CSF. Further development as a first line mobilisation product is warranted in autoimmune diseases, gene therapy and haematologic malignancies.

Disclosure of Interests: John Dipersio Shareholder of: Magenta, Consultant of: Cellworks, Tiana, RiverWest, Bioline, Asterias, Amphivena and Bluebird, Celgene, Incyte, NeoluneTech, Macrogenes, Steven Devine: None declared.
Conclusion: \((\rho = 0.470)\) of SSc patients was observed. ECV \((\rho = -0.485)\) or between myocardial ECV and peripheral muscle native T1 was determined to best identify myopathy with a sensitivity of 71% and a specificity of 84%.

Background: Peripheral myositis in systemic sclerosis (SSc) is associated with poor prognosis and myocarditis but not inflammatory myopathy, which also represents a significant cause of disability in SSc remains poorly understood. Cardiovascular magnetic resonance (CMR) T1 mapping studies in asymptomatic SSc patients show increased extracellular volume (ECV), suggestive of diffuse fibrosis in both the myocardium and thoracic muscle.

Objectives: To evaluate the feasibility of T1 mapping MRI and determine ECV in peripheral muscle of SSc patients with and without myopathy and explore the association between cardiac and peripheral muscle T1 mapping in SSc.

Methods: This was a hypothesis-generating pilot and feasibility study. SSc patients, fulfilling the 2013 ACR/EULAR criteria, with no cardiovascular disease or myositis but either minimal muscle symptoms (non-inflammatory myopathy) or no muscle involvement and healthy volunteers (HV) underwent peripheral muscle T1 mapping-MRI for native T1 and extracellular volume (ECV) quantification of the dominant thigh. Patients also had T1 mapping CMR, and creatine-kinase (CK) measured. Non-inflammatory myopathy was defined as current history of minimally raised CK \((>600 \text{ IU/l})\) with no clinical symptoms (including proximal myasthenia and/or myalgia), and a Manual Muscle Testing (M1T) score \(<5\) in the thighs.

Results: 12 SSc patients and 10 HV were recruited. SSc patients had a median (IQR) age of 52 (41,65) years, 9/12 had limited cutaneous SSc, 4/12 interstitial lung disease, 7/12 non-inflammatory myopathy. Higher skeletal muscle ECV was recorded in SSc patients compared to HV \([\text{mean (SD)} 23(11)\%\) vs 11(4)\% \(p=0.04]\). Skeletal muscle native T1 values were comparable between the 2 groups although modestly higher in SSc patients \([\text{mean (SD)} 23(11)\%\) vs 11(4)\% \(p=0.04]\) compared to HV. No difference was observed between SSc patients with and without myopathy. The sensitivity and specificity of ECV were 71% and 84% respectively.

Conclusion: Peripheral muscle ECV was significantly higher in SSc patients compared to HV. This study was limited by its small sample size and the use of T1 mapping-MRI for ECV quantification. Further research is needed to validate these findings in larger and more diverse cohorts.

**Background:** Systemic sclerosis (SSc) is a systemic autoimmune disease characterized by progressive cutaneous and internal organ fibrosis. Orofacial manifestations are disabling and treatment options are limited. Fat Tissue Grafting (FTG) can be used for treating facial manifestations of the fibrosis.

**Objectives:** In this study, we aimed to assess the safety and efficacy of FTG of our cohort of patients with SSc.

**Methods:** We enrolled 20 SSc (18W, 2M) patients, from 2016 to 2019, suffering from facial sclerosis and restricted mouth opening capacity. FTG was carried out in accord with modified Coleman’s procedure (1): fat tissue was taken from periumbilical or trochanteric areas and was injected in 8 different points around the mouth. No side effects or adverse reactions have been documented. Evaluations included mouth opening capacity by measuring interincisal distance, oral functionality (MHISS scale) and patient global satisfaction (by Global Health scale).

**Results:** A 11 mm (8 - 18mm range) median increase of interincisal distance was reported at month 6 and in 80% of patients at month 12, too (p<0.02). Significant improvement in MHISS scale was also observed (p<0.003). The patient satisfaction questionnaire showed 95% positive results and 80% of the patient replied affirmatively to the question about the repetition of FTG but only 2 patients required new FTG after 12 months.

**Conclusion:** Our results showed that FTG improved mouth opening capacity and that aesthetic and functional results were satisfying to about 90% of the patients; long-term effects of this type of treatment are currently unknown. However, our and literature data at 12 months follow-up seems to confirm the benefits in long term, despite the filling effect is over.

**ANTI-NXP2 ANTIBODIES: CLINICAL AND SEROLOGICAL ASSOCIATIONS IN A MULTICENTRIC ITALIAN STUDY**

**Rheumatology Unit Spedali Civili Università di Brescia, Brescia, Italy; 2Rheumatology Unit Humanitas, Rozzano, Italy; 3Rheumatology Unit AOU Pisana, Pisa, Italy; 4Rheumatology Unit Policlinico San Matteo, Pavia, Italy; 5Rheumatology Unit Università di Ferrara, Ferrara, Italy; 6Rheumatology Unit Università di Perugia, Perugia, Italy; 7Rheumatology Unit, Università di Cagliari, Cagliari, Italy; 8Immunoallergologia, AO Universitaria Pisana, Pisa, Italy; 9Microbiologia e Virologia Ospedale San Carlo Borromeo, Milano, Italy; 10Policlinico Umberto I, Roma, Italy; 11Laboratorio Patologia Clinica Policlinico Bari, Bari, Italy.

**Background:** anti-NXP2 antibodies is considered a serological marker of dermatomyositis (DM), with calcinosis, severe myositis and, in some series, cancer. Historically, these associations have been detected with immunoprecipitation (IP), but in the last few years commercial line blot (LB) assay have been released. Objectives: to analyze the clinical features associated to anti-NXP2 antibodies, including the onset of concomitant cancers, both with LB and homemade IP.

**Methods:** clinical and serological data from medical charts of 213 patients with a diagnosis of inflammatory miosidites without anti-NXP2 (NXP2-), followed-up by two third-level Centers, and 61 anti-NXP2+ patients from 10 Rheumatological centers were analyzed. Anti-myositis specific (MSA) and anti-myositis associated antibodies (MAA) were detected in single centers by LB (Electromun Autoimmune Inflammatory Myopathies 16 antigens). Anti-NXP2 was confirmed by protein and RNA IP, as previously described (1).

**Results:** clinical diagnosis of anti-NXP2+ positive with LB were 42 DM, 11 PM, inclusion body myositis (IBM) 4, necrotizing myositis and overlap (OM) 1 each. Anti-NXP2+ showed a lower age at onset (p<0.0001) more frequent diagnosis of DM (68.8% vs 56.5% OR3.3), and IBM (5.6% vs 0%) and OR 6.12). In addition, patients with anti-NXP2+ showed higher MSA titers (93% vs 77% OR 3.3). Anti-NXP2+ antibodies had significant association with other autoantibodies: MSA (12.7%vs2%, OR6.41) and lower rate of features associated with OM or anti-synthetase syndrome. Serum from 49 NXP2+ was available and IP analysis excluded other autoantibodies. Anti-NXP2+ was confirmed by protein and RNA IP as previously described (1).

was made with the confirmation of NXP2 in 31 sera (63.2%) with the following diagnosis: DM 27 cases, PM 3, IBM 1. Whilst the majority of the associations were confirmed comparing NXP2+IP+ with the IBM NXP2-, some peculiar associations were found significant only for the double positive patients: dysphagia (53% vs 30%, OR 2.56) and calcinosis (22% vs 6.5%, OR 48) whereas IBM diagnosis and the presence of concomitant MSA antibodies were lost. Survival time from cancer onset is shown in figure.

IP did not confirm anti-NXP2 antibodies in 18 sera: in 4 cases at least one MSA/MAA was identified by IP; these 18 patients did not show differences when compared with 213 anti-NXP2 patients.

Conclusion: Protein IP confirmed anti-NXP2 antibodies in 63% of LB+ sera. Double positive cases showed more typical DM features and rarely occurred in IBM not DM. Anti-NXP2 positivity by LB should be confirmed by other methods in order to correctly diagnose and characterize IIM patients.

HOSPITAL ANXIETY AND DEPRESSION SCALE AND SENSE OF COHERENCE 13-ITEM SCALE IN A SWISS COHORT OF SYSTEMIC SCLEROSIS PATIENTS: VALIDITY, RELIABILITY AND SENSITIVITY TO CHANGE

A. Garaiman1, C. Mihai2, R. Dobrota3, S. Jordan2, B. Maurer1, O. Distler1, M. O. Becker1.
1University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland

Background: Depression, anxiety and distress affect the quality of life of patients with systemic sclerosis (SSc) [1]. The Hospital Anxiety and Depression Scale (HADS) and Sense of Coherence 13-item scale (SOc-13, measuring comprehensibility, manageability and meaningfulness) are screening tools used in patients with different medical conditions. However, their validity, reliability and sensitivity to change in SSc patients has not been evaluated yet.

Objectives: To examine the psychometric properties of HADS and its subscales HADS-A and HADS-D (measuring anxiety and depression symptoms, respectively), and unidimensional SOc-13 in a large cohort of Swiss SSc patients.

Methods: Consecutive patients fulfilling the ACR/EULAR 2013 classification criteria for SSc who completed the HADS, SOc-13, Short Form-36 Health Survey (SF-36) and Scleroderma Health Assessment Questionnaire (SHAQ) were included in a cross-sectional and longitudinal analysis. Cronbach’s α, split-half reliability and construct validity were measured. Sensitivity to change (Cohen’s d coefficient) was assessed in patients who worsened within 12±3 months, defined as occurrence of any of the following events: decline in forced vital capacity (FVC) >10%, new diagnosis of intestinal lethal disease (ILD) on high-resolution computed tomography (HRCT), progression of known ILD to >20% lung involvement on HRCT (ILD20), new-onset pulmonary hypertension (PH), increase in European Scleroderma Study Group activity index (EScSG-AI) >3 points, new active digital ulcers, increase in modified Rodnan skin score (mRSS) > 7 points.

Results: Of 345 patients (aged 59.34±17.1; 82.9% female, 18.8% with diffuse cutaneous SSc, 47.6% anti-centromere Ab-positive, 23.5% anti-Scl-70 Ab-positive, 13% anti-U1RNP Ab-positive and 11.3% anti-RNA polymerase III Ab-positive) 85 participated with a second visit to the sensitivity to change analysis. Internal consistency was excellent for the HADS (Cronbach’s α=0.91; split-half reliability r=0.92), and very good for HADS-A, HADS-D and SOc-13 (Cronbach’s α=0.85-0.89; split-half reliability r=0.86-0.89).

Regarding construct validity, all four scales showed a strong to very strong correlation to each other, as well as with the mental components of SF-36 (Spearman’s r=0.63-0.85). There was a moderate to strong correlation with the SHAQ (Spearman’s r=0.45-0.64).

Regarding sensitivity to change: HADS-A showed a large to very large effect size (ES) for progression of ILD as assessed on HRCT and increased in EScSG-AI (Cohen’s d=1.163), and a very small to small ES for changes in FVC, DU and mRSS (Cohen’s d=0.02-0.45). HADS-D showed a large ES for changes in the ILD20, mRSS and EScSG-AI (Cohen’s d=0.82-1.0), and moderate ES for changes of FVC, ILD, PH, DU (Cohen’s d=0.10-0.49). SOc-13 showed generally a very small to small EF, except for change in mRSS (Cohen’s d=0.56).

Conclusion: The HADS(A/D) and SOc-13 are valid and easy-to-use tools to detect depression, anxiety and distress in SSc. However, their sensitivity to change might be limited by the respective type of organ involvement and its impact on the patients’ psychological wellbeing.
classification criteria, in annual follow-up (for a total of 165 patients/year) with Pulmonary Function Tests (PFTs), Health Assessment Questionnaire - Disability Index (HAQ-DI), Scleroderma Health Assessment Questionnaire (sHAQ) and Cochin Hand Function Score (CHFS). Hand disability index was assessed by CHFS and global disability index was assessed by HAQ and sHAQ. Patient reported arthritis activity was assessed by Visual Analog Scale for Arthritis Activity (VAS3). Based on the median of VAS3, patients were classified in two groups and the evaluation of global and hand disability index was performed for each group. Furthermore, we assessed the correlation between the change of VAS3 and the modification of disability scores (sHAQ, sDHQ, CHFS) over 12 months of follow-up. Following analysis of distribution, Spearman or Pearson Test were used to determine correlation coefficients, as appropriate (Prism 7).

Results: The median disease duration was 5 years (IQR 3-10). The median of VAS3 was 35 (IQR 2-66). In patients with VAS3 <35 and VAS3 ≥35 the HAQ-DI medians were 0.625 (IQR 0.25-1.114) and 1.701 (IQR 1.234-2.059), respectively, (p<0.001); and the CHFS medians were 4 (IQR 0-19) and 28 (IQR 10-46) respectively, (p<0.001). A significant correlation was observed between VAS3 and HAQ (r=0.463, p<0.0001), sHAQ (r=0.651, p<0.0001), CHFS (r=-0.497, p<0.0001); between ∆VAS3 and ∆SHAQ (r=0.493, p<0.0001).

Conclusion: This analysis of a monocentric non-selected population supports the key role of joint involvement in determining global patient reported functional and hand disability in SSC. Severity of musculoskeletal involvement should be carefully considered when interpreting PROs in patients with SSC.

Background: Pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD) are the major life-threatening complications in systemic sclerosis (SSC). Data on the impact of PAH and/or ILD in SSC patients (pts) are limited by their low prevalence.

Objectives: To assess differences in demographic/clinical characteristics of SSC pts according to presence of PAH and how these are affected by ILD. The impact on characteristics and survival of PAH + ILD was also assessed.

Methods: We compared data on SSC pts without PAH from the Spanish registry of patients with SSC (RESCLE) (SSC pts) and SSC pts with PAH from the Spanish registry of pts with PAH (REHAP) (SSC-PAH pts). Only data common in both registries were used. Sub analyses were performed according to the presence/ absence of ILD. Transplant-free survival from diagnosis of PAH was estimated using the Kaplan-Meier method.

Results: 1,579 pts with SSC (RESCLE) and 364 pts with SSC-PAH (REHAP) were analyzed. Compared to SSC pts, SSC-PAH pts had worse functional status (NYHA FC III/IV: 70.6% vs. 8.2% in SSC pts) and pulmonary function (lower mean forced vital capacity [FVC, 81.2±20.6% vs. 93.6±20] and diffusing capacity for carbon monoxide [DLCO, 45.3±17.7% vs. 79.0±36.6%]). More patients had FVC/DLCO ≥1.4 (77.8% vs. 34.8%), tricuspid regurgitation (91.4% vs. 46.1%) or pericardial effusion (30.0% vs. 5.1%). Mean systolic pulmonary artery pressure (sPAP) was higher (70.0±21.9 vs. 86.2±18.6) and lower DLCO (39.4±17.0 vs. 49.1±17.9) both Pe0.001. Five-year survival rate was 35% in SSC-PAH pts with ILD vs. 45% in SSC-PAH without ILD (P=0.444 [figure 1]).

Conclusion: PAH has a profound impact on functional status, pulmonary function and right ventricle function of SSC patients, independently of presence of ILD. Despite the deleterious effect of functional status and pulmonary function, in pts with SSC and PAH, presence of concomitant ILD has no impact on 5-year survival.

Figure 1. Survival rate estimates in SSC-PAH pts with and without ILD

SARCOPENIA IS ASSOCIATED WITH MALNUTRITION IN PATIENTS WITH SYSTEMIC SCLEROSIS

V. Hax1, R. Cavalheiro Do Espirito Santo1, E. Pena1, L. Rodrigues1, R. T. Pedro1, J. Miranda de Souza Silva1, N. Pamplona Bueno de Andreade, A. A. Gasparin1, R. Xavier1, R. Mendoza Da Silva2,1, Hospital de Clínicas de Porto Alegre, Department of Rheumatology, Porto Alegre, Brazil

Background: Sarcopenia is one of the major health problems in older patients and is defined as a progressive decrease in muscle mass and function1. Sarcopenia has only rarely been studied in systemic sclerosis (SSc) and its impact in clinical characteristics of SSc is poorly investigated.

Objectives: To evaluate the associations between sarcopenia and clinical features in SSc patients.

Methods: Cross-sectional study, including 82 patients who met the ACR/EULAR 2013 classification criteria for SSc. Dual-energy X-ray absorptiometry, handgrip strength, and short physical performance battery were used to assess sarcopenia and physical function, respectively. Ewing Workgroup criteria endorsed by European Working Group on Sarcopenia in Older People’s (EWG- SOP) diagnostic criteria updated in 20193. Malnutrition was evaluated according to the European Society of Clinical Nutrition and Metabolism (ESPEN)4, using the Malnutrition Universal Screening Tool (MUST) to screen risk for malnutrition.
Results: The mean age was 60.4 years and 91.5% were women (table 1). Scleroderma was identified in 15 (18.3%) SSc patients. Malnutrition was diagnosed in 15 (18.3%) SSc patients, with a mean age of 48.75 years (range from 10 to 74). Acute myeloid leukemia was the most frequent cause of the transplant in 11 patients (39.3%). Transplant-related complications were reflected in Table 1 and the clinical manifestations, therapies received and their response were collected. The statistical analysis was done with Microsoft Excel 2007.

Results: Seventeen (60.7%) patients were male and 11 (39.3%) were women with a mean age of 48.75 years (range from 10 to 74). Acute myeloid leukemia was the most frequent cause of the transplant in 11 patients (39.3%). Transplant-related complications were reflected in Table 1 and the clinical manifestations, therapies received and their response were collected. The statistical analysis was done with Microsoft Excel 2007.

ECOG: Eastern Cooperative Ongology Group scale to assess the quality of life

Conclusion: Non-specific joint symptoms such as stiffness, edema or arthromyalgia in patients undergoing allogeneic transplantation of hematopoietic progenitors may be factors that predict the development of sclerotic GVHD type eosinophilic fasciitis-like and should be closely monitored in order to be able to perform early stage diagnoses of the disease. It is necessary to deepen the pathogenesis of this entity and the multidisciplinary approach to improve the prognosis of patients with GVHD

PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS IS NEARLY ALWAYS ACCOMPANIED BY A LOW DIFFUSING CAPACITY

A. Hu1, T. Nevskaya2, M. Baron3, J. Pope4 on behalf of Canadian Scleroderma Working Group (CSRG).
1Western University, London, Canada; 2McGill University, Montréal, Canada

Background: Scleroderma (systemic sclerosis; SSc) has high morbidity and mortality. Pulmonary hypertension (PH) and pulmonary arterial hypertension...
Tacrolimus (TAC), an immunosuppressant, can be used in second-line maintenance therapy of interstitial lung disease (ILD) in patients with dermatomyositis (DM) [1]. In Japan, TAC is approved for DM-ILD and often used as induction therapy for severe cases, especially in patients with anti-MDA5-Ab (melanoma differentiation-associated gene 5 antibody) positivity, in combination with glucocorticoids (GC) and intravenous cyclophosphamide (IVCY). Some studies reported the clinical efficacy of initial high trough level TAC for DM-ILD in combination with GC and IVCY [2]. Adjustment to target concentration of TAC was used containing more than 1300 SSC patients with a mean disease duration of 8 years. All patients with at least one follow up visit and DLCO recorded at least twice were eligible for enrolment into this nested case control study. Diagnosis of PH was verified using several algorithms within the database including R heart catheterization, use of PH medications and physician response of ‘yes’ to question has this patient been diagnosed with pulmonary hypertension. Sensitivity, specificity and positive (PPV) and negative predictive values (NPV) were calculated for DLCO<50% and presence of PH/PH.

**Methods:** The Canadian Scleroderma Research Group (CSRG) database was used containing more than 1300 SSC patients with a mean disease duration of 8 years. All patients with at least one follow up visit and DLCO recorded at least twice were eligible for enrolment into this nested case control study. Diagnosis of PH was verified using several algorithms within the database including R heart catheterization, use of PH medications and physician response of ‘yes’ to question has this patient been diagnosed with pulmonary hypertension. Sensitivity, specificity and positive (PPV) and negative predictive values (NPV) were calculated for DLCO<50% and presence of PH/PH.

**Results:** At time of PH diagnosis, the mean DLCO% predicted was 47% (N=30) vs no PH 73% (N=960) P<0.001, and proven documented PAH also showed the differences (PAH, N=22 DLCO% predicted 51% vs. PAH negative (N=968) DLCO% pred 72%, P<0.0001) (Table 1). The OR of a DLCO%predicted less than 60 was 4.7 for PAH and 7.6 for PH (both P<0.001) and even higher if DLCO<50% (OR 11.5 for PH and 7.6 for PAH). Table 2 shows the PPV of DLCO at varying levels.

**Table 1.** DLCO comparison between PH+ and PH- SSC patients and between PAH+ and PAH- SSC patients, at the time of diagnosis.

**Conclusions:** A low DLCO is associated with a high odds of PH/PH in SSC and the NPV is very high at both DLCO<50% predicted and <60% predicted. This may aid in determining who should receive a right heart catheterization in SSC patients.

Comparisons of the Rituximab (RTM) in monotherapy regimen and mycophenolate mofetil (MMF) efficacy and Safety in Systemic Sclerosis (SSc) with interstitial lung disease (ILD)

O. Koneva1, L. Ananieva1, L. Garzanova1, O. Desinova1, O. Ovsyannikova1, M. Starovoytova1, I.V. A. Nasonov Research Institute of Rheumatology, Moscow, Russian Federation

Background: Although ILD occurs in the majority of patients with SSc, treatment options for this manifestation is empirical and at present consists of cyclophosphamide or MMF. However, the immunosuppressants (IS) use leads to rather limited improvement of ILD and is associated with many adverse reactions. The search for novel, more efficacious agents has been continued, such as attracting much attention RTM.

Objectives: To compare the impact of MMF and RTM as a first-line agent for ILD treatment in the patients with SSc, and in the patients with less pronounced ILD and cardiopathy.

Methods: 80 patients with the confirmed SSc diagnosis and ILD evidence based on MSCT findings were enrolled into the study. All patients received low and moderate-dose glucocorticoids regimen. Group A(n=35) received RTM as a single therapy agent for 13.3±2.3 months at total dose 1.35±0.5g (the average age 49±13 years, females 91%, SSc duration 7.1±5 years, diffused/localized forms 1/1.3). Group B(n=36) received MMF for 12±6 months at total dose 10.6±5 g (the patient's average age was 45.0±15 years, female proportion 80%; SSc duration 6.3±2.3 years; diffused/localized forms 1.3/1). Group C(n=29) received RTM as a monotherapy regimen for 13.3±2.3 months at total dose 1.35±0.5g (the av average age 45±13 years, females 91%, SSc duration 7.1±5 years, diffused/localized forms 1/1.3). The time courses of FVC, DLCO, modified skin count (mRss, points), activity index (EScSG, points), and cardiac rhythm and conductivity disorders (ECG) were assessed into the study.

Results: In Groups A and B the therapy was associated with significant decrease in mRss(p=0.02 and 0.009, respectively) and EScSG(p=0.00017 and 0.000165, respectively). Reducing the number of patients with cardiac conductivity disorders was observed only in MMF-treated patients (p=0.03).

Conclusion: Both agents effectively alleviated skin induration and EScSG, and limited improvement of ILD and is associated with many adverse reactions. The search for novel, more efficacious agents has been continued, such as attracting much attention RTM.

Prognostic Factors for Steroid-Free Remission in Patients with Idiopathic Inflammatory Myopathies: Importance of Anthropometric Measurements

J. S. Lee1, S. H. Nam1, S. J. Choi1, W. J. Seo2, S. Hong3, C. K. Lee1, B. Yoo1, J. S. Oh1, Y. G. Kim4

University of Ulsan College of Medicine, Asan Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2 Seoul Veterans Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 3 Asan Medical Center, Department of Biomedical Informatics, Seoul, Korea, Rep. of (South Korea)

Background: Several studies have been conducted on factors associated with mortality in idiopathic inflammatory myopathies (IIM), but few studies have assessed prognostic factors for steroid-free remission in IIM.

Objectives: We investigated the various clinical factors, including body measurements, that affect IIM treatment outcomes.

Methods: Patients who were newly diagnosed with IIM between 2000 and 2018 were included. Steroid-free remission was defined as at least three months of normalisation of muscle enzymes and no detectable clinical disease activity. The factors associated with steroid-free remission were evaluated by a Cox regression analysis.

Results: Of the 106 IIM patients, 35 displayed steroid-free remission during follow-up periods. In the multivariable Cox regression analyses, immunosuppressants’ early use within one month after diagnosis [hazard ratio (HR) 6.21, 95% confidence interval (CI) 2.61–14.74, p < 0.001] and sex-specific height quartiles (second and third quartiles versus first quartile, HR 3.65, 95% CI 1.40–9.51, p = 0.008 and HR 2.88, 95% CI 1.13–7.32, p = 0.027, respectively) were positively associated with steroid-free remission. Polymyositis versus dermatomyositis (HR 0.21, 95% CI 0.09–0.53, p = 0.001), presence of dysphagia (HR 0.15, CI 0.05–0.50, p = 0.002) and highest versus lowest quartile of waist circumference (WC) (HR 0.24, 95% CI 0.07–0.85, p = 0.027) were negatively associated with steroid-free remission.

Conclusion: The early initiation of immunosuppressant therapy, type of myositis and presence of dysphagia are strong predictors of steroid-free remission in IIM; moreover, height and WC measurements at baseline may provide additional important prognostic value.

In Myositis Patients, Sjögren’s Syndrome is Associated with Inclusion Body Myositis and With Anti-cN1A Antibodies Independently of the Myositis Subtype

1 Strasbourg, Strasbourg, France; 2 Hôpitaux Universitaires, Strasbourg, France; 3 Hôpital Privé Metz, France; 4 Pontarlier, Pontarlier, France; 5 Colmar Colmar, France; 6 Paris, Paris, France

Background: Myositis are characterized by weakness and muscle inflammation. They encompass heterogeneous conditions, which include dermatomyositis (DM), inclusion body myositis (IBM) and polymyositis (PM) according to the EULAR/ACR 2017 criteria. We recently recorded a high prevalence of IBM in a cohort of primary Sjögren’s syndrome (SS) (1). The signification of SS in the setting of myositis is unanswered.

Objectives: To refine the signification of SS in the setting of myositis.

Methods: Among a monocentric myositis cohort (according to the EULAR/ACR 2017 criteria), SS patients (according to the ACR/EULAR 2016 criteria) were identified (myositis/SS+ group) and compared to myositis patients without SS (myositis/SS- group).

Results: Among 414 myositis patients, SS criteria were available for 96 patients. Thirty two (33%) presented SS. Patients with SS tended to be more frequently women (F/M ratio 9.7 vs 3.0, p = 0.07). Age at diagnosis of myositis was similar in both groups (53 years [range 21-74] vs 53 years [range 16-77], p = 0.51).

Myositis subtypes repartition (as defined by EULAR/ACR 2017 criteria) was different in myositis/SS+ and myositis/SS- groups (p = 0.021). IBM being four-fold more prevalent in myositis/SS+ group (25% vs 6%, p = 0.018). Accordingly, the delay between the first muscle symptoms and myositis diagnosis was longer in myositis/SS+ group (7 months [0-336] vs 4 months [0-122], p = 0.041). Moreover, aside anti-cN1A antibodies, myositis-specific antibodies were less frequently found in myositis/SS+ patients than in myositis/SS- ones (16/32 [50%] vs 46/44 [72%], p = 0.035).

Disclosures of Interest: None declared

DOI: 10.1136/annrheumdis-2020-eular.4235

708 Friday, 05 June 2020

Scientific Abstracts
Anti-cN1A antibodies were more prevalent in myositis/SS+ patients (33% vs 5.8%, p = 0.0032). However, in myositis/SS+ group, anti-cN1A were frequent in each of the EULAR/ACR 2017 myositis subtypes and the association between SS and anti-cN1A positivity was maintained in a multivariate analysis adjusted with the diagnosis of IBM (p = 0.023).

Seven of the myositis/SS+ patients (22%) had systemic involvement typical of SS (vs 6% of the myositis/SS- patients, p = 0.12) including polyneuropathy (6% vs 6%), and type 2 cryoglobulinaemic vasculitis (1% vs 1.6%). In addition, 2 (6%) myositis/SS+ patients developed a lymphoma (one B diffuse large lymphoma of the parotid and one non-Hodgkin lymphoma), vs none of the myositis/SS- patients (p = 0.11). Only one (3%) of the myositis/SS+ patients developed myositis-associated cancer (diagnosed within 3 years of myositis diagnosis) versus 6% of the myositis/SS- patients (p = 0.66).

Aside hydroxychloroquine, more frequently used in myositis/SS+ group (38% vs 16%, p = 0.018), no significant difference was found in the management of the patients (taking into account the myositis subtype).

Conclusion: Myositis patients with SS have more frequently IBM than myositis patients without SS. They also have more frequently anti-cN1A antibodies, independently of the myositis subtype. They might develop systemic complications of SS.

References:

Eleven patients were positive for anti-PM-Scl100, 14 for anti-MDA5, and 14 for anti-Pl-12. The positive control for each antibody was set at 100%. The patient's antibody titre was calculated as 100 minus the absorbance of the sample. The results were expressed as a ratio of the patient's titre to the positive control. The cutoff for positivity was set at 0.5.

**COMBINATION OF COMPUTED TOMOGRAPHY SCAN AND SERUM MYOSITIS SPECIFIC/ASSOCIATED AUTOANTIBODIES HELPS EARLY IDENTIFY AND TREAT PATIENTS WITH IPAF AND CTD-ILD**

S. Lyu1, H. C. Chen1, T. S. H. Lee1, Y. Li1, C. J. Cho1, F. C. Liu1, C. Y. Cheng1, S. J. Chu1, S. Y. Kuo1, D. M. Chang2, C. C. Lu1, 1-TriService General Hospital, Taipei city, Taiwan, Republic of China; 2-Taiwan Normal University, Taipei City, Taiwan, Republic of China; 3-Taipei Veteran General Hospital, Taipei city, Taiwan, Republic of China

Background: Idiopathic inflammatory myopathies (IIM) are a group of immune-mediated diseases characterized my muscle weakness, skin rash and systemic involvement. Myositis-specific antibodies (MSA) and myositis-associated antibodies (MAA) play a major role in IIM diagnosis, classification and prognosis. Nevertheless, MSA/MAA testing is not standardized and there very few studies addressing their relationship with other diseases.

Objectives: To describe a cohort of patients tested positive for MSA/MAA, and to explore its relationship with IIM and other autoimmune diseases.

Methods: We retrospectively review all the serum samples obtained from patients tested for MSA/MAA during 2019 in the Immunology department of Ramón y Cajal University Hospital (Madrid, Spain). These antibodies were tested by a new method (EUROLINE: Autoimmune Inflammatory Myopathies 16 Ag) with highly purified MSA/MAA. Positivity was established according to absorbance titer and adjusted by positive control of each test (arbitrary units, AU). Patients were diagnosed with IIM according to their clinician diagnosis. Diagnosis and classification were confirmed by an independent rheumatologist (JL) according to current understanding of IIM classification.

Results: Three-hundred-seventy-five samples were tested for MSA during the study period. Two-hundred-seventy-nine were negative for all antibodies tested. Ninety-six samples were positive for one or more MSA/MAA, corresponding to 74 patients (11 patients had 2 different samples). Forty-nine (66.2%) of the patients who tested positive were female and 25 (33.8%) were male. Mean age was 56.85 years. Only 22 patients (29.7%) had a confirmed diagnosis of IIM, 24 (32.4%) had a diagnosis of other autoimmune disease, and 11 (14.9%) were diagnosed with interstitial lung disease (ILD) (Figure 1). Six ILD patients had anti-PM-Scl or anti-Ku antibodies, which are associated with scleroderma or overlap-CTD myositis, nevertheless, they remained classified as ILD as no other features were described in this group.

Seventeen patients were positive for more than 1 MAA or MSA, including 14 patients positive for anti-Ro-52. Antibody titer was higher in the IIM group compared to non-myositis group (59.59 vs 44.16, p=0.015). Anti-M2 was positive in 4 ILD without any other myositis features, and high titer anti-SRP (n=4, mean 59.75 AU) was found in primary biliary cirrhosis (PBC) patients. Additionally, 5 patients positive for anti-Jo-1 using ELISA (Thermo Fisher) were diagnosed with antisynthetase syndrome. IIM diagnosis and its relationship with antibody titer is represented in table 1.

Conclusion: Only 28.7% of the patients that were MAA/MSA positive had a diagnosis of IIM. Other autoimmune diseases and ILD were commonly found in this group of MSA/MAA positive patients.
Indian patients with IIM suffer high early mortality attributable to RP ILD, cancer and infections. Positive anti-MDA 5 and a negative ANA predict poor survival.

**Results:** Of the 69 (54 female and 15 male) patients of median age 40 (23-51) and disease duration 3 (IQR 1-6) months, Dermatomyositis (DM) was the most common subset 26 (37.6%) (Fig. 1B). Myositis Specific and Myositis Associated Antibody (MSA and MAA) were positive in 30 (43.4%) and 11 (17%) respectively (Fig. 1C).

Forty-eight patients followed up over 10 (IQR 4.5-13) months accounting for 473 patient years, of which 8 (16.6%) suffered mortality and three PM were reclassified (Fig. 1B). Four (10%) had minimal, 3 (7.5%) had moderate and 33 (82.5%) had a major clinical response (Fig. 2A) with treatment. Eight (20%) of the 40 who survived had a relapse and 13 (32.5%) had steroid related complications. Eleven (27.5%) had at least 1 infection and it correlated with duration of steroid use (p<0.009 RR 0.78, 0.6-0.9) but not the cumulative dose of steroid (p=0.147).

Duration of symptoms prior to treatment, subtype of myositis, MSA or presence of ILD did not predict the short-term response.

6-month survival was 83.3% (Figure 2B). Rapidly progressive ILD was the most common cause of death followed closely by malignancy and infection (n=3, 37.5%) (Table 1). Diagnosis of Cancer associated myositis (OR 6.1), positive anti-MDA 5 and a negative ANA (OR 5.8) were predictors of early mortality.
BACKGROUND: Systemic sclerosis (SSc) is a connective tissue disease with heterogeneous manifestations. It affects different organs and therefore requires interdisciplinary diagnostic and therapeutic management.

OBJECTIVES: The aim of this study is to evaluate the frequency and characteristics of ocular manifestation in patients with systemic sclerosis.

METHODS: The study involved 31 patients with SSc. All the study subjects underwent complete ophthalmological examination involving visual acuity assessment, examination of anterior and posterior eye segments, Schirmer I test, diameter and mobility of pupils, as well as eyelid mobility assessment of intraocular pressure and ultrasound assessment of vitreous body. Data regarding age, gender, SSc subtype, disease duration, age at diagnosis, nailfold capillaroscopic pattern, systemic corticosteroid or chloroquine use, blood pressure, ocular symptoms and detailed ophthalmic history were recorded.

RESULTS: 31 patients (3 male, 28 female, mean age 42.7 ± 14.3 years; mean disease duration 10.3±8.1 years) were enrolled in this study, 7 (22.58 %) of whom had no ophthalmic symptoms. Among the patients with ocular symptoms, 20 (64.52 %) complained of decreased vision, 13 (41.93 %) of glare, 14 (45.16 %) of burning, 8 (25.81 %) - of eye fatigue, 4 (12.90 %) - of ocular pain, 4 (12.90 %) - of foreign body sensation, 16 (51.61 %) - of dry eye, 5 (52.03 %) - photophobia, 2 (6.45 %), - of floaters, 10 (32.26 %) - of redness. Pain, 4 (12.90 %) - of foreign body sensation, 16 (51.61 %) - of dry eye, 5 (52.03 %) - photophobia, 2 (6.45 %), - of floaters, 10 (32.26 %) - of redness. Hardening and thickening of palpebral skin was noted in 27 (87.10 %) patients. Ophthalmological examination revealed higher incidence of the following abnormalities in the study group: myopic astigmatism - in 20 (64.52 %) eyes, vascular abnormalities within fundus - in 24 (77.41 %) eyes, increased intracocular pressure (> 21 mm Hg) - in 13 (20 %) eyes. Mean IOP values were 18.21 ± 4.2 mm Hg. eyelid telangiectasias was noted in 9 (29.03 %) patients, chronic blepharitis - in 13 (41.94 %). Lens opacity was found in 16 (51.61 %) patients (27 eyes), mostly in the form of posterior subcapsular cataract (in 20 eyes), nuclear cataract (in 6 eyes) and cortical cataract appearing as focal cataract opacities (in 1 eye). The mean age of patients with cataracts was 49.2 ± 12.3 years (11.4 years older than patients without cataracts). Additionally, 14 of the patients with cataracts were either currently taking or had previously taken systemic corticosteroids. Superficial conjunctival hyperaemia was noted in 20 (64.52 %), and varicose dilatation of subconjunctival and episcleral blood vessels in 9 (29.03 %) and 7 (23.81 %) patients, respectively. In 14 (45.16 %) patients there was conjunctival hyperemia. In 8 (25.81 %) patients, limbal telangiectatic vessels were noted, and in 10 (32.26 %) patients redness. In 20 (64.52 %) patients, 13 (41.93 %) of which were noted in patients with SSc, the mean age was 52.5 years.

Conclusion: In patients with SSc numerous abnormalities within the vision of organ may be found. Ocular symptoms are relatively common complications of SSc, and may result in serious, irreversible changes in the organ of vision. Regard body composition, physical activity and nutritional status. The aim was to assess body composition and physical activity of SSc patients and healthy controls (HC) and the association with selected inflammatory cytokines/chemokines and laboratory markers of nutritional status and lipid metabolism in SSc. The aim of the study was to assess body composition and physical activity of SSc patients and healthy controls (HC) and the association with selected inflammatory cytokines/chemokines and laboratory markers of nutritional status and lipid metabolism in SSc.

Early interstitial lung disease is a major risk factor for mortality in SSc. The aim of the study was to assess body composition and physical activity of SSc patients and healthy controls (HC) and the association with selected inflammatory cytokines/chemokines and laboratory markers of nutritional status and lipid metabolism in SSc.

RESULTS: Data are presented as mean±SD.

Serum levels of several inflammatory cytokines/chemokines (specifically MCP-1, IL-6, IL-21), and serum levels of BMD, BCM, and DEXA were also significantly decreased in patients with SSc compared to HC. Additionally, serum levels of IL-17 and IL-21 were higher in SSc patients compared to HC. Additionally, serum levels of IL-17 and IL-21 were higher in SSc patients compared to HC. Additionally, serum levels of IL-17 and IL-21 were higher in SSc patients compared to HC. Additionally, serum levels of IL-17 and IL-21 were higher in SSc patients compared to HC.

Conclusion: SSc-PH had a different cytokine profile compared with non-SSc-PH. We suggested that the serum IL-17 and IL-21 levels effect the hemodynamics in CTD-PH.

ADVANCED MICROCIRCULATORY DAMAGE IS ASSOCIATED WITH INCREASED PULSE WAVE REFLECTIONS IN PATIENTS WITH SSc
E. Pagkopoulos1, S. Soulaïdopoulos2, E. Triantafyllidou2, N. Katsiki2, G. Kitas3,4, A. Karagiannis5, A. Garyfallo1, T. Dimitroulas1. 1Aristotle University of Thessaloniki; 2Manchester, Manchester, United Kingdom; 3Thessaloniki, Greece; 4Aristotle University of Thessaloniki; 5Second Department of Internal Medicine, Hippokration Hospital, Thessaloniki, Greece; 6Department of Internal Medicine, University of Manchester, Manchester, United Kingdom

Background: In systemic sclerosis (SSc), inflammation and microvascular damage are fundamental in the progressive fibrotic process. Although the presence of accelerated atherosclerosis in SSc is not as well-described as in other systemic disorders namely rheumatoid arthritis, it appears that individuals suffering from the disease are at higher risk for cardiovascular events. Nailfold Video Capillaroscopy (NVC) is a non-invasive and reproducible imaging technique of the capillary vascular bed, used in the evaluation of microvascular involvement in SSc. Previous data on the association between micro- and macrovascular damage are scarce.

Objectives: The aim of this study was to examine the association between micro- and macrovascular involvement in patients with SSc.

Methods: This is a cross-sectional study including consecutive SSc patients attending to a Scleroderma Outpatient Clinic between March and September 2018. All the study participants underwent NVC and the findings were classified in one of the following qualitative patterns: early, active, and late NVC pattern. Capillary’s density was evaluated in the distal row of each finger, based on the number of capillaries per 1 mm and the mean capillaroscopic skin ulcer risk index (CSURI) was automatically calculated with software image analysis. Carotid intima-media thickness (cIMT) was measured in the common carotid artery, according to the relevant guidelines. Aortic blood pressure (BP), heart rate adjusted augmentation index [AIx(75)] and carotid-femoral pulse wave velocity (PWV) were evaluated with applanation tonometry (Sphygonocor).

Results: Sixty-four (95.3% women) SSc individuals with mean age 57.54±12.99 years were included in this analysis. AIx(75) was significantly associated with CSURI (n=0.261; p=0.038) and inversely associated with the number of capillaries (r=−0.271; p=0.030) suggesting a link between the degree of microvascular disease and arterial stiffening. Regarding SSc-specific NVC patterns, AIx(75) were marginally lower in patients with early compared to active or late patterns (25.95±11.27 vs 32.50±11.17 vs 31.62±10.32%; p=0.081 and p=0.083) confirming a trend between progressive microvascular vasculopathy and arterial stiffness. Mean cIMT was negatively correlated with enlarged capillary loops. Brachial or aortic systolic BP (SBP) and pulse pressure (PP) levels were not correlated with any of the studied NVC parameters.

Conclusion: Microvascular vasculopathy is associated with higher wave reflections, indicating an association between atherosclerotic disease and microvascular injury in SSc patients. Such observations may provide possible explanations for the excessive cardiovascular and mortality risk in this population.

CAPILLAROSCOPIC VERY EARLY MORPHOLOGICAL AND QUANTITATIVE SPECIFIC ABNORMALITIES ANTICIPATE THE DEVELOPMENT OF THE “SCLERODERMA PATTERN” IN PATIENTS WITH RAYNAUD’S PHENOMENON
M. Pendolino1, C. Pizzorni1, S. Paolino1, F. Goegan1, E. Gotelli1, C. Scheneone1, F. Catelan1, M. Patanè1, E. Alessandri1, A. Sulli1, V. Smith2, M. Cutolo1.

1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Italy; Genova, Italy; 2Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, Ghent, Belgium

Background: Nailfold videocapillaroscopy (NVC) abnormalities in subjects with isolated Raynaud’s phenomenon (RP) may be present before transition to secondary RP(SRP) and development of a NVC “scleroderma pattern” and are known to predict for evolution to a connective tissue disease (CTD) within few years [1]. In a previous study, we have demonstrated that the very early increase of capillary diameter over 30 μm is an independent predictor for development of Systemic Sclerosis (SSc) associated SRP [2].

Objectives: Present pilot retrospective study aimed to investigate in a cohort of patients affected by CTD-related RP the presence of very early capillaroscopic morphological and quantitative abnormalities in the acquired pictures of NVC performed before the development of the NVC scleroderma-pattern. In particular, the study was addressed to identify a “very early” scleroderma pattern, in order to intercept patients with RP at high risk of evolution in a CTD, specifically SSc.

Methods: We selected the NVCs of 273 SSc patients presenting one of the validated NVC “scleroderma pattern”. We enrolled 26 SSc patients having a NVC analysis performed before the development of the “very early” NVC pattern. As controls, we evaluated 26 patients affected by other CTDs with stable non-scleroderma pattern over time. The 16 images per patient obtained by NVC examination were analyzed for total number of capillaries, number and the limbs diameters of capillaries with a diameter >30 μm, and microhemorrhages. Statistical analysis was performed using non-parametric tests.

Results: All 26 SSc patients showed dilated capillaries with a diameter >30 μm in their previous NVC. Patients later developing scleroderma pattern had statistically higher number and percentage of capillaries with a diameter >30 μm (p=0.004 and p=0.005), as well as a larger apical dilatation >40 μm (p=0.002). A progressive and significant increase in all capillary diameters were only detected in patients later diagnosed for SSc (apical p=0.006, venous p=0.02, arterial p=0.03). A significant homogeneous and progressive dilation was observed from the apical region and then involving both venous and arterial branches, only in SSc patients (p=0.002).

Conclusion: Present pilot study demonstrates, for the first time that, before to develop a validated NVC scleroderma-pattern, all potential SSc patients present significant very early morphological and quantitative NVC changes. In particular, the progressive and homogeneous capillary loop dilation over 40 μm in over 40%
of total number capillaries significantly could contribute to identify RP patients who will develop a SSC pattern after 4-5 years.

**Background:** Pulmonary hypertension (PH) is a life-threatening complication of systemic sclerosis (SSc), thought to be more commonly found in limited cutaneous (lcSSc) compared to diffuse (dcSSc) subset. Since lcSSc has a better prognosis, it is unclear whether a higher occurrence of PH in lcSSc reflects survival bias.

**Objectives:** To compare the PH incidence in disease subsets, after accounting for death as a competing event, in a large multi-center SSc cohort.

**Methods:** Cumulative incidence of PH was studied in 1431 Canadian Scleroderma Research Group (CSRG) database patients (57% lcSSc; follow-up 3.5±2.9 years, range 1-14) by Fine-Gray analysis, unadjusted and adjusted for sex, age and SSC-related autoantibodies (SAS 9.4). Survival curves, predictors of PH development and survival were analyzed by Kaplan-Meier and Cox proportional hazards analyses (SPSS 25.0). Subgroup analysis was performed for PAH.

**Results:** 157 SSc patients had PH (including 117 PAH), either confirmed by RHC or postmortem. Compared to those without PH, lcSSc-PH patients had longer disease and older age at SSc diagnosis, while dcSSc-PH patients - more severe peripheral vascular and gastrointestinal involvement. The cumulative incidences of PH/PAH were similar in dcSSc and lcSSc after accounting for death in the adjusted competitive risk model (Table 1; Fig 1). 47% of PH- and 42% of PAH-patients died over a FU period. Male gender (p<0.0001) and anti-ScI-70 (p<0.001) were associated with earlier PH development, while older age (p=0.006) - with PAH (Table 2). ACA-negativity and older age predicted worse PH prognosis.

**Conclusion:** Cumulative incidence of PH, after accounting for death as competing event, was comparable in SSc subsets. Vigilance should be considered in males, ScI-70 positive and late age-onset SSC.

**Table 1.** Sub-distribution Hazard ratio of incident PH and PAH.

DOI: 10.1136/annrheumdis-2020-eular.3847
Background: Cardiac involvement is a serious complication of idiopathic inflammatory myopathy (IIM). Early diagnosis and intervention can improve prognosis. At present, myocardial biopsy is the gold standard for its diagnosis, but it is not commonly used because of its invasiveness. Biomarkers can be invoked as a non-invasive and convenient choice. The traditional markers of myocardial injury, as troponin and creatine kinase are lack specificity in inflammatory myopathy, so the novel biomarkers are getting attention. GDF-15 can predict the risk of cardiovascular disease and the prognosis of coronary atherosclerosis, heart failure and other diseases.

Objectives: This article was intended to investigate the diagnostic value of GDF-15 for myocardial involvement in inflammatory myopathy.

Methods: This retrospective study included 54 patients with inflammatory myopathy from May 2018 to October 2019. Of these, 30 patients underwent cardiac magnetic resonance examination due to increased myocardial markers, excluding 1 case of severe lung infection. 33 patients with systemic lupus erythematosus (SLE), 16 normal patients were used as the control group. The concentration of GDF-15 in the serum of all groups of patients was measured by ELISA.

Results: There were significantly differences in GDF-15 levels in patients with inflammatory myopathy, systemic lupus erythematosus and normal subjects (H = 39.870, P < 0.001). 29 patients with cardiac magnetic resonance on the myocardial biopsy is the gold standard for its diagnosis, but it is not convenient and expensive. The traditional markers of myocardial injury, as troponin and creatine kinase are lack specificity in inflammatory myopathy, so the novel biomarkers are getting attention. GDF-15 can predict the risk of cardiovascular disease and the prognosis of coronary atherosclerosis, heart failure and other diseases. The best cut-off value was calculated by ROC curve, and comparing GDF-15 and CKMB with the optimum cut-off values in predicting cardiac involvement in IIM. GDF-15 levels were statistically significant between the myocardial injury group (1765.868±1068.549 pg/ml) and the group without myocardial injury (689.967±458.12 pg/ml)p < 0.001). At the same time, the creatine kinase isoenzyme CKMB (158.583±119.389 U/L vs 57.965±52.673 U/L, p < 0.005) was statistically different between the two groups. GDF-15 was positively correlated with the sensitivity of 0.765 and specificity of 0.900. The AUC of the ROC curve for the joint detection of GDF-15 and CKMB was 0.888%. The best cut-off value calculated was 0.3985, the sensitivity 0.941 and the specificity 0.800. The combined detection of the two increased the sensitivity of myocardial damage detection in IIM patients by an average of 0.3% per unit of GDF-15 (OR = 1.003, 95% CI 1.000–1.005).

Conclusion: GDF-15 can predict myocardial injury in patients with inflammatory myopathy which have high specificity. The prediction sensitivity can be improved by combining with the traditional myocardial enzyme CKMB. More further studies are needed to confirm the specific mechanism of GDF-15 for myocardial involvement to assess the prognosis of such patients and guide further treatment.

of Pathology, Boston, United States of America; ‡The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: The CD4 T cell subsets plays an important role in its pathogenesis, and its new research are constantly being published, but its specific changes between SSc and MCTD are still unclear.

Objectives: The aim of the present study was to explore the absolute numbers of CD4 T subsets in peripheral blood (PB) of patients with SSc and MCTD using our modified flow cryometric method and investigate the role in the pathogenesis of both.

Methods: The PB samples from 54 patients with SSc, 51 patients with MCTD as well as 30 healthy control subjects were analyzed for lymphocyte subsets using flow cytometry. Of these patients, 19 had pulmonary involvement, including 9 patients with SSc and 10 patients with MCTD. Using directly the percent-ages from flow cytometry combined with internal standard beads calculated absolute number of peripheral lymphocyte subsets from the subjects in each group.

Results: Although there were some changes among CD4 T cell subsets in PB from these SSc patients and MCTD patients, the major alteration was the reductions of Treg cells. Compared with the normal controls, the absolute number of CD4+CD25+FOXP3+ Treg cells were significantly decreased in SSc patients and MCTD patients, and the absolute number of Th1 cells in MCTD patients is also significantly reduced. Notably, the absolute numbers of Th17 and Th2 cells were not different from those of normal controls, but the ratios of Th17/Treg in SSc patients and MCTD patients were significantly higher, causing by insufficient number of Treg cells (Fig 1). In addition, in patients with pulmonary involvement, we found that the absolute number of Treg cells was significantly reduced in patients with MCTD, while the absolute number of Th2 cells and Th17 cells was significantly reduced in patients with SSc (Fig 2).

Conclusion: The number of peripheral Treg cells in patients with SSc and MCTD was significantly reduced, suggesting that SSc and MCTD progression is associated with the imbalances between pro-inflammatory cells to anti-inflammatory Treg cells. In addition, we also found that the decrease in peripheral numbers of Treg cells may contribute to the development of MCTD-associated lung disease, whereas in SSc patients who had lung involvement, the reduce in peripheral number of Th17 cells may result in a severe imbalance of Th17/Treg cells, thereby promoting disease progression.

Fig 1. Comparison of the levels of CD4 T lymphocyte subsets in SSc patients, MCTD patients and healthy controls: (A) The absolute number of peripheral Th1 cells in patients with MCTD was significantly reduced; (B and C) There was no significant difference in the absolute number of Th2 cells in peripheral blood of different subjects; (D and E) The ratio of Th17/Treg cells in PB of patients with MCTD were higher.* P < 0.05; ** P < 0.01; *** P < 0.001.

FRI0262 INCREASED PLASMA LEVELS OF HSP90 ARE ASSOCIATED WITH MORE SEVERE LUNG AND SKIN INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS

H. Štokánová1,2, S. Oreska1,2, M. Špírovič1, B. Heılmánková1, K. Bubova1,2, M. Komarc1, K. Pavelka1,2, J. Vencovsky1,2, J. Distler1, L. Senoit1,2, R. Bečvář1,2, M. Tomčik1,2, Institute of Rheumatology, Prague, Czech Republic; 2Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

Background: Our previous study demonstrated that Hsp90 is overexpressed in the skin of patients with systemic sclerosis (SSc), in cultured SSc fibroblasts and preclinical models of SSc in a TGF-β dependent manner. We showed that Hsp90 is a new regulator of canonical TGF-β signaling and its inhibition prevents the stimulatory effects of TGF-β on collagen synthesis and dermal fibrosis. We postulate that overexpression of Hsp90 also plays a role in the development of lung involvement in SSc.

Objectives: The aim of this study was to evaluate plasma Hsp90 of SSc patients and characterize its potential association with skin changes and SSc-related features.

Methods: A total of 92 patients (79 females; mean age 52.7; disease duration 6.0 years; diffuse cutaneous (dc)SSc / limited cutaneous (lc)SSc = 38/54) and 92 age- and sex-matched healthy individuals were included. Plasma Hsp90 levels were measured by ELISA (eBioscience, Vienna, Austria). Data are presented as median (IQR).

Results: Plasma Hsp90 levels were increased in SSc patients compared to healthy controls [12.5 (9.6–17.9) vs. 9.8 (7.7–12.4) ng/mL, p=0.0001].
levels in all patients positively correlated with CRP (r=0.271, p<0.015). Furthermore, Hsp90 concentrations were negatively associated with functional parameters of ILD: FVC (r=-0.291, p<0.013), FEV1 (r=-0.248, p=0.038), DLCO (r=-0.290, p=0.012), and SP	extsubscript{O}2 (r=-0.317, p<0.038). When adjusted for CRP these correlations still remained significant in multivariate analysis. Higher Hsp90 concentrations were associated with presence of synovitis [176 (14.5 - 24.0) vs. 12.2 (9.3 - 17.3), p=0.039]. In addition, only in patients with dcSSc, Hsp90 levels positively correlated with the mRSS (r=0.437, p=0.006). In a prospective analysis of patients with progressive SSC-ILD treated with 6 (n=21 patients) or 12 (n=14 patients) monthly i.v. pulses of cyclophosphamide (CPA, 10 g/m²) we did not observe any significant differences between the baseline sample (month 0) and blood drawn after 1, 6 and 12 months. However, baseline Hsp90 was able to predict the long-term response after one year of CPA treatment (DLCO, r=-0.494, p=0.037). Moreover, change in Hsp90 after one month of CPA treatment (Hsp90m1-m0) was able to predict the short-term inflammatory response (CRPm3-m0, r=-0.495, p=0.019; ESR m3-m0, r=-0.496, p=0.031). Concentrations of extracellular Hsp90 were not significantly affected by other main clinical parameters of SSC.

Conclusion: We demonstrated higher plasma levels of Hsp90 in SSC patients compared to healthy controls. Concentrations of extracellular Hsp90 increase with higher inflammatory activity, with deteriorated lung functions in ILD and also with the extent and severity of the skin involvement in patients with diffuse cutaneous SSC. These data further highlight the role of Hsp90 as a significant regulator of fibroblast activation and tissue fibrosis in SSC. In addition, Hsp90 could become a predictor of treatment response.

FRI0264 EFFECTIVENESS, SAFETY AND PATTERNS OF USE OF RITUXIMAB IN SCLERODERMA, IN CLINICAL PRACTICE: 9 YEARS’ EXPERIENCE IN A TERTIARY HOSPITAL

Background: Systemic sclerosis (SSc) is a clinically complex and heterogeneous disease. Interstitial lung involvement (ILD) is the main cause of mortality, but progression of skin fibrosis has also been associated with pulmonary dysfunction and mortality. Recently, Rituximab (RTX) has been postulated as a promising therapeutic alternative to cyclophosphamide (CF) or mycophenolate (MFM), but long-term experience is scarce.

Objectives: To describe the effectiveness, safety and long-term use of RTX, in a series of cases with SSc.

Methods: Retrospective observational study of patients with SSc (EULAR/ACR 2013 criteria) treated with RTX in a university hospital from 2010 to 2019. Socio-demographic data related to SSc and treatments were collected. The effectiveness of RTX was evaluated at 6-12 months and at the end of follow-up, by means of these main outcomes: Rodnan’s modified cutaneous index (mRSS) for skin fibrosis; CK levels for myopathy, variation >10% in forced vital capacity (FVC) and >15% in lung diffusion capacity of carbon monoxide (DLCO) for ILD. Adverse events (AE) were recorded. Statistical analysis performed with stata v.14 and statistical significance set for p<0.05.

Results: 14 women with SSc (mean age 47±13 years, mean evolution 6.2±4.5 years) were treated with RTX for ILD (n=9), skin involvement (n=11) and/or inflammatory myopathy (n=3). The mean±SD of follow-up was 3.36±2.17 years. SSc type: diffuse cutaneous 35.71%, limited cutaneous 21.44%, overlap 35.71% and sine scleroderma 7.14%. Type of antibodies: 50% anti-Scl-70, 14.3% anti-centromere, 21.4% anti-RNA polymerase III and 7.14% anti-Ku. ILD was classified as NINE in 8 patients and NIU in 1. The first cycle of RTX included 2 infusions of 1g and was initiated a mean of 3.36±2.17 years after diagnosis. The retreatments were initially fixed every 6 months and later on demand in 4 patients, and in the rest on demand from the beginning, according to duration of clinical response. A mean of 3.9±2.5 cycles/patient (range: 1-11) were administered. 30% of patients received previously received CF and 21.5% MFM. RTX was administered in association with other DMARDs (MTX 64.29%, hydroxychloroquine [HCQ] 35.71%, MFM 57.14%, others 14.28%), CF (14.29%), intravenous immunoglobulins (7.14%) and prednisone (78.57%). In the final visit, the percentage use of DMARDs (50% MTX, 50% MFM and 28.57% HCQ) and prednisone (62.5% patients, 30% doses) was reduced. mRSS improved significantly. Muscle weakness disappeared in 3/3 with normal CK levels in 2/3
patients with myopathy. The FVC improved or stabilized in 22% and 56% of ILD, respectively, and the DLCO stabilized in 66.70% (not significant). TACAR stabilized in 55.56% of ILD, with some degree of worsening in the rest. Outcomes evolution in the Table:

CK: Creatine kinase; SD: Standard deviation; CI: Confidence interval; m: months.

Results:

Of 1257 included patients, 282 (22.4%) showed a regression of skin fibrosis, 883 (70.2%) were categorized as stable patients and 92 (73%) showed progression of skin fibrosis at 12±3 months. Median long-term follow-up for organ involvement/death was 4.2 years. Cox regression analyses indicated that skin fibrosis regression had a significantly lower probability of later FVC decline ≥10% than non-regressive (stable and progressive) patients when controlled for baseline mRSS (p=0.013). No significant association of skin fibrosis regression was found with other organ manifestations or all-cause death. Conversely, associations of skin fibrosis progression were found for later FVC decline ≥10% with a more significant p-value (p<0.001, Figure 1), and there was also an association with all-cause death (p=0.026).

Conclusion: Progression of skin fibrosis is stronger associated with organ changes and all-cause death at follow up than improvement of skin fibrosis. These data suggest a prevention of progression paradigm for clinical practice. They also suggest that clinical trials designed for prevention of skin fibrosis progression are more meaningful for long-term outcome of SSC patients than trials designed to show improvement of skin fibrosis.

FR10266

THE REAL-WORLD EFFICACY OF THE 2015 EULAR/ACR RECOMMENDATIONS FOR THE MANAGEMENT OF POLYMYALGIA RHEUMATICA WITH ADDITIONAL TOCILIZUMAB THERAPY

M. Yamamura1, Okayama Saiseikai General Hospital, Center for Rheumatology, Okyama City, Japan

Background: A Part of patients with polymyalgia rheumatica (PMR) are refractory to the 2015 EULAR/ACR algorithm for the management of PMR. Recent
reports have demonstrated that tocolizumab (TCZ) may be efficacious for refractory and relapsing PMR.

Objectives: To determine the real-world efficacy of the 2015 EULAR/ACR algorithm for the management of PMR plus introduction of TCZ for refractory and relapsing PMR.

Methods: Patients who had been diagnosed with PMR according to the 2012 EULAR/ACR provisional classification criteria for PMR were recruited in the study. Registered variables included demographic data, disease characteristics, prednisolone (PSL) dosage and duration, addition of methotrexate (MTX) and TCZ, adverse effects, and clinical outcomes.

Results: There were 101 patients who had originally diagnosed as PMR (50 males and 65 females) and followed up for at least one year; the mean ± SD age at onset was 73 ± 11 years at onset, with the mean observational period being 44 ± 26 months. Their treatments were initiated with PSL of 15.5 ± 4.3 mg/day. 41 patients experienced disease recurrence after 9.6 ± 6.7 months (median 9 month) of GC therapy, while receiving PSL at 5 ± 4.5 mg/day (3.7 mg/day). Baseline factors that were associated with relapse in our cohort were higher-grade thrombocytosis and higher-dose of initial GC by multivariate analysis. In 30 of the 41 patients who failed GC monotherapy, MTX was added. Five patients reached GC-free remission, but 25 patients failed GC tapering. In such refractory patients to a combination of GC plus MTX, 8 patients agreed to add TCZ therapy, and 5 of them reached drug-free remission. At present, 67 of the total 101 patients maintained drug-free remission, but most others were still receiving low-dose GC and/or MTX (n=17). No significant adverse effects did not occur during therapy, except for GC-related adverse effects such as diabetes, dyslipidemia and osteoporotic fractures.

Conclusion: Our experience indicated that there is notable heterogeneity across PMR patients in terms of drug response, and the patients with severe inflammation, e.g., thrombocytosis, may need higher-dose of initial GC and addition of biologics such as TCZ on the 2015 EULAR/ACR algorithm.

**CLINICAL CORRELATES AND RELEVANCE OF UCLA GIT 2.0 FOR ESOPHAGITIS AND INDICATION FOR ESOPHAGOGASTRODUODENOSCOPY IN REAL-LIFE PATIENTS WITH SYSTEMIC SCLEROSIS**

N. Zampatti1, A. Garaiman1, S. Jordan1, M. O. Becker1, B. Maurer1, R. Dobrota1, O. Distler1, C. Mihai1. 1University Hospital Zurich, Zurich, Switzerland

**Background:** The gastrointestinal (GI) tract is frequently involved in systemic sclerosis (SSc). The University of California Los Angeles Scleroderma Clinical Trial Consortium Gastrointestinal Tract Instrument 2.0 (UCLA GIT 2.0) is validated to capture GI morbidity in patients with SSc (1). The routine clinical investigation of GI involvement in these patients is not standardized and there is no consensus about when and how frequently an esophagogastroduodenoscopy (EGD) should be performed.

**Objectives:** The main aim of this study was to analyze the capacity of UCLA GIT 2.0 to identify patients with erosive esophagitis in an unselected, real-life SSc patients’ cohort. Secondary aim was to determine whether the UCLA GIT 2.0 could discriminate SSc patients for whom an expert rheumatologist would recommend an EGD.

**Methods:** We selected patients fulfilling the ACR/EULAR 2013 criteria for SSc from the Zurich cohort, having completed at least once the UCLA GIT 2.0 questionnaire. We reviewed the medical charts of SSc patients from 2013 to 2019 and recorded data on EGD. We analyzed by univariable logistic regression several parameters, including UCLA GIT 2.0, considered as potentially associated with 1) the referral to EGD and 2) macroscopic esophagitis according to the Los Angeles criteria.

**Results:** We identified 346 patients (82.7% female, median age 63 years, median disease duration 10 years, 23% with diffuse cutaneous SSc) satisfying the inclusion criteria, who filled in 940 UCLA GIT 2.0 questionnaires. From 940 visits, 31 were excluded because EGD was done within 3 months before completing the UCLA GIT 2.0. In the 909 remaining visits, EGD was recommended by the expert rheumatologists in 128 cases. In logistic regression, UCLA GIT 2.0 total score and some of its subscales, but also the modified Rodnan skin score (mRSS) and esophageal and stomach symptoms by past medical history, associated with the referral to EGD (Table 1).

</tbody>
</table>

We found data on 177 EGD performed in 150 patients, meaning that 49 EGD were performed on indication by another physician. In logistic regression, mRSS and esophageal symptoms correlated with esophagitis, while neither the total ULCA GIT 2.0 score nor the reflux subscale or any of the other subscales showed an association with esophagitis (Table 2).

</tr>
<tr>
<td>Total score of UCLA GIT 2.0</td>
<td>0.67 (0.28 - 1.60)</td>
<td>0.367</td>
</tr>
</tbody>
</table>

**Conclusion:** In a real-life setting, UCLA GIT 2.0 subscales (reflux, distention/bloating, social functioning, emotional wellbeing) and total score strongly associated with expert interpretation of gastrointestinal symptoms and consecutive referral to EGD. However, they showed no correlation with esophagitis on EGD. The main clinical association of esophagitis was the presence of esophageal symptoms.

**Spondyloarthritis - treatment**

**FRI0268**

**REMISSION IN AXIAL SPONDYLOARTHRITIS: IS THERE A DIFFERENCE BETWEEN NSAIDS AND BIOLOGICS IN THE REAL LIFE?**

C. Baeten1, C. Mouafo Toukam2, T. Sokolova2, A. Nzeusseu Toukak1. 1Saint Luc university hospitals, Rheumatology, Brussels, Belgium

**Background:** Randomized-controlled trials (RCTs) done in axial spondyloarthritis (AxSpA) patients have shown that remission in AxSpA and nonradiographic...
axial SpA patients treated without biologics (BIOL) occurs infrequently (Ref 1, 2). Few are known about remission rate (RR) in daily clinical practice.

Objectives: Our aim was to assess the remission rate (RR) in AxSpA patients in Real life, and to compare the RR in AxSpA patients on NSAIDs to RR for those on Biologics (TNFs blockers or IL-17A blockers).

Methods: This cross-sectional study reviewed clinical data from a single center (St-Luc university hospitals, UCLouvain, Brussels) from 01/2013 to 03/2019. Last visit available for clinical assessment was evaluated. Disease activity was measured using the Bath Ankylosing Spondylitis disease activity index (BASDAI), and the Ankylosing Spondylitis disease activity score (ASDAS) using the C-reactive protein. Remission was defined as BASDAI < 4 and ASDAS < 1.3

Results: Data from 551 AxSpA patients were reviewed. 353 were men (64.3%). In the entire cohort, 478 BASDAI and 317 ASDAS were recorded. The RR according to the BASDAI was 46.7% (n = 223), and 17.3% for the ASDAS (n = 55). To look for the treatment-related RR, we stratified by the treatment (NSAIDs vs Biologics). We had 285 patients on NSAIDs (177 men, 62.5%) and 266 on BIOL (176 men, 66%). 245 BASDAI were available for NSAIDs and 233 for BIOL. 110 patients on NSAIDs (44.9%) and 113 on BIOL (48.5%) were in remission for BASDAI. Regarding ASDAS (table below), data from 172 patients on NSAIDs and 144 on BIOL were available. Out of them, 27 (15.7%) and 28 (19.4%) were in remission for NSAIDs and BIOL respectively. Chi-square test: p = 0.853.

Table. Distribution of ASDAS values in both groups.

<table>
<thead>
<tr>
<th>ASDAS Value</th>
<th>NSAIDs (n = 172)</th>
<th>BIOL (n = 144)</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;1.3</td>
<td>N = 27 (15.7%)</td>
<td>N = 28 (19.4%)</td>
</tr>
<tr>
<td>≥1.3 &lt;2.1</td>
<td>N = 41 (23.8%)</td>
<td>N = 30 (20.8%)</td>
</tr>
<tr>
<td>≥2.1 &lt;3.5</td>
<td>N = 70 (40.7%)</td>
<td>N = 57 (39.6%)</td>
</tr>
<tr>
<td>≥3.5</td>
<td>N = 34 (19.8%)</td>
<td>N = 29 (20.1%)</td>
</tr>
</tbody>
</table>

Conclusion: The real life RR in AxSpA seems to be higher on BIOL, even if compared to NSAIDs, the difference is not significant. However, many patients on NSAIDs achieve the remission.

Disclosure of Interests: Charlotte Baert: None declared, Chariote MOUAFO TOUKAM: None declared, Tatiana Sokolova: None declared, Adrien Nzeusseu Toukap Grant/research support from: AbbVie, Celgene Corporation, Janssen, Pfizer, UCB – consultant, Speakers bureau: AbbVie, Eli Lilly, Janssen, Novartis, UCB – advisory board member DOI: 10.1136/annrheumdis-2020-eular.6462

FR0269

CHARACTERIZATION OF PATIENTS WITH ANKYLOSING SPONDYLITIS WHO INITIATED SECUKINUMAB: ELECTRONIC HEALTH RECORDS DATA FROM THE COLUMBUS REPOSITORY

H. Busch1, J. Curtis2, P. Hur3, E. Yi4, Science and Research Institute, Inc, Jupiter, United States of America; 2)The University of Alabama at Birmingham, Birmingham, United States of America; 3)Novartis Pharmaceuticals Corporation, East Hanover, United States of America

Background: Secukinumab was the first anti-interleukin 17A monoclonal antibody treatment approved by the FDA for ankylosing spondylitis (AS). There is scarce information on the characteristics of secukinumab vs other biologic initiators with AS.

Objectives: To describe real-world physician and patient characteristics, and treatment patterns of secukinumab and tumor necrosis factor inhibitor (TNFi) initiators.

Methods: Electronic health records (EHR) data from adult patients with AS who initiated a biologic therapy between January 2016 and March 2019 (index date) were included from the Columbus Repository, a network capturing EHR data from 120 US rheumatology providers. Physician and patient characteristics, and treatment patterns were reported for patients who were prescribed secukinumab and TNFis (adalimumab, etanercept, certolizumab pegol, infliximab, infliximab-ada, and golimumab). Categorical variables were summarized using frequency counts and percentages and continuous variables were presented using means and standard deviations. Standardized mean differences and P values were used to compare treatment groups.

Results: As of March 2019, AS treatment data were available for 82 seukinumab initiators and 160 TNFi initiators. Regarding overall practice size, 33% of practices had a single physician, and 65% of physicians were located in the South US region. Secukinumab initiators were younger than TNFi initiators (47.4 vs 49.8 years) and had a similar prevalence of HLA-B27 positivity (= 55%, Table 1). Comorbid psoriatic arthritis (PsA) was more commonly reported among secukinumab initiators vs TNFi initiators (17% vs 9%), while hypertension (5% vs 11%), obesity (2% vs 11%), and uveitis (2% vs 9%) were less common (Figure 1). Secukinumab initiators were more likely to have prior opioid use vs TNFi initiators but were less likely to have prior methotrexate use (Figure 2A); 67% of secukinumab initiators and 49% of TNFi initiators were biologic experienced, of whom 73% and 76%, respectively, used 1 prior biologic. 25% and 20% used 2 prior biologics, and 22% and 4% used ≥ 3 prior biologics (Figure 2B). The most common reasons for discontinuation of prior biologics among secukinumab and TNFi initiators were because the biologic was no longer required (47% vs 41%) and lack of efficacy (20% vs 24%) (Figure 2C).

Table 1. Baseline Demographics and Disease Characteristics Among Patients With AS at the Index Date.

SMD, standardized mean difference.
* Comparisons with SMD > 0.1 were suggestive of clinically relevant differences.

Conclusion: Secukinumab initiators with AS were younger and more opioid and biologic experienced, were more likely to have a PsA diagnosis, and were more likely to discontinue their previous biologic because the biologic was no longer required compared to patients who initiated TNFIs.

ONE-YEAR EFFECTIVENESS, RETENTION RATE AND SAFETY OF SECUKINUMAB IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS: A REAL-LIFE MULTICENTRE STUDY

1Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy; 2Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome, Italy; 3Unit of Allergology, Immunology and Rheumatology, Department of Medicine, University Campus Bio-Medico di Roma, Rome, Italy; 4Istituto di Reumatologia e Scienze Affini Università Cattolica del Sacro Cuore- Fondazione Policlinico Universitario Agostino Gemelli – IRCCS- Presidio Columbus, Rome, Italy; 5Unit of Allergology, Immunology and Rheumatology, Department of Medicine, University Campus Bio-Medico di Roma, Rome, Italy; 6Department of Clinical and Molecular Medicine, Sant’Andrea University Hospital, Sapienza University of Rome, Rome, Italy

Background: Secukinumab (SEC) is the first interleukin-17A inhibitor showing efficacy in both ankylosing spondylitis (AS) and psoriatic arthritis (PsA) in randomised trials, but real-life data are lacking.

Objectives: In this prospective observational study, we evaluated the effectiveness and safety of SEC in patients with AS and PsA in a real-life setting.

Methods: From September 2018 to September 2019, data were collected from 188 consecutive outpatients at baseline (T0) and at 6 (T6) and 12 months (T12) after starting SEC (39 AS, 23%; 129 PsA, 77%).

Results: Significant improvement was seen at T6 and T12 for all clinical variables, including TJC, SJC, ESR, CRP, DAPSA, ASDAS-CRP and BASDAI, as well as in patient-reported outcomes such as VAS-pain. By multivariable regression analysis, in AS patients high BASDAI at T0 correlated with diagnostic delay (R²=0.4; p=0.009) and peripheral joint involvement (R²=0.4; p=0.04). During follow-up, reduction of BASDAI positively correlated with high ESR (R²=0.65; p=0.04). ASDAS-CRP at T0 positively correlated with high ESR (R²=0.34; p=0.04). Reduction of ASDAS-CRP from T0 to T6 correlated with current smoking status (R²=0.42; p=0.0005). In PsA patients, reduction of DAPSA score from T0 to T12 negatively correlated with the presence of metabolic syndrome (R²=0.41; p=0.0025). Retention rate showed good drug survival and an influence of female sex (Figure 1) in the survival curve in only AS patients, but no differences based on BMI, gender and lines of treatment were observed (Figure 2). SEC was well tolerated: Eleven patients discontinued treatment for non-severe adverse events.

Conclusion: We demonstrated the effectiveness and safety of SEC in patients with AS and PsA in a real-life setting for the first time. No gender differences were observed; however, less clinical improvement was seen in smokers and in patients with metabolic syndrome

IMPACT OF HLA-B27 STATUS ON CLINICAL OUTCOMES AMONG PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH SECUKINUMAB

1 Oregon Health & Science University, Portland, United States of America; 2 Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, United States of America; 3 Charité – Universitätsmedizin Berlin, Berlin, Germany; 4 Novartis Pharmaceuticals Corporation, East Hanover, United States of America; 5 Stanford University School of Medicine, Palo Alto, United States of America; 6 The MetroHealth System and School of Medicine, Case Western Reserve University, Cleveland, United States of America

Background: Ankylosing spondylitis (AS) is strongly associated with the genetic marker HLA-B27. Approximately 80%-90% of white patients with AS express HLA-B27 compared with < 8% of the general population. In patients with AS, negative HLA-B27 status is a predictor of worse response to TNFis. The impact of HLA-B27 status on clinical efficacy of secukinumab, a fully human monoclonal antibody that selectively inhibits IL-17A, has not been studied.

Objectives: To analyze the impact of HLA-B27 status on clinical outcomes at Week 16 in patients with AS treated with secukinumab vs placebo.

Methods: Patients with AS were pooled from the MEASURE 1-4 studies (NCT01358175, NCT01649375, NCT02008896, and NCT02159053) and stratified by HLA-B27 status. All trials included patients who received secukinumab 150 mg every 4 weeks with or without an initial loading dose (10 mg/kg IV at Weeks 0, 2, 4 or 150 mg SC at Weeks 0, 1, 2, and 3) or placebo control. MEASURE 3 included patients receiving secukinumab 300 mg every 4 weeks following the initial IV loading dose. Efficacy at Week 16 was determined by the proportion of patients achieving ASAS20/40, ASAS6/6, ASAS partial remission, BASDAI50, ASDAS-CRP < 2.1, and improvement in Patient Global Assessment (VAS) and total spinal/back pain (VAS) scores. In MEASURE 1, 2, and 4, quality of life (QOL) was assessed at Week 16 by the SF-36 PCS, SF-36 MCS, and ASQOL. ASAS, BASDAI, and ASDAS-CRP responses were analyzed by nonresponder imputation, and all other outcomes by mixed models for repeated measures. For hypothesis generation, outcomes at Week 16 with secukinumab vs placebo within HLA-B27 strata were compared by logistic regression analysis without adjustment for multiple comparisons.

Results: Baseline characteristics were balanced across treatment groups, although more HLA-B27+ patients than HLA-B27– patients were male (71%-73% vs 43%-50%). HLA-B27+ patients receiving any dose of secukinumab were significantly more likely to achieve ASAS40, ASAS partial remission (Figure 1A), and BASDAI50 (Figure 1B) responses than those receiving placebo (P < .05). Patients receiving any dose of secukinumab were more likely to achieve ASAS6/6 and ASDAS-CRP < 2.1 than those receiving placebo, regardless of HLA-B27 status (P < .05; Figure 1B). All secukinumab-treated patients experienced significant improvement in Patient Global Assessment at Week 16 vs placebo, regardless of HLA-B27 status, while only HLA-B27+ patients experienced significant reduction in total spinal/back pain vs placebo (P < .05; Figure 2A). Numerical improvements in QOL were observed in all patients receiving secukinumab 150 mg vs placebo; these reached significance for HLA-B27+ patients (Figure 2B).

Conclusion: Secukinumab may be effective in patients with AS regardless of HLA-B27 status; HLA-B27+ patients may derive increased therapeutic benefit compared with HLA-B27– patients.

DOI: 10.1136/annrheumdis-2020-eular.1448
Background: Pooled safety data has been reported with secukinumab (SEC) in patients (pts) with Psoriatic arthritis (PsA), Ankylosing Spondylitis (AS) and Psoriasis (PsO).1

Objectives: To report longer-term safety data of SEC treatment in PsA, PsO and AS from post-marketing safety surveillance, of pts with PsO, PsA and AS, SEC was well tolerated, with a safety profile consistent with previous reports.1

Methods: The integrated clinical trial safety dataset included data pooled from 28 randomised controlled clinical trials of SEC 300 or 150 or 75 mg in PsO (11 Phase 3 and 8 Phase 4 trials), PsA (5 Phase 3 trials), and AS (4 Phase 3 trials), along with post-marketing safety surveillance data with a cut-off date of 25 December 2018. Adverse events (AEs) were reported as exposure-adjusted incident rates (EAIRs) per 100 pt-years. Analyses included all pts who received ≥1 dose of SEC.

Results: A total of 12,637 pts (8819, 2678 and 1140 pts with PsO, PsA and AS, with an exposure of 150631, 5984.6 and 35272 pt-years, respectively) were included. The most frequent AE was upper respiratory tract infection and EAIR per 100 pt-years for IBD, malignancies and MACE remained low. The EAIR per 100 pt-years for adverse events (AEs) of special interest are reported in Table 1. The cumulative post-market exposure to SEC was estimated to be >285,811 pt-years across the approved indications. Safety data from post-marketing surveillance are reported in Table 2.

PSUR, periodic safety update report; PTY, pt-treatment years

Conclusion: In this long-term analysis across clinical trials and post-marketing surveillance, of pts with PsO, PsA and AS, SEC was well tolerated, with a safety profile consistent with previous reports.1

Reference:
Background: Observational data on the use of secukinumab for the treatment of spondyloarthritis is still lacking. Large population-based registries that allow long-term follow-up have been increasingly used to investigate the performance of biologic drugs in a real-life setting.

Objectives: The aim of this study is to evaluate the effectiveness and the retention rate of secukinumab in psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) patients in a real-life setting over a 3-year follow-up period.

Methods: Data of all PsA and axSpA patients (diagnosed according to CASPAR and ASAS criteria, respectively) treated with secukinumab were prospectively collected in the Italian multicentric LORHEN registry. Effectiveness was measured as the mean change from baseline of Disease Activity in Psoriatic Arthritis score (DAPSA) in PsA and Ankylosing Spondylitis Disease Activity Score (ASDAS) in axSpA patients. Rates of DAPSA remission and ASDAS inactive disease were also computed. The 3-year retention rate was calculated by the Kaplan-Meier method and compared between PsA and axSpA by a log-rank test. A descriptive analysis of reasons for discontinuation was performed.

Results: The study population included 195 PsA (55.4% females, mean age 50.7 ±11.8 years, mean disease duration 10 ±7.8 years, mean baseline DAPSA 23.12 ±12.3) and 94 axSpA (61.7% males, mean age 49.1 ±12.7 years, mean disease duration 10.4 ±9.4 years, mean baseline ASDAS 3.41 ±1.1) patients who received secukinumab as first (26.5 and 33%, respectively) or subsequent biologic agent. Compared with baseline, the 3-, 6- and 12-month mean values of both DAPSA (12.6 ±9.9, 11.2 ±10.5 and 9.3 ±7.5, respectively) and ASDAS (2.23 ±0.9, 2.15 ±0.8, and 1.84 ±0.9, respectively) were significantly decreased (p<0.001 for all the timepoints). The 3-, 6- and 12-month rates of remission/inactive disease were 15.5, 25.4, and 30.5% in PsA and 18.3, 23.7, and 28.6% in axSpA group, respectively. One- and 3-year retention rate (figure 1) were respectively 79.4% and 66.6% in PsA and 72.3% and 70.1% in axSpA patients, with no significant difference between the two groups (p=0.517). The most frequent reason for withdrawal was inefficacy in both PsA (n=41) and axSpA (n=20), whereas only 8 PsA and 6 axSpA patients discontinued secukinumab because of adverse events.

Conclusion: Our data confirmed in a real-life setting the 1-year clinical efficacy and the 3-year survival of secukinumab in both PsA and axSpA. The safety profile of secukinumab was very favorable for both the indications. No significant differences were observed in the performance of secukinumab between axSpA and PsA.

FR0275

ONE-YEAR TREATMENT RETENTION OF SECUKINUMAB VERSUS TUMOR NECROSIS FACTOR INHIBITORS IN SPONDYLOARTHRITIS. RESULTS FROM FIVE NORDIC BIOLOGIC REGISTRIES

Background: Tumor necrosis factor inhibitors (TNFi) have been available for more than a decade for the treatment of spondyloarthritides (SpA). Secukinumab (SEC) represents a new mode of action, but few studies have compared outcomes in patients treated with SEC vs TNFi – and the optimal treatment strategy in routine care remains to be established. Comparative studies between SEC and adalimumab (ADA) are ongoing.

Objectives: To describe baseline characteristics and compare 1-yr treatment retention of SEC vs TNFi (ADA/certolizumab pegol (CLZ)/etanercept (ETN)/golimumab (GOL)/infliximab (IFX)) in SpA pts from 5 Nordic countries.

Methods: Observational, prospective cohort study. Pts with SpA (ankylosing spondylitis/non-radiographic axial SpA) starting SEC or any TNFi during 2015-2018 were identified in clinical rheumatology registries of the Nordic countries. Baseline characteristics were retrieved. Country-specific data were pooled. 1-yr treatment retention of SEC vs TNFi was assessed through crude survival probability curves, retention rates and adjusted Cox regression analyses (ADA reference). Analyses were stratified by line of bDMARD and TNFi type.

Results: In total, 10692 treatment courses (834 SEC, 9858 TNFi) in 7952 patients were included. SEC was rarely used as 1st bDMARD (Table 1), whereas it was the drug most frequently used as 3rd+ line (Table 2). Baseline characteristics were numerically similar for SEC vs TNFi (Table 1).

Figure 1: Kaplan-Meier curve of golimumab persistence in biologic-naïve (BN) and biologic-pretreated (BP) patients with axSpA.

EARLY TREATMENT WITH ANTI-TNF IS ASSOCIATED WITH HIGHER RESPONSE RATES IN PATIENTS WITH ACTIVE AXSpA

S. Gulie1, I. Sari1, E. Durak Ediboglu2, H. Candan3, F. Onen1, S. Akar1, D. Dokuz Eyyul University Hospital, Internal Medicine, Rheumatology, Izmir, Turkey

Background: Treatment options for axial spondyloarthritides (axSpA) is currently limited, and up to 40% of the patients require biologic therapies to control symptoms. Early commencement of biologics suggested to have higher response rates but data regarding this subject is limited.

Objectives: The primary aim was to investigate tumor necrosis factor inhibitor (TNFi) response and retention rates in axSpA patients who were treated in the early disease period (symptom duration ≤5 years). Our secondary aim was to identify factors predicting response to TNFi.

Methods: Adult axSpA patients who started TNFi treatments within the five years of their symptoms were included and defined as Group 1. Patients whose TNFi treatments started five years after their initial symptoms served as a control group (Group 2: 5–10 years and Group3: ≥10 years). Response and survival rates at 6, 12, and 24 months were calculated. Predictors of response on TNFi survival at 24 months were also analyzed.

Results: There was a total of 364 axSpA (Group 1: 95, Group 2: 82 and Group 3: 187) patients in the study (69.8% male, 46.8±12.6 years). Group 1 patients tended to be younger, with a lower baseline CRP tertles and lower HLA-B27 rate compared to the other groups. Drug survival rates were similar between the groups. This finding also remained similar when AS and nraxSpA patients analyzed separately. However, regardless of symptom duration, the drug retention rates were significantly higher in the AS group than in nraxSpA (Table 2).

Conclusions: In this study we showed the following: 1) TNFi started in the early disease course resulted in a better ASAS40 response at both 12 and 24 months, 2) TNFi timing (started in the early or late disease period) seems not affecting drug retention rates, and 3) baseline disease activity is the most important predictor in achieving ASAS40 response at 24 months.

Kaplan Meier Test; Log Rank (Mantel-Cox)

Friday, 05 June 2020
Conclusion: AS and nr-axSpA bDMARD initiators had a modest improvement in outcomes at six months. Twenty percent or fewer patients achieved ASAS20 or ASAS40, with many having residual impairment based on ASDAS, BASDAI, pain, and fatigue outcomes at six months. While patients are initiating biologic agents, room for improvement exists as many are not achieving optimal treatment response of inactive (ASDAS, <1.3) or low disease activity (ASDAS, <2.1).

IXEKIZUMAB IMPROVES SELF-REPORTED OVERALL FUNCTIONING AND HEALTH AS MEASURED BY THE ASAS HEALTH INDEX IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLARTHITIS: 52-WEEK RESULTS OF A PHASE 3 RANDOMIZED, ACTIVE AND PLACEBO-CONTROLLED TRIAL (COAST-X)

U. Kiltz1,2, J. A. Walsh3, R. B. Vargas4, T. Hunter1, R. Bolcoe5, D. Sandoval6, S. L. Leage6, A. Leung7, X. Liu8, E. Blue6, J. Braun1,2,1 Rheumazentrum Ruhrgebiet, Herne, Germany; 2Ruhr-University, Bochum, Germany; 3University of Utah, Salt Lake City, United States of America; 4Hospital General De Mexico, Mexico City, Mexico; 5Eli Lilly and Company, Indianapolis, United States of America; 6Eli Lilly and Company, Indianapolis, United States of America; 7Syneos Health, Morrisville, United States of America

Background: Ixekizumab has demonstrated efficacy in treating signs and symptoms of patients with non-radiographic axial spondyloarthropathy (nr-axSpA).1 The Assessment of SpondyloArthritis International Society Health Index (ASAS HI) is a composite measure consisting of 17 dichotomous items to assess overall functioning and health in patients with spondyloarthropathies.2

Objectives: To assess health outcomes using ASAS HI in patients with nr-axSpA treated with ixekizumab (IXE) for 52 weeks.

Methods: COAST-X (NCT02757352) was a 52-week, randomized, double-blind, placebo (PBO)-controlled study enrolling adults with an established diagnosis of axSpA (ASAS classification criteria, but not modified New York criteria for spondylitis), had Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score ≥4, back pain score ≥4, inflammation (spondilitis on magnetic resonance imaging [MRI]) per ASAS criteria) or an elevated C-reactive protein (CRP) level >5 mg/L, and inadequate response or intolerance to nonsteroidal anti-inflammatory drugs. Patients were randomized 1:1:1 to receive PBO or 80 mg IXE every 4 weeks (Q4W) or every 2 weeks (Q2W). Changing background medications or switching to open-label IXE Q2W, or both, was allowed after Week 16 at investigator discretion. Change from baseline in ASAS HI (score ≥0.17 with higher score indicating worse health) was analyzed using logistic regression analysis at Weeks 0, 4, 8, 16, 36, and 52. For the ASAS HI, the smallest detectable change was calculated as 3.0. Patients having an ASAS HI score ≤5 were defined as being in a good health state.3 Comparisons between IXE treatments and PBO were made using logistic regression analysis. Non-responder imputation was used for missing data. Patients who switched to open label IXEQ2W were considered non-responders after they switched.

Results: At baseline, ASAS HI scores were similar between the three groups (PBO 9.0 ± 3.7; IXE Q4W 8.6 ± 3.4; IXE Q2W 9.6 ± 3.4). Significantly more patients receiving IXE Q4W versus PBO achieved ASAS HI score ≤5 at Week 16 (p<0.05; Fig. A). From Week 36 to 52, significantly more patients receiving IXE Q4W and Q2W achieved ASAS HI score ≤5 (p<0.05; Fig. A). Significantly more patients receiving IXE Q2W versus PBO achieved a clinically meaningful improvement in ASAS HI score ≤3 at Week 16 (p<0.05; Fig. B). From Week 36 to 52 significantly more patients receiving IXE Q4W and Q2W achieved a clinically meaningful improvement in ASAS HI score ≥3 compared with PBO (p<0.05; Fig. B).

Conclusion: Ixekizumab improves overall functioning and health in patients with nr-axSpA as assessed by ASAS HI, with significantly more patients achieving good health status.

DO: 10.1136/annrheumdis-2020-eular.1361
Background: Treat to target is a goal in pregnant women with spondyloarthritides. There is increasing evidence on safe use with TNF inhibitors during pregnancy (1). Adjusted use of TNF inhibitors preconception and throughout pregnancy may stabilize disease activity and prevent flares (2). Low disease activity is also beneficial for the fetus.

Objectives: To study the use of TNF-inhibitors among women with spondyloarthritides in Norway before, during and after pregnancy.

Methods: RevNatus is a Norwegian, nationwide quality register that monitors treatment of inflammatory rheumatic diseases before, during and after pregnancy. Data from RevNatus in the period October 2017 to October 2019 were used to map the use of all types of TNF inhibitors among 208 women with spondyloarthritides, fulfilling the ASAS criteria. The use of medication was reported at the time of visit in outpatient clinic. The frequency of use of TNF inhibitors is registered at seven timepoints from pre-pregnancy to twelve months after delivery.

Results: The use of TNF-inhibitors was reported at each visit for all the women with spondyloarthritides. Most women are not using TNF inhibitors before and beyond conception, used certolizumab, etanercept, or adalimumab. Infliximab or golimumab were not used in pregnancy (tabell 2).

COMPARATIVE DRUG SURVIVAL OF TNF INHIBITORS AND SECUKINUMAB IN BIOLOGIC NAÏVE PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS

M. Cheila1, K. Douglas1, C. Koutsianas1. 1The Dudley Group NHS Foundation Trust, Department of Rheumatology, Dudley, United Kingdom

Background: Secukinumab (SEC) was approved for treating ankylosing spondylitis (AS) and psoriatic arthritis (PsA) in the UK in 2016/17 respectively, providing an alternative mechanism of action to TNF inhibitors (TNFI), which were, until that time, the most frequently prescribed biologic therapies for these rheumatic conditions. SEC’s efficacy and safety has been shown in clinical trials1,2, but real world data on its survival remains scarce.

Objectives: This study aimed to compare SEC and TNFí drug survival in AS and PsA biologic naïve patients.

Methods: Observational retrospective study of consecutive biologic naïve patients attending the Dudley Group NHS Foundation Trust (DGFT) with a clinical diagnosis of AS (fulfilling ASAS criteria) or PsA (fulfilling CASPAR criteria) who received at least one dose of biologic therapy between 01/07/2017 and 30/09/2019, with a follow-up period until December 31st, 2019. The biologics database, patient medical records and investigations were reviewed and data on demographics, disease characteristics, previous DMARD therapy and reasons for discontinuation of biologic were collected. Analysis was performed using descriptive statistics, Kaplan-Meier plots and Cox regression on SPSS version 23.

Results: We identified 153 AS or PsA patients starting biologic therapy in this time interval. 103 (68.7%) were biologic naïve, commencing either TNFI (38, 36.9%), SEC (63, 61.1%) or Ixekizumab (2, 1.9% -excluded from analysis) for AS (45,5%) and PsA (54,5%). The patients were evenly distributed in terms of sex (female 50,5%), had a mean ±SD age of 45 ±13.8 years and a median (IQR) disease duration of 5 (7.7) years. The median (IQR) follow up time was 13 (13) months.

The overall 1 and 2-year drug survival was 86.8% and 79.3% respectively for TNFI and 81.5% and 77.4% for SEC treated patients. There was no statistically significant difference between the estimated means for drug survival time for the two treatment modalities (TNFI: 24.4 vs SEC:22.9 months, log rank:0.991) (Figure 1). The analysis of SEC’s drug survival in AS in comparison to PsA did not show statistically significant difference (21.8 vs 22.0 months respectively, log rank: 0.419). We observed a trend for worse TNFI survival in AS compared to PsA, but this did not reach statistical significance (18.9 vs 26.1 months respectively, log rank: 0.09).

Figure 1. Comparative cumulative drug survival (months) in biologic naïve AS and PsA patients

No significant difference in reasons for discontinuation between treatments was observed. Age, sex, disease duration, previous DMARD use and extra-articular manifestations were variables that were not associated with drug survival on Cox regression analysis.

Conclusion: The estimated 1 year drug survival for TNFI and SEC was 86.8% and 61.5% respectively. Data from our cohort of real-life previously biologic naïve patients with AS and PsA showed no difference in drug survival and reasons for discontinuation between TNFI and SEC. Age, sex, previous DMARD use and extra-articular manifestations were not predictors for drug survival.

CONVENTIONAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS THERAPY HAS NO EFFICACY IN SLOWING SPINAL RADIOPHASIC PROGRESSION IN ANKYLOSING SPONDYLITIS: RESULTS FROM 18-YEAR LONGITUDINAL DATA

1Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Inje University Seoul Paik Hospital, Inje University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 3Hanyang University Hospital, Department of Radiology, Seoul, Korea, Rep. of (South Korea); 4Asan Medical Center, University of Ulsan College of Medicine, Department of Biomedical informatics, Seoul, Korea, Rep. of (South Korea); 5Asan Medical Center, University of Ulsan College of Medicine, Department of Clinical Epidemiology and Biostatistics, Seoul, Korea, Rep. of (South Korea)

Background: In the treatment of ankylosing spondylitis (AS), conventional disease-modifying antirheumatic drugs (cDMARDs) are generally recommended only in patients with peripheral arthritis. However in daily clinical practice, sulfasalazine (SSZ) and methotrexate (MTX) have still been considered on the basis of their anti-inflammatory effect when non-steroidal anti-inflammatory drugs (NSAIDs) are not available and when it is difficult to start tumor necrosis factor (TNF) inhibitors. Nonetheless there is few data about the impact of the cDMARDs on the prognosis of spinal progression.

Objectives: The aim of this study was to investigate the effectiveness of SSZ and MTX on the spinal radiographic progression in patients with AS.

| ESR (log) | † | † |
| BASDAI (square root) | † | † |

Not included in the model because the value did not show potentially significant association in univariate analysis (p > 0.1).

Methods: A total of 301 patients who have been treated with cDMARDs were enrolled from 1,280 patients in a single center cohort during 18 years of follow up. For each patient, time intervals of periods were created according to the prescription records. ‘On-DMARD’ intervals were time intervals of periods with SSZ or MTX treatment and ‘off-DMARD’ intervals were time intervals of periods without both SSZ and MTX treatment. The intervals were the periods excluding the treatment periods of TNF inhibitors. Radiographic progression was evaluated by the rate of Modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) change, an increase or decrease of mSASSS change per year. A generalizing estimation equation models were used for adjustment for confounding covariates were used to evaluate the efficacy of cDMARDs by the radiographic progression.

Results: The number of 732 on-DMARD intervals and 1,027 off-DMARD intervals were obtained. Among the on-DMARD intervals, the proportion of intervals treated with SSZ (on-SSZ intervals), MTX (on-MTX intervals) and both of them (on-SSZ/MTX intervals) were 96.2%, 19.9% and 16.1%, respectively. In the multivariable regression analysis, there was no significant decrease in the rate of mSASSS change during cDMARDs therapy (β = -0.081, p = 0.418) (Table 1). And the mean rate of mSASSS change were 0.61 during on-DMARD intervals and 0.69 during off-DMARD intervals after adjustment of other covariates.

Conclusion: Treatment with cDMARDs in AS did not show significant impact in retarding spinal progression. In patients with AS, treatment with biologics rather than cDMARDs may be more effective in slowing radiographic progression.
Background: Previous studies have suggested similar effectiveness, but longer treatment retention, for tumour necrosis factor inhibitors (TNFi), when used in combination with a conventional synthetic disease modifying anti-rheumatic drug (csDMARD) in psoriatic arthritis (PsA).

Objectives: To describe patients with PsA initiating a first TNFi as monotherapy compared to combination therapy, and to explore 1-year treatment retention of TNFi in the two groups.

Methods: Patients with PsA starting a first TNFi (2006-2017) were identified in biologics registers of 13 European countries, and data were pooled for analysis. Co-medication with csDMARD was determined at TNFi start.

Results: A total of 14778 patients with PsA starting a first TNFi were included. Baseline disease activity was similar within stratum B, but higher for the combination treatment group in stratum A (table 1).

</table>

Numbers are means (sd) unless otherwise stated.

The Kaplan-Meier curves for the treatment groups were similar within each stratum (fig 1), as were the proportions remaining on TNFi after one year, stratum A: monotherapy 86% (95%CI: 85-88) vs. combination 86% (84-87), stratum B: 71% (69-72) vs. 73% (72-74). The HRs for TNFi discontinuation (ref=TNFi monotherapy) were: (i) 1.06 (0.98-1.13), (ii) 0.94 (0.87-1.01), (iii) 0.89 (0.83-0.96), including 13078 patients (9 countries) for model (iii).

Conclusion: In this exploratory study no benefit in TNFi retention was observed for csDMARD combination therapy in crude analyses, while in adjusted analyses an 11% lower risk of TNFi discontinuation was found. These preliminary results offer limited support for use of combination therapy in PsA. Further analyses will explore to what extent the results are affected by inter-country heterogeneity and differences between TNFi.
BACKGROUND: Secukinumab (SEC) is a novel treatment for psoriatic arthritis (PsA), but data from real life are still missing.

OBJECTIVES: 1) to evaluate the effectiveness and safety of a wide cohort of PsA patients on SEC followed in 7 Italian rheumatologic centers for 24 months; 2) to compare the features and disease activity indices of SEC-treated PsA patients subdivided in naive biological drugs (group A) and in TNF-inhibitors (TNFi) failure patients (group B).

METHODS: Consecutive patients with moderate-severe PsA, who began SEC treatment were evaluated prospectively. Data on disease characteristics, previous and ongoing treatments, comorbidities and duration of follow-up were collected. Disease activity, functional and clinimetric scores and biochemical values were recorded at baseline (t0), at 6 (t6), 12 (t12), and 24 (t24) months. Anova (Kruskal Wallis) and general linear models were used to compare variables over time. Infections and adverse events were also collected.

RESULTS: PsA 345 patients [38.84% men; mean age 52.9 (11.27) years] were enrolled; mean treatment duration was 18.53 (9.97) years. SEC was prescribed as first line biologic treatment in 133 (38.55%) patients. Enthesitis was present as a prominent manifestation in 61.44% of patients (Figure 1).

In all population significant decrease in tender/swollen joints; Visual Analog Scale of pain (VASp) and general health (VASgh); Psoriasis Area and Severity Index (PASI); Bath Ankylosing Spondylitis Disease Activity Index (BASDAI); Bath Ankylosing Spondylitis Functional Index (BASFI); CRP; ESR; DAPSA, ASDAS respectively. Forty-three patients (12.46%) had a more erosive (p=0.04) and polyarticular pattern (p=0.04), a longer disease duration (p=0.001), a greater disease activity compared with placebo (PBO). 1 Selective JAK1 inhibition by FIL, an oral, selective Janus kinase 1 (JAK1) inhibitor, significantly reduced AS disease activity compared with placebo (PBO). 2 Selective JAK1 inhibition by FIL has the potential to simultaneously block multiple inflammatory pathways, thus we analyzed biomarker concentrations in serum samples from TORTUGA. 3Selective JAK1 inhibition by FIL has the potential to simultaneously block multiple inflammatory pathways, thus we analyzed biomarker concentrations in serum samples from TORTUGA.

BACKGROUND: Ankylosing spondylitis (AS) is a chronic, immune-mediated disease characterized by inflammation of the sacroiliac joints and spine, and a young age of onset of 20–40 years. In the recent TORTUGA study, filgotinib (FIL), an oral, selective Janus kinase 1 (JAK1) inhibitor, significantly reduced AS disease activity compared with placebo (PBO). 1 Selective JAK1 inhibition by FIL has the potential to simultaneously block multiple inflammatory pathways, thus we analyzed biomarker concentrations in serum samples from TORTUGA.

OBJECTIVES: To evaluate the impact of selective JAK1 inhibition with FIL on circulating disease associated biomarkers in adult patients with active AS enrolled in the TORTUGA study.

METHODS: TORTUGA (Clinicaltrials.gov identifier NCT03117270) was a 12-week, randomized, double-blind, placebo-controlled, phase 2 study. Patients were randomized 1:1 to FIL 200 mg (n=58) or PBO (n=58) once-daily. Serum samples (FIL n=56, PBO n=53) were collected at baseline (BL) and weeks 1, 4 and 12, and analyzed using the Meso Scale Discovery immunoassay platform (Meso Scale Diagnostics, Rockville, MD, USA) to evaluate 135 biomarkers. Biomarker concentration changes from BL were analyzed on paired patient data and clustering analysis was performed. Correlation between the 135 biomarkers and selected clinical scores at BL was assessed by Spearman rank correlation analysis.

RESULTS: FIL treatment produced significant reductions in serum concentrations of multiple biomarkers associated with AS disease activity. Five clusters of biomarker response were identified based on the kinetics and magnitude of percent changes from BL. These clusters also represented discrete biological functions:

Hertz2, 1University of Alberta, Edmonton, Canada; 2Gilead Sciences Inc., Foster City, United States of America; 3Galapagos SASU, Romainville, France; 4Galapagos BV Leiden, Netherlands

1. Background: Ankylosing spondylitis (AS) is a chronic, immune-mediated disease characterized by inflammation of the sacroiliac joints and spine, and a young age of onset of 20–40 years. In the recent TORTUGA study, filgotinib (FIL), an oral, selective Janus kinase 1 (JAK1) inhibitor, significantly reduced AS disease activity compared with placebo (PBO). 2 Selective JAK1 inhibition by FIL has the potential to simultaneously block multiple inflammatory pathways, thus we analyzed biomarker concentrations in serum samples from TORTUGA.

2. Methods: TORTUGA (Clinicaltrials.gov identifier NCT03117270) was a 12-week, randomized, double-blind, placebo-controlled, phase 2 study. Patients were randomized 1:1 to FIL 200 mg (n=58) or PBO (n=58) once-daily. Serum samples (FIL n=56, PBO n=53) were collected at baseline (BL) and weeks 1, 4 and 12, and analyzed using the Meso Scale Discovery immunoassay platform (Meso Scale Diagnostics, Rockville, MD, USA) to evaluate 135 biomarkers. Biomarker concentration changes from BL were analyzed on paired patient data and clustering analysis was performed. Correlation between the 135 biomarkers and selected clinical scores at BL was assessed by Spearman rank correlation analysis.

3. Results: FIL treatment produced significant reductions in serum concentrations of multiple biomarkers associated with AS disease activity. Five clusters of biomarker response were identified based on the kinetics and magnitude of percent changes from BL. These clusters also represented discrete biological functions:
Conclusion: In patients with active AS, FIL treatment significantly decreased levels of circulating biomarkers associated with active AS disease, including proinflammatory cytokines and chemokines, cell adhesion molecules, and markers of matrix remodelling. Clustering analysis revealed early and late biomarker changes associated with disease. These data are consistent with reduced AS disease activity in TORTUGA and suggest that FIL treatment leads to a rapid and sustained reduction of inflammation in AS.

Results: Baseline characteristics were available for 1,145 patients. Those with n-axSpA were more likely to be male, were older, and had longer disease duration (Table 1). Follow-up ASDAS was available in 290 patients. Two thirds of the patients achieved ASDAS low disease state at one year regardless of radiographic status (n-r-axSpA: 64.2% vs r-axSpA: 66.1, Diff: -1.9%, 95% CI -13.7 to 9.9). Further, no significant differences were seen between the groups in attaining ASDAS CII (n-axSpA: 50.7% vs r-axSpA: 44.7%; Diff: 6.0%, 95% CI -7.8 to 19.8%) or MI (n-axSpA: 20% vs r-axSpA: 18.7%; Diff: 1.3%, 95% CI 9.7 to 12.3%). Conclusion: Although there appeared to be some differences in the baseline characteristics when exploring this cohort, according to radiographic status, which are likely related to the natural history of the disease; the level of biologic response was comparable between the groups supporting the concept of axSpA as a single disease entity.

FR10288 TREATMENT PATTERNS AND PHARMACOUTILIZATION AMONG PATIENTS AFFECTED BY ANKYLOSING SPONDYLITIS: AN ITALIAN REAL-WORLD STUDY

V. Perrone1, S. Losi2, E. Filippo2, S. Antonelli,3 M. Giovanini3, E. Giacominii, D. Sangiorgii,1 L. Degli Esposti1,2 Clonic Srl, Health Economics and Outcomes Research, Ravenna, Italy;3Eli Lilly Italy S.p.A., Sesto Fiorentino, Italy;2Eli Lilly Italy S.p.A., Roma, Italy

Background: Ankylosing spondylitis (AS) is a chronic rheumatologic condition requiring lifelong treatments. To date, few real-world studies on AS patients in Italy are reported.

Objectives: Aims of the study were to evaluate treatment patterns and to analyse pharmaceuticals on patients affected by AS in a real-world setting of Italian clinical practice.

Methods: This observational study was based on administrative databases of a pool of Italian settings. A retrospective cross-sectional analysis was performed for years 2015-2017 to evaluate AS-diagnosed patients and, among them, to estimate percentage of treated and untreated ones. Patients were included if having a hospitalization discharge diagnosis at any level of AS (ICD-9-CM: 720.0) or exemption code for AS (non-steroidal anti-inflammatory drugs, disease-modifying antirheumatic drugs (DMARDs) - targetted synthetic (tsDMARDs) and biological (bDMARDs)) at ID were defined “treated”; Patients without such drug prescriptions at ID were considered “untreated”. To analyse treatment patterns of b/tsDMARDs-treated patients a longitudinal cohort study was conducted considering as inclusion periods the period from 07/01/2014 to 30/06/2020. ID was date of first b/tsDMARDs prescription during inclusion period. Follow-up (F-up) lasted one year after ID. The interruption of treatment was defined as the absence of prescriptions in the last 3 months of F-up.

Results: For cross-sectional-cohort: AS-diagnosed patients were 4,824 in 2015, 5,357 in 2016, 5,894 in 2017. In all years analysed, about 50% of patients were male. Mean age±SD ranged from 51.5±13.7 (2015) to 52.4±14.0 (2017). Untreated patients were 33.6% (2015), 35.1% (2016) and 37.9% (2017), while patients in therapy with b/tsDMARDs were 22.7% (2015), 22.3% (2016) and22.2% (2017). The remaining percentage of patients were treated with csDMARDs:NSAIDS: 43.7% (2015), 42.6% (2016), 39.9% (2017). In 2015 and 2016 all bDMARDs-treated patients were in therapy with anti-TNF agents, while the advent of IL-inhibitors was observed starting from 2017 (8.2% b/tsDMARDs-treated patients with IL-inhibitors). For longitudinal-cohort: in 2014, 310 patients had a b/tsDMARDs prescription and during 1-year F-up 11.9% of them interrupted the treatment after a mean time ±SD of 83.3±66.9 days. Of the 183 patients who had a prescription of b/tsDMARDs at ID during 2016-2017, 22.4% had a treatment interruption after a mean times SD of 134.4±86.1 days during F-up.

Conclusion: This real-world study provided insights on AS treatment patterns. Preliminary results showed that approximately one third of AS patients are untreated and about one in five are treated with b/tsDMARDs. Despite the improvement in treatment duration observed from 2014 to 2016/17, still 22.4% of b/tsDMARDs-treated patients interrupted therapy in the most recent cohort. A larger sample size is needed to confirm results.

Objectives: To describe the baseline characteristics and bDMARD response at one year in axSpA patients in the British Society for Rheumatology Biologies Register in Ankylosing Spondylitis (BSBR-AS) according to radiographic status.

Method: BSRBR-AS is a national prospective cohort including participants who fulfil the ASAS classification criteria for axSpA. In this analysis, cross-sectional baseline data of patients starting bDMARDs including clinical, demographic and patient-reported outcomes (PROs) were compared. Follow-up data at one year was identified if 12±4 months from baseline and PROs completed within 2 months of visit date. Ankylosing Spondylitis Disease Activity Scores (ASDAS) for low disease status, clinically important improvement (CII) and major improvement (MI) were used to measure treatment response.

JOSEPH SPOONER

DOES SMOKING AFFECT SECUKINUMAB TREATMENT OUTCOMES AND SAFETY IN PATIENTS WITH ANKYLOSING Spondylitis? – REAL WORLD DATA FROM THE GERMAN AQUILA STUDY

1Medizinische Hochschule Hannover, Clinic for Immunology and Rheumatology, Hannover, Germany; 2Rheumazentrum Ruhrgebiet, Herne and Ruhr-University Bochum, Herne, Germany; 3Rheumatologische Schwerpunktpraxis, Berlin, Germany; 4Ambulantes Rheumazentrum Erfurt, Germany; 5Novartis Pharma GmbH, Immunology, Hepatology & Dermatology, Germany; 6Universitätsklinikum, Rheumatology/Immunology, Würzburg, Germany

Background: There is growing body of evidence that smoking is associated with more active and severe disease in patients (pts) with ankylosing spondylitis (AS).1,2 The German non-interventional study AQUILA provides real-world data on the influence of smoking on therapeutic effectiveness and safety under secukinumab (SEC), a fully human monoclonal antibody that selectively inhibits interleukin-17A.

Objectives: The aim of this interim analysis is to describe selected baseline (BL) demographics, to evaluate SEC effectiveness on disease activity and global functioning and health, and to report safety profile depending on smoking status of AS pts.

Methods: AQUILA is an ongoing, multi-center, non-interventional study including up to 2700 pts with active AS or psoriatic arthritis. Pts were observed from BL up to week (w) 52. Real-world data was assessed prospectively and analyzed as observed. Assessment of CRP and validated questionnaires were used to collect data on disease activity (Bath Ankylosing Spondylitis Disease Activity Index, BASDAI), global functioning and health (Assessment of SpondyloArthritis-Health Index, ASAS-HI) and depressive mood (Beck’s Depression Inventory version II, BDI-II).

For calculation of proportion of pts who experienced (serious) adverse events (S)AEs, all AS pts were included who received at least one dose of SEC irrespective of further documentation of any study visit. This analysis focuses on the subgroups non-smoker (NS) and smoker (S).

Results: At BL, 311 AS pts were included: 42.1% (n=131) NS and 32.8% (n=102) S. Remaining subgroups were 15.1% (n=47) ex-smoker and 10.0% (n=31) of unknown smoking status. About half of AS pts in NS were male, while in S (89.6%) portion of men was more than twice as high as of women. S were slightly younger than NS (mean age: 43.9/49.0 years). During the study, CRP value decreased irrespective of smoking status with numerically higher fluctuations in S (Fig. 1A). BASDAI (NS: 5.2 at BL to 3.7 at w52, S: 5.6 at BL to 4.1 at w52) and ASAS-HI (Fig. 1B) scores numerically improved best in NS, whereas more variations were seen in S; the same was observed for BDI-II score values (NS: 11.8 at BL to 9.2 at w52, S: 13.0 at BL to 12.1 at w52).

Conclusion: In a real-world setting, SEC improved disease activity and global functioning and health in AS pts with slight (mostly non-significant) differences between NS and S. Overall, this interim analysis shows that SEC is an effective treatment with a favorable safety profile up to 52 weeks, irrespective of the pts smoking status. Further progress of the AQUILA study will reveal whether this trend will continue.

Table 1. Overview of AEs (and SAEs) under SEC treatment depending on smoking status in AS pts

Conclusion: In a real-world setting, SEC improved disease activity and global functioning and health in AS pts with slight (mostly non-significant) differences between NS and S. Overall, this interim analysis shows that SEC is an effective treatment with a favorable safety profile up to 52 weeks, irrespective of the pts smoking status. Further progress of the AQUILA study will reveal whether this trend will continue.
discontinuation was observed in patients who received golimumab as first biological drug vs second (HR 0.45, 95% CI 0.85-2.46, p=0.171).

PsA vs RA: A significantly lower discontinuation rate was observed in patients with PsA vs RA (HR 0.49, 95% CI 0.28-0.87, p=0.015).

SpA vs RA: A lower discontinuation rate was observed in patients with SpA vs RA (HR 0.56, 95% CI 0.31-1.00, p=0.050).

Overweight: The discontinuation rate was higher in overweight patients vs normal weight (HR 1.10, 95% CI 0.63-1.93, p=0.728).

Corticosteroids: A higher discontinuation rate was observed in patients treated with corticosteroids vs other DMARDs (HR 1.71, 95% CI 1.04-2.83, p=0.036).

Other DMARDs: The discontinuation rate was higher in patients treated with other DMARDs vs corticosteroids (HR 1.88, 95% CI 0.90-3.93, p=0.091).

Results: Secukinumab is a human monoclonal antibody directed against IL-17A, approved for the treatment of psoriatic arthritis (PsA) and ankylosing spondylitis and psoriatic arthritis in real clinical practice.

Methods: We conducted a retrospective longitudinal observational multicenter study of all patients with PsA and Spondyloarthritis (SpA) who had received at least one dose of secukinumab. Adverse events and drug retention were considered the main variables. In addition, we collected variables predicting drug retention. We estimated the total adverse event rate, by severity and type of event, and the total discontinuation rate as the main outcome. We estimated the total adverse event rate, by severity and type of event, and the total discontinuation rate as the main outcome. We estimated the discontinuation rate at one year in a population mostly refractory to biological therapy.

Conclusion: In this study of real clinical practice, secukinumab showed a 66% retention rate at one year in a population mostly refractory to biological therapy. The main cause of discontinuation was lack of efficacy. The AAs that led to drug discontinuation occurred mainly in the first 6 months of treatment.

FRID0291 SAFETY AND SURVIVAL OF SECUKINUMAB IN SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS: REAL-LIFE DATA. A MULTICENTER STUDY

I. Villa-Blanco1, S. Alonso Castro2, S. Fernández2, J. L. Martín-Varillas3, L. C. Charca Benavente4, M. Pino Martínez5, L. Riancho-Zarrabeitia6, I. Morante Bolado7, M. Santos Gómez8, A. Brandy-García9, E. Aurreroecoechea1, L. Carmona4, R. Queiró Silva1, Hospital Sierrallana, Torrelavega, Spain; 2Hospital Universitario Central de Asturias (HUCA), Oviedo, Spain; 3Hospital Universitario de Cabuérniga, Gijón, Spain; 4Instituto de Salud Carlos III, Madrid, Spain

Background: Secukinumab is a human monoclonal antibody directed against IL-17A, approved for the treatment of psoriatic arthritis (PsA) and ankylosing spondylitis (AS). The safety profile of secukinumab was favourable in clinical studies, but there is still scarce evidence in clinical practice.

Objectives: To analyze the retention rate and safety of secukinumab as well as the causes and factors associated with its survival in patients with ankylosing spondylitis and psoriatic arthritis in real clinical practice.

Methods: We conducted a retrospective longitudinal observational multicenter study of all patients with PsA and Spondyloarthritis (SpA) who had received at least one dose of secukinumab. Adverse events and drug retention were considered the main variables. In addition, we collected variables predicting drug retention. We estimated the total adverse event rate, by severity and type of event, and the total discontinuation rate as the main outcome.

Results: Secukinumab was the first line of treatment in 13 patients (8%), the second line in 46 (30%), the third line in 54 (35%) and sub- sequent lines in 2 cases of Crohn's disease occurred during the exposure. These changes were evident in treatment responders only.

Conclusion: Treatment with bDMARDs is associated with favorable changes of the body composition with increase of the muscle mass but not of the visceral fat. These changes were evident in treatment responders only.

FR10293 EFFECTIVENESS OF SWITCHING BETWEEN TNF INHIBITORS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: IS THE REASON TO SWITCH RELEVANT?

Background: It has been common practice to start a second TNF inhibitor (TNFi) in patients with axial spondyloarthritis (axSpA) who discontinue their first TNFi. It remains unclear if the reason for discontinuation of the first TNFi influences the response to the second TNFi.

Objectives: To assess if the reason of discontinuation of the first TNFi influences the response to the second TNFi.

Methods: Patients with axSpA from the ReumaPt registry, who discontinued their first TNFi and started a second TNFi, and who had complete data on Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) at baseline, 3 and 6 months for their first TNFi were included. Then, they were followed every 6 months up to 12 years. The main outcome was the ASDAS clinically important improvement (ASDAS CII). Secondary outcomes were ASDAS major important improvement (ASDAS MI); ASDAS low disease activity (ASDAS LDA); ASDAS inactive disease (ASDAS ID) and BASDAI 50. The reason for discontinuation of the first TNFi was defined as: i) Primary failure, ASDAS CII was not achieved at 3 or 6 months; ii) Secondary failure, ASDAS CII achieved at 3 or 6 months but lost in ≥1 follow-up visit; iii) Adverse events; iv) Other (e.g. pregnancy, surgery). The response to the first TNFi at 3 and 6 months was compared to the response to the second TNFi at the same visits, adjusting for age, gender and C-reactive protein (CRP). The association between the reason of discontinuation of the first TNFi and response to the second TNFi was assessed using generalized estimating equations (GEE) models adjusted for age, gender and CRP.

Results: In total, 193 patients (53% male, mean age 45 (SD:11) years) were included, with a median follow-up time on the second TNFi of 1.5 years. Patients had a lower response to the second TNFi compared to the first TNFi according to the main outcome (ASDAS CII) at 3 months (41% vs 51%) and 6 months (35% vs 56%). There was an association between the reason to discontinue the first TNFi and response to the second TNFi as defined by the most stringent outcomes (ASDAS MI and ASDAS ID), but not for ASDAS CII (Table). Compared to patients who discontinued their first TNFi due to primary failure, patients were more likely to achieve ASDAS ID with the second TNFi when they discontinued their first TNFi due to secondary failure (OR: 73.9 (95%CI: 1.9; 27.7)), adverse events (OR: 9.1 [2.5; 33.3]), or other reasons (OR: 7.7 [1.6; 37.9]).

Conclusion: In axSpA, response to the second TNFi is worse compared to the first TNFi. Patients with a secondary failure to the first TNFi have a better response to the second TNFi compared to those discontinuing the first TNFi due to primary failure, particularly for most stringent outcomes.

FR10294 MUSCULOSKELETAL MANIFESTATIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE TREATED WITH VEDOLIZUMAB

P Rodrigo-Merlos, A. M. Ruiz- Ramirez, C. Plassencia, V. Navarro-Compañ, C. Suarez-Ferrer, E. Martin-Arranz, M. D. Martin Arranz, D. Peitèlado, G. Bonilla, M. Sánchez Azofra, J. Poza Cordón, K. N. Franco Gomez, A. Balsa, University Hospital La Paz, Rheumatology Department, Madrid, Spain; University Hospital La Paz, Gastroenterology Department, Madrid, Spain
Background: Musculoskeletal manifestations (MEM) are frequent extraintestinal symptoms in patients suffering from inflammatory bowel disease (IBD), affecting up to 40% of them. Tumor necrosis factor inhibitors (TNFi) are effective in both IBD and IBD-related spondylarthritides (SpA). Additionally, vedolizumab (VDZ), an α4β7 integrin inhibitor with selective action on intestinal tissue, has been recently proposed as 1st line treatment on TNFi refractory IBD. The effectiveness of VDZ in MEM has not been properly evaluated but even exacerbation of previously diagnosed SpA has been described.

Objectives: The main objective is to analyse the occurrence of articular exacerbations in patients with IBD-related SpA treated with VDZ. The secondary objective is to analyse the new-onset MEM in IBD patients treated with VDZ.

Methods: Descriptive study of a retrospective cohort of every adult with IBD (Crohn’s disease -CD- and ulcerative colitis -UC-) patients starting treatment with VDZ in a tertiary hospital. All data were collected as a collaboration between the Rheumatology and Gastroenterology Departments, through revision of the clinical history and databases from both departments. In patients previously diagnosed of SpA exacerbation was assessed, defined as a clinical worsening causing a treatment modification. The patients with new-onset MEM were classified as: i) non-specific arthralgia (NsA), not suggestive of SpA; and ii) SpA according to ASAS criteria. A statistical analysis was performed using frequency charts.

Results: A total of 61 patients were included, 55.7% women and with an mean (SD) age of 50 (17) years. The proportion of UC and CD was similar (49% and 51%, respectively). Among the patients studied, 12 (19.7%) had a diagnosis of IBD-related SpA and 3 (25%) of them suffered articular exacerbation of SpA within 3,5 and 6 months of treatment. On the other hand, 9 (14.7%) patients showed new-onset MEM, 3 (33%) of them showed symptoms and clinical and/or radiological findings compatible with axial SpA. In 2 of the cases a treatment with a cDMARD was used and the other one required a combination therapy between ITNF and VDZ. The remaining 6 (7%) patients were classified as NsA and inflammatory arthritis was discarded. Table 1 shows the demographic and clinical characteristics of patients included in the analysis.

Conclusion: Switching TNFi treatment to VDZ in patients with IBD-related SpA was found to be associated with articular exacerbation of SpA in 1 out of 4 patients within the first 5 months. New-onset MEM is also observed in up to 15% of patients with IBD treated with VDZ. A multidisciplinary assessment of these patients is necessary in order to achieve a proper management of their diseases.

Conclusion: Adalimumab drug levels > 3 mg/L is a protective factor against treatment interruption.
Elanercept previous treatment was a risk factor for treatment interruption.

Results: There were 11 patients (9 male and 2 female), 4 patients were diagnosed as non-radiographic SpA. The mean disease duration was 29±12 years (range 12-49). The comorbidities of the patients included diabetes mellitus and hypertension in 1 patient, coronary artery disease in 1 patient, psoriasis in 1 patient, inflammatory bowel disease in 1 patient, Familial Mediterranean fever in 1 patient, systemic lupus erythematosus in 1 patient, and osteopenia in 2 patients. 3 of the patients had malignancies (bladder, rectum and stomach carcinomas) and 1 patient had chronic myeloproliferative disorder. 4 patients could never use the TNF-alpha inhibitors (1 rectum cancer, 1 bladder cancer, 1 systemic lupus erythematosus, 1 essential thrombocytrema). The median duration of pamidronate use was 6 (interquartile range 3-10). Mean Patient Global Assessment Score (PGAS) was 8±2 before the pamidronate treatment and 4±3 after the treatment (p<0.001). The treatment of 6 patients was terminated due to inadequate response which is shown in Table. One patient died from bladder carcinoma during follow-up.

Conclusion: In SpA patients, with biological agents (anti-TNF, IL-17) being con-traindicated due to malignancies and tuberculosis in some patients, alternative treatment methods such as pamidronate should be considered bearing in mind the results of our study showing the effectiveness and safety of it.

This study revealed that the patients experienced an average of a 52% reduction in the BASDAI score after 6 months of anti-TNF treatment compared to only a 6% reduction in patients on secukinumab (P 0.009). However, the disease activity improvement at 12 months was not sustained in the anti-TNF group and at this stage there was no difference between the groups. Overall both treatment groups...
showed an average reduction in the BASDAI score by more than 30% at each 3 monthly interval.

Figure 1. BASDAI percentage reduction at 3 monthly intervals between the two second line treatment groups using anti-TNF and Secukinumab.

Conclusion: A significant difference could not be demonstrated between the anti-TNF and secukinumab groups in this observational cohort. Interestingly, at 6 months, anti-TNF demonstrated better outcomes according to BASDAI scores than Secukinumab but this efficacy was lost at 12 months. It was difficult to interpret these isolated results without further testing, as this is a small non-randomised study. We observed similar outcomes to the Navarro-Compán review where there was a low percentage change in the BASDAI improvement in patients on second line therapy when compared to first line treatment BASDAI scores. Therefore, exploring the mechanism for the reduction in the BASDAI response would be an interesting future study. Moreover, to fully understand these results, randomised controlled studies would need to be conducted.

Spondyloarthritis - clinical aspects (other than treatment)

FRI0298
ASAS MODIFICATION OF THE BERLIN ALGORITHM AND THE DUET ALGORITHM FOR DIAGNOSING AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE SCREENING IN AXIAL Spondyloarthritis for Psoriasis, Iritis, and Colitis Cohort

Background: Patients presenting with back pain and psoriasis, iritis, or colitis represent a high-risk population for the presence of axial spondyloarthritis (axSpA). The Dublin Evaluation Tool (DUET), the Berlin algorithm, and the ASAS modification of this algorithm are recommended referral strategies aimed at early diagnosis of axSpA. DUET was developed for patients presenting with AAU. Validation of these algorithms in inception cohorts is limited.

Objectives: 1. To assess the performance of referral algorithms for diagnosis of axSpA when tested against the final local rheumatologist diagnosis in an inception cohort of patients presenting with undiagnosed back pain and extra-articular manifestations. 2. To determine whether different criteria for inflammatory back pain (IBP) impact the performance of the algorithms.

Methods: The multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study at 11 sites is aimed at early detection of axial SpA in patients presenting with undiagnosed back pain to the rheumatologist. Consecutive patients ≥45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, acute anterior uveitis (AAU), or colitis diagnosed by the relevant specialist undergo routine clinical evaluation by a rheumatologist for axial SpA. The rheumatologist determines the presence or absence of axial SpA at 3 consecutive stages: 1. After the clinical evaluation; 2. After the results of labs (B27, CRP) and radiography; 3. After the results of MRI evaluation. Final diagnosis by the rheumatologist was used as external standard to test the performance of the algorithms. We tested the following criteria for IBP in the algorm: ASAS, Berlin, rheumatologist global for likelihood of IBP >5 (0-10 scale), and DUET algorithm in AAU patients.

Results: A total of 246 patients were recruited, 73 presented with iritis, 46 with psoriasis, and 127 with colitis. 47.6% were diagnosed with axSpA. The diagnosis of axSpA was established in 45.7%, 61.6%, and 40.2% of patients with psoriasis, AAU, and IBD, respectively. The performance of the ASAS-modification of the Berlin algorithm was superior to the original algorithm as reported previously, primarily for enhanced sensitivity, and this was observed irrespective of the criteria used to define IBP (Table 1). Conversely, the performance of the DUET algorithm in the subset of patients with AAU was substantially worse than previously reported.

Conclusion: The ASAS modification of the Berlin algorithm is the preferred referral strategy for patients presenting with undiagnosed back pain to the rheumatologist.

Background: Enthesitis is a hallmark clinical feature of spondyloarthritis (SpA), but to date, few studies have investigated how the overall response to biological therapy relates to the evolution of enthesitis counts.

Objectives: Assess whether the variation in enthesis indices reflects the overall response to bDMARD therapy in SpA.

Methods: This longitudinal, retrospective study included patients who met Assessment of Spondyloarthritis international Society (ASAS) criteria for SpA followed at the Rheumatology Department of a tertiary hospital, under bDMARD therapy. Demographic, laboratorial and clinical data were collected, including Bath Ankylosing Spondylitis Metrology Index (BASMI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Score-C-reactive protein (ASDAS-CRP), Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), Leeds Enthesitis Index (LEI) and Spondyloarthritis Research Consortium of Canada (SPARCC) scores. All were evaluated at baseline and at 6, 12, 18 and 24 months after starting the first biological therapy. The variation in each parameter compared with the baseline values was calculated at 6, 12, 18 and 24 months and represented in the form of delta. Correlations between variables were assessed using Spearman test and comparison between groups using Wilcoxon, Mann-Whitney U and Kruskal-Wallis tests.

Results: We included 273 patients, 123 (45.1%) females, aged 42.0±12.3 years and with diagnosis of SpA for 15.4±11.2 years at the start of bDMARD therapy: Eighteen (6.6%) had depression. At baseline, mean BASDAI was 6.4±1.62, ASDAS-CRP was 4.0±0.86, median MASES was 1 (0–4), LEI 0 (0–1.75) and SPARCC 1 (0–4). Seventy-two patients (26.4%) started golimumab, 71 (26.0%) adalimumab, 66 (24.2%) infliximab, 54 (19.6%) etanercept, 9 (3.3%) certolizumab and 0.4% secukinumab. Enthesitis indices were significantly higher at baseline in females [median MASES-females 2 (0–5) vs 0 (0–2), p<0.001; LEI-females 0 (0–2) vs 0 (0–1), p=0.03; and SPARCC-females 2 (0–5) vs 0 (0–2), p=0.001], and remained so at 24 months [median MASES-females 1 (0–3.5) vs 0 (0–0), p<0.001; LEI-females 0 (0–0.5) vs 0 (0–0), p<0.001; and SPARCC-females 1 (0–3) vs 0 (0–0), p<0.001]. MASES and SPARCC, but not LEI, at baseline were significantly higher in patients with depression [median MASES-depression 3.5 (2–6) vs 1 (0–4), p=0.01; SPARCC-depression 4 (0–8) vs 1 (0–3), p=0.03], but at 24 months no differences were observed. There was a significant difference between each of the 3 scores of enthesitis when assessed at 6, 12, 18 and 24 months, compared to baseline (p<0.004). No differences were observed regarding the choice of bDMARD. At baseline, MASES had a significant correlation with patient visual analogic scale (VAS) (r=0.18; p=0.01), BASDAI (r=0.36; p<0.001) and BASFI (r=0.21; p=0.003); LEI had a significant correlation with BASDAI (r=0.31; p<0.001) and BASFI (r=0.21; p=0.003); SPARCC had a significant correlation with patient VAS (r=0.19; p=0.01), BASDAI (r=0.37; p<0.001) and BASFI (r=0.26; p<0.001), ΔLEI at 6 months had a significant correlation with ΔBASDAI (r=0.25; p=0.005), ΔASDAS (r=0.19; p=0.03), Δpatient VAS (r=0.23; p=0.01) and Δphysician VAS (r=0.25; p=0.01), but not with ΔESR, ΔCRP and ΔBASMI; no correlation was found at 6 months for ΔMASES or ΔSPARCC. At 12 months, ΔMASES had a significant correlation with ΔBASDAI (r=0.18; p=0.03); ΔLEI with ΔBASDAI (r=0.23; p=0.01) and Δpatient VAS (r=0.19; p=0.03); for ΔSPARCC no significant correlations were found. At 18 months and 24 months, no correlations were found.

Conclusion: The initiation of bDMARD led to improved enthesis indices over a 24-month period. ΔLEI correlates better with SpA activity scores and measurements than the other indices, especially at the first 12 months of initiation of bDMARD therapy.

ARE COPING STRATEGIES, ANXIETY AND DEPRESSION ASSOCIATED WITH DAILY PHYSICAL ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS?

M. Carro1, L. Overbeeke1, S. Arends1, Y. Kamma2, F. Wink2, D. Paap2, A. Spoorenberg1. 1University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Center for Human Movement Sciences, Groningen, Netherlands; 3Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands

Background: Patients with axial spondyloarthritis (axSpA) who are more physically active experience less pain and better physical functioning. Psychological factors such as anxiety and depression are associated with physical functioning and reduction of Quality of Life (QoL). Furthermore, evasive coping strategies are commonly used in health-related coping. However, as far as we know, no data is available regarding the influence of coping strategies, anxiety and depression on daily physical activity in axSpA.

Objectives: To determine if coping strategies, anxiety and depression are associated with daily physical activity in patients with axSpA.

Methods: Consecutive outpatients from the Groningen Leeuwarden AxSpA cohort (GLAS) participated in this study. Additionally to the standardized follow-up assessments, patients filled out the axSpA-Short Questionnaire to assess health-enhancing physical activity (axSpA-SQUASH), the Coping with Rheumatic Stressors (CORS) and the Hospital Anxiety and Depression Scale (HADS). Univariable and multivariable linear regression analyses were performed to explore associations of copings strategies, anxiety and depression, and patient- and disease related factors with daily physical activity. Additionally, patients were stratified into three tertiles of physical activity; low, intermediate and high. To identify group differences, Kruskal-Wallis test or Chi-Square test were used with post-hoc testing.

Results: In total 85 patients were included; 59% were male, mean age was 49.1±14, median symptom duration 19.5 years (IQR 12.0–31.0), 71% were HLA-B27 positive and mean ASDAS was 2.1±1.0. Median axSpA-SQUASH total physical activity score was 9406.3 (IQR 5538.8–12081.3). Median scores of HADS-Anxiety (scale 7-28) and HADS-Depression (scale 7-28) were scores of 12 (IQR 10.0-14.0) and 10 (IQR 8.0-12.5). The mostly frequently used coping strategy was comfort coping (for pain, range 9-36); median of 25.5 (IQR 22.0-28.0).

Univariable analysis showed that lower daily physical activity was significantly associated with gender (female), higher disease activity (BASDAI), worse physical function (BASFI), worse quality of life (ASQoL), coping strategies ‘decreasing activities’ and ‘pacing’, higher depression score (HADS) and higher perceived influence of axSpA on general well-being. In multivariable analysis, only the coping strategy “decreasing activity” was independently associated with physical activity (β=-419.3, R2: 0.155, P<0.001). Additionally, patients in the highest physical activity tertile had significantly more often male, had higher working status, lower BASDAI and ASDAS, better BASFI and ASQoL and scored lower on the coping strategy “decreasing activities”.

Conclusion: In this cross-sectional study in axSpA patients with established disease, multiple patient and disease related factors were associated with daily physical activity. The evasive coping strategy ‘decreasing activities’ was the only independently associated factor. These findings suggest that to improve daily physical activity in axSpA patients attention should be paid not only on targeting disease activity, but also to other patient and disease related aspects, especially coping strategies used.

DOI: 10.1136/annrheumdis-2020-eular.2724
Background: Current recommendations for axial spondyloarthritis (axSpA) include the treat-to-target concept and suggest that the ideal target should be remission or low disease activity (LDA). Also, the importance of a shared decision is highlighted. Unfortunately, the definition of remission is not consensual, and most of the definitions are difficult to evaluate in clinical practice.

Objectives: To propose an evaluation of remission by a single question to the patient, by comparing it to the different available definitions. To analyze the metric properties of the current definitions against patient’s perception

Methods: One-center cross-sectional study in a tertiary care hospital including consecutive patients with a diagnosis of axSpA (and fulfilling the ASAS criteria) were included between February to November 2019. Patient’s perception of remission and LDA was evaluated identically. The level of agreement between patients’ perception and the other available definitions was tested by the Prevalence and Bias adjusted Kappa (PABK). The metric properties Sensitivity (S) and Specificity (Sp) of the available definitions (BASDAI cut-offs, ASDAS disease states, ASAS criteria for partial remission and patient acceptable symptom state), were tested against the patients perspective, as the gold standard.

Results: A total of 105 axSpA patients were patients were included, 63.8% were males and 67.6% had radiographic sacroiliitis (Table 1). 21% and 72% of them considered themselves in remission and LDA, respectively. Physician’s perception was 45.7% and 81% for remission and LDA, respectively. The prevalence of the different definitions are shown in Figure 1. The best agreement for patients’s perception of remission was found with a BASDAI <2 + normal CRP (Table 2). This definition was also the most sensitive (S=72.7%) and specific (Sp=83.1%) when compared to the other definitions.

Conclusion: In this real-life population, the evaluation of remission by the patient through a single question was shown to be feasible and to present an acceptable agreement with other definitions.

lasting at least one to two t1/2 of IgG (24 days), it was hypothesized that IgG-gly-
diseases. Since these changes only occur in persistent inflammatory processes,
subject to specific alterations (i.e. undergalactosylation) in chronic inflammatory
elevated acute phase reactants such as C-reactive protein (CRP) or erythrocyte
temic inflammation.

ly-stage axial disease and therefore may reflect the cumulative exposure to sys-
dergalactosylation with disease activity and functional impairment in SpA

Conclusion:
– 0.80, p = 0.01, Figure 2) and SPARCC score (β

Figure 1. Example of a serum IgG-specific glycan profile. Adapted from (1), with permission.

Results: Glycan profiles were obtained from 376 SpA patients; UGS was scaled (mean = 0, SD = 1) for further analysis. UGS was independently associated with ASDAS-CRP (β = 0.15, 95% CI 0.04 – 0.26, p = 0.006) and BASFI (β = 0.44, 95% CI 0.16 – 0.72, p = 0.002) but not with BASDAI (β = 0.12, 95% CI -0.13 – 0.39, p = 0.34). UGS showed a weak to moderate correlation with CRP (R = 0.30, p < 0.001) and ESR (R = 0.27, p <0.001). In axial SpA, UGS was significantly higher in patients with ankylosing spondylitis compared to non-radi-

Methods: Serum samples were obtained from SpA patients at the baseline visit of Be-Giant: a Belgian observational cohort including SpA patients who fulfil the ASAS classification criteria for axial or peripheral SpA. IgG Fc N-glycans were released directly in whole serum by endo-β-N-acetyl-glucosaminidase from Streptococcus pyogenes (EndoS), fluorescently labeled with ATPS and analyzed by capillary electrophoresis, rendering glycan profiles with six peaks (Figure 1). Relative peak heights were combined in the undergalactosylation score (UGS), capturing the relative upregulation of non-galactosylated glycans normalized to the total peak height (1), Baseline radiographs (X-SIJ) and magnetic

Serum IgG Undergalactosylation Profiles Reflect Cumulative Exposure to Systemic Inflammation in Spondyloarthritis Patients
A. S. De Craemer1,2, Z. Lukasik1, L. Meuris1, L. Deroo1, T. Renson1,2, M. De Hooge1,2, P. Carron1,2, A. Van Hecke1,2, N. Callewaert1, F. Van den Bosch1,2, D. Ectors; on behalf of the Be-Giant Consortium. 1Ghent University Hospital, Rheumatology, Gent, Belgium; 2VIB, Inflammation Research Center, Gent, Belgium; 3Medical University of Lodz, Lodz, Poland; 4VIB, Center for Medical Biotechnology, Gent, Belgium; 5Ghent University, Department of Biochemistry and Microbiology, Gent, Belgium

Background: Inflammation in spondyloarthritis (SpA) is often not reflected by elevated acute phase reactants such as C-reactive protein (CRP) or erythrocyte sedimentation rate (ESR). It has been shown that IgG glycosylation patterns are subject to specific alterations (i.e. undergalactosylation) in chronic inflammatory diseases. Since these changes only occur in persistent inflammatory processes, lasting at least one to two t1/2 of IgG (24 days), it was hypothesized that IgG-glycan profiles could serve as a surrogate marker for chronic inflammation in SpA patients.

Objectives: To assess the value of serum IgG-undergalactosylation in SpA patients in relation to outcome measures for disease activity, determined by patient reported outcomes, serum inflammatory markers and imaging outcomes.

Methods: Serum samples were obtained from SpA patients at the baseline visit of Be-Giant: a Belgian observational cohort including SpA patients who fulfil the ASAS classification criteria for axial or peripheral SpA. IgG Fc N-glycans were released directly in whole serum by endo-β-N-acetyl-glucosaminidase from Streptococcus pyogenes (EndoS), fluorescently labeled with ATPS and analyzed by capillary electrophoresis, rendering glycan profiles with six peaks (Figure 1). Relative peak heights were combined in the undergalactosylation score (UGS), capturing the relative upregulation of non-galactosylated glycans normalized to the total peak height (1), Baseline radiographs (X-SIJ) and magnetic resonance images (MRI) of the sacroiliac joints (SIJ) were assessed by three calibrated readers for sacroiliitis (fulfillment of the modified New York criteria; grading 0 to 4 per SIJ) and for inflammatory lesions according to the Spondyloarthritis Research Consortium of Canada (SPARCC) method (score from 0 – 72) respectively. Grades and inflammatory lesions that were seen by at least 2 readers were used for further analysis.

Figure 2. Correlation between UGS and X-SIJ total grading of sacroiliitis. R = Spearman's correlation coefficient.

Serum IgG Undergalactosylation Profiles Reflect Cumulative Exposure to Systemic Inflammation in Spondyloarthritis Patients
A. S. De Craemer1,2, Z. Lukasik1, L. Meuris1, L. Deroo1, T. Renson1,2, M. De Hooge1,2, P. Carron1,2, A. Van Hecke1,2, N. Callewaert1, F. Van den Bosch1,2, D. Ectors; on behalf of the Be-Giant Consortium. 1Ghent University Hospital, Rheumatology, Gent, Belgium; 2VIB, Inflammation Research Center, Gent, Belgium; 3Medical University of Lodz, Lodz, Poland; 4VIB, Center for Medical Biotechnology, Gent, Belgium; 5Ghent University, Department of Biochemistry and Microbiology, Gent, Belgium

Background: Inflammation in spondyloarthritis (SpA) is often not reflected by elevated acute phase reactants such as C-reactive protein (CRP) or erythrocyte sedimentation rate (ESR). It has been shown that IgG glycosylation patterns are subject to specific alterations (i.e. undergalactosylation) in chronic inflammatory diseases. Since these changes only occur in persistent inflammatory processes, lasting at least one to two t1/2 of IgG (24 days), it was hypothesized that IgG-glycan profiles could serve as a surrogate marker for chronic inflammation in SpA patients.

Objectives: To assess the value of serum IgG-undergalactosylation in SpA patients in relation to outcome measures for disease activity, determined by patient reported outcomes, serum inflammatory markers and imaging outcomes.

Methods: Serum samples were obtained from SpA patients at the baseline visit of Be-Giant: a Belgian observational cohort including SpA patients who fulfil the ASAS classification criteria for axial or peripheral SpA. IgG Fc N-glycans were released directly in whole serum by endo-β-N-acetyl-glucosaminidase from Streptococcus pyogenes (EndoS), fluorescently labeled with ATPS and analyzed by capillary electrophoresis, rendering glycan profiles with six peaks (Figure 1). Relative peak heights were combined in the undergalactosylation score (UGS), capturing the relative upregulation of non-galactosylated glycans normalized to the total peak height (1), Baseline radiographs (X-SIJ) and magnetic resonance images (MRI) of the sacroiliac joints (SIJ) were assessed by three calibrated readers for sacroiliitis (fulfillment of the modified New York criteria; grading 0 to 4 per SIJ) and for inflammatory lesions according to the Spondyloarthritis Research Consortium of Canada (SPARCC) method (score from 0 – 72) respectively. Grades and inflammatory lesions that were seen by at least 2 readers were used for further analysis.

Figure 1. Example of a serum IgG-specific glycan profile. Adapted from (1), with permission.

Results: Glycan profiles were obtained from 376 SpA patients; UGS was scaled (mean = 0, SD = 1) for further analysis. UGS was independently associated with ASDAS-CRP (β = 0.15, 95% CI 0.04 – 0.26, p = 0.006) and BASFI (β = 0.44, 95% CI 0.16 – 0.72, p = 0.002) but not with BASDAI (β = 0.12, 95% CI -0.13 – 0.39, p = 0.34). UGS showed a weak to moderate correlation with CRP (R = 0.30, p < 0.001) and ESR (R = 0.27, p <0.001). In axial SpA, UGS was significantly higher in patients with ankylosing spondylitis compared to non-radiographic axial SpA (OR = 2.41, 95% CI 1.60 – 3.73, p <0.001) and showed an independent association with the total grading of the SIJ (β = 0.44, 95% CI 0.09 – 0.80, p = 0.01, Figure 2) and SPARCC score (β = 2.64, 95% CI 0.98 – 4.31, p = 0.002). All models were adjusted for age, gender, BMI, CRP, anti-TNF treatment and symptom duration.

Conclusion: This study shows and independent association of serum IgG undergalactosylation with disease activity and functional impairment in SpA patients. Moreover, UGS was significantly higher in advanced compared to early-stage axial disease and therefore may reflect the cumulative exposure to systemic inflammation.

References:
Conclusion: Although based on observational data, this work is to our knowledge, the first systematic review and meta-analysis concerned with this subject. SpA and PsA seem to be associated with an increased risk of preterm birth, small for gestational age and elective caesarean section. The analysis of the impact of pregnancy on disease activity in this setting is currently ongoing.

WOMEN WITH AXIAL SPONDYLOARTHRITIS HAVE COMPARABLE RATES OF COMPLICATIONS IN PREGNANCY TO WOMEN IN THE GENERAL POPULATION BUT MORE CAESAREAN DELIVERIES: RESULTS FROM NATIONWIDE CLAIMS DATA

I. Redeker, A. Strangfeld, U. Marschall, A. Zink, X. Baraliakos. 1German Rheumatism Research Centre, Berlin, Germany; 2BARMER Institute for Health Systems Research, Wuppertal, Germany; 3Charité – Universitätsmedizin Berlin, Berlin, Germany; 4Rheumazentrum Ruhrgebiet, Herne, Germany

Background: In contrast to other rheumatic inflammatory diseases, studies on pregnancy outcomes in axial spondyloarthritis (axSpA) are scarce, despite its onset in early adulthood affecting women in their reproductive years.

Objectives: To investigate maternal and infant pregnancy outcomes among women with axSpA compared with population-based controls.

Methods: Taking advantage of a large health insurance dataset, comprising the period 2006 – 2018, maternal and infant pregnancy outcomes and delivery outcomes of women with axSpA were assessed and compared with population-based controls (matched by maternal age and calendar year of birth). Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated using generalised estimating equation analyses.

Results: A total of 611 singleton births among 535 women with axSpA were included in the analysis. The mean age at delivery was 32.5 years. The pharmacological treatment within 12 months prior to and after conception is illustrated in the Figure. Infants of women with axSpA were only slightly more often receiving caesarean section (OR 1.35; 95% CI 1.06-1.73) (Table). The occurrence of pre-eclampsia, preterm birth, and small-for-gestational-age was moderately higher, but not significantly increased, among women with axSpA as compared to population-based controls.

Conclusion: Women with axSpA had no significantly increased risks for adverse maternal or infant pregnancy outcomes compared to non-axSpA women. However, a significantly increased risk for receiving caesarean section and a tendency for a higher number of preterm deliveries and of small-for-gestational-age infants was observed in women with axSpA.

Preterm birth (< week 37) 5.2% (32) 4.7% (29) 1.11 (0.66, 1.85)

DETERMINANTS OF PATIENT-PHYSICIAN DISCORDANCE IN GLOBAL ASSESSMENT IN SPONDYLOARTHRITIS

Background: Patient’s Global Assessment of Disease Activity (PGA) and Physician’s Global Assessment of Disease Activity (PhGA) are important measures in the evaluation of patients with Spondyloarthritis (SpA), but often provide discordant results.1 Both PGA and PhGA are assessed as part of ankylosing spondylitis disease activity score (ASDAS), that is a measure of axial SpA disease activity endorsed by the Assessment of SpA International Society (ASAS) and Outcome Measures in Rheumatology.2,3 In peripheral SpA, although there are no formally validated indexes, the American College of Rheumatology (ACR) and Disease Activity Score 28 (DAS28) response criteria have shown reliable discriminant characteristics and both include PGA and PhGA.3,4 The lack

</table>
of concordance between PtGA and PhGA may mislead treatment decisions, namely switches.

**Objectives:** To assess the determinants of patient-physician discordance in SpA patients under biologic treatment.

**Methods:** Cross-sectional study, including 72 with SpA according ASAS criteria. Physicians’ evaluation included comorbidities, parameters of inflammatory activity (erythrocyte sedimentation rate [ESR] and C-reactive protein [CRP]), PhGA, ASDAS PCR and, DAS 28, and Participants completed patient-reported outcomes (PROs) and sociodemographic characteristics. For statistical analysis, SRSS was used and significance level was 2-sided p<0.05.

**Results:** Clinical and laboratory characteristics of patients are shown in table 1. PtGA and PhGA were significantly different (34.8±21.2 vs 78±12.5 mm, respectively, p<0.001) and patient-physician discordance (ΔPtGA - PhGA) was 27.5±14.3 mm.

In peripheral SpA, patient-physician discordance had a correlation with patient age, Health Assessment Questionnaire (HAQ), Functional Assessment of Chronic Illness Therapy (FACT), EuroQol-5 dimension (EQ5D), Short Form (SF) Health Survey (SF-36), Hospital Anxiety and Depression scales (HADS), CRP, ESR, number of comorbidities and daily medication, and an association with employment status (employees had lesser discordance), anxiety/depression, fibromyalgia and osteoarthritis (OA). In multivariable analysis including employment status, SF-36, OA, number of comorbidities, and ESR (R² adjusted = .505), the main predictors of patient-physician discordance were lower SF36, higher number of comorbidities and employment status.

In axial SpA, patient-physician discordance had a correlation with nocturnal back pain and total back pain, FACT, EQ5D, SF-36, HADS, Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Activity Index (BASDAI) scales, age, number of comorbidities and daily medication, and an association with employment status (employees had lesser discordance), anxiety/depression, fibromyalgia. In multivariable analysis, including employment status, SF-36, fibromyalgia, and number of comorbidities (R² adjusted = .738), the main predictors of patient-physician discordance were lower SF36, higher number of comorbidities and concomitant diagnosis of fibromyalgia.

Neither for peripheral SpA nor for axial SpA an association with SpA subtype, HLA-B27 positivity, patient or physician gender, or patient education level was found.

**Conclusion:** This study shows the variability implied in patient-physician discordance. We have demonstrated that comorbidities, employment status, and other factors not directly related to the disease are determinants for the patient-physician discordance.

t1,2,1, Amsterdam Rheumatology & Immunology Center, Reade, Amsterdam, Netherlands; 2Amsterdam Rheumatology & Immunology Center, Amsterdam University Medical Center, location VUMc, Amsterdam, Netherlands; 3Amsterdam University Medical Center, location VUMc, Department of Cardiology, Amsterdam, Netherlands

**Background:** The overall mortality rate in ankylosing spondylitis (AS) patients is increased by 60–90% compared with the general population. This higher mortality rate is predominately caused by cardiovascular disease (CVD) comprising an increased prevalence of cardiac diseases such as valvular heart disease, conduction disturbances and cardiomyopathies as well as atherosclerotic diseases such as myocardial infarctions. However, there is a lack of contemporary studies. Therefore, we investigated current prevalences of cardiac disorders in a well characterized cohort of Dutch patients with AS compared to osteoarthritis (OA) controls.

**Objectives:** To assess the prevalence of CVD in AS patients in comparison to OA controls in a Dutch population.

**Methods:** We performed a cross-sectional study in AS and OA patients between 50-75 years. Subjects were recruited from a large rheumatology outpatient clinic (Reade) in Amsterdam, the Netherlands. Patients underwent echocardiography with 2D, spectral and Color Doppler imaging. The echocardiogram was evaluated by an experienced and certified cardiologist. Diastolic dysfunction was assessed according to the ASE/EACVI 2016 guideline. Furthermore, blood sample, surveys and physical examination were done. Disease activity and function were measured using the BASFI, BASDAI and the ASDAS-CRP.

**Results:** A total of 193 consecutive AS patients were included with a median age of 60 (±7) years of which 72% men (138). The control group consisted of 70 OA patients (table 1). In the AS cohort the disease activity measures, BASDAI, ASDAS-CRP and BASFI, indicated moderate disease activity and were, respectively 3.1 (1.6-5.0), 2.1 (±1.0) and 3.5 (1.7-5.7). Anti-TNF was used by 43% of the AS patients. History of cardiovascular disease (CVD), i.e. angina pectoris, myocardial infarction, stroke and/or peripheral ischemia was comparable between the AS and OA cohort, respectively 9% (17) and 10% (7), p=0.81. Antihypertensives were significantly more often used in AS patients, 85 (44%) vs 19 (27%), p=0.02. Prevalences of systolic dysfunction and diastolic dysfunction did not differ significantly in AS and OA patients, respectively 6 (5%) vs 2 (5%), p=0.96 in systolic dysfunction and 7 (3%) vs 2 (3%), p=0.86 in diastolic dysfunction. Prevalence of aortic valve (AV) regurgitation was significantly higher in AS patients compared to OA patients, respectively 68 (36%) vs 21 (33%), p=0.59. When corrected for age, gender and cardiovascular risk factors in a regression analysis, AS patients still had a substantially increased risk for AV regurgitation, odds ratio (OR) 2.8 95%CI 1.1-7.2, p=0.038.

*Angina pectoris, myocardial infarction, stroke and/or peripheral ischemia

**Conclusion:** This study demonstrates an almost tripled risk for developing AV regurgitation in Dutch AS patients. Although mostly mild in this age, due to the progressive nature of AV regurgitation in AS, echocardiographic screening should be considered in elderly AS patients.

**FRI0309 DAILY SELF-REPORTED FLARE PROFILES IN AXIAL SPONDYLOARTHRITIS: ASSOCIATIONS BETWEEN FLARE, SYMPTOMS AND BEHAVIOUR**

R. Barnett1,2, S. Ng1, S. Jones1, M. Young1, R. Sengupta1,2, 1University of Bath, Bath, United Kingdom; 2RNHRD, Bath, United Kingdom; 3White Swan, Exeter, United Kingdom

**Background:** Axial spondyloarthritis (axSpA) is a chronic inflammatory disease, characterised by fluctuating periods of flare and remission. Flare is a multidimensional change of disease state; whereby flare definitions have previously been formulated using validated composite indices, or through qualitative retrospective investigation of flare states. Smartphone technologies for tracking disease symptoms provide unique, daily insights into self-reported individual flare experience, and may present an opportunity to gain a more complete understanding of flare burden and symptom patterns.
Objectives: To assess frequency and characteristics of axSpA flares, utilising data collected in the uMotif symptom tracking app.

Methods: Patients with axSpA attending the Royal National Hospital for Rheumatic Diseases in Bath were invited to participate. Through the uMotif app, patients were sent daily reminders to log flare, pain, fatigue, sleep, recommended exercise, mood and stress using 5-point Likert scales, in addition to optional variables such as smoking and menstrual cycle. Self-reported periods of flare were identified. For each patient reporting flare within the study period, a mean ‘flare’ and ‘non-flare’ score was calculated for each variable. Paired t-tests were conducted for each variable, to investigate which variables correlate with flare status.

Results: Between 5th April 2018 and 8th March 2019, 174 patients consented for research and logged a mean of 99.73 (SD 99.97, range 1 - 323 days) days of data. 136/174 (78%) patients recorded at least 1 flare, with 1330 flares recorded in total. For patients reporting at least 1 flare, each flare lasted a mean of 2.20 days (SD 2.53 days, range 1 – 33 days), with a mean frequency of once every 45.19 days (SD 53.06, range 3.2 -314 days). Significant relationships were identified between flare status and uMotif scores (Table 1).

Conclusion: These findings demonstrate significant relationships between a variety of patient-reported symptoms and flare, including variables that to our knowledge, have not yet been explored in axSpA. Small estimated differences were found between scores for ‘flare’ versus ‘non-flare’. Further work is needed to characterise fluctuating flare/no-flare patterns of individuals tracking daily symptoms in the uMotif app. In future research, it will be important to determine whether there is a chronological pattern of variables during the pre-flare period that can predict a flare. Greater understanding of such patterns may allow identification of the optimal timing of intervention to prevent a period of flare and improve quality of life for patients with axSpA.

Table. IRs, presented as number of events per 1000 person-years at risk, and IRs for each fracture outcome.

Disclosure of Interests: Karin Bengtsson: None declared, Johan Askling Grant/research support from: JA acts or has acted as PI for agreements presented as number of events per 1000 person-years at risk, and IRs for each fracture outcome.

Results: 117 patients with AS (62.4% men), mean age 54.8 years (± SD: 15.7), disease progression of 14.7 ± 9.6 years were included. HLA B27 was positive in 75.4%. Mean values of ESR and CRP were 14.4 mm/h and 0.8 mg/dl, respectively, and the average of the BASFI and BASDAI scores were 26/100 and 30/100, respectively. The prevalence of heart rhythm disorders was 19.7% (95% CI 12.3-27.0), which was significantly associated with advanced age, arterial hypertension and body mass index (BMI). No association was found with other activity or functional disease parameters (CRP, BASDAl, BASFI). The rhythm disorders found were: 9.4% (95% CI: 4.0-14.8) of the patients presented supraventricular tachyarrhythmias; 77% (95% CI: 2.7-12.6) had atrioventricular blocks and 6.8% (95% CI: 2.2-11.5) intraventricular conduction disorders. Although no differences were found regarding the prevalence described in the general population, an associative trend was observed, although it did not reach statistical significance probably due to the small sample size recruited.

Conclusion: There seems to be an increased tendency of heart rhythm disorders in patients with AS compared to the general population, which may have clinical and therapeutic implications. However, studies with larger sample size are needed to corroborate these results. In addition, there was a relationship between the presence of arrhythmias and certain pro-inflammatory situations (older age and BMI, although not CRP), which supports the hypothesis that some underlying inflammation status in these patients could partly justify an increased arrhythmogenesis.

Figure 1. Univariate comparison of anti-CD74 IgA concentrations between nr-axSpA, AS and control patients (<45 y/o).

Conclusion: In this study, mean anti-CD74 IgA concentrations were higher in axial SpA patients compared to non-SpA controls. Application of this biomarker in young (<32 y/o) male nr-axSpA ASD patients yielded the highest sensitivity and specificity.

Disclosure of Interests: Andrea Delle Sedie Speakers bureau: MSD, Lilly, Novartis, Abbvie, Celgene, Emanuele Calabresi: None declared, Ilaria Romagnoli: None declared, Linda Carli: None declared, Marta Mosca: None declared DOI: 10.1136/annrheumdis-2020-eular.4099
**Objectives:** To investigate the annual diagnostic prevalence of AS in US health-care insurance claims databases.

**Methods:** A retrospective, observational cohort study was conducted using 2006–2014 data from US Medicare Fee-for-Service Claims (5% random sample of all enrolled patients [pts]) and Truven MarketScan®. Eligible pts were ≥20 years (yrs) and had ≥6 months of continuous medical and pharmacy enrolment prior to diagnosis. Diagnoses used relevant International Classification of Disease, 9th version (ICD-9) diagnosis codes: ICD-9 720.x [x=any number] for “AS” and other inflammatory spondyloarthropathies [SpA] or 720.0 for “AS”.

Two diagnosis definitions were used: Definition 1, ≥1 relevant ICD-9 code from hospital discharge or ≥2 from rheumatologist visit; Definition 2, ≥1 relevant ICD-9 code from hospital discharge or rheumatologist visit. Annual diagnostic prevalence of SpA/AS was calculated as “number of enrolled pts who met the definition of SpA/AS within each calendar yr and had full insurance coverage (medical and pharmacy)”; divided by “total number of pts with full insurance coverage in the same yr”. A primary analysis of SpA prevalence rates used Definitions 1 and 2, followed by a sensitivity analysis for AS prevalence rates using only Definition 2. All prevalence rates are shown per 10,000 pts enrolled.

**Results:** The annual diagnostic prevalence of SpA appeared to increase from 2006–2014 (Table). Similarly, the sensitivity analysis showed the annual diagnostic prevalence of AS appeared to increase during the period from 2006 (Medicare: 2.87/10,000 pts [n=1,046,107]; MarketScan: 2.14/10,000 pts [n=34,553,135]; P<0.001) to 2014 (Medicare: 4.77/10,000 pts [n=1,046,107]; MarketScan: 2.14/10,000 pts [n=34,553,135]).

**Conclusion:** The apparent increase in diagnostic prevalence of SpA and AS during the period from 2006–2014 may be a consequence of increased awareness and availability of effective treatments. Furthermore, the 2009 Assessment of SpondyloArthritis international Society development of the axSpA classification criteria to include pts with both established AS and nr-axSpA may have accelerated this increase.

**Background:** Growing evidence of similarities in male-female prevalence of axial spondyloarthritis (axSpA) has stimulated the need to evaluate gender differences in patient experiences.

**Objectives:** To evaluate gender differences in diagnostic journey, disease-characteristics and patient-reported outcomes (PROs) in axSpA patients.

**Methods:** Data from 2846 unselected patients of the European Map of Axial Spondyloarthritis (EMAS) through an online survey (2017–2018) across 13 countries were analysed. Socio-demographic characteristics, diagnosis, disease-characteristics, and PROs [BASDAI (0-10), spinal stiffness (3-12), functional limitation (0-54) and psychological distress (0-12, GHQ-12)] were compared between genders. X² (for categorical variables) and student-t (for continuous variables) were employed.

**Results:** 1,746 (61.3%) females participated in the EMAS, with homogeneous gender distribution across most countries (Fig 1). Compared to males, females reported longer diagnostic delay (6.1±2.4 vs 8.2±5.9, p<0.001), more visits to physiotherapists (34.5% vs 49.5%; p<0.001) and osteopaths (13.3% vs 24.4%; p<0.001) before being diagnosed (Table 1), higher disease activity in all BASDAI items and greater functional limitation, psychological distress and self-reported anxiety and depression (Table 2).

Conclusion: Important gender differences are observed in axSpA such as a longer
patient journey to diagnosis, poorer PROs, and greater psychological burden in females.
These results point to unmet needs in females with axSpA, requiring particular attention.

