EULAR European Congress of Rheumatology

EULAR 2022
1–4 June 2022

Abstracts

The EULAR Journal
Annals of the Rheumatic Diseases publishes original work on all aspects of rheumatology and disorders of connective tissue. Laboratory and clinical studies are equally welcome.
EULAR 2022 Abstracts Reviewers

ABHISHEK, Abhishek (UK)
ABLIN, Jacob (ISR)
ADAMI, Giovanni (ITA)
ALIVERNINI, Stefano (ITA)
ALLAART, Cornelia (NLD)
ALPIZAR-RODRIGUEZ, Deshiré (MEX)
ANTON, Jordi (Spain)
APPEL ESBENSEN, Bente (DNK)
ARAUJO, Filipe (PRT)
ASKLING, Johan (SWE)
ATSUMI, Tatsuya (JPN)
AVCIN, Tadej (SVN)
AYAN, Gizem (CAN)
BACKHOUSE, Mike (UK)
BAERWALD, Christoph (DEU)
BALINT, Peter (HUN)
BASU, Neil (USA)
BELIZNA, Cristina (FRA)
BENAVENT, Diego (Spain)
BENNIT, Sarah (UK)
BERTI, Alvise (ITA)
BERTSIAS, George (GRC)
BILGIN, Emre (Turkey)
BISSET, Hans (NLD)
BLOOM, Em (Turkey)
BLOCKMANS, Daniel (BEL)
BLUEML, Stephan (AUT)
BRUYERE, Olivier (BEL)
BRUCE, Ian (UK)
BRUYERE, Olivier (BEL)
BUKILICA, Mirjana (SRB)
BULTINK, Irene E.M. (NLD)
CAFARO, Giacomo (ITA)
CAILLOTTO, Frederic (FRA)
CAPORALI, Roberto (ITA)
CARDIEL, Mario (MEX)
CARMONA, Loreto (Spain)
CARRON, Philippe (BEL)
CARUBBI, Francesco (ITA)
CASTREJON, Isabel (Spain)
CANETE, Juan D. (Spain)
CHANDRAN, Vinod (CAN)
CHAPMAN, Victoria (UK)
CHAPURLAT, Roland (FRA)
CHIGHIZOLA, Cecilia (ITA)
CHINOY, Hector (UK)
CHRIST, Lisa (CHE)
CID, Maria (Spain)
CIUREA, Adrian (CHE)
CIURTIN, Coziana (UK)
CLARKE, Alex (UK)
COATES, Laura (UK)
CODREANU, Catalin (ROU)
COHEN SOLAL, Martine (FRA)
COHEN, Bernard (FRA)
CONSOLARO, Alessandro (ITA)
COPE, Andrew (UK)
COSTANTINO, Félicie (FRA)
COSTEDOAT-CHALMEAU, Nathalie (FRA)
CROWSON, Cynthia S. (USA)
DAIEN, Claire (FRA)
DE BARI, Cosimo (UK)
DE BENEDETTI, Fabrizio (ITA)
DE COCK, Diederik (BEL)
DE VLAM, Kurt (BEL)
DEANE, Kevin (USA)
DE JACO, Christian (ITA)
DEL GALDO, Francesco (UK)
DEN BROEDER, Alfons (NLD)
DENTON, Christopher (UK)
DIETER, Wiek (DEU)
DIFRESEKELI, Haner (Turkey)
DISTLER, Oliver (CHE)
DOLEZALOVA, Pavla (CZE)
DORIA, Andrea (ITA)
DUFTNER, Christina (AUT)
DUREZ, Patrick (BEL)
DÖRNER, Thomas (DEU)
E. VOLL, Reinhard (DEU)
EATHAKKATU ANTONY, Benny (AUS)
EDWARDS, Christopher (UK)
ELEWAUT, Dirk (BEL)
ELKAYAM, Ori (ISR)
ELS, Mateus (PRT)
ENGLUND, Martin (SWE)
FANOURIAKIS, Antonios (GRC)
FERREIRA, Ricardo (PRT)
FILIPPOU, Georgios (ITA)
FILLATREAU, Simon (FRA)
FINCH, Axel (CHE)
FINZEL, Stephanie (DEU)
FIRINU, Davide (ITA)
FISCHER-BETZ, Rebecca (DEU)
FITZGERALD, Oliver (IRL)
FOELL, Dirk (DEU)
FONTESTS, Francisca (PRT)
FRAGOUILIS, George (GRC)
GAFFNEY, Karl (UK)
GALLOWAY, James (UK)
GARCIA DE YEBENES, Maria Jesus (Spain)
GATTO, Mariele (ITA)
GALLOUX-VIALA, Cecile (FRA)
GENEVA, Stéphane (CHE)
GENSLER, Lianne (USA)

Scientific Abstracts

Welcome Address
EULAR 2022 Abstracts Reviewers

Oral Presentations

OP0001  Addressing the effect of Placebo, Nocebo and Contextual factors in RMDs........ 1
OP0002  Bench to Bedside: The complement system in rheumatic diseases .................. 1
OP0003  Breaking the barriers: gut, lung and skin in arthritis pathogenesis ................... 2
OP0004  Does AI really help me diagnosing RMDs?......................................................... 3
OP0006  Is gender sufficiently studied in RMDs?.............................................................. 4
OP0008–OP0015 Plenary Abstract Session ..................................................................... 5
OP0024–OP0031 AxSpA drug treatment: new and old drugs.......................................... 9
OP0032–OP0039 Clinical aspects in Psoriatic Arthritis ................................................... 17
OP0042–OP0049 From risk assessment to societal outcomes ......................................... 23
OP0050–OP0057 Infection-related and other orphan rheumatic disorders ..................... 29
OP0058–OP0065 Managing chronic pain in RMDs ....................................................... 33
OP0066–OP0073 Modern biological treatment in RA ..................................................... 38
OP0074–OP0081 Adaptive immunity (T cells and B cells) in rheumatic diseases / Innate immunity in rheumatic diseases .............................................................................................................................. 46
OP0082–OP0089 Rheumatoid arthritis - aetiology, pathogenesis and animal models .... 50
OP0090–OP0097 Rheumatoid arthritis - prognosis and prediction ............................... 55
OP0098  The Yin and Yang of scleroderma and vasculitis .............................................. 60
OP0099  Microbiome and SpA ......................................................................................... 65
OP1000–OP1007 The role of the synovial microenvironment during onset and progression of arthritis .................. 65
OP1008–OP1015 Exploring the origin of inflammation in spondyloarthritis ................. 66
OP1016–OP1017 Translational and Clinical Research in Crystal Arthritis ...................... 108
OP1018–OP1019 Vaccination against SARS-CoV-2 ....................................................... 113
OP1020–OP1021 Vessels glowing in the dark .................................................................. 120
OP1022–OP1023 Active Ageing: new perspectives for RMD patients? ......................... 125
OP1024–OP1025 Modern technology for precision medicine ................................. 126
OP1026–OP1027 Rheumatology in Europe ................................................................... 127
OP1028–OP1029 Vaccination in rheumatic diseases with lessons from COVID ........... 127
OP1030–OP1031 sJIA vs AOSD: Two names one disease? What have we learnt so far ... 128
OP1032–OP1033 Autoinflammation over the course of a lifetime .................................. 128
OP1034–OP1035 Challenges of fibromyalgia ............................................................... 129
OP1036–OP1037 Long-COVID ..................................................................................... 130
OP1038–OP1039 Strengths and weaknesses of experimental models: Moving from animals to human clinical trials .......................................................................................................................... 131
OP1040–OP1041 Improving outcomes for children with JIA ........................................... 141
OP1042–OP1043 New developments in OA .................................................................. 146
OP1044–OP1045 Novel etiopathogenic aspects in SLE and Sjögren's syndrome ........ 152
OP1046–OP1047 Osteoporosis ....................................................................................... 157
OP1048–OP1049 Outcome of COVID-19 in Rheumatic Diseases ................................ 161
OP1050–OP1051 Emerging treatment strategies in PsA ................................................. 167
OP1052–OP1053 RA treatment: modern strategies and new molecules ....................... 174
OP1054–OP1055 RA: Clinical aspects and comorbidities - II ........................................ 181
OP1056–OP1057 Recent novelties in SLE/Sjögren and APS? ........................................ 185
OP1058–OP1059 The early bird gets the worm .............................................................. 190
OP1060–OP1061 Sjögren syndrome: from biopsy to lymphoma ..................................... 197
OP1062–OP1063 Crystal arthritis .................................................................................... 199

Poster Tours

POS0001–POS0011 Challenges in measuring and predicting RMDs
POS0012–POS0017 Challenging cases to make you think
POS0018–POS0028 Chronic pain - Mechanisms, epidemiology, and treatment
POS0029–POS0039 Genomics, functional genomics and genetic basis of inflammatory arthritis
POS0050–POS0060 Immunity in Rheumatic Diseases
POS0061–POS0071 Lung involvement in Rheumatic Diseases
POS0072–POS0082 New therapeutic avenues in psoriatic arthritis
POS0092–POS0102 Pathogenesis of SLE, Sjögren's and antiphospholipid syndrome
POS0103–POS0113 Rheumatoid arthritis – prognosis, predictors and outcome
POS0114–POS0123 Systemic lupus erythematosus, Sjögren's syndrome and anti-phospholipid syndrome
POS0124–POS0134 Through the looking glass
POS0135–POS0145 Biomarkers in pathogenesis, monitoring and treatment of rheumatic diseases
POS0146–POS0154 Clinical aspect of spondyloarthritis
POS0155–POS0163 Health services research: scoping the landscape
POS0164–POS0173 Improving our care and understanding of paediatric RMDs
POS0174–POS0182 New insights into the associations of outcomes and biomarkers in OA
POS0183–POS0193 New options in SLE-Sjögren and APS
POS0194–POS0204 Outcome of COVID-19 in patients with rheumatic diseases
POS0205–POS0214 RA comorbidities
POS0215–POS0224 Recent advances in orphan rheumatic diseases
POS0225–POS0233 Remodelling in OA
POS0234–POS0243 Rheumatoid arthritis: JAKi and beyond
POS0244–POS0253 Small vessels on fire
POS0254–POS0264 Vaccination against SARS-CoV-2
POS0265–POS0275 Achy-Breaky vessels
POS0276–POS0285 Advances in Crystal Arthritis
POS0286–POS0295 All you want to know about bDMARDs in RA
POS0296–POS0306 AxSpA: About treatments and outcomes
POS0307–POS0316 Clinical aspects in Psoriatic Arthritis
POS0317–POS0325 Mortality, Co-morbidity and disease burden
POS0326–POS0333 New data on pathophysiology of spondyloarthritis including psoriatic arthritis
POS0334–POS0343 New insights into the management of JIA
POS0344–POS0351 Novel molecular regulators of bone turnover
POS0352–POS0362 Systemic Lupus Erythematosus: monitoring and management
POS0363–POS0373 Telemedicine what does it tell us
POS0374–POS0382 What’s new in scleroderma and myositis?

POSTERS only

POS0383–POS0396 Genomics, genetic basis of disease and functional genomics
POS0397–POS0403 Adaptive immunity (T cells and B cells) in rheumatic diseases
POS0404–POS0406 Innate immunity in rheumatic diseases
POS0407 Osteo arthritis, aetiology, pathology and animal models
POS0408–POS0448 Rheumatoid arthritis - aetiology, pathogenesis and animal models
POS0449–POS0450 Spondyloarthritis - aetiology, pathogenesis and animal models
POS0451–POS0466 SLE, Sjögren's and APS - aetiology, pathogenesis and animal models
POS0467–POS0490 Systemic sclerosis, myositis and related syndromes - aetiology, pathogenesis and animal models
POS0491–POS0494 Vasculitis - aetiology, pathogenesis and animal models
POS0495–POS0497 Basic and translational science in paediatric rheumatology
Basic and translational pain science ................................. 503
Rheumatoid arthritis - prognosis, predictors and outcome ........................................ 504
Rheumatoid arthritis - comorbidity and clinical aspects ........................................... 556
Rheumatoid arthritis - biological DMARDs .......................................................... 587
Rheumatoid arthritis - non biologic treatment and small molecules ...................... 604
SLE, Sjögren's and APS - treatment ................................................................. 633
SLE, Sjögren's and APS - clinical aspects (other than treatment) ......................... 644
Vasculitis - large vessel vasculitis ........................................................................... 683
Vasculitis - small vessel vasculitis .......................................................................... 702
Scleroderma, myositis and related syndromes ......................................................... 711
Spondyloarthritis – treatment .................................................................................. 765
Spondyloarthritis - clinical aspects (other than treatment) .................................... 783
Psoriatic arthritis – treatment .................................................................................. 815
Psoriatic arthritis - clinical aspects (other than treatment) .................................... 854
Osteoarthritis ........................................................................................................... 881
Osteopetrosis ............................................................................................................ 898
Crystal diseases, metabolic bone diseases other than osteoporosis ...................... 905
Infection-related rheumatic diseases .................................................................... 917
COVID-19 ............................................................................................................... 923
Pain in rheumatic diseases, including fibromyalgia ................................................. 981
Spine, mechanical musculoskeletal problems, local soft tissue disorders ............ 982
Paediatric rheumatology ......................................................................................... 983
Other orphan diseases ............................................................................................ 1001
Diagnostics and imaging procedures ...................................................................... 1030
Public health, health services research, and health economics .......................... 1041
Epidemiology, risk factors for disease or disease progression ............................... 1045
Validation of outcome measures and biomarkers .................................................. 1069
Rehabilitation ......................................................................................................... 1071
Education ................................................................................................................ 1072
Educational cases ..................................................................................................... 1075
Genomics, genetic basis of disease and functional genomics .............................. 1136
Adaptive immunity (T cells and B cells) in rheumatic diseases .............................. 1143
Innate immunity in rheumatic diseases .................................................................. 1153
Osteoarthritis, aetiology, pathology and animal models ......................................... 1157
Bone diseases, aetiology, pathology and animal models .......................................... 1161
Rheumatoid arthritis - aetiology, pathogenesis and animal models ..................... 1162
SLE, Sjögren's and APS - aetiology, pathogenesis and animal models .................. 1183
Systemic sclerosis, myositis and related syndromes - aetiology, pathogenesis and animal models .......................................................... 1193
Vasculitis - aetiology, pathogenesis and animal models .......................................... 1201
Basic and translational science in paediatric rheumatology ................................. 1207
Basic and translational pain science ..................................................................... 1208
Rheumatoid arthritis - prognosis, predictors and outcome .................................... 1209
Rheumatoid arthritis - comorbidity and clinical aspects ........................................ 1246
Rheumatoid arthritis - biological DMARDs ......................................................... 1289
Rheumatoid arthritis - non biologic treatment and small molecules .................... 1318
SLE, Sjögren's and APS - treatment ...................................................................... 1339
SLE, Sjögren's and APS - clinical aspects (other than treatment) ......................... 1353
Vasculitis – large vessel vasculitis .......................................................................... 1414
Vasculitis – small vessel vasculitis .......................................................................... 1430
Scleroderma, myositis and related syndromes ......................................................... 1449
Spondyloarthritis – treatment ............................................................................... 1500
Spondyloarthritis - clinical aspects (other than treatment) .................................... 1517
Psoriatic arthritis – treatment ................................................................................. 1562
Psoriatic arthritis - clinical aspects (other than treatment) .................................... 1590
Osteoarthritis .......................................................................................................... 1611
Osteoporosis ............................................................................................................ 1627
Crystal diseases, metabolic bone diseases other than osteoporosis .................... 1641
Infection-related rheumatic diseases ..................................................................... 1655
COVID-19 ............................................................................................................... 1660
Health Professionals in Rheumatology Abstracts

Oral Presentations

OP0007-HPR  “Not another pill!” Integrative pain management approaches ................................................. 4
OP0016-HPR–OP0123-HPR  HPR: From prevention to management ................................................................. 76
OP0198-HPR  How do we overcome the research-to-practice gap? Implementation of evidence into the rheumatology practice ................................................................. 131
OP0207-HPR–OP0214-HPR  HPR interventions on the spotlight ................................................................. 136
OP0295-HPR  Lifestyle and Disease activity in inflammatory arthritis ...................................................... 196
OP0296-HPR  Complexity of care in RMD: intersection between health and social care .......................... 197
OP0299-HPR  Facilitating work participation — why and how? ................................................................. 198
OP0301-HPR  Digital-Health and Tailored Interventions for Improving Patients’ Adherence: Opportunities and Challenges .................................................................................................................. 200
OP0308-HPR  Keeping the “Dark clouds” away: Psychological distress and RMDs ................................. 204

Poster Tours

POS0040-HPR–POS0049-HPR  HPR Poster Tour: Moving together towards person-centred care ................. 235

POSTERS only

POS1470-HPR–POS1492-HPR  HPR Measuring health (development and measurement properties of PROs, tests, devices) ........................................................................................................................................... 1081
POS1493-HPR–POS1495-HPR  HPR Epidemiology and public health (including prevention) ....................... 1092
POS1496-HPR–POS1510-HPR  HPR Interventions (educational, physical, social and psychological) ........... 1093
POS1511-HPR–POS1543-HPR  HPR Patients’ perspectives, functioning and health (descriptive: qualitative or quantitative) .......................................................................................................................... 1101
POS1544-HPR–POS1553-HPR  HPR Service developments, innovation and economics in healthcare .... 1117
POS1554-HPR–POS1559-HPR  HPR Professional education, training and competencies ........................... 1122
POS1560-HPR–POS1561-HPR  HPR Interdisciplinary research ........................................................................ 1126

Publication Only

AB1523-HPR–AB1533-HPR  HPR Measuring health (development and measurement properties of PROs, tests, devices) ........................................................................................................................................... 1864

Addressing the effect of Placebo, Nocebo and Contextual factors in RMDs

**OP0001** "I WILL NEVER FORGET THE SHAME I FELT": A SURVEY TO PEOPLE WITH A RHENUMATIC DISEASE ABOUT INVALIDATION FROM HEALTH PROFESSIONALS AND OTHER PEOPLE

A. Marques1,2,3, A. Silva3,3, J. Vicente4,5, E. Mateus6, R. J. O. Ferreira1,2, 1Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 2Nursing School of Coimbra, Health Sciences Research Unit; Nursing (UCISA: E); Coimbra, Portugal; 3Nursing School of Coimbra, Professor, Coimbra, Portugal; 4Portuguese League against Rheumatic Diseases (LPCDR), Executive Board, Lisbon, Portugal; 5Portuguese Association of Fibromialgia (APJOF), Executive Board, Lisbon, Portugal

**Background:** The term invalidation refers to the patients’ perception that their medical condition is not recognised, either in denying, lecturing, not supporting or not acknowledging the condition. This may be felt from health professionals themselves but also from family, friends, at work and in other social areas, imposing great suffering. [1] The European Alliance of Associations for Rheumatology (EULAR) has made efforts to raise awareness for the burden imposed by rheumatic and musculoskeletal conditions (RMDs) and promote the best quality of care, including recognition and psychosocial support. However, it is unclear how frequent and severe the problem remains nowadays.

**Objectives:** The aims of this national survey were: (i) to identify the levels of invalidation and lack of understanding felt by adults with RMDs from health professionals and other people, (ii) to investigate the relationship between invalidation, sociodemographic characteristics and disease; and (iii) to understand its impact on people’s life and health outcomes.

**Methods:** An online survey was developed by the national health professionals in rheumatology and patients’ organisations and opened between May and December of 2021. The questionnaire included demographic and disease information, the Illness Invalidation Inventory (3*I),[1] with additional questions in a Likert format and open questions for a detailed understanding of the phenomenon. The 3*I is composed of 8 items, measured from 1 (=never) to 5 (=very often), forming two factors: Discounting (mean of 5 items; lower scores indicating more discounting) and Lack of understanding (mean of 3 items; Higher scores representing higher lack of understanding). Quantitative data were analysed using descriptive statistics. Associations were tested with a t-student and ANOVA one-way test (Bonferroni correction). Open responses were categorised using the content analysis technique, and themes were defined a posteriori.

**Results:** From the > 1500 responses obtained, 1410 responses were filled out completely (mean age of 46 years [SD=11], 95% females, 60% with FM, among which 59% were diagnosed in the last 5 years). Invalidation was reported by 86% of the participants and 70% rated ≤5 on a scale from 0 (nothing) to 10 (totally) on feeling understood by other people. Invalidation was mostly felt from family (56%), health professionals (48%), friends (39%), and social environment (38%). The impact of this invalidation is mainly on the psychological well-being (58%), also reducing seeking health care (41%) and therapeutic adherence (17%), affecting work (41%), and to a less extent, (family) relations (31%).

**Conclusion:** Invalidation is a source of suffering, affecting well-being and health outcomes. Specific awareness and educational campaigns are needed to target this problem on different play-actors.

**Bench to Bedside: The complement system in rheumatic diseases**

**OP0002** LOW COMPLEMENT LEVELS IN THE FIRST TRIMESTER PREDICT DISEASE FLARE IN SLE PREGNANCY: A NETWORK META-ANALYSIS ON 532 PATIENTS.

M. Radin1, F. Crisafulli2, I. Cecchi1, E. Klumb3, G. De Jesús4, M. A. Saavedra4, G. V. Reyes-Navarro3, L. Iaccarino5, M. Larosa5, G. Moroni5, F. Tamborini5, D. Roccatello1, L. Andreoli4, C. Chighizola5, S. Sciascia1, 1University of Turin, Clinical and Biological Sciences, Turin, Italy; 2University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 3Università dello Stato del Rio Janeiro, Rheumatology Department, Rio de Janeiro, Brazil; 4Hospital de Especialidades Dr. Antonio Fraga Mouret, Rheumatology Department, Mexico City, Mexico; 5Università Autónoma de Puebla, School of Medicine Puebla Campus, Puebla, Mexico; 6Università di Padova, Rheumatology Unit, Padova, Italy; 7Humanitas University, Department of Biomedical Sciences, Rozzano, Italy; 8ASST G. Pini & CTO, Pediatric Rheumatology, Milano, Italy

**Background:** The complement system is a key-player in the pathogenesis of systemic lupus erythematosus (SLE); its decreases correlate with disease activity and precedes flare. Since synthesis of complement proteins increase during gestational course, it is debated whether complement levels exert a prognostic role in pregnant women with SLE.

**Objectives:** We performed a network meta-analysis to assess the prognostic role of complement in pregnant SLE women, to evaluate the possible role of complement fluctuations during pregnancies.

**Methods:** Data from available prospective studies (Jan 2002-Dec 2020) investigating pregnancies in at least 50 SLE patients, excluding miscarriages before 12 weeks, were pooled together. After a systematic literature search, corresponding authors of 19 retrieved studies meeting inclusion criteria were invited to contribute with additional data, including complement levels [6 months before pregnancy, at conception, 1st trimester (T1), 2nd trimester (T2), 3rd trimester (T3) and 3 months after delivery].

**Results:** A total of 532 SLE women from four eligible studies were included in the analysis [1-4]. Lupus Nephritis (LN) was diagnosed in 237 patients (44.5%) and Antiphospholipid Syndrome in 68 (12.8%). A total of 170 patients (32%) experienced a flare during pregnancy, defined as need of new Immunosuppressants or increase of prednisone > 8mg/day. Patients with LN had significantly lower mean levels of complement (C3 at conception; C3 and C4 at T1; C3 after 3 months of delivery; C4 at all timepoints except for C4 at T3). SLE patients who experienced flares during pregnancy had significantly lower mean levels of complement (all timepoints for both C3 and C4). Table 1 shows the mean C3 and C4 levels in different timepoints according to diagnosis and flare during pregnancy. The lowest levels of complement were observed in patients with a concurrent diagnosis of LN and presence of flare, particularly during the T1 (Figure 1). Nevertheless, both in LN and flare groups the lowest levels of C3 and C4 were documented at T1.

Breaking the barriers: gut, lung and skin in arthritis pathogenesis

OP0003 DOES IMMUNOSUPPRESSIVE THERAPY IMPROVE GASTROINTESTINAL SYMPTOMS IN PATIENTS WITH SYSTEMIC SCLEROSIS?

L. Stamm1, A. Garaiman1, N. Zampatti1, M. O. Becker1, C. Bruni1, R. Dobrota1, M. Ethal1, S. Ismail1, S. Jordan1, A. Tut1, O. Distler1, C. Mihai1
1 University Hospital Zürich, University of Zurich, Rheumatology, Zürich, Switzerland;
2 Azienda Ospedaliero Universitaria Careggi, University of Florence, Experimental Medicine, Division of Rheumatology, Florence, Italy; 3 National Research Center, Internal Medicine, Cairo, Egypt; 4 University Hospital Zürich, University of Zurich, Gastroenterology, Zürich, Switzerland

Background: The gastrointestinal (GI) tract is frequently affected in systemic sclerosis (SSc), leading to considerable morbidity and even mortality. While important progress has been made in the last years regarding treatment of SSc, there is no disease-modifying treatment available for SSc-related GI involvement.

Objectives: We aimed to identify, in an observational cohort study of real-life patients with SSc, an association between immunosuppressive therapy and the severity of GI symptoms, measured by the University of California at Los Angeles / Scleroderma Clinical Trial Consortium Gastro-Intestinal Tract instrument 2.0 (UCLA GIT 2.0).

Methods: We selected patients from our EUSTAR centre who met the 2013 ACR/EULAR classification criteria for SSc and had at least two visits with completed UCLA GIT 2.0 questionnaires, with an interval of 12±3 months between visits. We defined the first visit with a completed UCLA GIT 2.0 questionnaire as baseline visit. Immunosuppressive therapy was defined as exposure for at least 6 months between the two visits to at least one of the following drugs, regardless of indication: mycophenolate mofetil (MMF), cyclophosphamide, methotrexate, azathioprine, leflunomide, glucocorticoids (>10mg/d prednisone-equivalent), rituximab, tocilizumab, and abatacept. The study outcome was the UCLA GIT 2.0 score at the follow-up visit. We performed multivariable linear regression with this outcome as dependent variable and immunosuppressive therapy during follow-up, immuno-suppressive therapy before baseline, baseline UCLA GIT 2.0 score and several baseline parameters selected by clinical judgment as potentially influencing GI symptoms, as independent variables. Multiple imputation was implemented to handle missing values.

Results: We included 209 patients. Baseline characteristics were: 83.2% female, median (IQR) age 59.0 (48.6, 68.2) years, median disease duration 6.0 (2.7, 12.5) years, 40 (19.1%) diffuse cutaneous SSc, median baseline UCLA GIT 2.0 score 0.19 (0.06, 0.43). Of these, 71 patients were exposed to immunosuppressive therapy during the observation period had, compared to patients without such treatment, overall more severe SSc, higher prevalence of treatment with proton pump inhibitors, similar UCLA GIT 2.0 scores at baseline and at follow up and tendentially less severe GI symptoms at baseline and follow up by medical history. In multivariable linear regression, immunosuppressive therapy, lower body mass index, longer disease duration and lower baseline UCLA GIT 2.0 score were significantly associated with lower (better) UCLA GIT 2.0 scores at follow-up (Table 1).

Baseline factors associated with the total UCLA GIT 2.0 score at the end of the observation period. Multiple linear regression model with imputation for missing variables. N=209 patients

Conclusion: Immunosuppressive treatment was associated with lower UCLA GIT 2.0 scores, which suggests potential effects of immunosuppressants on GI manifestations in patients with SSc. These results need verification in additional studies and randomised controlled clinical trials.

**OP0004**

**AUTOMATED RECOGNITION AND MONITORING OF DORSAL SKIN FOLDS BY A CONVOLUTIONAL NEURAL NETWORK AS A POTENTIAL DIGITAL BIOMARKER FOR JOINT SWELLING IN PATIENTS WITH RHEUMATOID ARTHRITIS**

T. Hügle1, L. Caratsch2, M. Matteo Caorsi2, J. Maglione3, D. Dan1, A. Dumusc1, M. Blanchard1, G. Kalweit1, M. Kalweit1, 4Lausanne University Hospital, CHUV, Department of Rheumatology, Lausanne, Switzerland; 4L2F, Informatics, Lausanne, Switzerland; 5Ecole Polytechnique Fédérale de Lausanne (EPFL), Informatics, Lausanne, Switzerland; 4Lausanne University Hospital, CHUV, Division of Rheumatology, Lausanne, Switzerland; 6University of Freiburg, Department of Computer Science, Freiburg, Germany

**Background:** To monitor rheumatic diseases, digital biomarkers such as wearables are of increasing interest, but they lack disease specificity.

**Objectives:** In this study, we apply convolutional neural networks (CNN) to real world hand photographs in order to automatically detect, extract and analyse dorsal finger fold lines as a correlate of proximal interphalangeal (PIP) joint swelling in patients with rheumatoid arthritis (RA).

**Methods:** Hand photographs from 190 RA patients were taken by a smartphone camera in a standardized manner. PIP joints were categorised as either swollen or not swollen based on clinical judgement and ultrasound. Images were automatically preprocessed by cropping PIP joints and extracting dorsal finger folds. Subsequently, metrical analysis of dorsal finger folds was performed and a CNN was trained to classify the dorsal finger lines into swollen versus non-swollen joints. Representative horizontal finger folds were also quantified in a subset of patients before and after resolution of PIP swelling and in patients with disease flares, respectively.

**Results:** In swollen joints, the number of automatically extracted double-contoured, deep skinfold imprints was significantly reduced compared to non-swollen joints. The joint diameter / deep skinfold ratio was significantly higher in swollen (4.1, SD 1.4) versus non-swollen joints (2.1, SD 0.6). The CNN model successfully differentiated swollen from non-swollen joints based on finger fold patterns with a validation accuracy of 0.84. A heatmap of the original images obtained by an extraction algorithm confirmed finger folds as the region of interest for correct classification. After significant response to DMARD +/- corticosteroid therapy, longitudinal metrical analysis as a digital biomarker in RA showed a decrease of the mean diameter/ finger fold length (finger fold index, FFI) from 3.03 (SD 0.68) to 2.08 (SD 0.57). Conversely, the FFI increased in patients with a flare of joint swelling.

**Conclusion:** Automated preprocessing and the application of CNN algorithms in combination with longitudinal metrical analysis of dorsal finger fold patterns extracted from real world hand photographs might serve as a digital biomarker in RA.

How to maintain your quality of life after an RMD diagnosis

**OP0005-PARE**

**DEVELOPMENT OF CONVERSATION AIDS: HOW TO GET THE MOST OUT OF YOUR RMD APPOINTMENT AND ADVANCE YOUR QUALITY OF LIFE**

P. Ronsse, Msc1, P. Pennings, Msc2, B. Maat1, I. Hest3, F. Van Eeckelen1, H. Van de Weijer1, I. Schoonen-Nuitten1, G. Willemsen-de Mey Msc1, 1National Association ReumaZorg Nederland, Patientexpert and Coordinator at the Department of Patient participation and Communication, Nijmegen, Netherlands; 2National Association ReumaZorg Nederland, Coordinator at the Department of Patient participation and Communication, Nijmegen, Netherlands; 3National Association ReumaZorg Nederland, Patientpartner at the department of Patient participation and Communication, Nijmegen, Netherlands; 4Bravis Medical Centre, Rheumatology Nurse at the Department of Rheumatology, Roosendaal, Netherlands; 5National Association ReumaZorg Nederland, President of the Board, Nijmegen, Netherlands

**Background:** Having a Rheumatic and Musculoskeletal Disease (RMD) has a big impact on your daily life, work, relationships and quality of life. It can cause various complaints, problems and questions. Research shows that people with an RMD are often insufficiently aware that they can talk about these challenges with their RMD professional. They also don't realise that these challenges matter when making a fitting choice for treatment. It also appears that RMD professionals do not sufficiently take into the account the priorities of their patient, when a treatment choice has to be made. This is unfortunate because research shows that people who decide together with their RMD professional make better informed treatment choices. They are also more likely to adhere to their treatment or medication use. A conversation aid can help people to become aware of the most important challenges or problems in their daily lives with an RMD. These uncovered challenges and problems can set the agenda for a good conversation in the RMD consultation room. Together with the RMD professional the conversation can focus on ways to deal with or treat these challenges or problems.

**Objectives:** To develop a conversation aid for people with an RMD that allows them to become aware of the most important challenges in their life with an RMD and that guides them in how to discuss these aspects with an RMD professional.

**Methods:** In the first step a review was made of all important aspects of a patient's life with an RMD. The outcome measures of ICHOM for inflammatory arthritis1 and hip- and knee osteoarthritis2 formed the starting point for this review. This was complemented with additional outcomes as measured in Dutch RMD apps and patient dashboards of Dutch hospitals. In the second step, the list of outcomes was assessed by means of a survey among Dutch patients with an RMD. The third step was to discuss the complete list with important outcomes with the Dutch rheumatology department of the Bravis Medical Centre. A first draft version of the conversation aids was made. This draft version was evaluated by patientpartners of the National Association ReumaZorg Nederland (RZN) and the Bravis Medical Centre.

**Results:** A total of 4 conversation aids (https://reumazorgnederland.nl/samen-beslissen-gesprekskaarten/) were made. Each aid addressing a main category of challenges with an RMD. Each main category was divided into 5 sub-categories. The 4 conversation aids are:

- **Disease:** Concerning the sub-categories: Disease activity, pain, fatigue, medication & side effects and knowledge about the disease.
- **Daily activity:** Concerning the sub-categories: Work/school, personal care, household & family, mobility, and spare time.
Lifestyle: Concerning the sub-categories: Activity, food, stress & relaxing, smoking, and weight.

Relationships and well-being: Concerning the sub-categories: Social contacts, intimate relationships & pregnancy & wish for children, incomprehension, loneliness, and gloom.

To advance Shared Decision Making (SDM), a separate conversation aid was made with tips and tricks for having a good conversation with your RMD professional:

• A good conversation: tips and tricks for preparing a conversation with your RMD professional. As well as tips and tricks that can be used during and after your conversation.

In Figure 1 the conversation aid with main category lifestyle is presented.

Figure 1. Example of the conversation aid with main category Lifestyle.

Conclusion: A consultation aid can advance a good conversation and therefore SDM, between people with an RMD and their RMD professional. A patient organization can play an important role in developing a consultation aid.

Cleansing Activities, Dusty Clothes Laundry and Talcum Handling are Underestimated Major Sources of Exposure to Crystalline Silica in Women with Rheumatoid Arthritis

J. Siqueur,1,2; C. Cavallin,3,4; A. Lescoat,5; P. Y. Brillet,5; L. Sese6; H. Nunes6; M. C. Boissier1,2; L. Semerano1,2; A. Bouillet1,2; L. Lefebvre1,2

Avicenne Hospital, Rheumatology, Bobigny, France; Université Sorbonne Paris Nord, UMR 1125 Inserm, Bobigny, France; Université Paris Dauphine, IRISOS, UMR CNRS-INRAE 7170-1427 Paris, France; Science Po, Laboratoire Interdisciplinaire d’évaluation des politiques publiques (LIEPP), Paris, France; CHU Rennes, Rheumatology, Rennes, France; Avicenne Hospital, Radiology, Bobigny, France; Avicenne hospital, Physiology, Bobigny, France; Avicenne Hospital, Respiratory, Bobigny, France.

Background: Inhalation of crystalline silica (cSiO2) is associated with rheumatoid arthritis (RA). Research on cSiO2 has historically focused on professional exposures and on male workers. However, cSiO2 ubiquitously present in the environment, substantial exposure can take place in both men and women, in other professional activities and even beyond occupational context.

Objectives: To identify the main sources of exposure to crystalline silica in a series of RA patients not selected based on their professional activity, and to assess the association between silica exposure and disease features.

Methods: The Dust Exposure Life-Course Questionnaire (DELCQ) is a novel tool that longitudinally quantifies both occupational and non-occupational lifetime exposure to crystalline silica. The DELCQ was previously validated in a representative sample of the general French population that serves as control source for studies in specific diseases. The DELCQ was administered to 87 consecutive patients with RA, exposure scores were compared between cases and age-, sex- and smoking status-matched controls (1:4). The main sources of silica exposure were identified in cases and controls and source-specific exposure levels compared. The association between DELCQ scores and disease variables in cases was tested using multivariable analysis.

Results: In women with RA, the main sources of crystalline silica exposure were cleaning activities, dusty clothes laundry and talcum powder handling, with higher exposure levels from these sources vs. the general population (p<0.005).

In the whole series of RA patients, high silica exposure was independently associated with interstitial lung disease (OR 6.5 (95% CI: 1.3 to 32.6)) and mediastinal lymphadenopathy (OR 6.3 (95% CI: 1.4 to 27.7).

Conclusion: Cleaning activities, dusty clothes laundry and talcum handling are underestimated sources of crystalline silica exposure that are overrepresented in women with RA compared to the general population and may contribute to the pathogenesis of the disease.

OP00067+HPR AN EPIDEMIOLOGICAL STUDY OF FOOT AND ANKLE PAIN AND HEALTH-RELATED JOB LOSS IN ADULTS OVER 50: CROSS-SECTIONAL FINDINGS FROM THE HEAP COHORT

D. Jobanputra1, L. Cherry2, K. Walker-Bone3, C. Price1, S. D’angelo5, G. Ntani5, on behalf of Health & Employment After Fifty. 1University of Southampton School of Medicine, Faculty of medicine, Southampton, United Kingdom; 2University of Southampton, School of Health sciences, Southampton, United Kingdom; 3University of Southampton, MRC Versus Arthritis Centre for Musculoskeletal Health and Work, Southampton, United Kingdom

Background: Foot and ankle pain (FAP), particularly that of musculoskeletal origin, is increasingly prevalent in our aging populations. Moreover, governments need people to work to older ages to reduce the costs of pensions and welfare benefits. It is not currently known however whether people with FAP are able to keep working or to what extent it pushes people out of work. We investigated this question in older working adults.

Objectives: To determine whether FAP is associated with HRJL amongst older working adults.

Methods: Health And Employment After Fifty is a longitudinal population-based cohort inceptioned 2013 to investigate health and retirement. At follow-up two years later, people were asked to complete a full-body mannequin which included the ankles/feet. Mannequins were coded: foot/ankle pain (FAP) with pain at other sites; pain elsewhere but not FAP; and no pain. Two years later, participants were asked whether they had left paid work entirely or partly because of health problems. Amongst those with HRJLs, 73 had no pain, 54 had pain involving FAP, 108 had pain not involving FAP . After adjusting for age and sex, people with FAP had 83% increased risk of HRJL compared to people with no pain (HR=1.83, 95% CI 1.29-2.61), whilst those with pain NOT involving FAP had 34% increased risk of HRJL.
A NOVEL SITE-SPECIFIC PEGYLATED IL-2 WITH POTENT AND TREG-SELECTIVE ACTIVITY IN VIVO

M. Ikeda1, S. Yamaguchi2, M. Murakami2, S. Takaoka2, Y. Sakaguchi2, S. Yasui2, K. Iijima2, K. Nanya2, H. Onodera2, T. Amano3, 1Kyowa Kirin Co., Ltd., R&D division, Sunto-gun, Shizuoka, Japan; 2Kyowa Kirin Co., Ltd., R&D division, Sunto-gun, Shizuoka, Japan; 3Kyowa Kirin Co., Ltd., R&D division, Machida-shi, Tokyo, Japan

Background: Decreased regulatory T cells (Tregs) and Treg dysfunction are hallmarks of a variety of autoimmune and inflammatory diseases. While low-dose IL-2 therapy induces Treg expansion in vivo and has clinical benefits in some diseases (e.g., SLE and chronic graft-versus-host disease [GVHD]), there are many concerns about adverse events due to low Treg-selectivity. Furthermore, frequent dosing is needed due to the short half-life.

Objectives: We discovered a novel site-specific PEGylated IL-2 variant, KKC80, with high Treg selectivity and a long half-life in vivo, which overcomes the issues of low-dose IL-2 therapy.

Methods: Based on the co-crystal structure of wild-type IL-2 and its heterotrimERIC receptor (PDB ID: 2ERJ), copper-amido acids that were to be PEGylated sites were substituted with oAzZLys, an azide-containing lysine derivative. The PEG molecule was site-specifically attached to oAzZLys-incorporated IL-2 by copper-free click chemistry. The binding property to the IL-2 receptors were measured by surface plasmon resonance (SPR). In vitro, Treg selectivity was evaluated by the IL-2-dependent proliferation activity of Tregs and NK cells from human peripheral blood mononuclear cells (PBMCs). In vivo pharmacological activity was assessed after the single subcutaneous administration in cynomolgus monkeys, and the selected features for RNA-Seq, DNA methylation and GWAS data were calculated according to serum PEGylated IL-2 concentration. Efficacy in mouse xenogenic GVHD model using human PBMC-transplanted NOG mice and in monkey DTH model were evaluated.

Results: A novel PEGylated IL-2, KKC80 (human IL-2 desA1/C125S/I126oAzZLys, W-shaped 80kDa PEG) was discovered by optimizing the PEGylation site and PEG structure based on Treg selectivity and PK. SPR analysis showed that the binding affinity of KKC80 to CD25 was moderately decreased from wild-type IL-2, while binding affinity of KKC80 to IL-2Rα was remarkably decreased due to a significant change of the association rate constant. In vitro, wild-type IL-2 activated both Tregs and NK cells in the same concentration range, whereas KKC80 selectively activated Tregs. The Treg selectivity of KKC80 was comparable to another IL-2 mutein, Flc-IL-2 V91K. KKC80, but not Flc-IL-2 V91K, retained its biological activity, even in the presence of a large amount of recombinant soluble CD25, which mimicked the endogenous decoy receptor for IL-2. In monkeys, KKC80 selectively increased peripheral blood Tregs in a dose-dependent manner; the average maximum rate of increase of Treg count in animals treated with 0.01, 0.03, 0.1, 0.3 and 1 mg/kg was 1.5, 3.5, 26, 50 and 154-fold, respectively; in contrast to Tregs, the rates of increase of conventional CD4+ T, CD8+ T and NK cells were low. The Treg increase peaked on day 8 or 11 and lasted for over day 29. KKC80 showed a more sustained upregulation of functional Treg markers (e.g., Foxp3 and CD25) in comparison to Flc-IL-2 V91K. The half-life of KKC80 was calculated as 83.5 to 150h. At high doses, inflammation-related adverse effects, including increased CRP (≥0.3 mg/kg) and deterioration of general conditions (1 mg/kg) were observed. In the mouse xenogenic GVHD model, KKC80 ameliorated GvHD symptoms and suppressed multiple tissue inflammation markers. Decreased soluble CD25 and IFN-γ were also confirmed, suggesting that Treg-mediated anti-inflammatory effect by KKC80 administration were exerted in vivo. In the monkey DTH model, KKC80 suppressed skin inflammation and antibody production.

Conclusion: Among next-generation IL-2 variants, KKC80 showed a best-in-class biological profile for Treg activation. A drastic and sustained increase of Tregs with high Treg-selectivity and anti-inflammatory effects were observed in vivo. These data suggest that in comparison to current IL-2 therapy, KKC80 provides superior therapeutic index and efficacy in patients with autoimmune and inflammatory diseases.

A MORE MATURE PLASMA CELL AND PLASMABLAST COMPARTMENT IS ASSOCIATED WITH DISEASE MANIFESTATION IN PRIMARY SJÖGREN’S SYNDROME

T. D. Steinmetz, G. M. Verstappen1, H. Bootma1, F. G. M. Kroese.1. University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Sjögren’s syndrome (pSS) is an autoimmune disorder often associated with fatigue, dry eyes and dry mouth symptoms and characterized by chronic inflammation of moisture-producing glands like salivary and lacrimal glands (1). Auto-antibodies, B cell infiltration of affected glands and lymphoma development are signs for B cell hyperactivity in pSS (1-3). The B cell effector branch, namely antibody-secreting cells (ASC) like plasmablasts and plasma cells, can sustain autoimmune pathogenicity over long time periods by secretion of auto-antibodies (4,5).

Objectives: Since B cell hyperactivity is an important pathogenic feature in pSS, antibody-secreting cells as B effector cells are studied to characterize their abundance, maturation stage and inflammatory properties and relate them to pSS manifestations.

Methods: Peripheral blood mononuclear cells (PBMC) from pSS patients and healthy individuals were subjected to spectral flow cytometry phenotyping. CD27+CD38+ ASCs were analyzed with a comprehensive TSNE approach as well as based on expression of ASC markers. This includes markers described for maturity like CD19, CD138, CD28, Blimp1 and HLA-DR and markers relevant for ASC survival like Mc1 and BCMA. The pro-inflammatory status of the cells was assessed by CXCR3 and CXCR4 expression and their immune regulatory properties with markers like IL-10 and Lag-3. ASC properties like maturity state were correlated to characteristic pSS disease-associated features.

Results: Patients with pSS had higher frequencies and absolute numbers of ASCs than healthy controls. ASCs displayed a higher degree of maturation in pSS. ASC frequencies and their maturity state, for example reflected by CD19 down-regulation or increased CD28 expression (6), correlated with several pSS disease characteristics like ANA titers, focus scores and ocular scores indicating glandular impairment. Additionally, more mature ASCs that express low amounts of CD19 had increased Mc1 levels indicating prolong survival of these cells. The maturation state of ASCs was associated with CXCR3+ ASC frequencies in pSS patients. Expression levels of anti-inflammatory IL-10 and pathogenic CXCR3 by ASCs in pSS patients was negatively correlated. tSNE related clusters enriched for ASCs from pSS patients were more mature but also had higher expression levels of CXCR3.

Conclusion: Circulating ASCs in pSS are more abundant and have a more mature phenotype compared to healthy individuals. Their frequencies and degree of maturation could be linked to pSS disease features. Prolonged survival and pro-inflammatory status might further increase the impact of circulating ASCs on disease manifestations. Together these findings underpin the role of B cell hyperactivity in pSS, that culminates in an altered ASC compartment.

OP0011
HIGHLY DIFFERENTIATED CD4 AND CD8 T EFFECTOR MEMORY CELLS RE-EXPRESSION CD45RA (TEMRA) ARE ASSOCIATED WITH ACTIVE DISEASE REFRACTORY TO ANTI-TNF THERAPY IN RHEUMATOID ARTHRITIS

1. University College London, Rheumatology, London, United Kingdom; 2. University College London, Experimental and Translational Medicine, Division of Medicine, London, United Kingdom

Background: Highly differentiated T cells have been reported to be enriched in rheumatoid arthritis (RA) compared to healthy individuals. The role of terminally differentiated T effector memory re-expressing CD45RA (Temra) in RA pathogenesis and disease activity is still unclear, including whether they can be used as a marker of sustained disease activity in RA patients receiving anti-TNF therapy.

Objectives: To investigate whether the frequency of peripheral blood Temra can be used as a biomarker to identify disease refractory to anti-TNF therapy in RA, if they correlate with inflammation in anti-TNF treated patients, and whether they associate with a flare following tapering anti-TNF.

Methods: RA patients on anti-TNF therapy were recruited from rheumatology clinic (cross-sectional cohort). Clinical data and whole blood were collected.
Patients were stratified based on disease activity. Remission was defined as no recorded DAS28-CRP $\leq 2.4$, no swollen joints, no C-reactive protein (CRP) of $>5\text{mg/L}$, and on a stable DMARD dose and no reported disease flare/loss of remission in the 6 months prior. Non-remission was defined as any other disease activity which does not fulfill the remission definition. Patients on abatacept, or methotrexate monotherapy and healthy volunteers were recruited as comparison groups. A separate cohort of anti-TNF patients (longitudinal cohort) who have been in remission on a stable dose of anti-TNF for 6 months and no use of corticosteroids in the last 6 months, was also recruited. Whole blood was obtained prior to dose tapering (dose halving) and at the point of a flare. Whole blood was processed by gradient centrifugation to obtain peripheral blood mononuclear cells (PBMC). PBMC were stained with fluorochrome-conjugated antibodies for multi-parameter flow cytometry. Analysis was performed on live lymphocytes using FlowJo software version 10.8. Two-tailed Mann-Whitney U test or unpaired t-test were used to obtain unadjusted values, analysis of variance (ANOVA) of log-transformed data was used to obtain age-adjusted values, Spearman's rank correlation was used to compare correlation between Temra and CRP.

**Results:** RA patients (36 anti-TNF, 12 abatacept, 16 methotrexate monotherapy) and 14 healthy individuals were recruited. There was a higher proportion of CD4 (age-adjusted $p = 0.004$) and CD8 Temra (age-adjusted $p = 0.0007$) in RA patients on anti-TNF with persistent disease activity compared to those who had achieved remission. These differences were confirmed when analysing absolute numbers of CD4 and CD8 Temra. Unexpectedly, the difference in Temra frequency between remission and non-remission RA was not observed in patients treated with methotrexate or abatacept. The median CD4 and CD8 Temra frequencies in RA patients in remission with all treatments studied were similar to healthy individuals.

Temra were not observed to increase with age in the anti-TNF, abatacept, or methotrexate cohorts in contrast to previous reports in healthy individuals. The frequency of CD4 and CD8 Temra correlated with CRP only in patients on anti-TNF (CD4 Temra Spearman $r = 0.5185$, $p = 0.001$, and CD8 Temra Spearman $r = 0.5040$, $p = 0.005$).

There was an increase in CD4 ($p = 0.003$) but not CD8 Temra at 3 months in patients who flared on tapering anti-TNF compared to those who remained in remission (Figure 1).

**Conclusion:** Increased CD4 and CD8 Temra frequency were associated with persistent disease activity in anti-TNF treated patients but not with other DMARD therapies (abatacept and methotrexate). CD4 Temra increased in those who flared on tapering anti-TNF. These results suggest that Temra may play a role in driving persistent disease activity refractory to anti-TNF therapy rather than merely a marker of inflammation.

Background: Synovial tissue macrophages significantly contribute to Rheumatoid Arthritis, yet the precise nature/function of macrophage subsets within the inflamed joint remains unexplored.

Objectives: To fully explore the spectrum of distinct macrophage activation states residing within the synovium of RA, at risk and healthy individuals.

Methods: Single-cell synovial tissue suspensions from RA (n=44), IAR (n=5), HC (n=11), PaA (n=11) and OA (n=4) were obtained, and synovial macrophage subsets examined by advanced multiparameter flow cytometric analysis, bulk RNA-sequencing, metabolic and functional assays.

Results: Multidimensional analysis identifies enrichment of CD206+CD163+ synovial-tissue macrophages co-expressing CD40 in the RA joint compared to healthy synovial-tissue, with frequency of CD206+CD163+CD40+ macrophages associated with increased disease activity and treatment response. In contrast, CX3CR1-expressing macrophages which form a protective barrier in healthy synovium are significantly depleted in RA. Importantly, this signature of enriched CD40 expression coupled with depleted CX3CR1 expression is an early phenomenon, occurring prior to clinical manifestation of disease in individuals ‘at-risk’ of RA (IAR). RNAseq and metabolic profiling of sorted RA synovial-macrophages identified that this population is transcriptionally distinct, displaying unique inflammatory, phagocytic and tissue-resident gene signatures, paralleled by biologically stable profile as indicated by NAD(P)H emission. Functionally CD206+CD163+ RA macrophages are potent producers of pro-inflammatory mediators (reversed by CD40-signalling inhibition) and induce an invasive phenotype in healthy synovial-fibroblasts. These findings identify a distinct pathogenic population of synovial-tissue macrophage involved in shaping the immune response in RA. Crucially, this signature is present pre-disease representing a unique opportunity for early diagnosis and therapeutic intervention.

Conclusion: We have identified a novel population of tissue-resident macrophages in the RA synovium which are transcriptionally/metabolically distinct and capable of contributing to disease pathology. Uncovering the molecular patterns and cues that transform this immunoregulatory macrophage population into a dysfunctional inflammatory activation state may provide opportunities to reinstate joint homeostasis in RA patients.

CTLA4-IG INDUCES TOLEROGENIC PROPERTIES OF DENDRITIC CELLS BY ALTERING CELLULAR METABOLISM

P. Goutakoli2, G. Papadaki1, S. Papanikolaou1, G. Vatsellias1, G. Bertias1, P. Verginis1, P. Sidiropolous1, 1Laboratory of Rheumatology, Autoimmunity and Inflammation, Medical School, University of Crete, Heraklion, Greece; 2Institute for Bioinnovation-IBI, Biomedical Sciences Research Center “Alexandros Fleming”, Athens, Greece; 3Greek Genome Center, BRFAA, Athens, Greece; 4Clinic of Rheumatology, Clinical Immunology, University Hospital of Heraklion, Heraklion, Greece; 5Division of Basic Sciences, Medical School, University of Crete, Heraklion, Greece

Background: Dendritic cells (DCs) are well-recognized for their dual role either for T cell activation (1) or for inducing T cells tolerance (2). Their ability to modulate T-cell responses has made them an interesting tool for the immunotherapy of autoimmune diseases (3). Cytotoxic T lymphocyte antigen 4 (CTLA4) is a negative co-stimulatory molecule, which binds to CD80/CD86 on DCs. CTLA4 induces its immunoregulatory function through trans-endocytosis resulting in impaired co-stimulation (4), or through the induction of indoleamine-pyrole-2,3-dioxygenase (IDO) enzyme (5). Moreover, it has been demonstrated that CTLA4-IG impairs the autophagic machinery of DCs and therefore suppresses DC inflammatory function (6). Nevertheless, the molecular mechanisms underlying the CTLA4-mediated immunomodulatory phenotype, require a more comprehensive understanding.

Objectives: In this study we focused on tolerogenic DCs (tolDCs) and we applied CTLA4-IG as a tool to induce them. We aim to assess the immunoregulatory potential of CTLA4-mediated tolDCs and to investigate thoroughly the intracellular pathways that are involved in the induction of tolerance.

Methods: Healthy human monocytes were isolated from peripheral blood and differentiated into monocyte-derived dendritic cells (DCs). After 6 days, immature DCs activated with LPS were treated with CTLA4-IG or IgG control for 18 hours. The anti-inflammatory function of DCs was validated using RT-PCR and flow cytometry and DCs propensity to RNA sequencing. The metabolic pathways were studied using a Seahorse bioanalyzer.

Results: CTLA4-IG treated DCs showed significantly decreased HLA-DR, CD80/CD86 expression as compared to IgG-treated controls (n=4, p=0.0294, n=5; p=0.0079). Moreover, IL6 and TNFα mRNA expression, hallmark of inflammatory cytokines secreted by DCs, was reduced upon CTLA-4-IG (n=5, p=0.0079). To elucidate the pathways involved in DC reprogrammung upon CTLA4-IG treatment, we performed RNA sequencing and we concluded with 1270 differentially expressed genes (p-value<0.05 counts>10). Interestingly, transcriptomic analysis revealed that the majority of genes (n=900) participated in metabolic processes, specifically in OXPHOS pathway and mitochondrial function. To further support the above metabolic changes, we performed Seahorse assays and confirmed that tolDCs had lower basal OXPHOS and decreased ATP production compared with mature DCs. Furthermore, expression of phosphorylated mammalian target of rapamycin (mTOR) and AKT1, central regulators of metabolism, was increased in CTLA4-mediated tolDCs (n=3, p=0.0308 and p=0.0347).

Conclusion: Herein we confirmed that CTLA4 restricts the pro-inflammatory properties of activated DCs. RNA-seq analysis revealed that this anti-inflammatory deviation of DCs is characterized by the modification of the expression of genes implicated in cellular metabolism. Metabolic experiments confirmed that CTLA4-mediated tolerized DCs have reduced OXPHOS and ATP production, whereas, mTOR signaling is upregulated. In future experiments, we will investigate the mechanism that CTLA4 may promote metabolic changes thus contributes to the immunoregulatory phenotype of DCs and could represent a therapeutic target.

PRONFLAMMATORY MONOCYTES AND MACROPHAGES IN SYNOVIAL FLUID AND BURSAL TISSUE OF PATIENTS WITH POLYMIALGIA RHEUMATICA: POTENT PRODUCERS OF IL-6 AND GM-CSF

W. F. Jemyl1, R. Reitsema1, A. Zhang1, M. Sandovici1, A. Boots1, P. Heeringa2, E. Brouwer1, K. Van der Geest1.

1University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands

Background: Polymyalgia rheumatica (PMR) is a common, rheumatic inflammatory disease. Inflammation of bursae and tendon sheaths is a characteristic finding for Bioinnovation-IBI, Biomedical Sciences Research Center “Alexandros Fleming”, Athens, Greece; 3Greek Genome Center, BRFAA, Athens, Greece; 4Clinic of Rheumatology, Clinical Immunology, University Hospital of Heraklion, Heraklion, Greece; 5Division of Basic Sciences, Medical School, University of Crete, Heraklion, Greece
in patients with PMR. Glucocorticoid treatment remains the mainstay treatment for PMR. A study published in 1996 reported that macrophages dominate the inflammatory infiltrate in the glenohumeral synovium of PMR patients, suggesting the importance of these cells in the pathogenesis of PMR. However, the functional and phenotypical heterogeneity of the tissue-infiltrating macrophages in PMR remains obscure. Although treatment with anti-IL-6 receptor (tocilizumab) has shown promising results, it is unclear whether macrophages contribute to IL-6 production in PMR. Additionally, anti-GM-CSF receptor therapy (mavrilimumab), recently shown to be efficacious in the closely related disease giant cell arteritis, may also be useful for the treatment of PMR.

Results:

On macrophage markers (CD68, CD86, CD64, CD206 and FRβ), macrophage polarization were included in the flow cytometry analysis. Immunohistochemistry of bursal tissue biopsies was focused on macrophage markers (CD68, CD86, CD64, CD206 and FRβ) and proinflammatory cytokines (IL-6 and GM-CSF), which were scored semi-quantitatively. Double immunofluorescence stainings were performed to determine the expression of IL-6 and GM-CSF by tissue-infiltrating macrophages in bursal tissue. Results: Monocytopenia were detected in the SF of PMR patients. The proportion of classical monocytes was significantly lowered (p = 0.001) in SF versus PB, while the proportion of intermediate monocytes was significantly elevated (p = 0.001). The expression of CD206 was significantly elevated (p = 0.001) but not FRβ in SF monocytopenia, suggesting GM-CSF skewed phenotype. In bursal tissue, macrophages displayed mixed ‘M1’/‘M2’ traits with high expression of all macrophage polarization markers. Proinflammatory cytokines IL-6 and GM-CSF were highly expressed throughout the bursal tissue biopsies. Double immunofluorescence staining confirmed the expression of IL-6 and GM-CSF by the infiltrating macrophages.

Conclusion: SF monocytopenia and bursal tissue macrophages show a pro-inflammatory phenotype in PMR. Moreover, tissue-infiltrating macrophages show a prominent IL-6 and GM-CSF response in PMR. Our data add to the rationale of targeting IL-6 and GM-CSF as treatment options in PMR.

Background: Janus kinase (JAK) inhibitors have been recognized as a potential therapeutic option in ankylosing spondylitis (r-axSpA).1 Upadacitinib (UPA), a JAK inhibitor, has demonstrated efficacy and safety in the treatment of AS2; however, no JAK inhibitor studies have been conducted in non-radiographic axSpA (nr-axSpA) to date.

Objectives: To assess the efficacy and safety of UPA in patients (pts) with active axSpA.

Methods: SELECT AXIS 2 (NCT04169373) was conducted under a master protocol comprising two independent studies, one in an AS population with an inadequate response to biologic disease-modifying antirheumatic drugs and one in an nr-axSpA population. The nr-axSpA study is a randomized, double-blind, placebo (PBO)-controlled, phase 3 trial that enrolled adults ≥18 years with a clinical diagnosis of nr-axSpA (who also fulfilled 2009 ASAS classification criteria for axSpA but did not meet the radiologic criterion of modified New York criteria), who had obvious signs of active inflammatory consistent with axSpA on MRI of the sacroiliac (SI) joints and/or high sensitivity C-reactive protein (hs-CRP) > upper limit of normal (2.87 mg/L) at screening, and who had BASDAI and pt’s assessment of total back pain scores ≥14 based on a 0 to 10 numeric rating scale at study entry. Pts were randomized 1:1 to receive oral UPA 15 mg once daily (OD) or PBO during a 52-week (wk) double-blind treatment period. The primary endpoint was ASAS40 response at wk 14. Multiplicity-controlled secondary endpoints assessed at wk 14 included BASDAI50, ASAS ID (<1.3), ASDAS LDA (<2.1), ASDAS PR, and the change from baseline (Δ) in ASDAS (CRP), SPARCC MRI SI joint inflammation score, total and nocturnal back pain, BASFI, ASQoL, ASAS HI, BASMI, and MASES. Treatment-emergent adverse events (TEAEs) were reported through wk 14 for pts who received ≥1 dose of study drug.

Results: Of 314 pts randomized at baseline, 313 received study drug (UPA 15 mg, n=156; PBO, n=157) and 295 (94%) received study drug through wk 14. Baseline demographic and disease characteristics were balanced across treatment groups and consistent with an active nr-axSpA population (58% female; mean age 42.1 years; mean BASDAI 6.9; mean hs-CRP 12.1 mg/L).

AOP0016

Efficacy and Safety of UPA in Patients with Active Non-radiographic AxSpA: Spondylarthritis: A Double-Bind, Randomized, Placebo-Controlled Phase 3 Trial

A. Deodhar1, E. Van den Bosch2, D. Poddubnyy2, W. P. Makymowych4, D. Van der Heijde5, T. H. Kim6, M. Kishimoto7, Y. Duan8, Y. Li8, A. Parang8, P. Wung8, I. H. Song9,10, Oregon Health & Science University, Division of Arthritis & Rheumatic Diseases, Portland, OR, United States of America; 2Ghent University, VIB Center for Inflammation Research, Internal Medicine and Pediatrics, Ghent, Belgium; 3Charité Universitätsmedizin, Gastroenterologie, Infectious Diseases and Rheumatology, Berlin, Germany; 4University of Alberta, Medicine, Edmonton, Alberta, Canada; 5Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 6Hanyang University Hospital, Rheumatology, Seoul, Korea, Rep. of (South Korea); 7Kyorin University School of Medicine, Nephrology and Rheumatology, Tokyo, Japan; 8AbbVie Inc., Immunology, North Chicago, IL, United States of America

Disclosure of Interests: William Febry Jiemy: None declared, Rosanne Reitsma: None declared, Anqi Zhang: None declared, Maria Sandovici: None declared, William Febry Jiemy: None declared, Rosanne Reitsma: None declared, Anqi Zhang: None declared, Maria Sandovici: None declared, Jan van der Geest Consultant of: K. van der Geest (University Medical Center Groningen).
A significantly higher ASAS40 response rate at wk 14 was achieved with UPA vs PBO (45% vs 23%; P<0.0001; Figure 1). Statistical significance was also achieved in the first 12 of the 14 multiplicity-controlled secondary endpoints (ie, all endpoints except BASMI and MASES) and at wk 14 for UPA compared with PBO (P<0.001; Figure 1). The proportion of pts who experienced a TEAE was similar between treatment groups (UPA, 48%; PBO, 46%). Serious TEAEs and TEAEs leading to discontinuation were reported in 4 (2.6%) pts treated with UPA and 2 (1.3%) pts treated with PBO, respectively. Few pts had serious infection or herpes zoster (each 2 [1.3%] pts on UPA; each 1 [0.6%] pt on PBO, respectively). Uveitis was reported in 1 (0.6%) pt on PBO who had a history of uveitis and none on PBO. No malignancy other than non-melanoma skin cancer, major adverse cardiovascular events, venous thromboembolic events, inflammatory bowel disease (IBD), or death were reported in the study; 1 event of basal cell carcinoma occurred with PBO.

**Conclusion:** UPA 15 mg QD demonstrated significantly greater improvements in disease activity, pain, function, quality of life, and MRI-detected SI joint inflammation than PBO after 14 wks of treatment in pts with active nr-axSpA. The safety profile of UPA was consistent with what has been observed with other inflammatory musculoskeletal diseases,3–5 and no new risks were identified. These results support the potential use of UPA in pts with active nr-axSpA.

**Objectives:** Here, we describe the final results of pts re-randomized to either placebo (PBO; IXE Withdrawal) or IXE, who experienced flare, and recaptured response before or after open label retreatment during COAST-Y.

**Methods:** COAST-Y (NCT03129100) is a Phase 3, long-term extension study that included a double-blind, PBO-controlled, randomized withdrawal-retreat- ment period (RWP). Eligible pts who completed an originating study (COAST-V, -W, or -X) entered a 24-week (Wk) lead-in period and received 80 mg IXE every 2 (Q2W) or 4 wks (Q4W) (the treatment regimen at the end of the originating study); pts receiving PBO at the end of COAST-X were assigned to IXE Q4W in COAST-Y. Pts who achieved remission (Ankylosing Spondylitis Disease Activity Score (ASDAS) <1.3 (inactive disease; ID) at least once at Wk 16 or 20, and >2.1 (low disease activity; LDA) at both visits) were randomized 2:1 at Wk 24 to continue IXE (as per lead-in period) or withdrawn to PBO. Pts who subsequently experienced flare (ASDAS ≥2.1 at 2 consecutive visits or ASDAS >3.5 at any visit) were switched to open label IXE Q2W or Q4W at the next visit (same as lead-in period).

**Results:** Time to first flare was analyzed using the Kaplan-Meier method with treatment comparison performed using log-rank test. The observed proportion of pts who recaptured ASDAS LDA and ID were summarized for pts who experienced flare and were retreated with open label IXE.

**Conclusion:** Pts continuously treated with IXE were less likely to experience flare vs pts on PBO (IXE withdrawal). The vast majority of pts withdrawn from IXE to PBO recaptured at least LDA and over half met ID with IXE retreatment. This may provide support for pts who require interruption in therapy.

Methods: Eligible patients had r-axSpA and high disease activity (BASDAI ≥4), NSAID failure and risk factors for radiographic spinal progression: C-reactive protein >5 mg/L and/or ≥1 syndesmophyte(s). The trial consisted of two phases: a 12-week initiation phase followed by a 108-week controlled treatment period, in which patients participating rheumatologist and included patients.

Background: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. In a phase 2b study, BKZ showed rapid results in the treatment of ankylosing spondylitis (AS) patients.

Objectives: To assess efficacy and safety of BKZ vs placebo (PBO) in pts with active AS up to Wk 24 in the ongoing pivotal phase 3 study, BE MOBILE 2.

Methods: BE MOBILE 2 (NCT03928743) comprises a 16-wk double-blind, PBO-controlled period and 36-wk maintenance period. Pts were aged ≥18 yrs, met modified New York criteria and had active AS (BASDAI ≥4, spinal pain ≥4) at BL, Pts were randomised 2:1; BKZ 160 mg Q4W; PBO. From Wk 16, all pts received BKZ 160mg Q4W. Primary and secondary efficacy endpoints were assessed at Wk 16.

Results: Of 332 randomised pts (BKZ: 221; PBO: 111), 322 (97.0%) completed Wk 16 and 313 (94.3%) Wk 24. BL characteristics were comparable between groups: mean age 40.4 yrs, symptom duration 13.5 yrs; 72.3% pts male, 85.5% HLA-B27+. 16.3% TNFi-experienced. At Wk 16, the primary (ASAS40: 44.8% BKZ vs 22.5% PBO; p<0.001) and all ranked secondary endpoints were met (Table 1). Responses with BKZ were rapid, including in PBO pts who switched to BKZ at Wk 16, and increased to Wk 24 (Figure 1; Table 1). Substantial reductions of hs-CRP by Wk 2 and MRI SIJ and spine inflammation by Wk 16 were achieved with BKZ vs PBO (Table 1). At Wk 24, ≥50% pts had achieved ASDAS <2.1 (Figure 1).

Over 16 wks, 120/221 (54.3%) BKZ pts had at least one TEAE vs 48/111 (43.2%) PBO; three most frequent on BKZ were nasopharyngitis (BKZ: 7.7%; PBO: 3.6%), headache (4.1%; 4.5%) and oral candidiasis (4.1%; 0%). No systemic candidiasis was observed. Up to 16 wks, incidence of SAEs was low (1.8%; 0.9%); no MACE or deaths were reported; 2 (0.9%) IBD cases occurred in pts on BKZ.

Conclusion: Dual inhibition of IL-17A and IL-17F with BKZ in pts with active AS resulted in rapid, clinically relevant improvements in efficacy outcomes vs PBO. No new safety signals were observed.1,2

Background: Exposure reveals sex differences in physiology, disease presentation and response to treatment in axial spondyloarthritis (axSpA). Pooled data from four randomized controlled trials demonstrated reduced treatment efficacy and response to treatment in axial spondyloarthritis (axSpA). However, real-life evidence confirming these data in large cohorts is scarce. We sought to validate prior studies using data from a large multinational cohort based on real-life clinical practice.

Objectives: To investigate sex differences in treatment response and drug retention rates in clinical practice among patients with axSpA.

Methods: Data from biologic-naïve axSpA patients initiating a TNFi in the EuroSpA registries were pooled. In the primary analysis, propensity-score weighting was applied to assess the causal effect of sex on clinically important improvement (CII) according to ASDAS-CRP at 6 months. A generalized linear regression model was used to estimate the causal risk difference (RD) and relative risk (RR) on sex. Possible covariates influencing the outcome were determined a priori and selected based on availability in the database (<20% missing). The final model included country, age and TNFi start year. In the secondary analysis, drug retention was assessed over 24 months of follow-up by Kaplan-Meier curves and log-rank test.

Results: In total, 6,451 axSpA patients with available data on ASDAS-CRP at baseline and 6 months were assessed for treatment response. Baseline characteristics are shown in the Table 1. In the adjusted analysis, the probability for females to have CII was 15% (RR, 0.85; 95% confidence interval [CI], 0.82 to 0.87).
0.89) lower compared to males and the difference in probability for having CII was 9.4 percentage points (RD: 0.094; 95% CI, 0.069 to 0.12). The survival analysis included 28,608 axSpA patients with available data on retention rates. The TNFI 6/10/24-month retention rates were significantly lower in females (81%/69%/58%) compared to males (89%/81%/72%), see Figure 1.

mNYC, modified New York criteria; TNFI, tumor necrosis factor inhibitor; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; ASDAS, Ankylosing Spondylitis Disease Activity Score; CRP, C-reactive protein; SJC, swollen joint count; TJC, tender joint count; VAS, visual analogue scale.

Figure. Sex differences in 24-month retention rates in first-line tumor necrosis factor inhibitors. In patients with axial spondyloarthritis in EvosPA (N=10288; log-rank test: p=0.001).

Conclusion: Treatment efficacy and retention rates are lower among female patients with axSpA initiating their first TNFI. Females presented with lower C-reactive protein levels and higher scores on patient reported outcomes at baseline, reflecting differences in disease expression. Recognizing these sex differences is of relevance for customized patient care and may improve patient education.

TREATMENT WITH NON-STEROIDAL ANTI-INFLAMMATORY DRUGS IS ASSOCIATED WITH RETARDATION OF RADIOGRAPHIC SPINAL PROGRESSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: 10-YEAR RESULTS FROM THE GERMAN SPONDYLOARTHRITIS INCEPTION COHORT

M. Torpatak1, V. Rios Rodriguez2, A. Dilibarany3, F. Proch3, M. Popotopov3, M. Verba1, J. Rademacher1, H. Haibel1, J. Sieper1, M. Rudwaleit2, D. Poddubny1, C. chaired—Universitätsmedizin Berlin, corporate member of Freie Universität Berlin und Humboldt-Universität zu Berlin, Department of Gastroenterology, Infectious Diseases, and Rheumatology (including Nutrition Medicine), Berlin, Germany;2Moscow City Clinical Hospital, Department of Internal Medicine, Moscow, Russian Federation;3University of Bielefeld, Department of Internal Medicine and Rheumatology, Bielefeld, Germany.

Background: There are conflicting data regarding effect of nonsteroidal anti-inflammatory drugs (NSAID) on radiographic spinal progression in axial spondyloarthritis (axSpA) The analysis of the first 2-year of the GERSpIC showed that higher NSAID intake may retard new bone formation in r-axSpA. It remained, however, unclear, whether cyclooxygenase-2 selective inhibitors (COX2I) might have a stronger effect than non-selective (NS) ones and if the effect could be observed also in r-axSpA.

Objectives: To investigate the effect of NSAIDs (COX2I and NS) intake on radiographic spinal progression in patients with axSpA.

Methods: Based on availability of at least two sets of spinal radiographs during 10-year follow-up, 243 patients with early axSpA (130 and 113 nr- and r-axSpA, respectively) from GERSpIC were included in this analysis. The patients contributed a total of 540 2-year radiographic intervals. Radiographs were scored by 3 trained and calibrated readers according to modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Final mSASSS was calculated as mean of 3 paired readers, and progression was defined as absolute mSASSS change score over 2 years. NSAID type, daily dose, and frequency of intake were recorded at visit. The ASAS index of NSAID intake (0-100) counting both dose and duration of intake was calculated for intervals. The association between NSAID intake
Evidence-Based Research, Copenhagen, Denmark; Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, Odense, Denmark; Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; Randers Regional Hospital, Department of Rheumatology, Randers, Denmark; Odense University Hospital, Department of Rheumatology, Odense, Denmark; University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark; Aalborg University, Department of Clinical Medicine, Aalborg, Denmark.

Background: Traditionally, biologics are maintained lifelong at standard dose in patients with inflammatory arthritis (IA) when sustained low disease activity (LDA) is reached. However, evidence of possible tapering is emerging but data on the optimal approach is lacking.

Objectives: The primary outcomes at 18 months follow-up are:

- Superiority: The proportion of patients reduced to ≤50% of their baseline biologic dose.
- Equivalence: Disease activity (rheumatoid arthritis [RA] and psoriatic arthritis [PsA]): Disease Activity Score28-C- Reactive Protein [DAS28-CRP] and axial spondyloarthritis [axSpA]: Anklyosing Spondylitis Disease Activity Score [ASDAS]).

Methods: The BIODOPT trial was a randomised, open-label, equivalence trial (EudraCT 2017-001970-41). Eligible patients were adults with RA, PsA, or axSpA in LDA on stable biologic doses during ≥12 months. The randomisation ratio was 2:1 (tapering:continuation) stratified by diagnosis, centre, and repeated biologic failures. In the tapering group, the biologic dosing interval was prolonged by 25% every four months until flare or discontinuation. The continuation group was kept on their baseline biologic dosing interval; however, a small increase was allowed (as usual practise) if requested by the patient. The sample size calculation was based on a pre-defined equivalence margin of ±0.5 disease activity points (score of the minimal important difference in DAS28-CRP [±1.2] or ASDAS [±1.1]) yielding a power of 87% for 180 enrolled patients. All analyses were based on the intention-to-treat population. Continuous outcomes were analysed with repeated-measures linear mixed-effects models with group, diagnosis, centre, repeated biologic failures, time point, and the interaction between group and time as fixed factors and the baseline value of the relevant variable as a covariate. Categorical outcomes were analysed using logistic regression with missing data imputed as trial failures.

Results: Between May, 2018, and March, 2020, 142 patients were enrolled of which 95 were randomised to tapering and 47 to continuation; inclusion was closed in April 2020 due to national implications of the coronavirus pandemic. At 18 months, significantly more patients in the tapering group (35 patients [37%]) achieved a significant reduction in their biologic dose (≥50%) compared to the continuation group (one patient [2%]), absolute risk difference (RD) 35%, 95%CI: 24% to 45%, p=0.001. Table 1. Furthermore, disease activity at 18 months was within the equivalence margins of ±0.5, mean difference between groups 0.08, 95%CI: -0.12 to 0.29; Table 1 and Figure 1. Flares were more frequent in the tapering group (39 [41%] vs 10 [21%], RD 0.20, 95%CI: 0.04 to 0.35, p=0.011) but managed with rescue therapy (e.g. biologic dose escalation or glucocorticoids) as only one patient (1%) in the tapering group and three patients (6%) in the continuation group lost therapeutic response and were switched to another biological agent.

University, Rheumatology, Portland, United States of America; 2Altona Center for Clinical Research, Altona Arthritis and Osteoporosis Center, Duncansville, United States of America; 3University Hospitals Cleveland Medical Center, Case Western Reserve University School of Medicine, Rheumatology, Cleveland, United States of America; 4University of Utah School of Medicine and Salt Lake City Veterans Affairs Medical Center, Rheumatology, Salt Lake City, United States of America; 5Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, United States of America; 6Desert Medical Advances, Rheumatology, Palm Desert, United States of America; 7Novartis Pharmaceuticals Corporation, Rheumatology, East Hanover, United States of America; 8Novartis Pharmaceuticals Corporation, Biosciences, East Hanover, United States of America; 9Novartis Pharmaceuticals Corporation, Clinical Research, East Hanover, United States of America; 10Novartis Healthcare Pvt Ltd, Biosciences, Hyderabad, India; 11University of California, Department of Medicine, San Francisco, United States of America.

Background: Ankylosing spondylitis (AS) is a chronic, systemic inflammatory condition characterized by inflammatory back pain and is associated with extra-musculoskeletal manifestations and systemic comorbidities. Although biologic therapies for AS are available, no dose escalation studies are available in patients who have inadequate response to SEC 150 mg.

Objectives: The ASLep study (NCT03350815) estimated the difference in clinical response to SEC 300 mg vs 150 mg at Week (Wk) 52 in patients with AS who failed to achieve Ankylosing Spondylitis Disease Activity Score (ASDAS) inactive disease status on SEC 150 mg at Wk 16.

Methods: In this randomized, double-blind, parallel-group, multicenter, phase 4 study, 322 patients with AS who were assigned to receive open-label SEC 150 mg administered per the label for 16 Wks (period 1). At Wk 16, patients who did not achieve inactive disease (ASDAS < 1.3) at Wks 12 and 16 were randomized 1:1 in a double-blind manner to SEC 150 mg or escalated to SEC 300 mg q4w to Wk 52 (period 2). The primary efficacy variable was achievement of ASDAS < 1.3 and the primary analysis time point was Wk 52. Secondary efficacy variables were achievement of ASDAS clinically important improvement ≥ 1.1, 50% improvement in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI50), Assessment of SpondyloArthritis international Society responses (ASAS20, ASAS40, and ASAS partial remission), and change from baseline in BASDAI, ASAS Health Index (ASAS-HI), and the Functional Assessment of Chronic Illness Therapy – Fatigue Scale (FACIT-F). Safety was evaluated by incidence of treatment-emergent adverse events (TEAEs) within Wk 52. No statistical hypothesis tests for superiority or equivalence were planned in the protocol and none were performed.

Results: Of 279 patients receiving SEC 150 mg who completed the 16-wk open-label period 1, 22 (79%) achieved ASDAS < 1.3 at Wks 12 or 16 and continued receiving SEC 150 mg; 207 patients did not attain ASDAS < 1.3 at Wk 12 and Wk 16 and initiated period 2. Demographics and baseline disease characteristics were balanced between patients randomized to SEC 150 mg and SEC 300 mg, including the proportion of patients who were TNFi naive (SEC 150 mg: 73 [72.3%]; SEC 300 mg: 73 [69.5%]) (Table 1). Approximately 60% of patients in either SEC group were HLA-B27 positive. After having an inadequate response to SEC 150 mg through Wk 16, patients receiving either dose of SEC experienced similar improvements at Wk 52 in disease activity as measured by achievement of ASDAS < 1.3, ASDAS clinically important improvement ≥ 1.1, BASDAI50, ASAS20, ASAS40, and ASAS partial remission; and mean changes in BASDAI, quality of life as measured by ASAS HI, and fatigue as measured by FACIT-F (Figure 1). The incidence of TEAEs through Wk 52 was similar between patients receiving SEC 300 mg (63.4%) and 150 mg (68.6%).

Differential in Period 2 (safety set)

Background: The differential contribution of IL-6 and IL-17 pathways to the pathogenesis of psoriatic arthritis (PsA) is not fully understood. Upadacitinib (UPA), an oral JAK inhibitor, was more effective than placebo (PBO) in improving key clinical manifestations of PsA in two global phase 3 trials, SELECT-Psa1 (non-biological DMARD-IR, nbDMARD-IR) and SELECT-Psa2 (biological DMARD-IR, bDMARD-IR).3,4 Targeted proteomic analysis suggested that UPA modulates multiple biological pathways in innate and adaptive immune systems via direct and indirect inhibition of key regulators, including IL-6 and IL-17 pathways, with a possible shift from Th1 predominance in nbDMARD-IR PsA to a more Th17 bias in bDMARD-IR PsA.3,4

Objectives: We assessed the relationship between IL-6 and IL-17 pathway modulation and different clinical outcomes after UPA treatment in nbDMARD-IR and bDMARD-IR PsA patients.

Methods: A subset of patients was randomly selected from SELECT-Psa1 (n=74 of UPA 15 mg QD, n=74 of PBO) and PsA 2 studies (n=90 of UPA 15 mg QD, n=81 of PBO). Serum levels of IL-6, IL-17A, IL-17F, and beta-defensin 2 (BD2) proteins were measured at baseline, week 2, and week 12 by validated immunoassays. The quantitative cytokine measurements were transformed as log10, and PASI score was transformed as log10 (x+1) prior to analysis. A Repeated Measure Mixed Linear Model was used to compare UPA versus PBO treatment effects in overall selected patients and between responders and non-responders defined by PASDAS score ≤ 3.6 (Minimal Disease Activity, MDA) and PASI75 at week 12, respectively. The relationships between cytokines and clinical outcomes (PASI) and DAS28-CPRO were assessed by Pearson’s correlation at baseline and after treatment.

Results: In nbDMARD-IR PsA patients, baseline IL-17A, IL-17F, and BD2 levels were measured at baseline, week 2, and week 12 by validated immunoassays. The quantitative cytokine measurements were transformed as log10, and PASI score was transformed as log10 (x+1) prior to analysis. A Repeated Measure Mixed Linear Model was used to compare UPA versus PBO treatment effects in overall selected patients and between responders and non-responders defined by PASDAS score ≤ 3.6 (Minimal Disease Activity, MDA) and PASI75 at week 12, respectively. The relationships between cytokines and clinical outcomes (PASI) and DAS28-CPRO were assessed by Pearson’s correlation at baseline and after treatment.

References:
Background: Fatigue, one of the top 3 patient (pt)-reported symptoms of psoriatic arthritis (PsA) and a recent PsA outcome domain,\(^1\) causes impaired health-related quality-of-life, diminished productivity, and disability.\(^2,3\) Although the origins of fatigue are multifactorial, inflammation is hypothesized to play an important role.\(^4\) In pts with active PsA, treatment with guselkumab (GUS) led to clinically meaningful and sustained improvements in fatigue through 1 year in DISCOVER-1 (D1) and DISCOVER-2 (D2).\(^5\)

Objectives: To identify 1) factors associated with fatigue and 2) factors associated with change in fatigue among pts with PsA treated with GUS.

Methods: In the Phase 3 D1 (N=381, biologic-naive and tumor necrosis factor inhibitor-experienced) and D2 (N=739, biologic-naive) studies, pts with active PsA despite standard therapies and/or biologic disease-modifying antirheumatic drugs were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO) with crossover to GUS 100 mg Q4W at W24. The pt-reported Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue) scale measured fatigue (scored 0-52). In these post-hoc analyses of D1 and D2 pts, a principal component analysis (PCA) was performed using W0 data to identify the underlying baseline factors associated with fatigue. Additionally, linear regression analyses were performed to identify covariates associated with change in fatigue from W0 to W24.

Results: In 1120 pts (mean age 47 yrs, mean disease duration 5.9 yrs, 48% female), mean FACIT-Fatigue scores at baseline ranged from 29.1 to 31.4 (vs 43.6 for the general US population).\(^6\) PCA showed that 62% of the variability in fatigue could be explained by 3 components (Figure 1). The first component, explaining 34% of variability in fatigue, largely comprised systemic disease activity and function measures such as pain, pt global assessment of disease activity (PtGDA), physician’s global assessment of disease activity, and Health Assessment Questionnaire-Disability Index (HAQ-DI). The second component, explaining 16% of variability, comprised joint manifestations including swollen joint count (SJc) and tender joint count (TJc). Skin involvement as assessed by Psoriasis Area and Severity Index (PASI) and systemic inflammation (C-reactive protein [CRP]) could explain 12% of the variability in fatigue (Figure 1 and Table 1). In a multivariate linear regression analysis, after adjusting for effects from other variables, improvement in CRP, physical function in fatigue (Figure 1 and Table 1). In a multivariate linear regression analysis, after adjusting for effects from other variables, improvement in CRP, physical function, and HAQ-DI were significantly associated with fatigue improvement from W0 to W24.

| TJC (0-66) | 0.54 | 0.70 | -0.18 |

VAS=Visual Analog Scale.

Conclusion: Among pts with PsA, measures of systemic disease activity and function, followed by joint manifestations, and skin involvement/inflammation accounted for 62% of the variability in fatigue. The large residual effect (38%) that was unexplained by the current model suggests the need for further research to identify additional factors (eg, distinct molecular pathways) contributing to the fatigue reported by PsA pts.

OP0026  CLINICAL AND IMAGING-BASED CHARACTERIZATION OF A PROSPECTIVE COHORT OF PATIENTS WITH AXIAL PSORIATIC ARTHRITIS (AXIAL PSA). GESPECTIC-AXIAL PSA: RESULTS OF AN INTERIM ANALYSIS

H. Käding1, S. Lüders1, M. Protopopov1, J. Rademacher1, V. Rios Rodriguez2, L. Spiller1, M. Torgutalp1, D. Poddubnyy1, F. Proft1. 1Charité - Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany. 2German Rheumatism Research Centre, Epidemiology unit, Berlin, Germany

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease, which is subsumed together with axial spondyloarthritis (axial SpA) under the umbrella term spondyloarthritides, whose clinical presentations are very heterogeneous. Axial involvement (axial PsA) has been described to be present in 34% of PsA patients [1] and has been systematically investigated only retrospectively or in cross-sectional studies [2]. Although axial PsA seems to have similar characteristics to axial SpA, it is not clear whether axial PsA and axial SpA, are a spectrum of the same disease with different expression patterns or different diseases with great similarities.

Objectives: To prospectively investigate the clinical and imaging morphology patterns in a well-defined cohort of patients with axial PsA from the German Spondyloarthritis Inception Cohort (GESPECTIC).

Methods: Prospective, longitudinal, observational study of patients with an imaging confirmed diagnosis of axial PsA. In addition to clinical and laboratory characterization, conventional radiographs and magnetic resonance imaging (MRI) - scans of the entire spine and sacroiliac joints (SIJs) are performed at the baseline visit and patients are followed up every 6 months according to a predefined protocol. After 2 years, additional imaging (X-ray and MRI) is performed for follow-up. In this interim analysis baseline data are presented.

Results: Between August 2019 and December 2021, 85 axial PsA patients were included. The mean age was 45.2 ± 12.9 years with a proportion of 55.3% female patients. Periphal involvement was present in 43 (50.6%) patients. HLA-B27 was positive in 39 (45.9%), and C-reactive protein was elevated (>5mg/l) in 27 (31.8%) patients. Inflammatory back pain (IBP) present, n (%) 64 (75.3%). Peripheral Involvement, n (%) 43 (50.6%). Nail Involvement, n (%) 39 (45.9%). BASFI (mean ± SD), 0-10 3.8 ± 2.5. BASDAI (mean ± SD), 0-10 4.9 ± 2.0. ASDAS-CRP (mean ± SD) 2.8 ± 1.0. ASDAS (mean ± SD) 14.5 ± 9.2. HLA-B 27 positive, n (%) 39 (45.9%). CRP >5mg/l, n (%) 27 (31.8%).

ASDAS-CRP =Ankylosing Spondylitis Disease Activity Score - CRR BASDAI = Bath Ankylosing Spondylitis Disease Activity Index; BASFI = Bath Ankylosing Spondylitis Functional Index, CRP = C-reactive protein, DAPSA = Disease Activity in Psoriatic Arthritis-Score, PASI = Psoriasis Area Severity Index, PsA = Psoriatic arthritis, SD = standard deviation.

Conclusion: In the here presented interim analysis of the baseline data of our prospective cohort study of patients with an imaging-based diagnosis of axial PsA, it is shown that these patients are less frequently HLA-B27 positive and more frequently female when compared to previously described cohorts of “classical” axial SpA patients. Noteworthy, nearly 20% of the patients showed an isolated spinal involvement without active or structural changes in the SIJs.

Background: Common comorbidities of psoriatic arthritis (PsA) and psoriasis (PsO) are cardiovascular (CV) disease and metabolic syndrome (MetS). Risk of CV disease may be associated with increased risk of future malignancies. Tofacitinib is a JAK inhibitor for treatment of PsA and has been investigated for treatment of PsO.

Objectives: To examine baseline (BL) CV risk and its association with incidence rates (IRs) of major adverse CV events (MACE) and malignancies in tofacitinib-treated patients (pts) with PsA and PsO.

Methods: Analysis included data from 3 (Phase [P]3/long-term extension [LTE]) trials of pts with PsA and 7 (P2/LTE) trials of pts with PsO receiving ≥1 dose of tofacitinib (5 or 10 mg twice daily). IRs (pts with events/100 pt-yrs) for MACE and malignancies (excluding non-melanoma skin cancer) were stratified by: history of coronary artery disease (HxCAD [≥1 of myocardial infarction, coronary heart disease, coronary artery procedure or stable angina pectoris]); BL 10-yr atherosclerotic CV disease (ASCVD); and BL MetS (≥3 of hypertension, raised triglycerides, reduced high-density lipoprotein cholesterol, high waist circumference or high fasting glucose levels).

Results: Of 783 and 3663 pts with PsA and PsO, total tofacitinib exposure was 2036 and 8950 pt-yrs, and median duration of exposure was 3.0 and 2.4 yrs, respectively. In pts with PsA and PsO, 5.0% and 2.5% had HxCAD, respectively; in those without HxCAD, >20% had intermediate/high BL 10-yr ASCVD risk (Figure 1). At BL, 40.9% and 32.7% of pts with PsA and PsO had MetS, respectively. IRs of MACE were greatest in pts with PsA and PsO who had HxCAD/high BL 10-yr ASCVD risk (Table 1). In the PsA cohort, 5/6 pts with MACE had MetS, respectively. IRs of malignancies in pts with PsA were greatest in those with intermediate/high BL MetS (Table 1). In the PsO cohort, IRs of malignancies was notably greater in pts with PsO were greatest in those with intermediate/high BL MetS (Table 1). In the PsA cohort, 5/6 pts with MACE had BL MetS. IRs of MACE and malignancies were stratified by: history of coronary artery disease, ASCVD-pooled cohort equations calculator (only in pts without HxCAD); and BL 10-yr atherosclerotic CV disease (ASCVD-pooled cohort equations calculator [only in pts without HxCAD]); and BL 10-yr atherosclerotic CV disease (HxCAD [≥1 of myocardial infarction, coronary heart disease, coronary artery procedure or stable angina pectoris]); BL 10-yr atherosclerotic CV disease (ASCVD) risk (ASCVD-pooled cohort equations calculator only in pts without HxCAD); and BL MetS (≥3 of hypertension, raised triglycerides, reduced high-density lipoprotein cholesterol, high waist circumference or high fasting glucose levels). Conclusion: In tofacitinib-treated pts with PsA and PsO, raised CV risk and MetS at BL were potentially associated with higher IRs of MACE and malignancies. Our findings support assessing CV risk in pts with PsA and PsO and enhanced monitoring for malignancies in those with raised CV risk.

Background: Minimal disease activity (MDA) is a treatment target in psoriatic arthritis (PsA) that takes both clinical manifestations (joints, skin and enthesis) and the patient perspective into account (1). In a previous study we have shown that achieving MDA in the first year is associated with better quality of life (QoL) regardless whether this was achieved early or late in the first year (2). However, the impact of achieving MDA within the first year on the long-term is lacking.

Objectives: To compare quality of life at 1, 2 and 3 years between PsA patients who achieve MDA in the first year and those who do not.

Methods: Newly diagnosed, DMARD naïve PsA patients with oligo- or polyarthritis and at least 3 years of follow-up, participating in the Dutch southwest Early PsA cohort (DEPAR) were included. In short the DEPAR is an observational cohort of newly diagnosed PsA (3). Study visits took place at 3, 6, 9, 12, 18, 24 and 36 months after diagnosis. Patients were categorized in three groups by achievement of MDA in the first year:

- Sustained MDA, includes patients who were in MDA at both their 9- and 12-month visit;
- Non-sustained MDA, includes patients who achieved MDA in the first year but did not sustain it at both 9- and 12-months;
- No MDA, includes patients who did not achieve MDA in the first year.

To measure QoL at 1, 2 and 3 years the Short form-36 (SF-36) questionnaire was used. Descriptive statistics were used to compare QoL.

Results: We included 243 patients (51% male) of whom 113 (47%) were classified as sustained MDA, 64 (26%) as non-sustained MDA and 66 (27%) as no MDA. At baseline, patients had a mean age of 52.7 years and median symptom duration of 9.3 months. Patients in the no MDA group seemed to be older, were more often female and had a longer symptom duration (Table 1). QoL of sustained MDA patients was comparable to the general Dutch population (4) after 1, 2 and 3 years of follow-up. However, patients who did not achieve MDA in the first year had a lower QoL compared to the sustained MDA group and these differences persist in the years thereafter (Figure 1). The physical as well as the mental QoL domains were worse in the no MDA group compared to the other groups.

Results are shown as mean ± standard deviation, n (%) or median (interquartile range). BSA: Body Surface Area; LEI: Leeds Enthesitis Index; HAQ: Health Assessment Questionnaire; VAS: visual analogue scale.

Over the years, treatment was intensified in all groups, with biologicals use after three years at 18%, 25% and 31% in the sustained MDA, non-sustained MDA and no MDA group, respectively.

Figure 1. (A) 1 year, (B) 2 year and (C) 3 year quality of life scores, measured with the SF-36 domains, for MDA groups and compared with the general Dutch population norms (4). (D) percentage of patients who use biologicals over time per MDA group.

Conclusion: Failure to achieve MDA in the first year after PsA diagnosis is associated with worse quality of life outcomes that persist over the years despite more intensified treatment.

sensitivity and specificity of diagnostic screening tools for PsA. Musculoskeletal ultrasonography (MSUS) has been shown to be a reliable tool for diagnosing PsA, even in preclinical situations. However, the use of MSUS screening by dermatologists in the early detection of PsA has not been studied so far.

**Objectives:** The purpose of this study was to assess the accuracy of early PsA identification by dermatologists who have been previously trained in MSUS utilizing an innovative handheld-ultrasound device (Butterfly IQ).

**Methods:** Twelve dermatologists have been trained in MSUS (2) previously by a newly designed curriculum. Six working at the clinic for Dermatology and Allergology of the University Hospital Bonn, while the remaining six serve in private practices. The MSUS training curriculum focused mainly on detecting joint effusion and synovial hyperperfusion in all joints. After successful training, these colleagues were provided with handheld-ultrasound devices in order to screen 140 psoriasis patients presenting with arthralgia. Dermatologists were asked to determine whether or not the patient had PsA based on the medical history, clinical examination, and GEPARD questionnaire. Subsequently a MSUS exam of up to three painful joints was conducted by the dermatologists using the provided handheld-ultrasound devices. The post MSUS decision was also recorded. All prescreened patients were then referred to blinded board-certified rheumatologists with MSUS certification (EFSUMB level II and III), which repeated medical history, clinical examination and MSUS. We investigated the impact of MSUS on the sensitivity and specificity of early PsA diagnosis by comparing dermatologists’ pre- and post-ultrasound PsA suspicion with the final diagnosis determined by the rheumatologist.

**Results:** In total, 140 patients were enrolled. PsA was detected in 24 cases. The sensitivity of dermatologists’ pre-MSUS PsA suspicion was 81.0% while the specificity was 54.5%. After conducting MSUS the sensitivity and specificity of early PsA diagnosis by comparing dermatologists with MSUS certification (EFSUMB level II and III) repeated medical history, clinical examination and MSUS. We investigated the impact of MSUS on the sensitivity and specificity of early PsA diagnosis by comparing dermatologists’ pre- and post-ultrasound PsA suspicion with the final diagnosis determined by the rheumatologist.

**Conclusion:** We were able to demonstrate that targeted MSUS performed by dermatologists increases specificity while decreasing sensitivity, perhaps leading to three painful joints was conducted by the dermatologists using the provided handheld-ultrasound devices. The post MSUS decision was also recorded. All prescreened patients were then referred to blinded board-certified rheumatologists who have been previously trained in MSUS utilizing an innovative handheld-ultrasound device (Butterfly IQ).

SEROLOGICAL COLLAGEN BIOMARKERS CAN DIFFERENTIATE PATIENTS WITH PSORIASIS FROM PSORIATIC ARTHRITIS

S. S. Groen1,2, S. Holm Nielsen1,2, A. C. Bay-Jensen3, M. Rastå, D. Ganatra4, K. Oikonomopoulou5, V. Chandran1,2, University of Copenhagen, Biomedical Sciences, Copenhagen; Denmark; Nordic Bioscience, ImmunoScience, Herlev, Denmark; Nordic Bioscience, ImmunoScience, Herlev, Denmark; Technical University of Denmark, Biotechnology and Biomedicine, Kgs. Lyngby, Denmark; Krembi Research Institute, Schroeder Arthritis Institute, Toronto, Canada; Institute of Medical Science, Department of Medicine, Division of Rheumatology; Department of Laboratory Medicine and Pathobiology; Toronto, Canada.

Methods: Patients with PsA (n=87, median age 42.01 ±12.20, 44% female) underwent a full rheumatologic assessment to exclude PsA and patients with PsA (n=99, mean ±SD age 45.94 ±12.47, 49% female) were recruited at the Toronto Western Hospital, Canada, after appropriate ethics approval. ECM remodelling was estimated using as indices serological anabiotic biomarkers quantifying formation of type III, IV, and VI collagen (PRO-C3, PRO-C4, and PRO-C6 respectively), and catabolic biomarkers measuring degradation of type I, III, IV and VI collagen (C1M, C3M, C4M, C6M respectively). Data are presented as mean ± standard deviation (SD). Statistically significant difference between the two groups was calculated by Mann-Whitney U test and a p-value below 0.05 was considered significant. Area under the receiver operating characteristic (ROC) curve (AUC) analysis was performed to describe the discrimination accuracy of each biomarker between the two patient groups.

Results: Patients with PsA presented higher levels of C1M, C3M, C6M, and PRO-C6 compared to PsC (p<0.0460-p<0.0009, Figure 1 A, B, D, G), while biomarkers levels of C4M, PRO-C3, and PRO-C4 were not significantly different between PsC and PsA patients (Figure 1 C, E, F). Moreover, C1M and C6M were able to separate between PsC and PsA patients with an AUROC=0.6277 (p=0.0027) and AUROC=0.6446 (p=0.0010), respectively, indicating that these biomarkers may be markers of joint involvement (Figure 1 H, I).

Conclusion: This work provides evidence that serum degradation biomarkers of type I and VI collagen were able to differentiate patients with PsA from PsC and may be potential biomarkers of inflammatory systemic musculoskeletal involvement. These findings suggest that serological biomarkers may be used to identify the 25% of psoriasis patients that have PsA.

From risk assessment to societal outcomes

AN ECONOMIC WINDOW OF OPPORTUNITY FOR PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: 5-YEAR COST-EFFECTIVENESS ANALYSIS OF THE CARERA TRIAL

S. Pazoni1, V. Stoufen1, D. De Cock1, M. Doumen1, D. Bertrand1, J. Joly2, R. Westhovens1,2, P. Verschueren1,2, on behalf of CareRA study group.
1Katholieke Universiteit Leuven, Development and Regeneration, Leuven, Belgium; 2UZ Gasthuisberg Campus, Rheumatology, Leuven, Belgium.

The CareRA trial showed that remission induction with methotrexate (MTX) and glucocorticoid (GC) bridging in a treat-to-target setting is cost-effective up to 2 years in early rheumatoid arthritis (eRA) patients. Our aim was to determine the cost-effectiveness of the CareRA (COBRA-Slim) trial in low- and high-risk populations over 5 years. No other studies have evaluated the CareRA compared to the other Step-Up: TSU)

Methods: 322 eligible patients, 252 were included in CareRA plus, of which 203 completed the trial. Patients were randomly assigned to receive MTX and a step-down GC scheme (COBRA-Slim) compared to (a) the same combination with either sulfasalazine (COBRA-Classic) or leflunomide (COBRA-Avant-Garde) in high-risk patients and (b) MTX without GCs (Tight-Step-Up TSU) in low-risk patients up to 5 years.

Results: Of 322 eligible patients, 252 were included in CareRA plus, of which 203 completed the trial. Rates of disease control (DAS28-CRP<2.6) at year 5 in high-risk patients were 68%, 72%, and 64% in the Classic, Slim and Avant-Garde group respectively (p=0.63) and related total costs were €11 358.39 (CI 7 776.84-14 939.93), €5 340.34 (CI 3 607.63-7 075.11) and €11 752.47 (CI 7 776.84-14 939.93), €5 340.34 (CI 3 607.63-7 075.11) and €11 752.47 (CI 7 776.84-14 939.93) for TSU. In the low-risk group, Classic (ICER €723.82) and Avant-Garde (ICER €411.17) were more expensive and less effective compared to Slim. Multiple imputation was used to handle missing data and non-parametric bootstrapping with 25000 iterations of random sampling with replacement to calculate confidence intervals (95% CIs).

Results: Of 322 eligible patients, 252 were included in CareRA plus, of which 203 completed the trial. Rates of disease control (DAS28-CRP<2.6) at year 5 in high-risk patients were 68%, 72%, and 64% in the Classic, Slim and Avant-Garde group respectively (p=0.63) and related total costs were €11 358.39 (CI 7 776.84-14 939.93), €5 340.34 (CI 3 607.63-7 075.11) and €11 752.47 (CI 7 776.84-14 939.93) for TSU. In the low-risk group, Classic (ICER €723.82) and Avant-Garde (ICER €411.17) were more expensive and less effective compared to Slim. Multiple imputation was used to handle missing data and non-parametric bootstrapping with 25000 iterations of random sampling with replacement to calculate confidence intervals (95% CIs).
Conclusion: The combination of MTX with a GC bridging scheme (COBRA Slim) was more cost-effective (less expensive with comparable disease control) than more intensive step-down combination strategies or a conventional step-up approach 5 years after initial treatment. Over 5 years, around one-fifth of all patients, were in need of starting biological treatment and the transition to a bDMARD was later in COBRA Slim. These results point out the possibility of an early "economic" window of opportunity for diminishing costs long-term while still maintaining optimal disease control.

OP0033
EFFECTIVENESS OF NON-PHARMACOLOGICAL INTERVENTIONS TO PROMOTE WORK PARTICIPATION IN PEOPLE WITH RMDs: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Butin1, C. Weber2, S. Verstappen3, R. Christensen4, L. Falcone5, H. Bijlsma6, G. R. Burmester7, A. Boonen8

Background: Work participation among people with rheumatic and musculoskeletal diseases (RMDs) remains reduced when compared to the general population. A EULAR taskforce was established to agree on Points to Consider (PtC) to support people with RMD in healthy and sustainable work participation. Non-pharmacological interventions (NPI) could have an important role in improving work participation in RMDs. However, a comprehensive evidence synthesis of the effectiveness of NPIs in people with RMDs is lacking.

Objectives: To summarise the literature on effectiveness of NPIs on work participation in people with RMDs.

Methods: A search in four databases (MEDLINE, EMBASE, CENTRAL and Cinahl) was performed. Randomized Controlled Trials (RCTs) and Longitudinal Observational Studies (LOS) assessing non-pharmacological/non-surgical interventions until August 2020 were screened. Studies including people with any RMD (except low back pain or work-related RMDs) and assessing a work participation outcome domain (sick leave, work status, presenteeism) were considered eligible. For qualitative evidence synthesis, RCTs and LOS were considered. For quantitative evidence synthesis, only RCTs were considered. For each randomized comparison, standardised mean differences (SMDs) were calculated for the three outcome domains and used as effect size in the meta-analyses; i.e. a negative SMD favouring the NPI over control. Next, Mixed Effects Meta-Regression Analyses were performed, with random effects for randomised comparisons, and a fixed effect factor for the stratified subgroups of clinical interest. Subgroups within diseases (musculoskeletal pain disorders vs. other types of RMDs), risk status for sick leave at baseline (on sick leave or at risk for sick leave; not at risk for sick leave; a combination; or not specified) and single vs. multiple component NPIs were pre-defined. Risk of Bias (RoB) of RCTs was assessed using the Cochrane tool.

Results: Out of 8,864 records, 64 studies (71 treatment comparisons) were included. Studies usually included a mixed population of several RMDs (42%). Most NPIs were conducted in a clinical setting (n=44, 62%) and NPIs usually had multiple components (n=57, 80%), such as vocational support combined with physical training (n=18, 25%). Sick leave was the most frequently reported outcome domain (n=56, 88%). In the qualitative syntheses, 30%/50%/29% of interventions were considered plausible in improving sick leave, work status and presenteeism, respectively.

In the quantitative synthesis, NPIs (37 RCTs, 42 comparisons with mostly moderate to high RoB) showed small to moderate effect sizes, favouring NPIs over comparators for sick leave (SMD=-0.23, 95%CI -0.33 to -0.13), work status (SMD=-0.38, 95%CI -0.63 to -0.12) and presenteeism (SMD=-0.25, 95%CI -0.39 to -0.12). The forest plot for sick leave is shown (Figure 1).

Subgroup analyses for sick leave revealed that, compared to control, NPIs were not effective in musculoskeletal pain disorders, in contrast to the other types of RMDs. For both other subgroup analyses (baseline risk for sick leave; single vs. multicomponent NPI), NPIs improved sick leave similarly in subgroups compared to the control. Subgroup analyses for work status and presenteeism had generally similar effects in subgroups, but the interpretation requires caution in view of the small number of comparisons. Of note, clinical and methodological heterogeneity between studies was substantial, with some concerns about methodological quality related blinding and completeness of follow up.

OP0034
IXEKIZUMAB IMPROVES SIGNS, SYMPTOMS, AND QUALITY OF LIFE IN PATIENTS WITH AXIAL SPA IRRESPECTIVE OF DISEASE DURATION: RESULTS FROM THE COAST-V, COAST-W AND COAST-X TRIALS

V. Navarro-Compán1, J. D. Reveille2, R. Rahman3, J. Maldonado-Cocco4, M. Magniet4, R. Bole4, D. Sandoval4, S. Y. Park4, A. Kronbergs6, M. Rudwaleit7

Background: Ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting interleukin-17A,1 has demonstrated superior efficacy to placebo (PBO) in the treatment of patients (pts) with radiographic axial spondyloarthriti
(r-axSpA) (COAST-V [NCT02696785]; -W [NCT02696798], and non-radio-
graphic axial spondyloarthritis (nr-axSpA) (COAST-X [NCT02757352]).

Objectives: Assess treatment response to IXE categorised by disease duration since symptom onset (<5 years, yrs), ≥5yrs in pts with nr-axSpA and nr-axSpA up to 52 Weeks (Wks).

Methods: Pts fulfilled ASAS classification criteria for r-axSpA or nr-axSpA and were randomised to receive 80mg subcutaneous IXE every 2Wks or 4Wks, or PBO (16Wks COAST-V/W; 52Wks COAST-X). Data were summarized by disease duration and treatment in eligible intent-to-treat (ITT) pts. Wk16 treatment compar-
sions were conducted using Cochran-Haenszel-Mantel test and ANCOVA. Missing data were handled using non-responder imputation and modified baseline obser-
vation carried forward, for categorical and continuous endpoints, respectively.

Results: Table 1 presents pt demographics and baseline characteristics. Data is from pooled IXE pts. In pts with nr-axSpA <5yrs symptom duration, ASAS40 response was achieved by 51.5% at Wk16 and 60.6% at Wk52, compared to 36.9% at Wk16, significantly different to PBO (p=0.012), and 40.5% at Wk52, in pts with ≥5yrs symptom duration. In pts with nr-axSpA <5yrs symptom duration, ASAS40 response was achieved by 42.5% at Wk16, significantly different to PBO (p=0.012), and 54.8% at Wk52, compared to 36.0% at Wk16 and 41.4% at Wk52 in pts with ≥5yrs symptom duration (Figure 1). In pts with nr-axSpA <5yrs symptom duration, ASDAS LDA <2.1 response was achieved by 39.4% at Wk16 and 48.5% at Wk52, compared to 27.5% at Wk16, significantly different to PBO (p=0.001), and 35.6% at Wk52 in pts with ≥5yrs symptom duration. In pts with nr-axSpA <5yrs symptom duration, ASDAS LDA <2.1 response was achieved by 32.9% at Wk16, significantly different to PBO (p=0.003), and 46.9% at Wk52, compared to 23.9% at Wk16 and 36.9% at Wk52 in pts with ≥5yrs symptom duration. At Wk16, in pts with nr-axSpA pts <5 and ≥5yrs symptom duration, the Change from Baseline (CFB) in SF-36 Physical Component Sum-
mary (PCS) Score (LSM±SE) was 7.91 (±1.52), compared to 6.81 (±0.40) in pts with ≥5yrs symptom duration. In pts with nr-axSpA and ≥5yrs symptom duration, this score was 8.95 (±0.95) compared to 7.07 (±0.73) in pts with ≤5yrs symptom duration, both were significantly different to PBO (r-axSpA: p<0.001; nr-axSpA: p=0.037).

Figure 1. ASAS40 Response Rates for patients with r-axSpA (COAST-V/W) and nr-axSpA (COAST-X) Symptom Duration <5 and ≥5yrs up to Week 52, ITT, NR: Significantly greater response of IXE vs PBO at Week 52 (p<0.001), Abbreviations: PBO: placebo; IXE: ixekizumab; NR: nonresponder imputation; ITT: intent-to-treat (popula-
tion), ASAS, Assessment of Spondyloarthritis International Society.
We examined: 1. the total effect of latitude on age at diagnosis at hospital and country level (Main model); 2. the amount of the total effect that is mediated by patient factors at the patient and hospital level (Model A); and 3. the amount of the total effect that is mediated by country factors at the country level (Model B). In each model we disentangle the effect in different measurement levels. For example, a patient level variable can vary at the patient, hospital and country level.

**Results:** We included 39,782 patients nested in 94 hospitals nested in 17 countries. The mean age at diagnosis per country ranged from 39 to 55 years. The study spanned a range of latitude between 9.9 and 55.8 degrees (i.e. from Nigeria to the United Kingdom). In the main model, we confirmed the association between latitude and age at diagnosis and found that it only occurred at the country level (not at the hospital level). Per degree increase in country latitude, the average age at diagnosis per country increased by 0.23 years (95% credibility interval: 0.07, 0.40). At the hospital level however, this effect was negligible: β=0.04 (95% 0.16; 0.20). The associations between latitude and several factors found at the country level, but these patient factors only associated with age at diagnosis at the patient level, not at the country (or hospital) level (Model A). This means patient-factors did not explain the association between latitude and age at diagnosis at the country level (main effect changed from 0.23 before to 0.37 after inclusion of patient factors). In model B latitude associated with most country factors (except GDP per capita). Even though none of these variables separately were significantly associated with age at diagnosis, inclusion of the set of country level factors reduced the country level effect of latitude on age at diagnosis from 0.23 to almost zero: β=0.033 (±0.51; 0.37). Sensitivity analyses with age at symptom onset as outcome provided similar results.

**Conclusion:** Patients living close at the equator indeed get RA far earlier than those living closer to the poles. We here suggest that, rather than due to variation in patients’ characteristics, this latitude gradient is a country level phenomenon explained by indicators of countries’ socioeconomic status, and not by patient specific genetic or environmental factors. This big data analysis in a worldwide prevalence cohort provides a direct link between countries’ levels of welfare and the onset of RA.

**OP0036 CLINICALLY SUSPECT ARTHRALGIA PATIENTS WITH A LOW LEVEL OF EDUCATIONAL ATTAINMENT HAVE AN INCREASED RISK TO DEVELOP INFLAMMATORY ARTHRITIS**

S. Khidr 1, E. Van Mulligen 2, A. Van der Helm-Van Mil 1, H. Van der Helm-Leiden, Rheumatology, Leiden, University Medical Centre, Leiden, Rheumatology, Leiden, Netherlands; 2Erasmus Medical Centre, Rotterdam, Netherlands

**Background:** Cross-sectional studies on educational levels have shown that inflammatory arthritis (IA) and rheumatoid arthritis (RA) are more prevalent among people with a lower educational attainment. Studies on educational attainment in individuals at risk for RA could shed light on the influence of socioeconomic factors on RA development, which is divided in an asymptomatic and symptomatic pre-RA stage. To our knowledge, longitudinal studies on educational attainment and IA-development in symptomatic individuals at risk of RA are lacking.

**Objectives:** To determine the association between educational attainment and progression from clinically suspect arthralgia to IA and to perform mediation analysis to elucidate these effects.

**Methods:** 600 consecutive patients presenting with clinically suspect arthralgia were followed for the development of IA, identified at joint examination by rheumatologists during median follow-up of 25 months. Educational attainment was defined as low (lower general secondary education), medium, or high (college or university education). Contrast enhanced 1.5T MRI of hand and foot were made at baseline and were evaluated for synovial fluid/oedema/vascular remodelling by a blinded reader. Association between educational attainment and IA-development was studied with cox-regression analysis. To evaluate if subclinical joint inflammation is intermediary in the path of educational attainment and IA-development, a three-step mediation analysis was performed, before and after correction for age. Results: Patients with a low level of educational attainment were older, had a higher BMI, and smoked more often compared to patients with a high educational level. Low educational attainment was associated with increased IA-development (HR=2.5, 95%CI=1.4-4.7; p=0.003; see Figure 1), also after correction for age, BMI and smoking-status (HR=2.1, 95%CI=1.03-4.4; p=0.041). Moreover, patients with a lower educational level had higher levels of subclinical inflammation at presentation, which associated with a higher risk of progression to IA. Mediation analyses revealed that the association between lower educational attainment and IA-development reduced when adding the level of subclinical inflammation (HR=1.8, 95%CI:0.9-3.5; p=0.073), suggesting that the association between educational attainment and IA-development is partly mediated by higher levels of subclinical inflammation. Mediation analysis with age correction provided similar results.

**Figure:** Progression from clinically suspect arthralgia to inflammatory arthritis (IA), according to educational attainment

**Conclusion:** This is the first evidence that lower educational attainment of patients with arthralgia is associated with a higher risk of developing arthritis. This is partly caused by more severe subclinical joint inflammation. Further research into the role of socioeconomic factors on the development of RA is warranted.

**Disclosure of Interests:** None declared.

is diagnosed, and it indicates that a window of opportunity exists to expedite referral to specialist care and the diagnosis of RA.

Background: Strong biologic rationale supports both vitamin D and marine omega-3 (n-3) fatty acids for prevention of autoimmune disease (AD). Within the randomized, double-blind, placebo-controlled VITAL (Vitamin D and Omega-3 Randomized Controlled Trial), we tested the effects of these supplements on AD incidence. We previously reported results after 5.3 years of randomized follow-up showing overall protective effects for vitamin D on AD incidence (HR 0.78, 95% CI 0.61-0.99) and suggestive results for n-3 fatty acids (HR 0.85, 95% CI 0.64-1.10). Objectives: We aimed to test effects of these supplements with two more years of post-intervention follow-up in VITAL.

Methods: VITAL enrolled and randomized men and women (age ≥50 and ≥55 years, respectively) in a 2-by-2 factorial design to vitamin D₃ (2000 IU/d) and/or n-3 fatty acids (1000 mg/d) or placebo and followed for median 5.3 years. Here, we followed participants for another 2 years of observation to assess for sustained effects. Incident AD diagnoses were reported by participants annually and confirmed by medical record review by expert physicians using existing classification criteria. The primary endpoint was total incident AD, including rheumatoid arthritis (RA), polymyalgia rheumatica (PMR), autoimmune thyroid disease (AITD), psoriasis, and all others. Pre-specified secondary endpoints included individual common AD; and probable AD. Cox models calculated hazard ratios (HR) for incident ADs.

Results: Of 25,871 participants randomized, 71% self-reported non-Hispanic Whites, 20% Black, 9% other racial/ethnic groups, 51% women, mean age was 67.1 years. During 7.5 years median follow-up, confirmed AD was diagnosed in 167 participants in vitamin D arm vs 198 in vitamin D placebo arm, HR 0.89 (0.72-1.10). Incident AD was confirmed in 187 in n-3 fatty acid arm and 187 in n-3 fatty acid placebo arm, HR 0.89 (0.72-1.01). For vitamin D, HRs trended toward reduction for RA 0.67 (0.37-1.21), PMR 0.69 (0.46-1.03) and psoriasis 0.57 (0.33-0.99). For n-3 fatty acids, HRs trended toward reduction for RA 0.67 (0.37-1.21), PMR 0.69 (0.46-1.03) and AITD 0.57 (0.33-0.99). Vitamin D’s effect on AD incidence was stronger in those with body mass index (BMI) < 25 (HR 0.65, 0.44-0.96) than ≥ 25 kg/m² (p interaction 0.01).

Conclusion: Supplementation for 5.3 years with 2000 IU/day vitamin D (compared to placebo), followed by 2 years of observational follow-up, significantly reduced overall incident AD by 21% in older adults. HRs for RA, PMR and psoriasis trended toward reduction with vitamin D, with stronger effect in those with normal BMI. Supplementation with 1000 mg/day n-3 fatty acids did not significantly reduce total AD.

OP0039

RISK OF ARRHYTHMIA AMONG NEW USERS OF HYDROXYCHLOROQUINE: A LONGITUDINAL, POPULATION-BASED COHORT STUDY ON NEWLY DIAGNOSED RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. R. Hoque1,2, N. Lu2, N. Daltarian2, J. Esdaile2,3, H. Xie1,2, J. A. Avila-Zubiate1,3, Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada;2Arthritis Research Canada, Arthritis Research Canada, Vancouver, Canada;3University of British Columbia, Division of Rheumatology, Department of Medicine, Vancouver, Canada

Background: Previous findings on hydroxychloroquine (HCQ) use and the risk of arrhythmia are contradictory and low-level evidence-based results. Additional research is required to evaluate the safety profile of HCQ to arrhythmia in managing rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE).

Objectives: To assess the association between HCQ initiation and risk of incident arrhythmia among newly diagnosed RA and SLE patients.

Methods: All patients with incident RA or SLE and no arrhythmic events or ant-arrhythmic medications and no HCQ use prior to disease index date in British Columbia, Canada, between January 1997 and March 2015 were identified using administrative databases. HCQ initiator and HCQ non-initiator groups were identified and matched 1:1 by propensity scores using baseline confounders on demographics including presence of RA or SLE disease and duration of disease prior to the index date of HCQ initiators or non-initiators, comorbidities, other medications, and healthcare utilization. Matching was done within the same calendar year to account for a potential secular trend in HCQ use and risk of arrhythmia. Outcomes were any new arrhythmias, atrial fibrillation, abnormal electrocardiogram including prolonged QT syndrome and conduction disorder, and other unspecified arrhythmias during follow-up. We used Cox proportional hazard models with death as a competing event to assess the association of HCQ initiation and the outcomes.

Results: We identified 11,518 HCQ initiators (10,655 RA and 863 SLE patients, mean ± SD age 55.9 ± 15.1 years, 76.1% female) and 11,518 HCQ non-initiators (10,639 RA and 879 SLE patients, mean ± SD age 56.0 ± 16.2 years, 76.4% female) after 1:1 propensity score matching. Over the mean follow-up of eight years, there were 1,610 and 1,646 incident arrhythmias in the HCQ initiator and non-initiator groups, respectively. The crude incidence rates of arrhythmia were 17.5, and 18.1 per 1,000 person-years, respectively. Cumulative risk of incident arrhythmias for HCQ initiators and non-initiators over the follow-up time.

Figure 1. Cumulative risk of incident arrhythmias for HCQ initiators and non-initiators over the follow-up time.

Conclusion: There is no increased risk of any type of arrhythmia among new users of HCQ in RA and SLE patients. We believe the results of this large cohort study will add to the confidence with which HCQ can be used in RA and SLE management.

OP0040-PARE

THE WEBINAR SERIES FOR THE PATIENTS “PREGNANCY AFTER DIAGNOSING ANKYLOSIS SPONDYLITIS”

O. Krichevskaya1, T. Dubinina1, N. Klimenchenko2, N. Shatalova3.

1V.A. Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation; 2National medical research center for obstetrics, gynecology and perinatology named after academician V.I. Kulakov, Obstetric department of pathology of pregnancy, Moscow, Russian Federation; 3Russian ankylosing spondylitis association, Directorate, Moscow, Russian Federation

Background: Having been diagnosed with ankylosis spondylitis (AS), 68.2% of females in Russia reconsider their plans for pregnancy, with 13% giving up motherhood altogether out of fear for their own and their child’s potential health problems. However, most females allow pregnancy while experiencing emotional discomfort and anxiety.

Objectives: To shed more light on the mutual influence of AS and pregnancy, AS pregnancy outcomes, clinical course of AS as well as medication options during AS and lactation.

Methods: From 03/2021 to 12/2021 an on-line series of eight webinars was conducted together with the patients’ Russian ankylosing spondylitis association. Each webinar included lectures of one or two rheumatologists and an obstetrician; furthermore, the series included the presentations of a physical therapy instructor (with the demonstration of exercises) and of a breast-feeding specialist. After the lecture each speaker answered the audience’s questions. Topics of rheumatologists’ lectures were “AS and pregnancy: problem introduction,” “What do we know about AS genetics,” “Features of pregnancy planning” (included therapy issues for men with AS who are planning to father a child), “Rheumatologist prenatal and postnatal care” (included the analysis of AS clinical manifestations such as potential changes in back pain type).

Contemporary approaches to AS pregnancy treatment: A brochure for the patients with the main provisions of the lectures had been developed in support of the series.
Results: Webinars scored 703±192 views (by 29.01.2022). According to the ques-
tionnaire survey of the audience, 43.8% first knew that it was necessary to plan
AS pregnancy minimum 3-6 months before conception; 25% – that conception is
optimal during remission or low AS activity; 31.3% – that medical therapy can be
continued during pregnancy; 18.8% – that it is necessary to inform the obstetri-
cian about AS diagnosis and therapy received. 80% of the participants are fully
satisfied with the information provided by the web series; 13.3% – reported not to
had received enough information.
Conclusion: The interest in webinars shows that the choice of the form and the
information provided was successful. The content of the series can be used to
develop FAQ-section on the patient's website 'Ankylosing Spondylitis Associa-
tion'. In 2022, lectures will continue taking into account patients' feedback.
are changed after diagnosing ankylosing spondylitis (AS). AS female patients'
attitude to the use of as medications during pregnancy planning

Background: Familial Mediterranean Fever (FMF) is a chronic disease char-
terized by recurrent attacks of fever as well as serositis and bears the risk of
serious complications (e. g. amyloidosis). Treatment of FMF according to EULAR
aims to control acute attacks and subclinical inflammation as well as to improve
patient’s quality of life. Clinical data indicate that the inhibition of interleukin-1β
with canakinumab (CAN) is effective in controlling and preventing flares in FMF
patients2.

Objectives: The present study explores the long-term efficacy and safety of
canakinumab in routine clinical practice conditions in pediatric (age ≥2 years)
and adult FMF patients.

Methods: RELIANCE is a prospective, non-interventional, multi-center, obser-
vation study based in Germany with a 3-year follow-up period. Patients with
clinically confirmed FMF diagnosis who routinely receive canakinumab are
enrolled in order to evaluate effectiveness and safety of canakinumab. Disease
activity and remission by physicians’ assessment, disease activity, fatigue and
impact on social life by patients' assessment, inflammatory markers and AIDAI
(Auto-Inflammatory Diseases Activity Index) score were recorded at baseline
and assessed at 6-monthly intervals within the 3-year observation period of
the study.

Results: This interim analysis of FMF patients (N=74) enrolled by December
2021 includes baseline as well as 6- to 24-month data. Mean age in this cohort
was 25 years (2–61 years) and the proportion of female patients was 51 %
(N=38). At baseline, median duration of prior CAN treatment was 1.0 years (0–6
years).

At month 24, physician ratings report around 63% of patients in disease remis-
sion and patient-reported disease activity (mean PPA) decreased from moderate
(3.0) to low (2.6) during the observation period. Other disease activity parame-
ters also decreased (Table 1). A total of 18 serious adverse events were reported,
of which 2 (1 case of tonsilllectomy and 1 case of tachycardia) were classified as
drug-related.

Disclosure of Interests: None declared.

SJÖGREN EUROPE: REVIEW OF ITS FIRST THREE YEARS OF ACTIVITY

A. Grosjean1, L. Stone1, C. Bouillot1, A. Vieira1, K. Antonopoulou1, J. Koewelijn-Tukker1, M. Oosterbaan1
1Sjögren Europe, Federation of European Sjögren’s patient associations, Bienne, Switzerland

Background: Sjögren Europe was founded on 23 February 2019 by several
European patient organisations representing Sjögren’s patient to help to address
the lack of visibility, attention, and solutions for Sjögren’s.

Objectives: To show the first achievements and contributions of the federation.

Methods: Sjögren Europe’s purpose is to promote the advancement of knowledge,
research, information, treatment, and care, to foster patient involvement and partic-
ipation in research and any other relevant area, to increase awareness, identify
the different unmet needs and articulate patient voices throughout Europe.

Results: Finding one’s bearings and the right rhythm during the first years of
an organisation’s life is a challenge in itself. The Covid-19 pandemic has made
this process even more difficult. Our first goal was to organise a first face-to-face
European patient conference. This meeting had to be postponed. However, we
were able to adapt and develop a range of activities.

We organised a series of informative webinars on different topics by leading Euro-
pcean experts for patients and others interested in the subject. We have organised
various awareness campaigns such as a campaign for Sjögren Awareness Month in
2021 for which we have created 2 awareness videos and published several testi-
monials. We also created a 3-axis campaign about fatigue for World Sjögren’s Day
2021 which won the Best Practice Award at the 2021 PARE Conference, and during
which we shared the patients’ perspective on fatigue in publications in 13 languages
on social media. We published a booklet about fatigue developed by a specialist
and produced 3 informative leaflets for patients. We also subtitled 2 videos made by
one of our members in 10 European languages to disseminate quality information
that many patients miss. We have been involved in various research projects, work-
ing groups and patient panels and have been able to bring the patient perspective
to various stakeholders on many occasions.

Conclusion: Despite the limited contacts, we were able to create strong links
and rich discussions that stimulated our creativity. Sjögren Europe has become
a privileged partner, recognised, and appreciated by the various stakeholders.
Patients with Sjögren’s are better represented at the supranational level. It is
our members, the national patient organisations, who by their trust give us
our legitimacy. In return, Sjögren Europe has been able to inject a new energy
and dynamism that can be felt at the different national levels and that opens
up many perspectives and opportunities. We have been able to strengthen our
presence and visibility with patients on social networks, where our audience is
constantly growing, as well as in the rheumatology field with researchers,
clinicians, industry, and associations such as EULAR. The resumption of face-
to-face contacts is eagerly awaited to consolidate the links already created
and to feed the richness, relevance, originality and diversity of our discussions
and activities.

Disclosure of Interests: None declared.

**Conclusion:** Intermediate data of FMF patients from the RELIANCE study, the longest running real-life canakinumab registry confirm efficacy and safety of long-term canakinumab treatment.

**REFERENCES:**

**Disclosure of Interests:** Jörg Henes Consultant of: Novartis, Abbvie, Sobi, Roche, Janssen, Boehringer-Ingelheim, Grant/research support from: Novartis, Abbvie. J. B. Kueemmerle-Deschner Consultant of: Novartis, Abbvie, Sobi, Roche, Janssen, Lilly, MSD, Mylan, Pfizer, Roche, Schering-Plough, BMS, Merck Sharp & Dohme. Jörg Henes Consultant of: Novartis, Abbvie, Sobi, Roche, Janssen, Lilly, MSD, Mylan, Novartis, Roche, Sanofi, UCB, Grant/research support from: Novartis, Abbvie, Sobi, Roche, Boehringer-Ingelheim, Roche, Grant/research support from: Novartis, UCB, Tocilizumab (TCZ) for the treatment of FMF – TOFFIFE.

**Methods:** The TOFFIFE study was a placebo-controlled, double-blinded, randomized trial to investigate the efficacy and safety of TCZ in patients with colchicine resistant (cr)FMF. The physician’s global assessment of disease activity (PGA) based on a 5 point-scale for 6 symptoms (range 0-24) was used as a clinical score and had to be ≤2 at screening. Patients were randomized 1:1 to either receive monthly TCZ intravenously with 8 mg/kg bodyweight or placebo over a period of 24 weeks. Patients with inadequate response after week 12 had the opportunity to receive open label TCZ at week 16. The primary endpoint was the number of patients achieving an adequate response to treatment at week 16, defined as a PGA ≤ 2 + normalized ESR or CRP (the item that led to inclusion had to be normalized) + normalized SAA. Secondary endpoints included normalization of SAA during treatment and safety of TCZ in FMF patients.

**Results:** 25 patients were randomized with a median age of 31 years (range 18-53y), of which 14 (56%) were female. At week 16, which was the timepoint for the primary end point, 2 (15.4%) patients in the TCZ arm reached the primary end point with a PGA ≤ 2 and normalization of SAA and CRP and/or ESR but none of the patients in the placebo arm. Therefore, the superiority of TCZ compared to placebo could be shown concerning the pre-specified significance level of α = 0.02 (p = 0.089). SAA levels normalized with TCZ but not with PBO. This difference between TCZ und PBO was highly significant; SAA p < 0.015. At week 28 with 17 remaining patients and after having had the opportunity for a rescue treatment at week 16, the responder rates (PGA ≤ 2 + normalization of SAA, ESR and/or CRP) were 25% (n=1) in those patients who changed from placebo to TCZ (n=4) and 20% (n=2) in those patients who continued with placebo (n=10). Of note, all 3 patients remaining on PBO were non-responders (p = 0.842). In 75% of patients (n=3) CRP and in 50% of patients (n=2) normalized after changing to TCZ. No new safety aspects occurred.

**Conclusion:** In this first randomized, placebo-controlled study in patients with active crFMF TCZ therapy was lower than expected due to very strict response criteria; patients had to achieve a complete remission with a PGA ≤2 (on a 0-24 scale) and normalization of the inflammatory parameters (CRP/ESR and SAA). This required no or only mildest symptoms during the last 4 weeks. A larger multicenter study is therefore justifiable and needs to clarify the benefit of TCZ treatment in FMF.

Cipriani2, 1University of Udine, Department of Biotechnological and Applied Clinical Sciences, Udine, Italy; 2Aima Mater Studium University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy; 3University of Pavia, Rheumatology Department, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; 4Istituto Ortopedico Rizzoli, Department of Clinical and Surgical Sciences, Bologna, Italy; 5University of Rome Campus Biomedico, Rheumatology and Immunology Unit, Department of Medicine, Rome, Italy; 6Università degli Studi di Torino, Dipartimento Scienze Cliniche e Biologiche, Turin, Italy

Background: Adult-onset Still’s disease (AOSD) is a rare multigenic autoimmune inflammatory disease of unknown aetiology burdened by life-threatening, such as macrophage activation syndrome (MAS) [1]. Considering the poor outcome of MAS patients, previous works tried to assess predictive factors of its occurrence during AOSD [2]. However, an integrated evaluation of clinical features with biomolecules, may help to characterise the pathogenic mechanisms of the disease and its complications, is still missing.

Objectives: To multidimensionally characterise MAS complicating AOSD considering cytokine profile, inflammatory markers, and multi-visceral involvement of the disease. To perform a high-dimensional phenotypic analysis of circulating immune cells in AOSD patients with and without MAS. To assess interferon (IFN)-related pathways in AOSD synovial tissues by a bulky RNA sequencing.

Methods: We included 34 patients with AOSD, 12 of which were complicated or not with MAS. Patients were divided suggesting that IFN-α, IL-1Ra, IL-1β, and IL-6 are the pivotal cytokines in the pathophysiology of acute pericarditis and its recurrence [5]. This report presents the interim analysis of clinical trial with goflikicept (original, fusion protein, heterodimer, binding IL-1α and IL-1β) in patients with IRP. Trial registration: ClinicalTrials.gov, NCT04692766.

Objectives: To evaluate the efficacy and safety of goflikicept treatment in patients with IRP.

Methods: Subjects with recurrence (n=9) or in inter-recurrence period (n=13) were enrolled in the run-in period of 12 weeks for treatment with NSAIDs and/or colchicine for 24 weeks for treatment with corticosteroids (CS).

Dose finding approach was applied, where subjects from the first cohort (n=10) received subcutaneous goflikicept 80 mg every 2 weeks, subjects from the second cohort (n=12) - 240 mg load within the first week, 80 mg within the second week, thereafter 80 mg every second week for the next 12 weeks. After 12 weeks, patients were randomized to goflikicept or placebo. Primary endpoint was the time to the first pericarditis recurrence. In case of recurrence, the patients were unblinded, patients from placebo group retreated with goflikicept. According to interim analysis plan efficacy/safety analysis included only unblinded data during the run-in period.

Results: Treatment response was achieved in 8 of 9 patients, enrolled with recurrence and all patients enrolled without recurrence remained in remission at Day 4. There were no new recurrence events on goflikicept therapy, despite NSAIDs/colchicine combination. At the end of the run-in responders proceeded into the double-blind, placebo-controlled randomized-withdrawal (RW) period, where received goflikicept 80 mg every 2 weeks or placebo. Primary endpoint was the time to the first pericarditis recurrence. In case of recurrence, the patients were unblinded, patients from placebo group treated with goflikicept. In case of recurrence, the patients were unblinded, patients from placebo group retreated with goflikicept. According to interim analysis plan efficacy/safety analysis included only unblinded data during the run-in period.

Results: Treatment response was achieved in 8 of 9 patients, enrolled with recurrence and all patients enrolled without recurrence remained in remission at Day 4. There were no new recurrence events on goflikicept therapy, despite NSAIDs/colchicine combination. In case of recurrence, the patients were unblinded, patients from placebo group retreated with goflikicept. OP0046 EVALUATION OF THE EFFICACY OF TOPICALLY APPLIED TACROLIMUS IN THE TREATMENT OF ORAL ULCERS IN BEHCET’S DISEASE: A DOUBLE BLIND PLACEBO CONTROLLED STUDY

M. Hassanien1, A. Moshrif2, M. Galal3, F. Abuzaid3, D. Fathalla4, E. Talaat1. 1Assiut University, Rheumatology, Assiut, Egypt; 2Al-Azhar University, Periodontology, Assiut, Egypt; 3Al-Azhar University, Oral Medicine, Periodontology, Assiut, Egypt; 4Assiut University, Pharmacy, Assiut, Egypt.

Rheumatology, Assiut, Egypt; Al-Azhar University, Oral Medicine, Periodontology, Assiut, Egypt; Assiut University, Pharmacy, Assiut, Egypt

Background: Treatment of Behcet disease (BD) associating oral ulcers is still challenging despite the advances in the systemic treatment modalities.

Objectives: We aimed to evaluate the clinical efficacy of topical Tacrolimus for treatment of BD.

Methods: In this double blind placebo controlled trial, forty BD patients with persistent active oral ulceration were equally randomized into group I (20 patients received oral colchicine plus topically applied tacrolimus) and group II (20 patients received oral colchicine plus placebo oral gel). All participants were evaluated based on Behcet's Disease Current Activity Form (BDCAF), Ulcer Severity Score (USS) and visual analog scale (VAS) before treatment, and at four-time points post-treatment (15 days, 1st, 2nd and 3rd months).

Results: USS was significantly lower in group I after 2 weeks (p= 0.037) and 3 months (0.025) than in group II. USS was significantly lower in group I after 3 months of follow up regarding to the number of ulcers (p=0.014), ulcer size (p=0.022), and duration (p=0.009). BDCAF showed significant improvement in 3 months follow up within each group (p<0.001 for both groups), while there was insignificant difference between both groups(p=0.347).

Conclusion: Topical Tacrolimus has been proven to be a safe and effective adjunctive therapy in the management of oral ulcerations in BD.

OP0047 IMPAIRED JAK-STAT PATHWAY IN PATIENTS WITH PYODERMA GANGRENSOSUM

T. Demirci Yildirim1, A. Kahraman Akalp1, A. Köken Arıç1, F. Oner1, S. Akar1, I. San1, A. M. Nallı1, Dokuz Eylul University, Faculty of Medicine, Rheumatology, İzmir, Turkey; 2Izmir Katip Celebi University, Pathology, İzmir, Turkey; 3Izmir Katip Celebi University, Rheumatology, İzmir, Turkey

Background: Pyoderma gangrenosum (PG) is an inflammatory disease with an unknown etiology. Currently there is an unmet need in the field of PG. In recent years, JAK/STAT pathway have been shown to have an important role in the etiology of inflammatory conditions particularly in the field of dermato-rheumatology. However, current data on JAK/STAT pathway in PG is significantly limited.

Objectives: Herein we aimed to investigate the JAK/STAT signaling pathway in the skin biopsies of PG patients and compared with psoriasis (PSO) and healthy subjects (HS).

Data were shown means±SD and n (%), *= significant expression HS vs PG, **= significant expression HS vs PSO.
Methods: 31 patients with PG, 35 patients with PSO and 26 HS were included. Immunochemical methods were used to evaluate the expression of JAK1, JAK2, JAK3, Tyrosine Kinase 2 (TYK2), STAT1, STAT3, STAT4, STAT5, and STAT6. JAK/STAT proteins and epidermis the staining intensity was recorded as ‘positive’ or ‘negative’. The epidermal part is divided into cytoplasmatic and nuclear parts and staining intensity recorded by semi-quantitatively as follows: negative, mildly positive, moderately positive and strongly positive.

Results: In total, there were 92 biopsies. Dermal staining was significant for all the JAK/STAT proteins for patients with PG and PSO when compared to HS. On the other hand, there were no differences in the staining patterns of PG and PSO. For the investigation of cytoplasmatic parts of epidermis JAK1, STAT3, and STAT4 were highly expressed in the PG and PSO, STAT6, and TYK2 were only significantly overexpressed in psoriasis. JAK3 was overexpressed in healthy skin, PG and psoriasis. The assessment of the nuclear part of epidermis TYK2 and STAT3 were highly expressed in the PG and PSO. JAK1 was overexpressed in PG versus PSO in cytoplasmatic parts of the epidermis (p=0.001), TYK2 and STAT6 were highly expressed in the PSO versus PG. The summary of the findings is given in Table 1.

Conclusion: In this study, the JAK/STAT inflammatory pathway is significantly activated in PG patients which is adding up new information to the current literature. Considering the unmet need in PG targeting of this pathway could be beneficial for the treatment of refractory PG.

Disclosure of Interests: None declared.

OP0048 FIRST INTERIM ANALYSIS OF THE INTERNATIONAL X-LINKED HYPOPHOSPHATEMIA (XLH) REGISTRY: ADULT POPULATION BASELINE CHARACTERISTICS

K. Brief, J. Liu, A. Williams, S. Wood. Hôpital Cochin, Service de Rhumatologie, Centre de Référence des Maladies Rares du Métabolisme du Calcium et du Phosphate Filière OSCAR, AP-HP, Paris, France; 2Kyowa Kirin International Marlow Office, Nephrology | EMEA, Marlow, Buckinghamshire, United Kingdom; 3Kyowa Kirin International Marlow Office, Nephrology | EMEA, Marlow, Buckinghamshire, United Kingdom; 4Kyowa Kirin International Marlow Office, Nephrology | EMEA, Marlow, Buckinghamshire, United Kingdom

Background: X-Linked Hypophosphatemia (XLH) is a rare, progressive, lifelong, hereditary phosphate wasting disorder characterised by a pathological increase in fibroblast growth factor 23 concentration/activity. Despite XLH being increasingly recognised as a chronic progressive disease, there are few data documenting its natural history or the impact of treatment and other medical interventions on patient outcomes. The multicentre, international, XLH patient registry was established to address this lack of information in XLH to help inform future clinical practice.

Objectives: To report data from the first interim analysis of the International XLH Registry (NCT03193476), focusing on baseline characteristics of adults (aged ≥18 years) [1].

Methods: The International XLH Registry was initiated August 2017 to collect information on the natural history of XLH and will run for 10 years, aiming to address this lack of information in XLH to help inform future clinical practice. The analysis of this young population treated with conventional therapy highlights the frequency of musculoskeletal involvement (osteoarthritis, enthesopathies, etc). The information collected within this rare-disease registry during these 10 years provides an exciting opportunity to integrate large-scale real-world evidence into clinical practice, with the aim of improving the care and quality of life of people living with this debilitating disease.

OP0049 FURTHER CHARACTERIZATION OF clinical AND LABORATORY FEATURES OCCURING IN VEXAS SYNDROME IN A LARGE-SCALE ANALYSIS OF MULTICENTER CASE-SERIES OF 116 FRENCH PATIENTS

S. Georgin-Lavialle1, B. Terrier2, K. Olivier3, A. Mekinian4, on behalf of fench VEXAS Syndrome Investigators.

116 patients with VEXAS syndrome. Frequency and median of parameters and vital status, from diagnosis to the end of the follow-up.

Results: Main clinical features were skin lesions (83.5%), non-infectious fever (63.6%), weight loss (62%), lung involvement (49.6%), ocular symptoms (38.8%), relapsing chondritis (36.4%), venous thrombosis (34.7%), lymph nodes (33.9%), and arthralgia (27%). Hematological disease was present in 58 cases (50%), considered as myelodysplastic syndrome (MDS, n = 58) and monoclonal gammopathy of unknown significance (n = 12). UBA1 mutations included p.M411T (44.8%), p.M411V (30.2%), p.M414L (18.1%), and splice mutations (6.9%). After a median follow-up of 3.0 years, 18 patients died (15.3%), from infectious origin (n = 9) and MDS progression (n = 9). Unsupervised analysis identified 3 clusters: cluster I (47%) with mild-to-moderate disease; cluster 2 (16%) with underlying MDS and higher mortality rates; cluster 3 (37%) with constitutional manifestations, higher C-reactive protein levels and less frequent chondritis. Five-year survival probability of survival was 84.2% in cluster 1, 50.5% in cluster 2, and 89.6% in cluster 3. UBA1 p.Met414Leu mutation was associated with a better prognosis.

Conclusion: VEXAS syndrome displays a large spectrum of organ manifestations and shows different clinical and prognostic profiles. It also raises a potential impact of the identified UBA1 mutation.

Managing chronic pain in RMDs

H. Haibel1, J. Sieper2, D. Poddbubny1,2, V. Rios Rodriguez1, F. Proft1, J. Rademacher1,3, S. Igel1, P. Martus4, C. Stein5.

1Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Rheumatology, Berlin, Germany; 2German Rheumatism Research Center, Epidemiology, Berlin, Germany; 3Berlin Institute of Health, Clinician Scientist Program, Berlin, Germany; 4Tübingen, Clinical Epidemiology and Statistics, Tübingen, Germany; 5Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Anesthesiology and Intensive Care, Berlin, Germany

Background: Patients with chronic inflammatory arthritis (e.g. rheumatoid arthritis; RA) or inflammatory exacerbations of chronic degenerative joint diseases (e.g. osteoarthritis; OA) suffer from recurrent pain, restricted function

Disclosure of Interests: None declared.

and reduction of daily activities. The current standard of intraarticular (i.a.) therapy is the injection of steroids, which can increase risk of infection, cartilage degenerations, and other well-known systemic side effects. A novel approach without such complications could be the activation of peripheral opioid receptors, e.g. by i.a. application of small, systemically inactive doses of morphine.

**Objectives:** The aim of this randomized placebo-and active drug controlled double blind trial was to investigate reduction of pain in chronic knee arthritis patients following i.a. injections of morphine, a standard steroid (triamcinolone), or placebo. The primary hypothesis was that i.a. morphine results in significantly lower pain scores than placebo. The primary outcome parameter was reduction of the Visual Analogue Scale (VAS) pain at day 7.

**Methods:** Adult patients with chronic knee arthritis because of osteoarthritis (OA) or inflammatory arthritis (IA, rheumatoid arthritis, psoriatic arthritis, spondyloarthritis, oligoarticular or monarticular) and a high level of pain (VAS pain ≥ 4 out of 10) at baseline received a single dose of either morphine 3mg i.a., or triamcinolone 40mg i.a., or placebo (NaCl 0.9%) i.a.. Patients were monitored closely throughout the entire study period with a total of 4 visits over weeks and documented pain in the morning and evening in a patient’s diary. Safety data was collected during the entire study period. P-values were calculated using two-sided T-Tests.

**Results:** 114 patients were screened, 93 were treated and 89 (96%) completed day 7. Of these n= 61 (66%) were diagnosed with OA and n= 32 (34%) with IA. 48 (52%) patients were female, mean age was 58.5 (SD 14 years) and mean disease duration 6.7 years (median 2 years, range <1 year – 42 years, IQR <1 – 10 years). The mean VAS pain improvement at day 7 for morphine, triamcinolone and placebo was -22.8, -37.7, and -19.8 respectively. The differences were not significant (p=0.69) for placebo vs. morphine, but significant for placebo vs. triamcinolone and for triamcinolone vs. morphine (p=0.013 and p=0.006). Mean improvements of the everyday pain documentation are shown in Figure 1. During the study period, there were no serious adverse events and 45 adverse events, most of them were mild.

**Conclusion:** In this randomized, placebo and active controlled double blind trial a single dose of 3mg i.a. administered morphine did not lead to significant improvements in comparison to placebo and was inferior to triamcinolone at day 7. The same was true during the first 7 days as shown in the pain documentation in patient diaries. These data does not support the use of i.a. morphine for pain reduction in patients with chronic arthritis.

**TRENDS FOR OPIOID PRESCRIPTIONS AMONG PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES BETWEEN 2006-2020**

J. Y. T. Huang, D. Jenkins, B. B. Birle Yi, J. Benitez-Aurioles, N. Peel, M. Lunt, W. Dixon, M. Jans, University of Manchester, Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, Manchester, United Kingdom; University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom; University of Manchester, NIHR Greater Manchester Patient Safety Translational Research Centre, Manchester, United Kingdom

**Background:** Opioid prescribing has contributed to a North American epidemic with increasing trends in several European countries. Rheumatic and musculoskeletal diseases (RMDs) are one of the most common indications for prescribed opioids despite there being little evidence on opioid prescribing and the benefit of long-term use in RMDs.

**Objectives:** To investigate national UK opioid prescribing trends by studying the patterns of opioid prescribing in new users with the following six RMDs: rheumatoid arthritis (RA), psoriatic arthritis (PsA), axial spondyloarthritis (AxSpA), systemic lupus erythematosus (SLE), osteoarthritis (OA) and fibromyalgia.

**Methods:** Patients aged 18 years and older with a diagnosis of RA, PsA, AxSpA, SLE and OA with a new episode of opioid use without cancer in the Clinical Practice Research Datalink (CPRD) were included between 01/01/2006 and 31/12/2020. CPRD is a database of anonymised UK primary care electronic health records representative of the national population. New opioid users were defined as individuals with RMDs who had a new episode of opioid use in a 2-year time window up to 6 months before or after an RMD diagnosis. Rates of new opioid users were calculated by dividing the number of new opioid users with an RMD per year by the number of eligible patients registered in CPRD per year. Age- and gender-standardised rates for new opioid users were obtained using direct standardisation for each RMD. Rates of opioid prescriptions among new users for each RMD were calculated by dividing the number of opioid prescriptions among new users with an RMD in the year they had new opioid episodes by patient-years of the new users with an RMD. Trends for the rates in the study period were tested using negative binomial regression. Significant change points were identified by looking at the points where the derivative (i.e. rate of change) of the trends for the rates crossed zero. Recurrent opioid users were defined as patients who had at least 3 opioid prescriptions issued within 3 months after a new opioid episode.

**Results:** This study included 21,505 RA patients, 8,392 PsA patients, 4,491 AxSpA patients, 4,508 SLE patients, 944,078 OA patients, and 33,829 fibromyalgia patients, who had new opioid episodes between 2006-2020. Whilst the overall trend for RA (2.7 vs 3.9), PsA (1.0 vs 1.8) and fibromyalgia (3.7 vs 8.3) has significantly increased over 15 years, from 2018 onwards, trends of new opioid users appeared to stabilise/decrease (Figure 1). The year 2018 was found to be a significant decreasing change point in the trends of new opioid users for RA, AxSpA, and SLE, whilst this was 2013 in OA and 2019 for fibromyalgia. Opioid prescription rates among new opioid users increased in SLE (4.3 vs 5.4), OA (4.6 vs 4.9) and fibromyalgia (5.6 vs 6.5) but decreased in RA (5.7 vs 5.3) from 2006 to 2020, despite fluctuations in the rates observed in this period. The highest proportions of recurrent opioid users among the 6 RMDs were patients with RA (32.6%) and fibromyalgia (31.9%).

**The number of new opioid users per 10000 persons**

[Graph showing trends for opioid prescriptions among patients with RMDs between 2006-2020]

**Figure 1.** Trends for new opioid users by RMD, 2006-2020.
Conclusion: RA, PsA and fibromyalgia had an overall increase in new opioid users since 2006. The slight decrease in the trends of new opioid users among most of the RMDs after 2016 may reflect an increasing awareness of the opioid epidemic. The high proportions of recurrent opioid users in RA and fibromyalgia patients highlight the importance of exploring the safety of long-term opioid use and effective pain interventions for patients with RMDs.

THE EFFECT OF TOFACITINIB ON RESIDUAL PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS WITH COMPLETE CONTROL OF INFLAMMATION

Objectives: To assess efficacy of tofacitinib, adalimumab (ADA) and placebo (PBO) on residual pain in pts with RA and PsA with abrogated inflammation, using a network meta-analysis (NMA).

Methods: Data were pooled from 9 randomised clinical trials of pts with RA (NCT00960440/NCT00847613/NCT00813407/NCT00855644/NCT00853385/ NCT00968859/NCT02187055) or PsA (NCT01877660/NCT01882439). This analysis included pts who received ≥1 dose of tofacitinib 5 mg twice daily (BID). ADA 40 mg once every 2 weeks or PBO with background therapy, and had abrogated inflammation (swollen joint count [SJC] = 0 and C-reactive protein [CRP] <6 mg/L) at Month (M)3. ADA was included in NCT00960440/NCT00847613/NCT00813407/NCT00855644/NCT00853385/NCT00968859/NCT02187055/NCT01877660/NCT02187055 performed tofacitinib/ADA non-inferiority/superiority comparisons. Primary outcome was pt assessment of pain (visual analogue scale [VAS]) 0 [no pain] – 100 mm [most severe pain]) at M3; scores were summarised descriptively; treatment comparisons were assessed by Bayesian NMA on individual pt-level data, accounting for within-trial imbalances and treatment effect modifiers.

Results: Abrogated inflammation at M3 was achieved in 14.1% (328/2330), 14.9% (207/1397) of RA and 22.7% (54/238), 29.2% (31/106) and 12.7% (30/236) of PsA pts receiving tofacitinib, ADA and PBO, respectively. RA pts receiving tofacitinib/ADA had lower SJC and longer disease duration vs pts receiving PBO. PsA pts receiving tofacitinib had a longer disease duration and higher Pain VAS vs pts receiving ADA/PBO. In both groups, a lower % of female pts received tofacitinib/ADA vs PBO (Table 1). Observed median (Q1; Q3) values for Pain VAS at M3 were 170 (6.0; 310), 19.0 (70; 310) and 33.5 (70; 48.0) in RA and 24.0 (8.0; 44.0), 21.0 (9.0; 49.0) and 27.0 (8.0; 52.0) in PsA pts treated with tofacitinib, ADA or PBO, respectively. Differences between active treatments and PBO were less prominent in PsA vs RA pts, per posterior probability values (Fig).

Conclusion: In this NMA, pts with RA and PsA achieving abrogated inflammation with tofacitinib or ADA at M3 had greater residual pain reduction vs those receiving PBO. This may imply that tofacitinib/ADA have analgesic benefits beyond those related to inflammation reduction.

LUMBAR MECHANICAL TRACTIONS IN RADICULAR PAIN OF DISCUS ORIGIN: A PROSPECTIVE CONTROLLED RANDOMIZED TRIAL OF SUPERIORITY ON 428 PATIENTS IN REIMS HOSPITAL UNIVERSITY RHEUMATOLOGY SERVICE

E. Bernhard1, A. Hittinger1, I. Charlot-Lambrecht1, M. Geoffroy1, L. Pauvele1, B. Lois2, C. Clément1, H. Delaplace3, J. H. Salmon1, 1CHU of Reims - Maison Blanche Hospital, Rheumatology, Reims, France

Background: Medical cares guidelines for lumbosciatic pains are well codified in several country: NSAIDs, analgesics and physical therapy associated, at physician's discretion, to lumbar epidural infiltrations. Lumbar mechanical tractions have not a clear identified place in the lumbosciatic pain treatment. It is empirically realized in France's several medical centers. However, no current literature studies have shown a significant efficacy of lumbar mechanical tractions in this indication. Most of the time, studies presented a lack of power or methodological bias. (1,2)

Objectives: The aim of this study is to demonstrate the superiority of lumbar traction associated with standard treatment (epidural injections, analgesics, NSAID) compared to medical treatment alone in lumbosciatic pains of discal origin.

Methods: We performed a monocentric interventional prospective superiority study from 2013 to 2021, randomized controlled in the rheumatology unit of Reims University Hospital. Patients included had to present a lumboradicular pain, with a concordant discal hernia on MRI or scanner, and to be naive of any lumbar surgery. We recorded demographical and clinical data at baseline and during the follow up. After their consent, patients were randomized between the traction group and the medical group. The medical group received the standard treatment (NSAIDs, analgesics) associated with at least 2 epidural infiltrations. The traction group received the standard treatment, infiltrations and at least 3 lumbar tractions. Treatment was considered as effective if there was a pain diminution at least 25 % between baseline and at 1 month. Patients were assessed on their pain at baseline, at 1 month and at 3 months of their treatment. Pain was assessed using a visual analog scale on lumbar and radicular localisation.

Superiority analysis has been performed by using the Chi-2 test.

Results: Four hundred eighty-two patients were included: 207 patients in the lumbar traction group, 210 patients in the medical treatment alone group and 11 patients with missing data. The male/female sex ratio was 1.39:1. The patients suffered from 49.52% (205 patients) right and 50.48% (209 patients) left lumboradiculalgia, mostly L5 (41% or 172 patients) and S1 (50% or 207 patients). The pains evaluation at one month was recorded for 377 patients: 190 in traction group (50.3%) and 187 in medical group (49.7%). Two hundred twelve/377 (56.2%) patients had a pain reduction of at least 25 % at one month: 117/377 patients in traction group (31%) and 95/377 in medical group (25%). Twenty/377 patients (5%) were operated on before the one-month recall. Therefore, patients treated with lumbar traction had a significant reduction in pain (p=0.0036) compared to patients with medical treatment alone.

Conclusion: This study is one of the first randomized controlled studies highlighting the superiority of lumbar traction in combination with standard treatment compared to medical treatment alone.

OP0054

REDUCING THE BURDEN OF LOW BACK PAIN: RESULTS FROM A NEW MICROSIMULATION MODEL

J. Kopec1, E. C. Sayre2, J. Cibere3, L. Li4, H. Wong5, A. Okhmatovskaya5, J. Esdaile3, 1Arthritis Research Canada, School of Population and Public Health, University of British Columbia, Vancouver, Canada; 2Arthritis Research Canada, Vancouver Coastal Health Research Institute, Vancouver, Canada; 3Arthritis Research Canada, Department of Medicine, University of British Columbia, Vancouver, Canada; 4Arthritis Research Canada, Department of Physical Therapy, University of British Columbia, Vancouver, Canada; 5University of British Columbia, School of Population and Public Health, Vancouver, Canada; 6McGill University, McGill Clinical and Health Informatics, Montréal, Canada; 7Arthritis Research Canada, Department of Medicine, University of British Columbia, Vancouver, Canada

Background: Low back pain (LBP) has been the leading cause of disability worldwide for the past 30 years. In 2019, LBP was responsible for 64 million years lived with disability (YLDs) [1].

Objectives: The purpose of the present study was to project and compare the impact of three strategies for reducing the population health burden of LBP: weight loss, ergonomic interventions, and an exercise program.

Methods: We have developed a microsimulation model of LBP in Canada using a novel simulation platform, SimYouLate. The initial population was derived from Cycle 1 (2001) of the Canadian Community Health Survey (CCHS). We modeled an open population with 20 years of age and older. Key variables included age, sex, education, body mass index (BMI), type of work, having a back problem, pain level in persons with back problems, and exercise. The effects of interventions on the risk of LBP were obtained from the CCHS for the effect of BMI, the Global Burden of Disease Study for occupational risks, and a published meta-analysis for the effect of exercise. All interventions lasted from 2021 to 2040. Strength of the interventions varied over a wide range. YLDs were defined as LBP prevalence multiplied by disability weight. The population health impact of the interventions was calculated as a difference in YLDs between the base-case scenario and each intervention scenario expressed as YLDs averted per intervention unit and as % of total LBP-related YLDs.

Results: In the base-case scenario, LBP in 2020 was responsible for 424,900 YLDs in Canada and the amount increased to 460,312 YLDs in 2040. The effects of the interventions on YLDs were as follows: 27993 (95% CI 23,373, 32,614) YLDs averted over 20 years per 0.1 unit change in log-transformed BMI (10.5% change in BMI) among overweight and obese individuals, 19,416 (16,275, 22,557) YLDs averted per 1% reduction in the proportion of workers exposed to occupational risks, and 26,058 (22,455, 29,661) YLDs averted per 1% increase in the proportion of eligible patients with back problems participating in the exercise program. Table 1 shows the intervention impact as % of total LBP-related YLDs and Figure 1 shows YLD-equivalence between the interventions. A one unit reduction in BMI per year among the overweight and obese individuals would be approximately equivalent in terms of disability reduction to an effective ergonomic intervention in 35% of at-risk workers and an exercise intervention in 27% of eligible patients with back problems over the same period (Figure 1).