CAN THE MOMENT OF OCCURRENCE OF THE FIRST
EPISODE OF UVEITIS PREDICT DIFFERENCES IN THE
PROGNOSIS OF SPONDYLOARTHRITIS? DATA FROM
THE SPANISH REGISTRY REGISPONSER

G. G. Ignacio1,2,3, C. López-Medina2,4, M. Ladehesa Pineda1,2,3, M. D. C. Castro
Villegas1,2,3, P. S. Laura1,2,3, M. Á. Puche Larrubia1,2,3, J. M. Sequí-Sabater1,2,3,
F. U. Pilar1,2,3, R. Ortega Castro1,2,3, A. Escudero Contreras1,2,3, E. Collantes
Estevez1,2,3. 1Instituto Maimónides de Investigación Biomédica de Córdoba,
Córdoba, Spain; 2University of Cordoba, Córdoba, Spain; 3Hospital Reina Sofía,
Córdoba, Spain; 4Hospital Cochin, Paris, France

Background: Uveitis is one of the most usual extraaxial manifestations of spondyloarthrities (SpA) but the impact of the date of the onset is no well-known.
Objectives: a) To assess the prevalence of acute anterior uveitis (AAU) in the Spanish population with SpA; b) To describe the time of appearance of the AAU regarding
to the onset of rheumatic symptoms and SpA diagnosis; c) To evaluate the impact of
the moment of appearance of the AAU on the treatment and disease activity.
Methods: A cross-sectional study with data extracted from REGISPONSER registry. First, the prevalence of AAU was determined. Patients were classified as AAU
before/ concomitant/ after the onset of rheumatic symptoms and as AAU before/
concomitant/ after the SpA diagnosis regarding the date of appearance of each
symptom and SpA diagnosis. Treatment and disease activity were compared
between ‘AAU before or concomitant with rheumatic symptoms’ vs. ‘AAU after rheumatic symptoms’ groups, as well as ‘AAU before or concomitant with SpA diagnosis’
vs. ’AAU after the SpA diagnosis’ groups using Chi-square and T-Student tests.
Results: Among the 2346 patients included in REGISPONSER, 379 (16.2%)
had at least one episode of AAU. Information concerning the date of occurrence of rheumatic symptoms and SpA diagnosis was available in 280 and 284
patients, respectively. A total of 28 (9.7%), 31 (10.8%) and 229 (79.5%) patients
suffered the first episode of AAU before, concomitantly and after the rheumatic
symptoms, respectively; while 108 (38.0%), 38 (13.4%) and 138 (48.6%) suffered the episode of AAU before, concomitantly and after the SpA diagnosis,
respectively. The comparison of patients with ‘AAU before or concomitant with
rheumatic symptoms’ vs ‘AAU after rheumatic symptoms’ (Table 1), showed in
the second group a younger age of symptoms onset, a greater diagnosis delay,
higher disease activity (CRP and BASDAI), greater structural damage (BASRI).
No significant differences were found in the use of biological (27.9% vs. 23.2%)
or synthetic DMARDs (14.8% vs. 20.3%). The comparison of ‘AAU before or
concomitant with the SpA diagnosis’ vs. ‘AAU after the SpA diagnosis’ groups
(Table 1) showed similar results to the previous ones with no significant differences were obtained in the use of biological (28.8% vs 20.4%) or synthetic
(17.2% vs 20.4%) DMARDs.
Conclusion: These results suggest that patients who presented the first episode
of AAU prior to the onset of rheumatic symptoms showed a later start of the disease with a shorter diagnosis delay, lower disease activity and less structural
damage.

**Background:** A recent consensus from the ASAS MRI group has culminated in updated spine lesion definitions for axial spondyloarthritis (ASAS_MRI_def). There has been no central reader evaluation of MRI scans from the ASAS classification cohort (ASAS-CC) to determine the spectrum of MRI lesions in the spine of this cohort.

**Objectives:** To determine the spectrum of active and structural lesions on MRI images of the spine from the ASAS-CC according to the consensus ASAS_MRI_def update.

**Methods:** ASAS_MRI_def were recorded by 9 central readers in an eCRF for global assessment and detailed scoring of each discovertebral unit and postero-lateral structures. Vertebral corner bone marrow edema (VCBME) and corner fat (VCFAT) lesions were recorded if present on 2 slices; facet joint, lateral, and posterior inflammatory lesions were recorded if present on a single slice. Vertebral corner erosion, bone spurs, and ankylosis were each scored on a single slice. Comparison of active and structural lesion frequencies by local rheumatologist diagnosis of axSpA was assessed descriptively according to ≥2 and majority reader (≥5/9) concordant data.

**Results:** MRI scans of the spine were available from 69 cases with axSpA diagnosed in 44/64 (68.8%). VCBME was most frequent with ≥1 lesion in 32 (46.4%) and 19 (27.5%) by ≥2 and ≥5/9 readers, respectively. VCFAT was the most frequent structural lesion with ≥1 lesion in 24 (34.8%) and 14 (20.3%) by ≥2 and ≥5/9 readers, respectively. There were significantly more VCBME lesions in axSpA patients than non-axSpA patients (mean(SD):1.82(2.7) vs 0.3 (0.5) (p<0.001) while differences in VCFAT were not significant (Table). The presence of ≥2 VCBME had 90-95% specificity for axSpA. Significantly more VCBME and VCFAT were observed in the setting of radiographic sacroiliitis (modified New York criteria (mNY)).

**Conclusion:** Spine lesions on MRI are relatively frequent in patients with undiagnosed back pain presenting to the rheumatologist. The presence of ≥2 VCBME, but not VCFAT, may have some diagnostic utility.

Legend. Results are expressed as mean (SD) or number of patients (%). HLA: Human Leukocyte Antigen; N/D: not determined

Conclusion: Poor health status is associated with disease activity, poor quality of life and functional activity. ASAS HI has a good correlation with other parameters to evaluate SpA, reinforcing the construct validity of this new tool.

FRIO319 DO OBESITY AND OVERWEIGHT INFLUENCE DISEASE ACTIVITY MEASURES IN AXIAL SPONDYLOARTHRITIS? A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Ortolan1, M. Lorenzin1, M. Felicetti1, R. Ramonda1.1 University of Padova, Rheumatology Unit, Department of Medicine DIMED, Padova, Italy

Background: obesity is apparently related with worse treatment response in axial spondyloarthritis (axSpA). However, it is unclear whether obesity or overweight per se are associated to higher disease activity scores compared to non-obese individuals, and what is the effect size of this difference.

Objectives: to investigate whether overweight/obesity are associated to higher disease activity as measured by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) or Ankylosing spondylitis disease activity score (ASDAS) in axSpA patients.

Methods: MEDLINE, PubMed and Web of Science were searched using key terms corresponding to population (axSpA), exposure (overweight/obesity) and outcome (BASDAI, ASDAS). Predefined inclusion criteria were: 1) adult axSpA patients, both radiographic and non-radiographic 2) exposure classification according to Body Mass Index-BMI-; 3) BASDAI/ASDAS reported for each BMI group; 4) observational studies. Patients classified according to CASPAR and Moll&Wright criteria for psoriatic arthritis were excluded. Newcastle-Ottawa Scale for cohort, cross-sectional and case-control studies was used for quality check. BASDAI and ASDAS estimates were reported as mean difference (MD) and standard deviation (SD) between the normal BMI axSpA patients and the overweight or obese patients. The statistical heterogeneity of meta-analysis was assessed using the I2 statistic. Random-effects meta-analysis was used to pool results.

Results: A total of 330 references were generated by the database search. After removing duplicates, 250 references remained and were assessed for eligibility. A further 206 articles were excluded by titles and abstracts’ reading, 44 articles were examined full text. Only 11 articles fulfilled inclusion/exclusion criteria. Following quality check, 10 articles were finally included in the meta-analysis (Table). Among these, 4 studies reported two BMI groups (normal vs overweight); 6 studies reported three BMI groups, the MD between BASDAI of normal BMI and overweight only patients was -0.38 (95% CI: -0.56; -0.21) and -0.19 (95% CI: -0.29; -0.09). In the articles reporting 3 BMI groups, the MD between BASDAI of normal BMI and overweight only patients was -0.09 (95% CI: -0.33; 0.15); between normal BMI and obese only patients MD was -0.77 (95%CI: -1.07; -0.48, p=0.0001) (Figure). Heterogeneity statistics revealed low estimates, though with wide CI across all the groups (Figure).

Conclusion: disease activity scores of normal BMI axSpA patients tend to be lower than overweight or obese patients. However, this difference seems to be relevant in practice especially when normal BMI patients are compared to truly obese patients (BMI ≥ 30).
and preliminarily validated a self-administered screening questionnaire, called DETection of Arthritis in Inflammatory bowel diseases (DETAIL)1.

**Objectives:** To validate the DETAIL questionnaire in a multicenter cohort of IBD patients enrolled at ten Gastroenterology and Rheumatology Units in Italy.

**Methods:** The DETAIL instrument is a 6-item questionnaire developed through a Delphi method1. From October 2018 to March 2019, consecutive adult patients with IBD, Crohn's disease (CD) or ulcerative colitis (UC), filled out independently the DETAIL in the outpatient waiting room. Thereafter, within 2 weeks a blinded rheumatologist assessed all the patients, irrespectively of the DETAIL results, and classified them as having or not having SpA according to ASAS criteria. The performance of the DETAIL was evaluated trough Bayesian analysis, defining for each item of the questionnaire the sensitivity, specificity, positive (LR+) and negative (LR-) likelihood ratios.

**Results:** Overall, 418 IBD patients filled out the DETAIL questionnaire. Upon rheumatological evaluation, 102 (24.4%) patients received a diagnosis of SpA. Of the six questions, the best performances were found in item 6 (LR+ 3.77), reporting inflammatory back pain at night, and in item 3 (LR+ 3.31), exploring Achilles enthesis. The presence of back pain lasting more than three months (LR+ 2.91), of back pain with inflammatory features (LR+ 2.55) and a history of dactylitis (LR+ 2.55), showed also a fairly good performance, whereas a history of peripheral synovitis was slightly worse (LR+ 1.26). The combination of at least three items answered affirmatively yielded a post-test probability of SpA of 75% or more. The presence of alternative diagnoses, such as osteoarthritis and fibromyalgia, represented a minor confounder.

**Conclusion:** The DETAIL questionnaire is the first screening tool for the early detection of SpA/IBD that has been validated by a multicenter study group.

**UTILITY OF THE ASAS HEALTH INDEX QUESTIONNAIRE AS A TOOL FOR HEALTH ASSESSMENT IN PATIENTS WITH SPONDYLOARTHRITIS AND ITS ASSOCIATION WITH DISEASE ACTIVITY, FUNCTIONALITY, MOBILITY, AND STRUCTURAL DAMAGE**

M.Á. Puche Larrubia1, C. López-Medina1,2, M. D. C. Castro Villegas3, R. Ortega Castro1, M. Ladehesa Pineda1, P. S. Laura1, G. G. Ignacio1, J. M. Sequi-Sabater1, M. D. C. Abalos-Aguilar1, I. C. Aranda-Valera1, G. C. Juan Luis1, A. Escudero Contreras1, E. Collantes-Estevez1, Reina Sofia University Hospital, Rheumatology Service/IMIBIC/Cordoba University, Cordoba, Spain; 2Cochin Hospital, Rheumatology Service, Paris, France

**Background:** The ASAS Health Index (ASAS-HI) questionnaire, a tool that measures the impact of the disease on the health of patients in spondyloarthritis (SpA), has been recently validated. However, there are still studies evaluating the utility of this questionnaire in daily clinical practice.

**Objectives:** The objective of this study is to evaluate the association of ASAS-HI with disease activity, functionality, mobility, and structural damage in patients with SpA.

**Methods:** This is an observational, cross-sectional and single-center study in which 126 consecutive patients with SpA were included. Sociodemographic data, scores related to disease activity (BASDAI and ASDAS), functionality (BASFI), structural damage (cervical, lumbar and total mSASSS), mobility (BASMI and UCOASMI), quality of life (ASAS-HI) and the presence of concomitant fibromyalgia (evaluated with the FIRST questionnaire) were obtained from all patients. The ASAS-HI questionnaire was considered as the main outcome (scale from 0 to 10). Pearson's correlation coefficient was used to evaluate the association of the different continuous variables with each other. Student's t-test was used to compare the ASAS-HI between different subgroups of patients (men vs. women, ASDAS≥2.1 vs. ASDAS<2.1 and fibromyalgia + vs. fibromyalgia-). Finally, a multivariable linear regression was performed to determine which factors explain the variability of ASAS-HI in these patients. Results: Among the 126 patients included, 83 (65.9)% were men, with a mean age of 45.1±12.3 years and a mean disease duration of 18.7±14.5 years. The mean ASAS-HI score in all patients was 4.7±4.0, showing a “strong” positive linear correlation (r=0.60) with BASDAI and BASFI, and a “moderate” positive linear correlation (r=0.40 to 0.60) with GlobalVAS and ASDAS (Figure 1). Patients with fibromyalgia showed a significantly higher ASAS-HI score compared with patients without fibromyalgia (9.5±3.2 vs 3.7±3.4, respectively). In addition, patients with high disease activity (ASDAS≥2.1) showed a higher mean score in ASAS-HI compared with those with low activity (ASDAS<2.1) (5.8 ± 3.8 vs 2.0 ± 2.4, p<0.001).

**Figure 1.** Simple linear correlation (Pearson’s r) between the different variables studied.

Finally, multiple linear regression showed that 57.4% (R²=0.574) of the ASAS-HI variability is explained by the presence of concomitant fibromyalgia (β = 2.23, 95%CI 0.73 to 3.80, p=0.004), BASDAI (β = 0.62, 95%CI 0.25 to 0.97, p=0.001) and BASFI (β = 0.57, 95%CI 0.26 to 0.86, p<0.001).

**Conclusion:** In our study, the impairment of the quality of life in patients with SpA is mainly associated with a high disease activity (BASDAI), worsening functionality (BASFI) and with the presence of concomitant fibromyalgia. Neither mSASSS nor UCOASMI was associated with a change in ASAS-HI; thus, in our patients neither structural damage nor mobility seem to influence the quality of life. In a patient with a high ASAS-HI we must evaluate the presence of concomitant fibromyalgia.

**Acknowledgments:** The authors wish to thank all patients who participated in the study.

**Background:** Insulin resistance (IR) is a state in which a given concentration of insulin is associated with a subnormal glucose response. IR constitutes a major underlying abnormality driving cardiovascular disease in the general population.
and has been linked to inflammatory diseases. In this sense, several reports have confirmed that inflammation worsens IR and impairs pancreatic β-cell function in inflammatory diseases such as rheumatoid arthritis and systemic lupus erythematosus.

Objectives: In this study we aimed to determine the prevalence of IR in patients with spondyloarthritis (SpA) compared to controls, and whether IR can be explained by disease-related features in SpA patients.

Methods: Study of 577 subjects, 306 patients diagnosed with SpA according to ASAS criteria and 271 controls. Insulin and C-peptide serum levels, IR and β-cell function (%B) indexes by homeostatic model assessment (HOMA2), and lipid profiles were assessed in patients and controls. A multivariate regression analysis was performed to evaluate the differences in IR indexes between patients and controls and to determine how IR is associated with disease-related characteristics.

Results: SpA patients showed higher serum levels of insulin (8.7 [4.8-15.9] vs. 8.0 [5.7-11.2] U/l, p=0.001) and C peptide (1.4 [0.7-2.5] vs. 1.2 [0.7-1.7] mg/ ml, p=0.000) than controls in the univariate analysis. Similarly, HOMA2-β% and IR were all significantly higher in SpA patients. These differences were still evident when the comparisons were made after the multivariate analysis had been adjusted for traditional IR-related factors (sex, age, BMI, hypertension, dyslipidemia, smoking and, cholesterol), glucocorticoids intake, insulin and C-peptide. Moreover, HOMA2-β% and HOMA2-IR scores, both calculated with insulin or C-peptide, yielded statistically significant higher values in SpA patients than controls.

Classic IR-related factors (age, BMI, waist circumference, hypertension, obesity, dyslipidemia, atherogenic index, and triglycerides), as well as CRP serum levels, were all related, to a greater or lesser degree, with IR and β-cell function. Regarding disease-related data, ASDAS-CRP, BASFI and BASMI scores were positively associated with IR; and BASMI and BASDAI scores were positively related to HOMA2-β% and prednisone were, respectively, positive and negatively related to β-cell function. However, only some of the associations of the univariate analysis were maintained after adjusting for confounders. In this sense, disease duration (beta coefficient 2 [95% CI 1-3], p=0.001) and positivity for HLA-B27 (beta coefficient 30 [95% CI 12-49], p=0.002) were associated with higher β-cell functionality after the multivariate analysis.

Conclusion: Patients with SpA have an increased IR compared to controls. SpA disease-related data like disease duration and HLA-B27 are independently associated with β-cell dysfunction.

FR10323

THE PRESENCE OF SPONDYLOARTHRITIS IS ASSOCIATED WITH HIGHER CLINICAL DISEASE ACTIVITY IN PATIENTS WITH EARLY CROHN’S DISEASE: RESULTS OF A PROSPECTIVE COHORT STUDY

V. Rios Rodriguez1,2, M. Protopopov1, F. Proft1, S. Lüders1, J. Rademacher1,2, H. Halbel1, M. Verba1, J. Sieper1, E. Sonnenberg1, M. Schumann1, L. I. Kredel1, B. Siegmund1, D. Poddubnyj1,2,3, 1Charité – Universitätsmedizin Berlin, Berlin, Germany; 2Berlin Institute of Health, Berlin, Germany; 3Deutsches RheumaForschungszentrum (DRFZ), Berlin, Germany

Background: Inflammatory bowel disease (IBD) and specifically Crohn’s disease (CD) is known to be associated with spondyloarthritides (SpA). However, little is known about factors associated with the development of spondyloarthritides in CD.

Objectives: To identify factors associated with the presence of SpA in a cohort of patients with CD.

Methods: Patients with a definite diagnosis of CD naïve to or not being treated with biological agents for at least 3 months were included in a CD-arm of the German Spondyloarthritis Inception Cohort (GESPIC-Crohn). Gastroenterologists were encouraged to include consecutively recently diagnosed CD patients. Patients were classified according to the Montreal classification including location and behavior of CD. Patients received a structured assessment of SpA manifestations (including magnetic resonance imaging of sacroiliac joints and spine) by a rheumatologist who was responsible for the final diagnosis of SpA / no SpA. Clinical activity of CD was assessed by the Harvey-Bradshaw Index (HBI). In addition, colonoscopy was performed. Simple endoscopic Score for Crohn’s Disease (SES-CD) was determined and fecal calprotectin was measured.

Results: A total of 108 patients with CD were enrolled. The mean (± SD) age was 36.6 ± 12.7 years, and CD symptom duration was 5.3 ± 7.4 years. At baseline, 44 (40.7%) patients were treated with non-biologic immunomodulating drugs: 16 (14.8%) patients received mesalazine, 27 (25.0%) azathioprine, and 1 (0.9%) methotrexate. Oral steroids were given to 38 (35.2%) patients. A total of 103 (96.3%) patients were biologics naïve. SpA was diagnosed in 23 (21.3%) patients: 12 had axial SpA and 11 peripheral SpA. Patients with SpA had higher prevalence of HLA-B27, of clinical SpA features (back pain, inflammatory back pain, peripheral arthritis, enthesitis), higher level of CRP and higher activity of CD as measured by the HBI. There were not substantial differences between SpA vs. non-SpA patients in terms of CD duration, endoscopic activity, disease location or behavior, or treatment, except for mesalazine, which was more frequently administered in patients with SpA than non-SpA (39.1% vs. 8.2%, p=0.001, respectively).

Conclusion: SpA was present in 21% of patients with CD in this early cohort with almost equal proportions of axial and peripheral forms. Presence of HLA-B27 and higher clinical activity of CD were associated with the presence of SpA.

De Miguel5 on behalf of Esperanza Working Group. 1Hospital Universitario La Paz, Rheumatology, Madrid, Spain; 2Hospital Reina Sofia, Rheumatology, Córdoba, Spain; 3Hospital Universitario de Bellvitge, Rheumatology, Madrid, Spain; 4Hospital Universitario Basurto, Rheumatology, Bilbao, Spain; 5Hospital Universitario San Juan, Rheumatology, Alicante, Spain; 6Hospital de Galdakao, Rheumatology, Bilbao, Spain; 7Hospital 12 de Octubre, Rheumatology, Madrid, Spain; 8Hospital Universitario de Basurto, Bilbao, Spain; 9Hospital Universitario Moncloa, Rheumatology, Madrid, Spain

Background: Longitudinal studies about the change from non-radiographic axial Spondyloarthritis (nr-axSpA) to r-axSpA (radiographic axial Spondyloarthritis) are scarce but show a 9-10% progression rate over 2 years (1-2) and a 24% progression rate over 10 years in another study (3). However, in early cohorts such as DESIR, this only represents a 5% over 5 years (4).

Objectives: The aim of this study was to know the rate of progression from nr-axSpA to r-axSpA over 6 years in the early Esperanza cohort.

Methods: This study included 94 patients of the Spanish early spondylarthritides (SpA) Esperanza cohort, 60 fulfilled the ASAS classification criteria for SpA. Every patient had a baseline and a six years sacroiliac X-ray. Nine readers, blinded for the diagnosis, participated in the reliability exercise, all of them experienced of radiologists and members of the Spanish spondylarthritides working group (GREGS). Patients with SpA were classified as having raxSpA at baseline or after 6 years of follow-up, if they fulfilled the radiographic item of the modified New York criteria (mNY) (presence of radiographic changes in the sacroiliac joints -SI- of at least grade II bilaterally or grade III or IV unilaterally). The gold standard of SJ X-Ray was the categorical opinion of at least five of the 9 expert readers. For the statistical analysis, the Chi-square and Kappa tests were performed.

Results: Demographic data of the SpA patients were: mean age 33.4±7.5 years; 37 (61.7%) male; mean CRP 6.4±6.5 mg/dl and ESR 10.3±10.6; Present smokers 30.6%; and past smokers 16.3%. HLA-B27 (+) 56.7%. Regarding the presence of uveitis at the 6 year visit. The reliability of the readers was fair with a mean inter-reader kappa test of 0.375 (range 0.146 - 0.652) and a mean agreement of 73.7% (range 58.7% - 90%).

Conclusion: In this group of patients with early SpA no progression from nr-axSpA to r-axSpA over 6 years was observed. It appears that early diagnosis and standard treatment seem to reduce SJ radiographic progression.

D. Wendling1, C. Patil1, T. Lequerré2, C. Miceli Richard3, M. Dougdos3, A. Molto3, X. Guillot1, 1CHU, University Teaching Hospital, Rheumatology, Besançon, France; 2CHU, University Teaching Hospital, Rheumatology, Rouen, France; 3Cochin Hospital, Rheumatology, Paris, France; 1CHU, University Teaching Hospital, Rheumatology, Saint dens de la Réunion, Reunion Island

Background: Uveitis is the most frequent extra rheumatological manifestation in axial Spondyloarthritis (SpA). DESIR is a prospective multicenter cohort of patients with early inflammatory back pain suggestive of SpA. We reported previously a 8.5% baseline prevalence of uveitis for the patients included in the cohort; this history of uveitis at the first visit of the cohort was associated with inflammatory bowel disease (IBD) and preceding infection (1).

Objectives: The aim of the study was to evaluate the prevalence and incidence of uveitis over the first five years of prospective follow-up of the cohort, and to evaluate its associated factors.

Methods: DESIR is a prospective observational cohort of patients with recent onset inflammatory back pain (more than 3 months, less than 3 years), suggestive of axial SpA. All available factors in the database were compared between patients with and without uveitis at 5 years, by uni and then multivariate analysis.

Results: After 5 years, 91 patients (out of 480 with complete follow-up) had at least one uveitis episode, giving an estimated prevalence of 18.9% [95%CI: 15.4-22.4]. In multivariate analysis, uveitis was associated with dactylitis (OR 2.92 [2.06 – 4.14]; p=0.002*), ESR > 7mm (median value) (OR 2.19 [1.57 – 3.06]; p=0.018*).

New incident uveitis occurred in 31 cases over 5 years, giving an estimated incidence rate of 1.29 [0.84 – 1.74] / 100 patient-years. New incidence of uveitis was
associated in multivariate analysis with the following baseline factors: diagnosis of SpA (OR 9.65 [3.21 – 28.96]; p=0.039*), total sacro iliac MRI inflammatory SPARRC score (central reading) over median (OR 3.98 [2.26 – 7]; p=0.015*), dactylitis (OR 4.7 [2.65 – 8.36]; p=0.007**), syndesmophyte score over median (none declared) (OR 0.22 [0.1 – 0.46]; p=0.039*).

No significant association was found with HLA-B27, cs or b DMARDs, BASDAI, ASDAS, BASFI.

**Conclusion:** Five-years data of the DESIR cohort allowed an estimation of incidence rate of uveitis of 1.3/100p-y; over five years, uveitis was associated with dactylitis, biologic and sacro iliac MRI inflammation.

**FR10326 PREVALENCE AND IMPACT OF COMORBIDITIES IN AXIAL SPONDYLOARTHRITIS: SYSTEMATIC REVIEW AND META-ANALYSIS**

S. S. Zhao1,2, S. Robertson1, T. Reich1, N. L. Harrison2, R. J. Moots1,2, N. Goodson1,2, 1University of Liverpool, Liverpool, United Kingdom; 2Aintree University Hospital, Liverpool, United Kingdom

**Background:** Comorbidities are common among patients with axial spondyloarthritis (axSpA). The majority of axSpA patients have at least one comorbid medical condition in addition to any extra-articular manifestations [1]. Comorbidity ‘burden’ is associate with poorer function, quality of life and work-related outcomes [2]. They also influence treatment decisions and are key drivers of mortality.

**Objectives:** We performed a systematic review and meta-analysis to 1) describe the prevalence of commonly reported comorbidities, 2) compare the prevalence of comorbidities between axSpA and control populations.

**Methods:** A systematic review was performed in September 2019 using Medline, PubMed, Scopus and Web of Science, in accordance with PRISMA guidelines. Studies were included if they reported the prevalence of comorbidities on disease outcomes, and excluded if they focused on a single comorbidity or closely related diseases in one organ system. Two independent reviewers screened titles and abstracts, assessed full-texts for eligibility and extracted data from qualifying studies. Where possible, we performed meta-analyses for comorbidities reported by at least 3 studies using random-effects models. Pooled prevalence estimates were reported as percentages (95% confidence interval, I² statistic for heterogeneity).

**Results:** 36 studies reported prevalence of of individual comorbidities, amounting to a combined sample size of 119,427 patients. The most prevalent individual comorbidities were hypertension (pooled prevalence 22%), hyperlipidaemia (17%) and obesity (14%) (Figure 1). Eleven studies consistently showed higher prevalence of comorbidities in axSpA than controls (Table 1); odds ratios (OR) were particularly large for depression (pooled OR 1.80) and congestive cardiac failure (OR 1.84). There was significant heterogeneity for the majority of meta-analysis estimates.

**Figure 1.** Pooled prevalence of individual comorbidities.

**Conclusion:** Comorbidities are common in axSpA. Almost all comorbidities examined were more prevalent in axSpA patients than age and sex matched controls, with >80% higher odds for congestive cardiac failure and depression. Systematic and repeated assessments should therefore be integrated into routine clinical practice to ensure holistic patient-centred management. Additional studies are needed to validate comorbidities indices for axSpA research.

**FR10327 QUALITY OF LIFE, QUALITY OF SLEEP AND PRESENCE OF RESTLESS LEG SYNDROME IN ANKYLOSING SPONDYLITIS**

S. Zontul1, A. K. Cengiz2, Z. Altay3, 1Ministry of Health Batman District Hospital, Rheumatology, Batman, Turkey; 219 Mayis University Faculty of Medicine, Physical Medicine and Rehabilitation-Rheumatology, Samsun, Turkey; 3Inonu University Faculty of Medicine, Physical Medicine and Rehabilitation, Malatya, Turkey

**Background:** For chronic diseases like ankylosing spondylitis (AS), improving patients quality of life (QOL) is one of the main aims of the therapy. Sleep quality is an important determinant of QOL. Restless leg syndrome (RLS) is a frequent disorder that disturbs patients QOL.

**Objectives:** The aim of this study is to evaluate the sleep quality of patients with AS and to determine the possible reasons of sleep disorder like pain, disease activity, functional status, depression, anxiety, presence of RLS and its impact on patients QOL.

**Methods:** One hundred twenty two patients with ankylosing spondylitis were enrolled in the study. Quality of life was evaluated by using short form-36 (SF-36). Beck depression and Beck anxiety indices were used to evaluate the mood of the patients. Sleep quality was determined with Pittsburg Sleep Quality Index. International Restless Leg Study Group (IRLSSG) criteria was used to determine the co-existing restless leg syndrome. Demographic data including age, sex, height, weight, marital status, educational status, disease duration and medical treatments were noted. BASDAI (Bath ankylosing spondylitis disease activity index),BASMI (Bath ankylosing spondylitis metrology index) and BASFI (Bath ankylosing spondylitis functional index) are determined and perceived pain level was evaluated by visual analog scale for pain (VASpain) for all patients.

**Results:** According to Pittsburg Sleep Quality Index 48 patients (39.3%) had bad sleep quality. When patients with bad sleep quality were compared with the patients with good sleep quality according to SF-36, BASDAI, BASMI,BASFI, VAS pain, Beck depression and Beck anxiety indices worse scores were obtained in patients with bad sleep quality. The difference between two groups were statistically significant for almost all of the listed parameters (Table 1). Restless leg syndrome (RLS) was determined in 36.06% (44/122) of AS patients. RLS was more common in patients with bad sleep quality but the difference did not reach statistical significance.
**Conclusion:** Sleep disorders are common in patients with AS and these disorders are found to be closely associated with pain, disease activity, anxiety, depression and poor quality of life. Restless leg syndrome (RLS) is also common in patients with AS and it is not always associated with bad sleep quality. RLS was determined in 32.4% (24/74) of patients whose sleep quality is good according to the Pittsburg Sleep Quality Index. To improve the quality of life in AS, presence of RLS must be evaluated along with the sleep quality.

**PROFILING OF THE IMMUNE COMPARTMENT IN THE TISSUE ENVIRONMENT OF PSORIATIC ARTHRITIS USING RNASEQUENCE**

G. Ang1, P. Kumar1, D. Guo1, A. Lajam1, W. Fong2, Y. Y. Leung2, S. Albani1.

1Translational Immunology Institute, Singapore, Singapore; 2Singapore General Hospital, Singapore, Singapore

**Background:** Psoriasis is a chronic inflammatory disease of the skin with a reported prevalence of 0.09-11.4% of the population. 1 in 4 psoriasis patients also have psoriatic arthritis (PsA) [2], with additional joint involvement that can be associated with significant morbidity. Despite its relative commonness, the aetiology of psoriasis is not well understood, and there is no cure for this disease. Additionally, up to 30% of PsA patients with active disease are recalcitrant to treatment. Thus it remains a prerogative to understand the immune mechanisms contributing to the development of the disease in order to inform strategies for novel therapies.

**Objectives:** Our aim was to identify perturbations in local tissue immune networks that could contribute to the pathology of psoriasis and psoriatic arthritis. We hypothesise that psoriasis is driven by a disrupted tissue microenvironment, which then provides cues to a susceptible peripheral immune system to drive pathology. Thus as the first part of our study, we investigated the transcriptional profiles of normal and lesional skin.

**Methods:** Skin punch biopsies were obtained from both lesional and morphological normal skin of 4 PsA patients with active disease. CD45+ cells were isolated using magnetic enrichment for RNA purification and subsequent RNaseq. Differently expressed genes (DEG) were identified and pathway analysis performed using the integrated Differential Expression and Pathway (IDEP) analysis tool. Gene set enrichment analysis was performed using GSEA.

**Results:** Transcriptomic analyses of skin revealed that lesional skin, compared to non-lesional sites, was enhanced for expression of genes associated with immune processes (including genes such as IL17A, FCN1, and CTLA4) anti-microbial responses (such as DEF4BA and S100A8) and immune cell chemotaxis (notably CXCL13 and SELPLG), suggesting a possible inflammatory response to skin microbiota. Interestingly, lesional skin showed a deficiency in expression of genes associated with RNA metabolic processes (including AARS, YARS, and other aminoacyl tRNA synthetases), suggesting a possible defect in protein translation. Similarly, pathway analysis revealed an enrichment in humoral immune response pathways in PsA lesional skin, and a comparative deficiency in RNA metabolic pathways.

**Conclusion:** Our transcriptional approach provides a comprehensive overview of localised immunity in psoriasis and predicts intimate interactions with the peripheral immune system. Further studies are ongoing to uncover cell types involved, as well as parallels at other disease sites (joints). These findings will facilitate the identification of novel targets for treatment of PsA.

**FRI0329**

**ASSOCIATION BETWEEN PERITENON EXTENSOR TENDON INFLAMMATION AND ENTHESITIS IN TUNISIAN PATIENTS WITH PSORIATIC ARTHRITIS**

K. Ben Abdelghani1, H. Bousaia1, S. Miladi1, A. Fazaa1, K. Ouenniche1, L. Souabni1, S. Kassab1, S. Chekili1, A. Laatar1. 1Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

**Background:** Ultrasoundography (US) is a useful tool in assessing psoriatic arthritis (PsA) by detecting synovitis and Power Doppler (PD) activity. Enthesitis is well known as a cornerstone of PsA pathophysiology. Recently, more specific US features of PsA have emerged, such as peritenon extensor tendon inflammation (PTI) and edema of soft tissues, with value in the positive diagnosis of the disease.

**Objectives:** The aim of our study was to determine the association between PTI, edema and enthesitis in PsA patients.

**Methods:** Patients with peripheral PsA responding to the Classification Criteria for Psoriatic Arthritis (CASPAR) were included: US examination was performed by an experimented rheumatologist blinded to clinical data using a machine type Esate MyLab 60 with a linear probe of 6-18 MHz. Wrist, metacarpo-phalangeal (MCP), proximal inter-phalangeal (PIP) and distal inter-phalangeal (DIP) joints were assessed in mode B and PD. PTI was defined as a hypoechoic image surrounding the digitorum tendon with or without PD signal in the dorsal aspect of MCP joints. Soft tissue edema was defined as a diffuse enlargement of soft tissue around the flexor tendon, with an increased PD signal, from finger pad to MCP joint and was evaluated by volar scan. Enthesitis of the digitorum extensor tendon at the dorsal aspect of DIP joint and synovitis were defined according to the OMERACT definitions.

A p≤0.05 was considered statistically significant.

**Results:** A total of 600 joints were assessed in 20 PsA patients, 8 men and 12 women, with a mean age of 55 ± 11 [33-77] years old. The mean disease duration was of 10±8 [1-34] years. Clinically, 25% of joints were tender and 6% were swollen. The mean DAPSA (Disease Activity in PSoratic Arthritis) score was of 32±27 [4-112].

On US examination, synovitis was detected in 54 joints (9%), with PD signal in 53% of them. The sites of synovitis by decreasing order of frequency were: MCP in 38%, wrists in 26%, PIP in 19% and PID in 13% of cases. PTI was noted in 24 MCP joints (12%) with PD signal in one case, and soft tissue edema in 6 MCP joints (3%). Enthesitis was noted in 59 DIP joints (37%). The elementary lesions recorded were: entheseophytes in 64 %, erosions in 20 %, calcifications in 13 % and thickened and/or hypoechoic tendon in 12 % of cases. However, no PD signal at the enthesis was found.

PTI and soft tissue edema had no association with enthesitis (p=0.399 and p=0.374 respectively). PD synovitis showed a significant association with enthesitis (p=0.034), but not with PTI and soft tissue edema. GS synovitis had no association with any of these lesions.

**Conclusion:** Our study found PTI and soft tissue edema not to be associated with enthesitis as opposed to PD synovitis. A larger sample size is necessary to support the role of PTI as an enthesis related lesion in PsA patients.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.3931
Objective: Since obesity has been associated with higher inflammatory burden and worse response to therapy in patients with chronic inflammatory joint diseases (CJIDs), we aimed to confirm the potential association between body mass index (BMI) and disease activity in a large series of patients with CJIDs included in the Spanish CARdiovascular in rheumATOlogy (CARMA) registry.

Methods: Baseline data assessment of patients included from the CARMA project, a 10-year prospective study of patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) attending outpatient rheumatology clinics from 67 Spanish hospitals. Obesity was defined when BMI (kg/m²) was ≥30 according to the WHO criteria. Scores used to evaluate disease activity were DAS28 in RA, BASDAI in AS, and modified DAS for PsA.

Results: Data from 2,234 patients (775 RA, 738 AS and 721 PsA) were assessed. The mean±SD BMI at the baseline visit were: 26.9±4.8 in RA, 27.4±4.4 in AS and 28.2±4.7 in PsA. Multivariate analyses showed a positive association between BMI and disease activity in patients with RA (β-coefficient: 0.029; 95% CI: 0.01-0.05; p=0.007) and in those with PsA (β-coefficient: 0.036; 95% CI: 0.015-0.058; p=0.001). By contrast, there was no significant association between BMI and disease activity in patients with AS (β-coefficient: 0.001; 95% CI: -0.026-0.03; p=0.926).

In patients with RA, female gender (β-coefficient: 0.545; 95% CI: 0.316-0.775; p<0.001) and rheumatoid factor status (seropositivity for RF) (β-coefficient: 0.328; 95% CI: 0.106-0.549; p=0.004) also showed a positive association with disease activity, while physical activity revealed a negative association with disease activity (β-coefficient: -0.280; 95% CI: -0.479 to -0.081; p=0.006).

Besides BMI, female gender (β-coefficient: 0.302; 95% CI: 0.254-0.351; p<0.001), Psoriasis Area Severity Index (β-coefficient: 0.038; 95% CI: 0.012-0.066; p=0.005) and enthesitis (β-coefficient: 0.256; 95% CI: 0.199-0.313; p<0.001) were also positively associated with disease activity in PsA.

As observed in RA and PsA, female gender was also associated with disease activity patients with AS (β-coefficient: 0.585; 95% CI: 0.293-0.832; p<0.001).

Conclusion: BMI is associated with disease activity in RA and PsA but not in AS. Since obesity is a potentially modifiable factor, disease activity was associated with female gender and RF status in RA and with Psoriasis Area Severity Index and enthesitis in PsA. Adequate control over body weight may improve the outcome of patients with CJIDs and, therefore, weight control should be included in the strategy of management of these patients.

Disclosure of Interests: Since obesity is a potentially modifiable factor, disease activity was associated with female gender and RF status in RA and with Psoriasis Area Severity Index and enthesitis in PsA. Adequate control over body weight may improve the outcome of patients with CJIDs and, therefore, weight control should be included in the strategy of management of these patients.
Background: Psoriatic arthritis (PsA) is a chronic systemic disease with manifestations affecting musculoskeletal and extra-articular domains. Treatment and assessment of response are therefore major challenges in routine clinical practice. Minimal disease activity (MDA) is a multidimensional endpoint that can define a treatment target. In SPIRIT-H2H, a head-to-head clinical trial comparing the efficacy and safety of ixekizumab (IXE) versus adalimumab (ADA), the percentage of patients simultaneously achieving American College of Rheumatology 50 (ACR50) and Psoriasis Area and Severity Index 100 (PASI100), was the primary endpoint in order to reflect improvement in two domains of PsA.

Objectives: To evaluate how individual components of the simultaneous achievement of ACR50 and PASI100 compare with those of MDA at week 24.

Methods: Patients with active PsA (defined as those with a tender joint count [TJC] ≥ 3/6, a swollen joint count [SJC] ≥ 2/6 and a body surface area [BSA] of active plaque psoriasis ≥ 3%) were randomised 1:1 to approved dosing (active plaque psoriasis ≥ 3%) for ixekizumab or adalimumab. A head-to-head blinded study. The proportion of patients meeting each criterion of the composite endpoints was calculated for the intent-to-treat (ITT) population. The proportion of MDA responders at Week 24 (N=235). Missing individual responses were imputed with non-responder status. Spidergrams were generated using SAS 9.4.

Results: For both the overall ITT population and the MDA responders population, the use of PASI≤1 or BSA≤3% in the skin-related component of the MDA contributed to the higher response rate relative to the PASI100 response. Thus, the PASI100 response is a more stringent endpoint. Proportions of responders are similar across MDA and ACR50+PASI100 individual components for HAQ and SJC. The high baseline TJC levels (mean TJC: IXE=19.1, ADA=21.3) as opposed to lower levels observed for baseline SJC (mean SJC: IXE=10.1, ADA=10.7) made MDA-TJC criterion (≤5) more difficult to achieve than the equivalent criterion of the ACR50+PASI100 endpoint.

Conclusion: Despite the differences in criteria definitions, there are consistent response patterns in the individual components of the simultaneous ACR50+PASI100 and MDA endpoints in particular for the peripheral arthritis domain.

FR1033

ACHEVEMENT OF VERY LOW DISEASE ACTIVITY AND REMISSION TREATMENT TARGETS IS ASSOCIATED WITH REDUCED RADIOGRAPHIC PROGRESSION IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH CЕRTOLIZUMAB PEGOL

L. C. Coates1, J. F. Merola,2, A. Kavanaugh,3, P. J. Mease4, O. Davies5, O. Irvin-Sellers6, T. Nurminen7, D. Van der Heijde7, Nuffield Orthopaedic Centre, Oxford, United Kingdom; 2Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America; 3Division of Rheumatology, Allergy and Immunology, UC San Diego School of Medicine, La Jolla, United States of America; 4Swedish Medical Center and University of Washington, Seattle, United States of America; 5UCB Pharma, Slough, United Kingdom; 6UCB Pharma, Monheim am Rhein, Germany; 7Leiden University Medical Centre, Leiden, Netherlands

Background: Several disease activity measures and thresholds have been recommended as psoriatic arthritis (PsA) treatment targets, although consensus on the most appropriate assessment tool is lacking. Reports suggest low disease activity (LDA) and remission may be associated with minimal structural progression in PsA.
Objectives: To report the relationship between PsA disease activity and structural progression over 216 weeks (Wks) treatment with certolizumab pegol (CZP), an Fc-free, PEGylated, tumour necrosis factor inhibitor (TNFi) that has shown long-term efficacy and safety in PsA.²

Methods: Patients (pts) enrolled in RAPID-PsA (NCT01087788) with active PsA (≥3 tender joints; ≥3 swollen joints; ESR ≥28 mm/hour and/or CRP > upper limit of normal) who had failed treatment with ≥1 csDMARD were randomised 1:1:1 to CZP 200 mg every 2 wks (Q2W), CZP 400 mg every 4 wks (Q4W), or placebo (PBO). All CZP pts received CZP 400 mg at Wks 0/2/4. PBO pts were re-randomised to CZP 200 mg Q2W or 400 mg Q4W at Wk 16 or 24.²

Pts were heterogenous for structural damage and disease duration at baseline. Disease activity was assessed using minimal disease activity (MDA) criteria (MDA: 5–6/7 criteria; very LDA [VLDA]: 7/7 criteria), Psoriatic Arthritis Disease Activity Score (PASDAS) (LDA: >1.9–≤3.2; remission: ≤1.9), or Disease Activity Index for Psoriatic Arthritis (DAPSA) (LDA: >4–≤14; remission: ≤4). Radiographs were read in four reading campaigns using the van der Heijde modified Total Sharp Score (mTSS) for PsA. A risk of structural progression (RSP) subgroup (baseline mTSS > median for all pts) was also assessed. Mean change from baseline (CFB) in mTSS and associations with disease activity states were estimated using a hierarchical linear mixed effects model (fixed effects: reading campaign/interactions of concurrent disease activity states were estimated using a hierarchical linear mixed model). 

Results: 407/409 randomised pts were assessed for mTSS at least once. At Wk 0, mean (standard deviation) DAPSA=44.5 (22.7), PASDAS=6.0 (1.1), 3/409 (0.7%) pts reported MDA. The proportion of pts achieving remission/VLDA states increased to Wk 216, as did estimated mean mTSS. Estimated mean mTSS CFB remained low overall (0.46 at Wk 216, standard error 0.16; Figure). Across disease activity measures, remission/VLDA states were associated with mTSS estimated mean CFB ≤0 in both the overall group and RSP subgroup (Table).

Conclusion: These data indicate that achievement of remission in PsA is important to prevent further structural damage, particularly in pts with pre-existing structural changes. This supports the rationale for strict disease activity targets.

FRIO334

COMPARATIVE ASSESSMENT OF COMORBIDITY IN ANKLYOSING SPONDYLITIS, PSORIATIC ARTHRITIS WITH AND WITHOUT SPINAL INVOLVEMENT

A. Dadalova¹, E. Vasilenko¹, R. Samigullina¹, V. Mazurov¹, ‘North-Western State Medical University named after I.I.Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E.Eichwald, Saint Petersburg, Russian Federation

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease associated with a lot of comorbidities, especially the diseases of cardiovascular system. [1] These diseases not only lead to a decrease in the quality of life and disability of patients, but also to a decrease in life expectancy in comparison with the general population. [2]

Objectives: The goal of study is to identify the most significant and common comorbid conditions in patients with axial spondylitis and compare their prevalence in three groups: in patients with ankylosing spondylitis, patients with psoriatic arthritis with and without spinal involvement.

Methods: The study included 140 patients with a reliable diagnosis of axSpA (ASAS criteria, 2009), which were subsequently divided into three groups: patients with ankylosing spondylitis, patients with psoriatic arthritis with and without spinal involvement. In all patients comorbid conditions was evaluated.

Results: The most common comorbid conditions among patients with axSpA were overweight (65%), included obesity (44%), hypertension (45%), diabetes and prediabetes (31.4%), dyslipidemia (23.6%), coronary heart disease (9.3%), diseases of the gastrointestinal tract (38.6%). Then we analyzed the prevalence of these comorbidity pathologies in three groups.

The characteristics of the groups are presented in Table 1.
Table 1. Characteristic of the patients with axial spondyloarthritis (n=140).

Conclusion: The prevalence of diseases of the gastrointestinal tract is approximately equal in all three groups, which is probably due to the use of non-steroidal anti-inflammatory drugs and glucocorticoids. The prevalence of the other pathology presented is significantly higher in the groups of psoriatic arthropathies and this does not significantly differ depending on the involvement of the spine in the pathological process. Due to the high prevalence of cardiovascular disease among patients with psoriatic arthritis, careful monitoring and timely administration of therapy is necessary.

**FR0335**

**THE EFFECT OF TOFACITINIB ON RESIDUAL PAIN IN PATIENTS WITH PSOARTIC ARTHRITIS**

1Leiden University Medical Center, Leiden, Netherlands; 2Johns Hopkins University, Baltimore, United States of America; 3University of Oxford, Oxford, United Kingdom; 4Pfizer Inc, Montreal, Canada; 5Pfizer Inc, Collegeville, United States of America; 6Pfizer Inc, Paris, France; 7Pfizer Inc, Groton, United States of America

Background: Current treatments for PsA have proven effective in reducing patient (pt)-reported pain; however, residual pain often remains. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA.

Objectives: This descriptive analysis evaluated the effect of tofacitinib, adalimumab and placebo on residual pain in pts with PsA whose inflammation was attenuated after 3 months of therapy.

Methods: Data were included from OPAL Broaden (NCT01877668), a randomised, double-blind, placebo-controlled Phase 3 trial of 12 months' duration in pts with PsA. Pts were randomised to receive tofacitinib 5 mg BID, adalimumab 40 mg subcutaneous injection once every 2 weeks or placebo. This analysis assessed pts with ‘residual pain’ at Month (M)3. Residual pain was considered as pain in pts with complete attenuation of inflammation at M3, defined by a swollen joint count (SJC) of 0 and CRP levels <6 mg/L. Pain was measured by a visual analogue scale (VAS; 0 “no pain” – 100 mm “most severe pain”). Changes in pain from baseline to M3 and residual pain (VAS pain reported at M3) were assessed.

Results: Demographics and baseline disease characteristics have previously been reported in the primary study, and were generally similar between treatment groups. At M3, 100/422 (23.7%) pts with PsA had achieved SJC of 0 and CRP <6 mg/L at M3. More tofacitinib-treated (tofacitinib 5 mg BID, n=233/107 [21.5%]; tofacitinib 10 mg BID, n=33/104 [31.7%]) and adalimumab-treated pts (n=31/106 [29.2%]) achieved SJC of 0 and CRP <6 mg/L vs placebo (PsA: n=13/105 [12.4%]). Baseline pain appeared numerically higher in tofacitinib-treated pts (tofacitinib 5 mg BID, 54.7 mm; tofacitinib 10 mg BID, 58.4 mm) vs adalimumab- and placebo-treated pts (47.7 mm and placebo 50.4 mm). In pts who achieved SJC of 0 and CRP <6 mg/L at M3, improvements in pain from baseline to M3 appeared numerically greater in pts receiving tofacitinib vs those receiving placebo (Figure 1a). When considering absolute (residual) pain at M3, mean residual pain was similar across treatment groups (ranges from 22.7–29.2 mm; Figure 1b), despite a higher baseline pain in tofacitinib treatment groups.

Conclusion: Changes from baseline in pain and absolute pain at M3 suggest that in pts with PsA whose inflammation has been completely attenuated, tofacitinib might have an effect on residual pain not obviously attributable to inflammation. However, the sample population was small, and there were large standard deviations. To confirm these results and to understand the mechanisms by which tofacitinib may improve residual pain, a meta-analysis will be performed using individual participant data from pts with rheumatic disease who have participated in tofacitinib randomised controlled trials.

Background: For inflammatory arthritis, drug retention is accepted as an important indicator of the effectiveness and safety of biological drugs. Objectives: The objective of this study was to determine of the effects first and overall bDMARD drug retention rate during concomitant csDMARD in psoriatic arthritis (PsA).

Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a prospective, single center database of biological treatments since 2005. All PsA patients (469) who enrolled in HUR-BIO registry and prescribed at least once biologic DMARD (bDMARD) were included in the study. The subjects were divided into two groups depending on whether or not to use csDMARDs (methotrexate, sulphasalazine or leflunomide) at the last control visit. Demographic, clinical and therapeutic data were collected from this database. Baseline disease activity before the first bDMARD initiation was assessed with DAPSA and PsAID-12.

Results: HUR-BIO PsA registry included 469 PsA patients. Baseline, clinical and therapeutic data were collected from this database. The using overall bDMARD were adalimumab 294 (62.0%), etanercept 135 (28.8%), infliximab 119 (25.4%), certolizumab pegol 107 (22.8%), secukinumab 67 (14.3%), golimumab 58 (12.4%), ustekinumab 25 (5.3%) and tofacitinib 11 (2.3%). Two hundred eighty eight (61.4%) patients used concomitant csDMARDs. The median drug retention rate of overall bDMARD in using csDMARD and bDMARD were 92% and 85%, respectively. The median duration of use overall bDMARD (months) was 56.8 (69.4) months, Switching bDMARD (n (%) was 148 (52.5), Initial bDMARD (n, med, IQR) was 19.4 (11.7) months, Initial PsAID (n, med, IQR) was 5.7 (9) months, Final visit PsAID (n, med, IQR) was 2.8 (3.8) months, Final visit DAPSA (n, med, IQR) was 10.2 (12.4) months, Remission (n,% was 61 (23.9) months, Low disease activity (n, % was 111 (43.5), Moderate disease activity (n, % was 72 (28.2), High disease activity (n, % was 11 (4.3)

Conclusion: In this study, csDMARDs, either methotrexate or leflunomide/sulphasalazine have additional effect for both retention rate and treatment response of bDMARDs. On the other hand, using bDMARD monotherapy is relatively higher than rheumatoid arthritis (1).

FR0338 SIMILAR CARDIOVASCULAR COMORBIDITY AND HIGHER DEPRESSION RATES IN PSORIATIC ARTHRITIS COMPARED TO AGE- AND SEX-MATCHED RHEUMATOID ARTHRITIS AND DIABETES MELLITUS PATIENTS

G. E. Fragouli1, G. Evangelatou2, N. Tentolouris3, K. Fragiakiaki1, S. Panopoulos1, G. Konstantinos1, A. Ilipoulous2, K. Chatzidionysiou1, P. Sfikakis1, M. Tektandoned1, National and Kapodistrian University of Athens, “Laiko” General Hospital, First Department of Propaedeutic Internal Medicine, Joint Rheumatology Program, Athens, Greece; 417th Army Shared Fund Hospital “NIMTS”; Rheumatology Department, Athens, Greece; 5th National and Kapodistrian University of Athens, “Laiko” General Hospital, First Department of Propaedeutic Internal Medicine, Diabetes Centre, Athens, Greece

Background: Comorbidities are frequent in psoriatic arthritis (PsA) but it is not known how they differ from other high comorbidity burden diseases like rheumatoid arthritis (RA) and diabetes mellitus (DM).

Objectives: To compare the prevalence of comorbidities in PsA vs. RA and DM patients.

Methods: 215 PsA patients were age/gender-matched with 215 RA and 215 DM patients from two tertiary hospitals. Prevalence of comorbidities (hypertension, current smoking, hyperlipidemia, obesity (BMI≥30), coronary disease [CD], stroke, MACE [combined CD and stroke], depression, osteoporosis, history of malignancies) were compared across the three groups. Within PsA group, associations between comorbidities and demographic and clinical features (e.g enhetis), including PsA phenotypes (RA-like vs oligoarthritis pattern and Axial-involvement vs Non-Axial-involvement) were assessed.

Results: Hyperlipidaemia, obesity and depression were more frequent in PsA vs. RA. Depression and osteoporosis were more common in PsA vs DM. In contrast, hypertension was more frequent in DM. All other comorbidities, including frequency of stroke, CD and major adverse cardiovascular events did not differ between groups. Results remain unchanged after adjustments (Table 1).

Within PsA group, depression was associated with female gender (p=0.02), older age (p=0.03), higher disease duration (p=0.04) and current smoking (p=0.04). MACEs in PsA, were associated with male gender (p=0.03), older age (p=0.0002), dyslipidaemia (p=0.003) and hypertension (p=0.0001). No differences were found between different phenotypes of PsA.

Conclusion: PsA patients had higher BMI and hyperlipidaemia compared to RA but not to DM. MACE is comparable between PsA and RA or DM, while depression is more common in PsA. Taking into account certain risk factors, screening for and management of comorbidities in PsA is important in the clinical setting.

LONG-TERM EFFICACY OF THE ORAL SELECTIVE JANUS KINASE 1 INHIBITOR FILGOTINIB IN PSORIATIC ARTHRITIS: WEEK 52 RESPONSE PATTERNS IN INDIVIDUAL PATIENTS FROM AN OPEN-LABEL EXTENSION (OLE) STUDY (EQUATOR2)

1University of Toronto, Toronto, United States of America; 2Botnar Research Centre, University of Oxford, Oxford, United Kingdom; 3Ghent University Hospital, Ghent, Belgium; 4University of Leeds, Leeds, United Kingdom; 5Galapagos NV, Mechelen, Belgium; 6LACO, contracted by Galapagos NV, Mechelen, Belgium; 7Gilead Sciences, Inc, Foster City, CA, United States of America; 8University of Washington, Seattle, United States of America; 9Galapagos BV, Leiden, Netherlands; 10Swedish Medical Centre, Seattle, United States of America

Background: EQUATOR (NCT03101670) was a 16-week, Phase 2, multicenter, double-blind, placebo-controlled, randomized controlled trial (RCT) of filgotinib in patients with active psoriatic arthritis. Filgotinib demonstrated rapid efficacy compared with placebo across multiple domains, including the primary endpoint of Week 16 American College of Rheumatology (ACR) 20 response. Patients completing the RCT could join an ongoing 148-week OLE (EQUATOR2; NCT03332057).

Objectives: In this prespecified interim analysis at Week 52 of the OLE, individual patient responses with respect to disease activity were evaluated.

Methods: Placebo-treated RCT patients switched to filgotinib (200 mg once daily) at Week 16 and entered the OLE; patients previously assigned to filgotinib continued. Individual response patterns at Week 52 of the OLE were evaluated for ACR20/50/70, Psoriatic Arthritis Disease Activity Score (PASDAS) low disease activity (LDA), minimal disease activity (MDA), and MDA very low disease activity (VLDA).

Results: 124 patients (95%) completed EQUATOR; 122 (93%) enrolled in the OLE. At Week 52, 11 patients (9%) had discontinued treatment in the OLE. Median (range) exposure to filgotinib was 66.0 (0.4–104.1) weeks. Patients originally assigned to filgotinib, sustained efficacy was seen through to OLE Week 52 for ACR20/50/70, PASDAS LDA, MDA (Table; Figure 1a); 55.0% of RCT non-responders also achieved a treatment response in the OLE, meeting MDA/VLDA. In total, 77% and 93% of those achieving MDA and ACR50 response, respectively; Figure 1a shows individual patient response over time for MDA.

Conclusion: Data from this 52-week OLE interim analysis suggest that further improvement in disease activity can be expected with filgotinib beyond 16 weeks in patients with active psoriatic arthritis. Sustained efficacy was demonstrated across several measures of disease activity, including MDA and ACR50.

Comparison of Secukinumab Versus Adalimumab Efficacy on Skin Outcomes in Psoriatic Arthritis: 52-Week Results from the EXCEED Study

A. B. Gottlieb1, F. Behrens2, P. Nash3, J. F. Merola4, K. Ding,5 P. Pellegr5, L. Princ5, I. Moinnes6
1Icahn School of Medicine at Mount Sinai, New York, United States of America; 2Rheumatology University Hospital and Goethe University, Frankfurt, Germany; 3Griffith University, Brisbane, Australia; 4Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America; 5Novartis Pharmaceuticals Corporation, East Hanover, United States of America; 6Novartis Pharma AG, Basel, Switzerland; 7University of Glasgow, Glasgow, United Kingdom

Background: Psoriatic arthritis (PsA) is a heterogeneous disease comprising musculoskeletal and dermatological manifestations, especially plaque psoriasis. Secukinumab (SEC), an IL-17A inhibitor, provided significantly greater PASI 75/100 responses in a head-to-head trial versus (vs.) etanercept, a TNF inhibitor, in patients (pts) with moderate-to-severe plaque psoriasis. The objective of the EXCEED study (NCT02745080) was to investigate whether SEC is superior to...
adulimumab (ADA), a TNF inhibitor, as monotherapy in biologic-naive active PsA pts with active plaque psoriasis (defined as having at least one psoriatic plaque of ≥2 cm diameter or nail changes consistent with psoriasis or documented history of plaque psoriasis).

**Objectives:** To report the pre-specified skin outcomes from the EXCEED study in the subset of pts with at least 3% body surface area (BSA) affected with psoriasis at baseline.

**Methods:** Head-to-head, phase-3b, randomised, double-blind, active-controlled, multicentre, parallel-group trial: pts were randomised to receive SEC 300 mg subcutaneous at baseline, Week 1-4, followed by dosing every 4 weeks (q4w) until Week 48 or ADA 40 mg subcutaneous at baseline followed by same dosing q2w until Week 50. The primary endpoint was superiority of SEC vs. ADA on ACR20 response at Week 52. Pre-specified outcomes included the proportion of pts achieving a combined ACR50 and PASI 100 response, PASI 100 response, and absolute PASI score ≤3.

**Results:** 853 pts were randomised to receive SEC (n=426) or ADA (n=427). At baseline, there were 215 and 202 pts having at least 3% BSA affected with psoriasis in the SEC and ADA groups, respectively. A higher proportion of patients achieved simultaneous improvement in ACR50 and PASI 100 response with SEC vs. ADA (30.7% vs. 19.2%; P=0.0087 [Figure]). Higher efficacy was demonstrated for SEC vs. ADA for PASI 100 responses and for the proportion of pts achieving absolute PASI score ≤3.

**Conclusion:** In this pre-specified analysis, SEC provided higher responses compared to ADA in achievement of simultaneous improvement of joint and skin disease (combined ACR50 and PASI 100 response) and in skin specific endpoints (PASI 100 and absolute PASI score ≤3) at Week 52.

**Background:** Axial Involvement in psoriatic arthritis (PsA) is quite common [1]. Predictors of axial involvement at early-stage of disease haven’t been sufficiently studied.

**Objectives:** To identify predictors of axial involvement in PsA patients (pts) at early-stage of disease.

**Methods:** 85 patients (pts) (M/F–47/48) with early PsA fulfilling the CASPAR criteria were included. All pts had peripheral arthritis for≥2 years; no inflammatory back pain (IBP) pts were specifically selected. Mean (Me) age 36.5±10.7 yrs, disease duration 12.2±10.3 mo. Pts underwent standard clinical examination of PsA activity. Me disease activity indexes DAS=4.0±1.4, DAS28=4.2±1.1, BASDAI=4.5±1.6; Me pts global disease activity VAS 56.9±17.1. All patients were evaluated for the presence of IBP by ASAS criteria, underwent sacroiliac joints (SIJs) X-ray (pelvic radiographs) and HLA B27 antigen status study. MRI of SIJs was performed in 79 pts, regardless of IBP presence, on Sigma Ovation 0.35T. Radiographic sacroilitis (R-SI) was identified according to New York criteria (unilateral grade≥3 or bilateral grade≥2). Bone marrow edema/ osteitis on MRI (STIR) was considered active MRI sacroilitis (MRI-SI). X-ray and MRI results were evaluated by an independent reader. IBP was observed in 63 (66.3%) cases, MRI-SI in 28 of 79 (35.4%) examined cases, R-SI in 29 (30.5%) cases. Skin lesion severity was evaluated as body surface area (BSA) affected: minor at <3%, mild at 3-10%, severe at >10%. Pts were split into 2 groups (gr.): those with axial involvement (axPsA), that is with IBP and/or R-SI and/or MRI-SI; and those without axial involvement (having only peripheral PsA [pPsA]). The axPsA gr. included 65 (68.4%) cases, the pPsA gr. 30 (31.6%) cases. Multidimensional step-by-step discriminant analysis was used to identify a group of features that are more typical for the axPsA patients.

**Background:** Axial Involvement in psoriatic arthritis (PsA) is quite common [1]. Predictors of axial involvement at early-stage of disease haven’t been sufficiently studied.

**Objectives:** To identify predictors of axial involvement in PsA patients (pts) at early-stage of disease.

**Methods:** 85 patients (pts) (M/F–47/48) with early PsA fulfilling the CASPAR criteria were included. All pts had peripheral arthritis for≥2 years; no inflammatory back pain (IBP) pts were specifically selected. Mean (Me) age 36.5±10.7 yrs, disease duration 12.2±10.3 mo. Pts underwent standard clinical examination of PsA activity. Me disease activity indexes DAS=4.0±1.4, DAS28=4.2±1.1, BASDAI=4.5±1.6; Me pts global disease activity VAS 56.9±17.1. All patients were evaluated for the presence of IBP by ASAS criteria, underwent sacroiliac joints (SIJs) X-ray (pelvic radiographs) and HLA B27 antigen status study. MRI of SIJs was performed in 79 pts, regardless of IBP presence, on Sigma Ovation 0.35T. Radiographic sacroilitis (R-SI) was identified according to New York criteria (unilateral grade≥3 or bilateral grade≥2). Bone marrow edema/ osteitis on MRI (STIR) was considered active MRI sacroilitis (MRI-SI). X-ray and MRI results were evaluated by an independent reader. IBP was observed in 63 (66.3%) cases, MRI-SI in 28 of 79 (35.4%) examined cases, R-SI in 29 (30.5%) cases. Skin lesion severity was evaluated as body surface area (BSA) affected: minor at <3%, mild at 3-10%, severe at >10%. Pts were split into 2 groups (gr.): those with axial involvement (axPsA), that is with IBP and/or R-SI and/or MRI-SI; and those without axial involvement (having only peripheral PsA [pPsA]). The axPsA gr. included 65 (68.4%) cases, the pPsA gr. 30 (31.6%) cases. Multidimensional step-by-step discriminant analysis was used to identify a group of features that are more typical for the axPsA patients.
There are two main groups of patients with PsA: those who have enthesitis with associated arthritis and not its opposite. The significance of enthesitis in PsA remains less evident. This reinforces the idea that PsoA is an inflammatory arthritis.

**Objectives:**

- To assess the synovial joint, peritendinous and enthesic response of patients with PsoA in remission under controlled mechanical stress.
- To evaluate the consistency of the response to filgotinib across predefined relevant subpopulations participating in the EQUATOR trial.

**Methods:**

- Before-after study of a consecutive cohort of patients with PsoA (CASPAR criteria), of at least two years of disease activity and DAPSA≤14 at present.
- Patients with positive rheumatoid factor, patients with exclusively axial forms and patients on biological therapy at the beginning of the study were excluded. All patients underwent controlled basal ultrasound and post-dynamic exercise (CAMRY EH101-17) of the dominant hand which included the carpus, MCFs, IFPs and IFDs of the 2nd to 5th fingers. The ultrasound findings were scored according to EULAR recommendations in grey scale (GS) and power Doppler (PD) for synovitis, enthesitis and tenosynovitis (maximum scores 71 and 87, respectively). For statistical analysis, comparisons were made with the results of their baseline and post-exercise ultrasound scores between subjects diagnosed with PsA and controls. The Student’s T test was used for related and unrelated data according to correspondence.

**Results:**

- Nineteen patients and controls were included, of which 73.7% were male. Mean age: 42.2 SD 6.6 and 42.21 SD 8.28, respectively. Basal DAPSA was associated with rapid and significant improvements in multiple domains of active psoriatic arthritis versus placebo in the 16-week Phase 2, multicenter, double-blind, randomized EQUATOR trial (NCT03101670).
- A significantly greater proportion of patients receiving filgotinib, versus placebo, achieved the primary endpoint of 20% improvement in American College of Rheumatology (ACR) 20 response at Week 16 (80% vs 33%, respectively).

**Conclusion:**

- Treatment with the oral selective Janus kinase 1 inhibitor filgotinib was associated with rapid and significant improvements in multiple domains of active psoriatic arthritis versus placebo in the 16-week Phase 2, multicenter, double-blind, randomized EQUATOR trial (NCT03101670).
- A significantly greater proportion of patients receiving filgotinib, versus placebo, achieved the primary endpoint of 20% improvement in American College of Rheumatology (ACR) 20 response at Week 16 (80% vs 33%, respectively).

- The aim of this predefined analysis was to evaluate the consistency of the response to filgotinib across predefined relevant subpopulations participating in the EQUATOR trial.

- Methods: In EQUATOR, patients with active psoriatic arthritis were treated with filgotinib 200mg (n=85) or placebo (n=86) once daily for 16 weeks. Key clinical endpoints, including ACR20 and ACR50 (50% improvement) response rates. Psoriatic Arthritis Disease Activity Score (PASDAS), and Disease Activity Index for Psoriatic Arthritis (DAPSA) were evaluated according to the following baseline characteristics: sex, body mass index, disease duration, baseline disease severity, concurrent use of disease-modifying antirheumatic drug(s), and prior exposure to tumor necrosis factor inhibitor(s). For PASDAS and DAPSA scores, statistical analysis of changes from baseline was performed using analysis of covariance with factors for treatment, randomization stratification, subgroup, and an interaction between treatment and subgroup. Least-squares (LS) mean difference between treatment arms and the corresponding 95% confidence intervals (CI) were calculated. For ACR20 and ACR50 response rates, statistical analysis used the point estimate and corresponding 95% CI, based on the Newcombe method.

- Results: Sixty patients (92%) in the filgotinib group and 64 (97%) in the placebo group completed the study. The total number of patients in each subpopulation ranged from 18 to 104 (Figure 1). Differences in the proportions of patients achieving ACR20 consistently favored filgotinib, compared with placebo, across all subgroups (Figure 1); all differences reached statistical significance. Similarly, differences in the proportions of ACR50 responders and LS mean treatment differences for PASDAS and DAPSA consistently favored filgotinib, reaching statistical significance in most subgroups. No clinically relevant differences in the effect of filgotinib were observed across subgroups. Filgotinib was generally well tolerated and no new safety signals were identified.

**Figure 1. Effect of filgotinib on ACR20 response across subgroups.**

**Discussion of Interests:**

None declared

DOI: 10.1136/annrheumdis-2020-eular.6279
Conclusion: In the 16-week EQUATOR trial, the effects of filgotinib on key efficacy endpoints were generally consistent across a range of subgroups based on patient, disease, and treatment characteristics.

Figure 1. Change from baseline in lipid profile in non-obese and obese patients

THE LONG-TERM EFFECT OF TREATING PSEORUTIC ARTHRITIS WITH THE JANUS KINASE 1-SELECTIVE INHIBITOR FILGOTINIB ON LIPID PROFILES: AN ANALYSIS OF THE EQUATOR AND EQUATOR TRIALS

M. E. Husni1, D. D. Gladman1, P. Helliwell2, F. Van den Bosch3, C. Tassef3, L. Meuleners4, L. Gilles5, L. Gheyle2, M. Trivedi1, M. Alani1, R. Besuyen6, P. J. Mease1,7,8,9

Background: Cardiovascular (CV) comorbidities are common in psoriatic arthritis (PsA); patients are at high risk for major adverse cardiovascular events (MACE). In the Phase 2, double-blind, randomized EQUATOR trial, significant improvements across multiple PsA domains were observed with the oral selective Janus kinase (JAK) 1 inhibitor filgotinib compared with placebo. Inhibition of JAK signal transducer and activator of transcription signaling is associated with raised serum lipids.

Objectives: To evaluate the effects of filgotinib on the lipid profile of PsA patients and determine if those with higher MACE risk show similar changes in lipid profile compared with the overall population.

Methods: In EQUATOR, 131 patients with active PsA received filgotinib 200 mg (n=65) or placebo (n=66) once daily for 16 weeks. Patients completing EQUATOR could enter the ongoing EQUATOR2 open-label extension (OLE; NCT03320876), in which patients receive filgotinib 200 mg for up to 148 weeks. Effects of filgotinib on total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and TC/HDL-C ratio at OLE Week 52 (68 weeks after EQUATOR initiation) were analyzed. In a post hoc analysis, patients were classified into subgroups according to presence/absence of obesity (baseline body mass index [BMI]; ≥30 vs <30 kg/m², respectively), diabetes mellitus, arterial hypertension (≥130/80 mmHg), hyperlipidemia, and metabolic syndrome.

Changes in lipid levels were explored graphically.

Results: 124 patients (93%) completed EQUATOR; 122 (95%) enrolled in the OLE. Of these, 11 patients (9%) discontinued treatment by OLE Week 52. Median (range) exposure to filgotinib was 66.0 (0.4–104.1) weeks. In the OLE, TC, LDL-C, and HDL-C levels increased versus baseline with filgotinib, resulting in a decreased TC/HDL-C ratio. Changes in lipid levels were consistent irrespective of presence of obesity (n=56; Fig), diabetes (n=53), arterial hypertension (n=50), hyperlipidemia (n=108), or metabolic syndrome (n=36); baseline lipid values were greater in the higher risk groups. In patients who were assigned placebo in the randomized controlled trial (RCT), HDL-C increased on switching to filgotinib in the OLE (in a manner similar to that seen in filgotinib-treated patients during the RCT), and remained elevated compared with baseline (Fig). Triglyceride levels remained stable throughout, across all subgroups. Seventeen patients (13%) were taking lipid-lowering drugs (LLDs) prior to the start of the trial (and continued to do so); the effect of filgotinib on the lipid profile in these patients was similar to that in the overall population. During the RCT phase, another six patients in the filgotinib group and one in the placebo group began taking LLDs.

References:
Background: Multiple biologic DMARDs (bDMARDs) are available for the treatment of psoriatic arthritis (PsA), but there are few direct comparisons of their efficacy and safety. In SPIRIT-H2H study, ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting IL-17A, was superior to adalimumab (ADA) at Week 24 for simultaneous achievement of ACR50 and 100% improvement from baseline in the Psoriasis Area and Severity Index (PASI 100) in patients (pts) with active PsA. Efficacy on other PsA domains was shown.

Objectives: To provide individual patient data demonstrating the simultaneous improvement in musculoskeletal and skin symptoms as assessed by American College of Rheumatology (ACR) response criteria and Psoriasis Area and Severity Index (PSI) percent improvement, respectively.

Methods: Pts with active PsA fulfilling Classification for Psoriatic Arthritis (CASPAR) criteria, ≥3/6 tender and ≥3/6 swollen joints, ≥5% psoriasis body surface area (BSA) involvement, no prior treatment with bDMARDs, and prior inadequate response to ≥1 conventional synthetic DMARD (csDMARD), were randomized 1:1 to open-label IXE or ADA (label dosing according to presence/absence of moderate-to-severe psoriasis [baseline BSA≥10%, PASI≥12, and static Physician’s Global Assessment≥3]) in Study 11F-MC-RHCF (NCT03151551). In this analysis, max ACRx was defined as the maximum ACRx response a patient can achieve where ACRx derivation follows the typical ACR response criteria: ≥x% improvement in both tender joint count (TJC) and swollen joint count (SJC) and ≥x% improvement in ≥3 of the 5 remaining components, Health Assessment Questionnaire-Disability Index total score (HAQ-DI), C-reactive protein (CRP), Patient Global Assessment (PatGA), Physician Global Assessment (PhyGA), and patient assessment of joint pain (patJP).

Missing data were imputed using the last observation carried forward (LOCF) method.

Results: At baseline, demographic and disease characteristics were similar across treatment groups. Mean baseline values for the ACR core data set were 20.2 (TJC), 10.4 (SJC), 63.8 (PatGA), 10.2 (CRP), 59.2 (PhyGA), 1.2 (HAQ-DI), and 61.0 (patJP). Mean PASI total score was 7.8. Figures 1 and 2 show the maximum ACR response by PASI percent improvement at Weeks 24 and 52, respectively. Independent of joint improvement, more ixekizumab-treated patients compared to adalimumab-treated patients achieved ≥PASI 90 (76.6% vs. 57.5% at week 24 and 83.0% vs. 59.6% at Week 52). Evaluation of patient-level data showed that while very few patients had joint improvement but little skin improvement (max ACRx≥50 and PASI≤50; Figures 1 and 2) in both treatment arms (IXE: 1.8%; ADA: 1.4%), fewer patients treated with IXE had no little improvement in both joint and skin symptoms (PASI≥50 and max ACRx<50) than those treated with ADA at Week 24 (IXE: 3.6%; ADA: 13.3%). A similar pattern was observed at Week 52 (Figure 2).

Conclusion: Ixekizumab treatment was superior to adalimumab when evaluating the combination of musculoskeletal and skin symptoms of PsA as measured by ACR response and PASI response.

Fig. 1. OR analysis of relationship between BMI at BL and treatment response.
PERSISTENCE OF SECUKINUMAB AND USTEKINUMAB IN PSORIATIC ARTHRITIS: A REAL-WORLD MULTICENTRIC COHORT OF 409 PATIENTS

Background: Real-world data are missing for Ustekinumab (UST) and Secukinumab (SEK) in psoriatic arthritis (PsA).

Objectives: To evaluate the characteristics of the patients (pts) with PsA treated by UST or SEK and to assess real world persistence of UST and SEK in PsA.

Methods: This is a retrospective, multicenter study of pts with PsA (CASPAR criteria or diagnosis confirmed by a rheumatologist) initiating UST or SEK with a follow-up ≥ 6 months from January 2011 to April 2019. The comparison of persistence between UST and SEK was analysed using a Cox model with an inverse probability of treatment weighting propensity score including 11 confounding factors. Subgroup analyses (age>65 years, gender, Body Mass Index (BMI), Charlson score>2, psoriasis, CRP>5mg/L, number (nb) of prior biotherapies, proportion of pts on maximum dose of UST or SEK, combination with methotrexate (MTX), enthesitis and axial forms of PsA) were also performed to test the heterogeneity of UST and SEK persistence. Finally, 2 sensitivity analyses were performed, first excluding the pts treated before the marketing authorization of SEK, and then excluding the pts that underwent a molecule switch. Causes of discontinuation were also collected.

Results: 406 pts were included: 245 with UST and 161 with SEK. At baseline before propensity score-matching, the UST group has a higher BMI (28.9 ± 6.4kg/m² vs. 27.4 ± 6.0kg/m²), more peripheral forms (98% vs. 90.8%), a higher nb of pts with recommended dosing (97.3% vs 50.9%). The median follow-up ≥ 6 months from January 2011 to April 2019. The comparison of persistence between UST and SEK was analysed using a Cox model with an inverse probability of treatment weighting propensity score including 11 confounding factors. Subgroup analyses (age>65 years, gender, Body Mass Index (BMI), Charlson score>2, psoriasis, CRP>5mg/L, number (nb) of prior biotherapies, proportion of pts on maximum dose of UST or SEK, combination with methotrexate (MTX), enthesitis and axial forms of PsA) were also performed to test the heterogeneity of UST and SEK persistence. Finally, 2 sensitivity analyses were performed, first excluding the pts treated before the marketing authorization of SEK, and then excluding the pts that underwent a molecule switch. Causes of discontinuation were also collected.

PSORIATIC ARTHRITIS AND CENTRAL OBESITY: STRONG ASSOCIATION WITH FUNCTIONAL DISABILITY AND A WORSE QUALITY OF LIFE

M. Lo Monsanto1, 2, 3, G. Pistone1, G. Natale1, 2, 3, R. Daia1, C. Argano1, L. Calvo1, R. Malliaci Boccio1, 2, 3, R. Scondotto1, 3, S. Corraro1, 2, 3, National Relevance and High Specialization Hospital Trust ARNAS Civico, Di Cristina, Benfratelli, Internal Medicine with Rheumatology and Dermatology, Palermo, Italy, 1School of Medicine University of Palermo, Biomedicine and Neuroscience (BIND), Palermo, Italy, 2IE.ME.S.T., Organizational, Clinical, and Translational Research, Palermo, Italy, 3School of Medicine University of Palermo, Promozione della Salute, Materno-Infantile, Medicina Interna e Specialistica di Eccellenza “G. DiAlessandro” (PROMISE), Palermo, Italy, 4School of Medicine University of Palermo, Internal Medicine, Palermo, Italy

Conclusion: In this first real-world study comparing UST and SEK persistence in PsA, the persistence of SEK was longer than that of UST. Subgroup analysis revealed this difference of persistence was restricted to patients treated in combination with MTX.
Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with comorbidities like obesity, metabolic syndrome, and cardiovascular disease. Adipose tissue leads to a pro-inflammatory status in obese subjects. For this reason, central obesity may determine a worsening in both disability index or quality of life in PsA patients treated with biologic agents.

Objectives: Our study aimed to evaluate the relationship between central obesity and disability index or the impact of the disease on quality of life in a real-world sample of PsA patients.

Methods: A cross-sectional study was conducted. Patients with PsA were enrolled at the PsA clinic at the ARNAS Civico in Palermo (Italy) from March 2018 to December 2019. Clinical, pharmacological, anthropometric, laboratory, and patient-reported outcomes, including the Health Assessment Questionnaire (HAQ) and Psoriatic Arthritis Impact of Disease (PsAID) were evaluated. STATA 14.1 was used to perform statistical analysis.

Results: A total of 143 outpatients aged 55.6 (47.7-63.7) affected by PsA, according to CASPAR criteria, were consecutively evaluated. The average years of illness were 10.8 (9.5-12.1). Patients were treated with biological therapy (81.3%), DMARDs (41.6%), small molecules (9.9%), or their combinations. Both sexes were equally represented. 71.9% of enrolled patients had central obesity (64.9% men and 78.1% women) with an average waist circumference of 104.2 (101.8 - 106.6) for women and 103.6 (100.0 - 107.2) for men. Average HAQ was 1.05 (0.92 - 1.19), and data analysis showed 50.3% of patients with normal-mild functional disability, 30.1% moderate to severe disability, and 19.6% severe to very severe disability [Fig 1]. 51.7% of the sample had a high impact of the disease on life, according to the PsAID questionnaire [Fig 2]. A strong association was observed between functional disability measured by HAQ >2 and central obesity [OR (95% CI) 16.94 (2.22 - 129.48); p < 0.006]. Moreover, data analysis showed an association between high impact of disease on life (PsAID >4) and central obesity [OR (95% CI) 3.33 (1.56 - 7.13); p<0.002].

Conclusion: Our study demonstrated a high association between functional disability studied subjectively using the HAQ, the impact of the disease on patients' quality of life using PsAID, and central obesity in Sicilian outpatients affected by PsA. Data suggest that therapeutic goals should not be focused on treatment but also on waist circumference reduction in order to reduce inflammation and improve patients' functional ability and quality of life.

*Adjusted for sex by treatment arm, prior nonbiologic DMARD use, and baseline BMI

1Least square estimate (SE) change from baseline at week 24

2P-value is nominal and for comparison with MTX mono

3Adjusted risk ratio (SE)

4Adjusted for BMI by treatment arm and prior nonbiologic DMARD use

BMI, body mass index; BSA, body surface area; DMARD, disease-modifying antirheumatic drug; ETN, etanercept; LDI, Leeds Dactylitis Index; MDA, Minimal Disease Activity; Mono, monotherapy; MTX, methotrexate; PASDAS, Psoriatic Arthritis Disease Activity Score; SE, standard error; sPGA, static Physicians’ Global Assessment

Conclusion: Results suggest contextual factors may affect response to therapy in PsA. The treatment-interaction analyses suggest disparate responses to MTX+ETN by sex; BMI only affected skin response.

Fri0352 PROBABILITY OF ACHIEVING LOW DISEASE ACTIVITY OR REMISSION WITH APREMILAST TREATMENT AMONG DMARD-NAIVE SUBJECTS WITH ACTIVE PSORIATIC ARTHRITIS

P. J. Mease1, A. Kavanaugh2, A. Ogdie3, A. F. Wells4, M. Bergman5, D. D. Gladman6, F. Behrens7, S. Richter8, M. Brunori9, L. Teng10, B. Guerrera11, J. S. Smolen12, 1Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, United States of America; 2University of California, San Diego, School of Medicine, La Jolla, United States of America; 3University of Pennsylvania, Philadelphia, United States of America; 4Amgen Inc., Thousand Oaks, United States of America; 5University of California, San Diego, La Jolla, United States of America

Background: In psoriatic arthritis (PsA), contextual factors such as sex and body mass index (BMI) may affect response to therapy.

Objectives: To examine if sex and BMI influenced 24-week (wk) outcomes in a 48-wk PsA trial of methotrexate (MTX) and etanercept (ETN) as monotherapy (mono) or combined.

Methods: MTX- and biologic-naïve adult patients with active PsA were randomized to weekly: MTX 20mg (n=284), ETN 50mg (n=284), or MTX 20mg+ETN 50mg (n=283). Wk-24 outcomes included ACR 20, MDA, VLD, PASDAS, DAPSA, LDI, SARCPC, BSA, sPGA, and mNAPSI. Descriptive statistics examined outcomes in each treatment arm by sex (male vs female) or BMI (<30 kg/m² vs ≥30 kg/m²). Modeling analyses also examined sex or BMI effect on outcomes when comparing MTX mono to the ETN-containing arms (analyses were adjusted for any prior use of a nonbiologic disease-modifying antirheumatic drug; the model for the influence of sex also adjusted for baseline BMI status). Nominal P-values are provided.

Results: Baseline disease activity was slightly higher in women, especially with MTX+ETN. Descriptive statistics showed men and women had similar results at wk 24 in the MTX mono and ETN mono arms; with MTX+ETN, men had better outcomes for ACR20, MDA, VLD, and PASDAS. In treatment-interaction analyses, men had more favorable responses at wk 24 with MTX+ETN vs MTX mono for PASDAS, MDA, and LDI (Table). Baseline disease activity was similar in both BMI categories. Descriptive statistics in each treatment arm showed no consistent differences in results at wk 24 between BMI categories. In treatment-interaction analyses, BMI ≤30 kg/m² had a more favorable response at wk 24 with MTX+ETN vs MTX mono for sPGA (Table).
Background: Apremilast (APR) is associated with comparable ACR response rates in DMARD-naive vs DMARD-experienced patients (pts) with psoriatic arthritis (PsA). A question that remains is if DMARD-naive pts treated with APR have a lower chance of achieving treatment targets than DMARD-experienced pts. cDAPSA is a commonly used treatment target.

Objectives: To assess the predictive value of baseline (BL) clinical disease status on achieving long-term cDAPSA treatment targets at Wk 52 among DMARD-naive subjects in PALACE 4; to compare these findings vs those recently reported from the PALACE 1-3 studies in subjects with prior exposure to DMARDs; and to provide further evidence that at a group level, achievement of cDAPSA disease targets with APR is associated with no or mild articular and extra-articular disease activity by Wk 52.

Methods: This post hoc analysis included subjects assigned to APR 30 mg twice daily at BL who had available cDAPSA data at BL. We calculated the probabilities of shifting across different cDAPSA categories (remission [REM]; ≤4; low disease activity [LDA]; > 4 to ≤15; moderate disease activity [Mod]; > 15 to ≤32; high disease activity [HDA]; > 32) from BL to Wk 52. Mean values of articular and non-articular variables (e.g., PASI, SJC/TJC, MASES, dactylitis) from BL to Wk 52 were assessed by cDAPSA category achieved at Wk 52 to determine the association between achievement of targets and control of articular and non-articular manifestations. Results from the current analyses were compared with the previously reported results from PALACE 1-3.

Results: A total of 175 subjects receiving APR were included; at BL, 66.3% were in HDA, 31.4% in Mod, and 2.3% were in LDA. Overall, subjects who achieved treatment targets (LDA or REM) by Wk 52 had lower levels of disease activity at BL, as shown by a lower number of swollen and tender joints and lower prevalence of enthesitis and dactylitis. Higher prevalence of psoriasis-involved body surface area ≥3% at BL was observed. Subjects in Mod at BL were estimated to be more than twice as likely to achieve REM or LDA at Wk 52 vs subjects in HDA at BL; for subjects in LDA at BL, the estimated probability of achieving cDAPSA treatment targets was 100% (Figure). PALACE 4 subjects with LDA and Mod at BL exhibited higher estimated probabilities of achieving treatment targets (100.0% and 61.7%, respectively) than those observed in the DMARD-experienced population of PALACE 1-3 (71.1% and 46.9%). Subjects in PALACE 4 who achieved REM or LDA by Wk 52 showed no or mild articular and extra-articular disease activity by Wk 52, similar to what was observed in the PALACE 1-3 population.

Conclusion: DMARD-naive subjects in PALACE 4 who had LDA or Mod at BL had the highest likelihood of achieving treatment targets (cDAPSA REM or LDA) by Wk 52 with continued APR treatment. Results from the current probability analyses revealed higher probabilities than those observed in the DMARD-experienced PALACE 1-3 population; control of articular and extra-articular manifestations was observed in the DMARD-naive and DMARD-experienced populations.

<td></td>
<td>1.05 (1.00-1.11)</td>
<td>0.0342</td>
</tr>
</tbody>
</table>

Conclusion: In the PsA cohort, fibromyalgia and age were associated with lower levels of physical activity. DLOI, PASI, LEI did not predict physical activity in PsA. Multivariate analysis showed higher pain levels and lower self-efficacy scores were associated with lower physical activity across arthritides groups.

FR0355 IMPACT OF BIOLOGIC THERAPY ON THE INCIDENCE OF PSA AMONG PATIENTS WITH PSORIASIS

A. Ogdie1, T. Love2, J. Takeshita1, J. Geilfand2, J. Scher3, H. Choi1,5, R. Fitzsimmons1, C.T. Ritchlin2, J. F. Merola1,5,7, University of Pennsylvania, Philadelphia, United States of America; University of Iceland, Reykjavik, Iceland; New York University, New York, United States of America; Massachusetts General Hospital, Boston, United States of America; Harvard Medical School, Boston, United States of America; University of Rochester, Rochester, United States of America; Brigham Women's Hospital, Boston, United States of America

Background: One of the strongest known risk factors for the development of psoriatic arthritis (PsA) is psoriasis. A key question is whether treatment of psoriasis may prevent or delay onset of PsA.

Objectives: To compare the incidence of PsA among patients with psoriasis treated with a biologic compared to those treated with a non-biologic therapy for psoriasis

Methods: We performed a retrospective cohort study in the Optum de-identified Electronic Health Record dataset between 2006-2017. Patients with two or more ICD codes for psoriasis between the ages of 16 and 90, who were initiating an oral medication, a biologic therapy, or phototherapy (defined as no preceding codes for the therapy in the prior 12 months) were identified. Covariates at baseline were determined in the 12 months prior to therapy initiation. The outcome of interest was PsA as defined by one ICD code. The incidence of PsA was described overall and within each therapy group. We analyzed the data in two ways: a) a multivariable Cox model using a time varying exposure (once the patient was exposed to a biologic, they were considered always exposed) derived from automated stepwise regression and b) propensity score matching (greedy matching, caliper 0.1) between biologic-exposed patients and oral/phototherapy exposed patients.

Results: Among 215,386 patients with psoriasis without PsA at baseline, 9,848 were excluded for prior biologic exposure, and among the remaining, 60,258 initiated phototherapy, oral or biologic therapy during follow up. Among 22,461 new biologic initiations, 29,121 oral therapy and 8,676 phototherapy initiations, the mean age was lower in the biologics group compared to the non-biologic groups (46.9 vs 50.8), with a similar proportion of females and Caucasians. Observational time was also similar. A total of 1,643, 1,813, and 122 new PsA cases occurred over 60,739, 85,670, and 28,528 person/years (PY) of follow up, respectively. (incidence 27.1, 21.2 and 4.2 per 1,000 person years respectively). Using a traditional multivariable adjustment approach with time varying exposure, the age and sex adjusted and fully adjusted HR (95% CI) for biologic users compared to non-biologic users were 1.01 (0.99-1.04) and 0.93 (0.91-0.95), respectively. However, after propensity score matching, the HR (95% CI) was 1.64 (1.51-1.77). Survival curves cross, however, at approximately 8 years (Figure 1) and most of the new diagnoses of PsA occurred shortly after therapy initiation (Figure 2).
**FRI0356**

**BURDEN OF DISEASE IN PATIENTS INITIATING APREMILAST TREATMENT: 2014-2019 FINDINGS FROM THE CORRONA PSORIATIC ARTHRITIS/SPONDYLOARTHITIS REGISTRY**

^1^University of Pennsylvania, Philadelphia, United States of America; ^2^Corrona, LLC, Waltham, United States of America; ^3^University of Massachusetts Medical School, Worcester, United States of America; ^4^Amen Inc., Thousand Oaks, United States of America; ^5^Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, United States of America

**Background:** The prospective, US-based, observational Corrona PsA/SpA Registry collects real-world data on patients (pts) with PsA provided by pts and their providers.

**Objectives:** To examine trends in characteristics of pts initiating apremilast (APR) from 2014-2019 and compare characteristics of treatment-naive pts initiating APR or methotrexate (MTX).

**Methods:** PsA pts aged ≥18 yrs enrolled in the registry who initiated APR, MTX, and/or biologics for PsA from January 2014-August 2019 were included and stratified by year of initiation (2014-2019, 2015-2016, 2017-2018, or 2018-2019). Demographics, clinical characteristics, treatment history, disease activity, and pt-reported outcomes (PROs) were analyzed at treatment initiation.

**Results:** 1460 PsA pts started APR (n=238), MTX (n=178), and/or a biologic (n=1044), including treatment-naive APR (n=20) and MTX (n=99) initiators from 2014-2019. For APR initiators in the 3 successive time periods, respectively, mean disease duration was 10.5, 12.2, and 11 yrs, and 67.5%, 82.5%, and 68.6% of pts had prior use of csDMARDs (similar to biologic initiators: 77.9%, 77.2%, and 68.8%). Over time, lower joint, enthesitis, and dactylitis counts, composite disease activity, and PRO measures of disease burden were observed (Table). Compared with treatment-naive MTX initiators, treatment-naive APR initiators had longer duration of PsA (8.5 vs 5.5 yrs) and time since PsA diagnosis (3.3 vs 1.8 yrs). Rates of comorbidities such as hypertension (50.0% vs 37.8%), diabetes mellitus (38.9% vs 13.3%), and metabolic syndrome (53.3% vs 8.9%) were higher in treatment-naive APR vs MTX initiators. Greater proportions of treatment-naive APR initiators had high/very high disease activity according to CDAI, DAPSA, cDAPSA, PASDAS, and DAS-28 vs MTX initiators.

**Conclusion:** In this Corrona Registry analysis, PsA pts starting APR had lower disease burden in recent vs prior yrs, indicating use of APR earlier in the course of PsA is increasing in real-world practice. Treatment-naive APR initiators had greater disease activity and severity vs MTX initiators. Comorbidities were common at APR initiation.

IMPROVED PAIN AND FATIGUE WITH IXEKIZUMAB TREATMENT IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND PREVIOUS INADEQUATE RESPONSE TO TNF INHIBITORS: THREE YEAR FOLLOW-UP FROM A PHASE 3 STUDY (SPIRIT-P2)
A. M. Orbai1, K. De Vlam2, N. A. Arend3, J. Burt4, G. Gallo4, K. Stenger4, V. Geneus4, B. Combe5, 1Johns Hopkins University School of Medicine, Baltimore, United States of America; 2Universitaire Ziekenhuizen, Leuven, Belgium; 3School of Medicine Griffith University, Brisbane, Australia; 4Eli Lilly and Company, Indianapolis, United States of America; 5CHU Montpellier and Montpellier University, Montpellier, France

Background: Psoriatic arthritis (PsA) is a chronic and complex inflammatory disease with both articular and extra-articular symptoms. Pain and fatigue are two of the most common patient-reported symptoms. Improvements in pain and fatigue have been demonstrated with up to 2 years of treatment with ixekizumab (IXE) in patients who had an inadequate response or intolerance to tumor necrosis factor inhibitors (TNFi).1,2

Objectives: To report improvements in pain and fatigue in TNFi-experienced patients with PsA who were treated with IXE for 3 years (156 weeks).

Methods: SPIRIT-P2 (NCT02349295) was a 156-week, Phase 3 study that included patients who met the Classification Criteria for Psoriatic Arthritis (CASPAR) and had an inadequate response or intolerance to TNF inhibitors (TNFi).1,2

Results: The proportions of patients who completed Week 156 were 70/122 (57.4%) in the IXE Q4W group and 55/123 (44.7%) in the IXE Q2W group. At Week 156, mean change from baseline for the Joint Pain VAS was -28.9 (IXE Q4W) and -25.3 (IXE Q2W) (Fig. A). In addition, 51.8% of patients on IXE reported clinically meaningful improvement of joint pain (56.1% IXE Q4W, 47.5% IXE Q2W) at Week 156. Patients reported an 18-point mean improvement in the SF-36 bodily pain domain at Week 156 (Fig. B). Patients also reported improvements in fatigue up to Week 156 (Fig. C), with 35.0% of patients achieving the MCID on the Fatigue NRS (39.4% IXE Q4W, 30.6% IXE Q2W). Improvement in fatigue was supported by a 14-point mean improvement in the vitality domain of the SF-36 at Week 156 (Fig. D).

Conclusions: In patients with PsA who had an inadequate response or intolerance to TNF, improvements in pain and fatigue were sustained through 3 years of IXE treatment in both the Q2W and Q4W treatment groups.

USAGE OF C-REACTIVE PROTEIN TESTING IN THE DIAGNOSIS AND MONITORING OF PSORIATIC ARTHRITIS (PSA): RESULTS FROM A REAL-WORLD SURVEY IN THE US AND EUROPE
A. Ogdie1, W. Tiltiet2, L. Eder3, N. Booth4, S. Bruce Wirts5, O. Howell6, A. Schubert2, S. Peterson6, S. D. Chakraverty3, L. C. Coates3,5 Perelman School of Medicine, Philadelphia, PA, United States of America; 2University of Bath, Bath, United Kingdom; 3University of Toronto, Toronto, Canada; 4Janssen-Cilag, Solna, Sweden; 5Janssen-Cilag, Giftsburg, Germany; 6Janssen-Cilag, Solna, Sweden; 7Janssen-Cilag, Warsaw, Poland; 8Janssen Global Services, LLC, Horsham, PA, United States of America; 9Janssen Scientific Affairs, LLC, Horsham, PA, United States of America; 10Drexel University College of Medicine, Philadelphia, PA, United States of America; 11University of Oxford, Oxford, United Kingdom

Background: C-reactive protein (CRP) is an important non-specific marker of both acute and chronic inflammation and can be elevated in patients with PsA. The role of CRP in the management of PsA is unclear.

Objectives: To describe how CRP testing is implemented in real-world clinical practice for disease management of PsA.

Methods: A cross-sectional study among patients with PsA recruited by rheumatologists and dermatologists was conducted in France, Germany, Italy, Spain, UK and US. Data were collected from Jun-Aug 2018 via physician-completed patient record forms. Use of CRP testing was obtained by asking the physician to state (yes/no) whether CRP was used to aid PsA diagnosis, confirm the patient’s PsA and to monitor the patient’s PsA. If physicians stated use of CRP testing, they were then asked to provide the number of CRP tests conducted in the last 12 months.

Results: Data were collected for 2270 patients with PsA (595 US, 1675 EUS). In EUS, 78.7% of patients had CRP conducted to aid diagnosis (vs 43.4% in US) and 72.0% had CRP conducted to monitor their condition (vs 34.6% in US). Patients seen by rheumatologists (vs dermatologists) were at least 50% more likely to have CRP used for monitoring purposes, those seeing most pronounced in the US. In EUS, CRP was conducted a mean [SD] of 2.7 [1.7] times in the last 12 months, versus 2.0 [1.4] in the US. Country level usage of CRP testing is shown in Table 2.

IMPACT OF METHOTREXATE ON DISEASE PATTERN IN ACTIVE PSORIATIC ARTHRITIS PATIENTS ELIGIBLE FOR A RANDOMIZED CLINICAL TRIAL WITH USTEKINUMAB: COMPARATIVE BASELINE DATA FROM MULTICENTRE INVESTIGATOR-INITIATED MUST TRIAL

T Rossmann1,2, M. Kohnn1,2, U. Kiltz4, J. Rech5, G. R. Burmester2, H. Kellner2, A. Bulczak-Schadendorf1,2, A. C. Foldenauer1,2, H. Burkhardt1,2,3, F. Behrens1,2,3, Fraunhofer IME Translational Medicine and Pharmacology, Frankfurt, Germany; 2Fraunhofer Cluster of Excellence Immuno-mediated Diseases (CDM), Freytagstraße, Germany; 3Goethe-University Frankfurt, Rheumatology Department, Frankfurt, Germany; 4Rheumazentrum Ruhrgebiet, Herne, Germany; 5Universität Erlangen, Rheumatology Department, Erlangen, Germany; 6Universitätsmedizin Charité, Department for Rheumatology and Immunology, Berlin, Germany; 7Rheumaprasix, München, Germany

Background: Methotrexate (MTX) is a csDMARD treatment that is initiated as first-line therapy (after NSAID) in active psoriatic arthritis (PsA). Randomized clinical trials mostly require treatment failure or intolerance of csDMARD/MTX therapy before initiation of a biological treatment. We designed an investigator-initiated (ITI) randomised blinded study comparing PsA patients starting open label Ustekinumab (UST) with blinded MTX or placebo (PLC). Patients are stratified regarding their previous MTX therapy (continuation or discontinuation of MTX (MTX-pre-treated patients –group A) or newly initiate MTX or continue without MTX (MTX-naive patients – group B).

Objectives: To determine disease characteristics of patients with active psoriatic arthritis regarding their skin and musculoskeletal manifestations in dependence of their MTX treatment status.

Methods: A total of 186 patients with active PsA (defined as TJC ≥4, SJC ≥4, CPRS ≥ 48/66 (joint count) and DAS28 ≥ 3.2) were screened for eligibility. At baseline (BL) 173 patients starting open label UST were randomised to receive either MTX pre-treated (PsA patients with MTX therapy before initiation of a biological treatment) or newly initiate MTX or continue without MTX (PsA patients with no previous MTX therapy). At baseline, patients were stratified regarding their previous MTX therapy (continuation or discontinuation of MTX (MTX-pre-treated patients –group A) or newly initiate MTX or continue without MTX (MTX-naive patients – group B).

Results: Our preliminary blinded data export comprised all documented and released data for SCR and BL until Mid-January 2020 - in total 154 randomized patients. Thereof, 78 patients were randomized in group A and 76 in group B. BL characteristics were comparable between the two groups (PsA patients with previous MTX therapy and PsA patients without previous MTX therapy).

Conclusion: As examined by DCE MRI and dGEMRIS, there is a significant association between early cartilage loss and acute synovial inflammation in small joint psoriatic arthritis.
Background: Among treatment options for PsA, IL-12/23 inhibition with UST was the first new biologic mode of action after TNFi. Few real-world data comparing UST with TNFi are available.

Objectives: Comparison of UST and TNFi treatment effectiveness within the respectively followed PsA BIO cohort at 12-month (mo) follow-up.

Methods: The PsA BIO study (NCT02627768) evaluates effectiveness, tolerability and persistence of 1st, 2nd or 3rd-line UST or TNFi in PsA. Proportions of patients (pts) reaching MDA/very low disease activity (VLDA) and clinical Disease Activity index for Psoriatic Arthritis (cDAPSA) LDA/remission are described. Comparison across UST and TNFi cohorts was done on last observation carried forward up to 12 (±3) mo, with non-response imputation for pts who had stopped/switched initial treatment. Logistic regression analysis was used, including propensity score (PS) analysis to adjust for imbalanced prognostic baseline (BL) covariates: country, age, sex, BMI, smoking (yes/no), comorbidities (cardiovascular/metabolic syndrome), PsA type (axial, polyarticular, oligoarticular), psoriasis body surface area (BSA), disease duration, cDAPSA, 12-item PsA Impact of Disease (PsAID-12), dactylitis, enthesitis, Fibromyalgia Rapid Screening Tool (FiRST) score, line of biologic (b)DMARD, synthetic DMARD use, and steroid or NSAID use.

Results: Of 929 eligible pts, 893 had evaluable data at BL and at follow-up; 438 (95.6%) were treated with UST and 455 (96.6%) with TNFi (including switchers). UST and TNFi groups had BL differences in mean age (51.0 vs 48.8, respectively), concurrent comorbidities (68.7% vs 60.9%), time since diagnosis (7.5 vs 6.2 years), line of treatment (1st-line 45.0% vs 55.2%; 3rd-line 20.5% vs 12.1%), NSAID use (54.8% vs 68.8%), concomitant MTX use (29.9% vs 42.0%) and psoriasis skin involvement (BSA >10% in 26.6% vs 14.8%). In 714 pts with available data, mean (standard deviation) BL cDAPSA was 30.6 (20.2; n=358) for UST and 29.3 (18.6; n=356) for TNFi. Observed data showed differences in proportion of pts achieving MDA/VLDA and cDAPSA LDA/remission in favour of TNFi, but after PS adjustment for BL differences (such as line of therapy, skin psoriasis, concomitant conventional DMARD, etc.), odds ratios for reaching targets at 12 mo did not significantly differ between UST and TNFi groups (Fig. 1).

Conclusion: Various factors, including patient characteristics such as comorbidities, influence the physician’s selection of treatment modality for patients needing a bDMARD. Our real-world results demonstrate differences in observed clinical effectiveness between UST and TNFi. However, after PS adjustment for a number of BL differences, clinical results at 12 mo were comparable between UST and TNFi groups. Data at 12 mo also show sustained response with both UST and TNFi treatment, as well as a similar rate of pts achieving targets after 6 to 12 mo of treatment.

CLINICAL PREDICTORS OF SECUKINUMAB RETENTION IN A REAL WORLD COHORT OF PATIENTS WITH PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHROPATHY

A. Tindle1, A. Mcgucken1, S. Bato2, S. Siebert1. 1University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom; 2NHS Greater Glasgow & Clyde, Glasgow, United Kingdom

Background: There are increasing treatment options for patients with psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA). Whilst there is still some evidence identifying predictors of response to TNF inhibitors there is little data so far about the impact of these factors on treatment retention. We evaluated the factors associated with stopping treatment due to inefficacy in PsA and in AxSpA in a real world cohort.

Methods: Retrospective analysis of all rheumatology patients’ notes in Glasgow who had received secukinumab. Demographics, disease activity at baseline and retention of secukinumab were collected from medical records in patients with a diagnosis of PsA or AxSpA. Patients who discontinued due to adverse events or death (e.g. pregnancy) were excluded. Patients who remain on secukinumab but have not yet had their six-month review to assess response or who started secukinumab via a clinical trial were also excluded. Unpaired T-test of unequal variance was used to assess differences between groups with p-value ≤0.05 considered significant.

Results: 352 rheumatology patients in Glasgow had ever received secukinumab. 266 had PsA, 76 had AxSpA (others: SAPHO, JIA, reactive arthritis). 77 PsA patients discontinued secukinumab, 48 due to inefficacy. 157 PsA patients remain on secukinumab and have had at least an initial six-month review. Table 1 shows results for PsA. Inefficacy was associated with higher levels of current smoking and higher levels of ESR and CRP but not tender or swollen joints. There is a similar trend in AxSpA patients, reinforcing the importance of promoting smoking cessation. Higher levels of ESR and CRP negatively predicted secukinumab response in PsA. High BASDAI and low disease duration in AxSpA predicted inefficacy. These clinical factors may be helpful in informing treatment decisions in PsA and AxSpA in the absence of therapeutic biomarkers.

PREVALENCE OF THE METABOLIC SYNDROME IN PSORIATIC ARTHRITIS: SYSTEMATIC LITERATURE REVIEW AND RESULTS OF THE CARMA COHORT

A. Urribizcochea-Arang1, S. Castañeda2, E. Loza3, T. Otón2, D. Benavent4, M. A. Martin-Martínez5, M. A. González-Gay* on behalf of CARMA Project Collaborative Group. 1H. Can Misses, Ibiza, Spain; 2H.U La Princesa, Madrid, Spain; 3InMusc, Madrid, Spain; 4H.U La Paz, Madrid, Spain; 5Spanish Society Of Rheumatology, Madrid, Spain; 6H.U. Marqués de Valdecilla, Santander, Spain

Background: The cardiovascular burden in psoriatic arthritis (PsA) is well recognized.

Objectives: To analyze the prevalence of metabolic syndrome (MetS) in patients with PsA.

Methods: We conducted a systematic literature review (SLR) and a sub-analysis of the CARMA cohort. In the SLR, we searched in Pubmed, Embase, the Cochrane Central Library, and the ClinicalTrial until March 2019 using Mesh terms and free text words. We included SLR, clinical trials and observational studies analyzing the prevalence or frequency of MetS in PsA. Two reviewers selected articles, assessed the quality of the studies and collected data independently. The CARMA cohort was designed to establish the cardiovascular (CV) morbidity and associated risk factors for CV disease. It includes data from patients with chronic inflammatory rheumatic diseases (including PsA) of 67 Spanish hospitals. A sub-analysis of the prevalence of MetS in PsA was performed using the National Cholesterol Education Program Adult Treatment Panel III criteria updated in 2005, which requires the presence of ≥3 of the following: high waist circumference, low HDL cholesterol level, high triglyceride level, high blood pressure and high fasting glucose values.

Results: A total of 18 articles of moderate to high quality, were selected in the SLR. The included patients presented a balanced distribution by sex, with an average age ranging from 42 to 59 years. The frequency of MetS varied from 23.5% to 62.9% depending on the definition of MetS. The most widely used classification method was the National Cholesterol Education Program, followed by the method recommended by the International Diabetes Federation in 2009. A total of 724 patients with PsA were included in the CARMA study, of whom 327 (45.4%) were women and 157 (21.8%) smokers. The mean age at baseline was 51 ± 12 years and the mean duration of PsA disease 9 (4-16) years. Hypertension was the most frequently altered parameter (66.8%), followed by fasting glucose (42.6%) and hypertriglyceridemia (30.6%). Table 1 shows the frequency of MetS according to the number of MetS components. A total of 222 (30.6%) PsA patients presented metabolic syndrome.

Values are mean unless stated

21 AxSpA patients discontinued secukinumab, 13 due to inefficacy. 49 AxSpA patients remain on secukinumab and have had at least an initial six-month review. AxSpA patients who stopped due to inefficacy had higher mean BASDAI (8.47 vs 7.02, p=0.007) but there was no difference in mean ESR (31 vs 27.1, p=0.31) or CRP (23.6 vs 23.0, p=0.48). Surprisingly, disease duration was lower in inefficacy group (78 years vs 13.5, p= 0.003); this could reflect a higher proportion in the inefficacy group with non-radiographic AxSpA which is known to be associated with earlier disease and to have a lower response to biologic treatments than ankylosing spondylitis. Smoking did not show significant difference in AxSpA but numbers are small and there is numerically higher level of smoking in the inefficacy group (58% vs 32%, p=0.0063). No other significant differences in demographics or clinical characteristics were noted.

Conclusion: Smoking predicted inefficacy in secukinumab in PsA patients, with a similar trend in AxSpA patients, reinforcing the importance of promoting smoking cessation. Higher levels of ESR and CRP negatively predicted secukinumab response in PsA. High BASDAI and low disease duration in AxSpA predicted inefficacy. These clinical factors may be helpful in informing treatment decisions in PsA and AxSpA in the absence of therapeutic biomarkers.

Scientific Abstracts
REAL-WORLD EFFECTIVENESS AND SAFETY OF APREMILAST IN A LARGE COHORT OF GERMAN PATIENTS WITH PSORIATIC ARTHRITIS: 1-YEAR ANALYSIS OF AN ONGOING MULTICENTER, PROSPECTIVE, NON-INTERVENTIONAL STUDY

J. Wollenhaupt1, H. Strothmeyer2, M. Fiene3, S. Morys4, C. Bach4, J. Roemmler-Zehrer4. 1Rheumatologie im Struenseehaus, Hamburg, Germany; 2Rheumatologische Gemeinschaftspraxis Düsseldorf, Düsseldorf, Germany; 3Klinik für Rheumatologie, Demmin, Germany; 4Ammgen Inc., München, Germany

Background: Apremilast (APR) has been studied extensively in phase III randomized, controlled trials. However, real-world information is limited on the effectiveness and safety of APR in a large cohort of patients with active PsA from routine clinical practice settings in Germany.

Methods: In this multicenter, prospective, non-interventional study, the primary endpoint was the proportion of patients reaching ≥1-point improvement in the full analysis set. The mean age was 55 years, mean body mass index (BMI) 26.5 kgs/m2, and 60% were female. The mean duration of Psoriasis and PsA was 26 years and 18 years, respectively. At BL, 46.7% of patients had enthesitis based on the Leeds Enthesitis Index (LEI; mean [SD]: 2.9 [1.72]) and 23% had dactylitis (mean [SD]: 2.2±0.03); 74% of patients were biologic-naive. Effectiveness is shown after ~1 month (Visit 1 [V1]) and ~4 months (Visit 2 [V2]) and for up to 225 patients after 12 months (Visit 5 [V5]) of treatment (Table). Improvements were also seen in PIGA, overall pain, and pruritus. A subanalysis suggested APR was associated with greater benefits in biologic-naive compared with patients who previously received biologic therapy. Observed safety and tolerability through V5 were consistent with the known overall safety profile of APR. Common adverse events in clinical trials were similar, with a lower incidence of diarrhea (3.2%), nausea (15.3%), headache (3.9%), and respiratory tract infection (0.8%).

Conclusion: Data from this large, real-world cohort of patients with PsA show the effectiveness of APR. In patients with up to 12 months of follow-up, APR was associated with rapid and maintained improvements in physician-assessed and patient-reported outcomes. Safety and tolerability were consistent with the known profile of APR.

ANALYSIS OF DIFFERENCES IN RISK CLASSIFICATION USING CAROTID ULTRASOUND IN PSORIATIC ARTHRITIS: A CASE-CONTROL STUDY

D. A. Galarraza-Delgado1, J. R. Azpíriti-López2, I. J. Colunga-Pedraza1, D. E. Flores Alvarado1, O. I. Ilizaliturri Guerra1, J. C. Zarate Salinas1, P. F. Frausto Lerma1, A. Pérez Villar2, M. A. Reyes Soto1, A. C. Garza Acosta3. Hospital Universitario “Dr. José Eleuterio González”; UANL, Rheumatology, Monterrey, Mexico; Hospital Universitario “Dr. José Eleuterio González”; UANL, Cardiology, Monterrey, Mexico; Hospital Universitario “Dr. José Eleuterio González”; UANL, Radiology, Monterrey, Mexico

Background: Patients with psoriatic arthritis (PsA) have an increased risk of cardiovascular disease (CVD). Risk stratification algorithms for general population, such as cardiovascular risk calculators, have been developed to improve primary prevention and early detection of CVD; however, it underestimates cardiovascular risk in PsA patients. Carotid ultrasound, which measures both carotid intima-media thickness (cIMT) and carotid plaque (CP), is useful in the detection of subclinical carotid atherosclerosis improving risk stratification.

Objectives: This study aimed to evaluate the use of carotid ultrasound in the reclassification of cardiovascular risk in PsA patients and compare it with controls.

Methods: This cross-sectional study included 70 PsA patients that fulfilled the CASPARI criteria and 70 controls subjects matched by age and comorbidities. Patients with a history of previous atherosclerotic CVD and pregnancy were excluded. Clinical examination, blood tests and Framingham Risk Score Lipids and BMI based (FRS-Lipids/FRS-BMI) and ACC/AHA 2013 calculators were performed. Carotid B-mode ultrasonography was used for measurements of cIMT and CP presence. Increased cIMT was defined as ≥0.8mm. CP was defined as a focal narrowing ≥0.5mm of the surrounding lumen or a cIMT ≥1.2mm. Descriptive analysis was done with measures of central tendency and dispersion and comparisons with Chi-square, Student’s t and Mann-Whitney U tests.

Results: A total of 138 subjects were included. Clinical and demographic characteristics are shown in Table 1. Differences were found in the cardiovascular risk classification between the calculators and the carotid ultrasound. However, these were not significant when compared to controls, with the exception of the FRS-Lipids which had a significant difference when recategorized as high risk by the increase in the cIMT (p = 0.016). A 70.8% and a 56% of patients with PsA who had CP were not classified as high risk according to FRS-Lipids (p = 0.010) and ACC / AHA 2013 (p =0.001) respectively.

</tbody>
</table>

Conclusion: None of the traditional calculators used in the general population correctly estimates cardiovascular risk in patients with PsA. Among the calculators we performed, FRS-Lipids was the worst, underestimating PsA individuals with CP up to 70.8%. Therefore, it is advisable to perform a carotid ultrasound without relying on the results obtained by any of these calculators in order to achieve an adequate classification and accomplish a correct management of the disease.

Bone diseases, including osteoporosis and osteoimmunology: aetiology, pathology and animal models

FR10367

ADALIMUMAB IS MORE EFFECTIVE THAN ETA NERCEPT AT PREVENTING TNF-ENHANCED OSTEOCLAST DEVELOPMENT THROUGH DOWNREGULATION OF PRO-OSTEOCLASTOGENIC FACTORS ICAM-1 AND IGFBP2 AND UPREGULATION OF ANTI-OSTEOCLASTOGENIC FACTOR FABP4

B. Harvey1, L. Jin2, J. Maul2, C. Hu2, Y. Tian2, Z. Kaymakcalan1. 1AbbVie BioResearch Center, Biologics, Worcester, United States of America; 2AbbVie BioResearch Center, DMPK, Worcester, United States of America

Background: TNF has been shown to contribute to osteoclastogenesis independently and in conjunction with M-CSF and RANKL. We have previously demonstrated that TNF enhances the kinetics of RANKL-induced human osteoclastogenesis and that its effects are mitigated more effectively by the anti-TNF biologic adalimumab (ADA) as compared to etanercept (ETN).

Objectives: To determine the mechanism responsible for the difference in effectiveness between the two biologics, a label-free quantitative proteomics study was conducted on TNF-activated human osteoclasts (OC) upon biologic treatment.

Methods: Human bone marrow-derived OC precursors (OCP; 3 donors) were exposed for 5 days to M-CSF; M-CSF+RANKL (RANKL) alone or in combination with 100 ng/mL TNF +/- 5 ug/mL ADA, ETN or human IgG1 (IGG) as pre-formed complexes. OC differentiation was confirmed by measuring TRAP5b activity. Shotgun proteomics was performed on peptides generated from detergent based cell extracts subjected to methanol/chloroform precipitation and trypsin/ Lys-C digestion. Data acquisition was performed with Orbitrap Q Exactive™ HF-X mass spectrometer. MaxQuant was utilized to quantify proteins based on MS1 peak intensities. Data matrix was normalized, imputed and subjected to differential expression analysis by limma. DAVID pathway analysis (DPA) was used to identify pathways impacted by various treatment conditions based on proteins exhibiting significant (p<0.05) 1.2-fold change in expression as compared to RANKL. Protein levels within culture supernatant or cell lysate were verified by ELISA or MSD.

Results: Principle component analysis (PCA) of the proteomic profiling data for the 3 donors indicated that exposure of OCP to TNF induced a distinct profile from that of M-CSF and RANKL. The addition of ADA:TNF complexes restored the profile to that of RANKL, whereas those exposed to ETN:TNF complexes exhibited an intermediate profile matching differences observed in TRAP5b activity. DPA identified 3 pathways most associated with osteoclastogenesis: receptor-mediated endocytosis (e.g. CD163, IGFBP2), oxidation-reduction process (e.g. FABP4), and cell adhesion (e.g. ICAM-1, TGFBI) that were significantly impacted by TNF with ADA:TNF being more effective than ETN:TNF in restoring most pathway-associated proteins to RANKL levels. Based on ELISA, two pro-osteoclastogenic factors IGFBP2 and ICAM-1 were increased 2-fold in OCP culture supernatants in response to TNF with only ADA:TNF complexes reducing these levels of both to RANKL:TNF-induced reduction of intracellular levels of CD163, an M2 macrophage polarization marker, and TGFBI were not only restored to RANKL levels by ADA:TNF but brought to a level closer to M-CSF alone, unlike ETN:TNF. One anti-osteoclastogenic factor FABP4 was found to be increased intracellularly above that of RANKL only following exposure to ADA:TNF complexes.

Conclusion: Shotgun proteomic profiling of human OCP differentiated in vitro with TNF revealed at least 3 novel pathways by which TNF exerts its pro-osteoclastogenic effects. Only with the addition of ADA:TNF, not with ETN:TNF, were most pathway-associated proteins significantly restored to RANKL levels including pro-osteoclastogenic factors ICAM-1 and IGFBP2. Moreover, ADA:TNF complexes enhanced the intracellular levels of CD163 and the anti-osteoclastogenic factor FABP4, suggesting these complexes are exerting an effect on OCP beyond simple TNF neutralization. Additional in vitro and in vivo studies need to be performed to verify our findings.

FR10368

GLUCOCORTICOID THERAPY MIGHT SUPPRESS WNT SIGNALING BY REDUCING THE RATIO OF SERUM WNT3A TO WNT INHIBITORS, SFRP-1 AND WIFI-1, AND IMPAIR BONE FORMATION

M. Kawazoe1, K. KaneKO1, T. Nanki1. 1Toho University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Glucocorticoids decrease bone density by multiple mechanisms, including suppression of bone formation via Wnt-/beta-catenin signaling. Binding of Wnt ligands to a specific receptor and its co-receptors is required for activation of the Wnt pathway, whereas this pathway is inactivated by some negative regulators of Wnt signaling. Sclerostin (Scl) and Dickkopf-1 (Dkk-1) bind to Wnt co-receptors, and secreted Fizzled-related protein 1 (sFRP-1) and Wnt inhibitory factor 1 (WIF-1) bind to Wnt ligand, thereby inactivating the Wnt pathway [1-4]. However, the detailed changes of Wnt signaling in patients with glucocorticoid-induced osteoporosis have not been clarified.

Objectives: We measured serum levels of Scl, Dkk-1 and Wnt3a before and after starting glucocorticoid therapy in our previous study, and the results suggested that suppression of Wnt/beta-catenin signaling by increasing serum Scl and Dkk-1 might impaired bone formation at least in the first week of the initiation of glucocorticoid therapy [5]. However, the involvement of Wnt signaling following suppression of bone formation was unclear. The objective of this study was to investigate the involvement of the Wnt/beta-catenin signaling pathway and its clinical significance after the early phase of glucocorticoid therapy in glucocorticoid-induced osteoporosis.

Methods: A total of 53 patients with systemic autoimmune diseases who received initial glucocorticoid therapy with prednisolone (30-60mg daily) were prospectively enrolled. We measured serum levels of sFRP-1, WIF-1 and Wnt3a before starting glucocorticoid therapy and every week for four weeks after its initiation. Patients underwent measurement of bone mineral density (BMD) of the lumbar spine (L2-4) by dual-energy X-ray absorptiometry before starting therapy and after 16.3 ± 1.4 months (the mean ± SEM). Results: Serum sFRP-1 and Wnt3a level tended to decrease compared to before therapy from the first week. Serum level of Wnt3a also decreased from the first week. Both the ratio of Wnt3a to sFRP-1 and the ratio of Wnt3a to WIF-1 decreased from the first week onward. Moreover, we stratified the subjects into two groups according to the baseline serum sFRP-1 level at median and found that the decrease of BMD after initiation of glucocorticoid therapy in the High sFRP-1 group was larger than that in the Low sFRP-1 group. There was no difference in BMD changes between High WIF-1 and Low WIF-1 group, when stratified into two groups according to the median baseline Serum 1 level. Conclusion: Our previous study indicated that increase of Scl and Dkk-1 could inhibit Wnt signaling pathway in the early phase of glucocorticoid therapy. Current study suggested that the reduction in the ratio of Wnt3a to Wnt inhibitors, sFRP-1 and WIF-1, would suppress Wnt signaling, which might result in impairment of bone formation subsequent. Taken together, bone formation was impaired via suppressing Wnt signaling in patients treated with glucocorticoids. Furthermore, higher serum sFRP-1 level before glucocorticoid administration might be a predictor of future severity of glucocorticoid-induced osteoporosis.

MIMICKING GLUCOCORTICOID-INDUCED OSTEOPOROSIS USING AN IN VITRO TRABECULAR HUMAN BONE MODEL

A. Lang1,2, K. Diesing1, A. Damerau1,2, S. Uzun1, M. Pfeiffenberger1,2, T. Gaber1,2, F. Buttgerer1,2. 1Charité-Universitätsmedizin Berlin, Department for Rheumatology and Clinical Immunology; Berlin, Germany; 2German Rheumatism Research Center, Berlin, Germany

Background: The bone matrix consists of inorganic and organic components and a variety of specialized cells such as osteoblasts, osteocytes and osteoclasts. The bone-forming osteoblasts are responsible for the production of organic matrix components; they differentiate later into osteocytes which is accompanied by matrix mineralization. Osteoclasts are multinuclear giant cells, which resorb bone. Healthy homeostasis is characterized by a balanced, dynamic and coordinated bone remodelling (osteoblasts—osteoclasts) are commonly used to successfully treat patients with inflammatory rheumatic and other autoimmune diseases. However, long-term treatment with GC can potentially lead to several adverse effects such as the inhibition of osteoblast proliferation and the increase of osteoclastic activity resulting in osteoporosis.

Objectives: Hence, the aim of our project is to i) develop an in vitro trabecular human bone model, ii) integrate this bone model into a perfusion system to accelerate mineralization and provide biomechanical stimuli and iii) applying prednisolone to induce osteoporosis. Here we present our initial results describing the successful differentiation of osteoblasts and osteoclasts in a 3D environment, and the accomplished integration of the bone model into a perfusion system.

Methods: In a first step, different cultivation conditions were tested to allow optimal osteogenic or osteoclastic differentiation. To this end, a human bone marrow derived mesenchymal stromal cells (hMSCs) were treated with osteogenic medium, and b) monocytes (isolated from buffy coats) were differentiated into osteoclasts using following protocol: incubation for 3 days with 25 ng/ml RANKL. C

Results: We have been able to populate the TCP scaffold with monocytes, which were differentiated into osteoclasts (morphological changes) without any effect on cellular viability as measured by Live/Dead staining. The morphological changes of those osteoclasts such as formation of filopodia could be demonstrated by scanning electron microscopy. In addition, the cultivation of TCP in the presence of hMSCs in a perfusion system showed upregulation of osteoclastic markers (RUNX2, OSX) on mRNA level.

Conclusion: These first results of our approach to develop an in vitro 3D model for glucocorticoid-induced osteoporosis are promising. Our next step will be the co-cultivation of osteoblasts and osteoclasts under dynamic and optimized cultivation conditions. By combining several cell types, a suitable scaffold and biomechanical stimuli (perfusion), we aim to provide a valid testing platform to study underlying disease mechanisms and for drug development.

FRI0370

DUAL OXIDASE MATURATION FACTOR 1 POSITIVELY REGULATES RANKL-INDUCED OSTEOCLASTOGENESIS VIA ACTIVATING REACTIVE OXYGEN SPECIES PRODUCTION AND TRAF6-MEDIATED SIGNALING

C. H. Lee1, C. H. Chung1, Y. J. Choi2, W. H. Yoo3, J. Y. Kim1, M. S. Lee1. 1Wonkwang University Hospital, Internal Medicine, Iksan, Korea, Rep. of (South Korea); 2Chonbuk National University Hospital, Internal Medicine, Jeonju, Korea, Rep. of (South Korea); 3Wonkwang University, School of Medicine, Iksan, Korea, Rep. of (South Korea)

Background: Reactive oxygen species (ROS) are one of the significant factors of chemical or physical cell signaling in a wide variety of cell types including skeletal cells. Receptor activator of NF-κB ligand (RANKL) induces generation of intracellular ROS, which act as second messengers in RANKL-mediated osteoclastogenesis. Dual oxidase maturation factor 1 (Duox1) was first identified as a Drosophila Numb-interacting protein (NIP), and has been associated with the maturation of ROS generating enzymes including dual oxidases (Duox1 and Duox2). In the progression of osteoclast differentiation using mouse bone marrow-derived macrophages (BMMs), we identified that only Duox1 level showed an effective change upon RANKL stimulation, but not Duox1, Duox2, and Duox2.

Objectives: we hypothesized that Duox1 could independently act as a second messenger for RANKL stimulation and regulate ROS production during osteoclast differentiation.

Methods: Using siRNA or retrovirus transduction and knockdown of Duox1 via siRNA

Results: Duox1 level gradually increased during RANKL-induced osteoclast differentiation. We found that Duox1 regulated RANKL-stimulated osteoclast formation and bone resorption positively. knockdown of Duox1 via siRNA decreased the RANKL-induced ROS production. During Duox1-related control of osteoclastogenesis, activation of tumor necrosis factor receptor (TNFR)-associ- ated factor 6 (TRAF6)-mediated early signaling molecules including MAPKs, Akt, IκB, Btk, and PLC β2 was affected, which sequentially modified the mRNA or protein expression levels of key transcription factors in osteoclastogenesis, such as c-Fos and NFATc1, as well as mRNA expression of osteoclast-specific markers including OSCAR, ATP6V0d2, and CtsK.

Conclusion: Overall, our data indicate that Duox1 plays a crucial role in osteoclastogenesis via regulating RANKL-induced intracellular ROS production and activating TRAF6-mediated signaling.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.3505
Objectives: We investigated that BA could suppress RANKL-induced osteoclastogenesis and bone resorption.

Results: BA significantly suppressed osteoclastogenesis by decreasing the phosphorylation of Akt and IκB, as well as PLCγ2-CA2+ signaling, in pathways involved in early osteoclastogenesis as well as through the subsequent suppression of c-Fos and NFATc1. The inhibition of these pathways by BA was once more confirmed by retrovirus infection of constitutively active (CA)-Akt and CA-IκB retrovirus and measurement of CA2+ influx. BA also significantly inhibited the expression of osteoclastogenesis-specific marker genes. Moreover, we found that BA administration restored the bone loss induced through acute lipopolysaccharide injection in mice by a micro-CT and histological analysis.

Conclusion: Our findings suggest that BA is a potential therapeutic candidate for bone diseases involving osteoclasts.

FR10372 INCREASED EXPRESSION OF NOTCH RECEPTORS ON OSTEOCLAST PROGENITORS INDUCED BY RHEUMATOID ARTHRITIS

M. Filipović1, A. Šučur1, D. Flegar1, Z. Jajić2, M. Ikić Matijasević3, N. Lukac1, N. Kovacić1, T. Kelava1, D. Šišić1, K. Zrinski Petrović1, V. Katavić1, D. Grčević1

Background: Systemic and periarticular bone loss in rheumatoid arthritis (RA) is mediated by osteoclasts, multinucleated cells originating from the myeloid lineage. Recently, Notch signaling pathway has emerged as a potential regulator of osteoclast progenitor (OCP) differentiation and activation.

Objectives: The exact role of Notch signaling in the context of arthritis is still unknown; however, its inhibition has beneficial effects in animal arthritis models. We aimed to determine the expression of Notch receptors and ligands on specific OCP subpopulations and define changes that occur in murine collagen-induced arthritis (CIA) and RA patients.

Methods: Peripheral blood, synovial tissue and subchondral bone marrow were collected from RA patients, and periarticular bone marrow (PBM) and spleen (SPL) were harvested from male C57Bl6 mice immunized with chicken type II collagen. Notch 1 to 4 receptor expression on OCPs was analyzed by flow cytometry. Gene expression of Notch receptors/ligands was determined by qPCR from murine and human OCPs, as CD45+CD3-CD19-CD56-CD11b+CD14+CCR2+ respectively, specifically associated with arthritis. Flow cytometry revealed that majority of murine splenic and periarticular OCPs express Notch 2, whereas Notch 1 and 4 were expressed on approximately 10% of cells. In CIA, this highly osteoclastogenic population is associated with arthritis. Flow cytometry revealed that majority of human peripheral-blood OCPs express Notch 2 and 4, with a specific increase in the expression of Notch 1 and 3 in RA. In contrast, RA synovial-derived OCPs mostly express Notch 1 to 3, whereas subchondral OCPs mostly express Notch 1 and 4. Notch ligands were analyzed at mRNA level and revealed expression of Jag1, Jag2 and DLL1 in murine sorted OCPs and Jag1 and DLL1 in human sorted OCPs. Expression of Notch ligands was confirmed by IHC on arthritic murine hind paws, with Notch 2 expressed by bone marrow, synovial tissue and chondrocytes and Notch 1 expressed by chondrocytes and synovial tissue. Increased expression of Notch 1, Notch 2 and Jag1 was also confirmed in murine arthritic periarticular tissue by qPCR. During osteoclastogenic culture, murine and human OCPs exhibit a similar gene expression pattern with higher initial expression of Notch 1 and 2, and increase in the expression of Notch 3 and 4 with differentiation. Osteoclasts were also differentiated under Notch-ligand stimulation. Coating with DLL1 results in a greater number of cells expressing osteoclast-specific TRAP, whereas Jag1 seemed to inhibit osteoclastogenesis.

Conclusion: Our results indicate that murine and human OCPs express a distinct tissue-specific pattern of Notch receptors. Notch signaling in OCPs is increased in arthritis and may contribute to the osteoclastogenic potential and increased bone resorption. Our next aim would be to determine the effect of Notch inhibition on OCP activity and arthritis severity.

Background: Chronic non-bacterial osteomyelitis (CNO) is an immune-mediated disease associated with cytokine dysbalance.

Objectives: The aim of our study was to evaluate the cytokines levels in CNO and compare to juvenile idiopathic arthritis (JIA) – disease with immune-mediated mechanism.

Methods: The diagnosis of CNO made with criteria, proposed by Jansson (2007, 2009), after the exclusion of other causes of bone disease [1]. We included 42 patients with NBO, 28 patients with non-systemic juvenile idiopathic arthritis (JIA). We evaluated plasma levels of 14-3-3 protein, S100A8/S100A9-protein, interleukin-6 (IL-6), interleukin-18 (IL-18), interleukine-4 (IL-4), interleukine-17 (IL-17), interleukine-1β (IL-1β) and tumor necrosis factor-α (TNFα) in 2 groups by the ELISA. Statistical analysis was carried out with Statistica 10.0 software. We utilized descriptive statistics (Me; IQR), Mann-Whitney tests.

Results: We have found differences in the proinflammatory biomarkers between CNO, JIA. Patients with NBO had lower levels of studied cytokines, exclude14-3-3-protein, S100A8/S100A9 and interleukin-6 compared to JIA patients (Table 1).

Conclusion: Patients with CNO had less proinflammatory activity than JIA patients, besides IL-6 and S100A8/S100A9. Further investigations required for finding new more specific biomarkers and finding possible molecular targets for treatment.

VISFATIN EFFECTS ON MSCS DURING OD VIA DIFFERENTIAL REGULATION OF LINCRNA H19 AND MICRO RNA 675-3P

D. Küppers1, L. Taikaurai1, M. Hülsler1, K. Frommer1, S. Rehart1, C. Ospeit2, U. Müller-Ladner1, E. Neumann1.

1Justus-Liebig-University Gießen, Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Bad Nauheim, Germany; 2Agapeion Markus Hospital, Dept. of Orthopaedics and Trauma Surgery, Frankfurt am Main, Germany; 3University Hospital of Zürich, Dept. of Rheumatology, Center of Experimental Rheumatology, Zürich, Switzerland

Background: Long non-coding (lnc-)RNA are regulatory molecules transcribed from DNA similar to mRNA and interact directly with DNA, RNA and proteins. Some IncRNAs have been shown to contain micro (mi-)RNAs in their sequence that can be released by splicing and lead to active mRNA molecules, e.g. IncRNA H19 includes two miRNAs 675-3p and -5p in its sequence. Adipose tissue derived factors (adipokines) are involved in inflammation processes and osteoarthritis (OA) development. The proinflammatory adipokine visfatin has been shown to alter osteogenic differentiation (OD) of pluripotent mesenchymal stem cells (MSCs) and reduces elastic fiber expression, increases matrix mineralization and proinflammatory cytokine and chemokine production [1].

Objectives: We evaluated a novel effect of visfatin on IncRNA H19 in MSCs during OD. The goal was to explore the kinetics of the visfatin effect during OD with regard to H19 regulation and to investigate H19 downstream mechanisms leading to the observed altered MSC differentiation and osteoblast activity. Methods: MSCs isolated from a hip or knee bone (phMSCs) and commercially obtained healthy human (h)MSCs were differentiated towards osteoblasts without visfatin, resistin, leptin, TNF and Wnt/TGFβ1 pathway inhibitors. Supernatants were collected at days 2, 7, 9, 14 and 21 of OD, cell lysates at day 2, 7, 9, 14 and matrix mineralization assays conducted at day 21. H19 and miRNA expression was evaluated by real-time PCR after miRNA isolation. IL-6 was analyzed by ELISA.

Results: H19 was continuously upregulated in undifferentiated controls as expected during OD but also when combined with other adipokines. In contrast, stimulation with visfatin significantly decreased H19 (day 2 to 14 of OD, hip-phMSCs: p = 0.0097, knee-phMSCs: p = 0.0075, h-MSC: p = 0.044). Visfatin increased matrix mineralization and IL-6 production as expected (hMSC: p = 0.03, phMSC: p = 0.013) [1]. TNF stimulation during OD did not lead to a downregulation of H19 nor increased matrix mineralization, thus showing that the effects were visfatin-dependent. H19s endogenous miRNA 675-5p was changed in parallel with visfatin expression (e.g. day 14 p = 0.015). However, H19s endogenous miRNA 675-3p was inversely regulated, downregulated during controlled OD while visfatin stimulation attenuated this effect (e.g. day 14 p = 0.025). Altered Wnt-signaling and involvement of the TGFβ1 pathway could not be observed.

Conclusion: H19 is upregulated during OD and may therefore play a regulatory role in the process of osteogenesis. Visfatin stimulation of MSCs during OD showed pro-inflammatory effects, increased matrix mineralization while reducing elastic fiber production [1]. These effects were associated with a downregulation of H19, a specific visfatin effect not triggered by other adipokines or TNF. The H19 sequence includes two endogenous micro-RNAs 675-3p and 5p. We demonstrated miRNA 675-5p to be regulated in parallel to H19, whereas miRNA 675-3p was inversely regulated and increased continuously upon visfatin stimulation. Based on these results, we hypothesize that visfatin provides a specific stimulus for the splicing of miRNA 675-3p from H19, in turn leading to H19 reduction. miRNA 675-3p thus represents an effectors mechanism of visfatin that contributes to the observed functional effects in differentiating MSCs.

EFFECT OF CARBAMYLATED LOW-DENSITY LIPOPROTEINS ON BONE CELLS HOMEOSTASIS

B. Luchin1, M. Leopizzi2, T. Colasanti1, V. Di Maio1, C. Alessandri1, G. Valesini3, F. Conti1, M. Di Franco1, F. R. Spinelli1.

1Sapienza University of Rome, Dipartmento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy; 2Sapienza, Dipartimento di Scienze e Biotecnologie Medico-Chirurgiche, Roma, Italy

DOI: 10.1136/annrheumdis-2020-eular.1512
Background: Carbamylation is a post-translational modification occurring under several conditions such as uremia, smoking and chronic inflammation as in rheumatoid arthritis (RA). Low-density lipoproteins (LDL) represent a target of carbamylation. Carbamylated-LDL (cLDL) have an increased inflammatory and atherogenic potential. Growing evidence supports an influence of modified lipids on bone cells homeostasis. However, the role of cLDL on bone cells physiology is still unknown.

Objectives: Considering the rate of carbamylation and the role of anti-carbamylated proteins antibodies as markers of erosive disease in RA, the purpose of this study is to investigate the effect of cLDL on bone homeostasis.

Methods: In-vitro carbamylation of LDL was performed as previously described by Ok et al. (Kidney Int. 2005). Briefly, native LDL (nLDL) were treated with potassium cyanate (KOCN) for 4 hours, followed by excessive dialysis for 36 hours to remove KOCN. Both osteoclasts (OCs) and osteoblasts (OBLs) were treated at baseline with 20 μg/ml, 100 μg/ml and 200 μg/ml of cLDL or nLDL. To induce osteoclast differentiation, CD14+ monocytes were isolated from peripheral blood of healthy donors by magnetic microbeads separation and then cultured on a 96-wells plate in DMEM media supplemented with RANKL and M-CSF. After 10 days cells were fixed, stained for tartrate-resistant acid phosphatase (TRAP), a marker of OC differentiation, and counted. OBLs were isolated from bone specimens of 3 patients who had undergone to knee or hip arthroplasty for osteoarthritis and treated for 5 days with different concentrations of cLDL and nLDL. OBLs were fixed and stained for alkaline phosphatase positive activity (ALP), a marker of osteogenic differentiation. Total RNA was extracted from cell lysates. Copies of single-stranded complementary DNA (cDNA) were synthesized and analyzed by real-time PCR to evaluate RANKL and Osteoprotegerin (OPG) mRNA expression levels.

Results: In OCLs culture, cLDL significantly decreased the number of OC compared to untreated cells (200 μg/ml p=0.0015) and nLDL treated cells (200 μg/ml p=0.011; 20 μg/ml p=0.0014) (Fig 1). Moreover, treatment with cLDL induced an increase of not terminally differentiated OCs, reduced dimensions of OCs, less intense TRAP staining and vacuolization (Fig 2). In OBLs culture, cLDL (20, 100 μg/ml) significantly reduced the ALP activity of OBLs compared with untreated cells (p<0.05) (Fig 3). nLDL did not affect the ALP expression. Treatment with cLDL stimulated RANKL mRNA expression in osteoblasts increasing the RANKL/OPG ratio (Fig 4).

Conclusion: cLDL induce a significant depression of OC and OBL differentiation. Moreover, cLDL increase RANKL expression in OBL, unbalancing bone tissue turnover towards bone resorption. Accordingly, cLDL could be implicated in the bone loss characterizing several conditions associated to an increased carbamylation, such as RA.

FRIO377 BARIATRIC SURGERY: EFFECTS ON BONE METABOLISM

I. Vázquez-Gómez1, R. Trullenque Juan1, C. Morillas Aríz2, L. Montolio-Chiva1, A. V. Orenes Vera1, E. Flores1, E. Valls-Pascual1, D. Ybañez2, Á. Martínez-Ferrer1, I. Torné Hernández1, V. Núñez-Monje1, A. Sendra-García1, J. J. Alegre-Sanch1, 1Servicio de Reumatología, Hospital Universitario Dr. Peset, Valencia, Spain; 2Servicio de Cirugía General, Hospital Universitario Dr. Peset, Valencia, Spain; 3Servicio de Endocrinología y Nutrición, Hospital Universitario Dr. Peset, Valencia, Spain; 4Fundación para el Fomento de la Investigación Sanitaria y Biomédica de la Comunidad Valenciana (FISABIO), Servicio de Reumatología y Farmacia, Hospital Universitario Dr Peset, Valencia, Spain

Background: There are few data about variations in bone metabolism associated with weight loss in obese patients undergoing bariatric surgery.

Objectives: To assess the influence on the bone metabolism of bariatric surgery in morbidly obese patients.

Methods: Longitudinal pre-post study with analytical components. All morbidly obese patients undergoing bariatric surgery were, prior to this, referred to Rheumatology Department. In all cases, the baseline characteristics of the patients were collected and a complete bone metabolic analytical study and bone densitometry (BMD) were requested. This same study was repeated one year later, with a window period of 3 months. Statistical analysis was performed with the SPSS 20.0 software.

Results: Of the 91 patients included in the study and who underwent baseline BMD and analytical tests prior to surgery, only follow-up data of 27 patients could be collected at the time of the present data analysis. Within this sample, the median age was 54 years (AIQ 11), with 6 men and 21 women (11 premenopausal, 10 postmenopausal). Prior to surgery, median body mass index (BMI) was 39.2 (AIQ4.43) and median vitamin D (25OHD) level was 22 (AIQ 16). High values of PTH were detected in two patients. Regarding baseline BMD, 78% had normal values and 22% had values in the range of osteopenia.

After surgery, all patients presented a significant weight loss, being the median loss in BMI per year 9.8 Kg/m² (AIQ 3.6) as absolute value, and 25% (AIQ 8.12) as a percentage value. This weight loss was accompanied by a significant BMD worsening that was evident in all locations: lumbar spine (median -6.97%, AIQ 6.3), total hip (median -6.4%, AIQ 7.7) and femoral neck (median -3.57%, AIQ 8); so that an additional 22% of patients changed to osteopenia values. All this despite a significant increase in 25OHD levels in all cases (35.7%; AIQ 52.3). No clinical or morphometric fractures were collected. Despite the parallel...
evolutionary course, the loss of BMI only showed a tendency to correlate with the decrease in bone mass in the femoral neck (p-value 0.089), but not in the other locations.

Conclusion: In our sample of morbidly obese patients undergoing bariatric surgery, there is a significant and widespread loss of bone mineral density one year after the procedure, all this despite the supplementation and the increase in 25OHD levels. This loss only seems to be directly related to the decrease in weight at the femoral neck, just probably by a mechanism to reduce mechanical load.

GENERAL SAFETY AND TOLERABILITY OF SUBCUTANEOUS TANEZUMAB FOR THE TREATMENT OF OSTEOARTHRITIS: A POOLED ANALYSIS OF RANDOMIZED, PLACEBO-CONTROLLED TRIALS
F. Berenbaum1, T. Schnitzer2, A. Kivitz3, L. Viktrup4, A. Hickman5, G. Pixon6, M. Brown7, I. Davignon8, C. West9, S. Sorbonne Université, INSERM, AP-HP Hospital Saint Antoine, Paris, France; 2Northwestern University Feinberg School of Medicine, Chicago, United States of America; 3Altoona Center for Clinical Research, Duncansville, United States of America; 4El Lilly & Company, Indianapolis, United States of America; 5Pfizer Inc, Groton, United States of America; 6Pfizer Inc, Durham, United States of America

Background: Tanezumab, a monoclonal antibody against nerve growth factor, is in development for the treatment of signs and symptoms of osteoarthritis (OA).

Objectives: To assess the safety and tolerability of subcutaneous (SC) tanezumab in patients with OA.

Methods: Data were derived from 3 randomized placebo-controlled OA trials. SC treatment (every 8 weeks for 16–24 weeks with 8–24 week follow-up) included placebo, tanezumab 2.5mg, tanezumab 2.5/5mg (at day 1 and 5mg at week 8), and tanezumab 5mg. Overall treatment-emergent adverse events (TEAEs) and TEAEs of abnormal peripheral sensation were pooled from all 3 trials (placebo N = 586; tanezumab: 2.5mg N = 602, 2.5/5mg N = 219, 5mg N = 347). Pre-specified TEAEs potentially associated with sympathetic neuropathy (anhidrosis, bradycardia, hypohidrosis, orthostatic hypotension, or syncope) and pre-specified joint events (primary osteonecrosis, rapidly progressive OA [RPOA]) type 1 or type 2, subchondral insufficiency fracture, or pathological fracture; adjudicated by an independent committee of experts) were pooled from the 2 trials that included pre-specified joint outcomes: tanezumab, sympathetic and joint safety (placebo N = 514; tanezumab: 2.5mg N = 528, 2.5/5mg N = 219, 5mg N = 284). TEAEs are presented for the treatment period; joint safety is presented for the full study (treatment plus follow up) period.

Results: Patient demographics (80.7% white, 66.8% female, mean age = 63 years) and clinical characteristics were similar across groups. TEAE rates were: placebo = 51.7%, tanezumab 2.5mg = 52.3%, tanezumab 2.5/5mg = 47.0%, and tanezumab 5mg = 54.8%. Of TEAEs occurring in ≥2% of patients in any group, only oedema peripheral, joint stiffness, and paraesthesia had a higher incidence (95% confidence interval excluded 0) in any tanezumab group relative to placebo.

Conclusion: Tanezumab was generally safe and well tolerated in most patients, with rates of overall TEAEs and treatment/study discontinuations similar to placebo and no evidence of a sympathetic safety signal. TEAEs of abnormal peripheral sensation and joint safety events were infrequent but more common with tanezumab than placebo.

VARIATIONS IN THE UTILIZATION OF BILATERAL TOTAL KNEE ARTHROPLASTY IN THE MANAGEMENT OF OSTEOARTHRITIS
B. Mehta1, K. Ho2, J. Bido3, M. Parks4, L. Russell5, S. Goodman6, S. Ibrahim7, 1Hospital for Special Surgery, New York, United States of America; 2Well Cornell Medicine, New York, United States of America

Background: A third of knee osteoarthritis presents with bilateral symptomatic arthritis. In these patients, treatment options include either a staged Unilateral Total knee arthroplasty (UTKA) procedure, or a simultaneous Bilateral TKA (BTKA) procedure. Even though literature regarding outcomes in BTKA procedure has not consistently been favorable, it remains popular in select patients due to use of a single anesthetic, shorter overall surgical time, lower cost and lower overall use of narcotics. African Americans (AAs) have lower utilization and worse outcomes in UTKA literature. It is unclear whether these racial variations extend to BTKA.

Objectives: We sought to examine BTKA vs UTKA utilization rates and outcomes in AAs and Whites.

Methods: National Inpatient Sample (NIS) - Healthcare Cost and Utilization Project (HCUP) database (2007-2016) was used. We identified all patients ≥ 50 years who underwent elective primary TKA using ICD-9-CM code 81.54 for UTKA and BTKA from January 1, 2012 to September 30, 2015, and ICD-10-CM codes OSRCoX and OSRDox thereafter. Patients with inflammatory arthritis, pathologic fractures, metastatic disease and avascular necrosis were excluded. Major in-hospital complications included post-operative myocardial infarction, prosthetic device complication, surgical wound infection, and venous thromboembolism. Differences in temporal trends in utilization and major in-hospital complications of BTKA vs UTKA were compared between AAs and Whites. Multivariable logistic regression models were used to assess differences in both these trends between AAs and Whites after adjusting for individual (age, sex, race, payer type, height, weight, BMI, hospital volume, bed size, region and teaching status) and community level (median household income) variables. Discharge weights were used to enable nationwide estimates. Multiple imputation was performed for missing race variable (11.9%).

Results: From 2007 to 2016, an estimated 276,194 BTKA (unweighted observations 56,679) and 5,328,429 UTKA (unweighted observations 1,312,329) were identified (Table 1). Females had a higher proportion of TKAs performed (62.1% UTKA vs 55.9% BTKA). Patients had fewer comorbidities (measured by the Elixhauser Index) when undergoing BTKA compared to UTKA. The proportion of BTKA amongst all TKAs declined from 5.53% in 2007-08 to 4.03% in 2015-16. AAs continued to have significantly lower proportion of BTKA utilization compared to Whites (4.68% in AAs vs 6.08% in Whites in 2007-08, whereas 5.29% in AAs vs 5.94% in Whites in 2015-16, adj OR of AAs vs Whites for BTKA = 0.68, 95%CI 0.58-0.81). AAs had significantly higher in-hospital complication rates for UTKA and BTKA were significantly higher in Whites compared to AAs throughout the study period (0.77% in AAs vs 0.9% in Whites in 2007-08, whereas 0.69% in AAs vs 0.83% in Whites in 2015-16,
adjusted p < 0.001) (Figure 1b). The results were similar after imputation of missing race values.

**Conclusion:** In this nationwide sample of patients from 2007 to 2016, we found that AAs have lower utilization rate of BKTA compared to Whites, however the in-hospital complication rates were significantly higher in Whites.

**Fig. 1:** Ultrasound-guided identification of GNB target sites. Doppler mode. White arrows indicate genicular arteries. A. Superior medial genicular artery. B. Inferior medial genicular artery. C. Superior lateral genicular artery.

**Methods:** In this randomised, double-blind, placebo-controlled trial, participants with significant knee pain (≥ 40 mm on a 100-mm visual analog scale [VAS]), symptomatic knee OA (by ACR criteria) and ultrasound defined effusion-synovitis were randomised to receive Curcuma longa extract (80% aqueous based extract standardized to turmerosaccharides + 20% curcuminoids, 2 x 500 mg capsules/day) or identical placebo for 12 weeks. Knee MRI scans were obtained at baseline and 12 weeks. Co-primary outcomes were changes in knee pain assessed by VAS and change in knee effusion-synovitis volume assessed by MRI over 12 weeks.

**Results:** Among 70 participants (36 received Curcuma longa, 34 received placebo, age 61.8±8.6 years, 56% female), Curcuma longa significantly improved VAS knee pain compared to placebo (-9.11 mm, 95% confidence interval [CI] [-17.79 to -0.44]) over 12 weeks, equivalent to a standardised effect size of 0.50. There was no significant between group difference in change in effusion-synovitis volume (3.24 mL [-0.33, 6.82]). There were significantly greater reductions in WOMAC knee pain (-47.22 mm [-81.22, -13.22]), WOMAC function (-112.26 mm [-222.79 to -1.74]) and significantly more OARSI-OMERACT treatment responders (63% treatment vs. 38% placebo [Risk Ratio=1.64 (1.00 to 2.70)]) in the Curcuma longa group compared to the placebo group. There was no significant between-group difference in lateral femoral cartilage T2 relaxation time (-0.38 ms [-1.10 to 0.34]) assessed from compositional MRI. The incidence of adverse events was similar in the Curcuma longa group (n=14 (39%)) and placebo (n=18 (53%)) groups over 12 weeks (P=0.24).

**Conclusion:** An extract of Curcuma longa significantly improved knee pain in an inflammatory phenotype of knee OA patients over 12 weeks compared to placebo but had no effect on knee effusion-synovitis and cartilage composition assessed using MRI. The moderate effect size of the treatment supports the use of Curcuma longa extract for the symptomatic management of knee OA.

**A RANDOMISED PLACEBO-CONTROLLED CLINICAL TRIAL OF CURCUMA LONGA EXTRACT FOR TREATING SYMPTOMS AND EFFUSION-SYNOVITIS OF KNEE OSTEOARTHRITIS (CURKOA TRIAL)**

B. Antony1, Z. Wang1, T. Winzenberg1, G. Cai1, L. Laslett1, D. Atkin1, L. Hopper1, A. Singh1, R. Jones2, J. Fripp3, C. Ding1, G. Jones1. 1University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; 2Monash University, Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Melbourne, Australia; 3Royal Hobart Hospital, Department of Radiology, Hobart, Australia; 4University of Queensland, Biomedical Informatics & Imaging Group, CSIRO Health and Biosecurity, The Australian e-Health Research Centre, Brisbane, Australia

**Background:** Pharmacological therapies are limited, associated with off-target effects, are frequently contraindicated, and only modestly effective for pain in osteoarthritis (OA). Effusion and synovitis are common in OA and are associated with symptomatic and structural progression of OA. Curcuma longa (Turmeric) extract has anti-inflammatory effects and is gaining popularity in the treatment of OA despite the lack of high-quality evidence.

**Objectives:** The CurKOA trial aimed to determine the efficacy of Curcuma longa extract for reducing knee symptoms and effusion-synovitis in patients with symptomatic knee OA and knee effusion-synovitis.

**Methods:** In this randomised, double-blind, placebo-controlled trial, participants with significant knee pain (≥ 40 mm on a 100-mm visual analog scale [VAS]), symptomatic knee OA (by ACR criteria) and ultrasound defined effusion-synovitis were randomised to receive Curcuma longa extract (80% aqueous based extract standardized to turmerosaccharides + 20% curcuminoids, 2 x 500 mg capsules/day) or identical placebo for 12 weeks. Knee MRI scans were obtained at baseline and 12 weeks. Co-primary outcomes were changes in knee pain assessed by VAS and change in knee effusion-synovitis volume assessed by MRI over 12 weeks.

**Results:** Among 70 participants (36 received Curcuma longa, 34 received placebo, age 61.8±8.6 years, 56% female), Curcuma longa significantly improved VAS knee pain compared to placebo (-9.11 mm, 95% confidence interval [CI] [-17.79 to -0.44]) over 12 weeks, equivalent to a standardised effect size of 0.50. There was no significant between group difference in change in effusion-synovitis volume (3.24 mL [-0.33, 6.82]). There were significantly greater reductions in WOMAC knee pain (-47.22 mm [-81.22, -13.22]), WOMAC function (-112.26 mm [-222.79 to -1.74]) and significantly more OARSI-OMERACT treatment responders (63% treatment vs. 38% placebo [Risk Ratio=1.64 (1.00 to 2.70)]) in the Curcuma longa group compared to the placebo group. There was no significant between-group difference in lateral femoral cartilage T2 relaxation time (-0.38 ms [-1.10 to 0.34]) assessed from compositional MRI. The incidence of adverse events was similar in the Curcuma longa group (n=14 (39%)) and placebo (n=18 (53%)) groups over 12 weeks (P=0.24).

**Conclusion:** An extract of Curcuma longa significantly improved knee pain in an inflammatory phenotype of knee OA patients over 12 weeks compared to placebo but had no effect on knee effusion-synovitis and cartilage composition assessed using MRI. The moderate effect size of the treatment supports the use of Curcuma longa extract for the symptomatic management of knee OA.

**BODY COMPOSITION AS A MEDIATOR IN THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND PHYSICAL FUNCTION IN LOWER-LIMB OSTEOARTHRITIS: RESULTS FROM THE KHOALA COHORT**

M. Wieczorek1,2, C. Rotonda3,7, J. Sellam4, F. Guillemin1,5, A. C. Rat1,6. 1Université de Lorraine, EA 4360 APEMAC, Nancy, France; 2University Hospital Zurich, Waid City Hospital, Centre on Aging and Mobility, and University of Zurich, Zurich, Switzerland; 3Université de Lorraine, Centre Pierre Janet, Nancy, France; 4University of Technology Sydney, Sydney, Australia; 5University of Munich, Munich, Germany; 6University of Manchester, Manchester, UK; 7University of Roma Tor Vergata, Roma, Italy

**Background:** Physical activity and physical function decline in the lower-limb in OA and are associated with obesity. Changes in body composition (BC) have been shown to mediate this relationship, with an increase in lean mass and a decrease in fat mass associated with higher physical function in OA.

**Objectives:** To investigate if changes in BC mediate the relationship between physical activity and physical function in a large, population-based cohort of individuals with knee OA.

**Methods:** The KHOALA cohort (n=2376) was recruited from the general population and included individuals with knee OA (Kellgren-Lawrence ≥ 2) who were not receiving disease-modifying anti-rheumatic drugs at baseline. Participants completed the International Physical Activity Questionnaire (IPAQ) and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at baseline and year 1. Body composition was measured using dual-energy X-ray absorptiometry (DXA) at baseline and year 1. Change in physical function was assessed using the WOMAC function subscale and change in BC was assessed using the percentage change in total body fat mass and muscle mass.

**Results:** A total of 1461 participants had complete data for the analysis, with a mean age of 70.2±10.7 years and 54% female. Higher physical activity was associated with higher physical function (β=0.22, 95% CI: -0.28 to -0.15) and a greater percentage decrease in body fat mass (β=-0.13, 95% CI: -0.21 to -0.05) and a greater percentage increase in body muscle mass (β=0.10, 95% CI: 0.03 to 0.18) over 1 year. Change in body fat mass and muscle mass significantly mediated the association between physical activity and physical function (β=-0.05, 95% CI: -0.09 to -0.01 for body fat mass and β=0.05, 95% CI: 0.01 to 0.09 for body muscle mass).

**Conclusion:** Changes in body composition mediate the relationship between physical activity and physical function in lower-limb OA.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2020-eular.5139
**Background:** Many trials investigated the beneficial effect of physical activity (PA) on physical function (PF) in people with osteoarthritis (OA), but factors involved in this relationship are poorly understood. Considering the link between OA and obesity and obesity-related disorders, body composition (BC) could be one of these factors.

**Objectives:** To examine the relationships between baseline components of PA and 5-year PF scores, considering BC variables measured at 3 years as potential mediators in theses associations (Figure).

**Methods:** We used data from the KHQALA cohort, a French population-based multicenter cohort of 878 patients with symptomatic knee and/or hip OA, aged between 40 and 75 years old. Baseline PA intensity (Metabolic Equivalents of Task, MET), frequency (times/week), duration (hours/week) and type (weight-bearing or not) were assessed by the Modifiable Activity Questionnaire. PF was measured with the WOMAC questionnaire at 5 years (higher scores = greater functional limitations). Skeletal muscle mass (grams) and fat mass (grams) were measured by dual X-ray absorptiometry (DXA) in 358 patients at 3 years. Fat mass index (kg/m²), appendicular fat mass (kg), % of fat mass, lean mass index (kg/m²), appendicular muscle mass (kg), skeletal muscle mass index (kg/m² or %) were calculated based on DXA data. Sarcopenia was defined according to the FNIH Sarcopenia Project recommendations. A causal mediation analysis was used to highlight the mediating role of BC variables. Bivariate analyses (multiple linear and logistic regressions) were performed to select the variables of interest. Separate generalized linear models were used to describe the relationships between PA components, PF, and selected BC variables. Unadjusted and adjusted for baseline confounders (age, gender, number of comorbidities, disease duration, mental health and vitality scores) models were ran.

**Results:** A 1-MET increase in baseline PA intensity was significantly associated with an improvement in PF at 5 years (3 points). Weight-bearing PA was also significantly associated with better PF scores (-5 points). A 1-MET increase in PA intensity at baseline was associated with a subsequent decrease at 3 years in fat mass index (-0.86 kg/m²), an increase in skeletal muscle mass index (± 6%), and a decrease in % of fat mass (-2%). Non-weight-bearing PA was significantly associated with a decrease in fat mass index (-2.5 kg/m²). A 1-point increase in PF score was associated with a reduction in skeletal muscle mass index (calculated from body mass index, -0.3%) and an increase in skeletal muscle mass index (calculated from height, +3 kg/m²). The presence of sarcopenia was significantly associated with a degradation of PF (+7 points). Crude analyses indicated that 20.4% of the effect of baseline PA intensity on PF scores at 5 years was mediated by skeletal muscle mass index (calculated from height), 23.2% by fat mass index and 26.6% by % of fat mass. Similarly, 19.3% of the effect of baseline PA type on PF scores at 5 years was mediated by fat mass index and 15.1% by % of fat mass. After adjustment, we found no longer evidence of a mediating role of BC variables in these associations.

**Conclusion:** We found significant associations between a 1-MET increase in PA intensity, weight-bearing PA at baseline and improvement in PF at 5 years, without any mediating role of BC variables. Further studies are needed to better understand the factors involved in these associations, especially psychosocial variables.

study in at least one knee. After a follow-up period of 96 months, 209 participants developed KOA in at least one knee (KL ≥ 2) and were classified as incident group, whereas 331 did not develop the disease (KL = 0-1) and were classified as non-incident group. Statistical differences between the outcome groups were assessed by non-parametric Mann-Whitney U tests. In the qualification phase (n=540), univariate regression analyses were carried out to investigate whether the individual biomarkers were associated with the risk of KOA development. A clinical prognostic model was defined by stepwise regression analysis using clinical non-radiographic variables significantly associated with the OA incidence. The utility of the potential biomarkers, alone or in combination, was evaluated by comparing the Area Under the Curve (AUC) of the clinical prognostic model with the biomarkers plus clinical prognostic models. In addition, sen

Besides, we calculated mean points in each parameter in the scale and compared it with the maximum score in this parameter (in percent). Table 2 shows the results. The most severe change was bone attrition.

We didn't observe asymptomatic lesions in the medial meniscus, narrow abnormality in MFTJ and LFTJ, subchondral cysts in any location, ligament lesions. Despite minimal osteophytes almost in all individuals, they didn't have any clinical features of knee OA.

**Conclusion:** MRI of the knee joints in the cohort of young relatively healthy individuals without clinical features of OA revealed irreversible structural changes characteristic of symptomatic OA. There is no association between symptoms and structural damage. Based on these, we can make an assumption about asymptomatic stage of OA. In order to distinguish between definitions of early asymptomatic OA as a disease onset and asymptomatic structural changes as reflection of metabolic disorders it is necessary to follow up and to perform an in-depth examination of these individuals.

**A PROGNOSTIC MODEL OF PRE-RADIOGRAPHIC KNEE OSTEOARTHRITIS: DATA FROM THE OSTEOARTHRITIS INITIATIVE**

**Background:** The improvement of the existing diagnostic methods to detect pre-radiographic knee OA (KOA) may facilitate the development of preventive strategies. It has been postulated that combining biochemical with clinical markers, may increase the prognostic power to detect those who are at high risk for developing KOA.

**Objectives:** To validate and quality the ability of 6 proteins with biomarker potential to generate a prognostic model of knee OA prediction through the combination of validated OA biomarkers and clinical markers.

**Methods:** In the validation phase (Figure 1), 749 sera at the baseline visit belonging to participants from the Osteoarthritis Initiative (OAI) Cohort were randomly selected to blindly quantify 6 biomarkers using in-house custom sandwich microarrays built using the xMAP technology. Among these, only 540 participants have a Kellgren and Lawrence (KL) grade = 0-1 at the beginning of the OAI study. We didn't observe asymptomatic lesions in the medial meniscus, narrow abnormality in MFTJ and LFTJ, subchondral cysts in any location, ligament lesions. Despite minimal osteophytes almost in all individuals, they didn't have any clinical features of knee OA.

**Conclusion:** MRI of the knee joints in the cohort of young relatively healthy individuals without clinical features of OA revealed irreversible structural changes characteristic of symptomatic OA. **ARE WE OVERLOOKING OSTEOARTHRITIS? – A COMPARATIVE STUDY OF PAIN, FUNCTION AND QUALITY OF LIFE IN PATIENTS WITH HAND OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS**

**Background:** The improvement of the existing diagnostic methods to detect pre-radiographic knee OA (KOA) may facilitate the development of preventive strategies. It has been postulated that combining biochemical with clinical markers, may increase the prognostic power to detect those who are at high risk for developing KOA.

**Objectives:** To validate and quality the ability of 6 proteins with biomarker potential to generate a prognostic model of knee OA prediction through the combination of validated OA biomarkers and clinical markers.

**Methods:** In the validation phase (Figure 1), 749 sera at the baseline visit belonging to participants from the Osteoarthritis Initiative (OAI) Cohort were randomly selected to blindly quantify 6 biomarkers using in-house custom sandwich microarrays built using the xMAP technology. Among these, only 540 participants have a Kellgren and Lawrence (KL) grade = 0-1 at the beginning of the OAI study. The utility of the potential biomarkers, alone or in combination, was evaluated by comparing the Area Under the Curve (AUC) of the clinical prognostic model with the biomarkers plus clinical prognostic models. In addition, sen

**Conclusion:** We have generated a prognostic model for the prediction of KOA by combining biomarkers and clinical variables, which showed a putative utility in the clinical setting by improving the predictive capacity of a clinical prognostic model to identify patients at a higher risk to develop radiographic Interval (95%CI): 60-70% specificity and 88% (95%CI: 81-91%) sensitivity. Variables included in the regression model and all metrics comparing the biomarkers plus clinical prognostic model with the clinical prognostic model are shown in Figure 2A. The ROC curves of the biomarkers-only model, clinical prognostic model and biomarkers plus clinical prognostic model are represented in Figure 2B.