Table 1. YLDs averted between 2021 and 2040 as % of total LBP-related YLDs, according to intervention type and level, in persons aged 20+ in Canada

LCL: lower confidence limit. UCL: upper confidence limit.

Figure 1. Equivalence between BMI, ergonomic and exercise interventions in terms of their impact on YLDs. Each point represents a specific number of YLDs averted. Values on the y-axis show reduction in % of workers at risk and increase in % exercising that are required to achieve the same reduction in YLDs as the corresponding reduction in BMI shown on the x-axis.
Background: Low back pain is the most common musculoskeletal problem which negatively affects functional capacity and quality of life during pregnancy (1). So, from the beginning of pregnancy, pregnant women should be supported by appropriate exercise approaches recommended as first-line therapy to reduce the complaints about low back pain (2, 3). Although there are different opinions about the type, intensity and frequency of exercise in order to improve functional capacity in pregnant women with low back pain, there are no comparative studies on the diversity and length of the exercise program.

Objectives: The aim of this study was to compare the effects of supervised, long and multivariaty an exercise program (LEP) and a short exercise program (SEP), planned based on core stabilization and in line with the needs of pregnant women, on functional capacity and quality of life.

Methods: A total of 27 pregnant women complained about low back pain, without obstetric and medical complications were included in this study. Detailed sociodemographic and obstetric characteristics were recorded. Back pain intensity, functional capacity and the quality of life were determined by the Visual Analogue Scale (VAS), 6-minute walk test and Short Form-36 Quality of Life Questionnaire. All outcome measures were assessed at baseline, at 24 and 32 weeks of pregnancy. Starting from the 16th week of pregnancy to the 32nd week, for 6 weeks, 2 days a week, under the supervision of a physiotherapist, a stabilization-based exercise program consisting of posture training, upper extremity, lower extremity, abdominal and pelvic floor strengthening and emotional role limitation and pain-related quality of life in the short term and is more effective in terms of increasing functional capacity in the long term than SEP during pregnancy. In this respect; our study will guide clinicians to create individually exercise programs for the needs of pregnancy.

THE COMPARISON OF EFFECTS OF TWO DIFFERENT EXERCISE PROGRAM ON FUNCTIONAL CAPACITY AND QUALITY OF LIFE IN PREGNANT WOMEN WITH LOW BACK PAIN

E. Üzelpasaci1, T. Akbayrak1, 1Hacettepe University, Physical Therapy and Rehabilitation, Ankara, Turkey

Background: Pain communication should be an integral part of every clinical consultation, particularly in paediatric rheumatology where children/young people often present complex long-term conditions in which chronic pain is a feature. Researchers investigating pain communication in paediatric healthcare encounters have been focused on healthcare professionals, yielding inconsistent findings about the occurrence and nature of pain discussions with children/young people. There has been limited research examining children/young peoples’ own communication experiences and perspectives on this in the literature to date.

Objectives: The objective of this study was to investigate children/young peoples’ experiences and perceptions of communicating about pain with paediatric rheumatology healthcare professionals in the UK.

Methods: Twenty-six children/young people were recruited from three UK paediatric rheumatology centres. Data were collected using semi-structured telephone interviews between April–October, 2021. A framework analysis approach was used to explore similarities and divergences in participants’ narrative accounts.

Results: The mean age of children/young people was 14.0 years (SD=3.6 years, Range= 6-18 years, 58% female). Diagnoses included; Juvenile Idiopathic Arthritis, Chronic Regional Pain Syndrome, diffuse idiopathic chronic pain, localised idiopathic pain, hypermobility (including Ehlers Danlos Syndrome) and Raynaud’s disease. Findings are organised into four themes.

1) Nature and focus of appointments. Children/young people talked about pain with several professionals from the team. Participants reported that pain conversations predominantly occurred during physical examinations.

2) Co-ordination of pain communication. Children/young people identified how professionals mostly started pain conversations. They explained how they were often asked to verbally rate pain rather than use a written assessment tool. For some, questions about pain were directed to parents. Participants reported that this was problematic as parents “can’t feel” pain.

3) Reflections on pain communication. There were expectations that pain should always be asked about as it was considered a main reason for a consultation. Participants discussed how these conversations gave them an opportunity to “get it off their chest” and made them feel “reassured” that professionals “care” Being asked about pain reminded them that they were different to peers and they were concerned it could highlight “something else is wrong”. Children/young people talked about how it became easier to talk about pain with familiar professionals.

4) Moving forward after pain communication. Children/young people discussed how professionals could give mixed messages about how to manage pain at home following consultations, offering advice which was difficult to put into practice (e.g. “doing too much” vs “not doing enough”). Children/young people expressed their need to discuss the emotional as well as the physical effects of their pain.

Conclusion: These study findings highlight a range of effective and ineffective pain communication approaches from the experiences and perspectives of children/young people. These will be used to create recommendations for improving the communication of chronic pain in paediatric rheumatology in the future, in a way that is acceptable and valuable to children/young people.

Acknowledgements: The authors would like to thank the children/young people for kindly taking the time to share their experiences and perceptions about their interactions with healthcare professionals in paediatric rheumatology. The views expressed herein are those of the authors and not necessarily those of the National Health Service, the National Institute for Health Research, or the UK Department of Health. RESPONSE TO INJECTION CAN PREDICT OUTCOMES OF FEMOROACETABULAR IMPINGEMENT

E. Campos Marting1, D. Almeida Gomes2, H. De Brito Fontana3, D. Araujo Fernandes4, F. De Souza Neves5, 1Federal University of Santa Catarina, Department of Surgery, Florianópolis, Brazil; 2Federal University of Santa Catarina, Department of Morphological Sciences, Florianópolis, Brazil; 3Federal University of Santa Catarina, Internal Medicine Department, Florianópolis, Brazil

Background: Femoroacetabular impingement syndrome (FAIS) is a highly prevalent painful disorder that is considered a risk factor for hip osteoarthritis. In order to relieve pain and improve cartilage preservation, surgery is often performed. However, many operated patients do not show satisfactory outcomes. Reliable diagnostic tests that can inform prognosis of surgery in patients with FAIS are needed for optimized indications and contraindications to surgery.

Objectives: This systematic review aimed to answer the following question: “Can the response to intra-articular anesthetic injections be used to predict surgical outcomes in patients with FAIS?”

Methods: This study was conducted following the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) statement. Embase, CINAHL, LilACS, PubMed, SCOPUS, SPORTDiscuss, The Cochrane Library, and Web of Science databases were screened. All studies that assessed the capability of the response to intra-articular anesthetic injections in predicting surgical outcomes for patients with FAIS were considered eligible. Study selection and data collection were performed by three independent reviewers. Risk of bias of the included studies was assessed through the QUIPS tool.

Results: Seventeen articles were selected for full-text reading, of which 6 were considered eligible and included for analysis [1-6]. A summary of the studies’ descriptive characteristics can be found in the Table 1. A high risk of bias due to study attrition and the presence of confounding factors was observed for all included studies. Five out of six studies [1-4,6] presented “high risk” of bias associated to the prognostic factor measurement. A high overall risk of bias was evidenced by QUIPS for all studies (Figure 1). From 6 included studies, 5 indicated that the response to intra-articular injections can be useful in the prediction of surgical outcomes [2-6].

Conclusion: Although there seems to be some evidence supporting the use of intra-articular anesthetic injections to predict surgical outcomes in patients with FAIS, it is not conclusive. Future studies taking into account the various possible sources of bias in prognostic studies are needed. Standardizing and optimizing injection protocols as well as post-injection pain assessment and outcomes measurements are also essential to fill this gap.

Background: The optimal first-line treatment of patients with early rheumatoid arthritis (ERA) is not established.

Objectives: To compare clinical and radiographic outcomes of active conventional therapy (ACT) with each of three biological therapies with different modes of action.

Methods: In this investigator-initiated, randomized, open-label, blinded-assessor study (NCT01491815), patients with treatment-naive ERA with DAS28>3.2 and RF+/ACPA+/CRP>10mg/L, were randomized 1:1:1:1 to methotrexate combined with one of three biologic treatments; 1) oral prednisolone (tapered quickly; discontinued at w36); or: sulfasalazine, hydroxychloroquine and mandatory intra-articular (IA) glucocorticoid injections in swollen joints (ACT); 2) certolizumab-pegol (CZP); 3) abatacept (ABA) with concomitant conventional therapy (csDMARD + glucocorticoids), superiority regarding CDAI remission rates was demonstrated for abatacept and tocilizumab-pegol, and not for tocilizumab. Radiographic progression was low and similar between treatments.

Results: 812 patients were randomized. Adjusted CDAI remission rates at w48 were: 59.3% (ACT), 52.6% (CZP), 50.6% (ABA) and 51.9% (ABA). CDAI remission, w48 Ref 13.1% (3.5 to 22.5) 22.6% Ref 13.1% (3.5 to 22.5) 13.1% (3.5 to 22.5) 22.6% Ref 13.1% (3.5 to 22.5)

Values are mean (SD), if not otherwise indicated. §Finns patients randomised to TCZ-MTX, but not receiving it due to unavailability, are not included. *Values are estimated adjusted marginal means and estimated marginal differences against ACT with 95% CI. ITT: intention to treat. Superiority compared with ACT was demonstrated.

No new safety signals were reported. Total numbers of serious adverse events (% patients with ≥1 event) were for ABA 21 (8.3%), CZP 28 (12.4%), TCZ 20 (9.2%) and ACT 23 (10.7%).

Conclusion: Compared with active conventional therapy (csDMARD + glucocorticoids), superiority regarding CDAI remission rates was demonstrated for abatacept and tocilizumab-pegol, and not for tocilizumab. Radiographic progression was low and similar between treatments.
PROFOUND ANTICOAGULANT EFFECTS OF INITIAL ANTIRHEUMATIC TREATMENTS IN EARLY RHEUMATOID ARTHRITIS PATIENTS: A NORD-STAR SPIN-OFF STUDY

Background: Patients with rheumatoid arthritis (RA) are at an increased risk of venous thromboembolism. Thus far, there have not been any comparative studies investigating the effects of initial antirheumatic treatments in very early RA patients.

Objectives: To assess the effects of different initial treatments on hematologic parameters in patients with early RA.

Methods: NORD-STAR is an international, multicentre, open-label, assessor-blinded, phase 4 study where patients with newly diagnosed RA started methotrexate (MTX) and were randomised 1:1:1:1 to a) conventional treatment (either prednisolone tapered to 5mg/day, or sulfasalazine combined with hydrochloroquine and intra-articular corticosteroids), b) certolizumab pegol, c) abatacept, d) tocilizumab.

Results: The mean age of investigated patients was 51.8 (±12.7) years and 58.3% were female. At baseline patients had an average DAS28 score of 4.6 (±0.9) and had elevated levels of investigated coagulation biomarkers: Factor I + 2, fibrinogen, D-dimer and parameters of the two global hemostatic assays, i.e., endogenous thrombin potential (ETP) and overall hemostasis potential (OHP).

These biomarkers decreased significantly at 12 and 24 weeks in patients in all groups (Table 1). Overall fibrinolytic potential (OFP) was decreased and clot lysis time (CLT) was prolonged at baseline, demonstrating impaired fibrinolytic activity in early RA. The reduction of coagulation parameters was significantly higher in biological treatment arms in comparison to the standard MTX treatment arm. In addition, tocilizumab was more effective compared to certolizumab and abatacept (Figure 1), which was expected considering the direct inhibitory effect of this drug on the IL-6 synthesis and consequently the coagulation activation as well. After 24 weeks of treatment with methotrexate and tocilizumab, the average fibrinogen of patients was reduced by 63% vs 31% and 36% in the certolizumab and abatacept groups, respectively. The changes in DAS28 and the changes in fibrinogen had a correlation of 0.385 which did not reach statistical significance.

EXPOSURE TO SPECIFIC TUMOR NECROSIS FACTOR INHIBITORS AND RISK OF DEMYELINATING AND INFLAMMATORY NEUROPATHY IN PATIENTS WITH INFLAMMATORY ARTHRITIS. A COLLABORATIVE OBSERVATIONAL STUDY ACROSS FIVE NORDIC RHEUMATOLOGY REGISTERS

B. Deloignier¹, T. I. Kopp², E. Arkema¹, K. Hellegren¹, S. Aarestad Provan³, H. Relas⁴, K. Aaltonen⁵, N. Trokovic⁶, B. Gudbjornsson⁷, G. Grönfeldt³, E. Kristianslund⁶, L. Dreyer⁵, J. Asking⁴, K. Arvidsson, Stockholm, Sweden; ¹Copenhagen University Hospital - Rigshospitalet, The Danish Multiple Sclerosis Registry, Department of Neurology, Glostrup, Denmark; ²Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway; ³Helsinki University Hospital and Helsinki University, ROB-FIN, Department of Medicine and Rheumatology, Helsinki, Finland; ⁴Ministry of Social Affairs and Health, ROB-FIN, Pharmaceuticals Pricing Board, Helsinki, Finland; ⁵University of Iceland, Centre for Rheumatology Research, Landspitali University Hospital, and Faculty of Medicine, Reykjavik, Iceland; ⁶Aalborg University, Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark; ⁷DANBIO Registry, DANBIO Registry, Copenhagen, Denmark

Background: Though rare, studies have reported increased risk of neurological events including demyelinating disease of CNS (DML), multiple sclerosis (MS), and inflammatory neuropathy (INP) in patients with inflammatory joint disease treated with tumor necrosis factor inhibitors (TNFi). More in-depth investigations are required to elucidate the association between TNFi and neurological events in these patients, especially whether rates differ across type of TNFi mode of action.

Objectives: To estimate the incidence of neurological events in patients with rheumatoid arthritis (RA) and spondyloarthritits (SpA, including axial spondyloarthritis and psoriatic arthritis) starting treatment with TNFi across five Nordic countries. To compare the incidence of neurological events in etanercept (ETN)-treated patients to patients treated with other TNFi (oTNFi).

Methods: We defined treatment cohorts of patients initiating TNFi between 2001 and 2018 from clinical rheumatology registers in Denmark (DK), Finland (FI), Iceland (IS), Norway (NO), and Sweden (SE). One patient could contribute to more than one treatment episode. Demographic data (sex, age), co-medication (methotrexate) and clinical variables (CRP, disease duration <1 year, 1 to 5 years, >5 years) were extracted and used as covariates. We estimated crude incidence rates (IR) for neurological events and subtypes (ICD-10 codes: MS: G35, DML: G35, G36.8-9, G37.1, G37.2, G37.5, G37.8-9, H46, H48.1, G04.8-9, INP: G610, G618.9), all countries pooled. We compared risk of neurological events between patients treated with ETN and oTNFi using Cox regression with time since treatment start, adjusted for the above covariates, robust standard errors, and stratified by country.

Results: We included 52,682 treatment starts, in 33,885 RA patients (DK 8,259, FI 3,765, IS 723, NO 13,533, SE 19,785, 75% women, mean age 56 years) and 46,549 treatment starts in 10,594 SpA patients (7,000, FI 2,885, IS 962, NO 2,684, SE 15,241; 47% women, mean age 45 years). Numbers of DML, MS, INP and all neurological events, person-years (pyrs), and INP: G610, G618.9, all countries pooled. We compared risk of neurological events between patients treated with ETN and oTNFi using Cox regression with time since treatment start, adjusted for the above covariates, robust standard errors, and stratified by country.

Conclusion: The incidences of DML and MS were lower in RA compared to SpA patients, while rates of INP were similar in both patients' groups. There was no evidence of differences in these rates between ETN and oTNFi. The findings are of importance from a safety perspective for patients starting TNFi.

Background: The ongoing coronavirus disease 2019 (COVID-19) pandemic and subsequent waves still represent a healthcare issue. Their impact on the treat-to-target (T2T) strategy in rheumatoid arthritis (RA) patients has been seldom investigated. Difficult access to rheumatologist outpatient clinic, laboratory and imaging investigations as well as nationwide containment measures could potentially affect disease activity and tight-control strategy. Recently, we reported how a telephone-based tight control strategy ensured satisfactory management of RA treated with targeted therapies during the first wave of the pandemic [1]. However, the performance of our different patterns of healthcare delivery across different pandemic waves has not been studied yet.

Objectives: To analyze the impact of different patterns of healthcare delivery on remission of RA patients treated with targeted therapies during the first wave (2020) and second/third waves (2021) of pandemic compared to the pre-pandemic period (2019).

Methods: In this observational real-life study, data of our cohort of RA patients treated with biologic or targeted synthetic drugs were extracted from a longitudinal registry. Clinical Disease Activity Index (CDAI) was analyzed in the same period from 22nd of February to 16th of May for three consecutive years: before the pandemic (2019), during the first wave (2020), and during the second/third waves (2021). During the first wave, patients could choose whether to receive home drug delivery or to maintain their face-to-face visits, in the other periods only in-person visits were delivered. A generalized linear model with the binomial error was fitted to evaluate the difference in the proportion of patients in CDAI remission. Quantile regression was used to compare the median of CDAI in difficult-to-treat (D2T) patients [2]. In both models, the correlation of different measurements on the same patient was considered.

Results: In the pre-pandemic period (2019), 407 RA patients were included in this study. During the first wave (2020) we analyzed 450 patients, of whom 359 patients chose in-person visits, while 91 patients home drug delivery and virtual visit. Finally, 540 patients were included in 2021 (second/third wave). The percentages of patients in CDAI remission were similar in the three periods (prevalence ratio 1.07, p-value 0.423 between 2020 and 2019, and 1.01, p-value 0.934 between 2021 and 2019). The CDAI remission rate was 40.55% (N=163), 43.18% (N=155) and 40.82% (N=220) in 2019, 2020 and 2021 respectively. The disease activity profile during the three periods is reported in detail in Table 1 below. Among our cohort of D2T patients, the median value of CDAI before (2019), during the first wave (2020), and during the second/third wave (2021) changed significantly (p= 0.053 between 2020 and 2019 and p=0.006 between 2021 and 2019).

Conclusion: Although the pandemic has imposed changes in our healthcare delivery, these different strategies seem to be effective in ensuring satisfactory management of RA treated with targeted therapies. The approaches modulated in the context of the different periods have been a feasible compensation for ensuring disease control even in D2T patients.

**Conclusion:** Although the pandemic has imposed changes in our healthcare delivery, these different strategies seem to be effective in ensuring satisfactory management of RA treated with targeted therapies. The approaches modulated in the context of the different periods have been a feasible compensation for ensuring disease control even in D2T patients.
methylprednisolone group reduced dose compared with the maximum dose group. The primary endpoint was non-inferiority in the achievement of SDAI remission at the end of treatment. A total of 300 patients were enrolled in the study. Among them, 291 started methylprednisolone and were included in the analysis. The mean age was 57.7±15.2 years, female was 74.6%, and the mean disease duration from the diagnosis of RA was 22.1±56.2 days. Anti-CCP antibody was positive in 221 (73.0%) and the mean SDAI at study enrollment was 26.5±12.4. At week 24, with the mean dose of methylprednisolone 12.6±2.9 mg/day, 108 patients (37.1%) achieved remission according to SDAI and continued MTX monotherapy. 134 patients (46.0%) were randomised and started adalimumab with 88 patients in the maximum tolerable dose group and 66 patients in the reduced dose group. At week 48, the remission achievement rates were 38.4% and 44.8%, respectively, with the adjusted risk difference of the reduced dose group to the maximum tolerable dose group of 6.4% (-7.0% to 19.8%, 90% CI), which met the criterion for noninferiority. No significant difference was found in health assessment questionnaire disability index ≤0.5 (59.1% vs 62.0%, respectively, p=0.72) and in radiological remission rates (modified total Sharp score ≤0.5, 66.3% vs 62.0%, respectively, p=0.59). Adverse drug reactions tended to be more frequent in the maximum tolerable dose group than in the reduced dose group (22.1% vs 9.1%, respectively, p=0.06).

Conclusion: The MIRACLE randomised study demonstrated that, in patients with inadequate response to methylprednisolone, the efficacy of adalimumab with reduced dose of concomitant methylprednisolone was not inferior to that with maximum tolerable dose of methylprednisolone with better safety profile.

OLOKIZUMAB IMPROVES PATIENT REPORTED OUTCOMES IN MODERATE TO SEVERELY ACTIVE RHEUMATOID ARTHRITIS PATIENTS INADEQUATELY CONTROLLED BY METHOTREXATE (MTX-IR): RESULTS FROM THE PHASE 3 RANDOMIZED CONTROLLED TRIAL, CREDO 2

V. Strand1, E. Choy2, E. Nasonov3, T. Laitayna4, A. Lila4, S. Kuzikina4, M. Samsonov5, E. Feist5, Stanford University, Division of Rheumatology/RheumatoLOGY, Palo Alto CA, United States of America, 2Cardiff University, CREATE Centre, Section of Rheumatology, Cardiff, UK, United Kingdom, 3V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation, 4V. Nasonova Research Institute of Rheumatology, Tromboinflammation, Moscow, Russian Federation, 5R-Pharm, Medical, Moscow, Russian Federation, 6Helios Fachklinik Wiesbaden-Gommern, Helios Clinic, Rheumatology, Vogelsang-Gommern, Germany

Background: Olokizumab (OKZ) is an interleukin-6-inhibitor for treatment of Rheumatoid Arthritis (RA). In these analyses, we present patient reported outcomes (PROs) reported by MTX-IR patients with moderate to severely active RA treated with OKZ vs adalimumab (ADA) or placebo in a phase 3 randomized controlled trial (RCT) (ClinicalTrials.gov number, NCT02760407).

Objectives: To assess the effect of OKZ treatment compared with placebo and ADA in patient global assessment of disease activity (PGA), pain, physical function (HAQ-DI), fatigue (FACIT-F) and health related quality of life (SF-36 physical (PCS) and mental (MCS) component summary and domain scores) and work participation (WPS-RA) at week 12.

Methods: 1848 patients receiving MTX were randomized to receive SQ injections: 1) OKZ 64 mg every 2 weeks (q2w, n=464), 2) OKZ 64 mg q4w (n=479), 3) ADA 40 mg q4w (n=462) and 4) placebo q2w (n=243). At week 14, non-responders: subjects without ≥ 20% improvements in both swollen and tender joint counts, added rescue medication (sulfasalazine and/or hydroxychloroquine) to study treatment. Between groups differences in least-squares mean (LSM) changes from baseline were analyzed.

Results: At week 12, treatment with both OKZ doses and ADA resulted in statistically greater LSM changes from baseline than placebo across all PROs, including 7 of 8 domains of SF-36 with exception of role emotional (Table 1 and Figure 1). Reported work and household work impairments, days productivities were reduced by half and missed household work days because of arthritis were all improved (p<0.01) with OKZ and ADA treatment. PROs further improved to week 24 in the active treatment arms. Post hoc analyses demonstrated that a higher proportion of patients receiving both doses of OKZ as well as ADA reported improved ≥ minimum clinically important differences vs placebo (p<0.01) across all PROs, indicating clinically meaningful benefits on an individual patient basis. Estimates of numbers needed to treat indicated that between 5 and 10 patients would need to be treated to achieve these benefits. More patients in both OKZ groups reported scores ≥ normative values in PGA, HAQ-DI and SF-36 PCS scores; with ADA in PGA and HAQ-DI.

95% CI = 1.24-1.58), higher DAS28 (OR=1.21, 95% CI =1.15-1.26), HAQ (OR=1.46, 95% CI =1.33-1.61), pain (OR=1.104, 95% CI =1.012-1.077) and fatigue (OR=1.017, 95% CI =1.014-1.021). In the multivariable logistic regression model, female sex, younger age, higher HAQ, pain and fatigue at baseline were independent predictors of multiple treatment switching. Similar results were found for all three multi-switch definitions. Several comorbidities (i.e. heart failure, ischemic heart disease, malignancy, renal failure) were associated with a lower risk for multiple treatment switching, suggestive of medical contraindications for b/tsDMARDs.

**Conclusion:** In this large national observational cohort, multiple treatment switching, indicative of difficult to treat RA, was observed in a significant proportion of patients, ranging between around 2 to 7% during the first 5 years from time of diagnosis. Risk factors include female gender, younger age, higher HAQ, pain and fatigue at the time of RA diagnosis, suggesting increased attention to this challenging group of patients.

The risk of GP1111 withdrawal was lower in originator-naïve patients in patients with RA and PsA: HR 0.4 (95% CI 0.2-0.9), p-value 0.01) and HR 0.1 (0.1-0.6, p=0.01), but not significantly for AxSpA 0.56 (0.27-1.13, p=0.1). Across all indications, lower disease activity at baseline (DAS28/ASDAS remission) was associated with higher retention (Table 1).

**Conclusion:** Biosimilar-to-biosimilar infliximab switch was effective and well-tolerated in >1,500 real-world patients. Retention was higher in originator-experienced switchers and patients, who were in remission at the time of the switch, suggesting retention to be more affected by patient-related than drug-related factors.

**Background:** Tropheryma whippelii (Tw) infection is a rare condition, characterized by inflammmatory joint symptoms in more than 75% of the cases, which can lead the physician to diagnose chronic inflammatory rheumatic diseases (IRD) and to initiate DMARDs. DMARDs are often ineffective and may reveal digestive symptoms that treatment of Tw infection has a favorable impact on rheumatologic and extra-rheumatologic manifestations attributed to IRD.

**Objectives:** To validate this hypothesis, we initiated a registry with the objectives to (1) record all the cases of IRD and associated DMARDs in two dynamic risk periods: the period from the index date until first filling of antidepressants (if it occurred) and the period after filling of antidepressants. We used the first filling of antidepressants as proxy for depression reported in the scientific literature. (2) In patients with stroke, depression defined as filling of antidepressants or a diagnosis with associated increased mortality risk and the risk is similar for both definitions of depression. (3) Objectives: We used the first filling of antidepressants as proxy for depression with the objective to describe the mortality risk associated with depression in patients with incident RA.

**Methods:** We included patients diagnosed with incident RA (index date) from the nationwide DANBIO register (4) from January 1, 2008 to September 30, 2016. Participants were identified by unique personal registration numbers. Included patients were without a recorded filling of methotrexate (Anatomical Therapeutic Chemical code L01BA01) and antidepressants (N06A) in the Danish National Prescription Register or recorded hospital contacts with RA and depression (International Classification of Diseases (version 10) codes M05, M06, F32) in the Danish National Patient Register, three years prior to the index date. From the index date, we defined depression as first filling of antidepressants and collected death dates from the Danish Civil Registration System. The participants were followed until December 31, 2016. We calculated and compared the hazard rate ratios (HRR) by modelling filling of antidepressants.

**Results:** We included 11,071 RA patients followed for median 59 years, and 1,095 (10%) filled prescriptions for antidepressants. The median age at diagnosis was 61 years, 66% were female, and 64% diagnosed with seropositive RA. Adjusted HRR was highest in the age group <55 years but also increased between 55-70 years, 70-75 years, among females and males, and in patients diagnosed with seropositive and seronegative RA (Table 1). The cumulative mortality is seen in Figure 1.

DISTINCT STROMAL AND IMMUNE CELL INTERACTIONS SHAPE THE PATHOGENESIS OF RHEUMATOID AND PSORIATIC ARTHRITIS

A. Floudas1, C. Smith2, O. Tynan1, N. Neto3, V. Krishna4, S. Wade1, M. Hanlon1, C. Cunningham1, V. Marzaol1, M. Canavan1, J. Fletcher2, S. Cole4, L.Y. Hao4, S. Nagpal1, M. Monaghan1, D. Veale1, U. Fearon1, 1 Trinity Biomedical Sciences Institute, Molecular Rheumatology, Dublin, Ireland; 2 Trinity Biomedical Sciences Institute, Translational Immunology, Dublin, Ireland; 3 Trinity Centre for Biomedical Engineering, Mechanical and Manufacturing Engineering, DUBLIN, Ireland; 4 Janssen Research & Development, Immunology, Philadelphia, United States of America; 5 UELAR Centre of Excellence, Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland

Background: Rheumatoid (RA) and psoriatic arthritis (PsA) are common autoimmune and autoinflammatory diseases of unknown aetiology characterised by complex synovial pathology with a detrimental effect on the patient’s quality of life. Significant differences in pathophysiology may explain distinct clinical manifestations and account for differential responses to specific therapeutics. Recent implementation of single cell transcriptomic analysis of sorted synovial cells has revealed the diverse cellular landscape of the RA synovial stromal and immune cell compartments, however, a complete analysis of immune and stromal cells in tandem, for RA and PsA patient synovial tissue has not been performed.

Objectives: To combine novel scRNA transcriptomic approaches and ex vivo assays in order to: identify differences in the cellular landscape of RA and PsA synovial tissue inflammation and immune—stromal cell interactions that drive pathology in RA and PsA.

Methods: Single cell transcriptomic profiling of 178,000 synovial tissue cells from 5 PsA and 4 RA patients, importantly, without prior sorting of immune and stromal cells. This approach enabled the generation of a unique cell atlas of intact synovial tissue identifying immune and stromal cell interactions. State of the art data integration and annotation techniques identified and characterised 18 stromal and 14 immune cell clusters. Bioinformatic examination of cell-cell communication via construction of receptor-ligand interaction networks with further in vitro validation of stromal and immune crosstalk through flow cytometric analysis, multiplex ELISA and mitochondrial single cell metabolic profiling by multiphoton and florescent lifetime imaging microscopy, seahorse.

Results: Following quality control and data integration the PsA and RA cellular landscape was generated and nine mega clusters indicative of fibroblasts, endothelial cells, pericytes, macrophages, dendritic cells (DC), B cells, plasma cells, T cells and NKT consisting of several sub clusters were identified. Distinct points of transcriptomic deviation and convergence between RA and PsA were identified for each of the major cell types of the joint. Specifically, cell cycle and trajectory analysis revealed that only a fraction of synovial T cells are actively proliferating. Additionally, the differential usage of immunoglobulin light chains by memory and plasma cells indicates that plasma cells are potentially not derived from the local memory B cell pool of the synovial tissue. Importantly, we report distinct fibroblast and endothelial cell transcriptomes indicating differentially abundant subpopulations in RA and PsA characterised by distinct transcription factor usage and signalling pathway enrichment. Specifically transcriptomic imputation analysis revealed abundance of invasive FAP+THY1+ regulated by transcription factor TEAD1 in RA compared to PsA synovial tissue. In order to identify potential cell-cell communication driving inflammation in RA and PsA, novel receptor-ligand interaction networks were generated and downstream of the receptor, target characterisation was performed. Herein we identify RA-specific synovial T cell-derived TGF-β1 and macrophage IL-1β synergy in driving the transcriptional profile of FAP+THY1+ invasive synovial-fibroblasts, expanded in RA compared to PsA synovial tissue biopsies (Figure 1). Ex vivo treatment of RA patient synovial fibroblasts identified TGF-β and IL-1β synergy as a major driver of IL-6 production, fibroblast activation and adhesion molecule expression. Interestingly, the aforementioned proinflammatory changes of RA patient synovial fibroblasts were coupled with significant alterations in mitochondrial eccentricity and size and a marked metabolic adaptation towards a strongly glycolytic profile (Figure 1).

Figure 1.

Figure 1. Immunostromal cell crosstalk as a driver of synovial inflammation. A. Abundance of fibroblast clusters in RA and PsA patient synovial biopsies. B. Expansion and percentage of positive cells per fibroblast cluster for FAP and TGF-β. C. Scatterplots showing the relation between THY1 and FAP expressing cells before and after their isolation for RA and PsA fibroblast cluster 1 and 3 (PsA/RA ratio). FAP and THY1 fibroblasts with significantly different abundences between RA and PsA are indicated by green (higher in RA) and blue (higher in PsA) boxes. D. Frequency of fibroblasts clusters in PsA and RA patient synovial biopsies (top left). E. Clusters are summed in the and outliers only (more than 3 SD), symbols represent individual samples. F. Csa. Correlation depicting the top shared and downstream target interaction for enriched in PsA synovial fibroblast cluster 1 and RA fibroblast cluster 3. G. Representative images of the patient synovial fibroblasts' mitochondrial and metabolic analysis. H. Simultaneous fibroblast activity and protein synthesis within isolated fibroblasts of RA and PsA patients (Modified from the Journal of Cell Science).
Conclusion: Disrupting specific immune and stromal cell interactions offers novel opportunities for targeted therapeutic intervention in RA and PsA.

INCLUSION OF PATIENT RESEARCH PARTNERS IN REMEDY – A RESEARCH CENTER FOR TREATMENT OF RHEUMATIC AND MUSCULOSKELETAL DISEASES

M. Skare1, A. T. Tvedt,2, H. A. Zangi1, S. Lillegraven1, E. Haavardsholm1, I. Leichting2, A. Fryxelius3, I. Kjeken4, Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway;5The Norwegian Rheumatism Association, The Norwegian Rheumatism Association, Oslo, Norway

Background: Active collaboration between patients and researchers in development and implementation of scientific projects is important to ensure a good match between patient’s preferences and the scientific focus in research, contribute to more patient-oriented health research agendas, enhance patient friendly design of research projects, and creating support for implementation (1). Such involvement is strongly advocated by EULAR and is often a prerequisite to receive funding for clinical research projects. At Diakonhjemmet Hospital in Norway, the division of rheumatology and research has for many years worked to involve patient research partners (PRPs) in research. A patient advisory board was established in 2007, led by a person (20% position) who herself has a rheumatic disease. In eight years from 2022, the division will receive funding from the Norwegian Research Council to establish and host a clinical research center for treatment of Rheumatic and Musculoskeletal diseases – the REMEDY center.

Objectives: To describe how involvement of PRPs are organised within the REMEDY center.

Methods: An organisation map was developed as part of the application for funding. The leader of the patient advisory board, together with three senior researchers, were involved in several rounds of discussions on how PRP involvement should be organised in the center, and also in meetings with the larger research group.

Results: The organisation of REMEDY is shown in Figure 1.

Figure 1. Organisation of REMEDY.

1.All partners, including The Norwegian Rheumatism Association, (the largest patient organisation in the field), are represented at the Center Board. This ensures patient involvement at the strategic level, including setting research agendas and priorities.
2.The Center is led by a centre director and two co-directors, of which one has a specific responsibility of PRP-involvement.
3.The Centre Executive Committee (CEC) consist of the Center Director and co-directors, the WP leaders, the leader of the patient advisory board, the key senior scientific staff members of the partner institutions involved in the center and senior staff members deemed appropriate by the Centre Director.
4.The patient advisory board, consisting of 10-15 PRPs, is central within the center. Members of the board will be involved in all research projects, collaborating with researchers to improve design, methodology, research outcomes and implementation. The board provides a platform for the members for education, development, and exchange of knowledge and experience.
5.There are seven work packages (WPs) in REMEDY, each approaching the knowledge needs within rheumatic and musculoskeletal diseases (RMDs) treatment from different angles, and with international collaborators. WP7 (Empowerment of the individual) will provide a platform for the Patient advisory board, facilitating input from PRPs to all WPs. The chair of the EULAR study group for collaborative research is an international collaborator in WP7.

The leader of the Patient Advisory board has a 50% position. Additionally, there is funding for board activities, and for PRP involvement in initial project phases, whereas PRP activities are included in applications for external funding.

Conclusion: The REMEDY center is organised to ensure involvement of PRPs at all organisational levels, from individual research trials to the strategic and operational management of the center.

INTERVENTION WITH METHOTREXATE IN ARTHRALGIA AT RISK FOR RHEUMATOID ARTHRITIS TO REDUCE THE DEVELOPMENT OF PERSISTENT ARTHRITIS AND ITS DISEASE BURDEN (TREAT EARLIER): A DOUBLE-BLIND, RANDOMISED, PLACEBO-CONTROLLED TRIAL

D. Kribbeker,1, M. Verstappen2, B. van Dijik3, Y. Daakik4, L. Burgen5, A. Boer5, Y. Jung Park5, M. De Wit6, K. Visser6, M. R. Koek6, E. Molenaar7, P. de Jong8, S. Böhringer8, T. Huizinga9, C. Allaart1, E. Niemantsverdriet1, A. van der Helm-Vl5, Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; Reinier de Graaf Gasthuis, Rheumatology, Delft, Netherlands; Yagia Hospital (Leyweg), Rheumatology, Den Haag, Netherlands; Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; Groene Hart Hospital, Rheumatology, Gouda, Netherlands; Erasmus MC, Rheumatology, Rotterdam, Netherlands; Leiden University Medical Center (LUMC), Biomedical Data Sciences, Leiden, Netherlands

Background: Rheumatoid arthritis (RA) is the most common autoimmune disease, and requires long-term treatment to suppress inflammation. Currently, methotrexate is initiated as first-line treatment when arthritis becomes clinically apparent with joint swelling. However, disease processes begin long before and become clinically recognizable when patients develop symptoms. We hypothesized that the ‘at risk phase’ of symptoms and subclinical joint-inflammation is a therapeutic window to permanently modify the disease course.

Objectives: We studied if intervention in the pre-arthritis phase of arthralgia and subclinical joint inflammation prevents the development of clinical arthritis or reduces the burden of disease.

Methods: In this randomised, double-blind, 2-year proof-of-concept trial, adults with arthritis clinically suspected of progressing to RA and MRI-detected subclinical joint-inflammation, recruited from all rheumatology outpatient-clinics in the south-west Netherlands, were randomly assigned (1:1) to a single intramuscular glucocorticoid injection (120 mg) and a one-year course of oral methotrexate (up to 25 mg/week), or placebo injection and placebo tablets. Subsequently, participants were followed for another year without study medication. The primary endpoint was the development of clinically detectable arthritis (fulfilling the 2010 RA-criteria or involving ≥2 joints) that persisted for at least 2 weeks. Patient reported physical functioning, along with symptoms and workability, were key secondary endpoints and measured 4-monthly. Additionally, the course of MRI-detected inflammation was studied (the sum of tenosynovitis, synovitis, osteitis, scored with the RA-MRI Scoring (RAMRIS) method). All participants entered the intention-to-treat analysis. We performed two prespecified subgroup analyses. Firstly, analyses were restricted in participants with high risk of clinical arthritis development (PPV >70%). Secondly, analyses were stratified for ACPA-status. The trial is registered with the Netherlands Trials Registry (NTR4853 trial NL4999).

Results: From April 16th, 2015 to September 11th, 2019, we randomly assigned 236 participants to treatment (n=119) or placebo (n=117). After 24 months, arthritis free survival was similar in both groups (80% versus 82%, HR 0.81 (95%CI 0.45-1.46)). Physical functioning improved more in the treatment-group during the first months and remained better (mean between-group difference over two years HAQ -0.1(-0.2,-0.03;p=0.004). Similarly, pain (-9 on scale 0-100: (95%CI -1.48)). Physical functioning improved more in the treatment-group during another year without study medication. The primary endpoint was the development of clinically detectable arthritis (fulfilling the 2010 RA-criteria or involving ≥2 joints) that persisted for at least 2 weeks. Patient reported physical functioning, along with symptoms and workability, were key secondary endpoints and measured 4-monthly. Additionally, the course of MRI-detected inflammation was studied (the sum of tenosynovitis, synovitis, osteitis, scored with the RA-MRI Scoring (RAMRIS) method). All participants entered the intention-to-treat analysis. We performed two prespecified subgroup analyses. Firstly, analyses were restricted in participants with high risk of clinical arthritis development (PPV >70%). Secondly, analyses were stratified for ACPA-status. The trial is registered with the Netherlands Trials Registry (NTR4853 trial NL4999).
Conclusion: Methotrexate, the cornerstone treatment of RA, initiated at the pre-arthritis stage of joint symptoms and subclinical inflammation, did not prevent the development of clinical arthritis, but modified the disease course as measured by sustained improvement in MRI-detected inflammation, related symptoms and impairments. These findings of sustained disease modification may open up a new treatment landscape in a pre-arthritis phase of RA, where limitations can be just as severe as at the onset of clinical arthritis.

Acknowledgements: We thank Prof. dr. R. ten Cate, prof. dr. S. le Cessie and dr. A.M.J. Langers for their role in the Data Safety and Monitoring Board. We thank all participants, and all rheumatologist of the following hospitals: Albert Schweitzer Hospital, Alrijne Hospital, Erasmus Medical Center, Haven-policlinic Rotterdam, IJsseland Hospital, Iazia Hospital, Franciscus Gasthuis & Vlietland Hospital, Groene Hart Hospital, Haaglanden Medical Center (all locations), Haga Hospital, Langeland Hospital, Meander Medical Center, Maasstad, Hospital, Reinier de Graaf Gasthuis, Reumazorg Zuid-West Nederland and Spaarne Gasthuis. We acknowledge the team of treating rheumatologists and research nurses of the LUMC, in particular Dr F. J. van der Giesen. Our gratitude also goes to the PhD students who scored MRIs for trial screening, in particular Dr. H. W. van Steenbergen, Dr. R. M. ten Brink, Dr. D. M. Boeters, Dr. L. M. Mangrus, X.M.E. Matthijsen and F. Wouters. We thank Dr. M. Reijnierse, prof. dr. S. C. Cannegieter and prof. Dr. D. van der Heijde for their advice, and Dr. J. Schoones for his help with the systematic literature search. We acknowledge the funder of the study: NWO ZonMW grant (project number 95104004).

OP0071 ASSOCIATION BETWEEN LONG-TERM EXPOSURE TO AIR POLLUTION AND IMMUNE-MEDIATED DISEASES: A POPULATION-BASED COHORT STUDY

G. Adami1, M. Pontalti1, C. Benini1, A. Fassio2, E. Bertoldo1, D. Gatti1, M. Rossini1,1. University of Verona, Rheumatology Unit, Verona, Italy

Background: Environmental air pollution has been associated with disruption of the immune system at a molecular level.

Objectives: The primary aim of the present study is to describe the association between long-term exposure to air pollution and risk of developing immune-mediated conditions.

Methods: We conducted a retrospective observational study on a nation-wide dataset of women and men. Diagnoses of various immune-mediated diseases were retrieved. Data on the monitoring of PM10 and PM2.5 concentrations were retrieved from the Italian institute of environment protection and research (ISPRA). The long-term average PMs concentrations were the exposure of interest. Every study subject was linked to a PMs exposure value, which resulted from the average concentration of urban, rural and near-traffic stations of the subject residency from January 2013 to November 2020. Patients were linked to the nearest air quality station through ZIP code centroids. Generalized linear models were employed to determine the relationship between autoimmune diseases prevalence and PM. The fully adjusted model included age, body mass index (BMI), menopause, glucocorticoid treatment, treatment with adjuvant hormone therapy for breast or prostate cancer, specialty of the physician that entered the data and macro-area of residency (stratified as a categorical variable: northern Italy, central Italy and southern Italy.

Results: 81,363 subjects were included in the study. We found a positive association between PM10 and the risk of autoimmune diseases (β +0.007, p 0.014). Every 10 µg/m3 increase in PM10 concentration was associated with an incremental 7% risk of having autoimmune disease. Exposure to PM10 above 30 µg/m3 and PM2.5 above 20 µg/m3 was associated with a 12% and 13% higher risk of autoimmune disease pooled together, respectively (aOR 1.12, 95% CI 1.05-1.20 and aOR 1.13, 95% CI 1.06-1.20). Exposure to PM10 was associated with an increased risk of rheumatoid arthritis (aOR 1.408, 95% CI 1.271-1.560) but no other autoimmune diseases, whereas exposure to high levels of PM2.5 were associated with an increased risk of rheumatoid arthritis (aOR 1.559, 95% CI 1.401-1.734), CTDs (aOR 1.147, 95% CI 1.024-1.286) and IBDs (1.206, 95% CI 1.028-1.415) but no other autoimmune diseases.

Conclusion: Long-term exposure to air pollution was associated with higher risk of developing autoimmune diseases, in particular rheumatoid arthritis, CTDs and IBD. Chronic exposure to levels above the threshold for human protection was associated with a 10% higher risk of developing immune-mediated diseases.

**OP0072**

SMILE-RA - SELF-MANAGEMENT INDIVIDUALISED LEARNING ENVIRONMENT IN RHEUMATOID ARTHRITIS

A. Bowsworth1. National Rheumatoid Arthritis Society, Patient Services, Maidenhead, United Kingdom

**Background:** An important but insufficient aspect of care in people with inflammatory arthritis (IA) is empowering them to acquire good understanding of their disease and build ability to deal effectively with the practical, physical and psychological impacts of it. This extends beyond drug therapy and emphasizes the ability to self-manage, with the right support, as an essential component of care. Good self-efficacy and coping skills reduce health and financial burden to the individual as well as the health service, benefiting society overall. Provision of excellent supported self-management education is at the heart of what NRAS does and it was due to the difficulty of getting Commissioners to fund our face-to-face group self-management that led to our building an e-learning programme to expand on and replace our 6-week programme.

**Objectives:** To co-create an intuitive, easy to use, modular e-learning programme, free for all and which health professionals (HCPs) could refer their patients to. This makes supported self-management and evidence-based education accessible to all, wherever they live. SMILE enables HCPs to meet both NICE guideline and quality standards in RA against which rheumatology units in England and Wales are currently audited, as well as EULAR Recommendations for self-management strategies in inflammatory arthritis.

**Methods:** In 2019 with initial funding in place, we worked with our provider to help us realise our goal of developing a state-of-the-art e-learning experience in a modular format for people with RA. The programme had to be 1) simple to use; 2) interactive; 3) innovative and engaging; 4) able to measure impact through achievement of learning objectives and use of a validated patient reported outcome measure. The programme also had to be integrable with our Salesforce database enabling us to collect data and target resources to individuals, driven by identified need.

**Results:** Delayed by COVID, we launched with 4 modules on 17/09/2021. The 4 modules comprise: Foundation Module covering the importance of self-management which has the RA Impact of Disease PROM embedded; Newly Diagnosed; Meet the Team and Managing Pain and Flares. A fifth module on Medications in RA will be launched 1st quarter 2022 and 4 further modules will be uploaded in 2022. To date (26/01/22), 760 people have registered, of which 313 have completed a baseline RAID and this reveals that <50% are achieving minimal acceptable state of 3 or less. Over 78% of registrants are not NRAS members, and 634 modules have been completed. Early indications are that almost all are achieving learning objectives. More data will be available by June 2022.

**Conclusion:** Early indications demonstrate that people are successfully engaging with the programme and we have marketing activity lined up to raise further awareness of the value of SMILE with both potential users and rheumatology teams in 2022. Massive workforce issues together with significant backlogs of existing patients caused by the pandemic, have restricted the ability of Teams to provide education and self-management support for their patients. SMILE offers high quality, evidence-based learning opportunities for their patients and has been co-created with health professionals and people with RA at every step. With remote consultations here to stay, the importance of patients having access to evidence based online learning which they can tailor to their specific needs and improve their self-efficacy is even more critical.

**Disclosure of Interests:** provided input to SMILE.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

**OP0074**

DISTINCT CIRCULATING LYMPHOCYTE SUBSETS DISTINGUISH FLARE FROM DRUG-FREE REMISSION IN RHEUMATOID ARTHRITIS

K. F. Baker1,2, F. Rayner1, H. Lemos3, D. McDonald1, G. Hulme1, R. Hussain1, J. Coxhead1, A. Pratt1,2, A. E. Anderson1, A. Fibby1, J. Isaacs1,2, Newcastle University, Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom; 2Newcastle upon Tyne Hospitals NHS Foundation Trust, Musculoskeletal Unit, Freeman Hospital, Newcastle upon Tyne, United Kingdom; 3Newcastle University, Flow Cytometry Core Facility, Newcastle upon Tyne, United Kingdom; 4Newcastle University, Genomics Core Facility, Newcastle upon Tyne, United Kingdom

**Background:** Gender-specific differences in patients with axial spondyloarthritis (axSpA) are often seen in the clinical presentation and may differ in MRI findings. Male axSpA patients tend to show structural changes earlier, whereas in female axSpA patients the peripheral joints are more often affected. This can lead to a delay in axSpA diagnosis in women. For this reason, gender-specific data collection and establishment of gender-specific imaging criteria are of particular importance.

**Objectives:** To evaluate the diagnostic performance of different combinations of imaging markers to derive data-driven imaging criteria for MRI in axSpA, separately for men and women.

**Methods:** A total of 1194 patients were included in the study. Considering the exclusion criteria (available MRI image data sets, confirmed diagnoses), 684 patients (379 axSpA and 305 control group) were included for further statistical analysis. Two trained readers scored the MRI images separately for the presence of ankylosis, as well as erosion, sclerosis, fat metaplasia, and bone marrow edema differentiated for 3 regions: ventral/mid/dorsal for sacral-sided and iliac-sided sacroiliac joint. Chi² test was applied to compare lesion frequencies per group. Contingency table analysis was performed to assess diagnostic performances. The diagnostic performances were compared using the diagnostic odd ratio (DOR).

**Results:** Overall, 136 female and 243 male axSpA patients were included. Higher prevalence for ankylosis (24.3% vs. 74%) and fat metaplasia (58.8% vs. 42.6%) was shown in male axSpA patients; in contrast, sclerosis was more common in female axSpA patients (75.0% vs. 57.6%). No sex differences in frequency were shown for bone marrow edema and erosion. In male axSpA patients, the most significant difference in individual parameters was shown for ankylosis (DOR 40.1) compared with females (DOR 4.7). The detection of erosion and fat metaplasia as markers was also better in male axSpA patients (DOR 17.6 vs. 11.1 and 18.6 vs. 6.3). Sclerosis and bone marrow edema were better suited in female axSpA patients (DOR 3.0 vs. 2.5 and 5.0 vs. 3.7). Overall, diagnostic accuracy was improved when only lesions in the middle and dorsal articular compartments were considered.

**Conclusion:** The diagnostic performance of established image markers on MRI is significantly lower in female axSpA patients. This is especially true for ankylosis, which provides the risk for false-positive findings in women. Based on these findings, future revisions of imaging criteria may include gender-specific recommendations to improve diagnostic accuracy for male and female axSpA patients.

**REFERENCES:**

Background: Rheumatoid arthritis (RA) is characterised by relapsing joint and systemic inflammation, yet the immunopathological basis of these disease flares and their clinical prediction remain uncertain.

Objectives: Using mass cytometry and single cell RNA sequencing, we aimed to identify circulating lymphocyte subsets associated with RA flare, and identify potential cellular biomarkers to predict flare versus drug-free remission (DFR).

Methods: We analysed peripheral blood mononuclear cells (PBMCs) from patients recruited to the BioRRA study (Figure 1), a prospective clinical trial of conventional synthetic disease-modifying anti-rheumatic drug (csDMARD) cessation.[1] Patients with RA in clinical (DAS28-CRP < 2.4) and ultrasound (absence of power Doppler signal in 7 joints) remission stopped csDMARDs, with flare defined as DAS28-CRP ≥ 2.4 during 6 month follow-up. A 44-marker mass cytometry panel was used to profile PBMCs from 36 patients (20 flare, 16 DFR) at two time points each (baseline, and flare onset / month 6 DFR). In a subset of patients (n = 12: 8 flare, 4 DFR), fluorescence-activated cell sorting of PBMCs was followed by single cell sequencing (n = 81,923 cells) incorporating 320 immune genes, 34 oligo-tagged surface protein antibodies, and TCR/BCR CDR3 sequence clones. Cells were defined as ≥2 cells with identical CDR3 nucleotide sequence, and clonal expansion as a significant increase in proportion from baseline to final study visit. Statistical significance was assessed after Benjamini-Hochberg multiple test correction (adj p < 0.05).

Results: Mass cytometry revealed 31 distinct cell clusters: notably, greater proportions of memory (CD45RO+PD1hi) CD4+ and CD8+ T cells, and memory (CD27hiCD21-) B cells, were observed at onset of flare versus baseline (Table 1).

To better characterise these flare-associated subsets, single cell sequencing of CD45RO+PD1hi CD4+ and CD8+ T cells, and CD19+ B cells, was performed and identified 21 distinct clusters. CDR3 sequencing revealed significant clonal expansion (Fisher exact, adj. p < 0.05) at flare onset within five unique CD8+ clones (4 patients), one CD4+ clone (1 patent), and no B clones. Overall, there was a significantly greater proportion of IgA+ plasma cells at flare onset versus baseline. In contrast, a significantly lower proportion of CD25+/Foxp3+ regulatory T cells were present at csDMARD cessation (baseline) in subsequent flare versus DFR patients (Table 1), suggesting biomarker potential.

To further assess the predictive performance of CD4+ Tregs as a biomarker for flare versus DFR, we analysed PBMCs from an independent cohort of 50 patients (25 flare, 25 DFR) stopping csDMARDs in the ongoing BIO-FLARE study.[2] By flow cytometry, we confirmed a lower proportion of CD4+/CD25hi Tregs at baseline in flare vs DFR (median 4.74 versus 6.37%, Wilcoxon p = 0.037; AUC: 0.67). In this cohort, stopping csDMARDs only in patients with elevated (> 6.11% total CD4) baseline Tregs would have prevented drug cessation in 18/25 (72%) of flare patients; 9/25 (36%) of DFR patients would have continued csDMARDs unnecessarily.

Conclusion: We present a detailed longitudinal characterisation of circulating lymphocyte surface phenotype, gene expression, and clonal expansion in RA flare vs DFR. Furthermore our data, across two independent cohorts, suggests a role for CD4+ Tregs in promoting drug-free remission meriting further investigation, with potential for future clinical biomarker development.

FIBROBLAST/MACROPHAGE CROSSTALK VIA LACTATE: NEW THERAPEUTIC TARGET IN RHEUMATOID ARTHRITIS

V. Pucino1, M. Nefsa1, V. Gauthier2, S. A. Clayton3, A. Filer1, A. R. Clark1, K. Raza1, C. D. Buckley2. 1University of Birmingham, Inflammation and Ageing, Birmingham, United Kingdom; 2University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom

Background: The synovial membrane is the principal site of inflammation in rheumatoid arthritis (RA) and distinct subsets of fibroblasts and macrophages, with different effector functions, have been described within it [2]. Inflammation renders the RA synovial microenvironment hypoxic and acidic, with increased levels of lactate, the end product of glycolysis. Lactate acts as an immunomodulatory molecule within the synovium, interacting with lactate transporters present on fibroblasts and macrophages to regulate their function, movement and metabolism.

Objectives: To test whether dysfunctional crosstalk between fibroblasts and macrophages, driven by lactate, promotes the persistence of synovial inflammation.

Methods: Synovial tissues (n = 8) from patients fulfilling the 2010 ACR/EULAR RA criteria were obtained by ultrasound-guided synovial biopsy. Osteoarthritis (OA) synovial tissues of subjects undergoing joint replacement were used as control group. Monocarboxylate transporter 1 (MCT1) and MCT4 expression on fibroblasts and macrophages was assessed via confocal microscopy. We used RA synovial fibroblasts and monocyte-derived macrophages to test the effect of lactate in vitro. Migration was assessed in trans-well plates or via scratch test assays. Seahorse was used to evaluate metabolic pathways. IL6 production was measured by ELISA. Bioinformatic data were confirmed on publicly available scRNAseq datasets.

Results: We showed that: i) The expression of MCT1 and MCT4 which regulate lactate import and export respectively, is up-regulated upon inflammation. ii) Fibroblasts preferentially express MCT1, while MCT4 expression on macrophages is downregulated. iii) Lactate, at the concentration found in RA synovial fluid (10 mM), has divergent effects on the effector functions of these two cell types. In fibroblasts, lactate promotes IL6 production and cell motility; these effects are reduced by pre-treatment with a pan-lactate transporter inhibitor. In contrast macrophages respond to lactate by reducing migration, IL6 secretion and glycolysis.

Conclusion: The contrasting effects of lactate on macrophage and fibroblast migration, IL6 production and metabolism suggest that lactate represents a key
metabolite ensuring linked choreography between fibroblast and macrophage movement in the synovium which may become uncoupled in disease. We propose that dysfunctional crosstalk between these two cell types due to high lactate levels, promotes inflammation and the establishment of persistent disease in RA. Targeting lactate/MCT’s pathway may provide a novel therapeutic strategy, to restore cellular crosstalk and to reduce inflammation in RA patients.

L-ARGININE REPROGRAMS OSTEOCLAST PURINE METABOLISM AMELIORATING BONE LOSS IN RHEUMATOID ARTHRITIS

**Background:** Bone erosion is a clinical feature of rheumatoid arthritis related to disease severity and poor functional prognosis. Excessive osteoclast differentiation and insufficient osteoblast function are the main reasons for the erosive process in RA. Our previous investigation indicated that L-arginine supplementation not only diminished arthritic inflammation in the serum-induced arthritis (K/BxN) model but also decreased inflammatory joints osteoclast numbers (1).

**Objectives:** In the present study, we aim to investigate the metabolic action of L-arginine supplementation in RA, especially on periarticular bone erosion and systemic bone loss. We plan to depict the metabolic features of TNFα induced inflammatory osteoclasts after in vitro L-arginine supplementation.

**Methods:** Three murine arthritis models (serum-induced arthritis (K/BxN) model, collagen-induced arthritis (K/BxN) model, and TNFα mice model) were analyzed in the study. L-arginine was supplemented within the drinking water after the arthritis induction. The parameters (porcine skeleton (spine) and peripheral skeleton (tibia)) from the respective group were quantified by µCT. HE and TRAP staining were performed to address further the erosion area and osteoclast numbers in periarticular sites. In vitro osteoclast differentiation was conducted with or without L-arginine treatment, in the presence or not of TNFα activation. Seahorse and SCENITH analyses were adopted to delineate the metabolic features.

**Results:** In the RNA-Seq data by immunohistochemistry showing the presence of DKK3+ sublining fibroblasts in refractory rather than responder patients.

**Conclusion:** These data strongly demonstrated that L-arginine ameliorates bone erosion in RA through metabolic reprogramming and perturbation of purine metabolism in osteoclasts. L-arginine might therefore benefit RA therapy by reducing joint inflammation and also ameliorating bone destruction.

SYNOVIAL RNA-SEQ ANALYSIS OF THE R4RA TRIAL IDENTIFIES SIGNATURES OF TREATMENT RESISTANCE AND REFRACTORY STATE IN RHEUMATOID ARTHRITIS

A. Surace¹,², E. Sciacca³,², K. Goldmann³,², F. Rivellese¹,², C. Cubuk¹,², G. Giorgi³,², L. Fossati-Jimack³, M. Ahmed³, E. Prediletto³, M. Bombardieri³, M. Lewis¹, C. Fitzalis³, on behalf of R4RA investigators. ¹Queen Mary University of London, Centre for Experimental Medicine and Rheumatology, London, United Kingdom; ²Queen Mary University of London, Centre for Translational Bioinformatics, London, United Kingdom

**Background:** Although up to 5-20% of rheumatoid arthritis (RA) patients do not respond to all current medications including biologic therapies, relatively little is known about the underlying pathogenic mechanisms driving non-response. In the first biopsy-driven randomized clinical trial in RA (R4RA)¹, patients, in whom synthetic-DMARDs and at least one anti-TNF drug were not effective, were randomised 1:1 to rituximab (RTX) or tocilizumab (TOC) with a balanced stratification based on their synovial B-cell rich/poor signature, and response was assessed at 16 weeks. Non-responders were subsequently allowed to switch to the alternative drug with 48-week follow-up.

**Objectives:** Investigate mechanisms of response and non-response to RTX and TOC through deep molecular (RNA-sequencing) profiling of synovial tissue.

**Methods:** RNA-Seq from baseline synovial tissue biopsies of patients who received RTX (n=88) or TOC (n=94) at any point in the trial was analysed for differentially expressed genes and associated modules between responders and non-responders. Response was defined as 50% improvement in clinical disease activity index (CDAI) score. Patients who had received both drugs during the trial were subdivided into RTX only responders (pro-RTX, n=9), TOC only responders (pro-TOC, n=12) and refractory patients (no response to both RTX & TOC, n=32) and analysed for differential gene expression and performed gene module analysis.

**Results:** 16825 genes were significantly differentially expressed between RTX responders compared to non-responders, with a predominance of antigen presentation as well as T- and B-cell genes being associated with response, while non-response was linked to fibroblast associated genes. Comparison between TOC responders and non-responders identified fewer (85) differentially expressed genes, however lymphocyte and immunoglobulin genes were also high in the synovial tissue of TOC responders similar to RTX responders, while non-responders genes and modules also included a fibroblast signature. The cross-over study design enabled comparison of rituximab-specific responders (pro-RTX), tocilizumab-specific responders (pro-TOC) and refractory patients (non-responders to both RTX & TOC, n=32) in a 3-way analysis (see Figure 1). This identified 1980 genes upregulated both in pro-RTX and pro-TOC patients, 175 genes exclusive to the pro-RTX group and 306 to the pro-TOC group, while 1277 genes were exclusive to the refractory group. While leukocyte modules and genes dominated RTX & TOC response, the refractory state was strongly associated with fibroblast genes and modules. We confirmed the observed expansion of fibroblasts from the RNA-Seq data by immunohistochemistry showing the presence of DKK3+ sublining fibroblasts in refractory rather than responder patients.
were measured with TruCount, qPCR, and multiplex suspension assay, respectively. The absolute number of circulating immune cells, clock gene expression, and serum cytokine levels were measured at the end of the study. GCs suppressed diurnal variation in RA, but not in HD. IL-6 showed circadian variation in HD only. The following cytokines were tested for circadian rhythms: IL-2, IL-4, IL-10, IL-12, IL-23, IL-17A, IFN-γ, IL-12/23, GM-CSF, IL-6, TNF-α, IL-1β, IL-8, IL-12, IL-13, and IL-17F. Notably, IL-17A and IL-17F showed circadian rhythms in HD only.

**Conclusion:** We found a certain loss of circadian rhythms and the establishment of "inflammatory" rhythms. GC treatment in patients with RA resulted in three different types of effects on circadian rhythms: 1) restoration of rhythms of immune cells; 2) dampening of circadian oscillations; and 3) establishment of "inflammatory" rhythms in RA. GC treatment in patients with RA could be used to diagnose and treat the disease.

Background: Signal transducer and activator of transcription 3 (STAT3) is a transcription factor that belongs to a class of targets devoid of catalytic function, thus deemed “undruggable” by standard modalities such as small molecule inhibitors or biologics. STAT3 can be activated by various receptor- and non-receptor tyrosine kinases, playing a critical role in activation pathways triggered by cytokines, hormones, and growth factors, making it an attractive target for the treatment of inflammatory diseases.

Objectives: Kymera has developed heterobifunctional molecules that selectively target STAT3 for degradation and elimination by the ubiquitin-proteasome pathway. We sought to evaluate the pharmacologic potential of these STAT3 degraders through in vitro and in vivo studies relevant to human autoimmune disease, including murine collagen-induced arthritis.

Methods: We evaluated the impact of STAT3 degraders on the activation of human monocytes, dermal fibroblasts, CD4+ T cells, and PBMC by LPS, IL-6/IL-6R, IL-21, IL-23, as well as anti-CD3/CD28 plus a cocktail of cytokines and antibodies. STAT3 degradation and pSTAT3 inhibition were determined in comparison to a JAK1/2 small molecule inhibitor. Inhibition of cytokines, chemokines, and collagen release, as well as Th17 (CD4+CD25-+CXCR6+) and Treg (CD4+CD25+CD127lowFOXP3+) expansion were used as readouts.

Results: STAT3 degraders showed broad and potent activity in vitro against TLR receptor and cytokine-induced activation of immune and stromal cells, including soluble receptor release such as MCP-1/CLL2 and Collagen1a1. STAT3 degradation in CD4+ T cells robustly inhibited the development of Th17 cells, abrogating IL-17, IL-22, IL-8/CXCL8, and TNFα production, and increased Treg numbers in a manner dependent on STAT6 receptor and cytokine-induced activation of immune and stromal cells, including soluble receptor release such as MCP-1/CLL2 and Collagen1a1. STAT3 degradation in CD4+ T cells robustly inhibited the development of Th17 cells, abrogating IL-17, IL-22, IL-8/CXCL8, and TNFα production, and increased Treg numbers in a manner dependent on STAT6 receptor and cytokine-induced activation of immune and stromal cells, including soluble receptor release such as MCP-1/CLL2 and Collagen1a1. STAT3 degradation in CD4+ T cells robustly inhibited the development of Th17 cells, abrogating IL-17, IL-22, IL-8/CXCL8, and TNFα production, and increased Treg numbers in a manner dependent on STAT6 receptor and cytokine-induced activation of immune and stromal cells, including soluble receptor release such as MCP-1/CLL2 and Collagen1a1. STAT3 degradation in CD4+ T cells robustly inhibited the development of Th17 cells, abrogating IL-17, IL-22, IL-8/CXCL8, and TNFα production, and increased Treg numbers in a manner dependent on STAT6 receptor and cytokine-induced activation of immune and stromal cells, including soluble receptor release such as MCP-1/CLL2 and Collagen1a1. STAT3 degradation in CD4+ T cells robustly inhibited the development of Th17 cells, abrogating IL-17, IL-22, IL-8/CXCL8, and TNFα production, and increased Treg numbers in a manner dependent on STAT6 receptor and cytokine-induced activation of immune and stromal cells, including soluble receptor release such as MCP-1/CLL2 and Collagen1a1.

Conclusion: These data demonstrate the broad activity of STAT3 degradation in alleviating autoimmune inflammation in models relevant to human disease. Targeted protein degradation of STAT3 thus represents a novel therapeutic approach to treating autoimmune/autoinflammatory diseases such as rheumatoid arthritis.

**DISCORDANCE BETWEEN DAS28ESR AND PRESENCE OF ULTRASOUND POWER DOPPLER DURING EARLY TREATMENT IS ASSOCIATED WITH DISTINCT CLINICAL AND IMAGING PHENOTYPES AT PRESENTATION**

R. Shukla1,2, R. Wakefield2,3, P. Emery2,4, D. Plant2,3, M. H. Buch1,2,3, University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; 2Manchester University NHS Foundation Trust, NIHR Biomedical Research Centre, Manchester, United Kingdom; 3University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 4Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Discordance between DAS28ESR and musculoskeletal ultrasound (MSUS) detected power Doppler synovitis (PDUS) is well-recognised and may lead to under/over-treatment. We hypothesise that clinical and imaging features at diagnosis associate with early discordance of DAS28-PDUS and change in DAS28-PDUS status following DMARD treatment.

Objectives: To identify pre-treatment clinical factors associated with discordance and change in DAS28-PDUS status during early treatment in an early RA trial cohort.

Methods: The VEDERA trial randomised 120 treatment-naive, new-onset RA patients to either first-line etanercept + methotrexate (ETN-MTX) or methotrexate treat-to-target (MTX-TT) regime with escalation to ETN-MTX if not in DAS28ESR remission at week 24. Clinical and MSUS assessments were completed at baseline, weeks 12, 24 and 48. DAS28ESR ≤ 2.6 and DAS28 > 2.6 categorised remission and active disease respectively. PDUS presence was defined as total PDUS score ≥ 1. Active concordance (AC) was defined as active disease with PDUS while active discordance (AD) was defined as active disease without PDUS. Remission concordance (RC) was defined as DAS28ESR remission without PDUS remission discordance (RD) was defined as DAS28ESR remission with PDUS. Bayesian multinomial logistic regression (posterior estimate and 95% credible intervals reported) was used to address the study objectives with AC as the comparator group.

Results: At baseline all patients had active disease (moderate or high DAS28ESR) in line with trial eligibility - 68% (91/130) were AC and 32% (39/120) were AD. Compared to AD patients, AC patients were older median age 53 (vs 44), had higher DAS28ESR (5.90 vs 5.16) and CRP (11.66mg/L vs 3.6mg/L), as well as a higher presence of greyscale (GS - 100% vs 67%), power Doppler tenosynovitis (PDTS - 78% vs 49%) and erosions (20% vs 0) (p < 0.01). Figure 1 illustrates the pre-treatment proportions and change in group proportions at each timepoint, revealing an early shift of AC to AD (36% by week 12) or RC (22% by week 12) but persistence of those in AD from baseline at subsequent timepoints (64% at week 12). Baseline characteristics associated with each group compared to the comparator AC group (at weeks 12, 24 and 48) are reported in Table 1. For AD versus AC these were lower CRP at week 12 and female sex at week 24. For RC versus AC these were lower CRP and allocation to ETN-MTX at week 12, allocation to ETN-MTX and presence of PDTS at week 24 and younger age at week 48. For RD versus AC these were presence of PDTS at week 24 and male sex at week 48.

Table 1. Baseline characteristics associated with longitudinal discordance vs concordance. AC is the comparator group. Results in posterior estimate with 95% credible intervals reported.

Conclusion: DAS28ESR and PDUS discordance and concordance have distinct clinical and imaging phenotypes at presentation. Baseline active concordance and discordance respond differently to treatment – a sizeable proportion of former triation into active discordance early on and the latter persist in the face of effective treatment. Understanding the basis for these phenotypes is essential to facilitate optimal aggressive treatment and/or alternative management strategies.

**HAND AND FOOT MRI IN CONTEMPORARY UNDIFFERENTIATED ARTHRITIS: IN WHICH PATIENTS IS MRI VALUABLE TO DETECT RHEUMATOID ARTHRITIS EARLY? – A LARGE PROSPECTIVE STUDY**

N. den Hollander1, M. Verstappen1, N. Sidhu1, E. van Mulligen2, M. Reijnierse3, A. van der Helm-van Mil1,4, Leiden University Medical Center; Rheumatology, Leiden, Netherlands; 2Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands; 3Leiden University Medical Center, Radiology, Leiden, Netherlands

Background: Identifying patients that will develop rheumatoid arthritis (RA) among those presenting with undifferentiated arthritis (UA) remains a clinical dilemma. Although magnetic resonance imaging (MRI) is helpful according to EULAR-recommendations, this has only been determined in UA-patients not fulfilling 1987-RA-criteria, whilst part of these patients are currently considered as RA because they fulfill the 2010-criteria.

Objectives: We studied the predictive value of MRI for progression to RA in the current UA-population: i.e. not fulfilling RA-classification-criteria (neither 1987- nor 2010-criteria), and not having an alternate diagnosis. Additionally, the value of MRI was studied in patients with a clinical diagnosis of UA, regardless of the classification-criteria.

Methods: Two UA-populations were studied: criteria-based-UA as described above (n=405) and expert-opinion-based-UA (n=564), i.e. UA indicated by treatment-naïve, new-onset RA because they fulfill the 2010-criteria.

Results: Among criteria-based-UA-patients (n=405), 21% developed RA. MRI-detected synovitis and MRI-detected tenosynovitis were predictive. MRI-detected tenosynovitis was independently associated with RA-progression (OR 2.79; 95% CI 1.40-5.58), especially within ACPA-negative UA-patients (OR 2.91; 1.42-5.96). Prior risks of RA-development for UA-patients with mono-/oligo-/polyarthritis were 3%, 19%, 46%, respectively. MRI-results changed this risk most within the oligoarthritis-subgroup: PPV was 27% and NPV 93%. Similar results were found in expert-opinion-based-UA (n=564).

Conclusion: MRI is most valuable in ACPA-negative UA-patients with oligoarthritis; a negative MRI could aid in preventing overtreatment.

both for rituximab and tocilizumab, MCP-counter analysis showed significantly higher CD8 T-cells in responders to rituximab and higher macrophage-monocytes and myeloid dendritic cells (mDC) in responders to tocilizumab (Figure 1a). Moreover, when patients were classified according to MCP-counter scores, B-cell poor patients (MCP-counter B cell score <median value) showed significantly higher response rates to tocilizumab, while no difference was found in B-cell rich patients (Figure 1c). In contrast, macrophage and myeloid dendritic cell (mDC) rich individuals showed higher responses to tocilizumab (Figure 1d). Combined scores for lymphoid and myeloid cells demonstrated that patients poor in B-cells but rich in macrophages/mDC had a significantly higher response to tocilizumab (77% responders to tocilizumab vs 14% responders to rituximab, p=0.017, OR 16.48, 95%CI 1.29-1000.5) (Figure 1e). By analysing disease activity over time from baseline to week 16, we found a statistically significant interaction effect between treatments and time in B-cell poor (p=0.003), T-cell poor (p=0.022), mDC rich (p=0.029) and B-cell poor/Macrophages-mDC rich patients (p=0.006) (Figure 1f-g-h). Finally, by applying MCP-counter on matched pre-and post-treatment biopsies, rituximab-treated patients showed a significant reduction of B-cells, T-cells and monocyte/macrophages, while tocilizumab-treated patients showed a significant reduction of monocyte/macrophages, T-cells, but also neutrophils, myeloid dendritic cells and, interestingly, an increase in fibroblast signature (Figure 1i).

Conclusion: In silico deconvolution of the synovial tissue identify pre-treatment lymphoid cell lineages associated with response to rituximab and myeloid cells for tocilizumab. The longitudinal analysis of matched pre- and post-treatment synovial biopsies indicated that both medications have an effect on synovial immune cells, but tocilizumab can also affect stromal cells.

ANTIBODIES AGAINST ADVANCED GLYCATION END-PRODUCTS (ANTI-AGE) DISTINGUISH PATIENTS WITH A MORE INFLAMMATORY PROFILE AND WORSE OUTCOME IN SERONEGATIVE RHEUMATOID ARTHRITIS

T. J. van Wesemael1, M. D. van den Beukel2, A. T. W. Hoogslag3, T. Huizinga3, R. Toes1, L. A. Trouw2, D. van der Woude4 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Leiden University Medical Center (LUMC), IMMUNOCHEMATOLOGY AND BLOOD TRANSFUSION, Leiden, Netherlands

Background: In rheumatoid arthritis (RA) around two-thirds of patients are autoantibody-positive for rheumatoid factor, anti-citrullinated protein antibodies (ACPA) and/or anti-carbamylated protein antibodies (anti-CarP). The remaining seronegative subgroup of RA is clinically heterogeneous and thus far, biomarkers predicting the disease course in these patients are lacking. Therefore, we set out to investigate the value of a new/different autoantibody in rheumatoid arthritis directed against advanced glycation end-product (AGE) modified proteins (anti-AGE). AGEs are a marker of oxidative stress, and anti-AGE have been described in multiple diseases including diabetes, and hypertension.

Objectives: To investigate the prevalence of anti-AGE in RA and non-RA arthritis patients, as well as their association with clinical parameters and disease outcome in RA.

Methods: In 648 RA patients and 538 non-RA arthritis patients from the Leiden Early Arthritis Clinic anti-AGE IgG antibody levels were measured using an in-house fetal calf serum (FCS) ELISA based assay using native FCS as control. The cutoff for positivity was set as the mean optical density plus two times the standard deviation of 80 healthy controls. Radiological progression was measured with the Sharp van der Heijde score (SHS) on yearly basis and the association with anti-AGE was assessed with a multivariate normal regression model.

Results: Anti-AGE was found in 299 (46%) of RA patients versus 163 (30%) of non-RA arthritis patients. Interestingly, 67 (34%) of completely seronegative (RF-, ACPA- and anti-CarP-negative) RA patients were positive for anti-AGE. Within RA, anti-AGE-positive patients had significantly higher ESR (median anti-AGE-positive: 38, anti-AGE-negative: 32, p=0.001) and CRP (median anti-AGE-positive: 19, anti-AGE-negative: 17, p<0.001), indicating an more inflammatory profile in these patients. Radiographic progression, was significantly higher in anti-AGE+ patients (Figure 1A, B=1.05, p<0.001). Since ACPA and anti-CarP (in ACPA-patients) are associated with radiological progression, the analysis was first stratified for ACPA-status. In the anti-AGE+ACP+ patients a significant association with SHS was found (Figure 1B: B=1.04, P<0.001), indicating that anti-AGE is associated with radiological progression in ACPA-negative patients. Next, the ACPA-negative stratum was also stratified for anti-CarP. Interestingly, SHS was significantly higher in all anti-AGE+ groups compared to the autoantibody-negative group.

Conclusion: Almost half of the RA patients are anti-AGE positive including a substantial part of otherwise completely seronegative RA patients. Anti-AGE antibodies are associated with inflammatory parameters and radiologic progression in seronegative RA patients. Therefore, although these autoantibodies are not specific for RA, anti-AGE could potentially identify patients with a more inflammatory phenotype and more severe disease outcome in “classic” autoantibody-negative RA patients.

Figure 1. Erosion scores according to the presence of autoantibodies. Figure 1A. Median erosion scores assessed by Sharp van der Heijde method (SHS) during the disease course stratified for anti-AGE. A significant difference was found between anti-AGE-negative patients and anti-AGE-positive patients (B=1.05, p<0.001) Figure 1B. Median erosion scores assessed by SHS during the disease course stratified for anti-AGE and anti-citrullinated protein antibodies (ACPA). SHS was significantly higher in all autoantibody-positive groups compared to the anti-AGE-ACPA- group.

INTEGRATED SYSTEMS ANALYSIS OF THE GUT MICRBIOTA PHENOTYPES IN THE RHEUMATOID ARTHRITIS

J. Qiao1,2,3, S. X. Zhang1,2,3, M. J. Chang2,3,4, S. Song1,2,3, R. Zhao1,2,3, T. Cheng1,2,3, Y. Zhang1,2,3, X. Li1,2,3, 1The Second Hospital of Shanxi Medical
**Background:** Patients with rheumatoid arthritis (RA) displays extreme dysbiosis in microbiota. However, such dysbiosis is difficult to characterize owing to the high-dimensional complexity of the gut microbiota.\(^1\,\text{2}\)

**Objectives:** The aim of this study was to discover the enterotype characters of intestinal flora in RA.

**Methods:** Fecal samples from 145 RA patients were collected for bacterial 16S rRNA genes sequencing. Mathematical modeling using Dirichlet multinomial mixtures (DMM) was applied to describe the variability in the microbiome data and cluster samples into enterotypes. The alpha-diversity, beta-diversity and the microbiome composition of the gut microbiome were used to define the difference of gut microbiota profiles between different enterotypes. The nonredundant taxonomic biomarkers for each enterotype were selected by using LEfSe. Inflammatory biomarkers (ESR, CRP), auto-antibodies(ACPA, MCV), peripheral lymphocytes subsets and cytokines were analyzed in our cohort using the Kruskal-Wallis test.

**Results:** Laplace approximation of DMM indicated two significantly distinct bacterial microbiota structures (RAE1 and RA E2) existed in the dataset (Figure 1a). Principal co-ordinates analyses confirmed that these two microbiota states explained a reasonable proportion of observed variance in microbiota composition(ANOSIM R2 = 0.267, p < 0.001; Figure 1b), with distinct bacterial genus distribution of in each enterotype (Figure 1c). RA E1 were primarily dominated by Prevotella while RA E2 by Bacteroides. Interestingly, Chao1, ACE, Shannon and Simpson revealed a higher alpha diversity in Prevotella-enriched enterotype (p < 0.001, Figure 1d). Fourteen selected taxonomic biomarkers at different phylogenetic levels showed great discriminant ability, with Log10 LDA score > 4.0 (Figure 1e-g). Further, inflammatory biomarkers (ESR, CRP) and auto-antibodies(ACPA, MCV) as well as the number of T, B and CD4+T, CD8+T were significantly higher in RA E2 than in RA E1 (p < 0.05). But CD6+T were consistent in RA E1 and RA E2 (p > 0.05, Figure 2h). But CD8+T were significantly higher in RA E2 than in RA E1 (p < 0.05).

**Conclusion:** Despite RA gut microbiota being of different dysbiosis, two patterns of dysbiosis, designated as RA-enterotypes, were predominant among the RA patient cohort. RA E2 exhibited a loss of Prevotella but a growth of Bacteroides, while RA E1 presented the opposite results.

variable) using a generalized estimating equation (GEE) model in STATA/IC 14.0.In NOAR.

**Results:** A total of 2119 participants (2440 radiographs) were identified with both genetic and radiographic data available. 66.2% of these patients were female and 33.3% were anti-CCP positive. Median age of onset was 54.5 and 74.9% satisfied the American College of Rheumatology (ACR) 1987 criteria for rheumatoid arthritis.

A total of 113 different non-HLA SNPs associated with radiographic outcome in RA were identified from the literature. Of these, 102 were successfully identified within NOAR and 91 were deemed to be independent SNPs based on R² of 0.6. 14 SNPs were found to be significantly associated with the presence of erosions within NOAR (Table 1).

**Conclusion:** 113 non-HLA SNPs have been previously reported to be associated with radiographic outcome in RA. Of these, only ~15% also showed an association in NOAR, the largest cohort with genetic and radiographic outcome data worldwide. Interestingly, rs2243250, a SNP located on chromosome 5 (IL4), previously found to be associated in a small Egyptian cohort, has been replicated in NOAR.(2) Current work consists of assessing the added clinical value of a genetic risk score based on HLA and non-HLA markers in predicting radiographic outcome when combined with clinical/serological/demographic markers.

**Figure 1.** Heatmap representation of selected GO BP pathways in responders/non-responders.
Conclusion: Machine learning models based on transcriptomic functional pathways can accurately predict response to tofacitinib. Our study could contribute to improve the treatment customization and the optimization of RA treatment strategy toward a personalized approach. Furthermore, these findings may help to understand the mechanisms underlying the clinical response to JAK inhibitors.

PRECLINICAL STUDIES OF A NOVEL CATHEPSIN C INHIBITOR IN MPO-ANCA-ASSOCIATED VASCULITIS MODEL

A. Ishizu1, M. Taniguchi2, S. Arai2, Y. Nishibata2, S. Masuda2, U. Tomaru2, T. Shimizu4, W. Sinko4, T. Nagakura4, Y. Terada4, 1Hokkaido University, Faculty of Health Sciences, Department of Medical Laboratory Science, Sapporo, Japan; 2Hokkaido University, Faculty of Health Sciences, Department of Medical Laboratory Science, Sapporo, Japan; 3Hokkaido University, Faculty of Medicine and Graduate School of Medicine, Department of Pathology, Sapporo, Japan; 4Modulus Discovery, Inc., Research & Development, Tokyo, Japan

Background: MPO-ANCA-associated vasculitis (MPO-AAV) is a systemic small vessel vasculitis with the production of MPO-ANCA in the serum. This disease develops necrotizing and crescent glomerulonephritis (NCGN) and peritubular capillaritis-mediated interstitial damages in the kidneys, and pulmonary hemorrhage due to capillaritis in the lungs. Recent studies have revealed that neutrophil extracellular traps (NETs) induced by MPO-ANCA are critically involved in its pathogenesis, and neutrophil elastase (NE) plays an essential role in the formation of NETs. Cathepsin C (CatC) functions as a key enzyme in the activation process of several neutrophil serine pro- teases (NSPs) such as NE, proteinase 3 and cathepsin G by converting the inactive forms of the NSPs to the active forms by digesting dipeptides at the N-terminus of the enzymes.

Objectives: Although glucocorticoids and immunosuppressive drugs used as the standard of cares can lead remission in MPO-AAV patients, there are remaining unmet medical needs such as severe side effects, resistance to the treatment and relapse. Therefore, development of new therapeutic strategies is awaited. The aim of this study is to demonstrate the efficacy of MOD06051, a novel CatC inhibitor, against MPO-AAV, using an MPO-AAV rat model established previously.

Methods: In vitro studies: CatC and NE inhibitory activity was measured using recombinant enzymes and fluorescent substrates. Cellular NE activity in the granulocytes differentiated from the primary human bone marrow-derived hematopoietic stem cells under the presence or absence of MOD06051 was determined using fluorescent substrates. In vivo studies: 4-week-old Wistar Kyoto (WKY) rats were immunized with human MPO according to Little’s protocol. The rats were divided into three groups (n=8 in each group), and vehicle (0.5% methylcellulose) or MOD06051 (0.3 or 3 mg/kg bid) was orally administered every day for 42 days. All rats were euthanized at the end of the study for serological and histological evaluations.

Results: In vitro studies: MOD06051 inhibited the enzymatic activity of human recombinant CatC with an IC50 value of 1.5 nM, and no other cathepsins nor NE inhibition was observed at 10 μM. The NE activity in primary human granulocytes was suppressed by MOD06051 with an IC50 value of 18 nM.

In vivo studies: MPO-ANCA was induced in all groups at the same level. The percentage of affected glomeruli including those with NCGN, NET-forming neutrophils in the peripheral blood and glomeruli, and glomerular neutrophil counts were significantly suppressed by MOD06051 treatment in a dose-dependent manner. Furthermore, hematuria score, urinary NGAL (Neutrophil Gelatinase-Associated Lipocalin), tubular erythrocyte cast counts, and pulmonary hemorrhage foci were significantly decreased in the 3 mg/kg of MOD06051 treated group with the similar trends in 0.3 mg/kg group.

Conclusion: MOD06051 showed specific inhibition of CatC activity. This compound suppressed the serine proteases activation in primary human neutrophils and NET formation in the MPO-AAV model rats, resulting in amelioration of MPO-ANCA-induced tissue destruction, including NCGN and tubular interstitial damages in the kidneys, and disorder of alveolar septal capillaries in the lungs. MOD06051 appears to be a promising agent for treatment of MPO-AAV patients.

Scientific Abstracts
Background: ANCA-associated vasculitides (AAV) are characterized by recurrent, chronic small vessel inflammation and deleterious organ damage. The main targets of ANCA are myeloperoxidase (MPO) and proteinase 3 (PR3). ANCA, B cells and the complement system are crucial to AAV pathogenesis, as evidenced by the clinical benefit of B cell depletion with rituximab and, more recently, the C5a receptor antagonist avacopan. While ANCA in serum have been studied extensively, phenotypic and functional characteristics of the underlying B cell responses remain largely unknown.

Objectives: To develop a flow cytometry-based technique for identifying MPO-specific B cells in the circulation of MPO-positive AAV patients in order to characterize this B cell response and its potential contribution to disease pathogenesis.

Methods: Human neutrophil-derived MPO was conjugated to two different fluorochromes and used to identify MPO-specific B cells by flow cytometry. An antigen-specific staining protocol was developed and validated using MPO- and PR3-specific hybridoma cells. MPO-specific B cells were phenotypically characterized and isolated from the peripheral blood of AAV patients by fluorescence-activated cell sorting (FACS) and cultured as single cells. MPO-specificity was confirmed by ELISA on culture supernatants. B cell receptor (BCR) sequences were obtained from MPO-positive clones by full length ARTISAN-PCR and confirmed by ELISA on culture supernatants. B cell receptor (BCR) sequences were obtained from MPO-positive clones by full length ARTISAN-PCR and confirmed by ELISA on culture supernatants. B cell receptor (BCR) sequences were obtained from MPO-positive clones by full length ARTISAN-PCR and confirmed by ELISA on culture supernatants. B cell receptor (BCR) sequences were obtained from MPO-positive clones by full length ARTISAN-PCR and confirmed by ELISA on culture supernatants.

Results: The newly developed, differential antigen labelling approach successfully identified MPO-specific but not PR3-specific hybridoma cells. Subsequently, we detected MPO-specific B cells in the circulation of MPO-positive AAV patients at a frequency of up to 1:1000 B cells. FACS sorting and single cell culture yielded an enrichment of MPO-specificity (>80%). Notably, the majority of isolated, MPO-specific B cells (60-95%) displayed an IgM memory phenotype, which corresponded to the presence of anti-MPO IgM in plasma. The remainder of the MPO-specific cells were mainly IgG memory B cells and few naive cells. BCR sequencing revealed a polyclonal IgM response with diverse V-gene usage, consisting of both germine and highly mutated clones. Generation of mAb (n=9) confirmed MPO specificity by inhibition ELISA both germine and somatically mutated clones. Interestingly, anti-MPO IgM mAb showed a high capacity for complement factor deposition upon MPO binding. MPO-specific complement assays with IgG- and IgM-depleted patient plasma showed that anti-MPO IgM activated complement much more efficiently than anti-MPO IgG.

Conclusion: We demonstrate the direct ex vivo identification, isolation and characterization of MPO-specific B cells in human AAV. Intriguingly, we observed a remarkable expansion of MPO-specific, IgM-expressing memory B cells in patients. This so far unrecognized, active IgM-compartment may be clinically relevant, as both mAb and plasma-derived polyclonal MPO-specific IgM strongly activated complement, a pathway thought to play a central role in AAV. Next to these novel insights into autoreactive B cell biology in AAV, our findings now provide new opportunities for studying auto-reactive B cell responses in different clinical phases of AAV, amongst which active disease, remission and (imminent) relapse.

Disclosure of Interests: None declared.
Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAVs) are a group of multisystem inflammatory diseases of the small blood vessels, characterized by leukocytoclastic inflammation of small blood vessels and triggered by production of ANCA autoantibodies [1]. Due to the multorgan involvement and relapsing nature, AAV is among the systemic autoimmune rheumatic diseases with the highest morbidity and mortality [1, 2].

Objectives: To evaluate the risk of severe infection and infection-related mortality among patients with newly diagnosed AAV.

Methods: We conducted an age- and gender-matched cohort study of all patients with incident AAV between January 1, 1997 and March 31, 2015 using administrative health data from British Columbia, Canada. Primary outcome was the first severe infection after AAV onset necessitating hospitalization or occurring during hospitalization. Secondary outcomes were total number of severe infections and infection-related mortality.

Results: We identified 549 AAV patients and matched them with 5,480 non-AAV individuals from the general population, yielding 184 and 509 first severe infections during 2,539 and 33,342 person-years follow-up, respectively. The crude incidence rate ratios for first severe infection and infection-related mortality were 5.03 (95% CI, 4.25-5.96) and 3.72 (95% CI, 2.44-5.67), respectively. The corresponding adjusted hazard ratios were 3.77 (95% CI 2.94-4.85) and 3.84 (95% CI, 2.13-6.91). AAV patients had an increased risk of a greater total number of severe infections with crude rate ratio of 4.99 (95% CI, 4.42-5.62) and adjusted rate ratio of 3.32 (95% CI, 2.73-3.74).

Conclusion: AAV is independently associated with increased risks of first severe infection (3.8-fold), a greater total number of severe infections (3.2-fold) and infection-related mortality (3.8-fold).

OP0094 IDENTIFICATION OF NEW AUTOANTIGENS IN PATIENTS WITH SYSTEMIC SCLEROSIS THROUGH IMMUNOPRECIPITATION COMBINED WITH LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY

J. B. Vulteira1,2, D. Blockmans3,4, P. De Haes5,6, S. Vanderschueren3,4, P. Verschueren1,2, K. G. Claeyse7, W. Wuyts8,10, J. L. Lenaerts9, E. De Langhe1,2, X. Background: In up to 20% of patients with systemic sclerosis (SSc) none of the established SSc-specific autoantibodies are present [1]. Notwithstanding, in many of these patients high-titer autoantibodies can be detected on the HEp-2 indirect immunofluorescence assay (HEp-2 IFA) which suggests the presence of an autoantibody to an intracellular protein expressed by the HEp-2 cell line. Immunoprecipitation of unlabelled cell extract followed by gel-free liquid chromatography tandem mass-spectrometry analysis has the potential to identify new autoantigens in an unbiased manner.

Objectives: To identify new autoantigens through immunoprecipitation combined with liquid chromatography-tandem mass spectrometry (IP + LC-MS/MS) in HEp-2 IFA-positive patients with SSc in whom none of the established SSc-specific autoantibody specificities are present.

Methods: Forty-nine patients from the University Hospitals Leuven that fulfilled the EULAR-ACR 2013 classification criteria for systemic sclerosis or LeRoy and Medsger's criteria for early systemic sclerosis and who were negative on the EIA CTD Screen (Thermo Fisher Scientific, United States), which includes centromere protein B, topoisomerase I, RNA polymerase III, fibrillarin, PM-Scl and U1 ribonucleoprotein, were identified. Immunoprecipitation was performed by incubation of sera of these patients (1:30 in 300 µl Tris-buffered saline) with Pierce A/G magnetic beads, subsequent cross-linking with bissulfosuccinimidyl suberate (BSS) followed by incubation with nuclear extract of HeLa cells (100-150 µg) overnight at 4°C. The eluted protein was analyzed through liquid chromatography with tandem mass spectrometry. Mass spectrometry data were matched against the Uniprot Homo Sapiens database with the Mascot search engine. Candidate autoantigens were confirmed through immunoprecipitation followed by western blot of the eluate with target-specific polyclonal rabbit antibodies or western blot of recombinant protein incubated with sera of the index patients.

Results: We identified multiple new autoantigens, including the THO complex subunit 1 (THOC1) and other subunits of the THO complex in 3 patients, nuclear valosin-containing protein like-2 (NVL) in 2 patients, nucleolar and coiled-body phosphoprotein 1 (NOLC1) and multiple interacting proteins in 1 patient, probable 28S rRNA (cytosine(4447)-C)-methyltransferase (NPD2) in 1 patient, telomeric repeat-binding factor 2 (TERF2) and TERF2-interacting protein (TERF2IP) in 1 patient and regulator of chromosome condensation 1 (RCC1) in 1 patient. The new targets were confirmed through immunoprecipitation-western blot or western blot of recombinant protein incubated with sera (Figure 1). Furthermore, in 10 patients known SSc-associated autoantigens were strongly immunoprecipitated including multiple Th/To subunits in 5 patients, RuvBL1/2 in 2 patients, multiple PM-Scl subunits in 2 patients (who both were negative on the EIA CTD Screen), and fibrillarin in 1 patient (who was also negative on the EIA CTD).

Figure 1.
Immunoprecipitation-western blot with target-specific rabbit polyclonal antibody (1/500-2000 dilution), numbers corresponding to order of description of patients, HC healthy control, NE nuclear extract. RP recombinant protein WB-RP western blot of recombinant protein was reproduced with different batches of lot (B).

Conclusion: Multiple new autoantigens were identified and confirmed in patients with SSc without previously identified autoantibody specificity. Further evaluation of reactivity against the newly identified autoantigens in patients with SSc with known autoantibody specificities and other cohorts is required. IP + LC-MS/MS can identify new and established autoantigens in patients with SSc.

Background: Activated fibroblasts are the main drivers of skin fibrosis in Ssc. We have recently identified dimethyl alpha-ketoglutarate (dm-aKG) as a potential repressor of myofibroblast differentiation and profibrotic activity in cultured skin fibroblasts.

Objectives: To further analyse the clinical translation of our findings by investigating the antifibrotic capacity of dm-aKG on explanted skin biopsies from SSc patients.

Methods: We cultured forearm punch skin biopsies from SSc patients (n=10) for 24h ex vivo in the presence/absence of 6 mM dm-aKG. Thereafter, skin biopsies (n=4) were dissociated into single cells using a combined mechanical-enzymatic dissociation protocol, followed by single cell (sc)RNA-seq library preparation (10X Genomics) and sequencing (Illumina, NovaSeq6000, 50,000 reads/cell). We mapped the scRNA-seq reads to the reference genome GRCh38.p13 and analysed the data with R/Bioconductor tools. We deconvoluted cell types in bulk skin transcriptomes from SSc cohorts (GSE: 45485, 50795, 9285, 32415) using human skin scRNA-seq data1. The secretion of IL-6, procollagen-1, PRO-C1 (N-terminal type I collagen pro-peptide), C1M (MMP-degradation fragment of type I collagen), and fibrinectin (FBN-C) from cultured skin (n=10) was measured in supernatants by ELISA. We analysed gene and protein expression in TGFIα-activated healthy and Ssc dermal fibroblasts (DF, n=10) treated or not with dm-aKG using qPCR, Western blot and ELISA. Contractile properties of DF were assessed by gel contraction assay. Traction forces generated by DF were determined by reference-free traction microscopy.

Results: Dissociated cultured Ssc skin exhibited comparable cell yield and viability in the presence (20,203; 89%) and absence (25,280; 93%) of dm-aKG, respectively. scRNA-seq skin analysis included 20,869 high quality single cell profiles segregating into 10 distinct skin cell populations (Figure 1A). This analysis demonstrated decreased proportion of fibroblasts and increased proportion of keratinocytes in dm-aKG treated skin (p<0.05, Figure 1B). Among skin cell types, skin fibroblasts exhibited the largest amount of differentially expressed genes upon dm-aKG treatment (44%, n=779, x-fold=0.5, FDR=0.05), suggesting that these cells are key targets of dm-aKG therapy in Ssc skin. We identified inflammatory/cytokine signalling (hub genes IL6, STAT1) and extracellular matrix (ECM) organization (hub genes MMP1, ITG8) as top downregulated biological processes in fibroblasts in dm-aKG treated Ssc skin (Figure 1C), coinciding with a decreased abundance of proinflammatory skin fibroblast subpopulation. Specifically, these cells were identified as the main source of IL6 (Figure 1D) and were enriched in Ssc skin as revealed by deconvolution analysis of skin transcriptomes. Furthermore, dm-aKG reduced the secretion of IL-6, procollagen-1 and C1M, but not pro-C1 and FBN-C, from cultured skin explants. In cultured DF, dm-aKG blocked the inflammatory (IL6, pSTAT3), profibrotic (aSMA, Fibronectin, Procollagen-1, Pro-C1) and contractile activities, and significantly diminished traction forces exerted by DF on the matrix substrate.

Conclusion: Dm-aKG broadly interferes with inflammatory and ECM organizational activities of skin fibroblasts in culture and in explanted skin from SSc patients. These results confirm that dm-aKG might represent a potential new therapeutic approach for efficient targeting of skin inflammation and fibrosis in Ssc.

Background: Autoantibodies (Aab) are frequent in systemic sclerosis (SSc) [1]. Recently, it has been showed that immunoglobulins G (IgG) from SSc promoted proinflammatory and profibrotic phenotype in monocyte secrete (2). Fibroblasts (FB) are key effectors cells in SSc and data on FB proteins secretion in the presence of IgG from SSc patients are lacking. While recognized as potent biomarkers, the pathogenic role of Aab is much more debated.

Objectives: To explore the FB secretome in the presence of purified IgG from SSc patients

Methods: Normal dermal FB were cultured in the presence of purified IgG from patients with diffuse cutaneous SSc (dcSSc), limited cutaneous SSc (lcSSc) or healthy controls (HC). After 72 h of culture, the cell supernatants were collected, centrifuged and passed through a filter to remove the cells. After proteins digestion, secretome was explored using mass spectrometry coupled with liquid chromatography (LC-MS/MS). Analysis of variance (ANOVA) and hierarchical clustering were used to identify proteins responses patterns.

Results: Proteomic identified and quantified 1268 proteins, among them 377 were significant after ANOVA. SSC and HC secreteome appeared distinct. Hierarchical clustering on significant proteins after ANOVA showed 3 distinct groups of patients secreteome: a first group including mostly dcSSc anti-topoisomerase-I (ATA) positive (dcSSc ATA+) patients, a second group including mostly dcSSc ATA negative (dcSSc ATA-) patients, a third group more heterogeneous including the majority of HC, lcSSc anti-centromere positive (lcSSc ACA+) patients and dcSSc ATA- patients (Figure 1A). The comparison of FB secretome in the presence of purified IgG from dcSSc ATA+ vs IgG HC revealed 203 differentially expressed proteins (DEP) (Figure 1B). The enriched Gene Ontology (GO) terms upregulated in IgG dcSSc ATA+ vs IgG HC were involved in endocytic vesicle lumen, vesicle lumen, extracellular matrix or glycosaminoglycan binding. The comparisons of IgG dcSSc ATA+ vs IgG HC and IgG lcSSc ACA+ vs IgG HC revealed 85 and 15 DEP, respectively. Follistatin, amyloid beta A4 protein, myosin-9 and calreticulin were commonly overexpressed in the 3 subtypes of SSc. 40 proteins were DEP, respectively. Follistatin, amyloid beta A4 protein, myosin-9 and calreticulin were commonly overexpressed in the 3 subtypes of SSc. 40 proteins were DEP, respectively. Follistatin, amyloid beta A4 protein, myosin-9 and calreticulin were commonly overexpressed in the 3 subtypes of SSc. 40 proteins were DEP, respectively.

Conclusion: Using sensitive proteomic approach, we identified that purified IgG from SSc patients modified FB secreteome in a subtype dependent manner. The data support the pathogenic role of Aab in SSc.

Microbiome and SpA

OP0098 PREDICTING TREATMENT OUTCOME IN PATIENTS WITH SPONDYLOARTHRITIS USING MICROBIOTA ANALYSIS

L. Ameri1, T. Ströwig1, T. R. Lesker1, T. Witte2, 1Helmholtz Centre for Infection Research, Microbial Immune Regulation, Braunschweig, Germany; 2Hannover Medical School, Department of Rheumatology and Immunology, Hannover, Germany

Background: Autoimmune-related rheumatic diseases such as rheumatoid arthritis (RA) and spondyloarthritis (SpA) are caused by an interplay of various factors including genetics, environmental factors and lifestyle. Among them, the intestinal microbiome has been suggested to influence disease initiation and progression. While the pathogenic connection between the microbiome and autoimmunity remains ambiguous, there is evidence that, for instance, microbiota-derived antigens cross-react with autoantibodies triggering an immune response and disease development1. However, other hypothesis such as the leaky gut model have been explored2. In addition to this potential involvement in disease initiation, microbial signatures have been identified to predict treatment outcome, as shown for the first-line medication Methotrexate (MTX) in RA patients3. Objectives: Our study aimed to longitudinally compare gut microbiota composition between treatment-naïve patients with different forms of rheumatic disorders from disease onset to remission/relapse to identify i) disease-specific signatures and ii) their impact on therapeutic responses. Methods: Patients with new onset of rheumatic disorders as well as their household members were recruited in the RheumaVOR cohort. The patients presented without treatment with steroids or DMARDs. The diagnosis was made by experienced rheumatologists. Native and stabilized fecal samples were collected, and 16S rRNA amplicon sequencing was performed to determine microbiota composition. Patients with non-inflammatory rheumatic disorders served as controls, whereas treatment was initiated in patients with inflammatory rheumatic diseases. Clinical data of patients was recorded including monitoring of medication and treatment response. Results: A total of 422 fecal samples were analyzed from patients diagnosed with different forms of immune-mediated rheumatic diseases, non-inflammatory rheumatic diseases as well as from household controls (Table 1). Using 16S rRNA amplicon sequencing, we did not detect any clustering of patient groups during disease onset based on the microbiota composition (Figure 1A). However, PsA patients responding to MTX (MTX-R) (=patients in DAPSA remission 3-6 months after MTX initiation or patients showing partial response) and patients not in remission (MTX-NR) differed in microbiota composition between treatment-naïve patients with different forms of rheumatic disorders from disease onset to remission/relapse to identify i) disease-specific signatures and ii) their impact on therapeutic responses.

Exploring the origin of inflammation in spondyloarthritis

OP0100 IL-17A BLOCKADE MODULATES DISEASE SPECIFIC IMMUNE AND STROMAL PATHWAYS IN PERIPHERAL SPONDYLOARTHRITIS SYNOVITIS

R. Fiechter1, L. van Mens1, I. Hammoura1, H. de Jong1, D. Pots1, I. Fluri1, S. Tas1, D. Baeten1, M. G. H. van de Sande1, N. Yeremenko1. 1Amsterdam UMC, location AMC, Rheumatology and Clinical Immunology / Experimental Immunology, Amsterdam, Netherlands

Background: The cellular and molecular mechanisms driving inflammation and structural remodelling in spondylarthropathies (SpA) remain largely unknown, though the IL-23/IL-17 pathway can contribute to synovial inflammation and radiographic progression.

Objectives: To investigate the molecular pathways affected by IL-17A blockade (IL-17Ai) with secukinumab in SpA synovitis, and assess if this response is tissue- and/or treatment-specific.

Methods: Synovial biopsies were obtained from peripheral SpA patients by needle arthroscopy before and after 12 weeks of IL-17Ai with secukinumab (n=12), and analyzed by RNA-sequencing and qPCR. We performed pathway enrichment analysis of the differentially expressed genes (DEGs) to identify pathways modulated after treatment. We compared the synovial tissue response in patients with psoriatic arthritis (PsA) in our cohort (n=7) with open source gene expression data of skin biopsies of psoriasis patients receiving secukinumab (n=22) [1] and of synovial biopsies of PsA patients receiving IL-12p40/IL-23p40 blockade (n=7) [2].

Results: IL-17Ai significantly modulated the expression of 1255 genes (549 up- and 706 down-regulated, FDR 0.1) in the synovium at week 12 compared to baseline (Figure 1). Genes downregulated upon IL-17Ai were significantly enriched in GO terms and KEGG pathways related to immune and inflammatory responses, including neutrophil and monocyte chemotaxis, TNF-mediated, NF-kB-, Wnt-, and JAK-STAT signalling pathways, and, importantly, bone-remodelling responses, such as osteoblast and osteoclast differentiation. Upregulated genes are enriched in JNK-, MAPK-, Wnt-, and PI3K-Akt signalling and negative regulation of osteoblast differentiation. We validated differential expression of selected genes from several pathways by qPCR, including: IL1B, p=0.027; CXCL6, p=0.020; ADAMTS4, p=0.002; MMP3, p=0.020; and CHRD2L2, p= 0.039.

To assess if this response is tissue- and/or treatment-specific, we compared changes in gene expression by IL-17Ai in PsA synovium versus psoriatic skin, and in the PsA synovium after IL-17Ai versus IL-12p40/IL-23p40 blockade. While many inflammation-related GO terms and KEGG pathways were over-represented in both tissues and treatments, NF-kB-, JAK-STAT-, and PI3K-Akt-signalling were enriched in DEGs in both skin and synovium after IL-17Ai, whereas JNK cascade, IL-17 signalling pathway and Th17 cell differentiation were over-represented in DEGs after IL-17Ai in the synovium specifically. Remarkably, IL-17Ai, but not IL-12p40/IL-23p40 blockade, modulated multiple bone-remodeling related pathways. Also, IL-17Ai modulated ossification and collagen catabolic process terms in PsA synovium and psoriatic skin in the opposite direction: these terms were over-represented in downregulated genes in synovium, but in upregulated genes in skin. Accordingly, genes upregulated after IL-17Ai were enriched in negative regulation of osteoblast differentiation in the synovium, but in positive regulation of osteoblast differentiation in the skin.

Conclusion: These first in vivo human data provide molecular confirmation of previously reported animal data [3] that demonstrated down-modulation of disease-relevant immune and stromal pathways in the synovium in response to IL-17Ai.

OP0101 MECHANICAL LOAD-INDUCED BHLHE40 PROMOTES INFLAMMATORY ARTHRITIS

E. Gracey1, 2, I. Cambre1, E. Gillis1, F. Stappers1, G. Planckaert1, 3, A. Bozee4, D. Elewaut1, 2, 3
1Ghent University, Department of Internal Medicine and Pediatrics, Ghent, Belgium; 2Vlaams Instituut voor Biotechnologie, Center for Inflammation Research (IRC), Gent, Belgium; 3Ghent University Hospital, Orthopedics, Gent, Belgium; 4University Hospital Erlangen, Department of Medicine, Erlangen, Germany; 2Ghent University Hospital, Rheumatology, Gent, Belgium

Background: Force induced microdamage to joint tissue is hypothesized to trigger inflammatory events in the joint leading to arthritis. Patients with inflammatory arthritis, such as rheumatoid arthritis (RA) and spondyloarthropathies (SpA), are found to have inflammation in “mechanical hotspots” and mechanical loading in mouse models of these diseases is pro-arthritisogenic [1-7]. To date, the molecular mechanism involved in converting force to a biological signal that promotes arthritis is not known.

Objectives: This study aims to identify stretch induced genes in synovial fibroblasts, and the effect of these “mechano-sensitive” genes on arthritis.

Methods: Human synovial fibroblasts were stretched in vitro for 4hrs using the FlexCell system and analysed by microarray. Top stretch induced genes were measured in RA, SpA and healthy synovial tissue by qPCR. Patient synovium was further analysed by immunohistochemistry and collagenease digestion. Bhlhe40 deficient mice were subjected to collagen induced arthritis (CIA) and KBxN serum transfer arthritis (STA). FACS was performed on ankle synovium. uCT was performed on whole ankles, with morphological changes scored by blinded readers, and calcaneus erosions by customs scripts in Fiji.

Results: 600 genes were found to be differentially expressed in stretched synovial fibroblasts (fold change > +/-1.5, adjusted p<0.05). 25% of these genes were found to be transcription factors, which included BHLHE40. BHLHE40 mRNA was elevated in the synovial tissue of RA/SpA vs healthy subjects (1.56 fold change), and BHLHE40 protein was widely detectable in synovial fibroblasts and macrophages (Figure 1). Bhlhe40 deficient mice were completely protected against CIA (incidence: 0% vs 40%, n=30 per group), but Bhlhe40 deficiency was not blocked the generation of anti-collagen antibodies. Bhlhe40 deficient mice were partially protected against STA (peak clinical score at day 7: 5.2 vs 8.8, n=15 per group), with reduced synovial macrophage (CD11b+Ly6G-F4/80+) and neutrophil (CD11b+Ly6G+) frequency observed in the arthritic Bhlhe40 deficient mice compared to wildtype controls. Bhlhe40 had no impact on bone erosions with STA.

Figure 1. Heatmap of differentially expressed genes (DEGs) and pathway enrichment analysis of changes in peripheral SpA synovium 12 weeks after anti-IL-17A treatment (IL-17Ai). A. Hierarchical cluster analysis of the top 100 most significant DEGs (FDR < 0.1) modulated by IL-17Ai separates pre- and post-treated groups. Normalized and scaled log2 gene expression levels are shown. B. Pathway enrichment analysis through DAVID. Enriched (p < 0.05) gene ontology terms from IL-17Ai-induced up- and down-regulated DEGs in peripheral SpA synovium are shown.
Conclusion: BHLHE40 was identified as a force-induced gene in synovial fibroblasts and was found to be upregulated in patients with inflammatory arthritis. Importantly, Bhlhe40 strongly promotes joint inflammation in murine models of arthritis and uncouples systemic autoimmunity from joint tissue inflammation. Thus, we have identified BHLHE40 as a novel regulator of mechanical load-associated inflammation.

**GENE EXPRESSION PATTERNS RETRIEVED FROM SINGLE CELL RNA SEQUENCING REVEAL PHENOTYPIC TRAITS IN PATIENTS WITH PSORIATIC ARTHRITIS INITIATING TUMOUR NECROSIS FACTOR ALPHA INHIBITOR AND INTERLEUKIN-17 INHIBITOR**

M. Skougaard; C. Drachmann; Z. R. Stisen; S. B. Ditte; L. E. Jessen; L. E. Kristensen; Bispebjerg and Frederiksberg Hospital, The Parker Institute, Copenhagen, Denmark; Aarhus University Hospital, Department of Clinical Immunology, Aarhus, Denmark; Bispebjerg and Frederiksberg Hospital, Copenhagen Center for Translational Research, Copenhagen, Denmark; Technical University of Denmark, Department of Health Technology, Section of Bioinformatics, Kgs. Lyngby, Denmark

**Background:** Patients with Psoriatic Arthritis (PsA) suffer from heterogeneous debilitating symptoms caused by immune-mediated inflammation. However, great diversity in clinical response to available medical therapies targeting the immune response in PsA complicates treatment decision-making.

**Objectives:** The primary objective of the study was to evaluate gene expression profiles at baseline in responders versus non-responders of Tumour Necrosis Factor alpha inhibitor (TNFi) and Interleukin-17 inhibitor (IL-17i), respectively, to examine the foundation for future improved PsA patient stratification.

**Methods:** Single cell RNA sequencing (scRNAseq) was included to evaluate the transcriptome in responders versus non-responders of Tumour Necrosis Factor alpha inhibitor (TNFi) and Interleukin-17 inhibitor (IL-17i). Peripheral blood mononuclear cells (PBMCs) was isolated for scRNAseq and Disease Activity Score in PsA (DAPSA) retrieved in 40 PsA patients; 20 initiating TNFi and 20 initiating IL-17i. Responders and non-responders were stratified based on 50% improvement after 4-months (DAPSA50). The BD Rhapsody Whole Transcriptome Approach [1] was applied to prepare cDNA libraries sequenced to a depth of approximately 50,000 reads pr. cells on the Illumina NovaSeq 6000. The Seurat pipeline [2] was implemented for the analysis of gene expression on single cell level.

**Results:** A total of 273,515 cells were retrieved after initial quality control. Comparing patient demographics and characteristics at baseline revealed no difference between groups (Table 1). Dimensionality reduction with principal component analysis and additional clustering analysis indicated different phenotypic traits of responders and non-responders to TNFi and IL-17i (Figure 1).

**Conclusion:** High-dimensional data, retrieved from scRNAseq combined with bioinformatic data modelling and clinical knowledge, is important and should possibly be implemented to explore PsA disease heterogeneity and for better stratification of PsA patients prior to initiating available medical therapies.

**EXPANDED CD8+ T CELL CLONES FROM HLA-B*27+POSITIVE PATIENTS WITH SPONDYLOARTHROPATHIES SHOW SIGNS OF ANTIGEN-EXPERIENCE**

J. Rademacher; K. Deschler; S. Lacher; A. Huth; M. Utz; S. Krebs; H. Blum; E. Beltrán; D. Podubny; K. Dormair; Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Germany Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany; Berlin Institute of Health (BIH), BIH Biomedical Innovation Academy, BIH Charité (Junior) (Digital) Clinician Scientist Program, Berlin, Germany; Ludwig-Maximilians-Universität München, Institute of Clinical Neuroimmunology, Biomedical Center and Hospital of the LMU Munich, Munich, Germany; Gene Center of the LMU Munich, Germany, Laboratory for Functional Genome Analysis (LAFUGA), Berlin, Germany; German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany

**Background:** The pathogenesis of Spondyloarthritides (SpA) remains unknown but its strong association with some alleles of HLA-B*27 is peculiar. The arthritogenic antigen hypothesis assumes the existence of specific peptides presented by risk-conferring HLA-B*27 alleles to antigen-specific CD8+ T cells, which then initiate or sustain autoimmune reactions. Several studies analyzing T cell receptor (TCR) repertoire found preferred TCR chains and motifs in the hypertvariable complementary determining region (CDR) 3, but analyzed only TCR β-chains in bulk analyses<sup>1,2</sup>

**Objectives:** To analyze full sequence information of TCR including matching α- and β-chains from single CD8+ T cells and characterize the transcriptions of expanded and non-expanded clonotypes in synovial fluid (SF) of SpA patients.

**Methods:** We included 17 patients with active spondarthritis: 10 patients with HLA-B*27 positive (B27pos) SpA, 4 with HLA-B*27 negative (B27neg) SpA and 3 rheumatoid arthritis (RA) patients. Antigen-experienced CD8+ T cells were sorted out of SF by flow cytometry. Single cell sequencing was performed for all patients to
analyze matching TCR α- and β-chains. For 7 patients (3 B27pos SpA, 2 B27neg SpA, 2 RA), additionally whole transcriptome analyses were performed.

Results: We found strong biases when analyzing α- and β-chains of TCR Variable regions and CDR1 and CDR2 sequences (Figure 1 a,b): AV21, AV12-2, and AV17 were highly enriched in B27pos SpA as compared to B27neg subjects. Amongst the highest expressed clones, we could confirm enrichment for previously described TRBV genes as BV19, BV5-1 and BV6-2. We examined TCR αβ combinations and focused on those detected in at least three different B27pos SpA but not in any of the B27neg patients (Figure 1 c-f). The combinations TRBV19/TRAV21 and TRBV6-2/TRAV21 were most likely specific for B27pos SpA but not in any of the B27neg patients (Figure 1 c-f). The combinations and focused on those detected in at least three different B27pos SpA but not in any of the B27neg patients (Figure 1 c-f). The combinations TRBV19/TRAV21 and TRBV6-2/TRAV21 were most likely specific for B27pos SpA but not in any of the B27neg patients (Figure 1 c-f).

Sequences of CDR3 loops, which predominantly interact with HLA-bound antigenic peptides, revealed striking common structural motifs in α- and β-chains. Focusing on the most prominent TRAV21 chains pairing with TRBV19, 5-1 and 6-2 chains, revealed identical sequences in different patients and striking common structural motifs in α- and β-CDR3 sequences in other patients. Such marked similarities in the antigen-recognition loops of the β-chains associated with TRAV21 suggest common or highly similar antigens.

Gene expression levels provided evidence that expanded cell populations had tissue resident memory (TRM) phenotypes (elevated expression of activation, migration and tissue retention markers, downregulated genes characteristic for T cell egress), while this phenotype was not very pronounced in non-expanded cells. Furthermore, markers for T cell exhaustion and apoptosis were elevated in expanded cells of B27pos SpA patients.

Conclusion: Analysis of single antigen experienced CD8+ T cells from SF of B27pos SpA patients revealed significant clonal expansions and common motifs in the CDR loops. Two of the four CDR1 and CDR2 loops were highly homologous suggesting that these loops interact with α-helices of HLA-B*27. Common motifs in CDR3 loops of expanded clonotypes suggest recognition of a limited set of antigenic peptides presented by HLA-B*27. Many of the expanded clonotypes showed a TRM phenotype, were exhausted and on the way to become apoptotic, which suggests that these clones had sustained contact to specific antigens.

Figure 1. Distinct TCRαV chain usage in expanded clones from HLA-B27 positive SpA patients. A,B Mean number of all productive TRAV (A) and TRBV (B) genes used in expanded, antigen-experienced CD8+ T cell clones (>1% of all cells) from SF of 10 B27pos, 4 B27neg SpA and 3 B27neg RA patients. C-F TRAV chains paired with TRBV19 (C), TRBV5-1 (D), TRBV6-2 (E), or TRBV chains paired with TRAV21 (F) with corresponding TRAV sequences grouped into expanded clones (frequency ≥2) from all 10 B27pos SpA. Number of chains are 1250 (C), 868 (D), 1220 (E), and 4006 (F).
SOLUBLE PD-1 PROMOTES LOCAL IL-17A PRODUCTION IN THE INFILTRATING MICROENVIRONMENT IN SPA

E. Rasmussen1, R. Østgaard2, M. Hvild3, U. Syrbe1, D. Poddubnyy5, B. Deleuran1, A. Aarhus University, Department of Biomedicine, Aarhus University, Department of Rheumatology, Department of Rheumatology, Aarhus, Denmark; 2Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Department of Rheumatology, Berlin, Germany; 3Skjæbye Sygehus, Department of Rheumatology, Aarhus, Denmark

Background: Programmed death 1 (PD-1) is an immune checkpoint receptor expressed by activated T-cells. Activation of the PD-1 pathway reduces T cell activation and inflammation. Targeting PD-1 in cancer can result in autoimmune disease, which highlights the importance of this pathway in balancing inflammation. Both PD-1 and its ligands are present in soluble (s) forms, and we have previously shown that sPD-1 is associated to bone erosions in rheumatoid arthritis. Spondyloarthritis (SpA) is characterized by both bone erosions and bone formation. Current evidence suggests an important interaction between the PD-1 pathway and the proinflammatory cytokine IL-17A. IL-17A is central in promoting inflammation in SpA and direct osteoclast activation leading to bone erosion. We have previously demonstrated that the PD-1 ligand, PD-L2, reduces osteoclast formation under inflammatory conditions.

Objectives: We aimed at investigating the interplay between the PD-1 pathway and IL-17A in relation to inflammation and bone homeostasis in patients with SpA.

Methods: From early SpA patients, plasma was collected at baseline and after 1 year of treatment with Adalimumab. From chronic SpA patients, plasma, synovial fluid (SF), peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) were collected. Plasma and PBMCs were also collected from healthy controls (HC) for comparison. Disease activity was measured by ASDAS and progression by inflammation and new bone formation in the total spine.

Facet joint biopsies were collected from SpA patients during surgery for correction of rigid hyperkyphosis. Levels of sPD-1 and sPD-L2 were measured in plasma and SF. Surface expression of PD-1 and CCR6 was evaluated on PBMCs and SFMCs. Levels of IL-17A were measured in the supernatant from stimulated PBMC cultures with recombinant human (rh)PD-1. Facet joint biopsies were stained for the presence of PD-1, PD-L1, PD-L2 and CCR6.

Results: Plasma levels of sPD-1 and sPD-L2 were equally increased in both early and chronic SpA compared to HC. Plasma levels of sPD-1 and sPD-L2 did not change following one year of treatment. In chronic SpA patients, sPD-1 levels were higher in SF than in plasma. Levels of sPD-1 and sPD-L2 in plasma and SF did not correlate with any disease activity scores or progression. Expression of PD-1 on the cell surface of PBMCs from SpA patient was comparable to healthy controls. On SFMCs, PD-1 expression was increased, supporting continuous T-cell activation in the local microenvironment. After stimulation with anti CD3/CD28, SpA PBMCs produced more IL-17A when cultured with rhPD-1 compared to healthy control PBMCs.

Conclusion: Plasma levels of the PD-1 family is unaffected by addition of anti-TNFα antibody treatment in SpA. The early SpA cohort had a low degree of proliferation in structural changes in the observation period, which could explain the lack correlation with sPD-1 and sPD-L2 and disease progression. Soluble PD-1 is high in the inflamed microenvironment, where it may result in increased IL-17A production. Collectively, these data suggest that the PD-1 pathway could play a role in the pathogenesis of SpA, acting in the inflamed microenvironment.

NEW INSIGHTS IN THE GENOMIC “GRAMMAR” OF RHEUMATOID ARTHRITIS

I. Papageorgiou1, M. Zervou2, G. Zisios2, D. Vlachakis3, G. Bertias3, G. Goulielmis4, E. Eliopoulos5, 1Agricultural University of Athens, Department of Biotechnology, Athens, Greece; 2University of Crete, School of Medicine, Heraklion, Greece

Background: Rheumatoid arthritis (RA) is a complex disease, caused by a combination of genetic, epigenetic and environmental factors common to other related autoimmune diseases including Multiple Sclerosis (MS) and Systemic Lupus Erythematosus (SLE) [1]. Using state of the art Bioinformatics tools we are able to formulate an ensemble (an ensemble of associated components or “ensemble grammar”) for each disease and distinguish important differences and common aspects in a specific group of disease such as ensembles of autoimmune diseases [2].

Objectives: To create, collect and evaluate the most credible and unique gene variants, epigenetic variants and single nucleotide polymorphisms (SNPs) causing the basis of an immune disease (the genomic grammar of the disease), which could potentially assist in the process of the RA disease prevention, diagnosis and treatment [3].

Methods: RA related publications from the PubMed have been analyzed using data mining and semantic techniques towards extracting the candidate causative SNPs. The extracted knowledge has been filtered, evaluated, annotated, and classified in a structured database which also includes GWAS information regarding SNPs. Additional clinical, genomic, structural, functional and biological information was also extracted from biological databases including dbSNP, LitVar, ClinVar and OMIM and cross-correlated with other available autoimmune disease related SNP databases, including the Demetra application, Epione application and Panacea application databases [3, 4].

From gene to function: genetic basis of rheumatic diseases
Results: A holistic genetic map of the studied autoimmune diseases with more than 2000 related SNPs has been estimated and specific sub-clusters with crucial nodes have been identified across the RA, SLE and MS diseases. Based on these results, the three studied autoimmune diseases share a 10% common SNPs genetic background (Figure 1 and Table 1) [5]. The optimal genomic grammar of the RA contains 1682 SNPs, with 73% responding to non-coding regions and 27% responding to coding regions of more than 1,300 genes, pseudogenes, primers and promoters. RA also shares 464 common SNPs with SLE and 113 with MS.

Table 1. Common Related Genes based on the analyzed SNP targets in the studied disease.

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with unknown etiology involving multiple immune cells and has diverse clinical phenotypes. This heterogeneous nature has hampered a better understanding of SLE pathogenesis and the development of effective therapeutic agents. While recent single-cell RNA sequencing studies of SLE identified several important cell subpopulations, they were limited by sparse expression information at single-cell level and small sample sizes.

Objectives: This study aimed to elucidate the dysregulated gene expression pattern linked to multiple clinical statuses of SLE with a fine cellular resolution and higher sensitivity. We also attempted to resolve a complex interaction between risk variants and the transcriptome dysregulation seen in SLE patients.

Methods: We conducted a large-scale bulk transcriptome study of 6,386 RNA-sequencing data including 27 puriﬁed immune cell types in peripheral blood from 136 SLE and 89 healthy donors in the Immune Cell Gene Expression Atlas from the University of Tokyo (ImmuneXUT) cohort. At enrolment, SLE patients have diverse clinical manifestations (diseases unique to organ involvement and treatment proﬁles) and 22 patients were re-evaluated after belimumab treatment.

Results: We ﬁrst proﬁled two distinct cell-type-specific transcriptomic signatures: disease-state and disease-activity signatures, reﬂecting disease establishment and exacerbation, respectively.

Moreover, we demonstrated cell-type-speciﬁc contributions to diverse organ involvement, e.g., Th1 for mucocutaneous, monocyte-lineage cells for muscle-skeletal, neutrophil-lineage cells for renal activity, respectively.

We also observed the strong associations of disease-activity signatures with treatment effect: (i) belimumab suppressed activity signatures from B-lineage cells, especially in good responders and (ii) mycophenolate mofetil substantially suppressed activity signatures from plasmablast, Th1, and central memory CD8 cells.

However, through stratified LD score regression using large-scale SLE GWASs, we revealed that disease-activity signatures were less enriched around SLE risk variants than disease-state signatures. Consistent with this result, the directions of SLE risk alleles’ expression quantitative trait locus (eQTL) effects were significantly concordant with the directions of disease-state signatures, but not with those of activity signatures. These ﬁndings suggested that the current genetic case-control studies may not well capture clinically vital biology linked to drug target discovery for SLE. Meanwhile, we also detected some examples of activity signatures that might contribute to the disease risk by modulating risk allele’s eQTL effects.

Disclosure of Interests: None declared

Figure 1. Identification of eQTL effects. This figure shows the eQTL effects identified by the eQTL analysis. The x-axis represents the log2 of the odds ratio (OR), and the y-axis represents the expression level of the gene. The color of the points indicates the direction of the eQTL effect, with red indicating upregulation and blue indicating downregulation. The size of the points is proportional to the significance of the eQTL effect. The eQTLs identified by the analysis are shown in red, and the eQTLs identified by the literature are shown in blue. The eQTLs identified by the analysis are significantly different from those identified by the literature, indicating the potential for novel gene identification.
Background: Sjogren's disease (SjD) is an autoimmune disease characterized by reduced function of exocrine glands (i.e., salivary and lacrimal glands). Epithelial cell damage resulting from lymphocytic infiltration has been implicated in SjD etiology [1]. How genetic and epigenetic changes influence epithelial-immune cell interactions in SjD pathogenesis remain understudied.

Objectives: Evaluate the role of SjD risk loci in salivary gland tissue to gain insights into the potential genes involved in salivary gland dysfunction.

Methods: SNPs from 16 regions with SNP-SjD associations (P<5x10^-8) in our GWAS study (3232 SjD cases and 3566 controls) were interrogated for eQTLs using genotype-Tissue Expression (GTEX) minor salivary gland data. Subsequent analysis identified genes that were both eQTLs in minor salivary gland and significantly expressed in RNA-seq and ATAC-seq data from the submaxillary salivary gland epithelial cell line, A253. Pathway enrichment analysis was performed using gProfiler on the genes where coexpression of eQTL, RNA-seq, and ATAC-seq data was observed. To further validate the results, we performed transcriptome-wide association study (TWAS) analysis using GWAS summary statistics and minor salivary gland eQTL data.

Results: In total, 5884 genome-wide significant SNPs from 16 SjD risk loci were identified as potential minor salivary gland eQTLs using two discovery thresholds: p(FDR)<0.05 provided by eQTL study (3566 SNPs) and p(FDR)<0.05 and p<0.05 in eQTL study (2318 SNPs). Further analysis revealed 10 SjD risk loci with SNPs that were minor salivary gland eQTLs for a total of 155 unique genes that had a coalescence of RNA- and ATAC-seq data in A253 cells. Many SNPs altered the expression of the nearest gene to the risk allele (i.e., index gene), such as IRFS and TNPO3 on chromosome 7 at 128Mb; however, this locus had 12 additional genes that were eQTLs in minor salivary gland. In contrast, other loci had no reported eQTLs for the index gene, but several reported eQTLs for other genes, such as TYK2 on chromosome 19 at 10Mb that showed no change in TYK2 expression but eQTLs for 8 distant genes, including ICAM1. Pathway enrichment analysis revealed an enrichment in Butyrophilin (BTN) family interactions (R-HSA-8851 (Padj=1.56E+10-5), including the BTN2A1, BTN2A2, BTN3A1, BTN3A2 and BTN3A3 gene cluster in the MHC region. In further support, TWAS of the minor salivary gland and the SjD GWAS summary statistics (after Bonferroni correction) showed association between SjD and TWAS (p=1.24x10^-42), as well as many other loci in the MHC region. In addition, several loci including index genes on chromosome 17 were significant, peaking at RP11-259G18.1 (p=4.43x10^-10).

Conclusion: This study shows that SjD-associated risk alleles influence disease by altering gene expression in immune cells and minor salivary glands. Further, our analysis suggests that altered gene expression in the minor salivary gland extends beyond the identified minor salivary gland index genes and their neighboring regions. Interestingly, we observed minor salivary gland eQTLs for several BTN family genes, which act as cell-surface binding partners to regulate cell-cell interactions, including interactions between epithelial cells and activated T cells [3]. Future work will assess chromatin-chromatin-interactions within the 10 SjD risk loci in salivary gland cells and tissues to map local chromatin regulatory networks that regulate gene expression. Additional transcriptome-wide studies of SjD minor salivary gland tissues will provide further insights into how altered gene expression in the salivary gland influences SjD pathology.

rs6697139, located within trans-population meta-analysis, respectively. One of Japanese novel risk SNPs, (4)
33University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, School of Medicine, Kitakyushu, Japan; 34Torii Clinic; NA, Maizuru, Japan; 35Jluknai Takeada General Hospital, NA, Kyoto, Japan; 36Graduate School of Medicine, Kyoto University, Center for Genomic Medicine, Kyoto, Japan; 37Institute of Medical Science, The University of Tokyo, Laboratory for Gene Technology, Human Genome Center, Tokyo, Japan; 38Graduate School of Frontier Sciences, The Research Center for Molecular Science, University of Shizuoka, The Department of Applied Genetics, Shizuoka, Japan
Background: Genome-wide association studies (GWASs) have identified 29 disease-associated single nucleotide polymorphisms (SNPs) for systemic sclerosis (SSc) in non-human leukocyte antigen (HLA) regions (1-7). While these GWASs have clarified genetic architectures of SSc, study subjects were mainly Caucasians limiting application of the findings to Asians.
Objectives: The study was conducted to identify novel causal variants for SSc specific to Japanese subjects as well as those shared with European population. We also aimed to clarify mechanistic effects of the variants on pathogenesis of SSc.
Methods: A total of 114,108 subjects comprising 1,499 cases and 112,609 controls were enrolled in the two-stage study leading to the ever-largest Asian GWAS for SSc. After applying a strict quality control both for genotype and single nucleotide polymorphisms (SNPs), imputation was conducted using the reference panel of the phase 3v5 1,000 genome project data combined with a high-depth whole-genome sequence data of 3,256 Japanese subjects. We conducted logistic regression analyses and also combined the Japanese GWAS results with those of Europeans (6) by an inverse-variance fixed-effect model. Polygenicity and enrichment of functional annotations were evaluated by linkage disequilibrium score regression (LDSC), Haplotype and IMPACT programs. We also constructed polygenic risk score (PRS) to predict SSc development.
Results: We identified three (FCRLA-FCGR, TNFAIP3, PLD4) and four (EOMES, ESR1, SLC12A5, TP1P2) novel loci in Japanese GWAS and a trans-population meta-analysis, respectively. One of Japanese novel risk SNPs, rs6697139, located within FCGR gene clusters had a strong effect size (OR 2.05, P=4.9x10^{-11}). We also found the complete LD variant, rs10917688, was positioned in cis-regulatory element and binding motif for an immunomodulatory transcription factor IRF8 in B cells, another genome-wide significant locus in our trans-ethnic meta-analysis and the previous European GWAS. Notably, the association of risk allele of rs10917688 was significant only in the presence of the risk allele of the IRF8. Intriguingly, rs10917688 was annotated as one enhancer-related histone marks, H3K4me1, in B cells, implying that FCGR gene(s) in B cells may play an important role in the pathogenesis of SSc. Furthermore, significant heritability enrichment of active histone marks and a transcription factor C-Myc were found in B cells both in European and Japanese populations by LDSC and IMPACT, highlighting a possibility of a shared disease mechanism where abnormal B-cell activation may be one of the key drivers for the disease development. Finally, PRS using effects sizes of European GWAS moderately fit in the development of Japanese SSc (AUC 0.520), paving a path to personalized medicine for SSc.
Conclusion: Our study identified seven novel susceptibility loci in SSc. Downstream analyses highlighted a novel disease mechanism of SSc where an interactive role of FCGR gene(s) and IRF8 may accelerate the disease development and B cells may play a key role on the pathogenesis of SSc.

FUNCTIONAL GENOMICS IN PRIMARY T CELLS AND MONOCYTES IDENTIFIES MECHANISMS BY WHICH GENETIC SUSCEPTIBILITY LOCI INFLUENCE SYSTEMIC SCLEROSIS RISK

D. Gonzalez Serna 1, C. Shi2, M. Kerick 1, J. Hankinson 2, J. Ding 3, A. McGovern 4, M. Tulino 5, N. Ortego 6, J. L. Callejas-Rubio 7, J. Martin Ibanez 2, G. Orozo 2, 3, Institute of Parasitology and Biomedicine Lopez-Neyra, Consejo Superior de Investigaciones Cientificas (IPBLN-CSIC), Granada, Spain; 4The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; 5The University of Manchester, Division of Infection, Immunity & Respiratory Medicine, Manchester, United Kingdom; 6Institute for Biosanitary Research of Granada, Department of Internal Medicine, Hospital Universitario San Cecilio, Granada, Spain; 7Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom

Background: Systemic sclerosis (SSc) is a complex autoimmune disease with a strong genetic component. However, the underlying mechanism by which genetics increase disease risk is still unknown. The most recent GWAS studies have identified 27 independent signals associated to SSc [1]. However, the majority of these signals affect regulatory elements that can regulate genes often located hundreds of kilobases away.

The challenge in the post-GWAS era is to use functional genomics to translate genetic findings into patients' benefit, particularly in disease-relevant cell types.

Objectives: In this study we use chromatin conformation and gene expression analysis in patient derived primary cells and healthy individuals to assess potential mechanisms by which GWAS variants increase disease risk. We identify the potentially affected genes in a cell type specific manner and potential drug targets already in use or with potential for re-purposing.

Methods: Promoter capture Hi-C (pHi-C) and RNA sequencing experiments were performed in a total of 15 CD4+ T cells and CD14+ monocytes samples each isolated from peripheral blood from SSc patients and healthy controls. We linked SSc-associated variants with their target genes and performed differential expression and differential interaction analyses between both cell types. Potential drug targets were identified using a protein-protein interaction model and queried against the OpenTargets database.

Results: We linked SSc-associated loci to 39 new potential target genes, confirming 7 previously assigned genes. We highlight novel causal genes, such as CXCR5 as the most probable candidate gene for the DDX6 locus (Figure 1). We confirm some previously linked SSc genes such as IRF8, STAT4, or CD247 which interestingly showed cell type specific interactions. We also identified 15 potential drug targets already in use in other similar immune-mediated diseases that could be repurposed for SSc treatment. Furthermore, we observed that interactions are directly related with the expression of important genes implicated in cell type specific pathways.

Figure 1. Promoter Capture Hi-C interactions linking the DDX6 GWAS loci with the promoter of CXCR5 in CD4+ T cells and CD14+ monocytes. CD4+ T cells show significantly stronger interactions as well as CXCR5 gene expression.
Conclusion: Our study reveals potential causal genes for SSC-associated loci, some of them acting in a cell type specific manner, suggesting novel drug targets and biological mechanisms that may mediate SSC pathogenesis.

OP0114 IDENTIFICATION AND FUNCTIONAL PREDICTION OF LONG NONCODING RNA RELATED TO CONNECTIVE TISSUE DISEASE-ASSOCIATED INTERSTITIAL LUNG DISEASES

F. Dai1, Q. B. Zhang3, Y. X. He1, Y. P. Tang1, T. Y. Lei1, Y. Jiang1, Y. F. Qiao1. 1Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Nanchong, China; 2Institute of Rheumatology and Immunology, Research Center of Hyperuricemia and Gout, Department of Geriatrics, the Affiliated Hospital of North Sichuan Medical College, Nanchong, China

Background: Recently, the role of long noncoding RNA (IncRNA) in rheumatic immune diseases has attracted widespread attention1. However, knowledge of IncRNA in connective tissue disease-associated interstitial lung disease (CTD-ILD) is limited.

Objectives: To explore the expression profile of IncRNA in peripheral blood mononuclear cells (PBMCs) of CTD-ILD patients and the possible mechanisms of significantly differentially expressed IncRNA involved in CTD-ILD, especially systemic sclerosis (SSc)-ILD and rheumatoid arthritis (RA)-ILD.

Methods: LncRNA microarray analysis was used to identify the pattern of IncRNA dysregulation between CTD-ILD and connective tissue disease without associated interstitial lung disease (CTD-NILD). Differential genes were identified by bioinformatic analysis. Relative expression levels of five differentially expressed IncRNAs in 120 SSc and RA patients with or without ILD were detected by quantitative reverse-transcription PCR (qRT-PCR).

Results: The differential gene expression analysis revealed 46 IncRNAs were upregulated while 194 IncRNAs were downregulated in the CTD-ILD group compared to the CTD-NILD group (Figure 1). Gene Ontology and Kyoto Encyclopedia of Genes and Genomes pathway analyses identified several significant biological processes and signaling pathways, including NF-kappa B signaling pathway, IL-17 signaling pathway, Toll-like receptor signaling pathway, B cell receptor signaling pathway. qRT-PCR confirmed that the selected target genes were differentially expressed in different groups. In particular, the ENST00000604692 expression level was significantly higher in the ILD than the NILD group (p<0.05, Figure 1); T311354 and arginase-1 were significantly higher in SSc than RA group; Furthermore, the area under receiver operating characteristic curve for ENST00000604692 in predicting ILD from NILD was 0.797 (Figure 1).

Conclusion: This research has demonstrated, for the first time, the specific profile of IncRNA in PBMCs of CTD-ILD patients and the potential signal pathways related to the pathogenesis of CTD-ILD. ENST00000604692 can effectively distinguish ILD group from NILD group, which may be a diagnostic indicator of CTD-ILD, especially SSc-ILD and RA-ILD.

Background: The development of a tool capable of identifying patients suffering the rapid progressive knee Osteoarthritis (RPOA) was established as a goal to implement prevention strategies and to include them in clinical trials. Previous studies showed that mitochondrial DNA (mtDNA) variation plays a role in the incidence and progression of OA, but their influence on the development of RPOA is unknown.

Objectives: To find out new mtDNA variants related to RPOA in order to develop a predictive model based on genetic and clinical variables.

Methods: We used data from three independent prospective cohorts of patients: the Osteoarthritis Initiative (OAI) (N=1102) and the pooling of two European cohorts as replication cohort (N=706): the Cohort Hip and Cohort Knee (CHECK) and the Prospective Cohort of Osteoarthritis from A Coruña (PROCOAC). We classified the patients based on the following criteria:
- Rapid progressors (N Discovery=268, N Replication=107), subjects with baseline KL grade 0-1 and increase up to KL2/3 during 48-month follow-up; or baseline KL grade 2 and increase up to KL grade 4 during the follow-up.
- Non-rapid progressors (N Discovery=827, N Replication=992), subjects with the same baseline characteristics as rapid progressors, but with a slower or no evolution over time.

mtDNA variants were screened in the OAI by in-depth sequencing. Resulting variant was analyzed in the replication cohort by mini-sequencing techniques. Appropriate statistical approaches adjusting for confounding variables followed by a meta-analysis were applied.

Disclosure of Interests: None declared

We developed a functional study using two types of mitochondrial cybrids carrying the most common haplogroup H: one harboring the mtDNA variant m.16519C and the other the wild type m.16519T. Cybrids were used to assess mitochondrial biosynthesis and mitochondrial fitness/fusion by gene expression analyses, as well as cell viability under oxidative stress and mitochondrial reactive oxygen species (ROS) production.

Results: The in-depth sequencing of mtDNA showed the D-loop variant m.16519C significantly overrepresented in rapid-progressors [OR=1.506; 95% CI=0.848-2.675; p=0.162]. The analysis of this variant in the replication cohort showed a similar significant trend (OR=1.647; 95% CI=1.013-2.678; p=0.043). The logistic regression model revealed that, regardless of the different clinical variables, the variant m.16519C was significantly associated with RPOA in the OAI cohort (OR=1.559; 95% CI=1.125-2.161; p=0.008) (Table 1). The development of this model in the replication cohort showed a similar trend that bordered the statistical significance (OR=1.506; 95% CI=0.848-2.675; p=0.162) (Table 1). The subsequent meta-analysis for both ORs showed the variant m.16519C significantly associated with RPOA (OR=1.58; 95% CI=1.22-2.05; p<0.0027) (Figure 1).

Table 1. Binary regression model including clinical variables and m.16519C in both cohorts.

Figure 1. Forest plot of the meta-analysis of the ORs of the two predictive models

Cybrids harboring the mtDNA variant m.16519C showed lower levels of PGC-1α (p=0.0024) and FIS1 (p=0.0519) than cybrids with the wild type. Cybrids harboring the variant m.16519C showed lower average cell survival under oxidative stress conditions (23.42±8.88 vs 115.7±64.1; p=0.0043), as well as higher mitochondrial ROS production.

Conclusion: D-loop variant m.16519C increases the risk of developing a rapid progression of knee OA. Among the effects caused by this variant both mitochondrial biogenesis and fission/fusion processes, as well as cell survival under oxidative stress conditions and mitochondrial ROS production seem to be affected.

HPR: From prevention to management

OP0016-HPR PATIENTS’ EXPERIENCES OF GROUP-BASED COGNITIVE BEHAVIOURAL THERAPY FOR INSOMNIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: A QUALITATIVE STUDY

K. M. Latocha 1, K. Leppen 1,2, J. Jennum 3,4, M. Østergaard 1,2, R. Christensen 1,2, B. A. Esbensen 1,4, 1Copenhagen University Hospital - Rigshospitalet, Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Glostrup, Denmark; 2Copenhagen University Hospital - Rigshospitalet, Copenhagen Center for Cancer and Organ diseases, Department of Oncology, Copenhagen, Denmark; 3University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; 4Copenhagen University Hospital - Rigshospitalet, Danish Center for Sleep Medicine, Department of Clinical Neurophysiology, Glostrup, Denmark; 5Copenhagen University Hospital - Rigshospitalet, Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Glostrup, Denmark; 6Copenhagen University Hospital - Bispebjerg and Frederiksberg, Section for Biostatistics and Evidence-Based Research, the Parker Institute, Copenhagen, Denmark; 7University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense, Denmark

Background: Despite disease-modifying anti-rheumatic drugs, residual arthritic-related symptoms and burdens are still common in patients with rheumatoid arthritis (RA)1. In addition, insomnia – characterised by reduced sleep quantity and quality – is highly prevalent, occurring in up to 70% of patients with RA2. Insomnia is associated with increased pain, fatigue, and depressive symptoms. Cognitive behavioural therapy for insomnia (CBT-I) is recommended first-line treatment for chronic insomnia3 but has not been evaluated in patients with RA until now.

Objectives: The objective of this study was to explore patients’ experiences of CBT-I and how the components of CBT-I are incorporated in their sleep management.

Methods: Participants were patients with RA who had received CBT-I as experimental treatment for insomnia in a randomised controlled trial (RCT)4. Data were collected during an individual face-to-face interview using a semi-structured interview guide. The analysis was based on reflexive thematic method by Braun and Clarke5.

Results: Eleven participants (10 women and one man) from the intervention group of the RCT were interviewed. Prior to inclusion in the RCT, they had insomnia complaints for 8 years (median; interquartile range: 3/20 years).

Five themes emerged: 1) When knowledge contributes to an altered perception of sleep referring to the reduced misperception and increased motivation that followed sleep education, 2) Overcoming habits and perceptions to accelerate sleep onset referring to barriers related to sleep behaviour and mindset and how stimulus control was enabling them to find meaningful behaviour and rhythm, 3) The sleep window of challenges in learning how to sleep right referring to that payoff from sleep restriction did not come easily or by magic, and commitment led to progress and gave them confidence to continue, 4) Relaxation becomes a behavioural habit and goes beyond sleep referring to a means to achieve a relaxed body and mind and how they thereby copped better with RA-related symptoms, and 5) Break the cycle and regain control referring to how awareness of a vicious cycle was central to their perception of sleep and how trust in one’s own accomplishment was crucial to reducing worrying (See Figure 1).

Disclosure of Interests: None declared

[3] PMID: 28875581

Figure 1. The five themes with quotes from participants

Overall, the participants experienced CBT-I as challenging and demanding but at the same time meaningful. The participants considered persistency, stringency, and inflexibility necessary to succeed. After the intervention, the participants had continued using those components that enabled them individually to further improve their sleep.

Conclusion: The process towards eliminating insomnia was a bodily experience and involved a changed mindset that altered behaviour and cognitions.
OCT0118-HPR FROM CURING TO COPING: EXPLORING TASK-SHIFTING BETWEEN NORWEGIAN RHEUMATOLOGISTS AND OCCUPATIONAL THERAPISTS IN THE CARE OF HAND OSTEARTHRITIS

S. Zink1, I. Kjeken1, M. Feiring1,2, Diakonhjemmet Hospital, Norwegian National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; 2Oslo Metropolitan University, Department of Physiotherapy, Oslo, Norway

Background: Task-shifting between physicians and other health professionals is increasingly used as a strategy to optimise health care services. However, there is a lack of evidence regarding task-shifting within the field of rheumatology, specifically hand osteoarthritis (HOA). HOA is a highly prevalent rheumatic joint disease, and the number of people living with debilitating HOA will continue to rise in the coming decades. HOA is diagnosed based on clinical examination and the first choice of treatment is non-pharmacological. Despite this, patients with HOA are increasingly referred to rheumatologists (RTs) in specialist care, contributing to long wait times and bottlenecks within the health care service. A possible solution to this challenge is task-shifting to occupational therapists (OTs).

Objectives: To explore the process of task-shifting in the care of patients with HOA between RTs and OTs in a Norwegian health care context.

Methods: This is a multi-centre qualitative study. Individual semi-structured interviews were conducted in-person or digitally with RTs and OTs between December 2020–June 2021. They were audio-recorded and transcribed verbatim. Reflexive Thematic Analysis was employed to analyse the data, and carried out in NVivo.

Results: In total, 17 participants were interviewed: 9 RTs and 8 OTs. Majority of respondents were female (n = 14), had an average of 20.5 years of experience and were 48.5 years old. Interviews lasted on average 90 minutes, (range: 45–120 minutes). The analysis resulted in 5 main themes

1) Attitudes towards task-shifting of HOA care: Both RTs and OTs were overwhelmingly positive about task-shifting and reported OTs to be better suited for caring for patients with HOA than RTs. There was agreement amongst RTs that generally, they had little to offer HOA patients besides information.

2) Desirability of caring for HOA: RTs felt no occupational “ownership” of the HOA diagnosis due to the lack of curative medical treatment, and would prefer HOA patients to be seen by an OT. OTs on the other hand perceived themselves as a profession with tools, skills and competencies that would benefit patients with HOA.3) Practical and theoretical knowledge: OTs and RTs viewed different kinds of knowledge as central for task-shifting. Respondents emphasised that OTs must have good anatomical knowledge of the hand and confidence in identifying differential diagnoses that could potentially be more serious. Lack of knowledge lead to insecurity and hampered successful implementation of task-shifting.

4) Communication between RTs and OTs: RTs perceived OTs to be passive in communicating their willingness and competence in caring for this patient group. They expressed a wish for more “self-promotion” from OTs. OTs and RTs viewed communication between them as essential for task shifting. Good communication, understanding and inquisitive conversations acted as facilitators.

5) The importance of informal interpersonal relationships in the workplace: Informal interpersonal relationships facilitated trust and subsequent task-shifting between RTs and OTs. Personal relations directly affected engagement in the task-shifting process.

Conclusion: The findings show a unanimous wish for HOA care to be shifted from RTs to OTs. Attitudes towards HOA as a diagnosis, interpersonal relationships between RTs and OTs, and knowledge are key facilitators and barriers affecting this process. The findings contribute to the growing body of knowledge on strategies used to optimise health care services and can be used in the design and implementation of new care pathways for patients with HOA.

OCT0118-HPR GAMING FOR ADHERENCE TO MEDICATION USING E-HEALTH IN RHEUMATOID ARTHRITIS (GAMER) STUDY – A RANDOMISED CLINICAL TRIAL

B. Pouls1,2, C. Bekker2, J. E. Vriezekolk1, S. van Dulmen3,2, B. van den Beemt1,2, 1Sint Maartenskliniek, Department of Rheumatology Research, Nijmegen, Netherlands; 2RadboudUMC, Radboud Institute for Health Sciences, Nijmegen, Netherlands; 3Netherlands Institute for Health Services Research, Healthcare Communication, Utrecht, Netherlands

Background: Effectiveness of pharmacological therapy in rheumatoid arthritis (RA) is limited by inadequate medication adherence. Medication adherence can be influenced by implicit attitudes of personal medication needs and concerns about adverse consequences. We targeted these implicit attitudes using a serious puzzle game. Objectives: To assess the effectiveness of a serious game compared to usual care to improve adherence to disease modifying anti-rheumatic drugs (DMARDs) in patients with rheumatoid arthritis (RA).

Methods: A multicentre randomised clinical trial was performed with a 3 month follow-up period.[1] Inclusion criteria were adulthood, RA diagnosis, use of DMARDs and possession of a smartphone/tablet. All participants received usual care. In addition, intervention participants were invited to play the serious puzzle game at will. The game was designed to influence players’ attitudes toward medication.[2] Collected data consisted of serious game play data, Compliance Questionnaire in Rheumatology (CQR), Beliefs about Medication Questionnaire (BMQ), Health Assessment Questionnaire (HAQ) and Rheumatoid Arthritis Disease Activity Index (RADAI).

Primary outcome was DMARD implementation adherence at three months assessed as the difference in proportion of non-adherent patients (<80% taking adherence) between intervention and control group using the discriminant function of the CQR using the Chi-squared test. Two sample t-tests and Wilcoxon rank-sum test were performed to test for differences on secondary outcomes between study groups where appropriate.

Results: 229 participants were randomised and 186 participants completed the study. Of the 85 intervention participants, 70 (82%) played the serious game for at least one hour. The serious game was played a median of 36 sessions with an average playtime of 25 minutes leading to a median overall playtime of 9.7 hours. A total of 59 (69%) intervention participants showed at least 40 days of gaming activity. Control group adherence (54%) and intervention group adherence (63%) based on the dichotomised CQR-score did not differ at three months (p = 0.26) (see Table 1). Neither was there a significant difference in CQR continuous score (p = 0.20), beliefs about medication differential score (p = 0.43) or clinical outcomes (HAQ: p = 0.97; RADAI: p = 0.90) (see Table 1).

Abbreviations: no. – number; SD – standard deviation; CQR – Compliance Questionnaire on Rheumatology; BMQ – Beliefs about Medication questionnaire; IQR – interquartile range* Percentages of the total number of participants excluding missing data.
Conclusion: This multicentre randomised clinical trial showed that a serious puzzle game aimed at reinforcing a positive attitude towards DMARDs was frequently played during three months. Playing the game did not improve medication adherence nor influenced beliefs about medication or clinical outcomes in RA patients.

Objective: To explore differences between patients with a low to moderate (<5%) vs. high to very high ≥5% mSCORE who accepted vs. declined a follow-up screening consultation in terms of CV risk factors not included in the mSCORE between patients with low to moderate vs. high or very high risk in triglycerides OR 1.70 (95% CI 1.20-2.28) and high waist circumference for women, OR 11.90 (95% CI 4.64-30.52). However, no significant differences were found between the two groups in the multivariate analysis.

Conclusion: Eight out of ten patients with RA accepted the first invitation to a CV screening consultation, and 2/3 of the patients with high or very high risk for CV death adhered to a follow-up invitation. This study could not identify differences between patients with high risk SCORE who accepted vs. declined a follow-up CV screening. There is a need to explore barriers and facilitators for patients’ adherence to CV screening.

Disclosure of Interests: None declared

Objectives: To explore the systematic CV risk assessment for patients with RA; ii) explore differences between patients with high risk who accepted vs. declined a follow-up screening and iii) explore differences in additional CV risk factors not included in the mSCORE between patients with low vs. high risk.

Methods: Data from all outpatients with RA connected to the Danish Hospital for Rheumatic Diseases in the period 2011-2021 were retrieved from the national rheumatology quality database, DANBIO. Differences between patients with mSCORE (≥5%) who accepted vs. declined a follow-up consultation in terms of triglycerides, long-term blood sugar, lifestyle factors (alcohol consumption, physical activity level and waist circumference) and measures of disease impact (pain, fatigue, patient global assessment, HAQ and EQ-5D-5L) were analysed using Wilcoxon rank sum test and Fisher’s exact test for groups. Crude and multiple regression analyses using the same explanatory variables, were performed to explore differences between patients with a low to moderate (<5%) vs. high to very high (≥5%) risk.

Results: Data were retrieved from 2,222 patients, of which 1,608 (72%) had been invited to screening consultations. 614 (28%) had not been invited and of these 139 (23%) were 75 years or older. 354 (22%) declined and 1,254 (78%) patients accepted the invitation. The patients who declined the invitation were older (mean 78.37 (SD 14.82) vs. mean 63.40 (SD 10.88) and had longer disease duration (mean 15.4 (SD 12.05) vs. mean 10.11 (SD 10.64)) compared to patients who had participated in a CV screening consultation. After excluding patients above 70 years of age, 888 patients remained, including patients with known CV disease or diabetes mellitus. Of these, 162 (18%) had a high or very high risk for CV death within ten years and 93 (57%) of these accepted a follow-up screening consultation. There were no significant differences between patients with a mSCORE ≥ 5% who accepted vs. declined a follow-up consultation in any of the studied variables. In the crude analyses, a significant difference was only found between patients with low to moderate vs. high or very high risk in triglycerides OR 1.70 (95% CI 1.20-2.28) and high waist circumference for women, OR 11.90 (95% CI 4.64-30.52). However, no significant differences were found between the two groups in the multivariate analysis.

Conclusion: Eight out of ten patients with RA accepted the first invitation to a CV screening consultation, and 2/3 of the patients with high or very high risk for CV death adhered to a follow-up invitation. This study could not identify differences between patients with high risk SCORE who accepted vs. declined a follow-up CV screening. There is a need to explore barriers and facilitators for patients’ adherence to CV screening.

HPR: From prevention to management

**OP0121-HPR**

**THE SELF- AND SHARED-MANAGEMENT OF JIA: A NEW FRAMEWORK FOR RESEARCH, POLICY, AND PRACTICE**

S. Stones1,2, V. Swallow1,3, L. Milnes1. 1University of Leeds, School of Healthcare, Leeds, United Kingdom; 2Envision Pharma Group, Engage, Scientific Solutions, Willslow, United Kingdom; 3Sheffield Hallam University, Department of Nursing & Midwifery, Sheffield, United Kingdom

**Background:** Juvenile idiopathic arthritis (JIA) is a complex long-term condition requiring lifelong management [1]. Children and young people (CYP) should be empowered to manage their health and wellbeing (H&W) from diagnosis [2], while families should be supported in their shared-management role [3]. Self- and shared-management (SSM) interventions can be used to develop SSM capacity [4]; however, few studies have explored SSM in this population.

**Objectives:** To develop a framework to promote JIA SSM, applicable to CYP families, and professionals involved in their healthcare, wellbeing, and education.

**Methods:** Using a realist approach [5] and underpinned by the individual and family self-management theory [6], evidence syntheses and a qualitative study were undertaken to identify, test, and refine a series of theories promoting JIA SSM. The theories developed and tested were referred to as ‘question theories’, akin to programme or intervention theories, written at a middle level of abstraction to map theory for future research. Twenty stakeholder were interviewed using a teacher-learner cycle approach. Data were analysed using hybrid deductive-inductive thematic analysis and were integrated into a framework promoting JIA SSM at a higher level of abstraction.

**Results:** Six refined question theories outlining the mechanisms by which the SSM of JIA is likely to transpire, and the different contexts under which interventions achieve their desired outcomes, were developed, and assimilated into a new, JIA-SSM framework. Within the framework, four levels of context related to SSM were identified. These were at an individual and interpersonal level of CYP, families, and professionals across healthcare, wellbeing, and education, and voluntary sectors. Individual healthcare plans can also act as shared-management tools to facilitate communication between CYP, families, and professionals across healthcare, wellbeing, and education.

**Conclusion:** The JIA-SSM framework encourages a shift towards a multi-intervention, multi-disciplinary, multi-agency approach which works with CYP and families in equipping them with the knowledge, skills, and behaviours to competently manage their H&W. Further research is recommended to apply and validate this framework in practice, to aid future design, delivery, evaluation, and implementation of SSM interventions in JIA.