**Results:** The incident group showed significant higher serum concentrations at the baseline visit (p < 0.05) for all the potential biomarkers analyzed in this study. Moreover, 5 of them were also significantly associated with the future appearance of radiographic KOA, yielding Odds Ratios (OR) > 10 per 10 µg/ml increase. Among all the possible combinations, the inclusion of 2 biomarkers to the clinical prognostic model showed a significant improvement of the predictive capacity (AUCs = 0.78 vs 0.82, p = 0.044) with 65% (95% Confidence Interval (95%CI): 60-70%) specificity and 88% (95%CI: 81-91%) sensitivity. Variables included in the regression model and all metrics comparing the biomarkers plus clinical prognostic model with the clinical prognostic model are shown in Figure 2A. The ROC curves of the biomarkers-only model, clinical prognostic model and biomarkers plus clinical prognostic model are represented in Figure 2B.

**DOI:** 10.1136/annrheumdis-2020-eular.4450
Background: Osteoarthritis (OA) is frequently regarded by patients and health care providers as a normal consequence of ageing (1). On the other hand, it is well established that rheumatoid arthritis (RA) is a pathological condition requiring prompt and efficacious treatment and in which remarkable progresses have been achieved in the last decades. Pain and physical limitations are hallmarks of both conditions. Some previous studies suggest that OA and RA may have a similar burden (2,3).

Objectives: To compare levels of pain, physical disability and health-related quality of life in patients with primary hand osteoarthritis (hOA) and with RA: active disease (aRA) or in remission (rRA).

Methods: Observational cross-sectional study including patients of two clinical centres with hOA and RA, either in remission or with active disease (at least two swollen and/or tender hand joints). Matching for sex and age was performed. Patients were asked to complete a survey consisting of visual analogic scale (VAS) for pain, Health Assessment Questionnaire (HAQ) and Short Form 36 (SF36). Mean values for each domain were compared between the three groups using one-way ANOVA test with significance accepted for p<0.05.

Results: Thirty patients with hOA and 93 with RA (33 with aRA and 60 with rRA) were included. All patients were caucasian females with no significant differences in age between groups. Patients with hOA reported higher levels of pain in comparison with aRA patients (mean VAS 57.3 vs 49.3mm, respectively, p=0.265) and with rRA patients (57.3 vs 26.6mm, respectively, p<0.001) [F(2,120)=25.907, p<0.001]. Regarding physical function, patients with hOA reported levels of disability similar to rRA patients, but significantly lower disability than patients with aRA [F(2,120)=6.962, p=0.001]. Patients with hOA evaluated their quality of life significantly better than patients with aRA and in similar levels to patients with rRA, as measured by mental health and general health status domains of SF36.

Conclusion: Our results show that hOA may have similar or even higher burden of pain than RA; this is in line with previous studies, although most of them did not consider the level of inflammatory activity of RA. On the other hand, patients with hOA seem to preserve function and have better health-related quality of life despite the higher levels of pain. These results highlight OA as a cause of severe pain, which should lead us to try an optimal symptom control for these patients. These findings should also encourage rheumatologists to endeavor efforts to perform more studies in the field of OA, to better understand its pathogenesis and to eventually find disease modifying drugs.

TOWARDS ONE-STAGE ARTICULAR CARTILAGE REPAIR USING DEVICE BASED ARTHROSCOPIC MECHANICAL RELEASE OF SYNOVIAL MESENCHYMAL STEM CELLS WITH CHONDROGENESIS AUGMENTATION WITH AUTOLOGOUS PLATELET CONCENTRATE WITHOUT CELL CULTURE EXPANSION

A. Altaie1, E. Jones1, O. Wall1, D. McGonagle1.1 University of Leeds, LJRRM, Leeds, United Kingdom; 2NHS, Orthopaedics, Leeds, United Kingdom

Background: Synovial fluid contains resident mesenchymal stem cells (SF-MSCs) that are derived from the synovial membrane and may interact with superficial cartilage injury sites. We previously reported on a novel methodology for increasing the number of MSCs in the knee joints using synovial brushing combined with platelet lysate (PL) as a chondrogenic inducer [1, 2].

Objectives: The purpose of this study was to evaluate autologous and allogeneic PL as a chondrogenic inducer and the chondrogenic potential of the mobilised MSCs without further ex vivo expansion. The desired goal of the study was to provide in vitro proof of concept of direct chondrogenesis without resort to MSC expansion protocols, since adequate MSCs towards repair could be mechanically procured in a minimally invasive fashion.

Methods: SF-MSCs were derived from the joint cavity of patients undergoing arthroscopy procedures. For the mechanical release of MSCs ‘before’ and ‘after’ brushing the synovium with the novel device (Figure 1A), samples of irrigation fluid were collected and MSC numbers were evaluated by CFU-F assay and flow cytometry for stromal and immune populations. Standard chondrogenic assay was performed on uncultured and cultured expanded synovial MSCs. Pellet cultures were maintained in complete chondrogenic media (CCM), DMEM+50% autologous filtered platelet concentrate (GPC), 50% Sterumate (allogeneic human PL; Cook Regentec, Indianapolis, IN), or expansion media (control). Chondrogenesis was assessed by Glycosaminoglycan (GAG) and Toluidine blue staining. Autologous blood was processed through a gravity-based filtration system, HemaTrate® (HT; Cook Regentec, Indianapolis, IN), to produce a PC.

Figure 1. Flow cytometry analysis of stromal and immune populations before and after mechanically release of synovial with the novel device (CD90<sup>+</sup> CD45<sup>-</sup> in red circle) (A). Uncultured synovial cells after 21 days exposure to complete chondrogenic media Toluid Blue staining (B) Gags level (C) n=3.

Results: Mechanically mobilized SF-MSC numbers increased as measured by CFU-F assay and flow cytometry for CD90<sup>+</sup>CD45<sup>-</sup> cells (p<0.001), and CD14<sup>+</sup>HLA-DR<sup>-</sup>CD206<sup>+</sup>CD86<sup>+</sup> M2 macrophages also increased (p<0.05). The HT system significantly concentrated platelets and WBs by 6- (p<0.0001) and 1.8-folds (p<0.001), respectively. Device-mobilized SF-MSC proliferation significantly increased after 6 days in DMEM + 10% PC (p<0.001) and correlated with PC platelet number (p<0.005). Autologous PC increased GAG levels compared to control (p<0.0001), and there was no significant difference compared to allogeneic PL (p>0.5). Uncultured synovial cells produced significantly more GAG when cultured in CCM or DMEM + 50% autologous PC compared to control (p<0.0001). The GAG levels of uncultured synovial cells positively correlated with CFU-F (p<0.005). Chondrogenic potential of uncultured synovial cells that were mechanically mobilized with initial irrigation exhibited an increase (1.5-fold) in GAG levels (p<0.001) figure 1B and also positively correlated with CFU-F (p<0.005).

Conclusion: Synovial MSCs can be mechanically released in sufficient number to undergo in vitro chondrogenic induction with significant chondrogenic activity without the need for ex vivo culture expansion. In vitro, autologous PC can be used as chondrogenic inducer for uncultured SF-MSCs. The data presented here supports one stage arthroscopy procedures for cartilage repair

FR10390 IMPACT OF ULTRASONOGRAPHY-DETECTED QUADRICEPS CALCIFIC TENDONITIS ON PAIN AND FUNCTION IN PATIENTS WITH PRIMARY KNEE OSTEARTHRITIS

M. A. Mortada1, Y. A. Amer1,7, Zagazig University - Faculty of Medicine, Rheumatology, Zagazig, Egypt

Background: Calcific tendinosis is most commonly seen around shoulder joint. Few cases of quadriceps calcific tendonitis (QCT) were reported. Routine use of ultrasonography in diagnosis of knee osteoarthritis has resulted in detection of many cases of QCT.

Objectives: To compare pain, function, and clinical and radiological findings among primary OA patients with or without ultrasonography-detected QCT.

Methods: A prospective, observational study was conducted on 214 patients with knee OA in the period between February 2019 to July 2019. Ultrasonography of knee joints was done according to EULAR guidelines. Quadriceps calcific tendonitis is defined as hyperchoic mass within the quadriceps tendon with posterior shadowing. The patients were categorized into two groups according to the presence or absence of QCT.

Results: QCT were detected in 25 (11.6%) patients. Most cases of QCT were detected in vastus lateralis (72%), then in vastus intermedius (20%) and only 2 cases were detected in vastus medialis.

Conclusion: Quadriceps calcific tendinosis is not rare. Ultrasonography can detect QCT in many cases with advanced knee OA. QCT is associated with increased pain and dysfunction in knee OA.

FR10391 METABOLIC FACTORS ASSOCIATED TO RADIOGRAPHIC KNEE OSTEARTHRITIS IN INDIVIDUALS WITH KNEE PAIN

M. Andersson1,2, E. Haglund3,4, K. Alli1, A. Bremander5,7, F. Kindberg2, S. Bergmar2,7, Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden; 4Spenshuft Research and Development Centre, Halmstad, Sweden; 5Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden; 6Halmstad University, School of Business, Engineering and Science, Halmstad, Sweden; 7Halmstad University, School of Health and Welfare, Halmstad, Sweden; 8Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden; 9University of Southern Denmark, Denmark, Department of Regional Health Research, Odense, Denmark; 10Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden; The Sahlgrenska Academy, University of Gothenburg, Primary Health Care Unit, Department of Public Health and Community Medicine, Gothenburg, Sweden

Background: Metabolic factors have been shown to be associated to radiographic knee osteoarthritis (OA) [1]. More knowledge about associations between metabolic factors and early clinical knee OA is needed.

Objectives: The aim was to study associations between metabolic factors and radiographic knee OA in individuals with knee pain

Methods: In total 272 individuals with radiographs at baseline, from an ongoing cross-sectional study. At baseline BMI, waist circumference (WC) and visceral fat area (VFA) were assessed. Fasting plasma glucose, triglycerides, cholesterol, HDL-and LDL-cholesterol were analysed. Metabolic syndrome (MetS) was present if central obesity (WC ≥94 cm in men and ≥80 cm in women) plus any two of the following factors: raised blood pressure (systolic blood pressure ≥ 130 or diastolic blood pressure ≥ 85 mm Hg or treatment of hypertension), raised triglycerides (≥ 1.7 mmol/L or specific treatment), reduced HDL-cholesterol (men < 1.03 mmol/L and women < 1.29 mmol/L or specific treatment), raised glucose (glucose ≥ 5.6 mmol/L, or type 2 diabetes).

The individuals were divided in two groups according to Ahlbäck [2], one group, who had grade I or more in at least one knee (radiographic knee OA, ROA) n=62 and the other group, not fulfilling Ahlbäck criteria (no radiographic knee OA, No OA) n=211. The associations between metabolic factors and knee OA were calculated by crude logistic regression analyses, adjusting for age and sex.

Conclusion: There were associations between some metabolic factors and radiographic knee OA in individuals with knee pain. Fasting glucose was increased in both groups. The associations between metabolic risk factors and the development of knee OA needs to be assessed in longitudinal studies.

FR10392 AVERSE EVENTS IN PATIENTS WITH OSTEARTHRITIS TREATED WITH SUBCUTANEOUS TANEZUMAB: A POOLED ANALYSIS OF THE OVERALL POPULATION AND SELECTED SUBGROUPS FROM 3 RANDOMISED PLACEBO-CONTROLLED TRIALS

P. Berenbaum1, A. Kvit2, T. Schnitzer2, S. Brown3, S. Donovan4, A. Hickman5, M. Viktrup2, C. West6, T. Yamabe1, Sorbonne Universités, INSERM, AP-HP Hospital Saint-Antoine, Paris, France; 2Altoona Center for Clinical Research, Duncansville, United States of America; 3 Northwestern University Feinberg School of Medicine, Chicago, United States of America; 4Pfizer Inc., Groton, United States of America; 5Pfizer Inc., New York, United States of America; 6Eli Lilly and Co., Indianapolis, United States of America

Background: Tanezumab, a monoclonal antibody against nerve growth factor (NGF), is in development for the treatment of osteoarthritis (OA).

Objectives: To assess the effects of gender, age and body mass index (BMI) on the incidence of adverse events (AEs) in patients (pts) treated with subcutaneous (SC) tanezumab in pooled data from three phase 3 OA studies. Anti-NGF therapy has been associated with joint safety events. Here we focus on treatment emergent AEs, including abnormalities of peripheral sensation (APS).

Methods: All three randomised, double-blind, placebo-controlled studies enrolled pts with radiographically-confirmed OA of the hip or knee, who had inadequate response or could not tolerate standard of care analgesics. In the 16-week (wk) Study 1 (NCT01089725), pts received placebo, tanezumab 2.5mg, 5mg or 10mg at baseline and wk 8. Due to a clinical hold on NGF antibodies, <10% of pts received the 2nd dose at wk 8. Pts in the 16-wk Study 2 (NCT02697773), received placebo or tanezumab 2.5mg at baseline and wk 8 or tanezumab 2.5mg at baseline and 5mg at wk 8. Pts in the 24-wk Study 3 (NCT02709486), received
placebo, tanezumab 2.5 mg or 5 mg at baseline, wks 8 and 16. All treatments were given SC. AE data from the treatment period of each study were pooled for placebo, tanezumab 2.5 mg and 5 mg groups and examined by subgroups of gender, age and BMI. Data from the 10 mg group of Study 1 were not included due to the low sample size.

Results: The incidence of any AE was numerically higher in females across treatment groups and in pts with a BMI ≥30 kg/m² in the tanezumab 5 mg, but not 2.5 mg group, vs the overall population (Table 1). SAEs were infrequent but numerically higher across all tanezumab 5 mg subgroups vs placebo (Table 2). Paraeesthesia and hypoaesthesia were the most common AEs of APS and were increased in all tanezumab groups in the overall population vs placebo. In any of the subgroups, the incidence of paraesthesia or hypoaesthesia was ≤7.8% and ≤3.9%, respectively. The difference within a patient subgroup for paraesthesia or hypoaesthesia was typically comparable with that of the overall population across treatments.

MODERATE WEIGHT BEARING AND MINIMAL WEIGHT BEARING EXERCISE INDUCE ACUTE IMPACT ON COLLAGEN BIOCHEMICAL MARKERS RELATED TO OSTEOARTHRITIS IN HUMANS

J. Bjerre-Bastos1,2, H. B. Nielsen3, A. Mackey1, M. Karsdal4, A. C. Bay-Jensen2, J. R. Andersen5, M. Boesen6, Y. He4, A. R. Bihlet2. 1University of Copenhagen, Copenhagen, Denmark; 2Nordic Bioscience Clinical Development, Herlev, Denmark; 3Sanos Clinic, Herlev, Denmark; 4Nordic Bioscience, Herlev, Denmark; 5Nordic Bioscience Clinical Development, Herlev, Denmark; 6Bispebjerg Hospital, Copenhagen, Denmark

Background: Exercise is recommended in osteoarthritis (OA) to limit pain and preserve joint function. Cycling is considered healthy, while the safety of running in OA has been controversial. The acute impact on cartilage in response to exercise (weight bearing vs non-weight bearing) remains to be explored. Biomarkers originating from type I-III and VI collagen can be measured in serum and urine and may reflect cartilage turnover. We report the first ever data on acute effects of exercise on a panel of collagen biomarkers in OA.

Objectives: To investigate the effect of running vs cycling on biomarkers of collagen type I-III and VI reflecting cartilage turnover.

Methods: We conducted a randomized, crossover clinical study (approval number: H-18038807) of subjects with primary knee OA. Screening included a maximal heart rate test to standardize exercise intensity. Participants underwent 30 minutes of running and cycling on separate days with blood samples taken at baseline and 0.5, 1, 2 and 3 hours after exercise initiation and again 24 hours after the exercise in order to evaluate the dynamic levels of biomarkers. Urine samples were collected before exercise and approximately 1 hour and 24 hours after. Potential diurnal variation was taken into account by measurements at comparable times from participants on a separate day with no exercise (resting). Levels of serum CTX-I, C2M, C3M, C6M and urine CTX-II were measured by enzyme-linked immunosorbent assays. Biomarker dynamics were plotted. Error bars represent 95% CI. CTX-I and C6M are displayed.

Results: 20 subjects were included of which 20 completed cycling and resting and 15 completed running. Subject characteristics displayed in table.

CTX-I decreased significantly from baseline at three hours after both running (p<0.01) and cycling (p<0.05) and was still decreased the day after running (p<0.05). No change in CTX-I levels was seen during rest. This suggests that exercise acutely reduces bone-turnover.

C2M was decreased at 1 hour after running (Change: -9.4%, 95%CI: -18.4–-1.0, p<0.05), but was found to be increased from baseline at 2 hours after cycling (Change: 19.0%, 95%CI: 6.0–32.0, p<0.01). C2M decreased below baseline 24 hours after running (Change: -9.4%, 95%CI: -16.1–2.7, p<0.01). This suggests that the load from cycling and running, respectively, affects tissues containing type II collagen differently.

C3M was decreased at 2 hours after cycling (Change: -6.3%, 95%CI: -12.1–-0.5, p<0.05) and 3 hours after running (Change: -76%, 95%CI: -16.4–-8, p<0.05), and C3M levels had returned towards baseline after 24 hours. C6M was increased at 1 hour after initiating rest and decreased 1 and 2 hours after running (p<0.05) and cycling (p<0.01), and C6M levels had returned to baseline after 24 hours. These results indicate reduced enzymatic degradation of collagens type III and VI following exercise.

The variation in CTX-II was higher, compared with the serum-based markers. A trend of decreasing CTX-II in response to rest was observed, but no significant changes were seen in response to exercise.

Conclusion: Cycling and running acutely influenced markers of type I-III and VI collagen. The results suggest no harmful effects on bone and cartilage in OA. The sensitivity of biomarkers to physical activity and inactivity is important to take into account, when using them in clinical research.

Scientific Abstracts Friday, 05 June 2020 795
**How Does Osteoarthritis Pain Impact Function, Mobility and Requirement for Help in Daily Activities in European Patients?**

**Background:** Symptomatic osteoarthritis (OA) leads to functional limitations and loss of independence. OA management focuses on pain relief and preserving physical function using non-pharmacologic and pharmacologic therapy. Additionally, patients commonly manage OA pain by avoiding activities that exacerbate their pain. Informal care, i.e. assistance from an unpaid caregiver, plays a major role in the total care provided to patients with chronic diseases like OA.

**Objectives:** To evaluate how OA pain severity affects physical functioning and the subsequent need for assistance with mobility and daily activities in 5 EU countries: France, Germany, Italy, Spain and UK.

**Methods:** Data were drawn from the Adelphi OA Disease Specific Programme (2017-18), a point-in-time study of physicians and their OA patients. Patients rated their average pain intensity over the last week on a 0-10 scale (0 = no pain; 10 = worst possible pain) and were then categorised into mild (0-3), moderate (4-6) and severe (7-10) pain groups. Patients also provided an assessment of their physical function (0-10 WOMAC scale where higher scores indicated greater functional impairment), impact on mobility, whether caregiver assistance was required, daily activities requiring caregiver assistance and home modifications made due to their OA. Physicians also rated patients' functioning on a 0 to 10 scale (0 = fully functional; 10 = completely impaired). Comparisons among pain severity groups were made using chi-squared tests and analysis of variance.

**Results:** The analysis included 1750 OA patients: 24% mild pain (n=413); 47% moderate pain (n=822); 29% severe pain (n=515). The patients were predominantly women (58%) and had a mean (SD) age of 65.6 (11.5). Increased pain severity was associated with greater functional impairment scores as reported by patients (WOMAC scores: mild pain=2.1; moderate pain=4.1; severe pain=5.9) and physician-rated functional impairment (mild pain=3.5; moderate pain=4.3; severe pain=5.6). Mobility was impacted for 78% of patients with severe pain (vs. 41% mild; 63% moderate) and the need for a walking aid such as a walking stick or walking frame increased with worsening severity; wheelchair assistance was needed for 7% of severe patients (compared with <1% of mild or moderate patients). Furthermore, 31% of patients with severe pain reported having to modify their home due to their OA (vs. 11% mild; 18% moderate [p<0.001]), typically adapting their bathroom (23%) or fitting a stairlift (6%). The need for assistance from a caregiver to help with daily activities was associated with an increase in patients’ pain (9% mild; 20% moderate; 42% severe [p<0.001]). For most patients this was an immediate family member, however, the proportion of patients paying for professional care also increased with severity (1% mild; 2% moderate; 7% severe). Taking the patient to work or doctor’s appointments; help with shopping; preparing/cooking meals and help with travelling out of the home were most frequently reported activities needing caregiver assistance.

**Conclusion:** In this study of European patients, increased pain severity was associated with greater functional impairment and impact on mobility as expected; however, this study highlights the substantial need for assistance with daily activities as well as modifications to the home. The unseen costs to the patient with moderate to severe OA pain are significant.

**THE IMPACT OF OSTEOARTHRITIS DISEASE SEVERITY ON HEALTHCARE RESOURCE USE: ANALYSIS OF REAL-WORLD EUROPEAN DATA**

**Background:** Osteoarthritis (OA) is a chronic joint disease associated with pain and impaired activity. With increasing obesity trends and an ageing population, the prevalence of OA is expected to rise in the future. This represents an increasing societal problem which will lead to an increased burden on healthcare services.

**Objectives:** To understand the pattern of healthcare resource utilisation (HCRU) across France, Germany, Italy, Spain and the UK, as OA disease severity increases.

**Methods:** Data were drawn from the Adelphi OA Disease Specific Programme (2017-18), a point-in-time study of physicians and their OA patients. OA disease severity was reported by physicians, who categorised patients’ OA severity as mild, moderate or severe. Patients were excluded from the analyses if they suffered from back and neck OA only, and shoulder OA that had not been diagnosed by X-ray. Physicians provided information, on a patient record form, about OA-related visits to healthcare professionals (HCPs), tests/scans conducted, emergency room (ER) visits and surgeries. Statistical comparisons among disease severity groups were made by analysis of variance and chi-squared tests.

**Results:** The study included 488 physicians (primary care physicians, rheumatologists, orthopaedists) reporting on 3596 of their patients with OA: 24% mild (n=874), 53% moderate (n=1904) and 23% severe (n=818). Over the last 12
months, the mean number of consultations with HCPs increased with disease severity (3.7 mild, 4.2 moderate and 5.7 severe [<0.001]). This pattern was also observed in relation to the mean number of tests/scans conducted in the last 12 months (6.9 mild, 7.9 moderate and 9.3 severe [<0.001]). More than a quarter of severe patients visited the ER in the last 12 months (26% vs. 4% mild; 9% moderate vs. 0.001]) and visits to hospital increased with disease severity (Table 1). The proportion of patients that have had a surgery due to their OA rose with worsening disease severity (11%, 13% and 27% for mild, moderate and severe, respectively [<0.001]).

### Table 1. Physician-reported healthcare burden by OA disease severity

**COMPARISON OF THE EFFICACY AND SAFETY OF TWO HYALURONIC ACIDS IN THE TREATMENT OF KNEE OSTEOARTHRITIS**

B. Cortet1, S. Lombion2, O. Brure2, 1Department of Rheumatology and UR 4490, University-Hospital of Lille, Lille, France; 2SLC Consulting, Geneva, Switzerland. 1WHO Collaborating Centre for Public Health Aspects of Musculoskeletal Health and Ageing & Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium.

**Background:** Several viscosupplementation treatments are available to patients suffering from osteoarthritis (OA) but few comparative clinical trials have been conducted.

**Objectives:** The primary objective of the study was to demonstrate at 24 weeks the non-inferiority of an hyaluronic acid over a second one in terms of efficacy (pain relief) in knee OA patients (Kellgren and Lawrence radiologic stage II or III) with whom oral treatment had failed.

**Methods:** This was a prospective, multicenter, comparative, randomized, double-blinded study (one independent physician evaluator—one physician injector), comparing two viscosupplements: one containing a solution of hyaluronic acid (SYNOLIS® 490 80mg hyaluronic acid and 160mg sorbitol – Group HA1) and the other containing one of Hylan (SYNIVISC ONE® 48 mg Hylan GF-20 – Group HA2) over a period of 24 weeks. At inclusion, the average VAS Pain (1-100) was 62.5. The patients were randomized in 2 parallel groups at D0 and followed until D168. They received an injection of either HA1 or HA2. Efficacy was primarily observed using the WOMAC Pain index (daily assessed by the patient during the seven days following the injection, and then at D14). During the follow up visits (D28-D64-D168) WOMAC pain, stiffness and function scores were assessed as secondary objectives. At D168, efficacy and satisfaction were also evaluated by the evaluator and by the patient using Likert scale (7 points). Moreover, the number of responders strict each group was evaluated according to the OMERACT-OARSI criteria. According to methodology guidelines, the per protocol (PP) population has been used as primary analysis. The PP population included all patients from the intention to treat (ITT) population who completed the study without any major protocol violation.

**Results:** 202 patients were randomized (ITT population, 96 in the HA1 group and 106 in the HA2 group). Baseline demographic data for the PP population at the time of randomization by treatment group. Patients were predominantly female (66%). The median age of the whole population was 65 years and the median body mass index of 27.4 kg/m². No statistically significant differences between the two treatment groups were observed for any demographic criteria. At D168, 197 presented no protocol violations (94 in the HA1 group and 103 in the HA2 group). This population had a decrease on the overall score of the WOMAC Pain at -29.2+/- 24.1 (SD) in the HA1 group and -31.6+/-25.5 (SD) in the HA2 group confirming the non-inferiority (P = 0.57 for the difference between groups). Regarding the secondary endpoints, no significant difference has been observed at D14, D28, D84, D168, in the PP population for all the outcome except stiffness at D28. There was also no difference between the responders rate in two groups (79 % for HA1 and 77% for HA2). In terms of safety, both products were well tolerated. No case of allergy or infection in the course of the injection was reported. Serious adverse events have been reported by 4 patients in HA1 group and 3 in HA2 group.

**Conclusion:** In this study, we confirmed the non-inferiority of HA1 compared with HA2 in terms of both efficacy and safety.

FR0399

**COLCHICINE IS NOT EFFECTIVE FOR REDUCING OSTEARTHRITIC HAND PAIN COMPARED TO PLACEBO: A RANDOMISED, PLACEBO-CONTROLLED TRIAL (COLAH)**

C. Davis1,2, C. Fuedinger1,2, K. Dyer2, S. Lester2, S. Graf2, F. P. B. Kroon2, S. Whittle1,3, 1University of Adelaide, Discipline of Medicine, Adelaide, Australia; 2Queen Elizabeth Hospital, Rheumatology Department, Woodville South, Australia; 3Wakefield House Rheumatology, Adelaide, Australia; 4Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands.

**Background:** Current pharmacotherapies to treat or prevent hand osteoarthritis are limited. Colchicine, an anti-inflammatory agent effective at reducing joint pain and swelling in gouty arthritis, may offer relief in hand osteoarthritis, though this has not been investigated before.

**Objectives:** To investigate the efficacy of colchicine compared to placebo on VAS pain scores over 12 weeks in adults with hand osteoarthritis in a randomised, double-blind controlled trial.

**Methods:** 64 community-dwelling adults with hand osteoarthritis (American College of Rheumatology criteria)2 (54 females, 48-79 years) were randomised 1:1 to colchicine (0.5mg twice daily) or placebo for 12 weeks. VAS pain scores (worst affected hand) were obtained at baseline and weeks 6, 12, and after treatment withdrawal at week 16. Secondary outcome measures included grip strength, C-reactive protein (CRP) and tender and swollen joint count (TSJC). Grip strength, TSJC and CRP were obtained at baseline and week 12. Intention-to-treat analyses, adjusted for age and gender, were performed using constrained longitudinal data analysis models in Stata v16.3

This study is registered with the Australia New Zealand Clinical Trials Registry, ACTRN12617001524381.

**Results:** 58 participants completed the study (N=27 colchicine, N=31 placebo, withdrawal rate 9%). Mean (SD) VAS score of the affected hand at baseline was 71.4 (14.5) mm in the placebo and 65.4 (15.0) mm in the colchicine group (p = 0.11). VAS scores improved during treatment, but were comparable between groups at week 6, 12 and 16 (Table 1). There were no differences between groups at week 12 for CRP, TSJC or grip strength (Table 1). Adverse events related to study medications included nausea (n=4), diarrhoea (n=9), vomiting (n=3), bloating (n=1) and reflex (n=1).

**Table 1. COLAH study primary and secondary outcomes, from constrained longitudinal data analysis model**

EFFICACY AND SAFETY OF AN INTRA-ARTICULAR INJECTION OF JTA-004, A NOVEL ENHANCED PROTEIN SOLUTION, IN KNEE OSTEOARTHRITIS PAIN: A RANDOMISED, DOUBLE-BLIND CONTROLLED PHASE II/III STUDY

M. Bettonville1, M. Leon2, J. Margaux2, D. Urban-Choffray4, E. Theunissen5, T. Besse-Hammer6, Y. Fortems7, S. Verlinden8, O. Godaux1, A. S. Delmarcelle1, J. F. Kaux1, Bone Therapeutics S.A., Gosselies, Belgium; 2CHU Ambroise Paré, Mons, Belgium; 3Hopital Erasme, Bruxelles, Belgium; 4CHR de la Citadelle, Liège, Belgium; 5Clinique Saint-Pierre Ottignies, Ottignies, Belgium; 6CHU Brugmann, Bruxelles, Belgium; 7AZ Sint-Jozef Malle, Malle, Belgium; 8CHR Haute Senne, Soignies, Belgium; 9Clinique Saint-Pierre Ottignies, Ottignies, Belgium.

Background: Osteoarthritis (OA) is a degenerative, chronic, and progressive joint disease. It is associated with chronic pain, joint function impairments and disabilities, causing a poorer quality of life with physical and/or mental comorbidity. Along with population ageing and increasing obesity, the incidence of OA is rising and there is an urgent need for new treatment options.

Objectives: JTA-004 is a novel protein solution in development for the treatment of knee OA pain. Supplemented with hyaluronic acid and clonidine, it is designed to provide a fast-acting and long-lasting pain relief. To evaluate efficacy and safety and to select the most effective formulation, single intra-articular administration of 3 JTA-004 formulations were tested and compared to Hylan G-F 20 during a 6-month period.

Methods: In this prospective, multicentre, double-blind phase II/III trial (NCT02740231), eligible participants were 50-79-year-old men and women with primary knee OA classified with Kellgren-Lawrence grade II or III and a body mass index (BMI) under 35. 164 patients were randomly assigned to one of the three JTA-004 formulations or the reference treatment (Hylan G-F 20) in a 1:1:1:1 ratio. The three JTA-004 formulations differed in their clonidine concentration (50 or 100 µg/ml) and/or their volume of injection (2 or 4 ml) (Table 1). Patients were evaluated using Western Ontario McMaster Universities (WOMAC9) scores and Short-Form health survey (SF-12). The primary efficacy endpoint was the change from baseline at 6 months in WOMAC10 VA3.1 Pain Subscale. Safety was assessed by monitoring and reporting vital signs, physical examination, adverse events and concomitant medications throughout the study.

Results: At 6 months, patients in the three JTA-004 groups showed a better improvement in pain compared to patients in the reference group. The between-group difference (between each JTA-004 test group and reference group) in adjusted (adapted to difference in baseline values) mean change in WOMAC11 Pain Subscale from baseline ranged between -9.49 mm and -11.63 mm at 6 months post-injection. Statistical superiority of each JTA-004 formulation over Hylan G-F 20 was however not demonstrated (p-value between 0.052 and 0.141) (Figure 1, JTA 200/2, 100/2 and 200/4). As the three JTA-004 formulations had a similar efficacy in terms of pain reduction, a post hoc analysis was subsequently performed between the pooled JTA-004-treated patients and the reference group. This analysis showed a 26.1 ± 2.4 (adjusted mean ± SE) mm improvement in pain in the pooled JTA-004 group vs. 15.6 ± 4.1 mm in the reference group at 6 months, demonstrating a statistically significant superiority of JTA-004 over the reference (between-group difference = -10.57; p = 0.030) (Figure 1, pooled JTA).

Figure 1. Main and post hoc analyses.

All JTA-004 formulations were shown to be well tolerated and had a clinically acceptable safety profile. There was a trend for fewer treatment-related events in the JTA-100/2 group, notably no cases of post-injection mild and transient hypotension.

Conclusion: This study provides a first evidence of efficacy and safety of JTA-004 in the treatment of knee OA pain.

FRI0401 IMPLEMENTATION OF NICE GUIDELINES FOR OSTEOARTHRITIS IN PRIMARY CARE. FEASIBILITY STUDY OF JIGSAW-E IN SCOTLAND

H. Frost1, J. Cowie2, T. Tooman3, K. Dziedzic4. 1Edinburgh Napier University, Sighthill Campus, Edinburgh, United Kingdom; 2Glasgow Caledonian University, Glasgow; United Kingdom; 3University of Dundee, Dundee, United Kingdom; 4Keele University, Keele, United Kingdom

Background: In the UK osteoarthritis (OA) is a common musculoskeletal problem with 8.75 million people seeking treatment in 2015. Evidence-based guidelines are available for the management of OA but implementation into routine daily practice remains complex. The Joint Implementation of Guidelines for Osteoarthritis in Western Europe (JIGSAW-E) model of care was developed and evaluated in England and implemented in Europe with an aim to optimise quality primary care for OA, support self-management and promote use of NICE guidelines. The intervention includes: 1. An OA guidebook for patients. 2. A model OA consultation for primary care. 3. Training for practitioners to deliver the model consultation. 4. Measures of quality care using an e-template.

Objectives: To explore the feasibility of implementing the JIGSAW-E model to support people with OA in Scottish primary care.

Research questions were informed by the Theoretical Domains Framework with an aim of: 1) Exploring knowledge and beliefs about OA and its management in primary care. 2) Identifying determinants for change; barriers and facilitators to implementing the JIGSAW-E model in Scotland.

Methods: This qualitative study was comprised of 2 phases: Phase 1 included semi-structured interviews with health professionals (GPs and Extended Scope Practitioners) working in primary care. A purposeful sampling approach was used to identify geographical and professional representation across Scotland. Interviews were recorded, transcribed and analysed using a theoretically-informed thematic framework approach. Phase 2 involved an engagement workshop that allowed for refinement and direct validation of emergent findings.

Results: 90 invitations were sent to practice managers in primary care. 14 participants from 10 practices across 6 Health Boards in Scotland were recruited for interviews, including 6 GPs and 8 Physiotherapy Extended Scope Practitioners (ESP). 23 participants attended the engagement workshop (22 GPs, 1 ESP). Thematic analysis indicated four main themes related to the research questions: 1) Most participants were aware of NICE guidelines and believed they provided evidence-based OA care, and yet, for example, prescribing of co-codamol remained high. Physiotherapy ESPs were more likely to follow OA guidelines than GPs. 2) Adaptations of the JIGSAW-E model are needed to support OA management in the Scottish context. For example, in addition to adapting the guidebook for local relevance, the e-template was met with resistance due to technological barriers. 3) System-based barriers to implementation of the JIGSAW-E model included; lack of overall time for external training for practitioners; limited time in GP/patient appointments to consult and explain medication use and importance of physical activity. In part because patients usually present with multi-morbidities. 4) The roll out of ESPs across Scotland in primary care provides a potential key for the delivery of sustainable evidence-based care in the Scottish health system.

Conclusion: Overall, participants were in favour of the JIGSAW-E model in Scotland. Contextual adaptation of written materials would increase acceptance, ownership and usability by both practitioners and patients. The evolving role of GPs and ESPs is key to implementation, where ESPs provide leadership in the delivery of evidence-based care for patients with osteoarthritis.

FRI0402 MAGNETIC RESONANCE IMAGING EVALUATION OF CARTILAGE EROSION AND LIGAMENT INTEGRITY IN EARLY STAGE THUMB CARPOMETACARPAL JOINT OSTEOARTHRITIS

H. S. Gong1, K. J. Bae2. 1Seoul National University Bundang Hospital, Orthopedic Surgery, Seongnam-si, Korea, Rep. of (South Korea); 2SMG-SNU Boramae Medical Center, Orthopedic Surgery, Seoul, Korea, Rep. of (South Korea)

Background: Most of the studies on pathogenesis of thumb carpometacarpal joint (CMCJ-1) osteoarthritis were from cadavers or patients with advanced osteoarthritis, therefore the findings may not reflect any early changes of cartilage wear and ligament condition.

Objectives: We evaluated MRI to address arthritic degeneration begins and which ligaments are most often involved in the early clinical stage CMCJ-1 osteoarthritis.

Methods: We retrospectively analyzed MRI examinations of 26 patients with early clinical stage CMCJ-1 osteoarthritis without radiologic abnormality and 19 control patients without CMCJ-1 pain or osteoarthritis who underwent MRI for dorsal or ulnar wrist pain. Two independent and blind observers assessed chondral defect of the CMCJ-1 divided into four quadrants: volar-ulnar (VU), volar-radial (VR), dorsal-ulnar (DU), and dorsal-radial (DR). They assessed the integrity of the four major ligaments of CMCJ-1: the anterior oblique ligament (AOL), the intermetacarpal ligament (IML), the posterior oblique ligament (POL), and the dorsal radial ligament (DRL). The prevalence of cartilage lesion and ligament abnormality between the osteoarthritic and control patients was compared using Fisher’s exact test.

Results: Cartilage lesion was significantly more common in the VU quadrant of the trapezium in the osteoarthritic patients than in the control patients (17/26 vs. 2/19; P = 0.002). AOL abnormality was more common in the osteoarthritic patients than in the control patients (14/26 vs. 2/19; P = 0.009). In the osteoarthritic patients, 10 of 17 patients with VU quadrant cartilage erosion had AOL rupture, while four of nine patients without VU cartilage erosion had AOL rupture, thus there was no association between VU quadrant erosion and AOL rupture (10/17 vs 4/9, P = 0.484).

Conclusion: MRI evaluation of early clinical CMCJ-1 osteoarthritis commonly demonstrate cartilage lesion in the VU quadrant of the trapezium and ligament abnormality in the AOL. However, no association of cartilage erosion in the VU region and AOL rupture suggests that AOL rupture is not a mechanical factor leading to TMJ osteoarthritis in specific area, but a common finding secondary to arthritic changes.

FRI0403 CLINICAL FEATURES OF PROSTHETIC JOINT INFECTIONS DIFFER IN PATIENTS WITH INFLAMMATORY ARTHRITIS AND OSTEOARTHRITIS

M. Kapadia1, T. Pannellini, C. Moezinia, A. Miller1, M. Figgie1, P. Sculco1, M. Cross1, M. Henry1, L. Russell1, L. Donlin1, A. Nocon1, S. Goodman1.

1Hospital for Special Surgery, New York, United States of America

Background: Inflammatory arthritis (IA) patients are at increased risk for prosthetic joint infections (PJI). However, because active IA patients without infections can have elevated inflammatory markers that mimic joint infection, PJI diagnosis is challenging in this population.

Objectives: We used an institutional PJI registry to identify and compare the clinical, microbiologic, and histopathologic features of culture positive (CP) and culture negative (CN) total hip and knee PJI in IA and OA patients. We
also evaluated the relationship between culture positivity, IA, and clinical outcomes.

Methods: A retrospective cohort of THA/TKA PJIs, from 2009 to 2016, were identified by ICD codes, and confirmed by chart review. IA diagnosis was also confirmed by use of IA-specific medications. CN cases were defined as PJIs with no evidence of microbial growth in intraoperative cultures and CP PJI cases were defined by positive microbial growth in intraoperative cultures. Treatment failure was defined as subsequent surgical treatment for infection after the initial infection surgery; H&E slides of OA and IA PJI cases matched by age (+/-5) sex, and culture status were reviewed by a pathologist for evidence of the histopathologic features listed in Table 2. Fisher’s exact test, chi-square test, and Kaplan-Meier estimates were used.

Results: 807 PJI cases were identified including 36 IA (33 RA and 3 SLE) and 771 OA. A higher proportion of IA PJI were CN (N=10, 27%) vs. OA PJI (N=109, 14%, p=0.02). IA-PJI were younger, female, on glucocorticoids, and with more comorbidities. Type of surgical treatment did not differ significantly between IA and OA groups. Comparing CN-IA vs. CP-IA, no difference was observed in age, smoking, diabetes, surgical treatment, IA-specific meds or Charlson comorbidities. One-year survivorship of CN-IA and CN-OA were 66% and 87% (p<0.05). Across all CP groups, 57% were staphylococcal, with no differences between groups. Treatment failure was more frequent for CP-IA (42%) compared to CP-OA (14%, p=0.2).

Histopathology of 88 PJI cases (31 IA and 57 OA) was reviewed. The IA cohort presented with more chronic inflammation (p=0.001) than the OA cohort. Within the IA cohort, a higher proportion of CP-IA had >10PMN per HPF (p=0.003) and met MSIS criteria (p=0.009). Comparing CP-OA and CP-OA, there were no significant differences in histopathology findings or number of patients meeting MSIS criteria.

Conclusion: IA PJI are more likely to be culture negative than OA PJI. Although our analysis was limited by our cohort size, our findings including differences in histopathology, and better clinical outcomes suggest the presence of biologic differences between CN and CP PJI that require further study.

DOI: 10.1136/annrheumdis-2020-eular.4777
Background: Coll2-1 is a peptide of 9 amino acid located in the triple helix of type II collagen molecule reflecting cartilage degradation (1). Coll2-1NO2 is the nitrated form of Coll2-1 and considered as a biomarker of the inflammatory-related cartilage degradation (2). This peptide is involved in osteoarthritis (OA) physiology and pathophysiology since it was demonstrated that Coll2-1 induced synoviocyte in rat.

Objectives: To identify if biochemical markers s-Coll2-1 and s-Coll2-1NO2 are associated to knee osteoarthritis (OA), focusing on pain, function as well as structural features assessed by MRI in various knee compartments and to assess their ability at predicting knee OA worsening.

Methods: 116 subjects with knee OA were followed during one year with pain, function and MRI evaluation (PRODIGE study, NCT02070224). Type II collagen-specific biomarker Coll2-1 and its nitrated form Coll2-1NO2 were directly measured in serum using immunoassays at baseline and after three, six and twelve months follow-up.

Results: sColl2-1 and sColl2-1NO2 were associated to several baseline knee features quantified with Whole-Organ Magnetic Resonance Imaging Score (WORMS). S-Coll2-1 was significantly correlated with burrsits (r=0.29, P<0.01), bone attrition (r=0.25, P=0.01), cysts (r=0.24, P=0.02) and cartilage (r=0.23, P=0.03) WORMS sub-scores for the whole joint as well as with the medial femorotibial joint sum score (r=0.26, P<0.01) and medial femorotibial joint cartilage (r=-0.23, P=0.02). sColl2-1NO2 was correlated with WORMS total score (r=0.20, P<0.01), WORMS scores in the patellofemoral (r=0.23, P=0.02) and medial femorotibial compartments (r=0.21, P=0.03) and with osteophytes scores (r=0.27, P<0.01). Baseline sColl2-1NO2 was higher in subjects with a pain worsening (426.4 pg/mL [278.04-566.95]) as compared to non-progressors (306.84 pg/mL [278.04-566.95]).

Conclusion: Cartilage biomarkers sColl2-1 and sColl2-1NO2 are associated to several knee OA features quantified with WORMS scoring system on MRI. Serum values of Coll2-1NO2 are also associated to a worsening of target knee pain over one year. Coll2-1 and Coll2-1NO2, in association with other structural features, pain and function, could help at identifying OA phenotypes and patients at risk of OA worsening.

References:

treatments in general. The increased osteophytosis may be a bystander effect of cartilage repair activity related to intra-articular factors like TGF-β-1 and questions whether osteophytosis should necessarily be considered a hallmark of OA worsening.

FR40407 USER-FRIENDLINESS OF A NOVEL DEDICATED KNEE JOINT DISTRACTION DEVICE: EXPERIENCES FROM CLINICAL PRACTICE

M. Jansen¹, T. Struik¹, S. Mastbergen¹, R. Custers². ¹University Medical Center Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands; ²University Medical Center Utrecht, Orthopedic Surgery, Utrecht, Netherlands

Background: Knee joint distraction (KJD) is a validated surgical technique that aims to postpone arthroplasty for a prolonged time in younger knee osteoarthritis (OA) patients (<65 years). In absence of dedicated devices intended for KJD, this procedure has thus far been performed with general purpose external fixation devices.¹ The demonstrated clinical benefits of KJD raised a clinical demand for a dedicated device (DD), including a desire for increased user-friendliness and decreased treatment burden. As such, in a multi-disciplinary setting with clinicians, patients, and medical device experts, several desired device characteristics were determined. These included perpendicular positioning of bone pins relative to the longitudinal tibia axis, surgery time < 45 minutes, no protruding parts above the most proximal and below the most distal bone pins, and pin tracks that are accessible for pin tract care. Based on the desired characteristics, a dedicated distraction device was developed and made available for clinical application.

Objectives: To compare user-friendliness between the developed DD and previously used concept device (CD) used in regular care.

Methods: Patients were treated with either the CD (n=22) or DD (n=22) in clinical practice. For both devices, the surgical technique was identical: fixation to the tibia and femur with 8 bone pins (figure 1) and 5 mm distraction for 6 weeks. The intervention duration when placing the device (defined as time between first incision and the surgeon being finished) was registered for all patients. After treatment, patients were asked to fill out a custom questionnaire about user-friendliness of the device during treatment, consisting of 25 questions on difficulties performing activities regarding clothing, sleeping, device care, daily activities, movement and complications. Intervention duration was compared between groups using an independent t-test while for questionnaire answers Mann Whitney U tests were used. Chi-square tests were used when comparing (complication) occurrences between groups.

Results: Intervention duration was on average shorter for the DD (44 vs 56 minutes; p<0.001). 34 Patients (16 CD, 18 DD) completed the questionnaire. Patient user-friendliness of the DD was higher rated for 6 questions (all p<0.05), and similar to the CD for the remaining questions (all p>0.01). Besides advantages in daily living activities with the use of the DD, also less pin tract infections were registered with this device (88% of patients with CD vs 56% with DD). Results of all questions are provided in figure 1. Three patients who were treated with both devices (left and right knee, separately and subsequently) generally rated the DD similar to or slightly better than the CD.
Background: Knee osteoarthritis (OA) is a common cause of invalidity and is often treated with a total knee arthroplasty (TKA). While TKA is cost-effective, reduces pain and improves function, it brings a greater risk of a future revision surgery when performed in younger patients. Knee joint distraction (KJD) is a joint-preserving OA treatment that may postpone TKA and possibly prevent a revision. In the past years, multiple studies have investigated this surgical treatment.

Objectives: To evaluate short- and long-term clinical benefit and tissue structure changes after KJD treatment for knee OA.

Methods: MEDLINE, EMBASE and Web of Science were searched for eligible clinical studies evaluating a change in at least one of: Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), Visual Analogue Score (VAS), Knee injury and Osteoarthritis Outcome Score (KOOS), EuroQol-5D (EQ5D), radiographic joint space width (JSW) or MRI cartilage thickness after KJD. The primary clinical and structural outcome parameters were the WOMAC and minimum JSW, respectively. Random effects models were applied on all outcome parameters and outcomes were compared with control groups found in the included studies. For continuous data the mean difference (MD) and 95% confidence interval (95%CI) were calculated and for dichotomous data the risk difference and 95%CI, following the Cochrane handbook.

Results: In total 11 articles reporting on 7 different KJD cohorts with in total 127 patients and 5 control groups at multiple follow-up moments were included, with 2 of the studies being randomized controlled trials (RCTs). The WOMAC (figure 1) was compared to pre-treatment in 3 cohorts after 1 year (patients n=62) and 2 years (n=59) and in 1 cohort after 5 years (n=20) and 9 years (n=8), showing a significant increase at all time points (all p<0.001). The VAS-pain showed similar results at the same 4 time points, as did the KOOS and EQ5D, which were evaluated only after 1 (n=42) and 2 (n=39) years.

The minimum (figure 2) and mean JSW are reported in 3 cohorts after 1 (n=59) and 2 (n=59) years and in 1 cohort after 5 (n=20) and 7 (n=8) years. Both JSW measures were statistically significantly increased after 1 and 2 years, but after 5 and 7 years the JSW increase was no longer statistically significant. Similarly, the MRI cartilage thickness showed an increase at 1 and 2 years, but not at 5 years (all p<0.001).

Complications were reported in 5 studies with 87 patients, with 57 patients developing one or more pin tract skin infections, giving a risk of pin tract infections of 63% (95%CI 45-81), the majority of which could be treated with oral antibiotics. Only a small amount of other complications occurred and were all treated successfully.

Overall, clinical and structural outcomes were comparable with control groups, including high tibial osteotomy and TKA as compared after 1 and 2 years in the two RCTs. Apart from pin tract infections, complications were not different in severity and number between control groups and KJD.

Conclusion: KJD causes clear benefit in clinical and structural parameters over time, short- and long-term. Although the total number of patients is limited, effect sizes are large. Longer follow-up with more patients is necessary and could improve patient selection for this intensive treatment, while preventing pin tract infections could lighten the patients’ treatment burden. Irrespective, KJD provides an additional option in joint-preserving treatments for OA and a viable alternative to joint replacement, especially in younger patients.

Conclusion: Neuropathic pain exists during knee OA. We found it in 27.1% of patients followed in a hospital in Cameroon. It is associated with the severity of pain and functional disability.

References:
DOES SEVERE ACUTE POSTOPERATIVE PAIN RESULT IN MORE LONG-TERM PAIN AFTER TOTAL HIP OR KNEE ARTHROPLASTY (THA OR TKA) FOR OSTEOARTHRITIS?

D. A. J. M. Latijnhouwers1, C. H. Martini2, R. G. H. H. Nelissen1, H. M. J. Van der Landen1, T. P. M. Vliet Vlieland3, M. G. J. Gademan4, 1Leiden University Medical Center, Department of Anesthesiology, Leiden, Netherlands; 2Leiden University Medical Center, Department of Radiology, Leiden, Netherlands; 3Leiden University Medical Center, Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; 4Leiden University Medical Center, Department of Anesthesiology, Leiden, Netherlands.

Background: Chronic pain is a frequently reported unfavourable outcome of total hip and knee arthroplasties (THA/TKA) (7-23% and 10-34%, respectively) in osteoarthritis (OA) patients (1), which is difficult to treat as underlying mechanisms are not fully understood. Acute postoperative pain has been identified as risk factor for development of long-term pain in other surgical procedures, such as mastectomy and thoracotomy (2). However, the effect of acute postoperative pain on development of long-term pain in THA and TKA patients is unknown.

Objectives: To investigate if acute pain following THA/TKA in OA patients is associated with long-term pain and if acute pain affects the course of pain up to 1-year postoperatively.

Methods: From a longitudinal multicenter study, OA patients scheduled for primary THA or TKA were included. Acute pain scores, using Numeric Rating Scale (NRS), were routinely collected as part of standard care (≤72 hours after surgery). In case of ≥2 NRS scores the two highest scores were averaged (n=160), else the single score was taken. Pain was dichotomized into severe (NRS≥5) and mild (NRS<5). Pain was assessed preoperatively, at 3 (only THA), 6 and 12 months postoperatively using HOOS/KOOS subscale pain. Separate mixed-effect models for THA and TKA patients were used, with dichotomized acute pain as fixed-effect and long-term pain as outcome, while adjusting for confounders (age, sex, BMI, preoperative pain, mental component scale of the SF12 (MCS-12), and duration of the surgery and hospitalization). We included an interaction between time of measurement and acute postoperative pain to analyse whether effect modification was present. Missing values in preoperative pain and MCS-12 scores were imputed using multiple imputation methods.

Results: 81 THA and 87 TKA patients were included, of whom 32.1% and 56.3% reported severe acute pain. The results did not show an association between severe acute pain and long-term pain (THA: β=2.0, 95%-CI:10.9-7.0; TKA: β=3.8, 95%-CI:10.6-2.9). Furthermore, it seems that there is no effect present of difference in severity of acute pain and the course of pain over time (THA 6-months: β=6.4, 95%-CI:1.9-10.9 and 12-months: β=0.2, 95%-CI:-4.4-4.8; TKA 12-months: β=3.2, 95%-CI:-0.5-6.8).

Conclusion: We did not find an association between acute pain and the development of long-term pain nor that severity of acute pain affects the course of postoperative pain in THA and TKA patients. The fact that THA and TKA patients often experience chronic preoperative pain might be a possible explanation for this finding. Nonetheless, future studies including additional measures of acute pain and pain sensitization in patients with chronic preoperative pain are necessary to draw stronger conclusions.

FRI0412

THE ASSOCIATION OF OBESITY WITH OSTEOARTHRITIS IS LIMITEDLY MEDIATED BY HYPERTENSION AND SUBCLINICAL ATHEROSCLEROSIS

M. Loef1, R. J. Van der Gees2, H. J. Lamb2, R. De Mutsert2, F. Rosendaa2, 1UMC, Rheumatology, Leiden, Netherlands; 2UMC, Radiology, Leiden, Netherlands; 3UMC, Clinical Epidemiology, Leiden, Netherlands.

Background: Obesity-related metabolic dysregulation may lead to atherosclerotic vascular changes. It has been hypothesized that a compromised blood flow may cause detrimental changes to the subchondral bone and decrease nutrient supply to the cartilage. To which extent atherosclerosis may explain the association between obesity and OA has not been investigated.

Objectives: To investigate the role of hypertension and subclinical atherosclerosis (carotid intima-media thickness (IMT), popliteal vessel wall thickness (VWT), aortic pulse wave velocity (PWV)) as mediators of the association of obesity with hand and knee OA.

Methods: We used cross-sectional data from the population-based NEO study, excluding participants with concomitant rheumatic diseases (n = 323), resulting in 6,334 participants. Clinical hand and knee OA were defined by the ACR classification criteria. Popliteal PWV was assessed on MR images in a subpopulation (n = 1,095), using VesselMASS for semi-automated detection of the vessel wall boundaries. Aortic PWV was estimated on abdominal velocity-encoded MR images in a subpopulation (n = 2,580). Carotid IMT was assessed by ultrasonography. Hypertension was defined as a systolic blood pressure ≥ 130 mmHg or a diastolic blood pressure ≥ 85 mmHg, or using antihypertensive medication. Continuous variables were standardized (mean 0, standard deviation 1). Associations between BMI and OA were assessed with logistic regression analyses, adjusted for age, sex and education. Subsequently, possible mediators were added to the model and the percentage mediation was calculated.

Results: The population consisted of 55% women, with a mean (SD) age of 56 (8) years and BMI of 26 (4) kg/m². Hand OA was present in 8% and knee OA in 10% of participants. Hypertension was present in 61.6% of participants. Mean (SD) carotid IMT was 0.62 (0.09) mm, popliteal VWT was 0.53 (0.05) mm, and aortic PWV was 6.56 (1.30) m/s. BMI was associated with the presence of hand OA and knee OA (table 1). BMI was positively associated with hypertension and carotid IMT, but not with popliteal VWT and aortic PWV. The association between BMI and hand OA was partially mediated by hypertension (5.9%) and carotid IMT (10.6%). Hypertension (4.9%) showed a weak mediating effect for the association between BMI and knee OA.

Results are based on analyses weighted towards the BMI distribution of the general population (n = 6,334). Analysis regarding popliteal PWV (n = 1,095) and aorta PWV (n = 2,580) were assessed in a subpopulation Continuous variables were standardized (mean 0, SD 1). SD BMI = 4.41, SD carotid IMT = 0.09, SD popliteal VWT = 0.05, SD aorta PWV = 1.30.
Conclusion: We assessed whether the association between BMI and OA was mediated by hypertension and atherosclerosis. Our results imply that either such mediation is absent or trivial, or that the atherosclerosis measures were too weak.

FR01414 FACTORS ASSOCIATED WITH THE IMPACT OF GONARTHROSIS ON MUSLIM PRAYER

M. Hniaï1, K. Maatallah1, H. Ferjani1, W. Triki1, D. Kaffel1, W. Hamdi1
1Mohamed Kassab Institute of Orthopedics, Rheumatology Department, Manouba, Tunisia

Background: Gonarthrosis is a frequent and chronic pathology, which can cause painful functional impotence and limit the performance of activities of daily living[1].

Objectives: This study aimed to assess the patient's perception of the physical and psychological repercussions of his illness on the practice of prayer and to determine the factors associated with this repercussion.

Methods: It was a cross-sectional prospective study conducted in the rheumatology department in 56 patients with gonarthrosis who regularly practiced prayer before the onset of the disease. The socio-demographic data, the clinical characteristics of gonarthrosis were studied and a pre-established questionnaire was offered to patients to assess the physical and psychological impact of gonarthrosis on their prayer practice.

Results: Fifty-six patients were included, 83.3% of whom were female. The average age was 56.1 years [38-78 years]. The disease has progressed for an average of 6.14 years [1-13 years]. Gonarthrosis was bilateral in 80.4% of cases. The average body mass index (BMI) was 30.29 kg/m2 ± 3.061 with extremes ranging from 24 to 36 kg / m2. Quadriceps (Q) retraction was noted in 64.28% of cases. Gonarthrosis was classified as stages I, II and III according to the classification of Kellgren and Lawrence in 14.3%, 57.1% and 28.6% of patients respectively.

In 71.4% of cases (40 patients), the practice of prayer after the onset of gonarthrosis was considered more difficult with a degree of difficulty of 4.23/10 ± 2. Initial standing was considered possible by all patients. Inclination was possible in 89.2% of patients, whereas it was replaced by sitting on a chair by the rest. Prostration and final sitting station were considered impossible by 64.3% of patients and were therefore performed on chairs (36 patients). The limiting factor cited by patients was pain in 100% of cases. A psychological impact was reported in 53.6% of cases. It was explained by the feeling of guilt in 22 cases, the relatives' comments in 8 cases and the suffering related to disability in 7 cases.

Prayer position was associated with Q retraction (p = 0.001) and knee pain seniority (p <0.001) and Q retraction (1.361 vs 29.86 ± 1.130, p <0.001), with the lowering of the navicular bone (31.17 ± 2.885 vs 29.68 ± 3.304, p = 0.015), and flat podo- structural impression (p <0.001).

Conclusion: BMI is strongly associated with static foot disorders in gonarthrosis patients by aggravating the postural changes in the foot caused by knee osteoarthrosis [2]. Obesity is associated mainly with the existence of flat feet, pronation of the foot, toes deformities and hyperkeratosis.

FR01416 COMBINATION OF SERUM ADIPOKINES/RELATED INFLAMMATORY FACTORS AND RATIOS AS PREDICTORS OF INFRAFATellar FAT PAD VOLUME IN KNEE OSTeoARTHITIS PATIENTS: USE OF A COMPREHENSIVE MACHINE LEARNING APPROACH

H. Bonakdan1,2, G. Tardif1, F. Abram1, J.P. Pelletier1, J. Martel-Pelletier1
1University of Montreal Hospital Research Centre (CRUCH), Osteoarthritis Research Unit, Montreal, Canada; 2LaVal University, Department of Soil and Agri-Food Engineering, Quebec, Canada; 3Arthrolab Inc., Medical Imaging Research and Development, Montreal, Canada

Background: One of the hurdles in osteoarthritis (OA) drug discovery and the improvement of therapeutic approaches is the early identification of patients who will progress. It is therefore crucial to find efficient and reliable means of screening OA progressors. Although the main risk factors, age, gender and body mass index (BMI), are important, they alone are poor predictors. However, serum factors could be potential biomarkers for early prediction of knee OA progression.

Objectives: In a first step toward finding early reliable predictors of OA progressors, this study aimed to determine, in OA individuals, the optimum combination of serum levels of adipokines/related inflammatory factors, their ratios and the three main OA risk factors for predicting knee OA infrapatellar fat pad (IPFP) volume, as this tissue has been associated with knee OA onset and progression.

Methods: Serum and magnetic resonance images (MRI) were from the Osteoarthritis Initiative at baseline. Variables (48) comprised the 3 main OA risk factors (age, gender, BMI), 6 adipokines, 3 inflammatory factors, and their 36 ratios. IPFP volume was assessed on MRI with a neural network methodology. The best variables and models were identified in Total cohort (n=678), High-BMI (n=341) and Low-BMI (n=337), using an artificial intelligence selection approach: the adaptive neuro-fuzzy inference system embedded with fuzzy c-means clustering (ANFIS-FCM). Performance was validated using uncertainty analyses and statistical indices. Reproducibility was done using 80 OA patients from a clinical trial (female, n=57, male, n=23).

Results: For the three groups, 8.4±14 sub-variables were investigated and 48 models were selected. The best model for each group included five variables: the three risk factors and adipin/C-reactive protein combined for Total cohort, adipin/chemerin; High-BMI, chemerin/adiponectin high molecular weight; and Low-BMI, interleukin-8. Data also revealed that the main form of the ratio used in the model was justified by the use of six found form slightly decreased the performance of the model in both training and testing stages. Further investigation indicated that gender improved (13-16%) the prediction results compared to the BMI-based models. For each gender, we then generated a pseudocode (an evolutionary computation equation) with the 5 variables for predicting IPFP volume. Reducibility experiments were excellent (correlation coefficient: female 0.83, male 0.95).
Conclusion: This study demonstrates, for the first time, that the combination of the serum levels of adipokines/inflammatory factors and the three main risk factors of OA could predict IPFP volume with high reproducibility, and superior performance with gender separation. By using the models for each gender and the pseudocodes for OA patients provided in this study, the next step will be to develop a predictive model for OA progressors.

FRI0417 IDENTIFICATION OF THE MOST IMPORTANT FEATURES OF KNEE OSTEOARTHRITIS PROGRESSORS USING MACHINE LEARNING METHODS

A. Jamshidi1,2, M. Leclercq2, A. Labbe3, J. P. Pelletier4, F. Abram4, A. Droit2, J. Martel-Pelletier4, 1University of Montreal Hospital Research Centre (CRCHUM), Osteoarthritis Research Unit, Montreal, Canada; 2Laval University Hospital Research Centre, Quebec, Canada; 3HEC Montreal, Department of Decision Sciences, Montreal, Canada; 4ArthroLab Inc., Medical Imaging Research and Development, Montreal, Canada

Background: Knee osteoarthritis (OA), a leading cause of disability worldwide, can be difficult to define as its development is often insidious and involves different subgroups. We still lack robust prediction models that are able to guide clinical decisions and stratify OA patients according to risk of disease progression.

Objectives: This study aimed at identifying the most important features of knee OA progressors. To this end, we used machine learning (ML) algorithms on a large set of subjects and features to develop advanced prediction models that provide high classification and prediction performance.

Methods: Participants, features and outcomes were from the Osteoarthritis Initiative. Features were from baseline (1107), including articular knee tissues (135) assessed by quantitative MRI. OA progressors were ascertained by four outcomes: cartilage volume loss in medial plateau at 48 and 96 months (Prop_CV_48M, 96M); Kellgren-Lawrence (KL) grade ≥2; and medial joint space narrowing (JSN) ≥1 at 48 months. Subjects' numbers were as follows: 1598 for the outcome Prop_CV_96M, 1044 for the Prop_CV_48M, and 1468 for each KL grade ≥2 at 48 months and JSN ≥1 at 48 months. Six feature selection models were used to identify the common features in each outcome. Six classification methods were applied to measure the accuracy of the selected features in classifying the subjects into progressors and non-progressors. Classification of the best features was done using auto-ML interface and the area under the curve (AUC) to prioritize the top features, Sparse Partial Least Square (sPLS) method was used.

Results: For the classification of the best common features in each outcome, Multi-Layer Perceptron (MLP) achieved the highest AUC in Prop_CV_96M, KL and JSN (0.8, 0.88, 0.95), and Gradient Boosting Machine (GBM) for Prop_CV_48M (0.70). sPLS revealed that the baseline top five features to predict knee OA progressors are the joint space width (JSW), mean cartilage thickness of peripheral, medial, and central tibial plateau, and JSN.

Conclusion: This is the first time that such a comprehensive study was performed for identifying the best features and classification methods for knee OA progressors. Data revealed that early prediction of knee OA progression can be done with high accuracy and based on only a few features. This study identifies the baseline X-ray-based features as the most important for predicting knee OA progressors. These results could be used for the development of a tool enabling prediction of knee OA progressors.

Acknowledgments: This work was supported in part by the Osteoarthritis Research Unit of the University of Montreal Hospital Research Centre; the Chair in Osteoarthritis, University of Montreal, (both from Montreal, Quebec, Canada); and the Computational Biology Laboratory, Laval University Hospital Research Centre (Quebec, Quebec, Canada). A. Labbe received a bursary from the Canada First Research Excellence Fund through TransMedTech Institute, (Montreal, Quebec, Canada).

FRI0418 SELECTIVE PATELLAR RESURFACING IN TOTAL KNEE ARTHROPLASTY FOR THE OSTEOARTHRITIC KNEE: A PROSPECTIVE STUDY

I. Moriyama, 1,2 Ogikubo Hospital, Tokyo, Japan

Background: No widely accepted view or criteria currently exist concerning whether or not patellar replacement (resurfacing) should accompany total knee arthroplasty for osteoarthritis of the knee.

Objectives: We recently devised our own criteria for application of patellar replacement and performed selective patellar replacement in accordance with this set of criteria. The clinical outcome was analyzed.

Methods: The study involved 1150 knees on which total knee arthroplasty was performed between 2005 and 2019 because of osteoarthritis of the knee. The mean age at operation was 73, and the mean postoperative follow-up period was 91 months. Our criteria for application of patellar replacement are given below.

Criterion A pertains to evaluation of preoperative clinical symptoms related to the patellofemoral joint: (i) interview regarding presence/absence of pain around the patella, (ii) cracking or pain heard or felt when standing up from a low chair, (iii) pain when going upstairs/downstairs. Because it is difficult for individual patients to identify the origin of pain (patellofemoral joint or femorobital joint), the examiner advised each patient about the location of the patellofemoral joint when checking for these symptoms. Criterion B pertains to intense narrowing or disappearance of the patellofemoral joint space on preoperative X-ray of the knee. Criterion C pertains to the intraoperatively assessed extent of patellar cartilage degeneration, corresponding to class 4 of the Outerbridge classification. Patellar replacement was applied to cases satisfying at least one of these sets of criteria (A-a, b-c, B and C). Postoperatively, pain of the patellofemoral joint was evaluated again at the time of the last observation, using Criterion A-a, b-c.

Results: Patellar replacement was applied to 110 knees in accordance with the criteria mentioned above. There were 82 knees satisfying at least one of the Criterion sets A-a, b-c, 39 knees satisfying Criterion B and 70 knees satisfying Criterion C. (Some knees satisfied 2 or 3 of Criteria A, B and C). When the pain originating from patellofemoral joint (Criterion A) was clinically assessed at the time of last observation, pain was not seen in any knee of the replacement group and the non-replacement group.

Conclusion: Whether or not patellar replacement is needed should be determined on the basis of the symptoms or findings related to the patellofemoral joint, and we see no necessity of particular replacement in cases free of such symptoms/ findings. When surgery was performed in accordance with the criteria on patellar replacement as devised by us, the clinical outcome of the operated patellofemoral joint was favorable, although the follow-up period was not long. Although further follow-up is needed, the results obtained indicate that selective patellar replacement yields favorable outcome if applied to cases judged indicated with appropriate criteria.

FRI0419 LOW DOSE OF GLUCOCORTICOIDS FOR PAIN CONTROL IN THE ESTROGEN-DEPENDENT PRIMARY POLYARTICULAR OSTEOARTHRITIS

G. Puerta1, M. Bautista1, M. Urbanó1, F. Bonilla1, C. Cañas1, 1Valle del Lili Foundation, Reumatology, Cali, Colombia

Background: Low doses of glucocorticoids (GCs) can be useful in the management of osteoarthritis when it is related to progestogen states (estrogen-dependent primary polyarticular osteoarthritis [EDPOA]), that usually can appear after the menopause. Deflazacort is a GC that has similar anti-inflammatory effects than other steroids, but with fewer side effects.

Objectives: To describe the average dose of GCs that best controlled articular pain, based on tender joint count in patients with EDPOA.

Methods: The diagnosis of EDPOA was made in postmenopausal patients with polyarticular compromised (six or more joints affected), morning stiffness less
than 30 minutes, erythrocyte sedimentation rate less than 45mm/hour and imaging studies with changes related to osteoarthritis (radiography, magnetic resonance imaging or bone scintigraphy). Patients with autoimmune diseases such as rheumatoid arthritis, lupus or Sjögren syndrome were excluded.

The clinical records of patients diagnosed with EDPOA and treated between January 2015 and June 2019 at the Valle del Lili foundation Hospital were reviewed. The patients treated with deflazacort GC were included. Pain was assessed by the treating rheumatologist using the visual analog scale (VAS, possible score 0-10). Tender joints were those with VAS >5. The count of compromised joints was compared with inflammatory findings on bone scintigraphy (Figure 1).

The number of tender joints was recorded at the start of treatment, which was a dose of 6 mg/day of deflazacort for two months. Subsequently, the dose was reduced depending on the improvement of pain (items: intensity of pain and number of tender joints) until achieving a stabilization along the time with an improvement of 75% of the items evaluated. The number of painful joints was recorded again two months after the stabilization on pain control was achieved.

Quantitative variables were described with medians and interquartile ranges because the absence of normal distribution of the sample size. To assess the presence of a significant decrease on the number of tender joints the Wilcoxon range test was used, a value of p<0.01 was considered statistically significant.

The data were analyzed with Stata v.15.

**Results:** Twenty-eight patients with EDPOA were included, with a median of age 50 years (IQR 44-51), 56 years (IQR 52-66) and 61 years (IQR 54-69) at the time of menopause, onset of symptoms and the diagnosis of EDPOA respectively. A median of 18 tender joints (IQR 10-27) was obtained from the physical examination of the records reviewed. The dose of deflazacort that achieved stabilization on the improvement of the pain along the time was 21mg/week (IQR 12-21); after 8 weeks of treatment the number of tender joints was 2 (IQR 1-4), which implies a reduction of 14 (IQR 8-20; p<0.0001) on the tender joint count (Figure 2).

**Conclusion:** In this case series a media dose of deflazacort of 21mg per week (3mg/day) was useful to significantly reduce the number of tender joints in patients with EDPOA.

based on semiquantitative MRI assessment and to determine their risk for progression over 48 months.

**Methods:** The FNIIH was designed as a case-control study with knees showing either 1) radiographic and pain progression (i.e., “composite” cases), 2) radiographic progression only (“JSL”), 3) pain progression only, and 4) neither radiographic nor pain progression. MRI of both knees was performed on 3 T systems at the four OAI clinical sites. Two musculoskeletal radiologists read the baseline MRIs according to the MOAKS scoring system. Knees were stratified by subchondral bone, meniscus/cartilage and inflammatory phenotypes. A secondary, less stringent definition for inflammatory and meniscus/cartilage phenotype was used for sensitivity analyses. The relation of each phenotype to risk of being in the JSL or composite case group compared to those not having that phenotype was determined using conditional logistic regression. Only KL2 and 3 and those without root tears were included.

**Results:** 485 knees were included. 362 (75%) did not have any phenotype, while 95 (20%) had the bone phenotype, 22 (5%) the cartilage/meniscus phenotype and 19 (4%) the inflammatory phenotype. The bone phenotype was associated with a higher risk of the JSL and composite outcome (OR 1.81 [95% CI 1.14, 2.85] and 1.65; 95% CI [1.04, 2.61]) while the inflammatory (OR 0.96 [95% CI 0.38, 2.42] and 1.25; 95% CI [0.48, 3.25]) and the meniscus/cartilage phenotypes were not (OR 1.30 95% CI [0.55,3.07] and 0.99; 95% CI [0.40,2.49]).

In sensitivity analyses, the bone phenotype and having two phenotypes (vs. none) were both associated with increased risk of experiencing the composite outcome (bone: OR 1.65; 95% CI 1.04, 2.61; 2 phenotypes: OR 1.87; 95% CI 1.11, 3.16).

**Conclusion:** The bone phenotype was associated with increased risk of having both radiographic and pain progression together, or radiographic progression alone, whereas the inflammatory phenotype or meniscus/cartilage phenotype each individually were not associated with either outcome. Phenotypic stratification appears to provide insights into risk for structural or composite structure plus pain progression, and therefore may be useful to consider when selecting patients for inclusion in clinical trials.

**FR10423 CLINICAL BURDEN OF TREATING COMMERCIALLY-INSURED OSTEOARTHRITIS PATIENTS WITH PRESCRIPTION NSAIDS**

S. Silverman, J. Rice, A. White, N. Le, M. Somma, C. Beck, R. Robinson, P. Schepman, Cedars-Sinai Medical Center, Los Angeles, United States of America; University of California Los Angeles, David Geffen School of Medicine, Los Angeles, United States of America; Analysis Group, Boston, United States of America; Pfizer, New York, United States of America; Eli Lilly, Indianapolis, United States of America

**Background:** Prescription NSAIDs/Cox-2s ("NSAIDs") are commonly prescribed by physicians to treat patients with chronic pain, and much is known about the potential negative outcomes associated with their use. Such negative outcomes include gastrointestinal ("GI") issues and hepatoerational toxicity. In addition, CV risk of Cox-2s has not been completely clarified. However, less is known about the extent to which these outcomes are pervasive and problematic in specific patient populations such as those diagnosed with osteoarthritis ("OA")

**Objectives:** The goal of this research is to assess the clinical burden of commercially-insured patients diagnosed with OA of the hip and/or knee before and after treatment with prescription NSAIDs, in a large, national database in recent years.

**Methods:** The Optum Healthcare Solutions, Inc. data (1/2012-3/2017) were used to identify patients ≥18 years old with ≥2 diagnoses of hip and/or knee OA, and ≥90 days supply of NSAIDs during the three-year period from first prescription (index date) after their first OA diagnosis. Patients were required to be continuously-enrolled during the six months before (baseline period) and 36 months after (follow-up period) the index date. Selected clinical outcomes such as GI issues, CV events, and renal toxicity were compared between the baseline and follow-up periods. Costs and resource use were normalized to account for differential duration in analytic time periods.

**Results:** Data for 22,435 patients (60.8% as female, with an average age of 62) with hip and/or knee OA were analyzed. On average, patients were prescribed NSAIDs for 489 days during the follow-up period. From the baseline period to follow-up period, negative clinical outcomes associated with GI issues increased by 393% (1.5% v 7.5%), driven by a 667% (0.3% v 2.3%) increase in acute GI hemorrhages. Additionally, negative clinical outcomes
associated with CV events increased by 73% (40.7% v 70.6%), largely due to a 600% (0.3% v 2.1%) increase in acute myocardial infarction. Lastly, negative clinical outcomes associated with renal toxicity increased by 433% (1.5% v 8.0%), with a 740% (0.5% v 4.2%) increase in acute renal failure being the most substantial.

Conclusion: These findings suggest that prescribing of NSAIDs among OA patients is associated with an increase in negative clinical outcomes. This suggests that new treatment options other than NSAIDs should be evaluated.

FRR0424 PROGRESSION OF PAIN, STIFFNESS, FUNCTION CHANGES AND ULTRASOUND DETECTED CHANGES IN THE GROUP OF 151 PATIENTS WITH HAND OSTEOARTHRITIS OVER THREE YEARS

O. Slegova,1 O. Růžičková,1 K. Pavek1, L. Šenolt1 1Institute of Rheumatology Prague, Department of Rheumatology, 1st Medical Faculty, Charles University Prague, Prague, Czech Republic;2Institute of Rheumatology, Department of Rheumatology, 1st Medical Faculty, Charles University Prague, Prague, Czech Republic

Background: Hand osteoarthritis (HOA) is a common and frequent cause of pain. HOA is a heterogeneous group of disorders with two main subsets including non-erosive and erosive disease. Few studies demonstrated inflammatory-ultrasound changes and more severe clinical symptoms in patients with erosive compared with non-erosive disease, however the results are inconsistent.

Objectives: The aim of this study was to evaluate progression of pain, stiffness, physical impairment and ultrasound features in patients with erosive and non-erosive HOA in a three years longitudinal study.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Patients reported joint pain on 100mm visual ana-logue scale (VAS). Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes. Patients were examined at baseline and at the first, second and third year of follow-up.

Results: Altogether, 151 patients (16 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2020. Out of these patients, 84 (4 male) had erosive disease. The disease duration (p<0.05) was higher in patients with erosive compared with non-erosive disease. Pain reported on VAS was significantly higher (p<0.01) in patients with erosive compared with non-erosive disease at baseline. Progression of pain after the third year of follow up was significantly higher in patients with erosive disease (p<0.01). The number of painful and clinically swollen joints (p<0.05) was significantly higher in patients with erosive compared with non-erosive disease at baseline. It fluctuated over the second and third year of follow up, but it still remained statistically higher (p<0.01) at the third year of follow up in patients with erosive disease.

According to the AUSCAN, patients with erosive compared with non-erosive disease had more pain (p<0.01) and stiffness (p<0.01) at baseline. Pain (p<0.05), stiffness and also function (p<0.05) worsened in patients with erosive compared with non-erosive disease at the third year of follow up.

US-detected pathologies such as gray-scale synovitis (p<0.001), intensity of PDS (p<0.01) and number of osteophytes (p<0.01) were significantly higher in patients with erosive compared with non-erosive disease at baseline. There were improvements in gray-scale synovitis total score and intensity of PDS in patients with non-erosive disease while patients with erosive disease worsened after the second and third year of follow up. US-detected gray-scale synovitis and PDS (p<0.001) significantly higher in patients with erosive compared with non-erosive disease after the third year of follow up. On the other hand, the progression of US-determined osteophyte formation was observed in both groups but was significantly higher (p<0.05) in patients with erosive compared with non-erosive disease after the third year of follow up.

Conclusion: The findings of this study show that pain and number of painful and clinically swollen joints associated with US-detected synovial changes and osteophyte formation is more severe in patients with erosive HOA than in patients with non-erosive disease. In addition, osteophyte formation is more likely to progress independent of synovial inflammation.

FRR0425 EVALUATION OF THE DOYLE INDEX AS A MEASURE OF PAIN SENSITIVITY IN PERSONS WITH HAND OSTEOARTHRITIS: EXPLORATORY ANALYSES FROM THE NOR-HAND STUDY

P. Steen Pettersen1,2, T. Neogi3, K. Magnusson1, B. Slåtteskov-Christensen1, H. B. Hammer1,2, T. Uhlig1,2, T. K. Kvien1,2, L. K. Haugen1 1The King’s Fund Institute, London, United Kingdom; 2University of Oslo, Faculty of Medicine, Oslo, Norway; 3Boston University School of Medicine, Rheumatology, Boston, United States of America

Background: Pressure pain threshold (PPT) is a measure of pain sensitization; altered pain mechanisms in the peripheral and/or central nervous system causing increased pain sensitivity. PPT testing may be a useful tool to classify pain phenotypes but requires special equipment not available in the clinic. The Doyle index (DI) is a clinical measure of joint tenderness upon palpation. It is considered as an outcome measure of pain and disease activity in hand OA and is a potential alternative to PPT. It is unclear if joint tenderness could reflect pure nociceptive pain without sensitization.

Objectives: Using data from the Nor-Hand study we will explore how DI performs as a measure of pain sensitization in hand OA by examining associations and agreements between DI and PPT at joint level, and correlations between PPT values and DI sum score at person level.

Methods: PPT was tested with a hand-held algometer (FPX2x5, 1cm² flat rubber tip) at the dorsal side of the most painfull DIP/PIP and a non-painful DIP/PIP joint (local PPTs) and left radioulnar joint and mid-portions of the trapezius and tibialis anterior muscle (remote PPTs). Low local PPTs indicate peripheral or central sensitization, while low remote PPTs indicate central sensitization. According to DI, tenderness in the bilateral thumb base and finger joints were graded by a rheumatologist by pressing on the lateral joint margins: 0=no pain, 1=patient complains of pain, 2=patient complains of pain and winces, 3=patient complains of pain, winces and withdraws joint.

We examined whether increasing DI was associated with local PPT using mixed models. To assess agreement between DI and PPT, we categorized PPT of the painful finger joints into a semi-quantitative scale with the same number of categories (n=4) as DI. We identified the cut-offs for the PPT categories that maximized the agreement (weighted kappa) with DI. Finally, we examined Spearman’s correlations between DI sum score [range 0-90] and PPT’s of local and remote sites.

Results: The majority of the 285 eligible participants were women (88%) and mean (SD) age was 61 (6) years. Joints with high DI had lower PPT values (Figure 1). We found a linear association of lower PPT with increasing DI for all joints combined (beta -0.7, 95% CI -0.8, -0.6). Similar results were found for the painful joints (beta -0.8, 95% CI -1.0, -0.6), but weaker for non-painful joints (beta -0.5, 95% CI -1.0, 0.0) where few joints had DI grade 2-3 (Figure 1). The analyses on maximized agreement between DI and the PPT categories gave a weighted kappa equal to 0.32 (Table). Median (IQR) DI sum score was 9 (5, 15). We found weak inverse correlations between DI sum score and PPT at local (painful finger: p =0.24 (95% CI -0.32, -0.16), non-painful finger: p=0.22 (95% CI -0.29, -0.11) and remote sites (radioulnar joint: p=0.17 (95% CI -0.29, -0.08), trapezius: p=0.25 (95% CI -0.36, -0.14), tibialis anterior: p=0.20 (95% CI -0.31, -0.09) (Table 1).

Conclusion: DI was associated with lower PPT at painful finger joints. Large variance of PPT within each DI grade resulted in fair agreement. DI of non-painful
Finger joints were weakly associated with PPT, demonstrating that the DI does not differentiate pain sensitization in joints without ongoing nociceptive pain. Correlations between DI sum score and PPT of remote sites were also weak. The two measures seem to assess different constructs and are therefore not interchangeable.

DOI: 10.1136/annrheumdis-2020-eular.782
out strategies for pain management could improve this PCS values and therefore reduce the need for TKR. Furthermore, this study also highlights the two main types of OA etiology: mechanical and inflammatory. It suggests that inflammation is mostly responsible for OA progression in patients with low BMI, and plays a strong role in women pathology. Finally, specific treatments targeting central pain sensitization could also improve the management of the pathology in women.

Allanzia, Nuclemedizin Spitalerhof, Hamburg, Germany; 16King’s College London, London, United Kingdom; 17Cyprus League Against Rheumatism, Nicosia, Cyprus; 18IMMusc, Madrid, Spain

Background: Intra-articular therapies (IAT) are widely used in clinical practice to treat patients with rheumatic and musculoskeletal diseases (RMDs). Many factors influence their efficacy and safety. There is a wide variation in the way IATs are delivered by health professionals. In an attempt to standardize these procedures, evidence-based recommendations are the right way forward.

Objectives: To establish evidence-based recommendations to guide health professionals using IAT in adult patients with peripheral arthropathies.

Methods: At a first face-to-face meeting, the results of an overview of systematic reviews were presented to the multidisciplinary task force of members from 8 countries. The aim, scope and outline of the taskforce were also established at this meeting. Thirty-two clinical questions ranked for priority (relevance for practice plus feasibility) drove the systematic reviews performed by two fellows. A Delphi round was sent to the taskforce. The level of evidence was assigned (0 completely disagree, 10 completely agree). All panellists voted anonymously using a slips and an evaluation of between IPR and PROs. A multivariate regression analysis was conducted to assess the relationship and clinical characteristics as well as PROs between patients with and without IAT.

Results: Recommendations focus on practical aspects for daily practice to guide health professionals before, during and after IAT in adult patients with peripheral arthropathies. Five overarching principles were established, together with 11 recommendations that address the following issues: (1) patient information; (2) procedure and setting; (3) accuracy issues; (3) routine and special anesthetic care; (4) safety issues and precautions to be addressed in special populations; (5) efficacy and safety of repeated joint injections; (6) the usage of local anaesthetics; and (7) aftercare. The document includes the supporting evidence and results from the surveys, level of evidence and agreement.

Conclusion: We have developed the first evidence and expert opinion based recommendations to guide health professionals using IAT.

Acknowledgments: EULAR Taskforce grant CL/109

FRI0428 RESULTS FROM A CROSS-SECTIONAL, OBSERVATIONAL STUDY TO ASSESS INADEQUATE PAIN MANAGEMENT IN PATIENTS WITH KNEE AND/OR HIP OSTEOARTHRITIS IN CHINA

X. Zeng1, X. Leng2, K. Wei3, W. M. Tang4, C. H. Tang5, K. Tunceli2, J. Aggarwal6, D. Ramey7, F. Lozano8, I. Doshi9, C. Macahilig10, S. Oda11, K. Johnson12, 1Peking Union Medical College Hospital, Beijing, China; 2MSD Pharmaceutical, Shanghai, China; 3Merck & Co., Inc. Center for Observational and Real World Evidence, Kenilworth, United States of America; 4Pharmament International, LP, Boston, United States of America; 5Merck & Co., Inc., Global Medical Affairs, Kenilworth, United States of America; 6Medical Data Analytics, Research Operations, Parshippy, United States of America

Background: Osteoarthritis (OA) of the knee and hip is a leading cause of disability worldwide, particularly due to the primary symptom of pain in the weight-bearing joints. There is limited data that characterizes patients who experience moderate to severe pain despite analgesic treatment in China.

Objectives: This study estimates the real-world prevalence of inadequate pain relief (IPR) among patients with knee and/or hip OA who have been prescribed analgesic therapy and characterizes this patient population. The study was conducted in China, the Philippines, Thailand, Russia, and Mexico. This abstract presents results from research in China.

Methods: This is a multinational, multi-site, cross-sectional, observational study. Physicians managing patients with OA were recruited and asked to enroll patients over 50 years of age with knee and/or hip OA who had been prescribed topical and/or oral pain medication for at least 30 days prior to study visit. Patients tended to be older, have greater prevalence of obesity, have more comorbidities, and had longer disease duration. The majority (98%) of patients were receiving nonsteroidal anti-inflammatory drugs (NSAIDS), followed by chondroprotective

Results: 571 patients treated at 10 hospital centers in China were enrolled. 73% were female, the mean (SD) age was 62 (8.32) years. The number of years with OA ranged from less than one year to over 37 years, suggesting a broad sample of patients. Most patients were impacted by knee OA only (90%). Almost half (43%) of the study population reported that the definition of IPR tended to be older, have greater prevalence of obesity, have more comorbidities, and had longer disease duration. The majority (98%) of patients were receiving nonsteroidal anti-inflammatory drugs (NSAIDS), followed by chondroprotective
medications (23%). However, more patients with IPR mentioned being dissatisfied with treatment (38% vs. 21%). After adjusting for covariates, patients with IPR reported worse HRQOL, more functional limitations, and reduced work productivity compared to patients without IPR.

Conclusion: IPR is highly prevalent among individuals with knee and/or hip OA in China and is associated with decreased HRQOL and work productivity, impaired function, and treatment dissatisfaction. Developing awareness among healthcare professionals about the presence and potential impact of IPR is important for the ultimate improvement of OA patient management.

UROLITHIN B ATTENUATES THE INFLAMMATORY AND NITROSATIVE STRESS ON INTERLEUKIN-1 INDUCED CHONDROCYTES

F. C. Wu, J. Y. Peng, C. C. Wang, F. C. Liu. National Defense Medical Center, Taipei, Taiwan, Republic of China; Tri-Service General Hospital, Taipei, Taiwan, Republic of China

Background: Osteoarthritis (OA) is one of the most common degenerative disorders with cartilage degradation especially to the elderly resulting in disability. Many inflammatory cytokines involve the pathogenesis of the OA and cause cartilage destruction and decomposition of articular cartilage, including interleukin 1 beta (IL-1β). Urolithin B is a small polyphenolic compound, produced by gut flora from ellagitannins-rich foods, such as pomegranate, strawberries, raspberries, etc. Urolithin B has been documented in anti-inflammatory and antioxidant properties. However, the mechanism underlying the effects of Urolithin B on IL-1 stimulated human osteoarthritic (OA) chondrocytes remains unrevealed.

Objectives: The aim of this study was to investigate the biologic effects of Urolithin B on OA models and associated mechanism.

Methods: Primary culture of human chondrocyte, knee joint obtained from total knee replacement patients with osteoarthritic, were used IL-1β induced and treated with/without 100μM Urolithin B for 24 hours respectively. Total cell lysates were collected for western blotting to analyze the catabolic molecules. Culture medium were collected for gelatin zymography to analyze the secretion of MMP 2 and 9.

Results: Urolithin B inhibits the overexpression of not only inflammatory marker COX2 and nitrosative marker NOS2, but also matrix metalloproteinases (MMPs)-1, -3, -13 in IL-1β induced chondrocytes by western blotting. It also restored the IL-1β induced glycosaminoglycan degeneration in ex vivo articular cartilage evaluated by Safranin O stain. Meanwhile, Urolithin B can activate autophagy, increasing LC3 II/I ratio, in IL-1β induced chondrocytes.

Conclusion: Collectively, the study demonstrates that Urolithin B may be of value in the treatment of osteoarthritic through its anti-inflammatory, anti-oxidant and anti-proteinase activities.

THE NOVEL, INTRA-ARTICULAR CLK/DYRK1A INHIBITOR LORECIVINT (LOR; SM04690), WHICH MODULATES THE WNT PATHWAY, IMPROVED RESPONDER OUTCOMES IN SUBJECTS WITH KNEE OSTEARTHRITIS: A POST HOC ANALYSIS FROM A PHASE 2B TRIAL

Y Yazzci1, S. Kennedy1, C. Swearingen1, J. Tambiah1,1Samumed, LLC, San Diego, United States of America

Background: Lorcivint (LOR; SM04690) is a small-molecule, intra-articular (IA) CLK/DYRK1A inhibitor that modulates the Wnt pathway1 and has demonstrated some beneficial effects on patient-reported outcomes (PROs) relative to placebo (PBO) in two Phase 2 knee OA trials. With subjective measures such as PROs, meaningful benefits may be better characterized by representation as discrete threshold responses rather than by changes in mean or median estimates.

Objectives: To conduct a post hoc analysis of subjects in a 24-week Phase 2b study by measuring the proportions of subjects treated with LOR and placebo (PBO) who achieved 30%, 50%, or 70% threshold responses of improvement over baseline in Pain Numeric Rating Scale (NRS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain, WOMAC Function, and Patient Global Assessment (PGQA) at Week 12. Results from the Phase 3-selected dose of 0.07 mg LOR are presented here.

Methods: Subjects had ACR-defined knee OA, Kellgren-Lawrence (KL) grades 2–3, and Pain NRS scores ≥4 and ≥5 in the target knee and <4 in the contralateral knee. A single 2mL IA injection of 0.03mg, 0.07mg, or 0.23mg LOR, or vehicle PBO was given in the target knee at baseline. The proportion of subjects meeting 30%, 50%, or 70% threshold responses of improvement over baseline in Pain Numeric Rating Scale (NRS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain, WOMAC Function, and Patient Global Assessment (PGQA) at Week 12. Results from the Phase 3-selected dose of 0.07 mg LOR are presented here.

Results: In total, 635 subjects (91.4%) completed the study (mean age 59.0±8.5 years, BMI 29.0±4.0kg/m², female 58.4%, KL grade 3 57.3%). At Week 12, treatment with 0.07 mg LOR significantly (P<0.05) increased the odds of a 30% threshold response in Pain NRS (OR 2.47 [1.45, 4.19]) and WOMAC Function [OR 1.86 [1.10, 3.12]] and a 50% threshold response in WOMAC Pain (OR 1.75 [1.06, 3.03]) and PGQA (OR 2.28 [1.25, 4.16]). Numerically, more (not statistically significant) subjects achieved a 70% threshold response in all PROs. All improvements were maintained through Week 24.
Conclusion: In this post hoc analysis, LOR-treated subjects reported greater improvements in PRO threshold responses versus PBO from Week 12 through Week 24. LOR demonstrated significantly higher odds of achieving and maintaining improvements in PROs at 30% and 50% thresholds. Phase 3 studies of 0.07 mg LOR are ongoing.

Infection-related rheumatic diseases

FR0431 PROFILES OF INFECTIOUS SPONDYLODICTIS ACROSS THE SITE: UNIFOCAL VERSUS MULTIFOCAL

A. Ben Tekaya1, L. Ben Ammar2, M. Ben Hammamia3, O. Saida4, S. Bouden5, R. Tekaya4, I. Mahmoud4, L. Abdelmoula6, 1Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; 2Kassab Institute, Rheumatology, Tunis, Tunisia; 3La Rabta Hospital, Cardiovascular Surgery, Tunis, Tunisia

Background: Infectious spondylodiscitis is a therapeutic emergency and is a current problem. It can affect the different levels of the spine. Multifocal forms, touching several floors, however remain rare.

Objectives: To compare the clinical, biological, radiological and therapeutic aspects of unifocal versus multifocal spondylodiscitis.

Methods: This is a retrospective study of 113 patients admitted to our service over a period of 20 years [1998-2018]. The diagnosis is made on the basis of clinical, biological, radiological and bacteriological data.

Results: Our population was divided into 62 men (54.9%) and 51 women (45.1%) (p = 0.8) with an average age of 55 years [16-86]. Predisposing factors were found in 52.2% of cases: diabetes (23%), neoplasia (2.7%), hypophysitis (5.3%), long-term corticosteroid therapy (1.8%), recent surgery (3.5%), history of tuberculosis (2.7%) and consumption of unpasteurized dairy products (28.3%).

The approximate time between onset of symptoms and diagnosis ranged from 0.23 to 24 months (median 3 months). Impaired general condition was observed in 81% of the cases and fever in 34.5% of the cases. Radioculalgia was found in 46% of the cases and a neurological deficit was noted in 16% of the cases. Biological inflammatory syndrome was found in 91.2% of the cases.

The Infectious spondylodiscitis was multifocal in 24.8% and multistage in 12.4% of the cases. A disco-vertebral biopsy was performed in 70% of cases and was contributory in 44.3% of cases. The causative organism was tuberculosis in 55.8% cases, brucellosis in 21.2% cases and pyogenic germs in 23% of cases.

Conclusion: Imaging plays an important role in the diagnosis of spondylodiscitis. MRI is considered the key examination, capable of mapping injuries and detecting potentially serious neurological complications. The importance of imaging the entire spine to detect multifocal forms should also be emphasized.

FR0433 HAS THE PROFILE OF INFECTIOUS SPONDYLODICTIS CHANGED IN 20 YEARS?

A. Ben Tekaya1, L. Ben Ammar2, M. Ben Hammamia3, O. Saida4, S. Bouden5, R. Tekaya4, I. Mahmoud4, L. Abdelmoula6, 1Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; 2Kassab Institute, Rheumatology, Tunis, Tunisia; 3La Rabta Hospital, Cardiovascular Surgery, Tunis, Tunisia

Background: Infectious spondylodiscitis is a diagnosis and therapeutic emergency. Its clinical presentation can be insidious and standard radiographs can be falsely reassuring. This explains the interest of cross-sectional imaging and more particularly magnetic resonance imaging (MRI).

Objectives: To analyse the contribution of imaging in the diagnosis of infectious spondylodiscitis.

Methods: These are 113 cases of spondylodiscitis collected in a rheumatology department over a period of 20 years [1998-2018]. The diagnosis is made on the basis of clinical, biological, radiological and bacteriological data.

Results: The occurrence of immediate complications was more frequent in multifocal spondylodiscitis but with no statistically significant difference (p=0.2). Conclusion: Multifocal spondylodiscitis is seen mainly in immuno compromised subjects. Our study found that diabetes is the most common factor in immuno suppression. Note also the predominance of involvement of the posterior elements, tuberculous origin and immediate complications.

RETROSPECTIVE STUDY ON SERIOUS INFECTIONS IN PATIENTS WITH INFLAMMATORY ARTHRITIS TREATED WITH TNF INHIBITORS

**Objective:** To study the associated factors for serious infections in patients with inflammatory arthritis treated with TNF inhibitors

**Methods:** All the medical records of the patients with inflammatory arthritis being treated with TNF inhibitors at the beginning of 2016 were retrospectively reviewed. All serious infections suffered for these patients until the end of 2018 were recorded. Serious infections were defined as those which required to admitted at the hospital for intravenous treatments. Potential variables associated with the development of these infections including: demographic and clinical characteristics, concomitant treatments or comorbidity (by Charlson index) were studied. Standard statistical tests for descriptive and univariate analyses were used and a multivariable logistic regression model was built to check independent associations.

**Results:** Overall 334 patients (50.3% women) with a mean age of 56.67 (±12.853) were studied: 140 (41.92%) Rheumatoid arthritis (RA), 55 (16.46%) psoriatic arthritis (PsA) and 138 (41.62%) spondyloarthritis (Sp). Forty-five serious infections were observed in 30 patients, being respiratory (40%) and urinary (8.8%) the most frequent localizations. Only one patient died. By univariate analysis, disease duration, age, concomitant use of glucocorticoids (GC) (but not of synthetic DMARDs), Charlson index and specifically Diabetes Mellitus were associated with infection (p<0.06). The type of arthritis was not associated and the results in the subset of RA patients were overall similar. In the multivariate analysis the use of GC [OR: 5.31 (1.98:14.26)] and the Charlson index [OR:2.48 (1.70:3.60)] were found to be independently associated to infection.

**Conclusion:** In patients with inflammatory arthritis and treated with TNF inhibitors around a 10% developed any serious infection along three years of follow up. Use of GC and comorbidity emerged as the main risk factors for this complication.

DOI: 10.1136/annrheumdis-2020-eular.4347
Results: A total of 86 were included with a mean age of 62.75 (14.98) years old and predominating male sex (68.60%). 15 patients (17.44%) presented any kind of immunosuppression. Clinical data are summarized in Table 1. Blood cultures were positive in 39.71% and sample culture showed a reliability of 49%. Organism which grew were gram + (66.67%), gram – (12.70%), mycobacteria (12.7%) and fungi (7.94%). In only 16 cases (18.6%) there was isolated the same organism in blood and on biopsy culture. From admission to procedure, a mean of 6 days was observed. Antibiotic treatment had a median value of 2 days (0, 6) and its exposure did not modiﬁed the culture positivity (IC 95% [0.274-5.211] p=0.816). Detailed analysis was performed looking for the inﬂuence of the days of exposure, which also failed (IC 95% [0.939-1.101] p=0.747). The longer duration of the pain was related to a higher probability of obtaining a negative result on the biopsy (IC 95% [1.004-1.035] p=0.026) (graphic 1). Neither fever (p=0.303) or higher CRP (IC 95% [0.992-1.006] p=0.761) value modiﬁed the culture result.

*Considered as immunosuppressed patients

Conclusion: Even in cases under antibiotic treatment, CTGB displays an acceptable reliability. The longer the length of painful period before diagnosis was related to a higher chance of obtaining a negative result on culture. This result could be explained by a greater aggressiveness of pyogenic organisms that perhaps congregate in the lesser time span instead of non-pyogenic agents, that could deliver in more silent infection.

DOI: 10.1136/annrheumdis-2020-eular.6383
Background: Chikungunya virus (CHIKV) infection is an emerging disease which is responsible for several epidemics around the world. Systematic review and meta-analysis had shown that approximately 25% of cases of Chikungunya (CHIK) would develop CHIK-Chronic Inflammatory Rheumatism and 14% would develop persistent arthritis (or spondylitis).

Objectives: To describe the frequency of the clinical patterns of chronic arthritis & to characterize the clinical symptoms in a Bangladeshi cohort of CHIK patients 12months post-infection.

Methods: In 2017, a Chikungunya outbreak occurred in Dhaka, Bangladesh, during which a prospective cohort of CHIK patients with confirmed diagnosis was constituted. A longitudinal follow up of 60 patients from an initial cohort of 142 patients, attending the out-patient department of Rheumatology, BSMMU, was done. Patients having arthritis/arthralgia or both lasting more than 3 months were considered as chronic cases. Their baseline and follow-up symptoms at 3m, 6m and 12months were evaluated. Functional status was assessed with the Bengali Version Health Assessment Questionnaire (HAQ).

Results: Of the initial 142 patients enrolled in the study, 135(95.1%) had CHIKV-IgM and 29(20.4%) had IgG positive. Patients that followed up in-person were predominantly adult (age 43.73 ± 11.09 years) and female 34 (56.7%). The majority of the patients 35 (58.3%) had undifferentiated arthritis. After three months, 8 (16.3%) had oligoarthralgia, 26 (53.1%) had polyarthralgia and 8 (16.3%) had polyarthralgia with oligoarthritis. At the end of one year, 13 (21.7%) patients underwent complete remis-
sion. Among the 47 patients, 21 had joint involvement where 11(52.4%) had polyarthralgia & oligoarthritis. At the end of one year, 13 (21.7%) patients underwent complete remis-
sion. Among the 47 patients, 21 had joint involvement where 11(52.4%) had polyarthralgia & oligoarthritis. Among the 47 patients, mild, moderate and severe functional disability was present in 89.4%, 6.4% and 4.3% patients respectively.

Conclusion: After one year of follow up, one-third of the patients remained symptomatic. Polyarthralgia was the predominant clinical feature. Mild functional disability was also observed in a significant number of patients.

Figure 1: Distribution of patients by ultrasonographic findings (n=60)

Figure 2: Distribution of patients by functional disability after 1 year (n=47)
Enterococcus faecalis (39%) then staphylococcus aureus (17%) against 14% and 13% respectively in the entire IE Duke + group. In the group with cardiac PET-CT fixation, OAF was found in 10 patients (40%), 70% of whom were asymptomatic. Among them, there were 5 spondyloarthritids (2 cervico- thoracic and 3 exclusively thoracic), 2 gienachoerum arthritis (20%), 2 coxofemoral arthritids and 1 sternioclavicular arthritis. The IE affected the aortic valve in 60% of the cases, mitral in 30% of the cases and it was an infection on ICD in 10% of the cases. The main germs found were Enterococcus faecalis (30% of cases) and Staphylococcus epidermisid (20% of cases).

**Conclusion:** In patients with IE, PET-CT seems to be interesting in detection of osteoarticular infections, and consequently, could impact the diagnosis and the treatment modalities. In our cohort, 1 patient in 5 had an OAF and nearly 40% of them were asymptomatic. The overrepresentation of enterococcus is consistent with recent data in the literature.

**FRID0441**

**RISK FACTORS FOR CYTOMEGALOVIRUS INFECTION IN PATIENTS WITH AUTOIMMUNE DISEASES**

D. Kobayashi1, Y. Wada2, E. Hasegawa1, A. Wakamatsu3, T. Nakatseu2, H. Sato3, T. Kuroda1, I. Narita1, 1Niigata University School of Medical and Dental Sciences, Division of Clinical Nephrology and Rheumatology, Niigata, Japan; 2Niigata Rinko Hospital, Division of Clinical Rheumatology and Nephrology, Niigata, Japan; 3Niigata University, Health Administration Center, Niigata, Japan

**Background:** The risk for opportunistic infections in patients with autoimmune diseases requiring intensive immunosuppressive therapy is high and cytomegalovirus (CMV) infection is one of the most common opportunistic infections. Since 2011, we have performed weekly CMV pp65 antigen testing for patients at risk of opportunistic infections owing to autoimmune diseases to ensure appropriate patient management.

**Objectives:** To evaluate the risk factors that predict CMV infection in patients that received remission-induction therapy for autoimmune diseases.

**Methods:** We enrolled 254 patients (93 male, 161 female) from our hospital with autoimmune disease who received remission-induction therapy with prednisolone at a dose greater than 0.5 mg/kg/day between January 2011 and December 2018. We retrospectively analysed their clinical characteristics and laboratory data, including treatment regimens and CMV pp65 antigen test results. The presence of more than five CMV pp65 antigen-positive cells over two slides was considered a positive result. We conducted univariate and multivariate analyses to extract CMV risk factors.

**Results:** Of the patients we evaluated, 60 suffered from systemic lupus erythematosus (SLE), 55 from anti-nuclear cytoplasmic antibody-associated vasculitis (AAV), 31 from dermatomyositis (DM), 14 from interstitial pneumonia with anti-aminoacyl tRNA synthetase antibody, 14 from adult-onset Still's disease (AOSD), 14 from rheumatoid arthritis (RA), 11 from mixed connective tissue disease (MCTD), 10 from Takayasu's arteritis, and 45 suffered from other autoimmune diseases. Pulse therapy with methylprednisolone (mPSL) and methotrexate (MTX) were risk factors for CMV pp65 antigen positivity. Conclusion: Higher age, lower TLC, higher HbA1c, and treatment with mPSL pulse therapy were risk factors for acquiring CMV infection, as measured by the presence of the CMV pp65 antigen, in patients receiving remission-induction therapy for autoimmune diseases. Careful monitoring of these, at risk, patients is necessary.

**DOI:** 10.1136/annrheumdis-2020-eular.2693
Lyme disease (LD) is a multisystemic animal-borne disease caused by spirochetes of the *Borrelia burgdorferi* s.l complex and transmitted by ticks of the species *Ixodes ricinus*. In Spain, most cases occur in rural areas of the north-east region with a peak of maximum incidence between spring and early autumn. The diagnosis is based on a history of potential exposure to ticks, the recognition of characteristic clinical manifestations and serological testing.

**Objectives:** To assess the suitability of serological study for the diagnosis of LD in an urban area.

**Methods:** Retrospective observational study that included all LD serology tests made between April 2017 and September 2019 at a tertiary hospital in Barcelona covering a population of 450,000 people. Demographic data and the medical department that requested the serology test were collected along with serology test results. The medical records of patients with positive serology were consulted to identify which patients were finally diagnosed with LD along with their clinical manifestations, treatment and outcome.

**Results:** A total of 574 serological tests were included and 78 (13.59%) of them were positive. Only 1.04% (6) of all serological tests belonged to patients finally diagnosed with LD. The department that made most requests was Neurology (37), followed by Infectious Diseases (19%), Internal Medicine (14.5%), Emergency Medicine (4.7%), Dermatology (4.5%), Critical Care Medicine (2.3%) and Rheumatology (2.1%). 50% of the diagnosed patients were women with a mean age of 57±7.7 years. In 50% of diagnosed cases, patients remembered a tick bite during activities in the mountain or rural areas. The most common clinical manifestations were erythema migrans (67%), non-inflammatory arthralgias (50%), fatigue and malaise (67%), together with one case of meningoecephalitis and one case of knee monarthrosis. All diagnosed patients received antibiotic treatment with ceftriaxone (33%) or doxycycline (66%). Only one patient presented a complicated LD, which led to hospitalization (37.3%) followed by Infectious Diseases (21%), Internal Medicine (14.5%), Emergency Medicine (4.7%) and Dermatology (4.5%).

The serological test for LD in our center had a total individual cost of 15.75 eur, so it is cost effective compared with ceftriaxone (33%) or doxycycline (66%). Only one patient presented a complicated LD, which led to hospitalization.

**Conclusion:** The serological test for LD in our center had a total individual cost of 15.75 eur, so it is cost effective compared with ceftriaxone (33%) or doxycycline (66%). Only one patient presented a complicated LD, which led to hospitalization.

Conclusion: 53 adult patients infected HPV B19 in 10 years at community hospital in Japan. Epidemic season were 4-year cycle and skin eruption and joint symptoms appeared 4-5 days after upper respiratory symptoms. Previous study show that a second-phase illness with rash and arthralgia appear 10-11 days after the appearance of upper respiratory symptoms.21 In our study, a second-phase symptoms appeared about one week earlier than in previous study. Half of the patients were weakly ANA positive.

HLA-B27 IN POSTSTREPTOCOCCAL REACTIVE ARTHRITIS WITH ENTHESIS
I. Naishetel1, L. Khimion1, O. Yashchenko1, P. Dolinskiy1, National Medical Academy of Postgraduate Education named after P.L. Shupyk, Kyiv, Ukraine; 2The Institute of Traumatology and Orthopedics, Kyiv, Ukraine

Background: Poststreptococcal reactive arthritis (PSRA) is a very common diagnosis in rheumatology practice, which develops after recent pharyngeal streptococcal infection and characterized by aseptic inflammation in one or more joints and periarticular involvement. Now no diagnostic criteria have been agreed [2,4]; association of the expression of HLA-B27 and PSRA is not clear [1,3].

Objectives: In our study we analyzed the features of PSRA in presence of HLA-B27.

Methods: 88 patients (48 female and 40 male) aged between 18-55 years with complaints of pain, tender and swollen joints developed after recent pharyngeal streptococcal infection underwent standard physical and laboratory rheumatological examinations. Acute rheumatic fever and other inflammatory arthritis were excluded.

Results: 60 patients (68.2%) had oligo-polyarthralgia, 10 patients (11.4%) - monoarthritis, 24 patients (27.3%) had asymmetrical oligoarthritis, 4 patients (4.5%) had polyarthritides, enthesis was found in 4 (4.5%) patients, tenosynovitis of the palmar flexor tendons in 10 cases (11.4%) and the peroneal tendons of the ankles in 5 patients (5.7%), one-sided sacrolitits (confirmed by MRI) in 5 patients (5.7%). The mean level of ASL-O was 542 Ui/ml, CRP - 15mg/L, ESR - 34 mm/H; HLA-B27 was present in 24 (30.7%) patients. HLA-B27 positivity was connected to enthesisitis, sacrolitits, more joint involvement with higher levels of ESR and CRP.

Conclusion: 30% of patients with poststreptococcal reactive arthritis are HLA-B27 positive, the presence of HLA-B27 leads to more frequent development of enthesisitis, polyarthritides and sacrolitits with higher level of inflammatory activity which dictate the need for longer supervision of such patients for possible triggering of ankylosing spondylitis development.

FRID0446

VIRAL ARTHRITIS: DESCRIPTIVE ANALYSIS OF A SERIES OF 131 PATIENTS
A. V. Orenes Vera1, I. Vázquez-Gómez2, L. Montolío-Chiva1, E. Flores1, D. Ybañez1, E. Valls-Pascual1, A. Martínez-Ferrer1, A. Sendra-García1, V. Núñez-Monje1, I. Torner Hernández2, J. J. Alegría-Sancho1, N. Fernandez-Llanos3, 1Hospital Doctor Peset, Valencia, Spain; 2Hospital Arnau de Vilanova, Valencia, Spain

Background: Arthritis of viral aetiology is considered the most frequent cause of acute arthritis. The most common etiologic agent is parvovirus B19 (B19). Besides, other viruses can lead to inflammatory joint disease, such as Epstein-Barr virus (EBV), Cytomegalovirus (CMV), Human immunodeficiency virus (HIV), Rubella, Mumps, Hepatitis B and C virus (HBV and HCV) and Chikungunya (in transcontinental travellers or immigrants).

Objectives: To describe the epidemiological characteristics, clinical and analytical course, evolution and treatment of a series of patients with a confirmed diagnosis of viral arthritis.

Methods: A descriptive study was performed, considering a series of cases of viral arthritis collected between 2000 and 2019. Epidemiological (sex, age, the season of the year, diagnosis of children of pediatric age), clinical (joint pattern, prodromes, accompanying clinic) and analytical (CRP, ESR, ANA, RF) variables were collected. Statistical analysis was performed with the SPSS 22.0 program.

Results: The data of 131 patients (109 women, 22 men), with a mean age of 39.7 years (SD 11.9) were collected. 92.9% of the cases were produced by B19, 3.8% by EBV, and only 3 by other viruses (1 by CMV, 1 by HBV, 1 by Mumps). The highest incidence years were 2005 (55 cases), 2000 (10 cases) and 2016 (8 cases). Half of the almost half of the cases (46.6%) occurred in winter, while 32.8% in summer, 15.3% in winter and 5.3% in autumn. Contrary to the expectations, only 20% of the patients had children in pediatric age.

The most frequent clinical picture was acute polyarthralgia (53.4%), followed by inflammatory polyarthralgias (19.1%). Moreover, acute oligoarthritides was present in 10.7% of cases, and acute monoarthritides in 3.1% of cases. More than half of the patients (54.2%) had prodromes, most frequently respiratory symptoms, and the joint clinic was accompanied by a skin rash in 35.1% and fever in 29% of cases. Analytically, 33.6% presented high CRP, 39.7% high ESR, 18.9% transient anemia, 9.9% positive ANA (4.6% transiently), 9.1% anti ds-DNA (7.6% transiently), and 10.7% positive RF (3.1% transiently). In 79.4% of cases, the clinic picture was limited, with a mean duration of 36 days (SD 47.7), but 12.3% had recurrences. The 68.5% of the patients needed treatment with acetaminophen and/or NSAIDs (6.7% did not need treatment), but corticotherapy was needed in 21.4% of cases. 4.6% of the cases evolved to chronicity, which made DARD necessary in 3 patients (two of them with a final diagnosis of rheumatoid arthritis, being treated with Methotrexate and Leflunomide, and the third one had a diagnosis of undifferentiated connective disease, treated with Hydroxychloroquine).

Conclusion: B19 remains the most common cause of viral arthritis in our population. It appears with a sporadic, occasionally epidemic, pattern of presentation, predominantly in warm seasons. A clinical presentation as an oligoarthritides or an acute monoarthritides or even the positivity of autoimmunity markers, should not make us rule out this possible aetiology. One out of 20 cases can evolve to chronicity and even make necessary the addition of DARD.

FRI0447 FIRST COMPREHENSIVE LONG-TERM ASSESSMENT OF MUSCULOSKELETAL CONSEQUENCES AMONG EBOLA SURVIVORS

V. Y. M. Pers1, A. Dubois2, T. A. Barry3, M. D. Sall4, L. March5, M. S. Sow6, A. K. Keita5, B. Taverne5, J. F. Etard7, A. Toure4, M. Barry7, E. Delaporte8 on behalf of Postebogui Study Group. 1CHU Montpellier, Montpellier, France; 2Inserm U133, Montpellier, France; 3CHU Montpellier, Montpellier, France; 4Donka University National Hospital, Conakry, Guinea, 4LPED UMR 151, Aix Marseille Univ, IRD, LPED, Marseille, France; 5TransVHMI INSERM, IRD, University of Montpellier, Montpellier, France; 6Donka University Hospital, Conakry, Guinea; 7University Gamal Nasser, Conakry, Guinea

Background: The tremendous size of the 2013-2016 West African outbreak of Ebola virus disease (EVD) resulted in a sizeable population of survivors, many reporting short-term sequelae such as arthralgia and myalgia.

Objectives: We aimed to report a detailed and long-term description of patients’ musculoskeletal (MS) symptoms.

Methods: We performed a cross-sectional study following systematic rheumatological screening of patients included in the Postebogui cohort (Conakry district). We used regression models to establish the magnitude of EVD as a risk factor for developing chronic MS pain by comparison with a control cohort and to establish risk factors for developing MS pain among survivors.

Results: The study included 313 patients (55.6% female), with a median age of 28.2 years (IQR 21-37), and a median time from ETC discharge to rheumatological visit of 26.2 months (IQR 23-30). Chronic MS pain was reported in 216 (69%) patients, and was predominantly mechanical (48%). Enthesitis and painful peripheral joints were largely involved (91%) with symmetrical distribution. Previous Ebola infection was a major risk factor for chronic MS pain (aOR, 6.662 [95% CI, 4.522–9.921]). Among survivors, increasing age (OR 1.14, 95% CI 1.08–1.20) and a positive sexual health screen 1 year prior to presentation were associated with chronic MS pain. Risk factors for developing chronic MS pain among survivors are presented in table 1.

Conclusion: Our study provides the most accurate long-term description of MS disorders among Ebola survivors. Joint and muscle pain sequelae are frequent and require specialized care.

FRI0449 MANAGEMENT AND OUTCOME OF SEPTIC ARTHRITIS OF NATIVE JOINT: A NATIONWIDE SURVEY

S. Qureshi1, K. Moss1, A. Ezoezynej1, V. Sandhu1. 1St George’s Hospital, London, United Kingdom

Background: Sir William Osler once wrote: “He, who knows syphilis, knows medicine.”

Whilst the Tuskegee Syphilis trials live in infamy, the advent of successful penicillin treatment and sexual health education resulted in the lowest recorded incidence ever in 2001.

Unfortunately, cases of syphilis have nearly tripled in the past decade (from 2,847 in 2009 to 7,541 in 2018 in the UK).1 WHO now estimates the global median prevalence of Syphilis, among men who have sex with men, is 6%2.

The current cohort of clinicians will therefore have limited clinical experience of Syphilis, which can often mimic rheumatic conditions. We present the clinical experience of a tertiary teaching centre hospital.

Objectives: To identify the scope of clinical cases, with a diagnosis of Syphilis, during 2018-2019 at St Georges University Hospital, London, UK.

Methods: Clinical cases were identified by health professionals and a retrospective review of medical records was undertaken.

Results: There were 4 cases identified during 2018-19.

Case 1: The patient was diagnosed with bilateral uveitis secondary to primary syphilis, and immunosuppression may have contributed to this.

Case 2: The rash developed after the initial presentation and an extended infected screen was performed.

Case 3: The patient had a 6 month duration of symptoms and had had a negative sexual health screen 1 year prior to presentation.

Case 4: The patient had no features of extra pulmonary sarcoidosis and an infectious screen was undertaken.

All 4 cases were referred to the Infectious Disease Unit for treatment. 3 patients received standard treatment with Penicillin, and 1 patient received an oral course of Doxycycline, due to a penicillin allergy.

2 of the 4 cases had complete resolution of symptoms, and 2 of the cases had only partial resolution of symptoms at the time of publication.

Conclusion: Syphilis can present with an inflammatory arthritis, PMR and GCA –type symptoms, ocular inflammation, neurological disturbance and rashes that can mimic autoimmune conditions.

Our cases highlight the increasing incidence, as well as the risk of reactivation following immunosuppression. Current practice does not advise routine testing for syphilis prior to initiation of immunosuppressive therapy. However the rising incidence should prompt careful evaluation, and detailed sexual history, particularly in high risk groups. The diagnostic test interpretation and treatment requires close collaboration with Infectious Diseases Specialists.

MEASURES OF DISEASE SEVERITY PREDICT DISABILITY AND QUALITY OF LIFE DIFFERENTLY IN RHEUMATOID ARTHRITIS AND CHRONIC CHIKUNGUNYA DISEASE

1Hospital Infantil Universitario Niño Jesús, Pediatric; 2Aarhus University, Clinical Pharmacology; 3Aarhus, Denmark; 4Centro de Ciencias de la Salud, Universidad Federal de Roraima, Laboratorio de Parasitologia e Vetores da Amazonia, Boa Vista, Brazil; 5Instituto Leónidas e Maria Deane, FIOCRUZ, Manaus, Brazil; 6George Washington University, Surgery, Washington, DC, United States of America; 7George Washington University, Medicine, Washington, DC, United States of America; 8University of California San Diego, Medicine, San Diego, United States of America; 9George Washington University, School of Medicine and Health Sciences, Washington, United States of America

Background: Chronic rheumatological manifestations similar to those of rheumatoid arthritis (RA) have been described after chikungunya virus infection. However, the clinical significance of the symptoms and disease severity in the two conditions has not been directly compared.

Objectives: To compare, using identical measures of disease severity and patient outcomes, the impact of disease severity measures and symptoms on outcomes in RA and chronic chikungunya disease.

Methods: Forty patients with chronic chikungunya arthralgia two years post-infection and 40 matched patients with RA were enrolled in Roraima, Brazil. Twenty-eight joints were assessed for tenderness and swelling, a pain intensity visual analogue scale, musculoskeletal stiffness questionnaire, modified Health Assessment Questionnaire and the EuroQol EQ5D-5L quality of life assessment were completed. The importance of the various measures of disease severity were analysed using Spearman’s rank correlation and regression analysis.

Results: Tender and swollen joint counts, pain and stiffness were all predictive of the HAQ disability index in RA, but only stiffness was significantly associated with disability in chikungunya patients (Table 1). Tender and swollen joint counts, pain and stiffness were predictive for all EQ5D quality of life domains (except anxiety/depression) in RA patients. In contrast, in chikungunya disease, tender joint counts were predictive only of usual daily activities; pain was predictive of impaired mobility, self-care and discomfort, while stiffness was predictive for the mobility and anxiety/depression domains (Figure 1). Swollen joint counts were not associated with any of the patient outcomes in chikungunya disease. Linear regression analysis confirmed (p=0.003) that the effect of swollen joint count on the HAQ disability index depends on the underlying disease.

RELATIONSHIP BETWEEN MEMBRANE-BOUND AND SOLUBLE RECEPTOR FOR ADVANCED GLYCATION END PRODUCTS AND DISEASE ACTIVITY IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS

D. Clemente1, A. García-Salido2, G. Meiler1, M. Ramírez-Orellana2, J. C. López Robledillo1. 1Hospital Infantil Universitario Niño Jesús, Pediatric
**Rheumatology, Madrid, Spain; Hospital Infantil Universitario Niño Jesús, Madrid, Spain**

**Background:** Membrane-bound receptor for advanced glycation endproducts (mRAGE) expression increases in the presence of its ligands (e.g., High Mobility Group Box 1, HMGB1) and triggers an inflammatory immune response. In contrast, soluble RAGE (sRAGE) acts as a decoy receptor and downmodulates inflammation. Some studies have demonstrated that decreased sRAGE levels are negatively correlated with disease activity in juvenile idiopathic arthritis (JIA) but expression of mRAGE has not been studied.

**Objectives:** The aim of this study is to evaluate mRAGE and sRAGE on peripheral blood (PB) and synovial fluid (SF) mononuclear cells (MC) of patients with JIA and healthy controls and to assess whether there is an association with established inflammatory markers and clinical measures.

**Methods:** Matching samples of blood and synovial fluid were collected from patients with JIA (n=33) with active arthritis. RAGE expression on mononuclear cells was analyzed using flow cytometry. The intensity of RAGE expression was measured as mean fluorescence intensity (MFI). Levels of sRAGE and HMGB1 were determined with a specific ELISA kit in the serum and synovial fluid (SF) of patients with JIA. Relation between cellular RAGE and sRAGE with disease activity parameters [JADAS71, CHAQ, C reactive protein (CRP) and erythocyte sedimentation rate (ESR)] and HMGB1 were described. We compare mRAGE expression in PBMC and serum sRAGE levels between JIA patients and age-matched healthy controls (n=43).

**Results:** 24 patients with olioarticular JIA and 9 patients with poliartricular JIA were studied, 8/23 females with a mean age of 7.7 ± 3.6. MFI of mRAGE in PBMC and SFMC of JIA patients were significantly decreased in comparison with MFI of mRAGE in PBMC of healthy controls. Although serum levels of sRAGE were not different between patients and controls, sRAGE levels were lower in SF (570.2 [458.5-773.0]) compared to PB (759.7 [628.6-890.3]) in JIA patients, especially in the poliartricular group. By contrast, HMGB1 levels in SF were significantly higher than in PB of JIA patients. MFI of mRAGE in PBMC was correlated with JADAS71 (p 0.01) and CHAQ (p 0.07). There were no significant correlations between serum sRAGE and HMGB1 with JADAS71, CHAQ, CRP and ESR.

**Conclusion:** The sRAGE/RAGE system may be a modulator of inflammation in JIA patients. Differences between levels of sRAGE and HMGB1 in synovial fluid versus peripheral blood in patients with JIA may suggest a local role in the pathogenesis of JIA.

THE IMPACT OF SINGLE NUCLEOTIDE POLYMORPHISMS IN ADORA2A AND ADORA3 ON THE EARLY RESPONSE TO METHOTREXATE AND PRESENCE OF THERAPY SIDE EFFECTS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

**J. Roszkiewicz**, D. Michealek, A. Ryk, B. Szymy, E. Smolewska, J. Medical University of Lodz, Department of Pediatric Cardiology and Rheumatology, Lodz, Poland; Medical University of Lodz, Department of Biostatistics and Translational Medicine, Lodz, Poland; Medical University of Lodz, Department of Pediatrics, Oncology and Hematology, Lodz, Poland

**Background:** Juvenile idiopathic arthritis (JIA) is the most frequent rheumatic disease in children, with an estimated prevalence between 16 and 150 per 100 000 [1]. Methotrexate (MTX) administered at the dose 10-15mg/m² is currently recommended as the first-line treatment in most of JIA subtypes [2]. Despite its widespread use in rheumatology, the mechanism of MTX immunomodulatory action remains incompletely understood [3]. Free adenosine is one of the particles possibly associated with the action of MTX, acting via three types of adenosine receptor: ADORA2A, ADORA2B, and ADORA3 [4].

**Objectives:** The aim of our study was to determine the association between single nucleotide polymorphisms in ADORA2A (rs2236624, rs2293838 and ADORA3 (rs339333) receptors genes and the disease activity and presence of MTX therapy side effects in patients with JIA.

**Methods:** One hundred children with JIA of all subtypes treated with MTX were recruited to the study. Demographic and clinical parameters were collected at the baseline of MTX therapy and on a control visit 4-6 months (median 5.09 months) after starting MTX. The clinical parameters included inflammatory markers values, number of joints with active arthritis, number of joints with restricted range of movement, physician’s global assessment of disease activity, parent/patient global assessment of overall well-being, functional ability (measured by the Childhood Health Assessment Questionnaire – CHAQ) and the value of Juvenile Idiopathic Arthritis Disease Activity Score 71 (JADAS 71). Presence of MTX side effects was evaluated on the control visit. SNP genotyping was performed using genomic DNA isolated from peripheral blood samples.

**Results:** Both polymorphic variants of ADORA2A (rs2236624, rs2293838 - CC/CT) were significantly associated with 3.5 times higher odds of gastrointestinal side effects occurrence (OR: 3.52, 95%CI: 1.12-11.03, p=0.03 and OR: 3.49, 95%CI: 0.89-13.66 p=0.07) after adjustment to age, sex, dose and route of MTX administration. In addition, children with the ADORA3 T-CC/CT after six months of MTX treatment had significantly lower number of joints with active arthritis (0.0 vs 1.0, p=0.04), lower JADAS 71 score (3.0 vs 5.1, p=0.16) and lower value of CRP (0.6 vs 2.4, p=0.02).

**Conclusion:** Although future studies are needed to verify our findings, polymorphisms in ADORA2A and ADORA3 genes may become the determinants of MTX treatment efficacy and gastrointestinal toxicity in children with JIA.

COMPARATIVE GENE PROFILE IN MONOCYTES FROM CHILDHOOD- AND ADULT-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: CLUES TO DIFFERENT SYSTEMIC INVOLVEMENT

**Background:** Objectives: 1. This study, developed within the Innovative Medicines Initiative Joint Undertaking project PRECISESADs framework, aimed at identifying new inflammatory and oxidative stress determinants involved in the enhanced CV-risk present in SLE patients and to analyze the relevance of the sustained positivity for anti-dsDNA on the establishment of their atherothrombotic status.

**Methods:** One hundred and twenty-four SLE consecutive patients (not including patients with associated antiphospholipid syndrome), belonging to the PRECISESADs project, were evaluated for the presence of CVD and its association
with positivity for anti-dsDNA antibodies. A second cohort of 62 SLE patients was included, of which endothelial dysfunction, lipid profile, the presence of atheroma plaques (identified by a pathologic increase in the carotid intima-media thickness – CIMT), and the frequencies of anti-dsDNA positivity for 7 years, were evaluated. Serum inflammatory and oxidative stress biomolecules, and NETosis-derived bioproducts were further evaluated by multiplex assay and specific commercial kits, respectively. Besides, miRNomes were identified using next-generation sequencing. Clinical significance of the biomolecules analyzed was explored by correlation/association studies with immunological and CV-risk features.

Results: A significant relationship among the incidence of CVD (i.e., coronary artery disease or cardiac involvement) and the positivity for anti-dsDNA antibodies was recognized in the first SLE cohort. Accordingly, in the second SLE cohort, significantly impaired micro-vascular endothelial function (identified by reduction of hyperemia post-occlusion area), increased atheregenic index and pathologic increase in the CIMT were assessed in patients positive for anti-dsDNA in relation to anti-dsDNA-negative patients. Around a 65% of SLE patients displayed a sustained positivity for anti-dsDNA antibodies for more than 7 years. These patients showed a distinctive and specific molecular profile compared with patients that had remained negative for anti-dsDNA, including increased inflammatory profile (IL1B, IL2, IL6, IL17, EOTAXIN, FGf, GMCSf, IFNγ, IP10, RANTES, TNF), enhanced oxidative status (lipoperoxides), and higher NETosis (nucleosomes, elastase). Levels of those biomolecules were closely interconnected and associated to their regulatory miRNAs, which accordingly exhibited differential expression in SLE anti-dsDNA(+) vs anti-dsDNA(-) patients. Finally, the frequency for positivity of anti-dsDNA significantly correlated both with markers of endothelial dysfunction and with the presence of atheroma plaques in SLE patients, pointing at the direct involvement of anti-dsDNA-Abs in the development of these processes.

Conclusion: 1: Positivity for anti-dsDNA antibodies confers a specific inflammatory/oxidative profile linked to an enhanced CV-risk in SLE patients. 2. Moreover, the sustained positivity for anti-dsDNA antibodies fosters the establishment of an atherothrombotic status in these autoimmune patients.

FRI0454

UNDER DETECTION OF INTESTITIAL LUNG DISEASE IN JUVENILE SYSTEMIC SCLEROSIS (JSSC) UTILIZING PULMONARY FUNCTION TESTS. RESULTS FROM THE JUVENILE SCLERODERMA INCEPTION COHORT

Background: Juvenile systemic sclerosis (SSc) is an orphan disease with a prevalence around 3 in a million children. Pulmonary involvement in SSc occurs in the majority of the patients (10%–20%) in the inception cohort. Traditionally in SSc pulmonary function testing (PFT) with FVC and DLCO are used for screening and computed tomography (HRCT) was more reserved for those with abnormal PFTs. More recently, it has become apparent that PFTs might not be sensitive enough for detecting ILD in children.

Objectives: Using a prospective international juvenile systemic scleroderma cohort (JSSC) [2], to determine if pulmonary screening with FVC and DLCO is sufficient enough to assess the presence of interstitial lung disease in comparison to CT evaluation.

Methods: The international juvenile systemic scleroderma cohort database was queried for available patients with recorded PFT parameters and HRCT performed to determine sensitivity of PFTs detecting disease process.

Results: Of 129 patients in the JSSC, 67 patients had both CT imaging and an FVC reading from PFTs for direct comparison. DLCO readings were also captured but not in as many patients with tandem HRCT (n = 55 DCLO and HRCT scan). Therefore, initial analyses focused on the sensitivity, specificity and accuracy of the FVC value from the PFTs to capture the diagnosis of interstitial lung disease as determined by HRCT.

Overall, 49% of the patients had ILD determined by HRCT, with 60% of patients having normal FVC (>80%) with positive HRCT findings, and 24% of patients having normal DCLO (>80%) with positive HRCT findings. Fourteen percent (n = 3/21) of patients with both FVC and DLCO values within the normal range had a positive HRCT finding.

Conclusion: The sensitivity of the FVC in the JSSC cohort in detecting ILD was only 39%. Relying on PFTs alone for screening for ILD in juvenile systemic sclerosis would have missed the detection of ILD in almost 2/3 of the sample cohort, supporting the use of HRCT for detection of ILD in children with SSc. In addition, the cut off utilized, of less than 80% of predicted FVC or DLCO could be too low for pediatric patients to exclude beginning ILD. This pilot data needs confirmation in a larger patient population.

FRI0455

IS THERE AN INCREASE IN THE FREQUENCY OF INFAMMATORY DISEASES IN THE FAMILIES OF PATIENTS WITH FMF?

S. Yildirim1, M. Yildiz2, A. Aliyeva3, F. Haslak1, O. Koker1, A. Adrovic1, S. Sahin1, K. Barut1, O. Kasapcopur2, I. Istanbul University-Cerrahpasa, Pediatric Rheumatology, Istanbul, Turkey

Background: Familial Mediterranean Fever (FMF) is the most common periodic fever syndrome in childhood with an autosomal recessive inheritance pattern and is characterized by unprovoked fever attacks, serositis episodes. The causative gene of the disease is MEFY that encodes pyrin protein. The pyrin protein takes a role in pathways related to inflammation, and mutations of it lead to increased inflammation. It is already shown that frequencies of some certain diseases like PAN, HSP increase in patients with FMF. Nevertheless,
frequencies of inflammatory diseases in families of patient with FMF haven't been investigated.

**Objectives:** In this study, we have aimed to evaluate the comorbid disorders in a large cohort of families of patients with FMF.

**Methods:** Four hundred and ninety-eight children with FMF, one hundred and forty patients with JIA and ninety-two healthy children were interviewed between December 2019 and January 2020. In JIA group and healthy control group, patients who have family history for FMF were excluded from the study. Patients were asked about characteristics of their disease attacks and if there is a relative with any inflammatory diseases who does not have FMF in patient's 1st and 2nd degree relatives.

**Results:** Demographic features of study group have shown in Table 1. The most common MEFV mutations in patients with FMF were: M694V homozygotes (13.2 %), M694V heterozygotes (12 %), M694V homozygotes and R202Q homozygotes (6.8 %). Type II diabetes, asthma and hypothyroidism were the most commonly detected diseases in all cohorts. Frequency of Behçet's disease, allergic rhinitis and type II diabetes were significantly higher in families of patients with FMF than other groups (p<0.05) (Table 2).

†Familial Mediterranean Fever ††Juvenile idiopathic Arthritis "Erysipelis like erythema"

**Conclusion:** In this study, we have reported increased frequencies of Behçet's disease, allergic rhinitis and type II diabetes in families of patients with FMF. Our results suggest that possible increased mutation load among families of patients with FMF may cause increased inflammatory diseases.

Background: Tumour necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is one of the best-known monogenic auto-inflammatory disorders resulting from an autosomal dominant variation in the TNF superfamily receptor 1A (TNFRSF1A) gene. (1).

Objectives: To define best treatment approach in patients with TRAPS and effect on long-term outcomes.

Methods: We reviewed data on patients with TRAPS enrolled in the Eurofever international registry according the INSaID gene variant classification and the new Eurofever/PRINTO classification criteria (EPCC).

Results: Data on 226 patients were available. Patients not fulfilling the EPCC carrying likely benign/benign variants (21 patients, 9%) or VOUS/not classified variants (40 patients, 18%) displayed a milder disease than the patients fulfilling the EPCC with VOUS/not classified variants (38 patients, 17%) or pathogenic/likely pathogenic variants (127 patients, 56%). In particular, in patients not fulfilling the EPCC, less frequent abdominal pain and skin rashes, higher efficacy rate of colchicine and no development of AA amyloidosis have been reported. Almost 90% of patients fulfilling the EPCC required maintenance therapy and anti-inflammatory (IL)-1 drugs were the most frequently used, with the highest efficacy rate (>85% complete response), while Etanercept was less effectively used and discontinued in 65% of patients.

Conclusion: Anti-IL-1 drugs are the best maintenance treatment in TRAPS with potential to reverse the most serious disease complications of AA amyloidosis and infertility. The diagnosis of TRAPS should be considered very carefully in patients carrying VOUS/not classified variants not fulfilling the EPCC.

**Background:** Juvenile dermatomyositis (JDM) is a systemic, autoimmune inflammatory muscle disorder and vasculopathy that affects children younger than 18 years. Although the cause of JDM remains unknown it is clear that genetic and environmental influences play a role in the aetiology. New treatments are becoming available and being tested through international multicentre trials. Increasing evidence suggests a role for types I and II IFN in juvenile and adult dermatomyositis, including elevated IFN-response gene signatures in the muscle, skin and blood. It has recently been reported that patients with refractory JDM responded well to treatment with tofacitinib, a JAK inhibitor, with corresponding downregulation in selected IFN-response genes.

**Objectives:** In this study, we evaluated our cases with resistant JDM who received tofacitinib treatment.

**Methods:** Six patients who received tofacitinib because of severe skin involvement of JDM were included in the study. The data were obtained retrospectively from the hospital records.

**Results:** The age ranges of the cases were between 7-17 years and the ratio of girls and boys was 1 (3/3). The age of diagnosis was between 2-13 years, and the follow-up period was between 3-9 years. Calcinosis cuts in 5 cases, decreased muscle strength in 3 cases, joint involvement in 4 cases were detected. Systemic steroids, methotrexate, and non-steroid anti-inflammatory drugs were given in all cases before tofacitinib treatment. Pamidronate was used in 4 cases because of severe skin calcinosis, high dose intravenous immunoglobulin in 4 cases, myophenoliate monitir in 3 cases, rituximab in 3 cases and cyclophosphamide in 1 case previously. Tofacitinib treatment (10mg/gün) was started in six cases with treatment-resistant JDM. Five cases had been treated with tofacitinib for 6-24 month intervals. The treatment was discontinued in one case because of severe allergic reaction. Variable level of improvement were detected in the skin findings of all cases during the therapy period. The treatment was interrupted for 1 month in only one case due to neutropenia.

**Conclusion:** Tofacitinib seems to be an effective and safe treatment option in patients with JDM who are resistant to conventional treatments. More studies are needed on this subject.

**FRI0460 SAFETY OF BIOLOGICAL AGENTS IN JUVENILE IDIOPATHIC ARTHRITIS: A META-ANALYSIS OF OBSERVATIONAL STUDIES**

N. Cabrera1, G. Avila1, A. Belot2, J. P. Larbre3, G. Cathellivel3, E. Paredes4, B. Kassai6, A. Berard1, S. Mainbourg7, J. C. Lega1.

1University Lyon 1, Laboratoire de Biométrie et Biologie Evolutive, Lyon, France; 2Universidad Nacional de Asunción, Department of Research, San Lorenzo, Paraguay; 3Hospital Woman Mère Enfant - HCL, Department of Paediatric Rheumatology, Bron, France; 4Lyon Sud Hospital Center, Department of Rheumatology, Pierre-Bénite, France; 5Universidad Nacional de Asunción, San Lorenzo, Paraguay; 6University Lyon 1, Department of Pharma-Toxicology, Lyon, France; 7Lyon Sud Hospital Center, Department of Internal and Vascular Medicine, Pierre-Bénite, France

**Background:** Follow-up cohorts (observational studies) were initiated consecutively or simultaneously to the development of randomised controlled trials (RCTs) in JIA patients 1-5. They help to identify many complications observed only in clinic practice related to off label use, coadministration of treatments, drug misuse, delayed or interrupted or incomplete vaccination schedule, and due to using of immune-modulating drugs, e.g. systemic corticosteroids (CS), methotrexate (MTX) and biologics. Data presented with median and 25%-75%.

**Objectives:** To estimate the incidence of serious adverse events (SAEs) including serious infections, malignancies, and death in patients with juvenile idiopathic arthritis (JIA) treated with biological agents (BAs) in daily clinical practice using meta-analysis techniques.

**Methods:** We systematically searched, up to May 2019, Medline and Embase databases for observational studies performed in JIA disease under BA treatment. Outcomes were SAEs, serious infections, malignancies and all-cause mortality. Complementary, the incidence of SAEs in randomised controlled trials (RCTs) with withdrawal and parallel designs was performed by meta-analysis.

**Results:** A total of 31 observational studies were included (6811 patients totalising 17530 patients-years [PY] of follow-up). The incidence rate of SAEs was similar in observational cohorts and withdrawal RCTs (4.46 events per 100 PY, 95% CI 2.85-6.38, I²=95%) and 3.71 events per 100 PY (95%CI 0.0-13.34, I²=56%), respectively. The incidence of SAE was lower in parallel RCT. The incidence rate of serious infections, malignancies and death in observational cohorts was estimated at 0.74 events per 100 PY (95%CI 0.32-1.30, I²=83%), 0.10 events per 100 PY (95% CI 0.06-0.16, I²=0%), and 0.09 events per 100 PY (95% CI 0.05-0.14, I²=0%), respectively. Infections were the known cause of death in 8 of the 14 deaths. In meta-regression and subgroup analysis, variation of serious infections rates were partially explained by follow-up time (R²= 30.3%, p= 0.0008), JIA categories (all JIA versus polyarticular versus systemic JIA categories, p= 0.001) and cohort quality (Newcastle-Ottawa score ≥ 6 versus ≤ 5 stars, p= 0.0025).

**Conclusion:** Our results suggest that the incidence rate of SAEs related to BAs in JIA disease is similar to those observed in randomised withdrawal trials. The overall incidence remained low. However, unsatisfactory description of SAEs prevents analysis of hospitalisation causes. Infection and, to a lesser extent, cancer and death, explain only part of burden of BAs.

**FRI0461 THE ANTI-VACCINE ANTIBODY AGAINST MEASLES, PAROTITIS, RUBELLA, DIPHTHERIA AND HEPATITIS B IN 170 JUVENILE IDIOPATHIC ARTHRITIS PATIENTS**

N. Lybimova1, I. Fridman2, O. Goleva3, R. Raupov3, M. Kaneva3, S. Khan3,3, M. Kostil1,3,1Almazov National Medical Research Centre, Saint Petersburg, Russian Federation; 2Pediatric Research and Clinical Center for Infection Diseases, Saint-Petersburg, Russian Federation; 3Saint-Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation

**Background:** Patients with juvenile idiopathic arthritis (JIA) may have lower protective levels of anti-vaccine antibodies due to high inflammatory activity, interrupted or incomplete vaccination schedule, and due to using of immune-modulating drugs, e.g. systemic corticosteroids (CS), methotrexate (MTX) and biologics.

**Objectives:** The aim of our study was to find the predictors of low levels of anti-vaccine antibodies in patients with JIA.

**Methods:** In the present study were included data 170 JIA (55 boys and 115 girls) aged from 2 to 17 years, who received scheduled vaccination before the age of 2 years and before JIA onset against measles, parotitis, hepatitis B, diphtheria and rubella. In all patients the Ig G against-vaccine antibodies levels were detected with ELISA. In each patient we evaluate the type of the disease (oligoarthritis - 73, polyarthritis - 61, systemic-16 and enthesis-related arthritis - 20), onset age, presence of uveitis, duration of JIA, treatment with corticosteroids (CS), methotrexate (MTX) and biologics. Data presented with median and 25%-75%.

**Results:** The main demographic characteristics: age of inclusion in the study 11.4 (76-14.8) years, disease onset – 6.0 (3.7-9.0) years, disease duration – 3.8 (1.9-6.5) years. Treatment with CS was in 43 (25.3%), MTX in 154 (90.6%) and biologics 82 (48.2%) patients, among them 53 had TNFa-inhibitors. More than 1 biologic consequently received 16/62 (19.5%) patients. Protective levels of anti-measles antibodies was in 98 (57.6%) of all JIA population, anti-parotitis – 136 (80.0%), anti-hepatitis B – 85 (50.0%), anti-diphtheria – 88 (51.7%), anti-rubella – 167 (98.8%). Data of vaccination status and anti-vaccine antibodies levels in the table. In univariate and multivariate regression analysis the main risk factors for anti-measles antibodies levels were MTX using (p=0.045), more than 1 biologics (p=0.0004); for anti-hepatitis B – MTX (p=0.03), for anti-diphtheria antibodies: onset age (p=0.0002), JIA duration (p=0.0007), number vaccine doses (p=0.02), more than 1 biologics (p=0.01); combined treatment with biologics and other drugs (MTX or CS).

---

**Scientific Abstracts**

Friday, 05 June 2020
Conclusion: MTX, biologics and JIA durations are factors influenced on anti-vaccine antibody level. It is necessary to regularly check the levels of anti-vaccine antibodies, especially anti-measles and anti-diphtheria for creation of the individual vaccination plan for JIA patients, treated with MTX and biologics.

FR0462 PREDICTIVE FACTORS OF RELAPSE AFTER METHOTREXATE DISCONTINUATION IN JIA PATIENTS WITH INACTIVE DISEASE

S. Azevedo1, J. Tavares-Costa1, A. T. Melo2, R. Freitas3, M. Cabral2, M. Conde5, F. Aguiar5, A. F. Mourão6, F. Oliveira-Ramos2, M. J. Santos2, D. Peixoto1, F. Consolar4, Canhão H 20, Can methodology (RF), antinuclear and cyclic citrullinated peptide antibodies), MTX dose, discontinuation modality (tapering and spacing the doses or just tapering the dose), extra-articular manifestations, previous corticotherapy, family history, body mass index, JADAS, CHAQ index, inflammatory parameters, tender and swollen joint counts at MTX initiation or discontinuation nor with age at remission or at MTX suspension. Median persistence in inactive disease was significantly higher in patients with more than two years in remission before MTX discontinuation (p=0.034) and in those who did not use NSAIDs at time of MTX discontinuation (p=0.026)(Fig 2).

After adjustment for age at diagnosis, MTX tapering and JIA category, use of NSAIDs at the time of MTX discontinuation (HR, 1.98 95%CI 1.03-3.82) and less than two years in remission (HR, 3.12 95%CI 1.35-7.13) remained associated with relapse.

Conclusion: In this large cohort we found that the use of NSAIDs at the time of MTX discontinuation was associated with two times the likelihood of relapse. Like in other studies we also showed that the time in remission before MTX discontinuation is the main predictor of relapse. We found no association between the JIA category and the risk of relapse.

REFERENCES:
Background: Macrophage activation syndrome (MAS) is a severe, potentially life-threatening complication of systemic juvenile idiopathic arthritis (SJIA). However, early recognition of MAS remains challenging. Because it is clinically heterogeneous, hemophagocytosis is often not detected, and histopathological features lack the specificity associated with hemophagocytic syndromes. In addition, it is often difficult to distinguish early MAS from SJIA or sepsis-like syndromes.

Objectives: To identify early clinical and laboratory characteristics of MAS associated with SJIA.

Methods: This is a retrospective cohort study of 149 SJIA patients treated at the Children’s Hospital of Zhejiang University School of Medicine between January 2010 to December 2017. All patients fulfilled 2001 ILAR criteria for SJIA, and 27 fulfilled 2016 Classification Criteria for MAS. We evaluated the clinical and laboratory features of SJIA patients with MAS and compared them to those without MAS. We focused our analysis on early MAS, which was defined as the time when the initial clinical and/or laboratory abnormalities suggestive of MAS were first detected.

Results: The clinical features associated with early MAS were hypotension, absence of arthritis and lymphadenopathy, bone marrow hemophagocytosis, central nervous system dysfunction, and gastrointestinal involvement. The best laboratory parameters for early MAS detection were platelet counts ≤275.0 $\times$ 10^9/L, lactate dehydrogenase >596.0 U/L, aspartate aminotransferase >470 U/L, erythrocyte sedimentation rates ≤41.0 mm/hr, ferritin >1400.0 ng/mL, D-dimer >1.40 mg/mL, triglyceride >1.30 mmol/L, alanine aminotransferase >33.0 U/L, C-reactive protein ≤68.0 mg/L, fibrinogen ≤9.8 g/L, and white blood cell counts ≤9.8 $\times$ 10^9/L. The combination of cytokines of IFN-γ >17.1 pg/mL and IL-10 >7.8 pg/mL were found to be a specific and good prognostic cytokine pattern for early recognition of MAS, the sensitivity and specificity as 71.4% and 98.2%.

Conclusion: Sudden hypotension, absence of arthritis, and significantly increased IFN-γ and IL-10 levels are important clinical and laboratory markers for early MAS identification in addition to the traditional features of SJIA-associated MAS.

Genotyping and phenotyping patterns in patients with CAPS in Russian Federation

Background: Cryopyrin-associated periodic syndromes (CAPS) are a group of rare congenital auto-inflammatory diseases (AID) that include diseases such as familial cold auto-inflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and CINCA/NOMID syndrome. At present, there are limited data on demographic and clinical features of children with CAPS in Russia.

Objectives: To reveal demographic, genotype and phenotype characteristics in CAPS patients at the National Medical Research Center of Children’s Health, Moscow, Russian Federation; Biostatistics and Clinical Trials Center, Novosibirsk, Russian Federation

Methods: Retrospective study included 12 patients (7 females, 58.3%) with CAPS confirmed by next generation sequencing (NGS). Median age of disease onset was 8.7 (interquartile range (IQR) 0.5–12.8) years. Characteristics of disease onset as well as dynamics of disease activity during long-term treatment were evaluated.

Results: At the onset, systemic features were as follows: fever in 11 (91.6%) patients, rash in 8 (66.7%), hepatosplenomegaly in 7 (58.3%) patients, and lymphadenopathy in 6 (50%). Active arthritis in the onset of the disease was in 9/12
patients (75%), presented by polyarthritids in 7/9 (77.8%), and oligoarthritis in 2/9 (22.2%). Two patients (16.7%) had cataract, one (8.3%) had bilateral uveitis, and one (8.3%) had optic atrophy. Sensorineural hearing loss was observed only in 3/12 (25%). Hydrocephalus was detected in 3/12 (25%). Delayed mental and psycho-speech development was observed in 6/12 (50%) patients. In 3/12 (25%), the development of MAS was recorded.

All patients had nucleotide variants in NLRP3 gene. According to NGS results and clinical characteristics, 8/12 (66.7%) patients were diagnosed with MWS and 4/12 (33.3%) had CINCA/NOMID syndrome. In patients with MWS, heterozygous variant c.2113C>A in NLRP3 gene was the most common (5/8 (62.5%) patients). One of 8 (12.5%) patients with novel heterozygous variant c.2861C>T was detected; also one (12.5%) have heterozygous variant c.943A>G. Four patients with CINCA/NOMID syndrome also had heterozygous variants in NLRP3 gene: c.5898G>A, c.2173C>A, c.1919T>C and c.796C>T.

Prior to genetic testing, 12/12 (100%) patients received NSAIDs; 6/12 (50%) were treated with methotrexate. Biologics treatment included: 5/12 (41.7%) CAN, and 4/12 (33.3%) tocilizumab, and 1/12 (8.3%) etanercept. After genetic testing, 7/12 (58.3%) patients were successfully switched to CAN. Only 1/12 (8.3%) child with MWS developed secondary inefficiency on CAN treatment.

Conclusion: Systemic manifestations were detected in 91.6% of children, while active arthritis was observed in 75% of patients, which can cause difficulties in the diagnosis and treatment of CAPS. The effectiveness of canakinumab therapy was estimated in 91.6% of patients. The most frequent variant of the NLRP3 gene in MWS was c.2113C>A. In patients with CINCA/NOMID syndrome nucleotide variants were individual.

TOFACITINIB POPULATION PHARMACOKINETICS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A POOLED ANALYSIS OF DATA FROM THREE CLINICAL STUDIES

C. Yong, X. Wang, A. Hazra, A. Mukherjee, T. Nicholas, C. Chang, Pfizer Inc, Cambridge, MA, United States of America; 2Pfizer Inc, Groton, CT, United States of America

Background: Tofacitinib is an oral JAK inhibitor that is being investigated for juvenile idiopathic arthritis (JIA).

Objectives: To describe tofacitinib pharmacokinetics (PK) in patients with JIA, identify potential covariates accounting for variability in exposure, assess the formulation effect of oral solution vs tablet and propose a simplified dosing regimen.

Methods: This was a pooled analysis of data from 3 tofacitinib clinical studies in patients with JIA aged 2—<18 years: a Phase 1, open-label (OL), non-randomised study (NCT01513902); a Phase 3, randomised, double-blind, placebo-controlled, withdrawal study (NCT02592434); and an OL long-term extension study (NCT01500551). Tofacitinib was dosed at 5 mg twice daily (BID) in patients ≥40 kg or at body weight (BW)-based lower doses BID in patients <40 kg, to achieve average trough plasma concentrations (C0) comparable with those in patients receiving 5 mg BID. A sparse PK sampling scheme was applied, and the plasma samples were assayed using a validated, sensitive and specific high-performance liquid chromatography tandem mass spectrometric method (lower limit of quantification =0.100 ng/mL). A nonlinear mixed-effects modelling approach was used for the population PK model, and population parameter variability was assumed to be log-normally distributed. Covariates relating to patient demographics and disease characteristics, concomitant medications and formulation (oral solution vs tablet) were selected using a stepwise covariate modelling approach, and parameter-covariate relationships were evaluated using stepwise forward-inclusion (p<0.05) backward-deletion (p>0.001) procedures. The effect of time-varying BW on oral clearance (CL/F) and apparent volume of distribution (V/F) was characterised using an allometric model. Final model quality was assessed by Visual Predictive Checks (VPDCCs).

Results: Of 246 patients in the analysis, 74.0% were female; 87.8% were white, 2% were black, 10.2% were ‘other’ races and no patients were Asian. Median (range) BW was 46.3 (11.1—121.8) kg. Initially, 100 patients received oral solution and 146 patients received tablets; 11 patients switched formulations during the studies. A one compartment disposition model with first-order absorption and a lag time sufficiently described the data. Final estimates for CL/F and the first-order absorption rate constant (k0) for tablets were 26.1 L/hr, 89.2 L and 2.78 hr-1, respectively. The only statistically significant covariate was a formulation effect on k0. All parameters were estimated adequately. Estimated allometric exponents were 0.310 for CL/F and 0.537 for V/F. Absorption was described with an estimated lag time of 0.168 hr, and the oral solution had a 164-fold faster absorption rate than the tablet. VPCs sufficiently described the observed data over time, across BWs and ages. Given the PK characterisation and variability in patients with JIA, a simplified dosing scheme was proposed, targeting C0 values equivalent to those in patients receiving 5 mg BID: 3.2 mg BID solution in patients 10—<20 kg; 4 mg BID solution in patients ≥20 kg; and 5 mg BID tablet or solution in patients ≥40 kg. Conclusion: Tofacitinib population PK in patients with JIA were adequately described by a one compartment model parameterised in terms of CL/F, V/F and first-order absorption with a lag time. Drug absorption from the oral solution was faster than from the tablet. Tofacitinib does not require dose modification or restrictions for any covariates, except BW, to account for differences in C0. Based on the results of this analysis, a simplified BW-based dosing regimen was proposed.

FR10466

NO DISEASE PROGRESSION AFTER 36 MONTHS FOLLOW UP IN THE JUVENILE SYSTEMIC SCLERODERMA INCEPTION COHORT

J. Foeldvari, J. Klotsche, O. Kasapcopur, A. Adrovic, M. T. Terner, R. Chimaz, M. Katsikas, D. Nemcova, M. J. Santos, J. Brunner, M. Kostik, K. Minden, A. Patwardhan, K. Tokor, N. Helimus, 1Hamburg Centre for Pediatric and Adolescence Rheumatology, Hamburg, Germany; 2German Rheumatism Research Center, Berlin, Germany; 3JSSc Collaborative Group, Hamburg, Germany

Background: Juvenile systemic sclerosis (JSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children. There is rare longitudinal prospective follow up data of patients with JSSc. In the international juvenile systemic scleroderma cohort (JSSCC) patients are followed with a standardized assessment prospectively.

Objectives: To assess the changes regarding organ involvement pattern and patients related outcomes after 36 months follow up in the JSScc.

Methods: Patients diagnosed according the ACR 2013 criteria for systemic sclerosis were included, if they developed the first non-Raynaud symptom before the age of 16 and were under the age of 18 at the time of inclusion. Patients were followed prospectively every 6 months with a standardized assessment.

Results: 39 patients in the JSScc had 36 months follow up. 80% had a diffuse subtype. 96% of the patients were Caucasian origin. 31 of the patients were female (80%). Mean disease duration at time of inclusion was 3.5 years. Mean age onset of Raynaud's was 8.8 years and mean age of onset at the first non-Raynaud’s was 9.5 years. Around 30% of the patients were anti-Scl70 positive and none of them anti-centromere positive. The MRSS dropped from the time of the inclusion into the cohort from 13.9 to 11.8 after 36 months. Pattern of organ involvement did not show any significant change, beside the increase of the hand and foot capillary changes from 49% to 73% (p=0.037). No renal crisis occurred. No mortality was observed. They were positive significant changes in the patient related outcomes. The physician global disease activity decreased from 40.0 to 22.1 assessed on a VAS scale of 0 to 100 (p<0.001).

Conclusion: After 36 months follow up, we could observe a significant improvement of patient related outcomes and only one significant change in organ pattern involvement. In a mostly diffuse subset patient population this is a very promising result regarding outcome.

DOI: 10.1136/annrheumdis-2020-eular.2271

Background: Biological treatment (BT) has changed perspectives of JIA patients. Increasing data from real life experience have been reported.

Objectives: To compare drug survival, safety and efficacy of BT in patients with Juvenile Idiopathic Arthritis (JIA).

Methods: A retrospective observational study was conducted on JIA patients followed in a referral hospital and who had received at least one BT between 1999 and 2019.

Results: 218 BT in 130 JIA patients were analyzed. 67.7% were women with a median age at diagnosis of 8 years old IQR (3-13) and a median age at the beginning of the BT of 15 years old IQR(7.8-21). 21.5% of the patients had uveitis during follow-up. BT were indicated due to: arthritis(73.9%), uveitis(10.1%), arthritis and uveitis(2.7%), systemic activity(6.3%) and macrophage activation syndrome(1.8%). There were 130 BT started in 1st line, 55 in 2nd line, 20 in 3rd line, 10 in 4th line and 3 in 5th line.

The 1st line BT most frequently indicated was Etanercept(ETN) up to 40%, followed by 30% Adalimumab(ADA) and 16.2% Infliximab(INF). The median duration of the 1st line was 51 months IQR (14-109.3). However, 53.8% of the 1st line BT were switched: 28.3% due to adverse events, 25.7% due to 1st failure and 25.7% due to 2nd failure. The BT that were discontinued were: INF(76.2%) and Anakinra (ANAK) (75%) due to adverse events and ETN (59.6%) due to 1st and 2nd failure. 43.6% received ADA and 20% Tacilizumab (TCZ) with a median duration of 43 months IQR (12-90). 22 of 55 BT required a change: 75% of ETN and 59% of INF prescribed in 2nd line were discontinued. The causes were: 40% 1st failure, 28% 2nd failure and 12% remission. In 1st line 87.6% of patients received TNF inhibitors, 74% maintained the target in 2nd line. In 3rd line TCZ was the most frequent BT. 71.5% of patients continue on BT. BT was withdrawn in 20 of 130 patients due to remission (40%), adverse events (30%), and pregnancy (10%).

In the analysis by decades, 80 BT (36.7%) were started from 1999 to 2008 and 138 BT (63.3%) from 2009 to 2019. In the 1st decade ETN and INF were the most frequently prescribed and in the 2nd decade, ADA and TCZ (p <0.0001). The 1st BT in the 2nd decade were indicated sooner compared to the 1st decade: mean 119.5 months IQR(109.2); 2nd decade: mean 53.9 months IQR(99.7); p <0.0001). In 1st line BT, the BT prescribed in the 2nd decade had a shorter duration than those in the 1st decade (1st decade: mean 84.1 months SD(71.8); 2nd decade: mean 51.7 months SD(5); p <0.0001).

In the survival analysis, TCZ and ADA were the BT with the highest survival (p<0.0001). Of the 31 patients that started TCZ, 61.3% continue on TCZ, with a median duration of 46 months IQR(25-59) and 36/68(52.9%) still on ADA with a median duration of 61.5 months IQR(30.5-98).

Conclusion: 42.3% of patients required more than one BT. Since the onset of the BT there has been a change in prescription, probably related to the emerge of new targets and the evidence provided by clinical trials and guidelines. TCZ and ADA were the BT with the highest survival rate. On the other hand, INF and ANAK were the ones with the lowest survival rate. The most common causes of BT change in 1st line were adverse events in relation to INF and ANAK. In 2nd line there was a high rate of change in those patients who maintained TNF, related to 1st failure.

**SYSTEMIC AND CUTANEOUS POLYARTERITIS NODOSA IN COLOMBIAN PEDIATRIC PATIENTS: CUTANEOUS POLYARTERITIS IS NOT SO BENIGN**

A. Medina1, M. Calle2, R. Eraso1,2,4, L. Hernandez1,2,4, S. J. Peinado Acevedo1,2, M. Velasquez1, A. Vanegas1,2,3, D. Jaramillo Arroyave1,2,4, C. Muñoz1,2,5,6

1Universidad de Antioquia - Departamento de Pediatría, Medellín, Colombia; 2Universidad de Antioquia - Grupo de Estudio de Vascularis Sistémicas, Medellín, Colombia; 3Hospital Pablo Tobón Uribe, Medellín, Colombia; 4Universidad de Antioquia - Grupo de Reumatología, Facultad de Medicina. Departamento de Medicina Interna, Medellín, Colombia; 5Universidad de Antioquia - Grupo de Estudio de Vascularis Sistémicas, Medellín, Colombia; 6Hospital Universitario San Vicente Fundacion, Hospital Infantil, Medellín, Colombia; 7Hospital Universitario San Vicente Fundacion, Medellin, Colombia; 8IPS Universitaria - Servicios de Salud - Universidad de Antioquia, Medellín, Colombia

Background: Polyarteritis nodosa (PAN) is the third most frequent vasculitis in pediatrics, Cutaneous PAN (CPAN) being more common that Systemic PAN (SPAN). CPAN is frequently described as a benign disease. In children, PAN onset is frequent between 9 and 11 years of age, with no sex differences, and its clinical features may be nonspecific.

Objectives: To characterize pediatric patients who were diagnosed with CPAN and SPAN and to compare their clinical features, treatments, and outcome.

Methods: A descriptive study was conducted in two centers from Medellin- Colombia, using retrospect data from January 2010 to December 2019. Patients under 18 years of age classified as PAN according to EULAR/PRINTO/ PRES(1) criteria were included. CPAN patients were defined according to EULAR/PRINTO/PRES definition (2). Data from medical records were registered, and were expressed in median and ranges and mean and standard deviation (SD) according to their distribution. A univariate analysis was carried out by comparing signs, symptoms, and treatment between CPAN and SPAN, and a p-value <0.05 was considered as significant.

Results: Twenty patients were included. The median age at diagnosis was ten years. 60% were boys. The median follow-up period was 27 months. CPAN was diagnosed in 11 (55%) and SPAN in 9 patients (45%). The most frequent symptoms were cutaneous manifestations (95%), fever (60%) and Calf Pain (55%). Mucosal ulcers were described in four patients; 3 of them were defined as CPAN. Lingual necrosis was present in two CPAN, and peripheral nervous system involvement was found in one SPAN and two CPAN patients in skin affected with lesions; even though, no significant statistical differences between CPAN and SPAN were found in constitutional, cutaneous, muscle-skeletal manifestations and acute phase reactants. Artiographic anomalies as hepatic and renal microaneurysms, carotidal aneurysms without aortic involvement, and renal infarction were found in one patient each. Skin Biopsy was performed in 18 patients, being compatible with PAN in 16. All CPAN patients (CPAN and SPAN) required treatment with glucocorticoids. None of the patients died during the follow-up period.

Conclusion: In this Colombian pediatric cohort of PAN patients, the disease was more common in boys than girls, and CPAN was more frequent than SPAN, as already been described. As is evident in this cohort, although CPAN has been considered a benign disease, these patients may be severely ill, requiring glucocorticoid treatment. Pediatric CPAN patients should be strictly followed with particular attention to identify systemic involvement, considering that constitutional, cutaneous, and muscle-skeletal features may be very similar between CPAN and SPAN.

FR10469

**TO DISTINGUISH BETWEEN DISEASE FLARE AND ACTIVE INFECTION IN PEDIATRIC SYSTEMIC LUPUS ERYTHEMATOUSUS (SLE)**

K. L. Lu1, J. H. Lee2, B. L. Chiang3, 1National Taiwan University Children's Hospital, Taipei, Taiwan, Republic of China; 2National Taiwan University Children's Hospital, Taipei, Taiwan, Republic of China

Background: SLE is the autoimmune disease involving multiple systems. Infections might mimic SLE flare, leading to confusion over the diagnosis and appropriate treatment. To distinguishing acute infection from active flare always remains a clinical challenge.

Objectives: We aim to explore the potential parameters in identifying active infection and disease activity in pediatric SLE.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.4655
Methods: We reviewed the medical charts of the pediatric SLE patient in National Taiwan University Hospital from August 2015 to September 2019, and 50 SLE patients presented 185 episodes of suspicious activity or infection and received CRP, ESR, and Procalcitonin measurement were included. Time-matched other laboratory parameters and clinical assessments were also collected. Episodes were divided into 4 groups: infected-active, infected-inactive, noninfected-active, and noninfected-inactive. Association of parameters with outcomes were predicted by generalized estimating equation. The receiver operating curve and the area under the curve were used to evaluate the diagnostic performance. We also used multinomial logistic regression model for nominal outcome, by setting noninfected-inactive group as the reference category.

Results: There were 7 males (14%) and 43 females (86%), with the mean ages 13.9 ± 4.4 years old. Most of the patients had renal (72%) or mucocutaneous (72%) involvement. The most common infection site was respiratory system (56%). Multivariate GEE analysis showed Damage index(DI), SLEDAI-2k, neutrophil-to-lymphocyte ratio (NLR), hemoglobin, platelet, RDW-to-platelet ratio (RPR), and C3 are independent parameters for predicting SLE activity flare. Combination of these seven parameters resulted in a model with calculated AUC of 0.8964 and with sensitivity of 82.2 % and specificity of 90.9%. Multivariate GEE analysis showed DI, fever, CRP, Procalcitonin, lymphocyte percentage, NLR, hemoglobin, and renal score in SLEDAI-2k are independent parameters for predicting acute infection. These eight parameters resulted in a model with calculated AUC of 0.7886 and with sensitivity of 63.5% and specificity of 89.2%. We selected a total of 10 variables (DI, SLEDAI-2k, Fever, Procalcitonin, lymphocyte percentage, NLR, hemoglobin, platelet, RPR, C3) to establish multinomial logistic regression, then predict four groups with accuracy of 70.13% for infective judgement and treatment decisions for SLE patients.

Other orphan diseases

F. Allhaz-Oner1, R. Ergelen1, Y. Yildiz1, A. Yazio1, M. Aldaq2, A. Cefle2, B. Artim-Esen3, G. Mumcu3, T. Ergin3, H. Direskeneli4. 1Marmara University, School of Medicine, Rheumatology, Istanbul, Turkey; 2Kocaali University, School of Medicine, Kocaeli, Turkey; 3Bahceciyeh University, Cardiovascular Surgery Department, Istanbul, Turkey; 4 Istanbul University, Istanbul Medical School, Istanbul, Turkey; 5Marmara University, Health Science Faculty, Istanbul, Turkey; 6Marmara University, School of Medicine, Istanbul, Turkey

Background: Diagnosing Behcet’s disease(BD) is a challenge, especially in countries with a low prevalence. International Study Group Criteria, accepted to as diagnostic has low sensitivity, especially in early cases when major organ involvement such as uveitis or deep vein thrombosis(DVT) presents alone. We recently published a controlled study of assessing venous wall thickness(VWT) as a surrogate marker of venous disease in BD with ultrasound(US) and observed a very sensitive and specific VWT in male BD patients. The common femoral vein(CVF) thickness measurement, as the primary site of US with the cut-off values > 0.48-0.49 mm, had a high area under the receiver operating characteristic curve(>0.8) with sensitivity and specificity of around 80%(1).

Objectives: In this study, we aimed to investigate the diagnostic performance of CVF thickness measurement in BD including females comparing with multiple control disease groups.

Methods: One hundred-ten patients with BD, 47 healthy controls(HC), 21 patients with systemic vasculitides, 28 patients with venous insufficiency,29 patients with antiphospholipid syndrome (APS) having DVT history, were included the study. Bilateral CVF thickness was measured with US by an experienced radiologist blinded to cases(Figure 1).

FRIDAY, 05 JUNE 2020

ASSSESSMENT OF FEMORAL VEIN WALL THICKNESS WITH DOPPLER US AS A DIAGNOSTIC TOOL FOR BEHÇET’S DISEASE

Science Abstracts
Results: Bilateral CFV thickness was significantly higher in BD compared to all comparative groups (p<0.001 for all)(Table 1,Figure 2). No correlations were present between CFV thickness and both BSAS and CRP levels (p>0.05 for all). In only 2 (8%) patients with venous insufficiency and 2 (10%) patients with systemic vasculitis, bilateral CFV thickness was higher than the cut-off values. Interestingly, APS was the only control group with positivity, in 12 (41%) patients with APS, bilateral CFV thickness was higher than the cut-offs. There was no difference between male vs female BD patients regarding CFV thickness (right CFV:0.78 ± 0.3 vs 0.79 ± 0.3, p=0.96, left CFV 0.78 vs 0.8, p=0.80). Although a higher CFV thickness tendency was observed in VBD, no statistically significant difference was present between BD patients with (n=40) and without (n=58) vascular involvement (right CFV 0.82±0.3 mm vs 0.75±0.3 mm, p=0.122, left CFV 0.84 ± 0.3 vs 0.76±0.3, p=0.165).

Figure 2. Distribution of common femoral vein thickness in study groups

Conclusion: Increased CFV thickness is present in BD patients, independent of vascular involvement. We also found that CFV thickness is a distinctive feature of BD, rarely present in other inflammatory/vascular diseases such as ankylosing spondylitis (previously shown), systemic vasculitides and venous insufficiency (except APS with DVT). CFV thicknesses are easily and reliably measured by Doppler US. We, therefore, suggest that assessment of CFV can be a diagnostic tool for BD with a good specificity and sensitivity to differentiate BD from similar disorders.

FRI0474 IMMUNE CHECKPOINT INHIBITOR-INDUCED MUSCULOSKELETAL MANIFESTATIONS. A SYSTEMATIC REVIEW

F. Angelopoulos1, I. Antonopoulou1, D. Bogdanos2, T. Dimitroulas3, L. Sakkas3, D. Daoussis1.
1University Hospital of Patras, Department of Rheumatology, Patras, Greece; 2General University Hospital of Larissa, Department of Rheumatology, Larissa, Greece; 3Aristotle University of Thessaloniki, Department of Rheumatology, Thessaloniki, Greece

Background: Immune checkpoint inhibitors (ICIs) are potent anti-cancer drugs that associate with a wide range of immune related adverse events (Ir-AE), including musculoskeletal manifestations.

Objectives: We performed a systematic literature review of ICI-induced musculoskeletal manifestations aiming at exploring the following: 1) the prevalence of these manifestations and the time from first ICI administration to symptom onset, 2) the main clinical phenotypes and the type of treatment required to control symptoms (steroids/DMARDs), 3) the type of ICI (CTLA-4 vs PD-1/PD-L1 inhibitors) mostly associated with Ir-AE, 4) the percentage of patients with positive auto-antibodies and family history of autoimmune disease, 5) the percentage of patients requiring permanent ICI discontinuation due to musculoskeletal Ir-AE, 6) the association between musculoskeletal Ir-AE and oncologic response and 7) the risk of flare in patients with pre-existing autoimmune disease (PAd).

Methods: An electronic (PubMed) search was performed aiming at identifying all studies reporting musculoskeletal Ir-AE.

Results: We identified 3 prospective studies, 17 retrospective studies and 4 case series reporting 363 patients in total. Combined data from all 3 prospective studies provide a prevalence rate of 6.13%. Most patients were males (59.68%) and the vast majority (73%) were on programmed death-1 (PD-1)/programmed death ligand-1 (PD-L1) inhibitors. Most studies report a median time of ≥12 weeks from first ICI administration to symptom onset. The main clinical phenotypes reported were: a) inflammatory arthritis (57.57%), b) myositis (14.04%), c) polyarthritis (0.28%), and d) polyarthritis (12.12%). A total of 256 patients required steroids (70.52%) and 67 patients (18.45%) were treated with DMARDs. From the 363 patients reported in total, 265 (73%) were treated with PD-1/PD-L1 inhibitors in sharp contrast to only 11 (3.03%) with CTLA4 inhibitors with the rest patients receiving combination immunotherapy Positive auto-antibodies and family history of any autoimmune disease were present in 18.48% and 19.04% of cases, respectively. Only a few patients (19%) had to discontinue treatment due to musculoskeletal Ir-AE. Two prospective studies show that significantly more patients with musculoskeletal Ir-AE exhibit a favorable oncologic response compared to patients not exhibiting such manifestations whereas retrospective studies show that 77.22% of patients with musculoskeletal Ir-AE have a good tumor response.

Conclusion: One out of 15 patients treated with ICI will develop musculoskeletal Ir-AE; in most cases the severity of these manifestations is mild/moderate and usually Ir-AE is continued. Rheumatologists should familiarize themselves with this new clinical entity and develop relevant therapeutic algorithms.

FRI0475 STEROID SPARING AGENTS IN POLYMYALGIA RHEUMATICA: A SYSTEMATIC REVIEW

S. Banerjee1,2, K. Chaudhuri3, A. Desai3, M. Krishna3, N. Gulllick3. 1University Hospitals Coventry and Warwickshire, Rheumatology, Coventry, United Kingdom; 2Edge Hill University, Omskirk, United Kingdom; 3University Hospitals Coventry and Warwickshire, Coventry, United Kingdom

Background: Polymyalgia rheumatica (PMR) is the commonest chronic inflammatory musculoskeletal disease of the elderly. The mainstay of treatment for PMR is long term systemic glucocorticoid (GC), which is associated with significant systemic toxicity. There is a need for steroid sparing drugs in PMR to reduce GC cumulative dose and GC induced adverse effects.(1)

Objectives: To evaluate the role of steroid sparing agents in PMR.

Primary outcomes:
1. Steroid sparing effect of the intervention, measured by difference in cumulative glucocorticoid dose.
2. Percentage of patients in remission.

Secondary outcomes:
1. Mean reduction of CRP/ESR
2. Adverse event/toxicity the drugs being compared—measured as number of patients with adverse events in the compared groups
3. Percentage of patients with relapse during study period
4. Mortality

Methods: Electronic databases including Medline, Embase and Cochrane databases (CENTRAL) were searched since inception for prospective and retrospective, non-randomized trials, comparing disease modifying anti-rheumatic drugs (DMARDs) and biologics with systemic GC in PMR, published in English with more than 20 patients and a minimum study duration of 24 weeks. As different classification criteria for PMR exist, studies were included if they used any accepted classification criteria for PMR. Case series, case reports, retrospective, non-randomized trials, abstracts, systematic reviews and non English language trials were not included. Patients with Giant cell arteritis (GCA) were excluded. Risk of bias and quality was assessed using the Cochrane tool. The studies were assessed for cumulative GC dose, proportion of patients in remission, proportion of patients with relapse, reduction in inflammatory markers, adverse events and mortality.

Results: 5 studies were selected for final review—3 studies involving Methotrexate, one study on azathioprine, one on infliximab. The study on Azathioprine...
had high risk of bias, small sample size and low quality (Level 2 evidence) with high attrition rate but it revealed reduction of daily prednisolone with Azathioprine. A high quality RCT (Level 1) did not confirm a steroid sparing effect with Infliximab vs placebo, and there was no significant difference between relapse or remission rate. Methotrexate studies showed conflicting results: one high quality RCT (Level 1) and one low quality RCT (Level 2) on Methotrexate revealed statistically significant steroid sparing effect, however the remaining study did not demonstrate between Methotrexate and placebo. Two methotrexate studies assessed the risk of relapse, with conflicting results (relapses 73% placebo vs 47% methotrexate; or no difference).

Methotrexate was not associated with increased adverse effects in any of the studies. Azathioprine was associated with significant adverse events resulting in high attrition.

A meta analysis was not performed for methotrexate as the studies were heterogenous.

Conclusion: There is a lack of evidence regarding DMARDs and biologics in PMR. Methotrexate is an effective steroid sparing agent, and is not associated with increased adverse events. Azathioprine may be effective but is associated with significant adverse events. Infliximab is not an effective steroid sparing agent in PMR. More high quality RCTs are needed to study the efficacy of steroid sparing agents.

Objectives: To describe the serological features associated with long-lasting and severe Rh-iRAEs.

Methods: ICI-treated patients were identified. Patients’ demographics, histotype of cancer, ICI, time interval from ICI start to Rh-iRAE onset, characteristics of Rh-iRAEs were recorded. Patients were tested for autoimmunity panel (a-IP): RF, ACPA, ANA, anti-ssDNA, anti-SBB, anti-Sm, anti-RNP, anti-Jo1, ANCA, ASCA, AMAs, anti-citrullinated protein, anti-BCRF1, IgM and IgG anti-cardiolipin and anti-β2-glycoprotein I, cryoglobulins. All patients were treated with steroids (CS), in case of flare of the Rh-iRAE, csDMARDs or bDMARDs were started. Associations between a-IP status and need for DMARD start was evaluated. No parametric tests were used.

Results: 22 Rh-iRAE were included (see Table 1). Median age at Rh-iRAE onset was 70 (50 – 84) years. 2 patients (9%) had a personal history of psoriasis. Median time from ICI start to Rh-iRAE onset was 5 (1 – 26) months. Median time from ICI start to Rh-irAE was 10 (4.5 – 21) months. 11 patients (50%) developed a-IP+; a-IP was started upon steroids tapering. 9 patients (41%) were treated with methotrexate (MTX, 4, 18.2%) with hydroxychloroquine (HCQ, 2, 9.1%) with mycophenolate (MMF, 2, 9.1%) with colchicine (colch). 6 patients were treated with bDMARDs. 3 patients (50%) were treated with anakinra (ANK), 2 (33.3%) with IVIG and 3 (50%) with tocilizumab (TCZ). 13 patients (51.9%) were a-IP+. A significantly higher percentage of a-IP+ patients received DMARDs (11, 84.6%) compared to a-IP- patients (2, 22.2%, p = 0.0007). A significantly higher percentage of a-IP+ patients were treated with bDMARDs (7, 58.3%) compared to a-IP- patients (0, 0%, p = 0.05). A significantly higher percentage of a-IP+ patients (4, 66.6%) were treated with csDMARDs. A significantly higher percentage of a-IP+ patients (6, 75%) were treated with csDMARDs. A significantly higher percentage of a-IP+ patients (6, 75%) were treated with bDMARDs. 6 patients was higher in a-IP+ but we found no statistical significance (45.4% vs 0%, p = 0.487).

Conclusion: The presence of serological autoimmunity might be helpful in detecting patients with Rh-iRAEs refractory to steroid therapy.

DOI: 10.1136/annrheumdis-2020-eular.3827
Background: Histiocytoses are disorders characterized by tissue infiltration by macrophages, dendritic cells, or monocyte-derived cells. These diseases are classified in five groups based on histologic, clinical, and molecular features: Langerhans-related, cutaneous/mucocutaneous and malignant histiocytoses, Rosai-Dorfman disease, and hemophagocytic lymphohistiocytosis (1). Langerhans-related histiocytoses comprise Langerhans cell histiocytosis and Erdheim-Chester disease, both inflammatory myeloid-driven diseases characterized by clonal activating mutations along the MAPK or related pathways, most commonly BRAFV600E, and by severe tissue and systemic inflammation (2). Here, we describe and characterize a novel, related histiocytosis chiefly manifested with severe synovial involvement. 

Objectives: Here, we describe a novel histiocytosis whose histologic and clinical picture (severe synovial involvement, systemic inflammation, skin lesions, and diabetes insipidus) differed from known histiocytic disorder. In addition, we performed molecular studies aimed at identifying causative activating mutations. Finally, by means of a dynamic 3D tissue culture system we characterized immune-metabolic mechanisms underlying disease pathogenesis and clinical response to treatment.

Methods: The mutational status of oncogenes was determined with a mass spectrometry multiplexed genotyping approach (PentaPanel). Bioispy samples were cultured in RCCSTM bioreactor (Synthecos) in the presence/absence of a MEK inhibitor (GSK1220212, 1nM), and then either processed for immunohistochemical analyses, or lysed for western blot analysis. Culture supernatants were collected for cytokine, chemokine and metabolome determination. The Bio-Plex Multiple-Cytokine Assay (Bio-Rad) and the Ella assay (ProteinSimple) were used to determine cytokine concentrations in supernatants and serum, respectively. Metabolomic studies were performed as described (3).

Results: We identified a causative mutation in the proto-oncogene KRAS (KRASG12D, not previously reported in related histiocytoses). In addition, 3D culture studies of patient’s biopsies revealed KRAS-driven signaling, phenotypic, and immunometabolic features. These included constitutive ERK and AKT phosphorylation, up-regulated glucose metabolism with glycolysis and TCA cycle activation, and deregulated release of pro-inflammatory cytokines IL-1β, IL-6 and TNFα. All these features reverted upon pharmacologic inhibition of the MAPK pathway. Characterization of this novel condition instructed effective treatment of the patient with the MEK inhibitor cobimetinib.

Conclusion: Genetic, clinical, and histopathology features differentiate this condition from known histiocytic disorders. Mechanistically, KRASG12D causes constitutive activation of the MAPK pathway in macrophages, which results in maladaptive changes in cell energy metabolism sustaining rampant production of pro-inflammatory cytokines. Besides instructing effective treatment of this patient, these studies revealed metabolic rewiring as key to pathologic inflammatory activation of macrophages in human disease.

A bDMARD was initiated in 15 patients. In 7 of the 14 patients initially treated with anakinra this therapy was continued with benefit whereas in the other 7 patients the treatment was discontinued for primary inefficacy (1 patient), secondary inefficacy (3 patients) and adverse events (3 patients; 2 injection site reaction, 1 severe allergic reaction). After anakinra discontinuation, 5 patients were treated with canakinumab with a good response in 3 cases and a partial response in 1 case (persistent arthritis); 1 patient died during the treatment. No response was observed in 3 patients treated with TNF inhibitors as a 2nd or 3rd line bDMARDs, as well as in 1 case initially treated with tocilizumab (in which a good response was afterwards obtained with canakinumab). bDMARDs were associated with a csDMARD in 2 patients (methotrexate and methotrexate + cyclosporine).

In one case monoclonal gammapathy evolved into Multiple Myeloma and the patient died 15 years after the onset of symptoms. Idiopathic myelofibrosis and myelodysplasia were found in one and in two patients, respectively.

Conclusion: In most cases csDMARDs and bDMARDs like anti-IL6 and anti-TNFα were not able control the disease. In contrast, in some cases, a good response to colchicine was observed; refractory patients may be successfully treated with anti-IL1 agents. Patients should be supervised for possible evolution towards lymphoproliferative disease.

present work aims to obtain clinical and analytical data that can guide us to an etiological diagnosis.

**Objectives:** To describe and identify the differences between HPS secondary to AID and HOD during their admission to a tertiary hospital between 2005 and 2019.

**Methods:** This is a retrospective observational study. We include patient meeting the diagnostic criteria for HLH proposed by Henter JI. (1), or who presented haemophagocytic cells (HC) in the bone marrow biopsy (BMB), or who had HPS in the hospital discharge report. Demographic, clinical, analytical, etiological, underlying disorders and prognosis variables were collected. Continuous variables are described with the mean or median according to the degree of normality. Kruskal Wallis, Fisher test and Mann-Whitney U test were used for the bivariate analysis, and also a multivariate logistic regression analysis was performed.

**Results:** We found 30 patients with secondary HPS, 22 of which corresponded to the AID [Systemic Lupus Erythematosus (n=5)], Adult Still’s Disease (n=3), Rheumatoid arthritis (n=1) and IgG4 Sclerosing Disease (n=1)] and HOD [Non-Hodgkin’s Lymphoma (n=3), Myelodysplastic syndrome (n=3), Acute leukemia (n=3), Extranodal NK cell lymphoma (n=1), Multiple Myeloma (n=1) and probable lymphoproliferative process (n=1)]. The coincidence of an infectious disease with HPS was observed in 8 of the 22 cases [AID: 5 cases (2 Cytomegalovirus, 2 viral respiratory infections and 1 bacterial infection) and HOD: 3 cases (2 Epstein Barr virus and 1 bacterial infection)]. In two patients with HPS secondary to HOD (acute leukemia), allogeneic transplantation was associated as a possible trigger. In a patient with myelodysplastic syndrome, HPS was associated with the development of graft versus host disease. The age at diagnosis was lower in the AID [40 (26.5 - 56.3); p=0.001]. The HOD had more severe cytopenias [platelets 4500 (650 - 15,750; p=0.009), leucocytes 2050 (20 - 728; p=0.0001) and neutrophils 0 (0 - 280; p=0.002)]. Overall mortality (n=30 patients) was 43.3% (HOD: 40 (26.5 - 56.3); p=0.001). In the final multivariate model according to AID and HOD, the following independent associations were observed: age (p=0.002), platelets (p=0.031), GOT (p=0.012), GPT (p=0.015), total proteins (p=0.007) and mortality (p=0.007).

**Conclusion:** The HOD presented higher mortality and severe cytopenias. The AID presented a higher elevation of transaminases and better prognosis.

Background: Familial Mediterranean Fever (FMF), which is more common in groups in the Mediterranean basin, is a monogenic autoinflammatory disease characterized by recurrent attacks of febrile peritonitis, pleuritis and arthritis.

Objectives: In this study, we aimed to investigate the clinical, demographic and genotypic features that may be associated with subclinical inflammation in FMF and to determine the related parameters with subclinical inflammation.

Methods: FMF patients according to the Tel-Hashomer criteria were included into the study. The demographic characteristics of the patients, duration of the disease, concomitant diseases, MEFV genotype mutation, colchicine use and resistance were collected. Acute-phase reactants such as white blood cell count, erythrocyte sedimentation rate, and C-reactive protein levels during the attacks and attack-free periods were noted. Subclinical inflammation was defined as the continuation of the acute phase response (CRP) between episodes during attack-free periods. Subclinical inflammation was closely monitored for subclinical inflammation even during attack-free periods. Concomitant disease should be detected in FMF patients with subclinical inflammation.

Results: Eighty patients (72.5% female) with mean age 37.1 ± 11.2 years were recruited into the study. Twenty-three (28.7%) patients were determined as the continuation of the acute phase response (CRP) between episodes (Group 1 and Group 2, respectively) and these group parameters were compared with the parameters described above. Patients with infectious symptoms, family history of FMF, response to colchicine, attack time, attack in the last 6, delay in diagnosis parameters were not significantly different between groups (p > 0.05).

Conclusion: FMF patients whose elevated erythrocyte sedimentation rate and MEFV homozygous mutation should be closely monitored for subclinical inflammation even during attack-free periods. Concomitant disease should be detected in FMF patients with subclinical inflammation.

Disclosure of Interests: None declared.

SAFETY PROFILE, CLINICAL AND RADIOLOGICAL EFFICACY OF ANAKINRA, TARGETED AND COMBINED TREATMENT IN ERDHEIM-CHESTER DISEASE

N. Farina1, C. Campochiaro2, A. Tomelleri3, G. De Luca1, G. Cavalli1, L. Dagna1.
1IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy

Background: Erdheim-Chester disease (ECD) is a rare non-Langerhans histiocytosis. Combined treatment with anakinra (ANK) and targeted MAPK-inhibiting therapies ( vemurafenib – VMF - or cobimetinib - CBM) has been recently used to treat severe cases of ECD.

Objectives: To evaluate the safety and the clinical and radiological efficacy of ANK, targeted and combined treatments in ECD patients in a real-world setting.

Methods: ECD patients followed at our Center who received at least one targeted therapy and/or ANK were selected. Data about disease characteristics, adverse reactions, clinical and radiological efficacy (by means of CT, CT/PET, MRI when appropriate and repeated 6 months apart) were collected.

Results: Among the 48 ECD patients followed up at our Center, 27 were treated with at least one drug between VMF and CBM, accounting for a total of 22 and 10 therapy courses respectively. 12 patients were treated with ANK as monotherapy or combination treatment (a total of 17 therapy courses). Disease characteristics and adverse reactions to the treatments are shown in Table 1. All 3 drug proved to have a high clinical efficacy (Table 2). No patient treated with VMF or CBM showed radiological progression neither discontinued treatment due to inefficacy. Conversely, 75% of patients receiving ANK monotherapy showed radiological progression neither discontinued therapy and/or ANK were selected. Data about disease characteristics, adverse reactions, clinical and radiological efficacy (by means of CT, CT/PET, MRI when appropriate and repeated 6 months apart) were collected.

Results: Among the 48 ECD patients followed up at our Center, 27 were treated with at least one drug between VMF and CBM, accounting for a total of 22 and 10 therapy courses respectively. 12 patients were treated with ANK as monotherapy or combination treatment (a total of 17 therapy courses). Disease characteristics and adverse reactions to the treatments are shown in Table 1. All 3 drug proved to have a high clinical efficacy (Table 2). No patient treated with VMF or CBM showed radiological progression neither discontinued treatment due to inefficacy. Conversely, 75% of patients receiving ANK monotherapy showed radiological progression at imaging re-staging and inefficacy was the main discon- tinuation cause. ANK showed the lowest incidence of adverse reactions. Drug toxicity was instead the only reason for discontinuation of targeted monother- apies. The combined approach had a clinical efficacy in all cases and it was always associated with imaging improvement. One patient treated with ANK and CBM discontinued the therapy due to drug-related toxicity. No patient receiving both VMF and ANK experienced drug-related toxicities; in these patients ANK led to a reduction in mean acute phase reactants levels and concomitant prednisone dose (Figure 1).

Conclusion: Combined treatment had a higher clinical and radiological efficacy than ANK monotherapy and led to a reduction in targeted therapies-related toxicities, acute phase reactant levels and concomitant prednisone dose.

Methods: We retrospectively reviewed the records of 527 patients with a first diagnosis of IPF between January 2007 and March 2014, and investigated the length of time from first visit to the clinic for IPF diagnosis (baseline) to CTD diagnosis by an expert rheumatologist in patients with IPF. Multivariable Cox proportional-hazards models with backward elimination were used to investigate the risk factors for the development of CTD.

Results: CTD developed in 15 patients at a median of 2.1 years (range 1.2 to 4.8) after IPF diagnosis. All these patients had ANCA or autoantibodies that met the serology criteria for IPAF. A significant number of IPF patients with high titers of RF, ACPA or MPO-ANCA tested at first visit to the clinic progressed to CTD (Figure 1). Survival duration for IPF patients with progression to CTD was 5.3 [3.8; 6.7] years, which was significantly longer than for the IPF patients without progression to CTD (2.9 [1.7; 4.8], p = 0.001). Independent risk factors for development of CTD in IPF patients included female gender (adjusted hazard ratio (HR) 5.319, p = 0.0082), titer of rheumatoid factor (RF) (adjusted HR 1.006, p = 0.022), titer of anti-citrullinated protein antibody (ACPA) (adjusted HR 1.009, p = 0.0011), and titer of myeloperoxidase (MPO) ANCA (adjusted HR 1.02, p < 0.0001).

Background: Connective tissue disease (CTD) may be observed during the course of idiopathic pulmonary fibrosis (IPF). However, clinical factors associated with the development of CTD in patients with IPF have not yet been identified. These factors might be valuable clues for determining the pathogenesis of pulmonary fibrosis in patients with CTD. We hypothesize that some IPF patients have a clinically significant association with autoimmunity, and that autoantibodies are important biomarkers for identifying these patients.

Objectives: Based on this hypothesis, we investigated whether the serology criteria (anti-neutrophil cytoplasmatic antibody (ANCA) or autoantibodies that met the serology criteria for interstitial pneumonitis with autoimmune features (IPAF)) were associated with the development of CTD during the clinical course of IPF in the patients from our previous study(1), with a particular focus on which antibodies have a significant association with the development of CTD.

Methods: We retrospectively reviewed the records of 527 patients with a first diagnosis of IPF between January 2007 and March 2014, and investigated the length of time from first visit to the clinic for IPF diagnosis (baseline) to CTD diagnosis by an expert rheumatologist in patients with IPF. Multivariable Cox proportional-hazards models with backward elimination were used to investigate the risk factors for the development of CTD.

Results: CTD developed in 15 patients at a median of 2.1 years (range 1.2 to 4.8) after IPF diagnosis. All these patients had ANCA or autoantibodies that met the serology criteria for IPAF. A significant number of IPF patients with high titers of RF, ACPA or MPO-ANCA tested at first visit to the clinic progressed to CTD (Figure 1). Survival duration for IPF patients with progression to CTD was 5.3 [3.8; 6.7] years, which was significantly longer than for the IPF patients without progression to CTD (2.9 [1.7; 4.8], p = 0.001). Independent risk factors for development of CTD in IPF patients included female gender (adjusted hazard ratio (HR) 5.319, p = 0.0082), titer of rheumatoid factor (RF) (adjusted HR 1.006, p = 0.022), titer of anti-citrullinated protein antibody (ACPA) (adjusted HR 1.009, p = 0.0011), and titer of myeloperoxidase (MPO) ANCA (adjusted HR 1.02, p < 0.0001).

Conclusion: We observed development of CTD in IPF patients with ANCA or autoantibodies that met the IPAF serology criteria. Among these autoantibodies, RF, ACPA, and MPO-ANCA were significantly associated with the development of CTD in IPF patients. Progression to CTD is uncommon in IPF patients, but a significant number of IPF patients with high titers of RF, ACPA or MPO-ANCA progressed to connective tissue disease. IPF with high titers of RF, ACPA or MPO-ANCA might be the initial clinical manifestation of connective tissue disease. Further studies are needed to investigate the role of RF, ACPA, and MPO-ANCA in development of pulmonary fibrosis.

Figure 1. Connective tissue disease development in each autoantibody positive IPF patient. ACPA = anti–citrullinated protein antibody; ANA = antinuclear antibody; CTD = connective tissue disease; MPA = microscopic polyangiitis; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; RF = rheumatoid factor; UCTD = Undifferentiated connective tissue disease; SS = Sjögren’s syndrome.

Figure 1. Mean acute phase reactant levels and concomitant prednisone dose in Erdheim-Ches- ter disease patients treated with vemurafenib before and after the initiation of anakinara.
Background: Autoinflammatory periodic fever syndromes characterized by excessive interleukin(IL)-1b release and severe systemic and organ inflammation have been successfully treated with the anti-IL-1 inhibitor canakinumab (CAN). In clinical trial situations and real life, rapid remission of symptoms and normalization of laboratory parameters were observed in most patients.1-3

Objectives: The present study explores long-term effectiveness and safety of CAN under routine clinical practice conditions in pediatric and adult patients with CAPS (cryopyrin-associated periodic syndromes), FMF (familial Mediterranean fever), TRAPS (tumor necrosis factor receptor-associated periodic syndrome) and HIDS/MKD (hyperimmunoglobulinemia D syndrome/mevalonate kinase deficiency).

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a 3-year follow-up period. Pediatric (age ≥2 years) and adult patients with clinically confirmed diagnoses of CAPS, FMF, TRAPS and HIDS/MKD that routinely receive CAN are enrolled in order to evaluate effectiveness and safety of CAN in clinical routine.

Results: This first interim analysis of patient subgroups diagnosed with FMF, HIDS and TRAPS includes baseline data of 41 patients (10 TRAPS, 2 HIDS, 29 FMF), including preliminary 6-month data of a FMF-subset (N=16).

**APREMILAST IN MONOTHERAPY OR COMBINED IN NON-ULCER MANIFESTATIONS OF BEHÇET’S DISEASE. NATIONAL MULTICENTER STUDY OF 34 REFRACTORY CASES OF CLINICAL PRACTICE**

Background: Apremilast (APR) has demonstrated efficacy in orogenital ulceration of Behçet’s disease (BD). Response of other clinical manifestations remains unknown.

Objectives: To assess the efficacy and safety of APR in monotherapy or combined with disease-modifying anti-rheumatic drugs (DMARDs) in non-aphthous ulcers of BD.

Methods: National multicenter open-label study on 34 BD patients treated with APR at maintained standard dose of 30 mg twice daily.

Results: From a cohort of 51 patients with APR by refractory orogenital ulcers of BD, we selected 34 (24 women/10 men, mean age 43.8±14.3 years), cases with another clinical manifestation/s.

Excluding CTs, colchicine or NSAIDs, APR was given in monotherapy (n=21) or combined with conventional and/or biologic DMARDs in 13 cases (5 methotrexate, 3 azathioprine, 3 hydroxychloroquine, 1 sulfasalazine, 1 dapsone, 2 tocilizumab, 1 IFX). Other active manifestations present at APR onset were: arthralgia/ arthritis (16, true arthritis in 5), folliculitis/pseudofolliculitis (14), erythema nodosum (3), furunculosis (2), paradoxical psoriasis by TNF (2), intestinal ileitis (2), deep venous thrombosis (2), leg ulcers (1),

**CLINICAL AND LABORATORY FEATURES OF PATIENTS WITH REMITTING SERONEGATIVE SYMMETRICAL SYNOVITIS WITH PITTING EDEMA COMPARED TO PATIENTS WITH SERONEGATIVE RHEUMATOID ARTHRITIS**

M. Higashida-Konishi1, K. Izumi1, S. Hama1, Y. Hayashi1, Y. Okano1, H. Oshima1, 1National Hospital Organization Tokyo Medical Center, Department of Connective Tissue Diseases, Tokyo, Japan

**Background:** In the case of seronegative arthritis, it was difficult to make a differential diagnosis between remitting seronegative symmetrical synovitis with pitting edema syndrome (RS3PE) and seronegative rheumatoid arthritis (seronegative RA) because the distribution of affected joints was similar and the patients with RS3PE or seronegative RA may have edema.

**Objectives:** To compare the clinical characteristics of RS3PE and seronegative RA.

**Methods:** We retrospectively examine consecutive patients diagnosed with RS3PE or seronegative RA in our hospital from 2007 to 2019. Patients in whom both ACQA and RF were negative were included. The patients with RS3PE met the criteria of McCarty et al.: (1) pitting edema of the dorsum of both hands and both feet, (2) sudden onset of polyarthritis, (3) seronegative for ACQA and RF, (4) no radiologically evident erosions developed. The patients with seronegative RA met the EULAR/ACR 2010 criteria. The patients who were diagnosed with RS3PE at first and then diagnosed with seronegative RA afterward were included in seronegative RA group. The first analysis was performed on the affected joints, (CRP, ESR, Hb, LDH, edema, the history of malignancy 2 years before and after the diagnosis, treatment, and the history of infection requiring hospitalization after the start of treatment. The affected joints were shoulders, elbows, wrists, finger joints (the MCP and PIP joints), hips, knees, ankles, and toe joints (the MTP and PIP joints). The secondary analysis was performed on the above evaluations with a propensity score (PS) matching for age.

**Results:** In the first analysis, 20 patients with RS3PE and 122 patients with seronegative RA were enrolled. The mean ages (RS3PE, seronegative RA) were 81.1, 67.4 years old. Females were 60.0%, 63.1%. The mean observation period was 25.4, 63.6 months. The proportion of affected joints were shoulders...
phage activation syndrome (MAS) is sHLH in the context of rheumatology and autoimmunity. Secondary HLH (sHLH) presents in children or adults, and macrophage activation syndrome (MPS) presenting with fever, cytopaenia and multi organ failure, is more likely than seronegative RA. RS3PE had higher levels of CRP, ESR, MMP-3, 742.5 and 633.8 ng/mL (p = 0.14). The proportion of patients with high LDH levels (>222 U/L) was 13.6% and 9.0% (p = 0.028). The proportion of patients having the history of malignancy was 20.0%, 8.2% (p = 0.10). The patient treated with prednisolone as the initial treatment was 100% and 41.0%; the mean dose was 14.3 and 9.9 mg/d. After the start of treatment, the proportion of infection requiring hospitalization was 20.0 and 3.28% (p = 0.002).

In the secondary analysis with PS, 17 patients with RS3PE and 17 patients with seronegative RA were enrolled. The mean ages were 80.4, 78.9 years old. Females were 52.9, 76.4%. The affected joints with difference were elbows (11.8, 35.3%; p = 0.10), wrists (82.4, 100%; p = 0.06), and finger joints (82.4, 100%; p = 0.06). The mean levels of HB at diagnosis was 10.4, 11.4 mg/dL (p = 0.01). The proportion of patients having the history of malignancy was 23.5% and 0% (p = 0.03). After the start of treatment, the proportion of infection requiring hospitalization was 23.8% and 0% (p = 0.03).

Conclusion: When the ankles are affected and edema is observed, RS3PE is more likely than seronegative RA. RS3PE had higher levels of CRP, ESR, and LDH. The proportion of anemia was higher in RS3PE. The proportions of ferritin >10,000μg/L was observed in 100%, 17.21% (p <0.0001). The mean levels of the following parameters were higher in 34.2% male. 47.4% died within one year of ferritin >10,000μg/L. One patient was diagnosed with Adult Onset Still's Disease. Of the remainder, 73% had risk factors for sHLH.

Accurate assessment of sHLH incidence was not possible due to incomplete data, particularly triglycerides, fibrinogen, and BMA. AST is not routinely collected in PHT, therefore ALT was used for audit. Within these limits, fifteen patients had a probability >1% of sHLH, and five had a probability >50%. Only one patient had confirmed haemophagocytosis on BMA, and was treated for sHLH with oral steroids in addition to usual care.

Conclusion: Although only one patient had confirmed sHLH on BMA, five patients had a >50% probability of sHLH despite missing parameters for the HScore. It can be seen that potential cases of sHLH might easily be missed. Using a lower level ferritin cut-off for inclusion may have led to an even higher number of potential sHLH cases in our adult patient population. We suggest that sHLH should be considered as a plausible diagnosis in patients with raised ferritin, cytopaenia or organ failure. Local education work is planned to raise awareness of these learning points.

FRI0490 INVESTIGATING THE ROLE OF IL-THETA IN PATHOGENESIS OF BEHÇET’S DISEASE

G. Keskin1, M. Erkoç2, E. Ozbek3, K. Kose4, U. Olmez5, 1Ibn Sinan University Hospital, Immunology, Ankara, Turkey, 2Ibn Sinan University Hospital, Immunology, Ankara, Turkey, 3Ibn Sinan University Hospital, Ankara, Turkey

Background: Behçet’s disease (BD) is a chronic inflammatory disease that may involve many systems including mucocutaneous, vascular, articular, gastrointestinal, neurological and cardiopulmonary systems. Although the pathogenic mechanisms of BD remain unclear, increased release of proinflammatory cytokines and chemokines may play a role in inflammatory stages of the disease.

Objectives: IL-1 theta is a member of IL-1 family. A variety of tissue cells, such as endothelial cells, keratinocytes, dendritic cells macrophages, B cells can produce IL-1 theta under the stimulation of pro-inflammatory factors. Several studies have shown that IL-1 theta can promote the production of proinflammatory cytokines. In this study, we investigated the relationship between serum IL-1 theta levels and disease activity and clinical findings of BD.

Methods: 59 patients with BD (48 female, 11 male) and 20 healthy controls (17 female, 3 male; mean age 41.0 ± 9.3 years) were enrolled in this study. Thirty five patients were in active stage (mean age; 40.3 ± 11.0 years, median disease duration 7 years) and 24 patients were in inactive stage (mean age; 42.9 ± 13.2 years, median disease duration; 8 years). Serum IL-1 theta levels were evaluated by ELISA.

Results: The mean serum IL-1 theta levels were 8.65 ± 4.41 pg/mL in patients with BD and 3.9 ± 2.54 pg/mL in healthy controls. The mean serum IL-1 theta levels were 10.34 ± 5.52 pg/mL in active patients with BD and 6.92 ± 2.43 pg/mL in inactive patients with BD. Serum IL-1 theta levels were significantly high in active Behçet’s patients compared with inactive Behçet’s patients (p<0.01) and the controls (P>0.001).

Serum IL-1 theta levels were significantly higher in the presence of neurological, vascular and mucocutaneous involvement in subgroup analysis according to the clinical findings of Behçet’s patients. IL-1 theta levels were negatively correlation with Platelet count and ESR (r=0.332 p=0.050, r=0.382 p=0.024 respectively).

There was no statistically significant difference between IL-1 theta levels disease duration, and CRR
Conclusion: In this study, we demonstrated that serum IL-1 theta levels were significantly elevated in patients with BD. The high levels of serum IL-1 theta, in active and inactive patients with BD suggest that IL-1 theta may play a significant role in the pathogenesis of BD.

FR0491
IS THERE A RELATIONSHIP BETWEEN VOGT-KOYANAGI-HARADA AND INFLAMMATORY RHEUMATOID DISEASES
S. B. Koca1, M. Kay2, S. Guven3, Z. Ayhan4, A. O. Saat5, F. Onen6, I. Sari7,
1Dokuz Eylei University Faculty of Medicine, Rheumatology, Izmir, Turkey;
2Dokuz Eylul University Faculty of Medicine, Ophthalmology, Izmir, Turkey;
Ege University Faculty of Medicine, Ophthalmology, Izmir, Turkey

Background: Vogt-Koyanagi-Harada Disease (VKHD) is a systemic autoim- mune disease characterized by bilateral granulomatous panuveitis associated with systemic symptoms, including neurological, dermatological and audiovestibular systems. Due to its systemic nature, it may accompany with other autoimmune conditions. However, there is a considerably limited number of reports on the association of VKHD and rheumatoid diseases.

Objectives: To investigate the relationship between VKHD and inflammatory rheumatoid diseases.

Methods: Patients who had bilateral granulomatous uveitis and fulfilled the 2001 revised diagnostic criteria for VKHD were included in our study. All patients were systematically reviewed in terms of the presence of any rheumatological mani- festations including connective tissue diseases, spondyloarthritides (SpA), vasculitis, Behcet’s disease and sarcoidosis.

Results: Demographic findings: There were fifteen patients in the study (86.7%, female), the mean age at diagnosis was 31.2 ± 11.1 years. Comorbidities: Six patients (4 hashimoto thyroiditis, 2 diabetes mellitus) had comorbid diseases. Rheumatological findings: Mechanical back pain in 4 patients, 1 patient had morn- ning stiffness without any other SpA related features; 2 patients had inflammatory arthritis in small joints, 4 patients had sicca symptoms, 1 patient had arthritis in knee joint, 3 patients had oral aphthae and 1 patient had photosensitivity. Laboratory tests and autoantibodies: The acute phase reactants were within nor- mal ranges. The mean CRP value at the time of diagnosis was 2.7 ± 3.2 mg/L and ESR was 14.4 ± 9.2 mm/H. HLA test: HLA-B27 was negative in all patients. HLA-B51 and B18 were positive in 2 patients. MPO-ANCA was positive in one patient.

Conclusion: In this study, we showed that VKHD patients may have increased and high levels of alexithymia. Most adult patients with JIA (86.4%) have elevated and high levels of alexithymia. The predictors of JIA remission in adulthood are male sex (OR = 0.453; 95% CI 0.253-3.556); arthritis of more than 3 joints (OR = 0.459; 95% CI 0.347-0.770); wrist arthritis in childhood (OR = 0.082; 95% CI 0.009-0.739) and JADAS-10 in the disease onset (OR = 0.758; 95% CI 0.589-0.866) <6 points, treatment with bi in the history (OR = 0.767; 95% CI 0.554-0.811) and the duration of DMARDS treatment (OR = 0.741; 95% CI 0.636-0.863) > 15 years. The negative corre- lation of JADI-A and the patient’s physical well-being PCS (r = -0.27, p < 0.05) and physical functioning (r = -0.24, p < 0.05), pain intensity (r = -0.24, p < 0.05), general health (r = -0.24, p < 0.05), mental health (r = -0.22, p < 0.05) according to SF-36. The severity of extra-articular damages JADI-E correlated with PCS (r = -0.22, p < 0.05) and physical functioning (r = -0.28, p < 0.05), pain intensity (r = -0.20, p < 0.05), general health (r = -0.23, p < 0.05), and mental health (r = -0.23, p < 0.05), but also had a positive correlation with HAMA (r = 0.25, p < 0.05), depression scale (r = 0.28, p < 0.05) and PHQ-9 (r = 0.28, p < 0.05). Significantly lower level of physical health was established in patients who requires prosthetics (p < 0.001) compared to those who did not need prosthetics.

Conclusion: Based on the obtained results, algorithms of management of adult patients with JIA oligoarticular variants of JIA were developed, depending on the detected
articular and extra-articular damages and the need for prosthetics and the psychological status.

FRI0493

THE INTERLEUKIN-1B INHIBITOR CANAKINUMAB FOR REFRACTORY STILL’S DISEASE: LONG-TERM EXPERIENCE IN 50 CONSECUTIVE PATIENTS

1Joint Rheumatology Program, NKUA Medical School, Athens, Greece; 2Dept. of Rheumatology, St. Paul’s Hospital, Thessaloniki, Greece; 3Private Rheumatologist, Ioannina, Greece; 4Private Rheumatologist, Volos, Greece; 5Dept. of Rheumatology, Metropolitan Hospital, Athens, Greece; 6Dept. of Rheumatology, University of Patras, Patras, Greece; 74th Dept. of Internal Medicine, Aristotle University, Thessaloniki, Greece; 8Private rheumatologist, Kozani, Greece; 9Private rheumatologist, Chania, Greece; 10Rheumatology Clinic, Evangelismos Hospital, Athens, Greece; 11Dept. of Rheumatology, University of Athens, Larissa, Greece; 12Private rheumatologist, Alexandroupoli, Greece; 13Rheumatology Clinic, Asklepion Hospital, Athens, Greece; 14Private Rheumatologist, Kavala, Greece; 15First Dept. of Internal Medicine, Rheumatology Section, Aristotle University, Thessaloniki, Greece; 16Dept. of Rheumatology, Clinical Immunology and Allergy, University of Crete, Heraklion, Greece; 17Private Rheumatologist, Corinth, Greece; 18Dept. of Rheumatology, 251 Air Force General Hospital, Athens, Greece; 19Dept. of Rheumatology, KAT General Hospital, Athens, Greece; 20Private Rheumatologist, Patras, Greece; 21Private Rheumatologist, Thessaloniki, Greece; 22Rheumatology Clinic, University of Ioannina, Ioannina, Greece

Background: Interleukin-1 (IL-1) is a major mediator of the inflammatory cascade in Still’s disease and an established therapeutic target.

Objectives: To assess the efficacy and safety of the IL-1b inhibitor canakinumab in adolescent and adult patients with refractory Still’s disease.

Methods: We conducted a retrospective longitudinal outcome study of 50 consecutive patients (19 females, 31 males, median age 39 years; median duration of disease 12 years) fulfilling the 1990 American Rheumatism Association revised criteria for Still’s disease. Consecutive patients aged 39 years (median, range 14-72), fulfilling the Yamaguchi disease classification criteria, with active disease despite treatment with corticosteroids (CS) (n=11) and/or methotrexate (n=9) and/or biologics (n=30), were included. Median disease activity score (DAS) was 4 (range 3-84). Concomitant treatment included CS (n=41), methotrexate (n=12), anti-TNF (n=9), and/or leflunomide (n=5).

Results: Complete remission was initially achieved in 78% of patients within a median time of 3 months, irrespective of age at disease onset. Partial clinical and laboratory response was evident in 20%. Canakinumab was discontinued in one patient with resistant disease (primary failure) and in 6 out of 10 initial responders, who relapsed during treatment (secondary failure). Of 39 patients in complete remission, increase in drug administration interval and/or drug dose reduction was attempted in 7 of which only 1 relapsed, whereas drug discontinuation was attempted in 19 patients for a median time of 8 months (range 3-68), of which 8 relapsed. Overall, in half of all disease flares, canakinumab re-introduction or intensification was successful. Canakinumab had a significant CS sparing effect permitting weaning in 21 of 41 cases. Infections (20%, severe 4%) and leucopenia (6%) led to treatment cessation in one patient.

Conclusion: In this largest so far real-life patient cohort with refractory Still’s disease, high rates of sustained remission were induced by canakinumab both in adolescent and adult patients.

RHEUMATIC IMMUNE RELATED ADVERSE EVENTS OF CHECKPOINT INHIBITORS: A RETROSPECTIVE REVIEW OF 70 PATIENTS

T. Lenfant1, L. Calabrese1,2, C. Calabrese1,2

1Cleveland Clinic Foundation, Rheumatology and Immunology, Cleveland, United States of America

Background: Immune Checkpoint inhibitors (ICI) have revolutionized cancer therapy by achieving remarkable survival benefits however, at the cost of a myriad of immune-related adverse events (irAEs) [1]. Rheumatic irAEs can develop in 5-10% of patients although the true incidence is unknown given the lack of prospective studies [2]. Symptoms are heterogeneous and probably underreported with few data available about their management and outcome [3].

Objectives: To describe the clinical, biological, and radiological features of the largest cohort of rheumatic irAEs from ICI along with their therapeutic management, outcome and follow-up in real-world practice.

Methods: A referral process for emergent rheumatic irAEs was initiated in February 2016 between the oncology and rheumatology departments at the Cleveland Clinic Foundation. All patients were evaluated by authors CC and/or LHC. Patients’ characteristics were retrospectively collected from medical charts after IRB approval.

Results: 70 patients referred for one or more rheumatic irAEs between February 2016 and January 2020 were included. 66% were male, median age was 60.8 years. Among them, 24 (34%) had pre-existing rheumatic complaints. Melanoma was the most frequent malignancy (56%). ICI therapy included anti-CTLA4 (40%), anti-PD1/PD-L1 (79%), and dual therapy ipilimumab/nivolumab (41%). Rheumatic irAEs occurred in a median 4 months after ICI initiation, with phenotypes including inflammatory arthritis (32 patients), sicca-like symptoms (12), polymyalgia rheumatica-like (7), and myositis (2). Oral, intravenous or intraarticular glucocorticoids (GC) were administered to 54 patients (77%). Of these 54 patients, 22 (41%) required long term GC, 19 had bone density scan and 15 received pneumocystis (PJP) prophylaxis. One PJP case, 1 osteoprotective fracture and 2 avascular necrosis cases were reported. 16 patients received conventional DMARDs (23%) and 9 received biologics (13%). ICI therapy was held for rheumatic irAE in 31% of cases and for another systemic irAE in 29%. Median follow-up was 13.6 months, at end of follow-up 51 patients were still on ongoing treatment for rheumatic irAE and 41% of them were still symptomatic despite ongoing treatment.

Conclusion: Rheumatic irAEs are heterogeneous and often chronic requiring prolonged immunomodulatory therapy. Prospective studies are required to define optimal management of rheumatic irAEs that maintain long-term oncologic outcomes.

Disclosure of Interests: Tiphaine Lenfant: None declared, Leonard Calabrese Consultant of: AbbVie, GSK, Bristol-Myers Squibb, Genentech, Janssen, Novartis, Sanofi, Horizon, Crescendo, and Gilead, Speakers bureau: Sanofi, Horizon,
Background: Intstitial Lung Diseases (ILD) may present features suggesting an underlying autoimmune process, which seem to differentiate them from idiopathic interstitial pneumonias, although without fully meeting the classification criteria (CC) for a specific connective tissue disease. Different terms had been used to describe these conditions and, to reach a consensus, the European Respiratory Society/American Thoracic Society proposed the CC for an entity named Interstitial Pneumonia with Autoimmune Features (IPAF). Clinical evolution and prognosis of this entity are still poorly understood.

Objectives: To evaluate clinical evolution and prognosis of a population of patients with IPAF.

Methods: Retrospective analysis of clinical files of patients followed by the Pulmonology Department since 02/2012 until 06/2019, who met the CC for IPAF regarding clinical, functional and radiological evolution. Patients were considered to have a progressive phenotype in 24±3 months from their 1st evaluation if they fulfilled 1 of the 4 criteria: relative decline in FVC ≥10% predicted; relative decline in FVC ≥5–<10% predicted and worsened respiratory symptoms; relative decline in FVC >3–>5 predicted and increased extent of fibrosis on High-resolution Computed Tomography (HRCT); worsened respiratory symptoms and increased extent of fibrosis on HRCT.

Results: 22 (7.4%) of 296 ILD patients met IPAF CC. 50% were female with a mean age at the 1st evaluation of 66.7±12.4 years. They were all non-smokers (53.6%) or ex-smokers (36.4%). Serologic and morphologic criteria were both present in 21 (95.4%) and clinical criteria in 5 patients (22.7%). Antinuclear antibodies (ANA) were identified in 19, rheumatoid factor in 4, SSSA in 3 and anti-Jo-1 in 1 patient. HRCT patterns were identified in 21 patients: 15 nonspecific interstitial pneumonia (NSIP), 5 organizing pneumonia (OP) and 2 lymphocytic interstitial pneumonia (LIP). One NSIP and 1 LIP identified on HRCT were confirmed by histopathology. Three patients had inflammatory arthritis and 2 had Raynaud’s phenomenon. Immunosuppressive therapy was introduced in most cases (18 patients, including systemic corticosteroid therapy, in 17, azathioprine in 4, myco-phenolate mofetil in 1), azathioprin was prescribed in 2 patients and 3 remained without therapy. Regarding the follow up at 24±3 months from the 1st evaluation (3 patients were excluded due to too recent follow-up), 4 patients (18.2%) had progressive phenotype, 7 (31.8%) had a favorable evolution and 3 (13.6%) patients had died. During a follow-up of 31.1±19.8 months, this number rose to 6 patients (27.3%), all of them died by respiratory cause and had NSIP pattern. No differences were found in age, last FVC, therapy and time of disease evolution between those who died and the others.

Conclusion: Our study showed that a small proportion of IPAF patients had a progressive phenotype and the NSIP pattern seemed to be a poor prognosis factor for survival.

FREQUENCY OF POLYAUTOIMMUNITY IN RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERITEMATOSUS

M. D. C. Ordoñez Cañizares1, N. Mena-Vázquez1, R. Redondo1, S. Manrique1, O. Murata1,2, k. Suzuki1, N. Sasaki2, T. Takeuchi1, M. Maemondo1,2, Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 1wate Medical University School of Medicine, Division of Pulmonary medicine, Allergy, and Rheumatology, Department of Internal Medicine, Morioka, Japan

Background: Patients with idiopathic interstitial pneumonia (IIP) may have features of connective tissue diseases (CTD). The term interstitial pneumonia with autoimmune features (IPAF) has been recently proposed for such patients [1]. To date, only few studies have comprehensively described outcomes over a long-term period and choices of treatment [2-4].

Objectives: The aim of this study was to investigate the therapeutic strategies and long-term outcome among patients with IPAF, IIP, and CTD-ILD.

Methods: Six hundred- and seventy-two patients who had visited our department between April 2009 and March 2019 and were evaluated by chest HRCT scan. They were clinically and radiologically diagnosed as having interstitial lung disease (ILD), including IIP, CTD-ILD, undifferentiated connective tissue diseases associated ILD or other ILD. Then, we applied IPAF criteria to these patients, 68 patients were diagnosed as IPAF. We extracted the
Scientific Abstracts

FRI0498 DOES TESTING FOR SAA IS MORE BENEFICIAL THAN CRP FOR THE FOLLOW-UP OF FMF PATIENTS WITH M694V HETEROZYGOUS OR M694V HOMOZYGOUS MUTATIONS?

M. Oztas1, S. Ugurlu 1, O. Selvi 2, B. Ergezen 1, H. Ozdogan1, 1Istanbul University-Cerrahpasa, Department of Medicine, Division of Rheumatology, Istanbul, Turkey; 2Okmeydani Training and Research Hospital, Istanbul, Turkey

Background: In order to follow subclinical inflammation and adjust the therapy for an optimal Familial Mediterranean Fever (FMF) disease control, clinicians seek for readily accessible, affordable and reliable markers. C-reactive protein (CRP) is widely used for this purpose. Some suggest that CRP measures are not conclusive in all cases, especially at initial stages of inflammation. It is suggested that Serum Amyloid A (SAA) may be more reliable and sensitive in predicting an ongoing inflammation.

Objectives: In order to evaluate and to compare the sensitivity of SAA and CRP in FMF patients with M694V homozygous and M694V heterozygous mutations respectively.

Methods: Blood samples from 28 patients with M694V homozygous mutation and from 15 patients with M694V heterozygous mutation were obtained during a mean follow-up of 1 year. Multiple samples were drawn in both attacks and attack-free periods of FMF (153 from M694V Homozygous and 31 from M694V Heterozygous). For the analysis of the correlation, the folds of normal CRP and SAA levels were used. Serum levels of the given markers were measured with nephelometric kits (normal CRP levels <5 mg/L and SAA levels <6,8 mg/L). More than one-and-a-half-fold increase of CRP and SAA was defined as an active phase reactants were increased in 69 measurements, while in 13, CRP was high but SAA was normal and in 31, SAA was high however CRP was within normal limits. The mean increase in CRP of the whole cohort was 2,37 ± 3,22-fold of the normal, whereas mean increase in SAA was 6,77 ± 13,23-fold of the normal.

Conclusion: According to these results, serial testing of SAA does not provide any additional advantages over CRP. As it is readily accessible and affordable, CRP seems to be sufficient for the follow-up of FMF patients.

CARDIOVASCULAR DISEASE RISK ASSESSMENT IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER RELATED AMYLOIDOSIS

M. Romano1, M. Yilmaz2, B. Jackson3, C. Ackell4, D. Piskin5, R. Berard6, E. Demirkaya7, 1Istituto Ortopedico Gaetano Pini, Milan, Italy; 2Epidemiologic Health Solutions, Ankara, Turkey; 3Western University, London, Canada; 4Clinical Research International, Cologne, Germany

Background: FMF is an autosomal recessive disorder. Systemic inflammation in autoinflammatory disorders cause secondary systemic AA amyloidosis, which has been suggested as an important contributing factor to the excess cardiovascular disease (CVD) risk in patients with FMF.

Objectives: Our aim was to investigate the CVD-related clinical outcomes in patients with FMF-related amyloidosis and to define risk factors for CVD events (CVDEs).

Methods: A cross-sectional evaluation with prospective follow-up of consecutive patients with FMF-related amyloidosis or other non-diabetic primary glomerulonephropathy (PGN) was performed. Patients were followed for CVDEs. Flow-mediated dilatation (FMD), FGF-23 levels, serum lipid levels, hsCRP, BMI and homeostasis model assessment (HOMA) were assessed. A Cox regression analysis was performed to evaluate the probability of CVDEs associated with each risk factor.

Results: There were 107 patients in FMF-related amyloidosis group and 126 patients with PGN group. Forty-seven CVDEs were registered during the 4.2-years follow up; all 28 patients in the FMF-related amyloidosis versus 14/19 patients with PGN group who developed CVDEs before 40 years of age (P<0.002) (Figure 1). CVD mortality was 2.8 times higher (95% CI:0.8-7.67, P=0.03) in patients with FMF-related amyloidosis (n=12) than PGN (n=5). Mortality due to CVD was higher in patients less than 40 years old with amyloidosis than PGN (12/107 and 3/126 respectively, RR=4.71, 95% CI 1.4-16.25, P=0.006). Patients with CVDEs had higher levels of proteinuria, hsCRP and FGF23, and lower FMD compared to patients without CVDEs. Across both groups, FGF23 and FMD levels were independently associated with the risk of CVDEs (Table 1).

Conclusion: Patients with FMF-related amyloidosis are at increased risk of CVDEs with early mortality age. These patients should be closely monitored and if inflammation is poorly controlled with colchicine, biological agents must be added to treatment even if they develop amyloidosis. We also found that hsCRP, FGF 23 and FMD levels were the strongest predictors of CVD risk in patients with FMF. These biomarkers can stratify risk of early CVD in patients with FMF-related amyloidosis.

SEASONAL CLUSTERING OF ACUTE SARCOIDOSIS IN GERMANY AND ASSOCIATIONS WITH AIR POLLUTION

P. Rustler1, D. Schindler2, R. Voit3, F. Kollert2. 1Division of Rheumatology and Clinical Immunology, Department of Internal Medicine, University Medical Center Freiburg, Freiburg, Germany; 2Environmental Meteorology, University of Freiburg, Freiburg, Germany; 3Department of Rheumatology, Immunology & Allergology (RIA), Inselspital, University Hospital Bern, Bern, Switzerland

Background: Sarcoidosis is a multisystemic granulomatous disorder of unknown origin. The central role of macrophages and granuloma formation, the predominant involvement of lung and skin, and certain risk populations (e.g. firefighters1-2) might be explained by causative airborne antigen(s)3. Whether air pollution is involved in pathogenesis and seasonal clustering of sarcoidosis is uncertain.

Objectives: This study has been set to analyze seasonal clustering of acute sarcoidosis and associations to air pollution.

Methods: Patients with acute sarcoidosis, defined by bilateral lymphadenopathy, ankylosing swelling, and/or erythema nodosum plus physician's diagnosis,were included in this retrospective study. Disease onset (seasonal clustering) and associations to air pollution (particulate matter (PM2.5) and nitrogen dioxide (NO2)) were analyzed. Google Trends queries were conducted to address seasonal clustering on a global scale.

Results: A total of 185 patients with acute sarcoidosis were included; 48.7 % of the enrolled patients were female and Lofgren triad was complete in 73.5 % of patients. Acute sarcoidosis clustered from December to June in West Germany (p<0.005, Kendall τ=-0.68), peaking in January (17.8 % of cases) and in the first third of the year (54.5 %). Mean PM2.5 values clustered from December to April with values between 15 and 40 µg/m3. NO2 levels were measured highest from November to March (45 µg/m3) and lowest between April and August (25 µg/m3). Elevated air pollution markers (PM10 and NO2) were associated with higher monthly incidence rates of acute sarcoidosis (Cross correlation coefficient ranging between 0.7-0.8). Google Trends analysis yielded seasonal clustering (p<0.005, Kendall τ = -0.64) in winter and spring months on the northern hemisphere.

Conclusion: In Central Europe acute sarcoidosis peaks in winter and spring months (December until March) shortly after PM10 and NO2 maxima are reached. Whether components of particulate matter might be involved in the pathogenesis of sarcoidosis has to be elucidated by further studies.

of IgG4-related Kidney Disease Working Group of the Japanese Society of Nephrology;1 Nagaoka Red Cross Hospital, Nagaoka, Japan;2 Kanazawa University Hospital, Kanazawa, Japan;3 Tohoku University Hospital, Sendai, Japan;4 Toranomon Hospital, Tokyo, Japan;5 Kochi Medical School Hospital, Kochi, Japan;6 Kyorin University, Tokyo, Japan;7 Kobe University, Kobe, Japan;8 University of Tsukuba, Tsukuba, Japan;9 Yamaguchi’s Pathology Laboratory, Chiba, Japan;10 Sankyo Clinic, Fukuo, Japan;11 Fukuoka University, Fukuoka, Japan;12 Sankyo Clinic, Fukuoka, Japan;13 La Paz, Madrid, Spain;14 H. U. Ramón y Cajal, Madrid, Spain.

Background: The 2019 ACR/EULAR classification criteria for IgG4-RD have recently been published[1]. In the criteria, patients with an inclusion criteria score of >20 without exclusion criteria are classified as having IgG4-RD.

Objectives: To validate the 2019 ACR/EULAR classification criteria for IgG4-RD in a Japanese kidney disease cohort.

Methods: The study involved Japanese patients diagnosed as having kidney disease between April 2012 and May 2019, for whom sufficient clinical information and data on serum IgG4 values and/or immunohistological staining for IgG4 in renal biopsy samples were known. These patients were classified as having IgG4-RKD or non-IgG4-RKD (mimickers) based on the 2019 ACR/EULAR classification criteria for IgG4-RD, and the results were evaluated by expert opinion.

Results: Among 105 included patients, the expert panel diagnosed 55 as having true IgG4-RKD and 50 as mimickers. The final diagnoses among the mimickers were vasculitis (n=11), idiopathic tubulointerstitial nephritis (TIN) (n=5), drug-induced TIN (n=5), Sjogren’s syndrome (n=4) and others. Among the 55 true IgG4-RKD patients, 4 had exclusion criteria, and 50 of the remaining 51 had an inclusion criteria score of ≥20 points (sensitivity 90.9%). On the other hand, 49 of the 50 mimickers were classified as having non-IgG4-RKD (specificity 98.0%) (Table 1).

Blanco1, A. H. Marqués de Valdecilla, Santander, Spain;2 H. Perest, Valencia, Spain;3 H. U. de Donostia, Donostia, Spain;4 H. U. Basurto, Bilbao, Spain;5 H. Virgen de la Salud, Toledo, Spain;6 H. de Mérida, Mérida, Spain;7 H. General de Alicante, Alicante, Spain;8 H. U. La Paz, Madrid, Spain;9 H. La Princesa, Madrid, Spain;10 H. U. Virgen de la Macarena, Sevilla, Spain;11 H. San Pedro, Logroño, Spain;12 H. Sierrallana, Torrelavega, Spain;13 H. U. Valencia, Valencia, Spain;14 H. U. Guadalajara, Guadalajara, Spain;15 H. Clínico San Carlos, Madrid, Spain;16 H. U. Ramón y Cajal, Madrid, Spain.

Background: Tocilizumab (TCZ) has shown promising results in the treatment of inflammatory ocular disease, especially in uveitis (1-3). Graves orbitopathy (GO) is the most common complication of Graves’ disease (GD). Conventional immuno-suppressive drugs are not always effective or well tolerated. TCZ may be useful in the treatment of GO.

Objectives: To assess the efficacy of TCZ in corticoid-resistant GO.

Methods: Multicenter open study of corticoid-resistant GO. We measured clinical activity using the clinical activity score (CAS). CAS evaluates 10 different oculic items, ranging from 0 (no symptoms) to 10. We defined remission as the presence of CAS ≤ 3.

Results: We studied 48 (95 eyes) patients (TABLE). Besides oral corticosteroids, they had received iv Methylenpredisolone (n=43), methimazole (n=20), selenium (n=11) or radioactive iodine (n=5). According to the classification of severity (EUROGO group), before of TCZ onset our patients had severe (n=19) or moderate (n=29) disease. TCZ was used in monotherapy (n=45) or combined with methotrexate (n=2) or azathioprine (n=1) at a dose of 8mg/kg/iv/4 weeks (n=43) or 162mg/sc/week (n=5). TCZ yielded rapid and maintained improvement and most patients achieved remission (FIGURE).

After a mean follow-up of 16.1±2.1 months, most patients experienced ocular improvement, with TCZ withdrawal in 29 cases due to remission (n=25) or inefficacy (n=4). Only 5 relevant adverse events were observed (neutropenia, external oitis, costalostitus and gingivalhyperplasia). None of these events resulted in discontinuation of the treatment.

Conclusion: TCZ appears to be an effective and safe treatment in corticoid-resistant GO.

FR10505

TOCILIZUMAB DISCONTINUATION AFTER REMISSION ACHIEVEMENT IN PATIENTS WITH ADULT STILL’S DISEASE

H. Tamai1, Y. Kanie1, T. Takeuchi1.1 Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: The efficacy of tocilizumab, an interleukin (IL)-6 receptor inhibitor, has been proved in patients with adult Still’s disease on suppressing systemic inflammation and decreasing glucocorticoid dose. However, whether tocilizumab can be discontinued after remission achievement is unclear.

Objectives: To clarify the possibility of tocilizumab discontinuation in patients with adult Still’s disease who achieved remission with tocilizumab.

Methods: Consecutive patients with adult Still’s disease diagnosed according to the Yamaguchi’s criteria in our hospital from April 2012 until September 2019 were retrospectively reviewed. Patients who were in good control with tocilizumab were included in the analysis, and their clinical courses were collected from their medical charts. Patients were divided according to the presence of recurrence after tocilizumab discontinuation and compared.

Results: Among 43 patients with adult Still’s disease who had a history of intravenous tocilizumab of 8mg/kg use, 13 patients discontinued tocilizumab following a good disease control. During the mean observation period of 26.4 months, six patients (46%) remained in remission while seven patients (54%) developed recurrence after tocilizumab discontinuation. The sex and the mean observation period were not different between the patients with recurrence and those without (71% vs 50%, p=0.43; 27.3 months vs 25.4 months, p=0.93, respectively), but the age at tocilizumab discontinuation tended to be higher in the recurrence group than the non-recurrence group (64.0 years vs 46.5 years, p=0.08). The disease activity including swollen joint counts and laboratory data at tocilizumab discontinuation were comparable between the two groups (serum ferritin levels, 88 mg/dL vs 122 mg/dL, p=0.67). The duration of tocilizumab use was not different between the two groups (29.4 months vs 39.5 months, p=0.40), the mean interval of tocilizumab infusion at tocilizumab discontinuation in the recurrence group was 3.6 weeks, shorter than the 6.7 weeks in the non-recurrence group (p=0.03). The median dose of prednisolone at tocilizumab discontinuation was 5.0 mg/day in the recurrence group and 0.0 mg/day in the non-recurrence group (p=0.06). In the recurrence group, the duration from the last tocilizumab administration to recurrence was 7.8 months, and the median dose of prednisolone at recurrence was 0.0 mg/day.

Conclusion: Patients with adult Still’s disease remaining in remission with a longer interval of tocilizumab administration and a lower dose of prednisolone was likely to succeed in withdrawal of tocilizumab.

FR10506

EFFICACY AND SAFETY OF CANAKINUMAB IN ADULT-ONSET STILL’S DISEASE: A SINGLE-CENTER REAL-LIFE EXPERIENCE

A. Tomellini1, C. Campochiaro1, G. De Luca1, N. Farina1, E. Baldissera1, G. Cavalli1, L. Dagna1.1 San Raffaele Hospital, Milano, Italy

Background: The pro-inflammatory cytokine interleukin (IL)-1 has a central role in the pathogenesis of adult-onset Still’s disease (AOSD), a rare auto-inflammatory condition. Anakinra, has been for years the cornerstone of IL-1-blocking ther- apy in AOSD. More recently, the monoclonal antibody canakinumab, a new agent blocking IL-1, has become available

Objectives: To describe our real-life experience with CNK in a cohort of AOSD patients from a single Italian Center

Methods: AOSD patients diagnosed according to Yamaguchi’s criteria followed-up at our Autoinflammatory Unit and treated with CNK for at least 3 months were included. Demographic features, disease characteristics, reasons for CNK introduction, concomitant therapies, variation in systemic steroids dose, adverse events, and response to treatment were retrospectively evaluated. Non-parametric tests were used for statistical comparison

Results: 13 patients (5 women; median age 49 years, range 21-74), treated with subcutaneous CNK 4 mg/kg 4-weekly, were identified. Median disease dura- tion before CNK introduction was 12 (6-240) months. After CNK introduction, 2 patients were followed-up for 18 months, 3 for 12 months, 6 for 6 months, 2 for 3 months. CNK was introduced as first-line biologic DMARD in 6 patients. The other 7 patients had been already treated with at least one other bDMARD, for a total of 15 treatment courses (7, anakinra, ANK; 4, tocilizumab; 4, TNF-inhibitors), with a median bDMARD therapy duration of 8 (4-178) months. Previous bDMARDs had been interrupted because of inefficacy (8 cases) or adverse events (AE, 7 cases); of the 7 ANK-treated patients, therapy interruption was due to inefficacy in 3 cases. At CNK introduction, 11 patients were on systemic steroid therapy, pred- nisone (PDN) equivalent dose 15 (5-80) mg, and 10 were concomitantly receiv- ing a conventional DMARD (7, methotrexate; 2, colchicine; 1, cyclosporine-A).

Graphic 1 summarizes main clinical features at CNK introduction. After CNK start, a striking and rapid clinical response was observed, as demonstrated by a substantial decrease of modified Pouchot score and a normalization of acute phase reactants after only 3 months (see Table 1 for details). CNK showed also a significant steroid-sparing effect: median PDN dose was reduced to 7.5 (2.5-12.5) mg.

mg at month 3 and 5 (0.7-5) mg at month 6; PDN was stopped in 3 patients (1 at month 3, 1 at month 6, 1 at month 12) due to optimal disease control. CNK was temporarily held-off in 3 patients (zoster reactivation, 1; prostatitis, 1; mild leukopenia, 1). We observed no case of primary inefficacy.

Conclusion: Our real-life data confirm that CNK is highly effective and safe in AOSD treatment and has significant steroid-sparing effects. CNK showed its efficacy both as first-line therapy and after other bDMARDs failure, also in patients who have previously failed IL-1 inhibition through ANK.

COLCHICINE INTOLERANCE IN FMF PATIENTS AND PRIMARY OBSTACLES FOR OPTIMAL DOSING

H. Satılı1, B. Armagan1, E. Bodako2, N. Atlas1, A. Sarı3, D. Yazar1, N. S. Yasar Bilge⁴, R. Biliç Salman², G. K. Yardımcı², H. Babaoglu1, L. Kılıç⁵, M. A. Ozturk1, B. Goker1, S. Haznedaroğlu1, U. Kalyoncu², T. Kayıcı2, A. Tufan1, Gazi University Faculty of Medicine Hospital, Ankara, Turkey; ²Hacettepe University Faculty of Medicine, Ankara, Turkey; ³Eskişehir University Faculty of Medicine Hospital, Eskişehir, Turkey.

Background: Colchicine is the mainstay of treatment in FMF. However, in daily practice it is not easy to maintain effective colchicine doses in substantial number of patients, due to its side effects.

Objectives: It was aimed to investigate prevalence and risk factors for colchicine side effects that limit optimal drug dosing and permanent discontinuation.

Methods: All patients were recruited from “FMF in Central Anatolia” (FiCA) cohort, 915 adult subjects with minimum follow up time of 6 months and had compliance of treatment were included. Demographic and anthropometric data, FMF diagnosis of, ADDI: auto-inflammatory disease damage index, FMF: familial Mediterranean fever.

Results: Effective colchicine doses cannot be maintained in 172 (18.7%) subjects. Main side effects that limit optimal dosing were as follows; diarrhea in 99 (10.8%), elevation in transaminases in 54 (5.9%), leukopenia in 10 (%1.1), renal impairment in 14 (1.3%), myopathy in 5 (0.5%) and allergic skin reaction in two. Colchicine had to be permanently ceased in 18 (2%) patients because of serious toxicity. Male gender and obesity were found to be associated with liver toxicity and having normal body weight was associated with diarrhea. Chronic

MALIGNANCY AND IG44-RELATED DISEASE: THE INCIDENCE, RELATED FACTORS AND PROGNOSIS FROM A PROSPECTIVE COHORT STUDY IN CHINA

H. Yang1, H. Tang1, P. Zhang2, Y. Fei1, H. Chen1, X. Zhang1, Y. Zhao1, F. Zhang1, W. Zhang1, 2Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China.

Background: The association between IgG4-related disease (IgG4-RD) and malignancies is unclear. No epidemiological data for malignancies in Chinese IgG4-RD patients is available. It is also important to know the risk factors and prognosis for IgG4-RD patients harboring malignancies.

Objectives: To investigate the incidence, related factors and prognosis of IgG4-related disease (IgG4-RD) with malignancies in the Chinese cohort.

## Methods

We prospectively analyzed the IgG4-RD patients recruited in Peking Union Medical College Hospital from January 2011 to August 2018 and identified patients diagnosed with IgG4-RD complicating malignancies. Data regarding demographics, clinical features, treatment and prognosis of IgG4-RD patients complicating malignancies were collected and compared to those of age- and sex-matched controls.

## Results

Among the 587 Chinese patients with IgG4-RD, 17 malignancies were identified. Ten of them developed malignancy after the diagnosis of IgG4-RD, given a standard incidence ratio (SIR) of 2.78 (95% CI 1.33-5.12). Multivariate logistic analysis indicated that autoimmune pancreatitis (OR= 6.230, 95% CI 1.559-24.907, p=0.010) was positively associated with malignancy, whereas eosinophilia (OR= 0.094, 95% CI 0.010-0.883, p=0.039) was negatively related with malignancies.

During a median follow-up period of 61.4±26.4 months, all patients with IgG4-RD and malignancies survived.

## Conclusion

An increased incidence of malignancy was found in Chinese IgG4-RD cohort. Autoimmune pancreatitis is a potential risk factor, whereas eosinophilia is a possible protective factor for complicating malignancies.

## Methods

We aimed to compare the capacity of HS score and MS score for the diagnosis of adult-onset Still's disease associated macrophage activation syndrome.

## Results

We included 174 patients with pure AOSD and 35 patients with AOSD-associated MAS. Patients with AOSD-associated MAS were younger than those with pure AOSD (32.4±11.4 yrs vs 36.9±13.5 yrs, P=0.028). More death were observed among patients with AOSD-associated MAS (17.1% vs 3.4%, P=0.001). Patients with AOSD-associated MAS had higher HScore (median [range] 198[89-333] vs 68[33-156], P<0.001) and higher MS score (median [range] 132[126-265] vs -1.17[126-2.52], P<0.001) than those with pure AOSD. The difference of different parameters of these two groups of patients were detailed in Table 1 and Table 2. ROC curve analysis (Figure 1) revealed that HScore has stronger ability to diagnose AOSD-associated MAS compared with MS score (AUC=0.973 and 0.865 for HScore and MS score respectively, P<0.001). HScore120 perform best (sensitivity 96.9% and specificity 88.9%). MS score >= 25 yielded a sensitivity of 75% and a specificity of 73%.

## Conclusion

HScore seems to perform much better than MS score for the diagnosis of AOSD-associated MAS in our cohort.

## FRID0510

### THE FREQUENCY OF CONTRACEPTION DOCUMENTATION IN WOMEN ON AND OFF TERA TOGENIC ANTI-RHEUMATIC MEDICATIONS IN THE RISE REGISTRY

M. Clowse1, J. Li2, M. Biru Talabi3, A. Eudy1, G. Schmajuk2.

1Duke University, Durham, United States of America; 2UC San Francisco, San Francisco, United States of America; 3UPMC, Pittsburgh, United States of America

## Background

Several of the most commonly prescribed medications for women with rheumatic disease are teratogens, posing a risk for pregnancy loss and birth defects if taken in pregnancy. To prevent these life-altering complications, it is important that all women taking teratogenic medications avoid pregnancy through abstinence or contraception.

## Objectives

We sought to understand the accessibility to contraceptive data within the RISE Registry and to test whether, compared to other women,
those prescribed a teratogen would be more likely to have documentation of contraceptive.

Methods: Data were derived from Rheumatology Informatics System for Effectiveness (RISE), a national EHR-enabled rheumatology registry that passively collects data on all patients seen by participating practices. As of 2018, RISE held validated data from 1,113 clinicians in 226 practices, representing an estimated 32% of the U.S. clinical rheumatology workforce. Female patients between the ages 18-45 with an anti-rheumatic medication prescribed within the RISE system in 2018 were stratified into one of three groups: 1) Any teratogen (methotrexate, myco-phenolate, mycophenolic acid, cyclophosphamide, leflunomide, thalidomide, lenalidomide); 2) Only pregnancy-compatible medications (hydroxychloroquine, azathioprine, or a TNF-α inhibitors [TNF]); and 3) Any medication with unknown teratogenicity (non-TNF biologics and new small molecule medications). We identified the most recent contraceptive medication or device reported in 2018 using structured fields in the EHR. Contraceptive effectiveness was classified as ‘highly effective’ (IUD, Nexplanon, and surgical) and ‘effective’ (oral contraceptives, depot-provera, patch, ring, and unknown (type not reported)). Statistical signifi-
cance was assessed using Stata SE 15.1.

Results: In 2018, 110,359 women between the ages of 18-45 were prescribed an anti-rheumatic medication within the RISE Registry. Of these, 11,569 (10.5%) had a contraceptive documented at the last visit. The frequency of contraception doc-
cumented varied between practices, ranging from 0% to 28.7% (median 9.2%). Contraception was documented slightly less often in women receiving teratogens (9.8%) compared to women receiving only pregnancy-compatible medications (10.4%, p=0.04) and medications with unknown pregnancy risks (10.0%, p=0.67). The frequency of contraceptive documentation in women prescribed a teratogen varied significantly by race with white women having the highest rate (11.0%) compared to African-American women (7.4%, p<0.001), Hispanic women (5.5%, p<0.001), and Asian women (8.4%, p=0.08).

The type of contraceptive documented did not vary significantly between medica-
tion groups. Highly effective contraception was rarely documented (1.4-1.6%) and moderately-effective hormonal contraceptives were more frequently documented (6.3-8.2%).

Conclusion: This study is limited to the analysis of structured fields within the RISE Registry, thereby missing contraceptive documentation within the clinician notes. Increased uniformity in documentation and/or analysis of visit notes will be essential to use the RISE Registry to study the implementation of published contraceptive guidelines. While the documentation of contraception identified in this analysis of the RISE Registry likely under-estimates actual contraceptive use, it reveals important gaps in care. Contrary to what was expected, women prescribed a teratogen were not more likely than other women to have a docu-
mented contraceptive. Additionally, important racial disparities in contraception documentation suggest that rheumatologists may not addressing reproductive health needs equally across patient populations.

FRI0511 THE DESCRIPTIVE EPIDEMIOLOGY AND SECULAR TRENDS OF LOWER BACK PAIN PROCEDURES IN ROUTINE UK NHS CARE FROM 2000 TO 2016

D. E. Robinson1, J. Lane2, R. Craig1, A. Judge1,3, J. Bailey4, D. Yuf5, K. Jordan6, G. Peat7, R. Wilkie8, A. Silman2, V. Y. Strauss9, D. Prieto-Alhambra10, D. E. Robinson1, J. Lane2, R. Craig1, A. Judge1,3, J. Bailey4, D. Yuf5, K. Jordan6, G. Peat7, R. Wilkie8, A. Silman2, V. Y. Strauss9, D. Prieto-Alhambra10

1University of Oxford, NDORMS, Oxford, United Kingdom; 2University Of Oxford, NDORMS, Oxford, United Kingdom; 3Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom; 4School of Primary, Community and Social Care, Keele University, Keele, United Kingdom; 5University of Oxford, NDORMS, University of Oxford, Oxford, United Kingdom

Background: The lifetime prevalence of lower back pain is between 60% and 70%, with surgical treatments spared for those not responding to other options. Objectives: To investigate the age, gender and socio-economic status differ-

Methods: Data was obtained from primary care electronic medical records (CPRD GOLD) linked to English hospital admissions data. Lower back procedures in patients aged 35+ were identified using OPCS-4 codes for Decompression (Dc), Fusion (F), Therapeutic injections (Ti) and Denervation (Dn). Standardised incidence rates (IR) of each type of lower back procedures were calculated per 10,000 CPRD registered person years for each age group, gender, region and SES strata in 2000, 2008 and 2016. IR were also calculated for combinations of age and gender. Negative binomial regression calculated incidence rate ratios (IRR) and 95% confidence intervals.

Results: The IR of lower back procedures was 21.5 [20.7, 22.3] per 10,000 person years in 2000. This doubled by 2008 (45.5 [44.5, 46.5]) and trebled by 2016 (62.5 [60.8, 64.2]). Number of events and incidence rates of each procedure type are shown in table 1 below. The incidence of Dn has increased 6-fold whilst Dc and F have doubled. Female (IR in 2016 of 73.99 [71.43, 76.61] vs 50.08 [47.90, 52.33] in men, IRR 1.50 [1.41, 1.59]) and age are associated with back procedure rates (fig-
ure 1). Large socio-economic differences were observed, with higher procedure rates seen in the most deprived areas. These differences did however narrow over time during the study period (figure 2).

Figure 1. Age and Gender stratified incidence rate ratios of all back procedures in 2000, 2008 and 2016

Figure 2. Deprivation status incidence rate ratios by year
Conclusion: The incidence of lower back procedures has more than trebled since 2000. Women are more likely to have lower back procedures than men, with patients aged 65–74 the most likely to have a procedure. Procedures in those aged 75+ have become more common over time, potentially increasing the risk of post-operative complications. Socio-economic differences in the incidence of low back procedures are probably related to the known higher prevalence of back pain in deprived areas. Whether the observed narrowing in socio-economic variation over time is explained by a reduced need or by lowered provision needs further research.

FRI0512 INTEGRATED CARE NETWORK AS A BUILDING STONE FOR SUSTAINABLE AND COMPREHENSIVE CARE FOR PATIENTS WITH ARTHRALGIA

E. Van Delli1, 2, K. H. Ham1, J. Hazes3, D. Lopes Barreto4, A. Weel1, 2, 3, 4. 1Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; 2Erasmus School of Health Policy & Management, Health technology assessment, Rotterdam, Netherlands

Background: Western countries experience an increasing demand for care, particularly for inflammatory arthritis (IA), while the healthcare budget decreases1. The innovative value-based primary care strategy2 includes integrated care networks, where primary and secondary care bundle their expertise to improve patient value by providing the right care at the right place.

General practitioners (GPs) have difficulties recognising IA, leading up to only 20% IA diagnoses of all newly referred arthralgia patients. However, since IA needs to be treated as early as possible to overcome progression, it is worthwhile to analyse whether integrated care networks have an impact on patient outcomes and cost-effectiveness. Triage by a rheumatologist in a primary care setting is one of the most promising integrated care networks for efficient referrals3.

Objectives: To assess the effect of triage by a rheumatologist in a primary care setting in patients suspect for inflammatory arthritis.

Methods: The present study follows a cluster randomized controlled trial design. The intervention, triage by a rheumatologist in a local primary care centre, will be compared to usual care. Usual care means that patients are referred to a rheumatologist outpatient clinic based on the opinion of the general practitioners.

The primary outcome is the frequency of IA diagnoses assessed by a rheumatologist. Patient reported outcome measures (PROMs (EQ-5D)) and costs (work productivity (IPCO) and healthcare utilization (IMCO)) were determined at baseline, after three, six and twelve months. The target was to include 267 patients for the study population. In the usual care group this was n=52 (38.0%) of the patients and for n=137 (49.8%) in the triage group n=18 (64.2%) of referred patients were diagnosed with IA (6.7% of the total study population).

Conclusion: These preliminary results of an integrated care network are promising. Approximately three-quarters of all patients can be withheld from expensive outpatient care. PROMs data and cost-effectiveness analysis will give clear answers in order to provide evidence whether this integrated care network can be implemented as a standard of care.

FRI0513 TREATMENT PERSISTENCE IN PATIENTS CYCLING ON SUBCUTANEOUS TUMOR NECROSIS FACTOR-ALPHA INHIBITORS IN INFLAMMATORY ARTHRITIS – A RETROSPECTIVE STUDY

J. Dalén1, A. Puumatil2, K. Lutfropp3, C. Black2, 1ICON plc, Real World Evidence Strategy and Analytics, Stockholm, Sweden; 2Merck & Co., Inc, Center for Observational and Real-World Evidence, Kenilworth, NJ, United States of America

Background: Patient persistence with biologic treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) (collectively inflammatory arthritis, IA) may be considered a proxy for efficacy, safety and treatment satisfaction. Patients who discontinue their first line of subcutaneous tumor necrosis factor alpha inhibitors (SC-TNFis) and switch to at least one subsequent line of SC-TNFi can be defined as cyclers.

Objectives: To assess persistence by line of therapy in Swedish IA patients cycling on SC-TNFis.

Methods: Using data from the Swedish Health Data Registers, adult IA patients initiating treatment with any available SC-TNFi (adalimumab, etanercept, certolizumab, or golimumab) between May 1st 2010 and October 31st 2016 were eligible for inclusion. Treatment persistence was derived using information from filled prescriptions (e.g. dispensing date, pack information, and defined daily dose) with a 60-day grace period. Analyses were restricted to the first two lines of treatments (i.e. 1st and 2nd) in patients defined as SC-TNFi cyclers. Persistence estimates across treatment lines were assessed graphically using Kaplan-Meier curves. Unadjusted and adjusted marginal Cox proportional hazards models were fitted to estimate the relative risk of discontinuation across treatment lines, using robust sandwich covariance matrix estimates to account for intrapatient dependence (i.e. multiple treatment lines per patient). Covariates in the adjusted analysis included age, gender, diagnosis, year of treatment initiation, comorbidities, co-medication, and the number of specialized outpatient care visits and inpatient stays.

Results: Of 11,668 patients initiating SC-TNFi treatment, 3,181 patients were identified as cyclers. Among these, a majority were female (68%) with a mean age of 50 years; 46%, 28%, and 26% were diagnosed with RA, AS and PsA, respectively. Figure 1 indicated that, among cyclers, persistence with second line treatment was higher compared to first line treatment persistence. This finding was confirmed by the analyses accounting for intrapatient dependence. Both the unadjusted and the adjusted analyses showed that the relative

Compared to 1st line (Hazard Ratio [HR]; 0.60 [0.57, 0.63] and 0.59 [0.56, 0.62], respectively). This finding was also consistent across IA indications (Table 1).

Conclusion: In this preliminary analysis of IA patients cycling on SC-TNFis, persistence was greater in 2nd line compared to 1st line treatment. This finding was consistent across all IA indications. Hence, IA patients who fail to respond, lose response, or for other reasons discontinue their 1st line treatment may still benefit from switching to an alternative SC-TNFi as a 2nd line therapy.

USE OF OPIATE FOR HIP AND KNEE OSTEOARTHRITIS BEFORE AND AFTER JOINT REPLACEMENT SURGERY

C. Lao1, D. Lees2, D. White3, R. Lawrenson1,3, 1University of Waikato, Hamilton, New Zealand; 2Tauranga Hospital, Tauranga, New Zealand; 3Waikato Hospital, Hamilton, New Zealand

Background: Osteoarthritis of the hip and knee is one of the most common causes of reduced mobility. It also causes stiffness and pain. Opioids can offer pain relief but is usually used for severe acute pain caused by major trauma or surgery. The use of opioids for relief of chronic pain caused by arthritis has increased over the last few decades.[1]

Objectives: This study aims to investigate the use of strong opiates for patients with hip and knee osteoarthritis before and after joint replacement surgery, over a 13 years period in New Zealand.

Methods: This study included patients with osteoarthritis who underwent publicly funded primary hip and knee replacement surgeries in 2005-2017 in New Zealand. These records were identified from the National Minimum Dataset (NMD). They were cross referenced with the NZJR data to exclude the admissions not for primary hip or knee replacement surgeries. Patients without a diagnosis of osteoarthritis were excluded.

The PHARMS dataset was linked to the NMD to identify the use of strong opiates before and after surgeries. The strong opiates available for community dispensing in New Zealand and included in this study are: dihydrocodeine, fentanyl, methadone, morphine, oxycodone and pethidine. Use of opiates within three months prior to surgery and within 12 months post-surgery were examined by gender, age group, ethnicity, Charlson Comorbidity Index score and year of surgery. Differences by subgroup was examined with Chi-square test. Logistic regression model was used to calculate the adjusted odds ratios of strong opiates use before and after surgery compared with no opiates use.

Results: We identified 53,439 primary hip replacements and 50,072 primary knee replacements with a diagnosis of osteoarthritis. Of patients with hip osteoarthritis, 6,251 (11.7%) had strong opiates before hip replacement surgeries and 11,939 (22.3%) had opiates after surgeries. Of patients with knee osteoarthritis, 2,922 (5.8%) had strong opiates before knee replacement surgeries and 15,252 (30.5%) had opiates after surgeries. The probability of patients with hip and knee osteoarthritis having opiates decreased with age, increased with Charlson comorbidity index score, and increased over time both before and after surgeries. Male patients with hip and knee osteoarthritis were less likely to have opiates than female patients both before and after surgeries. New Zealand Europeans with hip and knee osteoarthritis were more likely to receive opiates than other ethnic groups prior to surgeries, but were less likely to have opiates than Asians post-surgeries. Patients who had opiates before surgeries were more likely to have opiates after surgeries than those who did not have opiates before surgeries. The odds ratio was 8.34 (95% confidence interval: CI: 7.87-8.84) for hip osteoarthritis and 11.94 (95% CI: 10.84-13.16) for knee osteoarthritis after adjustment for age, gender, ethnicity, year of surgery and Charlson comorbidity index score. Having opiates prior to surgeries also increased the probability of having opiates for 6 weeks or more after surgeries substantially. The adjusted odds ratio was 21.46 (95% CI: 19.74-23.31) for hip osteoarthritis and 27.22 (95% CI: 24.95-29.68) for knee osteoarthritis.

Conclusion: Preoperative opiates holidays should be encouraged. Multiple strategies need to be used to develop analgesic plans that allow adequate rehabilitation, without precipitating a chronic opiate dependence. Clinicians would also benefit from clear guidelines for prescribing strong opiates.

MATERNAL AND PERINATAL OUTCOMES IN WOMEN WITH RHEUMATIC DISEASES – A 10-YEAR EXPERIENCE FROM A PORTUGUESE TERTIARY CENTRE

A. R. Cruz-Machado1,2, S. C. Barreiro1,2, P. Martins1,2, M. Centeno1,3, C. Araújo2, L. Pinto1,3, S. Capela1,2, 1Hospital de Santa Maria, Servigo de Reumatologia e Doenças Metabólicas, Lisboa, Portugal; 2Instituto de Medicina Molecular (IMM), Unidade de Investigação em Reumatologia, Lisboa, Portugal; 3Hospital de Santa Maria, Departamento de Obstetrícia, Ginecologia e Medicina da Reprodução, Lisboa, Portugal

Background: Pregnant women with rheumatic diseases (RD) represent a population at a higher risk for adverse pregnancy outcomes (APO). At our unit, these patients (pts) are surveilled at a high-risk pregnancy clinic, by both rheumatologists and obstetricians.

Objectives: To assess pregnancy outcomes in pts with RD surveilled at our unit over the last decade.

Methods: Single-centre observational retrospective study of pregnant women with RD followed at a portuguese tertiary centre between 2009 to 2019.

Results: Overall, 353 pregnancies (preg) in 295 pts with RD were managed at our unit. Table 1 summarizes clinical data and the main APO recorded. Systemic lupus erythematosus (SLE) was the leading diagnosis followed by spondyloarthritides (SpA) and rheumatoid arthritis (RA). Antiphospholipid syndrome (APS) was diagnosed in 49 (13.9%) preg. We documented 284 (78%) live births (9 twin preg), 32 (10%) miscarriages, 7 (2%) elective abortions, 2 stillbirths (0.6%) and 2 ectopic preg; 35 (10%) of the overall preg were lost to follow up before delivery. Miscarriages occurred predominantly in pts with APS (34%). Fetal growth restriction (FGR) was recorded in 6% of preg, more than 1/3 of those in pts with APS. Preeclampsia (PE) complicated a total of 10 (4%) preg, 3 of those with superimposed HELLP syndrome, with SLE and APS accounting for 60% of the cases. Preterm births (15.5%) occurred mainly in APS, SLE and juvenile idiopathic arthritis (JIA) pts. Neonatal lupus ensued in 3 (3.8%) preg positive for anti-Ro/La antibodies. No neonatal deaths were recorded. SpA and RA represented the diseases which flared the most considering both pregnancy and the postpartum period.

Legend: gest; gestational; mic: miscarriage; NA: not applicable; PP: postpartum; preg: pregnancy; UCTD - Undifferentiated connective tissue disease; Continuous variables are presented as mean±SD. Categorical variables as n/mN, % - modified(m)N stands for total N after exclusion of non-applicable (n=0) or not applicable (m=0) or missing data categories. "Others" accounts for diagnoses with N<6, such as APS non syndrome, mixed connective tissue disease, myositis, overlap syndromes, Still’s disease and systemic sclerosis.

Conclusion: In pregnant women with RD, it is of vital importance to be aware of the increased risk for APO. In our cohort, APS and SLE were the conditions most associated with APO, while SpA and RA were responsible for most maternal miscarriages, while SpA and RA, respectively. SLE and APS were associated with decreased cervical cancer screening in patients with autoimmune disease. Increased cervical cancer screening might be a good strategy to be implemented in pregnant women with SLE or APS, but further research is needed.

FRIO517 POSSIBLE EARLY DETECTION OF ADVERSE EVENTS USING A STRUCTURED, STANDARD, 60-SYMPTOM CHECKLIST ON A MULTIDIMENSIONAL HEALTH ASSESSMENT QUESTIONNAIRE (MDHAQ)

K. Schroeder, S. Abu Mehsen, J. Castrejón, T. Pincus. Rush University, Rheumatology, Chicago, United States of America; Gregorio Marañon Hospital, Rheumatology, Madrid, Spain

Background: Adverse events of medications are reported to account for 5% of hospital admissions in the USA, including 10% in the elderly, despite extensive warnings to patients by health professionals and pharmacies concerning the problem. Some adverse events are relatively obvious, such as a severe rash or severely abnormal laboratory test. However, many adverse events are common symptoms, such as headache or fatigue, which may not necessarily be recognized as adverse events, particularly in elderly patients with many comorbidities. In clinical trials and other clinical research, a structured, standard, protocol-driven symptom checklist is recorded according to the "scientific method." In routine care, by contrast, recognition and recording of adverse events is elicited by health professionals at patient encounters or contact initiated by patients between visits, as 'subjective' medical history information, which may be highly variable. Use of a standard symptom checklist on an electronic patient questionnaire has been reported in oncology, pulmonology and other specialties, but not in rheumatology. A multidimensional health assessment questionnaire (MDHAQ) includes a standard 60-symptom checklist, to recognize comorbidities, provide a review of systems, and serve on a fibromyalgia assessment screening tool (FAST3) as a clue to identify patients with fibromyalgia. The MDHAQ 60-symptom checklist can identify new symptoms after initiation of a medication which may be adverse events.

Objectives: To analyze an MDHAQ 60-symptom checklist as a cost-effective approach to recognize medication-associated adverse events.

Methods: All patients at one site complete an MDHAQ at each visit, which includes a standard, structured 60-symptom checklist, in addition to RAPID3 (routine assessment of patient index data) and FAST3. Paper and electronic patient questionnaires are scanned into an Epic electronic medical record (EMR) and converted into a data repository for retrospective analyses. A list of common adverse events of many specific DMARDs (disease-modifying antirheumatic drugs) and biological agents used in treatment rheumatoid arthritis (RA) was compiled from websites of the FDA, pharmaceutical companies, and Up-to-date. Most listed symptoms are found on the structured MDHAQ 60-symptom checklist. A retrospective review of the first visit was conducted to recognize the presence or absence of self-reported symptoms which were listed as common adverse events for specific DMARDs on the MDHAQ 60-symptom checklist, using simple descriptive statistics. Only methotrexate (MTx) is presented here due to space limitations.

Results: All symptoms listed as adverse events of specific DMARDs were reported at higher frequencies in 379 DMARD-treated RA patients or 153 MTx-treated patients, compared to 149 DMARD-naive patients (Table). More than 30% of DMARD-treated patients reported headache and/or unusual fatigue, 27% anxiety; 10-20% cough, dizziness, hair loss, nausea, skin rash or hives,
stomach pain or cramps, eye problems, and/or weight loss; and 5-10% diarrhea, fever, and/or mouth sores (Table). Similar proportions were seen for Mtx-treated patients, although anxiety and cough were not listed as specific adverse events.

Conclusion: The MDHAQ symptom checklist may prove valuable to detect adverse events of high-risk medications, including on an electronic MDHAQ, which could be completed at home for 12 weeks after initiation of a new medication as a cost-effective approach for early detection of adverse events.

78.8%, 82.9%, and 87.2% remain on treatment with CTP-P13 in RA, AxSpa, and PsA respectively. The reasons for treatment withdrawing are reported in table 1.

The safety data are presented in table 2.

Conclusion: The results from this long-term follow-up period show that CTP-P13 was effective in inducing and maintaining remission in both naïve and switched patients. This real-life study did not highlight any new safety concerns.

† Including acute and delayed hypersensitivity reactions
‡ Including severe infections, tuberculosis, opportunistic infections, hepatitis.

Background: Objectives: REFLECT study has been carried out to assess in real life the use of CT-P13, the first monoclonal antibody biosimilar to infliximab (IFX) approved in France. Long-term real-life data on CT-P13 use are limited in patients (pts) suffering from rheumatic diseases and inflammatory bowel diseases.

Methods: REFLECT is a multicenter, prospective, observational study conducted in France which aims to describe characteristics of pts receiving CT-P13 and to assess its safety and effectiveness in real-life conditions. Eligible pts for inclusion were pts (≥6 years old) with RA, axSpA, PsA, and inflammatory bowel diseases.

Results: From 19 October 2016 to 31 January 2019, 1321 pts were included by 70 centres, and 616 pts with rheumatic diseases were analysed: 132 RA (25.0% males; mean age: 61.5 ± 10.5; median time since diagnosis: 12.9 years), 398 axSpA (59.0%; 48.0 ± 13.1 years; 10.7 years, respectively), and 86 PsA (41.9%; 53.0 ± 14.1 years; 10.3 years). Previous bDMARDs other than IFX were reported in 40.1%, 42.1% and 47.4% of RA, axSpA, and PsA pts, respectively. More than 1/3 of pts switched from the IFX originator to CT-P13 (40.2% of RA, 42.7% of axSpA and 35.5% of PsA). At the first administration of CT-P13, the majority of IFX-N pts had active disease (92.0% of RA, 76.4% of axSpA and 55.0% of PsA) compared to IFX-S pts (39.5% of RA, 23.1% of axSpA and 26.3% of PsA). At the first infusion of CT-P13, the median DAS28 scores were 4.8 and 2.4 for RA pts in IFX-N and INF-S pts, and 4 and 2.2 for PsA pts, respectively. In axSpA pts, the median BASDAI at baseline were 5.6 and 2.4 and the median BASFI was 5.3 and 2.8 in IFX-N and IFX-S pts, respectively. From the first administration of CT-P13 to 18 months follow-up the median DAS 28 decreased (-1 point) in both IFX-N pts and IFX-S for RA pts; for axSpA pts the BASFI and BASDAI scores decreased by -2 and -1, respectively in IFX-N and remained stable in IFX-S.

The analysis of pts suffering from PsA has not been reported due to the small number of patients with a follow-up at 18 months (4 IFX-N pts and 1 IFX-S pts).

Immunology and Inflammation, Immunology, Boston, United States of America

Background: Methods used in observational comparative effectiveness research (CER) are highly variable. Target trial emulation is an intuitive design approach that encourages researchers to formulate their question as a hypothetical randomised controlled trial (RCT), or the "target trial". Using observational data to emulate the target trial helps avoid common biases and has been shown to better align results with actual RCTs.

Objectives: We systematically reviewed observational CER studies in rheumatoid arthritis to provide examples of design issues that might have been avoided by using target trial emulation.

Methods: We searched for head-to-head effectiveness comparisons of biologic DMARDs in RA. Study designs were reviewed for components of target trial emulation: (1) eligibility criteria, (2) treatment strategies, (3) assignment procedures, (4) follow-up period, (5) outcome, (6) causal contrasts of interest (i.e., intention-to-treat or per-protocol effect), and (7) analysis plan. Reported methods were taken as the "emulation" of a corresponding target trial, to assess design issues that might introduce bias.

Results: We found 31 CER studies, the majority of which had one design issue belonging to one of the 7 protocol components (Table 1). The most common issues were: 1) 17 out of 31 studies used post-baseline information to define baseline eligibility (e.g. requiring ≥1 follow-up), which can bias results; 2) 26 out of 31 studies did not declare their causal contrast of interest, which is often made difficult by issue 1 and impacts data analysis and interpretation; and 3) 9 out of 31 studies used statistical selection of confounders rather than pre-defining them, which can also introduce bias (e.g. through adjustment of collider or intermediate variables).

Conclusion: The majority of observational CER studies in RA have one or more design issues that may introduce bias. Target trial emulation is a structured approach for designing observational CER studies that helps to avoid common biases.

FR10520 HOSPITALIZATIONS FOR HEMATOLOGICAL MALIGNANCIES WITH RHEUMATIC DISEASES: A NATIONAL INPATIENT SAMPLE ANALYSIS OF TEN YEARS (2005-2014)

Background: Several rheumatic conditions have been associated with increased risk of malignancies, especially hematopoietic and lymphoproliferative malignancies. Rheumatoid arthritis has been associated with a relative risk of 1.5-4 for the development of hematological malignancies (HM). A variety of immunosuppressive and immunomodulatory medications have also been linked to increased risk of HM. Moreover, with advances in the field of biologic agents being used in the treatment of rheumatic diseases (RD), the landscape keeps changing. To our knowledge, data on general trends of HM as well as in RD is limited.

Objectives: Our study aimed to determine the trends of hospitalizations for HM in patients with RD.

Methods: We identified admissions with HM with underlying RD (including rheumatoid arthritis systemic lupus erythematosus, inflammatory myositis, scleroderma, polymyalgia rheumatica, and connective tissue disease) from the NIS database using International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes from years 2005 to 2014. The primary outcome was the trends in hospitalizations for HM. We studied the yearly trends and the types of HM among hospitalizations with or without RD.

Results: 906,556 weighted hospitalizations were estimated for HM, and amongst those, 17,675 had underlying RD. The demographic analysis suggested that the average age of hospitalizations with HM and RD was higher, were more often females, and a higher number of comorbidities (Table 1). The average number of admissions remained stable for HM with and without HM, as described in Graph 1. There was a significant difference in the frequency of various subtypes in patients with and without RD (Graph 2). Non-Hodgkin’s Lymphoma was the most common subtype in HM without and with RD (35.8% and 47.14%).

Conclusion: To our knowledge, this is the first study to analyze trends in HM with RD. There has not been any significant change in the number of hospitalizations for HM from 2005-2014 with or without RD. The most common HM in admissions with RD were Non-Hodgkin’s Lymphomas (NHL) and myeloid leukemias, followed by multiple myeloma. The trends suggest no significant change in subtypes of HM over the study period.
Background: Chronic back pain (CBP) of the inflammatory type (IBP) is frequently reported in axSpA but also in the general population.

Objectives: We evaluated a recently proposed two-step referral system for early recognition of axSpA (concentrating on patients ≤45 years with chronic back pain who present with buttock pain, improvement by movement, psoriasis, positive testing for HLA-B27) in primary care and compare it to other combinations of symptoms and SpA-related items.

Methods: Consecutive patients ≤45 years who presented in PC to general practitioners or orthopedic surgeons working in PC with back pain lasting ≥2 months who had not been diagnosed before received questionnaires (Q1) relevant for the referral process. Thereafter, the PC physician asked the same questions in a separate questionnaire (Q2), including the decision on HLA-B27 testing. All patients were then referred to two experienced rheumatologists in a tertiary center who performed a complete workup including clinical, laboratory and imaging with radiographs and magnetic resonance imaging (MRI) examinations before their final diagnosis of axSpA or non-SpA (Q3).

Results: A total of 320 patients (mean age 35.9±10.3 years) was recruited. The proposed referral strategy (prS) was fulfilled by 127 patients in Q1 (39.7%), 160 in Q2 (50%), 102 by both, Q1 and Q2 (31.9%), and 83 with either Q1 or Q2 (25.9%). Overall, 47 patients were diagnosed with axSpA by the rheumatologist at Q3 (14.7%), 66% of which were male, mean age 34.7±10.1 years, 70.2% HLA-B27 positive, mean CRP 0.8±1.4mg/dl, mean ASDAS 3.2±0.8, mean BASDAI 5.1±2.0. Of these, 37 patients had fulfilled the prS in Q1 or Q2 (78.7%), and 31 in both Q1 and Q2 (66%), respectively. In the latter, the HLA-B27 prevalence was significantly higher (27/31, 87.1%) as compared to patients diagnosed with axSpA at Q3 but who did not fulfill the prS in Q1 and Q2 (5/16; 31.3%) (p<0.001).

The sensitivity and specificity of the prS was 78.7% and 69.2% in Q1, 78.7% and 62.2% in Q2, and in both, Q1 and Q2, 66% and 74%, respectively. AxSpA patients correctly identified by the prS in Q1 and Q2, were significantly more frequently positive for HLA-B27 and CRP and fulfilled more frequently the ASAS definition of inflammatory back pain in Q3.

Conclusion: A simple two-step referral strategy using a combination of clinical features for identifying axSpA patients in PC without laboratory and imaging examinations was confirmed in a large population from daily practice. This strategy performed well as selection for referral at the patient and PC physician level.

Background: In Japan, Methotrexate (MTX) has been approved in 1999, the first biologic DMARD (b/tsDMARD) in 2003, and the Janus kinase (JAK) inhibitors have been used since 2013. Although it is expected that the recent advancement of drug therapy would contribute the decrease in the incidence of orthopaedic surgeries by preventing structural damages1, 2, we are still facing a considerable number of patients who require surgical interventions3).

Objectives: To investigate the recent trends of patient’s background who underwent orthopaedic surgery for rheumatoid arthritis, number of orthopaedic intervention, and the type of the surgery.

Methods: We reviewed the records of 1569 patients with RA who underwent orthopaedic surgeries between 2004 and 2019 in our institution. The mean age of patients was 62.8 (22-88) years-old with disease duration of 20.9 (0.5-64) years. Data of these patients such as age, disease duration, medication (Glucocorticoid; GC, MTX, b/tsDMARD), type of surgeries (total joint replacement; TJR, hand surgery, foot surgery, spine surgery, and others), and preoperative serum CRP level were collected. We analyzed the annual change of these demographic and clinical data. Then, we compared them between CRP negative (<1.5g/l) and CRP positive group. Cochran-Armitage trend test, χ² square test, or unpaired T-test was performed for statistical analysis. P <0.05 was considered significant.

Results: Among all cases, 426 cases (27.2%) were treated with b/tsDMARDs at the time of operation. MTX and GC were used in 937 cases (59.7%) and 1015 cases (64.7%), respectively. The mean age and disease duration of RA showed an increasing trend, although the CRP level was dramatically decreased during the study period. While the rate of MTX use has not changed significantly (p=0.102), the number of cases treated by b/ts DMARD increased significantly to 46.7% (p<0.001). In contrast, the rate of GC use decreased significantly (p<0.001). Although the annual number of surgeries have not changed, the proportion of cases who performed TJR decreased dramatically (59.6% in 2011, 29.5% in 2019), and the surgeries for hand and foot increased significantly (p<0.001) (Fig 1). The annual mean preoperative CRP level also decreased from 18.8±1.95 to 4.89±0.81 (Fig 2). Compared to CRP positive group (n=1,113), the patients in CRP negative group (n=446) showed significantly younger age (p<0.001), shorter disease duration (p=0.031), lower late of GC use, and a higher rate of b/tsDMARD use. The proportion of patients who underwent TJR was significantly higher in CRP positive group (p<0.001).

Conclusion: Along with the increasing use of b/tsDMARD, the preoperative disease control of RA, as well as the type of demanded surgeries have dramatically changed.

Conclusion: Forty percent of U.S. rheumatologists participating in RISE used the registry for federal quality reporting. Physicians using RISE for reporting were disproportionately in small and solo practices, suggesting that the registry in fulfilling an important role in helping these practices participate in national quality reporting programs. Supporting small practices is especially important given the workforce shortages in rheumatology. We observed that practices reporting through RISE had higher measure performance than other participating practices, which suggests that the registry is facilitating quality improvement. Studies are ongoing to further investigate the impact of federal quality reporting programs and RISE participation on the quality of rheumatologic care in the United States.

FRI0526
THE INCIDENCE, PREVALENCE AND MEDICATION USE OF RHEUMATOID ARTHRITIS AMONG KOREAN WOMEN IN CHILDBEARING YEARS: A NATIONWIDE POPULATION-BASED STUDY
M. K. Chung1, J. S. Park2, H. S. Lim3, C. H. Lee3, J. Lee1, Division of Rheumatology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Rep. of (South Korea);2Division of Rheumatology, Department of Internal Medicine, National Health Insurance Service Ilsan Hospital, Goyang, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis (RA) predominantly affects women and has a significant impact on childbearing. Several population-based studies identifying incidence, prevalence, and medication use of RA have been reported, yet epidemiological studies focusing on women with RA in childbearing years are missing.

Objectives: We aimed to identify the incidence, prevalence and medication use of RA among Korean women in childbearing years.

Methods: From National Health Insurance Service (NHIS) data (2009-2016), containing inpatient and outpatient claim information for approximately 97% of the Korean population, we identified 9,217,139 women aged between 20-44 years. Incidence and prevalence of RA in the specific sociodemographic group of women in childbearing age were analyzed, and the prevalence of medication prescription were compared between women with RA and controls without rheumatic diseases such as RA, systemic lupus erythematosus, and ankylosing spondylitis. Individuals with RA were defined by the presence of International Classification of Disease, 10th revision code, M05. The medication use was defined as receiving > 90days prescriptions of NSAIDs, corticosteroids (CSs), and conventional synthetic (cs) disease modifying antirheumatic drugs (DMARDs) or > 1day prescription of biologic (b) DMARDs.

Results: Total 24,590 women with RA were identified. The average incidence of RA during 2011-2016 among women in childbearing years was 24.1/100,000 person-years (PYs) (95% CI 20.91-27.31) with a yearly increase from 20.99/100,000 PYs in 2011 to 28.38/100,000 PYs in 2016. The average prevalence of RA during 2009-2016 among women in childbearing years was 105.2/100,000 PYs (95% CI 99.0-111.5) with a minimum of 95.7/100,000 PYs in 2009 and a maximum of 110.5/100,000 PYs in 2016. There were increasing trends in both incidence and prevalence of RA according to age among women in childbearing years peaking in the age group of 40-44 years. The prescriptions of NSAIDs, Cs, csDMARDs and bDMARDs and dDMARDs were more frequent in women with RA than controls (NSAIDs; 24.21% vs 21.79%, Cs; 83.65% vs 4.28%, csDMARDs; 91.23% vs 0.41%, bDMARDs; 0.11% vs 0%, p<0.001).

Conclusion: The incidence and prevalence of RA are high among Korean women in childbearing years, and medication use was significantly more frequent in this specific population than controls. High disease burden is imposed upon women in childbearing years.

FRI0527
THE EFFECT OF A NURSE-LED PREDNISOLONE TAPERING REGIME IN POLYMYALGIA RHEMATOMA: A RETROSPECTIVE COHORT STUDY
C. Mork, M. Yde Matthiesen1, M. Callisen2, K. Keller1, Silkeborg Regional Hospital, Diagnostic Centre, Silkeborg, Denmark

Background: The cornerstone treatment of polymyalgia rheumatic (PMR) is prednisolone, which has several side effects such as osteoporosis and type 2 diabetes [1]. Therefore, the duration of prednisolone treatment should be as short as possible. Previous studies indicate that only 10-30% has discontinued prednisolone after 1 year and approximately 50% after 2 years [2].

Objectives: To investigate the efficacy of a nurse-led prednisolone tapering regime in patients with PMR compared to usual care.

Methods: The study is a single center retrospective cohort study with a 2-year follow-up. Prednisolone dose was evaluated after 1 and 2 years. A nurse-led PMR clinic was introduced June 1st, 2015 and patients diagnosed until June 7th, 2017 were included. Patients were diagnosed by a physician, and subsequently managed by nurses according to a specific protocol, with prednisolone tapering from 15 mg to discontinuation after 52 weeks. Regularly blood tests and telephone interviews were performed and a rheumatologist was involved if deemed necessary.

Patients diagnosed with PMR between June 1st, 2012 and June 1st, 2015 served as controls. They received standard care by a rheumatologist. The Danish guidelines for managing PMR remained unchanged throughout the study period.

The exclusion criterion was identified by searching the electronic patient journal for the PMR diagnosis. Data collection was performed by four experienced rheumatologists. Data were obtained from the Electronic Patient Journal of Central Denmark Region and recorded in the RedCap database.

Results: Five hundred and seventy patients were screened. Patients not diagnosed with PMR, with simultaneously giant cell arteritis, with relapse of known PMR, or prednisolone treatment for more than 4 weeks prior to the diagnosis were excluded. Sixty eight patients received standard care and 107 nurse-led care. There was no statistical difference between groups regarding reason for exclusion.

At baseline there was no difference between patients receiving standard care and nurse-led care regarding gender, mean age (70.7 years vs. 72.2 years), clinical findings, symptoms, level of C-reactive protein (43.4 mg/L vs. 39.7 mg/L), anti-citrullinated protein antibody and rheumatoid factor status. Median (IQR) prednisolone starting dose in the standard care group was 15 mg (15-25) vs. 15 mg (15-15) in the nurse-led care group (p=0.008).

After 1 year 29.4% of patients receiving standard care had discontinued prednisolone vs. 35.5% receiving nurse-led care (p=0.403). Median (IQR) prednisolone dose after 1 year was 3.75 mg (0.5-5) in the standard care group and 12.5 mg (0-3.75) in nurse-led care group (p=0.004). After 2 years 60.3% of patients receiving standard care had discontinued prednisolone vs. 82.2% receiving nurse-led care (p<0.001). Median (IQR) prednisolone dose after 2 years was 0 mg (0-2.5) in the standard care group and 0 mg (0-0) in the nurse-led care group (p=0.004).

There was no difference between groups regarding relapse of PMR and initiation of MTX treatment in either year 1 or 2.

Conclusion: A tight and systematic approach to prednisolone tapering in PMR is more effective than usual care. The results should be confirmed in a prospective setting.

FRI0529
INDICATORS OF EFFECTIVENESS AFTER 6 YEARS OF FOLLOW-UP OF PATIENTS IN THE FLS DR. NEGRIN
A. Naranjo1, A. Molina1, C. Sepúlveda2, F. Rubino3, S. Ojeda2, 1Hospital Universitario de Gran Canario Dr Negrin, Rheumatology, Las Palmas, Spain; 2Hospital Universitario de Gran Canario Dr Negrin, Las Palmas, Spain

Background: Data on the effectiveness of FLS in the medium and long term in Spain are needed

Objectives: To analyze the indicators of long-term persistence to treatment, refracture and mortality in our Fracture Liaison Service (FLS)

Methods: Throughout 2019, the medical records of patients with an indication of treatment to prevent new fractures whose baseline visit took place between 2012 and 2014 were reviewed. The data included those of the baseline visit (age, sex, type of index fracture, FRAX scale and DXA results) and for the follow-up (death and date, refracture including revision of spine x-rays - it was considered only the first refracture and, in the case of several fractures the most serious was chosen-, prescribed treatment, persistence of treatment trough electronic prescription on the date of review or death, and MPR or proportion of days covered by treatment).

Results: 399 patients were included, 335 of them women (84%), mean age 73.8 years (range 51-93) and average follow-up of 6 years (range 5.5-7 years).

Baseline visit.- The average FRAX was 15 and 7 for major fracture and femoral fracture respectively. DXA was normal in 22 patients (5.5%), osteopenia in 143 (35.8%) and osteoporosis in 234 (58.6%). 78 patients (19.5%) had a previous fragility fracture.

Type of fracture index: femur 126 (31.5%), forearm 119 (29.8%), humerus 76 (19%), vertebral 24 (6%), others 54 (13.5%). 80 patients (20%) had received prior treatment for osteoporosis.

Follow-up.- The persistence of treatment was assessed in 394 patients; 245 patients (62%) were prescribed a treatment on the most recent date, 200 (51%) with MPR>80%. When analyzing patients with prescribed treatment, in 176 cases (72%) a bisphosphonate was prescribed in a sustained manner, in 23 cases (9%) a bisphosphonate was prescribed and subsequently changed to denosumab, while in 45 cases (18%) it was initiated and maintained denosumab.

71 of 397 patients presented a new fracture (17.8%). The type of incident fracture was as follows: femur in 24 patients (34%), vertebral in 20 patients (28%), forearm in 9 patients (12%) and other fractures in 18 patients (25%). Refracture occurred in 9 patients in the first year, 16 in 2nd, 12 in the 3rd, 7 in 4th, 14 in 5th, 6 in 6th and 37th year. The persistence of treatment with MPR>80% was similar in patients with and without refracture (52 vs 51%). The average baseline age and FRAX for major fracture in the fractured and non-fractured were 75 vs. 73 years (p = 0.10) and 17 vs. 14 respectively (p<0.01).

92 patients (23%) died, 25% of them in the two years that followed the baseline visit and 61% in the following 4 years. The persistence of treatment was 37% in those who died and 69% in those who remained alive (p<0.01).

Conclusion: After an average of 6 years after the assessment in an FLS, the persistence of treatment was 62% (MPR>80% in 51%), the mortality was 23% and the percentage of refracture patients was 17%.

FRI0529
IS COTRIMOXAZOLE PROPHYLAXIS AGAINST PNEUMOCISTIS JIROVENCII PNEUMONIA RECOMMENDED IN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES REQUIRING IMMUNOSUPPRESSIVE THERAPIES? A SYSTEMATIC LITERATURE REVIEW.
C. A. Pereda Testa1, M. B. Nishishinya2, P. Diaz del Campo Fontecha3, N. Brito-Garcia3 on behalf of Rheumatology Evidence Based Working Group, Spanish Rheumatology Society., 1Hospital HLA Mediterraneo, Almeria, Rheumatology, Almería, Spain; 2Instituto Traumatológico Quirón, Barcelona, Rheumatology, Barcelona, Spain; 3Research Unit, Spanish Rheumatology Society, Madrid., Madrid, Spain

Background: The incidence of Pneumocystis jirovecii pneumonia (PCP) has increased substantially during the past years in patients with systemic autoimmune diseases (SAD). Mortality associated to PCP was reported to be up to 20 to 58%, particularly in those receiving immunosuppressive therapy, such as tumoral necrosis antagonist factors or glucocorticoid therapy. Though, there is clear evidence of the effectiveness of Cotrimoxazole against PCP, the risk of adverse effects is important, increasing morbidity and mortality. Up to date, there is no consensus about the need of PCP prophylaxis in SAD patients with immunosuppressed therapies.

Objectives: To analyse the efficacy and safety of Cotrimoxazole prophylaxis against PCP in SAD adult patients receiving immunosuppressive therapies.

Methods: We performed a comprehensive literature search, screening different databases, MEDLINE, EMBASE and Cochrane Library up to April 2019. Outcomes covered prevention of PCP or other infections, morbidity, mortality and safety. All categories of studies were included. Two reviewers selected and
extracted data from studies. The information obtained was summarized through a narrative review and results tabulated.

Results: From the initial 340 identified references, 12 were finally included. Two were randomized controlled trials, six observational studies, and four case reports. The quality in the majority of studies resulted moderate or low, with limited level of evidence. Besides, all Cotrimoxazole prophylaxis regimens described in each study were distinct. Results were consistent to exhibit the efficacy of Cotrimoxazole prophylaxis, compared to non-prophylaxis in the prevention of PCP in patients receiving immunosupresor therapy, particularly, those taking high glucocorticoid dose above 20mg/day. In terms of efficacy, Cotrimoxazole 400mg/80mg/day, given three times per week, or 200mg/40mg/day or in doses escape exhibited a similar performance. In contrast, Cotrimoxazole 400mg/80mg/day displayed a higher incidence of adverse effects.

Conclusion: Cotrimoxazole prophylaxis against PCP exhibited efficacy compared to non-prophylaxis, mainly in patients treated with high dose of glucocorticoids (≥20mg/day), causing a significant reduction in mortality. Positive efficacy results to non-prophylaxis, mainly in patients treated with high dose of glucocorticoids.

THE PREVALENCE AND DETERMINANTS OF SLEEP PROBLEMS IN PATIENTS ACROSS RHEUMATIC DISEASES AND THEIR CORRELATION WITH DISEASE INDICES USING THE ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3 (RAPID3) QUESTIONNAIRE.

C. Tan1, P. Cheung1,2, M. Lahiri1,1	Division of Rheumatology, University Medicine Cluster, National University Hospital, Singapore, Singapore; 2Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Background: Sleep problems are common in rheumatology patients. RAPID3 is a patient reported outcome measure (PROM) that efficiently screens for problems with sleep, anxiety or depression in routine care.

Objectives: To study prevalence and determinants of self-reported sleep problems across rheumatic diseases in Rheumatology clinics in Singapore, and its correlation with disease indices.

Methods: RAPID3 questionnaire was filled electronically over 6 months. Demographic data and SNOMED diagnoses codes were matched through hospital electronic medical records. RAPID3 comprised of 3 questions measuring the extent of difficulty getting a good night’s sleep and dealing with anxiety or depression. Significant problems were considered if they had “much difficulty” or were “unable to do” the component. The relationship of sleep with anxiety, depression, physical function (measured by modified health assessment questionnaire, mdHAQ), pain and patient global assessment (using visual analogue scale, VAS), was evaluated using Pearson’s correlation. Factors associated with significant sleep problems were evaluated by logistic regression.

Results: 4078 patients (mean (SD) age 55.8 (16.3) years, 67.9% female, 70.6% Chinese) were invited to participate, of which 2625 (64.4%) responded. SNOMED diagnosis codes were available for 1570 (59.8%) patients- majority had inflammatory arthritis (n= 843, 53.7%) (Figure 1). Mean mdHAQ was 0.3 (0.5), pain VAS was 2.4 (2.3) and global VAS was 2.6 (2.2). Data on disease duration, clinical features and medications were not available. 39.3%, 27.5% and 23% had problems with sleep, anxiety and depression respectively; and 7.3%, 4.5% and 4.3% had significant problems respectively. Sleep moderately correlated with anxiety (r=0.48), pain (r=0.001) and depression (r=0.436, p<0.001) and weakly correlated with mdHAQ (r=0.289, p<0.001), global (r=0.339, p<0.001) and pain VAS (r=0.314, p<0.001).

In multivariable logistic regression, significant sleep problems were associated with anxiety (OR 4.733, CI 2.172-10.310, p<0.001), mdHAQ score ≥ 1 (OR 2.920, CI 1.691-5.043, p<0.001) and pain VAS >3 (OR 1.884, CI 1.093-3.247, p=0.023). Patients with osteoarthritides and fibromyalgia were more likely than those with inflammatory arthritides to have significant sleep problems, though we were unable to adjust for body mass index as data were unavailable (Table 1).

Table 1. Determinants of significant disturbances in sleep in patients with rheumatic diseases

Conclusion: Sleep problems are common in rheumatology patients and correlate significantly with disease indices and psychological distress. Rheumatologists should routinely screen for sleep difficulties, especially in patients with osteoarthritides and fibromyalgia.

AIR POLLUTANTS AND DEVELOPMENT OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH AUTOIMMUNE DISEASES

H. H. Chen1,2, W. C. Chao1, Y. H. Chen2, D.Y. Chen3, C. H. Lin1. 1Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China; 2Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; 3China Medical University Hospital, Rheumatology and Immunology Center, Taichung, Taiwan, Republic of China

Background: Interstitial lung disease (ILD) is characterized by progressive inflammation and fibrosis, and accumulating evidence have shown that exposure to air pollutants was associated with the development of ILD. Autoimmune diseases are highly correlated with ILD, including connective tissue disease-associated ILD (CTD-ILD) as well as interstitial pneumonia with autoimmune diseases. We recently reported that exposure to air pollutants was associated with incident systemic lupus erythematosus (SLE). However, the impact of air pollutants on the development of ILD among patients with autoimmune diseases remains unknown.

Objectives: The study aimed to address the impact of accumulating exposure to air pollutant above moderate level, defined by Air Quality Index (AQI) value higher than 50, on the development of ILD in patients with autoimmune diseases including SLE, rheumatoid arthritis (RA) and primary Sjögren’s syndrome (SS).

Methods: We used a National Health Insurance Research Database in Taiwan to enroll patients with SLE (International Classification of Diseases (ICD)-9 code 710.0, n=33,211), RA (ICD-9 code 714.0 and 714.30–714.33, n=32,573), and primary SS (ICD-9 code, 710.0, n=15,246) between 2001 and 2013. We identified newly diagnosed ILD cases (ICD-code 515) between 2012 and 2013 and selected age, sex, disease duration and index-year matched (1:4) patients as non-ILD controls. The hourly levels of air pollutants one year prior to the index-date were obtained from 60 air quality monitoring stations across Taiwan, and the air pollutants in the present study consisted of particulate matter <2.5 μm in size (PM2.5), particulate matter <10 μm in size (PM10), nitrogen dioxide (NO2), carbon monoxide (CO), sulfur dioxide (SO2) and ozone (O3). We used a spatio-temporal model built by a deep-learning mechanism to estimate levels of air pollutants in 374 residential locations based on data of 3 quality monitoring stations near the location (8). Notably, we used cumulative exposed hours to air pollutants in the present study to exclude the effect of temporary exposure of high-level air pollutant. A conditional logistic regression was used to determine the association between exposure to air pollutant and the development of ILD, adjusting age, gender, Charlson Comorbidity Index (CCI), urbanization, family income, and medications for autoimmune diseases.

Results: A total of 272 patients with newly diagnosed ILD were identified among patients with autoimmune diseases, including 39 with SLE, 135 with RA, and 98 with primary SS. We found that the duration of exposure to PM 2.5 higher than modest level was associated with the risk of ILD development in patients with SS (adjOR 1.07, 95% CI 1.01–1.13), and similar trends were also found in patients with SLE (adjOR 1.03, 95% CI 0.95–1.12) and RA (adjOR 1.03, 95% CI 0.99–1.07). Intriguingly, we observed an inverse correlation between the duration of exposure to O3 and the development of ILD in patients with SS (adjOR 0.83, 95% CI 0.70–0.99); however, the finding was not found in patients with SLE (adjOR 1.13, 95% CI 0.92–1.37) and RA (adjOR 0.98, 95% CI 0.87–1.11).

Conclusion: In conclusion, we identified that longer exposure to PM2.5 higher than modest level tended to be associated with the development of ILD in patients with autoimmune diseases, mainly SS.

THE IMPACT OF GENETICALLY DETERMINED SERUM URATE LEVELS ON THE DEVELOPMENT OF CARDIOVASCULAR DISEASES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF MENDELIAN RANDOMIZATION STUDIES

J. Choi1, N. McCormick1,2, S. Marozoff2, M. De Vera1, H. Choi1,2. 1MGH, Boston, United States of America; 2Arthritis Research Canada, Richmond, Canada

Background: Conventional observational studies have identified serum urate (SU) as an independent risk factor for cardiovascular diseases (CVDs), but the causal relationships remain unsettled, with potential confounding and reverse causality. When applied correctly, Mendelian randomization (MR) employing genetic variants as instrumental variables can eliminate these biases and allow for causal inference.

Objectives: To conduct a systematic review and meta-analysis of English-language, peer-reviewed MR studies on the causal effects of SU on CVDs and assess validation of key MR assumptions.

Methods: A research librarian conducted a search ( inception to January 2020) of four databases (Medline, Embase, Cochrane Library, and Web of Science),
which was supplemented by hand-search. Titles and abstracts were screened by two independent reviewers, who subsequently evaluated and extracted data from full-text of selected articles. Pooled meta-analysis was performed using random-effects weighting.

Results: Of 1014 articles identified, 40 were selected for full-text review and 13 studies reporting on CVDs were included in the systematic review (Figure 1). The first was published in 2009 and five were published in 2018 or 2019 alone. The included studies were of varying quality in regards to satisfying the assumptions for MR design.

Overall, there was little evidence for a causal association between SU and risk of CVDs (Table 1). Random-effects meta-analysis revealed that SU was not significantly associated with risk of CVDs (OR=1.04; 95% CI=0.99-1.09) (Figure 2). 11 of the 13 studies reported null estimates for the effects of genetically-determined SU levels on CVDs. Two studies with small numbers of cases (N=125 and 222) reported significant associations, but these pertained to highly-specific subgroups.

Table 1. Summary of included studies. CAD: Coronary Artery Disease; CHD: Coronary Heart Disease; IDH: Icahemic heart disease; MI: Myocardial Infarction; MR: Mendelian Randomization; PVD: Peripheral Vascular Disease; SNP: Single Nucleotide Polymorphism

* Risk of pleiotropy (assumption 2) is low when utilizing few well-established SNPs

Fig 2: Pooled meta-analysis results.

Conclusion: Evidence from this systematic review does not support a causal role for SU levels and CVDs. As such, interventions targeting SU levels alone are unlikely to lower the risk of CVDs.

FR0533 SMOKING AS A PREDICTIVE FACTOR FOR SPONDYLOARTHRITIS RELATED UVEITIS: RESULTS FROM A SINGLE CENTRE CROSS-SECTIONAL STUDY.

E. Costa1, D. Almeida1, M. Cerqueira2, J. Redondo Costa3, A. R. Ribeiro3, J. Neves1, Hospital de Braga, Rheumatology, Braga, Portugal; 2Hospital de Braga, Rheumatology, Braga, Portugal; 3Unidade Local de Saúde do Alto Minho, Rheumatology, Ponte de Lima, Portugal

Background: Although spondyloarthritis (SpA) is primarily a musculoskeletal condition, ocular involvement is an important clinical feature and contributes to the burden of disease. Acute anterior uveitis (AAU) is causally described as the most frequent extra-articular manifestation of SpA and in some cases the first clinical presentation. The prevalence of AAU varies according to the subtype of SpA. In a systematic literature review, the mean prevalence of AAU was 32.7% and a positive association between HLA-B27 positivity, axial SpA, male sex and uveitis has been reported (1). More recently, some cross-sectional studies have described lower odds of spondyloarthritis-related uveitis (SpA-U) in smokers than in patients who are ex-smokers or never smokers (2). Predictors of SpA-U are poorly defined in literature and the influence of smoking status remains controversial.

Objectives: To analyse the factors associated with uveitis in SpA patients in a Tertiary Rheumatology Center.

Methods: An observational cross-sectional study was performed including patients fulfilling the ASAS criteria for axial SpA with a follow-up visit between January and June 2019. Clinical patients’ charts were reviewed and the following variables were considered: age, gender, history of uveitis (confirmed by ophthalmologist observation), number of AAU episodes, smoking status (never smoker or ever smoker), HLA-B27, disease duration, disease involvement (axially axial or peripheral), history of enthesitis and syndesmophytes. History of AAU and associated variables were determined in this subset of patients.

Statistical analysis was performed with logistic regression model. P value <.05 was defined as statistically significant.

Results: The study included 164 patients (82.3% men) with median age of 44.0 years (IQR 37 to 54) and a median disease duration of 14.6 years (IQR 9.28 to 20.32). SpA diagnosis was ankylosing spondylitis in 70.7% cases and the remaining were non-radiographic axial SpA. HLA-B27 was positive in 84.8%, 31.1% of patients were ever smokers and 21% had both axial and peripheral joint involvement. Twenty four percent of patients had at least one AAU episode. Recurrence of uveitis occurred in 70% of patients. Ever smoking (OR=2.256; 95%CI [1.077-4.276]; p<.05) and syndesmophytes (OR=1.25; 95%CI [1.009-4.475]; p<.05) showed a statistically significant association with uveitis in univaried logistic regression. Although not statistically significant, a trend to association was found between smoking and recurrence of AAU (OR=2.235; 95%CI [1.973-5.135]; p=.058). In multivaried logistic regression only ever smoking was independently associated with uveitis (OR=2.542; 95%CI [1.007-6.420]; p<.05). We did not find association between presence of uveitis and gender, age, disease duration, disease involvement, HLA-B27 positivity and enthesitis.

Conclusion: Contrary to few cross-sectional studies showing a possible protective effect of smoking in SpA-U, and in line with new data from Zhao et al (3), we report a statistically significant independent association between history of smoking and uveitis. Nevertheless, we emphasize the need of more studies to confirm these findings.

FR0534 PATIENT-REPORTED MEASURES OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS VARY ACROSS THE NORDIC COUNTRIES, RESULTS FROM A NORDIC COLLABORATION.

Background: Disease activity in rheumatoid arthritis (RA) patients is measured through composite scores which are considered treatment targets and thus facilitate clinical decision making. Scores often combine a mix of objective and
subjective measures, and, although the latter (e.g., pain, patient’s global, 28 tender joint count (TJC)) may be impacted by contextual and cultural factors, these clinical metrics are often assumed to be comparable across different settings and reflecting the RA disease.

Objectives: To explore whether there are systematic differences in patient-reported measures of RA disease activity (i.e., TJC and a measure of pain on a Visual Analog Scale (VAS)) across countries, at similar time-points in the course of the RA disease, taking objective measures of concomitant disease activity and other factors into account.

Methods: RA patients starting a first ever tumor necrosis factor inhibitor (TNF) 2008 through 2017 were identified in rheumatologic registers in five Nordic countries. Data were pooled for analysis. Clinical metrics were retrieved at three time-points: at TNFi start, and after three and twelve months, irrespective of treatment. Baseline clinical variables distributions were compared between countries. The correlation between pain and patient’s global VAS was calculated with the Pearson correlation coefficient (r). At each time-point the subjective measures (TJC and pain) were compared between countries and analyzed with linear models: (i) crude; (ii) adjusted for age, sex, birth decade, disease duration (DD), year of TNFi treatment start (year), C-reactive protein (CRP) and 28 swollen joint count (SJC) from the time-point in question.

Results: A total of 23 796 RA patients were included (Table 1). At baseline, the significant differences between Nordic countries for TJC and pain (crude model) were slightly modified after adjustment but remained statistically significant (Table 2). Compared to baseline, the inter-countries differences were reduced at 3 and 12 months, but also were statistically significant (Figure 1).

Figure 2: Country-specific cross-tabulation of median values of subjective measures (x axis: TJC, Pain VAS) versus objective measures (x axis: CRP, SJC). Baseline TNFi start (upper pane) and at 3 months (lower pane).

‡ adjusted for age, sex, birth decade, year, DD, CRP, SJC

Conclusion: In this observational study of 23 796 RA patients from 5 Nordic countries starting 1st TNFi, patient-reported variables related to RA disease activity (pain VAS, TJC) varied across countries. These differences were not explained by differences in demographic (age, sex, birth decade, year) or objective RA measures (DD, CRP, SJC). This implies a limit to the direct comparability of results obtained from subjective measures from different countries.

Results: Overall, 2307 RD patients and 78251 HC were included. Newly detected hyperthyroidism with treatment indication were significantly more frequent in RD patients at initial assessment (1.3% vs 0.5%, p < 0.001) and in total (2.9% vs 1.7%, p<0.001) (Table 1, Figure 1). Cox regression multivariate analysis revealed systemic lupus erythematosus (SLE), polymyositis dermatomyositis (PMDM), mixed connective tissue disease (MCTD) as significant risk factors of new developments of hyperthyroidism during follow up after adjusting confounders. (Table2)

Conclusion: Hyperthyroidism with therapeutic indications are considerably more frequent in RD patients (particularly with SLE, PMDM and MCTD) both at initial assessment and during follow up. We recommend routine screening at initial assessment and careful follow up of thyroid function test in those patients.

SEUM GOLIMUMAB CONCENTRATIONS AND ANTI-DRUG ANTIBODIES ARE ASSOCIATED WITH TREATMENT RESPONSE AND DRUG SURVIVAL IN PATIENTS WITH INFLAMMATORY JOINT DISEASES: DATA FROM THE NOR-DMARD STUDY

J. E. Gehin1,2, D. J. Warren1, S. W. Syversen3, E. Lie4, J. Sexton2, L. Loli5, A. Wierød6, T. Bjørn3, T. K. Kvien2,3, N. Bolstad1, G. L. Goel1. 1Oslo University Hospital, Radiumhospitallet, Department of Medical Biochemistry; Oslo, Norway; 2University of Oslo, Faculty of Medicine; Oslo, Norway; 3Diakonhjemmet Hospital, Dept of Rheumatology; Oslo, Norway; 4Oslo University Hospital; Ullevål, Dept of Internal Medicine; Oslo, Norway; 5Lillehammer Hospital for Rheumatic Diseases; Lillehammer, Norway; 6Vestre Viken Hospital trust; Drammen, Norway

Background: Lack or loss of response to TNFα-inhibitors can be caused by subtherapeutic drug levels and anti-drug antibodies (ADAb). Knowledge about associations between clinical efficacy and drug levels as well as occurrence of ADAb is limited in patients with inflammatory joint diseases (IJD) treated with golimumab.

Objectives: To identify the therapeutic target concentration and assess the frequency of ADAb in golimumab-treated patients with IJD.

Methods: 91 patients from the NOR-DMARD study with a clinical diagnosis of axial spondyloarthritis (n=41), rheumatoid arthritis (n=20) or psoriatic arthritis (n=20) starting treatment with golimumab, with an available biobank sample at 3 months follow-up, were included. Treatment response was defined by ASDAS Clinically important improvement in axial spondyloarthritis, EUULAR good/moderate response in rheumatoid arthritis and improvement of ≥50% in modified DAPSA (using 28 swollen/tender joint counts) in psoriatic arthritis. Serum drug concentrations were analysed in non-trough samples collected 3 months after treatment initiation, using an automated in-house target-based immunofluorometric assay. ADAb was measured with an inhibition assay that measures neutralising antibodies. The association between drug levels and treatment response was assessed by multivariable logistic regression (adjusted for age, sex and prior bDMARD (Y/N)).

Drug-survival was assessed by Kaplan-Meier curves and Cox proportional hazard regression analysis.

Results: Golimumab serum concentrations varied considerably between patients on standard dose (range 0.0-8.2 mg/L) with a median of 2.2 (IQR 1.0-3.5) mg/L. The proportions of responders after 3 months among patients with golimumab concentration <1.0, 1.0-3.9 and ≥4.0 mg/L were 19%, 49% and 74%, respectively (Fig 1). The likelihood of response after 3 months of treatment was significantly higher among patients with serum golimumab concentration ≥1.0 mg/L compared to those with golimumab <1.0 mg/L (OR 5.8 (95% CI 1.7-19.7), P =0.005). The proportion of responders was highest among patients with golimumab concentrations ≥4.0 mg/L, but the difference in response between patients with concentrations ≥4.0 mg/L compared to <1.0 mg/L was not statistically significant (OR 2.1 (95% CI 0.6-7.1), P=0.24). We also found a higher rate of treatment discontinuation in patients with serum golimumab concentration <1.0 mg/L compared to ≥1.0 mg/L (HR 3.6 (95% CI 1.9-6.9), P <0.001) (Fig 2). ADAb were detected in 5 of 91 samples and were associated with lower drug concentrations. Only 1 out of 5 ADAb-positive patients was a responder at 3 months, and all 5 ADAb positive patients discontinued treatment within the first 14 months.

Conclusion: Golimumab concentrations ≥1.0 mg/L were associated with improved treatment response and better drug survival, but our results also indicate that some patients might benefit from higher concentrations. ADAb were associated with lower drug concentrations and both reduced treatment response and drug survival. These findings suggest a rationale for personalised dosing guided by measurements of drug concentration and ADAb in golimumab-treated patients with IJD, which should be addressed in future randomised strategy trials.

Conclusion: Rituximab or CYC may stabilize pulmonary function but may not benefit on overall survival. Frequent ILD AE and respiratory failure are risk factors of mortality in pSS-ILD.

PREGNANCY IN WOMEN WITH RHEUMATIC DISEASES: MATERNAL AND FETAL COMPLICATIONS

K. Tatiana1, O. Ivanova1, T. Fedorova1, M. Vinogradova1, E. Rumiantseva2, A. Balakireva3, 1Federal State Budget Institution “Research Center for Obstetrics, Gynecology and Perinatology”; Moscow, Russian Federation; 2Lomonosov Moscow State University; Faculty of Fundamental Medicine, Moscow, Russian Federation

Background: Most of the rheumatic diseases are more common in women than in men. Because many of these conditions may interact with pregnancy, reproductive issues related to disease management should be discussed with all women with rheumatic diseases who are in reproductive age group. Some rheumatic diseases (i.e. systemic lupus erythematosus (SLE) are associated with flares in pregnancy, while others (i.e. rheumatoid arthritis (RA) have been known to improve or not deteriorate during pregnancy. However, pregnancies in women with rheumatic diseases are still at risk of maternal/fetal complications. Nevertheless, no detailed analysis of pregnancy outcomes in women with various types of systemic connective tissue diseases has been carried out in the recent studies.

Objectives: This study aimed to compare pregnancy outcomes in women with various types of systemic rheumatic disease and analyze influence of clinical features/laboratory parameters on risk of maternal and fetal complications.

Methods: A retrospective single-center cohort study 11/2014-12/2019: 191 pregnancies in 181 patients with proved rheumatic diseases > 20 weeks of gestation, mean age was 31.6 years. Proved SLE was observed in 67 patients, 8 of them had antiphospholipid syndrome (APS) secondary to SLE. 40 patients had proved RA, 24 – vasculitis, 18 – primary Sjögren syndrome (pSS), 30 – seronegative spondyloarthropathies (SpA). Clinical and laboratory parameters, renal function at conception and after delivery and pregnancy outcomes were collected. Preeclampsia (PE) was diagnosed by the 2008 WHO criteria.

Results: Rate of PE was significantly higher in women with SLE and SLE+APS compared to women with RA (p < 0.05). We found a threefold increase of PE risk compared to women with RA, vasculitis, systemic sclerosis (SSc), in women with SLE compared to women with SSc and SpA and in women with SSc compared to women with SpA (p < 0.05).

Rate of preterm birth was higher in patients with SLE+APS compared to women with SLE, RA and vasculitis, in patients with SLE compared to patients with RA and SpA, in patients with RA compared to patients with vasculitis, SSc and SpA (p < 0.05).

Birth weight was significantly higher in babies born to women with SSc compared to newborns to women with SLE, RA, pSS, SpA and SLE+APS and lower in newborns to women with SLE+APS compared to other groups (p < 0.05).

Newborns to women with SLE and SLE+APS had lower Apgar scores than newborns to women with RA, Low GFR (p = 0.004, OR = 1.03), high urea (p < 0.001, OR = 1.5, 95% CI 1.2-1.8), creatinine (p = 0.005, OR = 1.02, 95% CI 1.09) and LDH concentrations (p = 0.009, OR = 1.01, 95% CI 1-1.02) in 3rd trimester increased the risk of low Apgar scores of a newborn (p < 0.05).

Conclusion: Patients with SLE with/without secondary APS have significantly increased rates of preeclampsia, preterm birth and lower Apgar scores. Risk of adverse pregnancy outcomes can be significantly reduced by good disease control.

References:
CTD subtype was not specified in 2,067. CTD-PAH patients had a mean age of 55 years and 87% were female. Most patients (70%) had functional class III or IV disease and the mean 6-minute walk distance at enrollment was 327 m. Among registries that enrolled patients of all PAH etiologies (N=7,829), survival rates in the CTD-PAH subpopulation (n=2113) were 83%, 73%, and 62% at 1-, 2-, and 3- years, respectively. These survival rates were lower than those reported for the overall PAH population: 88%, 79%, and 72% at 1-, 2-, and 3- years, respectively. Numerically higher survival rates at 1-, 2-, and 3- years were observed in CTD-PAH patients treated in 2010 and later: 85% vs 90%, 74% vs 92%, and 65% vs 73%. Among all CTD-PAH patients, survival rates were lower for patients with SSc compared to those with SLE: 88% vs 92%, 75% vs 90%, 67% vs 87% at 1-, 2-, and 3- years, respectively (Figure).

Conclusion: Patients with CTD-PAH have a substantial risk of death, however, CTD-PAH patients treated within the last ten years have numerically higher survival rates than those treated earlier. This may be related to increased screening for PAH, especially in SSC (leading to earlier diagnosis) and/or the availability of new treatment approaches. Consistent with clinical observations, patients with SSC have worse survival rates than those with SLE. Given the high risk of mortality in these patients, early detection and upfront aggressive treatment are warranted.

DIFFERENT ASSOCIATION BETWEEN BONE MINERAL DENSITY AND OSTEOARTHRITIS ACCORDING TO THE SITE OF OSTEOARTHRITIS

Background: Osteoarthritis (OA) and osteoporosis (OP) are both high prevalence at old age, and there are various reports on the association between the two diseases. Some studies have shown that high bone mineral density (BMD) is a risk factor for OA incidence, while others have mentioned the possibility of OP contributing to onset of hip OA. Recent study described that higher BMD reduce the risk of hip OA and raise the risk of knee OA. So, the relationship between BMD and OA or the effects of BMD on different OA site are not clear yet.

Objectives: In this study, we investigated the association between BMD and radiographic OA using representative sample data of Korean adults.

Methods: The study included 6345 subjects aged 50 years or older who underwent BMD measurements using dual-energy X-ray absorptiometry and X-rays of at least one site of the spine, hip, and knee in the Korean National Health and Nutrition Examination Survey conducted in 2010-2011. OA was defined according to radiographic finding (KL grade ≥ 2). Weighted multivariable logistic regression was used to analyze the association between BMD and OA. Since gender differences are evident, men and women were analyzed separately.

Results: Spine OA was about 60% in both men and women, and hip OA was about 35% in men but only 1% in women. Knee OA was 76% in women and 58% in men. In men, the risk of OA increased 1.24 times as BMD increased by 1 g/cm2. By site, knee and spine OA were statistically significant in relation to BMD, but hip OA was not statistically significant. In women, the association between BMD and knee and hip OA was insignificant. In spine OA, the risk of OA increased 1.2 times when BMD increased by 1 g/cm2.

Conclusion: In conclusion, high BMD increased the risk of knee and spine OA in men, but did not affect hip OA. In women, high BMD increased the risk of spine OA. Differences in the mechanism of OA development by site are thought to be possible explanations for the differences in the association between BMD and OA.

(p<0.001), older age of onset (p=0.019), higher levels of RF IgM (p=0.027) and anti-CCP (p<0.001). Development of persistent spontaneous remission negatively correlated with polyarthritis (p=0.033), PF-positivity (p=0.034), anti-CCP-positivity (p<0.001). Positive seroconversion was observed of RF in 10 (4.7%) patients, 8 developed RA, of anti-CCP – in 3 (1.4%) patients, all developed RA.  

Conclusion: Seronegative oligoarthritis disease and highly seropositive disease are different subtypes of UIA. Combination of seronegativity and oligoarticular disease (n=52) associated with relatively rare development of RA (36.2%) and high proportion of persistent spontaneous remission (22.4%). Patients who were highly positive (>3 ULN) for both RF and anti-CCP developed RA in 97% of cases and never remitted spontaneously.

Figure 1. Kaplan Meijer curves on inflammatory arthritis development stratified for number of points based on LASSO regression. Legend: Points were based on the regression coefficients yielded by Cox LASSO-regression. 2 points were assigned for the risk factors ACPA-positivity and >2 locations of subclinical inflammation and 1 point was assigned for RF-positivity and presence of MCP-extensor peritendinitis.

FRIO542

OBTAINING HIGH POSITIVE PREDICTIVE VALUES FOR THE DEVELOPMENT OF CLINICALLY APPARENT ARTHRITIS IN PATIENTS PRESENTING WITH CLINICALLY SUSPECT ARTHRAILIA; IS IT FEASIBLE?

X. Matthijsen1, B. Van Dijck1, F. Wouters1, E. Niemantsverdriet1, A. Van der Helm-van Mil1,1, Leiden University Medical Center (LUMC), Leiden, Netherlands; 2Erasmus MC, Rotterdam, Netherlands

Background: The hypothesis that initiation of DMARD-treatment before arthritis becomes apparent could permanently modulate the disease process, such that persistent RA is prevented, is being studied in several ongoing trials. Essential for such studies is the ability to accurately predict clinically apparent inflammatory arthritis (IA). However there are two hurdles: first, it is insufficiently known whether it is possible to obtain high positive predictive values (PPV) in patients presenting with clinically suspect arthralgia (CSA). Second, none of current predictive models is validated in independent cohorts. We here aimed to evaluate the first question, incorporating improved markers of MRI-detected subclinical inflammation that were recently identified but have not yet been combined with other known predictors.[1]

Objectives: To assess the feasibility of achieving high PPVs in prediction of IA-development in patients with CSA by combining clinical, laboratory and imaging parameters.

Methods: 580 patients with CSA were consecutively included in the Clinically Suspect Arthralgia (CSA)-cohort and followed on the development of IA, determined by physical examination of joints. Unilateral contrast-enhanced 1.5 Tesla MRIs were made of MCP(2-5), wrist and MTP(1-5)-joints at baseline and scored in line with the RAMRIS. The number of locations with subclinical inflammation (0/1-2/3) and the presence of MCP peritendinitis were defined as described previously.[1] Other studied clinical and laboratory variables were based on the literature; initial localisation of complaints (small/large joints), functional disability (health assessment questionnaire (HAQ) ≥1), ACPA-positivity (Anti-CCP2), RF-positivity (IgM-RF) and elevated CRP.[2,3] LASSO Cox regression with a 10-fold cross-validated shrinkage parameter was used for predictor selection. Regression coefficients were rounded to the nearest number ending in .5 or .0 and multiplied by two, resulting in a weighted score. Kaplan Meijer curves were used to obtain PPVs of this weighted score and the area under the curve (AUC) was determined at 2-year follow-up.

Results: Mean age was 44, 78% was female, and 18% progressed to IA within 2 years. The following parameters were selected with LASSO: RR-positivity, ACPA-positivity, HAQ>1, >2 locations of subclinical inflammation and presence of MCP-extensor peritendinitis. Based on the beta of LASSO-regression, patients were assigned 2 points for the risk-factors ACPA-positivity and >2 locations of subclinical inflammation, 1 point for RF-positivity and presence of MCP-extensor peritendinitis and 0 points for HAQ>1. Kaplan Meijer curves show PPVs of 8%, 9%, 30%, 54%, 73%, 79% and 86% at two years (Figure 1). This model yielded an AUC of 0.79.

Conclusion: High PPVs for IA-development can be achieved in patients with CSA by weighting a combination of known predictors. Although encouraging, these data are based on one observational cohort study and have not been validated in independent cohorts, limiting the relevance. To support future research in the field of arthralgia, it is needed that different research groups work together to come to risk estimations that are validated and accepted.

declined during the 1st trimester of pregnancy (SLEDAI-2K:2.91±3.0, 1.70±2.23) but increased during the 1st and 2nd trimester post labor (SLEDAI-2K: 2.47±4.29 and 2.52±3.2).

Conclusion: This is the first Greek inception cohort with prospective monitoring of pregnant SLE patients. Adverse outcomes occur with prematurity being the most frequent. In our cohort disease activity tends to increase during the 1st and 2nd trimester post-labor without serious relapses. Vigilant monitoring during pregnancy and post-labour is advised.

THE EFFECT OF PATERNAL EXPOSURE TO IMMUNOSUPPRESSIVE DRUGS ON SEXUAL FUNCTION, REPRODUCTIVE HORMONES, FERTILITY, PREGNANCY AND OFFSPRING OUTCOMES: A SYSTEMATIC REVIEW

L. F. Perez1, R. Dolhain1, S. Vorstenbosch2, W. Bramer3, E. Van Puijenbroek2,4, J. Hazes1, B. Te Winkel1, Erasmus MC, University Medical Center, Rheumatology, Rotterdam, Netherlands;1Netherlands Pharmacovigilance Centre Lareb, 's-Hertogenbosch, Netherlands;2Erasmus MC, University Medical Center, Medical Library, Rotterdam, Netherlands;3University of Groningen, Groningen Research Institute of Pharmacy, PharmacoTherapy, Epidemiology and Economics, Groningen, Netherlands

Background: Information regarding the possible influence of immunosuppressive drugs on male sexual function and reproductive outcomes is scarce. Men diagnosed with immune-mediated diseases and a wish to become a father represent an important neglected population since they lack vital information to make balanced decisions about their treatment.

Objectives: To systematically review the literature for the influence of paternal immunosuppressive drug use on many aspects of male sexual health, such as sexual function, fertility, pregnancy outcomes and on their offspring health outcome.

Methods: A systematic literature search was performed in the bibliographic databases: Embase (via Elsevier embase.com), MEDLINE ALL via Ovid, Cochrane Central Register of Trials (via Wiley) and Web of Science Core Collection. Additionally, Google Scholar and the Clinical trial registries of Europe and the USA were searched. The databases were searched from inception until August 31th 2019. The searches combined keywords regarding male sexual function and fertility, pregnancy outcomes and offspring’s health with a list of immunosuppressive drugs. Studies were included if they were published in English and if they included original data on male human exposure to immunosuppressive drugs.

Results: A total of 5867 references were identified amongst which we identified 163 articles fulfilling the eligibility criteria. Forty nine articles included pregnancy and offspring outcomes and 116 articles included sexual health outcomes. With the exception of large Scandinavian cohorts, most of the identified articles included a small number of participants. While a clear negative effect on sperm quality was evident for sulfasalazine and cyclophosphamide a dubious effect was identified for colchicine, methotrexate and sirolimus. In 3 articles exposure to TNF-a inhibitors in patients diagnosed with ankylosing spondylitis resulted in improved sperm quality. The information regarding pregnancy and offspring outcomes was scant but no large negative effect associated with paternal immunosuppressive drug exposure was reported.

Conclusion: Evidence regarding the safety of immunosuppressive drugs in men with a wish to become a father is inconclusive. The lack of standardization on how to evaluate and report male sexual function, fertility and reproduction as study outcomes in men exposed to immunosuppressive drugs is an important contributor to this result. Future research on this topic is needed and should be preferably done using standardized methods.

FRI0545

A META-ANALYSIS OF GIANT CELL ARTERITIS TEMPORALLY AND ACROSS REGIONS

D. Semenov1, K. Li1, M. Turk1, J. Pope1 on behalf of Schulich School of Medicine & Dentistry, 1Schulich School of Medicine & Dentistry, London, Canada

Background: Giant cell arteritis (GCA) is an immune-mediated disease of the large vessels, and occurs in adults over 50 years old. It is the most commonly seen form of chronic vasculitis and is associated with significant rates of morbidity2. This meta-analysis examines the geographical and temporal epidemiology of GCA, including incidence, prevalence and mortality.

Objectives: 1.To identify changes in incidence rate, prevalence, and mortality rate over time 2.To compare these rates between geographic regions around the world

Methods: A systematic review of the English literature was conducted using the EMBase, Scopus and PubMed databases. Articles were included if they were cohort or cross-sectional studies with 50 or more patients with GCA and reported on population, location and time-frame parameters. Articles on mortality were included if they compared mortality to age and gender matched population. Review articles, case-control studies and case series were excluded. Two reviewers extracted data and a third verified inclusion of studies. Study quality was assessed by using the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) checklist. Mortality rate was standardized across cohorts to deaths per 1000 people per year.

Results: Of the 3569 citations identified by the literature search, 107 were included in analysis. The pooled incidence of GCA internationally was 10.00 [9.22, 10.78] cases per 100 000 people over 50 years old (Figure). This incidence was highest in Scandinavia 21.57 [18.90, 24.23], followed by North and South America 10.89 [8.78, 13.00], Europe 7.26 [6.05, 8.47], and Oceania 7.85 [1.48,17.19]. Nine studies reported prevalence. Pooled prevalence from these 9 was 51.74 [42.04,61.43] cases per 100,000 people over 50 years old. Overall, pooled mortality was 20.44 [17.84,23.03] deaths/1000 per year. Mortality had a generally decreasing trend over the years of publication.

Conclusion: The incidence of GCA varies regionally almost 3-fold. Likely genetic and environmental factors may explain this trend. Incidence and prevalence are important for tracking the efficacy and side effects of current therapies, as well as planning for the costs of biologic treatment.
RESULTS: A total of 655 participants were analysed, of which 82% were female (Table 1). We found women were older with a median of 53 years compared to 46 years in men (OR 1.02, CI 1.0-1.1). Smoking was higher in men (16%) compared to women (5%). (OR 0.3, CI 0.2-0.6). Women had longer disease duration, 9 years compared to 7 years in men (OR 1.0, CI 1.0-1.1). Rheumatoid arthritis (RA) was more prevalent in women (OR 2.7, CI 1.0-6.9), while ankylosing spondylitis (AS) and psoriatic arthritis (PsA) were more prevalent in men (OR 0.2, CI 0.1-0.4, and OR 0.3, CI 0.2-0.9 respectively). Women had more comorbidities than men (OR 1.8, CI 1.1-2.8) and used steroids more frequently (OR 1.7, CI 1.1-2.7). Differences in disease activity were not found, however we noticed high activity scores among participants.

Conclusion: In our study we found sex differences regarding age and disease duration, being higher in women. As expected, the prevalence of RA was higher in women and AS and PsA in men. Overall, women used more steroids than men. An interesting finding was that patients had high disease activity future longitudinal analyses will allow us to analyse sex differences in disease progression and treatment response.

1Colegio Mexicano de Reumatología, Universidad de Investigación, México City, Mexico; 2Colegio Mexicano de Reumatología, Mexico City, Mexico

Background: Most autoimmune diseases are more prevalent in women. Symptom severity, disease progression, response to therapy and overall survival differ between males and females with rheumatic diseases.

Objectives: To identify the characteristics of autoimmune diseases presentation and treatment between male and female population using information from the Mexican Adverse Events Registry (BIODAMEX). Methods: BIODAMEX is a Mexican ongoing cohort that collects the information of patients using biologic and biosimilar drugs since 2016. For this study we included all patients enrolled in the registry and compared baseline clinical and disease characteristics, treatment and presence of adverse events between genders. We used logistic regression to analyze unvariable associations.

Univariable logistic regression analysis. p<0.05. n=469, n=99, n=71, n=19.

Disclosure of Interests: Both Daniel Semenov and Katherine Li equally contributed to data collection and authored this manuscript. Funding in part was from the Canadian Rheumatology Association summer studentship.
which have a dynamic structure, are key to homeostasis. However, the failure of these mechanisms to work synchronously can lead to morbidity complicating the course of many chronic diseases.

Objectives: To evaluate the effect of anti-atherosclerotic liquid (AAL), anti-inflammatory capsules (AIC) and anti-oxidant liquid (AOL) supplementation on the flow-mediated dilatation (FMD), inflammatory, oxidative stress and endothelial dysfunction markers in patients with selected chronic diseases.

Methods: We analyzed data of 178 patients from cohorts with selected chronic diseases (Rheumatoid arthritis, familial Mediterranean fever, DM type-2, Hypertension, Multiple sclerosis, Chronic obstructive pulmonary disease, Alzheimer disease and Cancer) in this quasi-experimental study. Endothelial dysfunction was determined by FMD and serum asymmetric dimethylarginine (ADMA) levels. Serum ADMA, high sensitive C-reactive protein (hs-CRP), serum PTX3, malondialdehyde (MDA), Cu/Zn-superoxide dismutase (Cu/Zn-SOD), glutathione peroxidase (GSH-Px) levels and FMD were studied in baseline and after 12 weeks of Morinda citrifolia (AAL, 3 ml once per day), omega-3 (AIC, 3 capsules once per day) and extract with Alaskan blueberry and 21 different red purple fruit vegetables (AOL, 30 ml one per day). Stepwise multivariate regression analysis evaluated the association of FMD with clinical and serologic parameters.

Results: Serum ADMA, MDA, PTX3, hsCRP and albumin levels, and proteinuria were significantly decreased and Cu/Zn-SOD, GSH-Px and FMD levels were significantly increased following AAL, AIC and AOL therapies. FMD was negatively correlated with serum ADMA, MDA, PTX3, hsCRP levels, SBP and DBP and positively correlated to Cu/Zn-SOD and eGFR levels both at baseline and after the 12-weeks treatment period. Multivariate regression analysis revealed that ADMA and PTX3 levels were independently related to FMD both before and after AAL, AIC and AOL therapies (Table 1, Figure 1).

Conclusion: Our study shows that serum ADMA, MDA, PTX3 levels are associated with endothelial dysfunction in patients with selected chronic diseases. Short-term AAL, AIC and AOL therapies significantly improves FMD and normalizes ADMA, PTX3, hsCRP and MDA. This may have implications for adjunctive therapy in a number of chronic disorders.

Table 1. Analysis of association between change (Δ) in FMD and relevant parameters by univariate and multivariate linear regression analysis.

Δ FMD (%) (r²=0.30)

PMI, S. Schäfer1, S. H. Verspoel2, T. Holdener1, C. Behning3, P. Brossart3. 1University Hospital Bonn, Clinic for Internal Medicine III, Department of Oncology, Hematology and Rheumatology Bonn, Germany; 2University Hospital Bonn, Institute for Medical Biometry, Informatics and Epidemiology, Bonn, Germany

Background: Immune checkpoint inhibitors (ICIs) have improved cancer therapy and especially clinical outcomes for patients with many malignancies [1]. ICIs lead to a higher immune system activity and subsequent attack of tumor cells. However, this effect can cause rheumatological immune related adverse events (rh-irAE), which have not yet been extensively studied.

Objectives: To determine the prevalence and type of rh-irAE in patients treated with ICIs. Additionally, our study focused on duration, severity and therapy of rh-irAE as well as the correlation between tumor response rate and patients with or without rh-irAE.

Methods: We analysed 437 patients between January 2014 and October 2019, treated with ipilimumab (anti-CTLA-4) and/or nivolumab (anti-PD-1) or pembrolizumab (anti-PD-1) at the Department of Oncology, Hematology and Rheumatology at the University Hospital in Bonn, Germany.