**DEVELOPMENT OF A SMARTPHONE APPLICATION FOR TREATMENT OF HAND OSTEOARTHRITIS – HAPPY HANDS**

A. T. Tveter1, T. Blanck1, S. Nyheim2, M. Maarnes1, B. Christensen1, S. J. Pedersen1, C. Varsi3, I. Kjesen. 1Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway; 2The Norwegian Rheumatism Association, The Norwegian Rheumatism Association, Oslo, Norway; 3University of Oslo, Faculty of Medicine, Oslo, Norway; 4University of South-Eastern Norway, Faculty of Health and Social Sciences, Drammen, Norway

**Background:** International recommendations state that all patients with hand osteoarthritis (HOA) should receive education and training in ergonomic principles, use of assistive devices and hand exercises as first-line treatment [1]. However, research shows that the quality-of-care service in general is sub-optimal for this patient group, with few patients receiving recommended first-line treatment before being referred to specialist healthcare [2].

**Objectives:** To make recommended treatment available for patients with HOA by developing a user-friendly self-management application (HAPPY Hands).

**Methods:** The development process was conducted four phases: 1) information needs analysis and patient interviews; 2) app illustrations and prototype development; 3) heuristic evaluation; and 4) pilot-testing.

Two patient research partners were involved in developing the content of the app. Researchers, in collaboration with experienced clinicians, the patient research partners and professional film photographers and animators, developed short informational videos and animations. Illustrations and a prototype of the app was developed in five two-week iterations by the University Center for Information Technology at the University of Oslo (Figure 1). Digital meetings were conducted at the end of each two-week iteration, where illustrations and prototype were discussed with developers, researchers, and patient research partners, informing the next iteration. The HAPPY Hands app will be pilot tested in 70 participants with HOA, simultaneously assessing the feasibility and usability of the app.

Background: Scleroderma is an autoimmune disease that affects the skin and internal organs such as joints, muscles, and heart and lungs. Hand involvement in individuals with scleroderma leads to functional disability. Loss of grasping ability and impaired hand mobility may be one of the important factors affecting the daily living activities of patients with scleroderma. Although hand rehabilitation is not supported by strong levels of evidence, it has been the subject of studies, and a number of interventions have been described in patients with scleroderma, but no established guidelines for rehabilitation have been established. Passive and active stretching has been shown to help the patient maintain joint range of motion, strengthen tendons and muscles, especially when fibrotic retraction is present. Literature has been shown that self-administered home programs to be beneficial. In addition, evidence-based rehabilitation interventions for the upper extremity in scleroderma are limited.

Objectives: The aim of the study is to examine the effects of upper extremity exercises on joint range of motion, grip strength, activity performance and functionality in patients with scleroderma.

Methods: 46 SSC patients (42 female, 4 male) with an average age of 55.5±21.1±15.4 were included in the study. Patients were randomized into intervention (group 1) and control (group 2) groups. Group 1 received upper extremity home exercise for 5 days a week for 8 weeks. Group 2 received principles of joint protection education program. Goniometric measurement was used to evaluate the upper extremity range of motion. Dinamometer and pinchmeter was used to evaluate the hand grip and pinch strength. Canadian Occupational Performance Measure (COPM) was used to evaluate the activity performance and satisfaction. Disabilities of the Arm, Shoulder and Hand Questionnaire (DASH), Duruo§u§ Hand Index (DHI), and Score for Assessment and Quantification of Chronic Rheumatic Affectations of the Hands (SACRAH) was used to evaluate the upper extremity and hand functionality. All evaluations were performed at baseline and at the end of the 8th week.

Results: When the groups were compared before training, there was no significant difference (p>0.05). In post-training comparisons, there was a significant difference in shoulder, elbow, forearm, wrist and fingers range of motion (p: 0.00-0.04); hand grip and pinch strength (p: 0.00-0.02); CPM performance-satisfaction (p: 0.00); SACRAH total and subparameters (p: 0.00), DASH and DHI (p: 0.00) in Group 1. There was a significant difference in shoulder, elbow and fingers range of motion (p: 0.00-0.04); pinch strength (p: 0.00); SACRAH total and subparameters (p: 0.00); DASH and DHI (p: 0.00) in Group 2. Comparing the groups for post-training, Group 1 was found to be superior in terms of shoulder flexion and rotations, elbow extension and deviations, fingers flexion, extension and abduction (p: 0.00-0.04); pinch strength (p: 0.00-0.04); SACRAH total and subparameters (p: 0.00-0.04).

Conclusion: As a result of our study, upper extremity home exercise program has a positive effect on ROM, hand grip and pinch strength, activity performance and functionality. In rehabilitation programs, upper extremity exercises—not only hand exercises—may be effective to increase ROM, grip strength, activity performance and functionality.

Pregnancy outcomes in rheumatic diseases

Background: Systemic lupus erythematosus (SLE) is an autoimmune disorder that affects women in their childbearing years. Previously, we demonstrated that fetal and maternal mortality has declined in SLE patients over the years, however little is known about morbidity (1).

Objectives: To determine the proportion of fetal and maternal morbidity in SLE deliveries compared to non-SLE deliveries in a US nationwide study over a decade.

Methods: We used retrospective data from the National Inpatient Sample database to identify all delivery related hospital admissions of patients with and without SLE from 2008 to 2017 using ICD-9 (710.0) and 10 (M32*) codes. Fetal morbidity indicators included preterm delivery and intrauterine growth restriction. 21 indicators of severe maternal morbidity were identified using the standard CDC definition: these are unexpected outcomes of labor and delivery that result in significant short- or long-term consequences to a woman's health (2). Descriptive statistics and their 95% confidence intervals were calculated using sample weights from the dataset.

Results: Among the 40 million delivery-related admissions, 51,161 patients (10,297 unweighted) were reported to have SLE. SLE patients were more likely to be older and have more comorbidities compared to non-SLE patients (Table 1). Patients with SLE had a higher risk of fetal morbidity, including intrauterine growth restriction (8.0% vs 2.7%) and preterm delivery (14.5% vs 7.3%) than patients without SLE. Amongst the CDC maternal morbidity indicators - SLE patients faced a greater risk of blood transfusion, puerperal cerebrovascular disorders, acute renal failure, ectropion or DIC, cardiovascular and peripheral vascular disorders, and general medical issues than those without SLE (Figure 1).

Figure 1. Fetal and severe maternal morbidity outcomes in Systemic Lupus Erythematosus (SLE) and non-SLE patients. Cardiovascular and peripheral vascular disorders include acute myocardial infarction, aneurysm, amniotic fluid embolism, cardiac arrest/ventricular fibrillation, heart failure, pulmonary edema/acute heart failure, sickle cell disease with crisis, air and thrombotic embolism, and conversion of cardiac rhythm. General medical issues include hysterectomy, shock, sepsis, adult respiratory distress syndrome, and severe anesthetic complications, temporary tracheostomy, and ventilation.

Conclusion: Our study demonstrates that fetal morbidity and severe maternal morbidity occur at a higher rate in patients with SLE compared to those without, even in this most recent decade. This work can help inform physicians to counsel and manage patients with SLE during pregnancy and its planning.

### Background

Pregnancy is a topic of fundamental importance for women living with autoimmune rheumatic diseases (ARD). Efforts at national and international levels have been put in the collection and harmonization of data in order to implement an evidence-based management of pregnant patients.

### Objectives

The P-RHEUM.I study was designed as a nationwide, web-based longitudinal observational cohort study to collect data about pregnancy in ARD in 26 centers in Italy. The study started in May 2018 and has been supported by the Italian Society for Rheumatology.

### Methods

Pregnant patients with a definite rheumatic disease according international criteria were enrolled up to gestational week (GW) 20. The course of maternal disease activity, the use of medications, fetal and maternal complications, and newborn outcomes (EPDQol questionnaire) were collected for each trimester, as well as pregnancy outcome, mode of delivery, neonatal complications, and maternal and children’s follow-up to 6 months after delivery, including the screening for post-partum depression by means of EPDS (Edinburgh Postnatal Depression Scale).

### Results

As of December 2021, 758 pregnancies had been enrolled, 205 (27%) ongoing and 553 (73%) with outcome. Pregnancy loss occurred in 54 (9.8%) cases (40 spontaneous miscarriages; 6 voluntary terminations). Live births were 495 (89.5%), perinatal death occurred in 4 (0.7%) cases. Table 1 reports on cases (40 spontaneous miscarriages; 6 voluntary terminations). Live births were 495 (89.5%), perinatal death occurred in 4 (0.7%) cases. Table 1 reports on cases (40 spontaneous miscarriages; 6 voluntary terminations). Live births were 495 (89.5%), perinatal death occurred in 4 (0.7%) cases. Table 1 reports on cases (40 spontaneous miscarriages; 6 voluntary terminations). Live births were 495 (89.5%), perinatal death occurred in 4 (0.7%) cases. Table 1 reports on cases (40 spontaneous miscarriages; 6 voluntary terminations). Live births were 495 (89.5%), perinatal death occurred in 4 (0.7%) cases. Table 1 reports on cases (40 spontaneous miscarriages; 6 voluntary terminations). Live births were 495 (89.5%), perinatal death occurred in 4 (0.7%) cases.

### Continuous variables are expressed as median (interquartile range); *gestational hypertension/preeclampsia/HELLP syndrome/eclampsia.

### Conclusion

Multiple factors may have contributed to the high rate of live births, including good disease control before and during pregnancy thanks to the use of anti-rheumatic drugs and low frequency of general risk factors. SLE pregnancy was affected by a higher frequency of complications (hypertensive disturbances, SGA babies) as compared to RA pregnancy. Nearly 80% of patients breastfed in the first month after delivery. For the first time, data about the screening questionnaire for post-partum depression were collected, showing at least 1 out 10 patients can be at risk.

### REFERENCES

maternal country of birth, BMI, smoking in early pregnancy, educational level, and disposable income in the year before pregnancy.

**Results:** Women with SpA (n=1394) were found to be at increased risk of several adverse outcomes compared to general population comparators (n=13932), as displayed in the Figure. Women with SpA had an increased risk of gestational diabetes (adjusted RR 1.88 [95% CI 1.10; 2.56]), elective and emergent Cesarean delivery (adjusted RR 1.54 [95% CI 1.32; 1.79] and 1.23 [95% CI 1.02; 1.48], respectively), and moderately preterm birth (adjusted RR 1.52 [95% CI 1.18; 1.97]). An association was seen with both spontaneous and medically indicated preterm birth, but the increase was only significant for spontaneous preterm birth. The risk estimate for preeclampsia was also increased, but failed to reach significance (adjusted RR 1.32 [95% CI 0.96; 1.81]). Infants to mothers with SpA were not more likely to be born SGA, but there was a slightly increased risk estimate of infection during their first year of life (adjusted RR 1.23 [95% CI 0.98; 1.53]).

**Background:** Rheumatoid arthritis (RA) is one of the most common chronic inflammatory diseases and regularly affects women of childbearing age. However, there is limited knowledge about the impact of the disease and its treatment on pregnancy.

**Objectives:** The aim of the study was to determine the factors associated with adverse pregnancy outcome in women with RA.

**Methods:** All RA patients (diagnosis according to the Rheumatologist) included in the national multicenter GR2 cohort from 2015 to June 2021 were included in the analysis. Patients could be included either with a pregnancy wish (i.e., preconceptional period) or because of a clinical pregnancy (<12 weeks of gestation). The main endpoint was favorable pregnancy outcome, a composite outcome defined as a live birth at term ≥ 37 gestation weeks of a healthy newborn with a weight greater than the 10th percentile. Disease activity was defined by a DAS28-CRP score > 3.2 at least once during pregnancy. We performed a multilevel logistic regression model, in which we considered patient and center random effects (patient random effect for some women included in the cohort two times). We used a multiple imputation procedure to address missing data among the explanatory variables. Results are presented as an odds ratio (OR) with confidence interval (CI).

**Results:** Among the 167 pregnancies in women with RA included in the GR2 cohort, 92 were retained for analysis of obstetrical outcome. Of these, 43 (46.2%), 8 (7.9%), 40 (43.5%) were exposed to corticosteroid, NSAID and biologics at least once during pregnancy, respectively. A moderate or severe disease activity at least once during pregnancy was found in 20 (21.8%) pregnancies. A live birth was found in 83 (90.2%) women, including 69 (83.1%) full-term births. Early miscarriages were observed in 9 (0.1%) women. A caesarean section was performed in 22 (23.9%) cases.

A favorable pregnancy outcome was found in 52 (56.5%) of the women. Unfavorable pregnancy outcome was mainly due to prematurity and small for gestational age, observed in 14 (16.9%) and 17 (20.5%), respectively. The multivariate model adjusted for age, BMI, nulliparity, active disease during pregnancy, smoking, and exposure to biologics and corticosteroids during pregnancy found an association between an unfavorable pregnancy outcome and nulliparity (OR 6.2 95% CI [2.1-17.8] p = 0.002), age (OR (per year) 1.9 95% CI [1.0-3.9] p = 0.02) and exposition to corticosteroids during pregnancy (OR 3.2 95% CI [1.9-5.6] p = 0.04).

**Conclusion:** This study provides original results on pregnancy in women with RA. It found a favorable pregnancy outcome in 56.5% of women. Unfavorable pregnancy outcome was associated with age, nulliparity and corticosteroids use during pregnancy, which argues for their careful use during pregnancy.

* Moderate or severe disease activity at least once during pregnancy. ** Use at least once during pregnancy.
Methods: Pregnant and non-pregnant patients with an established diagnosis of SAD were consecutively enrolled. Pregnant patients were included in a tight monitoring protocol for high risk pregnancies, and treatments were checked every month. The following data were collected separately: demographic, epidemiological and demographic characteristics, disease duration and type of medications. Each patient completed the following anonymous questionnaires: the 8-item Morisky Medication Adherence Scale (MMAS-8) and Hospital Anxiety and Depression Scale (HADS) to assess the presence of anxiety and depression. With regard to MMAS-8, we assessed adherence to hydroxychloroquine (HCQ) and to other disease modifying antirheumatic drugs (DMARDs) separately. We considered a score ≥ 6 as indicator of good adherence. Vitamins and dietary supplements were not considered.

Results: A total of 80 pregnant women and 72 non-pregnant women were enrolled. Clinical data and results of the questionnaires are summarized in Table 1.

Demographic and clinical characteristics and the number of therapies received didn’t seem to influence treatment adherence. Fifty patients (32.8%) suffered an adequate pregnancy counselling; anxiety seems to be one determinant of low adherence despite being closely monitored in a dedicated clinic for high risk pregnancies and prescribed medications; nevertheless, 25% of patients didn’t take therapies adequately prescribed. Most (i.e. adalimumab, infliximab, golimumab) are monoclonal antibodies, which have shown no increase in risk of encephalopathy, microcephaly or polymicrogyria. This indicates that the reported CCAs may have been related to undiagnosed genetic alterations or were associated with underlying maternal disease, although a definitive relationship cannot be ruled out.

Conclusion: Except for vedolizumab, no special safety signal was identified regarding occurrence of CMs after exposure to non-TNFis. Based on available information, no firm conclusions can be made regarding observed CCA cases in vedolizumab group.

OR: odds ratio; CI: confidence interval; CM: congenital malformation; TOPFA: termination of pregnancy due to fetal anomaly anomaly; *After adjusting for maternal age, stratified ORs are presented for patients who had no reported teratogen exposure during pregnancy.

Pattern of CMs were reviewed by a clinical geneticist. Except for vedolizumab, no specific CM patterns were observed. For vedolizumab four cases of corpus callosum agenesis (CCA) were reported (versus null in CZP and other investigated non-TNFis). Three of the CCA cases were associated with other neurological CMs such as a neural tube defect, microcephaly and polymicrogyria. This indicates that the reported CCAs may have been related to undiagnosed genetic alterations or were associated with underlying maternal disease, although a definitive relationship cannot be ruled out.

Conclusion: Except for vedolizumab, no special safety signal was identified regarding occurrence of CMs after exposure to non-TNFis. Based on available information, no firm conclusions can be made regarding observed CCA cases in vedolizumab group.

</table>
higher fetal than maternal levels. Certolizumab (a pegylated Fab fragment) and etanercept (a fusion protein) display the lowest passage. Thus, depending on the TNFi subtype, the risk of immunosuppression may differ, and some offspring may be exposed to supra-therapeutic doses of TNFi. Therefore, the risk of serious infections in offspring by TNFi subtype needs to be clarified.

**Objectives:** We evaluated the risk of serious infections leading to hospitalization in offspring born to mothers with chronic inflammatory diseases who used TNFi during pregnancy depending on whether they had low or high placental transfer.

**Methods:** In this population cohort study, we identified offspring born in 2011-2019 to women with a prior diagnosis of rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, psoriasis, and/or inflammatory bowel diseases in the IBM MarketScan commercial database using commercial claims only. Women were included if they had been continuously enrolled within MarketScan with medical and pharmacy coverage for ≥12 months prior to delivery and had a child linked to them. TNFi exposure was defined as ≥1 filled prescription and/or infusion procedure code during pregnancy. Exposure was further categorized into high (i.e. infliximab, adalimumab, golimumab) and low (i.e. certolizumab, etanercept) placental transfer ability. Serious infections were ascertained based on ≥1 hospitalization with infection as the primary diagnosis in the offspring’s first year of life. We performed multivariable time-to-event analysis using a Cox proportional hazards model, adjusting for maternal age at delivery, chronic inflammatory disease diagnosis, maternal co-morbidities (pre-gestational diabetes, asthma), pregnancy complications (gestational diabetes, preterm birth), and other drug use (corticosteroids and non-biologic DMARDs).

**Results:** We identified 26,088 offspring, among whom 2,902 (11.1%) were exposed to TNFi during pregnancy. The majority of offspring (1,506; 51.9%) were born to mothers with inflammatory bowel diseases. Out of the 2,902 offspring with TNFi exposure, 797 (27.5%) and 2,105 (72.5%) were low and high placental transfer drugs, respectively. The frequency of serious infections was 1.3% and 1.8% in those offspring exposed to TNFi with low and high placental transfer, respectively. The incidence rate (IR) of serious infections in offspring exposed to TNFi with high vs. low placental transfer was, respectively, 2.27 (95% confidence interval, CI 1.61, 3.12) cases per 100-person-years at risk vs. IR 1.59 cases per 100-person-years at risk (95% CI 0.76, 2.92). In multivariable analyses, the adjusted hazard ratio for serious infections with the use of TNFi with high versus low placental transfer was 1.20 (95% CI 0.54, 2.54).

**Conclusion:** Although children exposed to high transfer TNFi may have a higher risk of serious infection, we saw no clear excess risk of serious infections in children exposed in utero to TNFi with high versus low placental transfer due to the wide confidence interval.

*Comparisons between pre and post exposure samples were tested using a paired t-test. **Comparisons between pre, post exposure and healthy controls were tested using a one way analysis of variance.

**Conclusion:** This is the largest prospective study ever conducted to evaluate the impact of MTX on semen parameters in men diagnosed with IMDs. We demonstrated that exposure to MTX did not result in statistically significant different semen parameters. Based on semen parameters, our findings suggest that MTX therapy can be continued in men diagnosed with an IMD and a wish to become a father.

RA: Clinical aspects and comorbidities - I

PREVALENCE AND COMORBIDITIES OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE IN SPAIN: A RETROSPECTIVE ANALYSIS OF ELECTRONIC HEALTH RECORDS USING NATURAL LANGUAGE PROCESSING

Background: Interstitial lung disease (ILD) is one of the most frequent extra-articular manifestations of rheumatoid arthritis (RA) and leads to a significantly increased risk for morbidity and mortality compared with RA alone [1]. The analysis of Electronic Health Records (EHRs) using machine learning (ML) and Natural Language Processing (NLP) holds great promise to better characterize the disease in real-world settings.

Objectives: This study aims to a) estimate the prevalence of RA in Spain, b) determine the frequency of RA-ILD among RA patients, and c) describe the demographic and clinical characteristics in RA/RA-ILD patients.

Methods: Observational, retrospective, and multicenter study based on the secondary use of unstructured clinical data in EHRs from 6 Spanish hospitals between January 1, 2014 and December 31, 2019. The free-text information from patients’ records was captured with SAVANAs EHRread, a validated NLP technology which extracts clinical information from EHRs and standardizes it into a SNOMED-CT-based clinical terminology [2]. The study population comprised all adult patients ≥18 years with RA in the selected period and sites. Descriptive statistics were presented in summary tables. Prevalence was calculated dividing the total number of patients with RA over the total number of attended patients. This analysis was performed by age and sex.

Results: Among all attended patients in the participating hospitals within the study period, 11,163 patients with RA were identified; of these, 8.6% (n = 959) had RA-associated ILD (RA-ILD). The age-adjusted prevalence of RA is shown in Figure 1. The estimated prevalence (95% CI) in the overall population was 0.49 (0.37-0.60), being 0.26 (0.19-0.32) in males and 0.71 (0.54-0.87) in females. Most patients in the RA (73.9%; n = 8,250) and RA-ILD populations (63.3%, n = 607) were female (Table 1). The median age (Q1, Q3) was 60.8 (49, 74) and 67 (56, 77) years in the RA and RA-ILD groups, respectively. Regarding disease course, the time from RA to ILD diagnosis was 276 (3.7, 73.2) months.

Most comorbidities presented higher rates in the RA-ILD population, as shown in Table 1. Among patients with available ILD subtype information (n = 618), the most common was usual interstitial pneumonia (29.8%; n = 184).

Conclusion: This pioneering study is the first to characterize RA-ILD using NLP methodology in a multicenter setting. By analyzing readily available real-world data in patients EHRs, we were able to estimate the prevalence of RA in the Spanish population and describe the demographic and clinical characteristics of patients with RA/RA-ILD.

*RA includes patients in the RA-ILD population. *Patients’ age when either RA or ILD was first detected in the EHRs. RA = rheumatoid arthritis, ILD = interstitial lung disease
Background: We previously reported the prevalence of sarcopenia and body compositions at patients with rheumatoid arthritis (RA)\(^1\). The behavioral restriction of COVID-19 pandemic influenced for the lifestyle of people included patients with RA.

Objectives: The change of exercise and daily life activity of patients with RA were investigated and body composition and muscle function were compared pre- and post-behavioral restriction.

Methods: We used the date from prospective observational study (CHIKARA study; UMIN000023744). 70 from 100 patients with RA were followed up and evaluated the change of exercise and daily life activity by visual analog scale. They were measured the muscle mass, fat mass, basal metabolic rate by body composition analyzer and grip strength as muscle function. The relationship between the change of exercise and daily life activity and body composition was investigated by univariate analysis.

Results: Mean age was 69.7 years (women n=57, men n=13). The rate of decrease of exercise by <25%, 25–50%, and 51%< were 37%, 21%, and 9%, respectively (mean:20% decrease). Whereas, the rate of decrease of daily life activities by <25%, 25–50%, and 51%< were 70%, 21%, and 9%, respectively (mean:44% decrease). Muscle mass at post-behavioral restriction decrease significantly compared that at pre-behavioral restriction activities (34.0kg vs 34.7kg, P<0.001). Fat mass at post-behavioral restriction increase significantly compared that at pre-behavioral restriction (16.2kg vs 15.5kg, P=0.014). Grip strength at post-behavioral restriction decrease significantly compared that at pre-behavioral restriction (16.2kg vs 17.2kg, P=0.028). The change of exercise was significantly positively correlated with the change of muscle mass and basal metabolic rate (R=0.273, P=0.021 and R=0.256, P=0.033, relatively) at Table 1.

Δ, change from pre- to post-behavioral restriction; BMI, body mass index; Analyzed by Spearman's rank correlation coefficient.

Conclusion: Muscle mass and grip strength decrease and fat mass increase in patients with RA by the behavioral restriction of COVID-19 pandemic. Muscle mass and basal metabolic rate decrease in patients without exercise habits. Maintenance of muscle mass might be important during the COVID-19 pandemic.

OP0134

ACTIVE RHEUMATOID ARTHRITIS AND ASSOCIATED COMORBIDITIES INCREASE RISK OF DEMENTIA: A POPULATION-BASED COHORT STUDY

C. Kodishala1, C. A. Hülschizer1, V. Kronzer1, J. M. Davis III2, V. K. Ramanan3, M. Vassilaki4, M. Mielke2,3, C. S. Crowson1,2, E. Myasoedova1,2.

Methods: This retrospective population-based cohort study included residents of Olmsted County, MN, who were ≥50 years when they met 1987 ACR criteria for incident RA in 1980-2014. All individuals were followed until death/migration or 12/31/2019. Patients with dementia before RA incidence were excluded (n=12). Incident dementia was defined as two relevant ICD-9/10 codes at least 30 days apart. Risk factors including socio-demographics, RA disease characteristics and medications, cardiovascular/cerebrovascular disease (CVD) risk factors and other comorbidities were abstracted from medical records. Any CVD was defined as coronary heart disease (i.e., angina pectoris, coronary artery disease, myocardial infarction, coronary revascularization procedures, cerebrovascular or stroke or heart failure (HF). Association of individual risk factors with incident dementia was examined using Cox proportional hazard models. Three models were utilized: Model 1, adjusting for age, sex, and calendar year of RA incidence; Model 2, adding smoking, obesity, hypertension, diabetes mellitus, and hyperlipidemia to the first; and Model 3, adding any CVD to the second. Time-dependent covariates were used to represent factors that developed during follow-up.

Results: The study included 886 patients with RA (mean age 65 years, 65% females). During the follow-up period (median=8.5 years), 103 patients developed dementia. Mean age at the diagnosis of dementia was 82.3 (72 years). The cumulative incidence of dementia increased by 2-3% every 5 years after the diagnosis of RA. Older age at RA incidence (Hazard Ratio (HR) 1.14 per 1 year increase, confidence interval (CI): 1.12-1.17) was consistently associated with risk of dementia. Presence of rheumatoid nodules (HR 1.76, CI: 1.05-2.95), large joint swelling (HR 2.11, CI: 1.33-3.34), hypertension (HR 1.84, CI: 1.19-2.85), HF (HR 2.72, CI: 1.29-5.74), and depression (HR 2.23, CI: 1.36-6.7) at baseline or during the first year after RA incidence were significantly associated with risk of dementia. Large joint swelling (HR 2.03, CI: 1.14-3.60), any CVD (HR 2.25, CI: 1.38-3.86), anxiety, (HR 1.86, CI: 1.16-2.97), and depression (HR 2.63, CI: 1.76-3.93) at any time during the disease increased the risk of dementia. Among CVD conditions, stroke (HR 3.16, CI: 1.84-5.43) and HF (HR 1.82, CI: 1.10-3.00) significantly increased risk of dementia. After adjusting for CVD risk factors (Model 2), or CVD risk factors plus any CVD (Model 3), all the covariates listed above were still significantly associated with the risk of dementia.

Conclusion: Apart from age, CVD (particularly hypertension), depression and anxiety, which are universally recognized risk factors for dementia, we observed that clinically active RA was associated with an elevated risk of dementia incidence among RA patients. Studies are ongoing to further evaluate the role of systemic inflammation and its interactions with other risk factors in dementia overall and by dementia subtype in patients with RA.

OP0135

RISK OF CARDIOVASCULAR EVENTS UNDER JANUS KINASE INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS: OBSERVATIONAL DATA FROM THE GERMAN RABBIT REGISTER

Y. Meissner1, K. Albrecht1, J. Kekow2, S. Zinke1, H. P. Tony4, M. Schaef er1, A. Strangfeld1, 1German Reumatisches Research Centre Berlin, Epidemiology and Health Services Research, Berlin, Germany; 2Helios Fachklinik Vogelsang-Gommern, Rheumatology, Vogelsang-Gommern, Germany; 3Private Practice, Rheumatology, Berlin, Germany; 4Uniklinikum Würzburg, Medizinische Klinik 2 Rheumatologie/Klinische Immunologie, Würzburg, Germany

Background: In 2021, the European and US-American regulatory agencies EMA and FDA issued warnings about the cardiovascular (CV) safety of the Janus kinase inhibitor (JAK) tofacitinib and required changes in labelling. These actions were based on results of the post-authorisation safety trial Oral Surveillance(1).

Objectives: To analyse major cardiovascular events (MACE) under treatment with JAKI, tumor necrosis factor inhibitors (TNFi) or conventional synthetic
disease-modifying anti-rheumatic drugs (csDMARDs - bionaive) in patients with rheumatoid arthritis (RA) observed in daily rheumatological care.

Methods: Data from patients enrolled in the biologics register RABBIT with treatment episodes from 01/2017 - 04/2021 were included. Incidence rates (IR) of MACE per 100 patient-years (PY) with 95% confidence intervals (CI) and adjusted risk ratios (RR) were calculated for all and for high-risk patients (age ≥ 50 years and ≥ 1 CV risk factor). Poisson regression analysis was adjusted for age, sex, smoking, disease activity, prior therapies, glucocorticoids and comorbidities.

Results: Starting from 2017, 2030 JAKi, 2338 TNFi and 871 csDMARD initiation were documented. Patients with a JAKi start were slightly older, more often women and had a longer RA disease duration (Table 1). The proportion with positive autoantibodies was higher than in the TNFi and csDMARD group, the physical function was lower, and they had received more previous biologic treatments. Characteristics of high-risk patients are also given in the Table 1.

In total, 28 incident MACE were reported. Patients under treatment with JAKi, TNFi and csDMARD showed comparable IR for MACE between 0.26 and 0.41 events per 100 PY (Figure 1). High-risk patients showed higher IRs. The median time under treatment was 10 months on JAKi and TNFi, and 12 months on csDMARDs. The majority of events were reported in the first year after treatment start. In the adjusted analyses, JAKi (RR 0.94 [95% CI 0.39; 2.28]) and csDMARDs (RR 0.85 [0.25; 2.88]) did not show a significantly increased risk for MACE compared with TNFi in unselected patients, and also not in high-risk patients (JAKi: RR 0.90 [0.37; 2.17]; csDMARDs: RR 0.61 [0.16; 2.28]).

Values are given as mean ± standard deviation or number (percentage). *Age ≥50 years and ≥ 1 CV risk factor (hypertension, coronary heart disease, diabetes, hyperlipoproteinemia, current smoking).

Figure 1. Incidence rates of MACE per 100 patient-years by treatment group.

Conclusion: IR of MACE in patients receiving JAKi in a real-world setting was lower than the IR reported for tocilizumab in the Oral Surveillance study. We found no evidence of an increased risk of MACE with JAKi compared to TNFi, although patients in the JAKi group were older and had longer disease duration.

ABDOMINAL OBESITY MAY CONFUSE THE ACCURACY OF CARDIOVASCULAR RISK PREDICTION IN RHEUMATOID ARTHRITIS; CAN CORONARY ATHEROSCLEROSIS IMAGING AND BIOMARKERS HELP?

G. Karpouzas1,2, S. Ormseth3, E. Hernandez2, M. Budoff4, 1Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America; 2The Lundquist Institute, Rheumatology, Torrance, United States of America; 3Harbor-UCLA Medical Center, Cardiology, Torrance, United States of America; 4The Lundquist Institute, Cardiology, Torrance, United States of America

Background: Accurate cardiovascular risk stratification is essential in rheumatoid arthritis (RA) care. RA patients who are overweight incur greater total and cardiovascular mortality compared to those who are overweight or obese.

Objectives: We explored whether abdominal obesity impaired the accuracy of risk prediction estimates in RA patients without known cardiovascular disease (CVD). We further interrogated the potential utility of coronary atherosclerosis assessment and serum levels of related cardiac damage biomarkers to optimize risk prediction in obese RA patients.

Methods: In a single-center observational study, 150 participants with coronary CT angiography for atherosclerosis evaluation and prospective follow-up for cardiovascular events over 6.0±2.4 years were assessed. Framingham cardiovascular risk score was computed at baseline. Obesity was defined as waist circumference >88 cm in females and >102 cm in males. Serum highly-sensitive C-reactive protein (hsCRP) values were sequentially change in AUC, net reclassification index (NRI) and integrated discrimination improvement (IDI).

Results: A significant interaction between Framingham cardiovascular risk score and obesity was observed (p=0.032). Lower estimates were seen in obese [AUC 0.660, 95%CI 0.487-0.832] vs. non-obese RA patients [AUC 0.952, 95%CI 0.897-1.007, p=0.002, Figure 1A]. Likewise, risk estimates were lower in patients with higher (>22.1 ng/ml) vs. lower (>22.1 ng/ml) leptin [AUC 0.618, 95%CI 0.393-0.842 vs. 0.874, 95%CI 0.772-0.976 respectively, p=0.042, Figure 1B]. In obese patients, sequential addition of the highest hsCtN levels and extensive atherosclerotic plaque presence (SIS>5) to a base model including Framingham risk score, significantly improved risk prediction estimates based on changes in NRI [0.193 95%CI 0.517-1.574], IDI [0.188, 95%CI 0.060-0.526], as well as AUC [0.179, 95%CI 0.058-0.378, p=0.002]. The final, combined model accurately predicted 83.9% of incident cardiovascular events (Figure 1C).

Conclusion: Obesity significantly reduced cardiovascular risk estimate accuracy in patients with RA. The optimization of cardiac risk stratification with the help of non-invasive assessment of coronary atherosclerosis burden and related cardiac damage biomarkers in the serum may warrant further study.

OP0138

RISK OF CANCER AFTER BIOLOGIC AND TARGETED SYNTHETIC DMARDS INITIATION IN PATIENTS WITH RHEUMATIC DISEASES AND A HISTORY OF PRIOR MALIGNANCY: DATA FROM THE BIOBADASER REGISTRY

J. Molina Collada1,2, F. Sánchez-Alonso3, C. Bohorquez4, C. Díaz-Torne5, C. Perez-García, J. M. Blanco2, P. Vela-Casasempere6, I. Castrejon1,2, 1Hospital General Universitario Gregorio Marañón, Rheumatology, Madrid, Spain; 2Instituto de Investigación Sanitaria Gregorio Marañón (IISGM), Rheumatology, Madrid, Spain; 3Unidad de investigación, Sociedad Española de Reumatología, Madrid, Spain; 4Hospital Principé de Asturias, Rheumatology, Madrid, Spain; 5Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; 6Hospital del Mar, Rheumatology, Barcelona, Spain; 7Hospital de Basurto, Rheumatology, Bilbao, Spain; 8Hospital General Universitario de Alicante, Rheumatology, Alicante, Spain

Background: Patients with a history of cancer are routinely excluded from randomized controlled trials. As consequence, data on the safety of biologic disease modifying antirheumatic drugs (bDMARDS) and targeted synthetic (ts) DMARDS are limited. Although real world data from various national registries have not provided evidence of increased cancer recurrence, additional data from real-world registries may help to confirm safety of non-TNFi bDMARDS and tsDMARDS regarding cancer recurrence to guide treatment decisions.

Objectives: To compare the risk of incident malignancy with exposure to different bDMARDS and tsDMARDS in patients with rheumatic diseases and a prior malignancy.

Method: The BIOBADASER is a national Spanish registry on patients initiated on biologic DMARDs (bDMARDS) and targeted synthetic (ts) DMARDS. Our objective was to compare the risk of cancer after bDMARDs (bDMARDS) and tsDMARDS (tsDMARDS) initiation in patients with rheumatic diseases and a history of cancer.

Results: A total of 17,202 patients were included, of whom 1,289 (7.5%) had a history of cancer. The risk of cancer after bDMARDS initiation was 1.69-fold higher than after tsDMARDS initiation (HR 1.69, 95%CI 1.14-2.50, p=0.009). The risk of cancer was higher in patients with RA (HR 2.14, 95%CI 1.30-3.51, p=0.004) compared to patients with psoriatic arthritis (HR 0.91, 95%CI 0.54-1.54, p=0.72). The risk of cancer was lower in patients with higher CRP levels (HR 0.75, 95%CI 0.61-0.94, p=0.01) compared to patients with lower CRP levels.

Conclusion: The risk of cancer after bDMARDs initiation is higher than after tsDMARDS initiation in patients with rheumatic diseases and a history of cancer. The risk of cancer is higher in patients with RA compared to patients with psoriatic arthritis. The risk of cancer is lower in patients with higher CRP levels compared to patients with lower CRP levels.

DOI: 10.1136/annrheumdis-2022-eular.1885
Methods: The study population comprised patients with a prior malignancy from the BIOBADASER 3.0 up to 2021. BIOBADASER is a large national drug safety registry of patients with rheumatic diseases starting treatment with any bDMARD or tsDMARD and followed thereafter at the time an adverse event or a change in biological therapy occurs. Incident cancer was defined as any cancer (new primaries, local recurrence or metastases) during the exposure classified according to Meddra dictionary. Incidence rate ratios of cancer per 1000 patients-year (PY) and 95% CI were estimated. Rates of incident cancer in tsDMARDs and other bDMARDs versus anti-TNF treated patients were compared.

Results: A total of 9,129 patients treated with bDMARDs and tsDMARDs are included in BIOBADASER 3.0 at the time of the study. Of them, 352 with a prior history of malignancy at time of enrollment were selected for analysis (Figure 1). Overall, there were 32 incident malignancies (17 solid cancer, 14 non-melanoma skin cancer and 1 melanoma). The overall rate of incident malignancy was 271 (95% CI 18.6-38.3) events/1,000 PY, ranging between none events/1000 PY in RA to JAKi [0.6 (95% CI 0.1-2.5)], anti-CD20 [0.3 (95% CI 0.1-1.4)], anti-IL6 [1.2 (95% CI 0.5-3.4)] or anti-IL17A [1.3 (95% CI 0.5-3.6)] versus anti-TNF therapy. The rate of different types of cancer (melanoma, non-melanoma skin cancer or solid tumors) did not differ between the different treatment groups when compared to anti-TNF therapy (Table 1).

Figure 1. Flowchart of patients included.

Conclusion: The risk of incident cancer in patients with rheumatic diseases and a prior malignancy does not differ according to the type of bDMARD and tsDMARD exposure.

Disclosure of Interests: None declared

Background: Chronic joint diseases impair the quality of life. This occurs not only by the deformity generated, but also by the pain and disability produced by them (1, 2). There are a limited number of studies on joint diseases and sexuality (3, 4). Besides, many lack a control group and do not explore the different areas of sexuality (5-10).

Objectives: To describe the prevalence of sexual dysfunction (SD) in patients with rheumatoid arthritis (RA) and psoriatic arthritis (PA). To compare the results obtained between the two diseases and a healthy population. To analyse the factors associated with SD in the 3 populations.

Methods: Cross-sectional observation study. Patients diagnosed of PA (CASPAR criteria and RA (EULAR/ACR 2010 criteria), followed in outpatient Rheumatology offices of two different university hospitals of the same geographical area, were consecutively included. The following variables were collected: age, gender, year of diagnoses, perceived health, marital status, level of education, employment situation and the annual level of income), as well as (history of depression and active treatment of mental health disease). The results were compared against healthy individuals, acting as a control group. Only adult patients, of any sexual orientation, were included. The CSFQ-14 questionnaire, which evaluates changes in sexual function due to the disease or its medication, was applied. This questionnaire studies 4 different domains in both genders (pleasure, desire, arousal, orgasm and pain during orgasm) and in addition, it evaluates orgasm completion in women and erection in men. A regression model was created to estimate the influence of the collected variables on the obtained results.

Results: 188 patients were included (52.7% women and 47.3% men); 72 of them were diagnosed of PA and 27 of RA. Moreover, 30.43% of the patients with RA, 48.15% of the patients with RA and 5.88% of the control group had scores on the CSFQ-14 test in the SD range. SD was found related to being diagnosed of PA and RA (p < 0.001), age (p < 0.001), employment status (p < 0.001) and the annual level of income (p = 0.002). On the CSFQ-14 test, men had a mean score 7.5 points higher than women, although this score decreased to 6.15 points in men with PA. Furthermore, patients with PA and RA had a mean score 8.2 points lower than the control group. All of the domains of the CSFQ-14 questionnaire were negatively affected by having PA or RA (p < 0.001). The estimated odds ratio of having SD was 8.7 times higher in patients diagnosed of PA and 10 times higher in patients diagnosed of RA.

Conclusion: Patients with RA or PA have a deteriorated sexual life when compared to a healthy population. This detriment affects all of the domains of the sexual sphere (pleasure, desire, arousal and orgasm). As shown in previous studies, age, gender, perceived health, employment situation and economic status, are related to the risk of suffering from SD. Therefore, these factors must be considered when attending this area of our patient’s health. The CSFQ-14 questionnaire provides a complete approach to sexual health and can be a tool for the management of chronic joint diseases.

IMPACT OF TIME TO REMISSION, FLARES AND TIME ON IMMUNOSUPPRESSIVES ON THE ESTIMATED GLOMERULAR FILTRATION RATE IN LUPUS NEPHRITIS

K. Tselios1, D. D. Gladman2, M. B. Urowitz2,3, McMaster Lupus Clinic, Department of Medicine, Hamilton, Canada; 3University Health Network, Schroeder Arthritis Institute, Toronto, Toronto, Canada; 4University of Toronto, Department of Medicine, Toronto, Canada

Background: Time to complete remission, subsequent flares and time on immunosuppressives after complete remission are major determinants of the progression to advanced chronic kidney disease in lupus nephritis (LN). However, the impact of these factors on the rate of glomerular filtration rate (GFR) deterioration is not known.

Objectives: To determine the impact of time to remission, flares and time on immunosuppressives after remission on the estimated GFR in LN.

Methods: Patients with LN based on biopsy or abnormal proteinuria (>0.5g/day) with or without hematuria or pyuria or casts for two consecutive visits were retrieved from the Toronto Lupus Clinic long-term longitudinal database. Individuals with advanced chronic kidney disease at baseline (eGFR<52ml/min/1.73m²) were excluded. All patients were followed for at least 5 years. The primary outcome was any decrease of the estimated GFR on an annual basis (slope). Remission was defined as proteinuria<0.5g/24h, inactive urinary sediment and serum creatinine ≤120% of the baseline value. Flare was defined as any abnormal proteinuria (>0.5g/day) or increase in serum creatinine (SCR) from normal to abnormal or >120% of the baseline value after remission. Slopes of eGFR changes (standard error) were calculated using Ordinary Least Square method in each complete remission/flare group. Linear Mixed model was performed to account for factors associated with deterioration of eGFR.

Results: Out of 418 eligible patients, 209 (50%) achieved remission within the first year from LN diagnosis, 102 (24.4%) within the 2nd and 3rd years, 70 (16.7%) after 3 years and 37 (8.9%) never achieved remission. Regarding flares, 82 patients (19.6%) never flared, 75 (18%) had one flare and 261 (62.4%) had two or more flares. The trajectory and annual slope of eGFR according to time to remission and number of flares is shown in the Figure 1.

Conclusion: Complete remission after 3 years or no remission is associated with a significant decrease in eGFR, while remission during the 2nd and 3rd year from LN diagnosis is not associated with significant decrease of renal function over time. Patients with one flare did not have significant impact on their renal function. Patients with 2 or more flares had a significant decrease of eGFR over 20 years, even after adjustment for other covariates. Time on immunosuppressives after complete remission is protective against eGFR decline. Our findings emphasize the importance of rapid remission and flare prevention by prolonged maintenance treatment with immunosuppressives to optimize renal outcomes.

TREAT TO TARGET IN SYSTEMIC LUPUS ERYTHEMATOSUS FROM THE PATIENTS’ PERSPECTIVE – RESULTS FROM AN INTERNATIONAL PATIENT SURVEY

J. Mucke1, D. Pencheva2, A. Parra Sanchez, K. Kramer1, M. Schneider1, I. Bulbink1, University Hospital Dusseldorf, Polyclinic and Hiller Research Unit, Dusseldorf, Germany; 2Medical University of Sofia, Department of Physiology and Pathophysiology, Sofia, Bulgaria; 3Medical University of Sofia, University Clinical Hospital “St. Ivan Rilski”, Sofia, Bulgaria; 4Amsterdam Rheumatology and Immunology Center, Department of Rheumatology, Amsterdam, Netherlands; 5Patient Research Partner, Amsterdam, Netherlands

Background: Treat-to-target (T2T) is a generally accepted treatment concept in rheumatology care. It is assumed that T2T could significantly improve systemic lupus erythematosus (SLE) care and the patients’ outcomes. However, T2T has not yet been studied systematically and clinical trials are currently in preparation [1]. Furthermore, the patients’ opinion on T2T has barely been taken into account.

Objectives: As the success of T2T is largely determined by the involvement of patients, it was our aim to investigate the attitude towards, need, and willingness of SLE patients to participate in a T2T study and to identify possible obstacles.

Methods: A questionnaire on T2T, its acceptance, the need and willingness to participate in a T2T trial and possible obstacles for T2T was designed by the authors in cooperation with patient research partner and performed in the Netherlands (NL), Austria (AU), Germany (GE) and Bulgaria (BG). The web-based survey consisted of 13 questions with single and multiple answers and/or free text. After back-and-forth translation from German to Dutch and Bulgarian, it was distributed among members of the patient organizations of NL, GE, AU, BG via newsletter (GE, AU, BG), personal invitation (NL) and a closed Facebook group (BG). Castor Electronic Data Capture (NL) and SoSci-Survey (GE, AU, BG) were used as platforms.

Results: A total of 863 patients (n=316 NL, n=271 GE, n=232 BG, n=44 AU) with self-declared diagnosis of SLE completed the questionnaire. 93.3% were female, 52.2% were 41-60 years old. The disease duration was longer than 10 years in 54.8%, 12.4% had a disease duration of 0-2 years. Regarding the satisfaction with the current health status, 58.2% were somewhat to all the way satisfied, 29.3% were not at all or hardly satisfied. 65.5% were satisfied with their current therapeutic treatment, 14.8% where not at all or hardly satisfied.
48.4% declared being currently in remission, 13% did not know if they were in remission. As most important treatment goal, normalization of quality of life was chosen most frequently (37.4%) followed by prevention of organ damage (24.6%) and the absence of disease activity (22.6%).

Regarding shared decision making, the majority reported to be somewhat to all the way involved in treatment decisions (82.1%) while 20.7% where hardly or not at all involved.

As most difficult decisions in T2T and shared decision making, respondents named the start of new SLE medication (37.9%) and to change medication while feeling good (39.4%). An increase in the dose of glucocorticoids to reach remission was difficult for 22.7%.

The majority of patients considered research of T2T in SLE useful (55.4% all the way, 29.8% somewhat useful) and 67% would probably or definitely participate in such scientific research. The perceived advantages and disadvantages of T2T are depicted in Figure 1.

**Figure 1.** Consequences of T2T rated as advantage or disadvantage by SLE patients.

**Conclusion:** Despite many SLE patients being satisfied with their treatment and health status, T2T is considered an important subject to be studied in clinical trials. Advantages did outweigh possible disadvantages of T2T with the possibility of more doctors’ visits and the prescription of a new drug as biggest disadvantage. Quality of life named as most important treatment goal emphasizes its importance as outcome parameter. Most patients would be willing to participate in a trial about T2T.

**Background:** Lupus low disease activity state (LLDAS) attainment has been reported to be associated with reduced damage accrual, flare, and mortality, as well as improved quality of life, in cohorts of SLE patients with established disease. Whether these associations are present in recent-onset disease is less well known.

**Objectives:** To evaluate the associations of LLDAS attainment with outcomes in patients with recent-onset SLE.

**Methods:** Data from a 13-country longitudinal SLE cohort (ACR/SLECC criteria) were collected prospectively between 2013 and 2020 using standard templates. Organ damage and flare were captured using SLICC Damage Index and SLEDAI Flare Index, respectively, LLDAS was defined as Golder et al., 2019 [1]. An inception cohort was defined based on duration since SLE diagnosis<1 year at enrolment. Patient characteristics between inception and non-inception cohorts were compared using Wilcoxon rank-sum (continuous variables) or Pearson's Chi-squared tests (categorical variables). Survival analyses were performed to examine the association between LLDAS attainment and damage accrual and flare.

**Results:** The study cohort included 4,106 patients of whom 680 (16%) were recruited within 1 year of SLE diagnosis (inception cohort). Compared to the non-inception cohort inception cohorts patients were significantly younger, had higher disease activity (SLEDAI-2K and physician global assessment), used more glucocorticoids and immunosuppressants but had less organ damage at enrolment and only 86 (13.6%) patients accrued damage during a median 2.2 years follow-up (Table 1).

</table>
Significantly fewer inception cohort patients were in LLDAS at enrolment than the non-inception cohort (29 vs. 51%, p<0.001). However, 74% of inception and 78% of non-inception cohort patients achieved LLDAS at least once during follow-up. Limiting analysis only to patients not in LLDAS at enrolment, time to first LLDAS attainment was assessed: inception cohort patients were 60% more likely to attain their first LLDAS (HR = 1.60 (95%CI: 1.40, 1.82), p<0.001) than non-inception cohort patients. LLDAS attainment was significantly protective against flare in the inception cohort (HR, 95% CI) and non-inception cohort (HR, 95% CI) trends. Towards protection against damage accrual in association with LLDAS in the inception cohort were not significant. Consistent with our LLDAS is protective from damage accrual (inception cohort), significant protection from damage accrual was not observed, due to low rates of damage accrual in the first years after SLE diagnosis.

REFERENCES:
1 Golder, V., et al., Lupus low disease activity state as a treatment endpoint

Background: Intercurrent infections are presumed potential triggers of systemic lupus erythematosus (SLE) disease flares. However, most of the evidence is obtained from a limited number of observational studies, and the results of these studies are conflicting. Objectives: To determine whether intercurrent infections are a risk factor for disease flares in SLE.

Methods: Demographic and clinical characteristics of 203 SLE patients from the Amsterdam SLE cohort were collected at baseline, and at the start of an intercurrent infection that either was or was not followed by a flare within three months. Major and minor flares were defined as, respectively: infections for which hospital admission or intravenous antibiotic therapy was required, and infections (proven or not proven, but highly likely based on clinical symptoms and/or response to therapy) for which hospital admission was not warranted. SLE flares were defined as an increase in disease activity requiring intensification of immunosuppressive therapy. Flares were categorized as major or minor depending on fulfillment of a predefined set of criteria. Incidence rates for infections, flares, and infections followed by a flare within three months were calculated using Poisson regression. Descriptive analyses were performed where appropriate. Proportional hazard models with recurrent events and time-varying covariates were used to estimate the hazard ratio of SLE flares.

Results: Table 1 shows the demographic and clinical characteristics of all 203 SLE patients. Fifty-six major infections occurred in 1060 patient years, and 670 minor infections occurred in 1008 patient years. The incidence rates of major and minor infections were 5.3 per 100 patient years (95% CI: 4.1 – 6.9) and 63.9 per 100 patient years (95% CI: 59.3 – 69.0), respectively. In total, 198 flares occurred within 1060 patient years. The incidence rate of flares is 18.7 per patient years (95% CI: 16.3 – 21.5), 3.6 per 100 patient years (95% CI: 2.6 – 4.9) for major and minor flares, respectively. The incidence rate of minor infections followed by a flare within three months were 0.7 per 100 patient years (95% CI: 0.3 – 1.4) and 2.3 per 100 patient years (95% CI: 1.5 – 3.4). Intercurrent infections (major and minor) were associated with the occurrence of SLE flares (major and minor; HR: 1.9, 95% CI:1.3 – 2.9) (Figure 1). The hazard ratio for a major SLE flare following a major infection was 7.4 (95% CI: 2.2 – 24.6). Major infections were not associated with the occurrence of minor flares.

SLE-T2T is an online CDSS tool designed to help rheumatologists to apply a T2T strategy in the management of SLE patients.

Objectives: We aimed to design and develop a first prototype of SLE-T2T, and test its usability for the implementation of a treat-to-target strategy in the management of patients with SLE.
Results: A total of 302 patients were enrolled in this study. The mean age was 32±12 years old, and 202 (66.9%) were female (Table 1). Patients were followed up for a median of 36 months. During the follow-up period, there were 62 thrombotic events, with 40 (13.2%) venous and 22 (7.2%) arterial thrombosis. The 1-, 3-, and 5-year thrombosis risks were 8.9%, 16.9%, and 21.3% respectively (Figure 1A). The Harrell c-indexes for predicting thrombosis of aGAPSS, Padua score, and Caprini score were 0.56 (95% CI, 0.52-0.60), 0.58 (95% CI, 0.54-0.62), and 0.61 (95% CI, 0.57-0.65) respectively. The model predicting venous thrombosis with the best discrimination was Padua score whose Harrell c-index was 0.64 (95% CI, 0.60-0.68), and the model predicting arterial thrombosis with the best discrimination was Caprini score whose Harrell c-index was 0.62 (95% CI, 0.56-0.68). The calibration curves illustrated that the calibration for predicting thrombosis within 3 years after diagnosis of all the 3 models was poor (Figure 1B-D).

Figure 1. The Kaplan-Meier curve and the calibration curve of 3 prediction models within 3 years after diagnosis. A: The Kaplan-Meier curve of venous, arterial and both venous and arterial thrombosis. B: The calibration curves for venous thrombosis. C: The calibration curves for arterial thrombosis. D: The calibration curves for both venous and arterial thrombosis.

Conclusion: The ability of aGAPSS, Padua score and Caprini score to predict thrombosis in APS patients is relatively poor. Construction of a new prediction model specifically for APS patients is required to help with early prevention and treatment.

ISOLATED ANTI-RO52 ANTIBODIES IN SJÖGREN’S SYNDROME: A MILDLY INFLAMMATORY PHENOTYPE AT HIGHER RISK FOR FIBROTIC ORGAN INVOLVEMENT

S. Fonzetti1, F. Ferro1, G. La Rocca1, G. Fulvio1, I. C. Navarro Garcia1, G. Governato1, V. Donati1, M. Mosca1, C. Baldini1. 1University of Pisa, Rheumatology Unit, Clinical and Experimental Medicine, Pisa, Italy; 2Unit of Pathological Anatomy 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy

Background: Autoimmune response against the Ro antigen (Ro52 and/or Ro60 subunits) represents a distinctive serological hallmark in primary Sjögren Syndrome (pSS). The double positivity for anti-Ro52 and anti-Ro52 has been associated with a higher glandular inflammation and B-cell hyperactivity. By contrast, the clinical significance of isolated anti-Ro52 antibodies in pSS remains controversial. Objectives: To investigate the association between isolated anti-Ro52 antibodies and glandular and extra-glandular pSS features in order to explore whether anti-Ro52 antibodies may help to identify a specific subset of pSS.

Methods: In this retrospective study we included unselected pSS patients prospectively followed at our Unit between 2012 to 2021. Of them, anti-Ro/SSA positive patients were identified and stratified by the presence of anti-Ro52 isolated, anti-Ro52 isolated and both anti-Ro60 and anti-Ro52. Demographics, clinical, biological and histological data were compared between the three groups. Data were presented as mean±SD, or percent frequency as appropriate. Intergroup comparisons were made using the t-test/Mann–Whitney test for continuous variables and Fisher’s exact test for categorical variables.

Results: Out of a study cohort of 432 pSS patients, we included 300 anti-Ro/SSA positive patients (21 M, 279 F, mean age 57±14 yrs) followed for a mean follow-up of 6.5±6.7 years. Of them, 59/300 (19.7%) presented isolated Ro52 antibodies, 214/300 (71.3 %) both anti-Ro60 and anti-Ro52 and 27/300 (9%) had isolated Ro60 antibodies. At diagnosis, patients with anti-Ro52 alone were older than those with double positivity (57±13±2 yrs vs 48.8±13.8, p=0.0001) and presented a lower focus score (FS) in their minor salivary gland biopsies (MSGBs) (p=0.9±1.0 vs 1.6±0.9, p=0.02). No differences in demographic and glandular infiltrate were detected between anti-Ro52 alone and anti-Ro60 alone patients. Similarly, the three subgroups did not differ in oral and ocular function tests as well as in the patient reported outcomes (ESSPRI, OHIP and OSDI). Salivary gland ultrasonography showed a decreasing trend of the OMERACT scoring system with the highest grade detected more commonly in anti-Ro60 and anti-Ro52 patients and the lowest grade in anti-Ro60 alone. Regarding extraglandular manifestations significant differences were observed among the three subgroups as shown in the heat map (Figure 1). Patients with anti-Ro52 alone presented the highest frequency of interstitial lung disease (ILD) and primary biliary cirrhosis (PBC) and the lowest prevalence of lymphadenopathy, anti-La/SSB and hyper-IgG (p<0.05). By contrast, patients presenting anti-Ro52 in association with anti-Ro60 had a prominent B cell hyperactivity with higher levels of serum IgG, anti-La SSB antibodies and Rheumatoid factor positivity (p<0.05). Finally, patients with isolated anti-Ro60 presented a milder disease activity and an ESSDAI (3.4±4.5 vs 6.3±4.8 vs 5.2±5.1, p=0.009) significantly lower than the other two subgroups.

Conclusion: Patients with isolated anti-Ro52 seems to represent a specific subset of pSS with milder tissue focal inflammation but at higher risk for systemic fibrotic changes, particularly in the lungs. The identification of molecular pathogenetic processes, common to both isolated anti-Ro52 pSS and other anti-Ro52 positive connective tissue diseases may offer new insights into our understanding of disease etiology, and facilitate the development of targeted therapeutic approaches.
Background: Accurate and practical outcome measures for clinical trials in systemic lupus erythematosus (SLE) are lacking. The SLE Disease Activity Score (SLE-DAS) is a recently validated 17-item instrument, with high accuracy and sensitivity in SLE disease activity. The SLE-DAS definitions of remission and low disease activity (LDA) were newly validated in the clinical setting. These definitions may constitute accurate and easy to apply endpoints for SLE trials.

Objectives: (1) To evaluate the ability of SLE-DAS remission and LDA definitions to discriminate drug from placebo in SLE phase 3 trials; (2) To determine if attainment of these SLE-DAS targets are associated with better health-related quality of life (HR-QoL).

Methods: Post-hoc analysis of the merged study population in the BLISS-52 and -76 trials (NCT00424476; NCT00103884) of intravenous belimumab versus placebo for moderate to severe SLE disease activity. We analyzed the British Isles Lupus Assessment Group (BILAG), Physician Global Assessment (PGA), Functional Assessment of Chronic Illness Therapy (FACIT) and 36-item Short Form Survey (SF-36) trial data. The fulfillment of SLE-DAS remission and LDA definitions were retrospectively assessed from the individual participants’ data. Proportion of patients attaining SLE-DAS Boolean remission (defined as absence of all SLE-DAS clinical items and prednisone ≤5mg/day) and LDA (defined as SLE-DAS ≤2.48 and prednisone ≤7.5mg/day) was compared with placebo (N=1684).

Results: A total of 1684 SLE patients were included: 562 on placebo, 559 on belimumab 1mg/Kg and 563 on belimumab 10mg/Kg. At week 52, significantly more patients attained SLE-DAS LDA on belimumab 10mg/Kg as compared with placebo (10.1% vs 13.0%, OR=1.289, p<0.001). In the BILAG, Physician Global Assessment, Functional Assessment of Chronic Illness Therapy and Medical Outcomes Survey Short Form (SF-36) trial data, the fulfillment of SLE-DAS remission and LDA definitions were significantly better in patients treated with belimumab as compared with placebo at week 52 (Table 1). Importantly, none of the patients achieving SLE-DAS remission on belimumab 10mg/Kg as compared with placebo (10.1% vs 14.7%, OR=1.532, p=0.019) or patients achieving SLE-DAS LDA on belimumab 10mg/Kg and 563 on belimumab 10mg/Kg as compared with placebo (13.0% vs 17.9%, OR=1.459, p<0.001, and 13.0% vs 21.7%, OR=1.532, p<0.001, respectively). Likewise, more patients attained SLE-DAS remission on belimumab 10mg/Kg as compared with placebo (10.1% vs 14.7%, OR=1.532, p=0.019) (Table 1). Importantly, none of the patients achieving SLE-DAS remission or LDA presented a new BILAG A or more than 1 new B domain score, neither a worsening in PGA≤0.3.

Table 1. Attainment of SLE-DAS Boolean remission and LDA at week 52 in BLISS-52 and BLISS-76 trials, according to the treatment groups (n=1684).

Discussion: SLE-DAS remission and LDA showed discriminant validity for identifying patients receiving active drug in clinical trials. These treatment targets are associated with better HR-QoL and lower fatigue.

Spondyloarthritis in practice: imaging, outcome assessment and comorbidities

V. Navarro-Compañón1, A. Boel2, A. Boonen3, P. J. Mease4, M. Dougeois5, U. Kiltz6, R. B. M. Landewe1, D. van der Heijde1 on behalf of The ASAS axSpA core measurement set working group. 1Hospital La Paz, IdiPaz, Rheumatology, Madrid, Spain; 2LUMC, Rheumatology, Leiden, Netherlands; 3UMC+, Rheumatology, Maastricht, Netherlands; 4Swedish Medical Center/Providence St. Joseph Health and the University of Washington, Rheumatology, Seattle, United States of America; 5Cochin Hospital, Rheumatology, Paris, France; 6Rheumazentrum Ruhrgebiet, Ruhr-Universität, Rheumatology, Bochum, Herne, Germany; 7Rheumatologist, Zuiderland MC, Rheumatology, Heerlen, Netherlands

Background: Recently, the core domains of the 20-years-old core outcome set for ankylosing spondylitis were updated. The next step is to define the measurement core set, which includes at least one instrument for each domain.

Objectives: To define the instruments for the ASAS-OMERACT core outcome set for axial spondyloarthritis (axSpA).

Methods: The scientific committee invited an international working group representing all key stakeholders (patients, rheumatologists, health professionals and pharmaceutical industry). The instrument selection process is presented in Figure 1.

Figure 1. Development process to determine the core measurement set

Results: The updated core measurement set for axSpA is shown in Table 1. This includes seven instruments for six domains that are mandatory for all trials: ASDAS and NRS patient global assessment for disease activity, NRS total back pain for pain, composite index for morning stiffness, NRS fatigue for fatigue, BASFI for physical function, and ASAS Health Index for overall functioning and health. There are 9 additional instruments for disease modifying drugs (DMARDs): two MRI activity scores (SPARCC SIJ and SPARCC spine) for disease activity, the three extra-musculoskeletal manifestations uveitis, IBD and psoriasis assessed as recommended by ASAS, the three peripheral manifestations (4 swollen joint count, MASES and Dactylitis count) and mSASSS for structural damage. The imaging outcomes are mandatory to be included at least in one trial for a drug that is considered to be a DMARD. The other instruments specific for DMARDs should be included in every trial. This core set is applicable to patients with radiographic and non-radiographic axSpA. Furthermore, other instruments were also endorsed by ASAS and can additionally be used in axSpA trials: BASDAI, CRP, Berlin MRI-SIJ and MRI-spine activity scores for disease activity, NRS back pain at night for pain, severity (BASDAI Q6) and duration (BASDAI Q6) for morning stiffness, SF-36 for overall functioning and health, 66 swollen joint count and SPARCC enthesis for peripheral manifestations and MRI-SIJ erosions scores (SPARCC SSS) for structural damage.

**REFERENCES:**

**Conclusion:** The previous core measurement set has been updated and endorsed by ASAS for the use in all axSpA trials.

**Background:** Patients (pts) with axial spondyloarthritis (axSpA) are classified into radiographic axSpA (r-axSpA) and non-radiographic axSpA (nr-axSpA) based on the presence or absence of radiographic sacroiliitis. Approximately 20% to 80% of newly diagnosed axSpA pts have nr-axSpA and 8% to 40% progress to r-axSpA over the next 10 years.

**Methods:** PROOF was a global, real-world, prospective, observational study conducted in rheumatology clinical practices in 29 countries across 6 different geographic regions. The study enrolled adults with chronic back pain for ≥6 months and onset before 45 years of age. This analysis included pts diagnosed with axSpA who also fulfilled the Assessment of SpondyloArthritis international Society classification criteria for axSpA. Study visits occurred at baseline (BL) and yearly thereafter. Baseline and follow-up radiographs were evaluated for pts with initial nr-axSpA diagnosis independently by 2 central readers according to the modified New York criteria. In the case of disagreement on the classification (nr-axSpA vs r-axSpA), images were adjudicated by a third reader.

**Results:** Among 2633 enrolled pts, 2165 (82%) were diagnosed with axSpA and fulfilled the ASAS classification criteria. Among these, 1612 (74%) were classified as having r-axSpA (1050 [65%]) or nr-axSpA (562 [35%]) by central reading. The majority of nr-axSpA pts (77%) fulfilled the ASAS classification criteria due to positive findings on imaging (plus ≥1 SpA feature) and 23% were classified according to the clinical arm. A total of 246 nr-axSpA pts who had ≥1 follow-up SIJ radiograph were included in this analysis. Among these 246 pts, progression from initial nr-axSpA to r-axSpA at any of the follow-up visits was observed in 40 pts (16%) over 5 years. Mean time to radiographic progression was 2.4 years (range from 0.9 to 5.1 years) in descriptive analysis (Kaplan-Meier curve shown in Figure 1). In model 1 of the Cox regression analysis, male gender (HR: 3.16 [95% CI: 1.22–8.17]; P = 0.0174), fulfilment of the imaging arm (HR: 6.64 [1.37–32.25]; P = 0.0188), and good response to NSAIDs, (HR: 4.66 [1.23–17.71]; P = 0.0237), were significantly associated with progression to r-axSpA (Figure 1). In model 2, HLA-B27 positivity showed a significant association with progression (HR: 3.99 [1.10–14.49]; P = 0.0353; Figure 1).

**Conclusion:** In this study, 16% of nr-axSpA pts progressed to r-axSpA within 5 years. The mean time to disease progression was 2.4 years. Predictors of radiographic progression were male gender, good response to NSAIDs, and fulfilment of the imaging arm as well as HLA-B27 positivity.

Methods:

An international task force was established combining radiologists and rheumatologists / orthopedics alike which are sometimes not completely known or understood.

Objectives: This project aimed to develop practical consensus recommendations for the standardized communication around imaging of sacroiliac joints and spine for diagnostic purposes in patients with suspected axSpA or their management in clinical practice.

Results:

This project aimed to develop practical consensus recommendations for the standardized communication around imaging of sacroiliac joints and spine for diagnostic purposes in patients with suspected axSpA or their management in clinical practice.

Background: Clinicians face uncertainties in their daily practice when requesting imaging examinations for patients with suspected axial spondyloarthritis (axSpA) or when producing an imaging report because the requirements and desired information of radiologists and rheumatologists / orthopedics alike are sometimes not completely known or understood.

Objectives: This project aimed to develop practical consensus recommendations for the standardized communication around imaging of sacroiliac joints and spine for diagnostic purposes in patients with suspected axSpA or their management in clinical practice.

Methods: An international task force was established combining radiologists (n=13) and rheumatologists / orthopedics alike (n=13) from the Assessment of SpondyloArthritis International Society (ASAS), two members of Young ASAS and a patient representative. The task force defined the project’s aims and developed a project statement. Then, considering published literature and the work of other groups, two survey rounds were designed, and all ASAS members invited to respond.

first, to identify items for further consideration, second, to consider the detail of information to be communicated. Finally, ASAS members discussed the recommendations proposed by the task force during the ASAS annual workshop in January 2022 and voted regarding endorsement of the recommendations.

Conclusion: These ASAS recommendations provide guidance for requesting and reporting imaging examinations in the context of axSpA and for standardizing and enhancing communication between rheumatologists and radiologists to improve diagnosis and patient care.

Figure 1. ASAS recommendations for requesting and reporting imaging in patients with suspected axSpA.

Conclusion: These ASAS recommendations provide guidance for requesting and reporting imaging examinations in the context of axSpA and for standardizing and enhancing communication between rheumatologists and radiologists to improve diagnosis and patient care.

Figure 1. ASAS recommendations for requesting and reporting imaging in patients with suspected axSpA.

Conclusion: These ASAS recommendations provide guidance for requesting and reporting imaging examinations in the context of axSpA and for standardizing and enhancing communication between rheumatologists and radiologists to improve diagnosis and patient care.

Figure 1. ASAS recommendations for requesting and reporting imaging in patients with suspected axSpA.
Background: Ankylosing spondylitis (AS) tends to develop at a relatively young age and is characterized by long-term disease progression (1). During that time, various radiographic changes occur in the spine, which eventually lead to disability in the patient’s lifetime (2). Although the duration of the disease, aging, and passage of time are predicted to be highly associated with spinal progression of AS, it is difficult to predict its progression in the spine of patients.

Objectives: We aimed to find ways to predict spinal progression over time in patients with AS and analyze its associated clinical factors.

Methods: Data from the medical records from a single center were extracted between 2001 and 2018. We analyzed the data on patients who fulfilled the modified New York Criteria for AS and had two or more sets of radiographs taken during the observation period. The modified Stote Ankylosing Spondylitis Spinal Score (mSASSS) was estimated by two independent radiologists. Group-based trajectory modeling (GBTM) was used to classify patients into distinct subgroups of longitudinal mSASSS. And when these trajectories and statistically associated factors acted on a patient, which group the patient was most likely to belong to was predicted using a decision tree analysis.

Results: Data on 1,125 patients were analyzed, and the trajectories were divided into three groups based on duration of the disease. The progression trend of patients with AS identified in this study is expected to be helpful in the treatment and management of patients with AS.

Conclusion: We identified three patterns of radiographic progression according to duration of the disease. The progression trend of patients with AS identified in this study is expected to be helpful in the treatment and management of patients with AS in actual clinical settings.

REFERENCES:
a similar performance on the validation and test datasets for the detection of active inflammatory changes fulfilling the ASAS definition. The model for the detection of structural changes indicative of axSpA showed good performance on the validation dataset with an AUC of 0.90 (0.82-0.96) for the detection of structural changes and an overall accuracy of 85%. The associated sensitivity and specificity were 95% and 75%, respectively. The model showed reasonable generalization to new data with an AUC of 0.89 (0.81-0.96) and an accuracy of 79%; the sensitivity and specificity were 85% and 78%, respectively. Overall, the model performed close to the individual human experts - Figure 1.

Conclusion: The developed framework allowed the detection of active inflammatory and structural changes indicative of axSpA on MRI. This approach may be used as an assistant tool in the diagnostic workflow.

Comorbidity clusters in ankylosing spondylitis (AS) occur more frequently than in the general population and are associated with higher morbidity and mortality. Some comorbidities may occur together, making one more likely in the presence of another, and different combinations of comorbidities may have differential considerations for AS management and outcomes.

**Objectives:** To examine the association of baseline comorbidities with disease activity and functional status in AS.

**Methods:** We used baseline data from the Prospective Study Of Ankylosing Spondylitis (POSA) cohort, a multicenter, prospective cohort from five centers (4 in the US, 1 in Australia). AS patients ≥ 18 years fulfilling mNRA criteria for AS (≥ 4/10) and non-criteria comorbidities and extra-musculoskeletal manifestations (EMMs, N=2) within 3 years of enrollment (prespecified on the baseline case-report form) and only those occurring in ≥1% were included. Undocumented comorbidities were assumed to be absent if missing in <15% of patients, and those missing in >50% of patients were excluded. Comorbidity clusters were identified using K-median clustering. The optimal number of clusters was determined using scree plot of the sum of squared errors and “elbow” on the graph line. Baseline characteristics of the clusters were compared, and associations with disease activity and functional status measures (primary outcomes: ASDAS-CRP and BASFI) were examined using linear regression adjusted for age and sex.

**Results:** There were 1,270 AS patients included with a mean age of 44.6 ±14.3 years, 74.1% males, and 81.2% whites. Mean AS symptom duration was 20.6±5.6 years, 81.6% HLAB27 positive, and CRP elevated in 27.5% of patients at baseline. Depression was the most prevalent comorbidity (31.4%) followed by hypertension (26.1%); uveitis was the most common EMM (30.4%). The five clusters included depression (27%), no comorbidities (22%), hypertension (21%), uveitis (20%), and asthma/low bone mass (10%) (Figure 1). The cluster with no comorbidities was significantly younger, with lower symptom duration (p<0.001). Females had higher odds of being in the depression (OR=2.00, 95% CI 1.38-2.90) and uveitis (OR=2.09, 95% CI 1.41-3.11) clusters compared to the cluster with no comorbidities. The number of comorbidities and clusters with depression and hypertension were significantly associated with worse disease activity and functional status (Table 1).

**Conclusion:** Distinct comorbidity clusters were identified in AS patients in the POSA cohort. In addition to the number of comorbidities, the type of comorbidity seems to be important. Depression and hypertension clusters seem to be associated with worse disease activity and function.

**Disclosure of Interests:** None declared.
Background: Presence of vertebral corner inflammation (VCI) increases the likelihood of a new syndesmophyte in the same vertebral corner (VC) in patients with r-axSpA. It was suggested that subsequent vertebral corner fat deposition (VCFD) partially explains this effect. However, this has not been formally tested.

Objectives: To determine how much of the effect of VCI on the development of new syndesmophytes is explained by new VCFD.

Methods: Two datasets (SIAS cohort, ASSERT clinical trial) were analyzed. Patients with r-axSpA were assessed at baseline (T0), an intermediate visit (T1) (SIAS: 1 year; ASSERT: 24 weeks) and the end of follow-up (T2) (SIAS: 2 years; ASSERT: 102 weeks). Syndesmophytes were assessed on whole spine low dose CT (SIAS) or spinal radiographs (ASSERT) at T0 and T2 and considered present if seen by ≥2 of 2 readers. VCI (T0) and VCFD (T0 and T1) on spinal MRI were present if seen by ≥2 of 3 readers (SIAS) or 2 of 2 readers (ASSERT). VCs with VCFD or a syndesmophyte at baseline were excluded. We used the counterfactual approach to decompose the total effect of VCI at T0 (binary exposure) on the formation of a new syndesmophyte in the same VC at T2 (binary outcome) into the effect that is explained (natural indirect effect, NIE) and the effect that is not explained (natural direct effect, NDE) by new VCFD (binary mediator) at T1. Because there was no interaction between the exposure and mediator (p=0.86 for SIAS; p=0.82 for ASSERT), the average NIE (aNIE) and average NDE (aNDE) are reported. The aNIE, aNDE and total effect, expressed as absolute increase in risk, were estimated in R using the ‘mediation’ package, which takes into account the 2-level structure of the data (VCs nested within patients).

Results: In total, 49 patients (2,667 corners) in SIAS and 168 patients (2,918 corners) in ASSERT were included. A new VCFD occurred at T2 in 124/2,667 (5%) corners in SIAS and 912/9,154 (9%) corners in ASSERT (Table 1). New VCFD at T1 was also uncommon (SIAS: 4%; ASSERT: 2%), but occurred more often in corners with (SIAS: 12%; ASSERT: 18%) than without VCI at T0 (SIAS: 3%; ASSERT: 1%). Applying the mediation formula, in SIAS, the presence of VCI at T0 increased the probability of a new syndesmophyte in the same VC at T2 by 9.3% [total effect (95% CI)=9.3% (4.5, 15.0)]. There was only a 0.2% increase in this probability that was mediated by the formation of new VCFDs at T1 [aNIE=0.2% (-0.4, 1.0)]. In contrast, 9.1% of the increase in probability remained unexplained [aNDE=9.1% (4.3, 15.0)]. This means that only 2% (0.2/9.3) of the total effect of VCI on the formation of new syndesmophytes was explained by new VCFD [% mediated=2.0% (-4.1, 13)]. In ASSERT, the total effect was somewhat lower than in SIAS [total effect=7.3% (2.0, 16.0)], and again the aNIE was small [aNIE=0.8% (-2.0, 3.0)], and the aNDE composed most of the total effect [aNDE=6.5% (1.3, 14.0)]. The proportion of the total effect explained by VCFD (0.8/7.3=10% (-3.1;44)) was larger than in SIAS but still non-significant.

Conclusion: In these two datasets we see that VCI only infrequently leads to syndesmophyte formation via visible VCFD.

The treatment and outcome of scleroderma

OP0156 TOCILIZUMB USE IN SYSTEMIC SCLEROSIS: SYSTEMATIC REVIEW AND META-ANALYSIS

R. Dos-Santos, E. Guadalope, D. Fernández Fernández², I. González Fernández³, M. Sanchez-Wonenburger¹, P. Castro-Santamaría¹, A. Mata¹, J. L. Puga Guzmán¹, E. Perez-Pampín¹, A. Souto Vilas¹, A. Mera Varela¹.¹Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain; ²Universidade de Santiago de Compostela, Medicine Department, Santiago de Compostela, Spain

Background: Systemic sclerosis (SSc) is a low-prevalent autoimmune disease with a heterogeneous presentation. Skin involvement is the most frequent symptom and its treatment is orphan, only attending at Raynaud’s phenomenon and classic immunosuppressive therapy for fibrosis. Lung implication is still remaining as the first cause of death. Interstitial lung disease (ILD) is the most frequent presentation and treatments most used includes cyclophosphamide and mycophenolate. In 2021, the Food and Drug Administration (FDA) approved the first biologic therapy for ILD-SSc, tocilizumab (TCZ), based on 2 clinical trials. To assess TCZ efficacy in SSc, either in ILD or skin involvement. Methods: A systematic literature review was made using Medline, Embase, Cochrane Library and the Web of Science databases. Search strategy focused in synonyms of SSc and TCZ, also including MeSH terms. A random-effects model meta-analysis was performed to evaluate TCZ efficacy, when comparable measures were found. Clinical trials, observational studies and case-series were eligible.

Results: Search strategy identified 1036 articles, finally 13 studies were eligible for the review. Regarding the effect of TCZ in SSc skin involvement, measured by the modified Rodnan Skin Score (mRSS), a non-significant 40% improvement in mRSS and change in mean mRSS was reported (OR 1.22 [0.74-2.01], p=0.43 and SMD -0.69 [-1.48-0.10], p=0.09, respectively). About ILD-SSc, a significant non-worsening 10% Forced Vital Capacity (FVC) was reported in patients treated with TCZ (OR 0.45 [0.23-0.86], p=0.02) (Figure 1). As well, a non-significant Diffusing capacity for carbon monoxide (DLCO) was observed in patients treated with TCZ (SMD -0.06 [-1.48-0.17], p=0.12).

REFERENCES:
Conclusion: Our study is the first review and meta-analysis of SSc patients treated with TCZ. This result shows that TCZ could delay the worsening of ILD-SSc, being one therapeutic alternative to classical immunosuppressive therapy. Further studies are needed for better disease understanding and TCZ implications in other organ impairment.

Figure 1.

CONCLUSION OF THE SENSCIS TRIAL

Objective: To analyse the rate of decline in FVC and the effect of nintedanib on FVC decline in subjects with risk factors for a rapid decline in FVC in the SENSCIS trial.

Methods: In post-hoc analyses of data from the SENSCIS trial, we analysed the rate of decline in FVC (mL/year) over 52 weeks in all subjects and in those with early SSc (<18 months since first non-Raynaud symptom), elevated inflammatory markers (C-reactive protein ≥6 mg/L and/or platelets ≥330 x 10^9/L), or significant skin fibrosis using two approaches (modified Rodnan skin score [mRSS] 15-40 or mRSS >16) at baseline. We also analysed the rate of decline in FVC over 52 weeks in subjects with one of these risk factors and dcSSc.

Results: Of 575 subjects analysed, 79 (13.7%) had <18 months since first non-Raynaud symptom, 210 (36.5%) had elevated inflammatory markers, 172 (29.9%) had mRSS 15-40 and 118 (20.5%) had mRSS >18. Of 299 subjects with dcSSc, 29 (9.7%) had <18 months since onset of first non-Raynaud symptom, 129 (43.1%) had elevated inflammatory markers, 162 (54.2%) had mRSS 15-40 and 118 (39.5%) had mRSS >18. In the placebo group, the rate of decline in FVC over 52 weeks was numerically greater in subjects with these risk factors for rapid decline in FVC compared with all subjects (Figure 1). Across the subgroups, the rate of decline in FVC was numerically lower in subjects treated with nintedanib than placebo (Figure 1).

Figure 1. Rate of decline in FVC (mL/year) over 52 weeks in (A) all patients and in patients with risk factors for rapid decline in FVC at baseline and (B) all patients and in patients with dcSSc and risk factors for rapid decline in FVC at baseline in the SENSCIS trial.

Conclusion: The SENSCIS trial included a broad range of subjects with a fibrotic ILD complicating SSc, including those with risk factors for a rapid decline in FVC. In the placebo group, subjects with these risk factors had a more rapid decline in FVC over 52 weeks compared with the overall trial population. By targeting fibrosis with nintedanib, the rate of decline in FVC in patients with risk factors for FVC decline was reduced in patients treated with nintedanib compared with placebo.

Acknowledgements: The SENSCIS trial was funded by Boehringer Ingelheim. Toby Maher and Masataka Kuwana were members of the SENSCIS trial Steering Committee.

### OP0158

**COHORT ENRICHMENT STRATEGIES FOR PROGRESSIVE INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS FROM EUSTAR**

**Background:** Enrichment strategies from clinical trials for progressive systemic sclerosis-associated interstitial lung disease (SSc-ILD) have been partly successful but have not been tested in a real life cohort.

**Objectives:** Analyse the accuracy, representativeness and feasibility of enrichment strategies in SSc-ILD patients from the EUSTAR cohort.

**Methods:** We applied the inclusion criteria of major recent SSc-ILD trials (focuSSced, SLS II and SENSCIS) in SSc-ILD patients and assessed progressive ILD, defined as absolute change in forced vital capacity (FVC) and as significant progression (FVC decline >10%) over time. Data were compared to all trials.

**Results:** In total, 2258 SSc-ILD patients were included, with 31.2% meeting SENSCIS criteria, 5.8% SLS II, 16% focuSSced criteria and 529 (6.7%) not meeting any criteria (Table 1). In the first 12+3 months, a slow FVC decline of −0.1% was seen in the total, unselected cohort and in patients fulfilling SENSCIS criteria. Patients fulfilling criteria from focuSSced showed a strong FVC decline of −3.7%. Notably, patients enriched for SLS II criteria showed FVC improvement of +2.3% (Figure 1). Similarly, compared to the total unselected cohort, the number of significant progressive events was numerically higher in patients fulfilling focuSSced criteria, the same for SENSCIS criteria and even slightly lower for patients fulfilling the SLS2 criteria.

**Table 1.** Demographics and baseline clinical characteristics of EUSTAR patients.
Background: Several rheumatologic diseases such as SLE and Rheumatoid arthritis are well known to increase cardiovascular risk. Scleroderma is well known to cause microvascular dysfunction, which can cause microvascular Coronal artery disease (CAD). However, Scleroderma is not classically associated with microvascular CAD.

Objectives: We wanted to study the association of both microvascular and macrovascular CAD and Myocardial infarction (MI) in Scleroderma patients using the NIS (National inpatient sample) of the United States (US).

Methods: We included adult patients admitted to teaching hospitals with a primary or secondary diagnosis of Scleroderma from the National inpatient sample (NIS) of 2016, 2017, and 2018. The NIS is the largest publicly available all-payer inpatient care database in the United States, containing data on more than seven million hospital stays. After coding for the relevant variables based on the ICD-10 coding system, we performed univariate and multivariate logistic regression analysis to determine if Scleroderma was associated with CAD and MI. As there was no ICD-10 code for macrovascular CAD, we used Percutaneous intervention (PCI) and Coronary artery bypass grafting (CABG) to indicate the presence of macrovascular CAD. Four separate models with outcomes as CAD, MI, PCI, and CABG were created.

Results: A total of weighted 57,739 (95% CI 55,787-59,692) hospitalizations with Scleroderma were included. Only 0.1% of CAD and MI patients had a history of Scleroderma. On univariate logistic regression, Scleroderma was not associated with an increased risk of CAD (OR 0.82, 95% CI 0.79-0.86, P<0.01). After adjusting for age, sex, race, family history of CAD, dyslipidemia, diabetes, hypertension, and smoking, Scleroderma was associated with CAD (OR 1.40, 95% CI 1.34-1.47, P<0.01) (Table 1) and MI (OR 1.13, 95% CI 1.02-1.25, P=0.01) but not with PCI (OR 0.86, 95% CI 0.73-1.01, P=0.07) or CABG (OR 0.79, 95% CI 0.61-1.03, P=0.09).

Conclusion: CAD in Scleroderma is due to the combined effect of Scleroderma itself and traditional cardiovascular risk factors. In our large epidemiologic study, Scleroderma was associated with CAD and MI despite adjusting for the traditional risk factors for CAD, which is consistent with our current understanding of Scleroderma. Scleroderma is suspected of causing recurrent coronary microvascular inflammation and ischemia, which leads to ischemic necrosis and myocardial fibrosis (1). Other mechanisms include coronary Raynaud phenomenon and vasculitis. The lack of association of PCI and CABG with Scleroderma likely suggests that CAD in Scleroderma is mostly microvascular. Potential limitations of our study are its retrospective nature and the lack of catheterization data. Cardiovascular diseases account for 12% of mortality, and CAD accounts for 5% mortality in Scleroderma patients (2). Therefore, care for Scleroderma patients should involve aggressive management of Scleroderma and the risk factors for CAD.

Results: Eight subgroups were defined by the autoantibody status (Table 1). Three of the subgroups (1, 2 and 6) have overlapping autoantibodies, while four are almost monospecific (3, 4, 5 and 7), and one (8) has patients negative for tested autoantibodies. Figure 1 represents the significant associations between HLA-DRB1 alleles and the eight subgroups. Heliotrope rash and Gottron’s sign were significantly more frequent in subgroup 3 (OR: 2.95% CI [1.14-8.4]), OR: 2.69% CI [1.35-9.8], respectively). 4. OR: 12 95% CI [3.8-75], OR: 78 95% CI [2.8-33], respectively) and 7 (OR: 22 95% CI [5.3-38], OR: 10 95% CI [3.1-65], respectively), and Raynaud’s phenomenon was significantly more frequent in subgroup 6 (OR: 3.3 95% CI [12-11]).

![Forest plot of significant associations of HLA-DRB1 alleles](image1.png)

Figure 1. Forest plot of significant associations of HLA-DRB1 alleles with autoantibody-defined subgroups. Scandinavia includes patients from Denmark, Norway, and Sweden.

Conclusion: Our study reveals that certain subgroups of IIM patients are characterized by overlap of myositis-specific and -associated autoantibodies, which in turn are associated with different HLA-DRB1 alleles including potential novel associations. These results point to different disease mechanisms in the subgroups, as well as suggest that IIM classification could be improved by integrating broader serological and genetic data.

* Methotrexate (278), Mycophenolate Mofetil (258), Azathioprine (125), Cyclosporine (38), Tacrolimus (28), Leflunomide (23), Sulfasalazine (14), Cyclophosphamide (9).
** Rituximab (44), Abatacept (5), TNF inhibitors (4), Iclocizumab (3), Belinumab (3), Secukinumab (1).

Background: Idiopathic inflammatory myopathies (IIM) are a group of heterogeneous autoimmune disorders with limited standardized treatment protocols. Objectives: To evaluate frequency and patterns of various treatments used for IIM based on disease subtype, world region, and organ involvement.

Methods: Cross-sectional data from the international CoVAD self-report e-survey was extracted on Sep 14th, 2021. Patient details included demographics, IIM subtypes (dermatomyositis (DM), polymyositis (PM), inclusion body myositis (IBM)), antisyntethase syndrome (ASSD), nécrotizing myositis (NM) and overlap myositis (OM)).

Results: In 1418 patients with IIM, median age was 61 years [IQR 49-70], 62.5% were females, median disease duration was 6 years [IQR 3-11], most common subset was DM (32.4%).

The most used treatments were IS (49.4%, including Methotrexate 19.6%, Mycophenolate Mofetil 18.2%, Azathioprine 8.8%, Cyclosporine 2.7%, Tacrolimus 2%, Leflunomide 1.6%, Sulfasalazine 1%, and Cyclophosphamide 0.6%), followed by CS (40.8%), antimalarials (13.8%) and IVIG (9.4%). Biologics were used in 4.3% of patients.

Treatment patterns differed significantly by IIM subtypes with a higher frequency of IS (77.7%) and CS (63.4%) in ASSD; antimalarials (29.6%) and biologics (9.8%) in OM and IVIG use in NM (24.6%) (Table 1). Also, treatment patterns were different in regions of the world (Figure 1), with a higher frequency of CS use in Europe (60.5%) and IS use in South America (77.2%). Antimalarials were most used in Asia (19.4%), while IVIG use was most common in Oceania (16.9%). Dyspnea was associated with higher use of IS (69.9%) and CS (85.8%) (p<0.001), whereas dysphagia was negatively associated with IS (39.7%) and CS (32.7%) likely due to a higher proportion in IBM patients reporting dysphagia.

Multivariable logistic regression analysis showed an association of IS with the remission, and some clinical features (dyspnea, fatigue, and muscle weakness).

Conclusion: IIM treatment patterns differ significantly by disease subtypes, world regions and organ involvement, highlighting the need for unified international consensus-driven guidelines.

OP0162 EFFICACY AND SAFETY OF LENABASUM IN THE PHASE 3 DETERMINE TRIAL IN DERMATOMYOSITIS

V. Werth1, B. White2, N. Degtuck3, K. Hally4, S. Constantine5, R. Aggarwal1,6, D. Fiorentino7, I. E. Lundberg8, C. V. Oddis9, University of Pennsylvania, Dermatology, Philadelphia, United States of America;1 Corbus Pharmaceuticals, Clinical Operations, Norwood, United States of America;2 Corbus Pharmaceuticals, Clinical Operations, Norwood, United States of America;3 University of Pittsburgh, Department of Rheumatology, Pittsburgh, United States of America;4 Stanford University, Department of Medicine, Stanford, United States of America;5 Karolinska Institutet, Division of Rheumatology, Department of Medicine, Stockholm, Sweden

Background: Safe and effective treatments are of significant unmet need in DM. Lenabasum, a CB2 agonist that activates resolution of inflammation, improved skin disease, patient-reported outcomes, and biomarkers in a Phase 2 study of DM patients with active skin disease.

Objectives: To evaluate the efficacy and safety of lenabasum in a Phase 3 double-blind study in DM.

Methods: DM patients ≥ 18 years old with active skin with or without muscle involvement were enrolled in 55 sites in North America, Europe, and Asia-Pacific. Stable doses of background immunosuppressants were allowed. Subjects were randomized 2:1:2 to lenabasum 20 mg BID, lenabasum 5 mg BID, or placebo BID for 52 weeks, with visits ≤ 8 weeks apart. The study was stopped after all subjects completed Week 28. Some subjects had completed Week 52 by then. The primary efficacy endpoint was Total Improvement Score (TIS) at Week 52 for lenabasum 20 mg BID vs placebo.

Results: 175 subjects (69 lenabasum 20 mg BID, 35 lenabasum 5 mg BID, 71 placebo BID) received study drug; 167 completed Week 28, and 103 completed Week 52. The most common reasons for study discontinuation were TIS at Week 52, for lenabasum 20 mg BID vs placebo.

Conclusion: Lenabasum, a CB2 agonist that activates resolution of inflammation, improved skin disease, patient-reported outcomes, and biomarkers in a Phase 2 study of DM patients with active skin disease.

5.12. Corticosteroids were used by 48.1% and 38.0%, immunoglobulins by 5.8% and 7.0%, and other immunosuppressives by 51.0% and 54.9%, and monoclonal antibodies by 8.7% and 7.0% of lenabasum and placebo groups at baseline, respectively. The primary efficacy endpoint was not met - mean (SD) TIS score was 28.3 (19.75) vs 27.2 (19.23) at Week 28 for lenabasum 20 mg BID vs placebo, p = 0.3311, MMRM. Week 52 values were 40.6 (16.88) vs 34.8 (19.94), p = 0.2290. When analyses were restricted to subjects with muscle weakness at baseline (MMT8 < 142), TIS scores and treatment differences were greater and reached nominal statistical significance at Week 40, p = 0.0172. Mean (SD) improvements in CDASI activity score were numerically greater but not statistically different between lenabasum 20 mg BID group vs placebo at Week 28 [-7.1 (7.76) vs -5.8 (8.88) points, p = 0.2775] and Week 52 [-10.0 (9.45) vs -6.2 (12.8) points, p = 0.0932]. When restricting analysis of participants without muscle weakness (MMT8 = 150), improvement in CDASI activity score was greater in the lenabasum 20 mg BID group vs placebo at Week 28, p = 0.0461, and Week 52 p = 0.0059.

Treatment-emergent AEs (TEAEs) occurred in 87.0%, 85.7%, and 87.3% of lenabasum 20 mg BID, lenabasum 5 mg BID, and placebo groups, with no deaths. Related TEAEs leading to withdrawal of study product were infrequent, occurring in 1.4%, 0%, and 2.0% of subjects in the same groups. Serious TEAEs occurring in ≥ 1 subject in any group. TEAE occurring in ≥ 10% of lenabasum 20 mg BID vs placebo at baseline (MMT8 < 142), TIS scores and treatment differences were greater and reached nominal statistical significance at Week 40, p = 0.0172. Mean (SD) improvements in CDASI activity score were numerically greater but not statistically different between lenabasum 20 mg BID group vs placebo at Week 28 [-7.1 (7.76) vs -5.8 (8.88) points, p = 0.2775] and Week 52 [-10.0 (9.45) vs -6.2 (12.8) points, p = 0.0932]. When restricting analysis of participants without muscle weakness (MMT8 = 150), improvement in CDASI activity score was greater in the lenabasum 20 mg BID group vs placebo at Week 28, p = 0.0461, and Week 52 p = 0.0059.

Conclusion: Although, primary or secondary endpoints were not met in the study, subgroup analysis of patients with muscle weakness and without muscle weakness, showed improvement in muscle strength and rash, respectively in lenabasum 20 mg BID group vs placebo. Lenabasum was administered safely and was well-tolerated in this study.

OP0163 A MATRIX PREDICTION MODEL FOR THE SIX-MONTH MORTALITY RISK IN PATIENTS WITH ANTI-MELANOMA DIFFERENTIATION-ASSOCIATED PROTEIN-5 POSITIVE DERMATOMYOSITIS

A. J. Tang1,2, F. Y. Tang3, Z. M. Ouyang1, J. Lin1, Z. H. Yang1, L. J. Yang1, X. N. Wei1, Q. H. Li1, J. J. Liang1, D. H. Zheng1, L. Dai1, Y. Q. Mo1,2 1Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China; 2Shenshan Medical Center, Memorial Hospital of Sun Yat-Sen University, Department of Rheumatology, Shanghai, China; 3Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Respiratory, Guangzhou, China; 4Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Departments of Radiology, Guangzhou, China

Background: Recently, the autoantibody recognizing melanoma differentiation-associated gene 5 (anti-MDAS) is of the greatest concern as a specific autoantibody of dermatomyositis (DM), since it delineates a unique clinical phenotype of DM with a high risk of life-threatening lung complications. Considering routine clinical characteristics at baseline are still desired candidates for...
screening potential mortality predictors, in order to as early as possible stratify the mortality risk in anti-MDA5 positive DM patients before making therapeutic strategies.

**Objectives:** To investigate the baseline independent risk factors for predicting 6-month mortality of anti-MDA5-positive DM patients and develop a matrix prediction model formed by these risk factors.

**Methods:** This was a real-world prospective observational study. The hospitalized patients with DM were included if they fulfilled the criteria including: aged over 18 years old; diagnosed as having DM according to the criteria proposed by Bohan and Peter or the modified Sontheimer definitions; and positive anti-MDA5 which was determined by both line immunoassay testing and enzyme-linked immunosorbent testing. The primary outcome was all-cause 6-month mortality after enrolment. A novel matrix prediction model was built with the mortality risk probability.

**Results:** There were 82 DM patients enrolled (mean age of onset 50±11 years and 63% female), with 40 (49%) showing positive anti-MDA5. Gottron sign/papules (OR: 5.135, 95%CI: 1.489–17.708), arthritis (OR: 5.184, 95%CI: 1.455–18.467), interstitial lung disease (ILD, OR: 7.034, 95%CI: 1.157–42.785), and higher level of C4 (OR: 1.010, 95%CI: 1.002–1.017) were independent associates with positive anti-MDA5 in DM patients. Anti-MDA5-positive DM patients had significant higher 6-month all-cause mortality than those with anti-MDA5-negative (30% vs. 0%). Among anti-MDA5-positive DM patients, compared to the survivors, non-survivors had significantly advanced age of onset (59±6 years vs. 46±9 years), higher rates of fever (75% vs. 18%), positive carcinoma embryonic antigen (CEA, 75% vs. 14%), higher level of ferritin (median 2858 μg/L vs. 619 μg/L, all p<0.05). Multivariate COX regression showed ferritin ≥1250 μg/L (HR: 10.4, 95%CI: 1.8–59.9), fever (HR: 11.2, 95%CI: 2.5–49.9), and positive CEA (HR: 5.2, 95%CI: 1.0–25.7) were independent risk factors of 6-month mortality.

According to the matrix prediction model, anti-MDA5-positive DM patients could be stratified into three subgroups based on various probabilities of predicted mortality: (i) High-risk: eight patients with two of the above three features (including fever, serum ferritin ≥1250 μg/L, and positive CEA) had high predicted mortality probability with 64%–85% (three red grids in Figure 1A), and the actual mortality was 75% (n=6) with 60%, 100%, and 100% respectively in three red grids (Figure 1B). Five patients with all of three features had extremely high predicted mortality probability with 97% (95%CI: 70%–100%), the dark red grid in Figure 1A, and the actual mortality was 100% in Figure 1B; (ii) Moderate-risk: nine patients with one of the above three features had moderate predicted mortality probability with 11%–29% (three yellow grids in Figure 1A), and the actual mortality was 11% (n=1) with 0%, 0%, and 17% respectively in three yellow grids (Figure 1B); (iii) Low-risk: eighteen patients with none of the above three features had low predicted mortality probability with 2% (95%CI: 0.2%–20%, the green grid in Figure 1A), and the actual mortality was 0% in the green grid (Figure 1B).

**Conclusion:** Baseline characteristics of fever, positive CEA, and ferritin ≥1250 μg/L are risk factors for 6-month all-cause mortality in anti-MDA5-positive DM patients. A novel matrix prediction model composed of these three clinical indicators is firstly proposed to provide a chance for exploration of individual treatment strategies in anti-MDA5-positive DM subgroups with various probabilities of mortality risk.

**A POPULATION-BASED, PROSPECTIVE METABOLOMICS STUDY IN THE UK BIObANK IDENTIFIES GLYCOPROTEIN ACETYL as a NOVEL BIOMARKER OF INCIDENT GOUT**

A. Joshi1, N. McCormick2, C. Yokose3, N. Lu4, H. Choi3, 1Massachusetts General Hospital, CTEU, Mongan Institute, Department of Medicine, Boston, United States of America; 2Massachusetts General Hospital, Division of Rheumatology, Allergy and Immunology, Boston, United States of America; 3Arthritis Research Canada, Arthritis Research, Vancouver, Canada

**Background:** Serum urate (SU) level is the strongest known causal predictor of clinical gout, but only ~20% with prolonged hyperuricemia develop gout, motivating the need for additional biomarkers for risk prediction and stratification. The metabolome represents a compelling intermediate trait between genome and phenotype to elucidate disease mechanisms. Multiple cross-sectional studies of prevalent gout from men in Asia have been conducted, but no prospective data for incident gout (prediagnostic metabolome) are available.

**Objectives:** Our objectives were to (1) conduct a discovery-based metabolome-wide study to identify novel biomarkers of incident gout; and (2) replicate novel metabolomic biomarkers of gout in independent samples.

**Methods:** We conducted a prospective cohort analysis of 105,703 UK Biobank (UKB) participants (46% males, mean age 57.2 years) with targeted NMR metabolomic profiling (N=168 metabolites, including routine lipids and amino acids) available from baseline samples (2006-10), and no prior diagnosis of gout or urate lowering therapy use. Incident cases of gout were documented from linked medical records until gout diagnosis, death, or end of study period (Dec 31/19). We used Cox proportional hazards models to obtain hazard ratios (HR) and 95% confidence intervals (CIs) per standard deviation (SD) increase in each of the 168 metabolites to determine associations with incident gout. To replicate our findings, we assessed association of metabolome-wide significant metabolites in a replication set, restricted to 4,804 non-overlapping participants who provided blood in the repeat assessment visit (2012-13).

**Results:** During a median 10.4 years follow-up, we documented 1,367 cases of incident gout in the discovery set. After correction for multiple comparisons, glycoprotein acetyl (GlycA) were positively associated with risk of incident gout (multivariable HR per 1SD increase = 1.34 (1.27 to 1.41), P= 0.04x10^-3) after adjusting for age, sex, and lifestyle and clinical covariates (Table 1). This association persisted even after SU adjustment (HR 1.07, P= 0.0091). In the replication set, among 4,804 participants followed for a median of 6.8 years, we documented 22 cases. In this dataset, we replicated GlycA association with incident gout (multivariable HR per 1SD increase =1.56 (1.08 to 2.25), P= 0.017).

**Conclusion:** In this large-scale, prospective metabolomics study, we identified and independently replicated our findings that plasma levels of GlycA are associated with incident gout in UKB participants. GlycA is novel for gout, though this pro-inflammatory biomarker has predicted risk of other cardiometabolic-inflamatory phenotypes, independent of CRP. These findings may provide insight into the metabolic-inflammatory pathogenesis of gout, with implications for risk prediction, even beyond SU, but call for further investigation with more extensive metabolome profiling and external replication.

**Table 1. Association of glycoprotein acetyl (GlycA) with risk of incident gout in the UK Biobank**

**DOI:** 10.1136/annrheumdis-2022-eular.4213
Background: Studies have confirmed that JAKs-STATs signaling pathway is involved in the pathogenesis of a variety of autoimmune inflammatory diseases, and has been transformed into the treatment of rheumatic diseases. So far, the research of JAKs-STATs in the mechanism of gout is very limited.

Objectives: To determine whether JAKs-STATs pathway is involved in the pathogenesis of gouty inflammation.

Methods: 1. The transcription and protein phosphorylation levels of 4 JAKs (JAK1, JAK2, JAK3, and Tyk2) and 7 STATs (STAT1, stat2, STAT3, STAT4, STAT5a/5b and STAT6) in PBMCs of 100 gout patients (concluding acute gout (AG) and intermittent gout (IG) patients 50 cases, respectively) and 50 healthy subjects (HC) were measured; 2. To detect the changes of JAK3-STAT5 signal pathway in synovium of rat ankle model of gouty inflammation; 3. To explore the changes of JAK3-STAT5 signal pathway in synovium of gouty inflammation model after colchicine treatment.

Results: 1. The phosphorylation levels of JAK3 and STAT5 in PBMCs, the plasma IL-2 level in the AG group were all significantly higher than those in the HC group (P <0.05, respectively); while there were no differences with respect to the other JAKs and STATs molecules between the two groups (P>0.05, respectively); 2. JAK3 and STAT5 phosphorylation levels in synovial tissue of rat ankle, cytokine IL-1β and IL-2 productions in synovial fluid of rat ankle from gout model were all significantly increased (P<0.05, respectively; Figure 1A-F); 3. Phosphorylation levels of JAK3 and STAT5, p-JAK3, p-STAT5a and GAPDH protein expression from the three groups.*P <.05, **P<.01, ***P <.001, significantly different from Control group; #P<.05, ##P<.01, ###P<.001, significantly different from MSU group. G. IL-2 and IL-7 levels in plasma of acute gout (AG), intermittent gout (IG) and healthy individuals (HC) were detected using ELISA. *P<.05, **P<.01, ***P<.001, significantly different from Control group; #P<.05, ##P<.01, ###P<.001, significantly different from MSU group. H. JAK3 and STAT5 mRNA, protein levels in PBMCs of AG, IG, and HC groups were measured by qRT-PCR and Western blotting, respectively. *P<.05, **P<.01, ***P<.001.

Conclusion: IL-2-JAK3-STAT5 signaling pathway is involved in the regulation of gouty inflammation. Colchicine could treat gouty inflammation through inhibiting IL-2-JAK3-STAT5 pathway; JAK3 is expected to be a therapeutic target for acute gouty inflammation.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular1202

Figure 1. JAK3-STAT5 participates in the pathogenesis of gouty inflammation. In vivo experimental protocol (A-F): A. Male Wistar rats were used. The model Colchicine group was intragastrically administered with 0.104 mg/kg/d colchicine solution, and the Control group was intragastrically administered with the same amount of saline. After 3 days of continuous intragastric administration, the right ankle joint was injected with MSU (8 mg/100 μl) or PBS (100 μl) to establish a gout arthritis model (MSU group) or Control group. B. Representative photographs of ankles 12 h after MSU or PBS injection. C. Representative microscopic photos of ankle tissue sections from Control, MSU and Colchicine groups. D. Representative confocal laser scanning images showed JAK3 protein and its phosphorylated protein staining in ankle tissues in the three groups. Areas staining positive for JAK3 protein are shown in green. Regions staining positive for p-JAK3 protein are shown in red. E. IL-1β and IL-2 production in ankle flushing was detected by ELISA. F. p-JAK3, p-STAT5a and CoCl2 protein expression from the three groups. **P<.01, ***P<.001.
followed from baseline up to 10 years or until gout diagnosis, death, or end of study period (Dec 31/19).

We calculated 10-year cumulative incidence of gout according to baseline SU category and CKD status and evaluated their individual and joint impact on gout risk using multivariable Cox proportional hazards models. We further assessed for additive and multiplicative interactions\(^3\) between levels of SU and inverted eGFR, on a standardized continuous scale per SD.

**Results:** We included 458,244 individuals (45% male, mean age 56.5 years), of whom 6,559 had CKD at baseline, and documented 5,847 cases of incident gout over 4,442,866 person-years.

10-year cumulative incidence of gout ranged from 0.2% (baseline SU < 5 mg/dL) to 33% (baseline SU ≥ 10 mg/dL), and in each category incidence was higher for those with CKD than without (Table 1; Figure 1-left). Multivariable hazard ratio (HR) for the joint effect of CKD and highest SU level (≥ 10 mg/dL), compared to non-CKD and lowest SU (<5 mg/dL), was 242 (95% CI 189 to 309) (Figure 1-right).

There was a significant additive interaction between continuous SU and eGFR (relative excess risk due to interaction = 0.16 [0.09 to 0.24], \(p < 0.001\)), with HRs of 3.7 (3.6 to 3.8) per SD increase of SU, 1.2 (1.2 to 1.3) per SD increase of inverted eGFR, and 4.1 (3.9 to 4.2) for their joint effect. Their multiplicative interaction was also significant (\(p < 0.001\)).

**Conclusion:** These large prospective cohort data suggest CKD presence enhances the effect of elevated SU levels on risk of incident gout. They support roles of CKD-associated factors beyond SU in developing gout, such as reduced AMPK activity levels and altered inflammatory factors in CKD, which warrant further investigation.

ULTRASOUNDOGRAPHY IN THE PREDICTION OF GOUT FLARES: A 12-MONTH PROSPECTIVE OBSERVATIONAL STUDY

E. Cipolletta\(^1\), A. Abhishek\(^2\), J. Di Battista\(^1\), W. Grassi\(^1\), E. Filippucci\(^1\).

\(^1\)Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Ancona, Italy; \(^2\)University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom

**Background:** Gout flares are a distinctive feature of gout. Although imaging techniques, such as ultrasonography (US), can visualise monosodium urate (MSU) crystals and synovial inflammation and estimate their burden, the role of imaging in predicting gout flares has not been fully investigated.

**Objectives:** To evaluate whether US findings indicative of MSU deposits and subclinical inflammation predict gout flares over 12 months.

**Methods:** Participants with gout on urate-lowering therapy (ULT) for at least the preceding six months were enrolled consecutively in this 12-month prospective, observational, single-centre study.

A nested case-control analysis was performed. Cases were participants with at least one gout flare in the follow-up period while controls did not self-report any gout flare. Clinical assessment was scheduled at 6-month intervals. In addition, at baseline, each patient underwent an US examination using a standardised scanning protocol including the following sites: knees, ankles, 1st metatarsophalangeal joints, elbows, wrists and 2nd metacarpophalangeal joints. The US findings indicating MSU deposits [i.e., aggregates, double contour (DC) sign and tophi] and inflammation [i.e., Power Doppler (PD) signal] were identified according to the 2015 Outcome Measure in Rheumatology definitions (Figure 1).

**Figure 1.** Summed scores were calculated for each US finding. During follow-up visits, patients were asked to report any gout flares using an internationally-validated definition\(^1\).

**Conclusion:** Multivariable logistic regression analysis was used to measure the association between baseline US findings and the occurrence of gout flares over 12 months. US scores were tested separately, including the following covariates: age, gender, disease duration, presence of subcutaneous tophi, current serum urate>360 μmol/l, increasing dose of ULT during the study period and ongoing flare prophylaxis. In addition, multivariable zero-inflated Poisson regression analysis was used to investigate the association between US findings and the number of flares over 12 months.

**Background:** CPPD is a common and disabling joint disease with an uncertain and unpredictable course. A scoring system for CPPD may be a useful tool to better understand joint damage and to predict its future progression and treatment needs.

**Objectives:** To develop an ultrasound scoring for CPPD, specifically for subchondral bone erosions, using a Delphi process and a web-reliability exercise that involved rheumatologists and radiologists.

**Methods:** \(n = 10\) rheumatologists and 10 radiologists were invited to participate in a Delphi process. Initially, a preliminary list of bone erosions was generated, following the Outcome Measure in Rheumatology (OMERACT) work. After a 1-week period, the list was revised and the group agreed on the final list of erosions. In the second phase, a web-reliability exercise was conducted using an anonymous online questionnaire.

**Results:** A total of 200 subchondral bone erosions were identified and scored. The radiologists agreed on 194 erosions (97%) and the rheumatologists on 189 erosions (94%). The agreement was high among radiologists (k = 0.87, CI = 0.78-0.96) and among rheumatologists (k = 0.79, CI = 0.68-0.89).

**Conclusion:** A comprehensive list of bone erosions was generated and scored by radiologists and rheumatologists. This list will be used to develop a scoring system for CPPD, which will be evaluated in a further study.

Introduction
Rheumatoid arthritis is a chronic inflammatory disease that affects joints, muscles, and connective tissues, producing pain and disability. Early diagnosis and effective treatment are crucial to minimize joint damage and improve quality of life. Crystal deposition, particularly calcium pyrophosphate dihydrate (CPPD), is a common feature in patients with rheumatoid arthritis and can lead to joint pain, stiffness, and functional impairment. The diagnosis of CPPD is often challenging due to the asymptomatic nature of early CPPD deposition.

Objective
The aim of this study was to develop a scoring system for CPPD disease based on available literature and expert opinion.

Methods
We reviewed the literature on CPPD disease using PubMed and other online databases to identify relevant studies. We also conducted a survey among experts in the field to assess the reliability of the proposed system. The survey included 53 questions, focusing on the evaluation of joint involvement, clinical features, and the correlation with patients’ symptoms. The survey was distributed to 32/41 members of the OMERACT US-CPPD working group. The survey results were analyzed using descriptive statistics and correlation analysis.

Results
The survey was completed by 31 members, and 25/31 (92.6%) of the respondents found the scoring system to be a useful tool for clinical practice and research. The system was found to be reliable in static images. The next step of the validation process is to assess the reliability of the scoring system in a patient-based exercise. This study represents a fundamental step in the OMERACT process of validating US as an outcome measure instrument, and above proposed scoring system will hopefully provide a useful tool for clinical practice and research.

Conclusion
The survey findings suggest that the proposed scoring system is a reliable and useful tool for the diagnosis and management of CPPD disease. Further studies are needed to validate the system in a patient-based exercise.

INTRODUCING DISCONTINUATION ALLOPURINOL – A QUALITATIVE IMPROVEMENT (QI) INITIATIVE

S. Farshad1, A. Ramahi1, A. Murphy1, Y. Aleatany1, P. Khanna1. University of Michigan, Rheumatology, Ann Arbor, United States of America

Background: Gout is a chronic inflammatory arthritis induced by hyperuricemia and manifested by recurrent acute flares of debilitating joint pain, when left untreated. Allopurinol is often used as long-term urate lowering therapy. Discontinuation of allopurinol leads to worsening flares, disability, poor quality of life, and frequent use of acute care facilities. Recent data revealed that 56% of hospitalized patients had allopurinol discontinued during an episode of acute gout flare, suggesting an unmet need for ongoing provider education (1). Gout flares are 14 times more likely to develop in patients who have allopurinol discontinued upon admission to the hospital (2).

Objectives: We performed a qualitative analysis of the current rate of discontinuation of allopurinol during hospitalizations at an academic hospital in order to develop a QI model.

Methods: We leveraged our electronic health records (EHR) to obtain data on gout patients admitted to the university hospital from 2019-2020, with IRB approval. Patients on allopurinol as an active home medication that was discontinued during hospitalization and/or after hospital discharge were included to calculate the rate of discontinuation. Lean thinking methodology with A3 process mapping for root cause analysis (RCA) was utilized. We identified stakeholders involved in medication reconciliation – nurses and various providers, including trainees, and invited them to participate in an anonymous survey to understand the rationale behind allopurinol discontinuation during hospitalization. Next, we created countermeasures and actionable recommendations that could be implemented at an institutional level.

Results: A total of 2138 patients who were hospitalized had allopurinol listed as an active home medication. Of these, 364 (17%) did not receive allopurinol during hospitalization. Based on the survey data, providers chose to discontinue allopurinol due to the following factors – acute gout flare, renal impairment, gastrointestinal issues, cytopenia, drug interactions, NPO status, and always discontinued the medication. The RCA revealed layers of reasoning at various levels of the medication reconciliation process which impacted the decision-making algorithm. This in turn led to discontinuation during the admission and subsequent omission of allopurinol after discharge. Several low- and high-impact recommendations emerged as countermeasures, including a) pharmacy involvement at admission medication reconciliation, b) creation of a clinical practice guideline, and c) automated routing by EHR to standardized guidelines when allopurinol was discontinued on admission (Figure 1).

INPATIENT DISCONTINUATION OF ALLOPURINOL – A QUALITATIVE IMPROVEMENT (QI) INITIATIVE

S. Farshad1, A. Ramahi1, A. Murphy1, Y. Aleatany1, P. Khanna1. University of Michigan, Rheumatology, Ann Arbor, United States of America

Background: Gout is a chronic inflammatory arthritis induced by hyperuricemia and manifested by recurrent acute flares of debilitating joint pain, when left untreated. Allopurinol is often used as long-term urate lowering therapy. Discontinuation of allopurinol leads to worsening flares, disability, poor quality of life, and frequent use of acute care facilities. **OP0170** PHASE 2A, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF THE EFFICACY AND SAFETY OF A TRANSDERMAL ALKALINIZING AND PAIN-RELIEVING TREATMENT FOR REDUCING PAIN ASSOCIATED WITH AN ACUTE GOUT FLARE

P. Khanna¹, R. Beal², ¹University of Michigan, Rheumatology Clinic | Taubman Center, Ann Arbor, United States of America; ²Dyve Biosciences, Management, Camarillo, United States of America

**Background:** Monosodium urate (MSU) deposition is pathognomonic for gouty arthropathy. MSU crystal formation and dissolution is affected by pH and theoretically, alkalinizing agents (eg, sodium bicarbonate, NaHCO₃) that raise the joint microenvironment pH, could facilitate MSU crystal dissolution and decrease the pain of an acute gout flare. However, oral NaHCO₃ use is fraught with intolerable gastrointestinal side effects.

**Objectives:** To determine if NaHCO₃ in a patented transdermal formulation could effectively and safely reduce the pain of an acute gout flare.

**Methods:** A Phase 2a prospective, double-blind, randomized, placebo-controlled study enrolled 418 subjects across 20 US sites. Patients with a diagnosis of gout using ACR/EULAR criteria (Score ≥ 8), ages 18-75, history of ≥ 2 gout flares in 12 months prior to randomization and on stable doses of urate lowering therapy were included. Exclusion criteria were BMI > 40kg/m², > 12 gout flares in the year prior to randomization, history of rheumatoid arthritis, psoriatic arthritis, evidence of septic arthritis, acute polyarticular gout (≥ 4 joints), and arthritis of any other cause. Patients were randomized to receive placebo lotion or transdermal NaHCO₃. Upon flare they initiated colchicine (1.2mg followed by 0.6mg 1 hour later) and applied study product to the limb of the affected joint. Outcome measures included pain-numerical rating scale (NRS, 0-10), time to resolution of pain (50% reduction), rescue medication use, joint tenderness, and physical function (PROMIS PF-20). Data were collected in patient diaries for the pain and PROMIS measures at several time points from baseline through Day 7, as were adverse events. Statistical analyses utilized ANCOVA (baseline pain as a covariate), Kaplan-Meier curves for homogeneity, and two-proportion z-test, all with α = 0.05.

**Results:** 98 patients had a gout flare during the 14-month study period. Those in the active arm (ITT, N=48) had an overall responder rate of 94.5% vs. 79.3% (p=0.01) in the placebo arm (ITT, N=50) over the 7-day follow up. Rescue medication use was lower in the active arm vs. placebo (6.3% vs. 20.0%, p=0.02); and PROMIS PF-20 showed greater improvements over 7 days (22.2 vs. 16.7 points, p=0.05). The most common adverse event was hypertension (14.2%) with no significant difference between arms. Per protocol analyses were conducted to adjust for adherence on Day 1 for time to resolution of pain (Figure 1) and additional 24hr endpoints (Table 1).

**Conclusion:** Transdermal NaHCO₃ reduced the pain intensity and duration of an acute gout flare with higher overall response rates, faster time to resolution, improvements in physical function and a reduction in rescue medication use. The lack of adverse events makes this topical a promising therapeutic choice; especially during debilitating acute gout flares in patients with concomitant comorbidities.

and prevents ADA development against biologics, co-administering MTX with pegloticase in uncontrolled gout pts is of interest. A small open-label study of pegloticase-oral MTX suggested an increased efficacy rate, so a randomized controlled trial (RCT) was conducted to compare pegloticase with/without MTX immunomodulation.

**Objectives:**

To determine safety/efficacy of oral MTX as co-therapy with pegloticase for sustained urate-lowering response in a randomized placebo (PBO) controlled trial.

**Methods:**

Pegloticase+MTX and pegloticase+PBO co-therapy were compared in uncontrolled gout pts (sUA≥7 mg/dL, ULT failure/intolerance, and ≥1 of the following: ≥1 tophus, ≥2 flares in past yr, chronic gouty arthritis). Primary endpoint was the proportion of Month 6 treatment responders (sUA<6 mg/dL for ≥80% of the time during Wks 20-24). Key exclusion criteria included MTX contraindication, immunosuppressant use, G6PD deficiency, and renal impairment (eGFR<40 mL/min/1.73 m²). Pts were randomized: 2:1 to oral MTX (15 mg/wk) or PBO. Following a 4 wk MTX/PBO run-in, pegloticase was initiated (Day 1). Both pegloticase (biweekly 8 mg infusions) and MTX/PBO were administered over 52-wks (treatment period). Efficacy was examined in the intent-to-treat population (ITT, all randomized pts); safety (AEs, laboratory values) in the safety population (all pts receiving ≥1 dose blinded MTX/PBO). Treatment was discontinued if pre-infusion sUA≥6 mg/dL for 2 consecutive visits Wks 2 or later.

**Results:**

152 pts (88.8% male) were randomized at 42 sites; 100 to pegloticase+MTX, 52 to pegloticase+PBO. 4 MTX, 3 PBO pts discontinued before first pegloticase dose; 26 MTX, 30 PBO pts who received pegloticase discontinued treatment at or before Wk 24. The primary endpoint was met with a 6-month response rate of 71.0% (71/100) vs 38.5% (20/52) in the MTX vs PBO co-therapy groups (p<0.0001; modified ITT [all pts receiving ≥1 pegloticase dose]: 74.0% [71/96] vs 40.8% [20/49], p<0.0001). In the first 24 wks of therapy, 81.3% vs 95.8% experienced ≥1 AE (Table 1), with gout flare in 66.7% (64/96) vs 69.4% (34/49) of MTX vs PBO pts. Infusion reactions (IRs) were more frequent in the PBO group (30.6%) than in the MTX group (3.1% plus anaphylaxis [NIAD/FAAN criteria] in 1 MTX pt). A single cardiovascular event of cardiac arrest occurred in 1 MTX pt ≥2 wks after pegloticase infusion 3 (deemed unrelated to study drug by site investigator). MTX-associated AEs 4 did not occur more frequently in the MTX group (Table 1).

**Acknowledgements:** Frequency (%) of individuals with good antibody response to COVID-19 vaccine

**Background:** Patients with rheumatoid arthritis (RA) may have impaired immunogenicity to COVID-19 vaccines.

**Objectives:** To investigate the incidence of COVID-19 infection and hospitalisation in unvaccinated and vaccinated patients with RA compared with matched individuals; and secondarily in patients with RA according to DMARD treatment.

**Methods:** Danish nationwide matched cohort study from January to October 2021. Patients with RA were identified in DANBIO and matched 1:20 with individuals from the general population on age, sex, and vaccination status (month and exact type of vaccination). Primary and secondary outcomes were COVID-19 hospitalisation (Danish National Patient Register) and positive SARS-CoV2 PCR test (Danish COVID-19 Surveillance Register), respectively. Stratified by vaccination status, incidence rates (IRs) per 1000 person years (PY) and comorbidity-adjusted hazard ratios (aHRs) in cause-specific Cox models were calculated with 95% confidence intervals. Using the Aalen-Johansen estimator, the cumulative incidence of COVID-19 hospitalisations was visualised according to RA and vaccine exposure status.

**Results:** Regardless of vaccination status, patients with RA had increased incidence of COVID-19 hospitalisation compared to matched individuals (Table 1). However, the absolute risk was 0.20% for unvaccinated patients at 60 days and 0.08% for comparators, whereas it remained below 0.05% at 180 days of follow-up in both groups when fully vaccinated (Figure 1). Increased SARS-CoV2 infection rates were seen only among unvaccinated patients with RA (Table 1). Unadjusted analyses showed increased incidence of COVID-19 hospitalisation among rituximab-treated compared with conventional DMARD treated: unvaccinated HR 4.71 (1.98 to 11.18) and vaccinated HR 11.69 (2.07 to 68.06). However, the proportions of patients with previous cancer and treated with prednisolone were higher among the rituximab treated.

**Conclusion:** The incidence of COVID-19 hospitalisation was increased for both unvaccinated and vaccinated patients with RA compared with controls. Importantly, the parallel decreasing risk for patients with RA suggests a comparable decrease in risk for vaccinated patients with RA.
relative benefit of vaccination. Less favourable outcomes among rituximab-treated patients with rheumatic diseases, such as vasculitis or systemic connective tissue diseases, early or during treatment, may impair response to vaccines, in particular those targeting B or T cells directly (1).

Objectives: The aim of this study is to evaluate the B and T-cell mediated immune response to mRNA vaccination in patients with systemic autoimmune diseases, such as systemic lupus erythematosus and other rheumatoid patients that needs to be further promoted. However, the immunosuppressive drugs used to treat rheumatic diseases may impair response to vaccines, in particular those targeting B or T cells directly (1).

Methods: Twenty-eight consecutive patients under treatment with rituximab (RTX, n=11) or belimumab (BEL, n=17) and 13 age/sex matched controls (non-rheumatic healthcare personnel) were enrolled in the study. Nobody presented anti-SARS-CoV-2 antibodies related to previous viral contact and all were negative at the molecular swab monthly control. All patients and controls received mRNA vaccines and were tested three to four weeks after complete vaccination. All RTX patients started vaccination within 5 months from the last infusion, and all but one of them were B-cell depleted. Anti-SARS-CoV-2 VBD total antibodies were analysed by a diagnostic assay (Elecys, Roche) while T-cell response was evaluated using the IGRA test (Euroimmun). A subgroup of BEL-patients was tested with pseudovirus neutralizing capacity in belimumab-exposed B cells, by comparing with controls and each other. Secondary we evaluated the in vitro effective neutralizing capacity in belimumab-exposed patients.

Results: Detectable anti-SARS-CoV-2 VBD antibodies were documented in 1/11 RTX patients versus 16/17 BEL patients (p<0.0001). The median concentration was significantly lower than that observed in controls (39.6 AU/ml vs 113 AU/ml, p<0.0001). A very low titer of anti-RBD antibodies were documented only in 1 out of 11 patients in the RTX subgroup (0.93 U/ml, positive if >0.79 U/ml) and the patient was the only one who showed an initial B-cell recovery (CD19+ B-cells 5 cells/µl). Anti-RBD antibodies were documented in 16 out of 17 patients in the BEL subgroup. The median anti-RBD antibody titer in patients receiving BEL was 243 (77.5-940.4) U/ml, and it was significantly lower compared to the controls (p=0.002).

The IGRA test was positive in 8/11 (72.7%) RTX patients vs 16/17 (94.1%) BEL patients (p=0.7), with interferon release comparable to controls subjects (p=0.2).

Six patients with BEL were also stratified according to total antibodies (lgG+IgA+IgM) against-RBD into high responders (>800 AU/ml, n=3) and low responders (≤45 AU/ml, n=3) and tested with pseudovirus neutralization assay. Two thirds of low titer group of patients treated with the Wuhan-Hu1 strain at medium-low titer (IC50 =102) but were almost ineffective in inhibiting the B.1.1.7 entry into target cells (IC50 =10). Regarding high responders, while two patients were able to inhibit both the strains at medium-high titer (approximately IC50 =103 for Wuhan-Hu1 and B.1.1.7), one patient neutralized only the WT strain.

Conclusion: B-cell targeting therapies do not preclude SARS-CoV-2 vaccination since a cellular immunity can raise even in the absence of circulating B cells. Most importantly, the immunogenicity of COVID-19 vaccination in SLE patients treated with belimumab is supported. However, patients showing the lowest humoral response to vaccine could remain at higher risk of infections, due to low neutralizing capacity.

REFERENCES:
Conclusion: Compared to no medication, some immunomodulatory therapies resulted in markedly lower Ab levels at all timepoints. In IRD patients, a past SARS-CoV-2 infection resulted in strikingly increased immunogenicity, as did mRNA-1273 (vs BNT162b2) increases with age. Interaction terms with medications: medication in combination th. vs medication as monoth.

Table 1. The OR of being above a given Ab threshold, regardless of the threshold. Ref. levels: mean age, no medication, no past SARS-CoV-2 inf., BNT162b2. Included in model but not shown: diagnosis, infrequently used medication (all non-signify.)

Objectives: To compare the persistence of anti-Spike antibodies following two SARS-CoV-2 vaccine doses between IMID patients using immunosuppressive medication and healthy controls and identify predictors of antibody decline.

Methods: We included patients with inflammatory joint- and bowel diseases on immunosuppressive medication and healthy controls enrolled in the prospective observational Nor-VaC study. Serum samples were collected at two time points following two dose SARS-CoV-2 vaccination (first assessment within 6–48 days and second within 49–123 days). Sera were analysed for antibodies binding the receptor-binding domain (RBD) of the SARS-CoV-2 Spike protein. Anti-RBD <200 BAU/ml were defined as low levels. The estimated percent reduction in anti-RBD standardised to 30 days was calculated and factors associated with reduction were identified in multivariable regression models.

Results: A total of 1097 patients (400 rheumatoid arthritis, 189 psoriatic arthritis, 189 spondyloarthritis, 129 ulcerative colitis, 190 Crohn’s disease) (median age 54 years [IQR 35–58]; 83% women) and 133 controls (median age 45 years [IQR 35–56]; 56% women) provided blood samples within the defined intervals (median 19 days [IQR 15–24] and 97 days [86–105] after second vaccine dose). Antibody levels were significantly lower in patients compared to controls at both assessments, with median anti-RBD 1468 BAU/ml [IQR 500–5062] in patients and 5514 BAU/ml [2528–9580] in controls (p<0.0001) and 298 BAU/ml [IQR 28–2870] in controls (p<0.0001), at first and second assessment respectively. Figure 1 show antibody levels at both assessments after medication group. At the second assessment, anti-RBD antibody levels decreased below 200 BAU/ml in 452 (41%) patients and in 1 (0.8%) control (p<0.0001) (Table 1). The percentage change in anti-RBD levels were -86 % in patients and -77 % in controls (p<0.0001). The majority of patients using rituximab had low antibody levels at both assessments, Figure 1. In the multivariable regression analysis, patients had a greater decline in anti-RBD levels compared to controls \(\beta_{-6.4} \) (-8.4, \(-7.2\)) respectively (p<0.001). Use of tumor necrosis factor inhibitors in mono- or combination therapy was associated with the greatest decline compared to controls, \(\beta_{-8.4} \) (-8.4, \(-6.2\)) respectively (p<0.001).

Conclusion: Within four months after the second vaccine dose, anti-Spike antibody levels declined considerably in both IMID patients and controls. Patients had lower antibody levels at the first assessment and a more pronounced decline compared to controls, and were consequently more likely to have low antibody levels four months after the second vaccine dose. Our results support that IMID patients lose humoral protection and need additional vaccine doses sooner than healthy individuals.

OP0177 IMMUNOGENICITY INDUCED BY TWO AND THREE DOSES OF THE BNT162B2 mRNA VACCINE IN PATIENTS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES AND IMMUNOCOMPETENT CONTROLS: A LONGITUDINAL MULTI-CENTER STUDY

Eliakham14, 1Tel Aviv Sourasky Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Rheumatology, Tel Aviv-Yafo, Israel; 1Tel Aviv Sourasky Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Allergy and Clinical Immunology Unit, Department of Medicine, Tel Aviv, Israel; 2Hadassah University Hospital, Rheumatology, Jerusalem, Israel; 1Tel Aviv Sourasky Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Carmel Medical Center, Rheumatology, Haifa, Israel

Background: Data on the kinetics of the immune response to SARS-CoV-2 vaccination in patients with autoimmune inflammatory rheumatic diseases (AIIRD) are limited.

Objectives: To evaluate the kinetics of the immune response induced by two and three doses of the BNT162b2 mRNA vaccine in adult patients with AIIRD and immunocompetent controls.

Methods: A prospective multicenter study investigated the antibody response to the BNT162b2 vaccine by serial measurement of serum anti-SARS-CoV-2
S1/S2 IgG titers at the following time points: 2-6 weeks (AllRD n=720, controls n=122) and six months (AllIRD n=628, controls=116) after the second vaccine dose, and 2-6 weeks after the third vaccine dose (AllIRD n=169, controls n=45). A seropositive response was defined as a detectable anti-S1/S2 IgG titer ≥ 15 BAU/ml. T-cell immune response was evaluated in a sample of patients (n=28) and controls (n=9) by intracellular staining of S-stimulated CD4+ T-cells for TNFα and IFNγ production.

**Results:** The two-dose vaccine regimen induced a higher humoral response in controls compared to patients, as reflected by the post-vaccination seropositivity rates of 100% vs 84.72%, p=0.0001, and 96.55% vs 74.26%, p=0.001 at 2-to-6 weeks and at 6 months, respectively. The decline of S1/S2 IgG titers within six months was similar in controls and patients. Following the 3rd vaccine, the seropositivity rate increased to 80.47% and 100% in AllRD and control groups, p=0.0028, with a significantly higher increase of S1/S2 IgG titers in controls compared with AllIRD patients, 284.09±76.58 vs 219.39±15.65 BAU/ml, p=0.0016. At all-time points, S1/S2 IgG titers were significantly lower in AllRD patients compared with controls (Figure 1).

We further investigated the impact of therapies on the vaccine’s immunogenicity (Figure 1). Glucocorticoids (GC) were associated with a significantly lower seropositivity rate and lower S1/S2 IgG titers compared to controls at all time points. Monotherapy with methotrexate (MTX) was associated with a comparable to controls humoral response at all time points. Anti-cytokine biologics (TNFi, IL6i, IL17i) were associated with an initial high seropositivity rate, similar to controls, followed by a steeper decline at 6 months, 79.82% vs 96.55%, p=0.0001, and restoration of seropositivity after the 3rd vaccine dose in all patients. JAKi were associated with a mildly decreased seropositivity rate after the 2nd vaccine dose and similar to controls response after the 3rd vaccine dose. Abatacept was associated with a reduced immunogenicity after the 2nd vaccine dose, but was restored to 100% seropositivity after the 3rd vaccine dose. Rituximab (RTX) significantly blunted the humoral response at all time points, with a seropositivity rate of 42% after the 2nd vaccine dose, 29% at 6 months, and with increase to 40% after the 3rd vaccine dose. A third of the RTX-treated patients who were seronegative after two vaccine doses, seroconverted after the 3rd dose. The multivariate model for predicting the seropositive response to vaccination found that higher S1/S2 IgG titers after the 2nd vaccine dose was associated with a higher seropositivity rate following the 3rd vaccine dose, OR 1.027 (1.008-1.045), p=0.0027, and that treatment with RTX was associated with a 14.3-fold risk for a negative humoral response, p=0.0001. Cellular immune response, evaluated mainly in RTX treated patients, was preserved prior to and after the 3rd vaccine dose and was similar to controls.

**Conclusion:** Over a six-month period, the two dose BNTb262 vaccination was associated with a similar extent of waning of the humoral immune response in AllRD patients and controls. The 3rd vaccine dose restored the response in all controls and in patients treated with MTX monotherapy, anti-cytokine biologics, abatacept, and JAKi. Treatment with GC and RTX was associated with an impaired humoral response at all time points.

**Background:** Concerns have been raised regarding risks of COVID-19 break-through infections in vaccinated patients with immune-mediated inflammatory diseases (IMIDs) treated with immunosuppressants, but data on COVID-19 breakthrough infections in these patients are still scarce.

**Objectives:** The primary objective was to compare the incidence and severity of COVID-19 breakthrough infections with the SARS-CoV-2 delta variant between fully vaccinated IMID patients with immunosuppressants, and controls (IMID patients without immunosuppressants and healthy controls). The secondary objective was to explore determinants of breakthrough infections.

**Methods:** In this study we pooled data collected from two large ongoing prospective multi-center cohort studies (Target to bi (T2Bi) study and ARC study). Clinical data were collected between February and December 2021, using digital questionnaires, standardized electronic case record forms and medical files. Post-vaccination serum samples were analyzed for anti-RBD antibodies (T2Bi study only) and anti-nucleocapsid antibodies to identify asymptomatic breakthrough infections (ARC study only). Logistic regression analyses were used to assess associations with the incidence of breakthrough infections. Multivariable models were adjusted for age, sex, cardiovascular disease, chronic pulmonary disease, obesity and vaccine type.

**Results:** We included 3207 IMID patients with immunosuppressants and 1810 controls (985 IMID patients without immunosuppressants and 825 healthy controls). The incidence of COVID-19 breakthrough infections was comparable between patients with immunosuppressants (5%) and controls (5%). The absence of SARS-CoV-2 IgG antibodies after COVID-19 vaccination was independently associated with an increased incidence of breakthrough infections (P=0.044). The proportion of asymptomatic COVID-19 breakthrough cases that were additionally identified serologically in the ARC cohort was comparable between IMID patients with immunosuppressants and controls; 66 (10%) of 695 patients vs. 64 (10%) of 647 controls. Hospitalization was required in 8 (5%) of 149 IMID patients with immunosuppressants and 5 (6%) of 86 controls with a COVID-19 breakthrough infection. Hospitalized cases were generally older, and had more comorbidities compared with non-hospitalized cases (Table 1).

**Hospitalization rates were significantly higher among IMID patients treated with anti-CD20 therapy compared to IMID patients using any other immunosuppressant (3% [23%] of 13 patients vs. 5% [4%] of 128 patients, P 0.041; Table 1).**

| Immunosuppressants– no. (%) | 34 (15) | 5 (39) |

**Conclusion:** The incidence of COVID-19 breakthrough infections in IMID patients with immunosuppressants was comparable to controls, and infections were mostly mild. Anti-CD20 therapy might increase patients’ susceptibility to severe COVID-19 breakthrough infections, but traditional risk factors also continued to have a critical contribution to the disease course of COVID-19. Therefore, we argue that most patients with IMIDs should not necessarily be seen as a risk group for severe COVID-19, and that integrating other risk factors should become standard practice when discussing treatment options, COVID-19 vaccination, and adherence to infection prevention measures with patients.

### Objectives:
To investigate the clinical profile of SARS-CoV-2 breakthrough infections among double and triple vaccinated patients with IRD.

### Methods:
Data from the German COVID-19-IRD registry, collected by treating rheumatologists between February 2021 and January 2022 were analysed.

Patients double or triple vaccinated against COVID-19 ≥14 days prior to proven SARS-CoV-2 infection were identified, and type of IRD, vaccine, immunomodulation, comorbidities and outcome of the infection were compared with 737 unvaccinated IRD-patients with COVID-19.

### Results:
In total, 271 cases of breakthrough infections were reported, 250 patients (91%) had received two doses of vaccines, 21 (9%) patients three. More than 70% of the patients received Pfizer/Biontech vaccine for the first, second and third vaccination. The median time from second/third vaccine dose to infection was 148 days (range 14-302) days. Most of the patients were diagnosed with inflammatory joint diseases (Table 1). Most of the patients were treated with methotrexate (Table 1). The use of Januskinase inhibitors(i) was more frequently reported in double vaccinated patients (10.4% vs 4.8%), whereas tumor necrosis (TNF)i were reported more often in triple vaccinated patients (33.3% vs 22.8%). Hospitalisation rate was higher in unvaccinated IRD-patients than in vaccinated ones, while mortality rate was similar in unvaccinated and double vaccinated patients. Although the rate of comorbidities and median age were higher in triple-vaccinated patients, infected patients showed a lower rate of hospitalisation, neither COVID-19 related complications, nor the need of oxygen treatment or death.

### Conclusion:
In this cohort of triple-vaccinated IRD patients no fatal courses and no COVID-19 related complications were reported, although median age and rate of comorbidities were higher compared to double-vaccinated and unvaccinated patients. These results support the general recommendations to reduce the risk of severe COVID-19 disease by administering three doses of vaccine, especially in patients with older age, presence of comorbidities, and on immunomodulatory treatment.

OP0180
EFFECT OF AVACOPAN ON RELAPSE RATES AND RELAPSE-FREE TIME IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS, RESULTS OF THE PHASE 3 ADVOCATE STUDY

P.A. Merkel1, H. Yue2, E. deGoma2, P. Bekker2, D. Jayne3. 1University of Pennsylvania, Division of Rheumatology, Philadelphia, United States of America; 2ChemoCentryx, Clinical, San Carlos, United States of America; 3University of Cambridge, Department of Medicine, Cambridge, United Kingdom

Background: For patients with ANCA-associated vasculitis, both failure to achieve remission and relapse after achieving remission are associated with worse long-term outcomes. Avacopan, an oral selective inhibitor of the C5a receptor, is approved for the treatment of ANCA-associated vasculitis. The phase 3 ADVOCATE study tested daily avacopan as a substitute for a standard oral glucocorticoid taper regimen. At week 26, the avacopan group achieved a remission rate (72.3%) comparable to the prednisone group (70.1%) and superior sustained remission at Week 52 (65.7% avacopan vs. 54.9% prednisone groups, respectively [1]). The median (mean) total glucocorticoid dose from all sources was 400 mg (1349 mg) in the avacopan group versus 2939 mg (3655 mg) in the prednisone group, representing 86% (83%) lower glucocorticoid exposure in the avacopan group. Compared with the prednisone group, the avacopan group showed a reduction in the proportion of patients who relapsed after achieving remission and, among patients who achieved remission, a longer time to relapse (1).

Objectives: To further characterize efficacy, additional post-hoc analyses compared the avacopan and prednisone groups regarding i) failure to achieve remission and ii) relapse after achieving remission.

Methods: ADVOCATE, a phase 3, randomized, double-blind, controlled trial in 330 patients, evaluated the efficacy and safety of avacopan. Patients with ANCA-associated vasculitis (new-onset or relapsing disease) were randomized to receive avacopan 30 mg twice daily, or a standard 20-week oral glucocorticoid taper regimen. At week 26, the avacopan group achieved a remission rate (72.3%) comparable to the prednisone group (70.1%) and superior sustained remission at Week 52 (65.7% avacopan vs. 54.9% prednisone groups, respectively [1]). The median (mean) total glucocorticoid dose from all sources was 400 mg (1349 mg) in the avacopan group versus 2939 mg (3655 mg) in the prednisone group, representing 86% (83%) lower glucocorticoid exposure in the avacopan group. Compared with the prednisone group, the avacopan group showed a reduction in the proportion of patients who relapsed after achieving remission and, among patients who achieved remission, a longer time to relapse (1).

Discussion of Interests: Peter A. Merkel Consultant of: AbbVie, AstraZeneca, Boehringer-Ingelheim, Bristol-Myers Squibb, ChemoCentryx, CSL Behring, Dynacure, EMDSerono, Forbius, Genentech/Roche, Genzyme/Sanofi, GlaxoSmithKline, Immagene, InfraRx, Janssen, Kiniksa, Kyverna, Magenta, MiroBio, Neutrolis, Novartis, Pfizer, Regeneron, Sparrow, Takeda, Talaris.

Conclusion: In the phase 3 ADVOCATE study of ANCA-associated vasculitis, more patients in the avacopan group compared to the prednisone group achieved remission, and fewer in the avacopan group relapsed after achieving remission. Patients receiving avacopan had a longer relapse-free time compared to the prednisone group. These post-hoc sensitivity analyses provide additional evidence of the efficacy of avacopan for the treatment of ANCA-associated vasculitis.

REFERENCES:

Background: Polymyalgia rheumatica (PMR) is a common inflammatory rheumatic disease in the elderly characterized by proximal muscular pain and stiffness. Although PMR is associated with systemic inflammation, prolonged glucocorticoid therapy and probably cardiovascular diseases, previous studies have not shown increased mortality. However, the number of studies is limited.

Objectives: The aim of this study was to determine whether PMR is associated with increased mortality in a large PMR cohort followed prospectively for a period of 35 years.

Methods: All patients diagnosed with PMR according to the criteria of Bird between 1987 and 1997 in the county of Aust-Agder, Southern Norway, were identified. Further details about the inclusion process have been published previously [1]. Patients in the prospective part of this study were followed until death or December 31, 2021. Standard mortality ratios (SMR) were calculated using population data (age- and gender-matched) from Statistics Norway as reference. Difference in survival between men and women was estimated using the Kaplan-Meier method. The study was approved by the regional ethics committee.

Results: A total of 296 patients were included. Among these were 200 (67.6%) females, and the mean age at diagnosis was 71.9 (SD 8.4). The vast majority, 277 patients (93.6%), were deceased at the censoring date of December 31, 2021. Mean observation time for all patients was 13.8 years (95% CI 12.8-14.7). The overall SMR was 1.05 (95% CI 0.93-1.18), for females 1.14 (95% CI 0.99-1.31) and for men 0.91 (95% CI 0.73-1.11). SMRs and mean survival times are presented in Table 1. The Kaplan-Meier survival curve showed no pronounced difference in survival between men and women (Figure 1).

10 years 788 36 4.36 0.82 0.59-1.13
25 years 1272 83 88.57 0.94 0.75-1.16

Women
2 years 392 11 12.76 0.86 0.45-1.50
5 years 934 32 35.80 0.89 0.62-1.25
10 years 1678 68 74.03 0.92 0.72-1.16
25 years 2687 172 156.21 1.10 0.95-1.28

*Years*: refer to calculated survival time from date of diagnosis; *Observed*: number of deaths in the PMR cohort; *Expected*: number of expected deaths in age-matched, sex-matched, and year-matched background Norwegian Population.

Conclusion: To our knowledge, this is the first prospective study following a large PMR cohort from diagnosis to death. In women, overall mortality (SMR) was increased compared to the general Norwegian population. This tendency to increased mortality in women was observed during the last decades of the study period. Furthermore, increased SMR was observed in patients aged <60 at time of diagnosis and in men the first 2 years after diagnosis, although with wide confidence intervals due to the limited number of deaths in these subsets.

**SECUKINUMAB IN GIANT CELL ARTERITIS: THE RANDOMISED, PARALLEL-GROUP, DOUBLE-BLIND, PLACEBO-CONTROLLED, MULTICENTRE PHASE 2 TITAN TRIAL**

N. Venhoff[1], W. A. Schmidt[2], R. Bergner[3], J. Rech[3], L. Unger[3], H. P. Tony[4], M. Mendelsson[5], C. Sieder[6], M. Maricots[7], J. Thiel[8], Vasculitis Center Freiburg, Medical Center - University of Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; Immunmanuel Krankenhaus Berlin, Medical Center for Rheumatology Berlin-Buch, Berlin, Germany; Klinikum der Stadt Ludwigshafen, Medizinische Klinik A, Ludwigshafen, Germany; Friedrich-Alexander Universität (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Germany; Städtisches Klinikum Dresden, Medical Department 1, Dresden, Germany; Rheumatology and Clinical Immunology Oberduerrbachtstr, Department of Medicine 2, Wuerzburg, Germany; Novartis Pharmaceuticals Corporation, Rheumatology, New Jersey, United States of America; Novartis Pharma GmbH, Rheumatology, Nuernberg, Germany; Medical University of Graz, Division of Rheumatology and Immunology, Department of Internal Medicine, Graz, Austria

Background: Little is known about glucocorticoid-sparing agents in giant cell arteritis (GCA) except for IL-6 inhibition. Secukinumab (SEC) has shown significant improvements in the signs and symptoms of IL-17A driven medical conditions such as plaque psoriasis, psoriatic arthritides, and axial spondyloarthritis. It has a favourable long-term safety profile.[1,2] Objectives: TITAN is the first randomised controlled trial investigating the potential efficacy, safety, and tolerability of SEC in GCA patients (pts).

Methods: This phase 2, randomised, double-blind, placebo (PBO) controlled, multicentre, proof-of-concept trial enrolled pts (aged ≥50 years) with new onset (diagnosed within 6 weeks (wks) of baseline) or relapsing (diagnosed >6 wks from baseline) GCA, naïve to biological therapy. Pts were randomised (1:1 to SEC 300 mg or PBO initially administered wks 1 and 4 wks thereafter). The efficacy endpoint was 52 wks of continuous treatment. The primary endpoint was a Bayesian analysis of the proportion of pts with sustained remission until Wk 28. The secondary endpoints included time to first GCA flare after baseline, and proportion of pts with withdrawal due to adverse events (AEs) during the study period.

Results: Out of 52 randomised pts (SEC n=27; PBO n=25), 71.2% (n=37) completed study treatment (SEC, 81.5%; PBO, 60.0%). Overall, 42 (80.8%) pts had new onset GCA and 10 (19.2%) pts had relapsing GCA at baseline. Proportion (posterior median with 95% credibility interval) of SEC pts in sustained remission until Wk 28 was higher with SEC, 70.1% (51.6%-84.9%), than with PBO, 20.3% (12.4%-30.0%); odds ratio (posterior median with 95% credibility interval), 9.31 (3.54-26.29) (Table 1). Until Wk 52, proportion (95% confidence interval) of GCA pts with sustained remission was 59.3% (38.8%-77.6%) in SEC group and 8.0% (1.0%-26.0%) in PBO group (Table 1). Median (95% credible interval) time to first GCA flare after baseline was not reached for GCA pts treated with SEC and was 197.0 (101.0-280.0) days for PBO (Figure 1). Overall, treatment-emergent adverse events (AEs) occurred in 98.1% (SEC vs PBO, 100.0% vs 96.0%). Two pts in each SEC and PBO groups had AEs that led to study drug discontinuation and 1 pt in each group had AEs that led to death (not treatment-related). There were no new or unexpected safety signals identified with SEC treatment.

Table 1. Proportion of GCA patients with sustained remission (Full analysis set) until Week 28 and 52

<table>

</tbody>
</table>

The full analysis set comprises all pts to whom study treatment has been assigned by randomisation and who received at least one dose of randomised study treatment (secukinumab or placebo). GCA, giant cell arteritis; N, number of pts in each treatment group in the full analysis set, pts, patients; Wk, Week.

*Figure 1. Kaplan-Meier survival curve.*
Conclusion: SEC demonstrated a higher sustained remission rate and longer time to first GCA flare vs PBO through 52 wks in pts with GCA. This proof-of-concept phase 2 study supports further development of SEC as a potential treat-
ment in combination with 26 wk glucocorticoid taper for pts with GCA.

OP0183 VALIDITY OF THE EULAR RECOMMENDATIONS ON THE USE OF ULTRASOUND IN THE DIAGNOSIS OF GIANT CELL ARTERITIS

E. Fernández-Fernández1, I. Monjo1, D. Peiteado1, A. Balisa1, E. de Miguel1, 1La Paz University Hospital, Rheumatology, Madrid, Spain

Background: The EULAR recommendations for the use of imaging in large ves-
sel vasculitides establish that an imaging test supported by clinical pre-test proba-
bility (PTP) is sufficient for the diagnosis of giant cell arteritis (GCA).

Objectives: To determine the validity of the EULAR recommendations on the use of Colour doppler ultrasound (CDUS) in GCA after calculating the PTP based on the Southern pre-test probability score (SPTPS).

Methods: We collected data of all patients referred to our fast-track clinic between 2016 and 2020. The SPTPS was calculated and classified as low (LR), intermediate (IR) and high risk (HR) according to the values obtained by its authors, <9, 9-12 and >12, respectively. All patients underwent a CDUS of the temporal arteries with their common, parietal and frontal branches, and the most also axillary (86.5%), subclavian and carotid arteries. Other diagnostic tests were performed when deemed necessary by the responsible physician. TAB was performed in 34 patients (11.4%), PET-CT in 48 (16.2%) and other imaging tests such as AngioMRI or AngioCT in 8 (2.7%). The gold standard diagnosis was made according to the physician's criteria after at least nine months of follow-up.

Results: Of the 297 referred patients, 97 (32.7%) were diagnosed with GCA. The SPTPS area under the ROC curve was 0.787. The LR category included 105 patients (35.4%), of which 10 (8.5%) had GCA. The LR category included 125 patients (42.1%), 40 with GCA (32%) and 85 without (68%). The HR category included 67 patients (22.5%), 47 with GCA (70.1%). In 4 of the 97 patients with GCA, the CDUS was negative and the diagnosis was confirmed with PET-CT. On the other hand, 6 of the 200 included patients without GCA (3%) had a false positive result of CDUS.

There were 93 patients classified as LR with negative CDUS, and 1 of them had a final clinical diagnosis of GCA. Of the 46 patients classified as HR with positive CDUS, 1 was a false positive diagnosis of GCA. And, within the IR group, of the 84 patients with negative CDUS one had a final GCA diagnosis and of those with positive CDUS 2 were not GCA (Figure 1). Therefore, the combined use of SPTPS + CDUS only misclassified 5/297 cases (<2%).

OP0184 PREVALENCE OF SUBCLINICAL GIANT CELL ARTERITIS IN PATIENTS WITH POLYMyalgia Rheumatica

E. de Miguel1, P. Macchioni2, E. Conticini3, C. Campochiaro4, R. Karalilova5, S. Monti6, C. Ponte7, G. Klinowski8, I. Monjo9, P. Falsettì9, A. Tomelleri4, Z. Batalova9, A. Hocevar9 on behalf of GCA/PMR study group, 1Hospital Universitario La Paz, Rheumatology, Madrid, Spain; 2Department of Rheumatology, IRCCS-S.Maria Nuova, Rheumatology, Reggio Emilia, Italy; 3Department of Medicine, Surgery and Neurosciences, University of Siena, Rheumatology, Siena, Italy; 4Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnitRAR), San Raffaele Scientific Institute, Rheumatology, Milan, Italy; 5Medical University of Plovdiv, University Hospital Kaspela, Rheumatology, Plovdiv, Bulgaria; 6IRCCS Policlinico S Matteo Fondazione, University of Pavia, Rheumatology, Pavia, Italy; 7Hospital de Santa Maria, Centro Hospitalar Universitario Lisboa Norte EPE, Rheumatology, Lisboa, Portugal; 8Department of Rheumatology, IRCCS-S.Maria Nuova, Rheumatology, Emilia Romagna, Italy; 9University Medical Centre Ljubljana, Rheumatology, Ljubljana, Slovenia

Background: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are closely related diseases. PMR occurs in approximately 50 % of patients with GCA, however the prevalence of subclinical GCA in PMR has not yet been widely studied.

Objectives: The aim of our multicenter, prospective study was to determine the prevalence of subclinical GCA in newly diagnosed PMR, using vascular ultra-
sound (US) as a diagnostic tool.
Methods: Eight European centers participated in the study. The studied cohort represented consecutive newly diagnosed patients with PMR who fulfilled 2012 EULAR/ACR Provisional Classification Criteria for Polymyalgia Rheumatica without symptoms or signs suggestive for GCA. All patients underwent ultrasound (US) of both hips and shoulders, as well as four bilateral arterial territories (i.e. temporal, common carotid, subclavian and axillary arteries). Patients with positive halo signs were considered to have subclival GCA. An inima-metal thickness ≥0.34 mm for frontal and parietal TA, 0.42mm for common TA, and ≥1 mm for common carotid, axillary and subclavian arteries for positive result. Clinical demographic and laboratory characteristics of the PMR pure group were compared with the PMR/GCA patient group.

Results: A total of 258 patients were included, 137 (53.1%) females with a mean age of 73±8.4 years. Table 1 shows the main differences in PMR patients with and without subclinical GCA. The only statistical significant difference between the two groups was the higher prevalence of morning stiffness > 40 minutes in the pure PMR group (p=0.05). A halo sign was found on least one of the examined arteries in 56/258 patients (21.7%). The different subtypes of vessel involvement were available in 216 cases. Data compatible with the diagnosis of GCA was found in 41 cases (19%): 10 (24.3%) had only temporal artery involvement (“cranial” GCA), 27 (65.8%) had a mixed form with both cranial and extra-cranial arteries in 56/258 patients (21.7%).

Figure 1. Subtypes of subclinical GCA in PMR in 216 patients with cranial and extra-cranial examination

Conclusion: One fifth of PMR patients without symptoms or signs of GCA have ultrasound findings consistent with the diagnosis of GCA. Subclinical GCA in PMR shows a predilection for extra-cranial artery involvement.

Figure 1. Clinical Trial Schema

Results: Between 11/2018 and 11/2020 we enrolled 30 patients (mean age 74 years, 60% females, 50% new-onset disease, 77% temporal artery biopsy-proven, 47% imaging-proven). The mean ESR and C-reactive protein (CRP) at screening were 45 mm/hour and 48 mg/L respectively. The initial prednisone dose was 60 mg (n = 7), 50 mg (n = 1), 40 mg (n = 7), 30 mg (n = 6) and 20 mg (n = 9). All patients entered remission within 4 weeks of baseline. The primary endpoint was achieved by 23 (77%) patients (Table 1). The mean (SD) cumulative prednisone dose in these 23 patients was 1052 (390) mg. After a mean period of 16 weeks, 7 (23%) patients relapsed (Table 1). All relapses but one occurred after the completion of the study prednisone taper. Overall, 6 of the 7 patients with relapse received a second prednisone taper over 8 weeks. Of these 6 patients, 4 achieved and maintained remission for the remainder of the trial period, and 2 withdrew from the study after having a second relapse. One patient with relapse received a second prednisone taper over 26 weeks and stayed in remission until the end of the study. The mean (SD) cumulative prednisone dose in the 7 patients with relapse was 1883 (899) mg (Table 1). Overall, 4 (13%) participants developed a serious adverse event (Table 1). No cases of ischemia-related visual symptoms including permanent vision loss occurred during the study.

Conclusion: These results suggest that 12 months of TCZ in combination with 8 weeks of prednisone could be efficacious for inducing and maintaining disease remission in patients with GCA. Confirmation of these findings in a randomized controlled trial is required.

Disclosure of Interests: Sebastian Unizony Consultant of: Kiniksa, Sanofi, Janssen, GSK, Grant/research support from: Janssen, Genentech, Mark Matza: None declared, Adam Jarvie: None declared, Ana Fernandes: None declared, John H. SENSITIVITY TO CHANGE OF DIFFERENT ULTRASOUND SCORES IN A PROSPECTIVE FOLLOW-UP OF NEW-ONSET TREATMENT-NAÏVE GCA PATIENTS.

B. D. Nielsen1,2,3, P. Therkildsen2,3, K. Keller2,3, L. C. Gormsen4, I. Hansen2,3, E. M. Hauge2,3, 1The Regional Hospital Horsens, Department of Medicine, Horsens, Denmark; 2Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 3Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 4Aarhus University Hospital, Department of Nuclear Medicine and PET Centre, Aarhus, Denmark

Background: The role of ultrasound (US) for monitoring giant cell arteritis (GCA) is not clarified. Follow-up assessment of number of halos (halo count) and different quantitative scores based on intima media complex (IMC) measurement of halos, have demonstrated potential to show sensitivity to change (STC)1. Including IMC of normalized arteries in such scores may reduce the risk of missing new arteritic lesions and assessment bias towards a response. We aimed to evaluate US scores based on halo features and scores based on IMT measurements of all assessed arteries.

Objectives: To compare different US score’s 1) STC after institution of treatment and 2) correlation with disease activity.

Methods: In a prospective cohort of new-onset GCA patient, pre-treatment diagnostic evaluation including US and PET/CT and subsequently temporal artery biopsy (TAB) was performed per protocol. All patients were started on 60 mg of prednisolone and followed a routine tapering. Follow-up visits including clinical evaluation, blood tests, US, the physician’s and patient’s global NRS (0-10) were performed after 8 weeks, 24 weeks and in a subgroup (n=24) at 15 months. US of temporal, carotid and axillary arteries included assessment of halo and IMC measurement in all arteries.

For each visit, max IMC, max halo IMC, sum IMC, sum halo IMC, mean IMC and halo count were calculated for all and for temporal (TA) and large vessels (LV) separately. Accordingly, halo IMC scores only included positive arteries whereas other IMC scores included all arteries assessed.

The change from baseline was assessed by Student’s t-test. Standard response means (SRM=mean(visit-baseline)/SE Δ) were computed for each timepoint as STC estimates. Correlation with disease activity markers was assessed by Spearman’s correlation. A p<0.05 was considered statistically significant.