Results: Of the 437 patients, 260 (60%) were males, 177 (40%) were females with a mean age of 64 years (SD ±14) at the beginning of the ICI-therapy. 152 patients (34.8%) displayed at least one irAE. We identified 20 patients (4.6%) with a minimum of one rh-irAE due to ICI-therapy, seven of those had a pre-existing rheumatological disease. Those 20 patients were initially treated for melanoma, lung cancer, head and neck tumor and gastrointestinal carcinoma. Rh-irAE occurred in one patient (2.6%) with ipilimumab, in nine patients (4.8%) with nivolumab, in nine patients (5.7%) with pembrolizumab and in one patient (1.9%) with a combination of ipilimumab and nivolumab.

Arthritis developed most frequently in nine of the 20 patients (45%). Arthritis and myositis occurred with equal frequencies, in three cases each (3 patients, 15%). Furthermore, three of the 20 patients (15%) developed a psoriatic arthropathy and one patient (5%) osteoarthritis. The time to the first rh-irAE after exposure to ICIs was in median 100 days (IQR 45 – 406 days). Most rh-irAE were classified as moderate severe (CTCAE [Common Terminology Criteria of Adverse Events] grade 2: 55%). 15 patients (75%) were treated with systemic corticosteroids. In three cases (15%) additional therapy with methotrexate and in one patient (5%) with tocilizumab was required. Other therapies including non-steroidal anti-inflammatory drugs and opioids were also used in eight patients. Even though patients benefited from ICI treatment, therapy had to be discontinued in nine of them (45%). Interestingly, patients with rh-irAE had a significantly higher tumor response rate compared to patients without any irAE (95% vs. 33%; p<0.0001).

Conclusion: Our results show, that rh-irAE occur under ICI-therapy and in patients with higher tumor response. However, they are not the most frequent irAE after ICI exposure: 10.2% of all irAE were rheumatological (22 rh-irAE cases in 20 patients of a total of 216 irAE cases in 152 patients). As the use of ICIs is increasing for different malignancies the incidence of rh-irAE can be expected to increase.

Background: Infectious disease is one of the leading causes of mortality in systemic lupus erythematosus (SLE). Among these infections, invasive fungal infection (IFI) carries high mortality rate (25-70%), but the literature of IFI in SLE is limited.

FRI0550 CAN CYTOKINE GENE POLYMORPHISMS BE USEFUL FOR THE THERAPEUTIC CHOICE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS?

S. Tsuimoto1, M. Shigesaka1, A. Tanaka1, Y. Ozaki1, T. Ito1, M. Inaba1, S. Nomura1.

Background: Rheumatoid arthritis (RA) is a common autoimmune disease. It is characterized by systemic synovitis with bone erosion and joint cartilage degradation(1). Production of autoantibody is important for autoimmune disease. Cytokines play crucial roles in its pathogenesis(2). SNP distribution varies between races. Few studies have examined SNP targeted at Japanese patients. The analysis of cytokine gene polymorphisms is important factor of pathophysiology and treatment.

Objectives: This analysis was aimed to investigate the association between cytokine gene polymorphisms and autoimmune and therapeutic response in Japanese RA patients.

Methods: This study subjects consisted of 100 RA patients and 50 healthy controls. We extracted data on patient sex, age, disease duration, rheumatoid factor (RF), anti cyclic citrullinated peptide (anti-CCP) antibody and therapeutic response including methotrexate (MTX) and biological DMARDs. Genomic DNA was isolated from peripheral blood, these were genotyped for TNFα, TGFβ1, IL-6, IL-10 and IFNγ polymorphisms. We analyzed these data using a chi-square test.

Results: IL-10 (-819) C/T and -592 C/A revealed that there were significant decrease in the frequency of IL-10 (-819) CC genotype and -592 CC genotype as compared to controls in RA patients. Genotyping of IL-10 showed that there was significant decrease ACC/ACC genotype (Table 1). IFNγ (+874 A/T) revealed that there was significant decrease in the frequency of TT genotype as compared to controls (Table 1).

Conclusion: IL-10 (-819 C/T, -592 C/A) and IFNγ (+874 A/T) polymorphism might be related to RA in Japanese population. In addition, TGFβ1 (+869 A/T) polymorphism might be associated with the production of anti-CCP antibody. These results suggest that the analyzing cytokine gene polymorphisms may offer promise as useful factors in the choice of treatment for Japanese RA patients.

PERFORMANCE OF THE 2019 AMERICAN COLLEGE OF RHEUMATOLOGY/EUROPEAN LEAGUE AGAINST RHEUMATISM SYSTEMIC LUPUS ERYTHEMATOSUS CLASSIFICATION CRITERIA

C. Vranciu1, I. Cona1, A. Boca1, M. Boloceanu1, C. Draganeascu1, M. Sasu1, C. Ciofu1, L. Macovei1, M. Bojinc1, I. Ancuta1, C. Mihal1, V. Stoica1, A. M. Gheorghiu1, 1Cantacuzino Clinical Hospital, Carol Davila University of Medicine and Pharmacy, Internal Medicine and Rheumatology, Bucharest, Romania

Background: Systemic lupus erythematosus (SLE) is a heterogenous autoimmune disease, with increased morbidity and mortality, often diagnosed in advanced stages. The recently published 2019 American College Of Rheumatology/European League Against Rheumatism (ACR/EULAR) classification criteria for SLE are weighted, hierarchically clustered criteria developed to increase reliability and the identification of early SLE.

Objectives: To compare the sensitivity and specificity of the 2019 ACR/EULAR criteria with the 2012 SLICC criteria in a large single-centre cohort of patients with SLE, diagnosed according to expert opinion.

Methods: Data of SLE patients evaluated in our centre between 1996-2019 have been retrospectively analyzed. The control cohort included patients with positive antinuclear antibodies of other ethiology than SLE, evaluated between 2001-2019. The sensitivity and specificity of the 2019 ACR/EULAR and 2012 SLICC criteria were tested using the McNemar test for correlated proportions.

Results: Four hundred and forty-six patients with SLE (413 women, mean±SD age 40.5±12.7 years, disease duration 10.1±9.2 years) and 67 controls (63 women, mean±SD age 50.4±12.6 years, disease duration 7.6±6.9 years; 29 systemic sclerosis (SSc), 18 mixed connective tissue disease (MCTD), 15 undifferentiated CTD, 2 rheumatoid arthritis (RA), 2 SSC – RA overlaps and 1 dermatomyositis) were included. The sensitivity of the 2019 ACR/EULAR and 2012 SLICC criteria were similar 85.4% and 83.6 %, respectively (p=0.3). The specificity of the 2019 ACR/EULAR and 2012 SLICC criteria were 70.2 % and 86.6%, respectively (p=0.007). In the SLE group, patients misclassified according to the new 2019 ACR/EULAR criteria were 65, whereas according to the 2012 SLICC criteria were 73; of them, 44 patients did not fulfill any criteria. In the control group, patients misclassified had mainly MCTD (13/20 patients according to the new 2019 ACR/EULAR, and 6/9 according to the 2012 SLICC criteria).

Conclusion: In this real-life cohort, the 2019 ACR/EULAR criteria have a similar sensitivity and lower specificity than the 2012 SLICC criteria, misclassifying especially MCTD patients. These results might be due to the long disease duration cohort.

FR0552

GLOBAL, REGIONAL, AND NATIONAL BURDEN OF LOW BACK PAIN, 1990-2019: A SYSTEMATIC ANALYSIS FOR THE GLOBAL BURDEN OF DISEASE STUDY 2019

D. Wu1, X. Wu2, J. Wu1, L. S. Tam1, J. Gu1. 1Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; 2Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hong Kong (SAR)

Background: Low back pain (LBP) has become a major public health problem worldwide although the burden and underlying causes differ across locations and demographic groups.

Objectives: To report the distribution, trend and risk factor in the burden of LBP from the Global Burden of Disease Study 2019 (GBD 2019).

Methods: Based on GBD 2019, decomposition analyses were performed according to gender, age, geography and sociodemographic index (SDI). The number and age standardized rate of incidence, prevalence and disability adjusted life years (DALYs) with 95% uncertainty intervals (UI) were calculated.

Results: In 2019, female patients have a slightly higher number of prevalence (17%), incidence (15%) and DALYs (16%) than male patients. Out of twenty 5-year age group, the number of incidences, prevalence, DALYs peak at 50-54 age group, while the rate of incidence, prevalence, DALYs peaked at 80-84 age group. From 5 SDI regions, the highest number and age-standardized rate of incidence, prevalence, DALYs were observed in middle and high SDI region, respectively. Considering 21 GBD regions, the highest number of incidence, prevalence, and DALYs were observed in East Asia, while the highest age standardized rate of incidence, prevalence and DALYs all found in Central Europe, High-income North America, High-income North America, respectively. In 204 countries and territories, the top 3 highest number of incidence, prevalence and DALYs were from China, India, United States of America. The top 3 highest age-standardized rate of prevalence, and DALYs were Georgia, United States of America, Denmark, while top 3 highest age-standardized rate of incidence were Poland, Vanuatu, Romania.

From 1990 to 2019, globally, the number of incidence, prevalence, DALYs increased by 50%, 47%, 47% to 223,738,363 (95%UI 187,935,799-253,303,243), 569,089,727 (95% UI 505,632,980-641,256,710), 63,533,528 (95%UI 44,883,714-84,975,210), while age standardized rate of incidence, prevalence and DALYs decreased by 13%, 16%, 16% to 2,750 (95%UI 2,427-3,108), 6,974 (95%UI 6,192-7,862), 778 (95%UI 548-1,043). In 5 SDI regions, low SDI region has the highest percentage increases in number of incidence, prevalence and DALYs, the highest percentage decrease in age standardized rate of incidence, prevalence and DALYs were observed in High-middle SDI. In 21 GBD regions, the highest percentage increase in number of incidence, prevalence and DALYs
were found in Central Sub-Saharan Africa, while East Asia has the highest percentage decrease in age-standardized rate of incidence, prevalence and DALYs. In 204 countries and territories, the greatest percentage increase in number rate of incidence, prevalence, and DALYs were observed in Qatar, while the greatest percentage decrease in age-standardized rate of incidence, prevalence, and DALYs were found in China.

In 2019, three risk factors account for 40% (95% UI: 36%, 40%) DALYs due to LBP, including smoking (16%, 95% UI: 12%, 20%), high body mass index (7%, 95% UI: 4%, 10%), occupational ergonomic factors (24%, 95% UI: 22%, 26%).

**Conclusion:** There is significant varied and increased disease burden of LBP by gender, age, and geography, partly due to population growth and ageing. The age-standardized rate of prevalence, incidence and DALYs are decreasing, especially in countries such as China and India. Cost effective interventions targeted risk factors are required to minimize the ongoing burden of this condition.

**FR010553 DEVELOPMENT AND VALIDATION OF A BIOMARKER-BASED CARDIOVASCULAR RISK PREDICTION SCORE IN RHEUMATOID ARTHRITIS**

J. Curtis1, F. Xie1, C. S. Crowson2, B. Mabey3, D. Flake4, R. Bamford3, C. Chin3, E. Sass4, E. Hitraya5, R. Ben-Shachar3, A. Gutin4, J. Lanchbury3. 1University of Alabama at Birmingham, Birmingham, United States of America; 2Mayo Clinic, Rochester, United States of America; 3Myriad Genetics, Inc., Salt Lake City, United States of America

**Background:** Rheumatoid arthritis (RA) patients are at elevated risk for cardiovascular (CV) events, but risk stratification based on CV prediction models is not part of routine rheumatology practice.

**Objectives:** To develop and validate a biomarker-based CV risk prediction model and compare it to alternative risk prediction models.

**Methods:** We constructed a cohort of RA patients - age ≥40 with ≥1 RA diagnosis from a rheumatologist, excluding patients with malignancy, past myocardial infarction (MI) or stroke - by linking Medicare administrative data from 2006-2016 to multi-biomarker disease activity (MBDA) test results obtained as part of routine care. The cohort was split 2:1 to create training and internal validation datasets. The composite CV outcome was MI, stroke or CV death occurring within 3 years. Clinical predictors examined were: age, sex, race, traditional CV risk factors (e.g., diabetes, hypertension, hyperlipidemia, high-risk CV conditions [e.g. angina]), RA-related factors (e.g., glucocorticoid use, MTX, number of prior biologics), adjusted MBDA score4 and its 12 biomarkers, log-transformed. Backward elimination was used to remove predictors with p ≥0.05. The resulting CV risk score was compared to four prediction models (age+sex; age+sex+CRP; age+sex+diabetes+hypertension+smoking+high risk CV [±CRP]) in the validation dataset. We evaluated: 1) incremental improvement in the likelihood ratio test (LRT) statistic, 2) discrimination (AUROC), and 3) goodness-of-fit (predicted vs. observed, based on Kaplan-Meier estimates). Validation analyses were prespecified.

**Results:** 30,751 RA patients with 904 CV events were linked to MBDA test results and eligible for analysis. Patient characteristics were mean (SD) age 68.7 (9.5) years; 23.4% age ≤65; 82% women. Comorbidities included diabetes (39%), hypertension (78%), smoking (24%) and history of high-risk CV condition (37%). RA-related features included use of glucocorticoids (58%), MTX (60%), TNFi (33%) and other biologics (16%). Mean (SD) MBDA score was 41 (14). The final covariates included in the MBDA-based CV risk score were age, diabetes, hypertension, smoking, history of high-risk CV conditions, adjusted MBDA score, leptin, TNFRII and MMP-3. Median (IQR) of the predicted 3-year CV risk was 3.4% (2.1–5.6%). Based on extrapolation to 10-year risk, 9.4% of patients would be considered low, 10.2% borderline, 52.2% intermediate, and 28.2% high risk per 2019 ACC/AHA guidelines.

**Conclusion:** A biomarker-based prediction score incorporating a few clinical risk factors appears to have good accuracy to predict CV risk in RA. Additional validation in independent cohorts will help verify its performance characteristics.

Disease activity in RA patients is usually measured by DAS28. A composite measure consisting of 28 swollen and/or tender joint counts (SJC28/TJC28), an acute phase reactant (APR, e.g. ESR/CRP) and patient’s general health typically using a visual analogue scale (VAS). Particularly assessment of joint counts is time consuming, requires a trained health professional and its inter-observer variability is high. The HandScan is developed to measure inflammation in hand joints using optical spectral transmission (OST, score 0 to 66) without taking time of a health professional and its inter-observer variability is high. The HandScan is particularly assessment of joint counts is time consuming, requires a trained professional. 2 We hypothesised that a composite measure including OST transmission (OST, score 0 to 66) without taking time of a health professional and its inter-observer variety is high. The HandScan is developed to measure inflammation in hand joints using optical spectral transmission (OST, score 0 to 66) without taking time of a health professional. 2 The correlation between DAS28 and a single measurement of OST is moderate. 3 We hypothesised that a composite measure including OST (representing joint inflammation), VAS and APR would lead to an appropriate disease activity index.

Objectives: To establish a method for assessing disease activity in RA patients using HandScan +/- other disease activity parameters, with cut-offs for remission and low disease activity (LDA).

Methods: RA patients, visiting the outpatient clinic of Máxima Medical Center Eindhoven, were eligible for inclusion. Inclusion criteria were: (1) RA according to classification criteria, (2) at least one HandScan and DAS28 measurement performed at the same visit, and (3) aged ≥18. Data was extracted from medical records. A random sample of 2/3 of included patients was used as development cohort, the remaining 1/3 was used as validation cohort. In the development cohort, linear regression analyses were performed to create a formula for an OST index (DASost). In these, DAS28 was the outcome variable and, OST, ESR and VAS were predictors. Also other parameters were tested in the model to see if they increased the fit of the model or modified the association between OST and DAS28. A final model was derived, based on statistical significance of predictors and improvement of model fit (adjusted R-square). Agreement of DAS28 with DASost was tested with the random one-way intraclass correlation coefficient (ICC). DAS28 based remission and LDA were calculated for DASost using the established DAS28 cut-offs (i.e. DASost<2.6 and DASost<3.2). A cut-off for DASost for Boolean remission was defined using receiver operating characteristic (ROC) curves and Youden’s index. In the validation cohort, diagnostic values were calculated for DASost using the cut-offs as defined above.

Results: Data of 3358 observations within 1505 unique RA patients were extracted. Patients' demographic and clinical data are shown in Table 1. The formula for DASost derived in the development cohort was: -0.44 + (OST*0.03) + (male*-0.11) + (LN(ESR)*0.77) + (VAS*0.03). The optimal cut-off on DASost found for Boolean remission was 2.2. The ICC was 0.88 (95% CI 0.87 - 0.89). The explained variance of DASost in the validation cohort was 78%. Diagnostic accuracy of DASost in the validation cohort for DAS28 based remission, LDA and Boolean remission are shown in Table 2. Diagnostic values of DASost

Conclusion: The HandScan could be used as a tool to quickly assess disease activity in RA patients, if OST is combined with other disease activity parameters into an index.

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis characterized by joint and enthesial inflammation seen in 30% patients with psoriasis (PsO). In 90% of patients, PsO precedes PsA. Inhibitors of tumor necrosis factor (TNFi) are efficacious treatment options for both, though whether they prevent development of incident PsA in PsO patients is unknown.

Objectives: To determine if the use of TNFi reduces the risk of developing psoriatic arthritis in PsO patients compared to those treated with methotrexate alone.

Methods: Records on all PsO patients seen at dermatology clinic at our University from January 2006 - June 2019 were reviewed. Patients with any musculoskeletal symptoms were referred to rheumatology and were considered to have PsA if they were diagnosed by a rheumatologist. We used Student’s t-test to compare continuous covariates and Pearson’s chi-squared test or Fisher’s exact test to compare categorical covariates. Variables that were found to be significantly associated with PsA diagnosis were included as potential confounders in the multivariate model. We used Cox proportional hazards models to compare the risk of incident PsA diagnosis for those who initiated TNFi compared to those who initiated methotrexate. A propensity score of TNFi therapy compared to methotrexate therapy was calculated using variables associated with treatment choice and adjusted for in the model. Variables that were associated with both treatment choice and PsA risk were not included in the propensity score. We used backwards stepwise variable selection to build the final model.

Results: Out of 154 PsO patients who did not have PsA at baseline, and were started exclusively on a TNFi or methotrexate during the study period, 85 (55.2%) initiated methotrexate and 69 (44.8%) initiated a TNFi. Mean duration of therapy for those on TNFi was 3.95 (standard error: 0.50) years while mean duration of therapy for those on methotrexate was 1.93 years (standard error: 0.28). Mean follow-up time for those on TNFi was 5.18 years (standard error: 0.49) and for those on methotrexate was 2.71 years (standard error: 0.37) Seventy nine (51.3%) of the cohort were women. Thirty five (22.7%) of subjects developed PsO over the course of the study. After adjusting for propensity score, nail pitting, body surface area (BSA) involved in psoriasis, and depression, TNFi did not significantly reduce the risk of PsA compared to methotrexate (HR: 0.68 [95% CI: 0.32, 1.41]).

Conclusion: Use of TNFi was not associated with a statistically significant decreased risk of incident PsA compared to methotrexate in this study, but a larger cohort with longer follow up will have better power to estimate the true association.

IAI free survival rates are showed in Figures 1 and 2.
in the MCP joints (p<0.01). They were detected in 42V MTP (31 subjects; 74%), in 10 II MCP (10 subjects; 2.4%), and in 3V MCP (3 subjects; 0.7%) joints. US synovitis was detected in 22/55 joints (40%) with bone erosions, in 17/41 subjects (42%). It was found in 48.6% of the V MTP in 20% of the II MCP and in none of the V MCP joints with bone erosions. A significant correlation between bone erosions and synovitis in the same joint was detected (Cramer’s V=0.22, p<0.01).

Seven out of the 55 joints (12.7%) with bone erosions were tender on physical examination: 14.3% of the V MTP, 10% of the II MCP, and none of the V MCP joints. US bone erosions: predicting development of IA

A total of 122 subjects (30.5%) developed IA (median follow-up: 301 days, IQR 112-721). The hazard ratios of the US findings for the development of IA (adjusted for age, sex, smoking, anti-CCP and rheumatoid factor titer) are reported in Table 1.

Background: Axial spondylarthritids (axSpA) can affect women in their childbearing age. But data on pregnancy in axSpA patients are mainly retrospective and highly heterogeneous [1].

Objective: The aim of this analysis was to investigate pregnancy outcomes and health of live born children in women with axSpA in four prospective cohort studies.

Methods: Data of European pregnancy registries that collaborate in the European Network of Pregnancy Registries in Rheumatology (EuNeP) were analysed: EGR2 (France), RePreg (Switzerland), RevNatus (Norway) and Rhekiss (Germany). Eligible women had a diagnosis of axSpA and a pregnancy outcome reported until June-September 2019. Data were analysed descriptively by every registry and provided to the coordinating centre.

Results: A total of 328 pregnancies in 288 women were investigated. Mean age of patients ranged from 31 to 33 years. Disease duration (3-8 years) and proportion of patients with a positive HLA-B27 (64-74%) varied (Table 1). The axSpA diagnosis was either classified by ASAS criteria (fulfilment in EGR2: 93%, RePreg: 85%, RevNatus: 86%) or by ASAS criteria for axial/ peripheral SpA (Rhekiss: 81/34%). Rates for preterm birth were ≤5%, and congenital malformations were reported in 4 out of 287 neonates (Table 2).

DOI: 10.1136/annrheumdis-2020-eular.579

BACKGROUND: Knee osteoarthritis (OA) is the most prevalent joint disease worldwide, but no disease-modifying treatments are available. Existing treatments largely focus on relieving symptoms, but they may have substantial adverse effects. Identifying risk factors affecting knee symptoms is important for developing safer prevention strategies of knee OA symptoms.

OBJECTIVES: To describe the associations between diet quality in childhood and adulthood and knee symptoms in young adults.

METHODS: Participants were from the Australian Schools Health and Fitness Survey (ASHFS) in 1985, which was conducted to provide benchmark data on the health and fitness of Australian schoolchildren. During 2004-2006, participants were followed up in the Childhood Determinants of Adult Health (CDAH) Study. Diet quality scores were collected in ASHFS (aged 10-19 years) and CDAH Study (aged 26-36 years) using food questionnaires. Diet quality was assessed by Dietary Guidelines Index (DGI), reflecting the adherence to Australian Dietary Guidelines. The DGI comprises 9 components and its maximum possible score is 100. A higher score indicated higher diet quality. During 2004-2010, participants (aged 34-41 years) were followed up in the CDAH Knee Study. Knee symptoms were collected using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Zero-inflated negative binomial regression analyses were used to assess the associations between diet quality and knee symptoms. Age, sex, body mass index, physical activity, total energy intake, and knee injury history were included as potential confounders based on biological plausibility.

RESULTS: A total of 399 participants (48.4% female) were included in the analysis. The average childhood and adult DGI was 46.5 and 55.4, respectively. The prevalence of knee pain, stiffness and dysfunction was 35.1%, 31.6% and 39.9%, respectively. The overall childhood DGI was not associated with adult knee symptoms. However, the limited intake of discretionary foods in childhood was associated with lower pain (Mean ratio (MR): 0.95, 95% confidence interval (CI): 0.92-0.98) and dysfunction (MR: 0.94, 95% CI: 0.90-0.99). The overall adult DGI was not associated with knee symptoms. However, replacing saturated fats with unsaturated fats in adulthood was associated with lower WOMAC (Pain: MR 0.93, 95% CI 0.87-0.99; stiffness: MR 0.93, 95% CI 0.87-0.99; dysfunction: MR 0.91, 95% CI 0.83-0.99), drinking water in adulthood was associated with lower stiffness (MR: 0.90, 95% CI: 0.83-0.99), and fruit intake in adulthood was associated with lower stiffness (MR 0.92, 95% CI 0.86-0.99).

CONCLUSION: Several DGI component scores in childhood and adulthood and some changes of DGI component score from childhood to adulthood were associated with knee symptoms in young adults. The results suggested that early-life diet quality may affect knee symptoms in young adults.

INCREASED RISK OF RHEUMATOID ARTHRITIS DIAGNOSIS IN STATIN USERS IN A LARGE NATIONALWIDE US STUDY

M. Peterson1, H. J. Dykhoff2, C. S. Crowson3, J. M. Davis III4, L. Sangaralingham3, E. Myasoedova1,5, Mayo Clinic, Rochester, United States of America; 6Mayo Clinic, Health Sciences Research, Rochester, United States of America; 6Mayo Clinic, Rheumatology, Rochester, United States of America

BACKGROUND: Studies evaluating the effect of statin use on the risk of rheumatoid arthritis (RA) onset have shown conflicting results. Most of these studies evaluated European populations while data from the US are scarce.

OBJECTIVES: We aimed to assess the association between statin use (and intensity) and RA occurrence using claims data from the US population.

METHODS: For this case-control study, we used the OptumLabs Data Warehouse, a large administrative database of commercially insured and Medicare Advantage beneficiaries, to identify cases of RA and matched controls. Cases were defined as patients with 2 or more diagnoses of RA in January 1, 2010 - June 30, 2019 who were ≥18 years old, filled ≥1 prescription for a conventional or biologic disease modifying anti-rheumatic drug, and had no diagnoses of RA during the prior year. Controls were persons without RA matched 1:1 to RA cases on age, sex, census region, calendar year of index date (corresponding to the date of second diagnosis code for RA), and length of prior medical/pharmacy coverage. Statin use was defined as any filled prescription for a statin medication during prior coverage (excluding any new statin prescriptions filled up to 90 days before first RA diagnosis or index date). Logistic regression models were used to estimate odds ratios (OR) with 95% confidence intervals (CI) adjusted for age, sex, race, census region, calendar year and Charlson comorbidity index (excluding RA component).

RESULTS: The study included 32,465 cases with RA (mean age 57.0, 72.2% female) and 32,465 matched controls (mean age 57.0, 72.2% female). There were 10,759 (33.1%) statin users among RA patients and 4,016 (12.4%) statin users among the matched controls. Statin use was associated with increased risk of RA (adjusted OR 3.34, 95% CI 3.19-3.49). All levels of statin intensity were associated with increased risk of RA (high OR: 3.60, 95% CI 3.28-3.94; medium OR: 3.20, 95% CI 3.04-3.37; low OR: 3.72, 95% CI 3.34-4.15) compared to non-users. Both former and current statin users showed an increased risk of RA (current OR: 3.04, 95% CI 2.80-3.30 and former OR: 3.37, 95% CI 3.20-3.54) compared to non-users.

CONCLUSION: This large nationwide study showed increased risk of RA in statin-users vs non-users. The lack of dose dependence may suggest confounding by indication or a common genetic predisposition for cardiovascular disease and RA. The underlying mechanisms for these associations require further investigation.

PRO-INFLAMMATORY DIETS ARE ASSOCIATED WITH INCREASED C-REACTIVE PROTEIN AND RHEUMATOID ARTHRITIS IN THE UK BIOBANK COHORT

J. Dainty1, E. Sayers2, M. Yates3, A. Macgregor4,5,1, Northwest Medical School, Centre for Epidemiology Versus Arthritis, Norwich, United Kingdom; 2Quadram Institute, Norwich, United Kingdom; 1Ipswich Hospital, Ipswich,
Background: Several individual dietary components have been associated with the risk of rheumatoid arthritis (RA) and recent studies have suggested that dietary indices, which account for the consumption of multiple foods, can be used as more complete measures of risk.

Objectives: In this study we aimed to use the Dietary Inflammatory Index (DII), an independent index of dietary variable associated with inflammatory biomarkers, to evaluate potential associations between pro-inflammatory exposures in the diet, an inflammation biomarker (C-reactive protein) and RA onset using the UK Biobank cohort.

Methods: The DII was calculated from data obtained in 24-hour dietary recall questionnaires collected on healthy participants on four separate occasions over an approximate annual period between Feb 2011 and April 2012. Cases of RA in the UK Biobank cohort were identified from the participants with appropriate ICD10 codes and compared against a randomly selected subsample of controls matched (20:1) for age, sex, smoking status and BMI.

Results: Among the 502,519 subjects enrolled in Biobank, 141,769 had completed 24-hour dietary recall questionnaires and had full data for the 18 dietary variables that were required to create the DII (mean=0.03, range: -3.88, 4.22). Higher (positive) DII values indicate more pro-inflammatory diets. This index was positively correlated (p<0.001) with C-reactive protein (CRP), attesting to the validity of this index for assessing dietary inflammatory potential. A total of 1,423 participants were classified as having RA (1% prevalence in ‘dietary’ cohort of 141,769) according to their ICD10 codes that were last updated in 2018. Their mean age at enrolment (2006-10) was 59 years. There was a significant association between DII and RA: OR 1.06 [1.01-1.10]; p=0.028) that suggested RA cases were more likely to be consuming a pro-inflammatory diet.

Conclusion: These data show a significant association between diet, inflammation (CRP) and RA in the UK Biobank population. The findings are consistent with a recent analysis of the US Nurse’s Health Study which was based on data only from females, indicating that these findings are likely to be robust and generalisable. Diet is one of the few modifiable factors that has the potential to reduce the risk of future RA onset. These results open the way to providing evidence-based health advice and for designing clinical interventions.

Epidemiology, risk factors for disease or disease progression.

COMPARISON OF TWO DIFFERENT APPROACHES TO INVOLVE PARTICIPANTS IN CONSECUTIVE ROUNDS OF A DELPHI CONSENSUS TECHNIQUE.

A. Boel1, V. Navarro-Compán2, R. B. M. Landewé3,4, D. Van der Heijde1. 1Leiden University Medical Center, Leiden, Netherlands; 2University Hospital La Paz, Madrid, Spain; 3Zuyderland Medical Centre Heerlen, Heerlen, Netherlands; 4Amsterdam University Medical Centre, Amsterdam, Netherlands.

Background: There is no guidance on which participants to invite to consecutive rounds of a Delphi exercise. There are two options: 1) Invite only participants that have completed the previous round for the consecutive round; 2) Invite every participant for all consecutive rounds irrespective of whether they have responded. It is unknown whether different invitation-procedures provide similar results.

Objectives: To investigate the effect of two different approaches to involve participants in consecutive rounds of a Delphi exercise on response rate and final outcome.

Methods: Patients with and experts in spondyloarthritis were invited to partake in a 3-round Delphi exercise to update a core outcome set. A randomised controlled study with 1:1 allocation to two experimental groups was built in, to compare two approaches of invitation. The ‘all-rounds group’ includes patients invited for each round independent of response to the previous round; the ‘respondents group’ includes patients invited for the next round only if they responded to the previous round. A 9-point Likert scale (1 = not important; 9 = critical) was used to score the importance of domains. Additionally, participants provided their six most important domains.

Results: The overall response rate after 3 rounds was lower in the ‘respondents’ compared to the ‘all-rounds group’ (64% vs. 61%) (table 1).

Table 1. Response rates per group per round of the Delphi exercise

Conclusion: Inviting people for all rounds irrespective of a response to the previous round increases the generalisability, while the content of the outcome of a Delphi procedure is similar to using data of those persons who participate in all rounds only.

Validation of outcome measures and biomarkers.

SERUM LEVELS OF IL-6 AND IL-8 IN ANKYLOSING SPONDYLITIS PATIENTS: ASSOCIATIONS WITH DISEASE ACTIVITY

E. Aleksandrova1, A. Novikov1, P. Kulakova1, A. Dorofeev2, N. Savenkova2, E. Volsukhin1, A. Kovalshik2, G. Lukina1. 1A.S. Loginov Moscow Clinical Research Federation of Spondylitis Patients; 2University of Moscow, Moscow Healthcare Department, Moscow, Russian Federation.

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease of the spine and sacroiliac joints characterized by new bone formation (syndesmophytes) and ankyloses. In AS cases, along with the damage to the musculoskeletal system, impairment of other organs and systems is often observed (uveitis, inflammatory bowel and heart diseases). Pro-inflammatory cytokines (TNF-α, IL-6,-17,-23,-21,-22,-31) and chemokines (IL-8) are key pathogenic markers in AS.

Objectives: The aims of the study were to determine the serum levels of IL-6 and IL-8 in AS and investigate their relationship with disease activity.

Methods: We studied 140 patients (pts) with AS fulfilled modified New York criteria (1984); (102M/38F); median and interquartile range (25th - 75th percentile) of age 43.0; 35.0-51.0 years; disease duration 6.0; 4.0-12.0 years; BASDAI - 5.4; 4.1 -6.6; ASDAS ESR - 3.6; 2.6-4.4; ASDAS CRP - 3.8; 2.7-4.5; 86% HLA-27 positive. In 50% of pts with AS, inflammatory bowel diseases (IBD) (Crohn's disease and ulcerative colitis) were diagnosed. The control group included 17 healthy donors (HD). The serum concentrations of IL-6 and IL-8 were detected by chemiluminescence immunoassay using IMMULATE 1000 analyzer (Siemens Healthcare Diagnostics, USA).

Results: AS pts had significantly higher serum level of IL-6 than HC (4.3; 0.1-8.0 pg/ml vs 2.3; 0.1-2.7 pg/ml, p <0.006). The median concentration of IL-8 didn't differ after the final round, the 4 outcomes with the highest percentage of votes were identical between experimental groups, with only small differences in percentages between groups (table 2). The only difference in the 6 most important domains was selection of disease activity by the ‘respondents group’, whereas the ‘all-rounds group’ selected overall functioning & health, while these domains were ranked as the 6th domain in the other group.

Table 2. Most important domains after round 3 for the ‘respondents’ and ‘all-rounds’ groups ranked in descending order, based on selection by the ‘respondents’ and matched in the ‘all-rounds group’; and the difference in percentage of votes between groups. Domains in italic and bold represent the top 6 in each experimental group.

Figure 1 Mean score (50) per domain for the ‘respondents group’ (in grey) and ‘all-rounds group’ (in blue) from the round when the domain was selected (i.e., the last available scores).
between AS pts and HC (10.5: 8.3-18.0 pg/ml vs 11.9: 8.2-18.3 pg/ml, p<0.05). The same levels of IL-6 and IL-8 were detected in AS with IBD and AS without signs of IBD (p>0.05). In AS pts, serum IL-6 concentration was positively correlated with ASDAS (r = 0.3), ESR (r = 0.3) and CRP (r = 0.3) (p<0.05); IL-8 was negatively associated with presence of fecal calprotectin (r = -0.3) (p<0.05).

Conclusion: Elevated serum concentration of IL-6 in AS is associated with clinical and laboratory markers of high inflammatory activity of the disease. The levels of IL-8 in the sera of AS patients were negatively correlated with the concentration of fecal calprotectin. Data on the relationship of IL-8 with the activity of the pathological process in AS require further study.

Disclosure of Interests: Elena Aleksandrova: None declared, Alexander Novikov: None declared, Polina Kulakova: None declared, Aleksey Dorofeev: Disclosure of Interests: logical process in AS require further study.

Background: Anti-cyclic citrullinated peptide (anti-CCP) auto-antibodies represent the current gold standard for the diagnosis of rheumatoid arthritis (RA). However, growing evidence suggests that a variety of other citrullinated self-proteins may act as autoantigens and lead to the production of autoantibodies (1). Furthermore, autoantibodies believed to be RA-specific have been detected also in patients with connective tissue diseases (CTDs). We recently demonstrated that antibodies against citrullinated alpha-enolase (anti-CEP1) are a biomarker of erosive disease and RA-associated interstitial lung disease (2).

Objectives: The purpose of this study was to investigate the prevalence and possible prognostic value of anti-CEP1 in patients with CTDs.

Methods: Two hundred and twelve consecutive patients with CTDs (51 systemic lupus erythematosus (SLE), 85 primary Sjögren’s syndrome (pSS) and 75 systemic sclerosis (SSc)) were studied and compared to 97 sex and age matched normal controls (NC) and 267 patients with RA. Anti-CEP1 IgG were detected in serum samples with a commercial ELISA kit (Euroimmun).

Results: The overall prevalence of anti-CEP1 in CTDs was 7% (15/212 patients). In detail, these antibodies were detectable in 4 out of 85 pSS (5%), 5 out of 51 SLE (10%) and 6/76 SSc (8%). The prevalence and the titer of anti-CEP1 were significantly higher compared to NC and significantly lower compared to RA. Anti-CEP1 positive patients did not display a specific clinical and serological picture. Unlike in RA, anti-CEP1 did not correlate with CTD-associated ILD.

Conclusion: This is the first study assessing anti-CEP1 in a large cohort of patients with CTDs. We demonstrated that the association of these autoantibodies with ILD is specific for RA since it is not observed in SLE, pSS and SSc. Furthermore, although being significantly more prevalent and at higher titer compared to NC, anti-CEP1 do not allow to discriminate different patient subsets displaying peculiar clinical or serological phenotypes. Based on our results, the application of anti-CEP1 in CTDs is not advisable, however larger studies may possibly identify correlations not evident in our cohort.

Background: The Flare assessment in rheumatoid arthritis (FLARE-RA) questionnaire has been developed to identify flares in patients with rheumatoid arthritis (RA). The first version was published by Berthelot et al. (2012) and consisted of 13 questions on a Likert-scale of 1-6 ranging from ‘completely untrue’ to ‘completely true’. When the FLARE-RA questionnaire was validated by Fautrel et al., 2 questions were removed, and it was rescaled to 0-10. The questionnaires’ usefulness has been tested in several studies. Further external validation in a well-defined cohort of patients with RA is needed.

Objectives: To externally validate the FLARE-RA questionnaire and determine cut-offs for identifying a flare in an established RA population in which biologicals are tapered.

Methods: Patients who were in remission according to the DAS28CRP or ESR (≥6 months) and treated with etanercept 50mg weekly (≥1 year), were enrolled between 2012 – 2014 in the pragmatic 1-year open-label randomised controlled TaperERA (Tapering Etanercept in RA) trial. Patients were randomised to continue etanercept 50mg weekly or taper to 50mg every other week. The FLARE-RA questionnaire (version of 2012) was completed every 3 months. Outcomes were based on 3 versions of the questionnaire (13 questions (13q), 11 questions (11q) and 11 questions rescaled (r11q)). Per time point, the average of the answers was calculated to obtain a total score of the FLARE-RA questionnaire. The total scores were compared between patients in remission (DAS28CRP <2.6), low (DAS28CRP ≥2.6 - ≤3.2), moderate (DAS28CRP >3.2 - ≤5.1) and high disease activity (DAS28CRP >5.1) using the Kruskal-Wallis test and between patients with and without a flare according to the OMERACT definition (increase in DAS28 >1.2 compared to baseline or increase in DAS28 >0.6 and current DAS28 ≥3.2) using the Mann-Whitney U test. The total FLARE-RA scores of the different time points were combined to determine the receiver operating characteristics (ROC) curves, the corresponding cut-off values and the area under the curve (AUC) for identifying an OMERACT flare. An AUC of <0.5, between 0.5 and 0.7 and >0.7 stands for having no, moderate and a good predictive value, respectively.

Results: FLARE-RA questionnaires of 66 patients (68% female, mean ± standard deviation (SD) age of 55 ± 11 years) were collected. The FLARE-RA score (13q) did increase when disease activity increased at month (M) 3 and M12 (p<0.01) (table 1). Patients presenting with an OMERACT flare had a statistically significantly higher total FLARE-RA score (13q) compared to patients without a flare, except at M12 (M3 and M6: p<0.05, M9: p<0.01). The AUC - ROC curve of the FLARE-RA questionnaire (13q) for identifying an OMERACT flare was 0.736 and the cut-off value was 2.3 (1-6 scale). The AUC - ROC curve was the same for the 11q and r11q version, namely 0.727. The cut-off values were 2.4 (1-6 scale) and 2.7 (0-10 scale), respectively (figure 1).

</tbody>
</table>

Conclusion: The FLARE-RA scores seem to reliably discern between patients with and without an OMERACT flare. A cut-off of 2.7 on the current questionnaire (r11q) had the optimal sensitivity and specificity to identify an OMERACT flare.

SERUM AMYLOID A: ASSESSMENT OF REFERENCE VALUE AND COMPARISON OF SERUM CONCENTRATION IN THE SUBJECTS AND PATIENTS WITH BEHÇET SYNDROME

T. Carboni1, M. C. Padula1, V. Pafundi2, C. Schievano2, N. Lascaro2, A. Padula2, P. Lecesse1, S. D’angelo1, 1IReL - Rheumatology Institute of Lucania - San Carlo Hospital, Potenza, Italy; 2Immunopathology Laboratory - San Carlo Hospital, Potenza, Italy; 3Innovative Statistical Research, Padova, Italy

Background: Serum amyloid A (SAA) is a family of acute-phase reactants. The rise of SAA concentration in blood circulation is a clinical marker of active inflammation in several auto-inflammatory diseases, including Behçet syndrome (BS). Despite its practical and analytical advantages, SAA measurement by ELISA has been mainly used as a research tool rather than for the routine laboratory testing due to the lack of a robust reference data in the literature.

Objectives: Using the recommended procedures of the International Federation of Clinical Chemistry and Laboratory Medicine (IFCC), we aimed to develop the SAA reference interval for a well-defined Italian healthy population (HC). Secondly, we compared the SAA serum concentration between HC and patients with BS.

Methods: Sera specimens were collected from adult healthy blood donors after rule out the exclusion criteria (inflammatory disorders, ongoing infections, pregnancy and breastfeeding, obesity, using oral contraceptives, use of any medication, or consumed of alcohol), and from unselected BS patients fulfilling the International Study Group (ISG) classification criteria. Serum SAA concentrations were detected and quantified with a commercial solid phase sandwich enzyme-linked immunosorbent assay (Human SAA ELISA kit, IBL International GmbH, Hamburg, Germany) used on automated analyzer (Immunoat, SERION Diagnostic, Allfex, Polversara (PD), Italy) according to the manufacturer’s protocol. Statistical analysis and data normalization of HC SAA values were carried out to determine the reference cut off. In the second step of the study, HC and BS patients were stratified in two groups according to the cut-off value.

Results: We recruited 141 HC (84 M and 57 F; mean age, 44.5±13.2 years) and 63 BS patients (39 M and 24 F mean age, 45.3±13.2 years) assessed for SAA. The reference cut-off was calculated as 225 ng/ml. No statistically significant differences were found between males and females when SAA means were compared, suggesting that not gender-partitioned reference range is recommended for this analyte. After the stratification according to the cut-off value (group 1: <225 ng/ml and group 2: ≥225 ng/ml), we found 53/63 (84.1%) BS patients and 133/141 (94.3%) HC with concentration less than cut-off value, respectively. We identified 10/83 (15.9%) BS patients and 8/141 (5.7%) HC within the second group. The difference was statistically significant (p=0.0177; OR: 3.14, 95% CI: 1.17-3.38).

Conclusion: This study allowed to define a widely accepted reference cut-off for the SAA detected by ELISA, responding to a unmet need of laboratory medicine. We found a statistically significant higher frequency of BS patients compared with HC when SAA values is higher than cut-off (225 ng/ml). This preliminary data could add significant information for better clarify the role of SAA as biomarker of inflammation and in guidance of clinical practice. Further studies will be required to stratify SAA values in relation to disease activity of BS.

IDENTIFICATION OF OSTEOPOINTEIN/SECRETED PHOSPHOPROTEIN 1 AS A BIOMARKER FOR PSORIATIC ARTHRITIS

F. Abji1, R. Machhar1, K. Liang2, J. Ye1, K. Oikonomopoulou1, V. Chandran3.

1University Health Network, Toronto, Canada; 2University of Waterloo, Waterloo, Canada

Background: Early diagnosis of psoriatic arthritis (PsA) can be facilitated by appropriate referral of psoriasis patients to rheumatologists. Soluble biomarkers for PsA may help screen psoriasis patients for PsA.

Objectives: To identify novel biomarkers for PsA by investigating serum levels of candidate biomarkers identified through proteomic analysis of synovial fluid (SF) and skin biopsies and literature review.

Methods: We first (discovery phase) identified markers using: i) proteomic analysis of SF1, ii) proteomic analysis of skin biopsies2, and iii) literature review. In verification phase 1, we measured serum levels of the selected potential protein markers, using commercially available ELISA kits, to identify differentially expressed markers in healthy controls and patients with PsA (≤3 swollen joints, not treated with biologics) and psoriasis without PsA (PsC; matched with PsA patients on age, sex and psoriasis duration) (100 subjects each group). In verification phase 2, using less strict criteria (no restriction on pharmacotherapy or disease activity) and larger sample size, we confirmed the association with PsA of markers identified in phase 1 using samples from 200 patients each with PsA and PsC. Statistical methods used included descriptive statistics, t-tests and logistic regression.

Results: The discovery phase identified the following 31 markers for testing in verification phase 1- hsCRP, MMP3, CD5L, M2BP, MPO, ITGB5, DKK1, FGF23, IL-6, IL-15, leptin, osteocalcin, OPG, OPN, SOST, TNFα, adiponectin, peristin, RANKL, YKL40, KLK8, KLK8, CS846, C2C, CPII, TNFSF14, COMP, ALP, CXCL10, S100A8/9 and DEFA. The following 21 markers remained differentially upregulated in PsA after testing in verification phase 1- hsCRP, MMP3, M2BP, ITGB5, leptin, OPG, OPN, SOST,TNFα, peristin, RANKL, YKL40, KLK8, C2C, CPII, TNFSF14, COMP, ALP, CXCL10, S100A8/9 and DEFA. Univariate logistic regression analyses adjusted for age, sex, and disease duration confirmed the association between hsCRP, OPN, S100A8/A9, OPG and the ratio CPII/C2C in verification phase 2. Multivariate logistic regression demonstrated that hsCRP and OPN (both p<0.001) are independently associated with PsA.

Conclusion: OCN, a cytokine involved in enhancing production of IFNγ and IL-12, reducing production of IL-10 and promoting attachment of osteoclasts to mineralized bone matrix, is a potential biomarker of PsA.

THE DIAGNOSTIC VALUE OF KL-6 IN RHEUMATOID ARTHRITIS ASSOCIATED WITH INTERSTITIAL LUNG DISEASE IN XINJIANG OF CHINA

G. Chen1, L. Wu1. 1People’s Hospital of the Xinjiang Uygur Autonomous Region, Urumqi, China

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease. Many researchers have observed that extra articular organs were highly involved in RA patients. The most common extra-articular manifestations were pulmonary involvement. Serum levels of KL-6 have been reported to be elevated in various ILD such as idiopathic pulmonary fibrosis, collagen vascular disease associated interstitial pneumonias, and other interstitial lung disorders. However, little is known regarding
the usefulness of this biomarker in connective tissue diseases related interstitial lung diseases (CTD-ILD). Especially, the diagnostic value of KL-6 in interstitial lung disease associated with rheumatoid arthritis (RA-ILD) still has a dispute.

**Objectives:** To assess the diagnosis of the serum Krebs von den Lungen-6 (KL-6) for RA-ILD patients in Xinjiang of China.

**Methods:** This retrospective study included 184 patients with RA in who visited the department of rheumatology and immunology of People's Hospital of Xinjiang Uygur Autonomous Region between January, 2015 and December, 2019. The patients were divided into RA-ILD group (n=95) and RA group (n=89) according to the presence of ILD. Serum KL-6 concentration (U/mL) was measured using the chemiluminescent enzyme immunoassay kit.

**Results:** The mean age (p < 0.001) and median value of CCP (p = 0.006) were significantly higher in the RA-ILD group. RA-ILD group had elevated serum KL-6 levels compared to RA group (447 (281, 687) U/ml vs 195 (151.5, 265.5) U/ml) (p < 0.001) (Figure 1). According to the Receiver Operating Characteristic Curve (ROC) analysis, the area under the curve was 0.879 and the optimal cut-off value of serum KL-6 to discriminate the presence of ILD was 277 U/ml, with sensitivity of 77.9%, specificity of 79.8% (Figure 2).

**Conclusion:** The present study confirms that KL-6 is a biological marker which is associated with RA-ILD. Furthermore, Patients with RA who are older and have a higher value of CCP are more likely to develop ILD.

Conclusion: Leptin-adjustment of the MBDA score reduced bias related to excess adiposity in women with RA. Adjustment results in lower MBDA scores in women with greater adiposity, and higher MBDA scores in women and men with lesser adiposity. The aMBDA may reduce misclassification due to excess adiposity and improve identification of active disease among patients with lower adiposity. High aMBDA scores among men with low adiposity may reflect severe disease or excess comorbidity in this group.

Background: Epigenetic factors such as non-coding RNA (miRNA) have been shown to be deregulated in Systemic Lupus Erythematosus (SLE). In particular, in mouse model (1), different miRNAs have been associated with lupus nephritis (LN), one of the most severe manifestations of the disease.

Objectives: The aim of the study was to evaluate the expression of miR-155 and miR-34a in renal tissue as biomarkers of organ involvement and inflammatory activity in patients with LN.

Methods: Thirty-two LN patients with active renal involvement were enrolled (age: 32.2 ± 9.2 years). The nephritic onset of the disease (early-SLE) was present in 13 patients (41%), while 19 patients (59%) showed a renal involvement during the follow-up (long-SLE). Clinical, laboratory and demographic data were collected for each patient. Disease activity was recorded using SLEDAI-2K and renal activity, using the total SLEDAI-2K fraction including the items related to the renal involvement. Ultrasound-guided renal biopsy has been performed for each patient for the definition of the nephritic class according to the ISN / RPS classification of 2003 revised in 2018(2). The expression of miR-155 and miR-34a in renal tissue was carried out by extraction of total RNA from paraffin-preserved biopsies and after a retrotranscription protocol was evaluated using SYBR® Green-based real-time PCR by relative quantification considering the ΔCt (Ct miRNA - Ct housekeeping gene)(3).

Results: MiR-155 and miR-34a expression in renal tissue were comparable in the different histological classes. Dividing patients on the base of nephritic onset, patients with early SLE showed lower expression of miR-155 (ΔCt 12.8 ± 10.6) and miR-34a (ΔCt 7.8 ± 7.9) than patients with long-SLE (miR-155: ΔCt 6.1 ± 8.7 p = 0.02; miR-34a: ΔCt 7.1 ± 9.0 p = 0.03). Furthermore, a direct correlation was observed between the expression of miR-155 and miR-34a (r = 0.91, p <0.001). Considering patients with early-SLE, the expression of miR-34a was slightly significant in patients who had relapsed (ΔCt 8.2 ± 11.4 vs ΔCt 18.4 ± 7.9 p = 0.08), although no correlation emerged between the expression of miR-155 and miR-34a both at the time of the biopsy and with the disease activity indices. At the histopathological evaluation, miR-155 and miR-34a were more expressed in Early-SLE patients who had wide loop lesions (miR-155: ΔCt 19.5 ± 7.7 vs ΔCt 7.3 ± 9.6 p = 0.05; miR-34a: ΔCt 21.7 ± 11.1 vs ΔCt 8.8 ± 9.7 p = 0.05) possibly associated with a greater activation of the inflammatory component.

Conclusion: MiR-155 and miR-34a may represent tissue biomarkers of inflammatory activation in patients with LN in particular the higher expression of these miRNA in Long-SLE patients could indicate a possible role of these biomarkers in renal involvement in patients with SLE with later renal onset. The increased expression of miR-34a could give indications of a disease recurrence suggesting a closer monitoring of the patient.

BIOMARKER ANALYSIS FROM THE RISE-SSC STUDY OF RIOUCIGAT IN EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (DCSSC)

O. Dieter2, F. Kramer, J. Höffer1, M. Ghadessi2, P. Sandner2, Y. Allainore3, C. Denton1, M. Kuwana4, M. Mattucci-Cerinic5, J. Pope1, T. Atsumi9, R. Beč6, M. Kowana6, M. Matucci-Cerinic7, J. Pope8, T. Ishii14

Objectives: To explore the safety and long-term effectiveness of riociguat in patients with diffuse cutaneous systemic sclerosis (dcSSc) with primary Raynaud’s phenomenon.

Methods: Patients with dcSSc (diagnosis ≤ 18 mo; modified Rodnan skin score [mRSS] 10–22 units) were randomized to riociguat 0.5–2.5 mg tid (n=60) or placebo (n=61). Biomarkers of target engagement (cGMP), inflammation and/or vascular endothelial function (e.g. high-sensitivity C-reactive protein [hsCRP]), soluble platelet endothelial cell adhesion molecule 1 [sPECAM-1], soluble E-selectin, chemokine ligand 4 [CCL4]), and fibrosis (e.g. alpha-smooth muscle cell actin [alphaSMA], pro-collagen mRNA expression) were measured in plasma, serum, and skin biopsies at baseline and Wk 14.

Results: Mean ± SD change from baseline in mRSS was –2.09±0.66 (n=57) with riociguat and –0.77±0.24 (n=52) with placebo (p=0.08). From baseline to Wk 14, plasma cGMP rose by mean (SD) 94% (78%) (n=52) with riociguat and 10% (39%) (n=52) with placebo (nominal p<0.001). Serum sPECAM-1 and CCL4 fell with riociguat vs placebo; changes in hsCRP or E-selectin differed little between groups (Fig 1). Pts with higher baseline sPECAM-1 showed larger mRSS reductions with riociguat vs placebo than pts with lower levels (nominal interaction p=0.004). In baseline skin biopsies, 34% and 31% of pts in the riociguat and placebo groups, respectively, had no alphaSMA-positive cells; other pts had +ve cells (alphaSMA counts 0.1–99.5, median 2.5), a potential indicator of higher disease activity. Pts with +ve baseline alphaSMA counts showed a reduction of mRSS with riociguat vs placebo (Fig 2). Skin collagen mRNA expression biomarkers in skin biopsies showed no differences between groups.

Conclusion: Primary study endpoint (change in mRSS) was not met. Plasma cGMP rose with riociguat, confirming engagement with the NO-ko-ECG-CGMP pathway. Serum sPECAM-1 (marker of endothelial activation) and CCL4 (marker of progressive SSc) fell with riociguat; hsCRP and E-selectin did not. Some serum and skin biomarkers of higher disease activity at baseline were associated with a greater effect of riociguat on skin fibrosis.

Disclosure of Interests: Oliver Distler Grant/research support from: Grants/ Research support from Actelion, Bayer, Boehringer Ingelheim, Competitive Drug Development International Ltd. and Mitsubishi Tanabe; he also holds the issued Patent on mir-29 for the treatment of systemic sclerosis (US20165379, EP2391143), Consultant of: Consultancy fees from Actelion, Aegerion Pharma, AnaMar, Bayer, Baecon Discovery, Blade Therapeutics, Boehringer, CSL Behring, Catenion, ChemomAb, Curzon Pharmaceuticals, Ergonex, Galapagos NV, GSK, Glenmark Pharmaceuticals, Inventiva, Italfarmaco, iQvia, medac, Medscape, Mitsubishi Tanabe Pharma, MSD, Roche, Sanofi and UCB, Speakers bureau:
Objectives: Protein biomarkers associated with RA and a better understanding of the molecular pathways.

Methods: Patients in the AMPLE study had an inadequate response to MTX and were naïve to biologic DMARDs. Protein abundance was assessed in baseline serum samples from 440 AMPLE study patients and 123 healthy individuals with matching demographics using the SomaScan® platform, with 5000+ slow off-rate modified aptamers and up to 8 log of dynamic range. Differential abundance testing was performed using linear models to identify differences in protein abundance in patients with RA vs healthy individuals. A separate analysis using a linear model was conducted in only the patients with RA to identify the proteins associated with DAS28 (CRP) and TSS. Pathway analyses were performed for proteins significantly (false discovery rate-adjusted p value <0.05) associated with RA and the disease severity measurements to identify over-representation of the molecular pathways.

Results: Compared with healthy individuals, >2000 serum proteins were significantly differentially expressed in patients with RA, including many proteins that have been associated with RA (e.g. serum amyloid A [SAA], CRP) and complement. Most of the protein expression differences were of small magnitude (fold change <2). Proteins that were differentially expressed between patients with RA and healthy individuals were enriched in interleukin signalling, neutrophil degranulation, platelet activation/degranulation and extracellular matrix organisation pathways. DAS28 (CRP) was significantly associated with several biomarkers, including SAA, fibrinogen and CRP; in general, proteins associated with DAS28 (CRP) were most strongly enriched in the platelet activation/degranulation pathways (Figure 1), also seen in patients with RA vs healthy individuals. Additionally, many proteins were significantly associated with TSS, including SAA, matrix metalloproteinase-3 and cartilage acidic protein 1. Here, the proteins were most strongly enriched in the extracellular matrix remodelling pathways (Figure 2).

Conclusion: Our study revealed that thousands of serum proteins are differentially expressed and several pathways are dysregulated between patients with RA and healthy individuals. Additional pathways were identified that reflect disease severity, including joint damage, distinct from those pathways associated with the disease. The SomaScan® platform provides a unique proteomic tool with a wide dynamic range for the identification of serum protein biomarkers associated with RA and disease severity. Proteomic signatures should be considered in clinical trials to better understand disease pathogenesis and predict risk in response to treatment.

Conclusion: Spinal mobility is an important assessment outcome in axial spondyloarthritis (axSpA). Until now, conventional metrology (Schober test, lateral flexion, BASMI, ...) has been used to assess spinal mobility. However, new technologies have been developed that provide better accuracy, reliability and responsiveness. Motion capture has been validated and Inertial Measurement Unit (IMU) sensors appear to be a promising alternative. To use these IMU sensors in axSpA patients, wireless systems must be developed and validated allowing to doctors and patients to use them in hospitals and at home.

Objectives: To develop an easy to use mobile app and IMU sensors system for analyse mobility for axSpA patients.

Methods: A mobile app has been developed (UCOTrack) that communicates with two IMU sensors (Shimmer 3D, Fig-a). These sensors are attached in different locations: at forehead and T12 for cervical mobility (Fig-c) and T12 and Sacrum for thoracolumbar mobility (Fig-b). The app provides mobility results for different tests (Fig-d) and store results in the cloud. Validation tests of these sensors, using Matlab®, were done previously [1]. Our study test the validity of this app against a motion capture system, the UCOTrack®, and its metrology index, the UCOASMI [2], and conventional metrology as reference standards. Patients with axSpA were recruited consecutively from the COSPAR cohort. Conventional metrology, PRO questionnaires and mobility (Cervical and thoracolumbar - flexion, lateral bending, rotation) using the UCOTrack app and the UCOTrack were registered. Intraclass Correlation Coefficients (ICC 3,1) between systems and correlations (spearman) with other axSpA outcome measures were performed for testing validity.

Results: 15 axSpA patients (47% female, age 52±12 years, disease duration 21±16 years) were included. Table shows ROM (SD) in degrees obtained for cervical and thoracolumbar spine measured using motion capture (UCOTrack) and the app (UCOTrack). In the last column appears the UCOASMI (SD) calculated using angles obtained by each system. All ICC were good (ICC>0.8), and correlations were significant (p<0.05, r>0.8) specially the UCOASMI. Cervical rotation using a goniometer was 106.2±36°, with a significant correlation with both systems (p<0.05; r>0.8). Schober correlation with lumbar flexion was poor (NS; r>0.5) but a good correlation appeared with lateral flexion (p<0.01;r>0.9). Mean BASMI was 4.0±1.8 with an excellent correlation with UCOASMI measured by Mocap (p<0.01;r=0.93) and by IMU (p<0.001;r=0.98).

Conclusion: New metrology tools are needed to improve features of conventional metrology. Motion Capture has proved to be valid but has feasibility problems. IMU sensor based systems provide similar results to motion capture but it can be faster and cheaper. A system based on mobile app connected to wireless IMU sensors could be a solution to improve metrology in axSpA. Further studies and developments are needed to introduce these technologies in research and clinical daily practice.

VITAMIN D LEVEL IN HEALTHY CANARIAN ADULT POPULATION

A. García Dorts1, H. D. Marta1, L. Medina Vega2, J. J. Villalobos Jiménez1, J. J. Bethencourt Baute1, Á. Álvarez Díaz1, C. Luna-Gomez1, F. Álvarez Reyes1, S. Machin García2, S. Bustabad1, Hospital Universitario de Canarias, Rheumatology, Tenerife, Spain; Hospital Universitario de Canarias, Laboratorio, Tenerife, Spain; Hospital Virgen de las Nieves, Rheumatology, La Palma, Spain; Hospital Universitario Nuestra Señora de Candelaria, Rheumatology, Tenerife, Spain; Maternal and child Hospital, Tenerife, Spain

Background: Vitamin D (VitD) was first used to treat rickets in children in 1918, because it has been associated with lower risk of suffering from multiple diseases and there is also a lack of consensus in establishing adequate levels for the general population. According to data of the ISTAC (Canary Institute of Statistics) with a level of accuracy of 0.79, the sociodemographic characteristics (age, sex and rural/urban population) of the 949 samples were representative of the Canary population in the period studied according to data of the ISTAT (Canary Institute of Statistics) with a level of accuracy of 0.7% for the vitD and a confidence level of 95%. Healthy (n=876, 92.3%) and sick subjects (n= 73, 7.7%) (renal failure, dialysis, Crohn’s, ulcerative colitis, osteoporosis, calcium supplements, vitD, bisphosphonates or calcitonin). The median and Interquartile range of vitD levels in the entire population studied was 26.3 (20.9-32.9) ng/ml.

Methods: Cross-sectional population study to determine VitD levels in healthy adults. The EPICRAN screen was used, a population study carried out in 2004 and 2005 to determine the prevalence of rheumatic diseases in the Canary Islands. In 949 serums, the levels of VitD, phosphorus and calcium were determined using a goniometer was 106.2±36°, with a significant correlation with both systems (p<0.05; r>0.8). Schober correlation with lumbar flexion was poor (NS; r>0.5) but a good correlation appeared with lateral flexion (p<0.01;r>0.9). Mean BASMI was 4.0±1.8 with an excellent correlation with UCOASMI measured by Mocap (p<0.01;r=0.93) and by IMU (p<0.001;r=0.98).

RHEUMATOID FACTOR IS ASSOCIATED WITH FALSELY ELEVATED RESULTS IN COMMERCIAL IMMUNOASSAYS: DATA FROM AN EARLY ARTHRITIS COHORT

J. E. Gehin1,2, R. A. Klaasen1, E. S. Noril3,4, S. W. Syversen3, G. L. Goll3, D. J. Warren3, T. K. Kvien3,5, K. J. Nustad3, M. D. Mjaavatten3, N. Bolstad3, 1Oslo University Hospital, Radiumhospitalet, Dept of Medical Biochemistry, Oslo, Norway; 2University of Oslo, Faculty of Medicine, Oslo, Norway; 3Diakonhjemmet Hospital, Dept of Rheumatology, Oslo, Norway; 4Martina Hansens Hospital, Sandvika, Norway

Background: Immunoassays are used to measure a range of analytes in clinical laboratories. Rheumatoid factor (RF) and other patient antibodies, such as heterophilic antibodies, can bind animal antibodies used in immunoassays and cause erroneous results, which may lead to misdiagnosis and incorrect treatment of patients.

Objectives: To assess RF reactivity to animal antibodies and to test if selected commercial immunoassays are vulnerable to interference from RF-positive sera.

Methods: Samples from 124 patients with RF-positive rheumatoid arthritis (RA) included in the Norwegian Very Early Arthritis Clinic (NOR-VEAC)-cohort1 were included in the study. Samples from patients with seronegative RA (n=51) and psoriatic arthritis (n=15) from the same cohort were included as controls. Reactivity to mouse IgG1, mouse IgG2a, rabbit IgG, bovine IgG, sheep/goat IgG and human IgG was analysed using in-house interference assays detecting antibodies able to cross-link the animal or human antibodies. RF-positive sera with strong reactivity to mouse IgG1 were selected for testing in three commercial immunoassays previously shown to be susceptible to interference from heterophilic antibodies; Abbott Architect Total β-hCG assay, Bio-Rad 27-plex cytokine assays and Roche Elecsys Soluble Transferrin Receptor (sTfR).2 Samples were tested before and after addition of blocking aggregated murine IgG1 (interference protection). Interference was defined as a discrepancy between the unblocked and blocked samples likely to influence clinical interpretation of the results and exceeding the reported assay imprecision with a considerable margin.

Results: We found considerably stronger reactivity toward animal antibodies, particularly mouse IgG1 and rabbit IgG, in sera from RF-positive RA patients compared to the control group (Fig. 1a-b). In the Abbott β-hCG assay, interference was shown in 6 out of the 30 tested sera (for 3-14 analytes). Furthermore, 17 out of the 27 cytokine assays were found to be susceptible to interference (Fig. 2b). Interference was shown in 2 out of 33 samples in the sTfR assay. In unblocked samples, sTfR values were 8.1 and 8.2 mg/L vs. 4.2 mg/L and 6.0 mg/L in blocked samples, respectively. Additionally, 3 sera had >25% relative difference, but the results were within the reference range.

Conclusion: Reactivity to animal antibodies used in immunoassays is common in sera from RF-positive RA patients and are associated with falsely elevated results in commercial immunoassays. In our cohort, interference was demonstrated in a considerable proportion of samples in the Abbott hCG and 27-plex cytokine assays. Physicians as well as researchers, laboratories and assay manufacturers must be alert to the risk of falsely elevated test results in RF-positive RA patients, particularly when results are unexpected or discordant with clinical findings. False test results may interfere with research results, and also lead to potentially harmful diagnostic and therapeutic interventions if unrecognised.

Discordance Between Objective Elbow Assessment and Patients Reported Outcomes (PROs) after Total Elbow Arthroplasty in Patients with Rheumatoid Arthritis

R. Harada1, K. Nishida1, Y. Nasu2, R. Nakahara2.1 Kurashiki Sweet Hospital, Orthopaedics, Kurashiki City, Okayama Pref., Japan;2 Okayama University Hospital, Orthopaedics, Okayama, Japan

Background: Patient-reported outcomes (PROs) have become widespread in daily clinical evaluation in patients with rheumatoid arthritis (RA). However, there are few reports for the relationship or discordance between the subjective assessment by the physician and the objective assessment by the patient with RA in surgical treatment.

Objectives: We examined the relationship or discordance about the PROs in patients with RA who underwent total elbow arthroplasty (TEA).

Methods: We retrospectively identified 53 elbows of 48 patients with RA who underwent TEA at Okayama University Hospital, collected from January 2012 to December 2016.

We collected clinical data for the grip strength, range of motion, the Mayo Elbow Performance Scale (MEPS) as objective assessments, and the Patient-Related Evaluation of Elbow (PREE) score as subjective assessments. For statistical analysis, we performed t-tests for pre- and post-operative physical findings and subjective evaluations, and Spearman rank correlation to examine the relationship between objective and subjective assessments.

Results: The mean age of the patients at the time of arthroplasty was 63 years, the average disease duration was 23 years, and the average postoperative observation period was 32 months. The average DASH2-CRP was 3.01, and biological use was 18 cases.

The range of motion of the elbow joint and the grip strength was significantly improved postoperatively. All outcome assessments improved significantly except for HAQ (see Table 1).

There was significantly correlated PREE with DASH, Hand20, and MEPS preoperatively. Postoperative PREE showed a significant and robust correlation in postoperative DASH, Hand20, whereas not associated with postoperative MEPS (see Table 2).

To investigate the discordance between PREE and MEPS, the relationship or discordance about the PROs in patients with RA who underwent TEA, we focused on changes in each item of PREE. Pain- and reach-related items improved postoperatively. But, it was difficult to improve in items affected by hand and finger functions, such as “tie shoelaces.”

To explore the effects of finger and hand functions on postoperative assessments, we performed multiple regression analyses. Both preoperative grip strength (unstandardized coefficient [β] = 0.07, 95% CI -0.148 to -0.006, 1 value = -2.18, P < 0.03) and preoperative Hand20 (B = 0.27, 95% CI 0.029-0.518, t=2.25, p<0.02) were significant predictors of postoperative PREE.

Conclusion: Surprisingly, the PROs of patients and the surgeon’s evaluations correlated well before surgery but resulted in discordance after TEA. We improved elbow functions by TEA, but since rheumatoid arthritis was a polyarticular disorder, improvement of a single joint function did not improve utterly subjective assessment in patients with RA. We found that the upper limb functions after TEA were significantly affected by preoperative finger and hand function. A rheumatologist should consider the dysfunctions of finger and hand when planning for elbow surgery in patients with RA.

Conclusion: In our trial of elderly rheumatoid arthritis patients, patients appeared to be mostly adherent according to conventional capsule counts. Results from adherence caps were highly discrepant with the capsule counts, with patterns suggesting patients did not use the bottle for daily dispensing, despite specific advice to do so.

Results: The study included 30 patients with SLE. Internal consistency of the MFIS was excellent with Cronbach’s $\alpha = 0.97$ for the complete scale. Excellent test-retest reliability was found with ICC = 0.95 (95% confidence interval: 0.88-0.98, p < 0.05). Construct validity was confirmed by Spearman’s correlation (VT-SF36: $r_s = -0.73$, p < 0.001 (Fig. 1). MH-SF36: $r_s = -0.74$, p < 0.001 (Fig. 2)) and PCA with explained variance from the first two principal components (PC) (VT-SF36: PC1 = 60.2%, PC2 = 8.5%. MH-SF36: PC1 = 58.5%, PC2 = 7.4%). No significant correlation was found between the MFIS and SLEDAI ($r_s = 0.04$, p = 0.84) or SLICC Damage Index ($r_s = 0.32$, p = 0.08).

Conclusion: The present study found the multidimensional assessment of fatigue with MFIS to be a reliable and valid instrument in SLE. The MFIS might provide more detailed information about fatigue in future studies. In agreement with some previous studies we found no association between fatigue and disease components exist.

SCREENING AND IDENTIFICATION OF BIOMARKERS IN MYOSITIS

W. Liu1, X. Zhang1 on behalf of Department of Rheumatology, Guangdong Provincial People’s Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China. 1Guangdong Provincial People’s Hospital, Guangdong Academy of Medical Sciences, Rheumatology, Guangzhou, China

Background: Myositis, including dermatomyositis and polymyositis, is autoimmune disorders that is characterized by muscle degeneration in the proximal extremities, with the complications of weakness of muscles, interstitial lung disease and vascular lesions, even leading to death in an acute progressive process[1,2]. However, the molecular mechanisms of myositis are rarely understood.

Objectives: Identify the candidate genes in myositis.

Methods: Microarray datasets GSE128470, GSE48280 and GSE39454 were extracted from the Gene Expression Omnibus (GEO) database. The differentially expressed genes (DEGs) and function enrichment analyses were conducted. The protein-protein interaction network and the analyses of hub genes were performed with STRING and Cytoscape.

Results: There were 98 DEGs, of which the function and pathways enrichment analyses showed defense response, immune response, response to virus, inflammatory response, response to wounding, cell adhesion, cell proliferation, cell death and macromolecule metabolic process. 20 hub genes were identified, of which 7 including IRF9 TRIM22 MX2 IFITM1 IFI6 IFI44 IFI44L had not been reported in the literature, related to the response to virus, immune response, transcription from RNA polymerase II promoter, cell apoptosis, cell death. The verification analysis about the 7 genes in GSE128314 showed significant differences in myositis.

Conclusion: In conclusion, DEGs and hub genes identified in our study showed the potential molecular mechanisms in myositis, providing the helpful targets for diagnosis and clinical strategy of myositis.

**HIGH-THROUGHPUT METHODOLOGY FOR EMR-BASED IDENTIFICATION OF CLINICAL SUB-PHENOTYPES IN COMPLEX PATIENT POPULATIONS**

M. Maurits1, T. Huizinga1, M. Reinders2,3, S. Raychaudhuri4,5, E. Karlson5, E. Van den Akker2,3, R. Knevel1,4, 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Delft University of Technology (TU Delft), Bioinformatics, Delft, Netherlands; 3Leiden University Medical Center (LUMC), Molecular Epidemiology, Leiden, Netherlands; 4Brigham and Women’s Hospital, Rheumatology, Boston, United States of America; 5Brigham and Women’s Hospital, Data Sciences, Boston, United States of America

**Background:** Heterogeneity in disease populations complicates discovery of risk factors. To identify risk factors for subpopulations of diseases, we need analytical methods that can deal with unidentified disease subgroups.

**Objectives:** Inspired by successful approaches from the Big Data field, we developed a high-throughput approach to identify subpopulations within patients with heterogeneous, complex diseases using the wealth of information available in Electronic Medical Records (EMRs).

**Methods:** We extracted longitudinal healthcare-interaction records coded by 1,853 PheCodes1 of the 64,819 patients from the Boston’s Partners-Biobank. Through dimensionality reduction using t-SNE2 we created a 2D embedding of 32,424 of these patients (set A). We then identified distinct clusters post-t-SNE using DBscan3 and visualized the relative importance of individual PheCodes within them using specialized spectrographs. We replicated this procedure in the remaining 32,395 records (set B).

**Results:** Summary statistics of both sets were comparable (Table 1).

Table 1. Summary statistics of the total Partners Biobank dataset and the 2 partitions.

We found 284 clusters in set A and 295 in set B, of which 63.4% from set A could be mapped to a cluster in set B with a median (range) correlation of 0.24 (0.03 – 0.58).

Clusters represented similar yet distinct clinical phenotypes; e.g. patients diagnosed with “other headache syndrome” were separated into four distinct clusters characterized by migraines, neurofibromatosis, epilepsy or brain cancer, all resulting in patients presenting with headaches (Fig. 1 & 2). Though EMR databases tend to be noisy, our method was also able to differentiate misclassification from true cases; SLE patients with RA codes clustered separately from true RA cases.

**Conclusion:** We have shown that EMR data can be used to identify and visualize latent structure in patient categorizations, using an approach based on dimension reduction and clustering machine learning techniques. Our method can identify misclassified patients as well as separate patients with similar problems into subsets with different associated medical problems. Our approach adds a new and powerful tool to aid in the discovery of novel risk factors in complex, heterogeneous diseases.

HOW TO GET FROM THE MULTIDIMENSIONAL HEALTH ASSESSMENT QUESTIONNAIRE TO STANFORD HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX SCORES IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS: DEVELOPMENT AND VALIDATION OF A CONVERSION ALGORITHM

E. Svensson1, K. Longaard1, L. Mithellh Orrberg2, R. Meincke2, J. K. Pedersen2, L. Dreyer4, N. Steen Krogh2, D. V. Jensen2, M. L. Hetland2, 1RKPP - the Danish Clinical Quality Program, Aarhus, Denmark; 2DANBIO, Copenhagen Center for Arthritis Research, Rigshospitalet, Copenhagen, Denmark; 3Svendborg Hospital, Svendborg, Denmark; 4Aalborg University Hospital, Aalborg, Denmark; 5Zitelab Aps, Frederiksberg, Denmark

**Background:** In the DANBIO quality registry in Denmark, patients with rheumatoid arthritis (RA) psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) have reported Patient Reported Outcomes (PROs) including the Stanford Health Assessment Questionnaire Disability Index (HAQ-DI) for nearly twenty years as part of routine care. Patients’ feedback have stressed a need for a shorter registration of disability (1). While the shorter Multidimensional Health Assessment Questionnaire (MDHAQ) is preferred by patients, the original HAQ-DI is the preferred tool in observational studies. Thus, a conversion algorithm between the MDHAQ and HAQ-DI scores is warranted.

**Objectives:** To develop and validate a simple conversion algorithm between MDHAQ and HAQ-DI scores in RA, PsA and axSpA patients.

**Methods:** Patients registered in DANBIO with a diagnosis of RA, PsA or axSpA who had completed both HAQ-DI and MDHAQ simultaneously at a visit +/- 30 days from start of conventional synthetic (cs)DMARD or biological (b)DMARD were eligible for the analysis, and randomly divided into development and validation cohorts stratified by diagnosis. The conversion algorithm was developed in the RA development cohort using linear regression with HAQ-DI as the dependent variable and MDHAQ as the independent variable. The predicted HAQ (pHAQ) scores were then...
calculated by applying the conversion algorithm to the MDHAQ scores in the RA, PsA and axSpA validation cohorts. The pHAQ was validated against the HAQ-DI in the validation cohorts regarding criterion, correlational and construct validity.

Results: We included 8883/4410/1760 patients with RA/PsA/axSpA, respectively. The conversion algorithm pHAQ=0.15+MDHAQ*1.08 had the best fit (R²=0.83) in the RA development cohort.

Criterion validity: The correlation coefficients between HAQ-DI/pHAQ and patient global score at baseline were 0.66/0.65. In groups of patients with high and low disability (defined as patient global score ≥50), standardized mean difference was -1.4 for HAQ-DI, and -1.4 for pHAQ.

Correlational validity: Correlation coefficients between HAQ-DI/pHAQ and ΔHAQ-DI/ΔpHAQ between baseline and first follow-up visit were r=0.91 and r=0.87, respectively. Correlation coefficients between HAQ-DI/pHAQ and pain score, DAS28CRP and physician global score were 0.63/0.64, 0.55/0.55 and 0.34/0.34, respectively. A Bland-Altman plot showed good agreement of HAQ-DI and pHAQ across all functional states.

Construct validity: HAQ-DI/ΔpHAQ at the first follow-up visit after baseline was comparable between Patient Acceptable Symptom State groups (PASS=No: mean 1.17 vs 1.18/PASS=Yes: 0.55 vs 0.60). Similar results were seen for the external anchor (Figure 1).

In PsA and axSpA validation cohorts, similar results were found.

Conclusion: A conversion algorithm from MDHAQ to HAQ-DI was developed in ≥4500 RA patients. In separate large validation cohorts of RA, PsA and axSpA patients, the predicted HAQ calculated from the MDHAQ scores showed good criterion, correlational and construct validity comparable to the original HAQ-DI.

Objective: To use a remote electronic MDHAQ, completed weekly at home, to recognize RAPID3 clinical status changes and adverse events on the 60-symptom checklist, for early detection of medication adverse events.

Methods: All patients with all diagnoses complete an MDHAQ at all visits in routine care at one rheumatology site. An electronic flowsheet (Table) is used to monitor 0-30 RAPID3, its components, and report of specific symptoms on the 60-symptom checklist, which appears required to document earlier absence of a common symptom and signal that a common symptom may be an adverse event. Results are depicted for an individual patient with pulmonary fibrosis, seen because of a positive rheumatoid factor.

Results: A flowsheet of a pulmonary fibrosis patient over 2018 indicates initial RAPID3 of 14/30 and 10 symptoms at first visit of 19 Jan (Flowsheet). Treatment with low-dose methotrexate (MTX) and prednisone (PRED) led to substantial improvement over 6 months - RAPID3 3.5 and 6 symptoms on 2 Aug. On 15 Aug, MTX and PRED were discontinued by another physician, who prescribed pirfenidone. The patient telephoned on 24 Sep indicating distress. A home-completed remote MDHAQ indicated RAPID3 of 19.5 and 15 symptoms - 7 not reported on 2 Aug were among 16 listed pirfenidone adverse events. Discontinuation of pirfenidone and resumption of PRED and MTX with weekly remote electronic MDHAQ monitoring documented improvement of RAPID3 to 4.2 and 6 symptoms, including resolution of pirfenidone-specific symptoms, on 24 Dec (Flowsheet).

Conclusion: Weekly remote electronic MHDAQ monitoring after initiation of a high-risk medication to monitor treatment responses and adverse events may provide a cost-effective approach to reduce morbidity and mortality of adverse events, involving about 10 minutes weekly (2 hours over 12 weeks) of patient time. 78-year-old man monitored over 2018—all data from self-report on MDHAQ – pirfenidone highlighted (many entries deleted for space considerations)

Acknowledgments: The authors thank all Danish patients and Departments of Rheumatology, who conscientiously report to the DANBIO registry.

FR01087 A NEW APPROACH TO EARLY DETECTION OF ADVERSE EVENTS OF HIGH-RISK MEDICATIONS USING A STRUCTURED, STANDARD, PROTOCOL DRIVEN WEEKLY REMOTE ELECTRONIC MDHAQ 60-SYMPTOM CHECKLIST

T. Pincus1, N. Steen Krogh2.

1Rush University, Rheumatology, Chicago, United States of America; 2ZeLab, Copenhagen, Denmark

Background: A multidimensional health assessment questionnaire (MDHAQ) includes RAPID3, which distinguishes active from control treatments in rheumatoid arthritis clinical trials, and documents change comparably to disease-specific indices in all diseases studied. The MDHAQ also includes a standard, structured 60-symptom checklist, to recognize comorbidities, provide a review of systems, and serve on a fibromyalgia assessment screening tool (FAST3) as a clue to identify patients with fibromyalgia. A new MDHAQ application is to recognize adverse events to high-risk medications on a standard, structured, protocol-driven MDHAQ 60-symptom checklist. A structured list, rather than a 'subjective' narrative medical history, is needed as many adverse events are common symptoms, e.g., headache, fatigue; prior negative data facilitates recognition of a new symptom as a possible adverse event. Similar strategies have been reported in oncology, pulmonology and other specialties, but not in rheumatology.

Methods: All patients with all diagnoses complete an MDHAQ at all visits in routine care at one rheumatology site. An electronic flowsheet (Table) is used to monitor 0-30 RAPID3, its components, and report of specific symptoms on the 60-symptom checklist, which appears required to document earlier absence of a common symptom and signal that a common symptom may be an adverse event. Results are depicted for an individual patient with pulmonary fibrosis, seen because of a positive rheumatoid factor.

Results: A flowsheet of a pulmonary fibrosis patient over 2018 indicates initial RAPID3 of 14/30 and 10 symptoms at first visit of 19 Jan (Flowsheet). Treatment with low-dose methotrexate (MTX) and prednisone (PRED) led to substantial improvement over 6 months - RAPID3 3.5 and 6 symptoms on 2 Aug. On 15 Aug, MTX and PRED were discontinued by another physician, who prescribed pirfenidone. The patient telephoned on 24 Sep indicating distress. A home-completed remote MDHAQ indicated RAPID3 of 19.5 and 15 symptoms - 7 not reported on 2 Aug were among 16 listed pirfenidone adverse events. Discontinuation of pirfenidone and resumption of PRED and MTX with weekly remote electronic MDHAQ monitoring documented improvement of RAPID3 to 4.2 and 6 symptoms, including resolution of pirfenidone-specific symptoms, on 24 Dec (Flowsheet).

Conclusion: Weekly remote electronic MDHAQ monitoring after initiation of a high-risk medication to monitor treatment responses and adverse events may provide a cost-effective approach to reduce morbidity and mortality of adverse events, involving about 10 minutes weekly (2 hours over 12 weeks) of patient time. 78-year-old man monitored over 2018—all data from self-report on MDHAQ – pirfenidone highlighted (many entries deleted for space considerations)

**The isotype with the best AUC for each clinical scenario. + Manufacturer cut-off value: 20UR/ml
When considering aPL asymptomatic patients and APS patients (both PAPS and SAPS), the only two aPL combinations that showed a statistically significant association with the APS group were aPS/PT IgG/IgM and/or α2GPI-D1 (OR 4.86, 95% CI 1.76-13.3, p<0.05) and Global APS Score >11 (OR 2.87, 95% CI 1.08-7.6, p<0.05). Interestingly, also adding the patients with suspect APS to the equation, the combination of aPS/PT IgG/IgM and/or α2GPI-D1 remained statistically significant (OR 2.61, 95% CI 1.02-7.05, p<0.05).

**Conclusion:** Combining anti-α2GPI D1 and aPS/PT improves the diagnostic power of aPL testing and might improve in risk stratification in patients with aPL positivity.

VALIDITY OF THE GERMAN VERSION OF BOTH THE PARENT ADHERENCE REPORT QUESTIONNAIRE (PARQ) AND THE CHILD ADHERENCE REPORT QUESTIONNAIRE (CARQ) - DATA OF THE INCEPTION COHORT OF NEWLY DIAGNOSED PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (ICON)

S. Kirchner1, C. Sengler1, J. Klotsche1, I. Liedmann1, M. Niewerth1, D. Windschall2, T. Kallinich3, G. Horneff4, T. Hospach5, F. Dressler6, J. B. Kuenemmer-Deschner4, K. Minden4,1,1, German Rheumatism Research Center, Berlin, Germany; St-Josef-Stift, Sendenhorst, Germany; 2Charité - Universitätsmedizin Berlin, Department of Pediatrics, Berlin, Germany; 3Asklepios Klinik St. Augustin, St. Augustin, Germany; 4Charité - Universitätsmedizin Berlin, Department of Pediatrics, Berlin, Germany; 5University Children’s hospital, Tübingen, Germany

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic inflammatory rheumatic disease in childhood. A multimodal treatment is needed to reduce pain, control inflammation and maintain joint functioning. Adherence to prescribed therapies is necessary for an optimal outcome. Measuring adherence in children with JIA and their caregivers by a validated questionnaire provides important information about benefits and problems with treatment.

Objectives: To evaluate adherence in JIA patients and to validate the German version of both the parent adherence report questionnaire (PARQ) and the child adherence report questionnaire (CARQ).

Methods: The PARQ and CARQ were translated from its original English version into German and cross-culturally adapted. Parents and children completed the PARQ and CARQ 4 years after enrolment in the Inception cohort ICON. These questionnaires measure child ability (by VAS 0-100, 100 = best) related to i) general level of difficulty in following treatment, ii) frequency of following treatment, iii) negative reactions in response to treatment (i)-iii) summarized to child ability total score), iv) perceived helpfulness of treatment, and 4 categorical questions on errors in medication behavior. Reliability was tested by re-administering the questionnaire after a mean of 13 days. Reproducibility was analysed using intraclass correlation coefficients (ICC). VAS scores were correlated with the Pediatric Quality of Life Inventory (PedsQL) treatment scale items for convergent validity, and with sociodemographic parameters for discriminant validity.

Results: 481 parents and 465 children completed the PARQ and the CARQ, respectively. 56 parents and 37 children took part in the re-test. The mean age at assessment was 10.1±3.7 years, mean disease duration was 4.7±0.8 years. The majority of patients suffered from oligoarthritis (49%), followed by rheumatoid-factor negative polyarthritis (30%). Treatment with a DMARD received 60% (MTX 46%), 28% received a biological drug, 16% both. Disease activity measured by the clinical juvenile arthritis disease activity score-10 (cJADAS-10) was 2.6 ± 3.4 (range 0 – 30, best = 0), functional status was good (mean CHAQ 0.2 ± 0.4). Exercise and splints were prescribed to 57% and 21% of patients, respectively.

PARQ/CARQ mean child ability total scores for medication were 73.1 ± 23.3/76.5 ± 24.2, for exercise: 85.6 ± 16.5/90.0 ± 15.0, for splints: 72.9 ± 24.2/82.9 ± 16.5. About a third of parents and children reported any error in medication behavior. Perceived helpfulness was highest for medication (PARQ/CARQ 74.7 ± 20.6/83.6 ± 26.1) and lowest for splints. (PARQ/CARQ 80.8 ± 28.4/73.5 ± 33.6).

ICCs related to medication indicated good to excellent concordance (PARQ ICC = 0.69 - 0.96; CARQ ICC = 0.53 - 0.75), to exercise moderate (PARQ ICC = 0.28 - 0.45; CARQ ICC = 0.67 - 0.93) and to splints disparate concordance (PARQ ICC = 0.01 - 0.90, CARQ ICC = 0.36 - 0.93). Scores for medications (PARQ: r 0.06 - 0.38, CARQ: 0.06 - 0.49), exercise (PARQ: r 0.33 - 0.30, CARQ: 0.01 - 0.34) and splints (PARQ: r 0.09 - 0.52, CARQ: 0.11 - 0.62) showed a fair to good correlation with the PedsQL scales. Gender and socioeconomic status were not associated with the level of adherence.

Conclusion: The German version of the PARQ and CARQ appears to be a valuable tool to measure adherence in patients with JIA and to evaluate helpfulness of treatments.

IMPACT OF INDIVIDUAL SYMPTOMS OF PSORIATIC ARTHRITIS ON PHYSICAL COMPONENT SCORE AND MENTAL COMPONENT SCORE OF SF-36 AS A MEASURE OF HEALTH RELATED QUALITY OF LIFE (QOL): AN OBSERVATIONAL COHORT STUDY

M. Skougard1, T. Schiødt Jørgensen1, M. J. Jensen1, C. Ballegaard1, J. Guldberg-Møller1, A. Egeberg3, R. Christensen1, J. F. Mero1a, L. C. Coates4, V. Strand5, P. J. Mease6, L. E. Kristensten1, 1The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark; 2Department of Dermatology and Allergy, Herlev and Gentofte Hospital, Copenhagen, Denmark; 3Department of Dermatology and Department of Medicine, Division of Rheumatology, Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America; 4Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; 5Division Immunology/ Rheumatology, Stanford University, Palo Alto, United States of America; 6Swedish Medical Centre, and University of Washington, Seattle, United States of America

Background: Patients with Psoriatic Arthritis (PsA) experience diverse symptoms including skin and nail psoriasis, swollen and tender joints, enthesitis, and fatigue that have shown to impair health related quality of life (QoL). We hypothesized that different elements of disease influence SF-36 physical (PCS) and mental (MCS) component summary scores differently.

Objectives: The objective of the study was to assess the interaction between change in disease activity (DAS28CRP), PsA symptoms (psoriasis [PsO], nail PsO, enthesitis, fatigue, pain, and physical function) with changes in PCS and MCS scores in a PsA patient cohort exploring effect of treatment on clinical manifestations and patient-reported outcome (PRO).

Methods: Data were obtained from the PIPA cohort (1) at baseline and after 4 months of treatment. Patients’ characteristics were described as medians with interquartile ranges (IQRs) and numbers with percentages. Data were presented as

Figure 1. Association between disease activity, individual symptoms and PCS/MCSPCS: physical component summary (green regression plane), MCS: mental component summary (blue regression plane). Arrows indicate the positive improvement vector. SF-36: short form-36, CI: Confidence Interval, DAS28CRP: disease activity score with 28 joints and c-reactive protein, PASI: Psoriasis Area Severity Index, SPARCC: Spondyloarthrits Research Consortium of Canada enthesis index, VAS: visual analogue scale, PsAID: Psoriatic Arthritis Impact of Disease, HAQ: Health Assessment Questionnaire
changes between baseline and follow-up with delta (Δ) values on xyz-plots. Associations between PCS and MCS scores, DAS28CRP, and PsA symptoms were described with fitted linear regression plane models. PCS and MCS were derived from 8 domains of SF-36 and ranged from 0-100 with lower values reflecting more impaired QoL.

**Results:** 71 PsA patients were included in the study; 40 (56%) patients were female with a mean age of 50 (IQR 41-60) years and disease duration of 2.15 (IQR 0.2-9) years. Figure 1 shows associations between PsA symptoms, DAS28CRP, and PCS (green regression plane) and MCS (blue regression plane). For all PRQs; pain, fatigue and physical function, improvements in both ΔPCS and ΔMCS scores were associated with improvements in either ΔPsAID fatigue, and/or ΔHAQ, and to a larger extent than improvements in ΔDAS28CRP. Improvements in Δnail PsO (rejection coefficient (RC): -0.22) and ΔPSASI (RC: -0.31) positively impacts ΔMCS, without a clear association in PCS scores (RC: 0.13 and 0.38 for Δnail PsO and ΔPSASI, respectively). Improvement in inflammatory features SPARCC enthesis and DAS28CRP showed improvement in both ΔPCS and ΔMCS.

**Conclusion:** Pain and fatigue are well-known factors to impair QoL in PsA patient. Here we show that diminishing these factors, pain and fatigue, improved both PCS and MCS scores more than changes in DAS28CRP. Improvements in skin and nail manifestations impacted MCS scores and are as important as changes in joint manifestations which affect PCS and MCS scores equally.

**Background:** WHO survey showed that the prevalence of anxiety and depression in Chinese population and Chinese patients with chronic diseases were between 3.1% - 4.2% and 3.1% - 7.3%, respectively. Ankylosing Spondylitis Disease Activity Score (ASDAS) and Hospital Anxiety and Depression Scale (HADS) are commonly used to evaluate AS patients’ disease activity and mental health. All those assessments were mainly performed by health professionals (HCPs) with paper questionnaire previously. SSDM is a novel smart disease management tool that allows patients to do self-assessments on ASDAS and HADS by mobile terminals.

**Objectives:** To estimate the prevalence of anxiety and depression in Chinese patients with PsA and to analyze the potential association between disease activity and mental health.

**Methods:** Under the guidance and training by HCPs, APs patients downloaded SSDM and performed self-assessments bundle of ASDAS and HADS with SSDM. ASDAS<=1.3, 1.3-2.1, 2.1-3.5 and >3.5 are defined as inactive (IDA), moderate (MDA), high (HDA) and very high (VHDA) disease activity, respectively. ASDAS score < =1.3 represents inactive disease status and achievement of T2T. HADS score > =8 can be diagnosed with anxiety or depression.

**Results:** From June 2016 to Jan 2020, 1,931 AS patients (1,118 male, 813 female) with a mean age of 34.09 ± 11.86 (12-82) years and the median disease duration of 2.61 years from 207 hospitals performed bundle self-assessments for 2,477 times in total. According to the HADS and ASDAS assessment results, the prevalence of anxiety and depression in all patients was 36.7% and 39.3% respectively, which was significantly higher than that in the WHO survey in Chinese population and chronic disease patients. The proportion of patients achieved and failed on T2T was 29% and 71%, respectively. The prevalence of anxiety (A) and depression (D) was 25% and 23% among T2T achievers; and 37% and 32% among T2T failures, respectively (p<0.05, p<0.05).

According to ASDAS, in IDA, MDA, HDA and VHDA subgroups, the prevalence of anxiety and depression was 27%, 36%, 41%, 52% and 29%, 38%, 45%, 56%, respectively. The correlation coefficients of anxiety (A) and depression (D) with ASDAS were r = 0.9908 and D = 0.9964. It suggested that with the increase of disease activity, the proportion of AS patients with anxiety and depression increased significantly. (Figure 1)

**Conclusion:** The prevalence of anxiety and depression in AS patients was significantly higher than that in the WHO survey in Chinese population and chronic disease patients. Higher prevalence of anxiety and depression were associated with higher levels of disease activity. SSDM is an effective mobile interface to monitor and study entanglement of disease activity and mental health in AS patients, which build a foundation for proactive interventions in future.

systemic autoimmune disease. They could be useful to distinguish patients with these characteristics that do not meet diagnostic and/or classifying criteria for any systemic autoimmune disease (SAD).

Objectives: To evaluate the use of anti-DFS70 in patients with suspicion of SAD.

Methods: A cross-sectional observational study was conducted at 2 tertiary-level hospitals. We included a cohort of patients visited in the last year by either rheumatologist or other specialties, under suspicion of SAD, in which the IgG isotype anti-DFS70 was obtained by recombination with the Euroline Immunoblot of Euroimmun. Demographic, clinical and immunological variables were collected.

Results: 102 patients (78% women) were included, median age of 49 years old. The descriptive statistics are summarized in Table 1. All patients had ANA titers > 1/80.

ANA (antinuclear antibody), IIF (indirect immunofluorescence), SLE (systemic lupus erythematosus), PsA (psoriatic arthritis), *p<0.05.

Background: Early treatment initiation in inflammatory arthritis (IA), and specifically in RA, is associated with improved outcomes but requires early identification of synovitis. However, healthcare professionals other than rheumatologists, e.g. general practitioners (GPs), experience difficulties in detecting early IA by joint examination. In this light, two Early Arthritis Recognition Clinics (EARCs) were initiated in the Netherlands in 2010. EARC patients are easy-access outpatient rheumatology clinics, intermediary between primary and secondary care, to which GPs can refer patients when in doubt about the presence of IA (instead of ‘watchful waiting’). Although this approach markedly reduced referral delay, it may not be easily implemented in other places due to shortage of rheumatologists. Therefore, other new tools to support early identification of IA are needed.

Objectives: Aiming for simple and time-efficient use in daily practice, we evaluated if just a single question on functional impairments could aid the identification of early IA.

Methods: Data from two EARCs in the Netherlands were studied. Between 2010 and 2014, 1997 patients with suspected IA visited the Leiden EARC (derivation cohort). Patients visiting the Groningen EARC (2010–2014, n = 506) and Leiden EARC (2015–2018, n = 557) served as validation cohorts. Physical functioning was assessed with the Health Assessment Questionnaire Disability Index (HAQ); IA by joint examination by rheumatologists. Discriminative abilities for IA of the 20 HAQ-questions were compared based on the area under the curve (AUC). For the best discriminating question, test characteristics and odds ratios (ORs) were calculated. ORs were adjusted for clinical characteristics that were previously reported to be predictive of the presence of IA (gender, age ≥60 years, symptom duration, acuteness of symptom onset, morning stiffness >60 minutes, number of painful joints, presence of patient-reported swollen joint(s) and difficulty with making a fist)2 using multivariable logistic regression.

Results: IA was identified in 43% (derivation cohort), 53% and 35% (validation cohorts). In the derivation cohort, presence of IA associated with higher mean HAQ-scores (0.84 versus 0.73, p = 0.003). The HAQ-question on difficulties with dressing yielded the highest AUC (0.58), which equaled discriminative ability of the total HAQ-score (AUC 0.55). Responses to this question were dichotomised into a simple binary score since loss of discriminative ability was minimal (AUC 0.57). Presence of any difficulties with dressing yielded ORs for IA of 1.80 (95%CI 1.39–2.33) in the derivation cohort; 2.00 (1.39–2.87) and 2.14 (1.48–3.10) in the validation cohorts. After adjustments for clinical characteristics the presence of any difficulties with dressing remained associated with the presence of IA; OR 1.71 (1.27–2.32) in derivation cohort and 1.64 (1.08–2.50) and 1.87 (1.20–2.92) in the validation cohorts. The prevalence of IA in case of presence of difficulties with dressing (positive predictive value) ranged 42–60% (see Figure).

**Conclusion:** A yes/no answer on a simple question (‘Are you able to dress yourself, including shoelaces and buttons?’) was helpful in discriminating patients with and without IA. Findings were validated in independent 1.5-line settings and need to be validated further in primary care. This is a step forward to arrive at practical tools that are helpful for GPs in identifying early IA.

**FRIO597 IMMUNOGLOBULIN A FOR CD74 AS AN ALTERNATIVE LABORATORY MARKER FOR DETERMINING THE ACTIVITY OF AXIAL SPONDYLOARTHRITIS**

**E. Vasilenkova1,2, V. Mazurov1, S. Lapin1, I. Kholopova1, A. Dadalova1, I. Gaydutkova1,2, North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E. Eichwald, St. Petersburg, Russian Federation; 2St. Petersburg Clinical Rheumatology Hospital No.25, St. Petersburg, Russian Federation; The First Pavlov State Medical University of St. Petersburg, St. Petersburg, Russian Federation**

**Background:** The level of acute phase indicators does not always correspond to the activity of axial spondyloarthritis (axSpA). The level of C-reactive protein (CRP) is remain normal in a third of cases of axSpA with present of active clinical symptoms [1]. Search for new biomarker that should have increased sensitivity and specificity compared to the CRP is needed. An alternative biomarker of axSpA activity could be an immunoglobulin (IgA) antibody to an invariant chain peptide associated with class II human leukocyte antigen (HLA) (anti-CD74) [2].

**Objectives:** to determine the level of IgA anti-CD74 in patients with axSpA and its relationship with traditional indicators of disease activity.

**Methods:** Totally, 137 patients with a reliable diagnosis of axial spondylitis (ASAS criteria, 2009) and 47 healthy volunteers were involved in the study. AxSpA activity indices (ASDAS, BASDAI) were calculated for all patients and IgA levels of anti-CD74, ESR and CRP were determined. The normal level according to the instructions for the laboratory kit for determining the level of IgA anti-CD74 is 12.0 U/L.

**Results:** Patients and volunteers characteristics are present in Table 1.

---

A direct relationship was found with a high power between an increase in the level of anti-CD74 (R=0.867) and an increase in the ASDAS (R=0.857) and BASDAI (R=0.842). The factor analysis showed that an increase in activity level according to ASDAS, BASDAI indices was associated with an increase in concentration of IgA anti-CD74. While CRP indicators (R=0.530) were associated only with the ASDAS index (R=0.760) (Table 2).

interest, and DMARD-free remission (DFR) is regarded an important future out-

Concentration of IgA anti-CD74 for healthy volunteers (left) and patients with axial spondyloarthritis (right)

As compared to controls sensitivity of IgA to anti-CD74 was 64.7%, specificity of this method was 68.1%.

Conclusion: The concentration of IgA to anti-CD74 is increased in 70.1% of pts with axSpA and associated with an increase in disease activity detected with ASDAS and BASDAI, independently from CRP. More data are needed in detection of sensitivity and specificity of IgA to CD74 in axSpA.

DMARD-FREE REMISSION IN RHEUMATOID ARTHRITIS: AN ACHIEVABLE AND SUSTAINABLE OUTCOME? A SYSTEMATIC LITERATURE REVIEW

M. Verstappen1, E. Van Mulligen2, P. De Jong2, A. Van der Helm - van Mil1,2,1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands

Background: Current treatment guidelines for rheumatoid arthritis (RA) suggest tapering DMARDs.1 Discontinuation of DMARD-treatment is of increasing interest, and DMARD-free remission (DFR) is regarded as an important future outcome.2 However, lack of knowledge on DFR prevalence, its sustainability, and the characteristics of patients achieving DFR currently hampers the use of DFR as primary outcome.

Objectives: To increase the understanding of DFR in RA, and to support studies aiming to include this as primary outcome, we systematically reviewed the literature to determine prevalence and sustainability of DFR. Potential predictors of DFR were evaluated to increase insight in patient characteristics favourable for achieving this outcome.

Methods: A systematic literature search was performed in March 2019 in multiple databases. All clinical trials and observational studies reporting on discontinuation of DMARDs in RA-patients in remission were included. Our quality assessment included a general assessment and assessment of the description of DFR. Prevalence of DFR and its sustainability, flares during tapering and after DMARD-stop were summarized. Also, potential predictors of achieving DFR were reviewed.

Results: From 631 articles, 51 were included, comprising 14 clinical trials and 5 observational studies. DFR-definition differed, especially for the duration of DMARD-free state. Considering only high and moderate-quality studies, DFR was achieved in 5.0%-24.3%, and sustained DFR (duration ≥12 months) in 11.6%-19.4%. Flares occurred frequently during DMARD-tapering (41.8%-75.0%) and in the first year after achieving DFR (10.4%-11.8%), whilst late flares, >1 year after DMARD-stop, were infrequent (0.3%-3.5%). Many patient characteristics lacked association with DFR. Absence of auto-antibodies and shared epitope alleles increased the risk of achieving DFR.

Conclusion: DFR is achievable in RA, and is sustainable in ~10%-20% of patients. DFR can become an important outcome measure for clinical trials, and requires consistency in the definition. Considering the high rate of flares in the first year after DMARD-stop, a DFR-free follow-up of >12 months is advisable to evaluate sustainability.

DOI: 10.1136/annrheumdis-2020-eular.1726
Objectives: To develop a disease activity tool for lupus MSK manifestations that is continuous, responsive, sensitive, and correlates with US-synovitis.

Methods: 133 patients who received depomedrone 120mg IM were assessed at 0, 2 and 6 weeks for 66/68 swollen and tender joint counts, BILAG2004 index, SLEDAI-2K, physician global and MSK-VAS, inflammatory markers, patient pain and disease activity-VAS. Total US score (OMERACT-EULAR) in the hands and wrists was calculated blinded to patient and clinical assessor. Patients reported overall disease activity using a Likert scale.

The LAMDA was developed by modelling a core set of clinical variables against total US score using penalized (Lasso) regression. Responsiveness was compared between LAMDA and other variables at week 6 using effect sizes. Minimum clinically important difference (MCID) was explored using the SEM and minimal disease activity threshold using ROC.

Results: The variables selected for the LAMDA score were swollen joint count, patient MSK pain VAS, physician MSK disease activity VAS and ESRI. A continuous score was derived. This had a theoretical range from 0 to 26.5 based on maximum ESRI of 10. The highest value observed in USEFUL was 15. LAMDA was significantly higher in patients with active US (mean SD) (5.71 2.86), n=78) compared to patients with normal US (3.27 (1.77), n=55; difference (95% CI) -2.45 (-3.26, -1.63), t=0.93, p<0.001). This difference remained significant in patients with no swollen joints (difference (95% CI) -0.71 (-1.40, -0.02), t=0.2, p=0.044).

Conclusion: The LAMDA score is a novel continuous disease activity instrument for MSK manifestations of SLE derived from variables familiar to rheumatologists. The LAMDA score is sensitive to imaging detected synovitis without swelling and more responsive than other instruments. LAMDA may improve the ability of clinicians to accurately determine therapeutic efficacy in clinical trials and practice. Future work will validate the LAMDA score in independent cohorts and randomized trials.

HPR Epidemiology and public health (including prevention).

**FR10601-HPR** IMPACT OF LIFE STYLE MODIFICATION TECHNIQUE IN SYSTEMIC SCLEROSIS (SSC) PATIENTS: A STUDY BY RHEUMATOLOGY NURSES COUNSELOR

S. Bachh1, R. Thakran1, C. Messi1, V. Yadav1, S. Kapoor1, S. Garg1, V. Kashyap1, A. Malaviya1.
1Indian Spinal Injuries Centre, Rheumatology, New Delhi, India

Background: Systemic sclerosis (SSc) is an autoimmune disease of the connective tissue that is clinically characterized by the involvement of skin (fibrosis, contractures of the finger joints), microvascular abnormalities (Raynaud's phenomenon and complications), gastrointestinal involvement (gastroesophageal reflux disease - GERD, the lower GI tract involvement), musculoskeletal involvement (polymyalgia, muscle disease), and involvement of internal organs (especially lungs, heart, and kidneys). Lifestyle modification techniques could have significant impact on various aspects of the disease including early disease control, increased drug adherence, positive attitude towards life, decreased financial burden of treatment, maintenance mobility and joints range of motion, minimizing or delaying joint contractures and decreased dependency with regular physical therapy. Counselling explaining the benefits of lifestyle modification related to these aspects of daily living may make a major difference in the quality of life of the patients with SSc.

Objectives: To assess the benefits of lifestyle modification technique in improving the quality of life in patients with SSc.

Methods: Patients with SSc attending the Rheumatology clinic of this institution, willing to participate in the survey, were enrolled in this study. All the information including the follow-up details were recorded in a pre-designed form. Their demographic information (age, gender) and disease characteristics (diagnosis, duration, treatment) were recorded. All the patients were explained the lifestyle modifications and their benefits, reinforced at each follow-up visit using posters (visual), written lifestyle modification techniques (using printed material) to raise their awareness of how to improve several of the above manifestations of SSc.

Results: One hundred fifty (n=150) consecutive SSc patients were included in the study. It was observed that with repeated counselling 125 (83.3%) patients adopted the lifestyle modification technique according to the advice imparted and felt a positive benefit in their daily life. However, 25 (16.6%) could not or did not follow the imparted lifestyle change advice on a regular basis. Those who were able to modify the lifestyle as counselled showed the following results:

- 80% were able to avoid exposure to cold by adopting the following measures: Wearing gloves and extra woolen socks, using mittens most of the time, wearing woollen undergarments to keep the central regions of the body region warm. These patients noted 55% decrease in the episodes of Raynaud’s phenomenon.
- Early evening meals and raising the head-end of the bed: 60% decrease in gastrointestinal symptoms.
- Regular physiotherapy: 65% decrease dependency on others; 55% could maintain flexibility with physical exercises.
- Regular application and rubbing of the skin with lanoline-containing skin moisturizers 60% improve your skin’s health
- 80% were able to avoid active and passive tobacco use.

Conclusion: The lifestyle modification techniques are important to control disease and its complications. Thus, after intense and regular counselling by the specialist rheumatology nurses on the lifestyle modification technique (83.3%) adopted the advised lifestyle modifications. The study showed the important role of specialist rheumatology nurses can play in educating patients and helping them improve their quality of life.
Disease Comorbid Index (RDCI). RACI consists of 31 comorbidities grouped into 11 categories: DAS 28 >3.6, local inflammation, smoking, tumors, systemic involvement, infection, vascular disease, bone health, mood, metabolic and cardiovascular disorders (score range 0-36). RDCI consists of 11 comorbidities (categories according to ICD-10) and a formula to calculate it (range 0-9). For both indexes; higher score, greater comorbidity.

**Results:** In this cross-sectional study, 345 patients were evaluated, of which 176 were included, 85.8% of the patients were female and the mean age was 52.7 ± 10.9 years; 31.2% of the cases finished primary school, the median of disease duration was 9 years (1-40), the mean DAS28 3.9 ± 1.4, and the mean CDAI 12.4 ± 11.3. 52.3% of the patients received treatment with glucocorticoids, 60.8% with NSAID, 60.2% with methotrexate, 39.2% with leflunomide, 17.6% with biologic DMARDs and 5.6% with tocilizumab. 90.3% of the patients (95% CI 84.8, 94.3) presented some comorbidity measured by RACI. The average score was 4.7 ± 3.4 and the most frequent comorbidity were: elevated DAS28 (40.9%), dyslipidemia (38.1%), AHT (36.4%), prednisone >5mg/d in 31.8%, endocrinopathies 19.3%. 73.3% of the patients had more than one comorbidity. Regarding RDCI, 47.2% of the cases presented some comorbidity with an average score of 0.95 ± 1.3; the most frequent were: AHT 36.4%, lung disease 12.5% and diabetes 8%. The oldest patients had more than one comorbidity (RACI), and also presented a higher HAQ score than those with only one (p<0.0001); Higher RACI score was associated with higher CDAI (p<0.001) and the use of glucocorticoids (p<0.0001).

**Conclusion:** The prevalence of comorbidities in RA by RACI was elevated (90.3%) and 73.3% of the patients presented more than one comorbidity. The patients with the highest RACI score had higher disease activity and used glucocorticoids more frequently.

**FRI0605-HPR**

MORTALITY AND SURVIVAL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN ARGENTINA. A MULTICENTER STUDY ON BEHALF GESAR-LES

**Objectives:** To analyze the factors associated with mortality, survival and causes of death in patients with SLE.

**Methods:** Longitudinal - multicenter study, in which 10 rheumatology centers of Argentina participated. Patients with SLE (ACR 1997 and / or SLICC 2012 criteria) with a minimum follow-up of 6 months monitored between January 2008 and December 2018 were included. Demographic, clinical, laboratory, therapeutic variables (treatments received during the evolution of the disease and within 60 days prior to death or last control); mortality, causes of death and survival at 5, 10 and 20 years were evaluated. Statistical analysis: descriptive statistics, Kaplan-Meier survival curves and Cox regression model.

**Results:** Three hundred and eighty two patients were included; 90% women and 82% mestizos. The mean of evolution time of SLE was 4.1 ± 6.7 years. The mean age at the last control or death was 372 ± 12.7 years, SLEDAI 3.2 ± 4.2 and SLICC 12 ± 1.9.

Mortality was 12% (95% CI [8-15]) and the causes of death were: Infections (27), cardiovascular disease (6), SLE activity (3), catastrophic antiphospholipid syndrome (2) and other causes (8). Using the variables associated with mortality in different Cox regression models, the variables that increased the risk of death significantly were: renal involvement (RR 3.3), cardiac involvement (RR 2.7), central nervous system involvement (RR 2.1), arterial thrombosis (RR 2.3), hypotension (RR 2.4), number of infections (RR 1.2) and last SLEDAI (1.1).

The time of HCQ use greater than 36 months decreased the risk of death in this cohort by 40% (p 0.03), Prednisone (maximum dose and time) was not associated with mortality (p NS). When analyzing the last treatment and adjusting it for final SLEDAI, HCO was a mortality protection factor (RR 0.4) while the use of cyclophosphamide alone or associated with prednisone was a risk factor for death (RR 5.2).

Significant differences were found when analyzing the causes of death according to the SLE evolution time (p 0.017); patients who died from infection had less evolution time (Me 2.25 years), than those who died due to cardiovascular causes (Me 10 years) or SLE activity (Me 15 years), in this cohort of patients, survival was 93% at 5 years, 88% at 10 years and 72% at 20 years.

**Conclusion:** Mortality in this series of patients was 12% and infection was the leading cause of death. The use of HCQ for a period greater than 36 months, decreased the risk of death 40%.

REMISSION IN SYSTEMIC LUPUS ERYTHEMATOSUS, WHAT IS THE IMPACT ON ACCUMULATED DAMAGE?

F. J. Hüttmann1, A. L. Barbaglia1, L. Gonzalez Lucero1, H. R. Suelo1, M. C. Bertolacci1, S. M. Mazza1, Y. Soria Curi1, M. L. Leguiuzamón1, G. V. Espasa1, M. L. Galindo1, M. Santana1, V. I. Bellomio1, H. Sueldo1, L. M. Galindo1, R. Agiló Maldonado1, M. García1, D. Capelusnik1, R. Rojas Tessel1, E. Picco1, M. E. Cresto Espindola1, R. Calvo1, S. Roverano5, M. Cosati1, C. Pisoni1, P. Avila1, M. Miceli1, M. Hu1, L. Alascio1, C. Goizueta1, V. I. Bellomio1.

**Objectives:** To determine the frequency of remission in a cohort of patients with SLE.

**Background:** The objective of the treatment in rheumatic diseases is to achieved the remission or minimal disease activity of these patients. Previous studies in Systemic Lupus Erythematosus (SLE) showed that reaching remission had a positive impact on the prognosis of the disease.

**Disclosure of Interests:** None declared

DOI: 10.1136/annrheumdis-2020-eular.5767
To evaluate the effect of disease activity on accrual damage.

Methods: A retrospective study was carried out from January 2010 to December 2018. Clinical records of patients with SLE (ACR criteria 1982/97) were reviewed considering baseline visit as the first clinical or control visit of 2010. For subsequent visits, data were collected annually until 2018. SLE activity was defined for each visit according to GLADEL’s definition: 1- Remission Without Treatment (RwT); SLEDAI ≤ 4, prednisone up to 7.5mg/ ay and/or IS in maintenance doses; 2- Remission on Treatment (RoT): SLEDAI 0, prednisone up to 5mg/day or immunosuppressive drugs in maintenance doses; 3- LDAS (Low Disease Activity Status): SLEDAI ≤ 4, prednisone up to 7.5mg/ ay and/or IS in maintenance doses; 4- Non-Optimal Activity Control (NOC): SLEDAI > 4, prednisone > 7.5mg/ day and/or IS in induction dose. The use of hydroxychloroquine was allowed for all groups. For the analysis, patients who remained in remission (with and without treatment) or LDAS for at least 75% of the follow-up time were grouped and compared with patients who remained active during that same period. Demographic, laboratory, treatment related variables and death were studied. Accrual damage was assessed with SLICC / SDI. Patients with less than two annual visits were excluded.

Statistical analysis: descriptive measures, Test T, Mann Whitney, Chi2 Test, Fisher’s exact test, bivariate correlation, logistic regression model with mixed effects.

Results: Two hundred eighty-five medical records were reviewed and 100 patients with SL were included, 89% women, mean age at baseline visit 38.5 ± 12 years old and mean time of disease 9.3 ± 7.3 years. The average SLEDAI and SLICC/ SDI baseline scores were 3.7 and 0.8 respectively. The SLICC/ SDI score at last visit was 2.2 and the average SLICC/SDI change (ΔSLICC) compared to baseline visit score was 1.4 ± 1.6.

The prevalence of patients who were in remission for at least 75% of the follow-up time was 38% (95% CI 26.6, 45.4) NOC patients and 29% in LDAS. The percentage of patients who were at least 75% of the follow-up time in remission (p 0.01) or LDAS (p 0.01) compared to those with NOC. In the Logistic Regression Model, the change of the SLICC/SDI score was 2.9 times higher for the NOC group than for RwT.

Conclusion: The frequency of remission in this cohort of patients with SLE was 38%.

Worse control of disease activity, was associated with higher accumulated damage.

1Hospital General de Agudos Dr. Cosme Argerich, Ciudad Autónoma de Buenos Aires, Argentina

Background: Infectious diseases are increased in patients with rheumatic disorders; vaccination improves morbidity and mortality

Objectives: The aim of this study was to describe the frequency of vaccination in patients with rheumatic disorders and to compare the results with those obtained in 2009 and 2013 in a similar population. We also identified factors leading to lack of vaccination and patients beliefs on vaccines.

Methods: Multicentric cross sectional study in patients with autoimmune diseases from external rheumatology offices. Evaluation of vaccination status and patients’ knowledge about vaccines were studied. A comparative analysis was carried out with the series registered in 2009 and 2013 in a similar population.

Results: Two hundred eighty-five medical records were reviewed and 100 patients with SL were included, 89% women, mean age at baseline visit 38.5 ± 12 years old and mean time of disease 9.3 ± 7.3 years. The average SLEDAI and SLICC/ SDI baseline scores were 3.7 and 0.8 respectively. The SLICC/ SDI score at last visit was 2.2 and the average SLICC/SDI change (ΔSLICC) compared to baseline visit score was 1.4 ± 1.6.

The prevalence of patients who were in remission for at least 75% of the follow-up time was 38% (95% CI 26.6, 45.4) NOC patients and 29% in LDAS. The percentage of patients who were at least 75% of the follow-up time in remission (p 0.01) or LDAS (p 0.01) compared to those with NOC. In the Logistic Regression Model, the change of the SLICC/SDI score was 2.9 times higher for the NOC group than for RwT.

Conclusion: The frequency of remission in this cohort of patients with SLE was 38%.

Worse control of disease activity, was associated with higher accumulated damage.

FRIO608-HPR SEVERITY AND PREDICTORS OF PAIN INTENSITY AND HAND DISABILITY IN PATIENTS WITH TRAPEZIOMETACARPAL OSTEOARTHRITIS

T. Hamasaw1,2, P. Harris1,2, N. Bureau1,2,3, N. Gaudreau1,4, N. Patenaude1,5, M. Choinière2,3.
1CHUM Hospital (Université de Montréal), Montréal, Canada; 2Université de Montréal, Montréal, Canada; 3Centre de recherche du CHUM (CRCHUM), Montréal, Canada; 4Université de Sherbrooke, Sherbrooke, Canada; 2Centre de recherche du CHUS (CRCHUS), Sherbrooke, Canada; 4CHUS Hospital (Université de Sherbrooke), Sherbrooke, Canada

Background: Trapeziometacarpal osteoarthritis (TMO) is one of the most prevalent and painful forms of hand osteoarthritis. It limits thumb mobility, reduces hand functions, and manual activities. Yet, no study has exhaustively documented the characteristics of this pathology using a biopsychosocial approach (e.g., pain, disability, psychological well-being, pain-related catastrophic thinking, quality of life). Furthermore, radiographic TMO severity and patient-reported disability are only weakly to moderately correlated. The extent to which biopsychosocial factors (e.g., pain duration, depression, education) contribute to interindividual variability in TMO pain and hand disability merits further investigation.

Objectives: This study aimed at 1) describing the pain experience of patients with trapeziometacarpal osteoarthritis (TMO) from a biopsychosocial perspective, and 2) identifying predictors of their pain intensity and hand disability.

Methods: A total of 227 TMO patients recruited from 16 healthcare institutions completed validated questionnaires assessing their biopsychosocial characteristics. The associations of pain severity and hand disability with various biopsychosocial characteristics were analyzed by linear regression.

Results: The participants’ mean age was 82.6 ± 8.5 years and 78% were women. Their mean pain intensity on the average in the last seven days was 5.8 ± 2.1 while their hand disability scores averaged 45.4 ± 18.8 on the QuickDASH. In terms of health-related quality of life, the participants’ scores on the physical and mental summary scales of the SF-12v2 were 41.0 ± 9.4 and 48.7 ± 9.7 respectively. Results of the multivariable linear regression analyses revealed that age, living condition, pain frequency, pain-related catastrophic thinking, and depression levels accounted for 43.3% of the variance in pain intensity while age, sex, pain intensity, pain-related catastrophic thinking, depression, level of education, employment status and living condition accounted for 60.6% of the variance in hand function.

Conclusion: This comprehensive study showed that patients with TMO experience pain of moderate to severe intensity which can affect various aspects

of their daily living and their physical health-related quality of life. Greater tendency to catastrophize in the face of pain and higher depression levels were associated with more severe pain suggesting that psychological interventions aiming at reducing these factors could be beneficial for some patients with TMO.

FRI0609-HPR NUTRIENTS INTAKE CONDITION RELATES TO MAINTENANCE LOW DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS DURING 6 YEARS: TOMORROW STUDY

Y. Matsumoto1,2, Y. Sugiyama3, M. Tada4, T. Okano5, K. Mamoto5, K. Inui5, D. Habu6, T. Koike1,2,3, 1Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Shirahama, Japan; 2Osaka City University Graduate School of Human Life Science, Department of Medical Nutrition, Osaka, Japan; 3Osaka City University Medical School, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; 4Osaka City General Hospital, Department of Orthopaedic Surgery, Osaka, Japan; 5Osaka City University Medical School, Department of Orthopaedic Surgery, Osaka, Japan

Background: We have previously reported that nutritional intake status might relate to disease activity (1). Nutritional survey on prospective cohort study in rheumatoid arthritis (RA) patients and information about relationship between nutritional intake status and disease activity was very limited.

Objectives: This study aimed to obtain data from a cohort study for new nutritional therapy in RA patients.

Methods: We used TOMORROW cohort study data which conducted from years of 2010 to 2020. Two hundred and eight RA patients, and 205 non-RA sex and age matched controls were investigated, and we analyzed data from 2011 to 2017. Nutritional intake status was compared between who maintain lower disease activity during 2011 to 2017 (LDA group) and being higher disease activity even once in 2011 to 2017 (non-LDA group). Disease activity was evaluated by DAS28-ESR in every year and nutritional intake status was surveyed by brief self-administered diet history questionnaire (BDHQ) in 2011 and 2017.

Results: In RA patients, the change value from 2011 to 2017 of iron (odds ratio; 2.37), thiamin (OR; 2.96) and folic acid (OR; 3.16) intake which adjusted by energy intake, age, rheumatoid factor and medication status were extracted as significant factors for maintaining LDA by multivariate logistic regression. These nutrients intake in RA patients was significantly lower than control both in 2011 and 2017. In RA patients, iron and folic acid intake in LDA group was significantly lower than non-LDA group in 2011. Folic acid intake was increased in LDA group and decreased in non-LDA group over time, and these nutrients showed significantly different changes in change value between LDA group and non-LDA group (p<0.05).

Conclusions: The overtime change value in iron, thiamin and folic acid related to maintain six years low disease activity in RA patients.

FRI0610-HPR B-ADRENERGIC RECEPTOR BLOCKING DRUGS ASSOCIATE WITH LOWER RISK OF KNEE OSTEOARTHRITIS AND KNEE PAIN CONSULTATIONS IN PRIMARY CARE: A PROPENSITY SCORE MATCHED COHORT STUDY USING THE CLINICAL PRACTICE RESEARCH DATALINK.

G. Nakajima1, M. Grainge2, A. Valdes1,2, N. Townsend3, C. Mallen4, W. Zhang1, M. Doherty1, M. Mamas5, A. Abhishek1,3. 1University of Nottingham, Academic Rheumatology, School of Medicine, Nottingham, United Kingdom; 2University of Nottingham, Epidemiology and Public Health, School of Medicine, Nottingham, United Kingdom; 3University of Nottingham, Nottingham NIHR-BRC, Nottingham, United Kingdom; 4University of Bath, Public Health Epidemiology, Department for Health, Bath, United Kingdom; 5Keele University, School of Primary, Community and Social Care, Keele, United Kingdom, 6Keele University, Cardiology, Keele, United Kingdom

Background: The pharmacologic management of OA is centred around optimising pain control but first-line analgesics only have modest efficacy1. Findings from several studies suggest that β-adrenoceptor blocking drugs (β-blockers) have anti-nociceptive effects2-3. However, evidence for the benefits of β-blockers in the context of OA pain is scarce. We recently demonstrated, for the first time, an association between beta-blockers and lower pain severity, and less opioid analgesic use in a secondary analysis of data for community dwelling adults with large-joint lower OA. This association, however, was not confirmed in a hospital-based study4.

Objectives: We examined [1] the association between β-blocker prescription and first primary care consultation for knee OA, hip OA, knee pain, and hip pain and [2] the classes of β-blocker drugs that reduce the risk of these outcomes.

Methods: This was a cohort study using data from the UK Clinical Practice Research Datalink. Participants aged ≥40 years, in receipt of ≥2 β-blocker prescriptions within 60 days were matched by age, sex, and propensity score (PS) for β-blocker prescription to one control using greedy nearest neighbour matching. Participants with chronic painful conditions, contra-indications to β-blockers,
maintenance analgesic prescriptions, and with <2-years registration before index or matched follow-up start date were excluded. Cox proportional hazard ratios (aHRs) and 95% confidence intervals (CI) were calculated to examine the associations adjusted for other covariates. Analyses were stratified according to β-blocker classes. Results: For 223,436 PS-matched exposed and un-exposed participants were included. β-blocker prescription associated with a significantly reduced risk of knee OA, knee pain, and hip pain consultations with aHR(95%CI) 0.90(0.83–0.98), 0.88(0.83–0.92), 0.85(0.79–0.90) respectively. The proportion of hip OA lacked statistical significance (aHR95%CI 0.94; 0.85-1.07) (Table 1). On stratified analysis, propranolol and atenolol had a statistically significant protective effect on knee OA and knee pain consultations with aHRs between 0.78 and 0.91 (Figure 1).

OA: osteoarthritis; *1,000 person-years; 1PS matched and, additionally adjusted for age, number of GP consultations, hospital out-patient referrals, hospital admissions in the 12 month period preceding cohort entry, total number of GP consultations for knee or hip injury prior to cohort entry and non-osteoartitectic fractures.

Figure 1. The association between individual β-adrenoceptor blocking drugs and incident knee osteoarthritis and knee pain 1Comparison group is unexposed to β-blockers; size of the square is proportional to number of events.

Conclusion: β-blockers appear to reduce consultations for knee OA, and knee or hip pain. Our results imply that, atenolol might be used preferentially for the treatment of people with cardiovascular comorbidities, while, propranolol with its anti-anxiety effect may be a suitable analgesic in people with OA and comorbid psychological conditions.
Background: Orthoses and footwear can play an important role in managing foot pathology in patients whose systemic disease is controlled. Foot orthoses are frequently prescribed in clinical practice as an intervention for people with rheumatoid arthritis (RA).

Objectives: The aim of our study is to evaluate the impact of thermofomable orthoses on the functional index of the foot (FFI) in patients with rheumatoid arthritis.

Methods: We conducted an open clinical trial, having consecutively included 14 patients (85.7% female, average age 54.8 ± 10 years) suffering from rheumatoid arthritis (median progression time of 9 years [5 - 12]). The average DAS28 was 2.7 ± 1.2 and the functional impact objectively by the Health Assessment Questionnaire (HAQ) was on average 0.9 ± 0.7. The median deadline from the start of RA and the onset of the foot problem was 3 years [0 – 7.75]. The foot problem was bilateral in 100% of the cases and inaugural in 85.7% of the cases.

We evaluated the functional impact of foot injury for all our patients at baseline and 8 weeks after the use of thermofromable orthoses, based on the FFI (Foot Function Index) measuring the impact of foot pathology on function in terms of pain, disability and activity limitation.

The comparison of the FFI domains before and after the use of orthoses was carried out using parametric or nonparametric paired tests using The SPSS statistical software.

Results: With the use of foot orthoses, FFI values decreased in all subscales (p<0.024) (pain, disability and activity limitation). This reduction was significant for disability (0.011) but not for pain and activity limitation.

There were no significant correlations between the global FFI and the progression of RA, the duration of foot damage and the functional impact measured by the HAQ.

Table 1. The comparison of the FFI domains before and after the use of orthoses.

p significatif if< 0.05; Test used: Non-parametric test for two linked samples.

Conclusion: Foot orthoses were effective as an adjuvant in the management of rheumatoid foot. They significantly reduced disability as measured by the FFI. The absence of factors associated with pain and limitation of activity could possibly be related to the small sample size.

[3] Alcohol consumption should be avoided, as it increases the likelihood of adverse effects from the treatment.

[4] Common side effects include nausea or gastrointestinal distress, loss of appetite, headache and/or fatigue after taking each weekly dose of the drug.

If this happens, you can take the daily dose in two doses, avoiding taking large amounts and drink plenty of water on the day of administration. If in spite of everything, they do not disappear, you should consult the Rheumatology Unit.

[5] It is recommended to use sun protection.

[6] Pregnancy and breastfeeding should be avoided while taking MTX. In case of pregnancy desire, you should consult the Rheumatology Unit in order to schedule a withdrawal of the treatment. In case of unplanned pregnancy, stop treatment and contact the Rheumatology Unit immediately.

[7] The annual flu vaccine is recommended. Consultation with the Rheumatology Unit is recommended for additional vaccines.

[8] The benefits of MTX take several weeks to appear, so you should not modify or interrupt the treatment on your own.

[9] Throughout the treatment, regular tests will be performed to monitor the safety and effectiveness of the drug.

[10] In case of doubts, and in case of infection, surgical intervention, oncological pathology or pregnancy, contact the Rheumatology Unit.

Conclusion: This leaflet is intended to resolve common doubts of patients receiving treatment with MTX, and thus contribute to improve the therapeutic adherence and avoid errors in the drug taking.

**CAN DEDICATED COMMUNITY HEALTH HUBS IMPROVE PHYSICAL ACTIVITY IN A MULTI-ETHNIC RHEUMATOLOGY PRACTICE?**

J. Begum1, M. K. Nisar2, L. Luton and Dunstable University Hospital, Luton, United Kingdom

Background: Self care is an important management strategy for people with inflammatory arthritis (IA). Focused education should enable people to manage their life with IA and optimise their health and well-being. Several studies have shown positive effects of dedicated health programs on a range of patient reported outcomes such as self-efficacy, pain, fatigue, quality of life and overall well-being. However these benefits are only achievable and long lasting if people are provided with professional support to stay motivated and make appropriate adjustments to obtain better health.

Objectives: The objective of our intervention was to assess the outcomes of a dedicated health education program delivered in a diverse community setting represented by minorities with poor educational and socio-economic background.

Methods: We partnered with our local authority to establish a dedicated rheumatology community health hub for our patients with long term rheumatic conditions. Both clinical and paramedical staff in rheumatology clinics advertised the service and those who consented were referred. They were offered a 1:1 assessment with a health and well-being practitioner who would refer onwards based on the needs of the patient. In this pilot study we analysed the outcomes achieved at one year.

Results: 187 patients were referred to the service. 158 had IA and 29 had osteoporosis. 57 (30%) were White, 86 (46%) Asian, 26 (14%) Afro-Caribbean and 18 (10%) of other ethnicities. Mean age was 64 years (range 36-95). Interventions included weight management (10%), general health check (4%), dedicated exercise program (30%), physical activities (46%) and talking therapies (8%) and smoking cessation (2%). 100% responded to the contact and signed up for the intervention. 80% completed a minimum of 12 week intervention. 89% continued to attend physical activity at least once a week long term. Only five service users were dropped out for varying reasons.

Conclusion: Physical activity programs can be successful in a diverse community setting with patients from low socio-economic and educational classes. There is a need to engage these patients and offer professional support which can produce carry-over effects on physical outcomes and enhance patients’ long-term adherence to such programmes. Our study demonstrates that patient activation for self management and improved physical activity can be attained irrespective of patients’ backgrounds.

upper limbs for many weeks results in changes in both the peripheral musculature and the central nervous system. It is well known that common complaints after upper limb fractures include weakness, pain, and stiffness; therefore, pain management is important in the early stages of the rehabilitation of upper limb fractures.

**Objectives:** This pilot study aimed to investigate the efficacy of graded motor imaginary (GMI) on pain, range of motion (ROM), and function in patients with posttraumatic stiff elbow.

**Methods:** Fourteen patients with posttraumatic stiff elbow (6 women, mean age: 45.42 ± 11.26 years, mean body mass index: 24.29 ± 3.38 kg/m² and mean duration of immobilization: 4.75 ± 1.03 weeks) were randomly allocated to either GMI or control groups. The GMI group received GMI treatment in addition to a structured exercise program, and the control group received a structured exercise program (two days per week for six weeks) (Figure 1). The assessments included pain at rest and during activity using the visual analog scale (VAS), elbow active ROM with a digital goniometer (Baseline Evaluation Instrument, Fabrication Enterprises, Inc., White Plains, NY), and upper extremity functional status using the Disability of the Arm, Shoulder and Hand Questionnaire (DASH). The assessments were performed at baseline and after the 6-week intervention.

**Results:** After the 6-week intervention, there was a significant increase in elbow flexion-extension ROM and supination-pronation ROM, and improvement in DASH score in both groups (p<0.05). However, improvement in VAS-rest and VAS-activity was significantly higher in the GMI group than the control group (p=0.03 and p=0.01, respectively).

**Conclusion:** A conservative treatment program consisting of GMI treatment in addition to a structured exercise program applied twice a week for 6 weeks, has been found more effective in decreasing pain in the posttraumatic stiff elbow. It could be concluded that GMI is an effective treatment method for elbow fracture in patients with predominant elbow pain.

THE EFFECT OF THERMOFORMABLE FOOT ORTHOSIS ON WALKING IN RHEUMATOID ARTHRITIS PATIENTS: PRELIMINARY RESULTS FROM AN OPEN CLINICAL TRIAL

1Faculty of Medicine and Pharmacy, Le Plessis Robinson, France
2Hôpital Marie Lannelongue, Marseille, UMR M2F Faculty of Medicine, Marseille, France
3International university of Rabat, Rabat, Morocco
4University Aix-Marseille, Marseille, UMR MD2 Faculty of Medicine, Marseille, France
5Rheumatology, Volgograd, Russian Federation

Background: Foot pain is common in rheumatoid arthritis and appears to persist despite modern day medical management.

Objectives: To evaluate the impact of thermofomable foot orthoses on walking in rheumatoid arthritis (RA) patients.

Methods: This is a open clinical trial, that included 14 consecutive patients (85.7% female, mean age 54.8 ± 10 years) with RA (median duration of progression of 9 [5-12] years), the average DAS28 was 2.7+/-1.2 and the functional impact objective defined by the Health Assessment Questionnaire (HAQ) was on average 0.9 ± 0.7. The foot problem was bilateral in 100% and inaugural in 85.7% of the cases.

The 14 rheumatoid subjects were examined and appropriate foot orthoses were prescribed according to each patient's needs. All the patients were evaluated at baseline and 8 weeks after use of orthoses. Gait pain, difficulty walking and the 10 Meter Walk test were noted at each appointment.

We used dynamic baropodometric analysis to assess postural evaluation. We calculated the lateral-medial index of each foot before and after the use of orthoses.

CHANGES IN LOCUS OF CONTROL LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER THE COURSE OF BIOFEEDBACK TRAINING

R. Greenhoff1, J. Zborovský2 Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation

Background:

Objectives: Our aim was to study the effect of biofeedback (BF) training on the locus of control in patients suffering from rheumatoid arthritis (RA), and to justify the use of this method in the complex treatment of the disease.

Methods: 40 RA patients hospitalized in the rheumatology department were examined. The average age of patients was 48.6 years ± 7.73 years (from 30 to 70 years), when examined for the majority = 26 (66%), the average duration of the disease was 12 years ± 3.44 years. We use J. Rotter's Locus of Control Scale in E.F.Bazhin adaptation. RA patients were divided into two groups: the main (20 patients) and control (20 patients). Patients of the main group received complex therapy with 12 sessions of BF training, mainly based on the parameters of the brain's electrical activity — EEG relaxation using the Reakor® psychophysiological rehabilitation complex manufactured by Medicom MTD (Taganrog).

Results: We revealed externality in RA patients in the general field (3.03 ± 0.3) as well as in the field of relation to the disease (3.26 ± 0.23) and in the field of production relations (4.33 ± 0.25). After BF training, an increase in internality was observed on the scales of the general sphere (p <0.05) and attitude to the disease (p <0.01) in patients of the main group. In the group of patients receiving conventional treatment, the dynamics of the results was unreliable.

Conclusion: It should be noted that the locus of control (or subjective control) is a quality that characterizes a person's tendency to attribute responsibility for the results of his activity to external forces, or to his own abilities and efforts. Externality is manifested when people prefer to shift responsibility for important events of their life to external circumstances, and external forces (bosses, colleagues, etc.). In the field of attitude to the disease, externality is manifested when patient behaves passively, and believes that he cannot influence the course of the disease in any way, shifting all responsibility for the treatment results to medical staff, which can lead to non-compliance with the treatment regimen and an increase in the level of anxiety and depression, decreased self-esteem. The onset of the disease and its associated social consequences (disability, loss of social roles, etc.) can cause a negative mental state of learned helplessness. Learned helplessness is defined as a condition that occurs as a result of uncontrolled, mainly negative events, which manifests itself in violations of emotional, motivational and cognitive processes. In other words, RA patient suffering from this condition expects treatment failures and reduces control over compliance with the treatment regimen. BF therapy can be used in order to correct and prevent the state of learned helplessness by increasing the level of internality.

It is assumed that increasing internality in the BF process is associated with teaching the patient the skills of self-regulation of physiological processes. The mechanisms of BF therapeutic effect are not only changes in physiological parameters (improvement of cerebral and peripheral blood flow, muscle relaxation, and improvement of sleep) but also in a shift in the locus of control from external to internal, which can increase compliance, reduce neurotic complaints, mobilize volitional potential and improve patient self-esteem. As a result of BF course, an increase in the internality was noted in patients on the scales of the general sphere and the sphere of attitude to the disease. It is advisable to use the BF to increase the compliance and effectiveness of complex treatment of RA patients.

DOI: 10.1136/annrheumdis-2020-eular.5698
Background: In chronic rheumatic diseases, non-adherence to treatment is associated with a progression of disease and an increased morbiditly (1). In spondyloarthritis (SpA), improving patients’ knowledge on their subcutaneous biologic disease-modifying anti-rheumatic drugs (bDMARDs) is a key factor to enhance medication adherence (2). The patient information has to ensure the acquisition of safety skills regarding their treatment management.

Objectives: To evaluate the impact of a pharmacist’s educational interview on knowledge and therapeutic adherence of subcutaneous bDMARDs in patients with SpA.

Methods: Population and study design: consecutive adult patients with well-controlled axial SpA, stable on subcutaneous bDMARDs were enrolled in a randomized, controlled, single-center, open-label, 6-months trial. Intervention: A pharmacist’s educational interview provided information on bDMARDs management at baseline in the intervention group (IG) and at month 6 (M6) in the control group (CG). A booklet containing essential information was given to the patient. Intervention allocation: After written consent, the study treatment was randomly allocated via a computer program by simple randomization, with an allocation ratio of 1:1. Outcome measures: The change in a weighted knowledge score (0 – 100) concerning the bDMARDs management and the change in the Medication Possession Ratio (MPR) at M6 were primary outcomes. The changes in disease activity (BASDAI) and patients’ satisfaction regarding the pharmacists’ interview were secondary outcomes. Statistics: Changes in knowledge score, MPR and BASDAI were compared between the two groups using the T-Student test. Statistical analysis was performed in intention-to-treat. Missing data was handled with multiple imputations.

Results: Patients’ characteristics at baseline were comparable among the 89 included patients (46 in IG, 43 in CG). The means ± SD of the knowledge score were 75.3 ± 14.2 versus 73.0 ± 13.2 and 86.3 ± 12.6 versus 76.0 ± 14.1 in the IG versus CG at baseline and at M6, respectively. The patient’s knowledge score improved at a greater magnitude in the IG (+11.0 ± 15.5 versus +3.0 ± 10.6 in the IG versus the CG, respectively, p < 0.0001). The MPR at baseline were very high in both groups (92.9 ± 14.6% versus 96.6 ± 15.6% in the IG versus the CG, respectively). There was a trend in a better adherence (+2.2 ± 13.9 versus -0.6 ± 18.9 in the IG versus the CG in the MPR score respectively, p = 0.691). The disease activity (changes in BASDAI) remained stable during the study in both groups. All the patients were mostly or totally satisfied by the pharmacists’ interview.

Conclusion: Pharmacists’ educational interview on subcutaneous bDMARDs is effective in improving the knowledge of patients with SpA on their treatment. Regarding therapeutic adherence, a trend in favor of an improvement was observed in the intervention group but did not reach the statistically significance. Nevertheless, the results observed in this study are an argument to propose to include the pharmacists in the multidisciplinary team in charge of the management of patients with SpA.

A SYSTEMATIC REVIEW OF JOB LOSS PREVENTION INTERVENTIONS FOR PERSONS WITH INFLAMMATORY ARTHRITIS

C. M. T. Madsen1,2,3, S. Kjaer2,3, J. Printhapple1,2,4, J. R. Christensen1, C. Von Bülow3,4,5, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; 1Department of Regional Health Research, University of Southern Denmark, Odense, Denmark; 2Research Initiative for Activity Studies and Occupational Therapy, 3Research Unit for General Practice, Department of Public Health, University of Southern Denmark, Odense, Denmark; 4Research Unit for General Practice, Department of Public Health, University of Southern Denmark, Aabenraa, Denmark; 5The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark

Background: Persons with inflammatory arthritis (IA) have a higher level of absenteeism from work than those without IA and up to 20-30% become permanently work-disabled during the first years after being diagnosed with IA. Despite developments of new pharmacological and surgical treatments, people with IA still report reduced work ability. It is therefore relevant to offer effective interventions designed to prevent job loss and improve work function (i.e. job loss prevention interventions) to support people with IA to stay connected to the labour market. Initial effects of job loss prevention interventions have been established in a Cochrane review by Hoving et al. 2014 (1), but as only three randomized controlled trials (RCT) were identified, it seems relevant to investigate if new evidence has emerged.

T. Hamasaki1,2, P. Harris1,2, N. Bureau1,2, N. Gaudefroy1, N. Patenaude1,2, M. Choinière3,4, CHUM Hospital, Montréal, Canada; 2Université de Montréal, Montréal, Canada; 3Centre de recherche du CHUM (CRUCH), Montréal, Canada; 4Research Centre of the CHUM, Montréal, Canada; 5Université de Sherbrooke, Sherbrooke, Canada; 6Centre de recherche du CHUS (CRUCH), Sherbrooke, Canada; 7CHUS Hospital (Université de Sherbrooke), Sherbrooke, Canada

Background: Trapeziometacarpal osteoarthritis (TMO) is one of the most debilitating forms of hand osteoarthritis (OA). According to the recent EULAR guidelines 1, 2 and a systematic review,3 the efficacy of topical/oral non-steroid anti-inflammatory drugs (NSAIDs), orthoses, hand exercises, and psychological interventions for hand OA or TMO are supported by scientific evidence. Cortisone injections and acetylsalicylic acid are generally not recommended. 1, 2 Besides, TMO management is suboptimal: only 21% of patients receive rehabilitative interventions prior to referral to hand surgeons.4

Objectives: We aimed at documenting the types of treatment TMO patients employ and their healthcare resource use.

Methods: A total of 227 TMO patients recruited from 16 healthcare institutions completed a questionnaire about 1) received interventions, 2) analgesic strategies, 3) healthcare professional consultations.

Results: Acetaminophen (64.3% of the participants), oral NSAIDs (31.7%), topical NSAIDs (11.9%), and nutraceuticals (79%) were the most commonly used medications. More than 70% of the patients reported having received cortisone injections (72.5%) and orthosis (75.7%). More than half employed hand exercises, massage and heat/cool application. Relaxation/respiration, meditation, distraction, assistive devices, and joint protection principles were used by smaller percentages of participants (13.0-30.9%). Patients with TMO reported having consulted various types of healthcare professionals: family physicians, plastic/orthopaedic surgeons, radiologists-interventionists, rheumatologists, physiatrists, occupational/physical therapists, osteopaths, chiropractors, pharmacists, and acupuncturists. Only 4.8% of the participants reported having received psychosocial interventions.

Conclusion: TMO patients use numerous types of modalities to relieve their pain. Provision of evidence-based interventions tailored to their needs is clearly needed.

HEALTHCARE RESOURCE USE IN PATIENTS WITH TRAPEZIOMETACARPAL OSTEOARTHRITIS

T. Hamasaki1,2, P. Harris1,2, N. Bureau1,2, N. Gaudefroy1, N. Patenaude1,2, M. Choinière3,4, CHUM Hospital, Montréal, Canada; 2Université de Montréal, Montréal, Canada; 3Centre de recherche du CHUM (CRUCH), Montréal, Canada; 4Research Centre of the CHUM, Montréal, Canada; 5Université de Sherbrooke, Sherbrooke, Canada; 6Centre de recherche du CHUS (CRUCH), Sherbrooke, Canada; 7CHUS Hospital (Université de Sherbrooke), Sherbrooke, Canada
**Objectives:** The aim of this study was to present an overview of the evidence of the effect of job loss prevention interventions, which can improve work participation and decrease absenteeism and job loss in persons with IA.

**Methods:** A systematic literature search was performed in the databases PubMed, EMBASE, CINAHL, PsycINFO and the Cochrane Library in two steps: 1) an update of the Cochrane review, restricted to studies published from January 2014 to February 2019 and 2) an additional search with updated keywords with no time restriction. Quality assessment and data extraction were performed independently by two authors. The results were summarized narratively.

**Results:** The first search identified 1276 titles and the second search identified 2384 titles. Six studies (including the three RCT’s included in the Cochrane review (1)) were included. The results indicated that job loss prevention interventions may have effect on work ability, absenteeism and in particular job loss, but the results across study outcomes, were not consistent. This may be due to heterogeneity in the interventions delivered (i.e. dose, duration and setting) and outcome measures used. Most of the studies were of low quality. Therefore, the results should be interpreted with caution.

**Conclusion:** Job loss prevention interventions may have an effect on work ability, absenteeism and in particular job loss among persons with IA. Further studies of high quality regarding job loss prevention interventions for people with IA are recommended.

**APPS TARGETING SYMPTOMS ASSOCIATED WITH Sjögren’s Syndrome and Potential Users’ Perceptions of Their Features: Content Analysis and Think Aloud Study**

C. Mccallum1, M. Campbell2, M. Higgs3, J. Vines1, T. Rapley1, K. Hackett1.
1Northumbria University, Newcastle upon Tyne, United Kingdom; 2Teesside University, Middlesbrough, United Kingdom

**Background:** Sjögren’s syndrome (SS) is a rheumatic disease requiring self-management which may be delivered through smartphones. When developing digital interventions it is important to review what is already available (market segmentation) to identify unique selling points and aid uptake and adoption. While there are no dedicated SS apps, many are publicly available for other rheumatic conditions. Understanding user preferences for existing apps may help to design an engaging app for SS self-management.

**Objectives:** To explore apps targeting SS symptoms of dryness, sleep disturbances, fatigue and pain. To explore views of people with SS on these app features.

**Methods:** Apple Store apps were retrieved on 04 March 2019 using the following search terms: dry, dry eye, sleep, insomnia, fatigue, tiredness and pain. Included apps were English and in Medical or Health & Fitness genres. Exclusion criteria were: duplicates, additional external devices required and apps targeting alcohol reduction or children. Included apps were grouped by symptom. App descriptions were open-coded to generate a thematic coding framework (i.e. full list of features) for each symptom which was then applied to all app descriptions. To obtain views of people with SS, several of the reviewed apps for each symptom covering the full list of features were given to 13 focus group participants to use in ‘think aloud’ sessions (n=4).

Audio data was recorded, transcribed and deductively analysed using the framework to gather opinions relating to each feature.

**Results:** Of 914 apps retrieved, 542 were included. Features within apps targeting dryness (n=15) provided dry eye information, self-assessment and reminders to blink or look away from screens. Apps targeting sleep (n=310) included features to support sleep restriction, sleep hygiene, sleep tracking (sleep onset and wake up times, time in bed, overall sleep quality), relaxing sounds, guided meditation, sleep stories, snore recording and alarms. Fatigue apps (n=79) included features to detect current physical and mental fatigue levels, support pacing (i.e. track fatigue, label tasks as ‘high energy’, prioritise tasks), and self-massage instructions. Apps targeting pain (n=138) featured pain tracking (of severity, affected body areas), guided exercises, and mindfulness.

Dryness apps prompted participants to reflect on its impact on daily activities, but further dryness features were desired relating to: using a humidifier; eye drop reminders; and dryness tips for other body areas e.g. vaginal dryness. Sleep restriction features were viewed to be irrelevant but viewing and selecting sleep hygiene tips to “try” were considered useful. Beyond entering sleep onset and wake up times, participants wished to track “when and why I woke up”; to understand night awakenings in relation to other symptoms. Fatigue detection features were felt to be more useful for those recently diagnosed, as experienced participants could easily identify when they were fatigued (“I don’t need an app to tell me!”). Participants valued pacing features but found them difficult to use. Daily pain tracking was considered demotivating, but useful for remembering and explaining issues to healthcare professionals. Participants believed that a dedicated app for SS would support self-management and raise SS awareness.

**Conclusion:** Existing apps targeting SS symptoms do not meet the needs of those with SS. App features should be tailored to SS by supporting dryness management in body areas beyond eyes, and night-awakenings. Pacing features must be easy to use. The ability to track pain should be optional and tracking prompts should be limited. Design considerations should be implemented alongside evidence-based behaviour change techniques to support self-management.

**DEVELOPMENT OF A TOOL TO SUPPORT PATIENT AND NURSE IN COMMUNICATING ON SELF-MANAGEMENT SUPPORT NEEDS PROJECT OF V&AN RHEUMATOLOGY RESEARCH GROUP**

A. J. L. Meier1, Y. Van Eijk-Hustings2, B. Maat3, Máxima MC, Department of Rheumatology, Regional Rheumatology Center, Eindhoven, Netherlands; Maastricht University Medical Centre, Department of Epidemiology and Medical Technology Assessment, Maastricht, Netherlands; ReumaZorg Nederland, Patient Research Partner, Nijmegen, Netherlands

**Background:** Self-management, ability of patients to optimally integrate their illness or disorder into their daily lives, is explicitly part of the new definition of health.

Self-management is considered essential in rheumatology care but is also a challenge for patients and rheumatology nurses. Often patients need support, but clarifying their support needs is difficult. Also, nurses experience difficulties in providing self-management support. A communication tool might help patients and nurses.

**Objectives:** In preparation for development of an online self-management program, a framework comprising 55 needs from 11 different domains has been developed (1). The objective of this study is to develop a tool, based on this existing framework that can support patients and nurses in making targeted choices for adequate support.

**Methods:** The tool was developed in two steps. First, it was explored if existing framework as such was useful as a basis for the tool. It was discussed in a brainstorming session with rheumatology patients and rheumatology nurses. Second, additional two workshops, one with patients and one with nurses were organised. In these sessions, yellow cards with 55 needs from the framework (1) were compared with a more generic framework for self-management support in chronic diseases: the self-management web (2), figure 1. Goal of the workshop was to gain insight into usability of models and to gauge the ideas for a tool. The choice for these two models was based on the scientific background as well as the use with patients with a chronic or rheumatic disease.

**Picture 1:** Workshop

**Results:** In the first brainstorming session 5 patients and 5 rheumatology nurses participated.
In the workshops, 11 patients and 130 nurses participated. Eligible adult patients, diagnosed with a rheumatic disease, were recruited by newsletter from the Dutch Arthritis Foundation. Nurses were recruited by newsletter from the Dutch Nurses Organisation (VAN). According to participants, the framework alone is only useable when additional explanation and illustration of concepts will be provided and following missing topics are added; communication between specialisms, knowledge of the healthcare system, responsibility allocation, faith, religion, culture, nutrition, lifestyle, prevention.

The self-management web appeared to be helpful. Not all cards with needs could be placed in this web. It was suggested to add following topics to the web: Peer support or experience experts’ contact, handling treatment recommendations, patient empowerment, defining limitations and supporting services like physiotherapy and municipality.

There is overlap between topics of the web: Lifestyle, leisure and self-care. It was suggested to place associated topics together or give the same colour.

Practical ideas for application of the web and about involving an experienced expert were discussed as well as the role of health professionals. Integration in e-health, linked to the medical file with visual support is preferred. Patients have to prepare themselves for consulting the nurse or doctor.

Communication plays a very important role for all elements. The tool should be usable for people with limited health literacy skills and nurses need skills like motivational interviewing for using the tool.

**Conclusion:** Existing frameworks seem useful as a scientific basis for the development of a communication tool for self-management support. Usability of a draft tool will be explored in a pilot study.

**COGNITIVE DISORDERS IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH JUVENILE-ONSET: ONE SINGLE CENTER EXPERIENCE**

M. Kalea1, N. Stepanenko1, I. Nikshiga1, V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation

**Background:** Juvenile-onset SLE (JsLE) is a more aggressive disease than in adult-onset SLE including cognitive dysfunction, significantly affected the compliance and social rehabilitation of patients (pts).

**Objectives:** To analyze the cognitive, emotional and communicative status of pts with JsLE.

**Methods:** The study included 31 pts (90.3% girls) with JsLE, verified in accordance to SLICC criteria 2012. All pts underwent standard examination in accordance with the diagnosis; in case of suspected neuropsychiatric disorders pts were examined by a neuropsychiatrist. Classifying of neuropsychiatric disorders was performed in accordance with the recommendations of the ACR, 1999. SLE-DAI 2K was used for disease activity assessment. All pts were examined by a clinical psychologist using the standard pathodiagnostic testing.

**Results:** The median age at the onset was 12.0 y.o. [10.6;14.5]. The median disease duration at the time of diagnosis - 0.75 ys [0.5;2.1]. 35.5% pts had neuropsychiatric disorders at the onset: psychoses - 12.9%, headaches - 12.9%, cognitive disorders - 19.4%, mood disorders - 16.1%, distal polynuropathy - 12.9%. MRI of the brain was performed in 15 pts: CNS vasculitis was diagnosed in 3 pts (2 - with psychosis, 1 - with cognitive impairment). Median disease activity by SLEDAI at the time of diagnosis was 15 scores [10;23].

At the time of examination by the clinical psychologist, the median age of pts was 15.2 ys [12.9;16.5]. The median disease duration was 1.1 ys [0.6;3.8]. Cognitive disorders were detected in 96.8% of the pts. The auditory-speech short-term memory was distributed between the medium and high levels (54.8% and 45.2%, respectively), and the high level of memorization prevailed in the long-term memory (67.7% high, 32.3% medium). A high level of indirect memory was revealed in 67.8% of pts, medium - in 25.8%, and low - in 6.4%. Distribution of the difficulties of attention were identified (64.5% - uneven distribution, 35.5% - sufficient distribution), as well as increased attrition of attention (74.2% - attrition is detected, 25.8% - no attrition). 58.1% of pts demonstrated a high level of inclusion into work, 41.9% - a low one. Concentration of attention was recognized as sufficient in 87.1% of pts, insufficient in 12.9%. The effectiveness of attention was rated as good in 87.1%, decreased – in 12.9%; stability is sufficient - in 64.5%, low - in 35.5%. In the operational side of thinking, a decrease in the level of generalization was revealed (48.4%); there were no disturbances in the motivational component, liability of thinking in the dynamic (12.9%). Various neurotic fears are characteristic for 54.8% of pts; the level of personal anxiety was increased in 41.9%, moderate - in 48.4%, low - in 9.7%. Signs of aggression were revealed in 19.4% of pts, a decrease in the level of social adaptation - in 9.16%. Communication difficulties experienced 83.9% of pts. According to the results of the clinical conversation, attention was focused on availability of conflict situations with peers in the disease onset in 38.7% of pts.

**Conclusion:** Cognitive disorders were detected in the majority of pts with JsLE regardless of the presence of neuropsychiatric disorders at the onset. The revealed features of the clinical and psychological status of pts with JsLE must be considered when working out an individual rehabilitation model and develop psycho-correctional programs.

**Disclosure of Interests:** None declared.

**EVALUATING A COMPLEX PACKAGE OF CARE IN THE EAST-MIDLANDS KNEE PAIN FEASIBILITY COHORT RANDOMISED CONTROLLED TRIAL**

P.A. Nomikos1,2,3, A. Fulle1,2,3, M. Hall1,2,3, B. Miller1,2,3, R. Ogollah1, M. Doherty1,2,3, R. Nau2,6,7, D. Wals1,2,3, A. Valdes1,2,3, A. Abhishek1,2,3

**NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; 1Pain Centre Versus Arthritis, University of Nottingham, Nottingham, United Kingdom; 2Academic Rheumatology, University of Nottingham, Nottingham, United Kingdom; 3School of Health Sciences, University of Nottingham, Nottingham, United Kingdom; 4Nottingham CTU, University of Nottingham, Nottingham, United Kingdom; 5Institute of Mental Health, University of Nottingham, Nottingham, United Kingdom; 6Division of Psychiatry & Applied Psychology, University of Nottingham, Nottingham, United Kingdom**

**Background:** The role of nurses in managing painful knee OA has been advocated but whether nurses can deliver such interventions as a package of care is unknown. The overall aim of this research is to develop and test a nurse-led complex intervention for knee pain comprising non-pharmacological and pharmacological components. In the first study phase, we report on fidelity and acceptability of a non-pharmacological intervention, to resolve possible challenges to delivery.

**Objectives:** To evaluate fidelity of delivery and acceptability of non-pharmacological components of a complex intervention.

**Methods:** This was a mixed-methods study. Participants with chronic knee pain were recruited from the community to receive the intervention, delivered in 4-sessions over a 5-week period by a trained research nurse. The intervention consisted of holistic assessment, patient education and advice, aerobic and strengthening exercise and weight-loss advice if required. All sessions were video-recorded. Fidelity checklists were completed by the nurse (nurse-rated) and two researchers from the video-recordings (video-rated). Median fidelity scores (%) and interquartile ranges (IQR) were calculated for each component of each session. Semi-structured interviews were conducted with participants. These were audio recorded, transcribed and analysed following the framework approach.

**Results:** 18 participants (34% women), with a mean (SD) age and BMI of 68.7 (9.0) years and 31.2 (8.4) kg/m², took part in the study. Of these, 14 completed all visits. In total, 62 intervention sessions were assessed for fidelity. Overall fidelity was rated high by both nurse-rated scores (97.7%) and video-rated scores (84.2%). The level of agreement between nurse-rated and video-recorded methods was 73.3% (CI 71.3, 75.3) and the inter-rater agreement was 65.5% (CI 60.3, 70.5). Fidelity of delivery was lower for advice on footwear modification and walking aids in all sessions and moderate for education in session 1 and for exercise in session 4 (Table 1).

**Table 1. Fidelity scores of the components of the intervention for each session**

*median (IQR)*

17 participants were interviewed. Most found advice supplied straightforward. They were satisfied with the package, which changed their perception of
managing knee pain, understanding it can be improved though self-management. However, too much information was provided in a short time-span and it was difficult to fit exercises into their daily routine.

**Conclusion:** Delivery of a non-pharmacological intervention by a nurse is feasible within a research setting. Most components of the intervention were delivered as intended, except for advice about the use of adjunctive treatment.

in routine care. The outcomes were I) SB2 retention rate (RR) II) SB2 discontinuation rate due to a presumed NE, defined as lack of efficacy with no objective criteria for increased inflammation or non-objective and non-specific adverse event, either occurring after the switch and disappearing after back-switch or change of biologic. Criteria for NSAE/NSS in the historical cohort were the same lack of efficacy or subjective adverse events and disappearance after change of biologic BD. Medium-term (12 months) SB2 outcomes were assessed and compared with I) the data obtained in the short-term (34 weeks) II) the data from an historical cohort of CIRD patients treated by OI in the same rheumatology department, using Kaplan-Meier survival curve.

Results: Forty-five patients were prospectively included for the switch from March 2018 to August 2018: 17 with rheumatoid arthritis (RA), 28 with spondyloarthritides (SpA); 55% were women, mean age was 53.2 (SD: 2.1), and mean time under OI was 113.5 (SD9.3). For the historical cohort, the 52 patients treated with OI between December 2016 and January 2017 were included and their data collected at baseline and one year. Fifty-nine percent were women, mean age at inclusion was 50.25 (12), and mean time under OI was 94.8 (9.4). SB2 RR did not differ from the OI RR in the historical cohort: 91.2% and 96.2% respectively at 34 weeks (p = 0.41); 84.4% and 88.5% respectively at 12 months (p = 0.52) (figure 1). The SB2 RR was significantly higher than in three other European cohorts at 34 weeks (mean RR 73.6%, p<0.05, ref.1) but not at 12 months (mean RR 80.9%, ref.2,3,4).

SB2 and OI discontinuations due to NSAE/NSS at 34 weeks were 2.2% and 1.9% respectively; at 12 months 6.6% and 1.9% respectively (p = 0.6).

Conclusion: An intervention based on a tailored communication with a prominent role of nurses was effective in reducing the NE when switching from OI to SB2 in the short term, compared with an historical cohort and other European cohorts. The one-year follow-up showed no statistical difference in RR or NE compared with our historical cohort. The present study shows that appropriate interventions may be developed to improve the outcome of switches to biosimilars.

Figure 1: Treatment withdrawal free survival curves (SB2 in switched cohort and OI in historical cohort).

Kaplan Meir survival curves. Comparison with Log-Rank test between OI to SB2 cohort and historical OI cohort; p = 0.520. OI: original infliximab.

DOI: 10.1136/annrheumdis-2020-eular.4388
Methods: there were examined 22 children at the age of 7 to 17 years old diagnosed with CAPS-9, TRAPS-8, FMF-5. Among them there were 12 boys and 10 girls. The diagnosis in all the patients was confirmed through detection of patho-
genetic mutations in the NLRP3, TNFRSF1A and MEFV genes. The following methods were used: a clinical conversation; memory diagnostics (learning by heart of 10 words, a pictogram using cues taking into account the patients' age); attention diagnostics (Schulte tables); thinking diagnostics (establishing a sequence of events, "four is a crowd"; simple analogies, interpretation of proverbs); emotional and communicative fields (the Eight-Color Luscher Test; CMAS (adaptation by A. Prikochnizan); STKTest, a drawing called "an animal that does not exist" and "a house-a-tree-a-man").

Results: The memory study revealed in all patients with TRAPS and FMF high and medium values of short-term and long-term memory, in patients with CAPS - a low level of short-term auditory-speech memory, information storage and indirect memorization in 1/3 of patients. In 100% of the examined patients with TRAPS, an important decrease in all processes of attention and distribution of attention. In 1/3 of patients with CAPS, an increased exhaustion of attention was registered and in 11% - a decrease in its stability. In patients with FMF, attention disorders were not detected. In 44% of patients with CAPS, a decrease in the level of generalization and difficulties in establishing causal relationships were registered. In 25% of patients with TRAPS a decrease in the level of generalization, in 12.5% - difficulties in establishing cause-effect relationships, inertia of thinking in 37.5%. In 60% of patients with FMF: a decrease in the level of generalization, in 80%: difficulties in establishing cause-effect relationships, inertia of thinking in 20%. In the emotional sphere, patients with CAPS, TRAPS, and FMF demonstrated signs of aggression (11.1%, 20% and 20% of patients, respectively), communicative disorders (77.3%-80% - 80%), and reduced social adaptation (55.5% - 80% - 80%), a tendency to form neurotic fears (22% - 40% - 40%). A high level of personal anxiety was noted in 1/3 of patients with CAPS and 40% of patients with FMF.

Conclusion: various psychological disorders in the cognitive and emotional fields were noted in the majority of the examined patients with monogenic auto-inflammatory diseases. In patients with TRAPS, attention processes are most significantly affected; in patients with CAPS, memory is more often affected. In patients with FMF, disorders in thinking processes are revealed more often. In the emotional sphere, most patients had all the three forms of AID note communicative disorders and social adaptation.

PHYSICAL AND SOCIAL ACTIVITY OF PATIENTS SUFFERING FROM JUVENILE IDIOPATHIC ARTHRITIS
T. Shelepina1

1V.A. Nasonova Research Institute of Rheumatology, Pediatric, Moscow, Russian Federation

Background: Juvenile Idiopathic Arthritis (JIA) is a chronic, disabling disease of a childhood age that significantly limits the patient’s capabilities and affects the life quality. Modern drug therapies can prevent most of the negative consequences of the disease and maintain satisfactory-functional abilities of patients.