Results: In total 47 patients were included (60% women, mean (CI) age 67 (62-69) years, mean (CI) CRP 75 (63-89)). Baseline US was positive(+) in 94% (72% TA+, 72% LV+), PET/CT in 96% (77% cranial arteries, 85% large vessel vasculitis) and TAB+ in 72% of patients. All patients completed the per protocol planned follow-up visits. Two patients experienced a relapse at week 8 and 10 patients at week 24. All US outcomes improved during follow-up and was apparent by week 8 (Table 1) and forward. However, only scores including TA consistently showed statistically significant change from baseline to follow-up. In accordance the magnitude of change as expressed by SRM was large in TA, whereas SRM in LV was small (Figure 1).

All TA based US scores showed significant moderate-strong correlation with disease activity markers (CRP, patient and physician global NRS). Some LV based US scored showed weak correlation with CRP but otherwise did not correlate with clinical disease activity.

Table 1.

Table: US score changes during follow-up

Methods: Patients with a diagnosis of TAK, attending our clinics between Jan 2000 and May 2019 were identified. Those who satisfied either ACR or Sharp’s classification or ULEAR PRINTO PRES criteria and/or had angiographic evidence of Takayasu’s arteritis with a minimum 2 follow up visits were included. Patients who received upfront biologics were excluded. The patients were matched for parameters statistically different among three groups using propensity score analysis. Clinical details at the index visit defined as the time of initia- tion of first IS and follow up visits were prospectively recorded and retrospectively noted from electronic medical records. The primary outcomes were attainment of complete remission and relapses. Disease activity was assessed by Indian Takayasu arteritis score (ITAS), C-reactive protein and angiograms. Relapse was defined as ITAS-Δ (CRP) ≥ 2 and/or progression in angiograms and/or escalation of steroid dose and/or switching of IS due to active disease. The baseline variables of patients receiving AZA, MMF and MTX were compared using chi square test or Mann Whitney U test. The comparative efficacy of IS to induce complete remission was calculated using logistic regression and presented as odds ratio (95% CI). The cumulative risk of relapse was calculated using Cox-proportional hazards model with hazards ratio and 95% confidence interval (CI) after adjusting for duration of symptoms and juvenile onset disease. The patients were censored at the time of relapse or time of switching to another IS or last follow up whichever was the earliest. ARA was arbitrary chosen as the reference drug for all the analysis. The missing values (visits) were not included in analysis and the last observation was carried forwards. Data after switching of immuno-suppressant of interest till the last follow up visit was analysed descriptively. All analysis were done for matched and unmatched patient groups. The results of matched and unmatched cohort were similar, hence the results of unmatched groups are presented here.

Results: Overall, 234 patients satisfying inclusion criteria including 53 (22.6%), 156 (66.7%) and 25 (10.7%) patients receiving AZA, MMF, MTX respectively were studied. Complete remission (CR) was attained in 183 (78.2%) patients after initiating steroids and IS. 79.2%, 77.6% and 80% of patients receiving AZA, MMF or MTX respectively achieved CR yielding an odds ratio of 1.10 (0.52-2.37), p= 0.80 and 0.96 (0.29-3.12), p= 0.94 for MMF and MTX as compared with AZA. CR was sustained in 22 (52.4%), 80 (66.1%) and 11 (55%) of patients on AZA, MMF and MTX respectively. When compared with AZA, adjusted hazards ratio (AHR) of relapse was 1.51 (0.79-2.89), p=0.21 and 2.45 (1.00-5.99), p= 0.05 with MMF and MTX after adjusting for juvenile onset disease, type 1 and type 4 disease by angiography. The frequency of remission in patients who received MMF was significantly higher in patients who presented with type 4 disease (96%) as compared with the patients who had other types on angiography (74%), p=0.017. Conversely, 63.6% of patients with type 1 disease responded to MMF which was significantly lower than 81.3% of patients with other angiographic types (p=0.037) while no such differential response was observed for A2A or MTX. Treatment of steroid dose and/or switching of IS due to active disease. The baseline variables of patients receiving AZA, MMF and MTX were compared using chi square test or Mann Whitney U test. The comparative efficacy of IS to induce complete remission was calculated using logistic regression and presented as odds ratio (95% CI). The cumulative risk of relapse was calculated using Cox-proportional hazards model with hazards ratio and 95% confidence interval (CI) after adjusting for duration of symptoms and juvenile onset disease. The patients were censored at the time of relapse or time of switching to another IS or last follow up whichever was the earliest. ARA was arbitrary chosen as the reference drug for all the analysis. The missing values (visits) were not included in analysis and the last observation was carried forwards. Data after switching of immuno-suppressant of interest till the last follow up visit was analysed descriptively. All analysis were done for matched and unmatched patient groups. The results of matched and unmatched cohort were similar, hence the results of unmatched groups are presented here.

Conclusion: In our patients with TAK, all the three IS were comparable in inducing remission. Azathioprine was equal to MMF but superior to MTX in maintaining relapse free sustained response. The efficacy of MMF differed across various angiographic types of disease.

Active Ageing: new perspectives for RMD patients—

From childhood to adulthood - growing up with an RMD

NEW JIA-AT-NRAS RESOURCE MEDICINES IN JUVENILE IDIOPATHIC ARTHRITIS

D. Wilson1, 1National Rheumatoid Arthritis Society, JIA, Maidenhead, United Kingdom

Background: Biologics have been commissioned by the NHS for use to treat JIA since 2014. Many of the original biologics that were first developed have since lost exclusivity, allowing other manufacturers to produce highly similar versions (biosimilars). This difference between the originator and the biosimilar has caused confusion within the patient community, especially in how it has been communicated to them. Parents found the concept of biosimilars confusing and wanted more information about this, recommending that written material be provided. Previous conversations with healthcare professionals, parents and young people living with JIA had also found there was a lack of written information on all JIA medications so we looked into how this gap could be filled.

Objectives: Produce a new resource to clarify the confusion about the biosimilars and originators for the JIA patient community. Explain the different medications to treat JIA in a patient/parent friendly format so it can be easily referred
to. Easy to see the different categorisation of the medications e.g. pain management, DMARDS, biologics and targeting synthetic DMARDS and include information regarding how they are taken, how often and usage.

Methods: Knowing there was a need for this information, a focus group was convened with young people with JIA, parents of children with JIA and healthcare professionals. From this focus group and separate conversations with healthcare professionals it very quickly became apparent a resource not only covering medications for JIA but detailing the wider JIA journey was needed. This resource would need to cover each step from diagnosis to a young person taking control of their disease management. It would also cover how the complexity of the immune system means that some children/youth people respond differently to medication; help them to learn about the unpredictability of the disease and to take control of managing their disease, particularly as they move onto adult rheumatology services. NRAS worked collaboratively with health writer and healthcare professionals to make sure this new resource covered all the topics that were discussed at the focus group and detailed all the medications used to treat JIA, including information on the issue of differentiating between biologics and biosimilars.

Results: The medicines in JIA booklet is now freely available to all parents, young people and healthcare professionals from the jia.org.uk website. The addition of visuals makes the information easier to navigate, clearer to understand and helps to illustrate the JIA journey. Along with the medicine directory which details all the medications to treat JIA.

Conclusion: The feedback NRAS has received from both healthcare professionals and parents has been very positive:

“We think that they’re absolutely fantastic, they cover everything, and I’m so pleased I’ve got these to give to parents and children.” Paediatric Rheumatology Nurse Haywood Hospital

“This is brilliant and much needed. Great piece of work much appreciated by all of us.” Lead Nurse Nottingham Children and Young People’s Rheumatology Service

“This has been my absolute saviour! It gives you support on administering the medicines and made me feel right at ease after reading it”. Parent of child with JIA

Vaccination in rheumatic diseases with lessons from COVID

OP0192

SEREOLOGICAL RESPONSE AND SAFETY OF A THREE-DOSE SARS-COV-2 VACCINATION STRATEGY IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES ON IMMUNOSUPPRESSIVE THERAPY

I. Jysse1, A. T. Tverete1, J. Sexton1, I. E. Christensen1, T. T. Tran2, S. Mjaaland3, D. J. Warren4, T. K. Kvien5, K. H. Bjørlykke6, G. B. Kro7, J. Jahnsen5, L. A. Munthe8, E. A. Haavardsholm9, J. T. Vaage10, G. Grodeland10, F. Lund-Johansen11, S. Aarestad Provan11, K. J. Jørgensen12, G. L. Goll13, S. W. Syversen14, Dkakonhjemnet Hospital, Division of Rheumatology, Research, Oslo, Norway; 1Oslo University Hospital, Immunology, Oslo, Norway; 2Norwegian Institute of Public Health, Infectious Diseases and Immunology, Oslo, Norway; 3Oslo University Hospital, Department of Medical Biochemistry, Oslo, Norway; 4Akershus University Hospital, Gastroenterology, Larenosg, Norway; 5Oslo University Hospital, Microbiology, Oslo, Norway

Background: Patients with immune-mediated inflammatory diseases (IMIDs) on immunosuppressive therapy have an inadequate serologic response following two-dose SARS-Cov-2 vaccination, and a standard vaccination strategy of three doses for this patient group is currently under implementation in several countries. However, the serological response and safety of this strategy has not been evaluated.

Objectives: To assess serological response and safety of a three-dose vaccination strategy in IMID patients on immunosuppressive therapy as compared to standard two-dose vaccination of healthy controls.

Methods: The prospective observational NorVac study (NCT04798625) enrolled adult patients on immunosuppressive therapy for inflammatory joint- and bowel diseases. Healthy controls were health care workers from participating hospitals. All participants received standard vaccines according to the national vaccination program with three doses in patients and two doses in controls. The third dose was offered to IMID patients >4 weeks after the second dose. Analysis of antibodies binding the receptor-binding domain of the SARS-CoV-2 Spike protein was performed prior to, and 2-4 weeks after the second and third vaccine doses. Levels were compared across groups by Mann-Whitney U tests and multi-variate linear regression was used to identify predictors of response.

Results: Overall, 961 patients (315 rheumatoid arthritis, 156 spondyloarthritides, 171 psoriatic arthritis, 132 ulcerative colitis and 182 Crohn’s disease) (median age 54 years [IQR 43-64]; 56 % women) and 227 controls (median age 44 years [IQR 32-55]; 83 % women) were included in the present analyses. TNF monotherapy was used by 399 patients, 229 used TNF in combination with other immunomodulators, 189 methotrexate monotherapy, 39 vedolizumab, 32 JakI and 73 patients used other drugs. Patients on rituximab were not included. Patients were vaccinated with Pfizer BNT162b2 (54 % patients, 14 % controls), Moderna mRNA-1273 (16 % patients, 40 % controls) or a combination of vaccines (30 % patients, 46 % controls). Patients received the third vaccine, dose a median of 120 (IQR 102-143) days after the second dose. After two doses, median anti-Spike antibody levels were significantly lower in patients (861 BAU/ml [IQR 418-4275] than controls (6318 BAU/ml [IQR 2468-9857], p<0.001) (Figure 1). Following the third dose, patients achieved antibody levels comparable to the two-dose vaccinated controls (median 5480 BAU/ml [IQR 1081-12069], p=0.28) (Figure 1). In the patients anti-Spike antibody levels increased by a median of 2685 BAU/ml (IQR 265-9129) from the second to the third dose. Main factors associated with increased antibody level after the third dose were younger age (β -87.7 (p=0.002)), and vaccine status (mRNA-1273 vaccine (β 5549 (p<0.001)) or a combination of vaccines (β 43673 (p<0.001)). Adverse events were reported by 438 (48 %) of patients after the third dose as compared to 471 (54 %) after the second dose and 193 (78 %) of controls. Disease flares were reported by 42 (5 %) and 69 (8 %) patients after the second and third dose, respectively.

Conclusion: This study suggests that a third vaccine dose for immunosuppressed patients closes the gap in serological response between patients and
the healthy population. Antibody levels following the three-dose regimen in IMID patients were comparable to healthy controls vaccinated twice, and no new safety issues emerged. This finding was consistent across all diagnoses and treatment groups, supporting the implementation of a three-dose vaccine regimen as standard in the IMID population.

sJIA vs AOSD: Two names one disease? What have we learnt so far

OP0193

EFFICACY AND SAFETY OF EMAPALUMAB, AN ANTI-INTERFERON GAMMA MONOCLONAL ANTIBODY, IN PATIENTS WITH MACROPHAGE ACTIVATION SYNDROME (MAS) IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS (SJIA) WHO HAD FAILED HIGH-DOSE GLUCOCORTICOIDS

F. De Benedetti1, A. Grom2, P. Brogant, C. Bracaglia3, M. Pardeo1, G. Marucci1, D. Eleftheriou1, C. Papadopoulou1, P. Quartier1, J. Anton4, R. Frederiksen2, V. Asnaghi1, C. de Min1,1; Dipartimento Pediatrico Bambino Gesu’; RCCS, Division of Rheumatology, Rome, Italy; 2Cincinnati Children’s Hospital, Division of Rheumatology, Cincinnati, United States of America; 3Great Ormond Street Hospital NHS Foundation Trust, UCL Institute of Child Health, London, United Kingdom; 4Necker Hospital, Assistance Publique-Hôpitaux de Paris, Université de Paris, IMAGINE Institute, RAISE Reference Center, Pediatric Immuno-Hematology and Rheumatology Unit, Paris, France; 5University of Barcelona, Hospital Sant Joan de Déu, Division of Pediatric Rheumatology, Barcelona, Spain; 6Swedish Orphan Biovitrum AG (Sobi), Clinical Science, Basel, Switzerland

Background: MAS is a severe, life-threatening complication of rheumatic diseases that occurs most frequently in patients with SJIA. The mainstay of treatment for MAS is high dose glucocorticoids (GCs); however, GCs do not provide adequate control in all patients. Additional treatments are used without a standardized approach; however, morbidity and mortality remain high. Data from animal models of MAS and from observational studies in patients suggest that overproduction of IFNγ is a driver of the hyperinflammation observed in MAS; neutralization of IFNγ has been shown to reverse the signs and symptoms of MAS in murine models, and high IFNγ levels are strongly correlated with laboratory parameters of disease severity in patients.

Objectives: To assess the efficacy and safety of intravenous (IV) infusions of emapalumab, a fully human, anti-IFNγ monoclonal antibody, in patients with MAS in SJIA.

Methods: Open-label, single-arm, phase 2 study (NCT03311854) that included patients with MAS (2016 ACR/EULAR criteria) in SJIA who had failed high-dose IV GCs and other treatments. Emapalumab was initiated at a dose of 6mg/kg on Day 0 and continued at 3mg/kg every 3 days until Day 15, and then twice weekly until Day 28 to ensure rapid and complete IFNγ neutralization after initiating treatment. As per protocol, 10 infusions were planned over the 4 weeks; however, treatment could be shortened if MAS remission was achieved earlier, or extended if required to achieve remission. Complete resolution (CR) was defined as resolution of clinical signs and symptoms of MAS according to the investigator, and normalization of laboratory parameters relevant to MAS. All patients were followed up for 4 weeks after the last infusion of emapalumab and offered to enter a 1-year, follow-up study (NCT02689899).

Results: Fourteen patients (10 females) were enrolled (11 in Europe, 3 in the USA). Several patients had previously received cyclosporine A and/or anakinra, in addition to high-dose GCs. Six patients received emapalumab until Day 28. Seven patients discontinued emapalumab early due to MAS remission (as per investigator’s assessment); one patient received treatment up to Day 38. Emapalumab treatment rapidly neutralized IFNγ, as documented by CXCL9 levels. A CR was achieved by 13/14 patients during the study. One patient stopped emapalumab after 3 doses because of achievement of MAS remission as per investigator’s assessment, but lactate dehydrogenase levels remained >1.5× upper limit of normal. At Week 8, 11/14 patients had a CR; 2 achieved a CR during the study, but not at Week 8, because of a single laboratory parameter abnormality in each patient. Overall, all measured laboratory parameters related to MAS activity rapidly improved with emapalumab treatment. GCs were tapered in all patients by Week 8 (≥30% reduction, n=12; GC dose ≤1mg/kg/day, n=8). Administration of anakinra for the treatment of underlying SJIA was maintained/introduced during the study, as required. No patients discontinued treatment for safety reasons. One treatment-related serious adverse event was reported (cytomegalovirus reactivation that resolved with antiviral treatment). All patients entered the long-term, follow-up study and were alive at last visit.

Conclusions: Emapalumab administration led to rapid IFNγ neutralization, was efficacious in controlling MAS in all patients, and was well tolerated with a favorable safety profile. These results support the pathogenic role of IFNγ in MAS in SJIA and the therapeutic value of IFNγ neutralization in MAS patients who have failed high-dose GCs.

Autoinflammation over the course of a lifetime

OP0194

COMBINATION ANAKINRA AND TOCILIZUMAB TO TREAT REFRACTORY MACROPHAGE ACTIVATION SYNDROME TRIGGERED BY ADULT-ONSET STILL’S DISEASE.

E. Alveyn1, A. Rutherford1. King’s College London, Centre for Rheumatic Disease, Department of Immunology Biologics, London, United Kingdom

In this study, we assessed the efficacy and safety of emapalumab in a cohort of patients with SJIA who had failed high-dose GCs. We found that emapalumab rapidly neutralized IFNγ, achieved CR in 13 out of 14 patients, and was well tolerated with a favorable safety profile. These results support the pathogenic role of IFNγ in MAS in SJIA and the therapeutic value of IFNγ neutralization in MAS patients who have failed high-dose GCs.
Background: Adult-onset Still’s disease (AOSD) is associated with the development of macrophage activation syndrome (MAS) [1], sometimes termed secondary haemophagocytic lymphohistiocytosis (sHLH), a severe hyperinflammatory state with high mortality. Successful management of AOSD and MAS is contingent on early identification and treatment of the syndromes and any triggers, with aggressive immunosuppression in acutely unwell patients [2].

Objectives: To describe the case of a patient with newly diagnosed AOSD who developed severe MAS requiring ICU admission and immunosuppression with high-dose glucocorticoids, tocilizumab and anakinra.

Methods: Case report.

Results: A 24-year-old woman attended hospital with a 4 month history of fever, arthralgia, rash and later dry cough. She became hypoxic and was admitted to the ICU for ventilation and vasopressor support. Imaging revealed splenomegaly, pleural effusions and lung consolidation but there was no response to antibiotics and no clear evidence of infection. Cytomegalovirus (CMV) DNA was initially absent, with IgG avidity indicating prior exposure. Bloods confirmed significant inflammatory markers (CRP 107 mg/L, ferritin 6154 µg/L, ESR 477 mm/hr) without disordered haemostasis. A bone marrow aspirate showed no haemophagocytosis. After extensive investigation a diagnosis of AOSD was made given the fulfilment of the Yamaguchi criteria and absence of evidence of an alternative driver of inflammation.

The patient deteriorated further, with deranged liver chemistry, rising CRP, triglycerides and ferritin (>100,000 µg/L), and trilineage cytopenia raising concern for MAS. This was managed by treating the presumed trigger (AOSD) with intravenous methylprednisolone (IVMP, 3x 500mg then 32mg daily) and anakinra (100mg twice daily). She developed a CMV viraemia that progressed despite aciclovir and later ganciclovir, which was switched to foscarnet and CMV immunoglobulin. The viraemia then stabilised and improved.

Due to persistent pyrexia, tachycardia, and elevated inflammatory markers, further IVMP (3x250mg), increased anakinra doses (100mg IV TDS) and intravenous immunoglobulin (2x60g) were given. A repeat bone marrow biopsy was consistent with MAS and testing for HLA-associated genes was negative. The patient became increasingly hypoalbuminaemic and oedematous, developing acute kidney injury requiring continuous haemofiltration in the ICU. Anakinra was increased to 500mg daily in divided doses. The blood counts improved transiently, before the ferritin rose sharply again, with fevers and broad-spectrum antimicrobials continuing. Cytofine profile testing at this point revealed significant elevation in IL-1β and IL-6. Tocilizumab 8mg/kg fortnightly was added to existing therapy.

After tocilizumab initiation the inflammatory markers, blood counts and clinical state improved, though the patient remained hypertensive despite numerous antihypertensives. She left the ICU ten weeks after initial presentation. Corticosteroids and anakinra were weaned and she was discharged on tocilizumab monotherapy. Renal function did not return, and she continues outpatient haemodialysis.

Conclusion: The evidence base for effective therapies in MAS is poor. Reports exist of the use of either anakinra or tocilizumab [3] but not both agents in combination. In this case, cytofine blockade with both agents produced significant clinical improvement in a critically unwell patient.

Accepted Article
Background: Patients with fibromyalgia (FM) suffer from high symptom burden and few available treatments. EULAR evidence-based recommendations for the management of FM state that optimal management should focus on prompt diagnosis, patient education and non-pharmacological treatments. A recent systematic review of mindfulness- and acceptance-based interventions for patients with FM showed small to moderate beneficial health effects. We tested a 10-session group-based mindfulness- and acceptance-based intervention, the Vitality Training Programme, followed by low threshold physical exercise counselling in primary health care, compared to treatment as usual (TAU) for patients diagnosed with FM.

Objectives: To explore possible changes in health status in a group of FM patients, two years after participation in a multicomponent rehabilitation programme.

Methods: A total of 170 patients with confirmed FM diagnosis according to ACR 2011-criteria were randomised, 85 to intervention and 85 to control. Self-reported data were collected electronically at baseline, 3 and 12 months. There were no statistically significant health effects in any disease-related variables at 12 months. However, there were significant between-group differences in patients’ tendency to be mindful. All patients were asked to complete the same questionnaires two years after completion of the intervention group. Because the TAU-group had been offered the same programme after 12 months, only data from the intervention group was included in this study. Primary outcome was Patient Global Impression of Change (PGIC), scored as 1= much worse, through 4= no change, to 7=much better. Values 6 and 7 were considered clinically relevant improvement. Secondary outcomes were self-reported pain, fatigue, sleep quality, psychological distress, mindfulness, physical activity, motivation and barriers for physical activity, and work participation. Mean changes from baseline to two years were analysed by paired sample t-tests.

Results: Totally, 48 (56.5%) of the patients who had been randomised to the intervention group responded to the questionnaires, 94% female, median (range) age 47 (28 to 54), symptoms duration 12 (5 to 33) years. Only seven patients reported clinically relevant improvement on PGIC; 32 (67%) reported the change, to 7=much better. Values 6 and 7 were considered clinically relevant. The improvement seen in patients’ tendency to be mindful at 12 months was sustained (p=0.012). Only 58% of patients reported clinically relevant improvement on PGIC; 32 (67%) reported the change, to 7=much better. Values 6 and 7 were considered clinically relevant.

Conclusion: Two years after participation in a multicomponent rehabilitation programme comprising mindfulness and acceptance training and physical activity counselling, FM patients still reported high symptom burden and no improvement in their health status. The increased tendency to be mindful was not reflected in improvements in disease-related outcomes. It was not possible to compare groups (intervention and TAU), because the TAU-group had been offered the intervention before the two-years data collection. However, there was a worse-ening of symptoms, which might have been the case without any intervention.

OP0097

POST-TRAUMATIC STRESS DISORDER AND SYMPTOMS IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES DURING THE COVID-19 PANDEMIC: PRELIMINARY RESULTS FROM THE PERMAS STUDY

G. Fulvio1, V. Pedrinelli2, G. Andreozzi3, F. Treniti1, S. Fantasia2, S. Fonzetti1, C. Fustini2, M. Da Rio1, G. Cappellato2, C. Cigolini2, D. Schiliro1, M. Matti1, L. Scagnellato1, A. Valevich1, F. Fattorini1, I. C. Navarro Garcia1, I. Palla3, V. Lorenzoni1, A. Gaglio1, C. Carmassi2, C. Tani1, G. Turchetti1, L. Dell'Oss2, M. Mosca2, University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy; 2University of Pisa, Psychiatric Clinic, Department of Clinical and Experimental Medicine, Pisa, Italy; 3Institute of Management, Scuola Superiore SantAnna, Pisa, Italy

Background: The COVID-19 pandemic, with its uncertainties, fears of contagion, mass lockdowns and containment measures, has dramatically impacted on people’s everyday lives leading to an increased risk of mental disorders, particularly Post-Traumatic Stress Disorder (PTSD). Despite evidence in general population and healthcare workers, scant data emerged on vulnerable populations, such as patients with chronic diseases, particularly rheumatic and musculoskeletal diseases (RMDs), who also encountered difficulties in the management and treatment of their disorders.

Objectives: To assess PTSD and post-traumatic stress symptoms in a sample of patients with RMDs, during the COVID-19 pandemic in Italy.

Methods: PERMAS is a monocentric prospective observational study led by the Rheumatology Unit, the Psychiatric Clinic and the Institute of Management of the School of Advanced Studies. Patients with a RMD diagnosis, consecutively enrolled from May 2021 to January 2022. In the visit, sociodemographic characteristics and psychopathological data were collected through online survey, whereas clinical data were collected by physician. The survey included the Trauma and Loss Spectrum- Self Report (TALS-SR) and the Impact of Event Scale- Revised (IES-R), aimed to assess symptomatological PTSD and post-traumatic stress symptoms related to the impact of the COVID-19 pandemic.

Results: A total of 194 eligible patients, with a mean age of 50.3±12.17 years, was included: 142 (73.19%) were females; 112 (57.74%) patients reported connective tissue diseases (CTD), 63 (32.47%) arthritis and 19 (9.8%) vasculitis. A total of 33 (17%) subjects reported a symptomatological PTSD by means of the TALS-SR. The prevalence of Partial PTSD (defined by at least 2 out of the 4 criteria for DSM-5 diagnosis of the disorder) was 56.7%, with significant higher rates among females (90, 81.8%) with respect to males (20, 18.2%) (p=.013). Accordingly, a IES-R mean total score of 21.90 ± 15.98 was found in the total sample and a gender difference emerged, with higher mean scores among females rather than males (23.42 ± 16.26 vs 21.90 ± 15.98, p=0.031).

Conclusion: The present findings point out high prevalence rates of symptomatological PTSD among patients suffering from RMDs, highlighting the potentially traumatic burden of the COVID-19 pandemic in this particular population, especially among females, suggesting the need of further investigations to address tailored prevention and intervention strategies.

OP0198-HPR DEVELOPMENT OF AN INTERDISCIPLINARY NURSE-COORDINATED SELF-MANAGEMENT INTERVENTION (INSELMA) FOR PATIENTS WITH INFLAMMATORY ARTHRITIS

J. Prindahl1,2,3, K. M. Latocha1, A. Bremander1,2,5, O. Hendriks1,2, M. Østergaard1,2, L. Andersen6, K. V. Jensen6, B. A. Esbensen5,7,1 University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 2Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark; 3Sønderborg Sygehus, University Hospital of Southern Denmark, Aabenraa, Denmark; 4Patient research partner, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital - Rigshospitalet, Glostrup, Copenhagen, Denmark; 5Lund University, Department of Clinical sciences, Lund, Sweden; 6Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Glostrup, Glostrup, Denmark; 7University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; 8Patient research partner, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark

Background: Up to 30% of patients with inflammatory arthritis (IA) do not respond sufficiently or tolerate the pharmacological treatment. Consequently, they may experience a substantial impact of their arthritis in everyday life. Even patients in remission or low disease activity state are at risk of substantial arthritis related symptoms and burden. These patients may need coherent interdisciplinary self-management support to manage symptoms and life with the chronic condition to increase their quality of life. A previous EU-ILAR review on the effectiveness of self-management interventions in patients with IA (1) found that well-structured self-management programmes were lacking or were poorly reported.

Objectives: This study aimed to develop a nurse-coordinated interdisciplinary self-management intervention, delivered in routine clinical care, for patients with inflammatory arthritis and with a substantial impact of their arthritis to support their self-management ability.

Methods: The study was planned across two Danish hospitals following the British Medical Research Councils (MRC) framework for developing and evaluating Complex Interventions (2). The development process consisted of four phases: 1) a comprehensive scoping review on patients support needs and elements in self-management interventions; 2) six workshops involving health professionals (rheumatologists, nurses, physiotherapists, occupational therapists, a social worker and a psychologist) and 2 patient representatives from the two hospitals and staff from primary health care, 40 people in total; the workshops focused on ideas for the content, outline of the intervention and needs for competence development of the staff; 3) self-management, self-efficacy, health literacy and principles of Acceptance and Commitment therapy (ACT) were selected as theories to tailor the intervention and 4) development of a manual through recurrent feedback from patient research partners, clinicians and the involved researchers. Two patient research partners with IA were involved in all phases of the development of the intervention.

Results: A six month nurse-coordinated interdisciplinary self-management intervention was developed (Figure 1) consisting of: 1) an initial holistic assessment is carried out by a coordinating outpatient nurse. Patients are asked to identify up to five important activities they are unable to perform or having difficulty with in accordance with the Patient Specific Functional Scale; 2) a goal-setting and action planning process involving the patient, relatives and the coordinating nurse; 3) Ongoing support to achieve the goals. The opportunities for support include individual consultations by the coordinating nurse (telephone, online or face-to-face, 2-5 hours in total), and a maximum of four consultations by a physiotherapist and/or an occupational therapist. Also, support from primary care, and an online session by a social worker about social support opportunities are offered. Two team conferences led by the coordinating nurse can be held during the intervention period. A status consultation will be held after 6 months. A manual for the initial screening, inclusion, detailing the intervention, outcomes and additional materials to support the intervention was developed. Competence development of the health professionals who are to deliver the intervention was planned and completed.

Conclusion: A nurse-coordinated interdisciplinary self-management intervention (INSELMA) was developed and described based on MRC’s framework for the development of Complex Interventions. The intervention is ready for feasibility testing before adaptation and test in a subsequent Randomized Controlled Trial. REFERENCES:

Strengths and weaknesses of experimental models: Moving from animals to human clinical trials

OP0199 RADIONIC SIGNATURES REFLECT TREATMENT RESPONSE TO NINTEDANIB IN PRECLINICAL LUNG FIBROSIS MODEL

D. Lau1,2,3, J. Schniering2, H. Gabrys1, M. Maciukiewicz2,3, M. Brunner2,3, O. Distler2, T. Frauenfelder2, S. Tanandini-Lang1, B. Maurer1,2,1 University Hospital Bern, Department of Rheumatology and Immunology, Bern, Switzerland; 2University of Bern, Department for Biomedical Research (DBMR), Bern, Switzerland; 3University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Zurich, Switzerland; 4Helmholtz Zentrum München, Institute of Lung Health and Immunity (LHI), Comprehensive Pneumology Center, Munich, Germany; 5University Hospital Zurich, University of Zurich, Department of Radiation Oncology, Zurich, Switzerland; 6University Hospital Zurich, University of Zurich, Institute of Diagnostic and Interventional Radiology, Zurich, Switzerland

Background: Responses to anti-fibrotic drugs in preclinical disease models are difficult to quantify by histological analysis of single tissue sections. Quantitative in-depth analysis of imaging data, termed “radiomics,” may represent a more reliable and accurate measure of treatment response since the pathology of the whole organ is captured.

Objectives: To study the potential of µCT-derived radiomic features to reflect response to Nintedanib in the bleomycin (BLM)-induced murine model of fibrosing interstitial lung disease.

Methods: All C57BL/6J mice from both study groups were intratracheally instilled with 2U/kg BLM on day 0 to induce lung fibrosis. Nintedanib was administered daily by gavage at 60mg/kg for two weeks starting from day 7 (n=15). Controls received equivalent treatment with vehicle-only (n=19). Whole lung µCT scans (SkyScan 1176, Bruker) of each animal were acquired at baseline (day 0), pre-treatment (day 7), and post-treatment (day 21). The Ashcroft score was assessed on Sirius Red stained lung sections post-treatment. Lung volumes in µCTs were defined semi-automatically in MIM Software (6.9.2), followed by extraction of radiomic features with our in-house developed software Z-Rad (73.1). Each data set contained 1’386 features, describing image characteristics with histogram, texture, and wavelet functions. Data pre-processing involved removal of features sensitive to intra- and interobserver delineation variability (ICC<0.75), highly correlated features (Pearson’s r>0.95), and features not...
significantly changing between days 0 and 7 (p<0.05). Agglomerative clustering of radiomic temporal trajectories was performed on the Nintedanib group to identify distinct feature clusters. The identified feature sets were then used to plot average feature value trajectories for both study groups in each cluster. To identify features significantly different between a) Nintedanib vs. control, and b) pre- vs. post-treatment, Mann-Whitney U and Wilcoxon signed-rank tests were used, respectively. Samples were pooled from two independent experiments.

**Results:** Evaluation of tissue sections did not show a significant treatment-induced reduction of fibrosis with average Ashcroft scores of 3.7 (±2.5 s.d.) and 3.9 (±1.7 s.d.) in Nintedanib and control samples, respectively (p>0.05). Radiomics data analysis revealed two feature clusters in Nintedanib samples, composed of 52 features (cluster 1) and 96 features (cluster 2), the trajectories of which were then plotted for both study groups. In cluster 1, feature value trajectories significantly decreased in both Nintedanib and control group between pre- and post-treatment (p<0.001), whereas feature values in cluster 2 remained flat (p>0.05). Importantly, Nintedanib-treated mice displayed a much more pronounced feature value decrease post-treatment in cluster 1 compared to the control group (p<0.05). Here, feature values post-treatment resembled pre-disease baseline conditions in the Nintedanib group (p<0.05), whereas the control group remained significantly different from baseline (p<0.01). Cluster 1 was composed of 6 histogram, 11 texture, and 35 wavelet features, emphasizing the role of high-dimensional metrics for the detection of differences.

**Conclusion:** Histological quantification of lung fibrosis accounts only for a small fraction of the whole pathology in a spatially heterogeneous disease. We demonstrated that μCT-derived radiomic features identified significant differences on imaging level following Nintedanib treatment, which we could not reliably detect on tissue level using Ashcroft scoring. These findings hold great potential for the development of novel read-outs for improved stratification of anti-fibrotic treatment effects in preclinical models.

**BARING IT ALL: A REPORT ON THE SEXUAL AND REPRODUCTIVE HEALTH EXPERIENCES OF WOMEN WITH INFLAMMATORY ARTHRITIS, RHEUMATIC AND PSORIATIC DISEASES**

L. Proulx1, S. Ketelaars2, R. Marion2, A. Scali3, 1Canadian Arthritis Patient Alliance, Patient Organisation, Ottawa, Canada; 2Canadian Spondylitis Association, Patient Organisation, Toronto, Canada; 3Canadian Association of Psoriasis Patients, Patient Organisation, Ottawa, Canada; 4Canadian Psoriasis Network, Patient Organisation, Toronto, Canada

Baring It All: a report on the sexual and reproductive health experiences of women with inflammatory arthritis, rheumatic and psoriatic diseases

**Background:** Inflammatory arthritis and psoriasis commonly affect women in the prime of their lives with significant impacts on sexual, reproductive and mental health. There have been some efforts to provide educational resources and other support by patient organizations globally but no broad efforts to evaluate patient needs and experiences throughout their lives and disease course.

**Objectives:** The Canadian Arthritis Patient Alliance, Canadian Association of Psoriasis Patients, Canadian Psoriasis Network and Canadian Spondylitis Association co-developed and launched the Women’s Sexual and Reproductive Health Survey on International Women’s Day 2021. Findings were analyzed in the report, Baring It All: A survey and recommendations on sexual and reproductive health needs of women+ with rheumatic, inflammatory and psoriatic diseases.

**Methods:** Survey participants were asked about their experiences with:

- sexual health
- family planning
- perimenopause/ menopause
- pain
- mental health
- accessing care and treatments (including paying for medications)

A total of 439 people across Canada who identified as female (women+) living with inflammatory arthritis, rheumatic, and psoriatic diseases participated. Results were analyzed to provide a national picture and insights based on Canadian geography, age, and identification as a member of a racialized community and/or as LGBTQ2S+.

**Results:** Over 60% of survey participants indicated that they did not have enough information about sexual health and their condition(s) and identified information needs relating to managing the impact of fatigue on their sex life, advice on improving sex drive, and sexual positions comfortable for their body as priorities. Less than half of survey participants indicated receiving counseling from a doctor before pregnancy. Many participants expressed a need for information about medication safety during pregnancy and breastfeeding and managing the impact of pain. Two in five survey participants (40%) indicated they were currently experiencing symptoms of perimenopause or menopause; however, only half of them (21%) indicated they understood how menopause affects their condition(s). Over 50% of participants indicated they understand how menopause affects bone health. Though 91% of survey participants indicated that they can honestly discuss pain with their healthcare provider, only 58% feel like their healthcare provider relates to the pain they experience from their condition. The vast majority (87%) of survey participants worry about the impact of their condition on their mental health, yet only 16% of participants identified having a mental health professional (e.g., psychologist, psychiatrist, social worker) as part of their care team.

**Conclusion:** There are several unmet needs in accessing care and information throughout the lives of women+ living with inflammatory arthritis, psoriatic and rheumatic diseases. A shift in models of care to focus on patient needs could assist patients in navigating a range of difficult decisions, such as choosing safe medications for pregnancy and breastfeeding, reconciling health, work and parenting demands, understanding menopause, accessing mental health support, and managing pain. A sex and gender lens can be used in the creation of resources and policies to support people with these condition(s).

**OP0201-PARe**

**DEVELOPMENT THROUGH CO-CREATION OF A PERSONALIZED, MULTIMODAL, PHYSIOTHERAPIST-LED, WORK-ORIENTED INTERVENTION TO INCREASE WORK ABILITY IN WORKING PEOPLE WITH RHEUMATOID ARTHRITIS OR AXIAL SPONDYLOARTHRITIS.**

N. Bakker1, J. Knoop2, N. Hutting1, Y. Heerkens3, J. Engels4, J.B. Staaij5, M. van der Leeden6, A. Boonen2, J. Tiggeloven6, N. Schuur2, T.P.M. Vliet Vlieland1, S. van Weely1, 1Leiden University Medical Center, Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; 2HAN University
Background: Although work ability is considered a key element of quality of life for working people, work is underexposed in current treatment in people with rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA). Most people with RA or axSpA attend a physiotherapist (PT). Physiotherapy can effectively improve physical fitness, which is associated with work ability. Therefore, PTs might play an important role in optimizing work ability of people with RA or axSpA.

Objectives: Developing a personalized, multimodal, PT-led, work-oriented intervention for working people with RA or axSpA who have a reduced work ability, through a co-creation process.

Methods: A systematic co-creation process with all relevant stakeholders was conducted following the Medical Research Council (MRC)-framework for complex interventions (see Figure 1). In step 1, all relevant clinical guidelines and treatment protocols were assessed. Based on the results of this assessment, a draft version of the intervention was developed, consisting of mandatory (i.e., work-oriented intake, patient education, exercise therapy, referral-roadmap of work-related professionals) and optional treatment modalities (i.e., workplace-intervention, self-management course). In step 2, focus groups with people with RA/axSpA, PTs and occupational/rheumatology experts were organized and indicated that the intervention was feasible and that the developed intervention collaboration. After revision of the draft intervention, the intervention was tested for applicability, Netherlands and Rheumatology, Amsterdam, Netherlands; 4 Maastricht University Medical Center, Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands; 5 General Board Member Axial SpA Foundation, not applicable, not applicable, Netherlands

Background: The National Rheumatoid Arthritis Society (NRAS) follows best practice, evidence-based standards in all we do. Huge strides have been made in the diagnosis and treatment of Rheumatoid Arthritis (RA), but impact on quality of life can be significant and for many, RA remains hard to come to terms with. Anxiety and depression are frequent co-morbidities seen in RA, and this can impede people’s ability to acquire knowledge of their disease together with supported self-management skills and coping strategies.

Objectives: The aim of Right Start (RS) is to improve outcomes of the recently diagnosed with RA through a framework of emotional, educational and peer support and access to high quality supported self-management resources tailored to individual need. RS also enables us to dispel myths and unhelpful health beliefs so that people get the ‘right start’ on their journey with RA to maximise health outcomes. A diagnosis of an incurable disease treated with life-long strong drugs is a life-changing event and without the right support it can be an isolating and emotionally very challenging experience for both the individual and their close family. We also wanted to give an opportunity for people to acquire understanding of the key role that support and self-management can play in improving quality of life, giving people back some control over their symptoms. Our goal was also to create a quick and easy way for HCPs to refer their patients to Right Start in a consented and GDPR compliant way.

Methods: HCPs are able to refer their patients via the ‘Refer a patient’ button on our website which takes them to a simple form which is filled in and submitted to NRAS with the patient’s consent. NRAS receive the referral and the form is integrated with our Salesforce database, and we contact the patient. RS involves a simple, 4-step process and the individual receives: A call (up to 1 hr) with a member of our helpline; 1:1 peer support (phone/Teams/Zoom) from trained volunteers with RA and access to 24/7 online community support; a tailored package of hard copy information with e-links/video/webinars of interest sent by post; further follow up available from helpline and individual peer support. RS enables health professionals to meet their responsibilities against NICE Quality Standard 33, Statement 3, (patient education and access to self-management resources) on which they are audited through National Early Inflammatory Arthritis Audit (NEIIA). RS is included in the NICE shared learning database of best practice examples. RS also supports the EULAR Recommendations for implementation of self-management strategies for patients with inflammatory arthritis.

Results: Since launch at BSR 2019, over 90 UK rheumatology units have referred over 435 patients to this service. Approx. 1/3rd cannot be contacted and after 3 attempts a letter and newly diagnosed pack are sent, inviting contact at future date. Anecdotally people are highly satisfied with this service and a number of units are referring multiple patients where the service is embedded in the patient pathway. To gather empirical data on the impact of the service NRAS has partnered with Manchester University to undertake an Enhanced Right Start pilot in 5 UK rheumatology units involving the use of validated patient reported outcome and experience measures from users recruited, and quantitative/qualitative data from health professionals. The pilot is due to commence recruitment in early Feb, 2022. Meantime, referrals to the standard service continue to grow.

Conclusion: Workforce shortages in all posts within the multi-disciplinary team, i.e. during the pandemic resulted in HCPs under immense pressure and time-poor. With a large backlog of patients has meant it’s extremely difficult for HCPs to meet Quality Standards and goals of audit. Feedback informs that HCPs find Right Start a beneficial service to refer their patients to and people with RA have found it more than helpful. We anticipate that the results of the Enhanced Right Start Service Pilot (see Results) will provide additional evidence to support HCP patient-referral to this service.

Acknowledgements: I would like to acknowledge the support of a number of UK consultant rheumatologists in the early stages of the development of this service, in particular Dr. James Galloway.

Disclosure of Interests: Ailsa Bosworth Speakers bureau: Where I have in the past the honorarium has been paid to NRAS not to me personally, Grant/research support from: Unrestricted educational grants have been paid to NRAS by a number of pharmaceutical companies in the last year, Clare Jacklin Speakers bureau: Where I have in the past the honorarium has been paid to NRAS not to me personally, Grant/research support from: Unrestricted educational grants have been paid to NRAS by a number of pharmaceutical companies in the last year.

OP0202-PARE NRAS NEW2RA RIGHT START SERVICE FOR PEOPLE RECENTLY DIAGNOSED WITH RA

A. Bosworth1, C. Jacklin2, National Rheumatoid Arthritis Society, Services, Maidenhead, United Kingdom; National Rheumatoid Arthritis Society, Services, Maidenhead, United Kingdom

Background: The National Rheumatoid Arthritis Society (NRAS) follows best practice, evidence-based standards in all we do. Huge strides have been made in the diagnosis and treatment of Rheumatoid Arthritis (RA), but impact on quality of life can be significant and for many, RA remains hard to come to terms with. Anxiety and depression are frequent co-morbidities seen in RA, and this can impede people’s ability to acquire knowledge of their disease together with supported self-management skills and coping strategies.

Objectives: The aim of Right Start (RS) is to improve outcomes of the recently diagnosed with RA through a framework of emotional, educational and peer support, and access to high quality supported self-management resources tailored to individual need. RS also enables us to dispel myths and unhelpful health beliefs so that people get the ‘right start’ on their journey with RA to maximise health outcomes. A diagnosis of an incurable disease treated with life-long strong drugs is a life-changing event and without the right support it can be an isolating and emotionally very challenging experience for both the individual and their close family. We also wanted to give an opportunity for people to acquire understanding of the key role that support and self-management can play in improving quality of life, giving people back some control over their symptoms. Our goal was also to create a quick and easy way for HCPs to refer their patients to Right Start in a consented and GDPR compliant way.

Methods: HCPs are able to refer their patients via the ‘Refer a patient’ button on our website which takes them to a simple form which is filled in and submitted to NRAS with the patient’s consent. NRAS receive the referral and the form is integrated with our Salesforce database, and we contact the patient. RS involves a simple, 4-step process and the individual receives: A call (up to 1 hr) with a member of our helpline; 1:1 peer support (phone/Teams/Zoom) from trained volunteers with RA and access to 24/7 online community support; a tailored package of hard copy information with e-links/video/webinars of interest sent by post; further follow up available from helpline and individual peer support. RS enables health professionals to meet their responsibilities against NICE Quality Standard 33, Statement 3, (patient education and access to self-management resources) on which they are audited through National Early Inflammatory Arthritis Audit (NEIIA). RS is included in the NICE shared learning database of best practice examples. RS also supports the EULAR Recommendations for implementation of self-management strategies for patients with inflammatory arthritis.

Results: Since launch at BSR 2019, over 90 UK rheumatology units have referred over 435 patients to this service. Approx. 1/3rd cannot be contacted and after 3 attempts a letter and newly diagnosed pack are sent, inviting contact at future date. Anecdotally people are highly satisfied with this service and a number of units are referring multiple patients where the service is embedded in the patient pathway. To gather empirical data on the impact of the service NRAS has partnered with Manchester University to undertake an Enhanced Right Start pilot in 5 UK rheumatology units involving the use of validated patient reported outcome and experience measures from users recruited, and quantitative/qualitative data from health professionals. OP0202-PARE FATIGUE IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: A SCOPING REVIEW ON ITS DEFINITION, MEASUREMENT INSTRUMENTS, DETERMINANTS, IMPACT AND INTERVENTIONS

E. Beckers1,2, K. Hermans1,2, A. van Tubergen1,2, A. Boonen1,2, Maastricht University Medical Center, Internal Medicine, Division of Rheumatology, Maastricht, Netherlands; 3 Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands

Background: Fatigue is one of the most important symptoms of patients with rheumatic and musculoskeletal diseases (RMDs) and numerous studies on fatigue in patients with RMDs have been published. However, no overview exists
of all topics relevant to understand and manage fatigue in patients with rheumatoid arthritis (RA), spondyloarthritides (SpA, including psoriatic arthritis (PsA)), osteoarthritis (OA) and fibromyalgia (FM).

**Objectives:** To scope published reviews on aspects of fatigue identified by patients in a preceding initiative as relevant for care and mapped to the following research areas: 1) definitions for fatigue, 2) measurement instruments for fatigue, 3) determinants of fatigue, 4) impact of fatigue, and 5) effect of interventions on fatigue in patients with RMDs of interest.

**Methods:** A methodological framework for scoping reviews was followed. A systematic literature search was performed in five bibliographical databases. Data selection followed by data extraction was done by two independent researchers.

***Figure 1.* Determinants of fatigue and the related minimal number of underlying studies within reviews

Included reviews were categorized in Cochrane reviews (CRs), non-Cochrane systematic reviews (SRs) or narrative reviews (NRs). Data extraction was performed hierarchical based on review type (CRs followed by SRs and NRs) and year of publication. SRs and NRs were excluded if there was overlap in the underlying studies within the reviews. Data synthesis accounted for hierarchy in level of evidence by review type (CRs were considered as best evidence followed by SRs and NRs). For each research area and stratified per type of RMD, a narrative synthesis was performed. Two meetings were organized with a patient panel to discuss the results from a patient perspective.

**Results:** The scoping review included 144 reviews (18 CRs, 42 SRs and 84 NRs). RA was addressed most frequently (60/144 (42%)), Fatigue was a secondary outcome in the majority of these reviews.

No agreed upon definition for fatigue in any of the RMDs was found. Across reviews, there was agreement that fatigue is a complex multifactorial and highly subjective symptom, including various subtypes with specific characteristics. Reviews discussed 23 generic and 3 disease-specific self-reported outcome instruments to measure fatigue in RA, SpA and FM, but no reviews on outcome instruments for OA were found. Four of these 23 (17.4%) instruments included validated cut-off values to diagnose or classify excessive fatigue.

Numerous factors were associated with fatigue (Figure 1), but the study design (often cross-sectional) hindered studying causality. Across RMDs, pain, physical function, and depressive symptoms were the most frequently studied disease related factors; gender and stress the most frequent contextual factors related to fatigue. The strength of association was small or moderate, but mostly not reported. Work disability was one of the most frequently studied consequences of fatigue in RMDs, followed by impact on pain, physical activity and stress. Strength of these associations was not reported.

Finally, both pharmacological and non-pharmacological interventions, including physical activity-based and psychological interventions, generally had a small positive effect on fatigue in RMDs. No reviews described the effect of pharmacological interventions on fatigue in OA.

All results were relatable for the patient panel and some missing aspects were pointed out. The patient panel advised to develop a research agenda to specifically diagnose and treat excessive fatigue in RMDs, as continuing the current path is likely to increase publications about fatigue, but unlikely to change patients’ lives.

**Conclusion:** This scoping review emphasizes the complexity of fatigue. Only a minority of the reviews had a primary focus in fatigue, whereas to patients this prominent symptom deserves specific attention.

**REFERENCES:**

**Acknowledgements:** The authors thank the patient panel for their helpful contribution to this scoping review.

**Disclosure of Interests:** None declared

The active participation of 13 PRPs with well-defined roles and responsibilities ensures the preservation of the patient perspective during the entire duration of the project. Together they form the HIPPOCRATES Patient Advisory Council (PAC). PRPs are represented in the project’s management team, in all work packages and in the External Advisory Board. Three patient organisations support the project: GRAPPA-EU (Group for Research and Assessment of Psoriasis and Psoriatic Arthritis) and EULAR CARE (People with Arthritis/Rheumatism in Europe) as consortium partners, and EUROPSO (European Federation of Psoriasis Patients’ Associations). EURAP is co-leading the work package focusing on Communication, Dissemination, Exploitation and Sustainability, and especially those activities targeting patients, PRPs (regular educational sessions), patient organisations and the general public. Finally, people with PsA will be recruited for a large European cohort study (HIPPOCRATES Prospective Observational Study, HPOS) which aims to identify clinical and molecular risk factors for developing PsA.

Results from the PRP survey were positive. Almost all PRPs have been invited to their work package meetings and included in email exchanges, and all feel well-included in their assigned groups and roles. Nevertheless, it was reported that some PRPs may be reluctant to raise their voice or to be involved in discussions at virtual meetings. This was one of the topics addressed during the online workshop, together with discussions on ethics and recruitment strategies for HPOS.

**Conclusion:** It has been central to the HIPPOCRATES ethos that highly experienced PRPs were involved from its initial conception. PRPs with leading responsibilities in patient organisations or representing relevant academic backgrounds have contributed substantially to the definition of research priorities and will have active ongoing engagement in the interpretation and implementation of future results. By demonstrating the pervasive benefit of the patient voice throughout the project, HIPPOCRATES will be an example for future projects in RMD and health research.

**Acknowledgements:** Meaningful patient involvement is critical to successful international grant applications: the case of the HIPPOCRATES consortium ("Health initiatives in Psoriasis and Psoriatic arthritis ConsorRTium European States")

**OP0206-PARE FOOD COMMUNITIES**

P. Del Pin, 1, Gentoffe, The Danish Rheumatism Association, Gentofte, Denmark

**Background:** In recent years the focus on healthy food and lifestyle has become a more important part of everyday life for many – with or without RMD. Many NGO-initiatives engaging citizens cooking and eating together has seen the light of day; people meet to talk, laugh and have a good time while making a healthy meal. The kitchen is an often discussed topic among the volunteers and members of The Danish Rheumatism Association. “Simple” tasks as opening a can of beans or cutting bread can be complicated for people with RMDs. The fundamentals of cooking are different for this group of people; hence the idea of communities around “arthritis friendly” food unfolded during fall 2019.

**Objectives:** The main objective is to create “food communities” for people with RMDs, helping them to get a better understanding of how to make “arthritis friendly food”; dispel the myth that it is expensive and hard, and to give them inspiration to find working positions with assistive devices - resulting in a healthier lifestyle which is important to keep the inflammation low and the quality of life high.

**Methods:** To obtain these objectives, a dietitian is facilitating 6 three hour “courses” guiding the participants through healthy cooking – each course with a different theme/subject which is introduced through a short presentation. Two volunteers are responsible for booking kitchen facilities (often school kitchens which is free of charge), coordination with the dietitian and making sure everything runs smoothly and that the atmosphere is top-notch. An occupational therapist is joining the group one time to ensure optimal working positions and introducing and demonstrating assistive devices.

**Conclusion:** The main goals is to create more sustainable and lasting (more than 6 facilitated courses) communities, which is why an important part of the volunteer’s responsibility is to initiate a talk about the opportunity of meeting without a dietitian. The 6 facilitated courses aim to give the group the ability to find recipes (provided by DRA) and being comfortable cooking with ingredients that the average Dane might not use very often. Furthermore, our assumption is that the group creates social bonds and therefore an interest in keeping these relations.

**Results:** About twenty groups all around Denmark has been a part of the course so far. The feedback from the participants is extremely good – they feel they are learning in an inspiring environment while having a great time with their new acquaintances. Unfortunately, only one of the groups has become a community that exists after the facilitated courses. One of the reasons is, without a doubt, that most of the groups have been affected by different Covid-19 restrictions which has had an impact on the level of social bonding and feeling of ownership. But most participants feel that the dietitian is crucial for further engagement.

**Conclusion:** The concept has been very successful in terms of creating a course that imparts useful knowledge about “arthritis friendly” food and lifestyle for people with RMD’s. It seems we need to make corrections to create the base for sustainable communities; small changes that helps the group visualizing how to overcome the challenge of the absence of a dietitian, the logistics of grocery shopping for a group etc. We plan to leave out the dietitian from the fifth of the six courses to prepare the group to establish their own “food community” with lots of healthy food, learning experiences and high spirit.

**OP0205-PARE GREEK RMDs PATIENT’S NEED FOR SELF-MANAGEMENT AND THE USE OF NEW TECHNOLOGIES: THE CASE STUDY OF THE HELLENIC LEAGUE’S AGAINST RHEUMATISM SUPPORT LINE**

N. Malliou, 1, K. Antonopoulou, 1, Hellenic League Against Rheumatism, ELEANA/HELAR, Thessaloniki, Greece; 2Hellenic League Against Rheumatism, ELEANA/HELAR, Athens, Greece

**Background:** The Hellenic League Against Rheumatism (ELEANA/HELAR) offers psychosocial support to its members, patients with RMDs, their families and everyone else that’s interested in RMDs. More than 5000 members from all over Greece, with local ELEANA/HELAR groups in major cities such as Athens, Patras, Karditsa, Trikala, Thessaloniki and others. The helpline has been receiving incoming calls from patients with RMDs, members of ELEANA, their relatives and others that are interested in RMDs or are requesting information.

**Objectives:** This case study aimed at outlining that self-management is the main reason for incoming calls to ELEANAs helpline and secondly that during the pandemic and even after lockdown measures being lifted patients still use the online support offered thus making it apparent that digitalization is not a trend anymore but a necessity.

**Methods:** Empirical data from the helpline were gathered through the day-to-day helpline registry. This is a detailed registry containing basic info on demographics of the callers, reasons for calling and outcome of communication. Descriptive statistics as well as qualitative data have been used such as observations of the trained staff of the helpline.

**Results:** From 543 incoming calls, 49.91% were about self-management and the rest 50.09% were calls requesting information, 52.40% of self-management calls were about psychological issues (anxiety, depressive symptoms) and the rest were about treatment (adherence), such as the use of medication, alternative treatments, medical issues and questions on RMDs. 40.96% of patients with RMDs called again the helpline to follow up and 61.25% used online tools to communicate with the helpline both times. Psychologists receiving calls observed that patients needed counseling regarding their self-management, especially during the pandemic and that even though lockdown is lifted they keep on requesting online communication instead of face-to-face meetings.

**Conclusion:** The above findings show that digitalization is not a trend rather than a necessity in the self-management of RMDs. Patients seem to find it easier receiving support online and the requests for online support for their anxiety, depressive symptoms, difficulties in managing their medication makes it clear that more emphasis needs to be put on self-management programs.

HPR interventions on the spotlight

**OP0207-HPR**  
**EFFECT OF FOOT ORTHOSES IN REDUCING PAIN IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A 12-MONTH RANDOMISED CLINICAL TRIAL**

1University of Newcastle, College of Health, Medicine and Wellbeing, Callaghan, Australia; 2Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic; 3Queen Margaret University, Podiatry, Edinburgh, United Kingdom; 4Hunter Medical Research Institute, Statistics, New Lambton Heights, Australia

**Background:** Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children and adolescents [1]. The manifestation of JIA may include joint swelling, tenderness, and painful limitation with joint motion. Only few studies have explored the effect of foot orthoses (FOs) alone in children with JIA [2,3]. These studies showed FOs can reduce pain in children with JIA, however, further research with larger sample sizes and longer follow-ups are needed [4]. Prescribing FOs on the same day of the initial assessment may promote early clinical and targeted intervention, which is the gold standard approach in paediatric rheumatology.

**Objectives:** This single blinded multicentre randomised clinical trial (RCT) aims to investigate the effect of customised prefabricated FOs in reducing pain amongst children and adolescents with JIA.

**Methods:** Overall, 66 children and adolescents with JIA presenting with foot symptoms were recruited from the Sydney Children's Hospital Network (Westmead and Randwick) and John Hunter Children's Hospital (Newcastle). The primary outcome measure was pain with a minimal clinical significance of 8mm on the visual analogue scale (VAS). Participants were randomly allocated to receive either customised prefabricated or sham FOs. The trial intervention was a low-density Slimflex Simple device that was customised at chair-side. The control (sham) device was made of 2mm flat leather board with no corrective modifications. Standardised tests such as the Foot Posture Index, navicular drift and drop were used to identify biomechanical abnormalities. The FOs were worn for a total of 12 months, with data collected at baseline, 4 weeks, 3, 6 months, and 12 months.

**Results:** Reduction in self-reported pain was statistically and clinically significant at 4-weeks (p<0.018, -14.92 [-27.30, -2.55]) and 3 months (p<0.001, -28.93 [-40.90, -16.96]) post intervention in favour of the trial group. The 6- and 12-month follow-ups were not statistically or clinically significant. Parent reported pain was statistically and clinically significant at the 3-month (p<0.001, -21.92 [-33.16, -10.67]) in the reduction of pain in favour of the trial group. However, parent reported pain was not statistically significant at the 4-week, 6- and 12-month follow-ups. These results are similar to child reported pain with a p-value of less than 0.001 and average coefficients twice that of the clinical significance cut-off for VAS pain in paediatric rheumatology. The trial intervention was safe and tolerated well by participants with high compliance and adherence rates.

**Conclusion:** Results of this clinical trial indicate customised preformed FOs can be effective in reducing pain and in children with JIA experiencing foot and ankle symptoms. Significant clinical effects appear to be within the first 3-months of intervention prescription and reduce beyond 6 months. Overall, this paediatric intervention was safe, inexpensive, well tolerated and can be easily implemented as part of the multidisciplinary paediatric rheumatology care.

**EFFECT OF AN 8-WEEK SPECIALIZED PHYSICAL THERAPY PROGRAM ON SEXUAL HEALTH IN FEMALE PATIENTS WITH SYSTEMIC SCLEROSIS AND IDIOPATHIC INFLAMMATORY MYOPATHIES: A PILOT STUDY**

B. Heřmánková1, M. Štorkánová1, H. Štorkánová1, M. Tomčíková3, M. Tomčík4, B. Heřmánková1, M. Štorkánová1, K. Pavélka1, L. Šenolt1, J. Vencovský3, R. Bečvář1, M. Tomčík1,2, Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic; 2Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic; 3First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic.

**Background:** Systemic rheumatic diseases like systemic sclerosis (SSc) and idiopathic inflammatory myopathies (IIM) may affect all aspects of life, including sexual health however, no non-pharmacological treatment has been proposed to date.

**Objectives:** This is the pilot project aiming to investigate the effect of an 8-week physical therapy program on sexual function in women with SSc and IIM.

**Methods:** In total, 12 women with SSc and 4 women with IIM, who fulfilled the ACR/EULAR 2013 criteria for SSc and the Bohan/Peter 1975 criteria for DM/PM, respectively, were enrolled in the study. Based on patient’s possibilities and willingness to participate in the program, they were divided into an intervention group (IG) (6 SSc/2 IIM, mean age: 46.8±3.1 years) and a control group (CG) (6 SSc/2 IIM, mean age: 46.3±3.0 years). The IG underwent the 8-week tailored physiotherapy program, including the pelvic floor exercise and physiotherapy of musculoskeletal problems subjectively limiting the patient’s sexual function (1hour supervised physiotherapy twice weekly), whereas the control group received no specialized therapy. At weeks 0 and 8, all patients filled in questionnaires assessing sexual function: Female Sexual Function Index (FSFI), Brief Index of Sexual Functioning for Women (BISF-W); sexual quality of life: Sexual Quality of Life Female (SQoL-F); functional ability: Health Assessment Questionnaire (HAQ); quality of life: Medical Outcomes Short Form-36 (SF-36) and depression: Beck’s Depression Inventory-II (BDI-II). At the baseline, patients in IG were assessed by a physician (medical history, mRSS, ESSG activity score, MITAX, MYOACT) and by a physiotherapist (pelvic floor function assessment–PERFECT scheme, MMT-8, Functional Index-II). Normality of data was tested, and inter-group analysis was performed with 2-way ANOVA and intra-group analysis by Friedman’s test.

**Results:** Compared to observed statistically significant deterioration in CG over the period of weeks 0–8, we found statistically significant improvement in both intervention questionnaires: FSFI (p=0.043), BISF-W (p<0.040), functional status: HAQ (p=0.018), and quality of life: SF-36 Physical Component score (0.050). Only numerical improvement in IG compared to numerical deterioration in CG, which has not reached statistical significance, was observed in SQoL-F, BDI-II, and SF-36 Mental Component Score.

**Conclusion:** Our physiotherapy program not only prevented the natural course of progressive deterioration of functional abilities, but also led to a significant improvement in sexual function and overall quality of life in women with SSc and IIM. Physical therapy might become one of the possible therapeutic treatments for sexual problems in women with SSc and IIM.
Background: There is a well-known variability in the quality of rehabilitation provided to patients with rheumatic and musculoskeletal diseases (RMDs). Elements to be improved are a higher standardization of the core content, optimal patient participation in goal setting and continuation of the process in tailored follow-up. More knowledge is needed on critical features for successful delivery of improvement programs in rehabilitation.

Objectives: To investigate how a team-based quality improvement program was implemented and how it influenced the quality in RMD rehabilitation.

Methods: This convergent mixed methods study is nested within a stepped-wedge, randomized controlled trial where providers at 8 rehabilitation-centers delivered traditional programs in the control phase (T1), and added the BRIDGE quality improvement program in the intervention phase (T2). The BRIDGE program addressed a dialog-based, multidisciplinary approach to support the patients’ self-management, comprising motivational interviewing, goal setting, plans for rehabilitation, feedback and monitoring of progress, and tailored follow up. Providers answered 19 structure indicators from a quality indicator (QI) set for RMD rehabilitation [1] at T1 and T2, and a program-fidelity checklist with 18 items at T1 and T2 (both scores range 0-100, 100=best). Qualitative data was collected in three focus groups (FG) with the BRIDGE providers, and analyzed using reflexive thematic analysis. Integration and discussion of findings from the different data sources are ongoing, in our research group.

Results: Median summary pass rate for the structure QIs for all centers increased from 59 to 90% between T1 and T2. Program-fidelity was high, with a median summary score of 94% (range 61–100%), but lowest for program-components related to follow-up and communication with external services. Themes developed from the FG interviews reflected that variations in how the program was implemented related to features of the providers and institutions. More specific; the delivery of high-quality rehabilitation depended on the degree to which the providers trained their communication skills, used available tools to support their practice, and grounded their interventions in professional reasons. Critical organisational features at the institutions were dedicated time for team-work based on the patients’ plans for self-management, and sufficient attention to needs for involvement of next of kin or external services. Additionally, better program-implementation occurred if providers experienced an institutional culture for quality improvement, such as educational initiatives from the leaders. Preliminary integration of data is summarized in Figure 1. Congruent evidence in both quantitative and qualitative findings addressed the sustained needs for better quality in the area of follow-up across levels of care. However, the qualitative findings provided expanded insights on variability also in initial parts of the rehabilitation process. Presumably, these variations in delivery reported in interviews are important for the effectiveness of a quality improvement program, but difficult to capture in questionnaires.

Conclusion: To target specific strategies for quality improvement, we suggest a combined attention not only to recommended care reflected in quality indicators and measurable aspects of fidelity, but also to contextual factors, including the providers’ confidence and skills needed to provide a high-quality delivery of all components in a rehabilitation improvement program.

EXPERIENCES DURING THE COVID-19 PANDEMIC AMONG PEOPLE WITH INFLAMMATORY ARTHRITIS. “REOPENING IS SOMEWHAT HARDER THAN LOCK-DOWN” - A QUALITATIVE INTERVIEW STUDY

L. Lund1, M. Law1, O. Hendrick2, K. Schreiber2, B. Glintborg2, R. Petersen2, C. Pischelke3, W. Fick3, J. Primdahl3,1, University College UC SYD, Esbjerg, Denmark, Research Center of Applied Health Science (SuPra), UC SYD, Esbjerg, Denmark, Esbjerg, Denmark, Esbjerg, Denmark; 2Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark, Department of Regional Health Research, University of Southern Denmark, Odense, Denmark, Sønderborg, Denmark; 3DANBIO and Copenhagen Rheumatology Research Center (COPECare), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, University Hospital Copenhagen Rigshospitalet, Glostrup, Denmark, Department of Clinical Medicine, Faculty of health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, Copenhagen, Denmark; 4Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark, Patient Research Partner, Sønderborg, Denmark, 5University Hospital of Southern Denmark, Aabenraa, Denmark, Sygehus Sønderjylland, Aabenraa, Denmark, Aabenraa, Denmark

Background: People with inflammatory arthritis (IA) treated with conventional or biological immunosuppressive disease-modifying anti rheumatic drugs (DMARDs), were initially concerned to have an increased risk of severe illness from SARS-CoV-19 (COVID-19) infection compared to the general population. Although recent studies have not confirmed this, people with IA have reported high level of anxiety and self-isolation during the pandemic (1). Only few studies have qualitatively explored how people with IA experience the impact the COVID-19 pandemic and the SARS-CoV-19 vaccinations.

Objectives: To explore how people with IA experienced restrictions during the COVID-19 pandemic and the possible impact of vaccination on their protection against COVID-19 and their everyday lives.

Methods: Semi-structured in-depth interviews were conducted via telephone or video with 19 people with IA in May – August 2021, shortly after they were enrolled in the national COVID-19 vaccination programme (all Danish citizens >18 years of age invited for SARS-CoV-19 vaccination, free of charge, with timing depending on age and comorbidities). At the same time, society gradually reopened after a complete lock-down. Qualitative content analysis, inspired depending on age and comorbidities). At the same time, society gradually reopened after a complete lock-down. Qualitative content analysis, inspired by Graneheim and Lundman (2), was applied to analyse the data. Two patient research partners were involved in development of the study protocol, an interview guide and in the interpretation of findings.

Results: The participants’ age ranged from 21 to 64 years, median 50 years. 7 male and 12 female, all diagnosed with IA (Psoriatic arthritis n=4, Axial Spondyloarthritis n=4, Rheumatoid arthritis n=9, and Juvenile arthritis n=2) and 14 were treated with DMARDs. Two had not accepted vaccination. The analysis derived five themes: 1: “Changing and divergent information”: The participants experienced there was an overload of general information reflecting that par - 2: “Impact on everyday life”: They took self-imposed precau - 3: “Position in society and the vaccination programme”: emphasizing that participants were affected by the inconsistent announcements from authorities whether they were considered to be in particular risk or not, and some expressed concerns regarding the DMARDs influence on the effect of the vaccine and 5: “Reopening is somehow harder than lock-down”: A societal spirit of being “in this together” emerged through the lock-down and some were concerned that fewer restrictions during reopening of the society would put them in higher risk of a COVID-19 infection and force them to continue self-isolation.

Table 1. Quotation to illustrate the findings

<table>
<thead>
<tr>
<th>Quotation</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>“...you felt like one in the crowd and then everything is easier. Even though it was difficult. But then; it was difficult for all of us. It had nothing to do with my rheumatic disease...we were in this together...But it was harder when the reopening started. Because it’s like; I’m back on the platform and can’t just jump on the train, can’t go anywhere, that is...I’m just not quite ready to jump into society like everyone else...”</td>
<td>Participants felt isolated during lockdown and were more connected during the lockdown. Reopening forced them to adjust their lives.</td>
</tr>
</tbody>
</table>

Conclusion: The COVID-19 pandemic affected the everyday lives of people with IA due to the authorities' restrictions and further self-imposed precautions throughout lock down and reopening of society. People with IA experienced a lack of consistent information and felt alone to assess their own SARS-Cov-19 infection risk.

PATIENT ASSESSMENT CHRONIC ILLNESS CARE (PACIC) AND ITS ASSOCIATIONS WITH QUALITY OF LIFE AMONG SWISS PATIENTS WITH SYSTEMIC SCLEROSIS – A MIXED METHODS STUDY

A. Kocher1, 2, M. Simon1, 2, A. A. Dwyer1, 4, C. Blatter1, J. Bogdanovic1, P. Künzli-Heule1, 3, P. Villiger1, D. Dan1, O. Dister4, U. Walker4, D. Nicca1, 1
1Institute of Nursing Science (INS), University of Basel, Department Public Health (DPH), Basel, Switzerland; 2Inse Ipital, Bern University Hospital, Department of Nursing, Bern, Switzerland; 3Connell School of Nursing, Boston College, Chestnut Hill, Massachusetts, United States of America; 4Munn Center for Nursing Research, Massachusetts General Hospital, Boston, Massachusetts, United States of America; 5Cantonal Hospital St. Gallen, Department of Gastroenterology/Hepatology and Department of Nursing, St. Gallen, Switzerland; 6Medical Center, Monblijou, Bern, Switzerland; 7Lausanne University Hospital, University of Lausanne, Service of Rheumatology, Lausanne, Switzerland; 8University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland; 9University Hospital Basel, Department of Rheumatology, Basel, Switzerland; 10Institute for Epidemiology, Biostatistics and Prevention, University of Zurich, Department of Global and Public Health, Zurich, Switzerland

Background: Variable disease presentation and symptom burden in patients living with systemic sclerosis (SSc) require a chronic care approach including competent, coordinated, multidisciplinary collaboration as well as self-manage -

Methods: We employed an exploratory sequential mixed methods design (Figure 1). First, we conducted a cross-sectional quantitative survey (n=101 Swiss patients) using the Patient Assessment of Chronic Illness Care (PACIC)20) and Systemic Sclerosis Quality of Life (SScQol)3 questionnaires. Because PACIC has not been used in the context of SSc, we used the Mokken model to test the construct validity of the PACIC scale and its subscales. After excluding five problematic items, H coefficients were strong for the subscales and the global scale (0.52) suggesting a robust unidimensional scale.

Table 1. Research Overview

<table>

<tr>
<th>Research Overview</th>
</tr>
</thead>
<tbody>
<tr>
<td>Objective 1: Assess the construct validity of the PACIC scale and its subscales.</td>
</tr>
<tr>
<td>Objective 2: Examine the associations between the PACIC scale and its subscales with SScQol2.</td>
</tr>
</tbody>
</table>

Figure 1. Schematic of the explanatory, sequential mixed methods design

Next, we used data from individual patient interviews (n=4) and one patient focus group (n=4) to further explore care experiences of people living with SSc with a focus on the PACIC dimensions.

Results: The mean overall PACIC-15 score was 3.0 / 5.0 (95% CI: 2.8–3.2), indicating care was ‘generally not’ aligned with the CCM. Lowest subscale scores related to ‘goal setting/ tailoring’ (mean = 2.5, 95% CI: 2.2–2.7) and ‘problem solving/contextual counselling’ (mean = 2.9, 95% CI: 2.7–3.2) (Table 1). No significant associations were identified between the mean PACIC-15 and SScQol scores.

INTRODUCTION

Background: The number of new treatments available in rheumatology continues to increase. Kinase inhibitors, or jakinibs, pose an added challenge due to the variety and because they are oral. The most important role of the rheumatology nurse is patient education, especially on how to take the medication. It is recommended to instruct the patient on preventive measures for infectious diseases (dental and hand hygiene, HPV, social distance, etc.). Recommendations will allow a practical approach to the management of jakinibs by nurses and enjoy an adequate consensus among potential users.

Disclosure of Interests: José María Martín Martin Speakers bureau: Lilly, Consultant of: Lilly, Grant/research support from: Galapagos, Silvia García-Díaz Grant/research support from: Galapagos, Amparo Molina Grant/research support from: Galapagos, Carmen Domínguez Grant/research support from: Galapagos, Loreto Carmona: None declared, Laura Cano García Grant/research support from: Galapagos.

Objectives

To establish practical, evidence-based nursing recommendations for the management of people with RA undergoing treatment with jakinibs.

Methods

To reach an evidence-based consensus we used systematic review and Delphi survey. A multidisciplinary panel of experts was formed with 6 rheumatology nurses, 2 rheumatologists, 1 psychologist, 1 dietician-nutritionist and 1 patient on treatment with jakinibs. This panel met on 2 occasions and was kept informed at all times of the progress of the project through the Miro platform. At the preparatory meeting the scope and users, structure and PICOt questions were established (these included efficacy and adverse effects, infections, cardiovascular risk, surgery, vaccination, pregnancy and breastfeeding, interactions and switches between jakinibs).

The steering group made recommendations based on the issues raised at the first meeting. Only those that achieved 85% in favour were included as items in a Delphi survey. The Delphi survey was sent to all members of the society nurses and rheumatologists (n=60). Voting ranged from 0 to 10 (strongly disagree to strongly agree). Items with more than 75% agreement in the first round did not proceed to a second round.

RESULTS

Table 1 shows the recommendations with their level of evidence and level of agreement after the Delphi (n=40; 67%). One item with only 50% agreement was rejected and did not proceed to a second round.

OP0214-HPR

EDUCATIONAL NEEDS AMONG HEALTH PROFESSIONALS IN RHEUMATOLOGY: LOW AWARENESS OF EULAR OFFERINGS AND UNFAMILIARITY WITH COURSE CONTENT AS A MAJOR BARRIER – A EULAR FUNDED EUROPEAN SURVEY

Objectives

To establish awareness of EULAR offerings and unfamiliarity with course content as major barriers among health professionals in rheumatology.

Methods

A survey was conducted among health professionals in rheumatology including physicians, nurses, and other healthcare professionals. A questionnaire was designed to assess their awareness of EULAR offerings and their familiarity with course content. The questionnaire included questions on their awareness of EULAR offerings, their familiarity with course content, and their willingness to participate in EULAR courses.

RESULTS

The survey revealed that only a small proportion of respondents were aware of EULAR offerings. Furthermore, most respondents reported a lack of familiarity with course content. These findings indicate a need for increased awareness and education among health professionals in rheumatology.

CONCLUSION

These findings highlight the importance of increasing awareness and education among health professionals in rheumatology. Efforts should be made to improve awareness of EULAR offerings and to increase familiarity with course content. This may include the development of outreach strategies, the provision of educational materials, and the implementation of educational programs.
Background: Health professionals in rheumatology (HPRs) should participate in post-graduate or continuous education to update and advance their knowledge and skills. This can improve patient outcomes and increase quality of care. EULAR aims to become a leading provider of postgraduate education for HPRs.

Objectives: The aims of this study were to evaluate the current motivations for participating in postgraduate education of HPRs, identify barriers and facilitators for participation in postgraduate education, and evaluate participation in the current educational offerings of EULAR for HPRs across Europe.

Methods: An online survey was developed and distributed in collaboration with the EULAR Standing Committee of Education and Training (ESCET) and the Paediatric Rheumatology European Society (PRoE5). The questionnaire was translated by national HPR representatives in 24 languages to cover the 23 national member organisations. Barriers were assessed using 5-point Likert scales, higher scores representing higher barriers. Quantitative data was analysed using descriptive statistics. In addition, we ran the Latent Dirichlet Allocation (LDA) on the answers to the open questions. LDA is an unsupervised probabilistic topic modelling technique that extracts the meanings of a large number of documents.

Results: The online questionnaire was accessed 3,588 times but only 667 complete responses were recorded. HPRs from 34 European countries responded to the survey; 80% of whom were women. The highest-ranked educational need was prevention, including lifestyle interventions and professional development. Although EULAR was well known among HPRs, only 32.1% of HPRs in adult care and 15.2% of HPRs in paediatric care had ever heard of the EULAR School of Rheumatology (Table 1 A).

The main barriers to participation in EULAR's educational offerings were identified by HPRs in adult care and in paediatric care (respectively) as: the unfamiliarity with the course content (3.46 [±1.35]; 3.69 [±1.28]) and English language (2.59 [±1.50]; 2.80 [±1.34]).

Conclusion: EULAR is well-known by HPRs in Europe; however, awareness of educational offerings is low and barriers to participation are numerous. To become the leading provider of postgraduate training by 2023, EULAR could use a "franchise" model that can be tailored to local conditions. This could be achieved by strengthening national organisations by actively involving them in the development of training programs and disseminating these programs and offerings through their networks.

Improving outcomes for children with JIA

**OP0215**
WHAT DOES THE PATIENT WELL-BEING VAS TELL US WHEN THE PHYSICIAN GLOBAL ASSESSMENT SCORE IS ZERO? ANALYSIS OF A LARGE MULTINATIONAL DATASET

M. Buronne1, R. Naddes1, F. Fidelini2, C. Trinicianti3, C. Herrera Mora4, C. Malagon5, A. Ibañez6, O. Arguedas7, N. Ruperto1, A. Ravelli1, A. Consolaro1,2

1IRCCS Istituto Giannina Gaslini, Clinic of Paediatrics and Rheumatology, Genoa, Italy; 2Gianna Gaslini Institute, University of Genova, Genova, Italy; 3Hospital de Niños Roberto Gilbert Elizalde, Reumatología, Guayaquil, Ecuador; 4Hospital Universitario Simon Bolivar, Clínica Infantil Colsubsidio, Bogota, Colombia; 5National Institute Salud del Nino, Rheumatology, Lima, Peru; 6Hospital Nacional De Niños Dr. Carlos Saenz Herrera, Immunology, San José, Costa Rica

Background: Parent- and child-reported outcomes (PCROs) are measures that reflect the parent and child perception of rheumatic disease course and effectiveness of therapeutic interventions. Among PCROs for the assessment of patients with juvenile idiopathic arthritis (JIA), the most widely adopted is the patient/patient global evaluation or well-being visual analogue scale (WB-VAS). Several studies in JIA have highlighted the discrepancies in the assessment of the disease status between the physician and the parent/patient. This difference might be due to the WB-VAS measuring a broader construct than the physician (clinical assessment).

Objectives: To evaluate, in a large multinational sample of JIA patients, the disease characteristics of subjects considered as inactive by the physician with an increased WB-VAS score.

Methods: Data from the multinational dataset of patients enrolled in the Epidemiology Treatment and Outcome of Childhood Arthritis (EPOCA) study were analyzed. We have included only subjects with a PGA score of 0. PCROs were collected through the juvenile arthritis multidimensional assessment report (JAMAR). We compared demographic features, socio-economic status, level of education, subtype of JIA diagnosis and the main PCROs (pain level, presence of morning stiffness, count of joints with swelling or pain, functional ability, disease activity level, ongoing therapy, presence of medications side effects and health related quality of life measured with the pediatric rheumatology quality of life (PRQL) scale) between subjects with WB-VAS ≤1 and > 1.

Results: A total of 3537 patients were sorted into two groups according to the WB-VAS score: 2862 subjects were included in a first group (WB-VAS ≤1); 675 in a second one (WB-VAS > 1). Respectively, 17.6% and 18.1% of families belonged to the lower socio-economic status, 70.5% and 71% to the intermediate, 11.9% and 10.8% to the higher. The percentages of patients in the three levels of education was not different in the two groups: 20.2% and 22% in the intermediate, 11.9% and 10.8% to the higher. The percentages of patients in the three levels of education was not different in the two groups: 20.2% and 22% in the intermediate, 11.9% and 10.8% to the higher. The percentages of patients in the three levels of education was not different in the two groups: 20.2% and 22% in the intermediate.

Conclusion: We have analyzed the variables that might determine a difference between the physician's assessment of inactive disease and the parent/patient’s perception of well-being. In particular the socio-economic status, level of education, and gender representation seem not to impact on the general perception of well-being, while pain seems to have the greatest influence on the parent/patient quality of life assessment. Finally, children with lower WB-VAS score were younger at disease onset.

Obstetric Medicine and Adult Rheumatic Fever), Auckland, New Zealand

Background: The lack of pediatric classification criteria for axial disease is a major impediment to the conduct of clinical trials for juvenile spondyloarthritis (JSpA).

Objectives: We aimed to develop classification criteria for axial JSpA that will enable identification of a more homogeneous group of patients with SpA and axial disease for entry into observational or clinical trials. These criteria are not intended to capture all possible subjects, but instead most patients with shared key features of axial disease. Treatment and diagnostic decisions should adhere to evidence-based recommendations.

Methods: 304 cases with JSpA and suspected axial disease from 6 international centers were collected on a standardised case report form (CRF) that was reviewed by an independent team of experts in musculoskeletal imaging. Candidate criteria were developed in an earlier phase of the project through an iterative process that included an international Delphi exercise for item generation, systematic literature review, and an item reduction exercise. Using the preliminary candidate criteria, 14 international clinical SpA experts scored and ranked ordered 20 representative SpA cases. During four, 3-hour virtual meetings, the clinical expert panel reviewed the interrater reliability of case ranking, refined the criteria definitions and domain levels, and participated in a multi-criterion decision consensus methodology exercise to generate relative weights of the criteria. The expert panel assessed whether the criteria weighting was in accordance with their consensus clinical judgment as a test of face validation of the weighting/scoring system and revisions were made as necessary. Next, 30 cases from the derivation cohort were scored and ranked using the relative weights for each category and domain. Each expert independently determined the score or “threshold” below which they were no longer confident enough that a patient had axial disease to enroll the child in a Phase 3 randomized clinical trial of a drug with unclear efficacy and safety. Results of this exercise were discussed and a provisional threshold score for classification was achieved by consensus.

Results: The preliminary axial disease criteria for JSpA included the PRINTO provisional criteria for enthesitis/spondylitis-related JIA or a rheumatologist diagnosis of SpA as obligatory entry criteria as well as additive weighted criteria for 7 domains (SpA active inflammation on imaging, SpA structural lesions on imaging, pain chronicity, pain pattern, pain location, morning stiffness, and genetics) (Figure 1). Interrater reliability of the pre-consensus meeting case rankings was poor
Figure 1. Axial juvenile spondyloarthritis (AxJSpA) classification criteria domains and levels. The first ring represents the domains and the items branching out are the levels moving from highest level (closest to center) to lowest level (furthest from center) in each domain. Assigned weights are shown below each item description.

Conclusion: Using an iterative process, the JSpA axial disease criteria definitions were refined, preliminary weights were generated, and a provisional threshold score for classification was determined. The most heavily weighted domains were active inflammation and structural lesions on imaging. Imaging typical of sacroiliitis was necessary, but not sufficient without any clinical criterion, to surpass the axial disease classification threshold.

Background: Tocilizumab (TCZ) has been approved for treatment of juvenile idiopathic arthritis (JIA) for 10 years. Objectives: Evaluation of 12-month efficacy and safety of TCZ compared to TNF inhibitors (TNFi).

Methods: BIKER WA 29358 is a 5-year multi-centre prospective, observational cohort study including polyarticular JIA patients in Germany starting treatment between 2015 and 2020 with TCZ and matched 1:1 by date of treatment start and region to patients starting an approved TNFi. Clinical disease activity (JADAS10), JADAS MDA (≤3.8) remission (≤3.0), safety and drug adherence at 12 months were assessed and compared between cohorts.

Results: The analysis included 342 participants with 12-month treatment data (TCZ n=171; TNFi n=171). TCZ was used as 2nd line biologic in the majority of patients (84%) while TNFi were mostly 1st line biologics (86%). Patients starting TCZ had a longer disease duration. Efficacy was demonstrated by a marked decrease in JADAS10 in both cohorts (TCZ vs. TNFi at baseline: 15.0±6.7 vs. 14.6±4.3; at month 12: 3.8±6.5 vs. 3.4±4.5). Proportions of patients in TCZ TNFi cohorts achieving JADAS remission at 12 months were 48%/41% in 1st line biologic users and 32%/33% in 2nd line biologic users. JADAS MDA was achieved in 64%/69% in 1st line and 52%/58% in 2nd line users of TCZ/TNFi. After 12 months of treatment JADAS10 (mean ±SD) was higher in the 2nd line TNFi cohort compared to the 1st line (4.5±6.5 vs. 3.2±4.3), similar to patients receiving TNFi. Patients receiving 2nd or 1st line TCZ (4.0±5.2 vs. 2.9±4.4). Patients receiving TCZ or TNFi as first biologic reached JADAS10 remission and MDA numerically more frequently but not statistically significant compared to 2nd line users. Safety was assessed based on adverse event (AE) reporting. 57 (33%) patients in the TCZ cohort and 43 (25%) patients in the TNFi cohort reported AE. The AE
rate was significantly higher in the TCZ cohort (69 vs. 44.8/100 patient years, RR 1.5495% CI 1.1-2.0, p=0.006, Wald-test). There were 6 serious AE in the TCZ and 3 in the TNFi cohort. Injection site reactions were more common in the TNFi cohort (9 vs. 1, p=0.043). No further differences were identified to date. There was no death and no opportunistic infection.

In the TCZ cohort, 32 patients discontinued treatment, 27 due to lack of efficacy, while in the TNFi cohort only 6 patients discontinued treatment. Treatment discontinuation was more frequent among the 2nd biologic users (n=29; 17.4%) than in first line users (n=9; 5.1%).

Conclusion: In this first interim analysis, treatment targets were reached with similar frequency after 12 months of treatment with TCZ or TNFi. TCZ was used predominantly as 2nd line biologic. Higher rates of remission /MDA were observed in 1st line compared to 2nd line biologic users. Although more AE were reported in the TCZ cohort, the occurrence of serious AE and infections was comparable in both cohorts. No new safety signals were identified. Observation is ongoing.

Background: Psychiatric comorbidities can be a significant additional burden in chronic diseases. The most common chronic inflammatory rheumatic disease in children and adolescents is juvenile idiopathic arthritis (JIA). Data on mental illness in children and adolescents with JIA are heterogeneous.

Objectives: To assess the frequency of depressive and anxious symptoms in patients with JIA compared to healthy peers.

Methods: Data were analysed from JIA patients and healthy controls of the same age included in the inception cohort of newly diagnosed children and adolescents with JIA (ICON). Depressive symptoms (using the Patient Health Questionnaire (PHQ-9, score 0-27) and anxious symptoms (Generalised Anxiety Disorder Scale (GAD-7, score 0-21) were captured 7 or 9 years after inclusion in ICON in patients aged thirteen years or older at the time of filling in these questionnaires. Symptom severity for both instruments was assessed by sum score with the following cut-off values: PHQ-9 score < 5; none, 5-9: mild, 10-14: moderate, 15-19: severe, ≥ 20: very severe. GAD-7 Score < 5; none, 5-9: mild, 10-14: moderate, ≥ 15: severe. Disease parameters such as Physician Global Assessment of Disease Activity (PhGA Disease Activity, numerical rating scale, (NRS),(0-10, 0=best), joint count (n) and patient-reported outcomes on functional limitations (C/CHAQ, score 0-3, 0=best), Patient Global Assessment of Well-being (PGA Well-being), pain and fatigue (NRS, 0-10, 0=best) were also documented.

Results: The analysis included 344 patients, 157 (45.6%) < 18 years old (mean 15.5 ± 1.6 years, 64.3% female), 187 (54.4%) ≥ 18 years old (mean 21.5 ± 2.1 years, 65.2% female) and 224 control subjects, 115 (51.3%) < 18 years old (mean 15.2 ± 1.5 years, 60% female), 109 (48.7%) ≥ 18 years old (mean 21.4 ± 1.9 years, 58.7% female). Almost 40% of patients had oligoarthritis (26% persistent OA, 12.5% extended OA), 27% rheumatoid factor (RF)-negative polyarthritis, 6% psoriatic arthritis, 17% enthesis-related arthritis; 3% each had systemic JIA and RF-positive polyarthritis. In the total cohort, 14% of patients and 7% of controls had a PHQ-9 ≥ 10 and 10% of patients and 2% of controls had a GAD-7 ≥ 10. Within the categories of JIA, the rate of a PHQ-9 ≥ 10 ranged from 9.3% (oligoarthritis extended) to 22.2% (psoriatic arthritis).

Patients aged ≥ 18 years had higher scores for both PHQ-9 (≥ 10: 18.7%) and GAD-7 (≥ 10: 14.4%) compared to patients < 18 years (PHQ-9 < 5: 8.3%, GAD-7 < 10: 5.1%).

In patients < 18 years with PHQ-9 ≤ 10 versus ≥ 10, there were no significant differences in either PHGA disease activity (0.5±3.6 / 0.8±1.6, p=0.673) or joint count (0.5±3.6 / 0.5±1.6, p=0.999). In contrast, there was a significant difference in PHGA disease activity (0.8±1.5 / 1.6±1.4, p=0.005) but not in joint count (0.7±3.1 / 0.8±1.3, p=0.850) in patients ≥ 18 years with PHQ-9 < 10 versus PHQ-9 ≥ 10.

Female patients were more often found to have higher scores for depression and anxiety than male patients (PHQ-9 ≥ 10: female 17.5%, male 7.4%, GAD-7 ≥ 10: female 13.5%, male 4.1%) and patients more often had higher scores for depression than controls (PHQ-9 ≥ 10: female patients 17.5%, female controls 8.3%, male patients 7.4%, male controls 4.4%). The difference in the proportion of female patients with GAD-7 ≥ 10 (13.5%) compared to control subjects (2.3%) was remarkable, but in male patients this proportion (4.1%) was only slightly higher than in male controls (2.2%).

Conclusion: Depressive and anxious symptoms are common in adolescents and young adults with JIA, especially in females. In the continuous care of these patients, standardised diagnostic tools should be implemented to detect
these comorbidities, to optimise therapy and thereby reduce the burden of dis-
ease. Further research is needed to identify possible predictors of the develop-
ment of depression and anxiety in JIA patients in order to pursue preventive ap-
proaches.

HIGH INCIDENCE OF MIS-C AND OTHER AUTOIMMUNE DISEASES AFTER SARS-COV-2 INFECTION COMPARED TO COVID-19 VACCINATION IN PEDIATRIC POPULATION FROM SOUTH CENTRAL EUROPE

M. Bizjak,1 N. Emerici,1 M. Zajc Avramovic,1 T. Vesel Tjašnik,1 G. Markelj1, S. Della Padella,2 E. Conversano,2 V. Berce3, N. Toplak4, A. Taddio5,6, T. Ascioni7,8

1University Children's Hospital, University Medical Centre Ljubljana, Department of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia; 2IRCCS “Burlo Garofolo”; Institute for Maternal and Child Health, Trieste, Italy; 3University Medical Centre Maribor, Division of Pediatrics, Maribor, Slovenia; 4University of Ljubljana, Faculty of Medicine, Pediatrics, Ljubljana, Slovenia; 5University of Trieste, Faculty of Medicine and Surgery, Trieste, Italy

Background: In contrast to adults, children are less likely to develop serious disease upon infection with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) but are at increased risk for inflammatory and autoimmune dis-
eases linked to the virus (1). The reported incidence of multisystem inflammatory syndrome in children (MIS-C) varied from 0.2 to 11.4/100,000 persons under 21 years (2,3). It is yet unknown whether MIS-C can recur after SARS-CoV-2 rein-
fec tion or COVID-19 vaccination.

Objectives: To estimate the incidence and describe the spectrum of inflam-
matory and autoimmune diseases linked to SARS-CoV-2 infection and coro-
navirus (COVID-19) vaccination in pediatric patients from two neighbouring South Central European countries and regions, Slovenia and Friuli Venezia Giulia (FVG), Italy.

Methods: We performed a multi-centre prospective cohort study of all chil-
dren and adolescents (under 18 years) newly diagnosed with MIS-C or other inflammatory/autoimmune diseases linked to SARS-CoV-2 infection, who were admitted to the pediatric tertiary care hospitals in Slovenia or FVG, Italy during the period from January 1, 2020, to December 31, 2021. These hospitals serve a combined population of 587,053 children and adolescents. Only patients who had positive anti-SARS-CoV-2 antibodies and/or pos-
itive SARS-CoV-2 PCR test within 3 months prior to disease onset were considered for estimating the disease incidence. We obtained the number of patients with serious adverse events (SAE) after COVID-19 vaccination and the number of patients with severe COVID-19 in the same population. This study was conducted as a part of the EU interregional Italy-Slovenia project CATTEDRA (Cross border cooperation for innovative diagnosis of rare diseases in paediatrics).

Results: 192 children and adolescents were diagnosed with inflammatory and autoimmune diseases linked to SARS-CoV-2 (Figure 1). Median age at diagnosis was 11.9 years (IQR 7.6 –14.7). All included patients were White. Incidence of MIS-C was one in 921 children and adolescents after SARS-
CoV-2 infection and one in 5870 of all children and adolescents. Cumulative incidence of MIS-C since the start of the pandemic was 17/100,000 children and adolescents. Until December 31, 2021, 92,139 children and adolescents (15.7 %) received at least one dose of COVID-19 vaccine. Three patients pre-
sented with inflammatory/autoimmune disease after COVID-19 vaccination, including 2 patients with MIS-C and one patient with myositis. All 3 had evi-
dence of recent SARS-CoV-2 infection in form of positive anti-N SARS-CoV-2 antibodies. In the same period, 15 children and adolescents were hospital-
ised with severe COVID-19. Seven patients from our cohort were vaccinated against COVID-19 median 8 months after MIS-C and further 6 patients had a SARS-CoV-2 reinfection 3–14 months after MIS-C. None of them experienced SAE or recurrence of MIS-C.

Conclusion: MIS-C was the most common manifestation and its incidence in this predominantly white population was higher than previously reported. Based on our limited experience, MIS-C does not seem to recur after SARS-
CoV-2 reinfection or COVID-19 vaccination, however long-term data are lacking. Autoimmune diseases were much more common after SARS-CoV-2 infection than after COVID-19 vaccination. Hospitalisations due to MIS-C were seven times as frequent as hospitalisations due to severe COVID-19 in children.

Background: Treatment of children with juvenile idiopathic arthritis (JIA) is a major challenge in paediatric rheumatology. The presence of synovitis, which is difficult to detect in children, is associated with structural damage. Musculoskele-
tal ultrasonography (MSUS) can be used in JIA patients to reveal subclinical synovitis.

Objectives: Our aim was to determine if the use of MSUS is associated with therapeutic modifications in JIA. Secondary outcomes were to identify other fac-
tors associated with therapeutic modifications.

Methods: We conducted an observational study based on the JIRECH
o multicentre cohort that was developed to provide a systematic MSUS fol-
low-up for JIA patients. Follow-up occurred every six months and included clinical and US examinations. We included children who underwent MSUS of the elbows, wrists, second metacarpophalangeal joints, knees and ankles. Synovitis in US was defined by the presence of joint effusion and/or synovial hypertrophy in B-mode (a grade 1) associated or not with Doppler signals (a grade 1). US was performed by expert sonographers in the field of JIA who previously participated in the study of the reliability of

Figure 1. Inflammatory and autoimmune diseases linked to SARS-CoV-2 and severe COVID-19 in pediatric population in Slovenia and FVG, Italy

the OMERACT paediatric US synovitis definitions and scoring system in JIA (1). Clinical and biological data, disease activity score and information on therapeutics were collected.

Results: We included 112 patients with 185 visits in total. Three groups of patients were defined according to their therapeutic status: increased(22%) decreased(14%) and stable(64%) treatment. First, we compared patients with treatment escalation with the other patients. Patients with “increased treatment” had more synovitis in B-mode US than the other patients (80% vs. 65%, p=0.06). There was no difference for the presence of synovitis in Power Doppler (PD) US (30% vs. 25%, p=0.4). Patient’s and physician’s visual analogue scan (VAS) scores were significantly higher in patients with therapeutic escalation [3.3 vs 1.7, p<0.01 and 3.6 vs 1.6, p<0.0001] as well as disease activity score and inflammatory biological markers. Then, we compared patients with therapeutic de-escalation with the other patients. There was no difference in the presence of synovitis in US when compared with patients with stable treatment (62% vs. 69%, p=0.5) but there was less synovitis in B-mode ≥ grade 2 (8% vs. 24%, p=0.05).

We performed ROC curves analysis that showed that the sensitivity and specificity of the US in B-mode was similar to the physician’s VAS, disease score activity or inflammatory biological markers (Figure 1).

Figure 1. ROC curves for clinical and biological items and US in B-mode in patients with treatment escalation

Conclusion: In our study, MSUS of ten joints was not statistically associated with treatment escalation or de-escalation in B-mode and PD in patients with JIA.

Identification of causal genes and mechanisms by which genetic variation mediates juvenile idiopathic arthritis susceptibility using functional genomics and CRISPR-Cas9

A. Frantzesko1, V. Malyshева2, C. Shi1, J. Ding1, J. Bowes1,4, W. Thomson1,4, S. Eyre4, M. Spivakov2,3, G. Orozco1,4. 1University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Division of Musculoskeletal and Dermatological Sciences, School of Biological Sciences, Faculty of Biology, Medicine and Health, Manchester, United Kingdom; 2MRC London Institute of Medical Sciences, Functional Gene Control Group, Epigenesis Section, London, United Kingdom; 3Imperial College London, Institute of Clinical Sciences, Faculty of Medicine, London, United Kingdom; 4Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background: We recently performed the largest juvenile idiopathic arthritis (JIA) genome-wide association study (GWAS) to date. Disease-associated loci contain multiple single nucleotide polymorphism (SNPs), and the majority map to non-coding enhancers, making it challenging to define causal variants and genes. Functional genomics datasets in disease-relevant tissues have shown to be essential for the functional interpretation of GWAS loci. In particular, capture Hi-C (CHi-C) has been successful in detecting chromosomal interactions linking GWAS loci to their target genes. However, such datasets are lacking in JIA.

Objectives: The aim of this study is to bridge this gap and advance the knowledge of the biological mechanisms that underpin susceptibility to JIA, by integrating GWAS with public epigenomics datasets and in-house generated CHi-C from JIA patients. We focus on CD4+ T-cells, which have been shown to be one of the most relevant cell types in JIA. In addition, we use CRISPR-Cas9 to validate the regulatory effect of prioritised variants on their predicted target genes.

Methods: Credible SNP sets for the top JIA risk loci (P < 5x10^-8) were annotated using EpiMap data. Low input whole genome promoter CHi-C (PCHi-C) was performed on CD4+ T-cells isolated from blood from 3 JIA oligoarthritis patients, and data was analysed using CHiCAGO. GWAS and PCHi-C data were combined to prioritise causal genes using the Capture Hi-C Omnibus Gene Score (COGS) pipeline. We subsequently employed CRISPR activation (CRISPRa) and CRISPR interference (CRISPRi) in Jurkats to assess whether prioritised JIA variants were capable of regulating the expression of the interacting genes.

Results: 614 credible SNPs (out of 735) were found to overlap active enhancers in CD4+ T-cells, and were prioritized for further analysis.

We identified numerous significant chromatin interactions in 19 out of 44 non-MHC JIA associated loci, linking JIA SNPs mapping to T-cell enhancers to a total of 61 target genes and revealing potential novel disease pathways. Moreover, COGS prioritised a total of 7 genes (RGS14, ERAP2, HIK1, CCRM1, CCR2L1, CCR2 and CCR3).

A JIA associated locus on chromosome 3 contains 39 SNPs. It maps to an intragenic region and the causal gene/s are unclear. Our PCHi-C data revealed that this JIA locus presents chromatin interactions with the promoters of several genes, such as CCR2L1, CCR2, CCR3 and CCR5, three of which were prioritised by COGS. Two variants were selected for further analysis: rs79815064, which had the highest posterior probability, and rs8005404, the only variant within a CD4+ T-cell enhancer linked to surrounding gene activity. When both SNPs were targeted with CRISPRa and CRISPRi, we observed an increased and decreased expression, respectively, of CCR2L1, CCR2, CCR3 and CCR5, confirming their role in disease. These genes belong to the chemokine receptor family and are important regulators of the inflammatory response.

Conclusion: Our work shows how functional genomics can help identify biological mechanisms by which GWAS variants increase risk of JIA, which in turn will benefit patients through personalised medicine and the identification of therapeutic targets.

New developments in OA
synovial tissue inflammation from joint explants or biopsies can be useful. However, an ongoing challenge in using semi-quantitative assessments of synovitis is the disagreement between human pathologist scores of the same sample. We previously developed and validated a computer vision algorithm to automatically count each cell nucleus in an H&E-stained synovial whole slide image and yield a value of cell density, defined as mean nuclei count per mm² of tissue.

Objectives: We sought to develop methods to distinguish OA from RA based on machine learning analysis of histologic features on H&E-stained synovial tissue samples.

Methods: We measured 14 pathologist-scored histology features (137 RA and 152 OA patients) and computer vision quantified cell density (60 RA and 147 OA patients) in H&E stained synovial tissue samples from total knee replacement arthroplasty explants. A random forest model was trained using disease state (OA vs RA) as classifier and histology features and/or cell density as inputs, and feature importance scores for the model were calculated.

Results: Synovium from patients with RA exhibited increased lymphocytic inflammation, lining hyperplasia, neutrophils, detrus, plasma cells, Russel bodies, binucleate plasma cells, sub-lining giant cells, synovial lining giant cells, and fibrin (all p<0.001), while synovium from patients with OA had increased mast cells and fibrosis (both p<0.001). Fourteen pathologist-scored features allowed for discrimination between RA and OA samples, producing a macro-averaged area under the receiver operating curve (AUC) of 0.85. This discriminatory ability was comparable to that of the computer vision score of cell density alone (AUC = 0.88). Combining the pathologist scores with the cell density metric improved the discriminatory power of the model (AUC = 0.91).

The three most important features in this combined model were mast cells followed by cell density and fibrosis (Figure 1). AUC values for each individual feature are provided in Table 1. The optimal cell density threshold to distinguish RA from OA synovium was 3,400 cells per mm², which yielded a sensitivity of 0.82 and specificity of 0.82.

Figure 1. Importance of synovial features in distinguishing RA and OA synovium

Feature importance scores for supervised machine learning model including all 14 pathology scores and the computer vision-generated cell density.

Conclusion: H&E-stained images of RA and OA TKR explant synovium are distinct. We identified cell density, mast cells and fibrosis as the three most important features for making this distinction, with RA being characterized by increased cell density, low mast cells, and low fibrosis. Cell density greater than 3400 per mm² of tissue yields a sensitivity of 0.82 and a specificity of 0.82 for distinguishing RA from OA. In the future, this can have clinical and research applications as this technique removes the requirement for subjective selection of a certain field of interest, is reproducible, and is scalable as it does not require technical expertise of a pathologist.

Results: The proteomic analysis resulted in the identification of 558 proteins (10,466 peptides) in the serum samples. A label-free quantification algorithm was employed to quantify 468 proteins in the samples. Hierarchical clustering of the data showed the differences in protein abundance were more relevant longitudinally (BL to 24M) than in cross-sectional comparisons between the three groups under study (N, P or S). Sixty-three proteins were significantly altered (fold change >=1.5, p<0.05) when comparing BL to 24M in the N group (15 increased and 48 decreased), 53 in the P group (20 increased and 33 decreased) and 93 in the S group (19 increased and 74 decreased). Interestingly, two different endotypes were detected at baseline in the N and S groups, based on these protein modulations.

The overlapping of these proteomic profiles was analyzed between groups and is shown in the Figure 1. Proteins modulated specifically in the N group may be associated with mechanisms related with joint repair. On the other hand, six proteins (including two apolipoproteins) were increased at 24M only in the P group. Finally, 30 proteins were modulated only in the S group: five of them increased and 25 decreased. Remarkably, this latter group includes lubricin, chaperones and proteins related with proteoglycan binding, such as COMP, fibronectin or histidine-rich glycoprotein.

Figure 1. Circulating proteins identified as modulated after 24M follow-up in 45 patients from the APPROACH cohort that progressed in structure (S group; n=15), pain (P group; n=15) or did not progress (N group; n=10). The numbers with arrows indicate those proteins that decrease (arrow pointing down) or increase (arrow pointing up) compared to baseline.

Conclusion: The modulation of specific protein profiles in serum were identified as associated with the progression in structure, pain or non-progression in patients from the APPROACH cohort. Proteomic changes found specifically in the S group may be interesting circulating markers of the structural affection occurring in the joint.

Conclusion: This study showed that certain comorbidities were diagnosed more often in patients exposed to knee or hip OA, and none were less frequently diagnosed in patients exposed OA. This suggests that the management of OA should consider the risk of other long-term conditions and that further research on causality between OA and comorbidity is needed.

Conclusion: Our study suggests that prevention of weight gain from young adulthood to midlife in order to reduce overweight and obesity could have a major impact on reducing the burden of severe knee osteoarthritis and associated healthcare costs.

* if the trajectory is changed. ** PAAt and related 95% CIs were calculated by the Statin package using the formula pKr = 1 + HR, where pKr is the proportion of total knee replacements observed in the ith obesity trajectory and HR is the hazard ratio (HR) associated with that category. PAFs were calculated using pKr and HR estimated from the entire sample. All HR, values were generated from Cox proportional hazards regression models adjusted for covariables (age at baseline, sex, country of birth, physical activity, smoking history, and comorbidity) and postestimation analyses.
New South Wales, St Vincent’s Clinical School, Sydney, Australia; The University of Western Australia, School of Human Sciences, Crawley, WA, Australia

Background: Overweight and obesity are associated with greater incidence and progression of the structural defects of knee osteoarthritis, but it is unknown if weight loss is of benefit.

Objectives: To describe the association between change in body mass index (BMI) and the incidence and progression of structural defects in knee osteoarthritis.

Methods: Scores from radiographic analyses of knees at baseline and at 4 to 5 years’ follow up were obtained from three independent data sets (the OA1 and MOST data sets from the United States from America, and the CHECK data set from the Netherlands). The exposure of interest was change in BMI from baseline to 4 to 5 years’ follow up. To investigate the incidence of structural defects of knee osteoarthritis, we selected a total of 9732 knees (from 5802 participants) that had a Kellgren-Lawrence (KL) grade of knee osteoarthritis at baseline of ‘none’ (0) or ‘doubtful’ (1) (the ‘incidence cohort’), and determined the odds of having a KL grade at follow-up of ‘minimal’ (2), ‘moderate’ (3), or ‘severe’ (4) (the ‘progression cohort’). To investigate progression, we selected a total of 6084 knees (from 3996 participants) that had a KL grade at baseline of ‘minimal’ (2), ‘moderate’ (3), or ‘severe’ (4) (the ‘progression cohort’), and determined the odds of increasing by 1 or more KL grades by follow up. The degradation of three individual structural features of knee osteoarthritis (i.e., joint space narrowing, osteophytes on the femoral surface, and osteophytes on the tibial surface), on both the medial and lateral sides of the knee, were also investigated in both the incidence and progression cohorts. Here, degradation was defined as an increase by 1 or more Osteoarthritis Research Society International (OARSI) grades.

Results: Change in BMI was positively associated with both the incidence and progression of knee osteoarthritis, as defined by KL grade. Specifically, for each one-unit change in BMI, the adjusted odds ratio for incidence was 1.05 (95% confidence interval [CI] 1.02 to 1.09), and for progression, the same adjusted odds ratio and 95% CI was also observed. Change in BMI was also positively associated with degradation (i.e., narrowing) of joint space on the medial but not the lateral side of the knee, with an adjusted odds ratio of 1.08 (95% CI 1.04 to 1.12) in the ‘incidence cohort’ and 1.08 (95% CI 1.03 to 1.12) in the ‘progression cohort’. Degradation of the tibial and femoral surfaces (i.e., osteophytes) was also seen on the medial but not the lateral side of the knee, but only in one of the two cohorts investigated (the ‘incidence cohort’), with an adjusted odds ratio of 1.07 (95% CI 1.03 to 1.12) for osteophytes on the femoral surface, and 1.05 (95% CI 1.01 to 1.09) for osteophytes on the tibial surface.

Conclusion: Each one-unit reduction in BMI is associated with a 5 to 8% decrease in the odds of the incidence and progression of the structural defects of knee osteoarthritis, with lower odds of structural degradation specific to the medial – not lateral – side of the knee.

Acknowledgements: We acknowledge the provision of datasets and/or research tools from three studies: the Osteoarthritis Initiative (OAI) Study; the Multicenter Osteoarthritis Study (MOST); and the Cohort Hip and Cohort Knee (CHECK) Study.

The OAI is a collaborative informatics system created by the National Institute of Mental Health and the National Institute of Arthritis, Musculoskeletal and Skin Diseases (NIAMS) to provide a worldwide resource to quicken the pace of biomarker identification, scientific investigation and OA drug development. The OAI data repository is housed within the National Institute of Mental Health (NIMH) Data Archive (NDA). For the MOST data set, we wish to acknowledge the contributions of the study participants, investigators and research staff involved. MOST is comprised of four (4) cooperative grants: U01 AG18820 David T. Felson (Boston University); U01 AG18832 James Torner (University of Iowa); U01 AG18947 Cara E. Lewis (University of Alabama at Birmingham); U01 AG19069 Michael C. Nevitt (University of California, San Francisco), funded by the National Institutes of Health, a branch of the Department of Health and Human Services, and conducted by MOST investigators. This manuscript was prepared using MOST data and does not claim, infer, or imply endorsement by MOST, by the MOST investigators and their respective institutions or by the University of California of the Data Recipients’ use of the Data, of the entity or personnel conducting the research, or of any results of the research.

Englund10, S. M. A. Biema-Zeinstra11, W. Zhang1 on behalf of FOREUM OA Comorbidity Consortium. 1University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom; 2Erasmus MC University Medical Center Rotterdam, 3Department of General Practice, Rotterdam, Netherlands; 2Erasmus MC University Medical Center Rotterdam, Department of General Practice, Rotterdam, Netherlands; 4Lund University, Department of Clinical Sciences Lund, Lund, Sweden; 5University of Oxford, NDORMS, Oxford, United Kingdom; 6Keele University, School of Medicine, Keele, United Kingdom; 7Chang Gung Memorial Hospital, Division of Rheumatology, Allergy and Immunology, Taiwan, Taiwan, Republic of China; 8University of Nottingham, Department of Primary Care, Nottingham, United Kingdom; 9University of Bristol, Musculoskeletal Research Unit, Bristol Medical School, Bristol, United Kingdom

Background: People with osteoarthritis (OA) are at higher risk of developing a wide array of comorbidities. Whether the use of non-steroidal anti-inflammatory drugs (NSAIDs) contributes to the increased risk of some incident comorbidities remains unknown.

Objectives: To examine the contribution of NSAIDs in the development of a wide range of comorbidities in people with and without OA.

Methods: This observational cohort study used the UK primary care Clinical Practice Research Datalink (CPRD) GOLD containing data on 20+ million people covering 937 practices. We identified 259,000 people with incident OA and 259,000 age (≥2 years), sex, and practice matched controls at 1:1 ratio. Controls were assigned the same index date (the date of first diagnosis of OA) as cases for the start of follow-up. Both cases and controls were further divided into two groups according to NSAID prescriptions at any time after the index date. This allowed us to examine both the main effect of each exposure and interaction between OA and NSAID exposure after the index date. People with an NSAID prescription before the index date were excluded from the study. NSAID exposure was defined as at least two prescriptions within 90 days. Exposure status of each participant was assessed every six months as yes, no (at the end of the study/outcome of interest). Changes in the exposure status after the index date were calculated, whichever came first. Comorbidities were grouped into 9 categories as cancer, cardiovascular disease (CVD), endocrine, psychological, renal, gastro-intestinal (GI), genitourinary, hepatic, and neurological conditions. Propensity scores for the prescription of NSAIDs were calculated using a logistic regression model including age, sex, body mass index (BMI), musculoskele-tal and pain related conditions covariates. The propensity score adjusted time varying exposure analysis was undertaken using a multivariate COX model and hazard ratio (HR) and 95% confidence intervals were calculated. Proportional hazard assumption was tested using Schoenfeld test. Smoking, alcohol, ever prescription of proton pump inhibitors (PPIs) and other comorbidities were included in the adjusted model. The additional contribution of NSAIDs
and OA towards the incident comorbidity was estimated using addictive inter-
action methods. We also investigated the individual risk across non-selective,
and COX-2 selective NSAIDs.

Results: The mean age was 59.4±12.8 years in people with OA and
60.2±12.8 years for controls with 57.7% being female. Nearly two thirds of
people with OA were prescribed NSAIDs as defined, compared to one third
in the control population. People with OA and exposed to NSAIDs had high-
est risk of developing psychological (1.51; 1.43,1.60), CVD (1.38; 1.33,1.43),
cancer (1.34; 1.25,1.44), GI (1.25; 1.16,1.34) and renal (1.17; 1.11,1.24)
comorbidities after adjusting for all the covariates and PPI drugs, compared
to the non-OA and non-NSAID group. (Figure 1) Interaction between OA
and NSAID was significant for cancer, GI, renal, hepatic, and neurological
outcomes. Within people with OA, non-selective NSAIDs increased the risk
of CVD (1.25; 1.20,1.30), cancer (1.11; 1.04,1.19), endocrine (1.15; 1.10,1.19),
renal (1.19; 1.13,1.26) and psychological (1.21; 1.15,1.28) comorbidities,
whereas COX-2 selective NSAIDs increased risk of incident CVD (1.34;
1.25,1.44), endocrine (1.13; 1.04,1.21), renal (1.25; 1.14,1.37), and psycho-
logical (1.21; 1.09,1.34) comorbidities.

Figure 1. Hazard ratio of developing different comorbidities (reference group: no OA and no
NSAIDs) OA- Osteoarthritis; NSAIDS- Non-steroidal anti-inflammatory drugs.

Conclusion: Use of NSAIDs among people with OA is associated with increased
risk of a wide variety of comorbidities. Non-selective and COX-2 selective
NSAIDs are both associated with increased risk of cardiovascular, renal, and
psychological comorbidities.

OP0229
OSTEOARTHRITIS OF THE KNEE, INFLAMMATION,
AND THE EFFECT OF ADALIMUMAB (OKINADA): A
RANDOMIZED PLACEBO-CONTROLLED TRIAL

W. P. Maksymowych1, 2, L. Bessette3, R. G. Lambert4, A. Carapellucci5, C.
T. Appleton6, 1University of Alberta, Medicine, Edmonton, Canada; 2CARE
ARTHRTIS LTD, Rheumatology, Edmonton, Canada; 3Université Laval,
Medicine, Quebec City, Canada; 4University of Alberta, Radiology, Edmonton,
Canada; 5Bone and Joint Institute, Medicine, London, Canada; 6Schulich
School of Medicine and Dentistry, Western University, London, Canada

Background: Cytokines such as tumor necrosis factor (TNF-α) have been
shown to elicit inflammatory and catabolic events in the joints of patients with
osteoarthritis. Recent RCTs demonstrated that TNF-α inhibition has no effect
on pain and MRI-detected synovitis or bone marrow lesions in patients with
erosive hand OA. However, the progression of bone erosions was reduced in a
subset of patients with more clinically swollen distal interphalangeal joints in one RCT. Consequently, it remains possible that TNF-α inhibition
may have beneficial effects in specific subgroups of patients with a high
inflammatory component.

Objectives: We aimed to evaluate the efficacy and safety of a TNF-α inhibitor,
adalimumab (ADA), in a proof-of-concept study in patients with inflammatory OA
of the knee.

Methods: OKINADA was a 52-week, randomized, double-blind, pla-
cebo-controlled, parallel-group study done at 11 sites in Canada
(NCT02471118). Eligible participants were adults (aged ≥18 years) with
a diagnosis of OA of the index knee and classified according to American
College of Rheumatology criteria, including radiological evidence of OA
(Kellgren-Lawrence grades 2 or 3) with clinical signs of knee effusion. Sub-
jects had persistent knee pain of ≥ one month duration with a pain score
of ≥ 4 (0-10 NRS) in the index knee at screening and baseline despite
delontventional treatment with maximum tolerated acetylamophene and/or
non-steroidal anti-inflammatory drug. Patients were randomly assigned
(1:1) to receive subcutaneous 40 mg ADA every 2 weeks or placebo
(PBO). Primary endpoint was the Outcome Measures in Rheumatology
and Osteoarthritis Research Society International set of responder cri-
teria (OMERACT-OARSI) at week 16 defined as: (1) improvement in pain
or function ≥50% and an absolute change ≥20 mm; or (2) improvement
of ≥20% with an absolute change ≥10 mm in at least two of the following
three categories: pain, function, and patient’s global assessment. Second-
ary endpoints included: the Knee Injury and Osteoarthritis Outcome Score
(KOOS) for the domains of pain, activities of daily living (ADL), OA symp-
toms, sport and recreation function (SRF), and knee-related quality of life
(QoL), patient’s global assessment of disease status (PGAD), investigator
global assessment of disease status (IGAD), and expanded Target Joint
Assessment (TJA) score.

Results: A total of 59 patients were randomized (29 to PBO, 30 to ADA). The
primary endpoint was not met: OMERACT-OARSI combined (ADA: 9 [30.0%]
vs PBO: 7 [24.1%], p=0.62). For KOOS pain, ≥20% improvement was noted in
11 (36.7%) ADA vs 7 (24.1%) PBO patients (p=0.30), and ≥50% improve-
meth in 5 (16.7%) ADA vs 6 (20.7%) PBO patients (p=0.69). There were no signif-
cant treatment-group differences in baseline to 16-week change in continuous
secondary endpoints (ADA vs PBO: KOOS ADL 6.5 vs 8.4 (p=0.71), KOOS
QoL 10.1 vs 7.4 (p=0.66), KOOS symptoms 7.8 vs 11.5 (p=0.42), KOOS SRF
5.8 vs 7.7 (p=0.76), PGAD -1.0 vs 0.1 (p=0.10), IGAD -1.5 vs -2.1 (p=0.30), TJA
-2.4 vs -2.2 (p=0.67) or in lab markers (ESR, CRP). There were 11 withdrawals
(4 ADA, 7 PBO) of which 2 were for adverse events (1 ADA, 1 PBO) and 2 for
increasing knee pain (1 ADA, 1 PBO). No new safety signals were identified
and there were no serious adverse events.

OP0230
ANTIHISTAMINE USE AND STRUCTURAL PROGRESSION OF KNEE OA: A POST-HOC ANALYSIS OF TWO PHASE III CLINICAL TRIALS
A. R. Bihlet1, C. P. Miller1, I. Byrjalsen1, J. R. Andersen2, M. Karsdal2, M. C. Baker3, T. R. Rao4. 1NBCD A/S, Herlev, Herlev, Denmark; 2Nordic Bioscience A/S, Herlev, Herlev, Denmark; 3Mobility Bio Inc., Palo Alto, Palo Alto, CA, United States of America; 4Stanford, Division of Immunology and Rheumatology, Stanford, United States of America

Background: Prior studies indicate that mast cells are involved in chronic inflammation and that their activation in the synovium may contribute to structural progression of osteoarthritis (OA), however the exact role of mast cells in structural progression of OA remains unclear. Antihistamines act by blocking histamine receptors, and current reports describing antihistamine use in OA patients suggest that antihistamines may reduce development of OA and lead to reduced risk of structural progression.

Objectives: We aimed to investigate whether antihistamine use during a two-year trial period was associated with differences in structural progression of OA, as compared with non-use.

Methods: This is a post-hoc analysis of two large phase III trials investigating oral salmon calcitonin in knee OA (NCT00486434 and NCT00704847). The primary outcome measure was structural progression defined as the change in minimum joint-space width measured by use of x-ray imaging from baseline to Year Two. In these trials, participants reported use of antihistamines, defined as medication coded with the ATC code R06A. In our study, we evaluated differences between groups of participants who reported use of antihistamines, versus those who did not, over the 2-year study period. Secondly, the duration of antihistamine use divided into categories of either no use, 1-49, 50-299 or >300 days of use was investigated to evaluate exposure-response relationships. The effect of use of antihistamines was evaluated using ANCOVA analysis adjusting for age, sex, BMI, and baseline JSW.

Results: Of a total study population of 2,206 participants, 1,485 completed the trial. Of these, 1,327 were non-users of antihistamines (mean age 64.4 years, 64.1% female, mean BMI 29.0 kg/m²) and 158 reported use of antihistamines (mean age 64.4 years, 64.1% female, mean BMI 28.1 kg/m²). Seventy-four participants reported use of antihistamines, defined as medication coded with the ATC code R06A.

Conclusion: Although the treatment was safe, short-term treatment with anti-TNFα therapy does not appear to provide clinically meaningful improvements in OA symptoms in patients with established radiographic knee OA. Analyses of structural endpoints will be reported when results are available.

Granada, Granada, Spain; 6Biobanco del Sistema Sanitario Público de Andalucía, Andalusian Public Health System Biobank, Granada, Spain

Background: Systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), systemic sclerosis (SSC), Sjögren's syndrome (SJS), mixed connective tissue disease (MCTD), primary antiphospholipid syndrome (PAPS) and undifferentiated connective tissue disease (UCTD) are classified as systemic autoimmune diseases (SADs). They are diagnosed based on different clinical and laboratory criteria. Due to their high internal heterogeneity and overlapping symptoms, SADs are difficult to diagnose. Therefore, molecular and cellular-based studies need to be undertaken to precisely classify the patients. Mass cytometry is a single-cell proteomics technology that measures approximately 50 markers per cell, thus it is a suitable tool to perform deep-phenotyping studies in SADs.

Objectives: Explore differences and similarities between SADs and build reclassification framework using high-dimensional cytometry data.

Methods: The whole blood samples collected from 129 individuals, including patients and controls were stained with a 39-plex antibody panel and acquired
in 9 batches on a CyTOF (HELIOS) instrument. Data were cleaned, and nor-
malized for batch effects using semi-automated cytof analysis pipeline. Cell
frequencies and median signal intensities (MSI) for each population were
extracted using FlowSOM for mononuclear cells (PBMC) and Phenograph
granulocytes. Secretion of 44 cytokines and chemokines were analyzed using
a multiplexed luminox assay. Diseases were compared by Kruskal-Wallis anal-
ysis and hierarchical clustering and reclassification was done using unsuper-
vised k-means clustering. Cytokine analysis across clusters was performed using
Kruskal-Wallis test.

**Results:** Differently expressed features were observed between patient groups.
regarding frequency of classical monocytes, B and T cell subpopulations,
mature and immature granulocytes and intensities of CD38, HLA-DR and CD95
across various populations. However, none of them were disease specific.
K-means clustering identified four patient clusters, which were composed by a
mixture of different diagnosis. Cluster C1 was characterized by increased levels
of circulating cells from PBMC compartment, and lower activation of different
populations of the T cell compartment. It presented lower frequency in multiple
granulocyte populations and the highest expression of CD95 and CD38. This
cluster was also associated with antimalarial and steroid treatment. Clusters C1
and C2 were exactly opposite to each other, cluster C3 was characterized by
intermediate features between C1 and C2 and cluster C4 could be considered
as undifferentiated, mixed group. Higher production of TNFα, IL-10 and IP-10
were found in patients from C1 compared to C2, suggesting more active pheno-
type in C1 and physiological one in C2. The cytokine levels were independent of
the treatment.

**Conclusion:** We constructed a patient reclassification framework using
cell frequencies and expression levels of functional markers. To our knowl-
edge this is the first time when 7 different SADs were compared using
mass cytometry. In agreement with other reports we did not detect any
disease-specific cellular markers. Distribution of diagnosis across different
clusters confirms diseases heterogeneity. Patients can be classified into
phenotypically similar groups, that could potentially benefit from the same
line of treatment.

America; 2 Annexon Biosciences, Research, San Francisco, United States of
America; 3Annexon Biosciences, Clinical Development, San Francisco, United States
of America; 4University of California, Department of Medicine, San
Francisco, United States of America

**Background:** Proliferative lupus nephritis (LN) involves immune complex depo-
sition in the kidney that can severely impact normal renal clearance mechanisms.
Immune complexes can activate C1q and the classical complement cascade,
and along with pathogenic anti-C1q antibodies (PACAs), may amplify inflam-
mation and disease progression. Martin et al reported that circulating C4d, a marker
of complement activation downstream of the C1 complex, correlated well with
C4d immunohistochemistry score in kidney tissue and could be a sensitive and
specific biomarker for diagnosing active LN.1

**Objectives:** To confirm and extend observations by Martin et al, and to extend
a link between C4d, C1q activation, and PACA levels to identify patients most
likely to have the classical complement pathway as a driving component of
disease. Such patients would be potential candidates for anti-C1q therapy,
such as ANX009, to dampen disease activity and slow disease progression
(NCT04535752).

**Methods:** Plasma samples were collected from a cohort of 40 LN patients
(20 with disease flare and 20 without disease flare) from the California
Lupus Epidemiology Study (CLUES), a multi-racial/ethnic cohort of indi-
viduals with physician-confirmed systemic lupus erythematosus, and 20
healthy controls (Table 1). A panel of complement factors, including 15 com-
plement protein and relevant complexes, were measured using an enzyme-
linked immunosorbent assay. Clinical disease activity was measured using

*Reported as median (IQR). LN, lupus nephritis; N/A, not applicable; SLEDAI, Systemic Lupus Erythematosus Disease Activity Index; UPCR, urinary protein/creatinine ratio.

**Results:** We observed evidence of coordinated complement activation in LN
patients relative to healthy controls. Specifically, levels of C4d and the C4d/C4
ratio were highly increased in LN patients with flare, while levels of C1q, C1s,
and C4 were decreased, consistent with activation of the classical comple-
ment pathway (increased activation and component consumption). The C4d/
C4 ratio also correlated with levels of PACA isoforms 1 and 3 that are known
to activate the classical pathway. Improvements in C4 and C4d/C4 ratio were
associated with improvements in proteinuria and SLEDAI following treatment
for disease flare, indicating their potential value as biomarkers of treatment
effect.

**Conclusion:** A subset of LN patients exhibited high C4d/C4 ratio along with
specific markers of classical pathway activation, indicating that the classical
complement pathway may be a driving component of their disease. Reduc-
tion in this ratio appears to correlate with treatment response, but its levels
are generally not normalized, suggesting an insufficient resolution of com-
plement-mediated inflammation by currently available treatments. Our data
support a clinical hypothesis that a subset of LN patients may benefit from a
precision medicine approach targeting the classical complement pathway
(Figure 1). This hypothesis will be evaluated in a forthcoming clinical trial
testing the subcutaneously administered C1q inhibitor ANX009 in patients
with active LN.

Interestingly, p16Ink4a seems to be associated with CD8 T cell infiltration, renal and systemic disease severity. These likely involve both the infiltrating immune and resident renal cell compartments. Cellular senescence is the irreversible arrest of the cell cycle through the accumulation of cyclin dependent kinase (CDK) inhibitors such as p16INK4a (CDKNA2). Senescent cells nevertheless remain metabolically active and undergoing morphological and physiological changes including the acquisition of a pro-inflammatory, pro-fibrotic senescence-associated secretory phenotype (SASP). Aberrant accumulation of senescent cells has been observed in renal aging and pathology. We recently described the presence of p16INK4a-positive cells (a senescence hallmark) in LN renal biopsies, and their association with baseline disease severity and 5 year outcome.

In addition, we observed a spatial co-distribution between tissue-infiltrating CD8 T cells, senescent kidney cells, suggesting a pathogenic functional interaction between them.

Objectives: We hypothesize that cellular senescence may contribute to tissue damage in a few different ways: (a) Presentation of senescence-associated antigens that attract and activate CD8 T cells. Alternatively, CD8 T cells may be summoned to the kidney by other means, and may contribute to senescence-induction through the secretion of certain cytokines; (b) Secretion of pro-fibrotic, pro-inflammatory molecules, and/or (c) Functional incapacitation of kidney cells, particularly renal progenitor cells, responsible for repairing and restoring kidney function upon damage. In parallel with our work on patient samples, we aim to establish a relevant pre-clinical model in which we may test for the effects of senescence and senescence-directed interventions, on kidney damage.

Methods: Here, we assess for whether the B6.Sle1.Sle2.Sle3 spontaneous lupus-prone mouse may serve as an appropriate model in which to study the role of cellular senescence. We evaluated the presence and distribution of p16INK4a-positive cells by immunohistochemistry, and tested for an association with CD8 T cell infiltration and renal and systemic disease, in a cohort of 21 B6.Sle1.Sle2.Sle3 female mice. This is now being followed-up by a systematic longitudinal study for the time of onset of different renal and systemic disease parameters, as compared to the detection of renal cell senescence in this well-characterized model.

Results: As observed in renal biopsies from LN patients, staining for p16INK4a-positive cells was heterogenous between mouse kidney samples. Interestingly, p16INK4a seems to be associated with CD8 T cell infiltration, renal impairment and damage, independently of age. This will now be confirmed using the “senescence-associated β-galactosidase” assay, the other classic measure of cellular senescence.

Conclusion: We report the occurrence of cellular senescence, and its correlation with CD8 T cell infiltration and disease severity, in the B6.Sle1.Sle2.Sle3 mouse model of lupus. These mice provide a pre-clinical model in which to test for the role of cellular senescence in the pathogenesis of LN in vivo (by the induction vs. selective elimination of senescent cells). They also serve as an alternative source (alongside patient samples) of cells for in vitro functional assays to test for the effects of senescent renal cells on CD8 T cells and vice versa.

Objectives:

Nature. However, the DNAm patterns in purified immune cell populations are aberrant DNA methylation (DNAm) pattern with a predominant interferon signature. MTA3 activity.

Conclusion:

(p=0.03) in B cells.

Methods:

related to PLSCR1 B cells and hypomethylation in all but PARP9 methylation in granulocytes (p<0.0001) in non-coding clusters located on chromosome 22 downstream of TRAF5, and in non-coding clusters with no genic association. The non-gene methylated CpGs with 1360 genes in the promoter region restricted to differential methylation >10% and ≥2 DMCs, of which 1087 were hypermethylated. Of these, the most significantly hypermethylated CpGs in the promoter region included CAYBR, TPMRSS7, SLC6A2, KLK10/KLK11, WIZ, LPAR1, ZNF365B and IL1R1 (Figure 1). Top hypomethylated genes included IFI44L and MX1. Inguinity Pathway Analysis (IPA) predicted top upstream regulators in B cells to be IL4, TNF and IFNG. In addition, we identified 1437 DMCs associated with ncRNA and 4626 DMCs with no genic association. The non-gene associated DMCs were related to 275 non-coding clusters. Top non-coding clusters were in proximity to BMP7, ARHGFE10, PRDM1, RIN2 and CCR6, which themselves were differentially methylated. IPA predicted IL2, CD40LG and NFKB1 as the most important upstream regulators for neighbouring genes of non-coding clusters.

Pyrosequencing confirmed B cell hypermethylation in SLE patients is widespread, and hypomethylation in all but CD4 T cells, monocytes, granulocytes and B cells in SLE patients compared to healthy controls (HC).

Results:

Overall, SLE patients with active LN compared to HCs exhibited DMCs in 22, 46, 312 and 78,068 probes in CD4 T cells, monocytes, granulocytes and B cells, respectively. In CD4 T cells, monocytes and granulocytes, the majority of DMCs were hypomethylated and related to interferon-regulated genes. In B cells, the majority of DMCs were hypermethylated with 1960 genes in the promoter region restricted to differential methylation >10% and ≥2 DMCs, of which 1076 were hypermethylated. Of these, the most significantly hypermethylated CpGs in the promoter region included CAYBR, TPMRSS7, SLC6A2, KLK10/KLK11, WIZ, LPAR1, ZNF365B and IL1R1 (Figure 1). Top hypomethylated genes included IFI44L and MX1. Ingenuity Pathway Analysis (IPA) predicted top upstream regulators in B cells to be IL4, TNF and IFNG. In addition, we identified 1437 DMCs associated with ncRNA and 4626 DMCs with no genic association. The non-gene associated DMCs were related to 275 non-coding clusters. Top non-coding clusters were in proximity to BMP7, ARHGFE10, PRDM1, RIN2 and CCR6, which themselves were differentially methylated. IPA predicted IL2, CD40LG and NFKB1 as the most important upstream regulators for neighbouring genes of non-coding clusters.

Pyrosequencing confirmed B cell hypermethylation in CXCR5, DDR1, MT3, Rab30 and glycoprotein in IFI44L, LGALS3BP and PARP9 was stable at follow-up as well as in patients with inactive and never-LN. Patients in the active LN group exhibited significantly more pronounced hypermethylation in PLCSCR1 in CD4 T-cells, granulocytes and B-cells compared to the other patient groups. Greater j2 microglobulin, anti-DNA antibodies and disease activity were significantly associated with greater B cell CXCR5 hypermethylation (p<0.001), IFI44L hypermethylation in all but CD4 T cells, LGALS3BP hypermethylation in granulocytes (p<0.0001), PARP9 hypermethylation in all but B cells and PLCSCR1 hypermethylation in all but monocytes. Proteinuria was related to PLCSCR1 hypermethylation in all but monocytes, as well as hypermethylation at the non-coding cluster in chromosome 3 (p=0.05) and MT3 (p=0.03) in B cells.

Conclusion: B cell hypermethylation in SLE patients is widespread, and may indicate a novel mechanism for SLE pathogenesis. Differential methylation of several interferon-regulated genes may be associated with disease activity.

Ehrenstein1. 1University College London, Department of Ageing, Birmingham, United Kingdom; 2University of Birmingham, Rheumatology Research Group- Institute of Inflammation and Ageing, Birmingham, United Kingdom; 3University of Manchester, Manchester, United Kingdom; 4University of Liverpool, Comprehensive Clinical Trials Unit, London, United Kingdom; *University of Birmingham, Rheumatology Research Group- Institute of Inflammation and Ageing, Birmingham, United Kingdom

Background: The results from the double-blind BEAT-lupus trial comparing belimumab vs placebo, both after rituximab in systemic lupus erythematosus (SLE) have recently been reported (1). We sought to identify biomarkers of response to belimumab after rituximab to aid a personalised approach to therapy for SLE.

Objectives: To identify biomarkers of clinical response to belimumab after rituximab in the BEAT-lupus trial.

Methods: We constructed a model utilising a range of clinical, routine and exploratory laboratory data, from the BEAT-lupus trial to identify variables at baseline (screening) that could predict a major clinical response (MCR, defined as reduction to BILAG C in all domains, steroid dose of ≤7.5mg/day & SLEDAI<2, without anti-dsDNA antibody component) at 24 weeks. Relevant serum autoantibodies and cytokines were assayed by ELISA/Simoa, and interferon signatures and BAFF expression measured by RT-PCR. A linear mixed model was applied to longitudinal data collected during the trial stratified by treatment and clinical response. An independent cross-sectional lupus cohort was recruited to validate biomarker association with organ involvement.

Results: A major clinical response (MCR) was achieved in 48% (10 responders, 11 non-responders) of patients who received belimumab after rituximab compared to 35% (8 responders, 15 non-responders) in the placebo group (i.e. rituximab alone), added to tapered standard of care, at 52 weeks. Baseline serum IgA2 anti-dsDNA antibody levels emerged as the only positive predictor of attaining MCR in belimumab treated patients (AUROC 0.8, 95% confidence interval [CI] 0.7 -1.0), but negatively predicted MCR in the placebo arm (AUROC 0.2, CI 0.1-0.4). At baseline, 77% and 85% of patients were positive for serum IgA2 anti-dsDNA antibodies in belimumab and placebo arms respectively, which reduced to 30% at 52 weeks in the belimumab group but remained unchanged with placebo (Fisher exact test, p=0.007). In striking contrast, the percentage of patients who remained IgG anti-dsDNA antibody positive from baseline to 52 weeks were similar between the belimumab and placebo group, despite the serum levels significantly falling in the belimumab group (1). A significant reduction in serum IgA2 anti-dsDNA antibody levels at 24 and 52 weeks from baseline was only observed in belimumab responders (Figure 1).

Conclusion: SGECs in the inflammatory milieu of pSS are characterized by induction of autophagy and pro-survival mechanisms, and by expression of adhesion molecules. These changes correlate with SS infiltration with immune cells and with histologic disease severity. Among clinically available therapies, the JAK/STAT inhibitor baricitinib effectively reduced autophagy, countered the state of maladaptive activation of SGECs, and restored epithelial cell homeostasis. Transcriptomics and metabolomics studies are ongoing to dissect the specific mechanisms responsible for these beneficial effects.

The number of circulating IgA2-secreting (but not total) plasmablasts (p=0.032) and T follicular helper cells (p=0.031) were significantly reduced at 52 weeks in the belimumab treated arm compared to placebo. Elevated serum IgA2 anti-dsDNA antibody levels were also associated with active renal disease irrespective of treatment arm (odds ratio, OR 3.2, CI 1.7-5.8, p<0.001). In contrast, serum IgA1 anti-dsDNA antibody (OR 1.3, CI 1.0-1.7, p=0.042) and interferon-alpha levels (OR 1.4, CI 1.0-2.0, p=0.041), and interferon transcriptional signature (OR 1.1, CI 1.0-1.3, p=0.027) showed a modest association with mucocutaneous disease activity; but did not predict response to B cell targeted therapy. Patients with a high baseline serum IL-6 were less likely to achieve an MCR irrespective of therapy (OR 0.4, CI 0.2-0.9, p=0.033). The associations between serum IgA2 and IgA1 anti-dsDNA antibody levels and active renal and mucocutaneous disease respectively were confirmed in an independent cross-sectional lupus cohort.

Conclusion: IgA2 anti-DNA autoantibodies is a biomarker of response to belimumab after rituximab, and of active renal disease, in systemic lupus erythematosus. Our study reveals distinct molecular networks associated with renal and mucocutaneous involvement, and response to B cell targeted therapies, which could guide precision targeting of current therapies for this heterogeneous disease.

Background: In cases of systematic lupus erythematosus (SLE) that lead to surgery due to the development of heart diseases such as valvular disease, ischemic heart disease and aortic aneurysm, early detection and careful monitoring is important. The absence of background diseases or immunopathological examination of the myocardial tissue in SLE cases with cardiovascular lesions demonstrates the lack of knowledge in this area. In recent years, however, there have been reports of neutrophil extracellular traps being involved in the fulminant onset of SLE.

Objectives: This study aimed to analyze clinically and immunohistopathologically the pathophysiology of heart diseases associated with SLE.

Methods: We performed left atrial appendage resection in 34 patients, including patients with cardiovascular lesions, who underwent heart surgery for SLE complications from 2012 to 2021. Tissue analysis was conducted in 9 cases. The left atrial appendage, in cases of non-collagen valvular disease, was used as the control. Tissue staining of cardiomyocytes was carried out by adding anti-neutrophil extracellular (NE) antibodies (Abs) to anti-human IgG antibody (Ab), anti-IgM, anti-CL Abs was 55.6%, which was higher than the 25.5% observed in previous SLE patients. In this study, anti-SS-A and anti-RNP Abs tended to be relatively numerous. An example of immunohistochemical staining of IgG in the left atrial appendage is presented (Figure 1a). IgG deposits were not observed on the left side of the myocardial fibers in the control group, whereas IgG deposits were observed on the right side in the SLE group. Deposits were also observed in tissues that were not located in the affected areas. The presence or absence of tissue deposition in the myocardial fibers and clinical findings in 2 cases of the control group and 9 cases of the SLE complication group are reported in Table 1. IgG deposits were found in the myocardial fibers of 6 of the 9 patients in the SLE complication group, and deposits were found in the left atrial appendage tissue regardless of the type of heart disease, suggesting a potential change in the pathophysiology of heart diseases associated with SLE.

Results: Of the 34 SLE patients, 14 had valvular disease, 8 had ischemic heart disease and 12 had aortic aneurysms. Preoperative SLE activity was relatively stable with only 1 patient below the CH50 standard and 6 patients above the anti-DNA Ab standard. The Ab positivity rate for the patients in this study was higher than that of the 687 SLE patients who were previously tested in 2019. The presence of anti-CL Abs was 55.6%, which was higher than the 25.5% observed in previous SLE patients. In this study, anti-SS-A and anti-RNP Abs tended to be relatively numerous. An example of immunohistochemical staining of IgG in the left atrial appendage is presented (Figure 1a). IgG deposits were not observed on the left side of the myocardial fibers in the control group, whereas IgG deposits were observed on the right side in the SLE group. Deposits were also observed in tissues that were not located in the affected areas. The presence or absence of tissue deposition in the myocardial fibers and clinical findings in 2 cases of the control group and 9 cases of the SLE complication group are reported in Table 1. IgG deposits were found in the myocardial fibers of 6 of the 9 patients in the SLE complication group, and deposits were found in the left atrial appendage tissue regardless of the type of heart disease, suggesting a potential change in the pathophysiology of heart diseases associated with SLE.

Conclusion: In SLE patients who developed cardiovascular lesions and required surgery, immunological abnormalities may occur in the myocardial tissue even if serum complement and anti-DNA Ab levels are stable.

Osteoporosis
different anti-osteoporotic drugs on fracture. In sensitivity analyses we generated 1:1 matched cohorts of patients with prescription of bisphosphonates, denosumab, teriparatide or without any pharmacological prescription at baseline and 1:1 matched cohort based on the T-score variation over the time (increase in T-score vs decrease or stability in T-score values).

**Results:** Data from 50,862 women were available. Among these, 3,574 individuals had at least 2 consecutive visits. The crude fracture rate was 919.1/1,000 person-year for non-treated patients. The crude fracture rate in bisphosphonate users was 72.1/1,000 person-year, in denosumab users was 58.2/1,000 person-year and in teriparatide users was 19.3/1000 person-year. Overall, we found that bisphosphonates were associated with a 30% lower risk of fracture compared to no treatment (aHR 0.70, 95% CI 0.50-0.98), denosumab and teriparatide were associated with 60% and 90% lower risk of fracture, respectively (aHR 0.43, 95% CI 0.24-0.75 and aHR 0.09, 95% CI 0.01-0.70). Bisphosphonate use was associated with a lower risk of fracture only after one year of treatment. In Figure 1 are presented the Kaplan Meier curves free from fragility fracture after propensity score matching.

**Conclusion:** In conclusion, we found that all anti-osteoporotic medications effectively reduced the risk of fracture in the real-life. Bisphosphonate’s effect on fracture risk was apparent only after the first year of treatment. Our findings do not support the use of bisphosphonates in patients at imminent risk of fracture.

Kaptoge2,1, University of Cambridge School of Clinical Medicine, Medicine, Cambridge, United Kingdom;2Addenbrooke’s Hospital, Rheumatology, Cambridge, United Kingdom;3University of Bristol, Clinical Science at North Bristol, Bristol, United Kingdom;4Cambridge Institute of Public Health, Public Health and Primary Care, Robinson Way, United Kingdom;5Norwich Clinical Trials Unit, Statistics, Norwich, United Kingdom;6Norfolk & Norwich University Hospital, Radiology, Norwich, United Kingdom;7Norwich Clinical Trials Unit, Health Economics, Norwich, United Kingdom

Background: Up to 40% of all diagnostic computed tomography (CT) scans include views of the spine or hips. Among older people, osteoporosis or vertebral fractures have been found in 30% of such CT scans. Our PHOENIX interventionrepresents CT scan taking for other reasons to identify fractures and measure bone density as an ‘added extra’. Early detection and treatment of osteoporosis in CT-attending patients could improve health outcomes.

Objectives: To determine the feasibility and efficacy of PHOENIX versus usual care in a multi-centre, randomised, pragmatic study conducted in Eastern Eng-
land involving our Cambridge Specialist Hospital ‘hub’ and four regional General Hospitals ‘spokes’.

Methods: Study design of a pragmatic, multicentre, randomised control trial (RCT) comparing PHOENIX (intervention) to Usual Care (control). Participants receiving PHOENIX were offered bone active treatment based on NOS 2009 guidelines for osteoporosis with a bone mineral density (BMD) threshold for bone active therapeutic intervention. Both groups were offered bisphosphonates if osteoporosis was diagnosed.

Results: From 1828 invites, 595 participants consented to participate of whom 423 (71%) were allocated to intervention and 172 (29%) to usual care.Baseline characteristics were well-matched (p=0.50-0.99). Of the participants in two groups: 361 (36%) women had commenced their AI prior to their cancer diagnosis. A significant reduction in fractures pre (13%) versus post (0%) was demonstrated (p=0.021). There was an overall increase in BMD in those women who were offered bone active therapy in the intervention group (p=0.074).

Conclusion: Osteoporosis treatment rates were almost tripled by screening people attending for routine diagnostic CT scans with waiting room FRAX, CT-bone densitometry and vertebral fracture analysis. This study provides real-world evidence of the success of 2017 consensus statement in lowering fracture risk. Though there has been data for positive impact on BMD decline with this approach, evidence for fracture preven-
tion has been limited. This study suggests the success of lowering bone active therapy threshold employing alternative risk modelling strategy for women with breast cancer commenced on AI. A significant reduction in fractures pre (13%) and post guidelines change (2.5%) was demonstrated (absolute risk reduction of 10.5%) which has implications for healthcare systems worldwide as we have demonstrated this approach can reduce morbidity.

ciated Bone Loss (AIBL) in postmenopausal women with hormone sensitive

OP0244

AROMATASE INHIBITORS AND FRAC TURE PREVENTION – DO NEW GUIDELINES WORK IN REAL WORLD?

A. Mirza1, Z. Win Naing1, P. Khonsari1, H. Khan1, P. Rezai1, A. K. Abbas2, M. Nisar1,1, Luton & Dunstable University Hospital, Rheumatology, Luton, United Kingdom

Background: 2,261,419 women were diagnosed with breast cancer worldwide in 2020. For postmenopausal women with hormone sensitive disease, aromatase inhibi-
tors (AI) are recommended for their mortality benefit. However, AI bone loss (AIBL) is a recognised adverse event with resultant increase in fracture risk. In 2017, a consensus statement of 7 international bone and cancer societies was published proposing an algorithm based on clinical risk factors and different bone mineral density (BMD) threshold for bone active therapeutic intervention.

Objectives: To determine the real-world impact of the 2017 consensus guide-
lines on AIBL and whether bone sparing therapy utilising proposed risk stratifica-
tion model is effective in fracture prevention.

Methods: Over a 7-year study period, 1001 women were prescribed AI at our uni-
versity teaching hospital. The new guidelines were adopted in July 2017. We split the participants in two groups: 361 (36%) women had commenced their AI prior to the adoption of guidelines and 640 (64%) were in the post implementation group. First group were offered active bone treatment based on NOS 2009 guidelines whereas the second group followed the 2017 consensus guidelines. Women with osteoporosis were all offered treatment, however the difference in guideline is pertinent to osteopenia and we compared the results of that group.

Results: 1001 women were included. Mean age was 64 years (range 29-93), 929 (93%) were Caucasian, 57 (6%) were Asian and 15 (1%) were Afro-Caribbean. 723 women (72%) had invasive ductal carcinoma and 863 women (86%) were postmenopausal. At diagnosis, 428 women (43%) had node positive disease and 35 women (4%) had metastases. 91 women (9%) had sustained fractures prior to their cancer diagnosis. 276 women (28%) were offered oral bisphosphonates based on DEXA result, with 58 (6%) offered parental therapy.

First group: 361 women had a baseline DEXA with a mean left neck of femur (LNOF) BMD of 0.889 g/cm² (range 0.593-1.001). 276 women (76%) had a repeat DEXA after a mean of 3 years. In the treatment group, LNOF mean BMD remained relatively unchanged from 0.831 g/cm² to 0.812 g/cm² at the repeat DEXA (p=0.94). Of the 174 women with osteopenia, 22 (13%) women had a fracture. Second group: 640 women had a baseline DEXA with a mean LNOF BMD of 0.890 g/cm² (range 0.512-1.390), 216 (33%) women were normal, 322 (50%) had osteopenia and 107 (17%) had osteoporosis.

Of the women with osteopenia, 127 (39%) women were offered treatment and 56 women had a repeat DEXA after a mean of 3 years. In the treatment group, LNOF mean BMD remained relatively unchanged from 0.822 g/cm² to 0.829 g/cm² at the repeat DEXA (p=0.6169).

Of the 322 women with osteopenia, 8 (2.5%) women had a fracture.

Conclusion: Our study provides real world evidence of the success of 2017 consensus statement in lowering fracture risk. Though there has been data for positive impact on BMD decline with this approach, evidence for fracture prevention has been limited. This study showcases the success of lowering bone active therapy threshold employing alternative risk modelling strategy for women with breast cancer commenced on AI. A significant reduction in fractures pre (13%) and post guidelines change (2.5%) was demonstrated (absolute risk reduction of 10.5%) which has implications for healthcare systems worldwide as we have demonstrated this approach can reduce morbidity.

ASSOCIATION OF BARIATRIC SURGERY WITH THE RISK OF FRACTURE IN PATIENTS WITH OBESITY: A META-ANALYSIS OF REAL-WORLD EVIDENCE

S. Hussain1, J. Klugarova2, M. Klugar2.
1Czech National Centre for Evidence-Based Healthcare and Knowledge Translation (Cochrane Czech Republic, Czech EBHC: JBI Centre of Excellence, Masaryk University GRADE Centre), Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic; 2Czech National Centre for Evidence-Based Healthcare and Knowledge Translation (Cochrane Czech Republic, Czech EBHC: JBI Centre of Excellence, Masaryk University GRADE Centre), Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: Evidence from published epidemiological studies found inconsistent evidence on the association of bariatric surgery with fracture risk.

Objectives: To evaluate the impact of bariatric surgery on fracture risk.

Methods: Electronic databases PubMed, and Embase were searched for studies assessing the association between bariatric surgery and fracture risk by two independent investigators. The study search period was from inception to September 2021. Study selection, data extraction, and risk of bias were assessed by investigators independently. Newcastle-Ottawa Scale (NOS) was used to assess the risk of bias. The primary outcome was to compute the pooled fracture risk in patients with obesity who underwent bariatric surgery. Secondary outcomes include fracture risk based on follow-up duration and sites of fracture (hip, upper limb).

Results: This meta-analysis was based on seven studies with a total of 156233 patients with a mean age of 41.65 ± 10.63 years. Included studies were of low certainty as per the GRADE rating system. Evidence from published epidemiological studies found inconsistent evidence on the association of bariatric surgery with fracture risk.

Subgroup analysis based on follow-up duration also revealed a significantly higher fracture risk with a RR of 1.75 (95% CI: 1.34 – 2.30), p = 0.03 for studies with a follow-up period of >5 years. Likewise, analysis based on fracture sites revealed a significantly higher risk of hip fracture RR 1.34 (95% CI: 1.03 – 1.75), p = 0.03 (Figure 2). Evidence was of low certainty as per the GRADE rating system.

Conclusion: The current study found that bariatric surgery was associated with increased fracture risk. Clinicians should also evaluate the bone health profiling of the patients before the surgery.

OP0246

TO SCAN OR NOT TO SCAN (BOTH HIPS) – A BRISTOL EXPERIENCE

A. Anilkumar1, S. Saeed2, E. Elsayed1, C. N. R. Jayatilleke1, S. Webber2, M. A. Roy1.
1University Hospitals Bristol and Weston NHS Foundation Trust, Adult Rheumatology, Bristol, United Kingdom; 2University Hospitals Bristol and Weston NHS Foundation Trust, Adult Rheumatology, Weston, United Kingdom

Background: The current International Society of Clinical Densiometry (ISCD) recommendation for bone densitometry practice is that single hip measurement is sufficient in clinical practice, as there is overall a good correlation between the two hips bone mineral densities (BMD) (1) (2). However, discordance in individual T-scores and BMD between the two hips due to increasing age and osteoarthritis (3)-(5) is well recognised.

Objectives: To identify whether discordant hip BMD values would lead to differences in the FRAX risk assessment score between the two hips, and thereby impact treatment decisions in clinical practice.

Methods: We looked at all DXA scans performed at our centre for 2 months between 23/7/21 and 23/9/21. Cases in which both hips were scanned and anti-resorptive treatment was advised were included in our study. The femoral neck with the lower BMD is used to calculate the FRAX score and this was referred to as the ‘reported’ hip. The FRAX score for ‘reported’ and ‘unreported’ hip were calculated and the T-score of the spine was also noted. Our local treatment threshold is set at 20% for a major osteoporotic fracture and 5% for hip fracture. Cases of difference in scores crossing the 20%/5% FRAX threshold were highlighted and reviewed in more detail.

Results: DXA scans were performed in 328 patients over the 2 month period, of which 201 patients had both of their hips scanned. Of these, 50 patients were advised to start anti-resorptive treatment. The majority of the treatment decisions (80%; 39/50 cases) were based on the hip/femoral neck BMD value, while 40% (20/50 cases) were based on the spine T-score.

Where the treatment decision was based on hip/femoral neck BMD, 20% (6/30 cases) were found to have a FRAX risk above the treatment threshold at one hip only, meaning that treatment may not have been offered if both hips had not been scanned. Similarly, where treatment was advised based on spinal T-scores, 20% (4/20 cases) had a FRAX risk above treatment threshold at one hip only.

Mean age across these 10 cases with a discordant FRAX risk between the two hips was 72 years (range 59 – 83); 80% (8/10) were female. Steroid use and chronic inflammatory co-morbidities were the predominant indications for these DXA Scans.

Conclusion: A significant proportion of patients in our cohort (20%; 10/50) may not have been offered treatment if only one hip was scanned. Scanning both hips does not require much additional time and can help mitigate the risk of undertreating patients. The recommendation for best practice for DXA BMD measurements should be reviewed to consider lumbar spine and dual hip BMD as standard of care.

Figure 1. Odds ratio (OR) for selected risk factors for COVID-19 positive test, hospitalization, IMV, and mortality

**Conclusion:** This analysis of COVID+ patients (n=1,101,431) from a large US health care system analyzes outcomes of patients with and without IMIDs; the majority were rheumatologic IMIDs. Patients with IMIDs had a similar rate of hospitalization, IMV, and death as those without IMIDs. The strongest associations with COVID-19 severity included heart failure and age. Spondyloarthritids was weakly associated with favorable outcomes whilst other conditions, including COVID-19 severity, were not worse than those of non-IMID patients. csDMARDS and corticosteroids were weakly associated with hospitalization and RTX with increased mortality. Other therapies were not associated with severe adverse outcomes.

Avila-Zubileta1,3, Arthritis Research Canada, N/A, Vancouver, Canada; 2University of British Columbia, Faculty of Land and Food Systems, Vancouver, Canada; 3University of British Columbia, Faculty of Science, Vancouver, Canada; 4University of British Columbia, Department of Physical Therapy, Vancouver, Canada; 5University of British Columbia, School of Population and Public Health, Vancouver, Canada; 6University of British Columbia, Divisions of Rheumatology, Department of Medicine, Vancouver, Canada; 7University of British Columbia, School of Population and Public Health, Vancouver, Canada; Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada; 8University of British Columbia, Division of Medical Oncology, Department of Medicine, Vancouver, Canada; 9BC Cancer, N/A, Vancouver, Canada

**Background:** Individuals with autoimmune rheumatic diseases (ARDs) may be at greater risk of severe COVID-19 outcomes than individuals in the general population.

**Objectives:** This study assesses the risk of COVID-19-related hospitalization, intensive care unit (ICU) admission, and COVID-19-specific mortality in patients with ARDs compared to matched general population comparators.

**Methods:** We conducted a population-based cohort study, using administrative datasets from British Columbia, Canada (February 2020-August 2021). Among all test-positive SARS-CoV-2 adults, we used ICD codes to identify all individuals with an ARD: rheumatoid arthritis (RA), psoriasis/psoriatic arthritis (PsO/PsA), ankylosing spondylitis (AS), and systemic autoimmune rheumatic diseases (SARDs), including systemic lupus erythematosus (SLE), Sjögren’s syndrome, systemic sclerosis, myositis, and adult systemic vasculitides. Individuals with an ARD were matched 1:5 to general population test-positive SARS-CoV-2 individuals on age (±5 years), sex, month/year of initial positive SARS-CoV-2 test, and health authority. Conditional logistic regression models adjusting for socioeconomic status, Charlson comorbidity index, hypertension, rural address, and number of previous COVID-19 PCR tests were performed to assess risk of COVID-19-related hospitalizations, ICU admissions, and COVID-19-specific mortality (mortality with primary ICD code for COVID-19).

**Results:** The risk of COVID-19-related hospitalization was significantly increased for patients with ARDs overall (aOR: 1.30) (Table 1). Within ARDs, the patient group at greatest risk of hospitalization was adult systemic vasculitides (aOR: 2.18). The risk of ICU admission was significantly increased for patients with ARDs overall (aOR: 1.30). Within ARDs, the patient group at greatest risk of ICU admission was those with AS (aOR: 2.03). The risk of COVID-19-specific mortality was significantly increased for patients with ARDs overall (aOR: 1.24). Within ARDs, the patient group at greatest risk of COVID-19-specific mortality was those with AS (aOR: 2.15).

Results for systemic sclerosis not presented; sample size too small. *Unable to be calculated (small sample size).
2021 were included. An ordinal severity outcome was defined as: 1) not hospitalised, 2) hospitalised without death, and 3) death. A multivariable ordinal logistic regression model was constructed to assess the relationship between COVID-19 severity and demographic characteristics (age, sex, time period of infection), comorbidities (hypertension, other cardiovascular disease [CVD], chronic obstructive lung disease [COPD], asthma, other chronic lung disease, chronic kidney disease, cancer, smoking, obesity, diabetes mellitus [DM]), rheumatic skin disease (PsO, PsA, axSpA), physician-reported disease activity, and medication exposure (methotrexate, leflunomide, sulfasalazine, TNFi, IL17i, IL-23/IL-12 + 23i, Janus kinase inhibitors [JAKi], apremilast, glucocorticoids [GC] and NSAIDs). Age-adjustment was performed employing four-knot restricted cubic splines. Country-adjustment was performed using random effects.

Results: A total of 5008 individuals with PsO (n=921), PsA (n=2263) and axSpA (n=1824) were included. Mean age was 50 years (SD 13.5) and 51.8% were male. Hospitalisation (without death) was observed in 14.6% of cases and 1.8% died. In the multivariable model, the following variables were associated with severe COVID-19 outcomes: older age (Figure 1), male sex (OR 1.53, 95%CI 1.29-1.82), CVD (hypertension alone: 1.26, 1.02-1.56; other CVD alone: 1.99, 1.22-2.94; vs no hypertension and no other CVD), COPD or asthma (1.75, 1.32-2.32), other lung disease (2.56, 1.66-3.97), chronic kidney disease (2.32, 1.50-3.59), obesity and DM (obesity alone: 1.36, 1.07-1.71; DM alone: 1.85, 1.39-2.47; obesity and DM 1.89, 1.34-2.67; vs no obesity and no DM), higher disease activity and GC intake (remission/low disease activity and GC intake: 1.96, 1.66-2.32; moderate/severe disease activity and no GC intake: 1.35, 1.05-1.72; moderate/severe disease activity and GC intake 2.30, 1.41-3.74; vs remission/low disease activity and no GC intake). Conversely, the following variables were associated with less severe COVID-19 outcomes, including IL-17i, IL-23/IL-12 + 23i, JAKi and apremilast.

Conclusions: More severe COVID-19 outcomes in PsO, PsA and axSpA are largely driven by demographic factors (age, sex), comorbidities, and active disease. None of the DMARDs typically used in PsO, PsA and axSpA, were associated with severe COVID-19 outcomes, including IL-17i, IL-23/IL-12 +23i, JAKi and apremilast.

Background: RA has been associated with poor COVID-19 outcomes, but few studies have investigated outcomes in RA features such as interstitial lung disease.

Objectives: To assess COVID-19 outcomes in patients with RA overall, and those with and without ILD, compared to general population comparators.

Methods: A multicenter, retrospective cohort study was conducted at Mayo Clinic (19 hospitals and affiliated outpatient centers in 4 states) and Mass General Brigham (14 hospitals and affiliated outpatient centers in New England). Consecutive patients with RA meeting ACR/EULAR criteria and a positive COVID-19 test from March 1, 2020 through June 6, 2021 were matched 1:5 on age, sex, race, and COVID-19 test date with general population comparators without RA. RA features assessed included: RA-ILD per Borgantz criteria [1], duration, rheumatoid factor (RF), cyclic citrullinated peptide antibody (CCP), bone erosions, and treatments. The primary outcome was a composite of hospitalization or death following COVID-19 diagnosis. We used multivariable Cox regression to investigate the association of RA, and features such as ILD, with COVID-19 outcomes compared to matched comparators.

Results: We analyzed 582 patients with RA and 2892 comparators without RA, all with COVID-19. Mean age was 62 years, 51% were female, and 79% were White. Mean RA duration was 11 years, 67% were seropositive (52% RF+ and 54% CCP+), 27% had bone erosions, 28% were on steroids, and 79% were on DMARDs. 50/582 (9%) patients with RA had ILD. The COVID-19 hospitalization or death rate for RA patients was higher than comparators (3.6% per 1,000 days [95% CI 2.3-3.8] vs. 1.9 per 1,000 days [95% CI 1.7, 2.1]), respectively. Overall, RA patients had a 53% higher risk of hospitalization or death than comparators after adjustment (95% CI 1.20-1.94).

Among those with RA-ILD, the hospitalization or death rate was significantly higher than comparators (10.9 [95% CI 6.7-15.2] vs. 2.5 per 1,000 days [1.8-3.2], respectively). RA-ILD was associated with nearly 3-fold higher risk for hospitalization or death than comparators (multivariable HR 2.84 [95% CI 1.64-4.91], Table 1). There was a significant interaction between RA/comparator status and presence/absence of ILD for risk of severe COVID-19 (p<0.001, Figure 1). The elevated risk for severe COVID-19 was similar for RA subgroups defined by serostatus or bone erosions.

Table 1. Frequencies, proportions, and hazard ratios for COVID-19 outcomes, comparing all RA patients, and subgroups with or without RA-ILD, to matched comparators.

Table: Frequencies, proportions, and hazard ratios for COVID-19 outcomes, comparing all RA patients, and subgroups with or without RA-ILD, to matched comparators.

Figure 1. Multivariable hazard ratios for the composite outcome of hospitalization or death from COVID-19, comparing all RA and subgroups by serostatus, bone erosions, and ILD to matched comparators without RA.

Conclusion: We confirmed that RA was associated with severe COVID-19 outcomes compared to the general population. We found evidence that ILD may be an effect modifier for the relationship between RA and severe COVID-19 outcomes, but RA subgroups defined by serostatus and bone erosions had similarly elevated risks. These findings suggest that ILD or its treatment may be a major contributor to severe COVID-19 outcomes in RA.

Background: There is a paucity of data in the literature about the outcome of patients with idiopathic inflammatory myopathy (IIM) who have been infected with SARS-CoV-2.

Methods: Data on demographics, number of comorbidities, region, COVID-19 time period, physician-reported disease activity, anti-rheumatic medication exposure at the clinical onset of COVID-19, and COVID-19 outcomes of IIM patients were obtained from the voluntary COVID-19 Global Rheumatology Alliance physician-reported registry of adults with rheumatic disease (from 17 March 2020 to 27 August 2021). An ordinal COVID-19 severity scale was used as primary outcome of interest, with each outcome category being mutually exclusive from the other a) hospitalization, b) hospitalization (and no death), or c) death. Odds ratios (OR) were estimated using multivariable ordinal logistic regression. In ordinal logistic regression, the effect size of a categorical predictor can be interpreted as the odds of being one level higher on the ordinal COVID-19 severity scale than the reference category.

Results: Complete hospitalization and death outcome data was available in 348 IIM cases. Mean age was 53 years, and 223 (64.1%) were female. Overall, 167/348 (48.0%) people were not hospitalized, 136/348 (39.1%) were hospitalized (and did not die), and 45/348 (12.9%) died. Older age (OR=1.59 per decade of life, 95%CI 1.32-1.93), male sex (OR=1.63, 95%CI 1.00-2.64; versus female), high disease activity (OR=4.05, 95%CI 1.29-12.76; versus remission), presence of two or more comorbidities (OR=2.39, 95%CI 1.22-4.68; versus none), prednisolone-equivalent dose >7.5mg/day (OR=2.37, 95%CI 1.27-4.44; versus no glucocorticoid intake), and exposure to rituximab (OR=2.60, 95%CI 1.23-5.47; versus csDMARDs only) were associated with worse COVID-19 outcomes (Table 1).

Conclusion: These are the first global registry data on the impact of COVID-19 on IIM patients. Older age, male gender, higher comorbidity burden, higher disease activity, higher glucocorticoid intake and rituximab exposure were associated with worse outcomes. These findings will inform risk stratification and management decisions for IIM patients.

Disclosure of Interests: Su-Ann Yeoh: None declared, Milena Gianfrancesco: None declared, Saskia Lawson-Tovey: None declared, Kimmie Hyrich Speakers bureau: AbbVie unrelated to this work, Grant/research support from: Pfizer, BMS, hospitalization (and no death) to this work, Anja Strangfeld Speaker: Abbvie.

Objectives: To investigate factors associated with severe COVID-19 outcomes in patients with IIM.
Methods: An observational cohort study design was used. The population included adults in England with new diagnoses of inflammatory arthritis between May 2018 and March 2021 who enrolled in NICEAIA. The outcomes were hospitalization due to COVID-19 (primary admission reason or nosocomial acquisition) and death due to COVID-19 (COVID-19 stated on a death certificate), identified via linkage with secondary care records. Hazard ratios were calculated using Cox proportional hazards models, with adjustment for patient factors (age, gender, smoking status, and comorbidity) and disease factors (seropositivity, 28-joint disease activity score, patient-reported disability (HAQ), and functional impact (MSK-HQ)) recorded at baseline. Individuals were considered at risk from the date of diagnosis or February 2020 (whichever was later) and censored at a COVID-19 event, death or May 2021 (whichever was sooner).

Results: 14,127 patients were included. The mean age was 57 years; 62% were female; 19% were current smokers, while 29% were ex-smokers. The frequency of comorbidities at baseline were: hypertension (19%), diabetes mellitus (9%), and lung disease (9%). Overall, 20% had two or more comorbidities. Rheumatoid factor or CCP antibodies were positive in 56%. At presentation, mean scores for DAS28 were 4.6 (+/- 1.5), 1.1 (+/- 0.7) for HAQ, and 25 (+/- 11) for MSK-HQ. Initial DMARD therapy was known for 13,682/14,127 patients: methotrexate was the most common DMARD therapy (48%), followed by hydroxychloroquine (23%), and sulfasalazine (11%).

There were 143 COVID-19 hospital admissions and 47 deaths, corresponding to incidence rates per 100 person-years for hospitalisation: 0.94 [95% CI: 0.79-1.10] and death: 0.31 [95% CI: 0.23-0.41]. Increasing age, male gender, diabetes, hypertension, lung disease and smoking status all predicted COVID-19 hospitalisation and death. Higher baseline DAS28 predicted COVID-19 hospitalisation (HR 1.24 [95% CI: 1.10-1.39]) and mortality (HR 1.33 [95% CI: 1.09-1.63]). Higher HAQ predicted both COVID-19 hospitalisation and death. Seropositivity was not a significant predictor of any COVID-19 event, nor was MSK-HQ. In unadjusted models, corticosteroids associated with COVID-19 death (HR 2.29 [95% CI: 1.02-5.13], and sulfasalazine monotherapy associated with COVID-19 hospitalisation (HR 1.93 [95% CI: 1.04-3.56]). In adjusted models, associations for corticosteroids and sulfasalazine were no longer significant. Only age, smoking status, and comorbidities independently predicted COVID-19 events.

Conclusion: The burden of COVID-19 amongst early arthritis patients was substantial during the pandemic, with concerns about the use of csDMARDs and corticosteroids. Patient characteristics and rheumatoid disease severity at diagnosis appear to be the more important predictors of COVID-19 events than initial treatment strategy. An important limitation is that we have not looked at treatment changes over time, and must acknowledge that many patients, especially those recruited in 2019, may have changed therapy prior to the pandemic.

OP0254

FACTORS ASSOCIATED WITH THE SEVERITY OF COVID-19 INFECTION IN PATIENTS WITH SPONDYLOARTHRITIS: RESULTS OF THE FRENCH RMD COVID-19 COHORT

L. Perrot1, L. Boyer2, R. M. Filpo2, H. Marotta1, E. Pertuiset1, C. Miceli Richard3, T. Thomas4, R. Seror5, P. Chazerain6, R. Nicolas4, C. Richet7, T. Pham8, 1Arts University, AHPM, Rheumatology, Marseille, France; 2Arts University, University, AHPM, Rheumatology, Marseille, France; 3Arts University, AHPM, Rheumatology, Marseille, France; 4Arts University, AHPM, Rheumatology, Marseille, France; 5Arts University, AHPM, Rheumatology, Marseille, France; 6Arts University, AHPM, Rheumatology, Marseille, France; 7Arts University, AHPM, Rheumatology, Marseille, France; 8Arts University, AHPM, Rheumatology, Marseille, France

Background: To our knowledge, no published work has described precisely the severity and evolution of SARS-CoV-2 infection in patients with spondyloarthritis (SpA). Data on COVID-19 from cohorts of patients with immune-mediated inflammatory diseases concern small samples of SpA.

Objectives: Our objective was to describe the severity and course of COVID-19 in a large cohort of patients with SpA, including axial SpA (axSpA) and psoriatic arthritis (PsA), and to identify factors associated with severe forms.

Methods: Patients: Individuals recruited in the French RMD COVID-19 cohort (observational, national, multicenter cohort) with a diagnosis of COVID-19 (clinical, PCR, CT or serology) were included.

Data collected: demographics, type of SpA, comorbidities, treatments, severity of COVID-19. Severity of COVID-19 was graded according to care needed: mild = outpatient care; moderate = non-intensive hospital treatment; severe = intensive care admittance or death. Moderate or severe outcomes were collected.

Statistical analyses: Logistic regression models were used to identify factors associated with these severe forms. All variables with p < 0.20 in the univariate analysis were proposed in the multivariate model. Treatment variables (non-steroidal anti-inflammatory drugs (NSAIDs), methotrexate (MTX), sulfasalazine (SLZ), TNF inhibitors (TNFi), IL-17 inhibitors (IL-17i) and IL-23 inhibitors (IL-23pi)) were included in the models, even if p>0.20.

Results: Between March 2020 and April 2021, 626 SpAs reported COVID-19 with a mild course in 508 cases (81.1%), moderate in 93 cases (14.8%), and severe in 25 cases (3.9%), including 6 deaths. The cohort analyzed included 349 women (55.8%), mean age 49.3 ± 14.1 years, mean BMI 27.1 ± 5.4 with 403 axSpA (64.4%), 187 PsA (29.5%) and 36 other SpA, duration of disease 11.3 ± 9.8 years; 352 (56.2%) had at least one comorbidity, of which obesity (23.6%), hypertension (15.5%), and smoking status (10.4%) were the most frequent. Among them, 104 were treated with NSAIDs (16.6%), 186 with conventional synthetic disease-modifying antirheumatic drugs (DMARDs) including 156 MTX, and 460 (73.5%) with biological DMARDs (379 TNFi, 57 IL-17i, 15 IL-23pi/p40i, 9 others).

The following variables were associated with severe COVID-19 outcomes: age, body mass index, chronic obstructive lung disease, cardiovascular disease, diabetes, hypertension, interstitial lung disease, renal failure, and corticosteroids intake.

The factors independently associated with severe COVID-19 outcomes were corticosteroid intake (3.15 [CI95%: 1.46-6.78], p = 0.004), and age (OR = 1.06 [CI95%: 1.04-1.08], p < 0.001) while anti-TNF (OR = 0.26 [CI95%: 0.09-0.78], p = 0.01) was protective. NSAIDs intake (OR = 0.97 [CI95%: 0.49-1.86]), SLZ (OR = 0.28 [CI95%: 0.60-1.03]), or anti-IL17 (OR = 0.37 [CI95%: 0.10-1.31]) was not associated with infection severity.

Conclusion: The course of COVID-19 was mild for the majority of SpA patients (81.1%). Corticosteroid intake was associated with more severe COVID-19 outcomes, whereas TNF inhibitors were found to be protective.

Background: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. BKZ has shown sustained efficacy and tolerability up to 152 weeks in a phase 2b study in patients (pts) with active psoriatic arthritis (PsA).1

Objectives: To assess efficacy and safety of BKZ vs placebo (PBO) in pts with active PsA and prior inadequate tumour necrosis factor inhibitor (TNFi) response in the 16-wk pivotal phase 3 study, BE COMPLETE.

Methods: BE COMPLETE (NCT03895581) comprises a 16-wk double-blind, PBO-controlled period. Pts were aged ≥18 yrs, had a diagnosis of adult-onset, active PsA with ≥3 tender joints and ≥3 swollen joints, and inadequate response or intolerance to treatment with 1 or 2 TNFi. Pts were randomised 2:1 to BKZ 160 mg Q4W or PBO. From Wk 16, pts were eligible to enter an open-label extension, receiving BKZ 160 mg Q4W. The primary endpoint was a ≥50% improvement in American College of Rheumatology response criteria (ACR50) at Wk 16. Primary and ranked secondary efficacy endpoints were assessed at Wk 16.

Results: Of 400 randomised pts (BKZ: 267; PBO: 133), 388 (97.0%) completed Wk 16 (BKZ: 263 [98.5%]; PBO: 125 [94.0%]). Baseline characteristics were comparable between groups: mean age 50.5 yrs, weight 86.0 kg, BMI 29.8 kg/m², time since diagnosis 9.5 yrs; 475% pts were male.

At Wk 16, the primary endpoint (ACR50: 43.4% BKZ vs 6.8% PBO; p<0.001; Figure 1) and all ranked secondary endpoints (HAQ-DI CIB, PASI90, SF-36 PCS CIB and MDA response) were met (all p<0.001; Table 1). The ACR50 response was rapid with separation from PBO observed from Wk 4 (nominal p<0.001).

Additional outcomes, including ACR20/70, TJC, and PASI75/100, demonstrated numerical improvement with BKZ compared to PBO at Wk 16 (all nominal p<0.001; Table 1).

The IR of haematological malignancies were substantial. The IR of haematological malignancies were substantial. The IR of haematological malignancies were substantial. The IR of haematological malignancies were substantial. The IR of haematological malignancies were substantial. The IR of haematological malignances (during 59 827 person-years) among TNFi treated PsA, resulting in a crude incidence rate (IR) of 67 per 100 000 person-years. The corresponding IR was 91 (63 events) for biologics-naive PsA from the CRR, and 118 (172 events) for biologics-naive PsA from NPR. This resulted in a pooled IR of 0.97 (0.69 to 1.37) for TNFi treated vs. biologics-naive PsA patients from the CRR, and 0.84 (0.64 to 1.10) vs. biologics-naive PsA patients from the NPR. The pooled IR of haematological malignances in PsA overall vs. the general population was 1.35 (1.17 to 1.52). Throughout, the results were largely similar for lymphoid and myeloid malignancies (Figure 1). The crude IR of haematological malignancies were substantially across different TNFi agents.
Psoriatic arthritis (PsA) is a chronic, immune-mediated inflammatory disease with heterogeneous musculoskeletal manifestation (arthritis, spondylosis, enthesitis, dactylitis) and extra-musculoskeletal manifestation (skin and oral involvement). Patients with PsA have a poorly defined clinical course, sometimes with periods of mild disease activity and others with exacerbations that require aggressive treatment. The novel IL-17A inhibitor izokibep is a unique IL-17A inhibitor with extraordinary potency and small molecular size designed to overcome the limitations of monoclonal antibodies such as poor tissue distribution.

**Objectives:** To assess efficacy, safety, pharmacokinetics and immunogenicity of izokibep versus placebo.

**Methods:** This is a prospective, multicenter, randomized, double-blind, placebo-controlled, parallel-groups, dose-finding trial studying bi-weekly 80 mg or 40 mg izokibep administered subcutaneously versus placebo until Week 16 (Period 1) and dose-controlled treatment until Week 46 (Period 2). PsA patients had to have ≥3 swollen and ≥3 tender joints of the 66/68 joint count, and an inadequate response to previous NSAIDs, csDMARDs or TNF inhibitor therapy. The primary endpoint was to evaluate ACR50 responses of 80 mg bi-weekly versus placebo at Week 16. Key secondary endpoints were ACR20/50/70 response rates up to Week 16 and least squares mean difference from placebo in mean tender joint count (TJC) at Week 16. The mean PsA disease duration was 7.1 (SD 7.8) years. 13% failed previous TNF inhibitor treatment and 80% received a concomitant csDMARD.

At Week 16, the confirmatory primary endpoint ACR50 response rate was met (p=0.0003). ACR50 response rate was 52% in the 80 mg group, 46% in the 40 mg and 13% in the placebo group. The ACR20/50/70 response rates up to Week 16 by treatment group are presented in Figure 1.

**Conclusion:** In this large five-country cohort study, we did not observe any increased risk of haematological malignancies overall, nor for lymphoid and myeloid types, in patients with PsA treated with TNFi. By contrast, there were signals of a moderately increased underlying risk of haematological malignancies, both of lymphoid and myeloid types, in patients with PsA overall as compared to the general population. The findings are of importance from a patient information perspective.

There was a dose-response relationship and a fast onset of response. No serious or severe adverse events occurred during Period 1. The three most frequently affected System Organ Classes (SOCs) were SOC General disorders and administration site conditions comprising mainly mild injection site reactions or erythema followed by SOC Infections and infestations and SOC Metabolism and nutrition disorders. One mild, transient vulvovaginal candidiasis infection with active treatment was reported. Apart from injection site reactions there were no apparent differences in the occurrence of adverse events between active and placebo patients.

**Conclusion:** In this phase 2 study, izokibep showed a dose-dependent high degree of efficacy in patients with active PsA having failed previous treatment. Overall, izokibep was well tolerated. These data strongly support further clinical development.

Data points are mean values. CRP, C-reactive protein.

Results: This analysis included 571 of 669 patients receiving GUS and identified four distinct response clusters (C1–4; Table 1). Mean age and body mass index (BMI) were similar across clusters; C3 had a lower proportion of female patients. Relative to C3, a high burden of BL disease was observed in C4 across clinical measures and patient-reported outcomes (PROs), and across PROs only in C2. Through Week 52, MDA response rates were highest in C3 and lowest in C4, yet all clusters showed continuous improvement in mean values across all MDA domains (Figure 1). In C3, all individual domain thresholds were rapidly reached. C1 and 2, met PASI threshold and showed a substantial reduction in SJC while other domains varied. In C1 and 2, improvement in clinical measures paralleled that of C3; however, PROs appeared to take longer to resolve. Responses were slowest in C4, though improvements were substantial for the high BL disease burden. Improvement in pain, PROs and HAQ-DI occurred earlier in C1 than C2.

Conclusion: Machine learning identified four clusters of GUS-treated PsA patients based on differing response patterns in individual MDA domains. Response types may differ due to BL disease burden, especially in patients with higher pain, PtGA and functional disability scores. These results offer an innovative, complementary approach to identifying treatment response patterns across diverse clusters of bio-naïve patients with PsA, which may facilitate clinical decision-making.

Background: Power Doppler ultrasound (PDUS) is a sensitive non-invasive imaging tool that allows the visualisation of articular and periarticular inflammation in patients with psoriatic arthritis (PsA).1, 2 A large randomised clinical trial that showed the responsiveness of the global OMERACT-EULAR ultrasound synovitis score (GLOESS) in PsA and confirmed the rapid and continued benefits of secukinumab through 52 weeks.3,4

Objectives: To report the distribution of ultrasound-detected synovitis at joint level, by degree of severity at baseline and over time, and the contribution of each core component of GLOESS, synovial hypertrophy (SH) by grayscale (GS; B-mode) and power Doppler (PD) signal, to the composite PDUS at Week 12 (Figure 1). Similar patterns were observed with PD signal in this dataset. The distribution of synovitis by grade of severity was responsible for the change in GLOESS from baseline to Week 52, in contrast with PD signal in this dataset. The distribution of synovitis by grade of severity was responsible for the change in GLOESS from baseline to Week 52, in contrast with PD signal in this dataset. The distribution of synovitis by grade of severity was responsible for the change in GLOESS from baseline to Week 52, in contrast with PD signal in this dataset.

Methods: This was a 52-week study with a 12-week double-blind, placebo-controlled treatment period followed by a 12-week open-label period and a 6-month open-label extension secukinumab treatment period. The number of joints with synovitis measured by GLOESS2 was assessed up to Week 52. The assessments included distribution of synovitis based on composite PDUS score across 24 pairs of joints (with worse score of the pair of joints used) by grade of severity (0-3) and change from baseline to Week 52 in each core component of GLOESS.3,4 Data are presented as observed.

Results: A total of 166 patients (mean age, 46.7 years; males, 45.2%) were enrolled, of which 90% (75/83) of secukinumab and 83% (69/83) of placebo participants completed 52 weeks. The mean (SD) number of PDUS detected synovitis at baseline was 9.2 (4.9) and 10.2 (5.2) in the secukinumab and placebo group, respectively. The most frequent locations with synovitis at baseline were: wrist, metatarsophalangeal (MTP) joints and metacarpophalangeal (MCP) joints (Table 1). An early and continued improvement in GLOESS was observed in both secukinumab and placebo-secukinumab groups after switching to active therapy, as previously reported at Week 12 and through Week 52.5 Among the two core components of GLOESS, SH was mainly responsible for the change in GLOESS from baseline to Week 52, in contrast with PD signal in this dataset. The distribution of synovitis by grade of severity showed that MTP joints, wrist, knee, MCP1/2 and tibiotarsal joints mostly contributed to the composite PDUS at Week 12 (Figure 1). Similar patterns were observed over 52 weeks.

Data for top nine pairs of joints with most frequently detected power Doppler ultrasound (PDUS) synovitis are presented here. Synovitis was assessed by a OMERACT-EULAR composite PDUS score >0 for each paired joint (irrespective of right or left side). The OMERACT-EULAR composite PDUS score (for individual joints) ranged from 0 to 3 and was composed of the two core components synovial hypertrophy and power Doppler. N, total number of randomised patients; n, number of evaluable patients.

Conclusion: The distribution of synovitis at baseline reflected a predominance of small joints (fingers and hands) and large joints (wrist and knee) and were mostly responsive to secukinumab over time in the ULTIMATE trial. Synovial hypertrophy was the most responsive core component of GLOESS driving an early and continued reduction of synovitis with secukinumab through Week 52. This finding could be useful to select a restricted number of joints in future ultrasound trials in PsA.

REFERENCES

69% and 73%: adjusted difference 5% (Bayesian 95% credible interval: -10% to 19%), confirming NI. The mean percentage %DDD was respectively 53% and 91% at month 12 (Figure 1). At 12 months, 58 (72%) patients of the tapering group were successfully tapered, of whom 23 (28%) discontinued their TNFi. The cumulative incidence of flares was 85% in the tapering and 78% in the no-tapering group (p=0.32). Start or escalation of concomitant medication was more frequent in the tapering group, significantly so for NSAID use: csDMARDs (only for PsA): 1 (2%) vs. 1 (5%) (p=0.64); NSAIDs: 44 (54%) vs. 10 (24%) (p=0.002); glucocorticoids: 24 (30%) vs. 7 (17%) (p=0.13). For serious adverse events, similar results were seen. The risks of grade 3/4 infections and injection site reactions were respectively 46% and 23% lower in the tapering group than the no-tapering group.

Conclusion: A T2T TNFi tapering strategy is non-inferior to a T2T strategy without tapering with regard to the proportion of patients still in LDA at 12 months and results in a substantial reduction of TNFi use, albeit with slightly more use of other medication.

B. Gudbjornsson1, 2, M. C. Kapetanovic1, 2, Lund University Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; Skåne University Hospital, Department of Rheumatology, Skåne, Sweden; University of Iceland, Faculty of Medicine, Reykjavik, Iceland; Lundspitali University Hospital, Department of Science, Reykjavik, Iceland; Landspitali University Hospital, Centre for Rheumatology Research, Reykjavik, Iceland

Background: Increased availability and a wide selection of b/tsDMARDs with different mode of action has made long-term remission a realistic treatment goal in psoriatic arthritis.

Objectives: To estimate the prevalence and possible predictors of sustained remission in patients with psoriatic arthritis (PsA) treated with biologic or targeted synthetic disease-modifying anti-rheumatic drugs (b/tsDMARDs) in Sweden.

Methods: All patients initiating treatment with bDMARDs or tsDMARDs for PsA in Sweden and registered in the national Swedish Rheumatology Quality Register (SRQ) were included. Data on disease and treatment characteristics from the start of the first b/tsDMARD (baseline) and all registered subsequent visits were extracted from SRQ. Sustained remission (SR) was defined as DAS28-CRP ≤ 2.6, DAPSA28 ≤ 4 or the evaluator’s global assessment of disease activity (0-4 on a Likert scale) = 0, during at least two consecutive visits over at least six months. To compensate for factors that may temporarily raise disease activity measures, such as concurrent infections, one visit with higher disease activity was allowed if the treatment regimen was not altered at that point and if less than two years between adjacent visits in remission. A sensitivity analysis was performed with a more stringent SR definition, not allowing any such visits with higher disease activity. Logistic regression was used to identify possible predictors of SR.

Results: 5 459 PsA patients with 50 811 visits were included in the analysis. According to DAS28-CRP, 78% of patients achieved a state of remission at some point, and 49% achieved SR at least once. When the more stringent DAPSA28 remission criteria were applied, 27% of patients reached a state of remission at some point, and 11% ever achieved SR. Corresponding figures using the evaluator’s global assessment were 64% and 34% for ever reaching remission or SR, respectively (Figure 1). The sensitivity analysis rendered similar results with a ≤3% difference from the main results for all outcomes. Higher age at start of the first b/tsDMARD therapy was associated with a lower likelihood of SR, but males were significantly more likely to achieve SR than females (OR 1.79-2.63 for reaching SR depending on the remission criteria used).

Figure 1. Proportion of patients achieving sustained and non-sustained remission at any point after SRQ registration.

Conclusion: Despite increased availability and a wider selection of b/tsDMARDs with different modes of action, a considerable proportion of PsA patients receiving such treatments never achieve a state of remission, and less than half ever achieve a more extended period of sustained remission. Males are more likely than females to enter sustained remission.

RA treatment: modern strategies and new molecules

OP0263

FAVORABLE BALANCE OF BENEFIT AND HARM OF LONG-TERM, LOW-DOSE PREDNISOLONE ADDED TO STANDARD TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS AGED 65+: THE PRAGMATIC, MULTICENTER, PLACEBO-CONTROLLED GLORIA TRIAL

1Amsterdam UMC, locatie VUMc, Rheumatology; Epidemiology & Data Science, Amsterdam, Netherlands; 2Carol Davila University, Rheumatology, Bucharest, Romania; 3Medical Centre Leeuwarden, Rheumatology, Leeuwarden, Netherlands; 4Maassstad Hospital, Rheumatology, Rotterdam, Netherlands; 5Faculdade de Medicina e Hospital da Universidade de Coimbra, Rheumatology, Coimbra, Portugal; 6Antonius Ziekenhuis, Rheumatology, Sneek, Netherlands; 7Meander Medical Center, Rheumatology, Amersfoort, Netherlands; 8Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 9Reumazorg Flevoland, Rheumatology, Emmeloord, Netherlands; 10Northwest Clinics, Rheumatology, Alkmaar, Netherlands; 11Institute of Medicine, University of Debrecen Faculty of Medicine, Rheumatology, Debrecen, Hungary; 12Charité – University 8 Medicine Berlin, Rheumatology and Clinical Immunology, Berlin, Germany; 13Piešťany, National Institute for the Rheumatic Diseases, Piešťany, Slovakia (Slovak Republic); 14Amsterdam UMC, locatie VUMc, Epidemiology & Data Science, Amsterdam, Netherlands; 15Department of Internal Medicine, University of Genoa, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Genoa, Italy; 16Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands; 17Amsterdam UMC, locatie VUMc, Rheumatology, Amsterdam, Netherlands.

Background: Low-dose glucocorticoid (GC) therapy is widely used in RA but the true balance of benefit and harm is still unknown.

Objectives: We studied the effects of prednisolone (5mg/day, 2 years) in RA patients aged 65+, requiring adjustment of antitherapeutic treatment (DAS28≥2.60).

Methods: Pragmatic double-blind placebo-controlled randomized trial; all co-treatments and changes therein were allowed during the trial except long-term open label GC; Ca/D supplementation was advised in all patients. Minimal exclusion criteria were tailored to seniors.

Harm outcome: the number of patients with ≥1 serious adverse event (SAE), or ≥1 ‘other adverse event of special interest’ (other AESI). Other AESI comprised any AE (except worsening of RA) causing study discontinuation, and GC-specific events (Table 1).

*AESI: Compares serious adverse events (SAE) and other AESI, defined by protocol. †’Other’ other AESI: non-serious AE outside of the above predefined categories, but associated with premature discontinuation.

Benefit outcomes: improvement in disease activity (DAS28) and joint damage progression (Sharp/van der Heijde).

Results: We randomized 451 RA patients in 7 EU countries, 449 received the intervention; of these 63% prednisolone vs 61% placebo patients completed 2 years of follow up. Discontinuations were similar in both groups: for AE (14%) and active disease (4%); the remainder mostly for trial fatigue and covid-related access issues (20%). Mean time on study drug was 19 (SD 8) months. 70% of patients were female, mean age was 72 (max 88) years, RA duration 11 years; 67% were RF+, 56% ACPA+, 96% had joint damage on radiographs: mean score 20, median 8. Mean DAS28 was 4.5. Most patients (79%) were on current DMARD treatment, including 14% on biologics; 47% had previously used GC, 14% changed DMARD therapy at baseline. Patients had mean 2.1 active comorbidities, and used median 7 drugs.

Benefit: Disease activity rapidly declined to stabilize after 1 year (Figure 1), and was lower on prednisolone (adjusted mean difference in DAS28 over 2 years: 0.37, 95% CL 0.23, p=0.0001). The contrast in early (3-month) response was larger in 331 patients adherent to protocol on stable treatment: mean difference in DAS28 0.62 (95% CL 0.44), more responders on prednisolone (Figure 1). Significant time-treatment interaction in secondary analyses suggested a decrease in contrast after the first year, most likely caused by significantly more changes in DMARD treatment on placebo. Joint damage progression over 2 years was significantly lower on prednisolone: mean 0.6 (SD 1.9) v 1.8 (6.4) score points on placebo, difference 1.2 (95% CL 0.2, p=0.02).

Harm: 80% prednisolone vs 49% placebo patients experienced the harm outcome: adjusted RR 1.24, 95% Cl 1.04, p=0.02; number needed to harm 9.5 (Table 1). During the study 1 v 2 patients died, and 3 v 0 died within 5 months of discontinuation. Per 100 patient-years, AE totaled 278 in prednisolone vs 206 in placebo patients, and the difference was most marked for infections (Table 1); these were mostly mild or moderately severe. Other GC-specific AESI were rare without relevant differences.

Conclusion: Add-on low dose prednisolone has beneficial long-term effects on disease activity and damage progression in senior RA patients on standard treatment. The tradeoff is a 24% increase in patients with mostly mild to moderate AE, suggesting a favorable balance of benefit and harm.
Cardiovascular Events in the Tofacitinib Clinical Programme

David A. Lippin

Aims and Methods: Cardiovascular (CV) events are an important measure of patient safety in RA clinical trials. Tofacitinib (TOF) is a JAK inhibitor approved for the treatment of RA. This Pooled Adenopathy and Cardiac Events Analysis (PACE) study investigated the incidence of major adverse cardiovascular events (MACE) using the TOF dataset from the PACE study and the wider tofacitinib RA clinical programme.

Background: PACE (NCT02585258) was a phase III, double-blind, placebo- and MTX-controlled, 4-year trial comparing the safety and efficacy of TOF 5 mg (n=2015) or 10 mg (n=2425) twice daily versus placebo (n=1008) and MTX 10 mg (n=1005) twice weekly versus MTX 20 mg (n=1010) twice weekly in previously MTX-naive patients with active RA. The first safety assessment occurred after 1 year, when the study was stopped early due to an increased incidence of MACE in the TOF 10 mg group and a risk of mortality in the TOF 20 mg group. This analysis includes data from the 3-year follow-up data analysis (January 2018).

Objectives: To evaluate the incidence of MACE in the TOF 5 mg and 10 mg twice daily treatment groups using data from the PACE study and the wider tofacitinib RA clinical programme.

Methods: Data from PACE were pooled with data from the wider tofacitinib RA clinical programme (24
double-blind, placebo-controlled studies). MACE were defined as: all-cause mortality, MI, or CHD. Risk was defined as age ≥50 years, male gender, ≥1 CV risk factor, and/or a 10-year risk of MACE ≥15%.

Results: The overall cohort included 7964 patients (average tofacitinib 5 mg BID, n=3969; average tofacitinib 10 mg BID, n=3995). Of these, 3125 (39.2%) patients were included in the CV risk-enriched cohort (average tofacitinib 5 mg BID, n=1614; average tofacitinib 10 mg BID, n=1511). In both treatment arms, as expected, higher proportions of patients in the CV risk-enriched cohort had a HxCAD or a high 10-year predicted risk of MACE at BL vs the overall cohort (Table 1).

Table 1. Proportions of pts with a HxCAD and pts without a HxCAD

<table>
<thead>
<tr>
<th>HxCAD</th>

</tr>
</tbody>
</table>

Conclusions: In the overall cohort, adjudicated MACE most commonly occurred in patients with a HxCAD (IR [95% CI] 0.98 [0.02, 5.47] and 1.05 [0.13, 3.78], respectively) vs the CV risk-enriched cohort (IR 0.72 [0.46, 1.09] and 0.67 [0.46, 0.93], respectively), and were similar between treatment arms. MACE IRs were lower than reported in the CV risk-enriched cohort (pts aged ≥50 yrs with ≥1 additional CV risk factor [current smoker, hypertension, HDL-cholesterol <40 mg/dL, diabetes mellitus, history of myocardial infarction (MI) or coronary heart disease (CHD)]). Data were summarised by average tofacitinib 5 or 10 mg daily (BID; average total daily dose of <15 or ≥15 mg, respectively). Incidence rates (IRs; pts with first events/100 pt-ys) for adjudicated MACE were calculated. MACE IRs were stratified by pt’s BL CV risk profile: pts were first categorised by history of coronary artery disease (HxCAD), then pts without a HxCAD were categorised by 10-year risk of MACE, per the ASCVD-PCE risk calculator with a 1.5 multiplier applied.

The overall cohort included 7964 patients (average tofacitinib 5 mg BID, n=3969; average tofacitinib 10 mg BID, n=3995). Of these, 3125 (39.2%) patients were included in the CV risk-enriched cohort (average tofacitinib 5 mg BID, n=1614; average tofacitinib 10 mg BID, n=1511). In both treatment arms, as expected, higher proportions of patients in the CV risk-enriched cohort had a HxCAD or a high 10-year predicted risk of MACE at BL vs the overall cohort (Table 1).

Conclusion: In the tofacitinib RA clinical programme, MACE were largely associated with BL CV risk in the overall cohort, consistent with results of ORAL Surveillance, although results should be interpreted with caution due to low pt-yrs of exposure in some pt groups. Noting this limitation, these findings emphasise the importance of assessing and addressing BL CV risk when treating pts with RA.

**COMPARISON OF THE EFFECT OF DIFFERENT JANUS KINASE INHIBITORS ON ACTIVATION, FUNCTION AND PROPERTY OF NK CELLS TO CONTROL CANCER CELL LINES PROLIFERATION: AN EX VIVO AND IN VITRO STUDY.**

L. Meudec,1,2, P. Richebé,1, J. Pascaud1, X. Mariette1,2, G. Nocturne1,2, 1Center for Immunology of Viral Infections and Autoimmune Diseases, INSERM UMR T184, Université Paris-Saclay, Kremlin-Bicêtre, France; 2AP-HP, Hôpital Bicêtre, Le Kremlin-Bicêtre, Kremlin-Bicêtre, France

**Background:** Janus kinase inhibitors (JAKI) are effective targeted synthetic DMARDs licensed in rheumatoid arthritis (RA) and in other immune-mediated diseases. Among the adverse events described, the increased risk of herpes zoster is specific to this therapeutic class but variable depending on the drug, especially lower with filgotinib (FilGLO). Recently the ORAL Surveillance study highlighted an increased risk of lymphoma and lung cancer with tofacitinib (TOFA) in RA patients older than 50 years with cardio-vascular risk factors. Because of their antitumor and antiviral role, especially against herpes viruses, effect of JAKI on NK cells may play a causal role in these adverse events. Our working hypothesis is that the different JAKI could have a differential impact on the activation and function of NK cells leading to the variability of the tolerance profiles observed between the molecules.

**Objectives:** To evaluate the phenotypic and functional impact of JAKI on NK cells.

**Methods:** We first performed ex vivo phenotypic analyses of NK cells in RA patients treated with TOFA or baricitinib (BARI) in comparison with patients treated with methotrexate (MTX). To go deeper, we phenotyped sorted NK cells from healthy donors after 6 days of culture with 4 JAKI (TOFA, BARI, upadacitinib (UPA) and FilGLO) or control (DMSO). We used 3 different doses carefully chosen to mimic in vivo exposure (therapeutic concentration (therap) defined as mean concentration in patients at the licensed dose, intra-therapeutic (infra, mean -2SDS) and supra therapeutic concentration (supra, mean +2SDS)). Thirdly, we stimulated sorted NK cells from healthy donors exposed to TOFA or BARI at theraph and supra concentrations with anti-NKp30 crosslinking to assess NK cells function: intra-cellular IFNγ/TNF production and degranulation (CD107a). Finally, we challenged sorted NK cells from healthy donors exposed in vitro to TOFA or BARI at theraph and supra doses with 2 different tumor cells line to assess degranulation and cytotoxicity: a lung cancer line A549 and a lymphoma cell line SU-DHL-4.

**Results:** Twenty-eight RA patients were included in the ex vivo assay (12 MTX, 6 TOFA, and 10 BARI). Patients under TOFA and not under BARI had a significant reduced CD69 (an activation marker) expression on NK cells (p<0.05) compared to MTX. After in vitro culture of NK cells with JAKI, we confirmed the negative impact of JAKI on NK cells activation (CD69), maturation markers (CD57, Tim3) and activating receptor (NKp30), more pronounced with TOFA and UPA (Figure 1A). After crosslinking with anti-NKp30, NK cells exposed to TOFA produced significantly less IFNγ/TNF and expressed less CD107a compared to DMSO (p<0.005). There was a non-significant trend for a dose-effect (Figure 1B). BARI did not induce any significant effect. Lastly, when NK cells were co-cultured with the cancer cell lines, previous exposition to TOFA but not to BARI led to a significant reduction of CD107a expression on NK cells (p<0.005) and to reduced cytotoxicity (p=0.05) of NK cells versus A549 at theraph dose. Studies regarding SU-DHL-4 are still in progress.

**Figure 1.** Impact of in vitro exposure to JAKI at theraph and supra dose on NK cells regarding phenotype (A) and function after crosslinking (B).

**Conclusion:** JAKI have a phenotypic and functional dose-effect impact on NK cells activation, both in ex vivo and in vitro experiments. TOFA has more impact than other JAKI on NK cells phenotype and function and has the property to impair the control of proliferation of lung cancer and lymphoma cell lines by NK cells. The question remains open if this mechanism could explain the increased risk of lung cancer and lymphoma observed with TOFA in the ORAL surveillance trial.

**DOI:** 10.1136/annrheumdis-2022-eular.2640
Background: The recently presented "ORAL Surveillance Study" has suggested increased risk of serious adverse events (AEs) with tofacitinib, a JAK-inhibitor (JAKi), compared to a comparator TNF-inhibitor (TNFi). Currently, there is limited real world evidence for the tolerability and safety of JAKi.

Objectives: To assess the safety of JAKi compared to other biologic agents in rheumatoid arthritis (RA) patients in a real-world population, by evaluating treatment discontinuation for AEs.

Methods: Pooled patient database from 16 national RA registries from across Europe, Quebec (Canada), Turkey, and Israel were used. Treatment discontinuation due to AEs by treatment groups, JAKi versus (vs) TNFi and JAKi vs OMA, were compared as an overall measure of tolerability and safety of JAKi.

Results: 90,478 treatment courses were included in the analysis (Table 1). We observed similar crude incidence rate of treatment discontinuation due to AEs between JAKi and TNFi, but less in JAKi vs OMA (Figure 1). The fully adjusted hazard rate of treatment stop for AEs was higher in women (HR = 1.29 (95% CI 1.21 – 1.37)) and in JAKi vs OMA (HR = 1.08 (95% CI 0.97 – 1.20)). The rate of treatment stop for AEs was higher in women (HR = 1.29 (95% CI 1.21 – 1.37)) and with an increasing number of previous b/tsDMARDs (HR = 1.50; 1.48; 1.68 for 1, 2, and 3 or more previous b/tsDMARDs, respectively).

Conclusion: After adjusting for potential confounders, the rate of treatment discontinuation for AEs was comparable between JAKi and OMA or TNFi. Treatment discontinuation for AEs comprises a wide range of AEs; future analyses will be performed to investigate specific AEs, such as cancer, serious infections or major adverse cardiovascular events.

REFERENCE:

while 341 (0.9%) in JAK-inhibitors and 571 (0.2%) in anti-TNF treated patients were VTE. Disproportionality analyses identified an increased risk of reporting VTE events in JAK-inhibitors compared to anti-TNF (DVT: ROR = 3.99 [95%CI: 3.15-5.04], PE: ROR = 3.47 [2.90-4.13], Figure 1). This risk was not modified after stratification by age or sex. No increased ROR for MACE was found.

**Figure 1.**

**Conclusion:** Based on real-world data, the analysis did not identify an increase in declaration of MACEs with JAK-inhibitor compared to anti-TNF whereas we could observe more than three times declarations of VTE in Vigibase with JAK-inhibitors compared to anti-TNF.

* Systolic RR < 90 or diastolic RR < 60. **Mean (SD)

No differences were seen in ACTH or cortisol levels: mean (SD) ACTH was 5.8 (4.1) in 23 prednisolone patients, and 5.1 (3.7) in 24 placebo patients; cortisol 296 (113) vs 310 (166), cortisol/ACTH 67 (40) vs 77 (54). Two prednisolone and one placebo patient had cortisol levels below 80. No evidence of clinical hypoadrenalism during further follow-up. 199 patients qualified for the disease flares sample, 99 prednisolone and 100 placebo; 4 patients failed on prednisolone tapering vs 31 on placebo, relative risk 1.43 (95% CI 0.99; 2.07; p=0.07).

Conclusion: Tapering prednisolone moderately increases disease activity to placebo levels (mean still at low disease activity levels) and numerically increases the risk of flare without any evidence of adrenal insufficiency. This suggests that withdrawal of low dose prednisolone is feasible after 2 years of administration.

OP0271 INCREASED RISK OF DEMENTIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONWIDE POPULATION-BASED COHORT STUDY

Y. Eun1, K. D. Han2, S. Y. Kang3, S. Lee4, H. S. Cha5, E. M. Koh6, J. Lee7, H. Kim8,9, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Department of Internal Medicine, Seoul, Korea, Republic of South Korea; 2Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Republic of South Korea; 3Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Republic of South Korea; 4Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Republic of South Korea

Background: There have been conflicting results of previous studies on the association between rheumatoid arthritis (RA) and the risk of dementia.

Objectives: In this study, we aimed to investigate the association between RA and dementia in a large nationwide population-based cohort.

Methods: Among patients diagnosed with RA between 2010 and 2017, patients who had undergone a national health examination within two years prior to RA diagnosis were included in the study (n = 138,592). Control group included age- and sex-matched non-RA controls who received a health check-up at the same time as RA patients (n = 692,960). The primary outcome of the study was incident dementia, which was defined by an ICD-10 code and the use of dementia medications. Kaplan-Meier curves and Cox proportional hazards regression analysis were used for the analysis.

Results: Mean follow-up duration of the study was 4.7 ± 2.2 years. RA patients had a 1.2 times higher risk of dementia than controls (adjusted hazard ratio [aHR] 1.19, 95% CI 1.16–1.23). In patients with RA, the aHR for Alzheimer's disease (aHR 1.24, 95% CI 0.84; 1.85) was higher than that of vascular dementia (aHR 1.10, 95% CI 0.99–1.21). In a stratified analysis according to age, gender, lifestyle factors and comorbidities, the association between RA and dementia was consistently found.

Conclusion: In a large nationwide population-based cohort, RA was associated with an increased risk of incident dementia. Appropriate evaluation of dementia is required when cognitive impairment occurs in RA patients. Further studies are needed to explore potential confounders.

OP0272 PREDNISONE USE AND THE INCIDENCE OF HYPERGLYCEMIA OR DIABETES IN PATIENTS WITH RHEUMATOID ARTHRITIS: A 10-YEAR SUB ANALYSIS OF THE BEST STUDY.

J. van der Pol1, S. A. Bergstra2, T. Huizinga3, C. Allaart4, 1Leiden University Medical Center, Rheumatology, Leiden, Netherlands

Background: Use of prednisone in rheumatoid arthritis has been questioned because it may trigger side effects such as hyperglycemia and diabetes.

Objectives: To assess whether in RA the use of prednisone is associated with the development of hyperglycemia and diabetes.

Methods: The BeSt study is a multicenter, assessor-blinded randomized controlled 10-years follow-up trial in 508 non-diabetic early RA patients. Patients were randomised to 4 dynamic DMARD treatment strategy groups: 1) sequential monotherapy, 2) step-up combination therapy, 3) initial combination therapy including prednisone (60 mg/day, tapered to 7.5 mg/day in 7 weeks) and 4) initial combination therapy with infliximab. In groups 1, 2 and 4, prednisone had a maximum dose of 75 mg/day by protocol. Treatment was steered at disease activity score (DAS) ≤2.4. We performed a GEE over time to assess whether current prednisone use or cumulative prednisone dose were associated with hyperglycemia (glucose levels ≥7.8) and cox regression analyses to investigate the relationship between cumulative prednisone dose, previous prednisone use and diabetes (defined as either use of anti-diabetic medication or two instances of a glucose ≥11.1) assessed at 3-monthly visits. All analyses were adjusted for potential confounders.

Results: In total, 33/508 patients (6.5%) developed diabetes during the trial; 12 of these (36%) had received prior treatment with prednisone (any dose). Median (IQR) duration of prednisone use in all 508 patients was 9 (15) months and cumulative doses ranged from 0 to 27942 mg. The mean cumulative dose ranged from 55.5 mg in group 1 to 6170.0 mg in group 3. Previous prednisone use or cumulative prednisone dose was associated with hyperglycemia or diabetes, with effect sizes ranging from a hazard ratio of 0.588 (95% CI 0.285; 1.21) for the association between any previous dose and diabetes to an odds ratio of 1.04 (95% CI 0.978; 1.13) for the association between cumulative prednisone dose and diabetes (Table 1). To identify potential causes for these results, we investigated the relationship between DAS and the same outcomes. We found a higher DAS was significantly associated with development of diabetes, but not with hyperglycemia.

C: confidence interval; GEE: Generalized Estimating Equations; OR: odds ratio; HR: hazard ratio; DAS: disease activity; hyperglycemia: glucose level above 7.8 mmol/L; diabetes: random glucose level above 11.1 mmol/L at least two time points; odds ratio per 500mg cumulative prednisone increase: adjusted for DAS, age, diabetes and BMI; adjusted for cumulative prednisone dose, age, gender and BMI; adjusted for DAS, age and BMI

Conclusion: In early RA patients, cumulative dose nor any previous prednisone use was associated with the risk of hyperglycemia or diabetes. A higher DAS was significantly associated with increased risk of development of diabetes. Potential risks of prednisone may have been mitigated by suppression of DAS.

Disclosure of Interests: Joy van der Pol: None declared, Systeke Anne Bergrsta Grant/research support from: Pfizer, Thomas Huizinga: None declared, Cornelia Allaart Grant/research support from: The BeSt study was supported by a government grant from the Dutch Insurance Companies, with additional funding from Schering-Plough B.V. and Janssen B.V.

OP0273 CHARACTERISTICS OF PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS IN FRANCE

S. Hecquet1,2, A. Combier2, A. Steelandt2, M. Pons3, D. Wendling4, A. Molto5, D. Breschard6, Y. Allainore7, J. Avouac8, Centre Hospitalier Regional Universitaire de Besancon, Rheumatology, Besancon, France; 2University of Franche-Comté, UR 4267 PEPITE, Besancon, France; 3Cochin Hospital, Rheumatology, Paris, France

Background: Recently, EULAR has proposed a definition of difficult-to-treat rheumatoid arthritis (D2TRA). However, descriptive data on D2TRA are scarce and only one Japanese publication details the D2TRA encountered in routine practice, no similar work has been done in Europe so far.

Objectives: To describe D2TRA patients encountered in France according to two definitions and evaluate their therapeutic responses to different targeted therapies.

Methods: We reviewed all patients with RA treated in day hospital at Cochin University Hospital between 2020 and 2021. We divided our population into two groups of patients, a D2TRA group and a non-D2TRA group. This division was made on the same population according to two different definitions of D2TRA, resulting in four patient groups. The first definition is the one proposed by EULAR (EULAR D2TRA) defining D2TRAs as RAs with failure of ≥2 csDMARDs (with different mechanisms of action) after failing csDMARD therapy. The second definition as D2TRA patients who have failed at least two targeted therapies, without pre-judging the mechanism of action (non-EULAR D2TRA). We analyzed clinical characteristics and evaluated their response to different targeted therapies. Disease activity was assessed using the DAS for 28 joints (DAS28) at the latest visit.

Results: In total, we included 320 patients, we identified 76 EULAR D2TRA patients (mean age 59 years, 87% female) with 244 of corresponding non-DTRA patients (mean age 60 years, 85% female) and 120 non-EULAR D2TRA patients (mean age 58.7 years, 87% female) with 200 of corresponding non-DTRA (mean age 61 years, 85% female). Compared to non-D2TRA patients, there were significantly more D2TRA patients from low socioeconomic backgrounds in both D2TRA groups. In the EULAR-D2TRA group, compared to the non-D2TRA, there were significantly more patients with diabetes (14% vs 6%, p=0.024). D2TRA patients in both groups had significantly more rheumatoid factor (RF), interstitial lung disease (ILD) and a higher DAS28 than non-D2TRA patients. No difference was noted regarding ACPA and erosions. We observed a lower proportion of remission in both D2TRA groups than in non-D2TRA group (21% in EULAR-D2TRA vs 34% in non-D2TRA, p=0.034 and 23% in non-EULAR D2TRA vs 36% in non-D2TRA, p=0.024). There were significantly fewer patients on Methotrexate in the non-EULAR D2TRA group compared to the non-D2TRA group (53% vs 64%, p=0.046). In the non-EULAR D2TRA group, there were significantly more patients in remission on Rituximab than on TNF inhibitors (41% vs 5%, p=0.0032). We did not observe a significant difference in achieving remission in patients on JAK inhibitors or IL-6 inhibitors in the two groups of D2TRA.
**Objectives:**

- Hospitalisation for tuberculosis and other opportunistic infections in patients with inflammatory joint diseases before and after the introduction of biological therapy.

**Methods:**

- All patients hospitalized in Western Australia in the period 1980–2015 over 2 decades of biological therapies (including TNF inhibitors, IL-1 receptor antagonist, IL-6 receptor antagonist, and JAK inhibitors).
- Assess the impact of biological therapy on the incidence of opportunistic infections.

**Results:**

- The incidence of opportunistic infections decreased significantly after the introduction of biological therapy.
- Tuberculosis was the most common opportunistic infection, followed by fungal and mycobacterial infections.
- The incidence of opportunistic infections was higher in the pre-biological therapy period.

**Conclusion:**

- Biological therapy has significantly reduced the incidence of opportunistic infections in patients with inflammatory joint diseases.
- Further studies are needed to evaluate the long-term impact of biological therapy on the incidence of opportunistic infections.

**Disclosure of Interests:**

- None declared.

**Conclusion:**

- The complication of managing RA patients can be explained by socio-economic status and the presence of comorbidities such as diabetes and ILD. Our work suggests that D2TRA patients have less Methotrexate and better response to Rituximab.

**Disclosure of Interests:**

- None declared.

status were extracted from the electronic medical record. Descriptive statistics were used to summarize disease features. A Kaplan-Meier curve was created to evaluate survival, and a Cox proportional hazards model was created to identify predictors of survival.

Results: 42 RA-ILD patients underwent LTx. The majority of patients were male (57.1%), seropositive (91.4%), with a mean RA disease duration of 12.9 years at LTx (Table 1). Over the study period, 16 (36%) patients died. Compared with patients who had survived, deceased patients were slightly older at the time of transplantation (59.0±9.7 vs. 57.3±11.5, respectively), and were more likely to have usual interstitial pneumonia (UIP) in the lung explant (87.7% vs. 56.0%, p < 0.05). The median follow up was 2.3 years (IQR 1.3, 4.7), and median survival time was 5.3 years (IQR 2.7–7.6; Figure 1). In the univariate Cox proportional hazards analysis, there was a relationship between the presence of UIP pathology and increased mortality, although this did not reach significance (HR 7.13, p = 0.06).

The shaded area represents the 95% confidence interval. Median time to death was 5.3 years (IQR 2.7–7.6). Kaplan-Meier survival curve for RA-LTx patients from time of LTx to death, or censor.

**RF or CCP

Figure 1. Kaplan-Meier survival curve for RA-LTx patients from time of LTx to death, or censor. The shaded area represents the 95% confidence interval. Median time to death was 5.3 years (IQR 2.7–7.6).

Conclusion: This single-center study of RA-ILD patients who underwent LTx demonstrated a median survival time comparable to other LTx cohorts. There appeared to be a relationship between the presence of a UIP pattern, and increased risk of mortality, though the small sample size may have precluded the ability to reach statistical significance. Future prospective studies are needed to validate these findings. Understanding the disease features of RA patients who undergo LTx may facilitate the early identification of RA patients at the greatest risk of developing progressive fibrosing phenotype.

RA predicted class assignment; those with higher perceived risk were more likely to belong to class 1. On average, the predicted uptake of treatment profiles estimating prevention candidates: abatacept, atorvastatin, hydroxychloroquine; tolerogenic cell-based therapy; and no treatment would be 50%, 10%, 9%, 18% and 0%, respectively. Finally, the maximum acceptable risk participants were willing to accept were 81%, 25% and 3% point increases in risk of mild side effects, serious infection, and serious side effects, respectively, for medicines that would reduce their risk of developing RA in the upcoming two years from 60% to 20%.

Conclusion: Effective preventive treatments for RA were acceptable to FDRs asked to assume a 60% chance of developing RA. Mode and frequency of treatment administration had a greater impact on treatment choices for participants with a lower perceived risk of RA. These findings are informative for target product profile development, endpoint selection, benefit-risk assessment, regulatory approval, and development of informational resources for those at risk of RA.

PERSISTENT EXCESS OF STROKE EVENTS IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY FROM HORDALAND, NORWAY FROM 1972 TO 2014

C. L. Aasling1,2, J. Iland3, G. S. Tell3,5, H. Naess5, T.W. Nystand4, B. T. Svanes3 on behalf of BeaBiRD - Bergen Group of Epidemiology and Biomarkers in Rheumatic Disease. 1Haraldsplass Deaconess Hospital, Department of Internal Medicine, Bergen, Norway; 2University of Bergen, Department of Clinical Science, Bergen, Norway; 3University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway; 4Western Norway University of Applied Science, Department of Health and Social Science, Bergen, Norway; 5Norwegian Institute of Public Health, Division of Mental and Physical Health, Bergen, Norway; 6Haukeland University Hospital, Department of Neurology, Bergen, Norway; 7University of Bergen, Department of Clinical Medicine (K1), Bergen, Norway; 8Stavanger University Hospital, Centre for Age-Related Medicine, Stavanger, Norway; 9Haukeland University Hospital/Health Bergen, Department of Rheumatology, Bergen, Norway

Background: Patients with rheumatoid arthritis (RA) have an excess risk of cardiovascular disease (CVD), including stroke [1]. After the introduction of biological DMARDs in 1999 and the treat to target strategy, more patients reach low disease activity and remission, which is associated with lower CVD risk [2]. Few previous studies have examined stroke occurrence in RA patients before and after these improvements in RA management.

Objectives: To investigate stroke events in RA patients diagnosed before and after 1999 compared with the total population.

Methods: We included 771 RA patients diagnosed during 1972-1998 and 1050 during 1999-2013 at the main rheumatological department of Hordaland county, Norway. The total population of the same county and time period were used as a comparison cohort. Data on stroke events were obtained from regional cardiovascular registries or hospital patient administrative systems during 1972-2014. Aggregated counts of stroke events and population counts from the comparison cohort were used to estimate expected counts of stroke hospitalisation in the RA cohort per 5-year age group, sex and calendar year. We then estimated standardised event ratios (SERs) by Poisson regression as a measure of excess stroke events in RA patients compared with the total population.

Results: In total, 152 stroke events occurred in 112 RA patients diagnosed during 1972-1998 over 15137 person-years of follow-up and 86 stroke events in 70 RA patients diagnosed during 1999-2013 over 8672 person-years of follow-up. RA patients diagnosed in the later period were on average 2.1 years older (56 years) at RA diagnosis, but the proportion of women was similar in both groups. Both RA patients diagnosed before and after 1998 had an excess of stroke events compared with the total population (SER 1.20, 95% CI 1.00-1.44 and SER 1.22, 95% CI 1.05-1.42 respectively). RA patients younger than 60 years of age did not appear to have significant excess stroke events in either group.

Conclusion: These results indicate a similar excess of stroke events in RA patients diagnosed before and after 1999. This warrants continued awareness regarding stroke prevention in RA patients, even after the recent improvements in RA treatment.

Background: The prevalence of the musculoskeletal immune-related adverse events (irAEs) is probably underestimated, as most studies report only severe side effects. The largest prospective study with systematic monitoring by a rheumatologist, for musculoskeletal irAEs, revealed that seroconversion is difficult to achieve in SLE to date.

Objectives: The main objective was to describe each type of musculoskeletal irAE: prevalence, clinical features, treatment regimen, ICI drug, time of occurrence and management of musculoskeletal irAEs. The secondary objectives were to describe irAEs/course ant to investigated tumor response at 3 months after introduction of ICI according to irAEs/grade, clinical features, pain patterns and the treatments used to manage musculoskeletal irAEs.

Methods: We conducted a retrospective study among patients who received ICI from 07/27/2014 to 05/08/2020 at the medical oncology department of the Institut Paoli-Calmettes, Marseille, France. All medical files were systematically reviewed by a rheumatologist who collected clinical features, time of occurrence, treatment regimen, irAEs management, course, outcomes and tumor response 3 months after introduction of ICI.

Results: In our cohort of 927 patients treated with ICI for a solid tumor, 118 patients (12.7%) presented a musculoskeletal irAE. Their median age was 66.5, 61% were male, and they mainly had a lung (57.6%) or urological cancer (27.1%). The most frequently involved ICI was an anti PD-1. Arthralgias and myalgias were the most frequent musculoskeletal irAEs (76.3%) and inflammatory rheumatic features were reported in 36 patients (30.5%) with elevated acute phase reactants and negative immunological markers. The median time of onset was 2 months (IC 95% 1.8; 2.7). Musculoskeletal irAEs were mainly mild and no deaths were related. Painkillers were the most widely used treatments (86.4%). Systemic corticosteroids were used in 38 patients (32.2%) with a mean dose of 43 ± 35 milligrams/day. Among the inflammatory rheumatic features, 20 (55.5%) were treated with systemic corticosteroids and 8 with csDMARDs (16.7%). bDMARDs were not used in our cohort. Musculoskeletal irAEs resulted in discontinuation of the responsible ICI in 23 patients (19.5%). The majority of the musculoskeletal irAEs (79.7%) resolved within a median time of 3 months (IC 95% 2.2;4.0). Tumor response at 3 months did not differ according to musculo-skeletal irAE severity, type of manifestation (arthralgias/myalgias versus inflammatory rheumatic features), pain patterns (mechanical versus inflammatory) or irAE treatments.

Conclusion: Our single-center cohort is the largest to our knowledge to describe all musculoskeletal irAEs in patients treated with ICI without focusing on severe or inflammatory manifestations. These musculoskeletal irAEs are frequent, mostly mild and well tolerated, resolving and allowing possible continuation of ICI treatment. Collaboration between oncologists and rheumatologists should be further encouraged to determine whether all musculoskeletal irAEs, even non-severe and non-inflammatory ones, are associated with a good tumor response to ICI.

Disclosure of Interests: None declared

Background: Lupus nephritis (LN) is a frequent complication of systemic lupus erythematosus (SLE). Severe (proliferative) forms of LN are treated with an induction immunosuppressive therapy (IST), followed by a maintenance IST, to target remission and avoid relapses. The optimal duration of maintenance IST for proliferative LN is unknown.

Objectives: The WIN-Lupus trial tested whether IST discontinuation after 2-3 years of LN proliferative was non-inferior to IST continuation for 2 more years.

Methods: WIN-Lupus is an investigator-initiated academic randomized controlled trial, conducted in 28 French centers. Patients on maintenance IST with azathioprine or mycophenolate mofetil for a minimum of 2 years and a maximum of 3 years, and who were taking Hydroxychloroquine, were randomized (1:1) between 2 groups: IST continuation and IST discontinuation. The primary endpoint was the relapse rate of proliferative LN at 24 months. Secondary endpoints were the rate of severe SLE flares, survival without renal relapse or severe flare, adverse events, kidney function, disease activity, corticosteroid exposure, patient-reported outcomes and medico-economic impact.

Results: Between 2011 and 2016, 125 patients were screened and 96 were randomized in the trial: 48 in the IST continuation group, 48 in the IST discontinuation group. In the per-protocol population, a relapse of proliferative LN occurred in 5/40 (10.4%) patients with IST continuation and in 12/45 (25%) patients with IST discontinuation (difference 14.8%, 95%CI [-19;31.5]). Non-inferiority was not demonstrated for relapse rate. Time to renal relapse did not differ between groups (p=0.092). Severe SLE flares (renal or extra-renal) were less frequent in patients with IST continuation compared to IST discontinuation (5/40 vs 14/44 patients, p=0.035). IST discontinuation was associated with lower health-related costs. Adverse events did not differ between groups.

Conclusion: Non-inferiority of maintenance IST discontinuation after 2 to 3 years was not demonstrated for renal relapse. IST discontinuation was associated with a higher risk of severe SLE flare.

The impact of anifrolumab on neuropsychiatric manifestations of depression and suicidality in patients with systemic lupus erythematosus

Background: Neuropsychiatric (NP) disease is more common in patients with systemic lupus erythematosus (SLE) than in the general population. Increased incidence of NP events (depression and suicidality) has been reported with biologic therapies, including SLE therapies. Depression and suicidality were evaluated in patients with SLE treated with anifrolumab, a type I interferon receptor antibody, in the TULIP-1 and TULIP-2 trials.

Objectives: To understand the impact of anifrolumab treatment on NP manifestations (depression and suicidality) in patients with SLE relative to standard therapy using pooled data from the TULIP trials.

Methods: TULIP-1/-2 were randomized, placebo-controlled, 52-week trials of intravenous anifrolumab every 4 weeks in patients with moderate to severe SLE despite standard therapy. Patients with active severe or unstable NP SLE were excluded. Patients who received ≥1 dose of anifrolumab 300 mg or placebo were analyzed for depression and suicidality. The Personal Health Questionnaire Depression Scale-8 (PHQ-8) and Columbia Suicide Severity Rating Scale (C-SSRS) were used to assess clinical depression and suicidal ideation and behavior, respectively. Incidence of adverse events (AEs) within the standardized Medical Dictionary for Regulatory Activities query of depression (excluding suicide and self-injury) and antidepressant use at baseline and during the study were also assessed.

Results: In the TULIP pooled analysis, 360 patients received anifrolumab and 365 received placebo. Mean PHQ-8 scores were in the mild range (25 to <10); 9.7 in both groups at baseline (Table 1). Excluding patients taking antidepressants, mean PHQ-8 scores were 9.5 in the anifrolumab group and 9.7 in the placebo group at baseline. No clinically meaningful worsening in mean PHQ-8 scores was observed from baseline to Week 52 in the anifrolumab (–2.0) or placebo (–1.3) groups; excluding patients taking antidepressants, mean changes in PHQ-8 were –2.0 and –1.2, respectively. Depression AEs during the study were reported in 11 anifrolumab-treated patients (3.1%) and 9 patients who received placebo (2.5%). At baseline, antidepressant use was comparable between groups (anifrolumab group, 7 patients [1.9%]; placebo group, 9 patients [2.5%]). During the study, 8 anifrolumab-treated patients (2.2%) and 12 patients who received placebo (3.3%) used antidepressants; 1 (0.3%) and 4 (1.1%) patients, respectively, initiated antidepressant therapy during the study (1 in the placebo group stopped therapy). Suicidal ideation or behavior, as assessed by C-SSRS, during the study was reported in 5 anifrolumab-treated patients (1.4%) and 11 patients who received placebo (3.0%). Excluding patients taking antidepressants, suicidal ideation or behavior during the study was reported in 4 anifrolumab-treated patients (1.1%) and 9 patients who received placebo (2.5%) (Figure 1).

Conclusion: Patients with SLE treated with anifrolumab did not experience increased depression, suicidality, or need for antidepressants when compared with standard therapy, irrespective of baseline antidepressant use.

Background: Mycophenolate mofetil (MMF) or low-dose intravenous cyclophosphamide (CYC) are recommended as initial (induction) treatment in many recommendations for the management of lupus nephritis (LN), and randomized controlled trials have shown their similar efficacy. However, there is little to no real-world data.

Objectives: We conducted the real-world analysis to compare the efficacy and safety of MMF and CYC for the induction treatment of LN.

Methods: Our patients came from PKUFH SLE cohort, a single-center longitudinal observational cohort set up in 2007, and only patients received initial remission induction therapy for initial or recurrence LN were analyzed. The primary outcome measure was complete renal remission (CR) as defined by (proteinuria <500 mg/24 hours and serum creatinine within 10% from baseline in 12 month. All statistical analyses were performed with SPSS 26.0 and two sides p < 0.05 was considered statistically significant.

Results: The 237 LN patients with a median age of 35.0 years had a mean duration of disease of 5.2 years. Of these, 97 patients received CYC, 98 patients received oral MMF, and 42 patients received other immunosuppressive agents or combination therapy. The CR rate in 6-month in MMF was significantly higher than CYC group (CR 57.6% vs 45.2%, p=0.005), and that also applied to 12 month (74.7% vs 66.3%, p=0.001). MMF group patients had lower serum creatinine (7.6±4.15 vs. 9.3±3±29, p=0.012), lower glucose, and lower albumin (11.4±3.9 vs. 11.2±5.6, p=0.05), and lower 24-hour protein level (0.4±0.7 vs. 0.7±1.0, p=0.017) than CYC group. However, MMF did not show superior to CYC in the LN induced remission (6 month:87.5% vs 73.7%, p=0.064, 12 month:87.7% vs 90.8%, p=0.632) after propensity score matching, just as the Kaplan-Meier analysis showed (Figure 1). Chinese patients usually adopted lower dose MMF (78.8% 15g/d) compared Caucasian populations, and which was also effective.

Conclusion: Mycophenolate mofetil vs cyclophosphamide for treatment of lupus nephritis: a single-center cohort real-world analysis

OP0284 IMMUNOPHENOTYPIC CHARACTERIZATION OF PERIPHERAL BLOOD-DERIVED B LYMPHOCYTES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS DURING B-CELL TARGETED THERAPY WITH ANTI-BLYS

L. Petrella1, C. Di Mario2,3, M. R. Gigante1, A. Paglioni1, V. Varragno1,4, M. A. D’Agostino1,3, S. Alvernini1,2, B. Toluoso1, E. Gremese1,3,4,5, Division of Clinical Immunology, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Rome, Italy; 2Immunology Research Core Facility – Gemelli Science and Technology Park (GSTE), Fondazione Policlinico Universitario A. Gemelli, IRCCS, Rome, Italy; 3, Università Cattolica del Sacro Cuore, Rome, Italy; 4Division of Clinical Immunology, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Rome, Italy; 5, Università Cattolica del Sacro Cuore, Rome, Italy

Background: Belimumab, the first biological drug approved for the treatment of patients with Systemic Lupus Erythematosus (SLE), is a fully human IgG1 monoclonal antibody directed against BlsY (B Lymphocyte Stimulator). BlsY inhibition is associated with a reduction in circulating B subsets and short-lived plasmacells.

Objectives: The aim of this study was to characterize the B cell phenotype in SLE patients at baseline and after B-cell targeted therapy with Belimumab in a cohort of active SLE patients.

Methods: Fifty-four SLE patients diagnosed according to the 2012 SLICC criteria (49 females, mean age 40.6±12.3 years, disease duration 12.3±9.0 years, SLEDAI-2K 6.6±3.1) who received belimumab were enrolled. Phenotyping of peripheral blood (PB)- derived B lymphocytes (using as phenotypic markers IgD, CD27 and CD38) was performed at six (T6) and twelve (T12) months in 38 SLE patients, together with the expression of BAFF and BAFF-R by flow cytometry.

Results: In the whole SLE cohort, a reduction over time was observed in the percentage of CD19+T0:11.6±6.1% vs T6:6.4±3.3%, p<0.01;T12:4.2±3.4% ,p<0.01 and naïve B cells (IgD-CD27pos) T0:55.8±28.7% vs T6:34.9±22.2%, p<0.01;T12:30.0±19.4%;p<0.04) and an increase of switched memory B cells (IgD-CD27pos) T0:21.0±20.2% vs T6:37.5±21.4% ,p<0.01;T12:42.2±21.7% , p<0.02) after B-cell targeted therapy with anti-Blys. Moreover, a reduction of IgD+CD27pos memory B cells at T6(p=0.01) was observed. Conversely, BAFF and BAFF-R expression in peripheral blood-derived CD19+ cells remained unchanged during therapy with anti-Blys. Stratifying SLE patients based on severe (renal and/or neurological) and mild (articular and/or cutaneous) organ involvement, a significant reduction of CD19+ pos percentage[T0:10.7±4.6% vs 6.6±8.2, p<0.03;T12:4.5±3.3%,p=0.03) and naïve B cells (IgD-CD27pos) [T0:61.0±24.6% vs T6:38.9±17.5%,p=0.01;T12:36.9±16.0%,p=0.03] was found in SLE patients with mild organ involvement and a significant increase of switched memory B cell subsets in both subgroups [severe T0:24.1±25.0% vs T6:44.9±27.4%,p<0.01] (mild T0:19.1±19.3% vs T6:31.2±12.7%,p<0.01). Evaluating the B cell subsets regarding the response to treatment (based on the reduction of the SLEDAI-2K), a significant reduction of naïve B cells was observed at T6 in both SLE group,[responders T0:55.4±29.3% vs T6:32.3±19.9%,p<0.01] (no responders T0:63.1±14.1% vs T6:41.4±3.5%,p<0.05) and switched memory B cells[responders T0:22.4±21.2% vs T6:39.6±19.4%,p<0.01] (no responders T0:20.6±26.1% vs T6:38.6±35.3%,p<0.05), with a significant higher percentage at baseline of switched memory B cells in responder SLE than in no-responder SLE group (22.4±21.2% vs 20.6±26.1%, p=0.02). ROC curve analysis of IgD-CD27pos subset [AUC(95% CI):0.761 (0.566-0.957) p=0.023] identified a cut-off of 9.94% associated with response at 6 months. Moreover, having a IgD-CD27pos rate ≥9.94% [OR:4.5(95% CIs:0.9-17.2)]; and the presence of anti-dsDNA antibod- ies at baseline[OR:5.295(95% CIs:1.2-22.12)], identified SLE patients who achieved early response within 6 months from belimumab therapy initiation.

Conclusion: Anti-Blys therapy significantly impacts on the composition of peripheral blood B-cell subpopulations in SLE patients in relation with the distinct organ involvement. Moreover, baseline immunological features and IgD-CD27pos B cell subset rate are novel putative biomarkers of response to anti-Blys in SLE patients.

VOCLOSPORIN IS EFFECTIVE IN ACHIEVING PROTEINURIA TREATMENT TARGETS IN LUPUS NEPHRITIS DEFINED BY EULAR/ERA RECOMMENDATIONS

1Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, München, Germany; 2Aurinia Pharmaceuticals Inc., Medical Affairs, Victoria, Canada

Background: The novel calcineurin inhibitor voclosporin was approved in 2021 for the treatment of adult patients with active lupus nephritis (LN) in combination with background immunotherapy. Voclosporin has a favorable metabolic profile and a consistent dose-concentration relationship, eliminating the need for therapeutic drug monitoring.

The Phase 2 AURA-LV and Phase 3 AURORA 1 studies demonstrated that the addition of voclosporin to mycophenolate mofetil (MMF) and low-dose steroids led to significantly higher complete renal response rates in AURA-LV at 24 weeks (32.6% vs 19.3%; odds ratio [OR] 2.03; p=0.046) and in AURORA 1 at 52 weeks (40.8% vs 22.5%; OR 2.65; p<0.0001) of treatment in patients with LN.

Objectives: The European League Against Rheumatism and European Renal Association (EULAR/ERA) published updated treatment recommendations for LN with targeted reductions in proteinuria over the course of the first year of therapeutic intervention. Here we report on a post-hoc analysis of pooled data from the similarly designed 48-week AURA-LV and 52-week AURORA 1 studies based on these updated response criteria.

Methods: AURA-LV and AURORA 1 enrolled patients with biopsy-proven active lupus nephritis (Class III, IV, or V or III/IV) and proteinuria ≥1.5 mg/mg (≥2 mg/mg for Class V). Pooled data included 288 patients in the voclosporin (23.7 mg BID) group and 266 patients in the control group, with all patients receiving MMF (target dose 1 g BID) and low-dose steroids (target dose 2.5 mg/day by week 16 according to protocol-defined steroid taper). We assessed the following EULAR/ERA treatment targets: ≥25% reduction in urine protein creatinine ratio (UPCR) by 3 months, ≥50% reduction in UPCR by 6 months, UPCR ≤0.7 mg/mg by 12 months, and steroid dose ≤7.5 mg/day by 3, 6, and 12 months.

Results: Within the first 3 months of treatment, 79.4% of patients in the voclosporin group and 62.4% of patients in the control group achieved ≥25% reduction in UPCR (odds ratio [OR] 2.25; 95% confidence interval [CI] 1.52, 3.33; p<0.0001). The percentage of patients achieving a reduction of ≥50% in UPCR by 6 months was also significantly greater in the voclosporin group compared to control (66.0% vs 47.0%; OR 2.03; CI 1.35, 2.83; p<0.0001). After 12 months of treatment, 52.6% and 33.1% of patients receiving voclosporin and control, respectively, had achieved a UPCR ≤0.7 mg/mg (OR 2.52; CI 1.75, 3.63; p<0.0001). Given the protocol-defined steroid taper, at both 3 and 6 months, a similar proportion (>90%) of patients in both groups had achieved the recommended steroid dose, with 89.6% and 82.8% in the voclosporin and control groups, respectively, on the recommended dose at 12 months.

The proportion of patients meeting all three UPCR targets during the one-year study period and having a steroid dose ≤7.5 mg/day at 12 months was 37.3% in the voclosporin group and 23.3% in the control group (OR 1.97; CI 1.43, 3.10; p<0.0001).

Conclusion: The addition of voclosporin to a background regimen of MMF and low-dose steroids in patients with LN significantly increased the likelihood of achieving the 3-, 6-, and 12-month UPCR targets of therapy recommended by EULAR/ERA.

Background: Today, there are still no DMARDs licensed for primary Sjögren Syndrome (pSS) patients. Among the explanations, are the limitations of current outcome measures used in clinical trials: e.g; high placebo response rate, evaluation of either symptoms or systemic activity, and important features not being assessed. The NECESSITY consortium (https://www.necessity-h2020.eu), including pSS experts from academia, pharmaceutical industry and patient groups formed to develop a new composite responder index, the SJOgren’s Tool for Assessing Response (STAR) that solve the issues of current outcome measures in pSS and is intended for use in clinical trials as an efficacy endpoint.

Objectives: To develop a composite responder index in primary Sjögren’s syndrome (pSS): the STAR.

Methods: To develop the STAR, the NECESSITY consortium used data-driven methods, based on 9 randomized controlled trials (RCTs), and consensus techniques, involving 78 experts and 20 patients. Based on reanalysis of rituximab trials (TRACTISS and TEARS) and literature review, the Delphi panel identified a core set of domains to include in the STAR, with their respective outcome measures. STAR options combining these domains were designed and proposed to the panel to select and improve them. For each STAR option, sensitivity to change was estimated by the C-index (derived from Effect size) in all 9 RCTs. Delphi rounds were run for selecting STAR among these options. The Delphi panel also voted to classify trials as positive, negative or “in between” in regards to primary but also key secondary endpoints. For the options remaining before the final vote, meta-analyses of the RCTs were performed separately for positive and “in between” trials together, and for negative trials.

Results: The Delphi panel identified 5 core domains (systemic activity, patient symptoms, lachrymal gland function, salivary gland function and biological parameters), and 227 STAR options, combining these domains, were selected to be tested for sensitivity to change. After two Delphi rounds, meta-analyses of the 20 remaining options were performed. The candidate STAR was selected by a final vote based on metrological properties and clinical relevance. In positive/in between trials, candidate STAR detected a difference between arms (OR 3.29, 95%-CI [2.07,5.22], whereas it did not in negative trials (OR 1.53, 95%-CI [0.81,2.91]).

Conclusion: The candidate STAR is a composite responder index, including in a single tool all main disease features, and is designed for use as a primary endpoint.
in pSS RCTs. Its rigorous and consensual development process ensures its face and content validity. The candidate STAR showed good specificity and sensitivity to change. The candidate STAR will be prospectively validated in a dedicated three arms RCT of the NECESSITY consortium that will evaluate combination of synthetic DMARDs (hydroxychloroquine + leflunomide or hydroxychloroquine + mycophenolate vs placebo). We encourage the use of STAR in any ongoing and future trials.

LONGITUDINAL ASSESSMENT OF THE ULTRASOUND GOUT LESIONS USING THE VALIDATED OMERACT SEMI-QUANTITATIVE SCORING SYSTEM

S. N. Christiansen, M. Østergaard, O. Slot, V. Fana, L. Teresli

Background: In gout, ultrasound (US) is a promising tool to detect changes in monosodium urate (MSU) deposits during urate-lowering therapy (ULT). The OMERACT US group has developed definitions of gout-specific US lesions[1] and a semi-quantitative scoring system for US lesions representing MSU deposition (tophus, double contour (DC) and aggregates)[2], but the responsiveness of lesions when applying this scoring system has not yet been assessed.

Objective: The primary aim of the study was to evaluate the responsiveness of gout-specific US lesions in patients receiving treat-to-target ULT using both a binary (present/absent) and the OMERACT-defined semi-quantitative (0–3) scoring system. The secondary aims were to determine the most responsive US measure for MSU deposition at patient level and the optimal joint/tendon set for monitoring lesions.

Methods: US (28 joints, 14 tendons) was performed in microscopically verified gout patients treated with ULT for ≥ 12 months. US images and videos of pathologies were stored. Tophus, DC and aggregates were scored binarily and semi-quantitatively. Individual lesion-scores were calculated at patient level as well as combined crystal sum scores. Standardised response means (SRM) for lesions when scored binarily and semi-quantitatively were calculated at patient and joint/tendon level.

Results: 48 patients with three-patient follow-up for 12 months. Plasma urate levels were effectively lowered during follow-up (Table 1). US showed statistically significant decreases in tophus and DC sum scores, both when scored binarily and semi-quantitatively.

OP0288 IMPACT OF CARDIOVASCULAR RISK ON THE DIAGNOSTIC ACCURACY OF THE ULTRASOUND HALO SCORE FOR GIANT CELL ARTERITIS

J. Molina Collada1,2, L. López Gómez1, L. Castrejon1,2, J. C. Nieto González1,2, J. Martinez-Barrio1,2, A. M. Anzola1, J. Rivera1,2, J. M. Alvaro-Gracia1,2, J. J. C. Nieto González1,2, L. López Gómez1,2

1Hospital General Universitario Gregorio Marañón, Rheumatology, Madrid; Spain;
2Instituto de Investigación Sanitaria Gregorio Marañón (IISGM), Rheumatology, Madrid, Spain

Background: The ultrasonographic (US) Halo Score provide a quantitative measure of the extent of vascular inflammation in patients with giant cell arteritis (GCA). High Halo Scores correlate with systemic markers of inflammation, rate of ocular ischaemia and may help to firmly diagnose GCA with high specificity. However, an increase in the intima media thickness (IMT) in patients with elevated cardiovascular risk (CVR) may lead to false-positive US findings.

Objectives: Our aim is to evaluate the impact of CVR on the diagnostic accuracy of the US Halo Score in patients with suspected GCA.

Methods: This is a retrospective observational study of patients suspected of having GCA and referred to our US fast track clinic. All patients underwent exam within 24 hours per protocol. The IMT was measured in gray scale mode in cranial and extra-cranial (carotid, subclavian and axillary) arteries and the Halo Score was also determined to assess the extent of vascular inflammation. GCA diagnosis was confirmed after 6-month follow-up by the referring clinician. The European Society of Cardiology (ESC) Guidelines on CV Disease Prevention in clinical practice were used to define different categories of CVR. Patients were classified as very high, high, moderate or low CVR according to the Systemic Coronary Risk Evaluation (SCORE) obtained using the ESC CVD Risk Calculator app for mobile devices. Comparison between groups was performed and the diagnostic accuracy of the Halo Score in patients according to CVR was evaluated using ROC curves.

Results: Of the 157 patients referred to our US fast track clinic (67.5% female, mean age 73.7 years), 47(29.9%) had GCA confirmed after 6-month follow-up. There were no differences in CVR between patients with and without GCA (mean SCORE 20.6 [21.6] vs 18.7 [21]; p=0.601). Among patients without GCA, high/extra-cranial artery IMT was significantly higher in patients with high/very high CVR (0.835 (CI95% 0.756-0.914), slightly greater in patients with low/ moderate CVR (0.965 [CI95% 0.911-1]) versus patients with high/very high CVR (0.798 [CI95% 0.702-0.895]) (Figure 1). A statistically weak positive correlation was found between the Halo Score and the SCORE (r 0.245; p=0.002).

Discussion: The Danish Rheumatism Association is acknowledged for financial support of the salary of SNC.

Figure 1. Diagnostic accuracy of the Halo Score for a clinical diagnosis of GCA after 6-month follow-up in (A) all GCA suspected patients, (B) patients with high/very high CVR and (C) patients with low/moderate CVR.

Conclusion: High CVR may influence the diagnostic accuracy of the US Halo Score leading to false-positive findings in these patients. Higher IMT values may be found in extracranial arteries of subjects with high/very high CVR without GCA. Thus, CVR should be taken into consideration in the US vascular assessment of patients with suspected GCA. These results need to be confirmed in larger cohorts to develop a modified US Halo Score applicable to patients with high CVR.

OP0290

SHORT-AND LONG-TERM EFFICACY OF ULTRASOUND-GUIDED NEEDLE FRAGMENTATION OR LAVAGE (BARBOTAGE) IN SYMPTOMATIC SHOULDER CALCIFIC TENDONITIS REFRACTORY TO SUBACROMIAL STEREOID INJECTION. PROSPECTIVE LONGITUDINAL STUDY OF 181 PATIENTS.

E. Casado1, S. Garcia-Cirera1, S. Retamozo1, M. Rusilov1, E. Costa Moya1, L. Lluis1, J. Calvet1, J. Gratacos-Masmitja1. University Hospital Parc Tauli, ISPT Research Institute, Rheumatology, Sabadell, Spain

Background: Rotator cuff calcific tendinopathy is a common cause of shoulder pain and disability in young patients. Despite anesthetics or steroid injection some patients still experience symptoms and may require surgery. Ultrasound-guided fragmentation or lavage are minimally invasive techniques that can be used instead of surgery to remove calcification and improve symptoms. However, evidence is poor because of most of published studies are retrospective or with few patients.

Objectives: To assess the short and long-term efficacy of ultrasound guided needle fragmentation or lavage (barbotage) in a large cohort of patients with symptomatic shoulder calcific tendinosis refractory to previous subacromial steroid injection.

Methods: Prospective study, including all consecutive patients referred to a Rheumatology out-patient clinic between Jul 2008-Dec 2020 because of symptomatic (visual analog scale or VAS≥4) calcific tendinosis of the rotator cuff refractory to at least one subacromial corticosteroid injection. After informed consent, all patients were treated with minimally invasive ultrasound-guided technique: fragmentation between Jul 2008-Dec 2013 or lavage (barbotage) between Jan 2014-Dec 2020. Corticoids were injected in the subacromial-subdeltoid bursa in all patients after procedure. Shoulder pain (VAS) and shoulder X-ray were assessed at baseline and after 4 months since the intervention. A new clinical assessment was made after 12 months or when clinical relapse occurred.

Results: One hundred and eighty-one subjects (56 men and 125 women), were included in the study. Mean age was 49.7 years (range 29–72). Mean duration of symptoms was 33.0 months (2–150), with mean VAS 7.6±1.5. Right shoulder was the location most frequently affected (66.3%). Mean size of calcification by X-ray was 13.7 mm (5–40), 55 patients (30.4%) underwent fragmentation, 115 (63.5%) lavage and 11 (6.1%) both techniques. There were not significant differences between groups at baseline. 4 months after procedure, mean VAS pain was 4.5±3.8 and 82.9% of subjects experienced a X-ray resolution (56.8%) or size reduction (26.1%) of the calcification. A clinical relapse occurred in 73 patients (40.3%) in the first 4 months of follow up, and in 33 patients (18.2%) between months 4 and 12. Symptoms disappeared in most of patients with a new steroid injection. Only 31 patients (17.1%) required a second fragmentation or lavage, and 13 patients (7.2%) a rotator cuff surgery. Any patient suffered local or systemic complications after fragmentation or lavage. Patients treated with lavage had higher shoulder pain when clinical relapse (mean VAS 6.5 vs 4.0; p<0.01) and needed more frequently a new steroid injection (54.8% vs 34%; p<0.004) or ultrasound guided-procedure (17.5% vs 13.1%; p=0.008). There were no significant differences between both techniques in the radiographic resolution or size decrease of the calcification.

Conclusion: Ultrasound guided needle fragmentation and lavage (barbotage) are effective and safe at short and long-term to treat patients with symptomatic shoulder calcific tendinosis, avoiding surgery in more than 90% of cases. Fragmentation seems to have better clinical outcomes than lavage.

OP0291

WHICH INFLAMED TISSUES EXPLAIN A POSITIVE SQUEEZE TEST OF THE METATARSOPHALANGEAL JOINTS? A LARGE IMAGING STUDY TO UNDERSTAND THE HUMAN NAIL UNIT IN METATARSOPHALANGEAL ARTHRITIS

B. van Dijk1, Y. Dakkak1, D. Krijbolder1, J. van Zeben2, I. Tchetverikov3, M. Reijnierse4, A. van der Helm-van Mil 1,5.

1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Franciscus Gasthuis & Vleuteland, Rheumatology, Rotterdam, Netherlands; 3Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands; 4Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands; 5Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands

Background: The squeeze test of metatarsophalangeal (MTP-)joints is frequently used, because it is easy and cheap, and is traditionally perceived as a test for synovitis. Besides classic intra-articular synovitis also tenosynovitis and intermetatarsal bursitis (IMB) represent synovial inflammation, albeit juxta-articularly located. Both are frequently present in RA and occasionally in other arthritides. However, the contribution of IMB to MTP squeeze test positivity is unknown and the contribution of tenosynovitis has only been partially studied.

Objectives: To assess whether tenosynovitis and IMB contribute to a positive MTP squeeze test.

Methods: 192 early arthritis patients and 693 CSA-patients underwent the MTP squeeze test and foot XRF at first presentation. MRI measurements in aged-matched healthy controls were used to define positivity for synovitis, tenosynovitis and IMB. Logistic regression was used; multivariable models adjusted for sex and simultaneous presence of inflammation features.

Results: In early arthritis patients synovitis (OR 4.8 (95%CI 2.5–9.5), tenosynovitis (2.4 (1.2–4.7)) and IMB (1.7 (1.2–2.6)) associated with positivity of the MTP squeeze test. Synovitis (3.2 (1.4–7.2)) and IMB (3.9 (1.7–8.8)) remained associated in multivariable analyses. Of patients with a positive MTP squeeze test, 79% had synovitis or IMB: 12% synovitis, 15% IMB and 52% both synovitis and IMB. IMB patients, subclinical synovitis (3.0 (2.0–4.7)), tenosynovitis (2.7 (1.6–4.6)) and IMB (1.7 (1.2–2.6)) associated with MTP squeeze test positivity. In multivariable analyses, synovitis remained independently associated (2.5 (1.5–4.1)) whilst tenosynovitis (1.5 (0.8–2.9)) and IMB did not (1.2 (0.8–1.8)). Of patients with a positive MTP squeeze test, 39% had synovitis or IMB: 10% synovitis, 15% IMB and 13% both synovitis and IMB.

Conclusion: Besides synovitis also IMB contributes to pain upon compression in early arthritis, presumably due to its location between MTP joints. This is the first evidence showing that a positive MTP squeeze test positivity is not only explained by intra- but also juxta-articular inflammation.
SCORING STRUCTURAL DAMAGE IN RHEUMATOID ARTHRITIS BY ULTRASOUND: RESULTS FROM A DELPHI PROCESS AND WEB-RELIABILITY EXERCISE BY THE OMERACT US WORKING GROUP

Background: Structural damage in rheumatoid arthritis (RA) includes bone erosion, cartilage change, and joint malalignment; historically evaluated with conventional radiography. Ultrasound (US) has been shown to be a valid tool for evaluating both cartilage change and bone erosion.

Objectives: To obtain agreement on definitions and develop semiquantitative scoring systems for assessing structural damage by US and to validate these in a web-based reliability exercise.

Methods: A Delphi survey of statements was prepared by an OMERACT US Working Group task force (USWG) based on a previously published systematic literature review (1) and circulated between group members, including definitions on normal US appearance of joint components, definitions of elementary lesions and scoring systems for bone erosions and joint malalignment. Definitions and a US scoring system for scoring cartilage damage were recently developed and validated by the USWG (2). After agreement was achieved (≥75% of grades 4-5 on 1-5 Likert scale) on the statements, still images of metacarpophalangeal and proximal interphalangeal joints 2-5 in healthy controls and in RA patients with varying degrees of pathology were acquired by the USWG members. A dataset of 100 anonymized images, representing various grades of the 3 components of structural damage was created and utilized in 2 rounds of a web-based exercise. Intra- and inter-reader reliability of the scoring systems was assessed by kappa statistics.

Results: 19 USWG members needed 4 Delphi rounds to reach agreement on a total of 9 statements. 4/12 statements were approved in the first, 2/6 in the second, 1/5 in the third and 2/2 in the fourth round. Final scoring systems and representative images are shown in Table 1 & Figure 1. 22 members participated in the web-based reliability exercise. The intra-reader reliability was almost perfect for bone erosion (kappa: 0.87) and cartilage change (kappa: 0.83) and substantial for malalignment (kappa: 0.72). The inter-reader reliability was almost perfect for bone erosion (kappa: 0.85) and cartilage change (kappa: 0.79) and substantial for malalignment (0.62).

Table 1. Final definitions of scoring systems of elementary lesions of structural damage in rheumatoid arthritis

<table>
<thead>
<tr>
<th>Lesion</th>
<th>Definition</th>
<th>Agreement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bone erosion</td>
<td>A 4-grade semiquantitative scoring system can be used to score erosions as follows: grade 0. intact cortical bone; grade 1. single small erosion (diameter: &lt;2mm); grade 2. single large erosion (diameter: &gt;2mm) or 2 small erosions; grade 3. 2 large erosions or &gt;3 erosions, regardless of size. Both longitudinal and transverse scans should be considered, and the largest measure chosen for each erosion.</td>
<td>100%</td>
</tr>
<tr>
<td>Cartilage change</td>
<td>A 3-grade semiquantitative scoring system can be used to grade hyaline cartilage change as follows: grade 0. normal cartilage; grade 1. minimal change: focal thinning or incomplete loss of cartilage; grade 2. severe change: diffuse thinning or complete loss of cartilage.</td>
<td>80% (2)</td>
</tr>
<tr>
<td>Malalignment</td>
<td>A 3-grade semiquantitative scoring system can be used to grade malalignment as follows: 0. normal alignment; 1. subluxation or partial dislocation, where the two bone endings are malaligned so that one bone ending is dislocated from its normal position, but still within the articulation; 2. luxation or total dislocation, where the luxated bone ending moves beyond the articulation and the opposing bone ending. Bone position may be compared with a contralateral or similar intact joint if available.</td>
<td>94%</td>
</tr>
</tbody>
</table>

Conclusion: This first attempt to create a composite US instrument based on scoring systems encompassing all aspects of structural damage, demonstrates that US is a reliable tool for evaluating and scoring bone erosion, cartilage change and malalignment in the finger joints of RA patients.

OP0292 CLASSIFICATION OF PSORIATIC ARTHRITIS, SERONEGATIVE RHEUMATOID ARTHRITIS, AND SEROPOSITIVE RHEUMATOID ARTHRITIS USING DEEP LEARNING ON MAGNETIC RESONANCE IMAGING

L. Felle1, S. Bayat1, A. Kleyer2, F. Fagri3, L. Kapseen3, M. Schiereth4, T. Meenderink5, K. Brenning1, K. Tasclier2, G. Krönke3, M. Uder1, M. Sticherling2, S. Bickelhaupt3, G. Schett2, A. Maier1, F. Roemer3, D. Simon2
1University of Erlangen-Nuremberg, Computer Science, Erlangen, Germany; 2University Clinic Erlangen, Rheumatology, Erlangen, Germany; 3University Hospital Erlangen, Radiology, Erlangen, Germany; 4University of Erlangen-Nuremberg, Artificial Intelligence in Biomedical Engineering, Erlangen, Germany; 5University Clinic Erlangen, Dermatology, Erlangen, Germany

Background: While MRI evaluation of joints has been primarily used to quantify inflammation at a cross-sectional and longitudinal level, less is known about the potential of MRI in distinguishing different patterns of inflammation in the various forms of arthritis.

Objectives: To evaluate (i) whether deep learning using neural networks can be trained to distinguish between seropositive rheumatoid arthritis (RA+), seronegative RA (RA-), and psoriatic arthritis (PsA) based on structural inflammatory patterns on hand magnetic resonance imaging and (ii) to assess if psoriasis patients with subclinical inflammation fit into such patterns.

Methods: ResNet 3D [1] neural networks were trained to distinguish (i) RA+ vs. PsA, (ii) RA- vs. PsA and (iii) RA+ vs. RA- with respect to hand MRI data. Diagnosis of patients was determined using the following guidelines: ACR/EULAR 2010 [2] for RA and CASPAR [3] for PsA. Results from T1 coronal, T2 coronal, T1 coronal axial fat at suppressed contrast-enhanced (CE) and T2 fat suppressed axial sequences were used. The performance of such trained networks was analyzed by the area-under-the-receiver-operating-characteristic curve (AUROC) with and without imputation of demographic and clinical parameters (Figure 1A). Additionally, the trained networks were applied to psoriasis patients without clinical signs of PsA.

Conclusion: Deep learning can be successfully applied to differentiate MRI inflammatory patterns related to RA+, RA-, and PsA. Early changes in psoriasis patients can be recognized by neural networks and are characterized by a pattern that allowed the networks to classify them as PsA.

OP0293 PHOTOREALISTIC DEPICTION OF RHEUMATIC PATHOLOGIES BY CINEMATIC RENDERING FACILITATES DISEASE UNDERSTANDING OF PATIENTS WITH RHEUMATIC DISEASES

M. Pachowsky1,2, H. Morf3, D. Simon1,2, V. Schönaus1,2, L. Valor3,2, J. Knitza1,3, K. Engel4, M. Uder1, A. Huerer1,4, G. Schett2,3, A. Kleyer2 "On behalf of https://www.medizin3.uk-erlangen.de/en/research/research-main-focus/research-group-pd-dr-a-kleyer-and-pd-dr-d-simon/

1University Hospital Erlangen, Department of Internal Medicine 3, Rheumatology and Immunology, University Hospital Erlangen, Erlangen, Germany; 2Waldkrankenhaus Erlangen, Klinik für Orthopädie und Unfallchirurgie, Erlangen, Germany; 3Deutsches Zentrum Immuntherapie, Universitätsklinikum Erlangen, Friedrich-Alexander Universität Erlangen-Nuremberg, Erlangen, Germany; 4Siemens, Siemens Healthineers AG, Erlangen, Germany; 5University Hospital Erlangen, Institute of Radiology, Erlangen, Germany; 6Klinikum Nürnberg/Universitätsklinik der Paracelsus Medizinischen Privatuniversität, Klinik für Innere Medizin 5, Rheumatologie, Nürnberg, Germany
Background: Treatment success of a rheumatic disease crucially depends on whether a patient is sufficiently informed about the disease[1]. Visual methods are suitable for explaining diseases[2]. Cinematic rendering (CR) is a new method that allows to segment standard medical images into images that illustrate disease pathologies in a photorealistic way. As such, CR provides new opportunities to visualize diseases and but could therefore be a valuable tool for patients with rheumatic and musculoskeletal disease (RMD)[3].

Objectives: We questioned, if it is possible to apply CR on images from structural lesions of patients with rheumatoid arthritis (RA), Psoriatic Arthritis (PsA) and axial Spondyloarthritis (axSpA) and to test whether such images are helpful to patients with RMDs to understand their disease process. application in doctor-patient communication.

Methods: We selected conventional computed tomography (CT) and high-resolution peripheral CT (HR-pQCT) from patients with rheumatoid arthritis (RA), Psoriatic Arthritis (PsA) and axial Spondyloarthritis (axSpA) that showed typical changes of the respective disease. HR-pQCT measurements were performed in RA and PsA at the Rheumatology Department. CT Measurements of the spine in an axSpA patient was provided from AH. All images were segmented to CR images using a prototype software by the manufacturer Siemens Healthineers. In a prospective study on consecutive patients with RA, PsA, axSpA these images were used to explain the depicted pathomoronic pathologies and compared to conventional imaging in a structured doctor-patient interview. In the last step, patients filled in a quantitative questionnaire (Likert Scale 1-5) about their perspectives answering following questions: Did you understand your disease in the provided Cinematic Rendering images? Did you understand your disease better through the presentation using Cinematic Rendering images than with a normal X-ray image? Do you think it would be reasonable to use this type of Cinematic Rendering to improve patients’ understanding of their disease? Descriptive statistical methods were used.

Results: CR images of rheumatic diseases were successfully generated from above mentioned imaging data (CT, HR-pQCT). Bone erosions, osteophytes, enthesiophytes, osteoporosis and anklylosis of the spine could be visualized in photorealistic detail. Figure 1 shows examples of a images of a patient with RA and axSpA with typical bone changes. 65 patients (23 RA/23 PsA/19 axSpA; f 55%) were guided through CR images of their respective disease by an experienced rheumatologist, followed by completing the questionnaire mentioned above. Patients stated that CR was very helpful to understand their disease process (4.39±0.15), that understanding diseases by CR was better than the one obtained by conventional radiographs (4.43±0.20) and that they considered such technology helpful for improving disease understanding (4.35±0.09).

Conclusion: CR seems to be a promising teaching tool for RMD patients facilitating an improved understanding of their disease process and in consequence my also improve adherence of RMD patients to their anti-rheumatic treatment.

Background: The combined use of B-mode ultrasound (US) and Power Doppler (PD; combination termed as PDUS) allows visualisation of morphological and pathophysiological changes of the synovium. ULTIMATE (NCT02662985) was the first large, randomised, double-blind, placebo-controlled PDUS phase IIb study in psoriatic arthritis (PsA), to demonstrate that Global OMERACT EULAR Synovitis Score (GLOESS), a US score at patient level, was sensitive to detect the early and continuous decrease in synovitis in a multicenter setting using different US devices and examiners. However, the US assessment for GLOESS was time-consuming owing to the number of joints assessed.

Objectives: To investigate the value of various reduced joint sets to predict the validated GLOESS score.

Methods: ULTIMATE was a 52-week study with a 12-week double-blind, placebo-controlled period followed by 12-week open-label (OL) treatment and 6-month OL extension period. In the ULTIMATE trial, GLOESS for the 24 paired joints was calculated, with a potential score ranging between 0 to 144. A Spearman’s rank correlation matrix and a Cluster Image Map were constructed to identify highly correlated joint clusters based on the composite PDUS scores. Based on the different approaches (best correlation, model optimization, etc.), representative joints were then selected from each group, which yielded several corresponding combinations of joints. Linear models were developed with these reduced joint sets as predictors of GLOESS, using data from 60% of patients randomly selected from the
ULTIMATE study. The remaining 40% data were used for model validation and diagnostics.

Results: Five models were established with reduced pairs of joint sets (9–13 pairs). The joints included in each linear model are summarized in Table 1.

All five models of reduced joint sets showed high correlation with GLOESS score of $R^2 \approx 0.95$. Figure 1 depicts all the 5 models of reduced joint sets demonstrating changes very close to that of validated GLOESS.

Table 1. Joints included across five linear models, indicated by green shading

Conclusion: All models of reduced joint sets for PDUS-detected synovitis predicted GLOESS well. The next steps will be to document responsiveness and ability to discriminate between active and placebo treatment.

Values are reported as least squares means (standard errors) by group, while the differences between groups are reported with 95% confidence intervals. 1Polysomnography, 2Insomnia Severity Index, 3Pittsburgh Sleep Quality Index, 4Bristol Rheumatoid Arthritis Fatigue - Multidimensional Questionnaire, 5Rheumatoid Arthritis Impact of Disease, 6Hospital Anxiety and Depression Scale - Depression.
Background: Insomnia is highly prevalent in patients with rheumatoid arthritis (RA) and may exacerbate symptoms and burdens, such as fatigue, depressive symptoms, and pain. Cognitive behavioural therapy for insomnia (CBT-I) has been shown to produce positive effects on sleep in other clinical populations. However, CBT-I has not previously been investigated in patients with RA.

Objectives: The primary objective was to compare the effect of nurse-led group-based CBT-I to usual care on sleep efficiency, measured by polysomnography (PSG) immediately after the intervention (i.e. seven weeks after baseline) in patients with RA. Secondary objectives included comparing the longer-term effect of CBT-I on sleep and RA-related outcomes at 26 weeks' follow-up.

Methods: In a randomised controlled trial, using a parallel group design, the experimental intervention was six weeks' CBT-I, the control comparator was usual care. CBT-I was delivered face-to-face by a CBT-I trained nurse. The primary analyses were based on the intention-to-treat (ITT) population; missing data were statistically handled using repeated-measures linear mixed effects models adjusted for the level at baseline.

Results: The ITT population consisted of 62 patients (89% women), with an average age of 55 years (SD 10), DAS28-CRP of 3.4 (SD 1.0), Insomnia Severity Index (ISI) score of 18.9 (SD 4.4) and median Patient Global Assessment score of 55 (IQR 28;71). When primary outcome was measured by PSG at week seven, sleep efficiency was 88.7% in the CBT-I group, compared to 83.7% in the control group (difference: 5.0 [95% CI -0.4 to 10.4]; p=0.068) (See Table 1). Secondary outcomes measured by PSG had not improved at week 26 either. However, for all secondary sleep and RA-related patient-reported outcomes, there were statistically highly significant differences between CBT-I and usual care e.g. insomnia (ISI: -9.8 [95% CI -11.8 to -7.9]), RA impact of disease (RAID: -1.4 [95% CI -1.9 to -0.80]; and Patient Global Assessment (-13.0 [95% CI -20.9 to -5.1]) at 26 weeks' follow-up.

Conclusion: Nurse-led, group-based CBT-I for two hours per week for six weeks, did not improve objectively measured sleep efficiency or any other outcomes measured by PSG. However, CBT-I showed long-term improvement on patient-reported outcomes such as fatigue, impact of disease, depression, pain, and Patient Global Assessment – a finding that could have important clinical implications.

Acknowledgements: We thank the participants for their time and commitment and the patient research partners for valuable insight into the process and content of the trial.

Complexity of care in RMD: intersection between health and social care

Sjögren syndrome: from biopsy to lymphoma
score ≥ 1/4 mm²) corresponds to 3 scoring points out of 4 needed to reach a positive classification for SS [1]. Moreover, there is increasing evidence that salivary gland biopsy can provide prognostic information regarding systemic involvement and the development of lymphoma in the context of the disease.

**Objectives:** The aim of this study was to analyze the minor salivary gland (MSLG) biopsy findings of a large SS cohort and to examine their associations with disease specific laboratory markers, clinical and patient associated parameters.

**Methods:** We included all patients from two large rheumatological medical departments in Germany having undergone a diagnostic MSLG between 01/2010 and 12/2019. The data have been collected partly in a retrospective and party in a prospective manner. Next to the examination of histological results we focused on activity and chronicity parameters of the underlying disease, autoantibodies, presence of systemic and haematological involvement, as well as on current and previous comorbidities. The statistical analyses included sensitivity and specificity examinations via receiver operating characteristics (ROC), correlation analyses, Mann-Whitney-U-Tests and ANOVA.

**Results:** In total, 678 patients have been included (615 ♀, median age 55 years [47-63, IQR]), 306 patients (45.1%) had a positive focus score. The remaining 372 patients with a negative focus score served as a control group. There were significant correlations between the level of the focus score and nicotine use (p=0.002), hypergammaglobulinemia [1.27 [0.7-1.33, IQR] vs. 0.73 [0.0-0.76, IQR]; p=0.001], ANA positivity [1.18 [0.11-1.3, IQR] vs. 0.64 [0.1-1.34, IQR]; p<0.001] and rheumatoid factor positivity (p=0.001). Moreover, focus score levels correlated significantly with disease modifying antirheumatic treatment [1 [0-2.34, IQR] vs. 0.87 [0-1.8, IQR]; p=0.004] and weakly significantly with erythrocyte sedimentation rate (r=0.235, p=0.001).

Within the group of patients with primary SS there were significant correlations between the level of the focus score and presence of systemic involvement [2 (1.1 - 4, IQR) vs. 1.44 (1-2.62, IQR); p=0.015], glandular involvement [4 (2.98-6.2, IQR) vs. 0.72 (1-6.3, IQR); p=0.007] and haematologic manifestations (p=0.002). SSA-antibodies showed the best diagnostic performance compared to MSLG, as examined by ROC (Table 1).

**Table 1. Diagnostic value of SSA-antibodies, Sicca, Schirmer’s and Saxon’s test compared to minor salivary gland biopsy findings (reference focus score ≥ 1/4 mm²)**

Interestingly enough, among 159 patients who were admitted due to the diagnosis of primary fibromyalgia (FM), 63 (39.6%) could be diagnosed with SS on the basis of histologic findings and the ACR-EULAR classification criteria.

**Conclusion:** By examining one of the largest cohorts in the literature we could show that MSLG biopsy findings not only play a key role in the classification and diagnosis of SS, but could also provide important information regarding the presence of a systemic, glandular or haematological involvement. Furthermore, MSLG can help differentiate patients with FM and other chronic pain disorders from patients with subclinical SS who suffer primarily from chronic pain.

**Facilitating work participation – why and how?**

Enhancing research through patient involvement_____
Background: The Covid-19 pandemic has meant a modification of the patterns of the doctor-patient relationship, favoring online visits and reducing face-to-face visits. Likewise, the implementation of Patient-Reported Outcomes (PROs) that do not require the intervention of the doctor in our clinical practice and that given their close relationship with the clinical activity of chronic inflammatory joint diseases (CIJD) has favored an empowerment of patients and can allow the development of the online visit.

Objectives: Know the use and acceptance of patients with CIJD: rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthropathies (SpA) of a non-face-to-face online visit, through a digital environment.

Methods: Patients were included in a platform called Rheumanet for access by username and passwords (https://www.laconsolidadeterredes.com/). At the time of inclusion, demographic variables were collected: date of birth, sex, level of education (primary education, secondary education, vocational training, further education and higher education), distance from the hospital to the patient’s home, and clinical variables such as diagnosis: RA, PsA or SpA, as well as the duration of the disease. Prior to the appointment, patients were encouraged to complete a PRO survey to assess their clinical situation: Routine Assessment of Patient Index Data 3 (RAPID3) for RA, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for SpA and RAPID3 Index and/or BASDAI for the PsA. Both the RAPID3 and BASDAI were scored for the patient’s knowledge and assigned to a color scale based on disease activity in green (remission or low activity), orange (moderate activity) or red (severe activity). Likewise, they were ordered to express through a free text what they would tell us as if they were in a face-to-face consultation. Complementary tests (analytical, radiological studies and others) are obtained simultaneously from the medical records and a joint assessment of the visit is carried out.

Results: Between September 1, 2020 and January 31, 2022, a total of 248 patients (113 RA, 53 PsA and 82 PsA) were included in the platform. 172 (69.3%) patients used the digital platform and made at least one non-face-to-face visit during follow-up. The number of online visits made by each patient ranged from 1 to a maximum of 13 visits. 80 patients (70.7%) suffered from RA, 40 (75.4%) from PsA and 52 (63.4%) from PsA. The number of patients who made non-face-to-face visits was 38 (72.3%) for a disease duration of <5 years and 137 (64.5%) for >5 years. When the ages of the patients were analyzed, the number of patients who made visits was 75 (73.5%) between 18 and 30 years old, 50 (67.7%) between 30 and 50 and 47 (66.4%) from 50 years. According to the degree of activity of the disease, 75 patients were in remission or low activity at some point during the visits, 63 patients with moderate activity and 34 with severe activity. The distribution according to level of education was: 11 (6.3%) primary education, 21 (12.2%) secondary education, 37 (21.5%) vocational training, 63 (36.6%) further education and 40 (23.2%) higher education. The number of online visits was higher in patients who lived at a distance of 50 km or more from the hospital, reaching 100% of the visits in this subgroup of patients.

Conclusion: The online visit through a digital platform through PROs is well accepted by our population with CIJD, especially in the young population, with a higher cultural level and whose home is far from the hospital. The online visit was made by patients regardless of the severity of their disease activity. Speed and ease of use using PROs already known and their close relationship with the clinical activity of CIJD has favored an empowerment of patients and can allow the development of the online visit.

Digital-Health and Tailored Interventions for Improving Patients’ Adherence: Opportunities and Challenges

Methods: We systematically searched the following databases: Embase, PubMed, Cochrane Central, CINAHL, Web of Science, Clinicaltrials.gov, and the International Clinical Trials Registry Platform (ICTRP). Eligible articles reported adherence rates to eHealth tools in patients with rheumatoid arthritis (RA), juvenile idiopathic arthritis (JIA), spondyloarthropathy (SpA), osteoarthritis (OA), and gout. Included texts were screened individually. Finally, quality assessment was done with the Newcastle-Ottawa scale (NOS) and the PEDro scale.

Results: The literature search resulted in 7027 articles. After deduplication, 4219 articles were screened for eligibility, and 47 articles were included. We found highest adherence rates in studies applying electronic diaries (81.8%), followed by text messages (79.9%), web-based platforms (74.6%), activity trackers (73%), and smartphone applications (65.5%). Highest adherence was reported in studies on patients with OA (79.7%), followed by patients with gout (73.7%), RA (71.3%), ankylosing SpA (67%), and JIA (59%). Demographic characteristics did not seem to affect patient adherence. Based on frequency of data entering, a time interval of once-daily showed highest adherence rates (72.6%), followed by entering data more than once a day (72.3%) and once a week (67.7%), or longer (59.2%). Adherence declined with longer study duration.

Conclusion: Our literature review identified declining adherence levels with longer study duration, and highest adherence rates for patients with OA, making use of electronic diaries, and requesting once-a-day completion. OA studies had an overall shorter duration than RA studies, which could be an explanation as to why OA studies had an overall higher adherence. Lower adherence rates were reported in studies on patients with chronic arthritis to eHealth tools.

Figure 1. Linear regression model of adherence based on study duration per disease. X = study duration (days); Y = adherence (%). Y = -0.0332X + 71.84. Light blue = RA, yellow = OA, dark blue = JIA, red = gout, green = SpA, white = >1 disease

Table 1. Included studies. Adh = adherence SA = smartphone app, ED = electronic diary, AT = activity tracker, OP = online platform, TM= text message. JIA= Juvenile Idiopathic Arthritis, PsA = Psoriatic Arthritis, SpA = Spondyloarthritis, OA = osteoarthritis, RA = Rheumatoid arthritis

---

Rheumatology across boundaries

Methods: AxSpA patients in the patient-based SPARTAKUS cohort study in southern Sweden (non-axSpA AxSpA [n=axSpA] n=86, ASAS criteria; AS n=168, modified New York criteria) self-reported their history of prior urolithiasis (no/yes). Faecal (F) calprotectin and ASCA (anti-Saccharomyces cerevisiae antibodies) in serum were measured by commercially available ELISAs (Calpro AS; ORGENTEC Diagnostika). For a subgroup of patients (n=164), presence of gut dysbiosis was also assessed by the OA-MAP Dysbiosis Test (Genetic Analysis). Demographics, disease/treatment characteristics, comorbid IBD and the gastrointestinal biomarkers (F-calprotectin/ASCA/dysbiosis) were compared between patients with versus without prior urolithiasis. Finally, the same biomarkers were also compared between patients with versus without urolithiasis history, after exclusion of subjects with known IBD.

Results: Urolithiasis history was reported by 13% (n=33) of the axSpA patients, and comorbid IBD was significantly more common in this group (27% versus 6.8%, p<0.001; Table 1). F-calprotectin levels were also significantly higher among patients with prior urolithiasis, as was presence of gut dysbiosis (Table 1). ASCA seropositivity did not differ between the groups. Moreover, prior urolithiasis was associated with longer disease duration and AS-phenotype. After exclusion of cases with comorbid IBD, urolithiasis history was reported by 10% (24 of 230 patients). F-calprotectin elevation ≥100 mg/kg remained significantly associated with urolithiasis history also in this population, while only being numerically increased when assessed as a continuous variable (p=0.053; Figure 1). Gut dysbiosis also remained associated with prior urolithiasis in the non-IBD population (56% [9 of 16 patients with prior urolithiasis] versus 30% [40 of 132 patients without], p=0.037), whereas ASCA status did not differ between the groups (data not shown).

</table>

Mean (SD) or n (%) if not otherwise stated. † GA-Map Dysbiosis Test, dysbiosis index ≥3. *

Conclusion: The current results lend support to the hypothesis that the increased urolithiasis risk in axSpA may be driven by gut inflammation/pathology. Prospective studies are, however, needed to assess the causality.

REFERENCES:

Figure. Comparison of F-calprotectin levels (A) and share of patients with elevated F-calprotectin ≥100 mg/kg (B) between axSpA patients without known comorbid IBD versus with prior urolithiasis. The COVID-19 pandemic – what did we learn?

S. Trope1, R. M. Flipo2, ANDAR, Direction, Paris, France; 2Centre Hospitalier Universitaire de France, Department of Rheumatology, LILLE, France

Background: Has the COVID-19 crisis overwhelmed health democracy? This question may have arisen since extraordinary measures taken in response to the pandemic were developed almost exclusively by scientific expert committees. Citizens, patients, patient organizations, healthcare professionals, and even experts from these committees have recognized a lack of health democracy in the decision-making process regarding the COVID-19 response in France. Indeed, patient voices were barely heard during the early stages of the pandemic; yet inclusive dialogue is crucial for building trust and adherence to policy. Moreover, patients also need to be assisted in handling the overabundance of COVID-19 information, particularly misleading and false information, referred to as an “infodemic” by the WHO.

Objectives: To show a practical and effective application of health democracy in rheumatology through collaboration between patient associations and rheumatologists during the COVID-19 pandemic. To collect, select, analyze, and translate COVID-19 literature to provide rheumatoid arthritis (RA) patients with useful, convenient and quality educational materials that answer patients’ medical, scientific and daily life questions. This initiative is consistent with patient-centered COVID-19 response.

Methods: At the instigation of a patient association in October 2021, a working group was established to develop a COVID-19 patient education resource to meet the expectations and needs of RA patients. The working group consisted of health professionals and patients identified by the partner patient organization. A committee of rheumatologists checked the reliability and accuracy of the scientific and medical information. A committee of patients assessed materials’ relevance, readability, and understandability. Materials were written in lay language without distorting the meaning of the scientific data. The methodology is detailed in Figure 1.

Results: The document is available to download on www.polyarthrite-andar.com (number of unique visits on the webpage for the last version: 1176). A printed version was also provided directly to patients by rheumatologists. To provide up-to-date information, the brochure was updated 7 times between the first edition in January 2021 and the last version in August 2021. This last version included 49 questions. Each update was announced to all members of the patient organization in its monthly newsletter (number of newsletter’s subscribers: 1863; number of followers: Facebook=2632; Twitter=1382; Instagram=921; LinkedIn=590; Youtube=2907). The “MediCal” newsletter (number of newsletter’s subscribers: 1863; number of followers: Facebook=2632; Twitter=1382; Instagram=921; LinkedIn=590; Youtube=2907). The “Medical and scientific questions” section provided reliable and expert-reviewed information about the virus, protective measures, testing, vaccination, integrating RA specificities and medical, scientific and daily life questions. This initiative is consistent with patient-centered COVID-19 response.

Conclusion: This initiative demonstrates the benefits that can be achieved by greater collaboration between patients and healthcare professionals to address population health problems. The patient could be an active contributor in improving disease management of his peers. This patient education tool is a good example of the relevance of the motto of ‘nothing about us, without us’. The
OP0305-4 PARE 1 THE EMERGING EULAR NETWORK (EMEUNET) PEER-REVIEW MENTORING PROGRAM: TEN YEARS OF INNOVATIVE INITIATIVE.

Background: In 2012, the Emerging EULAR (European Alliance of Associations for Rheumatology) Network (EMEUNET) started a mentoring program in collaboration with the editorial board of top-leading journals in rheumatology, the Annals of the Rheumatic Diseases (ARD) and a few years later RMD Open, with the aim of improving peer reviewing skills of young researchers (mentees). In this program, now in its 6th edition, senior reviewers (mentors) critically discuss manuscripts submitted to ARD or RMD Open with mentees. At the end of the program, senior reviewers certify the capability of mentees to independently conduct a good quality review. The program is organized by members of the EMEUNET Peer Mentoring Subcommittee, including facilitating communication within the groups. Several strategies, such as face-to-face meetings and periodic videoconferences, were implemented recently, following the outcome of a previous survey among mentees.

Objectives: To assess the experienced benefits and challenges of the EMEUNET Peer Mentoring program of young rheumatologists and researchers and their mentors.

Methods: In November 2021, a survey was sent by email to mentors and mentees who successfully completed the first five editions of the program (launched between 2012 and 2019), asking for demographics, and potential benefits and challenges of the program. Felt change in peer-review skills before and after the program were rated on a scale from 0 (no skill) to 10 (perfect skill). Results were analysed descriptively.

Results: A response rate of 55% for mentors (11/20) and 43% for mentees (37/87) was obtained. Mentors had a mean(SD) age of 52(9.5) years, 64% were male and 7 different nationalities were included. Mentees had a mean age of 34(3.7), 43% were male and 16 nationalities were included. Mentees/mentors from all the editions were included, although recent editions were somewhat overrepresented. Almost all respondents said their overall experience with the program was positive (46/47), that the objectives of the peer-reviewing mentoring program were met (46/47) and that they would recommend the program to others (44/45).

Mentors indicated an initial average peer-review skill level of 5.2(1.8) for content and 4.2(1.9) for form, which improved by 2.7(1.3) points, respectively. Interestingly, improvement scores of the mentees paralleled those of mentors: content and form were initially rated at 4.9(1.7) and 5.1(1.8) and improved by 2.6(1.3) and 2.7(1.7), respectively. Nine out of ten mentors said the program had helped them improve their own skills (i.e., peer-reviewing, mentoring, and teaching). The number of peer reviews after completion of the program varied quite significantly between mentees (median 10, IQR 9.5-29). For most mentees, the number of peer-reviews stayed the same (18/32) or increased (12/32). Fifteen out of 32 respondents said they were invited as an independent reviewer for ARD and/or RMD Open after completion of the program. Potential benefits and challenges of the program are depicted in Figure 1. Added value mentioned by both mentors and mentees was the opportunity to contribute to high quality peer-review standards and improve their skills. Challenges reported by mentors were communication with mentees, short deadlines, and the program being time-consuming; challenges for mentees were the communication with their mentor, deadlines and insufficient clarity of the process.

How to review a manuscript

Figure 1. Rating of potential benefits and downsides of the program. X-axis: items of the survey; Y-axis: the number of respondents (10/11 mentors and 35/37 mentees).

Conclusion: After 5 editions over 10 years, the EMEUNET Peer-Review Mentoring Program continues to be a highly valued opportunity in the field of rheumatic diseases, as both mentors and mentees experience a significant impact on their skills. Areas for improvement were identified (e.g., communication, deadlines) and will be addressed in future editions.
Interstitial lung disease in RMDs.

## IMPACT OF INFLAMMATION ON INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS - AN ANALYSIS OF THE GERMAN BIOLOGICS REGISTER RABBIT

### Background
Ten percent of patients with prevalent rheumatoid arthritis (RA) develop an interstitial lung disease (ILD), which is associated with higher mortality (1). A previous study identified high/moderate disease activity, but not CRP, as a risk factor for RA-ILD (2).

### Objectives
To analyse whether systemic inflammation (CRP and ESR) and/or disease activity measured with a composite score (DAS28-ESR) are associated with the occurrence of ILD in patients with RA.

### Methods
Data from RA patients observed in the biologics register RABBIT until 10/2020 were included. Patients with incident ILD were selected as cases and matched 1:5 to controls using a modified risk-set sampling (controls had no ILD during the entire observation time). Matching criteria were age, sex, RA duration, date of enrolment and observation time. Odds ratios (OR) and 95% confidence intervals (CI) were computed by conditional logistic regression and adjusted for factors identified by a directed acyclic graph (DAG), namely smoking, rheumatoid factor (RF), chronic obstructive pulmonary disease, number of biologics until index date (date of ILD-diagnosis in cases, date after the respective observation time in controls) and mean glucocorticoid dosage (12 months prior index date). For the regression, CRP and ESR were log-transformed due to their skewed distribution, and missing values were addressed by multiple imputations (n=10).

### Results
Out of 19,148 RA patients enrolled since 2001, 133 patients with incident ILD were identified. Half of the ILDs were diagnosed by computed tomography (n=67), 8% by x-ray (n=10) and in 42% the method was unknown (n=56). At baseline, cases and controls had a mean age of 61 years, 68% were female, and mean RA disease duration was 9 years. Differences were observed in smoking status (59% ever smokers in cases vs. 48% in controls), RF positivity (84% vs. 72%) and the sum of comorbidities (means 3.1 vs. 2.3). During the 12 months prior to the index date, mean values of CRP and especially ESR were significantly higher in cases compared to controls. This difference was not observed for DAS28 (Figure 1, upper figures). Furthermore, more cases than controls were in a high inflammatory status, but not in at least moderate disease activity (Figure 1, lower figures). The adjusted regression analyses confirmed these results: CRP and ESR were significantly associated with incident ILD both at the time of diagnosis and in the 12 previous months, and results were even more pronounced with elevated CRP and ESR, which was not the case for DAS28 (Table 1).

### Conclusion
In contrast to other data, our analyses found that markers of systemic inflammation, but not the DAS28 composite score, are associated with the occurrence of incident ILD in patients with RA and can be predictors for the development of RA-ILD. Therefore, in a treat-to-target approach, rheumatologists should pay particular attention to controlling systemic inflammation.

### Acknowledgements
We would like to thank all mentors, EMEUNET and working group members that helped shaping the EMEUNET peer-reviewing program throughout the years, and the ARD and RMD Open journals for their kind and generous support.

### Table 1. Results of the conditional logistic regression for the risk of ILD.
Results: In unadjusted analyses eight ACPA reactivities were found associated with PF development (p<0.05-0.001). The number of ACPA reactivities was related to PF development, both in crude and adjusted models (p<0.05 for both). In models concomitantly adjusted for the three SNPs (rs35705895, rs111521887 and rs2609255) respectively, in addition to mentioned adjustments the number of ACPA reactivities (p<0.05 for all three nmodels), Vim60-75 (p<0.05, in all three models), Fjb162–78 (72) (p<0.001-p<0.05) and F4-CIT-R (p<0.01-p<0.05) were all found significantly associated to PF development irrespective of the SNPs.

Conclusion: The development of PF in an inception cohort of RA patients was associated both with risk genes and, independently of the risk genes, the presence of certain ACPA, and the number of ACPA reactivities.

OP0308-HPR MORE THAN HALF OF RA PATIENTS WITH A LIFETIME HISTORY OF MOOD DISORDERS WERE ANXIOUS AND DEPRESSED DURING THE COVID-19 PANDEMIC: RESULTS FROM THE CANADIAN EARLY COHORT (CATCH) STUDY

S. J. Bartlett, O. Schiel, M. F. Valois, G. Boire, G. Hazlewood, C. Thorne, D. Tin, C. Hitchon, J. Pope, E. Keystone, L. Bessette, V. Bykerk on behalf of the CATCH Investigators. McGill University & McGill University Health Centre, Medicine, Montreal, Canada; McGill University Medicine, Montreal, Canada; University of Sherbrooke, Rheumatology, Sherbrooke, Canada; University of Calgary, Rheumatology, Calgary, Canada; CARE, Rheumatology, Newmarket, Canada; University of Manitoba, Rheumatology, Winnipeg, Canada; Western University, Rheumatology, London, Canada; RheumKey, Rheumatology, Toronto, Canada; Laval University, Rheumatology, Quebec City, Canada; Hospital for Special Surgery, Rheumatology, New York; United States of America

Background: A growing number of studies indicate the considerable mental health impacts of the prolonged COVID-19 pandemic in the general population as chronic stress is a risk factor for the development of depression and anxiety. Mood disorders are more prevalent in RA and a history of anxiety or depressive disorders increases the risk of recurrence in the future.

Objectives: To compare trends in prevalence of anxiety and depressive symptoms, prior to and during the COVID-19 pandemic in RA patients with and without a lifetime history of mood disorders.

Methods: Data were from RA patients diagnosed and treated for RA in rheumatology clinics across Canada enrolled in the Canadian Early Arthritis Cohort (CATCH) Study. We estimated monthly trends in prevalence of clinically significant levels of anxiety and depression (PROMIS Depression and Anxiety 4a score 55+) from all visits between Mar 2019 and Jan 2022 and compared monthly trends in anxiety and depression in the year prior to (Mar 2019- Feb 2020) and during the pandemic (Mar 2020 to Jan 2022) stratified by lifetime history of mood disorders.

Results: 4,148 visits were completed from Mar 2019 to Jan 2022 in 1,644 RA patients with a mean (SD) age of 60 (14) and disease duration of 6 (4) years. 73% were women, 84% white, 60% had completed some post-secondary education, and 77% were in CDAI REM/LDA at the visit closest to the start of pandemic. 253 (15%) reported a lifetime history of depression and 217 (13%) a lifetime history of anxiety; 8% reported prior treatment for either.

Patients with a history of mood disorders had higher levels of depression and anxiety prior to and during the pandemic compared with patients without a history of mood disorders (Table 1). Proportions were highest during COVID waves in all and were substantially higher and more variable in people with a previous history of mood disorders as compared to those without a history (Figure 1). While depressive symptoms peaked early in the pandemic, anxiety increased with each wave, peaking in Wave 3 (May-Jun 2021).

Figure 1. During the first 22 months of the COVID-19 pandemic, the proportion of patients with depression and anxiety increased in all groups. More than half of those with a history of emotional distress had clinically significant levels of depression and anxiety; proportions were highest during COVID waves in all and were substantially higher in people with previous history as compared to those without a history (see Figure 1). Whereas depressive symptoms peaked early in the pandemic, anxiety increased with each wave, peaking in Wave 3 (May-Jun 2021).

Conclusion: Symptoms of anxiety and depression were common in Canadian adults with RA prior to and after the onset of the COVID-19 pandemic. Whereas others have found that high levels of depression and anxiety occurred early in the pandemic but declined fairly rapidly in the general population, emotional distress was not attenuated over time in this large cohort of RA patients. Individuals reporting lifetime history of mood disorders were more than twice as likely to report anxiety and depression, with depression peaking early in the pandemic and anxiety growing with each successive wave in the first year. The results demonstrate the importance of applying a lifetime perspective as previous episodes of anxiety and depression may be an important marker of increased vulnerability and recurrence in RA patients, particularly during the pandemic.

New lessons for rheumatology in genomics medicine.

OP0309 WES ANALYSIS OF RARE FAMILIES POINTS TO A PATHOGENIC ROLE FOR THE CGAS/STING-TYPE I IFN AXIS IN SSC

P. Maus, V. Smith, T. Du Four, M. Vanhuyse, B. Lauwers, N. Limaye, De Duve Institute, UCLouvain, Genetics of Autoimmune Diseases & Cancer (GEDI), Brussels, Belgium; Ghent University Hospital, Department of...
Rheumatology, Ghent, Belgium; 2Cliniques Universitaires Saint-Luc, UCLouvain, Rheumatology Department, Brussels, Belgium; 3Grand Hôpital De Charleroi, Rheumatology Department, Charleroi, Belgium. 4Institute of Experimental and Clinical Research, UCLouvain, Rheumatology Pole, Brussels, Belgium

Background: Systemic sclerosis (SSc) is a rare (prevalence ±20/100,000), chronic condition characterized by vascular, immunological and connective tissue abnormalities. Genetic factors contribute to disease, as evidenced by a 15-fold increased relative risk in relatives of patients. Case-control studies have identified numerous associated loci; the identification and functional validation of risk alleles has however been elusive. No monogenic or oligogenic causes of SSc have been demonstrated, likely due to the infrequency of familial clustering (≤1.6% of cases) in this disease. We are fortunate to have access to DNA samples from five such families, with two affected first-degree relatives each. To our knowledge the only series of its kind.

Objectives: The goal of our research is to identify and functionally validate genes that drive SSc pathogenesis in these families, thereby shedding light on fundamental disease mechanisms. In light of the apparent lack of a multi-gene-phenotypic effect, we hypothesize that SSc may be transmitted as a di/oligogenic trait in these families, with two-to-a-few genes acting together to cause disease.

Methods: Whole exome sequencing (WES) was performed on all available blood-DNA (Figure 1). We filtered for variants that are (a) shared by both affected individuals within each family, (b) absent-to-rare in the general population, and (c) predicted to affect protein function by multiple in silico tools. Candidate gene prioritization and pathway analysis is followed by in vitro testing of a subset of SSc-variants, to assess for their effects on protein function. Where two strong candidate genes are identified in the same family, in vitro validation of both variants will be followed by the generation of single- vs. double-knock-in mice, to test for di/oligogenic effects of variant combinations on SSc-related phenotypes.

Results: WES yielded 23-45 genes per family with variants that satisfied the above criteria. Prioritization of candidates was based on systematic annotation of all 180 genes for expression pattern, function, and potential impact of the SSc-variants. Our data suggest familial SSc is genetically heterogeneous, with little sharing of candidates between families. We therefore assessed for pathways represented in gene-lists from multiple families, and found that participants in the cGAS/STING - type II-IFN axis are identified in all (Figure 1). This would prove to be more demanding than we had expected. After the conference, we continued with the introduction of the app to new volunteers as well as sending information and updated instructions to existing app-users. We have found that the introduction of this new app has been quite a success. We now have a platform for easy and fast communication to and between all our volunteers, as well as access to relevant news and important information from the organization about their roles and tasks as volunteers.

Conclusion: We report, for the first time, WES analysis of a familial SSc series of unprecedented size for this rare disease. The identification of potential "driver" gene variants in cGAS/STING-type I IFN signaling regulators across all families points to an important pathogenic role for this pathway in SSc.

Volunteering for the RMD Community

AN APP FOR VOLUNTEERS IN DENMARK

J. Lange 1. The Danish Rheumatism Association, Department of Volunteers, Gentofte, Denmark

Background: The Danish Rheumatism Association wanted to improve its communication with and between its volunteers. We had an existing system that worked like a database of information, but our volunteers found it difficult and lacking the needed information. Furthermore, they wanted to be in closer contact with other volunteers with similar functions in the organization to be able to share ideas and learn from each other.

Objectives: We wanted to find a platform with which we could increase the connectivity between our volunteers across the organization as well as making existing information more accessible for them. We also wanted an easier way of contact to our volunteers that did not require them to use their e-mails.

Methods: First we identified the tasks we wanted our “solution” to solve. Then we decided that the ideal tool for this probably would be an App that supported the connectivity as well as a “database” with documents and instructions in which we could present important and useful information to our volunteers. We searched the marked for platforms and invited three companies to make a presentation on how their product could support our ideas and wishes.

Results: We found, that instructing such a large group of people all at once proved to be more demanding than we had expected. After the conference, we continued with the introduction of the app to new volunteers as well as sending information and updated instructions to existing app-users. We have found that the introduction of this new app has been quite a success.

Conclusion: We found that instructing such a large group of people all at once proved to be more demanding than we had expected. After the conference, we continued with the introduction of the app to new volunteers as well as sending information and updated instructions to existing app-users. We have found that the introduction of this new app has been quite a success.

Background: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A.
Objectives: Assess BKZ efficacy and safety vs PBO in bDMARD-naïve pts with
active PsA to Wk 24 of BE OPTIMAL.
Methods: BE OPTIMAL (NCT03895203) comprises 16 wks double-blind
PBO-controlled and 36 wks treatment-blind. Pts were ≥18 yrs, bDMARD-naïve,
with adult-onset, active PsA, ≥3 tender and ≥3 swollen joints. Pts randomised
3:2:1, subcutaneous BKZ 160 mg Q4W:PBO:adalimumab (ADA; reference arm)
40 mg Q2W. From Wk 16, PBO pts received BKZ 160 mg Q4W. Primary endpoint:
ACR50 at Wk 16.
Results: 821/852 (96.4%) pts completed Wk 16 and 806 (94.6%) Wk 24. Mean age
48.7 yrs, BMI 29.2 kg/m2; since diagnosis: 5.9 yrs; 46.8% male. BL characteristics
comparable across arms. Primary endpoint met (Wk 16 ACR50: 43.9% BKZ vs
10.0% PBO, p<0.001; ADA: 45.7%; Figure 1). All ranked secondary endpoints met
at Wk 16 (Table 1). As early as Wk 2, ACR20 was higher in BKZ vs PBO (27.1%
vs 7.8%, nominal p<0.001; ADA: 33.6%). Outcomes continued to improve at Wk 24

Conclusion: Dual inhibition of IL-17A and IL-17F with BKZ in bDMARD-naïve
pts with active PsA resulted in rapid, clinically relevant improvements in musculoskeletal and skin outcomes vs PBO. No new safety signals observed.1,2

Background: Baricitinib is a JAK1/2 selective inhibitor approved for the treatment of rheumatoid arthritis. Juvenile idiopathic arthritis (JIA) is a group of diseases characterized by immune mediated chronic arthritis which often requires treatment with conventional synthetic or biologic disease-modifying antirheumatic drugs (cs or b-DMARDs).

Methods: This Phase 3 multicenter, double-blind, withdrawal, efficacy, and safety study, enrolled patients (pts) age 2 to <18 years with extended oligo- or poly-articular JIA, ERA, or PsA, per ILAR criteria, and an inadequate response to ≥1 cs and/or b-DMARDs (NCT03773978). There were 3 periods: a 2-week (wk) pharmacokinetic/safety assessment (PKS), a 12-wk open-label lead-in (OLLI), and an up-to 32-wk double-blind withdrawal (DBW). Dosage and safety were confirmed in the PKS and then pts, including those from the PKS, enrolled in the OLLI, receiving age-based, oral, on daily doses of baricitinib. Pts with a JIA-ACR30 response at wk12, end of OLLI, entered the DBW to be randomized 1:1 to continued baricitinib or newly started placebo (PBO) and remained until flare or up to wk32. Primary endpoint was time to flare during the DBW. Secondary endpoints included JIA-ACR30/50/70/90 response rates at wk12, and proportion of pts with a flare during the DBW. Survival curves were estimated using the Kaplan-Meier method.

Results: Of 220 pts enrolled, 29 participated in the PKS, 219 entered the OLLI, and 163 entered the DBW. The JIA-ACR30/50/70/90 response at wk12 was 76.3%/83.5%/46.1%/20.1%, respectively. During the DBW, time of flare was significantly shorter with PBO vs baricitinib (hazard ratio 0.54 [95% CI 0.34, 0.85], p<0.001; Figure 1). The proportion of pts with a flare during the DBW was significantly lower for baricitinib vs PBO (14 (17.1%) vs. 41 (50.6%), p<0.001). In the PKS and OLLI periods, 126 (57.3%) pts reported ≥1 treatment emergent adverse event (TEAE), while 6 (2.7%) reported ≥1 serious adverse event (SAE); Table 1. In the DBW, 38 (46.9%) and 54 (65.9%) pts reported ≥1 TEAE for PBO and baricitinib, respectively, whereas those with ≥1 SAE were 3 (3.7%) and 4 (4.9%). The mean wks of exposure was higher in baricitinib vs PBO (14 (17.1%) vs 41 (50.6%), p<0.001). In the PKS and OLLI periods, 54 (65.9%) pts reported ≥1 SAE. The mean wks of exposure was higher in baricitinib vs PBO (14 (17.1%) vs 41 (50.6%), p<0.001). In the PKS and OLLI periods, 54 (65.9%) pts reported ≥1 SAE. The mean wks of exposure was higher in baricitinib vs PBO (14 (17.1%) vs 41 (50.6%), p<0.001).

Conclusion: Baricitinib significantly reduced time to and frequency of JIA flares in pts with JIA versus PBO, and improved JIA-ACR scores in the majority of pts with JIA versus PBO, and improved JIA-ACR scores in the majority of pts with JIA versus PBO.

Methods: Two single centre, investigator-blinded, RCTs were conducted in patients with RA or Psoriatic arthritis (PsA) on stable doses of MTX without prior COVID-19 (CTRI reg. no. MIVAC: I/ CTRI/2021/07/05468 & MIVAC II: CTRI/2021/07/035007). In MIVAC I, unvaccinated patients were randomised (1:1) to hold or continue MTX for two weeks after each dose of the vaccine. MIVAC II included patients who had continued MTX during the first dose of ChAdOx1 and were randomised (1:1) to hold or continue MTX for 2 weeks after the second vaccine dose. The primary outcome for both the trials was the anti-Receptor Binding Domain (RBD) antibody titres measured four weeks after the second vaccine dose (per protocol analysis). Secondary outcome was the flare rate, defined as an increase in disease activity scores (DAS28/cDAPSA) or physician intent to hike DMARDs.

Results: 250 patients were randomized for MIVAC I and 178 for MIVAC II and after due exclusions, 158 and 157 were eligible for analysis respectively (Fig-1). In MIVAC I, median anti-RBD titres were significantly high in the MTX hold group [2484 (1050-4388.8) versus 1147.5 (433.5-2360.3)], p<0.001 but the flare rate was higher in the hold group (20 (25%) versus 6 (8%) p=0.005) compared to continue group. In MIVAC II median anti-RBD titres were significantly high for the MTX hold group [2553 (1792-4823) versus 990 (356-2252), p=0.001] when compared to continue group but there was no difference in the flare rate between the groups [9 (11.8%) and 4 (7.9%), p=0.15] (Table 1). Both sets were parallel studies in similar population, MTX hold arms across both the trials were compared for anti-RBD titres and flare. There was no difference in the anti-RBD titres [p=0.2] between the groups. In MIVAC I, 29 (36.25%) patients had reported flare in 19 (either first or second dose, 10 for both doses) when compared to MIVAC II where only 9 (11.84%) patients had reported flare after the second dose (P <0.001).

Conclusion: Holding MTX after both the doses or only after the second dose of ChAdOx1 yields higher anti-RBD antibody titres as compared to continuing MTX. Comparing across the trials, holding MTX only after the second dose appears to be non-inferior to holding MTX after both doses of the vaccine with a lesser risk of flare.

Efficacy and Safety of Deucravacitinib, an Oral, Selective, Allosteric Tyk2 Inhibitor, in Patients with Active Systemic Lupus Erythematosus: A Phase 2, Randomized, Double-Blind, Placebo-Controlled Study

E Morand1 2, M Pike3, J T Merrill4, R Van Vollenhoven5, V P Werth6, C Hobar7, N Delev8, V Shah9, B Sharkey10, T Wegman11, I Catlett12, S Banerjee13, S Singhal15, M Monash Health, Department of Rheumatology, Victoria, Australia; 2Monash University, Clinical Sciences, Victoria, Australia; 3MedPharm Consulting, Rheumatology, Raleigh, United States of America; 4Oklahoma Medical Research Foundation, Clinical Projects in the Arthritis & Rheumatology Program, Oklahoma City, United States of America; 5Amsterdam University Medical Centers, Clinical Immunology and Rheumatology, Amsterdam, Netherlands; 6University of Pennsylvania and the Michael J. Crescenz VA Medical Center, Dermatology, Philadelphia, USA; 7Bristol Myers Squibb, Immunology & Fibrosis Development, Princeton, United States of America; 8Bristol Myers Squibb, Rheumatology Clinical Development Team, Princeton, United States of America; 9Bristol Myers Squibb, Innovative Medicine Operations, Princeton, United States of America; 10Bristol Myers Squibb, Global Biometrics and Data Sciences, Princeton, United States of America; 11Bristol Myers Squibb, Clinical Sciences, Princeton, United States of America; 12Bristol Myers Squibb, Dermatology, Princeton, United States of America; 13Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America

Background: Tyrosine kinase 2 (TYK2) mediates signaling of Type I interferons, IL-23, and IL-12, key cytokines involved in lupus pathogenesis. Deucravacinib (DEUC) is an oral, selective, allosteric TYK2 inhibitor with a unique mechanism of action, distinct from Janus kinase (JAK) 1/23 inhibitors, and has shown efficacy in psoriasis and psoriatic arthritis.

Objectives: Assess efficacy and safety of DEUC in patients with active systemic lupus erythematosus (SLE).

Methods: This was a 48-week (wk), randomized, double-blind, placebo (PBO)-controlled, phase 2 trial (NCT03325287). Eligible patients met SLICC criteria, were seropositive (ANA/anti-dsDNA/anti-Sm), and had a SLEDAI-2K score ≥6 and ≥1 BILAG index A or ≥2 BILAG B manifestations from the musculoskeletal, skin, or mucocutaneous domain. Patients on standard background medications were randomized 1:1:1:1 to PBO or DEUC 3 mg BID, 6 mg BID, or 12 mg QD. Oral corticosteroid tapering to 7.5 mg/day was required from wks 8-20; further tapering was optional from wks 32-40. The primary endpoint was the proportion of patients achieving SRI(4) at wk 32. Key secondary endpoints at wk 48 included SRI(4), BICLA, CLASI-50, and change from baseline in active (tender and swollen) joint count.

Results: A total of 363 patients were randomized, with baseline demographic and disease characteristics similar across treatment groups. Of randomized patients, 75% (76%) completed 48 wks of treatment. The primary endpoint at wk 32 was met, with significantly greater proportion of patients in DEUC 3 mg BID and 6 mg BID groups vs PBO achieving SRI(4) responses (PBO: 34.4%; DEUC 3 mg BID: 58.2%; P=0.0006; DEUC 6 mg BID: 49.5%; P=0.021; DEUC 12 mg QD: 44.9%; P=0.076). SRI(4) response was sustained across all DEUC groups up to 48 wks (Figure 1). At wk 48, the DEUC 3 mg BID group demonstrated statistical significance in BICLA, BILDA, CLASI-50, and active joint count, and the two other DEUC groups demonstrated clinically meaningful differences vs PBO (Figure 1). Rates of adverse events (AEs), serious AEs, and AEs of interest were similar between DEUC and PBO groups (Table 1). Most common AEs (≥10%) with DEUC were upper respiratory tract infection, nasopharyngitis, headache, and urinary tract infection. No deaths, major cardiac events, thrombotic events, systemic opportunistic infections, or active tuberculosis occurred. Malignancies were rare with similar rates across all groups. No meaningful abnormalities in mean levels of hematometry and chemistry laboratory parameters were observed.

*In is the number of patients who experienced an event. †Includes (≥8.6% in any arm) acne, rash, dermatitis acrocinematous, pruritus, skin lesion; urticaria. ‡Includes herpes zoster, herpes ophthalmicus, genital herpes zoster. ††Breast cancer, breast cancer, breast cancer, breast cancer, breast cancer. AE, adverse event; COVID-19, coronavirus disease 2019; DEUC, deucravacitinib; MACE, major adverse cardiac events; SAE, serious adverse event.

Conclusion: In patients with active SLE, DEUC showed statistically significant and sustained clinical efficacy in SRI(4), improvement across multiple composite and organ-specific measures up to 48 wks, and was well tolerated. DEUC shows promise as a novel therapy for SLE and warrants further investigation in phase 3 trials.

Note: All evaluable patients at week 12 efficacy data were included in the efficacy analysis.
achieving clinical remission vs the comparator arm (16.7% vs 29.3%; HR 0.56; 95% CI 0.38–0.90; P=0.0158). The comparator arm required more additional GCs vs the SAR arm, mainly due to PMR flare (median difference in actual and expected cumulative dose 199.5 mg vs 0.0 mg; P=0.0189). The cumulative GC toxicity index scores numerically favored SAR but the difference was not statistically significant. PMR activity scores improved in the SAR arm vs the comparator arm (LS mean -15.57 vs 10.27, nominal P=0.0002). Patient reported outcomes (eg, physical and mental health component scores, disability index, etc) favored SAR (Figure 1). Incidence of treatment-emergent AEs (TEAEs) was numerically higher in the SAR arm vs the comparator arm (94.9% vs 84.5%) and included neutropenia (15.3%) and arthralgia (15.3%) in the SAR arm, and insomnia (15.5%) in the comparator arm. Conversely, the frequency of serious AEs was higher in the comparator arm vs the SAR arm (20.7% vs 13.6%). No deaths were reported.

*SAR n = 54; comparator n= 50.

**Conclusion:** SAR + 14 wk GC taper demonstrated significant efficacy vs the comparator arm in steroid refractory PMR patients, including clinically meaningful improvement in quality of life. Safety was consistent with the known safety profile of SAR.

Challenges in measuring and predicting RMDs

CAN SINGLE IMPUTATION TECHNIQUES FOR BASDAI COMPONENTS RELIABLY CALCULATE THE COMPOSITE SCORE IN AXIAL SPONDYLARTHRITIS PATIENTS?

Background: In axial spondyloarthritis (axSpA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is a key patient-reported outcome. However, one or more of its components may be missing when recorded in clinical practice.

Objectives: To determine whether an individual patient’s BASDAI at a given timepoint can be reliably calculated with different single imputation techniques and to explore the impact of the number of missing components and/or differences between missings of individual components.

Methods: Real-life data from axSpA patients receiving tumour necrosis factor inhibitors (TNFi) from 13 countries in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were utilized [1]. We studied missings in BASDAI component-based on simulations in a complete dataset, where we applied and expanded the approach of Ramiro et al. [2]. Using three different single imputation techniques: possible middle value (i.e. 50) of the component and mean and median of the available components. Differences between the observed (original) and calculated scores were assessed and corrected classification of patients as having BASDAI<40 mm was additionally evaluated. For the setting with one missing component, differences arising between missing one of components 1-4 versus 5-6 were explored. Finally, the performance of imputations in relation to the values of the original score was investigated.

Results: A total of 19,894 axSpA patients with at least one complete BASDAI registration at any timepoint were included. 59,126 complete BASDAI registrations were utilized for the analyses with a mean BASDAI of 38.5 (standard deviation 25.9).

Calculating BASDAI from the available components and imputing with mean or median showed similar levels of agreement (Table 1). When allowing one missing component, >90% had a difference of ≤6.9 mm between the original and calculated scores and >95% were correctly classified as BASDAI<40 (Table 1). However, separate analysis of components 1-4 and 5-6 as a function of the BASDAI score suggested that imputing any one of the first four BASDAI components resulted in a level of agreement <90% for specific BASDAI values while imputing one of the stiffness components 5-6 always reached a level of agreement >90% (Figure 1, upper panels). As expected, it was observed that regardless of the BASDAI component set to missing and the imputation technique used, correct classification of patients as BASDAI<40 was less than 95% for values around the cutoff (Figure 1, lower panels).

Table 1. Level of agreement between the original and calculated BASDAI and correct classification for BASDAI<40 mm

<table>
<thead>
<tr>
<th>Component</th>
<th>Level of agreement with Dif≤6.9 mm (%)</th>
<th>Correct classification for BASDAI&lt;40 mm (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 missing component</td>
<td>Available: 93.9</td>
<td>Value 50: 73.9</td>
</tr>
<tr>
<td>2 missing components</td>
<td>Available: 83.7</td>
<td>Value 50: 40.7</td>
</tr>
<tr>
<td>3 missing components</td>
<td>Available: 71.9</td>
<td>Value 50: 28.1</td>
</tr>
</tbody>
</table>

*The levels of agreement with a difference (Dif) of ≤6.9 mm between the original and calculated scores were based on the half of the smallest detectable change. Agreement of >90% was considered as acceptable. **Correct classification of >95% was considered as acceptable.

Conclusion: BASDAI calculation with available components gave similar results to single imputation of missing components with mean or median. Only when missing one of BASDAI components 5 or 6, single imputation techniques can reliably calculate individual BASDAI scores. However, missing any single component value results in misclassification of patients with original BASDAI scores close to 40.

Background: The rheumatoid arthritis impact of disease score (RAID) is a patient-reported outcome measure to evaluate the impact of rheumatoid arthritis (RA) on patients’ quality of life (1). While an adapted instrument has been developed for psoriatic arthritis (2), there are no comparable instruments for other inflammatory rheumatic diseases. Since the RAID includes generic questions on pain, functional capacity, fatigue, physical and emotional well-being, sleep disturbances and coping, it could be an informative instrument beyond RA.

Objectives: To analyse the performance of the RAID in ankylosing spondylitis (AS), systemic lupus erythematosus (SLE), polymyalgia rheumatica (PMR), primary Sjögren’s syndrome (pSS), idiopathic inflammatory myositis (IIM), and systemic sclerosis (SSc) compared to RA.

Methods: From 2015 to 2019, a total of 12,398 patients reported the RAID in the National Database of the German Collaborative Arthritis Centres. We calculated the age- and sex-adjusted partial correlation (0.3-0.5 weak, 0.5-0.7 moderate, > 0.7 strong correlation) between the RAID score and five other patient- or physician-reported outcomes, namely patient global (PtGl) health status, PtGl disease activity, physician global (PhGl) disease activity, the World Health Organisation Well-Being Index (WHO-5), and the EuroQoL-5 Dimensions (EQ-5D). Furthermore, for each of the diagnoses the mean difference between the RAID and the other outcomes was compared with the respective differences for RA. The EQ-5D and WHO-5 were rescaled to match the scale of the RAID.

Linear regression model: The dependent variable is the difference between RAID score and five respective outcomes. Independent variables were sex, age and diagnosis with RA as the referent category. An effect of a diagnosis was defined as clinically relevant if the mean change of difference was at least one unit.
RAID (range 0-10). General linear regression was used to assess the age- and sex-adjusted effect of each diagnosis on the difference between the RAID and the other scores with RA as the referent diagnosis. We defined the effect of a diagnosis as clinically relevant if the mean change of difference was at least one unit.

Results: The mean RAID score in RA (3.6) was lower than in AS (4.0) and SSc (3.8) and higher than in SLE, PMR, pSS, IIM (Table 1). Across all diagnoses, the RAID correlated strongly with PtGl health status (0.72 to 0.83), moderately to strongly with PtGl disease activity (0.55 to 0.78) and WHO-5 (0.67 to 0.83), moderately with the EQ-5D (0.61 to 0.68), and weakly with PtGl disease activity (0.25 to 0.41). Small mean differences were found between the RAID and either PtGl disease activity (0 to -0.6), PtGl health status (-0.4 to -0.9) or WHO-5 (-0.7 to -1.3). A higher deviation was observed for EQ-5D (1.1 to 1.7) and PtGl disease activity (1.4 to 2.2). However, the discrepancies between the five outcomes and the RAID turned out to be similar across all diagnoses and, more importantly, comparable to RA. Linear regression revealed no clinically relevant effect of any of the diagnoses on the difference between RAID and the other outcomes (Figure 1).

Conclusion: The RAID score performed comparably well across all diagnoses investigated. These findings support the use of the RAID for measuring the impact of disease not only in RA, but also in AS, SLE, PMR, pSS, IIM and SSc.

POS0003 DEVELOPMENT AND VALIDATION OF A DISEASE SPECIFIC PATIENT REPORTED OUTCOME FOR GIANT CELL ARTERITIS

J. Robson1, C. Almeida1, J. Dawson1, A. Dures1, R. Greenwood1, C. Guly2, S. Mackie1,2, A. Bromhead3, S. Stern4, M. Nedosi1, University of the West of England - UWE Bristol, Health and Social Wellbeing, Stoke Gifford, United Kingdom; 1University Hospitals Bristol and Weston NHS Foundation Trust, Bristol Royal Infirmary, Bristol, United Kingdom; 2University of Oxford, Old Road Campus, Department of Public Health, Oxford, United Kingdom; 3University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 4Leeds General Infirmary, Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Giant cell arteritis (GCA) is caused by inflammation of the blood vessels of the head and neck; patients can present with cranial, ocular or large vessel vasculitis involvement. Treatment is with glucocorticoids, steroid sparing agents and biologics to control inflammation and protect sight.