Objectives: to examine the nature of the daily physical and social activities of patients suffering from JIA.

Methods: the study included 236 patients aged from 4 to 17 years undergoing in-patient treatment. Among them, 148 (62%) - polyarthritis and spreading oligoarthritis, including 13 (5.5%) - with damage to the eyes, systemic JIA 22 (16%), enthesis-associated 8 (3%). The patients were divided into the following age groups: pre-school age (4-6 years old) – 26 patients (11%), primary school age (7-10 years old) - 54 patients (23%); an average school age (11-12 years old) – 49 patients (21%), senior school age (13-15 years old) -52 patients (22%), youth (16-17 years old) -55 patients (23%). The assessment methods: collection of their pharmaceutical history, questioning (with an author’s questionnaire) the parents of children aged from 4 to 10 years and other patients themselves, VAS pain evaluation, a CHAQ questionnaire.

Results: 10 (4%) patients received NSAID, 88 (38%) patients - synthetic basic anti-inflammatory drugs, biological therapy - 133 (56%), 5 patients (2%) did not receive any drug therapy. An average value of the VAS pain evaluation: 2.5 cm, the CHAQ functional insufficiency is low: 137 patients (58%), medium insufficiency in 86 patients (37%), severe insufficiency in 11 patients (4.5%). Children's educational institutions were regularly visited by 199 (85%) patients, leisure activities were enjoyed by 90 (38%) patients; at that, the highest rate of leisure activities was recorded for the age group 11-12 years (67% of the entire group), daily walks were recorded in 172 (73%) patients, doing homework on a regular basis by 155 (66%) patients, regular doing exercises of therapeutic gymnastics recorded in 55 (24%) patients.

Conclusion: The activity of patients suffering from JIA can be estimated as satisfactory, while their physical activity as inadequate. An adequate social and physical activation of patients with JIA being in the remission status is required.

This can be facilitated by educational programs for patients and their parents, a joint discussion of issues on the social and physical activity of patients and their parents with rheumatologists and rehabilitation therapy specialists.

Acknowledgments: I thank the Chief Researcher, E. S. Fedorov MD for his help in completing the work and preparing abstracts

LEVEL OF PHYSICAL ACTIVITY IN ANTIPHOSPHOLIPID SYNDROME AND ITS RELATIONSHIP TO ATHEROSCLEROSIS PROGRESSION – ANALYSIS OF THE SERBIAN COHORT
A. Djokovic1, 2, L. Stanisavljevic1, N. Stanisavljevic1, G. Bogdanovic2, S. Djokic1

1University Clinical Hospital Center Beznjaksa kosa, Cardiology, Belgrade, Serbia; 2Faculty of Medicine, University of Belgrade, Serbia

Background: Systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) are associated with an increased risk of developing cardiovascular diseases as a result of complex interaction between traditional risk factors, chronic inflammation and specific impact of antibodies on endothelium. There are very limited data regarding the physical activity (PA) in APS patients.

Objectives: To analyze different domains of PA in Serbian APS patients and their possible relationship to clinical and laboratory criteria of the main disease.

Methods: From a large Serbian APS database comprehending 527 APS patients (371 Primary – PAPS, and 156 APS associated with other autoimmune diseases, predominantly systemic lupus erythematosus (SLE)) we interviewed 51 APS patients, age range of 15-69 years: 29 patients with primary APS (PAPS), 25 women, 4 men, age 44±11.50, and 22 APS/SLE, 18 women, 4 men, age 48±11.75, using a long form of The International Physical Activity Questionnaire (IPAQ), translated onto Serbian language. Data on last seven days of PA divided onto leisure time PA, domestic and gardening (yard) activities, work-related PA and transport-related PA were acquired, and proposed scoring method was used. Based on the level of PA, patients were categorized to low, moderate or high level of PA. For the purpose of insight into atherosclerotic progression, we performed color Doppler scan of carotid arteries in all patients and presence of atherosclerotic plaques has been notified.

Results: Average total PA score was 7706.18±1177.19 MET-minutes/week. The greatest average values for different PA domains were for work (2733.21±6158.66 MET-minutes/week) and domestic/garden/yard (2522.31±3847.24 MET-minutes/week) and the lowest scores achieved in leisure time (500.67±695.45 MET-minutes/week). Majority of Serbian APS patients had low or moderate level of PA (37.3%, 43.1%, respectively) whereas lowest percentage was in high category of PA (19.6%). All domains of PA were significantly negatively correlated to age and BMI. There were no significant difference regarding PA scores between PAPS and APS/SLE patients. Although higher percentage of PAPS patients had high level of PA (2765 compared to 9.1% of SLE/APS), the overall difference was not significant. There was no significant difference regarding antiphospholipid antibody (aPL) type or thrombotic/obstetric events presence. Significant difference occurred regarding presence of carotid arteries plaques. APS patients with lower PA scores had significantly higher prevalence of carotid arteries plaque especially for PA in transportation (p<0.004), and total PA (p=0.025).

Conclusion: Serbian APS patients at younger age, tend to have low or moderate level of PA, with the lowest level of activity in leisure time. Low level of PA was undoubtedly related to progression of atherosclerosis in these patients, emphasizing a need for PA promotion in APS.

DOI: 10.1136/annrheumdis-2020-eular.2548
Conclusion: Motivation for surgery was strongly associated with women. The most common goals for surgery were to reduce pain and improve functional status, and quality of life level compared to other JIA subtypes. Yoga is used as an alternative therapy for children with ERA. However, no study was conducted related to yoga in pediatric population with rheumatic diseases.

Objectives: The aim of this study was to investigate effects of performing yoga or home exercises on functional status in children with ERA.

Methods: Twenty-one children with ERA were allocated into two groups as yoga (n=11) and home exercise group (n=10). Yoga group performed yoga exercise regimen according to individual patient characteristics (e.g. pain severity, personal goals and co-morbidities), as this may enhance take up and adherence, hence treatment effect of the intervention (Fernandes et al., 2013).

Results: The groups were similar regarding to physical characteristics, pain, and lower quality of life level compared to other JIA subtypes. Yoga is used as an alternative therapy for children with ERA. However, no study was conducted related to yoga in pediatric population with rheumatic diseases.

Conclusion: Yoga seems promising for improving functional status in children with ERA compared to a home-based exercise program. Therefore, yoga can be implemented as an exercise intervention in rehabilitation programs in children with ERA.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.3998
Objectives: The aims of this systematic review were: (1) to evaluate the current evidence for efficacy in randomised controlled trials (RCTs) of individualised exercise (IE) interventions for people with hip or knee OA; and (2) to compare this to the efficacy of non-individualised exercise (NIE).

Methods: A systematic search was carried out, up until March 6th, 2018, on the following databases: MEDLINE, CINAHL, AMED, PsyCINFO and EMBASE. RCTs of IE interventions, or with subgroup analysis based on specific patient characteristics, were searched. Standardised mean difference and 95% confidence interval (CI) were calculated using random effects model. Risk of bias was evaluated using the modified Cochrane tool. Pain was the primary outcome of interest. Results of IE interventions were then compared to the NIE interventions identified from a previous systematic review (Goh et al., 2019).

Results: We reviewed titles of 1,766 records in the systematic search. The screening process (Figure) identified 15 studies (1,626 participants) that met the inclusion criteria, of which 7 were included in a meta-analysis. Most included studies had high risk of bias. Blinding was a consistent problem due to the nature of the intervention. Within the trials exercise was individualised according to factors including severity of symptoms, exercise performance, lower limb muscle strength and presence of co-morbidities (e.g. heart failure, chronic obstructive pulmonary disease (COPD) and diabetes mellitus (DM) type 2).

The analysis showed that IE significantly improved pain, physical function, performance and quality of life outcomes (Table). When compared to NIE interventions, IE showed greater effect size for all outcomes but their 95% CIs were overlapping.

Table 1. Summary of results

<table>
<thead>
<tr>
<th>Outcome</th>
<th>Type of exercise program</th>
<th>ES 95% CI</th>
<th>Number of studies (Number of patients)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pain</td>
<td>IE 1.04 0.32 - 1.77 7 (991)</td>
<td>NIE 0.57 0.44 - 0.69 65 (4,723)</td>
<td></td>
</tr>
<tr>
<td>Function</td>
<td>IE 1.37 0.50 - 2.24 7 (931)</td>
<td>NIE 0.51 0.38 - 0.64 63 (4,829)</td>
<td></td>
</tr>
<tr>
<td>Performance</td>
<td>IE 2.00 0.07 - 3.93 2 (291)</td>
<td>NIE 0.51 0.08 - 0.63 66 (4,889)</td>
<td></td>
</tr>
<tr>
<td>QoL</td>
<td>IE 1.30 0.52 - 2.12 2 (226)</td>
<td>NIE 0.32 0.15 - 0.49 34 (2,545)</td>
<td></td>
</tr>
</tbody>
</table>

Conclusion: The results of this review show that IE may have better outcomes on people with hip or knee OA compared to NIE. However, the small study effect may inflate the estimates of the individualised exercise group, and further head to head comparisons are required.

HPR Interdisciplinary research

IMPACT OF PARENTAL MIGRATION IN THE CONTEXT OF THE MULTIFACTORIAL ETIOLOGY OF CHRONIC ARTHRITIS IN CHILDHOOD

L. Alloia1,2, C. Alloia1,2, Universitatea Alexandru Ioan Cuza, Iasi, Romania; Universitatea Alexandru Ioan Cuza, Iasi, Romania

Background: Migration of Romanians to work abroad began in 1990 with the aim to provide a better income and life for their family. Current studies show that the migration of one parent or both, even when it is temporary, produces negative long-term effects on the health and psychosocial evolution of the children affected. Children and adolescents exposed to chronic stress due to migration, misunderstandings between the parents, alcoholism, violence, divorce of the parents etc., present an increased risk of illness. More and more data from the literature suggest that prolonged stress and depression induces inadequate cortisol along with non-epinephrine secretion, increased synthesis of proinflammatory cytokines, which are the basis for autoimmune pathologies, such as chronic arthritis.

Objectives: Given the extended phenomenon of migration from Romania and the increase in the cases with autoimmune pathology in children and adolescents, we aimed to evaluate the association between the disorders related to the permanent stress induced by the parental migration abroad and the risk of developing arthritides during childhood.

Methods: The study included 201 children and adolescents aged 13.4 ± 3.7 years, who were in evidence of an outpatient health unit, from 2016-2019. These cases were included in a chronic disease registry with the diagnosis of Juvenile Idiopathic Arthritis (JIA), established by a pediatric rheumatologist. For the initial evaluation, we used a questionnaire that included the socio-demographic data. In comparison, we studied 40 healthy children (control group). The family drawing test was used for patients between 5 and 16 years of age to identify possible conflicts with certain family members, to assess the emotional and psychological maturity of the child or adolescent, and to find out if there are any problems at home.

Results: At the end of the study, only 181 (90%) of the eligible patients completed the questionnaire and the family drawing test. Demographic data showed that patients from rural areas predominated (71.8%), compared to 28.2% from urban areas. In terms of sex, 52.5% were male, compared to 47.5% female. Family history (mother, father, sister, brother, grandfather, aunt, uncle) of autoimmune disease was encountered in 28.1% of patients, as follows: spondyarthritics in 9.4% cases, rheumatoid arthritis in 8.8% cases, JIA in 3.9% cases and other autoimmune diseases (Systemic Lupus Erythematosus, Scleroderma, Diabetes, Asthma) in 6% cases. Patients from low-income families were in 82.3% of cases. 72.5% of the cases had a prolonged state of stress by migrant parents for working abroad (38.7% only one parent (30% mother) and both parents in 17.7% of cases), divorce in the family in 11.6% of cases, unmarried mother in 2.8% of cases, and a close relative recently deceased in 1.7% of patients.
Subcategories of JIA included: polyarticular JIA negative Rheumatoid Factor (RF) in 39.77% of cases, enthesitis-related arthritis in 27.07% of cases, polyarticular JIA positive RF in 14.36% of cases, oligoarticular JIA in 14.9% of cases, systemic JIA in 3.51% of cases and psoriatic JIA in 0.59% of patients.

**Conclusion:** Both the data from the questionnaires, but especially the family drawing tests, suggest that the prolonged state of stress with anxiety, sadness, pain and depression, in combination with starvation, lack of parental love and the genetic predisposition, have contributed to the emergence of chronic arthritis, pathology that is growing more and more in recent years in Romania.

**Efforts of vibroacoustic therapy in chronic musculoskeletal pain in children and adolescents**

C. Alloia1, L. Alloia2,1, Universitatea Alexandru Ioan Cuza, Medical Physics, Iasi, Romania

**Background:** Musculoskeletal chronic pain in children and adolescents is a major cause of locomotor and mental disabilities, with a significant impact on school activities and social costs. Vibroacoustic therapy is used to reduce stress, pain, anxiety and to increase the well-being of children and adults, in order to relax the body, brain and to relieve the symptoms of the disease. It was proved that sound waves imprint movement in water molecules, accelerate lymph and blood circulation, eliminate toxic metabolic waste, vitalize the "good bacteria" by suppressing the activities of "bad bacteria" and balancing the gut microbiota.

**Objectives:** Aim of study was to evaluate the effect of vibroacoustic therapy on pain and well-being of patients with chronic musculoskeletal pain.

**Methods:** Between 2017 and December 2019, 84 patients with a mean age of 11.9 years with chronic pain from different musculoskeletal disorders were studied. Patients were randomly divided into: group I (46 patients) received vibroacoustic therapy and group II (38 patients), control, received placebo vibroacoustic therapy. All patients and parents/legal guardians were informed about the treatment and signed an informed consent. Inclusion criteria were: diagnosis of the disease by the rheumatologist specialist and the initial pain measured on the Visual Analog Scale (VAS) >5. Exclusion criteria were: patients with acute inflammatory conditions, mental retardation, psychosis, high blood pressure, internal or external bleeding, pregnancy, hearing loss. Group I (46 patients) received vibroacoustic therapy with a special system, in which the patient listens in the headphones a healing music and at the same time, a therapist posts a special pillow that imprints music vibrations on the painful areas. Patients had a session three times a week, for 20 minutes, with a vibrational frequency of 115 Hz, for 4 weeks, then repeated the protocol after a break of 8 weeks. Group II (38 patients), control, was treated with conventional drugs and placebo vibroacoustic. Effects of vibroacoustic therapy were evaluated by the pediatric rheumatologist who completed a questionnaire for the evaluation of the functional ability in daily living activities (Child Health Assessment Questionnaire) (scores 0–3; 0 = without disabilities; 3 = disabled) and the intensity of the child’s pain by VAS score 0–10, (0 = no pain, 10 = severe pain), at the beginning of treatment, after 4 weeks and in the end.

**Results:** In group I, after 12 sessions of the vibroacoustic therapy, VAS pain scores decreased from 8.42 to 4.2, comparatively to only a decrease from 8.2 to 6.7 in the control group (p = 0.05); the functional activity score was improved with 47%, comparatively with only 23% in the control group (p = 0.02).

At the end of the study, the VAS pain score improvement in group I was 68%, compared to only 29% in the control group (p = 0.01). All patients who were treated with vibroacoustic music had a better functional activity score in the end of the study, significantly better compared to the placebo control group (p < 0.05).

**Conclusions:** Vibroacoustic therapy had positive effects in significantly reducing pain, and especially for the areas of the body where the vibrational cushion was applied, comparatively with control group (p < 0.05). Vibroacoustic therapy is a non-pharmacological, non-invasive, no-side-effect treatment modality which has induced patient relaxation, has reduced muscle tension and improved the range of motion, helping a lot in the process of patient’s rehabilitation. Sonic vibrations transmitted by the bone conduction adjust the balance of the autonomic nerves, deeply relax the mind and remove excess body tension.

Disclosure of Interests: None declared.

**Usefulness of isotopic radiosynoviorthesis in rheumatic diseases with chronic refractory synovitis.**

J. Anino-Fernández1, A. I. Rebollo Giménez1, M. A. Ramírez Huarranga1, D. Castro1,2, Hospital Ciudad Real, Rheumatology, Ciudad Real, Spain

**Background:** Radioactive synoviorthesis consists of the intra-articular injection of particles from a radioisotopic colloidal suspension, to achieve the selective destruction of the synovial membrane, respecting the cartilage and bone.

**Objectives:** To describe the experience of performing isotopic radiosynoviorthesis (ROSO) as an alternative technique to the traditional procedures in the treatment of chronic synovitis refractory in patients of our health area and to define the pathologies, clinical improvement and safety in patients treated with the above described method.

**Methods:** Observational, descriptive and cross-sectional study by reviewing radiosynoviorthesis performed in patients with chronic arthritis refractory between 2005 and 2019 at the General University Hospital of Ciudad Real and comparing to common treatments, which normally consist of corticosteroids, disease-modifying drugs, biological therapy, nonsteroidal anti-inflammatory drugs and opioids. The study group involved 65 patients aged 37 to 75 years that had been diagnosed of rheumatic diseases such as rheumatoid arthritis, spondyloarthropathy, gout, osteoarthritis, villonodular synovitis, lupus and undifferentiated arthritis. Once medical records were reviewed, and prior to the procedure, the following information was registered into a database: age, sex, pathology, treatment received, infiltrations, affected joint, mobility, radiographic stage, laboratory parameters (VSG and PCr), Health Assessment Questionnaire (HAQ) and visual analog pain scale (VAS). After 6 months of treatment, clinical improvement provided by radiosynoviorthesis was evaluated and a second database was created by collecting the following data: physical examination, HAQ, laboratory parameters (VSG and PCr), VAS, mobility and subjective perception of the patient. In addition, short-term complications were also recorded. After 6 months of radiosynoviorthesis treatment, clinical improvement was established as a consequence of the following parameters: absence of inflammation on physical examination, improvement of inflammation reactants in comparison to the beginning of the procedure –assuming a decrease of ≥2 mm in ESR and ≥0.2 mg / dl in CPR as such-, enhancement of HAQ –decrease of ≥ 0.25 compared to the beginning of the treatment-, EVA improvement defined by a reduction of ≥ 25%, in relation to the initial value and increase of mobility. Additionally, the subjective perception of the patient was also considered as evidence of the clinical improvement.

**Results:** On the sixth month of treatment, 58.4 % of the individuals perceived a good clinical improvement, which was qualified as excellent by 6.2% of them. 56.9% of patients also presented pain reduction in the VAS scale, together with a decrease in joint swelling in 66% of the cases and an enhanced joint mobility in 69.2% of them. No side effects appeared due to treatment. An improvement in HAQ was observed in 67.7% of the observations and inflammation parameters (both ESR and CRP) were reduced in 64.6% of the subjects. The pathologies in which the technique has been most frequently prescribed are villonodular synovitis (27.7%) and rheumatoid arthritis (20%).

**Conclusion:** Isotopic radiosynoviorthesis is a useful and safe therapeutic alternative, that leads to a clinical improvement demonstrated by a reduction of pain and inflammation and increased mobility in those patients with chronic synovitis refractory. Compared to usual treatments, currently available data supports the effectiveness and safety of radiosynoviorthesis as an alternative therapy for these patients.

**BARRIERS AND FACILITATORS FOR PHYSICAL ACTIVITY ARE MAINLY RELATED TO PSYCHOLOGICAL ISSUES IN INFLAMMATORY ARTHRITIS – A MIXED-METHODS STUDY OF 66 PATIENTS IN FRANCE.**

T. Davergne1, R. H. Moe2, B. Fautrel1, L. Gossec1, I. Sorbonne University – Assistance Publique Hopitaux de Paris, Paris, France; 2Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

**Background:** Patients with inflammatory arthritis (IA) like (ankylosing spondylitis (AS), rheumatoid arthritis (RA), and psoriatic arthritis (PsA) are more prone to physical inactivity but derive specific benefits from regular physical activity (PA).

(1) Barriers and facilitators to PA are key elements that have not yet been well described.

**Objectives:** To assess if barriers and facilitators for PA in patients with IA are mostly related to disease, psychological, social or environmental factors.

**Methods:** A list of the most important barriers and facilitators was derived from a systematic review of barriers and facilitators to PA in rheumatoid arthritis (2). This list was assessed for face validity by 11 experts from Rheumatology or physiotherapy then tested by 10 patients through structured interview.

The list of barriers and facilitators was completed in a binary way: “barriers or facilitators are relevant to me” yes or no, for 66 patients in a monocentric cross-sectional study. Then, patients assessed the level of each barrier or facilitator on a 0-10 scale. Statistics were descriptive. There was no imputation of missing data.

**Results:** The study included 66 patients (27 axial spondyloarthritids, 26 rheumatoid arthritis, 13 psoriatic arthritis), mean age 52.0 (standard deviation (SD) 16.6) years, mean disease duration 14.3 (SD 11.7) years, 53% women. Disease activity was moderate (mean DAS28 2.1 (SD 1.1), mean BASDAI 2.8 (SD 1.4), mean CRP 75.4% received a biologic. The main factors described by patients were related to the knowledge of the benefits of PA and symptoms (table 1).

**Psychological factors** were more reported and social factors less reported as influential for PA.

**Table 1. Barriers and facilitators for physical activity reported by patients with inflammatory arthritis.**

<table>
<thead>
<tr>
<th>Barriers or facilitators</th>
<th>Categories Modifiable (%) reporting this barrier or facilitator</th>
<th>Level of patients reporting this item (0-10) (mean (SD))</th>
</tr>
</thead>
</table>

Psych = psychological, Evmt = environmental, Phy = physical, Soc = social

**Conclusion:** The main factors that influence PA in patients with IA were mostly related to psychological aspects, and could be modifiable. The role of health professionals supporting patient PA is key. Interventions should be further explored to meet these important barriers and facilitators.

**References:**

Background: Rheumatoid arthritis (RA) is a chronic immune mediated systemic disease known to affect multiple organs. It is known that cardiovascular disease accounts for nearly half the mortality among RA patients. Osteoarthritis (OA), on the other hand, is not an inflammatory arthritis. No prior study has compared the prevalence of cardiovascular disease (CVD) among these two groups of patients.

Objectives: The purpose of this study was to compare the prevalence of CVD among U.S. veterans with RA versus those with OA.

Methods: The study was conducted in a metropolitan Veterans Affairs Medical Center in the U.S. Information was collected from 125 consecutive patients with RA and 125 consecutive patients with OA as they presented to the clinic.

Patient characteristics were noted as well as the presence of CVD and certain subgroups: Cardiac arrhythmias, coronary artery disease, congestive heart failure, cerebrovascular accident, abdominal aortic aneurysm, peripheral vascular disease, deep vein thrombosis, pulmonary embolism, or any other form of embolism. The chi square test and the mann-whitney test were used for statistical analyses.

Results: Patient characteristics did not differ between the two groups for age, smoking status, or for the presence of hypertension or diabetes. There were more women in the RA group. The OA group had a higher BMI and a higher prevalence of hyperlipidemia. RA patients compared to OA patients had a higher incidence of CVD as a whole (60% vs. 42%, p < 0.004) and of cardiac arrhythmias (33.6% vs. 13.6%, p = 0.001). There was no difference between the 2 groups for the incidence of CAD, CHF, CVA, AAA, PVD or DVT/PE. RA seropositive and seronegative patients did not differ in the prevalence of CVD. RA duration was not related to the increased prevalence of CVD. Among the cardiac arrhythmias, patients with RA had a higher prevalence of atrial fibrillation (19.2% vs. 8.8%, p < 0.03) and arrhythmias requiring pacemaker or defibrillator implant (12.8% vs. 4.0%, p < 0.02).

Conclusion: The findings of this study demonstrate that our patients with RA have a statistically higher prevalence of CVD compared to OA patients. Among the subgroups, RA patients had a higher prevalence of cardiac arrhythmias, specifically atrial fibrillation and arrhythmias requiring pacemaker or defibrillator implant.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

Y. Peters1, J. Vriezekolk1, C. Van den Ende1, Sint Maartenskliniek, Nijmegen, Netherlands

Background: In the Netherlands over 1.2 million people have OA of which almost half have knee OA. Recently, several international and national guidelines and quality standards have been developed and adopted to improve the quality of knee OA care. Mapping the patient perspective is a valuable and important step to get insight into the current status of the quality of knee OA care and the uptake of the quality of care standards endorsed by current guidelines.

Objectives: To investigate the quality of knee osteoarthritis care from the patients' perspective in the Netherlands.

Methods: Members of a large observational prospective cohort (n=622), consisting of people clinically diagnosed or suspected with knee OA, were invited to complete an online survey. Besides demographic characteristics participants were invited whether they contacted a health care professional(s) in the last year for their knee OA and, to fill in a slightly adapted version of the “OsteoArthritis Quality Indicators (OA-QI) questionnaire. In addition, participants rated the quality of knee osteoarthritis care in the Netherlands on a 10-point scale (1: very poor - 10: excellent), and were invited to make recommendations for knee OA healthcare improvement via open-ended questions.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

Y. Peters1, J. Vriezekolk1, C. Van den Ende1, Sint Maartenskliniek, Nijmegen, Netherlands

Background: In the Netherlands over 1.2 million people have OA of which almost half have knee OA. Recently, several international and national guidelines and quality standards have been developed and adopted to improve the quality of knee OA care. Mapping the patient perspective is a valuable and important step to get insight into the current status of the quality of knee OA care and the uptake of the quality of care standards endorsed by current guidelines.

Objectives: To investigate the quality of knee osteoarthritis care from the patients' perspective in the Netherlands.

Methods: Members of a large observational prospective cohort (n=622), consisting of people clinically diagnosed or suspected with knee OA, were invited to complete an online survey. Besides demographic characteristics participants were invited whether they contacted a health care professional(s) in the last year for their knee OA and, to fill in a slightly adapted version of the “OsteoArthritis Quality Indicators (OA-QI) questionnaire. In addition, participants rated the quality of knee osteoarthritis care in the Netherlands on a 10-point scale (1: very poor - 10: excellent), and were invited to make recommendations for knee OA healthcare improvement via open-ended questions.
Results: Between September and October 2019, 434 participants completed the survey. Preliminary results show that most participants (78%) contacted one or more health care professional(s) for their knee OA complaints in the last year; most often an exercise and/or physical therapist (53.2%), the general practitioner (43.8%) and/or an orthopedist/orthopedic surgeon (41.5%). Furthermore, there were large variations in self-reported quality indicator achievements (checked “Yes”) with the lowest rate for referral for weight reduction and, the highest rate for advice on managing/living with osteoarthritis (table 1). On average, a score of 6.5 was given by the participants for the quality of knee OA healthcare in the Netherlands. Participants’ suggestions for OA care improvement comprised of, among others, more attention to pain and fatigue symptoms, expanding and researching treatment options, more information on OA, more attention to the personal situation and, improvement of multidisciplinary care.

MAPPING THE PATIENT JOURNEY OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: PERSPECTIVE OF PROFESSIONALS AND PATIENTS

T. Oton1, C. Sastre2, L. Carmona1. 1InMusc Instituto de Salud Musculoesquelética, Madrid, Spain; 2Novartis Farmacéutica, S.A., Barcelona, Spain

Background: Non-radiographic axial spondyloarthritis (nr-axSpA) is a relatively new disease classification that has generated controversy amongayers.

Objectives: To explore the perspective of patients and health care professionals (HCPs) on the journey from first symptoms to a diagnosis of non-radiographic axial spondyloarthritis (nr-axSpA), in order to identify gaps and unmet needs.

Methods: Qualitative study in two phases: (1) focus groups with HCPs and personal interviews with patients; (2) nominal group in which results were discussed with all stakeholders and possible solutions were proposed. Content analysis, patient journey mapping, and ideas generation techniques were used.

Results: Five focus groups were organised with rheumatologists, GP, orthopaedic surgeons, physiotherapists, and radiologists, and six patient interviews were held. HCPs recognised poor communication among specialists and contradictory or redundant approaches. Non-rheumatologists recognise poor training on spondyloarthrits, difficulty in identifying red-flags, and biases in differential diagnosis. Rheumatologists recognise that SpA nomenclature can be confusing, nevertheless nr-axSpA term is defining an early stage of anklyosing spondylitis, and it could lead to over-diagnosis.

Most of the patients agreed in the narrative of a very long journey with a multitude of diagnoses, mostly wrong, ineffective treatments and much frustration; acknowledging the need for psychological support during the process and the importance of receiving a diagnosis in order to cope with the disease. The participants in the nominal group meeting recognised and discussed the problems derived from the diagnostic delay and care gaps that clearly affect people with nr-axSpA (Table 1).

Abbreviations: Pt, patient; PT, physical therapist; Or, orthopaedic surgeon; GP, general practitioner; Rh, rheumatologist; Ra, radiologist.

The following were indicated as possible solutions: (1) Improving relations between specialties, (2) High resolution consultations, (3) Rethinking disability scales, (4) Better information, (5) Visibility, (6) Resource maps and (7) Citizen training.

Conclusion: The patient's journey with an nr-axSpA is long, complicated and frustrating for both the person who experiences it and the HCPs who care for them. It is necessary to improve the knowledge about nr-axSpA among non-rheumatology health HCPs along with low back pain in general, among doctors and the general population, as well as other feasible measures that affect multiple levels.

OUTPATIENT FOLLOW-UP ON DEMAND IN RHEUMATOID ARTHRITIS HAS SAME CLINICAL AND RADIOGRAPHIC OUTCOMES BUT FEWER VISITS THAN SCHEDULED ROUTINE CARE

B. P. Poggenborg1, O. Rintek Madsen1, L. Dreyer2, O. P. Poggenborg1, A. Hansen1, 1Copenhagen University Hospital Gentofte, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; 2Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark

BACKGROUND: Medical treatment and care are often life-long in patients with rheumatoid arthritis (RA). During periods of stable disease, patients typically attend routine visits every 3–8 months at the rheumatology outpatient clinic. Between scheduled medical visits, it may be difficult to get acute appointments with the rheumatologist. Scheduled routine visits may be in a stable period without any symptoms and with no need for control and adjustment of treatment. Consequently, there is a demand for developing outpatient control procedures that cater to the needs of individual patients and which support the patient’s experience of active participation in the control and treatment of their own disease.

OBJECTIVES: To compare a patient self-controlled outpatient follow up system (Open Outpatient Clinic System (OOCs)) with traditional scheduled routine visits at a rheumatology outpatient clinic.

METHODS: A two-year randomised controlled trial with RA patients aged 18 to 80 years with a disease duration of at least one year. Patients were recruited divided respectively into two groups: the rheumatology outpatient clinic of a major university hospi-

tal in the Copenhagen region of Denmark from February 2015 to January 2017. Patients were randomised electronically. Joints were examined by a blinded rheumatologist. Patients in the OOCs group had no scheduled appointments but were allowed to book acute appointments with their contact rheumatologist within 5 days and had access to nurse-led consultations without pre-booking, and a nurse-led telephone helpline. Appointments for the control group were scheduled according to routine procedures. Outcome measures were collected at baseline year 1 and year 2. Clinical parameters: DAS28, CRP, VAS pain, 28-tender and swollen joint count (28-TJC and 28-SJC), HAQ score and radiographs of hands and feet. Psychological parameters: VAS patient satisfaction (Pt satisfaction) and quality of life (EQ-5D).

RESULTS: Of 282 patients, 266 completed the first year, 239 the second year. Patient characteristics (OOCs/control): age 61.4±10.5; 59±12.2 years, females 77/77%, ACRA positive 66/65%, treatment with synthetic DMARDs 67/65% and or biologics 33/35%. Clinical and psychological parameters are shown in Table 1. OOCs at year one and two was comparable to traditional scheduled routine procedures concerning clinical and psychological outcome measures. Radiographic progression was detected in 2.9% (4/138) and 2.1% (3/140) of the OOCs and control group, respectively (p=0.69; Chi-squared test).

Table 1. Outcome measures in patients with RA randomised to on-demand Open Outpatient Clinic System (OOCs) or traditional follow-up (control group) in a rheumatology outpatient clinic. Results are shown as means±SD.

*p<0.05; **p<0.0005, OOCs vs. control group (Student’s t-test).

CONCLUSION: The patient self-controlled outpatient follow up system OOCs was associated with fewer visits, but more phone calls to the nurse, and was comparable with traditional scheduled routine procedures regarding clinical, psychological and radiographic outcomes after two years. Thus, organisation of outpatient care according to OOCs may be applied to strengthen patient-centred care in patients with RA.

HYDROXYCHLOROQUINE PRESCRIBING AND OPHTHALMOLOGY SCREENING WITHIN RHEUMATOLOGY DEPARTMENTS IN THE NORTH-WEST OF THE UNITED KINGDOM: A PROSPECTIVE REGIONAL AUDIT

S. Juman1, T. Davis2, L. Gray3, R. Hamad4, S. Horton5, M. Ibrahim6, B. Khan1, Y. Khazaaleh1, M. Porter1, A. Sheikh6, P. Ho2, S. Wig1, L. Mercer7, 1PenneinacuateHospitalNHSTrust,Manchester,UnitedKingdom;2ManchesterRoyalInfirmary,Rheumatology,Manchester,UnitedKingdom;3 Trafford General Hospital, Manchester University NHS Foundation Trust, Manchester, United Kingdom; 4Bolton NHS Foundation Trust, Bolton, United Kingdom; 5Lancashire Care NHS Foundation Trust, Lancashire, United Kingdom; 6Royal Lancaster Infirmary, Lancaster, United Kingdom; 7Blackpool Teaching Hospitals Foundation Trust, Blackpool, United Kingdom; 8Manchester Royal Infirmary, Manchester, United Kingdom; 9Tameside Hospital NHS Foundation Trust, Tameside, United Kingdom; 10Manchester University NHS Foundation Trust, Manchester, United Kingdom; 11Bolton NHS Foundation Trust, Bolton, United Kingdom; 12Stockport NHS Foundation Trust, Stockport, United Kingdom

BACKGROUND: Hydroxychloroquine (HCQ) is widely used in the management of rheumatoid arthritis and connective tissue disease. The prevalence of retinopathy in patients taking long-term HCQ is approximately 7.5%, increasing to 20-50% after 20 years of therapy. Hydroxychloroquine prescribed at ≤5mg/kg poses a toxicity risk of <1% up to five years and <2% up to ten years, but increases sharply to almost 20% after 20 years. Risk factors for retinopathy include doses >5mg/kg/day, concomitant tamoxifen or chloroquine use and renal impairment. The UK Royal College of Ophthalmologists (RCOphth) 2018 guidelines for HCQ screening recommend optimal treatment dosage and timing for both baseline and follow-up ophthalmology review for patients on HCQ, with the aim of preventing iatrogenic visual loss. This is similar to recommendations made by the American Academy of Ophthalmology (2016).

Disclosure of Interests: A. Sheikh Consultant of: Alcon, Speakers bureau: Allergan

DOI: 10.1136/annrheumdis-2020-eular.1185
**Objectives:** To determine adherence to the RCOphth guidelines for HCQ screening within the Rheumatology departments in the North-West of the UK.

**Methods:** Data for patients established on HCQ and those initiated on HCQ therapy were collected over a 7 week period from 9 Rheumatology departments.

**Results:**
- 473 patients were included of which 56 (12%) were new starters and 417 (88%) were already established on HCQ. 79% of the patients were female, with median ages of 60.5 and 57 years for new and established patients respectively. The median (IQR) weight for new starters was 71 (27.9) kg and for established patients, 74 (24.7) kg. 20% of new starters exceeded 5mg/kg daily HCQ dose. 16% were identified as high risk (9% had previously taken chloroquine, 5% had an eGFR <60ml/min/m² and 2% had retinal co-pathology). Of the high-risk group, 44% were taking <5mg/kg.
- In total, 36% of new starters were referred for a formal baseline ophthalmology review. In the established patients, 74% were taking ≤5mg/kg/day HCQ dose and 16% were categorized as high risk (10% had an eGFR less than 60ml/min/m², 3% had previous chloroquine or tamoxifen use and 2% had retinal co-pathology).
- In the high-risk group, 75% were not referred for spectral domain optical coherence tomography (SD-OCT). 41% of patients established on HCQ for <5 years, and 33% of patients on HCQ for >5 years were not referred for SD-OCT. Reasons for not referring included: awaiting 5 year review, previous screening already performed and optician review advised.

**Conclusion:** This audit demonstrates inconsistencies in adherence to the RCOphth guidelines for HCQ prescribing and ophthalmology screening within Rheumatology departments in the North-West of the UK for both new starters and established patients. Plans to improve this include wider dissemination of the guidelines to Rheumatology departments and strict service level agreements with ophthalmology teams to help optimize HCQ prescribing and screening for retinopathy.

<th>FRI0650-HPR</th>
<th>SEXUAL DYSFUNCTION IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS</th>
</tr>
</thead>
</table>

**Background:** Sexual dysfunction is the alteration in one or several phases of sexual activity (desire, excitement, plateau, orgasm and resolution), which can culminate in frustration, pain and a decrease in the frequency of sexual intercourse. There are a few studies that associate sexual dysfunction with Systemic Lupus Erythematosus (SLE) due to the difficulty in assessing it and its multifactorial cause.

**Objectives:** To determine the frequency of sexual dysfunction and analyze associated factors in patients with SLE.

**Methods:**
- A descriptive cross-sectional study was conducted. We included patients who attended the Rheumatology unit between May and July 2019; over 18 years of age, with a diagnosis of SLE according to the ACR 1997 and / or SLICC 2012 criteria, and healthy patients matched by age as control. Demographic and disease-related variables were studied. The DASS-21 (Depression Anxiety Stress Scale) scale that evaluates depression, anxiety and stress, and the Female Sexual Function Index (FSFI) that assesses 6 domains (desire, excitement, lubrication, orgasms, satisfaction and pain) were applied with a cut-off point ≤ 26.5 to define sexual dysfunction.
- Women over 50 years old, with secondary Sjogren’s syndrome, menopause, severe depression and illiterate patients were excluded.

**Results:**
- Of the 94 randomized patients, 89 completed study: 44 in the “conventional monitoring” arm and 45 in the “connected monitoring” arm. The total number of physical visits between baseline and 6 month was significantly lower in the “connected monitoring” group (0.42 ± 0.58 versus 1.93 ± 0.55; p<0.05). No differences between groups were observed in the clinical and functional scores.
- A better quality of life for SF-12 subscores (Role-Physical, Social-Functioning and Role-Emotional) were found in the “connected monitoring” group.

**Conclusion:** According to our results, a connected monitoring reduces the number of physical visits while maintaining a tight control of disease activity and improving quality of life in patients with RA starting a new treatment.

DEVELOPMENT OF THE ADVANCED PRACTICE NURSING CONSULT IN RHEUMATOLOGY IN THE MULTIDISCIPLINARY APPROACH OF INFLAMMATORY DISEASES MEDIATED BY IMMUNITY

A. Lopez Esteban1, 2, P. Morales de Los Ríos Luna1, P. Villalpando G2, A. López Calleja1, T. Del Río Blasco2, B. Villarrubia Martín2, S. Sánchez Vázquez2, C. Lobo Rodríguez1, 1Hospital General Universitario Gregorio Marañón, CEIMI, Madrid, Spain; 2Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Patients with immunity mediated inflammatory diseases (IMID) often have clinical manifestations and comorbidity in the field of various medical specialties. A center has been created in our hospital for the comprehensive care of patients with IMID. It is an innovative healthcare model, that incorporate patients into its governance. Physicians, pharmacists and advanced practice nurses (APN), collaborates in consultation or in the day hospital (DH).

Objectives: To analyze the activity of the rheumatology APN consult integrated in the multidisciplinary team, and the impact on health care and quality of life on IMID patients.

Methods: Descriptive study of the rheumatology APN activity since the opening of the center for a year. The APN consultations were face-to-face (scheduled or demanded) or by telephone. Variables measured: demography, diagnosis, treatments, clinic activity and patient reported outcomes (PRO). In the face-to-face consultation, was included: integral valuation (clinical, functional and psychosocial), education for Health (information about disease and treatments, adverse effects, healthy living habits), drug administration, emotional support. In the telephone consultation, the rheumatology APN is the reference professional for monitoring, question solving and advice in case of flare or adverse event.

Results: 721 patients were evaluated, mean age 54.6 years, (range, SD) (20-90, 13.9), 61.3% women, with a total of 1737 consults. Diagnosis: 324 (44.9%) RA, 221 (30.6%) SpA, 100 (13.9%) PsA and 76 (10.5%) other diseases. Treatment modality: IV 293 (40.4) SC 399 (55.3%) and oral 29 (4.0%). Rheumatology APN activities are described in Table 1. 1415 face-to-face consultation were made, 82.7% scheduled and 17.2% demanded either by the patient, the rheumatologist or another member of the multidisciplinary work-team. Among the face-to-face consultations, 62 (4.4%) patients were attended the same day in the medic consult due to disease flare or other disease problems, 38 (2.7%) patients were sent to another specialist of the work-team due to comorbidity. The activity executed in the rheumatology APN consultation is shown in Table 2.

HPR Interventions (educational, physical, social and psychological)

FRIDAY, 05 JUNE 2020

AN OLEUROPEIN-BASED DIETARY SUPPLEMENT IMPROVES JOINT FUNCTIONALITY IN OLDER PEOPLE WITH HIGH KNEE JOINT PAIN

M. N. Horcajada1, M. Beaumont2, N. Sauvageot2, L. Poquet1, M. Saboudjian1, A. C. Hick1, B. Costes4, L. Garcia4, Y. Henriet5, 1Nestle Research, EPFL Innovation Park, Lausanne, Switzerland; 2Nestle Research, Clinical Development Unit, Lausanne, Switzerland; 3Nestle Research, Clinical Development Unit, Lausanne, Switzerland; 4Artialis SA, Liège, Belgium; 5University of Liège, Liège, Belgium

Background: OLE provides oleuropein the most prevalent phenolic component in olive leaves and has been shown to have potent anti-inflammatory and anti-oxidant effects potentially interesting for joint health (1).

Objectives: The aim of this study was to investigate the effects of a 6-month intervention with an Olive Leaf Extract (OLE) standardized for oleuropein content on knee functionality and biomarkers of bone/cartilage metabolism and inflammation.

Methods: The study was a randomized, double-blind, placebo-controlled, multi-center trial of 124 subjects with mild knee pain or mobility issues. Subjects were randomized equally to receive twice a day one capsule of either maltodextrin (control treatment, CT) or 125-mg OLE (BonoliveTM, an Olive Leaf Extract containing 50mg of Oleuropein) for 6 months. The co-primary endpoints were Knee pain and Osteoarthrits Outcome Score (KOOS) using a self-administered questionnaire and serum Coll1-1NO2 specific biomarker of cartilage degradation. The secondary endpoints were each of the five sub-scales of the KOOS questionnaire, Knee painVAS score at rest and at walking, QARSI core set of performance-based tests and serum biomarkers (Coll2-1, MPO, C1X1, osteocalcin, PGE2 and Vplex cytokines assay in serum) and concentration of Oleuropein's metabolites in urine.

Results: Primary (global KOOS score, biomarker Coll1-1 NO2) and secondary endpoints (the five sub-scales of the KOOS score) improved time dependently in both groups. OLE treatment showed significantly elevated urinary oleuropein metabolites (oleuropein aglycone, hydroxyrosylosol, homovanillyl alcohol and isomer of homovanillyl alcohol), and was well tolerated without significant differences in number of subjects with adverse events. At 6 months, OLE group showed a higher global KOOS score compared to placebo (treatment difference = 3.73; 95% CI = [-4.08;11.54]; p = 0.34), without significant changes of inflammatory and cartilage remodeling biomarkers. Subgroup analyses demonstrated a large and significant treatment effect of OLE in subjects with high walking pain at baseline (14.4; 95% CI = [11.9;27.63], p=0.03). This was observed at 6 months for the global KOOS score and each different subscale and for pain at walking (-23.07;95% CI = [-41.8;4.2]; p < 0.02). These treatment effects at 6 months were significant for KOOS score as well as for the subscales Pain and QoL and the pain at walking.

Conclusion: OLE was not effective on joint discomfort in people with low to moderate pain at baseline but significantly benefited subjects with high pain at treatment initiation. As oleuropein is well-tolerated, OLE can be used to relieve knee joint pain and enhance mobility in subjects with articular pain the most painful subjects.

Background: L-arginine is of great importance in numerous biological procedures in human body, e.g. it participates in the urea cycle for detoxification of ammonia, and functions as a modulator in immune responses (1). Our previous investigation demonstrated that treatment with L-arginine reduced clinical symptoms, bone erosion and osteoclast numbers in serum-induced arthritis (K/BxN) (2). In addition, a decreased concentration of L-arginine has been observed in the serum of rheumatoid arthritis (RA) patients. Altogether, it is suggesting that L-arginine supplementation might be a potential treatment against RA.

Objectives: This study aims to investigate the treatment role of L-arginine supplementation in murine arthritis models. The project also plans to delineate the metabolic action of L-arginine supplementation during osteoclast differentiation in the presence of an inflammatory milieu.

Methods: Three murine arthritis models (serum-induced arthritis (K/BxN) model, collagen induced arthritis model and hTNFtg mice model) were applied in the presence or not of oral L-arginine supplementation. MicroCT and histomorphometry analyses were performed to quantify bone erosion and numbers of osteoclasts. In vitro osteoclastogenesis were performed in the presence or absence of TNFa stimulation. The L-arginine induced osteoclast differentiation inhibition is likely due to an alteration of the RANKL/RANK/Traf6 pathway. L-arginine also boosted the intracellular Dihydrolipoamide sulfurtransferase activity, indicating that L-arginine supplementation might be a potential treatment against RA.

Results: Arthritis severities were reduced after L-arginine supplementation in arthritis models. Moreover, an amelioration of bone erosion and reduced osteoclast numbers were observed in arthritic mice treated with L-arginine. In vitro treatment of L-arginine inhibited osteoclastogenesis, especially in the latent phase of the differentiation, even with exposure to TNFa stimulation. The L-arginine induced osteoclast differentiation inhibition is likely due to an alteration in the RANKL/RANK/Traf6 pathway. L-arginine also boosted the intracellular production of ATP and ROS, promoting mitochondria-driven oxidative phosphorylation (OXPHOS), leading to the failure of activation and even death of the osteoclasts.

Conclusion: These data strongly suggested that L-arginine ameliorates bone erosion in RA through the inhibition of RANKL/RANK/Traf6 pathway as well as reprogramming of the cellular metabolism during osteoclastogenesis. The immunomodulation action of L-arginine might therefore help to reduce joint inflammation and destruction in RA.

INCREASED M1 INFLAMMATORY PHENOTYPE OF CIRCULATING MONOCYTES IS ASSOCIATED WITH HISTORY OF CARDIOVASCULAR EVENTS IN RA PATIENTS

A. Goecke1, C. Karasulovic1, J. Guerrero2, F. Tempić3, M. Lopez1
1University of Chile Clinical Hospital, Rheumatology, Santiago, Chile; 2Faculty of Medicine, University of Chile, Physiology, Santiago, Chile; 3Faculty of Medicine, University of Chile, Immunology, Santiago, Chile

Background: Cardiovascular (CV) Disease is the main cause of death in Rheumatoid Arthritis (RA). Current tools like Framingham or European SCORE underestimate CV risk in RA patients. Efforts to improve the assessment including RA biomarkers (disease activity) have been only partially successful. There is a need for better biomarkers to identify AR patients at high risk for CV disease. Monocytes have an important role in plaque development. Monocytes differentiate into 2 main phenotypes M1 and M2. In RA and in post-MI patients M1 monocytes are expanded (2). mTORC influences monocyte phenotype in vitro and has been associated with development of atheromatous plaque (3).

Objectives: To evaluate the phenotype of circulating monocyte in RA patient with or without previous CV events (RA-CV)(RA-CV-), and its possible association with mTORC activity.

Methods: 9 RA-CV(+)-patients aged between 18 and 65 yo with RA (EULAR/ACR 2010 criteria), were paired with RA-CV(-)-patients. 6 healthy individuals (H) were also studied. Pairing criteria were classic CV risk factors (AHA 2018), sex, age, years since RA diagnosis, comorbidities, number of DMARDs previously used and use of bDMARDS. M1 and M2 circulating Monocytes were evaluated in PBMC obtained from patients and controls by flow cytometry analysis. Intracellular inflammatory cytokines (IL1, IL6) and phosphorylated S6R (P-S6R) as a measure of mTORC activation was also evaluated. M1 was defined as CD14+HLA-DR+CCR2+ and M2 CD14+CD163+CCR2-. DAS28-RC, DAS28-ESR and Lipid profile was also measured. The differences among groups was analysed using Mann–Whitney U nonparametric. The relationship between variables with Spearman rank correlation test.

Results: There were no differences in demographic, RA characteristic and CV risk factors between RA-CV (+) and RA-CV (-) patients. Male/Female 4/5, age 62±3 and 63±2 respectively. HI were younger than RA patients (32.5±7). CV events were 8 patients with MI and one Stroke. DAS28-RCP was 2.96±0.23 and 2.88±0.43 respectively. One patient in each group had failed to more than 2 sDMARDs.

</table>

Conclusion: In this prospectively followed cohort of ACA-P+ subjects, higher levels of RF-IgM and RF-IgA at baseline were significantly associated with development of IA/RA within the follow-up period. Furthermore, there was a trend for rising levels of anti-CCP3 and RF-IgM and A to be associated with development of IA/RA. These finding support the use of higher and/or rising levels of autoantibodies as additional features to predict imminent onset of IA/RA in ACA-P+ individuals as well as potentially to use as outcomes of success of preventive interventions. Furthermore, the trend of increasing levels of RF-IgM and RF-IgA over time in individuals who developed IA/RA suggests that targeting pathways of RF development may lead to preventive interventions in a subset of RA.

References: None

and one in each group was receiving bDMARD. M1 circulating monocytes were expanded in RA as compared to HI. This difference was at RA-CV (+) expense. RA monocytes had higher intracellular levels of IL-1β and IL-6 as compared to HI. M1 from RA-CV (+) had higher intracellular levels of IL-1β and IL-6 than RA-CV (-). M1 monocytes have higher levels of inflammatory cytokines than M2, P-S6R protein, (mTORC activation), was higher in RA patients than HI. The highest levels of P-S6R was observed in M1 monocytes from RA-CV (+) population.

**FIGURE 2.** Circulating monocytes phenotype, intracellular cytokines and phosphorylated S6R in HI and RA-CV (+), RA-CV (-) and the combined RA patients.

A) *=0.02; B) *=0.016; C) ****=0.001; *0.002; D) ****=0.001, **=0.008, *=0.001, **=0.01; E) ****=0.001, **=0.002; F) ****=0.001, **=0.01, ***=0.003.

**Conclusion:** RA-CV+ patients, have a significantly higher number of pro-inflammatory circulating monocytes, using a multiparametric classification method. These monocytes also express higher levels of inflammatory cytokines and higher activation of mTORC, which also participate in the development of atheromatous plaque, suggesting that these monocytes could be a key element in the non-clarified-yet, excess of CV risk of RA patients.

**INHIBITION OF HEPATOCYTE GROWTH FACTOR-C/ MET SIGNALING ABRIDGES JOINT DESTRUCTION BY SUPPRESSING MIGRATION OF MONOCYTES TO SYNOVIA IN RHEUMATOID ARTHRITIS**

M. Hosonuma1,2,3, N. Sakai2,3, H. Funaya1, Y. Tesubokura1, S. Nishimi1, Y. Ikar1, S. Ishii1, A. Maeoka1, T. Tokunaga1, K. Wakabayashi1, T. Kasama1, M. Takami1,2, I. Isonokai1. Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan; Showa University School of Dentistry, Department of Pharmacology, Tokyo, Japan; Showa University School of Medicine, Pharmaceutical Research Center, Tokyo, Japan

**Background:** Hepatocyte growth factor (HGF), originally discovered as a mitogen of hepatocytes, binds to receptor-tyrosine kinase c-Met and has been shown to be a multi-functional cytokine that promotes processes such as cell proliferation, survival, differentiation, migration, and angiogenesis. Since HGF/c-Met signaling also leads to tumorigenesis and cancer invasion, that has recently attracted attention as a target for anticancer agents. However, in reports of rheumatoid arthritis (RA), though anti-inflammatory and antiangiogenic mechanisms related to HGF/c-Met signal inhibition have been reported, the role of HGF in RA bone destruction through monocyte migration remains unclear.

**Objectives:** To determine the expression of HGF in RA biological fluids, the role it plays in monocyte migration and the therapeutic effect of a savolitinib, a specific c-Met inhibitor, in arthritis model mice.

**Methods:** HGF/c-Met expression in serum, synovial fluid (SF), and synovial tissues (STs) obtained from RA patients and control subjects, as well as RA fibroblast-like synoviocytes (FLSs) was evaluated by ELISA and immunostaining. To determine the function of HGF in RA SFs, we preincubated RA SFs with a neutralizing anti-HGF antibody and measured the ability of these SFs to induce the human acute monocytic leukemia cell line (THP-1) chemotaxis. Additionally, examinations of SKG mice treated with savolitinib (2.5 mg/kg/day) for 4 weeks were conducted.

**Results:** HGF level in serum from RA patients was significantly higher as compared to the controls (930 ± 97 vs. 476 ± 97 pg/mL, p <0.01) and decreased by drug treatment for 2 weeks (1147 ± 284 vs. 539 ± 160 pg/mL, p <0.05). Additionally, HGF level in SF from RA patients was higher as compared to SF from osteoarthritics patients (1632 ± 366 vs. 566 ± 140 pg/mL, p <0.05). HGF and c-Met expressions were also noted in RA STs. Stimulation of RA-FLS with TNF-α increased HGF/c-Met expression in a concentration-dependent manner, and c-Met signal inhibition by SU1274 suppressed production of fractalkine/ CX3CL1, CXCL16, and MIP-1α/CCL3 (mean 50%, 56%, 50%, respectively). When HGF was removed by immunoprecipitation, migration of TNF-α in RA-SF was suppressed (mean 23%). In SKG mice, savolitinib significantly suppressed ankle bone damage on µCT, with an associated reduction in number of tartrate-resistant acid phosphatase-positive osteoclasts.

**Conclusion:** HGF is produced by inflammation in synovium associated with RA, and then activates monocyte migration to synovium tissue and promotes bone destruction through its own chemotactic effect as well as enhanced chemokine production. These results indicate that a strategy that targets c-Met signaling may be important for resolving bone destruction in RA.

**Background:** Blocking of the Tumor Necrosis Factor (TNF) activity is a successful therapeutic approach for 2 out of 3 Rheumatoid Arthritis patients. Identifying the patients that will not respond to this therapeutic approach is a major translational goal in RA. Association of seropositivity to rheumatoid factor (RF) or anti-cyclic- citrullinated antibodies (anti-CCP) with anti-TNF response has proven inconclusive, suggesting that other yet unexplored biomarkers could be more informative for this goal.

**Objectives:** We tested the association of two recently introduced biomarkers in RA: anti-carbamylated protein antibodies (anti-CarP) and anti-peptidylarginine deiminase type 4 (anti-PAD4).

**Methods:** A prospective cohort of n=80 RA patients starting anti-TNF therapy were levied and levels for four autoantibodies -RF, anti-CCP, anti-CarP and anti-PAD4- were measured at baseline. The change in DAS28 score between baseline and week 12 of therapy was used as the clinical endpoint.

**Results:** Single marker-analysis showed no significant association with drug response. However, when testing for interactions between autoantibodies, we found highly significant association with drug response. Anti-CarP and anti-PAD4 showed a positive interaction with the response to anti-TNF therapy (P=0.00068), and anti-PAD4 and antiCarP titers showed a negative interaction with the clinical response at week 12 (P=0.0062). Using an independent retrospective sample
Background: Histamine-releasing factor/transiently controlled tumor protein (HRF/TCTP) stimulates cancer progression and allergic responses. Increased expression of HRF/TCTP occurs in joints of rheumatoid arthritis (RA) patients, but the role of HRF/TCTP in RA remains undefined.

Objectives: In this study, we explored the pathogenic significance of HRF/TCTP and evaluated therapeutic effects of HRF/TCTP blockade in RA.

Methods: HRF/TCTP transgenic (TG) and knockdown (KD) mice with collagen-induced arthritis (CIA) were used to determine experimental phenotypes of RA. HRF/TCTP levels were measured in sera and joint fluids in patients with RA and compared to those with osteoarthritis, ankylosing spondylitis, Behçet disease, and healthy controls. HRF/TCTP expression was also assessed in synovium and fibroblast-like synoviocytes (FLS) obtained from RA or OA patients. Finally, we assessed effects of HRF/TCTP and dimerized HRF/TCTP binding peptide-2 (dTBP2), an inhibitor of HRF/TCTP, in RA-FLS and CIA mice.

Results: Our clinical, radiological, histological, and biochemical analyses indicated that inflammatory responses and joint destruction were increased in HRF/ TCTP TG mice, and decreased in KD mice compared to wild-type littermates. HRF/TCTP levels were higher in sera, synovial fluid, synovium, and FLS of patients with RA than in control groups. Serum levels of HRF/TCTP correlated well with disease activity in RA. Tumor-like aggressiveness of RA-FLS was exacerbated by HRF/TCTP stimulation and ameliorated by dTBP2 treatment. dTBP2 exerted protective and therapeutic effects in CIA mice, and had no detrimental effect in a murine tuberculosis model.

Conclusion: Our results indicate that HRF/TCTP represents a novel biomarker and therapeutic target for diagnosis and treatment of RA.

INDIVIDUAL FUNCTIONS OF THE HISTONE-ACETYLTRANSFERASES CBP AND P300 IN REGULATING THE INFLAMMATORY RESPONSE BY AFFECTING HISTONE ACETYLATION AND mRNA STABILITY

M. Krošel1, 2, M. Gabathuler3, K. Walker2, M. Tomsic1, O. Distler2, C. Ospelt2, K. Keßler1

1Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia; 2Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland

Background: Prolonged TNF-induced H3K27 acetylation (H3K27ac) and increased mRNA stability in rheumatoid arthritis (RA) synovial fibroblasts (SF) are leading to a sustained inflammatory response. Underlying enzymes coordinately regulating these pathways have not been identified so far. The histone acetyl transferases cAMP-response element binding protein binding protein (CBP) and p300 are writers of activating H3K27ac marks and close homologues with widely accepted redundant functions.

Objectives: To analyze individual functions of CBP and p300 in regulating the inflammatory response of SF.

Methods: SF were isolated from patients with RA undergoing joint replacement surgery. The expression of CBP and p300 was silenced by transfection of antisense LNA gapmeRs (12.5nM). SF were stimulated with TNF (10ng/ml) for 24h, Actinomycin D (10 μg/ml) was added 4h after TNF-treatment for 2h and 4h (n=9) to test mRNA stability. Transcriptomes were determined by RNA-seq (Illumina NovoSeq 6000, n=6). We mapped raw reads from RNA-seq reference genome using STAR. Counts for genes were obtained using Feature counts. We searched for differential expression genes (DEG) across experimental conditions using general linear models (glm) implemented in edgeR package of R. Significantly affected genes (a fold change > 1,5, FDR < 0,05, top 3000 genes included) entered pathway enrichment analysis for Gene Ontology (GO) biological process, and KEGG pathways in DAVID. Changes in the mRNA (n=12-14), and protein expression (n=6-12) were confirmed by quantitative Real-time PCR and ELISA. The levels of activating histone marks H3K27ac and nuclear localization of p50 and p65 were analyzed by Western blotting.

Results: DEG revealed that silencing of p300 affected the expression of 6026 and 5138 genes in unstimulated and stimulated SF, respectively. In contrast, only 285 and 1911 genes were affected by CBP silencing in unstimulated and stimulated SF, respectively. In TNF-stimulated SF, pathway enrichment analysis of DEG revealed a key role of CBP in regulating the “type I interferon signaling pathway” (p=2.12x10^-10). Both, silencing of CBP and p300 regulated genes enriched in the “TNF signaling pathway” (CBP: p=0.005; p300: p=0.031). In contrast to CBP silencing that had anti-inflammatory effects, silencing of p300 had pro-inflammatory effects. ELISA experiments suggested that silencing of CBP reduced the secretion of the IL6 (p<0.01), CCL2, CXCCL1 (p<0.05), and CXCCL12 (p<0.001). Silencing of p300 reduced the secretion of CCL2 (p<0.001) and CXCCL3 (p<0.05) but increased the expression of IL8 (p<0.001) and CXCCL2 (p<0.05). Western blotting revealed that neither CBP nor p300 silencing affected the nuclear expression of the NF-κB subunits p50 and p65. Silencing of p300 reduced the levels of H3K27ac by 30% in unstimulated SF, and by 61.4% (p<0.03) in presence of TNF in addition to regulating H3K27ac. Silencing of p300 regulated the expression of TNF-induced cytokines by increasing the mRNA stability of IL8, IL6 and CCL2 mRNA but not of CXCL2. Silencing of CBP reduced H3K27ac by 43.5% only in presence of TNF and did not affect TNF-induced mRNA stability of cytokines. This is in line with the enrichment of the GO biological process “regulation of mRNA stability” (p=2.61x10^-10) being enriched only after silencing of p300.

Conclusion: Our results suggested that p300 is the major writer for H3K27ac marks in SF. Additionally, p300 regulated cytokine expression by affecting mRNA stability in a target-specific manner. We identified overlapping and distinct functions for CBP and p300 in regulating the inflammatory response of SF.

DOI: 10.1136/annrheumdis-2020-eular.3244
Conclusion: Levels of IL-6 and TNF-α were decreased in EC-18-treated mice, whereas the incidence rate in EC-18-treated mice was 17%. Furthermore, fibrosis severities in the curdlan-administered mice, which were attenuated in EC-18 treated bronchial alveolar tissue damage and massive leukocyte infiltration, and fibrosis. Histological analysis showed severe pulmonary destruction, including 8 weeks post-injection and remained unchanged thereafter. At 20 weeks post-injection, lung sections were stained with H&E and Masson’s trichrome. Using the Opal method, multiplexed immunofluorescent staining of lung tissue was performed. According to the scale by Ashcroft et al., fibrosis severities of lung sections was assessed by a system of eight grades. Analysis of serum cytokines by the luminex multiplex cytokine assay was performed at 20 weeks post-injection.

Results: Oral administration of EC-18 decreased arthritis score significantly until 20 weeks post-injection and remained unchanged thereafter. At 20 weeks post-injection, histological analysis showed severe pulmonary destruction, including bronchial alveolar tissue damage and massive leukocyte infiltration, and fibrosis in the curdlan-administered mice, which was attenuated in EC-18 treated mice. In particular, 67% of curdlan-administered mice showed ILD-like phenotype, whereas the incidence rate in EC-18-treated mice was 17%. Furthermore, immunofluorescent-staining showed both IL-17A and neutrophil accumulation in lung and curdlan-administered mice; these were decreased in EC-18-treated mice. Interestingly, at 20 weeks post-injection, EC-18 treatment down-regulated serum levels of IL-6 and TNF-α and up-regulated sIL-7R (anti-fibrotic molecule).

Conclusion: Taken together, EC-18 exerts an anti-arthritis effect in early phase, but a long-term effect was not indicated. We emphasize the effect on ILD prevention of EC-18 via up-regulation of sIL-7Rα and inhibition of neutrophil accumulation, suggesting a therapeutic agent potentially for RA-ILD.

ANTI-CD30 IMMUNOTHERAPY AMELIORATES BONE AND CARTILAGE DESTRUCTION IN EXPERIMENTAL MODEL OF RHEUMATOID ARTHRITIS IN MICE

M. Matsuhashi1, K. Nishida1, Y. Nasu1, R. Nakahara1, M. Watanabe1, Y. Hotta1, T. Ozaki1. 1Department of Orthopaedic Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan

Background: CD30 is a member of the TNF-receptor family and commonly expressed on lymphocytes of Hodgkin lymphoma and anaplastic large cell lymphoma. It has been reported that levels of soluble CD30 in serum and joint fluid is significantly elevated in rheumatoid arthritis (RA). Although RA patients may develop lymphoproliferative disorders (LPD) as a result of immunosuppression by MTX or bDMARDs, safety medications after the regression of LPD for RA have not yet been established.

Objectives: To explore the potential of CD30 targeting therapy for RA.

Methods: (1) Immuno-histological staining of CD30 was performed for fresh synovial tissues of RA and osteoarthritis (OA). In addition, double immunofluorescence staining of CD30 with CD3, CD20, CD68, CD138 were performed on RA synovial tissue. (2) Brentuximab vedotin (BV) is an anti-CD30 antibody conjugated with monomethyl auristatin E, designed to induce apoptosis of CD30 expressing cells. A multiple myeloma cell line (RPMI8226) was used as a non-lymphoma cell line and plasma cell-like cell line. Immunocytological staining of CD30 was performed on RPMI8226. Cells were cultured and harvested on days 0, 1, and 3 to evaluate the effects of BV (50 μM / ml per well). Cytosin pin specimens were stained by May-Grünwald-Giemsa (MGG) staining for cell counting and by FITC-terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) staining for detection of apoptosis. (3) Collagen antibody induced arthritis (CAIA) was induced in DBA/1 mice by arthritogenic cocktail of monoclonal antibodies against type II collagen. BV was administered to the treated groups (30mg/kg and 70mg/kg n=4 each) and evaluated clinical score, histological findings and levels of SAA, IL-6, and TNFα in serum by ELISA. Student’s t-test (two-tailed) was used to determine statistical significance for analysis of synovial tissues and cell line assay. Two way ANOVA with Dunnett’s post hoc analysis was used for multiple comparisons of mice model.

Results: (1) The number of CD30-positive cells was significantly higher in RA synovial tissue than in OA synovial tissue (p<0.01) (Fig. 1). CD30-positive cells were detected around the lymphoid follicles. Double immunofluorescence showed CD30 and CD138 double-positive cells in the synovial tissue of RA, suggesting CD30 is predominantly expressed by plasma cells. (2) RPMI8226 cells expressed CD30, BV caused apoptosis of RPMI8226 cells, and the number of cells treated with BV decreased to 95% compared to controls. (3) All control mice (n=4) developed severe arthritis, and their scores reached a peak (score: 13.3) on day 10. In the mice of treatment group of 30mg/kg, paw swelling was slightly decreased, their clinical score reached a peak (score: 9.3) on day 10. In contrast, paw swelling was significantly reduced in the 70mg/kg treatment group. The peak of the clinical score was 4.3 on day 10 (Fig.2). Histological score evaluated synovitis with infiltration of inflammatory cells, pannus formation, and erosion of bone and cartilage. Histological score of hind paws were 3.0 ± 0.8 for the control group, 2.7 ± 1.0 for 30mg/kg group, and 0.7 ± 1.1 for 70mg/kg group (p<0.01), respectively. The serum levels of SAA and IL-6 of treatment group were lower than those of no treatment group (p<0.01).

Conclusion: We showed the expression of CD30 on synovial tissue of RA and the expression of CD30 on plasma cells. In addition, the current study provides the first evidence that BV depletion of CD30-positive cells suppressed arthritis and osteochondral destruction in CAIA mice. Our results may provide an important clue for the development of an effective treatment for RA with iatrogenic immunodeficiency-related LPD.

suppresses RA-FLS proliferation (1). However, glutaminolysis has been known to suppress autophagy by activating mTORC1 or counteracting ROS production (2). Given the possibility of autophagy upregulation following glutaminolysis inhibition, therapies targeting both autophagy and glutaminolysis may be more effective in suppressing cell growth of RA-FLS, yet the relation between glutaminolysis and autophagy in RA-FLS has not been investigated.

**Objectives:** To examine the effects of inhibiting both glutaminolysis and autophagy on RA-FLS and autoimmune arthritis in SKG mice.

**Methods:** GLS1 inhibitor, compound 968 (C968), was used to suppress glutaminolysis, and Chloroquine (CQ) was used to inhibit autophagy. To detect autophagy, the expression of ATG5 and LC3B was measured by real-time PCR and the production of LC3-II was analyzed by Western blotting. The formation of autophagic vacuoles was identified by immunofluorescence. Cell growth was evaluated by BrdU assay. Apoptosis was analyzed by flow cytometry staining with Annexin V-FITC and PI. C968 and CQ were administered subcutaneously to Zymosan A-injected SKG mice.

**Results:** C968 upregulated the expression of ATGS and LC3B, and increased the protein level of LC3-II in RA-FLS. C968 also facilitated autophagosome formation. These results suggested that inhibition of glutaminolysis promoted autophagy in RA-FLS. The combined treatment with C968 and CQ significantly suppressed cell proliferation of RA-FLS more strongly than did C968 or CQ alone. In addition, C968 combined with CQ increased the apoptosis rate, whereas either C968 or CQ alone did not. Furthermore, combination of C968 and CQ significantly attenuated the degree of arthritis in SKG mice, while C968 or CQ monotherapy did not (Figure).

**Methods:** We investigated the reactivity of autoantibodies in plasma pools from 15 anti-CCP positive and 10 anti-CCP negative RA patients and 10 healthy donors against more than 1600 human proteins in native configuration using the Immunome high-density protein microarray.

**Results:** We identified 86 native proteins that were recognized by IgG antibodies from anti-CCP positive RA patients and 76 native proteins recognized by IgG antibodies from anti-CCP negative RA patients, but not by antibodies from healthy donors. Examples of proteins recognized by both patient subgroups are calcium/calmodulin-dependent protein kinase type II subunits, histone deacetylases, keratin, and vimentin. Reactivity against the ribonucleic protein SSB was observed in anti-CCP negative RA patients only.

**Conclusion:** Several human proteins in their native conformation are recognized by autoantibodies from anti-CCP positive as well as anti-CCP negative RA patients. In general, anti-CCP positive patients had higher autoantibody activity than anti-CCP negative patients and healthy donors.

**Background:** The majority of patients with rheumatoid arthritis (RA) produce autoantibodies against proteins that have undergone post-translational modification, e.g. citrullination or carbamylation. There is growing evidence of their relevance and their potential utility to improve diagnosis, patient stratification, and prognosis for precision medicine. Investigating new autoantibody patterns may allow further stratification of patients and identifying subsets of patients that benefit from different treatment modalities. Following the discovery of high autoantibody reactivity against multiple modified proteins the interest in native targets decreased. Even though antibodies reacting with native proteins may also have a role in RA pathogenesis, their reactivity patterns are much less studied.

**Objectives:** To identify novel native autoantigens in RA patients and elucidate patterns within autoantibody reactivity against native autoantigens.

**Conclusion:** The GLS1 inhibitor C968 promotes autophagy in RA-FLS. C968 in combination with CQ reduces proliferation and enhances apoptosis in RA-FLS, and ameliorates the arthritis in SKG mice. Suppressing C968-induced autophagy may be a promising therapy for arthritis.

**PIM-1 KINASE IS A MEASURABLE MEDIATOR OF CD4+ T CELL DYSREGULATION AND THERAPEUTIC TARGET IN EARLY RHEUMATOID ARTHRITIS**

N. Maney1, H. De Paula-Lemos1, B. Barron-Millar1, A. Mellor1, J. D. Isaacs1, A. Anderson1, A. Pratt1, 2. *Newcastle University Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom; 3. Musculoskeletal Services Directorate, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*

**Background:** As well as being an established oncprotein and a therapeutic target in cancer, Proimal Integration site for murine Moloney leukemia virus-1 (pim-1) has been implicated in human autoimmunity. We previously confirmed this serine-threonine protein kinase to be strikingly upregulated in circulating CD4+ T cells of untreated rheumatoid arthritis (RA) patients as a consequence of IL-6 signalling1-2. Evidence for the relevance of pim-1 signalling in the disruption of RA synovial fibroblast (RASF) homeostasis2 further supports its candidacy as a therapeutic target.

**Objectives:** To investigate PIM1 and its family members (PIM2 and PIM3) as potential candidates for drug repurposing in RA.

**Methods:** A flow cytometric assay for PIM1 transcript measurement in circulating CD4+ T cells of early arthritis patients was validated against real-time PCR in paired cells isolated by bead selection. Synovial protein expression in tissue from the same cohort of untreated RA patients and disease controls was determined by quantitative multiplex immunofluorescence. The functional consequences of manipulating pim kinase family expression in freshly purified CD4+ T cells (TGF-β treated) and CD4+ T cells from early RA patients and explored. The impact of pim-1 specific and pim-1-3 (pan-pim) kinase inhibition on progression of the IL-6 dependent collagen-induced arthritis (CIA) model was assessed.

**Results:** The percentage of circulating CD4+ T cells positive for PIM1 transcript by flow cytometry proved a faithful surrogate for gene expression in early arthritis (Figure 1A), distinguishing RA from other pathologies (Figure 1B). Pim-1 protein expression was increased in the synovium of untreated RA compared with disease controls, including amongst infiltrating CD4+ T cells.

**Acknowledgments:** The Department of Clinical Immunology at Rigshospitalet Copenhagen is acknowledged for providing the healthy donor blood. The study is part of the PROCIT study financed by the Danish Council for Independent Research (grant no. DFF - 7016-00233). (Figure 1C-D). *In vitro*, exposure of TCR-stimulated early RA CD4+ T cells to pim kinase inhibitors restrained their activation and proliferative capacity; diminished pro-inflammatory cytokine production (IFN-γ and IL-17) and an expanded CD25+Foxp3+ regulatory T cell (Treg) fraction were also observed in treated versus un-treated cells. Finally, administration of pim inhibitors robustly attenuated clinical scores of arthritis in the CIA model, with reduced cartilage loss observed in animals treated with a pan-PIM inhibitor compared with vehicle control (Figure 2).

**Experimental and Observational Rheumatology Unit, Santiago de Compostela, Spain**

**Background:** Fibroblast-like synoviocytes (FLS) are pivotal in inflammation and joint damage of rheumatoid arthritis (RA). These cells acquire an aggressive and invasive phenotype and secrete inflammatory mediators, metalloproteases and cathepsins that perpetuate inflammation and lead to cartilage and bone damage. We have previously shown that non-canonical Wnt/β-catenin pathway is involved in the aggressive phenotype of FLS by increasing their migration and invasion ability, and by stimulating the inflammatory response. The non-canonical Wnt signaling pathway included the planar cell polarity (PCP), through Rho-ROCK pathway and the activation of MAPKs, ERK and P38, as well as the activation of AKT and GSK3β.

**Objectives:** To elucidate the therapeutic potential of the ROCK inhibitor (Y-27632) in the K/BxN serum transfer arthritis model.

**Methods:** Two groups of C57BL/6J mice were used, in the control group, mice were treated with physiological serum and in the experimental group with a ROCK inhibitor (Y-27632). Arthritis was induced by intraperitoneal injection of 100 µl of K/BxN serum on days 0 and 2. In the experimental group, mice were treated with intraperitoneal injections of 10 mg/kg from day 0 until sacrifice, on day 10. Control mice were treated with the same volume of physiological serum. Arthritis was assessed by two observers using a semiquantitative clinical score. For histological analysis, it was decided to obtain the right ankle joints and foot. Mice were fixed in formalin for 6h and were decalcified and embedded in paraffin. Sections were stained with hematoxylin and eosin (H&E) and toluidine. Finally, total RNA was obtained from wrist and ankle joints of mice and the expression of inflammatory mediators and metalloproteases was analyzed by real-time PCR.

**Results:** Arthritis was induced in C57BL/6J mice, which were treated with Y-27632 (ROCK inhibitor) or with physiological serum. The incidence of arthritis was 100% in both groups of mice and there were no differences in the course of the disease. Clinical score was significantly lower in the Y-27632-treated mice, all along the follow-up, compared with controls. Similar results were observed in the histological analysis. We also analyzed the effect of ROCK inhibitor on the inflammatory response of K/BxN serum-transfer induced arthritis. This analysis revealed that expression of IL6, IL1α, CXCL1, MMP3, MMP9 and MMP13 were significantly decreased in Y-27632-treated mice compared with control mice. In addition, TNF and NOS2 expression was reduced in Y-27632-treated mice to reach the same levels that observed in C57BL/6J mice without arthritis.

**Conclusion:** These results indicate that the inhibition of the Rho-ROCK pathway decreases the severity of arthritis in the K/BxN serum transfer model, and point to ROCK as potential therapeutic target for RA. Supported: ISCIII / PI17 / 01660.

**DEVELOPMENT OF FIBROBLAST-LIKE SYNOVOCYTE ASSAYS FOR TARGET DISCOVERY IN RHEUMATOID ARTHRITIS**

D. Ruelas1, C. Chen1, H. Truong1, V. Lira1, Y. Moazami1, K. Currie1, J. A. Di Paolo1, H. Yu1, G. Min-Oo1. 1Gilead Sciences, Inc., Foster City, United States of America

**Background:** The rheumatoid arthritis (RA) synovium is characterized by an overabundance of fibroblast-like synoviocytes (FLS), which play a central role in the initiation and perpetuation of disease via multiple mechanisms. 2 FLS promote disease progression by producing high levels of proinflammatory factors, recruiting immune cells and invading cartilage and bone, and promoting self-proliferation and resistance to apoptosis. Our current understanding of the molecular mechanisms that govern FLS-mediated pathology in the synovial joint remains incomplete. Importantly, almost 30% of treatment-naïve early RA patients exhibit a strong fibroid phenotype that correlates with relatively poor response to disease-modifying anti- rheumatic drugs. 3 Yet, current therapies in RA are not directly aimed at FLS pathology, creating an opportunity for novel therapeutic target discovery.

**Objectives:** We develop a broad suite of screening assays in RA patient-derived FLS for the discovery of target pathways that control multi-pathological properties, including cytokine secretion, migration, and invasion.

**Methods:** A sensitive high-throughput RA-FLS secretion assay was developed to examine the ability of small-molecule inhibitors to block the production of interleukin (IL)-6 and matrix metalloproteinase (MMP)-3 in response to stimuli. To create a physiologically relevant stimulus, a surrogate synovial fluid cocktail (composed of 12 factors) was defined and titrated for optimal concentration selection. Small-molecule inhibitors (N=170) of diverse biological pathways were screened using the full cocktail or individual stimulation (TNFα, IL-1α, or IL-17) to characterize assay performance. In addition, an FLS platelet-derived growth factor (PDGF)-mediated migration screening assay was developed using a live cell imaging system (Incucyte) to quantify real-time FLS migration.

**Results:** Due to the variability and limited volume of synovial fluid, we developed a surrogate synovial fluid cocktail to mimic the relevant stimulation of RA-FLS in the inflamed joint. The surrogate cocktail was composed of 12 factors: TNFα, IL-1α, IL-17, IFNγ, OSM, IFN, GM-CSF, IP-10, VEGF, PDGF, AREG, and FGF2. Individual titration of these factors demonstrated that only 3 stimulatory factors (TNFα, IL-1α, and IL-17) resulted in a robust increase of IL-6 production. Importantly, when all 12 factors were combined, a synergistic increase in IL-6 and MMP-3 production by FLS was observed. Screening results identified several reference compounds, including an inhibitor of transforming growth factor-β-activated kinase 1 (TAK1), that was previously reported to block cytokine secretion in FLS. 4 Treatment with this compound showed complete inhibition of IL-6 and MMP-3 secretion. In addition to the cytokine secretion assay, treatment of FLS with this TAK1 inhibitor resulted in almost complete inhibition of migration (Fig. 1).

**Conclusion:** Novel FLS assays were developed to discover new targets and interrogate pathways involved in multiple disease-driving mechanisms of FLS in RA. In order to mimic the inflammatory environment present in the RA synovium, we developed a 12-factor surrogate synovial fluid cocktail. A synergistic release of both IL-6 and MMP-3 was demonstrated following cytokine stimulation compared to individual cytokines. This points to the important contribution that multiple factors play in the FLS pathogenic processes and will allow us to uncover pathway interactions that may not be captured with single stimuli. In addition, the development of a real-time, 96-well, imaging-based assay to interrogate FLS migration allows us to identify targets that control this critical pathological function of FLS.

**METABOLIC CHANGES INDUCED BY ANTI-MALONDIALDEHYDE/MALINDIALDEHYDE-ACETALDEHYDE ANTIBODIES PROMOTE OSTEOCLAST DEVELOPMENT**

K. Sakuraba1,2, A. Krishnamurthy1, A. Circiumaru1, M. Sun1, V. Joshua1, M. Engström1, X. Zheng1, C. Xu1, K. Amana1, V. Malmström1, S. B. Catrina1, C. Griswold1, B. Réthi1, A. Catrina1, 1Karolinska Institute, Department of Medicine, Rheumatology Unit, Stockholm, Sweden; 2National Hospital Organization Kuyasu Medical Center, Department of Orthopaedic Surgery, Fukuoka, Japan; 3Karolinska Institute, Molecular Medicine and Surgery, Stockholm, Sweden

**Background:** Malondialdehyde (MDA) is a highly reactive compound produced by lipid-peroxidation in situations associated with oxidative stress. MDA can irreversibly modify proteins residues such as lysine, arginine and histidine. In addition, MDA adducts can further react with acetaldehyde to generate malondialdehyde-acetaldehyde (MAA) modifications. Such modifications can give rise to immunogenic neo-epitopes that are recognized by autoantibodies. In fact, anti-MAA IgG antibodies are significantly increased in the serum of patients with autoimmune diseases, such as rheumatoid arthritis (RA) (1) and systemic lupus erythematosus (2). Recently, we have shown that anti-MAA/IgG antibodies are able to promote osteoclast (OC) differentiation in vitro (1).
**Objectives:** To investigate the molecular mechanisms triggered by anti-MDA/MAA autoantibodies during osteoarthritis.

**Methods:** OCs were generated from monocyte-derived macrophages in the presence of the cytokines TNF-α, IL-1β, and M-CSF. A development of OCs was monitored by light microscopy following tartrate-resistant acid phosphatase (TRAP) staining and erosion area on synthetic calcium phosphate-coated plates. Three different recombinant human monoclonal anti-MDA/MAA antibodies, cloned from single synovial B cells of RA patients, control antibodies and Fab fragments of the antibodies were added to OC cultures. Glycolysis was inhibited by 2-deoxyglucose, and Fc-gamma receptor I or II by anti-CD64 or anti-CD16 neutralizing antibodies. IL-6 levels were measured by enzyme linked immunosorbent assay. Cellular metabolism was monitored using Seahorse XF Analyzer (extracellular acidification rate and oxygen consumption) and a colorimetric L-Lactate assay.

**Results:** Lactic acid production correlated with the osteoarthritis genetic effect of some but not all anti-MDA/MAA antibodies on OCs. A-β-AR antagonist, was added to the drink of mice receiving SNS. In addition, control groups were treated with placebo, or anti-MDA/MAA antibodies or control antibodies. The glycolysis inhibitor 2-deoxyglucose completely abolished the osteoarthritis genetic effect of the anti-MDA/MAA antibodies at drug concentrations that did not influence the baseline OC development. Fab fragments of the osteoarthritis genetic effect of the anti-MDA/MAA antibodies had no effect on OC development and metabolism. In accordance with this, Fc-gamma receptor I neutralizing antibodies completely abolished the osteoarthritis genetic effect of the anti-MDA/MAA antibodies. The osteoarthritis genetic effect of the anti-MDA/MAA antibodies was independent of IL-8 production. In contrast to anti MDA/MAA antibodies, ACPA-mediated osteoarthritis was independent of glycolysis and Fc-gamma receptors but dependent on IL-8.

**Conclusion:** Our results describe a novel glycolysis-dependent mechanism by which anti-MDA/MAA antibodies promote osteoclast development that is different from the one previously described for ACPA.

**THE THERAPEUTIC EFFECT OF STIMULATION OF THE SPLENIC NEUROVASCULAR BUNDLE IN MICE WITH CHRONIC INFLAMMATION: IS ENHANCED BY CONCOMITANT ANTI-TNF TREATMENT**

T. Simon1, C. Panzolini1, J. Lavergne1, N. Hypolite1, N. Glaienhans1, M. Vervoordeldonk1, P. Biancou1, Université Côte d’Azur, CNRS/PMC, Valbonne, France; 2Galvani Bioelectronics, Stevenage, United Kingdom

**Background:** Vagus nerve (VN) stimulation has shown to improve the disease development in animal models of arthritis and in patients with RA. However, the VN can affect respiratory, cardiovascular, endocrine and gastro-intestinal physiology. The splenic nerve (SpN) has been confirmed to be the principal effector nerve for the VN-mediated immune control. Previous studies have shown that stimulating the splenic nerve resulted in an increase of noradrenaline in the spleen, as well as a significant reduction in LPS-induced TNF (1).

**Objectives:** To test the therapeutic efficiency of splenic nerve stimulation (SNS) in collagen-induced arthritis (CIA) model of mice alone or in combination with anti-TNF treatment.

**Methods:** CIA was induced in DBA/1J mice by immunization with bovine type II collagen at days 0 and 21. At day 11, mice were implanted with micro-cuff electrodes (CorTec) onto the SpN or VN. From day 16 to day 45, SNS were applied as rectangular charged-balanced biphasic pulses with 650 µA pulse amplitude, 200 µs pulse duration at 10 Hz frequency for 2min 1 or 6 times a day using a Plexon stimulator. In order to investigate the mechanism of action in more detail, propranolol, a beta-adrenergic receptor (β-AR) antagonist, was added to the drinking water of mice receiving SNS. In addition, a control group was treated with anti-TNF (etanercept, 3x per week; 10mg/kg i.p.).

**Results:** These studies demonstrate that SNS suppresses pro-inflammatory cytokine production, and reduces clinical symptoms in mice with CIA which is at least partially mediated by the β-AR. The additive effect of anti-TNF in reducing the clinical scores demonstrates that that mechanism of action of SNS is not primarily mediated by reducing TNF levels. Moreover, anti-TNF potentiating the inhibitory effect of SNS is supporting a combined use of these treatments, or even a combination of SNS with other biologicals, to treat RA, potentially getting more patients closer to remission. In conclusion, the data is providing compelling scientific rationale and pre-clinical evidence that spinal neuromodulation might be a new treatment modality for RA.

MOMELOTINIB, A JANUS KINASE II AND ACTIVIN RECEPTOR 1 INHIBITOR, AMELIORATES JOINT INFLAMMATION, SYSTEMIC TH17 DIFFERENTIATION AND ARTHRITIS-LINKED ANEMIA IN PRE-ClinICAL AUTOIMMUNE RA

P. Tymoszuk1, V. Petzen2, M. Aschoff1, A. Schroll1, M. Seifert1, R. Hansen2, S. Mlitunovic2, B. Strouse1, C. Hassig2, G. Weiss3, I. Theurl1. 1Medical University Innsbruck, Department of Internal Medicine II, Innsbruck, Austria; 2Sierra Oncology, San Diego, United States of America

Background: Janus kinases (JAKs) serve as signaling hubs orchestrating inflammation, innate and adaptive immunity and erythropoiesis. Unfortunately, some of these agents cause suppression of JAK-dependent erythropoiesis, thereby exacerbating inflammation-associated anemia, leading to potential under-dosing and reduced therapeutic benefit. We previously showed that the JAKI momelotinib (MMB) can correct anemia in a rat model of RA, an effect that has been clinically reproduced in myelofibrosis patients treated with MMB. Subsequently, the molecular basis for MMB’s anemia benefit was determined to be a consequence of its potent inhibition of Activin Receptor Type 1 (ACVR1), resulting in decreased hepcidin and, as a consequence, increased systemic iron availability and improved erythropoiesis.

Objectives: The goal of the current study was to investigate the effects of MMB on arthritis in pre-clinical RA models.

Methods: The anti-arthritic activity of daily administration of MMB was assessed in Streptococcus cell wall-induced arthritis in Lewis rats (PG-PS model) and in collagen antibody-induced arthritis (CAIA) in DBA/1 mice. Consecutive assessment of arthritis was performed by joint thickness measurements and paw scoring. Following 3 weeks of treatment, synovial immune cell infiltration and T cell subset differentiation was quantified. Cytokine gene expression was profiled by quantitative rt-PCR. Anemia was assessed by determination of blood hemoglobin and serum, spleen and liver iron levels.

Results: MMB reduced inflammatory granulocyte and macrophage infiltration in synovial tissue by more than 60% at all tested doses as compared to vehicle treatment in PG-PS animals. Importantly, MMB treatment effectively decreased arthritogenic Th17 cell differentiation and overall CD4+ T cells in the synovia beginning at the lowest tested dose and coincided with complete remission of joint swelling at 25 mg/kg. Anti-arthritic activity of MMB was confirmed with significant reductions in arthritis scoring, which demonstrated non-inferiority versus the TNF-α inhibitor, etanercept, in the CAIA model. Consistent with its inhibitory activity on the ACVR1-hepcidin axis, MMB reduced circulating hepcidin levels and mobilized systemic iron, resulting in substantial improvement of the RA-associated anemia in rats.

Conclusion: MMB is a highly efficacious anti-arthritic agent that ameliorates local joint inflammation and reduces the systemic differentiation of major arthritogenic effector cell population, Th17 lymphocytes. In accord with our previous report, MMB is distinct from other JAKi due to its ability to inhibit ACVR1 signaling leading to decreased plasma hepcidin, improved iron homeostasis and increased erythropoiesis. The dual anti-inflammatory and anemia-improving pharmacologic activities of MMB position it as a promising and differentiated therapeutic agent for the treatment of RA and other inflammatory diseases with an anemia component.

SAT0021
STRUCTURAL EFFECTS OF LOCAL CRYOTHERAPY IN RHEUMATOID ARTHRITIS: A STUDY IN ADJUVANT-INDUCED ARTHRITIS

C. Peyronnel1, V. Petticol1, P. Totoson1, H. Martin1, E. Verhoeven1, C. Demougeot1. 1PEPITE EA4267; 2Rhumatologie, CHRU Besançon, Besançon, France; 3Rhumatologie, CRHU Besançon, Besançon, France

Background: The control of joint destruction caused by rheumatoid arthritis (RA) is a key issue in the treatment of this disease. Recent evidence showed that radiographic progression of joint damage occur despite a sharp decrease in disease activity and the use of aggressive Disease Modifying Anti-Rheumatic Drug (DMARD) therapies [1]. Whether alternative treatments such as cryotherapy may have beneficial effects on joint destruction at the early stages of the disease remains to be demonstrated, but such strategy would be of interest as it would not interfere with DMARDs treatment.

Objectives: The aim of this study was to evaluate the effect of a 14-days-treatment of local cryotherapy on radiological outcomes in rat adjuvant induced arthritis.

Methods: Adjuvant-induced arthritis (AIA) was induced in 6-weeks old male Lewis rats by injection of Mycobacterium butyricum in Freund’s incomplete adjuvant at the basis of the tail. A control group received saline. At the onset of arthritis, AIA rats were treated or not by application of cryotherapy on paws using either a cold spray or ice, twice a day for 14 days. Arthritis score and combined, in the treatment of rheumatoid arthritis: two-year clinical and radiographic results from the TEMPO study, a double-blind, randomized trial. Arthritis Rheum. 2006.

Conclusion: These data demonstrated that local cryotherapy had positive effects on structural damage in adjuvant-induced arthritis. The mechanisms involved remain now to be determined. These results suggest that local cryotherapy would be an interesting complement to conventional DMARDs in early RA.

CXCL7 PROMOTES OSTEOCLASTOGENESIS IN RHEUMATOID ARTHRITIS

X. Wang1, L. Sun1, J. Zhao1. 1Peking University Third Hospital, Department of Rheumatology and Immunology, Beijing, China

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease characterized by bone destruction[1]. Chemokine signaling by skeletal cells or by other cells of the bone marrow niche regulates bone formation and resorption[2]. Recent studies have found that CXCL7 enhanced the osteoclast formation in mouse bone marrow cells[3, 4]. Whether CXCL7 plays a role in human osteoclastogenesis especially in RA patients remains unclear.

Objectives: To examine the functional role of CXCL7 in the induction of osteoclastogenesis in RA.

Methods: The level of CXCL7 in CD14+ monocyte supernatant was assessed via enzyme-linked immunosorbent assay. Osteoclastogenesis of CD14+ monocyte from RA patients and healthy donors were evaluated by TRAP staining and F-actin ring immunofluorescence. Bone resorption pit was observed by scanning electron microscopy. We performed quantitative reverse transcription polymerase chain reaction (RT-PCR) to detect changes in osteoclast markers. RAW264.7 macrophages were also used to investigate specific signaling pathway by which CXCL7 stimulated during osteoclast formation.

Results: CXCL7 level in CD14+ monocyte supernatant from RA patients (5690 ±6270.5 pg/ml) was significantly higher than that in healthy controls (2301 ±35.52 pg/ml) (n=5, P<0.001). In the presence of M-CSF and RANKL, CXCL7 promoted osteoclast formation(Figure 1A and B) and increased bone resorption area(Figure 1C) of CD14+ monocyte from healthy donors in the low concentration (10ng/ml) group (n=3, p < 0.05). While in high concentration of CXCL7 (50ng/ml) group, there were no significant changes in the number of osteoclasts. Transcription level of the osteoclast markers RANK, cathepsin K, and MMP-9 was significantly increased in CD14+ monocyte from RA patients, the optimal concentration of CXCL7 was 50ng/ml, which significantly increased the number of osteoclasts. Transcription level of the osteoclast markers RANK, cathepsin K, and MMP-9 was significantly increased in the CXCL7 (10ng/ml) group after 3 days in the presence of M-CSF and RANKL (n=3, p < 0.05). When using CD14+ monocyte from RA patients, the optimal concentration of CXCL7 was 50ng/ml, which significantly increased the number of osteoclasts (Figure 2A and B) and bone resorption area (Figure 2C) (n=3, p < 0.01). Flow cytometry analysis revealed that a higher proportion of CD14+ monocytes expressed CXCR2 from healthy donors than those from RA patients (n=6, p < 0.01). Consistent with the results obtained in CD14+ monocytes, the effects of exogenous CXCL7 on osteoclast formation were also observed in RAW264.7 cells (p < 0.01). The addition of CXCL7 dramatically promoted phosphorylation ERK1/2 in RAW264.7 cells, but it did not affect the phosphorylation of P65.

Conclusion: CXCL7 level in CD14+ monocyte supernatant was higher in RA patients than that of healthy donors. CXCL7 promoted osteoclastogenesis in CD14+ monocyte both from RA patients and healthy donors. CXCL7 could be a potential therapeutic target for bone destruction in RA.

SAT0023

THE ROLE OF ADAM12 UPREGULATED PROLIFERATION OF SYNOVIAL MEMBRANE IN RHEUMATOID ARTHRITIS

M. Watanabe1, K. Nishida1, Y. Nasu1, R. Nakahara2, M. Matsushashi2, Y. Hotta1, T. Ozaki1, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; 2Okayama University Hospital, Okayama, Japan

Background: ADAM12 is a member of a disintegrin and metalloproteinase family and has been reported to participate in the development of a variety of tumors by degrading ECM and shed precursors, thus promoting cell proliferation, invasion, and metastasis[1]. Additionally, ADAM12 is involved in chondrocyte differentiation from osteoarthritis (OA) patients by regulation of TGFβ1-induced IGF-1 and RUNX-2 expressions[2]. However, there is no report on the role of ADAM12 for rheumatoid arthritis (RA).

Objectives: To investigate the expression and role of ADAM12 in the synovial tissue of RA.

Methods: (1) The expression of ADAM12 in synovial tissues from RA (18 cases), OA (5 cases) and healthy control (HC) (3 cases) was examined by immunohistochemistry. The synovial tissues of HC were obtained during surgery of hemiarthroplasty for bone tumors. Three researchers evaluated the positive cell ratio. The samples were scored according to the percentage of positive staining: 0 points (weak positive, positive expression was less than 5%), 1 point (moderate positive, positive expression was between 5% and 50%) and 2 points (strong positive, positive expression was greater than 50%). In addition, the samples were scored according to the staining intensity: 0 points (weak intensity), 1 point (moderate intensity) and 2 points (high intensity). (2) The cultured synovial fibroblasts obtained from RA patients at the surgery (RASF) were stimulated by TNFα (1, 5, 10ng/mL), TGFβ1 (1, 5, 10ng/ML), PDGF-BB (1, 5, 10ng/mL) and TNFα+TGFβ1+PDGF-BB (all 10ng/mL), and the expression levels of ADAM12 relative mRNA was examined by realtime PCR. (3) siADAM12 was transfected in RASF, and the proliferation was examined by WST-1 assay, and the expression of ADAM12 protein was examined by western blotting.

Results: (1) ADAM12 positive cells were found in synovial lining cells, plasma cells, and vascular endothelial cells. ADAM12 was highly expressed in RA synovial tissues. The immunostaining scores of RA, OA, and HC were 3.9±0.01, 1.9±0.27, and 0.8±0.18, respectively. (2) Stimulation by TNFα, TGFβ1, and PDGF-BB resulted in the upregulation of the expression of ADAM12 relative mRNA in RASF, and TGFβ1 stimulation notably tended to increase the expression by about 5 to 6 times. (3) siADAM12 successfully suppressed the expression of ADAM12 protein and simultaneously suppressed the proliferation of RASF.

Conclusion: ADAM12 might be involved in the pathogenesis of RA, promoting the cell proliferation of RASF.

SAT0024
JAK-INHIBITION WITH BARICTINIB INHIBITS ACTIVATION OF NLRP1/CASPASE1/GSDMD PYROPTOSIS PATHWAY IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

W. Xie1, Z. Zhang1, 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Synovial fibroblasts (SFs) play a major role in the pathogenesis of rheumatoid arthritis (RA) and develop an aggressive phenotype destroying cartilage and bone, thus termed RASFs.

Objectives: We aim to examine the presence of GSDMD-mediated pyroptosis and its role in activated RASFs.

Methods: Fibroblasts were isolated from RA synovium obtained from knee replacement surgeries. NLRP1, Caspase-1, GSDMD expression in synovial tissue and TNF-treated RASFs were assessed by qPCR and Western blot. Interleu-kin (IL)-1 was measured by ELISA in supernatant after pretreated with TNF and baricitinib. LDH release was measured using the CytoTox 96 Non-Radioactive Cytotoxicity Assay Kit. Endogenous NLRP1, Caspase-1, and GSDMD was knocked down using small interfering RNA.

Results: The expressions of NLRP1, pro-Caspase-1, Caspase-1 p10, GSDMD and its pyroptosis-inducing fragment GSDMD-N were greater in RA synovium than OA synovium. TNF-induced NLRP1, pro-Caspase-1, Caspase-1 p10, GSDMD, and GSDMD-N expression at the transcript and protein level in a time-dependent manner (P < 0.05). Meanwhile, the release of LDH and IL-1 were significantly increased in RASFs after treated with TNF. We also confirmed the presence of pyroptosis in electron microscopy. Furthermore, blocking the JAK pathway with baricitinib significantly reduced TNF-induced pyroptosis at the transcriptional, protein and activity levels (P < 0.05). Finally, blocking the JAK pathway, we observed a reduction of IL-1 bioactivity in RASFs (P < 0.05).

Conclusion: Our results demonstrate an important role of GSDMD-mediated pyroptosis and shed lights on a potential pyroptosis-targeted treatment. Meanwhile, JAK inhibition alleviates inflammasome-induced pyroptosis by blocking pyroptosis pathway in RASFs.

SAT0025
NEUROMEDIN U SUPPRESSES COLLAGEN-INDUCED ARTHRITIS THROUGH ACTIVATION OF ILC2

Y. Zhang1, Y. Qin1, Z. Chen1.1 The First Affiliated Hospital of USTC, Rheumatology and Immunology, Hefei, China

Background: Reduction and dysregulation of ILC2 was linked to delayed resolu-tion of arthritis. The neuropeptide Neumedin U (NMU) has been reported to rapidly activate ILC2 and initiate a Th2 type immune response through NMUR1 expressed on the surface of ILC2. However, one previous study reported that NMU promoted autoantibody-mediated arthritis.

Objectives: The aim of this work was to investigate the effect of NMU on colla-gen-induced arthritis (CIA) mice and the potential mechanisms.

Methods: CIA was induced in C57BL/6 WT and C57BL/6™/deficient mice on day 1. WT mice were treated i.p. daily by NMU-23 (20ug/mice) or by PBS for 10 days from day 1 to 5 and day 21 to 25. The clinical scores of CIA mice were assessed every two days from day 22 and determined on a scale of 0–4 for each paw. The proportion of ILC2 as well as Th1, Th2, Th17 and Treg in spleen, mesenteric lymph node (mLN) and joints of arthritic mice were analyzed by flow cytometry on day 42.

Results: NMU-23 dramatically inhibited clinical onset and severity of arthritis in treated WT mice compared with control mice. Interestingly, NMU-deficient mice also developed significantly less severe arthritis compared with WT control (Fig 1). Flow cytometry analyses showed that the proportion of ILC2, which defined as Lin-CD45+CD127+KLRG1+ICOS+ST2+, was elevated in the joint but not in the spleen and mLN of arthritic mice treated with NMU-23. In contrast, the proportion of ILIC2 was significantly lower in the spleen of NMU-deficient mice than WT control. The percentage of Th2 cells in the spleen and mLN tend to be higher in NMU-23 treated mice, but there is no statistical significance. Surprisingly, Th1 cells were increased in the mLN of NMU-23 treated and NMU-deficient mice compared with control whereas Th17 was comparable among groups. In addition, the proportion of Treg was decreased in the joint of NMU-23 treated and NMU-deficient mice compared with control mice.

Conclusion: Our preliminary results show that repeated injection of NMU-23 during early and development (late) stage of CIA strongly suppressed clinical onset and severity of arthritis, which might be ascribed to activation of ILC2 in the joint. Further study is needed to explore other cellular and molecular mechanisms in the effect.

Conclusion: These results suggest that higher levels of IgM anti-PC are associated with a lower risk of incident CV events over 10 years in younger patients. The favourable atheroprotective effect of IgM anti-PC may be a part of explanation of lower risk of atherosclerotic disease in younger females in comparison with seronegative RA.

SAT0027 DEVELOPMENT AND VALIDATION OF A NOMOGRAM COMBINING CLINICAL AND HISTOPATHOLOGICAL SYNOVIAL FEATURES FOR PREDICTING EARLY TREATMENT RESPONSE IN NAIVE TO TREATMENT RHEUMATOID ARTHRITIS

S. Alivernini1, B. Tolusso2, M. Gesoli3, M. R. Gigante3, A. Mannocci3, L. Petriceca4, S. Perniola2, C. Di Mario4, A. L. Fedele2, L. Buà4, A. Capacci5, D. Bruno6, G. La Torre6, F. Federico1, G. Ferraccioli1, E. Gremente1, Fondazione Policlinico Universitario A. Gemelli IRCCS - Università Cattolica del Sacro Cuore, Rome, Italy; 2Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; 3Sapienza University of Rome, Rome, Italy; 4Università Cattolica del Sacro Cuore, Rome, Italy

Background: Rheumatoid Arthritis (RA) is characterized by synovial tissue (ST) heterogeneity at disease onset in terms of inflammatory degree and microanatomical organization being related to treatment response. Objectives: To develop a multiparametric tool for baseline treatment response prediction including disease characteristics and histopathological features of ST biopsies, using a large single center (SYNGem Unit) naive to treatment RA cohort. Methods: 240 naive to treatment RA who underwent US-guided ST biopsy, at the first clinical evaluation, were enrolled. Clinical and immunological characteristics were recorded for each patient. All ST FFPE samples were stained with H&E and classified by a pathologist, blinded to clinical characteristics, using the Krenn score [1] to assess the degree of ST inflammation. All naive to treatment RA were treated according to the T2T scheme and DAS remission rate at 6-12 months was recorded. On the basis of the regression analysis, a nomogram was constructed that incorporated the significant factors predicting the “achievement of DAS-Remission at 6 months follow-up” in naive RA. The performance of the nomogram was assessed by discrimination and calibration.

Results: Univariate analysis showed that RA who achieved early (6 months) DAS-remission had, at baseline, significantly lower total Krenn score (p=0.001), shorter symptoms duration (p=0.005) and lower disease activity (p<0.001) than RA not achieving this clinical outcome. ROC curve analysis revealed that RA having, at baseline, a total Krenn score <4.5 [AUC(95%CI): 0.67(0.60-0.74), p=0.001] achieved more likely DAS-remission at 6 months (53.1%) than RA with total Krenn score ≥4.5 (28.9%, p<0.001). Interestingly, RA whose ST was biopsied within 3 months from joint symptoms beginning showed significantly lower ST inflammation as total Krenn score than RA whose ST was analyzed among 3-12 months (p=0.04) or after 12 months (p=0.002) since symptoms beginning. However, in terms of follicular structure presence, the microanatomical organization of the synovial inflammatory infiltrate did not differ comparing RA whose ST was biopsied within 3 months from joint symptoms beginning (44.4%) and RA whose ST was biopsied among 3-12 months (476%), p=0.74) or after 12 months (52.7%, p=0.33) since symptoms beginning. Logistic regression analysis revealed that, at baseline, being VERA, not having HDA and having a total Krenn score <4.5 were synergistic factors of DAS-remission achievement at 6 months [OR:10.5(95%CI:2.28-48.01), p<0.05]. Based on the regression analysis, a nomogram integrating baseline clinical (disease activity and duration) and histological (total Krenn score) characteristics was developed in which the value of each of the variables was given a point score. A total score was calculated by adding each single point score and, by projecting the value of the “total points” score to the “probability” line up to 87.5%.

Conclusion: Krenn score is a reliable tool for the semi-quantitative assessment of ST inflammation on US-guided ST biopsies being contingent to baseline disease characteristics and can be integrated within a nomogram to better predict the therapeutic response in naive to treatment RA.

The FLARE-RA questionnaire can predict flares in patients with established rheumatoid arthritis participating in the tapering trial.

D. Bertrand1, D. De Cock1, V. Stouwen2, S. Pazmino2, A. Moeyersoons2, J. Joly2, R. Westhoven2,1, P. Verschueren1,2, KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; 2UZ Leuven, Rheumatology, Leuven, Belgium

Background: The Flare assessment in Rheumatoid Arthritis (FLARE-RA) questionnaire was developed to identify Rheumatoid Arthritis (RA) flares, but it is unknown if this questionnaire can also predict flares.

Objectives: To identify if the FLARE-RA questionnaire has a predictive capacity for OMERACT flares in patients with established RA participating in a tapering trial.

Methods: Patients, participating in the 1-year open-label pragmatic randomised controlled TapERA (Tapering Etanercept in RA) trial, were included in the analysis. Patients had to be in DAS28CRP or ESR remission (≥6 months) and treated with etanercept 50 mg weekly (≥1 year). Participants were randomised to continue etanercept 50 mg weekly or to taper to 50 mg every other week.

The FLARE-RA questionnaire was completed every 3 months in the trial. This questionnaire consists of 13 questions on a Likert-scale from 1 to 6 reflecting completely untrue to completely true. Validation by Fautrel et al. led to elimination of 2 questions (steroid intake and overall worsening of RA) and rescaling to 0-10. Our outcomes were based on these 3 versions of the questionnaire, namely 13 questions (13q), 11 questions (11q) and rescaled 11 questions (r11q). The FLARE-RA questionnaire can be divided into 2 subscales: the FLARE-RA arthritis subscale (questions regarding morning stiffness, night disturbances, joint swelling, joint pain, analgesics) and the FLARE-RA general symptoms subscale (questions regarding fatigue, functional limitation, irritability, mood disturbances, withdrawal, need for help).

The total FLARE-RA score was calculated by taking the average of all the questions per time point. A flare was defined according to the OMERACT definition, namely an increase in DAS28CRP >12 compared to baseline or increase in DAS28CRP >0.6 and current DAS28CRP >3.2. All the total FLARE-RA scores of the baseline, month 3, 6 and 9 visit were grouped and the mean ± standard deviation (SD) FLARE-RA score was compared between patients with or without an OMERACT flare on the next study visit using the Mann-Whitney U test. Logistic regressions using the total FLARE-RA score to predict an OMERACT flare 3 months later were carried out for the 13q, 11q and r11q versions and the FLARE-RA subscales. Missing data were imputed using expectation maximisation.

Results: Sixty-six patients (68% female, mean ± SD age of 55 ± 11 years) completed the FLARE-RA questionnaire. This yielded 264 FLARE-RA scores, of which the total mean ± SD FLARE-RA score was 2.1 ± 1.0 and 2.7 ± 1.1 for patients without and with an OMERACT flare on the next study visit, respectively (p<0.01). This was comparable for the 11q and r11q versions (Table 1). For the total FLARE-RA score (13q), the odd ratio of having an OMERACT flare 3 months later is 1.6 (95% confidence interval CI 1.2 – 2.2, p=0.004). This was 1.5 (95% CI 1.1 – 2.1, p=0.006) for the 11q and 1.2 (95% CI 1.1 – 1.4, p=0.006) for the r11q version. The odds ratio of having an OMERACT flare on the next visit was 1.5 (95% CI 1.2 – 2.0, p=0.002) and 1.4 (95% CI 1.0 – 2.0, p=0.025) for the arthritis and general symptoms subscale, respectively.

Conclusions: Higher total FLARE-RA questionnaire scores seem to indicate a higher risk of an OMERACT flare 3 months later, regardless of which versions or subscales of the FLARE-RA questionnaire were used. Hence, our findings suggest that the FLARE-RA questionnaire could be used as a predictive tool for flares.

Patient-physician discordance in assessment of disease activity in rheumatoid arthritis

L. Brites1, F. Costa1, R. Dinis de Freitas1, M. Luis1, A. R. Prata1, H. Assunção1, L. Saravia1, M. Sousa1, A. R. Cunha1, J. A. P. Da Silva1,2,3, A. Cuarte1,2,3, Centro Hospitalar e Universitario de Coimbra, Rheumatology, Coimbra, Portugal; 1Centro Hospitalar Baixo Vouga, Aveiro, Portugal; 2Coimbra Institute for Clinical and Biomedical Research iCIBR, Faculty of Medicine, Coimbra, Portugal

Background: In rheumatoid arthritis (RA), global disease activity is commonly assessed, from the patient’s and the physician’s perspective, through a 100mmVAS. Previous studies have commonly shown a considerable discrepancy between the patient’s and physician’s assessment.

Objectives: This study aimed evaluating patient-physician discordance in the assessment of disease activity and to explore its determinants.

Methods: Cross sectional study including RA patients (ACR/EULAR 2010 classification criteria), aged ≥ 18 years, followed in a single tertiary centre. Data were collected from the most recent evaluation including sociodemographic features, disease duration (years), disease activity (DAS 28 3V-PCR), tender and swollen joint count 0-28 (TJC and SJC), VAS-pain-patient, patient and physician global assessment (PGA and PhGA respectively), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Health assessment questionnaire (HAQ) and EuroQol five-dimension scale (EQ5D). The discrepancy between patients and physicians (ΔPHGA) was defined as PGA minus PhGA, and a difference > 20mm was considered as “discordant”. A descriptive analysis was performed and variables described as proportions or means (+/- SD), as adequate. Correlation between ΔPHGA and other variables was assessed through Pearson’s correlation and comparison between groups through t-test. Variables with p<0.05 or otherwise considered clinically relevant were included in multiple linear regression analysis to identify predictors for ΔPHGA. A p<0.05 was considered statistically significant.

Results: In total, 467 patients with RA were included (81.2% female, mean age 63.9% ± 12.2 years). PGA and PHGA were discordant in 61.7% of the cases. The patient scoring higher than the physician in 95% of these cases. The proportion of concordance increased (p < 0.01) when considering only patients in remission (DAS 28 3V < 2.6). (Graph 1). ΔPHGA was moderately correlated with VAS-pain-patient (r = -0.59) and weakly correlated with SJC (r = -0.12), HAQ (r = 0.27), EQ5D (r = -0.28) and age (r = 0.21); all p<0.01. In multivariate analysis, VAS-pain-patient (β 0.74, 95% CI 0.62-0.88, p=0.00) and TJC (β 0.16, 95% CI 0.45-0.48, p=0.02) remained associated with a higher ΔPHGA.

Conclusion: Our study confirmed that a significant discrepancy between patients and physicians in the assessment of global disease activity is frequent in clinical practice, probably due to valorization of different parameters. This was much less pronounced among patients in remission. Higher VAS-pain-patient and TJC were independent predictors of greater discrepancy between patients and physician’s assessment.

A novel association between anti-carbamylated antibodies and interstitial lung disease in patients with rheumatoid arthritis

R. Castellanos-Moreira1, S. Rodriguez-García1, K. Cajiao1, G. Jimenez1, M. J. Gomara2, V. Ruiz1, I. Casafont-Solé2, J. Ramirez1, J. Gomez Puerta1, S. Holgado Pérez3, J. D. D. Cañete1, I. Haro1, R. Sammarti1. 1Hospital Clínico de
Background: Interstitial lung disease (ILD) is associated with a significant increase in morbidity and mortality in patients with rheumatoid arthritis (RA). Therefore, an early diagnosis is fundamental. Anti-carbamylated proteins (Anti-CarP) have been described in different chronic respiratory diseases without a previous history of RA.

Objectives: The aim of this study was to analyse the association between Anti-CarP and ILD in RA patients.

Methods: We performed a cross-sectional study, including RA patients fulfilling the 2010 ACR/EULAR criteria. The main population comprised 2 groups: 1) RA patients diagnosed with ILD (RA-ILD group) and 2) RA patients without ILD (non-ILD RA group). ILD was diagnosed by high-resolution tomography and confirmed by a multidisciplinary committee. Three IgG Anti-CarP autoantibodies against fetal calf serum (Anti-FCS), fibrinogen (Anti-Fib), and fibrin/fibrinogen homocitrullinated peptide (Anti-CFFHP) and one IgA against FCS (Anti-FCS-IgA) were determined by home-made ELISA. Associations between Anti-CarPs and ILD were explored using multivariable logistic regression adjusted by a set of variables known to be related to the development of ILD: smoking, sex, age, RA disease duration, RF and ACPA. An independent replication sample was obtained to validate our findings from another hospital.

Results: The main population included 179 patients: 37 were included in the RA-ILD group, and 142 in the non-ILD RA group. Most patients were female (79%), with a mean age of 59.7±13 years with a mean disease duration of 6.6±5 years. Baseline features are shown in Table 1. The replication sample was composed of 25 patients in the RA-ILD group and 50 patients in the non-ILD RA group. We found that Anti-CarP specificities were more frequent in RA-ILD patients (Anti-FCS 70% vs. 43%; Anti-Fib 73% vs. 51%; Anti-CFFHP 38% vs. 19%; Anti-CarP-IgA 51% vs. 20%; p<0.05 for all comparisons). Serum mean titers of Anti-CarPs were higher in RA-ILD patients with significant statistical differences for all of them, except Anti-Fib. The multivariate analysis showed that Anti-CarP specificities were independently associated with ILD (Anti-FCS (OR: 3.42; CI95%: 1.13-10.40), Anti-Fib (OR: 2.85; CI95%: 0.83-9.70), Anti-CFFHP (OR: 3.11; CI95%: 1.06-9.14) and Anti-FCS-IgA (OR: 4.30; CI95%: 1.41-13.04). In the replication sample our findings were validated only for Anti-FCS (OR: 10.42; CI95%: 1.68-64.46).

**Conclusion:** A strong association between RA-ILD and Anti-CarP was found independently of confounders, including RF and ACPA. Our findings suggest a possible link between Anti-CarP and the development of ILD.

INCIDENCE OF RHEUMATOID ARTHRITIS IN PATIENTS WITH NEW ONSET OF MUSCULOSKELETAL SYMPTOMS AND ANTI-CPP POSITIVITY COMPARED TO ANTI-CPP NEGATIVE PATIENTS

S. Dauth1,2, M. Köhm1,2,3, T. Oberwahrenbrock1,2,4, U. Henkemeier1,2,4, T. Rossmanith1,2,4, F. Behrens1,2,3,4, D. Fraunhofer IME Translational Medicine and Pharmacology, Frankfurt, Germany; Fraunhofer Cluster of Excellence Immune-Mediated Diseases CIBM, Frankfurt, Germany; Goethe-University Frankfurt, Rheumatology Department, Frankfurt, Germany; Centre of Innovative Diagnostics and Therapeutics Rheumatology/Immunology CIRI, Frankfurt, Germany; Goethe-University Frankfurt, Institute for General Practice, Frankfurt, Germany

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory joint disease. Biomarkers for its early detection and diagnosis are of high importance as prompt treatment improves clinical and structural outcome. Autoantibodies against cyclic citrullinated proteins (anti-CCP) have been associated with RA-development. Non-specific musculoskeletal (nsMSK) symptoms are often described prior to RA development. Majority of patients with nsMSK symptoms present to their general practice (GP) first. Studies of early arthritis cohorts have shown that many early arthritis patients cannot be accurately diagnosed at their first visit and are often referred as undifferentiated arthritids patients.

Objectives: To evaluate the incidence of anti-CCP positivity in patients with new onset of nsMSK symptoms and the incidence of RA in these patients over a 3-year follow-up period compared to anti-CCP negative patients.

Methods: In this prospective study (PANORA), 978 patients with new onset of nsMSK symptoms and the incidence of RA in these patients over a 3-year follow-up period compared to anti-CCP negative patients. From 978 included patients, 105 (10.7%) were CCPoint® positive. 96 were tested with ELISA and 27 (28.1%) were confirmed anti-CCP positive. 9 (33.3%) were diagnosed with RA at the first RD visit (study visit 2); 4 further patients were diagnosed with RA during the follow-up (FU) period so far. Overall, 48.1% of ELISA-positive (ELISA+) patients were diagnosed with RA up to now; 11 ELISA+ patients are still in the FU period of the study. Of the 868 CCPoint® negative patients, currently, 282 have filled out a 1-year FU questionnaire; 3.5% of those reported a RA diagnosis. As expected, clinical parameters at V2 (e.g. CRP, swollen and tender joint count) were worse in the ELISA+/RA+ group compared to the ELISA-/RA- group, but no obvious differences were detected between ELISA+ patients who were diagnosed with RA during the FU period (after V2) and ELISA-/RA- patients.

* 1 year-questionnaire for Point-of-Care Test and ELISA negative patients or every 6 months follow-up for ELISA positive patients; **Patient-reported; ***patients are still in the follow-up phase of the study

Conclusion: Currently, 48.1% of anti-CCP+ (ELISA) patients have received a RA diagnosis, whereas 3.5% of the anti-CCP. CCPoint® received a RA diagnosis (patient reported), which underlines, that anti-CCP can be used as a marker to identify patients in GP setting. While clinical parameters are correlated with the diagnosis of RA, they are not suited for predicting future RA development alone. Anti-CCP, possibly in combination with additional parameters imaging, might increase the likelihood to early diagnosis or predict RA development.
trajectories demonstrated that 3683 of the stable, disease-associated chromosomal loops were shared by all 3. However, 4496 were associated with distinct response trajectories, with 1221, 2574 and 701 loops unique to R, NR and IR respectively.

**Conclusion:** The stable chromosomal architecture unique to each treatment trajectory suggests that various underlying molecular endotypes may exist. Moreover, the stable loops common to all groups allude to a baseline level of dysregulation in RA and offers the potential to discover novel drivers of disease. This work provides the foundation to further our understanding of RA pathogenesis and the potential of finding a biomarker that would be of significant value in a clinical setting.

**CLINICAL SIGNIFICANCE OF ANTI-CARBAMYLATED PROTEIN ANTIBODIES IN PREMENOPAUSAL RHEUMATOID ARTHRITIS WOMEN: RELATION TO DISEASE ACTIVITY AND BONE LOSS**

R. Elnemr1, R. Bastawy2, R. Ghazala3, M. Abdelrazek4, N. Elsawy5, 1Faculty of Medicine, Alexandria University, Physical Medicine, Rheumatology and Rehabilitation, Alexandria, Egypt; 2Alexandria University; Alexandria, Egypt; 3Alexandria University, Medical Biochemistry, Alexandria, Egypt; 4Alexandria University, Alexandria, Egypt; 5Alexandria University, Alexandria, Egypt

**Background:** Anti carbamylated protein anti carP are present in patients with Rheumatoid Arthritis RA and are associated with erosions. However their association with systemic or local bone loss in RA patients is still not confirmed.

**Objectives:** The purpose of this study was to measure the serum level of anti carP in premenopausal women with RA and determine its relation to disease activity and bone loss.

**Methods:** This case control study was conducted on forty eight RA premenopausal female patients diagnosed according to 2010 ACR/EULAR criteria and forty eight ages and body mass index matched healthy premenopausal females. RA patients with other autoimmune diseases, viral hepatitis malignancy or erosive joint disease and systemic diseases that affect bone quality were excluded from the study. All RA women were subjected to history taking, clinical examination, assessment of disease activity using disease activity score-28 DAS28 and clinical disease activity index CDAI functional assessment using health assessment questionnaire HAQ physical activity assessment using international physical activity questionnaire short form IPAQ fatigue assessment using modified fatigue impact scale MFIS, routine laboratory investigations, serological tests as well as Anti carP using ELISA kit. Moreover the bone mineral density was measured by a lunar Prodigy Advanced DEXA scanner system and plain x-ray of both hands and wrists in the anteroposterior view was done to assess the juxta articular osteopenia and erosions.

**Results:** Anti carP level was significantly higher in RA patients than in healthy controls table.1 The serum level of anti carP had a significant positive correlation with RA DAS, CDAI, HAQ, IPAQ, MFIS and erosion and joint space narrowing in original sharp score. Also the anti carP had a significant negative correlation with the bone mineral density BMD of spine. The AUC of anti carP level showed a high level of accuracy AUC 0.857 figure 1 and the calculated cutoff value >65 can precisely discriminate subjects with RA from those without RA with 85.42% sensitivity and 85.11% specificity.

**Conclusion:** Anti carbamylated antibodies were higher in premenopausal RA women compared to ages and body mass index matched healthy women. Anti carP are associated with higher RA disease activity, increased disability and decreased physical activity. Moreover anti carP are associated with systemic trabecular bone loss manifested by decreased bone mineral density of the spine as well as local bone loss as manifested by increased number of joint erosions in premenopausal RA women.

**SAT0035**

**RESPONSE TO ABATASEPT OF DIFFERENT PATTERNS OF INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS: NATIONAL MULTICENTER STUDY OF 263 PATIENTS**

Background: Interstitial Lung Disease (ILD) is a severe extraarticular manifestation of rheumatoid arthritis (RA). In this line, several radiological patterns of RA-ILD have been described: i) usual interstitial pneumonia (UIP), ii) nonspecific interstitial pneumonia (NSIP), iii) obliterating bronchiolitis, iv) organizing pneumonia, and mixed patterns. Abatacept (ABA) could be an effective and safe option for patients with RA-ILD, although the response in the different radiological patterns is not well defined.

Objectives: Our aim was to assess the response to ABA in different radiological patterns of ILD.

Methods: Observational retrospective multicenter study of RA-ILD treated with ABA. ILD was diagnosed by HRCT and classified by radiological patterns in 3 different subgroups of RA-ILD: a) UIP; b) NSIP and c) other. ABA was used sc. or iv at standard dose. We assessed: a) Dyspnoea (MMRC scale; significant variation ≥1); b) Functional tests (significant changes ≥10% in FVC and DLCO); c) HRCT imaging; d) DAS28 e) prednisone dose.

Results: We included 263 patients: 106 UIP, 84 NSIP and 73 others (150 women / 113 men), mean age 64.6±10.10 years. Total patients positive for RF or CCPA were 235 (89.4%) and 233 (88.6%), respectively. In 26 out of 263 patients, the development of ILD was closely related to the administration of sDMARDs (MTX n = 11 and LFN n = 1) or bDMARDs (ETN n = 5, ADA n = 4, CZP n = 2 and IFX n = 3). Patient characteristics are shown in table 1. Figure 1 shows the evolution of the cases with available data after a mean follow-up of 22.7±19.7 months. Mean DLCO at the end of study (%) 62.04±18.86, FVC at baseline (%) 82.60±21.39; DLCO at the end of study (%) 66.06±18.70; FVC at baseline (%) 89.85±21.14; FVC at the end of study (%) 89.44±17.53.

Conclusion: ABA could be a good choice of treatment in patients with RA-ILD independently of the radiological pattern of ILD.

SAT0036 ULTRASOUND IN THE ASSESSMENT OF JOINT DAMAGE IN RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW BY THE OMERACT ULTRASOUND WORKING GROUP

I. Gessl1, B. Wildner2, P. Ballint3, M. A. D’agostino4, P. Mandl1. 1Medical University of Vienna, Div. of Rheumatology, Department of Internal Medicine III, Vienna, Austria; 2Medical University of Vienna, University Library, Vienna, Austria; 3National Institute of Rheumatology and Physiotherapy, 3rd Rheumatology Department, Budapest, Hungary; 4Hospital Ambroise Pare, Department of Rheumatology, APHP, Paris, France

Background: The detection of damage in patients with rheumatoid arthritis (RA) is crucial for monitoring of therapy targets as well as for early diagnosis. Conventional radiography (CR) is commonly used to detect structural damage, in the form of bone erosions or loss of hyaline cartilage. Over the last years, musculoskeletal ultrasound (MSUS) was shown to be a sensitive and reliable method to detect erosion and cartilage loss as well as damage to soft tissue structures.

Objectives: To identify and synthesize the evidence for the use and measurement properties of MSUS in assessing structural damage in patients with RA.

Methods: A systematic literature search (SLR) of the PubMed, Embase and Cochrane Library was performed. Original articles were included that were published in English until 01/01/2019, reporting MSUS of bone erosion, cartilage loss or damage and tendon damage, and the measurement properties of MSUS according to the OMERACT Filter 2.1.

Results: Of the 1266 identified articles 79 were finally included, most of which reported on cross-sectional studies. The majority of the studies used the OMERACT definitions for ultrasonographic pathology. Among these, erosions were assessed in 72 (91.1%), cartilage damage in 12 (15.2%), tendons in 4 (5.1%) studies and enthesophytes in a single (1.3%) study. Erosions were rated by binary grading in 56 (77.8%) studies and by semiquantitative scoring in 27 (37.5%) studies. Global or sum scores were calculated in only 9 (12.5%) studies. Among 23 studies assessing erosions both by US and CR, only 1/23 (4.3%) study found a higher sensitivity of CR as compared to MSUS. Among studies assessing tendons, 3 (75%) used a semiquantitative score and one scored tendon rupture as being present or absent. Cartilage damage was graded in binary fashion, quantitatively by measuring cartilage thickness or semi-quantitatively. Hand joints were the most frequently evaluated joints (58, 73.4%). The overwhelming majority of studies assessed structural damage bilaterally (68, 86.1%), with 5 (6.3%) studies assessing only the dominant hand, 5 (6.3%) studies evaluating the clinically more affected side and 1 (1.3%) study assessing only the right hand. Validity, reliability and responsiveness were assessed in only 8 (10.1%), 10 (12.7%) and 4 (5.1%) studies respectively. Feasibility was not considered in any of the studies.

Conclusion: While the results of this SLR suggest that US is a sensitive and feasible tool to detect damage in RA, they also highlight the need for further research and validation. Findings of this SLR will inform the next steps of the Working Group in developing an ultrasound score for assessing structural damage in patients with RA.

Disclosure of Interests: None declared.

HIGH AGREEMENT BETWEEN ANTIBODIES AGAINST MALONDIALDEHYDE PROTEIN ADDUCTS AND ANTIBODIES AGAINST MALONDIALDEHYDE-ACETALDEHYDE ADDUCTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Gonzalez1, L. Rodríguez-Martínez1, C. Regueiro2, E. Perez-Pampín1, A. Mera Varela.1 Instituto Investigación Sanitaria-Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain

Background: Rheumatoid arthritis (RA) presents high levels of oxidative stress and reactive species such as malondialdehyde, which modifies proteins forming malondialdehyde adducts (MaP) and, in the presence of acetaldehyde generates adducts called malondialdehyde-acetaldehyde (MaAP). Recently, the presence of malondialdehyde modified proteins in the synovium and antibodies against these adducts (AMaPA) in the serum of patients with RA has been described (1). Previously, a high frequency of antibodies against MaAP (AMaPA) had been reported in patients with RA (2).

Objectives: We aimed to confirm the presence of AMaPA in patients with RA and define its relationship with AMaaPA.

Methods: The sera of 204 healthy controls and 205 patients with established RA that met the 1987 ACR classification criteria and selected to represent the different AMaPA status were studied. All had information on their status for FR, anti-CCP and AMaPA antibodies (IgG, IgM and IgA). The AMaPA were determined by indirect ELISA using malondialdehyde-modified serum bovine albumin as antigen and specific secondary antibodies against the IgG and IgM isotypes following the same protocol of the previous study (1). The results were analyzed with the gamma coefficient (γ) for concordance in status and with the Spearman coefficient (ρ) for correlation of titres. The study was approved by the CEIC of Galicia.

Results: The AMaPA showed higher titres in the patients with RA than in the controls, the positive frequencies being: 17.1% for IgG AMaPA and 25.4% for IgM AMaPA. An important fraction of the patients with RA showed the same status with the two AMaPA isotypes, as reflected in the significant concordance between them (γ = 0.74, Table 1). When comparing the AMaPA and AMaaPA status in patients with RA, a remarkable concordance was observed among the antibodies of the same isotype, especially between the IgM AMaPA and IgM AMaaPA: γ = 0.63 (Table 1). There were fewer patients with the same status when different antibody isotypes were compared, although some of these comparisons reached statistically significant concordance. However, the titres were not significantly correlated in any of the comparisons, even in those that showed the greatest agreement in status (Table 1).

Table 1. Relationship of antibodies against malondialdehyde adducts (AMaPA) with other autoantibodies in patients with RA.

In relation to the typical RA autoantibodies, significant concordances were observed between the IgM AMaPA and RF or anti-CCP, although they were lower than those observed with the AMaPA. In contrast, the IgG AMaPA showed no significant agreement with RF or anti-CCP antibodies. These low levels of concordance were reflected in the lack of significant difference in the prevalence of AMaPA between seronegative and seropositive patients (24.1% vs. 35.4%, P = 0.1).

Conclusion: The presence of AMaPA in patients with RA has been confirmed, and a high concordance between the AMaPA and AMaaPA status has been observed, especially between those with an IgM isotype. However, the lack of correlation in the titres indicates that these two types of autoantibodies are independent. The potential utility as biomarkers of the AMaPA should be similar to that of the AMaaPA.

DOI: 10.1136/annrheumdis-2020-eular.8579
Objectives: To investigate deep learning for the prediction of individual disease activity in RA.

Methods: Demographic and disease characteristics from over 9500 patients with 65,000 visits from the Swiss Quality Management (SCQM) database were used to train and evaluate an adaptive recurrent neural network (AdaptiveNet). Patient and disease characteristics along with clinical and patient reported outcomes, laboratory values and medication were used as input features. DAS28-BSR was used to predict active disease and future numeric individual disease comes, laboratory values and medication were used as input features. DAS28-BSR values with a mean squared error of 0.9.

Conclusion: Deep neural networks have the capacity to predict individual disease outcome in RA. Low specificity remains challenging and might benefit from alternative input data or outcome targets.

Therefore, this study examined the characteristics of RA-ILD patients with AE, and the variables associated with mortality due to AE of RA-ILD.

**Objectives:** To investigate the risk factors for AE and mortality of RA-ILD.

**Methods:** We retrospectively collected the clinical data of 165 RA-ILD patients admitted to our hospital between July 2010 and October 2019. We compared clinical characteristics between patients who developed AE (AE group) and those who did not (non-AE group), and identified the variables significantly associated with AE occurrence. We also compared the admission characteristics of those who survived (survivor group) and those who died (non-survivor group) after admission for AE. AE was defined using previously proposed criteria [3], which were modified slightly for application to RA-ILD.

**Results:** The mean patient age was 73.6 ± 9.7 years and 97 (71.9%) patients were female. Thirty (22.2%) patients developed AE, of whom thirteen (43.3%) died (mean follow-up, 64.9 months). In univariate analyses UIP pattern and MTX were not associated with AE. However, in multivariate analyses, UIP pattern was associated with AE (OR 2.68, 95% CI 1.10–6.52, p=0.03). Median age (70 vs. 80 years, p=0.003), non-use of MTX (70.6% vs. 23.1%, p=0.025), and C reactive protein level (median 9.38 vs. 18.12 mg/dl, p=0.02) on admission were significantly higher in patients who died of AE. In the Cox proportional hazard model, UIP pattern (HR 4.67, 95% CI 1.02–21.5, p=0.048) and non-use of MTX (HR 0.16, 95% CI 0.04–0.72, p=0.016) were associated with death.

**Conclusion:** Our data suggest that the UIP pattern is related to AE, and non-use of MTX and UIP pattern are related to death due to AE of RA-ILD.

**EFFECT OF INTRA-ARTICULAR GLUCOCORTICOID INJECTION ON RADIOGRAPHIC DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS**

J. H. Ko1, H. N. Lee2, S. G. Lee2.1 Bucheon St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Bucheon, Korea, Rep. of (South Korea); 2Pusan National University Hospital, Busan, Korea, Rep. of (South Korea)

**Background:** Intra-articular glucocorticoid injection (IAGI) has been used as part of a treat-to-target strategy in patients with rheumatoid arthritis (RA). However, recent studies revealed that repeated intra-articular triamcinolone injection into knees with osteoarthritis resulted in significant greater cartilage volume loss after two years. Limited knowledge exists about the long-term efficacy of IAGI in RA, assessed by radiographic changes.

**Objectives:** To investigate whether IAGI have an additional benefit on achieving remission or low disease activity (REM/LDA) after 3 months, and radiographic progression over the next two years. Additionally, we identified the factors associated with early achievement of REM/LDA and radiographic progression.

**Methods:** We performed a retrospective study of RA patients who had active arthritis in the hand or wrist joints and received IAGI adjunct to disease modifying anti-rheumatic drugs, compared with those never had received IAGI. Short-term efficacy was assessed by changes of disease activity score in 28 joints (DAS28) after 3 months and long-term efficacy by changes of Sharp score of hand radiographs (HSS) taken before and two years after the onset of active arthritis. The radiographic progression was defined as ΔHSS/year ≥ 1.5. Conditional logistic regression analysis was used to identify predictors for radiographic progression.

**Results:** We identified 116 RA patients who received IAGI on the hand or wrist joints and 102 IAGI-naïve patients. After 3 months after active arthritis, 61% patients treated with IAGI and 39% of IAGI naïve patients achieved low disease activity or remission (P = 0.009). In the next two years, 45% of patients with IAGI and 34% of IAGI-naïve patients were radiographically progressed (P = 0.114). The ΔHSS/year of patients received IAGI was 1.0 (interquartile ranges [IQR], 0–3.8), while that of IAGI-naïve patients was 0 (IQR, 0–2.5) (P = 0.005). After adjusting disease duration, baseline HSS and 3-month DAS28, IAGI and wrist joint involvement were associated with radiographic progression.

**Conclusion:** IAGI given in the hand and wrist joints of patients with RA were associated with short-term control of disease activity, however, long-term structural damage in the subsequent two years. Wrist joint arthritis had higher potential for radiographic progression, which should be carefully monitored.

**PREDICTIVE VALUE OF IMMUNOLOGICAL AND IMAGING BIOMARKERS ON ACHIEVING REMISSION AT 6 MONTHS IN RHEUMATOID ARTHRITIS PATIENTS TREATED BY INTRAVENOUS BDMARD**

B. Laurent1, S. Giuliani1, H. Mezghani2, I. Duprat-Lomon2, A. Luc2, M. De Carvalho Bittencourt3,4, C. Baumann1,5, I. Chary Vaclkaire1,5, D. Loeuille1,5.

**Background:** RA is the most prevalent chronic inflammatory rheumatism, responsible of functional impairment.

**Objectives:** To investigate the value of biological and imaging biomarkers on predicting DAS 28 remission at 6 months, in RA patients initiating IV bDMARD.

**Methods:** From 2008 to 2017, 317 RA patients fulfilling ACR 1987 and/or ACR-EULAR 2010 criteria for RA, initiated IV bDMARDs in our department of Rheumatology. Patients were excluded in cases of lack of information on disease activity assessment before and at 6 months of treatment and on immunological status and titers (ACPA, RF, ANA) at baseline. For patients receiving successive IV bDMARDs during this time period (n=30), a randomization permitted to select 1 treatment sequence. On 173 patients eligible to the study, 4 were lost to follow-up and 14 stopped treatment due to adverse events before 6 months. Clinical, biological and imaging (US and RX) data were collected when available at treatment initiation. US examination was performed on 12 targeted joints (wrist, MCP2-3-5 and MTP2-3-5) with qualitative and quantitative evaluation on B mode and Power Doppler (PD) for synovitis, tenosynovitis and erosion. The modified Sharp/Pvan der Heijde erosion score was performed by 2 independent readers blindly from clinical and US informations. Remission was defined by a DAS 28 < 2.6 at 6 months. Only variables with a p<0.2 in univariate analysis were included in the multivariate model.

**Results:** On 155 RA patients, 11 had a disease duration < 2 year, 44 (28.3%) were on first line of IV bDMARDs and 111 patients received at least one IV bDMARD (mean 2.5 (1.3)).

All qualitative variables with a p value <0.2 on bivariate analysis were incorporated in the multivariate model (RF +, ACPA +, US erosive RA, Nb B mode synovitis, Nb PD+ synovitis, RX erosive RA). Only patients with all data available were incorporated in the multivariate logistic regression analysis (n=103/155). In multivariate analysis only the number of B mode synovitis was still significant with OR = 1.1 (95% CI: 1.0-1.3) (p=0.019).

Conclusion: In RA patients treated by IV bDMARDs, number of PD+ synovitis on ultrasonography was the only predictive biomarker of DAS 28 remission. Objectives: To evaluate the changes promoted in levels of circulating inflammatory mediators in RA patients in response to TNF- α inhibitors (TNFi) and anti-CD20 therapies, in order to identify biomarkers of clinical efficacy and potential predictors of therapeutic response to these drugs. Methods: In a prospective RA cohort multicenter study, we collected serum from RA patients with moderate or high disease activity prior and after 6 months of treatment with TNFi or rituximab (RTX), and analyzed levels of 27 proteins that constitute a multi-biomarker test of the inflammatory profile of these samples, using a multiplex immunoassay. Patients’ response was determined according to the EULAR response criteria (good/moderate/na). We compared basal levels of inflammatory mediators between the differential response patient groups and analyzed their discriminative ability. Logistic prediction models were created to assess the added value of potential inflammatory predictors. Results: Among 111 total RA patients, 50 of 85 (59%) patients in the TNFi group and 16 of 26 patients in the RTX group (69%) responded to the biologic treatment. High DAS28 or SDI scores, or titers of auto-antibodies (RF or ACPA) at baseline were not predictive of response to any treatment. Instead, smoking habit and hyperlipidemia at baseline were predictors of a worse response to any of these bDMARDs. Of the molecules analyzed by the multiplex assay, 14 inflammatory mediators showed a significant downregulation on patients’ responders to TNFI therapy. Moreover, the decline in 7 biomolecules was related to reduced DAS28. After RTX treatment, 15 inflammatory mediators were reduced in patients with good clinical response; downregulation in 4 of those biomolecules correlated with reduced DAS28.

In the search for predictors of response to each bDMARD, by using the Metabo-Analyst software, we could classify patients with distinctive therapeutic response based on the baseline levels of the inflammatory molecules analyzed. Receiver operating characteristic (ROC) analyses for those multiple biomarkers allowed us to further identify specific signatures of inflammatory biomolecules that may serve as predictors of response to each bDMARD therapy with high sensitivity and specificity. Thus, a signature of five biomolecules was identified as potential predictor of TNFI response [Vascular endothelial growth factor (VEGF), Eotaxin, RANTES, IL7 and IL-17]. Indeed, a signature including three highly expressed cytokines/chemokines in RA serum were identified as predictors of RTX response [interferon-inducible protein 10 (IP10), Eotaxin and monocyte chemoattractant protein 1 (MCP-1)].

Conclusion: The extensive analysis of serum inflammatory profile allowed to identify specific and distinctive signatures of biomolecules that, in coordination with known clinical and serological profiles, might predict the response of RA patients to TNFI or RTX treatments. SAT0044

ADIPOCYTOKINE FLUCTUATES WITH INFLAMMATORY MARKERS OR DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM FIVE-YEAR DATA OF TOMORROW STUDY

K. Mamoto1, K. Inui2, T. Okano1, Y. Sugiioka1, M. Tadaa, T. Koike2,3, H. Nakamura4, 1Osaka City University Graduate School of Medicine, Department of Orthopaedic Surgery, Osaka, Japan; 2Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; 3Osaka City General Hospital, Department of Orthopaedic Surgery, Osaka, Japan; 4Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan

Background: Leptin and adiponectin have been thought to be adipocytokines that promote or suppress inflammation, respectively. Objectives: The aim of this study was to investigate the relationship between adipocytokines and inflammatory markers or disease activity in patients with rheumatoid arthritis (RA) by using 5-year data of TOMORROW study which is a cohort study and started from 2010. Methods: We evaluated inflammatory markers, disease activity score (DAS)-CRP; medication and levels of adipocytokines in 202 patients with RA (mean age, 58.6±7; medication with biological agents, 54.9%) and 202 age- and sex-matched healthy volunteers (controls; mean age, 57.4±7). We eventually compared leptin or adiponectin concentrations in 183 RA patients and 190 controls from 2010 (BL) to 2015 (SY) and investigated the relationship between adipocytokines and CRP or DAS in patients by using Spearman correlation analysis. Results: The levels of leptin and adiponectin in patients were significantly higher than controls at all time points. Adiponectin level of patients significantly increased from BL to SY compared to controls (Table 1). In patients, adiponectin showed significant negative correlation with CRP at both of BL and SY (BL: R= -0.22; SY: R= -0.240; p<0.05), however, not with DAS at BL and SY. Leptin positively correlated with CRP at SY (R=0.207; p<0.05), but not with CRP at BL or DAS at any time. Adiponectin levels at BL and SY were significantly higher in biologics users at BL and significantly increased from BL to SY compared to patients without biologics. No association between leptin levels and the use of biologics (Table 2). Conclusion: The level of adiponectin in RA patients with continuous treatments for 5 years increased, and the trend was more pronounced in biologics users. These results might indicate that adiponectin is a cytokine involved in anti-inflammatory effects.

DOI: 10.1136/annrheumdis-2020-eular.5589

Methods: Anti-CCP positive individuals with musculoskeletal symptoms but no clinical synovitis (CCP+ at-risk) were recruited as part of a national prospective cohort study. Comprehensive periodontal examination was performed at baseline by a dentist; six sites per tooth were assessed for clinical attachment level (CAL), pocket depth (PD) and bleeding on probing (BOP). Periodontal disease sites (PDD) were defined as CAL ≥2 mm and PD ≥4 mm. The distribution of PDD was classified in line with recent guidelines (2). The severity i.e. total burden of periodontal inflammation, was quantified at patient level using the periodontal inflamed surface area (PISA) index.[3] CCP+ at-risk were monitored for progression to IA. Multivariable Cox regression was used to assess the effect of PDD distribution and PISA on progression to IA.

Results: 126 CCP+ at-risk underwent full periodontal examination and were followed up for median 23.4 months (range 0.6 – 56.8 months). Mean age was 49 years, 86 (68%) were females. At baseline, 42 (33%) subjects had no PDD, 51 (40%) had localised PDD (<30% teeth with one or more PDD site) and 33 (26%) had generalised PDD (≥30% of teeth with one or more PDD site). Mean (SD) PISA for all subjects was 267 (319) mm², 31 subjects (25%) progressed to IA after median of 12.6 months (range 0.6 – 49.5 months). Progression to IA was significantly higher in subjects with localised PDD compared with those without PDD (33% vs 16%, HR (95% CI) 2.45 (1.02, 5.94), p=0.02), figure 1. Interestingly, this association was not seen in subjects with generalised PDD (19% progression, HR 0.68 (0.20, 2.32). In addition, severity (i.e. total burden) of periodontal inflammation (PISA) was not significantly predictive of progression to IA alone (HR 1.001 (0.999 – 1.002), p=0.08). However, when adjusting for distribution of PDD, PISA was significantly associated with progression to IA (HR 1.0016 (1.0003-1.003), p=0.00163).

Conclusion: Periodontal inflammation predicts progression to IA in CCP+ at-risk individuals without clinical synovitis. The severity (i.e. total burden) of periodontitis appears to be particularly predictive of progression to IA in patients with localised periodontitis. These data suggest periodontitis may be an important factor in the development of RA and provide rationale for periodontal intervention with the aim of arthritis prevention in at-risk individuals.

SAT0046  MODIFIED DISEASE ACTIVITY SCORE AT 3 MONTHS IS A SIGNIFICANT PREDICTOR FOR RAPID RADIOGRAPHIC PROGRESSION AT 12 MONTHS COMPARED WITH OTHER MEASURES

M. Movahedi1, 2, D. Weber1, P. Akhavan1, E. Keystone1, 3Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada; 1Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, Canada

Background: Progressive rheumatoid arthritis (RA) is responsible for joint damage causing disabilities with no agreement on which disease measures best predict radiographic progression

Objectives: We aimed to determine which disease activity measures including disease activity score (DAS), modified (M) DAS28 (CRP), clinical disease activity index (CDAI), and health assessment questionnaire disability index (HAQ-DI) best predict rapid radiographic progression (RRP) in early RA patients at baseline (BL) and 3 months.

Methods: PREMIER data, a 2-year, multicenter, double-blind active comparator-controlled study with methotrexate (MTX) naïve RA patients and active disease <3 years were used. Only patients in the MTX arm were analyzed. RRP was defined as change in modified total Sharp (mTSS) > 3.5 at month 12. Logistic regression analysis assessed impact of measures at BL and 3 months on RRP at 12 months. Best cut-off points of M-DAS28(CRP) was also estimated using area under the receiver operating characteristic curve.

Results: 149 patients were included: female (n=113; 75.8%), positive RF (n=127; 85.2%), mean (SD) age 52.9 (13.3) years, disease duration 0.8 (0.9) year, DAS28(CRP) 6.3 (0.9). After adjusting for potential confounders, only M-DAS28(CRP) at BL (adjOR=3.69; 95% CI: 1.70-6.36) and 3 months (adjOR=2.56; 95% CI: 0.83-7.38) strongly predicted RRP at 12 months. M-DAS28(CRP) 4.5 and 6.5 at BL and 3 months maximized sensitivity and specificity for prediction of RRP. Conclusion: M-DAS28(CRP) was a stronger predictor at BL and 3 months for RRP compared with other disease activity measures. Removing tender joint count and patient global assessment from DAS28(CRP) improves prediction of RRP.

SAT0047  RISK FACTORS FOR THE POSTOPERATIVE DELAYED WOUND HEALING IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH A BIOLOGICAL AGENT

S. Okita1, 2, 3, H. Ishikawa1, A. Abe1, S. Itó2, A. Murasawa4, K. Nishida4, T. Ozaki2

1Okayama City Hospital, Orthopedic Surgery, Okayama, Japan; 2Niigata Rheumatic Center, Rheumatology, Shibata, Japan; 3Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Orthopedic Surgery, Okayama, Japan

Background: It has been suggested that perioperative use of biological disease-modifying anti-rheumatic drugs (bDMARDs) in rheumatoid arthritis (RA) patients carries risks for the surgical-site infection and the delayed wound healing (DWH); however, the risk of DWH with perioperative use of bDMARDs has not reached a general consensus.

Objectives: This retrospective study aimed to investigate the risk factors associated with DWH after orthopedic surgery in RA patients treated with bDMARDs.

Methods: We reviewed medical records of 277 orthopedic procedures for 188 RA patients treated with bDMARDs between from 2014 to 2017 in Niigata Rheumatic Center. As preoperative nutritional status assessment, we evaluated body mass index (BMI), prognostic nutritional index (PNI), and CONtrolling NUTritional status (CONUT). In addition, we evaluated DAS28-CRP, DAS28-ESR, face scale for pain, global health (GH), and Health Assessment Questionnaire-Disability Index (HAQ-DI) to assess the disease activity. Univariate and multivariate logistic regression analyses were performed to evaluate the risk factor for DWH.

Results: The major characteristics of the patients in 277 procedures were mean age of 63.2 years old and mean disease duration of 18.2 years. Surgical site were hand and wrist (145 procedures), foot and ankle (76), hip and knee (31), elbow and shoulder (24), and spine (1). Seventy-four patients were treated with tocilizumab, 62 with etanercept, 50 with golimumab, 49 with abatacept, 16 with infliximab, 15 with adalimumab, and 6 with certolizumab. According to nutritional assessment in PNI and CONUT, 63% (n=115) and 47% (n=130) were normal nourished patients, respectively.

In 277 procedures, DWH were identified in 24 patients (8.6%). The following variables were significant in the univariate analyses: disease duration (OR 1.053; 95% CI 1.010–1.099; p=0.016), foot and ankle surgery (OR 7.091; 95% CI 2.130–23.603; p=0.001), tocilizumab (OR 0.286; 95% CI 0.093–0.881; p=0.029) (Table 1). These variables were entered into a multivariate model, and it was revealed that pre-operative use of tocilizumab (OR 0.265; 95% CI 0.074–0.953; p=0.042) and procedures in the foot and ankle (OR 6.915; 95% CI 1.914–24.976; p=0.003) were associated with an increased risk of DWH (Table 1).

Conclusion: As previous study on tocilizumab described, the current retrospective study suggested that pre-operative use of tocilizumab and procedures in the foot and ankle were risk factors for DWH. Pre-operative disease activity and baseline nutritional status were not independent risk factors for an increase in the prevalence of DWH.

SAT0048  THE CLINICAL USE OF F-18 NAF BONE PET/CT FOR EVALUATING DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. J. Park1, J. W. Lee2

1International St. Mary’s Hospital, Catholic Kwandong University College of Medicine, Incheon, Republic of (South Korea); 2International St. Mary’s Hospital, Catholic Kwandong University College of Medicine, Nuclear Medicine, Incheon, Republic of (South Korea)

Background: Bone position emission tomography/computed tomography (PET/CT) using F-18 sodium-fluoride (NaF) has been widely used in various bone and joint diseases. However, only a few studies had evaluated the clinical implication of F-18 NaF bone PET/CT in patients with rheumatoid arthritis.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2020-eular.34242
Objectives: The aim of our study is to investigate the clinical usefulness of F-18 NaF bone PET/CT for evaluating disease activity in patients with rheumatoid arthritis.

Methods: Seventeen patients with rheumatoid arthritis prospectively enrolled. All patients underwent whole-body F-18 NaF bone PET/CT and ultrasonography simultaneously. The baseline disease activity score with 28 joints using erythrocyte sedimentation rate (DAS28-ESR) and the results of blood tests were collected. From F-18 NaF bone PET/CT images, uptake of the 28 joints used in DAS28-ESR, expressed as standardized uptake value (SUV), and joint-to-normal bone uptake ratios of those joints were measured for each patient. Using SUV and joint-to-normal bone uptake ratios of the 28 joints, the relationship of bone PET/CT findings with clinical factors and ultrasonography findings were assessed.

Results: SUVs and joint-to-normal bone uptake ratios in the joints with active synovitis were significantly higher than those in the joints without definite synovitis (p < 0.05). The sum of SUVs and joint-to-normal bone uptake ratios of 28 joints showed significant positive correlations with DAS28-ESR as shown in Figure 1 and Figure 2 (p < 0.001 and correlation coefficient 0.775 for SUV, p < 0.001 and correlation coefficient 0.828 for joint-to-normal bone uptake ratio) and patient global assessment score (p = 0.002 and correlation coefficient 0.697 for SUV, p = 0.002 and correlation coefficient = 0.705 for joint-to-normal bone uptake ratio). On correlation analysis with blood test results, only serum ESR level showed a positive correlation with the sum of SUVs and joint-to-normal bone uptake ratios (p = 0.047; correlation coefficient = 0.470) and other serum markers showed no significant association with bone PET/CT results (p > 0.05). On correlation analysis with ultrasonography findings, both power Doppler and gray-scale joint inflammation scores showed significant positive correlations with both the sum of SUVs and joint-to-normal bone uptake ratios of ultrasonography-examined joints (p < 0.05).

Conclusion: The sum of joint uptake on F-18 NaF bone PET/CT has significant positive correlations with DAS28-ESR, serum ESR level, and ultrasonography findings in patients with rheumatoid arthritis. The findings on F-18 NaF bone PET/CT might be used as an imaging biomarker for disease activity of rheumatoid arthritis.

BACKGROUND: Previous studies have shown that early diagnosis and treatment of rheumatoid arthritis (RA) is important for achieving comprehensive disease control and have identified established disease as an independent predictor of worse clinical outcomes. However, it is not clear whether these differences are driven by patient-reported or objective outcome measures.

Objectives: The aim of this analysis was to compare the time to achieving low disease activity (LDA) and remission based on both objective and patient-reported outcomes in people with early vs. established RA followed in routine clinical care.

Methods: RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) registry that were not in a low disease state at baseline based on the CDAI, SJC28, PtGA, pain and fatigue criteria below, and had at least six months of follow-up, were included in the analysis. LDA was defined as CDAI≤10, SJC28≤2, TJC28≤2, PGAs≤2cm, pain≤2cm, fatigue≤2cm, and MDGAs≤2cm; remission was defined as CDAI≤2.8, SJC28≤1, TJC28≤1, PGAs≤1cm, pain≤1cm, fatigue≤1cm, and MDGAs≤1cm. Between group (early vs. established) differences in time to first LDA/remission were assessed with Kaplan-Meier survival analysis and the log-rank test.

Results: A total of 986 patients were included, 347 (35%) with early RA and 639 (65%) with established RA. At baseline, patients with early RA were significantly younger (55.8 vs. 58.0 years) and were less likely to have a comorbidity (94.5% vs. 97.5%), or an erosion (26.7% vs. 62.6%), be RF-positive (65.6% vs. 74.2%), use bDMARDs (75% vs. 26.6%), and be non-smokers (38.9% vs. 47.3%).

Time to achieving LDA based on CDAI (HR [95%CI]: [1.23 [1.07,1.43]), SJC28 (1.32 [1.15,1.51]), TJC28 (1.18 [1.02,1.36]), MDGA (1.28 [1.10,1.49]), PGAg (1.23 [1.05,1.44]), and pain (1.29 [1.09,1.52]) were significantly shorter in early RA compared to established RA. Similarly, time to achieving remission based on CDAI (HR [95%CI]: [1.50 [1.22,1.84]), SJC28 (1.35 [1.17,1.55]), MDGA (1.25 [1.06,1.47]), PGAg (1.22 [1.02,1.47]), and pain (1.37 [1.14,1.65]) were significantly shorter in early RA. However, no differences were observed in time to remission based on TJC28 (1.12 [0.96,1.31]) and either LDA or remission based on fatigue (LDA: 1.10 [0.94,1.30]; remission: 1.09 [0.92,1.31]). Adjustment for age, gender, presence of comorbidities, and baseline scores did not alter the results.

Conclusion: Time to achieving low disease state or remission based on various objective and patient-reported measures is significantly shorter in early compared to established RA with the exception of fatigue.

Objectives: To characterize the level of heterogeneity of RA patients in remis-
se by identifying clusters based on the DAS28 components; and to describe
inter and intra-class cluster demographic and clinical characteristics.

Methods: Patients from Hospital Clínico San Carlos cohort; stored in a depart-
mental electronic health record from January 1st, 2000 to December 30th,
2018, diagnose with RA according ACR 1986/2010 criteria were eligible for
this study. Only observations with a DAS28 Erythrocyte Sedimentation Rate
(ESR) value < 2.6 value were considered. ESR, patient's Global Health (GH),
tender and swollen joints were used for calculating the clusters. Different
aggregation levels for joints were studied as well as the input variable types.
Isolated joints, joints grouped by the type of affection (swollen or tender) or
anatomic location or laterality aggregation levels were considered. Variables
expressed as present or absent (i.e. dichotomous), continuous (count of joints)
and categorical (type of joints) were also studied. Gower's distance, used for
dealing with variables of different type, was employed to calculate the distance
matrix. The number of suitable clusters was chosen from two to seven clusters
based on the width value of a Silhouette analyses. Finally, Partitioning Around
Medoids (PAM) was used as the clustering algorithm. Differences among clus-
ters regarding demographic and clinical characteristics were analyzed using
t-student chi2 test.

Results: 812 patients with 1,431 observations were analyzed in this study.
The joint aggregation level which showed a highest Silhouette width value
(0.708) was the anatomic one. In this aggregation level, five dichotomous
variables (presence of tenderness and/or swelling in right and/or left shoul-
der, elbow, wrist, knee and hand (including both metacarpophalangeal and
proximal interphalangeal joints) and two continuous variables (ESR and
GH) were used. Two clusters were found: the cluster A with 1,305 observa-
tions and 742 patients and the B with 126 observations and 115 patients. Cluster
b) had a statistically significant higher DAS28-ESR value (higher
number of tender and swollen joints, and higher GH, but lower ESR), longer
follow-up time (6.5 vs. 4.7 years), higher VAS-pain score (10 vs. 2), and
higher HAQ score (0.25 vs. 0.12). In addition, the proportion of patients
treated with oral corticosteroids (63% vs. 50%) and biological therapy (29%
vs. 12%) was higher.

Conclusion: We have identified two clinically distinct populations of RA patients
in remission according to DAS28-ESR < 2.6. Each subgroup could be associated
with different outcomes during follow-up, such as radiographic progression or
risk of relapse.

SAT0052 THERAPEUTIC STRATEGIES IN DIFFICULT-TO-
TREAT RHEUMATOID ARTHRITIS: PRELIMINARY
RESULTS OF A SYSTEMATIC LITERATURE REVIEW
INFORMING THE 2020 EULAR RECOMMENDATIONS
FOR THE MANAGEMENT OF DIFFICULT-TO-
TREAT RHEUMATOID ARTHRITIS

Semmelweis University, Department of Genetics, Cell- and Immunobiology &
Department of Rheumatology, 3rd Department of Internal Medicine, Budapest,
Hungary; Leiden University Medical Center, Department of Rheumatology,
Leiden, Netherlands

Background: Rheumatoid arthritis (RA) patients treated according to European
League Against Rheumatism (EULAR) recommendations failing ≥2 biological or
targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) with
a different mode of action who still have complaints which may be suggestive
of active disease may be defined as suffering from difficult-to-treat RA Man-
agement recommendations for RA focus predominantly on the earlier phases of
the disease and specific recommendations for difficult-to-treat RA patients are
currently lacking.

Objectives: To systematically summarise evidence in the literature on pharma-
cological and non-pharmacological therapeutic strategies for difficult-to-treat RA
patients, informing the 2020 EULAR recommendations for the management of
difficult-to-treat RA.

Methods: A systematic literature review (SLR) was performed: PubMed, Embase
and Cochrane databases were searched up to December 2019. Relevant papers
were selected and appraised.

Results: Thirty articles were selected for therapeutic strategies in patients with
limited DMARD options due to contraindications, 73 for patients in whom previ-
ous b/tsDMARDs were not effective (true refractory RA), and 51 for patients with
predominantly non-inflammatory complaints. For patients with limited DMARD
options, limited evidence was found on effective DMARD options for patients
with concomitant obesity, and on safe DMARD options for patients with con-
comitant hepatitis B and C. In patients who failed ≥2 bDMARDs, tocilizumab,
tofacitinib, baricitinib, upadacitinib and filgotinib were found to be more effective
than placebo, but evidence was insufficient to prioritise. In patients who failed ≥1
bDMARD, there was a tendency of non-tumour necrosis factor inhibitor (TNFi)
bDMARDs to be more effective than TNFi (Figure 1). Generally, b/tsDMARDs
become less effective when patients failed more bDMARDs, this tendency was
not clear for upadacitinib and filgotinib (Figure 2). In patients with predominantly
non-inflammatory complaints (mainly function, pain and fatigue), exercise, edu-
cation, psychological and self-management interventions were found to be of
additional benefit.

Conclusion: This SLR underscores the scarcity of evidence on the optimal treat-
ment of difficult-to-treat RA patients. As difficult-to-treat RA is a newly defined
disease state, all evidence is to an extent indirect. Several b/tsDMARDs were
found to be effective in patients who failed ≥2 bDMARDs and generally effective-
ness decreased with a higher number of failed bDMARDs. Additionally, a benefi-
cial effect of non-pharmacological interventions was found on non-inflammatory
complaints.

SAT0053

ESTIMATING REAL-WORLD UNMET NEEDS FOR REACHING REMISSION IN THE FIRST YEAR FOLLOWING EARLY RA DIAGNOSIS: RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT (CATCH)

1 Canadian Early Arthritis Cohort (CATCH), Montreal, Canada; 2 McGill University/ MUHC, Montreal, Canada; 3 Johns Hopkins Medicine, Baltimore, United States of America; 4 McGill University/ MUHC, Montreal, Canada; 5 Université de Laval, Quebec City, Canada; 6 Université de Sherbrooke, Sherbrooke, Canada; 7 University of Calgary, Calgary, Canada; 8 University of Manitoba, Winnipeg, Canada; 9 University of Toronto, Toronto, Canada; 10 Western University, London, Canada; 11 Southlake Regional Health Center, Newmarket, Canada; 12 Hospital for Special Surgery, New York, New York, United States of America

Background: Several composite RA disease activity indices are commonly used in clinical practice and research. Different disease activity indices however can be inconsistent in classifying remission (REM).

Objectives: 1) Compare remission prevalence across 4 common RA indices; 2) compare changes in remission across indices; and, 3) Identify predictors of persistent active disease across all indices, in real-world early RA patients over 1 year follow up.

Methods: Data were from patients with early RA (symptoms < 1 year) enrolled in the Canadian Early Arthritis Cohort (CATCH) between 2007 and 2018. Participants had active disease at enrolment, were treated with csDMARDs and completed standardized clinical assessments every 3-months. Remission status was assessed using 4 indices: 1) DAS28< 2.6 OR DAS28CRP < 2.5, 2) CDAI ≤ 2.8, 3) SDAI≤ 3.3, and 4) ACR/EULAR Boolean remission – SJC28, TJC28, CRP, PGA all ≤1. T-tests/ chi-squared tests were used to compare differences in remission prevalence by 1 year, and changes in remission before and after a QI program. Logistic regression was used to identify predictors of persistent active disease on all 4 indices.

Results: 1202 adults were eligible for this analysis. At enrolment, 877 (73%) were women, mean (sd) age was 55 (14), average disease activity was high (DAS28 5.1 (14); CDAI 27 (14); SDAI 29 (15)). Prevalence of remission by 12-months follow up was 14-21% higher when estimated with the DAS28 compared with CDAI, SDAI and Boolean criteria, and 378 (31%) did not achieve remission according to any of the 4 indices (Fig 1). Improvement in remission after a QI program however was similar across all indices (≈15-17%). In adjusted logistic regression, Persistent active disease across all measures was most strongly associated with positive serostatus and smoking in men, and with obesity and more tender joints in women. Pain and lower education were predictors in BOTH men and women (Table 2).

Conclusion: In the absence of a single “best measure” that also takes into account the patient’s perspective, we estimate unmet needs for achieving remission in the first year of follow up in 1 in 3 ERA patients who did not achieve remission by ANY of the 4 indices.

PREVALENT AND PREDICTORS OF METHOTREXATE-ASSOCIATED ADVERSE EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Sherbini1, J. Gwinnutt1, K. Hyrich1, S. Verstappen1 on behalf of RAMS Co-Investigators. 1The University of Manchester, Centre for Epidemiology

Methods: Methotrexate (MTX) is the first-choice treatment for rheumatoid arthritis (RA), but the exact prevalence rates and predictors of important adverse events (AEs) associated with MTX treatment are less well investigated.

Objectives: To determine the prevalence of MTX AEs (gastrointestinal (GI), mucocutaneous, neurological, haematological, pulmonary, and liver enzymes elevation), and to identify baseline demographic, clinical and drug related predictors of liver and GI AEs.

Results: In total, 2089 participants were included (mean age=58.4±13.5 years; 1390 (65.5%) women). Of those, 1816 and 1584 completed their visits at 6 and 12 months, respectively. The frequency of abnormal ALT values (>1×ULN) was 10.8% (183/1685) and 11.6% (170/1461) at 6 and 12 month follow-up visits, and 15.3% (286/1845) for either visits. The number of patients who reported GI AEs was 777 (40.6%) within 1 year of follow-up. The prevalence of mucocutaneous, neurological, haematological and pulmonary AEs were 441 (23.1%), 487 (25.5%), 116 (6.1%), and 406 (21.3%), respectively.

Male sex, having high ALT at baseline and a history of diabetes were all associated with increased risk of ALT elevation during the study period (Table 1). Contrarily men were 47% less likely to report GI AEs compared to women. Furthermore, younger age and higher baseline disease activity score (DAS28-CRP) were associated with increased risk of GI AEs occurrence.

Table 1. Baseline predictors of elevated alanine transaminase (ALT) and gastrointestinal (GI) adverse events

Conclusion: GI events were the most commonly reported AEs among patients with RA in the first year of MTX treatment, followed by neurological, mucocutaneous and pulmonary AEs. Identifying predictors of AEs may help to optimise drug therapy in RA by tailoring the dosage strategy or frequency of monitoring. This may lead to increased adherence and consequently improved effectiveness.

available. In the future, machine learning applications may allow fast and reliable decisions on flare prediction in RA patients. These data can guide decisions about DMARD tapering at in real time during the physician-patient contact and allow to reduce costs not only by selective treatment tapering but also by sparing additional laboratory examinations.

SAT0057 INITIAL PRESENTATION OF RHEUMATOID ARTHRITIS (RA) – IS IT STILL “SYMMETRIC POLYARTHRITIS”? T Sokka-Istler1, K Paalanen1, M Kauppi2, E Nikphorou3, KSSHP, Jyväskylä, Finland; 3PHHYKY Lahti, Finland; 1King’s College Hosp., London, United Kingdom

Background: RA is traditionally described as a symmetric polyarthritis. The ACR/EULAR 2010 criteria are met if patient has high positive ACPA, symptoms >=6 wks and one small joint swollen. The public and all steps of health care have been informed for many years that RA should be found early.

Objectives: To study variations in pattern on first presentation of RA.

Methods: All patients with the new diagnosis of RA were extracted from the GoTreatIT clinical database between 2008 to 2019 at a single RA clinic that covers a population of 250,000. Demographic data, clinical variables, labs, x-rays, joint status and PROs at baseline were included in the analysis. Appropriate parametric/non-parametric tests were used to study differences between groups.

Results: A total of 1044 (73.5% CCP+) patients with no prior diagnosis of RA were included. 683 (65%) female, mean age 56, 361 (35%) male, mean age 61. At initial presentation in 2008, 60% had >=6 swollen joints (Figure) and a mean DAS28 of 4.4 compared to 22% and 3.8 respectively in 2019 (p=0.007). Duration of symptoms prior to diagnosis decreased from 6 to 4 months (p=0.033), and the proportion of patients with erosions from 20% in 2008 to 14% in 2019 (ns). Symptoms (PROs) such as pain, fatigue and global health were similar/slighty worse in 2019 compared to 2008.

Conclusion: RA cannot be marketed as “symmetric polyarthritis”, as more than half of the patients have a maximum of 2 swollen joints at the time of the diagnosis at the most recent years. Patients with RA can be identified earlier, with less disease activity and damage, compared to previous years.

Background: As rheumatoid arthritis (RA) is more common in women compared to men, most studies of disease predictors have mainly included women, and data on risk factors in men are limited. Smoking is an established predictor of RA. A negative association between body mass index (BMI) and the risk of RA in men has been reported from several studies of Scandinavian populations.

Objectives: To investigate whether the impact of smoking and BMI on the risk of subsequent development of RA in men differs by age.

Methods: A total of 22 444 men from a defined catchment area were included in a Preventive Medicine Program (PMP). Height and weight were measured as part of the health survey, and BMI was calculated as weight (in kg)/height (in m²). Information on smoking was obtained using a structured self-administered questionnaire. Normal BMI, overweight and obesity was defined according to the WHO criteria. From this population, we identified individuals who developed RA after inclusion by linking the PMP register to the local community based RA register and to local and national patient administrative databases. In a structured review of the medical records, patients were classified according to the 1987 ACR criteria for RA. Four controls for each validated case, matched for sex, year of birth and year of screening, who were alive and free of RA when the index person was diagnosed with RA, were selected from the PMP register. The impact of BMI category and smoking on the risk of RA was examined in multivariable conditional logistic regression models, stratified by age at inclusion in the health survey (above vs below the median).

Results: A total of 151 men were diagnosed with RA and fulfilled the ACR criteria after inclusion in the PMP (median time to diagnosis 13 years, inter-quartile range 9-19; 76 % rheumatoid factor positive at diagnosis). These pre-RA cases were compared to 604 matched controls. Among men aged >46 years, overweight/obesity was associated with a significantly reduced risk of subsequent RA (odds ratio (OR) 0.40; 95 % confidence interval (CI) 0.21-0.76, adjusted for smoking), whereas there was no such association in younger men (adjusted OR 0.75 (95 % CI 0.42-1.36). Smoking was a significant predictor of RA in men aged >46 years (Table 1). There was a similar trend in those aged ≤46 years, but it did not reach statistical significance (Table 1).

Conclusion: Overweight/obesity was associated with a reduced risk of subsequent RA in men aged >46 years. The relative importance of lifestyle factors for the risk of RA may be greater in older men compared to younger.

Background: Adiponectin is an adipokine that circulates in blood in three main forms, low molecular weight trimers, middle molecular weight hexamers, and high molecular weight (HMW) multimers [1]. It is still unclear which form of adiponectin is the predominant one to mediate the protein functions. Total adiponectin levels are elevated in both serum and synovial fluid of patients with rheumatoid arthritis (RA) [2], and total circulating adiponectin levels associate with inflammatory markers in a population at high risk for future RA [3]. However, the association of circulating adiponectin with markers of disease activity in subjects with RA is still matter of debate.

Objectives: The aim of the study was to determine whether total and/or HMW adiponectin levels associate with markers of disease activity and/or plasma chemokine levels in a cohort of subjects with untreated early RA.

Methods: The cohort consisted of 70 untreated subjects with newly diagnosed RA. Clinical disease activity markers, including DAS28, CDAI, CRP and ESR, were assessed and data on patient history were recovered from clinical files. The plasma levels of 15 chemokines were measured with LEGENDplex™ Human Proinflammatory Chemokine Panel or ELISA, and total and HMW adiponectin plasma levels were determined with ELISA. Multivariate factor analysis was used to examine the association between total and HMW adiponectin plasma levels with clinical disease activity markers and plasma chemokine levels. The multivariate models were used to select potentially associated markers and chemokines, which were then tested with linear regression.

Results: Both total and HMW adiponectin levels were associated with several clinical markers of disease activity (CRP, ESR, DAS28-ESR). Total adiponectin levels were also associated with DAS28-CRP. Furthermore, a positive association was found between total adiponectin levels and the pro-inflammatory chemokines CXCL10, CXCL9, and CCL2, whereas HMW adiponectin levels only associated with CXCL9.

Conclusion: This study shows for the first time that both total and HMW adiponectin levels are associated with several markers of disease activity as well as pro-inflammatory chemokines in a well-characterized cohort of subjects with untreated early RA. Those findings indicate adiponectin as a potential disease marker in subjects with RA.

The multivariate models were used to select potentially associated markers and chemokines, which were then tested with linear regression.

Results: Both total and HMW adiponectin levels were associated with several clinical markers of disease activity (CRP, ESR, DAS28-ESR). Total adiponectin levels were also associated with DAS28-CRP. Furthermore, a positive association was found between total adiponectin levels and the pro-inflammatory chemokines CXCL10, CXCL9, and CCL2, whereas HMW adiponectin levels only associated with CXCL9.

Conclusion: This study shows for the first time that both total and HMW adiponectin levels are associated with several markers of disease activity as well as pro-inflammatory chemokines in a well-characterized cohort of subjects with untreated early RA. Those findings indicate adiponectin as a potential disease marker in subjects with RA.

SAT0060

OVERLAPPING SJOGREN’S SYNDROME REDUCES THE PROBABILITY OF REACHING TARGET IN RHEUMATOID ARTHRITIS PATIENTS: A PROPENSITY SCORE MATCHED REAL-WORLD COHORT FROM 2009 TO 2019

H. Zhang1, H. Zhang1, D. Gao1, Z. Zhang1. 1Peking University First Hospital, Beijing, China

Background: Overlapping Sjogren’s syndrome (SS) is not uncommon in rheumatoid arthritis (RA), and considered as a probable detrimental factor of RA. But data on the impact of overlapping SS on RA therapeutic response is limited.

Objectives: Our current study aimed to identify the effect in a real-world cohort from 2009 to 2019.

Methods: The medical records of RA patients who attended the outpatient department of our medical center from 2009 to 2019 were reviewed, and the disease activity based on DAS28-ESR, DAS28-CRP, SDAI and CDAI at each follow-up point were collected. To correct confounders which may affect the therapeutic response between those RA patients with SS (RA-SS) and without (RA-noSS), we compared both the propensity score-matched and unmatched cohorts using the Cox proportional hazards model.

Results are adjusted for sex, age and BMI

Figure 1. Linear regression analysis of total and HMW adiponectin with CRP

Results are adjusted for sex, age and BMI

Figure 2. Linear regression analysis of total and HMW adiponectin with CXCL10

DOI: 10.1136/annrheumdis-2020-eular.1295
Results: Among the 1099 RA patients, 129 (11.7%) overlapped with SS validated by positive anti-SSA or pathological minor salivary gland biopsy (MSGB). After propensity score matching based on their baseline characteristics, 126 of 129 RA-SS and 126 of 970 RA-noSS patients were statistically extracted. Overlapping SS was associated with a 29%, 26%, 18%, 22% lower probability of reaching remission in RA patients based on DAS28-ESR, DAS28-CRP, SDAI, CDAI, respectively, which trend kept true for reaching low disease activity (LDA) either. Although overlapping SS had the most significant impact on ESR (HR 0.69, 95%CI 0.61-0.79), other components assessing RA disease activity were also in jeopardy. When stratified by age, RA duration, RF and ACPA status, baseline DAS28-CRP, the trend remained.

Conclusion: Overlapping SS is associated with a lower probability of reaching target in RA patients, and should be regarded as one of the poor prognostic factors in the management of RA.

<td>0.48</td>
</tr>
</tbody>
</table>

Conclusion: SE is strongly related to ACPA and a greater burden of disease in RA pts. In pts receiving standard treatments including biologics, SE is predictive of a greater increase in DA, which is partially mediated by the presence of ACPA.

OBJECTIVES: To assess the incidence rate (IR) of first-time SAB in patients with RA and to estimate the incidence rate ratio (IRR) of SAB with a general population cohort without RA serving as the reference.

Methods: Individuals with no prior history of SAB or RA were included consecutively from 31 December 1996, their 18th birthday or date of immigration, whichever came latest, and followed until first-time SAB, death, emigration or 31 December 2017, whichever came first. Information on RA diagnosis, vital status, age, sex, place of residence, comorbidities, medication and first-time SAB were achieved on an individual level through cross-linkage between five virtually complete Danish nationwide registries (Civil Registration System, National Patient Registry, Register on Medicinal Product Statistics, DANBIO rheumatology registry and the SAB database). We used Poisson regression to estimate adjusted IRRs overall and stratified by age and sex.

Results: In total, 6,127,150 individuals were included of whom 34,627 individuals developed RA. In the RA cohort, 228 first-time SAB events occurred during 283,186 person years (PY) of follow-up (IR 80.5/100,000 PY) compared with 25,268 events during 87,521,120 PY of follow-up in the general population cohort (IR 28.9/100,000 PY). Median follow-up was 7.2 years (IQR 3.5-12.3) after RA diagnosis and 18.7 years (IQR 6.8-21) in the general population cohort. Individuals with RA who developed SAB were more often women, had an orthopaedic implant and had recent use of glucocorticoids compared with individuals with SAB without RA. (Table 1) IRRs of SAB were higher among patients with RA compared with the general population in all age categories. The IRRs increased with age and were higher in men, both in patients with RA and in the general population cohort. After adjustment, the IRR remained higher for individuals younger than 70 years with RA compared with the general population but was similar for older individuals. (Figure 1)

Conclusion: In this nationwide cohort with more than 25,000 observed first-time SAB events, patients with RA younger than 70 years old had a 1.5-2 times higher incidence rate compared with the general population. The significance of anti-rheumatic treatments on risk and the prognosis of SAB in patients with RA remain to be explored.

Acknowledgments: We wish to thank patient representative Pia Lüchau Pedersen.

*Results from Poison regression model. Adjusted for age (as a continuous variable), calendar year (6-year intervals), diabetes mellitus, alcohol abuse, chronic dialysis, cancer, orthopedic implants, cardiac or vascular implants, chronic obstructive pulmonary disease and chronic heart failure. Follow-up time was split according to exposure status of these time-dependent covariates.
Background: Respiratory tract infections are among the leading causes of hospitalization in rheumatoid arthritis (RA) and Streptococcus Pneumoniae (Sp) is one of the most frequent pathogens involved. For these patients, the CDC recommends a combined vaccination scheme (CVS) using two types of Sp vaccines but evidence on its effectiveness remains insufficient.

Objectives: To assess the impact of the combined vaccination scheme on the incidence of Sp infections in patients with RA treated with DMARD.

Methods: A cohort was nested in a register including patients with RA who were prescribed a bDMARD or tsDMARD—either naive or switch—from 2000 to March 2019. The target outcomes were invasive pneumococcal disease (IPD) and all-cause community-acquired pneumonia (CAP), as defined by relevant MedDRA codes. Demographic and clinical features were also retrieved. Each participant informed about the date when they implemented a systematic Sp vaccination protocol and whether they were using the CVS. Those not adopting this practice were excluded from the analysis.

Crude incidence rates (IRs) were calculated for each outcome as well as for its combination (combined variable defined as “Sp infections”). Exposure was split into two periods, considering the date when the CSV was officially recommended in Spain (May 2015). The incidence rate ratio (IRR) comparing pre and post implementation periods was estimated with a Poisson regression model adjusted for sex, age and comorbidities (Charlson Index).

Results: 1704 patients were included, their characteristics are shown in Table 1. One centre was excluded for not using any Sp vaccination protocol while the remaining ones reported using the CVS. Crude IRs by periods (pre and post CVS implementation) and age groups are shown in Table 2. The IRR of the post-vaccination period after adjusting for age, sex and comorbidities (Charlson index) was 0.40 (95% CI: 0.29 - 0.56), p<0.001.

Conclusion: Vaccination rate against pneumococcal was 78.9% (versus 55% in 2013, p<0.0001) and 60.4% for influenza (versus 60% in 2013). The main reason for non-vaccination was absence of vaccine proposal (59.2%) for pneumococcal, 20.9% for influenza, 15.7±10.5 years, 58.2% were treated with methotrexate (MTX), and 68.6% with a biologic. Vaccination rate against pneumococcal was 78.9% (versus 55% in 2013, p<0.0001) and 60.4% for influenza (versus 60% in 2013). The main reason for non-vaccination was absence of vaccine proposal (59.2%) for pneumococcal, and fear of vaccines (56.7%) for influenza. In the multivariate analysis, a higher level of education (OR [CI95] 4.4 [2.3-8.4], p<0.0001), a very good opinion on vaccination (2.1 [1.1-4.1], p=0.003), vaccination against influenza done (2.3 [1.3-4.2], p=0.006), and exposure to biologics (4.0 [2.2-7.4], p<0.0001) were associated with vaccination against pneumococcal. Age over 65 years old (2.0 [1.2-3.2], p=0.006), participation in a patients’ association (3.6 [1.4-8.9], p=0.006), vaccination against pneumococcal done (2.4 [1.3-4.5], p=0.004), exposure to biologics (2.1 [1.2-3.7], p=0.006), a good (3.3 [1.4-8.9], p=0.03) and a very good opinion on vaccination (6.6 [2.8-15.6], p<0.0001) were associated with vaccination against influenza.

Conclusion: Vaccination rate against pneumococcal increased over the last 5 years but remained stable for influenza vaccine in French RA patients. This could be improved with patient’s information and education, especially in patients age under 65, biologic naïve and with a bad opinion about vaccination.

SAT0064 VACCINATION RATE AND RISK FACTORS FOR NON-VACCINATION IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL PROSPECTIVE MULTICENTRIC OBSERVATIONAL STUDY

C. Rempengault1, T. Barnetche2, M. Magnot3, B. Castagne4, M. Pugibet5, E. Berard2, M. E. Truchetet6, P. Vergne-Salle7, A. Tournadre8, A. Ryssen-Witrand9, C. Lukas1. 1Montpellier Rheumatology, Montpellier, France; 2Bordeaux, Rheumatology, FHU ACRONIM, Bordeaux, France; 3Toulouse, Rheumatology, Toulouse, France; 4Clermont-Ferrand, Rheumatology, Clermont-Ferrand, France; 5Limoges-Cité, Rheumatology, Limoges-Cité, France

Background: Rheumatoid arthritis (RA) patients are at increased risk of infections, some of which could be prevented in part by vaccination (1). Influenza and pneumococcal vaccines are recommended in RA (2). However, vaccination coverage of these patients remains very low. Five years ago, we found in a previous study that vaccination rates in France were 55% for pneumococcal and 60% for influenza vaccines (3).

Objectives: The aim of our study was to evaluate the vaccination rate among RA patients, compare it with our previous results, and identify factors associated with non-vaccination.

Methods: We conducted a cross sectional multicentric observational study in the rheumatology departments of 5 university hospitals in France. Data were collected from December 2018 to July 2019. Outpatients and hospitalized adult patients with RA according to the ACR/EULAR 2010 criteria were included. Data were collected during a single visit through an anonymous questionnaire completed by the patients. Pearson Chi-squared analysis and multivariable logistic regression were used to compare characteristics of vaccinated versus non vaccinated patients.

Results: 584 patients (773% of women, mean age 61.8±12.6 years old) were included. 81.7% were RF and/or ACPA positive, with a mean RA duration of 15.7±10.5 years, 58.2% were treated with methotrexate (MTX), and 68.6% with a biologic. Vaccination rate against pneumococcal was 78.9% (versus 55% in 2013, p<0.0001) and 60.4% for influenza (versus 60% in 2013). The main reason for non-vaccination was absence of vaccine proposal (59.2%) for pneumococcal, and fear of vaccines (56.7%) for influenza. In the multivariate analysis, a higher level of education (OR [CI95] 4.4 [2.3-8.4], p<0.0001), a very good opinion on vaccination (2.1 [1.1-4.1], p=0.003), vaccination against influenza done (2.3 [1.3-4.2], p=0.006), and exposure to biologics (4.0 [2.2-7.4], p<0.0001) were associated with vaccination against pneumococcal. Age over 65 years old (2.0 [1.2-3.2], p=0.006), participation in a patients’ association (3.6 [1.4-8.9], p=0.006), vaccination against pneumococcal done (2.4 [1.3-4.5], p=0.004), exposure to biologics (2.1 [1.2-3.7], p=0.006), a good (3.3 [1.4-8.9], p=0.03) and a very good opinion on vaccination (6.6 [2.8-15.6], p<0.0001) were associated with vaccination against influenza.

Conclusion: Vaccination rate against pneumococcal increased over the last 5 years but remained stable for influenza vaccine in French RA patients. This could be improved with patient’s information and education, especially in patients age under 65, biologic naïve and with a bad opinion about vaccination.

References:

Background: Pneumococcal vaccinations are recommended for patients with rheumatoid arthritis (RA). There is evidence that pneumococcal vaccinations are less effective when administered after starting conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs). Vaccination guidelines have changed over time, since 1992 UK guidelines recommend pneumococcal vaccination for the immunocompromised, and in 2003 was expanded to all individual’s age ≥65 years. Guidelines from British Society of Rheumatology (2011) and EULAR (2019) advise to vaccinate prior to starting csDMARDs where possible. There is little evidence about whether these guidelines are being followed.

Objectives: The aims of this study were to explore the timing of pneumococcal vaccination in patients with RA in relation to starting csDMARDs and examine whether this has changed over time.

Methods: This was a cross-sectional study using UK electronic health records from primary care between 1st January 2000 and 31st December 2018. To be included in the study patients needed to 1) have a diagnosis of RA, 2) be prescribed csDMARDs up to 3 months prior to, or after RA diagnosis date and 3) have received a pneumococcal vaccination. Index date was considered the start of csDMARDs and vaccinations were required to be up to 5 years prior to the index date or after index date until leaving the practice, death or the end of the study period. For each patient it was determined if the first vaccination was prior to starting csDMARDs. For those vaccinated up to 3 years prior to, or up to 3 years after starting csDMARDs, the time between vaccination and starting csDMARDs in months was determined and this distribution was plotted in a bar chart. To explore how timing of vaccination has changed over time the proportion (with 95% confidence intervals (CI)) of people vaccinated prior to starting csDMARDs was plotted by year.

Results: Of 21461 people with RA identified who were prescribed their first csDMARD on or after 1st January 2000, there were 8205 (38.2%) patients vaccinated and eligible to be included in the study. The cohort had a mean age 62 years, 66.4% were female. There were 2997 (36.5%) patients vaccinated prior to starting csDMARDs. Those vaccinated prior to starting csDMARDs were older, with 72% (n=2168) being aged 65 years or over vs 28% (n=1465) in those vaccinated after starting csDMARDs. 5358 (65.3%) were vaccinated up to 3 years prior to, or up to 3 years after starting csDMARDs. The distribution showed that the most frequent time of vaccination was in the 3 months after starting csDMARDs and the frequency was higher in the months after starting csDMARDs than in the months preceding (Figure 1). Of those vaccinated outside these times, 1000 (12.2%) were vaccinated >3 years prior and 1844 (22.5%) were vaccinated >3 years after starting csDMARDs. The proportion vaccinated prior to starting csDMARDs has increased over time from a minimum of 17.2% in 2001 to a maximum of 55.6% in 2016. The greatest increases were seen between 2003 and 2007 (Figure 2).

Conclusion: This study shows that timing of pneumococcal vaccination is improving with a trend towards increasing vaccination prior to starting csDMARDs and a high proportion of patients were vaccinated around the time of csDMARD initiation. However, just over a fifth (22.5%) were vaccinated more than 3 years after starting csDMARDs. Rheumatologists need to continue to work to raise awareness of the importance of vaccinations through better communications to patients and primary care physicians, to ensure best practice is being followed.

SAT0066

BURDEN OF MALIGNANCY, VENOUS THROMBOEMBOLISM, ANEMIA, AND INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO SWITCHED FROM A FIRST CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUG TO ANOTHER DISEASE-MODIFYING ANTI-RHEUMATIC DRUG REGIMEN

1Robin K. Dore, MD, private practice, Austin, United States of America
2Gilead Sciences, Inc., Foster City, United States of America
3Squibb, Consultant of: AbbVie, Bristol-Myers Squibb, Eli Lilly, Galapagos, Gilead, GSK, Pfizer Inc, Roche, UCB, William Dixon Consultant of: Bayer and Google

Background: EULAR and ACR guidelines recommend a variety of treatment options for rheumatoid arthritis (RA) patients who failed a first conventional synthetic disease-modifying antirheumatic drug (csDMARD). The recent launches of Janus kinase inhibitors (JAKi) have stimulated interest in comorbidities such as malignancy, venous thromboembolism (VTE: deep vein thrombosis [DVT] or pulmonary embolism [PE]), anemia, and infections in patients with RA. Understanding the epidemiology of these conditions can help optimize treatment decisions within the treat-to-target approach following the first csDMARD.

Objectives: Estimate the real-world prevalence, incidence, and costs of these comorbidities among patients switching from a first csDMARD to another DMARD.

Methods: From a large US health claims database, the study selected adults with RA (≥2 RA claims ≥30 days apart) who started a csDMARD regimen as first DMARD, then switched (index date [ID], 1/1/2012–3/31/2017) to another DMARD regimen (monotherapy or combination with csDMARD). All patients had continuous enrollment 1 year before and ≥1 year after the ID. The study estimated baseline prevalence (%) and on-treatment incidence (per 100 patient-years [P100PY]) of malignancy, VTE, anemia, and infections (any, serious, opportunistic, and herpes zoster). Generalized linear models with gamma distribution and log link function estimated the impact of baseline characteristics on mean annualized healthcare costs per-patient-per-year (PPPY) associated with incident conditions. The recycled prediction method calculated adjusted total costs differences of these conditions.

Results: Among study patients (N = 7,816, median age 54 yrs, 74% female), the 38% on monotherapy index treatments had mean (standard deviation) treatment
Conclusion: In the real world, RA patients were affected by VTE, malignancy, anemia and infections prior to switching from first csDMARD. During next treatment, the incidence rates (PI00PY) were: 0.7 for VTE, 2.1 for malignancy, 7.8 for anemia and 79.4 for infection (Figure 1). Modeling showed that total healthcare cost more than doubled for RA patients with vs without incident occurrence of malignancy (2.9), followed by PE (2.7) and DVT (2.1) ($30,638 vs $29,515, vs $26,723, opportunistic infections $39,239 vs $28,947, and herpes zoster $30,638 vs $29,515.

The recent incidence of surgical site infection and delayed wound healing after elective orthopaedic surgeries for patients with rheumatoid arthritis who treated with b/tsDMARDs

Y. Hotta1, Y. Nasu2, K. Nishida1, M. Matsuhashi1, M. Watanabe1, R. Nakahara2, T. Ozaki1.1 Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Science, Department of Orthopaedic Surgery, Okayama, Japan; 2Okayama University Hospital, Department of Orthopaedic Surgery, Okayama, Japan

Background: In Japan, Methotrexate (MTX) has been approved in 1999, the first biologic DMARD (bDMARD) in 2003, and the Janus kinase (JAK) inhibitors have been used since 2013. Although it is expected that the recent advancement of drug therapy would contribute the decrease in the incidence of orthopaedic surgeries by preventing structural damages1, 2), we are still facing a considerable number of patients who require surgical interventions3).

Objectives: To investigate the recent trends of patient’s background who underwent the orthopaedic surgery for rheumatoid arthritis, number of orthopaedic intervention, and the type of the surgery.

Methods: We reviewed the records of 1569 patients with RA who underwent orthopedic surgeries between 2004 and 2019 in our institution. The mean age of patients was 62.8 (22-88) years-old with disease duration of 20.9 (0.5-64) years. Data of these patients such as age, disease duration, medication (Glucocorticoid; GC, MTX, b/tsDMARD), type of surgeries (total joint replacement; TJR, hand surgery, foot surgery, spine surgery, and others), and preoperative serum CRP level were collected. We analyzed the annual change of these demographic and clinical data. Then, we compared them between CRP negative (<1.5g/l) and CRP positive group. Cochran-Armitage trend test, χ2 square test, or unpaired T-test was performed for statistical analysis. P<0.05 was considered significant.

Results: Among all cases, 426 cases (27.2%) were treated with b/tsDMARD at the time of operation. MTX and GC were used in 937 cases (59.7%) and 1015 cases (64.7%), respectively. The mean age and disease duration of RA showed an increasing trend, although the CRP level was dramatically decreased during the study period. While the rate of MTX use has not changed significantly (p=0.102), the number of cases treated by b/ts DMARD increased significantly to 46.7% (p<0.001). In contrast, the rate of GC use decreased significantly (p<0.001). Although the annual number of surgeries have not changed, the proportion of cases who performed TJR decreased dramatically (59.6% in 2011, 29.5% in 2019), and the surgeries for hand and foot increased significantly (p<0.001) (Fig 1). The annual mean preoperative CRP level also decreased from 18.8±1.95 to 4.89±0.81 (Fig2). Compared to CRP positive group (n=1,113), the patients in CRP negative group (n=446) showed significantly younger age(p<0.001), shorter disease duration (p=0.031), lower late of GC use, and a higher rate of b/tsDMARD use. The proportion of patients who underwent TJR was significantly higher in CRP positive group (p<0.001).

Conclusion: Along with the increasing use of b/tsDMARD, the preoperative disease control of RA, as well as the type of demanded surgeries have dramatically changed.

DOI: 10.1136/annrheumdis-2020-eular.1133
Background: The risk of tuberculosis (TB) has decreased in biologic disease modifying anti-rheumatic drugs (bDMARDs) treated rheumatoid arthritis (RA) patients, but remains unaltered 4-fold increased in bio-naïve RA patients compared to the general population in Sweden (1). In absolute numbers, most TB cases in contemporary RA patients occur in the group of bio-naïve patients. Knowledge about risk factors for TB and TB characteristics in bio-naïve RA patients is still limited.

Objectives: To investigate risk factors for TB and TB characteristics in bio-naïve RA patients.

Methods: Population-based case-control study. A national bio-naïve RA cohort was identified from the National Patient Register and the Swedish Rheumatology Quality Register. RA cases with TB were identified by linkage to the Swedish Tuberculosis Register (with mandatory TB registration) 2001-2014 (n=42). For each case, four matched RA controls without TB were identified. Clinical data were obtained from medical records. Univariate and multivariable logistic regression analyses were used to estimate risk for TB expressed as adjusted (adj) odds ratio (OR) with 95% confidence intervals (Cl).

Results: After review of the medical records and validation of diagnoses, 31 cases with RA and TB and 122 controls remained in the study. The TB cases had a median of 3 (1-6) reported TB risk factors, and almost 90% were born before 1950. Only one case was screened for TB (with negative result of tuberculin skin test). Active TB occurred at a mean of 15 years after RA diagnosis, and all except three cases were considered as reactivation of latent TB. Exposure to leflunomide (5 cases, 4 controls) (adj OR 6.02; 95% CI 1.47-24.65) and azathioprine (5 cases, 6 controls) (adj OR 3.85; 95% CI 1.06-13.79) were associated with increased risk for TB. Methotrexate, used in 67.7% of cases and 73.9% of controls, was not associated with increased risk of TB (adj OR 0.83; 95% CI 0.34-1.98). Exposure to corticosteroids was more common among cases than controls (74.2% vs 53.8%, p= 0.04), and was associated with an adj OR for TB of 2.44 (95% CI 1.00-5.92). No significant differences were identified between prednisolone-treated cases and controls in terms of maximum dose ever of prednisolone, treatment duration before TB, or cumulative dose of prednisolone during the last year before diagnosis of TB. Obstructive pulmonary disease was the only comorbidity linked to an increased TB risk (adj OR 3.94; 95% CI 1.45-10.69). Pulmonary TB dominated (84%) followed by TB lymphadenitis (19%). Treatment success was 94%, comparable to TB patients in general.

Conclusion: Several RA-associated risk factors may contribute to increased TB risk in bio-naïve RA patients (treatment with leflunomide, azathioprine, or prednisolone and concomitant obstructive lung disease). We could not confirm previous findings of an association with the use of moderate to high doses of prednisolone (≥15mg). TB risk seems difficult to predict with precision in the individual bio-naïve patient based on RA-associated risk factors. To further decrease the TB risk in RA patients screening should also be considered in the group of bio-naïve patients.

SAT0071

SUBCLINICAL SYNOVITIS IN ARTHRALGIA: HOW OFTEN DOES IT RESULT IN CLINICAL ARTHRITIS? A LONGBITUDINAL STUDY TO REFLECT ON STARTING POINTS FOR DMARD TREATMENT

C. Rogier1, F. Wouters2, L. Van Boheemen3, D. Van Schaardenburg3, P. De Jong1, A. Van der Helm-van Mil1,2. Erasmus MC, Rheumatology, Rotterdam, Netherlands; 1Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands; 3Reade, Rheumatology, Amsterdam, Netherlands

Background: Clinically apparent arthritis is mandatory for diagnosing and classifying RA. It is often used as endpoint in arthralgia cohorts and as a starting point for DMARD therapy in clinical practice. In recent literature subclinical synovitis, visualized with MRI or ultrasound, is increasingly used as a starting point for DMARD therapy in absence of clinically apparent arthritis. However, not all patients with a subclinical synovitis will develop clinically apparent arthritis, and thus may be overtreated. It has even been suggested to replace the entry-criterion of clinical arthritis by subclinical synovitis within the 2010 criteria of RA and therefore introduce considerable overtreatment.

Objectives: To determine the frequency of non-progression to clinical arthritis in patients with subclinical synovitis, also after considering the 2010-criteria.

Methods: Three individual cohorts of arthralgia patients without clinically apparent arthritis (n=166, 473 and 168) were followed for 1-year on the development of inflammatory arthritis (IA). At baseline subclinical synovitis in hands or feet was visualized with ultrasound (US) (defined as greyscale≥2 and/or power-doppler≥1) in cohort 1 and 3 and MRI (synovitis score ≥1 by two readers) in cohort 2. For all patients with subclinical synovitis the proportion of progressors (true positives) and non-progressors (false positives) were determined. The same analysis was done in the subgroup of patients that fulfilled the 2010 criteria for RA, if subclinical synovitis was used as entry criterion. Analyses were stratified for ACPA status.

Results: At baseline 36%, 41% and 31% of patients had subclinical synovitis. Of the ACPA-positive arthralgia patients with subclinical synovitis 46%, 56% and 29% respectively developed IA, whereas 54%, 44% and 71% did not progress. Within ACPA-negative arthralgia patients with subclinical synovitis 34%, 15% and 10% developed IA; whereas 66%, 85% and 90% did not progress (Figure 1A). Similar results were seen in the subgroup of patients that fulfilled the 2010 criteria with subclinical synovitis as entry criterion (Figure 1B).

Conclusion: Replacing clinical arthritis by subclinical synovitis in arthralgia introduces a high false-positive rate: 44-71% (ACPA-pos) and 66-90% (ACPA-neg) of patients with subclinical synovitis did not develop clinically apparent arthritis within one year. Applying the 2010-criteria in this setting did not diminish the false positive rate. Starting DMARDs in patients without clinical synovitis may therefore introduce considerable overtreatment.

SAT0072

THE IMPACT OF COMORBIDITIES ON ABSENTEEISM, PRESENTEEISM AND EMPLOYMENT STATUS IN PEOPLE LIVING WITH RHEUMATOID ARTHRITIS

A. Bradshaw1, A. Bosworth2, K. Walker-Bone3, L. Lunt1, S. Verstappen1.
1Centre for Musculoskeletal Research, Manchester, United Kingdom; 2NRAS, Maidenhead, United Kingdom; 3MRC Versus Arthritis Centre for Musculoskeletal Health and Work, Southampton, United Kingdom

Background: Many people with rheumatoid arthritis (RA) have comorbidities. However, there is limited research on the impact of multimorbidity on absenteeism (e.g. sick leave) and presenteeism (i.e. reduced productivity while at work due to ill health) in people with RA.

Objectives: i) to explore the impact of comorbidities on absenteeism and presenteeism in patients with RA and ii) to evaluate the association between multimorbidity and employment status.

Methods: A cross-sectional survey was conducted by the National Rheumatoid Arthritis Society (NRAS), UK, collecting information on: demographics, education, employment status (i.e. employed (Empl), stopped/retired early because of RA (Stop_RA), stopped/retired early because of other health issues (Stop_Health)), and disease related variables (e.g. symptom duration, rheumatoid arthritis impact of disease (RAID) questionnaire). Participants were asked to report whether they

Figure 1. Percentage of arthralgia patients with subclinical synovitis that did and did not develop IA, in three independent cohorts: (A) Percentage of patients with subclinical synovitis that did and did not progress to IA after one-year follow-up, stratified for ACPA status. (B) Percentage of patients with subclinical synovitis and ≥6 points at baseline that did and did not progress to IA after one-year follow-up stratified for ACPA status.

Figure 2. Area under the ROC curve to determine the number of B-lines at LUS to define a significant RA-ILD, applying the 10% of fibrosis at chest HRCT measured by OsiriX as external criterion.
had or were treated for any of 15 predefined comorbidities (categorised into 0, 1, 2, 3, or ≥4 (Table)). Percentage of number of hours missed due RA (i.e. absenteeism) and presenteeism (10-point Likert scale) were assessed using the Work Productivity and Activity Impairment Questionnaire (WPAI-RA). For the purpose of this study both absenteeism and presenteeism outcomes were dichotomized (no presenteeism/absenteeism versus any) and only patients aged <65yrs were included.

Logistic regression analysis were applied to assess the association between number of comorbidities and absenteeism/presenteeism, adjusting for the categorical variables age, gender and education. Chi2-square test was applied to assess frequencies of individual comorbidities between the three employment status groups. **Results:** 868 participants were included; 91.7% women with a median symptom duration of 8.3 years [IQR 4.4-13.7]. The average RAID score was 5.2 (SD 2.2). 80.4% were in paid employment, including those currently on sick leave, 16.9% stopped early because of their RA and 2.7% reported stopping early because of other health reasons. In those employed mostly commonly occurring comorbidities were: back pain (28.8%), osteoarthritis (21.5%), depression (26.3%) and anxiety (22.6%). Compared to people with RA with no comorbidities, the odds associated with time off work due to RA increased from 1.7 up to 3.4 with increasing number of comorbidities (Table). Although a similar trend was observed for presenteeism, the effect sizes were smaller. Significant differences (p<0.05) in frequencies of the following comorbidities were observed between the three employment status groups (Empl, Stop_RA, Stop_Health, respectively): heart pressure, lung disease, diabetes, ulcer or stomach disease, kidney disease, liver disease, anemia or other blood disease, cancer, depression, anxiety, OA, back pain, osteoporosis and Sjögren. **Conclusion:** Although the study is cross-sectional and no temporal association can be determined, this study shows that not only personal and work related contextual factors should be considered when preventing worker productivity loss, but also other comorbidities.

### SAT0074

#### RHEUMATOID ARTHRITIS AT TREATMENT WITH BDMARD OR TSDMARD: VACCINATION RATES AND INCIDENCE OF RESPIRATORY INFECTIOUS DISEASES, RESULTS FROM A COHORT

**R. Dos Santos Sobrin1, E. Perez-Pampín1, N. Perez Gómez2, A. Mera Varela3.**

1Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain

**Background:** Vaccination regimes have been evaluated for long time in rheumatic diseases, being a strong recommendation to vaccinate against Influenza and Pneumococcus (13 and 23-valent). Rheumatoid arthritis (RA) patients have higher rates of infectious diseases, caused by many reasons, being patient’s comorbidities, rheumatic disease and treatments used the most important1,2.

**Objectives:** To analyze the incidence of respiratory infectious diseases in these patients regarding for vaccination status. Also prove the degree of accomplishment of vaccination calendar.

**Methods:** Patients diagnosed of RA at treatment with bDMARD or tsDMARD, in Rheumatology Department of aforementioned hospital, during Influenza vaccination campaign in 2018 (October 2018 – February 2019) were included. Clinical, demographic and therapeutic data were reviewed. Stata 15.1 was used to perform statistical analysis.

**Results:** 237 patients finally fulfilled inclusion criteria, excluding decesses or finished treatment (460 patients were diagnosed of RA and 954 patients conform all bDMARD and tsDMARD of Rheumatology Department). Mean age at beginning of vaccination campaign was 61.5 years old (SD 13.6), 79% were female. Mean time of diagnosis was 15.4 years (SD 9.4), 79% patients receive Influenza vaccine, although higher rates were found in Pneumococcal vaccine (86.9% 13-valent and 81.8% 23- valent). Most patients were at treatment with anti-TNF (57.2%), the most prevalent was etanercept 27.5% followed by adalimumab 11.0% and infliximab 10.2%). csDMARD concomitant was achieved by 67.4% patients (methotrexate 73%) and 61% receive corticosteroids. Only 3 patients got hospitalized by pneumonia. As opposed, 39 patients suffer from a respiratory infectious disease without hospitalization (mean of 1.33 infections/ patient). After multivariate analysis, only 13-valent Pneumococcal vaccine is responsible statistically significant with higher incidence of respiratory infectious diseases (Chi2=6.25 p=0.012; OR 2.86 CI95% 1.12 to 6.88). Other variables analyzed were kind of bDMARD/tsDMARD, Influenza vaccine, 23-valent Pneumococcal vaccine, concomitant csDMARD/corticosteroids, but no relationship was found.

**Conclusion:** Vaccination status is still incomplete in majority of rheumatic patients. Its benefits have been explained in a variety of studies. That is the

Background: Interstitial Lung Disease (ILD) is an extra-articular complication of rheumatoid arthritis (RA) that is associated with increased morbidity and mortality. Conventional disease-modifying drugs (DMARDs) such as methotrexate (MTX) have been implicated in the development and exacerbation of a pre-existing ILD.

Objectives: The aim of our study was to check the influence of combined MTX treatment in patients with RA-ILD treated with abatacept (ABA).

Methods: National multicentre retrospective registry of 283 patients with RA-ILD treated with ABA. RA was diagnosed according to the ACR classification criteria of 1987 or by the EULAR/ACR criteria of 2010. ILD was diagnosed by high resolution computed tomography (HRCT). In this study we have done a subanalysis of the 46 patients treated with ABA in combination with MTX (ABA+MTX) vs. 217 patients treated with ABA in monotherapy or in combination with other synthetic DMARDs. Efficacy was evaluated according to the following parameters: a) Dyspnea (MMRC) considering variations ≥ 1; b) Lung function test (FEV1) considering variations ≥ 10% in FVC and a variation of DCO ≥ 10%; c) Imaging test (HRCT) d) DAS28 score e) prednisone dose. Variables were collected at the beginning of the study and at months 3, 6, 12 and then every 12 months until a maximum of 60 months.

Results: 263 patients with ILD associated with RA were included in the study with a mean age 64.6±10 years, RF or CCPA were positive in 235 (89.4%) and 233 (88.6%) cases, respectively, with a mean follow-up of 22.7±19.7 months. Baseline characteristics of both groups are shown in Table 1, while data obtained during evolution of this complication are presented in Figure 1.

Conclusion: Despite the baseline differences of both groups, the good evolution in the ABA+MTX subgroup suggests that this therapeutic strategy can be a safe combination for patients with RA-ILD.

Quevedo-Abeleido 1, Hospital Universitario de Canarias, La Laguna, Tenerife, Spain; Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de GC, Spain

Background: There are differences in the characteristics of patients with Rheumatoid Arthritis (RA) depending on their age at onset with two traditional groups: YORA (young onset RA) and EORA (elderly onset RA). These aspects have not been studied in cases of very late onset (≥ 80 years).

Objectives: To describe the clinical characteristics, treatments and evolution at one year in “very elderly onset RA” (VORA). Compare these characteristics with YORA (40-50 years) and EORA (60-70 years).

Methods: Retrospective and longitudinal study of RA patients from 2 spanish hospitals. From their databases, VORA patients were identified and their clinical characteristics were analyzed at onset, treatments at diagnosis and in the first 12 months, as well as DAS28-ESR activity after 1 year. These variables
were compared between cases belonging to one of the hospitals and 2 control groups of YORA and EORA patients of the same center, matched by sex, diagnosis date ± 2 years, RF and / or ACPA status and presence of erosions in baseline Rx.

Results: A total of 2790 records of RA patients were analyzed, identifying 59 cases of onset in “very elderly” (2% of the total). Table 1 shows its clinical, analytical characteristics and treatments at diagnosis.

Table 1. Demographic and clinical data of the 59 VEORA patients

</table>

Comorbidity

- Hypertension, n(%) 54 (92)
- Diabetes, n(%) 19 (32)
- CV disease 20 (34)

Clinical and analytical data at diagnosis

- Acute onset, n(%) 26 (44)
- Polymyalgia Rheumatica, n 16
- Rheumatoid factor, n(%) 40 (68)
- ACPA, n(%) 24 (41)
- DAS28-ESR 5 (4.4-5.7)
- high activity, n(%) 32 (54)

First visit treatment

- NSAIDs, n(%) 5 (9)
- Steroids, n(%) 55 (93)
- starting dose, mg/day* 10 (7,5-15)
- Methotrexate 36 (61)
- starting dose, mg/week 10 (7-15)
- Combined therapy 5 (8)

DAS28-ESR and the number of patients in remission or low activity at one year showed no differences between EORA and VEORA, or between these groups and that of younger patients.

Elderly patients (EORA and VEORA), compared with YORA, presented with higher frequency hypertension and CV disease, higher elevation in acute phase reactants at the onset and disease activity at diagnosis. VEORA patients, compared to EORA, showed a higher frequency of dyslipidemia (p = 0.04). There were also no significant differences between VEORA and EORA in the distribution and type of joints affected, time to diagnosis, acute phase reactants or disease activity at the onset. A higher frequency of special forms (such as PRM or RSSPE) was close to statistical significance in the VEORA group (p = 0.054).

Regarding initial treatment, both EORA and VEORA received steroidal treatment more frequently and a lower dose of Methotrexate during the first year. Biological treatments was also significantly higher in YORA (p<0.000). When comparing VEORA and EORA, differences related to the use of NSAIDs were found, lower in VEORA (p = 0.000), as well as in the maximum dose of Methotrexate reached in the next 12 months, higher in the EORA group (p = 0.01). No differences in adverse events with DMARDs were observed.

Conclusion: There have been few differences in the comorbidity profile and clinical characteristics at the onset between VEORA and EORA patients. Despite the differences observed in their management (more conservative in EORA and very elderly), we have not observed differences in its management (more conservative in EORA and very elderly). Despite the differences observed in its management (more conservative in EORA and very elderly), we have not observed differences in the distribution and type of joints affected, time to diagnosis, acute phase reactants or disease activity at the onset. A higher frequency of special forms (such as PRM or RSSPE) was close to statistical significance in the VEORA group (p = 0.054).

CARDIOVASCULAR RISK ASSESSMENT WITH CAROTID ULTRASONOGRAPHY IN ADDITION TO THE TRADITIONAL CARDIOVASCULAR RISK FACTORS IN RHEUMATOID ARTHRITIS PATIENTS: A CASE CONTROL STUDY

R. González Mazaro1, J. J. Frago-Gil1, P. Martinez Calabuig4, E. Grau García4, M. De la Rubia Navarro3, C. Páez Perales2, S. Leal Rodriguez1, I. Martinez Cordellia2, J. Iovra Cortés1, R. Negueroles Albuixech1, J. E. Oller Rodriguez1, L. González Puig1, C. Alcama Escandell1, I. Chalmeta Verdejo1, F. M. Ortiz Sanjuán3, E. Vicente Bermeu1, J. Cánovas Olmos2, C. Nájera Herranz2, J. A. Román Iovra1, Hospital Universitario y Politécnico de La Fe, Rheumatology, Valencia, Spain; 2University Católica de Valencia, Medical School, Valencia, Spain

Background: Cardiovascular disease (CV) is the most frequent cause of death in rheumatoid arthritis (RA) patients. It is well known that RA acts as an independent cardiovascular risk factor.

Objectives: To assess the CV risk in RA patients using carotid ultrasonography (US) additionally to the traditional CV risk factors.

Methods: A prospective transversal case control study was performed, including adult RA patients who fulfilled ACR/EULAR 2010 criteria and healthy controls matched according to CV risk factors. Population over 75 years old, patients with established CV disease and/or chronic kidney failure (from III stage) were excluded. The US evaluator was blinded to the case/control condition and evaluated the presence of plaques and the intima-media thickness. Statistical analysis was performed with R (3.6.1 version) and included a multivariate variance analysis (MANOVA) and a negative binomial regression adjusted by confounding factors (age, sex and CV risk factors).

Results: A total of 200 cases and 111 healthy controls were included in the study. Demographical, clinical and US data are exposed in table 1. Not any difference was detected in terms of CV risk factors between the cases and controls. In both groups a relationship between age, BMI and high blood pressure was detected (p<0.001).

Patients showed higher intima-media (both right and left) thickness compared to controls (p<0.006). Moreover it was also related to the disease duration and DAS28 score (p<0.001). A higher plaque account was noted in cases(p<0.004) and it was also related to the disease duration (p<0.001).
Background: Increased awareness of the efficacy of MTX in rheumatic disease is leading to more MTX use in patients from HIV endemic areas. While HIV related immunosuppression may contribute to improvement of some rheumatic diseases, immune reconstitution from highly active antiretroviral therapy (HAART) may lead to exacerbation or presentation of autoimmune disorders for which MTX therapy may be warranted. Most management guidelines for rheumatic disease do not address MTX use in the context of HIV.

Objectives: To systematically review the published literature on the safety of using MTX ≤30mg per week in HIV.

Methods: We searched CINAHL, Embase, Global, MEDLINE and World of Science databases (Jan 1990 to May 2018) for terms including 'methotrexate' and 'human immunodeficiency virus'. We also searched citations from review articles. Titives, abstracts or full manuscripts were screened independently by 2 reviewers to identify studies reporting HIV in patients taking MTX. Study quality was assessed using the McGill Mixed Methods Appraisal Tool (MMAT). Data was extracted on MTX and HIV adverse events (MTX toxicity; HIV viral load; CD4 count). Descriptive summaries are presented for studies providing outcomes in patients taking MTX ≤30mg per week.

Results: After removing duplicates and studies not meeting criteria or not providing sufficient information, 42 of the 2714 identified reports were included (1 clinical trial, 2 cohort, 1 cross-sectional study, 38 case reports/case series). Most reports (81%) originated from USA or Europe. Study quality was generally good with most studies fulfilling 50-100% of MMAT criteria. The randomized controlled trial (USA) assessing MTX on atherosclerotic disease in HIV showed that adverse events were more common in MTX versus placebo (12.8% vs 5.6%, p non-inferiority <0.05) and included infection, transient CD4 and CD8 drop, pulmonary toxicity, and death (1 attributed to MTX/HIV, 1 unrelated). One cohort study (South Africa) reported 43 RA patients on MTX who acquired HIV. In this cohort, RA generally improved despite only 5 individuals continuing MTX. No data on MTX adverse event rates was reported. One cohort study (USA) reported 13 HIV patients with myositis. One received MTX (with other immunosuppression) without MTX adverse effects but died due to AIDS. A cross-sectional study (France) of 43 HIV pts with autoimmune disease reported one patient on MTX (and other immunosuppression) developed an adverse event (cytopenia) compared to 5/33 patients not on MTX (cytopenia). The 38 case reports/series described 54 individuals with HIV receiving MTX. Of these studies, 27 (describing 42 subjects) reported on MTX adverse events and 35 (describing 46 subjects) reported on HIV adverse events. MTX adverse events developed in 29 subjects (hematologic 13, renal/hepatic 1, opportunistic infections 10, other events 2). HIV adverse events were noted in 23 subjects (Kaposi’s sarcoma 4, CD4 decrease 16, HIV viral titer increase 4). Five deaths were reported (2 infection, 1 infection and wasting, 2 HIV related deaths). Most subjects also received corticosteroids or other immunosuppressants including biologics.

Conclusion: There remains limited data on the safety of low dose MTX in HIV. Surveillance for HIV is warranted for individuals on MTX who are at risk for acquiring HIV. Caution and careful monitoring for MTX toxicity, opportunistic infections and HIV state is suggested if MTX is used in the setting of HIV particularly if combined with other immunosuppression.

Background: Depression and cognitive impairment have been frequently reported in rheumatoid arthritis (RA) [1]. Studies of the molecular mechanisms behind these phenomena attract increasing attention. We previously reported that signaling through the insulin-like receptor is impaired in RA and has consequences for pain processing (2).

Objectives: We investigated the central and peripheral footprint of the major neurotrophin in the central nervous system, brain-derived neurotrophic factor (BDNF), on pain and mood perception of RA patients.

Methods: Pain symptomatology was assessed in 216 female RA patients (mean age 52.9 years, mean disease duration 10 years) by a visual analogue scale (VAS), 18 tender points count (TPC), and by pressure-induced pain threshold measurement. The mood was patient-reported based on the Hospital Anxiety and Depression Scale (HADS). Clinical RA activity was assessed by DAS28. Serum levels of BDNF, IL6, IL1b, IL10 and IFN-gamma were measured by ELISA. Transcript of FOXO1 and FOXO3 was measured by RT-PCR in whole-blood RNA. Effect of BDNF signaling in leukocytes was assessed by differentially expressed gene (DEG) analysis in RNAseq of 24 female RA patients (R-studio, Bioconductor). High-resolution brain MRI was performed in a representative selection of patients with high and low serum BDNF, respectively.

Results: In RA patients, high serum levels of BDNF were associated with low inflammation parameters DAS28 and serum insulin (p<0.001), but low resistin (p=0.059). No correlation was found between BDNF with either serum IGF1 or inflammation parameters DAS28 and IL6. Serum BDNF was functional, since the RA patients with high BDNF had significant (p<0.001) higher TPC (4.1 vs 5.3, p=0.04) and TPC (18) (p<0.001) than patients with low BDNF. BDNF production was measured in CD4-CD8- PBMC and was significantly lower (p=0.05) in the CD4-CD8- PBMC compared to the CD4-CD8+ PBMC. The mood was patient-reported based on the Hospital Anxiety and Depression Scale (HADS). Clinical RA activity was assessed by DAS28. Serum levels of BDNF, IL6, IL1b, IL10 and IFN-gamma were measured by ELISA. Transcript of FOXO1 and FOXO3 was measured by RT-PCR in whole-blood RNA. Effect of BDNF signaling in leukocytes was assessed by differentially expressed gene (DEG) analysis in RNAseq of 24 female RA patients (R-studio, Bioconductor). High-resolution brain MRI was performed in a representative selection of patients with high and low serum BDNF, respectively.

Conclusion: The frequency of fragility fracture in the study groups was comparable (p>0.05), despite the age of patients. But, the frequency of refractures was higher in patients with RA-onset at young age, which, apparently, is a consequence of long RA disease duration and use of glucocorticoids.

SAT0083
PREVALENCE OF DYSPHAGIA AND ASSOCIATED RISK FACTORS IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

T. Matsumoto1, S. Tsuiboi1, T. Amano2,3, Shizuoka Welfare Hospital, Department of Rheumatology, Shizuoka, Japan; Shizuoka Welfare Hospital, Department of Orthopedic Surgery, Shizuoka, Japan

Background: Dysphagia (swallowing disorder) is an important health concern among the elderly that is associated with a poor prognosis [1]. Rheumatic diseases such as dermatomyositis are thought to represent an important risk factor for dysphagia, but few studies have described the association between dysphagia and rheumatoid arthritis (RA), and details on the prevalence of dysphagia in RA patients is not known [2] [3].

Objectives: The present study aimed to determine the prevalence of dysphagia and associated risk factors among elderly patients with rheumatoid arthritis.

Methods: We conducted a cross-sectional study including 93 patients with RA and osteoarthritis (OA) over 65 years of age. OA patients were included in the study as healthy controls. Patients with a history of stroke, neuromuscular disease, or head and neck tumors were excluded from the study. From July to November 2019, the water swallowing test (WST) and repetitive saliva swallowing test (RSST) were performed to evaluate the presence or absence of dysphagia in the patients. We also checked oral conditions, hoarseness, temporomandibular joint symptoms, cervical range of motion limitations, and grip strength. In addition, interviews were conducted to investigate swallowing ability and aspiration history. We compared the prevalence of dysphagia between RA and OA patients and explored potential risk factors for dysphagia in RA patients using logistic regression models.

Results: Our study subjects comprised 63 RA patients (mean age, 73.8 years; 86.3% female) and 30 OA patients (mean age, 75.8 years; 82.3% female). The WST and RSST revealed that RA patients had a significantly higher prevalence of dysphagia than OA patients (23.8% vs 6.7%, p<0.05). While RA patients with dysphagia (n=15) were significantly older and had a longer disease duration than the OA patients, we observed no difference in disease activity or administrated drugs. Of the RA patients with dysphagia, 60% reported no previous episodes of aspiration. Increasing age (odds ratio (OR) 3.21, 95% confidence interval (CI) 1.08-4.56), cervical range of motion limitations (OR 3.14, 95% CI 1.02-7.24), opening disorder of the jaw (OR 2.26, 95% CI 1 .12-4.86), and decreased grip strength (OR 1.96, 95% CI 1.01-4.15) were identified as factors related to the presence of dysphagia. Coexistence of Sjogren's syndrome did not significantly affect the prevalence of dysphagia.

Conclusion: Dysphagia was more prevalent among RA patients than in OA patients, suggesting an association with temporomandibular involvement, cervicomandibular disorder, and muscle weakness. Subclinical dysphagia should be assessed and monitored carefully in the clinical course of elderly patients with RA.

**SAT0084**

**SEPARAksamplike profile in patients with rheumatoid arthritis treated with TNF-inhibitors**

M. Novella-Navarro1,2, B. Hernández-Breijo2, F. Generé3, L. Lera-Gómez3, V. Pulitó-Cueto4, L. Nuño1, A. Villalba1, A. Balsa1,2, C. Plasencia1,2; 1Hospital Universitario La Paz, Madrid, Spain; 2Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and in Metabolic Bone Diseases of the Musculoskeletal System. IDIVAL, Santander, Spain

Background: In recent years, the relationship between obesity and autoimmune diseases has taken interest, since adipose tissue has been identified as an endocrine organ that secretes cytokines (adipokines), among which leptin stands out.

Objectives: i) to analyse the influence of BMI on clinical response in Rheumatoid Arthritis (RA) patients who initiate TNF-inhibitor (TNFi) therapy; ii) to analyse the differences in the serum profile of adipokines (leptin and adiponectin) according to BMI and their association with response to treatment.

Methods: Observational study of a prospective cohort of 73 RA patients who initiated biological treatment with TNFi from the Complex Therapy Unit (CTU) of our Hospital. Patients were classified according to their BMI in normal-weight (BMI<25) and overweight/obesity (O/O) (IMC≥25). Demographic, clinical and laboratory variables were collected at baseline and at 6 months. Our outcome measures were DAS28- VSM remission (DAS28<2.6) at 6 months after TNFi initiation. Serum leptin and adiponectin levels were measured by Enzyme-Linked Immuno Sorbent Assay (ELISA) at baseline and at 6 months. A descriptive sample analysis was performed for the characteristics of both patient subgroups was performed using Chi-square, T-test for independent samples and U-Mann Whitney. Likewise, a bivariate analysis was carried out by means of binary logistic regression to assess the probable association of the parameters studied with remission.

Results: Of the 73 patients studied, 51% were classified in O/O group. The O/O patients presented higher levels of baseline CRP (16.69±6 vs 8.74±3.81, p=0.01). No statistically significant differences were observed in the remaining variables (sex, age at the beginning of the TNFi, disease duration, baseline DAS28), as well as therapeutic variables (use of previous DMARDs and doses of methotrexate and/or steroids). Patients with overweight/obesity presented higher DAS28-ESR values at 6 months of treatment (3.59±1.14 vs 2.93±1.27, p=0.02) and achieved remission less frequently (18.9% vs 48.6%, p=0.007). Serum leptin levels were significantly higher in O/O patients, both baseline (29.39±2.150 vs 13.49±4.78, p=0.001) and 6 months (33.96±22.03 vs 14.77±4.50, p=0.001) after TNFi initiation. In addition, O/O patients were less likely to reach remission at 6 months than normal-weight patients. [OR= 4.04 IC95% (1.40-11.64); p=0.009]. Lower frequency of remission was associated to greater leptin levels at 6 months than normal-weight patients. [OR= 4.04 IC95% (1.40-11.64); p=0.009]. Serum leptin and adiponectin levels were measured by Enzyme-Linked Immuno Sorbent Assay (ELISA) at baseline and 6 months. A descriptive sample analysis was performed for the characteristics of both patient subgroups was performed using Chi-square, T-test for independent samples and U-Mann Whitney. Likewise, a bivariate analysis was carried out by means of binary logistic regression to assess the probable association of the parameters studied with remission.

Conclusion: In this RA patient cohort, overweight/obesity was associated with i) a reduced response to TNFi therapy and ii) a lower short-term remission rate. Within the adipokine profile, leptin seems to play a relevant role in the maintenance of pro-inflammatory activity with a negative influence on the response to TNF therapy in O/O patients.

**Metabolic Syndrome and its Association with rheumatid diseases in Paraguayan patients**

A. Paas1, V. Valinoti1, R. Acosta1, L. Roman1, M. Duarte1, O. Centurión1, P. De Abreu1, T. Martínez1, G. Avila1, I. Acosta-Colman1, S. Cabrera-Villalba1.

Background: Metabolic syndrome (MS) is associated with increased abdominal adipose tissue and production of inflammatory cytokines. Patients with MS are at increased risk for developing cardiovascular disease and diabetes mellitus, which are among the leading causes of death in chronic rheumatic diseases. Objectives: To characterize patients with rheumatic disease and MS and its association with inflammatory markers.

Methods: Descriptive, cross sectional, prospective study, in 3 Paraguayan cohorts of patients with rheumatoid arthritis (RA), systemic sclerosis (SSc) and systemic lupus erythematosus (SLE). This study had two phases: the first one included a standardized questionnaire according to the variables included in the Cardiovascular Risk project (PINV15-0346), from the Consejo Nacional de Ciencias y Tecnología (CONACYT), and physical examination; the second one included laboratory sample collection performed by a specialized laboratory for serum biomarkers measurement for cardiovascular risk prediction (i.e endothelin, alpha-TNF, E-selectin, t-PA, VCAM, PAI-1 and high sensitivity-CRP levels). MS patients were categorized according to 2007 ALAD criteria. All patients signed informed consent. SPSS Statistics v23 was used for data analysis. Quantitative variables were presented as means and qualitative variables as frequencies. Chi square test was performed for comparisons between dichotomous variables. A p value ≤ 0.05 was used for statistical significance.

Results: We included a total of 253 patients, 100 with RA, 100 with SLE and 53 with SSc. Metabolic syndrome was found in 23.8% (50/212). There was no significant difference in MS prevalence between diseases, but there was a higher frequency of increased abdominal circumference in RA and low HDL in SLE. Frequencies for different features of MS in RA, SLE and SSc are detailed in table 1.

Conclusion: We found a similar frequency of metabolic syndrome in our cohorts of RA, SSc and SLE Paraguayan patients but they had a different clinical and serological profile, suggesting that the pathways leading to metabolic syndrome are dissimilar in each disease. We need more studies to confirm this hypothesis.

DOI: 10.1136/annrheumdis-2020-eular.6121
Background: Patients with rheumatoid arthritis have more cardiovascular comorbidities which contributes to hospitalization and mortality.

Objectives: This study aims to investigate whether there is an association between cardiovascular comorbidities in RA with subgroup of patients and clinical findings of the disease

Methods: This study is a cross-sectional part of Rheumatoid Arthritis in Real Life (REAL), which is a multicenter prospective study conducted in Brazil, involving 13 centers specialized in the care of patients with RA. All subjects met the ARA (1987) or ACR/EULAR (2010) RA classification criteria. Subjects were submitted to clinical interview with physical exam and review of medical records. A sample of 1161 patients was selected for convenience. The association between cardiovascular comorbidities (systemic arterial hypertension (HA), diabetes mellitus (DM) type2, dyslipidemia, stroke and heart failure), the clinical characteristics and laboratory parameters of RA was evaluated through chi-square hypothesis tests, Student’s t-test, Fischer exact test, correlations test and ANOVA. Also, correlation Bonferroni test was used for multiple comparisons. Differences were considered statistically significant only when p < 0.05.

Results: 89% of the patients were female, with a mean age of 58 years. 62% of patients with RA had comorbidities, with HA the most prevalent. There were statistically significant association between cardiovascular comorbidities with age (61.71±9.69 years old vs 53.03±12.10) (p < 0.001), lower educational level (n=282±66.5vs 143±33.5) (p < 0.001), lower physical activity (n=132±73.3 vs 48±26.7) (p < 0.001), disease duration (18.5±9.75 years vs 14.4±8.61) (p < 0.001), positive anti-CCP test (60.5% vs 39.5%) (p = 0.027), high clinical disease activity index CDAI (65.9%vs 34.1%) (p < 0.001), DAS28VHS (3.72±1.46 vs 3.45±1.58) (p = 0.008) and HAQ score (1.00±0.76 vs 0.83±0.77) (p < 0.001).

Conclusion: The frequency of cardiovascular comorbidities is high in RA patients and is associated with age, disease duration and positive anti-CCP test. It is important to note that these comorbidities are more common among patients with lower frequency of physical activity and lower functional capacity, higher disease activity score and lower level of education. Better control of disease activity and extensive information to patients about the importance of exercise should be parallel objectives in RA.

SAT0087 ESTIMATED SLEEP DURATION AND CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS: A CASE CONTROL STUDY

D. Á. Galarza-Delgado1, J. R. Azpíri-López1, J. C. Colunga-Pedrana2, M. A. Reyes Soto3, A. Pérez Villar1, I. C. Zárate Salinas2, P. F. Frausto Lerma1, 1Hospital Universitario “Dr. José Eleuterio González”, UANL, Rheumatology Service, Monterrey, Mexico; 2Hospital Universitario “Dr. José Eleuterio González”; UANL, Cardiology Service, Monterrey, Mexico

Background: Sleep is essential to human health and it is increasingly regarded as an important lifestyle behavior. The reduction in sleep duration have been linked to an increased risk of cardiovascular disease (CVD) and death in general population (1). Patients with rheumatoid arthritis (RA) have a higher risk of CVD and as in other pain conditions, commonly report poor sleep quality as well as feeling unrested and fatigued after sleep (2). This can be attributed to a lack of awareness of sleep hygiene.

Objectives: To determine the prevalence of self-reported estimated duration of total daily sleep, daytime naps and quality of sleep of patients with RA and without rheumatic diseases and its association with cardiovascular risk factors.

Methods: Observational, cross-sectional study. RA patients aged 40 to 75 years that fulfilled 2010 ACR/EULAR criteria and controls (without RA) were included. Sleep duration and quality, daytime naps and awareness of sleep hygiene were assessed with self-administered questionnaire. Descriptive analysis was done with frequencies (%), mean (SD), median (q25-q75). Comparisons with Chi-square, Mann-Whitney U test and Wilcoxon. Binary regression analysis was used to test association between estimated sleep duration (<6h), cardiovascular risk factors and RA diagnosis.

Results: A total of 217 subjects were included. RA patients 93 (91.2%) vs 55 (47.8%) controls were female. Mean (SD) age was RA 56.68 (± 10.73) vs 57.27 (± 10.07) controls. Estimated total sleep duration (<6h) was higher in RA with 20.6% vs 8.7% in controls (p=0.012). There was no significant difference of the awareness of sleep hygiene 78% and 12.2% in the case and control group, respectively (p= 0.291). Obstructive sleep apnea was higher in controls 9.6% (p=0.047). The rest of the characteristics are displayed in table 1. Binary regression showed that having RA makes you 60% more like sleep less than six hours OR 0.40, 95% CI (0.17-0.92) (p=0.031). Patients with estimated sleep duration (<6h) had higher prevalence of Hypertension 51.6% vs 48.4% (p=0.022).

Conclusion: Patients with RA had a higher frequency of less estimated sleep time, this is associated with hypertension, risk of deaths and major cardiovascular events. Additionally, to inflammation and coexistence of CVD risk in RA, there was an absence of awareness of most of the individuals of sleep hygiene. Therefore, in clinical practice, assessment and education of sleep patterns may be of value
in identifying higher risk individuals. An integrated care approach may contribute to the awareness of healthcare professionals to develop appropriate interventions.

### SAT0088

**NO INCREASED RISK OF FALLS IN PATIENTS TREATED WITH BIOLOGICS COMPARED TO THOSE UNDER csDMARDs**

T. Rudl1, M. Schaefer1, B. Manger2, A. Zink1, A. Strangfeld1. 1German Rheumatism Research Centre, Berlin, Germany; 2University Erlangen, Erlangen, Germany; 3German Rheumatism Research Centre, Charité University Medicine, Berlin, Germany

**Background:** Adults with rheumatoid arthritis (RA) have an increased risk of falling. Previous studies on causes of falls have neither sufficiently nor adequately considered the effects of bDMARDs. In addition, a risk analysis of the individual substances has been lacking until now.

**Objectives:** To analyze the fall risk under exposure to TNFi’s, abatacept (ABA), rituximab (RTX) and tocilizumab (TOC) in comparison to csDMARDs taking co-medication and other risk factors such as disease activity, comorbidities and other biological risks into account.

**Methods:** Data of RA patients observed in RABBIT from 01/2009 - 02/2018 with a follow-up of up to 5 years was used for the analysis. In accordance with consensus guidelines, a fall was defined as “an unexpected event in which participants come to rest on the ground, floor or other lower level” [1].

Effects of bDMARDs were examined using “inverse probability weighting” (IPW) with time-varying treatment on a monthly basis. Directed acyclic graphs were applied to support causal considerations.

**Results:** The percentage of patients with falls (2.7%) was significantly lower than the previously reported 10% and 50% [2]. This underreporting is explained by the fact that falls in RABBIT are reported by the physicians and are not recorded in patient diaries. In line with other studies, falls occurred with older age, longer disease duration, poorer physical function and higher DAS28. Patients with a higher number of comorbidities had a significantly higher risk of falling. The number of patients treated with analgesics was higher in the fall group and fallers had higher glucocorticoid doses. However, the values for pain and fatigue were comparable between the two groups (Table 1). The descriptive analysis showed that patients starting second/third line biologic therapy had a shorter duration from the initiation of treatment to the fall event than patients starting with cs-DMARDs. None of the regression models showed an increased risk for biologics compared to csDMARDs.

**Conclusion:** None of the inferential analyses could demonstrate an increased risk of falling for any of the bDMARDs compared to csDMARDs. Although descriptive analyses pointed to an earlier fall event in patients treated with second/third line biologics, these results could be explained by their particular characteristics. These patients tended to be older and were more affected by RA. This suggests that these risks override the effects of bDMARDs.

differences were found. A moderate correlation was found between the number of red blood cells and the concentration of IL-8 (r = -0.3), IL-10 (r = -0.4), TNF-α (r = -0.3). The relationship between the concentration of hemoglobin and IL-6 (r = -0.6), IL-10 (r = -0.4), TNF-α (r = -0.3) was revealed.

**Conclusion:** In RA patients, IDA, ACD, as well as their combination, may occur. It is very important to clarify the genesis of anemia. ACD should be isolated separately because it has a complex pathogenesis, one of the important components of which are cytokines and their effect on erythropoiesis. The increased concentration of IL-6 in the group of patients with ACD, as well as the presence of a correlation between IL-6, red blood cells and hemoglobin, indicate the importance of this cytokine in the development of anemia. An increase in the concentration of ferritin and CRP also reflects the inflammatory genesis of anemia in patients with this anemia. The presence of a correlation between IL-10, TNF-α, and ferritin also reflects the inflammatory genesis of anemia. The presence of anemia in patients with RA is a risk factor for cardiovascular disease (CVD).

**SAT0090**

**EFFECTS OF ADHERENCE TO MEDITERRANEAN DIET ON RHEUMATOID ARTHRITIS IMPACT OF DISEASE (RAID) SCORE**

F. Ingegnoli1,2, I. Scotti1, T. Schioppo1, T. Ubiali1, G. Marano2, P. Boracchi2, O. De Lucia1, A. Murgo1, R. Caporali1,2. 1G Pini Hospital, Milan, Italy; 2Università degli Studi di Milano, Milan, Italy

**Background:** Mediterranean diet (MD) is a well-balanced, nutritionally adequate and potentially anti-inflammatory diet that encompasses all food groups. Presently, there are conflicting data about the benefits of MD in rheumatoid arthritis (RA). Not enough evidence support a role of MD in the prevention and treatment of RA, and a modest impact of MD on laboratory parameters has been described. Greater effect on subjective aspects of the disease such as joint pain, morning stiffness, and fatigue was reported.

**Objectives:** To investigate whether the adherence to MD affects RA perception as measured by Rheumatoid Arthritis Impact of Disease (RAID) score.

**Methods:** Consecutive patients ≥65 years with RA attending our outpatient clinic were enrolled in this cross-sectional study. For each patient we collected: 1) RAID that consists of 7 single-item domains (pain, functional disability, fatigue, sleep, physical well-being, emotional well-being and coping), each rated by patients on a 11-point numerical rating scale from 0 (best) to 10 (worst) [1], and 2) MD score, a self-reported questionnaire that evaluates the adherence to MD through the consumption of 11 food groups, ranging from 0 (no adherence) to 55 (high adherence) [2]. Univariate analysis was performed using MD score as independent variable. Moreover, to evaluate the adjusted relationship between the single item of RAID and MD score, a multiple regression model was used.

**Results:** 205 RA patients were enrolled: median age at visit 53 (q1-q3: 44-59) years, female 85.0 %, median MD and RAID score were 35 (q1-q3: 32-39) and 2.42 (q1-q3: 0.63-51.51) respectively. RAID total score had a statistically significant negative relationship with MD score (regression coefficient -0.08; p-value=0.016). Concerning the single RAID items, a statistically significant negative association was found for pain (regression coefficient -0.08; p-value=0.025), functional disability (regression coefficient -0.13; p-value=0.001), sleep (regression coefficient -0.08; p-value=0.041), physical well-being (regression coefficient -0.08; p-value=0.027) and coping (regression coefficient -0.11; p-value=0.008).

Multiple regression analysis to evaluate the relationship between significant RAID items and MD score did not show any statistical significance as all items are strongly related to each other.

**Conclusion:** To our knowledge, this is the first study addressing the relationship between the adherence to MD and the perception of RA impact. A better MD adherence was associated with lower self-reported composite total RAID score as well as lower pain, functional disability, sleep, physical well-being and coping. The effect of MD adherence on overall RAID is relevant but, at the same time, a prominent effect of one single item on the others could not be documented. This study confirmed the importance of non-pharmacological interventions, such as diet, in RA management.

**SURVEY OF CARDIOVASCULAR DISEASE AND RISK FACTOR MANAGEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS ACROSS 5 WORLD REGIONS: RESULTS FROM THE SURF-RA**

A. G. Semb1, E. Ikhdair1, J. Sexton1, G. Kitas2, P. Van Riel3, C. S. Crowson4, R. I. Graae1, S. Rollesfad4 on behalf of SURF-RA collaborators. 1Diakonhjemmet University Hospital, Oslo, Norway; 2Russells Hall Hospital, West Midlands, United Kingdom; 3Radboud Hospital, Nijmegen, Netherlands; 4Mayo Clinic, Rochester, United States of America; 5Trinity College Dublin, Dublin, Ireland

**Background:** Patients with rheumatoid arthritis (RA) are at high risk for cardiovascular disease (CVD). Observational data suggest a need for improved risk factor recording and management in such subjects.

**Objectives:** The aim of this survey was to evaluate updated information on CVD risk factors, comorbidities, RA and CVD preventive medication in patient with RA.

**Methods:** The audit is termed SURFyve of cardiovascular disease Risk Factors in patients with Rheumatoid Arthritis (SURF-RA) and was performed in 53 centres in 19 countries across 5 world regions during 2014 and 2019. SURF-RA is part of the SURF family of audits which have been performed in patients with CHD, in primary care [2], and now in patients with stroke and SLE. Data including demographics, RA disease characteristics, CVD, risk factors and medications was collected. The survey was approved by the Data Protection Officer (2017/2743) and a General Data Protection evaluation has been performed (10/10/2018).

**Results:** Among 14 503 patients with RA in West (n= 8 493) and East (n=923) Europe, Latin (n=407) and North (n=4030) America and Asia (n=650) the mean (SD) age was 59.9 (13.6) years, and 2/3 or more were female (table). RA disease duration was comparable across the world regions, ranging from 9.9 to 12.6 years. The average disease activity score was low, disease activity score including 28 joints and C-reactive protein; DAS28CRP: mean (SD): 2.6 (1.2). The prevalence of atherosclerotic CVD (ASCVD) was lowest in Latin America (2.5%) and highest in East Europe (21.4%), and this pattern was similar regarding familial premature CVD. The mean prevalence (% of each entity) of blood pressure above 140/90 mmHg was 5.3%, of low density lipoprotein cholesterol > 2.5 mmol/L 63.3%. Overall, 29% used anti-hypertensive medication, lowest in West Europe (17.4%) and highest in East Europe (57.0%), and 26.4% used lipid lowering agent(s), lowest in Asia (7.2%) and highest in North America (31.1%). Body mass index > 30 kg/m2 was present in 26.6%, with the smallest waist circumference in Asia [mean: 84.1 (13.6) cm] and highest in East Europe [92.5 (15.5) cm]. The proportion of current smokers was on average: 16.2 %, lowest in Asia (7%) and highest in East Europe (28.5%).

**Conclusion:** The high prevalence of CVD risk factors and ASCVD in patients with RA across five world regions shows that there is still an unmet need for vigilance and improved implementation of preventive measures in this high CVD risk patient population.

CARDIOVASCULAR RISK ASSESSMENT IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES: AN ITALIAN RHEUMATOLOGISTS' SURVEY

F. R. Spinnelli, 1 F. Cacciapaglia, 2 F. Atzeni, 3 G. Erre, 4 A. Manfredi, 5 E. Bartoloni Boccà, 6 M. Piga, 7 G. Sakellariou, 8 O. Viapianta, 9 E. Gremeresse 10,11. 1 Sapienza Università di Roma, Rheumatology Unit, Roma, Italy; 2 Azienda Ospedaliera Policlinico di Bari, Reumatology Unit, Bari, Italy; 3 Azienda Ospedaliera Universitaria Policlinico Gaetano Martino, Rheumatology Unit, Messina, Italy; 4 Azienda Ospedaliera Universitaria Sassari, Rheumatology Unit, Sassari, Italy; 5 Policlinico di Modena, Rheumatology Unit, Modena, Italy; 6 Università degli studi di Perugia, Rheumatology Unit, Perugia, Italy; 7 Università di Cagliari, Rheumatology Unit, Cagliari, Italy; 8 Università degli studi di Pavia, Rheumatology Unit, Pavia, Italy; 9 Università degli studi di Verona, Rheumatology Unit, Verona, Italy; 10 Università Cattolica del Sacro Cuore, Rheumatology Unit, Rome, Italy; 11 Fondazione Policlinico Universitario A. Gemelli IRCCS, Rheumatology Division, Rome, Italy

Background: Cardiovascular (CV) disease is the leading cause of morbidity and mortality in patients with inflammatory arthritis. The growing attention to the CV risk characterizing patients with autoimmune inflammatory disease led EULAR to provide recommendations on CV risk management (1). To date, there are no data on the adherence to EULAR recommendation among Italian rheumatologists.

Objective: Our objective was to measure the level of awareness and the attitude to manage CV risk.

Methods: Italian rheumatologists were invited to anonymously answer a web-based questionnaire designed by the steering committee of the Cardiovascualr and Obesity in Rheumatic Diseases (CORDIS) study group of the Italian Society of Rheumatology. The first part of the questionnaire concerned demographic information; the subsequent questions concerned the attitude to assess CV risk and the limitations for not assessing, the specific CV risks considered in the clinical practice and their management. Data are presented using standard summary statistics and were expressed as mean±standard deviation or median (interquartile range) according to variables' distribution.

Results: One thousand-three hundred rheumatologists (of whom 500 are under 40 and 100 over 70 years of age) have been invited by email to complete the survey. The questionnaire has been filled by 102 rheumatologists (7.85%); (53 females and 49 males) with a median age of 38 years (32-48) and a median of 4 (0-15) years of specialization. Most of the physician who answered the questionnaire works in University Hospitals (67/102; 65.7%), 22 out of 102 (21.6%) in non-academic Hospitals, and the remaining 12.7% in territorial outpatient clinics. When asked if they usually evaluate CV risk in patients with autoimmune rheumatic diseases, 67/102 (67.2%) answered positively, 18 no (17.6%) and 7 did not answer the question; 82% of those who routinely assess the CV do it by themselves. The barriers limiting the assessment of CV risk included: i) lack of time (79%); ii) complex management (12%); iii) inadequate training (9%). As for the CV risk factors, lipid profile, hypertension and diabetes are assessed by most of the rheumatologists (90%, 89% and 88%, respectively), family history by 78% and body mass index by 75.3% and waist circumference only by 25% of those who completed the survey. Finally, only 18.6% stated that they manage by themselves CV risk in patients with autoimmune rheumatic diseases while 50% refer patients to other specialists and 23.4% to general practitioner.

Conclusion: Despite the growing awareness on the CV risk characterizing patients with autoimmune rheumatic disease, about one third of young Italian rheumatologists do not strictly adhere to the EULAR recommendations on CV management, mostly due to insufficient time during the routine care visits.

Disclosure of Interests: None declared.
Background: The problem of sarcopenia (SP) in rheumatoid arthritis (RA) is particularly significant in terms of assessing the risk of fractures, since SP leads to falls, which are an independent risk factor for fractures along with RA and osteoporosis. Objectives: To evaluate the bone mineral density (BMD) and fracture risk in women with RA and SP.

Methods: 79 women with RA based on the 2010 ACR/EULAR classification criteria were included: 20 (25%) women with confirmed SP (age median 59 [53; 64]) according to EWGSOP2 criteria and 59 (75%) women without SP (age median 60 [55; 67]) (p<0.05). We assessed clinical data: age, body mass index (BMI), disease duration, anthropometric measurements, C-reactive protein level, disease activity score in 28 joints–erythrocyte sedimentation rate (DAS28-ESR), previous medication use including glucocorticoids and methotrexate, muscle strength and function. Dual-energy X-ray absorptiometry (DXA) to measure BMD of lumbar spine (LS), femoral neck (FN) and total hip (TH) was performed. The 10-year probability of major osteoporotic fracture (clinical spine, forearm, hip or shoulder fracture) and the 10-year probability of hip fracture was calculated using the Russian version of the FRAX® tool. Statistical analysis was performed using non-parametric methods. All patients signed an informed consent to participate.

Results: Median BMD in LS was 0.892 [0.772; 1.024] g/cm² in patients with SP and 0.910 [0.785; 1.028] g/cm² - without SP (p=0.05). There was a significant difference between groups in the proximal femur BMD: 0.760 [0.731; 0.826] g/cm² in patients with SP and 0.910 [0.785; 1.028] g/cm² - without SP (p>0.05). There was significant difference in the proximal femur BMD: 0.760 [0.731; 0.826] g/cm² in patients with SP and 0.910 [0.785; 1.028] g/cm² - without SP.

Conclusions: Our study showed that the probability of major osteoporotic fracture was significantly higher in patients with RA and SP compared with patients without SP. There was a significant difference in BMD between groups with SP. The probability of major osteoporotic fracture and hip fractures was significantly higher in patients with RA and SP compared with patients without SP.

SAT0095

REAL LIFE SEVERE INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS ON TREATMENT WITH BIOLOGICAL THERAPY AND JAKI

I. Vega1, I. Calvo1, O. Ibarguenzita1, M. L. Blanco1, D. Montero1, C. Garcia1, M. E. Ruiz1, A. R. Inchaurre1, I. Torre1, C. Perez2, O. Fernandez1, E. Cuande1, I. Gorostiza2, M. L. Garcia Vivar1, E. Galindez1, Basurto University Hospital, Investigation, Bilbao, Spain

Background: Infections are one of the main complications among patients with rheumatoid arthritis (RA) with immunosuppressive treatment. The differences between treatments and the influence of other factors are unclear. Objectives: To evaluate the frequency and factors associated with serious infections in patients with RA treated with biological therapy (BT) and JAKI and the differences between treatments.

Methods: Descriptive and retrospective study (January 2015–December 2019) of patients with RA treated with BT (TNFi, non-TNFi) and JAKI (tofacitinib, baricitinib) in a single center. Severe infection was considered a life-threatening infection or one that required hospitalization and intravenous treatment. Epidemiological variables, clinical characteristics, Charlson comorbidity index, type of BT or JAKI and concomitant treatment were collected. For the analysis frequencies and percentages are used in qualitative variables, and mean ± SD in the quantitative ones. Statistical analysis was performed with non-parametric methods. All patients signed an informed consent to participate.

Results: Totally 163 patients were enrolled in the study. Clinical composite disease activity scores and all the components were significantly correlated with the total GS and PD scores (p<0.01 for all). But the relation between the clinical disease parameters and total PD score became weak, with the agreement of ΔTSJ. For the patients with ΔTSJ > 5, the total PD score was only correlated with CRP, EGA and PGA, while the total GS score was only correlated with CRP. Similarly, no correlation between total PD score and clinical parameters, except for SJC, was observed in patients with ΔPEG < 0 (p < 0.05).

Conclusion: Total PD/GS score was correlated well with the clinical parameters of disease activity, including both the subjective and objective indexes. For the patients with a ΔTSJ > 5 there was no correlation between total GS/PD scores and clinical composite disease activity scores, except that only the objective index (CRP, SJC and EGA) were more likely to correlate with total GS/PD scores.

DO COMORBIDITIES IMPACT PERSISTENCE OF FIRST TUMOR NECROSIS FACTOR INHIBITOR TREATMENT IN RHEUMATOID ARTHRITIS? DATA FROM TURKBIIO

T. Yuce Inel1, S. B. Kocaer1, Y. Erez1, S. Gulie1, A. Karakas1, A. Koken Aver1, S. Uslu1, G. Can1, I. Sarı1, M. Birlik8, E. Đalkılıç1, Y. Pehlivan3, S. Akar3, B. Goker3, G. Yildirim Cetin6, S. Haznedaroğlu7, Ş. Yavuz5, T. Pirildar5, H. Direskeneli1, N. Akkok5, F. Önen1 on behalf of Turkbio Registry Group. 1Dokuz Eylül University Faculty of Medicine, İzmir, Turkey; 2Uludag University Faculty of Medicine, Bursa, Turkey; 3Kâtip Çelebi University Faculty of Medicine, Konya, Turkey; 4Gazi University Faculty of Medicine, Ankara, Turkey; 5Süleyman İmam University, Kahramanmaraş, Turkey; 6Bilkent University, İstanbul, Turkey; 7Celal Bayar University, Manisa, Turkey; 8Marmara University, İstanbul, Turkey; 9Celal Bayar University, Manisa, Turkey

Background: Studies indicate that patients with rheumatoid arthritis (RA) are at increased risk of developing several comorbid disorders. Comorbidities affect treatment decisions, the effectiveness of the treatment, quality of life, RA prognosis, and survival rate [1].

Objectives: The aim of this study was to investigate the impact of comorbidity on the first TNF inhibitor treatment persistence in RA.

Methods: In the TURKBIO database, patients with an ICD 10-diagnosis of RA (M05 or M06) who started TNF inhibitor therapy between January 2011 and June 2019 were enrolled. Demographic and clinical characteristics, acute phase reactants, disease activity scores (DAS 28 CRP, HAQ, CDAI, VAS global), initial comorbidities and numbers, drug persistence, were evaluated. Kaplan-Meier plots and Cox proportional hazard regression analyses were performed.

Results: A total of 1172 patients >18 years of age treated with TNF-a inhibitors were included in the study. The most prevalent comorbidities were: hyperton in 262 patients (32.6%), obesity in 254 (32.6%), osteoporosis in 178 (22.3%), chronic lung disease in 143 (17.9%) and depression in 126 (15.8%). The baseline characteristics are summarised in Table 1. The presence of comorbidity did not affect the survival rate of the first TNF inhibitor therapy in the RA patients (p = 0.65). Comorbidities had no effect on DAS28 CRP (p = 1.2 reduction) responses at 6 and 12 months of treatment (p = 0.18; p = 0.83, respectively). As the mean disease duration increases, the persistence of the first TNF inhibitor decreases by 5%.

Conclusion: This study demonstrated the increasing burden of comorbidities in RA. However, it suggested that the presence and number of comorbidities did not influence the rate of persistence in the first TNF inhibitor drug and the response to treatment.

SAT0008

TREATMENT OF A COHORT OF PATIENTS WITH INTERSTITIAL LUNG DISEASE AND RHEUMATOID ARTHRITIS

C. Aquilera Coss1, M. Gomez Vargas2, R. J. Gil Velez3, J. A. Rodriguez Porta1.
1University Hospital Virgen del Rocío, Department of Rheumatology, Seville, Spain; 2University Hospital Virgen del Rocío, Department of Pneumology, Seville, Spain

Background: There is no specific treatment for interstitial lung disease (ILD) secondary to Rheumatoid Arthritis (RA) other than the treatment of RA without extra-articular involvement. Current regimens usually include corticosteroid therapy with or without immunosuppressants (IS), there is no consensus for the treatment.

Objectives: To analyze the different treatment regimens in a cohort of patients with ILD and RA in our clinical practice.

Methods: Descriptive study of 57 patients treated in our Hospital (1/1/2018 until 12/31/2019) with a diagnosis of RA (ACR 2010 criteria) and secondary ILD. The most recent American Thoracic Society (ATS)/European Respiratory Society (ERS)/Japanese Respiratory Society (JRS)/Latin American Thoracic Society (ALAT) guidelines define three HRCT (High Resolution Computed Tomography) patterns of fibrosing lung disease in the setting of idiopathic pulmonary fibrosis (IPF): definite Usual Interstitial Pneumonia (UIP) (traction bronchiectasis and honeycombing), possible UIP and inconsistent with UIP. The distinction between definite UIP and possible UIP in these to the presence or absence of honeycombing. Approved by the Ethics Committee.

Quantitative variables are expressed as mean (SD) and dichotomous variables as percentages (%). Statistical analysis with SPSS version 21.

Results: 21 men and 36 women were included, with a mean age of 69 ± 10 years (mean ± SD), history of smoking (smokers 14%, non-smokers 43%, former smokers 42%). Clinical ILD at diagnosis (dyspnea 61%, dry cough 56%, cracking 70%, acropathy 7%). 84% were positive rheumatoid factor and 70% positive anticitrullinated protein antibody.

Diagnosis of ILD by HRCT in 100% of patients with different patterns: defined UIP 26 (45%), probable UIP 2 (3%) and not UIP 29 (50%). The diagnosis of ILD was confirmed by biopsy in 12 patients. 79% underwent T (Treatment) prior to the diagnosis of ILD with glucocorticoids and disease-modifying drugs (DMARD). Among the traditional DMARDs used were: Methotrexate 68% (there were no cases of MTX pneumonitis), Leflunomide 47%, Hydroxychloroquine 26% and Sulfasalazine 21%. Biological therapy in 15 patients: Etanercept 19%, Adalimumab 5%, Infliximab 3% and Certolizumab 2%. Two patients presented an exacerbation and rapid progression of the ILD during the T with Etanercept with the final result of death. T with IS after the diagnosis of ILD in 80% of patients (Azathioprine 15, Rituximab 14, Abatacept 10, Tocilizumab 4, Sarilumab 1, Moetil mycophenolate 1 and Cyclophosphamide 1).

Two patients with defined UIP perform T with antifibrotic: 1st Nintedanib (INBUILD Trial, This article was published on September 29, 2019, at NEJM.org) 2nd Pirfenidone (initial diagnosis of IPF Idiopathic Pulmonary Fibrosis and subsequent of seropositive RA with UIP). Both improved greater than 10% in forced vital capacity (FVC) and diffusion capacity of the lung for carbon monoxide (DLCO) in the 6 months after onset of T.

Conclusion: Our results, in general, agree with what is published in the literature. Prospective, multicentre and larger sample studies are necessary to better define what patients would benefit more from IS T or antifibrotic T (or if the antifibrotic should be added to the previous IS).

SAT0009

BMI AND TREATMENT SURVIVAL IN RA PATIENTS STARTING TREATMENT WITH TNF-α INHIBITORS: LONG TERM FOLLOW-UP IN THE REAL LIFE METEOR REGISTRY

S. A. Bergstra1, D. Vega-Morales2, E. Murphy3, M. De Buck4, K. Solomon-Escoto5, T. Huizinga1, C. Allaart1, 1LUMC, Rheumatology, Leiden, Netherlands; 2University Hospital Virgen de la Victoria, Malaga, Spain; 3University Hospital Virgen de la Victoria, Malaga, Spain; 4Kings College Hospital, London, United Kingdom; 5University of Massachusetts Medical School, UMass Memorial Medical Center, Worcester, Massachusetts, United States of America

Background: BMI appears to be associated with treatment response on TNF-inhibitors in rheumatoid arthritis (RA), but large heterogeneity between studies exists. More extreme BMI categories are rarely studied and it is unclear if differences exist between various TNFI.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2020-eular.4907
**Objectives:** To study whether there is an association between BMI category and drug survival in RA patients starting treatment with various TNFi in a real life longitudinal international registry.

**Methods:** Data from 5230 RA patients starting a TNFi were included from the METEOR registry. Timing of follow-up visits was daily practice based. Follow-up was censored at 5000 days (±13.5 years). Patients were divided into 6 BMI categories (WHO definition): underweight BMI <18.5, normal weight BMI 18.5-25, pre-obesity BMI 25-30, obesity class I BMI 30-35, class II BMI 35-40, and class III BMI >40. Missing data were imputed using chained equations. The association between BMI category and time on treatment was investigated using Kaplan-Meier (KM) curves and Cox regression analyses, for time on first TNFi and for the first prescribed course of adalimumab (ADA), etanercept (ETA) and infliximab (IFX) separately. All analyses were adjusted for the potential confounders age, gender, smoking, baseline DAS28, concomitant glucocorticoid use and country. Potential effect modification by reported pain was tested by adding an interaction term between BMI category and baseline pain category (VAS pain 0-25, 25-50, 50-75 and 75-100).

**Results:**
- Most patients had a normal weight (46%) or pre-obesity (32%), 4% of patients were underweight, 10% had obesity class I, 3% obesity class II and 1% obesity class III. N=2936 patients ever started ETA, n=2069 ADA, n=1390 IFX, n=263 certolizumab and n=84 golimumab.
- The KM curve in fig 1A shows TNFi survival in patient starting their first TNFi per BMI category. Patients with normal weight and pre-obesity had longest drug survival and patients with obesity class II and especially patients with obesity class III had shortest drug survival. The adjusted Cox regression support these findings, with statistically significantly shorter drug survival for patients with obesity class III [HR (95% CI) 1.67 (1.29; 2.18)] and class II [1.28 (1.06; 1.54)], but also for underweight patients [1.3 (1.07; 1.58)], compared to normal weight patients. KM curves for individual TNFi showed shortest drug survival on ADA for patients with obesity class II and III (fig 1B), on ETA for patients with obesity especially in class III (fig 1C) and on IFX, for patients with obesity class II and III and underweight patients (fig 1D). After adjustment in Cox regression, statistically significant BMI-drug survival associations remained for patients with pre-obesity starting ADA [HR (95% CI) 0.86 (0.75; 0.99)], for patients starting ETA with obesity class II [HR (95% CI) 1.27 (0.98; 1.65)] or class III [1.79 (1.25; 2.45)] and for patients on IFX who were underweight [HR (95% CI) 1.9 (1.20; 2.76)] or in obesity class II [1.49 (0.98; 2.26)]. No effect modification was found for reported pain.

**Conclusion:** Both underweight (as identified in IFX treated patients) and overweight patients (in ADA, ETA and IFX treated patients) discontinued a first TNFi treatment earlier than normal weight patients. Reported pain was not the main effect modifier. Potential effect modification by reported pain was tested by adding an interaction term between BMI category and baseline pain category (VAS pain 0-25, 25-50, 50-75 and 75-100).

**SAT0100**

**ASSOCIATION BETWEEN LOW HEMOGLOBIN AND RADIOGRAPHIC PROGRESSION OVER 52 WEEKS IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM A PHASE 3 TRIAL OF SARILUMAB**

G. R. Burmester1, J. P. Morello1, O. Hagnio2, A. Praestgaard3, S. Fiore3, M. C. Genovese4, 1Charité – University Medicine Berlin, Berlin, Germany; 2Regeneron Pharmaceuticals Inc., Tarrytown, NY, United States of America; 3Sanofi, Bridgewater, NJ, United States of America; 4Sanofi Genzyme, Cambridge, MA, United States of America; 5Stanford University, Palo Alto, CA, United States of America

**Background:** Anemia is a common comorbidity in patients with rheumatoid arthritis (RA).

**Objectives:** Assess whether low hemoglobin (Hb) identifies a subgroup of patients at increased risk of joint damage progression, and investigate whether sarilumab modulates this risk.

**Methods:** The 52-week, double-blind, Phase 3 MOBILITY trial (NCT01061736) in patients with active RA and inadequate response to methotrexate (n = 1197) demonstrated the tolerability and efficacy (clinical and radiographic) of subcutaneous sarilumab 150 and 200 mg every 2 weeks versus placebo, both in combination with methotrexate (MTX). In this post hoc analysis, baseline characteristics and radiographic outcomes in MOBILITY were analyzed by baseline Hb category (low or normal) according to World Health Organization criteria, with low Hb defined as <120 g/L for women and <130 g/L for men. Nominal P values are presented.

**Results:** A total of 414 patients (35%) had low Hb at baseline. Patients with low Hb were more likely than patients with normal Hb to be female (86% vs 79%, respectively), Asian (14% vs 5%), younger (mean age 49 vs 51 years), and to have lower body weight (mean 69 vs 77 kg); all nominal P <0.01. Duration of RA, prior biologic use, rheumatoid factor positivity, and baseline tender and swollen joint counts were similar between patients with low and normal baseline Hb, but there was a nominally significant difference in C-reactive protein (mean 30.2 [SD 28.5] vs 17.3 [18.5] mg/L; P <0.0001). Patients with low Hb generally exhibited more joint damage progression over 52 weeks than patients with normal Hb (Table). In the sarilumab + MTX groups, joint damage progression was mitigated compared with placebo + MTX in patients with low Hb and in patients with normal Hb. Mean change from baseline in Hb at 52 weeks in the placebo + MTX, sarilumab 150 mg + MTX, and sarilumab 200 mg + MTX groups was +3.7 (SD 10.8), +14.7 (12.1), and +14.0 (10.5) g/L, respectively, in patients with low Hb at baseline, and –2.5 (9.9), +6.2 (9.3), and +8.0 (9.9) g/L in patients with normal Hb at baseline.

**Conclusion:** Overall, sarilumab slowed joint damage progression in patients with RA. Additionally, in those patients with low Hb, who may suffer greater damage than those with normal Hb, sarilumab also increased Hb.

**Acknowledgments:** Study funding and medical writing support (Matt Lewis, PhD, of Adelphi Communications Ltd, Macclesfield, UK) were provided by Sanofi Genzyme (Cambridge, MA, USA) and Regeneron Pharmaceuticals, Inc. (Tarrytown, NY, USA) in accordance with Good Publication Practice (GPP3) guidelines.

**Conclusion:** Overall, sarilumab slowed joint damage progression in patients with RA. Additionally, in those patients with low Hb, who may suffer greater damage than those with normal Hb, sarilumab also increased Hb.

Background: The prevalence of interstitial lung disease (ILD) in rheumatoid arthritis (RA) varies in the medical literature from 1% to 67% and is a major cause of mortality. Previous works have identified increased age, smoking and anticytokeratin protein antibodies (ACPA) titre as risk factors for RA-ILD (RA-ILD). Conventional treatments for RA may lead to a new onset or worsening of RA-ILD, so treatment should be identified to prevent the onset or exacerbation of RA-ILD. Studies have shown that abatacept (ABA) may improve the outcome of RA-ILD.

Objectives: The aim of our study is to evaluate ABA effectiveness and safety in patients with RA-ILD.

Methods: We enrolled RA-ILD patients who started treatment with ABA. All patients underwent thoracic high-resolution computed tomography (HRCT) at the beginning of ABA treatment and after 18 months of therapy. HRCT abnormalities were evaluated using a computer-aided method (CaM). At each visit clinical, laboratory and respiratory function characteristics were collected and the Clinical Disease Activity Index (CDAI) and the Health Assessment Questionnaire Disability Index (HAQ-DI) for disease activity and functional disability were measured. The cohort was divided into three groups based on the CaM-HRCT results: patients with a lung fibrosis progression of 15% or more were defined as ‘worsened’ those with a reduction of 15% or more were defined as ‘improved’; all other patients were defined as ‘stable’. The 15% threshold of change, derived from the CaM assessment, results from the determination of the standard deviation of the mean value change after 18 months of follow-up of the cohort. The multivariate regression model was used to assess the strength of the association between RA characteristics and HRCT response to ABA.

Results: Forty-four patients (81% women) with a mean age of 59.1 ± 8.0 years and a mean duration of the disease of 7.5 ± 3.1 years were recruited. Twenty-three (52.3%) patients were positive for ACPA and 28 (63.6%) for rheumatoid factor. Five patients (11.4%) showed deterioration of ILD, 31 (70.6%) were in the ‘stable’ group, and 7 patients (16.0%) experienced improvement over a mean follow-up period of 18 months. The factors related to ILD deterioration were use of methotrexate (MTX) (p = 0.0078), and current smoking habit (p = 0.0054), according to multivariate regression analysis (Table).

Conclusion: Treatment with ABA is associated with an RA-ILD stability or improvement rate of 86.6% of patients, while the worsening rate is 11.4%. Concomitant treatment with MTX and current smoking habit are factors associated with RA-ILD worsening. MTX discontinuation and smoking cessation should be strongly promoted in patients with RA-ILD.

24 when treated with sarilumab versus placebo or adalimumab. Patients with and without BL NIP had greater improvements in pain when treated with sarilumab versus adalimumab. The difference in clinical improvement was greater among patients with BL NIP versus without BL NIP for most measures. These trends support the emerging concept that mechanisms other than direct inflammation may contribute to pain in RA, potentially mediated via IL-6 signaling.

SAT0103
THE EFFECT OF BODYWEIGHT ON RESPONSE TO INTRAVENOUS OR SUBCUTANEOUS TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Davies1, A. Vivekanantham2, M. Lunt3, K. Watson4, K. Hyrich1,5, J. Bluett6,7 on behalf of BSRBR-RA Contributors Group. 1University of Manchester Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 3Manchester Academic Health Science, National Institute of Health Research Musculoskeletal Biomedical Research Centre, Manchester, United Kingdom; 4University of Manchester, Versus Arthritis Centre for Genetics and Genomics, Manchester, United Kingdom

Background: Tocilizumab is an IL-6 receptor humanised monoclonal antibody treatment option in rheumatoid arthritis (RA) who have not responded or are intolerant of disease modifying anti-rheumatic drugs (DMARDs) or other biologics. Tocilizumab was available initially as an intravenous (IV) preparation, dosed according to weight, and more recently as a subcutaneous (SC) preparation given at 162mg/weekly irrespective of bodyweight.

Obesity is highly prevalent in RA and there has been concern that starting or switching patients to SC tocilizumab could reduce its effectiveness in those patients with a higher body weight when compared to IV tocilizumab.

Objectives: To investigate the relationship between bodyweight and DAS28 response at 6 months in tocilizumab naïve RA patients starting IV or SC tocilizumab.

Methods: The study population comprised RA subjects recruited to the BSRBR-RA up to 30/11/2018 commencing IV or SC tocilizumab for the first time. Patients had to be tocilizumab naïve and have at least one six monthly study follow-up recorded after starting tocilizumab. Baseline characteristics at point of starting tocilizumab are described. Linear regression, fully adjusted for relevant confounders, was used to investigate the relationship between change in DAS28 score from baseline to six months and body weight per ten kilograms (kg), and in a separate analysis, as BMI category. Multiple imputation was used to handle missing data.

Results: 1241 patients starting tocilizumab (902 IV, 339 SC) were eligible for analysis. The median age was 59 years, majority were female, and had median disease duration of 11 years at baseline. Over seventy percent had prior biologic exposure. Median weight was 77kg for IV and 76kg for SC starters, and the majority of patients were categorised as normal weight (30% IV, 37% SC) or pre-obesity (31% IV & SC) according to BMI. Median DAS28 score was 5.8 (IV) and 5.5 (SC) at start of treatment with median improvement after 6-months of 1.50 and 2.02 units respectively. The fully adjusted linear regression model showed no association between body weight or BMI and change in DAS28 score at six months for patients starting IV or SC tocilizumab. (Table).

*Fully adjusted for age, gender, disease duration, baseline DAS28 score, baseline HAQ score, co-morbidities, and number of previous biologics

Conclusion: Data from this study show that body weight does not appear to affect initial response to IV or SC tocilizumab. This is reassuring given that patients are likely to be given SC tocilizumab due to ease of administration and reduced hospital costs.

SAT0104
MAINTENANCE OF SDAI REMISSION AND PATIENT-REPORTED OUTCOMES (PROS) FOLLOWING DOSE DE-ESCALATION OF ABATACEPT IN MTX-NAIVE, ANTI-CITRULLINATED PROTEIN ANTIBODY (ACPA)+ PATIENTS WITH EARLY RA: RESULTS FROM AVERT-2, A RANDOMISED PHASE IIIB STUDY

P. Emery1, Y. Tanaoka2, V. Bykerk3, T. Huizinga4, G. Citera5, C. Bingham6, S. Banerjee7, S. Connolly7, J. Zhuo2, R. Wong2, K. H. G. Huang2, K. Lozenski2, Y. Elbez2, R. Fleischmann7,8, LIRMM, University of Leeds, NIHR BRC LHTH, Leeds, United Kingdom; 9University of Occupational and Environmental Health, Kitakyushu City, Japan; 10Hospital for Special Surgery, New York, United States of America; 11Leiden University Medical Center, Leiden, Netherlands; 12Instituto de Rehabilitacion Psicofisica, Buenos Aires, Argentina; 13Johns Hopkins University, Baltimore, United States of America; 14Bristol-Myers Squibb, Princeton, United States of America; 15Ecolelya, Boulogne-Billancourt, France; 16University of Texas, Dallas, United States of America

Background: The Phase IIb Assessing Very Early RA Treatment (AVERT)-2 trial (NCT02504268) evaluated SC abatacept (ABA) + MTX vs ABA placebo (PBO) + MTX in ACPA+ patients (pts) with early, active RA. Results from the 56-wk induction period (IP) showed a significantly greater proportion of pts treated with ABA + MTX (vs MTX alone) reported clinically meaningful improvements in HAQ-DI, global disease activity and pain, which were sustained at 52 wks.

Objectives: To report maintenance of SDAI remission and PROs from the AVERT-2 dose-escalation (D-E) period.

Disclosure of Interests: P. Emery: None declared, Y. Tanaoka: None declared, V. Bykerk: None declared, T. Huizinga: None declared, G. Citera: None declared, C. Bingham: None declared, S. Banerjee: None declared, S. Connolly: None declared, J. Zhuo: None declared, R. Wong: None declared, K. H. G. Huang: None declared, K. Lozenski: None declared, Y. Elbez: None declared, R. Fleischmann: None declared, LIRMM, University of Leeds: None declared

DOI: 10.1136/annrheumdis-2020-eular.2015
Methods: Pts received blinded SC ABA (125 mg once wkly [QW]) + MTX or ABA PBO + MTX induction treatment for 56 wks. In this analysis, pts who completed induction with ABA + MTX and had sustained SDAI remission (≤3.3 at Wks 40 and 52) were re-randomised 1:1:1 to ABA QW + MTX, stepwise D-ABA (ABA every other wk + MTX for 24 wks then ABA PBO + MTX for 24 wks), or ABA QW + MTX PBO for 48 wks in the D-E period. PROs included physical function (HAQ-DI [0–3; decrease=improvement] and Short-Form 36 [SF-36] v2.0 Physical Functioning Scale [PF6]; 0–100; increase=improvement), and fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue [FACT-F] score; 0–52; decrease=improvement). Endpoints included: proportion of pts in SDAI remission and pts with HAQ-DI response (decrease from IP Day [D]1 in HAQ-DI D0.30); adjusted mean change (adMC) from D-E D1 in HAQ-DI, SF-36 PFS or FACT-F to D-E Wk 48. adMCs were estimated using a mixed effect model with repeated measures.

Results: 147 ABA + MTX-treated pts were re-randomised in the D-E period. Across re-randomised arms, the range of mean scores was 1.87–5.25 for SDAI and 0.18–0.30 for HAQ-DI at entry into D-E period (D-E D1). 74% of pts receiving ABA QW + MTX maintained SDAI remission at D-E Wk 48 (Fig 1); this proportion was higher than in the ABA withdrawal and ABA QW + MTX PBO arms. Pts continuing ABA QW + MTX maintained HAQ-DI response during D-E (Fig 1), but by D-E Wk 48 the proportion of pts with HAQ-DI response in the ABA withdrawal arm declined by 30%. At D-E Wk 48, a small numerical decrease (adMC –0.04) in HAQ-DI was observed in the ABA QW + MTX arm; increases were seen in the withdrawal (adMC 0.28) and ABA QW + MTX PBO arms (adMC 0.16). By D-E Wk 48, SF-36 PFS adMC increased (adMC 1.68) in the ABA QW + MTX arm but decreased in the withdrawal (adMC –3.34) and ABA QW + MTX PBO arm (adMC –1.45) arms. FACT-F score increased during D-E in all arms, but the increase at D-E Wk 48 was lower in the ABA QW + MTX arm (adMC 0.79) vs the withdrawal (adMC 4.12) and ABA QW + MTX PBO (adMC 2.41) arms. Similar trends were seen for other PROs including Work Productivity and Activity Impairment-RA; while activity impairment remained stable in the ABA QW + MTX arm, there was a trend for worsening in the withdrawal arm.

Conclusion: In the AVERT-2 D-E period, continued combination therapy (abatacept + MTX) resulted in maintenance of benefits for PROs, particularly physical functioning, in seropositive pts with early RA. D-E of abatacept followed by complete withdrawal was associated with the greatest loss of remission as well as worsening of PROs. The PRO results corresponded well to the maintenance of clinical (SDAI) remission.

SAT0105

INFLUENCE OF RITUXIMAB ON DIASTOLIC FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Fejskhanova1, S. Laphchina2, O. Rybakova2. 1KSMU, Kazan, Russian Federation; 2KSMU, Kazan, Russian Federation

Background: One of the drugs used in the treatment of rheumatoid arthritis (RA) is rituximab. RA affects not only the joints, but, in addition to other organs, and the heart, our interest has caused the likelihood of the impact of rituximab on non-articular manifestations of rheumatoid arthritis, in particular, related to the cardiovascular system.

Objectives: to study the effect of rituximab on the development of diastolic dysfunction of the heart in patients with RA.

Methods: 98 patients with RA were examined, of which 28 patients took rituximab 1000 mg according to the scheme for 6-12 months and methotrexate up to 25 mg per week per os (1st group), and 70 patients – only methotrexate up to 25 mg per week at least 12 months (2nd group). They were held echocardiography with calculation of the E/a of mitral valve, E/a of tricuspid valve, end-diastolic size of left ventricle, electrocardiography with calculation of the dispersion of QT interval and vectorcardiography with determination of the areas of the P loop, QRS loop, T loop, and the maximum vector (MV), MV-azimuth and MV-lift.

Results: the E/a of mitral and tricuspid valves in 1st group were higher than in 2nd group (p<0.05). In 1st group, a correlation was found between the E/a of both valves and the MV-lift, and also between the dispersion of QT interval and the maximum vector (p<0.05). Conclusion: in patients taking rituximab, there is a relationship between diastolic dysfunction, electrical instability of the ventricles and signs of electrophysiological remodeling. In addition, the use of rituximab is associated with a lower severity of diastolic dysfunction of both ventricles and a lower risk of life-threatening arrhythmias compared to the group that did not take this drug.

Disclosure of Interests: None declared. DOI: 10.1136/annrheumdis-2020-eular.6342
Background: A proportion of adult patients with rheumatoid arthritis (RA) are refractory to tumor necrosis factor inhibitors (TNFi), and treatment with subsequent biologics is commonly associated with reduced response. Sarilumab is a human IL-6 receptor inhibitor approved for the treatment of adults with moderate to severely active RA. In the Phase 3 TARGET study (NCT01709578), significant improvements in the signs and symptoms of RA and physical function were shown with sarilumab plus conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) versus placebo in patients refractory to TNFi.

Objectives: To investigate long-term safety and efficacy of subcutaneous sarilumab over 5 years in patients with 1 or >1 TNFi treatment failure prior to their enrollment in TARGET, who continued onto the open-label extension (OLE) study, EXTEND (NCT01466660).

Methods: In the 24-week randomized controlled trial (RCT), patients received placebo, sarilumab 150 mg, or sarilumab 200 mg every 2 weeks (q2w), and were eligible to receive open-label sarilumab 200 mg q2w in the OLE. Dose reduction to 150 mg q2w was permitted per investigator’s discretion, or to manage laboratory abnormalities. Safety outcomes are presented for the entire follow-up period from RCT baseline through the OLE. Efficacy was assessed using Clinical Disease Activity Index (CDAI) score.

Results: Of the 546 patients randomized in the RCT, 454 (83%) entered the OLE, of whom 339 had 1 TNFi failure and 115 had >1 TNFi failure. Patients with >1 TNFi failure were older and had a longer duration of RA than patients with 1 TNFi failure (mean age [SD]: 55.3 [12.8] vs 52.5 [11.9] years, mean RA duration [SD] 13.9 [9.1] and 11.1 [8.8] years, respectively). Kaplan–Meier estimates of the probability of continuation at 5 years were similar between groups: 48% and 54% for patients with >1 and 1 TNFi failure, respectively. At the time of data cut-off (January 15, 2019) 199/546 patients (36%) had discontinued through the RCT and OLE. The rates per 100 patient-years of treatment-emergent adverse events (AEs) and AEs leading to discontinuation for patients with >1 and 1 TNFi failure were 290.6 and 267.9, and 6.5 and 8.1, respectively. Clinical efficacy of sarilumab was sustained leading to discontinuation for patients with >1 and 1 TNFi failure were 290.6 and 267.9, and 6.5 and 8.1, respectively. Clinical efficacy of sarilumab was sustained in the OLE through 5 years in both groups, regardless of initial treatment in the RCT (Table).

Objectives: (csDMARDs) versus placebo in patients refractory to TNFi.

with sarilumab plus conventional synthetic disease-modifying antirheumatic drugs

Improvements in the signs and symptoms of RA and physical function were shown

DOI: 10.1136/annrheumdis-2020-eular.332
Objectives: To characterize the effect of Abatacept on the expression and proteolytic activity of the immunoproteasome.

Methods: Effects of Abatacept on the proteasome system were investigated in 39 patients with rheumatoid arthritis over a period of 24 weeks. Using real time PCR, transcript expression levels of constitutive and corresponding immunoproteasome catalytic subunits were investigated at baseline (T0), week 16 (T16) and week 24 (T24) in sorted blood cells. Proteasomal activity and induction of apoptosis after proteasome inhibition were also evaluated in cellular subsets.

Results: Upon treatment with Abatacept, remission or low disease activity according to DAS28 was achieved in 55% of patients at T16 and in 70% at T24. By Two-(time and type of response) way ANOVA, a significant reduction of proteasome immunosubunit β1i expression was seen only in CD4+ and CD8+ T cells of prolonged responders at both T16 and T24 (P = 0.0390 and P = 0.0198, respectively). One-way ANOVA analysis for each response group separately confirmed the results and showed significant reduction at T24; P = 0.0396 difference between T0 and T24, P = 0.0260 between T16 and T24 in CD4+ T cells of the same group. Abatacept did not influence chymotrypsin like activity of proteasome, which is carried out by the subunit β5i and had no effect on induction of apoptosis under exposure to a proteasome inhibitor in-vitro.

Conclusion: Treatment with Abatacept showed a clear effect on the expression of the proteasome immunosubunit β1i. This phenomenon was only seen in CD4+ and CD8+ T cells of prolonged responding patients with RA suggesting an association between persistent induction of β1i and failure to the T cell directed therapy with Abatacept.

DOI: 10.1136/annrheumdis-2020-eular.4265
Background: Sarcopenia is characterized by loss of muscle mass and strength, which lead to lower physical ability, less quality of life (QoL), frailty and mortality. Rheumatoid arthritis (RA) is considered to be one of the causes of sarcopenia. Objectives: To clarify the effectiveness of biologic disease modifying anti-rheumatic drugs (bDMARDs) on sarcopenia, including physical ability, body composition and nutritional status. Methods: This is a prospective cohort study including consecutive 48 patients (male 11, female 37, age 64.2±15.1) with RA who started bDMARDs in Niigata Rheumatism Center. Diagnosis of sarcopenia was according to the diagnostic algorithm of European Working Group on Sarcopenia in Older People (EWGSOP). We monitored disease activity of RA, physical ability, body composition, nutritional status and QoL at baseline, 6 months and at 12 months. Disease activity was measured by disease activity score-28 count joint based on erythrocyte sedimentation rate (DAS28-ESR), clinical disease activity index (CDAI). Physical activity was measured by Health Assessment Questionnaire (HAQ). 10m walking test (10MWT). Nutritional status was measured by controlling nutrition status (CONUT) score, and prognostic nutritional index (PNI). Overall QoL was measured by EuroQol 5 dimensions (EQ5D).

Results: Among 48 patients who started bDMARDs, 21 patients were classified as having sarcopenia. The bDMARDs used were adalimumab in 10 cases, certolizumab pegol in 9 cases, abatacept in 7 cases, tocilizumab in 5 cases, infliximab in 5 cases and etanercept in 3 cases. DAS28-ESR (4.7±1.4 vs. 2.7±1.0, p<0.001) and CDAI (18.4±9.4 vs. 7.4±5.5, p=0.001) were significantly decreased by 12 months of bDMARDs therapy. Physical activity was significantly ameliorated after 12 months of bDMARDs; HAQ(1.1±0.9 vs. 0.6±0.8, p=0.001), 10MWT(15.0±7.9 m/s vs. 17.0±6.0, p=0.002), EQ-SD was also ameliorated(0.63±0.15 vs. 0.74±0.19, p=0.0022). As for body composition analysis, there were significant increase in body weight [5.4±1.2 kg vs. 5.3±1.6 kg, (p=0.006), but there was no significant increase in skeletal muscle mass index[5.9±1.1 kg/m2 vs. 5.9±1.1 kg/m2, (p=0.229)] Among 21 patients who were classified as sarcopenia when starting bDMARDs, the number of patients having sarcopenia significantly decreased after 12 months of bDMARDs (100% vs. 52.3%, p=0.0005) and skeletal muscle index of these patients were significantly increased (5.1±0.5 kg/m2 vs. 5.3±0.7 kg/m2, p=0.046).

Conclusion: Twelve months of bDMARDs therapy significantly ameliorated disease activity, nutritional status and physical activity. In RA patients with sarcopenia, bDMARDs significantly increased skeletal muscle and may be effective for treatment of sarcopenia.

The bDMARDs used were adalimumab in 10 cases, certolizumab pegol in 9 cases, abatacept in 7 cases, tocilizumab in 5 cases, infliximab in 5 cases and etanercept in 3 cases. DAS28-ESR (4.7±1.4 vs. 2.7±1.0, p<0.001) and CDAI (18.4±9.4 vs. 7.4±5.5, p=0.001) were significantly decreased by 12 months of bDMARDs therapy. Physical activity was significantly ameliorated after 12 months of bDMARDs; HAQ(1.1±0.9 vs. 0.6±0.8, p=0.001), 10MWT(15.0±7.9 m/s vs. 17.0±6.0, p=0.002), EQ-SD was also ameliorated(0.63±0.15 vs. 0.74±0.19, p=0.0022). As for body composition analysis, there were significant increase in body weight [5.4±1.2 kg vs. 5.3±1.6 kg, (p=0.006), but there was no significant increase in skeletal muscle mass index[5.9±1.1 kg/m2 vs. 5.9±1.1 kg/m2, (p=0.229)] Among 21 patients who were classified as sarcopenia when starting bDMARDs, the number of patients having sarcopenia significantly decreased after 12 months of bDMARDs (100% vs. 52.3%, p=0.0005) and skeletal muscle index of these patients were significantly increased (5.1±0.5 kg/m2 vs. 5.3±0.7 kg/m2, p=0.046).

Conclusion: Twelve months of bDMARDs therapy significantly ameliorated disease activity, nutritional status and physical activity. In RA patients with sarcopenia, bDMARDs significantly increased skeletal muscle and may be effective for treatment of sarcopenia.

SAT0113
DISCORDANCE OF CLINICAL REMISSION AND IMAGING REMISSION BY ULTRASONOGRAPHY IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH BIOLOGIC AGENTS

Y. Kondo1, Y. Kaneko1, S. Saito1, Y. Ohita1, K. Sakata1, Y. Inoue1, C. Takahashi1, K. Hiramoto1, J. Inamo1, T. Takeuchi1, 1Keio University School of Medicine, Division of Rheumatology, Tokyo, Japan

Background: Residual synovitis can be detected by sensitive modalities such as ultrasonography in patients with rheumatoid arthritis in clinical remission. On the other hand, a previous study has shown that ultrasound-guided treatment provides modest benefit compared to a conventional strategy aiming clinical remission in early patients. It is still unclear how discordant clinical remission provides modest benefit compared to a conventional strategy aiming clinical remission in early patients. It is still unclear how discordant clinical remission provides modest benefit compared to a conventional strategy aiming clinical remission in early patients. It is still unclear how discordant clinical remission provides modest benefit compared to a conventional strategy aiming clinical remission in early patients. It is still unclear how discordant clinical remission provides modest benefit compared to a conventional strategy aiming clinical remission in early patients.

Objectives: To clarify the discordance between clinical remission and imaging remission in patients with rheumatoid arthritis treated with biologic agents.

Methods: Patients with rheumatoid arthritis who were treated with biologic agents and in clinical remission defined as disease activity score for 28 joints (DAS28)<2.6 were enrolled. All patients were performed comprehensive ultrasound examination of 44 joints as well as physical examinations. Ultrasound images of gray scale (GS) and power doppler (PD) were evaluated with a semi-quantitative score of 0-3. Imaging remission with ultrasound was defined as no PD signal detected in any joints. Clinical information was collected from their medical charts.

Results: A total of 41 patients were enrolled with 22 patients treated with tumor necrosis factor (TNF)-α inhibitors and 19 with interleukin (IL)-6 inhibitors. The mean age, female ratio, the mean disease duration, and the mean duration of clinical remission were 60 years old, 87%, 5.1 years and 11.5 years. The imaging remission by ultrasonography was observed only in 51.2%.

Conclusion: Our results showed that there was substantial discordance between clinical remission and imaging remission, especially in the patients treated with IL-6 inhibitors. In patients treated with biologic agents, clinical remission should be assessed more stringently than the usual 2.6, and ultrasonography-guided management may be useful.

SAT0114
IMPACT OF DOSE TAPERING REIMBURSEMENT POLICY ON PRESCRIPTION PATTERN OF ADVANCED THERAPY FOR RHEUMATOID ARTHRITIS IN TAIWAN

C. H. Tang1, C. L. Chang2, W. Y. Shau2, C. Y. Hsin2, K. J. Li3. 1Taipei Medical University, School of Health Care Administration, Taipei City, Taiwan, Republic of China, 2Pfizer Ltd, New Taipei City, Taiwan, Republic of China, 3National Taiwan University Hospital, Department of Internal Medicine, Taipei City,Taiwan, Republic of China

Background: Rheumatoid arthritis (RA) patients treated with advanced therapy (biologic disease-modifying antirheumatic drugs and targeted synthetic disease-modifying antirheumatic drugs) may be considered dose tapering after reaching treatment goal.1 In EULAR 2016 recommendations, dose reduction can be considered if patients reach sustained remission.2 A dose tapering policy of advanced therapy was introduced in the treatment guidelines of RA since 2014 under the National Health Insurance (NHI) in Taiwan. The new reimbursement policy requests the dosage to be tapered in patients who received advanced therapy for 2 years and reached low disease activity defined by DAS28 (ESR).

Objectives: This retrospective study aims to investigate the impact of dose tapering policy on prescription pattern of advanced therapy for RA patients in Taiwan.

Methods: This study was an observational retrospective analysis on the population-based National Health Insurance Research Database (NHIRD) in Taiwan. Patients with RA aged ≥18, initiated an index advanced therapy - abatacept, adalimumab, etanercept, golimumab, tocilizumab, or tofacitinib, during 2011-2017 were included (Figure 1). Patients were followed-up until the index advanced therapy was switched/discontinued or the end of data, whichever came first. The 4-week moving average of proportion of days covered (PDC) of the index therapy within each 12-week period were assessed. The outcome variable was whether dose tapering occurred which was defined as PDC being less than 0.5. The odds ratios (ORs) and the 95% confidence intervals (Cls) were estimated using Generalized Estimating Equation (GEE) with logistic specification to examine the independent effect of tapering policy and treatment

References:
duration on the probability of dose tapering, after controlling for age, sex, and index advanced therapy.

Results: The study comprised 9,094 patients initiated advance treatment for RA, with mean age of 57.3 (SD 13.3) years and 78.8% were female. The median PDC dropped remarkably after 28 months since treatment initiation (Figure 2). Probability of dose tapering increased significantly when treatment duration ≥24-month (OR=2.73, p=0.001). When treatment duration <24-month, Dose Tapering policy was not significantly associated with tapering prescription. However, implementation of the policy further increased the probability of dose tapering for patients with treatment duration ≥ 24-month, OR for interaction of treatment duration ≥24-month vs <24-month (OR=2.73, 95% CI: 2.45, 3.05) <.001). When treatment duration < 24-month, Dose Tapering for patients with treatment duration ≥ 24-month, OR for interaction of treatment duration ≥24-month vs <24-month (OR=2.73, 95% CI: 2.45, 3.05) <.001).

Conclusion: For RA patients, PDC of advanced therapy dropped notably after patients received advanced therapy for more than 24 months. The tapering policy implementation significantly increased the probability of dose tapering of advanced therapy in patients with treatment duration ≥ 24 months.

SAT0116 COMPARISON OF THE EFFICACY OF ABATCEPT ON ELDERLY AND YOUNG PATIENTS WITH RHEUMATOID ARTHRITIS

S. Murao 1, Y. Yamada 2, W. Hirose 3, H. Kono 4, S. Yasuda 5, T. Nanki 6, 1Toho University, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 2Hirose Clinic of Rheumatology, Saitama, Japan; 3Tokyo University School of Medicine, Department of Internal Medicine, Tokyo, Japan; 4Hokkaido university, Department of Rheumatology, Endocrinology and Nephrology, Sapporo, Japan

Background: The widespread use of biologic agents has greatly improved the prognosis of rheumatoid arthritis (RA). On the other hand, elderly patients with RA are relatively increasing. Although achieving low disease activity is a goal for those elderly patients as well as young patients, the efficacy of tumor necrosis factor inhibitors were reported to be equally or slightly less effective in elderly patients than in young patients. There is a lack of evidence for the efficacy of abatacept (ABT) in elderly patients.

Objectives: In this study, we aimed to clarify the efficacy of ABT in elderly and young patients with RA compared to csDMARDs.

Methods: This is a multicenter, open-label, prospective,observational study. All patients with RA enrolled this study are refractory to csDMARDs and have not received any biologics. Either ABT or csDMARDs was administered at the discre- tion of physicians to elderly (65 years and older) and young (20-64 years) patients (ABT-elderly, ABT-young, control (CTL)-elderly, and CTL-young groups). Compar- ison was made between 4 groups of patients. The primary study endpoint was a good response by EULAR response criteria at week 24 after administration. The research procedure has been approved by the ethics committee of Toho University School of Medicine (Approval number: A17112).

Results: A total of 219 patients, 127 in the ABT group and 92 in the CTL group, were enrolled in this study. The majority of patients were women (82.7%) with a mean age (±SD) of 64.9±13.6 years (74.5±5.9 years in the elderly group and 52.4±10.1 years in the young group). The ABT group had higher disease activity, higher HAQ, and higher steroid use rates and dosage than the CTL group. These were also observed in the elderly group. In the young group, although the ABT group had higher disease activity and higher HAQ than the CTL group, no difference was observed in steroid use rates and dosage. The ABT group more frequently achieved a good response by EULAR response criteria compared to the CTL group at week 24 (58.8% and 27.2%, respectively, p<0.0001). The ABT group also achieved higher efficacy than the CTL group in the elderly and young groups with a good response. Regarding the improvement in DAS28-ESR and DAS28- CRP, the ABT group was also superior to the CTL group. There was no difference on efficacy between elderly and young patients from the ABT groups. Based on propensity score matching for disease activity at baseline, 61 matched pairs of patients treated with ABT or csDMARDs were statistically extracted. Although there was no significant difference in the rate of patients with a good response by EULAR response criteria between the ABT and the CTL groups, the ABT group showed significantly better response than the CTL group in the elderly. Furthermore, the ABT group was superior to the CTL group in improvement in both DAS28-ESR and DAS28-CRP, and similar results were obtained in the elderly. However, there was no significant difference between the ABT group and the CTL group in the young. In addition, elderly patients had significant improvement in DAS28-ESR compared with young patients in the ABT group.

Conclusions: Treatment with ABT showed higher efficacy compared with Cs DMARDs particularly in elderly patients with RA.

SAT0117 TRIMESTER EXPOSURE AND PREGNANCY OUTCOMES IN WOMEN EXPOSED TO GOLIMUMAB – RESULTS FROM THE COMPANY PHARMACOVIGILANCE DATABASE

M. Otero-Loquito 1, S. Esslinger 2, S. Gabriël 3, M. Clark 4, P. Sheridan 4, A. Gielhof 1, 1Janssen Biologics BV, Leiden, Netherlands; 2Janssen LLC, Research & Development, Horsham, United States of America; 3Janssen LLC, Research & Development, Springhouse, United States of America

Background: Rheumatologic disorders and inflammatory bowel disease can affect women of childbearing potential. Golimumab (GLM) is approved for several rheumatologic indications and ulcerative colitis (UC).

Objectives: To characterize pregnancy outcomes in patients treated with GLM, data obtained from maternal exposure to GLM are presented.

Methods: This dataset includes individual patient cases reported to the man- ufacturer through 06 April 2019. Cases included in the analysis were medically confirmed cases of maternal exposures to GLM during pregnancy or within 3 months prior to conception, and a reported pregnancy outcome. Both prospectively and retrospectively reported cases (ie, pregnancy outcome not known when first reported) and retrospectively reported cases (ie, pregnancy outcome known when first reported) were included. Cases originated from various sources, including spontaneous reporting, clinical studies, and registries.

Results: Two hundred eight pregnancy cases (131 rheumatologic indications; 43 UC; and 34 other) with 211 reported birth outcomes were identified. Of these, 208 pregnancy cases, 119 were prospective and 89 were retrospective. Average maternal age was 31.9 years. Of the 119 prospectively reported pregnancy cases, 89 (74.8%) resulted in live births, 19 (16.0%) resulted in spontaneous abortion of these, 42.1% (8/19) received GLM in combination with methotrexate (MTX), 10 (8.4%) resulted in induced/elective abortion, and 1 (0.8%) resulted in ectopic pregnancy. Overall, 9 congenital anomalies were reported (2 prospective and 7 retrospective cases).

For 183 of the 208 pregnancy cases with reported outcomes, the trimester of expo- sure to GLM was known. Among the 110 prospectively reported cases, 82 (74.5%) were exposed during trimester 1 or 0 of pregnancy, 19 (28.0%) were exposed to GLM through trimesters 1-3 and all resulted in live births (none with con- genital anomalies; 1 infant with exposure to GLM and MTX was born preterm).

Conclusion: The rates of congenital malformations and spontaneous abortions were consistent with published background rates for the general population. Persistent exposure throughout pregnancy was rare. Limitations of this analysis include the lack of a direct comparison group, the variable amount of data available in the reports, and the possible bias towards reporting more negative outcomes in retrospective cases.

PARADOXICAL NEUTROPHIL ACTIVATION BY ANTI-IL6 THERAPY: TRANSCRIPTOME ANALYSIS SHOWS A RATIONALE FOR DERMATOLOGICAL ADVERSE REACTIONS AND DECREASED NEUTROPHIL COUNTS AFTER TOCILIZUMAB TREATMENT

M. Sakamoto1, A. Senoh2, Y. Sato3, H. Iijima4, M. Yamaguchi2, T. Higuchi3, Y. Koyama1. 1Japanese Red Cross Okayama Hospital, Division of Rheumatology, Center for Autoimmune diseases, Okayama, Japan; 2DNA Chip Research Inc, Tokyo, Japan

**Background:** Skin rashes as a side effect of Tocilizumab therapy (TCZ-Tx) has not been paid much attention, because the incidence was only 1~2% in the drug information sheets. However, we experienced several RA cases with development of various skin rashes associated with neutrophil activation after TCZ-Tx. On the other hand, it is well known that the neutrophil counts in peripheral blood decreases after TCZ-Tx, whereas it does not affect the rate of serious infections. The detailed mechanism is still unclear.

**Objectives:** To detect the characteristics of the changes in gene expressions of peripheral blood associated with TCZ-Tx and the development of skin rashes as its side effect.

**Methods:** Total of 14 RA patients with TCZ-Tx were included. Among them, 4 patients developed TCZ-related rashes (group S) and 10 patients did not show any side effects (group C). Peripheral whole blood at just before (pre) and 3 months after (post) TCZ-Tx from each patient were subjected to the analysis. Total RNAs were extracted with PAXgene miRNA kit and analyzed by using oligonucleotide microarray. Furthermore, we investigated the development of skin rashes using the information sheets. However, we experienced several RA cases with development of skin rashes associated with neutrophil activation after TCZ-Tx.

**Conclusion:** In this real-world population of US patients with RA who had prior TNFi exposure, there was no statistically significant or clinically meaningful difference in the effectiveness of therapy in patients who initiated TCZ + MTX compared with TNFi + MTX.

**Acknowledgments:** This study was sponsored by Corrona, LLC. Corrona is supported through contracted subscriptions with multiple pharmaceutical companies. The abstract was a collaborative effort between Corrona and Genentech, Inc., with financial support provided by Genentech, Inc.

were subjected to a hierarchical clustering analysis. The DEGs (group S vs. C and post vs. pre) were also investigated with weighted gene co-expression network analysis (WGCNA) and GO analysis. Meanwhile, the total eigengene expressions of the important modules identified by WGCNA in each cases were also calculated.

**Results:** Surprisingly, 8 out of the top 10 enriched GO terms in the up-regulated genes were relevant to leukocyte activation such as 'neutrophil migration' by the analysis of DEGs (post vs. pre) in group C. The cluster analysis of 'pre' genes confirmed that the patterns of gene expression between group S and C was different. WGCNA analysis of DEGs (group S vs. C) revealed that genes related to acute inflammation such as 'leukocyte mediated immunity' were activated in group S. Interestingly, it was not correlated with disease activity score (DAS) of RA. By the analysis of DEGs (post vs. pre) of upregulated genes, we found that the total eigengene expressions of the module enriched with genes related to 'cell adhesion' or 'leukocyte migration' were significantly increased in all cases of group S.

**Conclusion:** This is the first evidence that the genes associated with neutrophil migration is significantly activated after TCZ-Tx. It is noteworthy that the gene activation was observed in cases without any side effects. The decreased neutrophil counts in peripheral blood have been known after initiation of TCZ-Tx, which did not affect the rate of serious infections. Recently, It was reported that TCZ affects neutrophil trafficking to the bone marrow\(^a\). Our findings will provide a rationale for its cause. On the other hand, we experienced several RA cases with development of various skin rashes associated with neutrophil activation after TCZ-Tx. However, majority of patients do not develop the side effect, even though genes related to 'neutrophil migration' are activated. In group S, our findings indicate that the genes related to 'leukocyte mediated immunity' was already activated at the initiation of treatment without correlating to DAS of RA. Furthermore, the gene upregulation related to 'leukocyte migration' was more prominent after TCZ-Tx. Although it is difficult to predict the patients developing skin rashes before TCZ-Tx, we do not recommend to use TCZ for the patients with neutrophilic dermatosis which is often associated with RA.

**UNITED STATES RHEUMATOLOGY PRACTICE-BASED REAL-WORLD EVIDENCE OF INFUSION REACTIONS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH INTRAVENOUS GOLIMUMAB OR INFLIXIMAB: IMPACT OF PRIOR BIOLOGIC EXPOSURE AND METHOTREXATE UTILIZATION**

**S. Schwartzman**\(^1\), A. Broadwell\(^2\), A. Kivitz\(^3\), S. Xu\(^4\), W. Langhoff\(^5\), S. Katka\(^6\). \(^1\) Weill Cornell Medical College, NY, United States of America; \(^2\) Rheumatology and Osteoporosis Specialists, LA, United States of America; \(^3\) Altona Center for Clinical Research, PA, United States of America; \(^4\) Janssen Scientific Affairs, LLC, PA, United States of America; \(^5\) Janssen Research & Development, LLC, PA, United States of America

**Background:** AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is an ongoing Phase 4 comparator study designed to provide a real-world assessment of intravenous golimumab (GLM) and intravenous infliximab (IFX) in patients (pts) with rheumatoid arthritis (RA). The study recently reached its primary endpoint (comparison of overall incidence of infusion reactions in GLM- vs IFX-treated pts after 52 weeks) with the last patient reach-in on the 18th of November 2020. AWARE also records Cox proportional hazard analysis of infusion reactions in AWARE in subsets of patients ± prior biologic use or ± concurrent MTX.

**Methods:** AWARE is a prospective, noninterventional, observational, multicenter, 3-year study conducted in the US. RA patients (1,270 adults) were enrolled at the time of initiating treatment with GLM or IFX. All treatment decisions were made at the discretion of the treating rheumatologist. An infusion reaction was any adverse event that occurred during an infusion or within 1 hour after the infusion of either GLM or IFX. Imputations were not performed on these AWARE data. Data shown are mean ± standard deviation.

**Results:** Demographics are shown in Table 1 and the incidence of infusion reactions in different subsets of AWARE pts is shown in Table 2. GLM and IFX pts were comparable in sex and utilization of MTX at baseline. Age and disease duration of GLM pts was greater than IFX pts by ~2 years. There was a higher proportion of bioneive pts in IFX-treated group compared to GLM-treated group. Overall, infusion reactions occurred more frequently among IFX-treated pts compared to GLM-treated pts. The difference in infusion reaction rates between IFX- and GLM-treated pts was also evident among subgroups of bioneive vs non-bioneive pts, and among MTX non-users vs MTX users (characteristics reported at baseline). GLM pts did not report any serious or severe infusion reactions. These were reported rarely (3/585 pts) in IFX-treated pts. Among GLM and IFX pts with an infusion reaction, 55.6% of GLM and 77.1% of IFX pts had at least one medication for infusion reaction. Infusion reactions accounted for 9.7% and 35.1% of discontinuations due to adverse events in GLM and IFX pts, respectively.

**SAT0121**

**PAIN AND OTHER PATIENT-REPORTED OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO DID OR DID NOT ACHIEVE TREATMENT RESPONSE BASED ON IMPROVEMENT IN SWOLLEN JOINTS IN TOCILIZUMAB CLINICAL TRIALS**

**A. Sabba**\(^1\), J. Han\(^2\), S. Mohan\(^2\). \(^1\) Arthritis Associates, Palm Harbor; United States of America; \(^2\) University of South Florida, Tampa; United States of America

**Background:** Significant improvements in pain and other patient-reported outcomes (PROs) have been shown in large clinical trials in patients with rheumatoid arthritis (RA) who receive tocilizumab (TCZ) compared with placebo (PBO). Recent data suggest that pain in RA may be noninflammatory as well as inflammatory, and...
improvement in pain scores and other PROs may be seen in patients who do not respond to treatment based on disease activity measures that evaluate inflammation. 

Objectives: To assess changes in pain scores and other PROs in patients with RA who did or did not achieve ≥ 20% improvement in SJC in TCZ clinical trials.

Methods: Data from patients with active RA who received intravenous TCZ 8 mg/kg + MTX or PBO + MTX in 3 Phase III studies (OPTION [NCT00106548], TOWARD [NCT00106574] and LITHE [NCT00109408]) were included. All patients had moderate to severe RA with an inadequate response or intolerance of MTX (OPTION, LITHE) or conventional synthetic disease-modifying antirheumatic drugs (csDMARDs; TOWARD). Changes in pain (visual analog scale [VAS], 0-100 mm), Health Assessment Questionnaire Disability Index (HAQ-DI; 0-3), 36-Item Short Form Survey (SF-36) physical component score (PCS) and mental component score (MCS; 0-50) and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score (0-52) from baseline to Week 24 were evaluated. Results were compared between patients receiving TCZ + MTX and those receiving PBO + MTX in both patients who achieved ≥ 20% improvement in SJC (responders) and those who did not (nonresponders). The changes from baseline were analyzed using a mixed model with repeated measures, including the following covariates and interactions: treatment, visit, baseline of endpoint, region, baseline DAS28 and interactions: treatment, visit, baseline of endpoint, region, baseline DAS28 and of baseline DAS28-CRP at 52 weeks after bDMARD initiation were assessed with univariate and stepwise forward multivariate logistic regression analyses. This cohort study was not randomized. Propensity score (PS) matching was used to align patient backgrounds to avoid selection bias.

Results: Data from 1254 responders (TCZ + MTX, n = 831; PBO + MTX, n = 423) and 620 nonresponders (TCZ + MTX, n = 225; PBO + MTX, n = 395) were included. Patients receiving TCZ + MTX had significantly greater improvement in pain scores and HAQ-DI compared with PBO + MTX in the responder group (–27.19 vs –16.77 and –0.55 vs –0.34, respectively; P < 0.0001 for both) and nonresponder group (–9.59 vs 2.53 and –0.20 vs 0.01; P < 0.0001 for both) at Week 24 (Figure 1). Similar results were seen at Week 16 in the nonresponder group (–11.06 vs –2.38 and –0.23 vs –0.04; P < 0.0001 for both) prior to initiation of rescue treatment. At Week 24 in the responder group, patients receiving TCZ + MTX had significantly greater improvement compared with PBO + MTX in SF-36 PCS and MCS (9.16 vs 5.71 and 6.55 vs 3.79, respectively; P < 0.0001 for both) (Figure 2) and FACIT-Fatigue (8.39 vs 5.11; P < 0.0001). In the nonresponder group, patients receiving TCZ + MTX had significantly greater improvements compared with PBO + MTX in SF-36 PCS at Week 16 (3.81 vs 1.65; P = 0.0006) and Week 24 (4.42 ± 1.01; P = 0.0001) (Figure 2) and FACIT-Fatigue at Week 24 (3.82 ± 1.32; P = 0.0039) and Week 24 (3.90 ± 1.40; P = 0.0111).

Conclusion: Patients with RA who received TCZ + MTX had significantly greater improvement in pain scores and other PROs than those who received PBO + MTX regardless of whether they achieved ≥ 20% improvement in SJC. Clinical outcome at Week 24 correlated well with PBO, with a relatively larger improvement in pain score and other PROs in the responder group than in the nonresponder group; relative to PBO + MTX, these improvements appear numerically similar in the responder and nonresponder groups with consistently smaller difference between the groups in TCZ-treated arms. The consistent effect of TCZ on PBO in both responder and nonresponder groups warrants further study on the impact of TCZ on sources of pain independent of that caused by joint inflammation.

SAT0122

HIGHER DOSES OF METHOTREXATE ASSOCIATED WITH DISCONTINUATION OF ORAL GLUCOCORTICOID USE AFTER INITIATION OF BIOLOGICAL DMARDS: A RETROSPECTIVE OBSERVATIONAL STUDY BASED ON DATA FROM A JAPANESE MULTICENTER REGISTRY STUDY

M. Suzuki1, T. Kojima1, N. Takahashi1, S. Asai1, K. Terabe1, N. Ishiguro1 on behalf of TBCR group. 1 Nagoya University Graduate School of Medicine, Orthopedics, Aichi, Japan

Background: Glucocorticoids exert anti-inflammatory effects and are important drugs used to treat rheumatoid arthritis(1). We recommend glucocorticoid discontinuation as soon as possible because glucocorticoid caused several side effects, but many patients continue to take oral glucocorticoids long-term in daily clinical practice. The frequency of use of glucocorticoid has gradually declined, and there are several reports on discontinuation of glucocorticoid due to the initiation of biological disease-modifying antirheumatic drugs (bDMARDs)(2). However, there is no report showing the relation between discontinuation of glucocorticoid and MTX dose.

Objectives: The present study aimed to explore factors associated with glucocorticoid discontinuation at 52 weeks after initiating bDMARDs. 

Methods: We established the large observational cohort, the Nagoya University orthopedic facility multicenter study (TBCR), and a total of 3119 patients used bDMARD and examined the status of oral glucocorticoid use at 52 weeks after initiating the 1st bDMARD. In predictive analyses, the outcome variable was glucocorticoid discontinuation at 52 weeks after bDMARD initiation. Factors associated with baseline characteristics at bDMARD initiation were assessed with univariate and stepwise forward multivariate logistic regression analyses. This cohort study was not randomized. Propensity score (PS) matching was used to align patient backgrounds to avoid selection bias.

Results: Subjects were 564 patients administered glucocorticoids and methotrexate (MTX) following initiation of the 1st bDMARD (Figure 1). Mean DAS28-CRP at bDMARD initiation was 4.70 ± 1.16. Percentages of patients with low, moderate, and high disease activity as evaluated by DAS28-CRP at bDMARD initiation were 4.7%, 23.5%, and 71.8%, respectively. By 52 weeks after bDMARD initiation, 164 patients (29.1%) discontinued glucocorticoids. Multivariate analysis identified age and high disease activity as evaluated by DAS28-CRP at bDMARD initiation were 4.7%, 23.5%, and 71.8%, respectively. By 52 weeks after bDMARD initiation, 164 patients (29.1%) discontinued glucocorticoids. Multivariate analysis identified age (odds ratio [OR], 0.98), MTX dose (OR, 1.11), and glucocorticoid dose (OR, 0.87) as factors independently associated with glucocorticoid discontinuation at the time of bDMARD initiation (Table 1). After adjusting for baseline characteristics using propensity score matching among patient groups administered MTX ≤ 8 mg/week and MTX > 8 mg/week, 105 pairs remained. Among patients administered MTX ≤ 8 mg/week, 41.0% discontinued glucocorticoids. Among those administered MTX ≤ 8 mg/week, 22.9% discontinued glucocorticoids, with a significant difference between the two groups (Figure 2, P=0.007).

Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; Department of Rheumatology of Children and Adults, Motel Treatment Hospital, Prague, Czech Republic; Department of Internal Medicine, Division of Rheumatology, Hacettepe University, Ankara, Turkey; Abbvie Inc., North Chicago, United States of America; Division of Clinical Immunology, Allergology and Rheumatology, Department of Internal Medicine, Dübrawa University Hospital, University of Zagreb School of Medicine, Zagreb, Croatia; Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; Department of Rheumatology and Physiotherapy, Polyclinic of the Hospital Sisters of St. John of God, Semmelweis University, Budapest, Hungary; Faculty of Medicine, University of Crete, Heraklion, Greece; Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background: Patient characteristics, their treatment preferences and goals are important determinants of treatment success in rheumatoid arthritis (RA).

Objectives: SENSE study aimed at assessing the impact of inadequate response to disease-modifying anti-rheumatic drugs on disease outcomes, and analyze their attitude, their treatment and disease.

Methods: Non-interventional, cross-sectional study conducted in 18 countries in Europe, Asia, and America. Adult RA patients with moderate/high disease activity were eligible. Patient satisfaction was assessed by Treatment Satisfaction Questionnaire for Medication, Version 14 (TSQM v1.4). Treatment adherence, patient preferences, and expectations were evaluated by visual analog scale. eHealth Literacy Scale was employed for evaluating DHL. Work Productivity and Activity Impairment Questionnaire-Rheumatoid Arthritis, v2.0 (WPAI-RA) was used to assess workability and patient documentation for healthcare resource utilization (HRU).

Results: 1624 patients were included in this analysis; most were female (84.2%), middle-aged, and had a mean (standard deviation [SD]) disease duration of 10.5 (9.3) years. 11.9% of the patients had retired early and 6.0% were unemployed due to RA. Mean (SD) total WPAI-RA score was 55.1% (25.7). In the previous 3 months, the mean (SD) number of healthcare professional and emergency rooms visits was 2.2 (5.5) and 1.6 (13), respectively. Mean (SD) TSQM v1.4 global satisfaction subscore was 60.9 (20.9), with only 13.5% reporting good treatment satisfaction (TSQM global ≥80). The leading treatment expectations were ‘general improvement of arthritis,’ ‘less joint pain’ and ‘lasting relief of RA symptoms,’ with mean (SD) scores of 5.7 (16–17) for each. 60.7% of patients preferred oral administration and 31.3% preferred not to use drug combinations for RA. Preferred time to effect was predominantly ‘up to one week’ (71.1%). Least frequently side effects rated ‘acceptable’ were ‘increased risk of malignancies’ (3.5%) and ‘increased risk for cardiovascular diseases’ (3.3%). Most patients (67.4%) had poor DHL. Good adherence (in 87.4% of patients) was significantly associated with lower levels of joint pain.

Conclusion: Suboptimal disease control has a significant impact on satisfaction, workability, and HRU. Our results can support shared decision-making when setting RA treatment strategy.

Data are presented as mean ± standard deviation.

Conclusion: Data from the TBCR revealed that, from a clinical perspective, glucocorticoid use decreased among RA patients treated with bDMARDs. Higher doses of MTX (> 8 mg/week) at the time of bDMARD initiation were found to be associated with glucocorticoid discontinuation in patients treated with bDMARDs. In addition, we found that aggressive use of MTX was sufficient to fulfill the Treat-to-Target approach, demonstrating that glucocorticoid discontinuation is a viable option.
Background: Both Abatacept (ABT) and Tacrolimus (Tac) suppress T cell immunity, but it is unknown whether combinations of these will increase the risk of adverse events in patients with rheumatoid arthritis in Japan when compared to ABT or Tac alone. Further evaluation is needed.

Objectives: To evaluate whether combining ABT and Tac increases the risk of infection and malignancy compared to their individual use in Japanese rheumatoid arthritis (RA) patients.

Methods: We conducted a retrospective cohort study of RA patients using the multicenter database in Japan (NinJa). The database was clinical information at a certain point within each year, and the point was any point selected by a registered physician. RA was clinically diagnosed in the dataset. (1)

Results: Among the 27032 RA patients in the registry, 2009 patients were who used TNF inhibitors, IL-6 inhibitors, and Jak inhibitors in the first year. We analyzed the data from RA patients registered in NinJa during the period from April 2010 to March 2019. In this study, we compared three groups who had just begun initiating treatment with ABT or Tac, and we excluded patients from April 2010 to March 2019. In this study, we compared three groups who had just begun initiating treatment with ABT or Tac, and we excluded patients who used TNF inhibitors, IL-6 inhibitors, and Jak inhibitors in the first year. The primary outcome was defined the composite events including infections that require hospitalization, newly diagnosed malignancy, and death from any cause after initiation of ABT or Tac. We assessed whether the combination contributed to increase the risk of outcome by performing a Cox regression analysis.

Conclusion: The combination of ABT and Tac does not increase the risk of adverse events in patients with rheumatoid arthritis in Japan when compared to the use ABT or Tac alone. Further evaluation is needed.

S. Unizony1, J. Dang2, J. Han2, M. Michalska2, J. H. Best2. 1Massachusetts General Hospital, Harvard Medical School, Boston, United States of America; 2Genentech, Inc., South San Francisco, United States of America

Background: The efficacy and safety of intravenous (IV) and subcutaneous (SC) tocilizumab (TCZ) in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and as monotherapy in patients with rheumatoid arthritis (RA) has been demonstrated in large clinical trials and real-world data studies. The Health Assessment Questionnaire Disability Index (HAQ-DI) is commonly used to assess physical function in patients with RA. While HAQ-DI outcomes at Week 24 in TCZ clinical trials have been reported, outcomes at Week 12 and results stratified by treatment response categories at Weeks 12 and 24 have not been previously described.

Objectives: To report the association between change in HAQ-DI from baseline to Weeks 12 and 24 and Disease Activity Score in 28 joints (DAS28) response categories in patients who received TCZ or comparators in TCZ clinical trials.

Methods: Data from patients with active RA who received TCZ or a comparator from 6 Phase III or IV TCZ-IV studies (OPTION [NCT00106548], RADIATE [NCT00108552], TOWARD [NCT00106574], LITHE [NCT00105038], ACT-RAY [NCT00810199]) and ADACTA (NCT01119859) and 1 Phase III TCZ-SC study (BREVACTA [NCT0123569]) were analyzed. Mean change in HAQ-DI score at Weeks 12 and 24 was assessed in patients stratified by DAS28 disease activity level (DAS28 < 2.6 [remission], DAS28 ≥ 2.6 to ≤ 3.2 [low disease activity; LDA], DAS28 > 3.2 to ≤ 5.1 [moderate disease activity; MDA], DAS28 > 5.1 [high disease activity; HDA]) at Weeks 12 and 24. The adjusted least squares mean (LSM) change from baseline was estimated using a mixed model with repeated measures, including region (North America vs non-North America), RA duration (> 2 years vs ≤ 2 years), baseline HAQ-DI and DAS28, treatment, visit, visit by treatment and visit by baseline HAQ-DI.

Results: Data from 5051 patients were included. Across all studies, the mean duration of RA ranged from 6.3 to 12.6 years. At baseline, patients had severe RA with a mean DAS28 ≥ 6.3; baseline HAQ-DI was ≥ 1.5. At Week 12, patients who achieved remission or LDA had greater improvements in HAQ-DI than those in MDA or HDA (Figure 1). Results were similar at Week 24 (Figure 2). Among patients who received TCZ and achieved remission or LDA, mean improvement in HAQ-DI was ≥ 0.85 and ≥ 0.44, respectively, at Week 12 (Figure 1) and ≥ 0.48 and ≥ 0.43 at Week 24 (Figure 2). Mean changes in HAQ-DI were similar between patients who received TCZ-IV in combination with MTX or as monotherapy (ACT-RAY) and in those who received TCZ-IV or ADA as monotherapy (ADACTA).

Conclusion: Patients with long-standing, severe RA who received IV or SC TCZ as monotherapy or in combination with csDMARDs had improvement in physical function and disease activity at Week 12 that was maintained at Week 24. Overall, across all the trials, response to treatment was associated with improvement in physical function.

Conclusion: Median drug survival of the first biological is 1.6 years. Drug survival time is prolonged if patients are using co-medication and shortened in the presence of erosions. Furthermore, drug survival diminishes with the number of bDMARDs that are used.

Objectives:

1. To compare demographic, laboratory findings, and biological treatments of adult-onset rheumatoid arthritis (AORA) and late-onset rheumatoid arthritis patients (LORA) who were included in the TURKBIO registry cohort between the dates of 2011 and 2020.

2. To evaluate the effect of age on response to anti-TNF treatment in AORA and LORA.

3. To assess the role of shared epitope (SE) on the effectiveness of TNFi treatment in patients with rheumatoid arthritis.

Methods:

1. A retrospective cohort study was conducted using the TURKBIO registry, which includes data on 2111 patients with RA from 10 centers in Turkey.

2. The study cohort was divided into two groups based on age at symptom onset: AORA (<60 years) and LORA (≥60 years).

3. Demographic, clinical, and laboratory data were collected for both groups.

4. The effectiveness of anti-TNF treatment was assessed using clinical, biological, and therapeutic features.

5. The presence of the shared epitope (SE) was determined using HLA-DRB1*0401 genotyping.

Results:

1. Of the 484 TNFi patients included in the study, 68.8% were SE+.

2. SE+ patients were more likely to be rheumatoid factor positive, have erosive joint damage, and show higher changes in laboratory markers compared to SE- patients.

3. The use of anti-TNF was lower, and the use of rituximab was more frequent in LORA.

4. The frequency of LORA who uses bDMARDs was 8.8% in our data.

Conclusion:

The frequency of LORA who uses bDMARDs was 8.8% in our database. In the elderly patient population, there are some reservations about the use of biological drugs in general due to several co-morbidities and concomitant drug used. Although data on this issue are limited, appropriate biological use can be effective and reliable in required patients.

SAT0129

ROLE OF SHARED EPITOPE ON THE EFFECTIVENESS OF TNFI TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Zhuo1, J. Bryson1, Q. Xia1, N. Sharma2, C. Samai2, S. Lama1, M. E. Weinblatt3, N. Shadick3, Bristol-Myers Squibb, Lawrenceville, United States of America; 2Mumbai, Bangalore, India; 3Brigham and Women's Hospital, Boston, United States of America

Background:

Rheumatoid arthritis (RA) has been shown a strong genetic association with particular HLA-DRB1 alleles containing shared epitope (SE). However, whether SE is clinically useful in treatment choices is insufficiently investigated and previous studies have presented mixed findings in the role of SE in the response of TNFi therapies.

Objectives:

1. To assess the role of SE in response to TNFi treatment in real-world RA patients (pts).

Methods:

1. Pts enrolled in a large RA registry, Brigham and Women’s Hospital RA Sequential Study, with known SE and received TNFi therapies were included for the analysis. TNFi pts were identified by the first-time use of the drugs between March 2003 to June 2018. For this analysis, all pts were followed up to 1 year. Summary statistics are reported for demographics, serostatus and disease activity (DA) at baseline and follow-up, stratified by SE status. Given the strong association of SE and anti-citrullinated protein antibody (ACPA), the analysis was further stratified by ACPA status. The effect of SE on change in DA was assessed using linear regression model with age, gender, RA disease duration, baseline DA, smoking status, SE, ACPA and ACPA-SE interaction as covariates.

Results:

Of the 484 TNFi pts included in the study, 68.8% were SE+. SE+ pts (vs SE-) were more likely to be rheumatoid factor positive, have erosive joint damage, and show higher changes in laboratory markers compared to SE- pts.

disease and a higher disease duration, irrespective of ACPA status. No difference in the change of DA was observed by SE. In SE- pts, ACPA- pts had a greater reduction of DA than ACPA+ pts (Table 1). After accounting for baseline differences, there was no significant effect of SE status on the mean change from baseline in any of the 3 DA measures. (Figure 1) The change in DA was not associated with ACPA but was significantly affected by disease duration and baseline DA.

Logistic regression analyses (adjusted for gender and age)

**Conclusion:** In this observational study of >8000 patients with RA starting a first csDMARD, current smoking was associated with lower odds of achieving remission on methotrexate and higher chance of having started bDMARD compared to never smokers. Seropositivity may be an intermediate variable. Further analyses are planned to study impact of comorbidities and other co- founding factors.

**CARDIO- AND CEREBROVASCULAR RISK WITH CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTIMHUMATIC DRUGS (CSDMARDS) IN RHEUMATOID ARTHRITIS (RA): A REAL-WORLD COMPARATIVE ASSESSMENT**

A Prats-Uribe1, B Illingens2, D Vizzaya3, J Weaver4, E Burn5, R Sawan6, K Mariner7, P Ryan4, D Prieto-Alhambra5,6 on behalf of European Health Data and Evidence Network (EHEDEN) RA Research Group, 1University Of Oxford, Oxford, United Kingdom; 2Beth Israel Deaconess Medical Center, Department of Neurology, Harvard Medical School, Harvard, United States of America; 3Bayer Iberia, Barcelona, Spain; 4Janssen Research and Development, New Jersey, United States of America; 5Idiap Jordi Gol, Barcelona, Spain; 4Abbvie, Health Economics and Outcomes Research, North Chicago, United States of America; 6Servier, Suresnes, France; 7Janssen Research and Development, New Jersey, United States of America; 8University of Oxford, NDORMS, Oxford, United Kingdom

**Background:** RA is associated with an increased cardiovascular (CV) risk. csDMARDs are first-line treatments for RA and can mitigate this risk, but limited data exist on their CV effects. Previous trials have reported protective effects for methotrexate (MTX) and hydroxychloroquine (HCQ), but no similar data exist on sulphasalazine (SSZ) or leflunomide (LEF).

**Objectives:** To assess the comparative effect of csDMARDs on the risk of myocardial infarction (MI) and stroke in RA patients

**Methods:** Data from 6 claims/electronic health records databases across Germany, US, and UK, all mapped to the Observational Medical Outcomes Partnership (OMOP) common data model. A cohort study was conducted including patients ≥18 years old, with first RA diagnosis in 2005-2019, initiating csDMARD monotherapy with MTX, HCQ, SSZ, or LEF. Those with a prior diagnosis of other inflammatory arthritis or <1 year prior follow-up were excluded. Patients were followed until first outcome, death, loss of or 5 years follow-up. Propensity score stratification was used, and hazard ratios (HR) estimated for HCQ, SSZ and LEF compared to MTX in each dataset using Cox regression. HR were calibrated (cHR) for residual confounding using negative control outcomes. Estimates were pooled where I² for heterogeneity <0.4. Intention to treat and an on treatment analyses are reported.

**Results:** 145,248 patients were included (MTX: 73,996, HCQ: 49,752, SSZ: 12,256, LEF: 9,244). Pooled rates of MI and stroke for MTX were 7.64 and 10.26 per 1,000 person years respectively. Detailed estimate cHRs are shown in Figure 1 for the intention to treat analysis. MI risk with SSZ and LEF was comparable to MTX. Risk of stroke was similar between LEF and MTX, but reduced for HCQ and SSZ compared to MTX, with pooled cHR (95% CI) 0.86 (0.78 to 0.95) and 0.71 (0.52 to 0.98) for HCQ and SSZ respectively. Similar results were found for “on treatment” analyses.

**Conclusion:** Overall, all four csDMARDs had similar effects on MI risk. HCQ and SSZ use were associated with a decreased risk of stroke compared to MTX. The observed differences may be attributable to differential effects on the atherosclerotic process, differential disease control, or both. Database estimates not reported where adequate covariate balance not attained. Meta-analysis results not reported where I²>0.4. MEDIcare did not pass diagnostics for SSZ and LEF analyses. cHR: calibrated Hazard Ratio; CI: Confidence Interval; MTX: Methotrexate; HCQ: Hydroxychloroquine; SSZ: sulphasalazine; LEF: Leflunomide; THIN: The Health Improvement Network (UK); Optum: Optum de-identified Clininformatics Datamart (US); MDCR: Medicare (US); GERMANY: IQVIA Disease Analyzer EMR (Germany); CCAE: IBM MarketScan Commercial Claims and Encounters (US); AMBEMR: IQVIA Ambulatory EMR (US)

**DOI:** 10.1136/annrheumdis-2020-eular.3463
Background: Treatment with Janus Kinase inhibitors (JAK-i) (Tofacitinib, Baricitinib) can cause an increase of serum lipids such as total cholesterol, low-LDL and high-HDL density lipoproteins in patients with arthritis (1). On the other hand, JAK-i can reduce systemic inflammation and have therefore a beneficial effect on the cardiovascular system of treated patients. However, the effects of JAK-i on the CV system have not been adequately examined. In particular, we are not aware of any “real world” data concerning CV risk of patients receiving JAK-i treatment.

Stiffness of the aortic vasculature is a modifiable, valid and independent surrogate marker of CV risk and can be measured by carotid femoral pulse wave velocity (cfPWV). Its predicted value has been shown in a series of epidemiological studies and cfPWV is characterized as the gold standard marker for the assessment of aortic stiffness (2).

Objectives: Aim of this study was to evaluate for the first time changes of cfPWV, lipid profile and traditional CV risk factors in patients receiving JAK-i therapy.

Methods: Measurements of cfPWV, total cholesterol, LDL, HDL and inflammation markers were performed directly before and 5-7 months after initiation of JAK-i therapy. Additionally, traditional CV risk factors such as nicotine, obesity (Body-Mass-Index), diabetes and arterial hypertension were documented for both time points next to clinical activity measurements.

Results: 29 patients with rheumatoid arthritis (RA) (72.4%, female) with a median age of 61.5 (51-75, IQR) years and a median DAS28-CRP of 5.27 (3.62-6.21, IQR) were recruited before and at night, and awakened by pain in morning decreased by 64%, 70%, and respectively (p<0.05, n = 23). Three study adverse events (AEs) were registered with an incidence of 0.22 (62.5%). VAS sleep scores were significantly improved (p<0.05) at 12 weeks, and 15 out of 24 patients achieved an overall HAQ-DI reduction of 0.22 (62.5%). DAS28-CRP score at Week 12. Secondary endpoints included a safety analysis, proportion of patients achieving ACR20/50/70, the mean change in HAQ-DI and the proportion of patients achieving a ACR20/50/70 response rates were 58.3%, 37.5%, and 16.7%, respectively (Figure 1).