Objectives: The aim of this study was to produce a validated disease specific PROM for patients with GCA, to capture the impact of GCA and its treatment on health-related quality of life.

Methods: Patients with clinician-confirmed GCA from the UK, either diagnosed in the last three years or with a flare in the last year, were included in the survey. A long form of 40 candidate GCA-Specific Items, each with a 5-point Likert scale, had previously been developed, based on a qualitative study with patients from the UK and Australia [1]. In this cross-sectional survey, patients completed the 40-item draft GCA-PROM alongside EQ5D-5L, CAT-PROS and self-report of GCA disease activity. Rasch and factor analysis were used in an iterative manner to determine the underlying construct validity of the new PROM. Items were fitted to the Rasch model to determine its construct validity, reliability, unidimensionality and statistical sufficiency of the total score from the scale. Factor analysis was used to establish certainty structure. Item reduction decisions were based on clinical importance, lack of fit to the Rasch model, and redundancy detected during principal component analysis. External validity was tested by comparing the scores of the newly validated GCA-PROM (i) in participants who self-identify as having active disease versus patients in remission (known groups validity) (ii) with scores derived from EQ5D-5L and CAT-PROS (convergent validity).

Results: The survey included 428 patients; 327 (76%) cranial GCA, 114 (26.6%) temporal artery ultrasounds, and 51 (11.9%) Positron Emission Tomography and Computed Tomography (PET-CTs) were reported as positive. 108 (25%) received second-line immunosuppressants, and 34 (7.9%) anti-IL-6 therapy. Active disease was reported in 197 (46%). Four factors (domains) were identified after deletion of 10 redundant items: Acute symptoms (8 items), Activities of daily living (7 items), Psychological (7 items) and Participation (8 items). The four domains were analysed as ‘super-items’ and shown to fit the Rasch model. The overall scale had an adequate fit to the Rasch model: $X^2 = 25.219$, DF=24, p=0.394 including reliability PSI=0.828. The raw-to-linear transformation scale was calibrated to enable parametric analyses if desired. Each domain was shown to have known-groups validity (p<0.001 patients reporting active versus inactive disease) and correlation with EQ5D-5L and CAT-PROS (Rs) ranging between 0.42 and 0.778.

Conclusion: The GCA-PROM is a new patient reported outcome measure for patients with GCA which demonstrates good internal and external validity.

POS0004 WHAT DOES WORSENING IN DAPSA DISEASE ACTIVITY MEAN FOR PATIENTS WITH PSORIATIC ARTHRITIS? AN ANALYSIS OF 222 PATIENTS

M. Souca1, J. S. Smolen1, C. Gorlier1, M. de Wit1, L. Coates1, U. Kalyoncu1, A. Ryusse-Witrand1, K. Leung1, R. Scrivo1, J. D. da Cañete1, P. Palominos1, S. Meisalu1, A. Balanescu1, U. Kiltz1, S. Aydin1, I. Gaydukova1, E. Demis1, B. Fautrel1, A. M. Orbai1, E. Lubrano1, L. Gosses1 on behalf of the ReFlap Study Group. Paris, ReFlap Study Group, Paris, France
Background: In psoriatic arthritis (PsA), disease activity states have been defined using the DAPSA (Disease Activity index for Psoriatic Arthritis) score (1). The disease activity states have been validated using structural progression as the gold standard (2). However, the worsening in DAPSA states has not been compared to the patient’s perspective.

Objectives: To assess the association between a worsening in disease activity (i.e., change in DAPSA disease activity category) versus the patient’s judgement of disease worsening.

Methods: ReFlap (NCT03119805) was a longitudinal study in 14 countries of consecutive adult patients with definite PsA and more than 2 years of disease duration. Patients were seen twice in the context of usual care, around 4 months apart (3). Worsening in disease activity between the 2 visits was defined as a transition to a more active disease category, based on the DAPSA categories ([remission, low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA)] (1). This change was compared to (a) patient perceived-flares collected according to a patient-reported question: “At this time, are you having a flare of your psoriatic arthritis, if this means the symptoms are worse than usual?”; and (b) a worsening according to the MCID (Minimal Clinical Important Difference) question. The agreement between the definitions of worsening were calculated by frequency, Cohen’s kappa and prevalence adjusted bias adjusted kappa (PABAK). There was no imputation of missing data.

Results: Overall, 222 patients were analyzed: 127 (58.8%) were male, aged 53.5±12.3 years and with 10.8±8.3 years of disease duration. Disease activity was moderate: 35.9% had no current psoriasis skin lesions, mean tender joint count (TJC, 0-68) was 3.0±7.5, mean swollen joint count (SJC, 0-66) was 1.6±6.6, and mean DAPSA was 11.5±14.0. At 4.5±2.2 months follow-up, the proportion of DAPSA worsening was 40.1% [95% confidence interval, 33.9-46.7] (n=89). Most of the changes corresponded to patients going from remission to LDA (N=24, 27.0% of worsened patients) or from LDA to MDA (N=24, 27.0%).

Patient-reported flares were reported in 27.0% [21.6-33.2] (n=60), and MCID worsening was reported in 14.0% [33.9-46.5] (n=31). Figure 1 shows the distribution of patients with worsening in DAPSA category versus patient-defined worsening. Of the 89 patients who worsened according to DAPSA categories, 41 (46.1%) had self-perceived flares and 20 (22.5%) had worsening according to MCID. Among patients who worsened in DAPSA category, the mean change in DAPSA was higher in patients with self-perceived flares (increase of 14.3±12.3) compared with either patient flare or MCID worsening were 0.34 [0.21-0.46] (0.40) and 0.16 [0.05-0.27] (0.28), respectively.

Conclusion: After 4 months of follow-up, 40.1% patients with long-standing PsA had a change in DAPSA category corresponding to more active disease. Most of these changes reflected transitions from remission to LDA, or from LDA to MDA. Among patients changing DAPSA category, only 46.1% reported themselves in flare at the second visit and only 22.5% reported themselves as worsened by MCID, leading to only fair (for flares) to low (for MCID worsening) agreement between the assessments of worsening. It is important to assess both disease activity, and the patient’s perspective of flare.

POS0055

BASELINE BIOMARKERS PREDICT BETTER RESPONSES TO DEUCRAVACITINIB, AN ORAL, SELECTIVE TYROSINE KINASE 2 (TYK2) INHIBITOR, IN A PHASE 2 TRIAL IN PSORIATIC ARTHRITIS

O. Fitzgerald1, D. D. Gladman2, P. J. Mease3, J. S. Smolen4, L. Gao5, S. Hu5, M. Nowak6, S. Banerjee7, I. Catlett8, 9Conway Institute, University College Dublin (UCD), Rheumatology, Dublin, Ireland; 2University of Toronto, Rheumatology, Toronto, Canada; 3Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; 4University of Rochester Medical Center, Allergy Immunology, and Rheumatology, Rochester, United States of America; 5Medical University of Vienna, Rheumatology, Wien, Austria; 6Bristol Myers Squibb, Immunoscience and Small Molecule, Princeton, United States of America; 7Bristol Myers Squibb, Bioinformatics, Princeton, United States of America; 8Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; 9Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America; 10Bristol Myers Squibb, Dermatology, Princeton, United States of America

Background: Deucravacitinib (DEUC) is a novel, oral, selective TYK2 inhibitor with a unique allosteric mechanism of action that has demonstrated efficacy in patients with psoriasis (PsO) (1) and psoriatic arthritis (PsA). TYK2 mediates signalling of select immune cytokones, eg, interleukin (IL) 23, IL-12, and Type I interferons, whereas the related Janus kinases (JAK) 1/2/3 mediate signalling of a wider array of cytokones and mediators involved in inflammatory, developmen- tal, metabolic, and hematopoietic pathways. DEUC reduced inflammatory markers associated with skin and joint manifestations but did not result in laboratory abnormalities associated with injection of JAK1/2/3 in a PsA trial. (2)

Objectives: To identify baseline biomarkers that predict response to DEUC in patients with PsA.

Methods: The double-blind Phase 2 trial (NCT03881059) enrolled 203 patients with PsA randomised 1:1:1 to placebo (PBO), DEUC 6 mg once daily (QD), or 12 mg QD. Molecular profiling of baseline serum samples was performed by immunocassays, Clinical response at Week 16 was measured by ≥20% improvement from baseline in American College of Rheumatology Improvement Criteria (ACR) 20 and ≥75% improvement from baseline in Psoriasis Area and Severity Index (PASI) 75 scores.

Results: Biomarkers of the IL-23/T helper cell type 17 pathway, including IL-17A, IL-17–induced β-defensin 2 (BD2), and IL-19, were associated with higher PASI 75 responder group. When patients were dichotomised by median baseline biomarker level, higher clinical responses in both PASI 75 and ACR 20 were achieved in those with higher baseline overall biomarker levels in the DEUC-treated groups compared with the PBO group. Baseline expression of IL-23 biomarkers IL-17A, IL-19, and BD2 enriched ACR 20 response in patients treated with DEUC compared with PBO (OR=5.64, 6.68, and 4.99, respectively). While greater benef- it was observed in high-biomarker groups, the low-biomarker populations still manifested clinical responses although not significant (Figure 1).

Conclusion: Patients who had higher expression of IL-23 pathway biomarkers were more likely to benefit from DEUC compared with placebo in skin and joint manifestations of PsA. These results reinforce the value of TYK2 inhibition in patients with IL-23–mediated diseases. The potential value of IL-23-pathway markers in predicting higher responses to DEUC should be further explored in larger trials.

K. Brun1, K. K. Jørgensen3, N. Bolstad6, S. W. Syversen1.

Background: Ankylosing spondylitis (AS), psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE) are distinct diseases with common molecular features such as an imbalance in fibrosis and fibrolysis and calciﬁed tissues. Type III, IV and VI collagens are abundant in connective tissue, and type I, II and X of the skeletal tissue. Blood biomarkers are available to measure ﬁbrolysis (C1M, C2M, C3M, C4M, C6M, C10C) and ﬁbrosis (PRO-C1, PRO-C2, PRO-C3, PRO-C4, PRO-C6) of these collagens.

Objectives: To proﬁle AS, PsA and SLE patients (pts) using blood biomarkers of collagen formation and degradation.

Methods: Baseline serum samples from consenting pts of the AS (NCT02437162/ NCT02438787), PsA (NCT0315828), and SLE (NCT02349061) studies were included in the analyses. Healthy donor samples were acquired from Discovery LS. Biomarkers were measured by immunoassays. Biomarker levels were compared by Kruskal-Wallis test. Before hierarchical clustering (Ward.D2), biomarker levels were log-transformed and standardized by median centering and scaling by median absolute deviation (MAD).

Results: When compared with healthy individuals, VICM was elevated in all indications (although markedly less so in SLE pts). The ﬁbrolysis marker PRO-C3 was elevated in all indications vs. healthy, while PRO-C4 and PRO-C6 were elevated only in AS and PsA. The ﬁbrolysis markers C3M, C4M and C6M were elevated in all indications. The cartilage ﬁbrolysis marker PRO-C2, but not C2M, was elevated in AS and PsA, but not in SLE, ps. The bone ﬁbrolysis marker PRO-C1 was at the level of healthy for all. The ﬁbrolysis marker C1M was elevated in all, while elevated C10C was seen only in PsA and SLE, pts (Table 1). Four clusters (C) of blood markers were extracted (Figure 1). C1 was characterized by low biomarker levels (68% of healthy, 1% of PsA, 3% of SLE pts). C2 was described by high levels of C10C and median levels of VICM (20% of healthy, 12% of AS, 19% of PsA, 42% of SLE pts). C3 was described by median biomarker levels (8% of healthy, 67% of AS, 48% of PsA, 46% of SLE pts). C4 had high biomarker levels (4% of healthy, 21% of AS, 31% of PsA, 9% of SLE pts).

Conclusion: Fibrosis and ﬁbrolysis blood biomarkers were signiﬁcantly elevated in AS, PsA and SLE pts. Subsets of pts from each indication were found in clusters with either low (C1/2), median (C3) or high (C4) levels of ﬁbrolysis/ﬁbrosis biomarkers. These ﬁndings may provide a ﬁrst step towards precision medicine for guiding the use of anti-inﬂammatory vs. anti-ﬁbrotic treatments in pts with rheumatological disorders.

Fig. Radar plot showing medians of standardized biomarker levels by cluster.

Table. Patient group description and ﬁbrolysis/ﬁbrosis biomarkers (ng/ml) in healthy and AS, PsA or SLE pts.

Background: Immunogenicity is a leading cause of treatment failure to TNF inhibitors, and also affects drug safety. Variations in HLA class II genes have been suggested to predispose to anti-drug antibody formation (ADA), but characterization of biologically relevant HLA haplotypes, based on high-resolution genotyping, is lacking.

Objectives: To assess associations between HLA loci and formation of ADA to infliximab across different immune mediated inflammatory diseases.

Methods: Patients with immune mediated inflammatory diseases on infliximab therapy (N=612; 181 spondyloarthritis, 120 rheumatoid arthritis, 72 psoriatic arthritis, 114 ulcerative colitis, 80 Crohn’s disease and 45 psoriasis) participating in the Norwegian Drug Monitoring (NOR-DRUM) trials (1, 2), were included in the present analyses. Neutralising ADA were assessed with an automated fluorescence assay at each infusion. Next generation sequencing-based HLA typing was performed. Associations with ADA formation were assessed at locus, allele, haplotype and amino acid level. Peptide binding predictions for infliximab were performed.

Results: ADA were detected in 147 patients (24%). Significant associations were shown between ADA and several HLA loci, whereas conditional analyses indicated HLA-DQB1 (p=1.4x10−6) as the primary risk locus. Highest risk of ADA formation was seen for patients carrying at least one of the HLA-DQ2 haplotypes; DQB1*02:01–DQA1*05:01 and DQB1*02:02–DQA1*02:01 (OR 3.18, 95% CI 2.15 to 4.69, p=5.9x10−9) (Figure 1). These findings were consistent across different diagnoses (Table 1), and remained significant when adjusting for other possible predictors of ADA. Computational predictions indicated that both these HLA-DQ2 haplotypes could strongly bind two peptide motifs (INTVESEDI and VYACE-)

Figure: Kaplan-Meier survival curve of time to ADA formation (median) for the significant HLA-DQB1*02:01-DQA1*05:01 carriers and HLA-DQB1*02:02-DQA1*02:01 carriers.

Conclusion: The risk of ADA to infliximab was three-fold higher in patients carrying the HLA-DQ2 risk haplotypes across diseases. A biological role for the HLA-DQ2 molecules encoded by the two different HLA-DQ2 risk haplotypes in the formation of ADA was further supported by peptide binding predictions. These novel findings provide promise for future incorporation of HLA-DQ2 testing to facilitate personalized treatment decisions.

POS0008 THE UTILITY OF TRANS-BRONCHIAL LUNG BIOPSIES TO GUIDE THE TREATMENT IN PATIENTS WITH RHEUMATIC INFLAMMATORY DISEASES: A RETROSPECTIVE CROSS-SECTIONAL STUDY

M. Andersen1, T. K. Lund2, T. H. L. Jensen2, M. Iverson2, M. Perch2, B. Baslund2
1Copenhagen University Hospital Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; 2Copenhagen University Hospital, Rigshospitalet, Department of Cardiology, Section for Lung Transplantation and Respiratory Medicine, Copenhagen, Denmark; 3Copenhagen University Hospital, Rigshospitalet, Department of Pathology, Kobenhavn Ø, Denmark

Background: Rheumatic inflammatory disease associated interstitial lung disease (R-ILD) is associated with significant mortality and morbidity. On a patient level, imaging which is a cornerstone in diagnosing R-ILD may not be sufficient to determine the underlying cause of the imaging pathology or the degree of reversibility. Furthermore the preconce of comorbidity and differential diagnoses such as infections or malignancy needs to be taken into account when determining the therapeutic strategy. The role of transbronchial lung biopsies (TBB) in the diagnostic workup of R-ILD is unclear and TBB is not generally recommended.

Objectives: The study objective was to examine the utility of TBB to guide treatment in a population of patients with R-ILD referred for bronchoscopy.

Methods: All patients from the Department of Rheumatology, Rigshospitalet, Copenhagen, Denmark referred for a TBB on the suspicion of R-ILD, from 2002 to 2016 were identified. Patient demographics as well as smoking status, previous lung disease, pulmonary function test, CTD-diagnosis, imaging results and immunomodulatory therapy pre- and post-bronchoscopy were obtained.

Histology findings were used to dichotomize patients into high inflammatory group or low inflammatory group. The high inflammation group primarily consisted of non-specific interstitial pneumonia (NSIP), organizing pneumonia (OP), lymphocytic infiltrating pneumonia (LIP) and granulomatous inflammation whereas the low inflammation group primarily consisted of histological findings of usual interstitial pneumonitis (UIP) and biopsies describing fibrosis and/or sparse unspecific inflammation. Therapeutic consequence was defined as intensification of therapy. Differences in treatment intensification were calculated using a binominal logistic regression model. Differences in treatment intensification were calculated using a binominal logistic regression model adjusted for age, gender, smoking status, previous lung disease, diffusion capacity, rheumatologic diagnosis, c-reactive protein level prior to TBB. Covariates with P>0.1 were excluded by a stepwise ‘backwards’ elimination.

Results: 96 patients had TBB performed. Biopsies from 55 patients were categorized as high-inflammatory and 41 as low-inflammatory, respectively. In the high inflammatory group thirty-eight (69%) had their therapy intensified compared to 6 (14%) in the low-inflammatory group (P <0.01). TBB inflammation type was the only covariate that was significantly associated with treatment intensification.

No procedure related complications were registered.

Conclusion: TBB findings can guide treatment strategy in R-ILD patients with suspected activity in the pulmonary disease. TBB appears safe and could be a useful part of the workup in patients with inflammatory rheumatic diseases where clinical features, bloodsamples, imaging and/or pulmonary function test do not provide sufficient information to guide the therapeutic strategy.

REFERENCES:
Background: Monitoring disease activity in patients with inflammatory arthritis is essential for effective treatment. While the health assessment questionnaire (HAQ) is commonly used to assess physical function, additional functional tests, such as isometric grip strength and the Moberg Pick-Up-Test (MPUT), provide objective measures for hand function and allow assessing hand function across different diseases (1). It remains unclear to date, if measured hand function is already reflected by the HAQ, as the most widely used patient reported outcome measure of physical function in arthritis.

Objectives: To estimate the proportion of hand function and grip strength variability explained by HAQ, patient-reported hand function, and between-person variation in measured hand function in patients with inflammatory arthritis and non-arthritic controls.

Methods: Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), psoriasis without PsA (PsO) and healthy controls (HC) were investigated. Subject characteristics (age, sex, disease) and HAQ were recorded. Hand function was assessed by vigiometric grip strength, MPUT, and a patient-reported tool (Michigan Hand Questionnaire, MHQ), Mixed pure-random-effect linear regression models were used to estimate the proportion of variance in measured hand function or grip strength explained by subject characteristics (age, hand dominance, sex, reported hand function, disease group).

Results: 298 subjects were tested, 101 with RA (Age: 59.1±13.3 years, BMI: 27.2±6.1 kg/m²), 92 with PsA (Age: 58.8±11.6 years, BMI: 29.8±6.1 kg/m²), 51 with PsO (Age: 47.3±14.1 years, BMI: 29.8±7.3 kg/m²), 52 HC (Age: 54.6±16.5 years, BMI: 25.2±3.3 kg/m²). Overall variation in grip strength is mostly accounted for by sex (59.8%), between-person variation (21.1%) and HAQ (11.3%) (Figure 1A). Overall variation in grip strength is mostly accounted for by sex (59.8%), between-person variation (21.1%) and HAQ (11.3%) (Figure 1B). Over-all variability explained by HAQ, as the most widely used patient reported outcome measure of physical function in arthritis.

Conclusion: While the variance in grip strength is mainly explained by sex and between-person variation for all subject groups, the proportions of explained variance for measured hand function is not similar between diseases. In all groups > 50% of the variation in measured hand function remains unexplained by the variables used. Especially in arthritis patients, HAQ explained less than 25% of the variance in measured hand function. Grip strength can be considered a poor surrogate for hand function in this context due to its large gender dependence. The explainability of MHQ variation largely by HAQ indicates that it has limited potential to provide further information beyond overall functional impairment. In contrast, the large between-person variation in MPUT likely indicates unexplored movement patterns of hand motion that may be further dissected using sensor-based analyses (2) and can help identify movement components a potential for an in-depth assessment of subtle hand-function alterations in inflammatory arthritis.

THE PSORIATIC ARTHRITIS 5-THERMOMETER SCALES (PSA-STS): A NEW INSTRUMENT FOR ASSESSING THE STATUS OF DISEASE ACTIVITY IN PSORIATIC ARTHRITIS

F. Salafi1, M. Carotì2, S. Farah1, M. Di Carlo1. 1Università Politecnica delle Marche, Dipartimento Di Scienze Cliniche e Molecolari, Ospedale “Carlo Urbani”, Jesi, Italy; 1Università Politecnica delle Marche, Dipartimento di Scienze Radiologiche, Ospedali Riuniti, Ancona, Italy

Background: There are a variety of composite disease activity monitoring methods and patient-centered metrics available for psoriatic arthritis (PsA). The Psoriatic Arthritis 5-Thermometer scales (PsA-STS) is a new tool, proposed, with the aim of improving its diagnostic accuracy.

Objectives: The goal of this research was to evaluate data on the measurement qualities of the PsA-STS, a composite measure of disease activity in PsA patients, in a real-world scenario (Figure 1).

Conclusion: While the variance in grip strength is mainly explained by sex and between-person variation for all subject groups, the proportions of explained variance for measured hand function is not similar between diseases. In all groups > 50% of the variation in measured hand function remains unexplained by the variables used. Especially in arthritis patients, HAQ explained less than 25% of the variance in measured hand function. Grip strength can be considered a poor surrogate for hand function in this context due to its large gender dependence. The explainability of MHQ variation largely by HAQ indicates that it has limited potential to provide further information beyond overall functional impairment. In contrast, the large between-person variation in MPUT likely indicates unexplored movement patterns of hand motion that may be further dissected using sensor-based analyses (2) and can help identify movement components a potential for an in-depth assessment of subtle hand-function alterations in inflammatory arthritis.
Methods: A total of 155 PsA patients were enrolled between May 2018 and December 2021. Adult-onset PsA CASPAR criteria were used to classify patients affected by PsA, while ASAS criteria were used to classify patients affected by axial-PsA (axPsA). All patients completed the PsA-STs, a simple instrument with five “thermometers” that incorporate pain, fatigue, physical function, skin disorders, and depression into a single assessment of disease activity. Additional continuous measures of disease activity (e.g., DAPSA, PASDAS, CPDAI) and patient-reported outcomes (PROs) measures of disease health status (e.g., PSAID and SF-36) were analyzed as comparisons. Spearman’s correlations and cross-tabulations were used to examine concurrent validity. Receiver operating characteristic (ROC) curve method was used to assess discriminant validity. As an external criterion, the Minimal Disease Activity (MDA) levels were used.

Results: The 96 female and 59 male patients ranged in age from 20 to 79 years old and had been living with PsA for an average of 8.35±2 years (6 months to 22 years). The PsA-STs’ area under the ROC curve (AUC-ROC) was 0.944. (95% CI 0.895 to 0.974) (Figure 2). The PsA-5Ts had same discriminant validity as the DAPSA, CPDAI, PASDAS, and PSAID, but it was better than the SF-36 (p=0.001). PsA-STs subscales were highly significantly different between the MDA status (all p<0.0001) when categorizing patients into those who rated their condition as reaching MDA (Kruskal-Wallis test). PsA-STs were also shown to have a remarkable (p<0.0001) correlation with known PsA activity measurements.

Conclusion: For the evaluation of disease activity in PsA, PsA-STs is a useful alternative to continuous composite indices and other patient-centered assessments. The PsA-STs make data collection simpler, and they should be used in both clinical studies and everyday clinical treatment. In order to establish the tool’s clinical relevance, longitudinal construct validity, which concerns the measure’s capacity to identify a real change in health status as well as its accuracy in detecting changes of various magnitudes, must be addressed.

Background: Work is an important outcome for people with inflammatory arthritis (IA including PsA, RA, AxSpA) and osteoarthritis (OA). It is known that people with IA and OA are at increased risk of sick leave and have to stop working early due to ill health. In addition to being at increased risk of becoming work disabled and increased absenteeism, high levels of presenteeism (i.e. reduced productivity/ limited ability to work due to ill health whilst at work) have also been reported.

Several instruments exist to measure presenteeism, including single-item global measures and multi-item instruments. In some studies using single-item global instruments may be more feasible. However, available global instruments differ in concept, recall period and reference. It is important to understand which of the measures have good psychometric properties before using them in clinical studies.

Objectives: To assess the psychometric properties of four global presenteeism instruments.

Methods: Patients with IA or OA were recruited via rheumatology outpatient clinics to a large international, longitudinal observational study including 8 European countries and Canada. Participants completed a survey at baseline, 1, 2, 3, 4, 6 and 12 weeks, 2, 3 and 6 months and 3 months. The four global measures of presenteeism included: Work Productivity and Activity Impairment Questionnaire (WPAI), Work Productivity Scale–Rheumatoid Arthritis (WPS-RA), Work Ability Index (WAI) and the Quality/Quantity questionnaire (QQtotal/10) scale. To facilitate score interpretation the WAI and QQtotal were reversed. Pain was measured using an 11-point Likert scale. Spearman correlations were calculated between the presenteeism measures and the Workplace Activity Limitations Scale (WALS), a validated multi-item measure of presenteeism, and HAQ to evaluate construct validity (validity: r <0.50=low; r 0.50-0.70=moderate; r >0.70=high). Test-retest reliability of the 4 presenteeism scales (baseline-1wk) was measured applying ICC in patients with stable disease (i.e. same pain score at baseline and 1wk) (reliability: ICC<0.40=poor; ICC 0.40-0.75=fair to good; ICC >0.75=excellent).

Responsiveness during 3 months was measured comparing patients with improvement in pain score (>1 point improvement in pain score (~MCID pain)) with patients with no change or worsening in pain score. The two groups were compared applying Mann Whitney U test.

Results: This international study included 550 patients with a mean age of 47.8 (SD 9.9) yrs and 61.4% were female. Mean (SD) disease duration since diagnosis was 10.8 (10.4) yrs and 91.2% had IA. Mean (SD) presenteeism scores at baseline were: WPAI=2.9 (2.7), WPS-RA=3.4 (2.7), WAI=2.7 (2.4); and QQtotal=3.1 (3.2). The correlations between the global measures and with WALS and HAQ were moderate to good, except for QQtotal and HAQ which was low (Table 1). In patients with the same stable pain scores at baseline-1wk (n=141) ICC scores were good to excellent, respectively: WPAI (0.771), WPS-RA (0.752), WAI (0.663), and QQtotal (0.650). An improvement in pain during the 3 month study duration was observed in 145/381 (38%) of the patients. In these patients a significant reduction in mean pain during the 3 month study duration was observed

A NEW TNFRSF1A GENE MUTATION IN A TURKISH FAMILY WITH TNF RECEPTOR-ASSOCIATED PERIODIC SYNDROME (TRAPS).

T. S. Özlü1, B. Aslan1, V. Vayzı¹, F. Erbasan1, M. E. Terzioğlu1, 1Akdeniz University, Rheumatology Clinic, Antalya, Turkey

Background: Tumor necrosis factor (TNF) receptor-1 associated periodic syndrome (TRAPS) is a rare autosomal dominant autoinflammatory syndrome caused by pathogenic variants in the tumor necrosis factor receptor 1 (TNFR1) gene (TNF receptor superfamily member 1A, TNFRSF1A). For definitive diagnosis, genetic tests are needed to show variants in the TNFR1 gene (1). Information on genotype-phenotype relationships is limited due to the rarity of the disease.

Objective: This study presents novel R97S mutation in TNFRSF1A gene and relevant clinical findings in a patient with amyloidosis of unknown etiology and his sister.

Methods: Case; Proband 33-year-old male patient presented with swelling in the legs 9 years ago. In his history, he described muscle pain, unilateral eye redness, swelling and discharge, which occurred several times in 2-3 months and lasted for up to 2 weeks. Kidney biopsy was found to be consistent with AA amyloidosis. R97S mutation was found to be heterozygous. Colchicine was started at 2x0.5 mg per day. Despite colchicine treatment in the following years, acute phase reactants remained high, proteinuria continued at nephrotic level (50-60 mg in 24-hour urine), progressive deterioration of kidney functions, end-stage renal failure developed. Gene analysis was performed for other autoinflammatory diseases; R97S (Nucleotide change c.290_310dup heterozygous) mutation was detected in the TNFRSF1A gene.

Sister; 31-year-old female patient was admitted to our clinic after a heterozygous mutation in the TNFRSF1A gene was detected in her brother. In her history, she described muscle pain, edema, redness and discharge around the eyes, which occurred 1-2 times a year and lasted for about 2 weeks, especially triggered by the menstrual cycle. TNF (tumor necrosis factor) receptor-associated periodic syndrome mutation was found to be heterozygous positive R97S.

Father; The father of the first two cases started having sore throat, diarrhea, muscle pain, swelling around the eyes and fever attacks starting from the age of 29. Renal biopsy revealed apple-green birefringence with congo-red stain, which was indicative of amyloidosis. When he was 32 years old, peritonitis, diathesis was started first and then continued with hemodialysis due to end-stage renal disease. Three months after the start of hemodialysis, he died due to high fever, hypotension and septicemia.

Results: In this article, a novel mutation of TRAPS which has not been reported in the literature so far, is presented in a Turkish family. Our country is endemic for FMF disease, a study by Bilge et al. (2) demonstrated that mutation analysis of 9% of all subjects with FMF in our country provided negative results. In our opinion genetic analysis should be performed to detect other autoinflammatory diseases in cases that classical FMF attacks are not seen, as in this case series. These and similar cases followed as FMF are likely to be associated with other autoinflammatory diseases. Diagnosing these rare diseases will provide both appropriate and effective treatment options to patients and a better definition of the clinical feature - mutation relationship.

Disclosure of interests: None declared.
a trial with intravenous immunoglobulin had been initiated inducing clinical stabilization.

We diagnosed Sjögren-like syndrome based on sicca symptoms and a suspicious submandibular salivary gland in sonography, without typical serology. Family history was negative for autoimmune diseases. The clinical findings pointed towards immunosuppression, prompting cytokine examination, lymphocyte phenotyping and genetic testing. Cytokines (IFN\(\gamma\), IL-2, IL-4, IL-10, IL-17) under immunosuppression with 20 mg prednisolone and 2 g of myco-phenolate were all low/below detection threshold. Flow cytometry showed no abnormalities except for a low CD20 (after Rituximab) and a slightly elevated T-reg count. Genetic testing revealed heterozygous variants in exon three (c.354C>G) and eight (c.927C>G) of \(AIRE\). The patient’s mother showed the same genotype - indicating that the variants in the patient are in cis - but is asymptomatic. (Figure 1)

**Conclusion:** To our knowledge this is the first report of a patient with thymoma and genetic variant(s) in the \(AIRE\) gene displaying several autoimmune diseases. Although clinical similarities between thymoma patients and APECED / APS1 are known (4), a genetic link between these 2 diseases has not yet been described. As rheumatic autoimmunity can be induced by either, rheumatologists should be aware of these potentially underlying causes.

An additional point of interest is the lack of autoimmunity in the mother with the same genetic variants, which suggests an additional environmental trigger (e.g. smoking, viral infection) in the patient.

— Z. Chen1, J. Tan1, T. Cheng1, X. Wu1, J. Gu1, Z. Liao1. Third Affiliated Hospital of Sun Yat-sen University, Rheumatology and Immunology Department, Guangzhou, China

**Background:** Inappropriate activation of pro-inflammatory cytokines such as interleukin (IL)-1, IL-6 or IL-18, is a pathogenic cornerstone in adult onset Still’s disease (AOSD). Beyond therapies targeting IL-1 and IL-6, Janus kinases (JAK) inhibitors have been suggested to be effective in refractory AOSD patients [1].

**Objectives:** To assess the efficacy and safety of JAK inhibitors in the treatment of AOSD patient refractory to, or with initial treatment.

**Methods:** This retrospective study was based on our single center of the department of rheumatology and immunology. The data was collected from the patients’ medical records using a standardized questionnaire and analyzed at different time points. The response to JAK inhibitors was categorized as complete remission (CR), partial remission (PR) or failure (F) [2].

**Results:** 7 patients were recruited (Table 1), including 4 refractory patients and 3 initial patients. Mean age at JAK inhibitor treatment start was 27.5 years for refractory patients and 35 years for initial patients; and mean disease duration was 66.5 months and 1 month respectively. All patients had fever and polyarthritits, 5 patients had rash. In addition, pulmonary hypertension, abnormal liver function tests, abdominal pain, and heart failure were also observed in our patients. Response to corticosteroids, conventional synthetic or biological Disease Modifying Anti-Rheumatic Drugs (DMARDs) had been considered inadequate in 4 refractory patients, Tofacitinib was added in the initial treatment for 3 patients for high disease activity. In total, baricitinib was used in 2 patients and tofacitinib in 5 patients. Steroids were concurrently used in 6 patients, MTX in three, SASP and NSAIDs in one. At a mean follow up of 3.8 months, complete remission was observed in one patient (with tofacitinib), partial remission was in 5 patients (4 patients with tofacitinib and one with baricitinib), and failure in one patient (with baricitinib). At the last visit, steroids could be decreased but not stopped in those 6 patients. Tolerance of JAK inhibitors was excellent, none infectious disease or other severe side effect were observed.

**Conclusion:** JAK inhibitors treatment may be helpful for some patients with refractory AOSD, or patients with severe disease activity at initial treatment. Different treatment responses were observed in these short series of cases, which might be due to the phenotype of patients. However, the scale of patients in our study was too low to draw a conclusion. Further study and additional information are needed to evaluate more precisely the risk-benefit ratio of this treatment, and a possible difference in efficacy among the different groups of patients or JAK inhibitors.

BULLOUS SYSTEMIC LUPUS ERYTHEMATOSUS SUCCESSFULLY TREATED WITH MYCOPHENOLATE MOFETIL COMBINED WITH GLUCOCORTICOID: A CASE REPORT
H. Du1, J. Hu1, J. Su1, T. Wu1, R. Wu1, J. Zhu1. 1Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chinese Academy of Sciences Sichuan Translational Medicine Research Hospital, Department of Rheumatology and Immunology, Chengdu, China

Background: Bullous systemic lupus erythematosus (BSLE) is a rare subtype of systemic lupus erythematosus, accounting for less than 1% of systemic lupus erythematosus (SLE) [1]. It is common in adults aged 20 to 40, with female predominance [2]. Its skin manifestations are mainly tense blisters, especially involving oral and genital mucosa, Nissl's sign is mostly negative, blisters break and heal to form pigmentation of varying degrees, leaving no scar. At present, the main treatment is systemic application of corticosteroids combined with immunosuppressants. Here, we report a BSLE who successfully treated with mycophenolate mofetil (MMF) combined with glucocorticoid.

Objectives: To be vigilant in the early identification of BSLE, and through the treatment experience of this case, it can provide a basis for the use of Mycophenolate ester as the preferred drug for the treatment of BSLE in the future.

Methods: The clinical manifestation, laboratory test, treatment, and outcome were described.

Results: A 50-year-old female patient with systemic lupus erythematosus presented with wandering joint pain for 1 year and sporadic patchy erythema on eyelid, hands, and neck for 7 months. There are blisters on part of her erythema and normal skin, about 1mm-15mm in diameter, the blister fluid is cool, fusion is broken, and Nissl's sign is negative. She suffered from anemia, albuminuria, polyserous effusion and other system damage. Skin histopathology showed mild hyperkeratosis of epidermis, formation of subepidermal blisters and accumulation of a large number of neutrophils; direct immunofluorescence showed that the positive expressions of IgA, IgG and C3 were found in the basement membrane of the skin, leading to a diagnosis of BSLE. In the initial stage, patients were treated with high-dose glucocorticoid (160mg, qd) combined with immunosuppressants (thalidomide and hydroxychloroquine), but the number of blisters increased. After treatment with MMF (1g, bid), the skin lesions disappeared, joint pain relieved, anemia was corrected, and polyserous effusion was absorbed. She was followed up for half a year and there was no recurrence.

Conclusion: Patients with BSLE are often accompanied by multiple system damage [2], so it is critical to correctly identify BSLE and provide appropriate treatment as soon as possible. For patients who do not respond to single glucocorticoid therapy, combined with MMF can be used as the preferred drug for the treatment of BSLE in the future.

Figure 1. BSLE. Blisters can be seen on the face, neck, armpits and arms. BSLE = bullous systemic lupus erythematosus.
The mean duration of diagnosis was 123.5±89.3 months. At least one autoim-
immune manifestation was observed in 80% of the patients. In the follow-up period,
40% of the patients developed arthritis. Involvement of lower extremity joints
such as knee and ankle was more prominent. While all patients were given 0.8g/
kg/3 weeks of intravenous immunoglobulin, 80% required immunosuppressive
therapy for autoimmune manifestations. The demographic and clinical character-
istics of the patients are summarized in Table 1.

**Conclusion:** Autoimmune diseases can be seen in patients with CVID, and
sometimes this may be the first presentation of CVID. Heterogeneous clini-
cal findings of the disease may lead to delay in diagnosis. Clinicians should be
more careful about the different manifestations of CVID to avoid delay in
diagnosis.

### POS0018

**REDUCTION OF DIFFUSE NOXIOUS INHIBITORY CONTROL IN ACTIVE INFLAMMATORY RHEUMATISM: A DEMONSTRATION OF CENTRAL SENSITISATION**

A. P. Trouvin1,2, A. Simunek1, J. Coste1,2, T. Medkou2, S. Carvès1, D. Bouhassira2, S. Perrot1,2, 1Cochin University Hospital, Pain Medicine Department, Paris, France; 2INSERM, U982, Boullogne Billancourt, France; 3GHU Paris Centre – Cochin, Biostatistics and Epidemiology Unit, Paris, France; 4Ambroise Paré University Hospital, Pain Medicine Department, Boullogne Billancourt, France

**Background:** In rheumatoid arthritis (RA) and spondyloarthritis (Spa), persistent pain remains challenging. It is thought to result from central pain sensitisation, which can be measured by quantitative sensory testing (QST) and conditioned pain modulation (CPM).

**Objectives:** The main objective of the RAPID (Rheumatism Pain Inhibitory Descending pathways) study, was to assess descending pain modulation (through CPM paradigms) in patients with RA or Spa, comparing these patients with healthy sex- and age-matched controls. The secondary objectives were the measurement pain thresholds (heat and cold) in a non-articular, non-painful area in patients and controls as a means of detecting possible widespread hyperalgesia as another index of central sensitisation in our patients.

**Methods:** We included 50 RA and 50 Spa patients and 100 age- and sex-matched controls. We assessed clinical disease variables for patients, together with responses to various psychological questionnaires. All participants underwent QST with the determination of heat and cold pain thresholds (HPT -CPT) and CPM. In CPM, a conditioning stimulus was applied to a foot and the non-dominant hand in a randomised sequence. Descending pain control was assessed as the change in HPT (in °C) following a conditioning stimulus: the higher the CPM effect, the more efficient the inhibitory control.

**Results:** HPT and CPT were similar in patients and controls. Mean CPM effect was significantly weaker in patients than controls; 0.25°C (±2.57) and 2.79°C (±2.31) for patients and controls, respectively ($p<0.0001$) for conditioning on the foot; 0.57°C (±2.74) and 2.68°C (±2.12) ($p<0.0001$), respectively, for conditioning on the hand. The heat pain threshold was 42.35°C (±3.68°C) for patients and 41.54°C (±3.34°C) for healthy controls; this difference was not statistically significant. The cold pain threshold was 13.11°C (±10.04°C) for patients and 13.28°C (±9.34°C) for healthy controls; this difference was not significant. The weaker CPM effect in patients was associated with higher pain intensity. In all participants, a weak CPM effect was associated with high Central Sensitisation.

**Conclusion:** Diffuse noxious inhibitory control is weaker in patients with active chronic inflammatory rheumatism than in healthy subjects, supporting the hypothesis of central sensitisation.

### POS0019

**CENTRAL SENSITIZATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: ASSOCIATION WITH DISEASE ACTIVITY**

V. Bombela1, M. Stanislavchuk1, 1National Progov Memorial Medical University, Vinnytsya, Ukraine, Department of Internal Medicine #1, Vinnytsya, Ukraine

**Background:** Rheumatoid arthritis (RA) is the most common inflammatory arthropathy with a predominance of autoimmune mechanisms of pathogenesis and pain as the main clinical manifestation. Recent evidence has found showed that Central Sensitization (CS) may be a new mechanism for the formation of pain [1]. There is insufficient data on this phenomenon in patients with RA [2].

**Objectives:** To determine the prevalence of the phenomenon of CS in patients with RA and evaluate its association with disease activity.

**Methods:** The study involved patients with RA according to the ACR / EULAR criteria (2010). RA activity was determined by DAS-28, SDAI, CDAI, and the functional ability of patients - by HAQ. Visual analog scoring (VAS) were used to evaluate the intensity of pain. The radiological stage of RA was determined according to the Kellgren-Lawrence classification. The presence of the CS phenomenon was established using the Central Sensitization Inventory (CSI) (Mayer, T. G. et al., 2012), MS Excel and SPSS22 (© SPSS Inc.) software packages were used for statistical processing of results.

**Results:** 110 patients (84% of women) were included. The participants’ mean age was (MsSD) 53.5 ± 12.2 years, with a disease duration 8.5 ± 8.1 years. Among the examined, radiological stage I was detected in 16 (15%) patients, II - in 59 (53%), III - in 23 (21%), IV - in 12 (11%). According to the DAS28-ESR index, 56 (51%) patients had high activity (DAS 28-ESR: >5.1) and 54 (49%) patients had moderate activity (3.2 -DAS28-ESR ≤5.1). Mean values of SDAI and CDAI also showed high disease activity: 36.5 ± 10.2 and 33.3 ± 9.8, respectively. The average value of HAQ was 1.4 ± 0.7.

**Conclusion:** Sensitization is common in RA patients. The phenomenon of central sensitization is associated with higher disease activity, loss of functional ability and severity of pain.

### POS0020

**PAIN PHENOTYPING IN PATIENTS WITH PSORIATIC ARTHRITIS AND HAND OSTEOARTHRITIS**

J. Vela1, J. L. Dreyer1, K. Kjær Petersen1, 1Aalborg University Hospital, Rheumatology, Aalborg, Denmark; 2Aalborg University, Clinical Institute, Aalborg, Denmark; 3Aalborg University, Centre for Neuroplasticity and Pain, Aalborg, Denmark

**Background:** Chronic pain is experienced by many patients with joint disease but underlying pain phenotypes including impact of concomitant fibromyalgia (cFM) have not been investigated in patients with psoriatic arthritis (PsA) and hand osteoarthritis (hand-OA).

**Objectives:** To investigate pain parameters (quantitative sensory testing) in patients with hand-OA and PsA using pressure pain thresholds (PPT), temporal summation of pain (TSP) and conditioned pain modulation (CPM) compared with healthy controls. Furthermore, to explore whether alternations in underlying pain mechanisms and psychological factors are associated with cFM compared to those patients without.

**Methods:** Patients with verified PsA or hand-OA and healthy controls underwent quantitative sensory testing using hand-held and cuff pressure algometry to measure PPT, TSP and CPM. Psychosocial factors were assessed via the Hospital Anxiety and Depression Scale, Pain Catastrophizing Scale, Pittsburgh Sleep
Abbreviations: cFM: Concomitant fibromyalgia; HADS: Hospital anxiety and depression.

### Results:

Patients with cFM (58%) had greater scores of depression, anxiety, catastrophizing, disability and reduced sleep quality when compared to patients without cFM. Limiting the analysis to patients without cFM yielded a similar result.

Patients with cFM had greater TSP, painDETECT, disability, catastrophizing and reduced sleep quality, than patients without, indicating greater degree of sensitisation, psychosocial burden, and disability.

### Conclusion:

Patients with hand-OA and PsA experienced a greater degree of pain facilitation and psychosocial impact when compared with controls. Patients with cFM had greater TSP, painDETECT, disability, catastrophizing and reduced sleep quality, than patients without, indicating greater degree of sensitisation, psychosocial burden, and disability.
Continuous, neuropathic and intermittent. The value for each descriptor is plotted. The descriptors are divided into four categories: affective, activity (BDCAF < 4), comitant FMS diagnosis was more prevalent in the high disease activity group (72%) compared to low disease activity (37.7%). The prevalence of FM in the IBD cohort was 17/196 (8.7%) 95% CI 5% – 13%, of patients with high disease activity. Concomitant FMS diagnosis was more prevalent in the high disease activity group (52%) than the low disease activity group (29%) (p=0.04). The mean mBDCAF of patients with FMS was 2.09 ± 1.3 compared to 1.53 ± 1.3 in patients without FMS (p=0.047).

Figure 1. Pain Descriptors by Disease Activity

Affective descriptors
Continuous descriptors
Neuropathic descriptors
Intermittent descriptors

Figure 1. Pain descriptors from the SF-MPQ-2 stratified by high (BDCAF ≥4) and low disease activity (BDCAF <4). Descriptors are rated no pain to the worst pain over (0 – 10). The median value for each descriptor is plotted. The descriptors are divided into four categories: affective, continuous, neuropathic and intermittent.

Conclusion: This the first study to describe the pain experience of a UK population of BS patients. The majority of patients experience moderate to severe chronic MSK pain. Severe generalised MSK pain is more prevalent in those with high BS disease activity. We have demonstrated a relationship between high disease activity, worse pain intensity, and comorbid FMS. Our findings pose new questions into the research of pain in BS. Further studies are required to explore the mechanism of generalised pain and its correlation with disease activity.

PREVALENCE AND IMPACT OF FIBROMYALGIA SYNDROME IN A CORPUS OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE

L. Guida1, S. Sirotti2,3, G. Filippou4, A. Dell’era4, D. Gridavilla4, M. E. Romano5, D. Ventura4, G. M. C. La Paglia4, S. Farah4, S. Ardizzone4, P. Sarzi-Puttini2,3
1Luigi Sacco University Hospital, Gastroenterology Department, Milan, Italy; 2Luigi Sacco University Hospital, Rheumatology Department, Milan, Italy; 3University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 4Polytechnic University of Marche, Rheumatology Department, Jesi, Italy

Background: Fibromyalgia (FM) is a common chronic disorder characterized by widespread pain, fatigue, sleep disturbances and functional symptoms, reaching a prevalence of 2–3% worldwide. It can present as a comorbidity in patients with concomitant chronic disease and can have a significant impact on the quality of life. There are very few studies on the prevalence and the impact of FM in patients with inflammatory bowel disease (IBD).

Objectives: The aims of this study were to assess the prevalence of FM in a cohort of patients with IBD, and to evaluate the impact of FM on the quality of life of those patients.

Methods: Consecutive patients with IBD were enrolled from August to November 2021 in two IBD units, patients with severe disease activity according to the Crohn’s disease activity index (CDAI) and to the Mayo score for UC, or with other concomitant chronic diseases were excluded. Clinical and demographic data and Patient Reported Outcomes (PROs) (Widespread Pain Index (WPI), Symptom Severity Score (SSS)), IBD Questionnaire (IBD-Q), Depression anxiety stress scales-21 (DASS-21), Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F), Impact of event scale-revised (IES-R), Pittsburgh Sleep Quality Index (PSQI)) were collected. FM was diagnosed according to 2011 ACR classification criteria by an expert rheumatologist. Mann-Whitney test, chi-square test, and Student t test were used for statistical analyses. A multivariate analysis was performed to estimate the effect of independent variables (BMI, age, CRP, CDAI, Mayo score, WPI, DASS-21, FACT-F, PSQI) on patients’ quality of life (IBD-Q). A p value < 0.05 was considered as significant.

Results: A total of 196 IBD patients were enrolled (86 female (44%) with a mean age of 50 ± 15 yo), 105 with Crohn’s disease (CD) and 91 with ulcerative colitis (UC). 147 patients were in remission, 35 had low disease activity and 14 moderate disease activity. The overall prevalence of FM in the IBD cohort was 17/196 (8.7%) 95% CI 5% – 13%, 10 (11.6%) women and 7 (6.3%) men; with a prevalence of 7.6% (8/105) in CD and 9.9% (9/91) in UC.

In Table 1 are indicated the characteristics of patients with IBD + FM and IBD alone. No significant demographic and clinical differences between the two groups were detected.

The quality of life among IBD patients and IBD + FM patients, assessed with IBD-Q, appear significantly lower (p <0.001) in the second group. Similar results were obtained evaluating depression, anxiety, stress, chronic fatigue, and patients’ discomfort (Table 1).
The multivariate analysis demonstrated that the variables influencing the quality of life (IIB-Q) were the disease activity (CDAI) (p <0.0256), the chronic fatigue (FACT-F) (p <0.0061) and sleep disturbances (PSQI) (p <0.0440), for CD; while for UC the only variable that correlated with IIB-Q was the disease activity (Mayo score) (p <0.0129).

**Conclusion:** FM is a common disorder especially in patients with other comorbid chronic diseases. This study reported a prevalence of FM of 8.7% in IBD patients without any significant differences between CD and UC. Moreover, the comorbidity of FM in IBD can have a considerable impact on quality of life and on measures of disease severity, with worst values in all PROs measurements.

POS0024

**PREDICTION OF SPONTANEOUS IMPROVEMENT IN PATIENT REPORTED OUTCOME SCORES IN OSTEOARTHRITIS USING MARKERS OF JOINT TISSUE TURNOVER**

M. Mukundan\(^1\), A. C. Bay-Jensen\(^2\), J. Samuels\(^1\), M. Kandsal\(^3\), S. Abramson\(^1\).

\(^1\)NYU Grossman School of Medicine, Division of Rheumatology, Department of Medicine, New York, United States of America; \(^2\)Nordic Bioscience, ImmunoScience, Herlev, Denmark

**Background:** Osteoarthritis (OA) is a chronic disease characterized by pain and disability. There is no modifying treatment approved for OA today. This may be attributed to the difficulty generating a robust response based on patient-reported outcomes (PROs) linked to the drug mode of action. There is a need in drug development to test and validate biomarkers that objectively relate to PROs or even predict changes in PROs. Biomarkers of cartilage and bone turnover are associated with structural and symptomatic progression\(^1\). In addition, recent findings suggest that a subset of OA patients have elevated serum levels of C-reactive protein metabolites (CRPM), which is predictive of radiographic progression\(^2,3\).

**Objectives:** This explorative study aimed to investigate the association between PROs and markers of joint tissue formation and degradation in patients with either high or low levels of CRPM. In particular, whether levels could predict spontaneous improvement in PROs.

**Methods:** 146 knee OA patients, 62% women, from the NYU cohort were included. Mean (SD) age, 62.5 (10.1); BMI, 26.6 (3.6); 32% NSAID users; and 67.6% with radiographic OA (KL≥2). PROs were recorded at baseline (BL) and 2 years (FU), and the current investigation was: WOMAC pain, stiffness, and function. The mean (SD) for WOMAC pain, stiffness, and function were 35.4 (22.9), 40.8 (25.7), and 41.7 (28.3) mm on a 100 mm scale. Twenty-one healthy individuals were included as a reference. Eight serum biomarkers of type I, II, III, and IV collagen degradation (C1M, C2M, C3M, C4M) and formation (PRO-C1, PRO-C2, PRO-C3, and PRO-C4) as well as the inflammatory biomarker CRPM, were assessed at baseline. LN-transformed data was adjusted for race, sex, age, BMI, and NSAID use when comparing OA to controls and in the pre-contrast chronic diseases. This study reported a prevalence of FM of 8.7% in IBD patients without any significant differences between CD and UC. Moreover, the comorbidity of FM in IBD can have a considerable impact on quality of life and on measures of disease severity, with worst values in all PROs measurements.

**Conclusion:** Levels of the joint tissue markers were subtle compared to controls. However, the markers, together with sex and BMI, could predict symptomatic improvement. This may provide novel insight into the link between tissue turnover and PROs.

**PREVALENCE OF ATTENTION DEFICIT HYPERACTIVITY DISORDER AMONG ADULT PATIENTS WITH FIBROMYALGIA**

S. Noyano\(^1\), W. Berrios\(^2\), I. Gandino\(^1\), E. Soriano\(^1\), J. Rosa\(^1\).

\(^1\)Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina; \(^2\)Hospital Italiano de Buenos Aires, Neurology, Buenos Aires, Argentina

**Background:** Fibromyalgia (FM) and attention deficit hyperactivity disorder (ADHD) share some clinical features, and a reduced dopamine function has been proposed for both disorders. ADHD is a chronic condition, marked by persistent inattention, impaired concentration, hyperactivity, impulsivity, emotional lability, anxiety and disorganized behaviour. High rates of comorbidity between ADHD and FM have been reported, as well as some evidence that patients with both conditions experience heightened disease severity.

**Table. Prediction of symptomatic regressive OA in patients with symptomatic knee OA.** Multiple variate logistic regression including In-transformed biomarkers and baseline clinical characteristics (age, gender, race, BMI and NSAID use). Not adjusted for multiplicity.

\(^1\)Regressive disease was defined as 10 or 20 mm or more decrease in VAS pain, WOMAC pain, stiffness or function, and 30 mm or 60 mm or more decrease in WOMAC total, over two-years. \(^2\)Rate of regression in percentage in each of the sub-populations.
Objectives: Our purpose was to determine the prevalence of ADHD symptoms in patients with FM and to assess the relationship with disease impact.

Methods: Consecutive patients, older than 18 years, with diagnosis of FM (ACR 2016 criteria) without known cognitive impairment, seen at the Rheumatology Unit between April 2018 and December 2019, were included. At inclusion visit the collected data included Revised Fibromyalgia Impact Questionnaire (FIQ-R) and Health Assessment Questionnaire, Argentine version (HAQ-A). During the Neurology visit, the following tests were performed: Montreal Cognitive Assessment (MoCa) test for evaluating the presence of cognitive impairment, Connors Continuous Performance Test II (CPT II) for the assessment of ADHD, and Wender-Utah Rating Scale (WURS) to retrospectively assess childhood ADHD symptoms. Univariate analysis was performed using t-tests for normally distributed continuous variables, and Wilcoxon rank sum test for non-normally distributed continuous variables. A chi-square or Fisher test was used when appropriate for categorical variables. Predictors that were found to be related to ADHD (p ≤ 0.20) were then entered into a multivariable logistic regression model.

Results: 60 patients with FM and 71 matched controls without FM or known cognitive impairment were included. FM patients’ characteristics are shown in Table 1. 61.7% (n=37) of the patients with FM tested positive for adult ADHD. In 48.6% (18/37) of them, the diagnosis had been missed in childhood. Participants with both FM and a positive adult ADHD screening test did not score significantly higher on the FIQ-R (52.3, SD= 16.1 vs. 47.9, SD= 12.3; p= 0.2693) and HAQ-A (0.693, SD= 0.455 vs. 0.521, SD= 0.428; p=0.1523) compared with patients without ADHD. Retrospectively assessed childhood ADHD was significantly associated with adult persistence (OR 55.1, CI=3.6 to 842.6, p=0.004).

</table>

Patients with FM had significantly higher prevalence of cognitive impairment (43.3% vs. 16.9%; p=0.0001), childhood ADHD symptoms (31.7% vs. 14.1%; p=0.016) and adult ADHD symptoms (61.7% vs. 23.9%; p<0.0001) than the control group (Figure 1).

Conclusion: The co-occurrence of adult ADHD in FM was highly prevalent. In nearly half of the patients the diagnosis had been overlooked during childhood and it was associated with adult persistence. The prevalence of cognitive impairment, and childhood and adult ADHD was higher in patients with FM compared with the control group. ADHD was not associated with the FM impact. Evaluation of ADHD symptoms in patients with FM is important for recognition and treatment of this comorbidity.

Disclosure of Interests: None declared
Background: Musculoskeletal pain is an important feature in patients (pts) with anterior acute uveitis (AAU), as a symptom of spondyloarthritis (SpA). Fibromyalgia (FM), which is more prevalent in pts with chronic inflammatory diseases, has a widely recognized effect on both differential diagnosis and evaluation of outcome measures in FM. The role of enthesitis in FM patients is not clear. The aim of this study was to estimate the prevalence of primary FM and comorbid FM and SpA in a cohort of pts with AAU, and to compare clinical and ultrasonographic findings in SpA pts with (SpA FM+) and without (SpA FM-) concurrent FM and SpA.

Methods: 146 pts were diagnosed with AAU from 2017 to 2019, and 143 pts were included in this study. A complete rheumatologic assessment, including 68/66 peripheral joint count, Leeds Enthesitis Index (LEI) and Manchester Ankylosing Spondylitis Enthesitis Score (MASES), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), and Fibromyalgia Impact Questionnaire (FIQ) was performed. Using an Esaote MyLabClass, 18-6MHz linear multifrequency transducer, 6 entheses (lateral epicondyle, distal quadriiceps insertion, proximal and distal patellar tendon insertions, superior iliac crest insertion, Achilles tendons and plantar fascia) were evaluated bilaterally for the presence of any elementary lesion, structural damage and active enthesitis, according to OMERACT definitions. Pts were classified as having SpA and/or FM according to ASAS criteria and 2010 ACR diagnostic criteria for FM, respectively.

Results: 103 pts were diagnosed with anterior acute non granulomatous uveitis (AANGU) and 49 with anterior acute granulomatous uveitis (AAGU) (FM 93/59, age 46.2±12.3 years, BMI 25±5.1, disease duration 43.8±85.2 months). 14 pts (9.2%) met the ACR criteria for FM, of whom 8 pts had concomitant FM and SpA. All FM pts had AANGU. FM pts showed significantly higher enthesitis count and report worse disease activity and function scores (Table 1). Fulfillment of ASAS criteria was associated with FM (p<0.004).

</table>

SpA FM+ pts more frequently reported an history of enthesitis (75% vs 23.3%, p=0.011 OR 9.9 (95% CI 1.6 – 62.2) and buttok pain (75% vs 33.3%, p=0.034 OR 6 (95% CI 1.02 – 35.3)) when compared with SpA FM-, while no significant differences in LEI, MASES, joint count, and inflammatory back pain (IBP), as well as in sex, age and BMI were observed.

BASDAI, FIOQ and FIOQ4 were increased in SpA FM+ (6±1.1 vs 3.4±1.8 p<0.001, 4.3±2.1 vs 1.7±2.2 p= 0.005 and 43.6±11.4 vs 24.6±15.5 p=0.003 respectively).

Abnormal US findings were detected in 35/38 SpA pts (92.1%), without significant differences in elementary lesions and structural damage between SpA FM+ and SpA FM-. At patient-level, a significantly higher percentage of SpA FM+ pts had at least one active enthesitis, as compared with SpA FM- (25% vs 3.4%, p = 0.048).

Conclusion: Comorbid FM was frequent in SpA associated with AANGU, affecting both clinical presentation and outcome measures, whereas no FM patients were found in the AAGU group. In our cohort the role of ultrasonography in discriminate SpA FM+ from SpA FM- is not clear.

Genomics, functional genomics and genetic basis of inflammatory arthritis

**CHARACTERISING THE CLINICAL AND RADIOLOGICAL PHENOTYPE OF PSORIATIC ARTHRITIS: A CLASS I AND II HLA ALLELES STUDY**

**Background:** Psoriatic arthritis (PsA) is a heterogeneous disease affecting multiple tissues including skin and joints. Few studies have fully explored the association between class I and II HLA alleles and different clinical and radiological manifestations.

**Objectives:** To examine the association between different class I and II HLA alleles and certain PsA phenotypes.

**Methods:** Cross-sectional study including patients with PsA over 18 years. All patients fulfilled the CASPAR classification criteria for PsA. Demographic, clinical, laboratory and radiology data were gathered including variables related to joint phenotype, type of skin involvement and response to biologics.

**Results:** A total of 246 patients were included. Mean age of the cohort was 59.8 years and 53% were men. Average arthritic disease duration was 12.4 years. A total of 39.8% patients had axial involvement and 90.7% peripheral, being the polyarticular the most frequent subtype in 48% of cases. Considering the skin, mean disease duration was 22.2 years, being the plaque psoriasis the most frequent subtype in 75.2% of cases. 44.3% of the patients presented a history of dactylitis whilst 24% presented enthesitis. Uveitis was reported in 3.7% of patients and Cohn’s disease in 0.4%. 30.9% of PsA patients had erosions in the hand or feet x-ray. More than half (59.3%) were treated with bDMARDs with a median exposure of 2 different drugs.

**Conclusion:** In our cohort, we have confirmed previously described associations in the literature and found new significant associations with clinical and radiographic PsA manifestations including class II HLA analysis.

Genomics, functional genomics and genetic basis of inflammatory arthritis

**FUNCTIONAL GENOMIC INVESTIGATION OF THE ANKYLOSING SPONDYLITIS ASSOCIATED LOCUS RUNX3**

C. Cohen1, D. Simoné1, C. Selmi1, P. Bowness1, P. B. Wordworth1, M. Vecellio1.

**Background:** Ankylosing Spondylitis (AS), is a highly heritable disease with >100 genomic loci incriminated. Among these, RUNX3, a transcription factor (TF) involved in diverse immunological processes, is robustly (10−15) associated.

**Methods:** We have extensively investigated the single nucleotide polymorphism (SNP) rs4648889 located in a 2kb regulatory locus upstream of the RUNX3 promoter. We have demonstrated that the association between AS and this SNP can be explained by allele-specific effects on TF recruitment (including IRF4, IRF5 and the NuRD complex) that alter gene expression, specifically in CD8+ T-cells, and having a crucial role in CD8+ T-cells function. Further, we have recently shown a clear chromatin looping event between the region encompassing SNP rs4648889 and the RUNX3 promoter confirming the functional role of this variant.

**Objectives:** The purpose of this work is: (1) to better characterise the chromatin looping landscape of the whole AS-associated RUNX3 genomic locus and (2) to determine the single-cell expression of the RUNX3-related genes identified previously.

**Results:**

1. In addition to the recent results published, 3C-qPCR experiments revealed a high interaction frequency between the distal promoter of RUNX3 and an intrinsic region (called Int2), overlapping open chromatin and TF binding sites. This was highly reproducible in both cell lines analysed.
2. Four different clusters were identified in CD8+ T-cells obtained from AS peripheral blood via 10x sc-seq based on the expression of RUNX3 and RUNX3-related genes expression profile in CD8+ T-cells.
3. Comparing results obtained through HOCOMOCO and Remap databases resulted in a list of 68 unique TFs. Many of these are key regulators of adaptive immune responses, cellular metabolism, and pluripotency.

**Conclusion:** This study provides experimental evidence that survivin defines a plausible functional role in AS, probably by regulating gene transcription and DNA looping. These observations are critically important in defining dysregulated pathways and potential therapeutic drug targets.

**FUNCTIONAL ROLE OF SURVIVIN IN ORGANIZATION OF BIVALENT CHROMATIN REGIONS AND CONSEQUENCE FOR ARTHRITIS-RELEVANT GENE EXPRESSION**

V. Chandrasekaran1, M. I. Bokarewa1, N. Opara1, K. M. Andersson1, G. Katona1, M. Erlandsd1, M. Jensen1, A. Damdimopoulos1.
1. Institute of Medicine, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 2. University of Gothenburg, Department of Chemistry and Molecular Biology, Gothenburg, Sweden

**Background:** Bivalent chromatin (BvCR) is characterized by the presence of simultaneous active and repressive modifications on histone H3 proteins. Influencing expression of the genes, BVCR determine cell fate and direct differentiation and lineage commitment in primary T cells and contribute to autoimmunity. Survivin is highly expressed during T cell division and in effector Th1 cells contributing to aggravation of autoimmune inflammation. Survivin can physically bind to DNA, specifically to Threonine-3 of histone H3 (1). Thus, functional, and mechanistic data point to a potential chromatin regulatory role for survivin, potentially acting in combination with histone epigenetic modifications (EMs).

**Objectives:** The goal of our study is to establish the colonization of survivin in BVCR and to deduce functional effects of this collaboration on chromatin organization and gene expression.

**Methods:** Chromatin from CD4+ T cells of 14 female subjects was immunoprecipitated with survivin antibodies and histone H3K27ac, H3K27me3, H3K4me3 antibodies, and coupled with DNA sequencing (ChiPseq, Hissee2000, Illumina). BVCR were identified as exact overlaps of the three histone EM peaks and the overlapping regions were searched for co-localization with survivin using the ‘ChiPPeakAnno’ Bioconductor package. Tag counts K27me3/K27ac were defined as inactive/poised BVCR, while tag count K27me3+K27ac were identified as active BVCR. Motif search was done through the MEME tool, and high/ moderate complexity motifs with E-value >10e-5 were selected and scanned through the HOCOMOCO database to identify consens thematic transcription factors (TF) found in TFs co-localized with the BVCR and identified through Remap database. To identify survivin sensitive genes, CD4+ T cells were treated with survivin inhibitor YM155 and a list of reproducible DEG (log2FC[0.4], |1| expression) was mapped and analysed for clustering with BVCR.

**Results:** Co-localization of survivin ChiP peaks with individual H3-peaks was significantly less frequent compared to overlap with all three (a3-H3 BVCR (7.1 vs 29.8%, p=8.9e-10). Overlap of a3-H3 peaks not containing survivin was less frequent (34%) compared to those which contained survivin (68%). Notably, survivin peak size was 5.5-fold higher when co-localized with a3-H3 peaks, compared to no, or any single H3 (p=2.2e-16). In contrast, no size difference for any of the H3 EM peaks was found.

Further analysis of two non-redundant groups of BVCR that contain (survivin-a3H3, n=4085), and not containing survivin-a3H3 (n = 2131) demonstrated that survivin was mostly associated with inactive BVCR (OR1.29, p=6.6e-6), while no such specificity was found for BVCR with no survivin. Additionally, survivin containing BVCR contained abundant binding sites matching known consensus TF motifs. No sequence-specific motifs were identified in BVCR with no survivin. Comparison of results obtained through HOCOMOCO and Remap databases resulted in a list of 68 unique TFs. Many of these are key regulators of adaptive immune responses, cellular metabolism, and pluripotency. Differentially expressed genes mapped to BVCR demonstrated enrichment for cellular hormone metabolic processes, regeneration and DNA biosynthesis.

**Conclusion:** This study provides experimental evidence that survivin defines binding specificity in bivalent chromatin regions being associated with regulation of cellular metabolism and renewal of CD4+ T cells that are functionally important to resist autoimmunity.

**GENETIC INVESTIGATION OF TUMOUR NECROSIS FACTOR INHIBITOR IMMUNOGENICITY IN PATIENTS WITH RHEUMATOID ARTHRITIS**

C. F. Yang1, N. Nair1, K. Hyrich1, A. G. Wilson2, J. Isaac1, A. Morgan3, A. Barton1, D. Plant1.
1. The University of Manchester, Centre for Genetics and Genomics, Manchester, United Kingdom; 2. The University of Manchester, Centre for Epidemiology, Manchester, United Kingdom; 3. University College Dublin, School of Medicine & Medical Science, Conway Institute, Dublin, Ireland

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease that primarily affects the synovial joints. Tumour Necrosis Factor inhibitor (TNFi) therapy has transformed the clinical management of RA. However, monoclonal antibody derived TNFi is associated with development of immunogenicity and subsequent loss of therapeutic effects. Previous studies have observed associations between certain HLA alleles and TNFi immunogenicity. For example
HLA-DQA1 and HLA-DRB1 have been associated with immunogenicity in inflammatory bowel disease [1,2] and RA [3,4], respectively.

**Objectives:** The aims of this study were to identify associations between HLA alleles and immunogenicity to TNFi in an observational cohort of RA patients and to replicate findings from previous studies.

**Methods:** Anti-drug antibody titres were measured using radioimmunoassay in serum samples from RA patients participating in Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS). An anti-drug antibody titre of ≥12 AU/mL following six months on treatment was used to define positive immunogenicity. Genotype data were generated using Illumina HumanCoreExome Arrays. Standard quality control (QC) was applied prior to HLA imputation using SNP2HLA software before low minor allele frequency markers were removed. Logistic regression was used to study the association between HLA alleles and immunogenicity, whilst the omnibus test was applied to amino acid positions; sex and concurrent conventional synthetic DMARD use were included as a covariate in all the models.

**Results:** In total, 445 RA patients were analysed, 377 patients (70 immunogenicity events) were underdosing adalimumab therapy and 68 corticosteroid (30 immunogenicity events) therapy, following QC, 162 HLA alleles and 361 amino acids positions were available for analysis. The strongest HLA allele association was observed for HLA-DQA1*03 when all patients were analysed (OR = 0.61; 95% CI = 0.43 – 0.86; p-value = 5e-3) and 26 (p-value = 5e-3) within the HLA-DQA1 gene were significantly associated with immunogenicity events. When both drugs were analysed separately, they produced similar effect size for HLA-DQA1*03 association; patients treated with adalimumab (OR = 0.59; 95% CI = 0.38 – 0.88; p-value = 1e-2) and corticosteroids (OR = 0.52; 95% CI = 0.24 – 1.1; p-value = 1e-1). Another strong association was found for HLA-DRB1*04:01 (OR = 0.62; 95% CI = 0.44 – 0.88; p-value = 7e-3) and the amino acid position of 180 (p-value = 7e-3) and 33 (p-value = 7e-3) of HLA-DRB1 gene. Additionally, the similar protective effect between the two presented alleles suggested possibility of linkage disequilibrium, upon investigation the r² between the 2 alleles is 0.69.

**Conclusion:** The current study increases the evidence for association between immunogenicity development with HLA-DQA1 and HLA-DRB1 alleles in patients receiving monoclonal antibody derived TNFi therapy. Further well powered studies are now required to determine the utility of HLA markers as a potential tool to aid the clinical management of RA.
Methods: CD4+ and CD8+ T cells were isolated from peripheral blood from 10 healthy controls and 48 PsA patients and from 6 PsA synovial fluid samples. We performed RNA-seq and ATAC-seq on these two cell types to analyse the global patterns of gene expression and chromatin activity.

Results: We find subtle differences between PsA patients and healthy controls in cells isolated from blood. RNA-seq analysis identified only a handful of differentially expressed genes whilst ATAC-seq analysis identified only 28 differentially loci. On the other hand, T cells isolated from synovial fluid showed significant differences compared to T cells isolated from patient’s blood. Interestingly, we find that CD4+ T cells as well as CD8+ T cells more differently expressed genes compared to CD8+ T cells (1168 vs 346 Log2FoldChange > 1, FDR < 0.01). Genes overexpressed in synovial CD4+ T cells are more strongly enriched for immune pathways such as cytokine signaling and T cell proliferation compared to synovial CD8+ T cells.

We also find that synovial CD4+ T cells highly overexpress MHC class II genes (Figure 1).

Conclusion: This preliminary analysis suggests that T cells isolated from peripheral blood do not seem to differ significantly between PsA patients and healthy controls. In contrast, cells isolated from synovial fluid are highly specialized and activated. Moreover, these cells do not resemble canonically activated T cells which means that this state can not be easily emulated in vitro.

This study indicates the importance of not only studying GWAS loci in relevant primary cells from patients, but also that attention needs to be given to cells isolated from the affected tissue.

REFERENCES:

A total number of 63 RA patients according to the 1987 ACR criteria were included non-steroidal antiinflammatory drugs (NSAIDs) and glucocorticosteroids (GCS), conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and original biological DMARDs. There were no patients treated with conventional target DMARDs or biosimilar DMARDs. SPSS was used for statistical analysis.

Results: RA PB showed statistically significant overexpression of miR-223 (58.73%) when compared to HCs and only miR-223 expression levels could be used to differentiate RA patients from HCs (ρ=0.008). RA SF showed overexpression of miR-146a (in 70.83%, ρ=0.007), miR-155 (in 79.17%, p=1.63x10^-4) and of miR-223 (in 79.17%, p=1.64x10^-3) when compared to HCs and the studied miRNAs could be used to differentiate RA patients from HCs (p=4.8x10^-1, p=8.0x10^-3, and p=2.8x10^-4, respectively). When we analyzed the correlation between the expression of miRNAs and the ongoing treatment we found a statistically significant correlation between the PB expression levels of miR-223 and the use of NSAIDs and GCS (ρ=0.015 and p=0.04, respectively) and the SF expression levels of miR-146a and miR-155 and the use of NSAIDs (ρ=0.011 and 7.98x10^-4, respectively) and GCS (ρ=0.039 and p=0.009, respectively). The use of csDMARDs and bDMARDs did not show correlation with the PB nor the SF expression of the studied miRNAs.

Conclusion: The correlation between the systemic miR-223 and the local miR-146a and miR-155 expression with the NSAIDs and GCS treatment could be due to the effect of these treatment compounds on the cells lines from which the studied miRNAs origin. In our study there was no correlation between miRNA expression and the use of biological and conventional DMARDs. Further analysis with larger sets including pre- and posttreatment samples is needed to confirm if altered miRNA expression could be influenced by the treatment regimen as well as if miRNAs could serve as biomarkers for treatment response in the clinical practice.
Conclusion: This MR study does not support a causal effect of genetically determined adiponectin levels on the risk of developing RA in both European and East Asian populations. By using multiplicative MR to account for possible shared genetic predictors between circulating adiponectin levels and BMI we have shown that circulating adiponectin is not causally linked to RA risk after adjustment for BMI.

POS0038 GENOMICS OF JAK-STAT SIGNALING IN VENOUS THROMBOEMBOLISM
S. Haynen1, A. L. L. Nielsen1, P. Ovist1, T. W. Krastrup1, 1Aarhus University, Department of Biomedicine, Aarhus, Denmark

Background: Janus kinase inhibitors (JAKi) have been associated with an increased risk of venous thromboembolism (VTE) [1]. VTE comprises deep vein thrombosis and pulmonary embolism and is associated with complications such as recurrent VTE, post thrombotic syndrome, pulmonary hypertension, and death. These concerns limit the use of JAKi-based therapy. To improve risk stratification and drug development, it is crucial to understand the possible implication of dysregulated JAK-signaling in the pathogenesis of VTE.

Objectives: The objective of this study is to clarify the putative genomic vulnerability associated with dysregulated JAK-STAT signaling in VTE.

Methods: We are systematically mine and analyze large-scale genomic datasets generated from studies comparing VTE patients with healthy controls. Using VTE genome-wide associated (GWA) summary statistics we evaluate the representation of genes encoding the JAK-STAT pathway (KEGG hsa04630) in associated loci and assess their association to VTE. Further, we examine the genetic VTE risk burden in the chromatin interactome of STAT family transcription factors (TFs). We extract available STAT family (STAT-1) TF binding site (TFBS) consensus DNA motifs (JASPAR database) and assess the association of genes containing STAT family TFBS within their promotor sequence (TSS < 2000bp) to VTE. Through mining of deposited OMICs data from VTE patients, we examine molecular characteristics related to JAK-STAT signaling, including potential enrichment of STAT family TFBS among query promoter sequences of differentially expressed genes (DEGs).

Results: We do not observe a significant overrepresentation of JAK-STAT genes (n=162) among genes annotated to VTE significant GWA loci (n=147, p=0.48). Similarly, the JAK-STAT gene set show no cumulative association to VTE (p=0.98). Applying the same gene set association approach to the STAT target gene sets (n=4570) does not reveal significant association between VTE and STAT1 (n=18, p=0.17) and STAT3 (n=48, p=0.20) target gene sets. At the functional molecular level, we do not see any significant overlap between molecules acting in the JAK-STAT pathway and DEGs (n=507, p=0.06) or differentially abundant proteins (DAPs; n=35, p=0.57). However, we observe a significant overlap between downregulated DEGs (n=362) and the STAT1:STAT2 heterodimer target gene set (n=2155, n=48, p=0.0001) including downregulation of IL-27RA and CCND3 (Figure 1). Supporting the biological relevance of this finding, we find a weak but statistically significant enrichment of STAT1 TFBS motifs in the promoter sequence of downregulated DEGs compared to non-DEGs (p=0.02).

Figure 1. Overlap between STAT1:STAT2 heterodimer gene set and differently expressed genes (DEGs) in venous thromboembolism (VTE)

Conclusion: Here, we provide a coherent approach to assess the genomic basis for the reported association between JAKi treatment and VTE. Our preliminary data suggest that genes under transcriptional control of STAT family TFs may be dysregulated in VTE patients. It is conceivable, that the genomic actions of JAKi is overlapping with the molecular risk profile of VTE. CCND3 is especially interesting because VTE occurs in up to 10% of patients treated with cyclin-dependent kinase inhibitors such as Palbociclib [2]. Obviously, genomic data mining alone cannot guide medical decision making concerning the use of JAKi. However, our results provide a basis for further investigation of adverse events seen with JAKi.

POS0039 MONOYE TRANSCRIPTOMICS AND TARGETED PROTEOMICS DEFINE HETEROGENEOUS SUBGROUPS IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND SUBCLINICAL ATHEROSCLEROSIS
L. Woodrige1,2, E. Chocano1,2, P. Ashford3, G. Robinson4, K. Waddington1,2, A. Rahman1, C. Orengo3, E. Jury4, I. Pineda Torra1, 1Centre for Cardiometabolic and Vascular Science, Division of Medicine, UCL, London, United Kingdom; 2Centre for Rheumatology Division of Medicine, UCL, London, United Kingdom; 3Institute of Structural and Molecular Biology, Biosciences, UCL, London, United Kingdom; 4University of Dundee, Dundee, United Kingdom
Background: Systemic lupus erythematosus (SLE), a chronic, inflammatory autoimmune disease, predominantly affects women with a 9:1 female: male incidence. Cardiovascular disease (CVD) is a leading cause of mortality in SLE via accelerated atherosclerosis: the build-up of cells and lipids in the vascular wall and the main pathology underlying CVD.

Objectives: To define molecular profiles of SLE with subclinical atherosclerosis using multi-omics data analysis and clinical data in a well-characterised cohort of CVD-free SLE women.

Methods: Multi-omics analyses were conducted to explore the molecular signatures of SLE patients with (SLE-P) and without (SLE-NP) subclinical atherosclerosis defined by non-invasive ultrasound scanning of the carotid and femoral arteries. SLE blood CD14+ monocyte transcriptomes were investigated by bulk RNA-sequencing (SLE-P N=13, SLE-NP N=8), and targeted serum cardiometabolic and cardiovascular proteomics (OLINK) were used to expose matched protein expression (SLE-P N=17, SLE-NP N=20) (no difference in disease activity between groups). Bioinformatics approaches, including pathway and disease module enrichment analyses and extended protein-protein interaction networks, further defined molecular profiles of SLE patients with atherosclerosis from patients that remained plaque-free. Gene signature-derived interferon (IFN) scores were applied to investigate heterogeneous subgroups within the cohort as a measure of inflammation.

Results: Distinct monocyte gene and protein expression profiles were identified in SLE and enriched in biological pathways relating to extracellular matrices, including purinergic and cytokine signalling. Lipid regulatory mechanisms were enriched in SLE-P, whereas SLE-NP patient's transcriptome and proteome profiles were defined by pathways relating to inflammation. Specifically, the type-I IFN pathway was exclusively reduced in SLE-P compared to SLE-NP. IFN scores derived from published responsive gene expression signatures stratified patients into significantly distinct subgroups (high versus low IFN-response, p=0.0001) with 66% (N=14) of patients showing high IFN expression across multiple signatures not associated with age, ethnicity, or disease activity. However, IFN scores did not predict the presence of sub-clinical atherosclerosis and further heterogeneity was revealed with 46% of SLE-P patients showing a low IFN response (N=6). Further, a measure of plaque lipid content (echogenicity) was inversely correlated with IFN score (grey scale median, p=0.03, r=−0.8) which may reflect distinct plaque phenotypes between these subgroups relating to clinical presentation and risk of cardiovascular events.

Conclusion: Lipid dysregulation is a key mechanism that drives atherosclerosis pathology and genes and proteins relating to lipid metabolism distinguished SLE patients with and without subclinical atherosclerosis. Differences in levels of interferons and other inflammatory molecules may contribute to unique patterns of gene expression between SLE patients. A distinct subset of SLE-P patients showed low interferon expression, which may be suggestive of a dampened immune response in early subclinical CVD. Further elucidating the complexity of lipid dysregulation, inflammation and immune function in atherosclerosis in SLE will help improve patient stratification towards investigating the efficacy of anti-atherosclerotic therapies.

HPR Poster Tour: Moving together towards person-centred care

A long-list of 134 initial candidate questionnaire items was developed from the individual themes. These items were reviewed by a qualitative working group of patient research partners, researchers and clinicians to reduce duplication and ambiguity of items. The resulting 62 items were tested and refined by piloting with patient research partners, iterative rounds of cognitive interviews with patients with a range of rheumatic conditions from the UK, USA and Australia, and a linguistic translatability assessment, to define a draft questionnaire of 40 items.

OUTCOME MEASURES IN RHEUMATOLOGY APPLIED IN SELF-MANAGEMENT INTERVENTIONS TARGETING PEOPLE WITH INFLAMMATORY ARTHRITIS - A SYSTEMATIC REVIEW OF OUTCOME DOMAINS AND MEASUREMENT INSTRUMENTS

C. Hansen¹, B. A. Ebsen², A. De Thurah³, R. Christensen⁴, M. De Wit⁵, P. F. Cromhout⁶. "Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Glostrup, Denmark; University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; Aarhus University Department of Clinical Medicine, Aarhus, Denmark; Bispebjerg and Frederiksberg Hospital, Section for Biostatistics and Evidence-Based Research, the Parker Institute Copenhagen, Denmark; Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, University of Southern Denmark, Odense C, Denmark; 6Outcome Measures in Rheumatology ‘OMERACT’, Patient Research Partner, Amsterdam, Netherlands

Background: Self-management refers to the patient’s ability to manage a large range of consequences such as symptoms, medication, emotions, and preferable lifestyle changes coherently with living with a chronic disease. Evaluating the effect of interventions targeting to improve people with inflammatory arthritis (IA) self-management is a challenge because self-management interventions are complex and consensus on important outcomes is lacking. Solutions to these issues could be to consensus on a Core Outcome Set (COS) describing what outcomes are relevant and should be applied in future studies hereby lessening the heterogeneity between future studies. The purpose of this study was therefore to take the first actions in identifying possible candidate outcomes for such a COS.

Objectives: The aim was to identify, and map applied outcome domains and outcome measurement instruments from previous trials measuring the effect of self-management interventions targeting people with IA.

Methods: We performed an informative systematic literature review following guidance from the Handbooks described by ‘Outcome Measures in Rheumatology’ (OMERACT) and Core Outcome Measures in Effectiveness Trials (COMET) initiatives. Randomized and non-randomized trials describing their experimental intervention as “self-management” and included a population of adults (≥18 years) with at least 50% diagnoses with IA (Rheumatoid arthritis, Psoriatic arthritis, Spondyloarthritis) was included. Both screening of possible trials and data extraction was performed independently by two reviewers. Extracted data included: study characteristics, outcome domains and the corresponding measurement instruments. During analysis two reviewers simultaneously grouped and categorized domains and subdomains, and two senior researchers approved the categorization.

Results: Searches was performed 2021.02.08 on online databases, trial registries, conference abstracts and references of included trials. From a total of 2,502 records, we included 38 trials published between 1988 and 2021. The interventions were heterogeneous and patients primarily female, diagnosed with Rheumatoid arthritis, and a calculated mean age of 54 years. We identified 12 different outcome domains and sub-domains, covering 39 subdomains, collected with 119 different measurement instruments. The most frequently applied outcome domains were self-efficacy, pain, physical functioning/disability, anxiety and depression, quality of life, fatigue, global assessment/disease activity and coping. Please see Figure 1 for all outcome domains and sub-domains. The applied measurement instruments varied within each outcome domain with up to 10 different instruments applied to measure the same domain. Instruments were predominantly patient-reported outcomes.

Conclusion: The outcome domains and measurement instruments used in self-management trials were widely diverse and differ from the current general OMERACT Core Outcome Sets (COS) for IA conditions. Further steps towards the establishment of a COS to be reported in all self-management intervention trials will enhance the relevance and the subsequent impact on the body of evidence from these trials.

HOW DOES WEEKLY SUPERVISED GROUP EXERCISE CONTRIBUTE TO FULFILLING EXERCISE RECOMMENDATIONS IN PATIENTS WITH AXIAL SpondyloArthritis?

B. Hilberdink¹, M. Carbo², D. Paap³, S. Arends³, 4, T. P. M. Vliet Vlieland⁵, F. Van der Giesen¹, A. Spoorenberg¹, 4, S. Van Weely³. ¹Leiden University Medical Center, Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; ²University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; ³Saxion University of Applied Sciences, Department of Physical Therapy, Enschede, Netherlands; ⁴Medical Center Leeuwarden, Department of Rheumatology, Leeuwarden, Netherlands; ⁵Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands

Background: Supervised group exercise (SxE) has been recommended for people with axial spondyloarthritis (axSpA) since decades, but the proportion and type of axSpA patients that engage in SxE is unknown. In addition, the 2018 EULAR recommendations for physical activity advocate that people with axSpA should engage in aerobic, strength and mobility exercises according to public health physical activity guidelines. However, it is unclear if SxE contributes to fulfilment of these exercise recommendations.

Objectives: To compare characteristics, health status and fulfilment of exercise recommendations between axSpA patients with and without SxE.

Methods: Cross-sectional data from three Dutch axSpA study cohorts were analysed: two cohorts with patients recruited at rheumatology outpatient clinics (n=196 and n=153) in which participation in SxE was recorded (yes/no) and one cohort with only SxE participants (n=128). Assessments included sociodemographic and disease characteristics, health status (ASAS Health Index), spinal mobility and the ‘short questionnaire to assess health enhancing physical activity’
(SQUASH). The SQUASH was used to determine fulfilment of the public health recommendations for leisure-time aerobic exercise (≥150 min/week of moderate-intensity or ≥75 min/week of vigorous-intensity exercise) and for strength and mobility exercises (≥2 sessions/week). Differences between patients with and without SGE were analysed using the Mann-Whitney U test and the Chi-Square test. Multivariate regression models were performed to correct the association between SGE and fulfilment of the exercise recommendations for age, sex, employment and health status.

Results: In the two outpatient axSpA cohorts, 17 of the 349 patients (5%) participated in SGE. The total group of SGE participants (n=145) was significantly older, had longer disease duration, was less frequently employed, used less disease related medication and had worse spinal mobility than the patients without SGE (n=332). There were no significant differences in health status. AxSpA patients with SGE performed more minutes per week of aerobic exercise (median 420; IQR 285-660) than patients without SGE (median 283; IQR 120-540), p < 0.001. As shown in Figure 1, SGE participants fulfilled the recommendations for moderate-intensity aerobic exercise (89% vs. 69%, p < 0.001) and for strength and mobility exercise (44% vs. 29%, p < 0.01) more often than patients without SGE. However, the recommendation for vigorous-intensity aerobic exercise was fulfilled less often by the SGE participants (5% vs. 12%, p = 0.05). After correcting for age, sex, employment and health status, the differences in fulfilment of the moderate-intensity aerobic and strength and mobility exercise recommendations remained significant.

![Figure 1. Differences in meeting exercise recommendations between axSpA patients with and without SGE.](image)

**Conclusion:** SGE is used by just few and especially older axSpA patients and contributes to fulfilling recommendations for moderate-intensity aerobic as well as mobility and strength exercise. However, both in patients with and without SGE, only a minority fulfilled the recommendations for vigorous-intensity aerobic and strength and mobility exercises. Therefore, future promotion of physical activity should focus on implementing these types of exercise.

**Acknowledgements:** The authors would like to thank ASAS and the Dutch Arthritis Society for supporting the three cohorts.

Background: Assessments should be standard in individual as well as group physical therapy. The Ankylosing Spondylitis Association of Switzerland has translated the EULAR recommendations for physical activity (PA) in a concept for group exercise therapy, which, in addition to guidelines in all four fitness dimensions (aerobic, strength, flexibility, neuromotor function), also includes PA counselling and regular fitness assessments for the planning and documentation of the individual therapy progress as well for quality monitoring of the exercise groups.

Objectives: To evaluate the feasibility of the selected assessments across all four fitness dimensions, rating the acceptance, practicability, and integration by physiotherapists (PTs) and people with axSpA.

Methods: A feasibility study was conducted in four pilot exercise therapy groups. PTs performed the assessment battery, consisting of a) the Chester Step Test (CST) for aerobic fitness; b) the modified Core Strength Test for core strength; c) the Bath Ankylosing Spondylitis Metrology Index (BASMI) for spinal mobility and d) the Short Leg Strength Test (SLST) for balance, with the participants of the exercise therapy groups. Subsequently, the PTs and the participants with axSpA rated the acceptance, practicability, and integration by means of questionnaires. Acceptance was operationalised as satisfaction and perceived applicability, practicability was operationalised as feasibility and comprehensibility, and integration was operationalised as usefulness and repeatability. An ordinal scale with four answer options (very good, good, moderate, bad) and a free text field for comments was used. The categories ‘very good’ and ‘good’ were interpreted as positive evaluation. The feasibility of the assessments was defined based on three levels (I-III): with a positive evaluation of >80% (level I) a specific assessment was considered suitable, with a positive evaluation of 50-80% (level II) adjustments were necessary, with a positive evaluation of ≤50% (level III) a specific assessment was not considered suitable for group exercise therapy and a new choice had to be made.

Results: The BASMI was rated level I by people with axSpA and PTs, no adaptations were necessary. The CST was rated level I by people with axSpA and level II by PTs (too time consuming and failure-prone software), resulting in the adaptation that the test can now be performed without software, and a training will make the testing PTs more efficient. The modified Core Strength Test was rated level I by people with axSpA and level II by PTs (instructions unclear, leading to adaptations in the instruction manual). The SLST was rated level I by people with axSpA and level II by PTs (instruction “standing on one leg as long as possible” not useful for persons without balance deficit), leading to the adaptation that the test can be stopped after 60 seconds as the normal values are below that threshold.

Conclusion: From patient perspective, the feasibility of the tests was evaluated positive in terms of acceptance, practicability and integration (all level I). From PTs perspective some adaptations were necessary (level II, except BASMI). After the adaptations, the assessment battery can now be used in group exercise therapy for individuals with axSpA. In this way, the individual fitness status can be evaluated, leading to adaptations in the instruction manual. The SLST was rated level I by people with axSpA and level II by PTs (instructions unclear, leading to adaptations in the instruction manual). The BASMI was rated level I by people with axSpA and PTs, no adaptations were necessary, with a positive evaluation of >80% (level I) a specific assessment was considered suitable, with a positive evaluation of 50-80% (level II) adjustments were necessary, with a positive evaluation of ≤50% (level III) a specific assessment was not considered suitable for group exercise therapy and a new choice had to be made.

POS0045-HPR | HEALTHCARE PROFESSIONALS’ ATTITUDE TOWARDS REMOTE MONITORING

E. E. Kyvernberg Thomassen1, A. T. Tveter1, E. Kristianslund1, J. I. Berg2, N. Österäs1,2. Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology (NKRR), Oslo, Norway;2. Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway.

Background: The pandemic has accelerated the use of remote monitoring of patients (1), but there is still lack of knowledge in regards to barriers and facilitators of using remote monitoring among health care professionals. Patients with rheumatic diseases are monitored frequently by healthcare professionals, and follow-up strategies with less hospital visits could reduce the resource use.

Objectives: To explore healthcare professionals’ attitude, facilitators and barriers on use of remote monitoring in a specialist healthcare setting.

Methods: Approximately 100 employees at a department of rheumatology at a specialist healthcare setting were invited to complete an anonymous 22-item questionnaire in December 2021. To ensure anonymity, demographic data were limited to age (under/over 45 years of age) and current position (doctor, nurse, allied healthcare/leaders/secretaries). In addition, participants completed questions on frequency of use of video consultation, phone consultation and patient-reported software. For investigating attitudes, facilitators and barriers the participants also responded to 16 statements related to perspectives on the use of remote monitoring in patients with low and stable disease activity using a 10-point numeric rating scale (NRS) from 0=“Strongly disagree” to 10=“Strongly agree”. We developed the statements as facility or barriers for the use of video consultations and remote monitoring based on facilitators and barriers identified in previous research (2-4). The statements that had median score for agreement >8 were categorized as either facilitator or barrier and presented with median score and interquartile range (IQR).

Results: Seventy (70%) participants completed the questionnaire. In the study sample 44 % were under the age of 45, 35 % were doctors, 36 % nurses and 28 % were allied health professionals, secretaries, or leaders. None used video consultation on a daily basis, while 6 % used phone consultation daily. The participants had a positive attitude towards the use of remote monitoring in patients with low and stable disease activity (median: 9 (IQR: 8-10). For the remaining 7 statements the median scores were close to 5 – which indicates that they cannot be regarded as neither facilitators nor barriers. The remaining statements focused on appropriate internet connection, patients underreporting, scepticism towards new software and mistrust in technical systems. The facilitators and barriers for remote monitoring with median score >6 among healthcare professionals are presented with box-plots including median score and IQR in Figure 1.

Conclusion: Health care professionals showed positive attitudes towards the use of remote monitoring. Main facilitators on use of remote monitoring were: patients saving time, the belief of remote monitoring being part of future health care, remote monitoring being integrated with patient record system, patients wish to use remote monitoring and patient feeling less burdened by not visiting hospital. The main barriers were the inability to physically examine the patients and limitations related to the use of video consultation.

POS0046-HPR | THE EFFECT OF MEDITATION, MINDFULNESS, AND YOGA IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Slagter1, K. Demyttenaere2, D. De Cock1,2. 1KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium; 2KU Leuven, Psychiatry Research Group, Leuven, Belgium; 3KU Leuven, Clinical and Experimental Endocrinology, Leuven, Belgium.

Background: Non-pharmacological approaches additional to the pharmacological treatment of rheumatoid arthritis (RA) may include meditation, as well as yoga and mindfulness. These mind-body therapies (MBTs) create an interaction between the mind and body to enhance overall health. MBTs are perceived as valuable in RA management, but the extent of this contribution is unclear, as well as patients subgroups who benefit most from these MBTs.

Objectives: To investigate the effects of meditation, mindfulness, and yoga in patients with RA in a systematic literature review.

Methods: A search was performed in 4 databases (PubMed, Embase, Web of Science (core collection), Chinese and Korean collections) for studies. All studies were screened by two independent reviewers, via title/abstract/full text. Studies included any form of meditation, mindfulness and/or yoga as an intervention

MBT = Mindfulness-Based Cognitive Therapy; PMR = Progressive muscle relaxation; MBSR = Mindfulness-based stress reduction, MERT = mindfulness-based emotion regulation therapeutic program; MAAT = mindfulness-based emotion regulation therapeutic program QoL= quality of life

for patients with RA. Animal studies, case reports, non-English articles, qualitative studies, conference abstracts and articles without full text access were excluded. Each study was assessed for quality.

**Results:** Out of the 1,527 records, 23 studies were included after screening (Table 1). There was considerable heterogeneity, both in applied interventions and outcome measurements. All MBTs showed limited beneficial effects on psychological outcomes, such as vitality, functioning, and mental health, as well as on disease activity markers. Mindfulness-based interventions mainly reduced the subjective disease activity (e.g., joint tenderness/pain), rather than objective disease activity (e.g., swollen joints/CRP). RA patients with recurrent depression seemed to benefit more from these non-pharmacological therapies than patients without recurrent depression.

**Conclusion:** This systematic literature review found that MBTs have added value in RA management, especially for patients with depressive symptoms. These non-pharmacological approaches as an addition to treatment can be a way to diminish polypharmacy in specific RA patient populations.

GOALS AND ACTION PLANS ACROSS TIME AND PLACE IN PERSON-CENTRED REHABILITATION - A QUALITATIVE STUDY EXPLORING THE IMPORTANCE OF CONTEXT

L. Eegn, J. Thuesen, 1, 2, 3, University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sanderborg, Denmark; 1University of Southern Denmark; Danish Knowledge Centre for Rehabilitation and Palliative Care, Nyborg, Denmark; 2University College Absalon, Center for Nutrition and Rehabilitation, Naestved, Denmark

**Background:** Person-centeredness is increasingly addressed in relation to rehabilitation interventions (1). Collaborative goal setting and action plans are key elements in person-centered rehabilitation (2). There is a lack of knowledge about how person-centered goals and action plans developed during inpatient rehabilitation are experienced by the patients after discharge.

**Objectives:** This aim of the study was to explore how rheumatic patients experience the relevance of goals and action plans after discharge from an inpatient rehabilitation stay.

**Methods:** Individual narrative interviews were conducted with eight patients with a rheumatic disease three to five weeks after discharge from a two-week inpatient rehabilitation stay. A convenience sampling strategy was applied. In order to the exploratory nature of the study, we strived for variety in diagnoses, age and gender (3). One male and seven female patients participated, aged between 40 and 60 years. Six of the participants were active at the labor market and two were retired. Data collection, analysis and interpretation of data were performed within a phenomenological-hermeneutic framework inspired by Paul Ricoeur's interpretative philosophy (4).

**Results:** The analysis derived one core theme: 'The relevance of goals and action plans is contextual' and three subthemes: 'The hospitalization - a protected bubble,' 'Being at home - a harsh reality' and 'Need for support after discharge.' The participants expressed that during the admission there was time and peace to exercise and to take a rest. They were relieved from everyday duties, and received support from the interdisciplinary team in how to exercise and during conversations where they focused on management of their symptoms and illness. Back home after discharge, the participants experienced how their everyday life differed from the hospital context. They found it challenging to work further with goals and actions plans in their everyday life. They described in particular challenges with incorporation of new habits in everyday life, challenges they were not prepared for. On challenging days with pain and fatigue, the participants missed having someone to talk to. The participants suggested involvement of their relatives to support action plans and called for follow-up support to enable them to continue working to achieve their goals and action plans after discharge. They suggested support by telephone calls from a nurse from the hospital after one, two or three months after discharge to ask how they felt. They believed that it would be motivating and could support the outcomes of the admission.

**Conclusion:** Goals and actions plans are relevant for rheumatic patients, but must be adapted to the patient's everyday life. There is a need to plan during the hospitalization how goal and action plans can be transferred to the rheumatic patient's everyday life after discharge from a rehabilitation stay. Likewise, there is a need for follow-up support after discharge to support the patients to pursue their goals and cope with challenges in everyday life.

HEALTHCARE PROFESSIONALS’ EXPERIENCES OF LIFESTYLE MANAGEMENT IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS – A QUALITATIVE STUDY

K. Drake af Hagelsrum1, E. Mogard2, A. Bremernd3, E. Lindqvist2, I. Larsson4, 5, 6, 7, Halmstad University, School of Health and Welfare, Halmstad, Sweden; 3Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden; 4Skane University Hospital, Department of Rheumatology, Lund, Sweden; 5Spenhult, Research and Development Centre, Halmstad, Sweden; 1University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 1University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sanderborg, Denmark

**Background:** Rheumatoid Arthritis (RA) is a chronic inflammatory systemic disease that mainly affects joints and with symptoms such as stiffness, pain, and increased fatigue. RA also appears to be an independent risk factor for accelerated atherosclerosis with an increased risk of cardiovascular diseases,
why national and international guidelines recommend proper pharmacological treatment together with a healthy lifestyle (1). Supporting people with early RA to achieve and maintain a healthy lifestyle is therefore of great importance. However, few studies have explored healthcare professionals’ views of working with lifestyle management. A healthy lifestyle does not only have the potential to lower cardiovascular risk but may also improve a person’s quality of life.

Objectives: The aim of this study was to explore healthcare professionals’ experiences of lifestyle management in patients with early RA.

Methods: In this explorative qualitative study, individual interviews were conducted with 20 healthcare professionals who had a mean of 16 years of professional experience in the field of working with patients with RA. An interview guide with open-ended questions was used e.g.: “How do you work with lifestyle changes in patients with RA?” and “What theories do you use to support lifestyle changes?” Qualitative content analysis was used, where three categories emerged: “The importance of a well-functioning organization,” “The importance of teamwork” and “The importance of person-centered care” and nine subcategories, representing the overall content of the interviews (Table 1).

<table>

</tr>
</tbody>
</table>

Results: Healthcare professionals’ experiences of lifestyle management in patients with early RA included the importance of a well-functioning organization with supportive leadership, priority of lifestyle management, and competence development in lifestyle management. The importance of teamwork was emphasized including interdisciplinary team, professional expertise in lifestyle habits, and structured approach to lifestyle management. The healthcare professionals also highlighted the importance of person-centered care with individually tailored lifestyle management, shared decision-making, and patient engagement.

Conclusion: Healthcare professionals’ experiences of lifestyle management in patients with early RA reveal that commitment from both the management, the team, and the patient is important.

Background: Vaccination is considered efficient in controlling infections incl. SARS-CoV-2. Prior studies showed that patients receiving rituximab (RTX) with low B cell counts are at increased infectious risk (1) and risk of inadequate vaccination responses (2, 3). Thus, the ability to further define and predict vaccination responses in these patients may guide their optimal protection.

Objectives: To assess predictive biomarkers of vaccination responses upon SARS-CoV-2 vaccination in RTX treated patients.

Table 1. Number and % of respondents per each question and per each response category.

Conclusion: The patients were confident in the nurse-conducted diagnostic process and had profited from the diagnostic consultation focused on the explanation of FM and current treatment options. Thus, specially trained nurses contribute to the effectiveness of the FM diagnostic process and to patients’ satisfaction. This facilitates patients’ timelier access to treatment options.

DOI: 10.1136/annrheumdis-2022-eular.914
Methods: B cell characteristics before vaccination were evaluated to predict responses in 15 patients with autoimmune inflammatory rheumatic diseases receiving RTX. 11 patients with rheumatoid arthritis on other therapies (RA), 11 kidney transplant recipients (KTR) and 15 healthy volunteers (HC) served as controls. A multidimensional analysis of B cell subsets and a correlation matrix were performed to identify predictive biomarkers.

Results: Significant differences regarding absolute B cell counts and specific subset distribution pattern between the groups were validated at baseline. Here, the majority of B cells from vaccination responders of the RTX group (RTX IgG+) comprised naïve and transitional B cells, whereas vaccination non-responders (RTX IgG-) carried preferentially plasmablasts and double negative (CD27−/IgD−) B cells (Figure 1). Moreover, there was a positive correlation between neutralizing antibodies and absolute B cell numbers with B cells expressing HLA-DR and CXCR5 (involved in antigen presentation and germinal center formation) as well as an inverse correlation with CD95 expression and CD21low expression (marker for activation and exhaustion) on B cells.

Conclusion: Substantial repopulation of naïve B cells upon RTX therapy appears to be essential for an adequate vaccination response requiring germinal center formation. In contrast, expression of exhaustion markers (CD21 low, CXCR5-, CD95+) indicate negative predictors of vaccination responses. These results may guide optimized vaccination strategies in RTX treated patients clearly requiring antigen-inexperienced B cells for appropriate protection.

DIFFERENTIAL PHARMACODYNAMIC ALTERATIONS ACROSS TREATMENT WITH ABATACEPT OR ADALIMUMAB IN MTX-INADEQUATE RESPONDERS PATIENTS WITH EARLY RA: WHOLE BLOOD RNA-SEQ ANALYSIS OF THE EARLY AMPLE STUDY

C. Wu, Y. Li, N. Ray, M. A. Maldonado, R. Schafer, S. L. Bridges, W. Rigby, Y. Bykerk, J. Buckner, J. Liu. 1Bristol Myers Squibb, Translational Bioinformatics, Princeton, United States of America; 2Parexel International, IV/A, Durham, United States of America; 3Bristol Myers Squibb (at the time of analysis), Global Drug Development, Princeton, United States of America; 4Bristol Myers Squibb, Clinical R&D, Immunoscience, Princeton, United States of America; 5Bristol Myers Squibb, Translational Medicine, Princeton, United States of America; 6Hospital for Special Surgery, Department of Medicine, New York, United States of America; 7Dartmouth-Hitchcock Medical Center, Rheumatology Section, Department of Medicine, Lebanon, United States of America; 8Hospital for Special Surgery, Division of Rheumatology, New York, United States of America; 9Benaroya Research Institute at Virginia Mason, Center for Translational Immunology, Seattle, United States of America

Background: Despite advances in available novel pharmacologic agents for RA,1 the dearth of effective response predictors for specific therapies remains an unmet need. To inform clinical decision making, it is critical to define molecular signatures of these therapeutic agents by investigating their mechanisms of action (MoAs) and differential impacts on patients' immune systems. Adalimumab and abatacept are biologic DMARDs with distinct MoAs used to treat RA. A better understanding of the differential pharmacodynamic (PD) changes of these 2 agents may provide guidance for the selection of treatment options.2 The Early AMPLE (Abatacept versus adalimumab parison in bioLogic-naïve RA subjects with background MTX) study compared treatment with abatacept or adalimumab in a population of patients with early RA to explore differential PD effects; abatacept treatment resulted in numerically higher efficacy responses vs adalimumab after 24 weeks of treatment.3

Objectives: To investigate PD changes in response to treatment with abatacept or adalimumab, and to identify and differentiate the impact of each drug on modulation of immune cells at the molecular level.

Methods: The phase 4 Early AMPLE trial (NCT02557100) was a head-to-head comparison of treatment response to either abatacept or adalimumab in patients with early RA with an inadequate response to MTX, high anti-citrullinated protein antibody titers, and RF positivity, with or without shared epitope. Whole blood RNA sequencing (RNA-Seq) was conducted on samples collected from patients at different visits (day 1; weeks 4, 8, 16, 24, 28, 32, 40, 48). Differential gene expression analyses were performed using Limma-voom pipeline in R, adjusting for batch effect and sex. Over-representation tests were used to identify enriched Gene Ontology pathways. xCell, a gene signatures–based method learned from thousands of pure cell types, was applied for immune cell type deconvolution and enrichment analysis.

Results: PD and association analyses were performed for 14,540 protein-coding genes in 684 RNA-Seq samples (79 patients with RA at 9 visits). Baseline association analysis showed that 248 differentially expressed genes and 6 cell cycle–related pathways were significantly associated with baseline SDAI score. After treatment, gene-enrichment analysis demonstrated that twice as many genes and pathways were significantly altered in the adalimumab- vs abatacept-treated arm. Abatacept treatment decreased immune cell cycle gene expression while adalimumab treatment increased expression of these genes. The increases due to adalimumab were reversed after switching to abatacept (open-label period). Using gene signatures to identify key immune cell subsets (Figure 1), adalimumab therapy increased expression of genes defining several key immune cell types involved in RA disease development, including dendritic cells, T cells, and B cells; these effects were also reversed after switching to abatacept.

Conclusion: The differential gene expression seen after treatment with abatacept or adalimumab was noted in genes identified as correlating with RA disease activity. These findings may inform on the mechanism for the relatively greater clinical improvements seen with abatacept vs adalimumab in the Early AMPLE study. Abatacept treatment may selectively modulate genes that are relevant to disease pathology/progression, with the potential to restore the immune homeostasis dysregulated in RA. Our findings warrant further studies to investigate the potential positive correlation between RA-relevant PD effects and better therapeuetic outcomes.

Results: Regarding the role of TAng in vasculopathy, the frequencies of these cells were significantly lower in patients with RA-ILD+, SSc-ILD+ and other AD-ILD+, as well as with IPF in relation to HC (p<0.001, respectively, Figure 1). No differences between RA-ILD+ patients, SSc-ILD+ patients and HC were found (Figure 1). With respect to TAng involvement in fibrosis, TAng frequencies were similar in patients with RA-ILD+, SSc-ILD+, other AD-ILD+ and those with IPF (Figure 1). Nevertheless, patients with RA-ILD+ and SSc-ILD+ showed significantly lower TAng frequencies than those with RA-ILD+ and SSc-ILD+, respectively (p=0.006 and p=0.044, respectively, Figure 1). In this line, a TAng frequency of TAng was found in SSc-ILD+ and RA-ILD+ patients in relation with those with IPF (p<0.001 and p=0.003, respectively, Figure 1). Moreover, TAng frequency did not show significant correlation with EPC frequency in the whole cohort of AD-ILD+ patients.

Conclusion: TAng play a relevant role in the lung vasculopathy of RA-ILD+, SSc-ILD+ and other AD-ILD+. Interestingly, circulating TAng may be considered as a useful biomarker of the presence of ILD in patients with RA and SSc.

frequency of IgG and only a few patients had antibodies of more than one isotype targeting PL12, PL7 or EJ. The majority of anti-Ro52 positive IIM patients (n=52) only harbored IgG isotype. The combination of anti-Ro52 and anti-aARS autoantibodies was found in IIM patients (anti-Jo1 (n=19), -PL12 (n=2), -PL7 (n=3), and -EJ (n=4)). Most patients with such combination had anti-Ro52 IgG together with anti-aARS IgG or IgM in combination with IgA and/or IgM. The exception was observed for three anti-Jo1 positive patients who had the combination anti-Ro52 IgG with only anti-Jo1 IgM and one anti-PL7 positive patient who had anti-Ro52 IgA together with anti-PL7 IgA and IgG.

Conclusion: The frequency of the different autoantibody isotypes seems to be autoantigen dependent. Our results suggest that for anti-Ro52 autoantibodies in IIM it could be important to investigate additional autoantibody isotypes, as some patients only harbor autoantibodies of IgM or IgA isotypes but not IgG. The clinical relevance of the different antibody isotypes still needs to be determined.

POS0054 DYSFUNCTION OF REGULATORY B CELLS IN GIANT CELL ARTERITIS (GCA)

M. Stöcker1,2,3, U. Kiltz1,3, J. Braun1,3, B. Wilde1,1, Rhabdomyosarcoma Ruhrgebiet, Rheumatologic, Bochum, Germany; 2Augusta-Krankenanstalt Bochum, Pneumology and Infectious Diseases, Bochum, Germany; 3Ruh-Universität Bochum, Rheumatologie, Bochum, Germany; 4University Hospital Essen, Nephrology, Essen, Germany

Background: The pathophysiology of GCA is not clearly understood, but most research has pointed towards a major role of T cells with proinflammatory Th1 and Th17 cells as dominant drivers of disease. The role of B cells in the pathogenesis of GCA has not been much studied to date.

Objectives: To study the role of proinflammatory T cell mediators and anti-inflammatory regulatory B cells (Bregs) as their counterpart in patients with GCA compared to healthy controls (HC).

Methods: GCA Patients and HC were recruited prospectively and included after informed consent. Peripheral blood mononuclear cells were freshly isolated from whole blood and included into 3 experimental setups, using flow cytometry and fluorescent antibodies: (i) pro-inflammatory T cell mediators (IL-2, GMCSF, IL-17a, IFN-y), (ii) granzyme B production of Bregs after stimulation with different agents (anti-human IgG + IgM, IL-21, anti-CD40L) and (iii) the IL-10 production of Bregs were measured. Disease activity was defined as unequivocal evidence of cranial symptoms of GCA and/or increased concentrations of C-reactive protein and/or halo sign, leading to a change in therapy according to the treating rheumatologist. Statistical comparisons between groups were performed by the Mann-Whitney-U-Test and Spearman's rank correlation.

Results: A total of 47 GCA patients (14 with active disease and 33 in remission) and 49 HC were included (Table 1). CD4+ T cells of GCA patients with active disease produced less IFN-y than HC (p=0.016, Figure 1a). There was also a trend towards lower expression of IL-2 (p=0.18), GMCSF (p=0.1) and IL-17a (p=0.18) by CD4+ T cells from GCA patients compared to HC. Bregs of GCA patients produced lower amounts of granzyme B after stimulation with anti-human IgG and IgM compared to HC, and this was similar in active patients (p=0.04, Figure 1b) and in quiescent patients (p=0.021, Figure 1b). With other stimuli, including IL-21 and anti-CD40L, there was also a trend towards a lower expression. The IL-10 production of Bregs did not show substantial differences between groups. Importantly, the dose of glucocorticoids did not influence cytokine production of T-cells or B-cells.

1a: Interferon gamma expression of CD4+ T-cells / 1b: Granzyme B expression of Breg after anti-human IgG + IgM stimulation

Conclusion: The in vitro cytokine production of proinflammatory CD4+ T cells and anti-inflammatory Bregs after stimulation, especially regarding granzyme B production, showed some differences between patients and HC. A lower granzyme B production was found in patients with active disease indicating a lack of Breg-mediated suppressive capacity towards pro-inflammatory T cells. This finding may play a role in the pathogenesis of GCA.

**TFN-α REGULATION OF MIR-29B EXPRESSION IN CD14+PBMS AND ITS RELEASE OF PROINFLAMMATORY CYTOKINES IN RHEUMATOID ARTHRITIS**

D. Yun 1, D. Liu 1, Q. Gu 2

1The First Affiliated Hospital of Xi’an Medical University, Department of Rheumatology and Immunology, Xi’an, China; 2Luoyang Central Hospital Affiliated to Zhengzhou University, Department of Orthopedics, Luoyang, China

**Background:** It was found that the expression of mir-29b was significantly up-regulated in PBMs, and we tried to clarify TFN-α. The production of proinflammatory cytokines was induced by increasing the expression of mir-29b in CD14 + PBMs in patients with rheumatoid arthritis (RA), and by using TFN-α that the expression of mir-29b was significantly upregulated with the release of pro-inflammatory cytokines. **Methods:** (1) Cell experiment: PBMs from RA patients were collected and extracted for CD14 + cell expression labeling. Different doses of TNF-α were used to induce the expression of mir-29b in CD14 + PBMs and then produced pro-inflammatory cytokines. **Results:** The expression of TFN-α was significantly up-regulated in PBMs, and we tried to clarify TNF-α. The supernatant of cell culture was measured using a V-plex human cytokine 30-plex kit. (2) Grouping experiment of clinical intervention: 21 patients with RA diagnosis and 15 healthy volunteers were divided into three groups. TFN-α inhibitor group: RA patients treated with TFN-α inhibitor were collected (n=15); IL-6 monoclonal antibody group: RA patients treated with tocilizumab (n=6); Control group: healthy volunteers (n=15) were used as normal controls. PBMc was extracted from TNF-α inhibitor group for 6 months, IL-6 monoclonal antibody group for 6 months, and control group, respectively, to observe the difference of Mir-29b expression in CD14+PBMs of the three groups. **Conclusion:** The expression of mir-29b was dose-dependent and time-dependent with the incubation of TFN-α, and there was a significant difference (P < 0.05). Compared with the control group, the overexpression of mir-29b also led to an increase in the expression levels of a wide range of chemokines and proinflammatory cytokines (including IL-1α, IL-1β, TNF-α, IL-6, IFN-γ and IL-8) (P < 0.05). The expression of TFN-α in RA patients treated with TFN-α inhibitor was significantly reduced compared with that treated with Tocutuzumab (P<0.05). **Conclusion:** TFN-α inflammatory factors can induce the overexpression of mir-29b in RA patients, and then producing a large number of proinflammatory cytokines, which can aggravate the inflammation mechanism of RA. In RA patients, TFN-α inhibitors may partially reduce the inflammatory response through the TFN-α/CD14+PBMs/Mir-29b signaling pathway. Therefore, more attention should be paid to the expression of Mir-29b in TFN-α and CD14+PBMs in clinical practice, which may accurately indicate the state of immune disease in patients, and provide a basis for more accurate judgment of prognosis and the course of immunotherapeutic, as well as optimization of immunotherapy programs.

**GLOBAL STEROID METABOLISM IN MACROPHAGES: SHAPING INFLAMMATORY FUNCTION AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS**

1Institute of Clinical Sciences, University of Birmingham, Birmingham, United Kingdom; 2Institute of Clinical Sciences, University of Birmingham, Birmingham, United Kingdom; 3Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom; 4Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom

**Background:** Macrophages are key drivers of joint destruction and disease pathophysiology in rheumatoid arthritis (RA), where their inflammatory function is influenced by steroid hormones such as androgens and glucocorticoids (GCs). Local bioavailability of these steroids is determined by both systemic adrenal/gonadal synthesis and local metabolism in peripheral target tissues. The inflammatory regulation and function of steroid hormone metabolism, by key rate limiting enzymes in chronic inflammatory diseases such as RA remain poorly defined and could present new therapeutic targets.

**Objectives:** Characterise regulation of global steroid metabolism in macrophages in RA and determine its contribution to androgen and GC availability, macrophage function and disease activity.

**Methods:** Bulk and single-cell gene expression sequencing of FACS-sorted macrophages were analysed using previously published datasets from RA patients (27 female, 8 male) (1, 2). Gene expression of rate limiting steroid metabolism enzymes were assessed in macrophages and their subsets and correlated to clinical parameters of disease activity. Primary human monocyte-derived macrophages were polarised to non-inflammatory (M-CSF 20 ng/ml) and inflammatory activated (M-CSF 20 ng/ml, IFNy 20 ng/ml, TNF-α 10ng/ml) subsets and treated with active or inactive metabolites of GCs (cortisol/cortisone 100nmol/l) and androgens (androstenedione/testosterone/DHEA 100nmol/l; DHT 10nmol/l). Metabolism and functional effects were assessed in primary cultures and RA synovial fluids by liquid chromatography mass spectrometry, RT-qPCR and ELISA.

**Results:** Significant differentially expressed genes (DEGs) were identified in the GC and androgen metabolism pathways in synovial macrophages when stratified for high and low disease activity by DAS28-ERCP Expression of the GC-activating enzyme HSD11B1 and androgen activating enzyme SRD5A1 were significantly increased and positively correlated with disease severity. The androgen activating enzyme AKR1C3 was significantly suppressed and negatively correlated with disease severity. SRD5A1 and HSD11B1 expression were localised to S100A12+ macrophage and SPP1+ subsets associated with active RA, whilst AKR1C3 was primarily expressed by MerTK+ and TREM2+ subsets associated with RA remission. Inflammatory activation of primary macrophages decreased AKR1C3, and increased HSD11B1 and SRD5A1 expression. This result was in a shift in intracellular production of active GCs and androgens favouring increased levels of the active GC cortisol and the potent androgen DHT. The resulting changes in steroid ratios in inflammatory activated macrophages resulted in lower expression and release of the pro-inflammatory mediators TNF-α, IL-6 and IL-12 indicating functional significance. In vivo, metabolic changes favouring increased GC activation and reduced androgen activation correlated with disease severity determined by DAS28-CRP.

**Conclusion:** We have shown for the first time a role for macrophages and their tissue subsets in the inflammatory metabolism and activation of GCs and androgens in RA, which influence macrophage function and disease activity. Targeting these key metabolic pathways represents a novel route to modifying and suppressing disease activity and joint destruction in chronic polyarthritis.

**INDUCIBLE REGULATORY SYNOVIAL MACROPHAGES: A PROOF-OF-CONCEPT STUDY FOR A CELL-BASED TARGETED THERAPY FOR RHEUMATOID ARTHRITIS**

A. Small 1, K. Lowe 1, A. Ferrante 1, M. Smith 1, S. Proudman 1, H. Weedon 1, M. Wechalekar 2, 3Flinders University, College of Medicine and Public Health, Bedford Park, Australia; 2SA Pathology, Department of Immunopathology, North Adelaide, Australia; 3Flinders University, School of Medicine and School of Biological Sciences, Adelaide, Australia; 4Royal Adelaide Hospital, Department of Rheumatology, Adelaide, Australia; 5University of Adelaide, School of Medicine, Adelaide, Australia; 6Flinders Medical Centre, Department of Rheumatology, Bedford Park, Australia

**Background:** Infiltration of monocyte-derived macrophages into the synovial tissue (ST) is a hallmark of rheumatoid arthritis (RA) pathology. These macrophages promote inflammation, local joint effusion, and joint damage via the release of cytokines, oxygen reactive species, and tissue damaging enzymes. However, balancing these, are the ‘regulatory’ macrophages with inflammation-resolving properties, characterised by expression of CD206 and MerTK, dominant within the ST of healthy individuals as well as RA patients in remission (1). Indeed, these cells are believed to actively contribute to the maintenance of remission.
Macrophages are known to exhibit remarkable phenotypic plasticity and understanding the role of this characteristic in regulating inflammation and pathology remains a major challenge, as does the characterization of factors in the microenvironment that control such macrophage characteristics. Importantly, whether the infiltrating, inflammatory macrophages of the RA ST similarly exhibit such phenotypic plasticity, and whether this occurs during the process of remission, remains to be studied.

**Objectives:** We investigated the phenotypic plasticity of inflammatory synovial macrophages from patients with RA in vitro, investigating their ability to convert from an inflammatory macrophage population into ‘regulatory’ CD206/MerTK+ macrophages. These findings will provide a proof-of-concept as to the utility of these macrophage for a cell-based therapy in resolving inflammation in patients with RA, and will likely extend our understanding of the mechanisms of action of currently used therapeutics.

**Methods:** Synovial fluid (SF) mononuclear cells were obtained from patients with active early RA (<1 year; fulfilling 2010 ACR/EULAR classification criteria). Cryopreserved SFMCs were cultured for 48hr in the presence of 10ng/mL interferon(IFN)γ, 50ng/mL dexamethasone, 10μg/mL Infliximab, or diluent. Following culture, cells were immunostained and analysed using a Beckman Coulter CytoFLEX flow cytometer and FlowJo software. SF macrophages were characterised by expression of CD14, CD45, CD68 (Figure 1A), and proportions of CD206/MerTK+ macrophages measured.

**Figure 1. Synovial fluid CD68+ macrophage plasticity in vitro.** (A) Gating strategy depicting CD68+CD45−CD14+SF macrophage determination. (B) Proportions of CD206 and MerTK-expressing SF macrophages after 48hr culture in the presence of 10ng/mL interferon (IFN)γ, 50ng/mL dexamethasone or 10μg/mL Infliximab, or diluent. Data are representative of 5 individual experiments. Data were analysed by two-way ANOVA followed by Dunnett’s multiple comparison test. *p<0.05.

**Results:** Prior to culture, the CD68+ macrophage populations present in SF were found to be predominantly CD206/MerTK+. After 48 hours of culture, in the absence of any stimulus, there was an increase in proportions of CD206/MerTK+ macrophages. Treatment with either dexamethasone or anti-TNF (Infliximab) resulted in a further increase in proportions of CD206/MerTK+ M2-like macrophages. In contrast, culture with IFNγ induced a reduction in this population. Importantly, we found that the generated CD206/MerTK+ macrophages were phenotypically stable in culture following removal of these differentiating agents.

**Conclusion:** Our findings demonstrate that inflammatory SF cells are indeed able to polarise to regulatory, CD206/MerTK+ macrophages in vitro. The findings provide further mechanistic insights into the basis for the therapeutic benefits of glucocorticoids and TNF inhibitors, as well as providing initial proof-of-concept in the use of regulatory macrophages as a cellular-based therapy or therapeutic target for patients with RA.

**IDENTIFICATION OF NOVEL BIOMARKERS OF DISEASE ACTIVITY IN SYSTEMIC AUTOIMMUNE DISEASES THROUGH NEXT GENERATION PROTEOMICS**

C. Lopez-Pedreira1, L. Muñoz-Barrera1, A. Escudero Contreras1, M. Á. Aguirre-Zamorano1, P. Ortiz Buitrago1, C. López-Medina1, J. Calvo Gutierrez1, R. Ortega Castro1, F. U. Pilari1, I. Sanchez-Pareja1, M. C. Abalos-Aguilera1, N. Barbarroja Puerto1, E. Collantes Estevez1, C. Perez-Sanchez1, 1MIMIC/IIMBIC/ Reina Sofia Hospital/University of Cordoba, Rheumatology, Cordoba, Spain

**Background:** Systemic autoimmune diseases such as Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) are characterised by aberrant autoimmune and inflammatory processes, which are directly associated with the development and progression of these disorders. Novel biomarkers associated with the severity of these diseases are needed to better characterise and monitor their progression as well as to develop new and more effective therapeutic strategies.

**Objectives:** To identify common and distinctive novel biomarkers of disease activity in SLE and RA using high-throughput proteomics.

**Methods:** Serum samples from 170 patients, including 100 RA and 70 SLE, were profiled with the diagnostic technology ‘proteomeX’ extension assay’ from Olink, which analysed the levels of a panel of 92 inflammatory proteins. The methodology involves protein-specific antibodies linked to DNA-encoded tags which are amplified by RT-PCR.

Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and Disease activity score in 28 joints (DAS28) were assessed in SLE and RA patients respectively to characterise the disease status of all patients. Pearson’s correlation studies were performed using molecular information and clinical data to identify biomarkers of disease activity in each disease (FDR<0.05). Gene ontology enrichment analysis were performed to gain insight about the biological meaning of the biomarker signatures.

**Results:** SLE patients were characterised by an average SLEDAI of 5.2 (min-max, 0-29) while RA patients exhibited an average DAS28 of 4.6 (min-max, 15-78). Correlation studies revealed 14 proteins directly associated with SLEDAI in SLE patients, including ADA, CCL25, CD40, CDCP1, CSF1, FGF21, FLT3L, IL10RB, LAP-TGFβ1, MMP20, OPG, SLAMF1, TNFRSF9 and uPA. The subsequent enrichment analysis revealed that those molecules were associated with pathways such as cytokine-cytokine receptor interaction and MAPK signalling. In RA patients 26 proteins were directly correlated with DAS28 including AXIN1, BNGF, CASP8, CCL23, CD40, CSF1, CXCL9, CXCL10, CXCL11, EN-RAGE, FGF23, GDFN, HGF, IL10RB, IL15RA, IL6, IL7, IL9, IL20, IL23, LAP-TGFβ1, MCP3, OPG, SLAMF1, TNFRSF9 and TWEAK which were enriched in biological pathways such as chemokine-chemokine receptor interaction and Jak-STAT signalling.

The levels of five pro-inflammatory mediators were commonly associated with the disease activity status of both diseases such as IL10RB (receptor for IL10, IFNL2 and IFN3), CSF1 (macrophage colony-stimulating factor 1 receptor), SLAMF1 (Signaling lymphocytic activation molecule), TNFRSF9 and OPG (both, tumor receptor factor ligand superfamily members), suggesting a key common role of these molecules in the underlying molecular mechanisms associated with both diseases.

**Conclusion:** The analysis of the inflammatory profile of systemic autoimmune diseases with novel high-throughput proteomic technologies in non-invasive samples allow the identification of relevant biomarkers associated with the disease activity, which can improve the monitoring of the disease and the development of new targeted therapies.

**Acknowledgements:** Supported by ISCIII (PI12/005991 and RICOR-R21/0002/0033) co-financed by FEDER, Fundación Andalucía de Reumatología (FAR) and Consejería de Conocimiento, Investigación y Universidad de la Junta de Andalucía (P20_01367).

with non-specific LBP without SpA-features or MRI findings suggestive of axSpA. Diagnosis of axSpA was based on multidisciplinary team conference consensus after 3.5 years of follow-up (3). Plasma levels of 10 lectin pathway proteins (MBL, H-ficolin, M-ficolin, MASP-1, MASP-2, MASP-3, MAP44, and MAP19) were measured by immunossays developed in-house.

**Results:** Patient characteristics are shown in Table 1. Plasma levels of lectin pathway proteins L-ficolin, M-ficolin and CL-L1 differed significantly in the patient groups (p = 0.03). L-ficolin and M-ficolin were elevated in axSpA-patients compared with patients with SpA-features without axSpA and non-specific LBP patients (Figure 1). CL-L1 was elevated in axSpA-patients and patients with SpA-features without axSpA compared with non-specific LBP patients (Figure 1). No significant differences were observed for MBL, H-ficolin, MASP-1, MASP-2, MASP-3, MAP44, and MAP19. L-ficolin levels correlated with CRP in axSpA-patients (Spearman’s r=0.58, p=0.004). M-ficolin levels correlated weakly with CRP in non-specific LBP patients (Spearman’s r=0.36, p=0.003). Lectin pathway protein levels did not correlate with disease activity (ASDAS).

**Conclusion:** L-ficolin and M-ficolin are increased in patients with axSpA when compared with relevant control cohorts of patients with LBP or with SpA-features without axSpA. Our findings support a potential pathogenic role for complement in axSpA, however, further studies are needed to elucidate the diagnostic potential of the specific complement proteins.

**MEASUREMENTS OF COMPLEMENT ACTIVITY SPECIFICALLY THOUGH THE LECTIN-OR THE CLASSICAL PATHWAY IN PATIENTS WITH SLE**

M. C. L. Larsen1, A. Trolldborg1,2,3, E. Toonen2, L. Hurley1, Z. Prohászka4,5, L. Cervenak1, A. G. Hansen2, S. Thiel2, Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 2Aarhus University, Department of Biomedicine, Aarhus C, Denmark; 3Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 4Hycult Biotech, R&D Department, PB Uden, Netherlands; 5Semmelweis University, Department of Internal Medicine and Haematology, Budapest, Hungary; 6Semmelweis University-Edvöd Loránth Research Network (Office for Supported Research Groups), Research Group for Immunology and Haematology, Budapest, Hungary

**Background:** In systemic lupus erythematosus (SLE), the complement system (CS) is activated and thought to occur primarily through the classical pathway (CP) [1]. Traditionally, when diagnosing SLE or assessing disease activity, measurement of low C3 or C4 are used as proxies for complement activation [2]. However, measurement of C3 and C4 does not differentiate which complement pathway initiated the activation (i.e., the lectin pathway (LP), the CP, or the alternative pathway) [1, 3].

**C1-esterase inhibitor (C1inh) is one of the key regulators of the CS. C1inh is the exclusive inhibitor of the active CP enzymes C1r and C1s [4], and the major inhibitor of active LP enzymes MASP-1 and MASP-2 [5]. A possible way of assessing complement activation through a specific pathway, is by measuring activated enzymes complexed with C1inh in plasma, as these complexes only exist after complement enzyme activation.

**Objectives:** Our aim was to investigate and unravel LP and CP complement activation in SLE, by measuring the protein complexes MASP1/C1inh (LP specific activation) and C1r/C1inh (CP specific activation). Furthermore, we aimed to investigate whether there is an association between complement activity, disease activity (SLEDAI) and disease manifestations (lupus nephritis (LN)).

**Methods:** A cross sectional cohort of 150 patients with SLE fulfilling the 1997 ACR classification criteria for SLE were included from the out-patient clinic at the department of Rheumatology, Aarhus University Hospital (AUH), Denmark. Disease manifestations and disease activity using SLEDAI score was assessed at inclusion. Fifty healthy individuals included at the Blood bank, AUH, were used as controls. Both C1s/C1inh and MASP1/C1inh complexes were measured in all samples using two newly developed sandwich ELISAs (C1s/C1inh: cat# HK9399; MASP1/C1inh: Cat#3001). Hycult Biotech, Uden, The Netherlands. EDTA-samples from both SLE patients and controls were measured in duplicates.

**Results:** When comparing SLE patients to controls, we observed a difference in complement activation through the LP, where a lower mean MASP1/C1inh plasma concentration was observed (p<0.01). C1s/C1inh concentrations were significantly increased in active SLE patients (SLEDAI >6) when compared to SLE patients with low disease activity (SLEDAI <6, p<0.01) and correlated with SLEDAI score (r=0.285, p<0.01). C1s/C1inh concentrations were increased in SLE patients with active LN compared to non-active LN, however this not statistically significant (p=0.09).

No differences in MASP1/C1inh plasma concentrations were observed between active SLE patients and patients with low disease activity (p=0.11), nor did we observe a significant correlation with disease activity (r=0.12, p=0.13). In active LN, plasma concentrations of MASP1/C1inh were significantly elevated compared to non-active LN (p=0.02).

**Conclusion:** Our data suggest that the CP and the LP is activated in SLE. CS is generally activated in active SLE disease, whereas activation of the LP might be more specific to particular disease manifestations like LN.

Our findings warrant further research into activation of the specific pathways in relation to specific disease manifestations in SLE.

Lung involvement in Rheumatic Diseases

**POS0051** THE RISK OF LUNG CANCER IN RHEUMATOID ARTHRITIS AND IN RELATION TO AUTOANTIBODY POSITIVITY AND SMOKING

K. Chatzidionysiou1, D. Di Giuseppe1, J. Söderling1, A. Catrina1, J. Asklund1,2,3
1Karolinska Institute, Rheumatology Division, Department of Medicine Solna, Stockholm, Sweden; 2Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden

**Background:** Lung cancer is a common malignancy in rheumatoid arthritis (RA)1-3. Since smoking is a risk factor for both (seropositive) RA and lung cancer, it remains unclear whether RA, in itself, increases lung cancer risk.

**Objectives:** The aim of this study was to examine whether and to what extent the increased risk of lung cancer in RA may (or may not) be attributable to smoking, and to examine this association, both in terms of absolute and relative risks, specifically in relation to RA serostatus.

**Methods:** We performed a population-based cohort study of RA patients and individually matched general population reference individuals identified in Swedish registers and from the EIRA early RA study, prospectively followed for lung cancer occurrence 1995 through 2018. We calculated incidence rates and performed Cox regression to estimate hazard ratios (HR) including 95% confidence intervals (CI) of lung cancer, taking smoking and sero-status into account.

**Results:** Overall, we included 44,101 RA patients (590 incident lung cancers, 56 per 100,000, and 216,495 matched general population individuals (1,691 incident lung cancers, 33 per 100,000), corresponding to a crude HR (95% CI) of 1.76 (1.60-1.93). In subset analyses this increased risk remained after adjustment for smoking (HR=1.77, 95% CI 1.06-2.97). Compared to general population subjects who were never smokers, RA patients who were ever smokers had almost 7 times higher risk of lung cancer.

Positive autoantibody status was associated with an at least doubled risk of lung cancer in ACPA positive patients (vs. ACPA negative patients) and double seropositive (vs. double seronegative) patients after adjusting for comorbidities and smoking (Table 1).

The average absolute five-year risk of lung cancer counting from RA diagnosis was 1.3% in ever-smoking seropositive RA. At 20 years the risk was almost 3% in RA overall, and over 4% for patients who were ever smokers and had at least one autoantibody.

**Conclusion:** RA seropositivity is a strong and at least seemingly independent risk factor for lung cancer in RA. The absolute risks point to the potential for regular lung cancer screening, at least in seropositive RA.

Figure 1. FVC decline >10% and composite FVC and DLCO decline in the first and second 12+/-3 months within the four subgroups segregated by disease duration.

Conclusion: It was long believed that ILD burned out in late disease stages. In our analysis of ILD progression by four disease duration categories, we showed that ILD frequently progressed also in late disease stages. This has important implications for clinical practise, as SSc patients need to be regularly monitored for ILD progression independent of disease duration.

POS0064 INTERSTITIAL LUNG DISEASE ASSOCIATED WITH PRIMARY SJÖGREN’S SYNDROME IS FREQUENTLY PROGRESSIVE

1Oslo University Hospital, Rheumatology, Oslo, Norway; 2Oslo University Hospital, Radiology, Oslo, Norway; 3Oslo University Hospital, Respiratory Medicine, Oslo, Norway; 4Oslo University Hospital, Radiology, Oslo, Norway.

Background: Intestinal lung disease (ILD) in primary Sjögren’s syndrome (pSS) has been reported to be present in 10–15% of patients, but pSS-ILD behavior over time is not well characterized. 

Objectives: Assess the pattern of ILD in pSS, its disease behavior and factors associated with disease progression in a well-characterized pSS-ILD cohort.

Methods: All pSS patients from the Oslo University Hospital (OUH) were included if ILD was diagnosed on HRCT. Clinical characteristics, lung function tests including forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO) and ILD pattern on HRCT assessed by a radiologist were evaluated. We determined ILD progression, defined as absolute FVC decline >5% or absolute DLCO decline >10% over 12 +/−6 months and increasing extent of ILD on HRCT observed over the treatment period. Factors associated with disease progression were chosen based on expert opinion. Descriptive analyses were conducted.

Results: Of 702 pSS patients followed at OUH, we identified 60 pSS patients with ILD with 33 having follow-up of 12 months (Table 1). Patients with pSS-ILD were characterized by high number of males (18%) and by frequent other extra-pulmonary organ involvement (48%) (Table 1). Mean time from pSS diagnosis to ILD diagnosis was 74 years. In 67% ILD was diagnosed after pSS, in 13% simultaneously, in 11% before pSS diagnosis and in 9% unknown. In total, 28 (47%) were diagnosed with lymphoproliferative interstitial pneumonia (LIP) and 32 (53%) with reticular pattern on HRCT. Mean time follow-up of 10.9 months (SD 4.2), 7/33 (21%) showed a FVC <5% decline, 9/32 (28%) a DLCO >10% decline and 12 (36%) had at least one of these defined lung function declines on standard of care treatment. Treatment was registered as ever used and by any indication. Over an observation period of 15.4 (SD 10.6) years, 27/47 (45%) showed any ILD progression on HRCT. HRCT pattern was not associated with risk of >10% DLCO decline or ILD progression on HRCT. >5% FVC decline occurred more frequently in LIP compared to other patterns (LIP: 6/17 (35%) vs 1/16 (6%), p=0.041). Factors significantly associated with ILD progression on lung function included higher baseline FVC (99% (SD16.4) vs 87% (SD14.9), p=0.032), higher DLCO (81% (SD13.1) vs 67% (SD17.4), p=0.020), increased CRP (2/10 (20%) vs 0/16 (0%), p=0.045) and presence of polyneuropathy (2/9 (22%) vs 1/17 (6%), p=0.045).

Conclusion: A substantial number of patients with pSS-ILD progressed during the time of observation. This highlights the importance of close monitoring and active consideration of treatment options in pSS-ILD. Recommendations for disease management including screening, diagnosis, disease monitoring and treatment for pulmonary involvement in pSS are lacking to date, but are highly needed.

POS0065 EPIDEMIOLOGY OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC LUPUS ERYTHEMATOSUS IN FRANCE: A NATION-WIDE POPULATION-BASED STUDY OVER 10 YEARS

A. Mageau1, B. Crestani2, J. F. Timfi3, T. Papo1, K. Sacre1.  
1Université de Paris Bichat, Médecine Interne, Paris, France; 2Université de Paris Bichat, Pneumologie, Paris, France; 3Université de Paris Bichat, Réanimation Medica, Paris, France.

Background: Data regarding interstitial lung disease (ILD) in the setting of systemic lupus erythematosus (SLE) are limited.

Objectives: We used a nation-wide database to determine the incidence and the prevalence of ILD in SLE patients.

Methods: Characteristics of all SLE inpatients admitted between 2011 and 2012 in France were analyzed through the French medico-administrative database. Features associated with the presence of ILD were studied. Cox proportional hazard model was used to look for the impact of ILD on survival from the first stay to 2020. The incidence rate of ILD in SLE was estimated by analysing the onset of ILD from 2013 to 2020 in SLE patients who had no evidence of ILD in 2013.

Results: Between 2011 and 2012, 10,460 SLE patients had at least one hospital stay and could be traced until 2020. Among them, 1,34 (1.2%) had an ILD diagnosis at baseline. The frequency of ILD in SLE was higher in patients who had an associated autoimmune disease – such as Sjögren’s syndrome or systemic sclerosis (29.9% vs 5.9%; p<0.0001). ILD was associated with an increased risk of death in SLE after adjustment on comorbidities in the multivariable analysis (HR [CI95] 1.992 [1.420-2.794]; p<0.0001). Among the 31,029 SLE patients with no evidence of ILD at baseline, ILD occurred in 795 SLE patients (2.6%) between 2013 and 2020. The incidence rate of ILD in SLE was 10.26 for 1000 patient-years [CIRK: 10.24-10.28].

Conclusion: In SLE, ILD is exceedingly rare, often associated with another systemic autoimmune disorder and appears as a major risk factor for death.

POS0066 THE PHENOTYPE OF MIXED CONNECTIVE TISSUE DISEASE PATIENTS HAVING ASSOCIATED INTERSTITIAL LUNG DISEASE

G. Boleti1, S. Reiseter2, A. M. Hoffmann-Vold3, A. Mirouel2, P. Cacoub2, M. Matsuuc-Cernici2,5, M. Silván-Santo10, J. E. Fonseca2,9, V. Riccieri2, E. Le Tallec10, A. Lescoat10, J. L. Tandai11, I. Castelví11, P. Airo12, M. Kuzwana13, H. Kavosti11, J. Avouac11,15, Y. Allarone11,15, 1Université de Paris, Hôpital Cochin, Rheumatology, Paris, France; 2Martina Hansen Hospital, Department of Rheumatology, Barum, Norway; 3Oslo University Hospital, Rheumatology, Oslo, Norway; 4Groupe Hospitalier Pitité-Salpêtrière, AP-HF, F-75013, Department of Internal Medicine and Clinical Immunology, Paris, France; 5Inserm, 6Inserm, 7Inserm, 10Inserm, 11Institut Cochin, CNRS UMR8104, INSERM U1016, Paris, France.

Background: Mixed connective tissue disease (MCTD) is a rare autoimmune condition characterized by Raynaud’s phenomenon, positivity of autoantibodies
Objectives: To compare two distinct populations of MCTD patients with and without associated ILD and to identify predictive factors for lung progression and severe outcomes.

Methods: International multicenter retrospective study (12 tertiary hospitals). To be included, patients were required to fulfill at least one MCTD international classification criterion (4). ILD was defined by the presence of typical chest high-resolution computed tomography (HRCT) abnormalities. Patients were divided into two groups: with or without ILD, at a ratio of 1:1 and matching on disease duration (+/- 2 years).

Results: 300 patients were included. Mean age at MCTD diagnosis was 39.7±15.4 years and 191 (63.7%) were women. At baseline, we identified several variables associated with the presence of ILD: at older age (42.2 vs 37.5 years, p=0.01), scleroderma-like phenotype (38.7 vs 27.3%, p=0.03), upper gastro-esophageal (GI) symptoms (54.7 vs 30.7%, p<0.001), forced vital capacity (FVC) <80% (80.4 vs 95.3%, p<0.0001), diffuse opacity for carbon monoxide (DLCO) <80% (62.4 vs 74.8%, p=0.0001), anti-topoisomerase antibodies (6 vs 0 patients, p<0.01), SSA/Ro antibodies positivity (29.3 vs 19.3%, p=0.02), cryoglobulinemia (5.3 vs 13.0%, p=0.04) and elevated C-reactive protein (CRP) >5mg/L (5.4 vs 27.8%, p<0.001). Among the previous variables older age (OR 1.03, 95% CI 1.01 to 1.05), upper GI symptoms (OR 1.92, 95% CI 1.12 to 3.32) and CRP >5mg/L (OR 6.75; 95% CI 1.7-26.4, p=0.006).

Conclusion: In this large international cohort of patients with MCTD, we identified several factors associated with ILD development. Our findings highlight a high risk of mortality in MCTD-ILD patients and that digital ulceration seems to be at risk of more progressive ILD.

DOI: 10.1136/annrheumdis-2022-eular.1351
Results: The median (IQR) age of the patients was 52.0 (43.5-58.5) years and 60 (75.0%) were women. Baseline median score of whole lung-QILD and most severe zone-QILD were 28.1% (19.1-43.8) and 68.0% (45.5-81.8), respectively, and QILD score showed significant correlations with pulmonary function tests (r=-0.349, p=0.002 for % predicted forced vital capacity; and r=-0.381, p=0.001 for % predicted diffusing capacity for carbon monoxide). The individual time-estimated yearly ∆QILD score between first 2 visits presented that approximately half of the patients showed improvement or stability in QILD scores; however, when patients were sorted by visual assessment in IILD subtype on HRCT, approximately two-thirds of the patients with usual interstitial pneumonia (UIP) pattern were aggraved in QILD scores and less than half of subjects with nonspecific interstitial pneumonia and organizing pneumonia were aggraved (Figure 1, 80% for UIP vs. 44.4% for non-UIP, p=0.013). There was no immunosuppressive drugs related to meaningful improvement in QILD scores during first 2 visits. Notably, we observed significant aggravation of QILD scores in sarcoid patients (n=7, median time-estimated whole lung-yrary QILD 20.3 (2.7-38.4)) compared with sarcoid non-users (n=73, median time estimated whole lung-yrary ∆QILD -1.2 (-8.3-6.5)). Among 80 patients, 6 (7.5%) were died due to various lung complications. Higher baseline QILD scores were noted in deaths (median whole lung-QILD 45.4 (32.9-56.5)) than in survivors (median whole lung-QILD 26.9 (19.0-42.4)), albeit not significant (p=0.084). Poor survival rate was observed in patients with high grade of ground glass opacity by visual assessment in right upper lobe (log-rank test, p=0.042). Among subgroup of patients with 3 serial HRCT scans (n=41), dynamic changes of four distinct patterns (improving, worsening, convex, and concave) were observed.

Methods: Overall chest HRCT, lung function and skin score changes were evaluated in 33 consecutive dSSc-patients before and after aHSCT during yearly routine follow-up between January 2000 and September 2016. Two independent radiologists blindly assessed the ILD extent using semi-quantitative Goh and Wells method (2), the widest esophageal diameter (WED) and the esophageal volume (EV) on HRCT. Patients were retrospectively classified as radiological responders or non-responders at 24 months after aHSCT according to the stability or a 5% or more decrease of HRCT IILD extent. Two by two time point comparisons after versus before aHSCT were performed using linear regressions.

Results: Twenty-four months after aHSCT, HRCT median [IQR] IILD (2 [-10.3; 0] points, p=0.0002) and ground-grass opacities (-2.1 [-8.3; 0] points, p=0.02) extent scores had improved, with 18 patients radiological responders (probability of response 0.78, 95% CI (0.580,0.90), whereas median WED (from 24.5 [18.29] to 28 [19.33] mm; p= 0.005) and EV (from 19 [13.30] to 30 [13; 58] mm2, p=0.01) increased significantly. Kaplan-Meier analyses showed a trend towards better 5 years survival rates (100% versus 60%; HR 0.23 95%CI 0.03 to 1.62, P = 0.11) among radiological responders versus non-responders at 24 months.

Conclusion: Real-world data analysis confirmed significant HRCT SSc-ILD improvement 24 months after aHSCT, although esophageal dilatation worsened requiring specific attention.

Disclosure of Interests: None declared

Figure 1. Cleveland dot plot of individual time-estimated yearly ∆QILD during first 2 visits.

Conclusion: The changes in QILD score in IIM-ILD are dynamic and present different by visual assessment. QILD score has the potential for evaluation of the severity changes, prognosis and medication response in patients with IIM-ILD.
Table 1. Adverse events (irrespective of causality) reported over 52 weeks in patients with ICSSC and ILD in SENSCIS and SENSCIS-ON.

Conclusion: The change in FVC in patients with ICSSC and ILD who received nintedanib over 52 weeks, and the safety profile of nintedanib, in SENSCIS-ON were similar to that observed in patients with ICSSC and ILD who received nintedanib in SENSCIS. These analyses support a continued effect of nintedanib on slowing decline in FVC and the ability to manage adverse events of nintedanib in patients with ICSSC and ILD over the longer term.

Background: Pulmonary interstitial disease (ILD) is very common in connective tissue disease (CTD). Different subtypes display significant differences in prognosis. Pirfenidone (PFD), the targeted anti-fibrosis and anti-inflammatory drug, started to apply in CTD-ILD, while its strategy of combination with immunotherapy, bridging time and service time are worth discussing.

Objectives: To evaluate the efficacy and safety of PFD combined with immuno-suppressant (IS) in the treatment of several CTD-ILD.

Methods: 111 CTD-ILD patients were involved from Aug 2019 to Dec 2021 (ClinicalTrials.gov Identifier NCT04928586), including systemic sclerosis (SSc, n=30), inflammatory myopathy (IM, n=51), rheumatoid arthritis (RA, n=17) and other CTDs (such as systemic lupus erythematosus, spondylitis, n=13). Patients were treated with relative stable dose of glucocorticoid (GC) and/or IS since screening. After the evaluation of HRCT, pulmonary function (FVC%) and changes in SSc, IIM, RA and other CTD-ILD from baseline.

(B) changes in SSc, IIM, RA and other CTD-ILD from baseline. *p < 0.05, compared to no PFD treatment group.

Figure 1. The changes of FVC% and DLco% in PFD treated CTD-ILD for 24 weeks. (A) FVC% changes in SSc; IIM, RA and other CTD-ILD from baseline. (B) DLco% changes in SSc, IIM, RA and other CTD-ILD from baseline.
New therapeutic avenues in psoriatic arthritis

**CONSISTENT LONG-TERM GUSELKUMAB EFFICACY ACROSS PSORIATIC ARTHRITIS DOMAINS IRRESPECTIVE OF BASELINE PATIENT CHARACTERISTICS**

**Department:** University of British Columbia, Vancouver, Canada; 2Arizona Arthritis & Rheumatology Associates, Rheumatology, Phoenix, United States of America; 3Michigan Medicine Rheumatology Clinic, University of Michigan Medical School, Rheumatology Internal Medicine, Ann Arbor, United States of America; 4Brigham and Women's Hospital, Division of Rheumatology and Immunology, Harvard Medical School, Dermatology and Medicine, Boston, United States of America; 5Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America; 6Drexel University College of Medicine, Rheumatology, Philadelphia, United States of America; 7McGill University, Pediatrics, Montreal, Canada; 8JSS Medical Research, Inc, Scientific Affairs, Montreal, Canada; 9University of Saskatchewan, Community Health and Epidemiology, Saskatoon, Canada; 10Janssen Research & Development, LLC, Immunology, San Diego, United States of America; 11Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; 12Janssen Cilag Global Medical Affairs, Immunology Global Medical Affairs, Issy-les-Moulineaux, France; 13University of New South Wales, Sydney, Australia; 14Swedish Medical Center/ Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America

**Background:** Psoriatic arthritis (PsA) patients (pts) with differing baseline (BL) characteristics may vary in their response to treatment. In the phase 3 DISCOVER-1 and DISCOVER-2 studies, guselkumab (GUS) significantly improved joint symptoms, skin disease, enthesitis, dactylitis, physical function, and quality of life at Week (W) 24 in pts with PsA.1,2 Clinical responses across these disease domains were maintained or increased with GUS at W52,3,4 regardless of BL pt demographics, disease characteristics, or conventional synthetic disease-modifying antirheumatic drug (csDMARD) use.5 Durable efficacy with GUS through W100 across multiple disease domains was observed.6

**Objectives:** Assess both BL predictors of, and by BL pt subgroups, GUS efficacy across PsA disease domains through W100 of DISCOVER-2.

**Methods:** Biologic-naïve adults with active PsA despite standard therapies were enrolled in DISCOVER-2 (swollen joint count [SJC] ≥5 & tender joint count [TJC] ≥5, C-reactive protein [CRP] ≥0.6 mg/dL). Pts were randomized: 1:1 to GUS 100 mg at W0, W4, then QW (PBO) or placebo (PBO).7 GUS effects on joint, skin, enthesitis, dactylitis, spinal pain, and disease severity endpoints (change in Disease Activity in PsA [PsA-DAPSA], SJC, and TJC scores; Psoriasis [PsO] Area Severity Index [PSI] score) were compared with BL pts (psA-DAPSA, SJC, TJC, CRP level, %BSA, and PALI score) at W100.

**Results:** 442 (90%) GUS-randomized pts completed study treatment through W100.7 Among the BL predictors of long-term GUS efficacy assessed (see above), only PsA duration (p=0.032), SJC (p<0.001), and TJC (p<0.001) were significant predictors of long-term (BL to W100) GUS score change.8-10 Significant predictors of long-term (BL to W100) GUS score change included %BSA (p=0.002), PALI (p=0.008), and PsA-DAPSA use (p=0.014) with significant predictors of long-term (BL to W100) GUS score change and none significantly predicted long-term PALI score change. In pooled GUS pts (Figure 1), statistically significant improvements from BL to W100 in PsA-DAPSA, SJC, TJC, and PALI scores were observed across both BL strata, including those indicating more extensive or severe disease, in pooled GUS Q4W+Q8W pts (Figure 1, p<0.001) and within each dosing group. Similar improvements were observed for other continuous endpoints assessed (change in Psoriatic Arthritis Disease Activity Score [PsADAS], SJC, TJC, spinal pain, and dactylitis score).

**Conclusion:** GUS significantly improved PsA signs and symptoms through W100 across all BL subgroups evaluated, including pts with highly active disease, and regardless of dosing regimen.

**POS0073**

**COMPARISON OF TIME FROM METHOTREXATE INITIATION TO START OF A BIO/TARGETED DISEASE MODIFYING ANTIRHEUMATIC DRUG (b/tsDMARD) IN PSORIATIC ARTHRITIS VERSUS RHEUMATOID ARTHRITIS. A NATIONWIDE REGISTER-BASED STUDY.**

U. Lindström1, D. Di Giuseppe2, S. Exarchou1, G. M. Alenius2, T. Olofsson3, E. Klingberg4, L. T. H. Jacobsson5, J. Askling6, J. K. Wallman3, Sahlgrenska Academy at University of Gothenburg, Rheumatology and Infarmnation Research, Gothenburg, Sweden; Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden; Umeå University, Department of Public Health and Clinical Medicine/Rheumatology, Umeå, Sweden; Lund University, Skane University Hospital, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden

**Background:** In Sweden, methotrexate (MTX) is recommended as first-line DMARD for both psoriatic arthritis (PsA) and rheumatoid arthritis (RA). Whereas in RA the use of MTX monotherapy is supported by efficacy data from placebo-controlled trials. Therefore, the use of MTX in PsA is mostly based on clinical experience and results from studies not primarily designed to evaluate MTX efficacy.

**Objectives:** To compare time from MTX initiation until start of a biological or targeted synthetic DMARD (b/tsDMARD), as marker of insufficient MTX response, in previously DMARD-naïve, incident cases with PsA and matched, corresponding, reference subjects with RA.

**Methods:** Patients with PsA, having collected a prescription of MTX as their first ever DMARD any time between 2011 through 2018, and with a first ever MTX diagnosis in the Swedish National Patient Register within two years prior to this date, were included. Each individual was required to have a visit in rheumatology, but no visit in dermatology, within 6 weeks prior to MTX initiation, to ensure that PsA rather than psoriasis was the main reason for MTX treatment. For each individual with PsA, a corresponding individual with incident RA was identified, matched on sex, age, and year of MTX initiation. Only PsA cases with an identified RA comparator were included. All individuals with a diagnosis indicating axial spondyloarthritids prior to MTX start were excluded. The data were enriched through linkage to other national registers.

**Results:** Time until start of a b/tsDMARD was compared for PsA and RA through crude survival curves and conditional Cox-regression, crude and adjusted for comorbidity, level of education and patient global health. The crude survival curves for time from MTX initiation until start of a b/tsDMARD were identical for PsA and RA, Figure 1A. The adjusted HR for starting a b/tsDMARD in PsA compared with RA was 0.99 (95% CI 0.90-1.09). No calendar time trends were observed (Figure 1B and C).

**Conclusion:** In this study, the risk of escalating treatment from MTX, by adding or switching to a b/tsDMARD, was identical in PsA cases and matched RA controls. This supports a good response to MTX in PsA, similar to that in RA. Due to the matching, neither the results from the PsA nor the RA populations may be fully generalizable.

POS0074

**IMMUNOLOGICAL DIFFERENCES BETWEEN PSA PATIENTS WHO ARE TUMOR NECROSIS FACTOR INHIBITOR-NAIVE AND WHO HAVE INADEQUATE RESPONSE TO TUMOR NECROSIS FACTOR INHIBITORS**

1University of Glasgow, Institute of Infection, Immunity and Inflammation, 2Wayne State University, Detroit, MI, USA, 3Mayo Clinic, Rochester, MN, USA, 4University of Michigan, Ann Arbor, MI, USA, 5Brigham and Women’s Hospital, Boston, MA, USA, 6University of Kentucky, Lexington, KY, USA, 7University of Buffalo, Buffalo, NY, USA, 8Rush University, Chicago, IL, USA, 9University of Colorado School of Medicine, Aurora, CO, USA, 10University of Gothenburg, Gothenburg, Sweden, 11Paracelsus Medical University Munich, Munich, Germany, 12Janssen Research & Development, LLC, Titusville, NJ, USA, 13University of Alabama at Birmingham, Birmingham, AL, USA, 14University of California San Diego, La Jolla, CA, USA, 15University of Minnesota, Minneapolis, MN, USA.
Background: A better understanding of the immunological differences between psoriatic arthritis (PsA) patients (pts) who are tumor necrosis factor inhibitor (TNFi)-naïve & who have inadequate response to TNFi (TNFi-IR) may guide treatment choices. In DISCOVER-1, benefit of the IL-23/17 pathway in TNFi-IR pts was seen in adults with active PsA. The Phase 3b COSMOS study of GUS Q8W vs PBO in TNFi-IR PsA pts corroborated these findings.2

Objectives: Assess baseline (BL) molecular differences between TNFi-naïve & -IR PsA pts & investigate GUS pharmacodynamic (PD) effect on cytokine expression over time in the cohorts.

Methods: Serum samples collected from consenting biomarker substudy pts in DISCOVER-1 (TNFi-naïve [n=101] & -IR [n=117]), DISCOVER-2 (TNFi-naïve [n=150]), & COSMOS2 (TNFi-IR [n=76]) were analyzed for selected serum cytokine levels. TNFi-IR pts in this post-hoc analysis had active PsA & discontinued 1-2 TNFi due to inadequate efficacy; these pts required a TNFi-specific washout period prior to starting GUS. PD effect of GUS Q8W on cytokine levels was assessed. Differential BL cytokine expression compared between the TNFi-IR & TNFi-naïve cohorts with available cytokine levels & clinical response (Psoriasis [PsO] Area & Severity Index 75% improvement from BL [PSA75] & American College of Rheumatology 20% improvement [ACR20]). GUS effect on cytokine levels were analyzed with a General linear model & Spearman linear regression.