Conclusion: Our results reveal that JAK-i induced hyperlipidaemia did not associate with an increase of a surrogate marker of CV risk, such as aortic stiffness. More data are needed to conclude whether JAK-i could have a (positive or negative) effect on the CV system.

A. Narvaez, A. J. De Agustin, V. Sharma, A. Calatasis, M. C. Genovese, M. Baker. 1Hospital Universitari Vall d’Hebron, Barcelona, Spain; 2Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; 3Hospital Moisés Broggi, Barcelona, Spain; 4Hospital Universitari Parc Salut Mar, Barcelona, Spain; 5Hospital Clinic de Barcelona, Barcelona, Spain; 6Hospital Universitari de Bellvitge, Barcelona, Spain; 7Clinica Diagonal, Barcelona, Spain; 8Vorso Corp., Redwood City, United States of America; 9Stanford University, Palo Alto, United States of America

Background: Despite the clinical benefit of current pharmacological treatments for rheumatoid arthritis (RA), there remains an unmet need for alternative treatment approaches. Vagus nerve stimulation (VNS) via an implanted device has been shown to attenuate RA disease severity in patients resistant to therapy, as evidenced by a reduction in the DAS28-CRP score following a month of daily stimulation.

Objectives: This pilot study investigated the safety and efficacy of a wearable (non-invasive) device that attaches to the outer ear to treat RA via electrical stimulation of the auricular branch of the vagus nerve.

Methods: Patients with active RA (≥4 tender/swollen joints based on a 28-joint count, Disease Activity Score-28 with C-reactive protein (DAS28-CRP) >3.8, active synovitis detected on ultrasound and MRI) and inadequate response to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), or csDMARD and biologic DMARDs (bDMARDs), were enrolled in this open-label study. Patients used the device for up to 30 minutes daily over the course of the 12-week study. The primary endpoint was the change in DAS28-CRP score at Week 12. Secondary endpoints included a safety analysis, proportion of patients achieving ACR20/50/70, the mean change in HAQ-DI and the proportion of patients achieving a HAQ-DI MCID of at least 0.22 over 12 weeks. Additionaly, sleep scores were assessed using a visual analogue scale (0-100) at baseline and 12 weeks.

Results: Thirty patients with active RA were enrolled, of which 27 patients completed the 12-week protocol. Three patients dropped out of the study: two patients decided to seek other treatment and one patient moved out of the country. Data for three additional patients was not included in this dataset as it was still being collected. Of the 24 patients with complete 12-week datasets, 88% were female, the average age was 54.9 years, mean disease duration was 7.3 years, and four patients had an inadequate response to one or two bDMARDs.

The mean change in DAS28-CRP from baseline to Week 12 was -1.43 (p<0.05; Figure 1) and ACR20/50/70 response rates were 58.3%, 37.5%, and 16.7%, respectively (Figure 2). HAQ-DI change from baseline was -0.50 (p<0.05) at 12 weeks, and 15 out of 24 patients achieved an overall HAQ-DI reduction of 0.22 (62.5%). VAS sleep scores were significantly improved over the 12-week study. Scores for trouble falling asleep, awakened by pain at night, and awakened by pain in morning decreased by 64%, 70%, and 60%, respectively (p<0.05, n = 23). Three study adverse events (AEs) were reported: two device related AEs due skin irritation at the earpiece insertion site and one AE due to mucous accumulation in the throat.

---

Figure 1. Calibrated hazard ratios (cHRs) of overall cancer risk with their respective confidence intervals (95% CI) from study database. Database estimates not reported where adequate covariate balance not attained. Meta-analysis results not reported where I2>0.4.

---

Figure 2. Average DAS28-CRP is shown for each study visit. Error bars indicate standard error of mean. Percentage of subjects meeting ACR20/50/70 at 12 weeks.
Background: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease potentially leading to disability, impaired functioning, and prematurity of death. Most treatment strategies include the early use of disease-modifying antirheumatic drugs (DMARDs) such as methotrexate (MTX) which is considered as an established ‘anchor’ therapy. Since it takes some weeks until MTX shows clinical efficacy, glucocorticoids (GC) are widely used for bridging.

Objectives: The aim of the study was to compare the efficacy and safety of two different dosages of prednisolone in early active RA (CORRA) is to compare the efficacy and safety of the standard GC bridging schedule vs. placebo in addition to MTX, following a treat-to-target regimen, in early RA.

Methods: CORRA is an investigator-initiated, randomised, multi-center, double-blind, placebo-controlled trial. Adult RA patients who were eligible for inclusion in the trial if they had a disease duration of less than 3 years and moderate or high disease activity were recruited in one hospital and 18 rheumatology practices in Germany. Patients were randomised (1:1:1) to receive 60 mg MTX and upadacitinib 15 mg+MTX showed the highest ACR response rates, followed by filgotinib 200 mg+MTX, filgotinib 100 mg+MTX, adalimumab 40 mg+MTX, and placebo+MTX. The upadacitinib, baricitinib 4 mg+MTX and baricitinib 4 mg+MTX groups showed significantly higher ACR50 and ACR70 response rates than adalimumab 40 mg+MTX. In terms of Herpes zoster infection, the ranking probability based on the SUCRA indicated that placebo+MTX were likely to be the safest treatments, followed by filgotinib 200 mg+MTX, filgotinib 100 mg+MTX, adalimumab 40 mg+MTX, tofacitinib 5 mg+MTX, adalimumab 15 mg+MTX, and tofacitinib 4 mg+MTX. Regarding safety analysis, no statistically significant differences were found between the respective intervention groups.

Conclusion: In RA patients with inadequate response to MTX, baricitinib 4 mg+MTX and upadacitinib 15 mg+MTX showed the highest ACR response rates, suggesting a difference in efficacy among the different JAK inhibitors.

SAT0137 RELATIVE EFFICACY AND SAFETY OF TOFACITINIB, BARICITINIB, UPADACITINIB, AND FILGOTINIB IN COMPARISON WITH ADALIMUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW

A. Sherbin1, S. Sharma1, J. Gwinnut2, K. Hyrich1, S. Verstappen1.
1. The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom

Background: The adverse events (AEs) associated with methotrexate (MTX) treatment for rheumatoid arthritis (RA) have been studied extensively, but precise estimates of the incidence and prevalence of AEs are lacking. There is also limited published data on the predictors of AEs.

Objectives: To summarise and pool incidence and prevalence rates of AEs in patients treated with MTX for RA, and to identify treatment, clinical and disease related predictors of AEs.
Methods: A systematic literature search was carried out using Embase, Medline, and CENTRAL databases to identify relevant studies published between 1/1/2005 and 12/2/2019. The eligibility criteria included RCTs, non-randomized trials, and observational studies of first-time users of MTX in adults (> 18 years old) with RA and reported incidence, prevalence or predictors of the most common MTX related AEs, including: any AE, serious AEs, discontinuation due to AEs, elevated liver enzymes, gastrointestinal (GI), mucocutaneous (MC), central nervous system (CNS), and pulmonary AEs. Pooled proportions of GI AEs and elevated liver enzymes of patients treated with MTX monotherapy were estimated using random effects meta-analysis.

Results: Of 3142 records screened, we included 46 articles (35 clinical trials and 11 cohort studies) with a total of 9646 patients, and a mean follow-up duration of 70±35 weeks (range: 13 - 104 weeks for RCTs, 40 - 156 weeks for observational cohorts). Six studies reported incidence rate (IR) of any AE (range: 196 - 595 per 100 person-years), and eight studies reported IR of serious AEs (range: 3.7 - 15.9 per 100 person-years). The percentage of patients with any AE, reported in 32 studies, varied between 37% and 100% in RCTs, and between 13% and 34% in observational studies. Discontinuation of MTX due to AEs ranged between 1% and 29% in RCTs, and between 8% and 38% in observational studies. The reported prevalence of MC events (4% - 54%), CNS events (12% - 59%) and pulmonary events (10% - 67%) varied between studies. The estimated pooled prevalence from studies with a MTX monotherapy arm was 14% (95% CI: 9%, 19%); N=7 studies) for liver enzymes elevation (Figure 1), and (10% - 67%) varied between studies.

No statistically significant predictors of "any AE" were identified. For discontinuation of MTX due to AEs, RF positivity was associated with lower risk of MTX discontinuation due to MTX (HR 0.37, 95%CI: 0.21, 0.64), while other studies found that baseline HAQ score (OR 1.87, 95%CI: 1.11, 3.15) and BMI (OR 1.21, 95%CI: 1.02, 1.44) were associated with increased risk of MTX discontinuation due to AEs.

ACPA positivity (OR 1.8, 95%CI: 1.1, 3.1), and high baseline alanine aminotransferase (ALT) (OR 3.1, 95%CI: 1.6, 6.2) were both independent predictors of two-fold elevation of ALT in one paper, and baseline creatinine (OR 1.03, 95%CI: 1.00, 1.07) and high baseline ALT (OR 1.03, 95%CI: 1.00, 1.06) were associated with increased risk of elevated ALT above the upper limit of normal in a different study.

Conclusion: These findings affirm the high prevalence of GI AEs and elevated liver enzymes among patients treated with MTX for RA. The identified predictors of MTX withdrawal and elevated ALTs may be useful for identifying future patients likely to experience these AEs early in the course of treatment. However, the results of the study should be interpreted with caution, and further work is needed to replicate the results in studies with larger sample sizes and to assess the prognostic value of established predictors.

SAT0138
DRUG-RELATED PANCYTOPENIA AND LEUKOPENIA IN RHEUMATOID ARTHRITIS: ARE ALL CSDMARDS EQUAL?

L. Carmona1, J. Weaver2, E. Burn3, B. Illingen3, D. Vizcaya4, R. Sawad5, T. Duarte-Salles6, P. Ryan7, D. Prieto-Alhambra8on behalf of European Health Data and Evidence Network (EHEDN) RA Research Group. 1InMusc, Madrid, Spain; 2Janssen Research and Development, Titusville, New Jersey, United States of America; 3University of Oxford, NDORMS, Oxford, United Kingdom; 4Harvard Medical School, Department of Neurology, Beth Israel Deaconess Medical Center, Boston, United States of America; 5Epidemiology, Bayer, Barcelona, Spain; 6AbbVie Inc, North Chicago, United States of America; 7Idiap Jordi Gol, Barcelona, Spain

Background: Cytopenia is a known side-effect of conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) in rheumatoid arthritis (RA). There is a lack of data on the comparative risk of cytopenia with different csDMARDs.

Objectives: To assess the comparative risk of leukenia and pancytopenia for the most frequently used first-line csDMARDs: methotrexate (MTX), hydroxychloroquine (HCQ), sulphasalazine (SSZ), and leflunomide (LEF).

Methods: The study used data from 7 databases from 4 countries: CCAE, MDCR, Optum, IQVIA Ambulatory EMR (US); IQVIA THIN IMRD EMR (UK); IQVIA Disease Analyzer EMR (Germany); and SIDIAP (Spain). Cohorts included adult patients with a diagnosis of RA from 2005 to 2019 with at least one-year prior follow-up, no prior inflammatory arthritis, initiation of first-line csDMARD, and no cytopenia in the preceding 30 days. Participants were followed from one day after treatment initiation to the earliest of event occurrence, treatment discontinuation/switching plus 14 days in the on-treatment analysis, five years in the intent-to-treat (ITT) analysis, or loss to follow-up. MTX was used as reference group. Cox models were fitted with propensity score stratification for observed confounding and negative control outcomes calibration for residual error. Estimates across database were pooled where I²<40% was seen.

Results: Overall 166,347 patients were included. Pooled rates of leukenia and pancytopenia for MTX were 10.9 and 3.2 per 1,000 person years, respectively. Figure 1 and 2 show the results for the different databases and pooled estimates where applicable. Database estimates are not reported where adequate covariate balance not attained, and meta-analysis not shown where I²>0.4. MTX showed slightly higher hazards of leukenia and of pancytopenia compared to LEF but no consistently differential risks compared to HCQ or SSZ.

Conclusion: Cytopenia is rare, and apparently more frequent with MTX and less with LEF. Since prior full blood counts were inconsistently obtained in fewer than

SAT0139

AGE-BASED (<65 VS ≥65 YEARS) INCIDENCE OF INFECTIONS AND SERIOUS INFECTIONS IN TOFACITINIB-, ADALIMUMAB- AND PLACEBO-TREATED PATIENTS WITH RHEUMATOID ARTHRITIS: A POST HOC ANALYSIS OF PHASE 2, PHASE 3 AND PHASE 3B/4 TOFACITINIB STUDIES

K. Winthrop1, D. Gold2, D. Henrohn 3, L. Wang 4, A. Shapiro 5, H. Shi 6, G. Citera, 7, Schulze-Koops 8, 9, Oregon Health & Science University, Portland, OR, United States of America; 2Pfizer Inc, Montreal, QC, Canada; 3Pfizer Inc, Sollentuna, Sweden; 4Pfizer Inc, Groton, CT, United States of America; 5Pfizer Inc, Peapack, NJ, United States of America; 6Pfizer Inc, Collegeville, PA, United States of America; 7Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina; 8Klinikum der Universität München, Munich, Germany

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). A recent ad hoc safety analysis (as of August 2019; may be subject to change) from an ongoing, open-label, randomised, post-authorisation safety study, Study A3921133 (NCT02092467), conducted in RA patients (pts) aged ≥50 years with ≥1 cardiovascular risk factor has shown that incidence rates (IRs) of serious infection events (SIEs) were higher with tofacitinib 10 mg BID vs tumour necrosis factor inhibitors (TNFi; adalimumab [ADA] and etanercept) and this difference was more pronounced in pts aged ≥65 years (Pfizer Inc; data on file).

Objectives: To assess the IRs of overall infection events and SIEs in pts from Phase (P)2, P3 and P3b/4 tofacitinib RA trials which had a TNFi (ADA) active control or comparator arm.

Methods: This is a post hoc analysis of Month 0–12 data pooled from P2 (A3921035; NCT00550446 [first 12-week randomised parallel treatment period only]), P3 (ORAL Standard; NCT00853385) and P3b/4 (ORAL Strategy; NCT02187055) studies. Pts randomised to receive tofacitinib 5 mg BID, tofacitinib 10 mg BID, ADA 40 mg subcutaneously every other week and placebo (PBO) were included and assessed overall and by age (<65 or ≥65 years). SIEs were defined as infections requiring hospitalisation or parenteral antimicrobial therapy, or meeting other criteria for a serious adverse event. IRs (pts/100 pt-years of exposure [PY]) and 95% confidence intervals (CIs) were calculated for all infection events and SIEs; only the first infection events that occurred up to 28 days after the last dose or to the data cut-off date were considered.

Results: Of 2180 pts included in the pooled studies (tofacitinib 5 mg BID: N=530 [554.3 PY]; tofacitinib 10 mg BID: N=306 [236.6 PY]; ADA: N=843 [554.3 PY]; PBO: N=167 [108.1 PY]), 1841 (84.4%) were aged <65 years and 339 (15.6%) were aged ≥65 years. In general, the IRs for all infection events and SIEs were higher with tofacitinib 5 mg BID, tofacitinib 10 mg BID and ADA in pts aged ≥65 years compared with pts aged <65 years. Overall and when stratified by age, IRs for all infection events were similar across the active treatment groups (Figure 1); IRs with PBO were lower vs the active treatment groups overall and in pts aged <65 years, and numerically lower vs the active treatment groups in pts aged ≥65 years. IRs for SIEs were comparable across active treatment groups in pts aged <65 years, while among pts aged ≥65 years, IRs were numerically higher for tofacitinib 10 mg BID vs ADA, and appeared to be similar for tofacitinib 5 mg BID and ADA (Figure 2).

Conclusion: In this analysis of data pooled from P2, P3 and P3b/4 tofacitinib RA studies which included a TNFI arm (ADA), the risk of SIEs or infections overall was similar for tofacitinib and ADA with the exception of a numerically higher rate of SIEs with tofacitinib 10 mg BID vs ADA in pts aged ≥65 years. In most countries, tofacitinib 10 mg BID is not an approved dose for the treatment of RA. This post hoc comparison is limited by variation in sample size and PY of exposure between treatment and age groups, and a small number of cases of SIEs in the ≥65-year age group resulting in wide 95% CIs; interpretation of results should be made with caution. The findings in the present analysis are consistent with increasing age being a known risk factor for infections.

SAFETY OF TOFACITINIB THERAPY IN HBsAg CARRIERS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY

L. Fang1, Z. Lin1, Z. Liao2, O. Jin1, Y. Pan1, J. Gu1. 1The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Targeted synthetic DMARDs (ts-DMARDs) are becoming more available and affordable in developing countries, where the prevalence of hepatitis B virus (HBV) infection is still an important public health issue. The safety of ts-DMARDs therapy in the reactivation of hepatitis B virus (HBV) infection need more concern. Rare data from a prospective study focus on the use of ts-DMARDs in patients with concurrent rheumatoid arthritis (RA) and HBV infection were available by now.

Objectives: To evaluate the influence of tofacitinib on reactivation of HBV infection in HBsAg carriers with RA.

Methods: In this 52 weeks observation, HBsAg carriers with active RA (DAS28>5.1) despite failed combined treatment with MTX and other non-biological DMARDs were enrolled. Patients must have normal liver function prior to study. All patients received therapy with tofacitinib (5mg twice daily) and concomitant MTX (10-15mg/w). Entecavir was prescribed preventively for patients who had a baseline HBV load >2000 copy/ml (group 1), and Lamivudin for patients with HBV load ≤ 2000 copy/ml (group 2). Liver enzymes (AST/ALT) and HBV viral load were monitored every 4 weeks. Increased viral load and abnormal liver function were managed according to expert opinion.

Results: Thirteen patients (10 female) were recruited. Nine patients had a baseline viral load >2000 copy/ml (group 1, with preventive Entecavir), and the other 4 patients had a viral load ≤ 2000 copy/ml (group 2, with preventive Lamivudin). Two patients from group 1 discontinued tofacitinib at week 12 due to ineffectiveness, and both continued taking Entecavir for another 3 months after the discontinuation of tofacitinib.

No reactivation of hepatitis B was observed in patients from group 1. One patients (female, 54 years old) from group 2 underwent a mild increase of both ALT and AST (67 and 56 IU/L, respectively) at week 16. An elevated viral load (4.966 copies/ml, baseline 1.436) and a HBV YMDD mutant was also found. The tofacitinib treatment continued. After prescription of Adefovir (combined with the pre-existing Lamivudin), both liver enzyme and viral load decreased to normal range in 8 weeks and remained normal throughout the study.

Conclusion: An aggressive Tofacitinib + MTX therapy may be a safe option for HBsAg carriers with cs-DMARDs refractory RA. More active and effective prophylaxis strategy may be recommended to reduce the risk of HBV reactivation during the treatment.

LONG-TERM EFFECTIVENESS OF TOFACITINIB IN CONVENTIONAL DMARDs NON-RESPONDERS WITH RHEUMATOID ARTHRITIS: RESULTS OF RUSSIAN NATIONAL REGISTER

1North-Western State Medical University named after I. I. Mechnikov, St. Petersburg, Russian Federation; 2Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 3Yaoroslavl State Medical University, Yaroslavl, Russian Federation; 4Moscow Clinical Scientific and Practical Centre named after Loginov AS, Moscow, Russian Federation; 5Russian Medical Academy of Post Graduate Education, Moscow, Russian Federation; 6Scientific and Research Institute of Health Care Organization, Moscow, Russian Federation; 7Municipal Clinical Hospital # 1 named after NI Pirogov, Moscow, Russian Federation; 8Amur Regional Hospital, Blagoveshchensk, Russian Federation; 9Kemerovo Regional Clinical Hospital, Kemerovo, Russian Federation; 10Siberian State Medical University, Tomsk, Russian Federation; 11Regional Clinical Hospital, V. Novgorod, Russian Federation; 12Republican Hospital No 1 of the Republic of Tuva, Kyzyl, Russian Federation; 13Kursk State Medical University, Kursk, Russian Federation; 14Clinical Rheumatological Hospital No 25, St. Petersburg, Russian Federation

Background: Tofacitinib is an oral Janus Kinase inhibitor for the treatment of rheumatoid arthritis (RA).

Objectives: To evaluate the three-year effectiveness of tofacitinib in RA conventional synthetic (cs) DMARDs non-responders.

Methods: Data from 374 patients from Russian national register OREL of patients with RA treated with tofacitinib not less than 3 years after failure of conventional DMARDs were included in the statistical analysis. Clinical and laboratory data from 4 consecutive visits with an interval of 12 months between the visits (± 28 days) were analyzed. Treatment with any biologics ever was an exclusion criteria. Demographical (age, sex) and disease-related characteristics of RA (symptoms duration, RF- and ACPA positivity, presence of joint erosions, DAS28, CDAL, number of tender and swollen joints (NfT, NsJ), erythrocytes sedimentation rate (ESR), C-reactive protein (CRP)) collected. Statistical analysis performed with statistical programs SPSS2017 and GraphPadPrizm. p-value < 0.05 considered as significant.

Results: Baseline characteristics of RA patients, involved in the analysis are presented in table 1.

Table 1. Baseline characteristics of the patients with RA (n=374).

A PHASE 1 STUDY IN HEALTHY VOLUNTEERS
EXPLORING THE SAFETY, PHARMACOKINETICS AND PHARMACODYNAMICS OF ATI-450: A NOVEL ORAL MK2 INHIBITOR

J. Schrøder1, J. Monahan1, W. Smith1, H. Hope1, D. Kelly1, D. Burt1, E. Huff1, A. Kaul1, A. Hildebrand1, B. Burnett1, N. Klug1, M. Bangs1, D. Gordon1. Aclaris Therapeutics, Inc, Wayne, United States of America

Background: ATI-450, an investigational small molecule inhibitor of the MAPK-activated protein kinase 2 (MK2)signaling pathway. This pathway drives the expression of multiple cytokines including TNFα, IL-1α and β, and IL-6.

Objectives: We evaluated the safety and tolerability of ATI-450 in healthy volunteers as well as pharmacokinetics (PK) and pharmacodynamics (PD). Here we present data from single and multiple ascending dose cohorts. The aim was to select a dose for evaluation in phase 2 in patients with rheumatoid arthritis.

Methods: Safety, PK and PD were assessed in a randomized, observer-blind, placebo-controlled, phase 1 study in male and female healthy subjects aged 18-55 (n=77).

• Part A: Single Ascending Dose (SAD) (n=32, 8 subjects per dose cohort - 2 placebo, 6 active). A single dose of 10mg, 30mg, 50mg and 100mg was tested.

• Part B: Multiple Ascending Dose (MAD) (n=30, 10 subjects per dose cohort - 2 placebo, 6 active). 10mg BID, 30mg BID and 50mg BID doses were tested over 7 days of administration.

Safety and tolerability of ATI-450 was evaluated based on adverse events, clinical laboratory, vital signs, 12-lead ECG, Holter monitoring, and physical examination.

Blood was drawn for PK analysis at 0.5, 1, 2, 4, 6, 8, 12 hours, 24, 36, and 48 hours post dose in the SAD cohort and on day 7 of the MAD cohort. PD of ATI-450 were explored by investigating the inhibition of a target biomarker, phospho-HSP27 (pHSP27) and proinflammatory cytokymes, TNFα, IL-1α and β, and IL-6.

Results: ATI-450 was generally well tolerated. No serious adverse events or severe adverse events were noted, though no adverse events led to discontinuation of the study medication. The most common adverse events (reported by 2 or more subjects who received ATI-450) observed during the trial were dizziness, headache, upper respiratory tract infection, constipation, nausea, and abdominal pain. All adverse events were mild. A trend of a decrease in absolute neutrophil count (ANC) was observed without correlated clinical sequelae.

At the 50mg BID dose, marked inhibition of TNFα (n=77).

Conclusion: Oral ATI-450 was generally well tolerated at all doses with no pro-portionality observed. The results suggest that once or twice daily oral dosing may be possible.

SAT0144

DOES POLYPHARMACY IN RHEUMATOID ARTHRITIS PATIENTS AFFECT THE TREAT TO TARGET STRATEGY?

J. F. Jaramillo Gallego1, J. Rosa1, M. Scolnik1, M. A. Tobar Jaramillo1, L. Fereyra1, E. Soriano1. 1Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Background: Polyphearmomy (PP) is an important risk factor for drug toxicity, delirium, falls, hospitalizations and death. Patients with rheumatoid arthritis (RA) often have comorbid conditions and have PP. Treat to target strategy (T2T) implies a drug escalation and rheumatologists may not apply it in patients with PP.

Objectives: Our objective was to analyze if PP affects T2T in a real-world scenario.

Methods: Observational, retrospective cohort study. Patients with a new RA diagnosis (ACR/EULAR 2010 criteria) after 2010, over 18 years old, belonging to a Health Management Organization (HMO) from a university tertiary hospital, with a minimum follow-up period of 2 years, were included. PP was defined as concurrent medication greater than or equal to 5 medications at the time of RA diagnosis, regardless of the medication used for RA, administered for a minimum period of 6 months.

T2T strategy was defined as accomplished if an escalation in treatment was done when the patient had moderate or high disease activity at medical visit (by DAS28 and/or CDAI), without a significant improvement with respect to the previous visit.

Prevalence of PP at RA diagnosis was calculated and RA patients were divided in those with PP at RA diagnosis time and those without. The first 2 years of disease were analyzed and compared between both groups: clinical and demographic characteristics, percentage of visits where T2T was applied, treatments received during that period. A multivariate logistic regression analysis was performed in order to identify factors associated with no T2T compliance.

Results: 147 patients with RA were included; 86% women, with an average age at diagnosis of 60 years (SD: 15.8). The prevalence of PP at RA diagnosis was 12% (17 patients). Table 1 shows the comparison between patients with and without PP.

Prevalence of PP was higher in women, with a longer disease duration, a greater use of corticosteroids at 2 years, higher percentage of hospitalizations and a higher mortality. In the multivariate logistic regression analysis, no compliance of the T2T strategy was only associated with the consumption of corticosteroids at 2 years (OR: 0.36, 0.15-0.85; p<0.019) and no association was found with PP at the beginning of the disease.

Conclusion: The prevalence of PP in our patients with a new RA diagnosis was 12% and was associated with more baseline erosions, a higher consumption of steroids, and a higher frequency of hospitalizations and mortality during the first 2 years of the disease. No relationship between PP and adherence to the T2T strategy was demonstrated. In the multivariate logistic regression analysis, no compliance with the T2T strategy was only associated to the consumption of corticosteroids at 2 years, may be reflecting a poorer disease control.

Disclosure of Interests: JOHN FREDY JARAMILLO GALLEG: None declared, Javier Rosa: None declared, Marina Scolnik: None declared, Mayra Alejandra Tobar Jaramillo: None declared, LEANDRO FERREYRA: None declared, Enrique Soriano Grant/research support from: AbbVie, Eli Lilly, GlaxoSmithKline, Novartis, Pfizer Inc, Sandoz; Consultant of: AbbVie, Eli Lilly, GlaxoSmithKline, Novartis, Pfizer Inc, Sandoz; Speakers bureau: AbbVie, Amgen, Biogen-Mysub, Eli Lilly, Novartis, Pfizer Inc, Roche

DOI: 10.1136/annrheumdis-2020-eular.5087
Background: Early treatment of RA within the therapeutic window (0-3 months from symptom onset), has been associated with improved clinical outcomes and physical function. However, ≤42% of RA patients (pts) visit a rheumatologist within 90 days of symptom onset.1,2

Objectives: To assess safety and efficacy of Upadacitinib (UPA), an oral, reversible, potent JAK1-1 selective inhibitor3, in pts with moderate to severely active RA who were MTX-naïve or had an inadequate response to csDMARDs/bDMARDs4,5.

Methods: In SELECT–EARLY, MTX-naïve pts with active RA and poor prognosis were randomized 1:1:1 to once-daily UPA monotherapy at 15 or 30 mg or weekly MTX (titrated up to 20 mg/week through Week 8). Efficacy (including ACR, DAS28(CRP), CDAI responses and change in mTSS) and safety outcomes from a post-hoc analysis of patients who received treatment within 90 days from diagnosis are reported here. The statistical significance defined as p<0.05 was exploratory in nature.

Results: A total of 270 pts commenced treatment within 90 days from RA diagnosis (median: 44 days [11, 89]). Pts in each arm were mostly female (70%), had moderate to severely active RA with mean DAS28(CRP) =5.9±1.02, had structural joint damage (mean mTSS =7.7±21.5) and were seropositive for both ACPA and RF at baseline (72%). At Week 24, compared to MTX, significantly greater proportions of pts receiving UPA 15 or 30 mg monotherapy achieved efficacy outcomes including ACR20, 50 and 70 responses, DAS28(CRP)<2.6, CDAI<2.8 or Boolean remission. Improvements in physical function (HAQ-DI) and decrease in pain were also significantly greater in pts receiving UPA 15 and 30 mg vs MTX at Week 24. Treatment with UPA was also associated with a greater inhibition of structural joint damage compared with MTX (Figure 1). Safety outcomes were consistent with the full study and the integrated safety analysis (all phase 3 studies of UPA). Compared to MTX, higher frequencies of serious infections and herpes zoster were reported in both UPA groups. There were 2 deaths in total (UPA 30 mg: 1 due to cardiovascular death and 1 due to pneumonia and sepsis) (Figure 2).

Conclusion: In RA pts, early initiation of treatment with UPA 15 mg and 30 mg monotherapy within 3 months from diagnosis was associated with clinically meaningful improvements in efficacy, including remission and inhibition of progression of structural joint damage compared to MTX. The safety profile was consistent with the overall study and the integrated phase 3 safety analysis. UPA seems to be a promising treatment option for more patients to reach their treatment targets of remission or low disease activity when treated within 3 months of diagnosis.

SAT0146 INHIBITION OF RADIOGRAPHIC PROGRESSION BY IGURATINOD IN 116 JAPANESE RHEUMATOID ARTHRITIS PATIENTS DESPITE CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS THERAPY

K. Katayama1, T. Okubo1, K. Yujiro2, R. Fukai3, T. Sato1, M. Yuichi4, S. Abe4, H. Ito3.

1Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan; 2Sapporo Rheumatology and Immunology Clinic, Sapporo, Japan; 3Fukai Pharmacy, Asahikawa, Japan; 4Asahikawa Medical University, Asahikawa, Japan

Background: Japanese double-blind clinical practice studies of Iguratimod (IGU) for active rheumatoid arthritis (RA) patients indicated an early and sustained efficacy as a new conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) [1] as well as the safety of the treatment[2]. IGU also inhibit activation of NFkB and production of RANKL, indicating strong inhibiting activity against bone destruction. However, studies focused on the inhibitory effects of joint destruction by IGU has been poorly documented in clinical practice (3).

Objectives: To evaluate inhibitory effect during 1 year by additional IGU therapy in 116 RA patients despite csDMARDs therapy.

Methods: Inhibitory effects of joint damage were evaluated by modified total Sharp scoring (mTSS) at baseline and 1 year after IGU prescription. RA activity was measured by DAS28-ESR.

Results: The subjects were 116 cases, 30 male, age 63.2 yrs, disease duration 93.7 months. MTX was used weekly (84 cases, 72.4%), and cs DMARDs were used as BUC 43 cases, SASP 13 cases, TAC 5 cases, and LEF 1 cases. bDMARDs were used even in 8 cases, and steroids were used in 3.9mg (70 cases, 60.3 %). Complications were observed in 70 cases (60.3%). DAS28-ESR were significantly improved from 4.29 (baseline) to 3.65 (6 months), 3.68 (12 months), respectively (P<0.0001). As shown in Figure 1, joint destruction measured by mTSS decreased significantly. As shown Figure 2, the safety profile was consistent with the overall study and had no major complications. (P<0.05). IGU cotreatment was well tolerated. IGU cotreatment was well tolerated.

Disclosure of Interests: Disclosures.
To investigate prognostic factor for CRRP, clinical data in baseline, 6, 12 months between ten patients with CRRP and 82 patients with structural remission were compared. As shown in Table 1, longer disease duration, more SJC were compared. As shown in Table 1, longer disease duration, more SJC were compared. Background: Sustained remission is the goal of rheumatoid arthritis (RA) care, and more patients reach and maintain this state on conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) with treat-to-target strategies. The knowledge about whether csDMARDs can be tapered in RA patients in sustained clinical remission is limited.

Objectives: The primary objective of the study was to assess the effect of tapering of csDMARDs on the risk of flares in RA patients in sustained clinical remission.

Methods: In the open, phase 4, non-inferiority ARCTIC REWIND trial, RA patients in clinical remission for ≥12 months on stable csDMARD therapy were randomised to continued stable csDMARD or half dose csDMARD. Patients had to be in DAS remission at inclusion with no swollen joints (of 44). The primary endpoint was the proportion of patients with a disease flare during 12 months (defined as a combination of DAS ≥1.6, change in DAS ≥0.6 and ≥2 swollen joints, or the physician and patient agreed that a clinically significant flare had occurred). Patients attended 2 visits every 4 months, with extra visits in case of flares. The non-inferiority margin was 20%, with a predefined superiority test if non-inferiority was not shown. Mixed effect logistic regression was used to test the inferiority null-hypothesis in the per-protocol population. Radiographs at 0 and 12 months were scored by van der Heijde Sharp score (average score of two readers, progression: ≥1 unit change/year). Clinicaltrials.gov NCT01881308.

Results: We enrolled 160 patients, 155 received the allocated treatment strategy. Baseline characteristics were overall well balanced (Table). 78% of patients in the stable csDMARD arm and 84% in the half-dose csDMARD arm used methotrexate monotherapy. In the primary analysis, we observed flares in 6% of patients on stable csDMARD, compared to 25% in the half-dose csDMARD arm, giving a risk difference (95% CI) of 18.3% (7.2% to 29.3%, Fig 1). Non-inferiority could not be claimed, with the results showing superiority of the stable arm over the half-dose arm (Fig 1). Similar results were found in methotrexate monotherapy users. In the stable arm, 2/5 (40%) escalated DMARD medication following the flares, compared to 18/19 (95%) in the tapering arm. No progression of radiographic joint damage was observed in 79.5% of patients on stable DMARDs and 62.7% of those tapering, difference (95% CI) -17.7% (-33.0%, -2.3%, Fig 2E). At 12 months, 92% of patients in the stable arm and 84% in the half-dose arm were in DAS remission (Fig 2C). The frequency of adverse events was 75 in the stable arm and 53 in the tapered arm, with serious adverse events in 2 (2.6%) of patients in the stable and 4 (8.5%) in the tapered arm, including two serious infections in the tapered arm. In methotrexate monotherapy users. In the primary analysis, we observed flares in 6% of patients on stable csDMARD, compared to 25% in the half-dose csDMARD arm, giving a risk difference (95% CI) of 18.3% (7.2% to 29.3%, Fig 1). Non-inferiority could not be claimed, with the results showing superiority of the stable arm over the half-dose arm (Fig 1). Similar results were found in methotrexate monotherapy users. In the stable arm, 2/5 (40%) escalated DMARD medication following the flares, compared to 18/19 (95%) in the tapering arm. No progression of radiographic joint damage was observed in 79.5% of patients on stable DMARDs and 62.7% of those tapering, difference (95% CI) -17.7% (-33.0%, -2.3%, Fig 2E). At 12 months, 92% of patients in the stable arm and 84% in the half-dose arm were in DAS remission (Fig 2C). The frequency of adverse events was 75 in the stable arm and 53 in the tapered arm, with serious adverse events in 2 (2.6%) of patients in the stable and 4 (8.5%) in the tapered arm, including two serious infections in the tapered arm.

Conclusion: In RA patients in sustained remission on csDMARDs, continued csDMARD therapy with stable dosage led to significantly fewer disease activity flares and less frequent radiographic joint damage progression than tapered csDMARD treatment.

Figure 2: Secondary endpoints

Figure 1: Non-inferiority plot of stable vs half-dose csDMARD treatment in per protocol set, full analysis set and in patients treated by methotrexate monotherapy. The broken horizontal lines represent the non-inferiority margin.
Background: Filgotinib is an orally administered small molecule that provides selective inhibition of JAK1, a signaling molecule that helps drive inflammatory pathways underlying rheumatoid arthritis (RA). Objectives: Exposure-response (ER) analyses were performed for efficacy following completion of Phase 2 studies over a wide range of doses to support evaluation of 200mg and 100mg once daily in Phase 3 studies. ER analyses were subsequently performed by using Phase 3 efficacy data to support selection of the proposed registrational dose. ER analyses for safety based on pooled Phase 2 and Phase 3 studies were conducted to examine the safety of evaluated doses. Method: Population PK analyses were conducted to estimate plasma exposures of filgotinib and GS-829845 (major circulating active metabolite of filgotinib) in both Phase 2 (DARWIN 1 and DARWIN 2) and Phase 3 studies (FINCH 1, FINCH 2, and FINCH 3) encompassing a dose range of 25 to 100mg twice daily and 50 to 200mg once daily. As both filgotinib and GS-829845 contribute to efficacy via JAK1 inhibition, their exposures were combined into single parameters, AUCC0-24 and Cmax (effective area under the curve and effective concentration at trough, by accounting for relative inhibition potency and molecular weight) in the ER analyses for various efficacy endpoints (e.g. ACR20/50/70 responses) at Week 12 and Week 24. The ER analyses for safety endpoints (the 5 most frequent treatment-emergent adverse events [TEAEs] and Grade 3 or 4 laboratory abnormalities, serious TEAEs, and serious infections) were performed separately for filgotinib and GS-829845 exposures to characterize the individual safety profile of each analyte. The 5 evaluated TEAEs were nausea, nasopharyngitis, upper respiratory tract infection, headache, and hypertension; the 5 Grade 3/4 laboratory abnormalities included lymphocytes decrease, glucose increase, phosphate decrease, triglyceride lipase increase, and creatine kinase increase.

Results: In the ER analyses for efficacy based on Phase 2 studies, high response rates were demonstrated in ACR20/50/70 across all octile groups in subjects with RA receiving filgotinib and the ER supported further evaluation of both 200mg and 100mg once daily doses in Phase 3 clinical studies. Similarly, ER relationships based on pooled Phase 3 studies across various endpoints (e.g. ACR20/50/70) consistently revealed high response rates across the exposure range for both the filgotinib 200mg and 100mg doses. A trend of increasing response with increasing exposure was observed across the exposure range for multiple secondary efficacy endpoints including ACR50 and ACR70 with the GS-829845 exposures (AUC0-24 and Cmax) and the most frequent TEAEs, Grade 3/4 laboratory abnormalities, serious TEAEs, or serious infections up to Week 52.

Conclusion: ER analyses demonstrate that both the 200mg and 100mg once daily filgotinib doses are efficacious in subjects with moderately to severely active RA without clear dose-dependent effects on safety. The trend towards greater efficacy with higher exposures for some secondary endpoints (ACR50 and ACR70) and a lack of exposure-safety relationship supports a dose of 200mg and 100mg once daily over 100mg once daily since it presents the best benefit/risk ratio among the doses tested.

Trends of increasing response, with increasing exposure, was observed across the exposure range for multiple secondary efficacy endpoints (ACR50 and ACR70) and the most frequent TEAEs, Grade 3/4 laboratory abnormalities, serious TEAEs, or serious infections up to Week 52. 

Conclusion: ER analyses demonstrate that both the 200mg and 100mg once daily filgotinib doses are efficacious in subjects with moderately to severely active RA without clear dose-dependent effects on safety. The trend towards greater efficacy with higher exposures for some secondary endpoints (ACR50 and ACR70) and a lack of exposure-safety relationship supports a dose of 200mg and 100mg once daily over 100mg once daily since it presents the best benefit/risk ratio among the doses tested.

SAT0151

EFFICACY AND SAFETY OF UPADACITINIB VERSUS ABATACEPT IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND PRIOR INADEQUATE RESPONSE OR INE-TOLEANCE TO BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (SELECT-CHOICE): A DOUBLE-BLIND, RANDOMIZED CONTROLLED PHASE 3 TRIAL

Background: Upadacitinib (UPA) is an oral, reversible, selective JAK 1 inhibitor approved for the treatment of moderate to severe rheumatoid arthritis (RA). The efficacy/safety of UPA has been demonstrated in phase 3 studies, including superiority to adalimumab in patients (pts) with prior inadequate response (IR) to methotrexate.1-4

Objectives: To assess the efficacy/safety of UPA vs abatacept (ABA) in pts with prior IR or intolerance to biologic DMARDs (bDMARDs).

Methods: Pts were randomized to once daily UPA 15 mg or intravenous ABA (at Day 1, Weeks [Wks] 2, 4, 8, 12, 16 and 20; 60-100 mg; >100 kg: 1,000 mg), with all pts continuing background stable csDMARDs. The study was double-blind for 24 wks. Starting at Wk 12, pts who did not achieve ≥20% improvement from baseline (BL) in both tender and swollen joint counts at two consecutive visits, had background medication(s) adjusted or initiated. The primary endpoint was change from BL in DAS28(CRP) at Wk 12 (non-inferiority). The non-inferiority of UPA vs ABA was tested using the 95% CI of treatment difference against a non-inferiority margin of 0.6. The two key secondary endpoints at Wk 12 were change from BL in DAS28(CRP) and the proportion of pts achieving clinical remission (CR) based on DAS28(CRP), defined as DAS28(CRP) <2.6. Both endpoints were to demonstrate the superiority of UPA vs ABA. Treatment-emergent adverse events (TEAEs) are reported up to Wk 24 for all pts who received at least one dose of study drug.

Results: Of 612 pts treated; 67% of pts had received 1 prior bDMARD, 22% received 2 bDMARDs, and 10% received ≥3 prior bDMARDs. 549 (90%) completed 24 wks of treatment. Common reasons for study drug discontinuation were AEs (UPA, 3.6%; ABA, 2.6%) and withdrawal of consent (UPA, 1.7%; ABA, 2.6%). Non-inferiority and superiority were met for UPA vs ABA at Wk 12 for change from BL in DAS28(CRP) (-2.52 vs -2.00; -0.52 [-0.69, -0.35]; p <0.001 for UPA vs ABA).

UPA also demonstrated superiority to ABA in achieving DAS28(CRP) <2.6 (30.0% vs 13.3%; p =0.001 for UPA vs ABA; Figure 1). Improvements in disease activity and remission rates were maintained through Wk 24. The proportions of pts achieving low disease activity (defined as DAS28(CRP) ≤3.2), ACR20, ACR50, and ACR70 responses were greater with UPA compared with ABA at Wk 12 (nominal p <0.05). More stringent outcome measures – CR, ACR50, and ACR70 responses - remained higher with UPA than ABA through Wk 24 (nominal p <0.05).

Incidence of serious TEAEs, AEs leading to discontinuation, hepatic disorders, and CPK elevations were numerically higher with UPA versus ABA (Figure 2). Eight cases of herpes zoster were reported (4 in each treatment arm). No malignancies were reported. One case of adjudicated MACE, two adjudicated cases of VTE (1 pt with DVT and 1 pt with PE; both pts had at least one risk factor for VTE), and one treatment-emergent death were reported with UPA.

Conclusion: In RA pts with a prior IR or intolerance to bDMARDs, UPA demonstrated superior improvement in signs and symptoms vs ABA based on change in DAS28(CRP) and in achieving CR at Wk 12. The safety profile of UPA was consistent with the phase 3 RA studies with no new risks identified.

EFFICACY OF BARICITINIB IN PATIENTS IN MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS WITH 3 YEARS OF TREATMENT: RESULTS FROM A LONG-TERM STUDY

J. S. Smolen1, L. Xie2, B. Jia3, P. C. Taylor4, G. R. Burmester5, Y. Tanaka6, A. Elias5, A. Cardoso2, R. Ortmann5, C. Walls5, M. Dougados5, 1Medical University of Vienna, Division of Rheumatology, Vienna, Austria; 2Eli Lilly and Company, Indianapolis, United States of America; 3University of Oxford, Oxford, United Kingdom; 4Charité - University Medicine Berlin, Berlin, Germany; 5University of Occupational and Environmental Health, Japan, Kitakyushu, Japan; 6Hospital Cochin Paris, Paris, France.

Background: Baricitinib (Bari) is an oral, selective and reversible Janus kinase 1 and 2 inhibitor approved for the treatment of adults with active RA. In addition to long-term safety which has been disclosed previously with data up to 7 years, [1], an important clinical consideration is whether treatment efficacy can be maintained over the long term.

Objectives: To evaluate the long-term efficacy of once-daily Bari 4 mg in patients with active rheumatoid arthritis (RA) who were either naïve or to who had inadequate response (IR) to methotrexate (MTX).

Methods: Post hoc analyses of data from two phase 3 studies, RA-BEGIN (MTX-naïve) and RA-BEAM (MTX-IR) for 52 weeks, and one long-term extension (LTE) study (RA-BEYOND) for an additional 96 weeks were conducted (148 weeks in total). At week 52, MTX-naïve patients initially treated with MTX monotherapy, Bari 4 mg monotherapy, or Bari 4 mg +MTX in RA-BEGIN were switched to open-label Bari 4 mg monotherapy for treatment in the LTE. Similarly, at week 52, MTX-IR patients initially treated with Bari 4 mg + (background MTX noted as (+MTX) for RA-BEAM) or adalimumab (ADA) (+MTX) in RA-BEAM were switched to open-label Bari 4 mg (+MTX) for treatment in the LTE. Patients who received placebo (+MTX) were switched to open-label Bari 4 mg (+MTX) at week 24. The analyses of efficacy (SDAI) and physical function (HAQ-DI) were conducted on all patients who were randomized into the RA-BEGIN and RA-BEAM studies and had received ≥1 dose of study drug after randomization (mITT population). The proportion of patients who reached low disease activity (LDA), as measured by SDAI ≤11, was evaluated along with change from baseline in HAQ-DI. The non-responder imputation (NRI) method was used for the categorical analysis.

Results: By week 24 in RA-BEGIN (N=584), 62% of patients treated with Bari 4 mg monotherapy or Bari 4 mg +MTX achieved SDAI LDA in comparison to 40% of pts in the MTX monotherapy group; response rates seen at week 24 in the Bari treatment groups were maintained through week 148 (Fig 1A). Similarly, by week 24 in RA-BEAM (N=1,305), 52% of patients treated with Bari 4 mg (+MTX) and 50% of patients treated with ADA (+MTX) achieved a SDAI LDA in comparison to 26% of patients from the PBO (+MTX) group. The response rate seen at week 24 with Bari 4 mg and ADA were maintained through week 148, even after patients switched from ADA to Bari 4 mg at week 52 (Fig 1B). Similar improvement and maintenance patterns in physical function measured by HAQ-DI were demonstrated. The overall discontinuation rate across treatment groups from RA-BEGIN (19.5%) and RA-BEAM (14.2%) have been published. In the LTE, the discontinuation rate from Bari treatment was 13.7% for patients originating from RA-BEGIN (1.1% due to lack of efficacy, 6.4% due to safety) and 12.6% for patients originating from RA-BEAM (1.8% due to lack of efficacy, 5.9% due to safety).

Conclusion: Long-term treatment with Bari 4 mg demonstrated the maintenance of clinically-relevant outcomes for up to 3 years. Low discontinuation rates during the LTE indicated that Bari 4 mg treatment was well-tolerated.

Figure 1. Proportion of patients achieving SDAI ≤11 in the NRI analysis in RA-BEGIN, rescue to Bari 4 mg + MTX was offered at week 24. In RA-BEAM, rescue to Bari 4 mg (+ MTX) was offered at week 16. At week 24, all PBO + MTX patients were switched to Bari 4 mg + MTX upon entering RA-BEYOND at week 52, MTX and ADA patients were switched to Bari 4 mg.

GENDER DOES NOT INFLUENCE CLINICAL RESPONSE TO JAK INHIBITORS IN RHEUMATOID ARTHRITIS: AN ITALIAN MULTICENTRE ANALYSIS

F. R. Spinelli1, M. S. Chimienti2, M. Vadacca3, C. Iannuccelli4, P. Coniglio5, S. L. Bosello6, F. Ceccarelli7, C. Garufi7, G. Raffone8, P. Di Noi9, D. Bruno10, A. Aletra1, R. Perricone2, F. Conti1, E. Gremese11 on behalf of FRS, MSC, PC, MV, CI, SLB and EG on behalf of RedO - Reumatologo Donne - association of Italian female rheumatologists, 1Sapienza Universita di Roma, Rheumatology Unit, 00161, Italy; 2University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy; 3Università Cattolica del Sacro Cuore, Rheumatology Division, Rome, Italy; 4Sapienza Universita di Roma, Rheumatology, Allergology and Clinical Immunology, Rome, Italy; 5Fondazione Policlinico Universitario A. Gemelli IRCCS, Rheumatology Division, Rome, Italy; 6Università Cattolica del Sacro Cuore, Rheumatology Division, Rome, Italy; 7Sapienza Universita di Roma, Rheumatology Unit, Rome, Italy.

Background: Gender medicine aims at describing how diseases differ between men and women in terms of epidemiology, clinical feature, therapeutic approach, treatment response and prognosis, psychological and social impact. Rheumatoid Arthritis (RA) affects women 2-3 times more than men. Female gender seems to be independently associated to a more refractory disease and a worse response to conventional synthetic Disease Modifying Anti-Rheumatic Drugs (csDMARDs) and biological DMARDs. Male patients achieve remission more often than females probably due to the higher number of tender joints reported by the latter.

Objectives: In the light of the effect of Janus kinases inhibitors (JAKI) on pain, the objective of the study was to investigate whether gender might affect the achievement of remission or low disease activity in RA patients treated with baricitinib and tofacitinib.

Methods: We performed a multicentric, prospective study on consecutive patients starting one of the two available JAKI: baricitinib and tofacitinib. Demographic and clinical data were recorded in a dedicate database and included: gender, age, disease duration, serological status (Rheumatoid Factor – RF; anti-citrullinated peptide antibodies, ACPA) number of previous csDMARDs and bDMARDs, number of tender joints (TJ) and swollen joints (SJ), C reactive protein (CRP), patient global assessment (PGA) and pain were recorded on a 0-100 mm visual-analogue scale (VAS). Disease activity score (DAS) 28 was calculated at baseline and at two follow-up visits (after 3-4 months and after 6-8 months). Data were expressed as mean±standard deviation or median (interquartile range) according to variables' distribution. Continuous variables were compared by Mann Whitney test while dichotomous ones by Chi-squared test; p value < 0.05 were considered statistically significant.

Results: We enrolled 182 RA patients (149 F:33M) with similar age (F 58±12 vs M 60±10) and disease duration (F 143±101 vs M 147±105 months). Females and males were previously treated with the same number of csDMARDs [2(2)] but female have previously received numerically more bDMARDs [2(3) vs 1(2)]. At the 3 timepoints females and males showed similar number of TJ, SJ, similar values of CRP, PGA and pain. We did not observe any difference in percentage

References:
of males and females achieving remission or low disease activity according to gender (figure 1A) nor in terms of reduction of TJ, SJ and PGA; only pain decreased significantly more in male than in female patients at both timepoints (figure 1B).

Conclusion: In RA patients treated with JAK inhibitors, even if the effect of JAK on pain seems to be more relevant in male than in female, gender seems not to influence the overall clinical response, allowing men and women the same probability of reaching the therapeutic target.

SAT0154
EXAMINATION OF CYP3A5 GENOTYPE IS USEFUL FOR INTRODUCTION OF TACROLISMUS TREATMENT IN OUTPATIENTS WITH RHEUMATIC DISEASES

S. Takahashi1, S. Horibata2, S. Hatachi3, M. Takahashi2, M. Katayama1, S. Mukohara1, N. Amano1, K. Yoshida1, K. Yorifuji1,2, S. Kumagai1,2,3
1Center for Rheumatic Disease, Shinko Hospital, Kobe, Japan; 2Shinko Institute for Medical Research, Kobe, Japan; 3Department of Pharmacy, Shinko Hospital, Kobe, Japan

Background: Though several studies showed the efficacy of tacrolimus (TAC) in patients with rheumatoid arthritis (RA) in a dose-depending manner [1], the relationship between efficacy and concentration of TAC remained unclear. Genetic polymorphisms of cytochrome P450 (CYP) 3A5 were reported not only to play an important role in pharmacokinetics of TAC but also to have an influence on clinical outcomes in patients of rheumatic diseases. Several reports showed that the blood concentration of TAC in patients with a CYP3A5 *1 allele (EX, expressor) was lower than that of patients with a CYP3A5 *3/*3 (NEX, non-expressor) [2].

Objectives: To assess the relationship between efficacy and concentration of TAC in patients with RA, and to examine the usefulness of CYP3A5 genotype screening to detect outliers suitable for TAC treatment.

Methods: We examined the relationship between disease activity score (DAS28-CRP) and concentration of TAC in patients with RA. TAC was taken after the evening meal and blood samples were taken 12±4h after TAC administration. Next we investigated the relationship between genotype frequencies of CYP3A5 and concentration of TAC in patients with rheumatic disease without having renal dysfunction (eGFR>60) and also investigated the influence of concomitant drugs, such as strong inhibitors of CYP3A4/5 or metabolized by CYP3A4/5 having renal dysfunction (eGFR<60) and also investigated the influence of concomitant drugs, such as strong inhibitors of CYP3A4/5 or metabolized by CYP3A4/5

Results: The concentration of TAC tended to be negatively correlated with the disease activity of RA. The C/D value in the NEX group (n=16) was 124.4±62.1, which was significantly higher than that in the EX group (n=23; 67.7±29.8; P=0.001). When comparing patients using concomitant drugs which are strong inhibitors of CYPA4/5 or metabolized by CYPA4/5 with patients not using those drugs, the each C/D value of NEX group was 122.9±52.3 (n=9) and 126.9±77.3 (n=7), and that of EX group was 71.3±32.2 (n=12) and 63.8±28.0 (n=11). There were no significant differences between these groups. In NEX group, when comparing concentration of TAC at first visit and second visit after starting TAC administration, the each concentration of TAC was 3.14±2.06 ng/ml and 3.80±2.20 ng/ml in NEX group (n=10), and that of TAC was 1.82±0.82 ng/ml and 2.69±1.52 ng/ml (n=11) in EX group (figure).

Conclusion: TAC showed efficacy in patients with RA in a concentration-dependent manner. EX patients may be impossible to achieve enough concentration of TAC even though using TAC of 3mg/day, approved dose for patients with RA in Japan, and NEX patients could make rapid attainment of enough concentrations of TAC in early stage of treatment, suggesting that we should consider induction of TAC only in NEX outpatients. Furthermore, drugs only slightly affected concentration of TAC in this study, suggesting that we can use TAC without any special attention to concomitant drugs.

SAT0155
WHOLE BLOOD TRANSCRIPTIONAL CHANGES FOLLOWING SELECTIVE INHIBITION OF JANUS KINASE 1 (JAK1) BY FILGOTINIB IN MTX-NAIVE ADULTS WITH MILDLY-TO-SEVERELY ACTIVE RHEUMATOID ARTHRITIS (RA) (FINCH3)

P.C. Taylor1, B. Downie2, E. Elboudwarej2, S. Kim2, A. Herz2, A. M. Mirza2, J. siegel2, R. E. Hawtin2, J. Liu2, 1University of Oxford, Botnar Research Centre, Nuffield Dept Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 2Gilead Sciences Inc., Foster City, United States of America

Background: Filgotinib (FIL), an oral selective JAK1 inhibitor, has shown efficacy and safety in multiple phase 3 studies in adults with moderately-to-severely active rheumatoid arthritis (RA). We have previously described the molecular response to FIL in large-scale RNA sequencing studies of gene expression in other RA populations1-3 and conducted a similar study in methotrexate (MTX) naïve RA patients (pts) (FINCH3).

Methods: MTX naïve RA pts who were enrolled in FINCH3 (ClinicalTrials.gov NCT02886728) received a stable dose of MTX with placebo (PBO+MTX), FIL 200mg alone (FIL 200mg monotherapy), or one of two doses of FIL once daily (QD) together with MTX (FIL 100mg+MTX, FIL 200mg+MTX). Whole blood samples were collected from pts using PAXgene tubes at baseline, week 4,
week 12, and week 24. RNA from these samples was extracted and sequenced on the Illumina HiSeq 2500 platform following globin RNA depletion. Correlations between baseline gene expression and disease measurements were performed using Spearman’s rank partial correlation to account for covariates. Differentially expressed genes (DEGs) were identified using voom-limma. Biological pathway analyses were performed on v6.1 of the Molecular Signature Database using single sample gene set enrichment analysis (GSEA) with the focus on immune signaling pathways from the Kyoto Encyclopedia of Genes and Genomes (KEGG). A false-discovery rate of 5% was applied for all analyses.

Results: Differential gene expression analyses comparing baseline samples with after-treatment samples revealed rapid onset of transcriptional changes in FIL-treated pts, most notably for the two FIL 200mg arms. Fewer DEGs were observed at all timepoints in PBO+MTX treated patients with a peak number at week 24, an observation consistent with the clinical response kinetics of MTX. Up to 3x as many significant DEGs were observed in the FIL 200mg+MTX arm compared to the FIL 100mg+MTX arm, a finding consistent with the superior clinical efficacy of the FIL 200mg dosage. As with other FIL clinical trial RNA-seq studies and consistent with the selective MoA of FIL, JAK-STAT pathway-induced genes SOCS2 and CISH were significant with the superior clinical efficacy of the FIL 200mg. As with other FIL clinical trial RNA-seq studies and consistent with the selective MoA of FIL, JAK-STAT pathway-induced genes SOCS2 and CISH were significantly downregulated across FIL treatment arms and timepoints, but not for PBO+MTX. RA disease activity-associated genes FAM20A and METTL7B were significantly reduced at all timepoints in FIL-treated pts, but only at week 24 in PBO+MTX pts. While no significant changes in KEGG immune signaling pathways were observed in the PBO+MTX arm, a dose-dependent effect on pathway modulation was observed in the FIL arms, including reductions in JAK-STAT, toll-like receptor, chemokine, and RIG-I like receptor signaling.

Conclusion: More rapid and sustained changes of transcriptional activity in the whole blood transcriptional profile of RA pts after FIL treatment were found compared to PBO+MTX. Dose-dependent changes were observed in FIL-treated pts, most notably in the KEGG JAK-STAT signaling pathway. These observations confirm an inhibition of JAK-STAT signaling by FIL and are consistent with the observed clinical efficacy of FIL in these pts.

Conclusion: The data showed that bari has a favorable effect on the radiographic progression of structural joint damage regardless of its dose in a real-world clinical setting. In consideration of the risk/benefit balance, we suggest that the dose of bari could be reduced in patients with favorable disease activity.
SAT0157
NINTEDANIB DOSE ADJUSTMENTS AND ADVERSE EVENTS IN PATIENTS WITH PROGRESSIVE AUTOIMMUNE DISEASE-RELATED INTERSTITIAL LUNG DISEASES IN THE INBUILD TRIAL

Background: In the INBUILD trial in patients with progressive fibrosing ILDs, the adverse event (AE) profile of nintedanib was characterised predominantly by gastrointestinal AEs. Dose adjustments were used to manage AEs.

Objectives: Assess AEs and dose adjustments in patients with autoimmune disease-related ILDs in the INBUILD trial.

Methods: Patients with progressive fibrosing ILDs other than idiopathic pulmonary fibrosis were randomised to nintedanib 150 mg bid or placebo. Dose reductions to 100 mg bid and treatment interruptions were permitted to manage AEs. AEs over 52 weeks of treatment (or 28 days after last trial drug intake for patients who discontinued drug before week 52) were assessed in patients who received ≥1 dose of trial drug.

Results: Of 663 patients in the INBUILD trial, 170 (82 nintedanib, 88 placebo) had Mount Sinai Hospitals, University of Toronto, Toronto, Canada; 1 Mayo Clinic College of Medicine and Science, Rochester, Minnesota, United States of America; 2 University of Erlangen-Nuremberg, Erlangen, Germany; 3 Scleroderma Research Consultants LLC, Aiken, South Carolina, United States of America; 4 Ruhrlandklinik, University Hospital, University of Duisburg-Essen, Essen, Germany; 5 Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany; 6 SCS Boehringer Ingelheim Comm. v. SAT0158
EFFICACY AND SAFETY OF FILGOTINIB IN METHOTREXATE-NAIVE PATIENTS WITH RHEUMATOID ARTHRITIS: FINCH 3 52-WEEK RESULTS

Background: Filgotinib (FIL) is a potent, selective JAK 1 inhibitor. FINCH 3 assessed FIL efficacy and safety in methotrexate (MTX)-naive patients (pts) with rheumatoid arthritis (RA): week (W)24 primary outcome results were previously presented.

Objectives: To report FINCH 3 (NCT02886728) results through W52. Methods: This global, phase 3, double-blind, active-controlled study randomised MTX-naive pts with moderately to severely active RA 2:1:1:2 to oral FIL 200 mg + MTX, FIL 100 mg + MTX (n = 207) FIL 200 mg (mono) + placebo (PBO), or PBO + MTX up to W52. Comparisons at W52 were not adjusted for multiplicity. Safety was assessed from adverse events and laboratory abnormalities.

Results: Of 1249 treated pts, 975 received study drug through W52. FIL efficacy was sustained up to W52. Treatment with FIL + MTX or FIL mono increased proportions of pts achieving ACR20/50/70 and clinical disease remission by Boehringer Ingelheim, Consultant of: Boehringer Ingelheim, Pfizer, Boehringer Ingelheim, Janssen, Astellas, Mitsubishi, Pfizer, Gilead, BMS, Janssen, Astellas, Mitsubishi, Takeda, Bayer, Gilead, BMS, Janssen, Astellas, Mitsubishi, Takeda, Bayer, Gilead, BMS, Janssen, Astellas, Mitsubishi, Takeda.

SAT0159

ASSOCIATION BETWEEN JANUS KINASE INHIBITORS AND ALL-CAUSE MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

W. Xie1, Z. Zhang1.1 Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: According to preliminary analysis of study A3921133, tocilizumab10 mg twice daily was associated with increased occurrence of all-cause mortality and pulmonary embolism compared with anti-tumor necrosis factor (anti-TNF), whereas 5 mg tocilizumab twice daily exhibited similar safety profile with anti-TNF.

Objectives: We aim to investigate the role of Janus kinase inhibitors (Jakinibs) in all-cause mortality among RA population via a meta-analysis of RCTs.

Methods: PubMed, Embase and Cochrane Library were systematically searched for RCTs reporting adverse events in RA patients receiving Jakinibs, from inception to October 2018. Absolute risk differences (RD) and 95% confidence interval (CI) were used as an effect measure using the Mantel-Haenszel fixed-effect method.

Results: A total of 31 RCTs randomizing 13,065 patients met the inclusion criteria. During the placebo-controlled phase, there were 16 and 6 deaths in Jakinibs and placebo respectively, accompanied by a numerically higher absolute incidence of mortality rate in Jakinibs than in placebo (0.651 vs. 0.531 per 100 patient-years). In direct pairwise comparisons, 2,194 and 2,246 patient-years of exposure in lower and higher Jakinibs reported a total of 19 deaths (10 with lower dose [0.456 per 100 patient-years] and 9 with higher dose [0.401 per 100 patient-years]). Compared with placebo, no significant difference was observed in tocilizumab (RD,0.01 events/person-year; 95% CI, -0.01 to 0.02; P =0.52); baricitinib (RD,0.00 events/person-year; 95% CI, -0.01 to 0.01; P =0.59); upadacitinib (RD,0.00 events/person-year; 95% CI, -0.02 to 0.03; P =0.71); placebo (RD,0.00 events/person-year; 95% CI, -0.05 to 0.06; P =0.86); decernotinib (RD,0.02 events/person-year; 95% CI, -0.03 to 0.06; P =0.44); tofacitinib (RD,0.00 events/person-year; 95% CI, -0.05 to 0.06; P =0.85). In pairwise comparisons, no dose-dependent impact of Jakinibs on all-cause mortality was not observed in tocilizumab (5mg vs. 10mg; bid), baricitinib (2mg vs. 4mg; qd) upadacitinib (15mg vs 30mg; qd).

Conclusion: Compared with placebo, there was no significant difference in the all-cause mortality rate observed in patients receiving Jakinibs treatments, but post-marketing data in real-life setting are sorely needed to ascertain their safety in general population.

Large, prospective, well-designed studies are needed to explore the effects of such drugs on diabetes development in the RA patients with high-risk diabetes.

SAT0160

EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS FROM CHINA, BRAZIL, AND SOUTH KOREA WITH RHEUMATOID ARTHRITIS WHO HAVE HAD INADEQUATE RESPONSE TO CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

X. Zeng, D. Zhao, S. Radominski, M. Keiserman, C. K. Lee, S. Meerwein, J. Enejosa, Y. Sus, M. E. Mohamed, W. Park.1 Department of Rheumatology, Peking Union Medical College Hospital (PUMCH), Chinese Academy of Medical Sciences, Beijing, China; 2National Clinical Research Center for Dermatologic and Immunologic Diseases (NCR-DID), Beijing, China; 3Shanghai Changhai Hospital, Shanghai, China; 4Universidade Federal do Paraná, Curitiba, Brazil; 5Pontifical Catholic University, Porto Alegre, Brazil; 6Asan Medical Center, Seoul, Korea, Rep. of (South Korea); 7AbbVie Deutschland GmbH & Co KG, Pharmaceutical Development, Ludwigshafen, Germany; 8AbbVie Inc., North Chicago, United States of America; 9Inha University Hospital, Incheon, Korea, Rep. of (South Korea)

Background: Upadacitinib (UPA), an oral, selective JAK-1 inhibitor was effective in global phase 3 trials in rheumatoid arthritis (RA) patients with inadequate response (IR) intolerance to csDMARDs and bDMARDs.

Objectives: This Phase 3, randomized, double-blind, placebo (PBO)-controlled study assessed the efficacy and safety of UPA in combination with csDMARDs in csDMARD-IR patients with RA from China, Brazil, and South Korea.

Methods: Patients were randomized 1:1 to receive UPA 15 mg once daily (QD) or PBO in combination with csDMARDs. The primary endpoint was ACR20 response at Week 12, using non-responder imputation.

Results: 338 patients were randomized, and 310 (91.7%) completed Week 12. At Week 12, statistically significantly more patients receiving UPA vs PBO achieved
the primary endpoint of ACR20 (71.6% vs 31.4%, p<0.001), UPA also demonstrated statistically significant improvements in all ranked secondary endpoints vs PBO at Week 12 (Table 1), including mean change in DAS28(CRP), HAQ-DI, and SF-36 PCS, and patients achieving DAS28(CRP) ≤3.2, DAS28(CRP) <2.6, and CDAI ≤10. Greater responses were also seen with UPA vs PBO for other key secondary endpoints including ACR50 and ACR70. Onset of UPA action was rapid with more patients on UPA achieving ACR20 by Week 1 (25.4% vs 5.9%, p<0.001). The frequency of AEs (61.5% vs 49.1%) and serious AEs (7.1% vs 3.0%) was higher with UPA vs PBO. The frequency of AEs of special interest was generally similar between UPA and PBO, with the exception of herpes zoster (1.8% vs 0.6%), hepatic disorders (9.5% vs 7.1%), neutropenia (3.0% vs 0%), and elevated creatine phosphokinase (1.8% vs 0.6%), which were higher with UPA. One case of breast cancer (on Day 1 of study) and one VTE (pulmonary embolism and deep vein thrombosis in a patient with history of deep vein thrombosis) were reported with UPA treatment.

Conclusion: Efficacy of UPA was demonstrated in this csDMARD-IR population from China, Brazil, and South Korea. The safety of UPA was comparable with the global Phase 3 program.

SAT0162 WITHDRAWAL OF LOW-DOSE STEROIDS IN SYSTEMIC LUPUS ERYTHEMATOSUS IN REMISSION: PREDICTORS OF FLARES AND DIFFERENCE IN OUTCOMES IN SEROLOGICALLY ACTIVE CLINICALLY QUIESCENT PATIENTS

S. Fasano1, L. Pierro1, M. A. Coscia1, L. Buco1, S. Scriffignano1, A. Riccardi1, F. Ciccia1, University of Campania Luigi Vanvitelli, Rheumatology, Naples, Italy

Background: According to the recent recommendations for Systemic Lupus Erythematosus (SLE), a progressive tapering until withdrawal of glucocorticoids (GC) is considered one of the main goals of SLE management (1). However, which patient may be a candidate for safe GC withdrawal has not been determined yet and a proportion of patients are kept on long-term low-dose prednisone despite clinical remission.

Objectives: to evaluate the rate of low-dose GC withdrawal in SLE patients in remission and to identify predictors of flares.

Methods: Eligible patients were SLE patients according to the ACR criteria (2) who were in prolonged clinical remission defined by a cSLEDAI=0 for at least 2 years and on a stable SLE treatment (immunosuppressive drugs and/
or hydroxychloroquine (HCQ) and daily 5 mg prednisone). A SACQ period was defined as at least 1-year period with persistent serologic activity without clinical manifestations. Flares were defined by SLEDAI-2K Flare Index (3). Disease was assessed by SLICC damage index (SDI); Data were compared by the unpaired student's t test or chi-squared test as appropriate. Predictors of flares after GC withdrawal were analyzed by Cox regression.

**Results:** Out of 246 SLE patients registered in the Naples Lupus Clinic database, 132 eligible patients were identified. Among them, we selected 57 (43%) patients in whom a GC withdrawal was attempted. 75 (57%) patients were in the prednisone maintenance group.

There were no significant differences between the two treatment groups (Table 1). The proportion of patients experiencing a flare was not significantly lower in the maintenance group than in the withdrawal group (15/75 vs 16/5). Moreover, the proportion of patients who had an increase in the SDI at the end of follow up was similar between the two groups (14/75 vs 8/5; p=0.48). However, among the withdrawal group, the rate of flares was significantly higher in SACQ patients (10/22 vs 6/35; p=0.02), while the majority of serologically inactive patients (82%) successfully stopped GCs without subsequent flares. At Cox regression analysis (Table 2), duration of HCQ therapy and >4 year remission at withdrawal were protective factors, while a SACQ disease and history of lupus nephritis (LN) increased the risk of disease flare.

</table>

**Conclusion:** GC withdrawal is an achievable target in SLE and may be attempted in patients in complete remission. In SACQ patients, maintenance of 5mg prednisone is superior to its withdrawal in order to prevent flares. Long-term HCQ therapy and prolonged remission can significantly reduce the risk of disease relapse after GC withdrawal.

**MC2-03 (CICLOSPORIN EYEDROPS) IMPROVES TEAR PRODUCTION IN SJÖGREN’S PATIENTS WITH MODERATE-TO-SEVERE KERATITIS: RESULTS FROM A PHASE 2B RANDOMIZED, CONTROLLED TRIAL**

**Background:** Sjögren Syndrome (SS) is a multifaceted disease with variable symptoms, but the SS associated keratoconjunctivitis is one of the most frequent disease manifestations of the syndrome and the manifestation that has the greatest impact on quality of life for these patients.

**Objectives:** To report the clinical efficacy of MC2-03 eyedrops in Sjögren's patients with moderate-to-severe keratitis from a 6-month trial looking at the Schirmer score which assesses the tear production by the lacrimal gland. A Schirmer score of ≤5 mm/min is one of the criteria used in the 2016 classification of ACR/EULAR to diagnose Sjögren’s syndrome.

**Methods:** The NORTHERN LIGHTS trial is a randomized, double masked, controlled multicentre European trial that assessed MC2-03 eyedrops (ciclosporin 0.03% and 0.06%) for the treatment of moderate-to-severe dry eye disease in 255 patients having corneal fluorescein staining score ≥3 or ≥4 at baseline. The Schirmer score (per 5 mm) was assessed during this trial. A total of 66 patients (25.9%) with medical history of Sjögren’s syndrome were randomized in the trial.

**Results:** Demographics and baseline disease characteristics were comparable between treatment arms: mean age 60.4 years, 90.9% were females (n=60) and the mean Schirmer score in the worst eye was -3.2mm (2.8mm – 3.2mm, except for the vehicle, mean Schirmer score of 5.5mm).

The mean Schirmer score improved rapidly from baseline to month 1 for MC2-03 0.03% eye drops (+2.4mm) reaching statistical significance versus vehicle (+0.5mm, p=0.028) and lubricant therapy (-0.6mm, p=0.020). This improvement was maintained at month 6 where the change was +2.5mm for MC2-03 0.03% eye drops compared to -1.1mm for vehicle (p=0.028). Statistical significance was also achieved at Month 6 comparing the higher strength MC2-03 0.06% eye drops (+2.8mm) to vehicle (-1.1mm, p=0.005) and lubricant alone (-0.5mm, p=0.009).

Three in eleven (27.3%) Sjögren’s patients treated with MC2-03 0.03% eye drops improved from a diagnostically low Schirmer ≤5mm at baseline (10/12, 83.3%≤5mm) to Schirmer >5mm at month 3 and month 6 (6/11, 54.5%≤5mm), while on the other hand 1 in 14 (7.1%) patients worsened in the vehicle group. A similar response was seen for MC2-03 eye drops 0.06%.

For Sjögren’s patients with Schirmer ≤5mm at baseline, a greater proportion of patients improved ≥3mm at month 6 when treated with MC2-03 eye drops 0.03% (44.4%, 4/9) and 0.06% (53.8%, 7/13) compared to vehicle (0%, 0/9) and lubricant (7.7%, 1/12). At month 6, a statistically significantly higher proportion of patients achieved clinically meaningful improvements in both corneal staining (≥2 grades improvement) and Schirmer score (≥3mm/5min) when treated with MC2-03 0.03% eye drops (45.5%, 5/11) compared to both vehicle (0%, 0/14, p=0.009) and lubricant (0%, 0/15, p=0.007). A higher number of patients treated with MC2-03 0.06% was observed without statistical significance.

**Conclusion:** MC2-03 eye drops once daily rapidly increased tear production and further improved corneal staining in Sjögren’s patients with moderate to severe keratitis, which both are objectives included as diagnostic criteria for Sjögren’s disease. MC2-03 eye drops were well tolerated with no unexpected safety findings.

Background: Incomplete B-cell and plasmablast depletion, as measured using highly sensitive flow cytometry (HSFC), is associated with lower response rates following rituximab in SLE [1]. Enhanced B-cell depletion with the type II anti-CD20 mAb obinutuzumab resulted in increased renal responses in proliferative lupus nephritis (LN) in the NOBILITY trial (NCT02550652) and will be further evaluated in the Phase 3 REGENCY trial (NCT04221477).

Objectives: To measure peripheral B-cells, B-cell subsets (naïve, memory and plasmablast) and B-cell activating factor (BAFF) levels and to assess associations between B-cell depletion and renal response in LN patients in a clinical trial of obinutuzumab.

Methods: 126 patients with active Class III/IV LN were randomized to obinutuzumab or placebo infusions in combination with mycophenolate and glucocorticoids. Peripheral B-cells were measured using a HSFC method with a lower limit of quantitation of 0.441 cells/μL. Serum levels of BAFF were evaluated using ELISA. Sustained depletion was defined by total B-cells below the limit of detection at both weeks 24 and 52. Renal response definitions from Phase 2 NOBILITY and Phase 3 REGENCY trials were used.

Results: Obinutuzumab resulted in rapid and complete depletion of total B-cells, memory and naïve B-cells, and plasmablasts from peripheral blood, with 88% of obinutuzumab patients depleted to < 0.441 total B-cells/μL at week 2 (Figure). Mean serum BAFF increased from 4.585 pg/mL at baseline to 14.601 pg/mL at week 52 in the obinutuzumab group. Sustained B-cell depletion was achieved in 32/52 (62%) of patients with complete data and was associated with higher renal response rate at week 76 (Table), although patients who achieved sustained depletion also had lower baseline proteinuria and serum creatinine.

Conclusion: Obinutuzumab, a type II anti-CD20 mAb, mediated rapid, complete and sustained depletion of peripheral B-cells and plasmablasts and large increases in serum BAFF. Similar to previous reports, sustained B-cell depletion was associated with increased renal response though there may be confounding factors. REGENCY is being conducted to further evaluate the therapeutic hypothesis with obinutuzumab in LN.

RACIAL DIFFERENCES IN THE IMPACT OF HYDROXYCHLOROQUINE ON IMMUNOLOGIC MARKERS IN SLE PATIENTS

L. Magder1, D. Goldman2, M. A. Petri3. 1University of Maryland School of Medicine, Epidemiology and Public Health, Baltimore, United States of America; 2Johns Hopkins University School of Medicine, Department of Medicine, Division of Clinical and Molecular Rheumatology, Baltimore, United States of America

Background: In patients with Systemic Lupus Erythematosus (SLE), Hydroxychloroquine (HCQ) treatment has been associated with reduced disease activity, lower rates of certain forms of organ damage, and improved survival1.

Objectives: To gain insight into the mechanisms involved, we examined the impact of HCQ treatment on immunologic biomarkers that have been associated with higher rates of organ damage. These include lupus anticoagulant, anti-dsDNA, low complement, and anti-cardiolipins (aCL).

Methods: We analyzed retrospective data on more than 56,000 quarterly clinic visits from more than 1000 patients in a large American clinical cohort of SLE patients. Patients visits were classified as “on HCQ” if they reported taking HCQ at that visit and at the previous visit. Patient visits were classified as “off HCQ” if they reported not taking HCQ at that visit and at the previous visit. For each patient, visits on and off HCQ were compared with respect to the rates of biomarker positivity. These comparisons were summarized across patients using conditional logistic regression controlling for age.

Results: Table 1 shows the results of our analyses. While on HCQ, the odds of being positive was significantly reduced for each biomarker: Lupus Anticoagulant (OR= 0.65), antidsDNA (OR=0.82), Low Complement (OR=0.71), aCL IgG (OR=0.26), and aCL IgM (OR=0.45). However, there was a substantial difference between Caucasian Americans (CAs) and African Americans (AAs) with respect to the impact of HCQ. Notably, HCQ was associated with a 62% reduction in the odds of lupus anticoagulant among CAs, but no association was observed among AAs.
In addition, HCQ was associated with a 34% reduction in antidsDNA among AAs, but no significant reduction among CAs.

1. P-value for difference between Caucasian and African Americans = <0.0001.

**Conclusion:** HCQ use was associated with a substantial decline in the rates of positive immunologic biomarkers in SLE patients. The different impact of HCQ in different races suggests the existence of racial differences in SLE subtypes and may indicate the need for different treatment strategies.

**References:**

**Disclosure:** This work was supported by NIH RO1 AR069572, AstraZeneca, UCB, Illoo, and Merck Serono, Speakers bureau: UCB. The online survey was completed by 2938 lupus patients from 36 countries. The survey consisted of 29 questions. Each participant was asked, among other things, to report their body weight (kg), daily HCQ dose and if they have received baseline and annually after 5 years of HCQ treatment.

**SAT0169 HYDROXYCHLOROQUINE PRESCRIPTION PATTERNS IN EUROPE - THE EUROPEAN SURVEY FOR LUPUS PATIENTS (ESLP)**

Z. Osmanli1, A. Cornet1, W. Zacourvis-Verweij1, S. Franke2, 1LUPUS/APS Committee, Patient Association NVLE, Utrecht, Netherlands; 2LUPUS EUROPE, Romford, United Kingdom

**Background:** Long-term use of hydroxychloroquine (HCQ) is very common in patients with lupus erythematosus. It has been associated with wide-ranging benefits and it is generally well tolerated. However, long-term use (i.e. > 5 years) and high-dose HCQ (i.e. > 5 mg/kg/day) are both considered to be risk factors for developing HCQ retinopathy.

**Objectives:** To assess whether recent EULAR guidelines regarding HCQ dosing and retinopathy screening are affecting prescription patterns and screening frequencies in Europe.

**Methods:** Patients in Europe were given the opportunity to complete the online European Survey for Lupus Patients (ESLP) initiated by LUPUS EUROPE. The survey was promoted on social media from the 26th of June – 11th of July 2019. The survey consisted of 29 questions. Each participant was asked, among other things, to report their body weight (kg), daily HCQ dose and if they have received baseline screening and/or regular eye examinations.

**Results:** The online survey was completed by 2938 lupus patients from 36 countries. The majority were female (86.5%) and diagnosed with SLE (85.7%). The daily HCQ dose (mg/kg) was available from 1678 patients (57.1%). The median ± IQR HCQ dose was 4.3 ± 2.5 mg/kg/day with a median treatment duration of 7 years (IQR: 3 – 14). The recommended daily HCQ dose of 5 mg/kg/day was exceeded by 618 patients (36.8%). Low HCQ dose (<1 mg/kg/day) was reported by 769 patients (45.8%). In addition, 284 out of 1786 patients (15.9%) reported they skipped HCQ once a week or more often. Nevertheless, only 8.7% of patients reported that they were more likely to skip HCQ than other medication. Patients from Belgium, Israel, France and Portugal reported the highest HCQ dosages. In contrast, patients from Spain reported the lowest HCQ dosages (Figure 1).
Moreover, 935 out of 1137 patients diagnosed in the past 10 years (82.2%) reported that they have received an ophthalmological screening at baseline. Lastly, 1167 patients reported long-term use of HCQ (i.e. ≥ 5 years). Only about 64% of them (n=748) reported that they receive regular eye examinations (i.e. at least once a year).

**Conclusion:** Studies have suggested that prescription patterns in the USA and UK were already affected by guidelines regarding HCQ dosing. We show large inter- and intra-country variations of HCQ dosing in Europe. Additionally, most centers fail to follow recent recommendations regarding annual screening of retinopathy in case of long-term HCQ use.

More research is needed to assess the clinical efficacy of low-dose HCQ and to confirm whether proper screening modalities are being employed as recommended by recent guidelines.

**SAT0170 COMPOSITE OF RELEVANT ENDPOINTS FOR SJÖGREN’S SYNDROME (CRESS)**

**S. Arends¹, J. F. Van Nimwegen², G. M. Verstappen¹, A. Vissink², N. Ray², F. G. M. Kroese¹, H. Bootsma¹, ¹University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; ²University Medical Center Groningen, Oral and Maxillofacial Surgery; Groningen, Netherlands; ³Bristol-Myers Squibb Company, Lawrenceville, United States of America.**

**Background:** Defining a primary study endpoint that is able to discriminate between active treatment and placebo is crucial for clinical trials in primary Sjögren syndrome (pSS). Recent trials used the validated ESSDAI as primary endpoint, but found large ‘response rates’ in the placebo group too. Since pSS is a very heterogeneous disease, a composite endpoint including multiple aspects (i.e., systemic, patient-reported, functional and biological) may be more appropriate to demonstrate clinical efficacy.

**Objectives:** To develop a composite endpoint for pSS based on expert opinion and analysis of trial data.

**Methods:** Based on expert opinion, 5 items were found to be most relevant to assess the effect of treatment in pSS patients: ESSDAI, ESSPRI, OSS, SWS and RF/IgG (Figure 1). These items were tested using data at week 24 of the randomized, double blind, placebo-controlled ASAP-III trial. ROC analysis was used to assess the discrimination of effect between the abatacept (n=40) and placebo (n=39) treatment groups. The optimal cut-off point per item was defined by the highest sum of sensitivity and specificity. The percentage of patients responding to the individual items (Figure 1) and the composite endpoint (named CRESS) was calculated.

**Results:** For ESSDAI, ROC analysis showed that both absolute and relative change in ESSDAI were not able to discriminate between treatment groups (AUC 0.536 and 0.599) and no optimal cut-off point could be identified. According to an in SLE developed endpoint and based on expert opinion, it was decided to aim for the validated definition of low disease activity (ESSDAI≤5)². For ESSPRI, ROC analysis (AUC 0.629) showed an optimal cut-off point of -13.8%. Therefore, the validated definition of ESSPRI response (≥15% or 1 point)² was used. For OSS and SWS, ROC analysis (AUC 0.555 for OSS;≥3 at baseline and AUC 0.556 for SWS>0 at baseline) could not identify an optimal cut-off point, so the definitions based on expert opinion were kept (Figure 1).

For serological items, ROC analysis (AUC 0.861 for RF<50 at baseline and 0.615 for IgG) showed optimal cut-off points of -23% and -2.2%, respectively. It was decided to round these numbers to ≥25% decrease in RF or ≥5% decrease in IgG. Responding to ≥3 of the 5 items discriminated best between the abatacept and placebo groups. The final response rate to our composite endpoint (CRESS responders) was 55% vs. 13% in the abatacept and placebo groups, respectively (P<0.001). Further analysis of how many patients who met the composite endpoint also met the single endpoints and vice versa demonstrated that all individual items contributed to the overall response rate.

**Conclusion:** This concept of the new ‘Composite of Relevant Endpoints for Sjögren’s Syndrome’ (CRESS) is developed. With this composite endpoint, it is possible to discriminate between abatacept and placebo response in pSS patients. Additional validation analyses in independent, global, multi-center, placebo-controlled trials of biological DMARDs in pSS and NECESSTY will be performed.

**Figure 1.** Overview of the Composite of Relevant Endpoints for Sjögren’s Syndrome (CRESS) domains, measurements, definition of response and percentage of responders at week 24 of abatacept and placebo groups.

**Acknowledgments:** The authors would like to thank Raphaelle Seror for initial discussions on potential components and criteria to be explored in the creation of a composite pSS endpoint. The authors would also like to acknowledge valuable discussions with Marleen Nys, Miroslawa Nowak, Dennis Grasela, Antoine Sreih and Subhashis Banerjee.
Disclosure of Interests: Suzanne Arends Grant/research support from: Grant/research support from Pfizer, Jolien F. van Nimwegen Consultant of: Bristol-Myers Squibb, Speakers bureau: Bristol-Myers Squibb, Gwenny M. Verstappen; None declared, Arjan Visserink: None declared, Neelanjana Ray Shareholder of: Bristol-Myers Squibb, Employee of: Bristol-Myers Squibb, Frans G.M. Kroese Grant/research support from: Unrestricted grant from Bristol-Myers Squibb, Consultant of: Consultant for Bristol-Myers Squibb, Speakers bureau: Speaker for Bristol-Myers Squibb, Roche and Janssen-Cilag, Hendrika Bootma Grant/research support from: Unrestricted grant from Bristol-Myers Squibb, Consultant of: Consultant for Bristol-Myers Squibb, Roche, Novartis, Medimmune, Unrestricted grant from Bristol-Myers Squibb, Consultant of: Bristol-Myers Squibb, Roche, Janssen-Cilag, Hendrika Bootma.

The purpose of the research was to study the therapeutic option of Rituximab (RTM), a chimeric anti-CD20 antibody, in SARDs such as ANCA-associated systemic vasculitis (AAV), cryoglobulinemic vasculitis (CV), systemic lupus erythematosus (SLE), systemic sclerosis (SS), primary Sjögren syndrome (pSS), and IgG4-related disease (IgG4-RD).

Methods: We present data on efficacy and safety of RTM in 515 patients (pts) with SARDs. 103 pts had AAV (58-granulomatosis with polyangiitis, GPA; 35-microscopic polyangiitis, MPA and 10-cryoglobulinemic polyangiitis with polypropyltis, EGPA), 21 pts had CV, 165-SLE, 90-SS, 100-pSS, 34-IgG4-RD. Characteristics of pts and results of RTM treatment are present in Table. Mean follow-up duration after initiation of RTM was 25-58 months.

Results: The average cumulative RTM dose in all groups exceeded 2.4 g. The majority of pts had received repeated RTM courses (0.5-1.0 g, 71%). A good clinical response was achieved in 70-93% pts, except for the SLE (49%-57% response). Usage of repeated RTM courses increased the clinical efficacy and reduced the risk of recurrence. Despite the fact that the study population included a high percentage of pts with severe or refractory SARDs, total mortality rate was about 6% during the follow-up period, highest in CV and AAV (14-11%). In AAV and SLE infections constitute a significant proportion of serious adverse reactions (10-11%). Late-onset neutropenia was only in pts with AAV (12%) and SLE (3%).

Conclusion: Treatment with RTM was highly effective in SARDs. In certain SARDs RTM safety profile of should be considered during treatment planning. Further studies of the targeted anti-B-cell therapy, including RTM efficacy and safety in SARDs, clarification of the indications and optimal RTM regimens are needed.

SAT0171

RITUXIMAB IN SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES: ONE CENTER EXPERIENCE OF TREATMENT 515 PATIENTS

E. Nasonova1, T. Beketova1, L. P. Ananyeva1, S. Solovyev1, V. Vasiliev1, O. Koneva1, O. Desinova1, S. Palshina1, E. Sokol1, E. Nikollaeva1, I.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: B cells have important functions in the pathogenesis of systemic autoimmune rheumatic diseases (SARDs).

Objectives: The purpose of the research was to study the therapeutic option of Rituximab (RTM), a chimeric anti-CD20 antibody, in SARDs such as ANCA-associated systemic vasculitis (AAV), cryoglobulinemic vasculitis (CV), systemic lupus erythematosus (SLE), systemic sclerosis (SS), primary Sjögren syndrome (pSS), and IgG4-related disease (IgG4-RD).

Methods: We present data on efficacy and safety of RTM in 515 patients (pts) with SARDs. 103 pts had AAV (58-granulomatosis with polyangiitis, GPA; 35-microscopic polyangiitis, MPA and 10-cryoglobulinemic polyangiitis with polypropyltis, EGPA), 21 pts had CV, 165-SLE, 90-SS, 100-pSS, 34-IgG4-RD. Characteristics of pts and results of RTM treatment are present in Table. Mean follow-up duration after initiation of RTM was 25-58 months.

Results: The average cumulative RTM dose in all groups exceeded 2.4 g. The majority of pts had received repeated RTM courses (0.5-1.0 g, 71%). A good clinical response was achieved in 70-93% pts, except for the SLE (49%-57% response). Usage of repeated RTM courses increased the clinical efficacy and reduced the risk of recurrence. Despite the fact that the study population included a high percentage of pts with severe or refractory SARDs, total mortality rate was about 6% during the follow-up period, highest in CV and AAV (14-11%). In AAV and SLE infections constitute a significant proportion of serious adverse reactions (10-11%). Late-onset neutropenia was only in pts with AAV (12%) and SLE (3%).

Conclusion: Treatment with RTM was highly effective in SARDs. In certain SARDs RTM safety profile of should be considered during treatment planning. Further studies of the targeted anti-B-cell therapy, including RTM efficacy and safety in SARDs, clarification of the indications and optimal RTM regimens are needed.

SAT0172

UTILIZATION OF HYDROXYCHLOROQUINE AND CORTICOSTEROIDS AMONG LUPUS PATIENTS WITH INCIDENT END-STAGE RENAL DISEASE (ESRD) ONSET: A LONGITUDINAL STUDY USING USRDS REGISTRY

A. R. Broder1, W. Mowrey2, A. Valle2, B. Goyal3, K. Yoshida3, K. Costenbader4, 5, 6, 7, 8, 9

1Montefiore/Einstein, Medicine/Rheumatology, Bronx, United States of America; 2Einstein, Bronx, United States of America; 3Montefiore, Bronx, United States of America; 4Montefiore, Bronx, United States of America; 5Harvard, Boston, United States of America

Background: The development of ESRD due to lupus nephritis is one of the most common and serious complications of SLE. Mortality among SLE ESRD patients is 4-fold higher compared to lupus nephritis patients with preserved renal function1 Mortality in SLE ESRD is also twice as high compared with non-SLE ESRD, even though SLE patients develop ESRD at a significantly younger age. In the absence of ESRD specific guidelines, medication utilization in SLE ESRD is unknown.

Objectives: The objective of this study was to investigate the real-world current US-wide patterns of medication prescribing among lupus nephritis patients with new onset ESRD enrolled in the United States Renal Disease Systems (USRDS) registry. We specifically focused on HCQ and corticosteroids (CS) as the most used medications to treat SLE.

Methods: Inclusion: USRDS patients 18 years and above with SLE as a primary cause of ESRD (International Classification of Diseases, 9th Revision (ICD9) diagnostic code 710.0, previously validated2). who developed ESRD between January 1, 2006 and July 31, 2011 (to ensure at least 6 months of follow-up in the USRDS), Patients had to be enrolled in Medicare Part D (to capture pharmacy claims). The last follow-up date was defined as either the last date of continuous part D coverage or the end of the study period, Dec 31, 2013.

Results: Of the 2579 patients included, 1708 (66%) were HCQ- at baseline, and 871 (34%) were HCQ+ at baseline. HCQ+ patients at baseline had a slightly lower duration of follow-up compared to HCQ- patients at baseline, median (IQR) of 2.32 (1.33, 3.97) years and 2.95 (1.44, 4.25) years, respectively, p<0.02. During follow-up period, only 778 (30%) continued HCQ either intermittently or continuously to the last follow-up date, 1306 (51%) were never prescribed HCQ after baseline, and 495 (19%) discontinued HCQ before the last follow-up date. Of the 1801 patients who were either never prescribed or discontinued HCQ early after ESRD onset, 713 (40%) were prescribed CS to the end of the follow-up period: 55% were receiving a low dose <10mg/daily, and 43 were receiving moderate dose (10-20mg daily)

Conclusion: HCQ may be underprescribed and CS may be overprescribed in SLE ESRD. Changing the current prescribing practices may improve outcomes in SLE ESRD

A. Fanourakis1, M. Kostopoulou, K. Cheema3, G. Bertisias4, D. Jayne5, D. Boumpas6.1University of Athens, Athens, Greece; 2G. Gennimatas; General Hospital, Athens, Greece; 3University of Cambridge, Cambridge, United Kingdom; 4University of Crete Medical School, Heraklion, Greece; 5University of Athens Medical School, Athens, Greece

Background: Lupus nephritis (LN) affects ~40% of patients with systemic lupus erythematosus (SLE) and is associated with significant morbidity. New data has emerged since the publication of the EULAR/EARA-EDTA recommendations for the management of LN, involving a multidisciplinary panel of experts.

Objectives: To analyze the current evidence, in order to inform the 2019 update of the EULAR/EARA-EDTA recommendations for the management of LN.

Methods: According to the EULAR standardised operating procedures, a Medline systematic literature review (SLR) was performed, from January 2012 until 31 December 2018. The final level of evidence (LoE) and grading of recommendations considered the total body of evidence, including the LoE of the 2012 recommendations.

Results: We identified 542 relevant articles. High-quality evidence supports the use of immunosuppressive treatment for class III and IV LN (LoE 1a) there is moderate quality evidence for immunosuppression in pure class V LN, with nephrotic-range proteinuria (LoE 2b). Treatment should aim for a 25% reduction in proteinuria at 3 months, 50% at 6 months and complete renal response (<500-700 mg/d) at 12 months (LoE 2a-2b). Strong evidence supports the use of mycophenolate mofetil/mycophenolic acid (MMF/MPA) or low-dose intravenous cyclophosphamide (CY) for the initial treatment of class III/IV LN (LoE 1a, Table). Combination of tacrolimus with MMF/MPA and high-dose CY are alternatives in specific circumstances (LoE 1a, Table). There is little evidence to guide optimal duration of immunosuppression in LN (LoE 3). In end-stage kidney disease due to LN, all methods of kidney replacement treatment have been used, but transplantation is accompanied by the most favourable outcomes (LoE 2b).

Conclusion: There is high-quality evidence to guide the initial and subsequent phases of class III/IV LN treatment. There is low-quality evidence to guide treatment of class V, monitoring and optimal duration of immunosuppression.

*Overall risk of bias was assessed using the Revised Cochrane risk-of-bias tool (ROB2)
Results: In TULIP-2 (anifrolumab, n=180; placebo, n=182) and TULIP-1 (anifrolumab, n=180; placebo, n=184), fewer patients experienced >1 BILAG-2004 flare in the anifrolumab groups (TULIP-2: 31.1%, n=56; TULIP-1: 36.1%, n=65) compared with the placebo groups (TULIP-2: 42.3%, n=77; TULIP-1: 43.5%, n=80; Figure 1). Results favoring anifrolumab were observed in time to first flare (TULIP-2: hazard ratio [HR] 0.65; 95% confidence interval [CI] 0.46–0.91 and TULIP-1: HR 0.76; 95% CI 0.59–1.06; Figure 2) and BILAG-based annualized flare rates (TULIP-2: adjusted rate ratio 0.67; 95% CI 0.48–0.94 and TULIP-1: rate ratio 0.83; 95% CI 0.60–1.14) across both trials.

Conclusion: Across 2 phase 3 trials, we observed reductions in the total number of flares and annualized flare rates, as well as prolongation of time to first flare with anifrolumab treatment compared with placebo. These results support the potential of anifrolumab to reduce disease activity and reduce flares, benefiting patients with SLE.

Women and Children's Health, San Bortolo Hospital of Vicenza, Vicenza, Italy; 4Department of Transfusion Medicine, San Bortolo Hospital of Vicenza, Vicenza, Italy; 5University of Padua, Department of Medicine-OIMED, Padova, Italy; 6San Bortolo Hospital Of Vicenza, Department of Medicine, Vicenza, Italy.

Background: Therapeutic apheresis (TA) represents a therapeutic option in pre-existing conditions or rheumatic diseases that occur during pregnancy. Although pregnancy per se is not a contraindication, it does present several added risks. In lupus nephritis, indications for TA treatment remain controversial due to the lack of evidence-based guidelines and the alleged risk of maternal and/or fetal adverse events, there is general resistance to its application during pregnancy.

Objectives: In this observational study we aimed to evaluate the efficacy and safety of TA in high-risk pregnancies in patients with rheumatic diseases, followed over a decade in a tertiary Center.

Methods: Between January 2005 and April 2019, 843 TA procedures were performed during 51 pregnancies in 43 patients: 745 plasma exchange sessions and 98 immunosorbation sessions. TA was performed in 29 (57%) pregnancies of 21 (48.8%) patients with antiphospholipid antibody syndrome (APS), in 20 (39.2%) pregnancies of 20 (46.3%) patients with congenital heart block (CHB), in 1 (1.9%) pregnancy of 1 (2.3%) patient with systemic sclerosis (SSc), and 1 (1.9%) pregnancy of 1 (2.3%) patient affected by nephrotic syndrome (SLE).

Results: During the period considered, apheresis sessions applied to pregnant women were 71% of the total (n = 13,251). The average age at the first treatment was 33 years (range 24-43). The mean management age at the first apheresic treatment was 21 weeks (range 4-32). Twelve (14%) apheresis sessions were complicated by adverse events, none required or prolonged hospitalization. There were 44 (86.3%) live births, 3 (5.9%) spontaneous abortions and 2 (3.9%) voluntary terminations of pregnancy. In 4 (7.9%) women, eGFR dropped by 40% at the 30th week from the 32nd SG until delivery, which occurred at the 36th SG, due to severe hypertension and proteinuria at the initiation of treatment were 46.8±11.5 mL/min/1.73m² and 7.7±3.4 g/gCr, respectively. Patients were initially treated with methylprednisolone pulse therapy followed by 0.8-1.0 mg/kg/day of prednisolone (PSL), 2-3 mg/day of tacrolimus and 1000 mg/day of MMF. At 6 months, eGFR and proteinuria improved to 72.9±11.3 mL/min/1.73m² and 0.19±0.03 g/gCr, respectively. At 12 months, eGFR and proteinuria further improved to 78.6±7.8 mL/min/1.73m² and 0.10±0.07 g/gCr, respectively and the dose of PSL was reduced to 6.6±1.5 mg/day. Three patients became positive for cytomegalovirus antigenemia and were successfully treated with antiviral therapy.

Conclusion: Multitarget therapy is effective in lupus nephritis even in patients presented with RPGN.

patients being able to restart HCQ after ophthalmologic examination in this study shows that it is important to perform multimodal imaging techniques in patients with retinal toxicity diagnosis. Since macular pathology can have a different etiologic background, an initial ophthalmologic examination is also necessary. Lack of difference in the duration of HCQ exposure and drug-free time between patients who restarted treatment and who could not may be a sign of personal sensitivity to HCQ toxicity.

SAT0179

ADHERENCE TO HYDROXYCHLOROQUINE INFLUENCES THE OCCURRENCE OF ORGAN DAMAGE DURING FOLLOW-UP IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. H. Kang1, S. E. Choi1, H. Xu1, D. J. Park1, S. S. Lee1, 1Chonnam National University Medical School & Hospital, Gwangju, Korea, Rep. of (South Korea)

Background: Objectives: Hydroxychloroquine (HCQ) is a cornerstone drug in patients with systemic lupus erythematosus (SLE), decreasing the risk of flares and comorbidities and improving survival. This study investigated the effects of HCQ adherence on clinical manifestations, disease activity, and organ damage in Korean patients with SLE.

Methods: Data on 299 SLE patients were obtained from the Korean Lupus Network registry. Demographic variables, clinical manifestations, laboratory findings, PGA, and SLEDAI-2000 and SLICC damage index scores were recorded at the time of enrollment and repeated annually for 4 consecutive years. Patients were divided into two groups according to the level of HCQ adherence. Adherence was defined by the medication possession ratio and dichotomized as ≤ 80% vs. > 80%. Univariate and multivariate analyses were performed to assess the impact of adherence to HCQ on clinical outcomes.

Results: Of the 299 patients, 31 (10.4%) showed poor drug adherence during the follow-up period. Patients with poor HCQ adherence were older (P=0.011), less insured (P=0.024), experienced lower employment (P=0.033), and had a higher rate of comorbidities such as hypertension (P=0.048) and depression (P<0.001). The non-adherent group had higher mean and changed SLICC damage index scores than the adherent group across all 4 years. In the multivariate analysis, HCQ non-adherence was significantly associated with older age (OR, 1.043; 95% CI, 1.006–1.081; P=0.021), depression (OR, 1.198; 95% CI, 1.099–1.306; P=0.042), and an annual increase in the SLICC damage index score (OR, 2.275; 95% CI, 1.369–3.779; P<0.002).

Conclusion: HCQ adherence might be influenced by age and depressive mood. Additionally, the poor adherence to HCQ in SLE patients was correlated with higher cumulative organ damage. Therefore, patients with SLE should be educated to take HCQ appropriately to improve their clinical outcome in clinical practice.

SAT0180

ANTI-MALARIAL DRUGS ASSOCIATED RETINOPTHY IN SYSTEMIC LUPUS ERYTHEMATOSUS

X. E. Larcro Rojas1, A. Crespo Golmar1, C. Moriano1, A. Lópeze Robles1, E. Diez Alvarez1, T. Pérez Sandoval1, 1Hospital Universitario de León, Rheumatology, León, Spain

Background: The antimalarials remain to be the main treatment for Systemic Lupus Erythematosus (SLE). Its most important limitation when you want to increase dose or remain using them is the occurrence of retinal toxicity, which appears in a small number of patients. Since the lesions can progress even with drug withdrawal is important to perform a screening for an early diagnosis.

Objectives: To describe ocular toxicity in patients with SLE treated with antimalarials that attended the rheumatology office and to identify possible associated risk factors.

Methods: We performed a cross-sectional, retrospective study of SLE patients diagnosed of antimalarial drugs associated retinopathy, that were included in the data base of the Rheumatology department in León’s Hospital between 2014-2019. Multiple clinical and therapeutic factors potentially associated with retinal toxicity were analyzed including: age, chronic kidney disease (CKD), liver failure, smoking, hypertension, Diabetes mellitus, presence of previous retinopathy, type of treatment, duration, daily dose and cumulative dose and tamoxifen intake. The diagnosis of retinopathy was performed by the Ophthalmology department. The dose of hydroxychloroquine (HCQ) used was of 400mg/day and chloroquine (CQ) 250mg/day.

Results: 437 medical records were analyzed, 20 patients diagnosed of antimalarial retinopathy were included (4.57%), 90% of them were women. The age of diagnosis was more than 40 years in 18 patients (90%) and more than 60 years in 10 (50%) with a median of 60 years (IQR: 32.25).

The duration of treatment was ≤ 5 years in 10 patients (50%), between 6-10 years in 6 (30%), between 11-15 years in 2 (10%) and between 16-20 years in 2 (10%) with a median of exposure of 5.5 years (IQR: 6.5); 15 patients (75%) were in treatment with HCQ, with CQ 2 patients (10%) and with both of them sequentially 3 patients (15%).

Of the group of patients treated with HCQ 35% were above the global accumulated recommended dose (1000g) and 71% of them were on treatment more than 10 years. In the group treated with CQ none were above the global recommended dose (460g). Of the 3 patients that took both drugs, two were above the recommended dose for HCQ.

25% of the patients had CKD and 10% liver failure, 20% of the patients were active smokers and 15% ex-smokers.

10% of the sample had previous retinopathy related with other comorbidities (age related retinopathy and diabetes), associating hypertension and diabetes mellitus in the same percentage (15%).

Severe retinopathy was found in 1 patient (5%), mild-moderate in 9 patients (45%), retinopathy stages were not specified in 10 patients (50%).

Conclusion: In our sample we observed a prevalence of antimalarials retinopathy of 4.57%, similar of what is found in the literature. Half of the patients had retinopathy in a period of treatment ≤ 5 years, being a described risk factor the duration of treatment of more than 6 years. This early manifestation could be related to the presence of other comorbidities like hypertension, diabetes and CKD.

Dose adjustment should be considered in patients with a period of treatment of more than 10 years. Age seems to be an associated factor for the development of antimalarials retinopathy and to perform a screening in the first year of treatment is important to rule out basal disease related with more risk to develop ocular toxicity.

ALTERATIONS OF PERIPHERAL LYMPHOCYTE SUBSETS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND THEIR CHANGES AFTER OUR NEW IMMUNOREGULATORY COMBINATION THERAPIES

J. Q. Zhang1, S. X. Zhang1, L. Xue2, J. Giao1, M. T. Qiu1, R. Zhao1, M. J. Chang1, Y. Li1, J. Luo1, G. Y. Liu1, C. Gao2, X. Li1, 1The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China; 2The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China; 3Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease characterized by abnormal activation of circulating lymphocytes and overproduction of autoantibodies. Breakdown of self-tolerance is considered as a critical cause in the development of SLE. However, the quantitative changes of lymphocyte subsets in SLE are unclear. Since low-dose IL-2 and several drugs have been used to promote the proliferation of regulatory T cells (Tregs), we developed immunoregulatory therapies using these drugs to rebalance effector T cells with Tregs and test whether they are beneficial to remission disease activity of SLE.

Objectives: To observe the different levels of peripheral lymphocyte subsets at the first laboratory examination of SLE patients with those of healthy controls (HCs) and to evaluate the effect of immunoregulatory combination therapies on levels of lymphocyte subsets in patients with SLE.

Methods: From September 2014 to December 2019, a total of 985 diagnosed patients with SLE (878 females, 107 males, mean age 42.9±13.37 years) and 206 healthy adults were enrolled in this retrospective cross-sectional study. And 795 patients with SLE (711 females and 84 males, mean age 38.26±15.242 years) were received the immunomodulatory drugs (IMDs) such as low-dose interleukin-2, rapamycin, metformin, retinoic acid, coenzymes Q10 or other immunomodulatory treatments. The absolute numbers of T, B, NK, CD4+T, CD8+T, Th1, Th2, Th17 and CD4+CD25+Foxp3+ regulatory cells (Tregs) in peripheral blood (PB) of these individuals were measured by Flow Cytometer (FCM) combined with standard absolute counting beads.
Results: As compared with those of HCs, patients with SLE had lower absolute numbers of total T, NK, and CD4+ T but higher proportions of all lymphocyte subpopulations except NK, CD4+T cells (P < 0.001) (Figure 1 A, C). Notably, the absolute numbers and proportions of Tregs as well as Th1 in CD4+ T subsets were decreased (P <0.05) (Figure 1 B, D). Further, there was a significant increase in the ratio of Teffs/Tregs such as Th1/Tregs, Th2/Tregs and Th17/Tregs (P <0.05) (Figure 1 E). After receiving immunoregulatory combination therapies, the absolute numbers and proportions of T, NK, CD4+ T, and CD8+ T were increased, while the proportion of B cells was decreased (Figure 2 A, C); the absolute numbers of most CD4+ T subsets as well as the proportions of only Th1 and Tregs were significantly increased (P < 0.001) (Figure 2 B, D). The ratios of Th1/Th2 and Th17/Tregs increased while that of Th17/Tregs and Th2/Tregs decreased (P < 0.01) (Figure 2 E).

Conclusion: Quantitative and functional alterations of peripheral lymphocyte subsets, especially reduced Tregs, play crucial roles in the pathogenesis of the patients. Immunoregulatory combination therapies mainly promote the proliferation and functional recovery of Tregs to rebalance pro- and anti-inflammatory T cells in patients with SLE for patients’ symptoms remission.

Evidence of any single organ system involvement previous or current was taken as having a BILAG score of A-D but not E. Disease activity was measured using BILAG-2004. Clinical response was defined as improvement by >=1 grade in active BILAG-2004 systems with no worsening in other systems. Autoantibodies were measured by immunoprecipitation of proteins by sera from 35S-labelled K562 cell lines, followed by SDS-PAGE separation and autoradiography. Autoantibodies not able to be detected by this technique (anti-RO/SS-A, anti-TS-DNA and aCL) were measured by ELISA. Autoantibody data was analysed in IBM SPSS and GraphPad Prism v8.2. Association between autoantibodies and RTX response was analysed using binary logistic interaction terms and Pearson’s Chi-Square test.

Results: Of the 224 patients (201 female, 23 male, median age 40 years) the most common system involvement from the 9 BILAG domains was musculoskeletal (164 patients) and the least ophthalmic (11 patients). Patients with anti-RO52 and anti-U1RNP/Sm had more frequent involvement of mucocutaneous (P < 0.038, P < 0.012) and musculoskeletal domains (P<0.015 for U1RNP) respectively.

There were 136 patients with sufficient data to define as either responders (n=67) or non-responders (n=69) to RTX at 6 months. RTX responders had a higher frequency of anti-U1RNP/Sm as compared to non-responders (Figure 1). Further Pearson’s Chi-Square analysis showed a significant association between presence of anti-U1RNP/Sm and better response to RTX (P<0.018).

Acknowledgments: Our findings suggest that the presence of U1RNP/Sm autoantibodies in a cohort of patients who have received treatment with RTX is associated with more frequent musculoskeletal and mucocutaneous involvement and predicts a more favourable response to treatment.

Disclosure of Interests: None declared.

SAT0182
THE ASSOCIATION BETWEEN AUTOANTIBODIES AND RITUXIMAB RESPONSE IN SYSTEMIC LUPUS ERYTHEMATOSUS

D. Lii1, H. Lu1, J. Dunphy2, T. Smith1, E. Vital3,4, I. N. Bruce5, N. McHugh1, The University of Bath, Pharmacy and Pharmacology, Bath, United Kingdom; Royal United Hospital Bath NHS Foundation Trust, Bath, United Kingdom; 3The University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Disease, Leeds, United Kingdom; 4Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 5The University of Manchester, Centre for Epidemiology Versus Arthritis, Faculty of Biology Medicine and Health, Manchester, United Kingdom

Background: Systemic Lupus Erythematosus (SLE) is clinically and immunologically heterogeneous with a variable response to treatment. MASTERSANS is an MRC-funded consortium that seeks to identify immunophenotypic subgroups of patients that predict response to therapy. Autoantibody profiles can differentiate subgroups of patients and have potential to predict response to treatment.

Objectives: To determine whether known and novel autoantibodies are associated with response to rituximab (RTX), and analyse the association between these autoantibodies and disease involvement in various organ systems.

Methods: Serum was obtained from 224 SLE patients in the BILAG Biologics Registry who received rituximab according to NHS England criteria (2). Patients were recruited if they were starting a first cycle of rituximab for active SLE (BILAG A or 2xBILAG B) despite previous cyclophosphamide or mycophenolate mofetil.

Results: Of the 224 patients (201 female, 23 male, median age 40 years) the most common system involvement from the 9 BILAG domains was musculoskeletal (164 patients) and the least ophthalmic (11 patients). Patients with anti-RO52 and anti-U1RNP/Sm had more frequent involvement of mucocutaneous (P < 0.038, P < 0.012) and musculoskeletal domains (P<0.015 for U1RNP) respectively.

There were 136 patients with sufficient data to define as either responders (n=67) or non-responders (n=69) to RTX at 6 months. RTX responders had a higher frequency of anti-U1RNP/Sm as compared to non-responders (Figure 1). Further Pearson’s Chi-Square analysis showed a significant association between presence of anti-U1RNP/Sm and better response to RTX (P<0.018).

SAT0183
STATUS OF LYMPHOCYTE SUBSETS IN PERIPHERAL BLOOD OF PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME AND THEIR CHANGES AFTER RECEIVING OUR NEW IMMUNOREGULATORY COMBINATION THERAPY: A RETROSPECTIVE CROSS-SECTIONAL STUDY

J. Y. Yang1, S. X. Zhang2, L. Hao2, Q. Y. Su1, J. Bai1, S. J. Guo1, J. Luo2, G. Y. Liu2, C. Gao3, X. Li4, 5Shanxi Medical University, Taiyuan, China; 6The Second Hospital of Shanxi Medical University, Taiyuan, China; 7Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America

Background: Primary Sjögren’s syndrome (pSS) is a chronic inflammatory autoimmune disease mainly involving exocrine glands and involving multiple organs and systems. Recent studies have reported that peripheral lymphocyte subsets such as Th1, Th2, Th17, and regulatory cells (Treg) have a key role in the pathogenesis of pSS3. However, the detailed statuses of lymphocyte subsets of pSS patients remain to be clearly evaluate and effects of immunomodulatory therapies on the lymphocyte subsets are unknown.

Objectives: To determine whether known and novel autoantibodies are associated with response to rituximab (RTX), and analyse the association between these autoantibodies and disease involvement in various organ systems.

Methods: Serum was obtained from 224 SLE patients in the BILAG Biologics Registry who received rituximab according to NHS England criteria (2). Patients were recruited if they were starting a first cycle of rituximab for active SLE (BILAG A or 2xBILAG B) despite previous cyclophosphamide or mycophenolate mofetil.

Results: Of the 224 patients (201 female, 23 male, median age 40 years) the most common system involvement from the 9 BILAG domains was musculoskeletal (164 patients) and the least ophthalmic (11 patients). Patients with anti-RO52 and anti-U1RNP/Sm had more frequent involvement of mucocutaneous (P < 0.038, P < 0.012) and musculoskeletal domains (P<0.015 for U1RNP) respectively.

There were 136 patients with sufficient data to define as either responders (n=67) or non-responders (n=69) to RTX at 6 months. RTX responders had a higher frequency of anti-U1RNP/Sm as compared to non-responders (Figure 1). Further Pearson’s Chi-Square analysis showed a significant association between presence of anti-U1RNP/Sm and better response to RTX (P<0.018).
Objectives: To explore the pathogenesis and evaluate the therapeutic effect of immunomodulatory drugs (IMiDs) by comparing the changes of lymphocyte subsets in peripheral blood (PB) before and after treatment.

Methods: This study included 1,221 pSS patients and 206 healthy controls (HCs). Among these patients, 759 patients were received our new immunoregulatory therapies such as low-dose interleukin-2, rapamycin, metformin, retinoic acid etc. The absolute numbers of T, B, NK, CD4+T, CD8+T, Th1, Th2, Th17 and Tregs in PB of these subjects were detected by flow cytometry combined with standard absolute counting beads. Data were expressed as mean ± standard deviation to the distribution. Independent-samples T test and paired-samples T test were applied. *P value <0.05 were considered statistically significant.

Results: The absolute numbers of circulating Tregs as well as T, NK cells in pSS patients were significantly lower than those of HCs (*P<0.05). After immunoregulatory combination treatments, the number of Tregs was significantly increased (*P<0.05). Though the absolute numbers of T, NK, CD4+T, CD8+T, Th1, Th2, Th17 and Tregs in PB of these subjects were detected by flow cytometry combined with standard absolute counting beads. Data were expressed as mean ± standard deviation to the distribution. Independent-samples T test and paired-samples T test were applied. *P value <0.05 were considered statistically significant.

Conclusion: The decrease of peripheral Tregs played an important role in the pathogenesis of primary Sjögren's syndrome. Immunoregulatory combination therapies promoted the increase of Tregs and might help for the recovery of pSS.

SAT0188
DEVELOPING PREDICTORS OF GLOBAL BILAG TREATMENT RESPONSE IN PATIENTS WITH LUPUS NEPHRITIS: MORE LESSONS FROM THE ASPREVA LUPUS MANAGEMENT STUDY GROUP (ALMS) DATA

S. Mcdonald1, S. Yiu2, L. Su3, C. Gordon3, N. Solomons4, I. N. Bruce5 on behalf of MASTERPLANS. 1University of Manchester, NIHR Manchester BRC, Manchester, United Kingdom; 2University of Cambridge, MRC Biostatistics Unit, School of Clinical Medicine, Cambridge Institute of Public Health, Cambridge, United Kingdom; 3University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom; 4Aurinia Pharmaceuticals, Victoria, Canada; 5Manchester University NHS FT, Manchester Academic Health Science Centre, Manchester, United Kingdom

Background: Lupus Nephritis (LN) occurs in up to 60% of patients with SLE and is often associated with other organ involvement, morbidity and mortality. Treatment response and clinical improvement rates are limited with conventional therapy. Little is known about clinical predictors of response in SLE overall or in LN. The ALMS induction trial compared mycophenolate mofetil (MMF) to IV cyclophosphamide (CYC) as induction for LN. MMF was deemed non-superior. The ALMS maintenance trial randomised responders to induction treatment at 6 months to MMF or Azathioprine, with MMF superior during follow-up.

Objectives: To identify predictors of overall clinical response at 6 and 12 months, in a cohort of SLE patients with LN.

Methods: Using the ALMS trial cohort, we analysed predictors of response in all the patients as a single cohort. ‘Classic’ BILAG scores were used to assess organ responses over time. Endpoints analysed were:

1) Improvement: defined as reduction in BILAG score ≤ one BILAG B and no new BILAG organ domains involved, no increase in steroids from baseline and no increase in SLEDAI from baseline.

2) Major Clinical Response (MCR): defined as reduction in BILAG score to BILAG C increase in SLEDAI from baseline.

Results: 370 patients enrolled in the ALMS induction trial. 227 patients were randomised at 6 months to maintenance. 313(84.59%) patients were Caucasian. The mean age was 31.9 years.

Conclusion: In this SLE cohort, most patients with proliferative LN achieved CRR. Proteinuria above 2g/day at baseline and diabetes mellitus were predictors of poor renal outcome, while positive anti-RNP was protective. Induction treatment with CYC was associated with poorer outcome as compared with MMF. Given the retrospective non-randomized nature of this study, caution is needed when drawing conclusions regarding both treatments efficacy.

DOI: 10.1136/annrheumdis-2020-eular.3775
236 (63.78%) patients had a disease duration of LN of < 1 year. Baseline mean (± SD) SLEDAI score was 15.28 (±8.78) and mean (± SD) numerical BILAG score was 19.61 (±7.67).

Improvement at 6 months was attained by 180 (48.65%). Predictors included older age (OR=1.03 [95% CI: 1.01-1.05] per year) and normal haemoglobin (OR=1.90 [95% CI: 1.19, 3.05] vs low hb). Activity (BILAG A or B) in haematological and mucocutaneous domains predicted less improvement (OR [95% CI] = 0.59 [95% CI: 0.38, 0.94] and 0.50 [95% CI: 0.31,0.82] respectively). Baseline damage (SDI >1) negatively predicted improvement (OR 0.54 [95% CI: 0.31,0.92]).

Improvement at 12 months was achieved by 139 (37.57%). Low IgG predicted improvement (OR 4.66 [95% CI: 1.34,16.23]). Black US patients were less likely to improve (OR 0.29 [95% CI: 0.06,0.90] vs Asian patients). MCR was achieved by 14(3.79%) and 40(10.81%) at 6 and 12 months. We found regional and racial differences in 12-month MCR responses (Figure 1). Baseline normal C4 predicted a decreased likelihood of MCR (OR 0.37 [95% CI: 0.170,64] vs normal C4).

Results of multivariate logistic regression with LASSO were consistent with the univariate analyses.

Conclusion: A number of factors were related to improvement and MCR in conventionally treated LN patients. Those with damage and active non-renal disease were less likely to improve at 6 months. Baseline low C4 increased MCR likelihood at 12 months. These factors may help stratify patients based on likelihood of response and help select patients who may need alternative treatment strategies.

Fig 1: Effects of Obexelimab Treatment on Time to Flare in SLE Patient Subsets Defined by Patterns of Gene Co-Expression Pathways

Disclosure of Interests: Stephen McDonald: None declared, Sean Yu: None declared, Li Su: None declared, Caroline Gordon Grant/research support from: Genzyme Sanofi, GSK, and UCB, Consultant of: Eli Lilly, AstraZeneca, currently by Aurinia Pharmaceuticals, Ian N. Bruce Grant/research support from:课题组，Employee of: Employed Shareholder of: Aurinia Pharmaceuticals, Inc. stock, Employee of: Employed.

Background: We recently reported Phase 2 SLE trial results of obexelimab, an FcγRIIB agonist (suppressor of B cell activation). Obexelimab did not meet the primary endpoint (% of patients without flare at Day 225) (p=0.183) but other endpoints such as time to flare (p=0.025) were met.

Objectives: 1. To assign SLE patients to phenotypic subsets based on patterns of gene expression in immune-related pathways.2 2. To explore the association of immune patterns and clinical response to obexelimab.

Methods: This analysis included 71 of the 104 participants in the obexelimab study, those who either completed the protocol or terminated for disease flare, if there were adequate blood samples (biomarker subset). At screening, patients were assigned to clusters based on 41 SLE co-expression signature modules from the Human Immune Phenotyping Consortium via unsupervised random forest and K-means clustering. Other markers of SLE disease were also examined. The BOLD study design mandated withdrawal of background immunosuppressants, supporting less ambiguous pharmacodynamic analysis as the trial progressed.

Results: Immune pathway expression patterns of 7 patient clusters (Fig 1a) confirmed our prior characterization of 200 non-overlapping SLE patients. The biomarker subset retained a trend of longer time to first flare in patients receiving obexelimab (n=38) vs placebo (n=33) (Fig1b, HR 0.61, p=0.11). A smaller set of only Clusters 3 and 6 demonstrated marked increased time to flare in the obexelimab group (n=13) compared to placebo (n=14) (Fig 1c, HR 0.22, p=0.025). Obexelimab had no effect on other clusters (Fig 1d). The responder clusters shared low expression of inflammation modules (p < 0.001) compared to other clusters and high expression of T Cell, immune response, cell cycle, mitochondrial modules (all p < 0.001) and B Cell modules (p=0.006). We therefore sorted patients by these specific features regardless of cluster assignment. Figure 2 shows significant impact of obexelimab on time to flare in 64 patients with B Cell pathway activation (HR 0.5, p=0.038), although less robust by itself than found in Clusters 3 and 6. In a group with high B or plasma cell modules but low inflammation (n=46), treatment effect increased (HR 0.35, p=0.019). Between Screening and Baseline, as brief steroids were given and background treatments withdrawn, expression of B Cell and Plasma Cell pathways increased. Both then decreased after treatment with obexelimab but not placebo (p< 0.0001 and p< 0.001 respectively), an effect not seen with other immune pathway modules.

Conclusion: Precision medicine for SLE has been hampered by heterogeneous immune signals with variable expression. Clustering of patients by gene co-expression pathways enabled an efficient, hierarchical array that reduplicated results of a prior SLE cohort, suggesting these are not random phenotypes. Of these 7 reproducible SLE subsets, the combination of clusters 3 and 6 distinguished an obexelimab responder population of 27 out of 71 subjects (38%) with high expression of B and T Cell modules and cell activation pathways. Focus on the defining features shared by these clusters revealed specific factors associated with response, enabling inclusion of some patients from other clusters in an optimized responder population of 46/71 (65% of subjects). B Cell and Plasma Cell pathways demonstrated mechanism-related pharmacodynamic effects of obexelimab. Lack of responders with high expression of inflammation modules could implicate inhibitory factors to obexelimab within inflammatory pathways, potentially targetable by complementary treatments.

SAT0188 HIGH-DOSE STEROIDS ARE IMPORTANT CONTRIBUTORS TO THE INFECTION BURDEN OF PATIENTS WITH LUPUS NEPHRITIS

A. Vornicu1, B. Obrisca1, R. Jurubita1, B. Sorohan1, A. Andronesi1, C. Achim1, E. Rusu1, D. Zilisteanu1, G. Ismail1, Fundeni Clinical Institute, Nephrology Department, Bucharest, Romania

Background: Infection remains a major cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE) and lupus nephritis (LN) treated with systemic immunosuppression (IS).

Objectives: We sought to describe the infection profile in patients with LN treated with aggressive immunosuppression (induction and maintenance therapy) and to identify the associated risk factors.

Methods: Patients with LN followed in the Nephrology Department of Fundeni Clinical Institute were retrospectively reviewed for any infection that occurred from initiation of induction therapy. Infections were graded (1-5) according to the Common Terminology Criteria for Adverse Events. Infection site and type of microorganism were also recorded. Univariate and multivariate Cox proportional hazard regression analysis were performed in order to identify independent risk factors for infection.

Results: The study cohort comprised 101 patients (86.1% females) with a mean age of 34 ± 14 years. Forty-eight patients (47.5%) had at least one infection with a total 92 episodes of infection occurring during a median follow-up of 17 months (IQR: 6.5-2.5 months). The majority of patients (31 of 48) had infections during the first 12 months since IS treatment initiation. The most common site was lung infection (in 24.8% of patients), followed by urinary tract (20.8% of patients), skin (16.7% of patients), eye (9.1% of patients), and bone (6.2% of patients). The majority of infections were due to bacteria (81.4%), with 44.6% of patients receiving pulse methylprednisolone (95% CI, 2.4-28.77, p=0.001) as risk factors for infection. After multivariate adjustment, neurological involvement (HR 4.33; 95% CI, 1.29-14.51, p=0.01), and high-dose oral corticosteroids (HR 7.6; 95% CI, 1.6-35.39, p=0.01) were identified as independent predictors of infection risk.

Conclusion: A high-dose oral corticosteroid regimen increased the risk for any infection and for severe infections by 4.7-fold and 7.6-fold, respectively. In addition, female gender and a higher SLEDAI score were identified as risk factors for any infection, while neurological involvement was associated with an increased risk for severe infections.

Disclosure of Interests: None declared

SAT0189 SAMPLE SIZES AND RECRUITMENT RATES ARE DECREASING WHILE PLACEBO RESPONSE RATES ARE INCREASING IN CLINICAL TRIALS FOR SYSTEMIC LUPUS ERYTHEMATOSUS - A MANDATE FOR NEW STRATEGIES

E. Olech1, E. Van Rijen1, F. Hussain1, G. Dennis1, A. Ashrafzadeh1, J. T. Merrill1, 1IQVIA, Rheumatology Center of Excellence, San Diego, 2Oklahoma Medical Research Foundation, Oklahoma City, United States of America

Background: Randomized controlled trials in Systemic Lupus (SLE) have shown disappointing results for decades. Key challenges may include the homogeneous population coupled with high placebo response rates.

Objectives: To evaluate trends in SLE study metrics over time and explore associations between primary endpoint failure and response in placebo/standard of care arms.

Methods: Data from Phase II or III trials which enrolled ≥ 100 patients with SLE and reported SRI-4 and/or BICLA responses after a minimum of 24 weeks were included in the analysis. Sample size, recruitment rates, regional patient distributions, and results in placebo arms (at 24-36 weeks or 48-52 weeks) were examined according to the start date of each study in order to determine trends over time. Placebo group SRI-4 response rates in studies that met their primary endpoint were compared with those that did not.

Results: Twenty-seven (14 phase II and 13 phase III) studies met the search criteria. Eleven of them met their primary endpoints. The study start dates ranged from Dec 2006 to Jan 2017. Mean/median total subject numbers were 461/349. Mean/median placebo subjects’ age at baseline were 39.9/39.2 and SLEDAI: 10.6/10.6. Mean/median placebo SRI-4 responses at Week 24-36 were 47.2%/45.8% and 42.8%/43% at Week 48-52. For BICLA, the rates were 40.3%/37.2% at Week 24-36 and 33.2%/33.5% at Week 48-52.

As expected, lower placebo response was found in trials that met primary endpoints vs studies that did not (p<0.005). Total subject numbers and recruitment rates decreased over time while placebo SRI-4 response rates increased overall (Figure). However, there has been a greater range of placebo responses in more recent trials. Similar trends were observed in BICLA responses at Week 24-36 and 48-52, and in a corticosteroid reduction endpoint (percent of patients with reduction in steroid dose by ≥25% and to ≤7.5 mg/day prednisone/ equivalent) at Week 48-52.

Conclusion: High placebo response rates pose a continuing challenge in SLE studies and are associated with primary endpoint failures. Clinical trial metrics have been changing over time, with declining size and recruitment rates, possibly due to competition from increasing numbers of studies.

Figure.
These trends should be considered while designing and conducting future trials. Attention to site training and data quality may be particularly important to control high placebo rates, especially as trial sizes decrease.

**SAT0190**

**CORTICOSTEROID AND OPIOID USE REMAIN HIGH IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS RECEIVING BIOLOGIC THERAPY: A RETROSPECTIVE CLAIMS DATABASE ANALYSIS**

J. Birt1, J. Wu1, K. Griffin1, N. Bello Vega1, N. Princic2, I. Winer2, C. Lew2, K. Costenbader2, Eli Lilly and Company, Indianapolis, United States of America; 2IBM Watson Health, Cambridge, United States of America; 3Brigham and Women’s Hospital and Harvard Medical School, Boston, United States of America

**Background:** SLE is managed by variable combinations of five drug classes: antimalarials, biologics, corticosteroids, non-steroidal anti-inflammatory agents, and immunosuppressants. Opioids are commonly prescribed to SLE patients despite not being effective for the management of long-term musculoskeletal pain.1

**Objectives:** To describe corticosteroid and opioid use among SLE patients in the United States, and the impact of belimumab initiation on prescribing patterns.

**Methods:** This retrospective study used MarketScan administrative claims databases to select insured adults, age ≥18, with a diagnosis (ICD-9: 710.0 & M32) of SLE between 1/1/2012 and 5/31/2018 (earliest SLE diagnosis = index date). Patients were followed from index through the earliest of health plan disenrollment or 5/31/2019 (minimum of 12 months). Corticosteroid use was measured in the 12 months following SLE index date. Average daily dose of oral corticosteroids in prednisone equivalents was measured for 12 months after corticosteroid initiation. Opioid use was measured overall, and by strength and length of treatment (chronic use defined as ≥90 days of supply). Oral corticosteroid and opioid use were compared in the 6 months before and after initiation of belimumab.

**Results:** Of 49,415 SLE patients eligible for analysis, mean [SD] age was 50.1 [14.0] years, 90.2% were female, and average follow-up was 3.6 [19] years. 89.8% of patients received any SLE treatment and 68.5% received corticosteroids. The average number of corticosteroid prescriptions was 4.6 [4.1] during 12 months of follow-up. 52.6% of patients had ≥1 claim for an opioid prescription in the 12 months after SLE index and 34.6% were identified as having chronic opioid treatment. Among patients with oral corticosteroid treatment and 12 months of study enrollment post-corticosteroid initiation, the average daily dose for oral corticosteroids was 19.4 [14.2] mg and average daily dose decreased by 9.1% (p=0.001), average daily dose decreased with oral corticosteroid treatment and 12 months of study enrollment post-corticosteroid initiation, the average daily dose for oral corticosteroids was 19.4 [14.2] mg and average daily dose decreased by 9.1% (p=0.001), average daily dose decreased with oral corticosteroid treatment and 12 months of study enrollment post-corticosteroid initiation.

**Conclusion:** These results suggest that a strikingly high proportion of patients with SLE are treated with corticosteroids to control the disease and opioid therapy to manage chronic pain. While there was no change in opioid use, corticosteroid use decreased following initiation of belimumab.

**SAT0191**

**PLASMA PROTEOMICS IDENTIFIES A PROTEIN SIGNATURE ASSOCIATED WITH RESPONSE TO RITUXIMAB IN PATIENTS WITH SLE**

J. Reynolds1, J. Prattley2, M. Lunt3, I. Bruce4, #University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom; #Sandwell and West Birmingham Hospitals NHS Trust, Rheumatology Department, Birmingham, United Kingdom; #University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; #Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom

**Background:** Rituximab (RTX) is B cell-depleting biological therapy used in the treatment of systemic lupus erythematosus (SLE). Response rates are typically around 50% and there are currently no robust biomarkers to identify which patients are more likely to respond.

**Objectives:** To determine whether proteomic analysis of baseline plasma samples could identify novel biomarkers of response to RTX in patients with active SLE.

**Methods:** Patients with SLE (≥ 4 ACR criteria) receiving RTX for active disease (BILAG A or B BILAG B scores) from the UK-based BILAG-BR register were included. Improvement at 12 months was defined as a reduction to ≤ 1 BILAG B score with no increase in either SLEDAI score or steroid dose. Proteomic analysis was performed on baseline plasma samples using sequential window acquisition of all theoretical fragment ion spectra mass spectrometry (SWATH-MS). Data were aligned and normalised to give relative protein abundance. A Lasso penalised logistic regression, with an outcome of improvement at 12 months, was used to perform the variable selection procedure using the R package glmnet. The penalty parameter was set at the value which minimised deviance in a 10-fold cross-validation procedure. Confounding variables of sex, age, ethnicity, oral steroid dose, and SLEDAI score had no penalty applied and were thus forcibly retained in the model. Protein-protein interaction networks were visualised using STRING v11.0.

**Results:** 70 patients of whom 63/70 (90%) were female with a median (IQR) age of 41 (32, 51) years and disease duration of 11 (6, 20) years at baseline were included. Patients had active disease with a median SLEDAI score of 10 (6, 16). All patients received RTX according to NHS England guidelines. Of 829 proteins, 815 were detected in at least 1 patient. We identified 9 proteins which were associated with clinical improvement at 12 months. A literature search identified that these proteins have relevance to T cell function, complement activation and lupus nephritis. Gender had the greatest weight in the model followed by Serpin Family A Member 10 (SERPINA10) and complement factor B (CFB). Protein interaction networks linked SERPINA10 to CFB by C3 complement (figure).

**DOI:** 10.1136/annrheumdis-2020-eular.1326
Conclusion: Plasma proteome analysis has identified a protein signature associated with response to RTX in SLE. These findings will be validated in independent cohorts and may offer the ability to predict response to RTX in lupus patients.

SAT0193

A PHASE 3, OPEN-LABEL, CONTINUATION STUDY EVALUATING LONG-TERM SAFETY AND EFFICACY OF BELIMUMAB IN PATIENTS FROM JAPAN AND KOREA WITH SYSTEMIC LUPUS ERYTHEMATOSUS, FOR UP TO 7 YEARS

Y. Tanaka1, S. C. Bae2, D. Bass3, M. Chu4, P. Curtis5, K. Derose3, B. Ji5, R. Kurrasch7, J. Lowe7, P. Meizlik2, D. Roth3, 1University of Occupational and Environmental Health, Kitakyushu, Japan; 2Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Rep. of (South Korea); 3GlaxoSmithKline, Collegeville, United States of America; 4GlaxoSmithKline, Uxbridge, United Kingdom

Background: Systemic lupus erythematosus (SLE) is an autoimmune disorder more prevalent in the Asian population vs Caucasians. Belimumab (BEL), a monoclonal antibody targeting B-lymphocyte stimulator, is approved in patients (pts) ≥5 years with active, autoantibody-positive SLE.

Objectives: Evaluate long-term safety and efficacy of intravenous (IV) BEL + standard SLE therapy (SST) in pts with SLE in Japan/Korea.

Methods: In this Phase 3, multicentre, open-label (OL) study (BEL114333; NCT01597622), eligible (≥18 years of age) completers (≥5 years with active SLE) were randomised to receive either IV BEL 10mg/kg IV weekly or IV placebo (Pbo) weekly for 7 years. Safety and efficacy were monitored at 12-month intervals.}

plus SST. Primary endpoints: safety assessments. Key secondary endpoints: SRH4 response rate at each scheduled visit (observed data), defined as a ≥4-point reduction from baseline in SELENA-SLEDAI score, no worsening in PGA (<0.5-point increase from baseline) and no new BIAlg1A2B organ domain scores; time to first severe SFI flare over time. Endpoints were analysed relative to first BEL dose (parent or current study). No follow-up data were collected after study withdrawal.

Depression/Suicide/cide/self-injury

1 Death from an AE of endocarditis that began ~1 month after the exit visit; the investigator considered it to be unrelated to the study drug

2 No serious suicide/self-injury AEs were reported during the study

Results: Overall, 142 pts were enrolled (Japan n=72; Korea n=70), 104 (73.2%) completed the study, 1 (0.7%) died and 37 (26.1%) withdrew. Overall, 139 (97.9%) pts had ≥1 adverse event (AE) (Table). Most frequent AEs included: nasopharyngitis (60.6%); headache (28.2%); cough, herpes zoster and viral upper respiratory tract infection (18.3%) each. Serious AEs (SAEs) occurred in 48 (33.8%) pts. Most common SAEs were infections and infestations, reported in 24 (16.8%) pts (Table). During this study, the annual incidence of AEs, including SAEs and AEs, remained stable or declined, with no trends of clinical concerns regarding the incidence of Grade 3 or 4 values for laboratory parameters. There was 1 transient positive immunogenicity result of no clinical concern.

The proportion of SRH responders was 478% at Year 1 (Week 24) and tended to increase numerically up to 84.6% at Year 7 (Week 48). The proportion of pts with a ≥4-point decrease from baseline in SELENA-SLEDAI score numerically increased from 51.5% at Year 1 (Week 24) to 84.6% at Year 7 (Week 48). Proportion of pts with no PGA worsening was 91.3-100.0% and the proportion with no new BIAlg1A2B organ domain scores was 93.3-100.0% up to Year 7 (Week 48). A total of 21 (14.8%) pts had 24 severe SFI flares.

Conclusion: BEL was well tolerated as add-on therapy to SST for ≤7 years in pts with SLE from Japan/Korea. Safety results were consistent with the known safety profile. Study funding: GSK.

SAT0194

LACK OF EFFICACY OF RIVAROXABAN IN THE TREATMENT OF ANTIPHOSPHOLIPID SYNDROME AND CLINICAL SIGNIFICANCE OF ANTIPHOSPHOLIPID ANTIBODIES

Background: Chronic anticoagulation with vitamin K antagonists (VKA) is the standard treatment to prevent thrombotic events in antiphospholipid syndrome (APS). But in recent years treatment schemes began to include rivaroxaban. Use of direct oral anticoagulants (DOAC) is an attractive and often preferred alternative to VKAs in other medical settings owing to greater ease of use, fewer food and drug interactions, and lower bleeding risks [1]. However, according to last guidelines, rivaroxaban should not be used in patients with triple aPL positivity due to the high risk of recurrent events [2].

Objectives: To determine the risk of recurrent thrombosis in single or double positive APS patients treated with rivaroxaban.

Method: 33 patients with confirmed APS (25 female (75.8%), 8 male (24.2%), mean age 43.2±11.6 years) were included in the study. 17 (51.5%) of investigated patients had primary APS, in remaining 16 (48.5%) APS was included in the framework of SLE. 18 (54.5%) patients were treated with warfarin 2.5-7.5 mg/daily, 15 (45.5%) patients with rivaroxaban 20mg/daily for a follow-up period of 12 months. The data is introduced as odds ratios (OR) with 95% confidence interval (CI). The results were considered significant when p<0.05.

Results: At baseline 21 (63.6%) patients had history of arterial thrombosis, 10 (30.3%) venous thrombosis, 17 (51.5%) - pregnancy loss. According to results of serum immunology check, 29 (87.9%) patients were anticardiolipin antibody (ACA) positive, 9 (27.3%) - LA positive, 19 (57.6%) - anti-2g-glycoprotein antibodies (anti-2g-gp) positive; 20 (60.6%) patients were double positive (12.4%) of them had positive ACA and anti-2g-gp, 6 (18.2%) - ACA and LA, and 2 (6.1%) - anti-2g-gp and LA, 4 (12.1%) patients were triple positive.

No association between vascular event and/or pregnancy loss in patients with single positive ACA was found. We have found positive association between arterial thrombosis and single positive anti-2g-gp (OR 95% CI = 9.4/3.2 – 105.8/, p<0.04). Recurrent thrombosis was detected in 16 patients; 2 patients (12.5%) were on warfarin, 14 (87.5%) - on rivaroxaban (10 (71.4%) arterial thrombosis, 4 (28.6%) venous thrombosis). No association between warfarin 2.5-7.5mg/daily and occurrence of recurrent thrombosis was detected. An association between use of warfarin and increased risk of bleeding was found, but the risk was not significant (OR /CI 95% = /0.06 /0.03 – 0.1/, p<0.01).

Conclusion: Rivaroxaban does not prevent recurrent thrombosis not only in triple positive patients (p<0.02), but also in double positive patients (OR /CI 95% = 9.4/3.2 – 105.8/, p<0.04).

SAT0195

ABNORMITY TFH SUBSETS INDICATE DISEASE ACTIVITY WHILE SIROLIMUS THERAPY RESTORES THE PD-1+ CD27+ TfhACTIVATED TFR BALANCE IN PRIMARY SJOGRÉN’S SYNDROME PATIENTS

Y Wang1, J Luo2, C Gaoo3, X.C. Zhao4. 1 The Second Hospital of Shanxi Medical University Taiyuan, China; 2 Brigham and Women’s Hospital, Boston, United States of America

Background: Immune imbalance between follicular helper T (Thf) cells and follicular regulatory T (Tfr) cells is a characteristic of primary Sjogren’s syndrome (pSS) [1]. The heterogeneity among Thf and Tfr can be elucidated by separating them into different subsets based on the expression molecular characteristics. Objectives: The aim of this study was to investigate the role of Thf and Tfr subsets, and to evaluate the effects of sirolimus on these cells.

Methods: In this study, we enrolled 51 pSS patient and 26 healthy controls (HCs), and analyzed the frequencies and absolute counts of circulating Thf and Tfr subsets, and serum levels of cytokines. Within these patients, analyses of above T
Background: ALPN-101 (ICOSL vIgD-Fc) is an Fc fusion protein of a human inducible T cell costimulatory ligand (ICOSL) variant immunoglobulin domain (vIgD™) designed to inhibit simultaneously the CD28 and ICOS inflammation pathways (1). ALPN-101 is under clinical development for the treatment of multiple rheumatic and other inflammatory diseases.

Methods: This was a first-in-human study of ALPN-101 (NCT03748836). 72 HV CLASS DUAL ICOS/CD28 ANTAGONIST, IN HEALTHY VOLUNTEERS (HV) patients (18 to 55 years) were allocated 6:2 to repeated IV doses of up to 1 mg/kg weekly x 4. Subjects were followed for 28 (SAD) or 49 (MAD) days to assess safety, PK, target saturation (TS) and PD changes on circulating CD4+ T lymphocytes.

Results: ALPN-101 was generally well-tolerated, with no treatment related serious adverse events, no cytokine release, no clinical immunogenicity, and no adverse events reported as dose-limiting. Dose-dependent PK, TS and PD including the inhibition of antibody responses to KLH immunization. These findings support future studies to evaluate the efficacy of ALPN-101 in multiple rheumatic and other inflammatory diseases.

SAT0196

A DOUBLE BLIND, PLACEBO CONTROLLED, SINGLE ASCENDING DOSE (SAD) AND MULTIPLE ASCENDING DOSE (MAD) STUDY OF ALPN-101, A FIRST-IN-CLASS DUALICOS/CD28 ANTAGONIST, IN HEALTHY VOLUNTEERS (HV)

J. Yang1, J. Hillson1, J. Lickliter2, K. Manjarrez3, A. Tercero1, J. Wiley1, G. Means1, R. Sanderson1, K. Carley1, S. L. Peng1.1Alpine Immune Sciences Inc, Seattle, United States of America; 2Nucleus Network, Melbourne, Australia

Background: ALPN-101 (ICOSL vIgD-Fc) is an Fc fusion protein of a human inducible T cell costimulatory ligand (ICOSL) variant immunoglobulin domain (vIgD™) designed to inhibit simultaneously the CD28 and ICOS inflammation pathways (1). ALPN-101 is under clinical development for the treatment of multiple rheumatic and other inflammatory diseases.

Objectives: To evaluate the safety, pharmacokinetics (PK), and pharmacodynamics (PD) of ALPN-101 in HV patients.

Methods: This was a first-in-human study of ALPN-101 (NCT03748836). 72 HV patients (18 to 55 years) were allocated 6:2 to repeated IV doses of up to 1 mg/kg weekly x 4. Subjects were followed for 28 (SAD) or 49 (MAD) days to assess safety, PK, target saturation (TS) and PD changes on circulating CD4+ T lymphocytes, the latter based on suppression of IgG responses to keyhole limpet hemocyanin (KLH).

Results: ALPN-101 was generally well-tolerated, with no treatment related serious adverse events, no cytokine release, no clinical immunogenicity, and no adverse events reported as dose-limiting, TS of circulating CD4+ lymphocytes

DOI: 10.1136/annrheumdis-2020-eular.2388

Figure 1. Mean ± SD Target Saturation of ALPN-101 on Circulating CD4+ T Lymphocytes

Figure 2. Mean ± SD Serum Anti-KLH IgG Change Relative to Baseline

Conclusion: ALPN-101 was well tolerated when administered as single doses up to 10 mg/kg or as repeated doses of up to 1 mg/kg weekly for 4 weeks, exhibiting dose-dependent PK, TS and PD including the inhibition of antibody responses to KLH immunization. These findings support future studies to evaluate the efficacy of ALPN-101 in multiple rheumatic and other inflammatory diseases.
SAT0197
NON MYOCARDIAL CARDIAC INVOLVEMENT IN ANTIPHOSPHOLIPID SYNDROME IN A SPANISH REFERENCE CENTER
A. Robles Marhuenda1, J. Álvarez Troncoso1, A. De Gea Grela1, G. Daroca Bengoa1, L. Ramos Ruperto1, A. Díez Vidal1, J. J. Rios1, C. Soto Abánades1, E. Martínez Robles1, A. Noblejas Mozo1, F. Arnalich Fernández1, 21Hospital Universitario La Paz, Department of Internal Medicine, Madrid, Spain

Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disease, associated with a hypercoagulable state and fetal loss and with other clinical manifestations including cardiac involvement. APS occurs as a primary disorder (PAPS) or secondary to another autoimmune disease (SAPS). Due to its vascular nature, various organs and tissues may be affected, including the cardiac system. Cardiac manifestations of APS are valve abnormalities (valve thickening and vegetations), occlusive arterial disease (atherosclerosis and myocardial infarction) and pulmonary hypertension (PH).

Objectives: To assess the prevalence of non-myocardial involvement (valvulopathy and pulmonary hypertension) in a cohort of patients with antiphospholipid antibodies (aPLs).

Methods: Retrospective observational study in a Spanish reference center for systemic autoimmune diseases. All patients with aPLs and performed transthoracic echocardiogram (TTE) were included in the study. Patients were divided between PAPS, SAPS and aPLs carriers. A cohort of 50 patients with systemic lupus erythematosus (SLE) without aPLs was used as a control. Anti-cardiolipin, anti-B2GPI and lupus anticoagulant antibodies were determined by standard techniques.

Results: A total of 220 patients were reviewed. 145 (65.9%) were female. The mean age was 42 years. Among all patients with aPLs, 102 were PAPS, 73 SAPS, and 45 asymptomatic carriers (silent APS). Patients with aPLs, unlike patients with SLE without aPLs, presented more often pathological TTE (114 patients, 52%) (p = 0.02), with more valvular involvement (87, 39%) (p = 0.005) and pulmonary hypertension (21, 9.5%, p = ns). Valve involvement was identified in 99 patients: 45 in PAPS, 27 in SAPS, 14 in aPLs carriers and 13 in the SLE without aPLs, these differences being statistically significant (p = 0.002). Valvulopathy was asymptomatic in the majority of patients but required valve replacement in two patients. Mitral valve was the most affected, especially in the form of insufficiency (57%), followed by aortic valve, combined mitral and aortic valve, and less frequently the pulmonary valve alone (3 cases).

</tbody>
</table>

Conclusion: Subclinical valve involvement was very common in patients with APS. There was no correlation with other clinical manifestations of APS nor were other risk factors identified. PH was less frequent than valvular involvement in patients with APS. However, despite not being statistically significant, close to 10% of patients with APS had PH compared to 6% of patients without APS.

Every patient with APS should have an echocardiogram in the initial study protocol in order to rule out both valvulopathy and pulmonary hypertension. This could modify the patient’s management both in the short and long term, as well as the prognosis.

SAT0198
PROBABILITY OF PULMONARY HYPERTENSION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ACCORDING TO ESC GUIDELINE 2015
H. Baharuddin1, N. F. Abdul Mana2, Z. Ismail3, K. S. Ibrahim4, M. Mohd Zaini1, S. S. Ching5, 1Universiti Teknologi MARA, Department of Internal Medicine, Rheumatology Unit, Selangor, Malaysia; 2Universiti Teknologi MARA, Department of Internal Medicine, Selangor, Malaysia; 3Universiti Teknologi MARA, Department of Public Health & Preventive Medicine, Selangor, Malaysia; 4Universiti Teknologi MARA, Department of Internal Medicine, Cardiology Unit, Selangor, Malaysia; 5Hospital Selayang, Rheumatology Unit, Selangor, Malaysia

Background: The prevalence of pulmonary hypertension (PH) in systemic lupus erythematosus (SLE) varied according to the definitions and investigations used. Echocardiography should always be performed when PH is suspected, based on symptoms and signs, which may be difficult to be assessed in patients with SLE because early symptoms of PH, including shortness of breath, fatigue, weakness, angina and syncope can be part of disease manifestation.

Objectives: To investigate the probability of PH in patients with SLE based on 2015 ESC Guideline, regardless of symptoms.

Methods: A cross-sectional study was conducted in a rheumatology centre in Malaysia which included patients aged 18 years and above, who fulfilled SLICC2012 criteria. Exclusion criteria were diagnosis of overlap syndrome and pregnancy. Demographic data and immunology profile were obtained from electronic medical records. TTE was performed by one technician who was blinded to other clinical details. Low, intermediate or high probability of PH was determined based on 2015 European Society of Cardiology (ESC) echocardiography criteria of PH.

Results: A total of 60 patients with SLE were recruited. The mean age was 41.6±10.9 years and SLE disease duration was 11.5±9.4 years. The cardiovascular co-morbidities were hypertension (38.3%), dyslipidaemia (25%), diabetes mellitus (5.0%) and ischemic heart disease (1.6%). Based on 2015 ESC echocardiography criteria for PH, 50 (83.3%) patients had low probability of PH, 8 (13.3%) had intermediate probability of PH and 2 (3.3%) with high probability of PH. (Table 1). Further analysis revealed that two patients with high PH probability were asymptomatic at the time of study. They were treated for active SLE after PH was diagnosed from TTE performed within a year of study period and subsequent RHC confirmed pulmonary artery hypertension (PAH). Among patients with SLE, 14 (23.3%) patients showed clinical manifestations of PH (low, intermediate, high), therefore there is high likelihood that SLE patients are prone to PH. PH manifestations were seen in 22 (36.7%) patients, with pulmonary hypertension, valvular involvement, subclinical valve involvement being very common in patients with APS. However, despite not being statistically significant, close to 10% of patients with APS had PH compared to 6% of patients without APS.

Table 1. The details of echocardiographic signs of PH in patients with SLE.

<table>
<thead>

patients with intermediate probability of 
PH, one patient had intermittent palpita- 
tion and chest pain, while others were asymptomatic including one patient with 
PAH based on RHC. The most prevalent auto-antibodies among patients with 
intermediate and high probability of PH were anti-Ro (8 patients), anti-nuclear 
antibodies (7 patients) and anti-dsDNA (5 patients).

**Conclusion:** We found 16.6% patients with SLE who had intermediate and 
high probability of PH, based on 2015 ESC echocardiography criteria for PH. 
All except one patient had symptoms suggestive of PH at the time of study. 
RHC performed subsequently on two patients with high PH probability con-
firmed PH.

**SAT0199 PARTICULARITIES OF SJÖGREN SYNDROME IN 
ELDERLY PATIENTS**

I. Naceur1, R. Abida1, T. Ben Salem1, F. Said1, M. Khairi2, I. Ben Ghorbel1, 
M. Lamioun1, M. H. Houman.1 Faculty of Medicine, Tunis-El Manar University, 
Internal Medicine, Rabta university Hospital, Tunis, Tunisia

**Background:** Sjögren syndrome (SS) is a systemic autoimmune disease mainly 
described in females at a peak incidence age of 50. It was suggested that elderly 
onset of disease has particular clinical and biological phenotype.

**Objectives:** The aim of our study is to determine the particularities of SS in 
elderly patients.

**Methods:** Data of 332 patient fulfilling the American European Consensus 
Group criteria for Sjögren’s syndrome over a period time of 18 years were stud-
ied. Clinical and biological features of elderly patients (G1) were described and 
compared to those of patients aged below 65 years old (G2) using the X2 and 
Fishers test.

**Results:** A total of 35 elderly were retained: 33 females and 2 males. The mean 
age of disease onset was 68.8 ± 4.4 years. The average delay (from first sign of 
the disease to diagnosis) was 1.27 years. The mean age at diagnosis was 70.3 
± 4.7 years. Xerostomia was described by 33 patients (94.3%). Focus score in 
the minor labial salivary glands pathology was ≥ 1 in 32 patients (91.4%). Two 
patients had abnormalities in parotid scintigraphy. Xeropthalmia was described 
in 20 cases (57.1%) and Break Up Time test was altered in 20 cases (57.1%). 
Arthralgia was the most frequent extra-glandular manifestation reported in 
74.3% of patients. Fatigue was noted in 12 patients. The other systemic manifesta-
tions were: intermittent extra-glandular manifestation reported in 74.3% of patients.

**Discussion:** We found that elderly patients had lower frequency of SS, 
mainly described in females at a peak incidence age of 50. It was suggested that 
elderly onset of disease has particular clinical and biological phenotype.

**Disclosure of Interests:** None declared

**SAT0200 RISK FACTORS FOR ADVERSE PREGNANCY 
OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS 
PATIENTS**

G. Çetin1, T. Saraç-Sivrizzo2, M. Ateş-Tikuz2, E. S. Torun1, A. Ersöy1, 
Y. Yuğrinoğlu2, A. Gür1, M. Iranc1, M. L. Ocak1, I. Kalellogil1, B. Arslan-
Esen1.1 Istanbul Faculty of Medicine, Rheumatology, Istanbul, Turkey; 2Istanbul 
Faculty of Medicine, Obstetrics and Gynecology, Istanbul, Turkey

**Background:** Pregnancies of patients with systemic lupus erythematosus (SLE) 
can be risky both for the mother and the fetus because of disease activity and 
pregnancy complications.1

**Objectives:** In this study, we evaluated the risk factors related to adverse 
pregnancy outcomes (APO) in our pregnant SLE cohort who were followed up by both 
Rheumatology and Obstetrics and Gynecology departments at our university.

**Methods:** 168 pregnancy data were analyzed from 136 patients who fulfilled 
ACR classification criteria for SLE. The course of pregnancies were monitored 
and fetal/neonatal outcomes were recorded. Unexplained fetal death after 12 
weeks of gestation, neonatal death, preterm birth due to preeclampsia, eclamps-
ia or HELLP and birth of small for gestational age (SGA) infant were defined as 
APO. Cumulative clinical, laboratory and serological findings, disease activity 
(SLEDAI-2K) and damage (SLICC/ACR), and conventional risk factors were 
compared between APO(+) and APO(-) groups.

**Results:** The comparison of demographics, conventional risk factors and dis-
ease characteristics in APO(+) and APO(-) groups are summarized in Table-1. In 
APO(+) pregnancies, the duration of disease was longer (p <0.05) and the 
frequency of chronic hypertension was higher (p <0.05) compared to APO(-) 
pregnancies. Renal and neuropsychiatric (NP) involvement, thrombocytopenia, 
antiphospholipid syndrome (APS), lupus anticoagulant and anti-cardiolipin IgM 
positivity were significantly higher in APO(+) group. Mean SLEDAI-2K scores of 
three trimesters and postpartum 6 months were higher in APO(+) patients 
compared to APO(-) patients (2.2 ± 3.6 vs 1.2 ± 2.04, p < 0.05; 4.9 ± 6.03 vs 2.7 
± 5.01, p = 0.02, respectively). Percentage of patients with damage at the begin-
n ing of pregnancy and the mean SLICC damage score were significantly higher in 
APO(+) group compared to APO(-) group (1.8 ± 2.1 vs 0.8 ± 1.3, p < 0.05). In 
APO(+) group, damage was significantly higher in neuropsychiatric, renal and 
cardiovascular and locomotor systems (p < 0.05).

**Conclusion:** Although an important proportion of SLE pregnancies result in 
live birth, active disease, especially renal and NP involvement, and presence 
of damage at the beginning of pregnancy increase the risk of maternal and fetal 
complications. Furthermore, the presence of APS or antiphospholipid antibody 
positivity are important risk factors for obstetric complications. In conclusion, 
pregnancy should be allowed after controlling the disease activity and patients 
should be closely monitored in coordination with Obstetrics and Gynecology clin-
ics. In case of presence of damage, both the patient and the physician should be 
aware of a possible adverse pregnancy outcome.

ASSOCIATION OF CARDIAC TROPONIN T MEASURED WITH A HIGHLY SENSITIVE ASSAY WITH CARDIOVASCULAR EVENTS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (TROPOPLUS STUDY)

J. Chezeli1, N. Costedoat-Chalumeau2, D. Rouzaud1, V. Le Guern1, C. Gobeaux2, N. Morel1, M. Pha3, Z. Amoura3, T. Papo1, K. Sacre1* on behalf of PLUS group. 1Université Paris Diderot, Paris, France; 2Université Paris Descartes, Paris, France; 3Université Pierre et Marie Curie, Paris, France

Background: Mortality is still 2 to 5 times superior in SLE patients as compared to general population and is mainly due to cardiovascular event (CVE). Although cardiovascular traditional risk factors contribute to early-onset atherosclerosis in SLE, the phenomenon is not fully explained by a higher frequency of smoking habits, hypertension, or dyslipidemia and the Framingham risk equation usually underestimates the 10-year cardiovascular risk in this population. Thus, identification of biological markers able to better stratify cardiovascular risks in SLE patients is needed.

Objectives: Our study aimed to determine whether serum cardiac troponin T measured with a highly sensitive assay (HS-cTnT) was associated with CVE in systemic lupus erythematosus (SLE) patients.

Methods: All SLE patients included between 2007 and 2010 in the randomized, double-blind, placebo-controlled, multicenter PLUS trial were retrospectively screened. Patients with no past history of CVE and a follow-up period of > 20 months were included. HS-cTnT concentration was measured using the electrochemiluminescence method on serum collected at PLUS inclusion. The primary outcome was the incident CVE. Factors associated with the primary outcome were identified and multivariate analysis was performed.

Results: Overall, 442 SLE patients (of the 573 included in the PLUS study) were analyzed for the primary outcome with a median follow-up of 110 (IQR: 99-120) months. Among them 29 (6.6%) experienced at least one CVE that occurred at a median of 67 (IQR: 31-91) months after inclusion. Six out of 29 patients had more than one CVE. In the multivariate analysis, dyslipidemia, duration of SLE disease and HS-cTnT were associated with the occurrence of CVE. Kaplan-Meier analysis showed that a concentration of HS-cTnT>4.27 ng/L at inclusion increased by 2.7 (HR 2.7 [1.3-5.6], p=0.0083) the risk of CVE in SLE.

Conclusion: HS-cTnT measured in serum is the first identified biomarker independently associated with incident CVE in SLE patients.

C4 LEVELS AS PREDICTOR OF DISEASE FLARES AND ADVERSE PREGNANCY OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS PREGNANCIES

E. Cirstoiu1, M. C. Gerard1, M. Filippini1, R. Gorla1, M. Fredi1, M. G. Lazzaroni1, M. Taglietti1, C. Nalli1, Z. Amoura3, A. Tincani1, ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 2ASST Spedali Civili and University of Brescia, Obstetrics and Gynaecology Unit, Brescia, Italy

Background: SLE pregnancies have an increased risk of Adverse Pregnancy Outcomes (APO). In clinical practice, low C3 and C4 levels are associated with active disease and, during pregnancy, complement activation products are shown to be associated with APO. APO occurs in 22% of pregnancies: 9 early miscarriages, 4 intrauterine fetal deaths, 3 severe preterm births, 6 PE (gestated in 1 intrauterine fetal death, 1 perinatal death; 2 preterm birth between 34th and 37th weeks and 2 term births). 13 cases (2 renal, 4 articular, 6 cutaneous and 1 neurological) were recorded in 11 (8%) pregnancies.

The mean C3 and C4 levels at each trimester are shown in table 1.

Table 1. C3 and C4 mean levels (mg/dL) at pre-conceptional visit (T0), 1st trimester (T1), 2nd trimester (T2) and 3rd trimester (T3).

Comparison of C3 and C4 mean levels between pregnancies with APO vs without APO: *
- T0, T1, T2, T3: ns; ** T0, T1, T2; T3: ns

Both in pregnancies with and with APO, there was no increase of C3 between the 2nd and the 3rd trimester and of C4 between the 1st and the 2nd trimester.

At preconception, mean levels of C4 were lower in pregnancies with APO compared to those without APO (images 1 and 2); during the 2nd and the 3rd trimesters the mean levels of both C3 and C4 were lower in pregnancies with APO.

In pregnancies with APO, the variation of C4 levels between the 2nd and the 3rd trimester was lower than in pregnancies without APO (-2.7 vs 4.3; p=0.01).

A higher frequency of low C4 was observed at pre-conceptional visit, 1st trimester and 3rd trimester (6/7 vs 25/103 p=0.002; 8/9 vs 56/106 p=0.04; 9/11 vs 33/96 p=0.003) in pregnancies with flare as compared with pregnancies without flares.

Conclusion: In our cohort of prospectively-followed SLE pregnancies, low C4 levels at preconception seems to predict flares during pregnancy. Low increase of C4 levels between the 2nd and the 3rd trimester could predict an APO.

Background: The antiphospholipid syndrome (APS) is defined by the development of venous and/or arterial thromboses, and pregnancy morbidity, in the presence of antiphospholipid antibodies (aPL): lupus anticoagulant, moderate-to-high titer anticardiolipin (aCL) and anti-II2-glycoprotein (aB2GPI). It has been suggested that the incidence of thromboembolic events was significantly higher in the triple positive subjects, and the rate of pregnancy loss was also significantly much higher in double positive subjects (1). On the other hand several studies showed that LAC is more highly associated with thrombosis risk (2).

Methods: The Hopkins Lupus Cohort is a prospective longitudinal cohort of Systemic Lupus Erythematosus (SLE) patients with single LAC positivity versus double and triple positivity in Hopkins Lupus Cohort.

Results: There were 805 patients with a complete profile of 7 antiphospholipid antibodies, with a total of 73417 person months (6118 person years) of follow up. For any thrombosis when compared to patients with LAC positivity only, double positivity had a lower point estimates but statistically not significant (Table 1). The relationship between thrombosis and aPL were adjusted for number of prior aPL assessment.

Conclusion: We found that triple or double positive aPL profiles are not superior to single LAC positivity in their association with any thrombosis in SLE patients.