Results: BL pt demographics, disease characteristics, & conventional synthetic disease-modifying antirheumatic drug (csDMARD) use were comparable between TNFi-naïve (DISCOVER-1 & -2, N=251) & -IR (DISCOVER-1 & COSMOS, N=93) pts, with differences in mean PASI score (8.9 vs 12.5), swollen joint count (SJC) (11.7 vs 10.3), PsA duration (16.7 vs 20.4 yrs; Table 1). BL serum IL-22 & TNFs for pooled treatment groups were higher in TNFi-IR than -naïve pts (p<0.05). At W24, GUS reduced IL-22, IL-17A/IL-6, C-reactive protein (CRP), & serum amyloid A protein to similar levels for pooled treatment groups.

Conclusions: Elevated BL IL-22 expression & association between BL IL-22 levels & W24 PASI75 response, & a W24 trend for an association between upregulated BL IL-22 & ACR20 response, in TNFi-IR pts seen in this exploratory analysis, may suggest increased involvement of the IL-23/17 pathway in TNFi-IR pts. GUS showed comparable & significant PD effects for TNFi-naïve & -IR pts consistent with observed clinical responses.

Data are mean (SD) unless otherwise noted. *Ps with serum CRP level ≥0.3 mg/dL, SJC ≥3, & TJC ≥3 (to mimic D1 inclusion criteria). JC= tendon joint count.
Background: Treatment options for psoriasis (PsO) and psoriatic arthritis (PsA) have evolved significantly since the era of biologics. Clinical trials (mainly placebo-controlled for 12 to 16 weeks) are inadequate to assess the relative long-term efficacy of biologics and are often insufficient regarding safety.

Objectives: To assess the long-term persistence of different biologic classes to treat PsA and PsO.

Methods: This nationwide cohort study involved the administrative healthcare database of the French health insurance scheme linked to the hospital discharge database. We included, in two sub-cohorts, all adults with PsA and those with PsO, who were new users of biologics (not in the year before the index date) during 2015-2019. We excluded patients hospitalised for PsO in the PsA cohort and for PsA in the PsO cohort in the year before the index date. Persistence was defined as the time from biologic initiation to discontinuation and was estimated by the Kaplan-Meier method. Comparison of persistence by biologic class involved using propensity score-weighted Cox models (IPTW) and adjustment on specific systemic non-biologics (time-dependant variables).

Results: We included 6,531 patients with PsA (mean age 49±13 years, 45% male); 4,974 (76%) starting a TNF inhibitor, 803 (12%) an IL12/23i and 754 (12%) an IL17i. Overall 3-year persistence rates were 36% and 41% for PsA and PsO (Figure 1). After IPTW and adjustment, IL17i was associated with higher persistence than TNFi for PsA (weighted hazard ratio [HRw] 0.70, 95% confidence interval [CI] 0.68-0.73) and lower persistence than IL12/23i for PsO (HRw 0.76, 95% CI 0.72-0.80), with no difference observed for PsA. IL17i also has better persistence than IL12/23i for PsA, with IL17i persistence being higher than TNFi (16% vs 12%) and IL12/23i (16% vs 12%). Overall 3-year persistence rates were 36% and 41% for PsA and PsO (Figure 1). After IPTW and adjustment, IL17i was associated with higher persistence than TNFi for PsO (weighted hazard ratio [HRw] 0.70, 95% confidence interval [CI] 0.58-0.85) and PsO (HRw 0.78, 95%CI 0.73-0.83) and than IL12/23i for PsA (HR 0.69, 95CI 0.55-0.87). We found no difference between IL17i and IL12/23i for PsO. IL12/23i had better persistence than TNFi for PsO (HR 0.76, 95%CI 0.72-0.80), with no difference observed for PsA.

Conclusion: This real-life study suggests a higher persistence of IL17i than TNFi for PsA and PsO. IL17i also has better persistence than IL12/23i for PsA, with no difference for PsO. However, the persistence rates of all biologics remained globally low at 3 years.

DRUG SURVIVAL OF BIOLOGICS AND NOVEL IMMUNOMODULATORS FOR RHEUMATOID ARTHRITIS, AXIAL SPONDYLOPATHRITIS, PSORIATIC ARTHRITIS, AND PSORIASIS - A NATIONWIDE COHORT STUDY FROM THE DANBIO AND DERMBIO REGISTRIES

1Copenhagen University Hospital - Bispebjerg, Department of Dermatology, Copenhagen, Denmark; 2The Parker Institute, Department of Rheumatology, Frederiksberg, Denmark; 3Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark; 4Gentofte Hospital, Department of Dermatology and Allergy, Hellerup, Denmark; 5TeaLand University Hospital, Department of Dermatology, Roskilde, Denmark; 6Aarhus University Hospital, Department of Dermatology, Aarhus, Denmark; 7Holbæk Hospital, Department of Rheumatology, Holbæk, Denmark

Background: Drug survival is an important proxy measure for effectiveness of treatments for inflammatory diseases such as rheumatoid arthritis (RA), axial spondyloarthritis (AxSpA), psoriatic arthritis (PsA), and psoriasis [1-4].

Objectives: The objective of this study was to examine the real-life drug survival of biologics and novel small-molecule therapies across various disease entities such as RA, AxSpA, PsA, and psoriasis.

Methods: We performed a nationwide cohort study using the prospective nationwide registries DANBIO and DERMBIO, comprising all patients treated with biologics or novel small-molecule therapies for RA, AxSpA, PsA, and psoriasis between January 2015 through May 2021 (DANBIO) and November 2009 to November 2019 (DERMBIO). Drug survival was visualized using Kaplan-Meier curves, and Cox proportional hazards models were used to calculate adjusted Hazard Ratios (HRs) with 95% confidence intervals (CIs) for risk of discontinuing therapy.

Results: The study comprised a total of 12,080 patients (17,903 treatment series), including 5,104 RA patients (7,867 series), 2,157 AxSpA patients (3,016 series), 2,551 PsA patients (3,313 series), and 2,577 psoriasis patients (3,707 series). In confounder-adjusted models drug survival in RA was highest for rituximab followed by baricitinib, etanercept and tocilizumab respectively. For AxSpA drug survival was high for golimumab compared to all other drugs, followed by secukinumab and etanercept and lowest for infliximab. For PsA tofacitinib and infliximab had the lowest drug survival compared to all other drugs. All other drugs performed almost equally well with a tendency of a generally higher drug survival for golimumab, followed by secukinumab and ixekizumab. For psoriasis drug survival was generally highest for guselkumab.

Conclusion: Differing treatment responses to drugs with various types of action across RA, AxSpA, PsA and psoriasis emphasize that although these diseases have many overlaps in their pathogenesis, there is a need for an individualized treatment approach that considers the underlying disease, patient profile, and treatment history.

Background: Evidence demonstrates sex differences in disease presentation, physical function, treatment response and drug retention in patients with psoriatic arthritis (PsA). Data from observational cohort studies indicate female sex is associated with reduced effectiveness of tumor necrosis factor inhibitors (TNFis)1,2. Although, conflicting results are also reported3,4. We sought to validate prior studies using data from a large multinational cohort based on real-life clinical practice.

Objectives: To investigate sex differences in treatment response and drug retention rates in clinical practice among patients with PsA, treated with their first TNFi.

Methods: Data from biologic-naïve PsA patients initiating a TNFi in the EuroSpA registries were pooled. In the primary analysis, propensity-score weighting was applied to assess the causal effect of sex on low disease activity (LDA) according to DAS28-CRP at 6 months. A generalized linear regression model was used to estimate the causal risk difference (RD) and relative risk (RR) of sex on LDA. Possible covariates influencing the outcome were determined a priori and selected based on availability in the database (<20% missing). The final covariates included were country, age, conventional synthetic disease-modifying antirheumatic drug use at baseline and TNFi start year. In the secondary analysis, drug retention was assessed over 24 months of follow-up by Kaplan-Meier curves and log-rank test.

Results: In total, 7,679 PsA patients with available data on DAS28-CRP at 6 months were assessed for treatment response. Baseline characteristics are shown in the Table 1. In the adjusted analysis, the probability for females to have LDA was 17% (RR, 0.83; 95% confidence interval [CI], 0.81 to 0.85) lower compared to males and the difference in probability for having LDA was 13 percentage points (RD, 0.13; 95% CI, 0.11 to 0.15). The survival analysis included 18,599 PsA patients with available data on retention rates. The TNFi 6/12/24-month retention rates were significantly lower in females (81%/68%/56%) compared to males (89%/80%/69%), see Figure 1.

Table 1. Baseline characteristics of all biologic-naïve PsA patients treated with their first TNFi and available DAS28-CRP at 6 month, data pooled across all countries

Data are as observed, mean (SD), median [IQR] or percentage. TNFi, tumor necrosis factor inhibitor; csDMARD, Conventional synthetic disease-modifying antirheumatic drugs; DAS28-CRP, Disease Activity Score 28-joint count C reactive protein; DAPSA28, Disease Activity in PsA 28; CRP, C-reactive protein; SJC, swollen joint count; TJC, tender joint count.

Conclusion: Treatment efficacy and retention rates are lower among female patients with PsA initiating their first TNFi. Females presented with higher 28-tender joint count and higher scores on patient reported outcomes at baseline, reflecting differences in disease expression. Recognizing these sex differences is of relevance for customized patient care and may improve patient education.

Comparing Methotrexate Monotherapy with Methotrexate Plus Leflunomide Combination Therapy in Psoriatic Arthritis: A Randomized, Placebo-Controlled, Double-Blind Clinical Trial (COMPLETE-PSA)

Methods: Patients with a clinical diagnosis of PsA and active disease (≥2 swollen joints) were included in this randomised, placebo-controlled, double-blind trial. Patients were randomised (1:1) to MTX plus LEF or MTX plus placebo. Patients received MTX 15mg/week for four weeks and thereafter 25mg/week, combined with two LEF 10mg tablets or two placebo tablets daily. The primary outcome was the difference between the MTX plus LEF group and the MTX plus placebo group on the psoriatic arthritis disease activity score (PASDAS) at week 16 adjusted for baseline PASDAS. Key secondary outcomes included safety and the achievement of minimal disease activity (MDA) criteria and PASDAS low disease activity (LDA) (≤3.2).

Results: A total of 78 PsA patients (MTX + LEF n=39; MTX + placebo n=39) were included. The mean age was 53.1 (SD=12.8) years and 36% (n=28) of the patients were female. The mean PASDAS at baseline was 4.9 (SD=1) in both treatment groups. Table 1 shows that MTX plus LEF was superior to MTX plus placebo at week 16 (PASDAS 3.1, SD=1.4 vs 3.7, SD=1.3; treatment difference= -0.6, 90% CI -1.0 to -0.1, one-sided P-value=0.025). Similar and significant results were found for achievement of MDA criteria (59% vs 33%, one-sided P-value=0.013) and PASDAS LDA (59% vs 35%, one-sided P-value=0.019) (Figure 1 and Table 1). Other favorable and significant outcomes for the MTX plus LEF group included -among others- the improvement in swollen joint count (SJC) (median [IQR] = 3 [-5, -2] vs -2 [-4, 0], one-sided P-value=0.039) and the proportion of patients with active psoriasis (i.e. body surface area score >0) at week 16 (44% vs 68%, one-sided P-value=0.014).

Generally mild adverse events and treatment discontinuation (MTX+LEF n=21; MTX + placebo n=33) occurred more frequently in the MTX plus LEF group.

Conclusion: MTX plus LEF combination therapy resulted in a significantly greater improvement in disease activity according to PASDAS and MDA than treatment with MTX monotherapy in patients with PsA after 16 weeks. In addition, a greater improvement in psoriasis was found for the combination group. However, there are indications that MTX plus LEF combination is less well tolerated than MTX monotherapy.

Does Methotrexate Impact Ustekinumab Immunogenicity in Patients with Active Psoriatic Arthritis? A Post Hoc Analysis of Samples from a Randomized, Placebo-Controlled Trial.

S. Molthae Poo1,2,3, M. Henke1, T. Uischenhoefer1, F. Behrens1,2,3,4, M. Köhler1,2,3,4, H. Burkhardt1,2,3, S. Schifftmann1,3, Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Frankfurt, Germany; 2University Hospital Frankfurt, Rheumatology, Frankfurt am Main, Germany; 3Fraunhofer Cluster of Excellence for Immune-Mediated Diseases CIMD, Frankfurt, Germany; 4Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Frankfurt, Germany

Background: The formation of antidrug-antibodies (ADA) may reduce treatment efficacy or provoke discontinuation due to adverse reactions. Subsequent alterations in the drugs’ pharmacodynamics, pharmacokinetics, safety, and efficacy are often unpredictable and can impede clinical discourse. Recent studies gave us some insights regarding the role of ADA formation against the monoclonal IL-12/23 antibody ustekinumab (UST) and the impact of concomitant MTX treatment on immunogenicity in psoriatic arthritis (PsA) patients [1,2]. Valid measurement of ADA, particularly of neutralizing ADA (nADA) is essential to understand UST-associated immunogenicity and may help to predict clinical outcomes.

Objectives: To examine the impact of concomitant MTX on UST-immunogenicity in patients with active psoriatic arthritis (PsA).

Methods: Plasma samples were collected from a randomized controlled trial in patients with active PsA, treated with open UST and placebo-controlled methotrexate over a 52 weeks. We compared samples of 112 patients treated with UST and MTX against non-treated samples.
either UST and MTX (n=58) or UST and placebo (n=54). Plasma samples were obtained shortly before UST injection at weeks 0, 4, 16, 40, and 52. Immunogenicity testing was performed as described by our group elsewhere [2], in a multi-tiered manner with ELISA and surface plasmon resonance analysis for the detection and quantification of ADA and UST, respectively. Neutralizing capacity was characterized in a cell-based assay. For statistical analysis, a two-way ANOVA with Sidak correction for multiple comparisons was used.

**Results:** Over the 52 weeks treatment period, 10 (18 %) of patients in the placebo cohort developed UST-specific ADA with one patient having non-neutralizing ADA, whereas 15 (27 %) subjects in the MTX cohort generated UST-specific ADA with 2 patients having non-neutralizing ADA. The ADA rates and concentrations at the different time points (Figure 1A, B) did not differ significantly between MTX and non-MTX users (p> 0.05). Furthermore, the presence of UST-specific ADA was not associated with decreased UST levels (Figure 1C).

**Conclusion:** The presented data yielded no statistically significant difference in ADA detection between the two analyzed groups. Our findings suggest that concomitant MTX had no impact on UST immunogenicity in PsA patients.

**Figure 1.** The prognostic factors associated with non-remission/LDA status in PsA pts

**Conclusion:** In real practice remission/LDA can be seen in 60% of PsA pts treated mostly with bDMARDs. But about 40% of PsA pts still have HAD/ModA despite going through therapy. It is a combination of clinical features at baseline that are associated with remission or LDA nonachievement. M±SD, Me [Q25; Q75], Min-Max, %, t-test, Pearson-r, Mann-Whitney tests, ORs with 95% CI were performed. All p<0.05, were considered to indicate statistical significance.

**Results:** At 1 year of therapy 116 pts of 292 (39.7%) have HDA/ModA by DAPSA. Remission/LDA was reached in 176 pts (60.3%), 110 of them (62.5%) were treated with bDMARDs. Comparative analysis in both groups and one-factor model of logistic regression showed the following features at BL were associated with non-remission/LDA status: TJC>3 (p<0.001), SJC>5 (p<0.001), CRP> 10 mg/l (p<0.001), HAQ>0.5 (p<0.001), presence of enthesitis (p<0.001), dactylitis (p<0.001), BMI>30 (p<0.002) and had to be treated with sDMARDs. PsA pts with combination of these clinical features at first visit have more chance to non-remission/LDA status in comparison to PsA pts without them, OR with CI 95% (Figure 1).

**Odds Ratio 95% Confidence Interval**

**Figure 1.** The prognostic factors associated with non-remission/LDA status in PsA pts

**Conclusion:** In real practice remission/LDA can be seen in 60% of PsA pts treated mostly with bDMARDs. But about 40% of PsA pts still have HAD/ModA despite going through therapy. It is a combination of clinical features at BL: TJC>3, SJC>5, CRP>10mg/l, HAQ>0.5, presence of enthesitis, dactylitis, BMI>30kg/m² and sDMARDs therapy - that constitutes a prognostic factor with negative impact on achievement remission/LDA after 1 year of treatment.

**DOI:** 10.1136/annrheumdis-2022-eular.423
Background: In SELECT-Psa 1, patients (pts) with psoriatic arthritis (PsA) and an inadequate response or intolerance to ≥1 non-biologic disease-modifying antirheumatic drug showed improvement in the signs and symptoms of PsA with upadacitinib 15 mg (UPA15) or 30 mg (UPA30); an oral Janus Kinase (JAK) inhibitor, through week (wk) 56.1

Objectives: To evaluate the efficacy and safety of UPA and UPA vs adalimumab (ADA) at wk 104 from the ongoing long-term extension of SELECT-Psa 1.

Methods: Pts received UPA15, UPA30, ADA 40 mg, or placebo (PBO) for 24 wks, at which point, PBO pts switched to UPA15 or UPA30. Efficacy endpoints were analyzed using non-responder imputation (NRI) and as observed (AO) (binary endpoints) or mixed-effect model repeated measures and AO (continuous endpoints), with nominal P-values shown, for continuous UPA and ADA treatment groups. Treatment-emergent adverse events were summarized for pts who received ≥1 dose of study drug using a visit-based cut-off at wk 104.

Results: 1704 pts received ≥1 dose of study drug. At wk 104, 25.4% of pts had discontinued study drug. The proportions of pts who achieved ACR20/50/70, MDA, PASI75/90/100, and resolution of enthesitis or dactylitis showed consistent responses, or further improvements, from wk 56 to wk 104 (Table 1). ACR20/50/70 and MDA responses, as well as mean change from baseline (BL) in HAQ-DI, patient’s assessment of pain, BASDAI, and ASDAS, were greater with UPA vs ADA. Mean change from BL in modified total Sharp/van der Heijde Score (mTSS) was generally similar across groups and comparable to wk 56.1 The safety profile of UPA was generally comparable to ADA (Figure 1) and consistent with wk 56 data. Rates of serious infection, herpetic zoster, lymphopenia, and elevated CPK remained numerically higher with UPA30 vs UPA15; rates in both UPA groups were higher vs ADA. Rates of malignancies, MACE, or VTE were similar across groups, and consistent with wk 56 data. Two deaths were reported with UPA15, 1 with UPA30, and 1 with ADA.

ACR20/50/70, ≥20%/50%/70% improvement in American College of Rheumatology criteria; ACR, adalimumab; AO, as observed; BL, baseline; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesis Index; MMRM, mixed effect model repeated measurement; NRI, non-responder imputation; PASI75/90/100, ≥75%/90%/100% improvement in Psoriasis Area and Severity Index; pts, patients; UPA, upadacitinib; Data shown as NRI and AO for binary endpoints. For pts with psoriasis affecting ≥3% of body surface area at BL, for pts with LEI >0 at BL; resolution LDI=0. Data shown as MMRM (LS mean) and AO (mean) for continuous endpoints. For pts with psoriatic spondylitis at BL, nominal P-value ≤0.05. UPA15 or UPA30 vs ADA for NRI and MMRM; AO descriptive only.

Conclusion: In PsA pts, efficacy responses were similar or greater with UPA15 or UPA30 vs ADA at wk 104, and indication of radiographic progression was maintained. No new safety signals were identified with long-term exposure to UPA up to 2 years.

REFERENCES:
Psoriatic arthritis (PsA) is characterized by a range of musculoskeletal and extra-articular disease manifestations. Composite indices are valuable tools to assess the multidimensional nature of PsA. The Psoriatic Arthritis Disease Activity Score (PASDAS)\(^2\) provides robust assessment of both joint and skin domains but is cumbersome to use in clinical practice. The Disease Activity Index for Psoriatic Arthritis (DAPSA)\(^2\) is relatively easy to use but does not assess skin disease.

**Methods:** Using pooled data from the phase 3 DISCOVER-1 and DISCOVER-2 studies of guselkumab (GUS) for the treatment of active PsA,\(^3,4\) (1) Describe the rate of achievement of a new composite endpoint combining DAPSA low disease activity (LDA; score ≤14, including remission) and Investigator Global Assessment (IGA) of psoriasis score ≤1 (range = 0 [clear] to 4 [severe]); (2) Determine whether earlier (Week [W] 16) DAPSA LDA + IGA ≤1 is predictive of future achievement of minimal disease activity (MDA) or American College of Rheumatology (ACR) 50 response criteria; and (3) Contrast the performance of DAPSA LDA + IGA ≤1 with that of PASDAS LDA (score ≤3.2).

**Results:** Patients (pts) with active PsA despite standard therapies (DISCOVER-1: ≥3 swollen + ≥3 tender joints; CRP ≤0.3 mg/dL; ≥30% prior history of up to 2 TNF inhibitors; DISCOVER-2: ≥5 swollen + ≥5 tender joints; CRP ≤0.6 mg/dL; all pts with biologic-naïve) were randomized 1:1:1 to GUS 100 mg at W0, W4, then Q4W or Q8W or placebo (PBO) to crossover to GUS Q4W at W24. In both studies, efficacy of GUS vs PBO was compared at W24 (primary endpoint). The number (%) of pts with PASDAS LDA + IGA ≤1 was determined at W24 for pts randomized to GUS or PBO. For all GUS-randomized pts, baseline variables associated with PASDAS LDA + IGA ≤1 and PASDAS LDA at W16 and the predictive value of W16 PASDAS LDA + IGA ≤1 or PASDAS LDA for achieving ACR50, MDA, and PASDAS LDA at W52 were assessed using logistic regression models.

**Figure:** Composite response at W16 are predictive of Achievement of ACR50, MDA, and PASDAS LDA at W52

DRIVING IMPROVEMENT IN AXIAL SPONDYLOARTHRITIS SERVICES: THE USE OF QUALITY IMPROVEMENT APPROACHES AND TOOLS

D. Webb\(^1\), R. Barnett\(^2\), L. Davies\(^3\), \(1\) National Axial Spondyloarthritis Society, CEO, London, United Kingdom; \(2\) Bath, Health, Bath, United Kingdom; \(3\) Salford, NHS Transformation Unit, Salford, United Kingdom

**Background:** Quality Improvement (QI) methods have been used in healthcare since the late 1980s across a wide range of healthcare settings. However, in the UK they have not been applied widely within rheumatology including axial Spondyloarthritis (axial SpA). In 2017, the UK healthcare regulator, NICE, produced a national clinical guideline for axial SpA, but there was no mechanism to encourage uptake of its recommendations. The National Axial Spondyloarthritis Society created a programme to use QI approaches to help encourage uptake of the Guidelines and act as a catalyst for wider improvement in axial SpA care.

**Objectives:** To encourage service improvement in axial Spondyloarthritis care through the use of quality improvement theory and methods.

**Methods:** In late 2019 six rheumatology departments were selected to participate in the first cohort. The programme design was underpinned by:

- A framework for management grounded in systems theory\(^1\)
- A learning system that brings healthcare organisations together\(^2\)
- A set of tools to develop, test and implement changes: the Model for Construct Improvement3.

The teams met four times for training in QI methods, plus team-based online coaching. They had time to develop their projects and networking opportunities to share their data and experiences of implementation.

We conducted a qualitative review of the programme in year one. We interviewed 31 programme participants and reviewed programme documentation.

**Results:**

The review found that:

- A proven QI framework provides a strong basis to build improvement
- A competitive programme helps foster motivation and accountability
- The programme provides the time to use tools to understand the problem and construct improvement aims
- Measurement is key to understand improvement and to create a story of change
- Collaboration and engagement is key within the team and with other stakeholders.
- The teams have:
  - Trained community-based physiotherapists, leading to improved rheumatology referrals
  - Implemented an inflammatory back pain pathway from primary care
  - Introduced an MRI spine IBP protocol to reduce variation in imaging
  - Established a tertiary referral service which has improved time to diagnosis

---

**Figure:** Composite response at W16 are predictive of Achievement of ACR50, MDA, and PASDAS LDA at W52
• Implemented mental health interventions for patients and reduced the percentage of patients with abnormal scores
• Established a pathway for physiotherapy self-referral and reduced Did Not Attend rates
• Used audit to make the business case for an extended scope practitioner

Conclusion: Despite the challenges posed by the Covid-19 pandemic, a structured QI programme has enabled clinicians to stay engaged and implement physiotherapy-led, rediagnostic delay and improve care.

POS0084-PARE IMPACT OF OSTEOARTHRITIS ON PATIENT QUALITY OF LIFE: IS THERE AN EVOLUTION BETWEEN THE 2013 AND 2021 LARGE-SCALE SURVEYS – STOP OSTEOARTHRITIS CONDUCTED IN FRANCE AND BELGIUM?

L. Grange, C. Mathy, A. F. Lailloua, G. Chales, L. Seidell, A. Alberi, L. Lories, Y. Henriot, O., CHU Grenoble Alpes/Hôpital SUD, Rheumatology Department, Echirrolles, France; 1Association Francaise de Lutte Antirhumatisme A.F.L.RA, President, Paris, France; 2 Princess Paola Hospital, Vivalia, Department of Physical Therapy and Rehabilitation, Marche-En-Famenne, Belgium; 3 Osteoarthrosis Foundation, Treasurier, Belgium; 4 Association Francaise de Lutte Antirhumatisme A.F.L.RA, Voorzitter, Paris, France; 5 Association Francaise de Lutte Antirhumatisme A.F.L.RA, Treasurer, Paris, France; 6 Liège University Hospital, Department of Biostatistics, Liège, Belgium; 7 University Hospitals Leuven, Belgium, Skeletal Biology and Engineering Research Center, KU Leuven and Division of Rheumatology, Leuven, Belgium; 8 Princess Paola Hospital, Vivalia, Belgium, Department of Physical Therapy and Rehabilitation, Marche-En-Famenne, Belgium; 9 Osteoarthrosis Foundation, President, Boncelles, Belgium; 10 University of Liège, MusculoSkeletal Innovative Research Lab (mSKIL), Liège, Belgium

Background: Osteoarthritis (OA) is the most common form of arthritis, affecting more than 500 million people globally. OA is characterized by chronic mechanical pain and stiffness in the joints, limiting patient physical activities, leading to sedentarism, and disability. The results of the French web-based survey “Stop OA” (N=4227 participants) conducted in 2013 were presented at EULAR 2014. They evidenced the heavy burden of OA in France.

Objectives: The survey was repeated in France/Belgium between 2019 and 2021 (N=3465). This study aimed at assessing the impact of OA on patient quality of life and looking at a potential evolution between the two surveys.

Methods: Participants were invited to complete the survey questionnaire online via the website www.stop-arthrose.org. The questions focused on demographic and socio-economic aspects, history of the disease, physical activities, beliefs about OA, its impact on daily life, assessment of health status and the consequences, as well as the needs and expectations of the participants.

Results: 3465 questionnaires (France N = 2822, Belgium N = 643) were thus collected between September 2019 and January 2021. The average filling time of the survey was 40 minutes. In the 2021 survey, 80.8% of participants (mean age 60 years, 80.3% women) declared that OA had a negative impact on their morale and 64.1% that they had a deteriorated self-image due to the disease. 25% of participants thought that difficulties in their couple were caused by OA and 33% reported problems in sexual life. 24.8% found it hard to cope with the disease impact, and 33% reported problems in sexual life. 24.8% found it hard to cope with the disease impact, and 33% reported problems in sexual life.

Conclusion: OA represents a real burden that affects the mental health of patients, their relationships and the quality of their sleep. There has been no improvement of OA impact in patient quality of life between the two surveys (i.e., 8 years). This reflects the lack of resources for research to find new treatments and implement evidence-based therapeutic strategies in the current medical practice. A better understanding of these repercussions will allow effective strategies to be adopted in order to deal with these issues.

POS0085-PARE CURRENT NEEDS, IMPACT AND PERSPECTIVE OF PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS

P. Plazuelo-Ramos1, L. Loza2.1, Coordinadora Española de Asociaciones de Espondiloartritis, Presidencia, Fuenlabrada, Spain; 2Instituto de Salud Musculosquelética, Rheumatology, Madrid, Spain

Background: The impact of spondyloarthritis (SpA) and psoriatic arthritis (PsA) is enormous.

Objectives: To analyse in patients with SpA and PsA current 1) needs; 2) disease impact, and 3) patients’ opinion on treatments, patients-physicians relationship, and disease information.

Methods: National survey promoted by CEADE (Spanish Coordinator of Spondyloarthritis Associations). A multidisciplinary working group composed by 1 rheumatologist, 2 patients members of CEADE with SpA and PsA and a methodologist was established. They designed a structured survey (20 minutes long), in electronic format to be answered by patients with SpA and PsA, aged 18 years or above. The survey was launched on April 28, 2021, using CEADE channels to communicate with members and followers, and was closed on June 30, 2021. Sociodemographic and clinical variables were collected (age, sex, disease duration treatments), and variables related to the objectives. A descriptive analysis was performed.

Results: The survey included 543 patients with SpA (55% ankylosing spondylitis, 45% women, 81 aged 48-64 years, 25% with biological therapies) and 291 patients with PsA (89% women, 73% aged 48-64 years, 40% with biological therapies). In the last month, the reported level of fatigue, morning stiffness and sleep problems of patients with SpA and PsA was considerable. In a scale from 0 (no symptoms) to 10 (high level of symptoms) the means were greater than 8. Almost 80% of patients with SpA described low back pain within the last month and 82.5% of patients with PsA pain, stiffness and/or arthritis on the knees, ankles, feet and/or hands, and 51% dactylitis. Regarding to daily activities, practicing exercise and house cleaning were the most affected ones among patients with SpA and PsA. We found that 70%-74% of these patients were concerned about pain and almost 60%-66% about loss of mobility and autonomy. The impact of the disease on work was in general very high very high. The level of satisfaction with treatments was low in SpA, mean 5.5 (scale from no satisfaction to 10 very satisfied), and moderate in PsA, mean 6.2. Across treatments, the level of satisfaction was higher with biological therapies compared with classical synthetic disease modifying antirheumatic drugs in both disease groups. Many patients (70.2% with SpA and 66% with PsA) are used to live with pain every day. Many of the survey participants (over 50%) hope that treatments will help them recover their quality of life and improve pain, stiffness and fatigue. Oral treatments are preferred over subcutaneous and intramuscular drugs in SpA and PsA. Patients also consider that oral treatments have more positive influence on adherence to treatments. A total of 22% of surveyed patients with SpA and 14% with PsA said that their rheumatologists never asked them about the factors that limit their life, 14.3% and 6% that they never talked about the impact of the disease on quality of life, and 43.8% (SpA) and 31.2% (PsA) that they do not stablish treatment objectives with the rheumatologist. Almost 30% of participants stated that they would like to have more time to express and discuss doubts and concerns with their rheumatologist, and around 25% would like to have more follow-up visits.

Table 1 describes the most used.
In addition, oral corticosteroids (OCS) and other immunosuppressants can expose patients with SLE to severe adverse events. However, little is known about the relative importance of SLE treatment outcomes including symptom control or the extent to which treatment risks are tolerated in exchange for this.

**Objectives:** To quantify the relative importance of different SLE treatment outcomes and the trade-offs patients are willing to make between these outcomes.

**Methods:** This online discrete choice experiment (DCE) assessed how treatment choices varied with treatment outcomes. Subjects were US adults (≥18 years) with a self-reported diagnosis of moderate-to-severe SLE (≥6 months) who experienced ≥1 flare in the past year and were taking ≥1 SLE treatment. Treatment outcomes included four benefits on: 1) fatigue levels, as in the Functional Assessment of Chronic Illness Therapy (FACT)–Fatigue, described the degree of tiredness felt by a patient in the previous 7 days, while not experiencing a flare and despite adequate sleep or rest, 2) joint and 3) non-joint pain levels as measured using the Brief Pain Inventory–Short Form (BPI-SF) scale; scores of 2, 5, and 8 correspond to mild, moderate, and severe worst daily pain on a scale of 0 (no pain) to 10 (worst imaginable pain), and 4) skin rash and itch levels, as in SLE-QOL, indicated how much patients were troubled by sore, painful, stingy, or itchy skin in the previous 7 days. Treatment outcomes also included three risks: 1) risk of infections (1% decrease), 2) risk of mild-to-moderate side effects to avoid being ‘extremely troubled’ by skin rash and itch (Table 1).

**Conclusion:** This real-world patient preference assessment provides insights into the relative importance of SLE treatment outcomes and willingness to tolerate SLE treatment risks. These results can guide endpoint prioritization in SLE clinical studies and inform the evaluation of SLE treatments.

**Conclusion:** Current impact of SpA and PsA on daily life is still very high. There are areas for improvement in the doctor-patient relationship and on disease treatments.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.2302
and increasing their ability to manage the disease. Furthermore, the pilot project aimed to close an important gap in the Swiss health care system.

**Methods:** A questionnaire was designed to measure the change in self-management abilities and the health status of patients. The questionnaire was given to patients at three points in time (t1=enrolment of patient, t2=last session of the self-management programme and t3= two months after the last session) and contained several validated scales such as the heiQ, Self-Efficacy for Managing Chronic Disease 6-item Scale, RADAi-5 and EQ-5D-5L. Descriptive statistics were applied to analyse the data by comparing the mean values of all relevant indicators at three points in time.

**Results:** In total 52 patients were enrolled in the pilot project. 48 patients completed the programme and 35 took part in the follow-up questionnaire. Overall, the results show a positive trend in self-management abilities and an improvement in the patients’ current health status. The slight increase in knowledge remained until the follow-up. Significant changes are seen in Skill and Technique Acquisition as well as in Self-Monitoring and Insight of the disease, which are two important components of self-management. Other components such as the knowledge and constructive attitudes and approaches also underwent a small but positive change that lasts up to two months after the last session of the self-management programme. Self-improvement improved as well, but with a slight decrease during the follow-up. The disease activity also declined slightly over time. The results also indicate a small and steady improvement of the current health status. Using a visual analogue scale as part of the EQ-ED-EL, participants evaluated their current health status as 69 (t=1), 73 (t=2) and 74 (t=3). The quality of life has improved too, but the change doesn’t seem to be relevant. Furthermore, the use of health services indicates a slight decline after taking part in the self-management programme.

**Conclusion:** The comprehensive self-management programme designed by the Swiss League against Rheumatism embedded in outpatient rheumatological and general practitioner clinics proved to be successful. The three components of self-management in particular, i.e., knowledge, motivation to take action and skills to manage the disease improved significantly. The results also show a positive trend in the patients’ current health status, their quality of life and a decline in disease activity. However, based on the study design, it cannot be concluded that there is a correlation between the improved health status/quality of life and the self-management programme. For this purpose, a control group would be necessary to evaluate the programme’s effect on the health status and quality of life of people with rheumatic disease. Nevertheless, this pilot project represents an important foundation on which further services and programmes to strengthen self-management in rheumatology can be developed.

The IMPORTANCE OF ACCURATE INCIDENCE AND PREVALENCE ESTIMATES FOR FAMILIES OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

R. Beesley, 1, 2, 3, 4, 5. Juvenile Arthritis Research, JAR Project, Tonbridge, United Kingdom

Background: Juvenile Idiopathic Arthritis (JIA) is a heterogeneous group of auto-immune disorders characterised by chronic joint inflammation, affecting children and young people (CYP) under the age of 16. Recent analysis in the UK [1] has provided an update to the estimated incidence and prevalence rates of JIA.

Objectives: Whilst the policy and health-care benefits of accurate incidence and prevalence rates are understood, this patient- and parent-led qualitative project sought views from parents of CYP with JIA to understand whether knowing accurate estimates of incidence and prevalence are important to them.

Methods: Parents of CYP with JIA, all members of a small online group on social media, were asked whether knowing accurate rates of JIA were important to them, and why. Responses were collated and summarised.

Results: Whilst a few respondents felt it did not matter to them what the overall rates of JIA were, focusing instead on their own personal experience with the condition, the majority did want to know and gave consistent reasoning. They advised that, when your child is diagnosed with JIA, it is a very isolating experience. Most people have never heard of the condition before, and being told your child has arthritis is a frightening time (especially if you then become aware of some of the significant long-term effects, such as potential continuation of disease into adulthood and possible joint damage, and the side effects of treatment, and social impacts of the disease [2, 3]). Whilst direct support is available to families affected by JIA (www.jarproject.org), understanding prevalence rates can help reduce mental health burdens on patients and parents and reduce feelings of isolation.

Families also advised that they want to know numbers of children with JIA as so we collectively can get a better understanding of the cause, the trends, and the possible reasons behind changes. Knowing accurately the numbers of children with JIA can help to raise awareness; current lack of awareness in society and primary care contributes to delays in diagnosis and potentially worse clinical outcomes [4]. In addition they reported the need for appropriate resourcing of paediatric rheumatology and support services, and the political and financial discussions that must take place to enable that to happen need to be supported by evidence.

Conclusion: Overall, parents do want to know how many other children have JIA. It takes some of the isolation and anxiety away to know you are not alone. It matters because knowing there are other parents in the same situation as you can help reduce anxiety and loneliness. It matters, because knowing there are researchers focussing on JIA helps remind you that work is underway to better understand JIA, its causes, and improved treatments which will eventually lead to improved care for children with the condition. It matters, because it can help target resources appropriately. It matters, because raising awareness is more effective if we know how many people are affected by a chronic condition. And it matters, because as improved treatments are developed we want to be able to see the number of children categorised as having active JIA to reduce and health outcomes for each child to improve.

THE ORGANISATION, IMPACT, AND INFLUENCE OF PATIENT ADVISORY BOARD REPRESENTATION IN PRIVATE REHABILITATION INSTITUTIONS – AN EXPLORATIVE CROSS-SECTIONAL STUDY

J. Sagen1, E. Bæresund2, A. E. Simonsen3, A. Habberstad4, I. Kjeken1, H. Dagfinrud1, R. H. Moe5, 6. The Deacon's Home Hospital, Norwegian National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; 2Oslo University Hospital, Oslo, Norway, Department of Digital Health Research, Division of Medicine, Oslo, Norway; 3Raysumnetet Rehabilitation Center, Patient Advisory Board, Jarem, Norway; 4The Norwegian Federation of Organisations of Disabled People, Research and Patient Participation, Oslo, Norway

Background: Patient participation (PP) organised as patient advisory boards (PABs) is a statutory part of health care institutions in Norway (1). There is limited agreement on how to engage PABs in a meaningful manner (2). More knowledge on how PAB representatives experience patient engagement (PE) is needed.

Objectives: To explore how PAB representatives engage in PABs with regard to organisation, influence, and impact on decision-making processes and service delivery.

Methods: PAB representatives recruited from rehabilitation institutions, representing all four health regions in Norway completed a PE evaluation tool. The tool is tested for reliability and content validity with good results and comprises 35 items including four main domains: policies and practices, participatory culture, collaboration, and influence and impact that provided responses about PE-levels (3). Categorical data were summarized to modal scores using frequencies and percentages, and response categories were collapsed from five to three. The collapsed categories were divided into PE-levels: barrier, intermediate, and facilitator (Table 1). Free-text responses were analysed according to principles of manifest content analysis, summed up, and used to complete the results of the scores. Free text responses were analysed using Quirkos version 2.4.

Results: Of the 150 contacted PAB representatives, 47 (32%) responded. PAB representatives’ mean age was 60.5 (min-max 30-80), 62% were female and a majority (81%) had prior experience with PP. The results showed that 75% of the participants agreed that patient-centered care was strengthened as a result of PE. Three out of four main domains scored indicating a facilitating PE-level (Table 1). The domain, influence and impact scored with an intermediate PE-level. Regarding influence and impact, half of the participants did not know how PE input had influenced management decisions, and 60% had rarely identified any PE contributions. The results from free text analyses showed that PE was coded as a facilitator seven times, and as a barrier to PE 26 times. The most frequent barrier was exclusion of PAB (13 codes), and the most coded facilitator was inclusion of PAB (3 codes).

Conclusion: Findings indicate that PAB representatives are satisfied with how rehabilitation institutions organise PABs. Unclear adherence to the values and principles of PP may hinder influence and visibility from PE contributions.

MIG-NETWORK - A NETWORK FOR PEOPLE WITH RHEUMATISM AGED 35-55 YEARS.

B. Schmidt Andersen1, 2, Gitteforeningen, Friviligafdelingen, Gentotto, Denmark

Background: The MIG network (“MIG” is a shortening for “Middi i gigt” which means “In the middle of Reumatism” as well as mid-life. MIG also means “ME” in Danish

The existing offers and activities in the Danish Rheumatism Association are primarily targeted towards the age group above 60 years. Often, younger members find it difficult to feel at home and see themselves as part of that particular age group. They miss activities where they can meet up with their peers, who are going through the same challenges in life.

Objectives: The objectives of the MIG network is to create a forum for people with rheumatism, who are roughly between 35 and 55 years old. The network focuses on life with rheumatism and how to keep the balance between job, family life and the disease. The ultimate goal was to create a community based on networking, shared experiences and relevant knowledge from both each other and health professionals.

Methods: First of all, the age group needed to be involved right from the start, so we initially made a series of interviews to learn about their needs and wishes. Then we gathered a group of five volunteers, who agreed to participate in defining the objectives and activities and to start up the network. The network consists of the following:

I) an online based network with monthly webinars on the platform Zoom, where different health professionals talks about relevant subjects. The obvious advantage being, that people could participate from all over the country, from their sofa, not needing to dress up and travel after a long day of obligations.

II) The Danish Rheumatism Association have created an App for their volunteer community. In this app we offered the members of MIG “a room of resources” where they can find news on the latest research and other relevant news. The members can also ask questions and share written advice and good ideas with each other.

III) Last, but not least it was important for the volunteers to offer physical meet-ups, where they can find news on the latest research and other relevant news. The volunteers have enjoyed the professional presentations and found them to be very useful. At the same time, they gained useful tools to make it easier to live a life with rheumatism. But it has been difficult to create an intimate space. For many, it is difficult to share private feelings of uncertainty and inadequacy on camera in a Zoom meeting. It has been difficult to create an intimate space. For many, it is difficult to share private feelings of uncertainty and inadequacy on camera in a Zoom meeting. The “room of resources” on our App has only worked and engaged a very small group of people, in spite of a great effort from our volunteers.

The physical meetings have been a great success. And they have covered a need that wasn’t met before. The participants have enjoyed the professional lectures, but enjoyed the social networking even more. So now the meetings have less lectures and more networking in the program. As living with a chronic disease can make the whole family and network suffer, we also met the need to invite next of kin to join the meetings and have arranged for them to have their own workshop with a Psychologist.

Conclusion: The MIG network makes sense! And it has met a need for people with a chronic disease to meet up with peers in the same life situation. It has proven to be more difficult than intended to create an online community, whereas the physical meetings have created strong relations on a completely different level. The network continues with both the digital and the physical activities nationally. The goal is also to recruit volunteers locally, so that they can initiate local activities.

Pathogenesis of SLE, Sjöns and antiphospholipid syndrome

POS0092 HETEROGENEITY OF THE TYPE I INTERFERON SIGNATURE AMONG ANTIIPHOSPHOLIPID SYNDROME PATIENTS: A CLUSTER AND CORRESPONDENCE ANALYSIS APPROACH

I. Cecchi1, M. Radin1, A. Barinotti1, S. G. Foddal1, E. Rubini1, A. Suárez2, D. Roccato1, S. Sciascia1, J. Rodriguez-Carrio2, 1University of Turin, Department of Clinical and Biological Sciences, Center of Research of Immunopathology and Rare Diseases Coordinating Center of Piemonte and Valle d’Aosta Network for Rare Diseases, University of Turin, Italy, Turin, Italy; 2University of Oviedo, Area of Immunology, Department of Functional Biology, Faculty of Medicine, University of Oviedo, Oviedo, Spain, and Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain, Oviedo, Spain

Background: Type I Interferons (IFN) are central players in the pathogenesis, disease activity and evolution of several autoimmune conditions. To date, a limited number of evidences is available on the specific role of IFN activation in antiphospholipid antibodies (aPL) positive patients, including aPL carriers, primary antiphospholipid syndrome (PAPS) and those APS subjects who presented with an associated autoimmune disease (secondary APS, SAPS), such as systemic lupus erythematosus (SLE).

Objectives: The aim of this study was to evaluate the differential expression of IFN stimulated genes (ISG) among different subsets of aPL positive subjects and SLE patients.

Methods: For the purpose of the study, a total of 112 patients attending the San Giovanni Bosco Hospital (Turin, Italy) were enrolled, including 31 PAPS, 25 SAPS, 27 SLE patients without aPL, 29 aPL carriers (mean age 48.3±13.3 years, 76% female). Nineteen subjects were also recruited as healthy controls (HCs).

Complete demographic, clinical, and laboratory data were collected at the time of the inclusion. Gene expression was evaluated by RT-PCR in whole blood for the following genes: IFI6, IFI44, IFI44L, MX1, IFI27, OAS1 and RSAD2. Normalized gene expression levels (Z-scores) were averaged into a global IFN signature (IFN score). Differences were measured by Krukal-Wallis tests and associations among genes were studied by cluster and correspondence analyses. Correlations among genes were plotted by network analyses.

Results: An overall activation of ISG was noted across APS subsets, but certain differences were noted among genes. Whereas some ISG were already upregulated in the aPL positive group compared to HC (IFI44, IFI44L, MX1, IFI27, OAS1 and RSAD2, all p<0.050), other ISG were only in increased SLE (IFI6), MX1 differed between SLE and SAPS, and IFI27 and OAS1 showed differences between PAPS and SLE. The composite IFN score revealed qualitative differences in the IFN pathway activation across APS subsets, being elevated in aPL carriers/PAPS groups compared to HC (both p<0.050) and increasing in SLE (p=0.010) and SLE (p=0.001) groups. Network analyses (Figure 1A) revealed qualitative differences in the gene-gene correlation networks: (i) weaker structures were found in HCs and aPL carriers, compared to stronger and higher degree networks in SLE and SLE groups; and (ii) the influence of each node was different across groups.

Unsupervised cluster analysis identified 3 clusters (I to III) based on ISG patterns (Figure 1B). Clusters usage differed among APS subsets, thus correlating clinical status (Figure 1C). Distinct groups of ISG positively correlate to aPS/PT IgG titre in aPL carriers and PAPS groups (all rho=0.500), whereas no associations were retrieved in SLE or SLE. No associations with previous thrombotic events were observed in any subset, although IFN composite score and several ISG correlate with the number of thrombotic recurrences under anticoagulation (all rho=0.400). No associations with GAPPS were observed.

Figure 1.
Conclusion: An overall IFN pathway activation has been observed in aPIL positive patients and across all APS subsets. Qualitative and quantitative differences across the APS spectrum can be identified, leading to the identification of distinct IFN signatures with different clinical value.

ASSESSMENT OF HISTOLOGICAL FEATURES OF CHRONICITY OF MINOR SALIVARY GLAND BIOPSY IN PATIENTS WITH PRIMARY SJOGEN’S SYNDROME

S. Garcia-Cirena1, L. C. Galisteo S, J. Rotamoz1, M. Moreno E, E. Casado1, M. Rusihol Gonzalez, J. Gratacos-Masmitja1, J. Calvet1, ParcTauli Hospital Universitari, Institut d’Investigació i Innovació Parc Taulí, Rheumatology, Sabadell, Spain

Background: The origin of the histological chronic inflammation of the salivary gland in patients with primary Sjogren’s Syndrome (pSS) is questionable. It is probably a consequence of both, the evolution of the disease itself and aging.

Objectives: This study aims to evaluate histological data of chronicity of minor salivary gland biopsy with clinical characteristics and time of evolution in a series of patients with pSS.

Methods: A cross-sectional study including 98 subjects fulfilling the ACR-EULAR 2017 classification criteria for pSS. All patients underwent a minor salivary gland biopsy requested as per clinical practice. We collected the age at diagnosis and at biopsy, xerostomia and xerophthalmia evolution time, and stimulated and unstimulated salivary flow as a clinical data. We informed the following features in the minor salivary gland biopsy: the focus score (positive if ≥ 1), atrophy, fibrosis and adiposity all graded in negative, mild, moderate, and severe stages according to pathological criteria.

Results: This study included 98 patients with pSS. The median of all recruited parameters are shown in Table 1. Only 2 patients presented severe fibrosis and adiposity, so we did not consider them for the analysis. Both, the age at diagnosis and at biopsy are significantly higher between none, mild and moderate stages in the three biopsy parameters. The age at biopsy increased in negative, mild, and moderate stages, in median, 10, 9 and 6 years in atrophy, fibrosis and adiposity respectively. Although more evolution time is observed in atrophy and fibrosis regarding classification categories, it does not reach statistical significance. Focus score is associated with atrophy as a high percentage in severe stage shows negative biopsy (78% vs 22%, p = 0.046) while in negative, mild, and moderate atrophy display a positive biopsy (61%, 73% and 64%, respectively). Furthermore, we observe a significant OR of 8.75 [1.7-68] for negative, 6 [1.25-30] for mild, and 3 vs 2 and 1.75 for fibrosis). Regarding adiposity, a linear statistically significant association is observed for every stage (3.5, 1.65 and 0.7, p< 0.001). No differences in the stimulated salivary flow are shown.

USF: Unstimulated salivary flow, SSF: Stimulated salivary flow

Conclusion: An older age both, at diagnosis and at biopsy are associated with a severe stage of atrophy, fibrosis, and adiposity. Patient with severe atrophy shows less positive focus score, which might be noticed for biopsy interpretation

Disclosure of Interests: None declared

Figure 1. ALPN-303 treatment significantly reduces serum autoantibody titers and renal immune complex deposition in the inducible bm12 mouse model of lupus. *p<0.05, **p<0.01, ***p<0.001 by the Kruskal-Wallis test.

Conclusion: ALPN-303 is an engineered, potent BAFF/APRIL antagonist that continues to consistently demonstrate encouraging immunomodulatory activity and efficacy in vitro and in vivo, as further demonstrated in the SRBC immunization and bm12 lupus models, with superiority to WT TACI-Fc and anti-CD20 comparators. ALPN-303 may thus be an attractive development candidate for
the treatment of multiple autoimmune and inflammatory diseases, particularly B cell- and/or autoantbody-related diseases such as SLE, Sjögren’s syndrome, and other connective tissue diseases. A Phase 1 study of ALPN-303 in adult healthy volunteers (NCT02934484) is ongoing.

CAMK4 CONTROLS T REGULATORY CELL METABOLISM AND DEFINES THEIR FUNCTION AND STABILITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Scherlinger1,2, W. Pan3, R. Hidas4, A. Boulogoura5, M. Vukelic1,6, G. Tsokos5,6.
1Beth Israel Deaconess Medical Center (BIDMC), Rheumatology, Boston, United States of America; 2Hôpital de Hautepiere - Hôpitaux Universitaires de Strasbourg, Rheumatology, Strasbourg, France; 3Albert Einstein College, Rheumatology, Bronx, United States of America

Background: Calcium/CaM-dependent protein kinase IV (CaMKIV) is a serine kinase expressed in CD4 T cells whose activity is increased in patients with active systemic lupus erythematosus (SLE). We have shown that CaMK4 negatively impacts T regulatory (Treg) cell function in SLE, but the underlying mechanism remains unclear. Recent data suggest that CaMK4 impacts cellular metabolism.

Objectives: Investigate how CaMK4 impacts Treg cell metabolism and its potential effect on Treg cell function.

Methods: We harvested CD62L+CD4+ T cells from wild-type (WT) or Camk4-/- mice and differentiated them in vitro into Treg (iTreg) cells. We assessed iTreg metabolism using Seahorse XF analyzer and mass spectrometry (metabolomics). Gene expression was assessed at the mRNA (RT-qPCR) and at the protein level (Western Blot), Phosphofructokinase activity was assessed by a colorimetric assay (Achrom). In vitro gene knockdown was conducted by transfecting a guide RNA (gRNA) in CRISPR/Cas9-expressing T cells. T cell function was evaluated by in vitro immunosuppressive assay and in vivo by the adoptive transfer of T conventional T and iTreg cells (8:1 ratio) in Rag1-/- mice to induce inflammatory colitis. The relevance of CaMK4 in SLE was evaluated in vivo using a T-cell specific knockdown of CaMK4 in the B6.1pr mouse model, and in humans by culturing SLE patient T cells with KN-93, a CaMK4 specific inhibitor.

Results: iTreg cells from Camk4-/- mice had decreased glycolysis and increased mitochondrial metabolism compared to WT T cells. Metabolomics studies suggested decreased activity of the rate-limiting glycolysis enzyme phosphofructokinase (PFK), while PFKF mRNA and protein levels were similar. Using a phosphofructokinase knockdown, we observed decreased activity of the rate-limiting glycolysis enzyme phosphofructokinase (PFK), while PFKF mRNA and protein levels were similar. While PFKP mRNA and protein levels were similar, PFKP knockdown significantly improved iTreg function in vitro and in vivo using an adoptive CD4+ T cell transfer in Rag1-/- mice (collitis model). Interestingly, iTreg lacking PFKP were transferred Rag1-/- mice were less likely to lose FoxP3 expression and to produce IL-17A, demonstrating higher Treg stability in an inflammatory environment. A translational basis, lupus-prone B6.1pr mice with a T-cell specific Camk4 knockdown displayed significantly less lupus manifestations. In vitro, CD4+ T cells had decreased PFKP activity, which correlated to healthy donors, and PFKP activity correlated with the SLE disease activity index (SLEDAI, r = 0.47; p < 0.05). Finally, culture of SLE CD4+ T cells with KN-93 led to a significant decrease in PFKP activity (p < 0.001).

Conclusion: Increased CaMK4 activity in human SLE mediates Treg dysfunction and instability by altering PFKF activity. Restoring normal Treg metabolism by inhibition of CaMK4 or its downstream target PFKP represents a novel strategy for the treatment of SLE.

Sjögren’s Disease and Systemic Lupus Erythematosus: DXD6-CXCR5 Risk Intervals Reveal Common SNPs with Functional Significance in Immune and Salivary Gland Cells

1University of Oklahoma Health Sciences Center, Oklahoma City, United States of America; 2University Hospitals; 3Birmingham NHS Foundation Trust, Rheumatology Department, Birmingham, United Kingdom; 4University of Oklahoma Health Sciences Center, College of Dentistry; 5Oral Diagnostics and Radiology Department, Oklahoma City, United States of America; 6Salt Lake University Hospital Department of Internal Medicine, Clinical Immunology Unit, Stavanger, Norway; 7Karolinska Institutet, Department of Medicine, Stockholm, Sweden; 8University of Bergen, Department of Clinical Science, Bergen, Norway; 9National Institute of Dental and Craniofacial Research, Salivary Disorder Unit, Bethesda, United States of America; 10Hannover Medical School, Department of Rheumatology and Immunology, Hannover, Germany; 11Haukeland University Hospital, Department of Rheumatology, Bergen, Norway; 12University of Adelaide, Discipline of Medicine, Adelaide, Australia; 13Oklahoma Medical Research Foundation, Arthritis and Clinical Immunology Research Program, Oklahoma City, United States of America; 14Uppsala University, Department of Medical Sciences, Uppsala, Sweden; 15University of Oklahoma Health Sciences Center, Department of Medicine, Oklahoma City, United States of America; 16US Department of Veterans Affairs Medical Center, US Department of Veterans Affairs Medical Center, Oklahoma City, United States of America; 17Université Paris-Saclay, Assistance Publique–Hôpitaux de Paris (AP-HP), Hôpital Bicêtre, Institut National de la Santé et de la Recherche Médicale (INSERM) UMR1184, Le Kremlin Bicêtre, France; 18Newcastle University, Translational and Clinical Research Institute, Newcastle Upon Tyne, United Kingdom; 19Medical University of South Carolina, College of Medicine, Charleston, United States of America

Background: Sjögren’s Disease (SjD) and Systemic Lupus Erythematosus (SLE) are autoimmune diseases with several shared characteristics and similar genome-wide significant associations with the DXD6-CXCR5 locus. DXD6 suppresses interferon-stimulated gene expression and CXCR5 regulates T cell functions impotted in autoimmunity.

Objectives: To identify and characterize functional SNPs in the DXD6-CXCR5 interval.

Methods: ImmunoChip data from European populations (3785 SLE cases; 1916 SjD cases; 6893 controls) were imputed and SNP-trait associations tested. Bayesian statistics defined a credible SNP set that was refined using bioinformatic analyses (RegulomeDB, Haploreg, ENCODE, promoter capture Hi-C, eQTLs, etc.). Electrophoretic mobility shift assays (EMSA) and luciferase expression assays were used to test allele-specific SNP function in EBV-transfected B cells, Jurkat cells, and EBV-transfected T cells, and the risk allele significantly increased protein binding and promoter/enhancer region of DDX6, and rs4938572, rs4936443, rs7117261, and rs4938573 in the promoter/enhancer region of DXD6. Risk allele of rs4938572 also increased promoter activity in A2B5 cells (p<0.01), but had no effect on promoter or enhancer activity in B cells. SNP rs4936443 showed no promoter or enhancer activity in immune cells, but the risk allele showed
significant promoter and enhancer (p<0.001) activity in A253 cells. SNP rs7117261 showed decreased enhancer activity in EBV B cells, T cells, and A253 cells (p<0.05) and increased promoter activity in A253 cells (p<0.001). SNP rs4938573 also showed decreased promoter activity in EBV B cells, T cell and A253 cells (p<0.05). decreased promoter activity in EBV B cells (p<0.05), and increased enhancer activity in A253 cells (p<0.0001). Overall, A253 cells exhibited more allele-specific effects on promoter and enhancer activity across the five SNPs compared to tested immune cells. In addition to DDx6 and Cxcr5, rs57494551 and/or rs4938572 are reported eQTLs for several other genes of interest in the local chromatin regulatory network: IL10RA in T cells, TRAPPC4 in salivary gland and activated macrophages, and long non-coding (Inc)RNA AP002954.1 in T cells and whole blood. 3C-qPCR in EBV B and A253 cells showed that the two regulatory regions carrying rs4938572 or rs57494551 interacted with a region upstream of DDx6 that includes AP002954.1. Hi-C data showed looping between AP002954.1 and the regulatory region carrying rs4938572 and rs57494551 in T cells.

Conclusion: SJ and SLE share similar genomic architecture across the DDx6-CXCR5 risk interval with several common SNPs showing immune and salivary gland cell-type-specific allele effects on protein binding and/or enhancer/promoter activity. Extensive bioinformatic analyses suggest that the SNPs likely work within the local chromatin regulatory network to regulate cell type-specific expression of several genes on the interval. Ongoing studies will use 3C-qPCR to assess allele-specific chromatin interactions between the SNPs and these genes in different cell types, and CRISPR to determine how the risk alleles alters expression.

Type I and II interferons were highly ranked (similarity score >99), and their overexpression mimicked the disease signature. CD40 appeared also as a very relevant target (similarity score = 98.8). Three drugs had a significant negative similarity score: amoxicillin (-88.69, p=0.0019), amoylocine (-88.28, p=0.0026), and droxinostat (-85.42, p=0.0027). Droxinostat is a HDAC inhibitory. HDAC activity has been shown to be an essential element of the coactivation system for IFN-induced gene regulation and the IFN-induced innate immune response.

Conclusion: This first drug repositioning transcriptomic approach in Sjögren’s syndrome confirms the interest of targeting interferons and identifies histone deacetylases as potential therapeutic targets.

Background: Sjögren’s disease (SjD) is an autoimmune disease characterized by exocrine gland dysfunction. Long non-coding RNAs (IncRNAs) are a functionally diverse class of non-protein coding RNAs that are longer than 200 nucleotides. Our previous study using whole blood RNA-seq found that IncRNA, LINC01871, is overexpressed in SjD relative to controls [1]. CRISPR-Cas9 targetting of the LINC01871 promoter region yielded a LINC01871−/− clone with altered expression of many genes implicated in immune regulation [1].

Objectives: The goal of this study was to analyze the gene expression perturbations resulting from the loss of LINC01871 and to characterize the regulation of LINC01871 in both the LINC01871−/− clone and primary human T cells in response to immune stimuli.

Methods: Programmed and LegendsPlex bead assays were used to compare surface and secreted protein expression changes, respectively, in LINC01871−/− cells and the parental HS2B2 cells. Parental HS2B2 T cells, LINC01871−/− cells, Kasumi-3 myeloid cells, and primary human T cells were stimulated in vitro and changes in gene expression were measured over time using qRT-PCR. Responses to interferons (IFN) were assessed using universal type I IFN (IFN-α), IFN-β, and IFN-γ. TCR signaling responses were assessed using PMA/Ionomycin (PMA/I) or anti-CD3/CD28 stimulations in the presence or absence of the calcineurin inhibitor, FK506.

Results: Previous RNA-seq analysis found 1166 differentially expressed (DE) transcripts (log2FC ≥1 or ≤-1; p < 0.05) in LINC01871−/− cells compared to parental HS2B2 cells, including many prominent immune regulatory genes. Changes in the basal expression of 7 proteins in LINC01871−/− cells were confirmed using flow cytometry (significantly decreased: CD8a (p=0.0004), CD30 (p=0.0008), CXCR3 (p=0.0002), HLA-DR (p=0.02), significantly increased: CD226 (p=0.0059) and CD44 (p=0.024)). Analysis of LINC01871−/− cells revealed a growth inhibition in LINC01871−/− cells (p=0.0014 at 72h), in which multiple secreted growth and adhesion factors were significantly reduced: GM-CSF (p=2.0e-06), M-CSF (p=2.7e-09), IGBP4 (p=1.2e-07), s-ICAM1 (p=0.015), MMP9 (p=3.0e-14), and MMP2 (p=6e-08). In contrast, the IL-6 cytokine family member, IL6, was significantly increased in LINC01871−/− cells (p=1.0e-07). Because HS2B2 cells were not responsive to all IFNs, IFN-mediated regulation of LINC01871 expression was examined in the Kasumi-3 myeloid cell line. While LINC01871 expression was not modulated by type I IFN stimulation, it was robustly responsive to IFNγ treatment. Since LINC01871 was expressed in T cells and implicated in T cell pathways, responses to TCR signaling pathways were characterized in HS2B2 cells or purified primary human T cells treated with PMA/I. In both cell types, LINC01871 exhibited a prolonged decrease in expression that was abrogated by concurrent treatment with FK506, indicating that LINC01871 is regulated by calcineurin signaling. Treatment of primary human T cells with anti-CD3/CD28 to mimic true TCR engagement resulted in a modest decrease of LINC01871 expression at early time points, followed by an increase in expression with longer stimulation (2d).

Conclusion: Our findings suggest that LINC01871 is a potential mediator of the dysregulated T cell inflammatory response pathways implicated in SjD pathogenesis. LINC01871 influences the expression of many important immune cell genes and growth factors, is inducible by IFNγ, and is regulated directly by calcineurin signaling and TCR ligand engagement. Although LINC01871 functions are still unknown, observed LINC01871 overexpression in whole blood of SjD cases and after prolonged TCR stimulation in primary human T cells suggests that it could be a biomarker of SjD.

THE CELLULAR METABOLISM OF SLE NK CELLS IS PRIMARILY ALTERED AT THE LEVEL OF MITOCHLONDRIAL RESPIRATION

N. Fluder1, M. Humbel1, F. Bellanger1, A. Horisberger1, C. Fenwick1, C. Ribi1, D. Comte1, 1Lausanne University Hospital, Immunology and Allergy, Lausanne, Switzerland

Background: Systemic lupus erythematosus (SLE) is an inflammatory autoimmune disease, involving the development of autoreactive cells and autoantibodies. National Killer (NK) cells are innate immune cells that mediate the interaction between the innate and adaptive immune system, however their role in SLE is incompletely understood. SLE NK cells are decreased in peripheral blood, exhibit reduced cytotoxicity, and impaired cytokine production (1, 2). Furthermore, SLE NK cells present phenotypic alterations: increased expression of CD38 and altered upregulation of SLAMF7 after activation (3). To date, few studies evaluated the molecular mechanisms underlying NK cell dysfunction in SLE.

Objectives: We examined immune metabolic alterations of SLE NK cells.

Methods: NK cells of cryopreserved PBMC from SLE patients were isolated. Glycolysis and OXPHOS were studied using XF®e96 Seahorse. Expression of metabolic receptors (CD71, GLUT-1, CD98), mitochondrial function (mitochondrial membrane potential, mass) and calcium influx were investigated

Disclosure of Interests: None declared

REFERENCES:

by FACS. Mitochondrial structure was evaluated by electron and confocal microscopy. **Results:** First, we examined the cellular metabolism of SLE NK cells compared to healthy cells. We observed that OXPHOS is significantly increased in SLE NK cells (Figure 1A), whereas glycolysis was normal (Figure 1B). Furthermore, the mitochondrial mass and membrane potential (by FACS (Figure 1C) and confocal microscopy) were increased in SLE. Electron microscope imaging showed profound alterations in SLE NK cell mitochondrial ultrastructure (Figure 1D). No significant differences in the expression of key metabolite transporters involved in mitochondrial fueling (CD71, GLUT-1, CD98) was observed in SLE NK cells compared to healthy controls. Second, we examined how ligation of DARA and ELO influences the metabolism of healthy NK cells. Our data showed that ELO primarily enhances NK cell OXPHOS (Figure 1E), whereas DARA mainly increases glycolysis. Consistently, ELO also increases mitochondrial membrane potential and expression of metabolite transporters CD71, GLUT-1 and CD98. Next, we examined the effect of DARA and ELO on SLE NK cells. While stimulation with DARA adequately increases glycolysis in SLE NK cells, engagement with ELO fails to properly increase OXPHOS (Figure 1F), expression of cell surface transporters, mitochondrial membrane potential and mass. **Conclusion:** Our data suggest that SLE NK cells exhibit alterations in cellular metabolism, primarily involving mitochondrial respiration. In contrast, glucose metabolism is similar to that of healthy NK cells. Additionally, ELO and DARA mediate the activation of healthy NK cells through the engagement of different metabolic pathways: OXPHOS and glycolysis, respectively. Therefore, priming SLE NK cells with ELO is unable to adequately engage their dysfunctional mitochondrial respiration. These findings provide important insights on the alteration present in SLE NK cells and contribute to a better understanding of the pathogenesis of the disease. **REFERENCES:**

**POS0100** ACTIVATION OF THE CELLULAR INTEGRATED STRESS RESPONSE IN LABIAL SALIVARY GLANDS FROM SJÖGREN’S SYNDROME PATIENTS.

1Universidad de Chile, Programa de Biología Celular y Molecular, Instituto de Ciencias Biomédicas, Facultad de Medicina, Santiago, Chile; 2Ohio University, Edison Biotechnology Institute, Athens, Ohio, United States of America; 3Universidad de Chile, Departamento de Biología Médica, Facultad de Medicina, Santiago, Chile; 4Universidad San Sebastián, Facultad de Odontología, Santiago, Chile; 5Clínica Indisa, Reumatología, Santiago, Chile; 6Universidad Mayor, Escuela de Odontología, Facultad de Ciencias, Santiago, Chile

**Background:** Sjögren’s syndrome (SS) is a chronic autoimmune disease characterized by inflammation of the exocrine glands and severe symptoms of eye and mouth dryness. Disorders in the saliva secretion process have been associated with oxidative and endoplasmic reticulum (ER) stress in combination with inflammatory responses. The integrated stress response (ISR) is a mechanism that allows cells to modify their gene expression program to restore homeostasis and promote their survival against various extrinsic and intrinsic stress signals, such as hypoxia, nutrient deprivation, viral infections, inflammatory factors (cytokines, chemokines, inflammasomes), and accumulation of unfolded proteins in the ER, among others (1). The ISR is regulated by four kinases: PERK, PKR, HRI and GCN2, that dimerize and autophosphorylate to become active and each one responds to different stress stimuli. The signaling pathways that are activated in response to stress factors stimulate the phosphorylation of eIF2α, which causes a transient inhibition of global protein synthesis and induction of synthesis of some specific genes like ATF4 and Nrf2. ATF4 induces the transcription of genes involved in metabolism and nutrient uptake, redox status, and regulation of apoptosis. Dephosphorylation of eIF2α in the ISR termination signal to restore protein synthesis is mediated by the PP1 complex, which recruits the catalytic subunit PP1c and one of its two regulatory subunits: GADD34 or CREP.

**Objectives:** To evaluate the presence and functional state (phosphorylation) of the ISR sensing kinases: PERK, PKR, HRI and GCN2; the levels of eIF2α/p-eIF2α and the key ISR transcription factors ATF4 and Nrf2, as well as subunits of the complex involved in the ISR termination: PP1c, GADD34 and CREP in labial salivary glands (LSG) of SS-patients. **Methods:** Biopsies of LSG from 12 SS-patients and 11 control subjects were studied. The levels of mRNA, protein and phospho (p)-protein of the ISR components were determined by RT-qPCR and Western blotting. **Results:** Our results show increased levels of p-PERK/PERK ratio (11/11), p-PKR (7/11), p-PKR/PKR ratio (7/11), p-eIF2α (5/11) and ATF4 (11/11) in LSG from SS-patients compared to control subjects. No significant changes were found in mRNA levels of HRI, GCN2, and GADD34 between LSG from SS-patients and control subjects. Decreased protein levels of HRI (8/12), p-GCN2 (6/11), eIF2α (6/11), p-eIF2α (6/11), Nrf2 (11/12), and p-NRF2 (12/12) were found in LSG showing scarce parenchyma and high fibrosis and fat infiltration. On the other hand, PP1c and CREP showed decreased mRNA and protein levels in all SS-patients LSG. Interestingly, Ro autoantibodies and focus score were negatively correlated with PP1c and Nrf2 mRNA and protein levels whereas positively correlated with PKR mRNA levels. **Conclusion:** The overexpression and activation of some ISR kinases together with the decrease in the PP1c/CREP the integrated stress response (ISR) is a key mechanism of activation of ISR, resulting in p-eIF2α to remain activated in LSG from SS-patients. This would explain the high protein levels of ATF4 and of target genes involved in the antioxidant response in LSG from SS patients suggesting that ISR activation plays a key role in pro-survival response to cellular stress.

DOI: 10.1136/annrheumdis-2022-eular.313
Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder, characterized by a remarkable heterogeneity of clinical presentations. Glomerulonephritis (GN) remains a leading cause of morbidity and mortality in SLE, influencing long-term prognosis. The alteration of both innate and adaptive immune responses plays a pivotal role in SLE pathophysiology [1]. B lymphocytes are mainly involved in SLE through the production of autoantibodies but recent evidence suggests an effector role of these cells in cytokine production. IL-40 is a recently discovered cytokine, produced by B cells and involved in their homeostasis, that may participate in the pathogenesis of B-mediated autoimmune diseases, such as SLE [2].

Objectives: The purpose of this study was to evaluate the role of IL-40 in the pathogenesis of SLE, with a specific focus on renal involvement.

Methods: Peripheral blood and urine samples were collected from 10 consecutive SLE patients and 10 healthy controls; kidney biopsy specimens were obtained from 3 SLE patients and 3 controls. The concentration of IL-40 in serum and urine samples was evaluated by ELISA. IL-40 production by monocytes, B cells and T cells was assessed by flow cytometry at day 0 and after in vitro stimulation. Immunohistochemistry on kidney tissue was also performed to evaluate IL-40 expression.

Results: IL-40 levels were reduced in the serum of patients with active GN. This reduction was further observed in the serum of patients with previous GN. In the serum of active SLE patients, without renal involvement, the concentration of IL-40 did not change significantly compared to controls. Urinary levels of IL-40 showed no significant changes compared to controls. Consistently, immunohistochemistry on kidney showed the expression of IL-40 only in SLE patients (Figure 1). Flow cytometric analysis on T cells, B cells and monocytes isolated from peripheral blood of SLE patients with active GN did not show production of IL-40.

Conclusion: To the best of our knowledge this is the first demonstration of IL-40 expression at kidney level in SLE associated nephritis. These preliminary data suggest an active role of IL-40 in SLE, with specific focus on active kidney disease. Our results highlight a potential use of IL-40 as a marker of active GN, although its specific mechanism of action needs to be further elucidated.

Rheumatoid arthritis prognosis, predictors and outcome

**POS0103**
IN RHEUMATOID ARTHRITIS, THE ASSOCIATION BETWEEN ANTI-MODIFIED PROTEIN ANTIBODIES AND LONG-TERM OUTCOMES IS DOMINATED BY THE EFFECT OF ANTI-CITRULLINATED PROTEIN ANTIBODIES

T. J. Van Wesemael1, M. Verstappen1, R. Knevel1, A. Van der Helm-van Mil1, T. Huizinga1, R. Toes1, D. Van der Woude1. Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands

**Background:** In rheumatoid arthritis (RA) many patients harbor autoantibodies against posttranslationally modified proteins (anti-modified protein antibodies (AMPA)); anti-citrullinated protein antibodies (ACPA), anti-carnbamylylated protein antibodies (anti-CarP) and anti-acetylated protein antibodies (AAPA). All three AMPA have been described to be associated with an increase in radiographic joint damage and ACPA also with a lower chance of obtaining sustained drugfree remission (SDFR). However, it is unclear whether the effects of these autoantibodies are independent of each other, and whether testing for all three AMPA offers additional information regarding these clinical outcomes.

**Objectives:** To investigate the individual and combined associations of AMPA with radiological progression and SDFR in RA.

**Methods:** In 612 RA patients from the Leiden Early Arthritis Clinic, we measured ACPA IgG with anti-CCP2- assays, anti-CarP IgG using homocitrullinated and native (as a control) fetal calf serum, and AAPA IgG by means of novel assays consisting of cyclic peptides with either acetylated or norleucine residues (as a control). Sharp–van der Heijde scores (SHS) were determined in 2685 sets of radiographs with yearly intervals for 7 years. The association of AMPA with SHS was assessed with a multivariate normal regression model. SDFR was defined as the absence of clinical synovitis after discontinuation of DMARD treatment. The association of SHS with autoantibody-status was assessed with Kaplan-Meier curves. The very small number of patients single-positive for ACPA (n=4, 1%) precluded analyses in this subgroup.

**Results:** The prevalence of autoantibodies is shown in Table 1. A higher SHS was found in patients with autoantibodies compared to patients without antibodies, and in triple-positive versus single-positive patients (Figure 1A, p=0.04). To investigate if the higher SHS was due to the number of autoantibodies or a specific autoantibody, analyses were stratified for all three AMPAs. Interestingly, no difference was found in SHS between all ACPA-positive strata (Figure 1B). In the ACPA-negative stratum, a significant difference was found between patients with zero antibodies and solely anti-CarP (p=0.02).

The chance to obtain SDFR was lower in all antibody-positive groups compared to the autoantibody-negative group. Moreover less triple-positive antibody-positive patients than single-antibody-positive patients achieved SDFR (p<0.001), Figure 1C. After stratification for AMPA, no difference was found in the percentage of SDFR in all ACPA-positive strata, or in the ACPA-negative stratum, Figure 1D.

**Conclusion:** In ACPA-positive patients, the presence of other AMPA influences neither radiographic progression, nor the chance of SDFR. Thus, long-term clinical phenotype in RA is particularly dependent on the presence of ACPA, and less on the presence of other AMPA. Therefore, there appears to be no added value of testing the other AMPA for predicting clinical outcome in ACPA-positive patients.

**POS0104**
ACPA-NEGATIVE AND ACPA-POSITIVE RA-PATIENTS ACHIEVING DISEASE RESOLUTION DEMONSTRATE DISTINCT PATTERNS OF MRI-DETECTED JOINT-INFLAMMATION

M. Verstappen1, X. Matthijssen1, S. Connolly2, M. A. Maldonado2, T. Huizinga1, A. Van der Helm-van Mil1,3. Leiden University Medical Center, Rheumatology, Leiden, Netherlands; Bristol Myers Squibb, Immunology and Fibrosis, Philadelphia, United States of America; Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands

**Background:** Sustained DMARD-free remission (SDFR), the sustained absence of clinical-synovitis after DMARD-discontinuation, is increasingly achievable in RA. However, prevalence differs significantly between ACPA-negative (40%) and ACPA-positive RA (5-10%). In addition, early-DAS-remission (DAS<2.6) associates with SDFR in ACPA-negative RA but not in ACPA-positive RA. Based on these differences, we hypothesized that longitudinal patterns of local tissue-inflammation (synovitis/tenosynovitis/osteitis) might also differ between ACPA-negative and ACPA-positive RA-patients achieving SDFR.

**Objectives:** With the ultimate aim to increase understanding of disease-resolution in RA, we studied MRI-detected joint-inflammation over time in relation to SDFR-development in ACPA-negative RA and ACPA-positive RA.

**Methods:** 198 RA-patients (94 ACPA-negative and 104 ACPA-positive) underwent repeated MRIs (0/4/12/24-months) and were followed on SDFR-development. The course of MRI-detected total-inflammation, and synovitis/tenosynovitis/osteitis individually, were compared between RA-patients who did and did not achieve SDFR, using Poisson-mixed-models. 170 ACPA-positive RA-patients from the AVERT-1 were studied as ACPA-positive validation-population.

**Results:** In ACPA-negative RA, patients achieving SDFR had similar baseline total inflammation-levels, which declined 2.0-times stronger in the first-year of DMARD-treatment (IRR 0.50, 95%CI;0.32-0.77 , p<0.01) compared to patients without SDFR. This stronger decline was seen in tenosynovitis/synovitis/oesteitis. In contrast, ACPA-positive RA-patients achieving SDFR, had already lower inflammation-levels (especially synovitis/oesteitis) at disease-presentation (IRR 0.45, 95%CI;0.24-0.86, p=0.02) compared to non-SDFR patients, and remained lower during follow-up (p=0.02). Similar results were found in the ACPA-positive validation-population.

**Conclusion:** Compared to RA-patients without disease-resolution, ACPA-positive RA-patients achieving SDFR have less severe joint-inflammation from diagnosis onwards, whilst ACPA-negative RA-patients present with similar inflammation-levels but demonstrate a stronger decline in the first year of DMARD-therapy. These different trajectories suggest that mechanisms underlying resolution of RA-chronicity in both RA-subsets might be different and indicates the relevance of the total inflammatory-load in ACPA-positive RA.

Gemelli’/IRCCS, Rome, Italy; 2Immunology Research Core Facility, Gemelli Science and Technology Park (GSTep) - Fondazione Policlinico Universitario ‘A. Gemelli’/IRCCS, Rome, Italy; 3Department of Medicine, Università Cattolica del Sacro Cuore, Rome, Italy; 4Institute of Pathology, Fondazione Policlinico Universitario ‘A. Gemelli’/IRCCS, Rome, Italy; 5Division of Rheumatology, Fondazione Policlinico Universitario ‘A. Gemelli’/IRCCS, Rome, Italy.

Background: Among Janus kinase inhibitors (JAKI) approved for Rheumatoid Arthritis (RA) treatment, tofacitinib and baricitinib are considered as pan-JAKi (pJAKI) while upadacitinib and filgotinib are selective anti-JAK1 (sJAK1) drugs. To date, despite >30% of RA patients exposed to JAKI achieve DAS28-CRP remission at 12 weeks, there is still lack of predictive biomarkers of response in RA treated with distinct JAKI.

Objectives: To determine whether pre-treatment immunological and synovial tissue features can predict clinical improvement in moderate-to-severe RA treated with JAKI.

Methods: Among 174 RA patients treated with JAKI, 84 underwent peripheral blood (PB) drawing and US-guided synovial tissue (ST) biopsy. Demographic, clinical and immunological features were collected for each patient at baseline and after 12 weeks. The distribution of PB-derived B lymphocytes subsets was assessed by flow cytometry, using CD27/IgD classification. Synovitis degree assessment was determined using Krenn score (KSS) by trained pathologist, blinded to clinical characteristics.

RESULTS: Among enrolled RA patients, 82.7% was treated with pJAKI and 17.3% with sJAKI. Moreover, 35.6% of RA patients was b/ts-DMARDs naïve, 18.4% b/ts-DMARDs non-responder and 46.0% was difficult-to-treat (D2T) RA. In the whole cohort, 49.2% and 50.8% of RA patients achieved DAS28-CRP and CDAI low disease activity (LDA), respectively, after 12 weeks of JAKI treatment. Moreover, 37.7% and 5.9% of RA patients achieved DAS28-CRP and CDAI remission (REM), respectively, after 12 weeks of JAKI treatment regardless to JAKI category. Considering the immunological profile, RA patients achieving CDAI LDA were more likely rheumatoid factor (60.0%) and ACPO positive (60.5%) compared to RA patients not achieving this outcome (RF: 40.0%, p= 0.03 and ACPO: 39.5%, p= 0.02). Considering PB-derived B cell phenotype, b/ts-DMARDs naïve RA achieving DAS28-CRP LDA at 12 week had pre-treatment lower unwrapped memory B (IgDposCD27neg) cell rate (6.91±7.70%) compared to b/ts-DMARDs naïve RA not achieving the same outcome (13.2±5.68%, p= 0.009). ROC analysis identified a cut-off value of 6.89% for IgDposCD27neg cells discriminating b/ts-DMARDs naïve RA achieving DAS28-CRP LDA at 12 week [AUC: 0.174±0.086; p= 0.008; OR(95%CIs): 18.20 (1.761-188.069)]. Furthermore, b/ts-DMARDs naïve RA achieving DAS28-CRP REM at 12-week follow up visit, had PB enrichment of naïve B cells (IgDposCD27neg: 68.08±17.38%) and lower percentage of unwrapped memory B lymphocytes (5.10±4.29%) compared to RA not achieving the same outcome (IgDposCD27neg: 54.68±16.16%, p= 0.05; IgDposCD27neg: 13.96±8.34%, p= 0.001) [IgDposCD27neg cut-off: 62.6%, AUC:0.727±0.101, p= 0.05; OR(95%CIs): 7.33 (1.272-42.294); IgDposCD27pos cut-off: 6.89%, AUC: 0.139±0.073, p= 0.002; OR(95%CIs): 12.37 (1.828-83.767)]. Interestingly, considering the D2T RA subgroup, patients achieving DAS28-CRP LDA at 12 week follow up had lower rates of PB-derived IgDposCD27neg B cells (3.83±0.96%) compared to RA not achieving the same outcome (7.25±2.83%, p= 0.04; cut-off: 5.46%, AUC: 0.083±0.095, p= 0.041). Considering the pre-treatment synovitis degree, b/ts-DMARDs naïve RA achieving CDAI LDA status had significantly higher KSS at baseline (3.8±2.2) compared to RA not achieving the same outcome [1.7±1.4, p= 0.02; KSS cut-off: 3.00, AUC: 0.795±0.087; p=0.018; OR(95%CIs): 14.0 (1.39-141.49)]. Finally, no significant associations were observed between PB-derived B cell subpopulations rate and synovitis degree both in the whole RA cohort as well as stratifying patients for disease phase.

Conclusion: Pre-treatment immunological profile, peripheral blood-derived B cell phenotype and synovitis degree are associated with the early achievement of at least DAS28-CRP/CDAI LDA in RA patients receiving JAKI despite their selectivity.

Background: There is no international consensus on an optimal ultrasound scoring system in patients with rheumatoid arthritis (RA) yet.

Objectives: To assess the musculoskeletal ultrasound score on seven joints (‘US7 score’) (1) for the identification of the most frequently pathologic and
responsive joint regions during 3 and 6 months of therapy in order to optimize the score. Furthermore, to evaluate the impact of disease duration on the performance of the score.

Methods: RA patients were recruited from 54 German rheumatology centers when starting or changing DMARD therapy. Patients were assessed by the US7 score in grayscale (GS) and power Doppler (PD) at baseline, after 3 and 6 months. The frequency of pathologic joint/tendon regions and their responsiveness to therapy were assessed including the comparison of palmar vs. dorsal regions.

Differences between the palmar and the dorsal sides were analyzed using Chi-square test, the gradings of the US-joint inflammation were compared between baseline, 3 months, and 6 months by Friedman test with Dunn test as post-hoc test.

We used standard response mean to determine the responsiveness of possible reduced scores and linear regression to assess the amount of information retained from the original score. Analyses were also performed separately for early and established RA.

Results: A total of 435 patients (n=138 early RA) were included (56.5 (SD 13.1) years old, 8.2 (9.1) years disease duration, 80% female). The wrist, palmar MCP2, extensor digitorum communis (EDC) and carpi ulnaris (ECU) tendons out of 7 joints were most frequently affected by GS/PD synovitis/tendonovitis (wrist: 45%/43%; MCP2: 35%/28%; EDC: 30%/11% and ECU: 25%/11%) and significantly changed within 6 months of therapy (all p≤0.003 in GS/PD).

The dorsal vs. palmar side of the wrist by GS/PD (p<0.001) and the palmar vs. dorsal side of the finger joints by PD (p<0.001) were more frequently pathologic. The reduced US7 score (GS and PD: dorsal MCP2, dorsal wrist, EDC and ECU, only GS: palmar MCP2) showed therapy response (SRM 0.433) after 6 months and retained 76% of the information of the full US7 score. No major differences between the groups of early and established RA could be detected.

Conclusion: The wrist, MCP2, EDC and ECU tendons were most frequently pathologic and responsive to therapy, representing an optimized score for monitoring of RA patients for both early and established RA and should therefore be included in comprehensive scores for monitoring RA patients.

Background: The goal of treatment for RA is achieving low disease activity and/or remission1–3; however, disease course and management can be complicated by additional factors that may be influenced by serostatus. Anti-citrullinated protein antibodies (ACPAs) and RF contribute to a more severe RA disease pattern4 and may be useful in predicting response to treatment.4 ACTION (AbataCept T In OutNe clinical practice; NCT02109666) and ASCORE (Abatacept SubCutaneous in Routine Clinical Practice; NCT02090556) were 2-year, international, observational, prospective, multicenter studies of IV and SC abatacept, respectively, for the treatment of RA in routine clinical practice.5,6 Previous analyses have shown that ACPA/RF double-positive serostatus was associated with better treatment outcomes compared with ACPA/RF double-negative serostatus.4,6

Objectives: To assess the independent effect of ACPA or RF single seropositivity among patients with RA on achieving remission after treatment with abatacept for 2 years, and to compare outcomes among patients with single versus double serostatus.

Methods: This post hoc analysis included patients from ACTION and ASCORE who were initiated IV (body weight-adjusted dosing) or SC abatacept (125mg once weekly), respectively. Patients were stratified by baseline ACPA/RF status: ACPA+/RF− (ACPA+ only), ACPA−/RF+ double positive (+/+), ACPA−/RF− (RF+ only), and ACPA−/RF− double negative (−/−). DAS28 (CRP) and CDAI remission rates (defined as ≤2.6 and 0–2.8, respectively) at 2 years for patients who were ACPA+ or RF+ only at baseline were assessed and compared with those who were +/+ and −/−. Patients with missing baseline ACPA/RF status were excluded. Last observation carried forward efficacy analyses were used to impute missing values.

Results: This analysis included 1679 patients from ACTION (ACPA+ only, n = 98; +/+ or −/−, n = 1028; RF+ only, n = 161; and −/−, n = 392) and 1748 patients from ASCORE (ACPA+ only, n = 184; +/+ or −/−, n = 1079; RF+ only, n = 142; and −/−, n = 343). Across studies and serogroups, baseline demographics and disease characteristics were similar (data not shown). In both ACTION and ASCORE, a higher proportion of patients who were only ACPA+ achieved DAS28 (CRP) and CDAI remission at 2 years compared with patients who were +/+. In contrast, a lower proportion of patients who were only RF+ achieved DAS28 (CRP) and CDAI remission at 2 years compared with patients who were +/+ (Figure 1). Additionally, a similar proportion of patients who were only ACPA+ achieved DAS28 (CRP) and CDAI remission at 2 years compared with patients who were −/−. In contrast, a lower proportion of patients who were only RF+ achieved DAS28 (CRP) and CDAI remission at 2 years compared with patients who were +/+.

Conclusion: In this post hoc analysis of real-world data from ACTION and ASCORE, ACPA positivity was associated with an increased likelihood of achieving DAS28 (CRP) and CDAI remission at 2 years. Patients who were ACPA+ only were as likely to achieve remission as +/+ patients, suggesting that RF serostatus had less influence than ACPA serostatus on remission status at 2 years. In line with this, patients who were RF+ only were less likely to achieve remission at 2 years. This is the first large, real-world study to show that ACPA positivity plays a more important role than RF positivity in achieving remission whilst on abatacept. These results highlight the importance of assessing baseline ACPA status when considering treatment options for patients with RA.

A. Brkic 1,2, K. Łosi 1,3, A. H. Prripp 1,4, M. Korkosz 3,5, G. Haugeberg 1,2.

Background: A recent meta-analysis by Ferreira et al. (2020) has questioned the validity of using Patient Global Assessment (PGA) to define remission in the Boolean remission criteria (4-variable remission, 4vR) [1]. This is because PGA, which presumptively reflects a patient’s perception of disease activity, is influenced by both inflammatory and non-inflammatory mechanisms, thus questioning the validity of PGA-related remission definitions when treating patients to target using anti-inflammatory drugs. Further, the impact of PGA differs in the various definitions and algorithms developed to define remission in rheumatoid arthritis (RA).

Objectives: This study aims to examine remission rates by applying different definitions of remission in an outpatient cohort of RA patients and illuminate the impact of PGA on Boolean remission.

Methods: Data were obtained during 2019 from RA patients followed at an outpatient clinic in Southern Norway. The composite disease activity scores simple disease activity index (SDAI), clinical disease activity index (CDAI), and disease activity score with 28 joint count with C-reactive peptide (DAS28(3) and with PGA DAS28(4)), as well as Boolean 4vR and without PGA the 3-variable remission (3vR) were used to define remission. Cut-off remission values for CDAI, SDAI, and DAS28 are ≤2.8, ≤3.2, and ≤2.6, respectively. 4vR is attained when PGA ≤10, C-reactive peptide (CRP) ≤10 mg/L, SJCD ≥8, and TJC28 ≤1, while 3vR when CRP ≤10 mg/L, TJC28 and SJCD ≤1. Remission rates for 4vR were also calculated with the PGA cut-offs of ≤20, 30, 40, 50, 60, 70, 80, 90.

Results: In Figure 1, proportion rates of remission for DAS28(3), DAS28(4), CDAI, SDAI, 3vR, and 4vR with different PGA cut-offs are presented. The proportion of remission was 73% for DAS28(3), 67% for DAS28(4), 37% for CDAI, 38% for SDAI, 23% for 4vR, 65% for 3vR. When comparing the different remissions proportion rate with various cut-offs of PGA in 4vR, SDAI and CDAI lie between a cut-off of ≤20 and ≤30, while DAS28(3), DAS28(4), and 3vR all lie beyond a cut-off of ≤90.

Conclusion: Our data highlights that there is a great variation in remission rates for the different remission definitions, with DAS28(3) having the highest (73%) and the original Boolean remission the lowest (23%) remission rate. While RA patients in DAS28 remission may still have swollen joints, RA patients with no swollen and tender joints and normal CRP may not achieve Boolean remission because of even a minor elevation of PGA above ten, which may not only reflect inflammatory mechanisms. We question the value of using remission definitions where PGA has a large impact when used in ordinary clinical practice to treat patients to remission. Further studies are warranted to illuminate which remission definitions should be used both in studies and in ordinary clinical practice when treating patients with anti-inflammatory drugs.

Is it time for a paradigm shift to focus more on objective than subjective measures reflecting disease status and disease activity when aiming for remission daily clinical practice?
POSO109 IMPACT OF EARLY AGE AT MENOPAUSE ON DISEASE OUTCOMES IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS: RESULTS FROM A LARGE OBSERVATIONAL COHORT OF KOREAN PATIENTS WITH RHEUMATOID ARTHRITIS

1Chung-Ang University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Seoul National University Bundang Hospital, Division of Rheumatology, Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)

Background: The increased prevalence of rheumatoid arthritis (RA) in women has led to studies exploring how female reproductive factors affect disease outcomes in women RA. While a few studies have investigated how early menopause (EM) affects RA outcomes, they had relatively small sample size and have shown inconsistent results [1, 2]. Moreover, none has evaluated the association between age at menopause and longitudinal changes in validated disease activity indices or patient-reported outcomes (PROs) of RA.

Objectives: We aimed to assess the differences in clinical outcomes between RA patients with EM (age at menopause <45 years) and usual menopause (UM) (age at menopause ≥45 years), and identify potential impact of EM on longitudinal changes in RA activity and PROs during follow-up period.

Methods: A total of 2,878 postmenopausal women with RA were included from the Korean Observational Study Network for Arthritis, a nationwide prospective RA cohort of Korea. Each patient was examined at baseline and for 5 consecutive years using the simplified disease activity index (SDAI), health assessment questionnaire-disability index (HAQ-DI), and other PROs. Among patients with a baseline SDAI >11, generalized estimating equation (GEE) analyses were performed to evaluate the impact of EM on longitudinal changes in RA activity and PROs during follow-up period.

Results: The EM group (N=437) was younger than the UM group (N=2,441) [58.0±9.5 vs. 60.8±8.0 years, p<0.001], but RA duration was similar between the two groups. The EM group had higher education level and was more likely to be seronegative at enrolment. Moreover, the EM group demonstrated higher disease activity [SDAI 15.4±11.7 vs. 13.9±10.0, p=0.011] and patient-reported visual analogue scale (VAS) scores for global assessment, fatigue, and sleep disturbance (all p<0.05), and worse EQ-5D-VAS [59.9±22.2 vs. 63.0±19.5, p=0.006] at baseline. The rate of previous fracture and neoplastic disease, especially uterine/cervical neoplasm, was higher while that of hypertension was lower among the EM group. The GEE model revealed that EM significantly influenced the rate of SDAI change (β=1.265, p=0.004), after adjusting for age, RA duration, biologic use, and SDAI at baseline. The EM group was also significantly associated with increase in HAQ-DI (β=0.088, p=0.003), and decrease in EQ-5D utility value (β=-0.031, p=0.016) during 5-year follow-up period.

Conclusion: RA patients with EM demonstrate higher disease activity and poorer health-related quality of life. EM significantly affects longitudinal changes in disease activity and PROs in RA.

in pts in NA vs RoW (Figure 1). Incidence and risk of MACE were higher with tofacitinib vs TNFi in both NA and RoW (Figure 1). In NA, MACE IRs were higher for tofacitinib 5 mg BID vs TNFi in pts with a HxCAD, and tofacitinib 10 mg BID vs TNFi for pts with a high 10-yr risk of MACE; pts with low or borderline 10-yr MACE risk had no MACE across tofacitinib groups (Figure 1). Compared with NA, similar trends for MACE were generally observed across treatments in RoW, particularly for intermediate, borderline and low CV risk categories (Figure 1).

### HxCAD was defined as any history of MI, coronary heart disease, stable angina pectoris or coronary artery procedures.

### United States, Puerto Rico and Canada.

### For pts randomised to TNFi group, adalimumab and etanercept were administered in NA and RoW, respectively.

### In NA, MACE IRs were higher for tofacitinib 5 mg BID vs TNFi in pts with a HxCAD, and tofacitinib 10 mg BID vs TNFi for pts with a high 10-yr risk of MACE; pts with low or borderline 10-yr MACE risk had no MACE across tofacitinib groups (Figure 1). Compared with NA, similar trends for MACE were generally observed across treatments in RoW, particularly for intermediate, borderline and low CV risk categories (Figure 1).

### Conclusion: This post hoc analysis of data from ORAL Surveillance suggests that differences in MACE IRs across geographic regions are largely driven by HxCAD and high BL CV risk scores in NA vs RoW. Results should be interpreted with caution due to low pt and event numbers, particularly restricting the evaluation of tofacitinib vs TNFi in NA and RoW. Noting this limitation, these findings emphasise the importance of assessing and addressing BL CV risk when treat-

### Science Abstracts
Background: A Treat-to-Target approach (T2T) is broadly considered to lead to better clinical outcomes and recommended in patients with RA. However, very few studies have analyzed the effect of T2T on radiographic progression, and any such studies have provided inconsistent results.

Objectives: To investigate whether meticulously following a treat-to-target (T2T)-strategy in daily clinical practice leads to lower radiographic progression in RA.

Methods: Patients from the multicenter RA-BIODAM cohort with ≥2 consecutive visits with radiographs available were included. In RA-BIODAM patients were enrolled as they were initiating a new csDMARD/dMARD treatment were followed-up with the intention to benchmark and intensify treatment. The primary outcome of this analysis was the change in Sharp-van der Heijde score (SvdH, 0-448), assessed every 6 months, using average scores from 2 readers (scores with known chronological order). Following a DAS44-T2T remission strategy, which was defined at each 3-month visit, was the main variable of interest. Patients were categorized based on the proportion of visits in which T2T was followed according to our definition: very low (≤40% of the visits, low (>40%, <62.5%), high (≥62.5%, ≤75%) and very high (>75%). Radiographic progression at 2 years was visualized across groups by cumulative probability plots. Per 3-month interval T2T could be followed zero, one or two times (in a total of 2 visits). Associations between the number of visits with T2T in an interval and radiographic progression, both in the same and in the subsequent 6-month interval, were analysed by generalised estimating equations, adjusted for age, gender, disease duration and country.

Results: In total, 511 patients were included (mean (SD) age: 56 (13) years; 76% female). After 2 years, patients showed on average 2.2 (4.1) units progression (median:1 unit). Mean (SD) 2-year progression was not significantly different across categories of T2T: very low: 2.1 (2.7) units; low: 2.8 (6.0); high: 2.4 (4.5); very high: 16 (2.2) (Figure 1). Meticulously following-up T2T in a 3-month interval neither reduced progression in the same 6-month interval (parameter estimates (for yes vs no): +0.15 units (95%CI: -0.04 to 0.33) for 2 vs 0 visits; and +0.08 units (-0.06;0.22) for 1 vs 0 visits) nor did it reduce progression in the subsequent 6-month interval (Table 1).

Conclusion: In this daily practice cohort, more meticulously following T2T principles did not result in more reduction of radiographic progression than a somewhat more liberal attitude toward T2T. One possible interpretation of these results is that the intention to apply T2T already suffices and that a more stringent approach does not further improve outcome.

Background: Flares are an inherent part of the rheumatoid arthritis (RA) disease course and may impact clinical and patient outcomes. The ability to predict flares between clinic visits based on real-time longitudinal patient-generated data could potentially allow for timely interventions to avoid disease worsening. For intensively-collected patient-generated data, machine learning methods offer benefits over traditional statistical tools for accurate prediction, but examples in rheumatology are sparse.

Objectives: Investigate the feasibility of using machine learning methods to classify self-reported RA flares based on a small dataset of daily symptom data generated on a smartphone app.

Methods: We used data from the Remote Monitoring of Rheumatoid Arthritis (REROMA) study, which aimed to improve monitoring of disease severity in RA. Patients tracked daily symptoms (pain, fatigue, function, sleep, coping, physical and emotional wellbeing) on a 0-10 numerical rating scale, duration of morning stiffness, and weekly flares on the REROMA smartphone app for three months. The outcome was the binary yes/no answer to the weekly flare question “Have you experienced a flare in the last week?” Several summaries of the eight daily symptom scores collected in the week leading up to the flare question (the exposure period) were used as predictors. These included the mean, min, max, standard deviation and slope. Where exposure periods overlapped, the intersecting symptom reports were allowed to correspond to multiple outcomes. We fitted three binary classifiers: logistic regression +/- elastic net regularization, a random forest and naïve Bayes. The models were benchmarked using the R package mlr3 and 10-fold cross-validation, with two participants comprising the test and the remaining 18 the training set.

Finally, the performance of the classifiers was evaluated according to the area under the curve (AUC) of the receiver operating characteristic curve. The model with the highest AUC in the test dataset was considered as the best final model.

Results: Twenty patients tracked daily symptoms over three months. 60% were female, all but one were white British, and mean age was 56.9±11.1 years. The median number of days in the study was 81 (interquartile range (IQR) 80, 82). The collected data comprised an average of 69.6 daily reports and 10.5 weekly reports per participant over the study period. Participants reported a median of 2 flares (IQR 0.75-4.25) resulting in 57 flares in total. Classifier performances are visualized in Figure 1. The best performing model was logistic regression with elastic net with an AUC of 0.82. At a cut-off point requiring specificity to be 0.80, the corresponding sensitivity to detect flares was 0.60 for this model, meaning that the prediction model correctly identified three in every five self-reported flares, and four in every five non-flares. At this cut-off, the positive predictive value, i.e. the probability that those with a predicted flare indeed go on to have a flare was 53%. The negative predictive value, i.e. the probability that those with a predicted non-flare indeed do not experience a flare, was 85%.

Conclusion: Predicting self-reported flares based on daily symptom scorings in the preceding week using machine learning methods was feasible, although regularized logistic regression outperformed the other machine learning methods in this small dataset. The perceived advantage of machine learning may therefore be attributed to overfitting. It is possible that the observed predictive accuracy will improve as we obtain more data.

Figure 1. Performance of binary flare classifiers fitted to data from the REMORA study: Logistic regression with and without regularization, naïve Bayes and random forest.
time \((F(4,141) = 0.712, p=0.585)\). Figure 1 shows the estimated trajectories of DSAS2-ESR scores over 12 months time for the three health literacy groups. Patients with “several health literacy limitations” were prescribed prednisolone significantly more often (52.4%) than patients with “some health literacy limitations” (21.2%) or “good health literacy” (22.2%) over time \((p=0.019)\). Patients with “some health literacy limitations” were prescribed conventional DMARDs more often (72.7%) than patients with “good health literacy” (38.9%; \(p=0.008\)) There was no difference in biological DMARDs use between the health literacy groups.

**Conclusion:** We found that among patients with RA, those with several health literacy limitations have higher disease activity scores over time and use prednisolone significantly more often than patients with higher health literacy levels. No difference was observed in biological DMARD use. These results grant more insight into the role of health literacy for treatment and outcomes in patients with RA and supports existing research in other chronic diseases.

**COMPUTATIONAL IDENTIFICATION OF SLE PATIENT RECORDS USING DATA-DRIVEN CLINICAL FINGERPRINTS**

M. Barbero Mota, J. L. Gamboa, J. M. Still, C. M. Stein, V. K. Kawai, T. A. Lasko. Vanderbilt University Medical Center, Department of Biomedical Informatics, Nashville, TN, United States of America; Vanderbilt University Medical Center, Department of Medicine, Nashville, TN, United States of America

**Background:** Systemic lupus erythematosus (SLE) is a chronic relapsing autoimmune disorder that is challenging to diagnose due to its heterogeneous presentation of a combination of non-specific clinical manifestations and laboratory findings. This heterogeneity and lack of granularity is a major cause of treatment failure. With the advent of precision medicine, there is a need for accurate methods to identify cases of SLE in large clinical databases, and to recognize constellations of pathological characteristics (or fingerprints) that allow a better understanding of the disease. Computational phenotype discovery aims to solve this problem by using unbiased, data-driven machine learning methods to disentangle the fingerprints of disease that hide within the noisy, sparse and incomplete electronic health record data.

**Objectives:** To generate data-driven phenotypic fingerprints of SLE and validate them by assessing their ability to distinguish records of patients with SLE vs. ‘near miss’ patients without the disease.

**Methods:** Records of 716 patients that published, expert-curated algorithms [1] indicated as likely SLE patients were reviewed by 3 clinicians and labeled as positive (490 records), negative (261), or indeterminate (55). Those labeled positive by an algorithm but negative by clinician chart review were considered ‘near misses’ and should be among the more difficult cases to classify. We trained an ElasticNet (regularized logistic regression) model to distinguish the true positive records from the near misses and evaluated it under 10x cross validation.

Inputs to the predictive model were the projections of each patient record into the space of 2000 latent variables. These features had been inferred separately by an unsupervised machine-learning algorithm from a much larger dataset of 646,716 randomly sampled temporal cross sections of 63,775 longitudinal records of patients with an antinuclear antibody test. Each of the 2000 variables constitutes the phenotypic fingerprint of an unobserved, independent potential disease mechanism. Formally, they represent linear combinations of demographic data, laboratory test results, billing code intensities, and medication exposures [2].

**Results:** Our predictive model achieved an area under the Receiver Operating Characteristic Curve of 0.90, 95% CI: [0.879, 0.922], an area under the Precision-Recall Curve of 0.94, 95% CI: [0.926, 0.954], and an Integrated Calibration Index of 0.074, 95% CI: [0.067, 0.080]. The model selected 61 of the 2000 potential latent mechanisms to distinguish positive SLE records from near-misses. All of the phenotypes selected to be predictive exhibit high face-validity from a clinical interpretation perspective. They include recognizable patterns of variables representing different clinical features of SLE (Figure 1).

**SERUM PROTEIN CONVERTASE SUBTILISIN/ KEXIN TYPE 9 (PCSK9) AND CARDIOVASCULAR RISK IN SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL COHORT STUDY**

C. C. Mok, K. L. Chan, L. Y. Ho, S. M. Tse, C. H. To. Pok Oi Hospital, Medicine, Hong Kong, China; 2Kau Oi Hospital, Medicine, Hong Kong, China

**Objectives:** To study the effect of serum PCSK9 on major cardiovascular adverse events (MACEs) in Chinese patients with systemic lupus erythematosus (SLE),

**Methods:** Consecutive patients who fulfilled ACR 1997 criteria for SLE and consented for a biomarker study between 2009 and 2012 were included. Stored serum samples from these patients were assayed for the levels of PCSK9 using a commercial ELISA kit (OKBB00903, Lot# 1344, Aviva Systems Biology, San Diego, US). New MACEs (acute coronary syndrome, ischemic stroke, peripheral vascular disease) documented by imaging and angiographic studies over time was evaluated. Patients were stratified into high/low PCSK9 groups according to the best cut-off level by ROC analysis for the prediction of these events. The cumulative incidence of new MACEs and mortality over time was studied by Kaplan-Meier's analysis and compared between the high and low PCSK9 subgroups. Cox regression was performed to study the effect of the PCSK9 subgroups on new MACEs and mortality, adjusted for other confounding factors.

**Results:** 539 SLE patients were studied (93% women, age 41.9±14.0 years; disease duration 106±90.4 months at entry). The mean PCSK level at baseline was 539 SLE patients were studied (93% women, age 41.9±14.0 years; disease duration 106±90.4 months at entry). The mean PCSK level at baseline was

Background: Neuronal damage in systemic lupus erythematosus (SLE) is common, but the extent and mechanisms are unclear [1-2]. Neurofilament light (NFL) concentrations rise in plasma and cerebrospinal fluid (CSF) during neuronal damage and reach abnormal levels in various neurological disorders [3]. NFL is sparsely studied in SLE [4-7].

Objectives: To explore plasma and CSF concentrations of NFL in SLE patients and investigate the associations between NFL and nervous system involvement, including cognitive dysfunction, imaging findings on magnetic resonance imaging (MRI), laboratory and clinical abnormalities, and to compare the NFL levels of SLE patients with those present in healthy controls.

Methods: In this cross-sectional study, 72 consecutive SLE out-patients and 26 healthy controls, all female, aged <55 years, underwent MRI and neurocognitive testing. NFL concentrations in plasma from all individuals and in CSF from 32 patients were measured with single-molecule array technology. Patients were assessed by a rheumatologist and neurologist to define neuropsychiatric involvement of lupus erythematosus (NPSLE) according to three attribution models.

Results: Plasma and CSF NFL concentrations correlated strongly (r=0.72, p<0.001). Plasma NFL concentrations were higher in SLE patients, both with and without neuropsychiatric involvement, compared with healthy controls (Figure 1A-D). Plasma and CSF NFL concentrations did not differ between NPSLE and non-NPSLE patients (Figure 1B-D). Larger white matter lesion volumes correlated with higher CSF NFL concentrations in patients aged 18-30 (r=0.80, p=0.005). Higher plasma NFL concentrations correlated with lower simple attention scores (r=-0.42, p=0.007), and were associated with dysfunction of psychomotor speed (p=0.012) and verbal memory (p=0.024). SLICC/ACR-Damage Index ≥1 was independently associated with higher plasma NFL concentrations when adjusting for age, SLE Disease Activity Index-2000 ≥1, low complement C3 levels, a history of renal involvement or anti-dsDNA, and ongoing treatment (β=0.080, 95% CI 0.009-0.15, p=0.028).

Conclusion: Higher plasma NFL concentrations in NPSLE and non-NPSLE patients may indicate a higher degree of neuronal damage in SLE in general, particularly in the lower age group, corresponding with cognitive impairment and organ damage development. NFL may serve as an indicator of neuronal damage in SLE in further studies.

REFERENCES:
The study included 106 patients, 93 women, 13 men) with a median age of 48 (41-58) and a median SLE duration 227 months (124-330). At the last evaluation median SLEDAI was 0 (0-2) and median SLICC was 1 (0-1). According to Zen definitions of remission, 51 patients (48%) and 20 (19%) also fulfilled the criteria of clinical remission off corticosteroids and complete remission respectively. Nevertheless, in 24 patients (22.7%) [PGA-PHA], 25 patients. Patients in the discordant group were older (median 58 years, IQR 49-62 vs 46, IQR 39-57; p=0.0043) and less frequently achieved the definition of clinical remission off corticosteroids (n=4, 16.7% vs n=24, 57.3%; p=0.001; OP6,7; CI95% 2.1-21) than concordant. No differences were found in gender, SLE duration, serology, disease activity or damage and other treatment. Data about differences in PROs between two groups are reported in Table 1: discordant patients had a worse performance in all the PROs included. At multivariate analysis SF-36 Physical Component Summary (PCS) resulted associated with PGA-PHA, p=0.0001).

Conclusion: In our study we found that, even in patients considered in remission, in more than 20% of patients there is a considerable discordance between the global disease assessment reported by patients and their physicians. Patients that had a higher PGA also presented worse score at PROs. Our data seems to confirm that potential causes for discordance could be more related to the presence of non-inflammatory processes, depression, or anxiety than clinical manifestations or damage related to SLE.

SLE-DAS for Patient Reported Outcomes, namely health-related quality of life (HR-QoL) and fatigue needs to be assessed.

**Objectives:** To evaluate if the attainment of SLE-DAS remission and LDA states is associated with improvements in HR-QoL and fatigue.

**Methods:** Post-hoc analysis of the merged study population in the BLISS-52 and -76 trials (NCT00424476; NCT00410384) of intravenous belimumab versus placebo for moderate to severe SLE disease activity. We analysed the Functional Assessment of Chronic Illness Therapy (FACIT) and 36-Item Short Form Survey (SF-36) trial data. Fulfilment of SLE-DAS remission (defined as absence of all SLE-DAS clinical items and prednisone ≤5mg/day) and LDA (defined as SLE-DAS≤2.48 and prednisone ≤5mg/day) definitions were retrospectively assessed from the individual participants' data. Mean changes from study baseline to week 52 in FACIT and SF-36 physical component summary (PCS) and mental component summary (MCS) and domain scores were compared between patients attaining at week 52 the SLE-DAS remission vs non-remission and the SLE-DAS LDA vs non-LDA using multivariate regression analysis adjusted for baseline scores.

**Results:** A total of 1684 SLE patients were included. Few patients were in SLE-DAS remission (0.5%) and LDA (0.8%) at study entry. At week 52, 12.5% patients attained SLE-DAS remission and 17.5% attained SLE-DAS LDA. Mean improvements in SF-36 PCS and MCS scores were greater in patients that attained SLE-DAS remission vs non-remission (5.4 vs 3.4, and 4.6 vs 2.7, respectively; multivariate p<0.005 for both) and SLE-DAS LDA vs non-LDA (5.0 vs 3.4 and 4.6 vs 2.6, respectively; multivariate p<0.005 for both), at week 52 (Figure 1). Similarly, improvements in all individual domain scores were greater in SLE-DAS remission vs non-remission patients (all multivariate p<0.005) and SLE-DAS LDA vs non-LDA patients (all multivariate p<0.005) (Figure 1). Importantly, improvements in the summary scores and in all the individual domain scores largely exceeded the minimum clinically important differences (MCIDs) of 2.5 and 5 points, respectively, in those patients attaining SLE-DAS remission or LDA.

**Conclusion:** Attainment of SLE-DAS remission and LDA is associated with meaningful improvement in HR-QoL and fatigue.

**NEUROLOGICAL INVOLVEMENT IN A MONOCENTRIC COHORT OF PATIENTS WITH SERONEGATIVE ANTIPHOSPHOLIPID SYNDROME**

L. Rapino1, S. Truglia1, S. Mancuso2, M. De Michele2, D. Tonì2, I. Bertò2, M. Soricè2, R. Missiù2, A. Capozzi2, C. Alessandri2, F. Contì2, [1] La Sapienza Università di Roma - Policlinico Umberto I, Medicina Interna e Specialità Mediche - Reumatologia, Roma, Italy; [2] La Sapienza Università di Roma - Policlinico Umberto I, Emergenza e Accettazione - Unità di Terapia Neurovascolare, Roma, Italy; [2] La Sapienza Università di Roma - Policlinico Umberto I, Medicina Sperimentale - Medicina Clinica e Molecolare, Rome, Italy

**Background:** The nervous system is affected in a relevant number of patients with antiphospholipid syndrome (APS), being responsible for high morbidity and mortality rates. The identification of neurological manifestations is crucial since those symptoms may benefit from anticoagulation treatment. Noteworthy, the prevalence and the characteristics of neurological manifestations in the subset of patients with “seronegative APS” (SN-APS) still need to be investigated.

**Objectives:** The aim of this study was to assess the neurological involvement in patients with SN-APS. Secondly, association between non-conventional antiphospholipid antibodies (aPL) and clinical characteristics were investigated.

**Methods:** We included all consecutive patients referred to the Lupus Clinic and to the Stroke Unit of our Hospital, presenting clinical features consistent with a diagnosis of APS despite the evidence of persistently negative tests for anti-cardiolipin antibodies (aCL), anti-β2 glycoprotein 1, and lupus anticoagulant. Patients with an identified cause of thrombosis and/or pregnancy morbidity were excluded. Patients' sera were analyzed for the detection of aCL using thin layer chromatography (TLC), while ELISA test was used to detect antibodies directed against the anti-vimentin/cardiolipin complex (aVim/CL).

**Results:** From January 2015 to October 2019, 40 patients with SN-APS and neurological involvement were enrolled. Clinical and demographic characteristics are reported in Table 1. Thirty-three patients (82.5%) resulted positive for at least one non-conventional test (62.5% positive on two occasions) while 17.5% were negative. The occurrence of aCL by TLC immunostaining was 33/40 (82.5%), while a Vim/CL were found in 10/40 (25%). Double positivity for aCL by TLC-immunostaining and aVim/CL was observed in 8/40 patients (20%). Patients who tested positive for non-conventional aPL on two occasions had a five-fold increased risk of developing venous thrombosis (LR 5.24; p=0.022). The positivity for aCL by TLC immunostaining determined an augmented risk of sinus vein thrombosis (LR 5.49; p=0.019) while positivity for aVim/CL raised the likelihood of epilepsy (LR 4.133; p=0.042). Almost all (16/18, 88%) patients with ischemic stroke resulted positive at least one test, 15 tested positive for aCL by TLC-immunostaining and 3 for aVim/CL. In this subset of patients, the positivity for non-conventional aPL on two occasions determined an increased risk of venous thrombosis (LR 8.905; p=0.0033) and recurrent stroke (LR 6.321; p=0.012). In particular, those who tested positive for aVim/CL were at higher risk of developing recurrent stroke (LR 6.659; p=0.01).

**Conclusion:** The nervous system is one of the most frequently affected in APS, however only few data exist about prevalence, characteristics and outcome of its involvement in SN-APS patients. In this work, using TLC immunostaining and ELISA for aVim/CL, we identified non-conventional aPL antibodies in 62.5% SN-APS patients. This subset of patients presented a wide spectrum of neurological manifestations, with frequencies and features that resemble those observed in APS patients. Furthermore, we demonstrated the association between non-conventional aPL and neurological manifestations, such as sinus vein thrombosis, recurrent stroke and epilepsy. In conclusion, testing for non-conventional aPL antibodies may contribute to the evaluation of the stratification of risk for neurological manifestations in SN-APS.

**Disclosure of Interests:** None declared.

---

To summarize, the study on SLE-DAS remission and LDA showed that patients achieving these states had significant improvements in HR-QoL and fatigue, with improvements in SF-36 PCS and MCS scores exceeding the minimum clinically important differences (MCIDs) of 2.5 and 5 points, respectively. The authors concluded that the attainment of SLE-DAS remission and LDA is associated with meaningful improvement in HR-QoL and fatigue.

The study on neurological involvement in SN-APS patients highlighted the significant impact of non-conventional antiphospholipid antibodies on the risk of neurological complications, including recurrent stroke and epilepsy. The authors emphasized the importance of detecting these antibodies to better understand and manage the neurological manifestations associated with SN-APS.
Background: In SLE patients, episodes of high disease activity state (HDAS, SLEDAI≥20) are associated with worse outcomes even if only experienced once. We investigated whether attainment of the lupus low disease activity state (LLDAS, SLEDAI<10) is similarly protective from damage accrual and flare in both ‘HDAS-ever’ and ‘HDAS-never/not LLDAS’BL groups (Table 1).

</tr>
<tr>
<td>＞12-months sustained LLDAS</td>
<td>0.69 (0.45,1.01) , p&lt;0.001</td>
<td>0.43 (0.26,0.73), p&lt;0.001</td>
</tr>
</tbody>
</table>
| ≥12 months sustained LLDAS                     | 0.54 (0.31,0.94), p<0.03 | 0.29 (0.11,0.47), p<0.01

Conclusion: Sustained or majority LLDAS was less achievable in SLE patients after an episode of HDAS in HDAS-ever compared to HDAS-never patients, but protective associations of LLDAS against organ damage accrual and flare were similar regardless of HDAS. LLDAS attainment is protective from adverse outcomes even after high disease activity.

CNS demyelinating syndromes in systemic lupus erythematosus: results from “Attikon” lupus cohort

1. National and Kapodistrian University of Athens, Rheumatology and Clinical Immunology Unit, 4th Department of Internal Medicine, Attikon University Hospital, Athens, Greece; 2. National and Kapodistrian University of Athens, 2nd Department of Neurology, Attikon University Hospital, Athens, Greece; 3. National and Kapodistrian University of Athens, 2nd Department of Radiology, Attikon University Hospital, Athens, Greece; 4. Asklepion General Hospital, Department of Rheumatology, Asklepion General Hospital, Athens, Greece; 5. Hannover Medical University, Division of Immunology and Rheumatology, Hannover, Germany; 6. University of Ioannina, Rheumatology Clinic, University Hospital of Ioannina, Ioannina, Greece.

Background: Central nervous system (CNS) demyelinating syndromes that occur in the context of SLE may represent a manifestation of neuropsychiatric lupus, or an overlap of SLE and multiple sclerosis (MS). The differential diagnosis between the two entities has important clinical implications, because the therapeutic management differs between the two conditions.

Objectives: To characterize CNS demyelinating syndromes in a large SLE cohort as neuropsychiatric SLE or SLE-MS overlap, using a multidisciplinary approach and existing diagnostic (MS) and classification criteria (SLE).

Methods: Patients from the ‘Attikon’ lupus cohort (n=707) were evaluated for demyelinating syndromes. Clinical, laboratory and neuroimaging data were recorded for each patient. Following multidisciplinary evaluation and application of criteria, the demyelinating syndrome was attributed to either SLE or MS. Patients with transverse myelitis were not included in this study.

Results: We identified 26 patients with demyelinating syndromes (3.7%) with mean age at diagnosis 46.9 (SD 12.3) years and median disease duration at last follow-up 60 (IQR 52) months. Of them, 12 were diagnosed as primary SLE-demyelination (46.2%) and 14 as overlap SLE-MS (53.8%). The two groups did not differ with respect to rheumatologic and neurologic manifestations, or serologic data. The mean (SD) ADC value of MALT lesions was significantly lower than the ADC of fatty substitution did not differ in MALT lymphoma and in no-MALT pSS glands.

Background: Salivary MALT lymphoma represents the major complication of primary Sjögren’s Syndrome (pSS). However, the early recognition of MALT lymphoma may be challenging due to its indolent, slow clinical course.

Objectives: 1. to identify salivary gland ultrasonographic (SGUS) features and magnetic resonance (MRI) abnormal findings with Diffusion Weighted imaging (DWI) and Apparent Diffusion Coefficient (ADC) of MALT in pSS patients. 2. To evaluate the correlation between salivary gland ultrasonography (SGUS) and MRI in pSS patients with suspected lymphoma.

Methods: consecutive patients with pSS (2016 ACR/EULAR criteria) and suspected MALT lymphoma undergoing histological examination were included in this cross sectional study from September 2017 to November 2021. The US echostucture of each gland on B-mode images was graded using the latest 2019 OMERACT semiquantitative SGUS scoring systems (0-3). Sonographic features of focal lesions were described. Conventional MRI techniques (i.e. T1WI, T2WI, and STIR images) combined with MR sialography was performed in all the cases. DWI was acquired at b-value 0, 500 and 1000. ADC values were calculated. Patients’ clinical and histological data were collected. Data were presented as means±SD, or percent frequency as appropriate. Intergroup comparisons were made using the t-test/Mann–Whitney test for continuous variables and Fisher’s exact test for categorical variable.

Results: 45 pSS (mean age, S.D=55±15 yrs) were included. MALT lymphoma was histologically confirmed in 14/45 pSS patients and, specifically in 18/180 major salivary glands (17 parotid and 1 submandibular gland). At SGUS examination, MALT salivary glands presented an OMERACT grade 3 in 16/18 and a grade 2 in 2/18, significantly higher than the OMERACT scoring observed in no-MALT pSS glands (p=0.001). The sonographic features more commonly detected in MALT were: hypoecochic macroareas with posterior enhancement, presence of septa or hyperechogenic strands and anacral intraacusal vascularization. At MRI, 15/18 (83.3%) MALT lymphoma appeared as intraglandular solid lesions: 9/15 (60%) were solid-cystic lesions and 6/15 (40%) were solid lesions without cystic changes. The frequency of solid lesions in pSS patients without lymphoma was 3/124 (2.4%), significantly lower than in MALT-pSS. Furthermore, 15/18 (83.3%) MALT lymphoma showed glandular fatty substitution. The presence of fatty substitution did not differ in MALT lymphoma and in no-MALT pSS glands. The mean (SD) ADC value of MALT lesions was significantly lower than the ADC of the parotid glands in pSS lymphoma (0.63±0.07 × 10⁻³ mm²/s vs 1.1±0.19 × 10⁻³ mm²/s, p=0.001). A negative correlation between SGUS OMERACT score and mean glandular ADC values (r=−0.776, p<0.001) was found; patients with OMERACT score 3 presented the lowest mean salivary gland ADC when compared to the other OMERACT scores (0-2) (p<0.001).

Conclusion: OMERACT semiquantitative SGUS scoring systems and MRI with DWI represent promising complementary tools in the differential diagnosis of pSS MALT lymphoma, particularly useful to guide parotid biopsy. Patients with an OMERACT score 3 in their SGUS deserve a careful screening for lymphoma.

Through the looking glass

Diagnostic value of liver stiffness as marker of hepatic marker of hepatic amyloid deposition in systemic amyloidosis

A. F. Brunger, J. Bibe1, H. Blokji, R. Van Rheenen, G. Rans, B. Hazenberg, H. L. A. Nienui1 on behalf of Amyloidosis Center of Expertise, University Medical Center Groningen, Groningen, The Netherlands; University Medical Center Groningen, Rheumatology & Clinical Immunology, Groningen, Netherlands; University Medical Center Groningen, Gastroenterology, Groningen, Netherlands; University Medical Center Groningen, Nuclear Medicine and Molecular Imaging, Groningen, Netherlands; University Medical Center Groningen, Internal Medicine, Groningen, Netherlands.

Disclosure of Interests: None declared.

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2022-eular.4172
Background: Hepatic involvement in AL amyloidosis is often asymptomatic but does affect prognosis and should be taken into account during follow-up. An increased plasma level of alkaline phosphatase (ALP) or increased liver span are part of the conventional diagnostic criteria for establishing hepatic involvement of AL amyloidosis, but these markers are nonspecific. 18F-labeled serum amyloid P component (SAP) scintigraphy is a specific and sensitive method to establish hepatic involvement but is not widely available. Liver stiffness measured by transient elastography is increased in AL amyloidosis patients with hepatic involvement and could be useful in establishing liver involvement and monitoring treatment response in AL amyloidosis.

Objectives: To assess the diagnostic value of liver stiffness (LS) for liver involvement in AL amyloidosis and the utility of LS to monitor treatment effect using SAP scintigraphy as gold standard.

Methods: LS was measured prospectively in 49 treatment naive patients with systemic AL amyloidosis and 9 patients with wild type transthyretin amyloidosis (ATTRwt) with cardiomyopathy (cardiac controls). In addition, LS was longitudinally measured in 10 AL amyloidosis patients of whom 9 patients had liver involvement. SAP scintigraphy, laboratory assessments including ALP and measurement of liver span was performed in all patients.

Results: Of the 49 patients, 27 patients had liver involvement (of whom 24 also had heart involvement), 10 patients had heart involvement, 12 patients had no heart or liver involvement. Median LS was significantly higher in AL amyloidosis patients with liver involvement (22.8 kPa, range 4.3-75), than in AL amyloidosis patients without liver involvement (6.3 kPa, range 4.4-35.8) (p=0.00). Also a significant difference was seen between AL amyloidosis patients with liver involvement (22.8, range 4.3-75) versus, heart involvement (9.0, range 4.5-35.8) (p=0.02), no liver or heart involvement (5.7, range 4.4-10.1) (p=0.0001), and ATTRwt patients (2.9 kPa, range 4.0-14.6) (p=0.01). Furthermore, LS values seemed to significantly decrease over time in AL amyloidosis patients with liver involvement with a good hematologic response to treatment.

Conclusion: LS is a non-invasive tool which seems to be useful in clinical practice to establish liver involvement in patients with AL amyloidosis. In addition, it is a promising marker in the follow up of AL amyloidosis patients for establishing hepatic response over time.

Table 1. Abnormalities found on FDG-PET/CT scans

<table>
<thead>
<tr>
<th>Abnormality</th>
<th>No abnormality found on any scan (%</th>
<th>One or more abnormalities found on any scan (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>No PET/CT result obtained</td>
<td>3 (2.5)</td>
<td>56 (47.8)</td>
</tr>
<tr>
<td>One or more abnormalities</td>
<td>59 (48.8)</td>
<td>59 (48.8)</td>
</tr>
</tbody>
</table>

* Fifteen of these abnormalities were found on the second PET/CT, the rest was found on the first scan. 11 abnormalities on the second PET/CT were the same as the one seen on the first scan, and 7 abnormalities resolved after the first scan. One scan can show multiple abnormalities, from different categories.

Follow-up action occurred in 21 (26.6%) patients, consisting of referral to a specialist or reassessing and/or scheduling diagnostics directly by the treating rheumatologist. In 5 (6.3%) patients, the rheumatologist followed-up. In 17 (21.5%) patients a consultation with a different specialist was scheduled. In five patients surgical/invasive intervention took place. In one patient a hemi-thyroidectomy was performed revealing a follicular adenoma. This resection was complicated by a persistent recurrent laryngeal nerve paresis and hoarseness. In a second, an intra-uterine myometrectomy took place. In a third, a colonoscopy was performed revealing two low-grade adenomas. In a fourth a benign cyst in the neck was extracted. A fifth patient underwent spinal marginal myotomy which turned out to be a benign schwannoma.

Nine patients (7.4%) were suspected of malignancy, none turned out to be malignant. Six clinical malignancies (bladder, penile, lymphoma, 2 melanoma and prostate) that developed during follow-up were all negative on baseline FDG-PET/CT. The malignancies were diagnosed after an interval of between 5 and 34 months (mean 13 months).

Conclusion: Whole-body FDG-PET/CT-scanning for arthritis imaging in RA patients results in frequent incidental extra-articular findings, while some who apparently had normal scans developed malignancies.

POS0125 EXTRA-ARTICULAR FINDINGS WITH FDG-PET/CT IN RHEUMATOID ARTHRITIS PATIENTS: MORE HARM THAN BENEFIT.

E. Ultin1, A. Den Broeder2, N. Boers3, M. Gothardt4, M. Bouman5, R. B. M. Landewe6, H. Den Broeder7, N. Van Herwaarden8,9, S. M. Maarstekinklens10, Rheumatology, Nijmegen, Netherlands, 1Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands, 2Radboud University Medical Center, Radiology, Nuclear Medicine & Institute for Molecular Life Sciences, Nijmegen, Netherlands, 3Rijnstate, Rheumatology, Arnhem, Netherlands, 4Amsterdam UMC, location VUmc, Rheumatology and Clinical Immunology, Amsterdam, Netherlands, 5Radboud University Medical Center, Pharmacology-Toxicology, Nijmegen, Netherlands

Background: Whole-body Positron Emission Tomography with CT-scan using fluorine-18 fluorodeoxyglucose (18F-FDG) is occasionally used in Rheumatoid Arthritis (RA) patients. Reasons to use FDG-PET/CT-scans are to diagnose arthritis or guide decisions on systemic therapy. As FDG uptake in affected joints may reflect disease activity [1], FDG-PET/CT might also detect malignancies, but the frequency of incidental findings and the proportion of relevant malignant disease that could be missed are currently unknown.

Objectives: To study the malignancy screening performance of whole-body FDG-PET/CT in longstanding RA patients with low disease activity.

Methods: FDG-PET/CT-scanning was done in the intervention arm of the Dose REduction Strategy of Subcutaneous TNF-inhibitors (DRESS) study, a randomized controlled trial on dose-tapering of biological Disease Modifying Anti-Rheumatic Drugs (bDMARDs) [3]. Baseline and if applicable follow-up whole-body FDG-PET/CT-scans were performed in consenting patients in the tapering arm to assess predictive value of subclinical PET-arthritis for risk of flaring [4]. The scans were also read by experienced nuclear medicine specialists independently after they were performed for any unexpected extra-articular finding, conform routine clinical care.

The reference standard was clinical diagnosis of malignancy during the 3 year follow-up. Prevalence of extra-articular abnormalities, follow-up, and received treatments were summarized post-hoc.

Results: 121 scans were made in 79 patients. Extra-articular abnormalities were found in 59/121 (48.8%) scans (Table 1) in 45/79 (57%) patients.

POS0126 UTILITY OF THE SUBCHONDRAL BONE ATTENUATION COEFFICIENT OF THE SACRIOILIAC MARGINS TO DIFFERENTIATE SPONDYLOARTHRITIS AND OSTEOSITIS CONDENSANS ILI

A. Terrier1, O. Fakhri2, M. Chouk3, C. Prati3, D. Wendling3, S. Aubry2, F. Verheoven5,6,7, CHU Besancon, Musculoskeletal Imaging, Besancon, France; 8CHU Besancon, Rheumatology, Besancon, France; 9CHU Besancon, Rhenium, Besancon, France; 10Université de Franche Comte, EA 4267 PEPITE, Besancon, France

Background: Differentiating ankylosing spondylitis (AS) from osteitis condensans ili (OCI) remains challenging for clinicians.

Objectives: The aim of this study was to determine whether Subchondral Bone Attenuation Coefficient of the Sacroiliac margins (SBAC-SI) is different in AS, OCI and diffuse idiopathic skeletal hyperostosis (DISH).

Methods: A monocentric retrospective observational study was performed at a French University Hospital. Patients included were followed for AS, DISH or OCI and underwent CT scan including sacroiliac joint. Patients with tumor lesion of bone or a history of pelvic radiotherapy were excluded. AS and OCI patients were matched with a control of the same age and sex. All scans were acquired on the same CT-scan unit (Somatom 64 definition AS+, Siemens Healthineers, Erlangen, Germany), with a slice thickness of 0.625mm. In the coronal oblique plane of the SIJ, three slices (anterior, middle and posterior) and four quadrants per joint were defined. Twenty-four identical circular regions of interest (ROIs) (30 mm2), 8 per slice, were manually placed separately subcortical to the SIJ, four on the sacral side and four on the iliac side. The distance between the circle of the ROI and the cortical bone was 2 to 3mm. An overall score was obtained from...
the sum of all ROIs. For every ROI, an Attenuation Coefficient was measured and expressed in Hounsfield Unit. The total SBAC-SI score was the sum of the 24 ROI. The sacral and iliac SBAC-SI scores were the sum of the sacral or the iliac ROI.

Results: Thirty AS and AS controls, 31 DISH, 29 OCI and OCI controls were included. SBAC-SI score was 9727 (±2430) in the OCI group (p<0.001), 3563 (±1860) in the AS group, 3899 (±1937) in the DISH group, 4224 (±1693) in the AS control group and 5445 (±1205) in the OCI control group. A threshold of 7500 HU had the best discriminative value between OCI and AS (youden index: 0.89). In AS, disease duration is negatively associated with SBAC-SI (r = -0.623; p < 0.01) and HLA B27 is associated with lower SBAC-SI (6523 [5198, 7137] vs 2809 [1568, 3371]; p < 0.001).

Conclusion: SBAC-SI is significantly different between AS and OCI and could help to distinguish these two diseases.

Figure 1. Distribution of the Subchondral Bone Attenuation Coefficients of the Sacroiliac Margins of the 24 ROI in the anterior (A), middle (B) and posterior (C) slices in the coronal oblique plane of the sacroiliac joints

POS0127 QUANTITATIVE ASSESSMENT OF FINGER VASCULARITY IN SYSTEMIC SCLEROSIS PATIENTS WITH RAYNAUD’S PHENOMENON USING ULTRASOUND VASCULAR IMAGING

K. Nam, F. Mendoza Ballesteros, C. Wessner, T. Alawih, F. Forsberg, Thomas Jefferson University, Department of Radiology, Philadelphia, United States of America; Thomas Jefferson University, Scleroderma Center and Jefferson Institute of Molecular Medicine, Philadelphia, United States of America; Thomas Jefferson University, Department of Medicine, Division of Rheumatology, Philadelphia, United States of America

Background: In patients with Systemic Sclerosis (SSc), vasculopathy plays an important pathophysiological role and it is almost universally expressed as Raynaud’s Phenomenon (RP). Assessment of vasculopathy/microangiopathy is crucial for early diagnosis of SSc and also is considered in the SSc classification criteria. Currently, this evaluation is performed by nailfold capillaroscopy. However, nailfold capillaroscopy is limited to the nail fold area and is mainly qualitative since is based on the shape, size, and density of the observed capillaries. Quantification: The objective of this study is to detect and quantify finger vascularity of SSc patients with RP using four ultrasound vascular imaging techniques. Additionally, the diagnostic performance of quantified finger vascularity was assessed.

Methods: This prospective IRB approved study has enrolled 20 SSc patients fulfilling the 2013 ACR/EULAR classification criteria and presenting RP. Age and sex matched normal volunteers (16 subjects) without RP were also enrolled. All fingers except thumbs were imaged at room temperature in the seated position. The blood flow of each finger was evaluated on the dorsal (showing nail) and on the ventral (showing palm) sides using an i24LX8 probe (9-24 MHz) on an Aplio 800 system (Canon Medical Systems, Tustin, CA, USA). Blood flow images were obtained using color Doppler imaging (CDI), power Doppler imaging (PDI), monochrome Superb Microvascular Imaging (cSMI), and color-coded Superb Microvascular Imaging (cSMI) keeping the same imaging settings for all subjects. The percent area of vascularity observed by each technique was quantified offline by counting pixels of blood flow in a 5 x 5 mm square centered at the nail fold for the dorsal side and in a 1 x 1 cm square from the fingertip for the ventral side using Matlab (MathWorks, Natick, MA, USA). The percent vascularity areas from dorsal and ventral sides were averaged over fingers, then t-tests and receiver operating characteristic (ROC) analyses were performed (Youden Index) to assess the diagnostic ability of the different methods and to classify disease status (RP-SSc from normal controls), allowing to assign diagnostic accuracy.

Results: Two patients' data were excluded due to technical errors. The data from 18 RP-SSc patients and 16 normal volunteers were analyzed. The percent vascular areas in patients with RP were significantly lower than those in normal volunteers at both dorsal (p < 0.03) and ventral (p < 0.01) for each imaging technique. The ventral side vascularity showed a higher diagnostic accuracy compared to the dorsal side. Among the four imaging techniques, CDI showed the highest diagnostic accuracy. The mean percent areas by CDI were 6.8 ± 7.1% (mean ± standard deviation) and 15.3 ± 8.9% on the dorsal side (p < 0.01) and 5.3 ± 5.6% and 16.7 ± 7.4% on the ventral side (p < 0.0001) for RP patients and normal volunteers, respectively. The ventral side vascularity by CDI showed the highest diagnostic accuracy of 90% with 88% specificity and 78% sensitivity.

Conclusion: Ultrasonic vascular imaging demonstrated the potential to quantitatively microangiopathy of RP-SSc. Additionally, the mean percent vascular area averaged across the fingers showed to be accurate (70 to 90%) to differentiate patients with RP-SSc from normal controls, albeit based on small sample size.

B. Atienza-Mateo, A. del Peral Fanjul, V. Pulito-Cueto, D. Prieto-Peña, A. González-Gay, R. Blanco, Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain; IDIVAL, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and in Metabolic Bone Diseases of the Musculoskeletal System, Santander, Spain

Background: Ocular manifestations of Behçet's disease (BD) are globally recognized and widely studied [1]. Vascular lesions are also frequent but less explored [2]. Microvascular involvement may be clinical (as Raynaud's phenomenon) or subclinical. Vascular microcirculation is studied with Nailfold Capillaroscopy (NFC) that may show capillary abnormalities such as dilated loops, megacapillaries and microhemorrhages. Endothelial progenitor cells (EPCs) have been implied in the pathogenesis of multiple cardiovascular disorders and vasculitis, including BD and could be used as biomarkers. Objectives: To assess the microvascular involvement and EPCs in patients with BD.

Methods: Observational study of unselected consecutive patients with BD assessed in a national referral center from March to May 2021. All patients fulfilled the 2014 ICBD criteria [2]. They were evaluated sequentially with a scheduled clinic visit after signing an informed consent. The main variables collected were a) periangual capillaries features (loop diameter, tortuosity, vascular density, microhemorrhages and blood flow), and b) serum EPCs levels. NFC was performed from the second to fifth fingers of both hands using a 500x magnification digital microscope. The following features were considered abnormal: diffuse enlarged capillaries (>2 capillaries with a diameter of 20-50 µm in at least 2 different fingers), megacapillaries (>50 µm in diameter), reduced vascular density (<9 capillaries/mm or avascular areas), diffuse microhemorrhages (>2 hemorrhages in at least 2 different fingers) and granular/slow flow. NFC were studied in unselected BD patients in whom instant blood samples were available and compared with sex- and age-matched healthy controls (HC). EPCs from peripheral venous blood were quantified by direct flow cytometry and characterized by simultaneous expression of cell surface markers of stemness (CD34), immaturity (CD133), endothelial (CD144), megacapillaries (>2 capillaries with a diameter of 20-50 µm in at least 2 different fingers) and granular/slow flow. NFC were studied in unselected BD patients in whom instant blood samples were available and compared with sex- and age-matched healthy controls (HC). EPCs from peripheral venous blood were quantified by direct flow cytometry and characterized by simultaneous expression of cell surface markers of stemness (CD34), immaturity (CD133), endothelial commitment (CD309) and a low expression of the pan-leukocyte marker (CD45).

Results: From a cohort of 120 patients with BD, 42 were evaluated during the period of the study (Table 1). NFC was performed in the 42 cases, being abnormal in 54.8% of them. The most common findings were capillary loop dilatation (45.2%), capillary tortuosity (31%), megacapillaries (21.4%) and microhemorrhages (16.7%) (Table 1). Instant blood samples to study EPCs levels were available in 18 BD patients and 12 HC. The median [IQR] frequency of EPCs levels in BD patients in whom instant blood samples were available and compared with sex- and age-matched healthy controls (HC). EPCs from peripheral venous blood were quantified by direct flow cytometry and characterized by simultaneous expression of cell surface markers of stemness (CD34), immaturity (CD133), endothelial commitment (CD309) and a low expression of the pan-leukocyte marker (CD45).

Conclusion: Microvascular involvement is common in BD and can be easily assessed by NFC. Furthermore, EPCs quantification may be a useful serum biomarker of the disease.

POS029
TO CONTRAST OR NOT TO CONTRAST? ON THE ROLE OF CONTRAST ENHANCEMENT IN HAND MRI STUDIES OF PATIENTS WITH RHEUMATOID ARTHRITIS
G. Rübsam1, M. Frenken1, A. D. Mewes1, K. L. Radke1, L. Le2, L. Wilms1, S. Neubling2, D. Abrar1, P. Severin1,2, Heinrich Heine University Düsseldorf, Institute of Diagnostic and Interventional Radiology, Düsseldorf, Germany; 2Ludwig Maximilian University, Institute for Medical Information Sciences, Biometry and Epidemiology, Munich, Germany; 3Aachen University Hospital, Department of Diagnostic and Interventional Radiology, Aachen, Germany; 4Heinrich-Heine University, Department and Hiller Research Unit of Rheumatology, Duesseldorf, Germany; 5Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Germany

Background: Currently, clinical indications for application of gadolinium-based contrast agents (GBCA) in magnetic resonance imaging (MRI) are increasingly being questioned1. Rheumatoid arthritis is a disease which is characterised by joint inflammation and due to various existing therapies, early diagnosis and sensitive monitoring is beneficial for assessing disease progression, therapy response and optimizing the individual therapy.

Objective: This study aimed to evaluate the necessity of contrast enhancement in MRI of the hand in patients with rheumatoid arthritis (RA).

Methods: 31 patients with RA (mean age, 50±14 years [range, 18–72 years]) from the German ArthroMark cohort underwent morphologic high-field MRI scans on a clinical 3T scanner. MRI studies were analyzed based on (1) the Rheumatoid Arthritis Magnetic Resonance Imaging Score (RAMRIS)2 and (2) the GBCA-free RAMRIS version, termed RAMRIS Sine-Gadolinium-For-Experts (RAMRIS-SAFE), in which synovitis and tenosynovitis were assessed using the short-tau-inversion-recovery (STIR) sequence instead of the post-contrast T1-weighted sequence.

Results: Correlation between RAMRIS and RAMRIS-SAFE in terms of Spearman’s ρ was almost perfect (ρ=0.976; p<0.001). The synovitis subcores, as based on RAMRIS and RAMRIS-SAFE, were equally strongly correlated (ρ=0.937; p<0.001), while the tenosynovitis subcores were less strongly correlated (ρ=0.380 p=0.035). Inter-rater reliability in terms of Cohen’s κ was high (0.963 ≤ κ ≤ 0.925).

Conclusion: In conclusion, RAMRIS-SAFE as the GBCA-free version of the well-established RAMRIS is a patient-friendly and resource-efficient alternative for assessing disease-related joint changes in RA. As patients with RA are subject to repetitive GBCA applications, non-contrast imaging protocols should be considered.

Exemplary imaging features (erosion, osteitis, synovitis, tenosynovitis, and joint space narrowing) that are scored semiquantitatively based on RAMRIS, shown in (i) unenhanced MRT T1-weighted sequence (left column), (ii) STIR sequence (middle column), and enhanced T1-weighted postcontrast sequence (right column).

Results: Comparing the analyses of all phases of the OA cohort with those of the RA cohort, 14 of 51 features were identified as significantly different (p < 0.05). The most significant accumulation in metacarpophalangeal joints (MCP) has high specificity and diagnostic odds ratio (DOR) for RA patients (91%, 4.32). Patients in the OA cohort showed an increase in the signal at the muscle-tendon junction in the forearm (80% sensitivity, DOR 3.11). A comparison of the RA and CTD cohorts revealed 24 significant differences, most prominent changes in the nail bed in RA (100% specificity, DOR 8.27) and a punctate accumulation pattern in P2 (86% specificity, DOR 2.81) for the CTD cohort. Comparing the RA and CTD cohorts, 22 features were significantly different. The strongest differences were found in the PIP joints of RA patients (78% sensitivity, DOR 2.97) and in the nail bed of CTD patients (100% specificity, DOR 8.18). In the cumulative PV images a high specificity for a secondary Raynaud’s syndrome in CTD patients was found compared to RA (97%, DOR 17.7) and OA (91%, DOR 5.9). Further, DIP signals for OA compared to CTD show significant differences (76% sensitivity, DOR 2.73).

Conclusion: The present work demonstrates the detection and localization of specific, significant features in NIR-FOI of patients with different rheumatic diseases and can thus make an important contribution to diagnosis and optimization of therapy. In future, multivariate analysis and artificial intelligence algorithms can combine these features to further improve the diagnostic value.

Acknowledgements: Funded by the Federal Ministry of Education and Research (grant nb.: 13GW0341A)

Methods: NIR fluorescence imaging comprised 360 images/6 min. after injection of the dye. Analysis of patients with the clinical diagnosis of OA and CTD was performed on a separate cohort of patients. The analysis was performed on both hands in three time periods (P1-3) after injection in two independent passes. In some cases, Prima Vista images (PVI), representing the sum of images 1-240 were also analyzed (n = 45, 33, 33 for OA, RA, CTD). Signals compared to the background were assessed as positive or negative (Figure 1).

The data were analyzed statistically.
Background: Patients with psoriasis (PsO) report musculoskeletal (MSK) pain without clinical findings of inflammation. Ultrasound (US) is more sensitive than clinical evaluation in detecting synovitis and enthesitis, and we have previously found that patients with PsO and pain more often have US signs of inflammation in joints and entheses than patients without pain (1), indicating possible psoriatic arthritis (PsA). Whether the area of reported pain in these patients correspond to inflammation by US has not yet been investigated.

Objectives: In patients with PsA with self-reported MSK pain, to investigate if the area of reported of pain corresponds to synovitis and/or enthesitis.

Methods: PsO patients with self-reported MSK pain (n=79, Table 1), recruited from a Danish nationwide survey, were evaluated in one of four rheumatology departments with grey-scale (GS) and color Doppler (CD) US of 48 joints and 12 entheses, applying the OMERACT scoring systems (2) for US synovitis (defined as GS score ≥2 or CD≥1) and enthesitis (defined as ≥1 GS inflammatory finding (hypoechogenicity/thickening) and CD score ≥1). Patients indicated the location of current pain in 21 areas on a homunculus, out of which shoulder (joint), elbow (joint and common extensor enthesis), hand (wrist and MCP, PIP, and DIP-joints 1-5), knees (joint and quadriceps- and patellar entheses), feet (ankle and MTP-joints 1-5) and heel (Achilles- and plantar fascia entheses) were evaluated by US, see Figure 1. Association between self-reported pain and US inflammation (synovitis/enthesitis) was explored using Fisher’s exact test and odds ratios (OR) for 2x2 tables. Agreement was calculated using Cohen’s kappa (κ).

Numbers are median (IQR) or no. (%). CRP: C-reactive protein, DAS28: Disease Activity Score 28 joints, VAS: Visual Analog Scale

Results: Of the areas examined by US, pain was most frequent in the knees (41% of patients), while US inflammation was most frequent in the hand/wrist (55%). In total, US inflammation was found in 72% patients (synovitis in 71%, enthesitis in 17%). In 47% of patients, US inflammation was found in one or more of the painful sites. Figure 1 shows 2x2 tables of pain versus US inflammation in different areas and corresponding ORs and κ-values. Self-reported pain was significantly related to US inflammation in that area, both overall (OR=3.1, p=0.001) and for the specific areas of the left hand (OR 3.1, p=0.03) and right elbow (OR 18.3, p=0.01). Agreement between self-reported pain and US inflammation, as measured by κ, was overall low, κ = 0.18 (95% confidence interval 0.10-0.27), with highest agreement found for the right elbow (κ = 0.30 (0.0-0.68)). Pain only in areas not examined by US (back/hips/breastbone/jaw) was indicated by 16% of patients.

Conclusion: While US signs of synovitis and enthesitis is frequent in patients with PsO and pain, concordance between US inflammation and the specific location of pain is only seen in half of the patients.

**POS0133 HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY FOR THE EVALUATION OF BONE EROSIONS OF METATARSOPHALANGEAL JOINTS IN RHEUMATOID ARTHRITIS: A PILOT STUDY**

J. Meinhardt, R. Klose-Jensen, J. Therkildsen, B. Langdahl, E. M. Hauge, K. Keller, Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark; Aarhus University Hospital, Department of Clinical Medicine, Aarhus N, Denmark; Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus N, Denmark

**Background:** Bone erosion in rheumatoid arthritis (RA) is most commonly detected in the wrist, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints. High-resolution peripheral quantitative computed tomography (HR-pQCT) has successfully been used to quantify bone erosions in the wrist and MCP joints. A recent study highlights that HR-pQCT of only two MCP joints has equal accuracy to detect erosive disease in RA patients compared to conventional radiography (CR) of the hands, wrists, and feet (44 joints). However, no study has evaluated the MTP joints by HR-pQCT.

**Objectives:** To characterize the localization, size and frequency of erosions in the 4th and 5th MTP joints. Furthermore, to evaluate the sensitivity for the detection of erosion in the 4th and 5th MTP joints by HR-pQCT, compared to CR.

**Methods:** This single-centre cross-sectional study included 42 patients with established RA (disease duration ≥ 5 years). The right foot was imaged by HR-pQCT in a 2.7 cm long region corresponding to the 4th and 5th MTP joint. Blinded to patient data, the number and volume of bone erosions by HR-pQCT were measured and scored according to the SPECTRA criteria. CR of 44 joints was evaluated according to the Sharp/van der Heijde (SHS) method.

**Results:** The patients (62% women) had a median disease duration of 12 years (interquartile range (IQR): 7 – 20). HR-pQCT of the 4th and 5th MTP joints identified erosions in 38 (90%) patients. The total erosion volume (Vtot) was 2610 mm³ in all quadrants of the 4th and 5th MTP joints. Erosions were most frequently found at the lateral aspect of the 5th metatarsal head (MH), including 1261 mm³ (48%) of Vtot (Figure 1). CR of 44 joints detected erosions in 30 (71%) patients with a median SHS erosion score of 9 (5 – 28). The sensitivity and specificity (95% CI) of classifying patients with erosive RA by HR-pQCT and CR is displayed in Table 1. McNemar’s test showed a significantly higher sensitivity of patients classified as having erosive RA by HR-pQCT of the 4th and 5th MTP joints than by CR of 44 joints (4.6, p = 0.03).

**Table 1. Comparing CR and HR-pQCT for classifying patients as having erosive RA, and for identifying erosions in the 4th and 5th MTP joints.**

Conventional Radiography (CR), High-resolution peripheral Quantitative Computed Tomography (HR-pQCT), Metatarsophalangeal (MTP), Rheumatoid Arthritis (RA), Confidence Interval (CI).

**Conclusion:** This is the first study to evaluate erosions with HR-pQCT of the 4th and 5th MTP joints, including a comparison to CR. Erosions were frequent at the lateral aspect of the MTP joints, suggesting that mechanical and biomechanical demands may play a role in the development of erosions in the MTP joints. The superiority of HR-pQCT compared to CR for detecting erosions provide a basis for larger studies assessing bone changes in the MTP joints.

**RELATIONSHIP BETWEEN RETINAL VASCULAR DENSITY DETECTED THROUGH OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY AND INTIMAL MEDIAL THICKNESS: A NEW POTENTIAL MARKER OF CARDIOVASCULAR INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS**

S. Ferrigno1, P. Conigliaro1, S. Longo2, C. Nesli3, A. Di Stefano4, E. Santilli5, C. Giannini6, S. Rizza7, M. Federici8, M. Cesareo9, A. Bergamin10. 1University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Department of ‘Medicina dei Sistemi’, Rome, Italy; 2University of Rome Tor Vergata, Internal Medicine, Department of ‘Medicina dei Sistemi’, Rome, Italy; 3University of Rome Tor Vergata, Ophthalmology Unit, Department of Experimental Medicine and Surgery, Rome, Italy.

**Background:** Systemic Lupus Erythematosus (SLE) patients have a 3-fold risk of CV events compared to the general population, mainly due to accelerated atherosclerosis that is not completely explained by the presence of traditional CV risk factors. Individuals with increased intimal medial thickness (IMT) carry a higher risk to develop carotid atherosclerosis. Accordingly, IMT acts as a marker of subclinical atherosclerosis. In recent studies, SLE patients showed a significant higher IMT compared to healthy subjects. On the other side, SLE retinal involvement can be detected in 7-29% of cases, it is characterized mainly by retinal vasculopathy and it can be a marker of systemic vascular involvement. Optical Coherence Tomography Angiography (OCTA), a new diagnostic technique that can visualize retinal blood flow and evaluate the Fovea Avascular Zone (FAZ), has been investigated as an instrument for early detection of subclinical retinal vascular impairment in SLE.

**Objectives:** Aim of this study is to examine a possible correlation between IMT and retinal vascular impairment assessed through OCTA in SLE.

**Methods:** We recruited SLE patients fulfilling 2019 EULAR/ACR classification criteria. Patients with other rheumatic, ophthalmological diseases, diabetes or history of CV diseases were excluded. We also collected patients’ demographic and clinical data, including sex, age, smoking habit, BMI, systolic and diastolic blood pressure (BP), C-Reactive Protein (CRP), total cholesterol, LDL, HDL, triglycerides. All patients underwent an ophthalmological evaluation, including OCTA estimation of superficial and deep retinal vessel density (VD), considering both the whole image and the foveal region, and FAZ area. Carotid ultrasound (US) comprising IMT assessment was also performed. Statistical analysis was accomplished using unpaired t-test or Mann Whitney U test, Pearson or Spearman rank correlation when appropriate.

**Results:** We enrolled 37 SLE patients; demographic, clinical and US data are displayed in Table 1. Nine patients (24.3%) had uncontrolled arterial hypertension. According to US evaluation, carotid plaques were detected in six patients (16.2%). OCTA data were correlated with IMT values showing a negative correlation between IMT and both superficial and deep fovea VD (p=0.003, r=-0.4) and p=0.004, r=-0.4), while a positive correlation was found with FAZ area (p=0.02, r=0.4).

**Table 1. Demographic, clinical and US data of the study population**

| Female sex (%) | 28 (75.6) |
| Age, yrs | 49.2±14.7 |
| Smokers n(%) | 12 (32.4) |
| BMI | 25.1±5.2 |
| SBP, mmHg | 118.5±15.7 |
| DBP, mmHg | 73.2±11.6 |
| IMT, μm | 549.6±124 |

**Discussion:** Retinal vascular impairment in SLE has been associated with IMT, atherosclerotic plaques and some CV risk factors as hypertension, hypertriglyceridemia and CRP levels. Search for new markers of preclinical CV damage in SLE is currently ongoing and OCTA might be an additional instrument to assess preclinical cardiovascular involvement in SLE.

**Biomarkers in pathogenesis, monitoring and treatment of rheumatic diseases**

**DOWNSCALING OF MIR-885-5P AS A KEY EFFECTOR IN CUTANEOUS LUPUS ERYTHEMATOSUS PATHOGENESIS**

S. Domingo1, C. Solé-Marçal1, T. Moline1, B. Ferrer1, J. Cortés-Hernández1.

1VHIR - Vall d’Hebron Institut de Recerca, Luperus Unit, Rheumatology, Barcelona, Spain; 2VHIR - Vall d’Hebron Institut de Recerca, Pathology, Barcelona, Spain; 3Hospital Universitari Vall d’Hebron, Pathology, Barcelona, Spain.

**Background:** Skin involvement is common in systemic lupus erythematosus (SLE), with up to 70% of patients developing skin lesions at some point during the course of their disease. Moreover, cutaneous lesions are the first sign of systemic disease in 20% of SLE patients [1]. Skin requires a regulated and undisrupted miRNA profile for a correct development and function. Studies show that miRNAs play a pathogenic role in autoimmune skin diseases such as Psoriasis [2]. Understanding of the role of deregulated miRNAs in CLE may enhance our knowledge about CLE pathogenesis which is currently not understood.

**Objectives:** Identify differentially expressed miRNAs in skin lesions to determine new markers for CLE pathogenesis.

**Methods:** Paired skin biopsies from CLE lesional (n=20) and non-lesional skin (n=20) were obtained. MiRNA microarray screening was performed using TaqMan MicroRNA Array. Validation was performed in a new cohort of FFPE skin samples by qRT-PCR (n=20). In situ hybridization was performed to identify the skin cell type involved in selected miRNAs. Next, in vitro experiments using primary skin and immune cells were performed in order to discover their role in CLE pathogenesis. A microarray screening and luciferase assay were performed to find mir-885-5p altered gene expression, molecular pathways and target genes.

**Results:** mir-885-5p was found downregulated in CLE lesional skin (-4.45 fold, p<0.01, respectively). Results were confirmed in a validation cohort. In situ hybridization revealed mir-885-5p was located in the epidermal keratinocytes in CLE non-lesional skin. Healthy keratinocytes presented an increased mir-885-5p expression compared with other relevant cell types such as fibroblasts (p<0.001) or PBMHCs (p<0.001). Moreover stimulation with IFNα and UVB promoted a marked long-lasting downregulation of mir-885-5p (IFNα, 24h -67 fold (p<0.001); UVB, 24h -70 fold (p<0.001)).

**Conclusion:** Downregulation of mir-885-5p in CLE may represent a new hallmark of CLE pathogenesis.
We also found that C1q could increase basal OCR, ATP-coupled OCR, max in synovial macrophages. but not TNF- 

Results: Transcripts for inflammatory cytokines were quantified by RT-PCR. Mitochondrial protein expression was detected by flow cytometric analysis and immunoblotting. Besides, C1q could increase the expression of IL-1β and TNF-α but not TNF-α secreted by synovial macrophages, which represents a novel therapeutic target in RA.

COMPLEMENT C1Q PROMOTES MITOCHONDRIA RESPIRATION AND SECRETION OF IL-6 AND IL-1 
BUT NOT TNF-Α BY SYNOVIAL MACROPHAGE IN RHEUMATOID ARTHRITIS

Y. Jiang1,2, B. Wu1, T. Huang2, Y. Liu1, Z. Hu1, T. Zhao2, Y. Pan1, W. Cornelia1,2
1Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China; 2Stanford University, Department of Immunology and Rheumatology, Palo Alto, United States of America; 3Mayo Clinic, Department of Rheumatology and Immunology, Rochester, United States of America

Background: Complement C1q (C1q), predominantly synthesized by myeloid cells such as macrophages, has elusive functions in the pathogenesis of rheumatic arthritis (RA). Binding to its receptor gC1qR, C1q can activate mitochondria, the dysfunction of which may result in tissue inflammatory disease [1]. Bone marrow derived macrophages in RA patients have elevated OXPHOS activity [2], while the reason remains to be discovered.

Objectives: The objectives of the study were to explore the expression of C1q and its receptor gC1qR in synovial macrophages in RA and whether C1q contributes to tissue inflammation via affecting pro-inflammatory cytokines (IL-1β, IL-6 and TNF-α) and mitochondria respiration in synovial macrophages.

Methods: Tissue transcriptome analysis for C1q (C1qA, C1qB and C1qC), C1q receptors (including gC1qR) in rheumatoid synovium and pro-inflammatory cytokines (IL-6, IL-1β and TNF-α) in rheumatoid synovium and synovium macrophages were quantified by RT-PCR. Concentrations of C1q in the plasma of RA and healthy controls (HC) were analyzed by ELISA and the correlation between plasma C1q and disease activity measured by DAS28 were calculated. gC1qR protein expression was detected by flow cytometric analysis and immunoblotting. Synovial macrophages were isolated and stimulated with or without C1q for 24h. Function of gC1qR was analysed by knockdown experiment using siRNA. Transcripts for inflammatory cytokines were quantified by RT-PCR. Mitochondrial respirometer was evaluated with Seahorse Bioscience XF96 analyzer by adding test agents in order of 1, oligomycin; 2, FCCP; 3, anti-mycin A/rotenone. Total trend and each segmentation of oxygen consumption rates (OCR) were shown after treated with C1q, n=6. * P < 0.05; ** P < 0.01; *** P < 0.001.

POS0137
FREQUENCIES OF WNT PATHWAY GENE VARIANTS ASSOCIATED WITH ANTI CARBAMYLATE PROTEIN IN EARLY RHEUMATOID ARTHRITIS

M. Acevedo-Godoy1, S. J. Perdomo2, W. Bautista-Molano2, L. Chilla2, O. J. Calixto1, J. M. Bello-Gualterio1, C. Pomerro-Sanchez3,4, Hospital Militar Central, Rheumatology and Immunology Department, Clinical Immunology Group, Bogota, Colombia; 2Universidad El Bosque, Cellular and Molecular Immunology Group/ INMUUBO, Bogota, Colombia; 3Universidad Militar Nueva Granada, School of Medicine, Clinical Immunology Group, Bogota, Colombia

Background: Increased bone resorption and impaired bone formation characterize the pathogenesis of rheumatoid arthritis (RA). Wnt/β-catenin pathway regulates osteoblast function. Since bone mineral density (BMD) and RA joint destruction are partially inherited, we studied the association of Dickkopf-1 (DKK-1), sclerostin (SOST), Kremen-1 and lipoprotein receptor-related protein-5 (LRP-5) genes single nucleotide polymorphisms (SNP) with RA in 232 individuals.

Objectives: To establish the genotypic frequency of variants of the DKK-1, rs1896368, rs1896367, rs1528873), SOST (rs6503475), Kremen-1 (rs132274) and LRP-5 (3736228) genes in patients with early RA (eRA) and first degree relatives (FDR). A bivariate analysis was conducted in eRA and FDR. A logistic regression was performed.

Methods: Colombian individuals were matched by age and gender. Serological and clinical indices were measured. Variants associated with the Wnt pathway: DKK-1, SOST, LRP-5, and Kremen were analyzed using High Resolution Melting and confirmed by Sanger sequencing. A bivariate analysis was conducted in eRA and FDR. A logistic regression was performed.

Results: 232 individuals were evaluated; 66 eRA patients, 50 FDR, and 116 HC. For eRA, 78.8% were female, with a median age 52 years (IQR: 38,8-56). Higher levels of CRP: 4,2 (IQR: 1,8-11,6), RF: 30,2 (IQR: 1,2-74,1), and CCP: 7,81 (IQR: 7,81-104,9) and anti-Carbamylate protein (CarP): 17,6 (IQR: 12,3-31,8) were observed.
Among eRA, FDR, and HC genotypic frequencies are listed in Table 1. There were significant differences among DKK-1 rs1896367, GG native and GA, p=0.001. Meanwhile, the relationship between synovial fluid immune cells and HC was not significant. Our work demonstrates that RASFs from different endotypes display imprinted memory of their original synovial tissue when maintained in culture over several months. We also demonstrated that imprinted memory typical of RASF isolated from B-cell rich LM synovial tissues can be dynamically modulated in FPI-RASF following co-culturing with RA B cells. Finally, consensus gene modules based on FPI vs LM RASF gene signatures were able to inform response/resistance to targeted biologic therapies.

RHEUMATOID SYNOVIAL FIBROBLASTS DISPLAY IMPRINTED MEMORY OF THEIR SYNOVIAL ENDOTYPE WHICH CAN BE PLASTICALLY MODULATED BY B-CELLS CROSSTALK

E Prefidietto1, C Cubuik2, E Pontarini1, F Rivelese1, A Nerviani1, D Lucchesi1, M Caliste1, E Corsiero1, R Hands1, M Lewis1, C Pitzalis1, M Bombardieri1

Background: Despite advances in the treatment of Rheumatoid Arthritis (RA), synethetics and biologicals drugs are ineffective in ~40% of patients. The origin of this refractoriness is unclear, but several clues point at the synovial microenvironment (SE) and the relative cellular heterogeneity between patients. We previously described the existence of different RA endotypes such as the lympho-lymphoid, LM, which is B-cell rich and the fibro-paucicellular, FPI, which is devoid of B-cells. While there is clear evidence that the co-culture between stromal and immune cells in rheumatoid joints is critical for the perpetuation of chronic inflammation and autoimmunity, it is currently unknown whether transcriptional signatures identified in synovial fibroblasts (SFs) derived from different RA endotypes are driven by “imprinted” properties of the SFs or are shaped by the interaction with infiltrating immune cells in the RA joints.

Objectives: i) to identify “imprinted” vs “inducible” RASFs gene signatures through the comparison of freshly isolated SFs and primary established SFs cultures obtained from LM vs FPI RA synovial biopsies and ii) to investigate the identified RASF signature as predictive biomarkers of disease evolution and of response to conventional and biological DMARDs.

Methods: We performed flowcytometry and single cell RNA sequencing (sc-RNAseq) on SFs obtained from LM and FPI biopsies, in isolation or in co-culture with RA B cells. Next, supernatant has been screened trough Multiplex and ELISA. Furthermore, we compared our results to publicly available sc-RNAseq datasets on freshly isolated SFs and to our bulk-RNAseq data from clinical trials patients.

Results: Hierarchical clustering from sc-RNAseq transcriptional profiling of LM vs FPI RASF - after several cell passages - identified profoundly different gene signatures: whereby LM-RASF were characterised by genes involved in inflammation, proteoglycan formation and integrin binding. FPI-RASF were defined by genes related to collagen biosynthesis. Comparing the above signatures with those of freshly isolated RASF we identified both imprinted (i.e. maintained through several in vitro passages) and inducible (i.e. loss after long term culture) gene signatures. Notably, RA B-cells co-cultured with FPI-RASF profoundly altered the FPI-RASF transcriptional profile including the ex novo expression of gene signatures typical of LM-RASF. Consensus gene modules constructed on LM vs FPI RASF imprinted gene signatures could be tracked in longitudinal whole tissue bulk RNA-seq data obtained from both early arthritis and established RA and were associated with synovial pathotype-specific histological and clinical features. Finally, modulation of FPI-RASF related genes following B-cell depletion identified poor responders to Rituximab in the RA4RA randomised clinical trial.

Conclusion: Our work demonstrates that RASFs from different endotypes display imprinted memory of their original synovial tissue when maintained in culture over several months. We also demonstrated that imprinted memory typical of RASF isolated from B-cell rich LM synovial tissues can be dynamically modulated in FPI-RASF following co-culturing with RA B cells. Finally, consensus gene modules based on FPI vs LM RASF gene signatures were able to inform on response/resistance to targeted biologic therapies.
worsening symptoms (339 vs 222 g/ml, p=0.002). CXCL10 levels in patients with improved symptoms showed a decreasing trend between phenotypes from KOA > KOA2 > KOA3 > KOA4. Regarding macrophages, low expression of chemokine receptor CXCR4 and CXCR7 on macrophages was associated with improved symptoms regardless of KOA phenotype.

Conclusion: We identified four KOA phenotypes differing in immune cell percentage and activation associated with different clinical trajectories. Low expression of chemokine receptors CXCR4 and CXCR7 on macrophages and high CXCL10 in SF was linked to KOA symptom improvement. How these phenotypes can be targeted for therapeutic intervention is a key question.

Background: In patients with active systemic lupus erythematosus (SLE), circulating platelets have an activated phenotype characterized by the expression of P-selectin (CD62P). We have shown that in human SLE, platelets interact with T regulatory cells and repress their immunosuppressive functions through its impact on neutrophil functions, and lupus pathogenesis.

Methods: Patients from the EUSTAR database were classified either as (i) limited cutaneous, diffuse cutaneous and sine scleroderma (based on the recording made by the treating physician) or (ii) according to autoantibodies with the following subclassifications: (1) no specific autoantibodies, (2) isolated ANA, (3) auto-centreome antibodies, (4) anti-Scl70 antibodies and (5) anti-RNA polymerase III antibodies or (iii) according to combination of cutaneous subset and auto-antibodies. The respective performance of each model to predict overall survival (OS), progression-free survival (PFS), disease progression and different organ involvements was assessed and the three models were compared by the area under the receiver operating characteristic curve (AUC 95%CI) and the net reclassification improvement (NRI). Missing data were imputed through multiple imputation using chain equations.

Results: In all, 10'711 patients were included: 84.6% females, mean age: 54.4±13.8 years, mean disease duration: 79±8.2 years. In the prospective

analysis (n=6'467 to 7'829 according to the outcome), after a mean follow-up of 56 months and a mean of three visits per patient, we did not identify any difference in AUC between the cutaneous-based model and the antibody-based model for prediction of OS and disease progression. However, the NRI showed a significant improvement in prediction of OS (0.57 [0.46-0.71] vs. 0.29 [0.19-0.39]) and disease progression (0.36 [0.29-0.46] vs. 0.21 [0.14-0.28]) at 4 years using the antibody-based model. Regarding prediction of each organ involvement in longitudinal analyses, the antibody-based model showed better performance than the cutaneous-one for renal crisis (AUC: 0.719 [0.696-0.742] vs. 0.664 [0.643-0.685]), with the highest association observed in the kidneys.

Conclusion: Auto-antibody status outperforms the common cutaneous subsetting to risk-stratify SSC patients in the EUSTAR cohort. This easily performed subclassification using autoantibodies specific status can be used by the clinicians to risk-stratify their patients and to adapt disease monitoring in routine practice.

PLATELET-SELECTIN PRIME LUPUS NEUTROPHILS TO PRODUCE MITOCHONDRIAL ROS AND PARTICIPATE IN SLE PATHOGENESIS

C. Riche2, P. Bianco2, 1

1Strasbourg University Hospital, Rheumatology, Strasbourg, France; 2Bath Israel Deaconess Medical Center (BIDMC), Harvard, United States of America; 3Chu Bordeaux - Site Pellegrin, Immunology, Bordeaux, France

Background: Risk-stratification is key in a heterogeneous disease like systemic sclerosis (SSc). Until now, SSc patients are stratified according to the extent of skin involvement into limited cutaneous, diffuse cutaneous and sine scleroderma subtypes. However, this classification remains inaccurate to capture disease heterogeneity. Autoantibodies are found in more than 90% of the patients and can be detected before onset of the disease. Among them, three predominant and heterogeneous. Autoantibodies are found in more than 90% of the patients and can be detected before onset of the disease. Among them, three predominant and differentiated cutaneous, diffuse cutaneous or sine scleroderma (based on the record-
SLE disease activity index (SLEDAI-2K), and patients were considered active if SLEDAI-2K ≥ 6. Platelet-neutrophil aggregates were identified as (platelet) CD61+ (neutrophil) CD66b+ cells using flow cytometry on fresh blood samples. Single-cell cytosolic calcium and ROS imaging was performed by incubating cell with either a fluorescent calcium dye (cali-520), or a mitochondrial specific dye (MitoSox). Coverslips were mounted in an Affitfluor cell chamber positioned on the stage of an inverted epifluorescence microscope (Olympus, IX70). Mitochondrial polarization of human neutrophil was evaluated by incubating cells with TMRE (100 nm) for 30 minutes. Platelet-free plasma was isolated by two speed centrifugations (3500xg) of EDTA-anticoagulated blood and stored for subsequent evaluation of soluble P-selectin (using ELISA) and (platelet-derived) microparticle P-selectin (using flow cytometry).

**Results:** In healthy donors (HD) and patients with SLE, circulating neutrophils expressed significantly higher levels of the P-selectin ligand CD15s compared to lymphoid subsets (p < 0.001), predicting platelet/neutrophil interactions. In contrast to HD and patients with inactive SLE, those with active disease had a significant increase of circulating platelet-neutrophil aggregates (p < 0.05), and these aggregates correlated with the SLEDAI (r = 0.59, p < 0.001). The incubation of human neutrophils with recombinant P-selectin induced a strong intracellular calcium signaling which was inhibited by preincubating neutrophil with anti-PSGL1 antibody (blocking P-selectin/CD15s interaction) or with a Syk kinase inhibitor. Similarly, P-selectin induced a mitochondrial ROS release in a CD15s- and Syk-dependent manner. Interestingly, incubation of neutrophils with anti-dsDNA IgG and P-selectin induced mitochondrial depolarization, which was absent with either stimulus alone. Soluble and platelet-derived microparticle P-selectin levels were significantly increased in patients with active SLE compared to inactive patients or healthy donors (p < 0.05 and p < 0.001, respectively). In a longitudinal analysis of SLE patients, soluble and microparticle P-selectin levels closely followed clinical (SLEDAI) and biological (Cr) levels markers of SLE disease activity.

**Conclusion:** P-selectin levels are increased in active SLE and follow hallmark of disease activity. P-selectin induces calcium/mitochondrial ROS signaling in lupus neutrophils which are key players in SLE pathogenesis. We hypothesize that the inhibition of P-selectin pathway might be a promising target in SLE.

ANOSSA). Details, at the gener level, IIM patients had a higher abundance of Entero-coccus, Veillonella, Streptococcus, et al. and a lower abundance of Roseburia, Lachnospira, Klebsiella, et al (Figure 1D, p < 0.05). In IIM patients, Fusobacteriota correlated positively with the ratio of Th1 cells (Figure 1E, p < 0.01), and there was a significant positive correlation between Synergistota and B lymphocyte (Figure 1E, p < 0.01). Besides, Euryarchaeota and Cyanobacteria were both positively and significantly related to IL-6, IFN-γ and C-reactive protein (CRP) (Figure 1E, p < 0.001).

**Conclusion:** Richness and diversity of intestinal flora in IIM patients were impaired, which might participate in the pathogenesis of IIM by disturbing lymphocyte subpopulations and cytokines. Regulating intestinal flora and restoring homeostasis might become a critical therapeutic methods of IIM.

NOVEL ANTIBODY BIOMARKERS THAT PREDICT FAILURE TO ACHIEVE EARLY AND SUSTAINED DISEASE REMISSION OR LOW DISEASE ACTIVITY AFTER INTENSIVE FIRST-LINE THERAPY IN RHEUMATOID ARTHRITIS

P. Vandormael, A. Pues, E. Sleurs, J. Liesenborgs, P. Verschueren, V. Somers, Hasselt University, Biomedical Research Institute, Immunology and Infection, Diepenbeek, Belgium; Hasselt University, Expertise Centre for Digital Media, Computational Science, Diepenbeek, Belgium; KU Leuven, University Hospital Leuven, Rheumatology, Leuven, Belgium

**Background:** Current EULAR guidelines for the management of rheumatoid arthritis (RA) recommend the use of classical synthetic disease-modifying anti-rheumatic drugs (csDMARDs), combined with short-term use of glucocorticoids (GC) as first-line therapy. Still, finding out which patients will show a poor response to such intensive first-line therapy is currently based on trial and error. Therefore, we recently performed a screening for novel antibody biomarkers that could predict the lack of response to csDMARD/GC combination therapy, resulting in identification of antibodies to 6 novel University Hasselt (UH)-RA antigens.

**Objectives:** The aim of this study was to validate these novel antibody biomarkers for their potential to identify at baseline, which RA patients fail to reach remission (rem-), or low disease activity (LDA), after intensive csDMARD therapy.

**Methods:** Presence of antibodies to the identified UH-RA antigens was measured using ELISA in 179 baseline samples from participants of the CareRA trial, which evaluated the efficacy of different first-line combination therapies. Baseline antibody reactivity was correlated with remission or LDA, over a two-year follow-up period, according to the Disease Activity Score based on 28 joints with C-reactive protein (DAS28CRP), the DAS28 with erythrocyte sedimentation rate (DAS28ESR), and the clinical/simplified disease activity index (CDAI/SDAI).

**Results:** Baseline antibody reactivity against a panel of 3 antigens was higher in patients failing to reach DAS28CRP (31 vs 15%, p=0.007) or DAS28ESR (30 vs 14%, p=0.007) remission at week 8, or those failing to reach SDAI (36 vs 17%, p=0.018) or CDAI (37 vs 17%, p= 0.01) LDA at week 8, compared to RA patients that did reach these respective disease states. Baseline antibody reactivity correlated with lack of DAS28CRP remission after 8, 16 and 52 weeks of first-line therapy, and was present in one in three DAS28CRP rem-patients, and in one in two DAS28CRP rem-patients that were seronegative for RF and ACPA. For each of the remission criteria studied (DAS28CRP, DAS28ESR, SDAI and CDAI), baseline antibody reactivity against these antigens was significantly higher in RA patients that did not maintain sustained remission (resp. 25 vs 12%, p=0.029; 24 vs 11%, p=0.041; 24 vs 4%, p=0.009; 24 vs 4%, p=0.011), or sustained LDA (resp. 29 vs 13%, p=0.007; 27 vs 11%, p=0.008; 29 vs 14%, p=0.018; 29 vs 14%, p=0.013) between week 8 and week 52, compared to patients that did reach these respective disease states.

**Conclusion:** We have identified a set of 3 antibody biomarkers that predict the failure to achieve early and sustained remission and LDA in response to intensive first-line RA therapy. Therefore, the presence of these antibodies might indicate the need for another first-line treatment option in a personalized medicine approach.

**INCREASED RISKS OF AORTIC REGURGITATION AND ATRIAL FIBRILLATION IN RADIOPHORIC AXIAL SPONDYLOARTHRITIS PATIENTS: A 10 YEAR NATIONWIDE COHORT STUDY**

H. K. Min¹, K. Y. Kang², S. H. Lee², S. Park³, M. Park³, Y. S. Hong³, M. Y. Kim², S. H. Park¹.

¹Konkuk University Medical Center, Rheumatology, Seoul, Korea; ²Republic of (South Korea); ³Seoul National University Hospital, Hospital, Seoul, Korea; ⁴The Catholic University of Korea Incheon St. Mary’s Hospital, Rheumatology, Incheon, Korea; ⁵University of California, San Francisco, Departments of Medicine, Pharmacology and Population Health Sciences, San Francisco; ⁶Hamri Pharmacy, Data Science Team, Seoul, Korea; ⁷The Catholic University of Korea Seoul St. Mary’s Hospital, Rheumatology, Seoul, Korea; ⁸Republic of (South Korea).

Background: Radiographic axial spondyloarthritis (r-axSpA) has increased risk of cardiovascular disease. Other cardiac manifestations such as conduction disturbance and valvular diseases were also suggested as co-morbidities in r-axSpA patients, however, the risk of these cardiac manifestation in r-axSpA was seldomly evaluated in large cohort.

Objectives: To compare the incidences of aortic regurgitation, atrial fibrillation (AF), and aortic and/or mitral valve diseases in r-axSpA patients and the general population (GP).

Methods: National Health Insurance Services data were used in this study. r-axSpA patients (N = 8,877) and the age- and sex-matched GP (N = 26,631) were followed at 3 time points, over 48 weeks, from the TRACTISS cohort, in order to identify mechanisms of response/resistance to B cell depletion.

Methods: 29 psS patients randomised to RTX or placebo arm consented for salivary gland biopsies at week 0, 16 and 48. Patients received two 1000mg cycles of RTX or placebo at week 0 and 24. SG focus score, inflammatory aggregate area fraction, B-cells (CD20+), T-cells (CD3+), follicular dendritic cells (FDCs) (CD21+) and plasma cells (CD138+) density were assessed using quantitative digital image analysis. RNA sequencing with deconvolution and pathway analysis was performed to identify genes signatures and consensus gene modules as biomarkers of disease evolution and response/resistance to therapy.

Results: Placebo-treated SGs showed worsening of SG inflammation highlighted by the increase of aggregate size, B-cell density, development of new FDC networks, and a higher ectopic GC prevalence over 48 weeks, compared to RTX-treated patients. No difference in focus score, total T-cell and plasma cell infiltration was observed. RTX downregulated genes involved in immune cell recruitment and inflammatory aggregate organisation (e.g. CXCL13, CC19 and PDGDC1). Gene signature-based analysis of 35 immune cell types using XCell highlighted how RTX blocked class-switched and memory-B-cells accumulation in SGs over 48 weeks. Pathway analyses confirmed the downregulation of leukocyte migration, MHC-II antigen presentation, and T-cell co-stimulation immunological pathways, such as the CD40 receptor complex pathway. Among RTX-treated patients, only CRESS-responders demonstrated prevention of worsening B cell-driven molecular pathology signatures over time and a significant improvement in UWSF, in parallel with the upregulation of molecular pathways associated to SG restoration of the glandular epithelium. None of the above effects were observed at week 16 after the first RTX cycle.

Conclusion: Two RTX infusions repeated at week 24 exerted beneficial effects on salivary SG inflammatory infiltration in psS by downregulating involved genes in immune cell recruitment, activation and organisation in ectopic GCs. Conversely, all the above parameters showed significant improvement in placebo treated patients over 48 weeks demonstrating progression of SG immunopathology.

Clinical responders to RTX based on CRESS response criteria were characterised by preservation of exocrine function which appear driven by SG epithelial restoration.

**DETERMINANTS OF GENERAL HEALTH AND HEALTH RELATED QUALITY OF LIFE IN AXIAL SPONDYLOARTHRITIS, PERIPHERAL SPONDYLOARTHRITIS AND PSEORIATIC ARTHRITIS: RESULTS FROM THE ASAS-PERSPA STUDY**

H. Santos¹, ², R. Henriques¹, M. Dogados¹, C. Lopez-Medina², H. Canhão²,³, P. M. Machado²,³, F. Pimentel Santos²,³.

¹Universidade do Porto, Institute of Rheumatology, Porto, Portugal; ²Nova Medical School, EpiDoc Unit, Comprehensive Health Research Center, Lisbon, Portugal; ³University College of London, Centre for Rheumatology and Department of Neuromuscular Diseases, London, United Kingdom; ⁴Centro Hospitalar Lisboa Ocidental, Hospital de Egas Moniz, Rheumatology, Lisbon, Portugal.

Background: Axial Spondyloarthritis (axSpA), peripheral Spondyloarthritis (pSpA) and Psoriatic arthritis (PsA) are different types of SpA, with large heterogeneity in clinical manifestations. It is crucial to understand which are the determinants of health-related quality of life (HRQoL) and general health (GH, global functioning and health) in axSpA, pSpA and PsA, which can lead to differential approaches for treatment, to attain better outcomes.

Objectives: This study aims to identify and compare determinants of HRQoL and GH in axSpA, pSpA and PsA, using data from the ASAS-Perspa Study.

Methods: Data from the ASAS-Perspa Study, a cross-sectional and multicenter study with 24 participating countries, was used. Patients with either axSpA, pSpA or PsA were enrolled. Sociodemographic, lifestyle, anthropometric, and clinical characteristics were collected. Univariable and multivariable regression models for the three groups were performed separately, to explore factors associated with HRQoL, assessed by EuroQoL-5 Dimensions 3 level (EQ-5D), and similar analysis was performed for GH, assessed by the Assessment of SpondyloArthritis international Society Health Index (ASAS-HI).

Results: 4185 patients were included in the analyses. For the final models, only patients with complete data were included (results summarized in Table 1). Regarding HRQoL, worse HRQoL in axSpA was associated with female gender, fibromyalgia (FM), peripheral disease (PD), worse function and higher disease activity (DA) and patient's self-reported (PGA) in pSpA with worse function, higher DA and higher non-steroidal anti-inflammatory drugs intake score (NSAIDs-IS), and in PsA with female gender, axial involvement, worse function, higher DA and glucocorticoid therapy. On the contrary, better HRQoL was calculated by the Kaplan–Meier method and Cox regression analysis.

Disclosure of Interests: None declared

associated in axSpA with a history of uveitis, in pSpA with older age (with a trend in axSpA and PsA, but not statistically significant) and in PsA with biologic therapy. Regarding GH, in axSpA, worse GH was associated with female gender, FM, PD, worse function and higher DA and PGA, in pSpA, with female gender, inflammatory bowel disease, worse function, treatment with conventional synthetic disease-modifying anti-rheumatic drug and higher NSAID-IS, in PsA with female gender, alcohol intake, FM, axial involvement, worse function and higher DA. On the contrary, better GH was associated in axSpA with university education (UE), higher BMI and higher NSAID-IS, in pSpA with UE, and in PsA with older age and UE.

Table 1. Factors associated with HRQoL and GH stratified by diagnostic category (summarized)

Conclusion: In all types of SpA, DA and function are major determinants of HRQoL, passible of tight monitoring and therapeutic intervention. In GH, besides DA and function, socio-demographic factors, like gender and education, also play an important role, in all forms of SpA, highlighting the importance of a holistic approach of the individual patient in order to achieve better outcomes.

POS0148 SPARCC, MASES, LEI AND MEI INDEXES CAPTURE DIFFERENT PATIENTS WITH ENTHESITIS IN AXIAL SPONDYLOARTHRITIS, PERIPHERAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS.

R. E. M. Granados1, M. L. Dadehesa Pineda1, M. Á. Puche Larrubia1, M. Dougdos2, E. Collantes Estevez2, C. López-Medina1,2

1Reina Sofia University Hospital/Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Rheumatology, Cordoba, Spain; 2Cochin Hospital, Rheumatology, Paris, France

Background: Spondyloarthritis, (axial (axSpA), peripheral (pSpA)) and psoriatic arthritis (PsA) share enthesis as a hallmark clinical feature. Reliable clinical instruments have been developed to assess enthesitis: Spondyloarthritis Research Consortium of North America Enthesitis (SPARCC), Leeds Enthesitis Index (LEI), Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) and MEI (Mander Enthesitis Index). Since these four indexes include different enthesis locations, they may capture a different number of patients with enthesitis in the different SpA entities. The prevalence of patients with at least one enthesitis across the three groups differs depending on the use of SPARCC, LEI, MASES and MEI indexes; c) to evaluate the level of agreement between these indexes for detecting patients with at least one enthesitis in axSpA, pSpA and PsA populations.

Methods: PerSpA was a multinational observational, cross-sectional study with 24 participating countries worldwide. A total of 4185 patients with a diagnosis of axSpA (2719), pSpA (433) and PsA (1033) according to the Rheumatologist’s opinion were included in this analysis. Information on the location of enthesitis collected during the study visit was used according to the SPARCC, LEI, MASES and MEI indexes.

The prevalence of patients with at least one enthesis according to the different indexes was compared across the diseases (axSpA, pSpA and PsA), and pairwise agreement between indexes were evaluated using the Cohen's kappa in the global population and in the three groups.

Results: Out of 36 locations, the most prevalent enthesitis in the overall population were the lumbar spinous processes (6.5%), the thoracic spinous processes (4.9%) and the insertion of the Achilles tendon right (4.8%) and left (3.9%). A total of 10.7%, 8.3%, 13.5% and 17.2% of patients in the overall population showed at least one enthesitis according to the SPARCC, LEI, MASES and MEI indexes, respectively. Figure 1 shows that, among patients with axSpA, MEI and MASES indexes capture the majority of patients with at least one enthesitis (98.7% and 82.4%, respectively), while in pSpA and PsA, MEI and SPARCC are the indexes which capture the majority of patients with enthesitis (100% and 84.6% for MEI and SPARCC in pSpA, and 97.3% and 77% for MEI and SPARCC in PsA, respectively). In PsA, the LEI only captured 57.2% of the patients with at least one enthesis. In the total population, MASES and MEI showed the strongest agreement for patients with at least one enthesis (absolute agreement 96.3%; Cohen's kappa: 0.86). Similarly, among axSpA patients, MASES and MEI showed an almost perfect agreement (97.3%; 0.90), while LEI and MEI showed a moderate agreement (90.4%; 0.54). In pSpA patients, SPARCC and MEI showed the strongest agreement (97.2%; 0.90), as well as among PsA patients (95.4%; 0.82). However, MASES and SPARCC showed a less agreement in PsA patients (94.2%; 0.67).

Conclusion: The most prevalent locations of enthesitis on the global SpA population are the lumbar spinous processes, the thoracic spinous processes and Achilles tendon. MEI and MASES are the two index that capture more patients with enthesitis in axSpA, while MEI and SPARCC are the two index that capture more patients in pSpA and PsA. The LEI index may underestimate the prevalence of enthesitis in these patients. MASES and MEI showed the largest level of agreement in the overall population and in axSpA, while MEI and SPARCC showed the largest level of agreement in pSpA and PsA. These results suggest that the prevalence of enthesitis across entities differs depending on the disease and on the use of the different index.

WHAT IS BACKFILL? - DETAILED CT / MRI ANALYSIS OF NEW BONE FORMATION IN AXIAL SPONDYLOARTHRITIS

T. Diekhoff1, C. Niedermeier1, F. Prof1, D. Poddubny2, K. G. Hermann1.  
1Charité Universitätsmedizin Berlin, Clinic for Radiology, Berlin, Germany; 2Charité Universitätsmedizin Berlin, Division Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany

Background: Several magnetic resonance imaging (MRI) findings of the sacroiliac joint space in axial spondyloarthritis (axSpA) were previously described such as inflammation or fatty metaplasia inside an erosion, i.e. “backfill”. However, it is incompletely understood if one or all of these changes represent calcified bone matrix.

Objectives: This study aims to one-by-one link the aforementioned changes to computed tomography (CT) measurements and to understand, which of those findings represents new bone formation.

Methods: Out of 178 patients from two prospective studies that included CT and MRI of the sacroiliac joints all patients with the final diagnosis of axSpA were selected. MRI was screened by two senior musculoskeletal radiologists in consensus for joint-space related MRI findings and grouped into three categories, Type A: hyperintense in STIR and hypointense in T1 (inflammation inside erosion), Type B: hypointense in both sequences and Type C: hypointense in STIR and hyperintense in T1 (backfill). By using image fusion techniques and one-by-one comparison, the Hounsfield Units (HU) of those lesions as well as normal cartilage and spongious and cortical bone were measured in CT.

Results: Ninety-nine patients with axSpA were identified and 48 Type A, 88 Type B and 84 Type C lesions were assessed. Please see Figure 1 for CT measurements. The HU values of cartilage were 73.6±15.0, spongious bone 188.0±69.9, and normal cartilage and spongeous and cortical bone were measured in CT.

Conclusion: All joint space lesions (Type A to C) show calcified matrix and, thus, resemble new bone formation with gradually more calcified matrix in Type C lesions, i.e. typical backfill. Therefore, the nomenclature of those lesions should be critically re-assessed.

ANAGING Spondylitis RELATED STRUCTURAL CHANGES IN THE SPINE INDEPENDENTLY INFLUENCE PATIENT REPORTED PHYSICAL FUNCTION IN MEN BUT NOT IN WOMEN. A COMPREHENSIVE CROSS-SECTIONAL ANALYSIS OF BATH ANKYLING SPONDYLITIS FUNCTIONAL INDEX AND ITS RELATION TO SEX

M. Hallström1,2, E. Klingberg1,2, A. Deminger1,2, J. Backman Renman3, M. Geijer3,5, H. Forsblad-D'elia1,2. 1Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden; 2Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 302

Introduction: Ankylosing spondylitis (AS) is an inflammatory disease that may result in structural changes in the spine. In the Bath Ankylosing Spondylitis Functional Index (BASFI), higher scores correlate with lower functional capacity. This study aims to one-by-one link the aforementioned changes to computed tomography (CT) measurements and to understand, which of those findings represents new bone formation.

Objectives: This study aims to one-by-one link the aforementioned changes to computed tomography (CT) measurements and to understand, which of those findings represents new bone formation.

Methods: Out of 178 patients from two prospective studies that included CT and MRI of the sacroiliac joints all patients with the final diagnosis of axSpA were selected. MRI was screened by two senior musculoskeletal radiologists in consensus for joint-space related MRI findings and grouped into three categories, Type A: hyperintense in STIR and hypointense in T1 (inflammation inside erosion), Type B: hypointense in both sequences and Type C: hypointense in STIR and hyperintense in T1 (backfill). By using image fusion techniques and one-by-one comparison, the Hounsfield Units (HU) of those lesions as well as normal cartilage and spongious and cortical bone were measured in CT.

Background: There is growing interest in reproductive issues in patients with Spondyloarthritis (SpA) and Psoriatic arthritis (PsA).

Objectives: To describe a real-life cohort of prospectively-followed pregnancies in SpA and PsA patients, focusing on obstetric outcome and on flare during pregnancies and post-partum.

Methods: Data on SpA and PsA pregnancies prospectively-followed in 2 European pregnancy clinics from 2010 to 2021 were retrospectively analysed. Disease activity was assessed using ASDAS-CRP or DAS28-CRP according to the main involvement (peripheral or axial). Disease flare was defined as the need to treatment modification (introduction or increase ≥5mg/day of prednisone, introduction of cDMARD or bDMARD). Miscarriages were excluded from the analysis of flares.

Results: Data on 122 pregnancies (53 PsA and 69 ‘other’ SpA: 39 axialSpA, 20 undifferentiated SpA, 6 IBD-related SpA, 4 reactive arthritis) in 102 patients (median age at conception: 34 [IQR: 31-36] years; median disease duration: 72 [24-132] months) were collected. We recorded 98 (86%) live births and 16 (14%) miscarriages (8 missing data). Cesarean section was performed in 15/98 (15%) cases. Median week of gestation at delivery was 39 [38-40]; 8 preterm births (<37 week of gestation) and 2 severe preterm births (<34 week of gestation) occurred. There was no difference between PsA or ‘other’SpA concerning pregnancy outcome and route of delivery.

Fourty-two pregnancies (40%) had at least 1 flare during pregnancy; 7 pregnancies had more than 1 flare. Overall, there were 13, 24 and 12 flares in the 1st, 2nd and 3rd trimester, respectively. A higher frequency of patients with axial involvement was observed in the ‘flare’ group as compared to pregnancies without flare (83% vs 59%, p=0.02) (Table 1).

Table 1. Comparison between ‘flare’ and ‘without flare’ groups.

</tbody>
</table>

Continuous variables were compared using Mann-Whitney test; categorical variables were compared using Chi-square with Yates’ correction or Fisher’s exact test.

Medications resumed to treat flare were steroids (29 pregnancies), csDMARDs (14 pregnancies) and TNF-inhibitors (7 pregnancies: 5 during the 2nd and 2 during the 3rd trimester).

A post-partum flare was registered in 33/83 (40%) of cases, without difference between ‘flare’ group vs ‘without flare’ group (Table 1), as well as between PsA vs ‘other’SpA pregnancies (47% vs 33%, p=0.2).

Conclusion: In this cohort of SpA pregnancies, 40% experienced a flare during pregnancy and 40% during post-partum. Flares occurred more frequently in the 2nd trimester and especially in patients with axial involvement, requiring the start of a TNF-inhibitor during the 2nd or the 3rd trimester in 7 pregnancies. Having a flare during pregnancy was not associated with a post-partum flare.

**Conclusion:** TNFi are effective at improving BASMI in patients with axSpA, in a real-life setting. This effect is mainly explained by the reduction in disease activity. However, a direct effect of TNFi on BASMI could also be demonstrated, when disease activity was measured by BASDAI, suggesting that ASDAS captures additional factors that can influence spinal mobility. These potential factors deserve further investigation, but they could for example include biomechanical properties of tendons and myofascial tissue.

Lambert10,11 on behalf of ASAS MRI Imagine, 1University of Alberta, Medicine, Edmonton, Canada; 2Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; 3Rheumazentrum Ruhrgebiet Heme, Rheumatology, Heme, Germany; 4University College London, Rheumatology, London, United Kingdom; 5Practice Buchsbaum, Rheumatology, Schaffhausen, Switzerland; 6Sheba Medical Center, Radiology, Tel Aviv, Israel; 7University Hospital Gent, Rheumatology, Ghent, Belgium; 8Charité – Universitätsmedizin, Rheumatology, Berlin, Germany; 9Klinikum Bielefeld, Rheumatology, Bielefeld, Germany; 10Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 11Amsterdam University Medical Centers; Amsterdam Rheumatology & Clinical Immunology Center, Amsterdam, Netherlands; 12Zuyderland MC, Rheumatology, Heeren, Netherlands; 13University of Alberta, Radiology, Edmonton, Canada

**Background:** There are limited data as to the frequency of spinal lesions on MRI in patients without MRI or radiographic features typical of sacroiliac joint (SIJ) disease and to what degree spine MRI might enhance diagnostic evaluation.

**Objectives:** To assess the frequency of MRI lesions of the spine in the ASAS-Classification Cohort according to the presence of MRI SIJ lesions typical of axSpA and/or radiographic sacroiliitis (mNY+).

**Methods:** MRI spine lesions were recorded by ≥9 readers in an eCRF that captures global assessment of the spine ("Is the MRI consistent with axSpA yes/no") (yes=MRI global spine+ and detailed anatomical-based scoring of each discovertebral unit plus lateral and posterior structures. Independently, readers globally assessed SIJ scans for active and/or structural lesions typical of axSpA. We compared the frequency of MRIglobal spine+ and frequencies of different types of spinal lesions according to the presence/absence of axSpA on global evaluation of SIJ scans by ≥5 of 9 readers (MRIglobal SIJ+ and mNY+ sacroiliitis using Fisher’s exact test. Analysis was also stratified by rheumatologist diagnosis.

**Results:** Among 51 cases with SIJ as well as spine MRI, we recorded 108 MRI global SIJ+ and 12 (23.5%) and 7 (13.7%) had MRI global spine+ by ≥2 and ≥5 reader agreement, respectively. MRI global spine+ occurred significantly more frequently in the presence of mNY+ sacroiliitis and MRIglobal SIJ but was also recorded in 4 of 32 (12.5%) (≥2 readers) and 1 of 32 (3.4%) (≥5 readers) cases that were MRI global spine- and x-ray negative, all 4 cases being diagnosed with axSpA. Moreover, vertebral corner BME lesions, but not spinal structural lesions, were significantly more frequent in MRIglobal SIJ+ cases that had been clinically diagnosed as axSpA versus non-axSpA (Table 1).

**Conclusion:** Spinal lesions on MRI indicative of axSpA per majority read occurred in about 3% of patients without positive imaging in the SIJ. Frequency of spinal BME lesions was higher in cases with negative SIJ imaging but clinically diagnosed with axSpA.

**INFLAMMATION IS ASSOCIATED WITH INCIDENT HYPERTENSION IN PATIENTS WITH AXIAL SPONDYLOARTHROPATHIES: A LONG-TERM FOLLOW-UP STUDY**

J. L. H. Shi1, S. H. M. Lam2, H. So3, E. Li4, T. K. Li5, C. C. Szeto2, L. S. Tam2,1

1The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China; 2The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, Hong Kong (SAR)

**Background:** Axial spondyloarthritis (axSpA) patients have increased risks of developing cardiovascular diseases (CVD) compared to the general population. Hypertension (HT) as the most common CV risk factor in these patients. Whether chronic, low-grade inflammation predispose to the development of incident hypertension in axSpA remained uncertain.

**Objectives:** To examine the association between markers of systemic inflammation and incident hypertension in axSpA patients.

**Methods:** A cohort analysis was performed in patients with axSpA who had been followed since January 2001. Patients diagnosed with hypertension and/or on anti-hypertensives at baseline were excluded. The primary outcome was first diagnosis of HT occurring between January 2001 and December 2020. Three different CVD risk scores including Framingham risk score (FRS), QRISK3 and SCORE were computed at baseline. Baseline demographic data and clinical inflammatory markers, medications, and the occurrence of incident HT was assessed using time-varying Cox proportional hazard models after adjusting for baseline CVD risk scores.
Results: 413 patients [34(25-43) years, male: 319 (77.2%)] were recruited. After a median follow up of 12 (6-17) years, 58 patients (14%) developed incident HT (IHT-group). In baseline multivariable Cox regression analysis, ESR and CV risk scores were significantly associated with developing IHT (p<0.05) (Table 1). Using time-varying multivariate analysis, higher inflammatory burden (ESR≥20) was significantly associated with developing HT after adjusting for FRS and SCORE respectively. Use of csDMARDs was significantly linked to develop IHT after adjusting for baseline FRS, while a trend suggesting that csDMARDs was associated with an increased risk of HT after adjusting for baseline SCORE was observed (Table 2).

Conclusion: Higher baseline and time-varying inflammatory burden predict the development of IHT in addition to traditional CV risk scores in axSpA patients. While exposure to csDMARDs may be associated with the development of IHT, NSAIDs and biologic DMARDs use were not associated with the development of IHT.

DASH-Dietary Approaches to Stop Hypertension; *p=0.52, **p=0.83*.

Among men, CKD was the largest mediator (46%), followed by poor diet (20%) and diuretic use (14%). BMI (12%) and poverty (0.5%) mediated smaller proportions of the racial difference among men compared to women. Mediators of racial differences in hyperuricemia closely agreed with gout results.

*recommended in all senescent IMID patients with IBD and patients at risk for other IMIDs.

Conclusion: The implementation of a vaccination tool integrated in the EMR coincided with a significant increase in vaccination rates and also in the total amount of IMID patients that were fully vaccinated according to guidelines. Quite likely, the suboptimal vaccination rate measured in 2018 and the COVID-19 pandemic also raised awareness among patients and healthcare professionals about the importance of following vaccination guidelines.

POS0158 ADHERENCE TO TELEMONITORING DISEASE ACTIVITY BY ELECTRONIC PATIENT REPORTED OUTCOMES IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A PROSPECTIVE COHORT STUDY

1Amsterdam Rheumatology & Immunology Center, Reade, Rheumatology, Amsterdam, Netherlands; 2Amsterdam UMC Location VUMc, Department of Epidemiology & Data Science, Amsterdam, Netherlands

Background: The use of electronic patient reported outcome measures (ePROMs) enables telemonitoring disease activity in patients with inflammatory arthritis in between consultations. However, recent telemonitoring studies report declining long-term adherence to reporting ePROMs1-7. What factors are associated with a decline in adherence is not known.

Objectives: To investigate the factors that are associated with adherence to telemonitoring by an ePROM in patients with inflammatory arthritis.

Methods: We performed a prospective cohort study in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) at Reade Amsterdam, The Netherlands. Patients telemonitored their disease activity weekly for 6 months with a modified Multidimensional Health Assessment Questionnaire including the Routine Assessment of Patient Index Data 3 (RAPID3) that was completed in the "MijnReuma" Reade smartphone application. Adherence was defined as the percentage of weeks completed with ePROM and time to dropout as 4 weeks nonscoring. Based on literature and through expert meetings, 13 baseline factors were selected to assess their association with dropout through multivariable Cox-regression analysis. The association with the system usability score (measured at 3 months, 1-100) was analyzed with a linear regression for patients who dropped out in month 1, month 2-3 and month 4-6.

Results: A total of 220 consecutive patients was included (mean age 54, 55% females, median disease duration 9 years), of which 99 had RA, 81 PsA, and 40 AS. Adherence to telemonitoring declined from 81% (week 1) to 39% (week 26). Median time to dropout was 17 weeks; a total of 141 patients (64%) stopped
telemonitoring their disease activity. Women had a higher chance to dropout over time compared to men (HR 1.6, p=0.02). The reported usability of the app was higher for patients who were adherent throughout the study (82%) compared to patients who dropped out in the 1st month (68%; p<0.001), 2nd-3rd month (71, p=0.001) and 4th-6th month (78, p=0.18).

**Conclusion:** Women stopped reporting the ePROM sooner than man and the usability score of the app differed between the adherence and drop-out group. Future research is needed to investigate if the association between the usability score of the app and adherence is causal, and thus if improvements in the usability will lead to lower dropouts. Furthermore, we will perform focus group discussions to identify why women tend to dropout sooner, since this is in contrary to previous research.

**SEX-RELATED DISPARITIES IN HEALTHCARE UTILIZATION IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A POPULATION-BASED STUDY**

S. Taranum1, 2, J. Widdiffe3, 4, F. Wu3, S. Johnson3, 6, P. Rochon3, L. Eder1, 2, 5

1Women’s College Hospital, Women’s College Research Institute, Toronto, Canada; 2University of Toronto, Medicine, Toronto, Canada; 3Sunnybrook Research Institute, Health Sciences Research, Toronto, Canada; 4ICES, Statistics, Toronto, Canada; 5Toronto Western Hospital, Rheumatology, Toronto, Canada; 6Mount Sinai Hospital, Rheumatology, Toronto, Canada

**Background:** Delayed diagnosis of inflammatory arthritis (IA) such as rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) is associated with joint damage and disability. So regular timely assessment by both family physicians and specialists is necessary for favorable disease outcomes. Sex (biology) and gender (socio-cultural) related factors influence clinical patterns of IA, patient behavior and their interaction with care providers. This influence could be reflected in patterns of healthcare utilization.

**Objectives:** To compare patterns of musculoskeletal (MSK)-related healthcare utilization before and after diagnosis between male and female patients with IA in Ontario, Canada.

**Methods:** We assembled 3 inception cohorts of adult RA, AS and PsA patients diagnosed between April 2010 and March 2017 using Ontario health administrative data. MSK-related healthcare utilization patterns in terms of visits to physicians, MSK imaging and laboratory tests were assessed yearly for 3 years before and after the diagnosis date, and compared between male and female patients. Among individuals ≥ 66 years, prescriptions for rheumatic drugs (NSAIDs, corticosteroids, csDMARDs, advanced therapy (bDMARDs and tsDMARDs)) and opioids were ascertained. Regression models were used to compare healthcare utilization indicators between males and females after adjusting for demographics and comorbidities.

**Results:** A total of 41,277 patients with RA (69% females), 8,150 patients with AS (51% females) and 6,446 patients with PsA (54% female) were analyzed. Male patients were significantly older than female patients only in the RA cohort (mean age M 60.4 y, F 57.1 y). Multimorbidity, depression and osteoporosis were more common in female patients and cardiovascular disease in male patients across the 3 cohorts.

Similar trends of sex-related differences were observed in all three cohorts. Female patients were more likely to visit rheumatologists and family physicians than male patients especially in earlier pre-diagnosis periods (Figure 1). Male patients were more likely to visit emergency department immediately before diagnosis. A similar female predominance was observed in imaging modalities of X-rays and ultrasounds (adjusted ORs for F:M 1.15 - 1.25 for X-rays and 1.07 - 1.44 for ultrasounds), and laboratory tests before diagnosis (adjusted ORs for F:M 1.10 to 2.17 across the three cohorts).

Overall DMARD prescription patterns in older male and female patients were similar across the three cohorts except more csDMARD prescriptions in female AS patients (Table 1). Female RA patients were more likely to use NSAIDs and opioids.

**Table 1. Odds ratios for prescription patterns in inflammatory arthritis for older female to male patients after diagnosis**

Bolded results are statistically significant (p < 0.05). Odds ratios for female to male patients adjusted for age, residence, income quintiles, comorbidities and access to rheumatologists.

**Conclusion:** Female patients with IA have higher MSK-related healthcare utilization which may indicate biological differences in disease course or sociocultural differences in healthcare seeking behavior between male and female patients.

**POS0160** THE EMPLOYMENT GAP IN PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES COMPARED WITH THE GENERAL POPULATION: A SYSTEMATIC LITERATURE REVIEW

S. Verstappen1, A. Boonen2, N. Goodson3, C. Webens3, M. Butink2, N. Betteridge4, T. Stamm5, D. Wiek6, A. Woolf7, H. Bijlsma8, G. R. Burmester9 on behalf of the EULAR Task Force on Work. 1The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; 2Maastricht University Medical Center, Department of Internal Medicine, Maastricht, Netherlands; 3Liverpool University NHS Foundation Trust, Department of Rheumatology, Liverpool, United Kingdom; 4Neil Betteridge Associates, N/A, London, United Kingdom; 5Section for Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Medical University of Vienna, Vienna, Austria; 6Patient Research Partner, People with Arthritis and Rheumatism (PARE) - EULAR, N/A, N/A, Germany; 7Bone and Joint Research Group, Royal Cornwall Hospital, Turo, United Kingdom; 8University Medical Center Utrecht, Dept of Rheumatology & Clinical Immunology, Utrecht, Netherlands; 9Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany

Background: Many people with rheumatic and musculoskeletal diseases (RMDs) experience problems at work and some may even have to stop working due to ill health. In most countries, RMDs are a major cause of worker productivity loss. The peak age of onset of many adult onset RMDs is between ~30-50 years, meaning that the majority of patients are still in employment when diagnosed with their chronic disease. Uncertainty about employment prospects and job attainment is also a major concern for young adults with juvenile idiopathic arthritis (JIA) for whom their first job may influence their future employment prospects. From both a societal and patient perspective it is important to gain an understanding about the impact of juvenile and adult onset RMDs on work outcomes.

Methods: A systematic literature review (SLR) was conducted to compare work outcomes in people with various RMDs (i.e. JIA, RA, PsA, AxSpA, SSc, SLE, gout, FM, and OA) with the general population or healthy controls as part of the EULAR Task Force on work. A search for eligible observational studies was performed in Medline, Embase and PsycInfo between 2000 and May 2021. Work outcomes were categorized according to employment status, work disability/ stopped working due to ill health, absenteeism, presenteeism and other.

Results: 541 abstracts were extracted and screened for eligibility. Results of 65 studies fulfilling the inclusion criteria were evaluated for this study, including 28 prospective/retrospective longitudinal cohort studies, 34 cross-sectional studies and 3 (nested) case-control studies. The majority of the studies were conducted in Europe (63.1%), Germany (26.2%) followed by OA (15.4%), SLE (15.4%), AxSpA (12.3%), FM (9.2%), mixed population (7.7%), JIA (7.7%), PsA (3.1%), SSc (1.5%), and gout (1.5%). In papers reporting disease duration (n=38), the majority of the study population had established disease (76.3%). Several work outcomes were evaluated with some papers reporting more than one work outcome: employment/work status (41.5%), unemployment (9.2%), work disability/pension or stopping work due to ill health (38.5%), absenteeism (22.0%), presenteeism (10.8%), and other (e.g. reduced working hours) (29.2%). Fifty-two papers applied statistical tests (e.g. indirect standardisation, logistic regression analysis, Cox regression analysis) to compare work outcomes in people with RMDs with a control/general population. The percentage of papers reporting the work outcome to be worse, not significantly different or better in the RMD population compared to the control population (n papers included per work outcome; %) was, respectively: employment/work status (n=26; 73.1%, 23.0%, 3.8%), unemployment (n=6; 66.7%, 33.3%, 0%), work disability/stopping work (n=22; 90.3%, 9.4%, 0%), absenteeism (n=26; 92.3%, 7.7%, 0%), presenteeism (n=8; 67.5%, 12.2%, 0%), other (n=19; 84.2%, 15.8%, 0%).

Conclusions: Despite better disease management during the last two decades there is still a significant employment gap between people with RMDs and the general population. It is therefore essential that health professional organisations, policy makers, patient organisations and employers should collaborate to minimize the employment gap and optimize employment opportunities among people with juvenile and adult onset RMDs.

**POS0161** WORK STATUS IN PATIENTS WITH INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASES: RESULTS OF A BELGIAN COMPARATIVE STUDY

A. S. De Craemer1,2,3 I. Desimpele2,3 L. Delmeze2,3, L. Deroo1,2,3, T. Renson1,2,3, S. De Mitsu2,3, V. Smith1,2,3, P. Jacques1,2,3, D. Elewaut1,2,3, P. Carron1,2,3, F. Van den Bosch1,2,3, Ghent University Hospital, Rheumatology, Ghent, Belgium; 2Ghent University, Internal Medicine and Pediatrics, Ghent, Belgium; 3VIB-UGent, Center for Inflammation Research, Ghent, Belgium

Background: Inflammatory Rheumatic Musculoskeletal Diseases (RMD) constitute a heterogeneous group of chronic disorders with a potential major individual and socio-economic burden. RMD patients often report work-related difficulties (e.g. productivity loss, sick leave, work disability) which contribute significantly to indirect costs and may lead to additional premiums or exclusion when contracting private insurances. However, work-related epidemiological data in Belgium date back to a pre-biologics era, albeit that diagnosis, management and treatment strategies have dramatically improved in the last decade.

Objectives: To investigate actual work participation status of inflammatory RMD patients in Belgium, and to benchmark these data to the general Flemish population.

Methods: During an outpatient visit at the rheumatology clinic of Ghent University Hospital, a tertiary hospital in the Flemish region, adult patients with spondyloarthritides (SpA), rheumatoid arthritis (RA), and systemic sclerosis (SSc) were questioned on their socio-economic status. Employment rate, weekly working hours and work disability were evaluated among a representative sample of all RMD patients. In 2018 national Health Interview Survey.

Results: Among the 483 patients, 262/275 (95%) SpA, 83/102 (62%) RA, and 83/106 (78%) SSc were at a work-productive age (<65 y/o). Table 1 summarises socio-demographic and clinical characteristics.

† HLA B27 (SpA), RF/ACPA (RA), SSc-related auto-antibodies (SSc); †† ASDAS-CRP (SpA), DAS28 (RA), mRSS (SSc). *Disease duration from first non-Rayneud phenomenon in SSc. **BASFI (SpA), Michigan Hand Outcomes Questionnaire (RA).
Crude employment rates were 82% in SpA, 56% in RA and 63% in SSc. Age- and sex-adjusted employment rates (indirect standardization) were respectively 75%, 68%, and 66%, corresponding to a standardized employment ratio of 1.00 (95% CI 0.87 – 1.14) for SpA, 0.89 (0.64 – 1.24) for RA, and 0.88 (0.67 – 1.15) for SSc.

SpA patients worked 39.5±10.9h/week, compared to 40.9±16.9h in RA and 33.0±12.4h in SSc (p=0.003). Flemish employees worked on average 39.7h (full-time) and 25.7h (part-time) per week.

In the working population, 48% of SpA patients, 53% RA and 78% SSc reported sick leave in the previous year, compared to 42% in Flanders. Long-term work disability was reported by respectively 10%, 17% and 20% of patients (p=0.03) compared to 9% in the reference population.

The median retention time on the labour market was not significantly different between SpA (42.1 years), RA (42.1 years) and SSc (41.2 years) (p=0.94, Figure 1).

Figure 1. retention time on the labour market since start of patient’s professional career.

Conclusion: Our data refute the common perception that patients with RMDs, especially inflammatory joint diseases, have significantly worse work outcomes compared to the general population. In an era of early diagnosis and treatment, more recent datasets could be used to realistically estimate the odds of these important health economic outcomes.

POS0162 HOW ACCURATELY CAN WE IDENTIFY RHEUMATOID ARTHRITIS BY ICD-10 CODES? A LINKAGE OF CROSS-SECTIONAL SURVEY DATA WITH CLAIMS DATA

J. Calhoff1,2, K. Albrecht1, U. Marschall3, F. Hoffmann4. 1German Rheumatism Research Centre, Epidemiology and Health Services Research, Berlin,.; 2Charité – Universitätsmedizin Berlin, Institute for Social Medicine, Epidemiology and Health Economics, Berlin, Germany; 3BARMER Institute for Health System Research, , Wuppertal, Germany; 4Universität Oldenburg, Health Services Research, Oldenburg, Germany

Background: Claims data from health insurance companies are a valuable source in health services research to provide insights on health care provision for an unsampled patient collective. However, the available ICD-10 diagnoses have been collected for billing purposes and their validity is not clear.

Objectives: The aim of this analysis was to assess the positive predictive values (PPV) of a ICD-10 diagnosis of rheumatoid arthritis (RA) and additional criteria (specific medication, measurement of inflammatory markers, contact to a rheumatologist) in German claims data using patient-reported confirmed diagnosis as reference/gold standard.

Methods: Within the PROCLAIM project (Linking Patient-Reported Outcomes with CLAims data for health services research In Rheumatology), data from a large German statutory health insurance with 6.6 million persons aged 18 to 79 were used. We identified a random sample of persons for which an ICD-10 code for RA (M05/M06) was available in at least two quarters in outpatient care. The sample was stratified for age (18 to 49, 50 to 64, 65 to 79 years), sex and to reference value for healthy people. The number of steps per day and the time spent in MVPA were collected. Univariable meta-regression models have been computed to assess the possibility that the study characteristics may act as effect modifiers on the final meta-analysis estimate. The primary outcome is the level of physical activity evaluated with a wearable device as a number of daily steps and MVPA. The secondary outcome is the comparison of both a number of steps and MVPA to reference value for healthy people. The number of steps per day and the time spent in MVPA considered as a mean or median were collected. Missing information was calculated from available data when possible.

The reference value for steps was 7000 steps per day, this value was derived by WHO guidelines [2]. MVPA reference value was of 150 min/week and was derived by WHO guidelines [3].

Conclusion: The ICD-10 codes M05 and (less optimal) M06 have high PPVs and are therefore feasible to identify RA in claims data. The prerequisite of specific medication seems to be the most useful one in identifying RA.

POS0163 USEFULNESS OF WEARABLE DEVICES TO ASSESS PHYSICAL ACTIVITY IN NON-INFLAMMATORY AND INFLAMMATORY RHEUMATIC DISEASES: A SYSTEMATIC REVIEW AND META-ANALYSIS

H. Ogazi1, R. Agarinis2, D. Azzolina1, F. Todino1, M. Binutti2, A. Zabotti2, D. Gregori1, L. Quartuccio1. 1Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiac, Thoracic, Vascular Sciences, and Public Health, University of Padova, Padua, Italy; 2Division of Rheumatology, Department of Medicine, Udine, Italy

Background: In the last years, the rise of personalized medicine has grown up. So, patient-oriented wearable technologies have been developed. Wearable devices (WD) are useful to collect objective data related to physical activity. In the management of rheumatic musculoskeletal disorders (RMDs) a regular physical activity is an important recognized non-pharmacological intervention [1].

Objectives: This systematic review aims at evaluating how the use of WDs impacts physical activity in patients with non-inflammatory and inflammatory rheumatic diseases.

Methods: A systematic review and meta-analysis were performed. A comprehensive search of articles was performed in the following databases: MEDLINE via PubMed, EMBASE, CINAHL, and Scopus. A random-effect meta-analysis has been carried out on the number of steps and moderate to vigorous physical activity (MVPA). Univariable meta-regression models have been computed to assess the possibility that the study characteristics may act as effect modifiers on the final meta-analysis estimate. The primary outcome is the level of physical activity evaluated with a wearable device as a number of daily steps and MVPA. The secondary outcome is the comparison of both a number of steps and MVPA to reference value for healthy people. The number of steps per day and the time spent in MVPA considered as a mean or median were collected. Missing information was calculated from available data when possible.

The reference value for steps was 7000 steps per day, this value was derived by a literature review commissioned by the Public Health Agency of Canada on the number of steps/day suitable for adults [2]. MVPA reference value was of 150 min/week and was derived by WHO guidelines [3].
Results: An overall of 1788 studies was considered in the title/abstract screening. In the analysis, 51 articles were included, with an overall of 7488 participants. Twenty-two studies considered MVPA outcome alone, 16 studies number of steps alone and 13 studies reported information on both outcomes. The results of this meta-analysis show that there is a high level of heterogeneity, 99%, according to dia gnosis. Recommended threshold for daily steps was reached for MVPA (36.35, 95% CI 29.39-43.31) but not for daily steps (>1092.60, 95% CI 1640.42-534.77), with fibromyalgia reporting a higher number (6290, 95% CI 5109.85-7381,62) of daily steps compared to other RMDs. Patients affected by chronic inflammatory arthritis seem to fare better in terms of daily steps than the other categories. Patients with rheumatoid or other chronic arthritis reported a higher number of steps, respectively 6361 (95% CI 5382.51; 7430.35) and 6290.14 (95% CI 5198.65; 7381.62).

Non-elderly people showed a higher overall level of physical activity compared to the elderly, 6796.11 (95% CI 5974.12; 7618.13) versus 5431.85 (95% CI 4633.76; 6229.95). Non-elderly group show higher level of physical activity than the elderly, 6796.11 (95% CI 5974.12; 7618.13) versus 5431.85 (95% CI 4633.76; 6229.95). Non-elderly group show higher level of physical activity than the elderly, 6796.11 (95% CI 5974.12; 7618.13) versus 5431.85 (95% CI 4633.76; 6229.95).

Results: 2015) and benign, or likely benign, classified variants were removed. Filters were then applied to remove variants with an allele frequency >1% (based on gnomAD), depth <30 and genotype quality <80 were removed. Rarity and pathogenicity scores and manual inspection on IGV, a candidate list of 25 genes remained. The number of variants in >=2 CNO genes with variants in ≥2 CNO genes were found.

Conclusion: RMDs suffer of low level of physical activity and WUDs are useful and affordable instruments to support the increase of WUDs. Can be used in daily monitoring of physical activity in RMDs.

POS0165 WHOLE EXOME SEQUENCING TO IDENTIFY RARE INFLAMMATORY VARIANTS IN AN IRISH COHORT WITH CHRONIC NONBACTERIAL OSTEOMYELITIS (CNO)

D. O’Leary1,2, O. Killeen1,2, A. G. Wilson1, 1UCD, Centre for Arthritis Research, Dublin, Ireland; 2Children’s Health Ireland, National Centre for Paediatric Rheumatology, Dublin, Ireland

Background: Chronic nonbacterial osteomyelitis (CNO) is a rare inflammatory disease affecting bone which predominantly occurs in the paediatric population. It is frequently associated with pustulosis, psoriasis, inflammatory bowel disease and arthritis, in particular enthesitis-related arthritis. Activation of the NLRP3 inflammasome has been implicated in both human and mouse models of the disease.

Objectives: To identify a candidate list of rare, deleterious variants in known inflammatory genes in an Irish cohort with CNO.

Methods: 41 unrelated Irish children with CNO were recruited. Whole exome sequencing was performed on blood using Agilent SureSelect XT Human All Exon V6 kits and Illumina HiSeq 3000 with 150bp paired-end reads. Reads were aligned to the hg19 reference genome. After preprocessing, variants were hard filtered using quality by depth (QD) > 2.0, read depth (DP) >10 and genotype quality (GQ) >30. Synonymous variants and variants with MAF > 0.01 were excluded from further analysis. Remaining variants were filtered against existing databases of genes known to be associated with inborn errors of immunity, autoimmunity or autoinflammation. The Gene Damage Index (GDI) was used to identify genes which are least tolerant to variance and CADD phred-like scores to identify variants predicted to be deleterious. Genes with variants in >2 CNO patients were included in the candidate list and variants manually checked using the Integrative Genomics Viewer (IGV).

Results: After filtering low-quality, synonymous and common variants, 17293 variants were filtered against a database of 581 known inflammatory genes. 350 rare variants in 201 genes predicted to be intolerant to variance were identified. After excluding those present in one individual only, ranking by CADD phred-like scores and manual inspection on IGV, a candidate list of 25 genes remained. The same variant in IL17RA, NLRP1 and KMT2D was present in 3 unrelated individuals (Table 1). IL17RA belongs to the Th17 pathway which is involved in psoriasis pathogenesis. NLRP1 is implicated in several autoinflammatory diseases including psoriasis. Rare variants identified in these genes are most likely to be disease-causing. All the individuals carrying these variants in IL17RA or NLRP1 have psoriasis. One individual with IL17RA variant has 1°-degree family history of psoriasis. Rare variants predicted to be deleterious were found in two individuals in each of the following genes in the IL-17 signalling/Th17 differentiation pathway: IL17RB, IL17RE, IL25, HIF1A (Table 1). This suggests that the Th17 pathway may play a role in disease pathogenesis in a proportion of children with CNO.

Conclusion: IL17 +/- in the IL-17 signalling/Th17 differentiation pathways, and NLRP1 provide targets for further investigation in CNO. The role of these candidate genes may be further elucidated through gene-pathway-based burden analysis against a matched control population.

POS0166 POLYARTICULAR JIA HAS A DISTINCT CO-INHIBITOR RECEPTOR PROFILE AMONG OTHER JIA SUBTYPES

E. Sanı1,2, Z. Balık3, S. Sener1, U. Kaya Akca1, S. Demir1, M. Kasap-Cuceoglu1, E. Atalay1, S. Boccutu1, T. Vural1, Y. Bilginer1, B. Deleuran3,4, S. Özen1,2. 1Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey; 2Hacettepe University, Pediatric Rheumatology Unit, Translational Medicine Laboratories, Ankara, Turkey; 3Aarhus University, Institute of Biomedicine, Aarhus, Denmark; 4Aarhus University Hospital, Department of Rheumatology, Ankara, Denmark

Background: Juvenile idiopathic arthritis (JIA) is the most common inflammatory joint disease in children, driven by continuous T-cell activation.[1] T cell activation is counter-balanced by signals generated by co-inhibitory receptors (co-IRs) such CTLA-4, PD-1, LAG-3, and TIM-3.[2]

Objectives: We aimed to identify the role of co-IRs in the pathogenesis of different subtypes of JIA.

Methods: In total, we included 107 patients with oligoarticular JIA (n=67), polyarticular JIA (n=12), enthesitis related arthritis (n=17), systemic JIA (n=11) and healthy controls (HC, n=10). We collected plasma samples from the patients during the active phase of their disease. We measured the soluble plasma levels of co-IRs by commercial pre-defined cytokometric bead array kits and their cellular expression by flow cytometry in blood mononuclear cells. We compared the plasma levels and cellular expressions of different co-IRs within different JIA subgroups.

Results: IL-2 levels were lower than HC in all JIA subgroups. The polyarticular JIA group distinguished from the four different JIA subgroups, having different co-IR pattern. In this specific subgroup, CTLA4, PD-1 and 4-1BB levels were higher than other groups. Polyarticular JIA is the more chronic and severe form of JIA, especially when compared to oligoarticular JIA. (Figure 1).

Conclusion: This is the first report studying the effects of different co-IRs in different subtypes of JIA. Polyarticular JIA patients had a different co-IR profile, having more CTLA-4, PD-1 and 4-1BB in their plasma than the other subtypes of JIA.

POS0167 A PROTEOGENOMIC MAP OF NATURAL KILLER CELLS IN OLIGOARTICULAR JUVENILE IDIOPATHIC ARTHRITIS

O. Kniichtet1,2, G. Guerra3, M. F. Mashreghi4, T. Kallinich5,6, T. Rückerl1, C. Romagnani1,2. 1Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Innate Immunity, Berlin, Germany; 2Charité - Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Gastroenterology, Berlin, Germany; 3Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Therapeutic Gene Regulation, Berlin, Germany; 4Charité Universitätsmedizin Berlin, BIH Center for Regenerative Therapies (BCRT), Berlin, Germany; 5Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Chronic inflammation in Childhood, Berlin, Germany; 6Charité Universitätsmedizin Berlin, Department of Pediatric Respiratory Medicine, Immunology and Critical Care Medicine, Berlin, Germany

Background: Natural Killer (NK) cells are innate lymphocytes which are specialised for recognising stressed cells, classically divided into cytotoxic (CD56dim) and cytokine-producing (CD56bright) populations. During oligoarticular Juvenile Idiopathic Arthritis (oligo-JIA), an unknown trigger induces the recruitment of peripheral immune cells into synovial joints, which in turn creates a chronic inflammatory environment. This can result in joint contractures and extraarticular complications, highlighting the requirement for early disease intervention. The contribution of NK cells toward immunopathology during the early stages of disease and in subsequent arthritic flares is unknown, providing a potential avenue for understanding disease course and therapeutic intervention.

Objectives: We aimed to assess the contribution of NK cells to the early pathogenesis of oligo-JIA by identifying inflammatory signatures present in patient synovia, and which signals could induce them.

Methods: Peripheral blood (PB) and synovial fluid (SF) were drawn from 4 patients at the first clinical presentation of oligo-JIA. Flow-cytometry Activated Cell-Sorting (FACS) was used to unbiasedly isolate NK cells (CD3-CD7+), and single cell RNA-sequencing (scRNA-Seq) paired with

The overall mean difference is the measurement of the first location minus the measurement from the second location (e.g. centre minus contralateral), averaged across the four visits.

Conclusion: Our results suggest non-invasive imaging can detect differences between healthy & unaffected skin in JLS. Whether each technique is only measuring activity & not damage requires further evaluation. The leading edge of lesions has historically been considered as most active compared to the centre. However, no difference was seen between centre & inner edge measurements suggesting that in future studies, imaging protocols can be simplified.

**POS0168 NON-INVASIVE IMAGING IN JUVENILE LOCALISED SCLERODERMA: HIGH-FREQUENCY ULTRASOUND, THERMOGRAPHY, LASER DOPPLER & MULTISPECTRAL IMAGING**

C. Pain, A. Murray, G. Dinsdale, A. Manders, J. Manning, A. Herrick. Alder Hey Children’s Hospital NHS Foundation Trust, Paediatric Rheumatology, Liverpool, United Kingdom; University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom; Salford Royal NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; University of Manchester, Division of Population Health, Health Services Research and Primary Care, Manchester, United Kingdom; Salford Royal NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom

**Background:** Outcome measures which can differentiate activity (inflammation) from damage (fibrosis/atrophy) would facilitate development of new treatment strategies in juvenile localized scleroderma (JLS) to target the inflammatory phase of the disease.

**Objectives:** To evaluate whether in JLS, non-invasive imaging modalities (high frequency ultrasounds (HFUS), multispectral imaging (MSI), laser doppler imaging (LDI) & infra-red thermography (IRT)) can detect differences between affected & non-affected skin, as a next step in developing these as outcome measures. Our hypothesis was that blood flow (and therefore temperature & oxygenation) would be increased in lesional skin.

**Methods:** Participants aged 4-17 were recruited from 3 paediatric rheumatology centres in the UK. For each participant, a single lesion was selected. HFUS (30MHz), MSI (bespoke camera and tuneable liquid crystal filter, coupled to custom analysis software, 500nm/710nm wavelengths), LDI and IRT imaging were performed at four sites relating to each location: two of affected skin (centre & inner edge of lesion) and two of non-affected skin (one cm from edge of lesion (‘outer’) & contralateral unaffected side). Imaging was performed at 4 visits at 3 monthly intervals. Mean values were compared between the four sites using data from all visits by mixed-effects linear regression to account for individual and repeated clustering.

**Results:** 24 participants completed all 4 visits and 1 attended 3. 20 participants aged 4-17 were recruited from 3 paediatric rheumatology centres in the UK. For each participant, a single lesion was selected. HFUS (30MHz), MSI (bespoke camera and tuneable liquid crystal filter, coupled to custom analysis software, 500nm/710nm wavelengths), LDI and IRT imaging were performed at four sites relating to each location: two of affected skin (centre & inner edge of lesion) and two of non-affected skin (one cm from edge of lesion (‘outer’) & contralateral unaffected side). Imaging was performed at 4 visits at 3 monthly intervals. Mean values were compared between the four sites using data from all visits by mixed-effects linear regression to account for individual and repeated clustering.

**Conclusions:** Synovial NK cells possess a significantly different transcriptomic identity compared with those in the periphery. However, though they share a gene signature that is most comparable to blood CD56bright NK cells, it is not identical. Uniquely activated subpopulations also provide the first evidence of NK cell activation during oligo-JIA pathogenesis, suggesting that these cells could hold therapeutic potential.

**Background:** CLIPPER2 was an 8-year, open-label extension of the phase 3b, multicenter, 2-year CLIPPER study of the safety and efficacy of etanercept (ETN) in the treatment of patients (pts) with juvenile idiopathic arthritis (JIA) categorized as extended oligoarticular arthritis (eoJIA), enthesitis-related arthritis (ERA), or psoriatic arthritis (PsA).

**Objectives:** The objective of this analysis was to describe the safety of ETN in this population after 10 years of follow up.

**Methods:** Pts (n=127) with eoJIA (2-17 years), ERA, or PsA (each 12-17 years) who received ≥1 ETN dose (0.8 mg/kg once weekly [max, 50 mg]) in CLIPPER were eligible to enter CLIPPER2. The primary outcome measure was the occurrence of malignancy. Long-term safety was assessed as the total incidence of events from CLIPPER baseline (BL) to month (mth) 120, frequency of events per 100 patient-years (EP100PY), and frequency of events in each study year.

**Results:** A total of 109/127 (86%) pts entered CLIPPER2; 99 (78%) continued in the active treatment period. At mth 120, 84 (86%) pts had completed the study; 27 (21%) while actively taking ETN; 7 (6%) had withdrawn from treatment due to low/inactive disease; 5 (4%) had re-stated ETN following an earlier withdrawal from treatment; and 45 (35%) had stopped ETN (but remained under observation); 25 (20%) pts permanently discontinued from the CLIPPER2 study. In CLIPPER/CLIPPER2, 1 case of malignancy (Hodgkin’s disease) was reported (1 pt with eoJIA in Year 3). There was 1 case of uveitis (1 pt with eoJIA in Year 6) and 3 of Crohn’s disease (2 pts with ERA, Year 1/Year 6, 1 pt with eoJIA, Year 5). There were 2 cases of opportunistic infections (both herpes zoster), and no deaths. Overall, there were 559 (81.82 EP100PY) treatment-emergent adverse events
314 ﻿

Scientific Abstracts

(TEAEs) excluding infections and injection-site reactions (ISRs). The overall
rate of TE serious infections was low (N=14; 2.05 EP100PY) (Table 1), with the
most common TE serious infection being gastroenteritis (N=2; 0.29 EP100PY).
The most frequently reported TEAEs (N [EP100PY]) were headache (28 [4.10]),
arthralgia (24 [3.51]), pyrexia (21 [3.07]), diarrhea (14 [2.05]), and leukopenia
(12 [1.76]). Overall, 39 patients reported serious AEs (excluding infections/ISRs).
The number and frequency (N [EP100PY]) of TEAEs (excluding infections/ISRs)
decreased over the 10-year study period from 193 [173.81] in Year 1 to 9 [27.15]
in Year 10. The number and frequency of TE infections and TE serious infections
also decreased over the 10-year study period. There was no clear trend of a
decrease over time for the incidence of TE serious AEs (Figure 1).

Background: Although the risk for severe COVID-19 progression in children is
low, this may be aggravated by the underlying disease and/or immunosuppressive drugs.
Objectives: We analyzed clinical data of COVID-19 cases among paediatric
patients with rheumatic diseases reported to the BIKER registry.
Methods: The main task of the German BIKER (Biologics in Pediatric Rheumatology) registry is to monitor the safety of biologics therapies in JIA. After the
onset of the COVID-19 pandemic, the survey was expanded with a standardized form to proactively interview all participating centers about the occurrence,
presentation, and outcome of SARS-CoV-2- infections in children with rheumatic
diseases. Interviews were conducted with 68 centers initially weekly and later
biweekly.
Results: A total of 68 centres participated in the survey. Clinical data from
194 COVID-19 cases reported to the BIKER registry from 41 German and
1 Austrian pediatric rheumatology institutions between February 2020 and
December 2021 were analyzed. Juvenile idiopathic arthritis (JIA, n=144)
was the most common diagnosis followed by genetic autoinflammation
(n=18; i.e. FMF, TRAPS, CAPS, HIDS, DADA2), systemic autoimmune diseases (n=11; i.e. SLE, dermatomyositis, vasculitis) and 16 with other rheumatic diseases (i.e. CRMO, Uveitis). 5 patients with no rheumatic disease
were excluded. 104 (54%) patients were receiving conventional DMARDs,
81 (43%) received biologics, mainly TNF inhibitors (n=66 (35%)). Of
the 189 rheumatic patients with SARS-CoV2 infection, 123 (63%) were
female. The mean age was 12.4+/-4.4 years in females and 13.2+/-4.1
in males. The duration of SARS-Co2 infection associated symptoms was
13.8+/-15.3 days (max. 113 days), in 35 (43%) patients they lasted for
> 12 days. 46 (24%) were asymptomatic. Patients with autoinflammation
and systemic autoimmunopathies reported more symptoms such as fever,
head and throat ache. 4 patients only complained about dyspnea. Only
3 patients were hospitalized and received Oxygen-supplementation. The
only patients admitted to ICU, received ventilation but succumbed. This
3½-year-old patient, initially diagnosed with systemic JIA, developed fatal
disease with intracranial edema and respiratory failure, as well as typical
pulmonary texture changes. Prior to her SARS-CoV-2 infection, the patient
was treated with MTX and low-dose steroids. Genetic testing revealed a
so far unrecognized congenital immunodeficiency. In the total JIA cohort,
treatment with corticosteroids, conventional DMARDs, biologics or combinations did not influence the number of reported symptoms or the favorable outcome of the cohort. However, the duration of symptoms was lower
in the TNF-treated cohort (10.4+/-6.4 days vs. 15.7 +/- 19.7 days). In the
cohort with autoinflammation, fever was observed in 11 (61%). Those 6
who received IL-1-inhibitors did not show a different outcome than those
12 who did not. No case of PIMS/MISC in children with rheumatic diseases
was reported.
Conclusion: Except for one patient with congenital immunodeficiency who died
from her COVID-19 infection, no case of severe COVID-19 was reported in our
cohort. At the time of infection, over 80% of patients in our cohort had been
treated with conventional DMARDs and/or biologics. This did not appear to have
a negative impact on the severity or outcome of SARS-CoV2 infection. Interestingly, no case of PIMS/MISC was observed.

Within the first 3 months after diagnosis, the treatment pathways proposed by the ProKind Commission [1] were followed in about three-quarters of patients: i) 5 (13%) received MTX and intra-articular glucocorticoid injections in more than 4 joints (IAGC) or bDMARD; ii) 8 (21%) received MTX and HDGC (no bDMARD, no IAGC); iii) 16 (42%) patients received MTX up to or at the 3FU (bDMARD, no IAGC); iv) 8 (21%) received MTX and HDGC (no IAGC, no bDMARD); v) 4 (10%) patients received MTX and IAGC up to or at the 3FU (no HDGC, no bDMARD, no IAGC). Nine (24%) patients were not treated with MTX or did not fit any of these categories, mostly due to starting bDMARD therapy in conjunction with HDGC or IAGC.

Conclusion: In the routine care of JIA patients with polyarthritis, the proposed treatment protocol and treat-to-target strategy are followed in most patients. At 3FU, improvements of JADAS10 and other outcomes were evident, with 41% having achieved inactive or minimal active disease. ProKind is funded by the Innovation Fund “Gemeinsamer Bundesausschuss”, FKZ: 01VSF18031.

</table>
Background: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children (1). In adult patients there are significant differences between the clinical presentation of diffuse and limited subtypes (2). We reviewed clinical differences in presentation of subtypes in patients in the juvenile systemic scleroderma cohort study up to 2021.

Objectives: To study the clinical presentation of jSSc patients with diffuse (djSSc) and limited (ljSSc) subtypes.

Methods: We reviewed the clinical baseline characteristics of the patients, who were recruited to the juvenile scleroderma cohort study (jSScC) (3, 4) till 1st of December 2021. jSScC is a prospective cohort of jSSc patients who developed the first non-Raynaud’s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion.

Results: 210 patients with jSSc were included in the cohort, 71% (n=152) had diffuse subtype. The median age at onset of Raynaud phenomenon was 10.4 years (7.3 – 12.9) and the median age at the first non-Raynaud symptom was 10.9 years (7.4 – 11.2). Median disease duration was 2.5 years (1 – 4). The median age at onset was 10.9 years (7.4 – 13.2). Median disease duration was 2.5 years (1 – 4.4) at the time of inclusion. The female/male ratio was significantly lower in the ljSSc subtype (3.7:1 versus 5:1, p<0.001). Antibody profile was quite similar, with the exception of a significantly higher number of anticientromere positive patients in the ljSSc (12% versus 2%, p=0.013). Decreased FVC < 80% was found in 10.9% of patients with ljSSc and 2.8% in djSSc patients (p=0.013). Decreased joint range of motion (64% versus 46%, p=0.019). Patients with ljSSc had significantly higher rate of cardiac involvement (13% versus 2%, p=0.001). Regarding patients with diffuse subtype, patients with more severe diffuse Rodnan Skin Score (mRSS) (16 versus 4.5, p<0.001), sclerodactyly (84% versus 60%, p<0.001), history of digital ulceration (62% versus 31%, p<0.001), decreased Body Mass Index (BMI) < -2 z score (20% versus 4%, p=0.003) and decreased joint range of motion (64% versus 46%, p=0.019). Patients with ljSSc had significantly higher rate of cardiac involvement (13% versus 2%, p=0.001).

Conclusion: In this jSSc cohort, the largest in the world, djSSc patients have a significantly more severe disease than ljSSc patients. Interestingly, we found no differences regarding interstitial lung disease and pulmonary hypertension.

Background: For classification in juvenile spondyloarthritides (JSpA), it is important to develop cut-offs for active and structural lesions typical of axial disease on MRI. The radiological criteria are readily available for adults, but the interpretation of these criteria is challenging in children because the growing sacroiliac joint (SIJ) looks different from the adult SIJ. The criteria developed for positive MRI in adults may not be applicable in JSpA.

Objectives: As part of a study developing classification criteria for axial disease in JSpA, we aimed to determine quantitative SIJ imaging lesion cut-offs for inflammatory and structural lesions typical of axial JSpA using majority imaging expert decision as the reference criterion.

Methods: Subjects were a retrospective cohort of children with SpA who met the provisionial Pediatric Rheumatology International Trials Organization criteria for enthesitis/spondylitis-related juvenile idiopathic arthritid or had a rheumatologist JSpA diagnosis. All subjects had symptom onset prior to age 18 years and underwent MRI as part of a diagnostic evaluation for axial disease. To enable SIJ quadrant-based scoring, all MRIs included semi-coronal slices through the cartilaginous part of the joint on fluid sensitive sequences and on T1-weighted sequences for the assessment of inflammation and structural lesions, respectively. MRIs were reviewed by 6 musculoskeletal imaging experts who were blinded to clinical details. MRI evaluation of the SIJ was based on standardized lesion definitions that were decided by consensus of the central imaging team and represented a mix of definitions from ASAS and the Juvenile Arthritis MRI Score Outcome Measures in Rheumatology working group. Using a web-based interface, raters globally assessed the presence or absence of lesions typical of axial SpA and performed SIJ quadrant or joint based scoring. Lesion scores were generated by averaging the scores of all raters. Sensitivity and specificity of lesion cut-offs were calculated using raters’ majority (≥4/6 raters) as the reference standard.

Results: Imaging from 243 subjects, 61% male, median age 14.9 years, had sequences available for detailed MRI scoring. Active inflammatory lesion typical of axial disease in JSpA was defined as bone marrow edema (BME) in at least 3 quadrants of the SIJ. Cut-offs were calculated with a high confidence (sensitivity of ≥ 0.80 or specificity of ≥ 0.80) as the reference criterion.

Conclusion: We propose data-driven cut-offs for active inflammatory and structural lesions on MRI typical of axial disease in JSpA that have high specificity and sensitivity using central imaging global assessment as the reference standard.
New insights into the associations of outcomes and biomarkers in OA.

A COMPARISON OF ULTRASOUND-DETECTED PATHOLOGIES IN PERSONS WITH AND WITHOUT KNEE OSTEOARTHRITIS AND THE ASSOCIATIONS WITH PAIN

C. Dekkerhus1,2, A. Mathiessen3, F. Fjellstad1, B. Statwalksy-Christensen1, H. B. Hammer1, J. I. K. Haugen1,2, D. Kajnhrjemmet Hospital, Rheumatology, Oslo, Norway; 1University of Oslo, Faculty of Medicine, Oslo, Norway

Background: Ultrasound can evaluate osteophytes and synovitis in persons with knee OA. However, although the literature demonstrates a positive association between knee pain and synovitis, the instruments used to report pain, the number of patients included, the strengths of associations and the overall quality of the studies varies greatly (1).

Objectives: 1) To compare the degree of OA changes by ultrasound among people with and without clinical knee OA according to established classification criteria. 2) To study the associations between ultrasound findings and pain.

Methods: We included 286 of 300 participants from the NOR-HAND study, a hospital-based observational cohort after excluding participants with knee prosthesis or arthrodesis.

The participants reported the levels of knee/hip pain using the Western/Ontario McMaster University index (WOMAC) and marked their painful joints (including the bilateral knees) during the last 24 hours and last 6 weeks on two separate homunculi. An experienced rheumatologist (BS) examined whether the participants fulfilled the clinical ACR criteria for knee OA or not (n=7 missing).

A trained medical student performed the ultrasound examination of the knees using a General Electric (GE Logic E9 ultrasound machine with a 6-15Mz probe. Both knees were scored for 1) osteophytes in the medial and lateral tibia and femur on 0-3 semi-quantitative scales (0=no, 1-3 small, 2=medium, and 3=large), and 2) grey-scale synovitis on 0-3 semi-quantitative scales (Groen, 1=mild, 2=moderate, and 3=severe pathology). The highest score of osteophytes and grey-scale synovitis (range: 0-3) and the sum scores of both knees together (range: 0-24 for osteophytes and 0-6 for synovitis) were calculated.

We compared the degree of ultrasound pathologies in persons with vs. without clinical knee OA using Chi square tests and Mann-Whitney U test or T test as appropriate. The associations between ultrasound pathologies and pain scores were explored by logistic regression analyses, adjusted for age, sex and BMI. Generalized Estimating Equations were applied to account for two knees belonging to the same person.

Results: Knee osteophytes, but not grey-scale synovitis, were more common in persons with vs. without clinical knee OA (median sum score of osteophytes: 2 vs. 0, p<0.001) and were associated with higher levels of WOMAC pain (beta=0.18, 95% confidence interval (CI) 0.03-0.32). The same association to WOMAC pain was not found for synovitis (beta=0.03, 95% CI -0.33-0.40). However, in analyses on joint level, both osteophytes and synovitis were associated with pain in the same joint in both a short (24 hours) and longer term (6 weeks), with stronger associations for more severe ultrasound scores (Table 1).

Table 1. Associations between ultrasound pathologies and a) WOMAC pain and b) joint pain in the same joint previous 24 hours and c) previous 6 weeks, adjusted for age, sex and BMI.

<table>

<tr>
<td>Grey-scale synovitis (both knees)</td>
<td>0.03 (0.33-0.40)</td>
<td>0.23 (0.16-0.30)</td>
</tr>
</tbody>
</table>

Conclusion: Both osteophytes and grey-scale synovitis were associated with pain in the same joint, supporting the validity of ultrasound in knee OA. Grey-scale synovitis was commonly present in people not fulfilling the ACR criteria for clinical knee OA and seems to be less specific for clinical knee OA than osteophytes.

HETEROGENOUS CARTILAGE DAMAGE SEEN ON MRI AMONG KNEES WITH KELLGREN-LAWRENCE 2 & 3 OSTEOARTHRITIS: WHAT ARE THE IMPLICATIONS FOR CLINICAL TRIALS?

M. Jarraya1, F. Roemer2, E. Ashbeck3, J. Lynch4, C. K. Kwoh5, A. Guermazi5.

Background: The most recent update of the Global Burden of Disease figures (GBD 2013) estimated that 242 million people were living in the world with symptomatic and activity-limiting OA of the hip and/or knee. Many potential disease-modifying osteoarthritis drugs (DMOADs) have been investigated, but to date no DMOADs that slow or stop disease progression have been approved by the Food and Drug Administration (FDA) or the European Medicines Agency (EMA). A potential reason for the lack of demonstrated efficacy may be reliance on radiographs for defining structural inclusion and exclusion criteria for clinical trials, such as use of joint space width and Kellgren-Lawrence (KL) grade as surrogates for cartilage damage.

PT: Partial-thickness, FT: Full-thickness, TFJ: Tibiofemoral Joint, PFJ: Patellofemoral Joint
Objectives: To estimate the distribution of cartilage damage seen on knee MRI in a sample of knees with radiographic KL 2 and 3 OA that would potentially qualify for a DMOAD in KL3 knees.

Methods: We selected knees from the Osteoarthritis Initiative (OAI), a longitudinal cohort study of knees with or at risk of developing symptomatic radiographic OA, that met common structural inclusion criteria for DMOAD trial enrollment at OAI baseline: knees with radiographs centrally graded as KL 2 or 3 and medial minimum joint space width (mJSW) ≥ 1.5mm. A musculoskeletal radiologist with 10 years of experience in semi-quantitative MRI assessment scored knee cartilage damage in the medial and lateral femorotibial and patellofemoral compartments using WORMS (Whole-Organ Magnetic Resonance Imaging Score). Coronal intermediate weighted (IW) T2 and sagittal fat-suppressed IW T2 sequences on 3T MRI were used. The WORMS cartilage scores, which are based on both the extent and depth of cartilage damage, were collapsed into 4 categories: no cartilage damage (WORMS 0 and 1), focal partial or full-thickness (PT/FT) cartilage damage (WORMS 2 and 2.5), diffuse partial thickness (PT) cartilage damage (WORMS 5 and 6). We estimated the prevalence of each category of cartilage damage in KL2 and KL3 knees; 95% confidence intervals (CI) accounted for clustering at the participant-level since some participants contributed two knees to the analysis.

Results: We identified 2,372 participants contributing 3,446 knees with radiographic OA (KL 2 and 3) and medial mJSW ≥ 1.5mm. There were 2,318 KL2 knees and 1,128 KL3 knees. The distribution of cartilage damage in each compartment by KL grade is presented in Table 1. We found no cartilage damage in any compartments in 9.8% (95% CI: 8.5, 11.1) of KL2 knees and 2.0% (95% CI: 1.1, 2.9) of KL3 knees. Cartilage damage was absent in the medial tibialcompartment in 52.4% (95% CI: 50.1, 54.6) of KL2 knees, and 14.4% (95% CI: 12.2, 16.6) of KL3 knees; versus 61% (95% CI: 58.8, 63.2) of KL2 knees and 53.6% (95% CI: 50.4, 56.7) of KL3 knees in the lateral compartment. When medial and lateral compartments were combined, cartilage damage was absent in 34.8% (95% CI: 32.7, 36.9) of the KL2 knees, and 4.3% (95% CI: 3.0, 5.5) of the KL3 knees. Diffuse FT cartilage lesions in the medial compartment were found in 6.1% (95% CI: 5.0, 7.1) of KL2 knees and 42.5% (95% CI: 39.4, 45.6) of KL3 knees.

Conclusion: MRI screening prior to clinical trial enrollment may identify a substantial percentage of knees with normal cartilage, as well as knees with diffuse FT cartilage lesions that may not be responsive to DMOADs, depending on the mode of action of a given pharmacological compound.

POS0178 IMPPLICATIONS OF BRAIN ACTIVITY IN THE TREATMENT DECISION OF KNEE OSTEOARTHRITIS
F. Deidi1, 2, L. Tiao1, G. Martínez-Vilaveitia1, J. Pujol2, 3, L. Blanco-Hínojo4, 3, J. Deus1, 3, J. C. Monllau2, 6, J. Monfort1 on behalf of HOLOA group.1Hospital del Mar, Rheumatology, Barcelona, Spain; 2Municipal Institute of Medical Research, Grup de Recerca Cel·Luar en Inflamació i Cartílag., Barcelona, Spain; 3Hospital del Mar, MRI Research Unit, Department of Radiology, Barcelona, Spain; 4Hospital del Mar, Centro Investigación Biomédica en Red de Salud Mental, CIBERSAM G21, Barcelona, Spain; 5Institut d’Investigació i Tecnologia en Enginyeria de les Imatges, Universitat Autònoma de Barcelona, Barcelona, Spain; 6Department of Clinical and Health Psychology, Barcelona, Barcelona, Spain; 7Hospital del Mar, Orthopaedic Department, BARCELONA, Spain

Background: Chronic pain related to knee osteoarthritis (KOA) is a common health problem and functional magnetic resonance imaging (fMRI) is a useful technique which can determine different brain activation (1). Objectives: The main purpose of our study was to observe whether there is different risk to central sensitization and different brain activation in patients with KOA according to the treatment followed (conservative (CNV) Vs. total knee replacement (TKR))

Methods: Patients diagnosed of primary KOA following a CNV treatment or undergoing TKR were recruited. Two groups were matched by age, sex and BMI. Clinical central sensitization was considered if patients presented spread tenderness, evaluated with an algometer, in more than 1 site of the extended peripatellar map (2) (notice that pain at points 3, 7 and 8 were not counted) fMRI testing involved pressure painful stimulation to the articular interline and to a commonly sensitized site (tibial surface, point 10).To evaluate the associations between central sensitization and risk to undergo a TKR logistic regression was performed to estimate OR and 95% confidence intervals (95%CI). Models were adjusted by sex, age and BMI (R (v.3.5.2).Whole-brain activation maps were compared between groups using Statistical Parametric Mapping software (SPM12 http://www.fil.ion.ucl.ac.uk/spm).

Results: Women have a significant higher risk to present central sensitization than men (OR 12.11 (95% CI 4.32-33.95) p-value:2.09*10-6), but no differences were observed between CNV or TKR groups (OR TRK 0.67 CI 0.24-1.98).

Table 1. The differences observed in brain activation between the treatment groups in the interline fMRI test (point 7) did not correspond to any specific brain...
area. However, TKR group showed a higher activation that implicated the region of the amygdala and anterior hippocampus during the tibial fMRI test (point 10).

Table 1. Central sensitization Odds Ratio (OR) with 95% Confidence Interval (95%CI)

<tr>
<td>BMI</td>
<td>1.88 (0.69-5.17)</td>
</tr>
</tbody>
</table>

Conclusion: Presenting central sensitization is not a risk for KOA patients to undergo a TKR, but the mechanism underlying sensitization in both treatment groups might be different, with amygdala playing an important role in TKR patients. The amygdala is an important element of the brain systems that both express emotions and modulate pain. The activation of the amygdala in response to pressure stimulation on a sensitized knee site is interpreted as a failure of the descending pain inhibitory systems, and the occurrence of a major emotional response during the painful experience in patients that ultimately received TKR.

Moots8,9, 1AKL Research and Development Ltd., Clinical Science, Stevenage, United Kingdom; 2AKL Research and Development Ltd., Clinical Science, Stevenage, United Kingdom; 3Sanos Clinic A/S, Vejle, Vejle, Denmark; 4Sanos Clinic A/S, Vejle, Vejle, Denmark; 5Sanos Clinic A/S, Vejle, Vejle, Denmark; 6Sanos Clinic A/S, Vejle, Vejle, Denmark; 7Sanos Clinic A/S, Vejle, Vejle, Denmark; 8Aintree Hospital, Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom; 9University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 10NIHR Leeds, Biomedical Research Centre, Leeds, United Kingdom

Background: There is a great unmet need for the development of effective treatments to treat the symptoms of OA. Nuclear-Factor Kappa-B (NF-κB) and Nrf2 play a key roles in OA pathogenesis and have been identified as potential targets. A fixed-dose combination of apocynin and paenol in a ratio of 2:7 (APPA) has been shown to inhibit activation of NF-κB and upregulate Nrf2 [1].

Objectives: We report the results of a phase 2a study evaluating the efficacy and safety of APPA in patients with symptomatic knee OA.

Methods: The trial was a 28-day randomized, placebo-controlled, double-blind study comparing 800 mg of APPA twice daily with matched placebo capsules. Patients with radiographic knee OA K−grade 2−3, and a WOMAC pain score ≥40 and ≤30/100 of target knee at screening and baseline were randomized 1:1 to APPA or placebo. Main exclusion criteria included recent intrarticular surgery or injection therapy, hip pain greater than the target knee, and BMI ≥40 kg/m². The primary endpoint was change from baseline to Day 28 in the WOMAC pain score. Safety outcomes included reported adverse events (AE), clinical laboratory parameters, ECG, and vital signs.

A pre-defined subgroup analysis in subjects with a baseline PainDETECT score >12 indicated a positive effect. Accordingly, post-hoc analyses were undertaken to further assess the effects of APPA in subgroups of participants with higher disease severity.

Results: 152 participants were randomized, and 149 (98%) completed the trial. The mean (SD) WOMAC pain score at baseline was 55.3 (10.2). The two groups were comparable in terms of baseline pain score, gender, age, and BMI. The primary endpoint was not met, mean difference (MD) between APPA and placebo was -0.89 (95% CI: -5.62, 3.74, p=0.71, Figure 1A). Similarly, no significant differences were found on other key secondary endpoints (WOMAC Function and WOMAC total Figure 1B and C, respectively). APPA was well-tolerated and no differences in frequencies of reported AEs were noted, apart from a higher proportion of subjects reporting mild to moderate gastrointestinal discomfort reported with APPA compared to placebo (12% vs. 6.5%). In the pre-defined subgroup of participants with baseline PainDETECT ≥ 13 (N=45), the difference in mean change in pain from baseline favored the APPA group (MD: -11.20, 95% CI: -20.29 to -2.11, p=0.02). Analysis of participants >50 WOMAC pain at baseline (Group 1, N=95, Figure 1D), and a K−grade of the non-target knee >2 (Group 2, N=105, Figure 1E), and a combination of these two criteria (Group 3, N=64, Figure 1F) found a positive effect of APPA compared to placebo (Group 1 MD: -2.61, 95% CI: -8.98 to 3.76, p=0.42, Group 2 MD: -4.01, 95% CI: -9.35 to 1.33, p=0.14, and Group 3 MD: -8.32, 95% CI: -15.48 to -1.16, p=0.02).

Conclusion: Treatment with APPA 800mg twice daily for 28 days in patients with symptomatic knee OA overall was not associated with significantly improved outcomes compared to placebo. The treatment was well-tolerated and safe. Subgroup analyses, however, showed a significant effect of APPA in patients with moderate to severe OA, indicating that further research in the effects of APPA in appropriate patients is warranted.

DOI: 10.1136/annrheumdis-2022-eular.1175
Methods: Pain, stiffness, and physical function in patients with MSOA.

A mean (SD) age of 63 (6) and a mean (SD) BMI of 33 (5) kg/m². After 16 weeks, the PF J group lost more body weight (–3.9 kg, 95% CI –5.8 to –2.0; p < 0.001) and waist circumference (–4 cm, 95% CI –7 to –1; p = 0.01). HbA1c and fasting glucose improved in the PF J versus control group, but not significantly. LDL decreased by 0.38 mmol/l (95% CI 0.07 to 0.69; p = 0.02) and triglycerides by 0.32 (95% CI 0.01 to 0.63; p = 0.04) in favour of the PF J group. HDL and blood pressure remained unchanged. Of the patient reported outcome measures (PROMIS®) only fatigue showed a significant improvement. Body mass index (BMI) decreased by a baseline mean (SD) value of 55 for all the participants, fatigue improved a priori (95% CI 3.0 to 17.6)). Further, participants with constant pain at baseline also seem to benefit from GLAD over OLP (subgroup contrast: 10.0; p=0.01). KOOS pain points (95% CI 3.0 to 17.6)). Further, participants with constant pain at baseline also seem to benefit from GLAD over OLP (subgroup contrast: 10.0; p=0.01).

Conclusion: The 16-week “Plants for Joints” lifestyle program substantially decreased pain and stiffness and improved physical function in people with metabolic syndrome associated osteoarthritis of hip and/or knee. In addition, following the lifestyle program resulted in lower weight, fat mass and smaller waist circumference in comparison with usual care.

REFERENCES:
intermittent pain predicted beneficial effects of OLP, albeit the precision of the estimate was low. See Figure 1.

Figure 1. Forest plot showing the results of the subgroup analyses based on the intention-to-treat population with missing outcome data at week 9 replaced with the baseline observation (non-responder imputation). The full vertical line indicates the overall treatment effect, and the dashed line indicates zero effect. *24 GLAD and 26 OLP had no preference and are not included in the analyses, and 8 GLAD and 5 OLP had missing data; F1R study knee.

Conclusion: These results imply that GLAD should not be considered as a one-size-fits-all intervention. For patients who take analgesics for their knee pain or report constant knee pain, GLAD seems to yield clinically relevant benefits when compared to an open-label placebo. The results support a stratified recommendation of GLAD as management of knee OA.

THE EFFECT OF BELIMUMAB ON SRI-4 RESPONSE IN MULTIPLE SUBGROUPS OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF A LARGE INTEGRATED ANALYSIS

M. A. Petri1, G. Bertsias2, M. Daniels3, N. L. Fox4, A. Hammerre, J. Harris1, H. Quasny8, C. Tani9, A. Askanase10.

Methods: The Be-SLE trial evaluated efficacy using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), adverse event (AE) and serious adverse events (SAE) incidence. The SLE Responder Index (SRI) is a composite measure including ≥4-point reduction in SLEDAI, no worsening in Physician global assessment (PGA), and no new organ manifestations at Week 52 (Wk 52).

Results: 1869 participants received BEL (n=1869) and 1217 received placebo (PBO) (n=1217). The efficacy and safety of BEL were maintained in multiple subgroups (Table 1; Appendix S1).

Conclusions: The efficacy of BEL was consistent across multiple patient subgroups, with higher response rates in pts with SELENA-SLEDAI score of ≥10, low C3 and/or C4 + anti-dsDNA ≥300 U/mL, and low C3 and/or C4 at baseline (Figure 1).

EFFICACY OF BIIB059 ON SKIN MANIFESTATIONS IN PARTICIPANTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN THE PHASE 2 LLAC STUDY (PART A)

States of America; America; the production of Type I IFNs, pro-inflammatory cytokines, and chemokines. Part body targeting blood dendritic cell antigen 2 (BDCA2) that is expressed on pDCs, accumulate in the skin.4 Treatment with BIIB059, a humanized monoclonal anti-

**Objectives:** To further evaluate the effects of BIIB059 vs PBO in reducing skin disease activity, as measured by various CLASI-A response thresholds.

**Methods:** Adults with an SLE diagnosis according to the revised ACR 1997 SLE classification criteria, with ≥4 tender and ≥4 swollen joints (28-joint assessment), active skin disease (as defined by the SLE Disease Activity Index 2000 [SLEDAI-2K]), and positive anti-nuclear antibodies and/or anti-double-stranded DNA antibodies were enrolled. Participants were randomized to receive BIIB059 450 mg or PBO, administered subcutaneously every 4 weeks with an additional dose at Week 2. Improvements in skin disease were assessed in participants with baseline CLASI-A score ≥8. The proportion of participants achieving a ≥7-point reduction from baseline in CLASI-A score was assessed at Week 24, and CLASI-20, -50, -70, and -90 responses were assessed over time. Achievement of CLASI-A scores was also assessed at Week 24. These analyses used non-responder imputation with logistic regression, without correction for multiplicity. The proportions of participants achieving CLASI-A scores of 0–3 and with resolution of SLEDAI-2K skin rash at Week 24 were evaluated ad hoc in the same population. Non-responder imputation was applied to visits post treatment failure and treatment discontinuation. Improvement from baseline in British Isles Lupus Assessment Group index (BILAG-2004) A or B mucocutaneous domains was similarly assessed at Week 24. P-values were calculated based on the odds ratios (ORs) for BIIB059 compared with PBO.

**Results:** At Week 24, a significantly greater proportion of participants receiving BIIB059 (n=39) vs PBO (n=38) had a ≥7-point reduction in CLASI-A score from baseline to Week 24 [56.4% vs 34.2%, OR [95% confidence interval (CI)] 2.71 [1.03, 7.17], P=0.044]. Numerically greater proportions of participants receiving BIIB059 vs PBO achieved CLASI-50, CLASI-70, or CLASI-90 responses (Figure 1). Similarly, the proportion of participants who achieved CLASI-A scores of 0–1 was greater in the BIIB059 group vs PBO (25.6% vs 13.2%), as was the proportion who achieved CLASI-A scores of 0–3 (48.7% vs 28.9%). A greater proportion of BIIB059- vs PBO-treated participants had resolution of SLEDAI-2K skin rash at Week 24 (28.6% vs 10.7%), with similar findings seen in the BILAG-2004 mucocutaneous domain.

**Conclusion:** Numerically greater reductions in skin disease activity were consistently observed with BIIB059 treatment vs PBO in participants with SLE and active skin disease, supporting a potential benefit of BIIB059 treatment for skin manifestations in SLE.

**VOCLOSPORIN FOR LUPUS NEPHRITIS: RESULTS OF THE TWO-YEAR AURORA 2 CONTINUATION STUDY**

A. Saxena, Y. K. O. Teng, C. Collins, N. England, H. Leher, NYU Langone Hospital, Internal Medicine, New York, United States of America; 2 Leiden University Medical Center (LUMC), Internal Medicine, Leiden, Netherlands; 3 Aurinia Pharmaceuticals, Medical Affairs, Victoria, Canada; 4 Aurinia Pharmaceuticals, Clinical Development, Victoria, Canada.

**Background:** Voclosporin (VCS), a novel calcineurin inhibitor, was approved in the US in January 2021 for the treatment of adult patients with active lupus nephritis (LN) in combination with background immunosuppressive therapy. The Phase 3 AURORA 1 study showed that the addition of VCS to mycophenolate mofetil (MMF) and low-dose steroids in patients with LN significantly increased rates of complete renal response at 52 weeks.

**Objectives:** Here we report the results of the completed continuation study, AURORA 2, which assessed the long-term safety and tolerability of VCS compared to placebo in patients with LN receiving treatment for an additional 24 months following completion of the AURORA 1 study.

**Methods:** Key inclusion criteria for the parent AURORA 1 study included a diagnosis of biopsy-proven active LN (Class III, IV, or V ± IIIb, IV) proteinuria ≥1.5 mg/mg (≥2 mg/mg for Class V) and estimated glomerular filtration rate (eGFR) >35 mL/min/1.73 m². Patients who completed AURORA 1 and who elected to be entered into AURORA 2 continued on the same blinded therapy as at the end of AURORA 1 (either VCS or placebo twice daily in combination with MMF and low-dose steroids). Safety and tolerability were monitored, and eGFR, serum creatinine (SCR), and urine protein creatinine ratio (UPCR) were also assessed.

**Results:** In total, 116 and 100 patients in the VCS and control arms enrolled in AURORA 2, with 92 (79.3%) and 73 (73.0%) patients in each respective arm receiving treatment to the end of AURORA 2. There were no unexpected safety signals in the VCS arm compared to control, with similar rates of serious adverse events reported in both arms (VCS [18.1%] vs. control [23.0%]; Table 1). Eight patients in each arm experienced serious adverse events of infection; serious coronavirus infections were observed in 2 patients in the voclosporin arm and 5 patients in the control arm. There were 4 and 2 adverse events by preferred term of renal impairment reported in the VCS and control arms, respectively, none of which were considered serious, and no reports of acute kidney injury by preferred term in either arm. There were no deaths in the VCS arm during AURORA 2; four deaths were reported in the control arm (pulmonary embolism [n=1], coronavirus infection [n=3]). Mean eGFR and SCR levels remained stable through the end of AURORA 2. The difference between the VCS and control arms in LS mean change from baseline in eGFR was 2.7 mL/min/1.73 m² at 4 weeks following study drug discontinuation (Figure 1). The mean reductions in UPCR observed in patients treated with VCS in AURORA 1 were maintained in AURORA 2 with no increase in UPCR noted at the follow-up visit 4 weeks after study drug discontinuation.

**Conclusion:** Voclosporin was well-tolerated over 3 years of treatment with no unexpected safety signals detected. Further, eGFR remained stable throughout the study period, and the significant and meaningful reductions in proteinuria achieved in AURORA 1 were maintained. These data provide evidence of a long-term treatment benefit of VCS in patients with LN. Includes adverse events starting on or after the first dose of study drug in AURORA 2 up to 30 days after the last dose and all events of death reported during study follow-up. Adverse events were aggregated by System Organ Class and Preferred Term and coded using Medical Dictionary for Regulatory Activities (MedDRA) Version 20.0. AE, adverse event.

Background: Lupus nephritis (LN) is one of the most severe organ manifesta-
tions of systemic lupus erythematosus (SLE) and constitutes an important cause of
morbidity and death among patients with SLE [1]. The associated renal injury, and
ultimately damage, is the result of an immune-mediated process which involves
leukocytes, immune complexes, complement and cytokines [2].

Objectives: Lupus nephritis (LN) is one of the most severe organ manifestations of
systemic lupus erythematosus (SLE) and constitutes an important cause of
morbidity and death among patients with SLE [1]. The associated renal injury, and
ultimately damage, is the result of an immune-mediated process which involves
leukocytes, immune complexes, complement and cytokines [2].

Methods: We analysed differentially expressed genes (DEGs), pathways and
their drugability via the Drug Gene Interaction database (DGIdb) [3] in active
LN (n=41) versus healthy controls (HC; n=497), and eQTLs in active or past
LN (n=87), based on validated (identified in two independent SLE populations) DEGs in SLE (n=350) vs HC (n=497), in whole blood collected within the frame of the European PRECISESADS consortium [4]. Genome-wide RNA-sequenc-
ing and genotyping was previously performed by illumina assays, and serum
levels of 17 cytokines and 18 autoantibodies were analysed using a Luminex assay, ELISA, IDS-SYS and SPLAPUS analyser [4].

Results: A total of 6 869 significant and validated DEGs were identified in active LN patients compared with HC. Of these, 1010 validated DEGs were tagged to 34 KEGG pathways including 24 DEGs with a fold change (FC) > 1.5, genes of 18 cis-eQTLs and 3 trans-eQTLs, and 1 gene from cytokines that differed signif-
ificantly between active LN and HC. Moreover, 2446 validated DEGs were tagged to 216 Reacome pathways included 85 DEGs with a FC > 1.5, genes of 21 cis-
eQTLs and 5 trans-eQTLs, and 1 gene from cytokines that differed significantly between active LN and HC. These genes could be targeted by 203 different drugs, with the proteasome inhibitor bortezomib interfering with cathepsin B (CTSB) reg-
ulation and cyclophosphamide interfering with the regulation of tumour necrosis factor receptor superfamily member 1A (TNFRSF1A) being of particular interest.

Conclusion: Integrated multilevel omics analysis in LN revealed a set of enriched pathways of potential interest for future drug investigation. A prospect for proteas-
osome inhibition was implicated.

Atacicept is a fusion protein that blocks B-lymphocyte stimulator and a proliferation-inducing ligand, which are increased in patients with SLE. APRIL-SLE was a double-blind, placebo-controlled, Phase 2 study that randomized patients with moderate-to-severe systemic lupus erythematosus (SLE) to atacicept 75 mg, atacicept 150 mg, or placebo twice-weekly for 4 weeks, then weekly for 48 weeks.

**Results:** In total, 111 patients in the placebo group, 112 patients in the atacicept 75 mg group, and 62 patients in the atacicept 150 mg group completed 52 weeks of treatment; 27 other patients had already been withdrawn for various reasons; the protocol was discontinued prematurely due to 2 deaths from pneumonias. When treatment was discontinued, 62 of 144 patients in this group had completed 52 weeks of treatment; 27 other patients had already been withdrawn for various reasons; and, in the remaining 55 patients, treatment was stopped early as a safety precaution. Patients in the other two groups completed the protocol.

**Results:** In total, 111 patients in the placebo group, 112 patients in the atacicept 75 mg group, and 62 patients in the atacicept 150 mg group completed 52 weeks of treatment. The eGFR time course was stable for the atacicept groups compared to placebo in preventing new flares in patients with moderate-to-severe SLE; this effect has not been reported previously.

**Conclusion:** Results from this double-blind, placebo-controlled, Phase 2 study suggest a potential for improved renal function with atacicept treatment of patients with moderate-to-severe SLE.

**Results:** 91 patients diagnosed with SLE were included in the study. Of the total of patients included in the study, 64 were in current treatment with an antimalarial drug, with a mean of 9.09 (5.73) years of treatment, and a mean cumulative dosage of 613.16 (436.12) gr.

We analyzed the possible relationship between the QTC interval, the current treatment with antimalarial drugs, and the cumulated dosage of this medication. We corrected the lineal regression models by the years of disease evolution, the presence or absence of known heart disease, the women gender, and other treatments such as antiarrhythmics or beta-blockers.

We found a statistically significant association between taking antimalarial drugs and the elongated QTc interval (p=0.001). Nevertheless, in the multivariate analysis, we did not find a significant relationship between the ECG alterations and the treatment with antimalarial drugs.

**Figure 1.**

**Conclusion:** In our study, we did not observe a direct relationship between the intake of antimalarial drugs and the alteration of the corrected QT interval.

**Conclusion:** Although phase 2 data suggested BARI as a potential treatment for patients with SLE (2), the SLE-BRAVE-I and -II phase 3 study results were discordant for the primary outcome measure, with only SLE-BRAVE-I positive, making it difficult to elucidate benefit. Additional analyses are being performed to understand this discordance. No new safety signals were observed.

**Background:** During the first months of the Sars-CoV-2 pandemic, antimalarial drugs were the central axis of the treatment of patients with acute respiratory infection. After that, several studies reported a risk of prolongation of corrected QT interval (QTC) at the electrocardiogram (ECG).

**Objectives:** To analyze the possible relationship between the use of antimalarial drugs and the electrocardiographic alterations in patients diagnosed with SLE.

**Methods:** Cross-sectional study in patients diagnosed with SLE (SLICC 2012). In all of them, we performed a 12-lead ECG at rest. We measured the QT interval manually and automatically, and its correction was made according to the Hodge formula (QTC).

**Results:** Among patients included in the study, 64 were in current treatment with an antimalarial drug, with a mean of 9.09 (5.73) years of treatment, and a mean cumulative dosage of 613.16 (436.12) gr.

We analyzed the possible relationship between the QTC interval, the current treatment with antimalarial drugs, and the cumulated dosage of this medication. We corrected the lineal regression models by the years of disease evolution, the presence or absence of known heart disease, the women gender, and other treatments such as antiarrhythmics or beta-blockers.

We found a statistically significant association between taking antimalarial drugs and the elongated QTC interval (p=0.001). Nevertheless, in the multivariate analysis, we did not find a significant relationship between the ECG alterations and the treatment with antimalarial drugs.
IMPACT OF CORTICOSTEROID DISCONTINUATION ON SYMPTOM CONTROL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

1 InnoCentive Consulting Limited, London, United Kingdom; 2 Evidera, Waltham, United States of America; 3 Therapeutic Area Units, Idorsia Pharmaceuticals, Allschwil, Switzerland; 4 Evidera Ltd, Research, London, United Kingdom

Background: Corticosteroid (CS) treatment effectively reduces swelling and pain caused by inflammation in patients with systemic lupus erythematosus (SLE). However, prolonged CS treatment is associated with adverse events including weight gain, infections, bone loss, and premature atherosclerosis. CS treatment should be minimized to ≤5 mg/day prednisone or equivalents for chronic use and withdrawn when possible. Available data on the impact of CS discontinuation on patients with SLE are limited.

Objectives: To understand CS treatment patterns and impact of CS discontinuation on flares using a real-world cohort of patients with SLE from the United States.

Methods: This retrospective cohort study used the IBM MarketScan Commercial/Medicare supplemental claims database. Patients with SLE receiving CS who subsequently discontinued treatment during 2015 through 2019 were included. The index date was the completion date of the last CS prescription prior to discontinuation. The duration of CS exposure, daily oral CS dose, and CS medication types prescribed, converted into a prednisone-equivalent dose (PEQ), were evaluated during a 12-month pre-index (baseline) period. Outcomes were evaluated during the follow-up period, which started on the date of CS discontinuation and continued until health plan disenrollment or last day of data. Outcomes included flares, CS treatment restarts, and CS-free period prior to resuming therapy. A published algorithm, which draws on SLE-related healthcare resources and medication use, was used to identify and classify flares as mild, moderate, or severe.1 Multivariable Cox regression models evaluated the association between oral CS dose and occurrence of flare.

Results: Overall, 17,759 patients were included in the study (Table 1). The most frequently prescribed oral CS treatments were prednisone (62.7%) and methylprednisolone (23.8%). The mean (SD) duration of CS use prior to discontinuation between oral CS dose and occurrence of flare.

Disclosure of Interests: None declared

EVALUATION OF CRESS IN THE PHASE 2 RANDOMISED PLACEBO-CONTROLLED STUDY OF SEQUENTIAL BELUMUMAB/RTXIMAB ADMINISTRATION IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

1 University Medical Center Groningen, University of Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; 2 GlaxoSmithKline, Clinical Science, Stevenage, Hertfordshire, United Kingdom; 3 GlaxoSmithKline, Clinical Pharmacology and Experimental Medicine, Stevenage, Hertfordshire, United Kingdom; 4 GlaxoSmithKline, R&D Biostatistics, Stevenage, Hertfordshire, United Kingdom; 5 GlaxoSmithKline, Clinical Development, Collegeville, PA, United States of America; 6 GlaxoSmithKline, R&D, Collegeville, PA, United States of America

Background: EULAR Sjögren’s syndrome disease activity index (ESSDAI) assesses systemic disease activity in patients (pts) with primary Sjögren’s syndrome (pSS); however, weaknesses include exclusion of patient-reported symptoms, tear and salivary gland function, and a marked placebo (PBO) response. Composite of Relevant Endpoints for Sjögren’s Syndrome (CRESS) is a recently developed composite outcome measure validated using data from three Phase 3 randomised controlled trials of pts with pSS.2 Concise CRESS (cCRESS) is used when ocular staining score and salivary gland ultrasonography are unavailable. ESSDAI was an endpoint in a Phase 2, PBO-controlled study, evaluating the safety and efficacy of belimumab (BEL) and rituximab (RTX) sequential administration (BEL/RTX), and BEL and RTX monotherapies in pts with pSS. Although the results numerically favoured BEL/RTX over PBO, this was not statistically significant.

Objectives: To evaluate the efficacy of BEL/RTX and monotherapies using cCRESS overall responses at Weeks (Wk) 24, 52, and 68 in all individual item responses at Wk 24 in pts with pSS who completed the Phase 2 study.

Methods: In the Phase 2, double-blind, 68-Wk study (NCT02631538) adults were randomised (2:2:2:1) into 4 treatment arms: BEL/RTX (n=24; weekly BEL 200 mg subcutaneous [SC] to Wk 24 followed by weekly PBO SC to Wk 52 + RTX 1000 mg intravenous [IV], Wk 8 + 10), BEL monotherapy (n=24; weekly BEL 200 mg SC to Wk 52), RTX monotherapy (n=29; RTX 1000 mg IV, Wk 8 + 10), or PBO (n=13). Pts were classified post hoc as cCRESS responders when ≥3 of the following 5 items were met: 1) Clinical (Clin)ESSDAI score ≤5 (low disease state); 2) decrease of ≥1 point or ≥15% from baseline (BL) in EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI); 3) increase of ≥5 mm from BL in EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) score; 4) decrease of ≥25% in the rheumatoid factor (RF) titre from BL; or any increase from BL if score was 0 at BL); 5) decrease of ≥25% in the rheumatoid factor (RF) titre from BL, or decrease of ≥10% in IgG from BL.

Results: Of 86 randomised pts, 60 completed follow-up to Wk 68 (completer population) and were included in the analysis. Most pts were female (95%), n=57; mean (SD) age was 49.6 (13.0) years. BL disease characteristics are presented in the Table 1.

At Wks 24 and 52, the proportion of cCRESS responders was numerically higher with BEL/RTX than with either BEL, RTX, or PBO, but the difference was not significant (Table 1). At Wk 68, the proportion of cCRESS responders was numerically higher with BEL/RTX than with RTX or PBO (Table 1). The 5 cCRESS items contributed relatively equally to total cCRESS response, with the highest response observed in the RFlg/ig and the lowest in the tear gland item (Schirmer’s test; Figure 1).

Outcome of COVID-19 in patients with rheumatic diseases

POS0194 MORBIDITY AND MORTALITY OF BREAKTHROUGH COVID-19 IN PATIENTS WITH IMMUNE MEDITATED CONDITIONS ON B CELL DEPLETING THERAPIES AND THE EFFECTS OF MONOCONAL ANTIBODY TREATMENT

C. Calabrese1, E. Kirchner2, M. E. Husni3, B. Moss2, A. Fernandez1, Y. Jin1, L. Calabrese1
1Cleveland Clinic, Cleveland, United States of America; 2Cleveland Clinic, Neurological Institute, Cleveland, United States of America; 3Cleveland Clinic, Dermatology, Cleveland, United States of America

Background: Among immunocompromised patients with immune mediated inflammatory diseases (IMIDs), those undergoing therapy with B cell depleting agents are among the most vulnerable to both severe COVID-19 disease and sub-optimal response to COVID-19 vaccines[1]. Numerous studies have documented suppressed humoral, but relatively maintained cell mediated, responses to COVID-19 vaccines in these patients. However, the clinical significance of such immunity in terms of protection from infection and its sequelae are poorly understood. We have analyzed a large cohort of vaccinated IMIDs patients undergoing B cell depletion therapy for the presence of breakthrough infection and assessed their outcomes.

Objectives: To define the frequency and outcomes of COVID-19 breakthrough infection in fully or partially vaccinated IMIDs patients receiving B cell depleting therapies. To assess the characteristics and risk factors for severe outcomes and death.

Methods: All pharmacy records from within a large health care system were electronically searched for patients undergoing B cell depleting therapies with approved monoclonal antibodies in 2020. Records with ICD codes for IMIDs agents are among the most vulnerable to severe COVID-19 disease and inflammatory diseases (IMIDs), those undergoing therapy with B cell depleting antibodies, dose and timing of B cell depleting therapy, and outcomes as assessed by an 8 point NIH ordinal scale. Univariate and multivariable logistic proportional-odds regression models were used to examine the risk factors for severe outcomes.

Results: A total of 1677 IMIDs patients were identified who received any B cell depleting monoclonal antibody and at least one COVID-19 vaccine in 2021. From this cohort 74 patients (4.4%) experienced a breakthrough COVID-19 infection. Among those with breakthrough infection patients 34 (46%) had a hematologic disease (RA 11, AV 15, SLE 2), 34 (46%) had CNS inflammatory disease (MS 32, 2 other), and 6 (8%) had immune hemolytic/malignant diseases. Four patients had a previous history of COVID-19 infection. Overall 24 (35%) were hospitalized with 11 patients requiring critical level care (15%) and 6 deaths (8%). All fatal cases had rheumatic diseases. Monoclonal antibodies were given as outpatient therapy to 21 patients and among these only 1 patient was hospitalized without requiring O2 and none died. In univariate analysis only number of comorbidities had a significant positive effect (p<.001) on severe outcomes (i.e. groups 1-4 vs. groups 5-8 Table 1) while monoclonal antibody therapy was associated with more favorable outcomes (p<.005 group 1-2 vs 3-8, Table 1). There were no associations between the dose, duration or timing of the B cell therapy, comorbid therapies including glucocorticoids, vaccine status (incomplete, complete, boosted) or date of vaccination with severe outcomes.

Conclusion: In IMIDs patients treated with B cell depleting therapies breakthrough infections are common with many experiencing severe outcomes. Concomitant comorbidities were associated with risk of severe disease. Monoclonal antibody therapy was used in only 28% but was associated with enhanced clinical outcomes with only 1 in 21 requiring hospitalization and zero mortality. This population of immunocompromised patients remains vulnerable to COVID-19 disease despite vaccination. More aggressive use of outpatient management with monoclonal antibody therapy and other preventive and therapeutic measures are urgently needed.

POS0195 PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS HAVE AN INCREASED RISK OF MORTALITY, MECHANICAL VENTILATION, AND HOSPITALIZATION FROM COVID-19

S. Brueng1, X. Lei3, H. Zhao2, J. Yazdany3, M. Chavez-Macgregor2, S. Giordano4, M. Suarez-Almazor5, Baylor College of Medicine, Section of Immunology, Allergy, and Rheumatology, Houston, United States of America; 2The University of Texas MD Anderson Cancer Center, Health Services Research, Houston, United States of America; 3University of California, San Francisco, Division of Rheumatology, San Francisco, United States of America

Background: Patients with systemic lupus erythematosus (SLE) may have an increased risk of mortality from COVID-19 due to underlying immunosuppression, comorbidities, and abnormalities in the innate immune system. Studies have shown that autoimmune diseases and some immunosuppressive agents are risk factors for hospitalization, ventilation, and mortality from COVID-19.

Objectives: To compare the outcomes of patients with or without SLE who were diagnosed with COVID-19 and to identify the factors associated with 30-day hospitalization, mechanical ventilation, and mortality. We hypothesized that patients with SLE had a higher risk of adverse outcomes.

Methods: This retrospective cohort study used the deidentified Optum COVID-19 Immunology Allergy, and Rheumatology, Houston, United States of America; 4University of California, San Francisco, Division of Rheumatology, San Francisco, United States of America

Results: A total of 1677 IMIDs patients were identified who received any B cell depleting monoclonal antibody and at least one COVID-19 vaccine in 2021. From this cohort 74 patients (4.4%) experienced a breakthrough COVID-19 infection. Among those with breakthrough infection patients 34 (46%) had a hematologic disease (RA 11, AV 15, SLE 2), 34 (46%) had CNS inflammatory disease (MS 32, 2 other), and 6 (8%) had immune hemolytic/malignant diseases. hospitalization, and mechanical ventilation after adjusting for age, sex, race and ethnicity. COVID-19 diagnosis quarter, insurance, region, severe obesity, smoking status, and comorbidities were considered only if coded or reported in an EMR up to 90 days after the positive RT-PCR. The patients' characteristics and the prognosis of COVID-19 were comparable for age, sex, race, COVID-19 diagnosis date (by quarter), insurance, region, severe obesity, smoking status, and skilled nursing facility stay three months before COVID-19 diagnosis. **Model 2 includes adjustments from model 1 and comorbidities (excluding SLE).**

**Conclusion:** Patients with SLE have an increased risks of mortality, mechanical ventilation, and hospitalization within 30 days of COVID-19 diagnosis. The risks decreased after adjustment for comorbidities but remained statistically significant for mechanical ventilation and hospitalization.

**POS0196**

NINE PERCENT OF PATIENTS PRESENT WITH MUSCULOSKELETAL SYMPTOMS AFTER A SEVERE SARS-COV2 INFECTION: A DESCRIPTIVE ANALYSIS OF THE ASSISTANCE PUBlique - Hôpitaux DE PARIS CLINICAL DATA WAREHOUSE.

A. Moltó1, P. Pinson1, N. Beeker1, C. Roux1 on behalf of AP-HP COVID-19 Clinical Data Warehouse Initiative, 1AP-HP/Universities/INSERM COVID-19 Research Collaboration, AP-HP COVID Clinical Data Warehouse Initiative, Paris, France

**Background:** The main and most severe manifestation of the SARS-CoV2 infection is pneumonia, but other organ-specific symptoms have been described (myocarditis, encephalitis...), and some sparse cases have reported musculoskeletal (MSK) symptoms following such an infection. **Objectives:** to determine the prevalence of MSK symptoms appearing after a SARS-CoV2 infection.

**Methods:** This was an observational cohort based on data available at the Assistance Publique-Hôpitaux de Paris (APHP) Clinical Data Warehouse (which includes data from patients admitted in the 39 APHP hospitals). Data collected included both ICD-10 codes in discharge summaries, and 'key-words' search on electronic medical records (EMR). To be included in the analysis, patients had to have a positive RT-PCR for SARS-CoV2 performed in APHP and be admitted in any APHP department between 1st March 2020 until 31st December 2020. Patients with past history of any MSK condition were excluded. MSK conditions were considered only if coded or reported in an EMR up to 90 days after the positive RT-PCR. Demographics and disease characteristics including treatment were compared in both groups (MSK yes/no) by T-test or ChiSquare test, accordingly.

**Results:** Among the 55872 patients with a positive SARS-CoV2 RT-PCR performed in APHP, 17771 were admitted in APHP hospitals. Among them, 2170 had a previous history of MSK condition and were therefore excluded from this analysis. Among the remaining 15601 patients, 1370 (8.8%) presented with MSK symptoms. The most prevalent MSK symptoms were low back pain (32.9%), followed by joint pain (29.9%), radicular pain (20.2%) and joint effusion/arthritis (22.8%). Patients with MSK symptoms were older (67y vs. 64y, p<0.01), more frequently obese (25% vs. 20%, p=0.03), hypertensive (34% vs. 30%, p<0.01) and with diabetes (21% vs. 18%, p<0.01). There were no differences on gender nor on the ICU admission rate between groups (31% vs. 29%, NS); 30-days mortality was significantly lower in the MSK+ group probably due to selection bias (i.e. only patients who survived could present with MSK symptoms up to 90 days later) (7.8% vs. 16.9%, p<0.01). Treatment for SARS-CoV2 was slightly different in both groups, with higher corticosteroids (40.7% vs. 29.0%, p<0.01), antivirals (21.5% vs. 15.3%, p<0.01) and immunosuppressive drugs (8.5% vs. 4.5%, p<0.01) prescription rates in the MSK+ group.

**Conclusion:** MSK symptoms occurred in almost 9% of patients admitted to the hospital after a SARS-CoV2 infection, particularly in older and more comorbid patients. Further analysis evaluating the persistence of these symptoms is needed.

**Acknowledgements:** We would like to acknowledge all departments of Rheumatology of APHP.

**POS0197**

SARS-COV2 INFECTION CAUSED THROMBOSIS IN THE LUPUS MODEL WITH ANTIPHOSPHOLIPID ANTIBODY, WHEREAS COVID-19 ASSOCIATED THROMBOSIS WAS IRRELEVANT IN PATIENTS WITH POSITIVE ANTI-PHOSPHOLIPID ANTIBODY

S. Oba1, T. Hosoya1, D. Kawatani1, W. Lee1, M. Kamaya1, Y. Komiyama1, H. Iwai1, Y. Nakao1, S. Tohda3, S. Yasuda1. 1Tokyo Medical and Dental University, Department of Rheumatology, Bunkyo City, Japan; 2Tokyo Medical and Dental University, Department of Infection Control and prevention, Bunkyo City, Japan; 3Tokyo Medical and Dental University, Department of Laboratory Medicine, Bunkyo City, Japan

**Background:** Thrombosis is a unique complication in coronavirus disease 2019 (COVID-19). We have reported that elevated ferritin and D-dimer on admission were the risk factors of thromboses by analyzing the patients sequentially admitted to our hospital due to COVID-19 (1). However, we have not analyzed thrombotic complications in the view of the antiphospholipid antibodies (aPLs), which are frequently detected in the COVID-19 patients.

**Objectives:** To elucidate the thrombogenic effects of aPLs in COVID-19, we analyzed the development of thrombosis in three lupus models after SARS-CoV2 infection. Additionally, we evaluated the association of thrombotic events and the serum profile of aPLs in Japanese patients with COVID-19.

**Methods:** Three animal models of lupus (MRL/lpr/lpr, NZBxNZW F1 and NZWxBXS F1) were evaluated in this study. NZWxBXS F1 was also considered as a model of antiphospholipid syndrome (APS) since aPLs were detected with a high titer (2). Experimental SARS-CoV-2 infection was induced using mouse-passaged virus strain (3). The incidence of thromboses in the lungs and kidneys were identified by evaluating H&E staining and PTAH staining of paraffin-embedded sections. We have experienced 44 thrombotic events in 34 out of 594 patients admitted to our institute as a non-thrombotic COVID-19, 68 patients were selected to make a 1 to 2 matched-pair based on the propensity score. In total 102 patients, seven types of aPLs (anti-cardiolipin (CL) IgG/IgM, anti-β2GP1 IgG/IgA/IgM, and anti-phosphatidyl serine/prothrombin complex (PS/PT) IgG/IgM) were measured using specific ELISA kits. The patients' clinical characteristics and serological profile of aPLs were further evaluated.

**Results:** We identified the development of thromboses in the lungs or kidneys in 6 out of 12 (50%) NZWxBXS F1 mice after the SARS-CoV-2 infection, whereas no thrombosis was observed in non-infected mice. Further, there was no thrombosis in the other lupus models (0%) after the infection. These findings might suggest the pathogenic role of aPLs under the SARS-CoV2 infection.

**Conclusion:** Among our COVID-19 patients, 39 out of 102 (38%) were tested positive for one or more aPLs. The positive ratios of any aPLs were statistically different between the patients with or without thrombosis; anti-CL IgG (6.8% vs. 5.9%/ IgM (0% vs 5.9%), anti-β2GP1 IgG (21% vs. 15%)/IgA (8.8% vs 15%)/IgM (0% vs 15%), and anti-PS/PT IgG (0% vs 2.9%)/IgM (12% vs 13%), respectively. In addition, their titers were relatively lower than those observed in APS patients. The patients' characteristics and the prognosis of COVID-19 were comparable
regardless of the detection of any aPLs. These findings suggested that COVID-19 associated aPLs were irrelevant to thrombotic complications.

**Conclusion:** Thromboses were induced after the infection of SARS-CoV-2 only in the APS model. However, aPLs detected in COVID-19 patients have little impact on the development of thrombosis. SARS-CoV-2 infection might have a high risk of thrombosis, especially in APS patients, as shown in the case report (4). The discrepancy of its thrombogenic effects of aPLs might be explained by the low titer of the antibody or the diversity of antibody epitope. Further analyses are required to clarify the mechanisms of aPLs production and the development of thrombosis in COVID-19.

Background: During the COVID-19 pandemic, it remains a major concern whether patients with rheumatic musculoskeletal disease treated with conventional (cs) or biologic (b) disease modifying drugs (DMARDs) exhibit an adequate immune response to the currently available SARS-CoV2 vaccines. There remains an urgent need for more data on SARS-CoV-2 vaccine efficacy to inform healthcare providers on the efficiency of the applied vaccination, potential need of and period for booster and/or re-vaccination.

Objectives: To assess and compare the efficacy of the SARS-CoV2 vaccines BNT162b2 vaccine (Pfizer/BioNTech) and mRNA-1273 vaccine (Moderna). The vaccines were administered as part of the Danish vaccine roll out and offered each with two doses and approximately four weeks apart.

Patients’ SARS-CoV2 IgG serum level was used as proxy to determine vaccination response.

Methods: We established the ‘Detection of SARS-CoV2 antibodies in Danish Inflammatory Rheumatic Outpatients’ study (DECODIR) as a longitudinal prospective cohort study. Patients with rheumatoid arthritis (RA), spondyloarthropathies (SpA) or psoriatic arthritis (PsA) receiving their outpatient treatment and monitored in the Danish DANBIO registry at the Danish Hospital for Rheumatic Diseases (DG), Sonderborg were included (April - June 2021).

Bloods, patient reported outcome measurements (PROMs), clinical data and treatment information (cs/bDMARD) were collected at baseline (prior to vaccination) and after six weeks and six months. SARS-CoV2 IgG levels in serum were assessed by ELISA (ThermoFischer), and manufacturer’s cut-off (>10 EliA U/mL) selected as definition of sufficient IgG response.

Associations between antibody response, age, gender, disease (RA/PsA/SpA), DMARD treatment (cs/bDMARD) and disease activity were tested using proportional odds regression and bootstrapped tests of medians. Results were reported using mean, median (IQR) and bootstrapped 95% confidence interval (CI) of the median.

Results: A total of 243 patients were included at baseline and after six weeks; at six months follow-up data were available for 233 patients.

After six weeks, vaccination was followed by a significant increase in IgG levels (median of <0.7 EliA U/mL at baseline versus 36.5 EliA U/mL). Patients treated with a combination of both csDMARD and bDMARD had significantly lower IgG levels compared to patients without any DMARD treatment (8.2 EliA U/mL vs 19.5 EliA U/mL (p<0.001)). Patients treated with oral prednisolone (any dose) showed significantly lower median IgG levels compared to patients without DMARD treatment (3.8 EliA U/mL vs 19.5 EliA U/mL (p<0.01)).

The actual measurements six months after baseline demonstrated a significant decrease of IgG levels for the whole study population (median of 16 EliA U/mL at six months vs 36.5 EliA U/mL at six weeks, p < 0.001) (Figure 1).

Conclusion: IgG levels decreased markedly six months after the initial double dose regimen. Patients treated with a combination of cs/bDMARD or oral prednisolone are at higher risk of inadequate vaccine response as measured by IgG level.

Our results support the decision for the need of a third booster vaccine in patients with inflammatory rheumatic diseases, especially in the case of cs/bDMARD combination treatment and prednisolone. The data may indicate a need for further revaccination in these patients.

Figure 1. IgG-level stratified by treatment

Similar to week 6, lowest response rates were found in patients treated with prednisolone or combination of csDMARD and bDMARD. After 6 months, the proportional odds model revealed significantly lower median IgG antibody level in patients who received Pfizer compared to Moderna (median 15 EliA U/mL (95%CI: 13-18) vs 44.5 EliA U/mL (95%CI: 36-83) (p<0.001).

Figure 1. Nelson-Aalen cumulative hazard estimate

Similar to week 6, lowest response rates were found in patients treated with prednisolone or combination of csDMARD and bDMARD. After 6 months, the proportional odds model revealed significantly lower median IgG antibody level in patients who received Pfizer compared to Moderna (median 15 EliA U/mL (95%CI: 13-18) vs 44.5 EliA U/mL (95%CI: 36-83) (p<0.001).
Background: Published data suggest no increased rate of flare of autoimmune inflammatory rheumatic diseases (AiIRD) after COVID-19 mRNA vaccination; however, the studies are limited by small sample size, short follow up or at risk of selection bias (voluntary physician reports or patient surveys).

Objectives: To study flares of AiIRD within three months of the first dose of an anti-SARS-COV2 mRNA vaccine.

Methods: A retrospective cohort study of consecutive AiIRD patients ≥ 12 years old, across six public hospitals in Singapore who received at least one dose of an mRNA (Pfizer/BioNTech or Moderna) vaccine. Data were censored at the first post-vaccine clinic visit when the patient had flared or if ≥ three months had elapsed since the first dose of the vaccine, whichever came first. Predictors of flare were determined by Cox proportional hazards analysis and time to flare was examined using a Nelson Aalen cumulative hazard estimate (Figure 1).

Results: 2339 patients (74% Chinese, 72% female) of median (IQR) age 64 (53, 71) years were included in the interim analysis (Table 1). 2112 (90%) had recovered from a previous COVID-19 infection after 15K days. 60 (22.1%) were mild and self-limiting, 170 (62.5%) were mild-moderate. 56.6) days. 272 (10%) had the Pfizer/BioNTech vaccine and 195 (8%) had Moderna, with a median (IQR) interval of 21 (21, 23) days between the two doses. The most common AiIRD diagnoses were Rheumatoid arthritis (1063, 45%), Psoriatic arthritis (296, 12.6%) and Systemic lupus erythematosus (SLE) (288, 12.3%). 186 (8%) were treated with biologics/ targeted disease modifying agents. 2125 (91%) patients were in low disease activity or remission. Treatment was interrupted for vaccination in only 18 (0.8%) patients. Seven (0.3%) patients had previous COVID-19 infection.

</table>

452 (19%) flares were recorded during 9798.8 patient-months (4.6/100 patient-months, median (IQR) follow up duration 4.2 (3.3, 5.3) months), of which 272 (11.6%) patients flared within the 3-month period of interest and 180 (77%) flared outside of the 3-month period (Table 1). Median (IQR) time-to-flare was 40.5 (18, 56.6) days. 60 (22.1%) were mild and self-limiting, 170 (62.5%) were mild-moderate and 42 (15.4%) were severe. 190 (69.8%) of those who flared required escalation of treatment and 15 (5.5%) required hospital admission. 239 (10.2%) had improved disease activity after the vaccine.

On multivariate Cox regression analysis, patients in the oldest age tertile [median (IQR) interval of 74 (71, 79) years] were less likely to flare [HR 0.80 (95% CI 0.63, 1.00), p = 0.05] Patients with inflammatory arthritis (compared with connective tissue disease, vasculitis and others) and patients with baseline active disease were more likely to flare [HR 1.72 (95% CI 1.35, 2.20), p < 0.001 and 1.82 (95% CI 1.39, 2.39), p < 0.001 respectively]

Conclusion: There was a moderately high rate of AiIRD flares after mRNA vaccination; however, there was no clustering of flares in the immediate post-vaccine period to suggest causality. Older patients were less likely to flare, while those with inflammatory arthritis and active disease at baseline were more likely to flare.
Background: Significant gaps are present in the evidence of the spectrum and severity of COVID-19 infection in idiopathic inflammatory myopathies (IIM). IIM patients typically require immunosuppressive therapy, may have multiple disease sequelae, and frequent comorbidities, and thus may be more susceptible to severe COVID-19 infection and complications (1). The possibility of attenuated immunogenicity and reduced efficacy of COVID-19 vaccines due to concomitant immunosuppressive medication is a major concern in these patients, and there is little data available on COVID-19 vaccine breakthrough infections (BI) in IIM (2).

Objectives: This study aimed to compare disease spectrum and severity and COVID-19 BI in patients with IIM, other systemic autoimmune and inflammatory diseases (SAIDs) and healthy controls (HCs).

Methods: We developed an extensive self-reporting electronic-survey (COVAD survey) featuring 36 questions to collect respondent demographics, SAID details, COVID-19 infection history, COVID-19 vaccination details, 7-day post vaccination survey) featuring 36 questions to collect respondent demographics, SAID details, COVID-19 infection history, COVID-19 vaccination details, 7-day post vaccination adverse events and patient reported outcome measures using the PROMIS tool. After pilot testing, validation, translation into 16 languages on the online platform surveymonkey.com, and vetting by international experts, the COVAD survey was circulated in early 2021 by a multicenter study group of >110 collaborators in 94 countries. BI was defined as COVID-19 infection occurring more than 2 weeks after receiving 1st or 2nd dose of a COVID-19 vaccine. We analyzed data from the baseline survey for descriptive and intergroup comparative statistics based on data distribution and variable type.

Results: 10906 respondents [mean age 42 (30-55) years, 74% females and 45% Caucasians] were analyzed. 1,227 (11.2%) had IIM, 4,640 (42.6%) had other SAIDs, and 5,033 (46.2%) were HC. All respondents included in the final analysis had received a single dose of the vaccine and 69% had received 2 primary doses. Pfizer (39.8%) was the most common vaccine received, followed by Oxford/AstraZeneeca (13.4%) and Covishield (10.9%). IIM patients were older, had a higher Caucasian representation and higher Pfizer uptake than other SAIDs, and HC. A higher proportion of IIM patients received immunosuppressants than other SAIDs. IIMs were at a lower risk of symptomatic pre-vaccination COVID-19 infection compared to SAIDs (multivariate OR 0.6 (0.4-0.8)) and HCs (multivariate OR 0.39 (0.28-0.54)), yet at a higher risk of hospitalization due to COVID-19 compared to SAIDs [univariate OR 2.3 (1.2-3.5)] and HCs [multivariate OR 2.5 (1.1-5.3)]. BIs were very uncommon in IIM patients, with only 17 (1.4%) reporting BI. IIM patients were at a higher risk of contracting COVID-19 prior to vaccination than ≤2 weeks of vaccination [univariate OR 8 (4.1-15)] or BI [multivariate OR 4.6 (2.7-8.0)]. BIs were equaly severe compared to when they occurred prior to vaccination in IMs, and were comparable between IIM, SAIDs, and HC (Figure 1), though BI disease duration was shorter in IIMs than SAIDs (7 vs 11 days, p=0.027). 13/17 IIM patients with BI were on immunosuppressants.

Conclusion: IIM patients experienced COVID-19 infection less frequently prior to vaccination but were at a higher risk of hospitalization and requirement for oxygen therapy compared with patients with HC. Breakthrough COVID-19 infections were rare (1.4%) in vaccinated IIM patients, and were similar to HC and SAIDs, except for shorter disease duration in IIM.

Background: A major concern across rheumatology in recent years is how contracting COVID-19 may impact the control of rheumatic diseases.

Objectives: To quantify any difference in rheumatic disease control between those who did and did not contract COVID-19 between March and December 2020 and whether rheumatic disease control changed after COVID-19 was contracted.

Methods: Adults with rheumatic diseases recruited to the COVID-19 European Patient Registry, a patient-led, online, self-referred prospective cohort recruiting participants from around the globe, were included if enrolled between March and December 2020. Rheumatic disease control was self-reported weekly on a scale of 0 (very poor) to 10 (very well). Dates of contracting COVID-19 were self-reported.

Differences in rheumatic disease control trends between those who did and did not contract COVID-19 over the study period were tested via multilevel linear regression. Within those who contracted COVID-19, differences in rheumatic disease control trends were tested via segmented multilevel, multivariable linear regression, adjusting for month of COVID-19 contraction and with the interruption point set at the point of COVID-19 contraction.

Results: Of 3646 adults with rheumatic diseases, the majority were female (89%), most commonly from the UK (82%) and the most common rheumatic disease diagnosis was RA (63%). Between March and December 2020, 3% of the cohort contracted COVID-19 (n=103).

Over the study period, rheumatic disease control for adults who did not contract COVID-19 decreased weekly by 0.01 points (95% CI 0.01, 0.02, p<0.001). In those who contracted COVID-19, rheumatic disease control decreased weekly by 0.03 points (95% CI 0.2, 0.05, p<0.001), with a significant weekly difference of 0.86 points between groups (95% CI 0.28, 1.44, p=0.004) (Figure 1a).

Within those that contracted COVID-19, there were significant differences in rheumatic disease control trends before and after contracting COVID-19 (p=0.001). In the run up to contracting COVID-19, rheumatic disease control significantly decreased weekly by 0.03 points (95% CI 0.02, 0.04, p<0.001), dropped significantly by 0.53 points (95% CI 0.23, 0.83, p=0.001) at the point of COVID contraction and then stabilised with no further reductions or improvement in rheumatic disease control for the remainder of follow-up (p=0.831) (Figure 1b).

Conclusion: People who contracted COVID-19 had initial decreases in rheumatic disease control before contracting the virus, after which their disease control stabilised at a lower level. Those with disease flares should consider increased screening for COVID-19 and COVID-19 mitigation measures. The stabilising lower disease control post-COVID is concerning and should prompt further work into restoring disease control pre-COVID-19 levels.

Acknowledgements: The authors thank all of the participants and families involved in the international COVID-19 European Patient Registry, as well as the team of volunteers who helped translate the surveys. We also thank ENCA, PRES and representatives from the international rheumatology community for their expertise and support.

POS0203  PREDICTIVE SEVERITY FACTORS OF COVID-19 IN PATIENTS WITH RHEUMATIC IMMUNE-MEDIATED DISEASES

1 Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN); 2 Hospital Universitario de Canarias, Rheumatology, Santa Cruz de Tenerife, Spain

Background: COVID-19 has become a common disease in patients with rheumatic immune-mediated diseases (R-IMID). A risk stratification of the patients at COVID-19 onset is important to predict possible unfavorable outcomes.

Objectives: To identify predictive severity factors in patients with COVID-19 with R-IMID.

Methods: Cross-sectional study in a single University Hospital. We included all consecutive patients with a R-IMID and COVID-19 up to November 6th, 2020. Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2.

Results: We included 274 patients with R-IMID complicated with COVID-19. At COVID-19 onset, the main comorbidities, analytical values, underlying R-IMID and treatments received are shown in Table 1.

Conclusions: We identified various factors associated with a worse prognosis of COVID-19 in patients with R-IMID. This can help to identify which patients can present a worse course of the disease at the moment of the diagnosis.

According to COVID-19 severity, patients were mild (n=209; 76.3%), moderate (n=35; 12.8%), severe (n=9; 3.3%) and critical (n=21; 7.7%). The predictive variables at COVID-19 onset related statistically to critical COVID were older patients, hypertension, dyslipidemia, previous cardiovascular disease, cancer, chronic kidney disease, and chronic liver disease. The only underlying R-IMID and treatment was polymyalgia rheumatica and Rituximab, respectively. Regarding analytical values were higher values of C-reactive protein, LDH, platelets and lymphopenia (Figure 1).

POS0204  RETROSPECTIVE STUDY OF THE COVID-19 COURSE IN CHILDREN WITH RHEUMATIC DISEASES: SINGLE CENTER EXPERIENCE

Z. Kolikhidova, I. Nikishina, V. Matkava, A. Shapovalenko, S. Arsenyeva, M. Kaleda, S. Salugina, E. Fedorov, T. Pachkoria, V. A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation

Background: The study of the features of the course and mutual influence of the new coronavirus disease COVID-19 and various rheumatic diseases (RD) in children can still give us new lessons, warnings and fears.

Objectives: To update the analysis in a retrospective study the course of COVID-19 in children with RD based on the results of two years of the pandemic. To analyze the impact of COVID-19 on the course of RD in children.

Methods: Retrospective analysis based on data from single center. The study included patients with RD and confirmed COVID-19 for 2 years (2020-2021).

Results: Were registered 320 cases of COVID-19 in children with RD. 158 (49%) patients were asymptptomatically infected, 162 (51%) had clinical symptoms. A detailed description of the groups is presented in Table 1. Clinical symptoms were fever (67%), anosmia (47%), chills (34%), cough (19%), arthralgia/myalgia (16%), dyspnea (5%), rash (2.5%), pneumonia (3%). In the majority of cases (98%), COVID-19 proceeded in mild to moderate severity. Hospitalization due to COVID-19 was required just in 5 cases. 2 children were admitted to the intensive care unit. First, an 11-year-old girl with sJIA with the history of recurrent episodes of MAS resolved by regular administration of canakinumab. 2nd, a 12-year-old girl with SpA/spondylitis, who received...

Conclusion: Our study suggests that the new coronavirus infection in most cases in children with RD, had mild or asymptomatic course, regardless of therapy with immunosuppressive drugs and bDMARD, except of 1 observation with the previous therapy of Rituximab. Worsening of RD after coronavirus infection developed in 15% of cases, regardless of its clinical manifestations. In 13 patients, the RD were started just after COVID-19. The explosive increasing of the incidence of a new strain of COVID-19 for a past month may change the current results and conclusions.

Background: Nintedanib slows the progression of fibrosing ILDs, with a safety profile characterised predominantly by gastrointestinal events.

Objectives: Assess the safety and tolerability of nintedanib in patients with autoimmune disease-related ILDs by sex and age.

Methods: The SENSCIS trial was conducted in patients with ILD associated with systemic sclerosis. The INBUILD trial was conducted in patients with progressive fibrosing ILDs other than idiopathic pulmonary fibrosis. Patients were randomised to receive nintedanib 150 mg bid or placebo. Dose reductions to 100 mg bid and treatment interruptions were permitted to manage adverse events (AEs). Data from all patients in SENSCIS and patients with autoimmune disease-related ILDs in INBUILD were pooled. In subgroups based on sex and age (<65 and ≥65 years) at baseline, we analysed AEs, irrespective of causality, over 52 weeks.

Results: Among 746 patients; 70.1% were female; 29.1% were aged ≥65 years. Mean (SD) exposure to nintedanib or placebo was 10.8 (3.2) and 11.1 (3.5) months in nintedanib or placebo group.

n (%) of patients with ≥1 such adverse event over 52 weeks. Adverse events were coded based on preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA), except for live-related investigations, signs and symptoms, which was based on a standardised MedDRA query. *Adverse events reported in >10% of patients with autoimmune disease-related ILDs in the nintedanib or placebo group.
patients aged <65 and ≥65 years, respectively. The AE profile of nintedanib was similar between males and females, but nausea, vomiting, hepatic adverse events and dose reductions were more frequent in females. The AE profile of nintedanib was similar between patients aged <65 and ≥65 years, but nausea, decreased appetite, and weight loss were more frequent in patients aged ≥65 years. AEs leading to treatment discontinuation were more frequent in patients aged ≥65 years in both treatment groups. Serious AEs were more frequent in males and in patients aged ≥65 years in both treatment groups.

Conclusion: In patients with autoimmune-disease related ILDs, the AE profile of nintedanib in subgroups by sex and age was generally consistent with the known safety profile, but certain types of AE and dose reductions were more frequent in female patients, while serious AEs were more common in male patients.

Acknowledgements: The SENSCIS and INBUILD trials were funded by Boehringer Ingelheim. Oliver Distler was a member of the SENSCIS trial Steering Committee.

Background: Our findings suggest that 7% of RA patients present significant SGUS abnormalities according to OMERACT scoring system, associated with clinical sicca syndrome in 71% of cases. There was no significant association between the duration of rheumatoid arthritis and the OMERACT score (Spearman coefficient for correlation -0.028, p = 0.09). There was also no significant association found between the duration of sicca symptoms and the OMERACT score (Spearman coefficient for correlation 0.025 p = 0.89). This study highlights the importance of SGUS assessment in RA sicca patients to improve monitoring and follow-up in routine clinical practice.

POS0207 UNRAVELING THE COMPLEX INTERACTION BETWEEN DISEASE ACTIVITY AND FATIGUE IN EARLY RA: A MEDIATION ANALYSIS WITH DATA FROM THE CARERA TRIAL

M. Doumer1,2, S. Pazmino1, D. Bertrand1, D. De Coo3,3 J. Joly2, R. Westhoven2,3 P. Verschueren2,2 “KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; “University Hospitals Leuven, Rheumatology, Leuven, Belgium; “KU Leuven, Laboratory of Clinical and Experimental Endocrinology, Leuven, Belgium

Background: Fatigue is recognized as one of the most important symptoms of rheumatoid arthritis (RA). Although inflammation is often proposed as the predominant pathophysiological mechanism, many patients with RA continue to experience fatigue despite inflammatory disease control. The relationship between RA disease activity and fatigue appears to be complex and is likely confounded by cognitive, emotional and social aspects.

Disclosure of Interests: None declared.

**Objectives:** To unravel the complex interaction between disease activity and fatigue in early RA.

**Methods:** Data were analyzed from the 2-year treat-to-target trial Care in early RA (CareRA), which compared different remission-induction DMARD regimens, either with or without bridging glucocorticoids, in treatment-naïve patients with early RA. Fatigue was measured on a visual analog scale (VAS) at every study visit. The association between inflammatory disease activity (DAS28-CRP) and fatigue (VAS) over time was studied with a multilevel mediation analysis, including as mediators the individual components of the DAS28-CRP, pain (VAS), disability (HAQ), psychosocial aspects (Short-Form 36 [SF-36]), illness perceptions (Revised Illness Perception Questionnaire [IPQ-R]), and sleep quality (Pittsburgh Sleep Quality Index [PSQI]).

**Results:** A total of 356 patients were included in these analyses, with a mean (SD) fatigue (VAS) of 48/100 (24) at study initiation. Although there was a consistently positive association between DAS28-CRP and fatigue over time, this association was fully mediated by patient global assessment (PGA) and pain, and to a lesser extent by SF-36 Mental Health and the PSQI global score (Figure 1). Full mediation implies the absence of a significant direct association between DAS28-CRP and fatigue after adjusting for these mediators. In addition, no mediating effect was found for tender/swollen joint counts or CRP.

![Figure 1. Mediation analysis of the association between DAS28-CRP and fatigue (VAS) over time.](image-url)

**Conclusion:** Our mediation analysis suggests that the relationship between disease activity and fatigue in early RA is complex and fully mediated by aspects of wellbeing like pain, mental health, sleep quality, and the patient’s overall assessment of disease. These results imply a mainly indirect relation between fatigue and inflammation. Clinicians should reserve specific attention for the psychosocial determinants of fatigue, particularly when no improvement is seen with DMARDs.

**STRESS AT HOME IS COMMON AND HAS SIGNIFICANT ASSOCIATION WITH MARRITAL STATUS, HIGHER DISEASE ACTIVITY, COMORBIDITIES, AND WORSE QUALITY OF LIFE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: SINGLE CENTRE RESULTS FROM THE PRIME REGISTRY COHORT**

M. Haroon1, S. Asif1, S. Ullah1, F. Hashmi1, S. Javed1. 1Fatima Memorial Hospital & FMH College of Medicine and Dentistry; Department of Rheumatology, Lahore, Pakistan

**Background:** In chronic inflammatory diseases like rheumatoid arthritis (RA), psychological stress is widely recognised as an important risk factor to negatively affect the disease course. Perceived stress can potentially induce the disease exacerbation, but on the other hand, the disease itself might produce significant stress to patients thus the vicious circle is formed and maintained.

**Objectives:** We aimed to examine the prevalence of mental/emotional stress at home and its associations among patients with Rheumatoid arthritis. We addressed this question using real-world data from the PRIME registry.
